We believe that the present reaction proceeds through an electron-transfer from HEH to the substrate to form a radical ion intermediate and the process is mediated by the ruthenium complex. Indeed, it is known that Ru(II) is photochemically reduced into Ru(I)[10)] and Pac et al. proposed a Ru-mediated electron-transfer mechanism for the photochemical reduction of activated olefins with BNAH.[11)] As shown in the last example in Table 3, when the phenylsulfonyl group in the substrate is substituted by a *p*-nitrophenylsulfonyl group, the yield decreases remarkably to only 14%. Since the radical anion intermediate from the *p*-nitrophenylsulfonyl substrate is so stable under the reaction conditions due to the electron-withdrawing character of the *p*-nitro group that the cleavage of the C-S bond to form (probably) a carbon free radical and a sulfinate anion is inhibited here. Thus, the substituent on the sulfonyl group has to be electron-defficient but not too much in order to undergo the reaction smoothly.

Synthesis of Dihydrojasmone. Jasmones are im-

Table 3. Photo-Reduction of β-Keto Sulfones

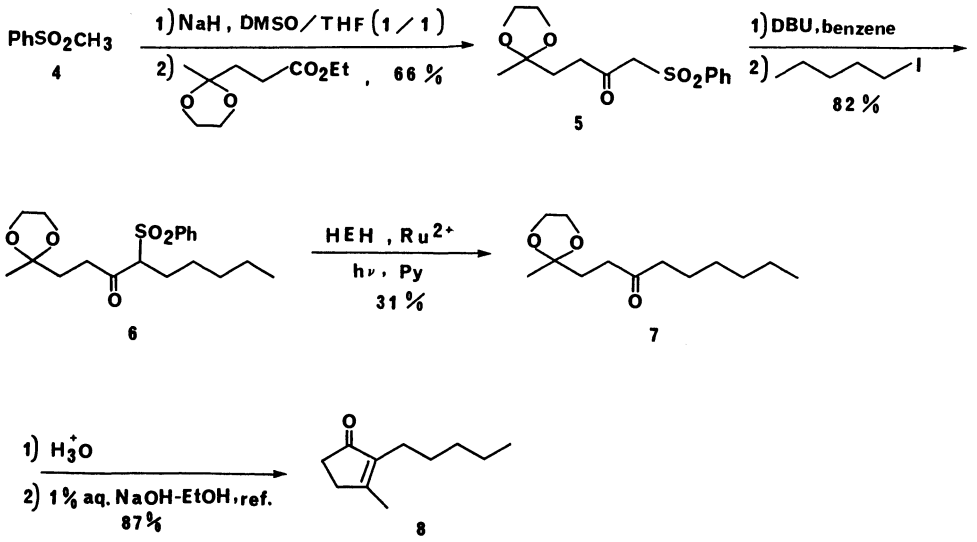
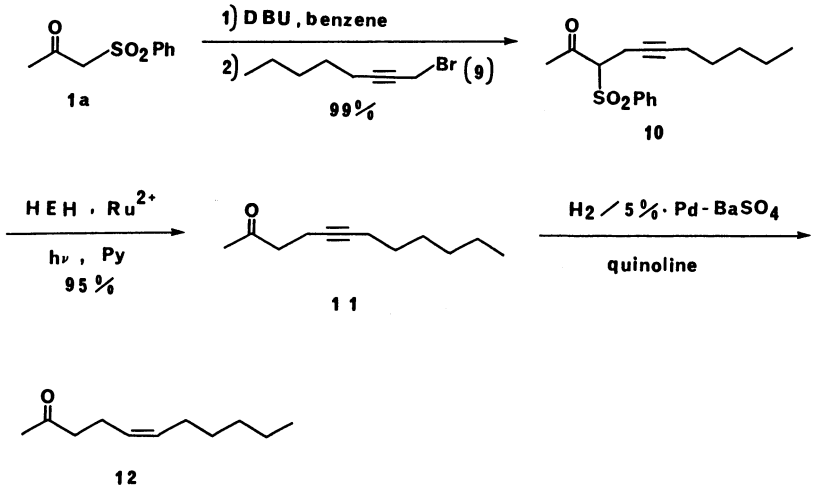


Scheme 1.

portant perfume components and have attracted a great attention of synthetic organic chemists.[12] We applied our alkylation-desulfonylation method to the synthesis of dihydrojasmone (**8**) along the process outlined in Scheme 1.

Methyl phenyl sulfone (**4**) was reacted with ethylene acetal of ethyl levulate in DMSO/THF (1/1) at 65 °C using sodium hydride as a base to afford the β-keto sulfone **5**, which was then alkylated with pentyl iodide in DBU/benzene system into the substituted β-keto sulfone **6**.

Desulfonylation of **6** was achieved with HEH in the presence of 1% mole of $RuCl_2(bpy)_3$ in pyridine under irradiation of visible light from a halogen lamp and the acetal **7** was isolated in 68% yield after purification on a column of silica gel. The acetal **7** was converted into dihydrojasmone (**8**) in 87% yield after an acid-catalyzed deprotection followed by reflux with 1% aq.



Scheme 2.

NaOH in EtOH.[13] Spectral data from **8** were identical with those reported in the literature[14] and the elemental analyses gave satisfactory results.

Synthesis of a Pheromone. (*Z*)-5-Undecen-2-one (**12**) was isolated as the principal volatile component of the pedal gland exudate of the bontebock, *Damaliscus dorcas dorcas*, by Burger et al.[15] They subjected the synthetic ketone **12** to the preliminary biological test as a mammalian pheromone and intense interest was shown by two captive animals. Application of our alkylation-desulfonylation method to the synthesis of this ketone provides a short (3 steps) and facile procedure and the ketone **12** was isolated in 79% overall yield (Scheme 2).

1-Phenylsulfonyl-2-propanone (**1a**) was regioselectively reacted with 1-bromo-2-octyne (**9**) in benzene with DBU to yield a β-keto sulfone **10** in 99% yield. Desulfonylation of **10** with the HEH-Ru(II)/*hν* system and subsequent purification on a column of silica gel afforded an acetylenic ketone, **11**, in 95% yield. Partial hydrogenation of **11** catalyzed by 5% Pd-$BaSO_4$ in the presence of quinoline gave the desired product **12** in 84% yield. The ^{1}H NMR spectrum indicated that the isolated product was consisted of the (Z)-isomer only. Other spectral data were also identical with those reported in the literature,[15] and the elemental analyses were satisfactory.

Experimental

Melting points were corrected with YANAGIMOTO MICRO MELTING POINT APPARATUS. Unless otherwise indicated, materials were purchaced from Nakarai Chemicals, Ltd.

Instruments. ^{1}H NMR spectra were measured at 100 MHz with a JEOL JN-FX100 fourier transform NMR spectrometer. IR spectra were recorded on a Hitachi EPI-S2 infrared spectrometer.

Elemental analyses were performed with a Yanaco MT-3 elemental analyzer. Gas chromatographic data were recorded on a Yanako G-1800 gas chromatograph (OV-330).

Alkylation: Preparation of 4-Phenyl-3-phenylsulfonyl-2-butanone (2a). A mixture of 1.98 g of 1-phenylsulfonyl-2-propanone (**1a**), 1.52 g of DBU, and 1.71 g of benzyl bromide in 50 ml of benzene was stirred at room temperature for 15 h. The reaction mixture was washed with three portions of each 50 ml of water and the organic layer was dried over anhydrous sodium sulfate. After removal of the solvent, the residue was purified by column chromatography on silica gel to give 1.83 g (64%) of 4-phenyl-3-phenylsulfonyl-2-butanone (**2a**), mp 92—93 °C.

^{1}H NMR ($CDCl_3$) δ=2.18 (s, 3H), 3.19 (q, 2H, *J*=14 Hz), 4.42, 4.45 (dd, 1H, *J*=11 Hz), 6.98—7.26 (m, 5H), and 7.52—7.90 (m, 5H). IR (KBr): 3000, 1723, 1320, and 1145 cm^{-1}. Found: C, 66.61; H, 5.52%. Calcd for $C_{16}H_{16}O_3S$: C, 66.64; H, 5.59%.

2b—g were obtained similarly. Results are summarized in Table 1.

2b: ^{1}H NMR ($CDCl_3$) δ=0.87 (t, 3H, *J*=7 Hz), 1.04—1.32 (m, 8H), 1.91 (q, 2H, *J*=7 Hz), 2.42 (s, 3H), 4.08 (t, 1H, *J*=7 Hz), and 7.29—7.88 (m, 5H). IR (neat): 3075 (m), 2930 (s), 1725 (s), 1305, and 1150 cm^{-1}(s). Found : C, 64.05; H, 7.88%. Calcd for $C_{15}H_{22}O_3S$: C, 63.80; H, 7.85%.

2c: ^{1}H NMR ($CDCl_3$) δ=2.34 (s, 3H), 2.79 (t, 2H, *J*=7 Hz), 4.30 (t, 1H, *J*=7 Hz), 5.80, 5.95 (dt, 1H, *J*=15, 7 Hz), 6.36 (d, 1H, *J*=15 Hz), 7.20 (m, 5H), and 7.42—7.85 (m, 5H). IR (KBr): 3000, 1723, 1315, and 1150 cm^{-1}. Found: C, 66.28; H, 5.49%. Calcd for $C_{18}H_{18}O_3S$: C, 66.43, H; 5.60%.

2d: ^{1}H NMR ($CDCl_3$) δ=2.76 (t, 2H, *J*=7 Hz), 4.93—5.22 (m, 3H), 5.40—5.80 (m, 1H), and 7.32—7.96 (m, 10H). IR (KBr): 3000, 1674, 1305, and 1145 cm^{-1}. Found: C, 68.30; H, 5.51%. Calcd for $C_{17}H_{16}O_3S$: C, 67.98; H, 5.37%.

2e: ^{1}H NMR ($CDCl_3$) δ=2.34—2.60 (m, 4H), 2.94—3.32 (m, 2H), 3.57 (s, H), 4.25 (q, 1H *J*=4 Hz), and 6.95—7.90 (m, 10H). IR (KBr): 3000 (m), 1740 (s, CO_2), 1715 (s, C=O), 1310, and 1140 cm^{-1} (s, SO_2). Found: C, 63.54; H, 5.54%. Calcd for $C_{19}H_{20}O_5S$: C, 63.32; H, 5.59%.

2f: Mp 92 °C. ^{1}H NMR ($CDCl_3$) δ=3.36 (d, 2H, *J*=4 Hz), 3.50 (s, 3H), 4.23 (dd, 1H, *J*=10, 4 Hz), 7.05—7.18 (m, 5H), and 7.48—7.97 (m, 5H). IR (Nujol): 2920 (s), 1735 (s, CO_2), 1310, and 1140 cm^{-1} (s, SO_2). Found: C, 63.06; H, 5.31%. Calcd for $C_{16}H_{16}O_4S$: C, 63.14; H, 5.30%.

2g: Mp 76—78 °C. ^{1}H NMR ($CDCl_3$) δ=3.18 (q, 2H, *J*=12 Hz), 4.04, 4.10, (dd, 1H, *J*=4 Hz), 7.20—7.38 (m, 5H), and

7.54—8.14 (m, 5H). IR (Nujol): 2930 (s), 2220 (w, CN), 1320, and 1160 cm^{-1} (s, SO_2). Found: C, 66.71; H, 4.69; N, 5.03%. Calcd for $C_{15}H_{13}NO_2S$: C, 66.40; H, 4.83; N, 5.16%.

Reductive Desulfonylation of β-Keto Sulfones: 4-Phenyl-2-butanone (3a). A solution of 288 mg (1 mmol) of **2a**, 750 mg of HEH (3 mmol) and 6.9 mg (0.01 mmol) of $RuCl_2(bpy)_3$ in 12 ml of pyridine was irradiated with visible light (USHIO HALOGEN LAMP JCD 100V-650W) at room temperature under an argon atmosphere for 20 h. The reaction mixture was poured into 100 ml of 2M hydrochloric acid (1 M=1 mol dm^{-3}) and extracted with ether. The organic layer was washed with water and brine, then dried on sodium sulfate. After removal of the solvent, the residue was chromatographed on silica gel with benzene as an eluent to give 143 mg (97%) of 4-phenyl-2-butanone (**3a**).

^{1}H NMR ($CDCl_3$) δ=2.12 (s, 3H), 2.60—3.04 (m, 4H), and 7.06—7.38 (m, 5H). IR (neat): 3000 (m) and 1715 cm^{-1} (s, C=O). Found: C, 80.94; H, 8.31%. Calcd for $C_{10}H_{12}O$: C, 81.04; H, 8.16%.

3b—e were obtained similarly. Results are summarized in Table 3.

3b: 87% yield. ^{1}H NMR ($CDCl_3$) δ=0.99 (t, 3H, *J*=6 Hz), 1.20—1.36 (m, 8H), 1.56 (t, 2H, *J*=7 Hz), 2.13 (s, 3H), and 2.43 (t, 2H, *J*=7 Hz). IR (neat): 3000 (s) and 1723 cm^{-1} (s, C=O). Found: C, 75.84; H, 12.91%. Calcd for $C_9H_{18}O$: C, 75.99; H, 12.76%.

3c: 83% yield. ^{1}H NMR ($CDCl_3$) δ=2.16 (s, 3H), 2.40—2.68 (m, 4H), 6.08, 6.23 (dt, 1H, *J*=6 Hz), 6.41 (d, 2H), and 7.20—7.36 (m, 5H). IR (neat): 3000 (m), 1710 (s, C=O), and 1600 cm^{-1} (m, C=C). Found: C, 82.90; H, 8.16%. Calcd for $C_{12}H_{14}O$: C, 82.72; H, 8.10%.

3d: 94% yield. ^{1}H NMR ($CDCl_3$) δ=2.36—2.60 (m, 2H), 3.04 (t, 2H, *J*=7 Hz), 4.90—5.16 (m, 2H), 5.68—6.08 (m, 1H), and 7.32—8.00 (m, 5H). IR (neat): 3000 (m), 1685 (s, C=O), and 1600 cm^{-1} (m, C=C). Found: C, 82.41; H, 7.75%. Calcd for $C_{11}H_{12}O$: C, 82.46; H, 7.55%.

3e: 44% yield. ^{1}H NMR ($CDCl_3$) δ=2.52—3.02 (m, 8H), 3.64 (s, 3H), and 7.10—7.28 (m, 5H). IR (neat): 3000 (m), 1740 (s, CO_2), and 1720 cm^{-1} (s). Found: C, 71.06; H, 7.54%. Calcd for $C_{13}H_{16}O_3$: C, 70.89; H, 7.32%.

Reduction of Methyl 3-Phenyl-2-phenylsulfonylpropionate (2f), 3-Phenyl-2-phenylsulfonylpropionitrile (2g), and 3-(*p*-Nitrophenylsulfonyl)-4-phenyl-2-butanone (2h). The reduction was carried out on 0.05 mmol scale of each substrate under the conditions as described for **2a**. The chemical yields of the corresponding reduction products were determined on GLC (OV330, 130 °C) employing hydroquinone dimethyl ether as an internal standard. No reduction product was detected from the reduction of **2f** and **2g**. 4-Phenyl-2-butanone was formed in 14% yield from **2h**.

Preparation of Dihydrojasmone (8) A mixture of 0.72 g (30 mmol) of sodium hydride, 4.68 g (30 mmol) of methyl phenyl sulfone (**4**) and 15 ml of dimethyl sulfoxide was heated to 65 °C with stirring until the evolution of hydrogen gas ceased (for about 30 min). The solution was cooled, diluted with 10 ml of tetrahydrofuran, and then a solution of 2.84 g (15 mmol) of ethyl levulate ethylene acetal in 5 ml of tetrahydrofuran was added. The resulting mixture was heated to 65 °C with stirring for 1 h, then cooled, poured into a mixture of ice and 2M hydrochloric acid, and extracted with six portions of chloroform. The combined organic extracts were washed successively with water, saturated aqueous sodium hydrogen carbonate, and brine, then dried and concentrated to leave the crude product which was column chromatographed on silica gel with hexane eluent to afford 2.60 g (66% yield) of 2-(4-phenylsulfonyl-3-oxobutyl)-2-methyl-1,3-dioxolane (**5**).

^{1}H NMR ($CDCl_3$) δ=1.28 (s, 3H), 2.00 (t, 2H, *J*=7 Hz), 2.73 (t, 2H, *J*=7 Hz), 3.85 (s, 4H), and 6.54—6.81 (m, 5H). IR (neat): 3000 (m), 1730 (s, C=O), 1310, and 1150 cm^{-1} (s, SO_2). Found: C, 56.63; H, 6.11%. Calcd for $C_{14}H_{18}O_5S$: C; 56.36, H; 6.08%.

A mixture of 2.12 g of **5**, 1.08 g of DBU and 1.40 g of pentyl iodide in 35 ml of dry benzene was stirred at room temperature for 15 h. The reaction mixture was worked up as described for **2a** to give 2.15 g (82%) of 2-methyl-2-(4-phenylsulfonyl-3-oxononyl)-1,3-dioxolane (**6**).

^{1}H NMR ($CDCl_3$) δ=0.81 (t, 3H, *J*=6 Hz), 1.15—1.36 (m, 6H), 1.28 (s, 3H), 1.74—2.09 (m, 4H), 2.72 (t, 2H, *J*=7 Hz), 3.88 (s, 4H), 4.15 (t, 1H, *J*=7 Hz), and 7.51—7.82 (m, 5H). IR (neat): 3000 (m), 1730 (s, C=O), 1310, and 1150 cm^{-1} (s, SO_2). Found: C, 61.82; H, 7.57%. Calcd for $C_{19}H_{23}O_5S$: C, 61.93; H, 7.66%.

A solution of 364 mg of **6**, 750 mg of HEH and 6.9 mg of $RuCl_2(bpy)_3$ in 12 ml of pyridine was irradiated with visible light at room temperature under an argon atmosphere for 20 h. The reaction mixture was worked up as described for **2a** to give 70 mg (31%) of 2-methyl-2-(3-oxononyl)-1,3-dioxolane (**7**).

^{1}H NMR ($CDCl_3$) δ=0.88 (t, 3H, *J*=6 Hz), 1.20—1.68 (m, 11H), 1.96 (t, 2H, *J*=7 Hz), 2.41 (t, 2H, *J*=7 Hz), 2.48 (t, 2H, *J*=7 Hz), and 3.92 (s, 1H). IR (neat): 2980 (m) and 1730 (s) cm^{-1}. Found: C, 71.53; H, 6.56%. Calcd for $C_{13}H_{14}O_3$: C, 71.54; H, 6.47%.

A solution of 228 mg (1 mmol) of **7** in 10 ml of acetone and a few drops of 2M hydrochloric acid was stirred at room temperature for 5 h. The reaction mixture was condensed in vacuo, diluted with 10 ml of ethanol and 2 ml of 1% aq. NaOH and then heated at 80 °C for 3 h. The solution was poured into 2M hydrochloric acid, extracted with dichloromethane and washed with water and brine. The organic layer was dried on sodium sulfate, condensed in vacuo, and purified by column chromatography on silica gel with hexane-ethyl acetate (2 : 1) mixture as an eluent. Dihydrojasmone (**8**) was obtained in 87% yield (144 mg) and showed satisfactory spectra compared with those reported in the literature.[12]

^{1}H NMR ($CDCl_3$) δ=0.88 (t, 3H, *J*=6 Hz), 1.20—1.36 (m, 6H), 2.04 (s, 3H), 2.20 (t, 2H, *J*=6 Hz), 2.34 (t, 2H, *J*=6 Hz), and 2.46 (t, 2H, *J*=7 Hz). IR (neat): 2930 (m), 1700 (s), and 1642 cm^{-1} (m). Found: C, 79.36; H, 11.03%. Calcd for $C_{11}H_{18}O$: C, 79.47; H, 10.91%.

Synthesis of a Pheromone, (*Z*)-5-Undecen-2-one (12). A mixture of 1.98 g of 1-phenylsulfonyl-2-propanone (**1a**), 1.52 g of DBU, 1.89 g of 1-bromo-2-octyne (**9**) in 50 ml of benzene was stirred at room temperature for 15 h. The reaction mixture was washed with water and the organic layer was dried over anhydrous sodium sulfate. After removal of the solvent, the residue was purified by column chromatography on silica gel to give 3.02 g (99%) of 3-phenylsulfonyl-5-undecyn-2-one (**10**).

^{1}H NMR ($CDCl_3$) δ=0.88 (t, 3H, *J*=6 Hz), 1.16—1.48 (m, 6H), 1.95—2.13 (m, 2H), 2.43 (s, 3H), 2.71—2.85 (m, 2H), 4.23 (t, 1H, *J*=8 Hz), and 7.44—7.91 (m, 5H). IR (neat): 2930 (s), 2212 (w), 1725 (s), 1310, and 1150 cm^{-1} (s). Found: C, 67.01; H, 7.27%. Calcd for $C_{17}H_{22}O_3S$: C, 66.63; H, 7.24%.

A solution of 305 mg (1 mmol) of **10**, 750 mg of HEH (3 mmol) and 6.9 mg (0.01 mmol) of $RuCl_2(bpy)_3$ in 10 ml of pyridine was irradiated with visible light at room temperature under an argon atmosphere for 20 h. The reaction mixture was poured into 100 ml of 2M hydrochloric acid and extracted with ether. The organic layer was washed with water and brine, and dried on sodium sulfate. After removal of the solvent, the residue was chromatographed on silica gel with benzene as an eluent to give 156 mg (95%) of 5-undecyn-2-one (**11**).

^{1}H NMR ($CDCl_3$) δ=0.88 (t, 3H, J=6 Hz), 1.20—1.60 (m, 6H), 2.02—2.20 (m, 2H), 2.13 (s, 3H), 2.18—2.28 (m, 2H), and 2.36—2.42 (m, 2H). IR (neat): 3000 (m) and 1715 cm^{-1} (s). Found: C, 79.30; H, 10.87%. Calcd for $C_{11}H_{18}O$: C, 79.46; H, 10.92%.

A mixture of 55 mg of **11**, 20 mg of 5% Pd/$BaSO_4$, 4 µl of quinoline in 10 ml of dry methanol under an atmosphere of hydrogen was stirred at room temperature for 6 h. The palladium catalyst was removed by filtration and the filtrate was concentrated in vacuo. The crude product was purified by column chromatography on silica gel with benzene as an eluent. The pure 5-undecen-2-one (**12**) was obtained in 84% yield and identified as the (*Z*)-isomer only by ^{1}H NMR analysis.

^{1}H NMR ($CDCl_3$) δ=0.88 (t, 3H, J=6 Hz), 1.20—1.40 (m, 6H), 2.02 (q, 2H, J=6 Hz), 2.11 (s, 3H), 2.29 (q, 2H, J=6 Hz), 2.41 (t, 2H, J=6 Hz), and 5.28 (qAB, 2H, J=6 Hz). IR (neat): 3000 (s), 1720 (s), and 1680 cm^{-1} (m). Found: C, 78.81; H, 12.32%. Calcd for $C_{11}H_{20}O$: C, 78.51; H, 11.98%.

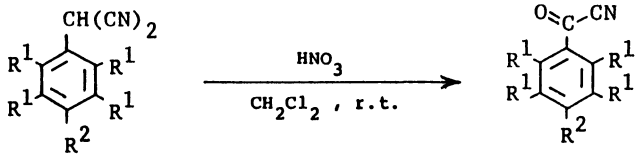
Anomalous Reaction of Arylmalononitriles with Nitric Acid. Para-Directing Nature of Dicyanomethyl Group and a Through-Ring Nitro/*aci*-Nitro Tautomerism of 4-Nitrophenylmalononitrile[1)]

Hitomi Suzuki,* Hideki Koide, and Takuji Ogawa*
Department of Chemistry, Faculty of Science, Ehime University, Bunkyo-cho, Matsuyama 790
(Received September 11, 1987)

Phenylmalononitrile reacts with nitric acid in dichloromethane at room temperature to afford 1,2-bis(4-nitrophenyl)-1,1,2,2-tetracyanoethane as an initial product, which readily suffers oxidative cleavage to give 4-nitrobenzoyl cyanide. Contrary to common understanding, dicyanomethyl group exhibits no meta-directing property. 4-Nitrophenylmalononitrile is found to exist in two stable tautomeric forms, which undergo a facile nitro/*aci*-nitro interconversion across aromatic ring depending on the nature of solvent employed.

Successive replacement of methyl hydrogen atoms in toluene by chlorine atoms changes the directing effect of methyl group from predominant ortho/para orientation to predominant meta orientation. Thus, benzyl chloride gives on nitration ortho, meta, and para nitro derivatives in 34, 14, and 53% yields, respectively,[2)] while the value is 7, 65, and 29% respectively for benzylidene trichloride.[3)] Since the cyano group is more strongly deactivating than chlorine atom, it is quite understandable that the substitution of two cyano groups into methyl group of toluene would change the directing nature of methyl group from ortho/para into meta. Indeed, Flürsheim and Holmes nitrated phenylmalononitrile (**1a**) with nitric acid in acetic anhydride and obtained 68 and 32% respectively of meta and (ortho plus para) nitration products.[4)] Their result has been taken as one of the examples of the substituent-dependent modification of the electron-releasing property of methyl group and no doubts seem to have been thrown for more than half a century.



1 **2**

In the course of our continuing study on the non-conventional aromatic nitration,[5)] we had an occasion to reinvestigate the reaction of several arylmalononitriles with nitric acid under various conditions. Rather surprisingly, dinitrile **1a** underwent a facile reaction both on aromatic ring and on side chain, giving 4-nitrobenzoyl cyanide (**2c**) in a good yield. In contrast to the literature report,[4)] no 3-nitro isomer could be detected in the product mixture.

A close inspection of this unexpected result revealed a new chemistry. Thus, when the reaction was quenched with water immediately after the addition of nitrating agent to a solution of **1a** in dichloromethane at room temperature and the organic phase was worked up as usual, the product was a pale yellow crystalline solid which, after several recrystallization from THF and ether, melted at 156—157 °C with decomposition. On dissolving into THF and acetone, it developed a pale yellow and an orange color respectively. Its solution in DMSO had a deep red color. Elemental analysis of this compound was consistent with the empirical formula $C_{18}H_8N_6O_4$. The IR spectrum (KBr) demonstrated the presence of cyano (2275 cm^{-1}) and nitro groups (1535 and 1360 cm^{-1}), while its ^1H NMR spectrum (100 MHz; $(CD_3)_2SO$) showed signals at δ 8.50 and 7.70 (d; J=9.6 Hz), relative intensity 1 : 1, due to vicinal aromatic protons. The ^{13}C NMR spectrum (90 MHz; $(CD_3)_2SO$) indicated the presence of cyano groups (δ 110.0), substituted aromatic carbons (δ 129.4 and 149.5), unsubstituted aromatic carbons (δ 124.6 and 130.0), and sp^3 carbons (δ 52.8). These spectral evidences allowed for the compound the formulation of 1,2-bis(4-nitrophenyl)-1,1,2,2-tetracyanoethane (**3**). Its structure was further confirmed by direct comparison with an authentic specimen obtained from the oxidation of 4-nitrophenylmalononitrile (**1c**) with yellow mercury(II) oxide in dichloromethane at room temperature. When kept in contact with nitric acid in the same solvent, **3** was converted into benzoyl cyanide **2c**. Under similar conditions, 4-methylphenylmalononitrile (**1b**) and 2,3,5,6-tetrachloro-4-methylphenylmalononitrile (**1d**) afforded the corresponding benzoyl cyanide **2b** and **2d** as the respective single product. Interestingly, dinitrile **1c** with two electron-withdrawing groups on aromatic ring reacted more easily with nitric acid than unsubstituted dinitrile **1a** or methyl-substituted dinitrile **1b** to produce **2c** in high yields.

We also carried out the nitration of **1a** according to the procedure given in the literature.[4)] The reaction proceeded quite rapidly, giving after 30 min 58% of **2c** and 22% of 4-nitrobenzoic acid along with several minor products. No 3-nitro compounds could be obtained again. Although the reaction mechanism remains to be clarified, the oxidation of dinitrile **1c** to acyl cyanide **2c** most likely involves a nitrated *aci*-nitro compound **4**, which is formed via a S_E2' type process in which the attack of an electrophile occurs on the oxygen atom of nitro group with the loss of proton

from the side chain. The intermediate **4** then undergoes attack of oxygen nucleophile on the electron-deficient exo-carbon to form acyl cyanide **2c** or dissociates into a radical **5** and nitrogen dioxide via the homolytic fission of a nitrogen-oxygen bond as sketched in Scheme 1. A stabilized radical **5** is expected to be in equilibrium with the dimer **3**.

Dinitrile **1c** is usually prepared by the action of cyanogen chloride on 4-nitrophenylacetonitrile anion[6] or by the arylation of malononitrile anion with 4-bromonitrobenzene.[7] It is described as pale yellow plates melting at 109—110 °C and characterized by its remarkable acidity.[7,8] When this compound was prepared by the literature method, there was obtained a pale yellow crystalline solid, mp 108.5—109.5 °C. Its IR, ^1H and ^{13}C NMR, and UV spectra were all consist-

ent with the aromatic structure **1c** (Table 2). When dissolved into methanol or DMSO, however, this yellow dinitrile developed a deep red color and the ^{1}H and ^{13}C NMR spectra of the solution thus obtained were completely different from those of chloroform or benzene solution (Figs. 1 and 2). A deep-colored methanolic solution was evaporated under reduced pressure to leave a dark red solid, which also exhibited an infrared spectrum very different from that of a pale yellow compound. The red dinitrile is soluble in acetone, DMSO, and methanol to form a red solution, but it is slightly soluble in benzene and chloroform to give a yellow solution. In contrast, the yellow dinitrile is soluble in most common organic solvents to give a yellow to deep red solution depending on the nature of solvent employed. Both dinitriles are interconvertible simply by choosing an appropriate solvent system. On the basis of spectroscopic and microanalytical data as well as their behaviors toward different solvent systems, a nitro structure **1c** was assigned to the yellow dinitrile and an *aci*-nitro structure **6** to the red one. Our finding represents an additional mode of nitro/*aci*-nitro tautomerism, which occurs through a long distance at the expense of aromatic stabilization of benzene nucleus.

Experimental

All melting points were determined on a hot-stage apparatus and are uncorrected. IR spectra were run as KBr pellets on a Hitachi 260-10 spectrophotometer and only prominent peaks are recorded. UV spectra were measured in chloroform with a Hitachi 220A spectrophotometer. ^{1}H and ^{13}C NMR spectra were obtained on Hitachi R-600 and JNM-FX-100 spectrometers using TMS as an internal standard. Unless otherwise stated NMR data refer to deuteriochloroform solutions. Mass spectra were determined on a Hitachi M-80B mass spectrometer with 70 eV ionizing current.

Arylmalononitriles were prepared by allowing the corresponding iodoarenes to react with malononitrile anion in the presence of copper(I) iodide in hot hexamethylphosphoric triamide (HMPA).[9] The following typical example illustrates the general procedure used in the synthesis of the dinitriles. In the preparation of **1c**, assistance by copper(I) catalyst is not necessary.

2,3,5,6-Tetrachloro-4-methylphenylmalononitrile (1d). A commercial 60% sodium hydride dispersion in mineral oil (ca. 4 g) was washed three times by decantation with hexane and the remaining solid was covered with dry HMPA (10 ml). A solution of malononitrile (3.3 g) in the same solvent (10 ml) was added with stirring under nitrogen. After the cease of gas evolution, 2,3,5,6-tetrachloro-4-iodotoluene (3.56 g) was added, followed by copper(I) iodide (2.0 g), and the mixture was gradually heated to 85 °C and kept at this temperature for 10 h. TLC monitoring of the reaction mixture at this time showed no unreacted iodide. The black mixture was then quenched with dilute hydrochloric acid and the organic phase was extracted several times with ether. The extracts were combined, washed with aqueous sodium sulfite, and evaporated under reduced pressure. The crude product was chromatographed on silica gel using a hexane-dichloromethane mixture as eluent to give dinitrile **1d** as a crystalline solid, mp 207—209 °C. Yield, 1.65 g (56%). MS (70 eV) *m/z* (rel intensity) 293 (M^+, 100), 264 (36), and 258 (37); ^{1}H NMR: δ=2.66 (s, 3H) and 6.11 (s, 1H); ^{13}C NMR: δ=20.67, 25.97, 109.20, 131.57, 132.22, 134.27, and 140.96; IR: 2240, 1550, 1440, 1400, 1385, 1360, 1135, and 1000 cm^{-1}. Found: C, 41.09; H, 1.39; N, 9.59%. Calcd for $C_{10}H_4N_2Cl_4$: C, 40.86; H, 1.37; N, 9.53%.

Phenylmalononitrile (1a): Mp 67—68 °C. ^{1}H NMR: δ= 5.06 (s, 1H) and 7.48 (s, 5H); IR: 2250, 1490, 1450, 1010, 910, and 725 cm^{-1}.[10]

4-Methylphenylmalononitrile (1b): Mp 57—58 °C. ^{1}H NMR: δ=2.39 (s, 3H), 4.93 (s, 1H), and 7.0—7.2 (m, 4H); IR: 2250, 1500, 1005, 805, and 755 cm^{-1}. Found: C, 77.19; H, 5.11; N, 18.22%. Calcd for $C_{10}H_8N_2$: C, 76.90; H, 5.16; N, 17.94%.

4-Nitrophenylmalononitrile (1c): Mp 109—110 °C. ^{1}H NMR: δ=5.21 (s, 1H), 7.76 (d, 2H; J=8 Hz), and 8.40 (d, 2H; *J*=8 Hz); IR: 2255, 1610, 1590, 1525, and 1350 cm^{-1}. Found: C, 57.81; H, 2.45; N, 22.33%. Calcd for $C_9H_5N_3O_2$: C, 57.76; H, 2.69; N, 22.45%.[6]

Reaction of Arylmalononitriles with Nitric Acid. The procedure used in each of the reactions described was identical; therefore, only a typical example of these reactions will be reported in detail. The results are summarized in Table 1.

To a solution of 4-methylphenylmalononitrile (**1b**; 0.156 g) in dichloromethane (1 ml), nitric acid (*d*=1.5; 0.5 ml) was added and the mixture was stirred at room temperature for several hours, during the course of which the initial slightly yellow color gradually deepened to yellowish green, then faded to light yellow after 5 h. Liberation of nitrogen dioxide was observed. The mixture was diluted with water and the resulting turbid solution was extracted with dichloro-

methane. The extract was washed three times with cold water, dried with sodium sulfate, and evaporated under reduced pressure to leave a pale yellow solid. The residue was recrystallized from hexane-chloroform to afford 4-methylbenzoyl cyanide (**2b**) as colorless needles, mp 50—51 °C. Yield, 0.108 g (74%). ^{1}H NMR: δ=2.49 (s, 3H), 7.40 (d, 2H: J=8 Hz), and 8.05 (d, 2H; J=8 Hz); IR: 2215, 1660, 1595, 1260, and 975 cm^{-1}. Found: C, 74.18; H, 4.89; N, 9.66%. Calcd for C_9H_7NO: C, 74.47; H, 4.86; N, 9.65%.

On heating with methanol, **2b** was converted into methyl 4-methylbenzoate, identical with an authentic sample.

4-Nitrobenzoyl Cyanide (2c): Mp 116—117 °C. ^{1}H NMR: δ=8.41 (br. s, 2H) and 8.43 (br. s, 2H); IR: 2215, 1680, 1525, 1345, and 1230 cm^{-1}. Found: C, 54.64; H, 2.29; N, 15.71%. Calcd for $C_8H_4N_2O_3$: C. 54.55, H, 2.29; N, 15.90%.

2,3,5,6-Tetrachloro-4-methylbenzoyl Cyanide (2d): Mp 126—129 °C. ^{1}H NMR: δ=2.63 (s, 3H); IR: 2200, 1700, 1540, 1350, 1340, 1240, 1160, 1055, and 920 cm^{-1}. Found: C, 38.03; H. 1.09; N, 4.71%. Calcd for $C_9H_3NOCl_4$: C, 38.20; H, 1.07; N, 4.95%.

Oxidative Coupling of 4-Nitrophenylmalononitrile to 1,2-Bis(4-nitrophenyl)-1,1,2,2-tetracyanoethane. A solution of dinitrile **1c** in dichloromethane was mixed with nitric acid and the green reaction mixture obtained was quenched with iced water after a few minutes. A pale yellow solid was collected by filtration and fractionally crystallized from tetrahydrofuran-ether. Mp 156—157 °C. Found: C, 58.06; H, 2.03; N, 22.27%. Calcd for $C_{18}H_8N_6O_4$: C, 58.07; H, 2.17; N, 22.57%.

The authors thank Advanced Instrumentation Center for Chemical Analysis, Ehime University, for NMR spectral determinations and elemental analyses.

Metal-Catalyzed Organic Photoreactions. Titanium(IV) Chloride-Catalyzed Photoreactions of Aldohexoses

Shuji Ichikawa, Kazuo Takahashi, Masato Tanaka, and Tadashi Sato*
Department of Applied Chemistry, Waseda University, Ookubo 3, Shinjuku-ku, Tokyo 160
(Received September 16, 1987)

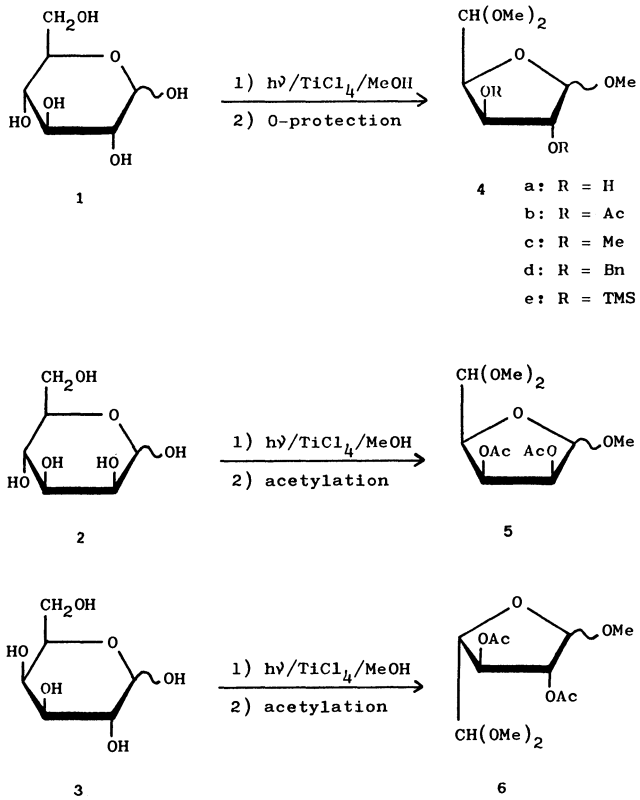
Under UV irradiation in the presence of titanium(IV) chloride in methanol, D-glucose, D-mannose, and D-galactose underwent a selective bond cleavage at the C5–C6 position, producing the corresponding pentodialdose derivatives. The reaction was interpreted in terms of the photoinduced electron transfer within a chelate of titanium ion with the carbohydrate molecule. The synthetic utilities of the photoproducts were discussed.

Although carbohydrate molecules are regarded as having either aldehyde or ketone group, the carbonyl groups are in a latent form, and they do not function as an effective chromophor to induce photoreaction. The photochemistry of the parent carbohydrate molecules has been performed either with conventional UV light (>200 nm) in the presence of molecular oxygen or sensitizers, or with shorter wavelength light (185 nm).[1] Under these conditions the reaction has been assumed to be initiated by hydroxyl radical produced from water molecule, and gives product as a mixture of various compouds. Most of the photoreactions of the carbohydrates have been carried out on derivatives having a chromophore at an appropriate position, and therefore they are regarded as the photochemistry of the chromophores, rather than that of carbohydrates themselves. Although these reactions usually proceed with high selectivity at the particular position, several steps are required to introduce the chromophore into the desired position, thus making the carbohydrate photochemistry discouraging in the synthetic chemistry field.

For some time, we have been investigating the effects of metal compounds on the photoreaction of organic molecules, and found that many photoreactions were remarkably affected by the presence of some metal compounds. One of the most unique types of reaction is the titanium(IV) chloride-catalyzed photocoupling reaction of carbonyl compounds with alcohols involving a C–C bond formation, and the reaction was applied successfully to the synthetic purpose.[2] In our previous papers,[3] we reported that D-glucose (**1**) and D-galactose (**3**), when irradiated with UV light in the presence of titanium(IV) chloride in methanol, underwent a selective cleavage of C5–C6 bond, producing pentodialdose derivatives **4** and **6**, respectively. We have schemed the reaction as involving formation of a five-membered titanium chelate with the C5, C6-diol system of the furanose form of the aldohexoses, followed by an electron transfer within the chelate.

In the present study, we irradiated D-mannose (**2**), an another aldohexose, under the same conditions, and obtained the corresponding pentodialdose derivative **5** in 50% yield. The starting carbohydrate was recovered as the corresponding methyl glycoside tetraacetate in 18% yield. Under these conditions, D-galactose was less soluble in the reacting solution, and much amount of the starting material remained unsolved even after 24 h irradiation. Although the reaction proceeded much faster when five-fold excess of titanium(IV) chloride was used, the yield of **6** was 30%, and 46% of the starting material **3** was recovered as methyl glycoside tetraacetate. The amounts of smaller fragments, which might have been derived from the carbohydrate, but of unknown structures, were also larger as compared with the other cases.

In accord with our previous observation that only the primary alcohol function was susceptible to the titanium(IV) chloride-catalyzed photoreaction,[2e] the bond cleavage at the other positions having secondary alcohol function occurred only to a minor extent, giving rise to the high selectivity of the bond cleavage at the C5–C6 position. The reaction is characteristic in that the metal compound imparts the photoreactivity to the carbohydrate molecules, which are otherwise

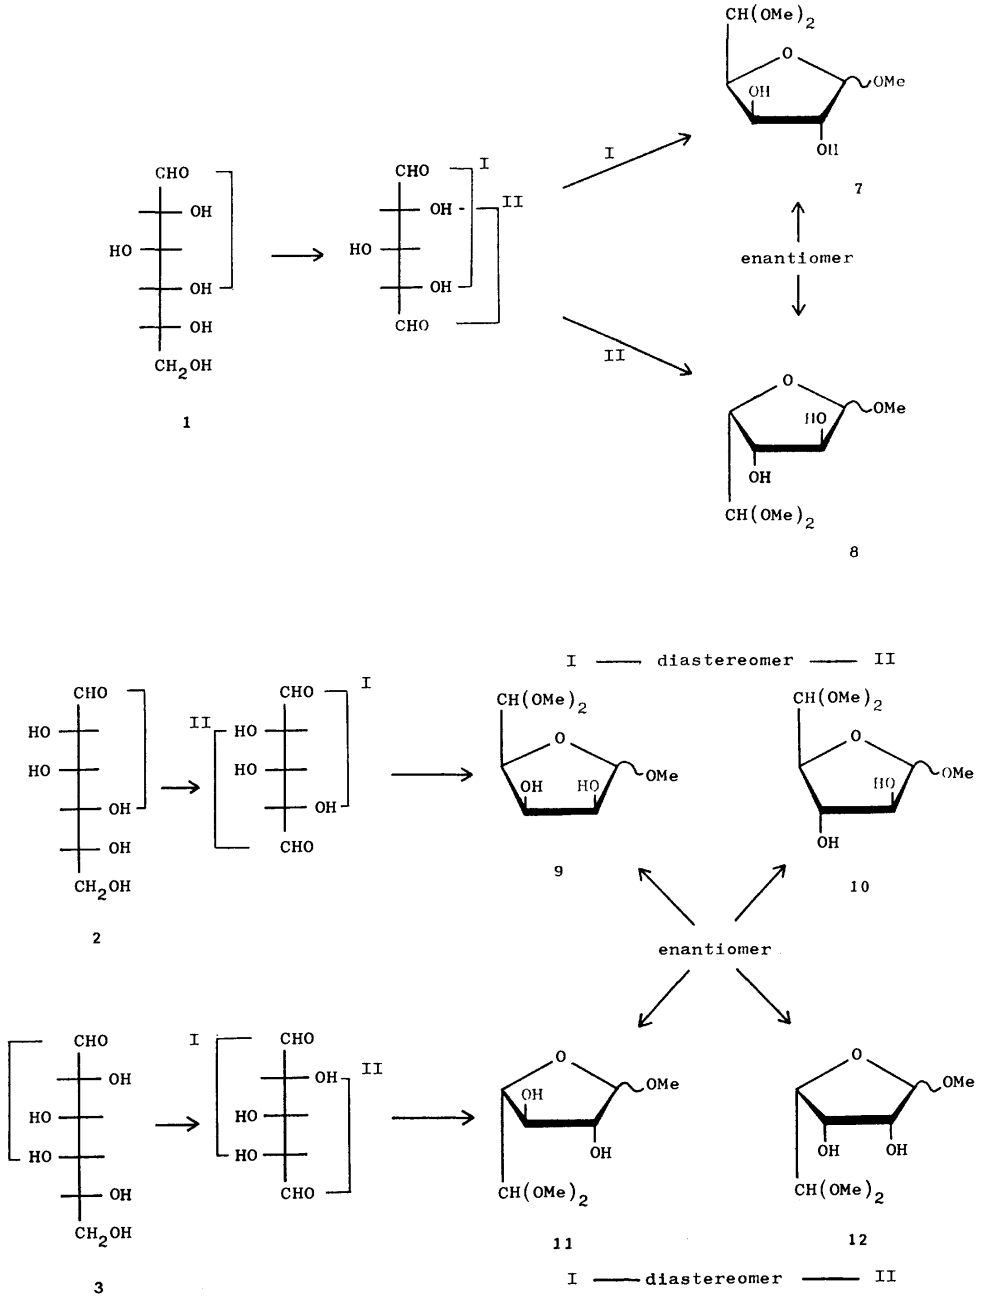


Scheme 1.

inactive towards the UV irradiation, and that the bond cleavage occurs at a specific position even without any prior protection on the carbohydrate molecules.

Since carbohydrate molecules have a series of asymmetric carbons of definite stereochemistry, they have been recognized as potential starting materials for the synthesis of chiral molecules.[4] The drawback in using the carbohydrates for this purpose is that the reactivity of each asymmetric center is quite similar, and hence it is not an easy task to carry out a specific reaction on a specific carbon. D-Glucose has been regarded as the carbohydrate that has the widest potential applicability for the synthetic purpose. It is not only because it is inexpensive, but also because it can be easily converted to some key intermediates, in which only specific positions could be brought into reaction. Therefore, in order to develop a chemisty of carbohydrates as chiral synthons, it is essential to supply with as many key intermediates as possible in which only particular positions could be reacted. We expected that the products of the present photoreaction, pentodialdose derivatives, could serve this purpose, and explored the reaction further into detail.

Since the present reaction proceeds under Lewis acid-methanol system, there might be a possibility of ring opening, and subsequent ring closure at another aldehyde group of the dialdose derivatives, resulting in the establishment of a net equilibrium between I and II (Scheme 2). If this ring scrambling occurred, the product from D-glucose (**1**) should be a racemic mixture,



Scheme 2.

7+**8**, while the products from D-mannose (**2**) and D-galactose (**3**) should be diastereomeric mixtures of **9**+**10**, and **11**+**12**, respectively. As evident from the Scheme 2, the mixture of **9**+**10** and that of **11**+**12** should be in the enantiomeric relation of the same set of compounds. Actually, however, it was shown ^{13}C NMR and GLC analyses that the products from **2** and **3** were not identical with each other, and no traces of the enantiomeric isomers were identified. Moreover, the products from D-glucose showed optical activities as shown in the Experimental part. From these observations, we concluded that the equilibrium between I and II does not exist under the present conditions, and only **7**, **9**, and **11** were the actual products from **1**, **2**, and **3**, respectively.

Kitagawa et al.[5] have obtained pentodialdose derivatives by electrolytic oxidation of uronic acids, but, under these conditions, the ring scrambling occurred, and D-mannuronic and D-galacturonic acids gave the corresponding enantiomers of the identical compounds.

In order to evaluate the utilities of these dialdose derivatives as chiral synthons, we investigated the chemoselectivity of the two aldehyde functions and the stereoselectivity in the reactions at C5, intending to apply the photoproducts to the synthesis of polyhydroxy compounds which are furnished with definite stereochemistry and are obtainable only with difficulty by other methods.

With these intentions, we carried out the reaction of **4** with various nucleophiles in the presence of Lewis acids. The results are shown in Table 1. As evident from these results, the reaction occurred predominantly at C5, but under severer conditions, the reaction occurred also at C1. The analysis of ^{13}C NMR signals of the anomeric carbons provided us with much information concerning with the stereochemistry of the products. As shown in Table 2, all these compounds had signals at around δ 100 and 107, characteristic of the anomeric carbons having α and β configurations, respectively.[6] The signal of each region further splitted into two peaks, which we assigned to those of C5 of the corresponding diastereomers, although we could not rule out the possibility of the signal splitting due to the presence of conformers of the furanose ring. Assuming that the intensities of the signals roughly correspond to the amount of each epimers,[7] we concluded that a fair to good diastereoselectivity has been attained in the reaction at C5. Generally, better selectivity has been obtained with acetate than with methyl ethers, but obviously, the selectivity was poor with α glycoside of **17c**.

Table 1. Products and Yields of the Reaction of **4** with Nucleophiles

β-**17c**		101.4 (54), 100.7 (46)
19c	100.4 (29), 100.3 (71)	107.8 (72), 107.5 (28)

a) See footnotes 6 and 7.

When the nitrile **17c** was treated with methanol-sulfuric acid, an anomeric mixture of ester **19c** was obtained. Lithium aluminum hydride reduction of **19c**, followed by methylation gave a diastereomeric mixture of permethylated hexofuranoses. The ^{13}C NMR spectrum of the product showed two sets of signals in a relative intensity of 70 : 30, and the minor set of the spectrum was completely identical with that of **24**, prepared from 1,2 : 5,6-di-*O*-isopropylidene-D-glucose by tandem partial deprotection at C5–C6, methylation, deprotection at C1–C2, and methylation. It was concluded, therefore, that the major product was methyl tetra-*O*-methyl-L-idofuranoside **23**.

The stereoselective alkylation of aldehyde **25** to produce 6-deoxyhexose derivatives **26** has been reported, and the reaction proceeds with chelating or non-chelating intermediate depending upon the reaction conditions.[8] However, all attempts at the preparation of hexose derivatives from **25** have been achieved only without any appreciable stereoselectivity.[9] It was found that the diastereoselectivity in the nucleophilic substitution at C5 of **4** stayed around 70 : 30, irrespective of the protective groups in **4** and the reaction conditions. The selectivity was also the same between allylation and acetonylation, since the Wacker oxidation of **13b** gave the same set of the diastereomers as

that obtained by the direct acetonylation of **4b**. Since we can prepare **4** from D-glucose in only two steps of photoreaction and methylation, the achievement of the higher selectivity could be very useful for setting up the configuration of L-idose system.

When the reduction product **16a** was methylated, it gave permethylated D-xylofuranoside **16c** in 85% yield, which was identical with the compound obtained in minor amount (12%) by the methylation of D-xylose. Since the methylation of D-xylose gave the permethylated product mostly in pyranoside form (85%), the present reaction could be a synthetic method for D-xylofuranoside derivatives. Lithium aluminum hydride reduction of **13c** gave an open chain compound **22c**. The products of the types of **21** and **22** are also promising as chiral synthons, because they have three different types of hydroxyl function of definite stereochemistry: One is unprotected, and the other two have two different protective groups from each other.

Since the preparation of the aldehydes corresponding to **25** from D-mannose and D-galactose in conventional manners are much more difficult as compared with the case from D-glucose, the manipulation of **2** and **3** would lead to an important development of the chemistry from these carbohydrates as chiral synthons.

Experimental

General Procedures and Instrumentation. GLC experiments were carried out on a 2.5 m×3 mm stainless steel column packed with Silicone SE30 or Carbowax 20M on silanized Chromosorb W. Preparative TLC was carried out on silica-gel plates using solvents as indicated. Unless otherwise stated, all the spectroscopic data were determined on a pure sample obtained by either distillation, preparative TLC, or column chromatography. ^1H NMR spectra (60 MHz) were recorded on a Hitachi R-24 or JEOL PMX 60SI spectrometer. ^1H NMR (90 MHz) and ^{13}C NMR spectra were measured on a Hitachi R-90H spectrometer. GC-MS spectra were taken on a Shimadzu QP-1000 mass spectrometer, and high-resolution mass spectra on a JEOL DX-300 mass spectrometer. UV spectra were measured on a Shimadzu UV-240 spectrometer.

All the irradiations were carried out using a high-pressure mercury lamp [Ushio UM 452 (450 W) or Sen HL-1000 (1 kW)] at the temperature of running water.

We tried several methods for the product isolation including column chromatography or HPLC, and found that distillation under the reduced pressure was the most convenient technique without appreciable difference in the product composition. Therefore we used the technique in most of the experiments.

Titanium(IV) Chloride-Catalyzed Photoreaction of D-Glucose (1). D-Glucose (2.0 g, 11.1 mmol) was dissolved in methanol (200 ml) containing $TiCl_4$ (1.5 ml, 13.8 mmol), and the solution was irradiated with a 1 kW lamp in a quartz vessel for 24 h. The solution was neutralized with 4 M NaOHaq (1M=1 mol dm^{-3}), and the precipitates of titanium hydroxide were filtered off. The filtrate was concentrated to dryness, and the residue was vigorously shaken with ethyl acetate several times. The solvent was removed in vacuo from the extract, and the residue was distilled under reduced pressure. After some amount of forerun (0.21 g), the main fraction was obtained as a viscous oil (1.4 g), bp 89—90 °C (0.07 mmHg (1 mmHg=133.322 Pa)). Although the purity

of the distillate could not be analyzed by GLC or TLC, the oil proved to be mainly **4a**, in view of the following results.

Acetylation: The crude **4a** (355 mg) was treated with acetic anhydride (1.4 ml) in pyridine (4.3 ml) for 18 h. Distillation with a Kugelrohr gave a main fraction as a viscous oil (288 mg), bp 150—170 °C (1 mmHg). GLC analysis showed that the fraction contained 85% of **4b**. Further distillation gave a pure sample of **4b**, which was shown to be a mixture of α and β anomers by GLC analysis. β Anomer was isolated in pure state by a preparative GLC, while α anomer was not completely freed from the β anomer. For β-**4b**: GC-MS, m/z (rel intensity) 261 (M^+−OMe, 0.5), 201 (0.3), 159 (4.0), 87 (10.4), 75 (100). ^{1}H NMR (CCl_4), δ=2.14 and 2.16 (6H, s×2, Ac), 3.39, 3.43, and 3.47 (9H, s×3, OMe), 4.21 (1H, dd, $J_{4,3}$=5.8 Hz, $J_{4,5}$=7.6 Hz, H_4), 4.47 (1H, d, $J_{5,4}$=7.6 Hz, H_5), 4.71 (1H, s, H_1), 4.90 (1H, br s, H_2), 5.26 (1H, br, d, $J_{3,4}$=5.8 Hz, H_3). ^{13}C NMR ($CDCl_3$), δ=169.4 (Ac-CO), 107.3 (C_1), 102.1 (C_5), 80.7 (C_4), 78.9 (C_2), 74.4 (C_3), 55.6, 54.5, and 53.0 (OMe), 20.8 and 20.6 (Ac-Me). IR 1738 (AcO), 1221 cm^{-1} (C-O). $[\alpha]_D^{24}$=+2.9 (c 0.05, $CHCl_3$). Found: C, 50.04; H, 6.68%. Calcd for $C_{12}H_{20}O_8$: C, 49.31; H, 6.90%. For α-**4b** (obtained by subtracting the data of β anomer from those of the mixture): GC-MS: same as that of the β anomer. ^{1}H NMR (CCl_4), δ=2.13—2.18 (6H, singlets, Ac), 3.39—3.44 (9H, singlets, OMe), 4.16—4.19 (2H, m, H_4, H_5), 4.79 (1H, br s, H_2), 4.96 (1H, d, $J_{1,2}$=4.5 Hz, H_1), 5.37 (1H, br d, $J_{3,4}$=6.0 Hz, H_3). ^{13}C NMR ($CDCl_3$), δ=169.6 (Ac-CO), 101.4 (C_1), 100.4 (C_5), 77.6 (C_4), 74.5 (C_2), 73.9 (C_3), 55.8, 54.5, and 53.0 (OMe), 20.8 and 20.6 (Ac-Me).

Methylation: Sodium hydride (350 mg, 14.6 mmol) was added to a solution of **4a** (400 mg, 1.9 mmol) in tetrahydrofuran, and the mixture was stirred for 30 min at room temperature. Methyl iodide (1.0 ml, 15 mmol) was added, and the solution was stirred for 20 h. After the addition of methanol, the solution was concentrated to dryness, and ice-water was added. The product was extracted with $CHCl_3$, dried over $MgSO_4$, and the distillation gave **4c** (358 mg), bp 110 °C (0.7 mmHg). GLC analysis showed two peaks corresponding to α and β anomers. Each anomer was separated on a preparative TLC (hexane/ether=1/2). For α-**4c**: GC-MS, m/z (rel intensity) 205 (M^+−OMe, 0.3), 173 (0.4), 161 (1.1), 145 (0.5), 130 (0.8), 75 (100). ^{1}H NMR ($CDCl_3$), δ=3.38, 3.43, 3.44, 3.46, and 3.50 (15H, s×5, OMe), 3.73—4.00 (2H, m, H_2, H_3), 4.20 (1H, t, $J_{4,3}$=$J_{4,5}$=6.3 Hz, H_4), 4.54 (1H, d, $J_{5,4}$=6.3 Hz, H_5), 4.99 (1H, d, $J_{1,2}$=4.5 Hz, H_1). ^{13}C NMR ($CDCl_3$), δ=101.8 (C_1), 101.0 (C_5), 85.7 (C_2), 83.8 (C_3), 77.2 (C_4), 58.5, 58.4, 55.5, 55.2, and 52.8 (OMe). $[\alpha]_D^{24}$=−1.2 (c 0.01, $CHCl_3$). For β-**4c**: GC-MS, same as that of the α anomer. ^{1}H NMR ($CDCl_3$), δ=3.38, 3.40, 3.43, 3.44, 3.47 (15H, s×5, OMe), 3.67—3.75 (2H, br, H_2, H_3), 4.09 (1H, dd, $J_{4,3}$=5.3 Hz, $J_{4,5}$=7.9 Hz, H_4), 4.57 (1H, d, $J_{5,4}$=7.9 Hz, H_5), 4.84 (1H, s, H_1). ^{13}C NMR ($CDCl_3$), δ=108.0 (C_1), 102.9 (C_5), 87.7 (C_2), 83.3 (C_3), 80.1 (C_4), 58.1, 57.3, 55.6, 55.4, and 53.1 (OMe). $[\alpha]_D^{24}$=+5.5 (c 0.013, $CHCl_3$).

Benzylation: The benzylation was carried out in the same way as for the methylation described above. The product **4d** was obtained through preparative TLC as an anomeric mixture (α/β=1/9) in 56% yield. For β-**4d**: ^{1}H NMR (CCl_4), δ=3.27—3.36 (9H, s×3, OMe), 3.88 (1H, br s, H_2), 3.91—4.25 (2H, m, H_3, H_4), 4.57 (1H, d, $J_{5,4}$=7.8 Hz, H_5), 4.79 (1H, s, H_1), 4.40 and 4.45 (4H, s×2, Ar-CH_2), 7.25 (10H, s, Ar). ^{13}C NMR ($CDCl_3$), δ=142.2—127.8 (Ar), 108.3 (C_1), 102.6 (C_5), 86.4 (C_2), 81.3 (C_3), 80.3 (C_4), 72.6 and 72.0 (Ar-CH_2), 55.6, 55.1, and 53.0 (OMe). For α-**4d** (obtained by subtracting the data of β anomer from those of the mixture): ^{13}C NMR ($CDCl_3$), δ=101.8 (C_1), 101.0 (C_5), 83.8 (C_2), 82.4 (C_3), 76.0 (C_4), 59.7, 59.3, and 57.0 (OMe).

Trimethylsilylation: The silylation was carried out using **4a** (620 mg, 3.0 mmol), hexamethyldisilazane (3 ml, 24 mmol), and chlorotrimethylsilane (0.4 ml, 4.4 mmol) in tetrahydrofuran (55 ml) by stirring at room temperature for 43 h. The product **4e** (1.028 g, 98% yield) was obtained in pure state by distillation, bp 190 °C (20 mmHg). For **4e** (as an anomeric mixture): GC-MS, m/z (rel intensity) 321 (M^+−OMe, 0.3), 305 (0.3), 247 (1.1), 231 (1.2), 217 (39.3), 133 (24.9), 75 (100), 73 (41.3). ^{1}H NMR (CCl_4), δ=0.04 (18H, s, TMS), 3.20—3.35 (9H, singlets, OMe), 3.68—4.09 (3H, m, H_2, H_3, H_4), 4.21—4.73 (2H, m, H_1, H_5). ^{13}C NMR ($CDCl_3$), δ=110.7 (β-C_1), 102.5 (α-C_1), 102.7 (β-C_5), 101.9 (α-C_5), 80.3 (β-C_4), 76.8 (α-C_4), 82.1, 78.4, 77.2, and 76.1 (C_2, C_3), 55.5, 54.6, 54.5, 53.0, and 52.6 (OMe), 5.26 (TMS). $[\alpha]_D^{25}$=+0.83 (c 0.380, $CHCl_3$).

Titanium(IV) Chloride-Catalyzed Photoreaction of D-Mannose (2). Under the same conditions as for D-glucose, the product **5** was obtained in 50% yield. For **5** (as an anomeric mixture): GC-MS, m/z (rel intensity) 261 (M^+−OMe, 0.4), 201 (1.6), 169 (3.4), 159 (3.0), 126 (7.1), 115 (3.3), 99 (4.3), 87 (11.0), 75 (100). ^{1}H NMR (CCl_4), δ=2.01—2.16 (6H, singlets, Ac), 3.35—3.41 (9H, singlets, OMe), 3.82—4.61 (3H, m, H_1, H_4, H_5), 4.75—5.19 (2H, m, H_2, H_3). ^{13}C NMR ($CDCl_3$), δ=170.3—169.5 (Ar-CO), 106.9 (α-C_1), 103.4 (β-C_1), 105.1 (α-C_5), 101.5 (β-C_5), 81.5 and 80.9 (C_4), 78.7 and 77.4 (C_2), 76.0 and 75.4 (C_3), 55.7—53.1 (OMe), 23.2 (Ac-Me). $[\alpha]_D^{27}$=+8.6 (c 0.070, $CHCl_3$). HRMS: Found: m/z 261.0984. Calcd for $C_{11}H_{17}O_7$ (M^+−OMe): 261.0974.

Titanium(IV) Chloride-Catalyzed Photoreaction of D-Galactose (3). The photoreaction was carried out using D-galactose (2.0 g, 11.1 mmol) and $TiCl_4$ (6.0 ml, 55.6 mmol) in methanol (200 ml) in the same way as above to produce **6** in 30% yield. For **6** (as an anomeric mixture): GC-MS, m/z (rel intensity) 261 (M^+−OMe, 1.9), 201 (1.6), 169 (3.4), 158 (4.6), 126 (9.8), 115 (3.3), 99 (5.3), 87 (14.0), 75 (100). ^{1}H NMR (CCl_4), δ=1.96—2.11 (6H, singlets, Ac), 3.27—3.41 (9H, singlets, OMe), 3.78—4.39 (3H, m, H_1, H_2, H_5), 4.72—5.14 (2H, m, H_2, H_3). ^{13}C NMR ($CDCl_3$), δ=170.3—168.8 (Ac-CO), 107.2 (α-C_1), 100.8 (β-C_1), 99.8 (α-C_5), 95.9 (β-C_5), 81.3 and 80.3 (C_4), 78.0 and 77.2 (C_2), 76.8 and 75.4 (C_3), 55.1—54.1 (OMe), 20.8 (Ac-Me). HRMS: Found: m/z 261.0985. Calcd for $C_{11}H_{17}O_7$ (M^+−OMe): 261.0974.

Titanium(IV) Chloride-Catalyzed Allylation of 4b. To a solution of **4b** (0.129 g, 0.33 mmol) in CH_2Cl_2 (4.7 ml) was added allyltrimethylsilane (0.16 ml, 1.0 mmol) and then a solution of $TiCl_4$ (0.127 g, 0.67 mmol) in CH_2Cl_2 (0.3 ml) at room temperature. The solution was stirred for 10 min at room temperature, added to cold water, and extracted with ether. The extract was washed with water and dried over Na_2SO_4. Evaporation of the solvent gave an oil, 0.104 g, which proved to be a mixture of **13b** (97%) and **4b** (2.5%) by GLC analysis. Pure sample of **13b** was obtained by a preparative TLC (ether/$CHCl_3$=1/9). For **13b** (as an anomeric mixture): GC-MS, m/z (rel intensity) 271 (M^+−OMe, 0.5), 261 (2.4), 217 (1.3), 201 (2.4), 159 (11.3), 126 (9.9), 115 (17.9), 85 (33.6), 43 (100). ^{1}H NMR (CCl_4), δ=2.02—2.13 (6H, singlets, Ac), 2.20—2.49 (2H, m, -C$\underline{H}_2$CH=CH_2), 3.35—3.53 (6H, singlets, OMe), 3.91—4.27 (2H, m, H_4, H_5), 4.61—5.22 (5H, m, H_1, H_2, H_3, -CH=C$\underline{H}_2$), 5.37—6.18 (1H, m,

-CH=CH_2). ^{13}C NMR ($CDCl_3$), δ=170.2, 170.1, 169.7, and 169.2 (Ac-CO), 134.2 and 134.0 (-CH=CH_2), 117.6 and 117.2 (-CH=CH_2), 107.1 and 106.3 (83:17) (R-C_1), 100.4 and 99.7 (15:85) (S-C_1), 82.9 and 80.0 (C_4), 79.9 and 78.5 (C_5), 76.9 and 76.3 (C_2), 75.1 and 74.4 (C_3), 58.8, 57.9, 55.9, and 55.5 (OMe), 35.3 and 34.8 (-CH_2-CH=CH_2), 20.8, 20.7, and 20.6 (Ac-Me).

When the reaction was carried out with larger amount of the Lewis acid, using **4b** (0.120 g, 0.33 mmol), $TiCl_4$ (0.15 ml, 1.33 mmol), and allyltrimethylsilane (0.21 ml, 1.33 mmol) under the otherwise same conditions as above, the product was **21b**, which was obtained in pure state on a column chromatography. For **21b** (as an anomeric mixture): GC-MS, *m/z* (rel intensity) 303 (M^+−OMe, 0.7), 271 (1.0), 183 (1.0), 169 (1.5), 137 (1.8), 85 (71.6), 55 (21.4), 43 (100). ^{1}H NMR (CCl_4), δ=1.95—2.11 (6H, singlets, Ac), 2.19—2.35 (4H, m, -CH_2-CH=CH_2×2), 3.35 (6H, singlets, OMe), 3.11—3.68 (3H, m, H_1, H_4, H_5), 4.66—5.30 (6H, m, H_2, H_3, CH_2=CH-×2), 5.44—6.13 (2H, m, CH_2=CH-×2). ^{13}C NMR ($CDCl_3$), δ=175.0—172.7 (Ac-CO), 134.0—133.6, 118.1—117.4, and 35.1—33.7 (allyls), 80.0, 79.6, 79.1, and 78.9 (C_1, C_5), 74.1 and 72.8 (C_4), 71.8, 71.7, 76.0, and 69.1 (C_2, C_3), 20.9 (Ac-Me). IR (neat), ν_{max} 3550 (OH), 1740 (acetate), 1650 cm^{-1} (olefin). Found: C, 58.12; H, 7.98%. Calcd for $C_{17}H_{28}O_7$: C, 59.28; H, 8.19%.

Trimethylsilyl Triflate-Catalyzed Allylation of 4b. A mixture of **4b** (0.12 g, 0.41 mmol), allyltrimethylsilane (0.16 ml, 1 mmol), and TMSOTf (22.2 mg, 0.1 mmol) in acetonitrile (2 ml) was stirred for 30 min. The solution was added to Na_2CO_3aq, and extracted with ether. After drying over Na_2SO_4, ether was evaporated to give **13b** (0.125 g, 100% yield) as a single product.

When the reaction time was prolonged to 46 h, or when the solution was refluxed for 1 h, in the above reaction, the crude product remained after the evaporation of ether showed two spots on a TLC. Separation on a preparative TLC gave a diallyl compound **20b** (48 mg, 60% yield) as well as the monoallyl compound **13b** (35 mg, 35% yield). For **20b** (as C_1, C_5-diastereomeric mixture): GC-MS, *m/z* (rel intensity) 281 (M^+−OMe, 0.16), 271 (3.1), 211 (3.0), 169 (8.4), 137 (14.0), 125 (10.3), 109 (10.2), 85 (54.3), 43 (100). ^{1}H NMR (CCl_4), δ=2.02 and 2.05 (6H, s×2, Ac), 2.10—2.40 (4H, m, -CH_2-CH=CH_2×2), 3.28 and 3.32 (6H, s×2, OMe), 3.04—4.32 (3H, m, H_1, H_4, H_5), 4.61—5.22 (6H, m, H_2, H_3, CH_2=CH-×2), 5.31—6.11 (2H, m, CH_2=CH-×2). ^{13}C NMR ($CDCl_3$), δ=169.6 and 169.5 (Ac-CO), 134.2—133.8, 117.4—117.1, and 35.1, 33.9 (allyls), 82.9, 82.2, 80.5, 80.3, 79.5, 79.0, 78.7, 76.7 (C_1—C_5), 58.5 and 58.3 (OMe), 20.9 and 20.8 (Ac-Me).

Acetonylation of 4b, 4c, 4d. 2-(Trimethylsilyloxy)-1-propene (0.16 ml, 1 mmol) was added to a solution of **7b** (0.1 g, 0.34 mmol) in acetonitrile (3 ml), and the solution was cooled to 0 °C. To the solution was added TMSOTf (0.01 ml, 0.05 mmol), and stirred for 20 min at 0 °C. The conventional workup produced crude **14b**, 106 mg. Pure sample was obtained by a preparative TLC. In the same way, methyl (**14c**) and benzyl (**14d**) derivatives were obtained. A preparative TLC of **14d** gave pure sample of (R)-C_1 anomer. For **14b** (as an anomeric mixture): GC-MS, *m/z* (rel intensity) 243 (M^+−Me−AcOH, 0.1), 217 (1.9), 183 (0.3), 158 (1.0), 157 (1.4), 153 (0.9), 115 (13.6), 101 (3.9), 87 (5.0), 43 (100). ^{1}H NMR (CCl_4), δ=1.98—2.13 (9H, singlets, AcO and Ac), 2.31—2.75 (2H, m, $AcCH_2$-), 3.19—3.40 (6H, singlets, OMe), 3.52—4.27 (2H, m, H_4, H_5), 4.65—5.59 (3H, m, H_1, H_2, H_3). ^{13}C NMR ($CDCl_3$), δ=206.6—205.8 (acetonyl-CO), 170.2—169.2 (Ac-CO), 107.4 and 107.3 (69:31, (R)-C_1), 100.2 and 99.9 (17:83, (S)-C_1), 82.7—74.2 (C_2—C_5), 59.3—55.2 (OMe), 46.1—44.3 (acetonyl-CH_2), 31.1—30.9 (acetonyl-Me), 20.7 and 20.6 (Ac-Me). For **14c** (as an anomeric mixture): GC-MS, *m/z* (rel intensity) 231 (M^+−OMe, 13.3), 204 (25.3), 161 (2.5), 101 (100), 88 (17.1), 75 (40.6), 73 (20.8), 45 (20.0), 43 (37.5). ^{1}H NMR (CCl_4), δ=2.12 (3H, s, acetonyl-Me), 2.43—2.61 (2H, m, acetonyl-CH_2), 3.31—3.47 (12H, singlets, OMe), 3.47—4.05 (4H, m, H_2, H_3, H_4, H_5), 4.55—4.82 (1H, m, H_1). ^{13}C NMR ($CDCl_3$), δ=209.2—207.9 (acetonyl-CO), 106.5 and 105.9 (73:27, (R)-C_1), 99.4 and 99.2 (30:70, (S)-C_1), 86.8—80.8 (C_2-C_5), 57.7—53.1 (OMe), 45.1—41.8 (acetonyl-CH_2), 30.5—27.6 (acetonyl-Me). For 1(R)-**14d**: ^{1}H NMR (CCl_4), δ=2.01—2.12 (3H, singlets, acetonyl-Me), 2.41—2.73 (2H, m, acetonyl-CH_2), 3.22—3.39 (6H, singlets, OMe), 3.73—4.17 (4H, m, H_2-H_5), 4.48 (4H, s, benzyl-CH_2×2), 4.87 (1H, d, $J_{1,2}$=7.9 Hz, H_1) 7.25 (10H, s, Ar×2). ^{13}C NMR ($CDCl_3$), δ=207.1 (acetonyl-CO), 108.3 and 107.2 (83:17, C_1), 85.8—75.4 (C_2—C_5), 58.6, 57.6, 55.9, and 54.8 (OMe), 46.8 and 46.2 (acetonyl-CH_2), 30.8 and 28.9 (acetonyl-Me), 72.0, 71.9, 139.7—126.7 (benzyl). For 1(S)-**14d** (obtained by subtracting the data of (R) anomer from those of mixture), ^{1}H NMR (CCl_4), δ=2.01—2.25 (3H, singlets, acetonyl-Me), 2.35—2.92 (2H, m, acetonyl-CH_2), 3.38—3.47 (6H, singlets, OMe), 3.78—4.23 (4H, m, H_2-H_5), 4.51 (4H, m, benzyl-CH_2), 4.81—4.97 (1H, m, H_1), 7.30 (10H, s, Ar). ^{13}C NMR ($CDCl_3$), δ=206.7 (acetonyl-CO), 100.5 and 99.7 (92:8, C_1), 84.9—74.9 (C_2—C_5), 58.1 and 55.0 (OMe), 45.1 and 44.9 (acetonyl-CH_2), 30.4 and 30.3 (acetonyl-Me), 72.0, 71.9, 137.8—127.5 (benzyl).

Methyl D-Xylofuranoside Trimethyl Ether 16c. A suspension of $AlCl_3$ (266 mg, 2 mmol) in ether (1 ml) was stirred at 0 °C for 30 min. To the mixture was added a slurry of LAH (26 mg, 0.67 mmol) in ether (1 ml), and stirred for 30 min. A solution of **4b** (100 mg, 0.34 mmol) in ether (1 ml) was added and stirred for 2 h at room temperature. The reaction mixture was quenched by adding 10% H_2SO_4aq and then neutralized with dil NaOHaq. The solid material was filtered off, and the filtrate was concentrated in vacuo to produce an oil. Upon methylation with MeI and NaH, the oil gave **16c** in 85% yield. This was identical (GC-MS) with the sample prepared by methylation of D-xylose in the same way as above.

Cyanation of 4b and 4c. To a solution of **4c** (80 mg, 0.33 mmol) in acetonitrile (3 ml) was added TMSCN (0.14 ml, 1 mmol) and TMSOTf (0.01 ml, 0.05 mmol), and the solution was stirred for 2.5 h at room temperature. After the reaction, 10% Na_2CO_3aq (10 ml) was added and extracted with ether. The extract was dried over Na_2SO_4, and the solvent was removed to give an oil (78 mg). Pure sample of **17c** (69 mg) was obtained by the bulb-to-bulb distillation. bp 115 °C (0.1 mmHg). A preparative TLC of **17c** gave pure sample of (S)-C_1 anomer. In the same way, the acetate **17b** was obtained from **4b** in 87% yield. Bp 120 °C (0.03 mmHg). The same compound was also obtained from **4b** using $TiCl_4$ as a Lewis acid in CH_2Cl_2 in 89% yield. For 1(S)-**17c**: GC-MS, *m/z* (rel intensity) 200 (M^+−OMe, 0.1), 161 (4.1), 149 (2.0), 140 (1.2), 129 (2.9), 101 (100), 88 (6.8), 75 (70.4). ^{1}H NMR ($CDCl_3$), δ=3.46—3.54 (12H, singlets, OMe), 3.29—4.49 (4H, m, H_2-H_5), [5.05 (1/2H, d, $J_{1,2}$=3.9 Hz) and 5.07 (1/2H, d, $J'_{1,2}$=3.9 Hz), H_1]. ^{13}C NMR ($CDCl_3$), δ=116.3 (CN), 101.4 and 100.7 (1:1, C_1), 85.2 and 85.1 (C_2), 83.0 and 82.2 (C_3), 76.6 and 76.4 (C_4), 70.8 and 69.9 (C_1), 58.8—55.8 (OMe). For

l(R)-**17c** (obtained by subtracting the data of l-(S) anomer from those of mixture): ^{1}H NMR ($CDCl_3$), δ=3.36—3.55 (12H, singlets, OMe), 3.71—4.55 (4H, m, H_2-H_5), 4.85 (1/5H, s, H_1), 4.91 (4/5H, s, H_1). ^{13}C NMR ($CDCl_3$), δ=117.2 and 116.4 (19:81, CN), 108.4 and 107.8 (76:24, C_1), 87.6 and 87.0 (C_2), 84.9 and 83.1 (C_3), 80.7 and 79.4 (C_4), 71.1 and 70.4 (C_5), 59.1—55.5 (OMe). For **17b** (as a diastereomeric mixture): GC-MS, *m/z* (rel intensity) 256 (M^+—OMe, 3.1), 217 (7.0), 157 (30.6), 154 (14.2), 129 (18.5), 115 (100), 87 (43.3). ^{1}H NMR (CCl_4), δ=2.02—2.15 (6H, singlets, Ac), 3.37—3.49 (6H, singlets, OMe), 4.02—4.61 (2H, m, H_4, H_5), 4.72—5.76 (3H, m, H_1, H_2, H_3). ^{13}C NMR ($CDCl_3$), δ=170.0—168.9 (Ac-CO), 116.3—115.4 (CN), 107.6 and 107.4 (65:35, (R)-C_1), 100.6 and 100.4 (7:93, (S)-C_1), 80.5—73.5 (C_2, C_3, C_5), 70.5—69.7 (C_4), 58.5—55.6 (OMe), 20.6—20.3 (Ac-Me).

Methanolysis of the Nitrile 17c. To a solution of **17c** (115 mg, 0.5 mmol) in methanol (5 ml) was added 98% H_2SO_4 (1.5 ml). The solution was kept at room temperature for 24 h, and poured into water. The solution was shaken with $CHCl_3$, and the extract was dried over Na_2SO_4. Evaporation of the solvent gave an oil **19c**, 120 mg. Bulb-to-bulb distillation gave pure sample, 116 mg. Bp 120 °C (0.1 mmHg). For **19c** (as an anomeric mixture): GC-MS, *m/z* (rel intensity) 205 (M^+—COOMe, 48.5), 161 (20.3), 145 (11.2), 129 (10.2), 101 (100), 75 (42.6). ^{1}H NMR ($CDCl_3$), δ=3.18—3.52 (12H, singlets, OMe), 3.76—3.83 (3H, singlets, COOMe), 3.86—4.16 (3H, m, H_2, H_3, H_4), 4.46—4.63 (1H, m, H_5), [4.85 (3/20H, d, δ=0.9 Hz) and 4.89 (7/20H, d, J=0.9 Hz), H_1 of l(R) anomer], 4.97 (1/2H, d, J=3.5 Hz, H_1 of l(S) anomer). ^{13}C NMR ($CDCl_3$), δ=171.4—170.1 (ester-CO), 107.8 and 107.5 (72:28, (R)-C_1), 100.4 and 100.3 (29:71, (S)-C_1), 89.5—76.6 (C_2—C_5), 58.8—54.9 (OMe), 52.6—51.2 (ester-Me). Found: C, 49.99; H, 7.63%. Calcd for $C_{11}H_{20}O_7$: C, 50.45; H, 7.51%.

Methyl L-Idofuranoside Tetramethyl Ether 23. To a solution of **19c** (90 mg, 0.33 mmol) in dry ether (5 ml) was added LAH (39 mg, 1 mmol), and stirred for 2 h at room temperature. Methanol and then 4 M HClaq were added to quench the excess LAH, and the solution was neutralized with 10% NaOHaq. The solid material was filtered off, and the filtrate was concentrated to dryness in vacuo. The remaining material was triturated with dry THF, and washed NaH (50 mg, 2.1 mmol) was added. After the mixture was stirred for 30 min, methyl iodide (1.6 ml, 5 mmol) was added, and the mixture was stirred for 18 h at room temperature. The excess NaH was quenched by addition of methanol, and the solution was concentrated in vacuo. The remaining material was dissolved in water, and extracted with $CHCl_3$. The extract was dried over Na_2SO_4, and the solvent was removed in vacuo. The crude material (84 mg), showing only one peak on a GLC analysis, was distilled to give an oil (77 mg). The ^{13}C NMR of the oil showed two sets of the signals in a ratio of 25:75. The set of the minor signals completely coincided with those of **24**, obtained in a way described below. The data of **23** were obtained by subtracting the data of **24** from those of the mixture oil. For **23**: GC-MS, *m/z* (rel intensity) 205 (M^+—CH_2OMe, 0.4), 173 (1.2), 161 (7.0), 145 (5.0), 101 (100), 75 (58.5), 59 (15.5), 45 (63.4). ^{1}H NMR ($CDCl_3$), δ=3.39—3.57 (15H, singlets, OMe), 3.60—4.36 (6H, m, H_2-H_6), 4.90 (1/2H, d, J=1.1 Hz, H_1 of α anomer (1R)), 4.95 (1/2H, d, J=3.0 Hz, H_1 of β anomer (1S)). ^{13}C NMR ($CDCl_3$), δ=108.1 (C_1 of α anomer), 100.4 (C_1 of β anomer), 87.0 and 85.2 (C_2), 83.3 and 83.0 (C_4), 81.3 and 76.3 (C_3), 79.9 and 77.6 (C_5), 72.2 and 72.0 (C_6), 60.7—55.2 (OMe).

Methyl D-Glucofuranoside Tetramethyl Ether 24. To a solution of 1,2-*O*-isopropylidene-D-glucofuranose (250 mg, 1.14 mmol) in dry THF (20 ml) was added NaH (400 mg, 16.7 mmol), and the mixture was stirred for 30 min. Methyl iodide (1.6 ml, 25 mmol) was added and the mixture was stirred for 18 h at room temperature. Methanol was added to quench the excess NaH, and the solution was concentrated in vacuo. Water was added, and the products were extracted with $CHCl_3$. After dried over Na_2SO_4, the solvent was removed in vacuo to give an oil. The oil (302 mg) was dissolved in methanol (12 ml) and 98% H_2SO_4 was added slowly. The solution was stirred for 20 h at room temperature, poured into water, and extracted with ether. After the extract was dried over Na_2SO_4, the solvent was removed in vacuo to give an oil, 220 mg. The oil was again methylated in the same way as above, and the crude product was distilled to afford a pure sample of **24**, 220 mg, bp 110 °C (0.03 mmHg). For **24**: GC-MS, *m/z* (rel intensity) 205 (M^+—CH_2OMe, 0.8), 173 (2.0), 161 (7.5), 145 (5.8), 101 (100), 75 (65.0), 59 (16.8), 45 (61.3). ^{1}H NMR ($CDCl_3$), δ=3.26—3.48 (15H, singlets, OMe), 3.47—3.91 (5H, m, H_2-H_6), 3.95—4.23 (1H, m, H_4), 4.81 (1/2H, s, H_1 of β anomer (1R)), 4.92 (1/2H, d, J=3.0 Hz, H_1 of α anomer (1S)). ^{13}C NMR ($CDCl_3$), δ=108.1 (C_1 of β anomer), 101.1 (C_1 of α anomer), 87.4 and 86.1 (C_2), 83.8 and 82.7 (C_4), 79.7 and 76.3 (C_3), 78.0 and 77.7 (C_5), 72.6 and 72.4 (C_6), 59.2—55.1 (OMe).

Trimethylsilyl Triflate-Catalyzed Allylation of 4c and 4d To a solution of **4c** (80 mg, 0.33 mmol) in dry acetonitrile (3 ml) was added allyltrimethylsilane (1.6 ml, 1 mmol), and then TMSOTf (0.01 ml, 0.05 mmol) at −30 °C. The mixture was stirred at this temperature for 20 min, and the workup in the same way as for **4b** gave a product **13c** (83 mg, 98% yield). The pure sample was obtained by a preparative TLC. In the same way, benzyl derivative **13d** was obtained from **4d** in 60% yield. For **13c** (as an anomeric mixture): GC-MS, *m/z* (rel intensity) 215 (M^+—OMe, 0.08), 205 (3.5), 173 (3.5), 161 (6.7), 145 (4.3), 101 (99.9), 85 (32.0), 75 (100). ^{1}H NMR (CCl_4), δ=2.09—2.33 (2H, m, -C<u>H</u>$_2$-CH=CH_2), 3.28—3.45 (12H, singlets, OMe), 3.09—4.03 (4H, m, H_2-H_5), 4.65—5.16 (3H, m, H_1, C<u>H</u>$_2$=CH-), 5.28—6.11 (1H, m, CH_2=C<u>H</u>-). For **13d** (as an anomeric mixture): ^{1}H NMR (CCl_4), δ=2.07—2.56 (2H, m, C<u>H</u>$_2$-CH=CH_2), 3.20—3.35 (6H, singlets, OMe), 3.62—4.09 (4H, m, H_2-H_5), 4.43 (4H, s, benzyl-CH_2), 4.72—5.11 (3H, m, H_1, C<u>H</u>$_2$=CH-), 5.42—6.25 (1H, m, CH_2=C<u>H</u>-), 7.25 (10H, s, Ar).

Butylation of 4d. To a solution of **4d** (130 mg, 0.33 mmol) in CH_2Cl_2 (3 ml) was added $TiCl_4$ (0.04 ml, 0.33 mmol) at −78 °C. A hexane solution of 1.4 M *n*-BuLi (0.72 ml, 1 mmol) was added at this temperature, and the mixture was warmed up to room temperature. After stirring for 1 h at room temperature, the mixture was worked up in conventional way to produce **15d** (132 mg, 64% yield) as an oil. Preparative TLC gave a pure sample. For **15d**: ^{1}H NMR (CCl_4), δ=[0.95 (3H, m) and 1.30 (6H, m), *n*-Bu], 3.21—3.37 (6H, singlets, OMe), 3.40—3.61 (1H, m, H_5), 3.73—4.22 (3H, m, H_2, H_3, H_4), 4.40—4.48 (4H, singlets, benzyl-CH_2), 4.55—4.80 (1H, m, H_1), 7.20 (10H, s, Ar).

Wacker Oxidation of 13b to 14b. Oxygen gas was bubbled into a solution of $PdCl_2$ (6.7 mg, 0.038 mmol) and CuCl (40 mg, 0.40 mmol) in a mixture solvent of DMF (1 ml) and water (0.4 ml) for 30 min. To the solution was added **20b** (103 mg, 0.34 mmol), and oxygen gas was bubbled into the

solution for another 6 h. After 3 M HClaq (0.2 ml) was added, the solution was shaken with CH_2Cl_2. The extract was washed with Na_2CO_3aq and then with NaClaq. After dried over Na_2SO_4, the solvent was removed in vacuo. The crude material (120 mg) was purified on a preparative TLC to give an oil which was identical with **14b** obtained from **4b**.

6) Due to the uncertainty concerning with the newly-created asymmetric center at C5, the anomeric nomenclature of α and β is ambiguous. Throughout the present paper, therefore, we termed α for all compounds having the same anomeric configuration as that of α-D-glucose.

7) The assumption could be generally supported because, with some compounds in which the α and β anomeric protons resonate at separate positions, the estimation from ^{13}C NMR and ^1H NMR spectra coincided.

Metal-Catalyzed Organic Photoreactions. Iron(III)-Catalyzed Photoreactions of Aldo- and Ketohexoses[1)]

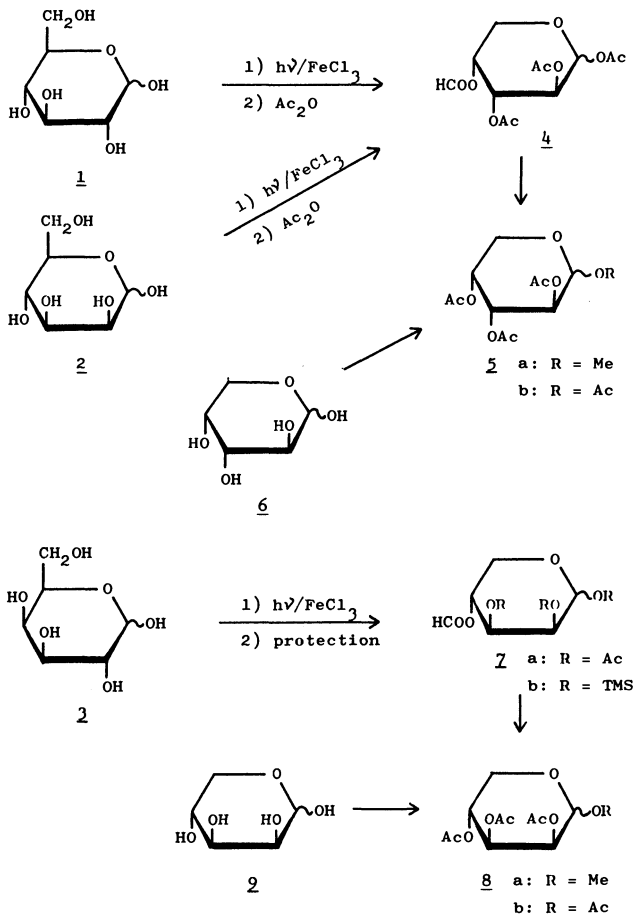
Shuji Ichikawa, Isao Tomita, Akira Hosaka, and Tadashi Sato*
Department of Applied Chemistry, Waseda University, Ookubo 3, Shinjuku-ku, Tokyo 160
(Received September 16, 1987)

Under UV irradiation in the presence of iron(III) chloride or iron(III) triflate in pyridine, D-glucose, D-mannose, and D-galactose underwent a selective bond cleavage at the C1-C2 position, producing 4-*O*-formyl-D-arabinopyranose and 4-*O*-formyl-D-lyxopyranose. D-Fructose, under the same conditions, gave arabino-γ-lactone. The reaction was interpreted in terms of the photoinduced electron transfer within a chelate of iron ion with the carbohydrate molecule.

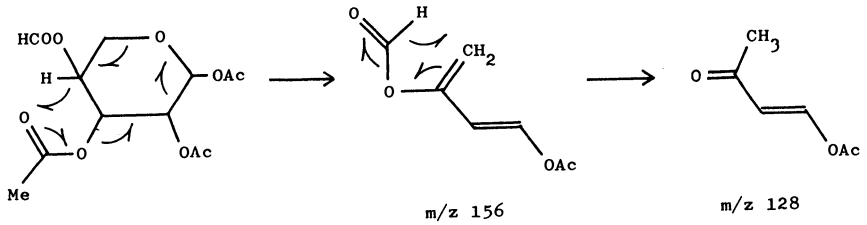
In our preceding papers,[2)] we found that the UV irradiation of D-glucose, D-mannose, and D-galactose in methanol in the presence of titanium(IV) chloride induced a selective bond cleaveage of C5-C6 bond of the carbohydrates, producing corresponding pentodialdose derivatives. It was also found that the aldehyde functions in these dialdose derivatives reacted with several nucleophiles with relatively high chemo- and stereoselectivities. In view of our previous observations[3)] that iron(III) chloride, as well as titanium(IV) chloride, exhibited remarkable effects upon the photoreaction of organic molecules, and that the iron(III) chloride-catalyzed photoreaction proceeded most satisfactorily in pyridine, we irradiated several monosaccharides under these reaction conditions, and found now that the iron(III)-catalyzed photoreaction of the carbohydrates in pyridine induced a selective cleavage of C1-C2 bond, in contrast to the C5-C6 bond cleavage by titanium(IV) chloride, and afforded pentose derivatives having formate function only at the C4 position. In view of good selectivity of the reaction and possible utility of the products as chiral synthons, we investigated the reaction in detail.

A pyridine solution of D-glucose (**1**) containing an equivalent amount of iron(III) chloride was irradiated with a high-pressure mercury lamp in a Pyrex tube for 24 h while oxygen gas was bubbled through. After irradiation, the products were isolated as acetates by treating the irradiated solution with acetic anhydride. The major product was an anomeric mixture of an aldopentose derivative **4** (α/β=1/1) in 38% yield, along with the starting material as pentaacetate in 41% yield (Scheme 1). D-Mannose (**2**) gave the same product **4** in 17% yield under the same conditions, along with the starting material as pentaacetate in 74% yield.

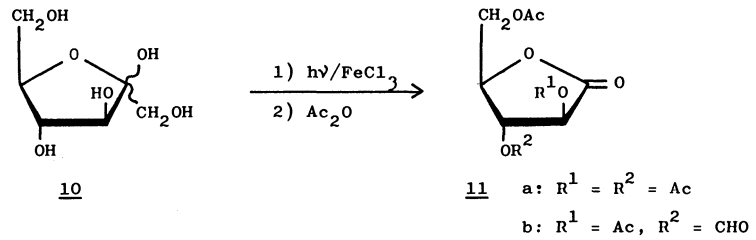
The structure **4** was determined in the following way. When the product **4** was treated first with titanium(IV) chloride in methanol, and then with acetic anhydride in pyridine, an oil was obtained which showed two peaks on a gas chromatogram. The oil proved to be an anomeric mixture of methyl D-arabinopyranoside triacetate (**5a**), because the same mixture was obtained by treating D-arabinose (**6**) with titanium(IV) chloride in methanol, followed by acetylation under the same conditions as above. The pyranose ring form for **4** was deduced from the fragmentation pattern of the mass spectrum, in which the M^+-73 peak, typical for the furanose structure (loss of the side chain),[4)] was lacking. The ^{1}H NMR spectrum of **4** indicated the presence of C5 methylene, referring to the data reported for **5b**.[5)] The position of the formate was assigned at C4 in view of the fragmentation peaks at m/z 156 and 128 of the mass spectrum, which could be ascribed to the ions depicted in Scheme 2, referring to the general mass spectrum fragmentation pattern of acylated pyranoses proposed by Biemann and his group.[6)]



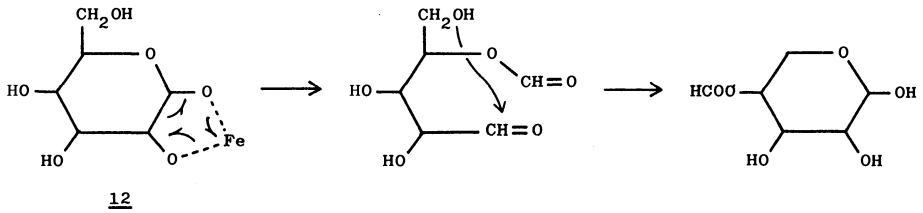
Scheme 1.



Scheme 2.



Scheme 3.



Scheme 4.

D-Galactose (**3**) gave an anomeric mixture **7a** (α/β=7/3) in 35% yield under the same conditions, with the recovery of the starting material in 36% yield. The structure **7a** was confirmed by converting the product into an anomeric mixture of D-lyxoside derivatives **8a**, which was identicai with that obtained from D-lyxose (**9**) in the same way as described for arabinose. When the irradiated solution was treated with trimethylsilyl chloride, a silyl derivative **7b** was isolated. By referring to the ^{13}C NMR spectrum, the product proved to be a single diastereomer. In contrast to the acetate **7a**, the NMR signal of proton on the formate-carrying carbon in **7b** appeared at well separated position from those of the other ring protons, featuring a definite ABMX fine structure. The similar pattern was also observed in **18b** and **18c**. This would be an another indication that the formate function stays at C4 position.

When D-fructose (**10**), a ketohexose, was irradiated under the same conditions, **11a** was obtained in 52% yield after the acetylation (Scheme 3). Evidently the reaction proceeded with selective bond cleavage at C1-C2 position as in the case of aldohexoses. The photoreaction of the ketose was faster than that of the aldohexoses, and no starting material was recovered after the irradiation for 5 h. The structure **11a** was confirmed by comparing the spectroscopic data with those of γ-D-ribonolactone triacetate, synthesized by the reported method.[7]

It has been known that D-glucose does produce D-arabinose under the irradiation in the presence of molecular oxygen in aqueous solution, and the reaction has been believed to be initiated by hydroxyl radical, giving many compounds in small quantities.[8] In view of the facts that the iron(III) chloride-catalyzed photolysis proceeded quite selectively, producing D-arabinose as the main product, and that the reaction proceeded even in the absence of molecular oxygen and water, the possibility of a mechanism involving any species originated from molecular oxygen or water was ruled out. We propose a reaction involving an electron transfer within an iron chelate **12**, followed by the recyclization of the fission product as shown in Scheme 4. In support of this scheme, methyl D-glucopyranoside and 1,2-*O*-isopropylidene-α-D-glucofuranose, lacking the system for the chelate formation, did not undergo the present reaction, and the starting materials were recovered as acetates.

The present reaction proceeded even in the absence of molecular oxygen, although the reaction was much slower under these conditions. Referring to the reaction scheme, iron(III) should have been reduced to iron(II). Presumably, molecular oxygen reoxidized the iron(II) to iron(III), thus resulting in the enhancement of the reaction efficiency. Expectedly, iron(III) chloride behaved as a catalyst in the presence of molecular oxygen, and the reaction proceeded effectively even with 1/100 equivalent of iron(III) to the carbohydrate

molecules, although the amounts of by-products increased to some extent under these conditions.

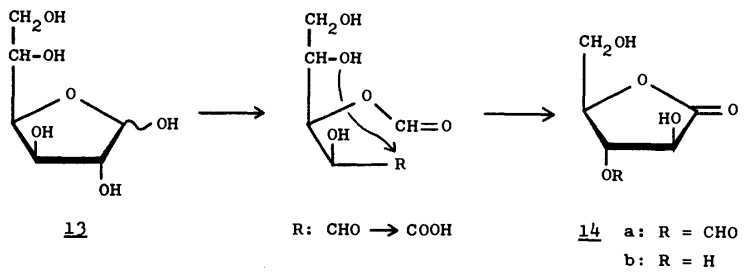
Although the yields of the present reaction were not necessarily high, the reaction was quite selective and the amounts of the smaller fragments or the products resulted from the bond cleavage at other positions were small. Remarkably, the reaction proceeded only in pyridine in the presence of iron(III) ion. The reaction using other metal salts or solvents gave poor results with little or no amounts of the aldopentoses. Later, we found that iron(III) trifluoromethanesulfonate (triflate) gave even better results than iron(III) chloride. Iron(III) triflate catalyzed the reaction more effectively than the chloride, and hence we could reduce the irradiation time and the amount of the metal compound extensively as shown in Table 1. Even in case of using only 1/100 equivalent of iron(III) triflate, the reaction proceeded quite cleanly, in contrast to the corresponding case using iron(III) chloride.

It has been known that the thermal oxidation of aldohexoses by lead(IV) acetate involves the initial cleavage of C1–C2 bond, followed by a stepwise shortening of the carbon chain.[9] As a comparison with these observations, we examined the thermal reaction of D-glucose and D-fructose under the otherwise same conditions as those of the present photoreaction. As in the case of the photoreaction, the thermal reaction of the ketose was faster than that of the aldose. Upon heating in pyridine at 100 °C in the presence of iron(III) chloride, D-glucose (**1**) gave two compounds **11a** and **11b** as the exclusive product after the acetylation. The triacetate **11a** was the exclusive product of the thermal reaction of D-fructose (**10**), indicating that the reaction pattern of the ketose was the same in the photo and thermal reactions. However, no trace of the photoproduct **4** was identified in the thermal reaction of D-glucose. The structure **11b** was deduced in view of the NMR and mass spectra, which showed that both **11a** and **11b** have identical gross structure. Although we could not distinguish experimentally between two possible structures of 2- and 3-formate for **11b**, the 3-formate structure would be preferable in view of the following reaction scheme (Scheme 5). It has been known that the lead(IV) acetate oxidation of D-glucose proceeds faster from furanose form than from pyranose form.[10] It could be assumed that the iron(III) chloride-initiated oxidation also proceeded from the furanose form of D-glucose **13**, and probably due to the overoxidation of the aldehyde intermediate, the product would be a lactone **14a**. The product suffered a partial hydrolysis of the formate group under the reaction conditions to give **14b**, and afforded the observed products **11a** and **11b** upon acetylation after the reaction. Remarkably, these observations show that the photoreaction proceeds from the pyranose structure, while the thermal reaction proceeds from the furanose structure, both structures being in an equilibrium under the present reaction conditions.

Table 1. Catalytic Activities of Iron(III) Chloride and Iron(III) Triflate in the Photoreaction of **1**

Iron salt	Mol ratio to carbohydrate	Reaction time / h	Relative yield/%	
			Product	Starting material
$FeCl_3$	1	24	45	55
$Fe(OTf)_3$	1	24	64	36
$FeCl_3$	1	2	15	85
$Fe(OTf)_3$	1	2	39	61
$FeCl_3$	1/100	24	19	81
$Fe(OTf)_3$	1/100	24	44	56
$FeCl_3$	1/100	2	7	93
$Fe(OTf)_3$	1/100	2	29	71

Shiraishi and his group reported that the photooxidation of D-glucose and D-mannose in the presence of iron(III) chloride in aqueous solution produced D-erythrose (**15a**) as major product, accompanied in some cases by a minor amount of D-arabinos (**6**).[11] They also found that D-erythrose was the sole product from D-fructose under their conditions. In search for the tetrose derivatives in our reaction, we carefully checked the foreruns obtained in small amounts, and isolated **15b** from **1** and **2** in 3% and 0.7% yields, respectively, and D-threose derivative **16** from **3** in 2.5% yield. We assumed that these compounds were produced by the C1–C2 bond cleavage of the primary products corresponding to **4** and **7**, followed by the ring closure in the similar way as that shown in Scheme 4. When D-arabinose (**6**) was irradiated under the same conditions, **15b** was obtained in 4% yield, while the starting material **6** was recovered as tetraacetate in 63% yield. D-Xylose, an another pentose, was also decomposed only to a minor extent under the same conditions, with the recovery of the starting material in 60% yield.



Scheme 5.

These observations indicate that the reaction from the aldopentoses is much slower than that from the aldohexoses. Although we can offer no reasonable explanation for the difference in the reactivity, it should be this difference that makes the present photoreaction fairly selective, terminating the photocleavage at the stage of pentose.

The UV spectroscopic studies also showed that an iron chelate system played an important role in our reaction. We observed that the intensity of the peak at 346 nm in the UV spectrum of iron(III) chloride in pyridine was decreased by the addition of the carbohydrate molecules. Figure 1 shows the change of the UV spectrum of iron(III) chloride in pyridine upon addition of D-galactose up to 100 equivalents. The same trend was observed with other carbohydrates, but the extent of the effect differed from one carbohydrate to another. In Fig. 2 are shown the spectra of iron(III) chloride in pyridine with several carbohydrates added in 100-fold excess. The absorption at 346 nm has been ascribed to the charge transfer from chloride ligand to iron(III) ion.[12] In accord with the assignment, iron(III) triflate did not show any peak in this region, as shown in Fig. 1. We speculated that the addition of the carbohydrate molecules resulted in the expulsion of the chloride ligand from the iron coordination sphere due to the iron chelate formation with the carbohydrate molecule, and we believed that this would be an experimental evidence for the reaction scheme proposed as shown in Scheme 4. myo-Inositol, a carbocyclic polyhydroxy compound, did not undergo the present type of the C–C bond cleavage. Notably, the UV spectrum of iron(III) chloride in pyridine was not affected at all by the addition of myo-inositol or ethylene glycol as the typical 1,2-diol system. Presumably, the presence of 1,2-diol system involving anomeric hydroxyl group was responsible for the chelate formation, and the chelate formation might be requisite for the present reaction to proceed. Although D-fructose, which exhibited the largest effect, actually underwent

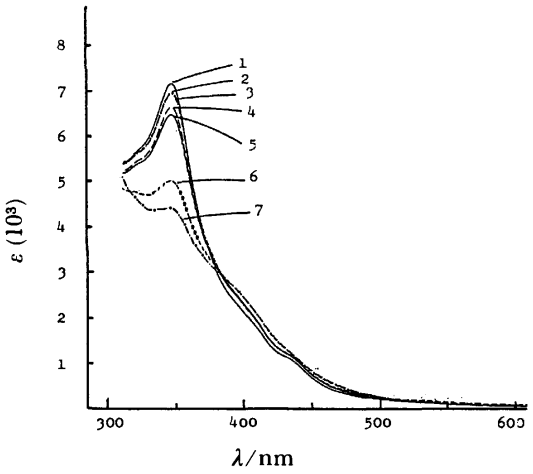


Fig. 1. Change of UV spectrum of iron(III) chloride in pyridine as a function of concentration of D-galactose. $FeCl_3$: 2.25×10^{-4} M. D-Galactose: $n\times 2.25\times10^{-4}$ M; 1: n=0; 2: n=1; 3: n=5; 4: n=10; 5: n=20; 6: n=60; 7: n=100.

the photoreaction most efficiently, there seemed to be no direct correlation between the reactivity and the extent of the influence upon UV spectrum.

The most characteristic point of the present reaction is that the aldohexoses produce the aldopentoses in which only C4 hydroxyl group is protected by formyl group. With a hope to utilize the products as chiral synthons for the synthetic chemistry, the selective manipulation of the formate group was next explored.

When the acetate **4** or **7a** was treated with aluminum chloride in an aqueous methanol, formyl group was removed selectively, producing anomeric mixture of **17a** or **18a** in 84% or 94% yield, respectively. The acetylation of **17a** afforded the corresponding anomeric mixture of tetraacetates **5b**, identical with the authentic samples prepared by the known method.[13] The column chromatography of **7a** afforded pure α anomer, which, upon the selective hydrolysis of the formate and succeeding acetylation, gave pure α anomer of **8b**, identical with the authentic sample.[14] This would be a reasonable indication that no neighboring group participation inducing the possible scrambling of the stereochemistry was involved under these conditions. Tosylation or mesylation of **17a** or **18a** gave the corresponding derivatives **17b**, **18b**, or **18c**. The tosylate **18b**, upon treatment with sodium methoxide, produced L-ribose derivative **19** in 53% yield. We are exploring further applicability of the photoproducts for the synthesis of chiral compounds.

Experimental

The general procedures and instrumentation were the same as those reported in our preceding paper.[2] The NMR spectral assiments were based on the data of structurally similar system.[5,15,16]

Iron(III) Chloride-Catalyzed Photoreaction of D-Glucose (1). A pyridine solution (150 ml) of D-glucose (**1**, 1.50 g, 8.3 mmol) and $FeCl_3 \cdot 6H_2O$ (2.25 g, 8.3 mmol) was irradiated in a Pyrex tube for 24 h while oxygen gas was bubbled through. Acetic anhydride (15 ml, 166 mmol) was added to the solution, and the solution was stirred for 12 h at room temperature. The solution was concentrated in vacuo, washed with dil HClaq, extracted with dichloromethane, and dried over $MgSO_4$. The distillation gave two main fractions. The main product **4** was obtained as the lower boiling fraction, bp 148—150 °C (0.35 mmHg (1 mmHg=133.322 Pa)), 0.958 g, 38% yield, and showed two peaks (1 : 1) on a gas chromatogram which were assigned as α and β anomers, referring to the spectroscopic data and chemical reactions described below. Since the separation of both anomers were unsuccessful, the spectroscopic data were obtained on the mixture sample. For **4**: GC-MS, m/z (for α anomer) 245 (M^+ −OAc, 10.7), 170 (20.2), 156 (60.0), 145 (65.8), 128 (73.1), 103 (78.4), 97 (100): (for β anomer) 245 (M^+ −OAc, 10.4), 170 (20.9), 156 (74.1), 145 (77.4), 128 (93.4), 103 (100), 97 (92.1). ^{1}H NMR ($CDCl_3$) δ=2.01—2.17 (9H, s, Ac), 3.75—4.34 (2H, m, H_5, $H_{5'}$), 5.11—5.53 (3H, m, H_2, H_3, H_4), 5.68 (1/2H, d, J=6.2 Hz, α-H_1), 6.32 (1/2H, d, J=3.7 Hz, β-H_1), 8.14 and 8.17 (1H, s×2, CHO).[5] ^{13}C NMR ($CDCl_3$) δ=20.5 and 20.7 (Ac-Me), 62.4 and 63.6 (C_5), 66.5 and 66.9 (C_4), 68.0 and 68.1 (C_2), 69.7 and 69.8 (C_3), 90.0 and 92.0 (C_1), 159.6—159.8 (CHO), 168.8—170.3 (Ac-CO).[15] HRMS, Found: m/z 245.0686. Calcd for $C_{10}H_{13}O_7$ (M−OAc): 245.0661.

The higher boiling fraction, bp 160 °C (0.35 mmHg), crystallized upon standing, mp 109—115 °C, 1.33g. The compound was identical (GLC, NMR, and MS) with the sample of D-glucose pentaacetate,[17] prepared by the reported method.

The minor amount of the forerun (bp 134—138 °C (0.15 mmHg)) was mostly **15b** (3% yield), identical with the sample obtained by the photoreaction of D-arabinose (see below).

Methyl D-Arabinoside Triacetate (5a). A mixture of **4** (50 mg, 0.16 mmol) and $TiCl_4$ (0.5 ml, 4.6 mmol) in dry methanol (10 ml) was refluxed for 12 h, and the solution was neutralized with dil NaOHaq. The precipitate was removed by the filtration and the filtrate was concentrated to dryness in vacuo. The residue was distilled with a Kugelrohr, bp 100 °C (0.05 mmHg), 38 mg, 80% yield, to afford **5a**. This was completely identical (GLC, NMR, MS) with the sample prepared from D-arabinose under the same conditions. For **5a**: GC-MS, m/z (rel intensity) 259 (M^+ −OMe, 2.2), 199 (1.6), 170 (56.5), 128 (73.8), 69 (100). ^{1}H NMR ($CDCl_3$) δ=2.02—2.14 (9H, s, Ac), 3.41 (3H, s, OMe), 3.63—4.03 (2H, m, H_5, $H_{5'}$), 4.34 (3/5H, m, H_1 of α anomer), 4.91 (2/5H, d, J=3.2 Hz, H_1 of β anomer), 5.07—5.27 (3H, m, H_2, H_3, H_4).

Iron(III) Chloride-Catalyzed Photoreaction of D-Glucose (1) under Anhydrous and Anaerobic Conditions. The reaction solution was prepared from anhydrous reagents and solvent, applying freezing and thawing method. The yield of the product **4** was 13%, and the starting material was recovered in 75% as pentaacetate.

Iron(III) Chloride-Catalyzed Photoreaction of D-Mannose (2). The reaction and the subsequent acetylation were carried out in the same way as described for D-glucose. The product **4**, bp 145—150 °C (0.3 mmHg), was identical with that obtained from D-glucose. The higher boiling fraction, bp 160 °C (0.3 mmHg), was D-mannose pentaacetate, identical with the product prepared from D-mannose. As in the case of D-glucose, **15b** (0.7% yield) was also isolated from the small amount of the forerun, bp 110 °C (0.05 mmHg).

Iron(III) Chloride-Catalyzed Photoreaction of D-Galactose (3). The reaction and the subsequent acetylation were carried out in the same way as described for D-glucose. The crude product gave two fractions as main portion upon distillation. The lower boiling fraction **7a**, bp 156—158 °C (0.2 mmHg), showed two peaks on a gas chromatogram with relative ratio of 7 : 3. The mass spectrum of each component was quite similar to that of **4**. The column chromatography of the crude product gave the major component α-**7a** in pure state, while β-**7b** was not freed from the α anomer. For α-**7a**: GC-MS, m/z (rel intensity) 245 (M^+ −OAc, 3.5), 156 (48.9), 145 (57.5), 114 (47.4), 103 (91.1), 97 (100), 69 (68.4). ^{1}H NMR ($CDCl_3$) δ=2.05, 2.16, and 2.17 (9H, 3s, Ac), 3.73—4.28 (2H, m, H_5, $H_{5'}$), 5.21—5.42 (3H, m, H_2, H_3, H_4), 6.05 (1H, d, J=3.1 Hz, H_1), 8.08 (1H, s, CHO). ^{13}C NMR ($CDCl_3$) δ=20.6 and 20.8 (Ac-Me), 61.6 (C_5), 66.1 (C_2), 68.1 (C_4), 68.2 (C_3), 90.6 (C_1), 159.4 (CHO), 168.3, 169.4 and 169.6 (Ac-CO). HRMS, Found: m/z 245.0690. Calcd for $C_{10}H_{13}O_7$ (M−OAc): 245.0661. For β-**7a**: GC-MS, m/z (rel intensity) 245 (M^+ −OAc, 4.0), 170 (10.4), 156 (44.6), 145 (51.4), 128 (56.9), 114 (63.3), 103 (85.4), 97 (100), 73 (89.5), 69 (93.5). ^{13}C NMR

($CDCl_3$, obtained by subtracting the data of α anomer from those of the mixture) δ=20.6 and 20.8 (Ac-Me), 61.2 (C_5), 66.4 (C_2), 67.1 (C_3), 67.8 (C_4), 89.7 (C_1), 159.4 (CHO), 168.2—170.7 (Ac-CO).

The forerun (bp 135—140 °C (0.2 mmHg)), obtained in only small amount, was mostly **16** (2.5% yield). The pure sample was obtained by a preparative GLC. For **16**: GC-MS, *m/z* (rel intensity) 173 (M^+ −OAc, 14.4), 127 (9.2), 101 (32.3), 85 (100), 73 (61.9). ^{1}H NMR ($CDCl_3$) δ=2.07—2.21 (6H, s, Ac), 3.81—4.75 (2H, m, H_4, $H_{4'}$), 5.25—5.60 (2H, m, H_2, H_3), [6.16 (1/2H, s) and 6.45 (1/2H, d, J=4.8 Hz), H_1], 8.15 (1H, s, CHO).

When the irradiated solution from 200 mg of D-galactose was refluxed for 1 h with chlorotrimethylsilane (5 ml) and hexamethyldisilazane (6 ml) being added, an oil (484 mg) was obtained after the purification on a Florisil column. The oil was further separated into two fractions of R_f's 0.7 and 0.6 on a preparative TLC ($CHCl_3$). The former fraction was identical (NMR, GC-MS) with the authentic pentakis-*O*-trimetylsilyl-D-galactose (298 mg, 50% yield). The latter fraction was **7b**, 151 mg, 34% yield. For **7b**: GC-MS, *m/z* (rel intensity) 394 (M^+, 0.26), 305 (2.4), 231 (11.1), 217 (32.9), 204 (100), 191 (89.1). ^{1}H NMR ($CDCl_3$) δ=0.14—0.17 (27H, s, TMS), 3.61 (1H, dd, $J_{2,1}$=4.6 and $J_{2,3}$=3.1 Hz, H_2), 3.65 (1H, dd, $J_{5',4}$=6.3 and $J_{5',5}$=12.0 Hz, $H_{5'}$), 3.85 (1H, dd, $J_{5,4}$=3.5 and $J_{5,5'}$=12.0 Hz, H_5), 3.98 (1H, dd, $J_{3,2}$=3.1 and $J_{3,4}$=6.4 Hz, H_3), 4.86 (1H, d, $J_{1,2}$=4.6 Hz, H_1), 4.95 (1H, ddd, $J_{4,3}$=6.4, $J_{4,5'}$=6.3, $J_{4,5}$=3.5 Hz, H_4). ^{13}C NMR ($CDCl_3$) δ=0.1, 0.5, and 0.6 (TMS), 61.4 (C_5), 70.5 (C_4), 71.5 (C_2), 73.4 (C_3), 95.4 (C_1), 160.1 (CHO). HRMS, Found: *m/z* 394.1573. Calcd for $C_{15}H_{34}O_6Si_3$ (M): 394.1618.

Methyl D-Lyxoside Triacetate (8a). A mixture of **7a** (51 mg, 0.17 mmol) and 12 M HCl (0.1 ml) (1M=1 mol dm^{-3}) in methanol (8 ml) was refluxed for 12 h. The solution was neutralized with dil NaOH and concentrated in vacuo. To the residue was added dry pyridine (5 ml) and acetic anhydride (2 ml), and the mixture was kept at room temperature for 7 h. Pyridine and acetic anhydride were removed in vacuo, and the residue was passed through a column (silica gel/$CHCl_3$) to produce **8a**, 37 mg, 77% yield, identical with the sample prepared from D-lyxose under the same conditions. For **8a**: GC-MS, *m/z* (rel intensity) 259 (M^+ −Me, 2.0), 199 (2.2), 170 (40.7), 128 (100), 115 (38.5). ^{1}H NMR ($CDCl_3$) δ=2.01—2.12 (9H, s, Ac), 3.38 (1H, s, OMe), 3.58—4.09 (2H, m, H_5, $H_{5'}$), 4.69 (1H, d, J=2.2 Hz, H_1), 4.97—5.29 (3H, m, H_2, H_3, H_4).

Iron(III) Triflate-Catalyzed Photoreaction of D-Glucose (1) and D-Galactose (3). Iron(III) triflate was prepared in the following way. Trifluoromethanesulfonic acid (12.3 g, 81.6 mmol) was gradually added to crystals of $Fe(NO_3)_3 \cdot 9H_2O$ (10.0 g, 24.8 mmol), and the mixture was heated to 250 °C in a porcelain vessel placed on a sand bath until the evolution of nitrogen oxides and water was not noticed. The white crystalline material (12.3 g, 99% yield) was allowed to cool in a desiccator, and used without further purification.

The photolyses of D-glucose (5.56 mmol) and D-galactose (5.56 mmol) were carried out using $Fe(OTf)_3$ (0.056 mmol), under the otherwise same conditions described for the $FeCl_3$-catalyzed photoreactions. The products **4** and **7a** were obtained in 32—40% yield and 29—36% yields, respectively.

1,2,3-Tri-*O*-acetyl-D-lyxopyranose (18a) and 1,2,3,-Tri-*O*-acetyl-D-arabinopyranose (17a). To a solution of **7a** (273 mg, 0.9 mmol, α/β=7/3) in a mixture solvent of methanol (20 ml) and water (1 ml) was added $AlCl_3$ (12 mg, 0.09 mmol) gradually, and the solution was stirred for 13 h at room temperature. The solution was concentrated in vacuo, and water (15 ml) was added. The mixture was shaken with dichloromethane, and, after the extract was dried over $MgSO_4$, the solvent was removed in vacuo. When the remaining oil was passed through a short column of Florisil, **18a** (273 mg, 94% yield) was obtained. Referring to the NMR signals of anomeric protons, the product was a mixture of α and β anomers with a ratio of 7 : 3. Purification on a preparative TLC (silica gel/$CHCl_3$-AcOEt (1 : 1)) gave a pure sample of major component, α-**18a**, 152 mg, 61% yield. For α-**18a**: ^{1}H NMR ($CDCl_3$) δ=2.08, 2.12 and 2.15 (9H, s×3, Ac), 2.96 (1H, br d, OH), 3.54—4.26 (3H, m, H_4, H_5, $H_{5'}$), 5.16 (1H, dd, $J_{3,2}$=3,3 and $J_{3,4}$=9.1 Hz, H_3), 5.22 (1H, dd, $J_{2,1}$=2.6 and $J_{2,3}$=3.3 Hz, H_2), 5.96 (1H, d, $J_{1,2}$=2.6 Hz, H_1). ^{13}C NMR ($CDCl_3$) δ=20.6 and 20.8 (Ac-Me), 64.6 (C_5), 65.0 (C_4), 68.4 (C_3), 71.6 (C_2), 90.9 (C_1), 168.5, 169.5 and 179.5 (Ac-CO). HRMS, Found: *m/z* 276.0845. Calcd for $C_{11}H_{16}O_8$ (M): 276.0891.

The hydrolysis of **4** (1.0 g) was carried out under the same conditions as above to afford the product **17a** (0.763 g, 84% yield). The column chromatography (silica gel/$CHCl_3$) gave β-**17a** in pure state, while α-**17a** was not completely freed from β-**17a**. For β-**17a**: ^{1}H NMR ($CDCl_3$) δ=2.08, 2.12 and 2.15 (9H, s×3, Ac), 2.98 (1H, br s, OH), 3.83 (1H, dd, $J_{5',4}$=2.2 and $J_{5',5}$=12.8 Hz, $H_{5'}$), 4.05 (1H dd, $J_{5,4}$=1.1 and $J_{5,5'}$=12.8 Hz, H5), 4.19 (1H, br, H_4), 5.25 (1H, dd, $J_{2,1}$=3.3 and $J_{2,3}$=9.4 Hz, H_2), 5.45 (1H, dd, $J_{3,2}$=9.4 and $J_{3,4}$=3.0 Hz, H_3), 6.31 (1H, d, $J_{1,2}$=3.3 Hz, H_1). ^{13}C NMR ($CDCl_3$) δ=20.55, 20.64 and 20.8 (Ac-Me), 64.6 (C_5), 66.7 (C_4), 67.3 (C_2), 69.6 (C_3), 90.4 (C_1), 169.1, 169.9 and 170.1 (Ac-CO). For α-**17a** (obtained by subtracting the data of β anomer from those of the mixture): ^{1}H NMR ($CDCl_3$) δ=2.06—2.15 (9H, s, Ac), 3.19 (1H, br, OH), 3.65—4.18 (3H, m, H_4, H_5, $H_{5'}$), 5.12—5.58 (2H, m, H_2, H_3), 5.67 (1H, d, J=6.2 Hz, H_1). ^{13}C NMR ($CDCl_3$) 20.62, 20.67 and 20.8 (Ac-Me), 65.2 (C_5), 65.6 (C_4), 68.3 (C_2), 72.0 (C_3), 91.8 (C_1), 169.0, 169.3 and 170.1 (Ac-CO).

1,2,3-Tri-*O*-acetyl-4-*O*-methylsulfonyl-D-lyxopyranose (18c). To a solution of **18a** (373 mg, 1.35 mmol, α/β=75/25) in dry pyridine (15 ml) was added methanesulfonyl chloride (0.4 ml, 5.2 mmol) dropwise with stirring. The reaction mixture was kept overnight at room temperature, and the solvent was removed in vacuo. The excess of the reagent was decomposed by the cautious addition of cooled water (15 ml), and the product was extracted with dichloromethane. After washed with water and dried over $MgSO_4$, the extract was passed through a Florisil column to give white crystals as an anomeric mixture of **18c**, mp 142—147 °C, 391 mg, 82% yield, α/β=8/2. Column chromatography (silica gel/ether) gave a pure sample of α-**18c**, 301 mg, 63% yield. For α-**18c**; mp 145—146 °C. GC-MS, *m/z* (rel intensity) 354 (M^+, 1.1), 295 (5.9), 206 (61.1), 193 (26.2), 181 (55.0), 139 (79.5), 114 (69.1), 68 (100). ^{1}H NMR ($CDCl_3$) δ=2.07 and 2.16 (9H, s×2, Ac), 3.06 (3H, s, $MeSO_2$), 3.74 (1H, dd, $J_{5',4}$=9.1 and $J_{5',5}$=11.1 Hz, $H_{5'}$), 4.13 (1H, dd, $J_{5',4}$=5.5 and $J_{5,5'}$=11.1 Hz, H_5), 4.98 (1H, ddd, $J_{4',3}$=9.2, $J_{4,5}$=5.5 and $J_{4,5'}$=9.1 Hz, H_4), 5.29 (1H, dd, $J_{2,1}$=2.2 Hz and $J_{2,3}$=3.2 Hz, H_2), 5.40 (1H, dd, $J_{3,2}$=3.2 and $J_{3,4}$=9.4 Hz, H_3), 6.01 (1H, d, $J_{1,2}$=2.2 Hz, H_1). ^{13}C NMR ($CDCl_3$) δ=19.8, 19.9 and 21.2 (Ac-Me), 38.2 ($MeSO_2$), 62.0 (C_5), 67.9 (C_2), 68.4 (C_3), 72.3 (C_4), 90.2 (C_1), 167.9, 168.0 and 169.2 (Ac-CO). HRMS,

Found: m/z 295.0482. Calcd for $C_{10}H_{15}O_8S$ (M-OAc): 295.0476.

1,2,3-Tri-*O*-acetyl-4-*O*-*p*-tolylsulfonyl-α-D-lyxopyranose (18b) and 1,2,3-Tri-*O*-acetyl-4-*O*-*p*-tolylsulfonyl-D-arabinopyranose (17b). A mixture of **18a** (276 mg, 1 mmol, α/β=9/1) and *p*-toluensulfonyl chloride (570 mg, 3 mmol) in dry pyridine (12 ml) was heated at 70 °C under a nitrogen atmosphere with stirring for 17 h. The reaction mixture was cooled, and poured slowly into cold water (20 ml). The solution was extracted with dichloromethane, and the extract was washed with water. After dried over $MgSO_4$, the solvent was evaporated in vacuo, and the product **18b** was isolated through a preparative TLC (silica gel/$CHCl_3$), 259 mg, 60% yield. Referring to ^{13}C NMR, the product was pure α-**18b**. For α-**18b**: GC-MS, m/z (rel intensity) 430 (M^+, 0.13), 371 (6.0), 282 (18.0), 269 (11.0), 215 (37.8), 173 (68.7), 155 (100), 91 (100). ^1H NMR ($CDCl_3$), δ=1.90—2.12 (9H, s, Ac-Me), 3.66—4.09 (2H, m, H_5, $H_{5'}$), 4.79—5.09 (1H, m. H_4), 5.13—5.35 (2H, m, H_2, H_3), 5.93 (1H, d, J=2.3 Hz, H_1), 7.36 and 7.80 (4H, ABq, J=8.3 Hz, Ar), 2.44 (3H, s, Ar-Me). ^{13}C NMR ($CDCl_3$) δ=21.5 (Ar-Me), 61.9 (C_5), 67.6 (C_2), 68.4 (C_3), 72.5 (C_4), 90.2 (C_1), 127.7, 129.8, 133.3, 145.1 (Ar), 169.2 and 169.5 (Ac-CO). HRMS, Found: m/z 430.0956. Calcd for $C_{18}H_{22}O_{16}S$ (M): 430.0934.

In the same way, tosylation of **17a** (172 mg, α/β=1/1) was carried out to give the product **17b** (149 mg, 56% yield) after the chromatograph on a silica gel column (ether). Referring to the NMR signals of anomeric protons, the product was an anomeric mixture (α/β=6/4). For **17b**: GC-MS, m/z (rel intensity) 371 (M^+ −OAc, 5.0), 269 (19.8), 215 (64.7), 172 (47.0), 155 (100), 91 (95.7). ^1H NMR ($CDCl_3$) δ=1.95—2.11 (9H, s, Ac), 2.45 (3H, s, Ar-Me), 3.53—4.11 (2H, m, H_5, $H_{5'}$), 4.90—5.31 (3H, m, H_2, H_3, H_4), 5.62 (3/5H, d, J=6.6 Hz, H_1 of α anomer), 6.31 (2/5H, d, J=3.2 Hz, H_1 of α anomer), 7.35 and 7.80 (4H, ABq, J=8.3 Hz, Ar). ^{13}C NMR ($CDCl_3$) δ=20.3—20.7 (Ac-Me), 62.6 and 63.5 (C_5), 66.2 and 66.7 (C_2), 67.6 and 69.5 (C_3), 73.2 and 75.1 (C_4), 89.9 and 91.7 (C_1) 127.6—145.1 (Ar), 168.6—170.2 (Ac-CO). Found: C, 50.30; H, 5.16%. Calcd for $C_{18}H_{22}O_{16}S$: C, 50.22; H, 5.15%.

1,2-Di-*O*-acetyl-3,4-anhydro-β-L-ribopyranose (19). To a solution of **18b** (α/β=9/1, 101 mg, 0.23 mmol) in methanol (10 ml) was added a methanol solution of NaOMe (0.35 M, 2 ml) dropwise at 0 °C with stirring. After being neutralized with dil HCl, the solution was concentrated to dryness in vacuo. The residue was treated with acetic anhydride (2 ml) and dry pyridine (5 ml), and the solution was concentrated in vacuo. The product was extracted with $CHCl_3$, and the extract was dried over $MgSO_4$. After evaporating the solvent, the product β-**19** was isolated on a preparative TLC (silica gel/ether) in 53% yield 27 mg. For β-**19**: IR (neat) ν_{max} 1740 (acetate), 1240, 895, and 835 (oxirane). GC-MS, m/z (rel intensity) 157 (M^+ −OAc, 12.7), 128 (14.1), 115 (100), 97 (10.2), 89 (39.1), 73 (48.1). ^1H NMR ($CDCl_3$) δ=2.10 and 2.16 (6H, s×2, Ac), 3.31—3.46 (1H, m, H_4), 3.63 (1H, dd, $J_{3,2}$=3.4 and $J_{3,4}$=4.5 Hz, H_3), 4.25 and 4.30 (2H, ABq, H_5, $H_{5'}$),4.97 (1H, dd, $J_{2,1}$=4.5 and $J_{2,3}$=3.4 Hz, H_2), 5.77 (1H, d, $J_{1,2}$=4.5 Hz, H_1). ^{13}C NMR ($CDCl_3$) δ=50.1 and 51.4 (oxirane), 60.7 (C_5), 67.6 (C_2), 89.7 (C_1).

Iron(III) Chloride-Catalyzed Photoreaction of D-Fructose (10). The photoreaction of D-fructose (1.1 g, 6.1 mmol) was carried out under the same conditions as described for D-glucose except shortening the irradiation time to 5 h. After treating with acetic anhydride (15 ml, 159 mmol) the crude sample was distilled to give **11a** as an oil, bp 150—153 °C (0.6 mmHg) 870 mg, 52% yield. The following spectroscopic data were very close to those of γ-ribonolactone triacetate.[7] For **11a**: IR (neat) ν_{max} 1796 (γ-lactone), 1738 cm^{-1} (acetate). GC-MS m/z (rel intensity) 275 (M^+ +1, 13.8), 232 (10.4), 201 (14.0), 172 (23.8), 154 (48.0), 128 (100), 115 (96.0), 100 (80.6), 86 (79.3). ^1H NMR ($CDCl_3$) δ=2.03—2.17 (9H, s×3 Ac), 4.31 (1H, dd, $J_{5',4}$=3.6 and $J_{5',5}$=8.5 Hz, $H_{5'}$), 4.48 (1H, dd, $J_{5,4}$=3.8 and $J_{5,5'}$=8.5 Hz, H_5), 4.60 (1H, ddd, $J_{4,3}$=0.9, $J_{4,5}$=3.8 and $J_{4,5'}$=3.6 Hz, H_4), 5.39 (1H, d, $J_{2,3}$=4.9 Hz, H_2), 5.61 (1H, dd, $J_{3,2}$=4.9 and $J_{3,4}$=0.9 Hz, H_3). ^{13}C NMR ($CDCl_3$) δ=20.3, 20.5 and 20.7 (Ac-Me), 62.2 (C_5), 72.4 and 72.7 (C_2, C_3), 77.5 (C_4) 170.2 (C_1), 168.3, 169.4 and 169.9 (Ac-CO).

Iron(III) Chloride-Catalyzed Thermal Reaction of D-Fructose(10) and D-Glucose (1). A pyridine solution (50 ml) of **10** (500 mg, 2.8 mmol) and $FeCl_3 \cdot 6H_2O$ (750 mg, 2.8 mmol) was stirred for 24 h at room temperature while oxygen gas was bubbled through. The solution was treated with acetic anhydride and worked up in the same way as described for the photoreaction. The product **11a** was obtained through a column chromatography (silica gel/$CHCl_3$) 380 mg, 50% yield.

The thermal reaction of **1** (1.2 g, 6.7 mmol) was performed by refluxing the same pyridine solution as that used for the photoreaction. Treatment with acetic anhydride gave an oil (635 mg), which showed two peaks on a GLC analysis with relative ratio of 6:4. The major component was isolated through a column chromatography (silica gel/hexane-ethyl acetate (1 : 1)), and was shown to be identical (GC-MS, NMR, IR) with **11a** (289 mg, 13% yield). Although the other component was not completely freed from **11a**, it was identified as **11b** from the following spectroscopic data obtained by subtracting the data of **11a** from those of the mixture. For **11b**: IR (neat) ν_{max} 1799 (γ-lactone), 1740 and 1736 cm^{-1} (esters). GC-MS: m/z (rel intensity) 261 (M^+ +1, 9.7), 218 (11.9), 201 (16.3), 128 (100), 99 (57.4), 69 (76.9). ^1H NMR ($CDCl_3$) δ=2.02—2.12 (6H, s, Ac), 4.09—4.44 (3H, m, H_4, H_5), 5.09—5.59 (2H, m, H_2, H_3), 8.10 (1H, s, CHO).

Iron(III) Chloride-Catalyzed Photoreaction of D-Arabinose (6). The photoreaction of D-arabinose (**6**, 1.28 g, 8.5 mmol) and the subsequent acetylation was performed in the same way as described for D-glucose (**1**). The crude product gave two fractions by distillation. The lower boiling fraction, bp 135—140 °C (0.15 mmHg), 98 mg, 5% yield, was **15b**. For **15b**: GC-MS, m/z (rel intensity) 173 (M^+ −OAc, 11.7), 127 (20.9), 101 (29.6), 85 (100). ^1H NMR ($CDCl_3$) δ=1.95—2.20 (6H, s, Ac), 3.81—4.52 (2H, m, H_4, $H_{4'}$), 5.05—5.70 (2H, m, H_2, H_3), 5.72 (1/3H, s, H_1 of β anomer),6.05 (2/3H, d, J=2.1 Hz, H_1 of α anomer), 7.70 and 7.95 (1H, s×2, CHO).

The higher boiling fraction, bp 148—152 °C (0.15 mmHg), was identified as D-arabinose tetraacetate (**5b**, 1.7 g, 63% yield) by comparing the NMR and mass spectra with those of the authentic sample.

Hydrogen Separation Using $LaNi_5$ Films Deposited on Polymer Membranes

Hiroki SAKAGUCHI, Gin-ya ADACHI,* and Jiro SHIOKAWA
Department of Applied Chemistry, Faculty of Engineering, Osaka University, Yamadaoka, Suita, Osaka 565
(Received July 27, 1987)

Hydrogen separation has been investigated using $LaNi_5$ films deposited by means of a sputtering method on a nickel-coated Teflon or on a nickel-coated polyimide membrane. Separation factors were estimated for an H_2(50 mol%)-Ar(50 mol%) gas mixture. The permeation rate of the Ni/$LaNi_5$ multilayered film was found to be larger than that of the Ni film. Hydrogen was concentrated to as high as 97.6 mol% under the best conditions.

Hydrogen separation has been studied using films of polymers, porous glasses, and metals.[1] A palladium film is known to exhibit excellent properties for hydrogen separation.[2] The film is, however, very expensive and must be operated at an elevated temperature. The use of a cheaper metal or an alloy instead of palladium would be advantageous for the hydrogen industries. $LaNi_5$ is considered to be a good candidate as a hydrogen separation material[3] because it is less expensive than Pd and has an admirable ability to absorb hydrogen at moderate temperatures and pressures. Some $LaNi_5$ films have been prepared by means of a flash evaporation[4-6] and of a sputtering method and have been investigated with respect to the hydrogen content in the films[7] and mechanical properties.[8] One of its most remarkable characteristics is that these films do not pulverize after more than 100 cycles of the hydrogen absorption-desorption process.

This finding led us to explore the possibility of hydrogen separation using the films.[9] We have previously reported the hydrogen-separation characteristics of the films deposited on a porous metal filter.[10]

In the present study, polymer membranes were used as a substrate on which the $LaNi_5$ layer was formed, and the hydrogen-separation capability for the $LaNi_5$-deposited polymer separator was investigated.

Experimental

Preparation of Films. The $LaNi_5$ ingot was supplied by the Santoku Metal Industry Co., Ltd., Kobe. The substrates were two kinds of polymer membranes, Teflon (Toyofuron, 25 μm thick, Toray Co., Ltd.) and polyimide (Kapton, 40 μm thick, Toray-Du Pont Co., Ltd.). These substrates were cleaned in an ultrasonic washing machine filled with acetone.

The metal layers were deposited with an r.f. magnetron sputtering apparatus made by the Daia Vacuum Engineering Co., Ltd., from an Ni or an $LaNi_5$ target. The r.f. generating power applied was 400 W, and the substrate temperature was in the range of 300—373 K. The atmosphere used for the discharge was 99.99%-pure argon at a pressure of 0.395 Pa. The $LaCo_5$ films were prepared by means of a flash evaporating method which has been described in previous papers.[4-6]

Measurement of Properties. A disk membrane 10 mm in diameter was inserted in a separation apparatus as is shown in Fig. 1. The stainless steel filter (Tokyo Seikoh Co., Ltd.) was used as a support for the film against the pressure.

An H_2 (50 mol%)-Ar (50 mol%) gas mixture with a pressure of 1.5×10^5 Pa at 368 K was applied to the $LaNi_5$-deposited side of the membrane. The gas passed through the film was collected in gas samplers at the outlet. The permeation rate was measured from the pressure variation, and the composition of the resulting gas was analyzed using a Hitachi RMU-6E mass spectrometer.

Results and Discussion

Structures of the Films. Figure 2 illustrates the structures of the films used for the experiments. Since the mechanical strength and the durability of the sputtered films were greater than those of the evaporated ones, the metal films were mainly prepared using a sputtering method.

Film b is an $LaNi_5$ film directly deposited on a

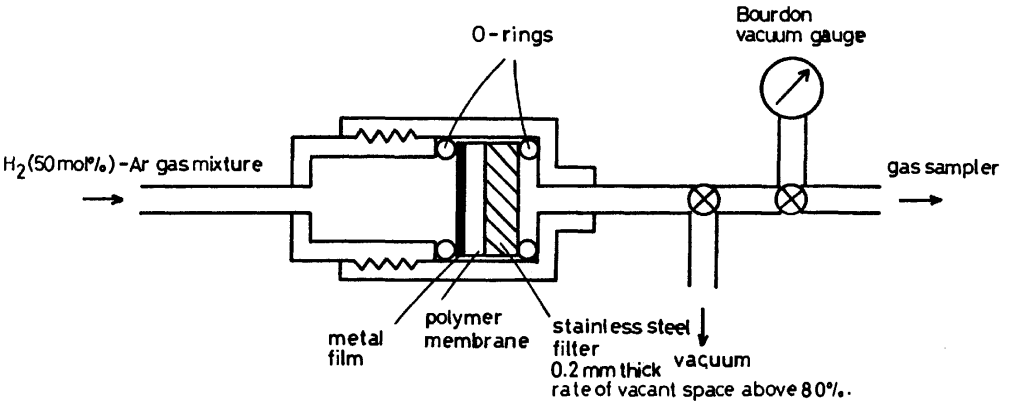

Fig. 1. Apparatus for gas separation.

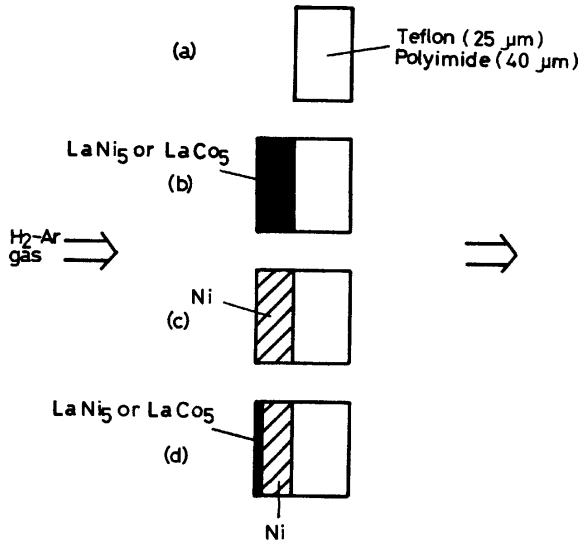

Fig. 2. Structure of films.

Teflon or on a polyimide membrane. The thickness of the metal layer was 0.75 μm. For film d, nickel was first deposited on the substrates (0.73, 1.23, or 1.48 μm thick). The nickel layer was to reinforce the durability of the films. Subsequently, $LaNi_5$ was deposited on the nickel layer. Films a and c were for blank tests.

Performance Characteristics of the Films. Nickel films with various thicknesses deposited on the Teflon membranes were prepared, and the effects of the thickness of the metal layer on the hydrogen separation were studied. As is shown in Fig. 3, for a 0.5 μm-thick film the hydrogen concentration in the permeated gas was slightly larger than that for the Teflon-only membrane. It seems probable that most of the gas mixture passed through pinholes in the nickel film. However, for a 0.75 μm-thick film the hydrogen concentration increased remarkably. It can be considered that, above thickness of 0.75 μm, the Teflon membrane was almost

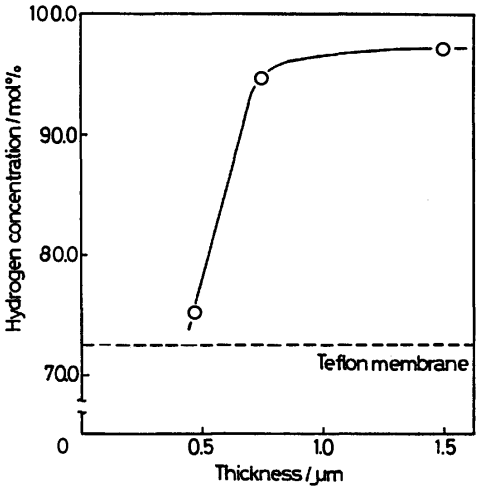

Fig. 3. Effects of thickness of nickel layer on hydrogen concentration in permeated gas.

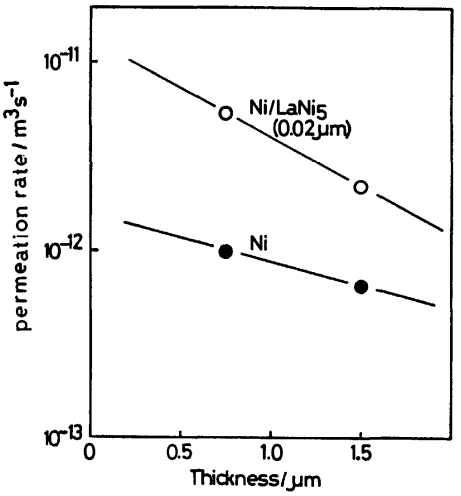

Fig. 4. Relationship between permeation rate and thickness of metal layer.

Table 1. Performance Characteristics of $LaNi_5$ and $LaCo_5$ Films Deposited on the Teflon Membrane

Gas composition / mol%	Film composition	Permeation rate / $m^3s^{-1}\times10^{-12}$	Permeability coefficient / $m^2s^{-1}Pa^{-1/2}\times10^{-16}$ a)	Hydrogen content after treatment / mol%	Separation factor
Ar(50)-H_2(50)	Teflon (T) (25 μm)	43	2400	74.8	2.97
	0.75 μm				
	T/$LaNi_5$	5.3	5.7	89.5	8.52
	T/Ni	0.99	1.1	94.7	17.9
	T/Ni/$LaNi_5$ (0.02 μm)	5.4	6.3	91.9	11.3
	T/$LaCo_5$	<0.5	<0.5	75.2	3.03
	1.50 μm				
	T/Ni	0.55	1.2	97.2	34.7

Table 3. Estimation of $LaNi_5$ Films Deposited on the Polymer Membrane for Hydrogen Separation

	Thickness of the metal layer μm	Permeation rate	Hydrogen-separation factor
Pd	100—200	1	Above 66
Metal filter substrate	50	$1/10^2$	2.25—20.6
Polymer substrate	1	$1/10^3$	10—40

completely covered with the nickel film and that the hydrogen applied permeated through the nickel layer.

Table 1 shows the hydrogen-separation ability of the $LaNi_5$ films deposited on the Teflon membrane. A gas of 50 mol% H_2 was found to be concentrated to 74.8 mol% by the use of the Teflon membrane alone. When the metal films were deposited on the Teflon, the hydrogen concentration increased greatly. It was found that the permeation rate of the $LaNi_5$ film was several times as large as that of the Ni film, though the hydrogen concentration for the $LaNi_5$ film was slightly lower than that for the Ni film. There were no differences in characteristics for the permeation rate and the separation factor between the $LaNi_5$ film and the Ni/$LaNi_5$ multilayered film. The nickel film is able to permeate hydrogen easily because the thin $LaNi_5$ film coated on the nickel surface dissociates the hydrogen molecule easily and absorbs much hydrogen. Figure 4 shows the relationship between the permeation rate and the thickness of the metal layer and also the effects of the $LaNi_5$ layer on the hydrogen permeation of the Ni film. The permeation rate decreased with the increase in the thickness of the metal layer. Also, for the 1.5 μm-thick film, the permeation rate for the Ni/$LaNi_5$ multilayered film was larger than that for the Ni film.

Table 2 shows the hydrogen separation characteristics of the $LaNi_5$ film deposited on the polyimide membrane. The polyimide membrane itself exhibited a high hydrogen-separation factor. The highest separation factor was obtained for the Ni/$LaNi_5$ multilayered film. The reason why the separation capability of the Ni/$LaNi_5$ film is excellent seems to be that the adhesion between the polyimide membrane and the metal film was superior to that between the Teflon membrane and the metal film.

An $LaCo_5$ film is not suited for the hydrogen separator because the mass of the permeated gas obtained from the films deposited on both the Teflon and polyimide membranes was extremely small and these separation factors were not so good (Tables 1 and 2). This seems to be caused by the small hydrogen concentration in the $LaCo_5$ film.[1)]

In Table 3, the characteristics of the $LaNi_5$ film using the polymer as a substrate for the hydrogen separation are compared with those of the $LaNi_5$ film deposited on a porous stainless steel filter as well as those of a Pd film.[2,12)] As for the thickness of the metal layer, high-purity hydrogen gas was obtained with a $LaNi_5$ film only 1 μm thick for the polymer-substrate sample. The permeation rate for the $LaNi_5$ film coated on the polymer is very low, but this is not a serious problem, because for the polymer membrane it is easy to increase the area of the gas contact surface. For instance, if a hollow fiber on which the metal layer is formed is bundled, a large surface area can be obtained.

The $LaNi_5$ films deposited on the nickel-coated polymer substrate are relatively cheap and easy to prepare.

Optical Isomer Effect on the Mechanochemical Interaction of Mandelic Acid with Talc Powder

Akiko IKEKAWA* and Sohachiro HAYAKAWA†

Faculty of Pharmaceutical Sciences, Showa University, Hatanodai, 1-5-8, Shinagawa-ku, Tokyo 142

(Received June 20, 1987)

Mandelic acid was ball-milled with talc powder, and the optical isomer effect on the IR spectral change was investigated. The change showed that a complex was formed between talc and the hydroxyl group and the COOH group of mandelic acid. It was also shown that the covalent character in the bond of the C=O group with talc was greater for (*RS*)-mandelic acid than for the R-isomer and the S-isomer. The change in the region of the carbonyl-stretching vibration was affected by the humidity in the ball-milling atmosphere, and the effect on the R-isomer was greater than the effect on the S-isomer. Magnesium mandelate powder was obtained from an ethanolic suspension of the ball-milled mixture with talc. The IR spectra and the elemental analysis showed that the C=O group was covalently bonded to Mg in the complex of the (RS)-compound and that it was ionically bonded in the complex of the R-isomer and the S-isomer. The thermal analysis showed that the decomposition temperature for the complex of the R-isomer was different from the temperature for the complex of the S-isomer. It was suggested that talc powder had a chiral surface when it was mechanically treated.

The optical isomer effect on a chemical reaction is of great interest with regard to the origin of life. Furthermore, it is of practical importance in pharmaceutics. Kwan et al. reported that (S)-(+)-mandelic acid was adsorbed on starch from an aqueous solution of the racemate preferentially over the (R)-(−)-isomer.[1] According to Nagwekar and Kastenbauder, the rate constant for the metabolism of the S-isomer in the human body was approximately twice the rate for the R-isomer.[2]

Previously, the authors reported the optical isomer effect on the racemization of mandelic acid at the surface of talc powder.[3] This paper will deal with the interaction of optically active and racemic mandelic acids with talc powder upon mechanical treatment.

Experimental

The materials used were (*S*)-(+)-mandelic acid [(*S*)-(+)-α-hydroxyphenylacetic acid] and (*R*)-(−)-mandelic acid purchased from the Aldrich Chemical Co, and (*RS*)-mandelic acid (guaranteed-grade), talc, and magnesium oxide (heavy, guaranteed-grade) of Wako Pure Chemicals Industries, Ltd. The ethanol, 2-propanol, 2-butanol, and formic acid were of a guaranteed grade. A 10-g portion of a mixture of mandelic acid with talc or a mixture with MgO was inserted into a stainless-steel mill (10 cm in diameter and with a capacity of 900 cm^3) containing ten stainless-steel balls (with a density of 8.2 $g\,cm^{-3}$ and a diameter of 2.5 cm) and thirty balls 1.9 cm in diameter. The mill was rotated at a velocity of 95 rpm. This procedure will be called "ball-milling" hereafter. The ball-milling was carried out between December and February with a relative humidity of 45—55% or in June and July with a relative humidity of 75—85%. The ball-milled samples were kept in a desiccator containing silica gel.

Various samples were prepared from a mixture of talc containing 10 w/w% of mandelic acid, which had been ball-milled under a relative humidity of 45—55% for 10 h. A suspension of 1.6 g of this mixture in 80 ml of ethanol was stirred at 5 °C for 1 h at a velocity of 380 rpm. It was then centrifuged, and the supernatant, A, was evaporated to dryness at 60 °C under reduced pressure. The powder thus obtained, A′, was weighed, and then 3 ml of ethanol was added to this. This suspension was set aside at 5 °C for 1 h after having been shaken vigorously; a supernatant, B, and a precipitate, C, were obtained by centrifuging. The precipitate C was washed twice with ethanol, dried at 60 °C, and weighed (powder C). Powder C was washed with ethanol eight more times and then dried at 60 °C (powder C′). The supernatant B and the powders, A′, C, and C′, obtained from mixtures of the (RS)-compound and the R-isomer or the S-isomer are, respectively, expressed by B_{RS}, B_R, B_S, A'_{RS}, A'_R, A'_S, C_{RS}, C_R, C_S, C'_{RS}, C'_R, and C'_S. The powders M-Mg and M-Mg′ were prepared as follows. A suspension of MgO in an ethanolic solution of (*RS*)-mandelic acid was set aside for several hours at 60 °C in order to prepare the M-Mg powder and at 5 °C in order to prepare the M-Mg′ powder. These suspensions were then centrifuged, and the precipitates were washed with ethanol several times and dried at 60 °C. These samples were kept in a desiccator containing silica gel.

The IR spectra were measured with a JASCO infrared spectrophotometer (Model 810). The absorption spectra were measured with a Hitachi recording spectrophotometer (Model 340). The optical rotation of the solutions was measured with a JASCO digital polarimeter. The DTA and TG measurements were carried out using a thermal analyser (Model DT-20B and TG-30) of Shimadzu Seisakusho. The supernatant B was developed on a thin layer of silica gel with a solvent system of 2-butanol-2-propanol-formic acid-water (15 : 15 : 4 : 10).[4]

Results and Discussion

IR Spectra. Figures 1 and 2 show the IR spectra of the ball-milled mixtures of mandelic acid and talc. The absorbances around 3400—3420 cm^{-1} and at 1700—1730 cm^{-1} decreased, while new peaks appeared in the 1600—1650 cm^{-1} region, on ball-milling. Under the relative humidity of 75—85%, new peaks appeared at 1610, 1630, and 1650 cm^{-1}, and the absorbance at 1650 cm^{-1} increased remarkably, at the first stage of ball-milling in the case of (*RS*)-mandelic acid. On the ball-milling of the mixture of the R-isomer or

S-isomer, new peaks appeared at 1600, 1620, and 1640 cm^{-1}. These changes were greater for the R-isomer than those for the S-isomer at the first stage. Under the relative humidity of 45—55%, a new peak also appeared at 1650 cm^{-1} upon the ball-milling of a mixture containing 30 w/w% of the (RS)-compound. However a broad absorption band appeared at 1600—1700 cm^{-1} in the other mixtures, and the optical isomer effect was slight. Figure 3 shows the IR spectra of the ball-milled mixtures in the region between 1200 and 1800 cm^{-1}. In the spectra of the mixtures of the (RS)-compound, the absorbance at 1350 cm^{-1} was high and the absorbance at 1410 cm^{-1} was low when the absorbance at 1650 cm^{-1} was high and the absorbance at 1600—1620 cm^{-1} was low. In the spectra of a mixture of the R-isomer or the S-isomer, the absorbance at 1390 cm^{-1} was high and the absorbance at 1410—1430 cm^{-1} was low when the absorbance at 1640 cm^{-1} was high and the absorbance at 1600—1620 cm^{-1} was low. According to Khadikar et al.,[5] the absorption band of the hydroxyl group is around 3260 cm^{-1} and the COO^- band is around 1600 cm^{-1} in the spectra of the complex of mandelic acid and a bivalent metal ion. It is clear from the above results that a complex is formed between talc and the hydroxyl group and the carboxyl group of mandelic acid. The IR spectra of the complexes of α-hydroxy carboxylic acids, amino acids, or EDTA with such metals as Cu, Ni, and Co have been reported by many workers, and the following facts have been confirmed.[6] When the metal–carboxylato bond is ionic, the asymmetric stretching vibration of the C=O group is in the 1550—1600 cm^{-1} region, and an increase in the frequency occurs with an increase in the covalent character. When the bond is covalent, the band is found at 1650 cm^{-1}. The symmetric stretching vibration of the C=O group for the ionic bond is at 1400—1410 cm^{-1}, and the band shifts to a lower frequency with the increase in the covalent character. It is clear from the above facts that the band at 1640—1650 cm^{-1} is due to the C=O group bonded to talc highly covalently and that the band at 1600—1610 cm^{-1} is due to the C=O group bonded with talc highly ionically. It may also be concluded that the C=O group of the (RS)-compound is more highly covalently bonded with talc than that of the R-isomer or the S-isomer.

Ball-milling conditions; the content of mandelic acid 10 w/w%, relative humidity 75—85%.

The area surrounded by a straight line, passing through the transmittance at 1780 cm^{-1} and at 1550 cm^{-1}, and the transmittance-wavenumber curve was divided into five parts at the wavenumbers of 1620, 1640, 1660, and 1690 cm^{-1} for the (RS)-compound, and at the wavenumbers of 1610, 1630, 1660, and 1700 cm^{-1} for the R-isomer and the S-isomer. Only the four parts except the part between 1660—w cm^{-1} were discussed, where w is 1690 for the (RS)-compound and 1700 for the R-isomer and the S-isomer. S_Z and S_Z' (Z=I, II, III, or IV) stand for the ratios of the area of each part to the total area for the (RS)-compound and for the R-isomer or the S-isomer respectively, where the wavenumber of part z, ν_z, is in the order of $\nu_I \geqslant \nu_{II} \geqslant \nu_{III} \geqslant \nu_{IV}$. As is

shown in Figs. 4—11, the change in these ratios at the first stage of ball-milling was greater under an atmosphere of high humidity. The effect of the humidity on S_{II} and S_{II}' was greater than the effect on the ratios for lower wavenumbers. The effect of the humidity on the mixture of the R-isomer was greater than the effect on the mixture of the S-isomer.

Magnesium Mandelate Powder. It was reported previously that mandelic acid was racemized when its anion was adsorbed very weakly at the surface of talc powder.[3] We have now measured the optical rotation and the absorption spectra for the supernatants of the ethanolic suspensions of the mixtures of mandelic acid with talc at the first stage of the ball-milling. It was clarified, from an analysis of these results, that the mandelic acid in the ball-milled mixture was not racemized, probably because of a strong interaction with talc. Table 1 shows the amounts of the A′ and C powders obtained from an ethanolic suspension of the ball-milled mixture. It is clear that the A'_R and A'_S powders contain more of an ethanol-soluble substance than A'_{RS}. According to many studies concerning the degradation of mandelic acid on γ-irradiation or oxidation, the main products are benzaldehyde, benzoic acid, and phenylglyoxylic acid.[7] By the thin-layer chromatography of B_R and B_S, mandelic acid, benzoic acid, and some substance other than the above three degradation products were detected, but mandelic acid was not detected for B_{RS}. A fine structure due to mandelic acid was observed in the absorption spectra of B_R and B_S, but a fine structure was not observed at all in the spectra of B_{RS}. It is considered that much of the ethanol-soluble substance in A'_R and A'_S powders is mandelic acid. In Table 1 are tabulated the amounts of mandelic acid in Solution A as inferred from the optical rotation of Solutions A and B.

In the IR spectra of C_R and C_S, the antisymmetric stretching vibration of C=O was around 1600 cm^{-1}, while it was at 1655 cm^{-1} in the spectra of C_{RS}. The spectra of C_{RS} were identical with those of M-Mg. In the spectra of M-Mg′ and the ball-milled mixture of mandelic acid with MgO, a broad band, which was a superposition of the bands at 1600 cm^{-1} and at 1655 cm^{-1}, was observed. Probably, powder C is the complex of mandelic acid and Mg, as M-Mg and M-Mg′ are considered to be the complexes of mandelic acid with MgO; this complex is also formed by ball-milling the mixture (Fig. 12).

Table 2 shows the contents of the C and H atoms in various C′ powders, as determined by the elemental

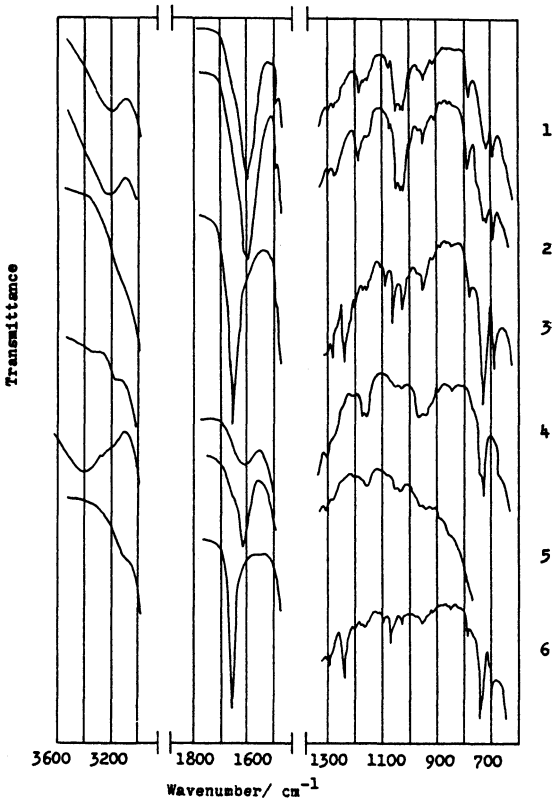

Fig. 12. IR spectra of various powders containing mandelic acid. 1 C_S, 2 C_R, 3 C_{RS}, 4 the ball-milled mixture of (*RS*)-mandelic acid and MgO (One g of mandelic acid and 9 g of MgO were ball-milled for 4 h.), 5 M-Mg′, 6 M-Mg.

analysis, and the values calculated for the substances of the molecular structures of K_A and K_B. A comparison between the found values and the calculated values suggests that the C'_{RS} powder is a substance with the molecular structure of K_B (x=0), mixed with a small amount of a substance with the molecular structure of K_A ($1<x<2$). The results also suggest that the C'_R and C'_S powders are substances with the molecular structure of K_A ($1<x<2$), mixed with only a small amount of a substance with the molecular structure of K_B (x=0).

Large exothermic peaks were observed at 300—400 °C and above 500 °C in the DTA thermograms of the C'_{RS} and C'_R powders. In addition, a small endothermic peak was observed at 280—320 °C in the thermogram of the C'_S powder. In the TG analysis, a mass loss was observed at these temperatures; the mass loss at 280—400 °C was 40—50%. It was determined from these measurements that the decomposition temperatures of the C'_{RS}, C'_R, and C'_S powders were 332, 320, and 282 °C respectively. A mass loss of approximately 4% was observed between room temperature and 100 °C in the case of the C'_S powder, but no mass loss was observed below the decomposition temperature in the cases of the C'_R and C'_{RS} powders. The water in these powders may be structural water, or it may coordinate with Mg, and the hydroxyl group and the COO^- group of mandelic acid may then bind with these coordinating water molecules.

Optical Isomer Effect. It is clear from the above results that the mechanochemical interaction of (*RS*)-mandelic acid with talc is different from the interaction of the R-isomer and the S-isomer. It is also clear that there is some difference between the interaction of the R-isomer and that of the S-isomer. The band of the free hydroxyl group is at 3515 cm^{-1} and this band shifts to a lower frequency upon hydrogen bonding.[8] The band of the hydroxyl group for the (RS)-compound is at 3400 cm^{-1}, while the bands for the R-isomer and the S-isomer are at 3420 cm^{-1}. This shows that intermolecular or intramolecular hydrogen bonds in the (RS)-compound are stronger than the bonds in the R-isomer or the S-isomer. Singurel[8] investigated the IR spectral change in mandelic acid upon interaction with proton acceptors. He pointed out that the C=O vibrations at 1718 cm^{-1} and 1762 cm^{-1} belonged to the dimer and to monomer mandelic acid respectively. When a proton acceptor complexed with the COOH group of mandelic acid, the C=O band

appeared between the monomer band and the dimer band. The C=O band for the optically active mandelic acids at 1715 cm^{-1} shifted to a frequency higher by approximately 10 cm^{-1} at the first stage of ball-milling, but no shift was observed in the C=O band for the (RS)-compound. These facts show that the proton acceptors at the surface of talc powder form hydrogen bonds only with the optically active mandelic acids. Probably this causes the difference between the interactions of (*RS*)-mandelic acid and optically active mandelic acids with talc. The difference between the interaction of the R-isomer and that of the S-isomer also suggests that talc powder has a chiral surface when it is mechanically treated.

The authors wish to express their thanks to the members of the Analytical Center of Showa University for the measurement of the IR spectra and the elemental analysis. The present work was partially supported by a Grant-in-Aid for Scientific Research (No. 61540427) from the Ministry of Education, Science and Culture, to which the authors are grateful.

On the Characterization of Fibonacci Numbers as Maximal Independent Sets of Vertices of Certain Trees

Sherif EL-BASIL†
Chemistry Department, University of Georgia, Athens, Georgia 30602, U.S.A.
(Received November 4, 1986)

Fibonacci numbers are identified for the first time as maximal independent sets of vertices of certain caterpillar trees. Their relation to king patterns of certain classes of polyomino graphs as well as polyhex graphs is illustrated.

More than a decade ago Hosoya[1] defined the concept of nonadjacent numbers in chemistry. Thus for a connected nondirected simple graph, G, the quantity $p(G,k)$ is defined to be the number of ways of choosing k disconnected lines from graph G with $p(G,o)$ being taken to be unity. The Z-counting polynomial, $H(G;x)$ is defined as

$$H(G;x)=\sum_{k=0}^{m} p(G;k)x^k \quad (1)$$

where m is the maximum number of k. The Z-index is the sum of the $p(G,k)$ numbers, i.e.,

$$Z(G)=H(G;1) \quad (2)$$

The above topological index was found to be applicable in many different areas including chemistry, mathematics, dimer statistics, and informatics.[2] The recent revival of interest in graph theory led to a natural extension of the $p(G,k)$ numbers to include other nonadjacent mathematical objects abstracted from molecular graphs. Thus when the concept is applied to benzenoid hydrocarbons[3] $p(G,k)$ becomes $r(B,k)$ i.e. the number of selections of k nonadjacent resonant sextets from the benzenoid graph B. In Clar sextet theory[4] the nonadjacent concept has been extended to sets of nonadjacent vertices $o(G,k)$ chosen from the corresponding Clar graph,[5] C. Further, the latter concept was also recently applied[6] to king polynomials of polyomino graphs.[7] In addition the nonadjacent concept relates to rook theory.[8] Thus, there is a one-to-one correspondence between labelled bipartite graphs with $a+b$ vertices and a chess board, R, with a rows and b columns such that $p(G,k)=\rho(R,k)$ where the latter function counts the number of ways in which one can arrange k non-attacking rooks on R, taking $\rho(R,o)=1$.

Some interesting relations arise for certain types of graphs. Thus the set $\{Z(G_n=L_n)\}$, where L_n is a path on n vertices is the set of Fibonacci numbers,[9] $\{F_n\}$, defined by

$$F_n=\sum_{k=0}^{[n/2]}\binom{n-k}{k} \quad (3)$$

while the set $\{Z(G_n=C_n)\}$, C_n being a cycle on n vertices, generates the Lucas sequence,[9] $\{L_n\}$, where

$$L_n=F_n+F_{n-2};\ n\geqslant 2 \quad (4)$$

The binomial functions of Eq. 3 are coefficients of the Chebyshev polynomials.[10] Because the Fibonacci numbers are well studied any relations to other fields such as chemistry or physics should be interesting. Two classical relations to the Fibonacci numbers are known in chemistry:

(1) The numbers of Kekulé structures, K, of the zigzag nonbranched benzenoid hydrocarbons (phenanthrene, chrysene, picene, fulminene, (benzo[c]picene), ···) are defined by[11]

$$K_n=F_{n+1} \quad (5)$$

n, is the number of rings in the polyhex graph.

The analogous relation in statistical physics is[12]

$$K(2\times n)=F_n \quad (6)$$

where $K(2\times n)$ is the number of perfect matchings in a $(2\times n)$ rectangular lattice.

(2) Let $\gamma_{i(n)}$ be the number of permutation integrals[13] involving i rings in a nonbranched zigzag polyacene containing n rings (observe that $\sum\gamma_i=1/2\sum R_i$, where R_i is a conjugated circuit over i rings,[14]) then[15]

$$\gamma_i(n)=\gamma_{i-1}(n-1) \quad (7)$$

$$\gamma_i(n)=\sum_{k=1}^{\theta} F_{\theta-k}F_{k-1}$$

where $\theta=n+1-i$.

Maximal Independent Sets. The vertices of a graph can be partitioned into a finite number of sets. A set of vertices in which no two vertices are adjacent is called an *independent* set of vertices. An independent set of vertices $\{V(r)\}$ in G is said to be *maximal*[16] if every vertex of G $\epsilon\{V(r)\}$ is adjacent to at least one of the r vertices of $\{V(r)\}$. Figure 1 shows three graphs $\mathcal{C}_1$, $\mathcal{C}_2$, and $\mathcal{C}_3$, arbitrarily labelled as shown. There are seven maximal independent sets of vertices in $\mathcal{C}_1$, viz., {1,4},

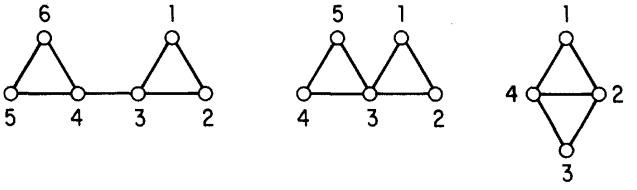

Fig. 1. Three labelled (Clar) graphs.

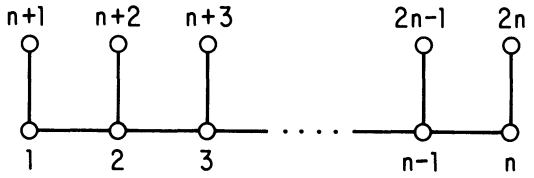
†Permanent address: Faculty of Pharmacy, Kasr El-Aini Street, Cairo, Egypt.

{1,5}, {1,6}, {2,4}, {2,5}, {2,6}, {3,5}, and {3,6}, while the vertices of $\mathcal{C}_2$, are partitioned into five maximal independent sets: {3}, {1,4}, {1,5}, {2,4}, {2,5}. For $\mathcal{C}_3$ there are only three such sets: {2}, {4}, and {1,4}. Actually $\mathcal{C}_1$ and $\mathcal{C}_2$ are the Clar graphs[5,17] of two nonbranched systems whose ring-annellation[18] sequences are respectively $L^2A^2L^2$ and $L^2A^2L^2$ while $\mathcal{C}_3$ is the Clar graph of pyrene. In fact, quite recently Herndon and Hosoya[17,19,20] identified the number of Clar *structures*[17] of a benzenoid hydrocarbon as the number of maximal independent sets of vertices in the corresponding Clar graphs.

The Comb Tree Graphs

We consider a special type of tree formed by the addition of a single (monovalent) vertex to each of the n vertices of a path, L_n. The resulting caterpillars[21] containing $2n$ vertices are also known as comb trees. The vertices of the original path moiety of such trees will be called *root vertices*. A comb tree will be given the symbol $Tn(1,1,\cdots,1)\equiv T_{n,1}$. An arbitrary labelling of the set of vertices $\{V(r)\}\varepsilon\, T_{n,1}$ is shown below



Let us consider the maximal independent sets of vertices of some of the lower members of comb trees.

$V(T_{1,1}) \supset$ {2}; {1}=$V_m(T_{1,1})$

$V(T_{2,1}) \supset$ {3,4}; {1,4}, {2,3}=$V_m(T_{2,1})$

$V(T_{3,1}) \supset$ {4,5,6}; {1,5,6}; {2,4,6}; {3,4,5}; {1,3,5}=$V_m(T_{3,1})$

$V(T_{4,1}) \supset$ {5,6,7,8}; {1,6,7,8}; {2,5,7,8};
{3,5,6,8}; {4,5,6,7}; {1,3,6,8};
{1,4,6,7}; {2,4,5,7}=$V_m(T_{4,1})$

$V(T_{5,1}) \supset$ {6,7,8,9,10}; {1,7,8,9,10}; {2,6,8,9,10};
{3,6,7,9,10}; {4,6,7,8,10}; {5,6,7,8,9,10};
{1,7,3,9,10}; {1,4,7,8,10}; {1,5,7,8,9};
{2,4,6,8,10}; {2,5,6,8,9}; {3,5,6,7,9};
{1,3,5,7,9}=$V_m(T_{5,1})$.

Where $V(T_{n,1})$ is the total set of vertices of $T_{n,1}$ and $V_m(T_{n,1})$ is a subset of it including all the maximum independent sets in $T_{n,1}$. Let $N(V(T_{n,1}))\equiv\zeta_n$ be the number of such sets. We observe the following results:

$\zeta_1=2,\ \zeta_2=3,\ \zeta_3=5,\ \zeta_4=8,\ \zeta_5=13;\ \zeta_3=\zeta_1+\zeta_2;\ \zeta_4=\zeta_3+\zeta_2;\ \zeta_5=\zeta_4+\zeta_3.$

Which reminds us of the Fibonacci numbers F_2, F_3, F_4, F_5, and F_6 respectively. Actually the above set counts recur in the following general way

$$\zeta_n=\zeta_{n-1}+\zeta_{n-2}, \tag{8}$$

where

$$\zeta_n=F_{n+1}. \tag{9}$$

There are two ways of proving (8) and (9).

A. Graph-Theoretical Reasoning

Define the function f such that f: $V_m(T_{n,1})=\overline{V}_m(T_{n,1})$ where

$$\overline{V}_m(T_{n,1})=\{vi/vi\varepsilon\, V_m(T_{n,1});\ i\varepsilon\,(1,2,\cdots,n);\ \notin(n+1,n+2,\cdots,2n)\},$$

where vi is a vertex whose label is i. Therefore the function f maps the set $V_m(T_{n,1})$ into a set of vertices *containing only root type vertices*. The resulting initial sets are:

$\overline{V}_m(T_{1,1})$={∅}; {1}

$\overline{V}_m(T_{2,1})$={∅}; {1}; {2}

$\overline{V}_m(T_{3,1})$={∅}; {1}; {2}; {3}; {1,3}

$\overline{V}_m(T_{4,1})$={∅}; {1}; {2}; {3}; {4}; {1,3}; {1,4}; {2,4}

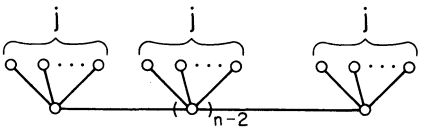
$\overline{V}_m(T_{5,1})$={∅}; {1}; {2}; {3}; {4}; {5};
{1,3}; {1,4}; {1,5}; {2,4};
{2,5}; {3,5}; {1,3,5}.

In general one can then write:

$\overline{V}_m(T_{n,1})$={∅};
{1}; {2}; ⋯ ; {n};
{1,3}; {1,5}; ⋯ ; {2,4}; {2,5}; ⋯ ; {i, i+2};
{1,3,5}; ⋯ ; {j; j+2; j+4}; ⋯ ,
{k,k+2, k+4, k+6, ⋯ }

The cardinalities of the above sets are nothing else but the independence numbers[5] of paths L_n. Alternatively they are simply the k-matchings of L_{n+1} (observe that L_n is the line graph[22] of L_{n+1}). The latters are indeed the graphical representations of the Fibonacci numbers[9] and since the f function is an injective (i.e. one-to-one) mapping of $V_m(T_{n,1})\rightarrow\overline{V}(T_{n,1})$ relations (8) and (9) become immediate.

The above ideas lead to the more general caterpillar



$T_{n,j}$; $j\geq 1$

Obviously,

$$\zeta(T_{n,j})=\zeta(T_{n,1});\ j\geqslant 1 \tag{10}$$

This is because

$$\overline{V}_m(T_{n,j})=\overline{V}_m(T_{n,1});\ j\geqslant 1$$

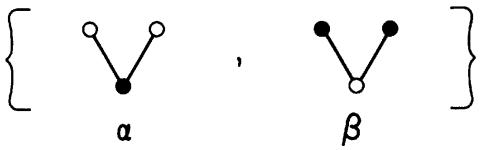
Note, however, that when j=0 the Fibonacci recursion is lost.[17,20]

B. Coloring Method

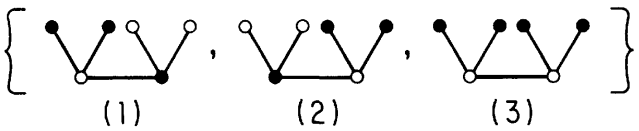
Another method of proving the above result (Eqs. 8 and 9) uses a special coloring scheme. Thus the vertices of a $T_{n,j}$, ($j\geqslant 1$); are colored in black and white such that (i) no two black vertices are adjacent and (ii) every white vertex is adjacent to at least one black vertex. The resulting colorings then correspond to maximal independent sets of vertices. For simplicity these indi-

ces are illustrated using $T_{n,2}\equiv T_n$ but the theory can be generalized to $T_{n,j}$.

Lemma 1. $T_{1,2}\equiv T_1$ generates two colorings, viz., α and β:



The "allowed" colorings of T_2 can be identified from lemma 1 and rules i and ii as:



All colorings of T_3 can be obtained by connecting one of the root vertices of (1)—(3) to the root vertices of α and/or β. However, because of (i), the coloring (1α) is not allowed and thus T_3 has $3\times2-1=5$ colorings. Similarly the colorings of T_n can be obtained from those of T_{n-1} and the set $\{\alpha,\beta\}$.

Theorem 1. Let ζ_n be the number of colorings of T_n. Let the number of colorings in a given set which contains a black root vertex at one (arbitrarily the right) end of the tree be β_n.
Then

$$\zeta_n=\beta_{n+2} \tag{11}$$

Proof. The set $\{\beta_{n+2}\}$ is a subset of the set of colorings $\{\zeta_{n+2}\}$ in which all root vertices at the (right) end are black. Now, because of (i), in any member of $\{\beta_{n+2}\}$ the root vertex adjacent to the one at the right end, i.e. the $(n+1)$th vertex is necessarily *white* and therefore the remaining n vertices must generate the set $\{\zeta_n\}$, i.e. $\{\zeta_n\}\varepsilon\{\beta_{n+2}\}$, and Eq. 11 is proved

Theorem 2.

$$\beta_{n+2}=\beta_{n+1}+\beta_n \tag{12}$$

Proof. Let w_n be the number of colorings in $\{A_n\}$ in which the (right) end root vertex is white. Obviously $\beta_n+w_n=\zeta_n$.

Now from rule (i) and lemma 1:

$$\zeta_{n+1}=2\zeta_n-\beta_n$$

and

$$w_n=\beta_{n+1}=\zeta_n-\beta_n$$

$$\text{i.e. } \zeta_n=\beta_n+\beta_{n+1}=\beta_{n+2}$$

Eqs. 11 and 12 lead to Eqs. 8 and 9.

Coloring Polynomial. A counting coloring polynomial, $\xi(T_{n,j};\,x)$ is conveniently defined by

$$\xi(T_{n,j};x)=\sum_{r}^{m}\theta(r)x^r, \tag{13}$$

where $\theta(r)$ is the number of colorings of $T_{n,j}$ containing r black vertices and m is the maximum value of r. Then $\xi(T_{n,j};\,1)=\zeta_n$. Inspection of the first few coloring polynomials of any $T_{n,j}$, $j\geqslant1$, induces Eq. 14, viz.,

$$\xi(T_{n,j};x)=\sum_{k=0}^{[n/2]}\binom{n-k}{k}x^{mn-(m-1)k} \tag{14}$$

As a corollary when $j=1$ the above function becomes simply a monomial in x.

A Special Class of Benzenoid Hydrocarbons. Figure 2 shows a homologous series of benzenoid hydrocarbons denoted as $B(T_{n,1})$'s. The number of Clar structures in which maximum numbers of hexagons are assigned to have resonant sextets of this series conforms to Eqs. 8 and 9. In principle homologation can be extended infinitely, although the polyhex graph

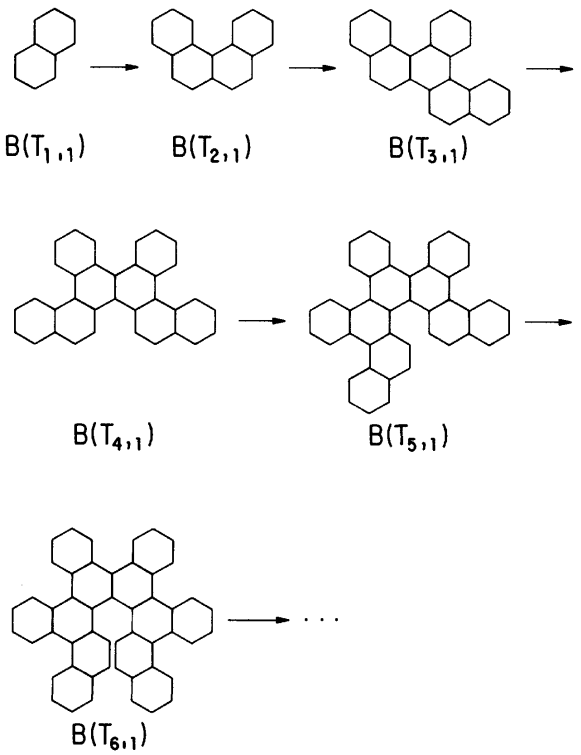


Fig. 2. A homologous series of benzenoid hydrocarbons. The Clar counts, ξ, of the individual members are Fibonacci numbers i.e. $\xi(B(T_{j,1}))=F_{j+1}$.

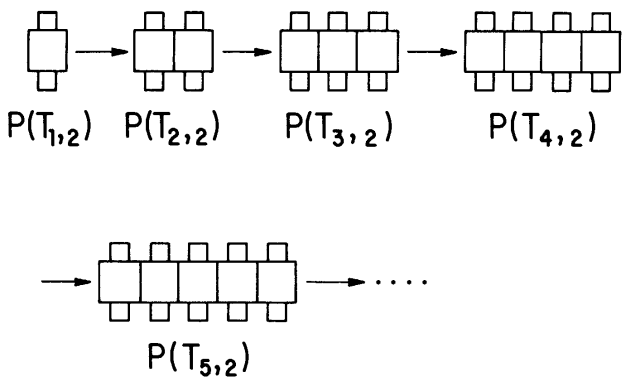

Fig. 3. A homologous series of "bidentate" polyomino graphs. Every graph corresponds to a caterpillar tree $T_{n,2}$, $n=1, 2, 3, 4, 5\cdots$. Relation to other objects is shown in Fig. 4.

above $B(T_{6,1})$ is no long planar. It is interesting to notice that

$$D(B(T_{n,1}))=T_{n,1}$$

where D(G) is the dualist graph[23] of G.

On King Patterns. Motoyama and Hosoya[7] were the first to define king polynomials and king patterns for lattices and polyomino graphs and showed their potential in dimer statistics and the problem of Kekulé count in chemistry. Balasubramanian and Ramaraj[6] demonstrated recently the equivalence between king polynomials and what they called color polynomials[6] of the dualist graphs of the appropriate lattice type. Figure 3 shows a special type of polyomino which corresponds to $T_{n,2}$. But extension to any $T_{n,j}$ is possible. Their king patterns are Fibonacci numbers.

Correspondence with King Pattern,[7] Domino Pattern,[7] and the Matching Pattern.[1,24] A king pattern, {K}, is simply a way of placing kings (circles) on chessboard so that no two kings can take each other. A Kekulé pattern (or dimer pattern), {M}, can be generated by identifying the cells in the chessboard that contain kings as the vertical bonds in the dimer pattern and the empty cells as horizontal bonds (cf. Fig. 4). A "domino pattern," {D}, can also be obtained from the dimer pattern by paving horizontal and vertical rectangles which correspond to horizontal and vertical dimers in the dimer pattern. These relations are depicted in Fig. 4. The set {ζ} is nothing else but the dualist graphs[23] corresponding to the modified polyominos, {P}. Hence one can define two rules of placing kings (circles) in {P} analogous to coloring rules (i), (ii), viz.,

(i′) No two kings are allowed to occupy adjacent cells.

(ii′) Every empty cell is adjacent to at least one occupied cell.

The resulting patterns generate Fibonacci numbers. The last set in Fig. 4, {L}, shows the corresponding matchings in path L_4. The following interesting relation is observed. Let $d\{K_i\}$ be the dualist graph[23] of a member K_i from set {K}, and $L\{L_i\}$ be the line graph[25] of the corresponding member L_i, then

$$d\{K_i\}=L\{L_i\}. \quad (15)$$

The last relation is significant since it is well known that the matching polynomials of the paths may be written as Chebyshev polynomials[26] in $(x/2)$.

Fibonacci numbers have been identified for the first time as maximal independence sets of vertices of certain caterpillar trees. Mappings of such sets to well known topological functions such as perfect matchings of a path as well as certain king patterns are discovered.

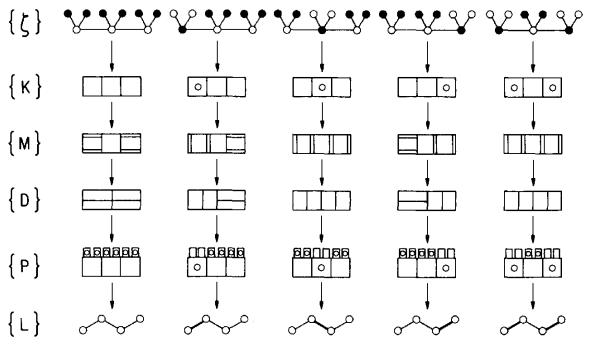

Fig. 4. Fibonacci colorings of $T_{2,2}$ and the corresponding patterns in chemistry and physics. The set {K} is the king pattern, {M} is the dimer pattern, {D} the domino pattern and {P} is a special polyomino pattern. The set {L} is the matchings of L_4.

The author thanks the U.S. Office of Naval Research for partial support of this work. Illuminating remarks of Professor R. B. King are greatly appreciated. Travel assistance from the Fullbright Commission in Cairo is acknowledged.

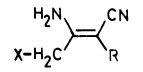
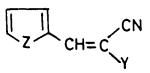
††Department of Chemistry, Faculty of Science, Cairo University, A.R. Egypt
(Received August 16, 1986)

Synthesis of polyfunctional pyrimidine derivatives via the reaction of acrylonitrile derivatives **1a** and **b** with α,β-unsaturated nitriles **2a—f** has been reported.

Studies on α,β-unsaturated nitriles have revealed that these easily obtained reagents are excellent starting materials for the synthesis of polyfunctionally substituted heterocycles.[1-3] Previously our group reported the use of compounds **1a**, **b**, and **2a—f** for the

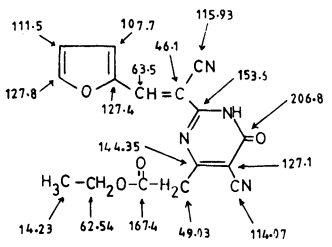


1a. R=X=$CO_2C_2H_5$
b. R=CN; X=$CO_2C_2H_5$
c. R=X=CN



2a. Z=O; Y=CN
b. Z=O; Y=$CO_2C_2H_5$
c. Z=O; Y=COPh
d. Z=S; Y=CN
e. Z=S; Y=$CO_2C_2H_5$
f. Z=S; Y=COPh

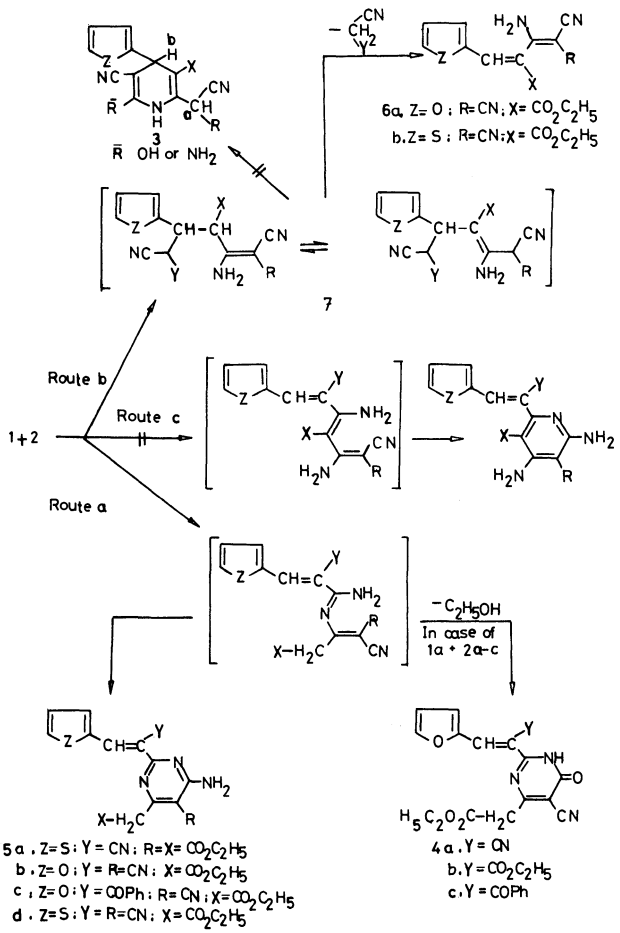
synthesis of pyrazoles,[4] pyranopyrazoles,[5] isoxazoles,[6] fused isoxazoles, pyridazines, and pyridine derivatives.[4] In continuation of this work, we report here the results of our investigations on the reactions of **1a** and **b** with **2a—f**. We found that **1a** reacts with **2a** to yield a product of molecular formula $C_{16}H_{12}N_4O_4$ (M^+=324, *m/z*). The ^{1}H NMR spectrum revealed that the reaction product cannot be the dihydropyridine **3**, which would be expected to be formed via a sequence similar to that suggested recently in literature.[7] High resolution ^{1}H NMR spectroscopy revealed signals for an ester function at δ 1.21 (t, 3H, CH_3) and at δ 4.33 (q, 2H, CH_2), as well as signals for furyl protons at δ 8.29, 7.82, and 6.46. In addition, a two-proton signals at δ 4.1 and a one-proton signal at δ 6.17 were observed. The signal at 4.1, overlapping in the 90 MHz ^{1}H NMR spectrum with the methylene signal, was shown to be due to two noncoupled magnetically equivalent protons and did not disappear on D_2O exchange. Hence, it cannot be assigned to the protons a and b in the dihydropyridine form **3**. The ^{13}C NMR spectrum confirms that the product has the pyrimidinone structure **4a** as it revealed C-4 at δ 206. If the product was the dihydropyridine **3**, extra sp^3 carbons should have been observed.



4a

Similarly, compound **1a** reacted with **2b** and **c** to yield the pyrimidinone derivatives **4b** and **c**. The formation of compounds **4a—c** in this reaction is assumed to proceed via addition of the amino function of **1a** to the cyano group in **2a—c** with elimination of ethanol (see Scheme 1). The structure of **4b** and **c** were well-documented by IR and ^{1}H NMR spectroscopy.

In contrast, compound **2d** reacted with **1a** to yield 1:1 adduct. The pyrimidine structure **5a** was formulated for the reaction product based on IR and ^{1}H NMR. Attempts at addition of **2e** and **f** to **1a** under



Scheme 1.

the same experimental conditions were unsuccessful. The reactants were recovered almost unchanged after reflux in ethanolic piperidine solution.

Compound **1b** reacted with **2a**, **c**, and **d** to yield 1 : 1 adducts which can be formulated as either the dihydropyridine **3** or as the pyrimidines **5b—d**. The establishment of a pyrimidine structure for the reaction products was based on spectral data which, in each case, revealed the presence of a signal for a CH_2 group. Such a signal cannot be assigned to alternative structures. On the other hand, attempted addition of **1b** to **2b** gave the furfurylidene derivative **6a** which could also be obtained from the reaction of **1b** with furfural. The formation of **6a** is assumed to proceed via the intermediacy of the Michael adduct **7**, which then loses ethyl cyanoacetate to yield the final isolated product. Similar ylidene formation on addition of α,β-unsaturated nitriles to active methylene reagents has been observed by us in several reactions.[8,9] In the same way, compound **1b** reacted with **2f** to yield the thenylidene derivative **6b**. The possible formation of **6** via a retro-aldol reaction of **2** affording an aldehyde which condenses with **1** cannot be completely excluded. In contrast to the observed formation of **6a** and **b** compound **1d** did not react with **2e**. The formation of pyrimidines from the reaction of **1a** and **b** with **2a—f** finds a parallel with the Frankland and Kolbe synthesis of pyrimidines.[10]

The results obtained in our investigation clearly reveal that the reaction of **1** with **2** proceeds via three different routes: i) Addition of the amino function to the cyano group and cyclization to yield pyrimidines

4a	2900, 2970 (CH and CH_3); 2180, 2200 (CN groups); 1715 (CO)	1.2 (t, 3H, CH_3); 3.1 (OH and DOH); 4.1—4.4 (m, 4H, $2CH_2$); 6.7 (s, 1H, ylidene CH); 7.4—8.3 (m, $3H_{furan}$)
4b	2950 (CH and CH_3); 2200 (CN); 1730 (br., CO groups)	1.2, 1.22 (two triplets, 6H, $2CH_3$); 3.3 (OH and DOH); 4.18 (m, 6H, $3CH_2$); 6.3 (s, 1H, ylidene CH); 7.3—8.2 (m, $3H_{furan}$)
4c	2900, 2960 (CH and CH_3); 2200 (CN); 1675, 1730 (CO groups)	1.2 (t, 3H, CH_3); 3.3 (OH and DOH); 4.16 (q, 2H, CH_2); 4.2 (s, 2H, CH_2); 7.0—8.2 (m, 9H, aromatic and ylidene protons)
5a	3200, 3300 (NH_2); 2900 (CH_3); 2200 (CN) and 1630 (CO)	Insoluble in available ^{1}H NMR solvents
5b	3200, 3300 (NH_2); 2900 (CH_3); 2180, 2200 (CN groups) and 1640 (CO)	1.2 (t, 3H, CH_3); 3.3 (br., 2H, NH_2); 4.1 (br, 4H, $2CH_2$); 6.8 (s, 1H, ylidene CH); 7.2—8.2 (m, $3H_{furan}$)
5c	3200, 3350 (NH_2); 2900 (CH_3); 2200 (CN)	Insoluble in available ^{1}H NMR solvents
5d	3050, 3200, 3300 (NH_2); 2150, 2200 (CN groups) and 1640 (CO)	1.3 (t, 3H, CH_3); 3.7 (br., 2H, NH_2); 4.2 (m, 4H, $2CH_2$); 6.7 (s, 1H, ylidene CH); 7.2—8.3 (m, $3H_{furan}$)
6a	3200, 3350 (NH_2); 2900, 2950 (CH and CH_3); 2190, 2200 (CN groups); 1715 (CO)	1.3 (t, 3H, CH_3); 3.6 (br., 2H, NH_2); 4.3 (q, 2H, CH_2); 6.65 (s, 1H, ylidene CH); 7.3—8.2 (m, $3H_{furan}$)
6b	3350, 3450 (NH_2); 2900 (CH); 2180, 2200 (CN groups); 1630 (CO)	Insoluble in available ^{1}H NMR solvents

(route a), ii) Michael addition to the activated double bond of **2** to afford the Michael adducts **7** (route b) (in our hands these adducts usually lose active methylene moiety affording the corresponding ylidene derivatives; cyclization of the Michael adducts into dihydropyridines followed by oxidation into pyridines, as has been reported in the literature,[7] could not be observed), or iii) addition of active methylene to the cyano group and cyclization which may afford the pyridine derivative **8** (route c). This route, which has been recently reported[11] for the reaction of **1a** and **b** with trichloroacetonitrile, did not also take place. The predominance of any of these routes is determined by relative activities of the ylidenic bond, the cyano group and also by the energy of the transition states leading to the end products. In complex systems like those we are dealing with it is very difficult to predect the predominant reaction path. The predominance of route a in our case can be attributed to a decrease in the reactivity of the double bond in **2** being counterbalanced by the effect of the electron-rich heterocycles.

This work shows again that the reaction of α,β-unsaturated nitriles with active methylene reagents do not necessarily follow the simple pattern of Michael addition and cyclization. Alternative structures should always be considered and strong arguments should be introduced when assigning structures to the products of these reactions.

Experimental

All melting points are uncorrected. IR spectrum were recorded (potassium bromide) on a Shimadzu-408 spectrophotometer. ^{1}H NMR were measured in a mixture of chloroform-*d* and methanol-d_4 on a Varian EM-390 spectrophotometer at 90 MHz with TMS as internal reference and chemical shifts are expressed as δ. Microanalytical data (C,H,N,S) were obtained from the Microanalytical Data Unit at Cairo University.

Condensation of Compounds 1a and b with Nitriles 2a—f. General Procedure: A suspension of compound **1a** or **b** (0.01 mol) and the appropriate nitrile **2a—f** (0.01 mol) in ethanol (50 ml) was treated with piperidine (1.0 ml). The reaction mixture was heated under reflux for four hours and then the mixture was evaporated in vacuo. The solid product, so formed, was collected by filtration and recrystallized from the appropriate solvent (see Table 1).

Condensation of 1b with Furfural: Furfural (0.01 mol) was added to a solution of compound **1b** (0.01 mol) in ethanol (50 ml) in the presence of piperidine (1.0 ml). The reaction mixture was heated under reflux for 4h and then evaporated in vacuo. The solid product, so formed, was collected by filtration and recrystallized from an ethanol-water mixture. The product was identical with compound **6a**.

Kinetics of Oxidation of Aliphatic Ketones with Bromamine-T in Acid Medium

Dandinasivara Siddalingaiah MAHADEVAPPA* and Putta SWAMY
Department of Chemistry, University of Mysore, Manasagangothri, Mysore 570006, India
(Received September 26, 1986)

The kinetics of oxidation of 2-propanone, 2-butanone, 2-pentanone, 3-pentanone, and 4-methyl-2-pentanone by sodium salt of *N*-bromo-*p*-toluenesulfonamide or bromamine-T (BAT) in presence of $HClO_4$ was studied at 30 °C. The rate law is:

$$-\frac{d[BAT]}{dt} = k[BAT]^0[ketone]^1[H^+]^1.$$

Variation of ionic strength of medium or addition of reaction product *p*-toluenesulfonamide have no effect on the rate. The dielectric effect is positive. The acid-catalyzed enolization of ketone is assumed to be the rate-limiting step and enolization rate coefficients have been calculated. Proton inventory studies made in H_2O-D_2O mixtures have been employed to calculate the isotopic fractionation factors. Isokinetic temperature is 320 K indicating enthalpy as a controlling factor.

Although the analytical applications and kinetic studies of reactions of the organic chloramines, chloramine-T (CAT) and chloramine-B (CAB) are reviewed,[1] there is scant information in literature about the bromine analogues. As a part of our mechanistic studies of oxidation of substrates by *N*-bromo amides, we report the kinetics of oxidation of aliphatic ketones, 2-propanone, 2-butanone, 2-pentanone, 3-pentanone, and 4-methyl-2-pentanone by bromamine-T (p-$CH_3C_6H_4SO_2NBrNa \cdot 3H_2O$ or BAT) in presence of perchloric acid.

Experimental

Bromamine-T was prepared by the method reported in literature.[2] The authenticity of the product was confirmed by checking iodometrically and then through its mass spectrum and UV, IR, ^1H, and ^{13}C-spectral data. An aqueous solution of BAT was prepared, standardized by the iodometric method and was preserved in brown bottles to prevent its photochemical deterioration.

Analytical grade acetone was used without further purification while other ketones (SDS, India) were redistilled. Aqueous solutions of ketones (≈0.2M) (1 M=1 mol dm^{-3}) were prepared by exact weighing of required quantity of the compound. All other chemicals were of analytical grade. Triply distilled water was used in preparing aqueous solutions.

Regression analysis of experimental data (to get regression coefficient r and standard deviation of the estimate, S) carried out on a TDC-316 (16 bits) computer supplied by Trombay Electronics, India.

Kinetic Measurements. Rate studies were made at 30 °C and details are described in some of the previous communications.[3] The course of reaction was studied for about three half-lives. The pseudo-zero-order rate constants obtained from the plots of $\{[BAT]_0-[BAT]\}$ versus time were converted into standard zero-order constants k_0 through the equation, $k_0=SN/V$ where S is the slope of the plot, N the normality of thiosulfate used for iodometric estimation of unreacted BAT and V is the aliquot of reaction mixture titrated. The pseudo-first-order rate constants k' were calculated by the relation, $k'=k_0/[ketone]$. The rate constants were reproducible to ±3%.

Stoichiometry. Studies on stoichiometry indicated that 2-propanone consumes 3 moles of BAT per mole of ketone corresponding to the formation of HCOOH and CH_3COOH. The ratio was 2 : 1 in the case of other ketones indicating the formation of diketones.

$$\begin{matrix} CH_3 \\ CH_3 \end{matrix}\!\!>\!CO + 3\,RNBrNa + 3\,H_2O \longrightarrow HCOOH + CH_3COOH + 3\,RNH_2 + 3\,Na^+ + 3\,Br^-$$

$$\begin{matrix} C_2H_5 \\ C_2H_5 \end{matrix}\!\!>\!CO + 2\,RNBrNa + H_2O \longrightarrow CH_3COCOC_2H_5 + 2\,RNH_2 + 2\,Na^+ + 2\,Br^-$$

$$\begin{matrix} CH_3 \\ R'CH_2 \end{matrix}\!\!>\!CO + 2\,RNBrNa + H_2O \longrightarrow R'COCOCH_3 + 2\,RNH_2 + 2\,Na^+ + 2\,Br^-$$

where R'=$-CH_3$ for 2-butanone, $-CH_2CH_3$ for 2-pentanone, $-CH(CH_3)CH_3$ for 4-methyl-2-pentanone and R=p-$CH_3C_6H_4SO_2$.

The sulfonamide (reduction product of BAT) was detected by paper chromatography.[3] Formic and acetic acids were identified through TLC followed by conventional spot test analysis and were estimated by titration with standard alkali (Table 1). The reaction mixture was extracted with ether and the diketones present were detected through TLC followed by spot tests. Biacetyl (bp 88—91 °C) formed had a bp of

90 °C (corrected) and was assayed as its 2,4-DNP derivative (Table 1).

Results

At constant excess ketone concentration (0.05 mol dm^{-3}) and [$HClO_4$]=0.1 mol dm^{-3}, plots of {[BAT]$_0$ −[BAT]} versus time were found to be linear (r>0.9968 S<0.0184) passing through the origin indicating zero-order dependence on [oxidant]. The pseudo-zero-order rate constants are found to be truly constant for different oxidant concentrations indicating that oxidation of substrate is complete (Table 2). The rate increased with [ketone]$_0$ and linear (r>0.9979, S≦0.0120) with unit slope (Table 3). Further, a plot of k_0 versus [ketone]$_0$ is linear (r>0.9988, S≦0.0156) passing through the origin confirming the first-order dependence on [substrate]$_0$ in each case. Increase in [$HClO_4$] increased the rate of reaction and a plot of log k_0 versus log[$HClO_4$] was linear (r>0.9969, S≦0.0208) with a slope of unity (Table 4) showing a first-order dependence on [H^+]. When k_0 versus [$HClO_4$] was plotted, it gave a straight line passing through the origin (r>0.9980, S≦0.0234) indicating that the reaction takes place only through the acid-dependent path. When ionic strength of solution was varied by adding $NaClO_4$, the rate was unaffected (Tables 1 and 2). Addition of reaction product, p-toluenesulfonamide (RNH_2) or Br^- ion had no influence on the rate. The solvent composition was varied by adding methanol to the reaction mixture (0—40% v/v). The rate increased with increase in methanol concentration and a plot of log k_0 versus D^{-1}, where D is the dielectric constant of medium gives a straight line (r>0.9971 S≦0.0126) with a positive slope. Blank experiments showed that

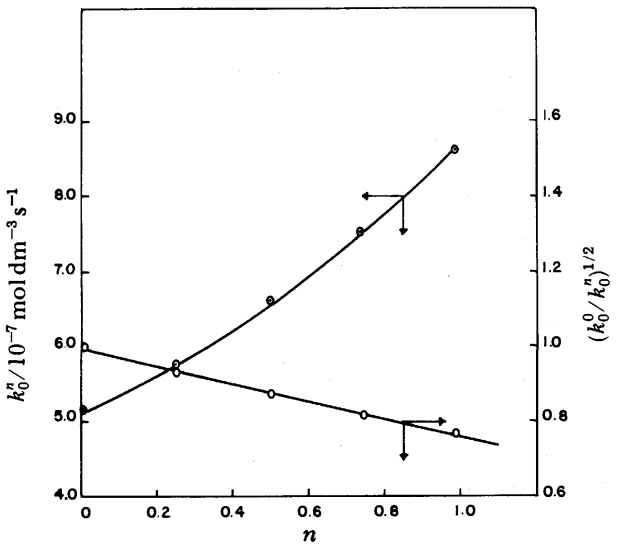

Fig. 1. Proton inventory plot for the oxidation of 2-propanone by BAT in H_2O–D_2O mixtures at 30°C. [BAT]$_0$=9.0×10^{-4} mol dm^{-3}; [ketone]$_0$=0.05 mol dm^{-3}; [$HClO_4$]=0.1 mol dm^{-3}.

methanol is not oxidized by BAT under the present experimental conditions.

Addition of reaction mixture to aqueous acrylamide did not initiate polymerization showing absence of free radicals.

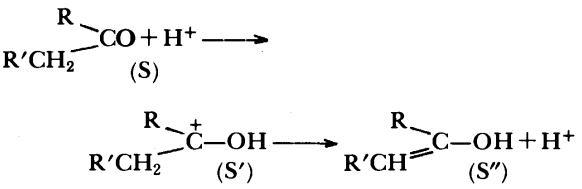
The reaction was studied at different temperatures (293—313 K) and from the Arrhenius plots of log k' versus T^{-1} (r>0.9985, $S\leq$0.037) the kinetic parameters were calculated (Table 5).

Solvent isotope studies were made in D_2O medium. For 2-propanone value of k_0 in D_2O was 8.57×10^{-7} mol dm^{-3} s^{-1} while the corresponding value in H_2O was 5.08×10^{-7} mol dm^{-3} s^{-1} leading to a solvent isotope effect $(k_0)_{H_2O}/(k_0)_{D_2O}$=0.59 with other conditions as in Table 2. Proton inventory studies with 2-propanone as the probe were made in H_2O–D_2O mixtures and these results are shown in Table 6. The corresponding proton inventory plot relating to the rate constant k_0^n in a solvent mixture of deuterium atom fraction n is given in Fig. 1.

Discussion

Bromamine-T is analogous[5] to chloramine-T and chloramine-B and with the assumption of similar equilibria in acidified aqueous solutions of oxidant, the possible oxidizing species in these solutions are RNHBr, $RNBr_2$, and HOBr where R=p-$CH_3C_6H_4SO_2$. But the zero-order dependence on [oxidant] precludes speculation about the identity of kinetically active species. It is likely that the free acid RNHBr which is in higher concentrations[5] compared to the other species would oxidize the ketones in a fast step.

Ketones form oxonium salts on protonation in presence of strong acids leading to enolization:



(1)

Here S represents the ketone, S′ its conjugate acid and S″ its enolic form.

The first-order dependence of rate on [ketone] and [H^+] and the zero-order in [BAT]$_0$ shows that the traditional mechanism of Bell and co-workers[6] is followed (Scheme 1):

$$S + H^+ \underset{k_{-1}}{\overset{k_1}{\rightleftharpoons}} S' \text{ (fast)} \quad \text{(i)}$$

$$S' \xrightarrow{k_2} S'' + H^+ \text{ (slow and r.l.s.)} \quad \text{(ii)}$$

$$S'' + n\,RNBrNa \xrightarrow{k_3} n\,RNH_2 + \text{Products (fast)} \quad \text{(iii)}$$

Scheme 1.

Here n=3 for 2-propanone and 2 for other ketones.

Scheme 1 leads to rate law (2) which is in agreement with the observed stoichiometry and kinetic orders:

$$-\frac{d[BAT]}{dt}=\frac{2k_1k_2}{k_{-1}+k_2}[\text{ketone}][H^+] \quad (2)$$

The positive dielectric effect indicates a charge dispersal in transition state pointing towards an ion-dipole reaction and is also in general agreement about its influence[7] on keto-enol equilibria.

The proposed mechanism is also supported by the magnitude of solvent isotope effect. The rate is enhanced in D_2O medium implying preequilibrium fast proton transfer with specific acid catalysis. It is well-known[8] that D_3O^+ is a stronger acid than the hydronium ion and hence a rate enhancement in D_2O should be expected. This is in agreement with the carbonium ion character of the transition state (Eq. 1) and lends support to the participation of enol form in the rate-limiting step. The proton inventory plot (Fig. 1) could throw light on the nature of transition state.[9,10] The dependence of rate constant k_0^n on n, the atom fraction of deuterium in a solvent mixture containing H_2O and D_2O is given by Eq. 3:

$$\frac{k_0^n}{k_0^0}=\frac{\prod_{\text{TS}}(1-n+n\phi_i)}{\prod_{\text{RS}}(1-n+n\phi_j)} \quad (3)$$

Here ϕ_i and ϕ_j are isotopic fractionation factors for isotopically exchangeable hydrogenic sites in the transition state (TS) and reactant site (RS) respectively. If it is assumed that the reaction proceeds through a single transition state, Eq. 3 takes the forms shown by Eqs. 4 and 5:

$$k_0^n=k_0^0(1-n+n\phi_j)^{-2} \quad (4)$$

$$\left(\frac{k_0^0}{k_0^n}\right)^{1/2}=[1+n(\phi_j-1)] \quad (5)$$

Equation 5 indicates a linear relation between $(k_0^0/k_0^n)^{1/2}$ and n and this is shown in Fig. 1 (r=0.9988, S=0.0391). The slope (ϕ_j-1)=−0.24, from which the fractionation factor is found to be 0.76. Kresge and Allred[11] have obtained a value of 0.67 for the fractionation constants of $HClO_4$ in H_2O-D_2O mixtures, while Gold[12] reported a value of 0.69±0.02. Considering the diversity of procedures employed, it may be assumed that there is agreement between the values and the fractionation factor refers to $HClO_4$. Exchange of ketone with D_2O was also checked for a primary isotope effect but this was found to be negligible for the duration of experiment. However, a trial experiment with ordinary acetone equilibrated in 60% D_2O over a period of 48 h showed that k_0=2.51×10^{-7} mol l^{-1} s^{-1} while the corresponding blank value (zero time) was 5.18×10^{-7} mol l^{-1} s^{-1} giving k_H/k_D=2.1. Reitz[13] has shown that acetone-d_6 reacts 7.7 times slower than ordinary acetone under identical conditions. It may therefore be inferred that exchange to an extent of about 27% has occurred in 48 h.

The reaction is characterized by a moderate energy of activation. The large negative ΔS^* values point towards a rigid transition state. Satisfactory structure-reactivity correlations cannot be drawn in the present studies due to the zero-order observed in [oxidant]$_0$. Values of the first-order rate constant $k'=k_0/[\text{ketone}]$ for the different ketones are almost the same indicating the absence of significant effects of structure on the enolization of ketones (Table 7). The enolization coefficients, $k''=k_s/[\text{ketone}][H^+]$ are shown in Table 7. The values for 2-propanone and 3-pentanone are 10.0×10^{-5} and 11.5×10^{-5} dm^3 mol^{-1} s^{-1} at 30 °C which are comparable with those obtained by Toullec and Dubois[14] in H_2SO_4 at 25 °C.

Table 5 shows that the activation parameters ΔH^* and ΔS^* decrease in the order:

4-methyl-2-pentanone<2-butanone
<2-pentanone<2-propanone<3-pentanone

An isokinetic relationship can be envisaged since a plot of ΔH^* versus $-\Delta S^*$ is linear (r=0.9983, S=0.24). From the slope, the value of isokinetic temperature β is 320 K. The relationship was tested through the Exner criterion[15] by plotting log k_{30} versus log k_{20} and was found to be genuine. From this plot, β was found to be 350 K. The value of β is slightly higher than the experimental temperature (303 K) indicating enthalpy as a controlling factor. Current views[16] do not attach much significance to the concept of isokinetic temperature, as the Exner criterion is a necessary follow up factor of the isokinetic relation. The constancy of ΔG^* values however indicates that a similar mechanism is operative in the oxidation of ketones by BAT.

It is noted in the present studies that a zero-order

dependence on $[BAT]_0$ indicates the operation of the traditional mechanism of Bell and co-workers[6] with enolization as rate-limiting step, while with the chlorine analogue, addition of halogen derivative takes place in the rate determining stage. A similar observation is made in the oxidation of dimethyl sulfoxide by the chloramines[17] and bromamines,[18] which probably is a reflection on the relative electrophilicity of the halonium cations, Cl^+ and Br^+ of the compounds, which are involved in the reaction sequence.

Molecular Motion in Some Hydrogen-Bonded Complexes of Trichloroacetic Acid as Studied by ^{35}Cl-NQR

Bolesław NOGAJ
Institute of Physics, A. Mickiewicz University, Grunwaldzka 6, 60-780 Poznań, Poland
(Received September 29, 1986)

The paper presents the results of ^{35}Cl-NQR frequency and spin-lattice relaxation time measurements as a function of the temperature in some solid hydrogen-bonded complexes: Trichloroacetic acid (TCA)-3-cyanopyridine, TCA-4-methylpyridine and $[CCl_3COO\cdots H\cdots OOCCCl_3]^-[K]^+$. The activation energies, E_a, for hindered rotation of CCl_3 group of the TCA molecule were determined. Employing the available E_a data for the other complexes of this type a linear dependence between the activation energy and ^{35}Cl-NQR frequency shift was obtained. This dependence allowed us to find $E_a=f(\Delta pK_a)$ as well as $E_a=f'(P)$ where P is the proton transfer degree. The influence of hydrogen bond on the potential barrier of the rotating CCl_3 groups of TCA in the complexes studied is also discussed.

A series of solid complexes formed by trichloroacetic acid (TCA) with different organic bases ranging from very weak to very strong, was investigated in Refs. 1—5. The purpose of these works was to analyze the proton transfer process in the series investigated via its effect on the chlorine NQR parameters. In the systems studied the hydrogen bond was found to change from the covalent form A–H···B through the symmetric hydrogen bond $A^{\delta-}\cdots H\cdots B^{\delta+}$ to the totally polar form $A^-\cdots H\text{-}B^+$. The more polar the hydrogen bond the lower is the mean NQR frequency of the TCA ^{35}Cl nuclei. The three ^{35}Cl-NQR lines observed for most of the complexes are the indication of crystallographic nonequivalence of the three chlorine atoms of the CCl_3 group in TCA complexed with a base. When the sample temperature is increased the CCl_3 groups would perform hindered rotations across potential barriers the heights of which are likely to depend on the polarity of the hydrogen bonding in the complexes considered. Temperature investigations of ^{35}Cl-NQR spin-lattice relaxation times T_1 allow determination of the activation energies for these hindered rotations. These, in turn should provide helpful data to distinguish between intra- and intermolecular effects in hydrogen-bonded complexes.

In a previous unpublished work, we had measured the ν_Q and T_1 temperature dependences of the ^{35}Cl-NQR in two TCA–B complexes (B=3-cyanopyridine and 4-methylpyridine) both being strongly hydrogen bonded. Moreover we had measured $\nu_Q(T)$ and $T_1(T)$ for complex $[CCl_3COO\cdots H\cdots OOCCCl_3]^-[K]^+$ which has a symmetric hydrogen bond.[6] Later, Fichtner et al.[3] provided further results on TCA complexes including weaker ones and they correlated the ^{35}Cl-NQR frequency shift and the ^{35}Cl-NQR line fading-out temperature for each complex. These facts led us to search for similar correlation between the activation energies and the frequency shifts, the frequency shifts and the $\Delta pK_a=pK_a(\text{base})-pK_a(\text{TCA})$ and consequently the activation energies and the ΔpK_a. In this paper we present the results of this investigation.

Experimental

The complexes with trichloroacetic acid were obtained in a crystalline form by dissolving the anhydrous bases in a small volume of a mixture of chloroform and carbon tetrachloride (1 : 3) and adding the acid.[5] The resulting precipitates were recrystallized from the chloroform-carbon tetrachloride mixture (1 : 3), and analysis results were satisfactory. Melting points were determined with a hot stage microscope and were presented in Ref. 5.

Measurements of ^{35}Cl-NQR frequency, ν_Q, and spin-lattice relaxation time, T_1, were performed on a laboratory built pulse spectrometer. The $\pi/2$-τ-π sequence was used, with typical pulse widths of 15 and 30 μs respectively. The output RF power of the transmitter was of the order of 1 kW. In order to improve the signal to noise ratio and permit signal recording, a two-channel boxcar integrator with a digital memory was used. High stability of the pulse duration, pulse intervals and sequence repetition period was ensured by a programmed digital generator enabling automatization of the measurements. The ^{35}Cl-NQR frequency was measured with an accuracy of ±1 kHz.

The sample was contained in a copper cell in a temperature-controlled cryostat which provided a temperature stability better than 0.1 K and an absolute accuracy of 0.2 K.

Selection of TCA Complexes for Molecular Motion Studies

In Ref. 5 66 complexes are reported among which three were investigated during the end of the experimental period so that they were not taken into account in the calculations we present in this paper. Consequently, only 63 complexes appear in Fig. 1. ^{35}Cl-NQR spectra of all complexes reveal different but always negative shift of the mean ^{35}Cl-NQR frequency with respect to the mean frequency for pure TCA, i.e. $\Delta\bar{\nu}_Q=\bar{\nu}_Q-\bar{\nu}_{TCA}<0$. The relation between $\Delta\bar{\nu}_Q$ and ΔpK_a allows us to draw the curve presented in Fig.1 which illustrates the proton transfer process in the hydrogen bond. The solid line in Fig. 1 has been drawn according to the equation:[5]

$$\Delta\bar{\nu}_Q=\frac{(\bar{\nu}_{HB}-\bar{\nu}_{TCA})+(\bar{\nu}_{PT}-\bar{\nu}_{TCA})\times 10^{\xi\Delta pK_a+C}}{1+10^{\xi\Delta pK_a+C}} \quad (1)$$

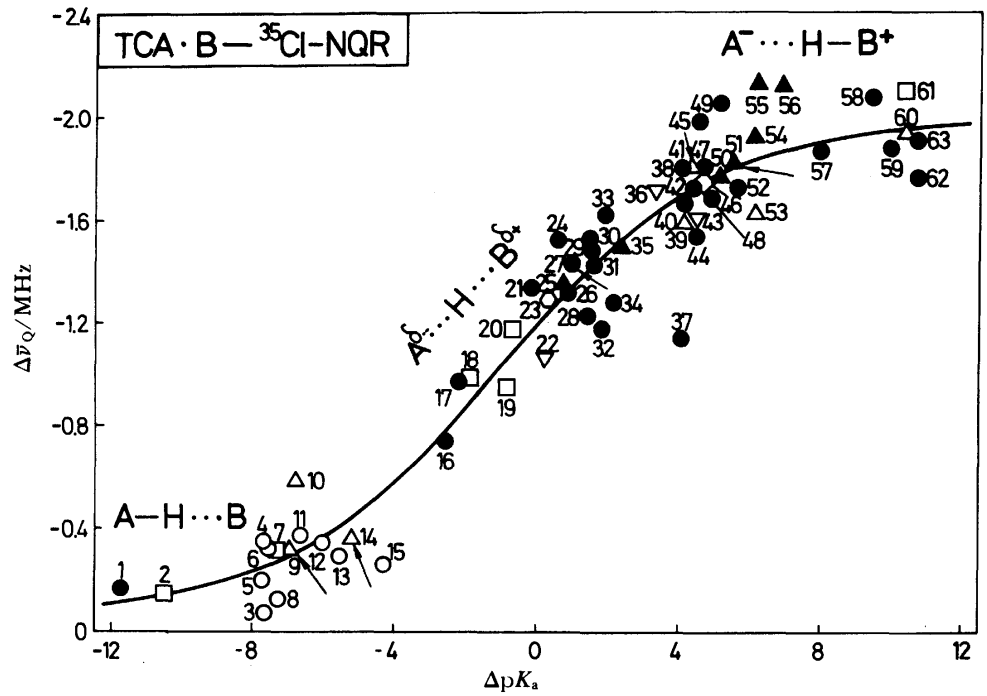

Fig. 1. Shift in mean ^{35}Cl-NQR frequency of the TCA–B complexes versus ΔpK_a. The complexes are labelled according to their base as follows; 1: nitrobenzene, 2: acetonitrile, 3: 2-methylbenzoic acid, 4: acetone, 5: benzoic acid, 6: benzaldehyde, 7: cyclohexanone, 8: phenol, 9: 2-methylbenzaldehyde, 10: 4-methylbenzaldehyde, 11: acetophenone, 12: *p*-anisaldehyde, 13: ethyl acetate, 14: 2,4,6-trimethylbenzaldehyde, 15: *t*-butyl alcohol, 16: triphenylphosphine oxide, 17: 4-nitropyridine *N*-oxide, 18: acetamide, 19: 2-pyrrolidone, 20: *N*,*N*-dimethylacetamide, 21: 4-chloropyridine *N*-oxide, 22: 2-bromopyridine, 23: pyridine *N*-oxide, 24: 3-methylpyridine *N*-oxide, 25: 4-methylpyridine *N*-oxide, 26: 2,6-dimethylpyridine *N*-oxide, 27: 3-cyanopyridine, 28: 4-cyanopyridine, 29: 2,4,6-trimethylpyridine *N*-oxide, 30: 4-benzyloxypyridine *N*-oxide, 31: 4-methoxypyridine *N*-oxide, 32: 4-hydroxypyridine *N*-oxide, 33: 4-methoxy-2-methylpyridine *N*-oxide, 34: 4-phenoxypyridine *N*-oxide, 35: 3-bromopyridine, 36: benzo[*h*]quinoline, 37: cytosine, 38: 8-methylquinoline, 39: aniline, 40: trimethylamine oxide, 41: *N*-methylaniline, 42: 8-quinolinol, 43: quinoline, 44: *N*,*N*-dimethyldodecylamine oxide, 45: 7-methylquinoline, 46: pyridine, 47: 6-methylquinoline, 48: isoquinoline, 49: 3-methylisoquinoline, 50: 4-methylquinoline, 51: 4-methylpyridine, 52: 3,5-dimethylpyridine, 53: *N*,*N*-diethylaniline, 54: 2,4-dimethylpyridine, 55: 2,6-dimethylpyridine, 56: 2,4,6-trimethylpyridine, 57: morpholine, 58: tributylamine, 59: *N*-ethylpiperidine, 60: triethylamine, 61: triethylamine, 62: piperidine, 63: dibutylamine.
Solid line represents the fit with Eq. 1. The complexes studied in this work are denoted by arrows. References: ○;[7] ◇;[8] ;[9] □;[10] ▲;[1] △;[3] ▽;[4] ●.[5]

where (for group of 63 complexes) $\bar{\nu}_{HB}$= 40.066 MHz, $\bar{\nu}_{PT}$=38.123 MHz, $\bar{\nu}_{TCA}$=40.124 MHz, ξ=0.145 and C'= 0.146.

As it has been already mentioned in the introduction the aim of the paper is to find the correlation between the character of the hydrogen bond and the height of the potential barrier for hindered rotation of CCl_3 groups. The investigation was performed on complexes of different degree of proton transfer corresponding to different points on the curve $\Delta\bar{\nu}_Q = f(\Delta pK_a)$ (Fig. 1). The complexes chosen for this investigation are shown by arrows in Fig. 1. They are also listed in Table 1 which gives the ^{35}Cl-NQR frequencies (ν_Q), mean frequencies ($\bar{\nu}_Q$) and corresponding frequency shifts with respect to pure TCA, and the pK_a of the bases. Moreover, Table 1 gives values of proton transfer degree, P, in the hydrogen bond of the complexes TCA-B, determined from the relation used by Chihara and Nakamura in Ref. 8:

$$\bar{\nu}_Q = \bar{\nu}_{HB} + P(\bar{\nu}_{PT} - \bar{\nu}_{HB}). \quad (2)$$

The analysis was performed for the complexes with a weak hydrogen bond (P=0.12; 0.14) as well as for the complexes with almost total proton transfer (P=0.88; 0.90). This table also gives the data for $[A\cdots H\cdots A]^-$-$[Me]^+$ type complexes in which the hydrogen bond remains unchanged while the cation changes. Investigation of this group of compounds will be only used to verify our considerations related to the TCA-B type

complexes.

Results of ^{35}Cl-NQR Frequency and Spin-Lattice Relaxation Study and Their Discussion

For compounds **3**, **5**, and **7** presented in Table 1 the temperature measurements of ^{35}Cl-NQR frequencies and spin-lattice relaxation times, were performed. The results of these measurements are shown in Figs. 2—6. For other complexes we employed the data available from Ref. 3. The ^{35}Cl-NQR spectra of all the complexes analyzed (Table 1) are composed of three lines which, in the case of TCA-B complexes, proves crystallographic nonequivalence of the sites of the three Cl atoms of CCl_3 group in TCA molecule. Moreover, only three lines in ^{35}Cl-NQR spectrum of $[A\cdots H\cdots A]^-[Me]^+$ complexes proves that the hydrogen bond in the dimer ion $[CCl_3COO\cdots H\cdots OOCCCl_3]^-$ is symmetrical. Each of the chlorine atoms of CCl_3 group performs torsional vibrations (librations), even at very low temperature. The amplitude of the librations increases with increasing temperature which results in still greater averaging of the electric field gradient evidenced as a decrease in ^{35}Cl-NQR frequency. At higher temperatures the energy of thermal excitations of CCl_3 group is sufficient to overcome the potential barrier separating the equilibrium sites of Cl atoms in the crystal.

The rate of hindered rotation of CCl_3 groups shows an exponential increase with temperature. Introducing the correlation time τ_c, which is a measure of the time a given CCl_3 group spends in the equilibrium position, we can consider the situation where $\tau_c > (2\pi\bar{\nu}_Q)^{-1} \approx 4\times10^{-9}$ s. In such a case the jumps of Cl atoms are not very frequent and the quadrupole transitions

Table 2. Parameters of the Fit of Experimental $\nu_Q(T)$ Values with Bayer Formula —Eq. 3 and Fade-Out Temperatures of the Resonance Lines

Complex	^{35}Cl-NQR line	a/MHz	b/MHz	c/K	$T_{\text{fade-out}}$/K
TCA-3-cyanopyridine	ν_1	38.200	1.912	240.06	145
	ν_2	39.030	3.708	313.05	
	ν_3	39.099	3.170	289.47	
TCA-4-methylpyridine	ν_1	38.031	1.402	173.08	145
	ν_2	38.170	1.270	179.88	
	ν_3	39.099	1.061	189.91	
$(CCl_3COO)_2HK$	ν_1	39.163	1.654	263.04	240
	ν_2	39.179	1.079	266.21	
	ν_3	39.862	1.040	183.75	

can occur if the CCl_3 group is in the stable equilibrium. That is why the slow hindered rotation does not influence the ^{35}Cl-NQR frequency. Thus, librations are mainly responsible for a decrease in NQR frequency with increasing temperature. This was the assumption taken by Bayer[11] who moreover treated a molecule as a quantum harmonic oscillator and obtained the following expression for the temperature dependence of NQR frequency:

$$\nu_Q(T) = a - \frac{b}{\exp(c/T)-1}, \tag{3}$$

$$a = \nu_Q(0);\ b = \frac{6\hbar\nu_Q(0)}{4I\omega_i - 3\hbar};\ c = \frac{\hbar\omega_i}{k}, \tag{4,5,6}$$

$\nu_Q(0)$ is the NQR frequency at 0 K, I is the relevant moment of inertia, ω_i is the librational frequency of the atomic group (here CCl_3). The experimental data of $\nu_Q(T)$ were fit with Eq. 3 (see Figs. 2—4). The appropriate fit parameters are given in Table 2. The data were also fit with other dependences that took into account the unharmonic character of vibrations but using the harmonic approximation of Eq. 3 is quite sufficient in the range of temperature studied which extend from 77 K to the fade-out temperature. At this temperature the lines became so broad and their intensity so small that they reach the sensitivity limit of the spectrometer. This happens when the frequency of the molecular reorientations is of the order of magnitude of the NQR line width. If the temperature is still increased the lines become unobservable. The highest fade-out temperature in this series is 240 K obtained for $(CCl_3COO)_2HK$ (Table 2; Figs. 2—4).

Let us consider now the influence of librations and hindered rotation discussed above on the NQR spin-lattice relaxation. According to Bayer[11] the fluctuations of the electric field gradient caused by librational motions lead to the following relation between T_1 and T:

$$T_1^{-1} = aT^n, \tag{7}$$

where a is a constant, n is usually close to 2. Abrupt changes in electric field gradient due to hindered rotation of molecular groups containing quadrupole nuclei lead to the exponential temperature dependence of relaxation time:[12]

$$T_1^{-1} = b \exp(-E_a/RT), \tag{8}$$

where b is a constant, R the gas constant, and E_a the activation energy of the hindered rotation.

As follows from the dependences $T_1^{-1}(T)$ obtained (Figs. 5—7), both mechanisms of quadrupole spin-lattice relaxation discussed above take place in the complexes studied. Their contribution to the relaxation process add up and this may be expressed as:

$$T_1^{-1} = aT^n + b \exp(-E_a/RT). \tag{9}$$

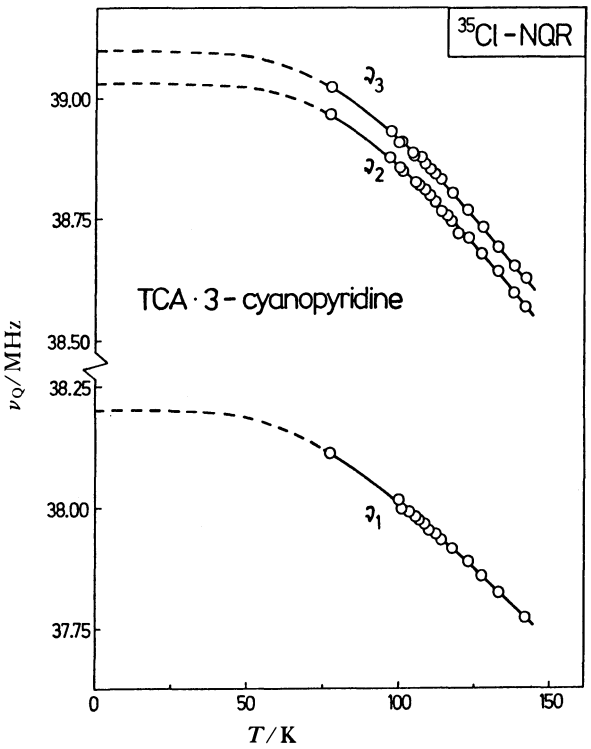

Fig. 2. Temperature dependence of the ^{35}Cl-NQR frequency in TCA-3-cyanopyridine complex. Solid and partly broken line represents the fit with Eq. 3; fitting parameters are given in Table 2.

The appropriate fit parameters between the experimental data of $T_1^{-1}(T)$ and Eq. 9 are given in Table 3. For us, most important are the values of the activation energy for hindered rotation of CCl_3 groups (E_a) in the complexes studied. As follows from Figs. 5—7 the relaxation process may be described at low temperatures by the first term of Eq. 9 only. This term characterizes the influence of librations on the relaxation. For higher temperatures, in the case of TCA-B complexes studied above 110—120 K while for $(CCl_3COO)_2HK$ complex above 170 K, the mechanism of hindered rotation becomes dominating. In these temperature ranges the dependence $T_1^{-1}(T)$ is described by the exponential part of Eq. 9. For the sake of comparison the results of $T_1^{-1}(T)$ for TCA[13] are presented (Table 3). However, this acid cannot be regarded as belonging neither to the TCA-B group nor to the group of $[A\cdots H\cdots A]^-[Me]^+$ complexes. Trichloroacetic acid is a dimer in which two hydrogen bonds of O-H ··· O type occur. It can only be used as a reference standard in investigations of the mean ^{35}Cl-NQR frequency shift in the analyzed complexes. A comparison between $T_1^{-1}(T)$ dependences obtained for the complexes analyzed and the dependence for TCA, taking

into account the $T_{\text{fade-out}}$, is given in Fig. 7.

As it has been already mentioned the main aim of the investigation of dynamics of hydrogen-bonded complexes is the determination of the activation energy for the rotation of the CCl_3 group and an attempt to correlate the E_a values with the nature of the hydrogen bond. Table 1 gives the values of E_a for all the complexes analyzed in this paper. An attempt has been made to relate these values with the shift of the mean ^{35}Cl-NQR frequency for TCA-B type complexes (Fig. 8). As a result we have found that with increasing $|\Delta\bar{\nu}_Q|$ i.e. with the hydrogen bond getting more polar the activation energy for CCl_3 group rotation increases. This relation can be described by the following linear expression:

$$E_a = a\Delta\bar{\nu}_Q + b, \qquad (10)$$

where $a=-10.7$ kJ mol^{-1} MHz^{-1} and $b=6.0$ kJ mol^{-1}. This kind of correlation has been supported by the linear dependence between E_a and $\Delta\bar{\nu}_Q$ for the complexes of the type $[CCl_3COO\cdots H\cdots OOCCCl_3]^-$ $[Me]^+$ (Fig. 9). This linear dependence can also be expressed by Eq. 10 but with $a=-85.5$ kJ mol^{-1} MHz^{-1}, $b=-28.8$ kJ mol^{-1}. Despite the fact that for both groups of complexes studied the dependence $E_a(\Delta\bar{\nu}_Q)$ has a linear character we cannot expect an agreement as to the numerical values of E_a, a, and b for the two groups. They are essentially different. In the group of TCA-B complexes the changing nature of hydrogen bond results in an increase in the potential barrier for the rotating CCl_3 groups. In the group of $[CCl_3COO\cdots H\cdots OOCCCl_3]^-$ $[Me]^+$ complexes the hydrogen-bond

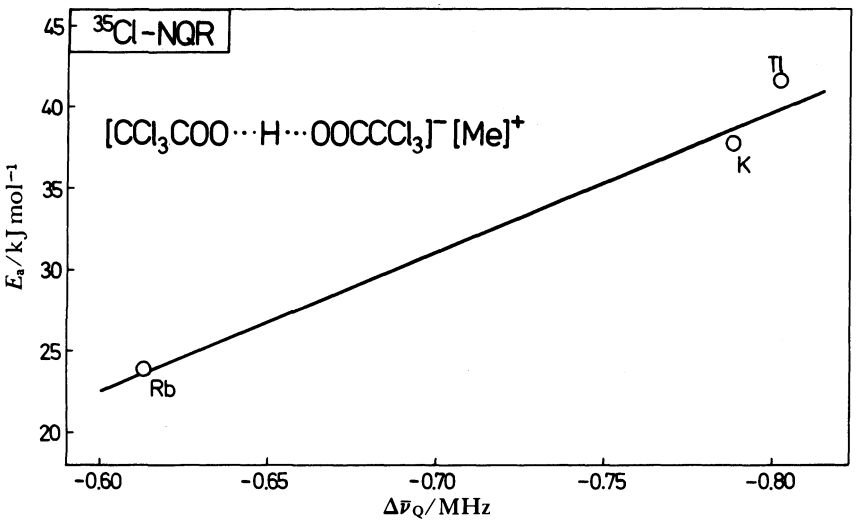

Fig. 9. Activation energy for hindered rotation of CCl_3 group in TCA versus the shift in mean ^{35}Cl-NQR frequency for $[A\cdots H\cdots A]^-[Me]^+$ type complexes. Solid line drawn according to Eq. 10; for fitting parameters see text.

remains the same (symmetrical bond) and the shift in the mean ^{35}Cl-NQR frequency is determined by the influence of $[Me]^+$ cation and in particular by its size as discussed in Refs. 14 and 15.

It is possible to relate the activation energy, E_a, for the rotation of the CCl_3 group in a complex of the series studied, to the parameter, pK_a, describing the strength of the base and acid forming the complex and obtain an expression $E_a=f(\Delta pK_a)$.

Using Eqs. 1 and 10 leads to:

$$E_a=\frac{E_a^{HB}+E_a^{PT}\times 10^{\xi\Delta pK_a+C'}}{1+10^{\xi\Delta pK_a+C'}}, \qquad (11)$$

where $E_a^{HB}=6.6$ kJ mol^{-1} is a constant equal to the activation energy for the rotation of CCl_3 group in a limit-case complex with a purely covalent structure, and $E_a^{PT}=27.3$ kJ mol^{-1} is a similar constant corresponding to the opposite limit case of a completely polar structure of the hydrogen bond. Figure 10 represents the curve corresponding to Eq. 11 for ΔpK_a ranging from -12 to $+12$. As follows from the above considerations the increase in the energy barrier for CCl_3 group rotation in TCA-B complexes is a direct result of the changing character of the hydrogen bond. The degree of proton transfer, P, being a significant parameter to describe the hydrogen bond, it is possible, using Eqs. 2 and 10, to express the activation energy, E_a, in term of this parameter:

$$E_a=20.7\,P+6.6, \qquad (12)$$

with $0\leqslant P\leqslant 1$.

Similarly, considering the series of complexes $[CCl_3COO\cdots H\cdots OOCCCl_3]^-[Me]^+$ it is possible to relate the ^{35}Cl-NQR frequency shift to the ionic radius of the cation (R). Using data available in Ref. 15 for

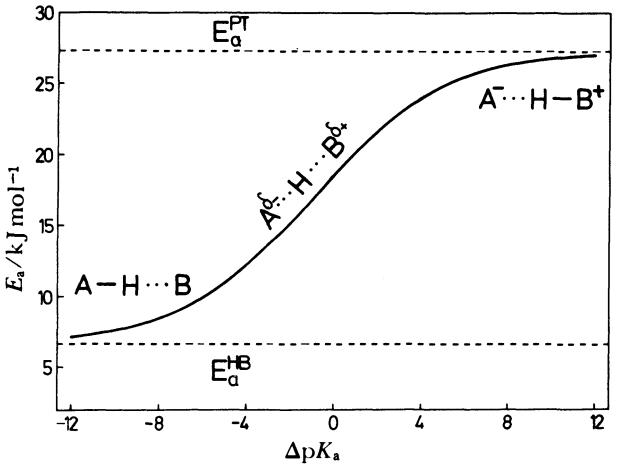

Fig. 10. Activation energy for hindered rotation of CCl_3 group of TCA versus ΔpK_a for TCA-B type complexes. The curve is drawn according to Eq. 11 with the fitting parameters given in the text.

the compounds studied here (Me=Rb, K, Tl) and also for Me=Na and NH_4 one gets the relation:

$$\Delta\bar{\nu}_Q[MHz]=12.3\,R[nm]-2.4. \qquad (13)$$

Then using Eqs. 10 and 13, the corresponding activation energy for the rotation of the CCl_3 group can be written as:

$$E_a=-1054.3\,R+179.9 \qquad (14)$$

However, this relation cannot be applied in a wide range of R values. Both Eqs. 13 and 10 have been derived for a very narrow range of R values: In the case of Eq. 13 R changed between 0.098 nm (Na^+) to 0.149 nm (NH_4) while in the case of Eq. 10 this range was even narrower. Moreover, Eq. 13 cannot be linear as

this is in contradiction to the dependence of the electric field gradient on r^{-3} where r is the distance between the nucleus considered and the charge producing the gradient in question. Despite the above limitations Eq. 14 applied for the appropriately narrow range of R values allows to obtain reasonable values of E_a.

On the other hand Eqs. 11 and 12 derived for TCA-B complexes can be applied on a wider scale. Eq. 1 was derived from the analysis of 63 complexes of ΔpK_a changing in a relatively wide range of values extending from −11.77 to +11.25. The relation between E_a and $\Delta\bar{\nu}_Q$ (Eq. 10) was also obtained for a wide range of ΔpK_a values (from −7.01 to +5.51). It should be however pointed out that the small number of experimental values of E_a which is a consequence of the time-consuming character of $T_1(T)$ measurements may also be a reason for the not very accurate E_a values obtained from Eqs. 11 and 12. In particular E_a^{HB}=6.6 kJ mol^{-1} seems to be too low for a relatively big and heavy CCl_3 group, in spite of the fact that the CCl_3 group in question is in an almost free TCA molecule without any interactions with the base. Nevertheless the relations obtained in this paper and expressed as mathematical formulae allow direct determination of the activation energy for rotation of CCl_3 group of TCA in its different complexes from the values of $\Delta\bar{\nu}_Q$ or from the tabulated pK_a or R values.

Moreover, it was found beyond doubt that the influence of hydrogen bond in TCA-B complexes on the height of the potential barrier of CCl_3 group of TCA forming that complex, is decisive. The hydrogen bond in TCA-B complexes is the main source of the changes in electric field gradient at the Cl nuclei. These changes affect the nuclei studied through induction and polarization effects. The weakening of the O-H covalent bond produced by hydrogen bond formation originates: (1) A charge rearrangement that is relayed to the Cl-C bond through the bonds of the TCA molecule and (2) through two polarization mechanisms consisting of (a) direct effect acting on the Cl atom and (b) an indirect polarization effect acting on the Cl-C bond. As shown in Ref. 14 an increase in the electron density on the nearest O atom in TCA will produce a direct contribution that will increase the Cl frequency while the indirect effect will produce an opposite shift. We can also consider the polarization influence of electric dipole of hydrogen bond which leads only to negative shifts in ^{35}Cl-NQR frequency.[1] In the complexes studied only the negative shifts of NQR frequency were observed. However, without data on the crystal structure of the complexes studied it is difficult to calculate and determine accurately the contribution of individual mechanisms in the eventual shift of ^{35}Cl-NQR frequency. Nevertheless all the mechanisms considered result in a gradual increase in intermolecular interactions with a growing proton transfer degree. This in turn implies an increase in potential barriers for rotating CCl_3 groups. In the case of $[CCl_3COO\cdots H\cdots OOCCCl_3]^-$ $[Me]^+$ type complexes it is also difficult to separate the influence of the cation radius resulting in weakening of intermolecular interactions from the effect of electrostatic interaction of the cation on the electric potential distribution in a dimer ion. However both effects directly influence intermolecular interactions strength and thus, the height of the potential barrier for rotation of CCl_3 groups in these complexes.

Investigation of quadrupole spin-lattice relaxation times T_1 versus temperature performed for a considerable group of complexes should give a more precise correlation between the values of E_a and $\Delta\bar{\nu}_Q$. On the other hand crystallographic studies of the complexes with a hydrogen bond would provide the possibility of more detail analysis of inter- and intramolecular interactions in them.

I would like to thank Professor L. Guibé for his kind reading of the manuscript.

A Conformational Study on Some Thiobenzophenones. Molecular Orbital Calculations

Rafie Hassan Abu-Eittah* and Abdel-Ghany El-Kourashy†
Department of Chemistry, Faculty of Science, King Abdulaziz University, Jeddah, Saudi Arabia
†Department of Chemistry, Faculty of Applied Sciences and Engineering, Umm Al-Qura University, Makkah, Saudi Arabia
(Received December 27, 1986)

MO calculations were performed on the different conformers of thiobenzophenone and on the planar conformer of a number of its derivatives using the INDO-CI procedures. A nonplanar conformer with an angle of 15° between the planes of benzene rings was predicted for thiobenzophenone. Dipole moment and charge density were calculated and correlated to the reactivity of the studied molecules. A Gaussian analysis was performed on the spectra of the studied compounds, results compared satisfactorily with the results of MO calculations.

Relatively, little work has been done on the MO calculations of thiobenzophenone especially in the recent years. However, many spectral studies have been reported on thiones, thiourea and many of their derivatives.

The effect of substitution,[1] solvent,[2] and irradiation[3] on the electronic spectra of thiobenzophenone have been reported. The spectrum of a crystal of thiobenzophenone—doped in a crystal of benzophenone—at 20K indicated that the transition along the C=S direction is intrinsically allowed.[4] Simple molecular orbital calculations (HMO) were performed on some aliphatic and aromatic thiocarbonyl compounds,[5-8] a linear correlation was observed between the wave number of the $n \rightarrow \pi^*$ transition and the Hückel excitation energy.

The crystal structure of thiobenzophenone and thiobenzophenone *S*-oxide were determined, the former is monoclinic whereas the latter is orthorhombic.[9] The photoelectron helium (HeI) spectra of aromatic thiocarbonyls and the corresponding *S*-oxides were determined. For thioketones the ordering of the outermost MO's is: n(S), π_7, π_6, π_5, π_4, π_3, n(S) being the HOMO.

Electron-rich olefins react with n,π^* triplet state of thiobenzophenone yielding 1,4-dithiane or thietane depending on the structure of the olefins whereas electron deficient olefins react with π,π^* singlet states of thiobenzophenone.[11] Photocycloaddition of thiobenzophenone to olefins substituted with electron releasing groups lead to the formation of 1,4-dithianes.[12] However, if the electron-rich olefins are substituted with bulky substituents their photocycloaddition to thiobenzophenone result in thietane and not dithiane derivatives.[13] Photocycloaddition of thiobenzophenone to olefins substituted by electron-withdrawing groups result in the formation of thietane derivatives through a nucleophilic attack on the olefin.[14] It was shown that the π,π^* state plays a role in the reaction which proceeds only on irradiation by 366 nm light.

In this work, INDO-CI molecular orbital calculations were performed on different conformers of thiobenzophenone and the planar conformers of a number of its derivatives. Gausian analysis of the spectra was performed. These results have not been reported before.

Method of Calculations

The all valence-electrons INDO method of calculations was followed. Details and parameterization are found elsewhere.[15] Interaction was considered between nine electronic configurations in which electrons are transferred from the three highest occupied MO's to the three lowest unoccupied MO's. If the wave function of an electronic configuration is ψ_m, the CI wave function ψ_{CI} is given by $\sum_m a_m \psi_m$. The energies of the resulted states are calculated by solving the determinant

$$\det\{H_{mn} - E\delta_{mn}\} = 0. \quad (1)$$

The diagonal elements are the expectation values of the energies of the different configurations whereas the off-diagonal elements of H_{mn} are the expectation values of the Hamiltonian averaged between the two configurations m and n. Calculation of the diagonal and off-diagonal elements of Eq. 1 requires the calculations of the integrals:

$$\varepsilon_{ij} = \langle \psi_i | H_{core} | \psi_j \rangle$$
$$\gamma_{ii} = (\psi_i\psi_i | \psi_i\psi_i)$$
$$\gamma_{ij} = (\psi_i\psi_i | \psi_j\psi_j)$$
$$\delta_{ij} = (\psi_i\psi_j | \psi_j\psi_i)$$
$$\zeta_{ik}^{jl} = (\psi_i\psi_k | \psi_j\psi_l)$$

Substituting the LCAO epression for the molecular orbitals (ψ) one gets[16]

$$\varepsilon_{ij} = \sum_{\mu\nu} C_{i\mu}C_{j\nu} \langle \phi_\mu | H_{core} | \phi_\nu \rangle$$
$$\gamma_{ii} = \sum_{\mu\nu} C_{i\mu}^2 C_{i\nu}^2 (\mu\nu|\nu\nu)$$
$$\gamma_{ij} = \sum_{\mu\nu} C_{i\mu}^2 C_{j\nu}^2 (\mu\nu|\nu\nu)$$
$$\delta_{ij} = \sum_{\mu\nu} C_{i\mu}C_{j\nu}C_{i\nu}C_{j\nu} (\mu\mu|\nu\nu)$$
$$\zeta_{ik}^{jl} = \sum_{\mu\nu} C_{i\mu}C_{k\mu}C_{j\nu}C_{l\nu} (\mu\mu|\nu\nu)$$

The letters i, j, k, and l refer to MO's whereas μ,ν, to AO's. The diagonal and off-diagonal elements of Eq. 1 are calculated as follows[17]

$$\langle\psi_G|\hat{H}|\psi_G\rangle = 2\sum_{i=1}^{n}\varepsilon_i + \sum_{i}^{n}\sum_{i}^{n}(2\gamma_{ij}-\delta_{ij})$$

$$\langle\psi_{k\to s}|\hat{H}|\psi_{k\to s}\rangle = 2\sum_{m}^{n}\varepsilon_m + (\varepsilon_s-\varepsilon_k) + \sum_{m}^{n}\sum_{l}^{n}(2\gamma_{ml}-\delta_{ml}) - \sum_{l=1}^{n}[(2\gamma_{kl}-\delta_{kl})-(2\gamma_{ls}-\delta_{ls})-\gamma_{ks}+2\delta_{ks}]$$

$$\langle\psi_G|\hat{H}|\psi_{k\to s}\rangle = \sqrt{2}\{\varepsilon_{ks} + \sum_{m=1}^{n}[2(mm|ks)-(mk|sm)]\}$$

$$\langle\psi_{k\to s}|\hat{H}|\psi_{l\to r}\rangle = 2(lr|ks)-(lk|sr)$$

$$\langle\psi_{k\to s}|\hat{H}|\psi_{k\to r}\rangle = \varepsilon_{rs} + \sum_{m=1}^{n}[2(mm|rs)-(mr|sm)] + 2(kr|sk)-(kk|rs)$$

$$\langle\psi_{k\to s}|\hat{H}|\psi_{l\to s}\rangle = -\varepsilon_{lk} - \sum_{m=l}^{n}[2(mm|lk)-(ml|km)] + 2(ls|ks)-(lk|ss)$$

The coefficients, c's, used to calculate the above integrals were the self-consistent ones and the two-center electron repulsion integrals were calculated using the Nishimoto-Mataga relation.[18] The computations were performed on IBM-370 computer using INDO-program obtained from QCPE center, to which a CI subroutine was added.

Results and Discussion

Conformational Analysis of Thiobenzophenone. The hexagonal nature of benzene imposes a steric hindrance on the planarity of the molecule. Ortho-ortho-hydrogen interaction will prevent the coplanarity of the two benzene nuclei. The extent of this steric effect is best investigated through the calculations of the total energy of the molecule as a function of angle of rotation of one of the benzene nuclei. The results help one to predict whether the molecule is a "free rotor," rigid or a "quasi-rigid" one. The total energy is calculated by MO calculations using the INDO procedures.

Previous electronic structure calculations were reported on S-containing compounds[19-21] excluding the contribution of the 3d sulfur atomic orbitals. In an ab initio calculation,[22] it has been shown that the 3d's orbitals of sulfur play a very minor role in the population analysis (and hence in bonding) as has been reported before.[23-27]

In this work, MO computations were performed neglecting the 3d sulfur atomic orbital. The configuration adopted (a) for the molecule is shown, bond length and bond angle were taken from the literature.[9] Molecular orbital calculations were performed on the planar conformer as well as nonplanar conformers whereby one of the benzene rings is rotated 15, 30, 45, 60, and 90° around the C_2-C_3 axis. A comparison of the total energy, dipole moment, energy of the lowest electronic transition and the oscillator strength is given in Table 1. The lowest electronic transition is forbidden (f=0.0, HOMO is "n+σ" and LUMO is π^*)

for the planar as well as the perpendicular conformer. For other conformers, mixing of orbitals does not permit the calculation of pure $n(n+\sigma)\rightarrow\pi^*$ transitions. The variation of the total energy of thiobenzophenone with the angle of rotation is shown in Fig. 1. The height of the barrier to internal rotation is of the order of 4 eV indicating that the molecule is not a free rotator. INDO procedures give good results for calculated ground state energy but not as good for the excited states. Generally, calculated energies by the INDO method are slightly higher than those calculated by other more accurate procedures. Results of this work indicate that the most stable conformer of thiobenzophenone has an angle of 15° between the planes of the benzene rings. The lowest $\pi\rightarrow\pi^*$ transition energy (3.37 eV) agrees satisfactory with experiment. Gaussian analysis was performed and the lowest electronic transition was found at 3.56 (in ethanol) and at 3.81 eV (in cyclohexane) Fig. 2.

Dipole moment measurements of a series of thioketones have shown that compounds in which thiocarbonyl group is not subjected to conjugative or resonance effects have smaller dipole moments than the corresponding ketones. This indicates that the polarity of the thiocarbonyl group is considerably smaller and possibly reversed compared with that of C=O group.[28,29] On the other hand, thioketones in which intramolecular perturbation of the C=S group is possible (for example within the aromatic series) have

Table 2. Experimental Values of Dipole Moments of Some Carbonyl and Thiocarbonyl Compounds in Benzene at 20 °C

dipole moments which indicate a higher polarizability for C=S than for the C=O. Table 2 compares some experimental results of dipole moments measured in benzene at 20 °C.[30,31]

Table 1 gives the calculated dipole moment for thiobenzophenone whereas Table 3 gives the dipole moments of substituted thiobenzophenones. The calculated dipole moments are only slightly higher than the experimental ones for thiobenzophenone and 4,4′-dihydroxy derivative but seems to be significantly higher for 4,4′-diaminothiobenzophenone. These effects are direct results of the method of calculation, parameterization, and configurations adopted. The dipole moments lie along the C_{2v} symmetry axis and are strongly dependent upon the orientations of the lone pair of electrons. Consequently, rotating one of the benzene nuclei of thiobenzophenone alters signifi-

Table 3. Comparison of the Calculated Dipole Moments and Total Energies of Some Substituted Thiobenzophenones

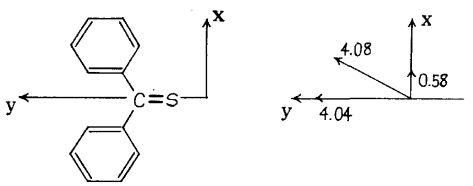
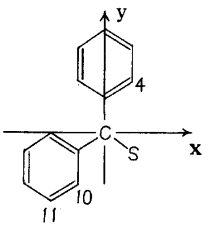
cantly the value of calculated dipole moment.

The calculated dipole moments of substituted thiobenzophenones reveal some important results. Generally, substitution by one or two hydroxyl, one or two amino groups increases the dipole moments and increases the polarization of the thiocarbonyl group. However, the calculated dipole moment of 4-hydroxyl-4′-aminothiobenzophenone is significantly smaller than that of the thiobenzophenone. Hence, the -OH and $-NH_2$ groups have acted in opposite directions with a net result of decrcasing the polarizability of the C=S.

The reactivity of a molecule can nicely be correlated with the charge density of the different sites of the molecule whereas the algebraic signs of the coefficients of the AO's constituting the HOMO and LUMO are directly concerned with the pathway of a chemical reaction. In Table 4 one compares the charge densities on the active sites of the molecule (S_1, C_2, C_4, C_5, C_{10}, C_{11}) in the different conformers. We cannot compare the coefficients of the MO's of the different conformers since rotation mixes the different orbitals on the benzene rings. The data in Table 4 indicates some interesting results. The thiocarbonyl group (C=S) has only a slight effect on the reactivity of the benzene rings since no pronounced excess of negative or positive charges is calculated on the different atoms. However, thiobenzophenone is a dipole with calculated moment of 4.08D (planar conformer) compared with the experimental 3.37D. The components of the dipole moment (in Debye) are: u_x=0.58, u_y=4.04, and u=4.08 (0.83





atomic and 3.34 polarization). The dipole moment vector is directed from the C=S to the benzene rings. In other words, there is a net built of negative charge on the benzene rings and one can say that the C=S group activates, though slightly, the molecule. The calculated dipole moment, 7.04D, for the most stable conformer of thiobenzophenoe is remarkably higher than the experimental one. This is probably due to the method of calculations used in this work. INDO procedures lead to relatively higher values of dipole moment, even for the planar conformer. The slight net negative charge on S-atom explains the role of C=S in cycloaddition.

It is interesting to correlate the charge density, on the benzene rings, to the angle of rotation of one of the benzene nuclei aroun the y-axis (b). As the results in Table 4 indicates, the rotation of the benzene ring led to excess of charge density on the S-atom and a lack of the rotating benzene ring from charge density. On the other hand, there has been an increase of charge density on the non-rotating benzene ring (C_{10}).

Rotation of one of the benzene rings is expected to affect the calculated value of the dipole moment. The lowest value of dipole moment, 4.08 D, is computed for the planar conformer whereas the highest value, 7.40 D, is computed for the perpendicular conformer. Rotation of the plane of the benzene ring by 15° almost doubles the dipole moment.

Electronic Structure of Substituted Thiobenzophenones. INDO-molecular orbital calculations were

performed on a series of 4,4′-disubstituted thiobenzophenone in order to correlate the reactivity of these compounds to the calculated parameters and to compare the reactivity of the different compounds. Computations were performed on the planar conformers only and Table 5 summarizes some of the calculated parameters for different substituted thiobenzophenone; those of thiobenzophenone are included for comparison. It is noticed that the net negative charge on S-atom is the highest in 4,4′-diamino derivative, it is high in 4-hydroxy- and 4,4′-dihydroxythiobenzophenones than it is in thiobenzophenone. The oxygen and nitrogen atoms of the substituents are σ-acceptor and π-donors[22)] but they did not lead to a decrease of the charge density on S-atom. Substitution by -OH or $-NH_2$ groups has not led to a built up of negative charge density than in the case of thiobenzophenone. The highest charge density (in hydroxy- or amino-thiobenzophenone) is on C_4 and C_{10}.

The numerical values of the coefficients of AO's forming the HOMO and LUMO are dependent on the

type of the substituent (Table 5). In the case of 4-aminothiobenzophenone the coefficient of S-atom is −0.0173 compared to −0.2487 in thiobenzophenone in the highest occupied molecular orbital (HOMO) and is −0.2454 compared to +0.2476 in thiobenzophenone (in the LUMO). Characteristic variations of the coefficients and the net charges are seen for the different atoms in the different MO's as indicated in Table 5.

Spectral Analysis. The electronic absorption spectra of some thiobenzophenones have been reported.[32] The observed bands correspond to highly overlapping transitions (Figs. 3a, b). In order to resolve the individual band parameters a curve analysis has been carried out.[33,34] The electronic absorption spectra were analyzed, using the Gaussian line shape, as shown in Fig. 2 for thiobenzophenone. The resolution of the observed absorption spectrum into its components is used to determine the appropriate values of the

parameters as indicated in Tables 6 and 7. Gaussian analysis shows that there are other transitions taken place underneath the two ultraviolet absorption bands observed experimentally. Such transitions are characterized by low oscillator strength, hence the parameters observed are not quite real due to the overlap of the transitions. Also, it is clear that the band parameters of the experimental curve are affected by both changing the medium and/or the substituent.

Comparison with Experiment. A comparison of the computed transition energy and oscillator strength with those obtained after Gaussian analysis of the spectra of some thiobenzophenones is given in Table 8. Many computed transitions are theoretically forbidden yet they are observed experimentally with weak intensity. From both the experimental and theoretical results it is clear that the spectral band corresponds to a number of overlapping transitions. This overlapping causes inaccuracy in the experimentally calculated oscillator strength and is the reason of the observed discreapancy between the calculated and experimental values. On the other hand, the correspondence between the calculated and experimental transition energies.

Conclusion

The method of calculations used in this work, INDO-CI, proved to be a satisfactory method in explaining and predicting the electronic structure of the studied thiobenzophenones. It has been shown that the most stable conformer of thiobenzophenone is nonplanar with an angle of 15° between the planes of the benzene rings. The height of the barrier to internal rotation is of the order of 4 eV revealing that the molecule is not a free rotator.

Calculations of the charge density and dipole moment led to some important conclusions. Generally, substitution in the benzene rings of thiobenzophenone resulted in an increase in the dipole moment except in the case of 4-hydroxy-4'-aminothiobenzophenone which has a dipole moment lower than the parent compound. This result indicates that the polarization of the C=S group has been diminished or even reversed in this compound. For the studied compounds there has been a net built up of charge density on the benzene rings, hence increasing the activity.

The experimental results of photocycloaddition of thiobenzophenone to substituted olefins[11-14] go along with the theoretical predictions of this work especially for the mechanism of nucleophilic attack of thiobenzophenone on the olefins and the formation of thietane derivatives. The calculated charge densities on C_2 and S_1 as well as their coefficients in the HOMO (Table 5) favors the polar addition of the olefins to the thiocarbonyl group.

No data is available on the reactivities of substituted thiobenzophenones. The results in Table 5 predict that substitution in the thiobenzophenone will affect its reactivity.

The Isomerization of 1-Butene to *cis*-2-Butene over CaO by Means of the Pulse-Reaction Method

Kazushi ARATA,* Makoto HINO,† and Sakari KOBAYASHI†
Hokkaido University of Education, Hachiman-cho, Hakodate 040
†Hakodate Technical College, Tokura-cho, Hakodate 042
(Received July 10, 1987)

Synopsis. The title reaction was studied over CaO catalysts which had been prepared by the calcination of $Ca(OH)_2$ in air, followed by heating in a He stream or by thermal decomposition in a He flow. The former catalysts gave high cis/trans ratios (up to 21.6), while the latter ones were higher in activity but showed much lower ratios (ca. 1).

It is well-known that alkaline earth metal oxides, like MgO and CaO, are solid bases which catalyze various kinds of reactions.[1-4] Among a number of reactions over the solid bases, double bond and cis-trans isomerizations of butenes have been studied by many workers to clarify the surface properties. It has been recognized that basic sites convert 1-butene into *cis*-2-butene via π-allyl anion intermediates formed by the abstraction of H^+ from 1-butene;[5,6] the ratio of *cis*-2-butene to *trans*-2-butene is large (8 for CaO and 16 for MgO), compared with 1—2 in the case of the acid catalysts.[7,8]

For the above experiments, the reactions have mostly been carried out in a closed circulating reactor with a fixed-bed catalyst pretreated in vacuo. In this study, the isomerization of 1-butene was performed over CaO under pulse conditions; the results were exceedingly far from those obtained with a recirculation reaction.

Experimental

The calcium oxide was prepared by calcining $Ca(OH)_2$ (Wako Pure Chemical, Ltd.) in air for 3 h. The reactions were carried out in a microcatalytic reactor (3 mm in diameter) of stainless steel with a fixed-bed catalyst [flow rate of He carrier gas: 20 ml/min; pulse size: 0.05 ml (in gas); catalyst: 30 mg (32-60 mesh); height of the catalyst bed: ca. 3 mm]. The reactants were injected into the reactor with a syringe. For analysis, the effluent products were directly introduced into a gas chromatographic column connected to the reactor (VZ-7, 4 m, 25 °C). Since the yields were almost constant with the pulse number, conversions were taken as an average of pulse values from the first to the fifth.

Results and Discussion

The catalytic activity of CaO for the isomerization of 1-butene to 2-butenes and the selectivity to *cis*-2-butene largely depend on the temperatures of calcination in air and of treatment in a He flow in the reactor. $Ca(OH)_2$ was calcined at 300—1000 °C in air, heated in He at various temperatures, and then employed for the reaction of 1-butene. The results are shown in Table 1. The CaO catalysts were also obtained by the thermal decomposition of $Ca(OH)_2$ in a He flow, without calcination in air. High activities were observed with the catalysts heated at 600 or 700 °C in air and then in He; high ratios of *cis*-2-butene to *trans*-2-butene (c/t) were obtained when it was treated at 500 °C in He after 600 or 700 °C in air, the value of 21.4 being exceedingly high. It may be seen that the ratios were lowered with treatment in He at high temperatures, in particular >700 °C. Conversions were high for the catalysts pretreated at higher temperatures, but they lowered with calcination in air at higher temperatures; for instance, the catalysts calcined at 600, 700, 800, 900, and 1000 °C in air, followed by treatment at 600 °C in He, gave conversions of 86, 83, 37, 24, and 0% respectively. The reaction of *cis*-2-butene was performed over the CaO calcined in air at 700 °C; the isomerization of cis- to trans-form was negligible under the conditions shown

a) In He stream for 1 h. b) $Ca(OH)_2$ was thermally decomposed in He for 1 h. c) Numerals in parentheses show values for the reaction of 1-pentene. d) Catalyst amount: 10 mg.

in Table 1 when the CaO was pretreated at 500—550 °C. The conversion and the c/t ratio were almost steady after a 30-min treatment. The CaO catalysts obtained by calcination in a He stream for 1 h were higher in activity, but much lower in the c/t ratio than those prepared by calcination in air.

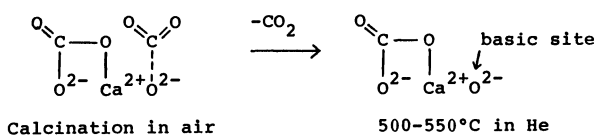
The surface areas measured by the BET method using nitrogen gas were 46 and 34 m^2/g for the catalysts calcined at 700 and 900 °C in air respectively. The base strength of the present catalysts was examined by a color-change method using acid indicators; the highest strength was $27.0 \leqq H_- < 33.0$. The CaO prepared by calcination in air and then in He at 600 °C was completely poisoned with butylamine, NH_3, H_2O, and CO_2.

The catalysts heated at 600 and 700 °C, which showed high activities and c/t ratios, were also examined in the isomerization of 1-pentene (Table 1). The reactivity and c/t ratio were lower than those in the case of 1-butene, the highest ratio being 18.8.

High c/t ratios were observed compared with the literature values,[7] and higher values still were obtained from the reaction of 1-butene at 0 °C. That is, the catalyst calcined at 600 °C in air, followed by treatment at 550 °C in He, gave the ratio of 32.6 with a 52% conversion (catalyst amount: 100 mg) and that of 41.6 with a 32% conversion in the case of the catalyst treated at 700 °C in air and 500 °C in He. As for the high ratio given by solid base catalysts, it has been reported that the ratio of 55 was obtained over Na/Na_2CO_3 with only a 5% conversion from 1-butene.[9] O'Grady et al. achieved a reaction at −60 °C over Na/Al_2O_3 in a flow system, where the c/t ratio was observed to be 21.5 with a 54% conversion.[10]

The basic properties of CaO have been studied in detail by Tanabe et al.[1,11,12] The active sites for the isomerization of 1-butene to *cis*-2-butene are strongly basic O^{2-} ions, which occupy a large fraction of the basic sites. The strong basic site, O^{2-}, is easily poisoned with the acidic molecule, CO_2; CO_2 is adsorbed on CaO as a unidentate complex when the pressure of CO_2 is high and as a bidentate complex at low pressure. When CaO is prepared by calcining $Ca(OH)_2$ in air, the basic sites are poisoned with CO_2, and it does not work as a basic catalyst. The CO_2 is removed by evacuation at 300—500 °C, resulting in a high selectivity to *cis*-2-butene; Ca^{2+} ions exposed by evacuation at high temperatures are active as acidic sites for the formation of *trans*-2-butene from 1-butene, the c/t ratio being low. The cis-trans interconversion also occurs on unusually strong basic sites, which appear on evacuation at 700—900 °C.[13]

In view of the above explanation, the high c/t ratios under the pulse conditions may be interpreted by the following scheme. The unidentate CO_2 is removed by



heating at 500—550 °C in a He flow, while the bidentate CO_2 remains at the surface; the exposed basic site, O^{2-}, is effective as the base catalysis for olefines. The following experimental phenomena seem to support this explanation: (1) When the catalyst was pretreated in He over 700 °C, the gas chromatographic peaks, as analyzed by a column connected to the reactor, were broadened; it is considered that the electrons of butenes were adsorbed on the Ca^{2+} created by the elimination of the bidentate CO_2. In this case, the conversion is high, and the c/t ratio is small, because of the acidic effect of Ca^{2+} (Table 1). (2) When CaO was prepared by the thermal decomposition of $Ca(OH)_2$ in a He stream, it is likely that the removal of CO_2 was easier; both acidic, Ca^{2+}, and basic, O^{2-} sites caused high conversions with low c/t ratios (Table 1). (3) The CaO catalyst obtained by calcination in air, followed by pretreatment in He at 450 °C, showed a 69% conversion for the reaction of 1-butene, but it was completely inactive when pretreated in air at 450 °C. (4) The cis to trans interconversion is more suppressed by the short contact time under the present pulse conditions than a closed circulating reaction.

(Received July 15, 1987)

Synopsis. X-Ray crystal structure analysis of the title compound is described. $C_6H_{12}N_2$,$2C_7H_8O$, *F. W.* 328.5, monoclinic, space group *C*2/*c*, a=18.494(1), b=9.250(1), c=11.414(1) Å, β=103.67(1)°, V=1897.4(3) Å^3, D_c=1.150 g cm^{-3} for Z=4. The DABCO molecule in the crystal is bound to two *p*-cresol molecules by the strong O-H ··· N hydrogen bonds, and the crystal is composed of *p*-cresol ··· DABCO ··· *p*-cresol complex units.

It has been reported that the optical resolution of tertiary alcohols, especially tertiary acetylenic alcohols, can easily be achieved by complexation with achiral amines, such as 1,4-diazabicyclo[3.3.3]octane (DABCO).[1] Recently, Toda and Tanaka found that DABCO also forms complex with phenols. In order to obtain structural informations on the complexation, the crystal structure of the 1:2 complex of DABCO and *p*-cresol has been determined by means of X-ray diffraction.

Experimental

The crystal used had approximate dimensions of 0.75×0.5×0.25 mm, which was sealed in a thin-walled glass capillary tube in order to prevent sublimation. X-Ray diffraction data were collected on a Rigaku rotating anode four-circle diffractometer using nickel-filltered Cu $K\alpha$ radiation by the θ-2θ scan technique up to 2θ=120°. The scan rate was 4° min^{-1} and the scan width $\Delta\theta$=(1.2+0.15 tan θ)°. Backgrounds were counted for 4 s at both ends of a scan. Three standard reflections measured after every 100 reflections to monitor the stability and orientation of the crystal showed no significant decay through the experiment. Of the 1414 reflections measured, number of reflections observed was 1317 ($|F_o|>2\sigma$ (F_o), where σ is the standard deviation obtained from the counting statistics). Usual Lorentz and polarization corrections were applied but absorption effect was ignored [μ(Cu $K\alpha$)=5.94 cm^{-1}].

Structure Solution and Refinement

The structure was solved by the direct method (*MULTAN* 78),[2] and was refined by the block-diagonal least-squares procedure (*HBLS* V).[3] The nonhydrogen atoms were refined anisotropically. The hydrogen atoms, which located on the difference Fourier map, were refined with isotropic temperature factors. The final R index was 0.073. The weighting scheme used at the final stage of the refinement was $w=[\sigma^2(F_o)+0.1582|F_o|+0.0013|F_o|^2]^{-1}$. Final atomic parameters are given in Tabler 1.†† Atomic scattering factors used were taken from International Tables for X-Ray Crystallography.[5] Computations were done on an ACOS 850S computer at the Crystallographic Research Center, Institute for Protein Research, Osaka University.

Results and Discussion

Molecular structure is shown in Fig. 1.[6] The remarkable feature of the structure is that the DABCO molecule, the center of which lies on a crystallographic two fold axis, is bound to two *p*-cresol molecules at its both ends by the strong O-H ··· N hydrogen bonds [O(1) ··· N(1)=2.713(3), O(1)-H(1)=1.03(4), H(1) ··· N(1)=1.69(4) Å, and O(1)-H(1) ··· N(1)=172(4)°] to form a linear 1:2 molecular complex of *p*-cresol ··· DABCO ··· *p*-cresol. The molecular symmetry of the central DABCO is 2 instead of $\bar{6}m2$ but has a similar structure as that determined by means of neutron diffraction at 298 K, and also as those observed in the 1:2 complex with (−)- and (+)-1-phenyl-1-(*o*-chlorophenyl)-2-propyn-1-ol.[7] The thermal ellipsoids of the C(8), C(9), and C(10) atoms are elongated along the direction approximately perpendicular to the N(1) ··· N(1′) axis of the molecule (equivalent isotropic temperature factors of these atoms are 13.8, 14.4, and

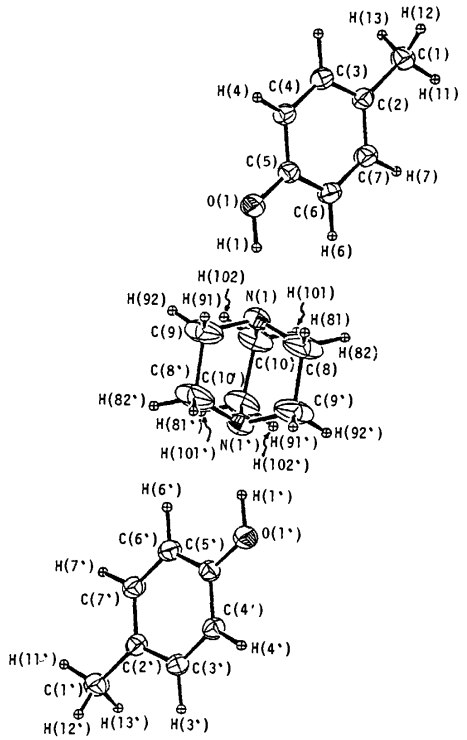

Fig. 1. A perspective view[6] of the 1:2 molecular complex of DABCO with *p*-cresol with the numbering scheme of atoms. Nonhydrogen atoms are drawn as thermal ellipsoids with 20% probability level, and hydrogen atoms with B=1.0 Å^2.

8.7 Å^2, respectively), which suggest a hindered rotation of the DABCO molecule along the N(1)···N(1′) axis. However, three C-N bond lengths [1.437(5), 1.442(7), and 1.447(8) Å] and C-N-C bond angles [108.6(4), 108.6(5), and 109.5(4)°] are respectively equal to the corresponding bond distances and bond angles determined by the neutron diffraction study[8] within the range of error, whereas, the C(8)-C(9′), C(8′)-C(9), and C(10)-C(10′) bond distances [1.56(1), 1.56(1), and 1.561(7) Å, respectively] are slightly smaller than those obtained by the same study. The *p*-cresol molecule attached to the DABCO by the hydrogen bonding has a normal structure.[9] The benzene ring is planar within 0.002 Å. The average C-C bond distance is 1.392 Å and the average C-C-C angle 120°. The C(6)-C(5)-O(1) angle [122.9(3)°] is larger than the C(4)-C(5)-O(1) [117.6(3)°].

As seen in Fig. 2, the crystal structure is composed of

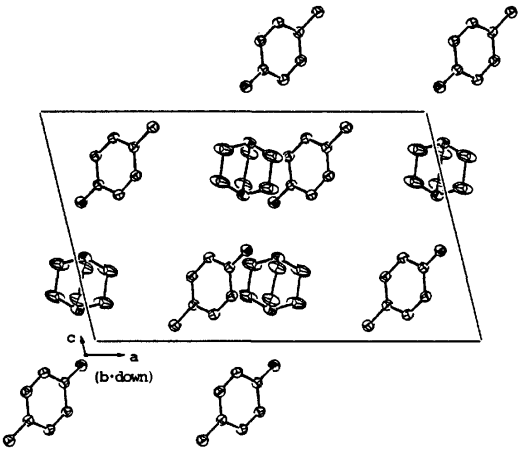

Fig. 2. Crystal structure[6] of the 1:2 molecular complex of DABCO with *p*-cresol projected along the b axis. Nonhydrogen atoms are drawn as thermal ellipsoids with 20% probability level. Hydrogen atoms are omitted for clarity.

a loose packing of the 1:2 complex. The closest intermolecular atomic contact[3.666(5) Å] is observed between the C(5) (x, y, z) and C(1) (0.5−x, −0.5+y, −0.5+z).

The present work was partially supported by a Grant-in-Aid for Scientific Research from the Ministry of Education, Science and Culture.

Time-Dependent Metastable Fragmentations. The H_2O Loss from Ethyl Acetate Ions

Ryuichi ARAKAWA
Institute of Chemistry, College of General Education, Osaka University, Toyonaka 560
(Received July 18, 1987)

Synopsis. The metastable transitions for $CH_3COOC_2H_5^+ \rightarrow C_4H_6O^+ + H_2O$ have been measured as a function of the ion lifetime of 0—200 μs by using trapped ion mass spectrometry (TIMS). The experimental data were well explained by tunneling corrections to the prior isomerization rate.

The H_2O loss from ionized ethyl acetate is the lowest energy process, only 0.3 eV higher than the ionization energy. This reaction has a strong metastable peak in a μs time-frame. The reaction mechanism for H_2O loss has been of much interest and has been studied by labeling experiments[1] and by means of the collisional activation spectra[2] for a daughter ion of $C_4H_6O^+$. These results previously reported suggest that all hydrogen atoms and both oxygen atoms participate in the complex reaction mechanism. The photoion-photoelectron coincidence(PIPECO) study by Baer and his co-workers[3] has provided close measurements of the dissociation rate as a function of the photon energy for the rate range of 10^5—10^6 s^{-1}. Moreover, the time-dependent kinetic energy releases have been measured for ion lifetimes up to 20 μs by means of double-focusing mass spectrometry[4] and by means of TIMS.[5] However, there is still an unresolved question as to the ethyl-acetate dissociation near the threshold.

The present paper will report on the slow metastable fragmentations of less than 10^5 s^{-1}, which have not previously been observed for an ethyl acetate system. The metastable intensities for H_2O loss were measured as a function of the ion-source-residence time by means of TIMS. The longest lifetime of 200 μs corresponds to the average rate of ca. 5×10^3 s^{-1}.

Experimental

The ion-trapping technique has been described in detail elsewhere.[6] Briefly, the space charge formed by a continuous 5-eV electron beam was used to trap ions produced when a negative pulse was applied to a filament. At a known delay time after the ionizing pulse, a positive pulse, 4 μs in duration and 5 eV in height, was applied to a repeller electrode in order to remove ions for mass analysis. The delay time was successively varied with a 3.7-μs step. The ionizing pulse was applied to the filament at a 0.5-ms interval. These pulse-sequence and data-acquisition systems were both computer-controlled.

The metastable parent ions, which are selected by the first magnet, decompose in the second-field-free region. The product ions are analyzed by the use of the second magnet. Several hours of data accumulation were statistically needed for the measurement. The temperature of the ion source was 423 K. The ion-accelerating voltage was 1.5 kV. The ion-source pressure was kept at 2×10^{-6} Torr (1 Torr=133.322 Pa). The collision-induced reaction in the field-free region was negligible, because the pressure was less than 1×10^{-6} Torr.

Results and Discussion

Figure 1 shows the metastable-to-main-beam intensity ratio at the electron-impact energy of 40 eV. This metastable decay, of course, reflects the rate constant, and its intensity at the ion-residence time of t is proportional to:[7]

$$m^*(t) \propto \int_0^\infty p(E)\,[\exp(-t_1 k(E)) - \exp(-t_2 k(E))]\,dE.$$

Here, $p(E)$ is the internal energy distribution, t_1 and t_2 are the time windows in the experiment (t_1=6.5+t and t_2=11.7+t μs), and $k(E)$ is the unimolecular rate constant. The photoelectron spectrum for ethyl acetate[8] was assumed to represent $p(E)$.

The PIPECO experimental rates previously reported by Baer and his co-workers[3] are shown in Fig. 2. The RRKM calculation has given a rate 100 times larger than the measured rates. This is mainly because of the low activation energy, that is, the low state density for the reactant. They therefore concluded that the parent ethyl acetate ion rearranges to a more stable structure prior to dissociation. The energy of its isomer, 0.62 eV lower than the ionization energy of ethyl acetate, was determined as a parameter, so that the RRKM rates agreed with the measured rates. Such a prior isomerization mechanism provides a rate-energy curve which is truncated at the threshold (Fig. 2). As may be seen in

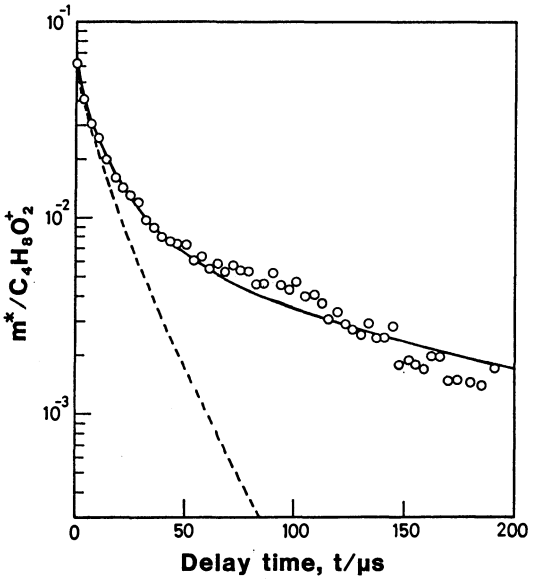

Fig. 1. A plot of the metastable-to-main-beam intensity ratios for $CH_3COOC_2H_5^+ \rightarrow C_4H_6O^+ + H_2O$ against the delay time: experiment(○) and calculated with the prior isomerization rate model, ---- and with the tunneling correction, ——.

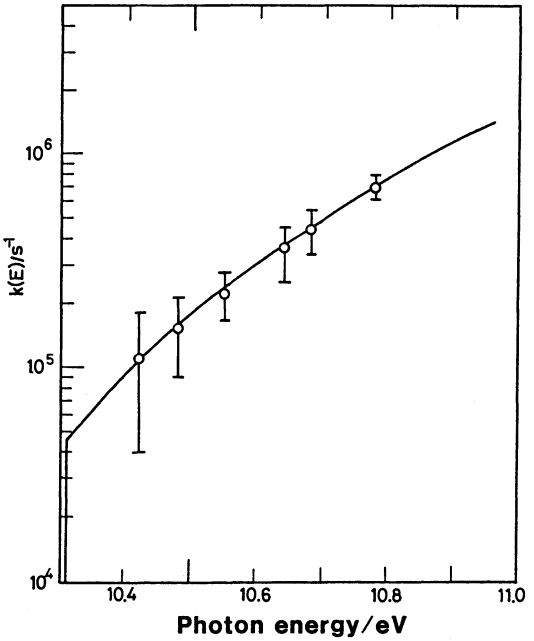

Fig. 2. The dissociation rate $k(E)$ vs. photon energy: the PIPECO experimental rate,[3] (O) and the RRKM rate arising from the prior isomerization mechanism(——).

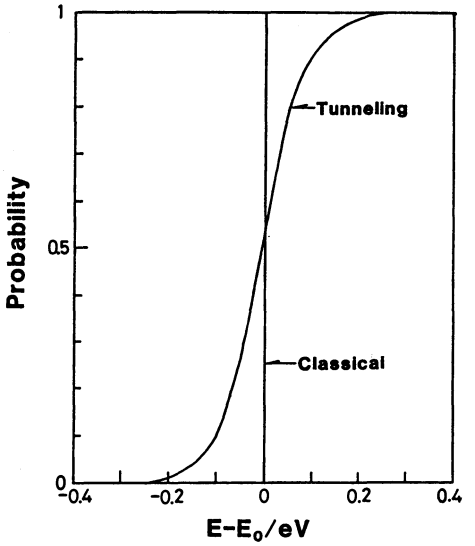

Fig. 3. Tunneling probability near threshold energy, E_0.

Fig. 1, this rate model fails to fit the experimental data. The reason for this failure is probably because the model provides no rate less than 10^4 s^{-1}. From the actual calculation it was found that a decrease in the metastable decay is dependent on the slope of $k(E)$ vs. E, especially in the range of 10^3—10^5 s^{-1}.[7]

In this study, the tunneling effect was examined to explain the slow fragmentations. Tunneling corrections to unimolecular rate constants have previously been investigated for neutral reactions by Miller and his co-workers.[9] Moreover, applications to metastable transitions have been reported for methane,[10] methanol,[11] and phenol[12] cations. These experiments have usually been carried out to observe the temperature dependence on the ratios of the metastable-to-main-beam intensity or on kinetic energy releases. For example, Klots predicted that the metastable intensity, if tunneling through a centrifugal barrier occurs, increases as a square of the temperature.[10]

The probability of tunneling is generally favored for the case of one-step hydrogen-bond cleavage. The H_2O loss of the ethyl acetate cation probably involves a hydrogen migration to a oxygen atom prior to dissociation. On the basis of a Miller modification with the generalized Eckart potential,[8] the tunneling probabilities were calculated, and they are shown in Fig. 3. For the calculation, the activation barrier of 0.92 eV was obtained from the PIPECO results;[3] the reverse barrier was assumed to be 0.5 eV, for the product structure of $C_4H_6O^+$ was not well defined. The probability depends strongly upon an imaginary frequency. Here, the imaginary frequency of 2300 cm^{-1} was taken from Ref. 6. The rate below the threshold was obtained by multiplying the rate at the threshold by the tunneling probability. The tunneling correction to the prior isomerization rate is very satisfactory for the experimental metastable decay in Fig. 1. It may be concluded that the decrease in the metastable intensity with the ion lifetime beyond 20 μs arises from tunneling through a potential barrier. This conclusion is supported by the good agreement between the experimental data and the results of calculation by taking the tunneling effect into account. In other words, this indicates that the hydrogen-atom migration is a rate-determining step for slow fragmentations. However, such consideration has not been definitely confirmed by direct observation. It has been well known that a OH or H_2O loss which involves hydrogen-atom migration is generally a complex mechanism.

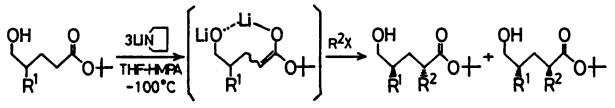
Stereoselective Alkylation of Lithium Enolates Generated from *t*-Butyl Esters of 4-Alkyl-Substituted 5-Hydroxypentanoic Acids

Yutaka UKAJI and Koichi NARASAKA*
Department of Chemistry, Faculty of Science, The University of Tokyo, Hongo, Bunkyo-ku, Tokyo 113
(Received July 18, 1987)

Synopsis. Alkylation of lithium enolates generated from *t*-butyl esters of 4-alkyl-substituted 5-hydroxypentanoic acid by treatment with lithium pyrrolidinide in THF-HMPA proceeded stereoselectively to afford the corresponding *anti*-α-alkylated esters.

Concerning remote chiral induction directed by a hydroxyl group, we reported that the lithium enolates of *t*-butyl 5-hydroxy carboxylates react with electrophiles such as alkyl halides, ketones and oxaziridines, giving the corresponding 2-substituted products with high diastereoselectivities.[1] In these reactions remote chiral induction (1,4-relationship) is considered to be efficiently controlled by the formation of a lithium chelate, therefore, we successively applied this concept to the stereoselective preparation of 2,4-disubstituted 5-hydroxypentanoates based on the following consideration.

When a 4-alkyl-substituted 5-hydroxypentanoate **1** is treated with lithium amide in tetrahydrofuran (THF) and hexamethylphosphoric triamide (HMPA), it is expected that the (*E*)-enolate would be generated stereoselectively[2] and would form an 8-membered chelate **2**,[1] which would successively react with alkylating reagents in a stereoselective manner.



1 **2** **3** **4**

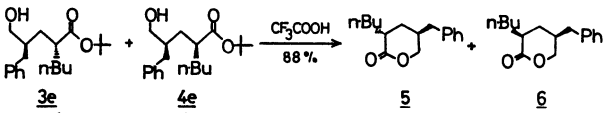
According to the above hypothesis, the enolization of 5-hydroxypentanoates **1A—C**, which have methyl, allyl or benzyl group as a 4-substituent, and the successive reaction with alkylating reagents were examined. The hydroxy ester **1** was treated with 3 molar amounts of lithium pyrrolidinide[3] in THF-HMPA at −100 °C for 1 h, and then the alkylation was performed at the temperature. The diastereoselectivities in these reactions are summarized in Table 1. Generally a good diastereoselectivity is observed and the 4-substituent slightly affects the selectivity. That is, in the case that the substituent is allyl or benzyl group, a higher selectivity is observed as compared with that in reaction of the methyl substituted ester **1A**.

Table 1. Diastereoselectivity in the Alkylation of **1**

R^1	R^2-X	3 : 4	Total yield/%
Me	Me_2SO_4	80 : 20[a)]	78
CH_2=$CHCH_2$	Me_2SO_4	85 : 15[a)]	81
CH_2=$CHCH_2$	$PhCH_2Br$	90 : 10[b)]	96
$PhCH_2$	Me_2SO_4	90 : 10[b)]	80
$PhCH_2$	*n*-BuI[c)]	91 : 9[d)]	76

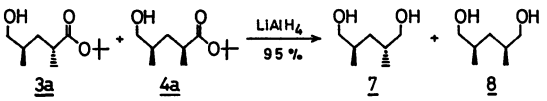
a) The ratio was determined by GLPC (PEG-HT). b) The ratio was determined by HPLC (Waters RESOLVE). c) After the addition of *n*-BuI, the reaction mixture was stirred for 1 h at −100 °C and gradually warmed to −78 °C.

The alkylated product **3e** was readily converted to the *trans*-2,4-disubstituted 5-pentanolide **5** by treatment with trifluoroacetic acid at room temperature. On the othe hand, an attempt to prepare the *trans*-pentanolide **5** from a cyclic compound such as 4-benzyl-5-pentanolide by the alkylation of the corresponding lithium enolate with butyl iodide failed, resulting in the formation of almost equal amounts of the both isomers (**5** : **6**=59 : 41). Therefore, the present reaction affords a stereoselective method for the preparation of *trans*-2,4-disubstituted pentanolide.



3e (91 : **4e** 9) **5** (91 : **6** 9)

The relative stereochemistry was confirmed by the transformation of **3a** to *dl*-2,4-dimethyl-1,5-pentanediol **7**. The mixture of **3a** and **4a** was reduced with lithium aluminum hydride to the diol **7** and **8** (4 : 1 mixture, respectively). The authentic *meso*-diol **8** was prepared from *meso*-2,4-dimethylglutaric anhydride, and the ^{13}C NMR spectrum of the authentic **8**[4] was identical with that of the minor isomer **8** obtained by the reduction of the mixture of **3a** and **4a**.



3a (4 : **4a** 1) **7** **8**

In conclusion, *anti*-2,4-disubstituted 5-hydroxy pentanoates **3** are prepared by the stereoselective remote alkylation of the 5-hydroxy esters **1**. The products **3** are considered to be useful synthetic intermediates, because the two different terminal oxygen functions can be effectively used for further transformation.

Experimental

Preparation of *t*-Butyl 5-Hydroxy-4-methylpentanoate (1A). To a THF (90 mL) solution of diisopropylamine (5.27 g, 52 mmol) was added butyllithium (49.6 mL in hexane, 52 mmol) at −78 °C under an argon atmosphere and stirred for 15 min. To the mixture was added a THF (10 mL) solution of ethyl propionate (5.28 g, 52 mmol) and stirred for 1 h at −78 °C. Then a THF (10 mL) solution of *t*-butyl acrylate (5.31 g, 41 mmol) was added to the mixture.[5] After being stirred for 1 h at the temperature, the reaction was quenched with sat. aqueous NH_4Cl and extracted with chloroform. The combined organic extracts were dried over Na_2SO_4, and condensed under reduced pressure. Purification by column chromatography on silica gel (hexane: ethyl acetate=15 : 1, volume ratio) gave the pure Michael

adduct, *t*-butyl 4-ethoxycarbonylpentanoate (6.66 g, 70%). IR (neat) 1730 cm^{-1}. ^1H NMR (CCl_4) δ=1.13 (3H, d, J=6.6 Hz), 1.24 (3H, t, J=7.0 Hz), 1.42 (9H, s), 1.52—1.95 (2H, m), 1.95—2.57 (3H, m), 4.01 (2H, q, J=7.0 Hz).

Next, to a THF (250 mL) solution of lithium aluminum hydride (3.29 g, 87 mmol) was slowly added a THF (20 mL) solution of the above Michael adduct (6.65 g, 29 mmol) at −78 °C under an argon atmosphere, and stirred for 8 h. The mixture was quenched with sat. aqueous Na_2SO_4 (25 mL) and the resulting precipitate was filtered off. The condensed filtrate was purified by column chromatography on silica gel (hexane : ethyl acetate=3 : 1, volume ratio) to give **1A** (2.97 g, 55%), bp 95 °C (bath temp)/2 mmHg (1 mmHg=133.322 Pa). IR (neat) 3430, 1730 cm^{-1}. ^1H NMR (CCl_4) δ=0.90 (3H, d, J=6.0 Hz), 1.20—1.80 (3H, m), 1.43 (9H, s), 2.03—2.53 (3H, m), 3.21—3.53 (2H, m).

4-Alkyl-substituted 5-hydroxy esters **1B** and **1C** were prepared by the method of Yamaguchi.[6] The spectra data are shown below.

***t*-Butyl 4-Benzyl-5-hydroxypentanoate (1C):** Bp 147 °C (bath temp)/2 mmHg. IR (neat) 3430, 1720 cm^{-1}. ^1H NMR (CCl_4) δ=1.20—1.71 (3H, m), 1.27 (9H, s), 1.92—2.28 (2H, m) 2.28—2.57 (3H, m), 3.28 (2H, d, J=4.0 Hz), 7.06 (5H, s).

***t*-Butyl 4-Hydroxymethyl-6-heptenoate (1B):** Bp 120 °C (bath temp)/2 mmHg. IR (neat) 3450, 1725, 1640 cm^{-1}. ^1H NMR δ=1.21—1.80 (3H, m), 1.43 (9H, s), 1.91—2.49 (4H, m), 2.68 (1H, br s), 3.40 (2H, d, J=5.6 Hz), 4.68—5.14 (2H, m), 5.31—6.07 (1H, m).

Stereoselective Alkylation of 1C with Dimethyl Sulfate. To a THF solution of lithium pyrrolidinide (1.67 mmol), which was prepared from pyrrolidine (173 mg, 2.44 mmol) and butyllithium (1.64 M hexane solution (1 M=1 mol dm^{-3}), 1.02 mL) at −78 °C, was added HMPA (0.58 mL, 3.33 mmol) at 0 °C under an argon atmosphere, and cooled to −100 °C. A THF (3 mL) solution of *t*-butyl 4-benzyl-5-hydroxypentanoate (**1C**, 147 mg, 0.56 mmol) was added to the mixture and stirred for 1 h at that temperature. Then a THF (3 mL) solution of dimethyl sulfate (251 mg, 1.99 mmol) was added to the mixture. After being stirred for 1 h at −100 °C, the reaction was quenched with sat. aqueous NH_4Cl and extracted with ether. The combined ether extracts were washed with water and brine, dried over Na_2SO_4, and condensed under reduced pressure. Purification by column chromatography (silica gel, hexane : ethyl acetate=10 : 1, volume ratio) gave *t*-butyl *anti*-4-benzyl-5-hydroxy-2-methylpentanoate (**3d**) and the *syn*-isomer **4d** (total 124 mg, 80%) in the ratio of 90 : 10, respectively.

The preparations of **3a,b,c,e** were carried out by the same procedure. All the alkylated products were isolated as a mixture of the *anti* and *syn* isomers **3** and **4**, which were not able to be separated by column chromatography or TLC. The following spectral data were for a mixture of the *anti* and *syn* isomers (91:9—80:20, respectively).

***t*-Butyl *anti*-5-Hydroxy-2,4-dimethylpentanoate (3a) and the *syn*-Isomer 4a:** IR (neat) 3430, 1720 cm^{-1}. ^1H NMR (CCl_4) δ=0.87 (3H, d, J=6.0 Hz), 0.99 (2.4H, d, J=7.0 Hz, anti), 1.00 (0.6H, d, J=7.4 Hz, syn), 1.20—1.98 (3H, m), 1.42 (9H, s), 2.03—2.60 (1H, m), 3.18—3.41 (3H, m).

***t*-Butyl *anti*-4-Hydroxymethyl-2-methyl-6-heptenoate (3b) and the *syn*-Isomer 4b:** IR (neat) 3430, 1725, 1640 cm^{-1}. ^1H NMR (CCl_4) δ=0.93—2.61 (6H, m), 1.09 (3H, d, J=7.0 Hz), 1.43 (9H, s), 2.97 (1H, br s), 3.27—3.55 (2H, m), 4.70—5.16 (2H, m), 5.35—6.09 (1H, m).

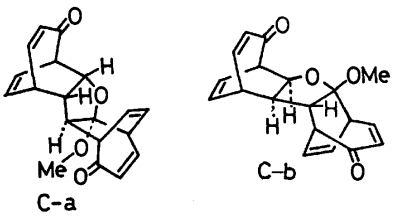
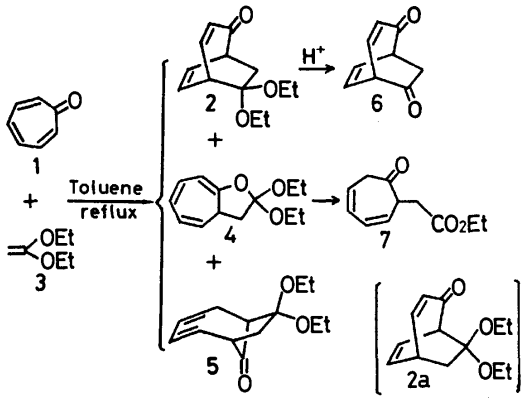
Synopsis. A reinvestigation of Cantrell's thermal cycloaddition of tropone to 1,1-diethoxyethene has led to the isolation of three products: [4+2], [6+2], and [8+2] cycloadducts. The structure of the [4+2] cycloadduct was revised on the basis of an NMR analysis of the hydrolyzed diketone, and newly identified was a superficial *anti*-Woodward-Hoffmann [6+2] cycloadduct. These adducts did not cause mutual isomerization by heating under formation conditions.

In connection to our continuing interest on the cycloadditions of tropones, we have recently carried out the reaction of tropone (**1**) with 2-methoxyfuran (**A**) to give 1:1- (**B**) and 2:1-cycloadducts (**C**), for which, the second step of the reaction should fall into a category of the cycloaddition of **1** to a 1,1-dialkoxyethene.[1]

After analyzing the interconversions of these adducts, we noticed a different regioselectivity between the [4+2] cycloadducts found in the C-type products and the Cantrell's [4+2] cycloadduct **2a** prepared from **1** and 1,1-diethoxyethene (**3**).[2] This superficial discrepancy prompted us to reinvestigate the Cantrell's experiment. The findings will be described herein.

When a toluene solution of **1** and **3** was refluxed under a nitrogen atmosphere for 17 h, the formation of two products (**2** and **4**) was recognized as being consistent with Cantrell's result;[2] they seemed to be identical with his [4+2] and [8+2] cycloadducts, respectively. Furthermore, the presence of a third cycloadduct (**5**) was recognized. However, when the reaction was carried out under aerial conditions at 90 °C, the mixture became dark-colored and showed an inferior material balance (Table 1).





Scheme 1.

Under 3000 bar, the yeilds of **2** and **4** showed considerable improvement (Table 2).

In view of the variable yields depending on the conditions, oxygen-susceptible **5** might be a non-electrocyclic, radical product. On the other hand, an increase in the yields of **2** and **4** by an increase in the pressure shows that **2** and **4** are electrocyclic, concerted reaction products.

The ^{1}H NMR spectrum of **2** disclosed four vinylic protons, as well as two signals due to ethoxyl groups, suggesting that it is the [4+2] cycloadduct. Therefore, the only point to be clarified was the regiochemistry: between two possibilities, Cantrell's proposal, **2a**, and the isomer, **2**. However, we could not discriminate one from the other, since its 100- and 270-MHz ^{1}H NMR spectra showed still overlapped bridge-head protons underneath the methylene signal. A mild hydrolysis of **2** by dil hydrochloric acid yielded a diketone **6**, whose ^{1}H NMR spectrum[3] disclosed, together with four vinyl proton signals, well-separated methylene proton signals with a large vic-coupling (J=19 Hz), and doubly-allylic methine proton signal at δ=3.91. The spin-coupling pattern of this signal had only two large vic-couplings, J=9 and 7 Hz, indicating that the newly-generated carbonyl group is adjacent to the doubly allylic carbon. Thus, **6** is bicyclo[3.2.2]nona-3,8-diene-2,6-dione, and **2** is the corresponding diethyl acetal. The regiochemistry of **2** was in accord to our [4+2]-[4+2] cycloadducts (**C-a** and **C-b**), whose second step of formation could reasonably be explained in terms of a HOMO-LUMO interaction; however, it did

Table 1. The Cycloaddition of **1** to **2**

Condition	Yield/% of product			Recovered
	[8+2]	[6+2]	[4+2]	**1**
90 °C, 48 h/sealed tube	9.2	0.7	1.9	38
110 °C, 17 h, N_2/reflux	47	5.2	15	9.2

Table 2. Change of Product Distributions and Pressure Effect

Condition	Yield/%			Recovery
	[8+2]	[6+2]	[4+2]	**1**
120 °C, 10 h, 1 bar	9.1	3.1	1.1	70
120 °C, 10 h, 3000 bar	17	—	13	84

not follow Cantrell's formula **2a**. Although his structure argument seemed to depend on the ^{1}H NMR criteria, the disclosed evidence alone did not allow any conclusion to be drawn.

The **4** was quantitatively converted to the keto ester **7**, even in chloroform at 50 °C. The ^{1}H NMR spectrum of **4** was identical with the reported figures by Cantrell,[2] and **4** is undoubtedly the [8+2] cycloadduct. The ^{13}C NMR spectrum of **4** disclosed a characteristic signal due to the ortho ester carbon at δ 124.6.

The structure of **5** was again elucidated by the NMR spectroscopy; its ^{1}H NMR revealed AA'BB'-type four vinylic proton signals and its IR showed a peak due to an unconjugated carbonyl stretching frequency at 1750 cm^{-1} and it is the [6+2] cycloadduct. Noteworthy was the occurrence of such a Woodward-Hoffmann-Rule-disallowed process.[4] However, the [6+2] cycloadduct, **5**, might not be a secondary product since its formation could not be explained by symmetry-allowed sigmatropic reactions from **2** or **4**. This was verified when we carried out thermal isomerizations of the adducts; all the cycloadducts were surprisingly stable up to 130 °C, higher than the formation conditions, and recovered the starting materials quantitatively. Therefore, **5** must be formed directly from **1** and **3**.

Experimental

Thermal Cycloaddition of 1 to 3.[2] a) An anhydrous toluene solution (4 cm^3) of **1** (97 mg) and **3** (1.0 g) was refluxed under an N_2 atmosphere for 17 h. After evaporation of the solvent in vacuo, the residue was chromatographed on a silica-gel column to give **4** [a yellow oil, 88 mg; 48%. Found: *m/z* 222.1257 (M^+).[5] Calcd for $C_{13}H_{18}O_3$: M, 222.1255. ^{1}H NMR δ=1.21 (3H, t, *J*=7 Hz), 1.23 (3H, t, *J*=7 Hz), 2.23 (1H, dd, *J*=13, 6 Hz), 2.64 (1H, dd, *J*=13, 10 Hz), 2.8—2.9 (1H, m), 3.67 (2H, q, *J*=7 Hz), 3.68 (2H, q, *J*=7 Hz), 5.00 (1H, dd, *J*=10, 4 Hz), 5.68 (1H, d, *J*=6.5 Hz), 6.07 (1H, ddd, *J*=9.5, 6, 1.5 Hz), 6.22 (1H, dd, *J*=11, 6 Hz), and 6.37 (1H, dd, *J*=11, 6.5 Hz). ^{13}C NMR[6] δ=15.2 (2C, q), 38.5 (d), 39.6 (t), 58.3 (t), 59.0 (t), 97.0 (s), 123.0 (d), 124.3 (d), 124.6 (d), 126.7 (d), 128.6 (d), and 150.7 (s). IR ν: 3000 and 1640 cm^{-1}], **2** [a yellow oil, 28 mg; 15%. Found: *m/z* 222.1256 (M^+). ^{1}H NMR δ=1.16 (6H, t, *J*=7 Hz), 2.16 (2H, overlapped s), 3.3—3.6 (6H, m), 5.79 (1H, dd, *J*=11, 2 Hz), 6.12 (1H, ddd, *J*=8.5, 7.5, 1.5 Hz), 6.44 (1H, ddd, *J*=8.5, 7.5, 1.5 Hz), and 6.88 (1H, dd, *J*=11, 9 Hz). ^{13}C NMR δ=15.2 (2C, q), 33.9 (t), 45.1 (d), 51.4 (d), 56.4 (t), 57.0 (t), 107.8 (s), 126.5 (d), 129.6 (d), 136.2 (d), 149.1 (d), and 197.2 (s). IR ν: 2980 and 1660 cm^{-1}], and **5** [a yellow oil, 10 mg; 5.4%. Found: *m/z* 222.1251 (M^+). ^{1}H NMR δ=1.14 (3H, t, *J*=7 Hz), 1.21 (3H, t, *J*=7 Hz), 2.49 (2H, d, *J*=6.5 Hz), 2.8—2.9 (1H, m), 3.19 (1H, d, *J*=7.5 Hz), 3.4—3.5 (4H, m), 5.37 (1H, dd, *J*=11.5, 7.5 Hz), 5.84 (1H, dd, *J*=10, 7.5 Hz), and 5.9—6.0 (2H, m). ^{13}C NMR δ=15.2 (2C, q), 40.3 (t), 46.4 (d), 56.8 (d), 58.8 (t), 59.6 (t), 112.5 (s), 123.3 (d), 125.5 (d), 125.9 (d), 129.8 (d), and 210.5 (s). IR ν: 3000 and 1750 cm^{-1}]. Recovery of **1** was only 9 mg (9.3%).

Thermal Cycloaddition of 1 to 3 under High-Pressure Conditions. A mixture of **1** (151 mg) and **3** (539 mg) in toluene (2 cm^3) was heated at 120 °C under 3000 bar for 10 h. The product distribution is compiled in Table 2. A careful inspection of every chromatographic fraction assured the absence of **5**.

Attempted Thermal Rearrangement of 2 and 4. Each toluene-d_8 solution (O_2 was carefully removed, 0.4 cm^3) of **2** (25 mg) and **4** (45 mg) was heated in a sealed glass tube at 130 °C for 6 to 7 h. Occasional NMR monitoring of the mixture indicated no occurrence of the reaction.

Hydrolysis of 2. A THF solution (10 cm^3) of **2** (40 mg) and conc HCl (0.5 cm^3) was refluxed for 10 min. The mixture was then diluted with water, and extracted with ether. Silica-gel column chromatography of the extract afforded **6** [a colorless oil, 17 mg; 64%. Found: *m/z* 148.0519 (M^+). Calcd for $C_9H_8O_2$: 148.0524. ^{1}H NMR δ=2.53 (1H, ddd, *J*=19, 5.5, 1.5 Hz), 2.65 (1H, dd, *J*=19, 1.5 Hz), 3.59 (1H, m), 3.91 (1H, ddd, *J*=9, 7, 1 Hz), 6.04 (1H, ddd, *J*=11, 2, 1 Hz), 6.34 (1H, td, *J*=8, 1 Hz), 6.59 (1H, ddd, *J*=8, 7, 1.5 Hz), and 6.91 (1H, dd, *J*=11, 9 Hz). ^{13}C NMR δ=32.1 (t), 50.1 (d), 55.8 (d), 128.6 (d), 132.2 (d), 134.5 (d), 143.9 (d), 193.2 (s), and 202.8 (s). IR ν: 1730 and 1670 cm^{-1}].

Different Acyl Specificity between Mold and Kidney Acylases: Correlation of Hydrolytic Rate to Molecular Size and Electronegative Property of Acyl Group in Acyl-L-phenylalanine Hydrolysis

Shinwon KANG,† Yoshihiro MINEMATSU, Yasuyuki SHIMOHIGASHI,* Michinori WAKI, and Nobuo IZUMIYA†
Laboratory of Biochemistry, Faculty of Science, Kyushu University 33, Fukuoka 812
(Received July 27, 1987)

Synopsis. A series of acyl-L-phenylalanines were hydrolyzed by mold and hog kidney acylases. The formyl was found to be the most susceptible for mold acylase, and the butyryl for kidney acylase, indicating the different preferences of these acylases in molecular size and electronegative property of acyl group of substrates.

A variety of optically active amino acids have been prepared by resolving acyl-DL-amino acids with enzymes. Hog kidney acylase I and mold acylase are the most frequently utilized enzymes in this procedure, and their substrate specificity has been studied focusing mainly on the side chain of acetyl- or chloroacetylamino acids.[1] Recently, mold acylase has become increasingly useful because of its availability in large scale and easy immobilization even in an industrial scale. To obtain a high efficacy of the enzyme in such a system, it seems to be important to find more effective acyl groups other than the acetyl and chloroacetyl, since more susceptible acyl group may preserve or even elicit the hydrolytic efficiency when amino acids having unfavorable side chain for the enzyme should be resolved. However, no systematic studies have been reported for the substrate specificity related to acyl groups. Thus, in this study we measured the acylase-catalyzed hydrolytic rate of a series of synthetic acyl-L-phenylalanine in order to analyze the efficiency of acyl groups on the basis of their molecular size and electronegative property.

Acyl groups to derivatize L-phenylalanine were the formyl (For), acetyl (Ac), propionyl (Prp), butyryl (But), pentanoyl (Pen), hexanoyl (Hex), and chloroacetyl (ClAc). Urethane type acyl groups such as ethoxycarbonyl (Eoc), *t*-butoxycarbonyl (Boc), and benzyloxycarbonyl (Z)[2] were also examined. These derivatives were prepared by the usual methods as described in the literature. For hydrolysis of each acyl-L-phenylalanine, the optimum pH was determined (pH 6.0—7.5 for mold acylase: see Table 1). Although the optimum pH might be above pH 8.5 for kidney acylase, no definite values could be determined because of precipitation of cobalt hydroxide at this pH range. Under the conditions without cobalt ion, acylamino acids have been reported to show a rather broad pH maximum between pH 6.7 and 8.0.[3]

The hydrolytic rates were measured at the optimum pH of each substrate for mold acylase and at pH 7.0 for kidney acylase as reported by others.[3] The relative rates of hydrolysis were shown in Table 1. For mold acylase, the formyl was found to be very susceptible, showing a 3.6-fold larger hydrolytic rate than that of the acetyl. Moreover, the formyl was much more easily hydrolyzed than the chloroacetyl. The order of susceptibility of acyl groups towards the acylase was For > ClAc > Ac > Prp > But > Pen > Hex. A very little hydrolysis was observed for Eoc-derivative, and no hydrolysis for Boc- and Z-derivatives. When the rates were compared among a series of acyl groups, H-$(CH_2)_n$-CO-, it was found that a progressive decrease in the number n of methylene units causes an increase in the rate, and thus the formyl with n=0 became the most labile acyl group to the hydrolysis. This result indicates that mold acylase prefers smaller acyl group in molecular size.

For kidney acylase, the order of susceptibility was But > ClAc > Prp > Pen > Ac > Hex > For (Table 1), indicating that the rate was maximized with n=3 in a series of H-$(CH_2)_n$-CO-. Interestingly, the formyl was quite insusceptible toward kidney acylase in contrast to its high susceptibility toward mold acylase. Similar result was also observed by Fones and Lee.[3] These results show that mold and kidney acylases have different substrate-preferences in molecular size of acyl group.

Shimohigashi et al.[4] reported that electronegative property of acyl group can be estimated by the chemical shift of amide proton of acyl-L-phenylalanine in ^{1}H NMR. The order of the extent of electronegativity was found to be ClAc > For > Ac > Prp ≈ But ≈ Pen ≈ Hex. Although the molecular size of the chloroacetyl is almost equal to that of the propionyl, the susceptibility of these groups were apparently different,

Table 1. Relative Hydrolytic Rate of *N*-Acyl-L-phenylalanines by Acylases[a]

Substrate	Mold acylase[b]		Kidney acylase[b]
Acyl-L-Phe-OH	Optimum pH	Relative hydrolytic rate	Relative hydrolytic rate
For-L-Phe-OH	6.0	3.6	0.19
Ac-L-Phe-OH	7.5	1.0	1.0
ClAc-L-Phe-OH	6.2	1.5	3.3
Prp-L-Phe-OH	7.5	0.46	1.7
But-L-Phe-OH	7.5	0.31	3.7
Pen-L-Phe-OH	7.5	0.24	1.3
Hex-L-Phe-OH	7.5	0.03	0.23
Eoc-L-Phe-OH	7.0	0.004	0.09

a)Substrate conc., 10 mM; Used pH, optimum pH for mold acylase, pH 7.0 for acylase I. b) Enzyme concentrations varied depending on the susceptibility of each acyl derivative.

†Present address: S. K.: Department of Chemistry, College of National Sciences, Pusan National University, Pusan, Korea; and N. I.: Kurume Institute of Technology, Kurume 830.

namely, ClAc>Prp toward both acylases. This means that the electronic state of amide bond in the substrate might be an important rate-determining factor in the hydrolysis and a higher acidity of amide proton seems to be favorable for rapid hydrolysis. However, for kidney acylase, the butyryl was hydrolyzed with almost the same rate as the chloroacetyl. This result clearly indicates that kidney acylase has a much more restricted substrate specificity of molecular size of acyl group than that of its electronegative property. For mold acylase, both factors of molecular size and electronegativity appear equally important, since the formyl, which is fairly electronegative, was hydrolyzed more easily than the chloroacetyl.

The usefulness of the formyl group for resolution was demonstrated by resolving For-DL-Orn(Z)-OH. After complete hydrolysis by mold acylase, H-L-Orn(Z)-OH and For-D-Orn(Z)-OH were separated by extraction in a high yield, and the formyl of For-D-Orn(Z)-OH was selectively removed under the mild condition of treatment with *p*-toluenesulfonic acid without cleaving the Z group. The resolved L- or D-Orn(Z)-OH can be used as an important starting block for constructing bioactive peptides and their analogs containing these optically active nonproteinous amino acid. Owing to a high resolution yield and easy preparation of formyl amino acids, the formyl should be one of the acyl groups which are the candidates for an efficient resolution process using the most common mold acylase.

Experimental

Amino acids were determined with a Hitachi amino acid analyzer KLA-5. Mold acylase and acylase I were purchased from Kyowa Hakko Kogyo Co., Ltd. (Tokyo, Japan) and Tokyo Kasei Kogyo Co., Ltd. (Tokyo, Japan), respectively, and used without further purification.

Synthesis of Compounds. Acylamino acid derivatives of L-Phe were prepared according to the literatures: For,[6] Ac,[7] ClAc,[7] Prp,[8] But,[8] Pen,[9] Hex,[8] Boc,[10] and Z-L-Phe-OH.[11] Eoc-L-Phe-OH was prepared essentially with the same method described for Z-L-Phe-OH[11] using ethoxycarbonyl chloride; yield of DCHA salt, 89%; mp 146—147 °C, $[\alpha]_D^{20}$ +36.5° (*c* 2, EtOH).

Determination of Optimum pH. To a solution of acyl-L-amino acid (0.02 mmol) and 0.1 M NaOH (0.2 ml) (1 M=1 mol dm^{-3}) in a 2-ml flask were added 1/7 M sodium barbital buffer (1 ml) with a specified pH, 1/40 M $CoCl_2$ (0.1 ml), and an aqueous enzyme solution (0.2 ml). The amount of enzymes was varied depending on the susceptibility of the acyl group toward the particular enzyme. The solution was made up to 2.0 ml with water. The reaction mixture was incubated at 38 °C, an aliquot being withdrawn after 1 h. Appearance of L-amino acid was determined with an amino acid analyzer: column, 0.6×10 cm; buffer, standard 0.2 M sodium citrate at pH 4.25. The amount of L-amino acid produced was calculated on the basis of the color value determined for a corresponding authentic amino acid with the analyzer.

Determination of Relative Hydrolytic Rate of Acylamino Acids by Acylases. A mixture of an acyl-L-amino acid (0.02 mmol), 0.1 M NaOH (0.2 ml), 1.7 M sodium barbital buffer (1 ml) with optimum pH of each substrate for mold acylase or with pH 7.0 for acylase I, 1/40 M $CoCl_2$ (0.1 ml) and an aqueous enzyme solution (0.2 ml) was made up to 2.0 ml with water. The rate of hydrolysis at 38 °C was followed by the analyzer under the conditions described above. The hydrolysis of substrates followed zero-order kinetics within experimental error. The relative hydrolytic rate to that of Ac-L-Phe-OH was calculated (Table 1).

Resolution of For-DL-Orn(Z)-OH by Mold Acylase. H-L-Orn(Z)-OH: For-DL-Orn(Z)-OH[12] (0.74 g, 2.5 mmol) was dissolved in aqueous triethylamine, the pH being adjusted to 7.4 (optimum pH). To the solution were added acylase (16 mg), 1/40 M $CoCl_2$ (12.5 ml), and water. After the solution (250 ml) had been left to stand at 38 °C for 7 days, the precipitate formed was collected and washed with water. Combined filtrates were evaporated to a small volume. Aqueous formic acid was added to adjust the pH to 5. Separated oily product was extracted with EtOAc. The extract was used for the preparation of For-D-Orn(Z)-OH. The aqueous layer was loaded on a column (1.7×10 cm) of Dowex 50×8 (H^+ form) to elute with 2 M aqueous ammonia (60 ml). The eluate was evaporated to dryness and the residue was recrystallized from water-EtOH; yield; 0.32 g (97%); mp 244—246 °C (decomp); $[\alpha]_D^{20}$ +19.2° (*c* 2, 5 M HCl). Reported values, mp 246—248 °C (decomp); $[\alpha]_D^{20}$ +18.9° (5 M HCl).[5]

For-D-Orn(Z)-OH: The extract obtained above was dried over Na_2SO_4 and evaporated. The residual solid was recrystallized from EtOAc-ether; yield, 0.33 g (88%); mp 66—70 °C (decomp); $[\alpha]_D^{20}$ −15.6° (*c* 2, EtOH).

H-D-Orn(Z)-OH: To a solution of For-D-Orn(Z)-OH (0.34 mmol) in a mixture of dioxane (9 ml) and water (1 ml) was added TosOH·H_2O (0.37 mmol). After being left at 50 °C for 9 h, aqueous triethylamine was added to adjust the pH to 7. The solution was evaporated to dryness, and the residual solid was recrystallized from water-EtOH; yield, 88%; mp 246—248 °C; $[\alpha]_D^{20}$ −17.7° (*c* 2, 5 M HCl). Reported value of the L-isomer, $[\alpha]_D^{20}$ +18.9° (5 M HCl).[5]

Strong Solvent and pH Dependence in the Photolysis of Diphenylmethanimine

Angelo G. GIUMANINI,* Giancarlo VERARDO, and Marco POIANA
Department of Chemistry, University of Udine, I-33100 Udine, Italy
(Received December 16, 1986)

Synopsis. Benzophenone imine photolysis shows a strong product solvent and pH dependence: Diphenylmethane is by far the dominating outcome in methanol.

Although a relatively large amount of work has been done on *N*-substituted imines of the general type R′-CH=NR″, the rarity itself of known imines of the type RCH=NH has prevented a wide study of their photochemical behavior. Previous works, nevertheless, have reported the photolytic outcome of diphenylmethanimine (**1**) in isopropyl alcohol.[1]

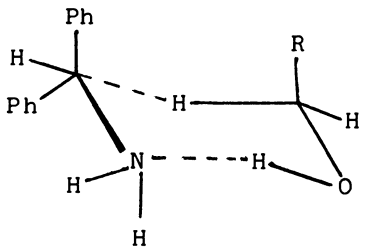
Experimental

Diphenylmethanimine (**1**) was prepared according to a described procedure.[2] The hydrochloride of **1** (**2**) was obtained by precipitating **1** from an ether solution with dry gaseous hydrogen chloride: The IR spectrum ruled out the presence of ketonic impurities. All other chemicals were obtained from commercial sources and conveniently purified before use.

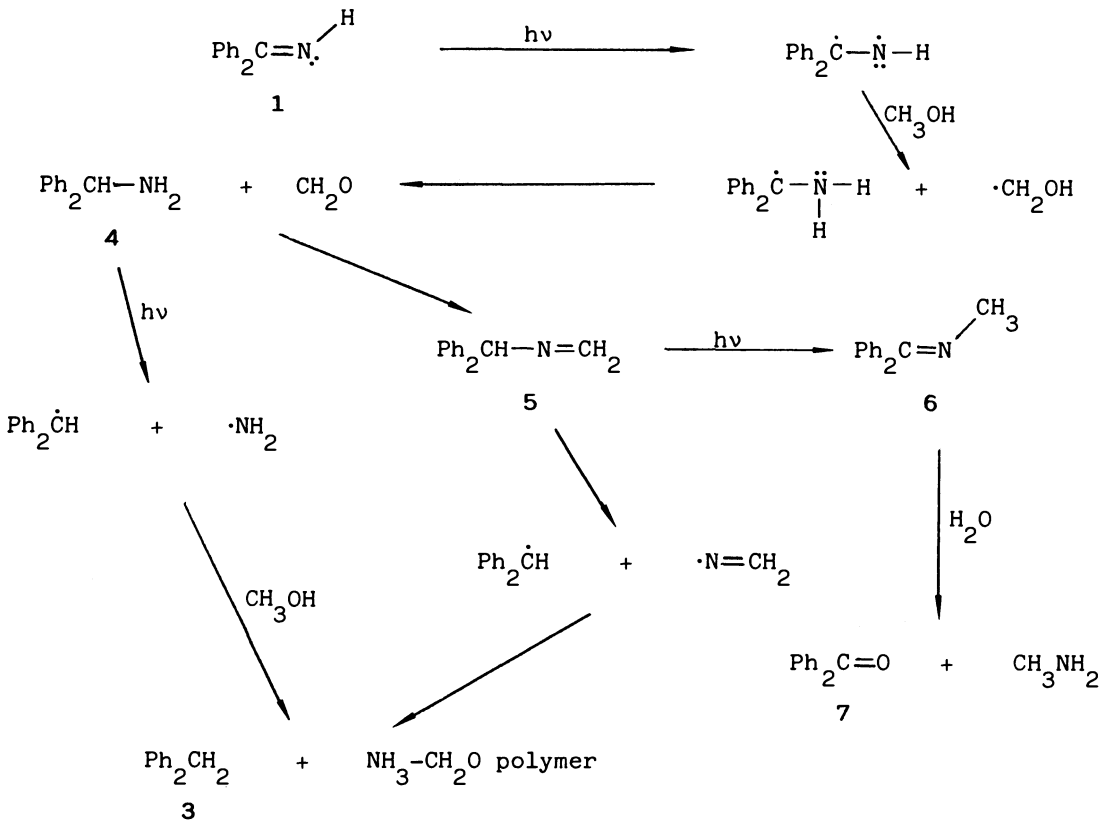
The yields of diphenylmethane (**3**) were determined by GC with a Carlo Erba HRGC Fractovap 4160 gas chromatograph equipped with an FID using a fused silica capillary column (FFAP, 25 m) by the internal standard (naphtalene) method using a calibration factor. The GC peak for **3** was found homogeneous under the whole area by capillary GC-MS analysis (Finnigan 1020 quadrupole mass spectrometer equipped with gas chromatograph and automatic data retrieval). IR spectrum (recorded with a JASCO DS-702G spectrometer) and ^{1}H NMR spectrum (recorded with a Bruker WP 80 SY spectrometer) of separated **3** were in agreement with those of a pure specimen.

Results and Discussion

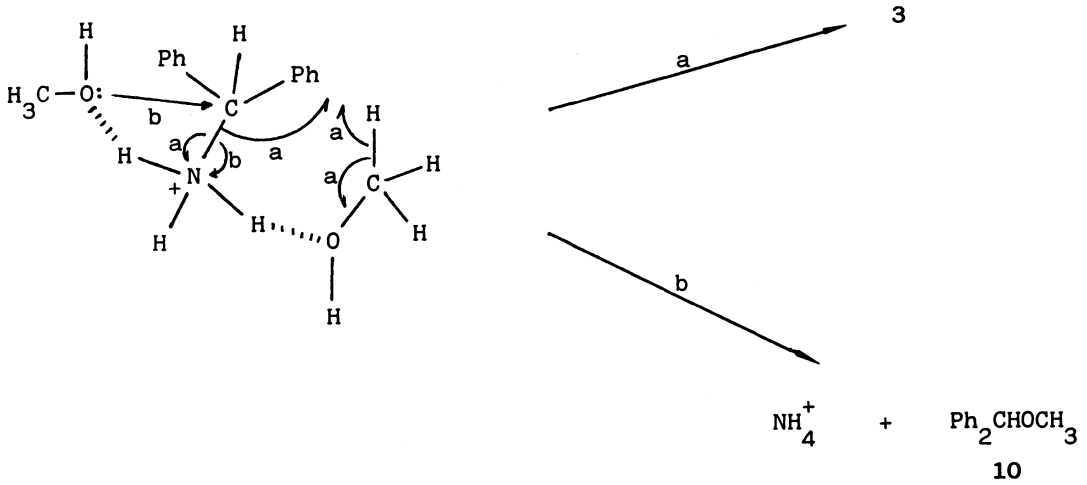
We have irradiated **1** with a Hanovia High Pressure lamp (350 W, 48 h) in methanol solution: The outcome was dramatically different, the sole product retaining the benzhydrylidene moiety being diphenylmethane (**3**), separated in 91.6% yield (GC yield:



8a R=H; **8b** R=CH_3



Scheme 1.



95%). This result indicates a strong solvent effect on product outcome. Since the donor property of hydrogen atoms is considered superior for isopropyl alcohol and the initial abstracting center should be the electronically excited imine's nitrogen atom interacting with the alcohol's tertiary hydrogen, this solvent dependence might be ascribed either to longer reaction times or to a true solvent effect. In fact, shorter reaction times did not change significantly the fate of **1**, only depressing the actual amount transformed.[3] This is an indication that any necessary intermediate in presence of methanol rapidly goes on to **3**. The obvious intermediacy of the reduction product benzhydrylamine[1] (**4**) requires the closer association of the solvent reactive molecule perhaps due to the limited steric hindrance, which allows the prompt capture of the separate fragments before recombination in the solvent cage, as in Scheme 1.

Amine **4** in methanol did photolyze[1b] to hydrocarbon **3**. This ruled out the occurrence of the possible intermediate **5**, as the obligatory passage to **3**: **4** would rather photolyze to isomeric **6**, a minor product eventually reacting with water to yield benzophenone (**7**) also present in traces. The action of light on **4** in methanol can actually be visualized as the interaction of hydrogen bonded tight adduct **8a**. 1,3-Interaction between one of the methyl groups of isopropyl alcohol would make the complex (or transition state) less tight allowing recombination or simply not favoring complete dissociation. In keeping with this rationale, photolysis of **1** in ethanol yielded a good amount (48%, 8 h) of **3**, but photolysis in xylene did not at all. In diethyl ether, capable of a similar but weaker association, adduct **8** again showed poor donor properties toward any eventual (but undetected) **4** (16% **3**, 24 h). Triethylamine, in keeping with this rationale, gave an yield of **3** (20%, 12 h), intermediate between ether and ethanol. When the hydrochloride of **1**, namely **2**, was used in the photolysis in methanol the reactivity pattern as resulting from product composition was deeply affected. The production of **3** was strongly depressed (0.56%, 4 h) and the retention of nitrogen in the molecular structure was favored. Alongside amine **4** (64%), monomethylation products of both the imine **1** and the amine **4** at the nitrogen center were present. They were probably generated by reaction with formed formaldehyde, followed by subsequent reduction induced by some photochemical process. Amine **4** as well as any nitrogen containing species is expected to be largely protonated under the photolysis conditions. Excitation of methanol solvated benzhydrylammonium cation has an additional neutral breakdown alternative, where one charged particle is generated, i.e., the diphenylmethyl cation (**9**) which is immediately captured by a molecule of methanol to eventually produce the observed ether **10**.

The role of apparently dimeric products as well as their precise identification are presently under study in our laboratory.

This work is partially supported by an Italian Ministry of Education Grant for university research in the year 1986.

3) It was reported[1b] that **1** gives 53% conversion of **1**: Less than 0.5% diphenylmethane (**3**) was produced. At the same time our conversion was about the same, but by far the largest product was **3**.

Crystal Structure and Molecular Structure of Neutral Nickel Bis(5,6-dihydro-1,4-dithiin-2,3-dithiolate), Ni(dddt)$_2$

Hyernjoo KIM,* Akiko KOBAYASHI, Yukiyoshi SASAKI, Reizo KATO,† and Hayao KOBAYASHI†

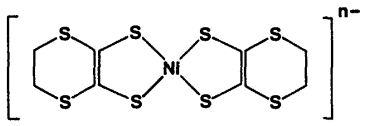
†Department of Chemistry, Faculty of Science, Toho University, Funabashi, Chiba 274
(Received June 1, 1987)

Synopsis. Neutral species of multi-sulfur 1,2-dithiolene complex, Ni(dddt)$_2$ (dddt=5,6-dihydro-1,4-dithiin-2,3-dithiolate), was synthesized and the crystal structure has been determined. Crystals are monoclinic, space group $P2_1/c$, with Z=4, a=18.350(10), b=4.672(1), c=20.326(12) Å, β=125.56(3)°, V=1417(1) Å^3. The structure was solved by the Patterson method, and refined by a block-diagonal least-squares method to R=0.081 for 1316 unique reflections. Two independent molecules of Ni(dddt)$_2$ are stacked along the b-axis separately, with interplanar distances of 3.76 Å and 3.74 Å, respectively.

Recent discoveries of the molecular conductors containing metal 1,2-dithiolene complexes have promoted to synthesize new inorganic conductors. In these compounds, the conduction pathways are formed by the overlapping of the ligand-centered π-system (predominantly the sulfur orbitals) and not principally of the metal orbitals.[1] The transverse intermolecular S··S contacts in the metal-dmit complex (dmit=2-thioxo-1,3-dithiole-4,5-dithiolate) suggest the probability of the multi-dimensional molecular conductors.[2]

Recently, we have synthesized M(dddt)$_2$, which is a multi-sulfur 1,2-dithiolene complex as M(dmit)$_2$ and also has ethylene moieties in the outer sides of the ligand as well-known BEDT-TTF (BEDT-TTF=bis-(ethylenedithio)tetrathiafulvalene; In M(dddt)$_2$, the central C=C double bond of BEDT-TTF is replaced by the transition metal). Unlike the case of planar M(dmit)$_2$, steric effect of the ethylene groups of M(dddt)$_2$ will prevent the face-to-face overlapping of the molecules and will enhance the two-dimensional (2-D) molecular contacts to produce the 2-D conductors similar to the BEDT-TTF compounds.

In this paper, we report the molecular and crystal structure of neutral Ni(dddt)$_2$ determined by X-ray analysis.



[Ni(dddt)$_2$]$^{n-}$

Experimental

(n-Bu$_4$N)[Ni(dddt)$_2$] was prepared following the method discribed by Kato et al.[3] The black powder of neutral Ni(dddt)$_2$ was prepared by I_2-oxidation of (n-Bu$_4$N)-[Ni(dddt)$_2$]. Black, needle-type single crystal was obtained during the process of recrystallization from benzene.

Crystal data are as follows: Ni(dddt)$_2$, $NiC_8H_8S_8$, F.W.=419.39, monoclinic, $P2_1/c$, a=18.350(10), b=4.672(1), c=20.326(12) Å, β=125.56(3)°, V=1417(1) Å^3, Z=4, d_c=1.97 g cm^{-3}, μ(Mo $K\alpha$)=24.8 cm^{-1}, crystal dimension=0.5 mm×0.08 mm×0.03 mm. X-Ray diffraction data were collected on a Rigaku AFC-6 automated four-circle diffractometer using graphite-monochromated Mo $K\alpha$ radiation (λ=0.71069 Å) and by the 2θ-ω scan technique. The three standard reflections were monitored every 100 reflections, and their intensities showed a good stability. A total of 3713 reflections in the range of 2θ<50° were collected. The intensity data were made for Lorentz and polarization corrections and not for absorption. The 1316 independent reflections with $|F_o|>3\sigma(|F_o|)$ were used for structure analysis. The structure was solved by the heavy atom method and refined by a block-diagonal least-squares method. The hydrogen coordinates were calculated and were included in the final cycles. The weighting scheme $w=(0.001+0.0045|F_o|^2)^{-1}$ for $|F_o|<15.0$ and $(\sigma(|F_o|)^2+0.0045|F_o|^2)^{-1}$ for $|F_o|\geqq 15.0$ was employed. Anisotropic thermal parameters were adopted for Ni, S, and C atoms, and the isotropic temperature factors of H atoms were fixed to 4.0 Å^2. The final R and R_w values are 0.081 and 0.108, respectively. The atomic scattering factors were adopted from International Tables for X-Ray Crystallography.[4] All the calculations were performed on HITAC M-680H computer at the Computer Center of the University of Tokyo, using the program UNICS III.[5]

Results and Discussion

The atomic coordinates are listed in Table 1. The bond distances and angles are shown in Fig. 1. The crystal structure is shown in Fig. 2. The molecules of Ni(dddt)$_2$ are on the center of symmetry. The unit cell contains four Ni(dddt)$_2$ molecules, and the half of

$B_{eq}=(4/3)(B_{11}a^2+B_{22}b^2+B_{33}c^2+B_{12}ab\cos\gamma+B_{13}ac\cos\beta+B_{23}bc\cos\alpha)$

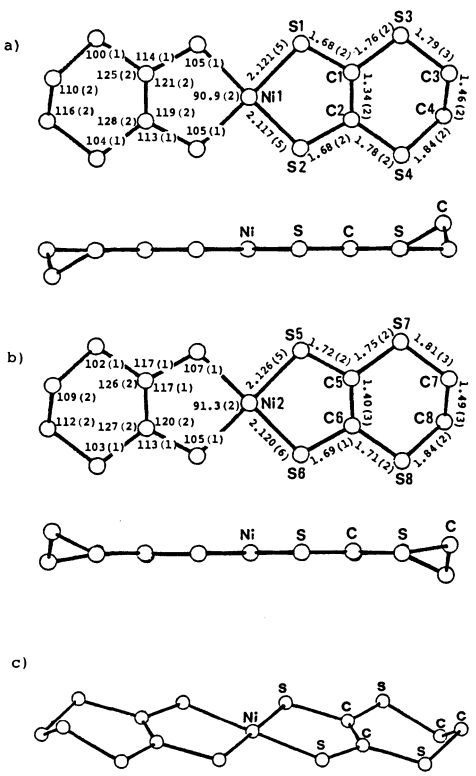

Fig. 1. Molecular structure, bond distances (l/Å) and bond angles (ϕ/°) of Ni(dddt)$_2$; a) molecule-A, b) molecule-B, and c) the conformation of terminal ethylene groups.

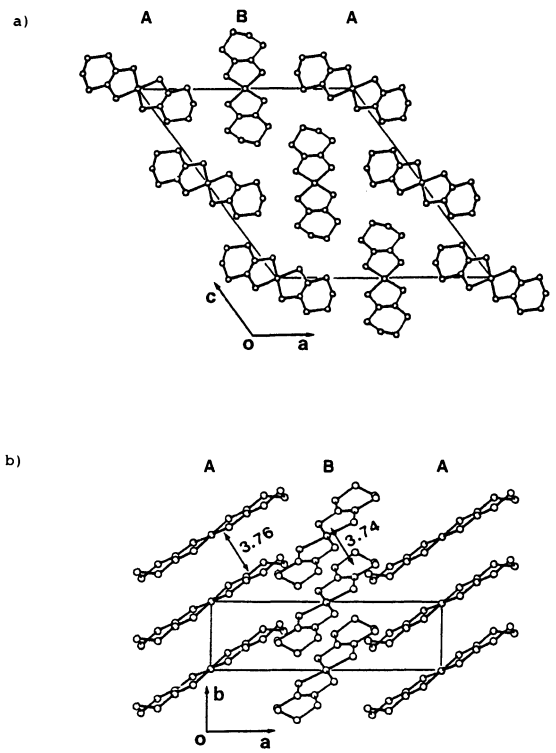

Fig. 2. Crystal structure of Ni(dddt)$_2$; a) projection along the b-axis, b) projection along the c-axis and the interplanar distances (l/Å).

molecule-A and the half of molecule-B are crystallographically independent. The Ni-S bond distance of Ni(dddt)$_2$ is 2.119(5) Å in molecule-A and 2.123(6) Å in molecule-B, which are shorter than 2.148(2) Å in $[Ni(dddt)_2]^{-1}$ anion[6] and are very close to those of other monoanionic nickel dithiolene complexes. Except the terminal ethylene groups, the planarity of molecule-A is better than that of molecule-B. The deviations of atoms from the least-squares planes calculated from all the atoms except the terminal ethylene groups are within 0.01 Å (molecule-A) and 0.04 Å (molecule-B). The equations of the least-squares planes and the deviations of all the atoms are listed in Table 2. Neutral molecule of Ni(dddt)$_2$, as well as $[Ni(dddt)_2]^{-1}$ anion of $(Et_4N)[Ni(dddt)_2]$,[6] has an inversion center, and the conformation of terminal ethylene groups of each side of a molecule is different from that of BEDT-TTF molecules which have pseudo-D_{2h} symmetry. The conformation of terminal ethylene groups of neutral Ni(dddt)$_2$ is shown in Fig. 1.

The molecule-A and molecule-B are arranged separately to form the independent uniform stacks along the b-axis. As for the crystal of neutral BEDT-TTF, we found a dimer structure composed by two neutral BEDT-TTF molecules.[7] But in both cases of neutral Ni(dddt)$_2$ and neutral Ni(dmit)$_2$,[8] they form uniform stacks. Within the stacks of Ni(dddt)$_2$, the Ni-Ni distance is given by the lattice constant of the b-axis, 4.672 Å. The interplanar distances are 3.76 Å in the stacks of molecule-A, and 3.74 Å in those of molecule-B. There is no short intermolecular S··S contact (<3.70 Å) within a stack, and between molecules of adjacent stacks along the c-axis.

The amplitudes of LUMO (lowest unoccupied molecular orbital) were calculated as to $[Ni(dddt)_2]^{-1}$ anion by means of the extended Hückel approximation, with the parameters adopted from Ref. 9, and are shown in Fig. 3. In $[Ni(dmit)_2]^{-1}$, the amplitudes of the "outer sulfur atoms" in the five-membered heteroring are about one-fifth as small as those of the "inner sulfur atoms,"[1] but in $[Ni(dddt)_2]^{-1}$ half as small as those of the "inner sulfur atoms." In M(dmit)$_2$, the side-by-side interactions are not so strong owing to the small amplitude on the "outer sulfur atoms" and the symmetry of LUMO. In BEDT-TTF, the amplitudes of HOMO (highest occupied molecular orbital) on the

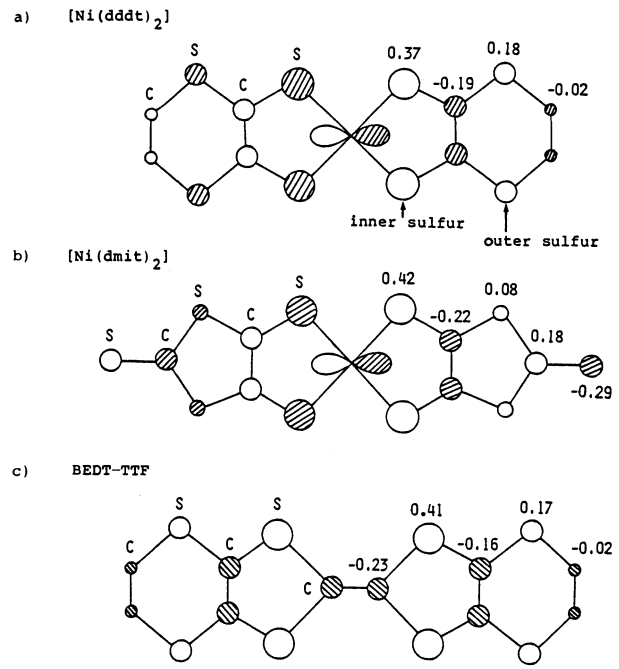

Fig. 3. Schematic drawing of a) LUMO of $Ni(dddt)_2$, b) LUMO of $Ni(dmit)_2$[1] and c) HOMO of BEDT-TTF.[10]

"outer sulfur atoms" are about 40% of those of the "inner sulfur atoms" (Fig. 3). Thus the side-by-side arrangement of $M(dddt)_2$ will be supposed to be sufficient for the realization of the 2-D molecular interaction similar in BEDT-TTF.

Both BEDT-TTF and $M(dddt)_2$ are approximately the same size and both of the molecules seem to have a tendency to form a 2-D layered type structure with close S··S contacts. As mentioned above, however, as for $M(dmit)_2$, we found that the side-by-side interactions by S atoms were weaker than those expected at first, and $M(dmit)_2$ had a tendency to form 1-D system.[1] This discrepancy is originated from the difference in the symmetries of HOMO of BEDT-TTF and LUMO of $M(dmit)_2$, from which the conduction bands are formed. Further, both $M(dddt)_2$ and $M(dmit)_2$ contain tetrathio-substituted ethylene moieties, and have the same type of delocalized π-MO. So that $M(dddt)_2$ is considered to be an intermediate between $M(dmit)_2$ and BEDT-TTF from the electronic and molecular structural points of view. At the same time, it should be recalled that the redox behavior is a very important factor in the systhesis of the molecular conductors. The most prominent difference between $[Ni(dddt)_2]^{-1}$ and $[Ni(dmit)_2]^{-1}$ is their redox behavior. $[Ni(dmit)_2]^{-1}$ is much more easily reduced to the dianion than $[Ni(dddt)_2]^{-1}$.[3] Therefore, further careful works will be required to examine the ability of formation of conducting complex of $[Ni(dddt)_2]$.

The coordinates of the hydrogen atoms, the anisotropic thermal parameters of the Ni, S, and C atoms, and the F_o—F_c tables have been deposited as a Document No. 8783 at the Office of the Editor of Bull. Chem. Soc. Jpn.

Counter Ion Effect on the ^{13}C NMR Paramagnetic Relaxation Rate of Water-Methanol or Water-Dimethyl Sulfoxide Mixed Solvent with Ni(II) Solute

Kanya KOBAYASHI, Masatoki YOKOI,* and Eiji KUBOTA
Department of Chemistry, Faculty of Science, Shinshu University, Asahi, Matsumoto 390
(Received June 4, 1987)

Synopsis. The paramagnetic-salt induced ^{13}C spin-lattice relaxation rate of solvents methanol and dimethyl sulfoxide was measured for $Ni(ClO_4)_2$, $NiSO_4$, and NiBDS (BDS: *m*-benzenedisulfonate) solutions in 50 wt.% mixture of each of the solvents and water. Relatively small relaxation rates were found for the solutions containing $NiSO_4$. This fact is ascribed to the exclusion of some solvent molecules from the first coordination shell of Ni^{2+} due to the coordination of SO_4^{2-} to Ni^{2+}.

In our previous paper[1] we have reported the ^{13}C spin-lattice relaxation rate, $1/T_1$, of some alcohol and DMSO molecules in their mixtures with water containing $Ni(ClO_4)_2$. From the data obtained, a conclusion of preferential solvation to Ni^{2+} ion was drawn. In this analysis, ClO_4^- anion was assumed not to coordinate to Ni^{2+} ion directly, and the first coordination sites to be saturated with water and/or solvent molecules. It has been established that in water and DMSO $Ni(ClO_4)_2$ exists as a hexasolvated cation and a non-coordinated ClO_4^- anion.[2,3] An interesting problem arises when an apparent Ni^{2+}-anion interaction exists. If an anion coordinates to Ni^{2+} directly and replaces some solvent molecules in the first coordination shell where the paramagnetic effect is most predominant, then observed $1/T_1$ is expected to decrease. Sulfate anion-cation interaction in solutions has been investigated by NMR,[4-6] Raman spectra,[7] and conductance[8,9] measurements, etc., and solvent-anion mixed ligand complex formation has been considered to explain these results. In this note the anion effect on the coordination of solvent to Ni^{2+} is investigated by measuring the paramagnetic-ion induced spin-lattice relaxation rate of ^{13}C of methanol and DMSO molecules in their mixtures with water containing $NiSO_4$ or NiBDS (BDS: *m*-benzenedisulfonate). These relaxation rates were compared with those of $Ni(ClO_4)_2$ solutions. Since $NiSO_4$ is not sufficiently soluble in neat solvents, its effect was studied in 50 wt.% aqueous mixtures. NiBDS was chosen for comparison with SO_4^{2-} because it has a divalent anion and has enough solubility in both neat solvent and 50 wt.% aqueous mixtures.

Experimental

The preparation of nickel perchlorate is described in Ref. 1. Commercially-available reagent-grade nickel sulfate was recrystallized from water and dried at room temperature. The water content of the salt was determined as 6 moles per mole of the salt by a total cation analysis using a cation-exchange column. The preparation of NiBDS was based closely on that outlined for CuBDS in Ref. 10. The water content of recrystallized NiBDS was 6 moles per mole of the salt. Methanol and DMSO solvents were both reagent grade and were used without further purification. NMR spectra were recorded on a JEOL FX-90Q FT NMR spectrometer by using the standard inversion-recovery technique at 35 °C. The error in the measurement of T_1 was less than 5%.

Results and Discussion

The observed spin-lattice relaxation rate of solvent nuclei in paramagnetic solution will be a sum of two major contributions:

$$\frac{1}{T_1} = \frac{X_M}{T_{1M}} + \frac{(1-X_M)}{T_{1B}} , \quad (1)$$

where the first term is for the electron-nuclear relaxation in the first coordination shell and the second term is the diamagnetic relaxation rate. $1/T_{1M}$ and $1/T_{1B}$ are the relaxation rates of the nuclei of the solvent molecules in the first coordination shell and those in the bulk, respectively. X_M denotes the fraction of the coordinated solvent molecules in the first coordination shell, and is expressed as

$$X_M = n\frac{C_i}{C_s} , \quad (2)$$

where C_i and C_s are the molar concentrations of the ion and the solvent molecule, respectively, and n is the number of coordinated solvent molecules. For the solution of $Ni(ClO_4)_2$ in neat solvent, Ni^{2+} is assumed to be surrounded by six solvent molecules. $1/T_{1M}$ can be obtained as the slope of plots of observed $1/T_1$ against X_M at low concentrations of Ni^{2+} ion. The $1/T_{1M}$ values thus obtained are 230 s^{-1} for methanol and 110 s^{-1} for DMSO. If $1/T_{1M}$ is assumed not to

change when water or anion occupies several of the six coordinate sites of Ni^{2+}, the number of coordinated solvent molecules is obtained from the slope of plots of $1/T_1$ against $C_i/(C_s \cdot T_{1M})$ at low Ni^{2+} concentrations. In Figs. 1 and 2, the $1/T_1$ values of $Ni(ClO_4)_2$ and NiBDS are plotted as a function of X_M in methanol and DMSO, respectively. In both the figures, the plots appear to fall on a common straight line. The same

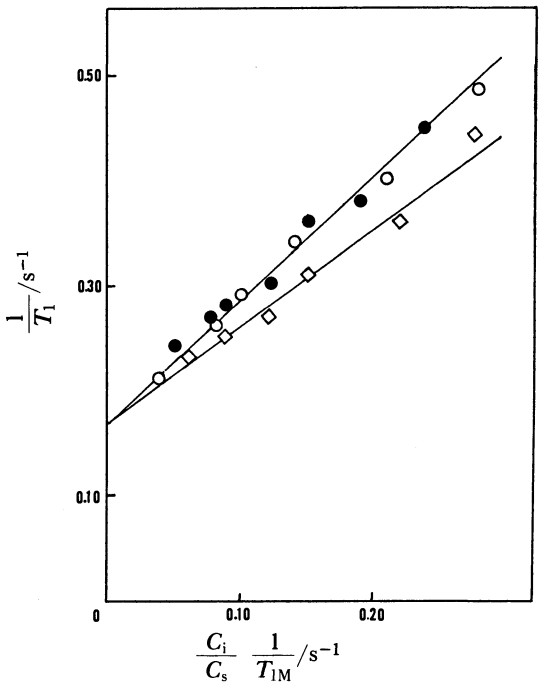

Fig. 4. Plots of ^{13}C spin-lattice relaxation rate versus $C_i/(C_s \cdot T_{1M})$ in water-DMSO system. ○: $Ni(ClO_4)_2$, ●: NiBDS, ◇: $NiSO_4$.

mention can be made for the aqueous methanol and aqueous DMSO systems. In Figs. 3 and 4, the $1/T_1$ values in 50 wt.% aqueous methanol and DMSO, respectively, are plotted versus $C_i/(C_s \cdot T_{1M})$. In both the figures, the plots for $Ni(ClO_4)_2$ and NiBDS appear to fall on their respective common straight lines. Thus for the NiBDS solutions, the possibility that BDS^{2-} replaces the solvent molecules in the first coordination shell may be considered negligible as with ClO_4^- in both neat and aqueous mixtures. The number, n, of the solvent molerules locating in the inner shell of Ni^{2+} is obtained as the slope of the plots shown in Figs. 3 and 4. For 50 wt.% methanol n=1.4 and for 50 wt.% DMSO n=1.1. Since the n values expected from the overall solvent composition are 2.2 and 1.1, respectively, the Ni^{2+} ion is solvated preferentially by water in 50 wt.% methanol, while no preferential solvation is found in 50 wt.% DMSO. On the other hand, in the case of $NiSO_4$, the downward deviation from the plots of $Ni(ClO_4)_2$ is apparent in both the aqueous mixtures. The deviation may be ascribed to the replacement of some solvent molecules by SO_4^{2-} anion in the inner shell of Ni^{2+} ion. The difference in the values between $Ni(ClO_4)_2$ and $NiSO_4$ is 0.3 for water-methanol and 0.2 for water-DMSO, so about 0.3 methanol or 0.2 DMSO molecule is considered to be replaced by SO_4^{2-} in forming the inner shell complex. If SO_4^{2-} anion could replace not only nonaqueous solvent molecules but also water molecules, SO_4^{2-} anion would replace more than 0.3 or 0.2 solvent molecule (nonaqueous or water) in the inner shell. Bechtold et al.[6] studied the Ni(II)-SO_4^{2-} interaction by ^{17}O NMR in aqueous solution. According to their results, $Ni(H_2O)_6^{2+}$ is the most predominant species, which occupies about 90% of the total Ni species at temperatures near 35 °C. The pres-

ent work has given a still higher percentage of the inner-shell complex containing SO_4^{2-}. The addition of nonaqueous solvent may enhance the coordination of SO_4^{2-} anion to Ni^{2+} ion directly. These tendencies are also found in $Al_2(SO_4)_3$-water-nonaqeous solvent systems from ^{27}Al NMR spectra.[4,5] Sulfate anion is a compact divalent anion, while BDS^{2-} is of much larger size and its minus charge is localized to some extent on the functional group. The difference in size and charge distribution would be one of proper explanations for the marked difference in behavior between SO_4^{2-} and BDS^{2-}. Hallada and Atkinson[8] reported a conductance work on MnBDS and $MnSO_4$ in aqueous methanol. The ion association constants evaluated from conductance data of $MnSO_4$ are much larger than those of MnBDS throughout in the solvent composition range studied. Similar results were obtained with systems of $CuSO_4$ and CuBDS in aqueous dioxane.[9] The difference between the ion association constants of the sulfate and the BDS salt may be ascribed to the feasibility of the inner shell coordination of sulfate anion.

The present work was partially supported by a Grant-in-Aid for Science Research No. 62540459 from the Ministry of Education, Science and Culture.

The Solubilization Equilibrium of 7-Ethoxycoumarins in Ionic Micelles

Tetsuo MORIYA
Electrotechnical Laboratory, 1-1-4 Umezono, Tsukuba, Ibaraki 305
(Received June 5, 1987)

Synopsis. The solubilization behavior of 7-ethoxycoumarin (7EC) and 7-ethoxy-4-methylcoumarin (7E4MC) in aqueous micellar solutions of sodium dodecyl sulfate (SDS) and hexadecyltrimethylammonium chloride (HDTC) was studied by fluorescence spectroscopy. The equilibrium constants for the binding of the fluorophores into micelles and their fluorescence yields in the micellar phase were determined.

Several authors[1,2] have studied the characteristics of micelles and vesicles formed of surfactants or phospholipids using hydroxy- and aminocoumarins as the pH indicator, since the absorption spectra of these compounds, when bound to the molecular aggregations, sensitively change reflecting the shift of acid-base equilibria. Recently, it has been revealed that 7-ethoxycoumarins are also solubilized into SDS micelles in aqueous solutions, and their fluorescence is greatly reduced above the critical micelle concentration (cmc) whereas the absorption spectra show little observable change.[3] Since the microenvironment around electronically excited molecules is detectable by means of fluorescence measurements, the fluorescence-probing technique is complementary to the absorption measurement that detects ground-state molecules. The fluorescence method using the coumarin derivatives is advantageous over the absorption method reported, because the latter must use buffer solutions or acids for the control of pH;[1,2] this introduces an inevitable complexity such as the problem of ionic-strength change into the analysis of data. Although several aromatic fluorescent probes have already been proposed,[4,5] heterocyclic compounds such as coumarins are very different from those in regard to interactions with the surroundings, and have interesting solubilization properties for anionic and cationic micelles.

Experimental

High-purity grade reagents of 7-ethoxycoumarin (7EC) and 7-ethoxy-4-methylcoumarin (7E4MC) were obtained from Molecular Probes Inc. and used without further purification. Sodium dodecyl sulfate (SDS, Wako) was of biochemical grade. Hexadecyltrimethylammonium chloride (HDTC, Wako) was treated with charcoal in ethanol, recrystallized, and then washed with ether. Sodium chloride (Kanto) was of special grade. Water was permeated and distilled.

The UV absorption spectra were obtained on a Hitachi 323 spectrophotometer and measurements of the fluorescence spectra and fluorescence yields were made on a Hitachi MPF 4 spectrofluorometer with an S-5 type photomultiplier tube. The temperature of the sample cuvette was thermostated with circulating water from a constant-temperature bath (25±0.1 °C). The wavelengths of excitation light were chosen to be 325 nm for 7EC and 322 nm for 7E4MC, which nearly coincided with their absorption maxima in various solutions; there was no disturbing absorption of surfactants or salts at these wavelengths. The dependence of the absorption spectra on the surfactant concentration was small, while that of the fluorescence spectra was so large that the whole spectrum of the fluorescence was carefully recorded under various conditions. The concentration of 7EC and 7E4MC in the sample solution was $4—5\times10^{-5}$ mol dm^{-3}.

Results

Fluorescence properties of 7-ethoxycoumarin derivatives in simple aqueous solutions have been fully investigated.[6,7] When 7EC or 7E4MC was dissolved in the aqueous SDS solution with a concentration higher than cmc,[8] the absorption spectra were changed slightly from those in the absence of SDS with a peak position red-shifted by ≈1.5 nm and with a peak value of molar extinction coefficient decreased by a few percent. On the other hand, the fluorescence behavior strongly depended on the SDS concentration. When SDS was added to the solution, the fluorescence intensity began to decrease drastically as soon as the cmc of SDS was reached and tended to be constant at higher SDS concentrations than 0.025 mol dm^{-3} for both 7EC and 7E4MC, while the peak position of a fluorescence band blue-shifted by ≈4 nm maintaining the spectral shape.

7-Ethoxycoumarins were also solubilized into cationic micelles such as hexadecyltrimethylammonium chloride (HDTC). The peak shifts of absorption and fluorescence spectra at 0.025 mol dm^{-3} HDTC were similar to those in the SDS solution. The HDTC solution, however, showed an even larger variation in the fluorescence intensity than the SDS solution. Figure 1

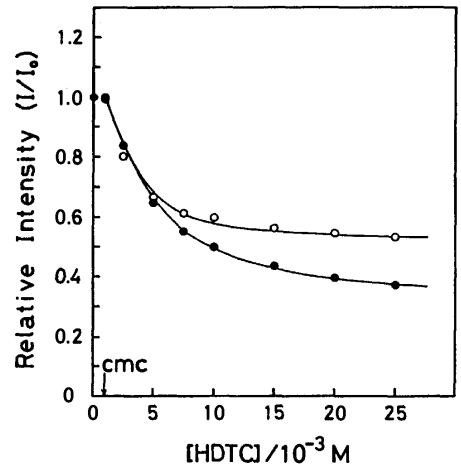

Fig. 1. Plots of the relative fluorescence intensity, I/I_0, vs. the concentration of HDTC at 25 °C. 7EC (●); 7E4MC (○). Solid lines are the theoretical curve predicted by Eq. 3; the aggregation number, n, is assumed to be 80.

presents a plot of the relative fluorescence intensity, I/I_0 vs. [HDTC], where I and I_0 are the fluorescence intensities in the presence and in the absence of HDTC. Since the cmc of HDTC is smaller than the cmc of SDS by about one order of magnitude,[8] a decrease in the fluorescence intensity by the addition of HDTC begins at a lower concentration of the surfactant. The fluorescence intensity tended to be constant for [HDTC]>0.025 mol dm^{-3}.

Since ionic surfactants have their counterions, the fluorescence-quenching phenomena due to various inorganic ions in the solution must be taken into account.[9] The quenching effect for 7EC and 7E4MC due to Na^+ and Cl^-, being the counterions of SDS and HDTC, was negligible in a simple aqueous solution.[6] When NaCl was added to SDS micellar solutions, the fluorescence of 7EC and 7E4MC decreased slightly (≈3% at [NaCl]=0.1 mol dm^{-3}). Considering that micellar parameters such as the aggregation number (n) or the degree of ionization (α) are delicately influenced by the addition of salts, this small change in the fluorescence intensity is, possibly, not due to quenching by Na^+ and Cl^- but due to a micellar parameter change. In either case, the fluorescence quenching by Na^+ and Cl^-, if any, is negligibly small because the employed concentration of SDS and HDTC is not more than 0.025 mol dm^{-3}. This is consistent with the result obtained by phosphorescence measurements of naphthalene in frozen SDS micelles with varying amounts of added NaCl, up to ≈0.2 mol dm^{-3}.[10]

Discussion

To analyze the fluorescence property of 7EC and 7E4MC in aqueous micellar solutions, we may adopt the two-reactive-state model for the light-emitting processes in the aqueous and micellar phases

$$\mathrm{N} \xrightarrow{\varepsilon} \overset{*}{\mathrm{N}} \xrightarrow{\eta} \mathrm{N} + h\nu \qquad (1)$$

$$\mathrm{D}_n\mathrm{N} \xrightarrow{\varepsilon'} \mathrm{D}_n^*\mathrm{N} \xrightarrow{\eta'} \mathrm{D}_n\mathrm{N} + h\nu'$$

and

$$\mathrm{D}_n + \mathrm{N} \underset{}{\overset{K}{\rightleftharpoons}} \mathrm{D}_n\mathrm{N}. \qquad (2)$$

Here, D_n represents the micelle formed of n surfactants. N and D_nN are the fluorescent molecules in the aqueous phase and in the micellar phase, respectively; $\overset{*}{N}$ and D_n^*N are their excited states generated on light illumination. $h\nu$ and $h\nu'$ are the emitted light quanta from the respective molecular species. ε and ε' are the molar extinction coefficients of N and D_nN, respectively. η and η' are the quantum efficiencies for the radiative transition of $\overset{*}{N}$ and D_n^*N to N and D_nN, respectively. Assuming that the fluorophore in an aqueous phase is in equilibrium with the fluorophore in a micelle (Eq. 2), the equilibrium constant is given by $K=[D_nN]/[D_n][N]$. The total concentration of the fluorescent molecule is defined by $C_N=[N]+[D_nN]$, and the total density of the micellar particle is given by $C_M=[D_n]+[D_nN]$. C_N is fixed throughout the measurement. C_M depends on both the added content of a surfactant (C_S) and n as $C_M=(C_S-\mathrm{cmc})/n$ above cmc.

When N and D_nN are excited by the light at a fixed wavelength, the generation rates of $\overset{*}{N}$ and D_n^*N are in proportion to ε and ε' at the wavelength, respectively. Then, the relative fluorescence intensity, I/I_0, is given by

$$\frac{I}{I_0} = \frac{1+(\eta'/\eta)(\varepsilon'/\varepsilon)K[\mathrm{D}_n]}{1+(\varepsilon'/\varepsilon)K[\mathrm{D}_n]}, \qquad (3)$$

where $[D_n]$ is obtained from the definitions of K, C_N, and C_M:

$$[\mathrm{D}_n]=[\{(1+KC_N-KC_M)^2+4KC_M\}^{1/2} - (1+KC_N-KC_M)]/2K. \qquad (4)$$

The detailed derivation of this result appeared in Ref. 3. For usual measurements, C_N was fixed around 4—5×10^{-5} M. If $1+KC_N \ll KC_M$, Eq. 4 predicts $[D_n]\approx C_M-C_N$. In contract, a full expression of Eq. 4 must be employed at small C_M in order to estimate $[D_n]$. Based on Eqs. 3 and 4, the theoretically predicted variation in I/I_0 can be compared with the fluorescence data obtained.

Since almost all fluorophores become solubilized into the micelle at $C_S \gg$ cmc, the ε' values of 7EC and 7E4MC in the micelle can be experimentally determined. ε'/ε for SDS at the excitation wavelength was 0.972 (7EC) and 0.965 (7E4MC); for HDTC, 0.953 (7EC) and 0.960 (7E4MC). The aggregation number of micelles was taken from independent experiments as n=62 (SDS)[11,12] and n=80 (HDTC).[13] Then, unknown parameters to be fixed in Eqs. 3 and 4 are η'/η, K, and cmc, which can be determined by a best-fit analysis for the data points. The theoretical curve derived is plotted with a thin solid line in Fig. 1. The theory explained very well the entire behavior of the data; the determined parameters are cited in Table 1. The inaccuracy in K is brought about by the n value employed; the scattering of n from experiment to experiment was about 10%, so that the same order of uncertainty exists in K, whereas η'/η and cmc are insensitive to such inaccuracy.

For the SDS micelle, K differs by an order of magnitude between 7EC and 7E4MC (Table 1), in spite of the small difference in the molecular structure. A larger K means a stronger binding of the fluorophore to the micelle. The change in the substituent group from hydrogen to methyl at the 4-position is supposed to

Table 1. Ratios of the Quantum Efficiency, η'/η, Equilibrium Constants, K, and Critical Micelle Concentrations, cmc, in Aqueous SDS and HDTC Solutions at 25 °C

Surfactant	Substance	η'/η	K / mol^{-1} dm^3	cmc / mol dm^{-3}
SDS[a]	7EC	0.74	2.8×10^4	6.0×10^{-3}
	7E4MC	0.88	2.6×10^5	
HDTC	7EC	0.30	3.5×10^4	1.0×10^{-3}
	7E4MC	0.51	9.0×10^4	

a) The values for SDS are taken from Ref. 3.

induce such a large influence on the solubilization, probably due to a hydrophobic interaction of the methyl group. This difference in K between 7EC and 7E4MC becomes rather smaller for the HDTC micelle (Table 1). SDS and HDTC form typical anionic and cationic micelles, having different carbon numbers in the alkyl chain (C_{12} and C_{16}, respectively). Although K will be affected by the charge on the micelle, the surfactant length, the solubilization site within the micelle, etc., it seems that the substituent effect would overcome the other factors to induce the higher K value for 7E4MC in both SDS and HDTC solutions.

The fluorescence intensity change in the mixed solvent of water-ethanol was examined as a function of the water content in a previous study.[3] If the quantum efficiency, η', appearing in Eq. 3 is essentially determined by the polarity around the site in the micelle occupied by the fluorophore, this result is conveniently related with η'/η in Table 1. When the fluorescence-yield in the mixed solvent is compared with η'/η=0.74 (7EC) and 0.88 (7E4MC) obtained in the SDS solution, the polarity of the solubilized site is revealed to resemble the polarity in the mixed solvent of 30 wt% aqueous ethanol, having the effective dielectric constant, D_{eff}=62±1 (25 °C).[14] No meaningful difference has been found between the D_{eff} values of 7EC and 7E4MC within an experimental error. Considering that the dielectric constant of a typical aliphatic compound is about 2 and that of water is 78.5, the solubilized fluorophore seems to be located not in the core region of the micelle but near its surface and may be partly exposed to the aqueous atmosphere around the micelle (in the palisade layer). This effective polarity ($D_{eff}\approx$62) is larger than 16—49 obtained for benzene derivatives and naphthalene.[5] Since 7-ethoxycoumarins are heterocyclic compounds with oxygen in the ring and in the substituent, and are insoluble in nonpolar solvents, their affinity to the alkyl chain in micelles is thought to be lower than aromatic compounds. Therefore, it is natural that the solubilized 7EC and 7E4MC is embedded at a shallower site than aromatic molecules.

For the HDTC micelle, D_{eff}=39±1 (25 °C). As is mentioned earlier, the aliphatic chain of HDTC is longer than SDS, so the flexibility of this longer chain may make easier the movement of the fluorophore toward the micelle core. Then, the location of the fluorophore in the HDTC micelle becomes deeper than in the SDS micelle. The interior of n-alkyltrimethylammonium bromide micelles is more polar than sodium n-alkyl sulfate micelles with the same n.[15] If the SDS (n=12) micelle is compared with the HDTC (n=16) micelle as in this work, the interior of the HDTC micelle may be less polar due to the longer alkyl chain of HDTC. By the use of naphthalene as a fluorescent molecule, it has been shown that its solubilized site within n-alkyltrimethylammonium bromide micelles is not close to the polar region of the micelle surface and, also, does not reside in the micelle core.[15] These results are consistent with D_{eff} for the HDTC micelle which is an intermediate value between D of pure water and typical aliphatic solvents. The K value difference between 7EC and 7E4MC may decrease in the HDTC micelle compared with that in the SDS micelle because the hydrophobic interaction of a methyl substituent is supposed to be less effective to distinguish 7EC from 7E4MC at a deeper part in the micelle.

The Crystal Structure of a Charge-Transfer Complex of Tetrakis(methylthio)-tetrathiafulvalenium Dibromoiodate, TMT-TTF · IBr_2

Kazumasa HONDA,* Midori GOTO, Masayasu KURAHASHI, Hiroyuki ANZAI,† Madoka TOKUMOTO,† and Takehiko ISHIGURO†

National Chemical Laboratory for Industry, Tsukuba, Ibaraki 305

†Electrotechnical Laboratory, Tsukuba, Ibaraki 305

(Received July 23, 1987)

Synopsis. The crystal structure of the title complex, a semiconductor, has been determined. The space group is $P2_1/n$, with a=8.207(3), b=11.537(4), and c=21.804(12) Å, β=91.88(5)°, and Z=4. The donor cations assume dimer structures with short intermolecular S··· S contacts of 3.43, 3.53, and 3.60 Å.

It has been proposed that two-dimensional electrical properties of a superconductor β-(BEDT-TTF)$_2I_3$ (BEDT-TTF=bis(ethylenedithio)tetrathiafulvalene) and its related compounds derive from the four outer sulfur atoms attached to the tetrathiafulvalene (TTF) skeleton.[1] Tetrakis(alkylthio)-substituted TTFs have also similar sulfur atoms, and the influence of alkyl groups on the dimensionality of the electronic systems has been investigated.[2] Wu and Zheng[3] reported of an X-ray analysis of the title compound, but no precise crystal structure was given. Here the present authors report its crystal structure and electrical properties.

Experimental

Black plates of TMT-TTF · IBr_2 were obtained by electrochemical oxidation[4] (at a constant current of 1 μA under nitrogen stream at 20 °C) from a 60 ml chlorobenzene solution containing 0.13 mmol of TMT-TTF and 0.26 mmol of tetrabutylammonium dibromoiodate. The electrical resistivity of single crystal was measured along the a axis by the four-probe method.

A crystal, with 10 faces, of 0.34×0.50×0.23 mm was mounted on a Rigaku AFC-4 four-circle diffractometer. Intensity data were collected at room temperature by using Mo $K\alpha$ radiation (λ=0.71069 Å, graphite monochromated) in the 2θ-ω scan mode with a scan width of $\Delta\omega$=(1.0+0.5 tan θ)° and a scan speed of 4.0° min^{-1} over the range of 2θ values from 3° up to 55°. Intensities of 5084 reflections were collected and 3147 independent reflections ($|F_o| \geqq 3\sigma(|F_o|)$) were obtained. Three standards measured every 50 reflections showed no significant X-ray damage or crystal decay. Absorption correction following the method of Busing and Levy[5] was applied.

Crystal Data. $C_{10}H_{12}S_8 \cdot IBr_2$: FW=675.43; monoclinic; space group $P2_1/n$; a=8.207(3), b=11.537(4), and c=21.804(12) Å and β=91.88(5)°; U=2063(2) Å^3; D_c=2.17 g cm^{-3} for Z=4; μ(Mo $K\alpha$)=64.4 cm^{-1}.

Structure Analysis and Refinement. The structure was solved by use of the Monte Carlo method.[6] Anisotropic thermal parameters were assumed for all non-hydrogen atoms. Hydrogen atoms were not located. The final full-matrix least-squares refinement for 3147 independent reflections led to the R value of 0.069 and the R_w value of 0.083 in conjunction with the weighting scheme of w=(0.011 $|F_o|^2-|F_o|+20)^{-1}$. The atomic scattering factors were taken from the International Tables for X-Ray Crystallography (1974). All the computations were carried out on a FACOM M-380 computer using the *UNICS* III system.[7]

Results and Discussion

The final atomic parameters of the non-hydrogen atoms are given in Table 1.[8] Wu and Zheng[3] reported that the crystal belongs to the monoclinic space group of $P2_1$ with a=8.21, b=11.56, and c=21.85 Å and β=92.1°. The lattice constants of our result are similar to those reported but the space group is different. Figure 1 shows the projection along the a axis. The

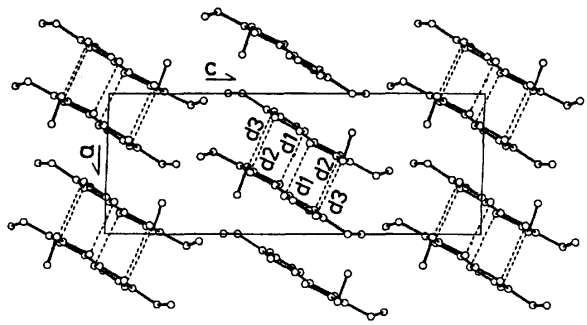

Fig. 2. The packing motif of TMT-TTF molecules projected along the b axis. The S···S contacts of $d1$=3.431(4) (S(1)···S(6)), $d2$=3.529(4) (S(2)···S(5)), and $d3$=3.598(4) (S(3)···S(8)) shorter than the van der Waals distance of 3.7 Å are indicated.

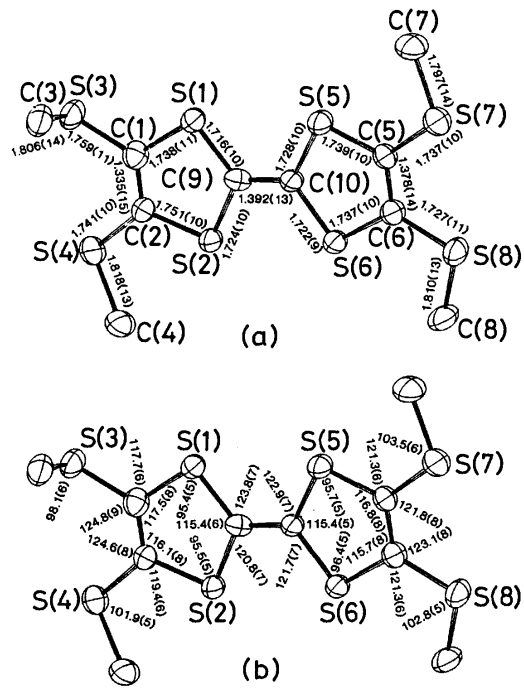

Fig. 3. Molecular structure[12] of TMT-TTF with the numbering system for the non-hydrogen atoms and the bond distances(Å) (a), and the bond angles(°) (b). Thermal ellipsoids are drawn at 40% probability. Bond distances of IBr_2 molecule are 2.698(2) Å and 2.711(2) Å for I-Br(1) and I-Br(2), respectively, and Br(1)-I-Br(2) bond angle is 178.5(1)°.

unit cell contains four TMT-TTF's and four IBr_2's in general positions. They are stacked in segregated columns extending along the a axis. In the case of other TMT-TTF complexes such as (TMT-TTF)-(HCBD)[10] (HCBD=hexacyanobutadiene) and (TMT-TTF)$I_{2.47}$[11] complexes, the stacks of donor TMT-TTF's and those of acceptors form alternate sheets, and the donor TMT-TTF's are aligned almost in the direction of their long axis. In the present complex the crystal does not possess such sheet structures, and the long axis of the TMT-TTF molecule in the position of (x, y, z) is almost perpendicular to those of the molecules in the position of ($1/2-x$, $1/2+y$, $1/2-z$). The extended terminal methyl groups and the anion columns prevent the intermolecular interaction between the donor columns. As shown in Fig. 2, the donor molecules TMT-TTF's face each other to assume a dimeric structure around the inversion center at (0, 1/2, 0) and (1/2, 0, 1/2), with close S···S contacts of $d1$=3.431(4) (S(1)···S(6)), $d2$=3.529(4) (S(2)···S(5)), and $d3$=3.598(4) (S(3)···S(8)), all shorter than the van der Waals distance of 3.7 Å. No close S···S contacts are found between the adjacent dimers. The bond lengths and angles of the TMT-TTF molecule are shown in Fig. 3 along with the molecular structure. It has been demonstrated that central C=C bond lengths of TTF analogues in charge-transfer complexes correlate well to the degree of charge transfer (ρ).[13] Katayama et al.[10] estimated the ρ value of the (TMT-TTF)(HCBD) complex to be 0.4—0.6 since the central C=C bond length of 1.382(6) Å is almost the mean value between 1.348(5) Å of the neutral TMT-TTF molecule ($\rho\equiv0$) and 1.438(12) Å of the (TMT-TTF)(AsF_6) complex ($\rho\equiv1$). In the present complex, however, the corresponding C=C length of 1.392(13) Å (C(9)-C(10)) is shorter than the value for the complete charge transfer (ρ=1) as expected from the chemical stoichiometry of donor TMT-TTF and acceptor IBr_2^-. This discrepancy is a subject for future study. The TMT-TTF molecule moiety without the terminal four methyl groups is nearly planar but slightly folded, possibly due to the dimer formation; the inner S···S contacts are shorter than the outer S···S contacts as mentioned above. The best-fit planes defined by S(1), S(2), S(3), S(4), C(1), and C(2) (plane I), S(5), S(6), S(7), S(8), C(5), and C(6) (plane II), and S(1), S(2), S(5), S(6), C(9), and C(10) (plane III) have dihedral angles of 175.2(1)° for planes I and III and 177.7(1)° for planes II and III. The three methyl groups (C(4), C(7), and C(8)) are not so much displaced from the molecular plane and the other one (C(3)) is almost normal to the plane, which may block the interdimer interactions.

The temperature dependence of the electrical resistivity along the a axis was also measured. The resistivity increases as temperature decreases, which indicates that this crystal is semiconductive ($\rho=1\times10^7$ Ω cm and activation energy E=5.0 eV at room temperature). The observed high resistivity and large activation energy are consistent with the poor interdimer interactions.

The authors thank Dr. Kin-ichi Tsunoda of National Chemical Laboratory for Industry for his elaborating the manuscript.

A BEDT-TTF Complex Including a Magnetic Anion, $(BEDT\text{-}TTF)_3(MnCl_4)_2$

Takehiko MORI* and Hiroo INOKUCHI
Institute for Molecular Science, Okazaki 444
(Received July 30, 1987)

Synopsis. The title charge-transfer complex is prepared and its crystal structure is determined (BEDT-TTF: bis(ethylenedithio)tetrathiafulvalene). One third of the BEDT-TTF molecules is incorporated in the anion sheet, and holds about 2+ charge. The remaining donors form a conducting sheet with a similar arrangement to β'-$(BEDT\text{-}TTF)_2ICl_2$.

In the past few years, a considerable number of BEDT-TTF complexes have been prepared and their structural and physical properties have been investigated. It has been observed that some of these BEDT-TTF complexes exhibit superconductivity; actually these BEDT-TTF superconductors form a most important family of organic superconductors. On the other hand, though magnetic impurity had been believed to be very harmful to superconductivity, the discoveries of the ternary rhodium borides and the Chevrel series compounds including lanthanoids demonstrated the coexistence of superconductivity and long-range magnetic order.[1] The recent investigations of the high-temperature oxide superconductors show that the substitution of magnetic lanthanides is no more harmful to the Y-Ba-Cu-O series of superconductors.[2] Very little investigation has been, however, done concerning the interrelation of localized spins and conduction electrons in organic systems. Thus it is interesting to explore the BEDT-TTF complexes including magnetic anions. In the present paper, we report the preparation and the crystal structure of $(BEDT\text{-}TTF)_3(MnCl_4)_2$, where the anion has a localized spin on Mn^{2+}.

Experimental

Crystals were obtained by electrochemical crystallization of BEDT-TTF in benzonitrile. The electrolyte $(Me_4N)MnCl_3$ (TMMC), which is well-known as a linear-chain antiferromagnet,[3] was prepared by the reaction of $(Me_4N)Cl$ and $MnCl_4 \cdot 4H_2O$ in hot ethanol, and pale pink crystals were recrystallized from ethanol.

Crystal data: $C_{30}H_{24}S_{24}Mn_2Cl_8$, F.W. 1547.46, triclinic, space group $P\bar{1}$, a=9.714(1), b=20.595(2), c=6.802(1) Å, α=89.70(1), β=101.66(1), γ=93.75(1)°, V=1329.8(3) Å^3, Z=1, and D_x=1.932 g cm^{-1}. Intensity data were measured by the θ-2θ scan technique on a Rigaku automated four-circle diffractometer with monochromatized Mo $K\alpha$ radiation. The structure was solved by the Patterson method and the succeeding Fourier syntheses and refined by the block-diagonal least-squares procedure to an R value of 0.033 by using 3479 independent reflections ($|F_o| > 3\sigma(|F_o|)$). Anisotropic thermal parameters were adopted for all non-hydrogen atoms, and the hydrogen atoms were refined isotropically.

Results and Discussion

For the electrolyte of electrochemical crystal growth of organic conductors, tetrabutylammonium salts are usually used because of their high solubilities in organic solvents. However, many tetrabutylammo-

D^+: (BEDT-TTF)$ReO_4(THF)_{0.5}$.[6]

nium salts of halogeno transition metals tend to become oily liquid. Tetraethyl- and tetramethylammonium salts are prepared as solids and can be recrystallized easily,[3] while the solubilities of these salts in organic solvents are generally low. Benzonitrile, which shows moderately high polarizability, can fairly dissolve both BEDT-TTF and these ammonium salts. Then we used the combination of the tetramethylammonium salt and benzonitrile. Nitrobenzene is sometimes applicable for the same purpose.

The atomic coordinates are listed in Table 1.[5] The crystal structure is shown in Fig. 1. The anion consists of discrete tetrahedron, $MnCl_4^{2-}$. In a unit cell, 1.5 donor molecules are crystallographically independent. The donors A present on general positions form an ordinary conducting sheet parallel to the (010) plane. On the other hand, the molecules B on inversion centers are incorporated in the anion sheet. Figure 2 shows the structure of the anion and the donors B sheet.

In order to estimate the positive charge present on the donors, the bond lengths of the TTF skeleton are listed in Table 2. In comparison with the reported

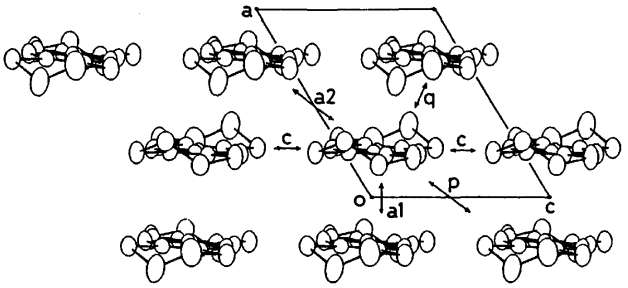

Fig. 3. Arrangement of the donors A in the conducting sheet.

data,[6] the charge on the molecule A is estimated to be about 1+. Therefore, from the neutrality of the crystal, the molecule B must hold 2+ charge. This agrees with the change of the bond lengths; in the B molecule, the central C=C distance is anomalously long, and the C-S distances are very short. This systematic change originates in the symmetry of the highest occupied molecular orbital (HOMO), which has nodes on each C-S bond, and bonding nature concerning to every C=C bond. Because even in the 2+ molecule all bond distances change systematically so as to keep the mmm symmetry of the molecule, it can be concluded that in the energy band there is no overlap between the highest occupied band and the next highest band. This observation justifies the energy band calculation which is done by using the HOMO only.[7] The molecule like B, which holds 2+ charge and incorporated in the anion sheet, has also found in (BEDT-TTF)$_5Hg_3Br_{11}$.[8]

The arrangement of the donors A in the conducting sheet is depicted in Fig. 3. The modes of the intermolecular interactions are analyzed according to the method in Ref. 7 (Table 2). Though there are some overlap between the donors B, these molecules contribute very little to the electron transport, because there is no (or little) conduction electrons. The arrangement of the donors A has close resemblance to that of β'-(BEDT-TTF)$_2ICl_2$.[9,10] Along the a axis the 90° interaction (a1) and the 30° interaction (a2) are repeated alternatingly to form a one-dimensional conducting path where the intermolecular overlap integrals are considerably larger than the other interac-

tions. Thus the resulting energy band structure is essentially the same as that of the β'-salt. A very important difference is the band occupancy: 3/4-filled for the β'-salt and 1/2-filled for the present salt. It is interesting that donor sheets with different electron filling exhibit the same structure.

The electrical resistivity is 0.04 Ωcm at room temperature and activated with an activation energy, 0.04 eV in the temperature range between room temperature and (at least down to) 60 K. Though the temperature dependence is semiconducting, it is surprising that the resistivity is lower than that of the β'-salts (>10 Ωcm), because the simple one-electron band model affords a metallic energy band for the β'-salts, and a semiconducting band for the present complex. The semiconducting resistivities of the β'-salts have been attributed to the electron correlation.[9-11] On the other hand, the comparatively low resistivity and the small activation energy of the present salts suggest that the semiconducting transport is not due to the intrinsic one-electron gap in the energy band but due to the electron correlation, where the charge distribution may be a little deviated from $A_2^+B^{2+}$ to result in a metallic one-electron energy band. Since the conduction mechanism of these salts seems to be dominated by the electron correlation, the simple one-electron picture is not helpful to estimate the magnitude of conductivity.

In a preliminary ESR work, there has been observed a rather wide signal whose peak-to-peak linewidth is as large as 360 G at room temperature.

Synthesis and Structure of *cis*(*O*,*O*),*trans*(*N*,*N*)-Chlorobis-(8-quinolinolato-N^1, O^8)nitrosylruthenium

Yukiko KAMATA, Eiichi MIKI, Reiko HIROTA, Kunihiko MIZUMACHI, and Tatsujiro ISHIMORI*
Department of Chemistry, College of Science, Rikkyo University, Nishi-Ikebukuro, Toshima-ku, Tokyo 171
(Received July 28, 1987)

Synopsis. Molecular structure of the title compound has been determined by the X-ray diffraction. The Cl atom is in cis to the NO group, the O atom of one of the two quinolinolato ligands is in trans to the NO group, and the coordinating N and O atoms of two quinolinolato ligands are in cis(O,O) and trans(N,N) configuration.

It is well-known that a coordinating NO^+ possesses weak σ-donor and strong π-acceptor abilities and its property affects synthesis and reactivity of transition metal nitrosyl complexes.[1,2] Recently, we prepared two geometrical isomers of [RuCl(2mqn)$_2$(NO)] (2mqn=2-methyl-8-quinolinolate ion), determined their structures by the X-ray diffraction, and discussed the trans shortening effect of the NO^+ group.[3] In this paper, we have examined the reaction of hydrous nitrosylruthenium(3+) chloride with 8-quinolinol which can coordinate to metal ion by deprotonation without steric hindrance compared with 2-methyl-8-quinolinol, determined the molecular structure of one of two geometrical isomers of [RuCl(qn)$_2$(NO)] (qn= 8-quinolinolate ion) chromatographically separated from the reaction products, and compared the structure of the [RuCl(qn)$_2$(NO)] with that of [RuCl(2mqn)$_2$-(NO)] having the same geometrical configuration.

Experimental

Preparation. A mixture (270 cm^3) of ethyl alcohol solutions of hydrous nitrosylruthenium(3+) chloride (Ru= 30.8%) (3.1 mmol) and 8-quinolinol (30 mmol) was refluxed for 6.5 h. After the solution had been left overnight at room temperature, it was evaporated up. The dried residue was dissolved in dichloromethane and the red filtrate was added on a silica-gel column (Wakogel C-200, ϕ 4 cm×14 cm). Major bands, the first and second red bands, were eluted with dichloromethane. The effluents were separately dried on a rotary evaporator. Terra rosa (**1**) and maroon (**2**) compounds were obtained from the first and second bands, respectively. Yield: 67%, 0.95 g (based on the starting ruthenium compound) for **1**; and 10%, 0.14 g for **2**. Found for **1**: Ru, 22.5; Cl, 8.2; C, 47.5; H, 2.6; N, 9.2%. Found for **2**: Ru, 22.1; Cl, 7.5; C, 47.8; H, 2.9; N, 9.1%. Calcd for [RuCl(qn)$_2$(NO)] ($RuC_{18}ClH_{12}N_3O_3$): Ru, 22.2; Cl, 7.8; C, 47.5; H, 2.6; N, 9.2%. The UV, IR, and conductivity data of **1** and **2** are as follows; **1**: UV (CH_2Cl_2) 31300 cm^{-1} (sh) (log ε 3.7) and 24880 cm^{-1} (log ε 3.85); IR (Nujol) 1838 cm^{-1} (N-O stretching of the NO group) and 338 cm^{-1} (Ru-Cl stretching); Λ_m(CH_2Cl_2, 5.21×10^{-4} mol dm^{-3}, 25 °C) 5.74×10^{-7} S m^2 mol^{-1}.[4] **2**: UV(CH_2Cl_2) 31300 cm^{-1} (sh) (log ε 3.6) and 24750 cm^{-1} (log ε 3.81); IR (Nujol) 1843 cm^{-1} (N-O stretching of the NO group) and 333 cm^{-1} (Ru-Cl stretching).

An X-Ray Crystallographic Analysis of 1. Although the crystals of **2** suitable for an X-ray structural analysis could not be obtained, the crystals of **1** were prepared by concentrating a dilute dichloromethane-acetonitrile solution. Crystallographic data: [RuCl(C_9H_6NO)$_2$(NO)], RuC_{18}-$ClH_{12}N_3O_3$, F. W.=454.9, monoclinic, space group $P2_1/c$, a=14.386(5), b=7.123(1), c=16.315(5) Å, β=95.31(3)°, V= 1664.5(8) Å^3, graphite monochromatized Mo$K\alpha$ radiation (λ=0.71073 Å), D_x=1.815 Mg m^{-3}, D_m=1.81 Mg m^{-3}, Z=4, μ(Mo$K\alpha$)=11.08 cm^{-1}, crystal dimensions 0.25×0.05×0.48 mm. The diffraction data were measured on a Rigaku AFC-4 automated four-circle diffractometer (the X-Ray Analysis Center of the Institute of Physical and Chemical Research). The intensities were collected by the (ω, ω-2θ) scanning technique in $2\theta \leqq 70°$ at a ω scanning speed, 4° min^{-1}. Independent 2614 reflections with $|F_o| > 3\sigma(|F_o|)$ were used for determining the structure. Three standard reflections were measured after every 100 reflections and no decomposition of the crystal was confirmed during the data collection. The ordinary Lorentz and polarization corrections were applied, but no absorption correction was made. The space group was determined with the observed systematic absences, and the lattice parameters were determined by the least-squares refinement using 18 strong reflections. The structure was solved by the heavy atom method and refined by standard Patterson, Fourier, and block-diagonal least-squares procedures. The final refinements were performed using anisotropic temperature factors for non-hydrogen atoms and isotropic ones for hydrogen atoms. The final R value was

Results and Discussion

The molecular structure of **1** is shown in Fig. 1. The coordination geometry was similar to that of **1** of [RuCl(2mqn)$_2$(NO)] (2mqn=2-methyl-8-quinolinolate ion) (named hereafter **A**) reported previously;[3] the Cl is in cis to the NO, the O atom of one of the two quinolinolato ligands is in trans to the NO, and the N and O atoms of the two quinolinolato ligands are in trans (N,N) and cis (O,O) configuration.

Table 2. Interatomic Distances (l/Å) and Bond Angles (ϕ/°) of the Coordination Sphere for [RuCl(qn)$_2$(NO)] (**1**) (qn=8-Quinolinolate Ion) (Their Estimated Standard Deviations in Parentheses)

Distance (l/Å)	
Ru-Cl	2.369(2)
Ru-N(1)	1.769(5)
N(1)-O(1)	1.120(8)
Ru-N(2)	2.059(4)
Ru-N(3)	2.082(4)
Ru-O(2)	2.029(4)
Ru-O(3)	1.991(4)
Angle (ϕ/°)	
Ru-N(1)-O(1)	175.9(5)
N(2)-Ru-O(2)	82.2(2)
N(3)-Ru-O(3)	80.9(2)
Cl-Ru-N(1)	89.9(2)
Cl-Ru-N(2)	95.7(1)
Cl-Ru-N(3)	88.7(1)
Cl-Ru-O(2)	173.1(1)
Cl-Ru-O(3)	88.4(1)
N(3)-Ru-O(2)	92.0(2)
N(1)-Ru-N(3)	97.9(2)
N(2)-Ru-N(3)	167.1(2)
N(2)-Ru-O(3)	87.1(2)
O(2)-Ru-O(3)	84.9(2)

The bond distances and angles in the coordination sphere are given in Table 2. The RuNO angle, ca. 176°, shows that the NO is formally bound as NO$^+$.[6] The Ru-N(1) and the N(1)-O(1) bond distances were comparable to those in other six-coordinate nitrosylruthenium(3+) complexes.[3,6] The Ru-O(3) bond distance trans to the NO was shorter than the Ru-O(2) bond distance trans to the Cl by 0.038 Å due to the trans shortening effect of the NO$^+$ as was discussed in Refs. 2 and 3. Furthermore, the Ru-O(2) and the Ru-O(3) bond distances of **1** were longer than those of **A** by 0.024 and 0.020 Å, respectively.[3] The phenolic oxygen atom of 2-methyl-8-quinolinolate ion seems to be slightly stronger as a π-donor than that of 8-quinolinolate ion due to electron-donating power of the methyl group. As the NO$^+$ group is a strong π-acceptor, the π-electron densities of the O(3) of **A** more favorably flow into the NO$^+$ through the Ru as compared with those of the O(3) of **1**; the Ru-O(3) bond distance of **1** is expected to be longer than that of **A**. As a chloride ion is considered to be weaker as a π-donor than the phenolic oxygen of the quinolinolate ion, the Ru-O(2) bond distance of **1** is also expected to be longer than that of **A**. The Ru-N(2) and Ru-N(3) bond distances of **1** were shorter than those of **A** by 0.053 and 0.018 Å, respectively because of exclusion of the steric hindrance of the methyl groups. This influence was also found to the bond angles; the Cl-Ru-N(2) and N(1)-Ru-N(3) bond angles of **1** were smaller than those of **A** by ca. 8° and 5°, respectively, while the N(3)-Ru-O(2), N(2)-Ru-N(3), and N(2)-Ru-O(3) bond angles of **1** being larger than those of **A** by 3—6°. The coordination geometry of **1** is close to regular octahedral compared with that of **A**.

The chemical composition of **2** was equal to that of **1**. The IR, visible spectra, and the chromatographic behavior suggest that **2** is geometrically isomeric with **1** as observed for two of the 2-methyl-8-quinolinolato complexes;[3] **2** is in cis(O,O) and cis(N,N) configuration with respect to the two quinolinolato ligands.

The more geometrical isomers of the formula [RuCl(qn)$_2$(NO)] were expected to be isolated because 8-quinolinolate ion can coordinate as bidentate ligand to nitrosylruthenium(3+) group without steric hindrance compared with 2-methyl-8-quinolinolate ion. However, the two geometrical isomers were isolated similarly to the 2-methyl-8-quinolinolato complexes.

The authors wish to express their thanks to Professor Makoto Shima (present: Yokohama National University), Professor Toshio Sakurai (present: Shinshu University), and Miss Kimiko Kobayashi of the Institute of Physical and Chemical Research for providing the X-ray facilities and for assisting the calculations of the structural analysis. The present work was partially supported by a Grant-in-Aid for Scientific Research No. 58470038 from the Ministry of Education, Science and Culture.

(Received July 11, 1987)

Synopsis. The reaction of aromatic amines with benzyltrimethylammonium tribromide in dichloromethane-methanol containing calcium carbonate powder for 0.5 h at room temperature gave bromo-substituted aromatic amines in good yields.

It has recently been shown in our laboratories that quaternary ammonium polyhalides such as benzyltrimethylammonium tribromide (BTMA Br_3) or tetrabutylammonium tribromide (TBA Br_3) are useful brominating agents.[2] In the present paper, we wish to report on a facile synthetic method of bromo-substituted aromatic amines **1** by the use of BTMA Br_3.

Results and Discussion

The reaction of aromatic amines **2** with BTMA Br_3 in dichloromethane-methanol containing calcium carbonate powder for 0.5 h at room temperature gave **1** in good yields. In these cases, the calcium carbonate powder was used in order to neutralize a generating hydrogen bromide; the reaction was remarkably promoted by the presence of methanol, as shown in previous our reports.[2b]

The reagent BTMA Br_3 (stable orange crystals, mp 100—101 °C)[2c] has one merit in that it can be quantitatively treated, compared with liquid bromine, because

a) Yield of isolated product. b) Product was isolated by column chromatography on alumina.

of its solid character. Furthermore, the end point of a reaction can be easily confirmed by a decolorization of the orange-colored solution. The results are summarized in Table 1.

Recently, Berthelot et al. reported that TBA Br_3 is a useful para-selective monobrominating agent for aromatic amines.[3] However, the reaction of aromatic amines with BTMA Br_3 gave polybromo-substituted aromatic amines since BTMA Br_3 is a stronger brominating agent than TBA Br_3.[25] Syntheses of bromomethoxyanilines and bromomethylnitroanilines are usually difficult. Our method easily gave these compounds in good yields.

We believe that the procedure for the bromination of aromatic amines using BTMA Br_3 is a highly useful method owing to its ease, simplicity, mildness of conditions, and good product yields.

Experimental

2,4,6-Tribromoaniline (1-*1*); General procedure: To a solution of aniline (**2-*1***) (0.50 g, 5.37 mmol) in dichloromethane (50 ml)-methanol (20 ml) was added BTMA Br_3 (6.49 g, 16.64 mmol) and calcium carbonate powder (2 g) at room temperature. The mixture was stirred for 30 min until a fading of the orange color took place. The solid calcium carbonate was filtered off, the filtrate was concentrated and to the obtained residue was added water (20 ml). The mixture was extracted with ether (40 ml×4). The ether layer was then dried with magnesium sulfate and evaporated in vacuo to give a residue which was recrystallized from methanol-water (1 : 3) affording **1-*1*** as colorless crystals; yield 1.65 g (93%); Mp 121—123 °C (lit,[4] Mp 119—120 °C).

2,4-Dibromo-6-ethylaniline (1-*5*): Mp 18—20 °C (1 : 3 methanol-water); ^{1}H NMR ($CDCl_3$) δ=1.15 (3H, t, J=7Hz, CH_3), 2.38 (2H, q, J=7Hz, CH_2), 4.10 (2H, s, NH_2), 6.98 (1H, d, J=2Hz, 3-H), and 7.33 (1H, d, J=2Hz, 5-H). Found: C, 34.17; H, 3.09; N, 4.58; Br, 56.97%. Calcd for $C_8H_9NBr_2$: C, 34.44; H, 3.25; N, 5.02; Br, 57.28%.

2,4,6-Tribromo-3-ethylaniline (1-*6*): Mp 68—70 °C (1 : 3 methanol-water); ^{1}H NMR ($CDCl_3$) δ=1.12 (3H, t, J=7 Hz, CH_3), 4.00 (2H, q, J=7 Hz, CH_2), 4.50 (2H, br. s, NH_2), and 7.50 (1H, s, 5-H). Found: C, 26.75; H, 2.45; N, 4.16; Br, 67.09%. Calcd for $C_8H_8NBr_3$: C, 26.85; H, 2.25; N, 3.91; Br, 66.96%.

2,4,6-Tribromo-3-methoxyaniline (1-*15*): Mp 83—84 °C (1 : 3 methanol-water); ^{1}H NMR ($CDCl_3$) δ=3.83 (3H, s, OCH_3), 4.63 (2H, br. s, NH_2), and 7.52 (1H, s, 5-H). Found: C, 23.37; H, 1.99; N, 4.15: Br, 66.46%. Calcd for $C_7H_6NOBr_3$: C, 23.37; H, 1.68; N, 3.89; Br, 66.61%.

2,4,6-Tribromo-3-ethoxyaniline (1-*18*): Mp 93—94 °C (1 : 3 methanol-water), ^{1}H NMR ($CDCl_3$) δ=1.44 (3H, t, J=7 Hz, CH_3), 4.00 (2H, q, J=7 Hz, CH_2), 4.50 (2H, s, NH_2), and 7.50 (1H, s, 5-H). Found: C, 25.64; H, 2.36; N, 3.97; Br, 64.25%. Calcd for $C_8H_8NOBr_3$: C, 25.70; H, 2.16; N, 3.75; Br, 64.12%.

We wish to thank Dr. Mamoru Nakai and Mr. Katsumasa Harada, Ube Laboratory, Ube Industries, Ltd., for the elemental analysis.

(Received July 11, 1987)

Synopsis. The reaction of aromatic amines with benzyltrimethylammonium dichloroiodate(1−) in dichloromethane-methanol in the presence of calcium carbonate powder for several hours at room temperature gave selectively iodo-substituted aromatic amines in good yields.

Recent work in this series has shown that a new reagent, benzyltrimethylammonium dichloroiodate (1−) (BTMA ICl_2), is an excellent iodinating agent to phenols.[2] In the present paper we wish to also report on a selective iodination of aromatic amines **1** by the use of BTMA ICl_2.

Results and Discussion

The reaction of **1** with BTMA ICl_2 in dichloromethane-methanol in the presence of calcium carbonate powder for several hours at room temperature gave iodo-substituted aromatic amines **2** in good yields.

Usually, the reaction of aniline, toluidines and xylidines with calculated amounts of BTMA ICl_2 gave the desirable mono- and diiodo-substituted corresponding aromatic amines. For instance, the reaction of aniline (**1a**) with 1.0 equiv of BTMA ICl_2 gave 4-iodoaniline (**2a**) in 94% yield, and with 2.1 equiv of BTMA ICl_2 gave 2,4-diiodoaniline (**2b**) in 75% yield, respectively. That is, the iodination of these compounds first occurred at the para-position of the amino group and subsequent iodination at the ortho-position.

However, as a limitation of this new iodination method by use of BTMA ICl_2, the reaction was unsuccessfully carried out with less reactive nitroanilines. The results are summarized in Table 1.

We noticed that the presence of methanol markedly facilitated the iodination of **1**. In this case, the main active species which generates I^+ is probably methyl hypoiodite produced from a reaction of BTMA ICl_2 with methanol. The reaction of **1** with the active intermediate methyl hypoiodite must give **2** and methanol, which can be empolyed repeatedly. The generated hydrogen chloride should be neutralized by additional calcium carbonate.

$$PhCH_2(CH_3)_3N^+ICl_2^- + CH_3OH \rightarrow PhCH_2(CH_3)_3N^+Cl^- + CH_3OI + HCl$$
$$\mathbf{1} + CH_3OI \rightarrow \mathbf{2} + CH_3OH$$

Experimental

Benzyltrimethylammonium Dichloroiodate(1−) (BTMA ICl_2): To a black solution of ICl (16.20 g, 0.1 mol) in dichloromethane (200 ml) was added dropwise a solution of benzyltrimethylammonium chloride (18.60 g, 0.1 mol) in water (100 ml) under stirring at room temperature. After the mixture was stirred for 30 min, the dichloromethane layer was separated and dried with magnesium sulfate, and then evaporated in vacuo to give a residue which was recrystallized from dichloromethane-ether (3 : 1) affording BTMA ICl_2 as stable brilliant yellow needles; yield 30.0 g (86%); Mp 125—125 °C. Found: C, 34.51; H, 4.67; N, 4.11%. Calcd for $C_{10}H_{16}NCl_2I$: C, 34.50; H, 4.63; N, 4.03%.

4-Iodoaniline (2a). Typical Procedure: To a solution of aniline (0.50 g, 5.37 mmol) in dichloromethane (50 ml)-methanol (20 ml) was added BTMA ICl_2 (1.87 g, 5.37 mmol) and calcium carbonate (0.7 g). The mixture was stirred for 30 min at room temperature, during which the color of the solution gradually changed from yellow to light brown. Excess calcium carbonate was filtered and filtrate was concentrated; then, to the obtained residue was added a $NaHSO_3$ solution (5%, 20 ml). The mixture was extracted with ether (40 ml×4). The ether layer was dried with $MgSO_4$ and evaporated in vacuo to give **2a** as colorless crystals (from 1 : 3 methanol-water); yield 1.13 g (96%); Mp 66 °C (lit,[3] Mp 67—68 °C).

4,6-Diiodo-2-methylaniline (2d): Mp 80—81 °C (1 : 3 methanol-water); ^1H NMR ($CDCl_3$) δ= 2.20 (3H, s, CH_3), 4.10 (2H, br. s, NH_2), 7.30 (1H, d, J=3 Hz, 3-H), and 7.80 (1H, d, J=3 Hz, 5-H). Found: C, 23.40; H, 1.87; N, 3.69%. Calcd for $C_7H_7NI_2$: C, 23.42; H, 1.97; N, 3.90%.

4-Iodo-2,3-dimethylaniline (2i): Mp 56 °C (1 : 3 methanol-water); ^1H NMR ($CDCl_3$) δ=2.15 (3H, s, 2-CH_3), 3.33 (3H, s, 3-CH_3), 3.59 (2H, s, NH_2), 6.33 (1H, d, J=8 Hz, 6-H), and 7.50 (1H, d, J=8 Hz, 5-H). Found: C, 38.90; H, 3.96; N, 5.59%. Calcd for $C_8H_{10}NI$: C, 38.89; H, 4.08; N, 5.67%.

4,6-Diiodo-2,3-dimethylaniline (2j): Mp 89—90 °C (1 : 3 methanol-water); ^1H NMR ($CDCl_3$) δ= 2.23 (3H, s, 2-CH_3), 2.41 (3H, s, 3-CH_3), 3.94 (2H, br. s, NH_2), and 7.95 (1H, s, 5-H). Found: C, 25.83; H, 2.48; N, 3.85%. Calcd for $C_8H_9NI_2$: C, 25.76; H, 2.43; N, 3.76%.

4-Iodo-2,5-dimethylaniline (2k): Mp 69 °C (1 : 3 methanol-water); ^1H NMR ($CDCl_3$) δ=2.06 (3H, s, 2-CH_3), 2.29 (3H, s, 5-CH_3), 3.55 (2H, s, NH_2), 6.69 (1H, s, 6-H), and 7.44 (1H, s, 3-H). Found: C, 38.96; H, 4.09; N, 5.64%. Calcd for $C_8H_{10}NI$: C, 38.89; H, 4.08; N, 5.67%.

4,6-Diiodo-2,5-dimethylaniline (2l): Mp 105—106 °C (1 : 3 methanol-water); ^1H NMR ($CDCl_3$) δ= 2.25 (3H, s, 2-CH_3), 2.83 (3H, s, 5-CH_3), 4.25 (2H, br. s, NH_2), and 7.52 (1H, s, 3-H). Found: C, 25.82; H, 2.45; N, 3.87%. Calcd for $C_8H_9NI_2$: C, 25.76; H, 2.43; N, 3.76%.

4-Iodo-3,5-dimethylaniline (2m): Mp 112—113 °C (1 : 3 methanol-water); ^1H NMR ($CDCl_3$) δ=2.36 (6H, s, 3 and 5-CH_3), 3.53 (2H, br. s, NH_2), and 6.44 (2H, s, 2 and 6-H). Found: C, 38.99; H, 4.10; N, 5.53%. Calcd for $C_8H_{10}NI$: C, 38.89; H, 4.08; N, 5.67%.

2,4-Diiodo-3,5-dimethylaniline (2n): Mp 95—96 °C (1 : 3 methanol-water); ^1H NMR ($CDCl_3$) δ=2.35 (3H, s, 5-CH_3), 2.80 (3H, s, 3-CH_3), 4.02 (2H, s, NH_2), and 6.50 (1H, s, 6-H). Found: C, 25.83; H, 2.45; N, 3.87%. Calcd for $C_8H_9NI_2$: C,

(Received July 13, 1987)

Synopsis. Asymmetric cyclization of a variety of bromohydrins with base was examined in the presence of an optically active cobalt(salen) type complex. Optically active oxiranes of modest optical purities were obtanied. *erythro*-3-Bromo-2-butanol and *threo*-3-bromo-2-butanol were cyclized similarly, and only *trans*-2,3-dimethyloxirane and *cis*-2,3-dimethyloxirane were obtained, respectively, indicating that the cyclization of bromohydrin proceeds by complete S_N2 type reaction.

An optically active cobalt (salen) type complex, (1*R*,2*R*)-*N*,*N*′-disalicylidene-1,2-cyclohexanediaminatocobalt(II), Co*, whose structure is well-defined as square-planar tetradentate Schiff base complex,[1] has been used as a catalyst for several kinds of asymmetric reaction, such as the kinetic resolution of oxiranes,[1] one-step synthesis of optically active oxiranes from racemic chlorohydrins,[2] asymmetric fixation of carbon dioxide,[3] and others.[4] In the course of our studies on the asymmetric synthesis of optically active oxiranes, we report here our attempts to evaluate the effect of alkyl substituents of bromohydrins on the asymmetric induction, and also to explore the mechanistic feature of the reaction.

Experimental

Measurements. The NMR spectra were taken on a JEOL JNM-PS-100 spectrometer. Optical rotations were determined by means of a Perkin-Elmer model 241 polarimeter. The GLC analyses were carried out with a Hitachi model K-53 or Yanagimoto model G80 Gas Chromatograph equipped with a column containing PEG. IR spectra were measured using a Hitachi model EPI-G3 spectrometer.

Materials. 2-Bromo-1-propanol was prepared from 2-bromopropanoic acid by treating with $SOCl_2$ and then with $LiAlH_4$; bp 58—59 °C/20 mmHg (1 mmHg=133.322 Pa), yield 50%. 1-Bromo-2-propanol was prepared by the $LiAlH_4$ reduction of bromoacetone; bp 50 °C/16 mmHg, yield 15%. 2-Bromo-1-butanol was prepared by the $LiAlH_4$ reduction of 2-bromobutanoyl bromide; bp 65—66 °C/15 mmHg, yield 50%. 1-Bromo-3,3-dimethyl-2-butanol was prepared according to the procedure of Jackman et al.[5] *erythro*-3-Bromo-2-butanol and *threo*-3-bromo-2-butanol were prepared by the method of Bigley et al.[6]

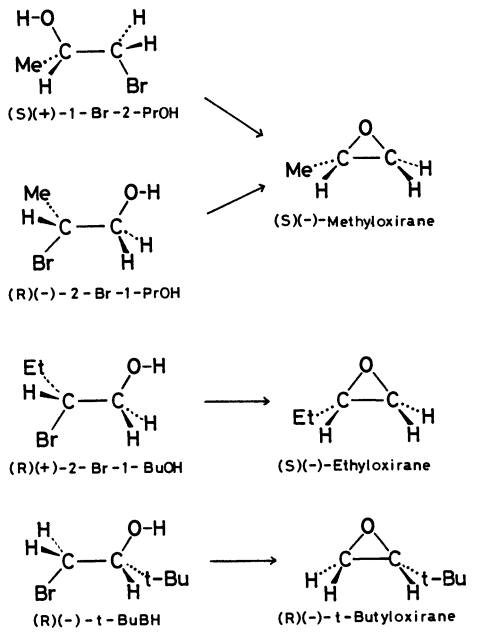
Asymmetric Reaction of Bromohydrins. Catalytic amount of Co* and K_2CO_3 (base) were added into a flask, and dried at 130—150 °C for 3 h in vacuo. To the flask were added the solvent and the substrate under a dry nitrogen atmosphere with stirring. After an appropriate reaction time, the mixture was analyzed by gas chromatography. The oxirane formed and the unreacted bromohydrin were seperated by fractional distillation and the optical activity was measured. The structure of the oxirane was confirmed by GC, IR, and NMR.

The optical purities (e.e.) of oxiranes were evaluated from the following values; $[\alpha]_D$=+12.53° (neat) for optically pure (*R*)(+)-methyloxirane;[7,9] $[\alpha]_D^{16}$=+12.4° for (*R*)-ethyloxirane;[8] $[\alpha]_D^{25}$=−20.4° (neat) and $[\alpha]_D^{25}$=−18.1° (*c* 1.83 benzene) for (*R*)-*t*-butyloxirane;[9] $[\alpha]_D^{25}$=+59.0° for (2*R*,3*R*)-2,3-dimethyloxirane.[11] The expected optical purities (e.e.$_{calcd}$)[2a] of methyloxirane were evaluated from the optical purities of the unreacted substrate by assuming the reaction to proceed by kinetic resolution mechanism : e.e.$_{calcd}$(%)($[\alpha]_D/[\alpha_o]_D$)×{(100−conv.)/conv.}×100; $[\alpha_o]_D$=−14.4° (neat) for (*R*)-(−)-2-bromo-1-propanol.[10]

Results and Discussion

Asymmetric Cyclization of Propylene Bromohydrins. The asymmetric cyclization of 2-bromo-1-propanol and 1-bromo-2-propanol were carried out with K_2CO_3 in the presence of Co*. The results are summarized in Table 1.

Optically active methyloxirane was formed selectively from 2-bromo-1-propanol and 1-bromo-2-propanol. The configuration of methyloxirane, both from the two substrates, was S, which was also the case with the corresponding chlorohydrins.[2a] The optical activity of methyloxirane formed and unreacted substrate show that (*R*)-(−)-2-bromo-1-propanol reacted preferentially to form (*S*)-(−)-methyloxirane by the inversion of asymmetric carbon. In the reaction of 1-bromo-2-propanol, the unreacted substrate could not be recovered and thus the optical rotation was not



Scheme 1.

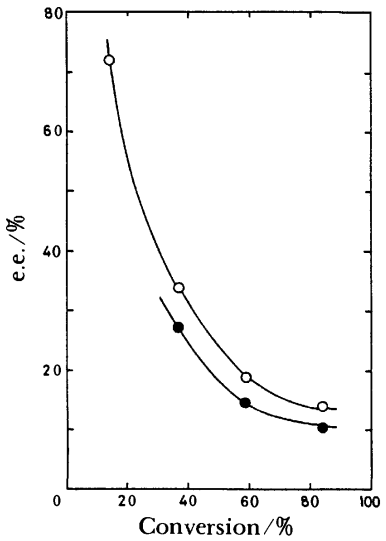

Fig. 1. The relation between e.e. (observed and calculated) of methyloxirane and conversion of 2-bromo-1-propanol. —○— e.e. of methyloxirane calculated from recovered 2-bromo-1-propanol, —●— e.e. of methyloxirane.

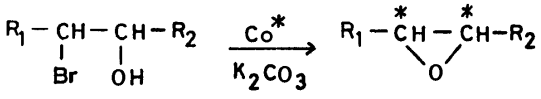
measured. However, the formation of (*S*)-(−)-methyloxirane (Table 1) indicates that (*S*)-(+)-1-bromo-2-propanol is preferentially cyclized because the asymmetric center is not involved in this cyclization reaction.

As the conversion increased, the optical purity of methyloxirane decreased, as shown in Fig. 1, showing that this asymmetric cyclization proceeds by the kinetic resolution. The highest optical yield of isolated methyloxirane was 27.1%, achieved in the reaction of 2-bromo-1-propanol with K_2CO_3 in dioxane at 37% of conversion. Much higher enantioselectivity is expected at the initial stage of this reaction. As the solvent for this asymmetric reaction, dioxane was found to be the best among the solvents examined; 1-propanol and 1,2-dichloroethane were found poor as the solvent, probably because the reaction proceeds significantly even without the asymmetric catalyst in these solvents.

Optical purity of methyloxirane did not vary significantly as reaction temperature was changed (at 40 °C, 21% e.e.; 25 °C, 24%; 5—10 °C, 21—25%); the high enantioselectivity was not observed even at lower temperature.

The observed e.e. values of methyloxirane are lower than the e.e.$_{calcd}$ values. The following explanation might be possible for the above differences between e.e. and e.e.$_{calcd}$; (1) the racemization of the prefered enantiomer of the substrate may occur in the cyclization by the catalysis of cobalt complex, (2) a side reaction with high enantioselectivity may take place in parallel with the above kinetic resolution. As by-products for the reaction, a small amount of propylene carbonate and polyether were confirmed by GC, IR, and NMR.

Asymmetric Cyclization of Some Bromohydrins. The interaction of chiral catalyst and the substrate is crucial for asymmetric induction in the catalytic asymmetric reaction. To evaluate the effect of substituent, a variety of bromohydrins were synthesized and the asymmetric cyclization were carried out with K_2CO_3 (Eq. 1).



(1)

The results are summarized in Table 2. Corresponding oxiranes were formed selectively in every cases. From 2-bromo-1-butanol, (*S*)-(−)-ethyloxirane was formed in 8.9% e.e., which was much lower than that for methyloxirane. The configuration of oxirane formed was S, which was the same as that of methyl-

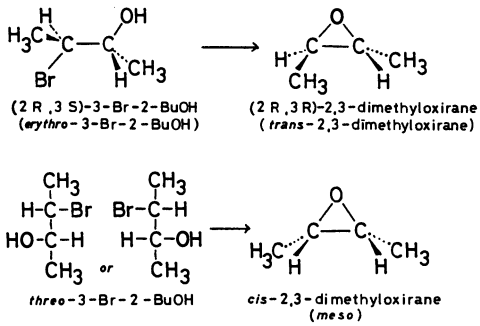
a) Solvent 40 cm^3, 25 °C, 5 days. b) BBH: commercial butylene bromohydrin (1-bromo-2-butanol/2-bromo-1-butanol=4/1), 2-Br-1-BuOH: 2-bromo-1-butanol, *t*-BuBH: 1-bromo-3,3-dimethyl-2-butanol, *erythro*-3-Br-2-BuOH: *erythro*-3-bromo-2-butanol, *threo*-3-Br-2-BuOH: *threo*-3-bromo-2-butanol. c) Molar ratio of K_2CO_3 to substrate (mmol/mmol). d) Diox: dioxane. e) Conversion of substrate. f) Oxirane formed/substrate converted (mmol/mmol). g) Specific rotation of oxirane formed. h) Optical purity of oxirane formed. i) Specific rotation of unreacted substrate recovered. j) Measured in benzene (*c* 13.0).

oxirane. The absolute configuration of 2-bromo-1-butanol is not known but based on the similarity of the reaction with 2-bromo-1-propanol, the absolute configuration of (+)-2-bromo-1-butanol is considered to be R. From 1-bromo-3,3-dimethyl-2-butanol(*t*-BuBH), (*R*)-(−)-*t*-butyloxirane was obtained. The optical purity of *t*-butyloxirane (4.0% e.e.) is also much lower than that of methyloxirane. The configuration of (−)-*t*-BuBH, which is preferentially cyclized in this reaction, is considered to be R, since the asymmetric carbon of the substrate does not participate in the cyclization as described for 1-bromo-2-propanol. Judging from the above two cases, the bulky groups do not necessarily induce high asymmetric induction. It is also interesting to note that methyl- and ethyloxirane were obtained in *S* configuration while *t*-butyloxirane in R configuration.

3-Bromo-2-butanol has two isomers, *erythro*-3-bromo-2-butanol and *threo*-3-bromo-2-butanol, which would be helpful in examining the mechanistic feature of this asymmetric cyclization. When the reaction proceeds by the complete S_N2 type cyclization, only *trans*-2,3-dimethyloxirane will be formed from *erythro*-3-bromo-2-butanol, and only *cis*-2,3-dimethyloxirane will be formed from *threo*-3-bromo-2-butanol. As was expected, the NMR and GC analyses of the products showed that only trans-oxirane was formed from erythro-isomer and only cis-oxirane from threo-isomer. The above results indicate that the reaction proceeds exclusively via the S_N2 mechanism in the presence of cobalt(salen) type complex. This results



Scheme 2.

lead to the conclusion that racemization of the selected substrate, mentioned before, is not likely to occur.

The optical activities of the substrate and product show that (2*R*,3*S*)-3-bromo-2-butanol[12] reacted preferentially to form (2*R*,3*R*)-dimethyloxirane by the inversion of the carbon at 3-position having bromide function. The results with 1-bromo-2-propanol and 2-bromo-1-propanol suggest that the S configuration is favored at the carbon bearing OH group, while R configuration at the carbon bearing Br atom. The result for (2*R*,3*S*)-3-bromo-2-butanol was, however, contrary to the prediction. It indicates that the enantioselection at the asymmetric moiety of the chiral cobalt complex is vulnerable to various factors. The idea of "Template"[13] may explain the results.

An Improvement of the Anderson Test by the Use of High Performance Liquid Chromatography

Toshifumi MIYAZAWA,* Takashi YAMADA, and Shigeru KUWATA
Department of Chemistry, Faculty of Science, Konan University, Higashinada-ku, Kobe 658
(Received July 25, 1987)

Synopsis. The replacement of the *N*-benzyloxycarbonyl (Z) group in the Anderson peptide (Z-Gly-L/D-Phe-Gly-OEt) by Z-L-Ala and the subsequent separation of the diastereomers of the resulting tetrapeptide by reversed-phase HPLC offer a more convenient version with higher accuracy to the original Anderson test for studying racemization in peptide synthesis.

There have been known a variety of tests[1] devised for the estimation of the racemization extent during peptide bond formation. Among them the model coupling of Z-Gly-L-Phe-OH[2] with H-Gly-OEt proposed by Anderson et al.[3] has widely been used for investigating coupling methods and conditions in peptide synthesis, through which extensive data have been accumulated.[4] Since this test measures the weight of racemate isolated by fractional crystallization, the limit of detection has been shown to be ca. 1—2% racemate.[1a] Moreover, in some cases the presence of by-products of the reaction is prone to make it difficult to separate the pure racemate. Kemp et al.[5] applied to the original the multiple isotope dilution procedure, which extended the sensitivity of the test by several orders of magnitude.[1a] However, this procedure still necessitates the isolation of a small amount of pure racemate by crystallization. Therefore, both the original and the improved procedures are not free from a troublesome manipulation of the separation. Thus, an improvement of the Anderson test is very desirable, which would omit the isolation of racemate and allow the analysis to be accomplished more conveniently and with higher accuracy.

Recently, we have found that the diastereomeric pairs of a series of protected tripeptides, Z-L/D-AA-Gly-L-Phe-OMe (where AA denotes various amino acid residues), can well be separated by reversed-phase high-performance liquid chromatography (RP-HPLC).[6] Moreover, the kinetic resolution was found to be almost negligible in the coupling of Z-L/D-AA-OH with H-Gly-L-Phe-OMe, probably because achiral Gly occupies the coupling site in the amino component. Thus, it is reasonable to anticipate that the replacement of the Z group in the Anderson peptide (**1**) by an appropriate Z-L-AA will make it possible to separate the diastereomers of the resulting tetrapeptide (**2**) by RP-HPLC for the quantitation of the epimer in **1** (Scheme 1). As shown in Table 1, this was the case with the tetrapeptides **2** for AA=Ala, Val, Leu, and Pro. When the *N*-hydroxysuccinimide ester of Z-L-AA-OH (Z-L-AA-OSu) (for AA=Ala, Val, and Leu) was reacted with H-Gly-DL-Phe-Gly-OEt,[7] the diastereomer ratio of the resulting tetrapeptide was close to 50 : 50.[8]

Z-Gly-L/D-Phe-Gly-OEt → H-Gly-L/D-Phe-Gly-OEt
1
→ Z-L-AA-Gly-L/D-Phe-Gly-OEt
2

Scheme 1.

Based on the above results, we chose the simplest Z-L-Ala and decided on our version for the Anderson test as follows. The crude product obtained through the coupling of Z-Gly-L-Phe-OH with H-Gly-OEt by the method under consideration is hydrogenated over Pd-carbon in ethanol in the presence of 1 equiv. of concd hydrochloric acid. The debenzyloxycarbonylated product is then reacted with 2 equiv. of Z-L-Ala-OSu in DMF in the presence of 1 equiv. of triethylamine for 24 h. The resulting tetrapeptide, after suitable washings, is submitted to a separation of the diastereomers by RP-HPLC. The limit of detection

Table 1. HPLC Separation of Diastereomers of Z-AA-Gly-Phe-Gly-OEt (**2**)[a]

AA	Mobile phase[b]	k'[c]		α[d]
		L-L	L-D

Val	B	8.79	10.45	1.19
Leu	C	7.82	8.99	1.15
Pro	B	6.61	8.59	1.30
Phe	B	8.76	8.76	1.00

a) Conditions: column, Cosmosil $5C_{18}$ (4.6 mm I.D.×150 mm); flow rate, 1.0 ml min^{-1}; column temperature, 30 °C; detection, 254 nm. b) A, 55% MeOH aq; B, 60% MeOH aq; C, 65% MeOH aq. c) Capacity factor, $k'=(t_R-t_0)/t_0$, where t_0 denotes the void time (ca. 1.5 min). d) Separation factor, $\alpha=k'_{L\text{-}D}/k'_{L\text{-}L}$.

Table 2. Racemization Extent during the Coupling of Z-Gly-L-Phe-OH with H-Gly-OEt by the DCC Method plus Additive[a]

Additive	D %[b]
None	5.3
HOBt	<0.1[c]
HOSu	<0.1[c]
HONB	<0.1[c]
Stearic acid	1.2
Oleic acid	2.8
Palmitic acid	2.8
Lauric acid	3.6
$CuCl_2$	<0.1[c]

a) Reaction conditions: Z-Gly-L-Phe-OH/H-Gly-OEt/additive/DCC, 1 : 1 : 1 : 1 equiv.; solvent, THF (reactant concentration, 0.083 mol dm^{-3}); duration and temperature, 24 h at 5 °C. b) Obtained as L-D % of the tetrapeptide **2** for AA=Ala. c) Sensitivity range, 0.01 a.u.f.s.

was estimated as ca. 0.1% epimer.

Table 2 shows the results obtained by our improved procedure on the racemization suppressing effect of several additives in the dicyclohexylcarbodiimide (DCC) mediated couplings affording the Anderson peptide. By the use of copper(II) chloride[9] as well as the common *N*-hydroxy compounds such as 1-hydroxybenzotriazole (HOBt), *N*-hydroxysuccinimide (HOSu), and *N*-hydroxy-5-norbornene-*endo*-2,3-dicarboximide (HONB),[10] practically no racemization could be detected. On the other hand, the effect of the long-chain fatty acids, regarded as factors ordering the reaction medium, whose usefulness as a new type of additives had been demonstrated using the conventional Anderson test,[4g] proved to be considerable but not complete. Probably this discrepancy is partly due to the fact that the reaction conditions in both cases were not identical; primarily, though, it is due to the difference in the procedure for the quantitation of the epimer in the Anderson peptide.

A combination of the present improvement utilizing the HPLC separation of the diastereomers of the tetrapeptide derived from the Anderson peptide, and the multiple dilution procedure as applied by Kemp et al.[5] would increase the limit of detection in the Anderson test with greater precision.

Experimental

All melting points are uncorrected. Optical rotations were measured with a JASCO DIP-4 polarimeter. TLC and preparative TLC were performed on Merck Kieselgel 60 F_{254} and Kieselgel GF_{254} (Type 60), respectively. The liquid chromatograph employed was a Shimadzu LC-3A instrument, equipped with a Shimadzu SPD-2A variable wavelength UV monitor and a Shimadzu Chromatopac C-R1A data processor. A prepacked ODS column (Cosmosil $5C_{18}$) was consisted of a stainless steel tube, 4.6 mm I.D. and 150 mm long.

Z-Gly-DL-Phe-Gly-OEt. This was prepared by the reaction of Z-Gly-OSu with H-DL-Phe-Gly-OEt·HBr[11] in CH_2Cl_2; yield, 85%; mp 132—133 °C (acetone aq). [lit,[12] mp 132—133 °C].

Z-Gly-L-Phe-Gly-OEt. This compound has previously been prepared through the coupling of Z-Gly-L-Phe-OH with H-Gly-OEt by various methods (Anderson test), while its preparation by the stepwise elongation procedure has not been reported so far, to our knowledge. The reaction of Z-Gly-OSu with H-L-Phe-Gly-OEt·HCl[11] (prepared through the debenzyloxycarbonylation of Z-L-Phe-Gly-OEt[13] by hydrogenation in the presence of 5% Pd-C and concd HCl) in CH_2Cl_2 afforded white crystals; yield, 87%; mp 118—119 °C (EtOAc-hexane); $[\alpha]_D^{25}$ −12.5° (*c* 1.0, EtOH).

HPLC Separation of the Diastereomers of Z-AA-Gly-Phe-Gly-OEt. Z-L-AA-OSu (for AA=Ala, Val, Leu, Pro, and Phe) (0.125 mmol) and H-Gly-DL-Phe-Gly-OEt·HCl (prepared through the debenzyloxycarbonylation of Z-Gly-DL-Phe-Gly-OEt by hydrogenation in the presence of 5% Pd-C and concd HCl) (0.125 mmol) were stirred in DMF (1.5 ml) in the presence of TEA (0.125 mmol) at room temperature overnight. The neutral fraction was separated from the reaction mixture as usual. This fraction was submitted to separation of diastereomers by RP-HPLC under the conditions described in Table 1.

On the other hand, Z-L-AA-Gly-L-Phe-Gly-OEt (for AA=the same residues) was prepared from Z-L-AA-OSu and H-Gly-L-Phe-Gly-OEt·HCl[11] in a manner similar to that described above, and submitted to HPLC analysis.

Z-L-Ala-Gly-L-Phe-Gly-OEt. Z-L-Ala-OSu (298 mg) and H-Gly-L-Phe-Gly-OEt·HCl (prepared through the debenzyloxycarbonylation of Z-Gly-L-Phe-Gly-OEt by hydrogenation in the presence of 5% Pd-C and concd HCl) (310 mg) were stirred in the presence of TEA (91 mg) at room temperature for 3 d. To the reaction mixture was EtOAc added, and the resulting suspension was washed successively with 5% HCl, water, sat. $NaHCO_3$, and water, and dried over Na_2SO_4. Removal of the solvent afforded crystals, which were recrystallized from MeOH; yield, 304 mg (66%); mp 189—190 °C; $[\alpha]_D^{25}$ −9.6° (*c* 1.0, DMF). Found: C, 60.66; H, 6.08; N, 10.97. Calcd for $C_{26}H_{32}N_4O_7$: C, 60.93; H, 6.29; N, 10.93.

Z-D-Phe-Gly-OEt. This was prepared from Z-D-Phe-OH and H-Gly-OEt·HCl[11] by the DCC method in CH_2Cl_2; yield, 90%; mp 110—111 °C (EtOAc-petroleum ether); $[\alpha]_D^{25}$ +17.3° (*c* 2.0, EtOH). Cf. lit[13] for the L isomer, mp 110—110.5 °C, $[\alpha]_D^{25}$ −17.1° (*c* 2, EtOH).

Z-Gly-D-Phe-Gly-OEt. This was obtained by the coupling of Z-Gly-OSu with H-D-Phe-Gly-OEt·HCl[11] as described for the corresponding L isomer; yield, 90%; mp 118—119 °C (EtOAc-hexane); $[\alpha]_D^{25}$ +12.4° (*c* 1.0, EtOH). Found: C, 62.76; H, 6.18; N, 9.47. Calcd for $C_{22}H_{27}N_3O_6$: C, 62.57; H, 6.16; N, 9.52.

Z-L-Ala-Gly-D-Phe-Gly-OEt. This was prepared from Z-L-Ala-OSu and H-Gly-D-Phe-Gly-OEt·HCl[11] as described for the corresponding L-L isomer. The final purification was conducted by preparative TLC with $CHCl_3$-MeOH (9:1) to afford the desired compound as a syrup; yield, 77%; $[\alpha]_D^{25}$ +1.6° (*c* 1.0, DMF). Found: C, 60.71; H, 6.42; N, 10.88.

Z-Gly-L-Phe-OH. A solution of Z-Gly-OSu (12.25 g) in acetonitrile (70 ml) was added to a solution of H-L-Phe-OH (9.91 g) and $NaHCO_3$ (10.08 g) in water (180 ml) with stirring at room temperature. After 6 h of stirring, the reaction mixture was concentrated to ca. 120 ml and acidified with concd HCl to pH 2. The separated oil was extracted with EtOAc, washed with water, and dried over Na_2SO_4. Evaporation of the solvent in vacuo afforded crystals, which were recrystallized from EtOAc-petroleum ether; yield, 11.86 g (83%); mp, 128.5—129.5 °C; $[\alpha]_D^{25}$ +38.7° (*c* 1.0, EtOH). [lit,[14] mp 127—128 °C, $[\alpha]_D^{25}$ +36.6°±0.5° (*c* 5, EtOH)].

A part of the sample was esterified with diazomethane in ether, hydrogenated in the presence of 5% Pd-C and concd HCl, and then coupled[11] with Z-L-Ala-OH using 1-ethyl-3-(3-dimethylaminopropyl)carbodiimide hydrochloride in the presence of HOBt in THF according to a previous report.[6] The HPLC analysis of the resulting product showed no presence of the D-L isomer, under the following conditions: mobile phase, 60% MeOH aq; flow rate, 1.0 ml min^{-1}; column temperature, 30 °C; detection, 254 nm; sensitivity range, 0.02 absorbance units full scale (a.u.f.s.). The L-L isomer of Z-Ala-Gly-Phe-OMe had t_R=11.10 min and the D-L isomer t_R=12.72 min.

Determination of Racemization in the Anderson Test. a) General Procedure: Z-Gly-L-Phe-OH (0.125 mmol) was coupled with H-Gly-OEt (0.125 mmol) by a certain coupling method. After suitable washes, the crude product obtained was dissolved in EtOH (5 ml), and hydrogenated in the presence of 5% Pd-C (15 mg) and concd HCl (0.011 ml). After filtration of the catalyst and a successive removal of the solvent, the residue was dried by the addition of MeOH followed by evaporation in vacuo and then dissolved in DMF (1 ml). To this solution Z-L-Ala-OSu (0.25 mmol) was added, followed by TEA (0.125 mmol). After the mixture had been stirred at 23 °C for 24 h, 1-(2-aminoethyl)piperazine (16 mg) was added and stirring was continued for 20 min. The mixture was distributed between EtOAc and 5% HCl, and the organic layer was further washed with 5% HCl, water, sat. $NaHCO_3$, and water, and dried over Na_2SO_4. After evapora-

tion of the solvent, the residue was dissolved in MeOH (3 ml). This solution (5 μl) was injected through a microsyringe into the HPLC apparatus under the following conditions: mobile phase, 55% MeOH aq; flow rate, 1.0 ml min^{-1}; column temperature, 30 °C; detection, 254 nm; sensitivity range, 0.02 a.u.f.s. The L-L isomer of Z-Ala-Gly-Phe-Gly-OEt had t_R=16.37 min and the L-D isomer t_R=18.99 min, while the void time was t_0=1.56 min.

Thus, the percentage of D isomer in the original Anderson peptide was determined by the percentage of L-D isomer of the tetrapeptide. The limit of detection was estimated as ca. 0.1% epimer.

b) Racemization during the Coupling by the DCC Method plus Additive: Reactions were run by dissolving Z-Gly-L-Phe-OH, H-Gly-OEt, and additive where pertinent (1 : 1 : 1 equiv.) in THF (reactant concentration, 0.018 mol dm^{-3}) and adding 1 equiv. of DCC. After the mixture had been stirred at 5 °C for 24 h, it was diluted with EtOAc and treated as usual. The crude product was hydrogenated, and then reacted with Z-L-Ala-OSu as described above. The results are summarized in Table 2.

Formation of *N,N'*-Disubstituted Methanediamine Derivatives from Hexamethyldisilazane and Aldehydes via Stepwise Reactions

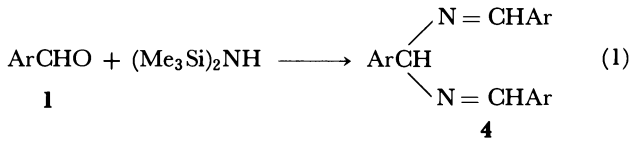
Kozaburo NISHIYAMA,* Masaki SAITO, and Makoto OBA
Department of Chemistry, Tokyo Metropolitan University, 2-1-1, Fukasawa, Setagaya, Tokyo 158
(Received July 31, 1987)

Synopsis. The $ZnCl_2$-catalyzed reaction of aldehydes with hexamethyldisilazane (HMDS) resulted in the formation of *N,N'*-disubstituted methanediamines, which were found to be formed stepwisely via 1:1- and 1:2-adducts of HMDS and aldehydes.

Although alkali metal salts of hexamethyldisilazane (HMDS) are well-known to be hindered bases for organic synthesis, only a few reports concerning the synthetic utility of disilazane itself can be found in the literature. Recently, two groups[1] reported the introduction of an amino moiety into organic molecules by using HMDS; the conversion of acyl halides into amides. On the other hand, we have been interested in the reactivity of a variety of Si-N bond of organosilicon compounds, e.g. silyl azide,[2] silyl isocyanate,[3] and silyl isothiocyanate.[4] As a continuation of our work in this area, the $ZnCl_2$-catalyzed reaction of aldehydes (**1**) with hexamethyldisilazane (HMDS), having two reactive Si-N bonds in a molecule, was investigated and we now report our results in this paper.

Results and Discussion

Treatment of benzaldehyde (**1a**) with 2 equiv of HMDS and a catalytic amount of $ZnCl_2$ in dichloromethane at room temperature for 24 h resulted in the formation of colorless needles (hexane), mp 100—101 °C, which were identified as *N,N'*-dibenzylidenephenylmethanediamine (**4a**). Without zinc chloride or in hexane, the reaction between benzaldehyde and HMDS did not proceed at all and starting materials were quantitatively recovered. When the reaction was interrupted in 1 h, the sole product was **4a** in a low yield (16%). Analogously, four *N,N'*-bis(arylmethylene)arylmethanediamines (**4b—e**) were obtained from the corresponding aromatic aldehydes (Eq. 1 and Table 1). On the other hand, Duffaut and



(1)

a, Ar=Ph, **b**, Ar=*p*-$MeOC_6H_4$, **c**, Ar=*p*-MeC_6H_4, **d**, Ar=*p*-CNC_6H_5, **e**, Ar=*p*-$NO_2C_6H_4$

Dupin reported that the treatment of ketones and benzaldehyde with silazanes [$(Me_3Si)_2NR$; R=H and Me] and silyl amines ($Me_3SiNHPh$ and Ph_3SiNH_2) in the presence of Zn/Cd at 165 °C for 40 h gave the corresponding imines (>C=NR; R=H, Me, and Ph) in yields of 30—95%.[5]

With *p*-cyanobenzaldehyde (**1d**), a trace amount of *N*-(*p*-cyanobenzylidene)-1-(*p*-cyanophenyl)-1-(trimethylsiloxy)methanamine (**3d**) with **4d** (46%) was isolated by fractional recrystallization from benzene and hexane. Since compound **3d** could be a precursor of **4d**, the reaction of **1d** with HMDS was again carried out for 10 h at room temperature. Consequently, compounds **3d** and **4d** were obtained in 23 and 32% yields, respectively. Similarly, the treatment of **1e** with HMDS for 24 h afforded a mixture of **3e**, which was too unstable to be fully characterized, and **4e** (30%). An attempt to separate the mixture by column chromatography on alumina (eluent; $CHCl_3$) gave *p*-nitrobenzylideneamino-*p*-nitrophenylmethanol (**3e'**).

Table 1. $ZnCl_2$-Induced Reaction of Carbonyl Compound with HMDS

Carbonyl compd	Product	(Yield/%)	Mp θ_m (bp θ_b)/°C

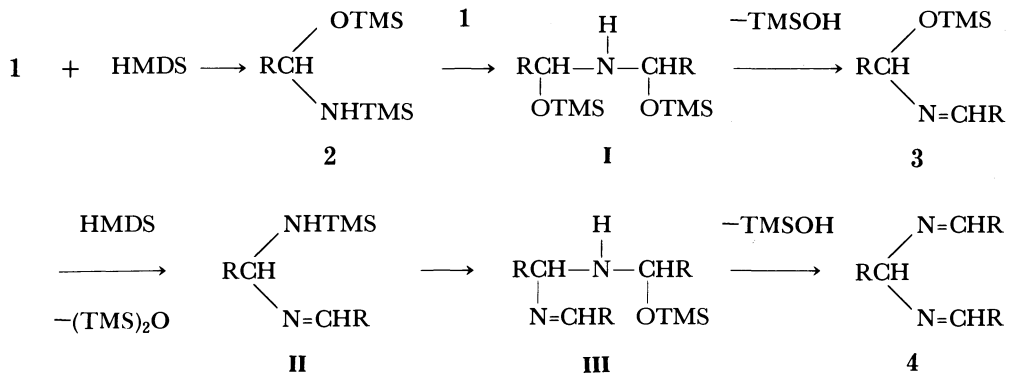
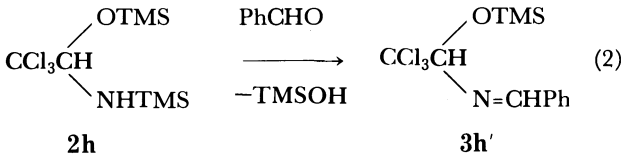
From these findings, it is clear that the formation of **4** involves stepwise reactions which must proceed via **3** and that an electron-withdrawing group of the aldehyde would retard either step(s) of the successive reactions. More remarkably, in cases of aliphatic aldehydes, the product was dependent upon an electronic rather than a steric effect of the alkyl group. With 2,2-dimethylpropanal (**1f**) and cyclohexanone (**1g**), *N,N'*-bis(2,2-dimethylpropylidene)-2,2-dimethyl-1,1-propanediamine (**4f**) and *N,N'*-dicyclohexylidene-1,1-cyclohexanediamine (**4g**) were produced in 42% and 53% yields,[6] respectively, as a sole product, whereas only a 1:1-adduct of trichloroethanal (**1h**) and HMDS, *N*-trimethylsilyl-1-trimethylsiloxy-2,2,2-trichloroethanamine (**2h**), was obtained in a 70% yield. The treatment of **2h** with benzaldehyde under similar conditions gave *N*-benzylidene-1-trimethylsiloxy-2,2,2-trichloroethanamine (**3h'**) in a 53% yield. As to this



Scheme

reaction course, it was postulated that the addition of the remaining Si-N bond in **2h** to benzaldehyde followed by the elimination of trimethylsilanol occurred to give **3h'** (Eq. 2).



(2)

On the basis of the above results, we suggest the reaction pathway shown in the Scheme to account for the formation of the *N,N'*-bis(arylmethylene)arylmethanediamines **4** from aldehyde with HMDS. The first and second steps are $ZnCl_2$-induced addition reactions of Si-N bonds to the carbonyl group of the aldehyde, giving the 1:1-adduct **2** and 1:2-adduct **I**, respectively. Furthermore, the latter undergoes the elimination of trimethylsilanol to produce *N*-benzylidenephenylmethane derivative **3**. Condensation of **3** with HMDS gives hexamethyldisiloxane and the diamino intermediate **II**; **II** adds to another aldehyde to give the adduct **III**, which would be subjected to the further elimination of trimethylsilanol, giving the final product **4**. The conversion step of **3** into **II** finds analogy in another study of ours; in which *gem*-diazides were found to be isolated via α-siloxy azides from the similar reaction of aldehydes[2] and ketones[7] with silyl azide. For these reactions, an electron-withdrawing group of aldehydes retards the addition process and compounds **4** having an electron-donationg group were obtained in higher yields under the conditions employed.

Compound **4** is important as an intermediate for trisubstituted imidazole derivatives; the dehydrogenation of *N,N'*-dibenzylidenephenylmethanediamine gives 2,4,5-triphenyl-1*H*-imidazole.[8]

Experimental

Melting points are uncorrected. Infrared spectra were measured on a Hitachi 260-10 infrared spectrometer. ^1H NMR spectra were determined with a Hitachi R-600 using tetramethylsilane as an internal standard. Mass spectra (MS) were obtained using a JEOL DX-300 spectrometer.

Hexamethyldisilazane (HMDS) and aldehydes were commercial products and were purified by distillation or recrystallization if necessary.

$ZnCl_2$-Induced Reaction between Aldehyde (1a—1f) and HMDS. General Procedure. A suspension of aldehyde (30 mmol), HMDS (60 mmol), and $ZnCl_2$ (6 mmol) in CH_2Cl_2 (30 cm^3) was stirred for 24 h at room temperature. The reaction mixture was poured into water (30 cm^3) and dichloromethane (30 cm^3). Extraction with three 30 cm^3 portions of dichloromethane followed by washing with water completed the work-up. The extract was dried over anhydrous $MgSO_4$ and concentrated in vacuo. The resulting mixture was triturated with hexane (for **4a—4d**) or benzene (for **4e**) and the precipitated solid was collected by filtration. The solid was recrystallized from an appropriate solvent (hexane, a mixture of hexane and benzene, or acetonitrile). When the product was liquid (**4f** and **4g**), it was directly distilled under reduced pressure. The yields of products are listed in Table 1. Spectral and physical data are as follows.

4a: colorless needles (hexane); mp 100—101 °C (lit,[9] 100 °C). IR (KBr) ν 1625 (C=N) cm^{-1}. MS *m/z* 194 (M^+ −N=CHPh). ^1H NMR ($CDCl_3$) δ=5.93 (s, 1H), 7.20—7.89 (m, 15H), and 8.51 (s, 2H). **4b:** colorless needles (hexane); mp 128—129 °C IR (KBr) ν 1620 (C=N) cm^{-1}. MS *m/z* 254 (M^+−N=$CHC_6H_4OCH_3$-*p*). ^1H NMR ($CDCl_3$) δ=3.75 (s, 3H), 3.81 (s, 6H), 5.80 (s, 1H), 6.84, 7.38 (ABq, 4H), 6.86, 7.74 (ABq, 8H), and 8.40 (s, 2H). Found: C, 74.15; H, 6.30; N, 7.20%. Calcd for $C_{24}H_{24}N_2O_3$: C, 74.21; H, 6.23; N, 7.21%. **4c:** colorless powder (hexane); mp 93—94 °C. IR (KBr) ν 1620 (C=N) cm^{-1}. MS *m/z* 222 (M^+−N=$CHC_6H_4CH_3$-*p*). ^1H NMR ($CDCl_3$) δ=2.32 (s, 3H), 2.40 (s, 6H), 5.87 (s, 1H), 7.13, 7.35 (ABq, 4H), 7.16, 7.68 (ABq, 8H), and 8.45 (s, 2H). Found: C, 84.96; H, 7.43; N, 8.01%. Calcd for $C_{24}H_{24}N_2$: C, 84.67; H, 7.11; N, 8.23%. **4d**: pale yellow powder (1:1 mixture of benzene and hexane), mp 122—124 °C. IR (KBr) ν 2210 (C≡N) and 1625 (C=N) cm^{-1}. MS *m/z* 244 (M^+−N=CHC_6H_4CN-*p*). ^1H NMR ($CDCl_3$) δ=6.06 (s, 1H), 7.62 (s, 8H), 7.67, 7.92 (ABq, 4H), and 8.53 (s, 2H). Found: C, 77.43; H, 4.24: N, 18.96%. Calcd for $C_{24}H_{15}N_5$: C, 77.20; H, 4.05; N, 18.75%. The mother liquor of **4d** was concentrated in vacuo and the residual solid was recrystallized from hexane, giving colorless needles, **3d**, mp 116—117 °C. IR (KBr) ν 2200 (C≡N), 1630 (C=N), and 1060 (Si-O-C) cm^{-1}. MS *m/z* 204 (M^+ −N=CHC_6H_4CN-*p*). ^1H NMR ($CDCl_3$) δ=0.20 (s, 9H), 6.30 (s, 1H), 7.57 (s, 4H), 7.66, 7.83 (ABq, 4H), and 8.50 (s, 1H). Found: C, 68.50; H, 5.85; N, 12.53%. Calcd for $C_{19}H_{19}N_3OSi$: C, 68.44; H, 5.74; N, 12.60%. **4e**: pale yellow plates (acetonitrile), mp 140 °C (decomp). IR (KBr) ν 1625 (C=N) and 1505, 1340 (NO_2) cm^{-1}. MS *m/z* 283 (M^+ −N=$CHC_6H_4NO_2$-*p*). Found: C, 58.23; H, 3.44; N, 15.98%. Calcd for $C_{21}H_{15}N_5O_6$: C, 58.20; H, 3.49; N, 16.16%. The ^1H NMR spectrum of **4e** could not be determined because the isolated **4e** did not disolve in $CDCl_3$ and CD_3CN and decomposed in DMSO-d_6. **3e'**: pale yellow powder ($CHCl_3$), mp 203—204 °C. IR (KBr) ν 3275 (OH), 1635 (C=N), and 1500,

1340 (NO_2) cm^{-1}. MS m/z 301 (M^+). Found: C, 55.40; H, 3.62; N, 14.00%. Calcd for $C_{14}H_{11}N_3O_5$: C, 55.82%; H, 3.68; N, 13.95%. **4f**: colorless liquid, bp 173 °C/2 mmHg (1 mmHg=133.322 Pa.). IR (neat) ν 1660 (C=N) cm^{-1}. MS m/z 154 (M^+ −N=CHBu-*t*). ^1H NMR ($CDCl_3$) δ=0.89 (s, 9H), 1.09 (s, 18H), 3.83 (s, 1H), and 7.49 (s, 2H). **4g**: colorless liquid, bp 155—163 °C/2 mmHg. IR (neat) ν 1660 (C=N) cm^{-1}. MS m/z 274 (M^+). ^1H NMR ($CDCl_3$) δ=1.00—2.40 (m).

Reaction of Trichloroethanal (1h) with HMDS. A mixture of **1h** (4.42 g, 30 mmol), HMDS (9.69 g, 60 mmol), and $ZnCl_2$ (0.82 g, 6 mmol) in CH_2Cl_2 (30 cm^3) was stirred for 75 h at room temperature. Direct distillation of the reaction mixture gave a colorless oil, which boiled at 80—82 °C/4 mmHg and was assigned to **2h**, yield, 6.48 g (70%). IR (neat) ν 3380 (NH) and 1250 (C-$SiMe_3$) cm^{-1}. MS m/z 190 (M^+ −CCl_3). ^1H NMR ($CDCl_3$) δ=0.20 (s, 9H), 0.25 (s, 9H), 4.63 (s, 1H), and 4.85 (s, 1H). Found: C, 30.81; H, 6.59; N, 4.55%. Calcd for $C_8H_{20}Cl_3OSi_2$: C, 31.12; H, 6.53; N, 4.54%.

When the reaction between **1h** (11.08 g, 75 mmol) and HMDS (12.13 g, 75 mmol) in the presence of $ZnCl_2$ (2.05 g, 15 mmol) in CH_2Cl_2 (75 cm^3) was carried out for 24 h at room temperature, repeated distillation afforded a detrimethylsilylated compound **2h'** (1-trimethylsiloxy-2,2,2-trichloroethanamine) instead of **2h**, yield 6.12 g (35%). Bp 49—50 °C/4 mmHg. IR (neat) ν 3400 and 3300 (NH_2) and 1250 (C-$SiMe_3$) cm^{-1}. MS m/z 118 (M^+ −CCl_3). ^1H NMR ($CDCl_3$) δ=0.18 (s, 9H), 2.00 (s, 2H), and 4.60 (s, 1H). Found: C, 25.55; H, 5.15; N, 6.08%. Calcd for $C_5H_{12}Cl_3NOSi$: C, 25.38; H, 5.11; N, 5.92%.

Reaction of 2h with Benzaldehyde. A mixture of **2h** (5.26 g, 17 mmol), benzaldehyde (**1a**, 1.81 g, 17 mmol), and $ZnCl_2$ (0.46 g, 3.4 mmol) in CH_2Cl_2 (17 cm^3) was stirred for 24 h at room temperature. After usual work-up, direct distillation (bp 108 °C/2 mmHg) of the dried mixture gave a pale yellow liquid which was characterized to *N*-benzylidene-1-trimethylsiloxy-2,2,2-trichloroethanamine (**3h'**), yield 2.1 g (38%). IR (neat) ν 1635 (C=N) and 1250 (C-$SiMe_3$) cm^{-1}. MS m/z 206 (M^+ −CCl_3). ^1H NMR ($CDCl_3$) δ=0.35 (s, 9H), 5.61 (s, 1H), 7.40—7.96 (m, 5H), and 8.53 (s, 1H). Found: C, 44.49; H, 5.26; N, 4.35%. Calcd for $C_{12}H_{16}Cl_3NOSi$: C, 44.39; H, 4.97; N, 4.31%.

Electroreduction of Phenylhydrazones in Methanol-Water Mixtures

Vepa KAMESWARA RAO, Chitoor Sivaramakrishnan VENKATACHALAM, and Chatty KALIDAS*
Department of Chemistry, Indian Institute of Technology, Madras 600036, India
(Received December 22, 1986)

Synopsis. The electroreduction of a few substituted phenylhydrazones on mercury cathode has been studied in methanol-water mixtures using polarography, cyclic voltammetry, micro- and macrocontrolled-potential electrolysis. These compounds are reduced in a single four-electron step to yield the corresponding amino products. A linear relationship between the half-wave potentials ($E_{1/2}$) and Hammett substituent constants (σ) has been observed.

The electrochemical reduction of various phenylhydrazones received the attention of several authors in recent years[1-5] in view of thier biological activity. In our earlier communications,[6,7] the electroreduction of some substituted phenylhydrazones in amphiprotic media has been reported. In continuation of this work, we present here the results of the electrochemical behavior of 2,2-dimethyl-1,3-dioxane-4,5,6-trione 5-(phenylhydrazone) (**1**) and 2,2-dimethyl-1,3-dioxane-4,5,6-trione 5-(4-acetylphenylhydrazone) (**2**) in methanol-water mixtures of varying composition and pH. The effect of substituents on the mechanism of the electrode reaction (Hammett correlation) is also discussed.

Experimental

The phenylhydrazones used in the present work, (**1** and **2**) were prepared by coupling the appropriate diazotized aromatic amine with Meldrum's acid (cyclic isopropylidene malonate). The yellow amber colored compounds were recrystallized from aqueous methanol or benzene-hexane mixture and their purity checked by TLC. The mp of **1** is 171—172 °C (reported[8] value 171—172 °C) and that of **2** is 182 °C. Analysis for compound **2**. Found: C, 57.59; H, 4.87; N, 9.61%. Calcd for $C_{14}H_{14}N_2O_5$: C, 57.69; H, 4.83; N, 9.61%.

Methanol (Reechem) was purified by standard procedure. Potassium chloride (AR) was used as the supporting electrolyte without further purification. Britton-Robinson[9] (BR) and Clark-Cubs (CL) buffers were used to control the pH of the experimental solutions. The dme had the following capillary characteristics: m=0.7933 mg s^{-1} and t=6 s at 53 cm height (uncorrected for back pressure) of the mercury column under open-circuit conditions. A Metrohm EA 290 hanging mercury drop electrode (hmde) having an area of 0.01296±0.006 cm^2 was used for cyclic voltammetric experiments. The polarographic measurements were carried out with a Metrohm E 506 polarecord, saturated calomel as the reference electrode and a platinum foil as the counter electrode. Cyclic voltammograms were recorded employing PAR 175 Universal programmer and PAR 173 potentiostat in conjunction with an x-y recorder (Digital Electronics, Bombay). Electrolysis products were analyzed by HPLC. The details of microcoulometric measurements for determining the number of electrons (n_{app}) transferred in the electrode process have been described previously.[10] Polarograms and cyclic voltammograms were recorded for solutions containing the depolarizer (1.0×10^{-3} M, (1M=1 mol dm^{-3})), the maximum suppressor (0.002% Triton-X-100), supporting electrolyte (KCl) and required amount of buffers (BR and CL) in methanol-water mixtures of various compositions.

All measurements were caried out at 30 °C.

Results and Discussion

The electrochemical reduction of **1** and **2** was carried out in 60—80% (v/v) methanol-water mixtures in the pH range 1.00—7.00. These compounds are found to be unstable in alkaline solutions as indicated by the decrease in polarographic currents with time. This might probably due to the hydrolysis of Meldrum's acid moiety in buffered alkaline media.[11] Both the compounds give a single well-defined dc polarogram and a single ac peak corresponding to the dc step at all pH values in different compositions of methanol-water mixtures. The polarographic data are presented in Tables 1 and 2. Analysis of the polarographic data revealed the diffusion-controlled nature of the electrode process. The half-wave potentials of the depolarizers are shifted cathodically with increase in pH values and with increase in composition of methanol. At a given pH and composition, the summit potentials (E_s) are more negative than the corresponding dc $E_{1/2}$ values thereby indicating the irreversible nature of the

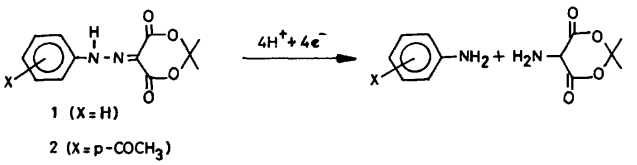
electrode process. The $(E_{3/4}-E_{1/4})$ and the slope values of $-E$ vs. $\log(i_d-i)/i$ plots also confirm the irreversible behavior.

The cyclic voltammetric data of phenylhydrazones indicate the diffusion-controlled and irreversible nature of the electrode processes. Figure 1 shows typical cyclic voltammograms of the compounds **1** and **2** obtained in 60% (v/v) methanol in acidic and neutral media. Both the compounds give a single cathodic peak in the forward scan and no anodic peak in the reverse direction indicating the irreversible behavior of the electrode process. The diffusion-controlled nature of the electrode process was indicated by the linear relationship between the cathodic peak current values ($i_{p,c}$) and the square root of the scan rate ($v^{1/2}$). In all the cases, however, an anodic peak (close to 0.0 V) is observed in the reverse scan in neutral buffered methanol-water mixtures. The peak separation of the redox couple (ΔE_p) around 0.070 V suggests a quasi-reversible single electron-transfer step in the oxidation of the product formed at the electrode surface in neutral media.

The microcoulometric experiments carried out at the limiting region of the polarographic waves of **1** and **2** showed a transfer of four electrons ($n_{app}=4$) in the reduction step. The controlled-potential electrolysis of **1** and **2** yielded aniline (retention time 3.3 min) and *p*-aminoacetophenone (retention time 3.14 min), respectively, as the final products. The retention times of the electrolysis products were found to be in good agreement with those of the authentic samples. The other expected product, namely, amino-substituted Meldrum's acid could not be identified possibly due to its hydrolysis during working up procedure in basic medium.

Based on the results obtained, the following stoichiometry is suggested for the reduction of the phenylhydrazones in buffered methanolic solutions under acidic and neutral conditions:



It may be pointed out that the deliberate addition of pure aniline or *p*-aminoacetophenone in the reduction of **1** and **2** did not increase the peak height of the anodic wave observed very close to 0.0 V in the reverse scan in cyclic voltammetric experiments. This positively suggests that the observation of the anodic peak during the reverse scan may be due to the oxidation of amino-substituted Meldrum's acid formed at the electrode surface during the cathodic reduction of phenylhydrazones.

An attempt has been made in the present investigation to correlate the half-wave potentials of phenylhydrazones with Hammett substituent constants (σ). Such a correlation was possible due to a similar behavior of these compounds at the electrode-electrolyte interface. The Hammett equation when applied to reversible as well as irreversible electrode processes, $dE_{1/2}=\rho\sigma$ belongs to the family of linear free energy relationships (LFER)-equations.[12] Figure 2 shows

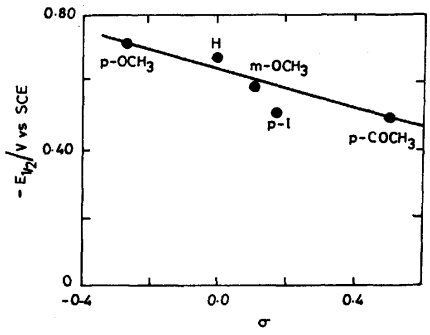


Fig. 2. Hammett correlation for various substituted phenylhydrazones in 60% (v/v) methanol-water mixtures at pH=4.00.

such a Hammett correlation for various substituted phenylhydrazones in 60% (v/v) methanol-water mixture at a constant pH. The linear plot has a ρ-value of 0.308 with a correlation coefficient 0.895. It may be noted from the correlation that the ease of reduction of these phenylhydrazones decreases in the order p-$COCH_3$<p-I<m-OCH_3<p-OCH_3 with decreasing order of the electron withdrawing nature of the substituents studied.

Atomization Enthalpies of Aliphatic Compounds with Alternately Adjacent Carbonyl Groups and Nitrogen Atoms†

Minoru SAKIYAMA,* Nobuhiro KURIYAMA, Akira IMAMURA, and Shigeo MURATA
Chemical Thermodynamics Laboratory, Faculty of Science, Osaka University, Toyonaka 560
(Received February 23, 1987)

Hückel MO calculations were made for the title compounds using Hess-Schaad heteroatom parameters. The bond-contribution values were determined for the total π-bonding energies of the acyclic compounds. No resonance stabilization is present for molecules with six-, eight-, and ten-membered rings composed of CO-N linkages. Graph-theoretical calculations gave a similar result. Atomization enthalpies were calculated from the available thermochemical data and analyzed within the framework of the Hess-Schaad theory. The destabilization energies of normal alkanamides and *N*,*N*-dimethylformamide are close to zero. Diacetamide is not destabilized, while *N*-butyldiacetamide and triacetamide showed small destabilization energies. Trimethyl isocyanurate is not significantly strained. The total strengths of the CO-N bonds are in this order: amide>(urea and diacetamide)>internal bond of acetylurea.

It is well-known that the π-electrons of a carbonyl group in an amide molecule interact with the conjugated lone-pair electrons on the adjacent nitrogen atom to provide the interconnecting C-N bond, which has a significant double bond character. This bond is an important one, since it occurs not only in amides and ureas, but also in proteins, DNA bases, and synthetic polyamides. In another paper,[1] the standard enthalpies of formation, in the gaseous state, of acetylurea and trimethyl isocyanurate [1,3,5-trimethyl-1,3,5-triazine-2,4,6(2*H*,4*H*,6*H*)-trione] were reported, and the estimated stabilization energies of acetamide and urea as well as of these compounds were empirically analyzed in order to study the effect of the elongation and cyclization of an alternating CO-N chain on the stabilization energy. The present study aims at the theoretical interpretation of the extensive thermochemical data for aliphatic compounds containing CO-N linkages, within the framework of the Hess-Schaad theory based on the Hückel MO method.

According to Hess and Schaad,[2,3] the atomization enthalpy of a conjugated alkene is expressed as a sum of the σ-bond contribution terms minus the π-bonding energy, B_π:

$$\Delta_a H = \sum E'(\dot{C}\text{-H}) + \sum E'(\dot{C}\text{-}\dot{C}) - B_\pi, \qquad (1)$$

where $E'(\dot{C}\text{-H})$ and $E'(\dot{C}\text{-}\dot{C})$ are the C-H and C-C σ-bond-contribution terms respectively. In this paper, a 2p electron that takes part in the formation of a π-bond or a lone-pair orbital of a nitrogen atom is denoted by a dot above the atomic symbol. In Method A of Ref. 3, the bond-compression terms were explicitly given, but in Method B they were included in B_π, as is shown in Eq. 1, by treating the resonance integral, β, as a parameter. This treatment was subsequently extended to conjugated amines,[4] ethers,[4] ketones,[5] thiols,[6] thioethers,[6] imines,[7] and fluorides.[8] In addition, Hess and Schaad showed that the difference between a properly calculated π-bonding energy and the corresponding estimated value based on the bond additivity of a cyclic compound is a reasonable measure for the Dewar resonance energy.[2-8]

† Contribution No. 117 from Chemical Thermodynamics Laboratory, Faculty of Science, Osaka University.

Calculation

Hückel molecular orbital calculations were carried out for forty cyclic and acyclic molecules with alternating CO-N skeleton, and with or without branching, using the Hess-Schaad heteroatom parameter set.[4,5] The π-electron energy of a single localized carbonyl group was $(2\alpha+2.212\beta)$, while that of a nitrogen atom was $(2\alpha+3\beta)$, where α and β are the Coulomb and resonance integrals of carbon atoms respectively. Dewar-type resonance energies were calculated also by means of Aihara's graph-theoretical method.[9]

Results and Discussion

π-Bond Order and π-Bonding Energy. The calculated π-bond orders are summarized in Table 1, while the classification of bonds is illustrated in Fig. 1. The bond order of a C-N bond that involves a branching nitrogen atom is systematically lower than the value for a C-N bond that does not involve a branching nitrogen atom.

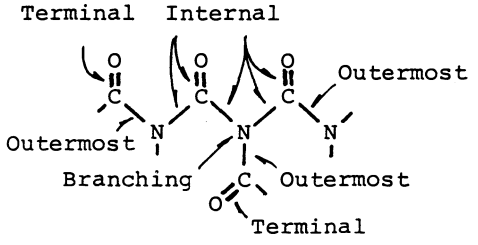

Fig. 1. Classification of bonds and atoms. Hydrogen atoms or alkyl groups bonded to terminal carbon or nitrogen atoms are not shown.

Table 1. C-N and C=O π-Bond Orders. Upper and Lower Bounds Are Shown. Parenthesized Values Are Those for C-N Bonds That Involve a Branching Nitrogen Atom. For Classification of Bonds, See Fig. 1

Bond	Position		π-Bond order
C-N	Open chain	amide	0.400
		outermost	0.392±0.003(0.374±0.001)
		internal	0.372±0.003(0.356±0.001)
	Ring	m=2	0.356(0.338)
	$+CO-N+_m$	m=3, 4, or 5	0.374(0.356)
C=O	Open chain	amide	0.899
		terminal	0.900±0.010
		internal	0.820±0.015
	Ring	m=2	0.837±0.006
	$+CO-N+_m$	m=3, 4, or 5	0.825±0.006

Table 2. Bond-Contribution Values B_π(C-N) and B_π(C=O) to Total π-Bonding Energy B_π of Acyclic Molecules. Parenthesized Values Are Those for C-N Bonds Involving a Branching Nitrogen Atom. For Classification of Bonds, See Fig. 1

Bond	B_π(bond)/β	Position	B_π(C=O)/β
C-N, amide	0.374	Amide	1.992
C-N, out[a]	0.367(0.360)	Terminal	1.992
C-N, int[b]	0.360(0.352)	Internal	1.992

a) Outermost C-N bond. b) Internal C-N bond.

The calculated π-bonding energies of acyclic molecules were empirically analyzed; the bond-contribution values thus derived are shown in Table 2. The bond contribution values were uniquely determined except for amide. It is notable that the value of B_π(C=O), which is the bond-contribution term from a carbonyl group to the π-bonding energy, of acyclic molecules other than amide is constant and equal to the π-bonding energy of a ketone or aldehyde molecule with an isolated carbonyl group. This implies that the delocalization energy of one of the molecules under study is given by the sum of the bond contribution terms of C-N bonds to the π-bonding energy. It was found that the delocalization energy, E_d, of a linear molecule is expressed by this equation:

$$E_d/\beta = 0.360(n_b - 1) + 0.374, \quad (2)$$

where n_b is the number of C-N bonds in the molecule. It follows that the bond-contribution term from the C-N bond of an amide molecule B_π(C-N,amide) is related to those of the outermost and internal C-N bonds, B_π(C-N,out) and B_π(C-N,int) respectively of other linear molecules by the equation:

$$B_\pi(\text{C-N,amide}) = 2B_\pi(\text{C-N,out}) - B_\pi(\text{C-N,int}). \quad (3)$$

Thus, the values of B_π(C-N,amide) and B_π(C=O) for amide were determined to be as is shown in Table 2. The latter value is equal to the value of B_π(C=O), which is common to the other acyclic molecules. By using the bond-contribution values given in Table 2, the π-bonding energy of acyclic molecules may be reproduced with deviations less than 0.004β.

Hess-Schaad Resonance Energies. π-bonding energies based on the additivity were calculated for the cyclic molecules without branching by using the bond-contribution values of the internal C-N bonds and that of a C=O bond of acyclic molecules; they were then compared with properly calculated values. As is shown in Table 3, no resonance stabilization was found for six-, eight-, and ten-membered ring molecules, while the four-membered ring molecule is, though quite slightly, destabilized.

Graph-Theoretical Resonance Energies. The total π-electron energies of real cyclic systems are compared with those of the corresponding hypothetical reference molecules in Table 3. The conclusion to be derived from the comparison is the same as that from the Hess-Schaad method.

σ-Bond Contribution Terms. CODATA key values for thermodynamics[10] were used to calculate the atomization enthalpies of the compounds given in Table 4 from the standard enthalpies of formation in the gaseous state.[11] The uncertainties for the atomization enthalpies were calculated by combining the related uncertainties by means of the error propagation equation.

The value of β employed in this paper is −128.0 kJ mol^{-1}, which is the mean among the values given by Hess and Schaad for conjugated alkenes (−128.4 kJ mol^{-1}),[3] imines (−127.1 kJ mol^{-1}),[4] amines (−128.1 kJ mol^{-1}),[5] ketones (−130.4 kJ mol^{-1}),[5] and ethers

(-125.9 kJ mol^{-1}).[6]

The atomization enthalpies were analyzed according to the following equation:

$$\Delta_a H = \sum E(\text{bond}) - B_\pi - E_{\text{destab}}, \quad (4)$$

where E(bond) is the σ-bond contribution term of a bond; the summation extends over all the σ-bonds in the molecule, and $E_{\text{destab}}(>0)$ is the destabilization energy.

As was described in the previous paper, the atomization enthalpy of normal alkanes may be expressed by the simplest bond-additivity scheme:

$$\Delta_a H(C_kH_{2k+2}) = (2k+2)E(\text{C-H}) + (k-1)E(\text{C-C}), \quad (5)$$

where E(C-H)=412.9 kJ mol^{-1} and E(C-C)=347.7 kJ mol^{-1}. These σ-bond-contribution values were transferred to the normal alkyl chains of the present compounds.

For σ-bond-contribution terms of the C-N and N-H bonds, $E(\text{C-}\ddot{\text{N}})$ and $E(\ddot{\text{N}}\text{-H})$, the values which were found to reproduce the atomization enthalpies of methyl-substituted amines[1] [$E(\text{C-}\ddot{\text{N}})$=297.0 kJ mol^{-1} and $E(\ddot{\text{N}}\text{-H})$=383.0 kJ mol^{-1}] were transferred to the present compounds. However, these values led to a significantly negative destabilization energy (-22 kJ mol^{-1}) for trimethyl isocyanurate, for which the energetic stabilization should have been fully accounted for by the π-bonding energy. Consequently, only the atomization enthalpy of methylamine was used to define the magnitude of [$E(\text{C-}\ddot{\text{N}})+2E(\ddot{\text{N}}\text{-H})$]. Likewise, initially we attempted to determine $E(\dot{\text{C}}\text{-C})$, $E(\dot{\text{C}}\text{-H})$, and $E(\dot{\text{C}}\text{-}\dot{\text{O}})$ from the atomization enthalpies of acetone, acetaldehyde, and formaldehyde. However, these terms were not uniquely determined, since the atomization enthalpy of acetaldehyde is expressed as the arithmetic mean of those of acetone and formaldehyde, in terms of the present bond-energy scheme. Cosequently, $E(\dot{\text{C}}\text{-C})$ was chosen as a parameter.

By analogy with the π-bonding energy, the following three assumptions were made to derive CO-N and C-O σ-bond contribution terms from the atomization enthalpies of the open chain compounds: (1) The CO-N bonds of the linear molecules are classified into three kinds by their position in a molecule. $E(\dot{\text{C}}\text{-}\ddot{\text{N}}\text{,amide})$, $E(\dot{\text{C}}\text{-}\ddot{\text{N}}\text{,out})$, and $E(\dot{\text{C}}\text{-}\ddot{\text{N}}\text{,int})$ are the terms for an amidic C-N bond, an outermost C-N bond, and an internal C-N bond respectively. (2) The following equation holds:

$$E(\dot{\text{C}}\text{-}\ddot{\text{N}}\text{, out}) = [E(\dot{\text{C}}\text{-}\ddot{\text{N}}\text{, amide}) + E(\dot{\text{C}}\text{-}\ddot{\text{N}}\text{, int})]/2. \quad (6)$$

(3) The bond-contribution term of a carbonyl group which is conjugated with lone-pair electrons of an adjacent nitrogen atom, $E(\dot{\text{C}}\text{-}\dot{\text{O}}\text{,conj})$, is a constant, independent of the position of the bond in the molecule.

If the value of $E(\dot{\text{C}}\text{-C})$ can once be tentatively assigned, the terms to be determined are $E(\ddot{\text{N}}\text{-H})$, $E(\text{C-}\ddot{\text{N}})$, $E(\dot{\text{C}}\text{-}\ddot{\text{N}}\text{,amide})$, $E(\dot{\text{C}}\text{-}\ddot{\text{N}}\text{,out})$, $E(\dot{\text{C}}\text{-}\ddot{\text{N}}\text{,int})$, and $E(\dot{\text{C}}\text{-}\dot{\text{O}}\text{,conj})$. It seems, at a glance, that these six terms can be determined from the atomization enthalpies of methylamine, acetamide, urea, acetylurea, and diacetamide, together with Eq. 6. However, the atomization enthalpy of diacetamide is equal to the sum of the atomization enthalpies of acetamide and acetylurea, minus that of urea, in the present scheme. Hence, these terms are not uniquely determined. Consequently, the atomization enthalpy of *N*-butylacetamide was used in place of that of diacetamide in the above method.

The derived bond-contribution values are presented in Table 5, and the experimental atomization enthalpies are decomposed into components according to Eq. 4 in Table 4. The values of $E(\text{C-}\ddot{\text{N}})$ and $E(\ddot{\text{N}}\text{-H})$ are slightly different from those given above; the present values lead to small destabilization energies for dimethylamine and trimethylamine. The values of $E(\dot{\text{C}}\text{-H})$ and $E(\dot{\text{C}}\text{-}\dot{\text{O}})$ given in Table 5 were derived by assuming that $E(\dot{\text{C}}\text{-C})$=347.0 kJ mol^{-1}. A change x in the value of $E(\dot{\text{C}}\text{-C})$ leads to other changes x and $-2x$ in the values of $E(\dot{\text{C}}\text{-H})$ and $E(\dot{\text{C}}\text{-}\dot{\text{O}})$ respectively. $E(\dot{\text{C}}\text{-}\ddot{\text{N}}\text{,amide})$, $E(\dot{\text{C}}\text{-}\ddot{\text{N}}\text{,out})$, $E(\dot{\text{C}}\text{-}\ddot{\text{N}}\text{,int})$, and $E(\dot{\text{C}}\text{-}\dot{\text{O}}\text{,conj})$ also depend on the value of $E(\dot{\text{C}}\text{-C})$. The values of these terms given in Table 5 are based on the assumption that $E(\dot{\text{C}}\text{-C})$=347.0 kJ mol^{-1}. By a change x in the value of $E(\dot{\text{C}}\text{-C})$, each of the values of the former three terms changes by x, while that of the latter one changes by $-2x$. It is notable that the sum of the σ-bond-contribution terms for a molecule being studied is not influenced by a change in the value of $E(\dot{\text{C}}\text{-C})$, because a carbonyl C-O σ-bond is always accompanied by two $\dot{\text{C}}$-C bonds, two CO-N bonds, or a $\dot{\text{C}}$-C bond and a CO-N bond, which are adjacent to the C-O σ-bond, in the molecules.

The value of $E(\dot{\text{C}}\text{-}\dot{\text{O}}\text{,conj})$ is lower by 29 kJ mol^{-1} than $E(\dot{\text{C}}\text{-}\dot{\text{O}})$, the difference being independent of x. This shows a weakening of a C-O σ-bond triggered by the π-electron interaction with an adjacent nitrogen atom. Correspondingly, $E(\dot{\text{C}}\text{-}\ddot{\text{N}}\text{,amide})$, $E(\dot{\text{C}}\text{-}\ddot{\text{N}}\text{,out})$,

Table 5. σ-Bond-Contribution Terms. For Classification of the Bonds, See Fig. 1 and the Text

Bond	E(bond) / kJ mol^{-1}	Bond	E(bond) / kJ mol^{-1}
$\text{C-}\ddot{\text{N}}$	301.0	$\dot{\text{C}}\text{-}\ddot{\text{N}}$, amide	358.7
$\ddot{\text{N}}\text{-H}$	381.0	$\dot{\text{C}}\text{-}\ddot{\text{N}}$, out	340.5
$\dot{\text{C}}\text{-C}$	347.0[a]	$\dot{\text{C}}\text{-}\ddot{\text{N}}$, out	322.2
$\dot{\text{C}}\text{-H}$	379.0	C-O, conj	474.1
$\dot{\text{C}}\text{-}\dot{\text{O}}$	500.0		

a) Tentatively assigned.

and $E(\dot{C}\text{–}\ddot{N},\text{int})$ can be expected to be higher than $E(\text{C–}\ddot{N})$, which is the case for the values given in Table 5.

The magnitudes of the σ-bond-contribution terms for CO–N bonds are in this order: $E(\dot{C}\text{–}\ddot{N},\text{amide}) > E(\dot{C}\text{–}\ddot{N},\text{out}) > E(\dot{C}\text{–}\ddot{N},\text{int})$, which is in accord with the trend of the π-bond contribution terms, the increment being larger in the former. This means that the total strength of a CO–N bond is highest for amide, in the second place for urea and diacetylimide, and in the third place for the internal bond of acetylurea, which, in turn, would be stronger than the C–N bond of methylamine.

Destabilization Energies. For normal alkanamides and *N,N*-dimethylformamide, the destabilization energies are close to zero, with the exception of pentanamide.

The destabilization energy of diacetamide with the CO–N–CO skeleton is nearly zero. The agreement between the calculated and experimental atomization enthalpies for diacetamide shows that the present treatment is a reasonable one. The small destabilization energy of *N*-butyldiacetamide is probably due to repulsion between the three groups bonded to the nitrogen atom.[12]

A triacetamide molecule contains three outermost CO–N bonds that involve a common branching nitrogen atom. For this kind of bond, the σ-bond-contribution value has not been determined. Consequently, the σ-bond-contribution value was assumed to be equal to that of the internal CO–N bond which does not involve a branching nitrogen atom, judging from the similarity in the value of π-bond order. The destabilization energy is attributable to repulsion between the three acetyl groups.[12]

Trimethyl isocyanurate is not significantly destabilized by ring strain. The experimental value for isocyanuric acid is not the atomization enthalpy, but the enthalpy difference between the atomic gases and the crystalline state. The value given in the column of destabilization energy seems to be of a reasonable magnitude as a sublimation enthalpy.

The negative of the destabilization energy (due to the ring strain) of 6-hexanlactam corresponds to standard enthalpy change for the following hypothetical gas-phase ring-opening polymerization reaction:

$$\boxed{\text{–CO–NH–(CH}_2\text{)}_5\text{–}} = (1/n)\{\text{–CO–NH–(CH}_2\text{)}_5\text{–}\}_n. \quad (7)$$

Thermochemical Stabilization Energies. In Ref. 1, the stabilization energies were evaluated for acetamide, urea, acetylurea(*trans–trans*), and trimethyl isocyanurate as standard enthalpy changes of the following gas-phase isodesmic reactions:

$$CH_3CONH_2 + C_2H_6 = CH_3COCH_3 + CH_3NH_2, \quad (8)$$

$$NH_2CONH_2 + 2C_2H_6 = CH_3COCH_3 + 2CH_3NH_2, \quad (9)$$

$$CH_3CONHCONH_2 + 3C_2H_6 = 2CH_3COCH_3 + CH_3NH_2 + (CH_3)_2NH, \quad (10)$$

$$\boxed{\{\text{CO–N(CH}_3\text{)}\}_3} + 6C_2H_6 = 3CH_3COCH_3 + 3(CH_3)_3N. \quad (11)$$

Enthalpy changes were decomposed into components according to Eq. 4; the results are shown in Table 6. As expected, in every reaction the contribution from π-bonding energies is more dominant than that related to the σ-bonding energies. It is notable that the contribution from the π-bonding energy is underestimated in the present treatment, because the destabilizing effect of bond compression has been included in this energy.[3]

Thus, the atomization enthalpies of the present compounds have been reasonably interpreted within the framework of the Hess–Schaad theory, and new findings have been obtained on the strength of the CO–N bonds of various molecules.

The authors are grateful to Dr. Junichi Aihara of Shizuoka University, who kindly supplied a BASIC program for the calculation of the graph-theoretical resonance energy prior to publication.

Catalytic Properties of Perovskite-Type Mixed Oxides (ABO_3) Consisting of Rare Earth and 3d Transition Metals. The Roles of the A- and B-Site Ions

Taihei NITADORI,†,* Tatsumi ICHIKI,†† and Makoto MISONO
Department of Synthetic Chemistry, Faculty of Engineering, The University of Tokyo, Hongo, Bunkyo-ku, Tokyo 113
†Central Research Institute, Japan Tobacco, Inc., Umegaoka, Midori-ku, Yokohama, Kanagawa 227
(Received April 1, 1987)

The catalytic activities of perovskite-type mixed oxides ($LnBO_3$ and $Ln_{0.8}Sr_{0.2}CoO_3$, Ln=rare-earth (lanthanoid) elements, B=3d transition metals) for the oxidation of propane and methanol have been studied comparatively. It has been found that the catalytic activities of $LnBO_3$ were principally determined by the B-site elements and were similar to those of the corresponding oxides of the B-site elements. The roles of the rare-earth ions of the A-site were secondary as long as they were trivalent. Upon the partial replacement of Ln^{3+} by Sr^{2+}, the catalytic activities of $LnCoO_3$ increased several times, the magnitude of the increase being similar among all the rare-earth ions. These results demonstrate that the kind and the valence of a B-site metal are of primary importance for the control of the catalytic activity for oxidation, almost regardless of the kind of trivalent rare-earth elements at the A-site.

Perovskite-type mixed oxides (ABO_3) are typical mixed oxides and many are known with various A- and B-site ions.[1] Because of this nature and the stability of the perovskite structure, the compositions and oxygen vacancies as well as the oxidation state of metal ions can be varied in a regular way. These oxides are, therefore, suitable model compounds for the study of the relationships between the solid state chemistry and the catalytic action of mixed metal oxides. Moreover, the perovskite-type mixed oxides with Co or Mn ions on the B-site have possible applications as fuel cell electrodes[2] and oxidation catalysts.[3,4]

We previously reported some remarkable effects of the valence control of the B-site ions and reasonably explained those effects in terms of the redox properties of the catalysts. For example, the Sr substitution for La of $LaCoO_3$ changed the catalytic activity greatly; paticularly, $La_{0.8}Sr_{0.2}CoO_3$ was the most active, and its activity for oxidation was higher than a Pt catalyst.[4] We further investigated the effects of the Sr, Ce, and Hf substitutions of $LaBO_3$ (B=Co, Fe, and Mn).[5–9] These studies confirmed that the valence of the B-site ions and the oxygen or metal vacancy in the bulk phase are the most important factors controlling the catalytic properties. It was revealed at the same time that the effects of those factors significantly changed with the kind of constituent element.

Therefore, in the present work, in order to elucidate more generally the roles of the constituent elements, we investigated comparatively the effects of rare-earth ions at the A-site and of 3d transition metal ions at the B-site. The effects on the valence control were examined in the case of the Sr substitution for $LnCoO_3$, which previously showed a remarkable positive effect. Although several works on those effects have been reported,[4,10–16] there have been very few studies in which both A- and B-site ions were varied simultaneously and extensively, and no studies about the effect of the A-site ion in valence control.

Experimental

Catalysts. The perovskite-type mixed oxides used as catalysts are summarized in Table 1. They were prepared from mixtures of metal nitrates of each component in the same manner as has been described in the previous paper.[4] The precipitates which had been obtained from mixed nitrate solutions by adding butylamine were filtered, decomposed in air at 300 °C for 3 h, and calcined in air, usually at 850 °C for 5—10 h. Some were calcined at 1100 °C for 10 h. Powder X-ray diffraction patterns were recorded on a powder X-ray diffractometer (Rigaku Denki, Rotaflex, RU-200) using Cu $K\alpha$ radiation. The surface areas of the samples were measured by means of the BET method (N_2 adsorption).

Component single oxides (rare earth=La, Ce, Pr, Nd, Sm, Eu, and Gd; 3d transition metal=Mn, Fe, and Co) were obtained by the calcination of metal acetates or nitrates of a reagent grade at 850 °C for 5 h in air. XPS measurements were carried out for $La_{1-x}Sr_xCoO_3$ with the Mg $K\alpha$ (1253.6 eV) source by the use of ESCA 750 (Shimadzu). The binding energies were calibrated with reference to a C1s electron line (285.0 eV).

Apparatus. Conventional flow, pulse, and closed circulation systems as described before[4–6] were used.

Procedure. Catalytic Oxidation of Propane and Methanol: The oxidation reactions of propane and methanol were carried out with the flow system following the procedure described previously.[4,9] Prior to the reaction, the catalysts (300 mg) were usually pretreated in an O_2 stream for 1 h at 300 °C. A gas mixture of propane (0.83%), O_2 (33.3%), and N_2 (balance) was used for the propane oxidation, and a mixture of methanol (6.0%), O_2 (9.0%), and N_2 (balance) for the methanol oxidation.

Reduction of Catalysts by CO: The reduction of catalysts by CO was carried out with the circulation system. Before the reduction, the catalysts (300 mg) were treated in

†† Present address: Tonen Sekiyukagaku K. K., Ohimachi, Saitama.

O_2 at 300 °C for 1 h, and then they were evacuated for 1 h at the reduction temperature. The initial CO pressure was about 20 Torr (1 Torr=133.3 Pa). The rates of the reduction were measured by the pressure decrease of CO, while the CO_2 produced was condensed in a trap kept at the temperature of liquid nitrogen.

Temperature-Programmed Desorption (TPD) of Oxygen: The TPD of oxygen was carried out using helium as a carrier gas (25 cm^3 min^{-1}) as has been described previously.[9] Prior to each run, the sample (1 g) was pretreated in an O_2 stream at 300 °C for 1 h (except for the $LnMnO_3$'s, which were pretreated at 800 °C). The rate of the temperature rise was 20 deg min^{-1}. In the first run for each sample, CO_2 and H_2O envolved in addition to O_2. In the subsequent runs, however, neither CO_2 nor H_2O was detected above the background level, and the TPD curves were reproducible. The data of the second runs were, therefore, adopted as in the previous papers.[5,9]

Results

Structures and Surface Areas of Perovskite Catalysts. The surface areas and the crystal structures of the catalysts used in the present study are summarized in Table 1. Perovskite-type structures of the samples were confirmed by reference to ASTM cards. The XRD patterns of these samples showed only the perovskite structure. The diffraction peaks of $LaFeO_3$ and $GdFeO_3$ calcined at 1100 °C became narrower, and the surface areas smaller, indicating the increased crystallinity. According to XRD, all of the rare-earth oxides were sesqui-oxides except for CeO_2 and Pr_6O_{11}; the oxides of the component 3d transition metals prepared were Mn_2O_3, Fe_2O_3, and Co_3O_4.

Table 1. Surface Area and Structure of Catalysts

Catalyst	Calcination		Surface area/m^2g^{-1}	Structure[a]
	Temp/°C	Time/h		
$LaCoO_3$	850	10	1.8	P(R)

a) P: perovskite structure, R: rhombohedral, C: cubic O: orthorhombic (judged from the splitting of the main peaks).

The surface composition of $La_{1-x}Sr_xCoO_3$, as estimated by XPS, is shown in Table 2. It was calculated from Eq. 1.[17]

$$\frac{N_a}{N_b} = \frac{n_a \cdot \lambda_a \cdot \sigma_a \cdot s_a}{n_b \cdot \lambda_b \cdot \sigma_b \cdot s_b} \quad (1)$$

where N: peak intensity, n: atoms per unit volume, λ: mean free path of electron, σ: ionization cross-section, and s: instrumental factor. The peak areas of La4d, Co2p (the average of 2p3/2 and 2p1/2) and Sr3d, including the satellite peak, were used for N, while the values of σ were taken from the literature.[18] "$\lambda \cdot s$" was assumed in this study to be constant, as has been suggested by the manufacturer. This assumption is not very accurate (though the errors are estimated to be no more than 15%), but it may be sufficient to compare the relative change in the surface composition for a series of catalysts. Therefore, the data in Table 2 may be considered as semi-quantitative values reflecting the trends of the surface segregation compared with the bulk composition. Thus, it may be stated, on the basis of the data in Table 2, that La was richer on the surface than in the bulk and that the Co content increased monotonically with an increase in the Sr content. The binding energies (780.3—780.9 and 795.5—796.1 eV), the spin-orbit splitting (15.2 eV), and the satellite splitting (9.8—10.0 eV) for Co2p were consistent with those of Co^{3+}.[19] Therefore, most of the Co in the surface may be Co^{3+}, although the possibility of the presence of Co^{4+} can not be excluded, since no data were reported for Co^{4+}.

Comparison of the Catalytic Activity for Oxidation. The catalytic activities of the perovskites and the rare-earth oxides for propane oxidation are shown in Fig. 1A, where are given the rates normalized to the unit surface area. CO_2 and H_2O were the only products in these experiments. It is notable that the Ln ions at A-site had a much smaller effect on the activity than did the transition metal ions at B-site, the order of the activity being always $LnCoO_3 > LnMnO_3 \gg LnFeO_3$. The activities of the component rare-earth oxides were very low. The activation energies obtained from the data at low conversion levels in these

experiments were 18.2—20.9 kcal mol^{-1} ($LnCoO_3$), 19.5—21.6 ($LnMnO_3$), and 24.0—25.8 ($LnFeO_3$), respectively. The greater effect of B-site ions than of Ln ions was also observed for methanol oxidation, as is shown in Fig. 1B (Co, Mn≫Fe). Complete oxidation was again the only reaction observed. The activation energies were 47—55 kcal mol^{-1}. The methanol oxidation was also measured over $LaFeO_3$ and $GdFeO_3$, which had been calcined at 1100 °C. In this case also, the difference in Ln had only a small effect.

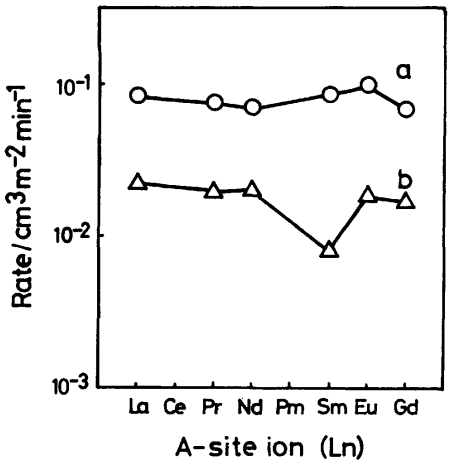

Fig. 3. Catalytic activities of $Ln_{0.8}Sr_{0.2}CoO_3$ for propane oxidation at 227 °C.
a: $Ln_{0.8}Sr_{0.2}CoO_3$, b: $LnCoO_3$.

The activity patterns of the perovskites and metal oxides containing the same 3d metals are compared in Fig. 2, including those of Cr[20] and Ni.[4] The differences in the activities among the catalysts on the whole were more than two orders of magnitude, whereas the differences between the perovskites and the corresponding B-site oxide were less than one order; also both the perovskites and B-site oxides showed very similar activity patterns, with twin peaks at Mn and Co. A similar pattern has been reported for $LaBO_3$ by Tascon et al.[21] This pattern resembles the trend reported for the oxidation of CH_4 and H_2[22] and may, therefore, be considered to reflect the ability of metal oxide to activate O_2. This pattern is different from the so called "Dowden pattern."[23] The Dowden pattern, which was often observed for hydrogenation reactions and which reflects the ability to activate H_2, has twin peaks at Cr and Co.

The Effect of Sr Substitution at A-Site for the Catalytic Activity. The effect of Sr substitution was examined for several rare-earth ions in the case of $LnCoO_3$, since a marked increase in the catalytic activity was previously found for $LaCoO_3$.[5,6] As shown in Fig. 3, the substitution by Sr for 20% of the A-site ions of $LnCoO_3$ increased 5—10 times the catalytic activity for propane oxidation; the magnitude of the increase was similar among the rare-earth ions. The surface areas tended to increase upon the Sr substitution, so the increases in the catalytic activity per catalyst weight were still greater. Figure 4 shows the effect of the extent of Sr substitution for $GdCoO_3$, together with the previous results for $LaCoO_3$.[4-6] The oxidation activity varied similarly for both systems, showing maxima at x=0.1—0.2. A similar effect was also found for methanol oxidation.

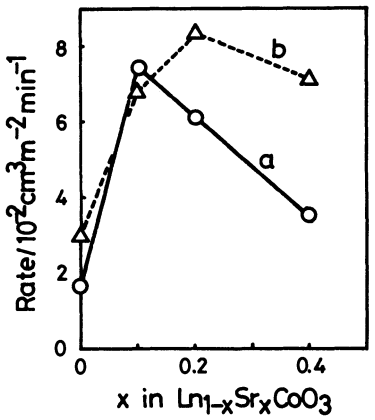

Fig. 4. Effect of Sr substitution on the catalytic activities of $LnCoO_3$ for oxidation of propane at 227 °C.

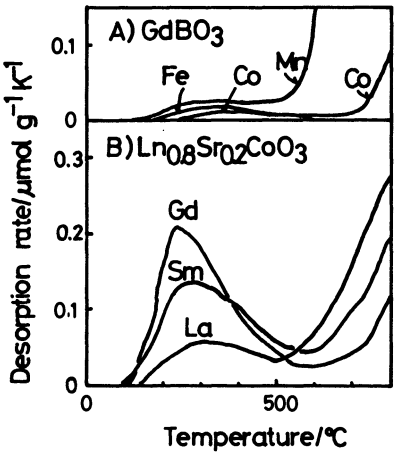

Fig. 5. TPD profiles of oxygen from perovskites.
A) $GdBO_3$, B) $Ln_{0.8}Sr_{0.2}CoO_3$.

TPD of Oxygen. Figure 5A shows the TPD of oxygen from $GdBO_3$ (B=Co, Fe, and Mn). Each TPD curve resembles that we previously reported for $LaBO_3$, with the same B-site element.[5,7,9] Broad and low peaks appeared at 150—500 °C for all three samples. The amounts of oxygen desorbed below 500 °C, which were previously indicated to be related to the catalytic function, were small, the order being Mn>Fe>Co. Even for $GdMnO_3$ the amount was only 0.12 cm^3 g^{-1}, which corresponded to 0.3 times the surface monolayer of oxygen. The large peak for Mn above 500 °C is likely to be due to the removal of excess oxygen, as has been discussed previously for $LaMnO_3$.[9]

The TPD profiles of $Ln_{0.8}Sr_{0.2}CoO_3$ (Ln=La, Sm, and Gd) are shown in Fig. 5B. The amounts of oxygen desorbed increased remarkably upon the Sr substitution, as has previously been reported for the $LaCoO_3$ system.[5,24] The amounts of oxygen desorbed

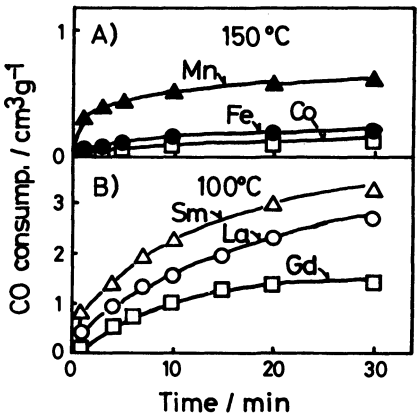

Fig. 6. Reduction of perovskite by CO.
A) $GdBO_3$, B) $Ln_{0.8}Sr_{0.2}CoO_3$.

below 500 °C were 0.34 (La)<0.82 (Sm)<1.00 (Gd) cm^3 g^{-1}. These values corresponded to about 0.6 (La) and 1.0 (Sm, Gd) surface monolayer. The amounts desorbed up to 800 °C were 1.17 (La), 1.40 (Sm), and 1.31 (Gd) cm^3 g^{-1}, which corresponded to 1.3—2.2 surface monolayers. Since the adsorbed oxygen is usually scarce, significant parts of the desorbed oxygen are from the catalyst bulk.

Reduction of the Catalyst by CO. Figure 6A shows the rate of the CO consumption of $GdBO_3$ (B=Co, Fe, and Mn) as measured in the circulation system at 150 °C. The amounts of CO consumed in 30 min were 0.1 (Co), 0.21 (Fe), and 0.63 (Mn) cm^3 g^{-1}, respectively, values which corresponded to 0.1—0.4 surface monolayer of oxygen. This tendency agreed with that of the amount of oxygen desorbed below 500 °C in the TPD described above (Fig. 5A). Figure 6B shows the results of the reduction for $Ln_{0.8}Sr_{0.2}CoO_3$ at 100 °C. $Ln_{0.8}Sr_{0.2}CoO_3$ was appreciably more easily reduced by CO than by $LnBO_3$ in spite of the lower reduction temperature. The amounts of CO consumed in 30 min were 2.27 (La), 3.35 (Sm), and 1.42 (Gd) cm^3 g^{-1}, corresponding to 2.6, 2.0, and 0.7 surface monolayers, respectively.

Discussion

Roles of A- and B-Site Ions. We have previously reported that the catalytic activities of $LaBO_3$ (B=Fe, Co, and Mn) for the oxidations of hydrocarbons and CO were approximately on the same level at those of the oxides of the B-site metals and that the catalytic properties reflected mainly the nature of the B-site metals.[4] This has also been pointed out by other investigators.[10-14] To explain this, the electronic state of the d electron of the B-site ion,[11] the binding energy of the B–O bond,[12] and the stabilization energy of the crystal field[13] have been proposed as the controlling factors of the catalytic activity. Although these factors are different, all of these explanations are based on the

nature of the B-site ions.

In this study, the rare-earth ion (Ln) at the A-site was changed variously. It was thus found that the effect of Ln was relatively small (Fig. 1) and that the activity patterns of the peroviske catalysts were the same as that of the oxides of the B-site transition metals (Fig. 2). By contrast, the order of the catalytic activities observed for the rare-earth oxides was quite different from that of the corresponding perovskites, and the activities were much lower. Among them, Pr_6O_{11} was the most active, and CeO_2, the least. This tendency is in agreement with the result reported for butane oxidation by Hattori et al.,[25] while it is different from the trend for $LnCoO_3$.

The physical properties of the rare-earth ions, such as the ionic radius, the charge density, and the magnetic moment, change significantly from La to Gd. The structures of the perovskites containing these elements also vary, for example, from $LaCoO_3$ (rhombohedral) to $GdCoO_3$ (orthorhombic). These changes would influence the electronic state of the B-site ion, but the effect seems less important than the B-site element itself. Thus, the effect of the A-site ion is presumed to be secondary as long as it is trivalent.

Nevertheless, several examples in which this secondary effect is significant have been reported. Parkash et al.[15] observed the highest activities for CO oxidation for Nd and Ho among $LnCoO_3$ (Ln=La, Pr, Nd, Gd, and Ho) and discussed this result based on the relative ratio of low- to high-spin Co^{3+}. Arakawa et al. reported that the catalytic activity of $LnFeO_3$ (calcined at 1200 °C) for methanol oxidation increased remarkably from La to Gd; they concluded that this was a result of the decrease in the covalency of the Fe–O bond.[16] In the present study, the catalytic activity for methanol oxidation over $LnFeO_3$ did not change much (Fig. 1B). Though the reason for this difference is not clear at present, the alteration of the composition on the surface and/or in the bulk of the catalyst might have occurred because of the different calcination conditions.

The Effects of Ln for the Valance Control of $LnCoO_3$. The catalytic activity increased several times upon the Sr substitution for Ln of $LnCoO_3$ regardless of the kind of trivalent rare-earth ion (Fig. 3). As for the extent of the substitution, a maximum was observed at x=0.1 for $Gd_{1-x}Sr_xCoO_3$ (Fig. 4). These results generally agree with our previous results for $La_{1-x}Sr_xCoO_3$.[6] The catalytic activity of $La_{1-x}Sr_x$-CoO_3 increased initially with an increase in x and showed a maximum at x=0.2. This variation in activity was semi-quantitatively explained as follows based on the change in the oxidation–reduction properties of the catalyst.[5,6]

Upon the Sr substitution, a part of the Co^{3+} is oxidized to Co^{4+} (Eq. 2). Since the Co^{4+} is unstable, however, the oxide ions tend to be removed and the Co^{4+} returns to Co^{3+} (Eq. 3):[5,6,24,26]

$$Ln^{3+}Co^{3+}O_3 \xrightarrow{Sr} Ln^{3+}_{1-x}Sr^{2+}_xCo^{3+}_{1-x}Co^{4+}_xO_3 \quad (2)$$

$$Ln_{1-x}Sr_xCo^{3+}_{1-x}Co^{4+}_xO_3 \longrightarrow Ln_{1-x}Sr_xCo^{3+}_{1-x+2\delta}Co^{4+}_{x-2\delta}O_{3-\delta} + (\delta/2)O_2 \quad (3)$$

This is in agreement with the present results that the oxygen desorbed in TPD increased remarkably and that the reduction by CO became much easier upon the Sr substitution (Figs. 5 and 6). This means that the oxidation power of $LnCoO_3$ is increased by the valence control. Since the increase in the oxidation power promotes the catalytic activity of the oxide catalysts for oxidation, the initial increase in the activity by the Sr substitution is understandable. The decrease in the catalytic activity at higher extents of substitution may be explained by the slower re-oxidation step in the redox cycle of the catalysts, as has been demonstrated previously,[6] or by the lower reactivity of the surface oxygen.[27] Therefore, the mechanism of the Sr substitution for $LnCoO_3$ in the valence control and the catalytic activity may be similar to that for $LaCoO_3$. The possibility that an unknown La- or Sr-rich phase segregated on the surface of the perovskites having high Sr contents and lowered the activity may not be excluded. However, this is not likely to be the main reason for the decrease in activity, since the surface compositions estimated by XPS indicated monotonous changes in the Co and Sr contents when x was increased (Table 2).

There were relatively small, but definite, differences between $LnCoO_3$'s, and the trends among the Ln ions observed for the TPD, the reducibility and the catalytic activity did not agree well with one another. For example, the amount of oxygen desorbed in TPD for $Ln_{0.8}Sr_{0.2}CoO_3$ (Fig. 6B; Gd>Sm>La for 25—500 °C) did not parallel the catalytic activity (Fig. 3; La>Gd>Sm) and the reducibility of $Ln_{0.8}Sr_{0.2}CoO_3$ (Fig. 6B; Sm>La>Gd). The reason for the disagreement observed for the secondary effects is not clear at present. Part of these discrepancies may, however, be related to the difference in the compositions between the surface and bulk or to the differences in the relative rates of the chemical processes on the surface to those in the bulk. A possible example of the chemical processes is the supply of oxygen species to surface sites. It can be from the gas phase through adsorption or from the bulk through diffusion.

The effect of Sr substitution on the Mn systems was examined only for $La_{1-x}Sr_xMnO_3$,[9] but the effects may be similar for other Ln ions, because it was reported by Raj et al.[28] that $LnMnO_3$ (Ln: La—Gd) calcined in air 950 °C has a similar oxidative nonstoichiometry. As the Sr content increases, the composition changes from oxygen-excess to oxygen-deficient and the catalytic activity changes moderately, showing maxima at about x=0.6.[9]

Conclusion

The following conclusions may be deduced for the roles of the A- and B-site ions of $LnBO_3$ for oxidation catalysis: (i) the kind and valence of the 3d transition metal ion at the B-site are of primary importance, (ii) the role of the rare-earth ion at the A-site is secondary as long as it is trivalent, (iii) the substitution of the A-site ion by ions with a different valence is very influential; this is caused by the change in the oxidation state of the B-site ion and the formation of an anion vacancy.[4-9]

A Conductance Study of 1:1 Complexes of 15-Crown-5, 16-Crown-5, and Benzo-15-crown-5 with Alkali Metal Ions in Nonaqueous Solvents

Yasuyuki TAKEDA,* Koji KATSUTA, Yoshihisa INOUE,† and Tadao HAKUSHI††
Department of Chemistry, Faculty of Science, Chiba University, Yayoi-cho, Chiba 260
†Basic Research Laboratory, Himeji Institute of Technology, 2167 Shosha, Himeji, Hyogo 671-22
††Department of Applied Chemistry, Himeji Institute of Technology, 2167 Shosha, Himeji, Hyogo 671-22
(Received June 18, 1987)

Conductivities of alkali metal salts in the presence of 15-crown-5 (15C5), 16-crown-5 (16C5), and benzo-15-crown-5 (B15C5) were measured at 25 °C in acetonitrile, propylene carbonate, and methanol. Formation constants (K_{ML^+}) of 1:1 complexes of 15C5 and 16C5 with alkali metal ions and conductance parameters (λ^0 and $\mathring{a}$) of the Na^+ complexes of 15C5, 16C5, and B15C5 were determined, λ^0 and $\mathring{a}$ being limiting ionic molar conductivity and distance of closest approach of ions, respectively. In general, selectivities of 15C5 and 16C5 for alkali metal ions show the size-fit correlation. In contrast to 15C5, 16C5 forms much the most stable complex with Na^+ in every solvent. Generally, K_{ML^+}-value sequences of a given crown ether complex for the solvents are the reverse of donor-number sequences of the solvents. Value of $\mathring{a}$ increases with an increase in the cationic size ($Na^+ \rightarrow Na(15C5)^+ \rightarrow Na(16C5)^+ \rightarrow Na(B15C5)^+$). Mobility of the Na^+-crown ether complex decreases with an increase in the size of the crown ether. From λ^0 values and Walden products of these Na(crown ether)$^+$ complexes and a tetrapropylammonium ion, it seems likely that $Na(15C5)^+$ and $Na(16C5)^+$ act as structure breakers in hydrogen-bonding solvents, whereas $Na(B15C5)^+$ as a structure maker.

Conductance measurements of a solution of alkali metal salt in the presence of crown ether provide two valuable information; that is, (1) stability of the crown ether–alkali metal ion complex, and (2) transport phenomena of the crown ether–alkali metal salt complex in the solution.[1] Many data have been reported on stabilities of 15-crown-5 (15C5)- and benzo-15-crown-5 (B15C5)–alkali metal ion complexes in solutions, but a few data on solvation behavior of the crown ether complexes in solutions.[2] It has recently been presented that 16-crown-5 (16C5), possessing the same number of donor oxygen atoms but reduced symmetry, exhibits much higher selectivity for Na^+ among alkali metal ions than 15C5.[3,20] In the present study, in order to obtain systematic and detailed information on stabilities and solvation behavior of 15C5–, 16C5–, and B15C5–alkali metal ion complexes, conductivities of alkali metal salts in the presence of these three crown ethers were measured at 25 °C in acetonitrile, propylene carbonate, and methanol.

Experimental

Materials. 15-Crown-5 (Nisso Co., Ltd.) was purified twice by distillation under vacuum (bp 128.5—129.5 °C, 2.5 mmHg (1 mmHg≈133.322 Pa)). The preparation of 16C5 was just the same as that described in the previous paper.[3] Benzo-15-crown-5 (Merck Japan Ltd.) was dissolved in heptane, and filtered while hot. Then it was recrystallized from heptane three times and, prior to use, dried at 40 °C in vacuo for 50 h.

Extremely pure $LiCl \cdot H_2O$, NaCl, KCl, RbCl, and CsCl were purchased from Merck Japan Ltd., and were used without further purification. Rubidium and caesium perchlorates were prepared by adding a little excess of perchloric acid to aqueous solutions of the RbCl and CsCl, respectively. Lithium, sodium, and potassium perchlorates were obtained from Merck Japan Ltd. All the perchlorates were recrystallized four times from distilled water and, prior to use, dried at 150 °C in a vacuum oven.

The method of purification of acetonitrile,[4] propylene carbonate,[5] and methanol[6] was previously described. Middle 70% of distillate of the solvents was used. Conductivities of the purified acetonitrile, propylene carbonate, and methanol were less than 3×10^{-7}, 6×10^{-8}, and 2×10^{-7} Ω^{-1} cm^{-1}, respectively.

Alkali metal chlorides were employed for the methanol system and alkali metal perchlorates for the other solvent systems.

Apparatus and Procedure. The conductance measurements were made on a Fuso conductivity apparatus, model 362A, in a water bath thermostated at 25±0.005 °C.

The experimental procedure to obtain formation constants of crown ether complexes with alkali metal ions was almost the same as that described in a previous paper.[5]

The experimental procedure to obtain molar conductivities (Λ) of the crown ether–sodium salt complexes was as follows. A solution of crown ether (6×10^{-3} mol dm^{-3}, 200 cm^3) was placed in the cell and the resistance of the solution was measured. Then a step-by-step increase in the sodium salt concentration was effected by a rapid transfer from a solution of the sodium salt (1×10^{-2} mol dm^{-3}) to the cell with a pipet, until the total concentration of the crown ether was about five times as large as that of the sodium salt. The resistance of the solution in the cell was remeasured after each transfer.

Results

The molar conductivity vs. $[L]_t/[M]_t$ plots of the $16C5/LiClO_4$/propylene carbonate system show an increase in Λ with an increase in the 16C5 concentration, $[L]_t$ and $[M]_t$ denoting total concentrations of the crown ether and the alkali metal, respectively. This indicates that a 16C5–Li^+ complex is more

mobile in propylene carbonate than a free Li^+ ion. For 15C5 and 16C5/LiCl/CH_3OH and 15C5/NaCl/CH_3OH systems, there is a negligible change in Λ in spite of an increase in the crown ether concentration. Consequently, the complex-formation constants could not be determined. When the complex is unstable or mobilities of the complex and the corresponding alkali metal ion are equal, conductometric determination of the complex-formation constant is impossible. For all the other systems, Λ vs. $[L]_t/[M]_t$ plots show a decrease in Λ with an increase in the crown ether concentration. This reveals that the crown ether complex is less mobile than the corresponding free alkali metal ion. By way of example, Λ vs. $[L]_t/[M]_t$ plots for 15C5/ and 16C5/acetonitrile systems at 25 °C are given in Figs. 1 and 2, respectively.

From Figs. 1 and 2, in the cases of 15C5/ and 16C5/$NaClO_4$ systems, the slope of each curve changes sharply at $[L]_t/[M]_t=1$. The same tendency was

observed for 16C5/$NaClO_4$/propylene carbonate system. It follows from this that the crown ethers form 1:1 complexes with Na^+. For the other systems, no such clear breaking point was observed.

When a crown ether forms a 1:1 complex with an alkali metal ion, the equilibrium equation is written as

$$\underset{\alpha[M]_t}{M^+} + \underset{[L]_t-(1-\alpha)[M]_t}{L} \rightleftarrows \underset{(1-\alpha)[M]_t,}{ML^+} \quad (1)$$

where M^+, L, and α are the alkali metal ion, crown ether, and the fraction of free alkali metal ions. Thus, the complex-formation constant, K_{ML^+}, is defined by

$$K_{ML^+} = [ML^+]/[M^+][L] = (1-\alpha)/\alpha[L]. \quad (2)$$

The observed conductivity, κ, is given by

$$\kappa = \kappa_{MA} + \kappa_{MLA}, \quad (3)$$

where A^- denotes an anion, and κ_{MA} and κ_{MLA} refer to conductivities of alkali metal salt and alkali metal crown ether salt, respectively. The molar conductivities are as follows.

$$\Lambda_{MA} = \kappa_{MA}/[M^+] = \kappa_{MA}/\alpha[M]_t, \quad (4)$$

$$\Lambda_{MLA} = \kappa_{MLA}/[ML^+] = \kappa_{MLA}/(1-\alpha)[M]_t, \quad (5)$$

Λ_{MA} and Λ_{MLA} designating molar conductivities of alkali metal salt and alkali metal crown ether salt, respectively. As a consequence of Eqs. 4 and 5, Eq. 3 can be transformed into

$$\Lambda = \kappa/[M]_t = \alpha\Lambda_{MA} + (1-\alpha)\Lambda_{MLA}. \quad (6)$$

In this study, corrections for viscosity changes were neglected. As a consequence of Eq. 6, Eq. 2 can be transformed into

$$K_{ML^+} = (\Lambda_{MA}-\Lambda)/(\Lambda-\Lambda_{MLA})[L], \quad (7)$$

where $[L]=[L]_t-[M]_t(\Lambda_{MA}-\Lambda)/(\Lambda_{MA}-\Lambda_{MLA})$. The K_{ML^+} value can be obtained by the following procedure. The Λ_{MLA} value is estimated from the Λ values at the points of large $[L]_t$ to $[M]_t$ ratios. Using this Λ_{MLA} value, the K_{ML^+} value in Eq. 7 is calculated. The actual K_{ML^+} and Λ_{MLA} values are calculated by a successive approximation method. The actual Λ_{MLA} values at nearly equal $[M]_t$ values are listed in Table 1. The log K_{ML^+} values are summarized in Table 2.

Conductance data of crown ether–sodium salt complexes (NaLA) were analyzed by the Fuoss–Onsager equations:[21]

$$\Lambda = \Lambda_0 - SC^{1/2} + EC\log C + JC \quad (8)$$

for unassociated electrolytes, and

$$\Lambda = \Lambda_0 - S(C\gamma)^{1/2} + EC\gamma \log C\gamma + JC\gamma - K_A\Lambda_0 f^2 C\gamma \quad (9)$$

for associated electrolytes, where K_A is ion-pair association constant and the other symbols have their usual meaning. In order to obtain the parameters of Eqs. 8 and 9, values of dielectric constants and viscosities listed in Table 6 were employed. It was found that every crown ether–sodium salt complex (NaLA) completely dissociates into cation and anion in the solvents. Limiting molar conductivities (Λ_0) and ion-size parameters (å) obtained in this work are summarized in Table 3.

Discussion

Stability of Crown Ether Complexes. As can be seen from Tables 2 and 4, selectivity of 15C5 for alkali metal ions shows the size-fit correlation except for the cases of Li^+ in acetonitrile and propylene carbonate and Na^+ in CH_3OH. In comparison with the case of 16C5, Li^+–15C5 complex is very stable among alkali metal ion–15C5 complexes in acetonitrile and propylene carbonate. It is interesting that, in contrast to 15C5, 16C5 forms much the most stable complex with Na^+ of all the alkali metal ions in every solvent. In particular, selectivity of 16C5 for Na^+ in propylene carbonate is the most striking of all the systems. Moreover, the 16C5–Na^+ complex in propylene carbonate is the most stable among all the 15C5 and 16C5 complexes. Thus, a remarkable enhancement of selectivity for Na^+ is caused by an extra methylene group in the 16C5 ring. The more closely an alkali metal ion fits into the 16C5 cavity, the more stable is the 16C5–alkali metal ion complex. This tendency can be explained by the size-fit concept.

Log K_{ML^+}-value sequences of a given crown ether–alkali metal ion complex for the solvents are acetonitrile>propylene carbonate>CH_3OH only except for those of 16C5–Na^+ complex for propylene carbonate and acetonitrile (Table 2). The log K_{ML^+}-value sequences are completely the reverse of donor-number sequences of the solvents (acetonitrile<propylene carbonate<CH_3OH, from Table 6). Donor number of the solvent seems to be a dominant factor governing the stability of the crown ether–alkali metal ion complex.[1] From Table 6, ε_r values of the solvents increase in the order CH_3OH<acetonitrile<propylene carbonate. This indicates that there is no relationship between stability of the crown ether–alkali metal ion complex and dielectric constant of the solvent.

A 15C5–alkali metal ion complex is more stable than the corresponding 16C5 complex except for the case of Na^+. In propylene carbonate and CH_3OH, the reverse is true of 15C5- and 16C5–Na^+ complexes. In acetonitrile, log K_{ML^+} values of 15C5- and 16C5–Na^+ complexes are almost the same. This tendency may be explained in terms of examination of CPK molecular models, that is, Na^+ has a more suitable size for the cavity of 16C5 than that of 15C5, and the donor oxygen atoms of 16C5 arrange more nicely around Na^+ compared to 15C5. However, lower symmetry of 16C5 causes more unfavorable orientation of the donor oxygen atoms for the less size-fitted cations, Li^+, K^+, Rb^+, and Cs^+.

Behavior of Crown Ether Complexes in Solutions. From Table 3, a slight association to ion-pairs is found for $NaClO_4$ in acetonitrile, but all the crown ether–sodium salt complexes completely dissociate into ions. Since mobilities of these three crown ether–Na^+ complexes are much smaller than that of a Na^+ ion in acetonitrile (Table 5), an apparent cationic size is much larger for the crown ether–Na^+ complexes

Table 5. Limiting Ionic Molar Conductivities (λ^0) in Various Solvents at 25 °C

than for the Na^+ ion. This is responsible for a complete dissociation of crown ether-$NaClO_4$ complexes into ions and a slight association of $NaClO_4$ to ion-pairs in acetonitrile.

Table 3 shows that $\mathring{a}$ value increases with an increase in the cationic size ($Na^+ \rightarrow Na(15C5)^+ \rightarrow Na(16C5)^+ \rightarrow Na(B15C5)^+$) regardless of a variety of anions and solvents. It follows from this finding that the anion does not always approach the sodium ion trapped in the cavity in a direction perpendicular to the plane of the crown ether ring.

By using ionic radii of $Na(15C5)^+$ (4.6 Å[5]), ClO_4^- (2.26 Å[28]), and Cl^- (1.81 Å[27]), center-to-center distance of the cation and the anion is calculated to be 6.86 Å for $Na(15C5)ClO_4$ and 6.41 Å for Na(15C5)Cl, which are greater than the largest $\mathring{a}$ values of B15C5-sodium salt complexes.

For 15C5 and 16C5, $\mathring{a}$ values of the crown ether-$NaClO_4$ complex in acetonitrile and propylene carbonate are much the same. Although ionic radius of Cl^- is 0.45 Å smaller than that of ClO_4^-, $\mathring{a}$ value of the crown ether-sodium salt complex in CH_3OH is larger than or nearly equal to those in aprotic solvents. The same behavior is observed for both sodium and tetrabutyl ammonium salts (Table 3). This may be attributed to much stronger solvation of Cl^- in CH_3OH compared to ClO_4^-.

It can be seen from Table 5 that the mobility of Na^+-crown ether complex decreases with an increase in the size of crown ether, indicating that the mobility of the complexed sodium ion is governed completely by the size of the complex. It is of interest to note that only an additional methylene group causes the lower mobility of $Na(16C5)^+$ compared to $Na(15C5)^+$. Mobilities of Na^+ in acetonitrile and CH_3OH show the same tendency as stated above, but that in propylene carbonate the opposite trend. It has been reported that the degree of solvation of large ions is determined predominantly by the dipole moment of solvent molecules, whereas that of small ions by the acid-base properties of solvent molecules.[22] Although propylene carbonate has a slightly larger and smaller donor number than acetonitrile and CH_3OH, respectively (Table 6), and has a larger dipole moment (4.94 D[33]) than acetonitrile (3.37 D[33]) and CH_3OH (1.73 D[33]), $Na(15C5)^+$ is more mobile than Na^+ in propylene carbonate, and the reverse is true of acetonitrile and CH_3OH. The lower mobility (the larger moving entity) of Na^+ in propylene carbonate may be attributed to the larger size of the propylene carbonate molecule (molecular radii of propylene carbonate, acetonitrile, and CH_3OH are 3.23, 2.75, and 2.52 Å, respectively[31]).

Although the ionic radius of $Na(15C5)^+$ is nearly equal to that of tetrapropylammonium ion (Pr_4N^+) (4.52 Å[34]), $Na(15C5)^+$ is less mobile than Pr_4N^+. For $Na(15C5)^+$, there exists a possible interaction of the central Na^+ with solvent molecules on two axial sides of the 15C5 plane, whereas, for Pr_4N^+, the charge of the nitrogen atom is effectively screened by four propyl groups. Consequently, the interaction of $Na(15C5)^+$ with solvent dipole seems to be stronger than that of Pr_4N^+. This may be responsible for the lower mobility of $Na(15C5)^+$ compared to Pr_4N^+.

In the cases of L=15C5 and 16C5, sequences of $|\lambda^0(Pr_4N^+)/\lambda^0(NaL^+)-1|$ value for the solvents are $CH_3OH < CH_3CN <$ propylene carbonate. This shows that a difference in mobility in CH_3OH between NaL^+ and Pr_4N^+ is the smallest of all the solvents. The same behavior was observed for the case of $K(18C6^{**})^+$ complex and tetrabutylammonium ion (Bu_4N^+).[4] In the previous papers,[4,35] it was reported that $K(18C6)^+$ acts as a structure breaker in hydrogen-bonding solvents. From Walden products of Pr_4N^+ in Table 6, Pr_4N^+ is more mobile in CH_3OH than in acetonitrile. It thus appears that hydrogen-bonded structure of CH_3OH scarcely decreases the mobility of Pr_4N^+. Although hydrogen bonds of ether oxygen atoms of 15C5 and 16C5 with methanol molecules would decrease mobilities of $Na(15C5)^+$ and $Na(16C5)^+$ complexes, the mobility of NaL^+(L=15C5 and 16C5) approaches that of Pr_4N^+ most closely in CH_3OH of

**18C6=18-crown-6.

all the solvents. Therefore, it can be considered that $Na(15C5)^+$ and $Na(16C5)^+$ in CH_3OH are more mobile than expected. This is supported by the data in Table 6; namely, Walden products of $Na(15C5)^+$ and $Na(16C5)^+$ in CH_3OH are larger than those in acetonitrile. Consequently, from the data of $K(18C6)^+$ [4,35] and the above discussion, it seems likely that $Na(15C5)^+$ and $Na(16C5)^+$ act as structure breakers in hydrogen-bonding solvents.

For $Na(B15C5)^+$, sequences of $\lambda^0(Pr_4N^+)/\lambda^0(Na(B15C5)^+)$ value for the solvents are $CH_3CN<CH_3OH<$propylene carbonate. The order of CH_3CN and CH_3OH for $Na(B15C5)^+$ is in the reverse of that for $Na(15C5)^+$ and $Na(16C5)^+$. This indicates that the mobility of $Na(B15C5)^+$ in CH_3OH is lower than expected on the basis of those of $Na(15C5)^+$ and $Na(16C5)^+$. Enforcement of a hydrogen-bonded structure of CH_3OH for the benzo group may decrease the mobility of $Na(B15C5)^+$. This is supported by the data of Walden products of $Na(B15C5)^+$ in Table 6; the $\lambda^0\eta_0$ value of CH_3OH of $Na(B15C5)^+$ is the smallest of all the solvents. This suggests that, on account of the benzo group, $Na(B15C5)^+$ acts as a structure maker in hydrogen-bonding solvents.

For these three Na(crown ether)$^+$ complexes as well as Pr_4N^+, Walden products in propylene carbonate, which has the greatest ε_r value, are the largest.

The Volumes of Hydrated Glucose, Sucrose and Raffinose Molecules, and the Osmotic Pressures of These Aqueous Saccharide Solutions as Measured by the Freezing-Point-Depression Method

Keitaro KIYOSAWA
Department of Biophysical Engineering, Faculty of Engineering Science, Osaka University, Toyonaka, Osaka 560
(Received April 21, 1987)

The osmotic pressures of aqueous saccharide solutions were calculated from the data obtained by means of the freezing-point-depression method. Thus, the water activity and the osmotic pressure of D-glucose, sucrose, and raffinose solutions were measured by the freezing-point-depression method. For dilute aqueous saccharide solutions, the freezing-point depression was proportional to their molal concentrations. However, the higher the molal concentration, the larger the freezing-point depression observed became than those to be expected from the molal concentration dependent on the size of the saccharide molecules. The osmotic pressures calculated from the data of the freezing-point-depression method were compared with those measured with semi-permeable membranes by Morse and his colleagues. To obtain the apparent volumes of hydrated D-glucose, sucrose, and raffinose molecules, their partial molal volumes were measured, together with the partial molal volumes of the water of their solutions. The partial molal volumes of the water were verified to be equal to the molar volumes of pure water up to the highest concentrations examined. The apparent volumes of the hydrated D-glucose, sucrose, and raffinose molecules were calculated to be 0.1865, 0.3525, and 0.5105 nm^3 respectively.

To physiologists who study water relations in plant and animal cells, and membrane phenomena, it has become common knowledge that the osmotic pressure inside and outside a cell[1-5] and the ionic component[6-8] both have important effects on its activities. Thus, various aqueous electrolyte solutions, such as KCl, NaCl, CsCl, RbCl, $RbNO_3$, RbF, $CaCl_2$, $Ca(NO_3)_2$, and $MgSO_4$,[7,9-12] have been used to control the ionic condition and the osmotic pressure inside and outside cells. Various saccharides, such as glucose, sucrose,[13,14] and raffinose, and their derivatives, such as mannitol,[2,15,16] and sorbitol,[17] have also been used.

Although we have very detailed data about the freezing-point depression of simple aqueous electrolyte solutions,[18] we have only a few data about the osmotic pressure of saccharide and its derivative solutions.[18-20]

In this paper, the water activity, the osmotic pressure, the activity coefficient of the water, and the osmotic coefficients of aqueous D-glucose, sucrose and raffinose solutions, as calculated from the freezing-point-depression data and the partial molal volume of the water as well as the partial molal volumes of these saccharides, are reported as functions of their concentration. The values of the partial molal volume thus obtained were then used to calculate the volume of a hydrated saccharide molecule.

Materials and Methods

The D-glucose, sucrose, and raffinose used were of a reagent grade from Nakarai Chemicals, Ltd., and Wako Pure Chemical Industries, Ltd. The raffinose, a hydrate, had been kept in a petri dish for a few months so as to make it in equilibrium with the water in the air. These saccharides were not further purified by the method of recrystalization from their hot concentrated aqueous solutions by adding alcohol because our preliminary test using the atomic-absorption method had shown that the saccharides were fairly free from contaminating electrolytes, such as K^+, Na^+, Ca^{2+}, and Mg^{2+}. On the other hand, ethyl alcohol which had been stored in a glass bottle for a long period contained a small amount of Na^+.

The water used had been distilled from a deionized supply. The air dissolved in the distilled water was not completely removed except when the effect of the dissolved air was examined. The air dissolved in the aqueous solutions was not a serious problem in measuring their density with the mechanically oscillating densimeter except in winter. The effect of the dissolved air in the solutions will be discussed later from the biological point of view.

The freezing-point depression was measured with an osmometer (Advanced Instruments, Inc.; Type 3W) which had been calibrated with standard aqueous NaCl solutions whose freezing-point depressions are listed in "Handbook of Physics and Chemistry".[21] The osmometer was equipped with a thermister to detect the freezing point of the aqueous solution to be examined and a cooling bath in which a glass tube containing the aqueous solution was designed so as to be cooled gently.

Calculation of osmotic pressure from the data measured with the osmometer: The osmometer expresses the freezing-point depression $\theta(=T°-T)$ in terms of mosmol, where $T°$ and T are the freezing points of pure water and the aqueous solution to be tested respectively. 1.0000 mosmol is defined as the molal concentration of an ideal aqueous solution, whose freezing-point depression θ is 1.86×10^{-3} °C.

The equation used to express precisely the freezing-point depression is as follows (cf. Appendix):

$$\Delta_{fus}Hm_{(1)}(T^\circ)\left(\frac{1}{T}-\frac{1}{T^\circ}\right) - \frac{1}{T}\int_T^{T^\circ}\{Cp,m_{(1)}^{l}(T'')-Cp,m_{(1)}^{s}(T'')\}dT'' + \int_T^{T^\circ}\frac{Cp,m_{(1)}^{l}(T'')-Cp,m_{(1)}^{s}(T'')}{T''}dT'' = -R\ln x_1 f_1 \quad (1)$$

$$= -\phi R\ln x_1 \quad (2)$$

where $Cp,m_{(1)}^{l}(T)$, $Cp,m_{(1)}^{s}(T)$, x_1, f_1, and ϕ are the molar heat capacities at a constant pressure of liquid and solid water as functions of the temperature; the mole fraction of water; the activity coefficient of water, and the osmotic coefficient of the solution respectively.

Actually, however, we are at present forced to adopt the following equation to calculate the water activity because of the lack of precise values of $Cp,m_{(1)}^{l}(T)$ and $Cp,m_{(1)}^{s}(T)$ in Eqs. 1 and 2 of the aqueous solutions to be examined (cf. Dorsey[22]). That is :

$$\Delta_{fus}Hm_{(1)}(T^\circ)\left(\frac{1}{T}-\frac{1}{T^\circ}\right) = -R\ln x_1 f_1 \quad (3)$$

$$= -\phi R\ln x_1. \quad (4)$$

It will be shown in the Discussion section that Eq. 3 or 4 gives values of the water activity of, at least, sucrose solutions fairly consistent with those obtained with semi-permeable membranes. Thus, from Eqs. 3 and 4, $\ln x_1 f_1$, f_1, and ϕ are calculated after T has been calculated from both T° and θ.

The osmotic pressure π which should be generated between an aqueous solution of the mole fraction x_1 and pure water $x_1=1$ across a semi-permeable membrane is defined as the osmotic pressure of the solution and is expressed by this equation:[23,24]

$$\Pi = -\frac{RT\ln x_1 f_1}{Vm_{(1)}(T,0)\left\{1-\frac{1}{2}\kappa_1(P'+P'')\right\}} \quad (5)$$

or by:

$$\Pi = -\frac{\phi RT\ln x_1}{Vm_{(1)}(T,0)\left\{1-\frac{1}{2}\kappa_1(P'+P'')\right\}} \quad (6)$$

where $Vm_{(1)}(T,0)$ is the molar volume of water extrapolated to zero pressure at the temperature T K; κ_1, the compressibility of water (4.6×10^{-5} atm^{-1} or 4.5×10^{-10} Pa^{-1} at 298.15K[22]); and P' and P'', the pressures of the pure-water phase and the aqueous-solution phase respectively.

Since, in ordinary solutions used in physiology, $1\gg1/2\kappa_1(P'+P'')$ and T=17—25 °C, we obtain:

$$\Pi = -\frac{TR}{Vm_{(1)}(298.15,0)}\ln x_1 f_1 \quad (7)$$

where $Vm_{(1)}$ (298.15,0) is the molar volume of water extrapolated to zero pressure at 25 °C: approximately 1.8075×10^{-2} dm^3 mol^{-1}. Therefore, in order to relate the results obtained from the freezing-point-depression method to the osmotic pressure, it is essential to calculate the value of $\ln x_1 f_1$ or $\phi\ln x_1$ from θ, T°, and T.

Partial molal volume of the water: In order to estimate the effect of saccharides on the water structures in their aqueous solutions, the partial molal volume of the water of the aqueous saccharide solutions were determined as functions of their concentrations. The partial molal volume of the water $Vm_{(1)}$ of an aqueous solution was determined as an intersect of the linear curve obtained by plotting the mean molar volume $V_{1,2}$ against the mole fraction of saccharide x_2 with the $V_{1,2}$-axis. $V_{1,2}$ was expressed by the mole fraction of the water x_1 and the solute x_2, the partial molal volume of water $Vm_{(1)}$ and a saccharide $Vm_{(2)}$ as :[24,25]

$$V_{1,2} = Vm_{(1)}x_1 + Vm_{(2)}x_2 \quad (8)$$

In this study, $V_{1,2}$ was calculated from the density ρ of the solution by means of this equation:

$$V_{1,2} = \frac{1}{\rho}\frac{1.0000+M_2m}{55.5093+m} \quad (9)$$

where M_2 and m are the molecular weight of the solute and the molal concentration of its aqueous solution and where 55.5093 moles is the mole number of 1.0000 kg of water respectively. In the calculation of the molal concentration of each aqueous solution, the buoyancy due to air was corrected.

The density of the saccharide solutions was measured with a mechanically oscillating densimeter (Shibayama SS-D-200) at 25.00±0.01 °C. The effects of the viscosity of the solution on the density measurement with the densimeter[26] was negligibly small up to the highest concentrations of the solutions tested in this study.

Results

Table 1 shows the freezing-point depression of D-glucose, sucrose, and raffinose solutions and the osmotic pressure calculated from the data of the freezing-point depression. They are averages of 4—9 measurements and are expressed in terms of mosmol; atm and Pa are, respectively, functions of the molal and molar concentrations. The activity coefficient f_1 and the osmotic coefficient ϕ, which were determined by means of Eqs. 3 and 4, are also shown in Table 1.

At higher concentration than about 420 mmol kg^{-1}, raffinose was precipitated when ice was formed by agitation in its supercooled aqueous solution. In concentrated D-glucose and sucrose solutions, the formation of ice seemed to occur more slowly by the same agitation in supercooled states.

Table 1. Freezing-Point Depression, Water Activity in Terms of $-\ln x_1 f_1$, Osmotic Pressure Π, Activity Coefficient of Water f_1, and Osmotic Coefficient ϕ of Aqueous Saccharide Solutions

The molal concentrations at which the osmolality of the solutions became larger than their molal concentration by 3% were about 800 mmol kg^{-1} for D-glucose, about 350 mmol kg^{-1} for sucrose, and about 150 mmol kg^{-1} for raffinose. In the dilute ideal aqueous solutions, plotting the osmolality against its molal concentration gives a linear curve. Actually, however, the degree of the deviation of the osmolality from the molal concentration depended on the molecular weight or the molecular volume. That is, the larger the molecular weight or the molecular volume, the larger the deviation became at the same concentration.

Table 2 shows the mean molar volumes $V_{1,2}$ of D-glucose, sucrose, and raffinose solutions at 25 °C. In order to obtain the partial molal volumes of water of the saccharide solutions, their $V_{1,2}$ values were plotted against the mole fraction of the saccharide x_2. All of them gave linear curves up to the highest concentrations examined, and all of the curves intersected with the $V_{1,2}$-axis at 0.01807 dm^3 mol^{-1}. Figure 1 shows plots of $V_{1,2}$ of the aqueous sucrose solution against x_2

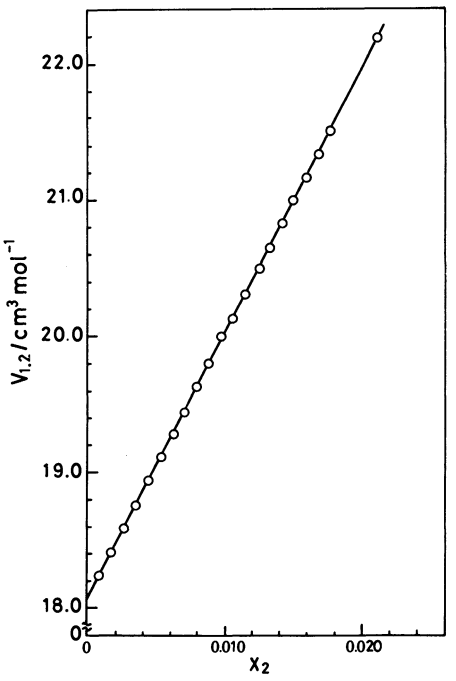

Fig. 1. Mean molar volume of aqueous sucrose solution $V_{1,2}$ as a function of sucrose mole fraction x_2.

as an example. The value of 0.01807 dm^3 mol^{-1} is almost equal to the molar volume of pure water, 0.0180685 dm^3 mol^{-1}, at 25 °C. This fact suggests that the aqueous saccharide solutions consist of a water phase which has the same property as bulky pure water and that of hydrated saccharide molecules scattered in the water phase, at least up to the highest concentrations examined in this study.

The partial molal volume $Vm_{(2)}$ of the 2 solute was calculated from the density ρ and the molar concentration c of the solution as follows. Assuming that the aqueous saccharide solution is composed of pure water and hydrated saccharide molecules, its density ρ is expressed by this equation:

$$\rho = \frac{M_2c+\rho_1(1.0000-Vm_{(2)}c)}{1.0000}\text{kg dm}^{-3} \qquad (10)$$

where M_2 and ρ_1 are the molecular weight of saccharide and the density of pure water respectively. By re-arranging Eq. 10, we obtain:

$$\rho = (M_2-\rho_1Vm_{(2)})c + \rho_1. \qquad (11)$$

Thus, if $Vm_{(2)}$ is constant, plots of the density ρ against c should give a linear curve whose slope is $(M_2-\rho_1Vm_{(2)})$ and $Vm_{(2)}$ can be calculated from the slope of this linear curve. After a linear relationship between ρ and c has been ascertained, the partial molal volume of a saccharide $Vm_{(2)}$ at each concentration c can also be calculated from the values of ρ, ρ_1, c, and M_2.

Table 3 shows the densities ρ of the D-glucose,

sucrose, and raffinose solutions as functions of the molal m and molar c concentrations. When the ρ values are plotted against c, they give straight curves in all the concentrations up to the highest in the freezing-point-depression experiments. The partial molal volumes of D-glucose, sucrose, and raffinose, as calculated from their slopes, were almost constant from diluted up to concentrated concentrations; they were 0.1123, 0.2123, and 0.3075 dm^3 mol^{-1} respectively. The values of the density ρ and the molal volume $Vm_{(2)}$ of the saccharides examined were almost coincident with those reported by Shahidi et al.[27]

Since the partial molal volume of the saccharide is constant up to an infinitely diluted concentration where the partial molal volume of the water is equal to the molar volume of pure water and where solute–solute interactions can be disregarded, it is safe to say that the partial molal volume of the saccharide is equal to the volume of the apparent volume of a hydrated saccharide molecule multiplied by the Avogadro number. Thus, the apparent volume of a hydrated saccharide molecule v_2° was obtained by dividing $Vm_{(2)}$ by the Avogadro number N_A, i.e.,

$$v_2^\circ = Vm_{(2)}/N_A. \tag{12}$$

The equivalent radius of a hydrated saccharide molecule r_2 was calculated as follows. Assuming that the hydrated saccharide molecule is spherical,

$$v_2^\circ = \frac{4}{3}\pi r_2^3. \tag{13}$$

Thus,

$$r_2 = \sqrt[3]{\frac{3}{4\pi}v_2^\circ}. \tag{14}$$

The calculated results are also shown in Table 3.

The apparent volume of one hydrated D-glucose, sucrose, or raffinose molecule was obtained as 0.1865, 0.3525, or 0.5105 nm^3 respectively. These values indicate that the apparent volume of the hydrated saccharide molecule is approximately proportional to the molecular weight.

Discussion

The present studies have made it clear that (1) the osmolality and the freezing-point depression of aqueous saccharide solutions are proportional to the molal concentration at dilute concentrations, although they become larger than the values of the molal concentration at higher concentrations; (2) the degree of the deviation depends on the molecular weight or the molecular volume of the solute; (3) the

activity coefficients of the water of aqueous saccharide solutions at the freezing point are almost unity up to 1.0 mol kg^{-1} for D-glucose, up to 0.65 mol kg^{-1} for sucrose, and up to 0.4 mol kg^{-1} for raffinose, while the osmotic coefficients of aqueous saccharide solutions tend to increase with an increase in the saccharide concentration; (4) the addition of saccharide molecules to the aqueous saccharide solution has little effect on the partial molal volume of the water, which is almost equal to the molar volume of pure water, at least up to the highest concentrations examined, and (5) the volume of a hydrated saccharide molecule is proportional to the molecular weight.

The fact that the addition of saccharide molecules to water or to its aqueous solution has little effect on the partial molal volume of the water suggests that their addition induces insignificant changes in the water structure, except in the vicinity of the solute molecules of the aqueous solution. Further, this suggests that we may ignore the effects of the saccharide molecules on the structure of the water phase surrounding the cell membrane, especially in the neighborhood of the inlet or outlet of the water-filled pores[28] and ion pores.

Miyajima et al.,[29] measuring the excess partial molar entropy, one of the thermodynamic quantities, of water for D-glucose, D-mannose, and D-galactose, reported that the ordering of water molecules occurred by the dissolution of these monosaccharides. Judging from the present results, their results may reflect an ordering of the water structure in the vicinity of the solute molecule as a result of hydration. However, this discrepancy between the present results and Miyajima et al.'s cannot be explained until an analysis of water structure is done by some other methods, such as X-ray diffraction or neutron scattering, that will enable us to detect some actual changes in the water structure.

Since the $R\ln x_1$ term is derived from the entropy of mixing $\Delta S_{1,2}$ on the basis of statistical mechanics,[25,30] the type of its expression should be different depending on the model adopted to evaluate the entropy of mixing. From primary statistical mechanics, the second term of the chemical potential equation, expressed as $R\ln x_1$, is derived based on the well-known lattice model under the assumptions that the solvent and the solute are nearly equal in size and that the distance between the lattice is constant, though arbitrary.

Based on the lattice model, some modified equations have been proposed to explain the entropy change of the mixing of solutions composed of solute and solvent molecules of different sizes.[31-35] However, since the present author thought of those models as less actual, he omitted the analysis of the molecular-weight or molecular-size dependence of $R\ln x_1$ as a function of the concentration.

Beginning in 1902[36] Morse and his colleagues extensively studied the osmotic pressure of rather dilute sucrose solutions using an apparatus of their own design, equipped with a semi-permeable membrane formed from both potassium ferocyanide and copper sulphate solutions. Since no one else has ever measured the osmotic pressure of dilute aqueous saccharide solutions using semi-permeable membranes, the present author has shown their results[37] in Table 4 to compare them with his own values calculated from the freezing-point-depression method. The osmotic pressure calculated coincides well with those directly measured by Morse et al. at 20 °C in the range of lower concentrations, while at higher concentrations the present results coincide well with those measured previously at 25 °C. However, the present results give values a little higher than Morse et al.'s at 0 °C. These small differences between the present results and Morse et al.'s might come from the difference between Eq. 1 and Eq. 3, used to calculate the water activity using the freezing-point-depression method. This problem should be checked when the molar-heat capacities of water and ice are precisely measured.

The equivalent radii of the hydrated saccharide molecules obtained by the present author are smaller

Table 4. The Osmotic Pressure of Sucrose Solutions as Functions of the Temperature (Morse et al.[37])

Concentration m	Osmotic pressure/atm					
	Temperature/°C					
	0	5	10	15	20	25

than those adopted by Durbin[38] to estimate the equivalent pore radius of the cellulose membrane. Hereafter, however, the equivalent radii of the hydrated saccharide molecules obtained by the present author will be used to estimate the equivalent pore radius of the membrane through which water and solute molecules pass, for the present author's procedure to obtain them seems to be more reasonable.

In studies of water and solute flows across such permeable membranes as the cell wall[39] and water and permeable-solute flows across the cell membrane,[40-42] not only the equivalent radius but also the properties of the surfaces of the saccharide molecules[43] and the permeable molecules are important, for solute–solute, solute–solvent, and solvent–solvent interactions at the inlet of the water-filled pores, those in the water-filled pores and/or ion pores, and solute-solvent-surface molecules of the water-filled pore and/or ion pore interactions at the inlet, and those in the water-filled pores and/or ion pores may have much to do with the membrane phenomena.[28,44]

The freezing point of the water containing dissolved air was lower than that of the air-free water by 0.36 mosmol, or 0.0007 °C on the average. However, under physiological conditions, the solutions inside (cytoplasm and vacuolar sap) and outside a cell can be considered to contain nearly equal amounts of such gases as N_2, O_2, and CO_2. Therefore, the effect of the dissolved air on the difference in the osmotic pressure between inside and outside the cell is not only practically, but also theoretically, insignificant.

Appendix

A Precise Equation of Freezing-Point Depression. The actual phenomena occurring in freezing-point depression in an aqueous solution consist of an unstable state caused by the creation of a chemical potential difference between the liquid water and the ice of the aqueous solution by supercooling up to a certain temperature T' K below the freezing point of the aqueous solution to be tested, T K, and pure water, T° K, a non-equilibrium process, which is followed by an equilibrium state. During the non-equilibrium process, ice grows and the temperature of the aqueous mixture containing the ice rises to T K from T' K, which is dependent on the water activity of the aqueous solution: this nullifies the difference in the chemical potential. The difference in temperature between T° and T is the freezing-point depression.

Thus, the difference in the chemical potential between the ice and the liquid water at T' K shouls be calculated as a function of the temperature. To do this, chemical potentials of both the ice and the water must be obtained as functions of the temperature and the water concentration. The chemical potentials of ice $\mu_1^{\circ s}(T)$ and of liquid water $\mu_1^{\circ l}(T)$ are formulated as, respectively:

$$\mu_1^{\circ s}(T) = \overset{s}{Hm}_{(1)}(T) - T\overset{s}{Sm}_{(1)}(T) \tag{1}$$

$$\mu_1^{\circ l}(T) = \overset{l}{Hm}_{(1)}(T) - T\overset{l}{Sm}_{(1)}(T) \tag{2}$$

where $Hm_{(1)}(T)$ and $Sm_{(1)}(T)$ are the partial molar enthalpy and the partial molar entropy of water respectively, and where the suffixes s, l, and 1 repesrent solid(ice) and liquid states, and water, respectively. For an ideal aqueous solution where the mole fraction of water is x_1:

$$\mu_1^l(T) = \overset{l}{Hm}_{(1)}(T) - T\overset{l}{Sm}_{(1)}(T) + TR\ln x_1. \tag{3}$$

Here,

$$\overset{s}{Hm}_{(1)}(T) = \int_0^T \overset{s}{Cp,m_{(1)}}(T'')\mathrm{d}T'' \tag{4}$$

$$\overset{l}{Hm}_{(1)}(T) = \int_0^{T^\circ} \overset{s}{Cp,m_{(1)}}(T'')\mathrm{d}T'' + \Delta_{fus}Hm_{(1)}(T^\circ) - \int_T^{T^\circ} \overset{l}{Cp,m_{(1)}}(T'')\mathrm{d}T'', \tag{5}$$

$$\overset{s}{Sm}_{(1)}(T) = \int_0^T \overset{s}{Cp,m_{(1)}}(T'')\frac{\mathrm{d}T''}{T''}, \tag{6}$$

$$\overset{l}{Sm}_{(1)}(T) = \int_0^{T^\circ} \overset{s}{Cp,m_{(1)}}(T'')\frac{\mathrm{d}T''}{T''} + \frac{\Delta_{fus}Hm_{(1)}(T^\circ)}{T^\circ} - \int_T^{T^\circ} \overset{l}{Cp,m_{(1)}}(T'')\frac{\mathrm{d}T''}{T''} \tag{7}$$

where $\overset{s}{Cp,m_{(1)}}(T)$, $\overset{l}{Cp,m_{(1)}}(T)$, and $\Delta_{fus}Hm_{(1)}(T)$ are the molar heat capacity of ice(solid) and liquid water as functions of the temperature at a constant pressure, and the molar heat of the fusion of ice at temperature T K, respectively.

In the equilibrium state,

$$\mu_1^l(T) = \mu_1^{\circ s}(T). \tag{8}$$

From Eqs. 1 and 3, Eq. 8 becomes:

$$\overset{l}{Hm}_{(1)}(T) - \overset{s}{Hm}_{(1)}(T) = T\{\overset{l}{Sm}_{(1)}(T) - \overset{s}{Sm}_{(1)}(T) - R\ln x_1\}. \tag{9}$$

Since

$$\overset{l}{Hm}_{(1)}(T) - \overset{s}{Hm}_{(1)}(T) = \Delta_{fus}Hm_{(1)}(T), \tag{10}$$

Eq. 9 becomes:

$$\frac{\Delta_{fus}Hm_{(1)}(T)}{T} = \overset{l}{Sm}_{(1)}(T) - \overset{s}{Sm}_{(1)}(T) - R\ln x_1. \tag{11}$$

For pure water, we have the same equation as Eq. 11, i.e.;

$$\frac{\Delta_{fus}Hm_{(1)}(T^\circ)}{T^\circ} = \overset{l}{Sm}_{(1)}(T^\circ) - \overset{s}{Sm}_{(1)}(T^\circ). \tag{12}$$

Thus, from Eqs. 11 and 12, we obtain this equation:

$$\frac{\Delta_{fus}Hm_{(1)}(T)}{T} - \frac{\Delta_{fus}Hm_{(1)}(T^\circ)}{T^\circ} + \overset{l}{Sm}_{(1)}(T^\circ) - \overset{l}{Sm}_{(1)}(T) - \overset{s}{Sm}_{(1)}(T^\circ) + \overset{s}{Sm}_{(1)}(T) = -R\ln x_1. \tag{13}$$

Since the molar heat of the fusion of ice at T' K, $\Delta_{fus}Hm_{(1)}(T')$, is expressed with the molar heat of the fusion of ice at T° K, $\Delta_{fus}Hm_{(1)}(T^\circ)$, by this equation:

$$\Delta_{fus}Hm_{(1)}(T') = \Delta_{fus}Hm_{(1)}(T^\circ) - \int_{T'}^{T^\circ} \{\overset{l}{Cp,m_{(1)}}(T'') - \overset{s}{Cp,m_{(1)}}(T'')\}\mathrm{d}T'', \tag{14}$$

introducing Eqs. 4, 5, 6, 7, and 14 into Eq. 13 and then rearranging it gives:

$$\Delta_{fus}Hm_{(1)}(T^\circ)\left(\frac{1}{T}-\frac{1}{T^\circ}\right) - \frac{1}{T}\int_T^{T^\circ}\{\overset{1}{Cp},m_{(1)}(T'')-\overset{s}{Cp},m_{(1)}(T'')\}dT'' + \int_T^{T^\circ}\frac{\overset{1}{Cp},m_{(1)}(T'')-\overset{s}{Cp},m_{(1)}(T'')}{T''}dT'' = -R\ln x_1. \quad (15)$$

This equation is a theoretically precise expression of the freezing-point depression in ideal aqueous solutions.

The author should like to thank Prof. Takashi Katayama, Dr. Tomoshige Nitta, and Dr. Manabu Yamaguchi, Department of Chemical Engineering, Faculty of Engineering Science, Osaka University, for permitting him to use the densimeter. He also wishes to thank Miss Atsuko Ookawa for typewriting this manuscript.

Kinetics of the Interaction between DNA and Acridine Orange

Naohisa KURE, Takayuki SANO,* Shoji HARADA, and Tatsuya YASUNAGA
Department of Materials Science, Faculty of Science, Hiroshima University, Hiroshima 730
(Received July 14, 1987)

Both static and kinetic investigations have been performed on the interaction of calf thymus DNA with Acridine Orange (AO). The binding isotherm obtained spectrophotometrically was analyzed by a site exclusion theory and revealed the presence of two binding modes of dye molecule corresponding to intercalation and dimerization on DNA. In the kinetic experiments focusing on the intercalation mode by the temperature-jump technique, three relaxations were observed. From the analyses of both the relaxation time and amplitude, the two fast relaxations were ascribed to parallel binding reactions including a bimolecular pathway for direct transfer of dye molecule on the polymer and the slow relaxation was attributable to a conformational change of DNA molecules. The binding parameters kinetically obtained suggest that 80% of bound AO is in intercalated form and the remainder is in partially intercalated one as an external bound form.

The interaction of acridine dyes with deoxyribonucleic acid (DNA) has been extensively studied because of their wide biological activities.[1-5] Acridine dyes have two binding modes on DNA with different affinities. Most experiments have been focused on the strong binding mode which has been related to the biological activity of the dyes, and elucidated that this binding mode structurally corresponds to an intercalation of dye between two adjacent base pairs of DNA.[6-12]

The stoichiometry of the binding of acridine dyes to DNA has been investigated by equilibrium dialysis[13-19] and/or visible spectroscopy.[13,20-22] The affinity of the intercalation mode has been found firstly to be independent of the base composition of DNA.[13,20,21] For this reason, various static and kinetic models have been proposed on the assumption of homogeneous DNA sites for the binding of acridine dyes.[16,23-27] However, the heterogeneity of the binding site has been pointed out from the fluorescence studies on several acridine dye-DNA complexes.[28-36] Given these circumstances, the investigation on more fundamental nature of the binding through the reexamination of the proposed binding models are desirable. For this purpose, Acridine Orange (AO) would be most favorable since this dye is known to form the intercalative complex independent of the base specificity of DNA.[32,33,35,37]

In this paper, thus the interaction between AO and calf thymus DNA focusing on the intercalative binding mode was studied by visible spectrophotometry and temperature-jump spectroscopy. A basic nature of the binding mechanism of acridine dyes with double stranded DNA was also discussed.

Experimental

Calf thymus DNA (sodium salt, type I) was purchased from Sigma Chemical Company and purified twice by phenol extraction. The hyperchromicity on thermal denaturation at 260 nm was 37—38% at pH 6.5 in the 1 mM† phosphate buffer. The concentration of DNA was determined using $\varepsilon_{260}=6600\ M^{-1}\ cm^{-1}$ per nucleotide. Acridine Orange (AO) was purchased from Eastman Kodak Company and was recrystallized twice as the base from a solution of Acridine Orange hydrochloride in a 1:1 water–ethanol mixture. The concentration of AO was determined spectrophotometrically at 492 nm by using the molar extinction coefficient proposed by Stone and Bradley.[38] Other chemicals used were reagent grade. All sample solutions were prepared in lmM phosphate buffer containing 0.2 M sodium chloride at pH 6.5.

Absorption spectra were measured with a Union Giken SM 401 spectrophotometer. Kinetic measurements were performed using the joule heating temperature-jump apparatus of which detail has been described elsewhere.[39] The light source was a halogen lamp (250 W) and the path length of the cell was 10 mm. The rise time and magnitude of the temperature-jump were about 10 μs and 7 °C, respectively. The orientational effect of DNA was canceled out by placing the polarizer between the cell and the monochromator.

All the static and kinetic measurements were performed at 25.0±0.2 °C. The data were analyzed on the basis of the neighbor exclusion model established by McGhee and von Hippel.[40]

Results

Binding Isotherm. The visible absorption spectra of AO–DNA complexes at various P/D (the ratio of DNA phosphate to dye) values in 0.2 M NaCl solution displayed an isosbestic point at 496 nm, in agreement with the results reported by Fredericq and Houssier.[17] They tried to obtain a binding isotherm from spectral shifts using the absorbance at 465 nm, but failed to obtain the consistent results with the equilibrium dialysis ones. This discrepancy in the binding data seems to come from the fact that molar extinction coefficient at 465 nm of bound AO varies significantly depending on the binding ratio r (bound AO/DNA phosphate).

In the present study, the binding isotherm was determined spectrophotometrically using the absorbance at 492 nm since the molar extinction coefficient on bound AO at this wavelength was reported to be

† 1 M=1 mol dm^{-3}.

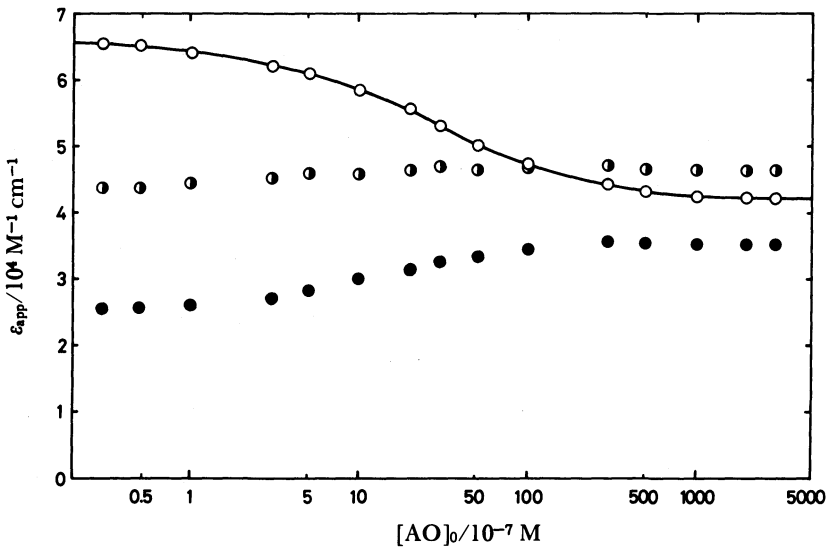

Fig. 1. Change in apparent molar extinction coefficient (ε_{app}) of AO–DNA solution with increasing AO concentration at a fixed P/D of 10 and 25 °C: (O), at 492 nm; (O), at 504 nm; (●), at 510 nm.

invariant for r below 0.2.[16] The apparent molar extinction coefficient (ε_{app}) of AO–DNA solutions were measured at various AO concentrations from 3×10^{-8} M to 3×10^{-4} M by holding P/D equal to 10, and represented in Fig. 1. In the solution of AO alone, generally, the dimerization equilibrium of the dye must exist. But in the system involving DNA under the present experimental condition of $r<0.2$, the contribution of dimeric species to the free AO molecule is less than 5%. Consequently, in the present analyses, the free AO molecule was regarded as all monomeric species. From the lower and higher limits of concentration in this figure, the extinction coefficients at 492 nm were obtained to be $\varepsilon_f=66000$ $M^{-1}cm^{-1}$ for free AO and $\varepsilon_b=42000\ M^{-1}cm^{-1}$ for bound AO, respectively. The concentration of free dye, A, and the binding ratio, r, were determined from the next equations:

$$A=\frac{\varepsilon_{app}-\varepsilon_b}{\varepsilon_f-\varepsilon_b}A_0 \tag{1}$$

$$r=\frac{A_0-A}{P_0} \tag{2}$$

where A_0 and P_0 are the total concentrations of AO and DNA (in phosphate unit), respectively. In Fig. 2, a Scatchard plot using these equations was illustrated together with those obtained from equilibrium dialysis experiments by Armstrong et al.,[16] and Fredericq et al.[17] A good agreement between these isotherms suggests the validity of the spectrophotometrical method employed in this study.

The obtained binding isotherm was analyzed by considering a dimeric species formed by an additional

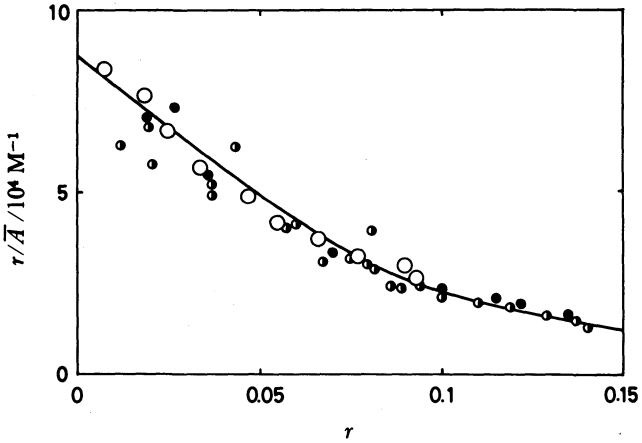

Fig. 2. Scatchard plots of binding of AO to DNA at 25 °C: (O), obtained from the present spectrophotometrical method in 0.2 M NaCl solution; (●), by Armstrong et al.,[16] in 0.2 M NaCl solution; (◑), by Fredericq and Houssier[17] in 0.1 M NaCl solution. The solid line shows the theoretical curve calculated using $n=3$, $K_I=1.8\times10^5\ M^{-1}$, and $K_D=3\times10^4\ M^{-1}$.

binding of free dye to bound dye on DNA reported by Armstrong et al.[16] The Scatchard equation, based on the site exclusion theory including such dimerization mode was reported to be[19]

$$\frac{r}{\bar{A}}=\frac{K_I}{2}\frac{\{(1-2nr)+2K_D\bar{A}(1-nr)\}^n}{\{[1-2(n-1)r]+2K_D\bar{A}[1-(n-1)r]\}^{n-1}} \tag{3}$$

where K_I, K_D, n, and the overbar refer to the binding constant for intercalation, that of dimerization on the polymer, the number of sites blocked by one bound

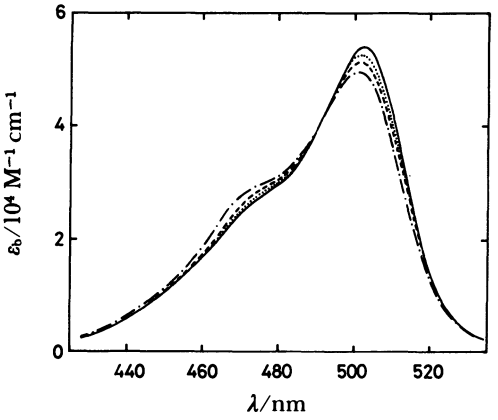

Fig. 3. Absorption spectra of AO-DNA complexes in 0.2 M NaCl solution at various values of binding ratio r: (——), r=0.01; (·····), r=0.032; (---), r=0.045; (—·—), r=0.076. The total dye concentration is 10^{-5} M.

dye, and the equilibrium concentration, respectively. The analysis of the binding isotherm using this equation yields the following binding parameters: K_I=1.8×10^5 M^{-1}, K_D=3×10^4 M^{-1}, and n=3. As can be seen in Fig. 2, all observed data fall on the theoretical curve calculated using these values within an experimental uncertainty. These results are consistent with the assignment of the binding isotherm to the intercalation and dimerization modes.

Spectral Properties of Intercalated AO. In order to examine the spectral properties of intercalative species, the absorption spectra of AO-DNA complex were measured for P/D values above 10 at constant DNA concentration, where the contribution of bound dimer species is negligibly small (estimated from the values of K_I and K_D). Figure 3 illustrates the spectra of bound dye molecules obtained by a substraction of the contribution of free dye. As judged from the figure, an absorption peak at longer wavelength is progressively depressed and a shoulder at shorter one increases gradually with binding. This kind of spectral behavior has been reported as characteristics of AO-AO interactions on polymers.[41] Since the bound dimer species is negligible under the present experimental condition of r<0.1, the observed spectral variation would be attributable to the interaction between monomeric intercalated AO molecules. This assignment is supported by other optical properties of bound AO observed in the corresponding range of r, e.g., fluorescence depolarization[17,35] and exciton splitting in circular dichroism.[17,42,43]

As an additional remark, it should be noted that the constant absorbance at 492 nm of bound AO in Fig. 3, led us to using of this wavelength to obtain the binding isotherm in the preceding section.

Characteristics of Relaxation. Since our primary attention is the intercalation mechanism, the temperature-jump measurements were performed in the range of r below 0.1. An instantaneous and small absorbance change, beyond the resolution time of the apparatus, was followed by three distinguishable relaxation processes as shown in Figs. 4a and 4b. These three processes are named fast, middle and slow processes in order of the time region fast to slow. The relaxation amplitudes of these relaxations are represented in Fig. 5. As shown in Fig. 5a, the spectra of relaxation amplitudes of the fast and middle processes are well correlated to the difference spectrum between free AO and intercalated AO (the difference spectrum was illustrated using the extinction coefficients in Fig. 1). On the other hand, as shown in Fig. 5b, the spectrum of relaxation amplitude of the slow process is quite similar to the difference spectra between intercalated AO at different binding ratios (the difference spectra were obtained from the spectra in Fig. 3).

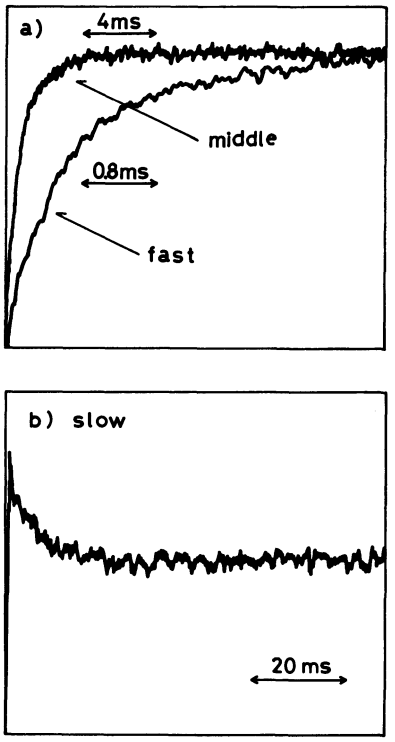

Fig. 4. Typical relaxation curves observed for AO-DNA system in 0.2 M NaCl solution at 480 nm (absorbance increasing upward): (a), fast and middle process, [AO]=1.0×10^{-5} M and [DNA]-phosphate=1.0×10^{-5} M; (b), slow process observed by averaging 4 repetitions, [AO]=3.0×10^{-5} M and [DNA]phosphate=9×10^{-4} M. The final temperature is 25 °C.

To see the reaction mechanism in more detail two kinds of concentration dependence of the reciprocal relaxation times were measured for each process: Figure 6 shows their concentration dependences at

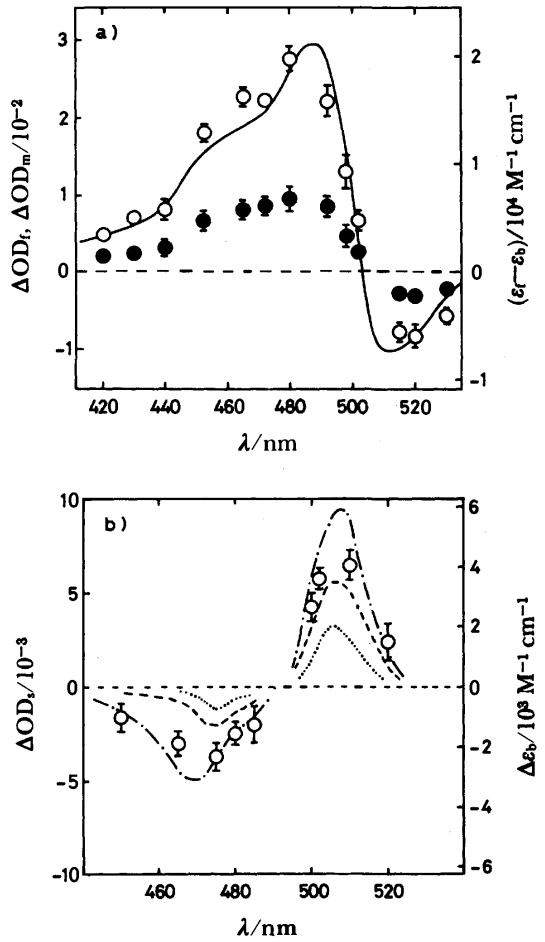

Fig. 5. Wavelength depedence of relaxation amplitude of each process. (a) , (○) and (●) represent the experimental values of ΔOD_f and ΔOD_m, respectively, at [AO]=1.0×10^{-5} M and [DNA]phosphate=1.0×10^{-4} M. The solid curve shows the difference spectrum between free and intercalated AO ($\varepsilon_f-\varepsilon_b$). (b), (○) represents the experimental values of ΔOD_s at [AO]=5×10^{-3} M and [DNA]phosphate=1.5×10^{-3} M. The curves show the difference spectra between intercalated AO at different values of r: (—·—), $\varepsilon_b^{0.01}-\varepsilon_b^{0.076}$; (---), $\varepsilon_b^{0.01}-\varepsilon_b^{0.045}$, (·····), $\varepsilon_b^{0.01}-\varepsilon_b^{0.032}$, where superscripts refer to binding ratio.

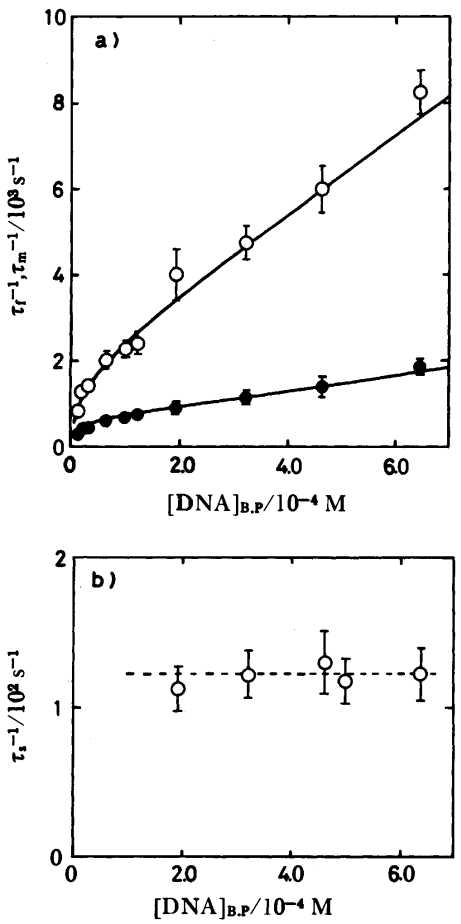

Fig. 6. Dependence of the reciprocal relaxation time of each process on total DNA concentration (base pairs unit) at P/D=10: (a), fast (○) and middle (●) processes, solid lines show the theoretical curves calculated from Eqs. 4 and 5 with constants listed in Table 1; (b), slow processes.

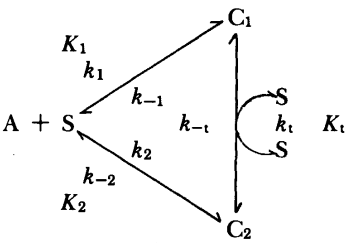
constant P/D=10; Fig. 7 shows the AO concentration dependences at 5×10^{-5} M of DNA (in base pairs unit) in the range of P/D≧10. As judged from Figs. 6a and 7a, the relaxation times of the fast and middle processes τ_f and τ_m are close to each other and both the relaxation times show similar dependences against DNA and AO concentration, respectively. While, the slow processes and the reciprocal relaxation time τ_s^{-1} displays no dependence on either DNA and AO concentrations (Figs. 6b and 7b).

Reaction Mechanism. The following three kinetic models have been proposed for the binding of several acridine and/or phenanthridine dyes to DNA on the assumption of homogeneity of intercalation sites:

$$A + S \underset{}{\overset{K_1}{\rightleftharpoons}} C, \qquad \text{(I)}$$

$$A + S \overset{K_1}{\rightleftharpoons} C_1 \overset{K_2}{\rightleftharpoons} C_2, \qquad \text{(II)}$$



(III)

where A, S, and C_i denote free dye molecule, free site, and bound species, respectively; K_i, k_i, and k_{-i} (i=1, 2, and t) are the equilibrium constant, forward and backward rate constants in each process, respectively. Model I represents a simple bimolecular binding which has been proposed for ethidium-poly[d(A-T)] system.[44] Model II is a two-step binding model which

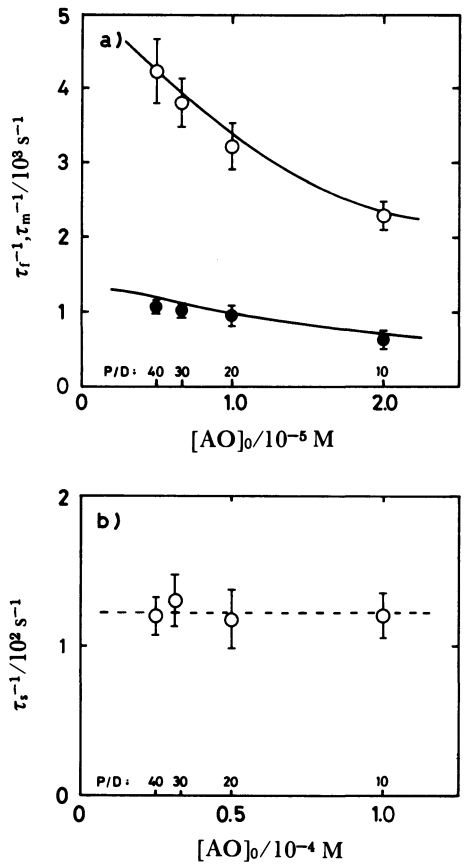


Fig. 7. Dependence of the reciprocal relaxation time of each process on total AO concentration at a constant DNA concentration: (a), fast (O) and middle (●) processes, solid lines show the theoretical curves calculated from Eqs. 4 and 5 with constants listed in Table 1; (b), slow process.

has been proposed for proflavine–DNA[23] and poly(A)–poly(U)[45] systems. The binding of AO to DNA has been interpreted by this model for the earlier studies using stopped-flow technique.[24,25] While Model III was originally proposed for ethidium–DNA system[26] and subsequently reported for several phenanthridine dyes and 10-methyl-9-aminoacridine.[27] The present kinetic data obtained for AO–DNA system were examined in detail for these three kinetic models.

(i) Fast and Middle Processes. At first, the fast and middle processes are analyzed since these are closely coupled and sufficiently faster than slow one. Among the kinetic models above, Model I of a single step reaction process can firstly be excluded from possible one. Secondarily, the concentration dependences of relaxation times calculated for Model II were quite different from the present observation. This fact also eliminated the Model II. Finally, Model III is examined. By an application of site exclusion theory, the kinetic analyses for this cyclic model give two relaxation times corresponding to the fast and middle processes (see Appendix A):

$$\tau_f^{-1} = \frac{1}{2}\{a_{11} + a_{22} + \sqrt{(a_{11} - a_{22})^2 + 4a_{12}a_{21}}\} \tag{4}$$

$$\tau_m^{-1} = \frac{1}{2}\{a_{11} + a_{22} - \sqrt{(a_{11} - a_{22})^2 + 4a_{12}a_{21}}\} \tag{5}$$

with

$$a_{11} = k_1(S_0 f(r) - \bar{A} f'(r)) + k_{-1} + k_t(S_0 f(r) + \bar{C}_1 f'(r)) - k_{-t}\bar{C}_2 f'(r), \tag{6}$$

$$a_{12} = k_1(S_0 f(r) - \bar{A} f'(r)) + k_t \bar{C}_1 f'(r) - k_{-t}(S_0 f(r) + \bar{C}_2 f'(r)), \tag{7}$$

$$a_{21} = k_2(S_0 f(r) - \bar{A} f'(r)) - k_t(S_0 f(r) + \bar{C}_1 f'(r)) + k_{-t}\bar{C}_2 f'(r), \tag{8}$$

and

$$a_{22} = k_2(S_0 f(r) - \bar{A} f'(r)) + k_{-2} - k_t \bar{C}_1 f'(r) + k_{-t}(S_0 f(r) + \bar{C}_2 f'(r)), \tag{9}$$

where S_0 and r denote the total concentration of binding site and the ratio of the bound dye to the total number of binding site, i.e., $r=(\bar{C}_1+\bar{C}_2)/S_0$, respectively; $f(r)$ and its derivative $f'(r)$ are the correction functions due to site exclusion and have the following general forms[44]

$$f(r) = \frac{(1-nr)^n}{\{1-(n-1)r\}^{n-1}} \tag{10}$$

$$f'(r) = \frac{\{(n-1)nr - 2n + 1\}(1-nr)^{n-1}}{\{1-(n-1)r\}^n} \tag{11}$$

The cyclic reaction of this model gives a relationship between six rate constants:

$$\frac{k_2}{k_{-2}} = \frac{k_1}{k_{-1}} \cdot \frac{k_t}{k_{-t}} \tag{12}$$

Seven unknown parameters (six rate constants and n) are involved in these equations. The analyses of τ_f^{-1} and τ_m^{-1} by a successive approximation method yield both $n=3$ and various sets of values for six rate constants which give the theoretical curves interpreting nicely all experimental data. However, a unique value for each rate constant could not be determined from this analysis. Accordingly, in order to determine unique values of six rate constants, the relaxation amplitudes of the fast and middle processes, ΔOD_f and ΔOD_m, were also examined on the basis of Model III. The relaxation amplitudes of ΔOD_f, ΔOD_m, and their ratio of $\Delta OD_f/\Delta OD_m$ are given by

$$\Delta OD_f = \frac{(\varepsilon_1 - \varepsilon_f) - (\varepsilon_2 - \varepsilon_f)\beta_m}{\beta_f - \beta_m} y_f^0, \tag{13}$$

$$\Delta OD_m = -\frac{(\varepsilon_1-\varepsilon_f)-(\varepsilon_2-\varepsilon_f)\beta_f}{\beta_f-\beta_m}y_m^0, \quad (14)$$

$$\frac{\Delta OD_f}{\Delta OD_m} = -\frac{(\varepsilon_1-\varepsilon_f)-(\varepsilon_2-\varepsilon_f)\beta_m y_f^0}{(\varepsilon_1-\varepsilon_f)-(\varepsilon_2-\varepsilon_f)\beta_f y_m^0}, \quad (15)$$

with

$$y_{f,m}^0 = \bar{A}\bar{S}\{\beta_{f,m}+\alpha K_1K_2+(1+\beta_{f,m})(1-\alpha)K_2(\bar{S}-\bar{A}f'(r))\}\delta K_1/\{1+(K_1+K_2)(\bar{S}-\bar{A}f'(r))\} \quad (16)$$

$$\beta_{f,m} = (\tau^{-1}{}_{f,m}-a_{22})/a_{12} \quad (17)$$

$$\alpha = \Delta H_2/\Delta H_1 = (\delta K_2/\delta K_1)(K_1/K_2), \quad (18)$$

where ε_f, ε_i, ΔH_i, and δK_i (i=1,2) denote the molar extinction coefficient of free AO, that of complex C_i, the standard enthalpies, and equilibrium shifts by the temperature-jump in process i, respectively. The derivation of these equations are shown in Appendix B. As can be seen from Fig. 5a, the wavelength dependences of ΔOD_f and ΔOD_m are not only quite similar each other, but both are well correlated with the difference spectrum between free and bound AO. Further, the value of $\Delta OD_f/\Delta OD_m$ calculated using the data in Fig. 5a is constant against wavelength within an experimental uncertainty as shown in Fig. 8. These experimental results require that both ΔOD_f and ΔOD_m in Eqs. 13 and 14 should be proportional to $(\varepsilon_b-\varepsilon_f)$, and that the representation of Eq. 15 for $\Delta OD_f/\Delta OD_m$ should be independent of wavelength. To satisfy these requirements, any one of the following three relationships among ε_1, ε_2, ε_f, and ε_b must be hold at every wavelengths: (a) $\varepsilon_1=\varepsilon_2=\varepsilon_b$, (b) $\varepsilon_1=\varepsilon_f$ and $\varepsilon_2=\varepsilon_b$, and (c) $\varepsilon_1=\varepsilon_b$ and $\varepsilon_2=\varepsilon_f$. Thus, the concentration dependences of $\Delta OD_f/\Delta OD_m$ was analyzed in detail using Eq. 15 for the cases (a), (b), and (c), respectively. In the cases of (a), (b), however, calculated values of $\Delta OD_f/\Delta OD_m$ were quite different from the experimental data. In the case of (c), Eq. 15 can be simplified as

$$\left(\frac{\Delta OD_f}{\Delta OD_m}\right)_c = -\frac{y_f^0}{y_m^0}, \quad (19)$$

where subscript c refer to the case (c). The analysis using this equation for the various values for α and rate constants obtained above yields α=0.9±0.1, n=3, and unique set of rate constants listed in Table 1, which fully satisfy all the experimental data. As shown in Fig. 9, a plot of $\Delta OD_f/\Delta OD_m$ measured versus $(\Delta OD_f/\Delta OD_m)_c$ calculated using the obtained parameters showed an excellent fitting. The all observed data of τ_f^{-1} and τ_m^{-1} fall on the theoretical curves calculated, for the same parameters, using Eqs. 4 and 5 as can be seen from Figs. 6a and 7a. These agreements confirm the plausibility of Model III as well as the equivalence in spectral behaviors of species C_1 with the bound AO and C_2 with the free AO.

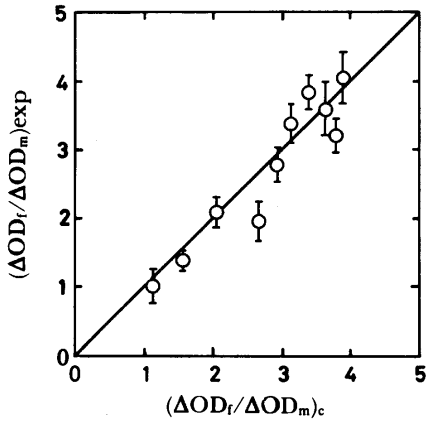

Fig. 9. A plot of $\Delta OD_f/\Delta OD_m$ obtained experimentally at various concentrations vs. $(\Delta OD_f/\Delta OD_m)_c$ calculated from Eq. 19 using parameters listed in Table 1.

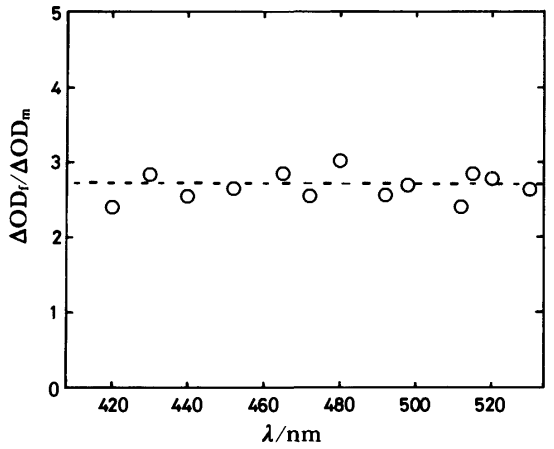

Fig. 8. Wavelength dependence of the experimental values of the relative amplitude $\Delta OD_f/\Delta OD_m$, obtained using the data in Fig. 5a.

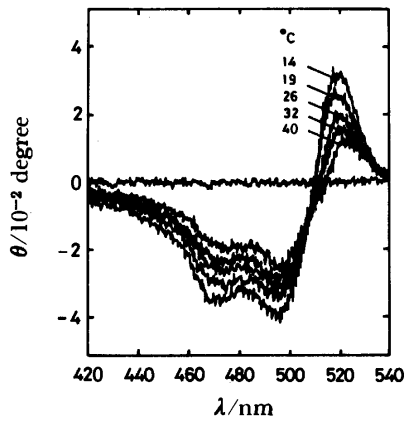

Fig. 10. CD spectra of AO in the presence of DNA in 0.2 M NaCl solution at various temperature in the premelt range. [AO]=3.3×10^{-5} M, [DNA]-phosphate=6.6×10^{-4} M (P/D=20).

Furthermore, the value of $n=3$ determined kinetically is identical with the value obtained from the analysis of the binding isoterm. The overall binding constant, $K_1+K_2=(1.6\pm0.3)\times10^5\ M^{-1}$, calculated from the obtained rate constants is nicely consistent with the binding constant for intercalation mode, $K_I=1.8\times10^5\ M^{-1}$, determined statically. These facts give further confidence for the present assignment.

(ii) Slow Process. As can be seen from Fig. 5b, the spectrum of the relaxation amplitude of the slow process is well associated with the spectral variations resulting from the interaction between intercalated AO molecules. To see this point further, the CD spectra of AO-DNA complex, which is sensitive to dye-dye interactions, were measured at P/D=20 as a function of temperature in the premelt range. As shown in Fig. 10, the exciton splitting due to intercalated AO-AO interaction[17,44] was observed, and decreased with elevation of temperature. Since the amount of bound dye can be regarded as approximately constant in this temperature range,[15,18] this CD shift clearly demonstrates that the interaction between intercalated dyes depends considerably on temperature. Furthermore, the direction of CD shift indicates that this interaction successively weaken with temperature increase. This is compatible with the direction of the relaxation observed by temperature-jump measurements. The slow relaxation process is thus attributable to intercalated AO-AO interaction which depends on temperature.

By the way, the strength of interaction between the intercalated dye molecules depends strongly on both the distance and angle between the interacting dye molecules.[46] In the case of intercalating dyes, these stereochemical parameters would be determined by the double helical structure of DNA. Therefore, the present relaxation seems to result from a thermally induced configurational alternation of DNA molecule itself, which brings about the changes on the steteochemical relationship between intercalated AO molecules. In the case that this configurational alternation arises from an equilibrium shift between two states of DNA structure, the reaction scheme for this process may be represented by the following simple form independent of the fast two relaxations:

$$[\mathrm{DNA}]_X \underset{k_{-3}}{\overset{k_3}{\rightleftharpoons}} [\mathrm{DNA}]_Y, \qquad \text{(IV)}$$

where $[DNA]_X$, $[DNA]_Y$, k_3, and k_{-3} denote the two states of DNA structure named X and Y, the forward and backward rare constants, respectively. The equation of the reciprocal relaxation time, τ_3^{-1}, is given by

$$\tau_3^{-1} = k_3 + k_{-3}, \qquad (20)$$

where the relaxation time is essentially independent of DNA and AO concentrations, which is consistent with the experimental results as seen in Figs. 6b and 7b. By averaging the experimental values of τ_3^{-1}, k_3+k_{-3} was obtained to be $120\pm10\ s^{-1}$. The states X and Y introduced above can not be identified in the present study. However, these may be associated with the thermally induced premelt transition of DNA which has been demonstrated by CD spectroscopies[47,48] and NMR studies.[49]

When the whole results are reviewed, it should be noted that the only faster two of three relaxations were assigned to the actual interactions between AO and DNA molecules. This is consistent with the fact that the overall association constant K_1+K_2 determined kinetically for the two fast relaxations agrees well with the binding constant K_I estimated statically.

Discussion

Intercalating Species. The present kinetic results elucidated the presence of two types of bound dye species (C_1 and C_2) in the range of $r<0.1$. The values of binding constants for these species, K_1 and K_2, listed in Table 1 indicate that more than 80% of bound AO is in complex form C_1. In addition, the absorption spectrum of C_1 determined from the analyses of the relaxation amplitude is approximately identical with that of statically observed intercalated AO. These results strongly suggest that the species C_1 is attributable to the intercalative species.

The values of rate constants for the formation of complex C_1 can be compared to those reported for other intercalating dyes, and for a nonintercalating dye. The present results of $k_1=(3.4\pm0.2)\times10^7\ M^{-1}\ s^{-1}$

and $k_{-1}=235\pm15\ s^{-1}$ at 0.2 M NaCl are similar to those obtained for the intercalating dyes; $k_f \fallingdotseq 10^6\ M^{-1}\ s^{-1}$ and $k_b=50—7000\ s^{-1}$ for 10-methyl-9-aminoacridine, ethidium, and several phenanthridine dyes-DNA systems at 1.0 M NaCl,[26,27] $k_f=1.7\times10^7\ M^{-1}\ s^{-1}$ and $k_b=30\ s^{-1}$ for ethidium bromide-poly[d(A-T)] at 0.1 M KCl,[44] and $k_{1f}=2.2\times10^7\ M^{-1}\ s^{-1}$ and $k_{1b}=200\ s^{-1}$ for (A-T) like site[50] and $k_{2f}=3.4\times10^7\ M^{-1}\ s^{-1}$ and $k_{2b}=120\ s^{-1}$ for (G-C) like site[51] for a typical base-specific acridine dye of proflavine at 0.1 M NaCl, but not to those for the nonintercalating dye; $k_{1f}=1.5\times10^8\ M^{-1}\ s^{-1}$, $k_{1b}=5\times10^4\ s^{-1}$ and $k_{2f}=1.4\times10^8\ M^{-1}\ s^{-1}$, $k_{2b}=4\times10^3\ s^{-1}$ for di-*t*-butylproflavine-DNA system at 0.2 M NaCl.[52] Especially, the values of forward rate constants of intercalation obtained at quite similar ionic strength of 0.1 and 0.2 are quite similar each other. This may indicate that differences in the structure of dye and the base specificity are not dominant factors determining the rate of intercalation, but some specific conformational alternation of DNA helix resulting from the intercalation of dye molecule may be the rate-determining step for the intercalation process.

Externally Bound Species. The analyses of the relaxation amplitude revealed that the absorption spectrum of complex C_2 is approximately same with that of free AO molecules. Similar results were reported for the monomeric AO-polyphosphate complex.[41] Consequently, the species C_2 is reasonably attributable to an externally bound species fixed on the surface of DNA. The value of binding constant $K_2=3\times10^4\ M^{-1}$ is fairly large compared with that of electrostatic binding of acridines to the negatively charged residues of synthetic polymers ($K \fallingdotseq 10^2\ M^{-1}$).[53-55] This fact indicates that bound species C_2 is different from a simple electrostatic binding between AO and phosphate residue of DNA. Meanwhile, the rate constants $k_2=(1.55\pm0.15)\times10^7\ M^{-1}\ s^{-1}$ and $k_{-2}=(5.55\pm0.15)\times10^2\ s^{-1}$ are similar to those of other intercalating dyes rather than that of the nonintercalating dye. Accordingly, as a possible mechanism for the formation of complex C_2, we propose the partially intercalationg model adopted for the binding some acridine dyes to DNA.[56] In the present case, either one of twe dimethylamino residues of AO molecule is partially intercalating between base pairs holding the electrostatic binding of the phosphate residue of DNA ribose and the acridine ring of AO molecule is remained in the outside of DNA helix; a heavily hydrated environment around DNA helix[57] may give the absorption spectrum of AO similar to that of free AO.

As for the dimerization of AO molecule on the DNA, which is expected to occur under the condition of $r>0.1$ beyond the present experimental condition, Armstrong et al.[16] assumed that an intercalated AO molecule affords an additional binding site for free AO to form a dimerized species on DNA helix. However, this model appears suspicious from a consideration of X-ray crystallographic studies of AO-iodo CpG crystals by Reddy et al.[57] They revealed that the acridine ring of intercalated AO as well as other acridine is almost fully sandwiched between upper and lower sides of base pairs. With regard to this point, the present results would afford a better interpretation that the dimerization of AO molecules on DNA helix most likely results from a binding of free AO to an external bound species C_2, but not to an intercalative species C_1.

Magnitude of Site Exclusion Effect. Among all studies on the binding of various acridine dyes to DNA reported so far, the present study is the first study in which the value of n, a parameter indicating the magnitude of site exclusion effect, was determined kinetically.

In earlier equilibrium dialysis studies by Armstrong et al.,[16] and by Fredericq and Houssier,[17] the binding isotherm of AO-DNA system has been analyzed with $n=2$. Fornaslero and Kurucsev,[19] however, have reanalyzed the data by Armstrong et al. and pointed out that the binding isotherm in 0.1 M NaCl solution could be satisfactorily interpreted with rather $n=3$ than 2. The present result of $n=3$ in 0.2 M NaCl solution supports further the results given by Fornaslero and Kurucsev. This value ($n=3$) indicates that the three consecutive intercalation sites are blocked by one bound AO molecule. The molecular basis of this effect may be afforded by γ-kinked B DNA structure proposed by Sobell et al.[58] in their X-ray crystallographic studies of intercalating dyes-dinucleoside monophosphate crystalline complexes.

Transfer of Bound Dye between Binding Sites. One of the most important feature of the kinetic mechanism (Model III) is to involve a bimolecular pathway for direct transfer of dye molecule from one site to another. Besides the present AO-DNA system, this kind of direct transfer process has kinetically been recognized for the binding of ethidium,[26] carboxy dimidium, ethyl phenidium, desphenyl dimidium and 10-methyl-9-aminoacridine to DNA.[27] Quite recent observations by Kubota and Fujisaki suggested that proflavine and acriflavine, typical base-specific acridines, also bind to DNA via the direct transfer pathway.[59] Moreover, such transfer reactions have been demonstrated in the protein-DNA system.[60] These facts indicate that the direct transfer reaction is one of the fundamental dynamic features of DNA interaction with various ligands, and this reaction may play an important role in translocation of ligands seeking specific binding sites on DNA. Since the kinetic studies are of great advantage for elucidation of such dynamic features, extensive studies of kinetics of DNA with various kind of ligands would be required.

Finally, we should refer to kinetic models proposed for AO-DNA system by other workers. Geacintov et

al.[61] proposed by using flash photolysis technique that the intercalation takes place bimolecularly, which is consistent with the present result. However, the process of direct transfer of dye molecules was not observed in their study. This is probably because that the flash photolysis technique is insensitive to the transfer of dyes. While, Sakoda et al.[24,25] observed a single reaction step by the absorption and fluorescence stopped-flow experiments in the concentration range below 5×10^{-5} M of DNA (base pairs unit), and proposed a two-step mechanism (Model II) on the basis of the independence of the relaxation time on concentration. The values of the reciprocal relaxation times (300 s^{-1}) reported by them are in good agreement with those of the present τ_m^{-1} in the corresponding concentration range. As can be seen from Fig. 6a, however, the dependence of τ_m^{-1} on the concentration becomes remarkable at higher concentration. This facts may suggest that the stopped-flow experiments by Sakoda et al. have been done under unfavorable concentration conditions for the unambiguous elucidation of the binding mechanism.

Appendix

[A]. The cyclic reaction presented by mechanism III affords two independent rate equations. In the case that the perturbation give to the system is small, these equations can be linearized as

$$-\frac{d}{dt}\delta C_1(t) = -k_1(\bar{A}\delta S(t) + \bar{S}\delta A(t)) + k_{-1}\delta C_1(t) + k_t(\bar{S}\delta C_1(t) + \bar{C}_1\delta S(t)) - k_{-t}(\bar{S}\delta C_2(t) + \bar{C}_2\delta S(t)), \quad (A1)$$

$$-\frac{d}{dt}\delta C_2(t) = -k_2(\bar{A}\delta S(t) + \bar{S}\delta A(t)) + k_{-2}\delta C_2(t) - k_t(\bar{S}\delta C_1(t) + \bar{C}_1\delta S(t)) + k_{-t}(\bar{S}\delta C_2(t) + \bar{C}_2\delta S(t)), \quad (A2)$$

where $\delta S(t)$, $\delta A(t)$, and $\delta C_i(t)$ are the time-dependent small deviations of each reaction species from the equilibrium states after the perturbation given at $t=0$.

According to the site exclusion theory proposed by McGhee and von Hippel,[40] a function $f(r)$ represented by Eq. 10 in the text denotes the fraction of free binding site, thus

$$\bar{S}/S_0 = f(r). \quad (A3)$$

The differential of Eq. A3 affords the small deviation for S:[44]

$$\delta S(t) = f'(r)S_0\delta r(t) = f'(r)(\delta C_1(t) + \delta C_2(t)), \quad (A4)$$

where the function $f'(r)$ is the derivative of $f(r)$ (see Eq. 11 in the text). While, mass balance condition for dye requires

$$\delta A(t) = -(\delta C_1(t) + \delta C_2(t)). \quad (A5)$$

Introducing Eqs. A3, A4, and A5 into Eqs. A1 and A2, we obtain

$$-\frac{d}{dt}\delta C_1(t) = a_{11}\delta C_1(t) + a_{12}\delta C_2(t), \quad (A6)$$

$$-\frac{d}{dt}\delta C_2(t) = a_{21}\delta C_1(t) + a_{22}\delta C_2(t), \quad (A7)$$

where the coefficients a_{ij} (i, j=1 or 2) are given by Eqs. 6—9 in the text. The reciprocal relaxation times (Eqs. 4 and 5 in the text) are obtained by solving characteristic equation for the matrix $[a_{ij}]$.

[B]. The total absorbance of the solution is given by the concentration of AO in its different states and the corresponding extinction coefficients:

$$OD = \varepsilon_f\bar{A} + \varepsilon_1\bar{C_1} + \varepsilon_2\bar{C_2}. \quad (B1)$$

The time variation of the absorbance after a temperature-jump is

$$\Delta OD(t) = \varepsilon_f\delta A(t) + \varepsilon_1\delta C_1(t) + \varepsilon_2\delta C_2(t). \quad (B2)$$

A substitution of $\delta A(t)$ from Eq. A5 into Eq. B2 leads to

$$\Delta OD(t) = (\varepsilon_1 - \varepsilon_f)\delta C_1(t) + (\varepsilon_2 - \varepsilon_f)\delta C_2(t). \quad (B3)$$

The normal concentration deviations are written by linear combinations of $\delta C_1(t)$ and $\delta C_2(t)$:

$$y_i(t) = y_i^0\exp(-t/\tau_i) = \beta_i\delta C_1(t) + \delta C_2(t) \quad (B4)$$

with

$$\beta_i = (\tau_i^{-1} - a_{22})/a_{12}. \quad (B5)$$

Where the subscript i (=f, m) refers to the normal modes corresponding to the fast and middle processes, and the superscript 0 represents the value for time $t=0$. From Eq. B4, it follows

$$\delta C_1(t) = \frac{-y_f^0\exp(-t/\tau_f) + y_m^0\exp(-t/\tau_m)}{\beta_m - \beta_f}, \quad (B6)$$

$$\delta C_2(t) = \frac{\beta_m y_f^0\exp(-t/\tau_f) - \beta_f y_m^0\exp(-t/\tau_m)}{\beta_m - \beta_f}. \quad (B7)$$

Inserting Eqs. B6 and B7 into B3 yields

$$\Delta OD(t) = \Delta OD_f\exp(-t/\tau_f) + \Delta OD_m\exp(-t/\tau_m), \quad (B8)$$

with

$$\Delta OD_f = \frac{(\varepsilon_1 - \varepsilon_f) - (\varepsilon_2 - \varepsilon_f)\beta_m}{\beta_f - \beta_m}y_f^0, \quad (B9)$$

$$\Delta OD_f = \frac{(\varepsilon_1 - \varepsilon_f) - (\varepsilon_2 - \varepsilon_f)\beta_f}{\beta_f - \beta_m}y_m^0. \quad (B10)$$

As judged from Eq. B8, ΔOD_f and ΔOD_m are the amplitudes corresponding to τ_f^{-1} and τ_m^{-1}, respectively. The normal concentration, y_i^0 in Eqs. B9 and B10 can be written using the equilibrium concentrations of the actually existing reactants ans the equilitrium shifts, δK_1 and δK_2 caused by a temperature rise. From Eq. B4, the following relation is

obtained for $t=0$:

$$y_i^0 = \beta_i \delta C_1^0 + \delta C_2^0 \tag{B11}$$

According to the general procedure for the derivation of the net concentration shifts of the reacting species, we have

$$\delta C_1^0 = -\frac{f'(r)\bar{A}\bar{S}\{1 + K_2(\bar{S} - f'(r)\bar{A})\}}{1 + (K_1 + K_2)(\bar{S} + f'(r)\bar{A})}\delta K_1 + \frac{K_1 f'(r)\bar{A}\bar{S}(\bar{S} - f'(r)\bar{A})}{1 + (K_1 + K_2)(\bar{S} - f'(r)\bar{A})}\delta K_2 \tag{B12}$$

$$\delta C_2^0 = \frac{K_2 f'(r)\bar{A}\bar{S}(\bar{S} - f'(r)\bar{A})}{1 + (K_1 + K_2)(\bar{S} - f'(r)\bar{A})}\delta K_1 - \frac{f'(r)\bar{A}\bar{S}\{1 + K_1(\bar{S} - f'(r)\bar{A})\}}{1 + (K_1 + K_2)(\bar{S} - f'(r)\bar{A})}\delta K_2 \tag{B13}$$

By defining α as $\Delta H_1/\Delta H_2$ (where ΔH_1 and ΔH_2 denote the standard enthalpies in each process), δK_1 and δK_2 are connected by the relation

$$\alpha = (\delta K_1/\delta K_2)(K_1/K_2), \tag{B14}$$

If Eq. B11 is rearranged using Eqs. B12, B13, and B14, the values of y_i^0 (i=f, m) are given by the forms represented by Eq. 16 in the text.

Stabilities and Transfer Activity Coefficients of Benzo-15-crown-5-Alkali Metal Ion Complexes in Various Solvents

Yasuyuki TAKEDA* and Toshihiro KUMAZAWA
Department of Chemistry, Faculty of Science, Chiba University, Yayoi-cho, Chiba 260
(Received July 15, 1987)

Stability constants in acetonitrile and methanol of 1:1 benzo-15-crown-5 (B15C5)–alkali metal ion complexes and the solubility of B15C5 in acetonitrile, propylene carbonate, methanol, and water were determined at 25 °C by conductometry and spectrophotometry, respectively. In general, selectivity tendency of B15C5 for the alkali metal ions except for Li^+ can be interpreted in terms of size-relationship. Stability sequences of the B15C5–alkali metal ion complex among the solvents, except for Rb^+ and Cs^+ complexes, are the reverse of solvation-ability sequences of the solvents to the corresponding alkali metal ion. By using the stability constants of the B15C5–alkali metal ion complexes, transfer activity coefficients (γ) of the B15C5 complexes were then calculated from γ values of B15C5 (obtained from solubilities of B15C5) and those of alkali metal ions. The γ value of the B15C5 complex from methanol to acetonitrile and propylene carbonate generally varies with a variety of alkali metal ions. From γ values of the B15C5 complexes, it is concluded that there exists a possible specific interaction between the alkali metal ion held in the B15C5 cavity and solvent molecules when the alkali metal ion is much smaller or larger than the B15C5 cavity.

In the previous study,[1] molar conductivities of alkali metal perchlorates were measured in propylene carbonate in the presence of benzo-15-crown-5 (B15C5), and stabilities and solvation properties of the 1:1 complexes of B15C5 with alkali metal ions were discussed from the standpoint of thermodynamics and transport phenomena, respectively. Stability sequences of the B15C5–alkali metal ion complexes in propylene carbonate are in the order $Na^+>Li^+>K^+>Rb^+>Cs^+$, which is consistent with the size-fit concept; namely, correlation between relative sizes of cation and crown ether cavity. In the cases of Na^+, K^+, Rb^+, and Cs^+, the size of the moving entity in propylene carbonate is larger for the B15C5 complex than for the corresponding alkali metal ion, whereas, in the case of Li^+, that is completely the reverse.

In the present study, in order to further investigate complexing-power tendency of B15C5 for alkali metal ions and medium effects on stabilities of the 1:1 B15C5–alkali metal ion complexes, formation constants of the B15C5 complexes in acetonitrile and methanol were conductometrically determined at 25 °C. In addition, by using the formation constants of the B15C5 complexes, transfer activity coefficients (γ) of the B15C5 complexes were then calculated from γ values of B15C5 (obtained from solubilities of B15C5) and those of alkali metal ions. From the γ values of the B15C5 complexes, properties of solute–solvent interaction of the B15C5 complexes were discussed in detail.

Experimental

Materials. The method of purification of B15C5 (Merck Japan Ltd.) was the same as that described previously.[1] Extremely pure alkali metal (Li, Na, K, Rb, Cs) chlorides were purchased from Merck Japan Ltd., and were used without further purification. Rubidium and caesium perchlorates were prepared by adding a little excess of $HClO_4$ to aqueous solutions of RbCl and CsCl, respectively. Lithium, sodium, and potassium perchlorates were commercially obtained from Merck Japan Ltd. All the perchlorates were recrystallized four times from distilled water and, prior to use, dried at 150 °C in vacuo. The method of purification of acetonitrile,[2] propylene carbonate,[3] and methanol[4] was previously reported. The conductivities of acetonitrile, propylene carbonate, methanol, and water thus purified were less than 3×10^{-7}, 5×10^{-8}, 2×10^{-7}, and 6×10^{-7} Ω^{-1} cm^{-1}, respectively. For conductometric titrations, alkali metal chlorides and perchlorates were used for methanol and acetonitrile systems, respectively.

Apparatus and Procedure. The conductance measurements were made on a Fuso conductivity apparatus, model 362 A, in a water bath thermostated at 25±0.01 °C. Two cells were used, cell constants of which were 0.059701 and 0.097765 cm^{-1}. Experimental procedures to obtain formation constants of B15C5–alkali metal ion complexes were the same as those described in a preceding paper.[3]

Solubilities of B15C5. A B15C5 suspension in a given solvent was stirred at 25±0.02 °C for 3 days, and then the solution saturated with B15C5 was filtered under nitrogen. The B15C5 concentration of the solution was determined spectrophotometrically (at 226, 222, 220, and 200 nm in acetonitrile, propylene carbonate, methanol, and water, respectively). Solubilities of B15C5 at 25 °C are 1.9, 1.2, 4.0×10^{-1}, and 1.1×10^{-1} M (1 M=1 mol dm^{-3}) in acetonitrile, propylene carbonate, methanol, and water, respectively.

Results and Discussion

The method for obtaining formation constants (K_{ML^+}) of B15C5–alkali metal ion complexes was the same as that described in a previous paper,[3] where $K_{ML^+}=[ML^+]/[M^+][L]$. M^+ and L denote an alkali metal ion and a crown ether, respectively. In this work, it is assumed that the association between a cation and an anion is negligible and that B15C5 forms a 1:1 complex with an alkali metal ion. The $\log K_{ML^+}$ values are summarized in Table 1.

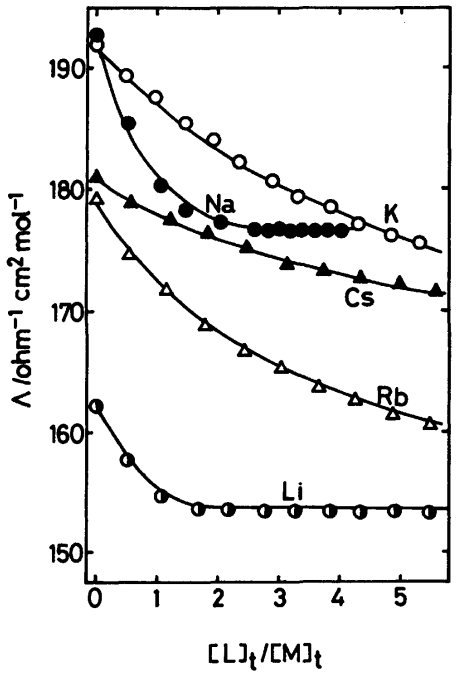

Fig. 1. Λ vs. $[L]_t/[M]_t$ curves for B15C5-alkali metal perchlorate systems in acetonitrile at 25 °C.
—— calculated curve by using K_{ML^+} value. $[M]_t$= (5.0—6.0)×10^{-4} M.

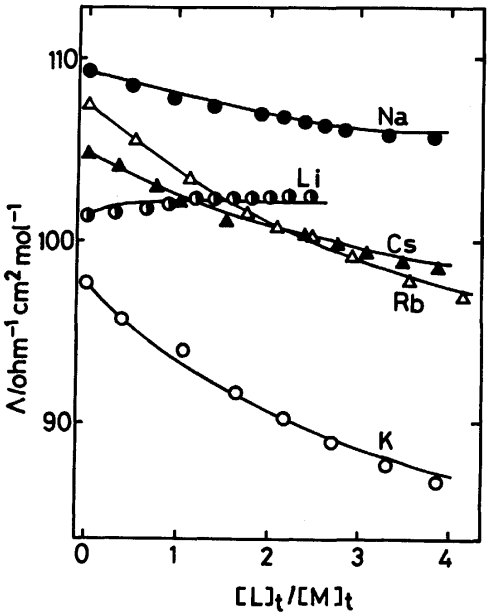

Fig. 2. Λ vs. $[L]_t/[M]_t$ curves for B15C5-alkali metal chloride systems in methanol at 25 °C.
—— calculated curve by using K_{ML^+} value. $[M]_t$= (6.0—8.0)×10^{-4} M.

acetonitrile and methanol are given in Figs. 1 and 2, $[L]_t$ and $[M]_t$ denoting total concentrations of B15C5 and the alkali metal ion, respectively. Every Λ vs. $[L]_t/[M]_t$ plot, except for the LiCl-CH_3OH system, shows a decrease in Λ with an increase in $[L]_t$, indicating that the mobility of the B15C5-alkali metal ion complex is smaller than that of the corresponding uncomplexed alkali metal ion. This can be expected on the basis of much larger size of the B15C5-alkali metal ion complex compared to the corresponding alkali metal ion. The Λ vs. $[L]_t/[M]_t$ plot of the LiCl-CH_3OH system, on the other hand, shows that moving entity of Li^+ is larger than that of the B15C5-Li^+ complex. Generally, such a phenomenon can be observed for the combination of smaller alkali metal ions (e.g., Li^+ and Na^+) and the smaller crown ethers compared to 18-crown-6 in a solvent of lower donicity (e.g., acetonitrile and propylene carbonate).[1,3] A possible explanation is as follows. In a solvent of lower donicity, a stable complex is formed even between a small alkali metal ion and a small crown ether which has a poor binding ability. On account of strong solvation of the small alkali metal ion and less solvation of its complex with the small crown ether, moving entity of the alkali metal ion is larger than that of its crown ether complex.

From Figs. 1 and 2, it is evident that a clear breaking point at $[L]_t/[M]_t=1$ is observed only in the case of the Li-acetonitrile system. It is responsible for the clear breaking point that B15C5 forms a very stable 1:1 complex with Li^+ and the complex has a lower mobility than a Li^+ ion.

Stability Constants. From Table 1, selectivity sequences of B15C5 for the alkali metal ions in acetonitrile, propylene carbonate, and methanol are as follows:

AN: $Li^+ > Na^+ \gg Rb^+ > K^+ > Cs^+$,
PC: $Na^+ > Li^+ > K^+ > Rb^+ > Cs^+$,
CH_3OH: $Na^+ > K^+ > Rb^+ > Li^+ > Cs^+$.

a) Acetonitrile. b) Propylene carbonate.

Selectivity tendency of B15C5 for the alkali metal ions except for Li^+ is roughly consistent with size-relationship regardless of a variety of solvents; that is, the more closely the alkali metal ion fits into the B15C5 cavity (cavity radius 0.85 Å[7]), the more stable is the B15C5–alkali metal ion complex. For Li^+ ion, however, log K_{ML^+} value is the greatest in acetonitrile, the second largest in propylene carbonate, and the second smallest in CH_3OH among alkali metal ions. Stability of the B15C5–Li^+ complex seems to be governed largely not only by the size-relationship but also by the strength of solvation of the solvent for the free Li^+ ion. Li^+ probably undergoes the strongest solvation of all the alkali metal ions. Solvation-ability (i.e., relative solubility) sequences of the solvents for Li^+ derived from the data[8] on transfer activity coefficients are acetonitrile≪propylene carbonate≪CH_3OH, and the difference in solvation-ability of solvent[8] between Li^+ and the other alkali metal ion increases in the order acetonitrile<propylene carbonate<CH_3OH. This is responsible for the above-mentioned results of the Li^+ complex.

Stability sequences of the respective B15C5–alkali metal ion complexes for the solvents are as follows:

Li^+: AN > PC > CH_3OH,
Na^+: PC > AN > CH_3OH,
K^+: PC ≥ CH_3OH > AN ≫ H_2O,
Rb^+: AN > CH_3OH ≥ PC,
Cs^+: AN > CH_3OH > PC.

Solvation-ability sequences[8,9] of the solvents for the alkali metal ion are as follows:

Li^+: AN ≪ PC ≪ CH_3OH,
Na^+: PC < AN < CH_3OH,
K^+: CH_3OH ≤ PC < AN ≪ H_2O,
Rb^+: CH_3OH < PC ≤ AN,
Cs^+: CH_3OH < PC ≤ AN.

Stability sequences of the respective B15C5–alkali metal ion complexes in the solvents, except for the cases of Rb^+ and Cs^+ complexes in acetonitrile, are the reverse of solvation-ability sequences of the solvents for the corresponding alkali metal ion. This indicates that the B15C5–alkali metal ion complex is stable in a solvent with poor solvation-ability to the free alkali metal ion and the reverse is true. The author cannot explain the exceptional behavior of Rb^+ and Cs^+ complexes in acetonitrile at the present time.

Transfer Activity Coefficient. Logarithm of transfer activity coefficient (log $^{s_1}\gamma^{s_2}(ML^+)^\dagger$) of a B15C5–alkali metal ion complex between solvent s_1 and solvent s_2 is calculated by Eq. 1.

$$\log {}^{s_1}\gamma^{s_2}(ML^+) = (\log K_{ML^+})_{s_1} - (\log K_{ML^+})_{s_2} + \log {}^{s_1}\gamma^{s_2}(L) + \log {}^{s_1}\gamma^{s_2}(M^+), \quad (1)$$

where log $^{s_1}\gamma^{s_2}(L)^\dagger$ and log $^{s_1}\gamma^{s_2}(M^+)^\dagger$ refer to logarithm of transfer activity coefficients of B15C5 itself and a free alkali metal ion between solvent s_1 and solvent s_2, respectively, and $(\log K_{ML^+})_s$ designates log K_{ML^+} value in solvent s. By way of example, a positive log $^{s_1}\gamma^{s_2}(ML^+)$ value means that the complex, ML^+, undergoes stronger solvation in s_1 than in s_2. Transfer activity coefficient values of ML^+, M^+, and L when s_1=CH_3OH are summarized in Table 2.

From the solubility data of B15C5 determined in this study, solubility sequences of B15C5 for the solvents are in the order acetonitrile>propylene carbonate>methanol>water although there exist hydrogen bonds between ether oxygen atoms and protic solvents such as water and methanol, and, moreover, the hydrogen bonding is much stronger in water than in methanol.[11] This may be attributed to superiority of lipophilic effects of the benzo and ethylene groups over hydrogen-bonding effects of ether oxygen atoms. Benzo-18-crown-6 (B18C6) is larger in size than B15C5

† $^{s_1}\gamma^{s_2}(X)=[X]_{s_1}/[X]_{s_2}$, X denoting ML^+, L, or M^+.

by an ether oxygen atom and an ethylene group. When s=AN and PC, the log $^{CH_3OH}\gamma^{s}$(L) value changes from negative to positive in going from B15C5 to B18C6. This may be due to the additional hydrogen bonding between the added ether oxygen atom of B18C6 and methanol.

It can be seen from Table 2 that, in general, the log $^{CH_3OH}\gamma^{s}$(ML^+) value of B15C5 varies with a variety of alkali metal ions when s=AN and PC. Positive log $^{CH_3OH}\gamma^{s}$(ML^+) values of B15C5 are found only for the case of Li^+. They are much larger compared to those of other alkali metal ions. From Eq. 1 and Tables 1 and 2, this is attributed completely to very large and positive log $^{CH_3OH}\gamma^{s}$(Li^+) values; namely, the fact that the B15C5-Li^+ complex undergoes much stronger solvation in methanol than in acetonitrile and propylene carbonate is due entirely to much stronger solvation of the central Li^+ in methanol than in acetonitrile and propylene carbonate.

For B15C5, the log $^{CH_3OH}\gamma^{s}$ value decreases on moving from M^+ to ML^+ when s=AN and PC, and the contrary holds for B18C6 except for the case of M^+=Na^+ and s=PC. This is owing largely to the fact that B15C5 is less solvated in methanol than in AN and PC, while B18C6 is more solvated in methanol than in AN and PC. The higher solvation of B15C5 in methanol than in H_2O is mostly responsible for the fact that the log $^{CH_3OH}\gamma^{H_2O}$ value increases in going from K^+ to B15C5-K^+ complex (Table 2).

In the cases of s=AN and PC, the log $^{CH_3OH}\gamma^{s}$(ML^+) value increases from B15C5 to B18C6. This shows that the B18C6-alkali metal ion complex is more solvated in methanol than in AN and PC in comparison with the B15C5 complex. In each case of s=AN and PC, the difference in log $^{CH_3OH}\gamma^{s}$(ML^+) values between B15C5 and B18C6 is roughly constant regardless of the alkali metal ions except for the system of M^+=K^+ and s=AN. As mentioned above for free B15C5 and B18C6, this may be caused primarily by the effect of the additional hydrogen bonding between the increased ether oxygen atom of B18C6 and methanol.

When L=B15C5, s=AN and PC, and M^+=Na^+ and K^+, log $^{CH_3OH}\gamma^{s}$ values for ML^+ and L are nearly the same. Log $^{PC}\gamma^{AN}$ values for B15C5-K^+ and B15C5 at 25 °C are identical (−0.2). This indicates that, generally, property of solute-solvent interaction of the B15C5-alkali metal ion complex mostly reflects that of the free B15C5 unless the alkali metal ion in the B15C5 complex is much smaller or larger than the B15C5 cavity; when log $^{s_1}\gamma^{s_2}$ values for B15C5-M^+ and B15C5 are fairly different from each other, it seems that there exists a specific interaction between the alkali metal ion in the B15C5 cavity and the solvents, where, in most cases, the alkali metal ion in the B15C5 cavity has a much smaller or larger size than that of the B15C5 cavity. A similar tendency is observed for B18C6 and its alkali metal ion complexes (Table 2 and log $^{PC}\gamma^{AN}$(B18C6)=0.92, log $^{PC}\gamma^{AN}$(M^+-B18C6)=0.7 (Na^+), 0.8 (K^+), 0.9 (Rb^+), and 0.58 (Cs^+) at 25 °C[10]).

Solvation-ability sequences of the solvents for the B15C5-alkali metal ion complex obtained from log $^{CH_3OH}\gamma^{s}$(ML^+) values in Table 2 are as follows:

Li^+-B15C5: $AN < PC \ll CH_3OH$,

Na^+-B15C5: $CH_3OH < PC < AN$,

K^+-B15C5: $H_2O < CH_3OH < PC < AN$,

Rb^+-B15C5: $CH_3OH < PC < AN$,

Cs^+-B15C5: $CH_3OH < PC < AN$.

From the solubility data of B15C5 in this study, solvation-ability sequences of the solvents for B15C5 are $H_2O<CH_3OH<PC<AN$; they agree completely with those for the B15C5-alkali metal ion complex except for B15C5-Li^+ complex. Solvation-ability sequences of the solvents for the B15C5-alkali metal ion complex are consistent with those for the corresponding alkali metal ion except for the cases of CH_3OH for B15C5-Na^+ complex and H_2O for B15C5-K^+ complex. Property of solute-solvent interaction of the B15C5-alkali metal ion complex is characterized by that of the corresponding free alkali metal ion and/or by that of the B15C5 itself. Whereas, property of solute-solvent interaction in AN, PC, and CH_3OH of the B18C6-alkali metal ion complex, whose ligand is larger than B15C5, is characterized by that of the B18C6 itself (solvation-ability sequences of the solvents for B18C6: $AN<PC\leq CH_3OH$).

Roles of Kinetic and Potential Energies in Conjugation. I. A Study of Prototypes

Hiroshi Ichikawa,* Yukiko Ebisawa, and Keiichiro Sameshima
Hoshi College of Pharmacy, Shinagawa, Tokyo 142
(Received August 3, 1987)

The analysis of the potential and kinetic energy changes between conjugative and nonconjugative structure in vinylamine and nitroethene led to the conclusion that there were two different types of conjugations: the conjugative stability caused by a decrease in the kinetic energy and that given by a decrease in the potential energy. Those two types could be termed conjugations of *kinetic energy origin* and *potential energy origin* respectively. The cojugative stability in vinylamine is produced by an excess decrease in the kinetic energy over the increase in the potential energy (*kinetic energy origin*), which was attributed to a release of the kinetic energy pressure of the lone pair of electrons on nitrogen. On the other hand, the conjugation of nitroethene causes an overwhelming decrease in the potential energy, especially in that belonging to the nitro group (*potential energy origin*).

Conjugation between a substituent and the π system (e.g., the phenyl group) produces a stabilization energy which is referred to as 'conjugation energy.' Conjugation also affects the electron density in a π system to determine the resultant appearance. According to the electronic effect, functional groups have been classified by organic chemists into two groups, i.e., the electron-donating and electron-withdrawing groups. Such an effect of a substituent on the π system is symbolized by using 'arrows' in organic electron theory. This arrow expression has been so widely used that it has come to be one of the basic concepts in organic chemistry. However, one cannot extract any physical meaning from such arrows.

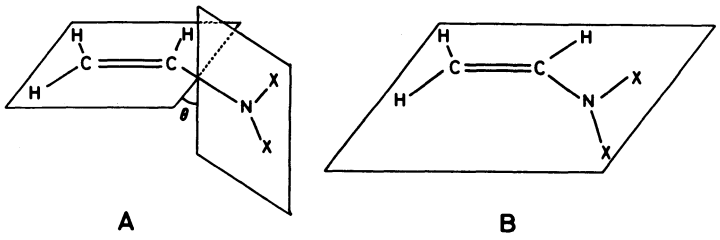
A large number of MO theoretical calculations have been carried out on substituted benzenes,[1] and the conjugation between a substituent and the phenyl group seems to be thoroughly understood. Indeed, an MO calculation reveals the electron density in the system, and the conjugation is usually interpreted in terms of the interaction between the π system and its substituent.[2] However, fundamental questions remain as to why they must interact, why such a conjugation stability is produced, and why a lone pair of electrons delocalizes into the π system. There may be various theoretical approaches. However, as far as organic chemistry is concerned, a theoretical study must contribute to the establishment of a bridge between the basic concepts of organic chemistry and those of physics.

The total energy of any molecular system consists of two fundamental components, the kinetic and potential energies, which are defined according to distinctly different concepts of energy in nature. The interpretation of chemical phenomena through such energy terms is most fundamental and decisive. Recently, we ourselves have shown that the kinetic energy of π electrons plays the decisive role in the stability or instability of an aromatic or antiaromatic system.[3] The physical meaning of aromaticity has been given as the relaxation of the kinetic-energy pressure of π electrons in isolated double-bonds.[4] The kinetic-energy pressure is a different expression of the most fundamental phenomenon and/or concept in modern physics,[5] i.e., Heisenberg's uncertainty principle.[6] Therefore, aromaticity/antiaromaticity, which is also one of the most fundamental concepts in organic chemistry, has been interpreted in terms of the basic principles of nature.

If wave functions are to provide an understanding of the behavior of electrons in a molecule, we must try somehow to extract information on the physically essential features of electronic energies. One of the methods along this line is energy partitioning. The Hamiltonian of a molecular system is composed of operators related to the kinetic energy, the potential energy for an electron in the field of a nuclear charge, and the repulsion energy between electrons. Thus, the electronic energy (E^{el}) is composed of the kinetic energy of electrons (E^T) and the electronic potential energies. The latter is further partitioned into the attractive one-electron potential (E^{V}) and the repulsive two-electron potential energies (E^J).[7] Our strategy in solving the present problems is to identify the roles of these partitioned energies in conjugation.

This paper will discuss the cases of vinylamine and nitroethene as prototypes of conjugation between a π system and an electron-donating or an electron-withdrawing substituent. These systems are appropriate for the present study in that the conjugation between the substituent and the ethenyl group can be terminated by making the conformation of the substituent orthogonal to the plane of the ethenyl group. As a sophisticated MO method, we used the 6-311 G** method[8] throughout this work.

It has been indicated that the components of the total energy are very sensitive to the scale factor of the wave function.[9] Since the scale factor applies to the electronic coordinates as well as the nuclear coordinates, the condition or threshold of geometry optimization is considered to affect seriously the



Scheme 1.

components of the total energy. Therefore, the threshold of geometry optimization was set at 0.00003 (maximum) as well as 0.00002 (rms) Hartree/Bohr or radian, which is one tenth of the standard geometry optimization.[10]

Driving Force Which Leads to Conjugation. Vinylamine and nitroethene have near-planar geometries.[11,12] Such a planarity may be maintained by conjugation. If there were no conjugation, the orthogonal structure might be considered to be the most stable geometry because it has the least interatomic repulsions (steric effect), just as ethane favors the staggered conformation. Therefore, we may expect that there are some driving forces that lead to conjugation.

Let us consider how conjugation takes place starting from an orthogonal structure. We suppose that the system follows the minimum-energy path. The orthogonal structure (θ=90° in Scheme 1) and the planar structure (θ=0°) have the maximum-energy and minimum-energy cols; therefore, the torsional forces, $\partial E/\partial\theta$, are zero. Except for these cols, the differential has a positive value. Take any geometry with $0<\theta<90°$, where a certain torsional force is imposed on the C–N bond to lead θ to $\theta-\Delta\theta$. Change in θ is followed by change in all geometrical parameters such as, $R_j \rightarrow R_j+\Delta R_j$ and $\phi_k \rightarrow \phi_k+\Delta\phi_k$, where R_j and ϕ_k are the bond lengths and the bond angles. The cause of the torsion that is put on the C–N bond may be interpreted as the cause of the conjugation.

The total energy is composed of the potential energy (V) and the kinetic energy of electrons (T):

$$E = T + V \tag{1}$$

$$T = E^T \tag{2}$$

$$V = E^V + E^J + E^N \tag{3}$$

where E^N is the nuclear repusion energy.

The differentiation of E with respect to θ gives:

$$\partial E/\partial\theta = \partial T/\partial\theta + \partial V/\partial\theta \tag{4}$$

where $\partial T/\partial\theta$ and $\partial V/\partial\theta$ are the forces due to the kinetic and potential energies, respectively. The

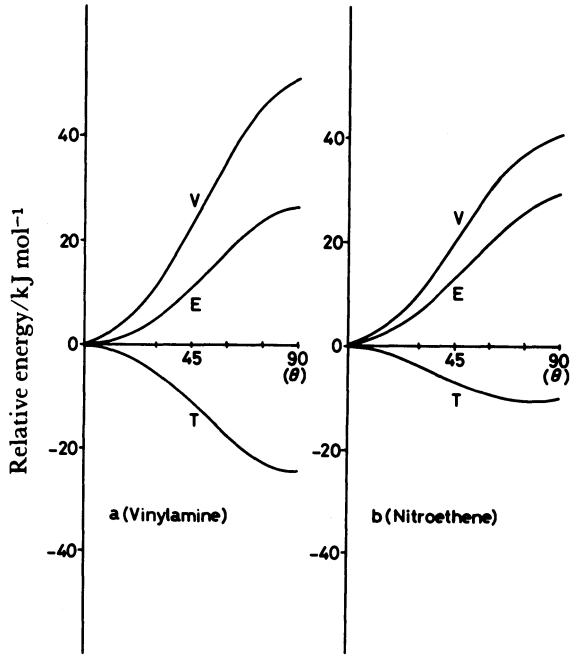


Fig. 1. Plots of the total (E), kinetic (T), and potential (V) energies (kJ mol^{-1}) vs. θ as the conformation changes from A to B through the minimum energy path in vinylamine (a) and nitroethene (b).

positive and negative values represent the increase and the decrease in the corresponding energies as θ increases. At θ=0 or 90°, $\partial E/\partial\theta$ is zero, with $|\partial T/\partial\theta| = |\partial V/\partial\theta|$. When $0°<\theta<90°$, these forces are not balanced. Before an analysis of these forces, let us look at the energy changes in the minimum energy path.

Figure 1 shows the changes in the total, kinetic, and potential energies as functions of θ, where all the geometrical parameters except θ were optimized with respect to the total energy. It is important to note here that these curves are not pure functions of θ, since geometry optimization is carried out at every θ.

Both total energies increase as θ increases. The difference in total energy between 0 and 90° may correspond to the conjugation energy. It is calculated as 26 and 30 kJ mol^{-1} respectively for vinylamine and nitroethene.[13] Nelander has shown that, if all bond lengths are optimized with respect to the total energy,

the virial theorem ($T=-V/2$) should hold, where angular coordinates have no contribution to the virial ratio.[14,15] The energy profiles of the components in Fig. 1 satisfy this requirement reasonably in vinylamine, but qualitatively in nitroethene. These results imply that the potential energy is always responsible for leading to conjugation, since the sign of the gradient of the potential energy is the same as that of the total energy. This is not true, however, since, as has been mentioned, geometry optimization does not take place at the same time as the change in θ, but *as a result of the change in* θ.

We estimated $\partial E/\partial\theta$, $\partial T/\partial\theta$, and $\partial V/\partial\theta$ by means of the divided differences, $\Delta E/\Delta\theta$, $\Delta T/\Delta\theta$, and $\Delta V/\Delta\theta$, which were obtained as follows. First, the energies were calculated at a θ value with full geometry optimization (except only for θ) to give $E(\theta)$, $T(\theta)$, and $V(\theta)$. Then, θ was increased by $\Delta\theta$ and, *without optimization*, those energies are obtained as $E(\theta+\Delta\theta)$, $T(\theta+\Delta\theta)$, and $V(\theta+\Delta\theta)$. The divided differences were $(E(\theta+\Delta\theta)-E(\theta))/\Delta\theta$, etc. We fixed $\Delta\theta$ at 1°.

The gradients of the curves in Fig. 1 correspond to the divided differences when the geometries at both θ and $\theta+\Delta\theta$ are optimized. In fact, the values at $\theta=45°$, for example in vinylamine, were calculated to be 0.51, −0.73, and 1.24 kJ mol^{-1} deg^{-1} for the total, kinetic, and potential energies respectively; these values correspond to the gradients at 45° in Fig. 1-a.

Table 1 shows the divided differences at $\theta=30$, 45, and 60°. In both vinylamine and nitroethene, $\Delta E/\Delta\theta$ is positive, showing that the systems resist the rotation of the substituent planes; i.e., both systems resist breaking conjugation. The divided differences of the energy components of vinylamine appear to be prominently different from those of nitroethene.

In vinylamine, $\Delta T/\Delta\theta$ is positive, while $\Delta V/\Delta\theta$ is negative, with the former being larger than the latter in quantity. This confirms that the force due to the kinetic energy resists breaking conjugation. The divided difference, $\Delta X/\Delta(-\theta)$ (where $X=E$, T, or V), means the force when the orthogonal conformation becomes the conjugative planar structure. Therefore, it may be deduced that the driving force that leads to conjugation in vinylamine is that by the kinetic energy of electrons.

Nitroethene gave the opposite results: $\Delta V/\Delta\theta$ is positive, while $\Delta T/\Delta\theta$ is negavive. This time, the force due to the potential energy is against the rotation of the functional group, while that due to the kinetic energy helps such a rotation. Since the former exceeds the latter, the planarity is maintained; therefore, it may be concluded that the potential energy is the cause of conjugation in nitroethene.

What Happens to Energy Components by Conjugation. This section will discuss the effect of conjugation on the energy components of the total energy. As has already been stated, if there were no conjugation, the orthogonal structure would be the most stable conformation in both vinylamine and nitroethene. Table 2 shows the geometrical parameters of the optimized orthogonal and planar structures. Considerable differences as to the C–C and C–N bonds can be seen between them. Such geometrical changes are considered to be brought forth by the introduction of conjugation.

Here let us make the point of the problem clear: it is conjugation that changes the molecular geometries; i.e., a change of geometry occurs following a presentation of conjugation. Thus, we regarded the orthogonal structure (A in Scheme 2) as the reactant structure for conjugation. With a retention of the bond lengths and the bond angles, the substituent was rotated to a planar structure (the intermediate structure: B′), and all the bond lengths and bond angles were optimized with respect to the total energy (the product structure: B). We investigated the energy changes between A, B′, and B: the energy change between A and B′ includes the effect of conjugation, while that between B′and B corresponds to the effect of the geometrical change after conjugation.

There is another way of considering this question. The optimized structure in conjugation (B) may appear to be near-planar. The rotation of the amino or nitro group in B involves an energy barrier which

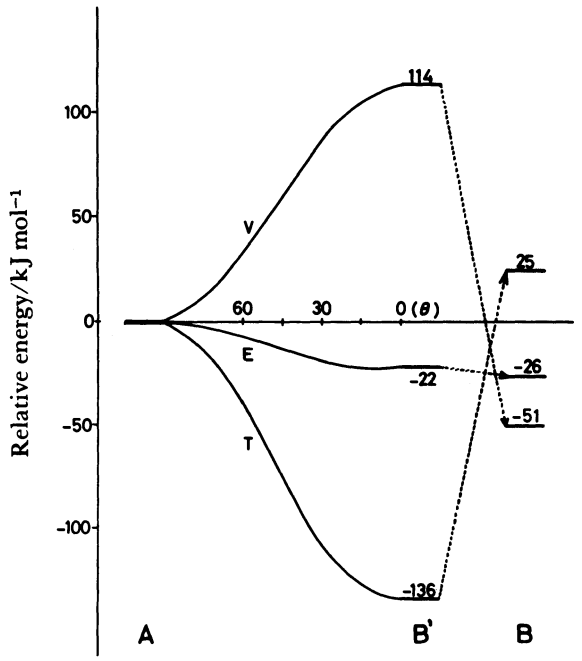

Fig. 2. Plots of the total (E), kinetic (T), and potential (V) energies (kJ mol^{-1}) vs. θ as the conformation changes from A to B′ in vinylamine.

may be caused by a broken conjugation. We also examined the energy change when the substituent at B was rotated to an orthogonal structure (A′), with bond lengths and bond angles being kept at those of B.

Vinylamine. Figure 2 shows the change in the total, kinetic, and potential energies of vinylamine as functions of θ. All the bond lengths and bond angles except for θ were kept the same as those in A. The geometries at θ=90 and 0° are equal to A and B′ respectively. As θ decreases, the total energy decreases by ca. 20 kJ mol^{-1} (at B′). Such a stabilization is produced by conjugation and is a driving energy toward a planar conjugative structure. It is important to note that the potential energy increases, while the kinetic energy decreases, as the geometry is varied from the orthogonal to the planar forms, and that the change in the kinetic energy is larger than that in the potential energy. This simply means that the decrease in kinetic energy is the original conjugation stability.

If all the bond lengths are optimized with respect to the total energy, the virial theorem ($T=-V/2$) should hold where angular coordinates make no contribution.[14-16] Therefore, the energy change between A and B may be supposed to satisfy this relationship:

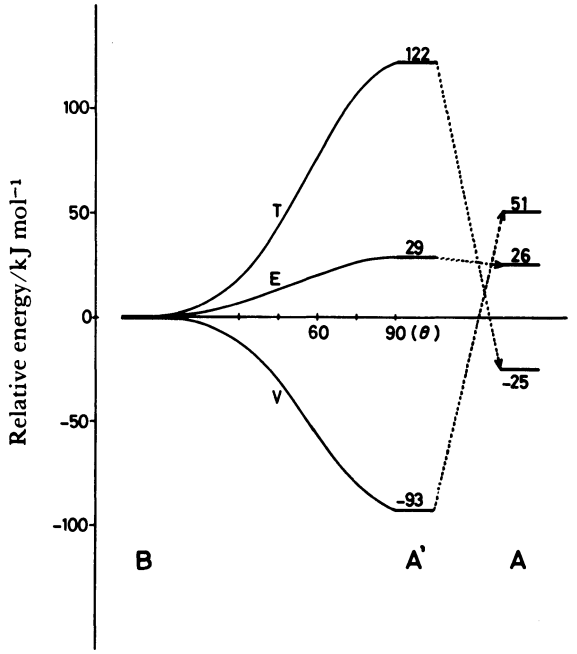

Fig. 3. Plots of the total (E) kinetic (T), and potebtial (V) energies (kJ mol^{-1}) vs. θ as the conformation changes from B to A′ in vinylamine.

$\Delta T=-\Delta V/2$. A comparison between B′ and B shows that the optimization of all geometrical parameters does not produce a large change in the total energy, but does in the potential and kinetic energies. The virial relationship can be seen with a reasonable accuracy.

Figure 3 shows the case when the conjugation between the ethenyl and amino groups is forced to terminate, i.e., the plots of the energy change vs. θ when θ is varied from 0° (B) to 90° (A′) with all the geometrical parameters at B except for θ. The total and kinetic energies increase monotonously as θ increases. At A′, the difference in total energy is around 29 kJ mol^{-1}, and we see that the kinetic energy is the main source of the increase in the total energy. Again, the optimization of all bond lengths and bond angles causes a large change in the potential and kinetic energies to meet the virial theorem, although the lowering of the total energy is less than 5 kJ mol^{-1}. From the results thus obtained, we may conclude that the kinetic energy is the factor in leading to conjugation in vinylamine.

Nitroethene. The nitro group is a representative substituent that withdraws the π electrons of the conjugated π system. Figure 4 shows the changes in the total, potential, and kinetic energies of nitroethene as functions of θ. Again, all the geometrical parameters but θ are kept the same as those in A. Although geometry optimization on B′ does not lower the total energy more than 2 kJ mol^{-1}, its components encounter a considerable change (more than 24 kJ mol^{-1}), much as in the case of vinylamine.

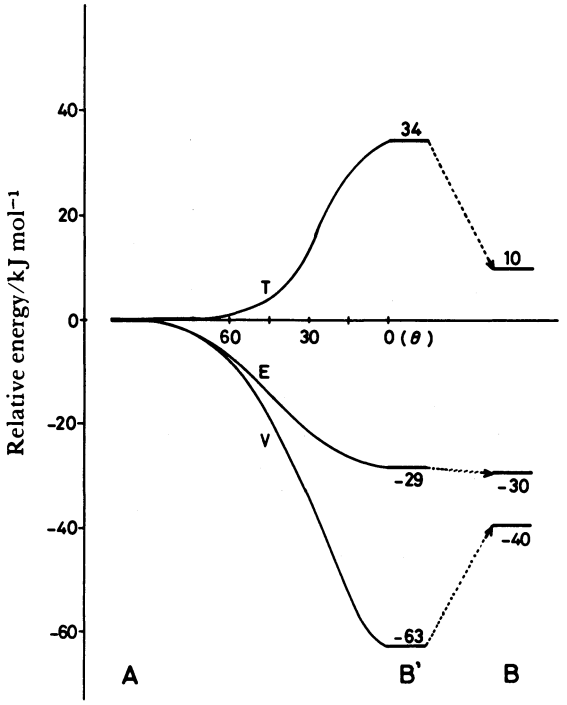

Fig. 4. Plots of the total (E), kinetic (T), and potential (V) energies (kJ mol^{-1}) vs. θ as the conformation changes from A to B′ in nitroethene.

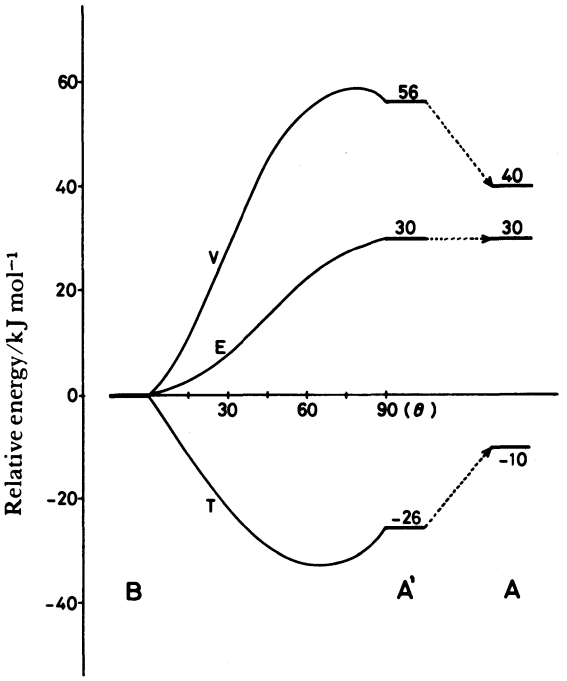

Fig. 5. Plots of the total (E), kinetic (T), and potential (V) energies (kJ mol^{-1}) vs. θ as the conformation changes from B to A′ in nitroethene.

The energy profile in Fig. 4 also seems similar to that in Fig. 2. However, the contents are the exact opposite of those of vinylamine in that as θ decreases, the kinetic energy increases, while the potential

energy decreases, and in that the amount of the decrease is larger than that of the increase. Therefore, it may be said that the conjugation stability is given by a decrease in the potential energy.

The energy profile in Fig. 5 is different from that in Fig. 3: the total and potential energies increase, while the kinetic energy decreases, as θ increases, leading to the conclusion that, contrary to the case of vinylamine, here the increase in the potential energy is the cause of the resistance against the rotation of NO_2. The conclusion in nitroethene is that the potential energy is the factor which leads to conjugation.

Concerning the Virial Theorem. We observed drastic changes in the partitioned energies between Structures A′ and A or between Structures B′ and B. Here we will give the reason.

The large change in the partitioned energies may be explained in terms of the scaling error. The virial relationship (i.e., $V=-2T$) may be supposed to hold at an equilibrium geometry. The scaling factor of the wave function for this geometry is unity. At a non-equilibrium geometry, however, the scaling factor must be adjusted in order to satisfy the virial relationship.[17]

If the molecular geometry is expressed by a set of internuclear distances R_j and angular coordinates ϕ_k, the virial theorem for a polyatomic molecule may be written as:[14,16]

$$2T+V+\sum R_j(\partial E/\partial R_j)=0 \tag{5}$$

Suppose that the total energy, geometry, and wave function at a non-equilibrium geometry are expressed by E, $G(R_j,\phi_k)$, and $\psi(\mu_i;R_j,\phi_k)$, where μ_i are the electronic coordinates. Here, we introduce a scaling factor η:

$G(R_j,\phi_k)$	$G(\eta R_j,\phi_k)$
$\psi(\mu_i;R_j,\phi_k)$	$\eta^{(3N/2)}\psi(\eta\mu_i;\eta R_j,\phi_k)$
E	E'
Unscaled system	Scaled system

where N is the number of electrons and E' is the total energy of the scaled wave function.

We can now obtain the normal virial relationship between the scaled potential and kinetic energies, i.e., $V'=-2T'$. Thus, each geometry has its own scaling factor that satisfies the virial relationship. If we consider the scaled wave function, a geometrical change from the one to the other gives rise to a scaling error for the wave function.

Pedersen and Morokuma[9] considered the effect of the scaling of the wave function on the total energy and its components. Introducing a scaling error $\gamma(=\eta-1)$ and expanding the differences between the scaled and unscaled energies in a power series or γ, they obtained these differences in energy:

$$\begin{aligned}\Delta E &= E(\gamma^2+\cdots\cdots)\\ \Delta T &= E(-2\gamma+3\gamma^2+\cdots)\\ \Delta V &= E(2\gamma-2\gamma^2+\cdots)\end{aligned} \tag{6}$$

These expressions clearly show that the kinetic and potential energies change in the first order of γ, while the total energy changes only in the second order. The present problem is a case of just this, since the geometries at A′ and B′ are non-equilibrium.

Here we must make another possibly confusing point clear. E' is always lower than E.[18] A question is, then: "Should we consider the scaled energies (T' and V') instead of the unscaled energies (T and V) at A′ and B′?" The answer is "No!" for the geometry for the scaled wave function is no longer the same as that for the unscaled wave function (namely, the R_j values are multiplied by η in G for the scaled wave function). What we need is the unscaled energy at A′ or B′ where the third term of Eq. 5 is surely far from null.

What Happens to the Substituent upon Conjugation. So far, we have discussed the changes in the partitioned energies in the whole system. In order to see the details of conjugation, this section will now deal with the changes in those energies for atoms in ethenyl and amino or nitro groups as the θ value changes.

Since, in the LCAO MO theory, each MO is expanded by a linear combination of atomic orbitals (AO's), and since, via the Fock matrix, the three- and four-center terms are reduced to two-center terms, the Hartree–Fock equation is formally expressed by the sum of monocentric (E_A) and bicentric (E_{AB}) terms:

$$E=E_A+\sum_{A>B}E_{AB} \tag{7}$$

These terms can be further partitioned as:

$$E_A=E_A{}^T+E_A{}^V+E_A{}^J \tag{8}$$

$$E_{AB}=E_{AB}{}^T+E_{AB}{}^V+E_{AB}{}^J+E_{AB}{}^N \tag{9}$$

where $E_{AB}{}^N$ is the nuclear repulsion energy between atoms A and B; it is, of course, one of the potential energies in the given system. The details of the calculation method have been given elsewhere.[3,7]

Following the method presented in the definition of Mulliken population analysis,[19] the kinetic and potential energies concerning the electrons belonging to a specified atom, X, $T(X)$, and $V(X)$, are defined as;

$$T(X)=E_X{}^T+1/2\sum_{A\neq X}E_{XA}{}^T \tag{10}$$

$$V(X)=E_X{}^V+E_X{}^J+1/2\sum_{A\neq X}(E_{XA}{}^V+E_{XA}{}^J+E_{XA}{}^N) \tag{11}$$

The electronic effect of enamine may be expressed in organic chemistry as follows.[20]

$$\overset{\curvearrowleft}{C_1}=C_2-\overset{\curvearrowleft}{\dot{N}} \longleftrightarrow C_1^- - C_2=N^+$$

1 2

Table 3. Electron Density, Kinetic Energy, and Potential Energy on an Atom in Orthogonal Conformation and Their Differences from the Planar Conformation(B′)

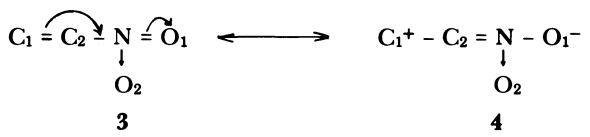
a) $D(B')-D(A)$ in 10^{-3} electron units. b) $X(B')-X(A)$ in kJ mol^{-1}, where X is the kinetic or potential energy.

These expressions indicate that some of the lone-pair electrons on the nitrogen atom flow to the π system and are localized on the β carbon atom.

Table 3 shows the differences, between A and B′, of $T(X)$ and $V(X)$, as well as the total atomic charges of the carbon, nitrogen, and oxygen atoms. Agreeing with the cannonical structure **2**, the conformation change from A to B′, i.e., the introduction of conjugation in vinylamine, reduces the electron densities of N as well as of C_2 and enriches that of C_1.[21] Since the potential energy and kinetic energy of electrons on an atom are essentially proportional to its electron density,[22] a change in electron density involves proportional changes in the kinetic and potential energies, which are agreeingly reproduced, as may be seen in Table 3.

The substituent effect of the nitrogen group on a π system may be symbolized as follows:



3 **4**

which indicates that conjugation makes the electron density of the β carbon atoms low and only one of the oxygen atoms high. The results in Table 3 coincide well with the above symbols. That is, on a conjugative structure, the electron density at the β carbon atom is reduced, while that of O_1 is increased. An increase in the electron density at C_2 is observed. This may be interpreted as C_2 being at the allylic position to O_1 and O_2, which have three or two lone pairs of electrons respectively.

An electron migration takes place because such a migration produces a stabilization energy; the degree of migration is determined by the lowest total energy, which is given by including all the interactions in the system. However, the only structural difference between vinylamine and nitroethene is in the substituent. Therefore, the differences in conjugation thus far discussed should be totally attributed to the nature of the substituent. That is, the sources of conjugation in vinylamine and nitroethene are the kinetic energy of electrons and the potential energy, which are given by the electronic effects of the amino and nitro groups respectively.

Concluding Remarks. In an orthogonal conformation, the movement of mobile electrons in both the ethenyl and substituent groups is restricted by the orthogonalized overlap of the p AO's, while in a planar structure those electrons are allowed to move. This produces two situations: (1) The electrons on the substituent move to the π system or (2) the electrons in the π system are withdrawn by the substituent.

The kinetic energy of an electron reflects the degree of the restriction of electron movement. An orthogonal conformation of vinylamine restricts the movement of the lone pair of electrons within the nitrogen atom, resulting in a high kinetic energy of the electrons, equivocally a high kinetic-energy pressure of the electrons. A planar structure allows the electrons to move. Such a less-restricted movement generally causes a decrease in the kinetic energy, i.e., a relaxation of the kinetic-energy pressure. This concept may be extended to any electron-donating substituent.

In nitroethene, the allowed movement of π electrons causes a localization of the π electrons on one of the oxygen atoms; this is a result of the strong electrostatic potentials of the hetero atom, which produces an increase in the kinetic energy, but also an overwhelming decrease in the potential energy. In this way, the cause of conjugation can be of either *kinetic-energy origin or potential-energy origin.*

The CO-H_2 Reaction over ZrO_2 to Form Isobutene Selectively

Ken-ichi MARUYA,* Tatsuichi MAEHASHI, Takashi HARAOKA, Shinichiro NARUI, Yukihiko ASAKAWA, Kazunari DOMEN, and Takaharu ONISHI*

Research Laboratory of Resources Utilization, Tokyo Institute of Technology, 4259 Nagatsuta, Midori-ku, Yokohama 227

(Received August 3, 1987)

The CO-H_2 reaction over ZrO_2 was studied in detail. Methanol and isobutene were selectively formed at 473—523 and 623—673 K, respectively. The activation energies for C_2, C_3, and linear C_4 hydrocarbon formation are 79, 84, and 96 kJ mol^{-1} (523—723 K), while that for branched-chain C_4 hydrocarbons is about 210 kJ mol^{-1} (523—623 K). At 673 K the rate of C_4 hydrocarbon formation is as follows: $r=kP_{H_2}\cdot P_{CO}^2$, while those of C_1, C_2, and C_3 are written by the functions having the maximum values regarding CO pressure. C_4 hydrocarbons consist mostly of isobutene at the temperature. From these results it was concluded that isobutene is formed via different path from those of C_1, C_2, C_3, and linear C_4 hydrocarbons. The addition of high electronegative oxides such as SiO_2 and Nb_2O_5 resulted in the decrease of isobutene and the increase of methane. The selective formation of isobutene proceeds over pure ZrO_2 and ZrO_2 modified with 3a Group and basic metal oxides. The nature of active site for isobutene formation was discussed.

There have been vast researches on the hydrogenation of CO over transition metal catalysts and the products obtained are mostly comprised of hundreds of hydrocarbons and oxgenated products. In those cases the carbon chains of the products are usually linear and the distributions of hydrocarbons are described by the Schulz-Flory rule. Therefore, there have been only few studies on the selective formation of special hydrocarbons,[1-5] and even in the cases with high selectivity the catalysts are not so stable for the long time reaction and the high temperature treatment, because of the delicate method of catalyst preparation.[2,4,5]

On the other hand, difficultly reducible metal oxides have been used as catalyst supports and only few have been studied as catalysts. One of the features of metal oxide catalysts is to form branched-chain hydrocarbon products directly from CO and H_2. Thus, ThO_2,[6] La_2O_3,[7] and Dy_2O_3[7] produce branched-chain, saturated, and aliphatic hydrocarbons such as isobutane under very severe conditions, and ZrO_2 selectively forms isobutene under mild conditions such as at 69 kPa and 623 K.[8] These catalysts are stable for the reaction at 723 K[6,8] and the pretreatment at 973 K.[8] The selective formation of isobutene is found out also in the other oxide catalysts such as CeO_2 and La_2O_3 under the mild conditions.[9] In this paper we describe in detail the CO-H_2 reaction over ZrO_2 to form isobutene selectively.

Experimental

Materials. Zirconium hydroxide was precipitated by hydrolysis of $ZrO(NO_3)_2$ with about 5% aqueous ammonia solution, washed with deionized water until no ammonia was detected with Nesler's test, dried overnight at 393 K, and calcined at 773 K for 3 h. Mixed oxides of ZrO_2 with oxides of Ca, Sc, Y, Nd, and Sm were prepared from the mixed solution of $ZrO(NO_3)_2$ and each of the nitrates in similar manners to the ZrO_2 case. The impregnated ZrO_2 catalysts with Al_2O_3 and SiO_2 were prepared using the nitrate and the ethoxide solution, respectively, and were calcined around 673 K for several hours in order to remove the nitrate and the ethoxide ions and then at 773 K for 3 h. A mixed hydroxide of ZrO_2 and Nb_2O_5 was precipitated from aqueous HCl solutions of $NbCl_5$ and $ZrOCl_2$ with aqueous ammonia solution, and treated similarly to the ZrO_2 case. Zirconium sponge was purchased from Mitsuwa Pure Chemicals.

Procedure. Reactions were carried out in a glass vacuum reaction system with a gas-circulating pump and also a flow system under the atmospheric pressure. In the reaction with the vacuum system a mixture of CO and H_2 (1:3) was purified by gas circulation through a trap at liquid nitrogen temperature for 1 h before contacting with the catalyst (1.5 g), which was preevacuated at 973 K for 3 h. The initial pressure was 69 kPa and the gas flow rate was about 35 ml(STP) min^{-1}.

The reaction was also carried out in the flow system with a quartz reactor of 12 mm of outside diameter, to investigate the pressure dependence of the reaction rate. The reaction temperature was measured by a thermocouple inserted in the catalyst bed (5.0 g). The catalyst was heated at 873 K for 3 h under a nitrogen stream at about 100 ml(STP) min^{-1}, and then H_2 and CO were introduced after cooling the catalyst to a given reaction temperature. The total flow rate was kept constant by changing that of nitrogen.

Analyses. Products except for methane were collected at the liquid nitrogen temperature. GC, IR, and MS were used for analyses of products and CO. Quantitative analyses were conducted by GC equipped with a Porapak Q column for CO_2, H_2O, methanol, dimethyl ether, and hydrocarbons including CH_4, VZ-7 and VZ-10 columns (Gasukuro Kogyo Inc.) for isomer of C_4 and C_5 hydrocarbons, and a molecular sieve 5A column (Nishio Industry Co.) for CO.

Results and Discussion

Temperature Dependence of Hydrocarbon Formation. Table 1 shows the yield of products formed from the CO-H_2 reaction over ZrO_2 using the gas-circulating glass reaction system at the temperature from 473 to 723 K for the initial 25 h. Yields of methanol and dimethyl ether reaches the maximum values around 523 and 573 K, respectively, and that of

Table 1. Product Yield from $CO-H_2$ Reaction over ZrO_2[a]

T/K	Yield/C-base μmol				
	Hydrocarbon	MeOH	Me_2O	CO_2	H_2
473	0.17	11	3.6	0.6	4.5
523	0.86	43	22	11	37
573	8.8	16	84	60	38

hydrocarbons increases rapidly with an increase in the reaction temperature. The temperature dependences of the yields of C_1 to C_4 hydrocarbons are shown in Fig. 1. The plots for C_2 and C_3 hydrocarbons are almost linear in the wide temperature range between 523 and 723 K and their apparent activation energies are 79 and 84 kJ mol^{-1}, respectively. Methane yields are close to those of C_2 and C_3 hydrocarbons, although they are rather scattered. The yields of linear C_4 hydrocarbons evaluated from the isomer distribution shown in Table 2 are plotted rather linearly in the temperature range and the activation energy is about 96 kJ mol^{-1}. On the other hand, the yield of branched-chain C_4 hydrocarbons has maximum value around 673 K. The activation energy evaluated in the narrow range between 523 and 623 K is about 210 kJ mol^{-1}. The isomer distributions in Table 2 show that at 523 K 1-butene is mainly formed but above 573 K the main product is isobutene and no or little skeletal isomerization takes place at 623 K. These results indicate that the branched-chain hydrocarbons are probably formed by the different path from the linear ones.

Pressure Dependence of Hydrocarbon Formation. Figure 2 shows the H_2 pressure dependences of the formation rates of hydrocarbons from C_1 to C_4. The rates are proportional to the pressure. For the rate of

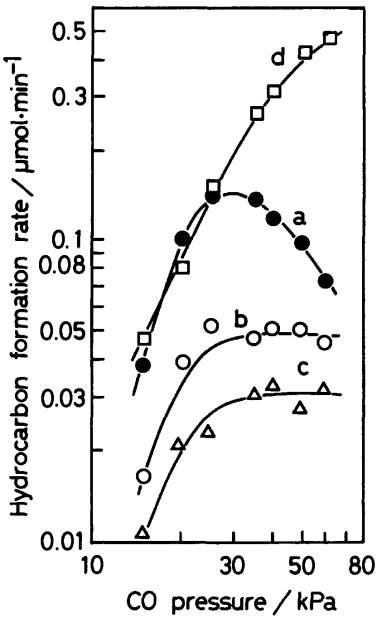

Fig. 3. CO pressure dependence of hydrocarbon formation rate at 673 K and 40 kPa of H_2.

methanation over metal catalysts it is reported that the exponents of the H_2 pressure vary between 0.7 and 1.6.[10,11] For the Fischer-Tropsch reaction various values between 0 and 2 are reported, although the exponent value under usual conditions is reported to be about 1.[12,13] Thus, oxide catalysts such as ZrO_2 show the same dependence on the H_2 pressure as the metal catalysts.

Figure 3 shows the CO pressure dependence of the rates. Differing from the H_2 pressure dependence, the plots are not linear for all hydrocarbons. The rates of C_1, C_2, and C_3 hydrocarbon formation increase with an increase in the pressure range of about 30 kPa. The rate of C_1 hydrocarbon formation reaches the maximum value around 30 kPa, while those of C_2 and C_3 become nearly constant above that value. On the other hand, the rate of C_4 hydrocarbon formation is almost proportional to the square of the pressure. Since C_4 hydrocarbons consist mostly of isobutene at the temperature shown in Table 2, the difference of the CO pressure dependence means that the mechanism of isobutene formation is probably different from those of linear hydrocarbons.

The formation of branched-chain, aliphatic, and saturated hydrocarbons in the isosynthesis reaction has been explained by the mechanism of the conversion of methanol which is produced as a primary product.[6,7] Since ZrO_2 is one of the isosynthesis catalysts[6] and methoxide species is observed on the ZrO_2 surface under the reaction conditions,[14] the surface methoxide species is one of the possible precursor for the hydrocarbon formations. The formation of linear hydrocarbons such as C_{1-3} and linear C_4 hydrocarbons might take place in a similar mechanism to isosynthesis reactions, because the Arrhenius plots are almost linear from the low temperature, at which methanol is selectively formed, to the high temperature and methoxide species are observed in the temperature range under the reaction conditions.[14] On the other hand, the formation of isobutene begins to take place above 623 K, at which the amounts of methanol and dimethyl ether decrease and the rate of the formation depends on the CO pressure in the second order. These results suggest that the formation of isobutene proceeds probably via some species in addition to the methoxide. That is, the formation path of isobutene from the CO-H_2 reaction over ZrO_2 may be different from the methanol conversion suggested in the isosynthesis. Recently, the mechanisms of aldol condensation type have been proposed for the formation of branched-chain olefins over ZrO_2[15] and CeO[16] catalysts. However, the lack of experimental evidence in the former case and the low selectivity of C_4 hydrocarbons in the latter case make obscure the agreement with the highly selective CO-H_2 reaction over ZrO_2 in the present study. Reaction mechanisms for the isobutene formation are under investigation.

Effect of Metal Oxide Additives over ZrO_2. It has been shown that the preparation methods of the ZrO_2 catalyst affect the product selectivity, i.e., ZrO_2 prepared from zirconium oxynitrate with aqueous ammonia solution produces isobutene selectively from CO and H_2, while ZrO_2 from the alkoxide with water produces methane.[17] Therefore, the modification of ZrO_2 by the addition of the second oxide component may lead to the change of product selectivity and the hydrocarbon formation activity. Table 3 shows the hydrocarbon yields and selectivities with some modified ZrO_2 catalysts. When the CO-H_2 reaction over Zr sponges proceeds, a large amount of H_2 was absorbed and small amounts of widely dispersed hydrocarbons were formed. Zirconium sponges pretreated with H_2 gives methane as a main product. Therefore, isobutene formation over the ZrO_2 catalyst hardly participates in low valent zirconium.

Among the mixed oxide catalysts, SiO_2- and Nb_2O_5-added catalysts are not C_4-selective but rather methane-selective. In the reaction using these catalysts the large amounts of hydrocarbons are produced than those of CO_2. On the other hand, in the case of the other mixed oxide catalysts the amounts of hydrocarbons formed are less than that of CO_2, indicating the presence of unrecovered carbon species. Since methoxide species and formate ions are formed on the ZrO_2 surface under the reaction conditions,[14] the time course of the reaction showed the large amount of CO-H_2 gas absorption in the initial few hours of the reaction, and no coke formation was

observed for 24 h reaction, most of the unrecovered carbon could be the surface-adsorbed species and a part of the carbon might be unrecovered higher hydrocarbons.

The presence of NaOH on ZrO_2 causes a little increase in the isobutene selectivity (85%) compared with that (77%) over the unmodified ZrO_2 catalyst, although the activity is lowered to about one forth. The addition of Al_2O_3 results in the lower selectivity for C_4 hydrocarbons. The SiO_2-added catalyst is rather methane-selective. These results indicate that there are two types of active sites on ZrO_2, one of which is effective for C_4 hydrocarbon formation and the other is for methane formation. Then, oxides of Sc, Y, some La Group elements, and Nb were used as difficulty reducible transition metal oxides. The addition of elements of lanthanum group, Sc, and Y oxides causes the selectivity and the activity to change only little, while that of Nb_2O_5 leads to the decrease of C_4 hydrocarbon and the increase of methane. Since the mixed oxide of SiO_2 or Al_2O_3 with ZrO_2 exhibits the solid acidity, which is not found on both oxides,[18] this selectivity change may relate to the electronegativity[19] of the additives. Figure 4 shows the relation of the electronegativity to the selectivity of C_1 and C_4 hydrocarbons. The addition of higher electronegative oxide results in the lower selectivity for C_4 hydrocarbons and the higher selectivity for methane. This may indicate that the increase in the acidity on ZrO_2 promotes the formation of methane and retards the formation of C_4 hydrocarbons. In the presence of NaOH with the much lower electronegativity than ZrO_2, the selectivity of C_4 hydrocarbons has the highest value. Thus, the pure ZrO_2 catalyst, ZrO_2 with 3a group and also basic metal oxides such as NaOH are the effective catalysts for selective formation of C_4 hydrocarbons, especially isobutene. This suggests the importance of basic character of active site for isobutene formation.

Solvation of Alkylbenzenes Studied by Photoelectron Emission Spectroscopy of Organic Solutions

To-oru NAKAYAMA, Iwao WATANABE,* and Shigero IKEDA
Department of Chemistry, Faculty of Science, Osaka University, Toyonaka, Osaka 560
(Received August 29, 1987)

The external ionization potentials for alkylbenzenes in acetonitrile and nitrobenzene have been measured by photoelectron emission spectroscopy to determine electronic polarization energies and reorganization energies. The polarization energy is used to discuss the solvation structure of alkylbenzene. The solvation behavior of alkylbenzene is found to be different from that of butylamine, previously reported. We have obtained the evidence of the approach of solvent molecules to the plane of benzene ring.

The radii of solvation sphere for butylamines in acetonitrile have been determined by using photoelectron emission (PEE) technique.[1] Though their molecular shapes are not spherical, their radii correlate excellently with the molecular sizes estimated from their densities. In the present study, PEE spectra are obtained for acetonitrile and nitrobenzene solutions of several alkylbenzenes including highly symmetrical hexamethylbenzene and *o*-, *m*-, and *p*-xylene to investigate the effect of solute–solvent interaction on the size of solvation sphere.

The linear correlation has been reported by Kochi et al.[2] between ionization potential in vacuum (I_p) and oxidation potential in solution (E_{ox}) for alkylbenzene. External ionization potential (E_t) determined from PEE spectra can be combined with I_p and E_{ox} to discuss solvation structure and mechanism. The E_t value is related to I_p or the standard oxidation potential (E°_{ox}) as follows,[1,3]

$$P_+ = I_p - E_t, \tag{1}$$

$$\Delta G_r = E_t - E^\circ_{ox} - \Delta G_H, \tag{2}$$

where P_+ is the polarization energy of the solvent molecules, ΔG_r is the reorganization energy, and ΔG_H is the potential of vacuum level referred to NHE, which is estimated to be 4.5 eV.[4,5]

The polarization of solvent molecule is induced by the positive charge of photoionized solute molecule and it depends on the number of solvating molecules and their geometrical arrangement. The P_+ is related to an effective solvation radius[1] (r_{P_+}) through Born type equation,

$$P_+ = e^2(1 - 1/\varepsilon_{op})/2r_{P_+}, \tag{3}$$

where e is the charge of an electron, and ε_{op} is the optical dielectric constant of the solvent. Thus the PEE technique is expected to provide us a new parameter, the effective solvation radius, which should be used to investigate solute–solvent interaction.

The ΔG_r contains the energy caused by the change in orientation of surrounding solvent molecules (R_{out}) which is closely related to the solvation radius, and the relaxation energy of the produced cation molecule (R_{in}).

Experimental

Materials. The alkylbenzenes were purified by distillation or recrystallization. Purities of the samples were certified to be >98% by HPLC. Acetonitrile of spectra-grade was fractionated from P_2O_5 after stirring overnight. Nitrobenzene was of reagent-grade and was dried over $CaCl_2$, decanted, and distilled under reduced pressure. Tetrabutylammonium perchlorate was of special-grade (Nakarai Chemicals Co.) and used as purchased.

Photoelectron Emission Spectra. The external ionization potentials for alkylbenzenes were measured as photoionization threshold energy (E_t) by PEE technique which has been reported.[1] Sample solutions were prepared just before measurement. PEE spectra were taken at −30 °C with 0.1 mol dm^{-3} concentration for benzene, toluene, *o*-, *m*-, and *p*-xylene, mesitylene and ethylbenzene in acetonitrile. The conditions for other samples were; +1 °C, 0.025 mol dm^{-3} for hexamethylbenzene and hexaethylbenzene in acetonitrile; room temperature, 0.1 mol dm^{-3} for all samples in nitrobenzene. PEE spectra in acetonitrile were also obtained at −15 °C and +1 °C. No dependence of E_t value on temperature was detected.

Water contents in acetonitrile and nitrobenzene used in this study were measured by Karl Fischer titration analysis and the contents were $3—15\times10^{-3}$ mol dm^{-3}. It was found, however, that water in the solvents does not affect PEE spectra at all.

Cyclic Voltammetry. Cyclic voltammograms (CV) were obtained for 5×10^{-3} mol dm^{-3} of *o*-, *m*-, and *p*-xylene, mesitylene, hexamethylbenzene, and hexaethylbenzene in nitrobenzene containing 0.1 mol dm^{-3} tetrabutylammonium perchlorate at room temperature in air-tight cell under nitrogen atmosphere. The scan rate was 8.42 V s^{-1} for all the samples. The working electrode was a 0.1 mm-diameter platinum disk electrode embedded in glass. The counter electrode was a platinum spiral wire. The reference electrode was Ag/$AgNO_3$ (0.1 mol dm^{-3}) in acetonitrile, separated from sample solution by a cracked glass. The electrode was calibrated relative to ferrocene/ferrocenium standard after every measurement and the potential was converted into NHE value by adding 0.400 V.[6]

Table 1. Photoionization Energies of Substituted Benzenes in the Gas Phase (I_p) and in the Solvents (E_t) (NB=Nitrobenzene, AN=Acetonitrile), the Oxidation Potential (E^p_{ox}), the Polarization Energies (P_+), the Reorganization Energies (ΔG_r), the Effective Solvation Radii (r_{P_+}), and the Radii of the Solute Molecules (r_d)

Results and Discussion

Correlations between E_t vs. I_p and E_t vs. E_{ox}. The E_t values obtained for alkylbenzenes are collected in Table 1, which includes I_p and anodic peak potentials of CV (E^p_{ox}). The values of I_p and E^p_{ox} in acetonitrile are taken from the work done by Kochi et al.[2] Figure 1 shows the correlation between E_t and I_p both in acetonitrile and nitrobenzene. The plot of E_t vs. I_p (except for benzene in acetonitrile) gives linear correlation as follows,

$$E_t = 0.78 \times I_p + 1.01 \text{ eV (in acetonitrile)}, \quad (4)$$

$$E_t = 0.69 \times I_p + 1.74 \text{ eV (in nitrobenzene)}. \quad (5)$$

The smaller values of the slopes than unity indicate that the polarization energy is smaller for alkylbenzene having smaller I_p value or for larger benzene in size. The linear correlation also exists between E_t and E^p_{ox} as shown in Fig. 2 and the slopes are almost unity.

$$E_t = 0.89 \times E^p_{ox} + 5.56 \text{ eV (in acetonitrile)}, \quad (6)$$

$$E_t = 1.04 \times E^p_{ox} + 5.17 \text{ eV (in nitrobenzene)}. \quad (7)$$

Polarization Energy, P_+. The polarization energy P_+ determined from the difference ($I_p - E_t$) gives us the

information about the size of solvation sphere around the photoionized cation radical molecule. The solvation structure of the cation molecule is exactly the same as that of the original neutral molecule, because the photoionization process is subjected to the Franck–Condon transition.

Figures 3 and 4 show the correlation between P_+ and the number n of alkyl groups introduced to a benzene molecule. Both in acetonitrile and nitrobenzene, P_+ decreases with n, which should be the effect of the alkyl groups working as insulator locating between the positive charge on benzene ring and solvent molecules.

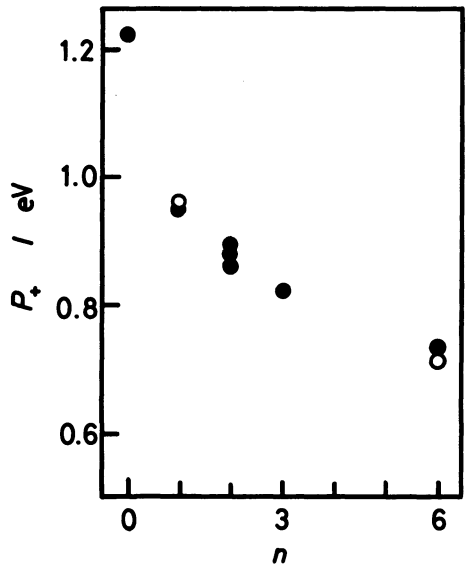

Fig. 3. The relationship between the polarization energies (P_+) and the number n of substituents introduced to benzene in acetonitrile.

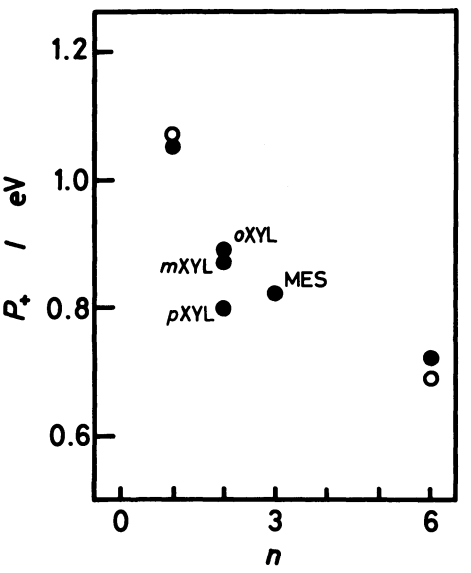

Fig. 4. The correlation of polarization energies (P_+) and the number n of substituents introduced to benzene in nitrobenzene. Closed circles are for methyl-substituted and open circles for ethyl-substituted benzenes. (*o*, *m*, *p*XYL: *o*-, *m*-, *p*-xylene, MES: mesitylene).

Symmetry of the sample molecule is distinguished by nitrobenzene solvent. Among the three dimethylbenzenes, *p*-xylene has the smallest P_+ value, and the value is even smaller than that for mesitylene. This is not the case in acetonitrile. This peculiar effect of the solvent should be related to the size, shape or dipole moment of the solvent molecule.

The change in substituent, methyl or ethyl group, causes no change in P_+ in both solvents. This will be discussed in the next section considering the effective solvation radius.

The Effective Solvation Radius, r_{P_+}. The effective solvation radius (r_{P_+}) calculated from P_+ value using Eq. 3 is compared with the radius (r_d) evaluated from the density (d) of pure substance,

$$r_d = 0.5 \times (M/dN_A)^{1/3}, \quad (8)$$

where M is the molecular weight and N_A Avogadro's constant, and the result is shown in Fig. 5. The solid line in the figure indicates the position where both of r

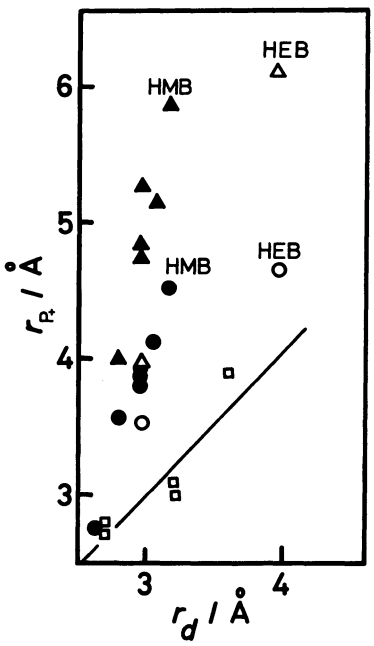

Fig. 5. The relationship between the radii calculated from the densities of the pure solutes (r_d) and the effective solvation radii calculated from the polarization energies (r_{P_+}). Closed circles are for methyl-, open circles for ethyl-substituted benzenes in acetonitrile, closed triangles are for methyl-, open triangles for ethyl-substituted benzenes in nitrobenzene. The data for butylamines are also included in this figure as open tetragons (Ref. 7). The solid line indicates the position of $r_{P_+}=r_d$.

values are the same. This figure includes the results for butylamines in acetonitrile which is previously reported.[7] While the points for amines come to the solid line excellently, the values of r_{P_+} for aromatic hydrocarbons are larger than r_d for all the samples except for benzene in acetonitrile. The experimental fact pointed out in the previous section that the substitution of methyl groups on the benzene molecule with ethyl groups does not affect the P_+ energy contradicts the prediction derived from Eq. 3. Though the value of r_d for hexaethylbenzene is significantly larger than that for hexamethylbenzene, their values of r_{P_+} are almost the same. Since the r_{P_+} is considered to be the distance of the nearest solvent molecules from the charge of the cation which locates at benzene ring,[8] the solvation structure for hexaethylbenzene can be considered to be the same as that for hexamethylbenzene. It means that the solvent molecules around hexaethylbenzene and hexamethylbenzene must locate above and beneath the benzene-ring plane of the sample molecule. If the nearest solvent molecules were in the benzene-ring plane beyond the alkyl groups, the change in length of the alkyl group should affect r_{P_+} and these two samples should have quite different r_{P_+} values.

The same trend is observed for the cases of toluene, ethylbenzene in both solvents.

Reorganization Energy, ΔG_r. The difference between E_t and the standard oxidation potential referred to the vacuum level is the reorganization energy (ΔG_r) after one-electron oxidation reaction (Eq. 2). The values of $E°_{ox}$ for alkylbenzenes used in the present work are not available because of their irreversible nature in CV both in acetonitrile[2] and nitrobenzene except for hexaethylbenzene. Therefore, the ΔG_r values can not be evaluated for most of the samples of this work. It is interesting, however, to point out that, according to the work by Kochi et al.,[2] the alkylbenzenes give reversible CV waves in trifluoroacetic acid. Therefore we have made great efforts to obtain PEE spectra of trifluoroacetic acid solutions, and yet could not obtain the spectra because of their high vapor pressure of the solvent. Kochi et al. also reported that the equilibrium oxidation potentials in trifluoroacetic acid $E°_{ox}$(TFA) correspond perfectly to the peak potentials E^p_{ox} measured in acetonitrile (at sweep rate of 100 mV s^{-1}) as $E°_{ox}(\mathrm{TFA}) = 1.01 \times E^p_{ox} - 0.001$. We may presume that real equilibrium potentials of alkylbenzenes in acetonitrile must not be very different from the standard oxidation potentials in trifluoroacetic acid, nor from the peak potentials in acetonitrile reported by them. Under such an assumption, the peak potentials will be used instead of the standard potentials to extract the alkyl substitution effect on the reorganization energy.

Figures 6 and 7 show the correlation between ΔG_r so determined and n. The ΔG_r has no relation with n,

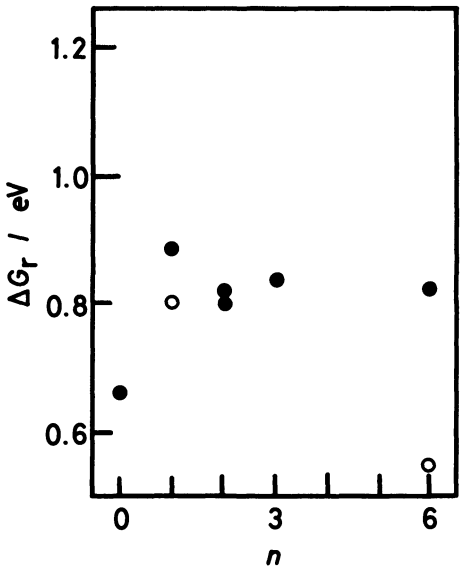

Fig. 6. The correlation of ΔG_r in acetonitrile and the number n of substituents introduced to benzene.

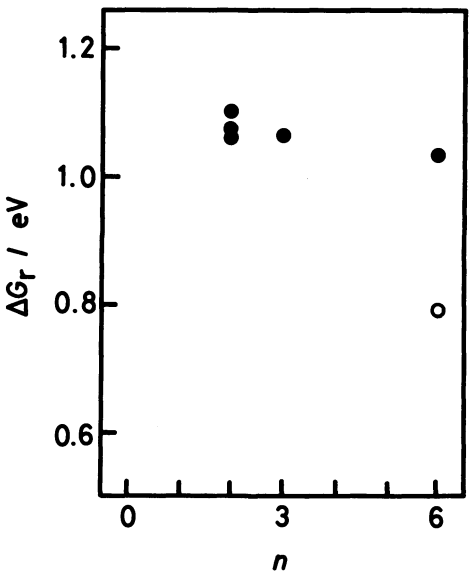

Fig. 7. The correlation of ΔG_r in nitrobenzene and the number n of substituents introduced to benzene.

but different alkyl group causes different ΔG_r value such as hexamethylbenzene/hexaethylbenzene or toluene/ethylbenzene.

It is noted that hexaethylbenzene has the smallest ΔG_r value, and displays totally reversible CV waves in both solvents. This fact may indicate that the reversibility of oxidation reaction of alkylbenzene depends on the degree of reorganization of the molecule.

This work was supported by Grant-in-Aid for Scientific Research Nos. 58540285 and 62540356, and for Special Project Research No. 60129031 from the Ministry of Education, Science and Culture.

Incommensurate Phase Transitions and Anomalous Lattice Heat Capacities of Biphenyl†

Kazuya SAITO,†† Tooru ATAKE,††† and Hideaki CHIHARA*
Department of Chemistry and Chemical Thermodynamics Laboratory, Faculty of Science, Osaka University, Toyonaka, Osaka 560
(Received September 9, 1987)

Heat capacities of crystalline biphenyl were measured between 3 and 300 K by adiabatic calorimetry and some thermodynamic functions including the calorimetric standard entropy were tabulated. Thermodynamic properties of the successive phase transitions were determined; for the twist transition at (40.4±0.2) K, $\Delta_{trs}H$=(5.02±0.08) J·mol^{-1} and $\Delta_{trs}S$=(0.129±0.003) J·K^{-1}·mol^{-1}, and for the lock-in transition at (16.8±0.1) K, $\Delta_{trs}H$=(0.15±0.02) J·mol^{-1} and $\Delta_{trs}S$=(0.009±0.001) J·K^{-1}·mol^{-1}. Anomalously large heat capacities at low temperatures were analyzed based on lattice dynamics calculation, and the crossover of the low temperature heat capacities of biphenyl and *p*-terphenyl was attributed to the greater activity of the twisting mode in biphenyl. The relation of the bond flexibility to the incommensurability is discussed through the comparison of the low temperature heat capacities of biphenyl, *p*-terphenyl, and 4,4′-difluorobiphenyl.

Biphenyl is an interesting molecule which changes its conformation according as the state of aggregation changes. While molecules are twisted by about 40° about its central C–C bond in the gaseous state[1,2] and about 30° in the liquid state,[2–6] they crystallize in the structure of the space group $P2_1/a$ with the planar conformation at room temperature.[7–14] On cooling, however, they resume the twisted conformation below the phase transition temperature at about 40 K;[15–17] a similar phase transition, "twist transition," has also been found in *p*-terphenyl[18–21] and in *p*-quaterphenyl.[22,23]

The soft-modes have been found by optical[24–26] and neutron scattering[27] experiments. The softening occurs at the general point (x^*, y^*, z^*) near the B (0, 1/2, 0) point in the reciprocal space and the new phase is of two dimensionally incommensurate structure[28,29] classified to the five dimensional Bravais lattice of $P^{P2/m}_{cmm}$.[30] The modulation wave which characterizes this phase is expressed as $q^*=\pm(\delta_a a^*-\delta_c c^*)\pm 1/2\times(1-\delta_b)b^*$. The mean approximate structure was obtained neglecting satellite reflections in the diffraction diagram and was classified to Pa.[15] Dworkin and Cailleau[31] reported the results of their heat capacity measurements on biphenyl, in which they could not detect any anomaly in the heat capacity curve. On the other hand, Cullick and Gerkin[32] found the temperature halt at 42 K in the cooling curves, which strongly suggested that the transition is of the first-order. However, other authors[24–27,33–38] reported by making use of several experimental techniques that the transition is of higher-order.

On further cooling, the incommensurate-commensurate transition (so-called lock-in transition) in the one direction takes place at about 17 K,[28,29,34] i.e. δ_a and δ_c equal 0 below the lock-in transition. Below this transition, however, the crystal still remains incommensurate along the b^* axis. The structure was determined to be of the super-space group $P^{P2_1/a}_{1\bar{1}}$ by using neutron diffraction technique.[16] The essential aspect of the incommensurate modulation was a torsion about the central C–C bond with an amplitude of 5.5° for each phenyl ring, the maximum twisting angle being 11°. The lock-in transition has been revealed to be of the first-order by using optical[34] and neutron diffraction[28,38] techniques. More direct evidence of the first-order nature is the co-existence of the two phases observed in neutron experiments. On the other hand, no abrupt change was observed in Brillouin scattering experiments[36] and in electronic spectra of molecules.[35]

The lock-in transition in the direction of the b^* axis has not been observed so far down to 1.4 K.[38]

Dynamics in the incommensurate phases have been investigated by using some experimental techniques. The dispersion of the phason and the amplitudon branches were determined by neutron[27,40] and Brillouin[36] scattering experiments. The damping of the phason branch near the zone center was rather small. NMR results by Liu and Conradi[41] showed the existence of the slow process ($\tau\simeq 10^3$ s at 4.2 K) in the incommensurate phases. They proposed the term, "incommensurate glass," in biphenyl in the lowest temperature region. Recently, Benkert and Heine[42] interpreted the slow process as the shifting of the modulation boundaries.

It must be noted that the pressure dependence of the transition temperatures are negative.[37,43] This clearly shows that the transitions are connected with a subtle balance between intra- and intermolecular interactions.

Since Hochstrasser et al.[44] discovered the phase

transition in biphenyl crystal, many interesting features have been revealed by making use of several experimental techniques as briefly summarized above. Theoretical treatments[39,42,45-50] have also been presented based on these experimental results. However, accurate thermodynamic properties have been lacking although they should give an important clue to the nature of the transition and provide a critical test of theory. These situations led us to begin a series of thermodynamic studies on the successive phase transitions in crystalline biphenyl and related substances, parts of which were published elsewhere.[51-59] This paper provides the full description of precision heat capacity measurements. The anomalous lattice heat capacity at low temperatures will be analyzed by using the method of lattice dynamics.

Experimental

Commercially available biphenyl (Nakarai Chemicals, Ltd.) was purified by fractional sublimation in vacuum at room temperature. In order to avoid possible formation of metastable phases and/or poor crystallinity, the sublimed specimen was melted under a helium atmosphere (10^5 Pa) and cooled gradually down to room temperature for recrystallization. The purity of the specimen was better than 99.9 moles per cent as confirmed by gas chromatography.

The powdered specimen was loaded into the calorimeter vessel and sealed off with some helium gas for heat exchange (3 kPa at room temperature). The contribution of the helium gas to the total heat capacity was negligibly small. The mass of the sample used for calorimetry was 17.950 g (0.11640 mol). The contribution of the sample to the total heat capacity including that of the calorimeter vessel was larger than 70 per cent below 20 K. It decreased to 46 per cent at 100 K as temperature increased; however, it increased again to 59 per cent at 300 K.

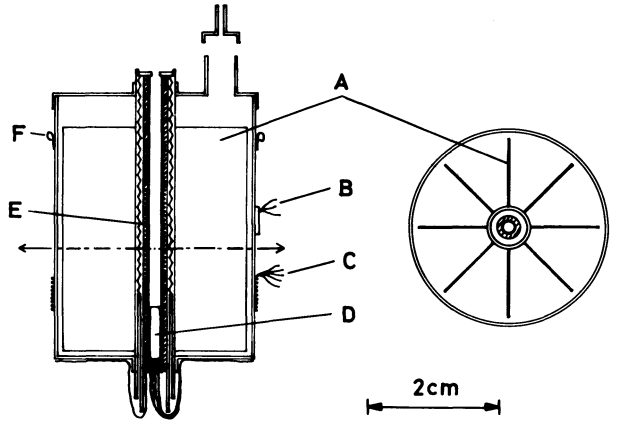

Fig. 1. Sectional plan of the new calorimeter vessel. A eight vanes to assist in thermal uniformity; B Au+0.07%Fe vs. Chromel-P thermocouples for adiabatic control (diameter 0.1 mm); C lead wires (diameter 0.1 mm); D germanium thermometer (model N2D, SI Inc.); E heater (KARMA, total 190 Ω); F hooks for hanging the vessel.

The apparatus for calorimetry has been described elsewhere.[59] A platinum resistance thermometer (model 8164, Leeds & Northrup Co.) and a germanium resistance thermometer (model CR-1000, CryoCal Inc.) were used. Their temperature scales are based on IPTS-68, helium gas thermometry, and the 1958 ^{4}He vapor pressure scale.[60,61]

The measurements using the ordinary calorimeter vessel failed to detect the lock-in transition at 16.8 K. To improve the sensitivity, a new calorimeter vessel was constructed with the following considerations; (1) use of a single, sensitive thermometer and one smooth temperature scale between 3 and 20 K, (2) amount of the sample that can be loaded and its packing in the vessel, and (3) attainment of better adiabatic conditions.

The sectional plan of the new calorimeter vessel (gold-plated copper) is shown in Fig. 1. In order to load a sufficient amount of the sample and to discard the use of helium gas for heat exchange in the vessel, the purified specimen was loaded and melted under a helium atmosphere (10^5 Pa) in the vessel before installation of the KARMA heater, the thermometer and thermocouples. The vessel was then evacuated and sealed off without addition of helium gas. The sample thus loaded weighed 24.957 g (0.16184 mol) in vacuum.

A germanium resistance thermometer (model N2D, SI Inc.) with commercial calibration was used. The calibration was based on the 1962 ^{3}He vapor pressure scale below 3.2 K and on the 1965 Provisional Helium Acoustic Scale between 2 and 20 K. The accuracy of the calibration was stated to be better than ±0.005 K below 5 K and better than ±0.01 K between 5 and 20 K. The 35 calibration points were fitted to the equation,

$$\ln(R/\Omega) = \sum_{i=1}^{9} A_i \{\ln(T/\mathrm{K})\}^{i-2}.$$

Since the main purpose of the measurements using this vessel was a search for the lock-in transition, an emphasis was placed on the smoothness of the temperature scale.

The Au+0.07%Fe vs. Chromel-P thermocouple (0.1 mm in diameter) was used for detecting the temperature difference between the vessel and the walls of adiabatic shield in order to improve the adiabatic conditions. The sensitivity of this thermocouple in the temperature region between 3 and 20 K is ten times as large as that of Chromel-P vs. Constantan thermocouple which has been attached to the ordinary vessel.

The new vessel thus constructed has an empty mass of 39.72 g with inside capacity of 25.06 cm^3. Other components of cryostat/calorimeter assembly were the same as used previously.[59] The sample contributed more than 85 per cent to the total heat capacity over the region studied (3—20 K) and the desired precision was attained.

Results and Discussion

Heat Capacities and Thermodynamic Functions.

The molar heat capacities measured with the ordinary (old) vessel are tabulated in Table 1 in the chronological order of measurement. The data obtained with the new vessel are shown as series 26 through 34 in Table 1. These were consistent with data obtained using the old vessel except for the lock-in

The ordinary calorimeter vessel was used in series 1 through 25, and the new vessel in series 26 through 34.

transition region. The temperature increment of each measurement may be deduced from the adjacent mean temperatures and it is sufficiently small to ignore the curvature correction in comparison with the experimental precision. After each energy input was over, thermal equilibrium within calorimeter vessel was attained in 1 min below 10 K, in 5 min at 50 K, and 15 min above 100 K in the measurements using the old calorimeter vessel as well as the new vessel. There was nothing anomalous concerning thermal equilibration in the transition regions contrary to the observation of Dworkin and Cailleau,[31] and in the lowest temperature region either, where the possibility of the "incommensurate glass" was suggested by Liu and Conradi.[41] Although our results are systematically larger by 0.4 per cent than the data reported by Huffman et al.,[62] the two sets of data are in satisfactory agreement within combined experimental uncertainties where comparison can be made.

Some molar thermodynamic functions derived from the measured data are tabulated in Table 2, where small contribution below 4 K was estimated by smooth extrapolation from the higher temperature side. The calorimetric standard entropy of biphenyl in the standard ideal gas state was calculated using the vapor pressure[63] and sublimation[64] data as summarized in Table 3.

Twist Transition. Generally, a small anomaly in a heat capacity curve can be made more prominent by plotting the equivalent Debye characteristic temperatures corresponding to the heat capacity values. It is shown in Fig. 2, where it is arbitrarily assumed that there are 9 degrees of freedom per molecule. A small, broad minimum is seen at about 40 K in Fig. 2. The normal portion of the heat capacity was evaluated by drawing a smooth interpolating curve as the lower and the higher temperature sides guide the eyes as shown by the solid curve in Fig. 2. This graph was used to separate the excess heat capacities that are shown in Fig. 3. The anomaly is very broad extending from 30 K to 47 K with a maximum at (40.4±0.2) K. The enthalpy and the entropy of transition were determined as (5.02±0.08) J·mol^{-1} and (0.129±0.003) J·K^{-1}·mol^{-1}, respectively, by graphical integration of the excess heat capacities.

Biphenyl is known to show the twist transition of

the displacive type associated with some soft-modes.[24-27] The properties of the twist transition in biphenyl are summarized in Table 4. The shape of the anomaly and the smallness of the entropy of transition are consistent with the higher-order, displacive nature of the twist transition. On the other hand, *p*-terphenyl and *p*-quaterphenyl crystals undergo the twist transition of the order-disorder type[21,65] at much higher temperatures (193.5 K[66] and 233.0 K,[55] respectively) compared with biphenyl. The heat capacity anomalies of biphenyl and *p*-quaterphenyl are both very broad but that of *p*-terphenyl is

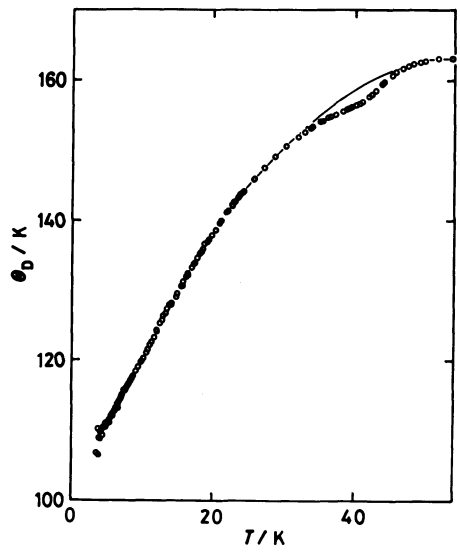

Fig. 2. Debye characteristic temperatures corresponding to the measured heat capacities of biphenyl assuming 9 degrees of freedom per molecule.

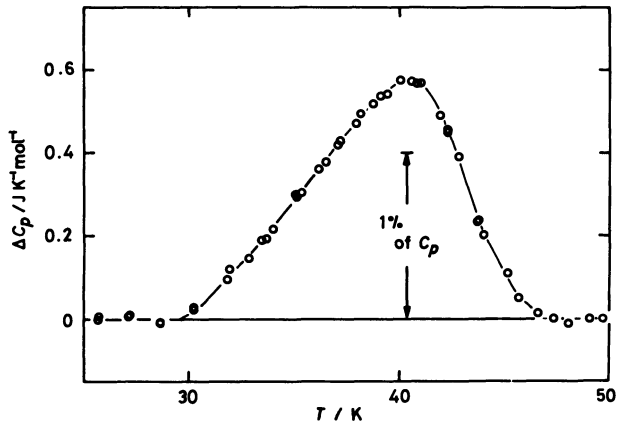

Fig. 3. Excess heat capacities due to the twist transition of biphenyl.

sharp.[66-68] The behavior of the three substances has been discussed[55] in terms of the molecular symmetry and the potentials for the intramolecular twisting modes.

Lock-in Transitions. No anomaly corresponding to the lock-in transition can be discerned in Fig. 2, which are the results obtained by using the old calorimeter vessel; the slight distortion at about 11 K is probably due to a failure in the germanium temperature scale.[51,52] The results of measurements using the new vessel are shown in Fig. 4 in the form of θ_D plot, where the data obtained in series 34 of measurements are shown. In this series, the temperature increment of each measurement was about 0.2 K. A broad anomaly is now clearly seen. The excess heat capacities were then separated by drawing the normal portion as shown by the solid

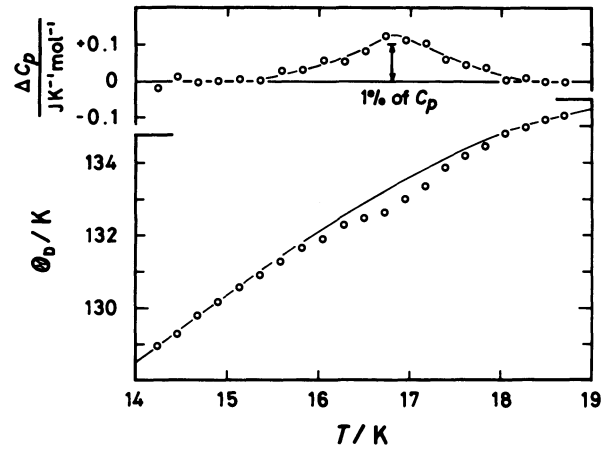

Fig. 4. Shape of the anomaly due to the lock-in transition of biphenyl (data of a typical run).

curve. The anomaly is broad extending from 15.3 K to 18.3 K with a maximum at (16.8±0.1) K, showing a large tail on the high temperature side. The enthalpy and the entropy of transition were determined as (0.15±0.02) J·mol^{-1} and (0.009±0.001) J·K^{-1}·mol^{-1}, respectively. This transition obviously corresponds to the reported lock-in transition by which the lattice becomes commensurate except for the b^* direction. The properties of the lock-in transition are also summarized in Table 4.

The shape of the anomaly and the smallness of the entropy of transition suggest that the lock-in transition is a higher-order transition. However, some evidences that the lock-in transition is of the first-order have been reported,[28,34,38] and the Landau's phenomenology[45,48] also predicts that it must be so. The present heat capacity results are smooth to within ±0.1 per cent at the top of the anomaly, 16.8 K, and there was no indication of latent heat. Similar discrepancy was reported in the case of K_2SeO_4.[69] There are two possible explanations of such a discrepancy on the notion that the transition is in fact of the first order. One is that the latent heat is so small that its effect is not reflected in the heat capacity runs. As one sees from the upper portion of Fig. 4, the anomalous part is smooth to within about 0.1 per cent; therefore the latent heat, if any, must be smaller than about 0.01 J·mol^{-1}. The other possibility, which is more likely, is that crystallites have a different lock-in transition temperature, i.e. the overall heat effects are smeared.

The large tail on the higher temperature side at the lock-in transition has been observed also in other substances,[69-71] and it may be accompanied with discommensuration mechanism proposed by McMillan.[72]

No further anomaly was found at lower temperatures in spite of a search for the other lock-in transition in the direction of the b^* axis. Any

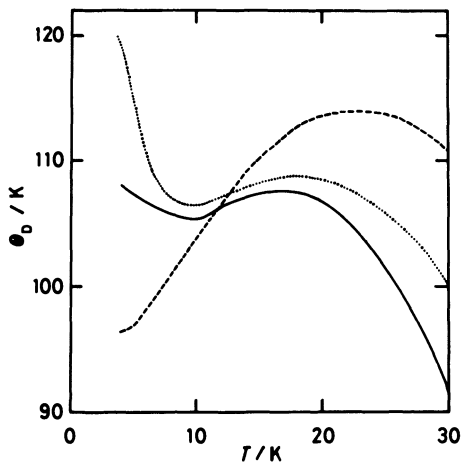

Fig. 5. Debye characteristic temperatures corresponding to the measured heat capacities of biphenyl (broken curve), *p*-terphenyl (solid curve) and 4,4′-difluorobiphenyl (dotted curve) assuming 6 degrees of freedom per molecule.

indication of freezing of some motional degrees of freedom was not observed either.[41] A simple interpretation of this fact is that the lock-in transition in the b^* direction could exist below 3 K, the lowest temperature reached in the present experiments. The other, more tempting interpretation is that the incommensurate phase could be stable down to the absolute zero. If the latter is the case, the crystal would represent a new type of thermodynamic stability. Determination of the spectroscopic entropy in the gas phase will give us a clue to this problem. It must be emphasized, however, the "residual entropy," if present, is expected to be very small taking the smallness of the entropy of lock-in transitions into account.

Crossover of Low Temperature Heat Capacities. The comparison of the low temperature heat capacities of biphenyl and *p*-terphenyl[53,66] is shown in Fig. 5 in terms of corresponding Debye characteristic temperatures assuming 6 degrees of freedom per molecule. Below about 20 K, the heat capacity of biphenyl decreases less steeply than that of *p*-terphenyl as the temperature decreases, and they cross each other at about 12 K. The crossover between biphenyl and *p*-quaterphenyl was also observed at about 6 K.[55]

Since biphenyl and *p*-terphenyl have similar crystal structures and their intermolecular interactions are also similar, one would expect that the relative magnitude of their heat capacities is determined primarily by the relative molecular mass, i.e. the heavier molecule should show a larger heat capacity at a low temperature, where only low-lying lattice modes are excited. Therefore, there must be some motional mode or modes in biphenyl for which the force constant is much smaller than for the corresponding mode(s) in *p*-terphenyl. The twisting mode about the central C–C bond in biphenyl seems to be the candidate of such a mode because (1) it is the only conceivable intramolecular mode that is susceptible to the crystal field, (2) the coupling of the twisting motion with the lattice vibration has been pointed out in many experimental[73–75] and theoretical[46,73,74,76,77] studies on the lattice vibrations of biphenyl crystal, and (3) the twisted conformation in *p*-terphenyl has been substantiated[20,23] below the order-disorder transition[21,65] in contrast with biphenyl. Thus, an attempt will be made to interpret the observed crossover by a simple model calculation of lattice vibration spectra for biphenyl and *p*-terphenyl crystals.

For biphenyl the average crystal structure at 22 K[15] was used, ignoring the incommensurability which will play an important role only in the very low temperature region where the contribution of phason becomes dominant.[78] The structure of *p*-terphenyl at 113 K[20] was corrected for thermal expansion down to 22 K by a linear extrapolation from the room temperature data.[21]

The intermolecular interaction was expressed by the sum of atom–atom pair potentials of Buckingham type, in which the parameters were taken from the literature.[79] The interactions were summed over molecules within a radius of 1 nm. Phenyl rings were assumed to be rigid.

The Lagrangian L of the system was written in terms of translational (superscript; t), rotational (r), and twisting (τ) coordinates in the harmonic approximation as follows:[80]

$$L = K - \Phi,$$

$$K = \frac{1}{2}\sum_{l}\sum_{\kappa}\sum_{\alpha} m\,[\dot{u}^{t}_{\alpha}(l\kappa)]^2 + \frac{1}{2}\sum_{l}\sum_{k}\sum_{\alpha,\beta} I_{\alpha\beta}(\kappa)\,\dot{u}^{r}_{\alpha}(l\kappa)\,\dot{u}^{r}_{\beta}(l\kappa) + \frac{1}{2}\sum_{l}\sum_{\kappa} I_{\tau}\,[\dot{u}^{\tau}(l\kappa)]^2,$$

$$\Phi = \Phi_0 + \frac{1}{2}\sum_{l,l'}\sum_{\kappa,\kappa'}\sum_{\alpha,\beta} \phi^{tt}_{\alpha\beta}(l\kappa; l'\kappa')\,u^{t}_{\alpha}(l\kappa)\,u^{t}_{\beta}(l'\kappa') + \frac{1}{2}\sum_{l,l'}\sum_{\kappa,\kappa'}\sum_{\alpha,\beta} \phi^{tr}_{\alpha\beta}(l\kappa; l'\kappa')\,u^{t}_{\alpha}(l\kappa)\,u^{r}_{\beta}(l'\kappa') + \frac{1}{2}\sum_{l,l'}\sum_{\kappa,\kappa'}\sum_{\alpha,\beta} \phi^{rt}_{\alpha\beta}(l\kappa; l'\kappa')\,u^{r}_{\alpha}(l\kappa)\,u^{t}_{\beta}(l'\kappa') + \frac{1}{2}\sum_{l,l'}\sum_{\kappa,\kappa'}\sum_{\alpha,\beta} \phi^{rr}_{\alpha\beta}(l\kappa; l'\kappa')\,u^{r}_{\alpha}(l\kappa)\,u^{r}_{\beta}(l'\kappa')$$

$$+\frac{1}{2}\sum_{l,l'}\sum_{\kappa,\kappa'}\sum_{\alpha}\phi_{\alpha}^{rr}(l\kappa;l'\kappa')u_{\alpha}^{r}(l\kappa)u^{\tau}(l'\kappa')$$

$$+\frac{1}{2}\sum_{l,l'}\sum_{\kappa,\kappa'}\sum_{\alpha}\phi_{\alpha}^{\tau r}(l\kappa;l'\kappa')u^{\tau}(l\kappa)u_{\alpha}^{r}(l'\kappa')$$

$$+\frac{1}{2}\sum_{l,l'}\sum_{\kappa,\kappa'}\sum_{\alpha}\phi_{\alpha}^{r\tau}(l\kappa;l'\kappa')u_{\alpha}^{r}(l\kappa)u^{\tau}(l'\kappa')$$

$$+\frac{1}{2}\sum_{l,l'}\sum_{\kappa,\kappa'}\sum_{\alpha}\phi_{\alpha}^{\tau r}(l\kappa;l'\kappa')u^{\tau}(l\kappa)u_{\alpha}^{r}(l'\kappa')$$

$$+\frac{1}{2}\sum_{l,l'}\sum_{\kappa,\kappa'}\phi^{\tau\tau}(l\kappa;l'\kappa')u^{\tau}(l\kappa)u^{\tau}(l'\kappa')$$

$$\phi_{\alpha\beta}^{ab}(l\kappa;l'\kappa')=\frac{\partial^2\Phi}{\partial u_{\alpha}^{a}(l\kappa)\,\partial u_{\beta}^{b}(l'\kappa')},$$

where u is the displacement from an equilibrium position and α and β mean x, y, or z permutatively. Thus, $u_{\alpha}(l\kappa)$ denotes the displacement of the κ-th molecule in the l-th cell in the direction α. The equations of motion derived from the Lagrangian were numerically solved for 512 points picked up uniformly in the first Brillouin zone.

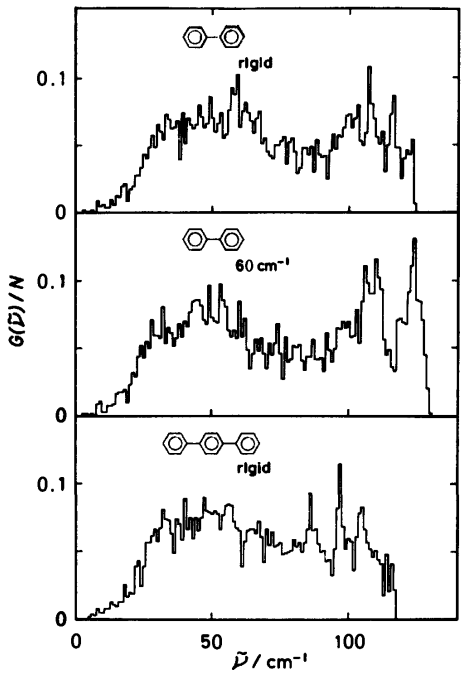

Fig. 6. Calculated density of states for rigid biphenyl, flexible biphenyl and rigid p-terphenyl.

The results of calculation are shown in Figs. 6 and 7. On the assumption of the rigid body, where there are no terms involving the twisting coordinates in the Lagrangian, p-terphenyl shows larger heat capacities than biphenyl at all the temperatures, as expected from the relative molecular mass. However, when one introduces flexibility into the biphenyl molecule with regard to the twisting of phenyl rings (a force constant corresponding to 60 cm^{-1} as the intramolecular contribution), biphenyl comes to show higher density of states in the low frequency region. On the other hand, p-terphenyl has higher density between 25 and 45 cm^{-1} due to its larger mass. Figure 7 shows the Debye temperature curve calculated from the spectra of Fig. 6 and the twisting flexibility is reflected in the crossover in the heat capacities at about 12 K. Now, we conclude qualitatively that the crossover can be attributed to the low-frequency twisting mode contribution of phenyl rings in biphenyl.

The same interpretation applies to the comparison between biphenyl and 4,4′-difluorobiphenyl which also has an analogous crystal structure at room temperature.[54,81–83]

The behavior of the Debye temperature of 4,4′-difluorobiphenyl[56] assuming 6 degrees of freedom per molecule is also shown in Fig. 5. The heat capacity of biphenyl is larger than that of 4,4′-difluorobiphenyl below about 13 K in spite of the smaller mass of the former molecule.[56] Thus, it is clear that the heat capacities of biphenyl crystal are much larger at low temperatures than those of the homologous molecules and derivatives. Therefore, the central C–C bond of biphenyl is extremely soft with regard to the internal rotation: The competing effect of the intra- and intermolecular interactions is very subtle and it plays

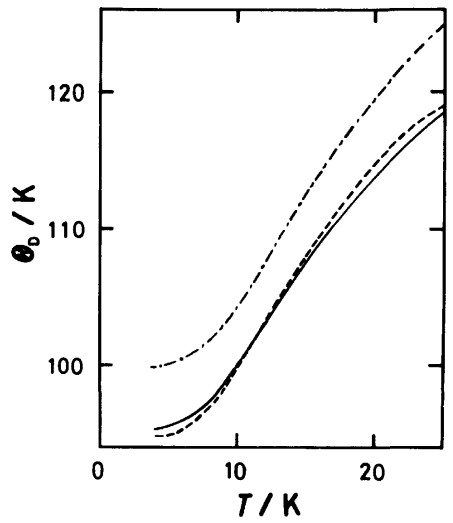

Fig. 7. Calculated Debye characteristic temperatures of rigid p-terphenyl(solid curve), flexible biphenyl (broken curve) and rigid biphenyl (dot-dash curve), assuming 6 degrees of freedom per molecule.

a critical role in the incommensurate structure of the crystal in such a way that the twisting mode in strongly coupled to the lattice vibration to such as extent that is not realized in similar other molecules.

Spectrophotometric Study of Complexation Equilibria between Lanthanoids(III) and 2-(5-Bromo-2-pyridylazo)-5-(*N*-propyl-3-sulfopropylamino)phenol

Emiko Ohyoshi
Yatsushiro National College of Technology, Hirayamashinmachi 2627, Yatsushiro, 866
(Received May 6, 1987)

Complex formation (1:1) between lanthanoids(III) and 2-(5-bromo-2-pyridylazo)-5-(*N*-propyl-3-sulfopropylamino)phenol (5-Br-PAPS, HL) has been studied by spectrophotometry at 25 °C and at I=0.1 ($NaNO_3$). The protonated complex MHL is found to exist in equilibrium with the normal complex ML at pH 5—6. The formation constants K_{ML} and K_{MHL} are obtained by a graphical analysis. The K_{ML} values uniformly increase with increasing atomic number except for those in the Gd-Ho region where a distinct decrease is observed. However, there is little variation in the K_{MHL} values with atomic number. A linear relation holds well between log K_{ML} values of 5-Br-PAPS and 4-(2-pyridylazo)resorcinol (PAR) complexes for the elements up to Eu(III), the intercept of which reflects the difference in the basicity of the oxygen atom ortho to the azo group between the two ligands. This is not the case for log K_{MHL} of the two systems.

Recently, a highly sensitive reagent 2-(5-bromo-2-pyridylazo)-5-(*N*-propyl-3-sulfopropylamino)phenol (5-Br-PAPS, HL) has been developed and shown to be useful for spectrophotometric determination of some transition metals.[1-3] It has the same reacting group as 4-(2-pyridylazo)resorcinol (PAR) but has a different substituent in the para position to the azo group. Shibata et al.[4] suggested that the dialkylamino group which is a strongly electron-donating group existing in the para position to the azo group may play an important role in the high molar absorptivity and stability of the metal complex. However, very few studies on the stability of the metal complex with this type of reagent have been reported.

In this paper, the complexation of 5-Br-PAPS with lanthanoids(III) is studied spectrophotometrically and the results are compared with those of the PAR complexes.[5]

Experimental

Materials. All chemicals used were of G. R. grade. 5-Br-PAPS was obtained from Dojindo Chemical Co., and its purity was checked spectrophotometrically by using the standard solution of Zn(II). The molar absorptivity of ZnL_2 (L=5-Br-PAPS) at 553 nm is 1.28×10^5 M^{-1} cm^{-1} (1 M=1 mol dm^{-3}) which agreed with the reported value of 1.3×10^5 M^{-1} cm^{-1}.[1] A weighed quantity of 5-Br-PAPS was dissolved in distilled water to prepare the stock solution of 1.0×10^{-2} M. The lanthanoid(III) nitrate solutions were prepared by dissolving the oxides or nitrates in nitric acid and were standardized by EDTA titration. 2-Morpholinoethanesulfonic acid (MES, Good's buffer reagent) and sodium nitrate were used to maintain the pH at 4.8—6.1 and the ionic strength at 0.1, respectively.

Procedure. The metal solution was added in small aliquots, 50 μl each, using a microliter pipet to a 10 ml of the buffered solution of 5-Br-PAPS ($1.5—2.0\times10^{-5}$ M), to give concentrations of 10^{-4}—3×10^{-3} M. Before and after the addition of the metal for each 50 μl, the absorbance at the peak of 5-Br-PAPS (446 nm) was measured by using a Shimadzu UV-260 spectrophotometer. No precipitation occurred under these experimental conditions.

Results and Discussion

Absorption Spectra of the Reagent (HL^-) and the Complexes. The absorption spectra of the reagent were studied at various pH adjusted with a dilute nitric acid or sodium hydroxide solution. Three species of the reagent, H_2L (λ_{max}=466 nm, pH<2.5), HL^- (λ_{max}=446 nm, pH 4—9), and L^{2-} (λ_{max}=512 nm, pH>11) are involved in its acid-base equilibria. The protonation constants of HL^- and L^{2-}, $K^H_{H_2L}=[H_2L]/([HL^-][H^+])$ and $K^H_{HL}=[HL^-]/([L^{2-}][H^+])$, were determined by the method of Schwarzenbach.[6] The values of 2.78±0.05 and 10.56±0.03 were obtained for log $K^H_{H_2L}$ and log K^H_{HL}, respectively at 25 °C and I=0.1. According to these values and the known acidity constants of analogous azo dyes,[4] $K^H_{H_2L}$ and K^H_{HL} refer to the protonation of the amino group and of the phenolic oxygen, respectively.

Under the conditions where the metal is in large excess over the ligand, the absorption spectra of the complexes had two maxima at 533 and 566 nm for all the lanthanoids(III). Their apparent molar absorptivities which were different for different lanthanoids(III) at constant pH increased with increasing pH and reached the limiting values of $4.6—5.0\times10^4$ M^{-1} cm^{-1} at 533 nm and of $5.5—6.0\times10^4$ M^{-1} cm^{-1} at 566 nm. The reagent 5-Br-PAPS is shown to be almost twice as sensitive as PAR[5] for the determination of lanthanoids(III).

Determination of the Complex Formation Constant. The formation of the 1:1 complex, ML, has been studied by measuring the absorbance of the ligand, L, in the absence (A_o) and the presence (A) of the metal, M, under conditions where $C_M \gg C_L$ (C_M and C_L are the total concentrations of M and L) and pH=constant.[7] The complex formation constant so obtained may be regarded as the conditional

formation constant, $K_{ML'}$, as defined by Eq. 1, by considering any side reactions.

$$K_{ML'} = [ML']/([M'][L']) \quad (1)$$

where [ML'], [M'], and [L'] represent all forms of the metal complexes, the uncomplexed metal and the uncomplexed ligand, respectively. The expressions for C_L and A are then given as follows:

$$C_L = [ML'] + [L'] \quad (2)$$

$$A = \varepsilon_{ML'}[ML'] + \varepsilon_{L'}[L'] \quad (3)$$

where $\varepsilon_{ML'}$ and $\varepsilon_{L'}$ are the apparent molar absorptivity of ML' and L', respectively. Combining Eqs. 1, 2, and 3, and substituting A_o for $\varepsilon_{L'}C_L$ and C_M for [M] (since $C_M \gg C_L$) in the resulting equation, we obtain

$$K_{ML'} - \frac{\varepsilon_{ML'}K_{ML'}}{\varepsilon_{L'}}\frac{A_o}{A} = (A_o/A - 1)/C_M. \quad (4)$$

From Eq. 4, a linear relation between $(A_o/A-1)/C_M$ and A_o/A should be obtained at a constant pH, the intercept of which yields the $K_{ML'}$ value. This value can be related to the formation constant K_{ML} by means of the side reaction coefficient, α, viz.

$$K_{ML'} = K_{ML}\alpha_{ML}/(\alpha_M\alpha_L) \quad (5)$$

where α_{ML}=[ML']/[ML], α_M=[M']/[M], and α_L=[L']/[L].

From the measured absorbance decreases at the peak of 5-Br-PAPS (446 nm) with increasing metal concentrations at a constant pH, we plotted the relation expressed by Eq. 4. Figure 1 shows the plots obtained at pH 5.51 for different lanthanoids(III). This linear relation was shown to be independent of C_L. The experimental data showed no detectable difference in the plots for Yb(III) and Lu(III) (line 1), and for Tb(III) through Ho(III) (line 6), respectively. Similar plots were obtained at different pH values as exemplified for the Eu(III)-5-Br-PAPS system in Fig. 2. As seen in Figs. 1 and 2, the $K_{ML'}$ values given as the intercept increase with either increasing atomic number (though a discontinuity is shown in the Gd–Ho region) or pH. From the pH dependency of $K_{ML'}$, the side reactions are considered to be the protonation of L and the formation of the MHL complex. The α coefficients for these reactions, α_L and α_{ML} are given by

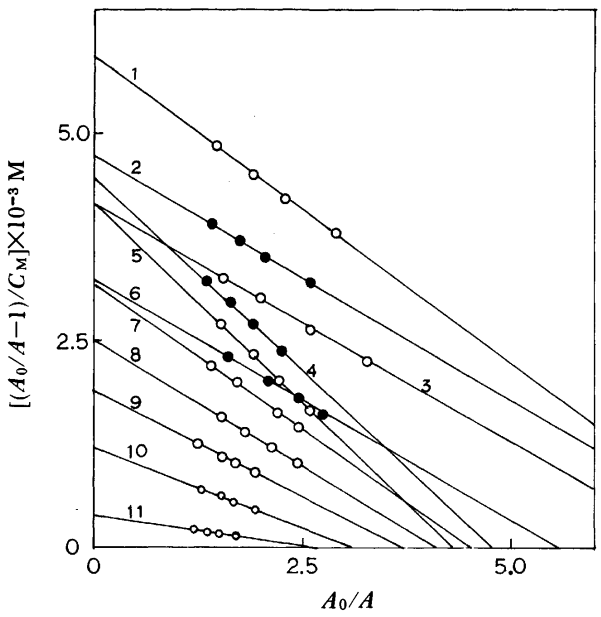

Fig. 1. Plots according to Eq. 4 at a constant pH of 5.51 for the system of 5-Br-PAPS and lanthanoids-(III). 1) Lu, Tb; 2) Tm; 3) Er; 4) Eu; 5) Sm; 6) Ho, Dy, Tb; 7) Gd; 8) Nd; 9) Pr; 10) Ce; and 11) La.

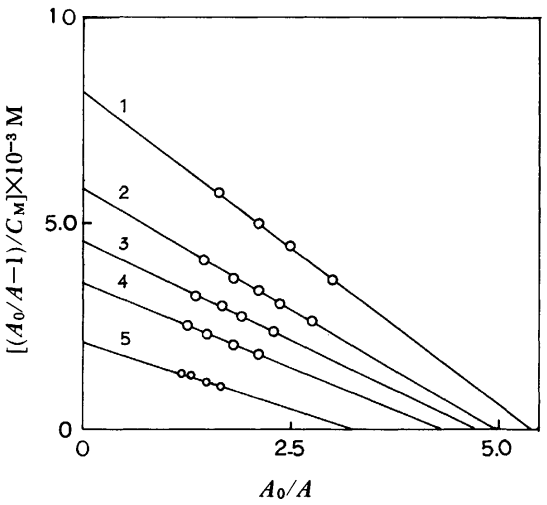

Fig. 2. Plots according to Eq. 4 at different pH values for the Eu(III)-5-Br-PAPS system. pH: 1) 5.81, 2) 5.65, 3) 5.51, 4) 5.40, and 5) 5.12.

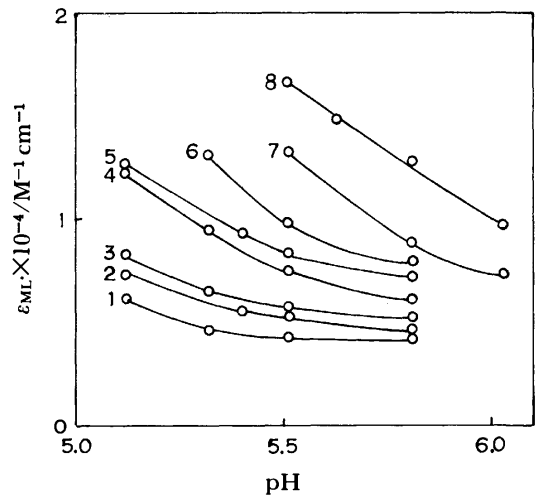

Fig. 3. Plots of the apparent molar absorptivity of ML', $\varepsilon_{ML'}$, at 446 nm vs. pH for the system of 5-Br-PAPS and lanthanoids(III). 1) Yb, 2) Tm, 3) Er, 4) Ho, 5) Eu, 6) Pr, 7) Ce, and 8) La.

$$\alpha_L = [L']/[L] = ([L] + [HL])/[L] = 1 + K^H_{HL}[H] \quad (6)$$

$$\alpha_{ML'} = [ML']/[ML] = ([ML] + [MHL])/[ML] = 1 + K^H_{MLH}[H] \quad (7)$$

where K^H_{HL}=[HL]/([H][L]) and K^H_{MLH}=[MHL]/([ML][H]). The relation between $K_{ML'}$ and α_L (Eqs. 5 and 6) coincides with the observed dependence of $K_{ML'}$ on pH, confirming that the former side reaction occurs. However, no such confirmation is given for the latter. This was found to occur by studying the dependence of the apparent molar absorptivity of ML', $\varepsilon_{ML'}$ on pH (Fig. 3). To calculate the $\varepsilon_{ML'}$ values we used the intercept of the A_0/A axis of the plot of Eq. 4 which equals $\varepsilon_{L'}/\varepsilon_{ML'}$. With increasing pH the $\varepsilon_{ML'}$ values for different lanthanoids initially decrease showing the presence of MHL and ML, and tend to reach the limiting values (ε_{ML}) different for different lanthanoids where only one component, ML exists. In the acidic media used in this study there are no hydroxo complexes.[8] No complexes with buffer ions were also found by studying the effect of buffer concentrations on the $K_{ML'}$ values. Thus,

$$\alpha_M \simeq 1. \quad (8)$$

Substituting Eqs. 6, 7, and 8 into Eq. 5, we obtain

$$K_{ML'}(1 + K^H_{HL}[H]) = K_{ML}(1 + K^H_{MLH}[H]) \quad (9)$$

With the formation constant of MHL, K_{MHL}=[MHL]/[M][HL])=$K_{ML}K^H_{MLH}/K^H_{HL}$, Eq. 9 is rewritten in the form

$$K_{ML'}(1 + K^H_{HL}[H]) = K_{ML} + K_{MHL}K^H_{HL}[H] \quad (10)$$

According to Eq. 10, a plot of the left-hand side of Eq. 10 against [H] by using values of $K_{ML'}$ obtained at constant pH yields K_{ML} as the intercept and K_{MHL} as the slope/K^H_{HL} ratio.

The results of the plots of Eq. 10 are linear with intercepts (Fig. 4), indicating the presence of both MHL and ML complexes in this pH range for all the lanthanoids(III). The formation constants K_{MHL} and K_{ML} calculated from the slope and the intercept of the plots in Fig. 4 by applying the least squares method are listed in Table 1 together with the corresponding values of the PAR complexes for comparison. It is noted that the difference in K_{ML} is greater than that in K_{MHL} for different elements. Comparison of the 5-Br-PAPS and PAR systems shows both the MHL and the ML complexes of 5-Br-PAPS to be less stable than those of PAR.

For the ML complexes, 5-Br-PAPS and PAR show a similar coordination trend to the lanthanoids(III) except for several elements heavier than Gd(III). It is seen from Fig. 5 that for the elements up to Eu(III) the

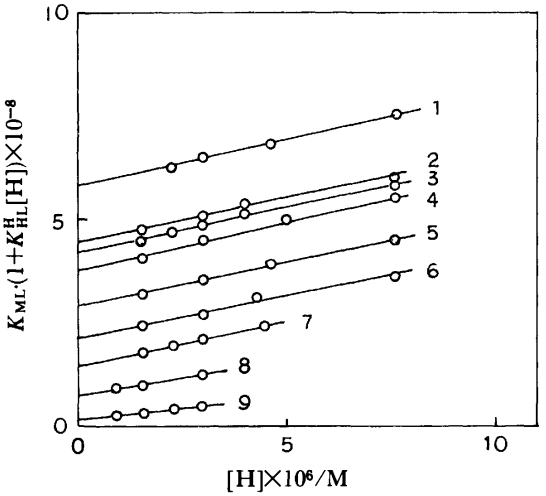

Fig. 4. Plots according to Eq. 10 for the system of 5-Br-PAPS and lanthanoids(III). 1) Lu, Yb; 2) Tm; 3) Eu; 4) Er, Sm; 5) Ho, Dy, Tb, Gd; 6) Nd; 7) Pr; 8) Ce; and 9) La.

Table 1. Formation Constants, K_{MHL} and K_{ML}, for 5-Br-PAPS and PAR Complexes of Lanthanoids(III) I=0.1 ($NaNO_3$), 25 °C

Element	5-Br-PAPS		PAR[5,7]	
	log K_{MHL}	log K_{ML}	log K_{MHL}	log K_{ML}
La	2.38	7.22	3.18	8.91
Ce	2.60	7.90	3.78	9.61
Pr	2.77	8.16	3.95	9.78
Nd	2.74	8.33	4.07	10.02
Sm	2.80	8.58	4.28	10.25
Eu	2.76	8.63	4.28	10.25
Gd	2.79	8.46	4.28	10.25
Tb	2.79	8.46	4.28	10.25
Dy	2.79	8.46	4.29	10.36
Ho	2.79	8.46	4.29	10.47
Er	2.80	8.58	4.31	10.52
Tm	2.76	8.65	4.34	10.57
Yb	2.79	8.77	4.39	10.70
Lu	2.79	8.77	4.39	10.70

The relative errors of K_{MHL} and K_{ML} are 8—12% and 4—8%, respectively.

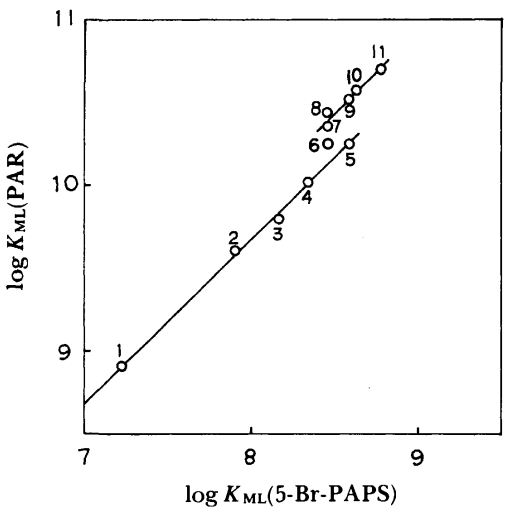

Fig. 5. Relationship between log K_{ML} values of 5-Br-PAPS and PAR complexes with lanthanoids(III). 1) La; 2) Ce; 3) Pr; 4) Nd; 5) Sm, Eu; 6) Gd, Tb; 7) Dy; 8) Ho; 9) Er; 10) Tm; and 11) Yb, Lu.

linear relationship holds well between log K_{ML} values of 5-Br-PAPS and PAR complexes with the slope of unity and the intercept of 1.7 which reflects the difference in the basicity of the ortho-oxygen atom to the azo group between the two ligands (log K^{H}_{HL}=12.30 for PAR[9] and log K^{H}_{HL}=10.56 for 5-Br-PAPS). This is not the case for log K_{MHL} of the two systems. A recent study,[10] showed that such a linear relation has been obtained between log K_{MHL} as well as log K_{ML} for the lanthanoid(III) complexes with a pair of ligands, PAR and 4-(2-thiazolylazo)resorcinol (TAR), both of which have a *p*- and an *o*-hydroxyl group. These facts suggest that the effect of the difference in character between 5-Br-PAPS and PAR on the formation of MHL is much larger than that on the formation of ML. These two ligands have a different functional group in the para position to the azo group, the dipropylamino group (5-Br-PAPS) or the hydroxyl group (PAR), and thus have one dissociable proton (5-Br-PAPS) or two (PAR), respectively.

When the complexation of PAR occurs at pH values lower than either values of log $K^{H}_{H_2L}$=5.50 (para) or log K^{H}_{HL}=12.30 (ortho),[9] it is assumed that protons are released preferentially from the *o*-hydroxyl group. This means that PAR reacts in the thermodynamically unfavored form, *HL$^-$ where *H denotes the para proton for which the dissociation constant is not known. Corcini et al.[11] proposed to use $1/K^{H}_{HL}$ (ortho) as an approximation. On the other hand, 5-Br-PAPS used in this study has only the proton (ortho) dissociable, existing as HL in the pH range studied. The lanthanoid ion thus reacts with HL to form the MHL complex in which the ortho proton does not dissociate. This type of coordination has been reported for the complexes of Be(II),[12] Cu(II),[13] and lanthanoids(III)[14] with 5-sulfosalicylic acid. Hence, the phenolic oxygen would weakly bond either to the proton or to the metal ion. This is consistent with the observation that the absorption bands due to the MHL complex overlap each of the peaks assigned to the HL (proton–ortho-oxygen bond) species and the ML (metal–ortho-oxygen bond) species. This was found by studying changes in the apparent molar absorptivity, $\varepsilon_{ML'}$ at each peak with pH, i.e., $\varepsilon_{ML'}$ at 446 nm (HL) decreased (Fig. 3) but those at 533 and 566 nm (ML) increased with increasing pH. Similarly, the absorption spectra of the PAR complexes of this type (MHL) showed the two maxima at 410 and 495 nm each of which is very close to that of HL at 415 nm and to that of ML at 505 nm.[5] From these facts, the structure of the MHL complexes of the PAR system might be similar to that of the 5-Br-PAPS system, i.e., PAR normally ionizes the para proton first on complexation. It may be reasonable to infer that the para phenolate ion O$^-$ enhances the negative charge on the azo nitrogen; this would make the stability of MHL for the PAR complexes larger and more different from metal to metal than that for the 5-Br-PAPS complexes.

A Quantitative Scale of the Spectrochemical Series for the Mixed Ligand Complexes of d^6 Metals

(the late) Yoichi SHIMURA
Department of Chemistry, Faculty of Science, Osaka University, Toyonaka, Osaka 560
(Received June 25, 1987)

Quantitative scale of a new parameter d has been proposed for the spectrochemical series of ligands in the mixed ligand complexes of d^6 metals, which enables us to predict the positions of low energy d-d absorption bands of a d^6 complex. Introduction of a new reduction parameter α has improved the prediction of the d-d bands of mixed cyano complexes of cobalt(III), mixed halogeno complexes of rhodium(III), iridium-(III), and platinum(IV), and also several mixed carbonyl complexes of low-valent d^6 metals.

Some quantitative scales were presented for the spectrochemical series of ligands,[1] i.e., ligand field splitting energy Δ(=10 Dq) of a given metal ion, or in an exact sense f(ligand) value of Jørgensen's formula $\Delta = f(\text{ligand}) \cdot g(\text{central ion})$,[2] but these are limited for non-mixed ligand complexes only. On the other hand, to predict the position of d-d absorption band of a mixed complex, Yamatera's δ parameters[3] have frequently been used, but they are also unsatisfactory because it has been reported that the Yamatera rule was not exactly fit for the mixed cyano complexes of cobalt(III)[4] and the mixed halogeno complexes of rhodium(III) or iridium(III).[5] In the present paper, a new quantitative scale will be proposed for the spectrochemical series of ligands in the mixed complexes of d^6 metals, which enables us to predict the energy values of long wavelength d-d absorption bands of almost all the d^6 complexes.

Results and Discussion

Spectrochemical Series of Ligands. The energies of three components of the first spin-allowed d-d absorption band of an octahedral complex $[ML_{(1)}L_{(2)}L_{(3)}L_{(4)}L_{(5)}L_{(6)}]$ (Fig. 1) may be written:

$$\begin{aligned} \sigma_{xy} &= \alpha(d_2 + d_3 + d_4 + d_5)/4, \\ \sigma_{yz} &= \alpha(d_1 + d_2 + d_4 + d_6)/4, \\ \sigma_{zx} &= \alpha(d_1 + d_3 + d_5 + d_6)/4, \end{aligned} \quad (1)$$

where d_n (n=1,2,...6) is a parameter of the ligand $L_{(n)}$ previously defined[6] as δ and α a reduction parameter. Then it becomes,

$$\begin{aligned} \sigma &= (\sigma_{xy} + \sigma_{yz} + \sigma_{zx})/3 \\ &= \alpha(d_1 + d_2 + d_3 + d_4 + d_5 + d_6)/6, \end{aligned} \quad (2)$$

where σ is a mean energy of the first d-d absorption band. When α=1.00, Eqs. 1 and 2 reduce to the

a) The value in sequare brackets is for the complexes of *trans*-[M a_4b_2] and -[M a_2b_4] types. b) As to the carbonyl complexes $[M(CO)_xX_{6-x}]$(X=N, O, Cl^-, Br^-, or I^-), α=0.86 for M=V(−I), 0.87 Cr(0), 0.94 Mo(0), 0.90 W(0), 0.95 Mn(I), 0.91 Re(I), 0.93 Ru(II), and 0.90 Os(II). c) An element symbol underlined shows a ligating atom.

Yamatera rule[3,6] and the rule of average environment,[7] respectively. Most of the N,O-mixed[6] and all of the non-mixed complexes of low-spin d^6 type obey Eqs. 1 and 2 with α=1.00, but the other mixed complexes, for example the mixed cyano complexes seem to have α values smaller than 1.00 as shown in Table 1, where α values are estimated empirically from a compilation of absorption data of a variety of d^6 complexes.

It has been found that only three different α values are sufficient for prediction of the first d-d band energies of a series of mixed complexes [M a_xb_{6-x}] (x=1—5) except for *mer*-[M a_3b_3]: one is for [M a_5b], *cis*-[M a_4b_2], *cis*-[M a_2b_4], and [M ab_5], amounting to 1.00−β ($0 \leqq \beta \leqq 0.4$), and the second is for *trans*-[M a_4b_2] and -[M a_2b_4], amounting to 1.00−2β, and the third is for *fac*-[M a_3b_3], remaining to be 1.00. This fact means that the reduction parameter α is related to the order of lowering (from O_h to D_{4h}) of the holohedrized symmetry[8] of a given complex. It is remarkable that all tris-chelate complexes have α=1.00 regardless of the ligating atoms.

The d value (in 10^3 cm^{-1}) of each ligand for different complexes of a given metal can be evaluated from the observed data of mean σ or its components σ_{xy}, σ_{yz}, or σ_{zx} using Eqs. 1 and 2. Of course the position of the first d-d band of a [M a_6]-type is equal to the d value of the ligand a for that metal, because α=1.00 in this case. For a bidentate ligand A~B, the d value can be defined as,

$$d\langle \mathrm{A}\sim\mathrm{B}\rangle^n = (d\langle -\mathrm{A}\rangle^n + d\langle -\mathrm{B}\rangle^n)/2, \quad (3)$$

where n means chelate ring size, for example n=7 for $d\langle NH_2CH_2CH_2CH_2CH_2NH_2\rangle^7 = d\langle -CH_2NH_2\rangle^7$, and n=6 for $d\langle\beta\text{-ala}\rangle^6 = d\langle NH_2CH_2CH_2CO_2^-\rangle^6 = (d\langle -CH_2NH_2\rangle^6 + d\langle -CO_2^-\rangle^6)/2$. Besides the d values for different unidentate ligands, those of such chelate ends are also arranged in Table 2.

Table 2 gives d_{Co} values obtained for 100 ligands (or chelate ends) of cobalt(III) complexes, ranging from the highest value 35.0 for CO to the lowest value 7.0 for $\langle -CH_2Se^-\rangle^5$, which is selenolato end of a bidentate ligand forming 5-membered chelate ring. In Table 3, σ_{obs} of the typical mixed cobalt(III) complexes are compared to σ_{calc} obtained from the d values in Table 2 by applying Eq. 1 or 2. The deviation Δ is generally within ±2%.

Spectrochemical Series of Metals. For the metals (M) other than cobalt(III), a series of d_M can be obtained from the existing data. A plot of d_M versus d_{Co} makes a straight line passing the origin (Fig. 2):

$$d_M = m d_{Co}, \quad (4)$$

where m is the spectrochemical parameter for the metal M. The m values obtained from Eq. 4 are tabulated in Table 4. The m value can be correlated to the Jørgensen's g (central ion) value[9] (Fig. 3), while d_{Co} (and d_M also) to the Jørgensen's f (ligand) value[9] (Fig. 4).

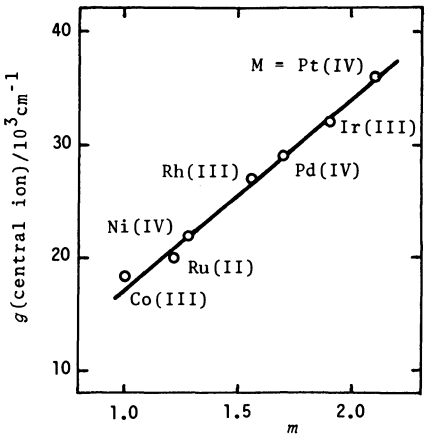

Fig. 3. A plot of m versus g (central ion).

In Table 5, σ_{obs} of the typical d^6 complexes are compared with σ_{calc} obtained from the d_{Co} and m values. The deviation Δ is generally within ±3%.

S- or Se-Ligands. As is seen in Table 2, the sulfur-donor (or selenium-donor) ligands distribute widely along the spectrochemical series, where the thiolato (or selenolato) ligands being on the weakest end. Houlding et al.[34] pointed out a striking characteristic of such thiolato (or selenolato) complexes of cobalt(III), i.e., that these have an extra shoulder band on the low-energy side of the first d-d absorption band. In Table 6, the splitting of the first d-d band of the thiolato (or selenolato), and the related S- (or Se-) ligands such as SCN^- and SSO_3^{2-} is interpreted by an assumption of anisotropy of the antibonding contribu-

tion of S (or Se) donor atoms, and then the $d_{(S)}$ parameter is written as:

$$d_{(S)} = (d_{(S)//} + d_{(S)\perp})/2. \quad (5)$$

Thus, in a CoN_5S-type complex containing the thiolato-like S atom, the three σ components are expressed by $\alpha d_{(N)}$, $\alpha(3d_{(N)}+d_{(S)//})/4$, and $\alpha(3d_{(N)}+d_{(S)\perp})/4$. If the S atom is no more anisotropic, the latter two components combine to give a degenerate one $\alpha(3d_{(N)}+d_{(S)})/4$. In the case of complexes Nos. 35—37, the component at longer wavelength is observed as a shoulder, and the next peak observed is an overlap of the two components at shorter wavelength.

Mixed Cyano Complexes. An empirical rule of Shimura,[39,40] which states that, for the first d-d bands of cis and trans isomers of [M a_4b_2] of a d^6 metal M, $\Delta\sigma=\sigma(cis)-\sigma(trans)<0$ if b is ahead of a in the spectrochemical series, while $\Delta\sigma>0$ if b is behind a, suffers from a few exceptions. An example is the isomers of $[Co(CN)_2(NH_3)_4]^+$ which show $\Delta\sigma_{obs}=+1.4$. By the present introduction of reduction parameter α, however, most of the exceptions can be explained reasonably because the different α values are assigned to the geometrical isomers (Table 7).

The introduction of the parameter α has also improved the predicted values of σ for a variety of mixed cyano complexes, which were heretofore regarded as serious exception of the Yamatera rule[4] (see complexes Nos. 2, 9, 19, and 38—43 in Tables 3, 5, and 7). Fujinami et al.[41] proposed an angular overlap treatment taking into account of (i) mixing of 3d orbitals with 4s and 4p by the lowering of symmetry in the mixed complexes and (ii) a configuration interaction between excited states, these factors being probably in line with the present introduction of empirical parameter α.

Mixed Halogeno Complexes. Ogino and Bailar[5] pointed out that there were big discrepancies between the predicted and the observed σ values of mixed halogeno complexes of rhodium(III) and iridium(III), when the predicted value was calculated from the d values obtained from the observed σ value of non-mixed halogeno complexes. Such discrepancies,

however, have disappeared in the present treatment with α, as is seen in complexes Nos. 23—27 in Table 5.

For the halogeno rhodium(III), iridium(III), and platinum(IV) complexes of the trans type, some irregularities were found in the empirical α values in Table 1. The α value for the trans isomer (in bracket in Table 1) is nearly equal to or only a little smaller than that for the cis isomer in the case of $[Rh(\underline{N})_xI_{6-x}]$-, $[Ir(\underline{N})_xI_{6-x}]$-, $[Pt(CN)_xCl_{6-x}]$-, and $[Pt(\underline{N})_xBr_{6-x}]$-type of complexes. The reason may be found in the strong spin-orbit coupling in such complexes.

Dynamic NMR as a Nondestructive Method for the Determination of Rates of Dissociation. XII. Dissociation of the Olefin in *trans*-Dichloro(4-methyl-1-pentene)(4-substituted pyridine 1-oxide)platinum(II) Complexes[1)]

Shinji Toyota and Michinori Ōki*
Department of Chemistry, Faculty of Science, The University of Tokyo, Bunkyo-ku, Tokyo 113
(Received June 30, 1987)

The rates of dissociation of the olefin in the title compounds were determined by the dynamic NMR technique by taking advantage of the line shape change due to the isopropyl-methyl protons. The rates of dissociation were independent of concentration in bromoform-*d* solutions. The free energy of activation was between 17.0 and 19.1 kcal mol^{-1} at 353 K for the compounds, of which line shapes were fully analyzed, depending upon the substituent in the pyridine ring and electron-withdrawing substituents giving low activation energy. The solvent effect was noticed on the dissociation rates: Aromatic hydrocarbons give higher rates of dissociation than halogenated hydrocarbons. Although solvents of strong affinity toward platinum(II) tend to decompose the complex, tetrahydrofuran-d_8 was found to give definitely higher rates of dissociation of the olefin in *trans*-dichloro(4-methoxycarbonylpyridine 1-oxide)(3-methyl-1-butene)platinum-(II) than bromoform-*d*, when it was used as a solvent. The mechanism of dissociation was discussed from the available data.

The dynamic NMR technique has been proved useful in investigation of bond breaking-and-forming processes as well as intramolecular dynamics.[2,3)] The bond breaking-and-forming processes are of particular interest because by the investigation of the kinetics the process provides fundamental knowledge for the understanding of dissociation reactions in a sense that the phenomenon could be observed in the absence of any foreign materials in the dynamic NMR technique.

The technique requires some molecular features. The molecule to be studied should possess a pair of diastereotopic nuclei of which magnetic sites are exchanged by dissociation-and-combination and the time scale must fall within the range suitable for the technique, 10^0—10^3 s^{-1}, although the rates are adjustable to some extent by changing temperatures of observation. If a molecule meets the requirements, it is possible to observe various dissociation processes. We have reported the dissociation of an organic halide,[4)] an organic carboxylate,[5)] ammonium salts,[6,7)] and amine ligands from organometallic compounds.[8)] The olefin–metal complex also falls in the category that can be investigated by this technique because chirality is found according to the face of the olefin to which a metal is bonded,[9)] and racemization takes place when the olefin dissociates and reforming of the bond from the other face of the olefin after rotation takes place. The point is how to find a suitable compound for the investigation by the dynamic NMR technique.

Platinum(II)–olefin complexes are well-known and the racemization of their optically active members has been studied by the classical methods. They are usually stable enough to be isolated as chemical entities to mean that the complexes should be in general destabilized for the investigation by the dynamic NMR technique because the time scale of NMR spectroscopy is much faster than the classical laboratory time scale.

Platinum(II)–olefin complexes are known to exchange the olefin in the presence of the excess of an olefin. Potassium trichloro(ethylene)platinate(II) is known to undergo the olefin exchange in the presence of ethylene faster than the NMR time scale even at low temperatures.[10)] The ethylene ligand can also be exchanged by other olefins if the olefin is present.[11)] There is wealth of information on the exchange of olefins in the platinum(II)–olefin complexes.[12–17)]

In the absence of the excess of olefin, the dissociation of the olefin in platinum(II)–olefin complexes seems to be very slow. There are only a few reports that have dealt with the dissociation of the complexes in the absence of an olefin. Frits and Sellmann reported that the coupling of the olefin protons with ^{195}Pt disappeared on dissolution of dichloro(ethylene)(4-substituted pyridine)platinum(II) complexes in acetone, if the 4-substituent in the pyridine ring was electron-withdrawing.[18)] Kaplan et al. generalized the loss of coupling of olefinic protons with the platinum nucleus in *trans*-dichloro(olefin)-(substituted pyridine)platinum(II) complexes in acetone at ambient temperature for the compounds that carry an electron-withdrawing substituent.[19)] The latter authors suggested the role of pyridine base which was present in a minute amount in the system in the olefin exchange.[20)] However, they did not report the kinetic data for the exchange.

There are two strategies to facilitate racemization of the platinum(II)–olefin complexes, as judged from the literatures. One is to use a less basic base to the trans position of an olefin: The strong base stabilizes the olefin complex by the trans influence.[21)] And the other is to use a solvent of strong affinity towards the

platinum(II) ion. On the basis of NMR point of view, it is also important to render the chemical shift difference of the two exchanging protons small in order that we observe the exchange process at low temperatures.

We started from *trans*-dichloro(olefin)(pyridine)-platinum(II) where the olefin was 3-methyl-1-butene that possesses the potential diastereotopic protons. It was not possible to observe the change in line shapes of the signals due to the diastereotopic protons in the olefin in nonpolar solvents and the complex decomposed in polar solvents. In order to facilitate the racemization, pyridine 1-oxide was introduced to the trans position of 3-methyl-1-butene. Although this compound showed a sign of racemization, namely line-broadening of the signals due to the isopropyl-methyl protons, it was not stable enough to survive the measurements at 100 °C or higher temperatures that were needed for the line shape analyses: The situation was improved relative to the pyridine case but was still not good enough for the dynamic NMR work. Finally we introduced 4-methyl-1-pentene as an olefin and 4-methoxycarbonylpyridine 1-oxide as a base in the trans position to the olefin to find that the complex was suitable for the NMR work. This paper reports the results of such investigations and discusses the substituent effects in the pyridine ring and the solvent effects on the rates of racemization as well as the mechanism of dissociation.

Results

The syntheses of the complexes used in this study were carried out in the following way. Potassium trichloro(ethylene)platinate(II)[22] was dimerized by acidification[23] and the dimer **1** was treated with 4-methyl-1-pentene to replace the ethylene ligand. The resulted olefin complex **2** was then treated with 4-substituted pyridine 1-oxide to give the desired compound **3**.[24]

The kinetic parameters obtained as the results of the line shape analysis are given in Tables 1—3. The feature of the data is that the electron-donating substituent in the 4-position of the pyridine ring reduces the rates of racemization considerably and we found that only line broadening to a small extent for the methyl and unsubstituted compounds. The plot of the free energy of activation for racemization at 353 K against pK_a values of the pyridine 1-oxide[25] gave a straight line, the correlation coefficient being

L=pyridine 1-oxide

Scheme 1.

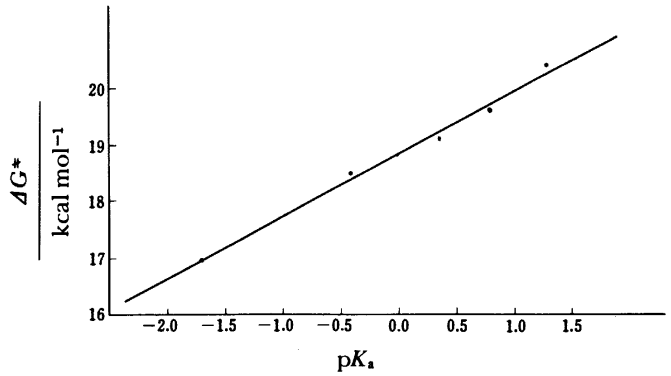

Fig. 1. Relationship between pK_a's of 4-substituted pyridine 1-oxide and free energies of activation for the dissociation of the olefin in *trans*-dichloro(4-methyl-1-pentene)(4-substituted pyridine 1-oxide)-platinum(II) at 353 K.

0.995, when ΔG^* for the methyl compound at 363 K is included (Fig. 1). We believe the inclusion of the latter data is permissible because the entropy of activation is small for other compounds in the series examined, rendering the change in the free energy of activation from 353 K to 363 K small.

Discussion

The results in Table 1 clearly indicate that the rates of racemization are not affected by the concentration of the substrate. This will exclude the mechanisms that involve the catalytic action of the free pyridine oxide that is present in a minute amount, though this mechanism was suggested by Kaplan et al.[20] Then we can assume the process be unimolecular, although solvent assistance in the dissociation is not ruled out. Then over simplified mechanism of the racemization can be written as in Scheme 1, where the species shown in the brackets are the intermediates that are not observed. The results in Table 2 together with the fact that the complex that contains pyridine to the trans position of the olefin ligand shows much slower rates of racemization than those listed in Table 2 are examples of typical trans effects.[26]

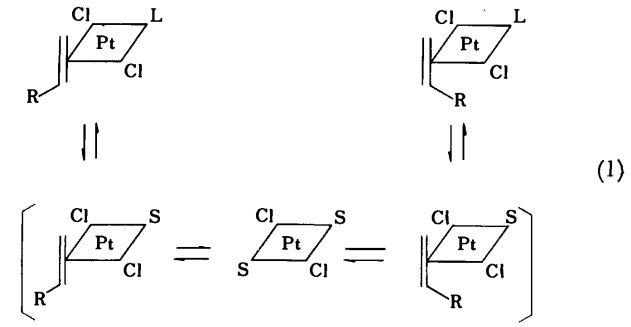
Since the role of solvent molecules is important in racemization of the olefin complexes, it will be of interest to see the solvent effect on the rates of racemization. Table 3 clearly indicates that, whereas halogenated hydrocarbons, $CDBr_3$ and $C_2D_2Cl_4$, give about the same free energy of activation, the aromatic solvents do again about the same free energy of activation, the aromatic solvents giving definitely larger rates of dissociation of the olefin. It is interesting to note that the rates of dissociation are not dependent on the polarity of the solvent molecules. Rather they seem to indicate that the affinity of the solvent molecule towards platinum(II) is important.

For further understanding we have changed solvents to see the effects on the rates of dissociation. However, the complexes tend to decompose in solvents such as dimethyl-d_6 sulfoxide, nitromethane-d_3, acetonitrile-d_3, methanol-d_4, and *N*,*N*-dimethylformamide-d_7. In tetrahydrofuran-d_8, the complex also decomposed at high temperatures. However, *trans*-dichloro(4-methoxycarbonylpyridine 1-oxide)(3-methyl-1-butene)platinum(II) was found to survive to afford kinetic data for dissociation at one point of temperature: 16.4 kcal mol^{-1} at 300 K.[27] Comparing the results with the fact that dissociation of the olefin was not detectable in the same complex in bromoform-*d* at 330 K, we conclude that solvent molecules coordinate to the platinum ion before ligand dissociation.

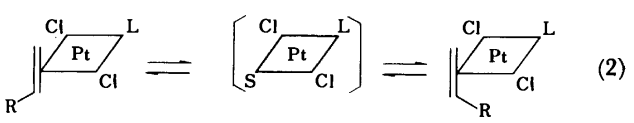
The entropy of activation should reflect the mechanism, dissociative or associative. Although it is known that the entropy of activation is large negative if a solvent molecule participate in an associative reaction,[17] the entropy of activation shown in Tables 1—3 are all close to zero except one case which is still closer to zero than -10 cal mol^{-1} K^{-1}. Recently, the

entropy of activation of dissociative reactions in platinum complexes has been reported to be small positive.[28,29] This quantity of entropy of activation agrees with those obtained for extrusion of a particle from an organic compound.[30] Thus interpretation of these results is difficult in a straightforward manner. It is also true that the entropy of activation should be discussed with care because some dissociative reactions are known to give negative entropy of activation[31] and associative reactions give positive entropy of activation.[16] It might even be the quality of kinetic data that give confusing results in entropy of activation or the randomly dispersing data of the entropy of activation might reflect factors that have not been considered. Therefore, we should like to defer further discussion on the quantity of entropy of activation except mentioning on one point. The participation of the solvent molecule in dissociation of the olefin ligand is apparent from the data given above. It is possible that in these cases of square planar complexes, to which a solvent molecule loosely associates even at the ground state, the entropy of activation could be near zero even in associative reactions, because acquiring freedom of motion by the olefin ligand in the transition state could be important. Further study on this point is awaited.

Admitting the participation of the solvent molecule in the dissociation of the olefin ligand, we can write two mechanisms. One is the process which proceeds via substitution of the solvent for the pyridine oxide ligand followed by the dissociation of the olefin ligand (Eq. 1). The other is the process in which the solvent assists directly the dissociation of the olefin without affecting the pyridine oxide ligand (Eq. 2).



(1)



(2)

If the first possibility is the case that we observe, the rate-determining step must be the dissociation of the pyridine oxide ligand, because, if the dissociation of the olefin were rate-determining, we could not explain the substituent effects seen in the dissociation of the olefin. If the second case is the one we observe, we may have to assume that, although the pyridine oxide ligand dissociates faster than the olefin ligand, there are species that permit dissociation of the olefin ligand, without affecting the pyridine oxide ligand.

It is difficult to determine which is the real case at present but we are inclined to conclude that the second is more likely to be the case for the following reasons. Firstly, although it is still to be confirmed, less basic ligands in the platinum complexes will dissociate more easily than the more basic. Since pyridine 1-oxides are weaker bases than pyridines and the dissociation of the pyridine base from platinum(II) complexes are known,[18-20] it is natural to assume that pyridine 1-oxides will dissociate much more easily than monosubstituted olefins. Therefore, that the rate-determining step in the dissociation of the olefin is the dissociation of the pyridine oxide ligand is less likely. Secondly, although more of the molecules are in the process of dissociation of the pyridine oxide ligand than those in the process of the dissociation of the olefin, we do not observe the dissociated or solvent-ligated molecules to mean that the concentration of the complex is practically the same during the process observed by the dynamic NMR spectroscopy. Therefore, the slow dissociation of the olefin and the fast dissociation of the pyridine oxide ligand do not hamper the Eq. 2 for being the true mechanism of the reaction.

Finally we should like to mention on another possibility of the racemization mechanism which had been proposed in a literature.[32] That is, a platinum-olefin complex would racemize via a sigma-complex. In this mechanism, the process has to pass a transition state or an intermediate which has charge separation. Should this situation take place, it is expected that solvents that stabilize ionic species should enhance the reaction rates. In spite of this expectation, aromatic hydrocarbons show lower barrier to the transformation than halogenated hydrocarbons, although every solvent parameter suggests that the latters should more stabilize ionic species than the formers.[33] Thus the possibility of intervention of a sigma-bonded intermediate (or transition state) is less likely. We favor the solvent assisted mechanism over the sigma-complex mechanism.

Experimental

Dynamic NMR Measurements and Analyses of the Data. The ^{1}H NMR spectra were obtained on a JEOL GX-270 spectrometer which operates at 270 MHz. Samples were dissolved to make up ca. 50 mmol L^{-1} solutions in appropriate solvents except for the determination of the effects of concentration (Table 1) on the rates and for 4-nitropyridine 1-oxide complex which was sparingly soluble in $CDCl_3$. In the latter case, the concentration was

14 mmol L^{-1}. Temperature was measured directly by a thermometer. The chemical shift differences of the signals due to isopropyl-methyl protons drifted when temperature was varied. The drift was measured at several points in the slow exchange limit and the linear relation between the temperature and the chemical shift difference was obtained as shown in Table 4. The chemical shift difference at the temperature of simulation was obtained by extrapolation with the use of the equations. The coupling constants between the methyl protons and the methine proton were independent of temperature (6.6—6.8 Hz), though small differences were noted from condition to condition. T_2's were determined by considering the line shapes in the slow exchange limit and were used throughout the temperature range examined. They were 0.08—0.17 s. The spectra were analyzed as the exchange $A_3B_3X \rightleftharpoons B_3A_3X$ with the use of DNMR 3 program.[34] The rate constants thus obtained were doubled to obtain rates of dissociation in order to accommodate the fact that the rates of racemization is twice of those of dissociation. The rate constants of dissociation are summarized in Table 5.

For the calculation of the line shapes of the complexes with 4-methyl and unsubstituted pyridine 1-oxide, the observed chemical shift difference, 10.7 and 11.1 Hz, respectively, were directly used. T_2's were 0.12 and 0.14 s, respectively, for the former and the latter. For the complex with 3-methyl-1-butene, the chemical shift difference, T_2, and rate constant at 300 K were 104.1 Hz, 0.10 s, and 6.7 s^{-1}, respectively.

Syntheses. Pyridine 1-oxide, 4-nitropyridine 1-oxide, 3-methyl-1-butene, and 4-methyl-1-pentene were available from Tokyo Kasei, Co. 4-Methoxycarbonylpyridine 1-oxide[35] and 4-chloropyridine 1-oxide[36] were prepared as were reported in literatures. The following is the typical method of synthesis of the complexes. The yields were 65—88%.

***trans*-Dichloro(4-methyl-1-pentene)(pyridine 1-oxide)platinum(II).** To a solution of 0.10 g (0.17 mmol) of tetrachlorobis(ethylene)diplatinum(II)[23] in 5 mL of dichloromethane was added 1 mL of 4-methyl-1-pentene and the whole was stirred for several minutes at room temperature. The volatile materials were evaporated and the residue was recrystallized from hexane to give 0.11 g of tetrachlorobis(4-methyl-1-pentene)diplatinum(II) as orange crystals. The crystals were dissolved in 5 mL of dichloromethane and stirred with 30 mg (0.32 mmol) of pyridine 1-oxide for 10 min. Evaporation of the solvent followed by recrystallization of the residue from dichloromethane–hexane afforded 89 mg (65%) of pale yellow crystals.

The melting point of this compound and analytical data are given in Table 6 together with those for other *trans*-dichloro(4-methyl-1-pentene)(4-substituted pyridine 1-oxide)-platinum(II) complexes. ^1H NMR data are given in Table 7.

trans-Dichloro(4-methoxycarbonylpyridine 1-oxide)(3-methyl-1-butene)platinum(II), mp 121—122 °C (decomp), was similarly prepared as described for the preparation of the 4-methyl-1-pentene complexes. Found: C, 29.36; H, 3.49; N, 2.73%. Calcd for $C_{12}H_{17}Cl_2NO_3Pt$: C, 29.46; H, 3.50;

Sulfur Inversion in and Molecular Structure of *meso*-3,4-Diethyl-3,4-dimethyl-1-phenylthiolanium Tetrafluoroborate

Michinori ŌKI,* Yasuhisa YAMADA, and Shigeru MURATA†
Department of Chemistry, Faculty of Science, The University of Tokyo, Bunkyo-ku, Tokyo 113
†Institute for Molecular Science, Myodaiji, Okazaki 444
(Received June 30, 1987)

Kinetics of sulfur inversion in the title compound was studied by the classical method to afford the following kinetic parameters for the process (1*r*,3*R*,4*S*)→(1*s*,3*R*,4*S*): $\Delta H^{\ddagger}$ 25.7±0.3 kcal mol^{-1}, $\Delta S^{\ddagger}$ −2.2± 0.8 cal mol^{-1} K^{-1}. X-Ray crystallography of one isomer (1*r*,3*R*,4*S*) in which the methyl groups are cis to the phenyl group shows some abnormal bond lengths and conformations due to the steric congestion in the 3,4-region of the thiolane ring. The anomalies in the structure are pointed out by comparing the structure with those closely related and the correlation of them with the barrier height to inversion is discussed.

Although racemization of optically active sulfonium ions attracted interests of many investigators[1] since the discovery of fairly facile racemization of this class of compounds by Darwish et al.[2] through sulfur inversion, the reports have mainly concerned with racemization at one point of temperature and the literatures which report enthalpy and entropy of activation are very few.[3] During the course of work on dissociation of molecular species by the dynamic NMR technique, we have come across an idea that entropies of activation can be used as decisive information in diagnosing the mechanism of topomerization,[4] and have felt the necessity of providing the kinetic data of sulfur inversion at various temperatures.

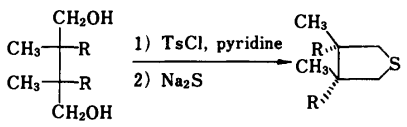
Our first aim of the investigation was to design a molecule that suits to both classical and NMR study of the kinetics of sulfur inversion. In principle, any barrier to a transformation may be reduced by either stabilization of the transition state for the transformation or the destabilization of the ground state. Since normal sulfonium salts racemize with a barrier of ca. 26—35 kcal mol^{-1},[1] it is necessary to design a molecule that possesses a lower barrier to sulfur inversion than usual, if we wish to investigate the inversion by the dynamic NMR technique. For the stabilization of the transition state for inversion, it seemed that we could do little: Although introduction of a phenyl group into the sulfonium moiety is known to cause reduction in the inversion barrier,[5] this may not be ascribed to the stabilization of the transition state, because the substituent constant (σ) of a methylthio group is close to zero,[6] and this is believed to be caused by poor 2p–3p conjugation relative to the 2p–2p case.[7] Thus we decided to work on destabilization of the ground state by introducing the steric effects. This paper reports the results of such investigations: Although the barrier was not reduced large enough to be amenable to the dynamic NMR investigation, it was indeed reduced by destabilizing the ground state by steric congestion, that is discussed from the molecular structure obtained by X-ray crystallography, even for a cyclic compound.

We decided to use a sulfonium salt which could be derived from a cyclic sulfide for two reasons. The first is the difficulty of selecting suitable alkyl groups in the open chains. The mechanism of racemization of sulfonium compounds is known to be three fold:[8] Simple sulfur inversion, sulfur inversion after dissociation when a stable carbocation is formed, and sulfur inversion with intermediates of a thioether and a product which is derived by the attak of the nucleophile on one of the alkyl groups attached to the sulfonium-sulfur. Since we are concerned in the entropy of activation of pure sulfur-inversion, any possibility of the dissociation mechanism must be avoided. There is a report that claims that even *t*-butylethylmethylsulfonium ion racemizes by a dissociation mechanism from a study of volume of activation.[9] We preferred therefore to use primary alkyl groups or aryl groups where possible in the sulfonium salt that gives large rates of inversion. This type of molecular design is not possible in the noncyclic compounds, because the bulky groups which are not directly bonded to the sulfonium-sulfur will avoid each other by taking a suitable conformation. The second is to use this restriction of the freedom of taking conformations in the cyclic compounds. Even though a sulfur atom may be bonded to two primary alkyl groups in a cyclic sulfide, it is possible to give large steric congestion by introducing substituents to the beta or farther positions relative to the sulfur.

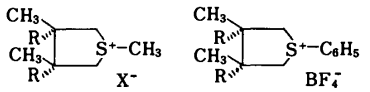
A literature reports that compounds **1** and **2** change their optical activity with rate constants, 1.08×10^{-4} and 0.81×10^{-4} s^{-1}, respectively at 100 °C in acetic acid.[10] If we could add another pair of *gem*-dimethyl groups in another beta-position relative to the sulfur, there could be a low barrier to inversion of sulfur. Because of the ease of syntheses, we selected the five-membered sulfide as a target molecule, though the 5-membered ring system could give higher barrier to inversion due to the small bond angle in the planar structure than the 6-membered.

1 2

2,2,3,3-Tetramethyl-1,4-butanediol (**3a**) had been known.[11] This compound was treated with *p*-toluenesulfonyl chloride in the presence of pyridine to afford the desired product, 3,3,4,4-tetramethylthiolane (**4a**). The thiolane was converted to 1,3,3,4,4-pentamethylthiolanium salts (**5a**): The iodide decomposed very easily because of the nucleophilic attack of the iodide ion, the tosylate also decomposed at above 100 °C, and the trifluoromethanesulfonate survived heating at above 150 °C. However, these compounds did not show evidence that the sulfur-inversion was taking place on the NMR time scale under the conditions of heating mentioned above. Although we introduced a phenyl group to the sulfur atom of the thiolane in a hope that **6a** should further lower the barrier to inversion, that trial did not work as expected. No change in the NMR line shapes was observed at 200 °C at 60 MHz.



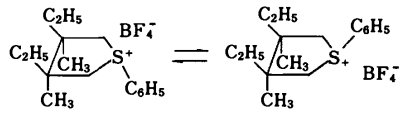
3 a : R=CH_3 b : R=C_2H_5 4



5 6

At this point we turned our attention to the synthesis of other compounds that might fit to the classical equilibration and decided to synthesize derivatives of *meso*-3,4-diethyl-3,4-dimethylthiolane (**4b**). The syntheses could be carried out analogously with the tetramethyl compound, although the corresponding diol **3b** was unknown. Methylation of the thiolane **4b** with methyl trifluoromethanesulfonate afforded a mixture of stereoisomers of **5b** (X=CF_3SO_3) which could not be separated, whereas phenylation of **4b** with diphenyliodonium tetrafluoroborate in the presence of copper(II) benzoate afforded a mixture of stereoisomers of **6b** which could give one pure isomer by recrystallization from ethanol. The stereochemistry of the recrystallized isomer was expected to be (1*r*,3*R*,4*S*)-**6b** from the kinetic consideration, because this isomer was the major product as well as because this form was the preferred of the two at equilibrium. However, it was not possible to determine the stereochemistry unambiguously by the chemical means. That the stereochemistry of this product is really 1*r*,3*R*,4*S* was established by X-ray crystallography.

The isomerization of **6b** in chloroform-*d* solutions was followed by ^{1}H NMR technique, using the signals due to 2,5-methylene protons, which show completely separated AB signals at 270 MHz for the two isomers. The rate constants thus obtained at 5 temperatures are listed in Table 1. From these results, the following activation parameters were obtained: $\Delta H^{\ddagger}$ 25.7±0.3 kcal mol^{-1} (1 cal=4.184 J), $\Delta S^{\ddagger}$ −2.2±0.8 cal mol^{-1} K^{-1}. The feature of the kinetic parameters is the near-zero entropy of activation and confirms that, if pure sulfur-inversion takes place, the entropy of activation is close to zero as is described in the literature.[3] This result is reasonable in that during the inversion of sulfur net charge does not change nor a new particle is formed.



(1*r*,3*R*,4*S*)-**6b** (1*s*,3*R*,4*S*)-**6b**

That we do not observe other reactions but real inversion of sulfur was proved by enriching the other isomer: the solution obtained by the equilibration of **6b**, that contained the product and the starting material in ca. 3:4 ratio was concentrated and fractionally recrystallized from ethanol. It was possible to enrich the product to 6:1 purity. Satisfactory elementary analyses of the enriched product and expected ^{1}H NMR spectra support the structure of the isomer. Furthermore, the product, when heated in chloroform-*d*, afforded the identical mixture of the isomers of **6b**, which was obtained by heating the original isomer.

The observed barrier to sulfur-inversion is indeed lower than that in **1** by ca. 2 kcal mol^{-1} and represents the lowest barrier known so far for purely aliphatic cyclic sulfonium salts, yet it is higher than that in 1-adamantylethylmethylsulfonium perchlorate.[3] We were thus interested in the investigation of the cause for the relatively high barrier to sulfur-inversion in compound **6b**, irrespective to the fact that the molecular models of the compound suggested that the high degree of congestion was possible in the molecule. Thus X-ray crystallography of the starting material **6b** was carried out. This as well provides unambiguous assignment of the stereochemistry of the isomers involved.

Atomic coordinates, bond lengths, bond angles, and some selected dihedral angles are given in Tables 2, 3, 4, and 5, respectively. The ORTEP diagram is given in Fig. 1 for the enantiomer of the molecule that is defined by the atomic coordinates in Table 2, for the convenience of the comparison with the molecule of **8**. It is clear that the prediction of stereochemistry given by considering both kinetic and thermodynamic preference is correct. The originally preferred compound is (1*r*,3*R*,4*S*)-3,4-diethyl-3,4-dimethyl-1-phenylthiolanium tetrafluoroborate. Thus the product by equilibration must be (1*s*,3*R*,4*S*)-3,4-diethyl-3,4-dimethyl-1-phenylthiolanium tetrafluoroborate.

The compound **6b** has some interesting structural features that follow. These must be caused by the presence of neighboring two pairs of *gem*-ethyl-and-methyl groups which interact strongly with each other. The methyls of the ethyl groups are directing outward relative to the five-membered ring to avoid the interaction with other groups. The C_3–C_4 bond is

very long as an sp^3–sp^3 carbon bond and is even longer than the C–C bond in tetramethylsuccinonitrile.[13] This is probably caused by the fact that the steric size of a cyano group is smaller than a methylene group.

Another interesting feature is that the C_4 occupies the tip of the envelope conformation of the thiolane ring in contrast to the fact that the sulfur atom occupies the tip position in 1-methylthiolanium iodide.[14] The cause was again considered to be the steric effects at the 3 and 4 positions, because, if the sulfur atom occupies the tip, the methyl and the ethyl groups at 3,4-positions must take near-eclipsing conformations

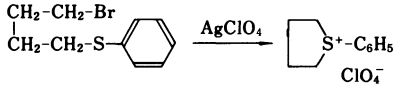
a) Equivalent isotropic temperature factor defined by Hamilton.[12]

that are of very high energy.

Another interesting point in the structure of **6b** is that the 1-phenyl group takes a conformation that is nearly perpendicular to the lone-pair orbital of the sulfur atom. This makes an interesting contrast to the structure of dimethylphenylsulfonium ion in which the phenyl group nearly bisects the CH_3-S-CH_3 angle.[15] To get further insight into the implication of the structure, we have carried out the X-ray crystallography of 1-phenylthiolanium perchlorate (**8**) which was easily prepared by treating (4-bromobutylthio)benzene (**7**) with silver perchlorate. The results are shown in Tables 6, 7, 8, and 9.



7 8

The diffraction data were best interpreted by assuming that there were two kinds of molecules in the crystals in addition to their enantiomers. The two independent molecules are those which differ in the positions of the carbon-3 of the thiolane ring. Thus they are diastereomers. However, their structures are similar except that the position of C_3 which is up or down relative to the plane made by others, C_2-S-C_5-C_4: the torsion angle $C_{1'}$-S-C_2-C_3 in molecule 2 is much larger than that in molecule 1, reflecting the relative positions of C_3. The ORTEP diagrams of these molecules are shown in Fig. 2. Thus only one form (molecule 2) will be used for comparison of the structures of **6b** and **8** that follows. It is interesting that in these molecules C_3 occupies the tip of the envelope. However, the cause for the difference between **8** and 1-methylthiolanium ion[14] is not well understood at present.

S-C_2-C_3-C_4	−37.9(12)	42.4(14)
C_2-C_3-C_4-C_5	42.9(14)	−46.9(16)
C_3-C_4-C_5-S	−28.1(13)	28.0(14)

The feature of the structure of **8** is that the phenyl group nearly bisects the angle C_2–S–C_5 although it is tilted a little toward C_4. It seems that in normal dialkylphenylsulfonium ions the phenyl group nearly bisects the C–S–C angle. The tilting of the phenyl group to a small degree in **8** must be caused by avoiding the van der Waals repulsion between the groups concerned. Since, if the phenyl group takes the similar conformation as in **8**, severe steric interactions between the 3-methyl group and the phenyl group are unavoidable in **6b**, the phenyl group seems to take the conformation that is observed by the X-ray crystallography. Indeed, the distance between $C_{2'}$ and the methyl group at C_3 and that between $C_{6'}$ and the same methyl group in **6b** are 4.16 and 4.37 Å, respectively. That is, the ortho carbons of the phenyl group are at about the same distance from the methyl group and are in close contact at about the sum of the van der Waals radii.

The sulfur pyramid in **6b** is not significantly different from that in the 1-phenylthiolanium perchlorate (**8**). However, the five-membered ring is a little more distorted in **6b** than in **8**. This is because, due to the steric effects in the 3,4-positions, the conformation about the C_3–C_4 bond is very close to the perfectly staggered. The carbon atom that occupies the tip of the envelope is 0.68 and 0.58 Å out of the average plane that is made by the other four atoms of the ring in **6b** and **8**, respectively.

We summarize from the structural features of the thiolanium ion discussed above that **6b** has an unusual structure about the C_3–C_4 region because of the steric effects of the two methyl and two ethyl groups. However, this abnormality may not affect the structure of the sulfur pyramid except that the phenyl conformation is unusual in **6b**. Although there is no evidence that the structure of the molecule in the solid state is taken in solution, it is tempting to consider that the lowering of the sulfur-inversion barrier in **6b** to a small extent relative to **1** is ascribable to the fact that the sulfur pyramid is not unusual except that the phenyl group takes a conformation that is perpendicular to the direction of the lone pair orbital of the sulfur atom. Namely the steric effect of the four alkyl groups in 3 and 4 positions appears only at the unusual conformations about the S–$C_{1'}$ bond as far as the barrier to sulfur-inversion concerns.

Experimental

Determination of Rates of Sulfur-Inversion. **6b** was dissolved in chloroform-*d* to make up ca. 0.1 mol L^{-1} solutions. The solution was heated in a thermostatted bath at a given temperature. The starting material and the product were analyzed with the use of ^1H NMR spectra of the methylene protons at 270 MHz. The spectrometer was a JEOL GX-270. The integration method and the weight method afforded agreeable data within the error limit. The data were treated by assuming the reversible first order reaction and the rate constants were put into the Eyring equation to afford kinetic parameters.

X-Ray Crystallography. Crystals suitable for the crystallography were grown from dichloromethane–hexane and acetone–hexane, respectively, for **6b** and **8**.

Colorless crystals (0.5×0.3×0.3 mm) were mounted on a Rigaku AFC-5 automated four-circle diffractometer and the intensity data were collected using Mo $K\alpha$ radiation (λ=0.71073 Å). The ω–2θ scan technique was employed at a scan rate of 3° min^{-1} in ω, and the scan range was calculated by $1.1°+0.5°\tan\theta$. For **6b**, 4218 independent reflections within the range $2\theta<55°$ were measured, and 1851 reflections with $|F_o|>3\sigma|F_o|$ were judged as observed and were used for the structure determination and refinement. For **8**, the total number of measured reflections and the observed reflections were 4644 ($2\theta<50°$) and 1299, respectively. The crystal data and the methods of structure determination were as follows.

6b: $C_{16}H_{25}BF_4S$, F.W.=336.24, triclinic, space group $P\bar{1}$, a=10.025(2), b=10.268(2), c=9.599(1) Å, α=69.91(1)°, β=99.42(2)°, γ=110.68(1)°, V=867.2 Å^3, Z=2, D_c=1.29 g cm^{-3}, μ=2.21 cm^{-1}. The structure was solved by direct methods (MULTAN 78) and refined by the block-diagonal least-squares technique with anisotropic thermal parameters for non-hydrogen atoms and isotropic for hydrogens. All the hydrogen atoms were located on a difference map but their positional parameters were not refined. The atomic scattering factors were taken from International Tables for X-Ray Crystallography.[16] Difference syntheses revealed the disorder of the tetrafluoroborate anion, and their positional and anisotropic thermal parameters were refined. The weighting scheme $w=[\sigma_c^2+(0.02|F_o|^2)]^{-1}$ was employed. The final R and R_w values were 6.13 and 8.44%, respectively.

8: $C_{10}H_{13}ClO_4S$, F.W.=264.72, monoclinic, space group $P2_1/n$, a=14.760(1), b=15.928(2), c=10.294(1) Å, β=94.18(1)°, V=2413.6 Å^3, Z=8, D_c=1.46 g cm^{-3}, μ=4.81 cm^{-1}. The structure was solved by direct methods (MULTAN 78), assuming the temperature factor of 2.30, to reveal the positions of four heavy atoms. Two kinds of independent molecules were found in a unit cell. Calculation of structure factors based on the four atoms gave an R value of 55.8%. The Fourier syntheses and successive difference syntheses indicated all the non-hydrogen atoms in addition to the disorder of the perchlorate anion, the positional and anisotropic thermal parameters of which were refined by the block-diagonal least-squares technique. The positions of all hydrogens were obtained by calculation. The positional and isotropic thermal parameters (assumed to be 10.5) of hydrogens were not refined, but were included in the calculation of structure factors. The final R and R_w values were 5.99 and 7.82%, respectively.

All the calculations were carried out on a HITAC M-200H computer with crystallographic computation program system, MULTAN and UNICS III, filed at the Computer Center of the Institute for Molecular Science. The complete F_o-F_c data are deposited as Document No. 8771 at the Office of the Editor of the Bulletin of the Chemical Society of Japan.

3,3,4,4-Tetramethylthiolane (4a). To a mixture of 5.4 g (37 mmol) of 2,2,3,3-tetramethyl-1,4-butanediol[11] and 17 mL of dry pyridine, was added 16.8 g (88 mmol) of *p*-

toluenesulfonyl chloride in portions with ice-cooling and stirring. After several hours of stirring, the mixture was allowed to stand in a refrigerator and then poured into 100 mL of water. The precipitates were collected by filtration to give the crude ditosylate, mp 98—107 °C, in 80% yield. ^{1}H NMR ($CDCl_3$) δ=0.83 (12H, s), 2.44 (6H, s), 3.79 (4H, s), 7.36 and 7.69 (8H, ABq, J=8.4 Hz). This crude ditosylate was directly used for the next reaction.

To a solution of 3.0 g (6.6 mmol) of the crude ditosylate in 100 mL of *N,N*-dimethylformamide, was added 3.0 g (13 mmol) of sodium sulfide nonahydrate. The whole was heated under reflux for 2 h and steam-distilled to give 0.7 g (74%) of the desired compound. The pure sample was obtained by sublimation, mp 151—152 °C (sealed tube). High resolution MS: M^+ 144.0973. Calcd for $C_8H_{16}S$: M^+ 144.0973. ^{1}H NMR ($CDCl_3$) δ=0.98 (12H, s), 2.69 (4H, s).

1,3,3,4,4-Pentamethylthiolanium Trifluoromethanesulfonate (5a: X=CF_3SO_3). To a solution of 0.1 g (0.7 mmol) of the thiolane in 2 mL of carefully dried (distilled from CaH_2) dichloromethane, was added 0.1 mL (0.15 g or 0.9 mmol) of methyl trifluoromethanesulfonate and stirred for 1.5 h at room temperature. Addition of ether to the mixture afforded 0.17 g (80%) of the desired compound, mp 120.5—122.0 °C. Recrystallization from ethanol afforded the pure sample, mp 123.5—124.5 °C. Found: C, 38.69; H, 6.16; S, 20.99%. Calcd for $C_{10}H_{19}F_3S_2O_3$: C, 38.95; H, 6.12; S, 20.79%. ^{1}H NMR ($CDCl_3$) δ=1.10 (6H, s), 1.23 (6H, s), 3.22 (3H, s), 3.44 and 3.68 (4H, ABq, J=13.5 Hz).

3,3,4,4-Tetramethyl-1-phenylthiolanium Tetrafluoroborate (6a). A solution of 0.12 g (0.83 mmol) of the thiolane, 0.31 g (0.84 mmol) of diphenyliodonium tetrafluoroborate,[17] and 10 mg of copper(II) benzoate in 3 mL of *N,N*-dimethylformamide was heated in an oil bath at 120—125 °C for 4 h. After the mixture was cooled, ether was added to the mixture and the precipitates were collected by filtration. Recrystallization from ethanol afforded 0.16 g (63%) of the desired product, mp 241.0—245.5 °C. Found: C, 54.51; H, 6.57; S, 10.87%. Calcd for $C_{14}H_{21}BF_4S$: C, 54.56; H, 6.87; S, 10.40%. ^{1}H NMR (DMSO-d_6) δ=1.06 (6H, s), 1.12 (6H, s), 3.97 and 4.07 (4H, ABq, J=13.5 Hz), 7.6—7.8 (3H, m), 7.9—8.1 (2H, m).

***meso*-2,3-Diethyl-2,3-dimethyl-1,4-butanediol (3b).** A solution of 14.0 g of *meso*-2,3-diethyl-2,3-dimethylsuccinic acid[18] in 50 mL of methanol was heated with 5 mL of sulfuric acid for 12 h and poured into water. The mixture was extracted with ether and the ether extracts were dried over magnesium sulfate. Evaporation of the solvent afforded 14.7 g of the crude half-ester of the succinic acid derivative. ^{1}H NMR ($CDCl_3$) δ=0.82 (3H, t, J=7.5 Hz), 0.87 (3H, t, J=7.5 Hz), 1.17 (3H, s), 1.20 (3H, s), 1.5—2.4 (4H, m), 3.68 (3H, s), 10.7 (1H, br s). A solution of the crude monomethyl ester (11.9 g or 55 mmol) in 50 mL of ether was added to 4.0 g (0.1 mol) of lithium tetrahydridoaluminate in 200 mL of ether with ice-cooling and the mixture was heated for 14 h. The mixture was treated with water and then with dilute sulfuric acid with ice-cooling and the ether layer was separated. The aqueous layer was extracted several times with ether. The combined ether extracts were washed with water and dried over sodium sulfate. Evaporation of the solvent afforded 9.4 g (78% based on the succinic acid) of the desired diol, which was purified by recrystallization from dichloromethane-pentane, mp 33.0—34.5 °C. Found: C, 68.67; H, 12.96%. Calcd for $C_{10}H_{22}O_2$: C, 68.92; H, 12.72%. ^{1}H NMR ($CDCl_3$) δ=0.77 (6H, s), 0.83 (6H, t, J=7.5 Hz), 1.1—1.7 (4H, m), 3.46 (4H, s), 4.55 (2H, br s).

***meso*-3,4-Diethyl-3,4-dimethylthiolane (4b).** This compound was obtained in a similar manner as described for the tetramethyl compound **4a**, starting from **3b**; tosylation of the diol followed by treatment with sodium sulfide. The yield was 66%. It was obtained as an oil. High resolution MS: M^+ 172.1308. Calcd for $C_{10}H_{20}S$: M^+ 172.1286. ^{1}H NMR ($CDCl_3$) δ=0.77 (6H, t, J=7.5 Hz), 0.93 (6H, s), 1.17 (4H, q, J=7.5 Hz), 2.58 and 2.73 (4H, ABq, J=10.5 Hz).

Methylation of 4b with Methyl Trifluoromethanesulfonate. To a solution of 0.1 g (0.6 mmol) of the thiolane (**4b**) in 2 mL of dry dichloromethane was added 0.1 mL (0.15 g or 0.9 mmol) of methyl trifluoromethanesulfonate. The product was a ca. 1:1.3 mixture of two isomers which were not assigned. Attempted separation of the stereoisomers failed. The following ^{1}H NMR ($CDCl_3$, δ) were collected. One isomer: 0.98 (6H, t, J=7.5 Hz), 1.05 (6H, s), 1.3—1.5 (4H, m), 3.12 (3H, s), 3.44 and 3.60 (4H, ABq, J=13.7 Hz). Other isomer: 1.01 (6H, t, J=7.5 Hz), 1.16 (6H, s), 1.54 (4H, q, J=7.5 Hz), 3.17 (3H, s), 3.30 and 3.80 (4H, ABq, J=13.6 Hz). The assignment of the peaks at δ 0.98 and 1.01 for the methyl protons may be reversed because their intensities were equal.

(1*r*,3*R*,4*S*)-3,4-Diethyl-3,4-dimethyl-1-phenylthiolanium Tetrafluoroborate (6b). The thiolane (0.60 g or 3.5 mmol) and 1.30 g (3.53 mmol) of diphenyliodonium tetrafluoroborate were treated similarly as described for the synthesis of **4a**. The precipitate (0.75 g) obtained by adding ether to the reaction mixture was recrystallized from ethanol to give 0.32 g (27%) of the desired material, mp 156.5—157.5 °C. Found: C, 57.00; H, 7.37; S, 9.39%. Calcd for $C_{16}H_{25}BF_4S$: C, 57.15; H, 7.49; S, 9.53%. ^{1}H NMR ($CDCl_3$) δ=0.99 (6H, t, J=7.4 Hz), 1.07 (6H, s), 1.49 (4H, q, J=7.4 Hz), 3.58 and 4.20 (4H, ABq, J=13.4 Hz), 7.56—7.61 (3H, m), 7.82—7.86 (2H, m). The crude product contained some stereoisomer of **6b** which was apparently removed by recrystallization.

After equilibration of **6b** by heating, the chloroform solution was concentrated to produce crystals that contained mainly (1*r*,3*R*,4*S*)-**6b**. The repetition of the procedure finally gave a 1:6 mixture of (1*r*,3*R*,4*S*)-**6b** and (1*s*,3*R*,4*S*)-**6b**. Recrystallization of the mixture from ethanol or dichloromethane-hexane did not improve the purity. Found: C, 56.98; H, 7.60%. Calcd for $C_{16}H_{25}BF_4S$: C, 57.15; H, 7.49%. The following ^{1}H NMR data ($CDCl_3$, δ) of (1*s*,3*R*,4*S*)-**6b** were obtained by subtracting the signals due to (1*r*,3*R*,4*S*)-**6b**: 0.89 (6H, t, J=7.3 Hz), 1.11 (6H, s), 1.39 and 1.49 (4H, AB part of ABX_3, J_{AB}=14.1 Hz, J_{AX}=J_{BX}=7.3 Hz), 3.74 and 4.06 (4H, ABq, J=13.2 Hz), 7.61—7.63 (3H, m), 7.78—7.81 (2H, m).

1-Phenylthiolanium Perchlorate (8). To a solution of 0.24 g (0.98 mmol) of (4-bromobutylthio)benzene (**7**)[19] in 20 mL of dichloromethane was added 0.20 g (0.96 mmol) of silver perchlorate and the whole was stirred overnight at room temperature. The precipitate was removed by filtration and the filtrate was concentrated in vacuo. The crystals thus obtained were recrystallized from ethanol to afford 0.20 g (77%) of the desired product, mp 90.0—91.5 °C. Found: C, 45.12; H, 4.96%. Calcd for $C_{10}H_{13}ClO_4S$: C, 45.37; H, 4.95%. ^{1}H NMR ($CDCl_3$) δ=2.55—2.61 (4H, m), 3.66—3.76 (2H, m), 4.17—4.26 (2H, m), 7.61—7.73 (3H, m), 7.80—7.82 (2H, m).

An X-Ray Diffraction Study on the Structures of Monochloropentakis(*N,N*-dimethylformamide)copper(II), Trichloromono(*N,N*-dimethylformamide)- and Tetrachlorocuprate(II) Complexes in *N,N*-Dimethylformamide

Kazuhiko Ozutsumi, Shin-ichi Ishiguro,* and Hitoshi Ohtaki†

†Department of Electronic Chemistry, Tokyo Institute of Technology, Nagatsuta-cho 4259, Midori-ku, Yokohama 227
(Received August 17, 1987)

The structure of the monochlorocopper(II), trichloro- and tetrachlorocuprate(II) complexes in *N,N*-dimethylformamide (DMF) has been studied by the X-ray diffraction method at 25 °C. The radial distribution curve obtained for a solution containing the monochlorocopper(II) complex as the predominant species reveals the presence of an axially elongated octahedral $[CuCl(dmf)_5]^+$ complex, three Cu–O(eq) and two Cu–O(ax) bond lengths being 199(1) and 239(4) pm, respectively. The chloride ion binds to the copper(II) ion at the equatorial site and the Cu–Cl distance is 220(2) pm. The Cu–O(eq) bond length within the $[CuCl(dmf)_5]^+$ complex is practically the same as that within the $[Cu(dmf)_6]^{2+}$ (203 pm). The X-ray scattering data of solutions containing the tri- and tetrachlorocuprate(II) complexes as the main species are well explained in terms of the existence of the distorted tetrahedral $[CuCl_3(dmf)]^-$ and $[CuCl_4]^{2-}$ complexes, respectively, in the solutions. The Cu–Cl and Cu–O bond lengths within the $[CuCl_3(dmf)]^-$ complex are 219(1) and 230(13) pm, respectively. The Cu–O distance within the complex is longer than that of the equatorial Cu–O bond within the $[Cu(dmf)_6]^{2+}$ and $[CuCl(dmf)_5]^+$ ions. The Cu–Cl bond length within the $[CuCl_4]^{2-}$ complex is 226(1) pm and is longer than that within the $[CuCl_3(dmf)]^{2-}$ complex. The nonbonding Cl···Cl distances within the $[CuCl_4]^{2-}$ complex are 346(3) and 412(6) pm.

The structure of complexes between copper(II) and chloride ions in aqueous $CuCl_2$ solutions with varying concentrations has been investigated by X-ray,[1,2] neutron diffraction,[3] and EXAFS methods,[4] and the data are interpreted in terms of the formation of various monomeric and/or polymeric chloro complexes. X-Ray scattering measurements have also been carried out for methanolic solutions of $CuCl_2$ and the presence of monomeric complexes with various numbers of chloride ions was proposed in the solutions.[5] However, the data analysis of the solutions so far examined was performed for the average structure of some complexes coexisting and no structural information has been given for individual complex species in solution with adjusting the concentration ratios of copper(II) to chloride ions on the basis of the stability constants of copper(II)–chloro complexes.

The structure of the $[CuCl_3]^-$ and $[CuCl_4]^{2-}$ complexes in crystal has been investigated from magnetic and thermochromic points of view. The former complex has been concluded to have a dimeric structure with a square-planar coordination geometry around a copper(II) ion,[6–8] and the latter has either a square-planar or a distorted tetrahedral structure.[9–18] The structure of the complexes in solution, however, has never been studied.

A series of mononuclear copper(II)–chloro complexes are formed and formation of the complexes is enhanced in aprotic solvents such as *N,N*-dimethylformamide (DMF), dimethyl sulfoxide, and acetonitrile and the formation constants of each complex have been determined.[19–22] In DMF the mono-, tri-, and tetrachloro complexes of copper(II) ion are formed as the main species at suitable concentration ratios of chloride to copper(II) ions.[19] Therefore, in the present study we determined the structure of the monochlorocopper(II), trichloro- and tetrachlorocuprate(II) complexes in DMF by the X-ray diffraction method. The structure of the dichlorocopper(II) complex was not determinable because the formation of the complex is suppressed in DMF.

Experimental

Preparation of Sample Solutions. All chemicals used were of reagent grade. *Copper(II) perchlorate DMF solvate* was prepared by the method described in a previous paper.[19] *Copper(II) chloride* was prepared by dissolving copper(II) oxide in hydrochloric acid and then recrystallized from aqueous dilute hydrochloric acid and dried in a vacuum oven at 100 °C. *Lithium chloride* was recrystallized from water and dried in vacuum at 200 °C. *N,N*-Dimethylformamide was purified as described elsewhere.[19]

Sample solutions A to D were prepared as listed in Table 1. Solution A was prepared by dissolving anhydrous

Table 1. The Composition (mol dm^{-3}), Stoichiometric Volumes V per Copper Atom and Densities ρ of the Sample Solutions

	A	B	C	D
Cu^{2+}	1.189	1.380	1.358	1.081
Cl^-	1.202	4.178	5.351	4.685
Li^+	—	1.418	2.635	2.523
ClO_4^-	1.176	—	—	—
DMF	12.28	12.06	11.87	12.10
$V/10^9$ pm^3	1.397	1.203	1.223	1.536
ρ/g cm^{-3}	1.133	1.127	1.162	1.137
C_{Cl}/C_{Cu}	1.011	3.027	3.940	4.334

copper(II) chloride and copper(II) perchlorate DMF solvate in DMF and solutions B to D by dissolving anhydrous copper(II) and lithium chlorides. Mole ratios C_{Cl}/C_{Cu}, where C_i represents the total concentration of species i, were so chosen that solutions A, B, and C contained the mono-, tri-, and tetrachloro complexes, respectively, as the main species according to the formation constants in the literature.[19] Since the solubility of LiCl in DMF is not sufficiently large, the tetrachlorocuprate(II) complex is not fully yielded in DMF. The yield of the complex in solution C was about 70 mol% of the total copper(II) ions, and therefore, in order to check the reproducibility of the structural analysis, solution D with the slightly higher C_{Cl}/C_{Cu} mole ratio than that of solution C was also examined. Solution A thus prepared is green, solution B orange and solutions C and D yellow. Concentrations of copper(II) ions in the sample solutions were determined by electrogravimetry. Concentrations of chloride ions were gravimetrically determined as AgCl. Concentrations of perchlorate ions in solution A and lithium ions in solutions B to D were evaluated by the material balance of ions in the solutions. Densities of the test solutions were measured pycnometrically.

X-Ray Scattering Measurements. X-Ray scattering measurements were performed on a θ-θ type diffractometer (JEOL DX-GO-Y) by using Mo $K\alpha$ radiation (λ=71.07 pm). The method of measurements and data treatments are described elsewhere.[23] The accessible range of scattering angle (2θ) was 2—140°, which corresponds to the scattering vector ($s=4\pi\lambda^{-1}\sin\theta$) range of 0.3×10^{-2}—16.6×10^{-2} pm^{-1}. Times required to accumulate 160000 counts were recorded at each angle of 2θ.

The reduced intensities $i(s)$ were extracted from the measured intensities $I(s)$, which had been scaled to the absolute ones after corrections for absorption, polarization and double scatterings of X-rays, according to Eq. 1:

$$i(s) = I(s) - \sum_i n_i[\{f_i(s) + \Delta f_i'\}^2 + (\Delta f_i'')^2], \quad (1)$$

where n_i is the number of atom i in a stoichiometric volume V per copper atom and $f_i(s)$ denotes the atomic scattering factors at s of atom i. $\Delta f_i'$ and $\Delta f_i''$ represent the real and imaginary parts of anomalous dispersion, respectively. The reduced intensities multiplied by s of the sample solutions are depicted in Fig. 1. The $s\cdot i(s)$ values were converted by the Fourier transform into the radial distribution function $D(r)$ as

$$D(r) = 4\pi r^2\rho_o + \frac{2r}{\pi}\int_0^{s_{max}} s\cdot i(s)\cdot M(s)\cdot\sin(rs)ds, \quad (2)$$

where ρ_o is the average scattering density in a stoichiometric volume of the solution and s_{max} denotes the maximum s-value attained in the measurement. $M(s)$ is the modification function defined as

$$M(s) = \frac{\sum_i n_i\{(f_i(0) + \Delta f_i')^2 + (\Delta f_i'')^2\}}{\sum_i n_i\{(f_i(s) + \Delta f_i')^2 + (\Delta f_i'')^2\}}\cdot\exp(-ks^2) \quad (3)$$

The damping factor k was chosen as 100 pm^2 in the present study. The differential radial distribution curves, $D(r)-4\pi r^2\rho_o$, for solutions A to D are shown in Fig. 2.

All calculations were performed by using programs KURVLR[24] and NLPLSQ.[25]

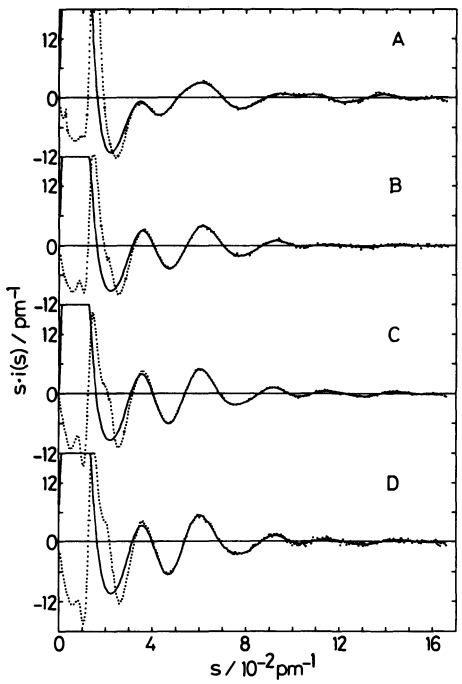

Fig. 1. The reduced intensities multiplied by s for solutions A, B, C, and D. The observed $s\cdot i(s)$ values are shown by the dotted lines and calulated ones by the solid lines.

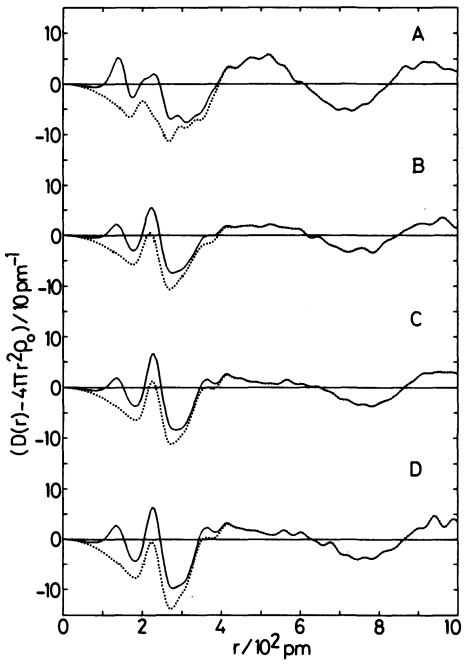

Fig. 2. The differential radial distribution curve, $(D(r)-4\pi r^2\rho_o)$, for solutions A, B, C, and D (solid lines). The dotted lines represent the residual curves after subtracting peaks due to the intramolecular interactions of DMF molecules for solutions A to D and perchlorate ions for solution A.

Results and Discussion

Structure of the $[CuCl]^+$ Complex. According to the stability constants for the copper(II)-chloro complexes in DMF,[19] the $[CuCl]^+$ complex is expected to be formed as the predominant species in solution A. Figure 3 depicts the $(D(r)-4\pi r^2\rho_o)$ curve of solution A as well as the calculated peak shapes for atom pairs in the solution which will be discussed later. In the curve four peaks appear around 130, 230, 290, and 410 pm, and a shoulder and a small hump are also observed at about 200 and 320 pm, respectively.

From the X-ray analysis of liquid DMF[26] it was shown that two peaks originating from the intramolecular interactions within DMF molecule appeared at 130 and 230 pm in the radial distribution function and no appreciable intermolecular interactions are observed because of its disordered liquid structure. Accordingly, the first peak at 130 pm should be due to the C-H, C=O, and C-N bonds within DMF molecules. The Cl-O bonds within perchlorate ions are also contained in the peak. The second peak at about 230 pm with a shoulder at 200 pm may be ascribable to interactions between

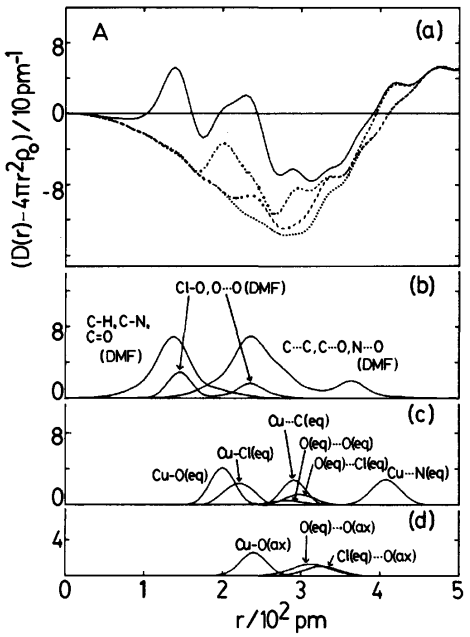

Fig. 3. (a) The $(D(r)-4\pi r^2\rho_o)$ curve for solution A. (b) The theoretical peaks for intramolecular interactions within DMF molecule and perchlorate ion. (c) The theoretical peak shapes due to the Cu-O(eq), Cu-Cl(eq), Cl···Cl, Cl···O, Cu···C(eq), and Cu···N(eq) interactions within the monochloropentakis(*N*,*N*-dimethylformamide)copper(II) complex. (d) The calculated peaks for Cu-O(ax), Cl···Cl, and Cl···O interactions within the mono-complex. The chain, dashed and dotted lines represent the residual curves after subtraction of the theoretical peaks in (b), (c), and (d), respectively.

copper(II) ion and ligand atoms within the monochlorocopper(II) complex. The nonbonding N···O, C···C, and C···O interactions within DMF molecules and the O···O contacts within perchlorate ions also contribute to the peak. The third peak and a small hump at 290 and 320 pm, respectively, may be due to the Cu···C interactions and the nonbonding interligand interactions within the monochlorocopper(II) complex. The Cu···N(DMF) nonbonding interactions should be involved in the peak at 410 pm as have been seen in the solvated copper(II) ion.[27]

At the first step of analysis of the radial distribution curve, the theoretical peak shapes due to the intramolecular interactions within DMF molecules and perchlorate ions were subtracted from the original curve. The structural parameter values were assumed to be the same as those obtained in liquid DMF and are quoted from the literature.[26] The residual curve drawn by the chain line (Fig. 3a) shows a large peak at 200 pm with a shoulder at 230 pm and three peaks around 290, 320, and 400 pm, which are all ascribable to the intramolecular interactions within the $[CuCl]^+$ complex. The peak at 200—230 pm should be due to the bonds between copper(II) ion and ligand atoms within the complex and the peak shape suggests that it consists of at least two interactions. However, the peak shape could not be analyzed by any assumption of only two kind Cu-O (ca. 200 pm) and Cu-Cl (ca. 230 pm) bonds with the values of the temperature factor of 20 and 70 pm^2,[3,5] respectively, and was possible to be explained by the introduction of a distorted octahedral model of the monochlorocopper(II) complex with three kinds of bonds: i.e., the equatorial Cu-O bond (ca. 200 pm) with the frequency factor 3, an equatorial Cu-Cl (ca. 220 pm) and two axial Cu-O bonds (ca. 240 pm). Moreover, the small peak observed at 320 pm was also explainable from the distorted octahedral model to be nonbonding interligand Cl(eq)···O(ax) interactions. The radial distribution curve and reduced intensities calculated on the basis of other structure models such as a square-planar four-coordination, a trigonal bipyramidal or a square pyramidal five-coordination structure did not fit the experimental values. Therefore, the monochlorocopper(II) complex was concluded to have a distorted octahedral structure.

The structure parameters of the $[CuCl(dmf)_5]^+$ complex were refined by a least-squares calculation for the $s\cdot i(s)$ curve over the region $s>4\times10^{-2}$ pm^{-1}, where the intramolecular interactions within the complex and those of DMF molecules and perchlorate ions mainly contribute to the $s\cdot i(s)$ values. In order to avoid errors introduced by neglecting long-range intermolecular interactions, the lower limit of the s-values was varied from 4×10^{-2} to 7×10^{-2} pm^{-1}. In the course of the calculation, the parameter values for the intramolecular interactions of DMF and perchlorate ion were fixed at the literature values.[26,28]

Table 2. Results of the Least-Squares Refinements of Solution A. Standard Deviations Are Given in Parentheses

a) The values were kept constant during the calculation. b) $r_{O(eq)\cdots O(eq)}=\sqrt{2}\,r_{Cu-O(eq)}$. c) $r_{Cl(eq)\cdots O(eq)}=\sqrt{r_{Cu-O(eq)}^2+r_{Cu-Cl(eq)}^2}$. d) $r_{O(eq)\cdots O(ax)}=\sqrt{r_{Cu-O(eq)}^2+r_{Cu-O(ax)}^2}$. e) $r_{Cl(eq)\cdots O(ax)}=\sqrt{r_{Cu-Cl(eq)}^2+r_{Cu-O(ax)}^2}$.

Some constraints were set for the distances of nonbonding interligand interactions as indicated at the footnote in Table 2 and the frequency factors of all interactions in the table were kept constant at the given values estimated from the distorted octahedral model of the complex in the course of the calculation. The Cu-O(eq), Cu-Cl(eq), and Cu-O(ax) bond distances were finally determined to be 199, 220, and 239 pm, respectively.

Structure of the $[CuCl_3]^-$ Complex. Solution B contains the trichlorocuprate(II) complex as the main species. Figure 4a shows the $(D(r)-4\pi r^2\rho_o)$ curve (solid line) of the solution, in which four peaks are observed around 130, 225, 360, and 410 pm. The first peak at 130 pm is due to the C-H, C=O, and C-N bonds within DMF molecules. The large peak at 225 pm is expected to be due to the Cu-Cl bonds from the sum of their ionic radii and partly to the Cu-O bonds within the $[CuCl_3]^-$ complex if some solvent molecules coordinate to copper(II) ion. The peak might also contain peaks due to intramolecular nonbonding N···O, C···C, and C···O interactions of DMF. The Li-O contacts within the solvated lithium ions also contribute, in part, to the peak as have been shown by a study of solution X-ray diffraction of solvated lithium ions.[29] However, because of the low concentration of lithium ions in solution B and the

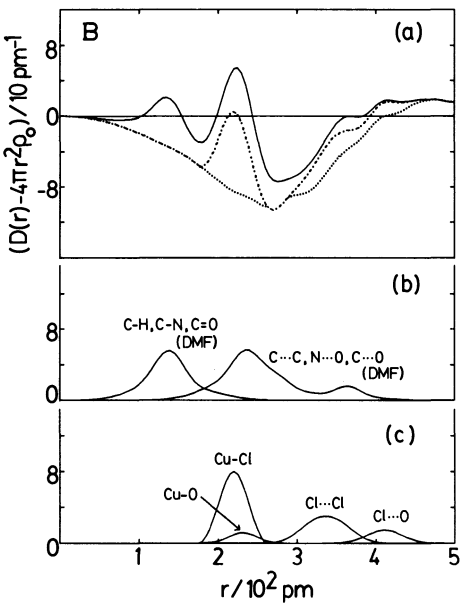

Fig. 4. (a) The $(D(r)-4\pi r^2\rho_o)$ curve for solution B, (b) The theoretical peaks for intramolecular interactions within DMF molecule. (c) The theoretical peak shapes due to the Cu-Cl, Cu-O, Cl···Cl, and Cl···O interactions within the trichloromono(*N*,*N*-dimethylformamide)cuprate(II) complex. The chain and dotted lines represent the residual curves after subtraction of the theoretical peaks in (b) and (c), respectively.

weak scattering power of lithium atom, the contribution of the solvated lithium ions to the scattered intensities is not significant, and it was neglected in the course of the data analysis. The third and fourth peaks around 360 and 410 pm, respectively, could be ascribed to the interligand interactions within the $[CuCl_3]^-$ complex.

After subtracting the theoretical peak shapes due to the intramolecular interactions within DMF molecules from the original curve, the residual curve expressed by the chain line (Fig. 4a) shows the predominant peak centered at 220 pm which can be attributed to the bonds between copper and ligand atoms in the trichlorocuprate(II) complex. The structure parameters of the complex were evaluated from the shape of the peak at 220 pm by a trial-and-error method. From the analysis a possibility of a dimeric structure ($[Cu_2Cl_6]^{2-}$) of the complex found in crystals[6-8] was ruled out since the peak area is appreciably smaller than that corresponding to four Cu-Cl bonds. The peak is well-reproduced by assuming three Cu-Cl bonds and one Cu-O bond with the lengths of 220 and 230 pm, respectively, as seen in Fig. 4a (dotted line). The Cu-O distance is also reasonably expected from the interligand interactions as discussed in the following section. The calculated $s \cdot i(s)$ values based on the structural model of $[CuCl_3(dmf)]^-$ give a better fit to the experimental ones than those of the trianglar or pyramidal $[CuCl_3]^-$ structure without a DMF molecule and of the $[Cu_2Cl_6]^{2-}$ dimer structure over $s>6\times10^{-2}$ pm^{-1}, where the intramolecular interactions within the complex and those of DMF molecules mainly contribute to the $s \cdot i(s)$ curve.

In the residual curve (chain line in Fig. 4a) two peaks, besides the peak at 220 pm, appear at about 350 and 410 pm which may be attributable to various combinations of nonbonding Cl···Cl and Cl···O interactions within the $[CuCl_3(dmf)]^-$ complex. These peaks could not be originated from a square-planar structure with the Cu-Cl bond length of 220 pm. The two peaks at 350 and 410 pm are only explainable when the complex has a distorted tetrahedral structure with the Cu-Cl and Cu-O bond distance of 220 and 230 pm, respectively.

A least-squares method was applied to the high-angle region ($s>4\times10^{-2}$ pm^{-1}) of the $s \cdot i(s)$ curve in order to refine the structural parameters obtained for the $[CuCl_3(dmf)]^-$ complex by a trial-and-error method. The initial structure parameter values inserted were those estimated from the analysis of the radial distribution curve as mentioned previously. In the course of the calculation the frequency factors of each interatomic interaction were kept at the same values as those obtained from the distorted tetrahedral model of the complex. The results are summarized in Table 3. The Cu-Cl and Cu-O lengths are finally evaluated to be 219 and 230 pm, respectively.

Structure of the $[CuCl_4]^{2-}$ Complex. The radial distribution curves for solutions C and D illustrated in Figs. 5 and 6, respectively, were analyzed by essentially the same procedure as that employed for solution B. Since the analysis of the intensity data by assuming the sole $[CuCl_4]^{2-}$ complex as the predominant species gave slightly different results between solutions C and D for the structure parameters of the complex, we can not neglect the $[CuCl_3(dmf)]^-$ complex coexisting in the solutions. The concentrations of the $[CuCl_3(dmf)]^-$ complex in solutions C and D are estimated to be 30 and 20 mol%, respectively, from the stability constants reported for the 1 mol dm^{-3} $LiClO_4$ DMF solution.[19]

Subtraction of theoretical peaks due to the C-H, C=O, C-N, N···O, C···C, and C···O interactions within DMF molecules and the Cu-Cl, Cu-O, Cl···Cl, and Cl···O pairs within the $[CuCl_3(dmf)]^-$ complex (Figs. 5b and 6b) from the radial distribution curve experimentally obtained leads to a residual curve

Table 3. Results of the Least-Squares Refinements of Solution B. Standard Deviations Are Given in Parentheses

Interaction	Parameter	B-I ($s>4\times10^{-2}$ pm^{-1})	B-II ($s>5\times10^{-2}$ pm^{-1})

a) The interatomic distances and bond angles are averaged values.

(chain line in Figs. 5a and 6a), in which a major peak and two humps appear at 225, 350, and 410 pm. The peak at 225 pm is ascribable to the Cu-Cl bonds within the $[CuCl_4]^{2-}$ complex. The peak area corresponds to four Cu-Cl interactions and was found no evidence that any solvent molecule coordinated to copper(II) ion. The two humps at 350 and 410 pm, which are attributable to the nonbonding Cl···Cl interactions within the $[CuCl_4]^{2-}$ complex suggest that the complex has not a regular tetrahedral structure which should give only one peak originating from six Cl···Cl pairs at about 370 ($=225\times\sqrt{8/3}$) pm.

The structure of the $[CuCl_4]^{2-}$ complexes with various cations in crystal[9-18] can be classified into two groups; complexes in the first group are those having a square-planar structure (D_{4h} symmetry) and the others have a flattened tetrahedral structure (D_{2d} symmetry). Crystallographic data of these complexes are summarized in Table 4. In the square-planar complexes the Cu-Cl bond length is 226—232 pm, which is slightly longer than the Cu-Cl bond within the distorted tetrahedral complexes (r_{Cu-Cl}=220—226 pm). The nonbonding Cl···Cl distances within the square-planar complexes are in the range of 320—330 pm for four Cl···Cl interactions and 450—460 pm for the other two Cl···Cl interactions, while the distorted tetrahedral complexes have slightly longer Cl···Cl interactions for four Cl···Cl pairs (330—350 pm) but shorter Cl···Cl ones for the other two (400—420 pm). Since two humps are observed at 350 and 410 pm for solutions C and D (Figs. 5a and 6a, respectively), we conclude that the $[CuCl_4]^{2-}$ complex has a distorted tetrahedral structure with D_{2d} symmetry.

The structure parameters for the $[CuCl_4]^{2-}$ complex were finally determined by a least-squares calculation for the $s\cdot i(s)$ values over the range $s>4\times10^{-2}$ pm^{-1}. The refinement was carried out by floating the values of interatomic distances and temperature factors of the complex as independent variables, while the frequency factors of the interactions were kept unchanged. The results obtained for solutions C and D are summarized in Table 5. Essentially the same results were obtained for both solutions. The Cu-Cl bond length thus determined is 226 pm and the nonbonding Cl···Cl distances are 346 and 412 pm. The Cl-Cu-Cl bond angles are 100° and 131° in the complex.

The structure of the $[CuCl(dmf)_5]^+$ complex is distorted octahedral as the $[Cu(dmf)_6]^{2+}$ ion is. The Cu-O(eq) bond length (199(1) pm) within the $[CuCl(dmf)_5]^+$ is practically the same as that within the $[Cu(dmf)_6]^{2+}$ (203(3) pm).[27]

Both $[CuCl_3(dmf)]^-$ and $[CuCl_4]^{2-}$ complexes have a distorted tetrahedral structure. The Cu-O bond length (230(13) pm) within the $[CuCl_3(dmf)]^-$ complex is significantly longer than that of the equatorial Cu-O bonds in the $[Cu(dmf)_6]^{2+}$(203(3) pm)[27] and the $[CuCl(dmf)_5]^+$(199(1) pm). The DMF molecule within the trichlorocuprate(II) complex much more weekly solvates the central metal ion than the DMF molecules within the $[Cu(dmf)_6]^{2+}$ and $[CuCl(dmf)_5]^+$ complexes. On the other hand, the Cu-Cl distance of 225(1) pm within the $[CuCl_4]^{2-}$ complex is longer than that (219(1) pm) in $[CuCl_3(dmf)]^-$. The lengthening of the coordination bond with an increase in the number of chloride ions bound to the copper(II) ion may be caused by an increase in the electron donation of the chloride ions coordinated to the central metal ion and in the electrorepulsive force among the ligands.

The work has been financially supported by the Grant-in-Aid for Special Project Research No. 61134043 from the Ministry of Education, Science and Culture. Computer calculations were performed at the computer center of the Institute for Molecular Science in Okazaki.

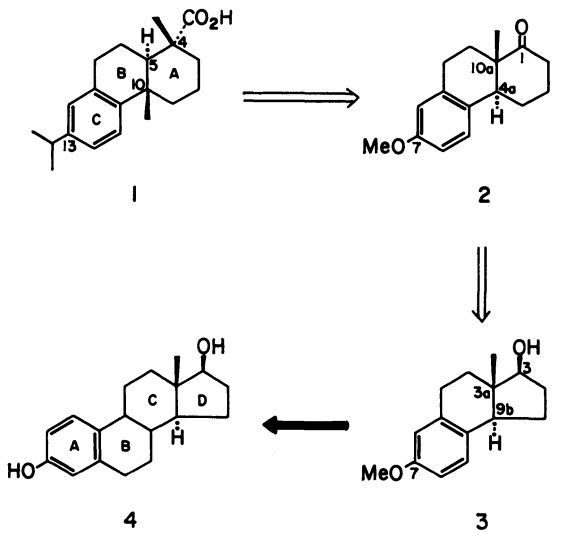
(Received April 24, 1987)

A resin acid, (+)-dehydroabietic acid, was converted into 3,4,4a,9,10,10a-hexahydro-7-methoxy-10aβ-methyl-4aαH-phenanthren-1(2H)-one (**2**) by the introduction of oxygen functions at the C-4 and C-13 positions, and a rearrangement of the angular methyl group to the C-5 position. The hydrophenanthrene derivative **2** was further transformed into 2,3,3a,4,5,9b-hexahydro-7-methoxy-3aβ-methyl-9bαH-1H-benz[e]inden-3β-ol (**3**). Since the conversion of **3** into steroidal hormones has already been reported, the present synthesis can be regarded as the synthesis of steroidal hormones from (+)-dehydroabietic acid.

The conversion of (+)-dehydroabietic acid (**1**) into steroidal compounds has been attempted by several groups.[1-4] Jeger et al. have reported the transformation of **1** into 3-oxo-17β-acetoxy-14α-methyl-Δ^4-8α,9β,10α,13α-esterene. However, other groups have carried out only partial modifications of **1**, and have not reported the synthesis of natural steroids. We have also investigated the utilization of **1** as a starting material for the syntheses of optically active steroids. In this paper, we describe the transformation of **1** into 2,3,3a,4,5,9b-hexahydro-7-methoxy-3aβ-methyl-9bαH-1H-benz[e]inden-3β-ol (**3**), a useful intermediate for the syntheses of steroidal hormones, which has already been converted into estradiol (**4**), adrenosterone, and so on.[5] Our basic strategy for the synthesis of steroidal hormones is the modification of the A, B, and C rings in the diterpene skeleton to the D, C, and B rings of the steroidal skeleton, as shown in Scheme 1. Namely, (+)-dehydroabietic acid (**1**) was converted into 3,4,4a,9,10,10a-hexahydro-7-methoxy-10aβ-methyl-4aαH-phenanthren-1(2H)-one (**2**) by the introduction of oxygen functions at the C-4 and C-13 positions, and a rearrangement of the angular methyl group at the C-10 position to the C-5 position. Ring contraction of the cyclohexanone moiety in **2** gave the corresponding cyclopentanol derivative **3**.



Scheme 1.

The oxidation of (+)-dehydroabietic acid (**1**) with chromium trioxide and acetic anhydride in acetic acid, followed by alkaline hydrolysis in refluxing diethylene glycol, afforded 13-acetyl-7-oxo-8,11,13-podocarpatrien-18-oic acid[6] (**5**: 8%) and 15-hydroxy-7-oxo-8,11,13-abietatrien-18-oic acid (**6**: 26%). The acid **6** was treated with diazomethane in ether and the resulting ester **7** (97%) was oxidized with t-butyl hydroperoxide in acetic acid containing concentrated sulfuric acid to give methyl 13-hydroxy-7-oxo-8,11,13-podocarpatrien-18-oate[6] (**8**: 76%). This compound **8** was also obtained in 32% yield from **5** by a series of reactions: esterification with diazomethane, Baeyer–Villiger oxidation with m-chloroperbenzoic acid, and alkaline hydrolysis. The methylation of **8** with methyl iodide and anhydrous potassium carbonate in refluxing ethyl methyl ketone gave a methyl ether **9** (97%), which was converted into methyl 13-methoxy-8,11,13-podocarpatrien-18-oate[7-9] (**10**: 87%) by acidic hydrogenolysis using Pd–C and perchloric acid in ethyl acetate. The Grignard reaction of **10** with phenylmagnesium bromide afforded a diphenylmethanol derivative **11** in 81% yield, which was then treated with lead tetraacetate and calcium carbonate in refluxing benzene to give a mixture of Δ^3, Δ^4, and $\Delta^{4(18)}$-19-nor compounds **12** in 70% yield. Ozonolysis of **12** in dichloromethane afforded 3,4,4a,9,10,10a-hexahydro-7-methoxy-4aβ-methyl-10aαH-phenanthren-1(2H)-one (**13**) in 60% yield. This ketone **13** was transformed into a tetraene compound **15** (93%) via a mesylate **14** by a series of reactions: lithium aluminium hydride reduction, mesylation, and refluxing with 2,4-lutidine. Subsequently, a rearrangement of the angular methyl group at the C-4a position to the C-10a position was carried out as follows. Epoxidation of **15** with m-chloroperbenzoic acid, followed by treatment with boron trifluoride etherate in dichloromethane, afforded a rearranged alcohol (**16**)[10] in 52% yield. This was then hydrogenated over Pd–C in ethanol to give 1,2,3,4,4a,9,10,10a-octahydro-7-methoxy-10aβ-methyl-4aαH-phenanthren-1β-ol (**17**: 99%) which gave an acetate **18** (96%). The β-configuration of the hydroxyl group in **17** was

supported from its ^1H NMR spectrum, which showed a broad signal due to the C-1 proton at δ 3.1—3.5, suggesting the presence of an axial α proton. Oxidation of **17** with pyridinium chlorochromate in dichloromethane afforded the desired ketone **2** in 89% yield.

According to the method of Rao and Banerjee,[11] the ketone **2** was submitted to oxidative cleavage with potassium hypoiodite and subsequent esterification with diazomethane to afford a dimethyl ester **19** in 49% yield. Dieckmann cyclization of **19** with potassium *t*-butoxide in refluxing benzene, followed by hydrolysis and subsequent decarboxylation, produced 3a,4,5,9b-tetrahydro-7-methoxy-3aβ-methyl-9bαH-1H-benz-[*e*]inden-3(2H)-one (**20**) in 78% yield. This was reduced with lithium aluminium hydride in ether to give the desired alcohol **3** in 91% yield.

Since the syntheses of steroidal hormones from **3** have already been reported, the present synthesis of **3** can be regarded as the synthesis of steroidal hormones from a resin acid, (+)-dehydroabietic acid (**1**).

Experimental

All melting points are uncorrected. The IR spectra and optical rotations were measured in chloroform, and the ^1H NMR spectra in carbon tetrachloride at 60 MHz, with tetramethylsilane as an internal standard, unless otherwise stated; s: singlet, bs: broad singlet, d: doublet, bd: broad doublet, dd: double doublet, t: triplet, m: multiplet. The column chromatography was performed using Merck silica gel (0.063 mm).

Oxidation of (+)-Dehydroabietic Acid (1) with Chromium Trioxide. Chromium trioxide (43.0 g) was added to a stirred solution of (+)-dehydroabietic acid (**1**) (30.0 g) and acetic anhydride (200 ml) in acetic acid (150 ml) with cooling in a water bath at 15—25 °C over a period of 2 h. After stirring at room temperature for 1 h, methanol (75 ml) was added dropwise to the stirred mixture with cooling in an ice-water bath at 10—15 °C over a period of 1 h. The mixture was concentrated in vacuo, diluted with water, and extracted with benzene. The benzene extract was washed with brine, dried over sodium sulfate, and evaporated in vacuo. The residue was chromatographed on silica gel (Mallinckrodt CC-4, 150 g) using ether-benzene (1:9 and then 3:7) as eluents, to give a mixture (25.1 g) of 15-acetoxy-7-oxo-8,11,13-abietatrien-18-oic acid and 13-acetyl-7-oxo-8,11,13-podocarpatrien-18-oic acid (**5**).[6]

The above mixture (25.1 g) was refluxed with aqueous potassium hydroxide (25%, 30 ml) in diethylene glycol (100 ml) for 2 h. The mixture was cooled, acidified with dilute hydrochloric acid, and extracted with ether. The ether extract was washed with brine, dried, and evaporated in vacuo. The residue was chromatographed on silica gel (Mallinckrodt CC-4, 300 g), using ether-benzene (15:85) as the eluent, to give **5** (2.6 g:8.3%). This was recrystallized from a mixture of acetone and hexane, mp 192—193.5 °C, $[\alpha]_D$ +29.7° (*c* 3.61), IR 3600—2300 and 1686 cm^{-1}, ^1H NMR ($CDCl_3$) δ=1.30 (3H, s) and 1.38 (3H, s) (C_4-CH_3 and C_{10}-CH_3), 2.63 (3H, s, -$COCH_3$), 7.48 (1H, d, J=8 Hz, C_{11}-H), 8.13 (1H, dd, J=8 and 2 Hz, C_{12}-H), 8.52 (1H, d, J=2 Hz, C_{14}-H), 9.5 (1H, bs, -CO_2H). Found: C, 72.41; H, 7.35%. Calcd for $C_{19}H_{22}O_4$:C, 72.59; H, 7.05%. Further elution with ether-benzene (35:65) gave 15-hydroxy-7-oxo-8,11,13-abietatrien-18-oic acid (**6**) (8.4 g:25.5%). This was recrystallized from benzene, mp 118—120 °C, $[\alpha]_D$ +10.4° (*c* 5.21), IR 3600—2300, 1698, and 1682 cm^{-1}, ^1H NMR ($CDCl_3$) δ=1.27 (3H, s) and 1.35 (3H, s) (C_4-CH_3 and C_{10}-CH_3), 1.58 (6H, s, -$C(CH_3)_2OH$), 7.34 (1H, d, J=9 Hz, C_{11}-H), 7.74 (1H, dd, J=9 and 2 Hz, C_{12}-H), 8.06 (1H, d,

J=2 Hz, C_{14}-H). Found: C, 72.40; H, 7.99%. Calcd for $C_{20}H_{26}O_4$: C, 72.70; H, 7.93%.

Methyl 15-Hydroxy-7-oxo-8,11,13-abietatrien-18-oate (7). The acid **6** (3.325 g) was treated with an ethereal diazomethane solution at room temperature for 30 min. After the usual work-up, the crude product was chromatographed on silica gel (0.063—0.200 mm, 120 g), using ether-benzene (3:7) as the eluent, to give an oily **7** (3.355 g:96.8%), $[\alpha]_D$ +15.0° (*c* 6.00), IR 3594, 1720, and 1678 cm^{-1}; ^1H NMR δ=1.23 (3H, s) and 1.30 (3H, s) (C_4-CH_3 and C_{10}-CH_3), 1.51 (6H, s, -C(CH_3)$_2$OH), 3.63 (3H, s, -CO_2CH_3), 7.21 (1H, d, J=8 Hz, C_{11}-H), 7.62 (1H, dd, J=8 and 2 Hz, C_{12}-H), 7.87 (1H, d, J=2 Hz, C_{14}-H). Found: C, 73.43; H, 8.11%. Calcd for $C_{21}H_{28}O_4$: C, 73.22; H, 8.19%.

Methyl 13-Hydroxy-7-oxo-8,11,13-podocarpatrien-18-oate (8). *a*): A stirred mixture of **7** (5.973 g), *t*-butyl hydroperoxide (70%, 5.0 ml), and concentrated sulfuric acid (1.2 ml) in acetic acid (59 ml) was heated at 50 °C for 3 h. The mixture was cooled, poured into aqueous sodium hydrogencarbonate, and extracted with ether. The ether extract was washed with brine, dried, and evaporated in vacuo. The residue was chromatographed on silica gel (0.063—0.200 mm, 60 g), using ether-benzene (1:9) as the eluent, to give **8** (3.966 g:75.6%). This was recrystallized from benzene, mp 197—198.5 °C, $[\alpha]_D$ −11.4° (*c* 7.47), IR 3325, 1720, and 1675 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.22 (3H, s) and 1.33 (3H, s) (C_4-CH_3 and C_{10}-CH_3), 3.65 (3H, s, -CO_2CH_3), 7.02 (1H, dd, J=9 and 2.5 Hz, C_{12}-H), 7.22 (1H, d, J=9 Hz, C_{11}-H), 7.54 (1H, d, J=2.5 Hz, C_{14}-H), 7.83 (1H, bs, -OH). Found: C, 71.78; H, 7.49%. Calcd for $C_{18}H_{22}O_4$: C, 71.50; H, 7.33%.

b): The acid **5** (1.920 g) was treated with an ethereal diazomethane solution at room temperature for 30 min to give a crude ester (2.003 g), IR 1722 and 1685 cm^{-1}.

The above ester (2.003 g) was refluxed with *m*-chloroperbenzoic acid (85%, 1.218 g) and *p*-toluenesulfonic acid (18 mg) in 1,2-dichloroethane (18 ml) for 4 h. The mixture was cooled, diluted with ether, and washed successively with aqueous potassium iodide, aqueous sodium thiosulfate, aqueous sodium hydrogencarbonate, and brine. After removal of the solvent in vacuo, the residue was refluxed with sodium hydrogencarbonate (1.40 g) and water (10 ml) in methanol (40 ml) for 2 h. The mixture was concentrated in vacuo, diluted with water, and extracted with ether. The ether extract was washed with aqueous sodium hydroxide and water, dried, and evaporated in vacuo. The residue was chromatographed on silica gel (0.063—0.200 mm, 30 g), using ether-benzene (1:9) as the eluent, to give the recovered methyl 13-acetyl-7-oxo-8,11,13-podocarpatrien-18-oate (582 mg).

The alkaline washing was acidified with dilute hydrochloric acid and extracted with ether. The ether extract was washed with brine, dried, and evaporated in vacuo. The residue was chromatographed on silica gel (0.063—0.200 mm, 30 g), using ether-benzene (1:9) as the eluent, to give **8** (581 mg:31.6%), whose IR and ^1H NMR spectra were identical with those of the authentic sample.

Methyl 13-Methoxy-7-oxo-8,11,13-podocarpatrien-18-oate (9). A stirred mixture of **8** (8.778 g), methyl iodide (6.2 ml), and anhydrous potassium carbonate (25.0 g) in ethyl methyl ketone (90 ml) was refluxed for 8 h. The mixture was cooled, diluted with ether, and washed successively with water, aqueous sodium thiosulfate, and brine. The dried solution was evaporated in vacuo. The residue was chromatographed on silica gel (0.063—0.200 mm, 200 g), using ether-benzene (3:97) as the eluent, to give an oily **9** (8.917 g: 97.2%), $[\alpha]_D$ +11.4° (*c* 3.78), IR 1725 and 1676 cm^{-1}, ^1H NMR δ=1.21 (3H, s) and 1.30 (3H, s) (C_4-CH_3 and C_{10}-CH_3), 3.63 (3H, s, -CO_2CH_3), 3.79 (3H, s, -OCH_3), 6.92 (1H, dd, J=9 and 3 Hz, C_{12}-H), 7.19 (1H, d, J=9 Hz, C_{11}-H), 7.33 (1H, d, J=3 Hz, C_{14}-H). Found: C, 72.34; H, 7.69%. Calcd for $C_{19}H_{24}O_4$: C, 72.12; H, 7.65%.

Methyl 13-Methoxy-8,11,13-podocarpatrien-18-oate (10). A mixture of **9** (21.268 g), Pd-C (10%, 4.0 g), and perchloric acid (60%, 4.0 ml) in ethyl acetate (100 ml) was hydrogenated at room temperature under an atmosphere of hydrogen for 9 h. After the usual work-up, the crude product was recrystallized from methanol to give **10** (13.328 g:65.6%), mp 79.5—80 °C, $[\alpha]_D$ +60.7° (*c* 1.52), IR 1720 cm^{-1}, ^1H NMR δ=1.14 (3H, s) and 1.21 (3H, s)(C_4-CH_3 and C_{10}-CH_3), 3.60 (3H, s) and 3.67 (3H, s) (-CO_2CH_3 and -OCH_3), 6.40 (1H, bs, C_{14}-H), 6.50 (1H, dd, J=8 and 2 Hz, C_{12}-H), 6.99 (1H, d, J=8 Hz, C_{11}-H). Found: C, 75.41; H, 8.54%. Calcd for $C_{19}H_{26}O_3$: C, 75.46; H, 8.67%. The mother liquor of recrystallization was evaporated in vacuo. The residue was chromatographed on silica gel (150 g), using ether-benzene (1:99) as the eluent, to give an additional **10** (4.378 g:21.5%).

Grignard Reaction of 10 with Phenylmagnesium Bromide. A solution of **10** (3.975 g) in dry ether (25 ml) was added to a stirred ether solution of phenylmagnesium bromide prepared from magnesium turnings (1.60 g) and bromobenzene (6.9 ml) in dry ether (15 ml). The mixture was refluxed for 30 min and the ether was removed. The viscous residue was heated at 90—100 °C for 5.5 h. After cooling, the mass was hydrolyzed with a mixture of dilute hydrochloric acid and ice, and then extracted with ether. The ether extract was washed succesively with aqueous sodium thiosulfate and brine, dried, and evaporated in vacuo. The residue was chromatographed on silica gel (150 g), using hexane-benzene (1:4) as the eluent, to give a diphenylmethanol derivative **11** (4.555 g:81.2%). This was recrystallized from acetone-hexane, mp 178.5—182 °C, $[\alpha]_D$ +65.8° (*c* 3.71), IR 3580 cm^{-1}, ^1H NMR δ=1.17 (3H, s, C_{10}-CH_3), 1.32 (3H, s, C_4-CH_3), 3.58 (3H, s, -OCH_3), 6.18 (1H, d, J=2.5 Hz, C_{14}-H), 6.43 (1H, dd, J=9 and 2.5 Hz, C_{12}-H), 6.94 (1H, d, J=9 Hz, C_{11}-H), 7.0—7.9 (10H, m, 2-C_6H_5). Found: C, 84.22; H, 8.01%. Calcd for $C_{30}H_{34}O_2$: C, 84.46; H, 8.03%.

Oxidation of 11 with Lead Tetraacetate. A stirred mixture of **11** (8.316 g), lead tetraacetate (91.4%, 12.30 g), and calcium carbonate (10.60 g) in dry benzene (110 ml) was refluxed for 5 h. The mixture was cooled, diluted with ether and water, and then filtered. The filtrate was extracted with ether. The ether extract was washed successively with aqueous potassium iodide, aqueous sodium thiosulfate, aqueous sodium hydrogencarbonate, and brine. The dried solution was evaporated in vacuo. The crude product was chromatographed on silica gel (200 g), using hexane-benzene (9:1) as the eluent, to give 13-methoxy-19-norpodocarpa-4(18),8,11,13-tetraene (**12**) 3.307 g:70.0%) containing small amounts of Δ^3- and Δ^4-isomers. ^1H NMR δ=0.96 (3H, s, C_{10}-CH_3), 3.78 (3H, s, -OCH_3), 4.64 (1H, bs) and 4.79 (1H, bs) (-$\overset{|}{C}$=CH_2), 6.48 (1H, bs, C_{14}-H), 6.55 (1H, dd, J=9 and 3 Hz, C_{12}-H), 7.07 (1H, d, J=9 Hz, C_{11}-H). Found: C, 84.50; H, 9.08%. Calcd for $C_{17}H_{22}O$: C, 84.25; H, 9.15%.

3,4,4a,9,10,10a-Hexahydro-7-methoxy-4aβ-methyl-10aα*H*-phenanthren-1(2*H*)-one (13). A solution of **12** (1.937 g) in dichloromethane (20 ml) was ozonized at −65 °C for 1 h. The solution was evaporated in vacuo. The residue was heated with zinc powder (1.37 g) in aqueous acetic acid (50%, 46 ml) at 80 °C for 1 h and then filtered. The filtrate was concentrated in vacuo and extracted with ether. The ether extract was washed with aqueous sodium hydrogencarbonate and brine, dried, and evaporated in vacuo. The residue was chromatographed on silica gel (50 g), using ether–benzene (2:98) as the eluent, to give **13** (1.172 g:60.0%). This was recrystallized from hexane, mp 70.5—71 °C, $[\alpha]_D$ +189° (*c* 3.93), IR 1707 cm^{-1}, ^1H NMR δ=0.99 (3H, s, C_{4a}-CH_3), 3.70 (3H, s, -OCH_3), 6.47 (1H, bs, C_8-H), 6.55 (1H, dd, *J*=8 and 2.5 Hz, C_6-H), 7.07 (1H, d, *J*=8 Hz, C_5-H). Found: C, 78.49; H, 8.19%. Calcd for $C_{16}H_{20}O_2$: C, 78.65; H, 8.25%.

2,3,4,4a,9,10-Hexahydro-7-methoxy-4aβ-methylphenanthrene (15). A solution of **13** (940 mg) in dry ether (10 ml) was reduced with lithium aluminium hydride (73 mg) at room temperature for 1 h. The mixture was poured into dilute hydrochloric acid and extracted with ether. The ether extract was washed with brine, dried, and evaporated in vacuo. The residue was dissolved in pyridine (4.5 ml) and mesylated with methanesulfonyl chloride (0.45 ml) at room temperature for 19 h. The mixture was poured into dilute hydrochloric acid and extracted with ether; the extract was washed successively with aqueous sodium hydrogencarbonate and brine. The dried solution was evaporated in vacuo to give a crude mesylate **14** (1.210 g), IR 1340 and 1175 cm^{-1}, ^1H NMR δ=1.21 (3H, s, C_{4a}-CH_3), 2.92 (3H, s, -OSO_2CH_3), 3.70 (3H, s, -OCH_3), 4.85 (1H, $W_{1/2}$=6 Hz, C_1-H), 6.46 (1H, bs, C_8-H), 6.54 (1H, dd, *J*=9 and 3 Hz, C_6-H), 7.02 (1H, d, *J*=9 Hz, C_5-H).

A solution of the crude mesylate **14** (1.210 g) in 2,4-lutidine (4.0 ml) was refluxed for 2.5 h under a stream of nitrogen. The solution was cooled, poured into dilute hydrochloric acid, and extracted with ether. The ether extract was washed with brine, dried, and evaporated in vacuo. The crude product was chromatographed on silica gel (25 g), using hexane–benzene (1:1) as the eluent, to give **15** (815 mg:92.8% from **13**). This was recrystallized from hexane, mp 69—69.5 °C, $[\alpha]_D$ +233° (*c* 3.41), ^1H NMR δ=1.34 (3H, s, C_{4a}-CH_3), 3.70 (3H, s, -OCH_3), 5.39 (1H, br, C_1-H), 6.40 (1H, d, *J*=3 Hz, C_8-H), 6.60 (1H, dd, *J*=9 and 3 Hz, C_6-H), 7.06 (1H, d, *J*=9 Hz, C_5-H). Found: C, 83.95; H, 9.08%. Calcd for $C_{16}H_{20}O$: C, 84.16; H, 8.83%.

1,2,3,9,10,10a-Hexahydro-7-methoxy-10aβ-methyl-1β-phenanthrenol (16). A mixture of **15** (303 mg) and *m*-chloroperbenzoic acid (80%, 315 mg) in dichloromethane (10 ml) was stirred at room temperature for 2 h. The mixture was diluted with ether and washed successively with aqueous potassium iodide, aqueous sodium thiosulfate, aqueous sodium hydrogencarbonate, and water. The dried solution was evaporated in vacuo. The residual oil was dissolved in dichloromethane (4.0 ml) and boron trifluoride etherate (0.49 ml) was added at 2—8 °C. After stirring at 2—3 °C for 40 min, the mixture was diluted with ether, poured into dilute hydrochloric acid, and extracted with ether. The ether extract was washed with water, dried, and evaporated in vacuo. The crude product was chromatographed on silica gel (15 g), using ether–benzene (1:9) as the eluent, to give **16** (168 mg:51.8%). This was recrystallized from acetone–hexane, mp 133.5—135.5 °C, IR 3610 and 3435 cm^{-1}, ^1H NMR ($CDCl_3$) δ=1.01 (3H, s, C_{10a}-CH_3), 3.80 (3H, s, -OCH_3), 5.99 (1H, t, *J*=3.5 Hz, C_4-H), 6.62 (1H, s, C_8-H), 6.71 (1H, dd, *J*=9 and 2 Hz, C_6-H), 7.47 (1H, d, *J*=9 Hz, C_5-H). Found: C, 78.40; H, 8.35%. Calcd for $C_{16}H_{20}O_2$: C, 78.65; H, 8.25%.

1,2,3,4 4a,9,10,10a-Octahydro-7-methoxy-10aβ-methyl-4aα*H*-phenanthren-1β-ol (17) and Its Acetate (18). *a*): A mixture of **16** (69.3 mg) and Pd-C (5%, 30 mg) in ethanol (15 ml) was hydrogenated at room temperature under an atmosphere of hydrogen for 3 h. After the usual work-up, the product **17** (69.0 mg:98.8%) was recrystallized from hexane, mp 100—101.5 °C, IR 3610 and 3450 cm^{-1}, ^1H NMR δ=0.69 (3H, s, C_{10a}-CH_3), 3.1—3.5 (1H, m, C_1-H), 3.73 (3H, s, -OCH_3), 6.35—6.65 (2H, m, C_6-H and C_8-H), 6.99 (1H, d, *J*=9 Hz, C_5-H). Found: C, 78.04; H, 9.27%. Calcd for $C_{16}H_{22}O_2$: C, 78.01; H, 9.00%.

b): A solution of **17** (39.0 mg) and acetic anhydride (0.5 ml) in pyridine (0.5 ml) was heated at 75—80 °C for 2 h. After the usual work-up, the crude product was chromatographed on silica gel (5.0 g), using benzene as the eluent, to give an acetate **18** (44.5 mg:96.2%). This was recrystallized from hexane, mp 141.5—142 °C, IR 1720 cm^{-1}, ^1H NMR (90 MHz) δ=0.75 (3H, s, C_{10a}-CH_3), 1.97 (3H, s, -$OCOCH_3$), 3.69 (3H, s, -OCH_3), 4.45—4.7 (1H, m, C_1-H), 6.49 (1H, s, C_8-H), 6.54 (1H, dd, *J*=9 and 3 Hz, C_6-H), 6.99 (1H, d, *J*=9 Hz, C_5-H). Found: C, 74.81; H, 8.61%. Calcd for $C_{18}H_{24}O_3$: C, 74.97; H, 8.39%.

Oxidation of 17 into 3,4,4a,9,10,10a-Hexahydro-7-methoxy-10aβ-methyl-4aα*H*-phenanthren-1(2*H*)-one (2). A mixture of **17** (38.0 mg) and pyridinium chlorochromate (56.5 mg) in dichloromethane (3.0 ml) was stirred at 0—5 °C for 5 min and at room temperature for 3 h. After the addition of aqueous sodium hydrogencarbonate, the mixture was extracted with ether. The ether extract was washed with water, dried, and evaporated in vacuo. The crude product was chromatographed on silica gel (5.0 g), using benzene as the eluent, to give **2** (34.1 mg:89.3%). This was recrystallized from hexane, mp 91—92 °C, IR 1701 cm^{-1}, ^1H NMR δ=0.94 (3H, s, C_{10a}-CH_3), 3.73 (3H, s, -OCH_3), 6.51 (1H, s, C_8-H), 6.58 (1H, dd, *J*=9 and 2 Hz, C_6-H), 7.05 (1H, d, *J*=9 Hz, C_5-H). Found: C, 78.48; H, 8.46%. Calcd for $C_{16}H_{20}O_2$: C, 78.65; H, 8.25%.

Methyl 1,2,3,4-Tetrahydro-6-methoxy-2α-methoxycarbonyl-2β-methyl-1α*H*-naphthalene-1-propionate (19). A solution of **2** (164.7 mg) in methanol (14 ml) was treated alternately with three drops of a solution of iodine (494.1 mg) in methanol (8.2 ml) and one drop of a solution of potassium hydroxide (889.4 mg) in water (1.8 ml) and methanol (4.9 ml) with vigorous stirring at room temperature under a stream of nitrogen over a period of 1 h. The mixture was allowed to stand at room temperature for 23 h and the methanol was removed in vacuo. The residue was acidified with dilute hydrochloric acid and extracted with ether. The ether extract was washed successively with water, aqueous sodium thiosulfate, and water. The dried solution was evaporated in vacuo and the residue was treated with ethereal diazomethane solution at room temperature for 30 min. After the usual work-up, the crude product was chromatographed on silica gel (10 g), using ether–benzene (1:99) as the eluent, to give an oily **19** (104.7 mg:48.5%), IR 1728 cm^{-1}, ^1H NMR δ=1.22 (3H, s, C_2-CH_3), 3.45 (3H, s) and 3.58 (3H, s) (2-CO_2CH_3), 3.69 (3H, s, -OCH_3), 6.43 (1H, bs),

6.51 (1H , dd, J=9 and 3 Hz), and 6.82 (1H, d, J=9 Hz) (aromatic protons). Found: C, 67.65; H, 7.79%. Calcd for $C_{18}H_{24}O_5$: C, 67.48; H, 7.55%.

3a,4,5,9b-Tetrahydro-7-methoxy-3aβ-methyl-9bα*H*-1*H*-benz[*e*]inden-3(2*H*)-one (20). A stirred mixture of **19** (63.0 mg) and potassium *t*-butoxide (220.6 mg) in dry benzene (4.5 ml) was refluxed for 5 h under a stream of nitrogen. The mixture was cooled, poured into dilute hydrochloric acid, and extracted with ether. The ether extract was washed with water, dried, and evaporated in vacuo to give an oil (60 mg).

A mixture of the above oil (60 mg), concentrated hydrochloric acid (1.5 ml), and water (0.4 ml) in acetic acid (3.0 ml) was refluxed for 1.5 h under a stream of nitrogen. The mixture was evaporated in vacuo. The residue was dissolved in methanol (5.5 ml) and aqueous sodium hydroxide (5%, 4.0 ml), and then refluxed for 1 h under a stream of nitrogen. After removal of the methanol in vacuo, the residue was extracted with ether. The ether extract was washed with water, dried, and evaporated in vacuo. The crude product was chromatographed on silica gel (10 g), using ether-benzene (2:98) as the eluent, to give **20** (35.2 mg:77.7%). This was recrystallized from hexane, mp 115.5—116.5 °C, $[\alpha]_D$ +5° (c 1.2), IR 1734 cm^{-1}, ^1H NMR δ=0.68 (3H, s, C_{3a}-CH_3), 3.73 (3H, s, -OCH_3), 6.4—6.7 (2H, m) and 6.90 (1H, d, J=9 Hz) (aromatic protons). Found:C, 78.19; H, 7.92%. Calcd for $C_{15}H_{18}O_2$: C, 78.23; H, 7.88%.

2,3,3a,4,5,9b-Hexahydro-7-methoxy-3aβ-methyl-9bα*H*-1*H*-benz[*e*]inden-3β-ol (3). A mixture of **20** (24.0 mg) and lithium aluminium hydride (10.0 mg) in dry ether (2.0 ml) was stirred at room temperature for 1 h. The mixture was poured into dilute hydrochloric acid and extracted with ether. The ether extract was washed with brine, dried, and evaporated in vacuo. The residue was chromatographed on silica gel (6.0 g), using ether-benzene (5:95) as the eluent, to give **3** (22.1 mg:91.3%). This was recrystallized from hexane, mp 72.5—73 °C[12] (lit,[5] mp 69 °C), IR 3610 and 3430 cm^{-1}, ^1H NMR δ=0.61 (3H, s, C_{3a}-CH_3), 3.72 (3H, s, -OCH_3), 6.4—6.9 (3H, m, aromatic protons). ^1H NMR (C_5D_5N) δ=0.89 (3H, s, C_{3a}-CH_3), 3.69 (3H, s, -OCH_3), 6.7—7.3 (3H, m, aromatic protons). Found: C, 77.56; H, 8.74%. Calcd for $C_{15}H_{20}O_2$: C, 77.55; H, 8.68%.

Friedel-Crafts Acetylations of Methoxy-4*H*-cyclopenta[*def*]-phenanthrenes and the 4-Ketones

Masahiro MINABE,* Masaaki YOSHIDA, Yutaka TAKABAYASHI, and Masatoshi MASUDA
Department of Industrial Chemistry, Faculty of Engineering, Utsunomiya University, Ishiicho, Utsunomiya 321
(Received June 27, 1987)

Acetylations of 2- and 3-methoxy-4*H*-cyclopenta[*def*]phenanthrene gave predominantly the 1- and 8-acetyl derivatives, respectively. The acetylation of the 1-methoxy compound afforded the 2-, 3-, 5-, 7-, and 8-yl ketones and the reaction of the 8-methoxy derivative yielded the 1- and 3-acetyl derivatives. Similar reactions of 1-, 2-, 3-, and 8-methoxy-4*H*-cyclopenta[*def*]phenanthren-4-one occurred mainly at the 2-, 1-, 8-, and 9-positions, respectively.

The hydrocarbon, 4*H*-cyclopenta[*def*]phenanthrene is one of the interesting polycyclic aromatic hydrocarbons[1] because of the combination of their ring moieties and for carcinogenic screening tests. Our previous papers concerned the electrophilic substitution of electron-attractive acetyl-, bromo-, and nitro-4*H*-cyclopenta[*def*]phenanthrenes[2] and the bromination of cyclopentaphenanthrenamine derivatives having an electron-donating property.[3]

The present paper deals with the Friedel–Crafts acetylations of 1- (**1a**), 2- (**2a**), 3- (**3a**), 8-methoxy- (**4a**), and 8,9-dihydro-2-methoxy-4*H*-cyclopenta[*def*]-phenanthrene(**5a**) in order to obtain further information regarding the reactivities of the parent hydrocarbon with electrophiles. It also concerns the acylation of the methoxy ketones, **6a—10a** (Scheme 1).

Acetylations of **1a—4a** were carried out according to the modified Perrier procedure[4] by means of the addition of a substrate into the resulting mixture of acetic anhydride and aluminium chloride. The reaction mixture was analyzed by means of gas chromatographic technique (Table 1). The reaction of **1a** afforded 2- (**1b**), 3- (**1c**), 5- (**1d**), 7- (**1e**), and 8-acetyl compound (**1f**). The reactions of **2a** and **3a** gave predominantly 2-methoxy-1-acetyl compound **2b** and 3-methoxy-8-acetyl derivative **3b**, respectively. The acetylation of **4a** yielded two isomers, **4b** and **4c**. Similar trends were observed in the case of acetyl chloride as the acylating agent.[5]

The orientations on these reactions can be explained by the combination of reactivities of methoxynaphthalene[6] and of parent 4*H*-cyclopenta[*def*]phenanthrene;[7] electrophile attacks mainly the 1- and 3-positions of the latter accompanied by a substitution at the 2- and 8-positions. The formations of **1c**, **1d**, and **1e** from **1a** are due to the original reactivity of the parent hydrocarbon. Also, the production of **1b** and **1f** (and a part of **1c**) are due to the 1-methoxy group

4a	2.2	90	20	8	37		63				88
4a	2.2	90	75	40	31		69				60
4a	3.3	90	20	86	67		33				13

which may accelerate the 2- and 8-positions by a resonance effect, as is 1-methoxynaphthalene. The reactions of **2a**, **3a**, and **4a** are postulated to be those of 2-methoxynaphthalene derivatives in which the 1-, 6-, and 8-positions are accelerated.

The methoxyl group on **2a** and **3a** enhances the acylation more than the case of **1a** and **4a**. Experiments at different temperatures show that the formation of **1b** is kinetically controlled and that the formations of **1c** and **1d** are thermodynamically controlled. Also **4b** and **4c** are formed from **4a** under kinetic and thermodynamic controls under these conditions. The molar ratio of aluminium chloride against the substrate influences not only the reaction rate but also the regioselectivities.[6] An increase in the ratio causes an acceleration of the reaction and gives kinetically-controlled products, such as **1b** and **4b**.

The acetylation of **5a** afforded predominantly **5b**. The second attack of the reagent occurred at the 1-position, giving 1,6-diacetyl compound **5c**. The reactivity at the 6-position of **5a** is accelerated by the methoxy group more than that of the 7-position of 2-methoxyfluorene.[8]

4*H*-Cyclopenta[*def*]phenanthren-4-one is less reactive to electrophile than the parent hydrocarbon and the reaction of the ketone occurs mainly at the 8-position accompanied by the minor 2-isomer.[9] The next interesting point concerns the Friedel-Crafts acetylations of 4-oxo derivatives of **1a—5a**. The reaction of **6a** afforded **6b** as the main product and **6c** as the minor product. The acetylation of **7a** occurred giving 1-acetyl-2-methoxy compound **7b** and the acetyl phenol **7c**. The isomeric **8a** gave the corresponding **8b**, and the another isomer, **9a** yielded **9b**. Also, the substitution of **10a** produced **10b**.

Because of the low reactivity due to the 4-carbonyl, the reaction required a long time in the presence of a large amount of acylating complex. A substitution adjacent to the methoxyl group causes a fission of the methyl group followed by the formation of a chelate ring, such as **6b**, **7c**, or **9b**, under these conditions.

The reactive position of **6a**, **7a**, **8a**, and **10a** are similar to that of **1a**, **2a**, **3a**, and **5a**, respectively. On the other hand, the excited position of **9a** to the electrophile is the 9-position, differing from the case of **4a**, but the same as that of *N*-acetyl-4*H*-cyclopenta[*def*]phenanthren-8-amine.[3] This should be simply interpreted as indicating that the 8-methoxy group is not an effective electron-donating group compared to the amino and acetylamino groups, and affects only on the adjacent 9-position of the deactivated ketone.

Experimental

All the melting points are uncorrected. The ^1H NMR spectra were measured using a Jeol JNM C-60 HL or a Varian VXR-300 spectrometer in $CDCl_3$ using TMS as an internal reference. The IR (KBr-pellet), UV data (cyclohexane), and mass spectra were recorded on a Jasco IR-G, a Shimadzu UV-180, and a Hitachi M-80 spectrometer, respectively.

1-Methoxy-4*H*-cyclopenta[*def*]phenanthrene (1a).[10] To a mixture of 4*H*-cyclopenta[*def*]phenanthren-1-ol[11] (434 mg, 2.1 mmol) in acetone (5 ml) was added aq KOH (1.12 g, 20 mmol) in H_2O (1 ml), and Me_2SO_4 (0.66 ml, 7 mmol) was added dropwise at room temperature giving 434 mg (90%) of **1a**: mp 99—100 °C (lit,[10] mp 96—98 °C); IR, 1241 cm^{-1}; ^1H NMR, δ=4.06 (3H, s), 4.29 (2H, s), 7.01 (1H, d, J=7.6 Hz), 7.58—7.66 (3H, m), 7.78—7.82 (2H, m), and 8.02 (1H, d, J=9.0 Hz); UV, λ_{max} 352 (log ε 3.62), 345 (3.16), 335 (3.45), 328 (3.16), 311 (4.13), 298 (4.08), 270 (4.36), 261 (4.44), and 252 nm (4.42); MS, m/z 220 (M^+) and 205. Found: C, 87.08; H, 5.69%. Calcd for $C_{16}H_{12}O$: C, 87.24; H, 5.49%.

2a; yield 95%; mp 86—87 °C; IR, 1192 cm^{-1}; ^1H NMR, δ=3.99 (3H, s), 4.31 (2H, s), 7.28 (1H, s), 7.36 (1H, s), 7.54—7.66 (2H, m), and 7.75—7.84 (3H, m); UV, λ_{max} 357 (log ε 3.53), 350 (3.17), 339 (3.33), 333 (3.08), 324 (3.03), 301 (3.99), 289 (4.00), 280 (4.12), and 257 nm (4.87); MS, m/z 220 (M^+), 205, and 177. Found: C, 87.22; H, 5.76%.

3a; yield 87%; mp 47—48 °C; IR, 1242 cm^{-1}; ^1H NMR, δ=4.01 (3H, s), 4.24 (2H, s), 7.06 (1H, d, J=8.4 Hz), and 7.39—7.72 (6H, m); UV, λ_{max} 349 (log ε 3.37), 342 (2.99), 333 (3.26), 312 (4.14), 300 (4.16), 277 (4.11), and 250 nm (4.70); MS, m/z 220 (M^+) and 205. Found: C, 87.43; H, 5.36%.

4a; yield 88%; mp 129—130 °C; IR, 1148 cm^{-1}; ^1H NMR, δ=4.12 (3H, s), 4.33 (2H, s), 7.04 (1H, s), 7.56—7.73 (5H, m), and 8.00 (1H, dd, J=7.9, 0.7 Hz); UV, λ_{max} 346 (log ε 3.29), 339 (2.92), 330 (3.19), 309 (3.92), 297 (4.08), and 248 nm (4.74); MS, m/z 220 (M^+), 205, and 177. Found: C, 87.06; H, 5.29%.

5a; yield 87%; mp 67—68 °C; IR, 1134 cm^{-1}; ^1H NMR, δ=3.11 (4H, s), 3.85 (5H, s), 6.71 (1H, d, J=1.6 Hz), 6.93 (1H, d, J=1.6 Hz), 7.07—7.15 (2H, m), and 7.30 (1H, d, J=6.9 Hz); UV, λ_{max} 281 nm (log ε 4.39); MS, m/z 222 (M^+), 207, and 178. Found: C, 86.70; H, 6.64%. Calcd for $C_{16}H_{14}O$: C, 86.45; H, 6.35%.

1-Methoxy-4*H*-cyclopenta[*def*]phenanthren-4-one (6a). To a mixture of **1a** (770 mg, 3.5 mmol) in pyridine (50 ml) was bubbled oxygen in the presence of Triton B (40% in MeOH, 0.35 ml) for 5 h at room temperature to give **6a** (663 mg, 81%); mp 186.5—187.5 °C; IR, 1706, 1626, and 1240 cm^{-1}; ^1H NMR, δ=4.08 (3H, s), 6.85 (1H, d, J=7.8 Hz), 7.54—7.79 (4H, m), 8.87 (1H, d, J=8.1 Hz), and 7.92 (1H, d, J=9.1 Hz); UV, λ_{max} 390 (log ε 3.05), 371 (3.13), 315 (4.21), 302 (4.14), and 243 nm (4.87). Found: C, 82.03; H, 4.32%. Calcd for $C_{16}H_{10}O_2$: C, 82.04; H, 4.30%.

7a; yield 75%; mp 140—141 °C; IR, 1712, 1628, and 1268 cm^{-1}; ^1H NMR δ=3.95 (3H, s), 7.24 (1H, d, J=1.7 Hz), 7.43 (1H, d, J=1.7 Hz), 7.44—7.49 (1H, m), 7.63—7.73 (3H, m), and 7.83 (1H, d, J=8.1 Hz); UV, λ_{max} 404 (log ε 2.84), 380 (2.85), 360 (2.87), 326 (3.84), 311 (3.72), 295 (3.74), and 242 nm (5.09). Found: C, 82.08; H, 4.19%.

8a; yield 56%; mp 123—124 °C; IR, 1704, 1624, and 1268 cm^{-1}; ^1H NMR, δ=4.14 (3H, s), 7.02 (1H, d, J=8.4 Hz), and 7.30—7.82 (6H, m); UV, λ_{max} 415 (log ε 3.14), 392 (3.22), 311 (3.73), 296 (4.22), and 231 nm (4.79). Found: C, 82.02; H, 4.21%.

9a; yield 89%; mp 201.5—202.5 °C; IR, 1704, 1626, and 1268 cm^{-1}; ^1H NMR, δ=4.04 (3H, s), 6.81 (1H, s), and 7.35—8.08 (6H, m); UV, λ_{max} 428 (log ε 2.81), 418 (2.79), 404 (2.95), 381 (2.95), 321 (3.67), 286 (4.02), 260 (4.10), and 236 nm (4.98). Found: C, 81.84; H, 4.05%.

10a; yield 90%; mp 116.5—117.5 °C; IR, 1702 and 1592 cm^{-1}; ^1H NMR, δ=3.00 (4H, s), 3.81 (3H, s), 6.75 (1H, d, J=1.8 Hz), 6.94 (1H, d, J=1.8 Hz), 7.05 (1H, t, J=7.4 Hz), 7.15 (1H, d, J=7.4 Hz), and 7.30 (1H, d, J=7.4 Hz); UV, λ_{max} 453 (log ε 2.96), 311 (3.58), 300 (3.85), 276 (4.75), and 266 nm (4.61). Found: C, 81.30; H, 5.32%. Calcd for $C_{16}H_{12}O_2$: C, 81.34; H, 5.12%.

Friedel-Crafts Acetylation of 1a—4a. General Procedure. To aluminium chloride (2.2—3.3 mmol) in 1,2-dichloroethane (60—180 ml), acetic anhydride (1.1 mmol) was added at 20 °C (or 75 °C) and the mixture was stirred until it became a homogeneous solution (30 min). All of the finely-powdered methoxy compound (1.0 mmol) was added and stirred for 5 min.

Upon the usual treatment of the reaction mixture, a part of the organic layer was submitted to GC (Shimadzu 6AMFP apparatus attached a column containing Dexsil 300 GC (5%), at 250 °C) after the addition of 2-acetyl-8,9-dihydro-4*H*-cyclopenta[*def*]phenanthrene as an internal standard.

Acetylation of 1a. To a mixture of Ac_2O (0.07 ml, 0.7 mmol) and $AlCl_3$ (150 mg, 1.1 mmol) in $PhNO_2$ (30 ml), **1a** (107 mg, 0.49 mmol) was added at room temperature, followed by stirring for 30 min. Upon the usual treatment, the organic layer was distilled with steam and the residue was chromatographed on silica gel with benzene. The first colorless band afforded 42 mg (39%) of **1a**, mp 98—100 °C.

The second light yellow band gave a trace amount of **1d**: mp 149—150 °C (EtOH); IR, 1664 and 1270 cm^{-1}; ^1H NMR, δ=2.61 (3H, s), 4.08 (3H, s), 4.46 (2H, s), 6.85 (1H, d, J=7.8 Hz), 7.39—7.91 (4H, m), and 7.84 (1H, d, J=7.8 Hz); UV, λ_{max} 377 (log ε 3.67), 360 (3.71), 329 (4.06), and 243 nm (4.53); MS, m/z 262 (M^+), 247, and 204. Found: C, 82.40; H, 5.43%. Calcd for $C_{18}H_{14}O_2$: C, 82.42; H, 5.38%.

The next yellow band was collected and gave the following three compounds: **1f** (24 mg, 19%); mp 154—155 °C (EtOH); IR, 1656 and 1274 cm^{-1}; ^1H NMR, δ=2.86 (3H, s), 4.07 (3H, s), 4.24 (2H, s), 6.98 (1H, d, J=7.8 Hz), 7.43—7.81 (3H, m), and 8.64—8.95 (2H, m); UV, λ_{max} 377 (log ε 3.67), 360 (3.71), 329 (4.06), and 243 nm (4.53); MS, m/z 262 (M^+) and 149. Found: C, 82.31; H, 5.55%.

1e (trace); mp 155—156 °C (EtOH); IR, 1664 and 1246 cm^{-1}; ^1H NMR, δ=2.82 (3H, s), 4.07 (3H, s), 4.32 (2H, s), 7.06 (1H, d, J=7.8 Hz), 7.63 (1H, d, J=7.8 Hz), 7.71 (1H, d, J=7.5 Hz), 8.21 (1H, d, J=9.2 Hz), 8.23 (1H, d, J=7.5 Hz), and 8.86 (1H, d, J=9.2 Hz); UV, λ_{max} 360 (log ε 3.30), 316 (4.06), 300 (4.15), and 250 nm (4.80); MS, m/z 262 (M^+) and 149. Found: C, 82.20; H, 5.25%.

1c (35 mg, 27%); mp 138—139 °C (EtOH); IR, 1668 and 1234 cm^{-1}; ^1H NMR, δ=2.77 (3H, s), 4.09 (3H, s), 4.48 (2H, s), 7.43 (1H, s), and 7.56—8.16 (5H, m); UV, λ_{max} 364 (log ε 3.36), 347 (3.34), 300 (3.90), and 260 nm (4.51); MS, m/z 262 (M^+), 247, and 149. Found: C, 82.21; H, 5.45%.

The next yellow band yielded a trace amount of **1b**; mp 78—79 °C; IR, 1672 and 1380 cm^{-1}: ^1H NMR, δ=2.81 (3H, s), 4.12 (3H, s), 4.30 (2H, s), 7.46—7.98 (5H, m), and 8.02 (1H, d, J=9.0 Hz); UV, λ_{max} 364 (log ε 3.02), 346 (3.12), 301 (4.19), 274 (4.70), and 266 nm (4.72); MS, m/z 262 (M^+), 247, and 149. Found: C, 82.35; H, 5.51%.

The Reaction of 2a. A mixture of Ac_2O (0.09 ml, 0.9 mmol) and $AlCl_3$ (190 mg, 1.4 mmol) in $PhNO_2$ (40 ml) was stirred with **2a** (140 mg, 0.64 mmol) at 20 °C for 30 min. Upon the treatment as described above, **2a** (17 mg, 12%, mp 82—84 °C) and **2b** (139 mg, 83%) were isolated by means of silica-gel column chromatography. **2b**; mp 128—129 °C; IR, 1656 and 1386 cm^{-1}; ^1H NMR, δ=2.72 (3H, s), 4.06 (3H, s), 4.34 (2H, s), 7.47 (1H, s), 7.57—7.68 (2H, m), 7.80 (1H, d, J=7.8 Hz), 7.88 (1H, d, J=9.1 Hz), and 8.06 (1H, d, J=9.1 Hz); UV, λ_{max} 364 (log ε 3.46), 347 (3.43), 299 (4.02), and 257 nm (4.67); MS, m/z 262 (M^+), 247, 232, 189, 176, and 149. Found: C, 82.65; H, 5.62%. Calcd for $C_{18}H_{14}O_2$: C, 82.42; H, 5.38%.

Acetylation of 3a. A solution of **3a** (220 mg, 1 mmol) was added into a mixture of Ac_2O (0.11 ml, 1.2 mmol) and $AlCl_3$ (290 mg, 2.2 mmol) in $PhNO_2$ (120 ml), and the resulting mixture was stirred at 20 °C for 30 min giving **3b** (240 mg, 92%); mp 156—157 °C; IR, 1650, 1258, and 1234 cm^{-1}; ^1H NMR, δ=2.84 (3H, s), 4.13 (3H, s), 4.37 (2H, s), 7.31 (1H, d, J=8.6 Hz), 7.71—7.73 (2H, m), 7.91 (1H, d, J=8.6 Hz), 8.48 (1H, s), and 8.81—8.84 (1H, m); UV, λ_{max} 332 (log ε 4.28), 286 (4.16), and 252 nm (4.62); MS, m/z 262 (M^+), 247, 223, 176, and 149. Found: C, 82.25; H, 5.39%. Calcd for $C_{18}H_{14}O_2$: C, 82.42; H, 5.38%.

Acetylation of 4a. A mixture of **4a** (116 mg, 0.53 mmol) was mixed with a mixture of Ac_2O (0.07 ml, 0.7 mmol) and $AlCl_3$ (150 mg, 1.1 mmol) in $C_2H_4Cl_2$ (30 ml) and stirred at 20 °C for 30 min. Upon the usual treatment, the resulting

residue was chromatographed on a silica-gel column. The first colorless eluate afforded 14 mg (12%) of **4a**, mp 129—130 C. The first fraction of yellow band gave 77 mg (56%) of **4b**; mp 160—161 °C; IR, 1654, 1246, and 1151 cm^{-1}; ^1H NMR, δ=2.81 (3H, s), 4.18 (3H, s), 4.37 (2H, s), 7.57—7.75 (3H, m), 8.05 (1H, d, J=7.8 Hz), 8.22 (1H, d, J=7.6 Hz), and 8.33 (1H, s); UV, λ_{max} 373 (log ε 3.93), 356 (3.83), 328 (4.12), 314 (4.04), 284 (4.13), 273 (4.15), and 258 nm (4.66); MS, m/z 262 (M^+), 247, 219, 176, and 149. Found: C, 82.50; H, 5.56%. Calcd for $C_{18}H_{14}O_2$: C, 82.42; H, 5.38%.

The second fraction yielded 32 mg (23%) of **4c**; mp 151—153 °C; IR, 1666, 1270, and 1149 cm^{-1}; ^1H NMR, δ=2.76 (3H, s), 4.14 (3H, s), 4.65 (2H, s), 7.04 (1H, s), 7.65—7.80 (3H, m), 8.02 (1H, d, J=7.7 Hz), and 8.10 (1H, d, J=8.4 Hz); UV, λ_{max} 336 (log ε 4.28), 323 (4.33), 280 (4.23), and 260 nm (4.58); MS, m/z 262 (M^+), 247, 204, 176, and 149. Found: C, 82.40; H, 5.63%.

Friedel-Crafts Reaction of 5a. A 1,2-dichloroethane (30 ml) solution of **5a** (111 mg, 0.5 mmol), Ac_2O (0.07 ml, 0.7 mmol), and $AlCl_3$ (150 mg, 1.1 mmol) was stirred at room temperature. Upon column chromatography (SiO_2), 54 mg (41%) of **5b** and a trace amount of **5c** were isolated. **5b**; mp 109—110 °C; IR, 1660 and 1286 cm^{-1}; ^1H NMR, δ=2.62 (3H, s), 3.13 (4H, s), 3.85 (3H, s), 3.90 (2H, s), 6.74 (1H, s), 6.96 (1H, s), 7.77 (1H, s), and 7.95 (1H, s); UV, λ_{max} 341 (log ε 4.47) and 326 nm (4.49); MS, m/z 264 (M^+), 249, and 221. Found: C, 81.57; H, 5.89%. Calcd for $C_{18}H_{16}O_2$: C, 81.79; H, 6.10%.

5c; mp 167—168 °C; IR, 1668, 1642, and 1286 cm^{-1}; ^1H NMR, δ=2.62 (3H, s), 2.63 (3H, s), 3.16 (4H, s), 3.95 (3H, s), 4.14 (2H, s), 6.83 (1H, s), 7.77 (1H, s), and 7.95 (1H, s); MS, m/z 306 (M^+), 291, 279, 247, 206, and 167. Found: C, 78.59; H, 5.80%. Calcd for $C_{20}H_{18}O_3$: C, 78.41; H, 5.92%.

In an another experiment with a long reaction time (1h), a small amount of 1,6-diacetyl-8,9-dihydro-4*H*-cyclopenta-[*def*]phenanthren-2-ol was obtained in addition to **5b** and **5c**: mp 228—230 °C; IR, 1666, 1631, and 1220 cm^{-1}; ^1H NMR, δ=2.62 (3H, s), 2.73 (3H, s), 3.12 (4H, s), 4.08 (2H, s), 6.76 (1H, s), 7.73 (1H, s), 7.94 (1H, s), and 13.13 (1H, s); MS, m/z 292 (M^+), 277, 249, 206, and 176. Found: C, 77.81; H, 5.68%. Calcd for $C_{19}H_{16}O_3$: C, 78.06; H, 5.52%.

The Friedel-Crafts Acetylation of 6a. Ketone **6a** (117 mg, 0.5 mmol) was added into a mixture of Ac_2O (0.32 ml, 3 mmol) and $AlCl_3$ (800 mg, 6 mmol) in $C_2H_4Cl_2$ (7.5 ml) and stirred at room temperature for 72 h. Upon the usual treatment, the residue was chromatographed on silica gel and the light yellow band afforded 89 mg (68%) of **6b**: mp 270.5—272.0 °C (from benzene); IR, 2600, 1706, 1630, and 1230 cm^{-1}; ^1H NMR, δ=2.79 (3H, s), 7.70—7.75 (1H, m), 7.82 (1H, d, J=9.0 Hz), 7.88 (1H, d, J=7.9 Hz), 7.98 (1H, d, J=8.0 Hz), 8.10 (1H, d, J=9.0 Hz), 8.21 (1H, s), and 14.85 (1H, s). Found: C, 78.06; H, 3.85%. Calcd for $C_{17}H_{10}O_3$: C, 77.85; H, 3.84%.

The next yellow band yielded 21 mg (15%) of **6c**: mp 229—230 °C (from cyclohexane); IR, 1694, 1668, and 1272 cm^{-1}; ^1H NMR, δ=2.79 (3H, s), 4.07 (3H, s), 6.76 (1H, d, J=7.8 Hz), 7.43—7.80 (3H, m), 8.42 (1H, s), and 8.73—8.89 (1H, m). Found: C, 78.68; H, 4.35%. Calcd for $C_{18}H_{12}O_3$: C, 78.25; H, 4.38%.

Reaction of 7a. A mixture of **7a** (117 mg, 0.5 mmol), Ac_2O (0.16 ml, 1.7 mmol), and $AlCl_3$ (400 mg, 3 mmol) in $C_2H_4Cl_2$ (7.5 ml) was stirred at room temperature for 10 h giving **7b** (71 mg, 51%) and **7c** (37 mg, 28%), respectively.

7b: mp 176.5—177.5 °C (from benzene-hexane) which was confirmed by oxidation of **2b** with oxygen in the presence of Triton B (40%) in pyridine; IR, 1718, 1668, and 1272 cm^{-1}; ^1H NMR, δ=2.69 (3H, s), 4.04 (3H, s), 7.51—7.54 (1H, m), 7.57 (1H, s), and 7.74—7.87 (4H, m); UV, λ_{max} 400 (log ε 2.98), 331 (3.82), 317 (3.75), 296 (4.00), and 244 nm (4.98). Found: C, 78.23; H, 4.43%. Calcd for $C_{18}H_{12}O_3$: C, 78.25; H, 4.38%.

7c: mp 213.0—213.5°C (from benzene); IR, 2630, 1706, 1624, and 1200 cm^{-1}; ^1H NMR, δ=3.91 (3H, s), 7.24 (1H, s), 7.32—8.04 (5H, m), and 14.14 (1H, s); UV, λ_{max} 440 (log ε 3.06), 392 (3.13), 346 (3.94), 330 (3.80), 313 (3.83), 300 (3.95), 270 (4.33), and 249 nm (4.74). Found: C, 77.82; H, 3.53%. Calcd for $C_{17}H_{10}O_3$: C, 77.85; H, 3.84%.

Reaction of 8a. A mixture of **8a** (234 mg, 1 mmol), Ac_2O (0.32 ml, 3.4 mmol), and $AlCl_3$ (800 mg, 6 mmol) in $C_2H_4Cl_2$ (15 ml) was stirred at room temperature for 10 h. The usual procedure afforded 14 mg (6%) of **8a** and 254 mg (92%) of **8b**. **8b**: mp 166.0—166.5 °C (from benzene-hexane); IR, 1702, 1662, and 1258 cm^{-1}; ^1H NMR, δ=2.80 (3H, s), 4.26 (3H, s), 7.18 (1H, d, J=8.8 Hz), 7.65—7.67 (1H, m), 7.82 (1H, d, J=7.0 Hz), 7.91 (1H, d, J=8.8 Hz), 8.32 (1H, s), and 8.92 (1H, d, J=8.4 Hz); UV, λ_{max} 383 (log ε 3.20), 334 (4.14), 303 (4.25), and 252 nm (4.67). Found: C, 78.28; H, 4.12%. Calcd for $C_{18}H_{12}O_3$: C, 78.25; H, 4.38%.

Reaction of 9a. Ketone **9a** (58.5 mg, 0.25 mmol) was treated with Ac_2O (0.16 ml, 1.7 mmol) and $AlCl_3$ (400 mg, 3 mmol) in $C_2H_4Cl_2$ (7.5 ml) at room temperature for 10 h to yield 34 mg (52%) of **9b** and 16 mg (27%) of **9a**. **9b**: mp 210.0—210.5 °C (from benzene-hexane); IR, 2650, 1708, 1664, and 1384 cm^{-1}; ^1H NMR, δ=2.97 (3H, s), 7.60—7.70 (3H, m), 7.91 (1H, d, J=6.7 Hz), 8.12 (1H, dd, J=8.0, 4.3 Hz), 8.27 (1H, d, J=8.0 Hz), and 16.61 (1H, s); UV, λ_{max} 359 (log ε 3.87), 325 (3.88), and 231 nm (4.75). Found: C, 78.02; H, 3.89%. Calcd for $C_{17}H_{10}O_3$: C, 77.85; H, 3.84%.

Reaction of 10a. A mixture of **10a** (321 mg, 1.36 mmol), Ac_2O (0.32 ml, 3.4 mmol), and $AlCl_3$ (800 mg, 6 mmol) in $C_2H_4Cl_2$ (30 ml) was stirred at room temperature for 34 h to give 25 mg (8%) of **10a** and 256 mg (68%) of **10b**, respectively. **10b**: mp 220—221 °C (red needles from benzene-hexane); IR, 1704, 1668, and 1264 cm^{-1}; ^1H NMR, δ=2.58 (3H, s), 3.06 (4H, s), 3.84 (3H, s), 6.80 (1H, s), 6.99 (1H, s), 7.89 (1H, s), and 7.91 (1H, s); UV, λ_{max} 452 (log ε 3.25), 340 (4.07), 326 (4.09), 291 (4.59), and 254 nm (4.26). Found: C, 77.47; H, 5.27%. Calcd for $C_{18}H_{14}O_3$: C, 77.68; H, 5.07%.

Friedel-Crafts Acetylation of 4*H*-Cyclopenta[*def*]phenanthren-4-one. A mixture of the ketone (404 mg, 2 mmol), Ac_2O (4.4 ml, 47 mmol), and $AlCl_3$ (10.6 g, 79 mmol) in $C_2H_4Cl_2$ (15 ml) was stirred at room temperature for 20 d to give the recovered ketone (195 mg, 48%) and 8-acetyl-4*H*-cyclopenta[*def*]phenanthren-4-one (45 mg, 9%); mp 171.5—173.0 °C (from cyclohexane); IR, 1706 and 1664 cm^{-1}; ^1H NMR, δ=2.84 (3H, s), 7.61—7.67 (2H, m), 7.83—7.90 (2H, m), 7.99 (1H, d, J=8.0 Hz) 8.43 (1H, s), and 8.89 (1H, d, J=8.4 Hz); UV, λ_{max} 340 (log ε 3.17), 307 (4.13), and 240 nm (4.82). Found: C, 83.04; H, 3.88%. Calcd for $C_{17}H_{10}O_2$: C, 82.91; H, 4.09%.

The authors wish to thank Emeritus Professor Kazuo Suzuki and Professor Takashi Toda Utsunomiya University for their valuable discussion.

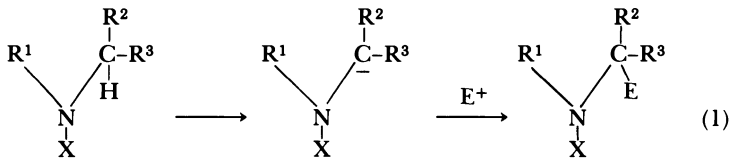
(Received July 7, 1987)

α-Siloxy amines, which were easily prepared by "silicon Polonovski reaction" of tertiary amine *N*-oxides with trialkylsilyl trifluoromethanesulfonate, were treated with various nucleophiles to give the corresponding α-functionalized tertiary amines in moderate to good yields. This new method has the advantage that it enables the α-substitution of amines not only by alkyl groups but also by alkenyl and aryl groups with sp^2 carbon as a reaction center, since the introduction of such groups is difficult in electrophilic substitution of dipole-stabilized α-lithio amines. Besides the organometallics such as Grignard and organoaluminum reagents, trimethylsilyl cyanide and silyl enol ether could also be employed as nucleophiles in the presence of an appropriate Lewis acid.

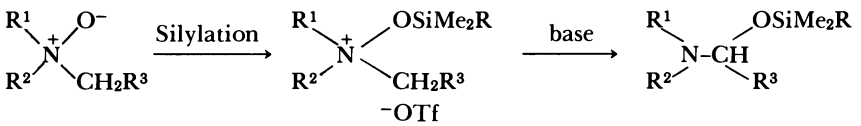
The carbon–carbon bond formation at the α-position of amines is one of the most important problems in the syntheses of nitrogen-containing natural products such as alkaloids. Although the electrophilic α-substitution methods have been developed extensively in recent years using dipole-stabilized α-lithio amines[1] as shown in Eq. 1, all of them are only applicable to secondary amine



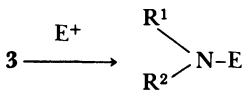
(1)

X=NO, COR, CH=N-Bu^t, etc.

derivatives and there are very few reports on the direct generation of α-carbanion of tertiary amines.[2] On the other hand, the conventional Mannich type of nucleophilic introduction of α-substituents into primary and secondary amines[3] have been studied widely but direct α-functionalization of tertiary amines has not been fully investigated. We have recently reported a facile formation of α-siloxy amines **3** ("silicon Polonovski reaction") by the base-promoted rearrangement of siloxyammonium salts **2** obtained by treatment of tertiary amine *N*-oxides **1** with trialkylsilyl trifluoromethanesulfonate and their reactions with some electrophiles (Eq. 2).[4]



1 **2** **3**



(2)

As an extension of the above reactions we have examined nucleophilic substitutions of the siloxyl group of **3** in the hope of the development of a new and general nucleophilic α-functionalization method for tertiary amines (Eq. 3).[5]

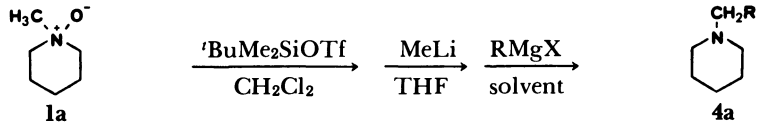
† Present address; Department of Chemistry, University of Tsukuba, Tsukuba, Ibaraki 305.

Results and Discussion

Nucleophilic Substitution with Organometallics.

a) Reactions with Grignard Reagents. The reactions of α-siloxy amines **3** with Grignard reagents as nucleophiles were examined. In the case of *N*-methylpiperidine *N*-oxide (**1a**), treatment of the corresponding α-siloxy amine **3a** obtained in situ from **1a** with several Grignard reagents afforded the expected α-substituted products **4a** in moderate to good yields when the solvent was replaced by toluene before the reaction with the Grignard reagents. These results are given in Table 1.



1a **4a**

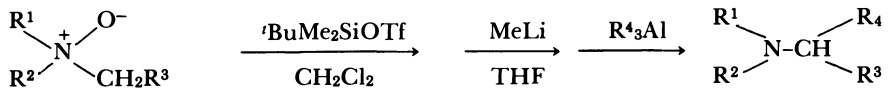
When the Grignard reagent was added without the solvent exchange into toluene, the yield of **4a** was somewhat diminished (Entry 1).

This α-substitution reaction was applied to the introduction of substituents into the 1-position of tetrahydroisoquinoline skeleton which is important in the alkaloid synthesis using *N*-methyl-1,2,3,4-tetrahydroisoquinoline *N*-oxide (**1b**) as a substrate. In this case the addition of Lewis acid before that of the Grignard reagent was necessary in contrast to the reaction of **1a**. The results listed in Table 2 show that the substitution proceeded most effectively when α-siloxy amine **3b** was treated with trimethylsilyl trifluoromethanesulfonate (TMSOTf).

1b **4b**

When this reaction was carried out in the absence of Lewis acid, the yield and reproducibility in the formation of **4b** became poorer.

b) Reactions with Trialkylaluminums. Substitution of the siloxyl group in **3** with trialkylaluminums was next examined.[6] The results obtained from the reactions of several amine *N*-oxides are given in Table 3 and in all cases the expected α-substitution products



1 **4**

4 were obtained in moderate to good yields. In contrast to the substitution reaction by Grignard reagents mentioned above, organoaluminum reagents gave the α-substitution products **4** in good yields without the solvent exchange into toluene before the addition of the orgnometallics except in the case of **1b**, where the α-substitution product **4b** was obtained only in 20% yield using dichloromethane as a solvent in the last step.[7]

Reactions with Other Nucleophiles. Lewis Acid-Promoted Nucleophilic Substitution of α-Siloxy Amines. Since the Lewis acidity of the organometallics seemed to play an important role in the above-mentioned nucleophilic substitution of α-siloxy amines **3** with organometallics, some attempts were made to extend this substitution to some other nucleophiles by use of an appropriate Lewis acid.

a) Reactions with Trimethylsilyl Cyanide; a New Synthesis of α-Cyano Amines.[8] When the α-siloxy amines **3** obtained in situ from the corresponding amine *N*-oxides **1** were treated with titanium tetrachloride and trimethylsilyl cyanide after replacement of the solvent into dichloromethane, the α-cyanated products **5** were obtained in good yields. As a Lewis acid titanium tetrachloride was most effective; trimethylsilyl trifluoromethanesulfonate (TMSOTf) and tin(IV) chloride could also be used but the yields of **5** were somewhat diminished. Results obtained from the reactions of several amine *N*-oxides are summarized in Table 4. The results suggest that, as in the dealkylation of tertiary amines via α-siloxy amines **3**,[4] the regioselectivity of this cyanation is controlled by the acidity of the α-hydrogen of substituents on the ammonium salt **2** which is deprotonated by the base. Thus, **1a** and *N,N*-dimethylcyclohexylamine oxide (**1d**) were cyanated at the methyl group and **1b** at the benzyl group exclusively, while *N,N*-dimethylbenzylamine oxide (**1e**) gave two regioisomers (**5e** and **5e'**). It appears that the deprotonation of the methyl group in

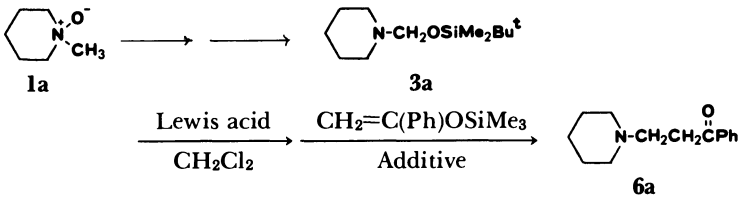
3 5

the reactions with **1a** and **1d** predominates over that of the methylene and methine groups but the preference between methyl and benzyl groups in the deprotonation depends on the structure of the *N*-oxides (**1e** vs. **1b**). In the absence of Lewis acids this cyanation did not proceed in contrast to the reactions with Grignard and organoaluminum reagents.

b) Reactions with Silyl Enol Ether. As another application of this Lewis acid promoted substitution reaction of α-siloxy amines, reactions with a silyl enol ether were examined. Thus, **1a** was converted into the corresponding α-siloxy amine **3a** and then after replacement of the solvent into dichloromethane **3a** was treated with α-trimethylsiloxystyrene in the presence of some kinds of Lewis acids. The results are given in Table 5. As a Lewis acid TMSOTf was most effective; with other Lewis acids the yiels of **6a** were much lower and the reaction became complicated. In this sustitution the addition of fluoride ion resulted in improvement of the yield (Run 4).



1a **3a** **6a**

In summary we have established a new and convenient α-substitution method for teriary amines not only by simple alkyl groups but also by alkenyl, aryl, cyano, and β-oxoalkyl groups using α-siloxy amines. In view of ready availability of amine *N*-oxides and nucleophiles and a wide variety of the synthetic application of this α-functionalization method described here, we believe that this type of transformation reaction of tertiary amines will provide a new methodology in organic synthesis, especially in the syntheses of nitrogen-containing natural products.

Experimental

All the melting points and boiling points were not corrected. ^{1}H NMR spectra were measured with Hitachi R-24B, Hitachi R-20B (60 MHz), and JEOL JNM-FX90Q (90 MHz) spectrometers using tetramethylsilane as an internal standard. ^{13}C NMR spectra were measured with a JEOL JNM-FX90Q (90 MHz) spectrometer. The NMR spectra were measured in deuteriochloroform at room temperature unless otherwise noted. MS spectra were measured with a JEOL JMS-D300 mass spectrometer. All the experiments were carried out in argon or nitrogen atmosphere. Chromatographic separation was carried out with hexane–ether as solvent. Isolated products were homogeneous in thin layer chromatography and their NMR spectra did not show the presence of impurity.

Materials. Amine *N*-oxides were prepared by oxidation of the corresponding amines by either 30% hydrogen peroxide or m-chloroperbenzoic acid. *N*-Methyl-1,2,3,4-tetrahydroisoquinoline[9] and *N*-benzylpiperidine[10] were prepared by the reported method. The other amines used were commercial products.

Reactions with Grignard Reagents. Reaction of *N*-Methylpiperidine *N*-Oxide (1a). The procedure with phenylmagnesium bromide is typical.

General Procedure. Transformation of 1a into *N*-Benzylpiperidine (4a). To a solution of **1a** (120.7 mg, 1.05 mmol) in 10 ml of dichloromethane was added TBDMSOTf (291 mg, 1.05 equiv), the solvent was carefully removed with a vacuum pump and then THF (10 ml) and MeLi (1.2 mmol, 1.1 equiv) were added at 0 °C. After further replacement of the solvent by toluene (10 ml) in a similar way, phenylmagnesium bromide (1.58 mmol, 1.5 equiv) was added at 0 °C and the mixture was stirred overnight at room temperature. After evaporation of the solvent the mixture was shaken with 50 ml of 5% aq NaOH solution and 50 ml of dichloromethane and the aqueous layer was extracted with dichloromethane (30 ml×3). The extracts and the organic layer were combined, dried over $MgSO_4$, and concentrated. The ^{1}H NMR spectrum of the resulting crude oil showed the exclusive formation of the expected *N*-benzylpiperidine (**4a**; R=Ph) and *t*-butyldimethylsilanol and the NMR yield of **4a** (R=Ph) was estimated 80%. Chromatography of the crude oil on alumina afforded **4a** (R=Ph) in 74% yield (136.4 mg) as a colorless oil.

Other reactions of **1a** listed in Table 1 were carried out in a similar way to the above-mentioned reaction with phenylmagnesium bromide to give the corresponding α-substituted products (**4a**; R=CH=CH_2, CH_2Ph, and CH_2CH_3) in 51, 52,

and 47% yields, respectively.

4a, R=CH=CH$_2$: ^{1}H NMR δ=1.2—2.1 (m, 6H), 2.3—2.7 (m, 4H), 2.9—3.1 (m, 2H), and 4.9—6.7 (m, 3H); MS, *m/z* 125 (M$^+$, 5%), 124 (8), 108 (6), 98 (15), 88 (52), and 75 (100); pale yellow oil.[11]

4a, R=CH$_2$Ph: ^{1}H NMR δ=1.0—2.0 (m, 6H), 2.0—2.7 (m, 4H), 2.2—3.1 (m, 4H), and 7.31 (s, 5H); MS, *m/z* 190 (2%), 189 (M$^+$, 6), 188 (3), 149 (3), 105 (23), 99 (38), 98 (100), 91 (9), and 77 (15); pale yellow oil.[12]

4a, R=CH$_2$CH$_3$: ^{1}H NMR δ=0.8—1.7 (m, 11H), and 2.0-2.5 (m, 6H); ^{13}C NMR δ=61.68, 54.74, 26.14, 24.65, 20.15, and 12.11; colorless oil.[13]

Reactions with *N*-Methyl-1,2,3,4-tetrahydroisoquinoline *N*-Oxide (1b). As a typical example of the reactions of **1b**, the procedure with phenylmagnesium bromide and trimethylsilyl trifluoromethanesulfonate is described.

Transformation of 1b to 4b. To a solution of *N*-oxide **1b** (130 mg, 0.8 mmol) in 10 ml of dichloromethane was added TBDMSOTf (232 mg, 1.1 equiv) and after the solvent exchange into THF (10 ml) was added MeLi (0.96 mmol, 1.2 equiv) at 0 °C. After replacement of the solvent into toluene (10 ml) was added MeLi (0.96 mmol, 1.2 equiv) at 0 °C. After the solvent was exchanged into toluene (10 ml) was added trimethylsilyl trifluoromethanesulfonate (TMSOTf) (213 mg, 1.2 equiv) at −78 °C and the mixture was warmed to room temperature with stirring. Phenylmagnesium bromide (1.2 mmol, 1.5 equiv) was then added to this mixture at 0 °C and the mixture was warmed to 70 °C with stirring for 24 h. It was then shaken with 50 ml of 5% aq NaOH solution and 50 ml of ether, and the aqueous layer was extracted with dichloromethane (30 ml×3). The extracts and organic layer were combined, dried over MgSO$_4$, and concentrated. Chromatography of the residual oil on alumina gave the α-phenylated product (**4b**, R=Ph) (100.2 mg, 56%) as a pale yellow solid.

4b, R=Ph: ^{1}H NMR δ=2.21 (s, 3H), 2.3—3.8 (m, 4H), 4.24 (brs, 1H), 6.5—7.5 (m, 4H), and 7.27 (s, 5H); MS, *m/z* 223 (M$^+$, 19%), 222 (15), 179 (17), 178 (10), 165 (6), 147 (22), 146 (100), 131 (6), 118 (2), 103 (2), 91 (5), and 77 (5); high-MS, *m/z* Found 223.1381, Calcd for C$_{16}$H$_{17}$N: 223.1361; mp 69—70 °C (lit,[14] 72 °C).

The other reaction of **1b** listed in Table 2 were carried out similarly to give the corresponding α-substitution products. In the case of the reaction with methylmagnesium iodide (Entry 7) the yield of **4b** (R=Me) decreased to 15% when toluene was used as a solvent instead of a mixed solvent (THF-ether=1:2).

4b, R=CH$_2$CH$_3$: ^{1}H NMR δ=0.84 (t, *J*=7 Hz, 3H), 1.5—2.1 (m, 2H), 2.33 (s, 3H), 2.4—3.6 (m, 5H), and 7.09 (s, 4H), MS, *m/z* 175 (M$^+$, 2%), 174 (28), 147 (9), 146 (100), 131 (4), 115 (2), 91 (2), and 77 (2); high-MS, *m/z* Found 175.1354, Calcd for C$_{12}$H$_{17}$N: 175.1360; pale yellow oil.

4b, R=CH=CH$_2$: ^{1}H NMR δ=2.1—3.4 (m, 4H), 2.39 (s, 3H), 3.70 (d, *J*=7.5 Hz, 1H), 4.9—6.1 (m, 3H), and 7.09 (s, 4H); MS, *m/z* 173 (M$^+$, 6%), 172 (7), 146 (55), 119 (13), 118 (100), 91 (20), 90 (46), 77 (13), 71 (39), and 57 (45); high-MS, *m/z* found 173.1205, Calcd for C$_{12}$H$_{15}$N: 173.1205; yellow oil.

4b, R=CH$_2$Ph: ^{1}H NMR δ=2.46 (s, 3H), 2.7—3.6 (m, 6H), 3.84 (t, *J*=6 Hz, 1H), and 7.0—7.5 (m, 9H); MS, *m/z* 237 (M$^+$, 8%), 236 (26), 234 (29), 160 (7), 147 (7), 146 (100), 145 (16), 144 (58), 131 (19), 105 (18), 91 (36), and 77 (15); high-MS, *m/z* Found 237.1467, Calcd for C$_{17}$H$_{19}$N: 237.1517; yellow oil.

4b, R=CH$_3$: ^{1}H NMR δ=1.39 (d, *J*=7 Hz, 3H), 2.48 (s, 3H), 2.4—3.7 (m, 5H), and 7.0-7.3 (m, 4H); MS, *m/z* 161 (M$^+$, 7%), 160 (5), 146 (20), 147 (100), 144 (7), 131 (8), 118 (12), 114 (17), 91 (6), and 77 (7); yellow oil.[15]

Reactions with Trialkylaluminums; α-Substitution of 1a by Triisobutylaluminum. To a solution of **1a** (165.6 mg, 1.44 mmol) in 10 ml of dichloromethane was added TBDMSOTf (424 mg, 1.1 equiv) and after the solvent exchange into THF (10 ml) was added MeLi (1.73 mmol, 1.2 equiv) at 0 °C. To this solution was added triisobutylaluminum (1.73 mmol, 1.2 equiv in 15% hexane solution) at −78 °C and then the mixture was warmed to room temperature with stirring. After stirring for 14 h, the solvent was evaporated and the resulting oil was subjected to chromatography (alumina, hexane-ether=5:2) to give *N*-isopentylpiperidine (**4a**; R=*i*-Bu)(100 mg, 45%) as a colorless oil.[16]

4a, R=*i*-Bu: ^{1}H NMR δ=0.7—1.1 (m, 6H), 1.1—2.0 (m, 9H), and 2.0—2.6 (m, 6H); MS, *m/z* 155 (M$^+$, 8%), 154 (1), 110 (4), 99 (9), 98 (100), 85 (4), 84 (4), 71 (5), and 57 (8).

Reactions of Other *N*-Oxides with Trialkylaluminums. Reactions of **1a** and **1c** with triethylaluminum were carried out similarly to the above-mentioned α-isobutylation to afford the corresponding α-ethylated products (**4a**, R=CH$_2$CH$_3$) and (**4c**, R=CH$_2$CH$_3$) in 69 and 75% yields, respectively. α-Methylation of **1b** with trimethylaluminum was carried out in dichloromethane instead of THF to give the α-methylated product (**4b**, R=CH$_3$) in 20% yield.

4c, R=CH$_2$CH$_3$: ^{1}H NMR δ=0.9 (t, *J*=8 Hz, 3H), 1.5—2.3 (m, 2H), 3.48 (ABq, δ_{AB}=0.42, J_{AB}=14 Hz, 4H), 3.59 (t, *J*=8 Hz, 1H), and 7.0—7.6 (m, 15H); ^{13}C NMR δ=140.44, 139.17, 128.96, 128.74, 127.88, 126.68, 64.01, 53.82, 24.30, and 11.67; MS, *m/z* 315 (M$^+$, 1%), 287 (13), 286 (46), 210 (3), 194 (8), 181 (5), 118 (4), 92 (9), 91 (100), and 65 (8); high-MS, *m/z* Found 315.1962, Calcd for C$_{23}$N$_{25}$N: 315.1987; yellow oil.

α-Cyanation. As a typical example of α-cyanations, the procedure with **1b** is described. Transformation of **1b** into **5b**. To a solution of **1b** (156 mg, 0.96 mmol) in 10 ml of dichloromethane was added TBDMSOTf (279 mg, 1.1 equiv) and after replacement of the solvent by THF (10 ml) was added MeLi (1.15 mmol, 1.2equiv) at 0 °C. After the solvent was again exchanged into dichloromethane (10 ml), titanium tetrachloride (237 mg, 1.3 equiv) was added at −78 °C and the mixture was stirred for 1 h at this temperature. To the greenish-brown suspension was then added trimethylsilyl cyanide (0.19 ml, 1.5 equiv) at −78 °C. After stirring overnight at room temperature, the mixture was shaken with 50 ml of 5% aq NaOH solution and 50 ml of dichloromethane, and the aqueous layer was extracted with dichloromethan (30 ml×3). The extracts and organic layer were combined, dried over MgSO$_4$, and concentrated. Chromatography of the residual oil gave 1-cyano-*N*-methyl-1,2,3,4-tetrahydroisoquinoline (**5b**) (103.9 mg, 63%) as a pale yellow solid.

5b: ^{1}H NMR δ=2.5—3.3 (m, 4H), 2.58 (s, 3H), 4.70 (s, 1H), and 6.9—7.3 (m, 4H); ^{13}C NMR δ=133.94, 129.72, 129.39, 128.50, 127.14, 126.49, 116.53, 56.96, 48.46, and 28.44; MS, *m/z* 172 (M$^+$, 45%), 171 (43), 149 (43), 146 (31), 145 (38), 144 (100), 129 (99), and 57 (27); high-MS, *m/z* Found 172.0999, Calcd for C$_{11}$H$_{12}$N$_2$: 172.0999; mp 75—77 °C (lit,[17] 76—78 °C).

The other reactions listed in Table 4 were carried out similarly to the above procedure to give the corresponding

α-cyano amines.

5a: ^{1}H NMR δ=1.0—2.0 (m, 6H), 2.2—2.7 (m, 4H), and 3.5 (s, 2H); ^{13}C NMR δ=114.87, 53.12, 46.89, 25.71, and 23.32; MS, *m/z* 124 (M^+, 40%), 123 (100), 98 (6), 96 (12), 83 (27), and 57 (22); high-MS, *m/z* Found 124.0973, Calcd for $C_7H_{12}N_2$: 124.0999; colorless oil.

5c: ^{1}H NMR δ=3.64 (ABq, δ_{AB}=0.5, J_{AB}=13.5 Hz,4H), 4.9 (s, 1H), and 7.0—7.7 (m, 15H); ^{13}C NMR δ=139.58, 137.71, 133.97, 128.74, 128.58, 128.17, 127.63, 126.82, 115.31, 57.32, and 54.99; MS, *m/z* 312 (M^+, 0.3%), 287 (4), 239 (2), 210 (4), 165 (12), 125 (10), 123 (28), 105 (14), 93 (33), 91 (100), and 55 (52); high-MS, *m/z* Found 312.1624, Calcd for $C_{22}H_{20}N_2$: 312.1624; white solid, mp 103—104 °C (lit,[18] 103—104 °C).

5d: ^{1}H NMR δ=0.8—2.5 (m, 11H), 2.37 (s, 3H), and 3.57 (s, 2H); ^{13}C NMR δ=115.99, 61.30, 42.44, 38.98, 29.96, 25.89, and 25.14; MS, *m/z* 152 (M^+, 10%), 110 (7), 109 (100), 96 (9), and 83 (8), high-MS, *m/z* Found 152.1304, Calcd for $C_9H_{16}N_2$: 152.1312; colorless oil.

5e: ^{1}H NMR δ=2.31 (s, 6H), 4.9 (s, 1H), and 7.1—8.0 (m, 5H); MS, *m/z* 160 (M^+, 50%), 159 (16), 116 (29), 92 (29), 91 (100), and 83 (95); high-MS, *m/z* Found 116.1007, Calcd for $C_{10}H_{12}N_2$: 160.1001; colorless oil.

5e′: ^{1}H NMR δ=2.35 (s, 3H), 3.38 (s, 2H), 3.55 (s, 2H), and 7.38 (s, 5H); ^{13}C NMR δ=137.09, 128.96, 128.58, 127.78, 114.52, 60.16, 44.18, and 42.23; MS, *m/z* 160 (M^+, 39), 159 (13), 118 (3), 92 (34), 91 (100), and 83 (44); high-MS, *m/z* Found 160.1000, Calcd for $C_{10}H_{12}N_2$: 160.1001; pale yellow oil.

Reactions with a Silyl Enol Ether. Transforation of 1a into 6a. As a typical example the procedure with **1a** in the presence of TMSOTf and potassium fluoride is described. To a solution of **1a** (134 mg, 1.17 mmol) in 10 ml of dichloromethane was added TBDMSOTf (324 mg, 1.05 equiv) and after the solvent exchange into THF (15 ml) was added MeLi (1.29 mmol, 1.1 equiv). After replacement of the solvent by dichloromethane (10 ml) TMSOTf (312 mg, 1.2 equiv) was added at 0 °C. The mixture was stirred for 2 h at room temperature and then to the mixture was added α-trimethylsiloxystyrene (270 mg, 1.2 equiv) at this temperature. After stirring for 1 h at room temperature potassium fluoride (75 mg, 1.1 equiv; dried by heating at about 100 °C in vacuo just before use) was added in one portion and the mixture was refluxed for 16 h. Then the mixture was shaken with 50 ml of 5% aq NaOH solution and 50 ml of dichloromethane, and the aqueous layer was extracted with dichloromethane (30 ml×3). The extracts were combined with the organic layer, dried over $MgSO_4$, and concentrated. Chromatography of the residual oil (alumina, ether-hexane=2:1) afforded the expected α-substituted product **6a** (120 mg, 47%) as a pale yellow oil.[19]

6a: ^{1}H NMR δ=1.2—1.7 (m, 6H), 2.4—2.6 (m, 4H), 2.6—3.3 (m, 4H), 7.3—7.7 (m, 3H), and 7.8—8.2 (m, 2H); ^{13}C NMR δ=199.36, 137.17, 132.94, 128.58, 128.07, 54.63, 54.01, 34.46, 26.03, and 24.32; MS, *m/z* 217 (M^+, 6%), 132 (7), 105 (30), 99 (8), 98 (100), 97 (33), 86 (10), 84 (16), and 77 (23).

The authors are grateful to Shin-etsu Chemical Co. Ltd. for the generous gift of chlorosilanes.

(Received July 14, 1987)

The I_3, ClO_4, and PF_6 salts of unsymmetrical donors containing fused pyrazino groups (DMPDSDTF and DM(DMP)DSDTF) were prepared electrochemically and their electrical conductivities were measured. The I_3 salt of DM(DMP)DSDTF exhibited a metallic behavior down to about 120 K. The radical salts of unsymmetrical donors showed much larger conductivities than those of the corresponding symmetrical donors containing pyrazino groups.

In the past decade, much attention has been concentrated on the construction of organic superconductors. It has been recognized in such studies that higher dimensionality is preferred because low dimensional systems of electrons intrinsically possess the instability against to a lattice distortion with a period of $1/2k_F$. Indeed, at low temperature many organic conductors undergo a CDW (Peierls), SDW or spin-Peierls transition, below which they behave as insulators.

One way to increase dimensionality of the system is compression of a sample under high pressure. The first organic superconductor $(TMTSF)_2PF_6$[1] has been obtained through application of high pressure of 0.65 GPa. Besides physical compression, there exists another strategy to increase dimensionality, i.e. chemical decoration of a molecule. TMTSF[1] and BEDT-TTF,[2] of which radical salts have been discovered so far to undergo a superconducting transition, are in fact analogues of one of the most famous donor, TTF.

From the second point of view, the donors containing nitrogen atoms are interesting because the lone pair electrons will possibly enhance the dimensionality of electronic systems in crystals. However, only a few reports have been published so far about the salts of such donors.[3-7]

Very recently, the superconductivity in $(DMET)_2Au(CN)_2$[8] (DMET: dimethyl(ethylenedithio)diselenadithiafulvalene) and $(DMET)_2AuBr_2$[9] has been discovered, which indicates that a symmetrical donor is not necessary to organic superconductors. These situation prompted us to start the studies on the unsymmetrical donors containing a pyrazino group. The donors we have chosen are DMPDSDTF (dimethyl(pyrazino)diselenadithiafulvalene) and DM-(DMP)DSDTF (dimethyl(dimethylpyrazino)diselenadithiafulvalene) (Fig. 1), which have a partial structure of TMTSF. If any properties of the partial structures of the donor contribute additively to the properties of crystals, enhanced dimensionality and high electrical conductivity will be realized. In order to clarify this point, some radical salts of the unsymmetrical donors were prepared and the electrical conductivities were compared with those of the corresponding symmetrical donors, BPTTF (bispyrazinotetrathiafulvalene) and BDMPTTF (bis(dimethylpyrazino)tetrathiafulvalene) (see Fig. 1).

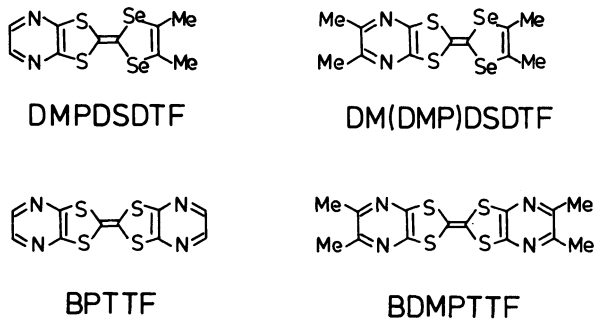

Fig. 1. Molecular structures of the donors.

Experimental

The unsymmetrical and symmetrical donors were synthesized according to the methods described previously.[10] The radical salts of the donors were grown at room temperature by the electrochemical method with constant current of 2 μA in dichloromethane. The supporting electrolytes used were $(n\text{-}Bu)_4N\cdot I_3$, $(n\text{-}Bu)_4N\cdot ClO_4$, and $(n\text{-}Bu)_4N\cdot PF_6$, which cover a variety of counter anions of linear, tetrahedral, and octahedral structures. The single crystals of ClO_4 salts of the unsymmetrical donors and of the PF_6 salt of BDMPTTF were needle-like, and others were plate-like.

The electrical conductivities were measured along the growth axis of the crystal by standard four probe AC (20 Hz) and DC methods at constant current (1—10 μA) between liquid nitrogen and room temperatures. As both methods of conductivity measurements gave consistent results, we will not mention about the methods in the following. The size of the samples used for conductivity measurements was typically $2\times0.3\times0.03$ mm^3.

Results and Discussion

The room temperature conductivities of radical salts are tabulated in Table 1. While all of the radical salts of DMPDSDTF, BPTTF and BDMPTTF

Symmetrical			
BPTTF	Semiconductor 0.68(0.38)	—[c]	—[c]
BDMPTTF	Semiconductor 0.060(0.20)	—[c]	—[c]

a) Below about 250 K, semiconductor with the band gap energy 0.09 eV. b) Below about 120 K, semiconductor with the band gap energy 0.04 eV. c) Single crystals could not be prepared.

exhibited semiconducting behaviors at room temperature, two radical salts of DM(DMP)DSDTF behaved as metallic. The band gap energies were deduced from Arrhenius plots of conductivities in semiconducting region and are also given in Table 1.

It is interesting to compare the properties of the single crystals of radical salts of symmetrical and unsymmetrical donors. Only a series of PF_6 salts is available for this purpose, as radical salts of other anions with symmetrical donors could not be prepared. The room temperature conductivity of the DMPDSDTF salt is larger than that of the BPTTF salt by an order of magnitude. Similarly, that of the DM(DMP)DSDTF salt is larger than that of the BDMPTTF salt by a factor 50. Moreover, ClO_4 and I_3 salts of DM(DMP)DSDTF showed metallic properties. Thus, introduction of a partial structure of TMTSF increases an electrical conductivity. It is noteworthy that in the case of I_3 salt of DM(DMP)DSDTF the conductivity perpendicular to the crystal growth axis was smaller than that along the axis by only a factor 5, which suggests that the salts have high dimensionality. Similar effects were observed also in salts of the unsymmetrical donor,[7] PEDTTTF, which has a partial structure of BEDT-TTF. Hence, we conclude that partial structures of a donor contribute additively to the electrical property of radical salts.

In addition to improvement of room temperature conductivity, there is another remarkable finding: Although all of three radical salts of DMPDSDTF were semiconducting, the radical salts of DM(DMP)-DSDTF showed a variety of temperature dependences of conductivity. The results of the conductivity measurements on a series of the salts of DM(DMP)-DSDTF are shown in Fig. 2. It is interesting that the higher is the symmetry of an anion, the lower is an electrical conductivity of the corresponding radical salt (Table 1). The PF_6 salt exhibits a semiconducting behavior in the temperature range studied. In contrast to the PF_6 salt, the I_3 salt behaves as metallic down to about 120 K, below which the salt is a semiconductor. It is emphasized that this is the second observation that an organic conductor consisting of an donor containing pyrazino group(s) shows a metallic behavior down to such a low temperature.[7] The ClO_4 salt is also metallic at room temperature though it is

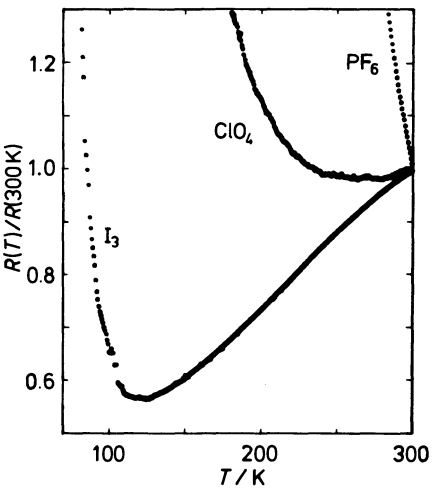

Fig. 2. Electrical resistivities of a series of radical salts of DM(DMP)DSDTF. Counter anions are indicated in the figure. For the values of R(300 K), see Table 1.

hardly recognized in Fig. 2. As the temperature dependence of the conductivity is very weak, it is hard to locate unambiguously the metal-insulator transition point on the basis of the present data.

Structural and high pressure studies are interesting and in progress in this laboratory. These will be published shortly.

This study was supported by the Grant-in-Aid for Scientific Research No. 6143003 from the Ministry of Education, Science and Culture.

Interference Effects of Helium on Motion of Xenon in Micropores of 5A Zeolites

Yusuke YASUDA* and Satoshi SHINBO
Faculty of Science, Toyama University, Toyama 930
(Received June 22, 1987)

Striking interference effects of He molecules on the motion of Xe in micropores of 5A zeolites have been found by the frequency response method. Results of the systems reveal that the absorbed Xe molecules may be divided into two abspecies, c_1' and c_2', in the presence of He molecules which were inert in a single component system: (i) at 273 K, c_1' diffuses faster and c_2' slower than pure Xe; (ii) at 255 K, c_1' diffuses faster than pure Xe, while the motion of c_2' is regarded as not diffusion but adsorption. The interference effects at 273 K have been explained quantitatively by decoupling a more general form of Fick's law containing cross terms.

Since zeolites have a molecular-sieve action, the binary or multicomponent diffusion of gases in the micropores of zeolites has been of considerable interest after the discovery of zeolite crystals in the late 1950s. However, conclusions seem controversial: (i) the diffusion of one component is enhanced in a mixture,[1] (ii) both diffusion coefficients of a binary gas mixture are considerably smaller than those of pure components,[2] and (iii) each component of a mixture (using He as a carrier gas) diffuses independently with the same intrinsic mobility as for single-component diffusion.[3]

In the first application of the frequency response (FR) method to a system of a binary gas mixture, CH_4+He or CH_4+Kr over Linde 5A at 195 K, striking mutual interference effects have been observed in the diffusion process.[4] The aim of the present article is to confirm that the interference occurs in micropores rather than on the exposed surface of a zeolite. The dependence of the effects on the crystal size of a zeolite was investigated using simpler gas systems of Xe+He over two kinds of 5A zeolites, Ca-A2 and Ca-A6, of which the mean crystal sizes were 2 and 6 μm, respectively.

Experimental

Zeolite Preparation and Materials. Synthetic 5A zeolites supplied by Toyo Soda Manufacturing Co., Ca-A2 and Ca-A6, were used; their properties are summarized in Table 1. SEM photographs of the samples are shown in Fig. 1. Crystal-size distributions of the two samples were determined by measuring the size of ca. 700 crystals; that of Ca-A2 was practically normal on a weight or volume fraction basis, but that of Ca-A6 was distorted.

Table 1. Cation Exchange and Size Distribution of 5A Zeolite Crystals

Zeolite	%Ca[a]	N[b]	$(2a_m/\mu m)$[c]	(σ/a_m)[d]
Ca-A2	96	660	1.7	0.28
Ca-A6	94	800	5.5	0.4

a) Expressed as % of original Na^+ ions replaced by Ca^{++}. b) Number of particles measured. c) Mean cube side. d) Relative standard deviation.

Powders were first pelleted under a pressure of ca. 1×10^3 kg cm^{-2}, crushed, and dehydrated at 383 K for 10 h. The temperature was then raised to 623 K and the system evacuated at that level for at least 20 h. Practically the same FR results were obtained for samples both with and without compression.

No impurities were detected in the Xe or He by mass spectrometer analysis.

Apparatus and Procedure. The FR apparatus was described in a previous paper.[4] The gas space V of the system was varied sinusoidally as

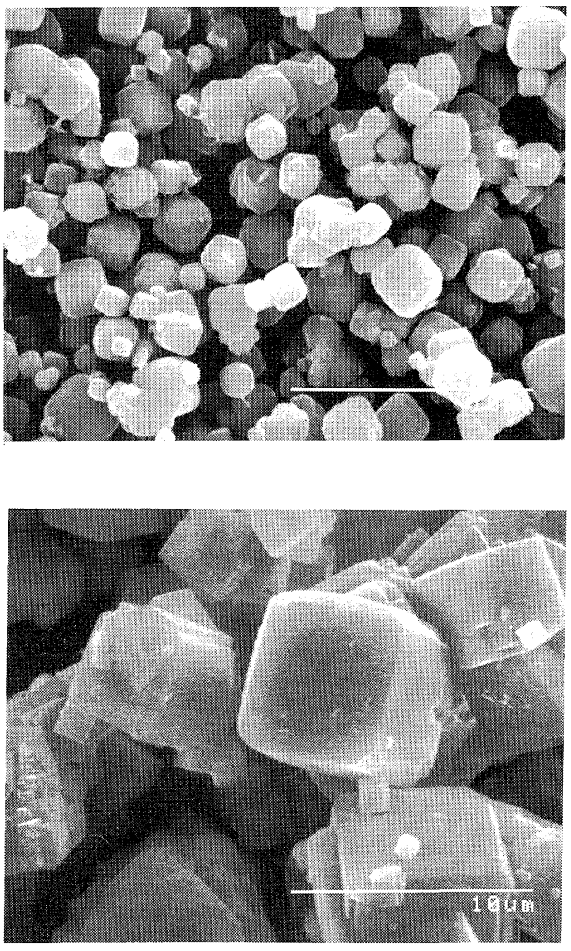

Fig. 1. SEM photographs of (a) Ca-A2 and (b) Ca-A6 zeolites.

$$V(t) = V_e(1 - ve^{i\omega t}), \quad (1)$$

where V_e is the equilibrium or the mean volume of the oscillation, v the relative amplitude and ω the angular velocity. The induced pressure variation can be well expressed by

$$P(t) = P_e\{1 + pe^{i(\omega t+\varphi)}\}. \quad (2)$$

In order to remove any apparent change in the p or φ characteristic of the apparatus due to a delay of the pressure-gauge reading, blank experiments were carried out without zeolites.

Actual values of v and φ were determined by

$$v = p_B \text{ and } \varphi = \varphi' - \varphi_B, \quad (3)$$

where p_B and φ_B denote the results obtained in a blank experiment carried out under almost the same conditions for P_e, T_e, and further at the same ω. φ' is the value of raw data obtained in a system with zeolites.

The various conditions for the pure Xe and Xe+He systems should be regarded as identical, since after each run of ω's for a pure Xe system was completed, small amounts of He were introduced into the system while repeating the scanning of ω. The (total) equilibrium pressure, P_e, was measured using a conventional mercury manometer.

Results

Dependence of p/v and φ on ω. In preliminary experiments for pure He systems, various results agreed with those of the blank experiments. It is concluded, therefore, that

$$p/v = 1 \text{ and } \varphi = 0 \quad (4)$$

with respect to the pure He system.

The results of p/v and φ obtained from single and binary gas systems of Ca-A2 at 273 K are shown in Figs. 2(a) and 2(b), for which the experimental conditions are given in Table 2.

If both Xe and He molecules behave independently in the mixture, the values of p/v and φ corresponding to ΔP_T in Fig. 3 are expected to be intermediate of those corresponding to ΔP_{Xe} and ΔP_{He} (as illustrated in Fig. 3). Calculated results from the triangle are represented by the dashed curves in Figs. 2(a) and 2(b). The discrepancy between the two dashed curves, one

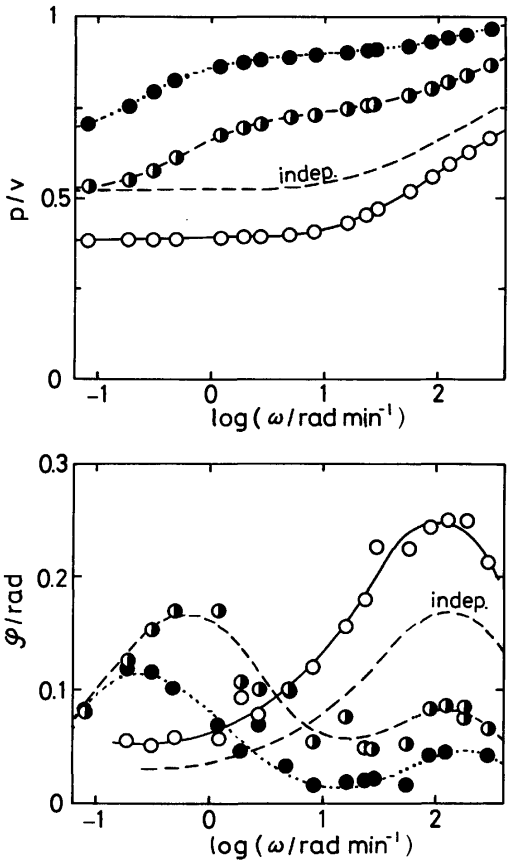

Fig. 2. Raw data of Xe and Xe+He mixtures over Ca-A2 at 273 K; (a) p/v and (b) φ versus ω. ○, pure Xe(Exp. No. 1); ◑, Xe:He=4:1(Exp. No. 2); ●, Xe:He=4:3(Exp. No. 3). The dashed curves indicated by "indep." represent calculated results under the assumption that each component of Xe:He=4:1 behaves independently.

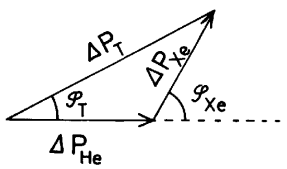

Fig. 3. Relations among total and partial pressure variation; $P_T(t)=P_T^{(e)}+\Delta P_T\cos(\omega t+\varphi_T)$, $P_{He}(t)=P_{He}^{(e)}+\Delta P_{He}\cos(\omega t+0)$, and $P_{Xe}(t)=P_{Xe}^{(e)}+\Delta P_{Xe}\cos(\omega t+\varphi_{Xe})$. An equality of $P_T(t)=P_{He}(t)+P_{Xe}(t)$ leads to the triangle.

experimental and the other calculated, suggests considerable interference effects between Xe and He. It should be noted that the *single* peak in φ's of the pure Xe system seems to split into *two* peaks in the presence of "inert" (see Eq. 4) molecules of He.

Frequency Response of the Systems. Results at 273 K: The in-phase and out-of-phase components of the FR, $(v/p)\cos\varphi$-1 and $(v/p)\sin\varphi$, respectively, which were calculated from the data in Figs. 2(a) and 2(b), are shown in Figs. 4(a) and 4(b). In order to demonstrate the effects of He, they are divided by a constant K_T (Table 2).

The value of K_T for a single-component system was determined by the gradient of the absorption isotherm:[5]

$$K_T = \frac{RT_0}{V_e}\left(\frac{dB^{(0)}}{dP}\right)_e, \tag{5}$$

where B denotes the amount of abspecies and the superscript, (0), indicates the value in a pure gas system.

The value of K_T of a multicomponent system may be given by (Appendix 1)

$$K_T = \frac{\sum_m x_m K_m/(K_m+1)}{\sum_n x_n/(K_n+1)}, \tag{6}$$

where x_m denotes the mole fraction of the m-component in the *gas* phase. K_m is defined as

$$K_m = \frac{RT_0}{V_e}\left(\frac{dB_m}{dP_m}\right)_e, \tag{7}$$

where B_m denotes the amount of the m-molecules absorbed; P_m is the partial pressure of the component.

In the present work, the absorption isotherm of pure Xe was practically unaltered by the addition of He. Therefore, the values of K_1 and K_2 (the subscript 1 and 2 refer to He and Xe, respectively) can be determined by those obtained in the single-component system:

$$K_1 = K_1^{(0)} (= 0)$$

and

$$K_2 = K_2^{(0)}\left(= \frac{RT_0}{V_e}\left(\frac{dB_2^{(0)}}{dP}\right)_e\right). \tag{8}$$

The amount of Xe molecules, $B_2^{(0)}$, was proportional to the equilibrium pressure. The constants of $K_2^{(0)}$ are given in Table 2. Consequently, K_T of the binary gas mixture can be evaluated by

$$K_T = \frac{x_2 K_2^{(0)}}{1 + x_1 K_2^{(0)}}. \tag{9}$$

The values of K_T, thus obtained, are given in Table 2; K_T is expected to be the upper limit of the in-phase components.[5]

Results of Ca-A6 are plotted in Figs. 5(a) and 5(b) together with those of Ca-A2 which were obtained

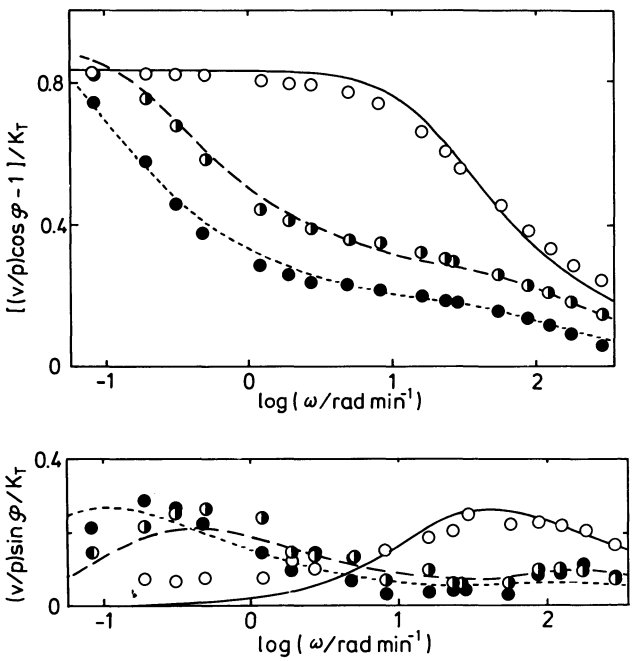

Fig. 4. Frequency response of Xe and Xe+He mixtures over Ca-A2 at 273 K; (a) in-phase and (b) out-of-phase components normalized by K_T versus ω. Notation is that of Fig. 2. Various curves represent calculated results according to Eqs. 10 and 11 with the parameters given in Table 3.

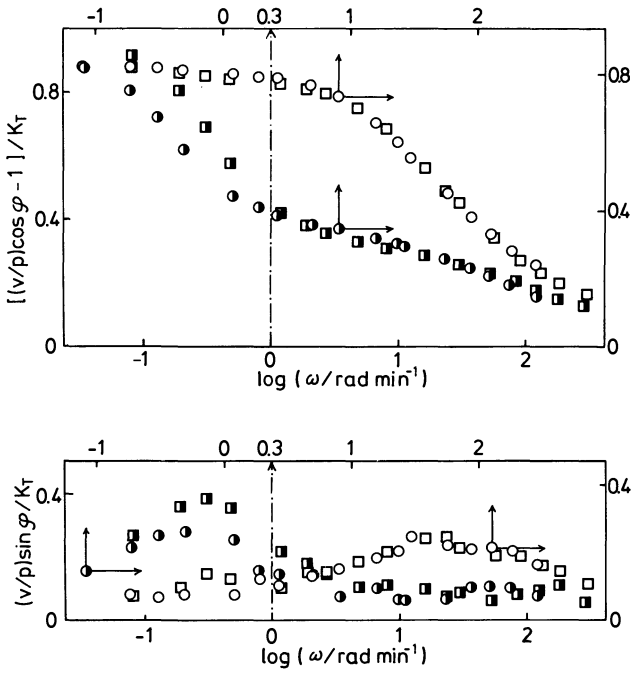

Fig. 5. Dependence of crystal size on FR of the systems; (a) in-phase and (b) out-of-phase components normalized by K_T versus ω. Squares are the results obtained from Ca-A6 systems; □, pure Xe (Exp. No. 4); ◨, Xe:He=3:1(Exp. No. 5). Circles correspond to those in Fig. 4.

under similar conditions; they were almost superimposable by being moved parallel to the abscissa of 0.30.

Results at 255 K: Similar experiments were carried out at 255 K. Their experimental conditions are summarized in Table 2. The values of FR of the various systems are shown together in Fig. 6. It is worthwhile noting that the results obtained in the lower ω region seem to be independent of the crystal size, whereas those in the higher ω region depend on it.

FR Data Analysis

FR at 273 K. On the basis of the experimental results, it is assumed that *two* diffusion processes are involved in the binary gas systems, so that the FR may be described by[4]

$$\{(v/p)\cos\varphi - 1\}/K_T = \tilde{K}_1\bar{\delta}_{3c}(2\omega a_m^2/D_1') + \tilde{K}_2\bar{\delta}_{3c}(2\omega a_m^2/D_2') \quad (10)$$

and

$$(v/p)\sin\varphi/K_T = \tilde{K}_1\bar{\delta}_{3s}(2\omega a_m^2/D_1') + \tilde{K}_2\bar{\delta}_{3s}(2\omega a_m^2/D_2'), \quad (11)$$

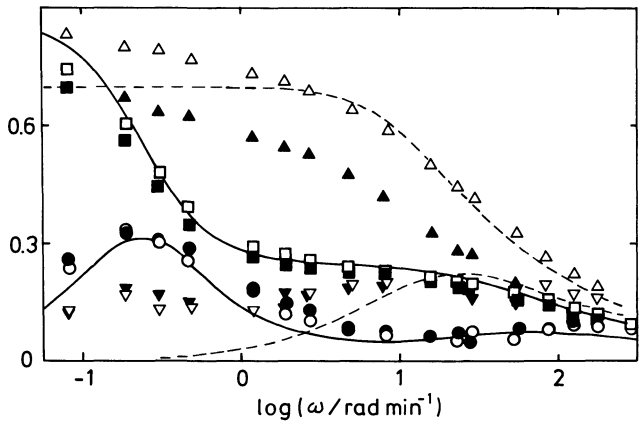

Fig. 6 Frequency response of Xe and Xe+He mixtures over Ca-A2 (open symbols) and Ca-A6(solid symbols) at 255 K. △(Exp. No. 6) and ▲(Exp. No. 8), in-phase(normalized) components of pure Xe systems; ▽ and ▼, out-of-phase(normalized) components of the same systems. □(Exp. No. 7) and ■(Exp. No. 9), the in-phase components of Xe:He=4:1 systems; ○ and ●, the out-of-phase components of the same systems. The solid curves represent calculated results according to Eqs. 13 14 with the parameters of $\tilde{K}_1$=0.25, D_1'/a_m^2=6.2 min^{-1}, $\tilde{K}_2$=0.63, and κ_{-2}=0.24 min^{-1}.

where $\tilde{K}_i$ is a constant giving the fraction of the i-th term; D_i' is the Fickian diffusivity.

The characteristic functions of $2\omega a_m^2/D_i'$ for the diffusion process, $\bar{\delta}_{3c}$ and $\bar{\delta}_{3s}$, were computed using

$$\bar{\delta}_{3j}(2\omega a_m^2/D_i') = \frac{1}{\sqrt{2\pi}\sigma}\int_0^\infty [\delta_{3j}(2\omega a^2/D_i') \exp\{-\frac{(a-a_m)^2}{2\sigma^2}\}]\,da, \quad (12)$$

(j = c or s)

where the values of a_m and σ in Table 1 were inserted. Two analytical functions of x, $\delta_{3c}(x)$, and $\delta_{3s}(x)$, were given explicitly in a previous paper.[5]

The theoretical results, thus calculated, are represented by various curves in Figs. 4(a) and 4(b), of which the parameters determined on a trial and error basis ($\tilde{K}_1$, D_1'/a_m^2, $\tilde{K}_2$, and D_2'/a_m^2) are summarized in Table 3.

FR at 255 K. Results obtained at 255 K could not be reproduced by the two-diffusion model of Eqs. 10 and 11. However, they seem to be described by

$$\{(v/p)\cos\varphi - 1\}/K_T = \tilde{K}_1\bar{\delta}_{3c}(2\omega a_m^2/D_1') + \tilde{K}_2\frac{1}{1+(\omega/\kappa_{-2})^2} \quad (13)$$

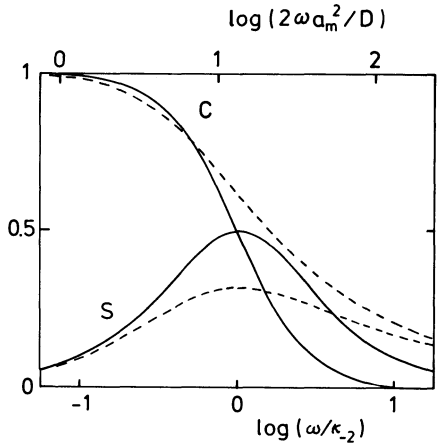

Fig. 7. Comparison of two kinds of characteristic functions: solid curves represent $1/\{1+(\omega/\kappa_{-2})^2\}$ (C) and $(\omega/\kappa_{-2})/\{1+(\omega/\kappa_{-2})^2\}$ (S) applicable to an adsorption-desorption process; dashed curves are $\bar{\delta}_{3c}$ (C) and $\bar{\delta}_{3c}$ (S) applicable to the diffusion process in Ca-A2(σ=0.28).

Table 3. Parameters for $\tilde{K}_i$ and D_i'/a_m^2 in Eqs. 10 and 11

Exp. No.	$\tilde{K}_1$	(D_1'/a_m^2)/min^{-1}	$\tilde{K}_2$	(D_2'/a_m^2)/min^{-1}
1	(0.83	3.05)		
2	0.23	18.1	0.67	3.0×10^{-2}
3	0.15	11.9	0.85	8.0×10^{-3}

and

$$(v/p)\sin\varphi/K_T = \tilde{K}_1\bar{\delta}_{3s}(2\omega a_m^2/D_1') + \tilde{K}_2\frac{(\omega/\kappa_{-2})}{1+(\omega/\kappa_{-2})^2}. \quad (14)$$

Each second term on the right hand side is a characteristic function for the adsorption-desorption process,[6] which is compared with $\bar{\delta}_{3c}$ or $\bar{\delta}_{3s}$ in Fig. 7; evidently they are very different.

The theoretical results for the systems of Ca-A2 are represented by the solid curves in Fig. 6.

Discussion

Pure Xe Systems. Almost all abspecies of Xe (more than 80%, see Fig. 4(a)) may be regarded as identical; the out-of-phase components could be reproduced by the solid curve stemming from a single term in Eq. 10 (see Table 3). The moved distance (0.30) in Figs. 5(a) and 5(b), on the other hand, leads to

$$\frac{D_2^{(0)}/a_m^2 \text{ of Ca-A2}}{D_2^{(0)}/a_m^2 \text{ of Ca-A6}} = 2.0, \quad (15)$$

where $D_2^{(0)}$ denotes the Fickian diffusivity of a pure Xe system. Substitution of the values of a_m's leads to

$$\begin{aligned} D_2^{(0)}/10^{-14}\,\mathrm{m^2\,s^{-1}} &= 3.7 \quad \text{for Ca-A2} \\ &= 19 \quad \text{for Ca-A6} \\ (&= 15 \quad \text{for Linde-5A})^{7} \end{aligned} \quad (16)$$

Contrary to our expectation, the difference in this diffusivity was considerable. It is noted, however, that the absorption isotherm of these two kinds of zeolites were considerably different (see $K_2^{(0)}$'s in Table 2). The diffusivities for small commercial zeolite crystals were found to be substantially smaller than for large laboratory synthesized crystals.[8] The reproducibility of the theoretical curves at 255 K was not so good (see dashed curves in Fig. 6).

Binary Gas Systems. Since the FR of mixture was affected by the change in the crystal size, the interference effects due to He would be attributed to processes occurring not on exposed surfaces, but within micropores.

The experimental results can be summarized as follows: (i) there is only one diffusion process in the pure Xe system, (ii) no FR of He was observed in a pure He system since the absorption of He was negligible and, thus, $K_1^{(0)}=0$ and (iii) (only) two diffusion processes were needed to theoretically reproduce FR data on a binary gas system. On the basis of these results, a more general form of Fick's law,

$$\frac{\partial c_m}{\partial t} = \sum_{n=1}^{2} D_{mn}\nabla^2 c_n, \qquad m = 1 \text{ or } 2 \quad (17)$$

is assumed. Here, c_m denotes the concentration of the m-component and D_{mn} is the Fickian diffusivity ($D_{11}>D_{22}$). Every D_{mn} would depend on both c_1 and c_2. However, since the perturbation of the FR method was very small (e.g. $v\sim10^{-2}$) and, therefore, $c_m\fallingdotseq c_m^{(e)}$, D_{mn} can be regarded as a constant.

The coupled equations may be decoupled by the transformations:

$$c_1' = \{1+(D_-/D_+)\}c_1 + (D_-/D_+)c_2 \quad (18)$$

and

$$c_2' = -(D_-/D_+)c_1 + \{1-(D_-/D_+)\}c_2. \quad (19)$$

In these equations the short notations

$$D_+ \equiv D_{21} + D_{12} \quad (20)$$

and

$$D_- \equiv D_{21} - D_{12} \quad (21)$$

are introduced.

Substitution of c_m' for c_m in Eq. 17 leads to

$$\frac{\partial c_m'}{\partial t} = D_m'\nabla^2 c_m' \qquad m = 1 \text{ or } 2, \quad (22)$$

where

$$D_1' = D_{11} + \frac{1}{2}D_-, \quad (23)$$

and

$$D_2' = D_{22} + \frac{1}{2}D_-. \quad (24)$$

The values of D_i' in Table 3 are expected to correspond to these eigenvalues.

In the present work, c_1 is sufficiently small. A comparison of Eqs. 18 and 19 with Eqs. 10 and 11 would lead to

$$\frac{\tilde{K}_1}{\tilde{K}_2} = \frac{(D_-/D_+)}{1-(D_-/D_+)}. \quad (25)$$

When the value of D_-/D_+ is found from the $\tilde{K}_i$'s (Table 3) all four coefficients, D_{mn}, can be evaluated successively (Appendix 2). The derived values are given in Table 4 and are plotted in Fig. 8.

Since the values of (D_{mn}/a_m^2)'s were determined after many steps of calculation from the raw data on $K_2^{(0)}$, P_e, ΔP, and φ, their absolute values are not very reliable; the ambiguity estimated is indicated by the vertical lines in Fig. 8 (most of the ambiguity would arise from errors in P_e's in the present work). However, the conclusions that

$$D_{12} \fallingdotseq D_{21} \fallingdotseq (D_{11}D_{22})^{1/2} \quad (26)$$

Table 4. Values of D_{mn}/a_m^2 Derived (in $\mathrm{min^{-1}}$ Units)

Exp. No.	D_{11}/a_m^2	D_{12}/a_m^2	D_{21}/a_m^2	D_{22}/a_m^2
2	16.9	3.44	5.80	1.21
3	11.6	1.51	2.05	0.28

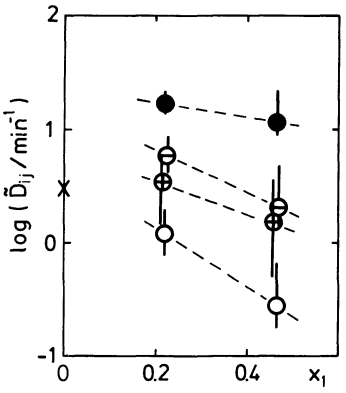

Fig. 8. Diffusional time constant $\tilde{D}_{ij}$'s of Xe+He/Ca-A2 systems at 273 K versus the mole fraction of He in gas phase, x_1. ●, $\tilde{D}_{11}$; ⊕, $\tilde{D}_{12}$; ⊖, $\tilde{D}_{21}$; ○, $\tilde{D}_{22}$, where $\tilde{D}_{ij}=D_{ij}/a_m^2$. × indicates the value of pure Xe.

and

$$D_{12} < D_{21} \tag{27}$$

should be reliable, since they are governed by the values of D_1'/a_m^2 and the *ratio* of $\tilde{K}_1/\tilde{K}_2$.

Four constants of D_{mn}'s with respect to a heptane+benzene over NaX system have been determined empirically by a sorption method.[9] The results lead to

$$D_{12} > D_{21} \tag{28}$$

in contrast to the result of Eq. 27, though the method is based on the supposition that all D_{mn}'s do not depend on the concentrations.

The cross-terms, D_{12} and D_{21}, have been determined by a random-walk approach.[10] The application of the method to a simultaneous sorption of two sorbates in an initially empty pore system shows very significant multicomponent effects due to the contribution of the cross terms.

In summary, Xe molecules in micropores may be divided into two species in a Xe+He mixture; the division into c_1' and c_2' species depends on the ratio of D_-/D_+; one of the two species becomes an adspecies with decreasing temperature.

Appendix 1

Since the vapor may be regarded as ideal,

$$p_T = x_1p_1 + x_2p_2, \tag{A1}$$

where the subscript T indicates the value of the total pressure. On the other hand, in consideration of a case at $\omega \fallingdotseq 0$, one finds

$$v - p_{0T} = K_1x_1p_{01} + K_2x_2p_{02}, \tag{A2}$$

where the subscript 0 indicates the value in the quasistatic state.

The asymptotic value of the in-phase component, K_T, is given by

$$K_T = (v/p_{0T}) - 1 \tag{A3}$$

since φ tends to zero as $\omega \to 0$. In the same way,

$$K_i = (v/p_{0i}) - 1. \tag{A4}$$

Eliminating p_{0T}, p_{01}, and p_{02}, one finds

$$K_T = \frac{\sum_{m=1}^{2} x_mK_m/(K_m + 1)}{\sum_{n=1}^{2} x_n/(K_n + 1)} = \frac{K_1K_2 + x_1K_1 + x_2K_2}{1 + x_1K_2 + x_2K_1}. \tag{A5}$$

Appendix 2

Other parameters, D' and d, are introduced:

$$D_{21} = D' + d \tag{A6}$$

and

$$D_{12} = D' - d \tag{A7}$$

or

$$D_+ = 2D' \tag{A8}$$

and

$$D_- = 2d. \tag{A9}$$

The ratio D_-/D_+ or d/D' is replaced by δ for simplicity:

$$D_-/D_+ = d/D' = \delta. \tag{A10}$$

Equations 23 and 24 lead to

$$D_1' - D_2' = D_{11} - D_{22} + D_-. \tag{A11}$$

In the transformation of Eqs. 18 and 19, the relation

$$c_1' + c_2' = c_1 + c_2 \tag{A12}$$

is always satisfied. This necessary condition requires a relation among the D_{mn}'s:

$$D_+^2 = 2D_-(D_{11} - D_{22} + D_-). \tag{A13}$$

Substitution of Eq. A10 into Eq. A13 leads to

$$D' = \delta(D_1' - D_2'). \tag{A14}$$

When δ is determined, Eq. A14 gives D' and Eq. A10 gives the value of d. Consequently, the four coefficients may be determined as

$$D_{11} = D_1' - d, \tag{A15}$$

$$D_{12} = D' - d, \tag{A16}$$

$$D_{21} = D' + d, \tag{A17}$$

and

$$D_{22} = D_2' + d. \tag{A18}$$

Notation

a : radius of an isotropic sphere (cubic crystals are approximated by the sphere).

a_m : mean radius of the sphere.

$B^{(0)}$: amount of molecules absorbed in a single component system.
B_m : amount of abspecies of m-component in a mixture.
c_m : concentration of abspecies of m-component in micropores.
$c_m^{(e)}$: c_m at an equilibrium.
c_i' : concentration of a mixed abspecies of c_1 and c_2 derived mathematically by decoupling coupled equations.
$D_2^{(0)}$: Fickian diffusivity of a pure Xe system.
D_i' : Fickian diffusivity of c_i'.
D_{mn} : Fickian diffusivity in a more general form.
$K_m^{(0)}$: coefficient calculated from the gradient of absorption isotherm of a pure gas system.
K_m : coefficient correlated to the gradient of absorption isotherm of m-component in a multicomponent system.
K_T : asymptotic value of the in-phase component at $\omega \rightarrow 0$ of a single or multicomponent system.
$\widetilde{K}_i$: coefficient indicating contribution of i-th characteristic function to FR data.
P : gas pressure.
P_e : P at an equilibrium.
P_m : partial pressure of m-component in a mixture.
p : relative amplitude of pressure variation.
T_e : equilibrium temperature of absorbent.
T_0 : (RT_0/V_e) is a conversion factor; T_0 is usually room temperature.
V : volume of gas space of a system.
V_e : V at an equilibrium.
v : relative amplitude of volume variation.
x_m : mole fraction of m-component in gas phase.

Greek Letters
δ_{3j} : characteristic function of diffusion for FR.
$\bar{\delta}_{3j}$: δ_{3j} modified by the crystal size distribution.
φ : phase lag between volume and pressure variation.
κ_{-2} : parameter characteristic of an adsorption-desorption process.
σ : standard deviation of a normal distribution.
ω : angular velocity of sinusoidal oscillation.

Excited-State Reactions of Coumarins in Aqueous Solutions. VI. Fluorescence Quenching of 7-Hydroxycoumarins by Chloride Ions in Acidic Solutions

Tetsuo MORIYA
Electrotechnical Laboratory, Umezono, Tsukuba, Ibaraki 305
(Received June 29, 1987)

The fluorescence behavior of 7-hydroxycoumarin and 7-hydroxy-4-methylcoumarin has been studied in acidic aqueous solutions by changing the concentration of chloride ions as a fluorescence quencher. The intensity decrease and lifetime change in fluorescence from neutral and tautomeric forms of photo-excited states are explained by an interaction between protonated molecules generated in excited state and chloride ions. The magnitude of quenching-rate constant is estimated under steady-state conditions and the result is compared with the analysis using time-dependent response.

Complex fluorescent behavior of coumarin derivatives with 7-hydroxyl substituent has been studied in various organic solvents, and in neutral, acidic, and basic aqueous solutions.[1-4] It has been revealed that four fluorescent species typically exist in the photo-excited state according to solvent conditions; they have been identified as neutral, anionic, tautomeric, and protonated species of the excited molecule.

In the acidic region where $[H^+] \approx 0.5$ mol dm^{-3}, a very interesting situation occurs in the fluorescence of aqueous 7-hydroxycoumarin (7HC) and 7-hydroxy-4-methylcoumarin (7H4MC) solutions. The fluorescence bands from neutral form ($\overset{*}{N}$) and tautomeric form ($\overset{*}{T}$) in their excited states are observable, but those from anionic form ($\overset{*}{A}^-$) and cationic form ($\overset{*}{C}^+$) are not detected.[4] This means that generated $\overset{*}{A}^-$ and $\overset{*}{C}^+$, if any, are instantaneously converted to $\overset{*}{N}$ or $\overset{*}{T}$ before they are deactivated radiatively to the ground state. Two fluorescence bands of $\overset{*}{N}$ and $\overset{*}{T}$ are separated in wavelength so enough that the measurement of each band is easily performed. Moreover, with the addition of chloride ions to the solution, these fluorescence bands are effectively quenched; this enables us to confirm detailed mechanisms of acid-base, phototautomerization, and fluorescence-quenching reactions.

The main purpose of this work is to analyze quantitatively the reaction kinetics of the photo-excited 7-hydroxycoumarins in acidic aqueous solutions. The theoretical consideration using rate-equation formulation will be useful to understand the feature of excited-state reactions. The fluorescence data under steady-state conditions and the fluorescence-lifetime measurements will be consistently explained by means of a unified model.

Experimental

Materials. The commercial grade reagents of 7-hydroxycoumarin (7HC) from Wako Pure Chemical Ind. and 7-hydroxy-4-methylcoumarin (7H4MC) from Tokyo Kasei were purified by recrystallization from ethanol and by washing with diethyl ether; 7HC, mp 234 °C; 7H4MC, mp 186 °C. Hydrochloric acid and perchloric acid were of pure quality from Wako Pure Chemical Ind. Water was permeated and distilled.

Methods. UV absorption and fluorescence spectra of the aqueous 7HC and 7H4MC solutions of $\approx 6 \times 10^{-5}$ mol dm^{-3} were measured at 20 °C. The pH of the solution was controlled with HCl and $HClO_4$, the chloride ion concentration being adjusted by changing their ratio. Fluorescence-lifetime measurements were performed by means of a time-correlated single-photon-counting fluorometer similar to that described in Ref. 5. Since the lifetime of fluorescers was close to the decay time of a repetitive short-pulsed light at 337 nm from an air-flash lamp, the data were deconvoluted to know the true decay character unaffected by a response function of the measurement system; the typical accuracy of this procedure was ± 0.05 ns.

Results

In a previous paper,[4] the complex pH dependence of absorption and fluorescence spectra of 7HC and 7H4MC in aqueous solutions has been fully investigated. Since the present interest is concentrated on the pH range with $[H^+]$ of ≈ 0.5 mol dm^{-3}, the spectral behavior of these fluorophores is summarized as follows. In the electronic ground state, there exists only a neutral molecular species (N), the absorption maxima of which are 324 nm (7HC) and 321 nm (7H4MC). If this neutral species is optically excited at the absorption-peak wavelength, two molecular species formed in the excited state are observable. One is usual neutral molecule ($\overset{*}{N}$), and the other is tautomeric molecule ($\overset{*}{T}$) in which a hydrogen of the 7-hydroxyl group is transferred to the carbonyl group at 2-position. As will be mentioned later, cationic form ($\overset{*}{C}^+$) protonated at the carbonyl group and anionic form ($\overset{*}{A}^-$) deprotonated at the hydroxyl group can exist in principle, but they are not spectroscopically detected around $[H^+]$ of 0.5 mol dm^{-3}. The fluorescence maxima of $\overset{*}{N}$ and $\overset{*}{T}$ are at 397 and 478 nm for 7HC, and at 390 and 475 nm for 7H4MC,

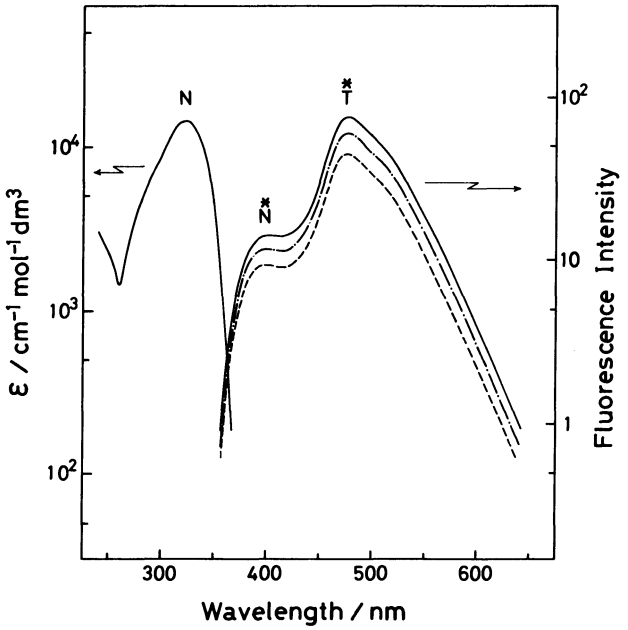

Fig. 1. Absorption and fluorescence spectra of 7HC in the acidic aqueous solution at 20 °C. $[HClO_4]+[HCl]=0.5$ mol dm^{-3}. (——), $[HCl]=0$; (—·—), $[HCl]=0.2$ mol dm^{-3}; (---), $[HCl]=0.5$ mol dm^{-3}. N describes the neutral ground state, and $\overset{*}{N}$ and $\overset{*}{T}$ describe the neutral and tautomeric excited state, respectively.

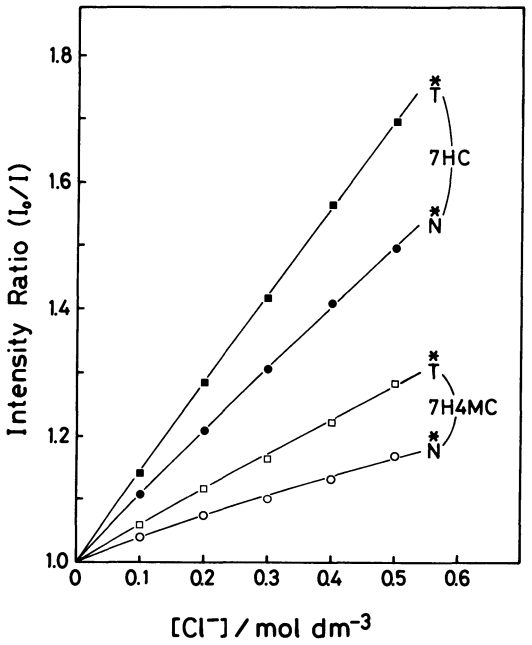

Fig. 2. Dependence of the fluorescence intensity ratio, I_0/I, on $[Cl^-]$ in the acidic aqueous solution ($[H^+]=0.5$ mol dm^{-3}) at 20 °C. 7HC (●), (■); 7H4MC (○), (□). $\overset{*}{N}$ and $\overset{*}{T}$ describe the excited states of neutral and phototautomeric molecular forms, respectively.

respectively. In Fig. 1, the absorption and fluorescence spectra of an aqueous 7HC solution with 0.5 mol dm^{-3} $HClO_4$ are shown by the solid lines.

When $[Cl^-]$ is changed by the amount of an added HCl component with holding pH of the solution as $[HClO_4]+[HCl]=0.5$ mol dm^{-3} ($H_0\approx0.20$),[6] the fluorescence intensity from $\overset{*}{N}$ and $\overset{*}{T}$ has been quenched depending on $[Cl^-]$ as shown by the dashed curves in Fig. 1. Since the fluorescence bands of $\overset{*}{N}$ and $\overset{*}{T}$ are separated far enough to each other, the respective fluorescence yields can be monitored at 397 and 478 nm (7HC), and at 390 and 475 nm (7H4MC), respectively. Figure 2 describes plots of I_0/I for $\overset{*}{N}$ and $\overset{*}{T}$ vs. $[Cl^-]$ where I_0 and I are the fluorescence intensity for each excited species in the absence and in the presence of chloride ions. Slight deviation from the usual Stern-Volmer linear relationship is observed for both I_0^N/I^N and I_0^T/I^T.

Under the pulsed light excitation at 337 nm which generates $\overset{*}{N}$ at the moment of light absorption, the decay characteristic of fluorescence from neutral and tautomeric fluorescers has been measured at the peak wavelength of each fluorescence band with keeping $[H^+]$ at 0.5 mol dm^{-3} but with different $[Cl^-]$. The time-dependent light intensity, $i^N(t)$ and $i^T(t)$, of $\overset{*}{N}$ and $\overset{*}{T}$ was fitted satisfactorily for the double-exponential decay character:

$$i^N(t) \propto \exp(-t/\tau_+) + C\cdot\exp(-t/\tau_-) \quad (1)$$

and

$$i^T(t) \propto \exp(-t/\tau_+) - \exp(-t/\tau_-). \quad (2)$$

The best-fitted values for τ_+, τ_-, and C are given in Table 1.

Table 1. Values for the Fluorescence Lifetime Parameters, τ_+, τ_-, and C, of 7HC and 7H4MC in Acidic Aqueous Solutions ($[H^+]=0.5$ mol dm^{-3}) at 20 °C

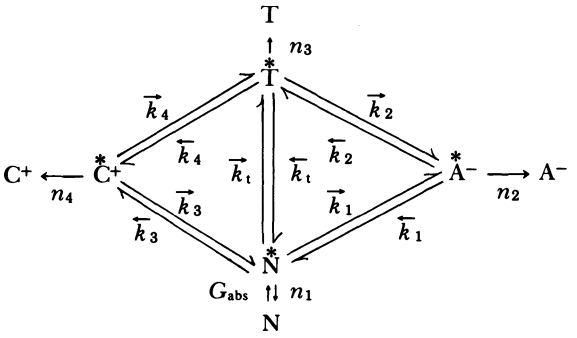
Discussion

Fluorescence Quenching by Chloride Ions in Acidic Solutions. Based on the generalized scheme for excited-state reactions of coumarins in aqueous solutions confirmed in Ref. 4, we may adopt the following scheme if only the neutral molecule exists in the ground state at $[H^+]$ of ≈ 0.5 mol dm^{-3}:



Scheme 1.

Here, G_{abs} is the generation rate of $\overset{*}{N}$ and n_j's are the transition rates of the excited species to their ground states. $\vec{k}_j$'s and $\overleftarrow{k}_j$'s are the protonation and deprotonation rate constants between acids and bases in the excited state. $\vec{k}_t$ and $\overleftarrow{k}_t$ represent the reaction pathway of tautomerization that does not involve stepwise protonation or deprotonation processes, i.e., the "nondissociative" reaction pathway.[4,7] Because the fluorescence of $\overset{*}{A}^-$ and $\overset{*}{C}^+$, which should appear in the wavelength region between $\overset{*}{N}$ and $\overset{*}{T}$ bands, is not detected at $[H^+]$ of 0.5 mol dm^{-3}, the following conditions will be satisfied:

$$\vec{k}_1 \ll \overleftarrow{k}_1[H^+],\ \vec{k}_2 \ll \overleftarrow{k}_2[H^+] \text{ and } \overleftarrow{k}_3[H^+] \ll \vec{k}_3,\ \overleftarrow{k}_4[H^+] \ll \vec{k}_4. \tag{3}$$

If all decay rates of the excited species, n_j's are of the same order, the ratio of fluorescence intensity of $\overset{*}{T}$ to that of $\overset{*}{N}$ in the absence of Cl^- is obtained by means of the rate equation analysis as carried out in Ref. 4 under the conditions of Eq. 3 (cf. Appendix):

$$\frac{I_0^T}{I_0^N} = \frac{n_3^r}{n_1^r} \frac{\vec{k}_t + \beta\overleftarrow{k}_3[H^+]}{n_3 + \overleftarrow{k}_t + \alpha\overleftarrow{k}_4[H^+]}, \tag{4}$$

where I_0's represent the fluorescence intensity at $[Cl^-]=0$, n_1^r and n_3^r are the radiative transition probabilities of $\overset{*}{N}$ and $\overset{*}{T}$ to their ground states, respectively, and

$$\vec{k}_t = \vec{k}_t + \vec{k}_1 \frac{\overleftarrow{k}_2[H^+]}{n_2 + \overleftarrow{k}_1[H^+] + \overleftarrow{k}_2[H^+]},$$

$$\overleftarrow{k}_t = \overleftarrow{k}_t + \vec{k}_2 \frac{\overleftarrow{k}_1[H^+]}{n_2 + \overleftarrow{k}_1[H^+] + \overleftarrow{k}_2[H^+]},$$

$$\alpha = \frac{\vec{k}_3}{n_4 + \vec{k}_3 + \vec{k}_4}, \text{ and } \beta = \frac{\vec{k}_4}{n_4 + \vec{k}_3 + \vec{k}_4}. \tag{5}$$

When 0.3 mol dm^{-3} NaCl is added to the acidic solution with 0.5 mol dm^{-3} $HClO_4$, the fluorescence of $\overset{*}{N}$ and $\overset{*}{T}$ is decreased, while the addition of 0.3 mol dm^{-3} $NaClO_4$ induces no fluorescence change. This fact shows that Cl^- affects the fluorescence-quenching phenomenon contrary to other inorganic ions such as Na^+ and ClO_4^-. It is observed in general that halide ions have the quenching ability in order of $Cl^- < Br^- < I^-$.[8] Further, the fluorescence of $\overset{*}{N}$, $\overset{*}{T}$, and $\overset{*}{A}^-$ does not depend on Cl^- quencher over the pH range where $\overset{*}{C}^+$ is not formed in the excited state (pH≧2).[4] All these results lead to the conclusion that $\overset{*}{N}$ and $\overset{*}{T}$ fluorescers are quenched only through an interaction of the protonated excited state, $\overset{*}{C}^+$, with Cl^-, and that the quenching mechanism will be essentially the same as proposed in Ref. 9:

$$W: \overset{*}{C}^+ + Cl^- \xrightarrow{k_q} C^+ + Cl^-. \tag{6}$$

Here, the fraction W of $\overset{*}{C}^+$ in Scheme 1 additionally obeys a collisional quenching process where the encounter complex, $(\overset{*}{C}^+ \cdot Cl^-)$, decays nonradiatively to C^+ and Cl^- with a rate of k_q; the remaining fraction $1-W$ of $\overset{*}{C}^+$ obeys the instantaneous or "static" deactivation process. The additional factor W (a function of the quencher concentration $[Cl^-]$) can be approximated by $\exp(-V[Cl^-])$, where V is the static quenching constant. If the model of Frank and Vavilov[10] is applied to the static quenching process, an instantaneous quenching results when the quencher is within the "sphere of action" having a volume of V/N', where N' is the Avogadro number per millimole.[11]

Since illuminating light is absorbed solely by neutral molecules under the experimental conditions and the fraction $1-W$ of $\overset{*}{C}^+$ is immediately quenched without emitting any light quantum, the effective generation rate of $\overset{*}{N}$, $\tilde{G}([Cl^-])$, must be somewhat reduced from G_{abs}.[9] However, this alteration does not appear explicitly in the ratio of fluorescence intensity of $\overset{*}{N}$ to that of $\overset{*}{T}$, I^T/I^N. In the presence of Cl^-, straightforward rate-equation analysis as before gives the relation:

$$\frac{I^T}{I^N} = \frac{n_3^r}{n_1^r} \frac{\vec{k}_t + \overleftarrow{k}_3[H^+] \dfrac{\beta}{1+\gamma[Cl^-]}}{n_3 + \overleftarrow{k}_t + \overleftarrow{k}_4[H^+] \dfrac{\alpha + \gamma[Cl^-]}{1+\gamma[Cl^-]}}, \tag{7}$$

where

$$\gamma = \frac{k_q}{n_4 + \vec{k}_3 + \vec{k}_4}. \tag{8}$$

From Eqs. 4 and 7, we have

$$\frac{I_0^T/I^T}{I_0^N/I^N} = \frac{1 + \{(n_3 + \overleftarrow{k'_t} + \overleftarrow{k}_4[H^+])/(n_3 + \overleftarrow{k'_t} + \alpha\overleftarrow{k}_4[H^+])\}\cdot\gamma[Cl^-]}{1 + \{\overrightarrow{k'_t}/(\overrightarrow{k'_t} + \beta\overleftarrow{k}_3[H^+])\}\cdot\gamma[Cl^-]} \quad (9)$$

and finally

$$\frac{1}{\{(I_0^T/I^T)/(I_0^N/I^N)\}-1} = \{\frac{n_3 + \overleftarrow{k'_t} + \overleftarrow{k}_4[H^+]}{n_3 + \overleftarrow{k'_t} + \alpha\overleftarrow{k}_4[H^+]} - \frac{\overrightarrow{k'_t}}{\overrightarrow{k'_t} + \beta\overleftarrow{k}_3[H^+]}\}^{-1} \times\{\frac{\overrightarrow{k'_t}}{\overrightarrow{k'_t} + \beta\overleftarrow{k}_3[H^+]} + \frac{1}{\gamma[Cl^-]}\}. \quad (10)$$

Since α, $\beta<1$, the first term on the right-hand side of Eq. 10 which is contained in curly brackets is positive. Therefore, the plot of $1/\{(I_0^T/I^T)/(I_0^N/I^N)-1\}$ vs. $1/[Cl^-]$ becomes linear and its slope is positive from the theoretical prediction.

The experimental result shown in Fig. 2 is replotted in Fig. 3 in accordance with Eq. 10. It is seen that the data follow very well the predicted linear dependence. By using the intercept and slope of this plot, $\{\overrightarrow{k'_t}/(\overrightarrow{k'_t}+\beta\overleftarrow{k}_3[H^+])\}\cdot\gamma$ and $\{(n_3+\overleftarrow{k'_t}+\overleftarrow{k}_4[H^+])/(n_3+\overleftarrow{k'_t}+\alpha\overleftarrow{k}_4[H^+])\}\cdot\gamma$ are given as 0.406 and 0.729 for 7HC, and 0.120 and 0.324 for 7H4MC, respectively. Although the exact value or γ is not obtained only from this information, its region becomes restricted by the relation:

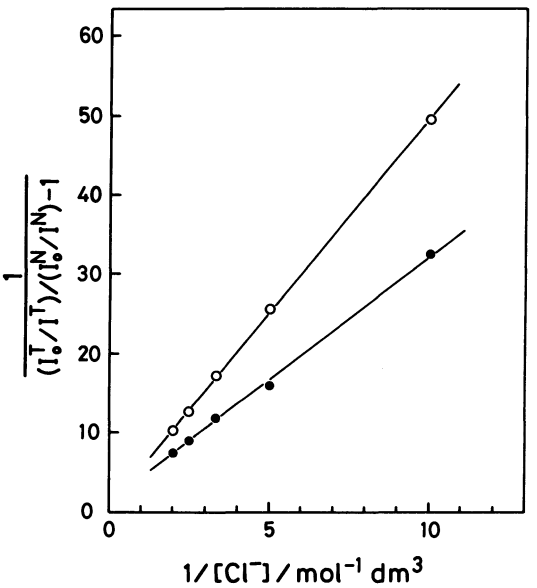


Fig. 3. Plots of $1/\{(I_0^T/I^T)/(I_0^N/I^N)-1\}$ vs. $1/[Cl^-]$ for 7HC (●) and 7H4MC (○) in the acidic solution ($[H^+]$=0.5 mol dm^{-3}) at 20 °C.

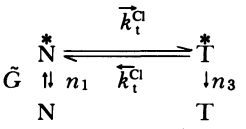
$$0.406<\gamma<0.729 \text{ for 7HC and } 0.120<\gamma<0.324 \text{ for 7H4MC.} \quad (11)$$

because $\alpha,\beta<1$. Considering the definition of γ (Eq. 8), these results mean that the quenching rate constant k_q is less than the decay rate of $\overset{*}{C}^+$ in the absence of quenchers, $n_4+\overrightarrow{k}_3+\overrightarrow{k}_4$, but has the same order of magnitude. From Eq. 11, it is seen that the quenching efficiency of 7H4MC due to Cl^- ions is lower than that of 7HC. Possibly, 4-methyl substituent acts protectively on the quenching process, which is conceivable from the general tendency observed in 7-ethoxycoumarins under various conditions.[8,9,12]

Fluorescence Lifetimes in Acidic Solutions. As described in Scheme 1, the real reactions in the excited state are complicatedly correlated with each other. However, the fundamental aspect of the transient response to a pulsed-light excitation will be approximated by the following simple scheme, if the rate equations are examined in detail under the same situation as discussed in the case of steady-state conditions (cf. Eq. 7):



Scheme 2.

where

$$\overrightarrow{k}_t^{Cl} = \overrightarrow{k'_t} + \frac{\beta\overleftarrow{k}_3[H^+]}{1+\gamma[Cl^-]} \text{ and}$$

$$\overleftarrow{k}_t^{Cl} = \overleftarrow{k'_t} + \frac{(\alpha+\gamma[Cl^-])\overleftarrow{k}_4[H^+]}{1+\gamma[Cl^-]} \quad (12)$$

Then, in accordance with Eqs. 1 and 2, the lifetimes $\tau_\pm$ of $i^N(t)$ and $i^T(t)$ for a light pulse of ideal δ-function are written as[13]

$$\tau_\pm^{-1} = \tfrac{1}{2}(n_1 + \overrightarrow{k}_t^{Cl} + n_3 + \overleftarrow{k}_t^{Cl}) \mp \tfrac{1}{2}[(n_1 + \overrightarrow{k}_t^{Cl} + n_3 + \overleftarrow{k}_t^{Cl})^2 - 4\{(n_1 + \overrightarrow{k}_t^{Cl})(n_3 + \overleftarrow{k}_t^{Cl}) - \overrightarrow{k}_t^{Cl}\overleftarrow{k}_t^{Cl}\}]^{1/2}. \quad (13)$$

From Table 1, the condition, $\tau_+ \gg \tau_-$, is satisfied for both 7HC and 7H4MC, which is equivalent to the case that the second term in the root of Eq. 13 contained in the curly brackets is much smaller than the first term. Then, we have approximate equations:

$$\frac{1}{\tau_+} \approx \frac{n_1n_3 + n_3\overrightarrow{k}_t^{Cl} + n_1\overleftarrow{k}_t^{Cl}}{n_1 + \overrightarrow{k}_t^{Cl} + n_3 + \overleftarrow{k}_t^{Cl}} \text{ and}$$

$$\frac{1}{\tau_-} \approx n_1 + \overrightarrow{k}_t^{Cl} + n_3 + \overleftarrow{k}_t^{Cl} \quad (14)$$

Further, letting the value of τ_+ at $[Cl^-]=0$ be τ_+^0, the following relation is obtained:

$$\frac{1}{(\tau_+^0/\tau_+)-1} = \left\{ \frac{n_1+\vec{k}_t'+(n_1/n_3)\overleftarrow{k}_t'+(n_1/n_3)\overleftarrow{k}_4[H^+]}{n_1+\vec{k}_t'+(n_1/n_3)\overleftarrow{k}_t'+\beta\overleftarrow{k}_3[H^+]+(n_1/n_3)\alpha\overleftarrow{k}_4[H^+]} - \frac{n_1+\vec{k}_t'+n_3+\overleftarrow{k}_t'+\overleftarrow{k}_4[H^+]}{n_1+\vec{k}_t'+n_3+\overleftarrow{k}_t'+\beta\overleftarrow{k}_3[H^+]+\alpha\overleftarrow{k}_4[H^+]} \right\}^{-1} \times \left\{ \frac{n_1+\vec{k}_t'+n_3+\overleftarrow{k}_t'+\overleftarrow{k}_4[H^+]}{n_1+\vec{k}_t'+n_3+\overleftarrow{k}_t'+\beta\overleftarrow{k}_3[H^+]+\alpha\overleftarrow{k}_4[H^+]} + \frac{1}{\gamma[Cl^-]} \right\}. \quad (15)$$

Equation 15 predicts the linear relationship for the plot of $1/\{(\tau_+^0/\tau_+)-1\}$ vs. $1/[Cl^-]$. Figure 4 shows the plot where the data in Table 1 are employed. It is seen from the result that the linear relationship is well applicable in the region where $\tau_+ \gg \tau_-$. By using the intercept and slope of the plot, the ratio of complicated combination of various rate constants is again obtained as in the case of steady-state analysis; $\{(n_1+\vec{k}_t'+n_3+\overleftarrow{k}_t'+\overleftarrow{k}_4[H^+])/(n_1+\vec{k}_t'+n_3+\overleftarrow{k}_t'+\beta\overleftarrow{k}_3[H^+]+\alpha\overleftarrow{k}_4[H^+]\}\cdot\gamma$ and $[\{n_1+\vec{k}_t'+(n_1/n_3)\overleftarrow{k}_t'+(n_1/n_3)\overleftarrow{k}_4[H^+]\}/\{n_1+\vec{k}_t'+(n_1/n_3)\overleftarrow{k}_t'+\beta\overleftarrow{k}_3[H^+]+(n_1/n_3)\alpha\overleftarrow{k}_4[H^+]\}]\cdot\gamma$ are 0.065 and 1.45 for 7HC, and 0.020 and 0.685 for 7H4MC, respectively. Although each rate constant cannot be estimated, the γ values restricted by Eq. 11 are consistent with this result if $n_1 > n_3$. Because of relatively low accuracy of deconvolution for the fast decay component (τ_- and C), the analysis is less fruitful than the consideration on τ_+, whereas the qualitative tendency is predictable according to the same assumption.

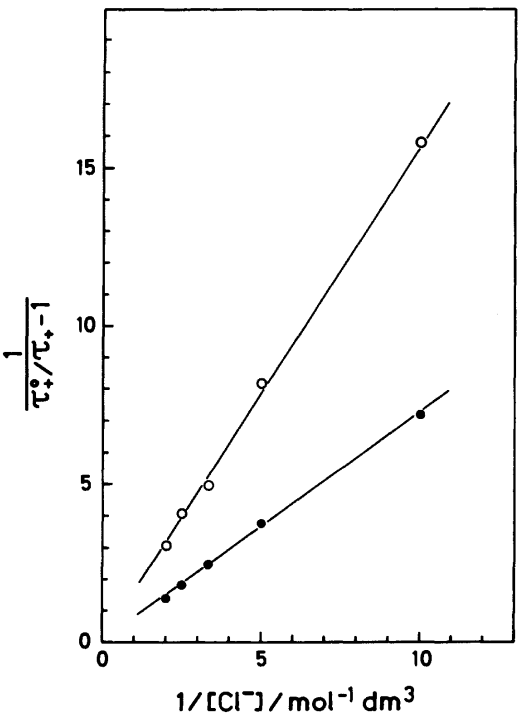


Fig. 4. Plots of $1/\{(\tau_+^0/\tau_+)-1\}$ vs. $1/[Cl^-]$ for 7HC (●) and 7H4MC (○) in the acidic solution ($[H^+]$= 0.5 mol dm^{-3}) at 20 °C.

The lifetime analysis based on the fluorescence components from $\overset{*}{N}$ and $\overset{*}{T}$ of 7HC and 7H4MC is analogous with the lifetime measurement on monomer and exciplex forms in aromatic compound-quencher systems where an exciplex is generated to result in fluorescence quenching.[13] It should be mentioned here that the excited-state reaction of coumarin derivatives is classified essentially into an acid-base reaction and has time constants of nanosecond order due to high mobility of participating species such as H^+ and Cl^-, whereas the exciplex-formation reaction is a usually slower phenomenon by one or more orders.

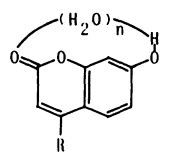
The Relationship between Fluorescence Yield and Fluorescence Lifetime Measurements. At the early stage of theoretical analysis on the fluorescence yield, we have assumed that the natural lifetimes, n_j^{-1}, of four molecular species generated in the excited state are of the same order. This is readily conceivable from the experimental result that the ground-state molecules, N, C^+, and A^-, have the similar values of molar extinction coefficients which are closely related to radiative transition probabilities.[14] The absorption spectrum of T cannot be observed in any pH range, because its ground state is energetically unstable in contrast to the other three species. However, theoretical calculations of the energy level and the transition moment of N and T have shown that optical characteristics of these two species are similar, whereas the molecular structure and the energy separation between the highest occupied and the lowest unoccupied orbital are very different.[15] It is thus expected for natural lifetimes of $\overset{*}{N}$, $\overset{*}{T}$, $\overset{*}{C}^+$, and $\overset{*}{A}^-$ to be in the range of 1.5—6 ns; it is supported by lifetime measurements over wide pH ranges in aqueous solutions.[4]

Generally, the analysis using fluorescence lifetimes is more tractable than the steady-state analysis in that the instantaneous or "static" quenching process does not appear explicitly. A clear example is presented by Efftink and Ghiron[11] who showed experimentally in an indole-quencher system that τ^0/τ is independent of the factor, $W=\exp(-V[Q])$, in contrast to I_0/I. In the present case, the fraction W of the excited state $\overset{*}{C}^+$ generated by light illumination is actually quenched by the collisional mechanism corresponding to the rate constant k_q. The remaining fraction $1-W$ is

deactivated almost instantaneously after being formed because the quencher Cl^- is accidentally positioned in the proximity of excited molecule and interacts strongly with the latter. Only when such a static quenching mechanism is appropriately included, the fluorescence-yield decrease of 7-hydroxycoumarins as well as of 7-ethoxycoumarins[9] in each fluorescence band under steady-state conditions is reasonably understood. It has been already shown that the static quenching effect is easily taken into account in the framework of rate-equation analysis, if the generation rate G_{abs} is replaced formally by $\tilde{G}(Q)=G_{abs}\cdot\{(n_1+\vec{k}_t'+W(Q)\overleftarrow{k}_3[H^+])/(n_1+\vec{k}_t'+\overleftarrow{k}_3[H^+])\}$.[9] Because both I^N and I^T contain $\tilde{G}(Q)$ as a common multiple factor, it has been an ingenious way for us to examine the ratio of I^T to I^N in order to avoid the appearance of W in the analytical formulation.

In the case of pulsed excitation, the rate equations for time-variations of $[\overset{*}{N}]$ and $[\overset{*}{T}]$ need not include the fraction of excited species that never give fluorescence over an observing interval typically of 50 ns. Namely, the generation rate G_{abs} of $\overset{*}{N}$ has only to be reduced formally in the first approximation to $\tilde{G}(Q)$ with maintaining the same equational form as $W=1$. Since $\tilde{G}(Q)$ is included only in the intensity amplitude of $i^N(t)$ and $i^T(t)$, the appropriately normalized intensity of them is in principle given by Eqs. 1 and 2 even if $W\neq1$, while the fluorescence yield integrated over a time range is not correctly derived without considering the quencher dependency of W. More rigorous treatment of such transient phenomena has appeared in the serial works of Ware et al.[13] who formulated it by introducing a time-dependent rate constant, instead of W, in the rate equation. However, two different ways of analysis give essentially the same result as pointed out by Effink and Ghiron.[11]

Reaction Pathways for the Phototautomerization. It has been shown in Ref. 4 that the tautomerization of $\overset{*}{N}$ to $\overset{*}{T}$ can be promoted by dissociative and nondissociative processes. The dissociative mechanism has two possible pathways: one generates the intermediate protonated species as $\overset{*}{N}\rightarrow\overset{*}{C}^+\rightarrow\overset{*}{T}$, and the other generates the intermediate deprotonated species as $\overset{*}{N}\rightarrow\overset{*}{A}^-\rightarrow\overset{*}{T}$. In aqueous solutions, there occurs another possibility that $\overset{*}{N}$ is directly converted to $\overset{*}{T}$ by means of concerted transfer of hydrogen from hydroxyl site to carbonyl site with the aid of hydrogen bonding of water molecules:



R = H, 7HC; R = CH_3, 7H4MC

Scheme 3.

Since the fluorescence of $\overset{*}{N}$, $\overset{*}{T}$, and $\overset{*}{A}^-$ are unaffected by the addition of Cl^-, the reaction pathways $\overset{*}{N}\rightarrow\overset{*}{A}^-\rightarrow\overset{*}{T}$ and $\overset{*}{N}\rightarrow\overset{*}{T}$ are not disturbed by Cl^- if the ionic strength does not vary largely. On the other hand, the reaction pathway $\overset{*}{N}\rightarrow\overset{*}{C}^+\rightarrow\overset{*}{T}$ is extremely disturbed by Cl^- due to the attractive interaction between $\overset{*}{C}^+$ and Cl^-. Probably, the electron transfer from Cl^- to $\overset{*}{C}^+$ within an encounter complex will result in the effective deactivation of $\overset{*}{C}^+$. The same discussion is applicable to three reversed reaction pathways from $\overset{*}{T}$ to $\overset{*}{N}$. In the pH region except for $[H^+]$ of ≈0.5 mol dm^{-3}, the fluorescence band of $\overset{*}{A}^-$ or $\overset{*}{C}^+$ is observable at a wavelength between the fluorescence bands of $\overset{*}{N}$ and $\overset{*}{T}$. It is only accidental for 7HC and 7H4MC that the fluorescence from both $\overset{*}{A}^-$ and $\overset{*}{C}^+$ is negligible at $[H^+]$ of 0.5 mol dm^{-3}, and this situation enables us to attain clear-cut understanding of the tautomerization reaction and of the quenching reaction by Cl^-.

Rapid Equilibration Limit. Consideration for the limiting case of rapid equilibration will help understanding the optically induced tautomeric reaction, although the limit is somewhat different from the real case of the present problem, i.e., $\tau_+\gg\tau_-$. If the transformation between $\overset{*}{N}$ and $\overset{*}{T}$ is rapid, a quasiequilibrium is realized in the excited state. Such a condition is described by $\vec{k}_t^{Cl}$, $\overleftarrow{k}_t^{Cl}\gg n_1$, n_3. Then, slow and fast decay components of lifetimes corresponding to Eq. 14 become as follows:

$$\frac{1}{\tau_+}\approx\frac{n_3\vec{k}_t^{Cl}+n_1\overleftarrow{k}_t^{Cl}}{\vec{k}_t^{Cl}+\overleftarrow{k}_t^{Cl}}\quad\text{and}\quad\frac{1}{\tau_-}\approx\vec{k}_t^{Cl}+\overleftarrow{k}_t^{Cl}. \tag{16}$$

Equation 16 clearly states that the excited-state equilibration is attained in a short time of τ_- and the total concentration of excited species will decrease rather slowly with the time constant of τ_+ which is the reciprocal of weighted average of decay rates, n_1 and n_3. Although the case of $\tau_+\gg\tau_-$ dose not completely coincide with the case of rapid equilibration, the similar situation will be realized in the present case of 7HC and 7H4MC based on rough order estimation of n_j's and k_t^{Cl}'s using meansured τ_+ and τ_-. From experimental data, $1/\tau_-$ is $\approx5\times10^9\,s^{-1}$, and n_1 and n_3 are supposed to be in the region of $0.2—0.5\times10^9\,s^{-1}$; therefore, $\vec{k}_t^{Cl}$ and $\overleftarrow{k}_t^{Cl}$ are estimated to be $\approx4\times10^9\,s^{-1}$ by using Eq. 14. Such conditions correspond nearly to the rapid equilibration limit.

Appendix

Derivation of Eqs. 4 and 5. Letting $I_0^N=n_1^r[\overset{*}{N}]$ and $I_0^T=n_3^r[\overset{*}{T}]$, $I_0^T/I_0^N=(n_3^r/n_1^r)\cdot([\overset{*}{T}]/[\overset{*}{N}])$. The ratio, $[\overset{*}{T}]/[\overset{*}{N}]$, can be obtained by using Eqs. 2—5 in Ref. 4 under steady-state conditions. Thus, we have

$$\frac{I_0^{\mathrm{I}}}{I_0^{\mathrm{N}}} = \frac{n_3^{\mathrm{I}}}{n_1^{\mathrm{I}}} \cdot \frac{\vec{k}_t' + \beta\overleftarrow{k}_3[\mathrm{H}^+]}{n_3 + \overleftarrow{k}_t'' + \alpha'\overleftarrow{k}_4[\mathrm{H}^+]}, \tag{4a}$$

where $\vec{k}_t'$ and β are given in Eq. 5, and $\overleftarrow{k}_t''$ and α' are given by

$$\overleftarrow{k}_t'' = \overleftarrow{k}_t + \vec{k}_2 \cdot \frac{n_2 + \overleftarrow{k}_1[\mathrm{H}^+]}{n_2 + \overleftarrow{k}_1[\mathrm{H}^+] + \overleftarrow{k}_2[\mathrm{H}^+]}$$

$$\text{and } \alpha' = \frac{n_4 + \vec{k}_3}{n_4 + \vec{k}_3 + \vec{k}_4} \cdot \tag{5a}$$

From Eq. 3, the relations

$$\frac{\vec{k}_1}{n_2 + \overleftarrow{k}_1[\mathrm{H}^+] + \overleftarrow{k}_2[\mathrm{H}^+]},$$

$$\frac{\vec{k}_2}{n_2 + \overleftarrow{k}_1[\mathrm{H}^+] + \overleftarrow{k}_2[\mathrm{H}^+]} \ll 1 \tag{17}$$

and

$$\frac{\overleftarrow{k}_3[\mathrm{H}^+]}{n_4 + \vec{k}_3 + \vec{k}_4}, \quad \frac{\overleftarrow{k}_4[\mathrm{H}^+]}{n_4 + \vec{k}_3 + \vec{k}_4} \ll 1 \tag{18}$$

are automatically satisfied. Since the n_1—n_4 are assumed to be of the same order, we obtain the inequalities:

$$n_3 \gg n_2 \cdot \frac{\vec{k}_2}{n_2 + \overleftarrow{k}_1[\mathrm{H}^+] + \overleftarrow{k}_2[\mathrm{H}^+]}$$

$$\text{and } n_3 \gg n_4 \cdot \frac{\overleftarrow{k}_4[\mathrm{H}^+]}{n_4 + \vec{k}_3 + \vec{k}_4} \cdot \tag{19}$$

The application of Eq. 19 to Eqs. 4a and 5a results in Eqs. 4 and 5. It is noted that, under the conditions of Eqs. 17 and 18, the fluorescence intensity from $\overset{*}{\mathrm{C}}{}^+$ and $\overset{*}{\mathrm{A}}{}^-$ (I_0^{C} and I_0^{A}) is negligibly small. If relations $n_2 \ll \overleftarrow{k}_1[\mathrm{H}^+]$ and $n_4 \ll \vec{k}_3$ are additionally satisfied, which have been assumed in Ref. 4 around pH≈0, $\vec{k}_t'$, $\overleftarrow{k}_t'$, α, and β in Eq. 5 are simplified as $\vec{k}_t' = \vec{k}_t + \vec{k}_1 \cdot \vec{k}_2/(\vec{k}_1 + \vec{k}_2)$, $\overleftarrow{k}_t' = \overleftarrow{k}_t + \vec{k}_2 \cdot \overleftarrow{k}_1/(\overleftarrow{k}_1 + \vec{k}_2)$, $\alpha = \vec{k}_3/(\vec{k}_3 + \vec{k}_4)$, and $\beta = \vec{k}_4/(\vec{k}_3 + \vec{k}_4)$.

Surface States of Titania(Rutile and Anatase)-Supported Vanadium Oxide Catalysts as Prepared by a Column-Exchange Adsorption Method and Their Catalytic Features

Yoshiya KERA,* Takashi INOUE, and Yoshihiro MATSUKAZE
Department of Applied Chemistry, Faculty of Science and Engineering, Kinki University, Higashiosaka, Osaka 577
(Received July 6, 1987)

Monolayer or less monolayer vanadium oxide catalysts supported on TiO_2(rutile and anatase), V_2O_5/R- and A-TiO_2, were prepared by a "column-exchange adsorption" method such as passing an oxovanadium ion solution, the pH of which was adjusted at 2, 4, and 7, through a column packed with titania (TiO_2) for impregnation. V_2O_5/R-TiO_2 pretreated at 450 °C showed an ESR spectrum with an unresoluved hfs for V(IV) ions at 77 K without depending upon the pH upon impregnation. V_2O_5/A-TiO_2 pretreated at room temperature showed quite small ESR signals due to Ti(III) and V(IV) ions. These signals tended to be intensive with increasing pH upon impregnation. After a heat treatment at 400 °C a huge and quite broad spectrum, which was ascribed to some reduced vanadia species($V_2O_{5-\delta}$), appeared in addition to the spectra for the Ti(III) and V(IV) ions, while such a change was never found in V_2O_5/R-TiO_2. Based on a theoretical treatment for the g-values, V(IV) ions on V_2O_5/R-TiO_2 have been confirmed to be replaced just into Ti ion sites on rutile(almost D_{2h} symmetry). With V_2O_5/A-TiO_2, V(IV) ions were shown to be placed so as to be partially subject to an anatase surface field(almost D_{2d} symmetry); that is, to be placed only near the vacant Ti ion site on anatase. From a comparison of the hf-coupling constant the vanadia species on rutile was clearly shown to interact more strongly with the surface than that on anatase. The 2-propanol decomposition rates over the catalysts were measured in the temperature range 270—350 °C as a test reaction. The activity of V_2O_5/R-TiO_2 was generally higher than that of V_2O_5/A-TiO_2. The lowest activation energy was obtained upon the impregnation at pH=2 for V_2O_5/R-TiO_2 and at pH=7 for V_2O_5/A-TiO_2. The best catalyst was not necessarily prepared through conditions with pH=4, which had been suggested as giving an effective monolayer-vanadia species.

Supported vanadium oxide catalysts have been widely used for the selective oxidation of hydrocarbons. They are usually prepared by the impregnation of oxovanadium ions on carriers; e.g., from aqueous solutions of NH_4VO_3,[1-3] oxalic acid solutions of NH_4VO_3[4] and V_2O_5,[5] and $VOSO_4$ aqueous solutions.[6] Their deposited states have been favorably investigated by analyzing ESR spectra for the V(IV) ion as a probe.[1-4,7,8] Roozeboom et al.[9-11] suggested that the so-called monolayer vanadium oxide catalyst could be favorably prepared by the impregnation of oxovanadium ions at a controlled pH of 4, since the oxovanadium ion has been known to be in such a polymerized state as decavanadate ion at pH=3—4 in aqueous solution.[12] Such a trial has already been reported by Sonnemans and Mars for the preparation of an alumina-supported MoO_3 catalyst[13] They showed that a vanadium oxide monolayer catalyst supported on titania(a mixture of rutile and anatase) is significantly active for methanol oxidation to formaldehyde.[11] Recently, many investigators have reported that "monolayered" vanadia deposited on titania, especially on anatase, has an excellent selectivity for the oxidation of hydrocarbons. They have discussed variously its deposited or interacting states according to ESR data, laser Raman spectroscopy, XPS, and TPD.[14-16] We have been interested in why such a supperior selectivity arises from the vanadia-titania system, especially from such monolayer vanadia on anatase. With respect to a rutile supported vanadia catalyst, which was prepared according to Roozeboom et al.,[9] we analyzed the deposited state of the vanadia species by ESR spectrometry and confirmed that the vanadia species dispersed quite homogeneously over the surface and that vanadium ions replaced mainly the surface Ti ion sites.[17]

In the present study, in order to make clear whether or not such pH-control upon impregnation is really effective, we prepared titania(rutile and anatase)-supported vanadium oxide catalysts by impregnation at different pH(=2, 4, and 7) and investigated their deposited states by ESR and their catalytic activitis for 2-propanol decomposition as a test reaction. In this paper we also discuss how the difference in the morphorogy of the carriers, rutile and anatase, affects the deposited state and catalytic features.

Experimental

1) Materials and Preparation Procedures. Anatase(A-TiO_2 Kanto Chem. Co. Ltd., guaranteed grade) were pulverised with an agate mortar and sieved between 100 and 170 meshes. Rutile(R-TiO_2), which was prepared from the anatase by heat treatment at 100 °C for 3 h, was pulverized and sieved between 100 and 170 meshes. V_2O_5 powder was prepared by the thermal decomposition of NH_4VO_3(Wako Pure Chem. Co. Ltd., guaranteed grade) in an air stream at 600 °C for 3 h for use as a reference catalyst.

7.9 grams of Sample R-TiO_2 was packed into a glass column (O.D.=15 mm), the length of which was about

75 mm. About 0.5 wt% of NH_4VO_3(Kanto Chem. Co. Ltd., guaranteed grade) aqueous solutions, the pH of which were exactly adjusted to 2, 4, and 7 by adding HNO_3 and NH_4OH, were poured into the column in order to cause the oxovanadium ion to be adsorbed. Each 3 ml of the effluent solution was collected in order to trace any changes in the pH and the concentration of vanadium ion while passing through the column. The effluent speed was about 0.1 ml min^{-1}. In the case of Sample A-TiO_2, 7.2 g were packed into the column; the NH_4VO_3 solution was also poured until both the pH and the vanadium ion concentration had recovered just to the original values. The values were determined by the use of a pH meter, TOA(model HM-7B), and by the usual Mohr salt method, respectively. The R- and A-TiO_2 adsorbing oxovanadium ion were dried at 110 °C for 8 h, and then calcined at 400 °C for 2 h in order to prepare titania supported vanadium oxide catalysts, V_2O_5/R-TiO_2 and V_2O_5/A-TiO_2, respectively.

2) Measurements and Computer Simulation. The surface areas of V_2O_5/R-TiO_2 and A-TiO_2 were determined by the usual BET method; N_2 gas adsorption at 77 K is shown in the 2nd column of Table 1. The surface area of V_2O_5 powder was similarily determined to be 8.5 $m^2 g^{-1}$. Those TiO_2 were identified by comparing their X-ray powder diffraction patterns with ASTM cards. The X-ray diffractometer used was a Rigagu Denki Model GF-Rad-γA; Cu *K*α- radiation(40 kV and 120 mA) and a nickel filter were also used. The deposited states of vanadium oxides were examined by ESR spectrometry. The ESR spectrometer used was a Nippon Denshi Model JES-PE(X-band 9.3 GHz and 100 kHz modulation). Computer simulation of the ESR spectrum was performed using an IBM 4381 system (described in detail later). The catalytic activities for 2-propanol decomposition, as a test reaction, were measured by the use of a closed circulation system(ca. 0.5 dm^3) connected directly to a gas chromatgraphy system with a Porapac-Q column(1 m). 20 mg of the catalysts were widely spread on the bottom of the vessel and preheated at the reaction temperature in air for 1 h before the reaction. The vessel containing 2-propanol was cooled by an ice-water bath during the reaction in order to maintain the vapor pressure constant at 8.4 mmHg (1 mmHg=133.322 Pa). The amount of the main product, which was confirmed to be propylene, was measured at intervals of 2 min. The decomposition rates were determined from the amount produced during the initial 20 min. The reaction temperature was controlled within±0.5 °C in the range 270—350 °C.

Results

1) The Amounts of Vanadium Oxide Deposited on Rutile and Anatase. When about 0.5 wt% of an ammonium metavanadate solution was poured into a glass column packed with rutile(R-TiO_2), the pH and vanadium ion (V-ion) concentration of the effluent solution varied as shown in Fig. 1. The pH initially increased from 2 to 5.5 in a run of pH=2, and from 4 to about 6 in a run of pH=4; it decreased from 7 to near 6 for pH=7. Eventually, they all returned to their original values. The amounts of oxovanadium ion adsorbed on R-TiO_2 were evaluated according to the

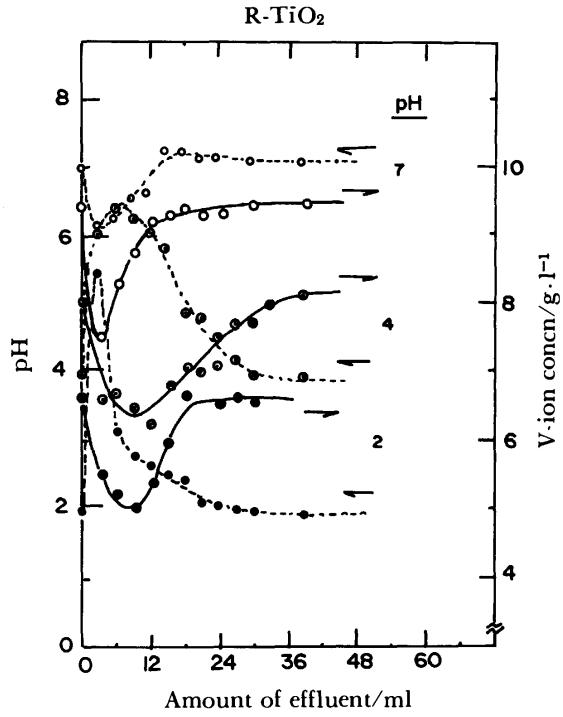

Fig. 1. The variations in the pH and the vanadium ion concentration of ammonium metavanadate solution during passing through the rutile-packed column. ----: pH changes and ——: V-ion concentration changes in the original solutions of pH=2, 4, and 7.

V-ion concentration vs. time-curve. The adsorbed amounts of oxovanadium ion, which was estimated under the assumption that it was deposited in the form of V_2O_5, are given in the 3rd and 4th column of Table 1 (in units of mg(V_2O_5)/g-carrier and mg-(V_2O_5)/m^2, respectively). The surface coverages are given in the 5th column of Table 1. They had been estimated under the assumptions that the V-O-V network of V_2O_5 extends two-dimensionally on the surface and that the V-O bond length is 2.0 Å.

For A-TiO_2, the changes in the pH and the V-ion concentrations of the effluent solutions are shown in Fig. 2. The pH value initially increased in all cases and then gradually returned to the original values. The pH initially increased up to 7.5, even in the run for pH=7; this suggests that the A-TiO_2 has a weak basisity. The vanadium ion concentrations initially decreased and then recovered to the original values accompanied by pH changes. We similarly estimated the amount of vanadium oxide deposited (given in the 3rd and 4th columns of Table 1; the surface coverage is given in the 5th column).

2) ESR Spectra of V(IV) and Ti(III) Ions on R- and A-TiO_2-Supported Vanadium Oxide Catalysts. The spectrum for an R-TiO_2-supported vanadium oxide catalyst (V_2O_5/R-TiO_2) impregnated at pH=2 is illustrated in Fig. 3. This is the most clear spectrum among the catalysts impregnated at pH=2, 4, and 7,

Table 1. Surface Areas of V_2O_5/R- and A-TiO_2 Catalysts, the Deposited Amounts of Vanadium Oxide (Reduced to V_2O_5), and the Surface Coverages

Catalyst	Surface area/$m^2 \cdot g^{-1}$	Deposited amount (V_2O_5) mg/g-carrier	Deposited amount (V_2O_5) $mg \cdot m^{-2}$	Surface coverage θ
R-TiO_2-carrier	2	—	—	—
V_2O_5/R-TiO_2 (pH=2)	2	2.66	1.30	0.66
V_2O_5/R-TiO_2 (pH=4)	2	4.88	2.44	1.2
V_2O_5/R-TiO_2 (pH=7)	2	1.81	0.90	0.47
A-TiO_2-carrier	8.5	—	—	—
V_2O_5/A-TiO_2 (pH=2)	6.7	3.2	0.48	0.25
V_2O_5/A-TiO_2 (pH=4)	6.4	6.6	1.03	0.53
V_2O_5/A-TiO_2 (pH=7)	6.5	10.2	1.57	0.82
V_2O_5-powder	8.5	—	—	—

which have been observed at 77 K after evacuation at 470 °C for 1 h. The spectrum had been regarded as containing poorly resolved hfs of vanadium(^{51}V) nucleus(I=7/2).[17] The result of a computer simulation is given along with a broken line in Fig. 3; the best-fit parameters used are given in Table 2. The spectrum was assigned to the V(IV) ion substituting the titanium ion site on the rutile surface.[17] V_2O_5/R-TiO_2 prepared at the other pH(=4 and 7) gave a similar spectrum, although the intensity was relatively low; thus, the spectrum could not be clearly observed.

An A-TiO_2 carrier, itself, gives a very weak signal due to Ti(III) ions. The intensity, however, became intensive along with the deposition of vanadium oxide. The ESR spectra for an A-TiO_2-supported vanadium oxide catalyst(V_2O_5/A-TiO_2) prepared at 2, 4, and 7 are illustrated in Figs. 4-b, c and 5-C. They

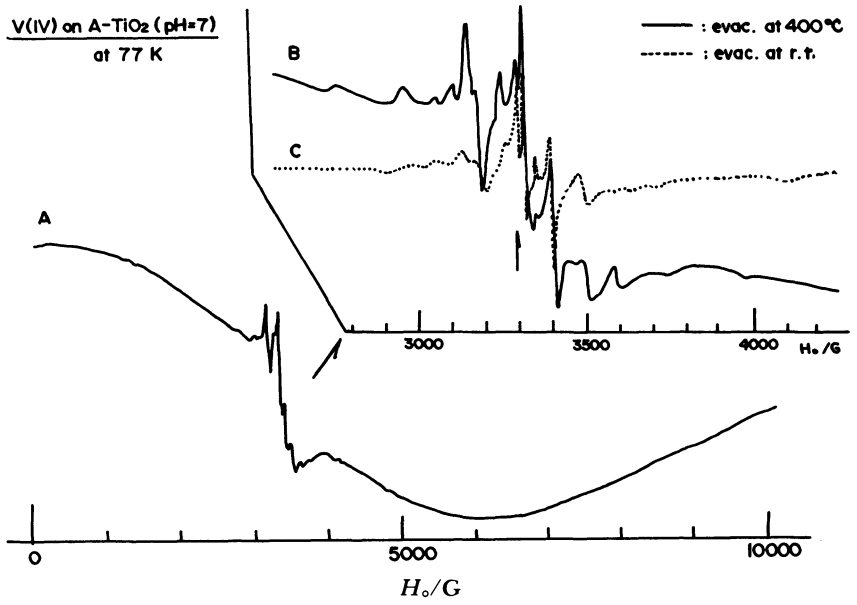

Fig. 5. The ESR spectrum of V_2O_5/A-TiO_2 impregnated at pH=7: Spectrum A indicates the wide range spectrum from zero to 10000 G, measured at 77 K after the evacuation at 400 °C: Spectrum B is the spectrum A that was recorded in the field between 2600 and 4200 G in order to show clearly the signal corresponding to the V(IV) and Ti(III) ions: Spectrum C the spectrum that was recorded in the field between 2600 and 4200 G at 77 K after the evacuation at room temperature.

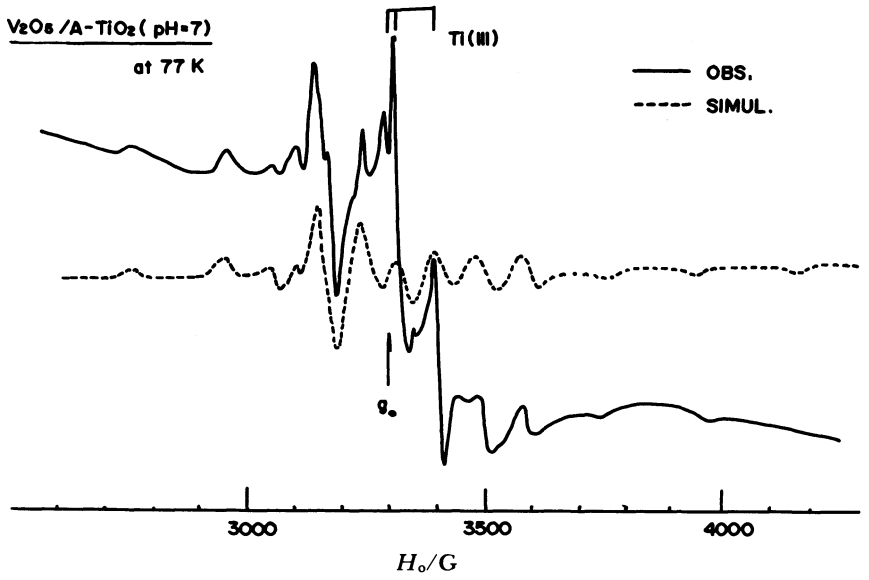

Fig. 6. The observed spectrum for V(IV) ion on V_2O_5/A-TiO_2(pH=7) and the best-fit spectrum simulated. ——: observed and ----: simulated.

were measured at 77 K after evacuation at room temperature for 1 h. The signal intensities for Ti(III) and V(IV) ions tends to increase simulteneously as the pH upon impregnation becomes high (pH=2→7). This change corresponds well to the surface coverage of the vanadia species (Table 1). When V_2O_5/A-TiO_2 was pretreated at 400 °C for 1 h, the spectrum varied greatly: A very large, broad signal appeared and the unresolved hf-lines ascribed to the V(IV) ion became more clear, while the intensity of the signal corresponding to Ti(III) ion almost didn't change

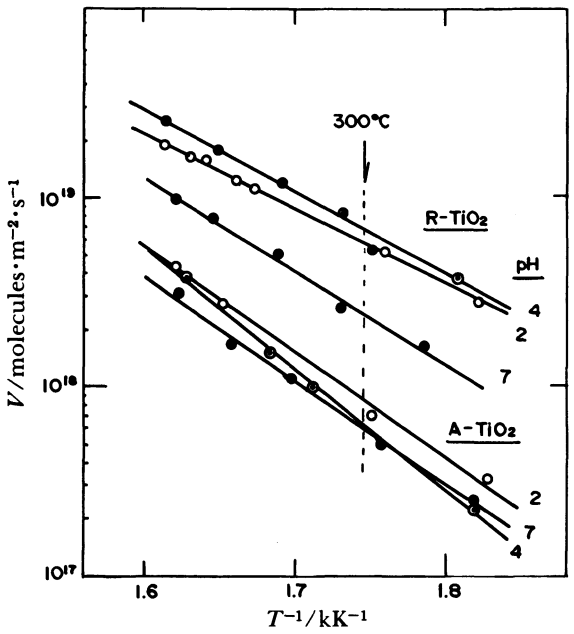

Fig. 7. Arrhenius plots of the 2-propanol decomposition rates over V_2O_5/R- and A-TiO_2 impregnated at various pH.

(Figs. 5-A and B). We applied a computer simulation to the component of the V(IV) ion in Fig. 5-B. The first derivative curve was calculated according to the usual simulation method[18,19] at intervals of 10 G (1G=10^{-4} T) in a magnetic field of 2500—4300 G (as described previously[17]). The intensity of the microwave absorption at each resonance field was obtained by numerical integrations at intervals of 1.5° to θ and ϕ for all directions under the assumption of a Gaussian shape function and 35 G of the half width. The best-fit parameters are given in Table 2 and the simulated spectrum for the V(IV) component is indicated by the broken line in Fig. 6. The g-tensor for the Ti(III) ion(Fig. 6) was estimated as $g_{//}$=1.94 and $g_{\perp}$=2.00 and 1.99 (Table 2).

3) Decomposition Rates of 2-Propanol over V_2O_5/R-TiO_2 and A-TiO_2. The rates of 2-propanol decomposition over titania-supported vanadium oxide catalysts were determined from changes in the GC-peak intensity for the produced propylene in the temperature range 270—350 °C. Arrhenius plots for the initial mean rates, thus obtained, are summarized in Fig. 7. Arrhenius parameters, log V_o and E_a, estimated from those plots, are given in Table 3. The minimum activation energy was obtained as 18.1 kcal mol^{-1} (1cal=4.184 J) for V_2O_5/R-TiO_2 prepared at pH=2, while the maximum as 29.6 kcal mol^{-1} for V_2O_5/A-TiO_2 prepared at pH=4. With respect to V_2O_5/R-TiO_2 the higher the pH upon impregnation, the larger the E_a. With V_2O_5/A-TiO_2, the catalyst prepared at pH=7 gives a minimum activation energy and that at pH=4 a maximum. The decomposition rate at 300 °C estimated with units of molecules/m^2s and molecules/mg(V_2O_5)s, are summarized in Figs. 8 and 9, respectively. The reaction rates over a V_2O_5 powder and the carrier, themselves(Blank), were added

Table 2. The Best Fitting Parameters Used for the Simulation of ESR Spectra of V(IV) Ion in V_2O_5/R- and A-TiO_2 Catalysts Evacuated at 400 °C

Catalyst	Species	g-value		A-value	
		$g_{//}$	$g_{\perp}$	$A_{//}$	$A_{\perp}$
V_2O_5/R-TiO_2	V(IV)	1.950	1.983	173.1	55
V_2O_5/A-TiO_2	V(IV)	1.912	1.981	200	75
V_2O_5/A-TiO_2	Ti(III)	1.94	1.99 2.00	—	—

Table 3. Arrhenius Parameters of 2-Propanol Decomposition over V_2O_5/R- and A-TiO_2 Catalysts Impregnated at pH=2, 4, and 7

Catalyst	log V_o/molecules·m^{-2}·s^{-1}	E_a/kcal mol^{-1}
V_2O_5/R-TiO_2 (pH=2)	25.6	18.1
V_2O_5/R-TiO_2 (pH=4)	26.5	20.3
V_2O_5/R-TiO_2 (pH=7)	27.1	23.0
V_2O_5/A-TiO_2 (pH=2)	27.8	26.0
V_2O_5/A-TiO_2 (pH=4)	29.0	29.6
V_2O_5/A-TiO_2 (pH=7)	27.3	25.1

in Figs. 8 and 9 for a comparison. The activity of V_2O_5/R-TiO_2, per m^2s, is 3—10 times higher than that of the carrier itself; also, the activity of V_2O_5/A-TiO_2 is about 3—4 times higher than that of the carrier itself. In both V_2O_5/R-TiO_2 and A-TiO_2 catalysts the activity, per mg(V_2O_5)s, became maximum upon impregnation at pH=2; further, those values are 50—130 times higher than that of V_2O_5 powder. Thus, it is evident that vanadium oxide is very effectively dispersed on the titania, especially on rutile impregnated at pH=2.

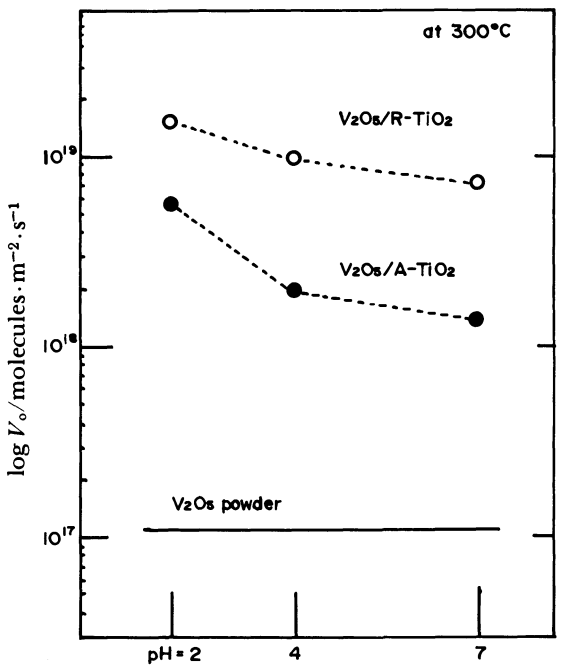

Fig. 9. Comparison of the activity(molecules/mg(V_2O_5)s) among the V_2O_5 powder and the supported catalysts at 300 °C.

Discussion

Deposited States of Vanadium Oxide on TiO_2-(Rutile and Anatase). Shimizu[20] has strictly investigated the relationship between the *g*-tensor and the crystal field splitting of the d-orbital for V(IV) ions doped in a TiO_2(rutile) single crystal subject to a D_{2h} symmetry field. We successfully applied the theory to an analysis of V(IV) ions placed into a V_2O_5 single crystal and subjected to the field of a distorted square pyramid.[21] Furthermore, the field symmetry around the V(IV) ions on rutile(V_2O_5/R-TiO_2) was clearly shown to be quite similar with that around V(IV) in the V_2O_5 single crystal.[17]

The anatase structure belong to the tetragonal symmetry of the space group $I4_1/amd$ and the Ti ion is in a distorted oxygen octahedra of the symmetry group D_{2d}:[22] Qualitatively oxygen ions placed on square corners of an octahedra deviate a little (althernatively up and down from the plane[23] accompanied by a transition of rutile to anatase) as the coordination model in Figs. 10-(a) and (b) shows. The relationship between the *g*-tensor and the crystal field splitting for d^1-metal placed in a tetragonal field (D_{4h} symmetry) and in a slightly distorted tetragonal field, e.g., rohmbic and trigonal distortions,[24,25] is given approximately as

$$g_{//} = g_0 - 8\lambda/\Delta \text{ and } g_{\perp} = g_0 - 2\lambda/\delta, \quad (1)$$

where Δ and δ are the crystal field splitting constants

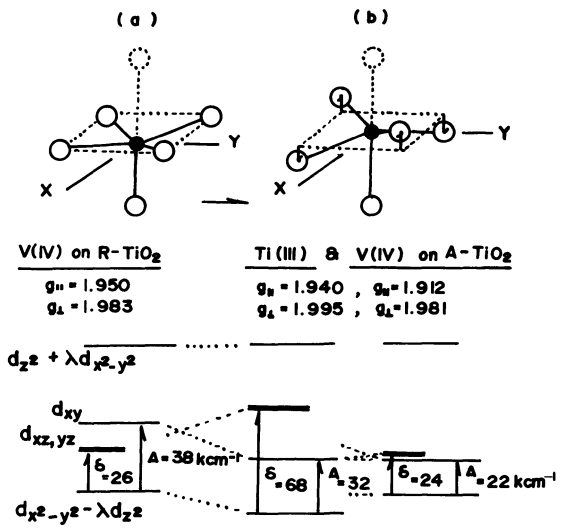

Fig. 10 Coordination model and crystal field splitting for the surface V(IV) ion in V_2O_5/R-TiO_2 and V_2O_5/A-TiO_2.

and λ the spin-orbit coupling constant (reasonably assumed to be 250 cm^{-1}[26]). If such a symmetry change as $D_{2h} \rightarrow D_{2d}$ accompanied by the transition, rutile→anatase, is not too large for the application of the theory to the present system, we can similarly estimate the field splitting around V(IV) ion on V_2O_5/A-TiO_2. Such a deviation of the oxygen ions should directly cause the d_{xy}-level to be lower and the $d_{x^2-y^2}$ to be lower to some extnet; however, the d_{xz} and d_{yz} increase to some extent. The field splitting around the Ti(III) ion, which was estimated by appling Eq. 1 to the g-value in Table 2, agrees well with the expected value, as shown in Fig. 10-(b). With the V(IV) ion the d_{xy}-level decreased considerably, but the degree of the increase in the d_{xz}- and d_{yz}-levels and the decrease in the $d_{x^2-y^2}$ are not as large as expected (Fig. 10-(b)). The energy diagram suggests that the V(IV) ion is partially subjected to a symmetry field of the anatase surface; therefore, it may be placed only near a vacant Ti site on the anatase surface. Since both λ/Δ and λ/δ were less than 0.1 in the present estimation,[26] this theory could reasonably well be applied to this system.

Wacks et al.[16] suggested that two types of vanadia species were present on anatase deposited with V_2O_5: A surface vanadia species coordinated to the anatase and the crystallites of V_2O_5. In V_2O_5/TiO_2(anatase) with 2% or less V_2O_5, a monolayer of surface vanadia species was formed without any crystallite V_2O_5. Inomata et al.[27] observed the same ESR spectrum with unresolved hfs for a multilayered vanadium oxide deposited on rutile and anatase. They indicated that the g-value, $\langle g \rangle$=1.971, was close to that in the V_2O_5 matrix. The present g-value corresponds well to that reported by Akimoto et al.[28] The present samples show almost the same extent of deposition with the monolayer or the less monolayer catalysts of Wacks et al.;[16] therefore, the deposited state is comparable with them. According to an FT-IR study by Miyata et al.,[29] the V=0 stretching band for the vanadia species on a less monolayer V_2O_5/anatase catalyst was found at 983 cm^{-1}. Kozlowski et al.[30] found by EXAFS and XANES measurements that a vanadium monolayer supported on anatase did not have the structural characteristics of crystalline V_2O_5 and suggested that the basic unit was a species with two terminal and two bridging bonds. The V(IV) ion placed near the site (expected by the coordination model in Fig. 10-(b)) may correspond to all these vanadia species. It was clearly mentioned in the discussion that the vanadia species were strongly affected by the surface field symmetry of the carrier; it was further suggested that V(IV) ions were placed just in and near the titanium ion vacant sites on rutile and anatase surfaces (cf. Figs. 10-(a) and (b), respectively. However, such models express only one of the possible deposited states and, of course, the possibility of a topochemical deposition of vanadium oxide just on the titania surfaces would not be ruled out.

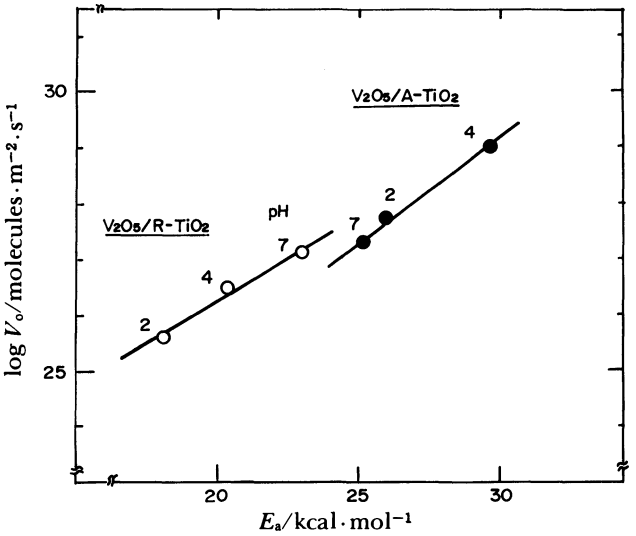

Fig. 11. Relationship between the pre-exponential factor(log V_o) and the activation energy(E_a) for 2-propanol decomposition over the titania supported vanadium oxide catalysts.

A huge ESR signal that appeared in V_2O_5/A-TiO_2 upon evacuation at 400 °C(Fig. 5) might have been due to a kind of dipole-dipole interaction between the V(IV) ions or to a triplet state of the V(III) ion. Reduced vanadia species were easily formed on an anatase supported vanadia catalyst, as also indicated by other authors.[15,16] Thus, the huge and broad ESR signal might be ascribed to some kind of reduced vanadia species that were placed in a micropore and were inhomogeneously dispersed on the anatase surface.

V_2O_5/R-TiO_2 showed a sharp ESR signal, which was assigned to the V(IV) ion, weakly interacting with the remaining oxygen molecules, upon evacuation at room temperature. No reduced type of spectrum was formed upon evacuation at 470 °C; only a simple spectrum with broad hfs for V(IV) ions has already been reported.[17] The hf-coupling constants($A_{//}$ and $A_{\perp}$) are considerably larger in V_2O_5/A-TiO_2 than V_2O_5/R-TiO_2, as shown in Table 2. This suggests that the unpaired electron is located to a much greater extent on V_2O_5/A-TiO_2 than V_2O_5/R-TiO_2; thus, the vanadia species interacts more weakly with anatase than the rutile surface. This may correspond to the suggestion by Kozlowski et al.[30] that differences occur in the structure of the active phase when supported on different materials.

Catalytic Properties of V_2O_5/R-TiO_2 and A-TiO_2. Previously, we found a kinetic compensation effect for alcohol decomposition over alkali-modified vanadium oxide catalysts for successfully analyzing its activated states.[31] In the activated state of an alcohol molecule the internal frictional rotation of the alkyl group, especially the methyl group, has been insisted

as being an important parameter. A compensation relation holds well between log V_o and E_a for catalysts impregnated at different pH(=2, 4, and 7) in Table 3, as shown in Fig. 11. A desired catalyst should be located(relatively) on the left-hand side and on the upperpart of log V_o vs. E_a-plots. From this point of view V_2O_5/R-TiO_2 is more desirable than V_2O_5/A-TiO_2, as can be clearly seen by comparing Figs. 8 and 9. Furthermore, with V_2O_5/R-TiO_2 the lowest activation energy was obtained upon impregnation at pH=2 and with V_2O_5/A-TiO_2 upon that at pH=7 instead of pH=4. Therefore, we could not find any special ability in catalysts prepared by impregnation at pH=4 (reported by Roozeboom et al. for preparation of a monolayer catalyst[9]). Through kinetic consideration, however, not only the kind of carrier but also the pH upon impregnation could be clearly demonstrated to delicately affect the deposit state of vanadia species, although ESR measurements have never detected such difference with the pH.

Many investigators have shown that monolayer vanadia species supported on TiO_2, especially on anatase, are superior catalysts for oxidation of *o*-xylene.[14-16] V_2O_5/A-TiO_2 seems to be considerably reduced during 2-propanol decomposition, while being kept in an oxidative state during the oxidation reaction. This means that the catalytic feature for 2-propanol decomposition can not be compared simply with that for oxidation. We will not discuss further their abilities as oxidation catalysts in the present paper.

The Temperature Dependence of the Quenching Rate of the 307.6 nm Zinc Resonance Line by Some Alkane Hydrocarbons

Shunzo YAMAMOTO
Department of Chemistry, Faculty of Science, Okayama University,
3-1-1, Tsushima-naka, Okayama
(Received July 15, 1987)

The intensities of the 307.6 nm resonance line of zinc were measured as a function of the alkane pressure at various temperatures between 556 and 696 K, and the quenching rate was determined on the basis of the Stern-Volmer plots. Assuming that the quenching rate constant, k_Q, of a certain alkane is equal to the sum of the quenching-rate constant, k_i, for each C-H bond, the ratios of k_s/k_p and k_t/k_p (k_p, k_s, and k_t are the quenching-rate constants for primary, secondary, and tertiary C-H bonds) were estimated from the ratios of the quenching rates of butane, isobutane, and neopentane. The differences in the activation energies for the quenching for primary, secondary, and tertiary C-H bonds were obtained from the temperature dependence of the ratios of k_s/k_p and k_t/k_p and were interpreted in terms of the modified bond-energy-bond-order (BEBO) method.

In a previous paper,[1] a remarkable dependence of the quenching of the cross section of the 307.6 nm zinc resonance line by alkane hydrocarbons on the C-H bond strength was reported. It was pointed out that the quenching cross-section of a certain alkane can be estimated as the sum of the quenching cross-section for each individual quenching site (C-H bond). The above findings show that the excited zinc atoms attack not only the weakest C-H bond, but all kinds of C-H bonds, with efficiencies which depend on the bond strength, and it was concluded that hydrogen-atom abstraction from hydrocarbons by means of excited zinc atoms plays an important role in the quenching of $Zn(^3P_J)$.

In this study, relative quenching-rate constants for butane, isobutane, and neopentane were determined over the temperature range of 556—696 K, and from these values the ratios of k_s/k_p and k_t/k_p (k_p, k_s, and k_t are quenching-rate constants for primary, secondary, and tertiary C-H bonds) were estimated at various temperatures.

Experimental

The apparatus and the procedure were the same as those described previously.[1,2]

The zinc metal used was high-purity zinc (99.9999%) manufactured by the Osaka Asahi Metal Co. The ethane, butane, isobutane, and neopentane (Tokyo Kasei Kogyo Co., Ltd.; G.R. grade) were freeze-pumped several times and repeatedly subjected to trap-to-trap distillation. Pure-grade argon (Daido Sanso Co.; 99.999%) was used without further purification.

When a cell containing zinc vapor was illuminated by the exciting lamp, a resonance line was observed at 307.6 nm. Upon the addition of argon, the intensity of the line increased with the increase in the argon pressure. This was attributed to the increase in the light intensity absorbed by zinc atoms as a result of the pressure broadening of the absorption line.[1,2] In order to minimize this effect of the pressure broadening of the absorption line, quenchers were diluted with a large amount of argon (total pressures: 1333—2666 Pa).

Results and Discussion

In a previous paper, the following reaction scheme was proposed for the quenching of $Zn(^3P_J)$[1,2]

$Zn(^1S_0) + h\nu(307.6\,nm) \longrightarrow Zn(^3P_1)$	I_a
$Zn(^3P_1) \longrightarrow Zn(^1S_0) + h\nu(307.6\,nm)$	k_0
$Zn(^3P_1) + M \rightleftharpoons Zn(^3P_0) + M$	k_1, k_{-1}
$Zn(^3P_1) + M \rightleftharpoons Zn(^3P_2) + M$	k_2, k_{-2}
$Zn(^3P_0) + Q \longrightarrow$ quenching	k_3
$Zn(^3P_1) + Q \longrightarrow$ quenching	k_4
$Zn(^3P_2) + Q \longrightarrow$ quenching	k_5.

Here, M denotes Ar and quenchers, and Q represents quenchers. By assuming the steady state for $Zn(^3P_{0,1,2})$, the following equation can be derived:

$$\frac{I^\circ}{I} = 1 + \frac{1}{k_0}\left(\frac{k_1}{k_{-1}}k_3 + k_4 + \frac{k_2}{k_{-2}}k_5\right)[Q]. \quad (1)$$

where I° and I are the intensities of the resonance line in the absence and in the presence of quenchers respectively. Stern-Volmer plots for the quenching by butane at various temperatures are shown in Fig. 1.

Similar plots were obtained for other quenchers. From the slope of the straight lines, the values of $k_Q\tau$ ($k_Q=(k_1/k_{-1})k_3+k_4+(k_2/k_{-2})k_5$ and $\tau=1/k_0$) were estimated; they are listed in Tables 1 and 2.

As has been mentioned above, k_Q is the composite rate constant for the quenching of $Zn(^3P_0)$, $Zn(^3P_1)$, and $Zn(^3P_2)$. Since the three triplet states are in equilibrium, $k_1/k_{-1}=(1/3)\exp(2.30\ \text{kJ mol}^{-1}/RT)$ and $k_2/k_{-2}=(5/3)\exp(-4.70\ \text{kJ mol}^{-1}/RT)$,[2] k_1/k_{-1} and k_2/k_{-2} are temperature-dependent. As these equations show, k_1/k_{-1} decreases slightly, and k_2/k_{-2} increases with an increase in the temperature, but their changes are small.

The quenching rate constant, k_Q, can be rewritten as follow:

$$k_Q = k_4\left(\frac{k_1}{k_{-1}}\frac{k_3}{k_4} + 1 + \frac{k_2}{k_{-2}}\frac{k_5}{k_4}\right) \quad (2)$$

Since the excitation energy increases in this order: $Zn(^3P_0)$, $Zn(^3P_1)$, and $Zn(^3P_2)$, the activation energies for k_3, k_4, and k_5 decrease in that order. Therefore, k_3/k_4 increases, and k_5/k_4 decreases, with the temperature. Since the changes in k_1/k_{-1} and k_2/k_{-2} are compensated for by the changes in k_3/k_4 and k_5/k_4, the temperature-dependence of the value in parentheses in Eq. 2 seems to be very small. It can be said that k_Q is approximately proportional to k_4.

In Fig. 1, the Stern-Volmer plots at various temperatures for butane are shown. The slope of the line increases with the temperature. A similar temperature-dependence was observed for the quenching by isobutane and neopentane.

As has been mentioned above, the value of $k_Q\tau$ can be obtained from the slope of the Stern-Volmer plots. These values for butane, isobutane, and neopentane are shown in Fig. 2 as a function of the temperature. As is shown in Fig. 2, the value of $k_Q\tau$ slightly increases with the temperature below about 606 K, while the $k_Q\tau$ value increases more rapidly at temperatures higher than 606 K. This indicates that the effective lifetime (τ) of $Zn(^3P_1)$ may be hardly lengthened at all by the radiation imprisonment below 606 K. However, the effect of imprisonment can not be neglected at temperatures higher than 606 K.

Therefore, the quenching rate constant, k_Q, can be calculated from the slope by using the natural lifetime (2.0×10^{-5} s)[3] as τ below 606 K, but not at higher temperatures. Only the relative rate constant can be estimated from the slope at higher temperatures.

The ratios of the imprisonment lifetime to the natural lifetime at various temperatures were calculated by the use of the following equation, given by Milne for infinite slab geometry:[4]

$$\tau/\tau_0 = 1 + (kl/\lambda)^2, \quad (3)$$

where k is the absorption coefficient at the line center, l is the thickness of the slab, and λ is the root between 0 and $\pi/2$ of the equation:

$$\tan y = kl/y. \quad (4)$$

Samson[5] has modified Milne's theory so that an equivalent opacity $\bar{k}\,l$ is used in Eqs. 3 and 4 instead of kl, the opacity at the line center. The equivalent opacity for the Doppler line-shape is defined by :

$$\exp(-\bar{k}l) = \frac{\int_{-\infty}^{\infty}\exp(-\omega^2)\exp[-kl\exp(-\omega^2)]d\omega}{\int_{-\infty}^{\infty}\exp(-\omega^2)d\omega}, \quad (5)$$

where $\omega=[2(\nu-\nu_0)/\Delta\nu_D](\ln 2)^{1/2}$ ($\Delta\nu_D$ is the Doppler breadth). k can be estimated by means of this equation:

$$k = (2/\Delta\nu_D)(\ln 2/\pi)^{1/2}(\lambda_0^2/8)(g_2/g_1)([Zn]/\tau_0) \quad (6)$$

where g_2 and g_1 are the degeneracies of the upper and lower states respectively, λ_0 is the wavelength at the center of the atomic line, and τ_0 is the natural lifetime of an excited atom. The values of $\bar{k}\,l$ for the Doppler case were obtained by the interpolation of the values given by Zemansky[6] and Blickensderfer et al.[7]

The values of τ/τ_0 calculted by Samson's method are shown in Table 3. As Table 3 shows, the imprisonment effect can be nearly neglected below 605 K, but it becomes significant at higher temperatures. This finding is in agreement with the tendency observed above.

In Fig. 3, the ratios of k_Q(butane)/k_Q(neopentane) and k_Q(isobutane)/k_Q(neopentane) are shown as a function of $1/T$. These plots give curves. This can be explained by considering that butane and isobutane have two types of reaction sites (the former has primary and secondary C-H bonds, while the latter

696	27.99	6.79	0.518±0.009	6.15

a) $\log(133.33P_{Zn}/\text{Pa}) = -7198/T + 9.664$: J. D. McKinley and J. E. Vance, *J. Chem. Phys.*, **22**, 1120 (1954). b) The absorption coefficient at the center of the Doppler-broadened line.

has primary and tertiary C-H bonds) and that the activation energies for the rates of quenching by these C-H bonds are not equal to each other.

In a previous paper,[1] we reported that the quenching cross section for any C_1—C_5 alkanes can be calculated by the following equation:

$$\sigma_Q = \sum n_i \sigma_i \tag{7}$$

where n_i is the number of the C-H bond of Type i (CH_3-H, primary C-H, secondary C-H, and tertiary C-H) and where σ_i is the cross section for each C-H bond of Type i. If a similar additivity can be applied for the quenching rates by butane, isobutane, and neopentane at every temperature examined, the following equations must hold:

$$\frac{k_Q(\text{butane})}{k_Q(\text{neopentane})} = \frac{6k_p + 4k_s}{12k_p} = \frac{1}{2} + \frac{1}{3}\frac{k_s}{k_p} \tag{8}$$

$$\frac{k_Q(\text{isobutane})}{k_Q(\text{neopentane})} = \frac{9k_p + k_s}{12k_p} = \frac{3}{4} + \frac{1}{12}\frac{k_t}{k_p} \tag{9}$$

Therefore, the following equations can be obtained:

$$\frac{k_s}{k_p} = \left\{ \frac{k_Q(\text{butane})}{k_Q(\text{neopentane})} - \frac{1}{2} \right\} \times 3 \tag{10}$$

$$\frac{k_t}{k_p} = \left\{ \frac{k_Q(\text{isobutane})}{k_Q(\text{neopentane})} - \frac{3}{4} \right\} \times 12 \tag{11}$$

From the experimental values for k_Q(butane)/k_Q(neopentane) and k_Q(isobutane)/k_Q(neopentane) shown in Fig. 3, the ratios of k_s/k_p and k_t/k_p at various temperatures can be calculated. In Fig. 4, the Arrhenius plots for k_s/k_p and k_t/k_p are shown. These Arrhenius plots give straight lines. The differences in the activation energies for k_s and k_p and for k_t and k_p were found to be 4.6±0.4 and 7.5±0.5 kJ mol^{-1} respectively.

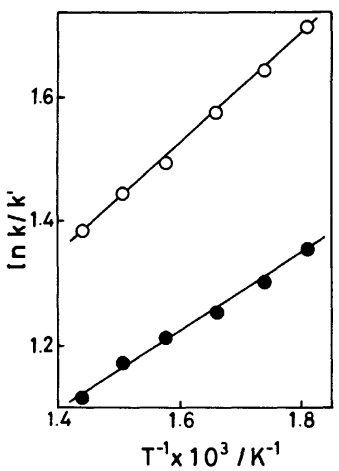

Fig. 4. Arrhenius plots for k_s/k_p (●) and k_t/k_p (○).

Since the imprisonment effect is nearly neglected below 606 K, as has been mentioned above, the quenching-rate constant, k_Q, can be calculated from the $k_Q\tau$ value using the natural lifetime as τ. In Table 2, the quenching-rate constants(k_Q') per C-H bond for neopentane and ethane, which have only primary C-H bonds, are shown. The optimized expressions for the rate constants(k_Q'), in the units cm^{3}molecule^{-1}s^{-1}, are:

$$k_Q'(\text{neopentane}) = (1.9 \pm 0.3) \times 10^{-10} \times \exp\{(-18.7 \pm 1.6)\text{kJ mol}^{-1}/RT\} \tag{12}$$

$$k_Q'(\text{ethane}) = (2.5 \pm 0.3) \times 10^{-10} \times \exp\{(-19.0 \pm 2.0)\text{kJ mol}^{-1}/RT\} \tag{13}$$

The activation energies for neopentane and ethane are in good agreement with each other. The activation energy for a primary C-H bond is determined to be 18.9±1.8 kJ mol^{-1}. The ratio (1.32) of the frequency factors of k'_Q for ethane and neopentane is approximately equal to the ratio (1.29) of the relative velocities for Zn*+ethane and Zn*+neopentane. This is in agreement with the prediction from the simple collision theory. Equations 12 and 13 show that the quenching cross-sections per C-H bond for neopentane and ethane are in agreement with each other at every temperature.

As has been mentioned above, the imprisonment effect below 605 K is very small and was neglected in the above treatment. If the imprisonment effect is taken into account, that is, if the effective lifetime of the excited zinc atoms shown in Table 3 is used, somewhat smaller quenching rate constants (k_Q'') are obtained from the $k_Q\tau$ values (Table 2). The activation energies calculated from these rate constants below 636 K are a little smaller (13.1±1.8 kJ mol^{-1} for neopentane and 14.8±1.8 kJ mol^{-1} for ethane) than those obtained using the natural lifetime.

Since the rate constant for neopentane calculated using the effective lifetime shown above decreases with the temperature above 636 K, and since the difference in the activation energies obtained from k_Q'' for ethane and neopentane is larger than that obtained from k_Q', and since the ratio of the frequency factors (1.8) of k_Q'' for ethane and neopentane is considerably larger than that predicted from the simple collision theory, the imprisonment lifetime shown in Table 3 does not seem to be precise (it may be too large at higher temperatures). The above estimation of the imprisonment lifetime may include some uncertainty because of the effect of collision broadening, the presence of the isotopes of the zinc atom, and the difference in the experimental conditions from the ideal conditions of infinite slub and uniform external excitation. Therefore, the activation energies calculated from k_Q'' seem to be lower limits, whereas those estimated from k_Q' (by neglecting the imprisonment effect) are upper limits. The activation energy for the

Table 4. Potential Energies of Activation as Calculated by the BEBO Method

Parameter	V_a/kJ mol^{-1}		
	Primary	Secondary	Tertiary
Old	7.5	4.9	3.7
Old modified[a)]	18.4	14.6	12.0
Gilliom's	6.4	3.9	2.3
Gilliom's modified[a)]	15.0	11.1	8.9
Experimental	16.5±2.5	11.9±2.5	9.0±2.5

a) The correction for zero-point energy is made using the calculated frequencies of the transition state and the stretching frequency of the reactant (Ref. 12).

primary C–H bond was concluded to be 16.5±2.5 kJ mol^{-1}. From this value and the values of the differences in the activation energies for k_p, k_s, and k_t shown above, the activation energies for secondary and tertiary C–H bonds were calculated; they are listed in Table 4.

Strausz et al.[8] calculated the potential energies of activation for the mercury-photosensitized decomposition of alkanes by the BEBO method by assuming the following model:

$$RH + Hg^* \longrightarrow R\text{--}H\text{--}Hg \longrightarrow R + HHg.$$

Since the repulsive triplet term was neglected, they pointed out that their calculation was somewhat oversimplified and that only the relative values were significant.

We have also applied the BEBO method to the quenching of excited zinc atoms by alkane by assuming the following model:

$$RH + Zn^* \longrightarrow R\text{--}H\text{--}Zn \longrightarrow R + HZn.$$

We could thus qualitatively interpret the relative decrease in the quenching cross section with an increase in the C–H bond strength.[1]

In the BEBO formulation, the value of the potential energy of activation, V_a, is obtained by finding the value of n, the bond order of the breaking C–H bond, that causes V to reach its maximum value, subject to the constraint that the sum of the bond orders of the forming Zn–H bond and of the breaking C–H bond is unity.[9]

$$V = D_{DH}(1-n^p) - D_{ZnH}(1-n)^q + C_1 D_{ZnC} B(n-n^2)^\gamma\{1+B(n-n^2)^\gamma\} \quad (14)$$

where:

$$B = C_2 \exp\{-\beta(R_{CH} + R_{ZnH} - R_{ZnC})\} \quad (15)$$

$$\gamma = C_3\beta \quad (16)$$

The BEBO parameters p and q are given by:

$$p = C_3 \ln(D_{HC}/D_{HeNe})(R_{HeNe} - R_{HC}) \quad (17)$$

$$q = C_3 \ln(D_{ZnH}/D_{KrHe})/(R_{KrHe} - R_{ZnH}) \quad (18)$$

In these expressions, C_1 is the factor of the anti-Morse function (the old, C_1=1, old-modified, C_1=2, as suggested by Mayer and Schieler,[10] Gilliom's, C_1=1 and Gilliom's modified parameters, C_1=2,[11] were used) C_2 is 0.5 for the old BEBO method and is 0.45 for the Gilliom's method, C_3 is the Pauling constant (Gilliom recommended C_3=0.28 rather than the older value of 0.26), β is the Morse-function parameter for ZnC, and D and R are the normal single-bond energy (corrected for zero-point energy) and the distance for the indicated molecule respectively.

Table 4 gives the potential energies of activation as calculated by the BEBO method using the parameters shown above. Table 4 shows that the old modified and Gilliom's modified methods, which are generally used for the hydrogen-atom abstraction by such triplet species as O(^{3}P), give activation energies which are almost within the limits of experimental error.

Gilliom[11] compared the activation energies calculated by the BEBO method with the experimental values for about 100 reactions and pointed out that the BEBO method in its original form gives an average error of 6.4 kJ mol^{-1}, while his method affords an average error of 5.4 kJ mol^{-1}. Thus, the agreement between experimental and calculated activation energies for the present study seems to be good considering the experimental error and the empiricism of the BEBO method.

As has been mentioned above, the experimental activation energies for the quenching of Zn(^3P_J) by alkanes are in good agreement with those calculated by the BEBO method by assuming this model: RH+Zn*→R--H--Zn→R+H-Zn. This strongly suggests that, in the initial stage of zinc-photosensitized reaction of alkanes, the hydrogen-atom abstraction by excited zinc atoms from alkane molecules occurs. In order to make sure of this point, further studies are in progress of the isotope effect on the quenching rate and of the zinc-photosensitized decomposition of ethane and propane based on product analysis.

Complexes of five bivalent metals with (*S*)-4-thiazolidinecarboxylic acid($\overline{CH_2\text{-}S\text{-}CH_2\text{-}NH\text{-}CH}$-COOH) have been prepared by three methods and characterized by means of infrared absorption, reflection spectra, magnetic susceptibility, thermal analysis, powder X-ray patterns, and single crystal X-ray diffraction. Two types of complexes were found. The first type[A] included $ML_2 \cdot nH_2O$ (M=Co(II), Ni(II), Cu(II), Zn(II), Cd(II); L=(*S*)-4-thiazolidinecarboxylate anion) and ZnClL(HL) was the second type[B]. In A-type complexes, the ligand coordinates to the metal with a nitrogen atom and an oxygen atom. From the results of single-crystal X-ray diffraction studies, the second type-B ZnClL(HL) was found to be orthorhombic, with the space group $P2_12_12_1$; a=9.719(2), b=22.194(4), c=5.8537(5) Å, U=1262.6(4) Å^3, Z=4, D_m=1.91 Mg m^{-3}, D_x=1.93 Mg m^{-3}, and μ(Mo $K\alpha$)=25.3 cm^{-1}. Block-diagonal least-squares refinements have led to a final R value of 0.045. The zinc atom is penta-coordinated, being ligated with one carboxylate oxygen atom of (*S*)-thiazolidinium-4-carboxylate, which has a zwitter ion structure, two carboxylato oxygen atoms and one nitrogen atom of (*S*)-4-thiazolidinecarboxylate anion, and a chloride atom. The structure comprises one-dimensional polymers by the carboxylate oxygen atom of this anion-type ligand. The plane extends in the direction of c-axis. In neither the A- nor the B-type complexes does the ligand coordinate to a metal with a sulfur atom.

In our laboratory, we have been investigating the syntheses, spectral properties[1] and crystal structures[2,3] of the metal complexes of various amino acids and their derivatives. This study is one part of that program. (*S*)-4-Thiazolidinecarboxylic acid is a very interesting ligand, since it has four coordination atoms. They are the sulfur and nitrogen atoms of the thiazolidine ring and two oxygen atoms of the carboxyl group.

Recently, this amino acid has been reported to be a new type of anticancer agent which can induce a reverse transformation.[4–7] Thus, many studies have been reported about the stability constants,[8–11] ESR[12] and NMR spectra[13,14] for metal complexes with this ligand in aqueous solution.

The crystal structures of copper(II),[15] zinc(II),[13] and cobalt(III) complexes[16] in the solid state have been reported and their IR spectra discussed.[8]

In the present work, we prepared bivalent metal complexes of (*S*)-4-thiazolidinecarboxylic acid (HL) and systematically investigated their spectral and thermal properties as well as magnetic susceptibilities in the solid state. We then determined the structure of ZnClL(HL) by the single-crystal X-ray diffraction method.

Experimental

Preparation of Compounds. Cobalt(II)-A complex was prepared by adding 0.01 mol cobalt(II) hydroxide to an aqueous solution containing 0.02 mol (*S*)-4-thiazolidinecarboxylic acid. The mixed solution was stirred and concentrated to a small volume in a water bath under 60 °C. The pink precipitate which formed was filtered and washed with water.

Nickel(II)-A, cadmium(II)-A, and zinc(II)-A complexes were prepared by the same method as used for the cobalt(II)-A complex. Zinc(II)-A complex was recrystallized from water.

Copper(II)-A complex was prepared by adding 0.01 mol copper(II) hydroxide to an ethanol solution containing 0.02 mol of this ligand in suspension. This solution was evaporated at room temperature. The resulting complex was recrystallized from methanol.

Zinc(II)-B complex was prepared by adding 0.01 mol of zinc(II) chloride to an aqueous solution containing 0.02 mol of the ligand. The mixed solution was stirred in a water bath, then concentrated to a small volume below 60 °C and filtered. The obtained crude crystals were recrystallized by water under 60 °C. All complexes were dried in vacuo.

Deuterated complexes were obtained by recrystallization in D_2O.

Reflection Spectra. Reflection spectra from 800 to 2000 nm were obtained with a Japan Spectroscopic Co. UVIDEC-590 spectrophotometer. The spectra from 370 to 800 nm were obtained with a Hitachi 624 digital spectrophotometer. Both spectrophotometers were equipped with a standard reflection attachment and a magnesium oxide standard.

† Present address: Division of Chemistry, General Education Department, Niigata University, 8050, Ikarashi, Nino-cho, Niigata 950-21.

Magnetic Studies. The magnetic moments of these complexes were obtained for the solid samples by the Gouy method, using $Hg[Co(SCN)_4]$ as the calibration standard at 23.5 °C. However, copper(II)-A type complex was measured by the Faraday method.

Infrared and Far Infrared Absorption Spectra. Infrared absorption spectra from 4000 to 400 cm^{-1} were measured using a Hitachi spectrophotometer, type EPI-G_2. Far-infrared absorption spectra from 700 to 200 cm^{-1} were measured using a Hitachi spectrophotometer, type EPI-L. Samples were prepared as KBr disks and Nujol mulls. The spectra were calibrated with polystyrene and atmospheric water vapor.

Thermal Analysis. Simultaneous TG-DTA measurements were carried out with a Rigaku Denki M8075, using a sample weight of about 9 mg in each operation. The heating rate was 10 °C min^{-1}, under static air, using α-alumina as a reference.

Powder X-Ray Diffraction. Powder X-ray diffraction patterns were obtained with a Rigaku RAD IIA powder X-ray diffractometer, using Cu $K\alpha$ radiation over a 2θ range from 50° to 5°.

Single-Crystal X-Ray Analysis. The reflection intensities were collected by the θ-2θ scan technique ($2\theta<70°$) on a Rigaku AFC-6A automated four-circule diffractometer. The intensities were corrected for Lorenz and polarization factors; however, no corrections were made for absorption and extinction $\mu r(=0.51)$. Independent reflections (2378) with $|F_o|>3\sigma(|F_o|)$ were used for a structure determination. All calculations were carried out on a HITAC M-680H computer at the Computer Center of the University of Tokyo, using a local version of UNICS.[17] The scattering factors were taken from Ref. 18.

The structure was solved by the heavy-atom method and refined by a block-diagonal least-squares method. The positions of the zinc and chlorine atoms were obtained from a three-dimensional Patterson map, while the positions of all the other non-hydrogen atoms were successively located by Fourier syntheses. Since the positions of hydrogen atoms were obtained by difference-Fourier syntheses, all of the positions were calculated and fixed. Their isotropic temperature factors were all assumed to be 3.0 $Å^2$. The weighting scheme was $W=1/[\{\sigma(|F_o|)\}^2+(0.02\times|F_o|)^2]$. In the last cycle of the refinement with anisotropic temperature factors for all non-hydrogen atoms, all the parameter shifts were less than one-third of the corresponding standard deviations. The final R values ($R=\sum||F_o|-|F_c||/\sum|F_o|$) was 0.045.

Results and Discussion

The results of elemental analyses and infrared spectra suggest that there are two types of complexes: A and B types. A type is $ML_2\cdot nH_2O$ (M=Co(II), Ni(II), Cu(II), Zn(II), Cd(II)); HL=(*S*)-4-thiazolidinecarboxylic acid; n=0, 2). B type is ZnClL(HL).

Reflection Spectra and Magnetic Moments. The results obtained from elemental analyses, reflection spectra and magnetic moment calculations are listed in Table 1. Each peak of these reflection spectra is due to a d-d transition. The magnetic moment of the cobalt(II)-A complex is within the range expected for high-spin complexes (4.1—5.2 B M for cobalt(II).[19] For nickel(II)-A and copper(II)-A complexes the magnetic moments are within the ranges expected for two unpaired electrons (2.8—4.0 B M for nickel(II)[19]) and for one unpaired electron (1.7—2.2 B M for copper(II)[19]), respectively.

Infrared Absorption Spectra. The infrared spectra data are listed in Table 2. The assignments of observed spectra have been made by referring to L-proline,[20] 4-hydroxy-L-proline[1] and their metal complexes,[1,20] and zinc(II) complex with (*S*)-4-thiazolidinecarboxylic acid.[8]

(*S*)-4-Thiazolidinecarboxylic Acid: X-Ray analyses showed that this amino acid has a zwitter ion structure.[21,22] Therefore, some absorption bands which shift to low-frequency regions on deuteration were assigned to NH_2^+ stretching and bending vibrations. The antisymmetric and symmetric stretching vibrations of the carboxyl group appear at 1625 and 1387 cm^{-1}, respectively.

A Type Complexes: According to the X-ray

analysis of Tatarowski et al. diaquabis((*S*)-4-thiazolidinecarboxylato)zinc(II) has an octahedral configuration with the two water molecules occupying cis positions and with nitrogen and oxygen atoms in the ligands.[13]

Zinc(II)-A complex has a few absorption bands which shift to lower-frequency regions on deuteration. These were assigned to NH stretching and bending vibrations. The antisymmetric stretching vibration of the carboxyl group shifts to a lower-frequency region compared with that of the ligand, and the symmetric stretching vibration shifts to a higher-frequency region. The C-S stretching vibration was observed at the same position as that of the free ligand. Therefore, in this complex, the zinc atom is not coordinated through a sulfur atom, but is coordinated through an oxygen atom of the carboxyl group and a nitrogen atom of the thiazolidine ring; this agrees with Tatarowski's result.[13]

Bigoli et al. have investigated the structure of *trans*-diaqua((*S*)-4-thiazolidinecarboxylato)((*S*)-4,5-dihydro-4-thiazolecarboxylato)copper(II) by a single-crystal X-ray analysis.[15] They reported that part of the thiazolidine ligand was oxidized during the reaction. Two different ligands were involved in the complex and the coordination polyhedron around copper(II) atom was a distorted tetragonal bipyramid with the apices of the elongated axis occupied unsymmetrically by water molecules. Since the results of the elemental analyses of copper(II)-A complex show that this complex has two molecules of (*S*)-4-thiazolidinecarboxylate ion for one copper atom, its structure must be different from that of the copper(II) complex which was determined by Bigoli et al.

The absorption bands due to the vibration of the carboxyl and the amino groups for cobalt(II)-A, nickel(II)-A, copper(II)-A, and cadmium(II)-A complexes appear in the same region as those of the zinc(II)-A complex (as shown in Table 2). Therefore, the metal is coordinated through one oxygen and one nitrogen atom for A-type complexes.

From 500 to 200 cm^{-1}, absorption bands which cannot be observed in the ligand appear in cobalt(II)-A, copper(II)-A, cadmium(II)-A, and zinc(II)-B complexes. These are assigned to the M-O stretching vibrations by comparing these spectra with those of metal complexes with L-proline[20] and 4-hydroxy-L-proline.[1] For nickel(II)-A and zinc(II)-A complexes, the corresponding bands could not be clearly observed due to water molecules.

The powder X-ray diffraction pattern of the cobalt(II)-A complex is similar to zinc(II)-A in crystal structure.

B Type Complex ZnClL(HL): The infrared absorption spectra of zinc(II)-B complex is different from that of zinc(II)-A complex. In zinc(II)-B complex, some absorption bands due to NH_2^+ vibrations could be observed in the same region as in the free ligand.

The bands which split at about 1600 cm^{-1} were assigned to the COO^- antisymmetric stretching vibrations of (*S*)-4-thiazolidinecarboxylate anion and of (*S*)-thiazolidinium-4-carboxylate, which has a zwitter ion structure, by making a comparison with the spectra of the free ligand and of zinc(II)-A.

The results of elemental analyses suggest that zinc(II)-B complex has two types of this ligand: the first is (*S*)-4-thiazolidinecarboxylate anion and the second is (*S*)-thiazolidinium-4-carboxylate, which has a zwitter ion structure.

Structure of ZnClL(HL). Crystal data are given in Table 3. The final atomic parameters are listed in Table 4.[23] The bond lengths and bond angles are shown in Tables 5 and 6, respectively. A perspective

drawing of the complex, together with the numbering scheme of the non-hydrogen atoms, is shown in Fig. 1. The projection of the unit cell along the c-axis is shown in Fig. 2.

As expected from the infrared absorption spectra and the elemental analysis, the complex has two types of ligands: one is (*S*)-thiazolidinium-4-carboxylate, which assumes a zwitter ion structure, and the other is (*S*)-4-thiazolidinecarboxylate anion.

The structure of the complex consists of a one-dimensional polymer chain bridged by the carboxylate group of the anionic ligand. One carboxylate

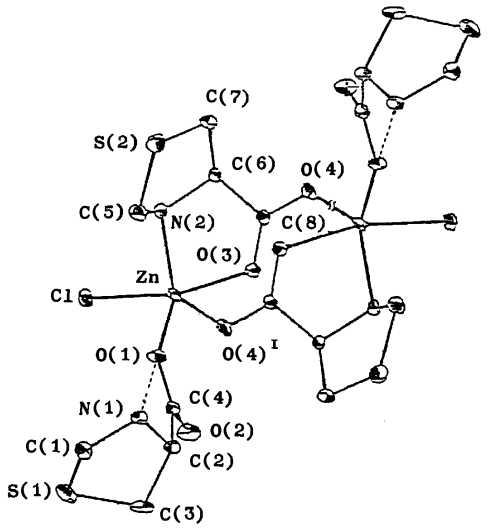

Fig. 1. The perspective drawing of ZnClL(HL) (zinc(II)-B) and the numbering scheme of non-hydrogen atoms.
-----: Hydrogen bonding.

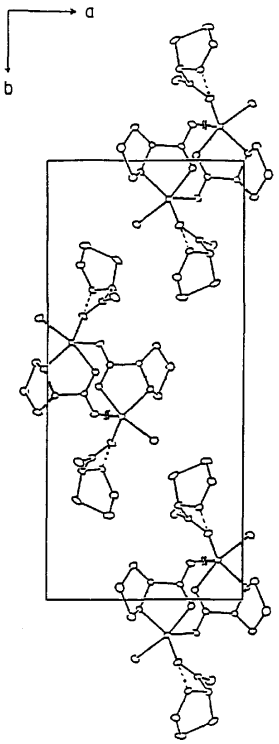

Fig. 2. The molecuar packing of ZnClL(HL) (zinc-(II)-B) along the c axis. -----: Hydrogen bonding.

oxygen atom of the anionic ligand is coordinated to the zinc atom and the other is coordinated to the neighboring zinc atom to form a Zn-O-C-O-Zn bridge. This polymer chain extends in the direction of the c-axis.

The zinc atom is surrounded by five atoms: one carboxylate oxygen atom O(1) of the non-charged ligand, one carboxylate oxygen atom O(3) and one nitrogen atom N(2) of the anionic ligand, one carboxylate oxygen atom $O(4)^I$ of the anionic ligand in the neighboring molecule, and one chlorine atom. It is novel that the same amino acid ligands have two types in one complex molecule.

This complex is in a distorted penta-coordinated trigonal bipyramidal geometry, which has a triangular plane formed by O(1), N(2), and $O(4)^I$. The angle of Cl-Zn-O(3) is 166.64(9)°. This angle is smaller than ideal bond angle 180°.

In this geometry, the plane formed by Zn, Cl, N(2), and O(3) is a fairly flat plane, as shown in Table 7. All other least-squares planes are listed in Table 7.

The bond length of Zn-O(3), 2.218(3) Å is longest among the three Zn-O bonds; Zn-O(3), Zn-O(1) and $Zn-O(4)^I$. The bond lengths of Zn-O(1) and $Zn-O(4)^I$ are shorter than Tatarowski's results[13] (Zn-O: 2.137(8)

and 2.172(8) Å).

The bond length of Zn–N(2), 2.071(4) Å and the bond angle of O(3)–Zn–N(2) 75.5(1)° are smaller than Tatarowski's results:[13] Zn–N: 2.149(12) Å and 2.134(12) Å, O–Zn–N: 78.1(4)°.

There are some differences in the bond lengths of the non-charged ligand and the anionic ligand, as shown in Table 5.

Let's compare the bond lengths of this complex with that of the free ligand determined by Chacko:[22] C(2)–C(4), C(6)–C(8), C(3)–S(1), and C(5)–N(2) are shorter than the corresponding bond lengths of the free ligand, while S(2)–C(5) is longer than that of the free ligand.

Thermal Analysis and Powder X-Ray Diffraction. The reaction temperature range and the mass loss obtained from TG and DTA curves of complexes are summarized in Table 8. Nickel(II)-A and zinc(II)-A complexes give endothermic reactions below about 180 °C. In these reactions, the percentages of the mass loss for both complexes agree with the values which were calculated by assuming that two molecules of water are released in these steps. Copper(II)-A and zinc(II)-B complexes give two steps of exothermic reactions with a mass loss, as shown in Table 8.

The powder X-ray patterns of the residual materials yielded by the final exothermic reactions are very similar to those of the corresponding metal oxide, except for cadmium (II)-A complex among the A-type complexes. Cadmium(II)-A complex seems to become cadmium(II) sulfide through an exo thermic reaction.

For the zinc(II)-B complex the data suggest that in the first exothermic reaction at 206 °C this complex becomes $ZnCl_2$ and ZnO, while in the second at 465 °C only $ZnCl_2$ sublimates.

$$2ZnClL(HL) \xrightarrow[\text{ca. } 206\,^{\circ}C]{\text{heat}} ZnCl_2 + ZnO \xrightarrow[\text{ca. } 465\,^{\circ}C]{\text{heat}} ZnO$$

The percentage of the mass loss calculated from this assumption is in good agreement with the experimental value, as shown in Table 8.

The authors wish to express their thanks to Professor Akira Ouchi of The University of Tokyo and Associate Professor Mamoru Shimoi of Tohoku University for X-ray diffractometer measurements. They would also like to thank Dr. F. S. Howell and Mr. H. Yamaguchi of Sophia University for their helpful advice and for correcting the manuscript.

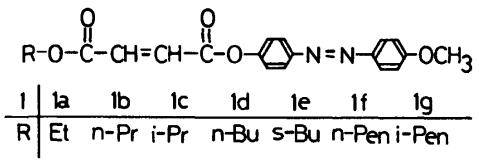
(Received July 24, 1987)

Senven enantiotropically nematic fumaric ester derivatives, 1-[[(*E*)-3-alkoxycarbonyl)acryloyl]oxy]-4-(4-methoxyphenylazo)benzene (**1**), were prepared. The **1** compounds which have unbranched ester alkyl groups showed decreased phase-transition temperatures and narrowed nematic states with the increase in the length of the alkyl chain, while the **1** compounds with terminal branched alkyl groups decrease drastically in nematic thermal stability. From the electro-optical effect originating in the dynamical scattering at the nematic state of the **1** compounds with unbranched ester groups, it was found that both the threshold voltage (E_{thres}) of deformation and the electro-optial response time (τ_r) decrease with the decrease in the chain lengh of alkyl groups. In addition, τ_r is scarcely influenced over the wide temperature range above 12 eV·cm^{-1} of the electric field.

During the last years, interest has been increasingly devoted to liquid crystalline side-chain polymers.[1-5] This interest has been justified by the creation of novel functional materials which bind the properties of low molecular liquid crystals to macromolecules.[6,7] In these polymers, the mesogenic groups become flexible polysiloxianes[1,3] or types of vinyl backbone, such as polyacrylates[4,7] and polymethacrylates.[2] On the other hand, it has been found that dialkyl fumarates can polymerize radically to produce nonflexible rodlike polymers with a high molecular weight.[8,9] In the course of an investigation of fumaric ester derivatives with properties of liquid crystals,[10,11] a series of polymerizable fumarates, 1-[[(*E*)-3-(alkoxycarbonyl)acryloyl]oxy]-4-(4-methoxyphenylazo)benzene, **1**, were prepared in an attempt to obtain a new type of liquid crystal side-chain polymers. In this paper, we would like to report the thermal and the electro-optical properties of **1**.



Scheme 1.

Results and Discussion

Thermal Properties. The **1** compounds were synthesized by a direct esterification of 4-(4-hydroxyphenylazo)anisole with (*E*)-3-(chloroformyl)acrylic acid alkyl esters. Alkyl groups were either ethyl(**1a**), propyl(**1b**), isopropyl(**1c**), butyl(**1d**), *s*-butyl(**1e**), pentyl(**1f**), or isopentyl(**1g**) as is shown in Scheme 1. A DSC study showed that all of the **1** compounds turned into enantiotropic liquid crystals, for showes two endothermic peaks and two exothermic peaks on heating and cooling cycles respectively. As a typical instance, the DSC curve of **1a** is shown in Fig. 1. The mesophase of **1** showed a schlieren texture and was

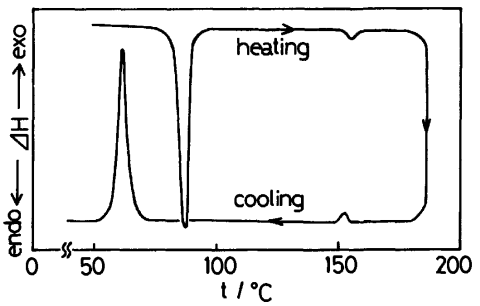


Fig. 1. DSC curve of **1a**.

Table 1. Phase Transition Temperatures and Electro-Optical Properties of **1** Compounds

Compound	R	Phase transition temperature[a]/°C	ΔT_N / °C	E_{thres}[b] / kV·cm^{-1}	Int[c] / %	τ_r[c] / ms
1a	Et	K 53.0 N 160.6 I	107.6	0.18	63	0.9
1b	*n*-Pr	K 50.0 N 153.1 I	103.1	0.28	45	1.0
1c	*i*-Pr	K 39.6 N 67.8 I	28.2	—	—	—
1d	*n*-Bu	K 27.0 N 114.4 I	87.4	0.26	80	5.7
1e	*s*-Bu	K 26.0 N 38.6 I	12.6	—	—	—
1f	*n*-Pen	K 34.0 N 118.3 I	84.3	0.40	50	4.5
1g	*i*-Pen	K 31.5 N 92.2 I	60.7	0.84	—	—

a) K, N, and I represent the crystalline, and nematic phases, and the isotropic melt respectively. b) E_{thres} was measured at T*°C(T_{N-I}−10 °C). c) Int represents the transmission intensity of the He-Ne laser. d) τ_r was measured on 16 kV·cm^{-1} of an electric field at T*°C(T_{N-I}−10 °C).

identified as a nematic phase by observation and a polarization microscopy of thin samples. The phase-transition temperature of **1** determined by DSC is compatible with the temperature obtained from the polarization microscopic and electro-optical measuremens to be described below. The results are tabulated in Table 1.

From the phase-transition temperature of **1**, the following conclusions can be drawn. Every fumarate exhibits an enantiotropically nematic phase independent of the ester alkyl groups. The phase-transition temperature is, however, strongly influenced by the structures of alkyl groups. In the case of unbranched alkyl groups (**1a**, **1b**, **1d**, **1f**), with an increase in the length of the alkyl chain the nematic-isotropic melt transition point loweres and the nematic state is narrowed. Comparing the unbranched type (**1b**, **1d**, **1f**), with the branched type (**1c**, **1e**, **1g**), the latter samples show lower transition temperatures. This suggests that the bulkiness of an alkyl group decreases the attractive interaction between the molecules; that is, a branching of a terminal alkyl group decreases the nematic thermal stability.[12,13] Especially, **1c** and **1e** with a methyl group at the α-position in the alkyl group are found to exhibit an extremely low nematic-isotropic melt transition. This explains the destruction of the molecular order by the methyl group at the α-position.[14]

Electro-Optical Properties. In order to obtain basic data for such practical uses as optical switching and display devices, electro-optical measurements were carried out for **1a**, **1b**, **1d**, and **1f** as follows. The sample cell was set in the optical path of a He-Ne laser(632.8 nm), and the change in the transmission with the application of an electric field was monitored by means of a photodiode.[15] As a typical example, the transmission intensity of the He-Ne laser through the **1a** cell on cooling cycles is shown in Fig. 2. The lines in Fig. 2 alternately indicate, the presence or absence of the dependence of the transmission intensities of the He-Ne laser through the cell on the applied voltage. When no voltage is applied, the transmission intensity decreases abruptly because of characteristic nematic light scattering just after the phase transition from the isotropic melt to the nematic phase at 160.6 °C, and then it gradually increases up to 63% of the original intensity by forming a stable nematic phase. On the other hand, upon the application of a voltage, the transmission intensity is zero over the nematic range of **1a** because of dynamical scattering caused by the d.c. current. The extent of these changes in the transmission intensity upon the application of an electric field is evaluated as a contrast in liquid-crystal displays. The threshold voltage of the observed deformation was measured at a definite temperature, T^* °C(T^*= T_{N-I}−10 °C), the results are listed in Table 1. Liquid crystals with a long alkyl group show a considerably higher threshold voltage of dynamical scattering. This is believed to be due to the higher viscosity of the nematic phase of **1** with the longer alkyl groups. The electro-optical response time (τ_r) of the decrease in the transmission caused by the voltage application was

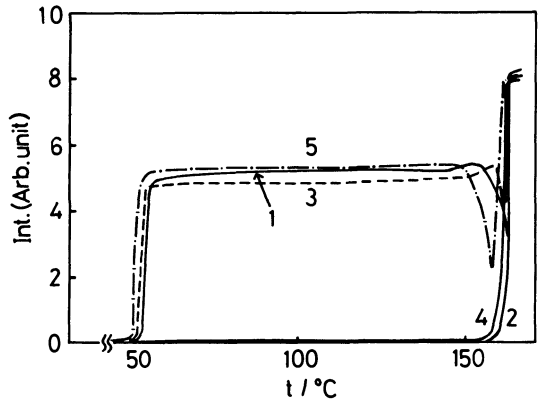

Fig. 2. Transmission intensities of a He-Ne laser for **1a** cell thickness; 50 μm, 1; (OFF), 2; 20 V(ON), 3; (OFF), 4; 40 V(ON), 5; (OFF).

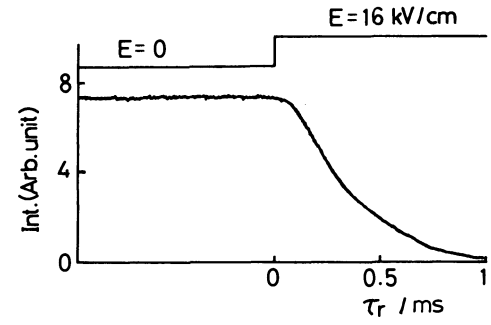

Fig. 3. Electro-optical response time(τ_r) in the nematic phase of **1a** at 16 kV·cm^{-1}.

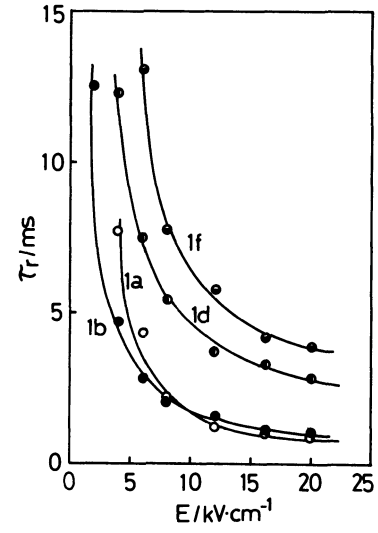

Fig. 4. Effect of electric field (E) on electro-optical response time (τ_r) for **1** at T^*° C(T^*=T_{N-I}−10 °C).

then measured over the voltage range from 5V (electric field, E=1 kV·cm^{-1}) to 100 V (E=20 kV·cm^{-1}) at T^* °C. In the case of **1a**, τ_r at 150.6 °C with E=16 kV·cm^{-1} is shown in Fig. 3. τ_r is the time taken to reach the stage of a transmission intensity decrease of 10%. τ_r for **1a** is, then, found to be 0.9 ms.

τ_r was also measured for other samples in a similar manner, by changing the applied voltage. The relation of τ_r and, the electric field applied at T^* °C is shown in Fig. 4. This figure shows that an increase in the applied voltage results in a faster optical response time, while an increase in the length of alkyl chain in **1** results in a slower response time. In order to clarify the effect of the electric field on the optical response time, τ_r was plotted on log-log graph paper as a function of the electric field, as is shown in Fig. 5.

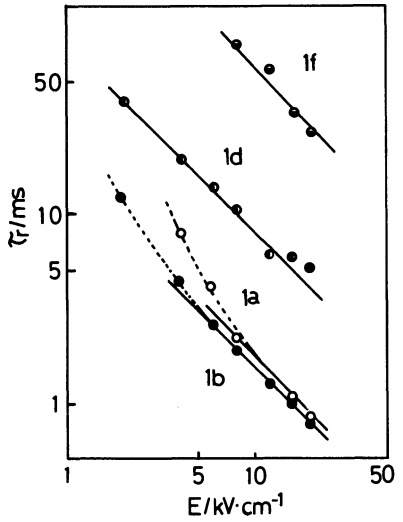

Fig. 5. Log-log plots of electro-optical response time (τ_r) and electric field (E) for **1** at T^*°C(T^*= T_{N-I}−10 °C).

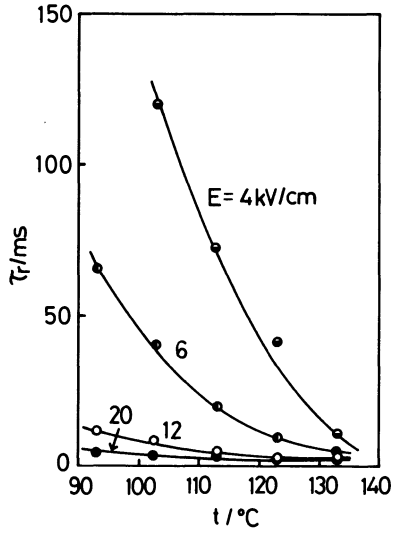

Fig. 6. Effect of temperature on electro-optical response time (τ_r) at various electric fields (E).

Since the slope of the lines is approximately −1, the τ_r of these liquid crystals is found to be proportional to the reciprocal of the electric field applied.[16] In the cases of **1a** and **1b** the plots deviate from the lines at somewhat lower electric fields. The reason for this phenomenon is now under consideration.

The effect of the temperature on τ_r was also studied by changing the applied voltage. As a typical example, the relationship between τ_r and the temperature for **1b** is shown in Fig. 6. It is found that τ_r is scarcely influenced over the wide temperature range above E=12 eV·cm^{-1} of the electric field. The transmission intensities of a He-Ne laser, τ_r, for **1a**, **1b**, **1d**, and **1f** are summarized in Table 1. Both a short response time and a clear contrast attributable to the change of transmission are realized with these liquid crystals. In general, the most desirable properties of a liquid crystal to be used as a material for display devices are as follows: i) the phase-transition temperature is low, and the temperature range of its mesophase is wide; ii) the optical response can occur at a low electric field and is accompanied by a high contrast; iii) the response times of rise and decay show an approximately exponential decrease with the temperature, and iv) the threshold voltage for the electric-field effect is proportional to the reciprocal of dielectric anisotropy. The liquid crystals obtained in this work can, therefore, be applied practically as display devices. The polymerization of **1** is now under investigation.

Experimental

Preparation of 1. 4-(4-Hydroxyphenylazo)anisole was obtained from the diazotization of *p*-anisidine and coupling with phenol according to the method used in the preparation of 4-(4-hydroxyphenylazo)benzonitrile.[17] 4-(4-Hydroxyphenylazo)anisole was dissolved in 300 mL of freshly distilled chloroform and 130 mmol of triethylamine. Then a trace of 1,4-benzoquinone was stirred in, the solution was cooled at 0 °C, and a 80-mmol portion of (*E*)-3-(chloroformyl)acrylic acid alkyl esters was dropped into the solution. After stirring for 2 h at 60 °C, ca. 200 mL of water was added to the reaction mixture. The chloroform layer was then washed with water and evaporated to dryness, and the residue was recrystallized from ethanol. **1** was chracterized by IR, ^{1}H NMR, and elemental analysis as follows:

1a (R=CH_3CH_2-): 65.6% yield; ^{1}H NMR ($CDCl_3$) δ= 1.26—1.66 (t, 3H, $C\underline{H}_3CH_2$-), 4.00 (s, 3H, $C\underline{H}_3O$-), 4.30—4.82 (q, 2H, $CH_3C\underline{H}_2$-), 7.34 (s, 2H, -C<u>H</u>=C<u>H</u>-), 7.88—8.62 (q, 8H, Aromatic): $C_{19}H_{18}O_5N_2$ (354.36); Found C, 64.3; H, 5.1; N, 7.7%. Calcd for C, 64.40; H, 5.12; N, 7.91%.

1b (R=$CH_3CH_2CH_2$-): 67.2% yield; ^{1}H NMR ($CDCl_3$) δ=0.90—1.40 (t, 3H, $C\underline{H}_3CH_2CH_2$-), 1.62—2.12 (sex, 2H, $CH_3C\underline{H}_2CH_2$-), 4.04 (s, 3H, $C\underline{H}_3O$-), 4.30—4.68 (t, 2H, $CH_3CH_2C\underline{H}_2$-), 7.36 (s, 2H, -C<u>H</u>=C<u>H</u>-), 7.54—8.56 (q, 8H, Aromatic): $C_{20}H_{20}O_5N_2$ (368.39); Found C, 65.3; H, 5.4; N, 7.4%. Calcd for C, 65.21; H, 5.47; N, 7.64%.

1c (R=$(CH_3)_2CH$-): ^{1}H NMR ($CDCl_3$) δ=1.34, 1.40 (s, s,

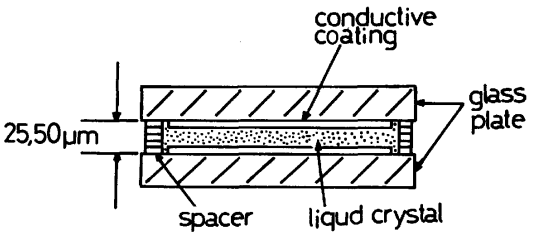

Fig. 7. Schematic representation of sandwiched cell for electro-optical measurement.

6H, $(CH_3)_2CH$-), 4.04 (s, 3H, CH_3O-), 5.16—5.52 (pent, 1H, $(CH_3)_2CH$-), 7.34 (s, 2H, -CH=CH-), 7.50—8.68 (q, 8H, Aromatic): $C_{20}H_{20}O_5N_2$ (368.39): Found C, 65.3; H, 5.4; N, 7.4 Calcd for C, 65.21; H, 5.47; N, 7.64%.

1d (R=$CH_3CH_2CH_2CH_2$-): 57.1% yield; ^1H NMR ($CDCl_3$) δ=0.92—1.06 (t, 3H, $CH_3CH_2CH_2CH_2$-), 1.32—2.06 (m, 4H, $CH_3CH_2CH_2CH_2$-), 3.98 (s, 3H, CH_3O-), 4.32—4.80 (t, 2H, $CH_3CH_2CH_2CH_2$-), 7.34 (s, 2H, -CH=CH-), 7.50—8.78 (q, 8H, Aromatic): $C_{21}H_{22}O_5N_2$ (382.42); Found C, 65.9; H, 5.8; N, 7.7%. Calcd for C, 65.96; H, 5.80; N, 7.33%.

1e (R=$CH_3CH_2(CH_3)CH$-): 74.5% yield; ^1H NMR ($CDCl_3$) δ=0.92-1.04 (m, 3H, CH_3-), 1.32-1.36 (d, 3H, CH_3-), 1.54-2.02 (m, 2H, $-CH_2$-), 4.10 (s, 3H, CH_3O-), 5.02-5.48 (m, 1H, -CH-), 7.34 (s, 2H, -CH=CH-), 7.50-8.80 (q, 8H, Aromatic): $C_{21}H_{22}O_5N_2$ (382.42): Found C, 66.0; H, 5.8; N, 7.1%. Calcd for C, 65.96; H, 5.80; N, 7.33%.

1f (R=$CH_3(CH_2)_3CH_2$-): 70.7% yield; ^1H NMR ($CDCl_3$) δ=0.86-1.20 (t, 3H, CH_3-), 1.32—2.12 (m, 6H, CH_3-$(CH_2)_3CH_2$-), 4.04 (s, 3H, CH_3O-), 4.34—4.66 (t, 2H, $CH_3(CH_2)_3CH_2$-), 7.36 (s, 2H, -CH=CH-), 7.54—8.56 (q, 8H, Aromatic): $C_{22}H_{24}O_5N_2$ (395.42): Found C, 66.4; H, 6.1; N, 7.2%. Calcd for C, 66.65; H, 6.10; N, 7.70%.

1g (R=$(CH_3)_2CHCH_2CH_2$-): 75.2% yield; ^1H NMR ($CDCl_3$) δ=0.98, 1.04 (s, s, 6H, $(CH_3)_2CHCH_2CH_2$-), 1.54—2.14 (m, 3H, $(CH_3)_2CHCH_2CH_2$-), 4.06 (s, 3H, CH_3O-), 7.36 (s, 2H, -CH=CH-), 7.54-8.64 (q, 8H, Aromatic): $C_{22}H_{24}O_5N_2$ (396.42): Found C, 66.4; H, 6.1; N, 7.1%. Calcd for C, 66.64; H, 6.10; N, 7.07%.

Measurements. The ^1H NMR measurements were carried out with a 100-MHz Jeol JNM-MH100 spectrometer. The phase-transition temperature were determined by means of differential scanning calorimetry, using a Rigaku Thermoflex apparatus DSC-8230B, with almost the same heating and cooling rates (10 K·min^{-1}). The sample sizes varied from 5 to 10 mg.

Microscopic investigations were performed by means of an Olympus microscope, with the temperature of the sample controlled by the heating stage. The thin samples were sandwiched between two glass slides whose surfaces had been unidirectionally rubbed with cotton wool to obtain a homogeneous alignment.[18-20] The spacing between top and bottom glass plates was 25 μm, with a stretched polyester film used as the spacer material. The samples were studied at both decreasing and increasing temperatures.

The sandwiched cell used in electro-opotical measurements is schematically illustrated in Fig. 7. The surfaces of the glass plates were coated with a transparent conductive material(InO_2); the surface resistance was about 100 ohms·square^{-1}. The spacings between top and bottom glass plates was 50 μm. A He-Ne laser(wavelength; 632.8 nm, output power; 1 mW) was used as the light source for the measurements of the transmission intensity. The incident light was performed with both an attenuator and a slit. The transmission lights were measured using a photomultiplier and were calculated using a microcomputer (NEC-9801).

Electrochemical Studies of Poly(mercaptohydroquinone) and Poly(mercapto-*p*-benzoquinone) Films Prepared by Electropolymerization. II. Fixation of Heavy Metals and Their Electrochemical Properties

Gorou Arai,* Takayuki Ishii, Sumi Yamamoto, and Iwao Yasumori
Department of Applied Chemistry, Faculty of Engineering, Kanagawa University, Kanagawa-ku, Yokohama 221
(Received July 30, 1987)

Heavy metal ions, Ag^+, Hg^{2+}, Cd^{2+}, Cu^{2+}, Pb^{2+}, Pd^{2+}, Fe^{3+}, and Pt^{4+}, were each fixed on a conductive redox film of poly(mercapto-*p*-benzoquinone) or poly(mercaptohydroquinone) by mercaptide formation. Of these mercaptide-modified electrodes, the Pt(IV)-, Pd(II)-, and Ag(I)-modified electrodes possess some catalytic properties for electrochemical hydrogen evolution. These mercaptide-modified electrodes display a nearly Nernstian response to their respective heavy metal ions in aqueous solution and exhibit good durability when stored under appropriate conditions. Especially, the Hg(II)-modified electrode displays an excellent function as an Hg^{2+} ion sensor. The effect of miniaturization of substrates upon response ability was investigated by using two different-sized Pt wires (0.5 mm and 0.03 mm in diameter).

Electrode surface modification using various electrocatalytic materials has been investigated in the field of electrocatalysis. Catalytic electrodes modified at the monolayer level have not successfully been utilized because they lack stability and conductivity.[1] Polymer-modified electrodes have recently been used for immobilization of metal ions and metal complex ions.[2] Many investigations have thus far been undertaken to devise more active and stabler catalyst systems for the electrochemical evolution of hydrogen,[3] the electrochemical reduction of oxygen,[4] and other inorganic and organic reactions.[5] Some basic applications[6] of catalytic electrodes have been reported. We prepared poly(mercapto-*p*-benzoquinone) (SQE_{Ox}) and poly(mercaptohydroquinone) (SQE_{Red}) films,[7] and reported their electrochemical properties.[8] Many heavy metal ions were fixed on the redox polymers (SQE, standing for SQE_{Red} and/or SQE_{Ox}) in the form of mercaptides. This fixation is easy and can be carried out under mild conditions as described below. Mercaptide-modified electrodes (ME-M's) are stable and possess a characteristic structure in which heavy metal atoms or particles are connected with a substrate electrode via a conductive polymer of SQE. As described in our previous paper,[7] the thickness of SQE can be controlled by the duration of electrolysis of mercaptohydroquinone. We report here on the method of fixing heavy metal ions on SQE and on some items of basic electrochemical behavior of various ME-M's.

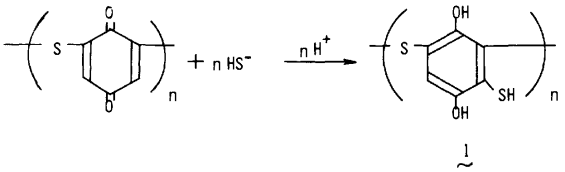
Experimental

Mercaptohydroquinone was synthesized and purified according to the method described in our previous paper.[7] The chemicals used for the synthesis of mercaptohydroquinone were of reagent grade. The other inorganic reagents were of reagent grade and used without further purification. Deionized water was used for the preparation of solutions, final washing of electrode surface, and rinsing SQE. The substrate electrodes used were two different-sized platinum wires ($Pt_{0.5}$ and $Pt_{0.03}$), 0.5 and 0.03 mm in diameter, respectively, and both ca. 5 mm in effective length,[9] and a Yanagimoto GC-P2 glassy carbon electrode (GCE) 3 mm in diameter. The apparatus used for the preparation of SQE on these electrodes was the same as that used in the previous paper.[7] The reference electrode used was a saturated calomel electrode (SCE). Voltammetric measurements were carried out with a three-electrode system consisting of an ME-M working electrode, a Pt plate counter electrode, and an SCE reference electrode having an agar salt bridge of saturated KNO_3. Purified nitrogen gas was bubbled for 30 min to remove dissolved oxygen. Current-potential curves were recorded on a Yanagimoto P-8 polarograph. Potentiometric measurements were carried out in the conventional manner. An ME-M was set in a glass beaker containing a test solution. An SCE was set in another beaker containing an aqueous solution saturated with KCl. The two glass beakers were connected with each other by an agar salt bridge of saturated KNO_3. Potentials of ME-M's were measured with a Toho Chemical Research EM-02 electrometer. Each test solution contained 0.1 M (1 M=1 mol dm^{-3}) KNO_3 to provide a constant ionic strength (μ=0.1) and was brought to pH 5.0±0.1 by addition of an appropriate quantity of dilute nitric acid. The test solution was prepared just before potentiometric measurement to avoid the dissolution of atmospheric carbon dioxide. All potentiometric measurements were carried out at 25±0.1 °C.

Results and Discussion

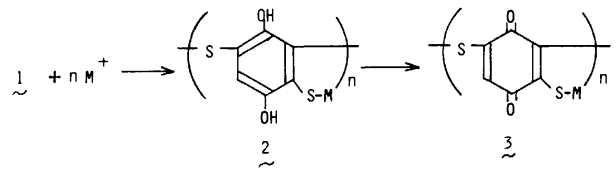
Fixation of Heavy Metal Ions on SQE. SQE_{Ox} was prepared on $Pt_{0.03}$, $Pt_{0.5}$, and GCE by an electrochemical oxidation of 0.4 mM mercaptohydroquinone at a constant potential of +0.3 V for 30 min in a Britton-Robinson buffer solution of pH 5.0 containing 20 vol% ethanol. When 0.3 mC cm^{-2} was passed during the electropolymerization under the conditions described above, the surface density of quinone units in the SQE_{Ox} thus prepared was found to be ca. 8×10^{14} cm^{-2} on each electrode surface by measurement

of the charge associated with the reduction of the SQE_{ox}. After finishing the electropolymerization, the SQE_{ox}-modified electrodes were thoroughly rinsed with water and then immersed in a Britton-Robinson buffer solution containing 1 mM NaHS for 1 h at room temperature under a nitrogen atmosphere for the conversion to **1** by the reaction



1

In order to confirm the above-described addition to have proceeded effectively, spectrophotometric measurements were carried out by using a pH 5.0 Britton-Robinson buffer solution containing 1 mM NaHS and 0.4 mM *p*-benzoquinone under a nitrogen atmosphere. The absorption spectrum with λ_{max}=246 nm due to *p*-benzoquinone rapidly decreased with lapse of time, while a new absorption spectrum with λ_{max}=298 nm increased. This absorption maximum is in fair agreement with that of 0.4 mM mercaptohydroquinone in wavelength and absorbance. On the basis of this spectrophotometric measurement, it is clear that the addition of HS^- ions to the majority of the quinone rings in SQE_{ox} has occurred to give **1**. After thorough rinsing with water, the **1**-modified electrodes were immersed in an aqueous solution containing 1 mM heavy metal ion for more than 1 h under a nitrogen atmosphere in order to fix the heavy metal ion on **1** by allowing its mercaptide to be formed which is insoluble or sparingly soluble in aqueous solution. Thus far Ag^+ or Hg^{2+} has been used for the titration of mercapto groups in various proteins.[11] After rinsing with a large amount of water to remove unreacted heavy metal ion, the **2**-modified electrodes were kept for 10 min at +0.3 V in 0.1 M KNO_3 solution in order to reduce **2** into **3** because the latter is superior to the former in durability:



2 **3**

where M^+ indicates a univalent heavy metal ion. The **3**-modified electrodes thus prepared were kept in an aqueous solution containing the same heavy metal ion (1 mM) and were rinsed with water just before use for measurement. In order to confirm the mercaptide formation described above, the reaction between mercaptohydroquinone and Ag^+ was followed spectrophotometrically in aqueous solution. Figure 1 shows that mercaptohydroquinone and Ag^+ rapidly undergo an equimolar reaction to give an insoluble Ag-mercaptide. The mercaptide formation was confirmed for the other heavy metal ions, Hg^{2+}, Pd^{2+}, Cd^{2+}, Pb^{2+}, Cu^{2+}, Fe^{3+}, and Pt^{4+}. Hence it has been established that these heavy metal ions can be fixed on SQE via the formation of mercaptide **2** or **3**.

Voltammetric Behavior in Aqueous Solution. Voltammetric measurements were performed with a GCE as the substrate electrode because of its higher hydrogen overvoltage than that of Pt. Each ME-M gave a cathodic voltammogram characteristic of the metal ion species fixed on SQE. Their cathodic voltammograms were reproducible except those obtained during initial two or three potential scannings. As shown in Fig. 2, hydrogen evolution potentials become more positive in the order: Pt≈Pd>Ag>Cu≈Cd>Hg. The order observed here is inversely proportional to the magnitude of their hydrogen overvoltages. Of the SQE's having no mercapto groups, only those which had been immersed in Pt^{4+} or Pd^{2+} solution in the same manner, were observed to show small positive shifts in hydrogen evolution potential even after repeated rinsings with a large quantity of water. However, these small positive shifts decreased quickly with repeated potential scannings between 0 V and the hydrogen evolution potential. This salient difference in voltammetric behavior between SQE having mercapto group and SQE alone which were each

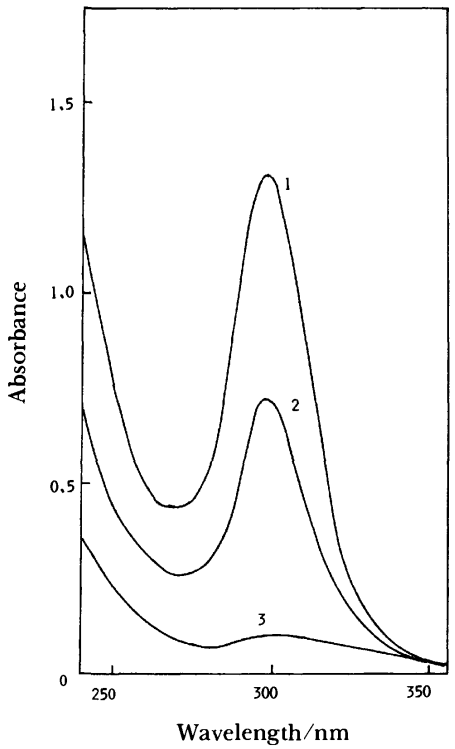


Fig. 1. Absorption spectra of mercaptohydroquinone (0.4 mM) in aqueous solution in the presence of Ag^+ in N_2 atmosphere. Concentration of $AgNO_3$: 1, 0 M; 2, 0.2 mM; 2, 0.4 mM.

immersed in the metal ion solution, strongly supports the above-mentioned judgment that the addition of HS^- ion to SQE_{Ox} gives **1**. Figure 3 shows that the hydrogen evolution potential of ME-Ag shifts negatively with an increase in the pH of buffer solution. This negative shift in hydrogen evolution potential was observed also with the other ME-M's. These results indicate that the electroactive sites where the hydrogen evolution occurs are solely the metals fixed on SQE and are neither the surface of GCE nor the SQE itself. Moreover, the above information strongly suggests that many metals which can form mercaptides may be electrochemically nucleated and grown on the electroactive sites, i.e., the metals fixed on SQE by means of the electroreduction of these metal ions in aqueous solution. The metal nucleation on the heavy metals fixed on SQE will be reported elsewhere.

Potentiometric Behavior in Metal Ion Solution. We reported that Pt electrodes modified with a few species of mercaptides show a nearly Nernstian response to the same heavy metal ion as that of the mercaptide in 0.1 M KNO_3 aqueous solution.[12] In this work, potentiometric measurements were carried out by using two different-sized Pt electrodes, $Pt_{0.5}$ and $Pt_{0.03}$, modified with **3** in order to investigate on the deterioration in durability caused by the miniaturization of the substrate electrode. As a result of this investigation, no marked difference in the response characteristics such as response time and response concentration range was found to exist between the two electrodes. However, $Pt_{0.03}$ modified with **3** was occasionally dislodged or bent on insertion of the electrode into a test solution containing heavy metal ions. These defects encountered are obviously attributed to the fine flexible body of $Pt_{0.03}$ itself and need, therefore, to be overcome by fixation of $Pt_{0.03}$ on some hard substrate. As shown in Fig. 4, ME-Ag(I) displays a good Nernstian response to Ag^+ and has good durability. The response characteristics of various mercaptide-modified $Pt_{0.5}$'s are summarized in Table 1. The ME-M's show an almost Nernstian

O: By Me-Ag(I) prepared just before the measurement, Δ: by ME-Ag(I) permitted to stand for one month.

Table 1. Response Characteristics of ME-M's ($Pt_{0.5}$)

Electrode	Test ion	Slope[a] mV/−log a	Range of linear response/M
ME-Ag(I)	Ag^+	60—61	$10^{-1.5}$—10^{-5}
ME-Hg(II)	Hg^{2+}	90—91	10^{-3}—10^{-5}
ME-Cu(II)	Cu^{2+}	27—28	5×10^{-3}—10^{-5}
ME-Pb(II)	Pb^{2+}	26—27	5×10^{-3}—10^{-5}
ME-Cd(II)	Cd^{2+}	30—31	5×10^{-3}—10^{-5}
ME-Fe(III)	Fe^{3+}	54—55	10^{-2}—10^{-5}

a) Each value range was obtained as the average from five or six measurements.

Table 2. Selectivity Coefficients (K_{Sel}'s) of ME-M's and Standard Redox Potentials (E^0's) of Mercaptide-Forming Heavy Metals

Electrode	K_{Sel}[a]	E^0[b] V vs. SHE
ME-Hg(II)	Ag^+, Cu^{2+}, Pb^{2+}, Cd^{2+}, Fe^{3+} ($<10^{-2}$)	+0.920($2Hg^{2+}/Hg_2^{2+}$)
ME-Ag(I)	$Hg^{2+}(10^2)$, $Fe^{3+}(1)$, Cu^{2+}, Pb^{2+}, $Cd^{2+}(10^{-2})$	+0.799(Ag^+/Ag)
ME-Fe(III)	$Hg^{2+}(10^2)$, $Ag^+(1)$, Cu^{2+}, Pb^{2+}, $Cd^{2+}(10^{-2})$	+0.771(Fe^{3+}/Fe^{2+})
ME-Cu(II)	$Hg^{2+}(10^3)$, Ag^+, $Fe^{3+}(10^2)$, Pb^{2+}, $Cd^{2+}(10^{-2})$	+0.337(Cu^{2+}/Cu)
ME-Pb(II)	$Hg^{2+}(10^3)$, Ag^+, Cu^{2+}, $Fe^{3+}(10^2)$, $Cd^{2+}(1)$	−0.126(Pb^{2+}/Pb)
ME-Cd(II)	Ag^+, Hg^{2+}, $Fe^{3+}(10^3)$, $Cu^{2+}(10^2)$, $Pb^{2+}(1)$	−0.403(Cd^{2+}/Cd)

a) K_{Sel}=[A]/[B] where [A] is the concentration of mercaptide-forming metal ion and [B] is that of interfering metal ion.
b) Ref. 15.

response to the heavy metal ions except ME-Hg(II) and ME-Fe(III). All of them respond within 10 s and usually have long service lives when stored in 1 mM nitrate solution weakly acidified with nitric acid. Especially, in the case of ME-Ag(I), its response behavior shown in Table 1 is fairly reproducible for at least one month when stored in a weakly acidic 1 mM $AgNO_3$ solution in a dark place. As we expected, the response characteristics, such as response range and response slope, of ME-Ag(I) were observed to be in good agreement with those of a naked Ag wire 0.5 mm in diameter, though the naked wire could respond more quickly. Similar agreement in response characteristics was also observed between ME-Cu (II) and a naked Cu wire. The potentiometric characteristics observed of ME-M's support the idea that some degree of interaction between heavy metals fixed on SQE and heavy metal ions in aqueous solution should cause the change in electrode potential of ME-M's, and suggest that the interaction between them is fundamentally equal to the reversible reduction-oxidation reaction between any naked metals and their ions in aqueous medium. The divalent and trivalent heavy metals fixed on SQE in the form of mercaptide should have more complicate bond structures than that given by -S-M in **2** or **3**. Especially, in the case of ME-Hg(II) and ME-Fe(III), large deviations in response slope from the Nernstian response expected for Hg^{2+} and Fe^{3+} were observed with the two electrodes, though their response characteristics were reproducible in five different measurements with five ME-Hg(II)'s or five ME-Fe(III)'s each prepared separately. Stricks et al.[13] have reported that the mercapto group in cystein (RSH) reacts with Hg^{2+} to give mercaptides such as $(RS)_2Hg$, $(RS)_2Hg_2^{2+}$, and $(RS)_2Hg_3^{4+}$ depending upon reaction conditions. However, from the fair reproducibility in response behavior observed of the two electrodes, it can be presumed that the two electrodes have certain definite bond structures under the preparation conditions used in this work. The selectivity coefficients (K_{Sel}'s) of the ME-M's and the standard redox potentials (E^0's) of the mercaptide-forming heavy metals are presented in Table 2. The K_{Sel}'s were determined by the mixed solution method described by Rechnitz et al.[14] These data show that ME-Hg(II) has an excellent selectivity to Hg^{2+} and that the electrode is subjected to negligible interference from the other heavy metal ions used here. Hence ME-Hg(II) possesses a useful function as a selective Hg^{2+} sensor. In addition, Table 2 shows that K_{Sel}'s are correlated closely to E^0's that is, the potential of any mercaptide-modified electrodes is very sensitive to interfering ions having more positive E^0's but is insensitive to those having more negative ones. This correlation between K_{Sel} and E^0 strongly suggests that certain redox reaction should occur in aqueous solution between any one species of heavy metal fixed on SQE and any one other species of heavy metal ion having more positive E^0, and supports the idea that the function of ME-M's as heavy metal ion sensors results from a redox interaction between the fixed heavy metal and its ion. Judging from their voltammetric and potentiometric characteristics observed in this work, it may be concluded that ME-M's

are applicable to many catalytic or selective electrochemical reactions and to the preparation of new types of metal ion sensors.

A Behavior of Donnan Salt within Membrane

Akira YAMAUCHI,* Masashi DATE, Yukiko YAMAMOTO, Yutaka HIRATA, and Hideo KIMIZUKA

Department of Chemistry, Faculty of Science, Kyushu University 33, Hakozaki, Higashi-ku, Fukuoka 812

(Received September 11, 1987)

In an amphoteric ion exchange membrane-electrolyte system, three independent experiments were carried out, that is, the membrane potential, membrane conductance and concentration of ions within membrane were measured, respectively. The electrolytes adopted in the systems were NaCl, $CaCl_2$, $LaCl_3$. From the analysis of the results, the specific conductance attributed to Donnan salt within membrane was separated. As a result, it was pointed out that the dynamic state of Donnan salt is obviously different from that of salt in aqueous solution. Furthermore, the comparison between the ions constituting Donnan salt and the counterions which interact with the ion-exchange sites suggested us the existance of two different dynamic states on the ions within membrane.

Up to the present, a number of investigations concerning ion transport phenomena in membrane-electrolyte solution system have been reported.[1-3] We have also studied the membrane phenomena in systems using an ion-exchange membrane or an amphoteric ion-exchange membrane.[4-10] There may be several factors controlling the membrane phenomena, such as ion flux through the membrane, distribution coefficient at the interface between the membrane and electrolyte solution, the ionic concentration within membrane and etc. Of these, the ions within membrane may play an important role in the transport phenomena. The ions may exist in two different states, that is, due to ion exchange with sites and due to Donnan adsorption. It would be interesting to separate the two states experimentally, and in particular, to compare the behavior of Donnan salt with that of free ion in solution. Moreover, it is predicted that in the amphoteric membrane having the cationic and anionic exchange sites, the ions within membrane behave differently from usual monotonic ion-exchange membrane.[6,11]

Unfortunately, the detailed investigation has not been done concerning the mobilities of Donnan salt within membrane. Therefore, in this work, first, it was tried to separate the two states, and second, the behavior of Donnan salt was discussed. In order to satisfy a story mentioned above, the measurements of membrane potential and membrane conductance, and the determination of ionic concentration within membrane were carried out.

Experimental

Materials. An amphoteric membrane used in this study was supplied by Tokuyama Soda Co. Ltd., of which the characterestics were described already elsewhere.[7-10] The electrolytes (NaCl, $CaCl_2$, $LaCl_3$) of extra pure reagents were used without further purification.

Apparatus. The cell for membrane potential and conductance was made of glass, and consisted of 20 cm^3 compartments. Two 1.57 cm^2 platinum black electrodes were equipped in the glass cells for membrane conductance. The membrane was placed between two compartments and the available areas of membrane were 3.14 cm^2. The details for the measurements were described elsewhere.[7-10]

The Determination of Ionic Concentration within Membrane. After the membrane (5×5 cm^2) was equilibrated with the sample solutions from 10^{-3} to 10^{0} mol dm^{-3} for 72 h, the membranes were transferred into the distilled water and stood for 72 h in order to remove the electrolytes due to Donnan adsorption. Then, the ions within membrane due to ion exchange with sites were eluted by 1.0 mol dm^{-3} HNO_3. The two different concentrations $\bar{C}^E$ and $\bar{C}^D$, were determined by the atomic absorption spectroscopy (Hitachi Co., Ltd., Model 180-50). In the case of La ion, the calorimetric method with arsenaso III reagent was employed because the sensitivity of the atomic absorption was insufficient.

During the course of this experiment, the solution phases were sufficiently stirred by the magnetic stirrers and temperature was kept at 25 °C.

Theoretical

The consideration[12] based on the nonequilibrium thermodynamics gives us the equation concerning the specific conductance of membrane, $\bar{\kappa}$,

$$\begin{aligned}\bar{\kappa} &= \nu_1 Z_1 \bar{C} F(\bar{U}_1 + \bar{U}_2) \\ &= \nu_1 Z_1 \bar{C} F(\bar{U}_{11} + 2\bar{U}_{12} + \bar{U}_{22}),\end{aligned} \tag{1}$$

where

$$\bar{U}_1 = \frac{Z_1^2 l_{11}}{\nu_1 Z_1 \bar{C}} F + \frac{Z_1 Z_2 l_{12}}{\nu_1 Z_1 \bar{C}} F \equiv \bar{U}_{11} + \bar{U}_{12}, \tag{2}$$

and

$$\bar{U}_2 = \frac{Z_1 Z_2 l_{21}}{\nu_1 Z_1 \bar{C}} F + \frac{Z_2^2 l_{22}}{\nu_1 Z_1 \bar{C}} F \equiv \bar{U}_{12} + \bar{U}_{22}, \tag{3}$$

where the subscripts 1 and 2 refer to cation and anion; ν, Z, $\bar{C}$, and F, the stoichiometric number, the ionic charge, the concentration of electrolyte within membrane, and Faraday constant, respectively; $\bar{U}_1$ and $\bar{U}_2$ are the ionic mobilities within membrane defined by Eqs. 2 and 3; l's are the phenomenological

coefficients involving the interactions between ions and it is assumed that Onsager's reciprocal relation is held among l's. Accordingly, the mobilities, $\bar{U}_1$ and $\bar{U}_2$, are also the quantities involving the effect of interactions between different ionic species, $\bar{U}_{12}$.

On the other hand, the concentration of electrolyte whthin membrane may be shared into two terms due to ion exchange with site and Donnan adsorption as

$$\bar{C} = \bar{C}^{E} + \bar{C}^{D}. \tag{4}$$

Corresponding to two kinds of concentrations in Eq. 4, there may be presumably two different transport processes which are characterized by the mobilities, $\bar{U}^{E}$ and $\bar{U}^{D}$. Each process may be described by means of Eq. 1. Provided the additivity between the processes can be assumed, the total specific conductance, $\bar{\kappa}^{T}$, is given as sum of the two processes. Therefore, one can write the following equation,

$$\begin{aligned}\bar{\kappa}^{T} &= \bar{\kappa}^{E} + \bar{\kappa}^{D} \\ &= \nu_1 Z_1 F \bar{C}^{E}(\bar{U}_1^{E} + \bar{U}_2^{E}) + \nu_1 Z_1 F \bar{C}^{D}(\bar{U}_1^{D} + \bar{U}_2^{D}),\end{aligned} \tag{5}$$

where $\bar{\kappa}^{E}$ and $\bar{\kappa}^{D}$ represent the contributions due to ion exchange and Donnan adsorption, and $\bar{U}^{E}$ and $\bar{U}^{D}$ also express the mobilities in the corresponding states, respectively. Under the experimental conditions that the concentrations of Donnan salt are nearly equal to zero, Eq. 5 is reduced to Eq. 6,

$$\bar{\kappa}^{T}_{\bar{C}^{D}\to 0} \simeq \bar{\kappa}^{E}. \tag{6}$$

Assuming that $\bar{\kappa}^{E}$ ($=\bar{\kappa}^{T}_{\bar{C}^{D}\to 0}$) can be separated into cationic and anionic contributions, the transport numbers, t_1 and t_2 may be defined as

$$t_1 = \bar{\kappa}_1^{E}/\bar{\kappa}^{E}, \tag{7a}$$

and

$$t_2 = \bar{\kappa}_2^{E}/\bar{\kappa}^{E}, \tag{7b}$$

where $\bar{\kappa}_1^{E}$ and $\bar{\kappa}_2^{E}$ denote respectively the specific conductances of cation and anion, which can not be directly obtained from the experiments. However, $\bar{\kappa}_1^{E}$ and $\bar{\kappa}_2^{E}$ may be easily separated by means of Eq. 7 provided t_1 and t_2 can be measured experimentally.

Moreover, when $\bar{C}^{D}$ is not zero but the finite value, $\bar{\kappa}^{D}$ in Eq. 5 is evaluated as the difference between the total specific conductance and that due to ion exchange. If the additivity for $\bar{\kappa}^{T}$ is assumed in the same manner as Eq. 7, the transport numbers, t_1' and t_2' may be described as

$$t_1' = (\bar{\kappa}_1^{E} + \bar{\kappa}_1^{D})/\bar{\kappa}^{T}, \tag{8a}$$

and

$$t_2' = (\bar{\kappa}_2^{E} + \bar{\kappa}_2^{D})/\bar{\kappa}^{T}. \tag{8b}$$

Generally, the apparent transport number, which can be obtained by the membrane potential, is approximately independent of the concentration of outer electrolyte solution.[4,10] Then, t_1' and t_2' may be equal to t_1 and t_2, respectively.

Thus, one can finally get to the following equations,

$$\bar{\kappa}_1^{D} = t_1'\bar{\kappa}^{T} - \bar{\kappa}_1^{E} = t_1(\bar{\kappa}^{T} - \bar{\kappa}^{E}), \tag{9a}$$

and

$$\bar{\kappa}_2^{D} = t_2'\bar{\kappa}^{T} - \bar{\kappa}_2^{E} = t_2(\bar{\kappa}^{T} - \bar{\kappa}^{E}). \tag{9b}$$

The specific conductance of Donnan salt, $\bar{\kappa}^{D}$, can be obtained from Eq. 9 as

$$\bar{\kappa}^{D} = \bar{\kappa}_1^{D} + \bar{\kappa}_2^{D} = \bar{\kappa}^{T} - \bar{\kappa}^{E}, \tag{10}$$

which is obviously the same as Eq. 5.

Results and Discussion

In Fig. 1, logarithms of the specific conductance of membrane, $\bar{\kappa}^{T}$ were given against logarithm of outer aqueous electrolyte solutions in the case of NaCl, $CaCl_2$, and $LaCl_3$, respectively. $\bar{\kappa}^{T}$ values increased with the concentrations of outer electrolyte solution which were equilibrated with the membrane. The order was $\bar{\kappa}^{T}(NaCl) > \bar{\kappa}^{T}(CaCl_2) > \bar{\kappa}^{T}(LaCl_3)$ in all the range of concentration examined in this study.

$\bar{C}^{E}$ and $\bar{C}^{D}$ obtained separately were given as the functions of the concentrations of outer electrolyte solution in Fig. 2 in which $\bar{C}^{E}$'s were constant within experimental errors, and $\bar{C}^{D}$'s increased with the concentration of outer electrolyte solution in the same manner as $\bar{\kappa}^{T}$. The difference of $\bar{C}^{E}$ between cation and anion may be neglected in this study. Taking allowance for Eq. 5, the increase of $\bar{\kappa}^{T}$ may be attributed to the Donnan salt, $\bar{C}^{D}$ as indicated later. Accordingly, $\bar{\kappa}^{E}$ can be determined from the values of

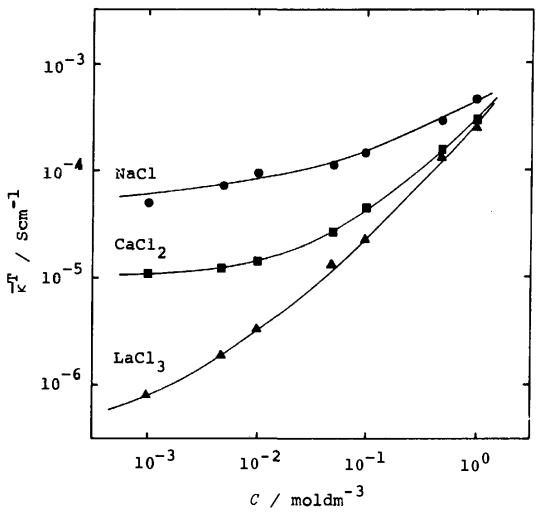

Fig. 1. Specific membrane conductance against the concentration of outer electrolyte solution equilibrated with membrane. ●: NaCl, ■: $CaCl_2$, ▲: $LaCl_3$.

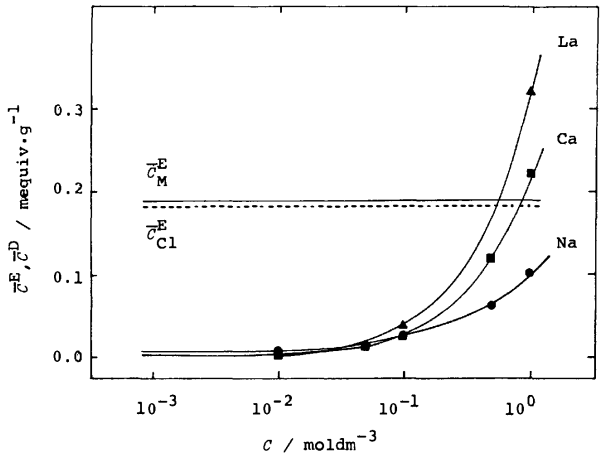

Fig. 2. Concentration of ion within membrane. Horizontal lines (solid and broken) denote the concentration due to ion exchange with sites, $\bar{C}^E$. Curved lines denote the concentration of Donnan salt, $\bar{C}^D$. ●: NaCl, ■: $CaCl_2$ ▲: $LaCl_3$. The abscissa is the same as in Fig. 1.

Table 1. Apparent Transport Numbers Evaluated from Membrane Potentials

Salt	t_M	t_{Cl}
NaCl	0.95	0.05
$CaCl_2$	0.91	0.09
$LaCl_3$	0.13	0.87

$\bar{\kappa}^T$ at $\bar{C}^D=0$ (Eq. 6). In general, $\bar{\kappa}^E$ should be constant independent of the concentration of outer electrolyte solution because it interacts strongly with ion-exchange sites having constant exchange capacity. The values were estimated as 5.37×10^{-5} (NaCl), 1.14×10^{-5} ($CaCl_2$), and 3.39×10^{-6} S cm^{-1} ($LaCl_3$) in this study, respectively. Inserting $\bar{\kappa}^E$ values into Eq. 5 or 10, $\bar{\kappa}^D$ can be obtained. The results as to 3 couples of electrolytes were given in Fig. 3.

On the other hand, the transport numbers in the system of NaCl, $CaCl_2$, and $LaCl_3$ were evaluated from the membrane potential measurements, and summarized in Table 1. As discussed in theoretical section, the experimental facts show that t's are approximately constant independent of the concentration of outer electrolyte solution.[9,10] Therefore, using the values in Table 1 and Eqs. 7 and 9, the cationic and anionic conductances of $\bar{\kappa}^E$ and $\bar{\kappa}^D$ were separately calculated. The results were given in Fig. 4 in which the broken lines indicate the constant $\bar{\kappa}^E$ originated from ion-exchange capacity, and the solid lines indicate $\bar{\kappa}^D$ due to Donnan adsorption.

Here, taking into account the electroneutrality for Donnan salt, and that the cationic and anionic exchange capacities are nearly equal, we can obtain the next relations,

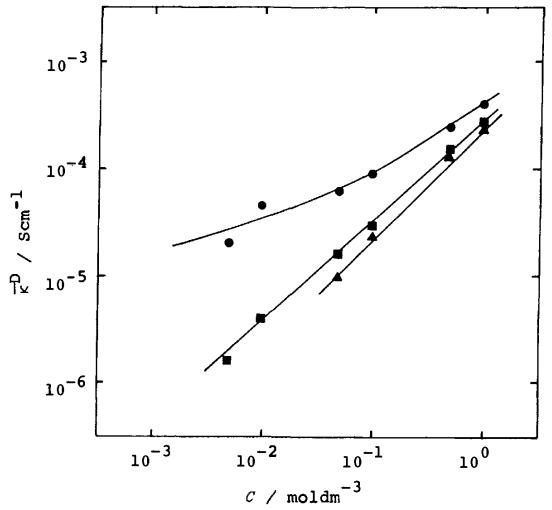

Fig. 3. Specific conductance originated from Donnan salt, $\bar{\kappa}^D$. Symbols and the abscissa are the same as in Fig. 2.

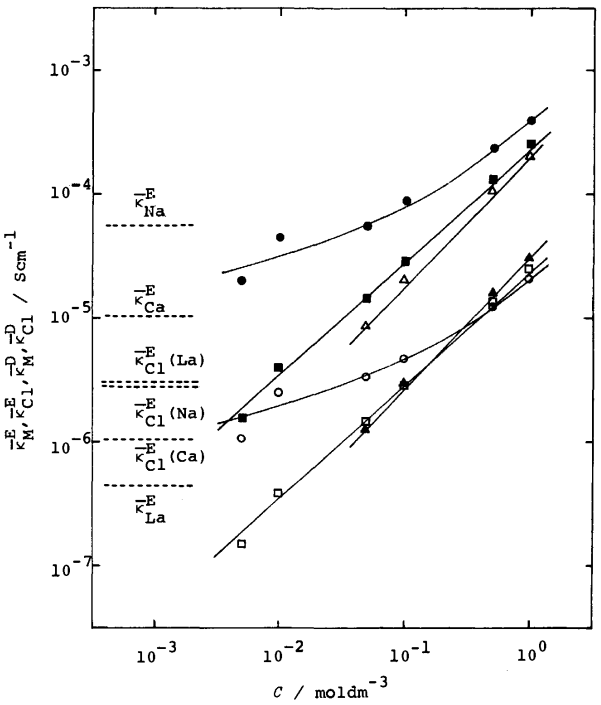

Fig. 4. Specific conductances of the respective ions. The broken lines are $\bar{\kappa}^E$ and indicate constant values in range of concentration examined though not seen in Fig. The solid lines are $\bar{\kappa}^D$. ●:Na, ■: Ca, ▲: La, ○: Cl(Na), □: Cl(Ca), △: Cl(La). The abscissa is the same as in Fig. 2.

$$\bar{C}^E = Z_1\bar{C}^E_1 \simeq Z_2\bar{C}^E_2, \tag{11}$$

and

$$\bar{C}^D = Z_1\bar{C}^D_1 \simeq Z_2\bar{C}^D_2. \tag{12}$$

On the other hand, rearranging Eqs. 6 and 10, we obtain,

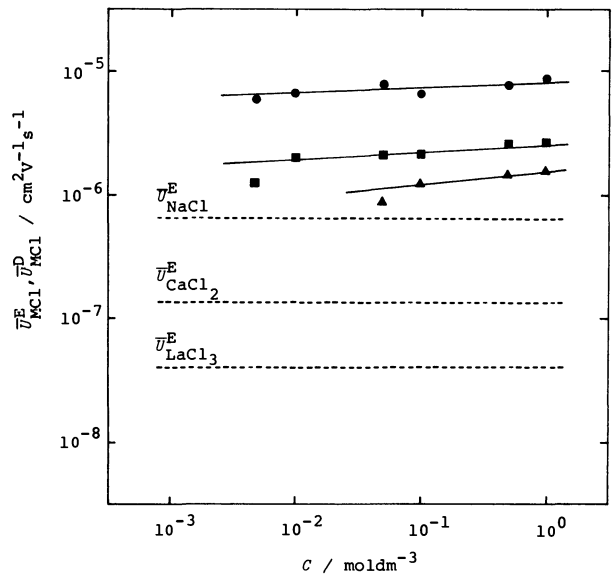

Fig. 5. Mobilities of salt within membrane. The broken lines denote $\bar{U}^{E}_{MCl}$. The solid lines denote $\bar{U}^{D}_{MCl}$. Note the difference between $\bar{U}^{E}_{MCl}$ and $\bar{U}^{D}_{MCl}$ depending upon ionic charges.

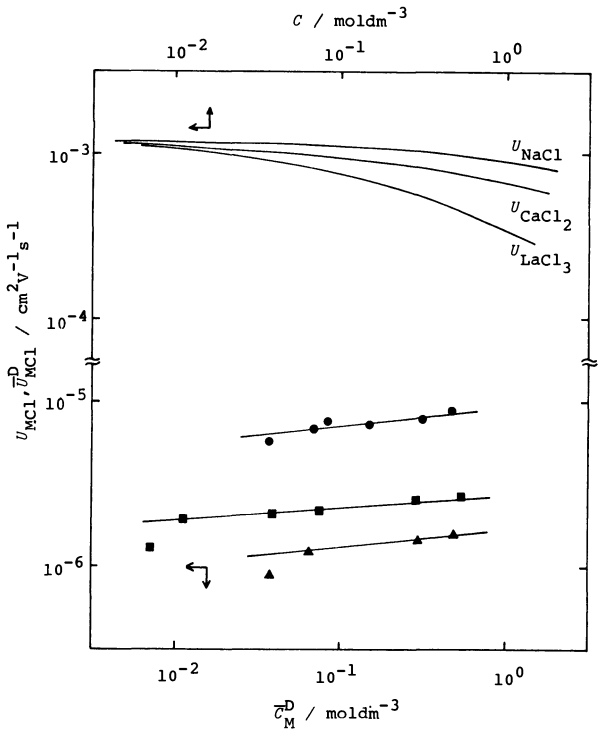

Fig. 6. A comparison between the mobility of Donnan salt and that of salt in solution. Lower abscissa indicates the concentration of Donnan salt. Symbols are the same as in Fig. 1.

$$\bar{U}^{E}_{MCl} = \bar{U}^{E}_{M} + \bar{U}^{E}_{Cl} = \bar{\kappa}^{E}/F|Z_M|\bar{C}^{E}_{M}, \quad (13)$$

and

$$\bar{U}^{D}_{MCl} = \bar{U}^{D}_{M} + \bar{U}^{D}_{Cl} = \bar{\kappa}^{D}/F|Z_M|\bar{C}^{D}_{M}, \quad (14)$$

where the subscript, MCl refers to the electrolyte, and M and Cl correspond to 1 and 2 mentioned before, respectively. According to the relations, Eqs. 11, 12, 13, and 14, we can calculate the mobility of the salt at each state. A comparison of $\bar{U}^{D}_{MCl}$ with $\bar{U}^{E}_{MCl}$ was given in Fig. 5, in which the difference of mobilities is evident. In contrast to $\bar{\kappa}^{D}$, the values of $\bar{U}^{D}_{MCl}$ indicated approximately constant independent of the concentration of outer electrolyte solution. The facts take out the following important conclusion: the increase of the specific conductance, $\bar{\kappa}^{T}$ is attributed to the increase of Donnan salt within membrane. The $\bar{U}^{D}_{MCl}$ increased slightly in concentrated range of outer electrolyte solution, but it is not clear at present whether the cause comes from the experimental errors or the variation of the water content within membrane. As for $\bar{U}^{E}_{MCl}$, the values are constant and obviously were less than $\bar{U}^{D}_{MCl}$. It can be therefore pointed out that there exist two different ionic states in the membrane from the results in Fig. 5.

For the comparison, the mobilities of salts in solution were calculated by means of the molar conductances, Λ_{MCl} in literature[13] as follow,

$$U_{MCl} = \Lambda_{MCl}/|Z_M|F. \quad (15)$$

In Fig. 6, $\bar{U}^{D}_{MCl}$ and U_{MCl} were plotted against the concentrations of Donnan salt and solution, $\bar{C}^{D}$ and C, respectively. It is shown in Fig. 6 that $\bar{U}^{D}_{MCl}$ which is about 10^{-6}cm^2 v^{-1} s^{-1}, reduces by three orders than U_{MCl} in solution. A comparison between the electrolytes examined in this study shows that the order of mobility of Donnan salts is $\bar{U}^{D}$(NaCl)>$\bar{U}^{D}$(CaCl$_2$)>$\bar{U}^{D}$(LaCl$_3$) corresponding to that in concentrated electrolyte solution. Contrary to our prediction, the experimental facts indicated that Donnan salt within membrane and salt in solution are in different states distinctly. One of the reasons is that Donnan salt is affected by the pore size in membrane matrix and is partly attributed to electric field around the exchange sites. Consequently, it is considered that the domains of membrane pores have an influence owing to the strong electric field produced by cation- and anion-exchange sites.[6]

Though the mobilities of salts have been discussed, so far, ionic mobility can be also estimated from the results in Fig. 4. The results were essentially the same as the case of salt. Therefore, the discussion as to the ionic form was excluded in this paper.

Application of Hydrogen Ion Sensitive Field Effect Transistor to the Kinetic Study of Fast Reaction in Solution

Thoru NAKATSUKA, Michihiro NAKAMURA,† and Takayuki SANO*
Department of Materials Science, Faculty of Science, Hiroshima University, Higashisenda-machi, Hiroshima 730
†Central Research Laboratories, Kuraray Co., Ltd., Kurashiki, Okayama 710
(Received September 19, 1987)

The ion sensitive field effect transistor(ISFET) developed for pH measurement was incorporated with the stopped flow apparatus for direct detection of the fast change in the hydrogen ion concentration. By the experiments on the dehydration reaction of carbonic acid, it was proved that the pH sensor has a fast response time (<2 ms) beyond the resolution time of stopped flow apparatus, and the constructed apparatus can be satisfactorily applied to the fast reaction kinetics with the sensitivity for the pH change more than 0.01 pH unit.

The stopped flow method is one of most useful methods for study of fast reaction in solution.[1,2] The modes of detection for monitoring the time course of reaction are classified as follows: optical[3,4] (absorption, fluorescence, ORD, CD, etc.), electrochemical[5] (conductivity, electrode detection), thermal,[6] and magnetic resonance[7,8] (ESR, NMR) detections. The choice of the detection mode depends on the information necessary for elucidation of reaction mechanism and on the detectable probe in the reaction system.

Hydrogen ion plays important roles in various kinds of reactions such as not only simple protolysis reactions but also biologically interesting reactions; e.g., proton pump by H^+-ATPases in mitochondria, chloroplasts and bacteria in which ATP is synthesized at the expense of a transmembrane proton gradient.[9-11]

On the other hand, the kinetic experiments on the reaction associated with the hydrogen ion have been widely performed using a pH indicator so far.[12] However, an addition of the indicator to reaction system makes its mechanism complicated, and, in some cases, the added indicator inhibits the intended reactions through its direct interaction with reaction species. Hence, the apparatus for direct detection of hydrogen ion with high resolution in both the sensitivity and response time is necessary for the study of the fast reaction in these interesting systems.

A glass electrode can detect directly hydrogen ion concentration. Some applications of the glass electrode to detection of fast reactions have been reported.[13-15] Sirs has applied the glass electrode to the stopped flow apparatus and attained maximum sensitivity of 0.004±0.0005 pH unit using 0.5 ml of solution for each run, but its time resolution is up to half-lives of 0.05 s. Meanwhile, the combination of the glass electrode with the continuous flow method has been tried by Rossi-Bernardi and Berger, and Nakamura, because this method dose not require the fast response of a detector. Rossi-Bernardi and Berger have constructed the apparatus having high resolution in both the reaction rate and sensitivity; the dead time of 3 ms and precision of ±0.005 pH unit, which are superior to those by Nakamura. However, the continuous flow method has disadvantage of requirement of a large quantity of sample solution. Thus, the continuous flow method is not suitable for invaluable samples. Consequently, the pH detector with fast response time was desired to combine with the stopped flow method which requires rather small amount of sample solution.

Recently, a new kind of pH sensor, i.e., ion sensitive field effect transistor (pH-ISFET),[16,17] has been commercially available. The sensor has the characteristics of its small dimensions and faster response time than 0.1 s.[18] In spite of these striking properties of the pH sensor, the application of the sensor to the kinetic study of the fast reaction have not been succeeded in yet. Accordingly, we examined the possibility of a sensor responsive much faster than 0.1 s and constructed a stopped flow apparatus incorporated with that pH sensor.

The present paper describes the applicability of the stopped flow apparatus equipped with a pH-ISFET (ISFET-stopped flow apparatus) to the kinetic study of fast reaction.

Experimental

The pH sensor (PH-2135, Kuraray Co., Ltd.) used in the present study, which is commercially obtainable as a part of the pH meter (KR-500), is developed for the medical use such as pH monitoring in a blood vessel and stomach. The sensor (diameter, 1.0 mm, 350 mm long) consists of the ISFET (0.15 mm thick, 0.40 mm wide, and 5.5 mm long) integrated with a temperature sensor, reference electrode, and a guard electrode for preventing induced noise, which are packed all together in a catheter. The reference electrode is made of silver-silver chloride. Physiological saline solution retained in the porous hollow fiber is used as a inner solution of the reference electrode.

The stopped flow apparatus (RA-401, Union Giken Co., Ltd.) used is the gas pressure-driven type. The dead time of this apparatus is determined to be 3 ms by test measurement

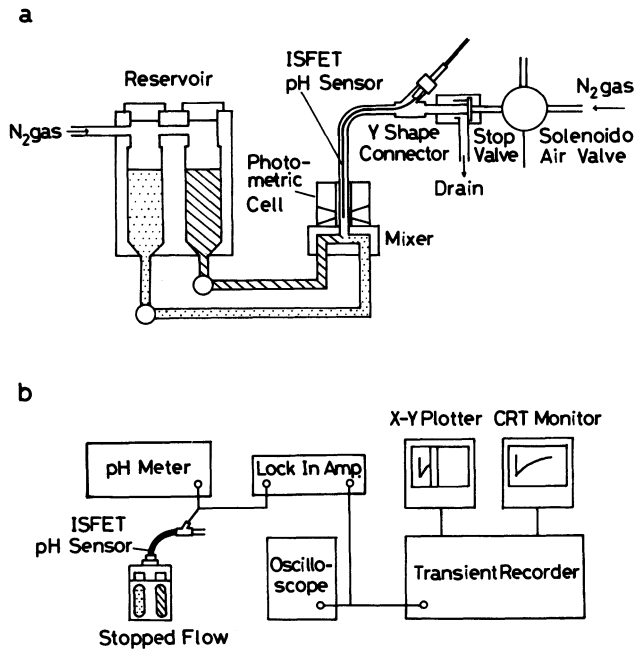

Fig. 1. (a) Combination of the ISFET pH sensor with the stopped flow apparatus. (b) Block diagram of the whole apparatus.

using optical detection. The solution of 0.2 ml is necessary for each run.

The sensor is inserted into the observation cell through the drain tube using the Y shape connector, as shown in Fig. 1(a). Figure 1(b) represents a block diagram of whole apparatus. For the rapid measurement of pH, the signal from the sensor is directly led to a lock-in amplifier and recorded with a transient recorder. A remarkably improved signal to noise ratio was obtained by shielding the equipment and by using a voltage regulator. The maximum sensitivity of the pH sensor was 0.0018 pH unit. For the optical detection experiments, Bromophenol Blue was used as a pH indicator. All experiments were carried out at 25±1 °C.

Results and Discussion

The response time of the pH sensor combined with stopped flow was examined by detecting pH change after mixing of $NaHCO_3$ and HCl solutions in which the pH change comes from the replacement of the mixed solution in equilibrium with new one prior to the slow reaction. The same measurement was performed with a pH indicator Bromophenol Blue. The rapid pH change detected in these ways is shown in Fig. 2 where the time constants were estimated to be 2 ms for both experiments. As a result, the response time of the sensor was proved to be so faster than 2 ms beyond the dead time of stopped flow apparatus.

Next, the experiments on the dehydration reaction of carbonic acid were carried out to check the validity of the ISFET-stopped flow apparatus. Figure 3 shows the reaction curves observed by two detecting ways:

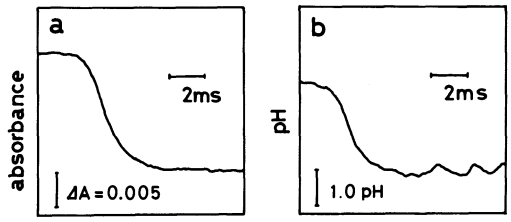

Fig. 2. Measurement of the response time of the pH sensor. A rapid pH change was caused by mixing 2.5×10^{-3} M HCl (1 M=1 mol dm^{-3}) and 5.0×10^{-3} M $NaHCO_3$ solution containing Bromophenol Blue (the concentrations are those after mixing) at 25 °C. (a) The rapid pH change detected spectrophotometrically at 435 nm and (b) that by using the pH sensor. The magnitude of absorbance change ΔA and that of pH change are indicated by the bar in the lower left-hand corner.

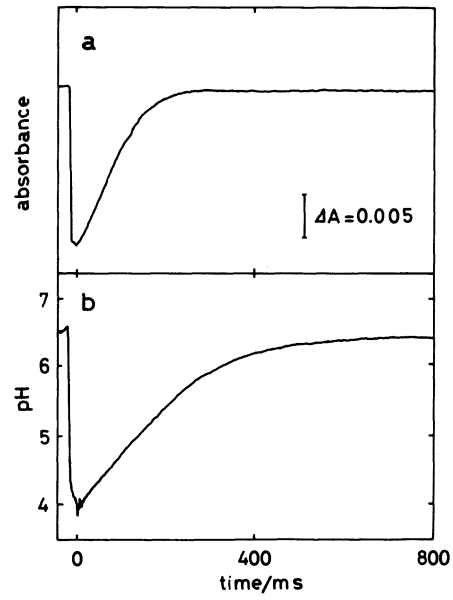

Fig. 3. Reaction curve of dehydration of carbonic acid; (a) by pH indicator and (b) by the pH sensor. The experimental conditions are the same as in Fig. 2.

one is to use the sensor and the other to use Bromophenol Blue as a pH indicator. As can be seen in Fig. 3, their time courses are apparently different. This is because the ordinates of the two curves are different, i.e., the scale for the sensor is pH, while that for the indicator is absorbance. In case of the optical detection, the relaxation time was obtained from the slope of the semilogarithmic plot of the absorbance change against time, as shown in Fig. 4(a). On the other hand, for the case of the pH sensor, the output signal should be converted to hydrogen ion concentration which was plotted in Fig. 4(b). The relaxation times estimated are 17.5±0.5 s^{-1} and 17.0±1.3 s^{-1} for the sensor and indicator, respectively. This good

agreement suggests the pH sensor incorporated with the ISFET-stopped flow apparatus is working correctly. In order to confirm this utility, kinetic experiments were continued under various concentrations.

The dehydration reaction of carbonic acid is represented by next reaction scheme

$$HCO_3^- + H^+ \underset{}{\overset{K_1}{\longleftrightarrow}} H_2CO_3 \underset{k_{-2}}{\overset{k_2}{\longleftrightarrow}} CO_2 + H_2O, \quad (1)$$

where K_1 and K_2 denote the equilibrium constants of the first and the second steps, and k_2 and k_{-2} forward and backward rate constants of the second step, respectively. Since the first step in the above reaction is faster than the second one, the relaxation time τ^{-1} for the second process can be represented by

$$\tau^{-1} = k_2 \left(\frac{[H^+] + [HCO_3^-]}{K_1 + [H^+] + [HCO_3^-]} + \frac{1}{K_2} \right). \quad (2)$$

According to this equation, the relaxation time obtained was plotted against concentration term which can be calculated by using K_1 and K_2. By using the values of 1.72×10^{-4} M^{-1} reported for K_1[19] and 4.7×10^2 assumed for K_2, a best straight line passing the origin was obtained as can be seen in Fig. 5. The slope of the straight line gives the value of (18±1) s^{-1} for k_2 and the value of k_{-2} was calculated to be $(4.0\pm0.2)\times10^{-2}$ M^{-1} s^{-1} from K_2 and k_2. As for the dehydration reaction, the values of (13.7—27.9) s^{-1} for k_2 and $(3.6—4.3)\times10^{-2}$ M^{-1} s^{-1} for k_{-2} have been reported.[14,20-23] The values estimated in the present work are in good accordance with these reported so far. Consequently, the ISFET-stopped flow apparatus constructed was proved to be nicely working.

As for the comparison of the two data obtained by pH sensor and pH indicator, it should be emphasized that pH indicator has some disadvantages; the change in absorbance of pH indicator can correctly reflect that in the hydrogen ion only for the small change in the concentration. In practice, obvious deviation from the straight line in Fig. 4(a) was recognized. Further, a single pH indicator can be used only at limited pH

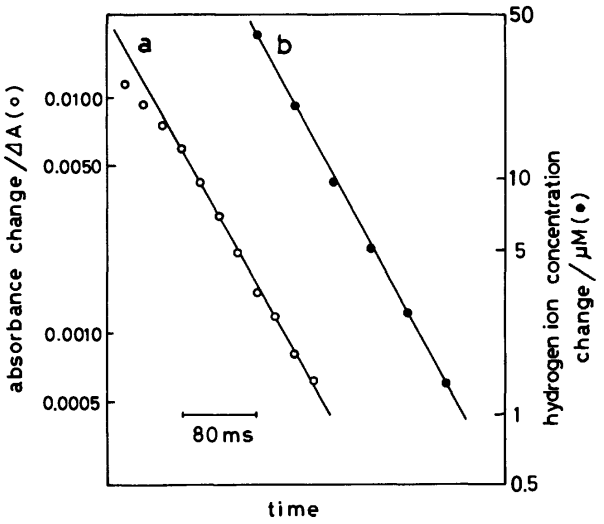

Fig. 4. Semilogarithmic plots of the observed reaction curve against time; (a) absorbance change detected by pH indicator and (b) hydrogen ion concentration change by the pH sensor.

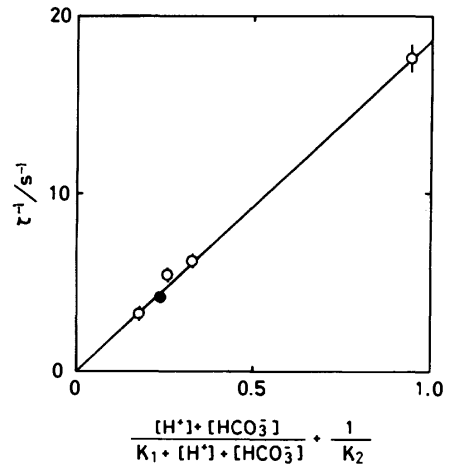

Fig. 5. A plot of τ^{-1} vs. the concentration term in Eq. 2. (●) denotes the data at ionic strength of 0.1 M.

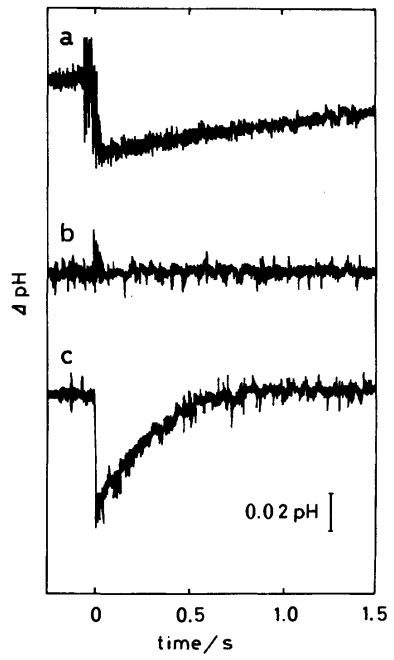

Fig. 6. Measurement of small pH change. (a) The artifact arisen from the flow of the 10^{-4} M NaCl solution. (b) Elimination of the artifact by the flow of 0.1 M NaCl solution. (c) Reaction curve of dehydration of carbonic acid at ionic strength of 0.1 NaCl; 1×10^{-4} M HCl and 5×10^{-5} M $NaHCO_3$ solution were mixed.

range. Meanwhile, the single pH sensor can be satisfactorily used for the kinetic study in solution over wide range of pH value 1—13.

In general, the pH measurement using an electrode is affected by the ionic strength of solution. This effect comes from the distortion and restoration of the ionic atmosphere around the tip of the reference electrode, and brings about the slowing down of its response time and the instability of the pH value. In the case of the pH sensor, such effect was observed as an artifact in the stopped flow experiments as shown in Fig. 6(a). However, as shown in Fig. 6(b), the artifact can be eliminated by holding the ionic strength at 0.1 M, and then the reaction curve could be nicely detected even for small change of 0.04 in pH unit as in Fig. 6(c); the relaxation time obtained from this data is also reasonably on the line in Fig. 5. In addition, most kinetic studies, especially for biological system, have been carried out at relatively high ionic strength around 0.1 M, therefore, the artifact must be not so serious problem.

In the present work, the pH-ISFET was, for the first time, combined with the stopped flow apparatus, and proved to be useful for the kinetic studies of the fast reaction up to 3 ms associated with the large change as well as small change in pH. Further, the present results may suggest the similar applicability of the ISFET developed for other ion to the kinetic investigation of fast reactions associated with biologically interesting ions such as Ca^{2+}, Mg^{2+}, K^{+}, and Na^{+}.

The authors are indebted to Drs. Kojiro Takahashi and Takao Kodama of Okayama University Dental School for giving a motivation to start the present work. This study was supported in part by a Grant-in-Aid for Scientific Research No. 61470165 from the Ministry of Education, Science and Culture.

The Solvent Extraction of Palladium(II) from Aqueous Chloride Media with 7-Tridecanone Oxime

Katsutoshi INOUE,* Yoshinari BABA, Kazuharu YOSHIZUKA, and Tetsuji OKA
Department of Applied Chemistry, Faculty of Science and Engineering, Saga University, Honjo-machi, Saga 840
(Received May 14, 1987)

The extraction behavior of palladium(II) from the aqueous ammonium chloride solutions with the title extractant in toluene was investigated in terms of the equilibrium and the kinetics, while the aqueous solubility and the interfacial adsorption equilibrium of the extractant were estimated. The extraction rate of the 1:2 palladium(II)–extractant complex was explained by the interfacial reaction model, in which the rate-determining steps were assumed to be the elementary reactions between the aquatrichloro- and tetrachloropalladate(II) in the aqueous phase and the extractant molecule adsorbed at the interface.

Great attention has been paid to developing solvent extraction or chelating ion exchange techniques in order to replace the conventional precipitation techniques for the recovery and purification of precious metals on commercial scale. Various extracting agents and chelating resins with high loading capacities and excellent selectivities to precious metals have become commercially available as novel techniques have been developed. The precious metals are extracted or adsorbed from aqueous chloride media rather than from nitrate, sulfate, cyanide, or thiocyanide media in the currently applied techniques.

Recently we have investigated the solvent extraction of palladium(II) from aqueous chloride media with various extracting agents, such as sulfur-containing extractants[1–4] and a hydroxy oxime.[5] In these works, the kinetics of the solvent extraction has been found to be significantly affected by the interfacial activities of the extracting agents as well as by their aqueous solubilities. In the extraction with dihexyl sulfide (DHS), triisobutylphosphine sulfide (TIBPS), and 2′-hydroxy-5′-nonylacetophenone oxime, all of which have low aqueous solubilities and high interfacial activities, the rate-determining complex formation reaction takes place at the interface between the aqueous and organic phases, while it takes place in the aqueous phase in the extraction with 1,2-bis(*tert*-hexylthio)ethane (*t*-BHTE), which has a very low interfacial activity and a relatively high aqueous solubility. The kinetic data of the former extraction systems were reasonably interpreted in terms of the heterogeneous interfacial reaction model, while those of the latter extraction system were interpreted in terms of the classical homogeneous heterophase reaction model of complex formation.

Holland et al.[6,7] investigated extensively the solvent extraction of metals with various kinds of dialkyl ketone oximes with relatively short alkyl chains, either symmetric or unsymmetric, and found that the so-called soft metals, such as palladium(II), silver(I), mercury(II), and gold(III), are effectively extracted into chloroform. However, their studies aimed at the analytical use of these oximes as extractants and were rather qualitative; the extraction mechanisms have remained unclarified.

This paper will report in detail on the extraction behavior of palladium(II) from aqueous chloride media with 7-tridecanone oxime, one of the symmetric dialkyl ketone oximes. The extraction equilibrium and kinetics, including the interfacial adsorption equilibrium of the extractant, were investigated quantitatively; the aqueous solubility of the extractant was also determined.

Experimental

Reagents. The 7-tridecanone oxime, abbreviated as 7-TDO and denoted by HR hereafter, was synthesized from 7-tridecanone in ethanol and an aqueous mixture of hydroxylamine hydrochloride and sodium acetate by a conventional method according to the following reaction:

$$(C_6H_{13})_2CO + NH_2OH\cdot HCl + CH_3COONa \longrightarrow (C_6H_{13})_2C{=}NOH + CH_3COOH + NaCl + H_2O$$

After washing with water and phase separation, the product was purified by means of vacuum distillation (bp 109—110 °C/0.1 mmHg (1 mmHg=133.322 Pa)). The purified viscous, pale yellow liquid product was identified by means of IR and NMR spectroscopies; the purity was confirmed by means of elemental analysis. Found: C, 73.11; H, 12.76; N, 6.63%. Calcd for $C_{13}H_{27}NO$: C, 73.18; H, 12.75; N, 6.56%. The organic phase was prepared on a gravimetric basis by diluting the purified reagent with toluene of an analytical grade. The aqueous phase was prepared by dissolving palladium(II) chloride in aqueous ammonium chloride solutions containing a small amount of hydrochloric acid (about 0.01 mol dm^{-3}).

Determination of the Stoichiometry of the Extracted Species. Under an excess concentration of 7-TDO over the palladium(II) concentration in the aqueous phase, the palladium(II) was almost completely extracted over the whole concentration region of chloride ions in the present experiment (0.01—6 mol dm^{-3}). The remaining amount of palladium(II) was too small for a precise quantitative analysis to be made. Therefore, only a loading test was carried out to determine the molar ratio of palladium(II) extracted into the organic phase to 7-TDO by varying the

concentration ratio of 7-TDO in the organic phase to that of palladium(II) in the aqueous phase under the conditions of a large excess of the palladium(II) concentrations, as in the extraction with DHS, TIBPS, and *t*-BHTE.[1,3,4]

Equal volumes (0.02 dm^3) of two phases of known concentrations were vigorously shaken for 2 h in a separatory funnel using an Iwaki V-DV-type mechanical shaker in a thermostated air bath maintained at 303 K. It had been confirmed by a preliminary experiment that the equilibrium was attained within 2 h. After the separation of the two phases, the palladium(II) concentration in the aqueous phase was determined by means of atomic absorption spectroscopy using a Nippon Jarrell-Ash model AA 782 spectrophotometer. The palladium(II) concentration in the organic phase was calculated from the mass balance of the aqueous palladium(II) concentrations before and after the equilibration.

Measurement of Aqueous Solubility of the Extractant. The distribution of 7-TDO between the organic and aqueous phases was measured spectrophotometrically at 303 K by a method similar to that described in previous papers.[1,4]

A toluene solution of 7-TDO of a known concentration and a 0.1 mol dm^{-3} aqueous ammonium choride solution with a volume ratio of the aqueous phase to the organic phase of 10:1 were shaken vigorously for 24 h using the mechanical shaker. After phase-separation, a portion of the aqueous phase (0.19 dm^3) was transferred into a separatory funnel. In order to convert completely any 7-TDO dissolved in the aqueous phase to its palladium(II) complex, 5×10^{-2} dm^3 of a 2 mmol dm^{-3} aqueous palladium(II) chloride solution containing 10 mmol dm^{-3} of hydrochloric acid and 1×10^{-2} dm^3 of toluene were added to the separatory funnel, after which the mixture was shaken for 24 h using a mechanical shaker. The absorbance of the palladium(II) complex in toluene was measured at 284 nm against a toluene blank using a Shimadzu UV 140 spectrophotometer.

Measurement of Interfacial Adsorption Equilibrium. The interfacial tension between the organic solution and the 0.1 mol dm^{-3} aqueous ammonium chloride solution was measured at 303 K by means of the pendant-drop method in order to examine the interfacial adsorption equilibrium of 7-TDO.

Measurement of Extraction Rate. The extraction rate of palladium(II) was measured using a batch-type glass stirred cell with an inner diameter of 0.1 m and a depth of 0.15 m; it was fitted with four baffles made of poly(tetrafluoroethylene), each of which was 0.01 m wide and 0.15 m long. It was the same as that used for the measurement of the extraction rate of palladium(II) with *t*-BHTE and TIBPS in the previous works.[1,4]

Stirring was carried out at a constant stirring speed of 1500 min^{-1} using a turbine impeller with six flat blades connected to a speed controller. Equal volumes (0.3 dm^3) of the organic and aqueous phases were introduced into the cell placed in a water bath maintained at 303 K. After the initiation of stirring, small amount of samples were taken out at definite time intervals in order to measure the variation in the palladium(II) concentration in the aqueous phase with time; the concentration was determined by means of atomic absorption spectrophotometry.

The initial palladium(II) concentration was 0.5 mmol dm^{-3} in all kinetic runs, while the concentrations of the extractant and chloride ion were varied over the ranges of 2—150 mmol dm^{-3} and 5×10^{-3}—5 mol dm^{-3} respectively.

Results

Selectivity of 7-TDO to Various Metals. Figure 1 shows the results of the solvent extraction of various metals from hydrochloric acid solutions with 7-TDO. Palladium(II) is completely extracted over the whole concentration region of hydrochloric acid, while relatively small amounts of mercury(II) and platinum(IV) are extracted, especially in the low-concentration region of hydrochloric acid. The base metals, such as copper(II), zinc(II), nickel(II), cobalt(II), and aluminum(III), are not practically extracted, not even in the high-concentration region of hydrochloric acid, though considerable amounts of copper(II) and nickel(II) were extracted in such high-concentration regions as above 0.1 and 2 mol dm^{-3} respectively in the extraction with 2-ethylhexanal oxime in a previous work[8]. Palladium(II) extracted by 7-TDO can be

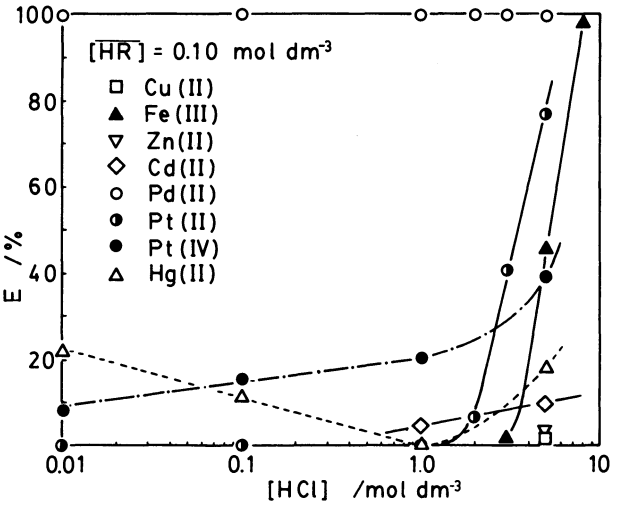

Fig. 1. Percentage extraction of various metals from hydrochloric acid with 0.1 mol dm^{-3} 7-tridecanone oxime in toluene. Initial metal concentration=100 ppm for Pd(II) and Pt(II and IV) or 0.01 mol dm^{-3} for other metals.

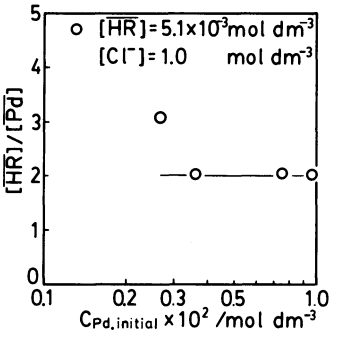

Fig. 2. Experimental results of the loading test.

easily and completely stripped by aqueous thiourea or ammonium thiocyanate solutions; however, only a partial stripping can be accomplished by aqueous ammonia and sodium or ammonium thiosulfate solutions. Thus, 7-TDO is an excellent extracting reagent, suitable for the separation of palladium(II) from platinum(II and IV) and base metals in the low-concentration region of hydrochloric acid in particular.

Stoichiometry of the Extracted Species. Figure 2 shows the result of the loading test. The mole ratio of 7-TDO to palladium(II) in the organic phase asymptotically approaches 2 with an increase in the aqueous palladium(II) concentration. This suggests that palladium(II) is extracted as a 1:2 metal:reagent complex into the organic phase.

Taking account of the results of the previous work,[8] the stoichiometry is expressed in manner similar to that used for copper(II) with 2-ethylhexanal oxime:

$$PdCl_i^{(i-2)-} + 2\overline{HR} \rightleftharpoons \overline{PdCl_2 \cdot 2HR} + (i-2)Cl^- \quad (1)$$

where the overline denotes the species existing in the organic phase.

Aqueous Solubility of 7-TDO. Assuming that free 7-TDO is monomeric, the distribution of 7-TDO between the organic and aqueous phases is expressed as follows:

$$\overline{HR} \rightleftharpoons HR \quad (2)$$

$$K_D = [HR]/[\overline{HR}] \quad (3)$$

where K_D is the partition coefficient of 7-TDO. From Eq. 3, we obtain:

$$\log[HR] = \log[\overline{HR}] + \log K_D \quad (4)$$

The partition coefficient is so small that the concentration of 7-TDO in the organic phase, $[\overline{HR}]$, is nearly equal to its initial concentration, C_{B0}.

As may be expected from Eq. 4, the plot of the logarithm of the concentration of 7-TDO in the aqueous phase against that in the organic phase gives a linear relationship, as is shown in Fig. 3. From the intercept of the straight line with the ordinate in Fig. 3, the partition coefficient was evaluated as $K_D = 7.0\times10^{-6}$ according to Eq. 4. This value is very close to that of TIBPS ($=5.4\times10^{-6}$).[4]

This result supports the idea that 7-TDO is monomeric in toluene, as has been confirmed by the measurement of the molecular weight by means of vapor-phase osmometry.

Interfacial Tension. Figure 4 shows the plot of the interfacial tension, γ, between an organic solution containing 7-TDO and a 0.1 mol dm^{-3} aqueous ammonium chloride solution against the concentration of 7-TDO in the organic phase. The interfacial tension decreases with an increase in the concentration of 7-TDO in its high-concentration region, which indicates that 7-TDO is interfacially active.

The adsorption equilibrium of 7-TDO at the interface is described as follows:

$$\overline{HR} \rightleftharpoons HR_{ad} \quad ; K_{ad} \quad (5)$$

where the subscript "ad" denotes the adsorbed species at the interface. The relationship between the interfacial tension, γ, and the concentration of 7-TDO in the organic phase, $[\overline{HR}]$, is given in Eq. 6, which has been obtained by combining the Gibbs adsorption isotherm with Langmuir's monolayer adsorption model applied to the above-mentioned adsorption equilibrium similarly as to the adsorption equilibrium of TIBPS:[4]

$$\gamma = \gamma_0 - (RT/S_{HR})\ln(1 + K_{ad}[\overline{HR}]) \quad (6)$$

where γ_0 denotes the interfacial tension between the pure diluent and the 0.1 mol dm^{-3} aqueous ammonium chloride solution and where S_{HR} denotes the interfacial area occupied by a unit mole of 7-TDO. From the results shown in Fig. 4, the values of K_{ad} and S_{HR} were evaluated by the nonlinear, least-squares

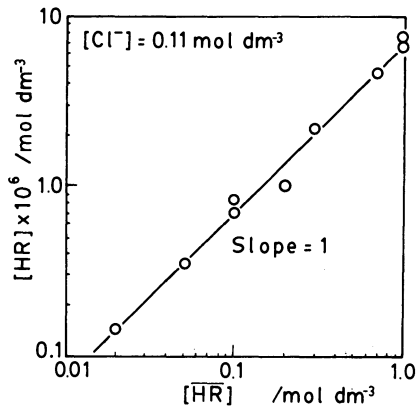

Fig. 3. Aqueous solubility of 7-TDO to aqueous ammonium chloride solution.

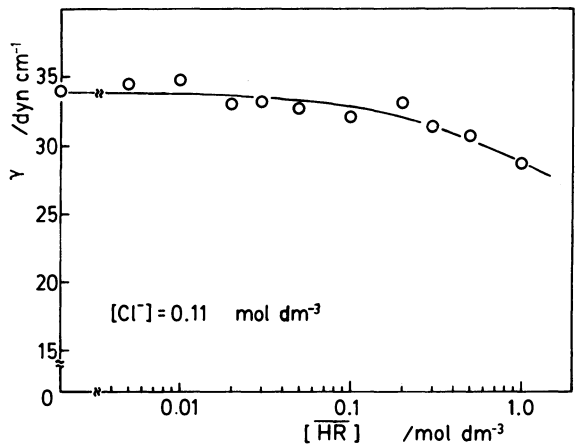

Fig. 4. Relation between interfacial tension and 7-TDO concentration in the organic phase.

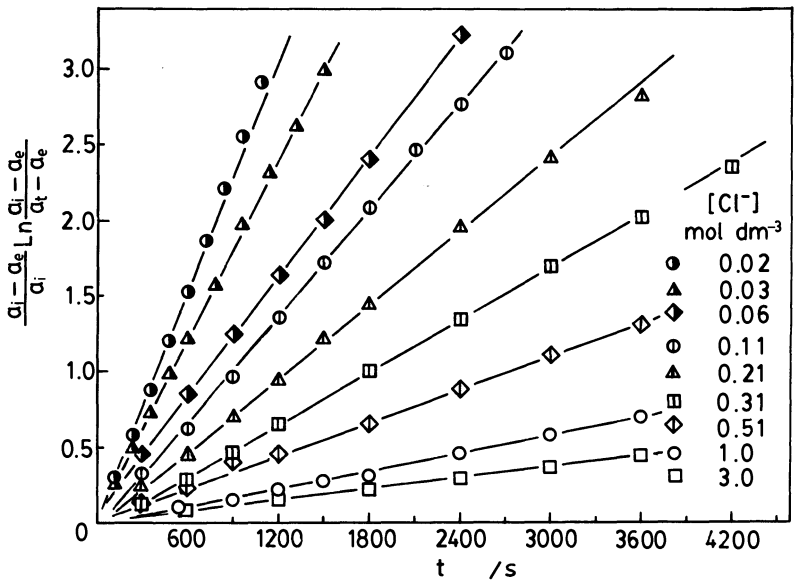

Fig. 5. A typical plot of the experimental results of extraction rate based on the pseudo-first-order rate expression ([$\overline{HR}$]=0.01 mol dm^{-3}).

method based on Eq. 6: K_{ad}=6.3 dm^3 mol^{-1}, S_{HR}= 9.6×10^5 m^2 mol^{-1}. These values are very close to those of TIBPS (K_{ad}=4.4 dm^{3}mol^{-1}, S_S=6.3×10^5 m^2 mol^{-1})[4]. The curve in Fig. 4 is calculated from Eq. 6 using these values. The calculated curve is in good agreement with the experimental results.

Extraction Kinetics. The variation in the palladium(II) concentration in the aqueous phase with time was rearranged and plotted according to Eq. 7 on the assumption that the forward and reverse reactions are pseudo-first-order with respect to the palladium(II) concentration in the aqueous and organic phases respectively:

$$\frac{a_i - a_e}{a_i} \ln \frac{a_i - a_e}{a_t - a_e} = k_f t \qquad (7)$$

where k_f represents the observed reaction rate-constant for the forward reaction and where the quantities with the subscripts "t", "i", and "e" denote the concentration after time t, at t=0, and at equilibrium respectively.

Figure 5 shows a typical set of the experimental results plotted according to Eq. 7. The plots in this figure give straight lines, as is to be expected from Eq. 7, suggesting that the forward reaction rate of palladium(II) extraction is first-order with respect to the palladium(II) concentration in the aqueous phase. The apparent reaction-rate constants were obtained from the slopes of these straight lines. Since the apparent reaction-rate constant was found in the preliminary experiment to be independent of the stirring speed over the range greater than 1300 min^{-1}, subsequent experiments were carried out at a constant stirring speed of 1500 min^{-1}, as will be discussed earlier.

Figure 6 shows the effect of the chloride-ion

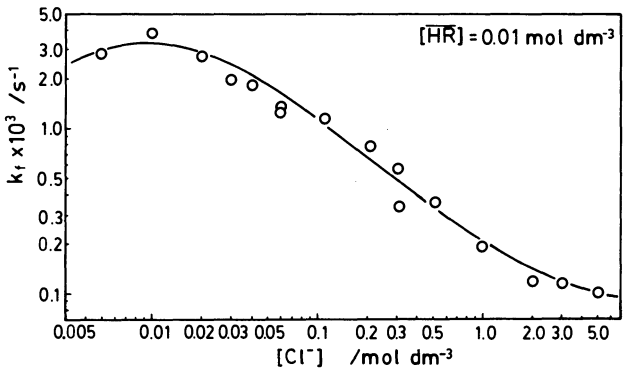

Fig. 6. Effect of chloride ion concentration on the observed extraction rate constant.

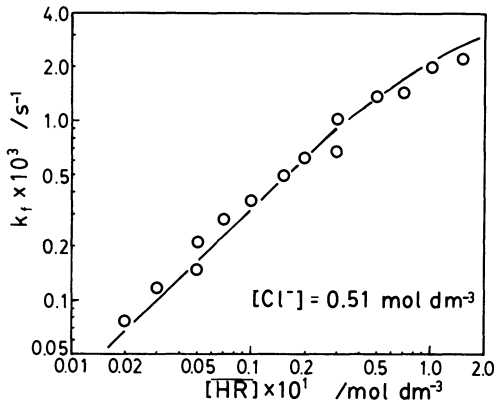

Fig. 7. Effect of 7-TDO concentration on the observed extraction rate constant.

concentration on the observed reaction-rate constant. The plots in this figure appear to approach a constant value with decrease or increase of the chloride-ion concentration in its low- and high-concentration regions respectively. Figure 7 shows the effect of the

7-TDO concentration on the observed reaction rate constant. The plots in this figure lie on a straight line with a slope of 1 and tend to approach a constant value in the high-concentration region.

These tendencies of the concentration dependencies of the reactant species on the extraction rate of palladium(II) are partly similar to those observed in the extraction with TIBPS.[4] Therefore, the experimental results of the extraction kinetics were analyzed on the basis of the heterogeneous interfacial reaction model applied to the analysis of the extraction kinetics by TIBPS[4], as will be described in the following section.

Discussion

The following results obtained in the present work suggest that a certain elementary process taking place at the interface plays an important role in the reaction mechanism of the present extraction system: (1) The aqueous solubility of 7-TDO is too low to assume that homogeneous reactions take place to any considerable extent in the aqueous phase; (2) 7-TDO has interfacial activity, and (3) the reaction order with respect to the extractant is less than unity in its high-concentration region.

Consequently, in a manner similar to that employed in the analysis of the extraction kinetics with TIBPS,[4] palladium(II) is considered to be extracted by 7-TDO from aqueous chloride media according to the following reaction scheme:

$$[PdCl_3(H_2O)]^- + HR_{ad} \xrightarrow{k_1} [PdCl_3 \cdot HR]^-_{ad} + H_2O \quad (8)$$

$$[PdCl_4]^{2-} + HR_{ad} \xrightarrow{k_2} [PdCl_3 \cdot HR]^-_{ad} + Cl^- \quad (9)$$

$$[PdCl_3 \cdot HR]^-_{ad} + HR \rightleftharpoons \overline{[PdCl_2 \cdot 2HR]} + Cl^- \quad (10)$$

Assuming that the parallel elementary reactions to form the intermediate complex at the interface, $[PdCl_3 \cdot HR]^-_{ad}$, as described by Eqs. 8 and 9, are rate-determining, and taking account of the fact that the aquatrichloro complex, $[PdCl_3(H_2O)]^-$, and the tetrachloro complex, $[PdCl_4]^{2-}$, are predominant under the present experimental conditions, the rate of the present extraction reaction can be approximately described as follows:

$$-\frac{da_t}{dt} = \frac{K_{ad}[\overline{HR}]}{1 + K_{ad}[\overline{HR}]} \left(\frac{k_1\beta_3 + k_2\beta_4[Cl^-]}{\beta_3 + \beta_4[Cl^-]}\right) a_t \quad (11)$$

where β_3 and β_4 denote the stability constants of aquatrichloro- and tetrachloropalladate(II). The effects of varying the concentrations of each reactant species on the extraction rates shown in Figs. 6 and 7 can be qualitatively interpreted by Eq. 11, derived from the proposed interfacial reaction scheme.

The optimum values of the rate constants, k_1 and k_2, of the rate-determining steps described by Eqs. 8 and 9 were calculated by the nonlinear, least-squares method from the data in Figs. 6 and 7, using the value of K_{ad} obtained in the preceding section and the stability constants of the palladium(II) chloro complexes in the literature[10] ($\beta_3=2.00\times10^{10}$, $\beta_4=7.94\times10^{11}$): $k_1=9.7\times10^{-2}$ s^{-1}, $k_1=1.3\times10^{-3}$ s^{-1}. The magnitudes of the orders of these values are very close to those observed in the extraction with TIBPS from hydrochloric acid ($k_1=6.1\times10^{-1}$ s^{-1}, $k_2=1.7\times10^{-3}$ s^{-1}). The solid lines shown in Figs. 6 and 7 are the curves calculated from Eq. 11 using these values. These lines are in fairly good agreement with the experimental results.

Conclusion

The partition coefficient of 7-TDO to the aqueous solution and its adsorption equilibrium parameters, the interfacial area occupied by a unit mole of the extractant, and the interfacial adsorption equiibrium constant are very close to those of triisobutylphosphine sulfide (TIBPS) as reported in a previous work.[4] Palladium(II) is extracted as a mononuclear complex by the use of 7-TDO, while it is extracted as a binuclear complex when TIBPS is used.

The experimental results of the extraction kinetics were quantitatively explained by the interfacial reaction model proposed for the kinetics of extraction with TIBPS, in which the ligand substitution between the extractant molecule adsorbed at the interface and aquatrichloro- and tetrachloropalladate(II) in the aqueous phase are rate-determining. The extraction rate was satisfactorily expressed by Eq. 11, which was derived from the interfacial reaction model presented above. The values of the reaction-rate constants in Eq. 11 were found to be close to those observed in the extraction with TIBPS.

The Wetting of Alumina Substrate by Liquid Gold†

Masumi USHIO* and Yoshihiro SUMIYOSHI
Department of Applied Chemistry, Faculty of Engineering, Gunma University,
Tenjin-cho, Kiryu-shi 376
(Received June 17, 1987)

The wetting of an Al_2O_3 substrate by liquid gold was investigated by means of the sessile-drop method in an atmosphere of argon. An empirical relation was estabilished between the contact angle and the temperature or surface tension of the liquid drop by the use of the diameter and the height of the sessile drop. The contact angle was constant with time, but decreased linearly with an increase in temperature. The variation in the contact angle with temperature is correlated with the surface tension of the sessile drop. The surface tension of liquid gold was obtained as 933 dyn cm^{-1} at 1080 °C and 917 dyn cm^{-1} at 1100 °C and the temperature coefficient of the surface tension of liquid could be estimated to be −0.80 dyn cm^{-1} $°C^{-1}$. The critical surface tension (γ_c) and the surface tension of liquid gold at 0 K of Al_2O_3 (γ°_{Lv}) were 20 and 2015 dyn cm^{-1}, respectively.

As was reported in the first part,[1] the wetting of an Al_2O_3 substrate by liquid Ag was investigated by the sessile drop technique under an atmosphere of argon. An empirical relation was established between the contact angle and the temperature or surface tension of the liquid drop, by use of Rhee's equation. The contact angle was constant with increasing time and decreased linearly with increasing temperature. The variation of the contact angle with temperature could be correlated with the surface tension of the sessile drop. The critical surface tension (γ_c) of Al_2O_3 is 923 dyn cm^{-1}, and the surface tension of liquid Ag at 0 K was 1130 dyn cm^{-1}.

In the present paper, the wettability of a sintered alumina substrate with a surface that was polished to be flat and smooth by liquid Au was investigated by the sessile drop techniques in an atmosphere of argon in much the same way as was reported in the first part.

This was done in order to obtain values of the surface tension of liquid Au, the temperature coefficient of the surface tension of liquid Au, the critical surface tension (γ_c), and the surface tension of liquid Au at 0 K. Since sufficient results were obtained, details are reported here.

Experimental

The sintered alumina (99.5%, Kyocera Co.) was used as a substrate with dimensions 20×20×3 mm^3, its surface was polished to a mirror-like finish. The high-purity gold (99.99%, Ishifuku Co.) was cut into a disk. The dimensions of the gold disk were 4 mm in diameter and 3 mm in thickness; its purity was 99.99%.

The sessile-drop apparatus used to measure the contact angle was the same as that mensioned in a previous paper.[1] A Pt-Pt13%Rh thermocouple was used for temperature measurements. The furnace was operated in an atmosphere of argon at a rate of about 0.9 L min^{-1}. The gold disk and substrate were cleaned with acetone and then dried in a vaccum. The gold disk after being placed on an alumina substrate was put queitly into the furnace.

After adjusting the horizontal position, argon gas was flowed. The furnace temperature was increased to a specified value and then maintained for 30 min.

The shadow of a sessile drop of gold was then photographed from the back by using light produced by a mercury lamp. The contact angle of the drop was bilaterally measured and its mean value was taken as the measured value.

In the case of a constant temperature of 1080 °C, the contact angle was measured at 5-minute intervals for a period of 60 min. On the other hand, for various temperatures from 1070 to 1100 °C, the contact angle of a gold drop was also measured at intervals of 5 °C. From many photographs, the diameters and heights of the sessile drops of gold were also measured. These diameters were used to calculate the surface tension of liquid gold as well as the critical surface tension for spreading (γ_c) for the Au/Al_2O_3 system.

The human error was found to be about ±1° by measuring the contact angle from ten photographs. The temperature deviation was ±2 °C. The regions of the gold drop/alumina substrate were using an optical microscope and a scanning electron microscope.

Results

In the case of a constant temperature of 1080 °C, the photographs used in measuring the contact angles of the gold drops are shown in Fig. 1, while the measured values of contact angles are shown in Table 1 and Figs. 2 and 3. These experimental results showed that a contact angle of the liquid gold sessile drop resting on an alumina substrate was about 127°. However there were some differences in the wettability, depending on the test pieces of alumina substrates. Each straight line in Figs. 2 and 3 represents the results of two independent runs.

In the case of different temperature between 1070 and 1100 °C, with the contact angle measured at intervals of 5 °C, the photographs used in measuring the contact angle of a liquid gold sessile drop resting on an alumina substrate are shown in Fig. 4. The effect of the temperature on the contact angle is shown

liable to wet an alumina substrate.

The state of the surface of an alumina substrate directly under liquid gold was investigated before and after thermal treatment. Before the thermal treatment, it was smooth and flat; however, it was revealed that

the flatness of the surface had been destroyed after the treatment. It seems that a reaction between an alumina substrate and liquid gold took place. A comparison with the case of liquid silver, showed that it had been destroyed less than for liquid gold.[1]

Discussion

The effect of time on the contact angle of a liquid gold sessile drop resting on an alumima substrate was examined at a contact temperature of 1080 °C for runs of (T-1) and (T-2). Each straight line in Fig. 2 can be fitted by means of the following equations:

Run (T-1)

$$\theta_1 = -0.0073x + 125.5$$
$$\theta_2 = 0.0105x + 127.9$$

Run (T-2)

$$\theta_1 = -0.023x + 129.0$$
$$\theta_2 = 0.017x + 128.5$$

In the above x is the time in minutes and θ is the contact angle.

The slopes of these equations were within the absolute value of $|0.0105—0.023|$; they were very small and near zero. Therefore, it can be assumed that the contact angle of liquid gold on an alumina substrate is scarcely changed at a constant temperature of 1080 °C. This result is the same as that observed for a system Ag/Al_2O_3.[1]

The effect of the temperature on the contact angle of liquid gold on an alumina substrate was also investigated for runs of (T-3) and (T-4). The values of the slopes of all the straight lines are negative, as is obvious from Fig. 5. This figure indicates that the contact angle decreases linearly with an increase in temperature and that liquid gold is apt to wet an alumina substrate better. The reason for this may be considered to be that the contact angle becomes small as the forces between molecules of gold decreases with an increase in temperature causing a decrease in the surface tension of gold. However, the contact angle of liquid gold on an alumina substrate was larger than that of liquid silver. That is, using liquid gold it was rather more difficult to wet an alumina substrate than using liquid silver.

The amounts of scatter in the measured values of the contact angle (θ_1 and θ_2) are shown in Tables 1 and 2. It may be assumed that this scatter was due to human measurements errors of ±2°, etc. That is, since sintered alumina was used as a substrate, the effect of binder agents, the difficulty in producing homogeneous finished goods, atmospheric effects, etc. must be considerd.

The alumina substrate was chemically inert to liquid gold in the temperature range investigated, judging from the optical-microscopy and scanning-electron microscope studies. However, the surface of an alumina substrate became fairly rough, judged from surface observations after thermal treatments.

If the surface of an alumina substrate was worn by a thermal treatment, the contact angle of the liquid gold was fairly influenced.

It is necessary to increase the reproducibility in order to produce homogeneous finished goods, to clean the surface of the alumina substrate, to standarize the roughness of the work surface, and to decrease the temperature fluctuation, etc.

Various values of the surface tension of liquid gold have been reported. Values of the surface tension ranged between 580 and 1000 dyn cm^{-1} at 1070 °C in air[2] and 1410 dyn cm^{-1} at 1027 °C.[3] On the other hand, the values of the surface tension of liquid gold by the creep method were 1100 dyn cm^{-1} at 1130 °C in air and 1400 dyn cm^{-1} at 1030 °C in helium.[4]

The surface tension at 1200 °C in hydrogen gas was 1120 dyn cm^{-1}. Another report concerning the surface tension of liquid gold at 1120 °C in hydrogen gas was 1128 dyn cm^{-1} and 1120 dyn cm^{-1} at 1200 °C and 1110 dyn cm^{-1} at 1300 °C.[6] In turn, the surface tension of the solid, that is, gold foil, was 1205 dyn cm^{-1} at 700 °C.[7]

The liquid-solid interface energy, γ_{LS}, is 133 dyn cm^{-1} for gold.[8] It has also been reported that for metal, $\gamma_{LS}=(0.12\pm0.03)\ T_m$, where T_m is the melting point (K).[9] From this equation, we can now estimate it to be between 121 and 201 dyn cm^{-1}, while Southin et al. and Zettlemoyer reported that $\gamma_{LS}=130$ dyn cm^{-1} of the mean value.[10]

Another emprical relation is

$$\gamma_{LS} = \frac{K\Delta H_m}{N_o^{1/3} V_m^{2/3}}$$

where ΔH_m is the latent heat of fusion per mole, V_m the molar volume, N_o Avogadro's number and $K=0.45$ for metals.[9] From this empirical equation, we estimate γ_{LS} to be 126 and 123 dyn cm^{-1}, using $K=0.45$, $N_o=6.02\times10^{23}$ mol^{-1}, $V_m=10.2_2$ cm^3, $\Delta H_m=12.7$ kJ mol^{-1},[11] and 2.955 kcal mol^{-1} (about 12.4 kJ mol^{-1})[12] respectively.

The temperature coefficient of the surface tension of liquid gold has not yet been reported.

From Dorsey's empirical formula,[13] based on Bashforth and Adams table, we can estimate the surface tension of liquid gold to be 933 dyn cm^{-1} at 1080 °C and 917 dyn cm^{-1} at 1100 °C, by using the present experimental results of the maximum diameter, the θ-value of the sessile drop and the distance from the sessile drop and the distance from the apex of the drop to be a 45° tangent: 0.468 cm, 127.6° (at 1080 °C), and 0.109 cm, respectively, and 0.478 cm, 125.5° (at 1100 °C), and 0.112 cm, respectively.

The temperature coefficient of the surface tension of liquid gold could be estimated to be −0.80 dyn cm^{-1} °C^{-1} from the present experiment results shown

in Table 2.

It is found that the calculated values of the surface tension of liquid gold by using other formulas[14] were about 15 to 25% smaller than the values predicted by the Dorsey formula.

We also attempted to calculate the critical surface tension and the surface tension at 0 K for the Au/Al_2O_3 system and, therefore, adopted the values obtained by using the Dorsey formula. The critical surface tension and the surface tension at 0 K were discussed by Rhee.[1,15]

As described above, the cosine of the contact angle increases linearly with an increase in temperature in the Au/Al_2O_3 system. The variation of the cosine of the contact angle with a decrease in the surface tension of liquid gold is shown in Fig. 7 for the Au/Al_2O_3 system. The extrapolation of the straight line to $\cos\theta=+1$ produces the critical surface tension for spreading ($\gamma_c=20$ dyn cm^{-1}) for the Au/Al_2O_3 system, with the surface tension ($\gamma_{LV}^{0}=2015$ dyn cm^{-1}) of liquid gold at 0 K.

For liquid gold, γ_c for Al_2O_3 system, with the surface tension ($\gamma_c=361$ dyn cm^{-1}),[1] but $\gamma_{LV}^{0}=$ for Al_2O_3 is larger that for liquid silver ($\gamma_{LV}^{0}=790$ dyn cm^{-1}).

The melting point and the boiling point for Au are 1063 °C and 2707 °C, respectively. For gold, the values of the vapor pressures follow the Antoine equation:

$$\log_{10} P = -\frac{52.23\,B}{T} + C,$$

where P is the vapor pressure of gold in mm of mercury and T is the absolute temperature. Values for constants B and C are 385 and 9.853, respectively.[16] For the temperature range 2315 to 2500 °C, vapor pressures of 121 values to 399 mmHg (1 mmHg= 133.322 Pa) can be obtained. Other vapor-pressure values are 20 mmHg at 2256 °C and 100 mmHg at 2521 °C, obtained from the Harlacher-Braun equation.[17]

When measuring values of the critical surface tension, etc, the gold vapor near the melting point may be ignored and assumed not being absorbed on the Al_2O_3 substrate.

Conclusion

1) The surface tension of liquid gold in argon was obtained as 933 dyn cm^{-1} at 1080 °C and 917 dyn cm^{-1} at 1100 °C, and expressed in the temperature range 1070 to 1100 °C by γ_{LV} (dyn cm^{-1})=1797−0.80 T(°C). On the other hand, for liquid silver, the surface tension was 650 dyn cm^{-1} (960 °C) and 610 dyn cm^{-1} (1000 °C), the surface tension was 650 dyn cm^{-1} (960 °C) and 610 dyn cm^{-1} (1000 °C), expressed in the temperature range 960 to 1000 °C by γ_{LV} (dyn cm^{-1})= 1610−1.0 T (°C).[1]

2) In a liquid gold/alumina system, a linear relation exists between the cosine of the contact angle and the surface tension of a gold sessile drop when the temperature of the system is varied. This result with a system Au/Al_2O_3 is the same as that with a system Ag/Al_2O_3.[1]

The temperature coefficient of the surface tension of liquid gold in argon was obtained to be −0.80 dyn cm^{-1} °C^{-1}, compared with −1.00 dyn cm^{-1} °C^{-1} of a liquid silver.[1]

3) The liquid-solid interface energy, γ_{LS} was obtained to be 123—126 dyn cm^{-1} in comparison with 115 dyn cm^{-1} of a liquid silver.

4) The critical surface tension, γ_c of a liquid gold was obtained 20 dyn cm^{-1}, against 361 dyn cm^{-1} of a liquid silver.[1]

5) The obtained surface tension at 0 K (γ_{LV}^{0}) for the Au/Al_2O_3 system was to be 2015 dyn cm^{-1} compared with 790 dyn cm^{-1} for liquid silver.[1]

6) According to the Antoine equation, the gold vapor near the melting point can be ignored and thought of as not being absorbed on the Al_2O_3 substrate same as for silver vapor.[1]

The difference between liquid gold and liquid silver of these measured values were attributed to the difference in the electronegativities or electric charges of the atomic nucleus for each metal, although a d-orbital (4s or 5d-orbital) and an s-orbital (5s or 6s-orbital) were similarly used to form the bond.

The authers wish to thank Mr. Hiroshi Watanuki for his assistance during the experimental work.

Preparation and Properties of Iron(II) Hydroxide-(Sodium Fluoride Tetrasilicic Mica) Intercalation Complexes

Kunio OHTSUKA,* Mitsuru SUDA, and Mikiya ONO
Research & Development Center, Ceramics, Mitsubishi Mining & Cement Co., Ltd.,
2270 Yokoze, Chichibu-gun, Saitama 368
(Received July 7, 1987)

Iron(II) hydroxide-(sodium fluoride tetrasilicic mica) intercalation complexes, which have a chlorite-like structure, were prepared by titrating iron(II) sulfate solutions in the presence of mica with sodium hydroxide under oxygen-free conditions. The formation of iron(II) hydroxide sheets between the silicate layers was evaluated by chemical analysis, XRD, DTA-TGA, and surface-area measurement. The presence of water is essential for the oxidizing of these complexes to occur at room temperature by air, because the O_2 attack on the surface of these iron(II) hydroxide sheets is hindered by the silicate layers. Fine highly dispersed iron metal particles (α-Fe) were formed on the external surface of the silicate by the H_2 reduction of the complexes.

We previously reported that ultra-fine, highly dispersed metal (Ni, Co) particles can be prepared on the external surface of silicates by the reduction of metal (Ni, Co) hydroxide-layer silicate complexes.[1,2] This method of preparation, providing isolated metal atoms on the carrier, leads to many applications for catalysts, magnetic materials, electronics, etc. Therefore, it is desired that this technique is applicable to the iron element as well as to the nickel and cobalt elements; the iron element is essential for those applications.

Besides, iron(II) hydroxide-layer silicate complexes, if possible. should be novel reducing agents which are easy to handle, for iron(II) hydroxide has a strong reducing power and this iron(II) hydroxide sheet would be sandwiched between the silicate layers.

Although many attempts have been made to prepare these iron hydroxide-layer silicate complexes,[3-7] no clear evidence for the formation of these complexes has yet been obtained. These attempts to study clay minerals have been connected with the transformation of expansible layer silicate (2:1 layer silicate) to metal hydroxide-layer silicate, which has a chlorite-like structure. Chlorites have a 2:1 layer structure with a metal hydroxide interlayer, and iron(II, III) is considered to exist in both the hydroxide sheet and the 2:1 layer of chlorites.[8-12]

In this work, the preparation and properties of iron hydroxide-layer silicate (sodium fluoride tetrasilicic mica) complexes were investigated. We have attempted to prepare these complexes with the iron(II) ion, not with the iron(III) ion, because we consider that there is an essential difficulty in forming an iron hydroxide interlayer with the iron(III) ion; the iron(III) ion in the metal hydroxide interlayer of chlorites must be introduced by the oxidation of the iron(II) ion or by coprecipitation as a minor constituent with a major constituent (Al, Mg etc.). One of the reasons why the preparation of iron hydroxide-layer silicate complexes has rarely been carried out with the iron(II) ion is evidently that iron(II)-ion solutions are easily oxidized by air. The problems of what kind of cations can give these hydroxide interlayers and of the mechanism of these transformations will be explained in detail in our next paper.

Experimental

Starting Materials. A 10 wt% sol of sodium fluoride tetrasilicic mica ($NaMg_{2.5}Si_4O_{10}F_2$), obtained from Topy Ind., Co., under the name of Na-TSM, was used. Since this mica sol contains a little α-cristobalite and magnesium fluoride richiterite ($Na_2Mg_6F_2(Si_4O_{11})_2$) as impurities, the sol was diluted with distilled water, and then most of the impurities were separated by centrifugation. Finally sodium fluoride tetrasilicic mica was dried in air at 100 °C.

The characteristics of this mica were described in detail in our previous work.[1] Sodium fluoride tetrasilicic mica is an expansible 2:1 layer silicate. Na^+ ions are located between the silicate layers to balance the negative layer charge of the −1 derived from the vacancies in the silicate layers. These Na^+ ions are exchangeable in water, the theoretical cation-exchange capacity being 254 meq/100 g·mica.

Preparation of Iron(II) Hydroxide-Mica Complexes. Iron(II) hydroxide-(sodium fluoride tetrasilicic mica) complexes were prepared by the titration method: iron(II) sulfate solutions in the presence of mica were titrated with sodium hydroxide under oxygen-free conditions.

The iron(II) ion is thermodynamically unstable with respect to atmospheric oxidation and, especially in alkaline solutions, is rapidly oxidized by the oxygen in the air.[13,14] Hence, great care was taken to prevent it from touching with O_2 during the preparation. The preparation procedures were operated under a N_2 gas atmosphere; N_2 gas was passed through a disoxidation agent in advance. All the solutions were prepared using distilled water free of O_2; dissolved oxygen was expelled by keeping N_2 gas bubbling through the boiling water.

Figure 1 shows the process of preparing the complexes, while Fig. 2 shows the scheme of the preparation system. Oxygen-free water was added to the mica powder, and then this suspension was refluxed in a N_2 flow to expel the oxygen absorbed on the surface of mica. As the iron(II) sulfate reagent has a few iron(III) ions, iron(II) sulfate solutions were aged for 1 day and then passed through glass filters by means of N_2-gas pressure to remove any iron(III) hydroxide. These iron(II) sulfate solutions, thus filtered and

transported to the reaction flask, were then mixed with the mica sol to give a 1 mol Fe/100 g·mica, where the concentration of Fe in these mixed suspensions was 0.1 M (1 M=1 mol dm^{-3}). These mixed suspensions were stirred for 1 day to promote ion-exchange between the iron(II) ion and the sodium ion within the mica. Subsequently, in order for the hydrolysis between the silicate layers to proceed, these suspensions were titrated with 0.1 M sodium hydroxide solutions at the rate of 20 ml h^{-1} to yield OH/Fe molar ratios of 0, 0.2, 0.4, 0.6, 0.8, and 1.0 respectively under vigorous stirring. After these additions, stirring was continued for 2 days. The resulting products were washed in oxygen-free water to remove electrolytes, the supernatant being taken out by means of N_2-gas pressure. Finally, these products were centrifuged, dried at 50 °C in a vacuum oven, and stored under nitrogen in a tightly closed desiccator.

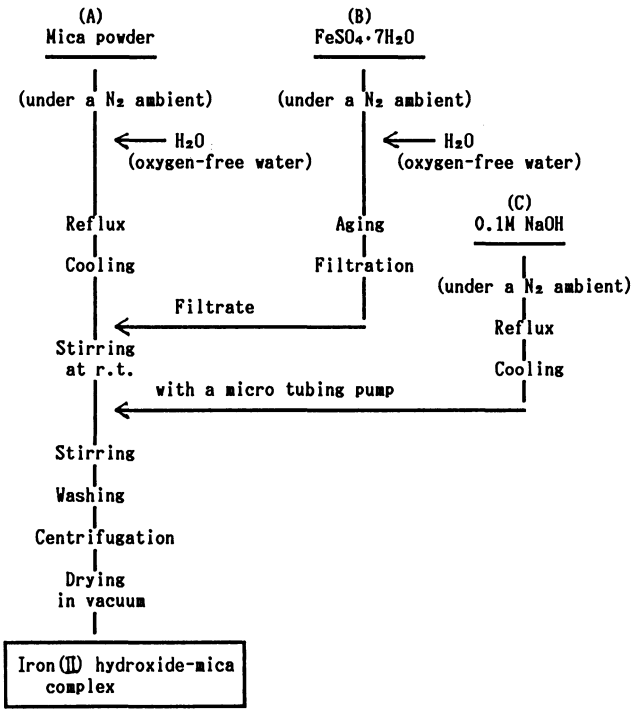

Fig. 1. Process of preparing iron(II) hydroxide-(sodium fluoride tetrasilicic mica).

Techniques of Characterizing the Complexes. Chemical analyses of the complexes were carried out by atomic-absorption analysis. The X-ray diffraction (XRD) patterns were obtained with a Rigaku diffractometer RU-200, using Cu $K\alpha$ radiation, from specimens basally oriented on glass slides. The surface areas were measured by the nitrogen-adsorption method at the temperature of liquid nitrogen with a Carlo Elba Sorptomatic, Series 1800. The samples were evacuated at 50 °C overnight prior to the measurements. Differential thermal analysis and thermogravimetric analysis (DTA-TGA) were made with a Rigaku Thermoanalyzer M8076 in a N_2 flow at a heating rate of 10 °C min^{-1}. Transmission electron microscopy (TEM) was performed with a JEOL, Model JEM-1200EX. The thermal stability of the complexes in an inert gas and their reduction behavior with H_2 were investigated in a range of 100—700 °C at a heating rate of 10 °C min^{-1}, because this mica is stable below 800 °C.

Measurement of the Room-Temperature Oxidation of the Complexes in Air. In our preliminary experiment, it was found that these complexes were not oxidized only by oxygen, but that the presence of water appeared to be essential for oxidizing to occur at room temperature by air. Therefore, the room-temperature oxidation of these complexes by air was investigated in an air flow with water vapor, the weight change during exposure to air being measured by means of the gravimetric McBain-Bakr balance technique. Samples of about 0.2 g were hung with a quartz spring and evacuated. Subsequently, N_2 gas with a saturated water-vapor pressure (at 30 °C) was passed over the sample (at 31 °C) at a flow rate of 100 ml min^{-1}, the relative humidity being 94%. After a constant weight was achieved, the flow was then switched to air with a saturated water-

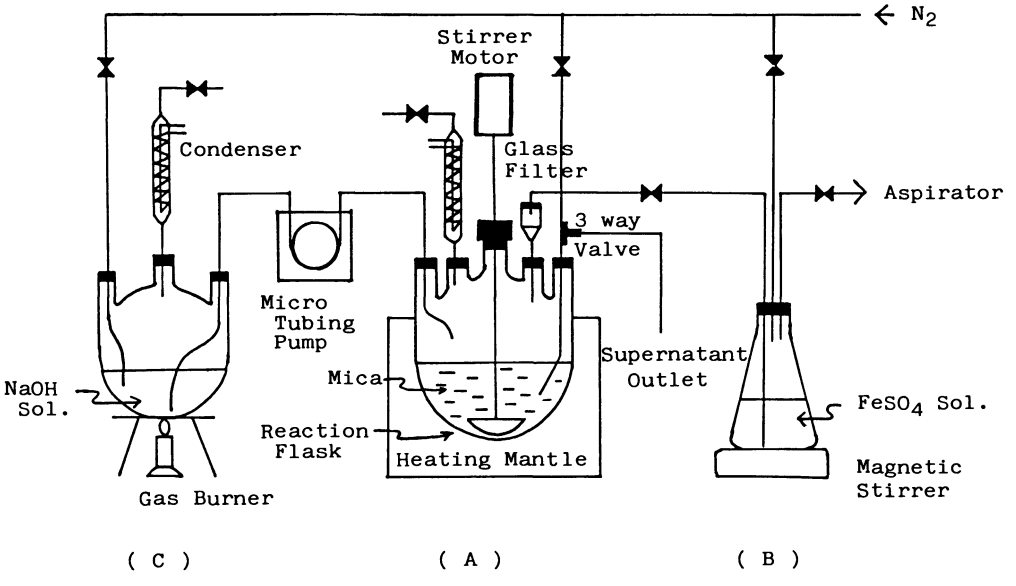

Fig. 2. Schematic of apparatus for preparing iron(II) hydroxide-(sodium fluoride tetrasilicic mica).

vapor pressure (at 30 °C) until the weight gain by oxidation was equilibrated.

Results and Discussion

Chemical Analyses. The results of the chemical analyses of the mica and its intercalation complexes are listed in Table 1. The iron content increased with an increase in the OH/Fe ratio, and the extent of the ion-exchange ratio in the resulting products was almost constant (81—82%). At an OH/Fe ratio of 1.0, the iron content of the complexes was 2.4 mol per formula unit of the mica 82% ion-exchanged, corresponding to 2.9 mol per formula unit of the mica 100% ion-exchanged. The ideal composition of the iron (II) hydroxide-mica complexes, which have a chlorite-like structure, is $[Fe_3(OH)_5(H_2O)](Mg_{2.5}Si_4O_{10}F_2)$;[1,2] the maximum iron content of the complexes is 3 mol per formula unit of the mica 100% ion-exchanged. Therefore, at an OH/Fe ratio of 1.0, the iron(II) hydroxide interlayers in the complex must be well-developed.

XRD Measurement and Specific Surface Area. The X-ray powder diffraction patterns of these complexes are shown in Fig. 3. The basal spacings of these complexes expanded to about 14.3—14.7 Å from the 9.6 Å basal spacing of the mica (Table 2); these basal spacings were almost independent of the iron content. Moreover, with an increase in the OH/Fe

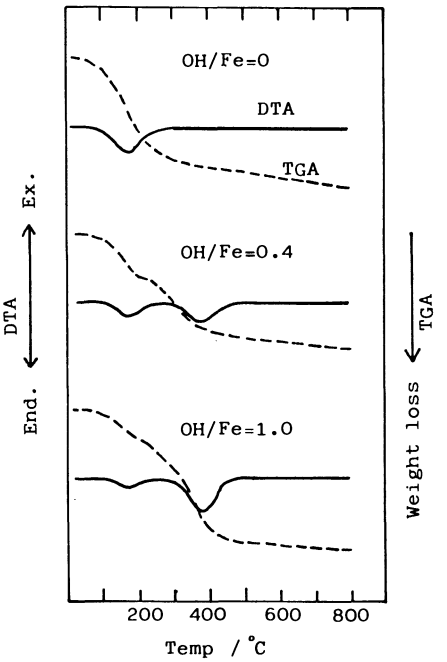

Fig. 5. DTA-TGA curves, obtained using a nitrogen atmosphere, for iron(II) hydroxide-(sodium fluoride tetrasilicic mica).

ratio, the (001) first-order reflection decreased in intensity; on the contrary, the (002)—(004) higher-order reflections increased in intensities. These changes in the relative intensities were the same as those observed in the formation reactions of nickel(II) or cobalt(II) hydroxide-mica complexes, indicating that an iron-(II) hydroxide-forming reaction took place between the silicate layers. The XRD patterns of the complexes with OH/Fe ratios of 0.8 and 1.0 showed the essential X-ray characteristics of chlorites. Moreover, XRD analysis revealed the absence of any iron oxide in these heat-treated samples.

The specific surface areas of the complexes are shown in Fig. 4. With an increase in the OH/Fe ratio, the specific surface areas decreased because the development of iron(II) hydroxide between the silicate layers begins at the cation-exchange sites, which are apart from each other, and finally the internal spaces are completely stacked with this iron(II) hydroxide interlayer. These changes are the same as those observed in nickel(II) or cobalt(II) hydroxide-mica complexes.

Thermal Analysis. The DTA-TGA curves for the complexes are shown in Fig. 5. Complexes with an OH/Fe ratio of 0.0 showed a single endothermic peak at about 170 °C. This dehydration is due to the hydration water associated with the iron(II) ions introduced by ion-exchange between the silicate layers. The composition of these iron(II) ions appears to be $[Fe(OH)_\delta(H_2O)_{6-\delta}]^{2-\delta}$, because the hydration water of the cation in expansible layer silicates is much more dissociated than in liquid water.[15] However, as the OH/Fe ratio increased, another peak appeared at about 375 °C, while the peak at about 170 °C was diminished. These findings indicate that iron(II) hydroxide $[Fe_x(OH)_y(H_2O)_m]^{2x-y}$ developed between the silicate layers with the progressive hydrolysis and olation of iron(II) cations by the addition of alkali. Therefore, the second peak corresponds to the loss of the hydroxyl group.

Table 2 shows the changes in the basal spacings after heat treatment in an Ar flow. Complexes with OH/Fe ratios of 0.8 and 1.0, which have a well developed iron(II) hydroxide interlayer, did not collapse even upon heat treatment at 300 °C. As iron(II) hydroxide decomposes to FeO at about 200 °C,[16] well-developed iron(II) hydroxide between the silicate layers has a higher thermal stability than iron(II) hydroxide in the bulk state and is strongly fixed to the silicate layers.

Reduction Behavior with H_2. The complexes were heated in a H_2 flow at 400—700 °C for 2 h. The XRD patterns of the reduced complexes with an OH/Fe ratio of 1.0 are shown in Fig. 6. These complexes collapsed to a basal spacing of 9.6 Å, and metallic iron (α-Fe) was detected above 500 °C. As the reducing temperature rose, the reflection intensity of iron increased and the (001) mica basal reflection peak became sharper: reduced iron atoms gradually migrated from the interlayer of the silicate to its external surface.

A TEM photograph of the H_2-reduced complexes with an OH/Fe ratio of 1.0 at 700 °C is shown in Fig. 7. Metallic iron particles with a clear cubic crystal habit are distributed on the external surface of the mica. The grain diameter of these metallic iron particles increased with an increase in the reducing temperature.

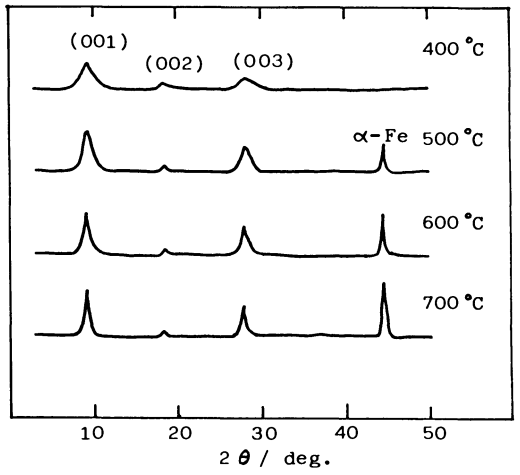

Fig. 6. X-Ray powder diffraction patterns of H_2 reduced iron(II) hydroxide-(sodium fluoride tetrasilicic mica) with a OH/Fe ratio of 1.0 at various temperatures.

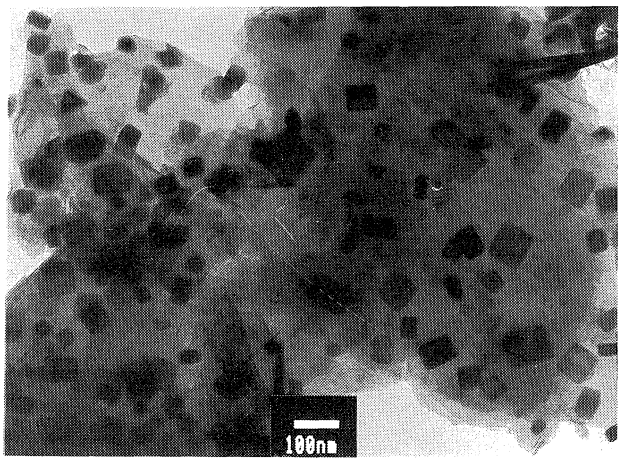

Fig. 7. Transmission electron micrograph of H_2 reduced iron(II) hydroxide-(sodium fluoride tetrasilicic mica) with a OH/Fe ratio of 1.0 at 700 °C.

Room-Temperature Oxidation of the Complexes in Air. Figure 8 shows the room-temperature oxidation of the complexes with time in air with water vapor (P_{H_2O}=4.24 kPa); temp=31 °C, R.H.=94%, air flow rate=100 ml min^{-1}. The weight-gain values are plotted against the time in the logarithmic scale. Oxidation occured gradually, and weight change by oxidation was large in the complexes with high OH/Fe ratios. The final weight-gain of the complexes with an OH/Fe ratio 1.0 was about 5 wt%. With the progress of oxidation, the color of the complexes changed from blue-green to yellow-orange and the chlorite-like structure was destroyed (Fig. 9). The oxidation rate was largely governed by the relative humidity and the reaction temperature, being controlled by the partial isomorphous substitution of

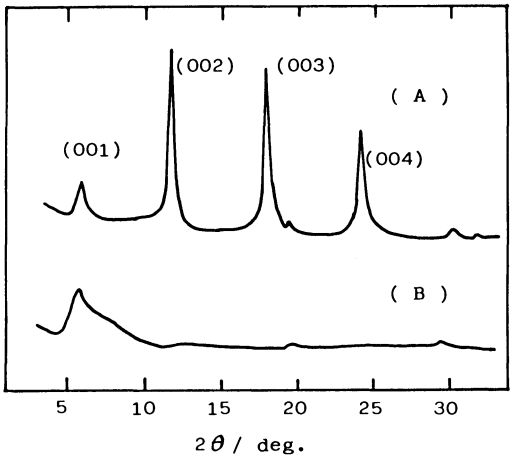

Fig. 9. X-Ray powder diffraction patterns of iron-(II) hydroxide-(sodium fluoride tetrasilicic mica) after oxidation in air.
(A): original iron(II) hydroxide-(sodium fluoride tetrasilicic mica) complex with a OH/Fe ratio of 1.0; (B): oxidized complex in air with water vapor (P_{H_2O}=4.24 kPa; R.H.=94%) at 31 °C for 2 d.

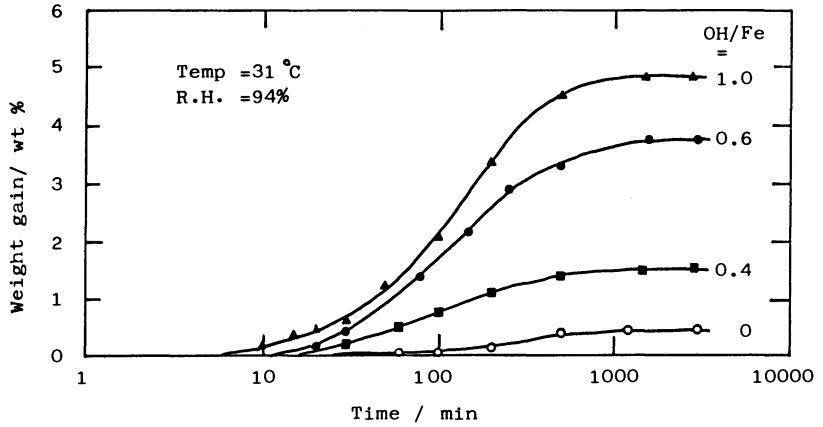

Fig. 8. Weight gain for iron(II) hydroxide-(sodium fluoride tetrasilicic mica) with time in air with water vapor (P_{H_2O}=4.24 kPa; R.H.=94%) at 31 °C. R.H.= relative humidity.

iron(II) ions. The details of this will be given in our next paper.

In contrast, iron(II) hydroxide in the bulk state is rapidly oxidized and ignites spontaneously on exposure to air because of its strong reducing power.

Mechanism of the Room-Temperature Oxidation of the Iron(II) Hydroxide Interlayer in Air. The oxidation of iron(II) hydroxide in air seems to be similar to that in aqueous solutions; the latter has been studied extensively. The oxidation processes in aqueous solutions can be classified into two types.

One consists of solid-phase reactions (surface reactions) which take place rapidly on the surface of iron(II) hydroxide with oxygen. This process is accepted as a topotactic reaction and follows this equation:[16,17]

$$\underset{\text{(hcp)}}{Fe(OH)_2} + 1/4\,O_2 \rightarrow \underset{\text{(hcp)}}{\delta\text{-FeOOH}} + 1/2\,H_2O. \quad (1)$$

This reaction process can be observed in strong alkaline solutions with a rapid oxidizing agent, because in strong alkaline solutions the concentration of iron(II) ions is extremely small.

The other type consists of liquid-phase reactions (dissolution-precipitation reactions) which take place gradually in the liquid phase.[18,19] When slow oxidation occurs by oxygen dissolved in the solution, iron(II) ions are oxidized in the solution and precipitated as α-FeOOH, γ-FeOOH, Fe_3O_4, or a mixture of them, according to the pH, the reaction temperature, and the kind of anion present.

Therefore, the oxidation process of iron(II) hydroxide in air can be considered to proceed as follows: on exposure to air, rapid oxidation on the surface of iron(II) hydroxide occurs (Eq. 1). However, since this reaction takes place with an evolution of heat, the oxidation and dehydration proceed simultaneously, and result in the formation of γ-Fe_2O_3:

$$Fe(OH)_2 + 1/4\,O_2 \xrightarrow[\text{rapid oxidation}]{\text{in air}} 1/2\ \gamma\text{-}Fe_2O_3 + H_2O. \quad (2)$$

In the case of the oxidation of iron(II) hydroxide–mica complexes in air, the solid-phase reaction on the surface of iron(II) hydroxide interlayers does not proceed, bacause these iron(II) hydroxide sheets are sandwiched between the silicate layers; the O_2 attack on the surface of iron(II) hydroxide sheets is hindered by the silicate layers. In fact, iron(II) hydroxide interlayers were not oxidized only by oxygen; the presence of water was indispensable to their oxidation by air at room temperature, as has been mentioned above. Hence, the oxidation of iron(II) hydroxide interlayers occurs in air with water vapor according to the liquid phase reaction: water is absorbed on the edge of the iron(II) hydroxide sheets, and then the dissolved Fe^{2+} ions are oxidized. Consequently, the oxidation rate is slow and depends on the water-vapor pressure. This oxidation process is different from that of iron(II) which is present in the 2:1 silicate layer of clay minerals.[20–23]

(Received August 17, 1987)

The crystal and molecular structure of the title compounds, [Co^{III}Cl(tpp)(H$_2$O)], has been determined by means of X-ray diffraction techniques. The compound crystallizes in the monoclinic system; space group $P2_1/c$. The unit cell has a=13.542(2), b=25.760(2), c=10.423(1) Å, β=99.33(2)°, and Z=4. The cobalt atom is coordinated by four porphyrinato nitrogen atoms, one chlorine atom, and one oxygen atom of water, and is displaced by 0.039(2) Å from the mean plane defined by the four porphyrinato nitrogen atoms towards the axial chlorine atom. The average Co–N(tpp) distance is 1.955(2) Å. The Co–Cl distance is 2.216(1), and the Co–O(water) distance, 1.979(3) Å. The porphyrinato core is significantly ruffled and has an approximate $\bar{4}$ symmetry. The [Co^{III}Cl(tpp)(H$_2$O)] molecules are stacked along the c axis by O–H···Cl hydrogen bonds.

In our investigation of chloro (*meso*-tetraphenylporphyrinato)cobalt(III), [Co^{III}Cl(tpp)], its characteristic phenomena, behavior, or properties have been found by the use of optical absorption, NMR, and ESR spectral techniques.[1] The crystallization of the complex from common solvents gives crystals of various external forms: obelisk, pyramid, prism, and/or bulky shapes from a dichloromethane or chloroform solution, and only obelisks from a methanol solution. A previous X-ray diffraction study[2] of the obelisk crystals isolated from a dichloromethane or chloroform solution demonstrated that the complex can be represented as a five-coordinate cobalt complex of tpp having square-pyramid structure with a chlorine atom at the apex. However, a subsequent X-ray diffraction study[3] of the pyramid crystals obtained from a dichloromethane or chloroform solution suggested that there is an unidentified atom in the sixth axial position. The possibility of the partial coordination of water at the sixth ligand position was considered, because it has been well known that the cobalt(III) complex is stable in the case of six-coordination.[4] Presumably, water in the atmosphere contaminated the solution being crystallized. However, an IR examination of the crystals did not find any OH stretchings. In order to elucidate the coordination of a water molecule as the sixth ligand, crystals of species with one water molecule, [Co^{III}Cl(tpp)(H$_2$O)], were prepared from a solution of dichloromethane saturated with water and then analyzed by means of X-ray diffraction. The result shows that when the water molecule coordinates at the sixth axial position, the crystal and molecular structure is completely different from that of [Co^{III}Cl(tpp)]. The present paper will deal with the structure of [Co^{III}Cl(tpp)(H$_2$O)].

Experimental

Materials. The chloro(*meso*-tetraphenylporphyrinato)-cobalt(III), [Co^{III}Cl(tpp)], was prepared by the method previously reported.[2] The complex was dissolved in a solution of dichloromethane saturated with water and evaporated spontaneously; metallic lustrous reddish-purple prismatic crystals were thus obtained.

Found: C, 72.71; H, 4.07; Cl, 4.90; Co, 8.37; N, 7.75; O, 2.40%. Calcd for $C_{44}H_{30}ClCoN_4O$ ([Co^{III}Cl(tpp)(H$_2$O)]): C, 72.88; H, 4.17; Cl, 4.89; Co, 8.13; N, 7.73; O, 2.21%.

X-Ray Measurements. The crystal used was 0.25×0.31×0.75 mm in size. The preliminary Weissenberg photographs showed that the crystal belongs to the monoclinic system. The systematic absences ($h0l$ for l odd and $0k0$ for k odd) led to the space group $P2_1/c$. The least-squares refinement of the setting angles of 24 reflections, measured on a Rigaku AFC-4 four-circle diffractometer with graphite-monochromated Mo $K\alpha$ radiation (λ=0.71073 Å), gave the following cell constants: a=13.542(2), b=25.760(2), c=10.423(1) Å, and β=99.33(2)°. The calculated density (1.342 g cm^{-3}) agreed with the observed value (1.345 g cm^{-3}) obtained by the floatation method in a tetrachloromethane–methylcyclohexane mixture. Intensity data within the range ($\sin\theta/\lambda$<0.75598 Å^{-1}) were collected by the use of the ω scan (2θ<30°) and ω–2θ scan methods (2θ≧30°), with a scan speed of 4° min^{-1} in ω. The three standard reflections ($\bar{2}$ 2 1, 0 2 5, and 6 10 0), measured every 100 reflections, showed no significant deterioration. The ordinary Lorentz and polarization corrections and absorption correction were applied. The absorption coefficient for Mo$K\alpha$ radiation was 5.899 cm^{-1}. The minimum and maximum transmission coefficients were 0.83 and 0.87 respectively. 13597 reflections were measured, and 5873 unique reflections obtained with $F_o \geqq 3.0\,\sigma(F_o)$. 7114 reflections were unobserved with the criterion of $F_o < 3.0\,\sigma(F_o)$.

Structure Analysis

The structure was solved by the heavy-atom method and refined by the block-diagonal least-squares method. Difference Fourier syntheses gave the positions of all the hydrogen atoms. In the final stage, the structure was refined by the full-matrix least-squares method, based on $|F_o|$, with isotropic and anisotropic temperature factors for hydrogen and non-hydrogen atoms respectively. The function minimized was $\sum w(|F_o|-|F_c|)^2$, where w=1.0. The final R and R_w values were 0.055 and 0.054 respectively. In

the final cycle of refinement, the largest shift/error was 0.931 for B_{33} of the C(9C) atom. The maximum and minimum heights in the final difference synthesis were 0.57 and −0.61 e Å^{-3} respectively. Calculations were carried out on the FACOM M-380 computer of this Institute using the UNICS III program system[5] and the best-plane calculation with the BP70 program.[6] The atomic-scattering factors, including anomalous scattering corrections, were taken from the International Tables for X-Ray Crystallography.[7]

Results and Discussion

The atomic coordinates except hydrogen atoms are listed in Table 1.[8] The molecular structure of [Co^{III}Cl(tpp)(H_2O)] is shown in Fig. 1, along with the atomic numbering and the thermal ellipsoids. The intramolecular bond distances(Å) are listed in Table 2, while the crystal structure projected along the a axis is shown in Fig. 2.

The coordination around the cobalt atom is

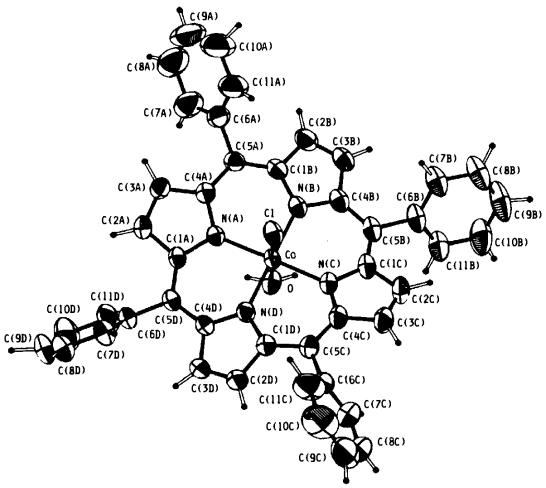

Fig. 1. The molecular structure.
The thermal ellipsoids are at 50% probabillity for non-hydrogen atoms (hydrogen atoms are arbitrarily scaled).

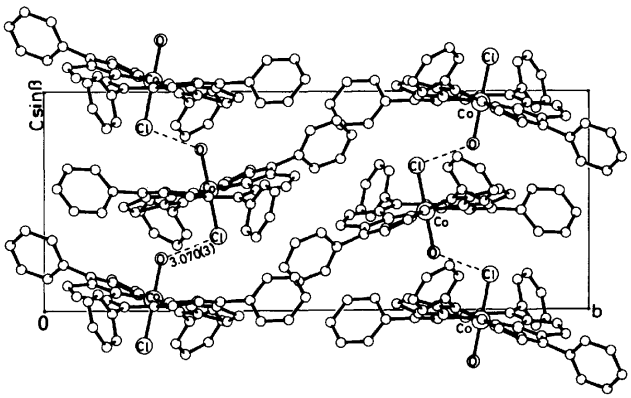

Fig. 2. The crystal structure projected along the a axis.
Hydrogen atoms are omitted for clarity. Broken lines show the O-H···Cl hydrogen bonds (distances in Å).

illustrated in Fig. 3. The cobalt atom is coordinated by four porphyrinato nitrogen atoms, one chlorine atom, and one oxygen atom of water. The axial Co–Cl distance of 2.216(1) Å is shorter than those of $[Co^{III}Cl(tpp)(py)]$ (2.251(3) Å)[9] and $[Co^{III}Cl(NH_3)_5]Cl_2$ (2.286(2) Å),[10] and it is close to the sum of the covalent radii[11] of Co(III)(1.22 Å) and Cl(0.99 Å). Another axial Co–O distance of 1.979(3) Å is longer than those

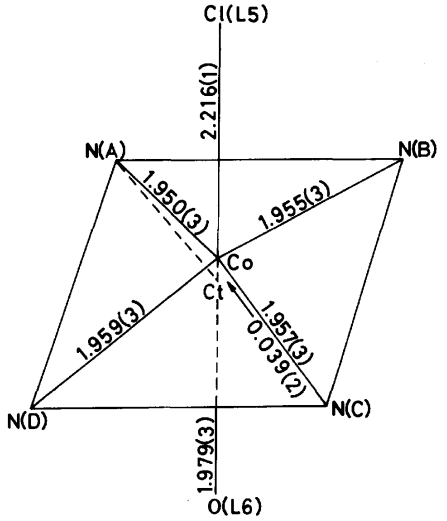

Fig. 3. Perspective diagram of the six-coordination around the cobalt(III) atom.
Ct represents the center of four porphyrinato nitrogen atoms.

of $[Co^{III}(tpp)(H_2O)_2]ClO_4$ (1.936(5) Å),[12] $[Co^{III}(CH_3O)(tpp)(py)]$(1.92 Å),[13] and $[Co^{III}(H_2O)(NH_3)_5]_2(S_2O_6)_3 \cdot 2H_2O$ (1.954(1) Å);[14] furthermore, it is longer than the sum of the covalent radii of Co(III) and O(0.66 Å) and comparable with that of the ionic radii of Co(+3) (0.63 Å) and O(−2)(1.40 Å).

The cobalt atom is displaced by 0.039(2) Å from the mean plane defined by four porphyrinato nitrogen atoms (4N plane) towards the axial chlorine atom, as is shown in Fig. 3. The displacement of the cobalt atom is common in five-coordinate complexes,[2,15,16] but is observed only for the present complex among the six-coordinate complexes.[9,13,17–19] A small displacement (0.013(2) Å) of the cobalt atom is observed for $[Co^{III}(NO_2)(tpp)(lut)]$,[20] but it is buried in the mean 4N plane(±0.04(2) Å). The displacement of the metal atom has been well-known in iron porphyrin complexes, depending on its oxidation state and spin state.[21] In the present complex, the Co–Cl distance is short, while that of Co–O is long; hence a rather strong coordination of the chloride ligand to the cobalt atom and a weak coordination of the water ligand. Therefore, the displacement of cobalt in the present complex may result from a compromise between (1) the necessity for the best σ-overlapping of the chlorine and oxygen atoms of axial ligands with the cobalt atom and (2) the planarity for the optimum π-bonding of the porphyrinato ligand.

The average distance between cobalt and the porphyrinato nitrogen atom (Co–N(tpp)) is 1.955(2)

Å. This distance is located near the lower end of the range of distances (1.948—1.985 Å) of the reported Co^{III}(tpp) complexes.[2,9,12,13,15-20] It is shorter than the Co-NH_3 distances of $[Co^{III}(NH_3)_6][Co^{III}(CN)_6]$ (1.972(1) Å),[22] $[Co^{III}Cl(NH_3)_5]Cl_2$ (1.976 Å), and $[Co^{III}(H_2O)(NH_3)_5]_2(S_2O_6)_3 \cdot 2H_2O$ (1.961 Å).

The average distances of other chemically analogous types are: N-Cα=1.377(6), Cα-Cβ=1.435(4), Cβ-Cβ'=1.334(8), Cα-Cm=1.389(6), and Cm-Cp=1.492(2) Å, where Cα and Cβ (Cβ') denote α and β carbon atoms in pyrrole rings; Cm, methine carbon atoms; and Cp, phenyl carbon atoms. The figure in parentheses is the standard deviation. Except for Cm-Cp, these distances are very similar to those of the reported Co^{III}(tpp) complexes.

The intramolecular bond angles are listed in Table 3. The average value of four N-Co-N angles is 90.0(2)° (max. —min.: 90.3(1)—89.4(1)°); the cobalt atom is surrounded by a square-planar array of pyrrole nitrogen atoms. The average angles of the other chemically analogous types are: Co-N-Cα=126.8(2), Cα-N-Cα=106.0(2), N-Cα-Cβ=109.5(2), N-Cα-Cm=125.5(2), Cm-Cα-Cβ=124.8(3), Cα-Cβ-Cβ'=107.5(2), Cα-Cm-Cα=122.1(2), and Cα-Cm-Cp=118.7(5)°. These angles are comparable to those of $[Co^{III}(NO_2)(tpp)(lut)]$ and $[Co^{III}(tpp)(H_2O)_2]^+$ in that the porphyrinato cores are ruffled, but differ somewhat from those of $[Co^{III}Cl(tpp)]$ in that the core is planar.

The deviations of 24 atoms from the least-squares plane of the porphyrinato core are shown in Fig. 4. The porphyrinato core is considerably ruffled. The ruffled core has an approximate $\bar{4}$ symmetry. As is usual, a local flatness (within 0.02 Å) is maintained in

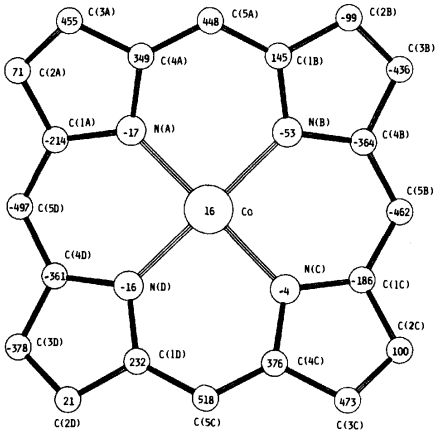

Fig. 4. A diagram of the porphyrinato core showing displacement of atoms, in units of 0.001 Å, from the mean plane at the 24 atom core.

the pyrrole rings. The four pyrrole rings are swiveled about the Co–N(tpp) bond; the dihedral angles between the pyrrole rings and the porphyrinato mean plane are 17.0, 14.9, 17.0, and 16.6°. Similar conformations have been observed for [$Co^{III}Cl$(tpp)(py)], [$Co^{III}(CH_3O)$(tpp)(py)], [$Co^{III}(NO_2)$(tpp)(lut)], and [Co^{III}(tpp)$(H_2O)_2]^+$. Recently, by comparing various Co^{III}(tpp) complexes, we found[23] a linear relationship between the ruffling of the porphyrinato core and the Co–N(tpp) distance; the porphyrinato core is ruffled as the Co–N(tpp) distance decreases.

The two oppisite phenyl groups are above, and the two other phenyl groups are below, the porphyrinato core, as is shown in Fig. 2. The dihedral angles between the mean plane of the porphyrinato core and the plane of the four phenyl groups are 59.9(2), 52.5(2), 61.5(2), and 62.2(2)°, their average value being 59°. In general, the angles smaller than 60° are precluded by steric interactions between the pyrrole hydrogen and phenyl hydrogen atoms.[9] The dihedral angle of 52.5° obtained from the present study is the smallest among those of Co^{III}(tpp) complexes thus far reported. Masuda et al.[12] have pointed out a linear relationship between the dihedral angles and the Cm–Cp distance. The average Cm–Cp distance of the present complex is 1.492(3) Å. This distance is the shortest among those reported of the Co^{III}(tpp) complexes; also it is close to that observed for the central C–C bond of the planar biphenyl molecule.[24] Through the short distance of Cm–Cp, the π-conjugate system of the porphyrinato core may be slightly delocalized over the phenyl rings, although the π-conjugate system might be weakened because of its ruffled conformation.[12]

The short C···C intermolecular van der Waal's contacts are shown in Table 4. Two less than 3.55 Å are observed between phenyl-carbon and pyrrole-carbon atoms. The shortest phenyl carbon–phenyl carbon distance (3.322(8) Å) is between C(7B) and $C(7B)^V$ atoms; the shortest pyrrole carbon–pyrrole carbon distance (3.411(6) Å) is between C(3A) and $C(3B)^{IV}$ atoms.

Table 4. The Short Intermolecular van der Waal's Contacts

Symmetry Code:

I	$1+x, y, z$	II	$-1+x, y, z$
III	$1+x, y, 1+z$	IV	$x, -y+1/2, z-1/2$
V	$-x, -y, -z$	VI	$1-x, -y, -z$
VII	$-x, y+1/2, -z+1/2$		

Type		l/Å
Pyrrole carbon ··· phenyl carbon		
C(2A) ···	$C(9B)^{VII}$	3.550(9)
C(2D) ···	$C(9A)^{I}$	3.549(12)
C(3A) ···	$C(9B)^{VII}$	3.732(8)
C(3D) ···	$C(9A)^{I}$	3.650(11)
C(2D) ···	$C(10A)^{III}$	3.696(9)
C(2B) ···	$C(9C)^{II}$	3.626(11)
C(1C) ···	$C(8B)^{V}$	3.665(7)
C(2C) ···	$C(9C)^{VI}$	3.643(10)
Pyrrole carbon ··· pyrrole carbon		
C(3A) ···	$C(3B)^{IV}$	3.411(6)
C(3A) ···	$C(4B)^{IV}$	3.539(6)
Phenyl carbon ··· phenyl carbon		
C(7B) ···	$C(7B)^{V}$	3.322(8)
C(11C)···	$C(11D)^{IV}$	3.568(8)

The porphyrinato core is almost vertical to the bc plane, as seen from the crystal structure shown in Fig. 2. The Co–Cl bond makes an angle of 16.6° from the c axis. The porphyrin molecule is transferred by the c glide operation and is stacked along the c axis. The hydrogen bond between an axial water molecule of a [$Co^{III}Cl$(tpp)(H_2O)] molecule and an axial chlorine atom of the neighbor [$Co^{III}Cl$(tpp)(H_2O)] molecule is zigzagged along the c axis direction. The hydrogen-bond distance, O–H···Cl, is 3.070(3) Å.

The authors are grateful to Dr. Haruo Honma of this Institute for his helpful advice on crystallization and on the elementary analyses of this complex.

^{57}Fe-Moessbauer and ^{13}C-CP-MAS NMR Spectroscopic Studies of the Reaction Products of Ruthenocene Derivatives with Lewis Acids

Masanobu WATANABE, Yuichi MASUDA, Izumi MOTOYAMA, and Hirotoshi SANO*
Department of Chemistry, Faculty of Science, Tokyo Metropolitan University, Fukasawa, Setagaya-ku, Tokyo 158
(Received August 18, 1987)

Adducts of ruthenocene with Lewis acids, such as $HgCl_2$, $SnCl_4$, and I_2, are studied mainly by means of high resolution solid state ^{13}C NMR spectroscopy and ^{57}Fe-Moessbauer spectroscopy. The large low-field shifts found in the ^{13}C-CP-MAS NMR spectroscopy suggest the presence of a direct chemical bond between the ruthenium and the Lewis acids. Ferrocenylruthenocene and biruthenocene give stable adducts with $HgCl_2$ and I_2. ^{57}Fe-Moessbauer and ^{13}C-CP-MAS NMR spectroscopic studies suggest the presence of a chemical bond, such as Ru-Hg, Ru-I, in the adducts.

The basicity of the nonbonding e_{2g} electrons around the iron and ruthenium atoms in ferrocene and ruthenocene derivatives respectively has been studied in the reaction of ferrocene and ruthenocene derivatives with protons in a solution, such as $CHCl_3$, CX_3COOH (X=Cl, F), and H_2SO_4.[1,2] Especially, [2]ferrocenophanes react with an appropriate Lewis acid species, such as $HgCl_2$, $SnCl_4$, and I_2, to give diamagnetic stable adducts with a direct chemical bond between the iron atom and the Lewis acids.[3-5] Ruthenocene also reacts with the Lewis acids and it gives much more stable adducts than ferrocene because ruthenocene has less steric hindrance in donating e_{2g} electrons than does ferrocene. Although [2]ferrocenophane and ruthenocene are well-soluble in most organic solvents, the adducts are less soluble in the solvents. Thus far, all attempts to obtain a single crystal of [2]ferrocenophane-3$HgCl_2$ and -1.5$SnCl_4$ have been unsuccessful, while a few adducts, such as ruthenocene-3$HgCl_2$ and -1.8$HgBr_2$, [2]ferrocenophane-2I_2, were obtained as single crystals in which direct metal-metal chemical bonds (Ru-Hg and Fe-I respectively) have been found on the basis of the results of X-ray diffraction studies.[5,6]

Recently, improvements in sensitivity, in the resolution in cross-polarization (CP), in dipolar decoupling, and in magic-angle-spinning (MAS) techniques have made it possible to obtain a high-resolution ^{13}C NMR spectrum, even in the solid state.[7-10] The present studies were undertaken to clarify the structure of some ruthenocene derivative-Lewis acid adducts, such as $HgCl_2$, $SnCl_4$, and I_2, by means of ^{57}Fe-Moessbauer and high-resolution ^{13}C-CP-MAS NMR spectroscopy.

Experimental

Materials: The ferrocenylruthenocene was prepared by the Ullmann coupling of bromoruthenocene and bromoferrocene, instead of iodoruthenocene and iodoferrocene, at 120 °C for 12 h.[11] Biruthenocene was prepared by the same method using bromoruthenocene. ^{1}H NMR ($CDCl_3$); δ=4.79(t)($H_{2,5}$), 4.54(t)($H_{3,4}$), 4.44(s)(π-C_5H_5) for the ruthenocene group, δ=4.23(t)($H_{2,5}$), 4.09(t)($H_{3,4}$), 4.05(s)(π-C_5H_5) for the ferrocene group in ferrocenylruthenocene, δ=4.69(t)($H_{2,5}$), 4.47(t)($H_{3,4}$) and 4.50(s)(π-C_5H_5) for biruthenocene. Ferrocenyl ruthenocenyl ketone was prepared by following the previously reported method.[12] The purity of the metallocenes was confirmed by elemental analysis. Adducts of ruthenocene with $HgCl_2$, $SnCl_4$, and I_2 were prepared by following the methods in the previous reports.[6,13,14] Adducts of ferrocenylruthenocene, biruthenocene, and ferrocenyl ruthenocenyl ketone with $HgCl_2$ were prepared in diethyl ether by a method similar to that used in the case of the ruthenocene-3$HgCl_2$ adduct. Found: C, 14.17; H, 1.27%. Calcd for ferrocenylruthenocene-5$HgCl_2$, $C_{20}H_{18}FeRu$-5$HgCl_2$: C, 13.55; H, 1.07%. Found: C, 17.02; H, 1.48%. Calcd for biruthenocene-3.5$HgCl_2$, $C_{20}H_{18}Ru_2$-3.5$HgCl_2$: C, 17.02; H, 1.29%. Found: C, 18.01; H, 1.50%. Calcd for ferrocenyl ruthenocenyl ketone-3.5$HgCl_2$, $C_{21}H_{18}OFeRu$-3.5$HgCl_2$: C, 18.10; H, 1.30%, respectively. Adducts of ferrocenylruthenocene and biruthenocene with I_2 were prepared by mixing I_2 with the metallocenes in a dry benzene-hexane mixture. Found: C, 26.00; H, 1.91%. Calcd for ferrocenylruthenocene-2I_2, $C_{20}H_{18}FeRu$-2I_2: C, 26.03; H, 1.97%. Found: C, 24.88; H, 1.98%. Calcd for biruthenocene-2I_2, $C_{20}H_{18}Ru_2$-2I_2: C, 24.81; H, 1.87%.

Measurements: The ^{13}C-CP-MAS NMR spectra were obtained at the frequency of 50.18 MHz using a JEOL FX-200 Fourier Transform NMR Spectrometer. Four thousands datum points at a sweep width setting of 20 kHz were collected by following a spin-locking cross-polarization sequence. Both the ^{1}H- and ^{13}C-rf field strengths were 50 kHz. Magic angle sample spinning rates of 3 to 3.5 kHz were achieved by using Kel-F rotors. The chemical shifts were measured with respect to external adamantane and then converted to the shifts from TMS. The ^{1}H and ^{13}C NMR spectra in solution were measured with the same spectrometer at 199.56 and 50.18 MHz respectively, using TMS as a standard. The assignment of the ^{13}C signals of the metallocenes was carried out by selective proton-decoupling experiments.

The ^{57}Fe-Moessbauer spectroscopic measurements were carried out by using a ^{57}Co(Rh) source moving in a constant acceleration mode. All the isomer-shift (I. S.) values for the ^{57}Fe-Moessbauer spectra are given relative to metallic iron; the experimental errors of the I. S. and quadrupole-splitting (Q. S.) values are estimated to be within $\pm$0.02 mm s^{-1}.

Results and Discussion

Figure 1 shows the ^{13}C-CP-MAS NMR spectra of the ruthenocene (a) and its $-3HgCl_2$(b), $-1.5SnCl_4$(c), and $-2I_2$(d) adducts; the ^{13}C chemical-shift (δ) values of the adduct and related compounds are listed in Table 1. The π-C_5H_5 ring carbon signal in the ruthenocene appears at δ=73.2, and its adducts, at δ=81.2, 89.1, and 93.4 for the $-3HgCl_2$, $-1.5SnCl_4$, and $-2I_2$ adducts, respectively. These large low-field shifts ($\Delta\delta$=8.0, 15.9, and 20.2 for the $-3HgCl_2$, $-1.5SnCl_4$, and $-2I_2$ adducts respectively) can be attributed to the Ru–Hg, Ru–Sn, and Ru–I bond formation in the adducts as has already been verified by means of X-ray-diffraction[6,13] and ^{119}Sn-Moessbauer spectroscopic studies.[4] The increasing values of the low-field shift in the Lewis acid adducts suggest that the interaction between the ruthenocene and the Lewis acids increases in the order of $HgCl_2<SnCl_4<I_2$. As has previously been mentioned, [2]ferrocenophane–Lewis acid adducts give large Q. S. values (3.29, 3.49, and 3.65 mm s^{-1}, for the $-3HgCl_2$, $-1.5SnCl_4$, and $-2I_2$ adducts, respectively) in their ^{57}Fe-Moessbauer spectra.[3-5] The fact that the order of the increase in

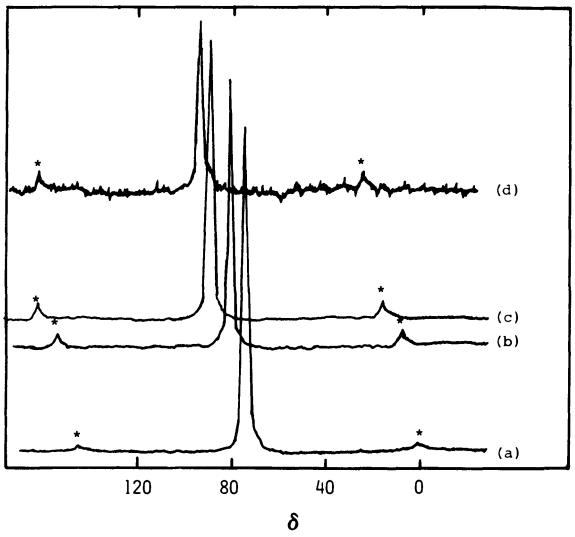

Fig. 1. ^{13}C-CP-MAS NMR spectra of the ruthenocene (a) and its $-3HgCl_2$(b), $-1.5SnCl_4$(c), and $-2I_2$ (d) adducts.
The sample spinning side band (SSB) is represented by * in the Figure.

Table 1. ^{13}C Chemical-Shifts of Ruthenocene and Related Compounds in the Solid State and in a Chloroform Solution

Compound	Ruthenocene δ	Ferrocene δ	
Ruthenocene	73.2		
Ruthenocene-$3HgCl_2$	81.2

*: Stands for a CD_3Cl solution.

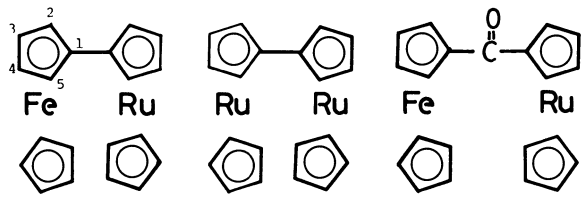
the low-field shifts of the ruthenocene-Lewis acids adducts is similar to that of the Q. S. values of the [2]-ferrocenophane-Lewis acid adducts suggests that the effect of Lewis acids on the ruthenium atoms in ruthenocene is similar to that on the iron atoms in [2]ferrocenophane.

Similar large low-field shifts are also observed for the ^{1}H NMR spectra of the ruthenocene-Lewis acid adducts in CD_3CN. The ^{1}H NMR spectra of the adducts are shown in Fig. 2, while their chemical shift values are summarized in Table 2. The fact that the decreasing shift ($\Delta\delta$=1.50) for the ruthenocene-$2I_2$ adduct is much larger than that of the -$3HgCl_2$ adduct ($\Delta\delta$=0.84), as in the case of the ^{13}C-CP-MAS NMR spectra, shows that the ruthenium atom interacts with the iodine atom more strongly than with the mercury atom in the solution.

Table 2. ^{1}H NMR Chemical-Shifts of Ruthenocene and Related Compounds in Acetonitrile

Compound	Chemical shift δ
Ruthenocene	5.37
Ruthenocene-$3HgCl_2$	6.21
Ruthenocene-$1.5SnCl_4$	5.35
Ruthenocene-$2I_2$	6.87
Biruthenocene	5.53($H_{2,5}$)
	5.30($H_{3,4}$)
	5.32(π-C_5H_5)
Biruthenocene-$2I_2$	6.90($H_{2,5}$)
	6.54($H_{3,4}$)
	6.65(π-C_5H_5)

Although the ruthenocene-$2I_2$ and $3HgCl_2$ adducts are stable in acetonitrile, the -$1.5SnCl_4$ adduct is unstable in the solution; i.e., the yellow solution of the -$1.5SnCl_4$ adduct dissociates in acetonitrile, becoming colorless in a few minutes after the dissolution, while the electronic spectrum becomes the same as that of ruthenocene itself. The ^{1}H chemical-shift observed in the ruthenocene-$1.5SnCl_4$ adduct (δ=5.35) in the solution corresponds well to that of the ruthenocene (δ=5.37), also indicating the dissociation of the -$1.5SnCl_4$ adduct in acetonitrile. It seems very reasonable to conclude that the structure of the -$1.5SnCl_4$ adduct can be expressed as $[(C_5H_5)_2Ru\text{-}SnCl_2\text{-}Ru(C_5H_5)_2]^{2+}(SnCl_5^-)_2$, on the basis of the ^{13}C-CP-MAS NMR data, as has already been proposed by Mann et al. based on their infrared spectroscopic study[14] and by us based on our ^{119}Sn-Moessbauer spectroscopic study.[4]



Ferrocenylruthenocene Biruthenocene Ferrocenyl ruthenocenyl ketone

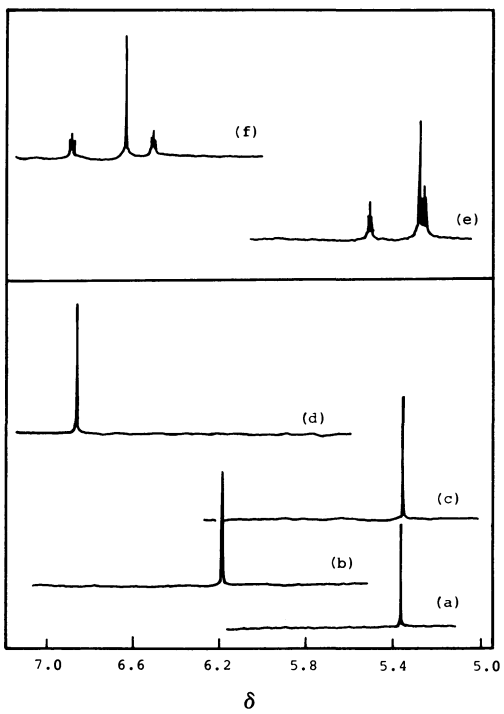


Fig. 2. ^{1}H NMR spectra of the ruthenocene(a), ruthenocene-$3HgCl_2$(b), ruthenocene-$1.5SbCl_4$(c), ruthenocene-$2I_2$(d), biruthenocene(e), biruthenocene-$2I_2$(e) compounds in the acetonitrile solution.

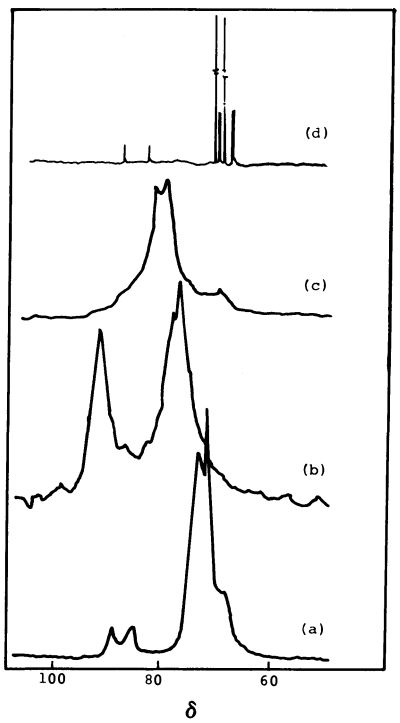

Fig. 3. ^{13}C-CP-NAS NMR spectra of ferrocenylruthenocene(a), and its -$2I_2$(b), -$5HgCl_2$(c) adducts and ^{13}C NMR spectrum of ferrocenylruthenocene(d) in chloroform solution.

Ferrocenylruthenocene was first synthesized by the reaction of the Ullmann coupling of iodoruthenocene with a large excess of iodoferrocene by Neuse in 1981.[11] In the present study, ferrocenylruthenocene is found to react with I_2 and $HgCl_2$ to give stable diamagnetic precipitates, which have been analyzed as ferrocenylruthenocene-$2I_2$ and ferrocenylruthenocene-$5HgCl_2$ adducts.[15] Figure 3 shows the ^{13}C-CP-MAS NMR spectra of the original metallocene(a) and its -$2I_2$(b), -$5HgCl_2$(c) adducts, together with the higher-resolution ^{13}C NMR spectrum of the metallocene in the $CDCl_3$ solution(d).

As is shown in Fig. 3(d), the two groups of resonances for the ferrocene and ruthenocene moieties are separately observed; i.e., the ferrocene signals appear at a higher field than do the ruthenocene signals, and these signals are in good agreement with the ^{13}C NMR spectra of biferrocene and biruthenocene in the same solution, as is shown in Table 1. The carbon signals were assigned by using selective proton decoupling experiments based on the results of previous reports.[11,16]

The broad ^{13}C-CP-MAS NMR spectra of ferrocenylruthenocene(a) cannot, however, be resolved into individual carbon signals. The ^{13}C chemical-shift values of the metallocene in the solid state are shown in Table 1. The signals of $C_{3,4}$ and $C_{2,5}$ for the ruthenocene moiety and of $C_{3,4}$ for the ferrocene moiety are not well resolved, being superimposed on by large and broad π-C_5H_5 signals in the ^{13}C-CP-MAS NMR spectra. Therefore, only the low-field shift values of π-C_5H_5 will be discussed. As is shown in Fig. 3-c, the two broad π-C_5H_5 ring signals (δ=81.4 for the ruthenocene moiety and δ=79.1 for the ferrocene moiety) are found in the ferrocenylruthenocene-$5HgCl_2$ adduct. The former value agrees with the value of the ruthenocene-$3HgCl_2$ adduct (δ=81.2). The observed low-field shifts ($\Delta\delta$=7.8 and 8.5 for the ferrocene and ruthenocene moieties respectively) are similar to that of ruthenocene-$3HgCl_2$ adduct ($\Delta\delta$=8.0). This fact shows the presence of two kinds of direct chemical bondings, Fe-Hg and Ru-Hg, in the -$5HgCl_2$ adduct.

On the other hand, broader signals (δ=93.6 for the ruthenocene moiety and δ=76.5 for the ferrocene moiety) are found for the ferrocenylruthenocene-$2I_2$ adduct (3-b). Although a small low-field shift in the ferrocene moiety ($\Delta\delta$=5.2) is found, a relatively large shift ($\Delta\delta$=20.7) is found for the ruthenocene moiety. The latter value is quite similar to that of the ruthenocene-$2I_2$ adduct ($\Delta\delta$=20.2). These facts indicate that only the ruthenium atom is bound with the iodine atom in the ferrocenylruthenocene-$2I_2$ adduct.

Figure 4 shows the ^{57}Fe-Moessbauer spectra of ferrocenylruthenocene(a) and its -$5HgCl_2$(b), -$2I_2$(c) adducts. An anomalously large Q. S. value (2.99 mm s^{-1} at 78 K) is found in the -$5HgCl_2$ adduct, showing direct chemical Fe-Hg bond formation, while a slightly smaller Q. S. value (2.16 mm s^{-1}) than that of the original metallocene (2.36 mm s^{-1}) is found in the -$2I_2$ adduct. The smaller Q. S. value may be caused by the decreased e_{2g} electrons of the iron atom in the -$2I_2$ adduct containing the Ru-I bond. The absence of a large Q. S. line, as in the case of the -$5HgCl_2$ adduct, shows that the iron atom is not bound to the iodine atom in the ferrocenylruthenocene-$2I_2$ adduct. The ^{57}Fe-Moessbauer results are in

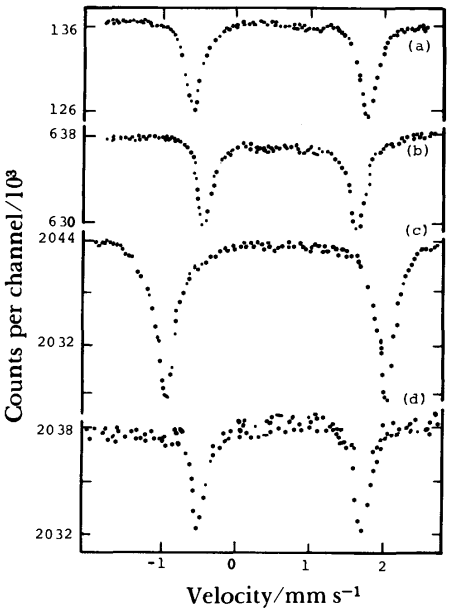

Fig. 4. ^{57}Fe-Moessbauer spectra of ferrocenylruthenocene(a) and its -$2I_2$(b), -$5HCl_2$(c) adducts and ferrocenyl ruthenocenyl ketone-$3.5HgCl_2$ adduct(d), all at 78 K.

Table 3. ^{57}Fe-Moessbauer Parameters of Ferrocenylruthenocene and Related Compounds

Compound	Temperature/K	Q. S./mm s^{-1}	I. S./mm s^{-1}
Ferrocenylruthenocene	78	2.36	0.53
	300	2.29	0.46
Ferrocenylruthenocene-$5HgCl_2$	78	2.99	0.57
Ferrocenylruthenocene-$2I_2$	78	2.16	0.52
	300	2.16	0.43
Ferrocenyl ruthenocenyl ketone	78	2.29	0.54
Ferrocenyl ruthenocenyl ketone-$3.5HgCl_2$	78	2.29	0.54

accordance with those of the ^{13}C-CP-MAS NMR spectroscopic studies of the ferrocenylruthenocene-$2I_2$ and -$5HgCl_2$ adducts. All the results obtained in the present studies indicate that the -$2I_2$ adduct may be expressed as $[(C_5H_5)(C_5H_4)Fe(C_5H_4)(C_5H_5)Ru\text{-}I]^+I_3^-$ in the solid state,[15] which is in accord with the elemental analysis datum.

The -$2I_2$ adduct is found to be unstable; that is, when the adduct is dissolved in acetonitrile, it turns green and an electronic absorption peak characteristic of a ferrocenium (λ_{max}=640 nm) increases rapidly, suggesting that the ferrocene moiety is rapidly oxidized in acetonitrile, giving ferrocenium-type cations. The fact that there is no evidence for Ru-I bond formation in the ferrocenylruthenocene-$2I_2$ adduct in acetonitrile in the studies done by means of ^{1}H and ^{13}C NMR agrees with the magnetic data, which show paramagnetism for the acetonitrile solution of the ferrocenylruthenocene-$2I_2$ adduct.

It is found that the ferrocenylruthenocene-$5HgCl_2$ adduct has two kinds of chemical bonds (Ru-Hg and Fe-Hg), while the ferrocenylruthenocene-$2I_2$ adduct has only a Ru-I bond in the solid state. These results can be explained on the basis of the fact that the van der Waals radius of iodine is much larger than that of the mercury atom. It is known that the Cp-rings are separated by 3.32 Å in ferrocene[17] and by 3.68 Å in ruthenocene.[18] The longer separation between the Cp-rings in the ruthenocene moiety may explain why only the ruthenocene moiety in ferrocenylruthenocene reacts with iodine, giving a stable Ru-I bond, while a ferrocene moiety does not give such a stable bond with an iodine atom bacause of van der Waals repulsion between Cp and the iodine atom.

Biruthenocene reacts with $HgCl_2$ and I_2, giving two stable adducts, analyzed as biruthenocene-$3.5HgCl_2$ and -$2I_2$ respectively. The ^{13}C-CP-MAS NMR spectra of the metallocene(a) and its -$3.5HgCl_2$(b), -$2I_2$(c) adducts are shown in Fig. 5, while the ^{13}C-chemical-shift values are shown in Table 1. A broad signal is found for the -$3.5HgCl_2$ adduct with the chemical-shift value of π-C_5H_5 ring (δ=81.2). This value corresponds to that of the ruthenocene-$3HgCl_2$ adduct (δ=81.2), and the relatively large low-field shift ($\Delta\delta$=8.9) shows the chemical-bond formation between the ruthenium and mercury atoms. These facts indicate that the two ruthenium atoms in the biruthenocene-$3.5HgCl_2$ adduct are bound equivalently to the mercury atoms.

On the other hand, two kinds of broad signals (δ= 92.9 and 77.4) are found for the -$2I_2$ adduct, as is shown in Fig. 5-c. The former value corresponds to that of the ruthenocene-$2I_2$ adduct(δ=93.4), and the latter to that of original biruthenocene itself (δ=72.3). The fact that two kinds of low-field shift values ($\Delta\delta$=20.6 and 5.1) are found indicates that only one of the ruthenium atoms in a biruthenocene molecule is

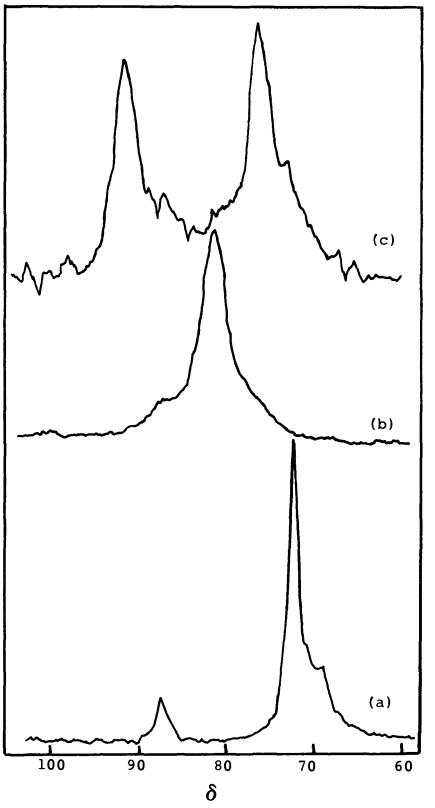

Fig. 5. ^{13}C-CP-MAS NMR spectra of biruthenocene (a) and its -$2I_2$(b), -$3.5HgCl_2$(c) adducts.

bound with the iodine atom; the adduct may be expressed as $[(C_5H_5)(C_5H_4)Ru(C_5H_4)(C_5H_5)Ru\text{-}I]^+I_3^-$ in the solid state, which is in good agreement with the elemental analysis data.

Although biruthenocene-$3.5HgCl_2$ is hardly soluble in acetonitrile, the -$2I_2$ adduct is well-soluble in acetonitrile. The ^{1}H NMR spectrum of the adduct is shown in Fig. 2(f), while the ^{1}H chemical-shift values of ruthenocene and biruthenocene in an acetonitrile solution are shown in Table 2. As in the case of the ^{13}C-CP-MAS NMR spectrum, large low-field shifts are found in the ^{1}H NMR spectra of the iodine adducts of the metallocenes in the acetonitrile. The smaller low-field shift of the Cp ring's ^{1}H chemical-shift of the biruthenocene-$2I_2$ adduct ($\Delta\delta$=1.33) compared to that of ruthenocene-$2I_2$ ($\Delta\delta$=1.50) was observed. The fact that the chemical states of the two ruthenocene moieties of the -$2I_2$ adduct are equivalent in the solution, while the chemical states are different in the solid state, suggests the possibility of a rapid exchange of the iodine between the two ruthenium atoms, $[Ru(C_5H_5)(C_5H_4)(C_5H_4)(C_5H_5)Ru\text{-}I]^+I_3^- \rightleftharpoons [I\text{-}Ru(C_5H_5)(C_5H_4)\text{-}(C_5H_4)(C_5H_5)]Ru]^+I_3^-$, in acetonitrile.

Ferrocenyl ruthenocenyl ketone was first prepared by Rausch et al. by means of the reaction of ferrocenyl chloride with ruthenocene in the presence of aluminum chloride.[12] Ferrocenyl ruthenocenyl

ketone is one of the most suitable compounds for the present studies. Recently, Clemance et al. have reported that diacetylferrocene reacts with a Lewis acid species, such as $AlCl_3$, $SnCl_4$, or $TiCl_4$, to give adducts. All the adducts show smaller Q. S. values (2.10—2.05 mm s^{-1} at 78 K) than the value of the original diacetylferrocene (2.14 mm s^{-1} at 78 K).[19] The results of the ^{57}Fe-Moessbauer spectroscopic studies indicate the absence of chemical bonding between the iron atom and the central metal atom of the Lewis acids, and it has been proposed that the central metal atoms of the Lewis acids are bound to the carbonyl oxygen atoms in the adducts.[19]

Ferrocenyl ruthenocenyl ketone reacts with $HgCl_2$ under the same conditions as those used in the preparation of the ferrocenylruthenocene-5$HgCl_2$ adduct, giving a stable diamagnetic adduct, expressed as ferrocenyl ruthenocenyl ketone-3.5$HgCl_2$ on the basis of the elemental analysis. The color of the adduct is purple, although most $HgCl_2$ adducts with ruthenocene or ferrocene derivatives are yellow or orange respectively. The ^{57}Fe-Moessbauer parameters of the adduct (I. S.=0.54 mm s^{-1}, Q. S.=2.29 mm s^{-1} at 78 K) are the same as those of the original ferrocenyl ruthenocenyl ketone, as is shown in Table 3 and Fig. 4(d). These facts suggest that there is no direct interaction between the mercury and iron atoms in the adduct.

The ^{13}C-CP-MAS NMR spectra of the metallocene(a) and its -3.5$HgCl_2$(b) adduct are shown in Fig. 6, while and the ^{13}C chemical-shift values of the metallocene and its adducts are shown in Table 1. The signals of $C_{2,5}$ and $C_{3,4}$ are overlapped with the

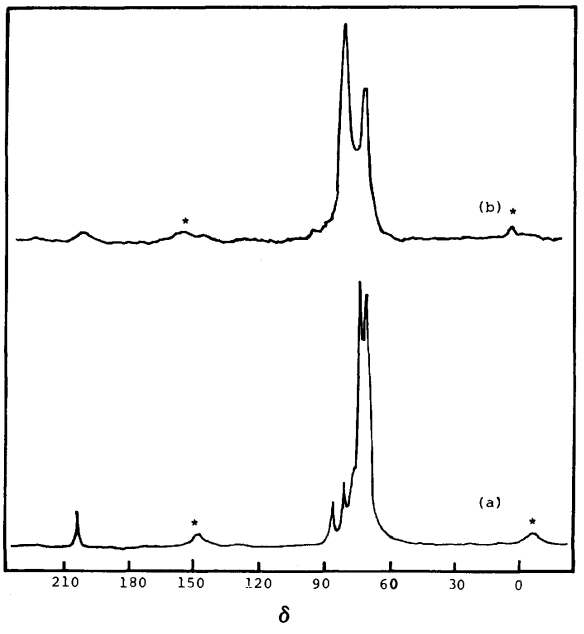

Fig. 6. ^{13}C-CP-MAS NMR spectra of ferrocenyl ruthenocenyl ketone(a) and its -3.5$HgCl_2$ adduct(b).

π-C_5H_5 ring main peaks. Two kinds of broad signals (δ=81.0 for ruthenocene and δ=72.6 for ferrocene) are found for the -3.5$HgCl_2$ adduct. The latter value is very similar to that of the original compound ($\Delta\delta$=0.9), whereas a relatively large low-field shift is observed for the former ($\Delta\delta$=8.3), its value corresponding to that of ruthenocene-3$HgCl_2$ ($\Delta\delta$=8.0). The carbonyl carbon signal appears at δ=195.2. This value is almost the same as that of the original metallocene (δ=197.9). The infrared spectrum for the original metallocene shows a strong band at 1610 cm^{-1} which can be assigned to a C=O stretching mode; this band is almost the same in position and intensity as that of the -3.5$HgCl_2$ adduct (1600 cm^{-1}). These facts indicate that there is only one kind of chemical bonding between the ruthenium and mercury atoms in the -3.5$HgCl_2$ adduct.

The absence of the chemical bonding between the iron and mercury atoms in the $HgCl_2$ adduct can be explained as follows; the steric hindrance in the ferrocene moiety makes it impossible to form a chemical bond between the iron and mercury atoms in the -3.5$HgCl_2$ adduct, whereas the ruthenocene moiety can form a chemical bond between the ruthenium and mercury atoms because it has less steric hindrance.

This work is partly supported by a Grant-in-Aid from the Ministry of Education (No. 60430014).

Effects of Methyl Substituent on Solvent Extraction of Copper(II) with *o*-, *m*-, and *p*-Methylbenzoic Acids

Hiromichi YAMADA,* Shiho HORIKAWA, Yukio FUJII, and Masateru MIZUTA
Faculty of Engineering, Gifu University, 1-1 Yanagido, Gifu 501-11
(Received August 27, 1987)

The extraction of copper(II) with *o*-, *m*-, and *p*-methylbenzoic acids in 1-octanol was carried out at 25 °C and aqueous ionic strength of 0.1 mol dm^{-3} ($NaClO_4$). In contrast to the extraction with benzoic acid, in which only the monomeric copper(II) benzoate is extracted, the dimeric copper(II) species is also responsible for the extraction of copper(II) with *o*- and *m*-methylbenzoic acids in 1-octanol together with the monomeric one. On the other hand, *p*-methylbenzoic acid has a poorer extracting capability than *o*- and *m*-methylbenzoic acids and only the monomeric copper(II) species is responsible for the extraction.

Compared with aliphatic carboxylic acids, aromatic carboxylic acids have been scarcely employed as extracting agents owing to their poor extracting capability. In the previous investigations on the extraction of copper(II) with benzoic,[1] and decanoic[2,3] acids, it has been shown that there was a remarkable difference in the extraction equilibrium between aromatic and aliphatic carboxylic acids. For example, copper(II) benzoate cannot be extracted in benzene, but can be easily extracted in 1-octanol as a monomeric species CuA_2 (A: carboxylate anion).[1] In the copper(II) decanoate extraction systems, the dimeric species $Cu_2A_4(HA)_2$ can be extracted in nonsolvating solvents such as benzene, while not only the dimeric copper(II) decanoates but also the monomeric ones are responsible for the extraction in solvating solvents[3-5] such as 1-octanol. These results suggest that the formation of the dimeric copper(II) carboxylate is essential for the extraction of copper(II) carboxylates into nonsolvating solvents such as benzene, and in solvating solvents the solvation of the monomeric copper(II) species by some solvent molecules makes possible the extraction of copper(II) without any detectable formation of the dimeric copper(II) species.

The present paper deals with the extraction of copper(II) with *o*-, *m*-, and *p*-methylbenzoic acids in 1-octanol. It was found that with *p*-methylbenzoic acid, the copper(II) ion is extracted through a mechanism different from the extraction with *o*- and *m*-methylbenzoic acids, in which the monomeric and dimeric copper(II) species are responsible for the extraction.

Experimental

Reagents. *o*-, *m*-, and *p*-Methylbenzoic Acids: Commercial methylbenzoic acids (purity: over 99%) were dissolved in 1-octanol. **Copper(II) perchlorate, sodium perchlorate, and 1-octanol** were the same as employed previously.[3] All other reagents were reagent grade and used without further purification.

Procedure. Partition was performed at a total copper concentration of 5×10^{-3} mol dm^{-3} and methylbenzoic acids concentration of 0.3—1.6 mol dm^{-3} in a bath thermostated at 25.0±0.2 °C. Ionic strength of the aqueous phase was adjusted to 0.1 mol dm^{-3} with sodium perchlorate. Shaking for about 1 h was sufficient for complete equilibration. The concentrations of copper(II) and hydrogen ions in the aqueous phase were determined by the same manner as employed previously.[1] The dissociation constants of methylbenzoic acids were potentiometrically estimated. In the determination of the partition constants of *o*-, *m*-, and *p*-methylbenzoic acids between water and 1-octanol, the absorption maxima at 279, 281, and 241 nm of the respective acids were used for the determination of the concentration of the respective acids in the aqueous phase.

Apparatus. For mechanical shaking in a thermostat, centrifugation, pH measurements, and spectrophotometric determinations, the apparatus were the same as employed previously.[1]

Results and Discussion

Partition of Methylbenzoic Acids. In the extraction of metals with carboxylic acids, it is indispensable to have information about the partition of the carboxylic acids. The following equilibria on the carboxylic acid HA should be considered: (a) The dissociation of HA in the aqueous phase ($K_a=[H^+][A^-]/[HA]$), (b) the partition of HA into the organic phase ($K_{D,HA}=[HA]_o/[HA]$), and (c) the dimerization of HA in the organic phase ($K_{2,HA}=[(HA)_2]_o/[HA]_o^2$). The dissociation constant of *o*-, *m*-, and *p*-methylbenzoic acids were potentiometrically determined at the ionic strength of 0.1 mol dm^{-3} ($NaClO_4$). The values obtained are summarized in Table 1. These values are in agreement with those already presented[6] with making activity coefficient corrections.

The partition of the respective methylbenzoic acids was carried out between 1-octanol and 0.1 mol dm^{-3} perchloric acid, in which the dissociation of the methylbenzoic acids can be neglected. The distribution ratio of methylbenzoic acids was observed to be constant, irrespective of the concentration of the acids. Then it was recognized that the dimerization of the respective acids in 1-octanol does not occur to any appreciable extent and that the distribution ratio of each acid is equal to its partition constant $K_{D,HA}$. The respective partition constants are shown in Table 1.

The partition constant obtained increases in the following order: *m*-methylbenzoic>*p*-methylbenzoic> *o*-methylbenzoic>benzoic acids. Replacement of a hydrogen atom on the aromatic ring in benzoic acid with methyl moiety results in an increase in the partition constant of the acids, as expected. From the information about three kinds of methylbenzoic acids, the concentration of monomeric methylbenzoic acids in 1-octanol can be regarded as the total concentration of the respective acids under the present experimental conditions, that is, $[HA]_o=C_{HA}$.

Extraction of Copper(II) with Methylbenzoic Acids. If a *j*-merized copper(II) methylbenzoate, $Cu_jA_{2j}(HA)_a$ is extracted, the extraction equilibrium can be represented as:

$$jCu^{2+} + (2j + a)(HA)_o \overset{K_{ex(ja)}}{\rightleftharpoons} (Cu_jA_{2j}(HA)_a)_o + 2jH^+$$

with the extraction constant:

$$K_{ex(ja)} = [Cu_jA_{2j}(HA)_a]_o[H^+]^{2j}[Cu^{2+}]^{-j}[HA]_o^{-(2j+a)} \quad (1)$$

where the subscript o refers to the organic phase.

Total concentration of copper(II) in the organic phase, $C_{Cu,o}$ is written as follows:

$$C_{Cu,o} = \sum_j \sum_a jK_{ex(ja)}[Cu^{2+}]^j[HA]_o^{(2j+a)}[H^+]^{-2j}. \quad (2)$$

Suppose that only $Cu_jA_{2j}(HA)_a$ is responsible for the extraction, the following expression can be obtained:

$$\log C_{Cu,o} = j(\log[Cu^{2+}] - 2\log[H^+]) + (2j + a)\log[HA]_o + \log j + \log K_{ex(ja)}. \quad (3)$$

Table 1. Various Constants (at 25 °C and Aqueous Ionic Strength of 0.1 mol dm^{-3})

Acid	pK_a	log $K_{D,HA}$	log $K_{ex(10)}$	log $K_{ex(20)}$	log K_{2,CuA_2}
o-Methylbenzoic	3.73	2.21	−7.84	−12.84	2.84
m-Methylbenzoic	4.09	2.41	−7.84	−13.15	2.53
p-Methylbenzoic	4.21	2.33	−7.84		
Benzoic[a)]	4.04	1.88	−7.70		

Solvent: 1-Octanol. a) Ref. 1.

According to Eq. 3, the degree of polymerization of the extracted species can be found from the slope of the plot of $\log C_{Cu,o}$ against $(\log[Cu^{2+}]-2\log[H^+])$ at constant $[HA]_o$.

The results are shown in Figs. 1 and 2. As shown in Fig. 1, the slope of the plots lies from 1.3 to 1.5 and tends to be steeper with increasing copper concentration in the organic phase. Therefore, it is expected that the monomeric and dimeric copper(II) methylbenzoates are responsible for the extraction with *o*- and *m*-methylbenzoic acids. On the other hand, the plots in Fig. 2 fall on a straight lines with a slope of 1.0. This suggests that only the monomeric copper(II) species is responsible for the extraction with *p*-methylbenzoic acid.

In the extraction of copper(II) with *o*- and *m*-methylbenzoic acids, the following relation can be derived from Eq. 2:

$$\log C_{Cu,o} - \log[Cu^{2+}] + 2\log[H^+] = \log K_{ex(1a)} + (2+a)\log[HA]_o + \log\left(1 + \frac{2K_{ex(2b)}}{K_{ex(1a)}}[HA]_o^{(2+b-a)}[Cu^{2+}][H^+]^{-2}\right) \quad (4)$$

where $K_{ex(1a)}$ and $K_{ex(2b)}$ represent the extraction constants of the monomer $CuA_2(HA)_a$ and the dimer $Cu_2A_4(HA)_b$, respectively. According to Eq. 4, by comparing the plot of $(\log C_{Cu,o}-\log[Cu^{2+}]+2\log[H^+])$ against $(\log[Cu^{2+}]-2\log[H^+])$ at constant $[HA]_o$ with the normalized curve, $\log(1+X)$ vs. $\log X$, the degree of polymerization of the extracted species can be identified. As shown in Fig. 3, the plots fit well with the normalized curve. It was proved that the monomeric and dimeric copper(II) species are responsible for the extraction with *o*- and *m*-methylbenzoic acids in 1-octanol.

In the region where the monomer prevails, that is, the whole region in Fig. 2 and the region on the straight line asymptotes with a slope of zero in Fig. 3, the following expression can be derived from Eq. 2:

$$\log C_{Cu,o} - \log[Cu^{2+}] + 2\log[H^+] = \log \sum_a (K_{ex(1a)}[HA]_o^{(2+a)}). \quad (5)$$

According to Eq. 5, the number of methylbenzoic acid molecules involved in the monomeric copper(II) methylbenzoates can be determined from the slope of the plot of $(\log C_{Cu,o}-\log[Cu^{2+}]+2\log[H^+])$ against $\log[HA]_o$. The results are illustrated in Fig. 4 for *o*-, *m*-, and *p*-methylbenzoates. The plots fall on the same straight line with a slope of 2.0 in each acid: $2+a=2$, that is, $a=0$. Then, the composition of the monomer is CuA_2, irrespective of the position of the methyl substituent. The extraction constant of CuA_2 for each acid can be obtained from the intercept of the straight line with a slope of two. The values are listed in Table 1 together with other constants. Though

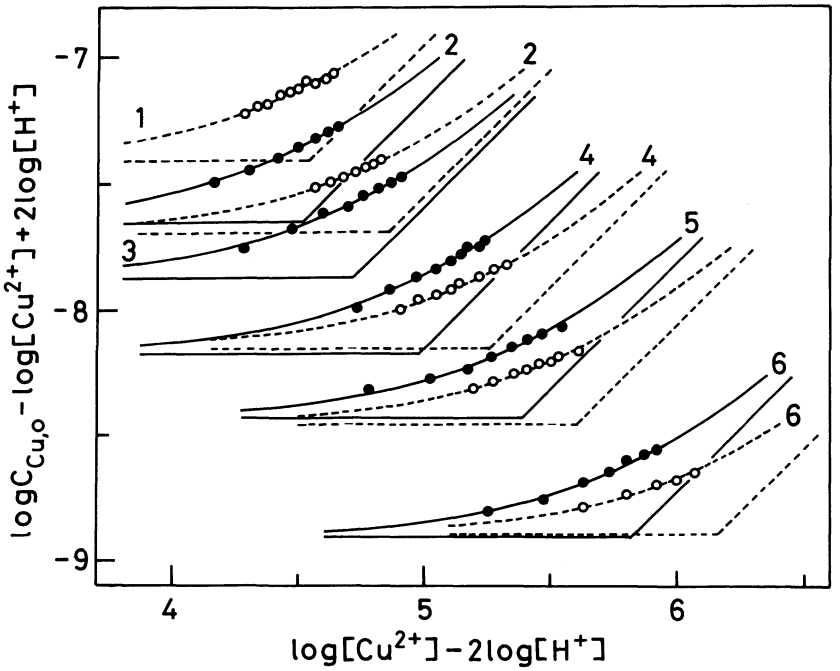

Fig. 3. The identification of the degree of polymerization of the copper(II) *o*- and *m*-methylbenzoates.
Symbols and numbers are the same as in Fig. 1. Curves are the normalized curve, $\log(1+X)$ vs. $\log X$. Straight lines are the asymptotes of the respective normalized curves.

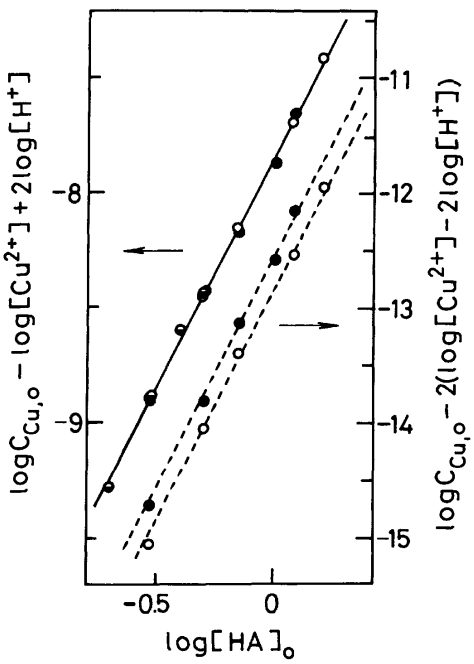

Fig. 4. Determination of the number of *o*-, *m*-, and *p*-methylbenzoic acid molecules involved in the monomeric and dimeric copper(II) species, respectively.
Solid and dotted lines are the straight lines with a slope of 2.0 and 4.0, respectively. Closed, open, and half-closed symbols refer to *o*-, *m*-, and *p*-methylbenzoic acids, respectively.

each of the three kinds of acids has a clear individuality, the same value for $K_{ex(10)}$ was obtained for each acid.

On the other hand, in the region where the predominant extracted species is the dimer, that is, the plots in Fig. 3 fit by extrapolation with the straight line asymptotes with a slope of unity, the following expression is derived from Eq. 2:

$$\log C_{Cu,o} - 2(\log[Cu^{2+}] - 2\log[H^+]) = \log 2\sum_b (K_{ex(2b)}[HA]_o^{(4+b)}). \quad (6)$$

According to Eq. 6, the number of the acid molecules involved in the dimeric copper(II) species was found to be four, as the plots of $\{\log C_{Cu,o} - 2(\log[Cu^{2+}] - 2\log[H^+])\}$ against $\log[HA]_o$ shown in Fig. 4 fell on the straight lines with a slope of 4.0 in both *o*- and *m*-methylbenzoates. The extraction constant of Cu_2A_4 can be determined from the intercept of the respective straight lines in Fig. 4. The values obtained are listed in Table 1 together with other constants.

Consequently, we conclude that the extraction equilibria for the present extraction systems are expressed as follows:

o- and *m*-methylbenzoic acids:

$$Cu^{2+} + 2(HA)_o \overset{K_{ex(10)}}{\rightleftharpoons} (CuA_2)_o + 2H^+$$

$$2Cu^{2+} + 4(HA)_o \overset{K_{ex(20)}}{\rightleftharpoons} (Cu_2A_4)_o + 4H^+,$$

p-methylbenzoic acid:

$$Cu^{2+} + 2(HA)_o \overset{K_{ex(10)}}{\rightleftharpoons} (CuA_2)_o + 2H^+.$$

Irrespective of the *o*- and *p*-orientations of the methyl group, the extraction equilibrium for copper(II) ortho-substituted benzoate coincides not with that for para-substituted one but for meta-substituted one.

In the extraction systems for *o*- and *m*-methylbenzoic acids the dimerization reaction of copper(II) species in the 1-octanol phase can be expressed as follows:

$$2(CuA_2)_o \overset{K_{2,CuA_2}}{\rightleftharpoons} (Cu_2A_4)_o,$$

where K_{2,CuA_2} refers to the dimerization constant of copper(II) *o*- and *m*-methylbenzoates, which can be calculated from the respective extraction constants. The values are summarized in Table 1. As the dimerization of copper(II) carboxylate in the organic phase in the extraction of copper(II) with a carboxylic acid results in an effect similar to the synergistic effect, substituting a hydrogen atom at the ortho- and meta-positions in benzoic acid by the methyl group can enhance the extractability of copper(II). It was found that the formation of the dimeric copper(II) species was not sterically hindered by the methyl group at the *o*-position.

The introduction of methyl substituent at the *p*-position in benzoic acid results in the decrease in the solubility of the acid in both water and 1-octanol. In this extraction system, the emulsion was observed in the region where the percent extraction of copper(II) exceeds 30%, and only the monomeric copper(II) species was responsible for the extraction under the conditions where the emulsion does not appear.

By preliminary experiments, it has been revealed that substituting a hydrogen atom at the *o*-, *m*-, and *p*-positions in benzoic acid by the methyl moiety has partially enabled the extraction of copper(II) using benzene as solvent, which was impossible in the unsubstituted benzoic acid–benzene extraction system. This is attributable to an increase in the affinity of copper(II) methylbenzoates for benzene by the introduction of the methyl substituent.

Judging from the present results, it seems reasonable to assume that the mesomeric effect of the methyl group on the conjugated system in benzoic acid has enabled the formation of the dimeric copper(II) species which was not perceived in the extraction of copper(II) with unsubstituted benzoic acid,[1] and some special function only for *p*-methylbenzoic acid will result in the fact that for *p*-methylbenzoic acid the dimerization of copper(II) species cannot be detected to any appreciable extent. This problem will be elucidated by the more detail investigations from different points of view.

The present work was partially supported by a Grant-in-Aid for Scientific Research No. 62540432 from the Ministry of Education, Science and Culture.

(Received September 1, 1987)

The Raman spectra were measured for the bis and mixed type cobalt(III) complexes with ethylenediamine-*N*-acetate (edma) in an aqueous solution in the skeletal vibration region. The Raman bands could be classified into five vibration modes; a totally symmetric stretching vibration mode in the 510—650 cm^{-1} region, a stretching vibration mode excluding the totally symmetric one in the 410—540 cm^{-1} region, a skeletal breathing vibration mode in the 370—490 cm^{-1} region, a skeletal bending deformation mode in the 270—420 cm^{-1} region, and a chelate ring deformation mode in the 220—270 cm^{-1} region. Differences in the skeletal vibrations were observed between the fac and mer isomers for the chelate ring arrangement. Further, differences for the chelate ring arrangement between the Raman spectra of sym-fac and unsym-fac isomers were observed in the skeletal bending deformation mode. The cobalt(III) complexes with the terdentate ligands containing N-methyl group exhibited Raman bands shifted to a lower frequency than those of the corresponding cobalt(III) complexes containing no N-methyl group in the totally symmetric stretching vibration mode region.

The Raman spectral criteria in the skeletal vibration region have recently been established for differentiating the geometrical isomers of several cobalt(III) complexes.[1] Further, the nitro-ammine series of cobalt(III) complexes have also been studied in order to establish the assignments of the Raman bands.[2] In previous works, the Raman spectra of $[Co(gly)_x(ox)_y(en)_z]$-type complexes[3] (gly, glycinate; ox, oxalate; and en, 1,2-ethanediamine), of tris(bidentate)cobalt(III) complexes containing six-membered chelate rings,[4] and of cobalt(III) complexes with the quadridentate ligands[5] have been investigated in order to ascertain the relation between their Raman spectra in the skeletal vibration region and the structures of these complexes. Furthermore, the $[Co(ida)_n(dien)_{2-n}]$-type complexes (ida, iminodiacetate and dien, 3-azapentane-1,5-diamine) have been established to possess clearly different Raman spectral features between the fac and mer isomers.[6]

In this work, the Raman spectra of bis and mixed type cobalt(III) complexes with an asymmetrical linear terdentate ligand, ethylenediamine-*N*-acetate (edma), are measured in order to extend the investigation of the $[Co(ida)_n(dien)_{2-n}]$-type complexes and to find more general information on the relation between the stereochemical properties and the Raman spectra of the bis(terdentate)cobalt(III) complexes. The abbreviations used for the ligands are as follows: edma, ethylenediamine-*N*-acetate ($NH_2CH_2CH_2NHCH_2COO^-$); dien, 3-azapentane-1,5-diamine ($NH_2CH_2CH_2NHCH_2CH_2NH_2$); ida, iminodiacetate ($^-OOCCH_2NHCH_2COO^-$); mdien, 3-methyl-3-azapentane-1,5-diamine ($NH_2CH_2CH_2N(CH_3)CH_2CH_2NH_2$), and mida, *N*-methyliminodiacetate ($^-OOCCH_2N(CH_3)CH_2COO^-$). The prefixes sym-fac, unsym-fac, and mer represent the chelate ring arrangements, and the fac(N_t), mer(N_t), trans(N_t), cis(N_t), cis(N_t)trans(O), cis(N_t)cis(O), fac(N), and mer(N) abbreviations represent the coordinated atom arrangements. The N_t and N_c symbols stand for the terminal and central nitrogen atoms respectively of the linear terdentate ligands.

Experimental

Complexes. The complexes were prepared and characterized according to the literature procedures: *sym-fac*-[Co(edma)(dien)]Cl_2,[7] *unsym-fac-fac*(N_t)-[Co(edma)(dien)]Cl_2,[7] *unsym-fac-mer*(N_t)-[Co(edma)(dien)]Cl_2,[7] *mer*-[Co(edma)(dien)]Cl_2,[7] *sym-fac-trans*(N_t)-[Co(edma)$_2$]Cl,[8,9] *sym-fac-cis*(N_t)-[Co(edma)$_2$]Br,[8,9] *unsym-fac-cis*(N_t)*trans*(*O*)-[Co(edma)$_2$]Cl,[8,9] *unsym-fac-cis*(N_t)*cis*(*O*)-[Co(edma)$_2$]Cl,[8,9] *unsym-fac-trans*(N_t)-[Co(edma)$_2$]Cl,[8,9] *mer*-[Co(edma)$_2$]Br,[8,9] *sym-fac*-[Co(ida)(edma)],[10] *unsym-fac-mer*(*N*)-[Co(ida)(edma)],[10] *sym-fac*-[Co(edma)(mdien)]SO_4,[7] *unsym-fac-fac*(N_t)-[Co(edma)(mdien)]Br_2,[7] *unsym-fac-mer*(N_t)-[Co(edma)(mdien)]SO_4,[7] *mer*-[Co(edma)(mdien)]SO_4,[7] *sym-fac*-[Co(ida)(mdien)]Cl,[11] *unsym-fac*-[Co(ida)(mdien)]Cl,[11] *mer*-[Co(ida)(mdien)]Cl,[11] *sym-fac*-[Co(mida)(edma)],[12] and *unsym-fac-fac*(*N*)-[Co(mida)(edma)].[12]

Measurements. The Raman spectra were recorded on a JASCO Laser Raman spectrometer, which was constructed specially with a double monochromator, model CT-25, a He-Ne laser, model NEC GLG-8500, and a data processor, model DP-500, as the main components. The sample solution was excited at 632.8 nm and the Raman spectra were calibrated with indene.

Results and Discussion

General Assignments of the Raman Spectra of [Co(edma)(dien)]$^{2+}$, [Co(edma)$_2$]$^+$, and [Co(ida)(edma)]. The possible geometrical isomers of [Co(edma)(dien)]$^{2+}$, [Co(edma)$_2$]$^+$, and [Co(ida)(edma)] are four, six, and four respectively, as is depicted in Figs. 1, 2, and 3.[7-10] The Raman spectral data in the skeletal vibration region of the isomers are summarized in

a) The following abbrevations are used: s, strong; m, medium; w, weak; vw, very weak; sh, shoulder; p, polarized; dp, depolarized; ν_{ts}, totally symmetric stretching vibration mode; ν, stretching vibration mode excluding the totally symmetric stretching character; ν_{br}, skeletal breathing vibration mode; δ_{sbd}, skeletal bending deformation mode; δ_{crd}, chelate ring deformation mode. The Raman band intensities (s, m, w, vw, and sh) are classified by a comparison of all the Raman bands among all the complexes. b) Consult the text. c) Ref. 3. d) Ref. 6.

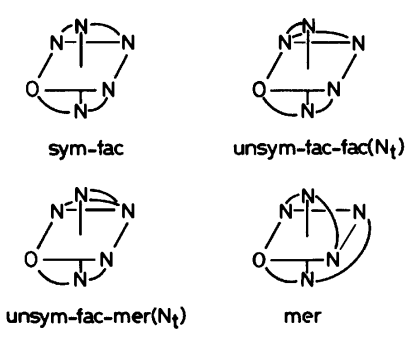

Fig. 1. Four geometrical isomers of [Co(edma)-(dien)]$^{2+}$.

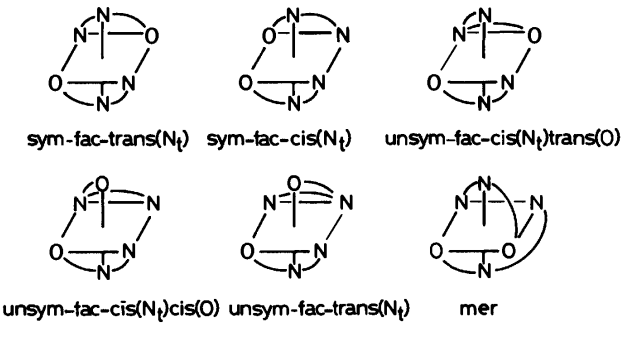

Fig. 2. Six geometrical isomers of [Co(edma)$_2$]$^+$.

Table 1, together with those of the related complexes of primary concern.

Figure 4 shows the Raman spectra of *unsym-fac-mer*(N_t)-[Co(edma)(dien)]$^{2+}$, [Co(gly)(en)$_2$]$^{2+}$, *unsym-fac-cis*(N_t)*trans*(O)-[Co(edma)$_2$]$^+$, and *trans*(O)-[Co(gly)$_2$(en)]$^+$, chosen as representative for a general spectral consideration. In a previous paper,[6] the Raman bands of *unsym-fac*-[Co(dien)$_2$]$^{3+}$ and *unsym-fac*-[Co(ida)(dien)]$^+$ have all been correlated to those of [Co(en)$_3$]$^{3+}$ and C_2-*cis*(O)-[Co(gly)$_2$(en)]$^+$ respectively except for one, which was assigned to the skeletal breathing vibration mode. The Raman bands at 547—635, 453—514, 306, and 247 cm^{-1} of *unsym-fac-mer*(N_t)-[Co(edma)(dien)]$^{2+}$ correspond to those at 521—584, 447—471, 374, and 279 cm^{-1} of [Co(gly)(en)$_2$]$^{2+}$ respectively, and the Raman bands at 570—649, 467—522, 305, and 261 cm^{-1} of *unsym-fac-cis*(N_t)*trans*(O)-[Co(edma)$_2$]$^+$ correspond to those at 523—596, 458—504, 368, and 275 cm^{-1} of *trans*(O)-[Co(gly)$_2$(en)]$^+$ respectively. Thus, a comparison of these spectra demonstrates that the cobalt(III) complexes with the edma ligand give the same spectral patterns as the tris(bidentate)cobalt(III) complexes[3] with the same donor atom arrangement, except for the Raman bands at ca. 400 cm^{-1}; this is characteristic of [Co(ida)$_n$-(dien)$_{2-n}$]-type complexes.[6] In addition, as is shown in Fig. 5, the Raman spectral patterns of *cis*(O)-[Co(edma)$_2$]$^+$ and *cis*(O)-[Co(ida)(dien)]$^+$ are similar to each other throughout the spectral regions except for the somewhat high frequency shift in the Raman bands of [Co(edma)$_2$]$^+$ in comparison with those of [Co(ida)(dien)]$^+$ and the difference in degree of the depolarization ratios of the Raman bands at ca. 500—530 cm^{-1}. On the basis of these observations and the Raman spectral characteristics summarized in Table 1, the Raman spectra of the present edma complexes can be classified into five vibration modes as in the case of the [Co(ida)$_n$(dien)$_{2-n}$]-type complexes;[6] that is, the polarized bands in the 510—650 cm^{-1} region, depolarized ones in the 410—540 cm^{-1} region, polar-

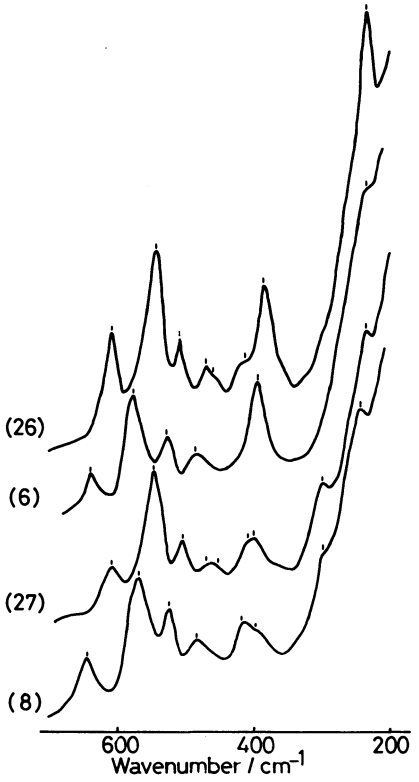

Fig. 5. Raman spectra of *sym-fac*-[Co(ida)(dien)]$^+$, *sym-fac-cis*(N_t)-[Co(edma)$_2$]$^+$, *unsym-fac*-[Co(ida)-(dien)]$^+$, and *unsym-fac-cis*(N_t)*cis*(O)-[Co(edma)$_2$]$^+$. Numbers in parentheses correspond to those in Table 1.

ized ones in the 370—490 cm^{-1} region, depolarized ones in the 270—420 cm^{-1} region, and polarized ones in the 220—270 cm^{-1} region can be assigned to the totally symmetric stretching vibration, the stretching vibration excluding the totally symmetric stretching character, the skeletal breathing vibration, the skeletal bending deformation, and the chelate ring deformation modes respectively. Furthermore, the skeletal breathing vibration mode can be regarded as the key bands for the bis(terdentate)cobalt(III) complexes with linear terdentate ligands.

Raman Spectral Characteristics of the Geometrical Isomers of [Co(edma)(dien)]$^{2+}$, [Co(edma)$_2$]$^+$, and [Co(ida)(edma)]. The *fac*- and *mer*-[Co(edma)(dien)]$^{2+}$ isomers exhibit a striking difference in the chelate ring arrangements on their Raman spectra (Fig. 6). Similar spectral behavior has also been substantiated for the *fac*- and *mer*-[Co(edma)$_2$]$^+$ isomers (Fig. 7). This spectral behavior corresponds well to that of the [Co(ida)$_n$(dien)$_{2-n}$]-type complexes.[6] That is, in the skeletal breathing vibration mode, the mer isomers exhibit sharp Raman bands at higher frequencies than the fac isomers; the Raman bands caused by the skeletal bending deformation of the mer isomers also appear at higher frequencies. Furthermore, the mer isomers have no bands in the chelate ring deformation mode region, as in the case of [Co(ida)(dien)].[6] These features can be ascribed to the difference in strain energy in the vibrational motion between the ligand of the meridional arrangement and that of the facial one. It has been reported in the previous paper[6] that the mer isomers of [Co(ida)(dien)]$^+$ and [Co(dien)$_2$]$^{3+}$ exhibit the polarized character in the stretching vibration region, while the fac isomers give depolarized Raman bands. A close inspection of the Raman frequencies, intensities, and depolarization ratios of *mer*-[Co(edma)(dien)]$^{2+}$ reveals a retention of the polarized character of the mer isomers of [Co(ida)(dien)]$^+$ and [Co(dien)$_2$]$^{3+}$. This polarized character, however, was found to be obscured in *mer*-[Co(edma)$_2$]$^+$; (an attempt at a reliable estimation of the Raman bands at 470 and 461 cm^{-1} relative to the polarized Raman bands was unsuccessful because they were too weak for their depolarization ratios to be measured precisely; rather, they were tentatively classified as depolarized ones based on the profiles of the polarized and depolarized Raman spectra in this region). The obscurity of the polarized character in *mer*-[Co(edma)$_2$]$^+$ may, in part, be attributed to the disturbance of the overall harmonic stretching vibrational motion by different terminal donor atoms and force constants.

The difference in the chelate ring arrangement between the sym-fac and unsym-fac isomers is noticeable in the skeletal bending deformation mode (Figs. 6 and 7). Each unsym-fac isomer has a

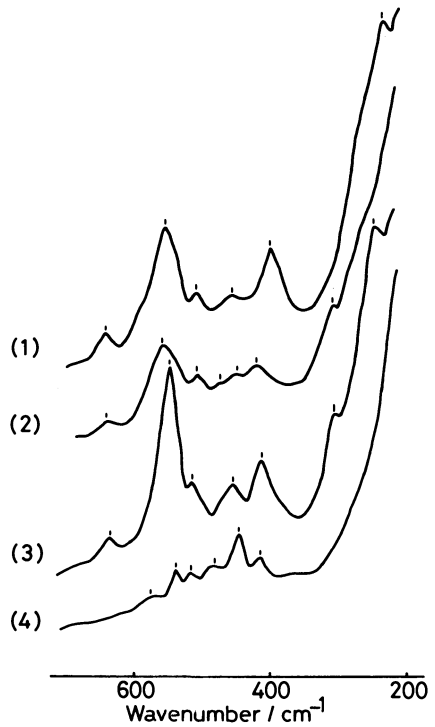

Fig. 6. Raman spectra of four geometrical isomers of [Co(edma)(dien)]$^{2+}$. Numbers in parentheses correspond to those in Table 1.

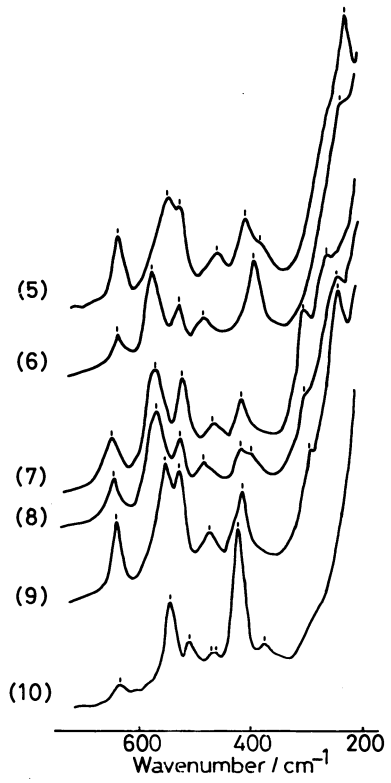

Fig. 7. Raman spectra of six geometrical isomers of [Co(edma)$_2$]$^+$. Numbers in parentheses correspond to those in Table 1.

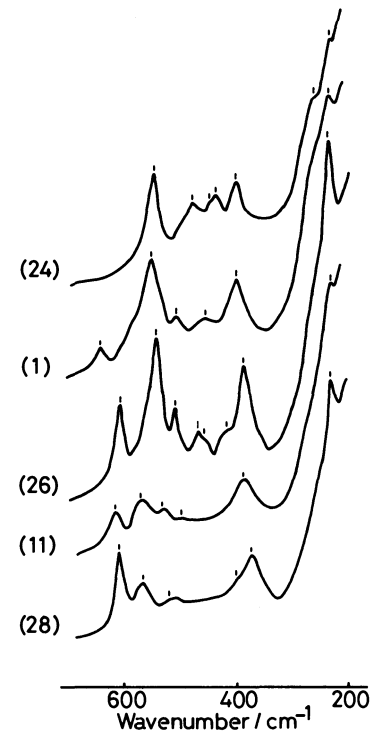

Fig. 8. Raman spectra of sym-fac isomers for chelate ring arrangement of $[Co(dien)_2]^{3+}$, $[Co(edma)(dien)]^{2+}$, $[Co(ida)(dien)]^{+}$, $[Co(ida)(edma)]$, $[Co(ida)_2]^{-}$. Numbers in parentheses correspond to those in Table 1.

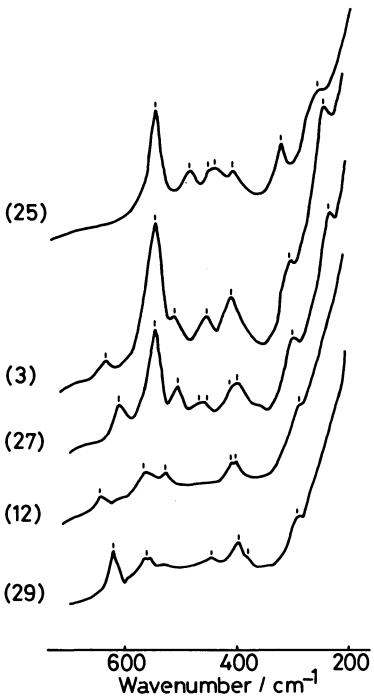

Fig. 9. Raman spectra of unsym-fac isomers for chelate ring arrangement of $[Co(dien)_2]^{3+}$, $[Co(edma)(dien)]^{2+}$, $[Co(ida)(dien)]^{+}$, $[Co(ida)(edma)]$, $[Co(ida)_2]^{-}$. Numbers in parentheses correspond to those in Table 1.

depolarized band, while the sym-fac isomers have none. This spectral feature has also been found in the $[Co(ida)_n(dien)_{2-n}]$-type complexes.[6] Furthermore, the *sym-fac-trans*(N_t)- and *unsym-fac-cis*(N_t)*cis*(O)-$[Co(edma)_2]^{+}$ with lower symmetries, C_i and C_1 respectively, give a doublet in the skeletal breathing mode, whereas *sym-fac-cis*(N_t)-, *unsym-fac-cis*(N_t)*trans*-(O)-, and *unsym-fac-trans*(N_t)-$[Co(edma)_2]^{+}$, having a higher symmetry, C_2, give only one Raman band in this region. By contrast, the Raman spectral difference between the trans(O) and cis(O) isomers of $[Co(edma)_2]^{+}$ is of no intrinsic importance. Accordingly, these findings suggest that, so far as the bis(terdentate)cobalt(III) complexes with equal numbers of coordinated nitrogen and oxygen atoms are concerned, the Raman spectral characteristics depend mainly on the arrangement of the chelate ring around the central metal atom.

Role of Coordinated Atoms on Raman Spectral Characteristics. Figures 8 and 9 show the Raman spectra of the sym-fac and unsym-fac isomers with different numbers of coordinated nitrogen and oxygen atoms. The Raman bands above 600 cm^{-1} of the sym-fac and unsym-fac isomers are intensified with an increase in the number of coordinated oxygen atoms, whereas those at ca. 460 and 550 cm^{-1} become weaker with a decrease in the number of coordinated nitrogen atoms. Accordingly, the former bands may have a largely Co–O stretching character, and the latter ones, a Co–N stretching character. Furthermore, it is observed that the number of Raman bands in the skeletal breathing mode increases with an increase in the number of coordinated oxygen atoms.

The Raman spectra of the isomers of $[Co(ida)(dien)]^{+}$ can be regarded as a superposition of those of $[Co(dien)_2]^{3+}$ and $[Co(ida)_2]^{-}$.[6] Moreover, as is shown in Fig. 5, the Raman spectra of the isomers of $[Co(edma)_2]^{+}$ can also be correlated to those of $[Co(ida)(dien)]^{+}$. It is not surprising that $[Co(edma)_2]^{+}$ can be considered to have both of the spectral features of the corresponding isomers of $[Co(dien)_2]^{3+}$ and $[Co(ida)_2]^{-}$, because the Raman spectral characteristics of the bis(terdentate)cobalt(III) complexes with equal numbers of coordinated nitrogen and oxygen atoms depend mainly on the arrangement of the chelate ring around the central metal atom.

In conclusion, the empirical rule derived from bis(terdentate)cobalt(III) complexes with symmetrical linear terdentate ligands holds also for those with asymmetrical linear terdentate ligands.

Raman Spectra of $[Co(edma)(mdien)]^{2+}$, $[Co(ida)(mdien)]^{+}$, and $[Co(mida)(edma)]$. The Raman spectra of $[Co(edma)(mdien)]^{2+}$ and $[Co(ida)(mdien)]^{+}$ are shown in Figs. 10 and 11 respectively. The Raman bands in the skeletal bending deformation mode region, which were observed on the unsym-fac isomers

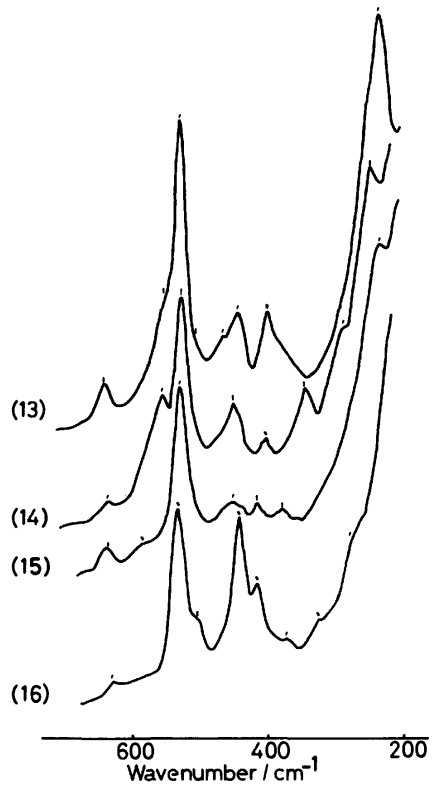

Fig. 10. Raman spectra of four geometrical isomers of [Co(edma)(mdien)]$^{2+}$. Numbers in parentheses correspond to those in Table 1.

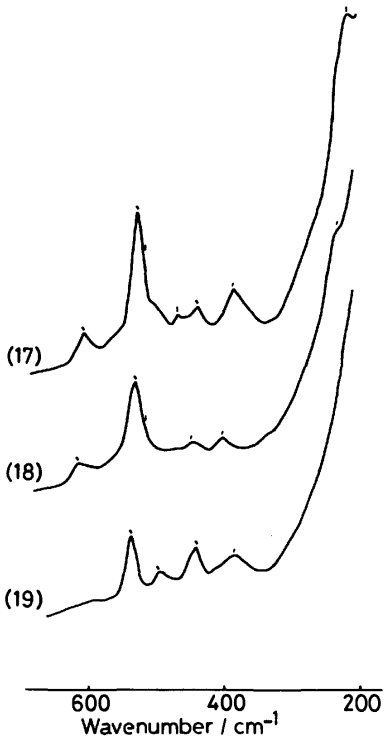

Fig. 11. Raman spectra of three geometrical isomers of [Co(ida)(mdien)]$^{+}$. Numbers in parentheses correspond to those in Table 1.

of [Co(edma)(dien)]$^{2+}$, [Co(ida)(dien)]$^{+}$, and [Co(ida)-(edma)] (Figs. 6 and 9 and Ref. 6), are no longer present in the Raman spectra of *unsym-fac-mer*(N_t)-[Co(edma)(mdien)]$^{2+}$, *unsym-fac*-[Co(ida)(mdien)]$^{+}$, and *unsym-fac-fac*(N)-[Co(mida)(edma)] (Table 1). By contrast, two Raman bands are observed in the skeletal bending deformation mode region for the unsym-fac-fac(N_t) isomer of [Co(edma)(mdien)]$^{2+}$. This may be related to the change in the O–Co–N_c angles caused by the steric interaction between the methyl group of the mdien ligand and the methylene group of the edma ligand.[7] With all these differences, the cobalt(III) complexes with the terdentate ligands, mdien and mida, exhibit Raman spectral features corresponding to those of the cobalt(III) complexes with terdentate ligands, dien, edma, and ida. Accordingly, the Raman bands of the cobalt(III) complexes containing an N-methyl group can also be classified into the five vibrational modes. Especially, the Raman bands above 600 cm^{-1}, those appearing at ca. 615 cm^{-1} for the ida complexes and at ca. 640 cm^{-1} for the edma complexes, can be used as vibrational criterion for differentiating complexes containing either ida or edma, except for [Co(ida)(edma)], which shows the Raman bands at 618 cm^{-1} characteristic of the sym-fac isomer and at 645 cm^{-1} characteristic of the unsym-fac-mer(N) isomer because of the intensification of the one at the sacrifice of the other.

The cobalt(III) complexes containing an N-methyl group also show some characteristic Raman spectral behavior. First, the strongest Raman bands attributable to the totally symmetric stretching vibration of the cobalt(III) complexes containing an N-methyl group, except for *mer*-[Co(ida)(mdien)]$^{+}$, appear at a lower frequency region compared with the Raman spectra of the corresponding cobalt(III) complexes containing no N-methyl group. This fact suggests the existence of a mass effect in the totally symmetric stretching vibration mode as a result of the replacement of a hydrogen atom on the imino nitrogen by a methyl group, similar to the isotope shifts, and/or the difference in the central metal–donor atom bond strength, which can be related to the ligand field strength. In fact, the first and the second absorption maxima shift to the lower energy side when the methyl group is introduced on the central donor atom of the terdentate ligands. However, the shift to the lower frequency region in the Raman bands of the cobalt(III) complexes containing an N-methyl group could not be found in other vibrational modes. The replacement of a hydrogen atom on the imino nitrogen by a methyl group is responsible for concomitant changes in the spectra depending on the geometrical structure of the complexes. Second, the cobalt(III) complexes with the mida ligand ([Co-(mida)(mdien)]$^{+}$,[6] [Co(mida)(edma)], and [Co(ida)-(mida)]$^{-}$[6]) exhibit several Raman bands in the

skeletal breathing vibration mode region. This feature may be correlated with the increase in the number of coordinated oxygen atoms, as in the case of the cobalt(III) complexes containing no N-methyl group. Third, the mer isomers of the cobalt(III) complexes containing an N-methyl group also exhibit spectral features appreciably different from those of the fac isomers. That is, the mer isomers have sharp Raman bands in a higher frequency region in the skeletal breathing vibration mode and have no Raman bands in the chelate ring deformation mode, except for *mer*-$[Co(mida)_2]^-$ and *mer*-[Co(mida)(mdien)]$^+$, which have two terdentate ligands containing an N-methyl group.[6] The fact that *mer*-$[Co(mida)_2]^-$ and *mer*-[Co(mida)(mdien)]$^+$ have Raman bands in the chelate ring deformation mode may be related to the high stability of these complexes; for example, *mer*-$[Co(mida)_2]^-$ has been found more stable than *mer*-[Co(ida)(mida)]$^-$ even in a weakly basic aqueous solution.[13] However, these features are in line with the general characteristics of the Raman spectra of the cobalt(III) complexes containing no N-methyl group.

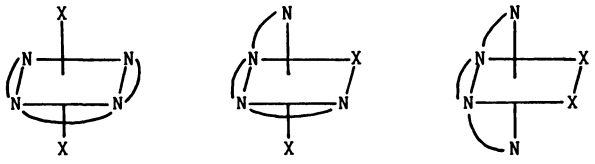
Reactions of Coordination Compounds in the Solid State. II. The Interconversion of the Isomers of Dichloro(triethylenetetramine)-cobalt(III) Chloride, $[Co(trien)Cl_2]Cl$, upon Heating in the Solid State

Terufumi FUJIWARA and John C. BAILAR, Jr.*
School of Chemical Sciences, University of Illinois, Urbana, Illinois 61801, U.S.A.
(Received July 30, 1987)

The three isomers of the ion $[Co(trien)Cl_2]^+$, where trien=triethylenetetramine, have been synthesized and their interconversion upon heating in the solid state has been studied. The trans isomer changes to the β-cis isomer, which in turn is converted to the α-cis isomer. The changes have been followed by proton NMR spectroscopy. The first change cannot be explained by a twist mechanism. Experiments with the trans monohydrate or hydrochloride in sealed tubes or in an atmosphere of HCl show that the presence of H_2O accelerates the conversion of the trans isomer to the cis-β isomer, and the presence of HCl accelerates the conversion of cis-β to cis-α, suggesting that the former conversion takes place through an aquation, followed by anation and for the latter conversion nucleophilic attack of a chloride ion on the cis-β isomer is important.

Octahedral complexes of the type $[M(trien)X_2]^+$ exist in three isomeric forms which are called trans, cis-α, and cis-β.



trans cis-β cis-α

Several investigators have studied the interconversion of the isomers of the cobalt(III) and chromium(III) compounds in which X represents Cl, but nearly all of their work has been concerned with the compounds in solution. Most notable is the work of Buckingham, Marzilli and Sargeson,[1] who made a thorough study of the cobalt(III) compounds. Even they has little to say about the behavior of these compounds in the solid, crystalline state. We have therefore made an extensive study of these isomers and their interconversion. In any case in which isomerization takes place, the trans isomer is converted to the cis-β form, which then goes more slowly to the cis-α form. The changes are not reversible, in which the cobalt(III) compounds seem to differ from their chromium(III) analogues.[2]

It has been pointed out[3] that the nature of X in $[Co(trien)X_2]^+$ makes a great difference in the relative stabilities of the isomers. Thus, if X=Cl, the order of stability in methanol is β-cis<trans<α-cis, but if X is H_2O, the order in aqueous solution is trans<α-cis<β-cis.

In addition, Asperger,[4] who studied the cobalt(III) complex of the analogous ligand, *N,N'*-bis[(*S*)-2-amino-3-phenylpropyl]-(1*R*,2*R*)-1,2-cyclohexanediamine, reported that the L-cis-β compound isomerizes to the trans compound in the solid state when heated to 110 °C. In that case, the conformation of the ring may exert an important influence.

Experimental

Preparation of Compounds. The triethylenetetramine (trien) compound, *trans*-$[Co(trien)Cl_2]Cl \cdot H_2O$, was prepared according to the published method.[1] The product was recrystallized by evaporating a saturated methanolic solution of the complex quickly in a steam of dry air to less than half of its volume. The hydrochloride of the trans form, *trans*-$[Co(trien)Cl_2]Cl \cdot 0.5HCl \cdot 2H_2O$, was prepared by recrystallizing the product from concentrated HCl, washing it with ethanol and acetone, and drying in air. The cis-isomers, *cis*-α- and *cis*-β-$[Co(trien)Cl_2]Cl$, was prepared and recrystallized as described in the literature.[3,5]

The 60—100 mesh sample of hydrochloride of the trans isomer was prepared by gently breaking larger crystals with a pestle, passing these through a 60 mesh screen, and catching the suitably sized particles on a 100 mesh screen. Samples of the finely powdered complex compounds were also prepared by grinding with a mortar and pestle. Elemental analyses of the chloride salts of the isomers are given in Table 1.

Physical Measurements. Proton magnetic resonance spectra were taken with a Varian XL-200 200-MHz FT-NMR Spectrometer fitted with a computer at the normal temperature of the probe (ca. 20 °C) and 100 transients (scanning times) were employed. Tetramethylsilane (TMS) was used as a reference standard. ^1H NMR spectra were observed in dimethyl-d_6 sulfoxide (DMSO-d_6). Although the complexes used here, especially the cis-α isomer, are sparingly soluble in DMSO, 4—5 mg of complex was dissolved in ca. 0.7 mL of solvent in the nmr tube by vigorous shaking[6] and the spectrum was recorded as soon as possible after dissolution.

Thermogravimetric analysis (TGA) was carried out with a Perkin-Elmer TGA 7 thermogravimetric analyzer. Samples weighing 4 to 6 mg, heated in a flow of He (ca. 20 mL min^{-1}) at a rate of 10° C min^{-1}, were employed.

X-Ray powder patterns were obtained using a 114.6-mm diameter camera and nickel-filtered Cu $K\alpha$ radiation. The samples used were contained in 0.7 mm glass capillaries, and exposure times ranged from 18 to 25 h.

Infrared spectra were obtained using a Perkin-Elmer 599B

Table 1. Analytical Data

Compound	Calcd/%				Found/%			
	C	H	N	Cl	C	H	N	Cl
cis-α-[Co(trien)Cl_2]Cl·1.5H_2O	21.29	6.25	16.55	31.42	21.36	6.11	16.57	31.24
cis-β-[Co(trien)Cl_2]Cl·H_2O	21.87	6.12	17.00	32.27	21.83	6.17	16.92	31.81

trans-[Co(trien)Cl_2]Cl·0.5HCl·2H_2O	19.70	6.20	15.32	33.92	19.62	6.33	15.27	33.99

Infrared Spectrophotometer. The KBr-disk method was employed for all spectral runs (1 mg of sample in 100 mg of KBr) with air in the reference beam.

Rate Studies. Kinetic studies in static air were conducted by heating solid samples of the complexes in the same way as described in our previous study,[9] using an Abderhalden drying apparatus and uncapped aluminum boats. Further, some samples were contained in glass tubes (ca. 3.5 mm in diameter, ca. 4 cm in length) which were sealed off with a torch. Water (bp 100 °C) and *N,N'*-dimethylformamide (bp 152 °C) were used in the boiler as liquids of appropriate boiling points. Kinetic runs in an atmosphere of HCl were also conducted by passing HCl gas at 100 °C into the Abderhalden apparatus, in which samples were mounted in uncapped platinum boats (11 mm in length, 4 mm in width) in place of the aluminum boats. The stream of HCl was preheated to 100 °C in another Abderhalden apparatus connected to the apparatus containing the sample. The stream of HCl was very slow, so the reaction took place in an almost static atmosphere of HCl. The 60—100 mesh and the finely powdered samples were all heated in static air. Samples of the powdered material were also heated in a sealed tube and in an HCl atmosphere. Generally, two to four of the samples (8—11 mg) were heated simultaneously. As soon as possible after taking each sample out of the heating apparatus but before the ^1H NMR measurement, the mass loss accompanying the heating was measured.

Results

NMR Studies. For *cis*-α-[Co(trien)Cl_2]Cl in DMSO-d_6, there are three peaks for the NH protons at δ 5.68, 5.76, and 6.15 with the intensity ratio 2:2:2 but the first two peaks are not separated clearly and the first absorption shows some fine structure (Fig. 1).

The cis-β isomer has six clearly separated NH absorptions of equal intensity (Fig. 2). Four of them show some fine structure with centers at δ 3.86, 4.96, 5.28, and 5.64, respectively, and the other two peaks are broad singlets at δ 7.36 and 7.77, respectively.

The trans isomer shows three NH bands (two quintets with centers at δ 5.13 and 5.58, respectively, and one singlet at δ 6.87) with the intensity ratio 2:2:2 (Fig. 3). The spectrum arising from the NH and NH_2 groups for the hydrochloride are almost identical to that for the monohydrate.

All CH_2 absorptions in these isomers appear at higher field than the NH absorptions and some fine structure, which is probably the superposition of two or more multiplets, is observed. The results in the CH region are even more complex than in the NH region;

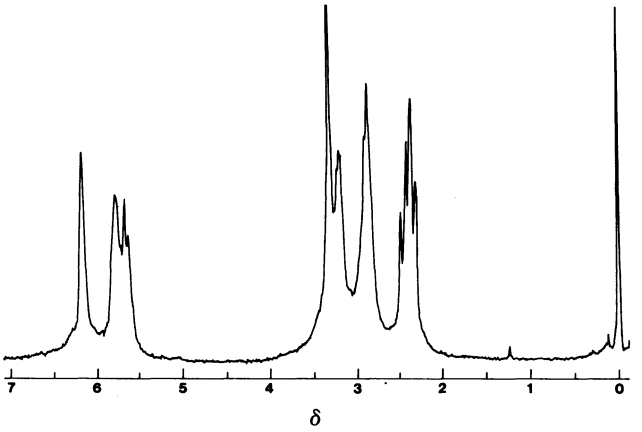

Fig. 1. ^1H NMR spectrum of *cis*-α-[Co(trien)Cl_2]Cl·1.5H_2O in DMSO-d_6.

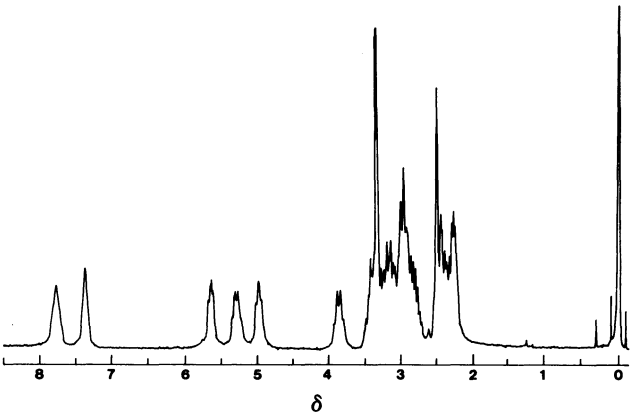

Fig. 2. ^1H NMR spectrum of *cis*-β-[Co(trien)Cl_2]Cl·H_2O in DMSO-d_6.

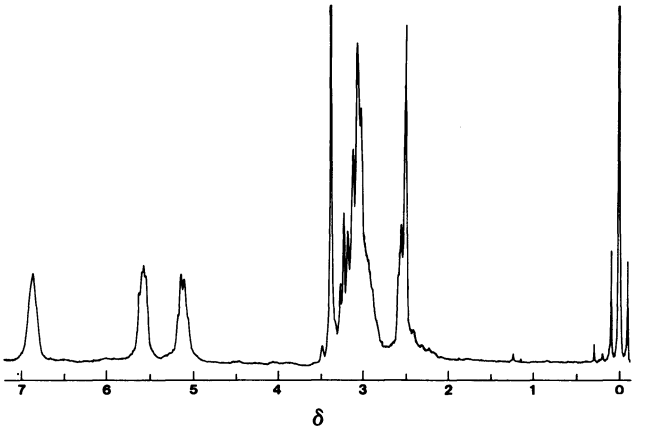

Fig. 3. ^1H NMR spectrum of *trans*-[Co(trien)Cl_2]Cl·H_2O in DMSO-d_6.

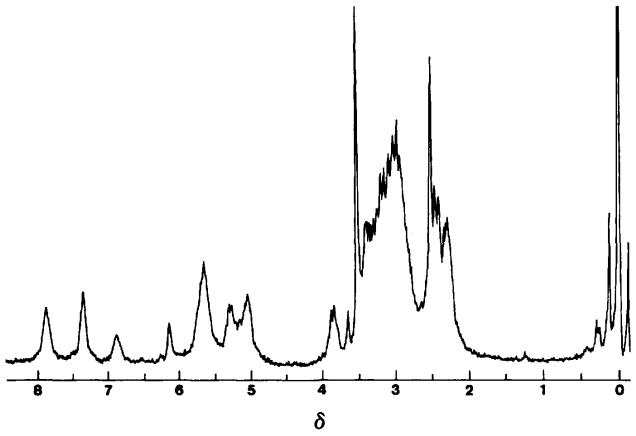

Fig. 4. ^{1}H NMR spectrum of a 60—100 mesh sample of *trans*-[Co(trien)Cl_2]Cl·0.5HCl·2H_2O in DMSO-d_6 after heating at 100 °C for 20.4 h in static air.

the spectrum of the cis-α isomer is less complex than that of the cis-β isomer, as is described in the literature[3] and the CH region in the trans isomer is more symmetrical than that in the cis-α isomer. Furthermore, the signal due to H_2O in the DMSO-d_6 solutions of the isomers and the solvent signal absorb at δ ca. 3.3[10] and 2.50, respectively, and overlap the spectra arising from the CH_2 groups for the cis isomers.

In a mixture of these isomers, overlapping of some NH signals is observed while one NH absorption at δ 6.15 for the cis-α isomer, the three at δ 3.86, 7.36, and 7.77 for the cis-β isomer, and the one at δ 6.87 for the trans isomer separate clearly from each other (for example, Fig. 4). These signals can be used to estimate the relative amounts of the cis-α, cis-β, and trans isomers if no other isomer or complex is present. However, the position of the NH resonance at the lowest field (δ 7.77) is strongly dependent upon the HCl concentration; this is due to the presence of the hydrochloride of the trans isomer. Furthermore, the H_2O peak moves downfield with increase of the HCl concentration and the shift results in overlapping of the H_2O signal with the NH signal at δ 3.86 in the spectrum of the cis-β isomer. For these reasons, only the NH absorption at δ 7.36 (one proton) in the cis-β isomer is used with the NH absorptions (two protons each) in the cis-α and trans isomers for the estimation of their relative amounts by calculating from the peak areas (or intensity ratios) of the NH protons. To check the method, samples of known composition were made and estimated by ^{1}H NMR with the calculated values to within ±3%.[11] In addition, the monohydrate of the trans isomer and the hydrochloride prepared here show the NH absorptions for the cis-β isomer with very small intensities indicating that the cis isomer is present in very small amounts (less than 4%).

TGA Studies. TGA runs on the hydrated chlorides of the cis-α, cis-β, and trans isomers show that dehydration starts soon after heating is begun (at about 30—35 °C). Anhydrous weight levels are attained at 110—120 °C for the cis-α isomer and at 130—140 °C for the cis-β and trans isomers. As the temperature is raised further, no loss of weight is observed until there is a slow loss due to decomposition at 215—230 °C for all of the isomers. The TGA curve for the hydrochloride of the trans isomer shows that the loss of HCl and H_2O takes place at the same time at 90—100 °C. This mass loss is complete at 150—160 °C, and a subsequent slow loss of weight resulting from the decomposition of the complex occurs at 220—230 °C. Similar single-step loss of HCl and H_2O has been reported for the hydrochloride salts of the chloride complexes, *trans*-[Co(en)$_2Cl_2$]Cl·HCl·2H_2O and *trans*-[Co(pn)Cl_2]Cl·HCl·2H_2O, which contain the $H_5O_2^+$ ion.[13]

Rate Studies. Heating *trans*-[Co(trien)Cl_2]Cl·0.5HCl·2H_2O to 100 °C yields a mixture of the cis-α, cis-β, and trans isomers as evidenced by comparisons of infrared[14] and ^{1}H NMR spectra; for example, Fig. 4 shows an ^{1}H NMR spectrum of the 60—100 mesh sample of the trans isomer which was heated at 100 °C for 20.4 h in static air (the product is 16% cis-α, 68% cis-β, and 16% trans). The data for the relative amounts of the isomers formed as a function of time, together with the data for % weight of the remaining material are shown in Fig. 5 for the isomerization of the 60—100 mesh and the finely powdered samples of the trans isomer by heating at 100 °C in static air. A rapid initial rate of isomerization of the trans isomer, mainly to the cis-β is observed. Similar behavior has been observed for the solid state racemization of several tris chelated complexes:[15-17] $K_3[Cr(C_2O_4)_3]$, $[Co(en)_3]X_3 \cdot nH_2O$, $[M(phen)_3]X_2$ (M=Fe, Ni), $[Co(phen)_3]X_3$, and $[Co(phen)_2en]X_3$. During this initial period, a very rapid loss of weight also occurs. Subsequently, the trans isomer isomerizes more slowly to a mixture of the cis-α and β isomers; the mass loss is also very slow. Nearly complete isomerization is observed after about 45 h, at which time dehydration-dehydrochlorination of the samples is almost complete. However, there is still slow conversion of the cis-β isomer to the cis-α isomer. The 60—100 mesh sample, after heating at 100 °C for 5.32 h, does not pass through the 100 mesh screen, indicating that no change in particle size of the sample occurs during the dehydration-dehydrochlorination.

Figure 5 shows that the 60—100 mesh and the finely powdered samples isomerize at considerably different rates. The initial isomerization of the powdered samples is slower than that of the 60—100 mesh samples. After this initial period, the powdered samples show only a slightly lower rate of isomerization. This behavior is contrary to the observation that the rate of isomerization of *trans*-[Co(pn)$_2Cl_2$](H_5O_2)-

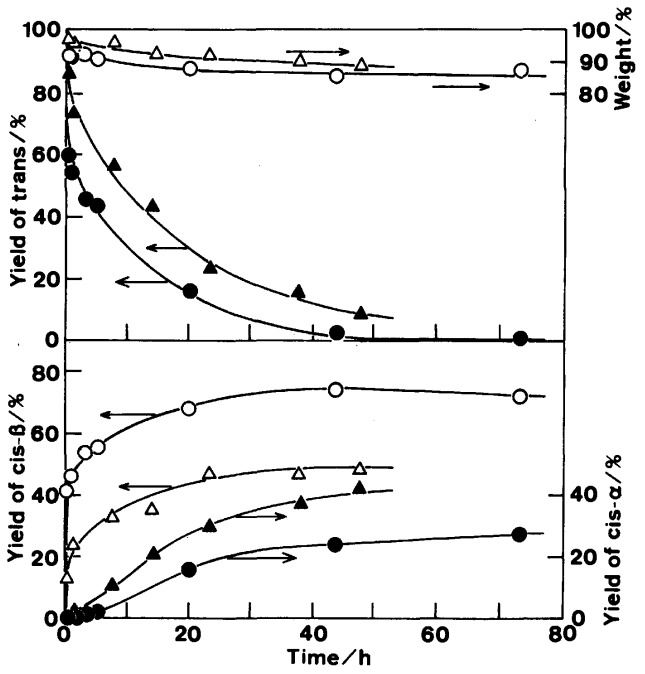

Fig. 5. Isomerization at 100 °C of 60—100 mesh (○, ●) and powdered (△, ▲) samples of *trans*-[Co(trien)-Cl_2]Cl·0.5HCl·2H_2O in static air, with about 10% weight of material remaining.

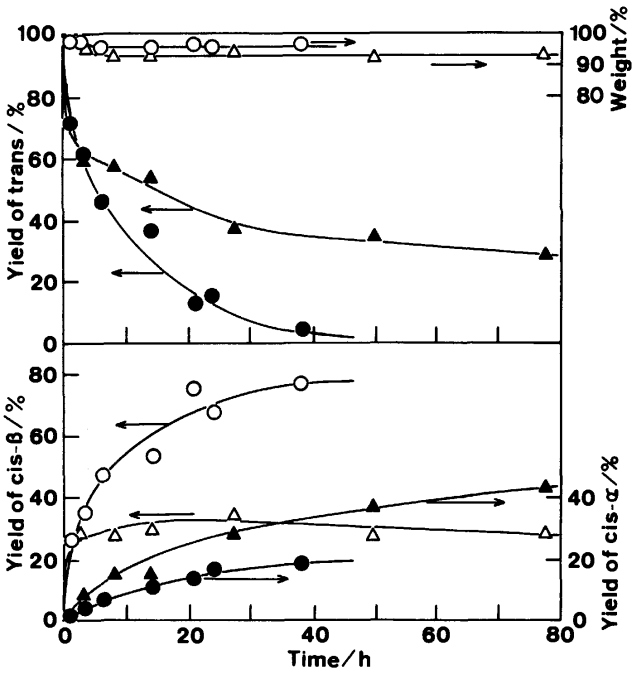

Fig. 6. Isomerization at 100 °C of powdered samples of *trans*-[Co(trien)Cl_2]Cl·H_2O in static air (○, ●) and *trans*-[Co(trien)Cl_2]Cl·0.5HCl·2H_2O in an atmosphere of HCl (△, ▲), with about 6% weight of material remaining.

Cl_2 increases as particle size is reduced.[18] On the other hand, for the solid-state racemization of [Co(en)$_3$]X_3, it was reported that there is little difference between the 20—40 and 200—325 mesh samples.[16] However, a higher rate of conversion to the cis-α isomer is observed for the powdered samples and apparent cessation of conversion to the cis-β isomer occurs (after about 25 h) prior to complete isomerization of the trans isomer; the extent of loss in weight for the powdered samples is smaller than that for the 60—100 mesh samples.

Heating the powdered samples of the trans isomer at 152 °C results in almost complete isomerization and dehydration-dehydrochlorination during the initial period; the product is a mixture of 42% cis-α, 57% cis-β, and 1% trans isomers. Thereafter, there is only slight conversion of the cis-β isomer into the cis-α isomer (less than 4% after about one day).

Although the trans hydrochloride undergoes no isomerization on standing at room temperature, even after one year, powdered samples of the trans monohydrate, *trans*-[Co(trien)Cl_2]Cl·H_2O,[19] (no hydrogen chloride of "crystallization") give 88% cis-β (12% trans) after three months and 95% cis-β (5% trans) after five months; neither product contains the cis-α isomer. This is similar to the reported conversion of the solid monohydrate into pure *cis*-β-[Co(trien)Cl_2]-Cl by heating at 90 °C.[1] However, Fig. 6 shows that heating powdered samples of the monohydrate at 100 °C results in isomerization to a mixture of the cis-α and β isomers, although the product is mainly the cis-β isomer; for example, 77% cis-β, 18% cis-α, and 5% trans after 38.2 h. The powdered monohydrate samples show a higher rate of isomerization than those containing HCl but the rate of conversion to the cis-α isomer is lower, and during this reaction the dehydration is not complete.

Table 2. Isomerization of *trans*- and *cis*-β-Dichlorotriethylenetetramine Complexes in Sealed Tubes at 100 °C

When powdered samples of trans hydrochloride are heated at 100° in an atmosphere of HCl, they isomerize more slowly than when heated in air (Fig. 6). After the initial period, conversion to the cis-β isomer seems to stop while the rate of conversion to the cis-α isomer is almost the same as that in air. Thus, there is a larger amount of the cis-α isomer than of the cis-β isomer in the reaction mixtures after about 30 h. Cessation of mass loss is also observed prior to complete dehydration-dehydrochlorination after the initial mass loss.

When the chlorides of the cis-α and β are heated to 100 °C in air or in HCl, there is no observable isomerization. When kept at 152 °C for 30 h, no significant isomerization occurs, other than a very small (less than 4%) conversion of the β chloride to its α isomer. This is rather surprising in view of the report that the trans chloride is prepared by heating the moist cis isomer to 180 °C.[20] When the chlorides are heated to 152 °C for a long time they develop a greenish cast. This appears after about 30 h. This may be due to some reduction of the cobalt to the +2 state,[1] for the ^{1}H NMR and infrared spectra do not show the presence of any of the green trans isomer. These results for the *cis*-dichloro cobalt(III) complexes are very different from those reported for the dichloro chromium(III) complex, which shows a reversible cis-$\beta \rightleftarrows$cis-α isomerization on heating to 70—285 °C.[2]

Runs in sealed glass tubes show that the powdered hydrochloride samples of the trans isomer isomerize completely to the cis-β isomer on heating within 30 min at 100 °C (Table 2). After the initial rapid conversion to the cis-β isomer, subsequent conversion to the cis-α isomer occurs at a lower rate and then, apparently, the reaction stops, when the mixture is 47% cis-α and 53% cis-β.

On the other hand, under similar conditions, two samples of the cis-β isomer containing no HCl, one of which had been made by rearrangement of the trans isomer at room temperature (5 months) and the other by crystallizing from solution, were converted more slowly to cis-α form than samples which contained HCl. The sample prepared by crystallization isomerized more slowly than the one prepared from the trans isomer. Heating the samples of the cis-β isomer at 152 °C in sealed tubes for 1.10 h gives a mixture of 2% cis-α and 98% cis-β isomers, but heating the cis-α isomer for 2.02 h gives no observable conversion.

X-Ray Studies. The main reflections from the X-ray powder photographs of samples of a series of the $[Co(trien)Cl_2]Cl$ complexes are given in Table 3. As samples of the hydrochloride of the trans isomer are isomerized along with dehydration–dehydrochlorination, great changes occur in the X-ray powder patterns, indicating that the crystal structure undergoes a change during the reaction. Similar behavior has been reported for the solid-state racemization of *l-cis*-$[Cr(en)_2Cl_2]Cl \cdot H_2O$, which occurs only during dehydration;[21] this is in contrast to the observation that the powder patterns taken before and after dehydration for (+)-$[Co(en)_3]X_3 \cdot H_2O$ (X=I^- and Br^-) are different, while heating the anhydrous complexes caused partial racemization but no changes in the powder patterns.[16] When the trans monohydrate isomerized at room temperature without dehydration, changes were evident in the powder patterns, suggesting that in this case, the crystal change seems to parallel isomerization. The products which form when the trans monohydrate is allowed to stand at room temperature for five months (almost pure cis-β isomer) and by heating the trans hydrochloride in a sealed tube at 100 °C for 0.5 h have almost the same crystal structure as a sample of the cis-β isomer crystallized from solution, as shown in Table 3. However, they isomerize at different rates.

Discussion

One can imagine several ways in which the

$[Co(trien)Cl_2]^+$ ion can isomerize, chief of which are (1) a twist mechanism, (2) a dissociation mechanism, in which the metal momentarily has a coordination number of five, and (3) an associative mechanism, in which the coordination number is seven. Twist mechanisms have been discussed for the isomerization of the complex of a tetradentate ligand.[22] The tetragonal (Rây-Dutt) twist[23] is not applicable to rearrangements of compounds of this type. The trigonal (Bailar) twist[24] and the rhombic (Springer-Sievers) twist[25] do not allow the trans isomer to isomerize to the cis-β isomer but lead to the α-isomer. Therefore, these twist mechanisms can be ruled out for the conversion of the trans isomer to the cis-β isomer. On the other hand, the cis-β isomer can be formed by a dissociation mechanism, with one of the primary nitrogen atoms moving to a position originally occupied by a chloro group in the trans isomer. In the solid state, such a dissociation mechanism seems to be a particularly unfavorable one since there is no possibility of solvation, either of the complex or of the freed amino group which would moderate the large energy required for the charge separation in the transition state caused by the bond breaking. In this study, the presence of water and/or HCl is found to be important to the conversion of the trans isomer to the cis-β isomer. This occurs during dehydration, is accelerated in sealed tubes, and is retarded in an atmosphere of HCl; these observations parallel dehydration and/or dehydrochlorination behavior. This behavior of the trans isomer can be explained by an aquation-anation pathway as proposed for the solid-state racemization of *l-cis*-$[Cr(en)_2Cl_2]Cl \cdot H_2O$[21] and the solid-state isomerization of *trans*-$[Co(pn)_2Cl_2](H_5O_2)Cl_2$.[18] It has been reported that in aqueous solution the trans isomer aquates stereospecifically to the cis-β-$[Co(trien)ClOH_2]^{2+}$ ion.[8] Assuming that the cis-β-chloroaqua complex is formed as an intermediate, it is also supposed that the rate-determining step is the first reaction in the following scheme:

$$\textit{trans}\text{-}[Co(trien)Cl_2]^+ \underset{-Cl^-}{\overset{+H_2O}{\longrightarrow}} \textit{cis}\text{-}\beta\text{-}[Co(trien)ClOH_2]^{2+}$$

$$\underset{-H_2O}{\overset{+Cl^-}{\longrightarrow}} \textit{cis}\text{-}\beta\text{-}[Co(trien)Cl_2]^+$$

in which in the presence of HCl the activity of H_2O is diminished by protonation and the dissociation of the Co–Cl bond is unfavorable.

Conversion of the trans isomer to the cis-α isomer by a twist (Bailar or Springer-Sievers) mechanism is unlikely, for heating the trans isomer in a sealed tube causes the immediate formation of the pure cis-β isomer; the subsequent conversion of the cis-β isomer to the cis-α isomer occurs slowly.

Runs in an atmosphere of HCl or in sealed tubes show that the conversion of the cis-β isomer to the cis-α isomer is accelerated by the presence of HCl, in direct contradiction to the conversion of the trans isomer into the cis-β isomer, and heating the hydrochloride in open boats yields larger amounts of the cis-α isomer compared with the monohydrate. However, there is little influence of a water molecule on the reaction. The effect of HCl cannot be understood on the basis of a twist mechanism. For the isomerization of *cis*-$[Co(trien)X_2]^+$, a pathway involving a "back-side attack" on the cis isomers by an incoming group has been postulated.[12] The isomerization pathway may explain the conversion behavior of the cis-β isomer if it is assumed that the chloride ion plays the role of a base as an incoming group,[26] although the "back-side attack" on the cis-β isomer will give equal amounts of the trans and cis-α isomers, and so the following reaction scheme may be assumed:

$$\textit{trans}\text{-}[Co(trien)Cl_2]Cl \underset{k_{-1}}{\overset{k_1}{\rightleftharpoons}} \textit{cis}\text{-}\beta\text{-}[Co(trien)Cl_2]Cl$$

$$\xrightarrow{k_2} \textit{cis}\text{-}\alpha\text{-}[Co(trien)Cl_2]Cl$$

where $k_1 > k_2 \simeq k_{-1}$.

It is found that as particle size is reduced, the rate of isomerization of the trans hydrochloride decreases and the rate of dehydration-dehydrochlorination also decreases while the conversion of the resultant cis-β isomer to the cis-α isomer increases (Fig. 5). An explanation of this by the process proposed here is reasonable if it is assumed that the rate of dehydrochlorination decreases more than that of dehydration as particle size is reduced. This follows from the fact that the presence of HCl causes a decrease in k_1 (conversion of the trans isomer) but an increase in k_2 (conversion of the cis-β isomer). Moreover, it has been reported that the *cis*-α-$[Co(trien)Cl(H_2O)]Cl_2 \cdot H_2O$ complex in the solid state dehydrates completely to the *cis*-α-$[Co(trien)Cl_2]Cl$ complex with retention of configuration,[27] suggesting that the cis-α form is the stable one.

The importance of lattice defects in determining the rate of racemization of some tris complexes in the solid state has been discussed;[16,17] the complex ions near a defect experience enhanced reactivity.[28] We found that the two substances, one of which is the almost pure cis-β isomer formed when the trans monohydrate is allowed to stand at room temperature for five months, and another, which is the cis-β monohydrate crystallized from solution, have almost the same lattices as evidenced by the X-ray powder patterns but isomerize at different rates in sealed tubes. This result may be explained by a difference in number of defects in the solid.

The work described in this paper was done under the sponsorship of the Petroleum Research Fund, administered by the American Chemical Society, for which the authors express their gratitude.

Reactions of Coordination Compounds in the Solid State. III. The Behavior of the Isomers of Dichloro(triethylenetetramine)cobalt(III) Bromide and Iodide, [Co(trien)Cl_2]X

Terufumi FUJIWARA and John C. BAILAR, Jr.*
School of Chemical Sciences, University of Illinois, Urbana, Illinois 61801, U.S.A.
(Received July 30, 1987)

The rearrangement of the isomers of dichloro(triethylenetetramine)cobalt(III) bromide and iodide upon heating in the solid state has been studied in relation to the corresponding isomers of the chloride. The behavior of the bromide and iodide has been found to be different from that of the chloride, supporting the existence of anion effects in the solid-state reactions. With respect to the nature of the anions, several factors which are responsible for the differences are discussed in relation to mechanism.

In the second paper of this series, the rearrangement of the geometrical isomers of dichloro(triethylenetetramine)cobalt(III) chloride was considered.[1] It has been found that the anion plays an important role in these isomerizations, and that the dichloro bromide and dichloro iodide do not behave in the same way as the chloride. These differences are described here. It is not yet clear whether these differences arise from differences in the crystal lattices, from charge transfer effects, from differences in hydrogen bonding of the hydrates or from some other cause. We hope to clarify this point in later communications. Here we record only the observed differences in behavior, with preliminary comments on possible causes.

Experimental

Preparation of Compounds. The bromide salts of the triethylenetetramine (trien) compound, *trans*-[Co(trien)Cl_2]Br·0.5HBr·2H_2O, *cis*-α-[Co(trien)Cl_2]Br, and *cis*-β-[Co(trien)Cl_2]Br·H_2O, were prepared by grinding a slurry of the solids of the corresponding chloride salts[1] in a mortar with concentrated HBr (twice) followed by filtration, washing with ethanol and acetone, and drying in air. The crystalline bromide salt of the trans isomer was identified as the dihydrate by a coulometric determination of lattice water with a Hiranuma AQ-3 Aquacounter and a Karl Fischer reagent in which the bromide salt was dissolved.

The cis-β complex was resolved by the method given by Sargeson and Searle.[2] The optically active salt, (−)$_D$-sodium bis(oxalato)(ethylenediamine)cobaltate, prepared following the improved procedure of Worrell,[3] was used as the resolving agent for the cis-β isomer and the optically active product was obtained as the iodide. A DMSO solution of (+)$_D$-*cis*-β-[Co(trien)Cl_2]I·0.5H_2O (3.02 mg in 25 ml) gave α_D +0.046, whence $[\alpha]_D$=+190. The optically active cis-β isomer has a CD curve similar to the curve for the corresponding cis isomer.[4] Elemental analyses of the bromide and iodide salts of the isomers are given in Table 1.

Physical Measurements. Proton magnetic resonance measurements were made as before[1] on a Varian XL-200 200-MHz FT-NMR Spectrometer operating at the normal temperature of the probe (ca. 20 °C). All spectra were run in dimethyl-d_6 sulfoxide (DMSO-d_6) solutions (ca. 0.5—0.6 wt% complex),[5] as described previously,[1] as soon as possible after dissolution and chemical shifts were measured relative to tetramethylsilane as a reference standard.

Optical rotations were measured in a 2-dm tube with a Rudolph Research Autopol III Automatic Polarimeter using a sodium lamp. CD curves were measured on a JASCO Model J-40/J-41 Automatic Recording Spectropolarimeter in a 1-cm cell. DMSO was used as solvent for the polarimetric measurements.[6] Thermogravimetric analysis (TGA) was obtained as before[1] but by using a Sinku-Riko Model TGD-3000-RH thermogravimetric analyzer and a flow of N_2 (ca. 40 ml min^{-1}).

Rate Studies. Powdered samples (8—11 mg) of the

complex salts used here were mounted in uncapped aluminum boats and were heated in an Abderhalden apparatus containing water (bp 100 °C) or *N,N*-dimethylformamide (bp 152 °C) as a liquid of appropriate boiling point in the same way as described in our previous studies.[1,7] Also samples of the optically active iodide were heated at 100 °C in glass tubes (ca. 3.5 mm in diameter, ca. 4 cm in length) which were sealed off with a torch.

Before the ^{1}H NMR and/or polarimetric measurements, the mass loss accompanying the heating was measured as soon as possible after removing the samples from the heating apparatus at fixed times. For the CD measurements, samples of the optically active cis isomer were weighed (4—5 mg) into a 5 mL volumetric flask, dissolved in DMSO by vigorous shaking, and diluted to volume.

Results and Discussion

The ^{1}H NMR spectra of the bromide and iodide of the cis-α isomer are similar to that of the chloride, for which there are three peaks for the NH protons with the intensity ratio 2:2:2 (Figs. 1 and 2). One of the NH absorptions, which shows fine structure, appears slightly downfield (a triplet at δ 5.70 for the bromide and a quintet with center at δ 5.75 for the iodide) while the other two peaks shift upfield (at δ 5.58 and 5.94 for the bromide and at δ 5.53 and 5.89 for the iodide, respectively). In the bromide and iodide of the cis-β isomer, four of the six NH absorptions of equal intensity appear at positions similar to those of the corresponding NH absorptions in the chloride (Figs. 3 and 4); three quintets with centers at δ 3.94, 5.32, and 5.60, respectively, and one singlet at δ 7.40 for the bromide, and the three quintets with centers at δ 3.95, 5.32, and 5.58, respectively, and one singlet at δ 7.43 for the iodide). On the other hand, the other two absorptions shift upfield; one quintet with the center at δ 4.34 and one singlet at δ 6.75, for the bromide and the quintet centered at δ 4.08 and the singlet at δ 6.26 for the iodide. An ^{1}H NMR spectrum arising from the NH and NH_2 groups for the hydrobromide of the trans bromide is almost identical to that for the corresponding chloride monohydrate, which shows three NH bands (two quintets with centers at δ 5.13 and 5.58, respectively, and one singlet at δ 6.87) with the intensity ratio 2:2:2 (Fig. 5).

All CH_2 absorptions in these isomers appear at higher field than the NH absorptions and show some fine structure, which is probably the superposition of two or more multiplets, as well as those for the

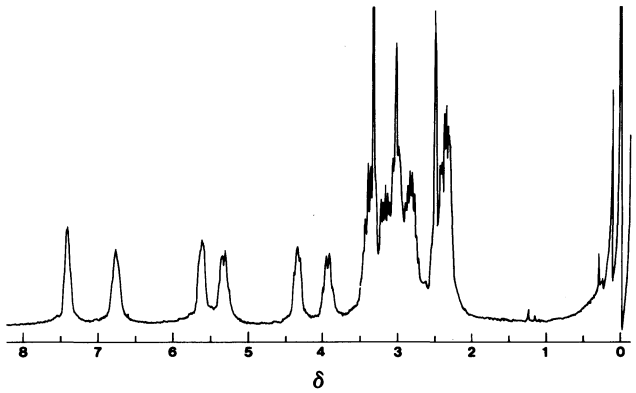

Fig. 3. ^{1}H NMR spectrum of *cis*-β-[Co(trien)Cl_2]Br·H_2O in DMSO-d_6.

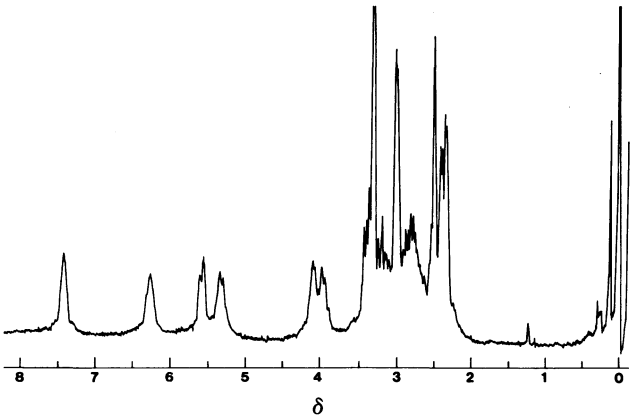

Fig. 4. ^{1}H NMR spectrum of *cis*-β-[Co(trien)Cl_2]I·$0.5H_2O$ in DMSO-d_6.

corresponding cis-α, cis-β, and trans chlorides.[1] Furthermore, the signal due to H_2O (mainly as an impurity) in the DMSO-d_6 solutions of the isomers and the solvent signal overlap the spectra arising from the CH_2 groups for the cis isomers as observed for DMSO-d_6 solutions of the chlorides.[1] For the estimation of the relative amounts of the cis-α, cis-β, and trans isomers for a mixture of them (or a product) by calculation of the peak areas (or intensity ratios) of the NH protons, the NH absorptions at δ 7.40, 5.94, and 6.87 for the bromides of the cis-β, cis-α, and trans isomers, respectively, can be used.[1]

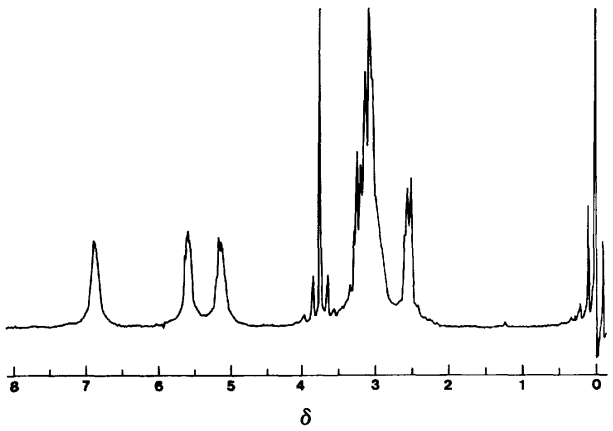

Fig. 5. ^{1}H NMR spectrum of *trans*-[Co(trien)Cl_2]Br·0.5HBr·2H_2O in DMSO-d_6.

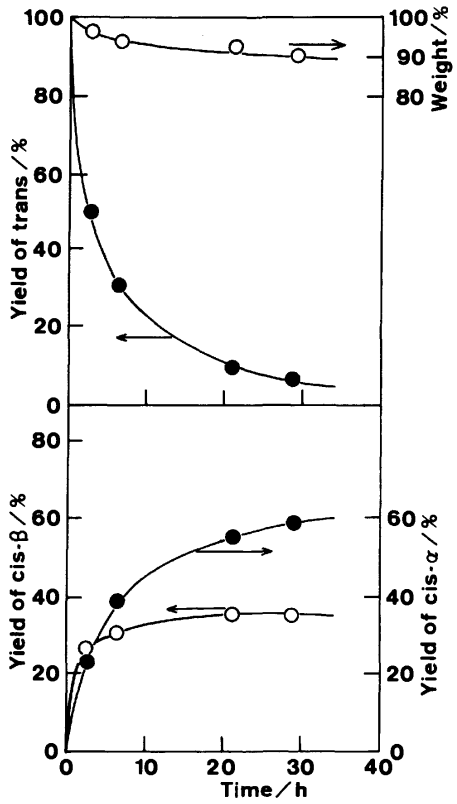

Fig. 6. Isomerization at 100 °C of powdered samples of *trans*-[Co(trien)Cl_2]Br·0.5HBr·2H_2O in static air, with %weight of material remaining.

In a previous study,[1] we found that heating the green chloride salt, *trans*-[Co(trien)Cl_2]Cl·0.5HCl·2H_2O, to 100 °C yields a mixture of the cis-α, cis-β, and trans isomers. In any case in which isomerization takes place, the trans isomer is converted to the cis-β form, which then goes more slowly to the cis-α form. Similarly, finely powdered samples of the trans hydrobromide, *trans*-[Co(trien)Cl_2]Br·0.5HBr·2H_2O, are isomerized to a mixture of the cis-α and -β isomers when heated at 100 °C in air (Fig. 6). Also, a TGA curve for the trans hydrobromide is similar to the curve for the trans hydrochloride.[1] There is a single-step loss of HBr and H_2O at 85—95 °C and the mass loss is complete at 150—160 °C. A subsequent slow loss of weight due to decomposition occurs at 230—240 °C.

The conversion of the trans isomer to the cis-β isomer cannot be expected by the Rây-Dutt,[10] Bailar,[11] or Springer-Sievers[12] twists, as discussed in previous papers.[1,13] Moreover, the green crystals of the dibromo bromide, *trans*-[Co(trien)Br_2]Br·HCl, show no isomerization during drying overnight at 90 °C or dehydrochlorination at 110 °C for two days.[14] The difference between the dichloro and dibromo complexes indicates that the rate of isomerization may be affected strongly by the Co–X bond strength. In the reaction mixtures, two new NH absorptions for the cis-α isomer appear at δ 5.88 and 6.08 in addition to the NH absorption at δ 5.98 which is similar to that of the bromide, *cis*-α-[Co(trien)Cl_2]Br. When the bromide of the cis-α isomer is prepared by the method described above, the ^{1}H NMR spectrum of the product has similar NH absorptions if the chlorobromo complex, *cis*-α-[Co(trien)ClBr]Br, is present as a byproduct. These indicate that the *cis*-α-[Co(trien)ClBr]$^+$ ion is formed as one of the products when the *trans*-[Co(trien)Cl_2]Br·0.5HBr·2H_2O is heated; such a ligand substitution cannot be expected by a twist mechanism. The conversion behavior of the trans bromide to the cis-β and the subsequent conversion of the cis-β bromide to the cis-α, as well as those of the corresponding trans and cis-β chlorides,[1] respectively, can be explained by an aquation-anation pathway[15] and a pathway involving a "back-side attack" on the cis isomer by an incoming group,[16] respectively.

The nature of the counterion and/or the HX is also important, as shown by the fact that the rate of isomerization for the hydrobromide is higher than for the hydrochloride but the rate of mass loss caused by dehydration-dehydrobromination is lower (dehydration-dehydrobromination is not complete, which was confirmed by a TGA run on the trans hydrobromide at a constant temperature of 100 °C). For example, a powder sample of *trans*-[Co(trien)Cl_2]Cl·0.5HCl·2H_2O,

on heating to 100°C, yields 49% cis-β and 42% cis-α in 48 h, whereas the corresponding bromide, *trans*-[Co(trien)Cl_2]Br·0.5HBr·$2H_2O$, upon heating for only 29.4 h, yields 35% cis-β and 58% cis-α (after about 3 h, there is more cis-α isomer in the mixture than cis-β). Similar effects appear in reactions of the solid-state racemization of $(+)_D$-[Co(en)$_3$]$X_3 \cdot nH_2O$[17] and thermal decomposition of [Co(NH_3)$_6$]X_3 in the solid state.[18] In the case of $(+)_D$-[Co(en)$_3$]X_3, the iodide was found to racemize the most readily, the bromide somewhat less so, and the chloride, hardly at all and it was presumed that hydrogen bonding of the type N-H···X is responsible for the rate differences in the series. In the case of [Co(NH_3)$_6$]X_3, the rate of decomposition decreases in the order of anions $I^- > Br^- > Cl^-$ and it was considered that electron transfer from an outer-sphere anion to the central cobalt(III) ion plays a role in forming the thermally less stable cobalt(II) complex. It may be that both factors are responsible for the above difference in the rate of conversion between the chloride and bromide of the trans or cis-β isomer of the trien complex studied here but it is not clear whether the rate differences arise from charge transfer effects or from differences in hydrogen bonding. The anion effects on the conversion of the trans and cis-β isomers may also be explainable in terms of a defect-diffusion mechanism proposed for solid-state reactions of coordination compounds by House.[19] For the conversion, the process involving anation would require that the anion leave a lattice site and migrate to the complex ion to form a transition state, which would involve the vacating of an anion site with the formation of a Schottky type defect (Fig. 2 of Ref. 19), and the activation energy required by the process would be expected to increase with increasing lattice energy. Since for a given cation the lattice energy would increase as the size of the anion decreases, it is reasonable that the chloride should have a higher lattice energy and so a higher activation energy than the bromide.

On the other hand, when the bromides of the cis-α and β are heated to 100 °C in air there is no observable isomerization. When the α or β bromides are kept at 152 °C for 30 h, no significant isomerization occurs, while a very small (less than 4%) conversion of the β chloride to its α isomer is observed in a previous study.[1] The optically active iodide $(+)_D$-*cis*-β-[Co(trien)Cl_2]I·0.5H_2O does not undergo significant racemization or isomerization upon heating in an open boat at 152 °C for 22.8 h or even in a sealed tube at 100 °C for 237 h whereas the cis-β chloride in a sealed tube at 100 °C is converted to cis-α form (11% after 70.4 h in Table 2 of Ref. 1), although TGA runs on the iodide and chloride of the cis-β isomer show that the iodide decomposes at a lower temperature (190—200 °C) than the chloride (215—230 °C[1]). A similar trend in anion effects on the conversion of the cis-β isomer to the cis-α isomer is observed for the solid-state racemization of [M(phen)$_3$]X_2 (M=Fe, Ni) and [Co(phen)$_3$]X_3,[20] where the rate differences would be attributed to a nucleophilic interaction of the counterions with the central metal: the donor ability of the chloride ion is larger than that of the bromide or iodide ion. On the other hand, these effects "opposite" to the above ones observed for the hydrobromide and hydrochloride salts of the trans isomer suggest that the rearrangements depend to a large extent on the packing of ions in the crystal, rather than upon any specific chemical property.

The work described in this paper was done under the sponsorship of the Petroleum Research Fund, administered by the American Chemical Society, for which the authors express their gratitude.

Synthesis and Reactions of Selenoketones

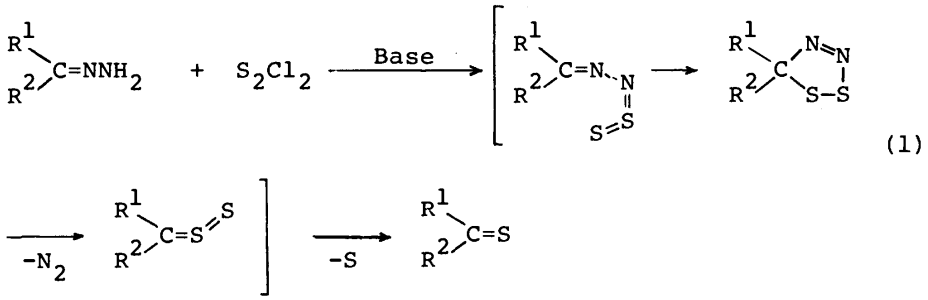
Akihiko Ishii, Renji Okazaki,* and Naoki Inamoto
Department of Chemistry, Faculty of Science, The University of Tokyo,
Hongo, Tokyo 113
(Received June 23, 1987)

A new, convenient method for the synthesis of selenoketones has been reported. The reaction of dimagnesium salts of ketone hydrazones with diselenium dichloride affords an intermediate tentatively assigned as tetraselenides, which are converted into selenoketones by heating in the presence of tributylamine. A comparative study on the reactions of 1,1,3,3-tetramethyl-2-indanselone and the corresponding thioketone with Grignard and organolithium reagents have been carried out. Analysis of the reaction products has revealed that the heterophilic attack of the organometallic reagents is much more significant in the reaction with the selone than with the thione.

Organoselenium chemistry is of current interest[1] and considerable attention has been paid to the chemistry of selenoketones in recent years. They have been used as synthetic intermediates for hindered olefins[2] and their physical properties have been studied rather extensively.[3] Until our preliminary communication in 1983,[4] however, there had been known only two synthetic routes to these compounds, i.e., 1) the reaction of triphenylphosphoranylidenehydrazones with selenium metal above their melting points developed by Barton and his co-workers[2a] and 2) the reaction of ketones with bis(tricyclohexyltin) selenide in the presence of boron trichloride.[5] At almost the same time as with our communication, Guziec, Jr. and Moustakis reported the synthesis of selenoketones by the reaction of hydrazones with diselenium dibromide.[6] As for the reactions of selenoketones, some interesting examples have been reported,[2a,7] but the reactions with Grignard and organolithium reagents have not been reported. This is in contrast with thioketones because considerable attention has been paid in recent years to their reactions with organometallics which show unique heterophilic nature.[8] The purpose of this paper is to describe a full account of the synthesis of selenoketones and their reactions with organometallics.[9]

Results and Discussion

Synthesis of Selenoketones. 1) Method A. We previously reported the method for preparation of thioketones from the corresponding hydrazones and disulfur dichloride (Eq. 1).[10]



(1)

We became interested in whether this method would be applicable to selenoketone synthesis by using diselenium dichloride (Se_2Cl_2) instead of disulfur dichloride.

Optimization of the reaction conditions were carried out by using the reaction of di-*t*-butyl ketone hydrazone (**1**) with diselenium dichloride and the results are shown in Table 1. The maximum yield of di-*t*-butyl selenoketone (**2**) (28%) was obtained in benzene at 60 °C in the presence of 4-dimethylaminopyridine as tertiary base (Run 6).

Table 1. Reaction Conditions and Yields for Method A[a]

Run	Base(equiv)	Temp °C	Yield of 2 %
1	Et_3N(3.6)	5	7
2	DABCO[b](5.0)	5	11
3	*n*-Bu_3N(5.0)	5	17
4	DMAP[c](5.0)	5	21
5	DMAP(5.0)	r.t.	24
6	DMAP(5.0)	60	28
7	DMAP(5.0)	refl.	0

a) All reactions were carried out in benzene. b) 1,4-Diazabicyclo[2.2.2]octane. c) 4-Dimethylaminopyridine.

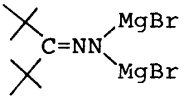
Table 2. Yields of Selenoketones by Methods A and B

Run	Selenoketone	Yield/%	
		Method A	Method B
1	$(t\text{-Bu})_2C{=}Se$ (**2**)	28	51(58)[a]
2	 (**3**)	31	82
3		7	24
4	$(1\text{-Ad})_2C{=}Se$	24	53
5	$(1\text{-Ad})(t\text{-Bu})C{=}Se$		43
6		3	35
7		14	18

a) A yield obtained by the simultaneous addition method. b) 1-Ad denotes 1-adamantyl.

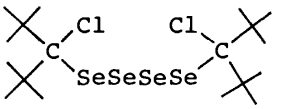
Under these optimized conditions some other selenoketones were synthesized and the results are summarized in Table 2. The yields of selenoketones by this method (Method A) are uniformly rather poor with a maximum (31%) for 1,1,3,3-tetramethyl-2-indanselone (**3**).

2) Method B. Since the yields by Method A were not satisfactory, we next attempted activation of hydrazones. Hydrazone **1** was converted to dimagnesium salt **4** by the reaction with 2 equiv of ethylmagnesium bromide in THF at 60 °C. After exchanging the solvent from THF to benzene, **4** was

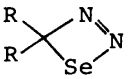


4

reacted with Se_2Cl_2 at room temperature in the presence of n-Bu_3N and the reaction solution was allowed to warm to 60 °C. Under these conditions selenoketone **2** was obtained in a 51% yield. The yields of other selenoketones were also increased (Table 2). If the reaction proceeds via a similar mechanism depicted in Eq. 1 for thioketones, a tertiary amine, tributylamine in this case, should be unnecessary. In the absence of tributylamine, however, only an orange material was obtained without formation of any selenoketone. This orange material, though stable during aqueous workup, was thermally not very stable and could not survive the chromatographic purification on silica gel, alumina, or Florisil undergoing decomposition with deposition of selenium. Although the instability did not permit further purification of this compound, its elemental analysis suggested the composition of $C_9H_{18}ClSe_2$. The ^1H NMR spectrum showed only one peak due to the t-butyl group at δ 1.4 and ^{77}Se NMR spectrum showed two peaks at 702 and 785 with almost comparable intensity along with some small peaks. On the basis of these data, the structure of the orange material is tentatively assigned as tetraselenide **5**, which would be converted into selenoketone **2** by treatment with tributylamine. Indeed, **2** was formed when a benzene solution of **5** was treated with tributylamine at 60 °C (60% yield based on **5**) or heated in vacuo (63% yield based on **5**). In contrast to this result it is interesting that Guziec, Jr. and Moustakis reported that 4*H*-1,2,3-selenadiazete **6** was an intermediate in the reaction of a



5



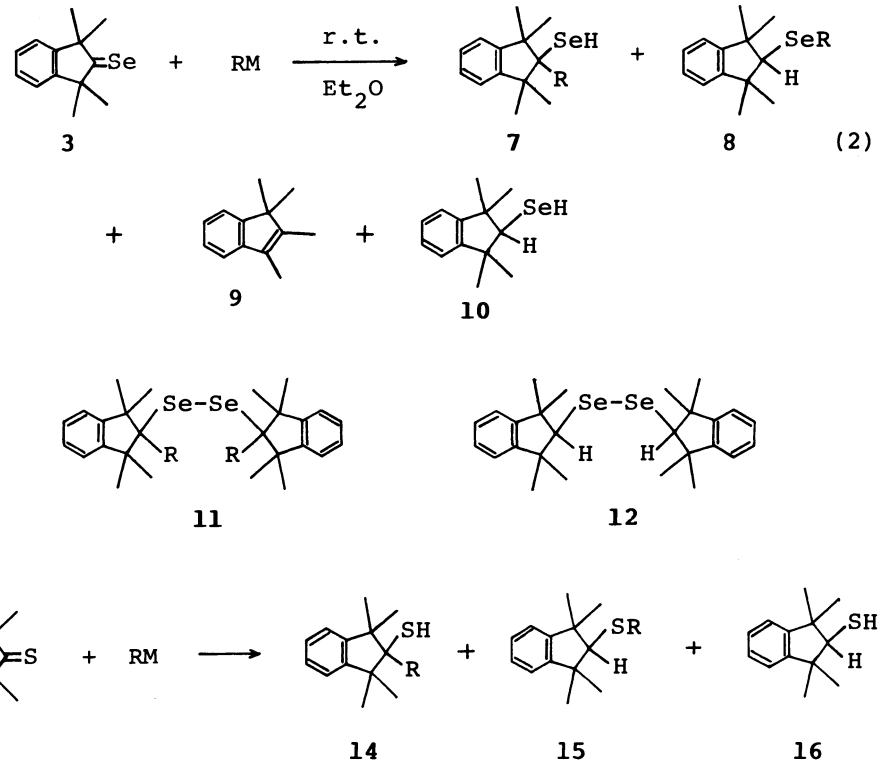
6

hydrazone and diselenium dibromide.[6] The formation mechanism of **5** is not clear at present. The formation of **5** was similarly observed in other selenoketone syntheses. Although the reactions of tributylamine with the tetraselenide were sometimes incomplete, selenoketones could be obtained by pyrolysis of the tetraselenide in vacuo in such cases.

The present method has some interesting features: (1) It provides selenoketones in a one-pot reaction unlike the Barton's method which requires isolation of the phosphoranylidenehydrazones. (2) Since the reaction is conducted under homogeneous conditions, there are none of the problems in a small scale synthesis encountered in the Barton's method where the reaction is conducted under heterogeneous conditions.[2a] (3) When two benzene solutions of dimagnesium salts of hydrazones and diselenium dichloride are added simultaneously and dropwise to a benzene solution of tributylamine, the yield is somewhat improved (Table 2, Run 1).

Reactions of 1,1,3,3-Tetramethyl-2-indanelone (3) with Grignard and Organolithium Reagents. Selenoketone **3** was selected for this investigation because **3** was obtained in a high yield and easily crystallized.

The reactions were carried out in ether at room temperature and four types of products **7**—**10** were isolated (Eq. 2). As **7** and **10** were easily oxidized to the corresponding diselenides in the air, their yields were determined after the conversion to diselenides **11** and **12**, respectively.



3 7 8 (2)

9 10

11 12

13 14 15 16 (3)

In order to compare the reactivity of the seleno- and thioketones, the reactions of the corresponding thioketone **13** with some organolithium reagents were also carried out under similar conditions (Eq. 3) to afford **14**—**16**. The results of these reactions are also shown in Table 3.

The products are classified as follows: (A) carbophilic addition products, **7** and **14**; (B) heterophilic addition products, **8**, **15**, and **9**; (C) reduction products, **10** and **16**. The results shown in Table 3 indicate that the reactions of organometallic reagents with selenoketone **3** are very unique in that the heterophilic nature is much more significant than those with thioketone **13**. Thus both selenophilic and carbophilic products were formed in the reaction of methyllithium with **3** whereas only the carbophilic product was formed for **13** (Run 1). The reaction of

Table 3. Reactions of **3** or **13** with Grignard or Organolithium Reagents

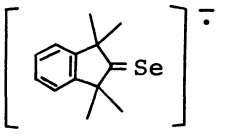
a) The yield was determined after the conversion to the corresponding diselenide.

t-butyllithium with **3** (Run 3) gave some selenophilic product **8**, while **13** did not afford any thiophilic product. In the reaction with phenyllithium (Run 6) the preference of the heterophilic attack is even more obvious; the selenophilic product **8** was the sole product from **3** whereas the carbophilic product **14** was a main product from **13**. At the present time we do not have a definite answer to the question why the heterophilic nature is larger in the reaction of the selenoketone than in that of the thioketone. One possible explanation, however, is that the spin density in an intermediary anion radical (see below) is larger on selenium than on carbon.

Other interesting features are the formation of the reduction product **10** and 1,1,2,3-tetramethyl-1*H*-indene (**9**). It has been reported[8] that the reaction between thioketones and organometallic reagents bearing a β-hydrogen gave the reduction product. This has been explained in terms of the hydrogen abstraction of the anion radical formed by single electron transfer (SET) from the organometallic reagent to the thioketone. In the present reactions the reduction product **10** is obtained only in the reactions with *t*-BuLi and *t*-BuMgCl. This suggests that these reactions begin with a SET process giving anion radical I, which would abstract a hydrogen from a

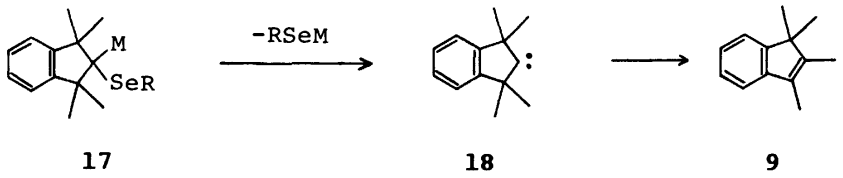


I

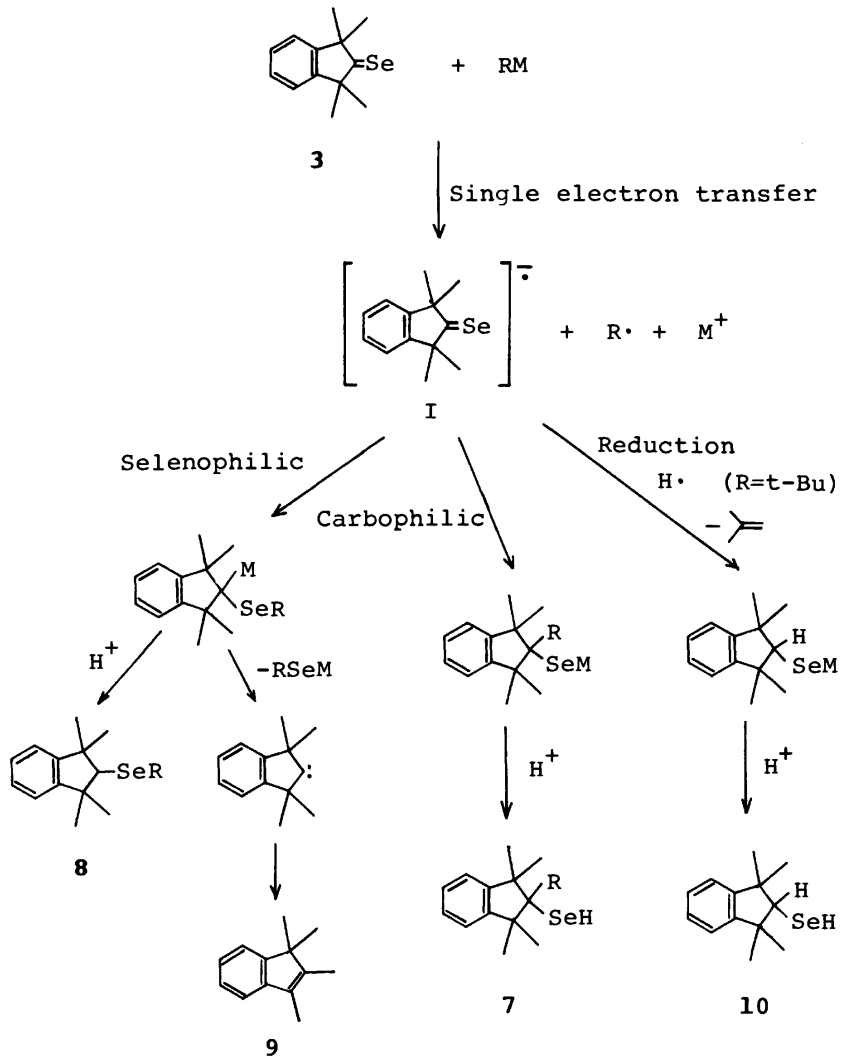
t-butyl radical to yield **10** (after protonation) and 2-methylpropene. Reactions with other Grignard and organolithium reagents also probably proceed via a SET process.

The formation of 1,1,2,3-tetramethyl-1*H*-indene (**9**) can be accounted for as shown in Scheme 1. Thus RSeM is eliminated from initially formed selenophilic adduct **17** to give carbene **18**, which then rearranges to **9**. There are some precedents of such carbene-forming reactions for sulfur-stabilized carbanions.[11] This type of elimination is known to occur when both a thioketone and an organometallic reagent are bulky and hence the cleavage of the intermediate is sterically accelerated and when the intermediate has a good leaving group. The present reactions of **3** with *t*-BuMgCl and PhMgBr meet these conditions: **3** is sterically crowded and the leaving group is either bulky (i.e., *t*-BuSe$^-$) or easily cleaved (i.e., PhSe$^-$). This type of carbene-forming reaction is, to our knowledge, the first example for selenoketones, although we recently reported a similar reaction between *O*-alkyl selenoformates and 2,4,6-tri-*t*-butylphenyllithium.[12]

The whole mechanistic scheme is shown in Scheme 2.



Scheme 1.



Scheme 2.

Experimental

Melting points are uncorrected. ^1H(89.60 MHz) and ^{13}C(22.53 MHz) NMR spectra were measured in $CDCl_3$ with a JEOL FX-90Q spectrometer using tetramethylsilane as an internal standard. ^{77}Se NMR spectra were recorded at 17.09 MHz with a JEOL FX-90Q spectrometer, whose chemical shifts were measured in $CDCl_3$ with dimethyl selenide as an external standard. Infrared spectra were recorded on a Hitachi 260-30 infrared spectrometer. Ultraviolet and visible spectra were taken on a Hitachi 343 recording spectrophotometer. Mass and high-resolution mass spectra were obtained with a JEOL D-300 mass spectrometer. All reactions were carried out under an argon atmosphere.

Materials. Diselenium dichloride (Se_2Cl_2),[13] di-*t*-butyl ketone,[14] di-1-adamantyl ketone,[14] and 1-adamantyl *t*-butyl ketone hydrazones[14] were prepared by the reported method. The hydrazones of 1,1,3,3-tetramethyl-2-indanone, fenchone, 2,2,6,6-tetramethylcyclohexanone, and 2,2,5,5-tetramethylcyclopentanone were prepared from the corresponding ketones by the method of Barton.[15]

Syntheses of Selenoketones. General Procedure. 1) Method A. To 4-dimethylaminopyridine (5 mmol) in benzene (7 ml), preheated at 60 °C, were added simultaneously a hydrazone (1 mmol) in benzene (7 ml) and Se_2Cl_2 (1.5 mmol) in benzene (7 ml) at about the same rate by using two dropping funnels during 25 min. After stirring for 4 h at this temperature were added water and ether. Red-brown precipitates were removed by filtration and the yellow-green filtrate was washed with water and dried over anhydrous $MgSO_4$. The solvent was removed under reduced pressure. Selenoketones in the residue were purified by silica-gel chromatography (hexane).

2) Method B. A THF (5 ml) solution of hydrazone (1 mmol) was added dropwise to ethylmagnesium bromide (2 mmol) in THF (5 ml) at 60 °C. The reaction occurred with evolution of ethane. After stirring for 1 h at this temperature, THF was removed under reduced pressure and benzene (80 ml) and tributylamine (1 mmol) were added. To this solution was added Se_2Cl_2 (1.2 mmol) in benzene (20 ml) at 5 °C during 20 min. Then the mixture was stirred at 60 °C for 3 h. After addition of water, the green-blue solution was washed with 2M HCl (1M=1 mol dm^{-3}) and water and dried over anhydrous $MgSO_4$. The residue obtained after the removal of the solvent under reduced pressure was heated at ca. 130 °C in vacuo (0.05 mmHg) (1 mmHg=133.322 Pa) in an apparatus with a cold trap. Crude selenoketones were purified by silica-gel chromatography (hexane). The yields of selenoketones by Methods A and B are listed in Table 1.

Di-*t*-butyl selenoketone,[3b,16] 1,1,3,3-tetramethyl-2-indanselone,[3b,7c] selenofenchone,[3b,16] and 2,2,5,5-tetramethylcyclopentaneselone[6] were identified by comparison of the chemical shifts of their ^1H and ^{13}C NMR spectra with their reported values.

Di-1-adamantyl Selenoketone: Blue crystals: mp 161—162 °C (hexane). ^1H NMR δ=1.61—1.81 (m, 12H), 1.92—2.21 (m, 6H), 2.21—2.42 (m, 12H); ^{13}C NMR δ=29.3, 36.6, 43.6, 63.7, 293.9 (C=Se, $^1J_{^{13}C-^{77}Se}$=209.0 Hz); ^{77}Se NMR δ=2134. IR(KBr) 2910, 2855, 1640, 1540, 1452, 1366, 1345, 1308, 1264, 1189, 1125, 1105, 1092, 1025, 1005, 982, 920, 825, 810, 736, 706, 670, 626 cm^{-1}. UV-VIS (cyclohexane) λ_{max} 712 nm (ε=23.7), 279 (6830), 239 (3990). Found: *m/z* 362.1511. Calcd for $C_{21}H_{30}{}^{80}Se$: M, 362.1513.

1-Adamantyl *t*-Butyl Selenoketone: Blue crystals; mp 39—41 °C (hexane). ^1H NMR δ=1.53 (s, 9H), 1.61—1.78 (m, 6H), 1.95—2.19 (m, 3H), 2.19—2.35 (m, 6H); ^{13}C NMR δ=29.2, 32.6, 36.6, 43.7, 60.4, 63.1, 292.9 (C=Se, $^1J_{^{13}C-^{77}Se}$=210.9 Hz); ^{77}Se NMR δ=2120. IR(KBr) 2900, 2845, 1636, 1535, 1472, 1444, 1392, 1358, 1342, 1308, 1258, 1216, 1180, 1118, 1096, 1046, 1028, 998, 946, 925, 818, 778, 715, 656, 634 cm^{-1}. UV-VIS (cyclohexane) λ_{max} 708 nm (ε=23.7), 274 (6920), 234 (3200). MS *m/z* 284(M^+), 227, 135 (base). Found: *m/z* 284.1064. Calcd for $C_{15}H_{24}{}^{80}Se$: M, 284.1043.

2,2,6,6-Tetramethylcyclohexaneselone: Blue liquid. ^1H NMR δ=1.41 (s, 12H), 1.81 (s, 6H);[6] ^{13}C NMR δ=18.3, 33.5, 38.4, 58.8, 294.4 (C=Se)[3d]; ^{77}Se NMR δ=2026 (lit,[3d] δ=2034); IR (neat) 3000, 2975, 2945, 2875, 1468, 1388, 1368, 1180, 1140, 1102, 1070, 1038, 1012, 990, 980, 952, 940, 882, 862, 778, 740, 668 cm^{-1}.[6] UV-VIS (cyclohexane) λ_{max} 686 nm (ε=24.3), 273 (6230), 227 (2300).[3d] Found: *m/z* 218.0582. Calcd for $C_{10}H_{18}{}^{80}Se$: M, 218.0572.

Reaction of Di-*t*-butyl Ketone Hydrazone (1) with Se_2Cl_2 in the Absence of Tributylamine. (a) Hydrazone **1** (63.0 mg, 0.403 mmol) was converted to bis(bromomagnesio)hydrazone **4** by Method B. This salt dissolved in benzene (6 ml) and Se_2Cl_2 (110 mg, 0.48 mmol) in benzene (6 ml) were simultaneously added to benzene (30 ml) at room temperature. The mixture was stirred at room temperature for 1 h. Water was added and the organic layer was washed with water and dried over anhydrous $MgSO_4$. The evaporation of the solvent gave an orange oil (88 mg), whose ^1H NMR spectrum showed a peak at δ 1.4 and the absense of di-*t*-butyl selenoketone. This orange oil was dissolved in benzene (40 ml) and tributylamine (0.12 g, 0.63 mmol) was added. After the resulting solution was stirred at 60 °C for 5 h, water was added. The organic layer was washed with 2M HCl and water and dried over anhydrous $MgSO_4$. From the residue obtained after the removal of the solvent, di-*t*-butyl selenoketone (24.8 mg, 30% based on the hydrazone) was collected in a cold trap in vacuo. (b) Hydrazone **1** (148 mg, 0.948 mmol) was converted to bis(bromomagnesio)hydrazone as described in Method B. This salt in benzene (5 ml) and Se_2Cl_2 (260 mg, 1.14 mmol) in benzene (5 ml) was simultaneously added to benzene (10 ml) at room temperature. The mixture was stirred for 1 h at room temperature and for 1 h at 60 °C. The organic layer was washed with water and dried over anhydrous $MgSO_4$ and the solvent was removed under reduced pressure. The resulting orange oil (272 mg), whose ^1H NMR spectrum showed a peak at δ 1.4, was pyrolyzed (ca. 100—200 °C) in vacuo and di-*t*-butyl selenoketone (79 mg, 38% based on hydrazone used) was collected in a cold trap. (c) Hydrazone **1** (316 mg, 2.02 mmol) in benzene (10 ml) and Se_2Cl_2(555 mg, 2.42 mmol) in benzene (10 ml) was simultaneously added to triethylamine (489 mg, 4.84 mmol) in benzene (20 ml) at room temperature. After water was added, the organic layer was washed with water and dried over anhydrous $MgSO_4$. The solvent was removed under reduced pressure and then volatile materials were removed completely in vacuo. ^{77}Se NMR spectrum of the residual orange oil showed mainly two comparable peaks at δ 702 and 785. Its elemental analysis was as follows: C, 34.59; H, 6.01; Cl, 9.55; N, 1.09%. These data suggested the composition

$C_9H_{18}ClSe_2$. Calcd for $C_9H_{18}ClSe_2$; C, 33.93; H, 5.69; Cl, 11.13%.

Reactions of 1,1,3,3-Tetramethyl-2-indanselone (3) with Methyllithium. To methyllithium (1.82 mmol) in ether (6 ml) was added the selone **3** (152 mg, 0.606 mmol) in ether (10 ml) at room temperature. The green solution became colorless after 80 min. After stirring for additional 30 min was added aqueous ammonium chloride. The organic layer was separated, washed with water, and dried over anhydrous $MgSO_4$. Removal of the solvent gave an almost colorless oil with characteristic smell of selenol, whose ^1H NMR spectrum showed a peak at δ −0.45 due to a selenol proton. To convert the selenol to the corresponding diselenide the mixture was dissolved in KOH (0.3 g)-MeOH (10 ml) and the solution was stirred at room temperature overnight. Methanol was removed and the residue was extracted with ether. The ethereal layer was washed with water and dried over anhydrous $MgSO_4$ and ether was evaporated. The products were separated by preparative thin-layer chromatography (silica gel, hexane) to give 1,1,3,3-tetramethyl-2-(methylseleno)indan (**8**, R=CH_3) (16 mg, 10%) and bis-(1,1,2,3,3-pentamethyl-2-indanyl) diselenide (**11**, R=CH_3) (118 mg, 73%). **8** (R=CH_3): colorless crystals, mp 54.5—55.0 °C. ^1H NMR δ=1.25 (s, 6H), 1.40 (s, 6H), 2.11 (s, 3H, $SeCH_3$), 3.30 (s, 1H), 7.18 (s, 4H); MS *m/z* (rel intensity) 268 (M^+, 32), 173 (60), 131 (100), 57 (68). Found: *m/z* 268.0722. Calcd for $C_{14}H_{20}{}^{80}Se$: M, 268.0728. **11** (R=CH_3): yellow crystals, mp 143.0—143.5 °C. ^1H NMR δ=1.37 (s, 12H), 1.52 (s, 18H), 7.1—7.2 (m, 8H); ^{13}C NMR δ=25.7, 28.3, 32.6, 50.6, 122.3, 127.0, 148.7; ^{77}Se NMR δ=628; MS *m/z* (rel intensity) 534 (M^+, 0.8), 506 (0.7), 348 (1), 268 (3), 187 (100), 171 (56), 145 (51), 131 (27), 57 (40). Found: C, 62.90; H, 7.11%. Calcd for $C_{28}H_{38}Se_2$: C, 63.15; H, 7.19%.

In a similar manner the following reactions were carried out.

With MeMgI. **3** (72.2 mg, 0.287 mmol) and MeMgI (3.4 equiv) were reacted overnight. **11** (R=CH_3): 53 mg (69%).

With *t*-BuLi. In the case of the reaction of **3** (154 mg, 0.612 mmol) with *t*-BuLi (3 equiv), **3** was not completely consumed even after 3 d. Therefore additional *t*-BuLi (1.5 equiv) was added. *t*-Butyl 1,1,3,3-tetramethyl-2-indanyl selenide (**8**, R=*t*-Bu; 9%): colorless crystals, mp 84.0—84.5 °C. ^1H NMR δ=1.21 (s, 6H), 1.38 (s, 6H), 1.50 (s, 9H, *t*-Bu), 3.04 (s, 1H), 7.19 (s, 4H); ^{13}C NMR δ=28.5, 28.7, 33.7, 38.3, 45.9, 62.8, 122.7, 126.7, 149.70; ^{77}Se NMR δ=325; MS *m/z* (rel intensity) 310 (M^+, 13), 254 (14), 239 (7), 173 (58), 157 (27), 131 (23), 119 (23), 86 (50), 84 (78), 57 (100). Found: *m/z* 310.1214. Calcd for $C_{17}H_{26}{}^{80}Se$: M, 310.1999. Bis(1,1,3,3-tetrametyl-2-indanyl) diselenide (**12**, 66%): yellow crystals, mp 140.5—141.0 °C. ^1H NMR δ=1.25 (s, 12H), 1.48 (s, 12H), 3.69 (s, 2H), 7.19 (s, 8H); ^{13}C NMR δ=28.2, 29.1, 46.9, 74.7, 122.5, 127.0, 149.0; ^{77}Se NMR δ=278; MS *m/z* (rel intensity) 506 (M^+, 0.8), 310 (4), 254 (5), 173 (26), 157 (11), 131 (14), 119 (9), 57 (100). Found: *m/z* 506.1032. Calcd for $C_{26}H_{34}{}^{80}Se_2$: M, 506.0990.

With *t*-BuMgCl. **3** (155 mg, 0.616 mmol) were reacted with *t*-BuMgCl (3 equiv) for 1.25 h. **8** (R=*t*-Bu) (28 mg, 15%), **12** (69 mg, 44%), and 1,1,2,3-tetramethyl-1*H*-indene (**9**) (21 mg, 22%)[17] were obtained.

With $PhCH_2Li$. **3** (107 mg, 0.427 mmol) and $PhCH_2Li$ (3.5 equiv) were reacted for 2 h. 2-Benzyl-1,1,3,3-tetramethyl-2-indanselenol (**7**, R=CH_2Ph; 86%): ^1H NMR δ=−0.5 (s, 1H), 1.5 (s, 6H), 1.6 (s, 6H), 3.3 (s, 2H), 7.0—7.6 (m, 9H); MS *m/z* (rel intensity) 344 (M^+, 2), 263 (20), 247 (12), 171 (8), 157 (8), 91 (65), 74 (64), 59 (100).

With PhLi. **3** (156 mg, 0.620 mmol) was reacted with PhLi (3 equiv) for 30 min. 1,1,3,3-Tetramethyl-2-indanyl phenyl selenide (**8**, R=Ph; 47%): mp 77.0—78.0 °C. ^1H NMR δ=1.31 (s, 6H), 1.32 (s, 6H), 3.49 (s, 1H), 7.1—7.8 (m, 9H); ^{13}C NMR δ=28.5, 28.7, 46.5, 70.9, 122.6, 126.9, 127.1, 129.0, 131.3, 134.2, 149.2; ^{77}Se NMR δ=234; MS *m/z* (rel intensity) 330 (M^+, 24), 173 (100), 158 (11), 131 (75), 99 (8), 91 (29), 85 (14), 71 (17), 57 (61). Found: *m/z* 330.0842. Calcd for $C_{19}H_{22}{}^{80}Se$: M, 330.0884.

With PhMgBr. The reaction of **3** (64 mg, 0.26 mmol) with PhMgBr (2 equiv) was so slow that 1 and 2 equiv. of PhMgBr were added after 7 and 18 h, respectively, and the mixture was warmed at 35 °C for 2 h. **8** (R=Ph) (2.4 mg, 3%) and **9** (6.3 mg, 14%) were obtained.

Preparation of 1,1,3,3-Tetramethyl-2-indanthione (13). **13** was prepared by the reaction of 1,1,3,3-tetramethyl-2-indanone hydrazone (1.04 g, 5.13 mmol) with disulfur dichloride (0.726 g, 5.38 mmol) in benzene.[10] Yield: 0.87 g (83%). Orange crystals; mp 38—43 °C (lit,[7c] 42 °C); ^1H NMR δ=1.47 (s, 12H), 7.31 (s, 4H);[7c] IR (KBr) 1100 cm^{-1}(C=S).

Reactions of 13 with Organolithium Reagents. The reactions were carried out in a similar manner to that described in the reactions of **3** with organometallic reagents.

With MeLi. **13** (102 mg, 0.498 mmol) was reacted with MeLi (3 equiv) for 30 min. 1,1,2,3,3-Pentamethyl-2-indanthiol (**14**, R=CH_3) (100 mg, 91%) was obtained: colorless oil, ^1H NMR δ=1.22 (s, 3H), 1.28 (s, 6H), 1.39 (s, 6H), 7.12—7.20 (br s, 4H); IR (neat) 2585 cm^{-1} (S-H).

With *t*-BuLi. **13** (124 mg, 0.606 mmol) and *t*-BuLi (3 equiv) were reacted for 12 h to give 1,1,3,3-tetramethyl-2-indanethiol (**16**) (40%, 57% based on the consumed thione) and recovered **13** (30%). **16**: mp 33.0—34.5 °C. MS *m/z* (rel intensity) 206 (M^+, 20), 173 (100), 157 (48). Found: *m/z* 206.1136. Calcd for $C_{13}H_{18}S$: M, 206.1129.

With $PhCH_2Li$. **13** (125 mg, 0.610 mmol) and $PhCH_2Li$ (3 equiv) were reacted for 3 h. 2-Benzyl-1,1,3,3-tetramethyl-2-indanethiol (**14**, R=CH_2Ph) (172 mg, 95%): mp 99.0—100.5 °C; ^1H NMR δ=1.1 (s, 1H), 1.4 (s, 6H), 1.6 (s, 6H), 3.1 (s, 2H), 6.9—7.5 (m, 9H); MS *m/z* (rel intensity) 296 (M^+, 2), 262 (45), 247 (52), 232 (8), 204 (23), 171 (67), 157 (21), 91 (100). Found: *m/z* 296.1603. Calcd for $C_{20}H_{24}S$: M, 296.1598.

With PhLi. **13** (165 mg, 0.809 mmol) was reacted with PhLi (3 equiv) for 4 h. 1,1,3,3-Tetramethyl-2-phenyl-2-indanethiol (**14**, R=Ph) (56%) and 1,1,3,3-tetramethyl-2-indanyl phenyl sulfide (**15**, R=Ph) (24%) were obtained. **14** (R=Ph): mp 87.8—89.2 °C; ^1H NMR δ=0.96 (s, 6H), 1.55 (s, 6H), 1.64 (s, 1H), 6.95—7.66 (m, 9H); MS *m/z* (rel intensity) 282 (M^+, 8), 267 (4), 249 (100), 233 (75), 218 (31), 202 (15), 159 (24), 105 (54), 91 (19). Found: *m/z* 282.1437. Calcd for $C_{19}H_{22}S$: M, 282.1442. **15** (R=Ph): ^1H NMR ($CDCl_3$) δ=1.31 (s, 12H), 3.46 (s, 1H), 6.95—7.66 (m, 9H); (C_6D_6) δ=1.27 (s, 6H), 1.36 (s, 6H), 3.49 (s, 1H), 6.87—7.63 (m, 9H).

Enantioselectivity in the Biotransformation of Mono- and Bicyclic Monoterpenoids with the Cultured Cells of *Nicotiana tabacum*

Hiroki HAMADA
Department of Fundamental Natural Science, Okayama University of Science, Ridai-cho, Okayama 700
(Received June 29, 1987)

The biotransformation of the enantiomeric pairs of *p*-menthane and bicyclo[2.2.1] and [3.1.1]heptane derivatives with the cultured cells of *Nicotiana tabacum* was investigated. It was found that (i) the cultured cells discriminate the enantiomers of *p*-menthan-2-ol and bicyclo[2.2.1]heptan-2-ol and bicyclo[3.1.1]heptan-3-ol derivatives, and enantioselectively convert these alcohols to the corresponding ketones, (ii) the cells reduce the carbonyl group of *p*-menthan-2-one derivatives to a high extent, but not that of *p*-menthan-3-ones, and (iii) the cells discriminate the enantiomers of bicyclo[3.1.1]hept-2-en-4-one (verbenone) and enantioselectively reduce the C-C double bond of the (1*S*,5*S*)-enantiomer.

The ability of cultured plant cells to metabolize foreign substrates and/or to convert these substrates to more useful substances is of considerable interest because of the specificity of the transformation which may be effected by such cells.[1-4] In such a status, many investigations on the biotransformation of the monoterpenoids[5-13] with the cultured cells of *Nicotiana tabacum* "Bright Yellow" are performed, and the cultured cells were found to not only reduce stereoselectively the C-C double bond adjacent to the carbonyl group of carvone and then the carbonyl group,[8,9] but also discriminate the enantiomers of monoterpene acetates and enantioselectively hydrolize one of the enantiomers.[6,12] The author has now investigated the enantioselectivity in the oxidative and reductive transformations of the enantiomeric pairs of mono- and bicyclic monoterpenoids, such as *p*-menthane and bicyclo[2.2.1] and bicyclo[3.1.1]heptane derivatives, with the cultured cells of *N. tabacum*.[14]

Results and Discussion

The same tobacco callus tissues induced from the stem of *N. tabacum* "Bright Yellow" as those used in our previous works were also used in this investigation. The callus tissues, just prior to use, were transplanted to the freshly prepared Murashige and Skoog's medium[18] containing 2 ppm of 2,4-dichlorophenoxyacetic acid as auxin and 3% of sucrose and then were grown with continuous shaking for 2—3 weeks at 25 °C in the dark. To these cultured cells, the filter-sterilized monoterpenoid was administered, and then the cultures were incubated at 25 °C for 7—10 d in a shaker. At a regular time interval, a part of the incubation mixture (suspension of cells and medium) was withdrawn with a pipette under sterile conditions and extracted with ether. Each ether extract, after removal of the solvent, was subjected to the GLC analysis to study the time-courses in the biotransformation of the enantiomeric pairs of the monoterpenoids.

Enantioselectivity in the Oxidation of the Secondary Alcohols. Enantioselectivity in the oxidation of monoterpenoids having a secondary hydroxyl group was examined with the enantiomeric pairs of 2- and 3-hydroxylated *p*-menthane derivatives, 2-hydroxylated bicyclo[2.2.1]heptane derivatives, and 3- and 4-hydroxylated bicyclo[3.1.1]heptane derivatives, such as (1*R*,2*R*,4*R*)-(−)- and (1*S*,2*S*,4*S*)-(+)-carvomenthols (**1a** and **1b**), (1*R*,2*S*,4*R*)-(+)- and (1*S*,2*R*,4*S*)-(−)-neocarvomenthols (**2a** and **2b**), (1*R*,3*R*,4*S*)-(−)- and (1*S*,3*S*,4*R*)-(+)-menthols (**3a** and **3b**), (1*R*,3*S*,4*S*)-(+)- and (1*S*,3*R*,4*R*)-(−)-neomenthols (**4a** and **4b**), (1*R*,2*S*,4*R*)-(+)- and (1*S*,2*R*,4*S*)-(−)-borneols (**5a** and **5b**), (1*R*,2*R*,4*R*)-(−)- and (1*S*,2*S*,4*S*)-(+)-isoborneols (**6a** and **6b**), (1*R*,2*R*,3*R*,5*S*)-(−)- and (1*S*,2*S*,3*S*,5*R*)-(+)-

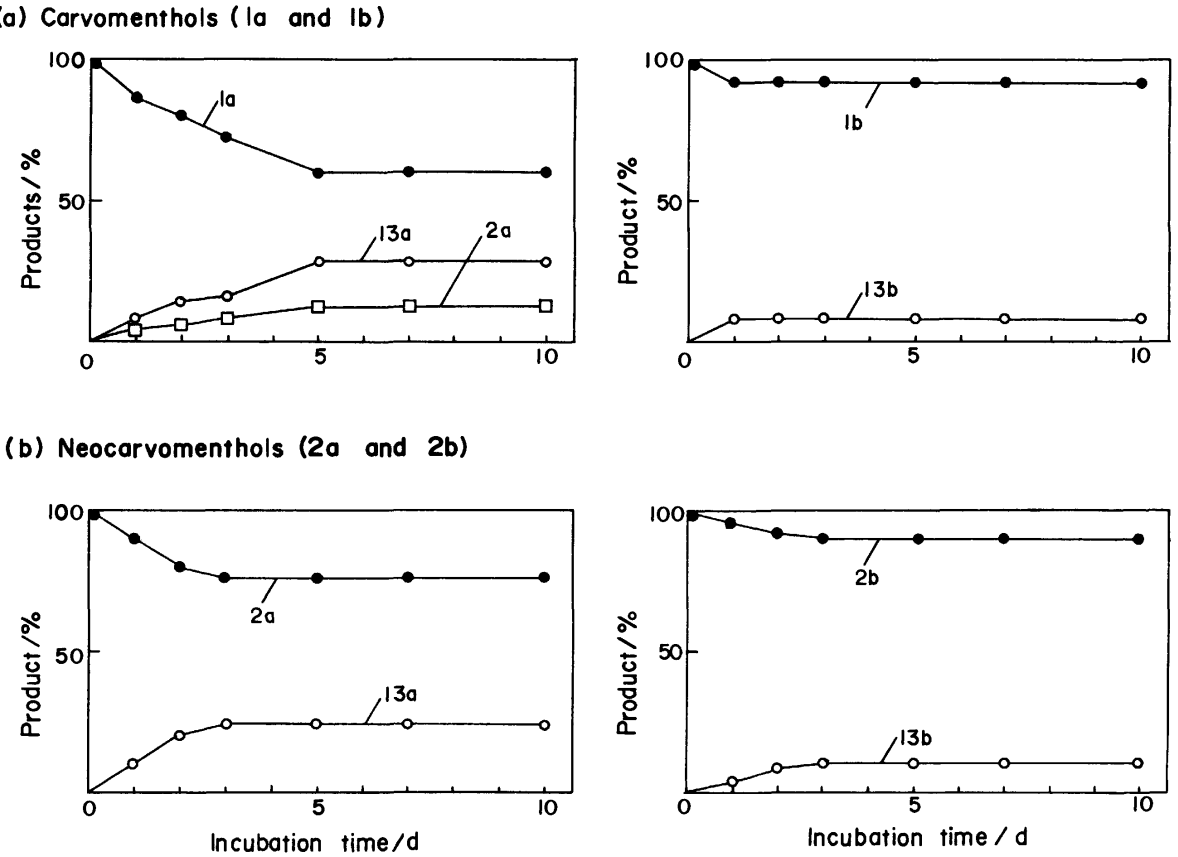

Fig. 1. The time-courses in the biotransformation of the enantiomeric pairs of (a) carvomenthols (**1a** and **1b**) and (b) neocarvomenthols (**2a** and **2b**).

isopinocampheols (**7a** and **7b**), (1*R*,2*R*,3*S*,5*S*)-(+)- and (1*S*,2*S*,3*R*,5*R*)-(−)-neoisopinocampheols (**8a** and **8b**) and (1*R*,2*S*,4*R*,5*R*)-(+)- and (1*S*,2*R*,4*S*,5*S*)-(−)-neoisoverbanols (**9a** and **9b**).

As shown in Fig. 1, the *p*-menthan-2-ols, **1a** and **2a**, were converted to (1*R*,4*R*)-(+)-carvomenthone (**13a**), whereas their enantiomers, **1b** and **2b**, were scarcely converted to the corresponding ketone **13b**. The biotransformation of **1a** gave, in addition to **13a**, (+)-neocarvomenthol (**2a**) as a minor product; the formation of **2a** may be caused by further reductive conversion of (+)-carvomenthone (**13a**). In the biotransformation of enantiomeric pairs of the *p*-menthan-3-ols, on the other hand, not only (1*R*,3*R*,4*S*)-(−)-menthol (**3a**) and (1*R*,3*S*,4*S*)-(+)-neomenthol (**4a**), but also their enantiomers, **3b** and **4b**, were scarcely converted to their corresponding ketones, **14a** and **14b**.

Figure 2 shows the time-courses in the biotransformation of the bicyclo[2.2.1]heptan-2-ols, such as borneols (**5a** and **5b**) and isoborneols (**6a** and **6b**). (1*R*,2*S*,4*R*)-(+)-Borneol (**5a**) and (1*R*,2*R*,4*R*)-(−)-isoborneol (**6a**) were quantitatively converted to (1*R*,4*R*)-(+)-camphor (**15a**), whereas the conversion of their enantiomers, **5b** and **6b**, to (1*S*,4*R*)-(−)-camphor (**15b**) occurred to a slight extent. Such an enantioselective transformation was further confirmed by feeding experiments of the racemic substrates of borneol (**5**) and isoborneol (**6**). After incubation of the racemic substrates with the cultured cells, the product and the unchanged substrate in the incubation mixture were separated from each other and then their optical

Table 1. Enantioselective Transformation of (±)-Borneol (**5**) and (±)-Isoborneol (**6**) into (+)-Camphor (**15a**) with the Cultured Cells of *N. tabacum*

Substrate used	**15a**			**5b** and **6b** recovered		
	$[\alpha]_D^{25}$/°	(*c*, solv.)	O.p.[a]	$[\alpha]_D^{25}$/°	(*c*, solv.)	O.p.[a]
(±)-Borneol (**5**)	+40.7	(1.4, EtOH)	92.1	−36.4	(0.6, EtOH)	95.5
(±)-Isoborneol (**6**)	+40.1	(1.0, EtOH)	90.7	+32.5	(2.0, EtOH)	94.8

a) O.p. denotes the optical purity (e. e. %), which was calculated on the basis of the specific rotation cited in the literature.[28]

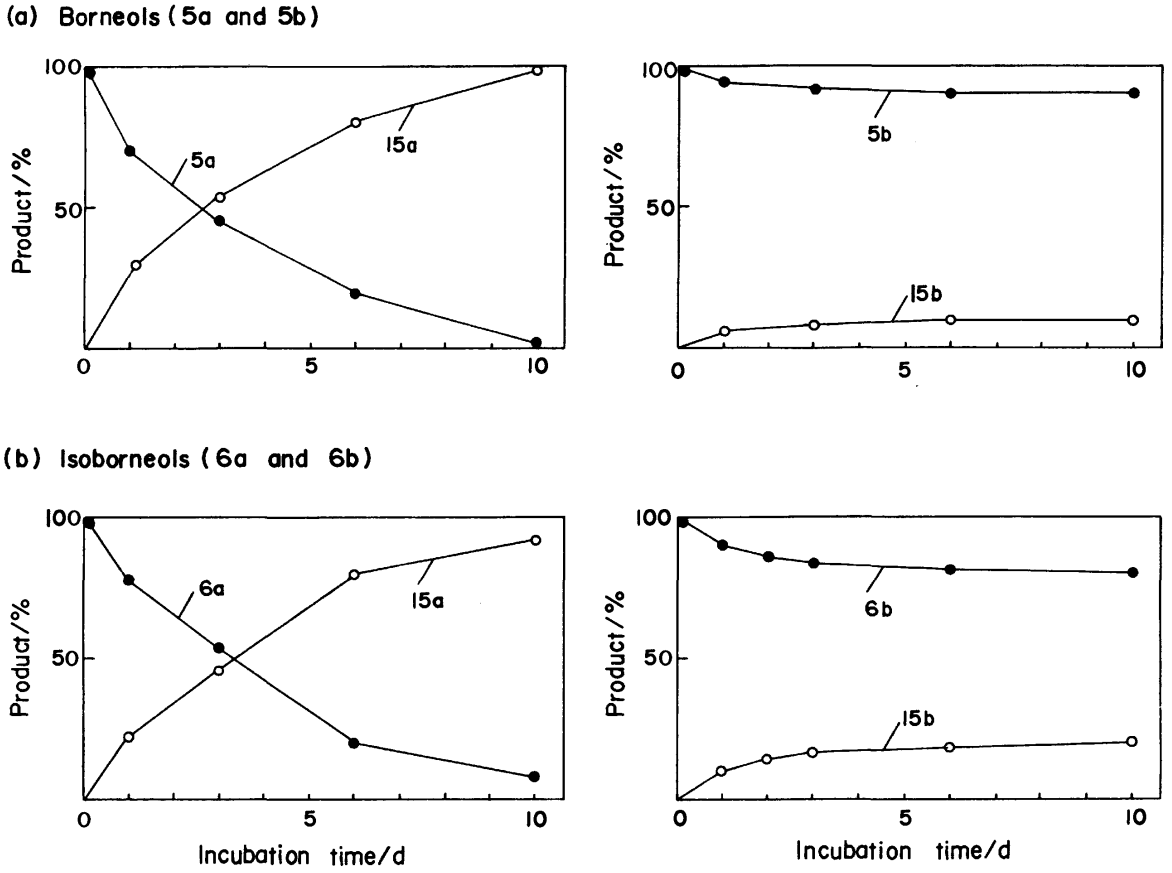

Fig. 2. The time-courses in the biotransformation of the enantiomeric pairs of (a) borneols (**5a** and **5b**) and (b) isoborneols (**6a** and **6b**).

purities were determined. The data given in Table 1 indicates that one enantiomer in the racemate was selectively susceptible to the oxidation with the cultured cells; (+)-borneol (**5a**) and (−)-isoborneol (**6a**) quantitatively transformed into (+)-camphor (**15a**), but their enantiomers remain unchanged.

The time-courses in the biotransformation of bicyclo[3.1.1]heptan-3-ols and -4-ols are shown in Figs. 3 and 4. (1*S*,2*S*,3*S*,5*R*)-(+)-isopinocampheol (**7b**) and (1*S*,2*S*,3*R*,5*R*)-(−)-neoisopinocampheol (**8b**) were quantitatively converted to (1*S*,2*S*,5*R*)-(−)-isopinocamphone (**16b**). However, their enantiomer, **7a** and **8a**, was hardly converted to their corresponding ketone. On the other hand, both enantiomers, **9a** and **9b**, of neoisoverbanol were quantitatively converted to their corresponding ketones **17a** and **17b**, respectively (Fig. 4).

Enantioselectivity in the Oxidation of the Allylic Alcohols. Enantioselectivity in the oxidation of monoterpenoids having an allylic hydroxyl group was

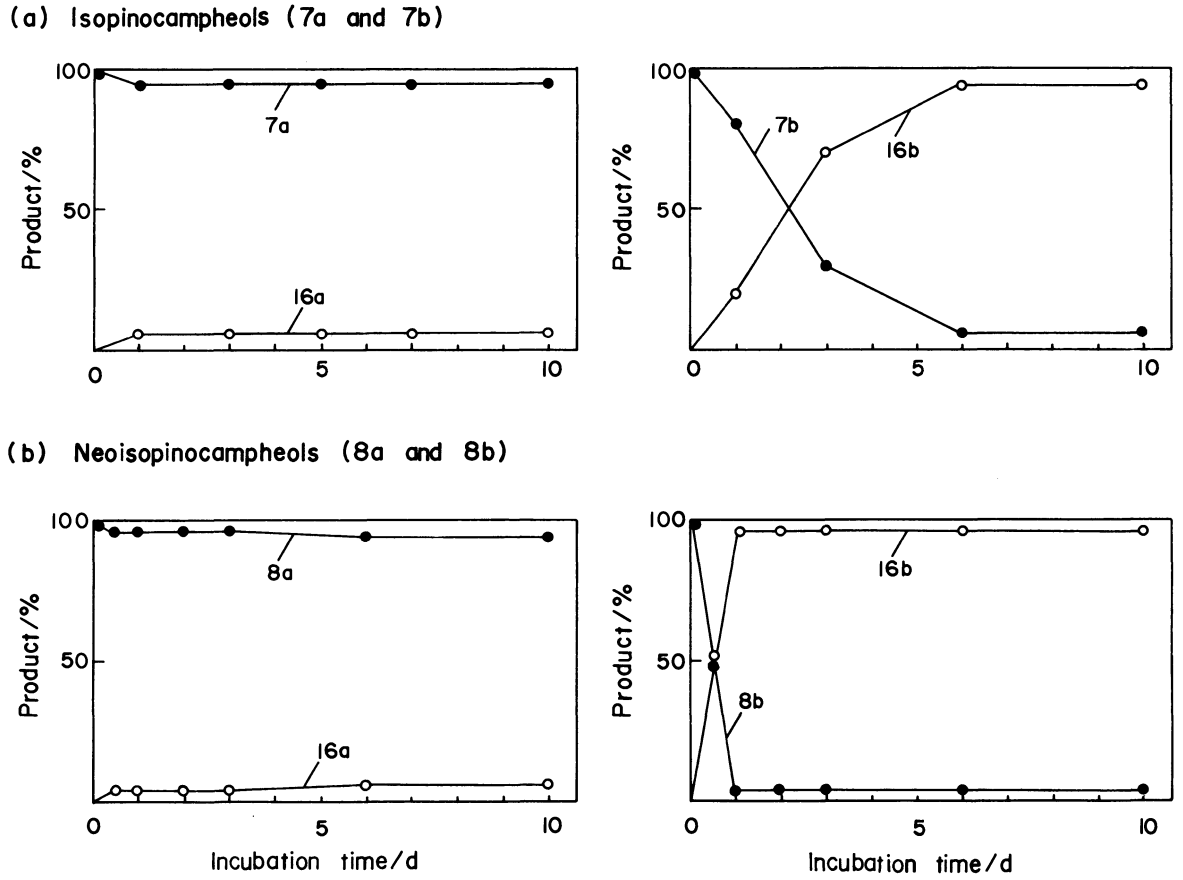

Fig. 3. The time-courses in the biotransformation of the enantiomeric pairs of (a) isopinocampheols (**7a** and **7b**) and (b) neoisopinocampheols (**8a** and **8b**).

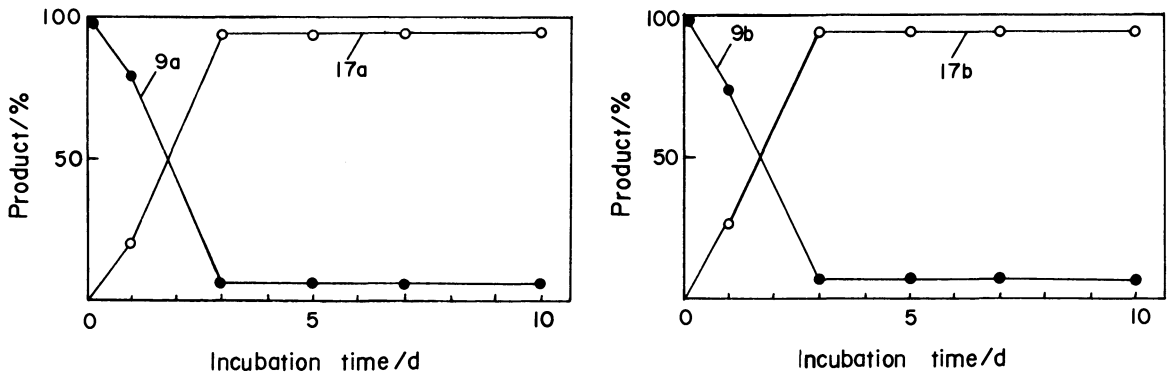

Fig. 4. The time-courses in the biotransformation of the enantiomeric pairs of neoisoverbanols (**9a** and **9b**).

examined with the enantiomeric pairs of 2-hydroxylated *p*-menthene derivatives and 4-hydroxylated bicyclo[3.1.1]heptene derivatives, such as (2*R*,4*R*)-(−)- and (2*S*,4*S*)-(+)-*cis*-carveols (**10a** and **10b**), (2*S*,4*R*)-(−)- and (2*R*,4*S*)-(+)-*trans*-carveols (**11a** and **11b**), and (1*R*,4*R*,5*R*)-(+)- and (1*S*,4*S*,5*S*)-(−)-*cis*-verbenols (**12a** and **12b**). Figure 5 shows the time-courses in the biotransformation of enantiomeric pairs of *cis*-carveol (**10a** and **10b**) and *trans*-carveol (**11a** and **11b**). The (2*S*,4*S*)-*cis*- and (2*S*,4*R*)-*trans*-carveols (**10b** and **11a**) were converted to the corresponding ketones **22b** and **22a** to a large extent, respectively, whereas the conversion of their enantiomers **10a** and **11b** to their corresponding ketones **22a** and **22b** occurred to a slight extent. These facts indicate that the cultured cells preferentially oxidize the allylic alcohols having the chirality of *S* at C-2 and this oxidation is independent of the chirality at C-4. In the biotransformation of *cis*-carveol (**10b**) a remarkable increase in the formation of neoisodihydrocarveol (**19**) after 3 d incubation was observed. However, it is not clear whether this formation was caused by the

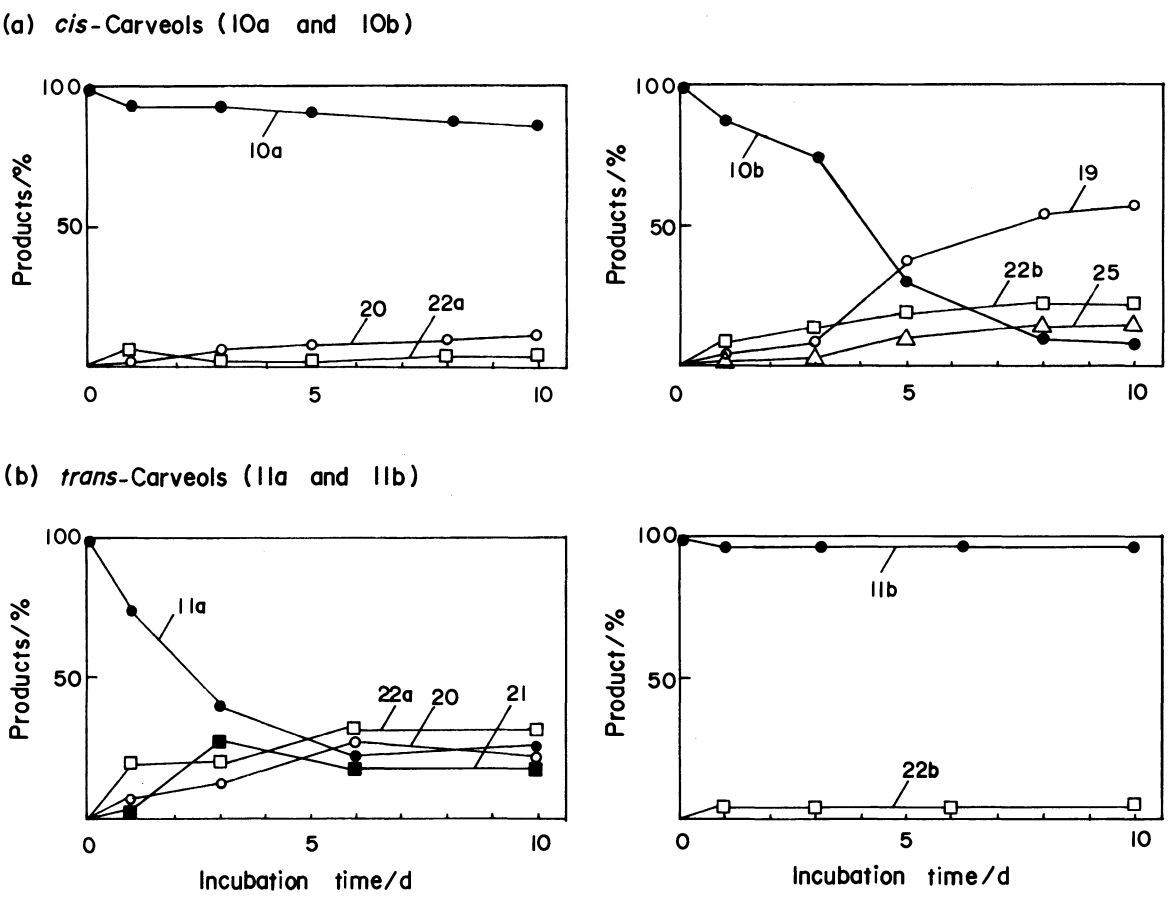

Fig. 5. The time-courses in the biotransformation of the enantiomeric pairs of (a) *cis*-carveols (**10a** and **10b**) and (b) *trans*-carveols (**11a** and **11b**).

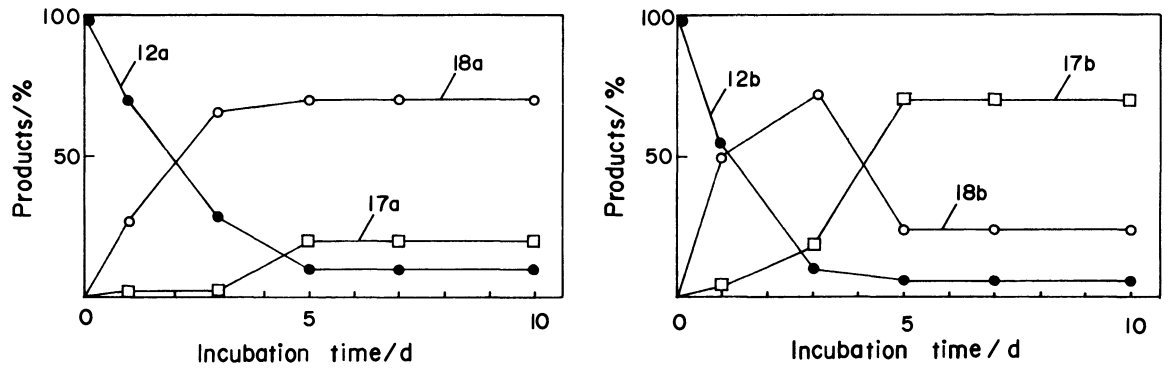

Fig. 6. The time-courses in the biotransformation of the enantiomeric pairs of *cis*-verbenols (**12a** and **12b**).

reduction of carvone (**22b**) produced or by the direct reduction of the C–C double bond of *cis*-carveol (**10b**). The time-courses in the biotransformation of enantiomeric pairs of *cis*-verbenol (**12a** and **12b**) are shown in Fig. 6. Both enantiomers were quantitatively transformed to their corresponding ketones **18a** and **18b** respectively, after 3 day's incubation. In the biotransformation of **12b**, the product **18b** was formed in high yield in the early stage of the incubation, but **18b** decreased after 3 d with a gradual increase in the formation of (1*S*,2*R*,5*S*)-*cis*-verbanone (**17b**). Such further transformation occurred to a small extent in the case of **12a**. Accordingly, in the biotransformation of the monoterpenoids having an allylic hydroxyl group, this hydroxyl group is enantioselectively oxidized to the carbonyl group and then the C–C double bond adjacent to the carbonyl group of α,β-unsaturated carbonyl compounds produced is stereoselectively hydrogenated to a saturated carbonyl compounds. However, the C–C double bond in the 1-methylethenyl group is not at all hydrogenated.

Enantioselectivity in the Reduction of the Carbonyl Compounds. Enantioselectivity in the reduction of monoterpenoids having a carbonyl group was examined with the enantiomeric pairs of *p*-menthan-2-one and -3-one derivatives and bicyclo[2.2.1]heptan-2-one and bicyclo[3.1.1]heptan-3-one and -4-one derivatives, such as (1*R*,4*R*)-(+)- and (1*S*,4*S*)-(−)-carvomenthones (**13a** and **13b**), (1*R*,4*S*)-(−)- and (1*S*,4*R*)-(+)-menthones (**14a** and **14b**), (1*R*,4*R*)-(+)- and (1*S*,4*S*)-(−)-camphors (**15a** and **15b**), (1*R*,2*R*,5*S*)-(+)- and (1*S*,2*S*,5*R*)-isopinocamphones (**16a** and **16b**), and (1*R*,2*S*,5*R*)-(+)- and (1*S*,2*R*,5*S*)-(−)-*cis*-verbanones (**17a** and **17b**). The time-courses in the biotransformation of carvomenthones (**13a** and **13b**) and menthones (**14a** and **14b**) are shown in Figs. 7 and 8. (1*R*,4*R*)-(+)-Carvomenthone (**13a**) was quantitatively converted to (1*R*,2*S*,4*R*)-(+)-neocarvomenthol (**2a**), whereas its (1*S*,4*S*)-(−)-enantiomer **13b** was converted to (1*S*,2*S*,4*S*)-(+)-carvomenthol (**1b**) and (1*S*,2*R*,4*S*)-(−)-neocarvomenthol (**2b**) in a ratio of 2:1. The preferential formation of (+)-neocarvomenthol (**2a**) and (+)-carvomenthol (**1b**) indicates that the carvomenthones (**13a** and **13b**) are stereospecifically reduced to the hydroxy compounds with the chirarity of *S* at the C-2. The extent of the stereoselectivity in the reduction of the enantiomers was different each other; the selectivity was very high for the reduction of (1*R*,4*R*)-carvomenthone (**13a**), but low for that of the enantiomer **13b**. On the other hand, the biotransformation of (1*R*,4*S*)-(−)- and (1*S*,4*R*)-(+)-menthones (**14a** and **14b**) gave (1*R*,4*R*)- and (1*S*,4*S*)-4-hydroxy-*p*-menthan-3-ones (**23a** and **23b**), respectively,[19] in addition to isomenthones (**24a** and **24b**) and menthols (**3b**, **4a**, and **4b**) (Fig. 8). The time-course experiments show that the reduction of the carbonyl group of

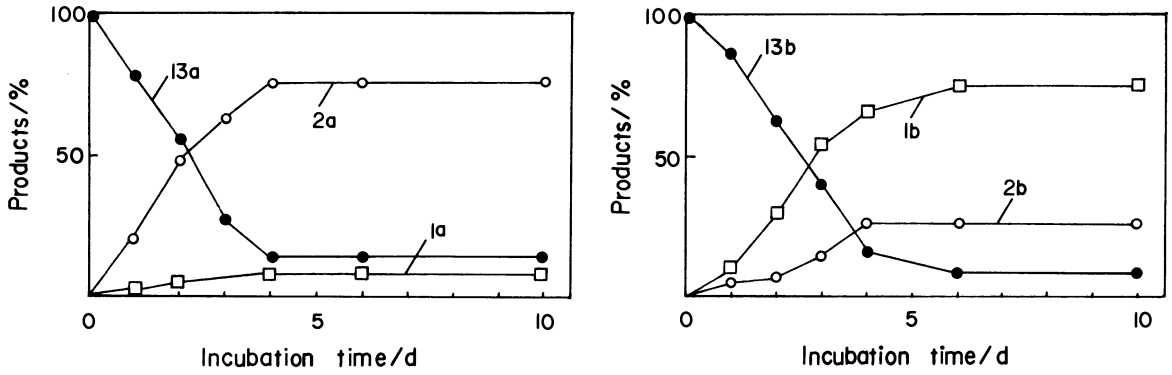

Fig. 7. The time-courses in the biotransformation of the enantiomeric pairs of carvomenthones (**13a** and **13b**).

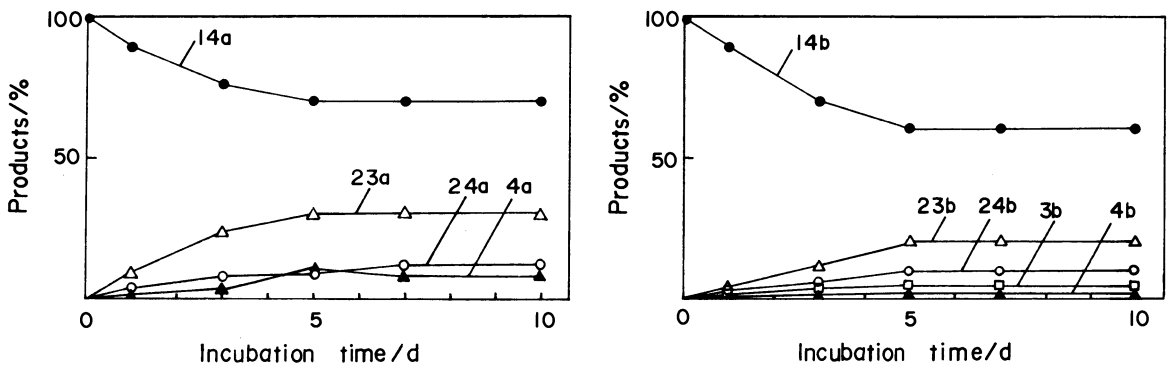

Fig. 8. The time-courses in the biotransformation of the enantiomeric pairs of menthones (**14a** and **14b**).

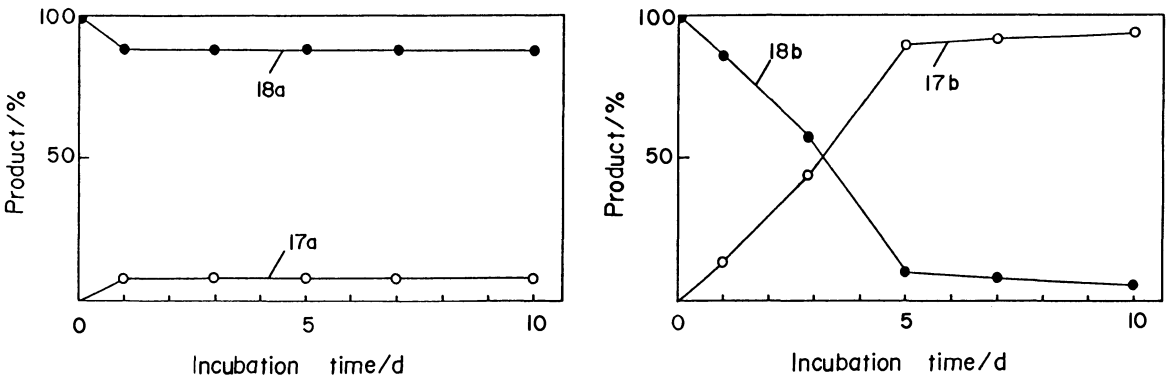

Fig. 9. The time-courses in the biotransformation of the enantiomeric pairs of verbenones (**18a** and **18b**).

menthones (**14a** and **14b**) occurred to a slight extent. This low conversion, as compared with the case of *p*-menthan-2-ones, **1a** and **1b**, may be caused by the steric hindrance owing to the 1-methyl ethyl group adjacent to the carbonyl group. On the other hand, (1*R*,4*R*)-(+)- and (1*S*,4*S*)-(−)-camphors (**15a** and **15b**), (1*R*,2*R*,5*S*)-(+)- and (1*S*,2*S*,5*R*)-(−)-isopinocamphones (**16a** and **16b**), and (1*R*,2*S*,5*R*)-(+)- and (1*S*,2*R*,5*S*)-(−)-*cis*-verbanones (**17a** and **17b**) were scarcely converted to their corresponding alcohols. These results may be explained by assuming that the balance of the equilibrium between the ketones and the corresponding alcohols in the oxidoreduction in the cultured cells is predicted to lie toward the side of the ketones.[10]

Enantioselectivity in the Reduction of the C–C Double Bond of α,β-Unsaturated Carbonyl Compounds. Enantioselectivity in the reduction of the C–C double bond of monoterpenoids having an α,β-unsaturated carbonyl group was examined with the enantiomeric pairs of bicyclo[3.1.1]hept-2-en-4-ones, such as (1*R*,5*R*)-(+)- and (1*S*,5*S*)-(−)-verbenones (**18a** and **18b**). Figure 9 shows the time-courses in the biotransformation of (1*R*,5*R*)-(+)-verbenone (**18a**) and its enantiomer **18b**. The (1*S*,5*S*)-enantiomer **18b** was quantitatively converted to (1*S*,2*R*,5*S*)-(−)-*cis*-verbanone (**17b**) after 10 d incubation, whereas the conversion of (1*R*,5*R*)-enantiomer **18a** to the corresponding ketone **17a** scarecely occurred. These facts indicate that the cultured cells discriminate the enantiomers and reduce the C–C double bond of the (1*S*,5*S*)-enantiomer **18b**. In addition, the hydrogenation of **18b** with the cultured cells gave only *cis*-verbanone (**17b**), but not its trans-isomer. This indicates that the hydrogen attack to the C–C double bond of **18b** stereospecifically occurs from the *re*-face at C-2 of **18b**. No further conversion of the *cis*-verbanone (**17b**) into neoisoverbanol (**9b**) was observed. This may be explained by assuming that the balance of the equilibrium between **17b** and its corresponding alcohol **9b** in the oxidoreduction in the cultured cells is predicted to lie toward the side of the *cis*-verbanone (**17b**), because the equilibrium constant in the oxidoreduction of **9b**⇄**17b** is estimated to be about 1.4 on the basis of the ^{13}C NMR chemical shift (δ 214.1) of the carbonyl carbon of **17b**.[10]

Concluding Remarks. The enantioselectivity in the oxidative and reductive transformation of the enantiomeric pairs of *p*-menthane and bicyclo[2.2.1] and bicyclo[3.1.1]heptane derivatives with the cultured cells of *N. tabacum* was established as follows. (i) The cultured cells discriminated the enantiomers of *p*-menthan-2-ols, bicyclo[2.2.1]heptan-2-ols, and bicyclo[3.1.1]heptan-3-ols, and enantioselectively oxidized these secondary alcohols, but this was not the case for the *p*-menthan-3-ols and bicyclo[3.1.1]heptan-4-ols. (ii) In the case of allylic alcohols, also, the cultured cells discriminated the enantiomers of 6-*p*-menthen-2-ols, and enantioselectively oxidized these allylic alcohols, but this was not the case for the bicyclo[3.1.1]hept-2-en-4-ol. (iii) The cultured cells discriminated the enantiomers of *p*-menthan-2-ones in their reductive conversion to the corresponding hydroxy compounds, but this was not the case for the *p*-menthan-3-ones. The hydrogen attack in the reduction took place preferentially from the *re*-face of the carbonyl group to give the alcohols with the chirality of *S* at the position bearing the hydroxyl group. (iv) The cultured cells discriminated the enantiomers of bicyclo[3.1.1]hept-2-en-4-one, and enantioselectively reduced its C–C double bond. The hydrogen attack in the hydrogenation took place stereospecifically from the *re*-face of the C–C double bond.

Thus, the main finding in the oxidative and reductive transformation is that the enantioselective transformation takes place for the only substrate having the methyl group on the vicinal position of the functional group.

Experimental

Analytical and preparative TLC were carried out on 0.25-mm and 0.5-mm thick silica-gel plates (Merck silica gel 60,

GF_{254}), respectively. GLC analyses were performed on an instrument equipped with FID and a glass column (3 mm×2 m) packed with 15% DEGS, 5% PEG-20M, and 2% OV-17 on Chromosorb W (AW-DMCS; 80—100 mesh) at 100, 120, and 90—200 °C (3 °C min^{-1}), respectively. ^1H NMR spectra were obtained at 60 and 90 MHz in $CDCl_3$ with TMS as an internal standared. GC-MS spectra were recorded on a mass spectrometer equipped with a gas chromatograph with 15% DEGS column (3 mm×2 m) by EI mode at 70 ev. The areas of the peaks on the gas liquid chromatogram were determined by using a Shimadzu C-R1B Chromatopac recording data processor for chromatography.

Substrates. (i) Monoterpene Alcohols. (1*R*,2*R*,4*R*)-(−)-Carvomenthol (**1a**) was prepared from (−)-dihydrocarveols[20] by hydrogenation in the presence of 10% Pd-C. The hydrogenation of (+)-neodihydrocarveol[20] in the presence of 10% Pd-C gave (1*R*,2*S*,4*R*)-(+)-neocarvomenthol (**2a**). (1*R*,3*R*,4*S*)-(−)-Menthol (**3a**) and its enantiomer **3b** were commercial materials of Aldrich Chem. Company. (1*R*,3*S*,4*S*)-(+)-Neomenthol (**4a**) was prepared from (−)-menthone[33] by reduction with $NaBH_4$. The reduction of (+)-camphor[28] with $LiAlH_4$ gave (1*R*,2*S*,4*R*)-(+)-borneol (**5a**) and (1*R*,2*R*,4*R*)-(−)-isoborneol (**6a**). (1*R*,2*R*,3*R*,5*S*)-(−)-Isopinocampheol (**7a**) was prepared by the hydroboration-oxidation of (+)-α-pinene.[21] The isopinocampheol (**7a**) was oxidized by pyridinium dichromate[23] to yield (+)-isopinocamphone,[21] which was reduced by $NaBH_4$ to give (1*R*,2*R*,3*S*,5*S*)-(+)-neoisopinocampheol (**8a**). (1*R*,2*S*,4*R*,5*R*)-(+)-Neoisoverbanol (**9a**) was prepared from (+)-*cis*-verbanone[34] by reduction with $LiAlH_4$. (2*R*,4*R*)-(−)-*cis*-Carveol (**10a**) and (2*S*,4*R*)-(−)-*trans*-carveol (**11a**) were prepared by the Meerwein-Pondorf reduction of (−)-carvone.[22] The reduction of (−)-verbenone[31] with $NaBH_4$ in MeOH at 0 °C gave (1*R*,4*R*,5*R*)-(−)-*cis*-verbenol (**12a**). On the other hand, the enantiomers of the alcohols described above were prepared from the corresponding compounds in the same manner as above.

(ii) Monoterpene Ketones. (1*R*,4*R*)-(+)-Carvomenthone (**13a**) was prepared from (+)-dihydrocarvone[20] by hydrogenation in the presence of 10% Pd-C. (1*R*,4*S*)-(−)-Menthone (**14a**) was prepared from (−)-menthol[26] by oxidation with pyridinium dichromate.[23] (1*R*,4*R*)-(+)-Camphor (**15a**) was prepared from (+)-borneol[28] by pyridinium dichromate oxidation.[23] Oxidation of (+)-neoisopinocampheol[21] with $Na_2Cr_2O_7$ gave (1*R*,2*R*,5*S*)-(+)-isopinocamphone (**16a**). (1*R*,2*S*,5*R*)-(+)-*cis*-Verbanone (**17a**) was prepared from (+)-verbenone[31] by hydrogenation in the presence of 10% Pd-C. (1*R*,5*R*)-(+)-Verbenone (**18a**) was prepared from (−)-α-pinene by oxidation with *t*-butyl chromate.[24] The enantiomers of the ketones described

above were prepared from the corresponding alcohols in the same manner as above. All the samples were >99% pure by GLC, and these physical data are given in Table 2.

Feeding of the Monoterpenes to the Tobacco Cultured Cells. The callus tissues used in this study were induced from the stem of *N. tabacum* "Bright Yellow" and have been maintained for about 15 years.[5] Just prior to use for this work, a part of the callus tissuse as transplanted to freshly prepared Murashige and Skoog's medium[18] (100 cm^3 in a 300 cm^3-conical flask) containing 2 ppm of 2,4-dichlorophenoxyacetic acid and 3% sucrose and grown with continuous shaking for 2—3 weeks at 25 °C in the dark. The substrate (10 mg/flask) was added to the suspension cultures (about 50—70 g cells/flask) and the cultures were incubated at 25 °C for 7—10 d on a rotary shaker (70 rpm) in the dark.

Isolation and Identification of the Products. The incubation mixture was filtered and the mass obtained was triturated with MeOH. The MeOH extract was concentrated and extracted with ether. The culture medium filtered was extracted with ether. The two ether extracts were bulked, since they exhibited the same behavior on TLC and GLC. Transformation products were isolated from the extract by prep. TLC on silica gel (EtOAc–hexane, 1:4) and identified by direct comparison of physical constants, TLC, GLC, and spectral data with those of authentic samples. The physical constants and spectral data of the products are given in Table 3. The minor products were identified by direct comparison of TLC, GLC and/or GC-MS with those of authentic samples.

Time-Course Experiments in the Biotransformation of the Substrates. The substrate (10 mg) was incubated at 25 °C for 10 d with shaking (70 rpm) in the dark. At a regular time interval, a part (10 cm^3) of the incubation mixture was pipetted out under sterile conditions and then extracted with ether. The yields of the products were determined on the basis of the peak area from GLC and are expressed as a relative percentage to the total amount of the whole reaction products extracted. These results are shown in Figs. 1—9 in the text.

The details of the time-course experiments are described below in the case of **1a** as an example. A part of the callus tissues was transplanted to 100 cm^3 of Murashige and Skoog's medium[18] in a 300 cm^3-conical flask and grown with continuous shaking for 2—3 weeks at 25 °C in the dark. The substrate **1a** (10 mg) was administered to the precultured cells (about 70 g) in a 300 cm^3-conical flask and the cultures were incubated at 25 °C in a rotary shaker (70 rpm) in the dark. At a regular time interval, a part of the incubation mixture (10 cm^3) was pipetted out under sterile conditions and extracted with ether. The ether extract was made up to 0.2 cm^3 and 0.002 cm^3 of the ether solution was subjected to GLC with a 15% DEGS column at 120 °C by use of a microsyringe. The yields of the products were determined on the basis of the peak area from the GLC and are expressed as a relative percentage to the total amount of the whole reaction products extracted. Identification of the products were performed by comparison (co-GLC and GC-MS) with authentic samples.[25,32] Thus, the time-course in the biotransformation of **1a** as shown in Fig. 1 was obtained.

The author wishes to express his heartfelt gratitude to Professor Takayuki Suga of Hiroshima University for his encouragement and guidance in the course of this work and his critical reading of the manuscript and to Dr. Toshifumi Hirata for his valuable suggestions.

The Fries Rearrangement of 4*H*-Cyclopenta[*def*]phenanthrenyl Acetate

Masahiro MINABE,* Masaaki YOSHIDA, Tsukasa AMIMOTO, Toshihiro NAGATA, and Masamichi KOBORI

Department of Industrial Chemistry, Faculty of Engineering, Utsunomiya University, Ishiicho, Utsunomiya 321

(Received July 4, 1987)

A Fries rearrangement of 4*H*-cyclopenta[*def*]phenanthren-1-yl acetate gave 2- and 7-acetyl derivatives. The reaction of isomeric 2-acetoxy compound afforded 1- and 7-acetyl derivatives. The acetyl group of the 3- and 8-acetoxy compounds rearranged into the 2- and 9-positions, respectively. In addition, 1-, 2-, 3-, 4-isopropyl compounds were derived from the corresponding acetyl derivatives.

The Fries rearrangement is one of the important synthetic methods for obtaining acyl-substituted phenols from the corresponding acyloxy compounds. This reaction has been investigated widely, but has scarcely been applied to polycyclic aromatic hydrocarbons (PAH).[1,2]

4*H*-Cyclopenta[*def*]phenanthrene (CPP) is one of the interesting PAH; some reactions involving CPP derivatives have been reported.[3] Recently, we have reported Friedel–Crafts acetylations of methoxy-4*H*-cyclopenta[*def*]phenanthrenes.[4] The effect of the methoxyl group was different from that of the amino group on CPP.[5]

The present paper deals with a Fries rearrangement of acetoxy derivatives of CPP, **1a—5a**. This is expected to yield valuable informations concerning both the reactivities of the electrophilic substitution of substituted CPP, and the mechanism of the Fries rearrangement (Scheme 1). The reactants, **1a—5a**, were synthesized by a rearrangement of the corresponding acetyl derivatives, **6a—10a**,[6,7] with *m*-chloroperbenzoic acid (MCPB) in moderate yields. Also, **6a—10a** were converted into isopropyl compounds: **6d—10d** via **6b—10b** and **6c—10c** (Scheme 2).

The acetyl group of 4*H*-cyclopenta[*def*]phenanthren-1- (**1a**), 2- (**2a**), 3- (**3a**), and 8-yl acetate (**4a**) migrated upon stirring with aluminium chloride in nitrobenzene, giving 2-acetyl-1-hydroxy- (**1b**), 1-acetyl-2-hydroxy- (**2b**), 2-acetyl-3-hydroxy- (**3b**), 9-acetyl-8-hydroxy-4*H*-cyclopenta[*def*]phenanthrene (**4b**), respectively, in moderate yields (summarized in Table 1). The phenolic compounds, **1e—4e**, were isolated as by-products of the reactions.

The reaction of **2a** afforded 7-acetyl-2-acetoxy compound, **2d**, accompanied by a trace amount of 7-acetyl-2-hydroxy derivative, **2c**, through a treatment in

a) Isolated yield.

1,2-dichloroethane at room temperature. On the other hand, **2b** was the main product under reflux conditions, similar to the case in nitrobenzene. Similar trends were observed in a reaction of **1a** in 1,2-dichloroethane.

A Fries rearrangement of the 8,9-dihydro-2-acetoxy derivative **5a** yielded 6-acetyl-2-hydroxy compound, **5c**, as the solely isolated product. A reaction of 4-acetoxy compound, **11**, gave no identified products.

These results fairly differ from reactions of the amino[5] and methoxy derivatives[4] of CPP. One of the remarkable results of Fries rearrangements in nitrobenzene is that the acetyl group is introduced into the adjacent position to the original acetoxyl group of **1a—4a**. This is similar to the cases of 1-, 2-, and 8-amines[5] and 1- and 2-ethers.[4] On the other hand, **2a** gives diacetyl derivative **2d** under relatively mild conditions using 1,2-dichloroethane; position 7 in the parent CPP is the most reactive position to electrophile.[3,8] These can be explained by the fact that the formations of **1d** and **2d** are kinetically controlled and those of **1b** and **2b** are thermodynamically controlled. The driving force of thermodynamic stabilities of the compounds would be caused by the formation of a chelating ring between the vicinal acetyl and the hydroxyl groups.

From the predominant formations of **1b—4b** by reactions in nitrobenzene it is postulated that the solvent prefers the formation of thermodynamically-controlled products, in spite of the fact that the attack of the electrophile on the ortho position of substituent requires more energy and may attack the other positions.[9] The solvated acetyl chloride-aluminium chloride complex is the attacking species in the Friedel-Crafts acetylation using nitrobenzene as a solvent.[10] Also, in this case, the solvated reactant-aluminium chloride complex furnishs the rearrangement by moving the acetyl group from the oxygen atom to the adjacent carbon in the solvated state under the reaction conditions.

The following mechanisms have been proposed for the Fries rearrangement:[1] (i) an intramolecular reaction, (ii) a Friedel-Crafts acetylation by acyl chloride to the aryl-$OAlCl_2$ formed from the original acyloxy compound with aluminium chloride, or (iii) a disproportionation reaction of two acyloxy derivatives (these would operate simultaneously). A brief experiment involving a cross-Fries rearrangement between **1e** and **2a** in the presence of aluminium chloride in nitrobenzene afforded a mixture of **1b** and **2b** in a ratio of ca 4:1; this supports the idea that the reaction proceeds via an intermolecular mechanism. The disproportionation mechanism (iii) would be one of the reasonable mechanisms, since fair amounts of **1e** and **2e** were obtained as by-products during the formations of **1d** and **2d**. The production of **1b—4b** in nitrobenzene has been explained by the intramolecular mechanism (i), since the yields of **1b—4b** are moderately high, in spite of the adjacent attack being restricted due to the steric factor.[9]

The acetates, **1a—5a**, were synthesized by Baeyer-Villiger rearrangements of 1- (**6a**),[6] 2- (**7a**),[6] 3- (**8a**),[6,7] 8- (**9a**),[6] and 8,9-dihydro-2-acetyl-4*H*-cyclopenta[*def*]-phenanthrene (**10a**)[6] with MCPB. The alkaline hydrolyses of **1a—5a** afforded phenols **1e—5e**. Reactions of **6a—10a** with methylmagnesium iodide gave the corresponding 2-substituted 2-propanol isomers, **6b—10b**. The alcohols were converted into propylene derivatives **6c—10c** by treatments with acetic anhydride. The olefins gave isopropyl compounds, **6d—10d**, by hydrogenation with Raney nickel.

Experimental

All of the melting points are uncorrected. The ^{1}H NMR spectra were obtained with a Jeol C-60 HL or a Varian VXR-300 spectrometers in $CDCl_3$ from TMS. The IR (KBr-pellet) and mass spectra were recorded on a Jasco IR-G and a Hitachi M-80 apparatus.

Acetyl compounds **6a—10a** were obtained according to the method described elsewhere.[6] Oxime of **6a**: mp 206.0—207.5 °C; yield 74%; IR, 3200 cm^{-1}; ^{1}H NMR (C_6D_6), δ=2.33 (3H, s), 3.88 (2H, s), 7.30—7.66 (5H, m), 7.82 (1H, d, J=9.0 Hz), 8.22 (1H, bs), and 8.58 (1H, d, J=9.0 Hz); MS, m/z 247 (M$^+$), 230, and 189. Found: C, 82.86; H, 5.40%. Calcd for $C_{17}H_{13}NO$: C, 82.57; H, 5.30%.

Oxime of **7a**: mp 193—194 °C; yield 95%; IR, 3250 cm^{-1}; ^{1}H NMR, δ=2.51 (3H, s), 4.39 (2H, s), 7.66—7.75 (2H, m), 7.86 (1H, d, J=8.7 Hz), 7.87 (2H, s), 7.98 (1H, bs), and 8.08 (2H, s); MS, m/z 247 (M$^+$), 231, and 189. Found: C, 82.60; H, 5.53; N, 5.92%. Calcd for $C_{17}H_{13}NO$: N, 5.66%.

Oxime of **8a**:[7] yield 77%; mp 151.5—152.0 °C; IR, 3300 cm^{-1}; ^{1}H NMR (C_6D_6), δ=2.24 (3H, s), 4.23 (2H, s), 7.36—7.89 (7H, m), and 8.52 (1H, bs); MS, m/z 247 (M$^+$), 231, 214, and 189. Found: C, 82.87; H, 5.60%.

Oxime of **10a**: mp 181.0—181.5 °C; yield 88%; IR, 3250 cm^{-1}; ^{1}H NMR, δ=2.34 (3H, s), 3.16 (4H, s), 3.91 (2H, s), 7.12 (1H, d, J=7.2 Hz), 7.21 (1H, t, J=7.2 Hz), 7.35 (1H, d, J=7.2 Hz), 7.41 (1H, s), 7.62 (1H, s), and 8.20 (1H, bs); MS, m/z 249 (M$^+$), 232, 217, and 191. Found: C, 82.15; H, 6.37%. Calcd for $C_{17}H_{15}NO$: C, 81.90; H, 5.30%.

3-Acetoxy-4*H*-cyclopenta[*def*]phenanthrene (3a) by the Baeyer-Villiger Rearrangement of the Corresponding Ketone. Typical Procedure. A mixture of **8a**[6,7] (1.392 g, 6 mmol) in $CHCl_3$ (100 ml, percolated through alumina before use) was cooled in a refrigerator; MCPB (690 mg, 4 mmol) was added and stirred. Additional MCPB (690 mg) was added after 8 and 16 h (total 2.07 g, 12 mmol). The stirring was continued for 3 d below 5 °C. After treatment with aqueous sodium hydrogencarbonate, the organic layer was evaporated. The residue was chromatographed on SiO_2 with benzene and the first colorless eluate gave **3a** (1.027 g, 69%); mp 109—110 °C (EtOH); IR, 1753 and 1193 cm^{-1}; ^{1}H NMR, δ=2.42 (3H, s), 4.23 (2H, s), 7.26 (1H, d, J=8.4 Hz), and 7.51—7.84 (6H, m); MS, m/z 248 (M$^+$), 206, 205, 189, and 177. Found: C, 82.43; H, 4.82%. Calcd for $C_{17}H_{12}O_2$: C, 82.24; H, 4.87%.

1a; yield 67%; mp 130—131 °C; IR, 1752 and 1205 cm^{-1}; ^{1}H NMR, δ=2.50 (3H, s), 4.35 (2H, s), 7.36 (1H, d, J=7.6 Hz), 7.64—7.74 (4H, m), and 7.83—7.88 (2H, m); MS, m/z 248 (M$^+$), 206, 205, 177, and 176. Found: C, 82.40; H, 4.92%.

2a; yield 67%; mp 111.5—112.5 °C; IR, 1751, 1219, and 1206 cm^{-1}; ^{1}H NMR, δ=2.41 (3H, s), 4.37 (2H, s), 7.44 (1H, s), 7.54 (1H, s), 7.62—7.77 (2H, m), and 7.78—7.89 (3H, m); MS, m/z 248 (M$^+$), 206, 205, 177, and 176. Found: C, 82.50; H, 5.00%.

5a; yield 74%; mp 124.5—125.0 °C; IR, 1751 and 1203 cm^{-1}; ^{1}H NMR, δ=2.25 (3H, s), 3.13 (4H, s), 3.83 (2H, s), 6.72 (1H, s), 6.94 (1H, s), and 6.98—7.31 (3H, m); MS, m/z 250 (M$^+$), 208, 207, 191, and 189. Found: C, 81.85; H, 5.71%. Calcd for $C_{17}H_{14}O_2$: C, 81.58; H, 5.64%.

11; obtained by acetylation of the corresponding alcohol[11] in 85% yield; mp 93—94 °C; IR, 1723 and 1223 cm^{-1}; ^{1}H NMR, δ=2.22 (3H, s), 6.93 (1H, s), and 7.30—7.65 (8H, m); MS, m/z 248 (M$^+$), 206, and 189. Found: C, 82.52; H, 4.78%. Calcd for $C_{17}H_{12}O_2$: C, 82.24; H, 4.87%.

4a;[12] yield 81%; mp 97—98 °C. Hydrolysis of **4a** gave **4e**,[12] in 68% yield; mp 167—168 °C.

4*H*-Cyclopenta[*def*]phenanthren-1-ol (1e). The acetate **1a** (620 mg, 2.5 mmol) was dissolved in EtOH (10 ml) and a solution of KOH (2.5 g) in H_2O (10 ml) was added in a small portion into a warmed (60—70 °C) solution of **1a**. After 5 min, the resulting mixture was allowed to stand at room temperature and acidified by HCl to give **1e**; 489 mg (95%); mp 148—149 °C (cyclohexane); IR, 3340 cm^{-1}; ^{1}H NMR, δ=4.22 (2H, s), 5.23 (1H, s), 6.93 (1H, d, J=7.8 Hz), and 7.39—7.84 (7H, m); MS, m/z 206 (M$^+$) and 189. Found: C, 87.46; H, 4.90%. Calcd for $C_{15}H_{10}O$: C, 87.35; H, 4.89%.

2e; yield 95%; mp 169—170 °C; IR, 3320 cm^{-1}; ^{1}H NMR, δ=4.23 (2H, s), 5.02 (1H, s), 7.14 (1H, s), 7.18 (1H, s), and 7.44—7.70 (5H, m); MS, m/z 206, 189, and 176. Found: C, 87.53; H, 4.66%.

3e;[7] yield 93%; mp 165—166 °C; IR, 3350 and 3250 cm^{-1}; ^{1}H NMR, δ=4.29 (2H, s), 5.05 (1H, s), 7.15 (1H, d, J=7.8 Hz), and 7.59—7.92 (6H, m); MS, m/z 206, 189, and 176. Found: C, 87.09; H, 4.64%.

5e; yield 96%; mp 155—156 °C; IR, 3200 cm^{-1}; ^{1}H NMR, δ=3.01 (4H, s), 3.83 (2H, s), 4.76 (1H, s), 6.62 (1H, s), 6.83 (1H, s), and 7.05—7.36 (3H, m); MS, m/z 208 (M$^+$), 191, and 189. Found: C, 86.34; H, 6.04%. Calcd for $C_{15}H_{12}O$: 86.51; H, 5.81%.

Fries Rearrangements of 1a—5a and 7. Typical Procedure. Into a mixture of powdered $AlCl_3$ (64 mg, 0.48 mmol) in $PhNO_2$ (5 ml) was added a solution of **1a** (50 mg, 0.2 mmol) in $PhNO_2$ (5 ml) and stirred for 2 h at room temperature. Upon stirring with aq. HCl for 3 h, the reaction mixture was analyzed with a suitable hydrocarbon as an internal standard by means of gas chromatography (Shimadzu 6AMFP apparatus attached a column containing Silicone SE-30).

A pure specimen of **1b** was obtained by the reaction of **1e** (41 mg, 0.2 mmol) in $C_2H_4Cl_2$ (10 ml) with Ac_2O (0.023 ml, 0.24 mmol) and $AlCl_3$ (64 mg, 0.48 mmol) at room temperature for 30 min, yield 40 mg (80%); mp 178—179 °C; IR, 3450, 2690, 1639, and 1385 cm^{-1}; ^{1}H NMR, δ=2.66 (3H, s), 4.03 (2H, s), 7.48—7.70 (5H, m), 7.94 (1H, d, J=9.0 Hz), and 13.76 (1H, s); MS, m/z 248 (M$^+$), 233, 205, and 176. Found: C, 82.21; H, 5.04%. Calcd for $C_{17}H_{12}O_2$: C, 82.24; H, 4.87%.

Compound **1d** was isolated from the reaction of **1a** (248 mg, 1 mmol) with Ac_2O-$AlCl_3$ in $CHCl_3$; yield 221 mg (76%); mp 155—156 °C; IR, 1751, 1660, and 1195 cm^{-1}; ^{1}H NMR, δ=2.39 (3H, s), 2.78 (3H, s), 4.27 (2H, s), 7.35 (1H, d, J=7.8 Hz), 7.58—7.70 (2H, m), 7.81 (1H, d, J=9.0 Hz), 8.15

(1H, d, J=7.8 Hz), and 8.91 (1H, d, J=9.0 Hz). Found: C, 78.40; H, 4.99%. Calcd for $C_{19}H_{14}O_3$: C, 78.60; H, 4.85%.

Diketone **1d** was hydrolyzed with aqueous KOH in EtOH to give **1c**; yield 38%; mp 183—185 °C; IR, 3250, 1645, and 1254 cm^{-1}; ^{1}H NMR (DMSO-d_6), δ=2.76 (3H, s), 4.32 (2H, s), 7.09 (1H, d, J=7.5 Hz), 7.59 (1H, d, J=7.5 Hz), 7.80 (1H, d, J=7.5 Hz), 8.10 (1H, d, J=9.6 Hz), 8.86 (1H, d, J=7.5 Hz), 8.70 (1H, d, J=9.6 Hz), and 9.90 (1H, s); MS, m/z 248 (M$^+$), 233, 217, 205, and 189. Found: C, 82.55; H, 5.06%. Calcd for $C_{17}H_{12}O_2$: C, 82.24; H, 4.87%.

Fries Rearrangement of 2a. Acetate **2a** (50 mg, 0.2 mmol) was treated with $AlCl_3$ (64 mg, 0.48 mmol) in $C_2H_4Cl_2$ (10 ml) at room temperature for 3 h. The composition of the reaction mixture was submitted to GC. The main portion was chromatographed on SiO_2 with benzene to give **2d**; yield 12 mg (20%); mp 196—197 °C; IR, 1758, 1659, and 1201 cm^{-1}; ^{1}H NMR, δ=2.40 (3H, s), 2.79 (3H, s), 4.27 (2H, s), 7.38 (1H, s), 7.52 (1H, s), 7.62 (1H, d, J=7.8 Hz), 7.88 (1H, d, J=9.0 Hz), 8.09 (1H, d, J=7.8 Hz), and 8.34 (1H, d, J=9.0 Hz); MS, m/z 290 (M$^+$), 248, 233, 205, and 176. Found: C, 78.86; H, 5.16%. Calcd for $C_{19}H_{14}O_3$: 78.60; H, 4.85%.

The diketone **2d** was hydrolyzed to give **2c**; yield 80%; mp 129—130 °C; IR, 3260, 1637, and 1217 cm^{-1}; ^{1}H NMR, δ=3.00 (3H, s), 4.27 (2H, s), 5.25 (1H, s), and 7.10—8.10 (6H, m). Found: C, 82.52; H, 4.96%. Calcd for $C_{17}H_{12}O_2$: C, 82.24; H, 4.87%.

The isomeric **2b** was obtained by the reaction of **2e** (103 mg, 0.5 mmol) with Ac_2O (0.057 ml, 0.6 mmol) and $AlCl_3$ (200 mg, 1.5 mmol) in $C_2H_4Cl_2$ (40 ml) at room temperature for 30 min; yield 87 mg (70%); mp 153.5—154.5 °C; IR, 3450, 2580, 1607, and 1210 cm^{-1}; ^{1}H NMR, δ=2.95 (3H, s), 4.17 (2H, s), 7.20 (1H, s), 7.45—7.84 (3H, m), 7.88 (1H, d, J=9.0 Hz), 8.02 (1H, d, J=9.0 Hz), and 14.27 (1H, s); MS, m/z 248 (M$^+$), 233, and 176. Found: C, 82.48; H, 4.71%.

Fries Rearrangement of 3a. A reaction of **3a** (50 mg, 0.2 mmol) was carried out similar as described above. The reaction mixture yielded **3b**; yield 12 mg (24%); mp 176—177 °C; IR, 3400, 3200, 1640, and 1300 cm^{-1}; ^{1}H NMR, δ=2.84 (3H, s), 4.33 (2H, s), 7.61—7.77 (5H, m), 8.33 (1H, s), and 12.59 (1H, s); MS, m/z 248 (M$^+$), 233, 205, and 176. Found: C, 82.04; H, 4.98%. Calcd for $C_{17}H_{12}O_2$: C, 82.24; H, 4.87%.

Fries Rearrangement of 4a. Compound **4a** (50 mg, 0.2 mmol) was treated in a manner similar to that described above, giving 25.5 mg (51%) of **4b**; mp 152.5—153.5 °C; IR, 3400, 2650, 1639, 1447, and 1380 cm^{-1}; ^{1}H NMR, δ=2.99 (3H, s), 4.27 (2H, s), 7.58—7.68 (3H, m), 7.83 (1H, d, J=7.2 Hz), 8.00 (1H, d, J=8.0 Hz), 8.22 (1H, d, J=8.0 Hz), and 16.62 (1H, s); MS, m/z 248 (M$^+$), 233, and 176. Found: C, 82.02; H, 4.79%. Calcd for $C_{17}H_{12}O_2$: C, 82.24; H, 4.87%.

The Reaction of 5a. Compound **5a** (125 mg, 0.5 mmol) was treated with $AlCl_3$ (160 mg, 1.2 mmol) in PhCl (10 ml) with refluxing for 1 h to give 10 mg (8%) of **5c** and 12 mg (10%) of **5a**. **5c**; mp 186—187 °C; IR, 3300, 1650, 1575, 1368, and 1288 cm^{-1}; ^{1}H NMR, δ=2.62 (3H, s), 3.12 (4H, s), 3.85 (2H, s), 5.45 (1H, s), 6.64 (1H, s), 6.83 (1H, s), 7.72 (1H, s), and 7.90 (1H, s); MS, m/z 250 (M$^+$), 235, 207, and 189.

Diketone **5d** was obtained by a treatment of **5c** with Ac_2O in benzene; mp 116.0—116.5 °C; IR, 3550, 1757, 1665, and 1200 cm^{-1}; ^{1}H NMR, δ=2.34 (3H, s), 2.65 (3H, s), 3.19 (4H, s), 3.93 (2H, s), 6.90 (1H, s), 7.11 (1H, s), 7.80 (1H, s), and 7.98 (1H, s); MS, m/z 292 (M$^+$), 250, 235, and 207. Found: C, 77.84; H, 5.40%. Calcd for $C_{19}H_{16}O_3$: C, 78.06; H, 5.52%.

Reaction of 11. Compound **11** (248 mg, 1.0 mmol) in PhCl (30 ml) was refluxed with $AlCl_3$ (170 mg, 1.3 mmol) for 1 h; only **11** (120 mg, 48%) was isolated from the reaction mixture.

2-(4*H*-Cyclopenta[*def*]phenanthren-1-yl)-2-propanol (6b). A mixture of **6a** (1.872 g, 8 mmol) in PhH (30 ml) was added dropwise into MeMgI (prepared from 2.0 g (12 mmol) of CH_3I and 290 mg (12 mg atom) of Mg in ether); the mixture was refluxed for 4 h. Upon the usual treatment, the residue was chromatographed on SiO_2 with PhH giving 1.517 g (76%) of **6b**, 263 mg (14%) of **6c** (mp 50—51 °C), and 56 mg (3%) of **6a**. **6b**; mp 113.0—114.5 °C; IR, 3270 and 1148 cm^{-1}; ^{1}H NMR, δ=1.83 (6H, s), 2.09 (1H, bs), 4.20 (2H, s), 7.52—7.86 (5H, m), 7.76 (1H, d, J=9.0 Hz), and 8.47 (1H, d, J=9.0 Hz); MS, m/z 248 (M$^+$), 233, 230, 215, and 189. Found: C, 87.29; H, 6.73%. Calcd for $C_{18}H_{16}O$: C, 87.06; H, 6.50%.

7b; yield 38%; mp 88—89 °C; IR, 3370 and 1168 cm^{-1}; ^{1}H NMR, δ=1.62 (6H, s), 2.43 (1H, s), 4.05 (2H, s), and 7.35—7.75 (7H, m); MS, m/z 248 (M$^+$), 233, 230, 215, and 189. Found: C, 87.20; H, 6.79%.

8b; yield 81% (crude); IR, 3420 and 1170 cm^{-1}; ^{1}H NMR, δ=1.79 (6H, s), 2.01 (1H, s), 4.54 (2H, s), and 7.57—7.80 (7H, m); MS, m/z 248 (M$^+$), 230, 215, 202, and 189. Found: C, 86.99; H, 6.46%.

9b; yield 86%; mp 108—109 °C; IR, 3320 and 1150 cm^{-1}; ^{1}H NMR, δ=1.93 (6H, m), 2.07 (1H, s), 4.33 (2H, s), 7.58—7.80 (5H, m), 7.84 (1H, s), and 8.40 (1H, m); MS, m/z 248 (M$^+$), 233, 230, 215, and 189. Found: C, 87.01; H, 6.63%.

1-Isopropenyl-4*H*-cyclopenta[*def*]phenanthrene (6c). A mixture of **6b** (248 mg, 1 mmol) in Ac_2O (4 ml) was refluxed for 5 h giving 209 mg (91%) of **6c** by column chromatography; mp 50.5—51.0 °C; IR, 1622 cm^{-1}; ^{1}H NMR, δ=2.32 (3H, s), 4.34 (2H, s), 5.23—5.24 (1H, m), 5.45—5.46 (1H, m), 7.53 (1H, d, J=7.3 Hz), 7.61—7.71 (3H, m), 7.82 (1H, d, J=7.7 Hz), 7.83 (1H, d, J=9.1 Hz), and 8.05 (1H, d, J=9.1 Hz); MS, m/z 230 (M$^+$), 215, and 189. Found: C, 93.87; H, 5.93%. Calcd for $C_{18}H_{14}$: C, 93.87; H, 6.13%.

7c; yield 68%; mp 65—66 °C; IR, 1612 cm^{-1}; ^{1}H NMR, δ=2.32 (3H, s), 4.27 (2H, s), 5.14 (1H, m), 5.42 (1H, m), and 7.50—7.90 (7H, m); MS, m/z 230 (M$^+$), 215, and 189. Found: C, 93.88; H, 5.86%.

8c; yield 26% from crude **8b**; mp 29.5—30.0 °C; IR, 1620 cm^{-1}; ^{1}H NMR, δ=2.32 (3H, s), 4.26 (2H, s), 5.20 (1H, s), 5.36 (1H, s), and 7.34—7.68 (7H, m); MS, m/z 230 (M$^+$), 215, and 189. Found: C, 93.64; H, 6.17%.

9c; yield 63%; mp 31.0—31.5 °C; IR, 1632 and 1624 cm^{-1}; ^{1}H NMR, δ=2.33 (3H, s), 4.30 (2H, s), 5.25 (1H, m), 5.40 (1H, m), and 7.47—8.00 (7H, m); MS, m/z 230 (M$^+$), 215, 213, and 189. Found: C, 93.58; H, 6.05%.

10c; yield 84% from **1e**; mp 55—56 °C; IR, 1614 cm^{-1}; ^{1}H NMR, δ=2.16 (3H, s), 3.08 (4H, s), 3.76 (2H, s), 4.92 (1H, s), 5.20 (1H, s), 6.87—7.13 (4H, m), and 7.33 (1H, s); MS, m/z 232 (M$^+$), 217, and 191. Found: C, 92.86; H, 7.14%. Calcd for $C_{18}H_{16}$: C, 93.06; H, 6.94%.

1-Isopropyl-4*H*-cyclopenta[*def*]phenanthrene (6d). A solution of **6c** (115 mg, 0.5 mmol) in EtOH (60 ml) was shaken with Raney nickel (W-7, 0.15 g) under an atmosphere of hydrogen for 15 min at room temperature to give **6d** (60 mg, 52%); mp 70—71 °C; ^{1}H NMR, δ=1.45 (6H, d, J=6.6 Hz), 3.73 (1H, sep, J=6.6 Hz), 4.21 (2H, s), 7.14—7.73 (6H, m),

and 7.90 (1H, d, J=9.0 Hz); MS, m/z 232 (M^+), 217, 215, 202, and 189. Found: C, 93.27; H, 7.21%. Calcd for $C_{18}H_{16}$: C, 93.06; H, 6.94%.

7d; yield 47%; mp 75—76 °C; ^{1}H NMR, δ=1.35 (6H, d, J=7.0 Hz), 3.00 (1H, sep, J=7.0 Hz), 4.14 (2H, s), and 7.30—7.75 (7H, m); MS, m/z 232 (M^+), 217, 202, and 189. Found: C, 93.27; H, 7.21%.

8d; yield 52%; mp 45.5—46.0 °C; ^{1}H NMR, δ=1.44 (6H, d, J=7.0 Hz), 3.37 (1H, sep, J=7.0 Hz), 4.34 (2H, s), and 7.54—7.82 (7H, m); MS, m/z 232 (M^+), 217, 202, and 189. Found: C, 93.02; H, 7.27%.

9d; yield 32%; mp 33.5—34.0 C; ^{1}H NMR, δ=1.50 (6H, d, J=6.6 Hz), 3.71 (1H, sep, J=6.6 Hz), 4.24 (2H, s), and 7.30—7.92 (7H, m); MS, m/z 232 (M^+), 217, 202, and 189. Found: C, 93.12; H, 6.68%.

10d; yield 60%; mp 97.5—98.0 °C; ^{1}H NMR, δ=1.30 (6H, d, J=6.9 Hz), 2.96 (1H, sep, J=6.9 Hz), 3.13 (4H, s), 3.86 (2H, s), 7.00 (1H, s), 7.07—7.18 (2H, m), 7.23 (1H, s), and 7.31 (1H, d, J=7.3 Hz); MS, m/z 234 (M^+), 219, 202, 191, and 189. Found: C, 92.26; H, 7.88%. Calcd for $C_{18}H_{18}$: C, 92.26; H, 7.74%.

We greatly thank Professor Takashi Toda and Emeritus Professor Kazuo Suzuki, Utsunomiya University for their continuing interest and encouragement.

Dehydrooligopeptides. VIII. Convenient Syntheses of Various Dehydrotyrosine Derivatives Protected with Useful N, O-Protecting Groups via *N*-Carboxy Dehydrotyrosine Anhydrides[1)]

Chung-gi SHIN,* Yasuchika YONEZAWA, Takumi OBARA, and Hiroaki NISHIO
Laboratory of Organic Chemistry, Faculty of Technology, Kanagawa University, Rokkakubashi, Kanagawa-ku, Yokohama 221
(Received July 22, 1987)

Various *N*-benzyloxycarbonyl (Cbz) O-protected dehydrotyrosine (*Δ*Tyr) esters have been successfully synthesized mainly via two routes, in which reactions of (diethoxyphosphinyl)glycine ester with *p*-substituted benzaldehyde were included. Subsequent hydrolyses of the esters under various alkaline conditions were carried out in order to produce corresponding Cbz-*Δ*Tyr-OH derivatives, which were further converted with thionyl chloride to give *N*-carboxy dehydrotyrosine anhydrides [*Δ*Tyr·NCA]. In addition to these topics, the transformation of *Δ*Tyr·NCA to various kinds of *Δ*Tyr derivatives and a discussion on the configurational determination of all the new compounds are presented.

In the course of our work on the syntheses of various α-dehydroamino acids (DHA), which seem to be important residues in naturally occurring[2-5)] and synthetic dehydropeptides (DHP),[6)] we reported on several versatile synthetic methods for DHA and DHP.[1,7-9)] Recently, such DHA and DHP derivatives have been utilized for studies on both structure-biological activity correlation[10)] and asymmetric hydrogenation.[11)] So far, the syntheses and reactions of various kinds of neutral aliphatic, aromatic, and acidic DHA and their DHP derivatives have been reported.[12,13)] In addition, we already reported that *N*-carboxy α-dehydroamino acid anhydrides (*Δ* NCA), derived from benzyloxycarbonyl (Cbz)-DHA and thionyl chloride, were very useful for syntheses of DHP and for transformations to other DHA derivatives.[8)] Consequently, the *Δ* NCAs and their derivatives became a very important synthon as the building block of DHP. However, the syntheses and properties of DHA and its *Δ* NCA derivatives, which have another functional group in their side chains, such as a hydroxyl group, have never been investigated in detail, except for our brief report.[12,14)] In particular, in the case of DHA as well as an α-amino acid ester possessing two functional groups, e.g., amino and hydroxyl, it is usually necessary to protect them with different protecting groups for peptide synthesis. Therefore, we thoroughly examined the syntheses of several dehydrotyrosine (*Δ* Tyr) and its *Δ* NCA derivatives (*Δ* Tyr·NCA) mainly concerning two routes; we also tried to protect their functional groups by various combinations of useful N,O-protecting groups.[12)]

Results and Discussion

Synthesis of Dehydrotyrosine Derivatives. Since it was found that the methoxymethyl (MOM) group is effective for the protection of the phenolic hydroxyl group,[15)] the starting *p*-methoxymethoxybenzaldehyde (**1b**), derived from *p*-hydroxybenzaldehyde and methoxymethyl chloride by the usual method, was used in the following type condensation. According to the Hemetsberger method,[16)] the condensation of ethyl 2-azidoacetate with **1b** in the presence of sodium ethoxide was performed in order to produce (*Z*)-2-azido-(*p*-MOM)oxycinnamate (**2**) in a 57% yield. Although the yield of **2** was slightly low, compound **2** was subsequently subjected to a reduction. The selective hydrogenolysis of the azido group of **2** with aluminum-amalgam (Al-Hg) was smoothly carried out to give (*O*-MOM)dehydrotyrosine ethyl ester [*Δ*Tyr(MOM)-OEt] (**3**) in an almost quantitative yield. Unfortunately, however, it was found that a subsequent acylation of **3** with Cbz-Cl in the presence of a base such as triethylamine (TEA) or sodium hydride in CH_2Cl_2 or tetrahydrofuran (THF), did not take place, whereas a similar treatment of aliphatic DHA with Cbz-Cl proceeded.[7)]

Furthermore, in the presence of pyridine, the analogous acylation of **3** took place to give Cbz-(*O*-MOM)dehydrotyrosine ester [Cbz-*Δ*Tyr(MOM)-OY] (**4b**; Y=Et) in only a 33% yield. In order to increase the yield of **4b**, phase-transfer catalyst, such as $[CH_3(CH_2)_3]_4NBr$ (TBAB), was added to a heterogeneous solution of **3** and Cbz-Cl in the presence of powdered NaOH in CH_2Cl_2 at room temperature. As a result, the yield of **4b** ultimately increased to a 63%.

On the other hand, recently, Schmidt and coworkers have reported an interesting and convenient synthetic method for DHA by using an *N*-acyl-2-(dialkoxyphosphinyl)glycine ester as a Wittig-Horner reagent to an arbitrary aldehyde.[17)] Using the above-mentioned method, *N*-Cbz-2-(diethoxyphosphinyl)-glycinemethyl ester was prepared and then reacted with several *p*-substituted benzaldehydes (**1**) in the presence of potassium *t*-butoxide in CH_2Cl_2 at room temperature to give the expected Cbz-*Δ*Tyr(R)-OMe [**4**: **a**; R=CH_3 (Me), **b**; R=CH_3OCH_2 (MOM), **c**; R=CH_3CO (Ac)] in ca. a 50% yield (summarized in

Table 1. Dehydrotyrosine Ester Derivatives **4**

Compound No.	Y	Yield %	Mp θ_m/°C	Formula	Found (Calcd)/% C	H	N

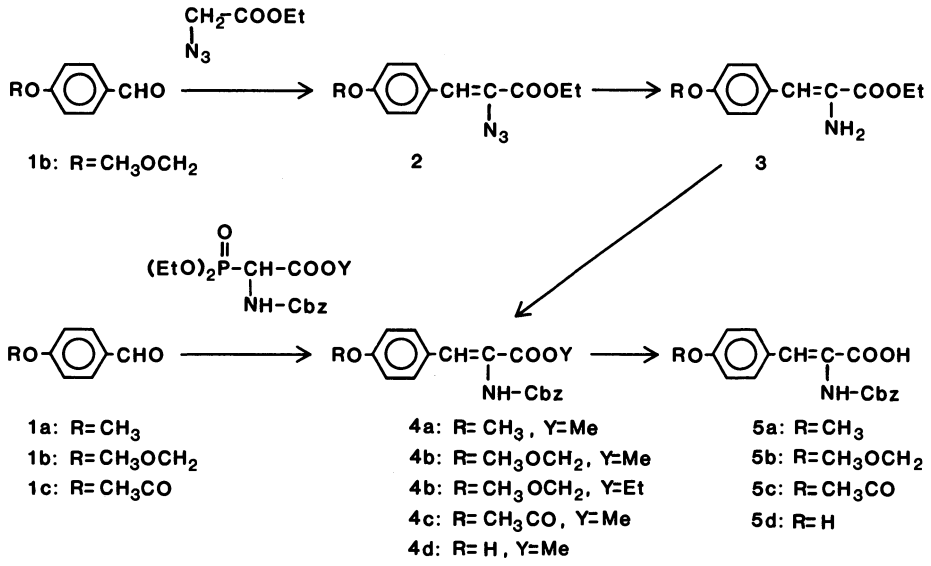
a) Measured in DMSO-d_6.



Scheme 1.

Tables 1 and 2). From the results, in the case of *p*-acetoxybenzaldehyde (**1c**), the obtained yield of Cbz-⊿Tyr(Ac)-OMe (**4c**) was a 69%. Moreover, Cbz-⊿Tyr-(R)-OMe (**4d**; R=H) was independently derived by the hydrolysis of **4c** with K_2CO_3 (as mentioned later).

Furthermore, in order to synthesize for the first time various kinds of useful ⊿Tyr·NCA derivatives, compounds **4a—c** had to be submitted to ester hydrolysis under mild conditions. The conventional hydrolysis of **4a** with 2-M† NaOH (1.0 equiv mol) at room temperature, even for more than 24 h, proceeded to give Cbz-⊿Tyr(Me)-OH (**5a**) in an only 10% yield. On the other hand, as shown in Tables 3 and 4, when 1-M LiOH instead of NaOH was used in the

† 1 M=1 mol dm^{-3}.

a) Colorless needles from benzene. b) Colorless prisms from ethyl acetate.

hydrolysis, the desired **5a** could be obtained within a short time of 3.5 h in ca. a 75% yield. In a similar manner, the hydrolysis of **4b** (Y=Me and Et) was also worked up to give Cbz-⊿Tyr(MOM)-OH (**5b**) almost quantitatively. However, when 1-M of LiOH or 1-M $Ba(OH)_2$ was used in the analogous hydrolysis of **4c**, two products, **4d** and Cbz-⊿Tyr-OH (**5d**), instead of expected Cbz-⊿Tyr(Ac)-OH (**5c**), were obtained in ca. a 76% overall yield (in about a 1:2 ratio) accompanying an elimination of the acetyl group.

In addition, in the case of 2-M LiOH (5.0 equiv mol) for 22 h, the ester hydrolysis and the elimination of the acetyl group of **4c** occurred simultaneously to give **5d** as the main product (71%). Consequently, a high-yield synthesis of **5c** was accomplished by the acetylation of **5d** with acetyl chloride by the usual method. On the other hand, when 1-M K_2CO_3 was used as a weak base, only a deacetylation of **4c** was found to take place to give **4d** in an 85% yield.

Eventually, in almost all the cases mentioned above, it was proved that the acetyl group as the O-protecting group of ⊿Tyr derivatives was always labile under alkaline conditions, while the ester was gradually hydrolyzed upon increasing the concentration of the base.

The yields, melting points, and spectral data (IR and ^{1}H NMR) of **4** and **5** are summarized in Tables 1, 2, and 4.

In the IR spectra of **4** and **5**, the characteristic absorption bands of NH, acid carbonyl, and carbon–carbon double bond functions appear at 3250—3310, 1685—1720, and 1632—1645 cm^{-1} regions, respectively. Furthermore, in the ^{1}H NMR spectra, all the olefin protons of **4** and **5** shift at the δ 7.40—7.16 region as a singlet. In particular based on the ^{1}H NMR spectral data, the configurations of **4** and **5** could be tentatively determined to be in the (*Z*)-geometry, since the chemical shifts and the spectral patterns of (*Z*)-configurational DHA derivatives, the olefin protons of which shifted at comparatively higher magnetic fields than those of (*E*)-isomer,[18] were quite similar to those of the ⊿Tyr derivatives. Accordingly, the configuration of **2** and **3** could be also confirmed to be (*Z*)-geometry.

Synthesis and Conversion of ⊿Try·NCA to Various ⊿Tyr Derivatives. In order to synthesize *N*-carboxy dehydrotyrosine anhydride derivatives (⊿Tyr·NCA) (**6**), compounds **5a—d** (mentioned above) were subjected to cyclization of **5a** and **5c** with $SOCl_2$ in CH_2Cl_2 proceeded smoothly to give *N*-carboxy (*O*-Me)dehydrotyrosine anhydride [⊿Tyr(Me)·NCA] (**6a**) and *N*-carboxy (*O*-Ac)dehydrotyrosine anhydride [⊿Tyr(Ac)·NCA] (**6c**) in high yields, respectively, according to our previously reported technique.[12] On the other hand, the cyclization of **5b** also took place, but the O-protecting MOM group was found to behave interestingly under certain reaction conditions. In particular, when acetyl chloride or CH_2Cl_2 was used as the solvent, the cyclization and partial deprotection of **5b** readily proceeded to give only *N*-

carboxy *O*-free-dehydrotyrosine anhydride [ΔTyr·NCA] (**6d**) almost quantitatively, instead of the desired *N*-carboxy (*O*-MOM)dehydrotyrosine anhydride [ΔTyr-(MOM)·NCA] (**6b**). However, interestingly, when diethyl ether was used as the solvent, a similar treatment of **5b** yielded another crystalline product in addition to a small amount of **6d** (17%). From the spectroscopic data and satisfactory elemental analytical results, the structure of the main isolated product was determined to be **6b**. As a result, the MOM protecting group was found to remain unchanged. Additionally, as shown in Tables 5 and 6, when the quantity of diethyl ether was doubled, only **6b** was obtained in an almost quantitative yield.

From the above results, it was found that diethyl ether used as the solvent behaved as a scavanger of the HCl gas that evolved during the reaction of **5b** with $SOCl_2$. Accordingly, in the former case in the absence of ether, it was clarified that the cyclization of **5b** initially formed **6b** as an intermediate, the MOM group of which was immediately eliminated with HCl to give **6d** in high yield. Consequently, it was clearly demonstrated that either compound **6b** or **6d** could be selectively prepared, according to the reaction conditions listed in Table 5. These results provide useful information for the dehydropeptide synthesis regarding the protection of side chain functional groups.

Furthermore, to be utilized in a wide variety of peptide syntheses, both the hydroxyl and amino groups of the ΔTyr derivatives must be easily and selectively protected with such groups as Cbz and *t*-butoxycarbonyl (Boc). In addition, we are interested in not only the protection but also the reactivity of the newly formed ΔNCA ring, itself. Thus, compound **6d** was chosen and directly applied for transformations to other DHA derivatives under various reaction conditions.

Compound **6d** was treated with di-*t*-butyl carbonate [$((CH_3)_3COCO)_2O$; $(Boc)_2O$] in the presence of a few drops of pyridine in THF; then, methanol was added. The resulting solution was made basic to pH 9 with *N*-methylmorpholine (NMM) in order to give *N*-free (*O*-Boc)dehydrotyrosine methyl ester [ΔTyr(Boc)-OMe] (**7a**) in an 80% yield. On the other hand, in the case of using Cbz-Cl instead of $(Boc)_2O$, a similar reaction was carried out to give the (*O*-Cbz)dehydrotyrosine methyl ester [ΔTyr(Cbz)-OMe] (**7b**) in an 84% yield (Scheme 2.)

From the above results and by a comparison with the reactivity of two reaction points of **6d**, the phenolic hydroxyl group was found to be acylated more easily than the imino group of the ΔNCA ring.

Furthermore, for one-pot syntheses of the ΔTyr

a) Colorless prisms from hexane. b) Colorless needles from diisopropyl ether.

derivatives N,O-protected with different groups, a similar treatment of **6d** with $(Boc)_2O$ in THF was worked up, followed by consecutive treatments with TEA and Cbz-Cl. Finally, the reaction solution was treated further with MeOH to give the expected *N*-Cbz-(*O*-Boc)dehydrotyrosine methyl ester [Cbz-ΔTyr-(Boc)-OMe] (**7c**) in ca. a 46% yield. Contrary to the above successive reactions, similar treatments of **6d** with Cbz-Cl, $(Boc)_2O$, and then MeOH were also performed to give *N*-Boc-(*O*-Cbz)dehydrotyrosine methyl ester [Boc-ΔTyr(Cbz)-OMe] (**7d**) in ca. a 52% yield (Table 7).

In conclusion, facile syntheses of various kinds of ΔTyr and ΔTyr·NCA derivatives were accomplished in high yield; detailed knowledge concerning their protection and deprotection mechanisms were obtained. These results should be very useful regarding dehydropeptide synthesis.

Experimental

General. Melting points were determined with a Yamato (Model Mp-21) micro melting-point apparatus, and were not corrected. IR spectra were recorded with a Hitachi EPI-G2 spectrometer. ^{1}H NMR spectra were measured with a JEOL LMN PS-100 spectrometer in a $CDCl_3$ or DMSO-d_6 solution with tetramethylsilane as the internal standard.

Ethyl (*Z*)-2-Azido-(*p*-MOM)oxycinnamate (2). Into a solution of ethyl 2-azidoacetate (5.12 g, 40 mmol) and **1b** (6.64 g, 40 mmol) in dry benzene (120 ml) was added sodium ethoxide (made from Na 0.9 g, 40 mmol) in dry ethanol (24 ml) drop by drop, with stirring, at 5—8 °C. After allowing the solution to stand at room temperature for 2 h, the reaction solution was diluted with benzene (100 ml) and washed with a saturated aqueous ammonium chloride solution and then with chilled water. The organic layer was dried over anhydrous sodium sulfate. After removing the solvent under reduced pressure, the residual syrup was purified on a silica-gel column using benzene as the eluent to give **2** as a colorless viscous syrup. Yield 57%. IR ν_{max}^{KBr} (cm^{-1}) 2153 (N_3), 1650 (C=C); ^{1}H NMR ($CDCl_3$) δ=6.86 (s, 1H, -CH=). Found: C, 56.48; H, 5.32; N, 15.33%. Calcd for $C_{13}H_{15}N_3O_4$: C, 56.31; H, 5.45; N, 15.16%.

(*Z*)-ΔTyr(MOM)-OEt (3). A solution of **2** (6.0 g, 22 mmol) in ether (70 ml) was added to a suspension of Al–Hg (made from 9.94 g of Al and 9.94 g of $HgCl_2$) in ether (200 ml) with vigorous stirring at room temperature. After a few minutes, the ether began to reflux; this was maintained by the addition of a few drops of water at about 20 min intervals. After completing the addition of the solution, stirring was continued for 3 h. After removing on insoluble substance, the filtrate was washed several times with ice-water. The organic layer was dried over anhydrous sodium sulfate and then evaporated under reduced pressure. The residual syrup was purified on a silica-gel column using a mixture of benzene and ethyl acetate (10:1 v/v) as the eluent to give **3** as colorless viscous syrup. Yield 97%. IR ν_{max}^{KBr} (cm^{-1}) 3360, 3350 (NH_2), 1640 (C=C); ^{1}H NMR ($CDCl_3$) δ=6.48 (s, 1 H, -CH=), 4.16 (bs, 2H, $-NH_2$). Found: C, 61.87; H, 7.03; N, 5.81%. Calcd for $C_{13}H_{17}NO_4$: C, 62.14; H, 6.82; N, 5.57%.

(*Z*)-Cbz-ΔTyr(MOM)-OY (4b; Y=Me and Et). a) Method A. Into a solution of **3** (5.0 g, 20 mmol) in pyridine (40 ml) was added slowly Cbz-Cl (6.4 g, 40 mmol), with stirring, at 5—8 °C. The resultant solution was allowed to stand at room temperature and then stirred continuously for 2 h.

After removing the solvent under reduced pressure, the residual syrup was dissolved in ethyl acetate (200 ml) and washed twice, successively, with a 10% citric acid solution and with water; it was then dried over anhydrous sodium sulfate. Evaporation of the solvent under reduced pressure gave a viscous syrup, which was then purified on a silica-gel column using a mixture of hexane and ethyl acetate (20:1 v/v) as the eluent to give **4b** (Y=Et) as a colorless syrup. Yield 33%.

b) Method B. Into a suspension of **3** (5.0 g, 20 mmol) and powdered NaOH (2.0 g, 50 mmol) in the presence of TBAB (0.66 g, 2 mmol) in dry CH_2Cl_2 (50 ml) was added a solution of Cbz-Cl (4.8 g, 30 mmol) in CH_2Cl_2 (10 ml), with stirring, at 5—8 °C. The stirring was continued at room temperature for 8 h. An insoluble substance was filtered off and the filtrate was diluted with $CHCl_3$ (50 ml). The resultant solution was washed twice, successively, with a 10% citric acid solution and with water and then dried over anhydrous sodium sulfate. By removing the solvent under reduced pressure a crude syrup was obtained which could be similarly purified on a silica-gel column to give **4b** (Y=Et). Yield 63%.

c) Method C. Into a solution of potassium *t*-butoxide (3.1 g, 28 mmol) in dry CH_2Cl_2 (40 ml) was added a solution of *N*-Cbz-2-(diethoxyphosphinyl)glycine methyl ester (10 g, 28 mmol), with stirring, at −60 °C. After stirring for 15 min, the resulting solution was further stirred with an appropriate aldehyde (**1a—c**; 28 mmol) below −60 °C. After allowing this solution to stand at room temperature for 12 h, the reaction solution was concentrated under reduced pressure to give a residual syrup, which was dissolved in ethyl acetate (150 ml). The resultant solution was washed, successively, with a saturated aqueous ammonium chloride solution and water and finally dried over anhydrous sodium sulfate. The evaporation of the solvent under reduced pressure gave a viscous syrup, which was similarly worked up to give **4a—c** as a colorless syrup or crystals. (See Tables 1 and 2).

(*Z*)-Cbz-⊿Tyr(Me)-OH (5a). a) Method A. A solution of **4a** (1.71 g, 5 mmol) in dioxane (4 ml) and 2-M NaOH (2.5 ml) was stirred at room temperature for 24 h. After removing the solvent under reduced pressure, the residue was dissolved in water (20 ml). The resultant solution was washed twice with ethyl acetate and then the aqueous layer was made acidic to pH 2 with 3-M HCl. The acidic solution was extracted three times with ethyl acetate; the combined extracts were then washed with saturated aqueous NaCl solution and dried over anhydrous sodium sulfate. The concentration of the solution under reduced pressure gave crude crystals, which were recrystallized from a mixture of ethyl acetate and hexane to give **5a** as colorless prisms. Yield 10%.

b) Method B. In a similar manner, the treatment of **4a** (5 mmol) in dioxane (4 ml) with a 1-M LiOH solution (5 ml) was worked up at room temperature for 3.5 h to give **5a**. Yield 75%

(*Z*)-Cbz-⊿Tyr(MOM)-OH (5b). Treatment of **4b** (Y=Me; 4.5 g, 12 mmol) in dioxane (9 ml) with 1-M LiOH solution (14 ml) was similarly worked up for 4.5 h to give a crystalline substance. The residue was dissolved in water (40 ml) and then washed twice with ethyl acetate. The aqueous layer was made acidic to pH 2 with 3-M HCl. The acidic solution was extracted three times with ethyl acetate; the combined extracts were washed with a saturated aqueous NaCl solution and then dried over anhydrous sodium sulfate. Removing the solvent under reduced pressure gave crude crystals, which were recrystallized from a mixture of ethyl acetate and hexane or benzene alone to give **5b** as colorless prisms. Yield 92%.

In a similar manner, the treatment of **4b** (Y=Et) with 1-M LiOH was worked up to give **5b** in an 89% yield.

(*Z*)-Cbz-⊿Tyr-OH (5d) and (*Z*)-Cbz-⊿Tyr-OMe (4d). Into a solution of **4c** (1.85 g, 5 mmol) in dioxane (5 ml) was added a 2-M LiOH solution (12.5 ml), with stirring, at room temperature. The resulting solution was stirred continuously for 22 h. After removing dioxane under reduced pressure, water (30 ml) was added to the residual substance; the aqueous solution, thus obtained, was washed twice with ethyl acetate. The aqueous layer was made acidic to pH 2 with 3-M HCl and then extracted twice with ethyl acetate. The combined extracts were washed with a saturated aqueous NaCl solution and finally dried over anhydrous sodium sulfate. After removing the solvent under reduced pressure, a crystalline product was obtained as a mixture of **5d** and a small amount of **4d**. The mixture was washed well with benzene; the remaining crystals were then collected. Recrystallization from ethyl acetate gave only **5d** as colorless prisms.

In a similar manner, the treatment of **4c** (1.85 g, 5 mmol) in dioxane (5 ml) with a 1-M K_2CO_3 solution (10 ml) was worked up at room temperature for 4 h and then made acidic to pH 3 with 3-M HCl to give crude crystals. Recrystallization from CCl_4 gave only **4d** as colorless prisms.

Furthermore, the treatment of **4c** with 1-M NaOH, 1-M LiOH, or 1-M $Ba(OH)_2$ was similarly worked up to give a mixture of **4d** and **5d**, except for the case of 1-M NaOH (Table 3).

(*Z*)-Cbz-⊿Tyr(Ac)-OH (5). Into a suspension of **5d** (1.57 g, 5 mmol) and acetyl chloride (0.47 g, 6 mmol) in dry CH_2Cl_2 (10 ml) was added pyridine (0.47 g, 6 mmol), with stirring, at room temperature. After stirring for 2 h, chloroform (30 ml) was added to the reaction solution. The resulting solution was washed, successively, with 1-M HCl and three times with a saturated aqueous NaCl solution and then dried over anhydrous sodium sulfate. After removing the solvent, the residual syrup was crystallized with cyclohexane; the crystals collected were then recrystallized from benzene to give **5c** as colorless needles.

⊿Tyr(Me)·NCA (6a). Into a suspension of **5a** (0.63 g, 2 mmol) in dry CH_2Cl_2 (6 ml) was added $SOCl_2$ (6 ml), with stirring, below 0 °C. The resulting solution was then stirred continuously at room temperature for 2 h. After removing the solvent and excess $SOCl_2$ under reduced pressure, the residual syrup was dissolved in CCl_4 (10 ml) and then concentrated under reduced pressure. This procedure was repeated three times; then, the crystals collected were recrystallized from ethyl acetate to give **6a** as colorless needles.

⊿Tyr(MOM)·NCA (6b) and ⊿Tyr·NCA (6d). A solution of **5b** (0.2 g, 0.56 mmol) and $SOCl_2$ (2 ml) in dry ethyl ehter (2 ml) was stirred below 0 °C for 1.5 h. The reaction solution was concentrated under reduced pressure and the residure, thus obtained, was dissolved in CCl_4 (6 ml) and again concentrated. This procedure was repeated three

times. Finally, the crude crystals collected were washed with warm chloroform and then recrystallized from dioxane to give **6d** as colorless prisms in a 17% yield. On the other hand, a chloroform filtrate was concentrated to give crude crystals, which were recrystallized from benzene to give **6b** as colorless needles in a 79% yield.

In a similar manner, the treatment of **5b** with $SOCl_2$ in dry ethyl ether (4 ml) was worked up to give only **6b** quantitatively. See Table 5.

⊿Tyr(Ac)·NCA (6c). Similarly, the treatment of **5c** with $SOCl_2$ in CH_2Cl_2 was worked up to give **6c** as colorless needles.

⊿Tyr·NCA (6d). In a similar manner, the treatment of **5d** with $SOCl_2$ was worked up to give crude crystals, which were recrystallized from dioxane to give **6d** as colorless prisms.

(*Z*)-⊿Tyr(Boc)-OMe (7a). To a solution of **6d** (0.2 g, 0.97 mmol) and $(Boc)_2O$ (0.23 g, 1.05 mmol) in THF (2 ml) was added pyridine (30 μl); the resulting solution was stirred continuously at room temperature for 12 h. After adding methanol (5 ml), the reaction solution was made basic to pH 9 with NMM and then stirred for 1 h. After removing the solvent under reduced pressure, the residue was dissolved in ethyl acetate (15 ml); the resultant solution was then washed with water and dried over anhydrous sodium sulfate. After concentrating the solution under reduced pressure, thus obtained, the residue was purified on a silica-gel column using a mixture of hexane and ethyl acetate (20:1 v/v) as the eluent. The fraction eluted was concentrated under reduced pressure to give residual crystals, which were recrystallized from hexane to give **7a** as colorless prisms.

(*Z*)-⊿Tyr(Cbz)-OMe (7b). To a solution of **6d** (0.2 g, 0.97 mmol) and pyridine (94 μl, 1.16 mmol) in THF (2 ml) was added, drop by drop, a solution of Cbz-Cl (0.17 ml, 1.06 mmol) in THF (1 ml) at room temperature. The reaction solution was similarly worked up to give **7b**.

(*Z*)-Boc-⊿Tyr(Cbz)-OMe (7c). A solution of **6d** (0.2 g, 0.97 mmol) and $(Boc)_2O$ (0.23 g, 1.05 mmol) in the presence of pyridine (30 μl) in THF (2 ml) was stirred at room temperature for 12 h. After first adding triethylamine (0.22 ml) and then a solution of Cbz-Cl (0.25 ml, 1.46 mmol) in THF (1 ml), the resulting solution was stirred for 4 h. Methanol (20 ml) was further added to the reaction solution, which was then made basic to pH 9—10 with NMM; stirring continued at room temperature for 3 h. After evaporating the solvent under reduced pressure, the residue was dissolved in ethyl acetate (20 ml); the resultant solution was then washed three times with water and finally dried over anhydrous sodium sulfate. After concentrating under reduced pressure, the residue, thus obtained, was purified on a silica-gel column using a mixture of hexane and ethyl acetate (20:1 v/v) as the eluent. The fraction eluted was concentrated to give residual crystals, which were recrystallized from diisopropyl ether to give **7c** as colorless needles.

(*Z*)-Cbz-⊿Tyr(Boc)-OMe (7d). To a solution of **6d** (0.2 g, 0.97 mmol) and pyridine (94 μl, 1.16 mmol) in THF (2 ml) was added, drop by drop, a solution of Cbz-Cl (0.17 ml, 1.06 mmol) in THF (1 ml) at room temperature. After stirring for 1.5 h, triethylamine (0.17 ml) and then $(Boc)_2O$ (0.27 g, 1.23 mmol) were added to the resulting solution. The reaction solution was similarly worked up at room temperature for 18 h to give **7d** as colorless needles.

(Received July 27, 1987)

Phthalazine undergoes dual photoreactions to simultaneously give two photoproducts, 1,2-dihydrophthalazine (**1**) and 1,1′,2,2′-tetrahydro-1,1′-biphthalazine (**2**), upon ultraviolet light irradiation in 2-propanol under nitrogen. There occurs neither photochemical nor thermal interconversion between **1** and **2**; these compounds are formed independently from a common intermediate through different reaction pathways. The results of quenching and sensitization experiments for both the reactions and the phosphorescence emission show that the lowest excited singlet and triplet states of phthalazine participate in the formation of **1** and **2**, respectively. The observed photochemical behaviors under various conditions lead us to propose a reaction mechanism: Phthalazine is photoreduced in the S_1 state to form 1,2-dihydro-1-phthalazinyl radical. The resulting radical in a solvent cage undergoes a subsequent hydrogen abstraction to form **1**. On the other hand, the same radical produced in the T_1 state escapes from the solvent cage to cause a dimerization which affords **2**.

The photochemical behavior of a variety of nitrogen heterocyclic compounds have been studied.[1,2] Especially, the photoreductions of acridine and phenazine have been extensively studied.[3–6] However, little is known concerning the photochemical behavior of ortho-diazines. Chen et al.[7] studied the photoreaction of 4-methylcinnoline in ethers, and showed that a 1,4-addition of the ethers occurred. Davis and Cohen[8] reported that benzo[*c*]cinnoline underwent a photoreduction to give 5,6-dihydrobenzo[*c*]cinnoline in a benzene solution containing triethylamine. In previous papers[9] we reported that the photoirradiation of benzo[*c*]cinnoline in acidified alcoholic solutions leads to the formation of 2,2′-diaminobiphenyl or carbazole as the final product, depending on the experimental conditions. It was found that 5,6-dihydrobenzo[*c*]cinnoline is formed through the lowest triplet state at the initial stage in both of these reactions.

As for phthalazine, there have not been many descriptions concerning its photochemical behavior. Previously, Wake et al.[10] reported that phthalazine undergoes photoalkylation in acidified alcohols. They also noted that a reductive dimerization product was obtained upon irradiation in 2-propanol without added acid. However, the mechanism of this reaction has not yet been ascertained.

In this paper, we describe photochemical reactions of phthalazine in 2-propanol. Analyses of the photoproducts are given, showing that two products were formed. The reactive excited states for each product which were determined are discussed along with the reaction mechanism in terms of the observed cage effects.

Experimental

Materials. Phthalazine was obtained from Aldrich Chem. Co. and was recrystallized from a mixture of benzene and hexane. 2,4-Hexadien-1-ol (Tokyo Kasei Kogyo) was purified by fractional crystallization, and 4,4′-bis(dimethylamino)benzophenone (Michler's ketone) was recrystallized from ethanol. Hexadecyltrimethylammonium chloride and bromide were obtained from Wako Pure Chemical Ind. and were recrystallized from a mixture of acetone and methanol.

Measurements. UV absorption spectra were measured with a Shimadzu UV-210A spectrophotometer. Phosphorescence spectra were recorded on a Shimadzu RF-500 spectrofluorimeter equipped with a cylindrical rotating sector at 77 K. IR spectra were obtained with a Hitachi EPI-G3 infrared spectrometer in a KBr disk. Proton NMR spectra were taken with a JEOL PS-100 100 MHz spectrometer in deuterated chloroform.

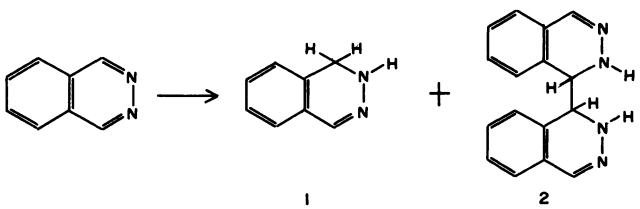
Light Source and Irradiation. In the preparative experiments, two light sources were employed using no filter: (I) a 400 W high-pressure mercury lamp (Rikagaku Sangyo UVL-400 HA) and (II) a 160 W low-pressure mercury lamp (Rikagaku Sangyo UVL-160 LA). For the 254-nm light irradiation, a 70 W low-pressure mercury lamp (Ushio UL1-7SQ) and a solution filter ($NiSO_4$ 500 g dm^{-3}) were used. For the 313-nm light irradiation, a 450 W high-pressure mercury lamp (Ushio UM-452) and a set of filters comprising a solution (1% K_2CO_3 containing 10^{-2} mol dm^{-3} K_2CrO_4) and a Corning glass (CS-7-54) were used. For the 366-nm light irradiation, a 450W high-pressure mercury lamp and Corning glass filters (CS-7-54 and CS-0-52) were used.

Unless otherwise noted, all irradiations were carried out in a 5×10^{-2} dm^3 quartz cylindrical vessel at room temperature. Solutions of phthalazine were flushed with nitrogen passed through a pyrogallol solution before and during irradiation.

Actinometry and Analysis of Products. For a determination of the quantum yields for photoreactions, the light intensities were measured using a potassium trioxalatoferrate(III) solution as an actinometer.[11] The amounts of photoproducts were spectrophotometrically determined using the molar extinction coefficients of the UV absorption bands of the products described in the text.

Isolation and Identification of the Photoproducts. A 3×10^{-3}mol dm^{-3} solution of phthalazine in 0.5 dm^3 of 2-propanol was irradiated for 5 h using light-source (I) under nitrogen. The irradiated solution was evaporated to dryness and the residue was subjected to TLC (silica gel, chloroform–methanol 30:1). The compound, thus obtained, showed the following properties: IR(KBr) 3250 (NH) and 1440 cm^{-1} (CH_2); ^{1}H NMR($CDCl_3$) δ=4.2(2H, s, CH_2), 5.3 (1H, m, NH) and 6.8—7.6(5H, m, aromatic H); mp 62.5—64.0 °C (decomp). The product **1** was identified as 1,2-dihydrophthalazine. Further supporting evidence for the identification of **1** was obtained from the benzoyl derivative of the isolated product. A treatment of the product with *p*-methylbenzoyl chloride gave a benzoyl derivative which was characterized by IR and elemental analyses.

A 1.5×10^{-2} mol dm^{-3} solution of phthalazine in 0.5 dm^3 of 2-propanol was irradiated for 8 h using light-source (II) under nitrogen. The irradiated solution was concentrated under reduced pressure. The precipitated crystals were collected by filtration and recrystallized twice from methanol. The physical properties of the crystals were identical with those of the dimerization product reported by Wake et al.[10] Product **2** was identified as 1,1′,2,2′-tetrahydro-1,1′-biphthalazine.



1 2

Results and Discussion

Reaction Products. The absorption spectral change caused by the irradiation of a 2-propanol solution of phthalazine is shown in Fig. 1. During the initial stage of the reaction, an absorption band appeared around 335 nm. With successive irradiation the absorption maximum shifted progressively to shorter wavelengths accompanying an increase in intensity. These spectral features indicate that there are at least two main photoproducts. From the preparative experiments mentioned above, two photoproducts

Irradiation time (min); I: 0, II: 10, III: 40, IV: 80, V: 160.

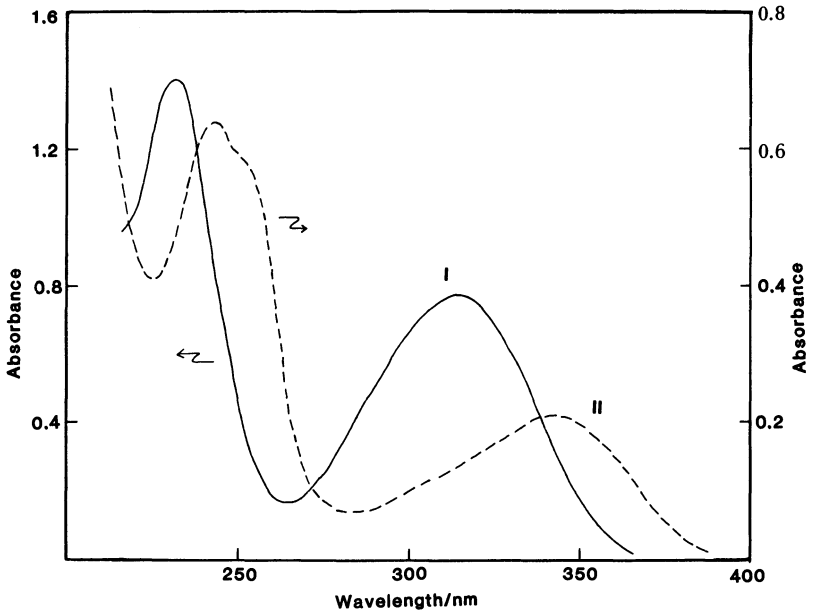

Fig. 2. Absorption spectra of the photoproducts in 2-propanol.
I: **1** (1.4×10^{-4} mol dm^{-3}), II: **2** (2.3×10^{-5} mol dm^{-3}).

were obtained: 1,2-dihydrophthalazine (**1**) and 1,1′,2,2′-tetrahydro-1,1′-biphthalazine (**2**). The absorption spectra of these compounds are presented in Fig. 2.

Changes in the concentrations of **1** and **2** during the course of the reactions were determined using the molar absorption coefficients of **1** and **2** (Fig. 3). It can be seen that the amount of **1** gradually increased with the irradiation time (37% yield based on the starting material at 140 min irradiation), whereas the amount of **2** reached a constant value after irradiation for an appropriate period (40% yield). However, **2** formed more rapidly than **1** during the initial stage of the reaction. These results could plausibly be interpreted as indicating that **2** was formed first, and then decomposed to give **1**. However, this is not the case (as indicated below).

In order to examine the possibilities of an interconversion between **1** and **2**, the photochemical behavior of **1** and **2** were studied using these compounds isolated in preparative experiments. Irradiation of 366-nm light for 50 min on a 2-propanol solution of **2** (3.6×10^{-5} mol dm^{-3}) resulted in the photodecomposition yielding phthalazine almost quantitatively.[12] Therefore, the saturation of the amount of **2** produced in the course of the photoreaction of phthalazine (curve II in Fig. 3) can be attributed to this backward photoreaction; the photostationary state could be established between phthalazine and **2** under the irradiation of light which could be absorbed by both compounds. On the other hand, the irradiation of 313-nm light on a solution of **1** did not cause a pronounced photoreaction. Consequently, it can be said that phthalazine undergoes photoreactions through two distinct pathways to afford **1** and **2** independently. A similar photochemical behavior has been found for acridine, which gives 9,10-dihydroacridine together with 9,9′,10,10′-tetrahydro-9,9′-biacridine.[13–16] Kira and Koizumi[17] reported that the photoproduct of 9,9′,10,10′-tetrahydro-9,9′-biacridine is acridine. This reaction is quite similar to the photoreaction of **2** (described above).

Quenching and Sensitization. In order to elucidate the reactive excited states for the observed photoreactions, triplet quenching experiments were conducted employing 2,4-hexadien-1-ol having a lower triplet energy (E_T=249 kJ mol^{-1})[19] than that of phthalazine (E_T=256 kJ mol^{-1}). Quenching data are presented in Fig. 4. The value of ϕ_0 (quantum yield without quencher) for **1** and **2** are 0.013 and 0.041, respectively. As can be seen from Fig. 4, the formation of **2** is apparently quenched, while that of **1** is not influenced by the addition of the quencher (up to 1.0×10^{-3}mol dm^{-3}). In addition, quenching for the phosphorescence emission of phthalazine in a mixture of ethanol and methanol (1:1 v/v) at 77 K has also been observed in the presence of the same quencher (Fig. 5).

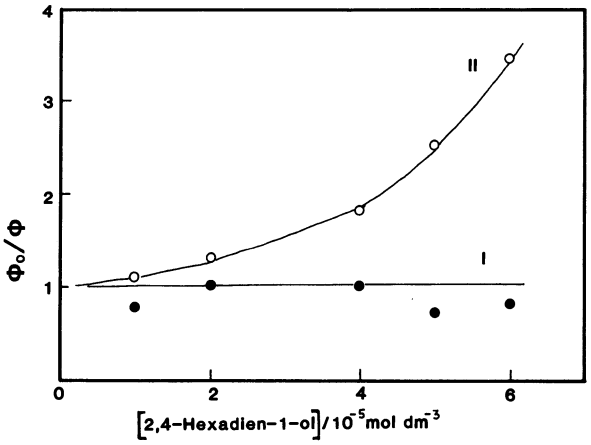

Fig. 4. Stern-Volmer quenching plots for the quantum yields of the formation of **1** (I) and **2** (II). [phthalazine]=2.0×10^{-4} mol dm^{-3}, excitation wavelength=313 nm.

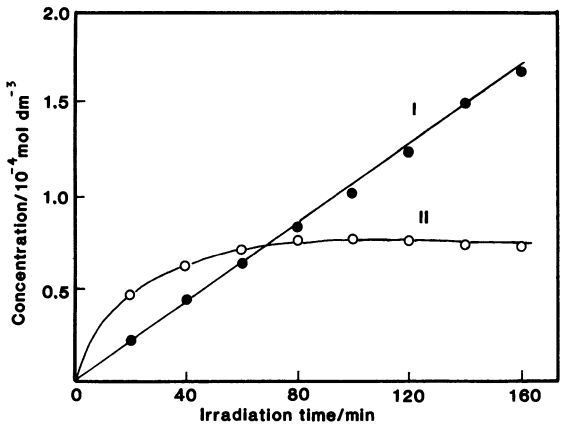

Fig. 3. Change in the concentrations of the products **1** (I) and **2** (II) with the 254 nm light irradiation of phthalazine (4.0×10^{-4} mol dm^{-3}) in 2-propanol.

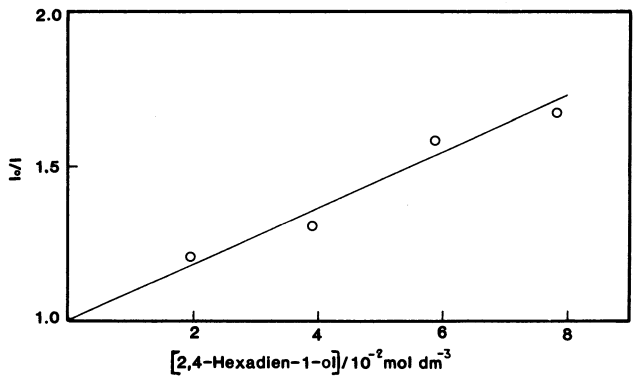

Fig. 5. Stern-Volmer quenching plots for the phosphorescence of phthalazine (480 nm) at 77 K. [phthalazine]=1.0×10^{-3} mol dm^{-3}, excitation wavelength=313 nm.

The feature of the reaction quenching plot (curve II in Fig. 4) differs from that of the phosphorescence. The observed upward curvature for the quenching plot at higher temperatures could be tentatively attributed to the quenching of two excited states, T_1 and T_2,[20] which are known to be located very close to each other;[21,22] thus, both states are in equilibrium at higher temperatures. However, further detailed studies need to be conducted before this subject can be solved.

Since the shapes of the absorption and the phosphorescence spectra of phthalazine have been confirmed to remain unaltered by the quencher, it may be considered that there are no specific interactions such as the ground-state complexing or an exciplex formation between the reactant and the quencher. In the present quenching system, a singlet-singlet energy transfer from the reactant to the quencher can evidently be ruled out as the quenching mechanism in view of the S_1 state energies of the compounds concerned.[23] Consequently, the quenching observed for the formation of **2** can be interpreted in terms of a triplet-triplet energy transfer. The obtained results suggest that the reactive excited states for the formations of **1** and **2** are the lowest excited singlet state and the lowest triplet state, respectively.

Supporting evidence for this suggestion has been provided by triplet sensitization studies. 4,4'-Bis(dimethylamino)benzophenone (Michler's ketone) was used as the triplet sensitizer under excitation with 366-nm light which was absorbed by only the sensitizer. This compound is photostable and has a triplet energy, E_T=259 kJ mol^{-1}.[24,25] A Stern-Volmer sensitization plot is shown in Fig. 6, in which a linear relationship is established between the reciprocal of the quantum yield and the reciprocal of the phthalazine concentration at a fixed concentration of the sensitizer (2.0×10^{-5} mol dm^{-3}). It can clearly be seen from Fig. 6 that the formation of **2** can be efficiently sensitized by Michler's ketone donor, while no sensitization is noted for the formation of **1**. In this connection, the occurrence of a triplet-triplet energy transfer from the ketone to the phthalazine acceptor can readily be recognized from the phosphorescence emission behavior illustrated in Fig. 7. A lack of the sensitization in the formation of **1** indicates that the S_1 mechanism is operative in the formation of **1** with a direct excitation of the substrate.

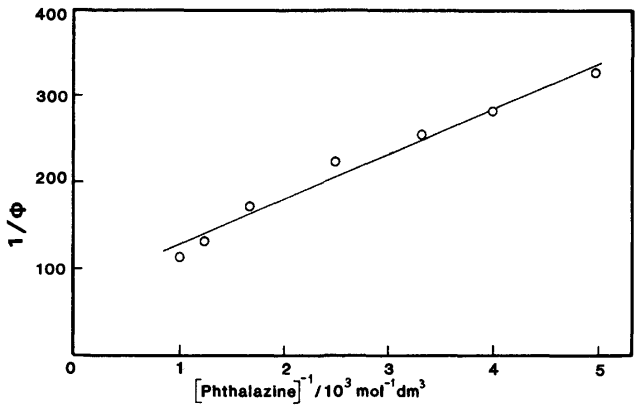

Fig. 6. Sensitization plots for the formation of **2**.
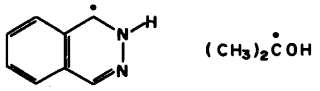
[4,4'-bis(dimethylamino)benzophenone]=2.0×10^{-5} mol dm^{-3}, excitation wavelength=366 nm.

According to the present reaction mechanism, an S_1-T_1 intersystem crossing is required to take place appreciably in order to account for the formation of **2**. In this connection, the triplet quantum yield of phthalazine was recently reported to be 0.43 at room temperature[22] and 0.49 at 77 K.[26]

Effects of Surfactants. In view of the type of both reactions described above, it may be probable that during the primary step phthalazine (P), both in the S_1 and T_1 excited states, similarly undergoes hydrogen atom abstraction from 2-propanol (RH) to afford an 1,2-dihydro-1-phthalazinyl radical (PH·) and an alcohol radical (**R**·). In fact, Kanamaru et al.[27]



PH· R·

reported the transient absorption spectrum of 1,2-dihydro-1-phthalazinyl radical generated in an alcoholic solution by flash photolysis method at room temperature. Castellano et al.[28] also obtained the same radical by UV irradiation at 115 K. It seems quite reasonable, therefore, that the production of **2** can be ascribed to the combination of 1,2-dihydro-1-

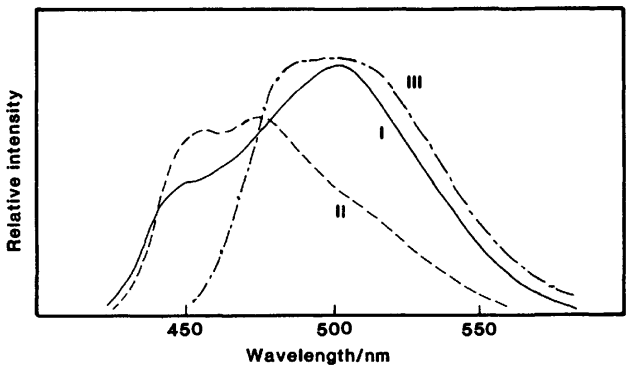


Fig. 7. Sensitization of the phosphorescence of phthalazine by 4,4'-bis(dimethylamino)benzophenone in a methylcyclohexane matrix.
I: [phthalazine]=6.0×10^{-4} mol dm^{-3}, [4,4'-bis(dimethylamino)benzophenone]=2.0×10^{-5} mol dm^{-3}, excitation wavelength=366 nm; II: [4,4'-bis(dimethylamino)benzophenone]=2.0×10^{-5} mol dm^{-3}, excitation wavelength=366 nm; III: [phthalazine]=6.0×10^{-4} mol dm^{-3}, excitation wavelength=305 nm.

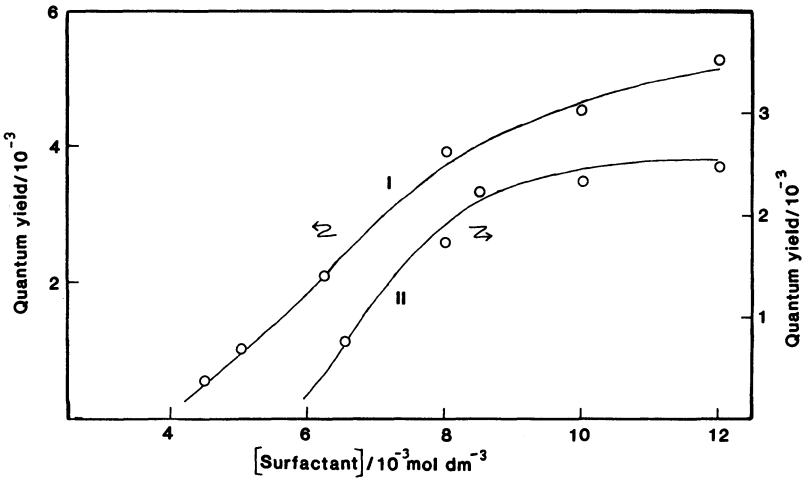

Fig. 8. Effects of the surfactants on the quantum yield of the formation of **1** in aqueous 2-propanol (0.3 mol dm^{-3}).

phthalazinyl radicals produced from the triplet precursor. A similar photoreductive dimerization was reported earlier for acridine.[13–16] Thus, the formation of 9,9′,10,10′-tetrahydro-9,9′-biacridine has been ascertained in the photoreduction of acridine in hydrogen-donating solvents; also, a semiquinone radical with an unpaired electron on 9-carbon atom is regarded as an intermediate in the dimerization.[17]

To obtain suggestive information concerning the mechanism for the formation of **1** as well as the origin of the different behavior between the 1,2-dihydro-1-phthalazinyl radical formed from the S_1 and that from the T_1 states of phthalazine, cage effects on the reactions were examined using surface-active agents. Micelles are known to become a good means for causing an efficient cage reaction of radical pair produced photochemically or thermally.[29–31] Figure 8 shows the results of the micellar effects on the photoreactions. The quantum yield for the production of **1** is significantly affected by the addition of the surfactants. The production of **1** is apparently observed above the cmc of surfactants.[32] On the other hand, **2** is formed to a very small extent, even at high concentrations of the surfactants. These results strongly indicate that **1** can be produced in micelles, but **2** cannot. Therefore, it is conceivable that for the photoreaction system in a 2-propanol solution, the 1,2-dihydro-1-phthalazinyl radical formed through the S_1 state and the alcohol radical are trapped as a radical pair in a solvent cage. This results in a further hydrogen abstraction, leading to product **1** and acetone. Although we cannot rule out the possibility of the participation of an alcohol molecule in the second hydrogen abstraction, at this time the hydrogen atom can be considered as coming from the alcohol radical, since the triplet sensitization reaction does not give product **1**. In any case, 2-propanol may be expected to give acetone; in fact, acetone has been detected in irradiated solutions by gas chromatography.

Here, it is particularly noteworthy that generally radical pairs produced from S_1 states undergo more effective cage reactions or micellar reactions than radical pairs from T_1 states.[30,33–35] Recently we have reported that some hydroxylamines undergo photorearrangements through a singlet-derived radical pair in a solvent cage as well as photofragmentation through a triplet-derived radical pair after escaping from a solvent cage.[36]

R·: 1-Hydroxy-1-methylethyl radical
^{1}[ ]: Singlet state radical pair in solvent cage
^{3}[ ]: Triplet state radical pair in solvent cage

In conclusion, we propose a reaction mechanism for the dual photochemical reactions of phthalazine, as illustrated in the scheme. The pathway, denoted I, refers to the reaction of the 1,2-dihydro-1-phthalazinyl radical in the S_1 cage. Process II is a plausible escape route for radicals from the S_1 cage, taking place in

competition with I. Although the extent of the contribution of this process to the formation of a free PH·radical is not clear, it cannot be ruled out only from the experimental results obtained here. Process III can be considered to result in a very efficient diffusion of the radical pair from the T_1 cage into solution. In a triplet cage, neither an intersystem crossing to the singlet radical pair nor a second hydrogen abstraction can take place sufficiently.

Accordingly, the results mentioned here are examples of photochemical reactions in which an excited molecule in the S_1 state abstracts hydrogen with an efficiency which is comparable to that of an intersystem crossing to the T_1 state. In this connection, the rate of the S_1–T_1 intersystem crossing (k_{ISC}) at room temperature has been reported to be about 1.5 ns^{-1}.[21,22]

Racemic Structure and Optical Resolution by Preferential Crystallization of (±)-Organic Ammonium Hydrogen Malates

Tadashi SHIRAIWA,* Yujin SADO, Mitsuo INOUE, Keiji SAKAMOTO, Hideya MIYAZAKI, and Hidemoto KUROKAWA
Faculty of Engineering, Kansai University, Yamate-cho, Suita, Osaka 564
(Received July 29, 1987)

Gibbs energies of formation of racemate, binary melting point diagrams, and ternary solubility diagrams indicate that (±)-propylammonium ((±)-PA salt) and (±)-1,1,3,3-tetramethylbutylammonium ((±)-TMB salt) hydrogen malates are conglomerates at room temperature, whereas (±)-TMB salt forms a racemic compound at its melting point. Free energies of critical nucleation in supersaturated solutions were examined to resolve (±)-PA and -TMB salts efficiently by preferential crystallization. Successive preferential crystallization of (±)-PA salt in methanol at 10 °C and that of (±)-TMB salt in water give (+)- and (−)-PA and -TMB salts with about 90% optical purity. Optically pure (+)- and (−)-malic acids are obtained from purified (−)- and (+)-salts.

Optically active malic acid (abbreviated as MAL) is a useful material for food additives and medicines and a resolving agent for racemic organic amines. (±)-MAL has been optically resolved by preferential crystallization in the form of (±)-ammonium[1] and (±)-α-methylbenzylammonium[2] hydrogen malates and by the diastereomeric procedure using (+)-tartaric acid[3] as a resolving agent. This paper describes an attempt to resolve optically (±)-organic ammonium hydrogen malates by preferential crystallization. The examined (±)-salts were methylammonium ((±)-MA salt), ethylammonium ((±)-EA salt), propylammonium ((±)-PA salt), isopropylammonium ((±)-IPA salt), butylammonium ((±)-BA salt), isobutylammonium ((±)-IBA salt), *t*-butylammonium ((±)-TBA salt), pentylammonium ((±)-PTA salt), hexylammonium ((±)-HA salt), octylammonium ((±)-OA salt), 1,1,3,3-tetramethylbutylammonium ((±)-TMB salt), anilinium ((±)-AN salt), diisobutylammonium ((±)-DIB salt), dicyclohexylammonium ((±)-DCH salt), dibenzylammonium ((±)-DBZ salt), and cyclohexylmethylammonium ((±)-CMA salt) salts.

The racemic structure of the (±)-salts was determined by thermodynamic analysis.[4,5] (±)-PA and -TMB salts which seemed to be conglomerates were subjected to a resolution by preferential crystallization. The free energy of critical nucleation in supersaturated solutions of the (+)- and (−)-salts was examined to find the appropriate conditions for the optical resolution.[6-8]

Experimental

Materials. (±)-Malic acid and amines were purchased from Wako Pure Chemicals Ind. and Kanto Chemical Co., Ltd., and (+)- and (−)-MAL were donated from Fuso Chemical Co., Ltd.; (+)-MAL $[\alpha]_D^{20}$+2.90° (*c* 30.0, methanol); (−)-MAL $[\alpha]_D^{20}$−2.92° (*c* 30.0, methanol) (lit,[9] $[\alpha]_D$−2.92° (*c* 30%, methanol)).

Preparation of Organic Ammonium Salt. A solution of 0.01 mol of (±)-, (+)-, or (−)-MAL and equimolar amine in acetone was allowed to stand overnight at 5 °C. The salt formed was filtered and recrystallized from an appropriate solvent; the PA salt was recrystallized from 1-propanol and the TMB salt from ethanol. The (+)-salts were formed from (−)-MAL and amines, and the (−)-salts from (+)-MAL and amines.

(±)-PA salt: Found C, 43.33; H, 7.78; N, 7.13% (calcd for $C_7H_{15}NO_5$: C, 43.52; H, 7.83; N, 7.25%); solubility 11.593 g/(100 cm³ methanol) at 10 °C. (+)-PA salt: Found C, 43.45; H, 7.82; N, 7.29%; $[\alpha]_{436}^{25}$+11.6° (*c* 1.00, methanol); solubility 5.135 g/(100 cm³ methanol) at 10 °C.

(±)-TMB salt: Found C, 54.53; H, 9.47; N, 5.35% (calcd for $C_{12}H_{25}NO_5$: C, 54.73; H, 9.57; N, 5.32%); solubility 8.640 g/(100 cm³ water) and 5.644 g/(100 cm³ methanol) at 10 °C. (+)-TMB salt: Found C, 54.56; H, 9.49; N, 5.34%; $[\alpha]_{436}^{25}$+11.9° (*c* 1.00, methanol); solubility 5.959 g/(100 cm³ water) and 3.320 g/(100 cm³ methanol) at 10 °C.

Optical Resolution. Preferential Crystallization: (±)-PA or -TMB salt was dissolved in 50 cm³ of methanol or water, respectively, at 40 °C to give racemic solutions with different degrees of supersaturation of 120—200%. The solution was slowly cooled to 10 °C and seeded with 0.050 g of the (+)-salt. After stirring the mixture at 10 °C, the precipitated salt was collected by filtration, washed with a small amount of diethyl ether, and dried.

Successive Preferential Crystallization: A methanol solution of (±)-PA salt with 180% supersaturation was seeded with 0.050 g of the (+)-salt at 10 °C. After stirring the mixture for 30 min at 10 °C, the precipitated salt was filtered. (±)-PA salt (0.918 g) was dissolved in the filtrate at 40 °C; the amount was equal to that of the crystallized salt. After seeding the solution with 0.050 g of the (−)-salt at 10 °C, the mixture was treated similarly to above.

An optical resolution of (±)-TMB salt was performed on an aqueous solution with 155% supersaturation, similarly to (±)-PA salt.

The degree of resolution of the (+)- and (−)-salts was calculated by

$$\text{Degree of resolution}/\% = [\text{YOPM}\times 100/\text{g}]/[(\text{Operation amount of the (+)- or (−)-salt/g}) - \text{M/g}],$$

where M is 2.898 g for the PA salt and 2.160 g for the TMB salt, and YOPM is the yield of optically pure modification.[10]

Preparation of Optically Active Malic Acid. The purified (+)- or (−)-PA salt (1.93 g) or -TMB salt (2.63 g) with 100% optical purity was treated as aqueous solutions through a 1.3×17.8 cm column of Amberlite IR-120 of H^+ form by eluting with water. The eluent was evaporated to dryness under reduced pressure at 40 °C; optically pure (+)-MAL was obtained in 1.12 g yield from the (−)-PA salt and in 1.29 g yield from the (−)-TMB salt, and optically pure (−)-MAL was obtained in 1.20 g yield from the (+)-PA salt and in 1.31 g yield from the (+)-TMB salt.

Measurements. Specific rotation was measured by a Union Giken PM-101 digital polarimeter with a quartz cell of 1.0 dm path length. Infrared spectra were obtained in the range 4000—400 cm^{-1} with a JASCO A-102 infrared spectrophotometer by the KBr disk method. Enthalpies of fusion and melting points were determined with a Rigaku Denki differential scanning calorimeter DSC-8230.

Saturated solutions of (±)- and (+)-PA and -TMB salts were prepared at 10 °C; methanol was employed as a solvent for PA salt and water for TMB salt. Refractive index was measured with a Shimadzu refractometer Abbe 3L. Solubility was determined by using the refractive index from calibration curves.

Results and Discussion

Racemic Structure. Racemic Structure at Melting Point: The Gibbs energy of formation of racemate (ΔG_T^F/kJ mol^{-1}) is calculated from enthalpies of fusion (ΔH^f/kJ mol^{-1}) and melting points.[4,5] These values are listed in Table 1; the ΔG_T^F value of (±)-TBA salt could not be calculated because (+)-TBA salt decomposed on heating.

All the (±)-salts give negative values of ΔG_{mp}^F at their melting points except (±)-PA salt. Eutectic temperatures and compositions calculated on the basis of ΔH^f and melting point[11] are listed in Table 1, together with observed melting points of mixtures with eutectic compositions. The melting points agree well with the calculated eutectic temperatures. Only PA salt shows a composition of 0.5 and the other salts those of 0.60—0.93; the binary melting point diagrams of PA and TMB salts are shown in Figs. 1 and 2, respectively. These results have led us to infer that only (±)-PA salt is a conglomerate at the melting point and that the other (±)-salts form racemic compounds.

Racemic Structure at Room Temperature: (±)-PA and -TMB salts give positive values of ΔG^{F}_{283} at 283 K, whereas the values of the other (±)-salts are negative. (±)-PA and -TMB salts show infrared spectra indentical with those of the corresponding (+)-salts and are more soluble than the (+)-salts as described in the experimental section. The ternary solubility diagram of TMB salt, shown in Fig. 3, illustrates the pattern of a conglomerate.[12] These results indicate that (±)-PA and -TMB salts are conglomerates at room temperature, though (±)-TMB salt forms a racemic compound at its melting point.

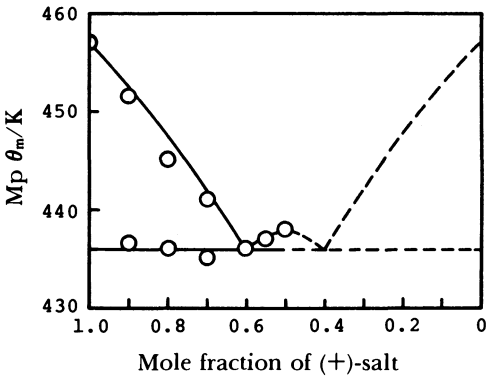

Fig. 2. Binary melting point diagram of 1,1,3,3-tetramethylbutylammonium hydrogen malate.

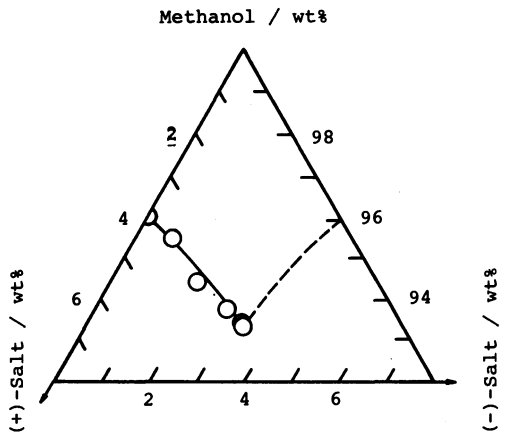

Fig. 3. Ternary solubility diagram of 1,1,3,3-tetramethylbutylammonium hydrogen malate. Solvent: Methanol. Temperature: 10 °C.

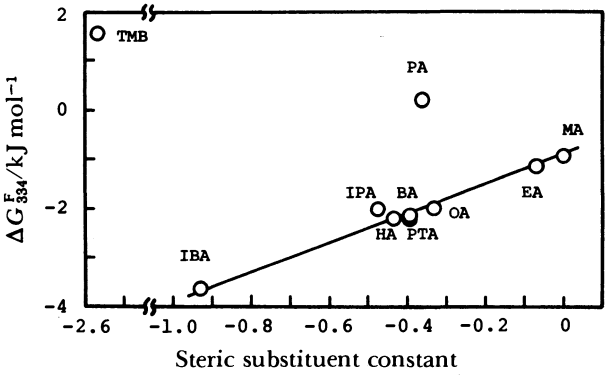

Fig. 4. Relationship between Gibbs energy of formation of racemate and steric substituent constant. ΔG^{F}_{334}: Gibbs energy of formation of racemate at 334 K. E_s: Steric substituent constant; see Ref. 13.

Since the infrared spectra of the other (±)-salts and (±)-TBA salt, of which the corresponding (+)-salt decomposes on heating, are different from those of the corresponding (+)-salts, these (±)-salts may be concluded to form racemic compounds at room temperature.

Substituent Effect on the Gibbs Energy of Formation of Racemic Compound: The formation of racemic compounds of the salts of (±)-MAL with primary amines having an alkyl side chain was examined from the relationship between steric substituent constant (E_S)[13] and ΔG^{F}_{334} value, shown in Fig. 4; the ΔG^{F}_{334} values at 334 K were calculated for comparison at the same temperature.[4,5]

(±)-PA and -TMB salts show positive ΔG^{F}_{334} values, whereas the ΔG^{F}_{334} values of the other (±)-salts are negative. The absolute value of ΔG^{F}_{334} tends to increase with an increase in the absolute value of E_S. Since (±)-PA and -TMB salts and (±)-salts with aromatic amines or secondary amines are out of this relationship, it is impossible to draw any conclusion on conglomerate formation from this relationship. However, Fig. 4 suggests that racemic compounds with smaller alkyl side chains become less stable. This may be related to the fact that the (±)-ammonium hydrogen malate with "the smallest side chain" has been optically resolved by preferential crystallization.[1]

Appropriate Conditions for Preferential Crystallization. (±)-PA salt was optically resolved by preferential crystallization in 50 cm^3 of methanol at 10 °C with 0.050 g of the (+)-salt as seed crystals, and (±)-TMB salt in 50 cm^3 of water. The amount of crystallization of the (+)- and (−)-salts calculated from results of optical resolution[10] and the relationship between the amount and resolution time are shown in Figs. 5 and 6, respectively. (±)-PA and -TMB salts have been confirmed from these results to be conglomerates at 10 °C.

Appropriate conditions for the optical resolution of (±)-PA and -TMB salts were estimated from the free energy of critical nucleation[6-8,14] (Δg_{max}/J nucleus^{-1}), the speed of crystallization of the (+)-salt ($R_{(+)}$/g min^{-1}), and the retardation time of crystallization of the (−)-salt ($\theta_{(-)}$/min);[8] the value of $R_{(+)}$ was calculated from the linear plots of Figs. 5 and 6, with $\theta_{(-)}$ defined as the resolution time before the (−)-salt begins to crystallize rapidly. The value of Δg_{max} and other related factors for crystallization are listed in Table 2.

Table 2. Free Energy of Critical Nucleation and Factors for Crystallization[a]

Salt	Degree of supersaturation / %	Δg_{max}[b] / 10^{-18} J nucleus^{-1}	$R_{(+)}$[c] / 10^{-2} g min^{-1}	$\theta_{(-)}$[d] / min	$W_{(-5)}$[e]/g Found	$W_{(-5)}$[e]/g Calcd[f]
PA[g]	160	2.88	1.25	75	0.879	0.837
	170	2.14	2.03	45	0.851	0.866
	180	1.66	3.00[i]	34[j]	0.897	0.878
	190	1.32	4.41	25	0.871	0.871
	200	1.08	5.72	20	0.852	0.845
TMB[h]	120	59.3	0.116	345	0.380	0.361
	140	15.8	0.501	75	0.336	0.435
	150	10.4	1.17	45	0.434	0.449
	155	8.73	1.36[k]	38[l]	0.447	0.451
	180	4.39	3.53	18	0.415	0.419

a) Conditions of crystallization: 50 cm^3 of solvent (methanol for PA salt; water for TMB salt); seed crystals 0.050 g of (+)-salt; temperature 10 °C. b) Δg_{max}: Free energy of critical nucleation at 10 °C. c) $R_{(+)}$: Speed of crystallization of (+)-salt. d) $\theta_{(-)}$: Retardation time for crystallization of (−)-salt. e) $W_{(-5)}$: Amount of crystallization of (+)-salt at $\theta_{(-)}-5$ min. f) The values were calculated from Eq. 5 or 6. g) PA: Propylammonium salt. h) TMB: 1,1,3,3-Tetramethylbutylammonium salt. i) The value was calculated from Eq. 1. j) The value was calculated from Eq. 2. k) The value was calculated from Eq. 3. l) The value was calculated from Eq. 4.

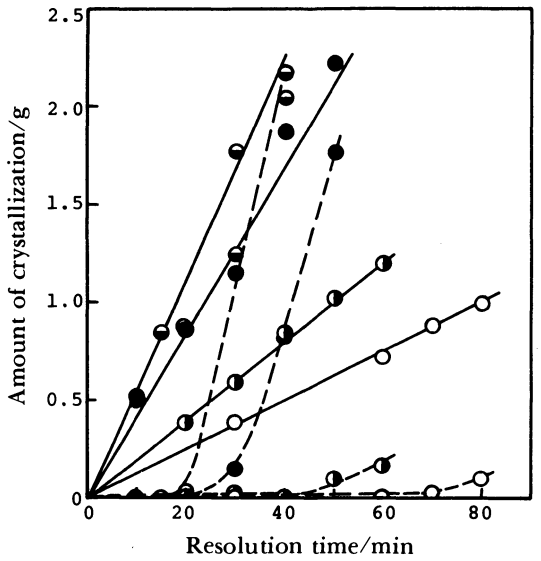

Fig. 5. Relationship between amount of crystallization and resolution time for propylammonium hydrogen malate.
Conditions: Solvent 50 cm^3 of methanol; temperature 10 °C; seed crystals 0.050 g of (+)-salt. Degree of supersaturation: ○ 160%; ◑ 170%; ● 190%; ◒ 200%, ——: (+)-Salt. ——: (−)-Salt.

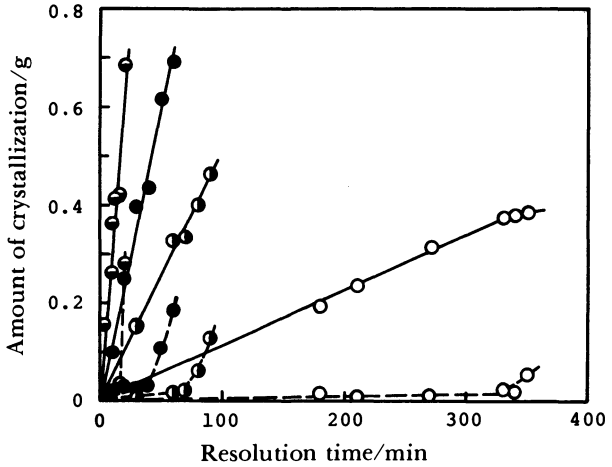

Fig. 6. Relationship between amount of crystallization and resolution time for 1,1,3,3-tetramethylbutylammonium hydrogen malate.
Conditions: Solvent 50 cm^3 of water; temperature 10 °C; seed crystals 0.050 g of (+)-salt. Degree of supersaturation: ○120%; ◑140%; ●150%; ◒180%. ——: (+)-Salt. ——: (−)-Salt.

For PA salt, the relationship between $R_{(+)}$ and Δg_{max} for different degrees of supersaturation of 160, 170, 190, and 200% and that between $\theta_{(-)}$ and Δg_{max} were obtained from the following equations:[8]

$$\ln R_{(+)} = -1.572 \ln \Delta g_{max} - 67.87, \quad (1)$$

$$\ln \theta_{(-)} = 1.332 \ln \Delta g_{max} + 58.08, \quad (2)$$

where the correlation coefficients for Eqs. 1 and 2 are 0.999 and 0.996, respectively. For TMB salt, the following equations were obtained for different degrees of supersaturation of 120, 140, 150, and 180%:

$$\ln R_{(+)} = -1.321 \ln \Delta g_{max} - 56.18, \quad (3)$$

$$\ln \theta_{(-)} = -1.140 \ln \Delta g_{max} + 48.43, \quad (4)$$

where the correlation coefficients for Eqs. 3 and 4 are 0.995 and 0.999, respectively.

The optical resolution at $\theta_{(-)}-5$ min seems to be a better criterion for evaluating results of optical resolution than that at $\theta_{(-)}$ min because the unseeded (−)-salt begins to crystallize rapidly after $\theta_{(-)}$ min. The amounts of crystallization of (+)-PA and -TMB

Table 3. Successive Preferential Crystallization of (±)-Propylammonium and (±)-1,1,3,3-Tetramethylbutylammonium Hydrogen Malate[a]

(±)-Salt	Run	Added amount of (±)-salt	Operation amount[b]/g		Resolution time	Salt obtained				
							Yield	Optical purity	YOPM[c]	Degree of resolution
		g	(+)	(−)	min		g	%	g	%
PA[d]	1	10.434	5.217	5.217	30	(+)	0.968	95.6	0.875	37.7
	2	0.918	4.779	5.654	30	(−)	1.634	94.6	1.496	54.3
	3	1.584	5.527	4.906	30	(+)	1.491	93.9	1.350	51.3
	4	1.441	4.852	5.581	30	(−)	1.907	90.1	1.668	62.2
TMB[e]	1	6.696	3.348	3.348	33	(+)	0.521	90.6	0.422	35.5
	2	0.471	3.137	3.559	40	(−)	0.734	91.7	0.623	44.5
	3	0.684	3.448	3.247	35	(+)	0.606	91.6	0.505	39.2
	4	0.556	3.195	3.499	35	(−)	0.696	88.6	0.567	42.3

a) Solvent: 50 cm^3 of methanol for PA salt; 50 cm^3 of water for TMB salt. Seed crystals: 0.050 g of (+)- or (−)-salt. Temperature: 10 °C. b) The operation amounts of (+)- and (−)-salts were calculated on the basis of analyses of the salt obtained in Runs 1—3. c) YOPM: Yield of optically pure modification. d) PA: Propylammonium salt. e) TMB: 1,1,3,3-Tetramethylbutylammonium salt.

salts ($W_{(-5)}/g=R_{(+)}(\theta_{(-)}-5)$) are given by the following equations, as derived from Eqs. 1—4:

$$W_{(-5)}^{PA} = 5.609 \times 10^{-5}\Delta g_{max}^{-0.2398} - 1.676 \times 10^{-29}\Delta g_{max}^{-1.572}, \quad (5)$$

$$W_{(-5)}^{TMB} = 4.268 \times 10^{-4}\Delta g_{max}^{-0.1807} - 1.992 \times 10^{-24}\Delta g_{max}^{-1.321}. \quad (6)$$

The value of Δg_{max} that gives the maximum $W_{(-5)}$ is calculated from Eqs. 5 and 6 to be 1.60×10^{-18} J nucleus^{-1} for (±)-PA salt and 8.38×10^{-10} J nucleus^{-1} for (±)-TMB salt. This Δg_{max} value for (±)-PA salt is approximately equal to the value for 180% supersaturation, and that for (±)-TMB salt to the value for 155% supersaturation.

The optical resolution of (±)-PA salt for 180% supersaturation and that of (±)-TMB salt for 155% supersaturation were carried out at $\theta_{(-)}-5$ min as calculated from Eqs. 2 and 4, respectively. The amounts of crystallization of the (+)-salts derived from their experimental results agree well with the $W_{(-5)}$ values calculated from Eqs. 5 and 6, as shown in Table 2.

Successive Preferential Crystallization of (±)-Propylammonium and 1,1,3,3-Tetramethylbutylammonium Salts. Based on the above results, the successive preferential crystallization of (±)-PA salt was carried out in 50 cm^3 of methanol at 10 °C by using a solution with 180% initial supersaturation, and that of the (±)-TMB salt by using an aqueous solution with 155% initial supersaturation, details being as listed in Table 3. (+)- and (−)-PA and -TMB salts with optical purity of 88—96% were obtained at degree of resolution of 37—62%. The purified (+)- and (−)-salts gave optically pure (−)- and (+)-MAL, respectively.

The authors are grateful to Fuso Chemical Co., Ltd. for the gift of (+)- and (−)-MAL.

14) In order to calculate the Δg_{max} of PA salt, the value of molecular volume (V_0) was measured at 10 °C in methanol to be 2.21×10^{-28} m^3; the molecular radius (r_0) was calculated to be 3.75×10^{-10} m on the assumption of spherical molecule. The values of the radius (r_{sa} 4.83×10^{-10} m) and interfacial energy (σ_{sa} 1.01×10^{-2} J m^{-2}) of the embryo in the saturated methanol solution at 10 °C were calculated on the basis of the solubility of (±)-PA salt according to the procedure described in Refs. 6—8; the average number (j_{sa}) of PA salt molecules forming the embryo in the saturated solution is 2.13. (±)-TMB salt in water at 10 °C: V_0 3.70×10^{-28} m^3; r_0 4.45×10^{-10} m; r_{sa} 5.67×10^{-10} m; σ_{sa} 9.25×10^{-3} J m^{-2}; j_{sa} 2.06.

Phase-Transfer-Catalyzed Azo Coupling Reactions in Two-Phase Systems

Yoji HASHIDA,* Kazuhiro KUBOTA, and Shizen SEKIGUCHI
Department of Chemistry, Faculty of Engineering, Gunma University, Kiryu, Gunma 376
(Received July 30, 1987)

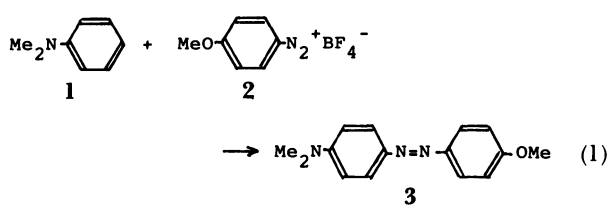
The azo coupling reaction of *p*-methoxybenzenediazonium tetrafluoroborate with *N,N*-dimethylaniline has been investigated in a water–1,2-dichloroethane system. It has been found that, among the several additives examined, the phenolate ion, generated from picric acid or 2,4-dinitro-1-naphthol, acted as an effective phase-transfer catalyst. Further, the reaction of *p*-diethylaminobenzenediazonium tetrafluoroborate with dimedone, an active methylene compound, has also been investigated in the same two-phase system; a remarkable acceleration in the rate was observed in the presence of tetraalkyl onium salts, and even in their absence.

Today, phase-transfer catalysis is a well-established technique in preparative chemistry.[1] However, it has been confined almost exclusively to nucleophilic or base-mediated reactions. On the other hand, azo coupling reactions under phase-transfer-catalyzed conditions have been intensively studied in recent years as a model for electrophilic substitution reactions. In such chlorinated hydrocarbons as chloroform and dichloromethane, pyrroles, arylamines, and phenol can easily react with diazonium salts in the presence of crown ether,[2] tetramethylammonium chloride,[3] tetraarylborate ion,[4] and/or silica gel,[5] showing their function as liquid-solid phase-transfer catalysts (PTC). It has also been claimed that tetraarylborate[4] and dodecylbenzenesulfonate[6] ions act as a PTC for the azo coupling reactions of arylamines in a water–dichloromethane two-phase system, although the effect of the latter might complicate the reaction by micelle formation.[7,8]

Here we wish to report that picrate and 2,4-dinitronaphtholate ions, as well as perchlorate and periodate ions, act as efficient anionic PTCs for an azo coupling reaction with an arylamine in a liquid-liquid two-phase system. Reactions with an active methylene compound in two-phase systems are also described in which a remarkable acceleration in the rate was observed in the presence of tetraalkyl onium salts, and even their absence.

Results and Discussion

Reaction with *N,N*-Dimethylaniline. The reaction of *N,N*-dimethylaniline (**1**), a neutral substrate, with *p*-methoxybenzenediazonium tetrafluoroborate (**2**) in the water–1,2-dichloroethane system was examined.



1 2 3 (1)

The rate measurements were performed by monitoring the absorbance at 410 nm due to **3**, in the presence of a 50-fold excess of **1** compared to **2**. Under these conditions, an excellent pseudo-first-order kinetic plot with respect to **2** was obtained with a correlation coefficient (r) greater than 0.99 in the range from 10 to 70% reaction in each run (Eq. 2):

$$\text{Rate} = k' [\text{Ar} - \text{N}_2^+]. \quad (2)$$

The influence of the stirring speed on the reaction rate was checked in the two-phase system (Fig. 1). Stirring at rates higher than about 600 rpm had essentially no effect on the reaction rate, suggesting that a transfer of the diazonium ion from the aqueous to the organic phase is fairly fast and that the rate is determined by the reaction in the organic phase.

The rates in the presence of several additives at 700 rpm are summarized in Table 1, including those in homogeneous solutions (Runs 1 and 2). The effects of arenesulfonate ions as PTCs were small (Runs 10 and 11). On the other hand, it is noteworthy that picric acid and 2,4-dinitro-1-naphthol exhibited considerable acceleration in the rate: the rate was proportional to the catalyst concentration, as has been observed in other phase-transfer-catalyzed azo coupling reactions.[4] In general, a phenol blocked by a substituent at the 2-, 4-, and 6-positions reacts with a diazonium ion to form covalently-bonded diazoether

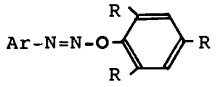
(**4**).[9] Indeed, no catalytic effect was observed for 2,4,6-



4

trichlorophenol; however, it immediately gave a compound with an absorption maximum at 357 nm, presumably due to its diazoether. On the other hand, it seems likely that a diazonium ion forms an ion pair with a picrate or dinitronaphtholate ion of low nucleophilicity, which migrates into the organic phase. The reactivity of the diazonium ion is thereby increased by a minimization of solvent interactions. The phenolate ion liberated in the organic phase is used in the next PTC cycle, i.e., it forms an ion pair with a protonated arylamine formed by proton abstraction from a σ-complex. It then reverts to the aqueous phase. It is also noteworthy that the rates (Runs 6—8) in the presence of picrate ion in a two-phase system exceed that of the diazonium tetrafluoroborate in dichloroethane (Run 2), suggesting that the reactivity of the diazonium ion with the picrate ion as a counter ion is higher than that with the tetrafluoroborate ion. The higher reactivity of the diazonium ion with the picrate ion may be ascribed to its weak ion-pairing; this is because a strong ion-pairing would be expected to cause a decrease in the electrophilicity of the diazonium ion.[10,11]

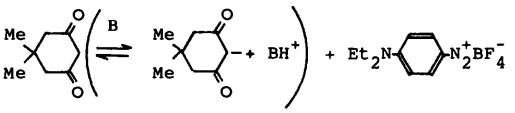
11	$ClCH_2CH_2Cl$	5.8×10^{-2}	6.8

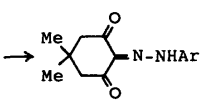
a) Reaction conditions: $ArN_2^+BF_4^-$ 5.0×10^{-5} mol dm^{-3}; Substrate 2.5×10^{-3} mol dm^{-3}.

The addition of such inorganic ions as perchlorate (Runs 12—15) and periodate (Run 16), which are of high extraction capability toward common onium cations into chlorinated hydrocarbon,[12] also accelerated the two-phase reaction. A similar acceleration by iodide ion to that by the perchlorate ion was observed. However, the iodide ion seems to be of no practical significance, since it catalyzed the homolytic decomposition[13] of the diazonium ion giving an impure azo compound.

Reaction with Dimedone. Secondary, the reaction of 5,5-dimethyl-1,3-cyclohexanedione (dimedone **5**, pK_a=5.2[14]), an active methylene compound, with *p*-diethylaminobenzenediazonium tetrafluoroborate (**6**) was selected, since the rate could be measured directly in all the solvent systems investigated.



5 **5′** **6**



(3)

7

Prior to the study in the two-phase system, the solvent effects on the reactivity of the carbanion (**5′**) were investigated in homogeneous solutions. The potassium salt of **5′** was completely solubilized into a solvent by adding 18-crown-6 (hereafter called crown), except for water and methanol. After a solution of **6** in the same organic solvent was added into this solution, the absorbance at 490 nm due to product **7** was followed under the pseudo-first-order kinetic conditions (Table 2). In contrast to the azo coupling reaction with *N,N*-dimethylaniline, in which no

significant solvent effects have been observed,[15] it can be seen that there are large differences in the rates between water and organic solvents; e.g., reactions in chlorinated hydrocarbons proceed faster than in water by ca. an order of magnitude of 8. Under these conditions, in which nearly an equivalent of the crown to the substrate was present, the crown probably tended to complex with the potassium salt of **5′** rather than **6**, giving a "naked carbanion" of high reactivity. The addition of a large excess of the crown, however, retarded the reaction (Runs 10 and 11), due to a partial conversion of the diazonium ion into its unreactive complex with the crown.[16]

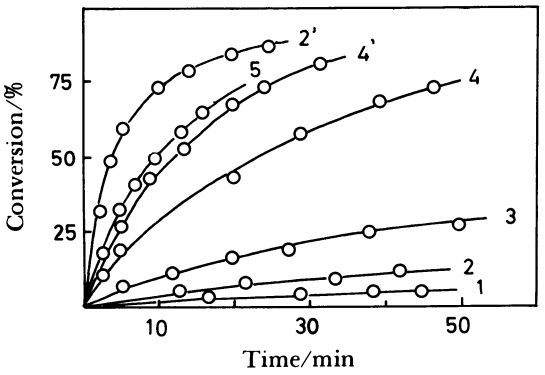


Fig. 2. Reaction of dimedone with *p*-diethylaminobenzenediazonium tetrafluoroborate in the water/1,2-dichloroethane at 15 °C: $ArN_2^+BF_4^-$ 1.0×10^{-4} mol dm^{-3}; substrate 6.0×10^{-3} mol dm^{-3}.
1) In water; 2) 300 rpm; 3) 400 rpm; 4) 500 rpm; 5) 700 rpm; 2′) 300 rpm; $Bu_4N^+Br^-$ 8.0×10^{-3} mol dm^{-3}; 4′) 500 rpm; $Bu_4N^+Br^-$ 6.5×10^{-4} mol dm^{-3}.

From these results, it was expected that the same reaction would be accelerated under appropriate conditions in synthetically more useful liquid-liquid systems. Figure 2 shows a typical rate profile for the reaction of **5** with **6** in the water–1,2-dichloroethane system. It can be seen that the reaction is remarkably accelerated in the two-phase system, even in the absence of a catalyst. Also, the stirring speed is quite important. These results may be understandable by postulating that when a part of both reactants, **5′** and **6**, transfer into an organic phase, the reaction immediately takes place. In contrast, when benzene or cyclohexane was employed as an organic phase, no appreciable acceleration in rate was observed, presumably because both reactants were essentially insoluble in the organic phase. The addition of quaternary onium salts,[17] which are common PTCs for reactions involving carbanion, accelerated the reaction (as illustrated in the case of tetrabutylammonium bromide). It has been expected that the combined use of PTCs for both reactants, i.e., diazonium ion and carbanion, might be effective in the present system. However, no pronounced catalysis was observed; e.g., the addition of tetrabutylammonium bromide and sodium 1-naphthalenesulfonate showed only a slight acceleration compared to a reaction when the former was employed alone. This result may be understandable since the catalytic activities of both PTCs should be decreased owing to a mutual interaction.

Synthesis of Azo Compounds. The usefulness of the present two-phase system was examined in the preparative scale by using various substrates, including particularly unreactive coupling components in

Table 3. Preparation of Azo-compounds

the conventional aqueous system (Table 3). In the case of *p*-toluenesulfonanilide (Run 7), its reactive form is considered to be an anion resulting from the ionization of the N-H bond.[18] The reaction was conducted by using an equimolar amount of a substrate. After the consumption of a diazonium ion was confirmed (except Run 1) through a test with 4-amino-5-hydroxy-2,7-naphthalenedisulfonic acid, resulting azo compounds were isolated by the usual work-up procedure. In contrast to the reaction in an aqueous solution in which the decomposition of the diazonium ion was the major reaction, it can be seen that the present PTC system is very useful for preparing azo compounds.

Experimental

Materials Arenediazonium tetrafluoroborates were prepared by using a general procedure.[19] The crude salt was washed with diethyl ether, dissolved in a minimum amount of acetonitrile, precipitated by adding diethyl ether, and then dried over diphosphorus pentaoxide in vacuo: **2** mp 143—144 °C (decomp); **6** mp 112—113 °C (decomp). Potassium 5,5-dimethyl-1,3-cyclohexanedionide was prepared by adding an equivalent of potassium hydroxide into a methanolic solution of **5**; the solvent was removed and the resulting residue was dried over silica gel. The other materials were obtained from commercial sources, and standardized before use.

Rate Measurements in Homogeneous Systems. The rates in homogeneous solution were measured by using a previously described procedure.[14] The solution (ca. 1×10^{-4} mol dm^{-3}) of a diazonium salt in chlorinated hydrocarbons was prepared as follows: a suspension of diazonium salt (6—7 mg) in a solvent (25 ml) was shaken vigorously for 10 min; then, the residual salt (if present) was filtered off. The fast reactions (Runs 3—11, Table 2) were followed by a stopped-flow technique on a Union Giken RA-1300 instrument.

Rate Measurements in Two-Phase Systems. A mixture of water (25 ml), buffered with sodium carbonate and sodium borate (1×10^{-2} mol dm^{-3} each) at ca. pH 9.5, and 1,2-dichloroethane (30 ml) containing a substrate and a PTC was stirred in a vessel thermostated at the prescribed temperature. After an aqueous solution (5 ml 6×10^{-3} mol dm^{-3}) of the diazonium salt was further added, the mixture was stirred with a flat-bladed mechanical stirrer rotating at a constant speed. At a definite time stirring was stopped and a portion was taken out from the organic phase and diluted with the same solvent to a definite volume. The absorbance due to any azo compound formed was then measured with a Hitachi Model 200-10 spectrometer.

Preparation of Azo Compounds. Into a flask with a mechanical stirrer was added water (100 ml), 1,2-dichloroethane (100 ml), dimedone (2.00 g, 14.3 mmol), sodium carbonate (2.32 g, 21.8 mmol), tetrabutylammonium bromide (0.46 g, 1.4 mmol), and finally *p*-diethylaminobenzenediazonium tetrafluoroborate (3.76 g, 14.3 mmol). The mixture was stirred vigorously for 30 min at 0—5 °C. The organic layer was separated, washed with water, dried over $MgSO_4$, and then evaporated. The residue was recrystallized from benzene–ligroin (1:1) to give 2-(4-diethylaminophenylhydrazono)-5,5-dimethyl-1,3-cyclohexanedione (**7**): mp 128—129 °C; MS, *m/z* 315 (M^+); UV ($ClCH_2CH_2Cl$) 490 nm (ε 22100). Anal. ($C_{18}H_{25}N_3O_2$) C, H, N.

The other azo compounds listed in Table 3 were obtained in a similar manner except that, in the cases of Runs 5, 8, and 10, the crude products were purified on a silica-gel column with benzene.

2-(4-Diethylaminophenylhydrazono)-4,4,4-trifluoro-1-(2-thienyl)-1,3-butanedione: Mp 161—162 °C; MS *m/z* 397 (M^+). Anal. ($C_{18}H_{18}O_2N_3SF_3$) C,H,N.

N-[4-(4-Chlorophenylazo)phenyl]-*p*-toluenesulfonamide: Mp 185—186 °C; MS, *m/z* 385 (M^+). Anal. ($C_{19}H_{16}N_3O_2SCl$) C, H, N.

2-(4-Methoxyphenylazo)-4-nitrophenol: Mp 188—189 °C; MS, *m/z* 241 (M^+). Anal. ($C_{13}H_{11}N_3O_2$) C, H, N.

4-(4-Methoxyphenylazo)-*N*,*N*-dimethylaniline: Mp 159—160 °C (lit,[20] 161—163 °C); UV ($ClCH_2CH_2Cl$) 410 nm (ε 31400).

The present work was partially supported by a Grant-in-Aid for Scientific Research (No. 60550600) from the Ministry of Education, Science and Culture.

The Oxidation of Some Naphthols with Benzoyl Peroxide

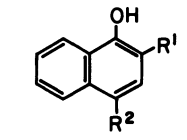
Takashi MATSUMOTO,* Sachihiko IMAI,* and Naoya YAMAMOTO
Department of Chemistry, Faculty of Science, Hiroshima University,
Higashisenda-machi, Naka-ku, Hiroshima 730
(Received August 3, 1987)

The reactions of four naphthols (1-naphthol (**1**), 2-naphthol (**2**), 4-isopropyl-1-naphthol (**18**), and 3-isopropyl-2-naphthol (**19**)) with benzoyl peroxide were examined under two reaction conditions (A and B). Each of the naphthols **1**, **2**, **18**, and **19** was oxidized with 0.95 equivalent moles of benzoyl peroxide at room temperature for 24 h (condition A) to give mainly the corresponding ortho-benzoyloxylated product which was isolated in moderate yield as an equilibrium mixture, resulting from its trans-benzoylation. The naphthols **18** and **19** were also oxidized with 2.25 equivalent moles of benzoyl peroxide at room temperature for 48 h (condition B) to give mainly 2,2-bis(benzoyloxy)-4-isopropyl-1(2*H*)-naphthalenone and 2,2-bis(benzoyloxy)-3-isopropyl-1(2*H*)-naphthalenone in good yields. The oxidations of **1** and **2** under condition B produced the same product, 2,2-bis(benzoyloxy)-1(2*H*)-naphthalenone, in low yields.

Although the oxidation of various phenols with benzoyl peroxide has been considerably investigated,[1,2] comparatively little research has been performed on the oxidation of naphthol compounds. In 1963, Edward and Samad[3] reported that both 1-naphthol (**1**) and 2-naphthol (**2**) yielded the same product, 2-(4-nitrobenzoyloxy)-1-naphthol (**3**), through oxidation with bis(4-nitrobenzoyl) peroxide in refluxing chloroform. However, when benzoyl peroxide was used, the corresponding benzoyloxy derivative could not be obtained. Bhatia and Mathur[1,4] also reported the oxidation of **2** with benzoyl peroxide in refluxing chloroform; they obtained a trace of 1-benzoyloxy-2-naphthol (**4**) and a small amount (1% yield) of 1,1-bis(benzoyloxy)-2(1*H*)-naphthalenone (**5**), the revised structure of which is described later. A similar oxidation[5] of **1** produced 4,4′-dihydroxy-1,1′-binaphthyl (**6**: 45%) and 1,4-naphthoquinone (**7**: 16%). However, 1-bromo-2-naphthol (**8**)[5] yielded only 1,2-naphthoquinone (**9**) in 25% yield. Mathur et al. further demonstrated the oxidations of two more bromonaphthols in refluxing chloroform. That is, 4-bromo-1-naphthol (**10**)[6] produced three compounds: 2-benzoyloxy-4-bromo-1-naphthol (**11**: 6%), 1,2-bis(benzoyloxy)-4-bromonaphthalene (**12**: 2%), and 2-benzoyloxy-1,4-naphthoquinone (**13**). On the other hand, 6-bromo-2-naphthol (**14**)[7] afforded two compounds: 1-benzoyloxy-6-bromo-2-naphthol (**15**: 13%) and 1,1-bis(benzoyloxy)-6-bromo-2(1*H*)-naphthalenone (**16**: 4%).

In connection with our synthetic study[8] of the natural coleon A (**17**),[9-11] we have also investigated the oxidations of various naphthol compounds with benzoyl peroxide in order to obtain further information on the introduction of oxygen functions in the naphthol skeleton. This paper describes the reactions of 1-naphthol (**1**), 2-naphthol (**2**), 4-isopropyl-1-naphthol (**18**), and 3-isopropyl-2-naphthol (**19**) with benzoyl peroxide.

Each of the naphthols was oxidized under two reaction conditions (A and B); the results are



1 $R^1=R^2=H$
3 $R^1=OCOC_6H_4NO_2(p)$, $R^2=H$
10 $R^1=H$, $R^2=Br$

summarized in Table 1.

The oxidation of 1-naphthol (**1**) with 0.95 equivalent moles of benzoyl peroxide in dichloromethane at room temperature for 24 h (condition A) afforded a ca. 1:1 mixture (25%) of 1-benzoyloxy-2-naphthol (**4**) and 2-benzoyloxy-1-naphthol (**20**), together with 2,2-bis(benzoyloxy)-1(2*H*)-naphthalenone (**21**: 4%), 4-benzoyloxy-1-naphthol (**22**: 3%), and the starting **1** (16%). However, the oxidation of **1** with 2.25 equivalent moles of benzoyl peroxide in dichloromethane at room temperature for 48 h (condition B) afforded a complicated mixture, from which **21** and 2-benzoyloxy-1,4-naphthoquinone (**13**) were isolated in low yields of 6 and 5%, respectively.

Similarly, 2-naphthol (**2**) was oxidized under condition A to give a ca. 1:1 mixture (52%) of **4** and **20**, **21** (8%), 1,1-bis(benzoyloxy)-2(1*H*)-naphthalenone (**5**: 3%), and the starting **2** (28%). Under condition B, **2** produced **21** and **5** in 26 and 6% yields, respectively.

The oxidation of 4-isopropyl-1-naphthol (**18**) under condition A afforded a ca. 2:3 mixture (42%) of 2-benzoyloxy-4-isopropyl-1-naphthol (**23**) and 1-benzoyloxy-4-isopropyl-2-naphthol (**24**), along with 2,2-bis(benzoyloxy)-4-isopropyl-1(2*H*)-naphthalenone (**25**: 14%), 4,4′-diisopropyl-2,2′-bi-1-naphthol (**26**: 7%), and a trace of 1,1′,2,2′-tetrahydro-4,4′-diisopropyl-1,1′-dioxo-2,2′-binaphthylidene (**27**: 1%). However, when **18** was oxidized under condition B, it gave a ca. 2:3 mixture (4%) of **23** and **24**, **25** (65%), **27** (3%), and 1,1-bis(benzoyloxy)-4-isopropyl-2(1*H*)-naphthalenone (**28**: 4%).

3-Isopropyl-2-naphthol (**19**) was also oxidized

Table 1. Oxidations of Naphthols with Benzoyl Peroxide in Dichloromethane at Room Temperature

Substrate	Condition[a]	Product (Yield/%)			
1	A	**4**+**20** (25)	**21** (4)	**22** (3)	—
	B	—	**21** (6)	—	**13** (5)
2	A	**4**+**20** (52)	**21** (8)	**5** (3)	—
	B	—	**21** (26)	**5** (6)	—
18	A	**23**+**24** (42)	**25** (14)	**26** (7)	**27** (1)
	B	**23**+**24** (4)	**25** (65)	**28** (4)	**27** (3)
19	A	**29**+**30** (66)	**31** (9)	—	—
	B	**29**+**30** (5)	**31** (65)	**32** (14)	—

a) A: 0.95 equivalent moles of benzoyl peroxide for 24 h. B: 2.25 equivalent moles of benzoyl peroxide for 48 h.

under condition A to give a ca. 1:1 mixture (66%) of 2-benzoyloxy-3-isopropyl-1-naphthol (**29**) and 1-benzoyloxy-3-isopropyl-2-naphthol (**30**), 2,2-bis(benzoyloxy)-3-isopropyl-1(2*H*)-naphthalenone (**31**: 9%), and the starting **19** (16%). The oxidation of **19** under condition B produced a ca. 1:1 mixture (5%) of **29** and **30**, **31** (65%), and 1,1-bis(benzoyloxy)-3-isopropyl-2(1*H*)-naphthalenone (**32**: 14%). The structures of the oxidation products were determined by the following chemical and spectroscopic studies.

Phenolic compounds, **4** and **20**, were obtained as a mixture (ca. 1:1), whose IR spectrum indicated the presence of hydroxyl (3575 and 3280 cm^{-1}) and benzoyloxyl (1745 cm^{-1}) groups. The ^1H NMR spectrum of the mixture showed doublet signals due to C-3 and C-4 protons at δ 7.22 and 7.65 for **4** and at δ 7.30 and 7.46 for **20**. The difference in these chemical shifts of the C-4 protons is obviously attributable to the C-1 substituent (hydroxyl or benzoyloxyl group): the presence of a hydroxyl group at the C-1 position causes an upfield shift of the C-4 proton. Therefore, the structures of **4** and **20** were assigned to be 1-benzoyloxy-2-naphthol and 2-benzoyloxy-1-naphthol, respectively. Acetylation of the mixture (ca. 1:1) with isopropenyl acetate and *p*-toluenesulfonic acid in refluxing toluene afforded two separable acetates,[12] **33** and **34**, in 28 and 71% yields. The ^1H NMR spectrum of **33** indicated signals due to an acetoxy methyl at δ 2.30 (singlet) and a C-3 aromatic proton at δ 7.43 (doublet, J=9 Hz), while that of **34** indicated the corresponding signals at δ 2.16 (singlet) and 7.35 (doublet, J=9 Hz). Since the acetoxy methyl and the C-3 proton in **33** were more deshielded than those in **34** by the effect of aromatic rings, the structures of **33** and **34** were assigned to be 1-acetoxy-2-benzoyloxynaphthalene and 2-acetoxy-1-benzoyloxynaphthalene, respectively.

Compound **21** (mp 195—196 °C) showed absorption bands at 1732 and 1709 cm^{-1} in its IR spectrum, indicating the presence of benzoyloxyl groups and a conjugated carbonyl group. The ^1H NMR spectrum of **21** showed two doublet signals due to C-3 and C-4 olefinic protons at δ 6.33 and 6.98.

Compound **5** (mp 239—240 °C) also showed similar spectral data: IR 1736 and 1695 cm^{-1}, ^1H NMR δ 6.56 and 7.50 (each 1 H and doublet). Comparisons of these spectral data with those of **21** suggested that the carbonyl group in **5** is conjugated with the C-3 and C-4 double bond. To obtain a further confirmation on the structures of **5** and **21**, the following reactions were carried out. Compounds **5** and **21** were each treated with acetic anhydride containing concentrated sulfuric acid to give the same product, 1,2,4-triacetoxynaphthalene (**35**),[4] in 90 and 73% yields, respectively. The catalytic hydrogenation of **5** over 5% Rh–Al_2O_3 in 1,4-dioxane afforded the corresponding tetrahydro ketone (**36**: 32%), along with a mixture of the phenolic compounds (**4** and **20**: 66%). This ketone **36** showed the presence of a nonconjugated carbonyl group (1727 cm^{-1}) in its IR spectrum. A similar catalytic hydrogenation of **21** also afforded the tetrahydro compound (**37**: 60%) and a mixture of **4** and **20** (38%). The IR spectrum of **37** showed absorption bands at 1735 and 1710 cm^{-1}, indicating the presence of benzoyloxyl groups and a conjugated carbonyl group. Thus, the structures of **5** and **21** were assigned to be 1,1-bis(benzoyloxy)-2(1*H*)-naphthalenone and 2,2-bis(benzoyloxy)-1(2*H*)-naphthalenone, respectively.

Bhatia and Mathur[4] prepared the bis(benzoyloxy)-naphthalenone derivative (mp 186—187 °C) and proposed its structure as being **5**. However, the reported melting point is quite different from that of **5**, but similar to that of **21**. For a direct comparison with the product of Bhatia and Mathur, 2-naphthol (**2**) was also oxidized under their reaction condition using one equivalent mole of benzoyl peroxide in refluxing chloroform[4] to give 2,2-bis(benzoyloxy)-1(2*H*)-naphthalenone (**21**: mp 195—196 °C) in 7.5% yield. Therefore, the proposed structure **5** must be revised to **21**.

Compound **22** showed the presence of a hydroxyl group (3580 and 3320 cm^{-1}) and a benzoyloxyl group (1730 cm^{-1}) in its IR spectrum. The ^1H NMR spectrum of **22** showed signals due to a pair of ortho-coupling aromatic protons at δ 6.61 and 7.07 (each 1H, doublet, and J=8 Hz). Thus, the structure of **22** was assigned to be 4-benzoyloxy-1-naphthol.

Compound **13** showed the presence of a benzoyloxyl group (IR 1749 cm^{-1}) and a *p*-quinone moiety [IR 1667 cm^{-1}, ^1H NMR δ 6.93 (1H, singlet, C-3 proton)]. This compound was also obtained by the oxidation of a phenolic mixture (**4** and **20**) with Jones reagent in 14% yield or by the oxidation of the naphthalenone compound **21** with *m*-chloroperbenzoic acid in 22% yield. Thus, the structure of **13** was assigned to be 2-benzoyloxy-1,4-naphthoquinone.

Phenolic compounds, **23** and **24**, were obtained as a mixture (ca. 2:3), the IR spectrum of which indicated the presence of hydroxyl (3570 and 3320 cm^{-1}) and benzoyloxyl (1740 cm^{-1}) groups. The ^1H NMR spectrum of the mixture showed signals due to hydroxyl, C-3, and C-8 protons at δ 6.10 (broad), 7.19 (singlet), and 8.31 (multiplet) for the minor phenol **23**, and at δ 5.85 (broad), 7.19 (singlet), and 7.84 (multiplet) for the major phenol **24**. The appearance of the C-8 proton signal of **23** in a very low field (δ 8.31) suggested the presence of a hydroxyl group at the C-1 position. Thus, the structures of **23** and **24** were assigned to be 2-benzoyloxy-4-isopropyl-1-naphthol and 1-benzoyloxy-4-isopropyl 2-naphthol, respectively. Acetylation of the mixture (**23** and **24**) with isopropenyl acetate and *p*-toluenesulfonic acid in refluxing toluene afforded an acetate (64%), the

structure of which was assigned to be 2-acetoxy-1-benzoyloxy-4-isopropylnaphthalene (**38**) by comparisons of its ^{1}H NMR spectrum with those of **33** and **34**. The hydrolysis of **38** with dilute hydrochloric acid in refluxing methanol produced **24** containing a small amount of **23**. This was dissolved in deuteriochloroform and then allowed to stand at room temperature for 24 h to give an equilibrium mixture of **23** and **24** (ca. 2:3).[13]

Compound **25** indicated the presence of benzoyloxyl groups (1727 cm^{-1}) and a conjugated carbonyl group (1703 cm^{-1}) in its IR spectrum. The ^{1}H NMR spectrum of **25** showed a singlet signal due to a C-3 olefinic proton at δ 6.18. Thus, the structure of **25** was assigned to be 2,2-bis(benzoyloxy)-4-isopropyl-1(2*H*)-naphthalenone. This structure was further supported by its UV spectrum (Fig. 1).

Compound **26** was identified as 4,4′-diisopropyl-2,2′-bi-1-naphthol by the following spectral data; MS *m/z* 370 (M$^+$), IR 3535 and 3270 cm^{-1}, and ^{1}H NMR δ 5.56 (singlet, hydroxyls) and 7.32 (singlet, C-3 and C-3′ protons).

Compound **27**, IR 1629 cm^{-1} (conjugated carbonyls) and ^{1}H NMR δ 8.29 (singlet, C-3 and C-3′ protons), was also obtained by the oxidation of **26** with potassium hexacyanoferrate(III) in an alkaline solution in 81% yield. Thus, the structure of **27** was assigned to be 1,1′,2,2′-tetrahydro-4,4′-diisopropyl-1,1′-dioxo-2,2′-binaphthylidene.

Compound **28** showed the presence of benzoyloxyl groups (1737 cm^{-1}) and a conjugated carbonyl group (1680 cm^{-1}) in the IR spectrum. Its ^{1}H NMR spectrum showed a singlet signal due to a C-3 olefinic proton at δ 6.51. Thus, the structure of **28** was assigned to be 1,1-bis(benzoyloxy)-4-isopropyl-2(1*H*)-naphthalenone. This structure was further supported by its UV spectrum (Fig. 2).

Phenolic compounds, **29** and **30**, were obtained as a mixture (ca. 1:1), the IR spectrum of which indicated the presence of hydroxyl (3575 and 3320 cm^{-1}) and benzoyloxyl (1737 cm^{-1}) groups. Recrystallization of the mixture afforded pure crystalline **30**. The ^{1}H NMR spectrum of **30** showed a singlet signal due to a C-4 aromatic proton at δ 7.60, while that of **29** showed a corresponding signal at δ 7.38. The appearance of the C-4 proton signal of **29** in a high field suggested the presence of a hydroxyl group at the C-1 position. Thus, the structures of **29** and **30** were assigned to be 2-benzoyloxy-3-isopropyl-1-naphthol and 1-benzoyloxy-3-isopropyl-2-naphthol, respectively. Acetylation of the mixture (ca. 1:1) of **29** and **30** with isopropenyl acetate and *p*-toluenesulfonic acid in refluxing toluene afforded 1-acetoxy-2-benzoyloxy-3-isopropylnaphthalene (**39**: 76%),[12] which was hy-

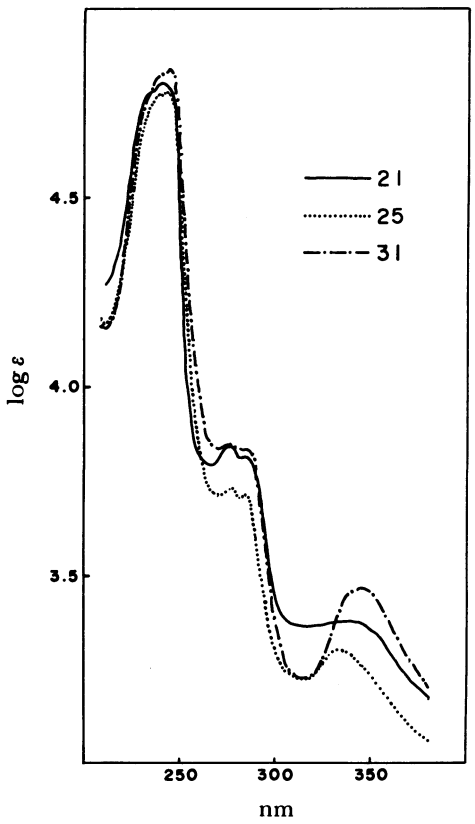

Fig. 1. The UV spectra of 2,2-bis(benzoyloxy)-1(2*H*)-naphthalenone derivatives **21**, **25**, and **31** in ethanol.

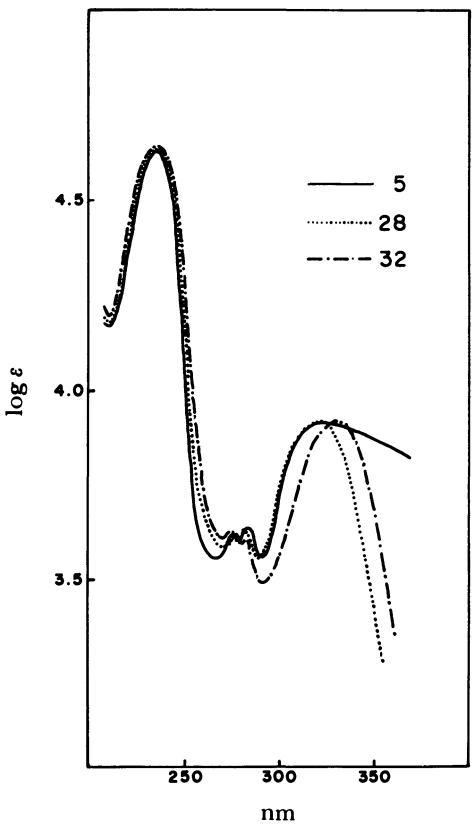

Fig. 2. The UV spectra of 1,1-bis(benzoyloxy)-2(1*H*)-naphthalenone derivatives **5**, **28**, and **32** in ethanol.

drolyzed with dilute hydrochloric acid in refluxing methanol to give **29** containing a small amount of **30**. This was dissolved in deuteriochloroform and then allowed to stand at room temperature for 24 h to give an equilibrium mixture of **29** and **30** (ca. 1:1).[13] Compound **30** was oxidized with Jones reagent to afford 2-benzoyloxy-3-isopropyl-1,4-naphthoquinone (**40**) in 32% yield.

Compound **31** indicated the presence of benzoyloxyl groups (1729 cm^{-1}) and a conjugated carbonyl group (1703 cm^{-1}) in the IR spectrum. Its ^1H NMR spectrum showed a singlet signal due to a C-4 olefinic proton at δ 6.88. Thus, the structure of **31** was assigned to be 2,2-bis(benzoyloxy)-3-isopropyl-1(2*H*)-naphthalenone. This structure was further supported by its UV spectrum (Fig. 1). The oxidation of **31** with *m*-chloroperbenzoic acid afforded the quinone **40** in 36% yield. Compound **31** was also treated with acetic anhydride containing concentrated sulfuric acid to give 1,2,4-triacetoxy-3-isopropylnaphthalene (**41**) in 86% yield.

Compound **32** was identified as 1,1-bis(benzoyloxy)-3-isopropyl-2(1*H*)-naphthalenone by the following spectral data: IR 1731 and 1683 cm^{-1}, ^1H NMR δ 7.23 (singlet, C-4 proton), and UV (Fig. 2). The treatment of **32** with acetic anhydride containing concentrated sulfuric acid produced the triacetate **41** in 83% yield.

As shown in Table 1, the naphthols **1**, **2**, **18**, and **19** were oxidized under condition A to give mainly the corresponding ortho-benzoyloxylated product which was isolated as an equilibrium mixture (**4**+**20**, **23**+**24**, and **29**+**30**), resulting from its trans-benzoylation. On the other hand, oxidations of these naphthols under condition B produced mainly the corresponding bis(benzoyloxy)naphthalenone derivatives **5**, **21**, **25**, **28**, **31**, and **32**, although in the case of **1** the yield was very low.

From the present study, it is clear that the benzoyl peroxide oxidation is effective for the introduction of oxygen functions to the naphthol skeleton, in contrast to the results of Edward and Samad,[3] and Mathur et al.[4-7]

Experimental

All melting points are uncorrected. The IR spectrum were measured in chloroform and the ^1H NMR spectra in deuteriochloroform at 90 MHz with tetramethylsilane as an internal standard unless otherwise stated; s: singlet, bs: broad singlet, d: doublet, dd: double doublet, m: multiplet. The column chromatography was performed using Merck silica gel (0.063—0.200 mm).

4-Isopropyl-1-naphthol (18). A solution of 4-acetyl-1-naphthol[14] (1.862 g) in dry tetrahydrofuran (20 ml) was added dropwise to a stirred ether solution of methylmagnesium iodide prepared from magnesium turnings (961 mg) and methyl iodide (2.49 ml) in dry ether (24 ml). The mixture was refluxed for 2 h, poured into a mixture of ice and aqueous ammonium chloride, and extracted with ether. The ether extract was washed with brine, dried over sodium sulfate, and evaporated in vacuo to give a crude 4-(1-hydroxy-1-methylethyl)-1-naphthol, IR 3600 and 3220 cm^{-1}.

The above crude product was refluxed with acetic anhydride (15 ml) and sodium acetate (3.0 g) for 7 h. After evaporation of the acetic anhydride in vacuo, the residue was diluted with water and extracted with ether. The ether extract was washed with aqueous sodium hydrogencarbonate and brine, dried, and evaporated in vacuo. The residue was chromatographed on silica gel (200 g), using benzene as an eluent, to give 1-acetoxy-4-isopropenylnaphthalene (2.163 g: 95.6%), IR 1765 cm^{-1}, ^1H NMR (60 MHz) δ=2.18 (3H, m, $C\underline{H}_3C(=CH_2)$), 2.44 (3H, s, $-OCOCH_3$), 5.03 (1H, m) and 5.37 (1H, m) ($-C(=CH_2)$), 7.17 and 7.29 (each 1H, d, and J=8.5 Hz, C_2-H and C_3-H), 7.30—7.65 (2H, m, C_6-H and C_7-H), 7.70—8.20 (2H, m, C_5-H and C_8-H).

A mixture of the above acetate (2.163 g), 5% Pd-C (540 mg), and concentrated hydrochloric acid (0.2 ml) in methanol (40 ml) was hydrogenated at room temperature under an atmosphere of hydrogen for 19 h. After the usual work-up, the crude product was chromatographed on silica gel (200 g), using benzene as an eluent, to give **18**[15] (1.430 g: 79.8%). This was recrystallized from hexane-cyclohexane, mp 65—66 °C, IR 3600 and 3325br cm^{-1}, ^1H NMR δ=1.35 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 3.64 (1H, m, $-C\underline{H}(CH_3)_2$), 5.17 (1H, bs, $-OH$), 6.74 (1H, d, J=8 Hz, C_2-H), 7.18 (1H, d, J=8 Hz, C_3-H), 7.33—7.52 (2H, m, C_6-H and C_7-H), and 7.96—8.28 (2H, m, C_5-H and C_8-H). Found: C, 83.75; H, 7.92%. Calcd for $C_{13}H_{14}O$: C, 83.83; H, 7.58%.

3-Isopropyl-2-naphthol (19). A solution of methyl 2-hydroxy-3-naphthoate (10.110 g) in dry ether (300 ml) was added dropwise to a stirred ether solution of methylmagnesium iodide prepared from magnesium turnings (7.292 g) and methyl iodide (18.7 ml) in dry ether (200 ml). The mixture was refluxed for 1.5 h, poured into a mixture of ice and aqueous ammonium chloride, and extracted with ether. The ether extract was washed with brine, dried, and evaporated in vacuo. The residue was refluxed with acetic anhydride (50 ml) and sodium acetate (15.0 g) for 7 h. After the work-up (as described above) the crude product was chromatographed on silica gel (250 g), using benzene as an eluent, to give 2-acetoxy-3-isopropenylnaphthalene (10.860 g: 96.0%), IR 1755 cm^{-1}, ^1H NMR (60 MHz) δ=2.12 (3H, bs, $C\underline{H}_3C(=CH_2)$), 2.28 (3H, s, $-OCOCH_3$), 5.11 (1H, m) and 5.21 (1H, m) ($-C(=CH_2)$), 7.30—7.58 (2H, m, C_6-H and C_7-H), 7.48 (1H, s, C_1-H), 7.58-7.90 (2H, m, C_5-H and C_8-H), and 7.72 (1H, s, C_4-H).

A mixture of the above acetate (10.860 g) and 5% Pd-C (2.80 g) in methanol (160 ml) was hydrogenated at room temperature under an atmosphere of hydrogen for 17 h to give 2-acetoxy-3-isopropylnaphthalene (10.366 g), IR 1750 cm^{-1}, ^1H MMR (60 MHz) δ=1.34 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 2.36 (3H, s, $-OCOCH_3$), 3.12 (1H, m, $-C\underline{H}(CH_3)_2$), 7.25—7.58 (2H, m, C_6-H and C_7-H), 7.48 (1H, s, C_1-H), 7.58—7.93 (2H, m, C_5-H and C_8-H), and 7.72 (1H, s, C_4-H).

The above crude acetate (10.366 g) was treated with lithium aluminium hydride (2.584 g) in dry ether (200 ml) at room temperature for 2 h. The mixture was poured into ice-aqueous ammonium chloride and extracted with ether. The ether extract was washed with brine, dried, and

evaporated in vacuo. The residue was chromatographed on silica gel (250 g), using benzene as an eluent, to give **19**[16] (7.562 g: 84.6%). This was recrystallized from hexane, mp 81—82 °C, IR 3590 and 3290 cm^{-1}, ^1H NMR δ=1.33 (6H, d, J=7 Hz, -CH(C$\underline{H}_3$)$_2$), 3.33 (1H, m, -C$\underline{H}$(CH$_3$)$_2$), 4.96 (1H, s, -OH), 6.98 (1H, s, C_1-H), 7.59 (1H, s, C_4-H), 7.14—7.45 (2H, m, C_6-H and C_7-H), and 7.45—7.80 (2H, m, C_5-H and C_8-H). Found: C, 83.97; H, 7.83%. Calcd for $C_{13}H_{14}O$: C, 83.83; H, 7.58%.

Oxidation of 1-Naphthol (1) with Benzoyl Peroxide. *a*): **The Condition A.** A solution of **1** (288.0 mg) and benzoyl peroxide (460.0 mg) in dichloromethane (6.0 ml) was protected from light and stirred at room temperature for 24 h. After the addition of ether (20 ml), acetic acid (0.2 ml), and aqueous potassium iodide (20%, 5.0 ml), the mixture was further stirred at room temperature for 3 h. The mixture was washed successively with water, aqueous sodium thiosulfate, and brine. The dried solution was evaporated in vacuo and the residue was chromatographed on silica gel (50 g), using hexane-benzene (1:1) as an eluent, to give the starting **1** (46.5 mg: 16.1%). Further elution with benzene and ether-benzene (1:99) afforded four compounds **4**, **20**, **21**, and **22**.

1-Benzoyloxy-2-naphthol (**4**) and 2-benzoyloxy-1-naphthol (**20**) in a ratio of ca. 1:1 (133.2 mg: 25.2%), mp 173—176 °C (ca. 1:1 mixture from chloroform), IR 3575, 3280br, and 1745 cm^{-1}. ^1H NMR of **4** δ=5.91 (1H, bs, C_2-OH), 7.22 (1H, d, J=8.5 Hz, C_3-H), 7.32—7.88 (7H, m, C_5-H, C_6-H, C_7-H, C_8-H, and C_3-H, C_4-H, C_5-H of benzoyloxyl group), 7.65 (1H, d, J=8.5 Hz, C_4-H), and 8.33 (2H, dd, J=8 and 2 Hz, C_2-H and C_6-H of benzoyloxyl group). ^1H NMR of **20** δ=6.18 (1H, bs, C_1-OH), 7.30 (1H, d, J=9 Hz, C_3-H), 7.32—7.88 (6H, m, C_5-H, C_6-H, C_7-H, and C_3-H, C_4-H, C_5-H of benzoyloxyl group), 7.46 (1H, d, J=9 Hz, C_4-H), 8.24 (2H, dd, J=8 and 2 Hz, C_2-H and C_6-H of benzoyloxyl group), and ca. 8.25 (1H, m, C_8-H). Found: C, 77.41; H, 4.43%. Calcd for $C_{17}H_{12}O_3$: C, 77.26; H, 4.58%.

2,2-Bis(benzoyloxy)-1(2*H*)-naphthalenone (**21**) (27.9 mg: 3.6%), mp 195—196 °C decomp (from acetone), IR 1732 and 1709 cm^{-1}, ^1H NMR δ=6.33 (1H, d, J=10 Hz, C_3-H), 6.98 (1H, d, J=10 Hz, C_4-H), 7.27—7.75 (9H, m, C_5-H, C_6-H, C_7-H, and C_3-H, C_4-H, C_5-H of benzoyloxyl groups), 8.08 (4H, dd, J=8 and 2 Hz, C_2-H and C_6-H of benzoyloxyl groups), and 8.18 (1H, bd, J=7.5 Hz, C_8-H). Found: C, 75.00; H, 4.08%. Calcd for $C_{24}H_{16}O_5$: C, 74.99; H, 4.20%.

4-Benzoyloxy-1-naphthol (**22**) (13.3 mg: 2.5%), IR 3580, 3320br, and 1730 cm^{-1}. ^1H NMR δ=6.61 (1H, d, J=8 Hz, C_2-H), 7.07 (1H, d, J=8 Hz, C_3-H), 7.30—7.70 (5H, m, C_6-H, C_7-H, and C_3-H, C_4-H, C_5-H of benzoyloxyl group), ca. 7.81 (1H, m, C_5-H), ca. 8.10 (1H, m, C_8-H), and 8.30 (2H, dd, J=8 and 2 Hz, C_2-H and C_6-H of benzoyloxyl group). Found: C, 77.50; H, 4.40%. Calcd for $C_{17}H_{12}O_3$: C, 77.26; H, 4.58%.

b): **The Condition B.** A solution of **1** (288.0 mg) and benzoyl peroxide (1090.0 mg) in dichloromethane (10 ml) was protected from light and stirred at room temperature for 48 h. After the work-up (as described in *a*)) the crude product was purified by column chromatography on silica gel to give **21** (45.8 mg: 6.0%) and 2-benzoyloxy-1,4-naphthoquinone (**13**) (29.9 mg: 5.3%), mp 118—119 °C (from acetone-hexane), IR 1749 and 1667 cm^{-1}, ^1H NMR δ=6.93 (1H, s, C_3-H), 7.38—7.93 (5H, m, C_6-H, C_7-H, and C_3-H, C_4-H, C_5-H of benzoyloxyl group), ca. 8.11 (2H, m, C_5-H and C_8-H), and 8.18 (2H, dd, J=8 and 2 Hz, C_2-H and C_6-H of benzoyloxyl group). Found: C, 73.59; H, 3.50%. Calcd for $C_{17}H_{10}O_4$: C, 73.38; H, 3.62%.

Oxidation of 2-Naphthol (2) with Benzoyl Peroxide. *a*): A solution of **2** (288.0 mg) and benzoyl peroxide (460.0 mg) in dichloromethane (6.0 ml) was treated under condition A (room temp, 24 h). The crude product was purified by column chromatography on silica gel to give the starting **2** (80.6 mg: 28.0%), a mixture (ca. 1:1) of **4** and **20** (274.0 mg: 51.9%), **21** (57.6 mg: 7.5%), and 1,1-bis(benzoyloxy)-2(1*H*)-naphthalenone (**5**) (21.4 mg: 2.8%), mp 239—240 °C (from acetone), IR 1736 and 1695 cm^{-1}, ^1H NMR δ=6.56 (1H, d, J=10 Hz, C_3-H), 7.26—7.62 (8H, m, C_6-H, C_7-H, and C_3-H, C_4-H, C_5-H of benzoyloxyl groups), 7.50 (1H, d, J=10 Hz, C_4-H), ca. 7.73 (2H, m, C_5-H and C_8-H), and 8.06 (4H, dd, J=8 and 2 Hz, C_2-H and C_6-H of benzoyloxyl groups). Found: C, 75.16; H, 3.97%. Calcd for $C_{24}H_{16}O_5$: C, 74.99; H, 4.20%.

b): A solution of **2** (288.0 mg) and benzoyl peroxide (1090.0 mg) in dichloromethane (10 ml) was treated under condition B (room temp., 48 h). The crude product was purified by column chromatography on silica gel to give **5** (49.1 mg: 6.4%) and **21** (202.6 mg: 26.4%).

c): **The condition of Bhatia and Mathur.**[4] A solution of **2** (1.440 g: 10.0 mmol) and benzoyl peroxide (2.495 g: 10.3 mmol) in chloroform (12.5 ml) was refluxed for 6 h and then treated by the following our method.[17] The reaction mixture was diluted with ether (15 ml), acetic acid (0.5 ml), and aqueous potassium iodide (20%, 20 ml). After stirring at room temperature for 3 h, the mixture was extracted with ether and the ether extract was washed successively with water, aqueous sodium thiosulfate, aqueous sodium hydrogencarbonate, and brine. The dried solution was evaporated in vacuo. The residue was purified by column chromatography on silica gel to give the starting **2** (341 mg: 23.7%), a mixture (ca. 1:1, mp 173—176 °C from chloroform) of **4** and **20** (653 mg: 24.7%), **21** (mp 195—196 °C decomp. from acetone, 287 mg: 7.5%), and **5** (mp 239—240 °C from acetone, 92 mg: 2.4%).

Oxidation of 4-Isopropyl-1-naphthol (18) with Benzoyl Peroxide. *a*): A solution of **18** (372.5 mg) and benzoyl peroxide (460.0 mg) in dichloromethane (6.0 ml) was treated under the condition A (room temp, 24 h). The crude product was chromatographed on silica gel to give five compounds **23**, **24**, **25**, **26**, and **27**.

2-Benzoyloxy-4-isopropyl-1-naphthol (**23**) and 1-benzoyloxy-4-isopropyl-2-naphthol (**24**) in a ratio of ca. 2:3 (258.9 mg: 42.3%), mp 138—142 °C (ca. 2:3 mixture from carbon tetrachloride), IR 3570, 3320br, and 1740 cm^{-1}. Found: C, 78.11; H, 6.01%. Calcd for $C_{20}H_{18}O_3$: C, 78.41; H, 5.92%. ^1H NMR of **23** δ=1.38 (6H, d, J=7 Hz, -CH(C$\underline{H}_3$)$_2$), 3.70 (1H, m, -C$\underline{H}$(CH$_3$)$_2$), 6.10 (1H, br, C_1-OH), 7.19 (1H, s, C_3-H), 7.33—7.73 (5H, m, C_6-H, C_7-H, and C_3-H, C_4-H, C_5-H of benzoyloxyl group), ca. 8.06 (1H, m, C_5-H), 8.26 (2H, dd, J=8 and 2 Hz, C_2-H and C_6-H of benzoyloxyl group), and 8.31 (1H, m, C_8-H). ^1H NMR of **24** δ=1.38 (6H, d, J=7 Hz -CH(C$\underline{H}_3$)$_2$), 3.70 (1H, m, -C$\underline{H}$(CH$_3$)$_2$), 5.85 (1H, br, C_2-OH), 7.19 (1H, s, C_3-H), 7.33—7.73 (5H, m, C_6-H, C_7-H and C_3-H, C_4-H C_5-H of benzoyloxyl group), 7.84 (1H, m, C_8-H), ca. 8.06 (1H, m, C_5-H), and 8.34 (2H, dd, J=8 and 2 Hz, C_2-H and C_6-H of benzoyloxyl group).

2,2-Bis(benzoyloxy)-4-isopropyl-1(2*H*)-naphthalenone (**25**) (121.1 mg: 14.2%), mp 195—197 °C (from benzene), IR 1727 and 1703 cm^{-1}, ^1H NMR δ=1.23 (6H, d, J=7 Hz, -CH($C\underline{H}_3$)$_2$), 3.17 (1H, m, -$C\underline{H}$(CH_3)$_2$), 6.18 (1H, bs, C_3-H), 7.30-7.70 (9H, m, C_5-H, C_6-H, C_7-H, and C_3-H, C_4-H, C_5-H of benzoyloxyl groups), 8.06 (4H, dd, J= 8 and 2 Hz, C_2-H and C_6-H of benzoyloxyl groups), and 8.23 (1H, bd, J=8 Hz, C_8-H). Found: C, 75.86; H, 5.43%. Calcd for $C_{27}H_{22}O_5$: C, 76.04; H, 5.20%.

4,4'-Diisopropyl-2,2'-bi-1-naphthol (**26**) (72.0 mg: 6.5%), mp 210—212 °C (from hexane-acetone), MS m/z 370 (M^+), IR 3535 and 3270br cm^{-1}, ^1H NMR δ=1.41 (12H, d, J=7 Hz, 2-CH($C\underline{H}_3$)$_2$), 3.72 (2H, m, 2-$C\underline{H}$(CH_3)$_2$), 5.56 (2H, bs, 2-OH), 7.32 (2H, bs, C_3-H and $C_{3'}$-H), 7.40—7.73 (4H, bm, C_6-H, $C_{6'}$-H, C_7-H, and $C_{7'}$-H), 7.98—8.27 (2H, bm, C_5-H and $C_{5'}$-H), and 8.27—8.53 (2H, bm, C_8-H and $C_{8'}$-H). Found: C, 84.54; H, 7.31%. Calcd for $C_{26}H_{26}O_2$: C, 84.29; H, 7.07%. Compound **26** (18.5 mg) was acetylated with acetic anhydride (1.0 ml) in pyridine (1.0 ml) at room temperature for 15 h to give the corresponding diacetate (20.8 mg: 91.5%), mp 166—167 °C (from methanol), IR 1760 cm^{-1}, ^1H NMR δ=1.41 (12H, d, J=7 Hz, 2-CH($C\underline{H}_3$)$_2$), 2.10 (6H, s, 2-$OCOCH_3$), 3.77 (2H, m, 2-$C\underline{H}$(CH_3)$_2$), 7.43 (2H, s, C_3-H and $C_{3'}$-H), 7.47—7.68 (4H, m, C_6-H, $C_{6'}$-H, C_7-H, and $C_{7'}$-H), 7.72—7.93 (2H, m, C_8-H and $C_{8'}$-H), and 8.05—8.28 (2H, m, C_5-H and $C_{5'}$-H). Found: C, 78.98; H, 6.71%. Calcd for $C_{30}H_{30}O_4$: C, 79.29; H, 6.65%.

1,1',2,2'-Tetrahydro-4,4'-diisopropyl-1,1'-dioxo-2,2'-binaphthylidene (**27**) (9.8 mg: 1.3%), mp 167—168 °C (from benzene), IR 1629 cm^{-1}, ^1H NMR δ=1.36 (12H, d, J=7 Hz, 2-CH($C\underline{H}_3$)$_2$), 3.26 (2H, m, 2-$C\underline{H}$(CH_3)$_2$), 7.27—7.63 (6H, m, C_5-H, $C_{5'}$-H, C_6-H, $C_{6'}$-H, C_7-H, and $C_{7'}$-H), 8.14 (2H, bd, J=8 Hz, C_8-H and $C_{8'}$-H), and 8.29 (2H, bs, C_3-H and $C_{3'}$-H). Found: C, 84.83; H, 6.49%. Calcd for $C_{26}H_{24}O_2$: C, 84.75; H, 6.57%.

b): A solution of **18** (372.5 mg) and benzoyl peroxide (1090.0 mg) in dichloromethane (10 ml) was treated under condition B (room temp, 48 h). The crude product was chromatographed on silica gel to give a mixture (ca. 2:3) of **23** and **24** (27.0 mg: 4.4%), **25** (557.8 mg: 65.4%), **27** (32.8 mg: 3.1%), and 1,1-bis(benzoyloxy)-4-isopropyl-2(1*H*)-naphthalenone (**28**) (35.8 mg: 4.2%), mp 204—205 °C (from methanol-acetone), IR 1737 and 1680 cm^{-1}, ^1H NMR δ=1.41 (6H, d, J=7 Hz, -CH($C\underline{H}_3$)$_2$), 3.35 (1H, m, -$C\underline{H}$(CH_3)$_2$), 6.51 (1H, bs, C_3-H), 7.30—7.87 (10H, m, C_5-H, C_6-H, C_7-H, C_8-H, and C_3-H, C_4-H, C_5-H of benzoyloxyl groups), and 8.06 (4H, dd, J=8 and 2 Hz, C_2-H and C_6-H of benzoyloxyl groups). Found: C, 75.82; H, 5.00%. Calcd for $C_{27}H_{22}O_5$: C, 76.04 H, 5.20%.

Oxidation of 3-Isopropyl-2-naphthol (19) with Benzoyl Peroxide. *a*): A solution of **19** (372.5 mg) and benzoyl peroxide (460.0 mg) in dichloromethane (6.0 ml) was treated under condition A (room temp, 24 h). The crude product was chromatographed on silica gel to give the starting **19** (59.5 mg: 16.0%) and three other compounds **29**, **30**, and **31**.

2-Benzoyloxy-3-isopropyl-1-naphthol (**29**) and 1-benzoyloxy-3-isopropyl-2-naphthol (**30**) in a ratio of ca. 1:1 (405.7 mg: 66.2%), IR 3575, 3320br, and 1737 cm^{-1}. The mixture was recrystallized from carbon tetrachloride to give pure **30**, mp 137—138 °C, ^1H NMR δ=1.36 (6H, d, J=7 Hz, -CH($C\underline{H}_3$)$_2$), 3.47 (1H, m, -$C\underline{H}$(CH_3)$_2$), 5.76 (1H, bs, C_2-OH), 7.27—7.87 (7H, m, C_5-H, C_6-H, C_7-H, C_8-H, and C_3-H, C_4-H, C_5-H of benzoyloxyl group), 7.60 (1H, s, C_4-H), and 8.34 (2H, dd, J=8 and 2 Hz, C_2-H and C_6-H of benzoyloxyl group). Found: C, 78.29; H, 5.89%. Calcd for $C_{20}H_{18}O_3$: C, 78.41; H, 5.92%. ^1H NMR of **29** δ=1.32 (6H, d, J=7 Hz, -CH($C\underline{H}_3$)$_2$), 3.18 (1H, m, -$C\underline{H}$(CH_3)$_2$), 5.85 (1H, br, C_1-OH), 7.29—7.89 (6H, m, C_5-H, C_6-H, C_7-H, and C_3-H, C_4-H, C_5-H of benzoyloxyl group), 7.38 (1H, s, C_4-H), ca. 8.20 (1H, m, C_8-H), and 8.26 (2H, dd, J=8 and 2 Hz, C_2-H and C_6-H of benzoyloxyl group).

2,2-Bis(benzoyloxy)-3-isopropyl-1(2*H*)-naphthalenone (**31**) (72.1 mg: 8.5%), mp 219—220 °C (from acetone), IR 1729 and 1703 cm^{-1}, ^1H NMR δ=1.11 (6H, d, J=7 Hz, -CH($C\underline{H}_3$)$_2$), 2.95 (1H, m, -$C\underline{H}$(CH_3)$_2$), 6.88 (1H, bs, C_4-H), 7.25—7.73 (9H, m, C_5-H, C_6-H, C_7-H, and C_3-H, C_4-H, C_5-H of benzoyloxyl groups), ca. 8.10 (1H, m, C_8-H), and 8.10 (4H, dd, J=8 and 2 Hz, C_2-H and C_6-H of benzoyloxyl groups). Found: C, 76.20; H, 5.13%. Calcd for $C_{27}H_{22}O_5$: C, 76.04; H, 5.20%.

b): A solution of **19** (372.5 mg) and benzoyl peroxide (1090.0 mg) in dichloromethane (10 ml) was treated under condition B (room temp., 48 h). The crude product was chromatographed on silica gel to give a mixture (ca. 1:1) of **29** and **30** (30.6 mg: 5.0%), **31** (554.4 mg: 65.0%), and 1,1-bis(benzoyloxy)-3-isopropyl-2(1*H*)-naphthalenone (**32**) (122.9 mg: 14.4%), mp 198—199 °C (from acetone), IR 1731 and 1683 cm^{-1}, ^1H NMR δ=1.27 (6H, d, J=7 Hz, -CH($C\underline{H}_3$)$_2$), 3.17 (1H, m, -$C\underline{H}$(CH_3)$_2$), 7.18—7.62 (9H, m, C_5-H, C_6-H, C_7-H, and C_3-H, C_4-H, C_5-H of benzoyloxyl groups), 7.23 (1H, bs, C_4-H), ca. 7.70 (1H, m, C_8-H), and 8.06 (4H, dd, J=8 and 2 Hz, C_2-H and C_6-H of benzoyloxyl groups). Found: C, 76.06; H, 5.24%. Calcd for $C_{27}H_{22}O_5$: C, 76.04; H, 5.20%.

2-Benzoyloxy-1,4-naphthoquinone (13). *a*): A mixture (ca. 1:1) of **4** and **20** (52.8 mg) was oxidized with Jones reagent (2.5 mol dm^{-3}: 0.24 ml) in acetone (2.0 ml) at 0—5 °C for 15 min. The mixture was diluted with water and extracted with ether. The ether extract was washed with brine, dried, and evaporated in vacuo. The residue was chromatographed on silica gel (5.0 g), using benzene as an eluent, to give a quinone (7.6 mg: 13.7%), the IR and ^1H NMR spectra of which were identical with those of **13**.

b): A solution of **21** (38.4 mg), *m*-chloroperbenzoic acid (80%, 25.8 mg), and *p*-toluenesulfonic acid monohydrate (4.0 mg) in dichloromethane (1.0 ml) was refluxed for 2 h. The solution was cooled, diluted with ether, and then washed successively with aqueous potassium iodide, aqueous sodium thiosulfate, aqueous sodium hydrogencarbonate, and brine. The dried solution was evaporated in vacuo. The residue was chromatographed on silica gel (5.0 g), using hexane-benzene (1:1) as an eluent, to give the recovered **21** (14.3 mg) and a quinone (6.0 mg: 21.6%), whose IR and ^1H NMR spectra were identical with those of **13**.

Oxidation of 26 with Potassium Hexacyanoferrate(III). A solution of potassium hexacyanoferrate(III) (150.0 mg) in aqueous potassium hydroxide (0.2 mol dm^{-3}, 15.0 ml) was added dropwise to a stirred solution of **26** (24.6 mg) in methanol (5.0 ml) with cooling in an ice-water bath. The mixture was further stirred at room temperature for 15 min. The precipitated product was collected and washed with water. The dried product was recrystallized from benzene to give **27** (20.0 mg: 80.7%), mp 167—168 °C, the IR and ^1H NMR spectra of which were identical with those of the

authentic sample.

1-Acetoxy-2-benzoyloxynaphthalene (33) and 2-Acetoxy-1-benzoyloxynaphthalene (34). A mixture (ca. 1:1) of **4** and **20** (63.0 mg) was refluxed with isopropenyl acetate (0.27 ml) and *p*-toluenesulfonic acid monohydrate (3.2 mg) in toluene (0.7 ml) for 3 h. The mixture was cooled, diluted with ether, and washed with aqueous sodium hydrogencarbonate and brine. The dried solution was evaporated in vacuo. The residue was chromatographed on silica gel (10 g), using benzene as an eluent, to give **33** (20.6 mg: 28.0%), mp 144—145 °C (from methanol), IR 1763 and 1740 cm^{-1}, ^1H NMR δ=2.30 (3H, s, $-OCOCH_3$), 7.40—7.95 (7H, m, C_5-H, C_6-H, C_7-H, C_8-H, and C_3-H, C_4-H, C_5-H of benzoyloxyl group), 7.43 (1H, d, J=9 Hz, C_3-H), 7.78 (1H, d, J=9 Hz, C_4-H), and 8.20 (2H, dd, J=8 and 2 Hz, C_2-H and C_6-H of benzoyloxyl group). Found: C, 74.56; H, 4.67%. Calcd for $C_{19}H_{14}O_4$: C, 74.45; H, 4.60%.

Further elution with ether-benzene (1:99) afforded **34** (51.8 mg: 70.5%), mp 99—103 °C (from methanol), IR 1763 and 1740 cm^{-1}, ^1H NMR δ=2.16 (3H, s, $-OCOCH_3$), 7.35 (1H, d, J=9 Hz, C_3-H), 7.40—7.98 (7H, m, C_5-H, C_6-H, C_7-H, C_8-H, and C_3-H, C_4-H, C_5-H of benzoyloxyl group), 7.78 (1H, d, J=9 Hz, C_4-H), and 8.29 (2H, dd, J=8 and 2 Hz, C_2-H and C_6-H of benzoyloxyl group). Found: C, 74.62; H, 4.58%. Calcd for $C_{19}H_{14}O_4$: C, 74.45; H, 4.60%.

1,2,4-Triacetoxynaphthalene (35). *a*): A solution of **21** (76.9 mg) in acetic anhydride (1.0 ml) containing concentrated sulfuric acid (30 mg) was stirred at 50 °C for 2 h. The solution was poured into ice-water and extracted with ether. The ether extract was washed successively with brine, aqueous sodium hydrogencarbonate, and brine. The dried solution was evaporated in vacuo. The residue was chromatographed on silica gel (10 g), using ether-benzene (5:95) as an eluent, to give **35** (44.3 mg: 73.3%), mp 137—138 °C (from methanol), IR 1775 cm^{-1}, ^1H NMR δ=2.31 (3H, s, $-OCOCH_3$), 2.43 (6H, s, 2-$OCOCH_3$), 7.28 (1H, s, C_3-H), 7.43—7.67 (2H, m, C_6-H and C_7-H), and 7.76—7.98 (2H, m, C_5-H and C_8-H). Found: C, 63.63; H, 4.65%. Calcd for $C_{16}H_{14}O_6$: C, 63.57; H, 4.67%.

b): A solution of **5** (19.2 mg) in acetic anhydride (0.25 ml) containing concentrated sulfuric acid (7.5 mg) was stirred at 50 °C for 2 h. After the work-up (as described in *a*)) the crude product was purified by column chromatography on silica gel (5.0 g) to give **35** (13.6 mg: 90.0%), whose IR and ^1H NMR spectra were identical with those of the authentic sample.

Catalytic Hydrogenation of 5 and 21. *a*): A mixture of **5** (76.9 mg) and 5% Rh-Al_2O_3 (23.1 mg) in 1,4-dioxane (1.5 ml) was hydrogenated at room temperature under an atmosphere of hydrogen for 3 h. After the usual work-up, the crude product was chromatographed on silica gel (10 g), using hexane-benzene (1:1) as an eluent, to give an oily 1,1-bis(benzoyloxy)-3,4-dihydro-2(1*H*)-naphthalenone (**36**) (24.6 mg: 31.8%) IR 1727 cm^{-1}, ^1H NMR δ=3.10—3.58 (4H, m, $-CH_2CH_2-$), 7.20—7.62 (9H, m, C_5-H, C_6-H, C_7-H, and C_3-H, C_4-H, C_5-H of benzoyloxyl groups), ca. 7.70 (1H, m, C_8-H), and 8.07 (4H, dd, J=8 and 2 Hz, C_2-H and C_6-H of benzoyloxyl groups), MS m/z 386 (M^+). Further elution with benzene afforded a mixture of **4** and **20** (34.6 mg: 65.5%), the IR and ^1H NMR spectra of which were identical with those of the authentic mixture.

b): A mixture of **21** (76.9 mg) and 5% Rh-Al_2O_3 (23.1 mg) in 1,4-dioxane (1.5 ml) was hydrogenated as described in *a*). The crude product was chromatographed on silica gel (10 g), using benzene as an eluent, to give an oily 2,2-bis(benzoyloxy)-3,4-dihydro-1(2*H*)-naphthalenone (**37**) (46.3 mg: 60.0%), IR 1735 and 1710 cm^{-1}, ^1H NMR δ=3.00—3.44 (4H, m, $-CH_2CH_2-$), 7.18—7.86 (9H, m, C_5-H, C_6-H, C_7-H, and C_3-H, C_4-H, C_5-H of benzoyloxyl groups), 8.06 (4H, dd, J=8 and 2 Hz, C_2-H and C_6-H of benzoyloxyl groups), and ca. 8.17 (1H, m, C_8-H), MS m/z 386 (M^+). Further elution with benzene afforded a mixture of **4** and **20** (20.1 mg: 38.0%), the IR and ^1H NMR spectra of which were identical with those of the authentic mixture.

2-Acetoxy-1-benzoyloxy-4-isopropylnaphthalene (38). A mixture (ca. 2:3) of **23** and **24** (66.8 mg) was refluxed with isopropenyl acetate (0.24 ml) and *p*-toluenesulfonic acid monohydrate (3.4 mg) in toluene (1.3 ml) for 5 h. After the work-up (as described above) the crude product was chromatographed on silica gel (10 g), using ether-benzene (1:99) as an eluent, to give **38** (49.2 mg: 64.2%), mp 142—143 °C (from methanol), IR 1769 and 1744 cm^{-1}, ^1H NMR δ=1.41 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 2.17 (3H, s, $-OCOCH_3$), 3.75 (1H, m, $-C\underline{H}(CH_3)_2$), 7.25 (1H, s, C_3-H), 7.30—7.71 (5H, m, C_6-H, C_7-H, and C_3-H, C_4-H, C_5-H of benzoyloxyl group), ca. 7.90 (1H, m, C_8-H), ca. 8.12 (1H, m, C_5-H), and 8.28 (2H, dd, J=8 and 2 Hz, C_2-H and C_6-H of benzoyloxyl group). Found: C, 76.13; H, 6.04%. Calcd for $C_{22}H_{20}O_4$: C, 75.84; H, 5.79%.

The acetate **38** (10.2 mg) was refluxed with dilute hydrochloric acid (15%, 0.1 ml) in methanol (0.9 ml) for 1 h. The mixture was diluted with brine and extracted with ether. The ether extract was washed with brine, dried, and evaporated in vacuo to give **24** (8.7 mg) containing a small amount of **23** (by ^1H NMR analysis). This was dissolved in deuteriochloroform and then allowed to stand at room temperature for 24 h to give an equilibrium mixture of **23** and **24** (ca 2:3).[13]

1-Acetoxy-2-benzoyloxy-3-isopropylnaphthalene (39) and 2-Benzoyloxy-3-isopropyl-1,4-naphthoquinone (40). *a*): A mixture (ca. 1:1) of **29** and **30** (91.2 mg) was refluxed with isopropenyl acetate (0.33 ml) and *p*-toluenesulfonic acid monohydrate (4.6 mg) in toluene (0.9 ml) for 5 h. After the work-up (as described above) the crude product was chromatographed on silica gel (0.040—0.063 mm, 15 g), using hexane-benzene (6:4) as an eluent, to give **40** (20.6 mg: 21.6%), mp 123—125 °C (from hexane), IR 1743 and 1672 cm^{-1}, ^1H NMR δ=1.32 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 3.43 (1H, m, $-C\underline{H}(CH_3)_2$), 7.42—7.87 (5H, m, C_6-H, C_7-H, and C_3-H, C_4-H, C_5-H of benzoyloxyl group), ca. 8.12 (2H, m, C_5-H and C_8-H), and 8.20 (2H, dd, J=8 and 2 Hz, C_2-H and C_6-H of benzoyloxyl group). Found: C, 75.01; H, 5.13%. Calcd for $C_{20}H_{16}O_4$: C, 74.99; H, 5.03%.

Further elution with hexane-benzene (25:75) afforded **39** (78.7 mg: 75.9%), mp 161—164 °C (from methanol), IR 1773 and 1741 cm^{-1}, ^1H NMR δ=1.32 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 2.18 (3H, s, $-OCOCH_3$), 3.19 (1H, m, $-C\underline{H}(CH_3)_2$), 7.32-7.90 (7H, m, C_5-H, C_6-H, C_7-H, C_8-H, and C_3-H, C_4-H, C_5-H of benzoyloxyl group), 7.71 (1H, s, C_4-H), and 8.25 (2H, dd, J=8 and 2 Hz, C_2-H and C_6-H of benzoyloxyl group). Found: 75.70; H, 5.88%. Calcd for $C_{22}H_{20}O_4$: C, 75.84; H, 5.79%.

The acetate **39** (10.5 mg) was refluxed with dilute hydrochloric acid (15%, 0.1 ml) in methanol (0.9 ml) for 1 h.

The mixture was diluted with brine and extracted with ether. The ether extract was washed with brine, dried, and evaporated in vacuo to give **29** (8.5 mg) containing a small amount of **30** (by ^{1}H NMR analysis). This was dissolved in deuteriochloroform and then allowed to stand at room temperature for 24 h to afford an equilibrium mixture of **29** and **30** (ca. 1:1).[13]

b): A solution of **30** (31.6 mg) in acetone (1.0 ml) was oxidized with Jones reagent (2.5 mol dm^{-3}: 0.12 ml) at 0—5 °C for 20 min. After the work-up (as described above) the crude product was chromatographed on silica gel (5.0 g), using hexane–benzene (1:1) as an eluent, to give **40** (10.4 mg: 31.5%), mp 123—125 °C, whose IR and ^{1}H NMR spectra were identical with those of the authentic sample.

c): A solution of **31** (21.3 mg), *m*-chloroperbenzoic acid (80%, 12.9 mg), and *p*-toluenesulfonic acid monohydrate (3.0 mg) in dichloromethane (0.5 ml) was refluxed for 8 h. After the work-up (as described above) the crude product was chromatographed on silica gel (5.0 g), using benzene as an eluent, to give **40** (5.7 mg: 35.6%), mp 123—125 °C, the IR and ^{1}H NMR spectra of which were identical with those of the authentic sample.

1,2,4-Triacetoxy-3-isopropylnaphthalene (41). *a*): A solution of **31** (85.2 mg) and concentrated sulfuric acid (30 mg) in acetic anhydride (1.0 ml) was stirred at 50 °C for 2 h. After the work-up (as described above) the crude product was chromatographed on silica gel (15 g), using ether–benzene (1:99 and then 3:97) as eluents, to give **41** (59.2 mg: 86.0%), mp 152—153 °C (from methanol), IR 1772 cm^{-1}, ^{1}H NMR δ=1.30 (6H, d, J=7 Hz, -CH(C$\underline{H}_3$)$_2$), 2.34 (3H, s), 2.39 (3H, s), and 2.46 (3H, s) (3-OCOCH_3), 3.24 (1H, m, -C$\underline{H}$(CH$_3$)$_2$), and 7.36—7.80 (4H, m, C$_5$-H, C$_6$-H, C$_7$-H, and C$_8$-H). Found: C, 66.29; H, 6.05%. Calcd for $C_{19}H_{20}O_6$: C, 66.27; H, 5.85%.

b): A solution of **32** (42.5 mg) and concentrated sulfuric acid (15 mg) in acetic anhydride (0.5 ml) was treated as described in *a*). The crude product was chromatographed on silica gel (5.0 g) to give **41** (28.4 mg: 82.8%), mp 152—153 °C, the IR and ^{1}H NMR spectra of which were identical with those of the authentic sample.

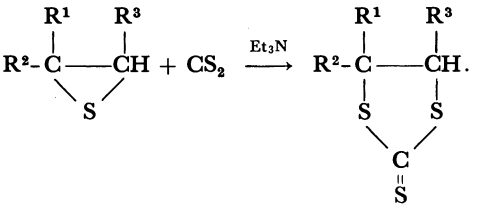
The Reaction of Oxiranes with Carbon Disulfide under High Pressure

Yoichi TAGUCHI,* Koshin YANAGIYA, Isao SHIBUYA, and Yasuo SUHARA
National Chemical Laboratory for Industry, Higashi, Tsukuba, Ibaraki 305
(Received August 4, 1987)

The reaction of 2,2-dimetyloxirane with carbon disulfide in the presence of triethylamine was accelerated under high pressure to give 5,5-dimethyl-1,3-oxathiolane-2-thione in a high yield, while 2-hexyloxirane under the same reaction condition formeds 4-hexyl-1,3-dithiolane-2-thione (**2b**) as the main product and 5-hexyl-1,3-oxathiolane-2-thione (**1b**) as a minor product. A feasible mechanism for this formation is that **1b** and 2-hexylthiirane (**4b**) are produced in the first stage of reaction, and that **2b** is then formed by the reaction of **1b** or **4b** with carbon disulfide. In reactions of a variety of oxiranes with carbon disulfide, 1,3-dithiolane-2-thiones were obtained in high yields under 800 MPa at 100 °C within 20 h. Concerning the effect of substituents in oxiranes, the selectivity for product **2b** is in the decreasing order; 2-phenyl->2-methyl->2-ethyl->2-hexyl->2,3-tetramethylene->2,2-dimethyl->2-(chloromethyl)-. Tertiary amines, such as *N,N*-dimethylethylamine, pyridine, and *N*-methylmorpholine, serve as good catalysts for the reaction.

There have been many reports[1-8] that oxiranes react with carbon disulfide to form various products such as thiiranes, 1,3-dithiolane-2-thiones, and 1,3-oxathiolane-2-thiones, but these products except thiiranes have not been obtained in good yield. Many organic reactions, when conducted under high pressure, show product selectivities different from those they show under ordinary pressure,[9] and we found that the reaction of thiiranes with carbon disulfide was accelerated under high pressure to give 1,3-dithiolane-2-thiones with high selectivity and yield:[10]



Therefore, it is expected that acceleration by compression may be observed also with the reaction of oxiranes, and that the formation of thiiranes, which are often main products under ordinary pressure, may be suppressed by compression.

In this paper, we report that the reaction of oxiranes with carbon disulfide is also accelerated by compression to give 1,3-dithiolane-2-thiones, 1,3-oxathiolane-2-thiones, 1,3-oxathiolan-2-ones, and thiiranes, and that the proportion of these products is dependent on pressure, temperature, the amount and kind of catalyst, and substituents in oxiranes. Furthermore, formation mechanisms for these products are discussed, and the reactivity of oxiranes is compared with that of thiiranes.

Results and Discussion

A reaction of 2,2-dimethyloxirane with carbon disulfide in a sealed tube at 100 °C for 20 h gave only 4% of 4,4-dimethyl-1,3-oxathiolane-2-thione (**1a**), but, when conducted under 800 MPa, gave 68% of **1a** and 8% of 5,5-dimethyl-1,3-dithiolane-2-thione (**2a**), which verifies that this reaction is to be accelerated remarkably by compression.

The structure of **1a** was assigned based on IR, ^{1}H NMR, and CI-MS spectra, and the spectral data of **2a** agreed with the known data.[10] The isomer of **1a**, 4,4-dimethyl-1,3-oxathiolane-2-thione, was not detected. Table 1 shows effects of pressure, temperature, and the kind of catalysts on the reaction. *N,N*-Dimethylethylamine, triethylamine, *N*-methylmorpholine, pyridine, and tetraethylammonium bromide are good catalysts under high pressure, and the ratio of **2a** to total yield decreases in the above-listed order (Runs 2 and 6—9). This order agrees with that of their catalytic activities for the reaction of 2,2-dimethylthiirane with carbon disulfide.[10] Table 1 also shows that the ratio of **2a** to total yield increases at higher temperatures or in the presence of strong catalyst (Runs 2 and 6).

Table 2 shows the effect of reaction conditions on the reaction of 2-hexyloxirane with carbon disulfide:

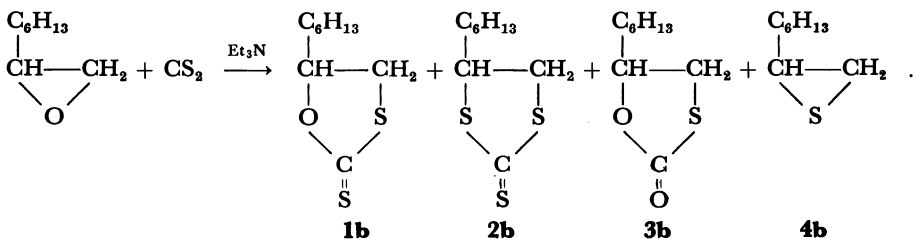
Table 3. Effect of Various Catalysts on the Reaction of 2-Hexyloxirane with CS_2[a]

Run No.	Catalyst	Conv.	Yield/%				
		%	**1b**	**2b**	**3b**	**4b**	Total
1	*N,N*-Dimethylethylamine	100	5	67	13	—	85
2	Et_3N	100	5	71	12	1	89
3	*N*-Methylmorpholine	100	30	46	13	—	89
4	Pyridine	100	20	43	8	1	72
5	Et_4NBr	64	13	9	11	3	36
6	LiCl	41	9	Trace	4	1	14

a) 2-Hexyloxirane 5 mmol; CS_2 25 mmol; catalyst 0.5 mmol; pressure 800 MPa; reaction temperature 100 °C; reaction time 20 h.

This reaction under 800 MPa at 100 °C for 20 h gave 4-hexyl-1,3-dithiolane-2-thione (**2b**) as the main product, and the yield of 5-hexyl-1,3-oxathiolane-2-thione (**1b**) was only 5%, in contrast to that for the reaction of 2,2-dimethyloxirane with carbon disulfide. 5-Hexyl-1,3-oxathiolan-2-one (**3b**) and 2-hexylthiirane (**4b**) were also produced as minor products. The structures of **1b** and **3b** were assigned based on their IR, ^1H NMR, and CI-MS spectra taken after purification by column chromatography, and the spectral data



of **2b** and **4b** agreed with the known data.[10] The isomer of **1b**, 4-hexyl-1,3-oxathiolane-2-thione, was not detected. For this reaction, at 100 °C the yield of **2b** increased as pressure or reaction time was increased (Runs 1—4 and 7), and at 40 °C **4b** was obtained as the main product though its yield was not high (Runs 5 and 7).

Table 3 shows the effect of various catalysts on the reaction. Lithium chloride has no catalytic activity for the reaction of thiiranes with carbon disulfide,[10] but it has a little catalytic activity for the reaction of 2-hexyloxirane (Run 6). A dependence similar to that indicated by the results in Table 1 was observed with respect to the ratio of **2b** to total yield, that is, the ratio decreased in the order; triethylamine≥*N*,*N*-dimethylethylamine>pyridine≥*N*-methylmorpholine>tetraethylammonium bromide>lithium chloride. As a result, it is suggested that **1b** is formed as the main product in the first stage and then converted into **2b** as reaction proceeds.

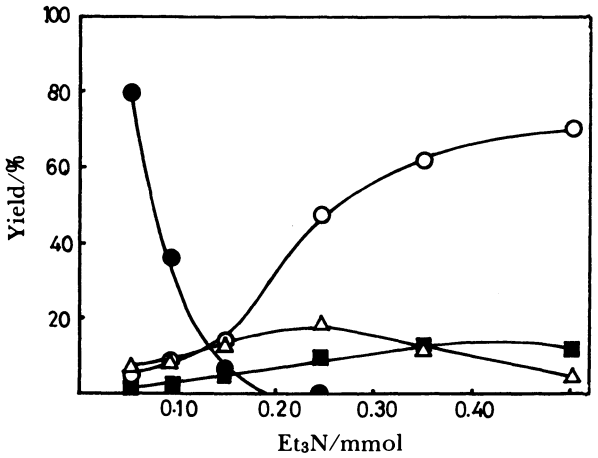


Fig. 1. Effect of amount of Et_3N on the reaction of 2-hexyloxirane with CS_2; reaction temperature: 100 °C, reaction time: 20 h, pressure: 800 MPa, 2-hexyloxirane: 5 mmol. CS_2: 25 mmol.
—△—: **1b**. —○—:**2b**, —■—: **3b**, —●—: 2-hexyloxirane.

Figure 1 shows the relation between products and the amount of triethylamine used as a catalyst for the reaction. As the rate of the reaction of thiiranes with carbon disulfide is proportional to the amount of triethylamine catalyst,[10] it is considered that the rate of the reaction of 2-hexyloxirane is proportional to the amount of triethylamine in the range 0.05—0.50 mmol. In the first stage **1b** was formed as the main product but its yield was not so much increased as reaction proceeded. On the other hand, the yield of **2b** increased as reaction proceeded even after 2-hexyloxirane was consumed completely. This fact also supports the suggestion that **2b** is formed as a result of the conversion of **1b**.

Table 4 shows products and yields for the reaction of various oxiranes with carbon disulfide. Two kinds of reaction conditions were used for comparison of reactivities of oxiranes. The conditions of Method A (catalyst *N*-methylmorpholine, 800 MPa, 70 °C, 20 h) is milder than that of Method B (catalyst triethylamine, 800 MPa, 100 °C, 20 h). 2-Phenyloxirane reacted with carbon disulfide to give 4-phenyl-1,3-dithiolane-2-thione with high selectivity even by

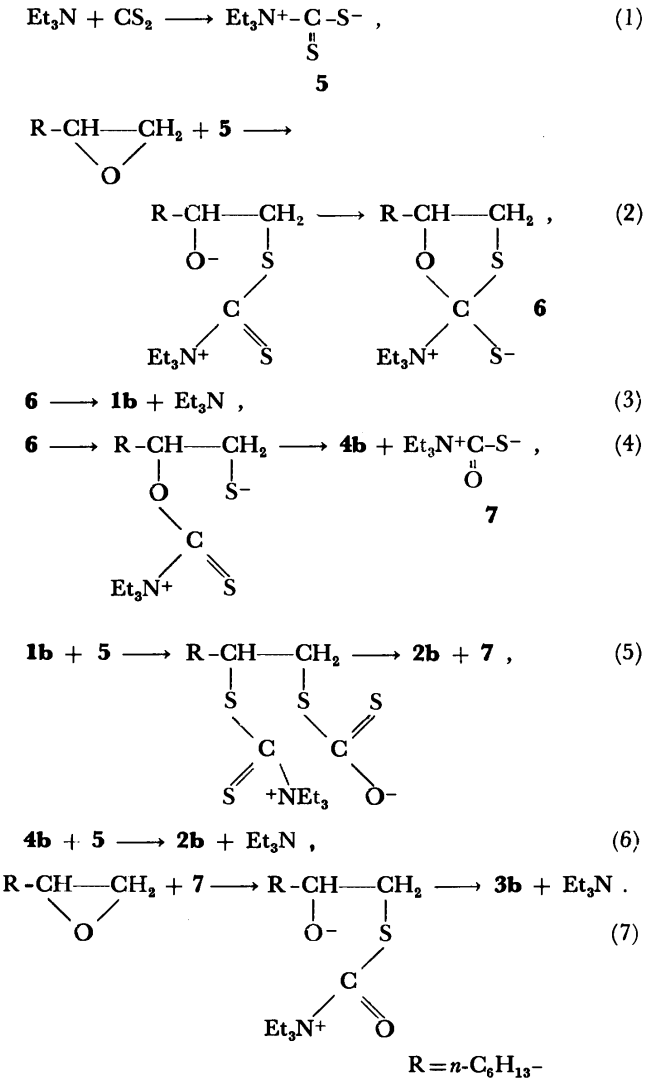
a) Epoxide 5 mmol; CS_2 25 mmol; pressure 800 MPa; reaction time 20 h. b) *N*-Methylmorpholine 0.5 mmol; reaction temperature 70 °C. c) Et_3N 0.5 mmol; reaction temperature 100 °C.

Method A. 2-(Chloromethyl)oxirane reacted with carbon disulfide to give **1** and **3** with low yields. This might be due to lowered catalytic activity caused by an interaction between chlorine atom and triethylamine. A similar low reactivity has been observed with the reaction of thiiranes with carbon disulfide.[10] For the series of these oxiranes, the ratio of **2** to total yield is in the decreasing sequence: 2-phenyl->2-methyl->2-ethyl->2-hexyl->2,3-tetramethylene->2,2-dimethyl->2-(chloromethyl)-.

The reaction of 2-hexyloxirane with carbon disulfide in the presence of triethylamine seems to proceed as follows:



Reaction 1, the first step of adduct **5** formation from carbon disulfide and triethylamine, is followed by Reaction 2, consisting successively of the addition of **5** to 2-hexyloxirane and the ring closure yielding **6**. Reaction 3 is the elimination of triethylamine from **6** to give **1b**. The two carbon atoms of the oxirane ring can be attacked by **5**, but in practice, only product **1b** was formed selectively, which product may be considered to have been produced by an selective attack of **5** at the less-hindered carbon atom of the oxirane ring. It is well-known that nucleophilic attack in the presence of base will occur at sterically less-hindered sites.[11] Thus, the formation of **1b** conforms to this rule on. In addition, part of **6** also is converted to **4b** and adduct **7** (Reaction 4). This conversion is similar in mechanism to the reaction of oxiranes with thiourea to produce thiiranes.[12] At such a low temperature as 40 °C a considerable amount of **4b** was formed (Runs 5 and 7, Table 2), which phenomenon suggests that the formation of **4b** proceeds faster than that of **1b**.

It was confirmed that the reaction of **1b** with carbon disulfide in the presence of triethylamine under 800 MPa gave 71% of **2b**. There are two possible mechanisms for the formation of **2b** from **1b**. One involves initial thermal dissociation of **1b** into **4b** and carbonyl sulfide; it has been reported that the reaction of oxiranes with carbon disulfide followed by pyrolysis will produce thiiranes.[7,8] However, it is questionable that the reaction in which one molecule (**1b**) decomposes into two molecules (**4b** and carbonyl sulfide) should be accelerated by compression, considering that **1b** can be stably distilled in vacuo above 100 °C. The other mechanism involves the attack of **5** at the 5-position carbon of **1b** followed by the elimination of **7** (Reaction 5). The 5-position of **1a** is expected to be hindered sterically, and consequently, **1a** is obtained as a main product even by Method B (Run 10, Table 4). This phenomenon supports the latter mechanism, so that Reaction 5 is more likely for the formation of **2b**. It is known that a carbon atom adjacent to a phenyl group is liable to be attacked by nucleophilic reagents,[13] and this liability can be responsible for the reaction in which phenyloxirane affords 4-phenyl-1,3-dithiolane-2-thione dominantly (Runs 6 and 7, Table 4). It has been reported that Reaction 6 is accelerated by compression,[10] and **3b** is considered to be derived via the reaction of 2-hexyloxirane with **7**, Reaction **7**, similar to Reaction 6.

Of Reactions 1—7, the compression is considered to have an accelerating effect on Reactions 1, 2, and 5—7, and the reason why **2b** is obtained as the main product under high pressure is considered to be connected with the acceleration of Reaction 5 by compression. Similarly, in the reaction of a variety of oxiranes with carbon disulfide under high pressure, 1,3-dithiolane-2-thiones can be obtained in high yields.

Experimental

Apparatus. The apparatus used for the reaction under high pressure was the same as that described previously.[13]

Measurement. GLC was carried out by a JEOL 20KF chromatograph with 20% SE-30 columns. ^{1}H NMR spectra were measured with a Hitachi R-40 spectrometer. Mass spectra were measured with a JEOL D-300 GC-MS

spectrometer by the CI (chemical ion) method with isobutane. IR spectra were obtained with a JASCO A-302 spectrophotometer.

Reaction of Oxiranes with Carbon Disulfide. The typical procedure is as follows: A homogeneous mixture of 2-hexyloxirane (5 mmol), carbon disulfide (25 mmol), and *N*-methylmorpholine (0.5 mmol) in a sealed Teflon tube was compressed to 800 MPa, heated at 70 °C, and maintained for 20 h in a high-pressure equipment. The resulting mixture was subjected to evaporation and the residue was distilled with a Kugelrohr. The distillate, a mixture of **1b—3b** was separated by column chromatography on silica gel using a mixture of hexane and chloroform (7:3 v/v) as an eluent. The spectral data of **2b** and **4b** agreed with the known data.[10] **1b**: IR 1189 and 1048 cm^{-1}; ^1H NMR δ=0.89 (t, 3H, CH_3), 1.32 (s, 8H, C_4H_8), 1.73—2.30 (m, 2H, CH_2), 3.35—3.80 (m, 2H, CH_2), and 4.95—5.35(m, 1H, CH); QM^+ 205. **3b**: IR 1736 cm^{-1}; ^1H NMR δ=0.89 (t, 3H, CH_3), 1.33 (s, 8H, C_4H_8), 1.65—2.25 (m, 2H, CH_2), 3.13—3.68 (m, 2H, CH_2), and 4.55—4.85 (m, 1H, CH); QM^+ 189.

2-Methyloxirane, 2-ethyloxirane, 2,2-dimethyloxirane, 2,3-tetramethyleneoxirane, 2-phenyloxirane, and 2-chloromethyloxirane were treated with carbon disulfide similarly to 2-hexyloxirane. The spectral data of 1,3-dithiolane-2-thione derivatives and 5-methyl-1,3-oxathiolane-2-thione from these reactions agreed with the known data.[10,15] The spectral data of the other products of these reactions are as follows:

5-Methyl-1,3-oxathiolan-2-one: IR 1729 cm^{-1}; ^1H NMR δ=1.53 (d, 3H,CH_3), 3.10—3.73 (m, 2H, CH_2), and 4.63—5.05 (m, 1H, CH); QM^+ 119.

5-Methyl-1,3-oxathiolane-2-thione: IR 1188 cm^{-1}; ^1H NMR δ=1.09 (t, 3H, CH_3), 1.53—2.20 (m, 2H, CH_2), 3.50—3.74 (m, 2H, CH_2), and 4.90—5.28 (m, 1H, CH); QM^+ 149.

5-Ethyl-1,3-oxathiolan-2-one: IR 1718 cm^{-1}; ^1H NMR δ=1.09 (t, 3H, CH_3), 1.28—2.12 (m, 2H, CH_2), 3.08—3.60 (m, 2H, CH_2), and 4.40—4.76 (m, 1H, CH); QM^+: 133.

1a: IR 1252, 1127, 1198, and 1086 cm^{-1}; ^1H NMR δ=1.67 (s, 6H, $2CH_3$), and 3.48 (s, 2H, CH_2); QM^+ 149. Found: C, 40.66; H, 5.43%. Calcd for $C_5H_8OS_2$: C, 40.51; H, 5.44%.

4,5-Tetramethylene-1,3-oxathiolane-2-thione: IR 1179 and 1041 cm^{-1}, ^1H NMR δ=1.00—2.65 (m, CH_2, C_4H_8), 3.54—4.00 (m, 1H, CH), and 4.13—4.65 (m, 1H, CH); QM^+ 175.

4,5-Tetramethylene-1,3-oxathiolan-2-one: IR: 1736 cm^{-1}; ^1H NMR δ=1.16—2.56 (m, 8H, C_4H_8) and 3.46—3.85 (m, 1H, CH); QM^+ 158.

5-Chloromethyl-1,3-oxathiolane-2-thione: IR: 1175 and 1035 cm^{-1}; ^1H NMR δ=3.62—4.08 (m, 4H, $2CH_2$) and 5.16—5.32 (m, 1H, CH); QM^+ 169.

5-Chloromethyl-1,3-oxathiolane-2-one: IR 1739 cm^{-1}; ^1H NMR δ=3.24—4.04 (m, 4H, $2CH_2$) and 4.72—5.10 (m, 1H, CH); QM^+ 153.

Reaction of 1b with Carbon Disulfide. A homogeneous mixture of **1b** (43.3 mg), carbon disulfide (200 mg), triethylamine (3.8 mg), and tetradecane (5.9 mg) in a sealed Teflon tube was compressed to 800 MPa, heated at 100 °C, and maintained for 20 h in a high pressure equipment. The GLC analysis using tetradecane as a standard showed that 71% of **2b** was obtained.

Studies on Chitin. 14. *N*-Acetylation Behavior of Chitosan with Acetyl Chloride and Acetic Anhydride in a Highly Swelled State

Keisuke KURITA,* Satoyuki CHIKAOKA, Mami KAMIYA, and Yoshiyuki KOYAMA
Department of Industrial Chemistry, Faculty of Engineering, Seikei University, Musashino-shi, Tokyo
(Received August 8, 1987)

N-Acetylation on chitosan has been studied in a highly swelled state with acetyl chloride in comparison with that with acetic anhydride under various conditions to establish the general possibility and scope of the acylation reactions on chitosan and other polysaccharides. A highly swelled chitosan precipitate prepared by pouring a chitosan solution in aqueous acetic acid/methanol into pyridine is quite suitable for efficient modifications, and the reaction with either acylating reagent proceeded smoothly and reproducibly under mild conditions. Although acetic anhydride is generally more appropriate in protic solvens, acetyl chloride is effective and advantageous especially in pyridine containing only small amounts of protic solvents.

Although chitin is structurally similar to cellulose and quite abundant in nature, it has been discarded and thus attracting much attention recently as an unutilized resource. It is considered of interest as a raw material of high potentials for developing new functional materials from the viewpoint of chemical modifications owing to the presence of the reactive amino groups in addition to hydroxyl groups.[1] Various types of reactions have been reported thus far for utilization of this amino polysaccharide, but severe conditions are generally necessary on account of the strong intermolecular hydrogen bonding which limits the solubility in ordinary organic solvents.[2,3] Among the modification reactions, acetylation is one of the most fundamental and important reactions to not only chitin but also many kinds of other polysaccharides to afford derivatives of a wide variety of attractive properties.

We have already reported the efficient acylation with acetic and some cyclic aromatic acid anhydrides in a highly swelled state by making use of the advantage of water-soluble nature of the 50% deacetylated chitin samples prepared under homogeneous hydrolysis conditions.[4,5]

Although acid anhydrides have been by far most commonly used for acylation, it is useful to establish the controlled acylation with more easily available and more reactive but less stable acyl chlorides under mild conditions. Several papers have dealt with the acylation of chitin, i.e., esterification at the hydroxyl groups, with a large excess of acyl chlorides,[6-10] but not much information has been obtained regarding the reaction on chitosan. Fujii and co-workers reported the acylation on chitosan where long-chain fatty acid chlorides were subjected to the reaction in a mixture of pyridine and chloroform under reflux to give polyacylated derivatives with degrees of substitution of up to 4.[11] These reactions have, however, been normally carried out under rather severe conditions, and thus difficulties are sometimes encountered in controlling the reactions. No attempt has been made to elucidate the conditions and course of the reaction on chitosan with varying amounts of acyl chlorides and also acid anhydrides for practical acylation. We have thus examined the progress of *N*-acetylation on chitosan with both acetyl chloride and acetic anhydride under mild conditions to provide a versatile modification for this naturally abundant amino polysaccharide.

Experimental

Chitosan with a degree of deacetylation of 88% was prepared by heating pulverized chitin in a 50% aqueous sodium hydroxide solution at 135 °C for 3.5 h under a nitrogen stream.[12] The degree of acetylation of the acetylated products obtained in this study was determined by IR spectroscopy.[13]

Acetylation of Chitosan with Acetyl Chloride in a Mixture of Aqueous Acetic Acid, Methanol, and Pyridine: Chitosan, 0.3 g, was dissolved in 8 ml of 10% aqueous acetic acid,

Table 1. Acetylation of Chitosan with Acetyl Chloride in a Mixture of Aqueous Acetic Acid, Methanol, and Pyridine

and the solution was diluted with 8 ml of methanol. The solution was poured into 100 ml of pyridine with stirring to afford a highly swelled precipitate of chitosan. The mixture was cooled at 0 °C in an ice bath, and a given amount of acetyl chloride was added dropwise with stirring. It was allowed to warm to room temperature, stirred for 16 h 40 min, and poured into 500 ml of a mixture of acetone and water (7:1) to coagulate the acetylated derivative. The product was isolated by filtration and washed with acetone and then with methanol. Without drying, it was treated with 100 ml of 1 M potassium hydroxide (1 M=1 mol dm^{-3}) in methanol at room temperature for 4 h. Filtration, washing with methanol and acetone, and drying in vacuo gave an acetylated product as a slightly yellow solid. The results are summarized in Table 1.

The reaction appeared to be fairly rapid and complete within 1 h, judging from the values of the degree of acetylation of the resulting products obtained after various periods of reaction. The reaction time was thus fixed at 3 h in the subsequent reactions.

Acetylation of Chitosan with Acetyl Chloride after Repeated Replacement of the Solvent by Pyridine: A solution of 0.1 g of chitosan in a mixture of 2.6 ml of 10% aqueous acetic acid and 2.6 ml of methanol was poured into 33 ml of pyridine. The mixture was centrifuged, and 25.5 ml of the supernatant was replaced by the same amount of fresh pyridine. After repeating this solvent replacement five times, acetyl chloride diluted with tetrahydrofuran to 5 ml was added dropwise at 0 °C with stirring. The mixture was allowed to warm to room temperature, and after 3 h the product was isolated in the same manner as described above. The results are listed in Table 2.

Acetylation of Chitosan with Acetic Anhydride: To 100 ml of pyridine was added a solution of 0.3 g of chitosan in a mixture of 8 ml of 10% aqueous acetic acid and 8 ml of methanol. Acetic anhydride was added, and the mixture was stirred at room temperature for 5 h. The product was isolated in the same manner. Table 3 shows the results.

Results and Discussion

Acetylations of chitosan with varying amounts of acetyl chloride and acetic anhydride were examined in order to make clear the general possibility and scope of the acetylation methods. The reactions were carried out in a highly swelled state brought about by pouring a solution of chitosan in a mixture of aqueous acetic acid and methanol into pyridine to enable efficient acetylation under mild reaction conditions. In the absence of methanol, the precipitate became rather sticky, and methanol helps disperse the swelled precipitate to realize an almost homogeneous mixture. Furthermore, methanol is effective to prevent phase separation of the reaction mixture on addition of hydrophobic organic reagents.

The resulting products with both acetyl chloride and acetic anhydride showed weak peaks in the IR spectra due to ester linkages formed by acetylation at the hydroxyl groups. The ester peaks were also observed even in the absence of pyridine with acetic anhydride. This indicates the reaction selectivity to the amino groups against the hydroxyl groups to be not sufficient. After the reaction, the products were thus treated with methanolic potassium hydroxide to ensure the removal of the ester groups and also to regenerate the amino groups lost by the salt formation with acetic acid. The treatment with 1 M methanolic potassium hydroxide for 4 h at room temperature was confirmed to be satisfactory for the purpose and not to harm the acetamide groups.

The resulting products showed medium to strong amide bands at 1650 and 1550 cm^{-1} and no distinct ester band at 1730 cm^{-1}.

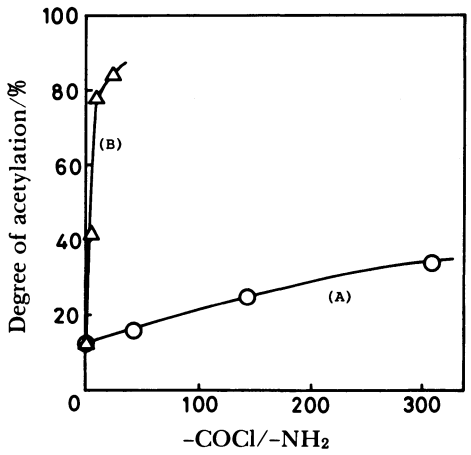

Fig. 1. Progresses of acetylation with acetyl chloride; (A) acetylation in a mixture of aqueous acetic acid, methanol, and pyridine, (B) acetylation after repeated solvent replacement by pyridine.

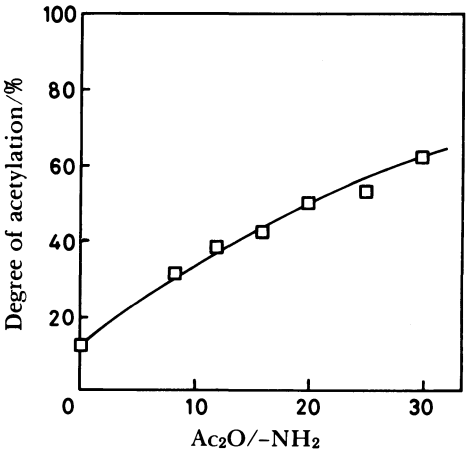

Fig. 2. Progress of acetylation with acetic anhydride in a mixture of aqueous acetic acid, methanol, and pyridine.

When acetyl chloride was added to a swelled precipitate of chitosan in aqueous acetic acid/methanol/pyridine, acetylation required a large excess of acetyl chloride as shown by the results in Fig. 1. With 307-fold excess acetyl chloride, an acetylated product with a degree of acetylation of 34% was obtained, indicating the acetyl chloride to have been consumed largely by some side reactions with the protic solvent components such as water and methanol during the expected reaction with the amino groups. Triethylamine was then added to the reaction mixture to regenerate the amino groups from the salt form for the facilitated reaction, but no improvement in the acetylation was observed. This is due to the high reactivity of acetyl chloride and suggested to decrease the contents of protic solvents for increased reaction efficiency.

The mixture containing a highly swelled chitosan precipitate was thus centrifuged, and the supernatant was replaced by fresh pyridine. After repeating this replacement procedure five times, the contents of protic solvents should have been reduced markedly, and noteworthily chitosan still remained highly swelled in the solvent yet. The reaction after this solvent replacement proceeded quite smoothly as expected, and in this way, a degree of acetylation of 78% was attained with only 10-fold excess acetyl chloride under these mild reaction conditions at 0 °C. The difference in the progress of the acetylation reaction under these different conditions is evident in Fig. 1.

The acetylation of chitosan was then examined with acetic anhydride in the same swelled state. Although the reaction was conducted in a mixture of aqueous acetic acid, methanol, and pyridine as in the first case of the reaction with acetyl chloride, acetylation proceeded fairly efficiently. As shown in Fig. 2, a 31-fold excess of acetic anhydride resulted in the formation of a derivative with a degree of acetylation of 62%. Qualitative solubility was examined in aqueous acetic acid, and the derivatives with degrees of acetylation below around 60% were soluble.

Consequently, these results indicate that 1) controlled acetylation on chitosan can be achieved effectively and reproducibly with either acetyl chloride or acetic anhydride under mild conditions in a highly swelled state, 2) a mixture containing highly swelled chitosan obtained by replacing the aqueous solvent by pyridine is especially suitable for efficient modifications of chitosan, and 3) acetyl chloride was found to be quite advantageous under these conditions, although acetic anhydride is generally more appropriate in the acetylation of chitosan in protic solvents.

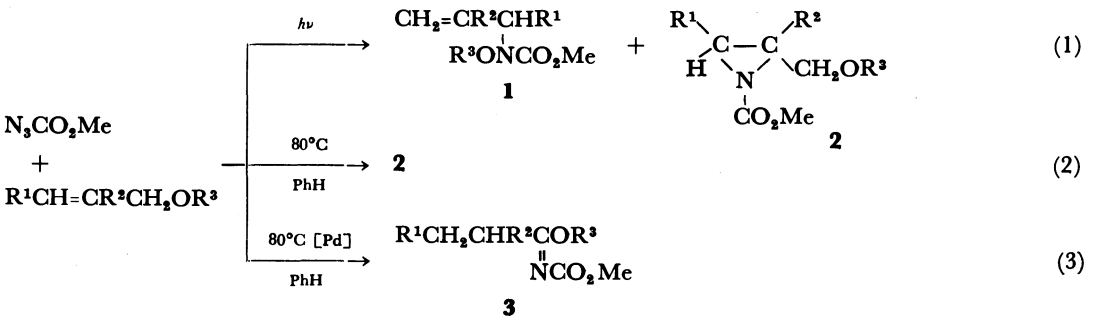
Nitrene-Transfer Reaction between Azide and Unsaturated Ether in the Presence of Pd(II) Catalyst

Toshihiko MIGITA,* Kazuya HONGOH, Hiroyuki NAKA, Setsuko NAKAIDO, and Masanori KOSUGI
Department of Chemistry, Faculty of Technology, Gunma University, Kiryu, Gunma 376
(Received September 7, 1987)

Azidoformate reacted with allylic ethers to give 1-alkoxy-1-(alkoxycarbonylimino)alkane under catalysis by $PdCl_2(PhCN)_2$. The same imines were formed almost quantitatively by noncatalyzed reaction of the azide with the corresponding vinylic ethers. The rate of the catalyzed reaction was found to be first order each in the allylic ether and in the azide. Easiness of the imine formation from the allylic ethers depended on the nature of azide, decreasing in the order of $N_3SO_2Me > N_3CO_2Me > N_3Ph$. Based on these results the most probable mechanism for the catalyzed reaction is proposed.

Photoreaction of azidoformate with allylic ethers has been known to give aziridines (nitrene adducts) **2** and rearranged insertion products **1**, while the thermal reaction at 80 °C in benzene gives only aziridines (30%).[1] In the presence of palladium catalysts, however, the thermal reaction has been found to give quite different products, 1-alkoxy-1-(alkoxycarbonylimino)alkanes **3**,[2] and dichlorobis(benzonitrile)palladium $PdCl_2(PhCN)_2$ has been reported to be the most effective catalyst for the imine formation.[3]



Furthermore, not only allylic but also other unsaturated ethers such as 3-butenyl or 4-pentenyl ethyl ether were found to react similarly giving the corresponding 1-alkoxy-1-(alkoxycarbonylimino)alkanes, **3**, (see Tabe 1).[4]

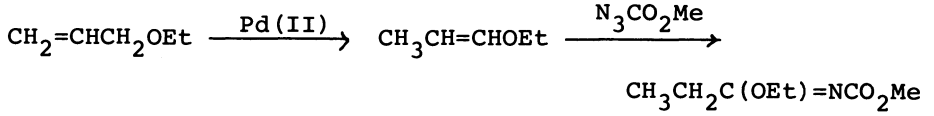
To elucidate the mechanism of the apparently peculiar nitrene-transfer reaction and to survey its scope and limitation, some kinetic and analytical studies were performed. Since vinylic ether reacts with azidoformate smoothly without any catalyst to give the corresponding **3**,[5,6] and olefinic compounds have been known to undergo double bond migration under Pd(II)-catalysis,[7,8] the most attractive mechanism might involve the Pd(II)-catalyzed isomerization of unsaturated ethers to the corresponding vinylic ether, which then reacts with azide to give **3**, as shown in Scheme 1.

The results shown below, however, suggest that the mechanism has more profound aspects involving ligand exchange in Pd(II) complex and isomerization of the ethers followed by interaction with azide in the Pd(II) coordinate sphere.

Results

Products of Pd(II)-Catalyzed Reaction of Unsaturated Ethers with Azidoformate. The reaction was carried out by heating a degassed solution of unsaturated ethers and azidoformate containing $PdCl_2(PhCN)_2$ (1 mol%) in a sealed tube at 80 °C for 24 h. The products detected in the reaction mixtures were listed in Table 1.

Imines **3** formed in good yields, and the corresponding aziridines were produced in only trivial amounts.



Scheme 1.

Table 1. Pd(II)-Catalyzed Reaction of Methyl Azidoformate with Unsaturated Ethers

Run	Ether	Product	Yield/%
1	CH_2=$CHCH_2OEt$	$CH_3CH_2C(OEt)$=NCO_2Me	67
2	CH_2=$CHCH_2CH_2OEt$	$CH_3CH_2CH_2C(OEt)$=NCO_2Me	72
3	CH_2=$CH(CH_2)_3OEt$	$CH_3(CH_2)_3C(OEt)$=NCO_2Me	72
4	CH_2=$CMeCH_2OEt$	$Me_2CHC(OEt)$=NCO_2Me	95
5	CH_2=$CHCHMeOEt$	$Me_2CHC(OEt)$=NCO_2Me	44[a]
6	CH_3CH=$CHOEt$	$CH_3CH_2C(OEt)$=NCO_2Me	100[b]

a) $CH_3CH_2C(OEt)$=NCO_2Me also formed, 8%. b) Without the catalyst.

The essentially same results were obtained when benzene was used as a solvent.

It is interesting that 1-methyl-2-propenyl ether reacted under these conditions to give the imine **3** identical to that obtained from 2-methyl-2-propenyl ether, indicating that the methyl group as well as the hydrogen atom on the allylic α-position of the substrate migrated to the adjacent carbon atom, and the C=N bond formed always at the α-position (Runs 4 and 5).

3-Butenyl and 4-pentenyl ethers (Runs 2 and 3) also afforded good yields of the corresponding imines **3**, in which C=N bonds were introduced again at the α-position of the ethers.

Pd(II)-Catalyzed Isomerization of Unsaturated Ether. Golborn et al. showed that allylic alkenyl phenyl ethers were able to isomerize to vinylic alkenyl phenyl ethers by the aid of $PdCl_2(PhCN)_2$, and the capability of the isomerization depended on the structure of the allylic alkenyl group.[8] But isomerization of alkenyl alkyl ether has not been studied. After 3-butenyl or 4-pentenyl ethyl ether was kept at 80 °C in the presence of 1 mol% of $PdCl_2(PhCN)_2$, the GLC analysis of the mixture showed that the double bond migration occurred considerably. It is noteworthy that the mixture contained allylic ether as shown in the following scheme, but not vinylic ether.

$$CH_2{=}CHCH_2CH_2OEt \xrightarrow[80°C,\ 1\,h]{PdCl_2(PhCN)_2} CH_3CH{=}CHCH_2OEt\ 30\% \quad (4)$$

$$CH_2{=}CHCH_2CH_2CH_2OEt \xrightarrow[80°C,\ 12\,h]{PdCl_2(PhCN)_2} CH_3CH_2CH{=}CHCH_2OEt\ 10\% + CH_3CH{=}CHCH_2CH_2OEt\ 36\% \quad (5)$$

This implies difficulty of isomerization of allylic to vinylic ethers in the presence of $PdCl_2(PhCN)_2$. In fact 2-methyl-2-propenyl ethyl ether which afforded **3** in 95% yield through the Pd(II)-catalyzed reaction with azidoformate (80 °C, 20 h) isomerized quite sluggishly in the presence of the Pd(II)-catalyst alone: after 72h at 80 °C only several % of 2-methyl-1-propenyl ethyl ether was detected.

$$CH_2{=}CMeCH_2OEt \xrightarrow[80°C,\ 72\,h]{PdCl_2(PhCN)_2} Me_2C{=}CHOEt\ \ 5\text{—}6\% \quad (6)$$

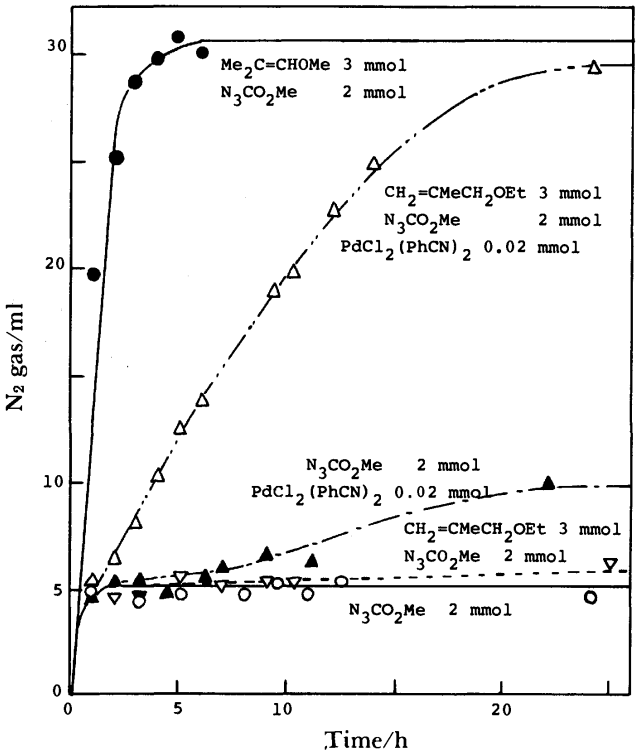


Fig. 1. Evolution of nitrogen.
Solvent=PhH 1 ml, Temp=80 °C.

Kinetic Observation. Rates of nitrogen evolution were followed under various conditions using 2-methyl-2-propenyl ethyl ether which was the best substrate for the Pd(II)-catalyzed reaction with azidoformate. Figure 1 shows amount of gas evolved vs. reaction time. As seen in Fig 1, spontaneous decomposition of azidoformate did not occur in any appreciable extent. The presence of the allylic ether did not promote the decomposition of the azide, although a binary system of the azide and the vinylic ether evolved nitrogen and the reaction was almost completed after several hours at 80 °C. Addition of 1 mol% of $PdCl_2(PhCN)_2$ in an azide solution at 80 °C slightly accelerated the decomposition of the azide, the yield of evolved nitrogen was only 25% based on the azide after 24 h. These facts suggest that some interaction arises between the azide and Pd(II), but the presence of allylic ether much accelerated the Pd(II)-catalyzed decomposition of the azide.

Table 2. The Reaction of Vinylic Ether with Methyl Azidoformate

	$CH_2=CMeCH_2OMe$	15	61	26
	$CH_2=CMeCH_2OEt$	15	74	26

The profile of amount of nitrogen evolved vs. reaction time for the system of azide–ether–Pd(II) showed a sigmoid curve, suggesting the consecutive nature of the reaction. Accurate kinetic treatment of the catalyzed reaction was difficult probably due to that the concentration of the species of the real catalysts could not be controlled easily. Semiquantitative survey using a benzene solution of azidoformate and 2-methyl-2-propenyl ethyl ether (molar ratio of 1: 2—8) containing 1 mol% of $PdCl_2(PhCN)_2$ and using a solution of the azide and 1 mol% of the catalyst in a large excess of the ether showed the first-order dependence of the catalyzed reaction rate on both the azide and the allylic ether. These observations show that the mechanism of the catalyzed reaction is not so simple as shown in Scheme 1, which involves a very slow isomerization of allylic ether followed by a relatively rapid bimolecular reaction.

Comparison with the Reation of Vinylic Ethers. In order to check the similarity in products between the Pd(II)-catalyzed reaction of an allylic ether and the reaction of the corresponding vinylic ether, various vinylic ethers were allowed to react with azidoformate, and the products were compared with those obtained from the corresponding allylic ether. The results were summarized in Table 2.

All vinylic ethers bearing no substituent on its α-position reacted with azidoformate to give the corresponding imines **3** almost quantitatively. As shown in Table 1, the Pd(II)-catalyzed reaction of 1-methyl-2-propenyl ethyl ether gave the methyl-migrated product and the demethylated imine in 44% and 8%, respectively. It is noteworthy that the α-substituted vinylic ether, 1-methyl-1-propyl methyl ether reacted with the azide without the catalyst gave the methyl migrated and the demethylated imines in 72 and 5%, respectively. Under the same conditions (in the presence of 1 mol% of the catalyst, in benzene at 80 °C for 24 h) both 1-methyl-2-propenyl methyl ether and 1-methyl-1-propyl methyl ether gave the same products in similar yields.

$$\begin{array}{l} CH_2=CHCHMeOMe + N_3CO_2Me \\ \quad 4\ mmol \quad\quad 2\ mmol \\ \qquad\qquad\quad \downarrow\ 0.02\ mmol\ PdCl_2(PhCN)_2,\ in\ PhH,\ 80°C,\ 24\ h \\ \quad 24\% \qquad\qquad\quad trace \\ Me_2CHC(OMe)=NCO_2Me,\quad EtC(OMe)=NCO_2Me \\ \quad 31\% \qquad\qquad\quad trace \\ \qquad\qquad\quad \uparrow\ 0.02\ mmol\ PdCl_2(PhCN)_2,\ in\ PhH,\ 80°C,\ 24\ h \\ MeCH=CMeOMe + N_3CO_2Me \\ \quad 4\ mmol \quad\quad 2\ mmol \end{array} \qquad (7)$$

Such similarity strongly supports the occurrence of the isomerization of allylic to vinylic substrates in the Pd(II)-catalyzed reaction of allylic ether.

Reaction of Other Azides. Table 3 shows the products of the reaction of methanesulfonyl and

Table 4. Reaction of Methyl Azidoformate with Allylic Sulfides in the Presence of $PdCl_2(PhCN)_2$

Sulfide	Product	Yield/%
CH_2=$CMeCH_2SMe$	CH_2=$CMeCH_2N(SMe)CO_2Me$	70
CH_3CH=$CHCH_2SMe$	CH_2=$CHCHMeN(SMe)CO_2Me$	65[a]
Me_2C=$CHCH_2SMe$	CH_2=$CHCMe_2N(SMe)CO_2Me$	60
CH_2=$CHCHMeSMe$	CH_3CH=$CHCH_2N(SMe)CO_2Me$	56

a) Cf. 26% (in photoreaction) and 27% (without the catalyst).

phenyl azides with allylic ethers in the presence of $PdCl_2(PhCN)_2$ catalyst, containing also the results on azidoformate for comparison. Without the catalyst, only aziridines (nitrene adduct to the double bond of the allylic ether) were produced in rather low yield. The presence of $PdCl_2(PhCN)_2$, however, lead the reaction to production of the corresponding α-imino ethers. And tendency toward α-imino ether formation decreases in the following order: N_3SO_2Me>N_3CO_2Me>N_3Ph.

$$R^1CH{=}CR^2CH_2OR^3 + N_3R \longrightarrow R^1CH_2CHR^2C(OR^3){=}NR + \underset{\text{aziridine}}{\text{(aziridine)}} \quad (8)$$

α-imino ether

Thus the catalyzed reaction of sulfonyl azide gave the α-imino ethers almost quantitatively. Phenyl azide gave the α-imino ethers as well as aziridines, and the distribution of the products seriously depended on the allylic structure.

On the other hand, these all azides gave the α-imino ethers almost quantitatively through the noncatalyzed reaction with vinylic ethers. These facts again imply that imine production from allylic ethers may be related to the Pd(II)-assisted isomerization of allylic to vinylic ether.

Reaction of Allylic Sulfides. The reaction of allylic sulfides, sulfur analogues of allylic ethers, with azidoformate did not give the imino compounds corresponding to **3**, but the [1·5] rearranged C–S nitrene insertion products even in the presence of $PdCl_2(PhCN)_2$ as shown in Table 4. Photo- and thermal reactions of allylic sulfides have been known to react with azidoformate to give the [1·5] rearranged C–S nitrene insertion products which is considered to form via the ylide formation between nitrene and the sulfur atom, and enamines which have been considered to be derived from adducts between the azide and the sulfides, in total yield of about 30%.[1] Comparing these facts with the present results, the presence of $PdCl_2(PhCN)_2$ is thought to enhance the formation of the nitrene-ylide.

Discussion

The results which allow us to discuss the mechanism of the Pd(II)-catalyzed reaction of azides with unsaturated ethers are summarized as follows.

(1) In the presence of $PdCl_2(PhCN)_2$ alone, isomerization of allylic to vinylic ether is extremely slow, although the more remotely functionated substrates isomerize to allylic ether (Eqs. 4 and 5).

(2) The catalyzed reaction is first order in the allylic ether as well as in the azide. Since the reaction of azidoformate with allylic ether without the Pd(II) catalyst does not give imine, the Pd(II)-catalyzed imine-formation is not, at least, zeroth-order in Pd(II). The overall kinetic observation shows that the transition state of the rate determining step should be composed of three species, Pd(II), allylic ether, and azide.

(3) Products of the catalyzed reaction of any kind of allylic ethers are the same as those of the reaction of the corresponding vinylic ethers, showing an important role of the Pd(II)-catalyed isomerization of allylic to vinylic ether.

(4) Easiness of formation of the imino products by the catalyzed reaction depends on the nature of the azide: the more electron-withdrawing group the azide has, the better yield of the imine is observed.

Based on these features, the mechanism shown in Scheme 2 is proposed to be most probable for the Pd(II)-catalyzed reaction of azides with allylic ethers. The mechanism involves the Pd(II)-catalyzed isomerization of allylic to vinylic ether as the rate-determining step. But the real catalyst is thought to be $PdCl_2(PhCN)(N_3R)$ which may be formed by the ligand exchange between $PdCl_2(PhCN)_2$ and the azide. Unfortunately preparative or spectroscopic evidences for the ligand exchange could not be obtained, perhaps due to that the complex thus formed is rather labile and the azide ligand is apt to decompose as seen in the gradual evolution of nitrogen from the system of the azide–$PdCl_2(PhCN)_2$(Fig. 1). Since the Pd(II)-catalyzed isomerization is essentially the hydride transfer between Pd(II) and the ether, the rate would be influenced by the nature of the ligand coordinated to Pd(II). The more electron demanding the ligand is, the faster the hydride abstraction from the allyic ether

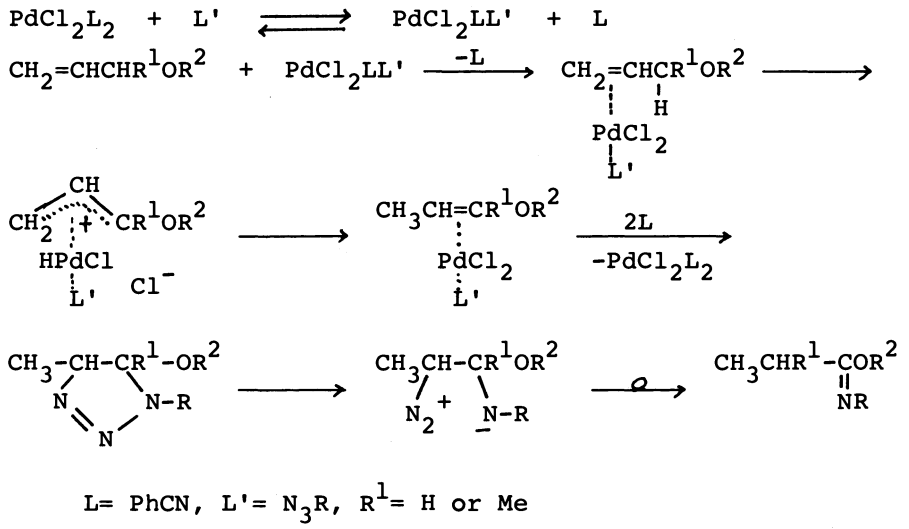
would be. The tendency is thought to be reflected on the yields of the imino-ethers from the reaction of a series of azides: the electron-withdrawing group on azide promotes the formation of the imino ether (Table 3).

Table 3 also clearly shows that 2-methyl-2-propenyl ether is a better substrate for the imino-ether formation than 2-propenyl ether. This result is quite interesting and probably due to the steric or electronic effects on the reaction in the Pd(II) coordinate sphere, although the real reason is not yet clear.

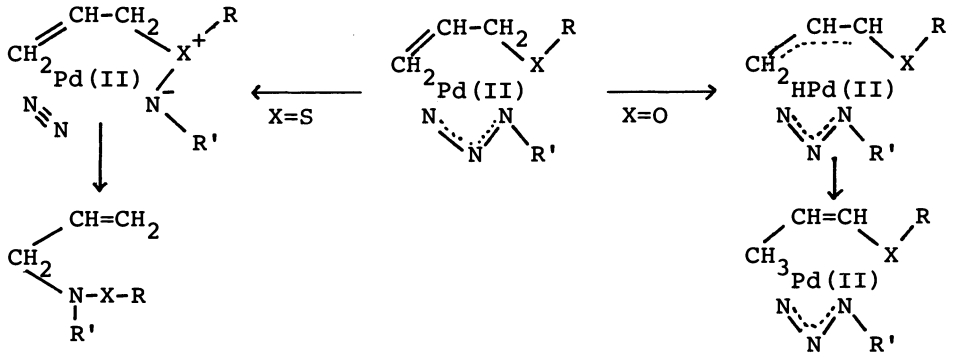
The vinylic ether thus formed reacts with the azide to give the imino-ether, via 1,3-dipolar addition followed by heterolysis of the triazoline as proposed by Huisgen et al. for the thermal reaction of enol ether with aryl azide.[5] Since appreciable amounts of vinylic ethers were not detected in the reaction mixtures during and after the reaction carried out in the large excess of allylic ethers, the interaction between the vinylic ether and the azide is considered to take place in the Pd(II) coordinate sphere, that is, the coordinated azide molecule is brought into the interaction with vinylic ether derived in the Pd(II) coordinate sphere.

On the heterolysis of the triazoline and evolution of nitrogen, a hydrogen atom or a methyl group located on the α-position of the ether can be migrated to the electron deficient β-carbon via 1,2-shift. Thus the α-methylated allylic or vinylic ethers afford the rearranged imino products (Tables 1 and 2). These ethers also gave the demethylated imino products as shown in Tables 1 and 2. Although their yields are quite low, the results may be interesting, suggesting new aspects of decomposition of the triazolines. Because the carbonium ion formed after nitrogen evolution is hardly thought to degradate with a C–C bond rupture. To elucidate its mechanism, however, further surveys are required.

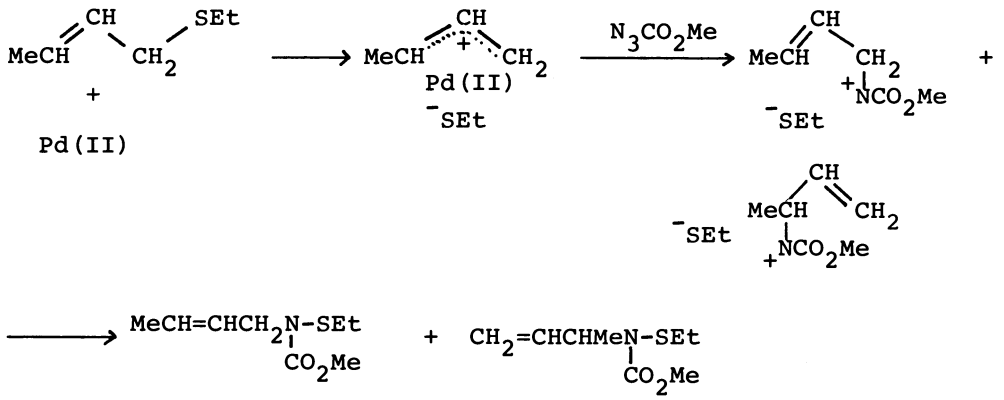
The Pd(II)-catalyzed reaction of allylic sulfides did not lead to formation of the imino products but [1·5] rearranged insertion products. This may be due to the greater nucleophilic reactivity of a sulfur atom compared with an oxygen atom. Much higher yields of the rearranged products in the catalyzed reaction compared with those in the ordinary thermal reaction (Table 4) and accelerated nitrogen evolution in the presence of $PdCl_2(PhCN)_2$ suggest that the production



Scheme 2.



Scheme 3.



Scheme 4.

of the insertion products are also controlled by the Pd(II) coordinate sphere.

The coordinated azide molecule has an enhanced electrophilicity and easily interacts with a nucleophilic sulfur atom of the sulfide, to produce the nitrene-ylide, which undergoes [1·5] rearrangement through the cyclic transition state as well documented.[1] In the case of sulfides, therefore, the ylide formation seems much faster than the hydride transfer between Pd(II) and the substrate sulfide. Summarized scheme involving allylic sulfide and ether are shown in Scheme 3.

The route shown in Scheme 4 in which a π-allyl complex is formed from allylic sulfide and Pd(II) and reacts with nitrene from the azide to give the insertion product is unlikely. If this were the true mechanism, unsymetrically substituted π-allyl complexes should give both rearranged and unrearranged insertion products, and the products through the attack of nitrene on the less sterically hindered site of the π-allyl complex would be the major. The results (Table 4) is not the case, showing the formation of the C–N bond exclusively at a γ-carbon atom of allylic sulfide, even though the site is more hindered.

Experimental

Materials. Methyl azidoformate (bp 36—37 °C/58 mmHg (1 mmHg=133.322 Pa)),[9] phenylazide (bp 41 °C/5 mmHg),[10] methanesulfonyl azide (bp 44—45 °C/1 mmHg)[11] were prepared by the known methods. 2-Methyl-2-propenyl alkyl ethers, and 3-butenyl and 4-pentenyl ethyl ethers were prepared by Williamson method[12] from the corresponding chloride, and 1-methyl-2-propenyl methyl ether (bp 55.5 °C)[13] was synthesized by the reaction of acrylaldehyde with methylmagnesium iodide. 1-Methyl- and 1-ethyl-2-methylpropene[14] were prepared from the corresponding acetals of 2-methylpropanal by the *p*-toluenesulfonic acid catalyzed elimination of alcohols. Dichlorobis(benzonitrile)palladium(II)[15] was obtained by treatment of palladium(II) chloride with benzonitrile.

Products of the Reactions. The reaction was carried out according to the procedure already described.[2] The structural determination of aziridines derived from allylic ethers[1] or [1·5] rearranged insertion products from allylic sulfides[1] has been described elsewhere. Analytical data of some unknown α-imino ethers are presented in Table 5.

Kinetic Measurement. i) Three stock solutions were prepared by dissolving a weighed amount of azidoformate (20 mmol) in 5 ml of benzene, $PdCl_2(PhCN)_2$ (0.2 mmol) in 25 ml of benzene, and acetophenone (the internal standard, 1 mmol) in 5 ml of benzene. To a 10 ml volumetric flask, 1 ml, 5 ml, and 0.5 ml of the stock solution of the azide, Pd(II), and the internal standard, respectively, were taken, and a weighed amount of 2-methyl-2-propenyl ethyl ether (8, 16, or 32 mmol) was added, and the solution was diluted to 10 ml. One ml of the solution was put into a reaction tube and degassed. The tube was sealed and immersed in a thermostatt kept at 80 °C. After an appropriate reaction time, the mixture was analyzed for the imine product by GLC. The amounts of the imine formed were accomodated approximately to the second-order rate law (first-order each in azide and in ether), and the apparent second-order rate constants obtained for the solution containing the ether at the concentration of 0.8, 1.6, and 3.2 mol·l^{-1} were almost constant, being 1.4, 1.5, and 1.4×10^{-6} s^{-1}·mol^{-1}·l, respectively.

ii) An amount (0.2 mmol) of $PdCl_2(PhCN)_2$ was dissolved in 25 ml of 2-methyl-2-propenyl ethyl ether. To a 10 ml volumetric flask, 1 ml of the above solution and weighed amounts of azidoformate (2 or 4 mmol) and acetophenone (the internal standard, 0.2 or 0.4 mmol) were taken and diluted by 2-methyl-2-propenyl ethyl ether to 10 ml. One ml of the solution was degassed and kept at 80 °C in a sealed tube. The amounts of the imine formed were determined by GLC. The rate obeyed to the psudo-first-order rate law, giving the rate constants 4.3 and 4.8 s^{-1} for the 0.2 and 0.4 mol dm^{-3} solution of the azide, respectively.

The present work was partially supported by a Grant-in-Aid for Scientific Research No. 59470015 from the Ministry of Education, Science and Culture.

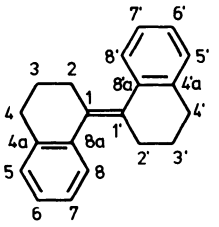
(Received September 8, 1987)

The crystal structure of the title compound was determined by X-ray diffraction. The crystals have monoclinic symmetry with a=13.481(5), b=8.285(5), c=13.092(3) Å. β=96.24(3)°, and space group $P2_1/n$ with Z=4. The final R-factor was 0.065 for 2191 independent reflections. The torsion angles of the C–Ph bonds are 47.4(4) and 44.4(4)°. The cyclohexene rings have approximate twist-boat conformations. The molecular structure in the crystal is compared with that in the solution phase, that of (*E*)-stilbenes, and the results of the molecular mechanics calculations. It is also discussed in relation to the molecular packing.

In connection with our continuing studies of the geometry of stilbene systems,[1,2] the molecular structure of the title compound (*E*)-1,1′-bitetralinylidene (**1**) is of interest, because **1** has the (*E*)-stilbene skeleton that is geometrically fixed by two methylene chains. Electronic absorption spectroscopic study of **1** has revealed that the torsion angle of the C–Ph bonds substantially deviates from 0° in the fluid and the glassy solution.[2] Molecular mechanics study using MMP1[3] has shown that the torsion angle of the C–Ph bonds is 54° and that the cyclohexene rings have approximate twist-boat conformations in the isolated molecule.[4] The purpose of the present study is to investigate the geometry of this molecule in the crystalline state and to compare it with that in the solution phase, with the geometry of (*E*)-stilbenes, and with the results of the molecular mechanics calculations.



1

Experimental

The sample of **1** was prepared by the method described in literature.[4] Single crystals were recrystallized from isopropyl alcohol.

Crystal Data. $C_{20}H_{20}$, M=260.36. Monoclinic, a=13.481 (5), b=8.285 (5), c=13.092 (3) Å, β=96.24 (3)°, V=1454 (1) Å^3 (by least-squares refinement on 20 reflections with $18 \leq 2\theta \leq 20°$, λ=0.71073 Å), space group $P2_1/n$, Z=4, D_x=1.190 g cm^{-3}, D_m not determined. The crystal used was a colourless plate. Approximate dimensions 0.8×0.4×0.2 mm, μ(Mo $K\alpha$)=0.0622 mm^{-1}. F(000)=560. T=296 K.

Data Collection and Processing. The integrated intensities were collected on a Rigaku AFC-4 automated four-circle diffractometer using graphite-monochromatized Mo $K\alpha$ radiation. The ω–2θ scan technique was employed at an ω rate of 4.0° min^{-1}. $2\theta_{max}$=55°, collection range h=−17 to 17, k=0 to 10, l=0 to 16. Three standard reflections $\bar{1}21$, 710, and 264 were measured every 100 reflections, intensity variation≤2.1%. 2419 reflections with $|F_o| > 3\sigma(F_o)$ were obtained. The intensities were corrected for Lorentz and polarization effects but not for absorption. 2191 reflections were unique and were used for refinement. 1298 reflections were unobserved.

Structure Analysis and Refinement. Structure was solved by direct methods with MULTAN78[5] and was refined by full-matrix least squares minimizing $\Sigma w(|F_o|^2 - |F_c|)^2$, $w=(0.00462|F_o|^2 - 0.06153|F_o| + 0.68041)^{-1}$. 16 H atoms were obtained by the difference Fourier synthesis and 4 H atoms were located by standard bond lengths and angles. Isotropic temperature factors were assigned to all of the H atoms. 261 parameters consisting of 120 positional parameters, 120 anisotropic temperature factors, 20 isotropic temperature factors, and a scale factor were refined. In the final least squares refinement, R=0.072, wR=0.083, S=1.1696, and $(\Delta/\sigma)_{max}$=0.790. The maximum and the minimum height in the final difference Fourier synthesis were +0.441 and −0.658 e Å^{-3}, respectively. For the structure at this stage (structure **A**), it was found that the temperature factors of C3 and C4 were exceptionally large (B_{eq}=9.9 Å^2 for C3 and B_{eq}=7.0 Å^2 for C4).

Therefore, further refinement was carried out on the basis of a disorder model constructed as follows. New atoms C3+ and C3− were located on the normal to the plane through C2, C3, and C4, which passes through C3, 0.25 Å above and below the plane, respectively. In a similar way, new atoms C4+ and C4− were located above and below the plane through C3, C4, and C4a. Then C3, C4, and hydrogen atoms attached to these atoms were deleted. Hydrogen atoms attached to the new carbon atoms were located by molecular mechanics calculations. Multiplicities of all of the new atoms were fixed to 0.5. For this model, 295 parameters consisting of 138 positional parameters, 132 anisotropic temperature factors, 24 isotropic temperature factors, and a scale factor were refined by full-matrix least squares minimizing $\Sigma w(|F_o| - |F_o|)^2$, $w=(0.00314\ |F_o|^2 - 0.04503\ |F_o| + 0.55851)^{-1}$. In the final least squares refinement, R=0.065, wR=0.063, S=0.9538, and $(\Delta/\sigma)_{max}$=0.007. The maximum and the minimum height in final difference Fourier synthesis were +0.342 and −0.249 e Å^{-3},

respectively.

Atomic scattering factors were taken from the International Tables for X-Ray Crystallography.[6] Crystallographic calculations were performed on FACOM M-380 and M-780 computers at the Institute and on FACOM M-360 at the University of Tokyo using UNICSIII program system.[7] The molecular mechanics calculations were performed using the MMP2 program[8] on a HITAC M-682H computer of the Computer Centre of the University of Tokyo.

Results and Discussion

The final atomic parameters are listed in Table 1[†††] and the geometrical parameters in Table 2. A perspective view of the molecule is shown in Fig. 1.

Table 2 and Fig. 1 show that the observed structure is asymmetric. However, in a rough approximation, it has a C_2 axis perpendicular to the ethylenic plane, in sharp contrast with (*E*)-stilbene (ES) and (*E*)-α,β-dimethylstilbene (EαβDMS), which have an inversion center (see Table 3).

The (*E*)-2-butene skeleton C8a-C1-C1′-C8′a holds the planar geometry. The double bond C1-C1′ has a normal length 1.347 Å. It is nearly equal to the length of the ethylenic double bond of EαβDMS and is a little longer than that of ES. Absolute values of the torsion angles of the C-Ph bonds of **1** are much larger than those of ES, but are significantly smaller than those of EαβDMS, in accordance with the results of our UV study.[2]

Another (*E*)-2-butene skeleton C2-C1-C1′-C2′ deviates from the planarity as shown by its torsion angle, and C2 and C2′ atoms, as well as other sp^3 carbon atoms, are placed on a same side of the ethylenic plane (C8a-C1-C1′-C8′a). The two cyclohexene rings have approximate twist-boat conformations as shown in Fig. 2.

These results are essentially consistent also with the results of molecular mechanics calculations using MMP2. The most stable molecular structure obtained by the calculations is nearly C_2 symmetric and has the following geometrical parameters (cf. Table 2): Bond length C1-C1′, 1.361 Å; torsion angles C1′-C1-C8a-C8, −49.3°; C1-C1′-C8′a-C8′, −49.4°; C2-C1-C1′-C2′, 157.1°; C2-C1-C1′-C8′a, −10.4°; C2′-C1′-C1-C8a, −10.5°.

One of the most interesting features of the X-ray structure is that there is a disorder in C3 and C4 but not in C3′ and C4′. This may be explained in terms of the intermolecular nonbonding interactions in the crystal as follows.

The crystal structure is shown in Fig. 3. In a unit cell, there are 28 intermolecular nonbonding atom pairs whose distances (2.64—2.87 Å for C···H and 2.12—2.39 Å for H···H) are slightly shorter than the sum of the relevant van der Waals radii (2.90 Å for

a) The bond lengths and angles related to the disordered atoms, C3± and C4±, are not listed in this table, because they are not reliable. They will be approximately equal to the corresponding ones in which C3′ and/or C4′ are involved.

C···H and 2.40 Å for H···H) as shown in Table 4,[12] where parts of the molecule are designated as follows. A half of the molecule that has the atom numbers without primes in Fig. 1 is designated as *n*. Another half that has atom numbers with primes in Fig. 1 is designated as *n*′. An atom of the methylene groups and an atom of the benzene ring in the half *n*(or *n*′) are designated as *M* (or M′) and *B* (or *B*′), respectively.

The fact that all of the 28 van der Waals contact atom pairs involve the half of the molecule *n*′ shows that it is sterically more crowded than the another half *n*. The fact that 4 van der Waals contact atom pairs involve atoms *M* while 16 van der Waals contact pairs involve atoms *M*′ shows that the methylene groups of the cyclohexene ring for which the disorder was observed are sterically much less crowded than those of the cyclohexene ring for which the disorder was not observed. The fact that there are 25 van der Waals contact atom pairs in which atoms of the benzene rings are involved shows that the benzene rings are sterically more crowded than the cyclohexene rings. Thus, the difference between the packing of the two halves of the molecule results in the asymmetrical molecular structure in the crystal.

(Received September 14, 1987)

The solvation structure of copper(II) ion in *N,N*-dimethylformamide (DMF) and *N,N*-dimethylformamide–acetonitrile (AN) mixtures has been investigated by means of X-ray diffraction at 25 °C. The X-ray scattering data for the copper(II) perchlorate DMF solution were well-interpreted in terms of the presence of the axially elongated octahedral $[Cu(dmf)_6]^{2+}$ ion in DMF. Among the six DMF molecules, four of them are at the distance of 203(3) pm at the equatorial position and the other two are at 243(5) pm at the axial one. On the other hand, in copper(II) perchlorate DMF–AN solutions with the C_{dmf}/C_{Cu} mole ratios of 5.308 and 7.435, where C_i denotes the total concentrations of species i, the copper(II) ion is coordinated with four DMF molecules within the square-plane and with no solvent molecule along the axis of the plane. The equatorial Cu–O bond length is 200(1) pm and practically the same as that within the $[Cu(dmf)_6]^{2+}$ ion in DMF. In copper(II) nitrate DMF solutions (1.086 and 1.500 mol dm^{-3}), a nitrate ion binds to copper(II) ion at the equatoral position and the distorted octahedral $[CuNO_3(dmf)_5]^+$ complex is formed.

Complex formation reactions between copper(II) and chloride ions in *N,N*-dimethylformamide (DMF) and in acetonitrile (AN) have been investigated[1,2] and it was found that the formation of copper(II)–chloro complexes ($[CuCl_n]^{(2-n)+}$, n=1—4) is more favorable in AN than in DMF. The more enhanced formation of the complexes in AN than in DMF is mainly ascribed to the difference in the donor property between the two solvents, i.e. copper(II) ion is more strongly solvated with DMF than with AN. Accordingly, copper(II) ion is preferentially solvated with DMF molecules in DMF–AN mixtures[3] and complex formation between copper(II) and chloride ions in the mixtures depends on the solvent composition.[4]

According to the X-ray diffraction study, copper(II) ion in aqueous solution is coordinated with six water molecules and the $[Cu(H_2O)_6]^{2+}$ ion has an axially elongated octahedral structure.[5] However, structural information on solvated copper(II) ion in other solvents has never been given by the diffraction method. In the present study we aimed at determining the solvation structure of copper(II) ion in DMF and in DMF–AN mixtures by the X-ray diffraction method. It was difficult to determine the solvation structure of copper(II) ion in AN because of a low solubility of copper(II) perchlorate in AN.

Experimental

Preparation of Sample Solutions. All chemicals used were of reagent grade. *Copper(II) perchlorate DMF solvate* was prepared by dissolving copper(II) perchlorate hydrate crystals in DMF and by repeated evaporation of DMF to remove water, and was finally isolated by adding ether. Crude crystals thus obtained were recrystallized from a DMF–acetone mixture. *Copper(II) nitrate DMF solvate* was obtained by a similar way to that used for copper(II) pechlorate DMF solvate and then recrystallized from DMF. Crystals thus obtained were dried at 40 °C in a vaccum oven for several days and stored in a vaccum desiccator over P_2O_5. From the electrogravimetric analysis of copper, the composition of the solvate crystals prepared was found to be $Cu(ClO_4)_2(dmf)_4$ and $Cu(NO_3)_2(dmf)_2$. *N,N*-Dimethyformamide and acetonitrile were purified by similar ways to those described in previous papers.[1,2]

Five test solutions A to E were prepared for X-ray diffraction measurements as shown in Table 1. Solution A was prepared by dissolving the copper(II) perchlorate DMF solv-

Table 1. The Composition (mol dm^{-3}), Stoichiometric Volumes V per Copper Atom and Densities ρ of the Sample Solutions

ate in DMF and was an almost saturated one at room temperature. Solutions B and C are copper(II) nitrate DMF solution in which the concentration of copper(II) ions is higher than that in solution A. Solutions D and E are copper(II) perchlorate solutions in DMF–AN mixtures of different molar ratios. Concentrations of copper(II) ions in the test solutions were determined by electrogravimetry. Concentrations of perchlorate and nitrate ions in the solutions were estimated from the stoichiometry of the copper(II) salts used. Densities of the sample solutions were measured by using a pycnometer.

X-Ray Scattering Measurements. X-Ray scattering measurements were carried out with a θ–θ type diffractometer (JEOL DX-GO-Y) by using an Mo X-ray tube (λ=71.07 pm). Scattered X-rays were monochromatized by a Johansson-type graphite monochromator and a pulse-height analyzer. The observed range of the scattering angle 2θ was from 2° to 140° and times required to collect 240000 counts at each angle were recorded. Corrections for the scattered intensities were made by the same manner as that described elsewhere.[6]

The reduced intensities $i(s)$ were obtained by subtracting independent coherent scatterings from the measured intensities $I(s)$ as follows:

$$i(s) = K \cdot I(s) - \sum_i n_i[\{f_i(s) + \Delta f_i\}^2 + (\Delta f_i'')^2], \quad (1)$$

where K stands for a normalization factor of the measured intensities to the absolute ones. n_i is the number of atom i in a stoichiometric volume V per copper atom of the test solutions. $f_i(s)$ represents the atomic scattering factors at s, and $\Delta f_i'$ and $\Delta f_i''$ denote the real and imaginary parts of anomolous dispersion, respectively, of atom i. The reduced intensities multiplied by s ($=4\pi\lambda^{-1}\sin\theta$) for the sample solutions are shown in Fig. 1.

The radial distribution function $D(r)$ was calculated by the Fourier transform of the reduced intensities according to Eq. 2:

$$D(r) = 4\pi r^2\rho_0 + \frac{2r}{\pi}\int_0^{s_{max}} s \cdot i(s) \cdot M(s) \cdot \sin(rs)ds, \quad (2)$$

where ρ_0 ($=\{\sum n_i \cdot f_i(0)\}^2/V$) is the average scattering density in a stoichiometric volume of the sample solution and s_{max} represents the maximum s-value attained in the measurement (s_{max}=16.6×10^{-2} pm^{-1}). The modification function $M(s)$ is given as

$$M(s) = \frac{\sum_i n_i\{(f_i(0) + \Delta f_i)^2 + (\Delta f_i'')^2\}}{\sum_i n_i\{(f_i(s) + \Delta f_i)^2 + (\Delta f_i'')^2\}} \cdot \exp(-ks^2). \quad (3)$$

The damping factor k was chosen as 100 pm^2 in the present case. The differential radial distribution curves, $D(r)-4\pi r^2\rho_0$, for the test solutions are depicted in Fig. 2.

A least-squares calculation for the refinement of the structure parameters was applied to the reduced intensities so as to minimize the error-square sum U,

$$U = \sum_{s_{max}}^{s_{max}} s^2\{i(s)_{obsd} - i(s)_{calcd}\}^2. \quad (4)$$

The theoretical intensities $i(s)_{calcd}$ arising from the inter-

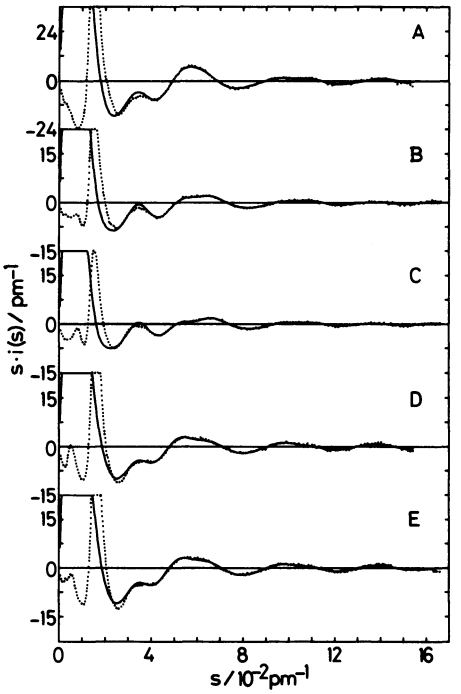

Fig. 1. The reduced intensities multiplied by s for solutions A to E. The observed $s \cdot i(s)$ values are shown by the dotted lines and calculated ones by the solid lines.

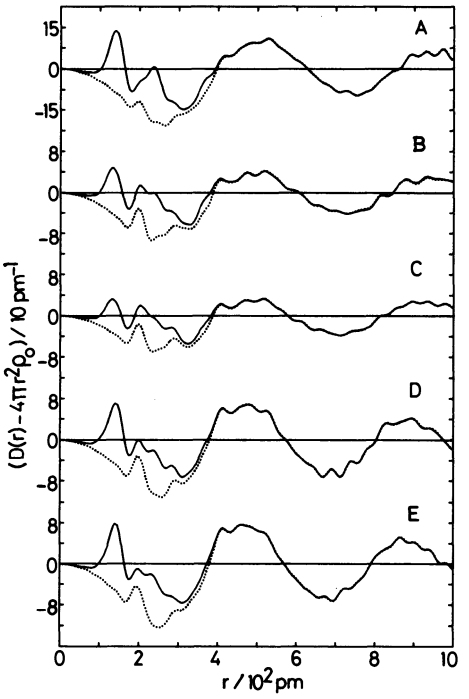

Fig. 2. The differential radial distribution curves, $(D(r)-4\pi r^2\rho_0)$, for solutions A to E. The dotted lines indicate the residual curves after subtraction of peaks due to intramolecular interactions of solvent molecules and anions.

atomic interactions in the solutions are obtained as follows:

$$i(s)_{calcd}=\sum_{i}\sum_{j\neq i} n_{ij}[\{f_i(s)+\Delta f_i\}\{f_j(s)+\Delta f_j\}+(\Delta f_i'')(\Delta f_j'')] \cdot \frac{\sin(r_{ij}s)}{r_{ij}s}\cdot\exp(-b_{ij}s^2), \quad (5)$$

where r_{ij}, b_{ij}, and n_{ij} represent the distance, the temperature factor, and the frequency factor of the atom-pair i-j, respectively.

All calculations were performed by using programs KURVLR[7] and NLPLSQ.[8]

Results and Discussion

The observed $(D(r)-4\pi r^2\rho_o)$ curves for solutions A to E drawn by the solid lines in Fig. 2 show five peaks around 140, 200, 240, 290, and 400 pm in the range of $r \leqslant 400$ pm. Two large peaks are observed around 400—600 and 800—1000 pm, which are due to ion-ion, ion-solvent, and solvent-solvent long range intermolecular interactions, and they, except for the small peak at 400 pm, are not analyzed in the present study. Diffraction studies on the structure of liquid DMF[9] and AN[10,11] showed that the peaks resulting from the intramolecular interactions within solvent molecules appeared at 130 and 230 pm for DMF and 130 and 260 pm for AN. The first peak at 140 pm, therefore, consists of peaks due to C-H, C=O, and C-N bonds within DMF molecules in solutions A to E and due to C-H, C-C, and C≡N bonds within AN molecules in solutions D and E. The Cl-O bonds within perchlorate ions in solutions A, D and E, and the N-O bonds within nitrate ions in solutions B and C also contribute to the peak. The third peak appearing at 240 pm is due to the nonbonding N···O, C···C, and C···O interactions within DMF molecules and the C···N interactions within AN molecules. The O···O contacts within perchlorate and nitrate ions are partly contained in the peak.

In order to extract peaks due to the sole intramolecular interactions within solvated copper(II) ion, the calculated peak shapes due to the intramolecular interactions of solvent molecules and anions must be subtracted from the observed radial distribution functions. For the calculation the structural parameters of each solvent molecule were assumed to be the same as those reported in the liquid state.[9-11] The parameter values of perchlorate and nitrate ions were also taken from the literature.[5,12]

The dotted lines in Fig. 2 represent the residual radial distribution curves after subtracting the theoretical peak shapes due to the intramolecular interactions of solvent molecules and anions, and the curve shows the peaks originating from the intramolecular interactions within the solvated copper(II) ion over the region $r<400$ pm. The structure parameters of the solvated copper(II) ions in DMF and in DMF-AN mixtures, details of which will be discussed in the following sections, were evaluated by analyzing the residual curves.

Copper(II) Perchlorate DMF Solution. Figure 3a depicts the $(D(r)-4\pi r^2\rho_o)$ curve of solution A. Subtraction of the calculated peak shapes due to the intramolecular structure of DMF molecule and perchlorate ion from the original curve (solid line) gives the residual curve (chain line), which shows three peaks at 200, 290, and 400 pm and a small hump at 240 pm. The peak centered at 200 pm is ascribable to the Cu-O(dmf) bonds similar to the Cu-O(H_2O) within the hexaaquacopper(II) ion.[5] The area under the peak gives the frequency factor of four for the Cu-O bond. The peak at 290 pm is attributable to the nonbonding Cu···C interactions when the DMF molecules at the equatorial position direct lone-pair electrons of the oxygen atom to the central copper(II) ion as found in $SbCl_5$·DMF solvate crystal.[13] The nonbonding interligand O(eq)···O(eq) interactions might also be contained in the peak. If the structure of DMF molecules within the metal solvate is the same as that in the liquid state,[9] it is expected that the nonbonding Cu···N(eq) distance should

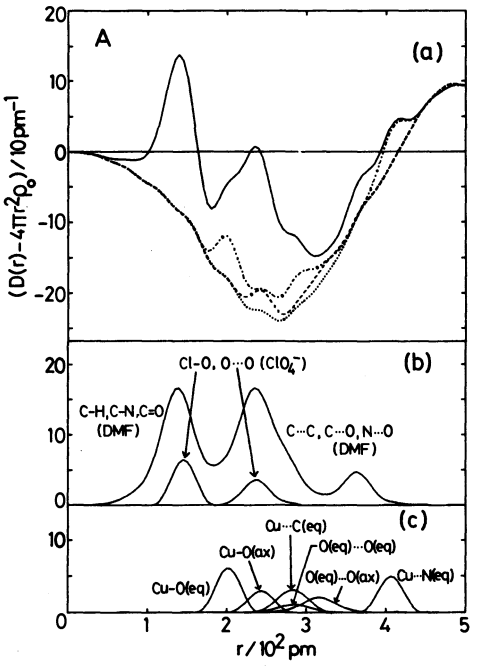

Fig. 3. (a); The $(D(r)-4\pi r^2\rho_o)$ curve for solution A. The chain line represents the residual curve after subtracting the theoretical peaks shown in (b). The dashed line indicates the residual curve after subtraction of the peak shapes due to the Cu-O(eq), Cu···C(eq), O(eq)···O(eq), and Cu···N(eq) interactions. The dotted line is finally obtained by subtraction of the caluclated peaks due to the Cu-O(ax) and O(eq)···O(ax) interactions. (b) and (c); The theoretical peak shapes of each atom-pair.

appear at about 400 pm, and the corresponding peak is in fact observed in the residual differential radial distribution curve.

Subtraction of peaks for the Cu–O(eq), Cu···C(eq), O(eq)···O(eq), and Cu···N(eq) interactions in the equatorial plane gives the residual curve (dashed line in Fig. 3a), in which a peak and a shoulder remain at 240 and 320 pm, respectively. The peak at 240 pm is thus ascribable to the Cu–O(ax) bonds within the distorted octahedral copper(II) ion. When the hexasolvated copper(II) ion has such a distorted octahedral structure, the interligand O(eq)···O(ax) interactions should cause a peak at about 320 pm. Since the areas under the peak at 240 pm and the shoulder at 320 pm correspond to two Cu–O bonds and approximately eight O(eq)···O(ax) interactions, respectively, we concluded that the solvated copper(II) ion in DMF has a distorted octahedral structure with six DMF molecules. Subtraction of the peaks due to the Cu–O(ax) and O(eq)···O(ax) interactions led to a smooth background curve (dotted line) having no appreciable peak remaining over the range $r<400$ pm.

The structural parameters for the $[Cu(dmf)_6]^{2+}$ ion were refined by the least-squares method for the $s\cdot i(s)$ values over the range $s\geqslant 4\times10^{-2}$ pm^{-1} (Table 2). Structure parameters of atom-pairs within DMF molecules and perchlorate ions were quoted from the literature[5,9] and were fixed at the given values in the course of the calculation. The interatomic distances and temperature factors of interactions between copper(II) ion and atoms within DMF molecule were refined as independent variables as seen in the table (Column A). Lengths of interligand O(eq)···O(eq) and O(eq)···O(ax) interactions between DMF molecules coordinating to copper(II) ion were determined by the optimized Cu–O(eq) and Cu–O(ax) distances. Frequency factors of all interactions were kept constant during the calculation at the given values listed in the table which were evaluated on the basis of the distorted octahedral $[Cu(dmf)_6]^{2+}$ structure model. The Cu–O(eq) and Cu–O(ax) distances within the $[Cu(dmf)_6]^{2+}$ in DMF were finally determined to be 203 (3) and 243 (5) pm, respectively.

a) The values were kept constant during the calculation. b) $r_{O(eq)\cdots O(eq)}=\sqrt{2}\,r_{Cu-O(eq)}$. c) $r_{O(eq)\cdots O(ax)}=\sqrt{r_{Cu-O(eq)}^2+r_{Cu-O(ax)}^2}$.

Copper(II) Nitrate DMF Solutions. Since concentrations of copper(II) ions in solutions B and C are much higher than the concentration in solution A, the structure analysis for the copper(II) ion in solutions B and C may give more reliable results than those obtained in solution A. However, a possibility of formation of contact ion pairs between copper(II) and nitrate ions should be taken into consideration in such concentrated solutions.

The $(D(r)-4\pi r^2\rho_o)$ curve of solution B depicted in Fig. 4a was analyzed by the similar way to that employed for solution A. We first assumed that the copper(II) ion in solution B has the same structure as that in solution A. Subtraction of theoretical peaks originating from the intramolecular interactions of DMF molecules and nitrate ions gave the chain line in Fig. 4a. Further subtraction of peaks arising from the Cu–dmf(eq) interactions, i.e., the Cu–O(eq), Cu···C(eq), O(eq)···O(eq), and Cu···N(eq), led to the residual curve expressed by the dashed line. In the curve we see a distinct peak at 245 pm and very broad humps around 320 and 370 pm. The peak at 245 pm is easily attributable to the Cu–O(ax) bond. Therefore, the first hump around 320 pm may be ascribable to the O(eq)···O(ax) interaction as also found in solution A. The broad hump around 370 pm has not been observed in solution A and thus it might be the one characteristic of metal nitrate DMF solutions. Such a broad peak has been observed in the radial distribution curve of nickel(II) nitrate DMF solution,[16] but not in DMF solutions of the perchlorate.[17] Accordingly, the peak is expected to be due to interactions between copper(II) ion and atoms within nitrate ion.[18]

Nitrate ion can coordinate to copper(II) ion as

The Cu–O(eq) bond length within the $[Cu(dmf)_6]^{2+}$ complex in DMF is longer than that within the $[Cu(H_2O)_6]^{2+}$ in aqueous solution (194—197 pm)[5,14] and that within the $[CuCl_n(CH_3OH)_{6-n}]^{(2-n)+}$ (n=1—3) in methanolic solution (192.6—195.0 pm).[15] On the other hand, the Cu–O(ax) distance within the $[Cu(dmf)_6]^{2+}$ ion is practically the same as that within the $[Cu(H_2O)_6]^{2+}$.[5]

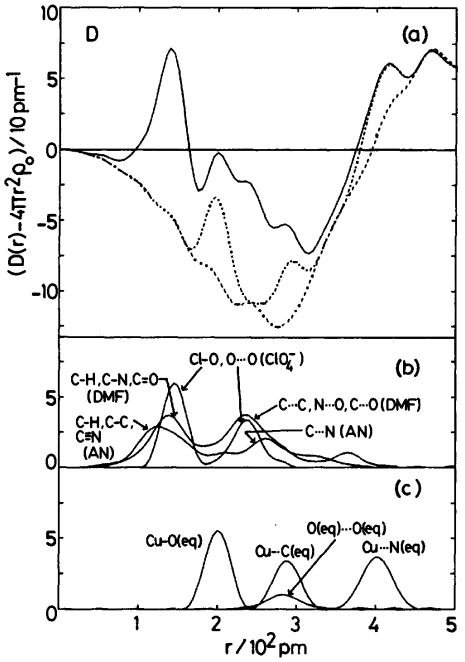

Fig. 5. (a); The $(D(r)-4\pi r^2\rho_o)$ curve for solution D. The chain line represents the residual curve after subtracting the theoretical peaks shown in (b). The dashed line indicates the residual curve after subtraction of the peak shapes due to the Cu-O(eq), Cu···C(eq), O(eq)···O(eq), and Cu···N(eq) interactions shown in (c). (b) and (c); The theoretical peak shapes of each atom pair.

either mono- or bidentate ligand. However, the broad peak at 370 pm observed could not be reproduced by a model that two oxygen atoms of a nitrate ion bind to copper(II) ion at the distance of 200 pm as a bidentate ligand. Therefore, it is suggested that a nitrate ion binds to copper(II) ion at the equatorial position to form $[CuNO_3(dmf)_5]^+$. In order to reproduce the peak at 370 pm, we examined various configurations of nitrate ion within the $[CuNO_3(dmf)_5]^+$ complex. The most plausible binding mode of a nitrate ion to the copper(II) ion is that a nitrate ion directs one oxygen atom toward the copper(II) ion with the Cu-O-N angle of ca. 120° in the equatorial plane of the copper(II) ion and the triangular plane of the nitrate ion is perpendicular to the square-plane within the complex. According to the model, the broad peak at 370 pm is due to two nonbonding $Cu\cdots O(NO_3^-)$ interactions. In fact, the area under the hump corresponds to two Cu···O interactions.

The $(D(r)-4\pi r^2\rho_o)$ curve for solution C was also well explained in terms of the formation of the $[CuNO_3(dmf)_5]^+$ complex having the distorted octahedral structure as has been seen in solution B.

The structure parameters for the $[CuNO_3(dmf)_5]^+$ in solutions B and C were optimized by least-squares calculations by using the data in the high-angle region of $s\cdot i(s)$ ($s \geqslant 4\times10^{-2}$ pm^{-1}) and the results are summarized in Table 2 (Columns B and C). Very similar results are obtained for both solutions. In the course of the calculation the $Cu\cdots N(NO_3^-)$ interaction was regarded as one of the four Cu···C(eq) interactions, since nitrogen atom is practically indistinguishable from carbon atom by the X-ray diffraction method and no significant error could be introduced by this simplification. Other assumptions adopted for the refinements are the same as those for solution A. The Cu-O(eq) and Cu-O(ax) bond lengths thus optimized are 201 (1) and 246 (4) pm, respectively.

Copper(II) Perchlorate DMF-AN Solutions. From the stability constants reported for copper(II)-dmf complexes in AN,[3] both $[Cu(dmf)_4]^{2+}$ and $[Cu(dmf)_6]^{2+}$ ions are expected to exist in solutions D and E.

The solid and chain lines in Fig. 5a represent the observed $(D(r)-4\pi r^2\rho_o)$ curve for solution D and the residual curve after subtraction of peaks due to the atom pairs within DMF, AN and perchlorate indicated in Fig. 5b from the original one, respectively. In

the residual curve three peaks appear around 200, 290, and 400 pm as seen in solutions A to C, which can be assigned to the Cu–O, Cu···C, and Cu···N interactions, respectively, in the equatorial plane, because the shape analysis of the peak at 200 pm gave the coordination number of four for the Cu–O bonds. On the other hand, no clear indication was obtained for the Cu–X(ax) bonds, where X denotes either oxygen atom within DMF or nitrogen atom within AN, over the region $r<300$ pm in contrast to the case of solutions A to C. Subtraction of peaks due to the Cu–O(eq), Cu···C(eq), O(eq)···O(eq), and Cu···N(eq) interactions led to the residual curve (dashed line in Fig. 5a), in which a small peak appearing at about 250 pm suggests that a part of copper(II) ions might have some interactions with the solvent molecules along the axis of copper(II) ion, but it is obvious that this peak is too small to conclude that all of copper(II) ions have the six-coordination structure as have been seen in solutions A to C.

The average scattering density ρ_o in a stoichiometric volume of solution D (1.993×10^{-4} pm^{-3}) is very close to the ρ_o value of solution B (1.934×10^{-4} pm^{-3}), and hence the background curves for both solutions should have the same feature. Therefore, the residual curve drawn by the dashed line in Fig. 5a, in which the Cu–X(ax) bonds were not taken into account, should overlap the one represented by the dotted line in Fig. 4a, which was obtained by taking the Cu–O(ax) bonds into consideration, in the region of $r<300$ pm. The two curves sufficiently fit each other and thus copper(II) ion in solution D is practically not solvated at the axial position within 300 pm.

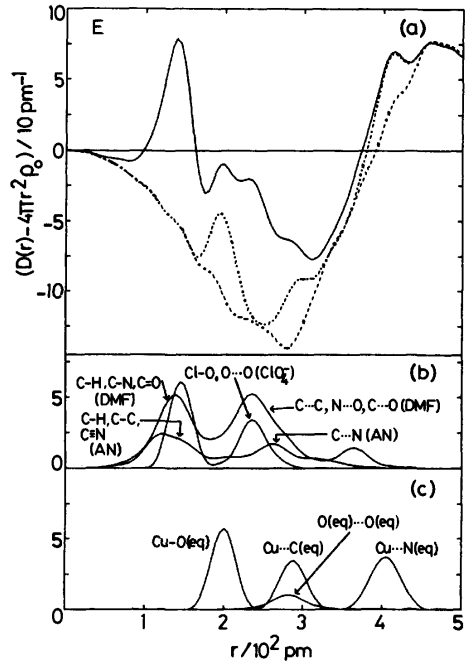

Fig. 6. (a); The $(D(r)-4\pi r^2\rho_o)$ curve for solution E. The chain line represents the residual curve after subtracting the theoretical peaks shown in (b). The dashed line indicates the residual curve after subtraction of the peak shapes due to the Cu–O(eq), Cu···C(eq), O(eq)···O(eq), and Cu···N(eq) interactions shown in (c). (b) and (c); The theoretical peak shapes of each atom pair.

Analysis of the $(D(r)-4\pi r^2\rho_o)$ curve shown in Fig. 6a for solution E, in which the concentration of DMF is higher than that in solution D, gave the similar result to that obtained for solution D. In the residual curve (dashed line) after subtraction of the peak shapes due to the intramolecular structure of DMF, AN and perchlorate and due to the Cu–O(eq), Cu···C(eq), O(eq)···O(eq), and Cu···N(eq) interactions, no distinct peak to be assignable to the Cu–X(ax) bonds was observed over the range $r<300$ pm. The X-ray scattering data for solution E colud be well reproduced by the same structural model as that for solution D and, therefore, we concluded that most of the solvated copper(II) ion in solutions D and E has the square-planar structure and solvent molecules do practically not coordinate to the copper(II) ion along the axis through the square-plane.

The structure parameters for the $[Cu(dmf)_4]^{2+}$ ion in DMF–AN mixtures were finally determined by least-squares calculations. The least-squares method was applied to the $s\cdot i(s)$ curve over the range $s\geqslant4\times10^{-2}$ pm^{-1} by using similar assumptions to those adopted for solutions A to C. The results obtained are listed in Table 3. The Cu–O(eq) distance is 200 (1) pm and practically the same as that within the $[Cu(dmf)_6]^{2+}$ ion in DMF.

In a previous calorimetric investigation of dilute solution of copper(II) ions in DMF–AN mixtures, formation of the $[Cu(dmf)_6]^{2+}$ complex is proposed in AN containing a large excess of DMF (ca. 1 mol dm^{-3}) compared with copper(II) ions.[3] In

DMF-AN mixtures of concentrated copper(II) perchlorate solutions which have relatively low C_{dmf}/C_{Cu} values of 5—7 examined in this study, the concentration of free DMF may not be sufficiently high to establish the equilibrium completely to the right-hand side

$$[Cu(dmf)_4]^{2+} + 2dmf \rightleftharpoons [Cu(dmf)_6]^{2+}$$

by forming the weak Cu-O(ax) bonds. Interactions between DMF and AN[19,20] may lower the activity of free DMF in the bulk of the mixture so as to prevent establishment of the equilibrium. Acetonitrile solvates copper(II) ion much more weakly than DMF does, and thus copper(II) ions in solutions D and E mainly exist as the square-planar $[Cu(dmf)_4]^{2+}$ species.

The work has been financially supported by the Grant-in-Aid for Special Project Research No. 61134043 from the Ministry of Education, Science and Calture. Computer calculations were carried out at the computer center of the Institute for Molecular Science in Okazaki.

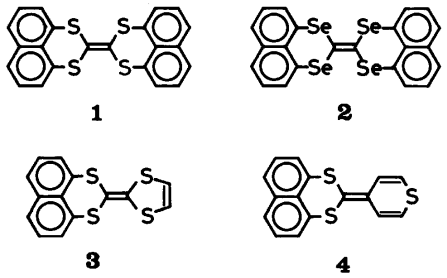
(Received October 3, 1987)

In order to discover new electron donors for conducting charge-transfer complexes, the four title compouds **1**—**4** composed of two heterocycles have been prepared via 1,8-dichalcogen-bridged naphthalene. The cyclic voltammetery indicates that symmetrical **1** and **2** are poor donors, but unsymmetrical **3** and **4** possess considerable donor abilities. The latter compounds are thus capable of forming some crystalline charge-transfer complexes with strong acceptors such as TCNQ, $TCNQF_4$, and DDQ, which are, however, semi-conducting.

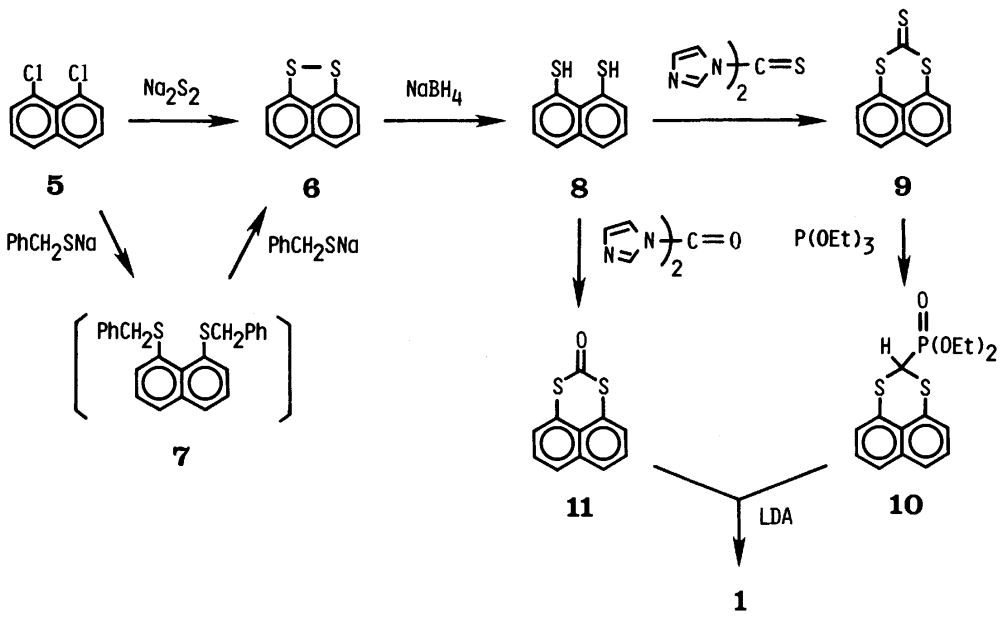
The discovery of tetrathiafulvalene (TTF) and tetraselenafulvalene (TSF), forming highly conducting charge-transfer salts, has stirred considerable interest in searching novel electron donors which have similar behavior.[1] 2,2′-Binaphtho[1,8-*de*]-1,3-dithiinylidene (**1**) and its selenium analog (**2**) involve not only six-membered heterocyclic fragments fused with a naphtho ring, but also the same tetrachalcogenaethylene skeleton as do TTF and TSF. From another viewpoint, they may be regarded as an extended type with ethylene conjugation of 1,8-dichalcogen-bridged naphthalenes, which have been noticeable as a novel class of donor.[2] These unique structural features have prompted us to examine the syntheses and properties of hitherto unknown **1** and **2**. In addition to the symmetrical series, we have studied two unsymmetrical compounds **3** and **4**, into which a structural fragment of TTF or bithiopyranylidene[3] is introduced as the counter heterocycle. They are also



interesting, since unsymmetrical donors often make better conductors than symmetrical ones.[4]

Results and Discussion

Syntheses: The synthetic route of the target molecule **1** is shown in Scheme 1. Nakayama et al. already reported a key intermediate **9**, which was, however, formed as a minor product on photolysis of

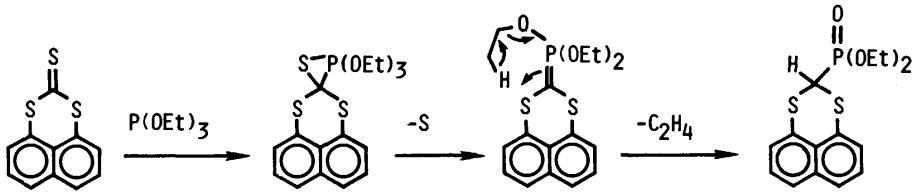


Scheme 1.

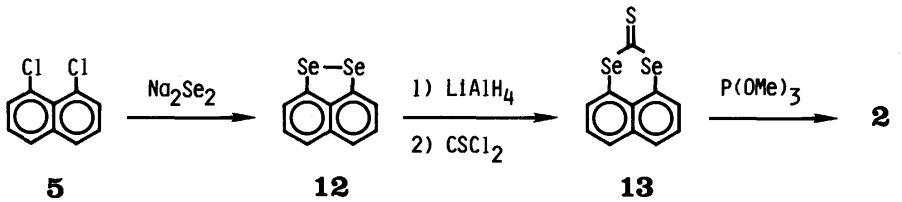
naphtho[1,8-*de*]-1,2,3-thiadiazine in carbon disulfide.[5] We have developed an alternative route to thione **9** via naphtho[1,8-*cd*]-1,2-dithiole (**6**), which is of choice on large-scale preparation. There have been known some methods in which the intermediate **6** may be formed, i.e., a direct thermal reaction of naphthalene and sulfur,[6] multistage reactions starting with diazotization of 8-aminonaphthalene-1-sulfonic acid,[7] and a reaction of 1,8-dilithionaphthalene with sulfur.[2] We have found that a nucleophilic substitution reaction of 1,8-dichloronaphthalene (**5**)[8] with sodium disulfide in hexamethylphosphoric triamide (HMPA) provide a convenient method of obtaining **6** (46% yield). However, it has later turned out that treatment of **5** with excess sodium α-toluenethiolate in HMPA gives a higher yield (78%) of **6** rather than 1,8-bis(benzylthio)naphthalene (**7**) as an expected product. This reaction is supposed to involve the initial substitution reactions to provide **7**, followed by reductive fission of the benzyl-S bond with excess sodium α-toluenethiolate and finally air-oxidation of the resulting 1,8-naththalenedithiolate forming S–S bond. Reduction of **6** with sodium borohydride in tetrahydrofuran-ethanol at RT gave almost quantitatively 1,8-naphthalenedithiol (**8**), which was subsequently treated with *N,N'*-thiocarbonyldiimidazole to afford **9** in 94% yield. Symmetrical TTF derivatives are generally prepared by desulfurizing coupling of two identical 1,3-dithiole-2-thiones using a phosphorus reagent.[9] However, all such conventional attempts to convert **9** into the target molecule **1** were unsuccessful. Treatment of **9** with triethyl phosphite at 110 °C gave diethyl [naphtho[1,8-*de*]-1,3-dithiin-2-yl]phosphonate (**10**) in 92% yield, though the other phosphorus reagents such as trimethyl phosphite and triphenylphosphine led to unidentified products. A plausible mechanism for the formation of **10** is shown in Scheme 2. However, **10** is available for another approach to **1** using a Wittig modification developed by Wadsworth and Emmons.[10] In this connection, naphtho[1,8-*de*]-1,3-dithiin-2-one (**11**) as a counterpart was prepared in 97% yield from a reaction of dithiol **8** and *N,N'*-carbonyldiimidazole. Thus, **10** was treated with lithium diisopropylamide at −78 °C to generate the corresponding phosphonate carbanion, which was then allowed to react with **11**, giving the desired product **1** in 92% yield.

The synthesis of the selenium analog **2** was carried out in a similar, but shorter route as shown in Scheme 3. Thus, a reaction of **5** with sodium diselenide in HMPA at 100 °C gave naphtho[1,8-*cd*]-1,2-diselenole (**12**) in 69% yield. The reduction of **12** with lithium aluminium hydride at RT in THF, followed by treatment with thiophosgene produced naphtho[1,8-*de*]-1,3-diselenin-2-thione (**13**) in 45% yield. In contrast to the above sulfur case, a reaction of **13** with trimethyl phosphite in toluene under reflux directly gave the desired product **2** in 66% yield.

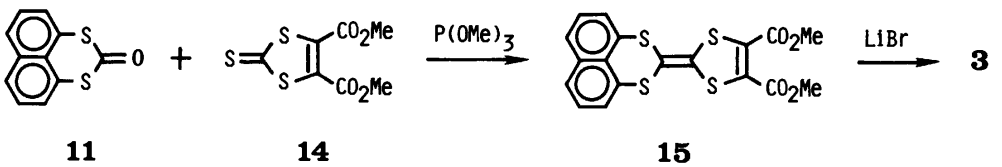
The synthetic route of unsymmetrical compound **3**



Scheme 2.



Scheme 3.

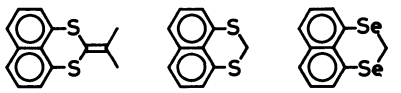


Scheme 4.

is shown in Scheme 4. A cross coupling reaction between **11** and dimethyl 2-thioxo-1,3-dithiole-4,5-dicarboxylate (**14**)[11] in benzene containing trimethyl phosphite at reflux smoothly proceeded to afford diester **15** in 45% yield. Hydrolysis/decarboxylation of **15** occurred on treatment with lithium bromide in HMPA at 150 °C, giving the desired compound **3** in 70% yield.

The synthetic route of another unsymmetrical compound **4** is shown in Scheme 5. The phosphonate carbanion from **10** was treated with 4*H*-thiopyran-4-one (**16**) to give tetrahydro derivative **17** in a quantitative yield. Direct conversion of **17** to **4** using chloranil or DDQ as a dehydrogenating agent failed. We then adopted a stepwise route via the conversion of sulfoxide to vinyl sulfide according to the procedure of Miller and Mckean.[12] Thus, sulfide **17** was oxidized with *m*-chloroperbenzoic acid in dichloromethane at RT to sulfoxide **18** in 63% yield, which was subsequently treated with *N,N′*-diisopropylethylamine and iodotrimethylsilane in dichloromethane at 0 °C to give dihydro derivative **19** in 86% yield. The same reactions were repeated for **19**, giving the desired product **4** in 43% overall yield.

In addition, three reference compounds **21**—**23** were prepared for spectroscopic comparison. Thus, **21** was accessible in 95% yield from a reaction between the phosphonate anion of **10** and acetone. Compounds **22** and **23** were obtained from treatment of diiodomethane with 1,8-naphthalenedithiolate in 26% yield and with the diselenolate in 32% yield, respectively.



21 **22** **23**

Properties: Table 1 summarizes the UV data as well as oxidation potentials of **1**—**4** together with reference compounds **21**—**23**. All the compounds **1**—**4** have two strong absorptions around 240 and 350 nm in the electronic spectra. The longer wavelength absorptions extend to visible regions, resulting in yellow or orange coloration. These absorptions very closely resemble the corresponding ones of reference compounds **21**—**23** in wavelength except in intensity. This evidently indicates that the principal chromophor is 1,8-dichalcogenonaphthalene and an extended

Table 1. UV Data and Oxidation Potentials of **1**—**4** and Reference Compounds **22**—**24**

Compound	Absorption maximum/nm (Intensity/ε)[a]	Oxidation peak/V[b]
1	239(56600), 352(30700)	1.19(1.14)[c]
2	244(47500), 352(25800)	1.17
3	243(33100), 326(21400), 339sh(13800)	0.87(0.79)[c], 1.22
4	244(31500), 354(38800)	0.66(0.76)[c], 1.08
21	246(36300), 268sh(6100), 337sh(10500), 350(11600)	1.28
22	246(26400), 274(2190), 339sh(9890), 348(10800)	1.36
23	255(14200), 354(9250)	1.21

a) Measured in tetrahydrofuran. b) Measured at 100 mV s^{-1} scan rate in benzonitrile solution (10^{-3}—10^{-4} mol dm^{-3} with added tetrabutylammonium perchlorate (0.1 mol dm^{-3}) using a Ag/AgCl reference electrode and platinum working and counter electrodes. c) Values in parentheses indicate half-wave oxidation potentials.

Table 2. Charge-Transfer Complexes of **3** and **4**

Complex	Appearance	DP[a]/°C	Found (Calcd)[c]/%			Conductivity[d]/S cm^{-1}
			C	H	N	
3·DDQ	Dark brown powder from chloroform	220	49.10 (49.72	1.45 1.52	5.20 5.27)	2.3×10^{-7}
3·$TCNQF_4$	Dark green powder from chloroform	187—188[b]	53.78 (53.79	1.33 1.39	9.48 9.65)	4.4×10^{-3}
4·DDQ	Black powder from acetonitrile	130	54.35 (54.86	1.88 1.92	5.95 5.33)	6.5×10^{-5}
4·TCNQ	Black needles from acetonitrile	179—184[b]	66.87 (66.91	2.94 2.81	10.39 11.15)	6.8×10^{-8}
4·$TCNQF_4$	Deep green powder from acetonitrile	225	58.76 (58.53	1.68 1.75	9.67 9.75)	1.8×10^{-7}

a) Decomposition temperature. b) With melt. c) Calculated as 1:1 stoichiometry of donor and acceptor. d) Measured on compressed pellets with a two-probe method at room temperature.

conjugation through the central olefin between the two chromophors is not significant. A structural consideration of **1** and **2** on a molecular model favors nonplanar conformers which are somewhat bent at the sulfur or selenium atoms. This nonplanarity is certainly responsible for reduction in extended conjugation.

The cyclic voltammetry of **21—23** demonstrates irreversible oxidation at 1.21—1.36 V vs. Ag/AgCl reference electrode in benzonitrile. On the other hand, **1** undergoes oxidation at a somewhat lower potential (1.19 V) and keeps a reversible redox cycle with a half-wave potential at 1.14 V, which is, however, still too high as an electron donor. The somewhat easier oxidation of **1** and the higher stability of the resulting radical cation, contrary to the above spectroscopic discussion, suggest the existence of some conjugation through the central olefin. The selenium analog **2** unlike **1** shows an irreversible oxidation, whose peak potential (1.17 V) is the almost same as that of **1** or a reference compound **23**. Thus, the substitution of selenium for sulfur in **1** does not serve to enhance its donor character, but rather leads to ready decomposition of the radical cation owing to introduction of labile C–Se bond relative to C–S bond. On the other hand, unsymmetrical compounds **3** and **4** have two oxidation steps, the first of which is reversible and the second is irreversible. The first oxidation potentials (0.87 V for **3** and 0.66 V for **4**) are drastically lower than those of **1** and **2**. Since the counter heterocyclic fragments can take aromatization in the oxidation state, i.e., 1,3-dithiolylium and thiopyranylium cations, they certainly make a significant contribution to the ready oxidations.

Owing to their poor donor strength, **1** and **2** could not form any charge-transfer complexes even with strong electron acceptors such as 7,7,8,8-tetracyanoquinodimethane (TCNQ), 2,3,5,6-tetrafluoro-7,7,8,8-tetracyanoquinodimethane ($TCNQF_4$), and 2,3-dichloro-5,6-dicyano-*p*-benzoquinone (DDQ). On the other hand, **3** and **4** bearing improved donor abilities formed deeply colored 1:1 charge-transfer complexes with such acceptors. As summarized in Table 2, the electrical conductivities measured on compressed pellets with a two probe method are 10^{-3}—10^{-8} S·cm^{-1}. This semi-conducting behavior suggests a mixed stacking mode of alternate donor and acceptor in the crystal structures.[13]

Experimental

General. Melting points are uncorrected. All solvents are of reagent grades. NMR measurements were made on a JEOL PMX-60 (60 MHz) or a Bruker-WM 360 spectrometer (360 MHz) using TMS as an internal standard. IR spectra were taken on a Hitachi 260-30 spectrophotometer, and MS spectra on a JEOL JMS-DX 300 spectrometer at 70 eV using a direct insertion technique. Electronic spectra were recorded on a JASCO UVIDEC-610A spectrophotometer. Cyclic voltammetry was performed on a Hokuto Denko HA-301 potentiostat and a Hokuto Denko HB-104 function generator.

Naphtho[1,8-*cd*]-1,2-dithiol (6). A) With Sodium α-Toluenethiolate. Into a stirred solution of sodium α-toluenethiolate, which was in situ prepared from α-toluenethiol (42.3 cm^3, 0.36 mol) and sodium hydride (60% oily, 15.8 g, 0.40 mol) in HMPA (400 cm^3), was added a solution of 1,8-dichloronaphthalene (**5**)[7] (11.8 g, 60 mmol) in HMPA (50 cm^3) under argon. The mixture was heated at 160—165 °C for 17 h and cooled to RT. After water (500 cm^3) was added, it was vigorously stirred with bubbling air for 20 h, poured into water, and extracted with benzene. The extract was thoroughly washed with water, dried ($MgSO_4$), and concentrated in vacuo. The resulting solid was purified by column chromatography on silica gel with hexane and then recrystallization from hexane to give **6** as

reddish brown plates (8.95 g, 78%): 123 °C (lit,[6] 116 °C); ^{1}H NMR (60 MHz, CCl_4) δ=7.1—7.7 (ABC m).

B) With Sodium Disulfide. A mixture of sulfur (48 mg, 1.5 mmol) and sodium (38 mg, 1.65 mmol) was heated at 110 °C in dry HMPA (3 cm^3) for 2.5 h under argon. Into the resulting blue solution of sodium disulfide was added a solution of **5** (99 mg, 0.5 mmol) in dry HMPA (2 cm^3). The mixture was heated at 150 °C for 27 h, poured into water, and extracted with benzene. In the same way as described in Method A, compound **6** was obtained from the extract (44 mg, 46%).

1,8-Naphthalenedithiol (8). A solution of **6** (9.51 g, 500 mmol) in dry THF (100 cm^3) was added into an ice-cooled suspension of sodium borohydride (5.00 g, 132 mmol) in ethanol (90 cm^3) under argon. The mixture was stirred for 30 min, quenched with 10% HCl, and extracted with chloroform. The extract was washed with water, dried ($MgSO_4$), and concentrated in vacuo to give **8** (9.45 g, 98%). Recrystallization from THF-hexane in an argon atmosphere afforded colorless leaflets: mp 122 °C (lit,[5b] 115 °C); IR(KBr) 2450, 2520 cm^{-1} (S-H); ^{1}H NMR (60 MHz, CCl_4) δ=3.97 (s, 2H), 6.95—7.65 (ABC m, 6H).

Naphtho[1,8-*de*]-1,3-dithiin-2-thione (9). A solution of *N,N′*-thiocarbonyldiimidazole (1.39 g, 7.04 mmol) in dry THF (30 cm^3) was slowly added into a stirred solution of **8** (1.22 g, 6.40 mmol) in dry THF (30 cm^3) at −15—−20 °C under argon. The mixture was gradually warmed to RT and allowed to stand overnight. After concentration in vacuo, the resulting solid was dissolved in chloroform, washed with water, and dried ($MgSO_4$). The solvent was evaporated, and column chromatography of the residue on silica gel with benzene gave **9** (1.40 g, 94%): orange needles from benzene-hexane, mp 201—202 °C (lit,[4] 199—201 °C); IR(KBr) 1040 cm^{-1} (C=S); ^{1}H NMR (60 MHz, $CDCl_3$) δ=7.1—7.7 (ABC m).

Diethyl [Naphtho[1,8-*de*]-1,3-dithiin-2-yl]phosphonate (10). Thione **9** (113 mg, 0.482 mmol) was heated at 110 °C in triethyl phosphite (6 cm^3) for 2 h under argon. After concentration in vacuo, the residue was filtered through a short column of silica gel with chloroform and then recrystallized from benzene-hexane to give **10** as colorless columns (150 mg, 92%): mp 120 °C; IR (KBr) 1243 (P=O), 1030, 1010, 970, 950 cm^{-1} (P-O-C); ^{1}H NMR (60 MHz, CCl_4) δ=1.20 (t, J_{CH-CH}=7.4 Hz, 6H), 4.02 (d, J_{CH-P}=17 Hz, 1H), 7.2—7.7 (m, 6H); Anal. ($C_{15}H_{17}O_3S_2P$) C, H.

Naphtho[1,8-*de*]-1,3-dithiin-2-one (11). A solution of *N,N′*-carbonyldiimidazole (357 mg, 2.2 mmol) in dry THF (15 cm^3) was slowly added into a stirred solution of **8** (385 mg, 2.0 mmol) in dry THF (30 cm^3) at −15 °C under argon. The mixture was warmed to RT and allowed to stand for several hours. After concentration in vacuo, the resulting solid was filtered through a short column of silica gel with hexane-benzene (1:1) and recrystallized from benzene-hexane to give **11** as colorless needles (391 mg, 97%): mp 140 °C; IR (KBr) 1630 cm^1 (C=O); ^{1}H NMR (60 MHz, CCl_4) δ=7.1—7.7 (ABC m); Anal. ($C_{11}H_6OS_2$) C, H.

2,2′-Binaphtho[1,8-*de*]-1,3-dithiinylidene (1). A solution of LDA (1 mol m^{-3}, 1.05 cm^3) in THF-hexane (1:2.7) was dropwise added into a stirred solution of **10** (340 mg, 1.0 mmol) in dry THF (10 cm^3) at −78 °C during 10 min under argon. A solution of **11** (240 mg, 1.1 mmol) in dry THF (6 cm^3) was successively added, and then the mixture was gradually warmed to 0 °C. The resulting precipitate was collected by filtration, washed with water, and dried. Recrystallization from carbon disulfide gave pale yellow fine prisms of **1** (372 mg, 92%): mp 297 °C; ^{1}H NMR (360 MHz, CS_2) δ=7.22—7.28 (m, 8H), 7.486 (dd, J=7.37 and 1.92 Hz, 4H); MS *m/z* 404 (M$^+$); Anal. ($C_{22}H_{12}S_4$) C, H.

Naphtho[1,8-*cd*]-1,2-diselenole (12). A mixture of selenium powder (4.03 g, 51 mmol) and sodium (1.17 g, 51 mmol) was heated at 120 °C in dry HMPA (35 cm^3) for 4 h under argon. Into the resulting reddish brown solution of sodium diselenide was added a solution of **5** (2.95 g, 15 mmol) in dry HMPA (15 cm^3). The mixture was heated at the same temperature for additional 19 h, poured into water (450 cm^3), and extracted with benzene. The extract was thoroughly washed with water, dried ($MgSO_4$), and concentrated in vacuo. The residual solid was purified by column chromatography on silica gel with benzene and then gel-permeation liquid chromatography with chloroform to give **12** (2.95 g, 69%): deep violet needles from hexane, mp 124 °C (lit,[2] 127—129 °C); ^{1}H NMR (60 MHz, CCl_4) δ=7.1—7.7 (ABC m).

Naphtho[1,8-*de*]-1,3-diselenin-2-thione (13). Compound **12** (142 mg, 0.50 mmol) was treated with LAH (10.4 mg, 0.275 mmol) in dry THF (7 cm^3) for 40 min at RT. Into the mixture at −30—−40 °C was slowly added a solution of thiophosgene (46 mm^3, 0.60 mmol) in dry THF (7 cm^3). The mixture was gradually warmed to RT and stirred further 1.5 h. After concentration, the residue was poured into aq. satd. ammonium chloride and extracted with chloroform. The extract was washed with water, dried ($MgSO_4$), and evaporated. The resulting solid was purified by column chromatography on silica gel with hexane and then gel-permeation liquid chromatography to give **13** (74 mg, 45%): orange needles from hexane, mp 153—154 °C; IR (KBr) 1021 cm^{-1} (C=S); ^{1}H NMR (60 MHz, $CDCl_3$) δ=7.2—7.9 (ABC m); Anal. ($C_{11}H_6SSe_2$) C, H.

2,2′-Binaphtho[1,8-*de*]-1,3-diseleninylidene (2). A mixture of **13** (73 mg, 0.22 mmol), trimethyl phosphite (0.10 cm^3, 0.88 mmol), and toluene (3 cm^3) was heated at reflux for 4 h. The resulting precipitate was collected by filtration, washed with cold acetone, and recrystallized from toluene to give pale yellow fine crystals of **2** (43 mg, 66%): mp 287—287.5 °C; ^{1}H NMR (360 MHz, CS_2) δ=7.286 (t, J=7.7 Hz, 4H), 7.476 (bd, J=7.3 Hz, 4H), 7.610 (bd, J=8.1 Hz, 4H); MS *m/z* 594 (M$^+$); Anal. ($C_{22}H_{12}Se_4$) C, H.

2-[4,5-Bis(methoxycarbonyl)-1,3-dithiol-2-ylidene]naphtho[1,8-*de*]-1,3-dithiin (15). A mixture of **11** (1.53 g, 7 mmol) and dimethyl 2-thioxo-1,3-dithiol-4,5-dicarboxylate (**14**)[10] (3.50 g, 14 mmol) was refluxed in dry benzene (50 cm^3) containing trimethyl phosphite (21 cm^3) for 1.5 h under argon. After concentration in vacuo, the residue was chromatographed on silica gel with benzene to give **15** (1.31 g, 45%): orange fine needles from hexane-benzene, mp 217—218 °C; IR (KBr) 1730, 1710 cm^{-1} (C=O); ^{1}H NMR (60 MHz, $CDCl_3$) δ=3.80 (s, 6H), 7.2—7.8 (m, 6H); Anal. ($C_{18}H_{12}O_4S_4$) C, H.

2-(1,3-Dithiol-2-ylidene)naphtho[1,8-*de*]-1,3-dithiin (3). A solution of diester **15** (1.31 g, 3.12 mmol) and lithium bromide monohydrate (3.27 g, 31.2 mmol) in HMPA (50 cm^3) was heated at 100 °C for one h and then at 150 °C for another h. The mixture was cooled to RT, poured into

water, and extracted with benzene. The extract was washed with water, dried ($MgSO_4$), and concentrated in vacuo. The residue was chromatographed on silica gel with hexane–benzene (1:1) to give **3** (0.66 g, 70%): lemon yellow prisms from benzene–hexane, mp 173.5—175 °C; ^{1}H NMR (60 MHz, $CDCl_3$) δ=6.33 (s, 2H), 7.2—7.8 (m, 6H); MS *m/z* 304 (M^+); Anal. ($C_{14}H_8S_4$) C, H.

2-(Tetrahydro-4*H*-thiopyran-4-ylidene)naphtho[1,8-*de*]-1,3-dithiin (17). A hexane solution of butyllithium (1.6 mol dm^{-3}, 9.4 cm^3, 15 mmol) was dropwise added into a stirred solution of **10** (5.11 g, 15 mmol) in dry THF (200 cm^3) at −78 °C under argon. A solution of 4*H*-thiopyran-4-one (**16**) (1.92 g, 16.5 mmol) in dry THF (30 cm^3) was subsequently added. The mixture was warmed to RT over a period of 3 h. After the solvent was evaporated, the residue was dissolved in chloroform, washed with brine, and dried ($MgSO_4$). After concentration, the residue was chromatographed on silica gel with benzene to give **17** (4.49 g, 99%): colorless plates from hexane, mp 142—143 °C; ^{1}H NMR (60 MHz, CCl_4) δ=2.85 (A_2B_2 m, 8H), 7.1—7.6 (ABC m, 6H); Anal. ($C_{16}H_{14}S_3$) C, H.

4-[Naphtho[1,8-*de*]-1,3-dithiin-2-ylidene]tetrahydro-4*H*-thiopyran *S*-Oxide (18). A solution of MCPBA (4.0 g, 23.2 mmol) in dichloromethane (20 cm^3) was dropwise added into a solution of **17** (4.54 g, 15 mmol) in dichloromethane (100 cm^3) at −15—−20 °C. The mixture was stirred at 0 °C for 2 h and then at RT for 30 min. It was successively washed with aq. satd. $NaHSO_3$, aq. 5% $NaHCO_3$, and water. The solution was dried ($MgSO_4$) and concentrated in vacuo. The residue was chromatographed on silica gel with chloroform to give **18** (3.0 g, 63%): colorless leaflets from benzene–hexane, mp 203—206 °C; ^{1}H NMR (60 MHz, $CDCl_3$) δ=2.95 (A_2B_2 m, 8H), 7.2—7.8 (ABC m, 6H); Anal. ($C_{16}H_{14}OS_3$) C, H.

2-(2,3-Dihydro-4*H*-thiopyran-4-ylidene)naphtho[1,8-*de*]-1,3-dithiin (19). Iodotrimethylsilane (3.58 cm^3, 25.2 mmol) was dropwise added into a stirred solution of **18** (4.0 g, 12.6 mmol) and *N*,*N*-diisopropylethylamine (4.81 cm^3, 27.6 mmol) in dry dichloromethane (100 cm^3) at 0 °C under argon. The mixture was stirred at 0 °C for 4 h and then at RT for 2 h, diluted with ether (100 cm^3), and poured into 10% sulfuric acid. The organic layer was separated, succesively washed with aq. 5% $NaHCO_3$ and with water, and dried ($MgSO_4$). After concentration in vacuo, the residual solid was chromatographed on silica gel with chloroform to give **19** (3.25 g, 86%): pale yellow leaflets from benzene–hexane, mp 117—118 °C; ^{1}H NMR (60 MHz, $CDCl_3$) δ=2.97 (A_2B_2 m, 4H), 6.35 (d, J=10 Hz, 1H), 6.99 (d, J=10 Hz, 1H), 7.1—7.8 (ABC m, 6H); Anal. ($C_{16}H_{12}S_3$) C, H.

4-[Naphtho[1,8-*de*]-1,3-dithiin-2-ylidene]-2,3-dihydro-4*H*-thiopyran *S*-Oxide (20). Compound **20** was obtained in 63% yield by oxidation of **19** with MCPBA in a similar manner as described for the synthesis of **18**: pale yellow crystals from acetone–dichloromethane, mp 158—160 °C; ^{1}H NMR (60 MHz, $CDCl_3$) δ=3.0 (A_2B_2 m, 4H), 6.42 (d, J=10 Hz, 1H), 7.0—7.8 (m, 7H); Anal. ($C_{16}H_{12}OS_3$) C, H.

2-(4*H*-Thiopyran-4-ylidene)naphtho[1,8-*de*]-1,3-dithiin (4). Compound **4** was obtained in 68% yield from **20** by the same method as described for the conversion of **18** into **19**: orange needles from benzene–hexane, mp 155—157 °C; ^{1}H NMR (60 MHz, $CDCl_3$) δ=6.37 (d, J=10 Hz, 2H), 7.0—7.8 (m, 8H); Anal. ($C_{16}H_{10}S_3$) C, H.

2-Isopropylidenenaphtho[1,8-*de*]-1,3-dithiin (21). Into a solution of **10** (42 mg, 0.12 mmol) in dry THF (2 cm^3) at −78 °C under argon were dropwise added a solution of LDA (1 mol m^{-3}, 0.13 cm^3) in THF–hexane (1:2.7) and subsequently a solution of acetone (9:6 mm^3, 0.13 mmol) in dry THF (0.5 cm^3). The mixture was gradually warmed to RT, poured into aq. satd. ammonium chloride, and extracted with chloroform. The extract was washed with water, dried ($MgSO_4$), and concentrated in vacuo. The residue was chromatographed on silica gel with hexane to give **21** (28 mg, 95%): colorless prisms from hexane, mp 106 °C; ^{1}H NMR (60 MHz, CCl_4) δ=2.06 (s, 6H), 7.1—7.6 (ABC m, 6H); Anal. ($C_{14}H_{12}S_2$) C, H.

Naphtho[1,8-*de*]-1,3-dithiin (22). A solution of **8** (1.05 g, 5.26 mmol) and diiodomethane (1.41 g, 5.26 mmol) in dry THF (300 cm^3) was dropwise added into a stirred suspension of sodium hydride (60% oily, 505 mg, 12.6 mmol) in dry THF (100 cm^3) at RT under argon. The addition took 40 h. After the addition, stirring was continued further 6 h. The reaction mixture was concentrated in vacuo, poured into water, and extracted with chloroform. The extract was washed with water, dried ($MgSO_4$), and concentrated. The residue was chromatographed on silica gel with hexane–benzene to give colorless plates of **22** (280 mg, 26%): mp 124—125 °C; ^{1}H NMR (60 MHz, CCl_4) δ=4.01 (s, 2H), 6.95—7.70 (ABC m, 6H); Anal. ($C_{11}H_8S_2$) C, H.

Naphtho[1,8-*de*]-1,3-diselenin (23). A solution of **12** (568 mg, 2.0 mmol) in dry THF (25 cm^3) was slowly added into a stirred suspension of sodium borohydride (267 mg, 7.06 mmol) in ethanol (8 cm^3) at RT under argon. It was then transferred into a dropping funnel. A solution of diiodomethane (836 mg, 3.2 mmol) in dry THF (25 cm^3) was placed in another dropping funnel. Both solutions were simultaneously added into a stirred THF solution (10 cm^3) at RT over a period of 3 h. The mixture was concentrated, dissolved in chloroform, and washed with water. After it was dried ($MgSO_4$) and again concentrated, the residue was purified by column chromatography on silica gel with hexane–chloroform (1:1) and then gel-permeation liquid chromatography with chloroform to give **23** (190 mg, 32%): pale orange leaflets from hexane, mp 128.5 °C; ^{1}H NMR (60 MHz, CCl_4) δ=3.91 (s and t, J_{Se-C-H}=7 Hz, 2H), 7.0—7.7 (ABC m, 6H); Anal. ($C_{11}H_8Se_2$) C, H.

Preparation of Charge-Transfer Complexes. All CT complexes described in this paper were prepared by mixing the two hot saturated solutions of donor and acceptor in chloroform or acetonitrile. The deeply colored complexes precipitated out immediately or on cooling in a refrigerator, which were collected by filtration.

This work was partially supported by a Grant-in-Aid of Scientific Research No. 62550635 from the Ministry of Education, Science and Culture, Japan and Mazda Foundation's Research Grant.

Liquid-Phase Dehydrogenation of 2-Propanol by Suspended Nickel Fine-Particle Catalyst

Michio NODA, Sumio SHINODA,† and Yasukazu SAITO*
Institute of Industrial Science, University of Tokyo, 22-1 Roppongi 7 Chome, Minato-ku, Tokyo 106
(Received June 26, 1987)

Nickel fine particles that were prepared by a gas evaporation method were used to catalyze the liquid-phase dehydrogenation of 2-propanol efficiently in the suspended state. Rate retardation due to the product acetone without catalytic-site deactivation was confirmed kinetically. High reaction rates were attained under the boiling conditions and a reasonable activation energy as well as adsorption heat of acetone was obtained. A useful application of the present catalytic process is proposed.

Dehydrogenation of 2-propanol in gas phase

$$(CH_3)_2CHOH \longrightarrow (CH_3)_2CO + H_2 \quad (1)$$

is unfavored thermodynamically below 202 °C, at which $\Delta G°$(gas) becomes zero.[1] Reactions over zinc oxide or other heterogeneous catalysts that yielded acetone and hydrogen required a rather high temperature (e.g., 350 °C for ZnO).[2]

When homogeneous[3–7] or heterogeneous[8–14] catalysts were used in the liquid phase, however, Reaction 1 proceeded at a moderate temperature (e.g., 82.4 °C for Raney Ni),[8,10] since hydrogen dissolved slightly in the solvent[15] and was easily separated as a gaseous substance.

Among solid catalysts active in the suspended state, nickel fine particles prepared by a gas evaporation method[16,17] have attracted our attention[14] on account of the following characteristics:[18,19]

1) Highly-crystallized spherical particles.
2) Sharp particle-size distribution.
3) Large specific surface area without pores.
4) High chemical purity except for surface oxide.
5) Stability of the suspended state in some polar solvents.

In the present study, the dehydrogenation of 2-propanol with a suspended nickel fine-particle catalyst was investigated from a kinetical viewpoint in order to explore useful applications.

Experimental

Catalyst. Fine particles of nickel were obtained as a soot-like product by evaporating molten nickel metal (99.99% pure) in an argon atmosphere.[16] They were slowly oxidized with nitrogen-diluted air to form thin surface oxide layers. These layers prevent the particles from deep oxidation at room temperature in air. According to electron micrographic measurements, nonporous highly-crystallized spherical particles with a sharp size distribution (average diameter: 19.7 nm) were prepared.[16] The surface-oxidized particles (oxygen content: 10 wt%) gave a BET specific surface area of 43.8 $m^2 g^{-1}$.[20]

Apparatus. Prior to the reaction, a heating treatment under a hydrogen atmosphere was required in order to disclose active sites by reducing the surface oxide.[21] A closed system consisting of a round-bottom three-neck flask (300 ml) and a gas buret (500 ml) was adopted for measuring hydrogen consumption. A flask containing the reduced catalyst and the reactant 2-propanol inside was connected to another set of gas burets (500 ml and 1 l) through a water-cooled condenser. In this closed system the gaseous product was pursued volumetrically.

An open-ended system was used for a long-period run, in which a round-bottom three-neck flask was connected to a gas-flow meter (STEC Inc., SEF series) and a gas sampler (Gasukuro Kogyo Inc., GS-5000 A). A data processor (Eto Denki Co., Thermodac 32) recorded time-sequentially such reaction data as the flow rate of the gaseous product and the temperature, either inside or outside the flask. The gaseous components were monitored by a gas chromatograph (Shimadzu Co., GC-8APT) with a peak integrator (Shimadzu Co., CR-2A) assisted.

Procedure. A prescribed amount (200 mg) of the nickel fine particles in the flask was heated under hydrogen up to 160 °C in 15 min, held at 160 °C for 1 min and rapidly cooled.[22]

After reduction and evacuation of the nickel fine particles, the flask was filled with the degassed 2-propanol reactant (200 ml) under an argon or nitrogen atmosphere and treated for dispersion with an ultrasonic vibration cleaner (Sharp Co., UTB-152) at room temperature for 1 min.

The reaction proceeded by heating the suspension under boiling conditions. The rate of hydrogen evolution was determined from the volumetric accumulation of hydrogen in the closed apparatus or pursued with a flow meter in the open-ended system. The temperature dependence of the reaction rate was examined by the addition of hexane to 2-propanol in order to decrease the boiling point.[11]

Products were analyzed by gas chromatography using active carbon (gas phase) and PEG 1000 (liquid phase) columns.

Results and Discussion

1. Dispersion Stability of the Nickel Fine Particles in 2-Propanol. The nickel fine particles were easily suspended in 2-propanol through an ultrasonic treatment. The suspension was sufficiently stable.

As shown in Fig. 1a, sedimentation of the nickel

† Present address: Department of Industrial Chemistry, Faculty of Engineering, Seikei University, 3-1 Kichijyoji-Kitamachi 3 Chome, Musashino-Shi, Tokyo 180.

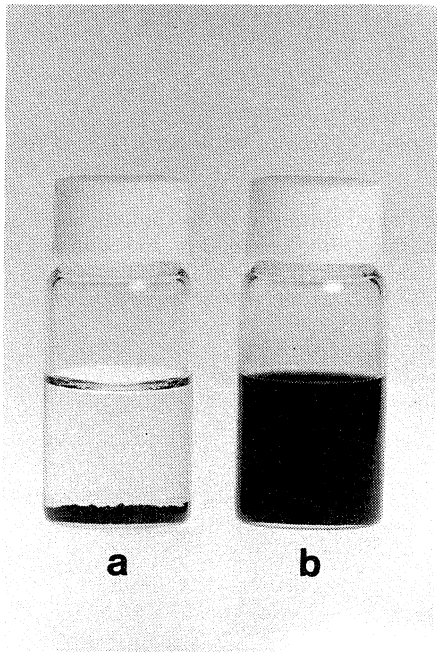

Fig. 1. Effect of the ultrasonic treatment on dispersion of nickel fine particles in 2-propanol.
(a) Effect of vigorous hand-shaking on the nickel fine particles (5 mg) in 2-propanol (5 ml). (b) Effect of the ultrasonic treatment on the same materials.

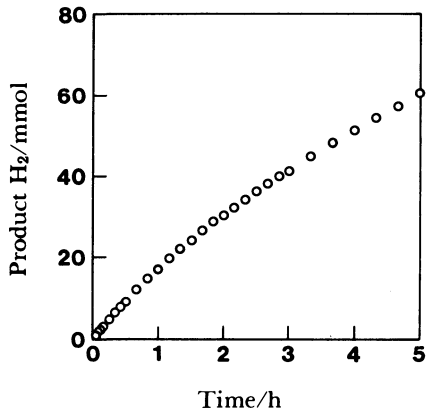

Fig. 2. Time course of H_2 evolution by liquid-phase dehydrogenation of 2-propanol with the nickel fine-particle catalyst under boiling conditions.
Nickel fine-particle catalyst (200 mg) suspended in 2-propanol (200 ml).

fine particles took place rapidly, when both materials (nickel 5 mg/2-propanol 5 ml) were hand-shaked vigorously. On the other hand, an ultrasonic treatment at a room temperature for 1 min resulted in a well-dispersed state (Fig. 1b). Without stirring, partial sedimentation was observed after 24 h. Continuous stirring with a conventional magnetic stirrer (1500 rpm) was sufficient for retaining the suspended state for a long period. The adopted stirring conditions were ascertained to sufficiently agitate the suspension, since the total time courses of hydrogen evolution were well-reproduced at different stirring rates.[23]

The ultrasonic treatment gave a stable suspension that could be maintained for 24 h or more by using the following solvents: dimethyl sulfoxide, *N*,*N*-dimethylformamide, bis(2-methoxyethyl) ether, methanol and cyclohexanol. On the contrary, sedimentation started within 1 h in suspensions of hexane, cyclohexane, toluene, ethylbenzene, triethylamine, diethyl ether, ethyl acetate, chloroform, carbon tetrachloride, nitromethane, tetrahydrofuran, acetone, and ethanol. Ethylene glycol, acetonitrile, 2-butanone, cyclohexanone, acetic acid, formic acid, and water gave an intermediately-stable suspension.

Since a well-dispersed state is important in liquid-phase reactions, nickel fine particles suspended in 2-propanol are of interest as a catalyst for Reaction 1.

2. Effect of Acetone on the Rate of 2-Propanol Dehydrogenation. The dehydrogenation of 2-propanol with suspended nickel fine particles gave no other reaction product than hydrogen and acetone gas-chromatographically.[14] Since only hydrogen passed the condenser, acetone gradually accumulated during the reaction. The concentration of 2-propanol remained almost constant, since it was used both as the solvent and as the reactant.

The time course of hydrogen evolution is shown in Fig. 2. A gradual decrease of the reaction rate observed regarding the nickel catalysts was similarly ascribed to a product retardation. The reaction rates were well-expressed by

$$v = k/(1 + K[\text{acetone}]), \quad (2)$$

where k was a rate constant and K was an equilibrium constant of acetone adsorption.[8-11] A linear correlation of the inverse rate with the product acetone can be derived from Eq. 2:[11]

$$1/v = 1/k + (K/k)[\text{acetone}],$$

which was verified to hold for a nickel fine-particle catalyst. The time course of Fig. 2 was converted into Fig. 3 as a function of the acetone. The retardation effect of acetone was ascertained by the following experimental approaches.

In the first place, the effect of acetone on a fresh catalyst was examined. In a reference experiment (Fig. 4a) the reaction started with neat 2-propanol and the product acetone accumulated up to 5.0% after 6 h. The 2-propanol/acetone premixed solvent prepared to be 5.0% of acetone was then used for the reaction (Fig. 4b). The initial rate of the latter was almost the same as the final rate of the former. Acetone was thus responsible for the rate decrease.

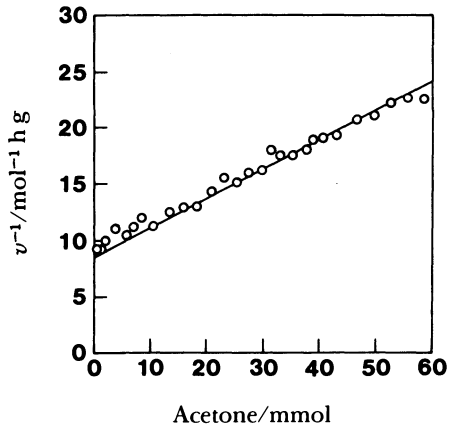

Fig. 3. Rate analysis of Fig. 2 on the postulate of acetone retardation.

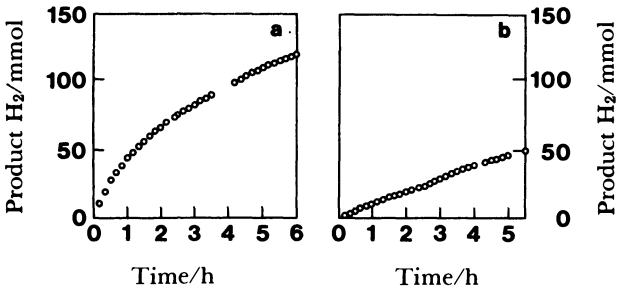

Fig. 4. Effect of initial addition of acetone on the liquid-phase dehydrogenation of 2-propanol with the nickel fine-particle catalyst.
Nickel fine particle catalyst (1.00 g) reduced on the severe conditions and suspended in (a) 2-propanol (200 ml) or (b) 2-propanol containing acetone (200 ml in total) prepared by initial addition of acetone upto the same concentration (5.0%) as in suspension a after the 6-h reaction.

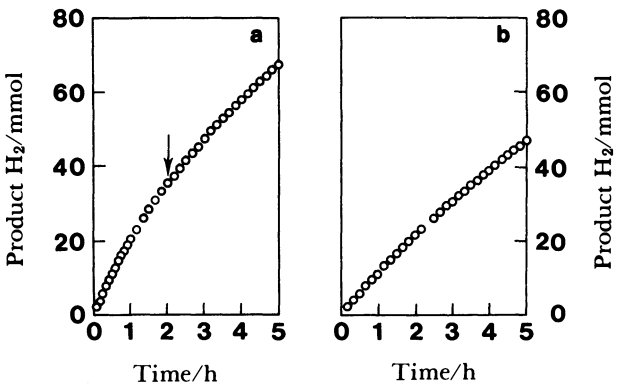

Fig. 5. Effect of partial removal of acetone on the liquid-phase dehydrogenation of 2-propanol with the nickel fine-particle catalyst.
(a) Nickel fine-particle catalyst (200 mg) suspended in 2-propanol (200 ml). (b) Partial solvent removal from suspension a after the 5-h reaction and the replenishment with neat 2-propanol to the same acetone concentration as the arrow-indicated level (1.2%).

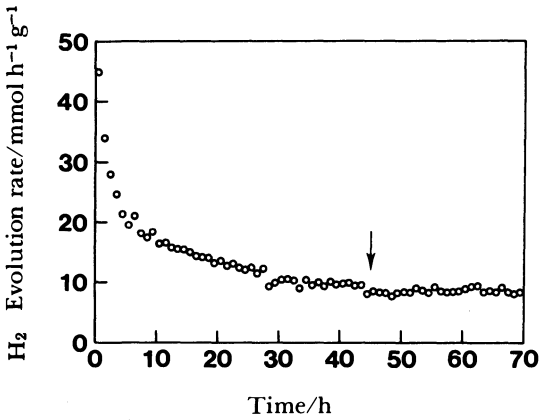

Fig. 6. Effect of accumulation and succeeding stationary removal of acetone on the liquid-phase dehydrogenation of 2-propanol with the nickel fine-particle catalyst.
Nickel fine-particle catalyst (200 mg) suspended in 2-propanol (300 ml) was used in the open-ended apparatus under partial distillation conditions.

The second approach was tried in order to reveal the equilibrium adsorption of acetone. After a 5-h reaction the suspension was rapidly cooled (Fig. 5a), followed by a partial removal of the solvent from the reactor under vacuum. Neat 2-propanol was added to the residual suspension until the liquid was supplemented in amount. Not only the amount of acetone left in the solvent after this transfer procedure but also the initial rate in the 2-propanol/acetone solvent thus prepared (Fig. 5b) was the same as that marked by an arrow. The rate-time correlation was obtained in a duplicated manner thereafter. The catalytically-active sites were occupied with acetone by a reversible adsorption from the bulk solvent.

The third experiment produced a state in which the concentration of acetone in the solvent was constant under partial distillation conditions.[10] Two kinds of condensers were set in series in the open-ended apparatus. The product acetone in excess and a small amount of 2-propanol were evaporated from the reactor and passed through the first condenser (57 °C). They were trapped with the second condenser (−10 °C). As shown in Fig. 6, a gradual rate decrease was observed in the initial reaction stage (0—45 h); then, the rate became constant and did not change thereafter (45—70 h). Except for the initial reaction stage, newly formed acetone was removed stationarily under the adopted distillation conditions.

Therefore, it is concluded that active sites of the nickel fine-particle catalyst are occupied by the product acetone without irreversible deactivation.

The rate constant of Eq. 2 of the nickel fine-particle catalyst (116 mmol h^{-1} g^{-1}) was larger than the values reported previously concerning Raney nickel (55

mmol h^{-1} g^{-1})[8] and nickel boride (60 mmol h^{-1} g^{-1})[11] catalysts. It has been pointed out that the equilibrium constant of acetone adsorption was sensitive to the conditions of acetone diffusion, which was regulated by the stirring rate. Sufficient stirring conditions resulted in an adsorption constant of 8.6 l mol^{-1} to the nickel boride catalyst. However, values as large as 10—16 l mol^{-1} were obtained for the Raney nickel catalyst under diffusion-controlling conditions.[11] A rather small adsorption constant (6.0 l mol^{-1}) was obtained for the well dispersed nickel fine particles (Fig. 3), suggesting that this catalyst was not affected by diffusion-controlling conditions.

3. Effect of Temperature on the Reaction Rate. An efficient removal of the product acetone from the catalyst surface was important to Reaction 1. The temperature effect on the reaction rates was examined with and without adopting the boiling conditions. In one series, an inert and soluble substance, i.e., hexane was added to 2-propanol little by little in order to maintain the boiling conditions at various temperatures.[24] In the other, the suspension was heated without boiling in the temperature region below 82.4 °C.[6]

As shown in Fig. 7, the reaction rates on the boiling conditions in the 2-propanol/hexane solvent prepared by the successive addition of hexane were higher than those in the neat 2-propanol without boiling. The rate difference was large in the low-temperature region. One possible interpretation is as follows: The retardation effect owing to acetone adsorption on the catalyst is large at low temperatures without boiling. Bubbles made under boiling conditions favor the desorption of acetone and result in a relatively high reaction rate.

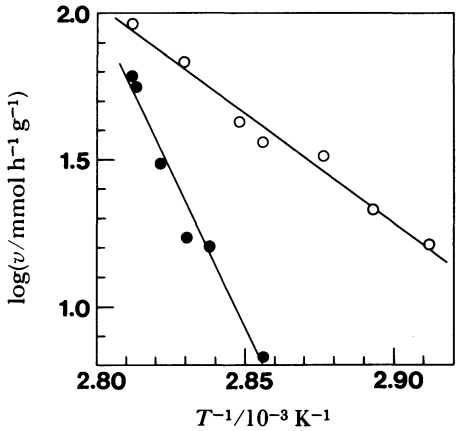

Fig. 7. Temperature dependence of the rate of 2-propanol dehydrogenation with the nickel fine-particle catalyst on boiling or non-boiling conditions. Reaction temperatures were controlled by adding hexane with the boiling conditions kept (○) or by varying the extent of heat supply without boiling (●).

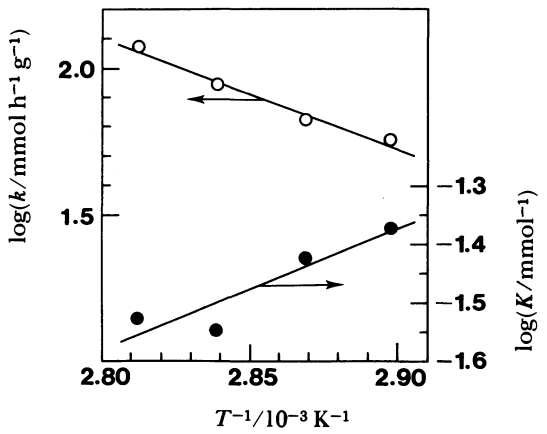

Fig. 8. Temperature dependence of the rate constant of 2-propanol dehydrogenation and the equilibrium constant of acetone adsorption of the nickel fine-particle catalyst under boiling conditions. Reaction temperatures were controlled by changing the amount of hexane added to the suspension.

An accurate temperature dependence of the kinetical parameters k and K in Eq. 2 was examined by the use of a series of 2-propanol (200 ml)/hexane solvents with 0, 8, 21, and 38 ml of hexane, which exhibited boiling temperatures of 82.4, 79.1, 75.4, and 72.0 °C, respectively. An Arrhenius plot and a similar plot of the constant K are shown in Fig. 8.

During each experiment the boiling point of the solvent was slightly lowered by the accumulated acetone. The frequency factor and the exponential coefficient of k and K were determined by a least-square optimization to all of the experimental values, during which slight changes in the boiling point were taken into account. The activation energy of the nickel fine-particle catalyst (71.4 kJ mol^{-1}), surpassing slightly the enthalpy change of this endothermic reaction (69.9 kJ mol^{-1}), was similar in magnitude to those of the heterogeneous nickel boride (85.8 kJ mol^{-1})[11] and Raney nickel (73.2 kJ mol^{-1})[8] catalysts or of the homogeneous tin(II)-coordinated rhodium(III) complexes (117 kJ mol^{-1}).[6] The adsorption heat of acetone of this catalyst (−33.3 kJ mol^{-1}) was a little larger than that of the nickel boride catalyst (−20.9 kJ mol^{-1}).[11]

4. Application of 2-Propanol Dehydrogenation by Suspended Nickel Fine-Particle Catalyst. The reverse of Reaction 1 is favored below 202 °C.

$$(CH_3)_2CO + H_2 \longrightarrow (CH_3)_2CHOH \qquad (3)$$

An endothermic low-temperature Reaction 1 in the liquid phase can be coupled to exothermic high-temperature Reaction 3 in the gas phase, as long as acetone (bp 56.3 °C) and 2-propanol (bp 82.4 °C) are separated by cooling through distillation. Since these reactions proceed at different temperatures, simul-

taneously and stationarily, a new heat-pump system will be constituted, with which low-quality heat at 80 °C can be partially upgraded to 200 °C by heat expense at 30 °C.[25] A heat supply is required for both the dehydrogenation reaction and the evaporation of organic compounds.

Appropriate catalysts are indispensable for this chemical heat-pump system. In order to efficiently convert the thermal energy of low-quality heat into chemical energy, 2-propanol dehydrogenation should be catalyzed with high activity and selectivity under boiling conditions.

The nickel fine-particle catalyst is advantageous for this purpose, since it is well-suspended through conventional stirring with an attainable high space-time yield. However, the development of a catalyst that is active in much acetone is desired, since both the low boiling point of the solvent and the large vapor pressure of acetone are favorable for this chemical heat-pump system.

(Received August 10, 1987)

The liquid-phase oxidation of *p*-methoxytoluene to *p*-anisaldehyde in the presence of Co based catalysts has been studied. With $Co(OAc)_2$ alone in acetic acid as a solvent, only a trace amount of *p*-anisaldehyde could be obtained; however, upon the addition of a second metal salt (e.g., $Mn(OAc)_2$ or $Ce(OAc)_3$) a considerable improvement in the yield (up to 60%) was observed. The synergism of Co and the second component as well as the optimization of the reaction conditions were investigated. $Co(OAc)_2$–$Ce(OAc)_3$–$Cr(OAc)_3$ (3:1:2) was finally found to be the most effective catalytic system, which gave a 76% yield of *p*-anisaldehyde under 3 atm O_2 at 110° for 3 h.

The liquid-phase oxidation of substituted toluenes to the corresponding aldehydes has been receiving increasing attention from an industrial point of view[1] owing to a growing demand for these aldehydes as manufactural key intermediates for the production of medicines, perfumes, agricultural chemicals and so on. The current processes for the production of these aldehydes, based mainly on the stoichiometric chemical oxidations, have several disadvantages regarding waste treatment, small manufactural scale as well as high costs.

Although the liquid-phase oxidation of hydrocarbons has been the subject of numerous studies for many years,[2] the feature of the reaction mechanism is not simple and there is still no unified view in terms of the control of the catalytic activity and selectivity to oxidize specific substrates. In general, the aldehydes are more reactive toward oxidation than the starting substances and, thus, the selective synthesis of the aldehyde with the liquid-phase oxidation has been regarded as not being easily achieved.

p-Anisaldehyde is an useful chemical as an additive for metal plating brighteners or perfumes, as well as a source material for medicines. Recently, several attempts to produce *p*-anisaldehyde from *p*-methoxytoluene through liquid-phase oxidation have been reported. Okada and Kamiya[3] reported that only less than 10% yield of *p*-anisaldehyde can be obtained by the liquid-phase oxidation of *p*-methoxytoluene with a Co–Cu–Br catalytic system. A relatively good yield (60%) was reported by Imamura et al.[4] using a Co based catalyst under optimized reaction conditions.

In the present study, a catalytic survey for a highly selective liquid-phase oxidation of *p*-methoxytoluene to *p*-anisaldehyde was performed; multicomponent metal systems, including the most efficient system Co–Ce–Cr, have been found to give a higher yield.

Experimental

p-Methoxytoluene (purchased from Tokyo Kasei), $Co(OAc)_2 \cdot 4H_2O$ (Wako), $Ce(OAc)_3 \cdot H_2O$ (Wako), $Cr(OAc)_3 \cdot H_2O$ (Wako) and the other reagents were used without further purification. A 50 ml stainless autoclave (SUS-316) was used for the reaction. Into the autoclave, were added the substrate, a solvent (AcOH), and metal salts with a magnetic bar. The autoclave was heated in a prewarmed oil bath with vigorous magnetic stirring at 110 °C under 3 atm of O_2. The products were isolated by TLC and the structures were assigned based on their IR, NMR, and mass spectra. Through routine procedures, these products were quantitatively analyzed by GC on SE-30 supported on Chromosorb W.

Results and Discussion

Oxidation with $Co(OAc)_2$–$Mn(OAc)_2$ Catalytic System. When 2 mmol of *p*-methoxytoluene was allowed in 10 ml of AcOH in the presence of 0.75 mmol of $Co(OAc)_2$ (generally known to be effective for a wide variety of liquid-phase oxidations of hydrocarbons) at 110 °C for 3 h under 3 atm O_2, an only trace amount of *p*-anisaldehyde was formed (although the conversion was close to 100%). As by-products, *p*-methoxybenzoic acid and *p*-anisyl acetate were formed, implying that the oxidizing capability of $Co(OAc)_2$, itself, is too high to give *p*-anisaldehyde in good yield.

The mixture of $Co(OAc)_2$ and $Mn(OAc)_2$ (known as an active catalytic system in several liquid-phase oxidation reactions[5–7]) was found to be effective for the present reaction. In Fig. 1, the yield of *p*-anisaldehyde is plotted against the Mn content per Co+Mn catalyst. The reaction was carried out at 110 °C for 3 h in the presence of 0.75 mmol of the total catalyst. The yield of *p*-anisaldehyde depended strongly on the Co–Mn ratio. $Mn(OAc)_2$, itself, showed only a limited activity toward the oxidation compared with $Co(OAc)_2$, whereas the selectivity to

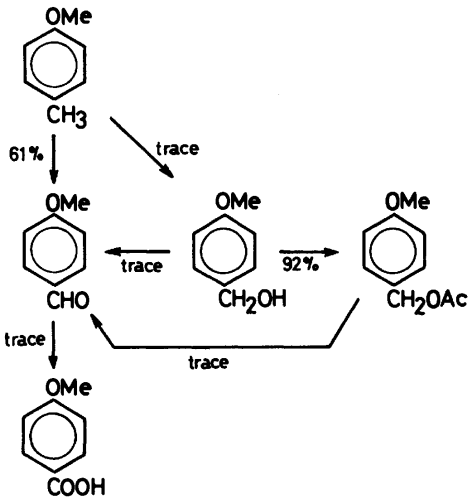
(△) Conversion, (○) *p*-anisaldehyde, (●) *p*-anisyl acetate.

p-anisaldehyde was higher. A mixture of the two metal salts in any composition gives a higher yield of the aldehyde. A synergism is therefore evident. The highest yield (61%) was obtained when the ratio of Co: Mn was 3:2.

In Fig. 2, the change in the liquid-phase composition with the reaction time is shown. 0.75 mmol of the Co-Mn (3:2) catalyst was used for these experiments. In the initial ca. 0.5 h, the induction period was observed. The following yield of *p*-anisaldehyde increased with the reaction time and reached the highest value after 3 h. The longer reaction time resulted in a lower yield, presumably because of a subsequent oxidation of the aldehyde into undetermined polymeric by-products. Neither the increase of the catalyst concentration nor the O_2 pressure significantly affects the yield.

In order to clarify the reaction pathways for producing *p*-anisaldehyde, *p*-anisyl alcohol, *p*-anisyl acetate, and *p*-anisaldehyde were oxidized, respectively, in the presence of $Co(OAc)_2$-$Mn(OAc)_2$ (3:2) at 110 °C. The amount of the substance used was 2.0 mmol each; the other reaction conditions were the same as employed for *p*-methoxytoluene oxidation. As summarized in Scheme 1, *p*-anisaldehyde was found to be reasonably stable under the reaction conditions. The oxidation of the acetate to the aldehyde is desirable in order to obtain a higher yield of *p*-anisaldehyde. *p*-Anisyl acetate, however, was found to be stable with regard to further oxidation, giving only a trace amount of the aldehyde. *p*-Anisyl



Scheme 1.

alcohol was not oxidized to *p*-anisaldehyde either, but was mainly converted to the acetate; this implies that *p*-anisaldehyde is formed directly from *p*-methoxytoluene, but not via the *p*-anisyl alcohol. Therefore, following factors seem to be the key factors for developing a more selective catalytic system: 1) the formation of alcohol should be suppressed and 2) the reaction conditions for retarding esterification is preferable. Based on these criteria, the medium oxidizing capability between $Co(OAc)_2$ and $Co(OAc)_2$-$Mn(OAc)_2$ may be suitable for the selective formation of *p*-anisaldehyde.

The Effect of Water or Anhydrous Acetic Acid. The additive effects of water[8] and anhydrous acetic

acid were examined (as summarized in Table 1). When 0.5 ml of H_2O was added to the Co–Mn catalytic system, the only obtained product was a 19.4% conversion to *p*-methoxytoluene for 3 h. When a longer reaction time was employed, a higher conversion was obtained; however, the yield of *p*-anisaldehyde was not high. Therefore, the addition of H_2O retards both the catalytic activity and the selectivity. The addition of anhydrous acetic acid or NaBr was also attempted. The addition accelerates the consumed rate of the reaction. When 0.5 ml of anhydrous acetic acid or 0.75 mmol of NaBr was added into the system, a 100% conversion of *p*-methoxytoluene was obtained in both cases. However, the yields of *p*-anisaldehyde were not very high. Anhydrous acetic acid and NaBr are known to be effective additives which can enhance the catalytic activity of the Co salt in several hydrocarbon oxidations.[2,9)] However, the use of these additives for the present reaction causes a further oxidation of the target product, *p*-anisaldehyde, and unfavorably lowers the selectivity.

The Effect of $Ce(OAc)_3$ Addition. It is generally believed that the enhancement of the catalytic activity upon the addition of the second metal component is due to the reoxidation of Co^{2+} to the catalytically active Co^{3+}. For example,[2)] the additive effect of the Mn^{2+} salt combining with the Co salt can be explained in terms of an electron transfer from the Mn^{3+} generated by the oxidation of Mn^{2+} with $RO_2\cdot$, as follows:

$$Mn^{2+} + RO_2\cdot \longrightarrow Mn^{3+} + RO_2^-$$

$$Mn^{3+} + Co^{2+} \longrightarrow Mn^{2+} + Co^{3+}$$

However, the addition of Mn in the present reaction rather lowers the oxidizing capability of the Co^{3+} species and enhances the selectivity for the production of *p*-anisaldehyde. Since the medium oxidizing capability between $Co(OAc)_2$ and $Co(OAc)_2$–$Mn(OAc)_2$ (as described above) was expected to be effective for the selective production of *p*-anisaldehyde, the other metal salt, which by itself slightly retards the oxidizing capability of the $Co(OAc)_2$ less than $Mn(OAc)_2$, seemed to be suitable as an additive for the present reaction. For these reasons the additive effects of several other metal salts, instead of $Mn(OAc)_2$, combined with $Co(OAc)_2$ were examined. The results are summarized in Table 2. In these experiments, the molar ratio of a metal salt to $Co(OAc)_2$ was fixed at 1:3. With $Co(OAc)_2$–$Ce(OAc)_3$, a considerable improvement in *p*-anisaldehyde yield was obtained, whereas the addition of $Cu(OAc)_2$ resulted in an apparent retardation of the catalytic activity. The addition of $Cr(OAc)_3$ and $Ni(OAc)_2$ also caused a further oxidation, yielding only a small amount of *p*-anisaldehyde.

The dependence of the *p*-anisaldehyde yield on the mixing ratio of $Ce(OAc)_3$ to $Co(OAc)_2$ is shown in Fig. 3. As in the Co–Mn system, a synergistic effect was evident. The highest yield (67.9%) of *p*-anisaldehyde was obtained when the molar ratio of Co:Ce was 3:1. With a smaller amount of Ce, the yield was low, although almost a complete consumption of *p*-methoxytoluene was observed. The addition of a greater amount of Ce caused a decrease in the catalytic activity, while the yield of *p*-anisyl acetate increased. The time course of the reaction in the presence of a $Co(OAc)_2$–$Ce(OAc)_3$ (3:1) catalyst is shown in Fig. 4.

The yield of *p*-anisaldehyde, as well as *p*-anisyl acetate, increased with time and reached a maximum value at 3 h. Any further reaction, however, tended to lower the yield of the aldehyde.

Oxidation with Three Components Catalysts. The additive effect of several metal salts into the effective catalytic system, $Co(OAc)_3$–$Mn(OAc)_2$ (3:2) and $Co(OAc)_2$–$Ce(OAc)_3$ (3:1), were examined (see Table 3). A slight improvement of the *p*-anisaldehyde yield was found upon the addition of $Cr(OAc)_3$ in both systems. The highest yield of *p*-anisaldehyde was obtained with a three-component catalytic system, $Co(OAc)_2$–$Ce(OAc)_3$–$Cr(OAc)_3$.

The effect of the added amount of $Cr(OAc)_3$ into a fixed amount (0.75 mmol) of $Co(OAc)_2$–$Cr(OAc)_3$ (3:1) was examined. The highest yield (72.7%) was obtained when the molar ratio of the components was 3:1:2 for Co:Mn:Cr. The change in the liquid-phase composition as a function of the reaction time

$Co(OAc)_2$–$Ce(OAc)_3$–$Cr(OAc)_3$ (3) (1) (2)	99.9	72.7	14.1	0	0
$Co(OAc)_2$–$Ce(OAc)_3$–$Cr(OAc)_3$[a] (3) (1) (2)	100.0	75.9	12.8	0	0

The catalyst amount of $Co(OAc)_2$–$Mn(OAc)_2$ (3:2) or $Co(OAc)_2$–$Ce(OAc)_3$ (3:1) was fixed, 0.75 mmol except the case, a) when the total catalyst amount was 1.75 mmol. O_2, 3 atm; 110 °C; *p*-methoxytoluene (Ph'CH_3), 2.0 mmol; solvent (AcOH), 10 ml; the reaction time, 3 h.

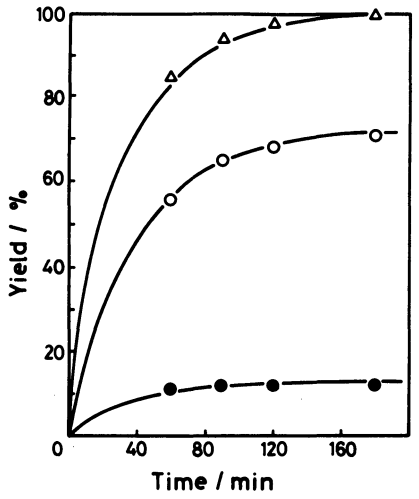

Fig. 5. The time course of *p*-methoxytoluene oxidation with $Co(OAc)_2$–$Ce(OAc)_3$–$Cr(OAc)_3$ catalyst. $Co(OAc)_2 \cdot 4H_2O$–$Ce(OAc)_3 \cdot H_2O$–$Cr(OAc)_3 \cdot H_2O$ (3:1:2), 0.75 mmol, *p*methoxytoluene, 2.0 mmol; AcOH, 10 ml; O_2, 3 atm; at 110 °C.
(△) Conversion, (○) *p*-anisaldehyde, (●) *p*-anisyl acetate.

catalyzed by this effective system is shown in Fig. 5. A similar feature of the reaction obtained in $Co(OAc)_2$–$Mn(OAc)_2$ and $Co(OAc)_2$–$Ce(OAc)_3$ systems was noted; the best reaction time for obtaining *p*-anisaldehyde was 3 h.

Finally, the dependence of the *p*-anisaldehyde yield on the catalyst concentration was examined. Reactions were performed at 110° for 3 h with $Co(OAc)_2$–$Mn(OAc)_2$–$Cr(OAc)_3$ (3:1:2). The yield slightly depended on the concentration in the range of the total amount of the catalyst, 0.5 to 2.0 mmol; the highest yield (75.9%) was obtained when 1.75 mmol of the total amount of the catalyst was used.

Okada and Kamiya reported that only a limited yield (2.7%) of *p*-anisaldehyde was obtained in the presence of $Co(OAc)_2$–$Cu(OAc)_2$–NaBr under 40 atm of air at 150 °C for 1 h.[3] Under their experimental conditions, the molar ratio of *p*-methoxytoluene: AcOH:Co was 4.2:100:0.33. Imamura et al. made a detailed investigation of suitable reaction conditions for the selective formation of *p*-anisaldehyde with a cobalt based catalytic system. They found that the highest yield (70%) of *p*-anisaldehyde was obtained with $Co(OAc)_2$ alone under 60 atm of O_2 at 120—124 °C. The molar ratio in this case was 10:100:2 for *p*-methoxytoluene:AcOH:Co. The yield was, however, significantly lower (<20%) under an ambient pressure of O_2. They examined the additive effect of several bromide additives (e.g., NaBr, HBr, $CoBr_2$) although no apparent improvement in the *p*-anisaldehyde yield was obtained. Compared with these systems, the present catalytic system is evidently more effective; a higher yield (76%) of *p*-anisaldehyde was obtainable under milder reaction conditions (at 110 °C and 3 atm of O_2, *p*-methoxytoluene:AcOH:Co was 1.1:100:0.45).

From an industrial point of view, the deactivation of the catalyst should be notable. Repeated oxidations of *p*-methoxytoluene were, thus, attempted using $Co(OAc)_2$–$Ce(OAc)_3$–$Cr(OAc)_3$. After the first reaction carried out under the same reaction conditions (described above), the catalyst was extracted with water and used for a subsequent experiment. Three repetitions of similar oxidations did not result in any deactivation, although the further repetitions caused a slight deactivation of the catalyst with a loss of the total amount of the catalyst in the extraction procedure.

†Department of Chemical Engineering, Kyoto University, Yoshida, Kyoto 606
(Received August 27, 1987)

Methods are described for the preparation of cobalt(II) deuteroporphyrin and cobalt(II) tetrakis(*p*-sulfonatophenyl)porphine anchored on alumina beads coated with polyaminesulfone-A. Wavelength dispersive X-ray microanalysis showed that the cobalt(II) porphine distributes within the catalyst outer surface layer of ca. 100 μm depth. The catalysts are highly active for the cycloreversion of quadricyclane to norbornadiene. A detailed kinetics of the isomerization using an isothermal recycle reactor gave a rate expression of Langmuir-Hinshelwood type. The catalysts gradually lose their activity, which can be regenerated completely by heating the catalysts at 200 °C in vacuo.

Heterogeneous catalysts have merit to eliminate disadvantages of homogeneous catalysts, the difficulties in separation of catalyst from product as well as the loss of expensive catalyst by entrainment. Solar energy storage system based on photochemical formation of highly strained molecules coupled with catalyzed reversion of the photoproduct is the case.[1-8] In the connection with the recent importance of solar chemical latent energy system, several heterogeneous catalysts have been developed for the conversion of quadricyclane (Q) to norbornadiene (NBD),[9-12] and the criteria for an ideal catalyst have been pointed out by King and Sweet.[9] A serious problem for the catalysts reported so far seems to be loss of catalyst activity upon repeated use and its regeneration.

This paper describes our new method for preparation of heterogeneous catalyst by immobilizing cobalt(II) porphine derivatives on alumina beads.

In evaluating the catalysis system, it is essential to know the kinetic profiles over a wide range of substrate concentration. Most of kinetic studies reported so far have been carried out at low quadricyclane concentrations (e.g., 0.1 mol·L^{-1})[9]. Here, we have examined kinetics of our heterogeneous catalysis system over a range of the substrate concentration of 0.1—1.0 mol·L^{-1} using an isothermal recycle reactor. Furthermore, energy releasing process (Q→NBD) has been run on an adiabatic fixed bed reactor and the temperature profiles of the system are discussed based on the kinetic studies.

Results and Discussion

Preparation of the Catalysts, Co(II)TPPS/PAS/Alumina (1) and Co(II)DPIX/PAS/Alumina (2). By soaking activated alumina beads (mean diameter of 3 mm) in aqueous solution of polyaminesulfone-A (PAS, **3**, MW=2×10^5), **3** was adsorbed on the alumina beads, and the alumina beads were modified to have the anion binding ability. Thus, upon contact with a solution of cobalt(II) sodium tetrakis(*p*-sulfonatophenyl)porphine (Co(II)TPP(*p*-$SO_3Na)_4$, **4**) in methanol the alumina beads coated with PAS adsorbed the porphynato cobalt(II) to afford the catalyst Co(II)-TPPS/PAS/Alumina (**1**). The adsorption was effective, and in typical run using 9.1 g of **4**, the complete disappearance of the color of **4** in the liquid phase was observed by the PAS/Alumina (190 g). For cobalt(II) deuteroporphyrin (Co(II)DPIX, **5**), pyridine was used as solvent. In this case, by the rapid adsorption of **5** by PAS/Alumina Co(II)DPIX/PAS/Alumina (**2**) was obtained. Four kinds of heterogeneous catalysts, A—D of **2** were prepared, which incorporated 19 mmol, 39 mmol, 72 mmol, and 139 mmol of **5** per 1 kg of the resulting catalyst, respectively. In each case adsorption of cobalt(II) porphines was carried out under unaerobic conditions. These cobalt contained catalysts are, however, stable to air in dry state. The conditions for the preparation of each catalysts are shown in Table 1.

Table 2. Activities of Cobalt(II) Porphines Anchored on Alumina Beads Modified by PAS for the Conversion of Q to NBD[a]

Catalyst[b]	Mol of Co(II) Porphine	$k_w \times 10^5$	k_p
	mol·g^{-1}	L·s^{-1}·g^{-1}	L·s^{-1}·mol^{-1}
1	0.043	2.45	0.57
2-A	0.019	2.95	1.6
2-B	0.039	6.00	1.5
2-C	0.072	7.93	1.1
2-D	0.14	10.8	0.77

a) Kinetic studies were carried out using pentane solution of Q, initially 0.02 mol·L^{-1} and ca. 70 mg of the catalysts at 21±1°C. b) A—D refer to the batch numbers in Table 1.

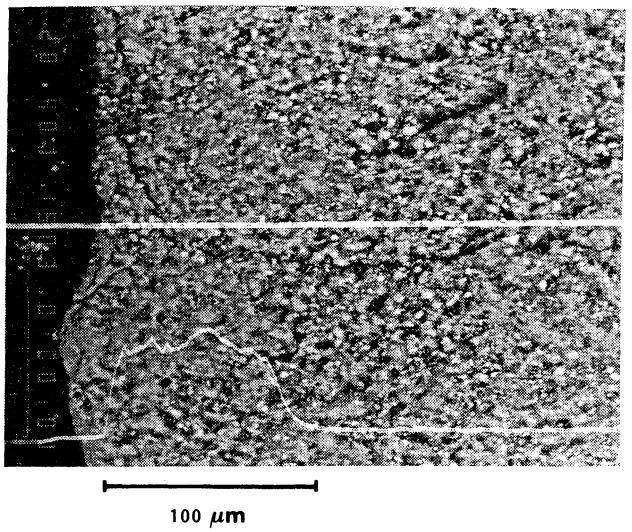

Fig. 1. SEM photograph as well as distribution of Co atoms for the cross section of the bead of Co(II)-TPPS/PAS/Alumina. The waved line shows the distribution of Co atoms along the corresponding white straight line.

Scanning Electron Microscopy (SEM) and Wavelength Dispersive X-Ray Microanalysis on Cross Section of Beads of Co(II)TPPS/PAS/Alumina (1). Figure 1 depicts SEM photograph of the cross section of the beads of **1**. The white waved line refers to distribution of Co atoms along the diameter on the cross section of the bead corresponding to the white straight line. As depicted by the waved line in Fig. 1, the distribution of Co atoms was found to be within a catalyst surface layer of 100 μm depth.

Activities of Co(II)TPPS/PAS/Alumina and Co(II)DPIX/PAS/Alumina as Catalysts. The catalysts **1** and **2** showed remarkably large catalytic activities for the reversion of Q to NBD. As one exmple, when a solution of 4 ml of Q in 6 ml of benzene was treated with 1 g of **2**-A, the exothermic reaction occurred immediately within 5 s, and the solution began to boil vigorously. After 1 min, more than 99% conversion of Q was observed by a GC analysis.

The conversion of Q to NBD catalyzed by these catalysts was followed kinetically in an isothermal batch reactor. The disappearance of Q (initial concentration=0.02 mol·L^{-1}), in pentane and the concomitant formation of NBD at 21±1 °C were monitored by GC. At such a low concentration of Q, a first order kinetic plots gave a straight line, whereas the reaction at higher concentration of Q could not be expressed by pseudo-first-order kinetic treatment. As the catalytic activities we use the values k_w L·s^{-1}·g^{-1} which are the first order kinetic constants normalized to 1 g of catalyst in 1 L of solution. The values were obtained from runs with ca. 70 mg of catalyst in 5 mL of solution (Table 2). In Table 2, k_p is the activity based on cobalt(II) porphine content. Table 2 shows the variation of the activity of **2** when the amount of Co(II)DPIX adsorbed was changed. At the low content of the cobalt(II) porphine below 39 mmol·g^{-1}, catalytic activity is proportional to the amount of Co(II)DPIX adsorbed. On the contrary, at higher content no correlation is observed, where k_w varies

Table 3. Pseudo-First-Order Kinetic Constants of Catalyzed Reversion of Q to NBD at Various Temperatures[a)]

Catalyst	Temperature °C	$k_{obsd} \times 10^4$ s^{-1}
1	19	3.27
1	24	3.65
1	29	4.10
1	34	4.65
2-A	16	3.88
2-A	21	4.46
2-A	25	4.69
2-A	30	5.65

a) First order kinetic constants were measured in an isothermal batch reactor using 5 mL of pentane solution of Q, initially 0.02 mol·L^{-1}, with 70 mg of the catalysts.

only from 6.00 to 10.8 L·s^{-1}·g^{-1} while the amount of Co(II)DPIX adsorbed varies from 39 to 140 mmol·g^{-1}. Although the reason of the lack of the correlation at higher amount of Co(II)DPIX is not apparent, it seems likely that the distribution of the catalyst monomer to deeper layer of the catalyst particle and the correspondingly occurring inner mass diffusion limitation might reduce the apparent activity of the catalyst monomer at its high content.

Temperature dependence of the pseudo-first-order kinetic constant is shown in Table 3. An Arrhenius plots corresponding to Table 3 gave energy of activation of the reaction of 16.9 and 18.8 kJ mol^{-1} for 1 and 2-A, respectively, indicating that the active species for each catalyst is fairly effective for the cycloreversion of Q to NBD.

Kinetic Study at High Quadricyclane Concentration by an Isothermal Recycle Reactor. A more detailed analysis was undertaken of the kinetics of the conversion of Q to NBD catalyzed by 1 and 2, i.e., kinetic profiles with respect to Q concentration and the retention of catalytic activities. These subjects are difficult to be examined by an usual batch type reactor. Here, the reaction rate was measured by an isothermal recycle reactor (batch of solid and flow of fluid, Fig. 2)[13] which eliminates the external mass transfer resistance. Isooctane was used as a solvent in this case.

In Fig. 2 C_{Bi} and C_B are concentrations of Q for inlet and outlet of the reactor, respectively. The solution was fed by steady rate of v m^3·s^{-1}. Catalyst of the weight of W kg was used. The value γ is recycle ratio, which was set large enough to treat the reactor as an ideal CSTR (continuous stirred tank reactor). Thus, we can set up Eq. 1 for the material balance

$$vC_{Bi} - vC_B - rW = 0 \quad (1)$$

where r denotes the reaction rate over catalyst (mol·s^{-1}·kg^{-1}). Thus the reaction rate normalized to

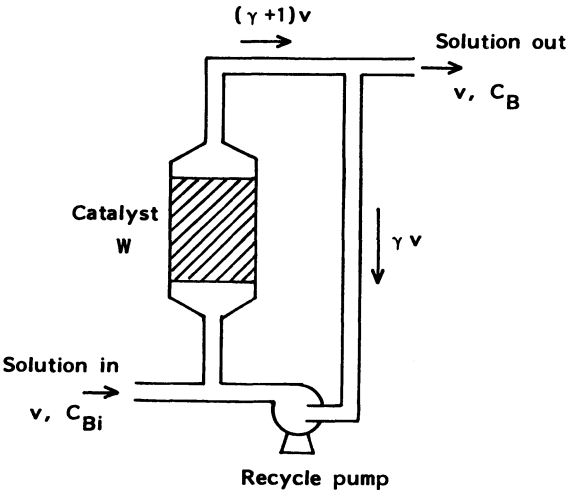

Fig. 2. Recycle reactor.

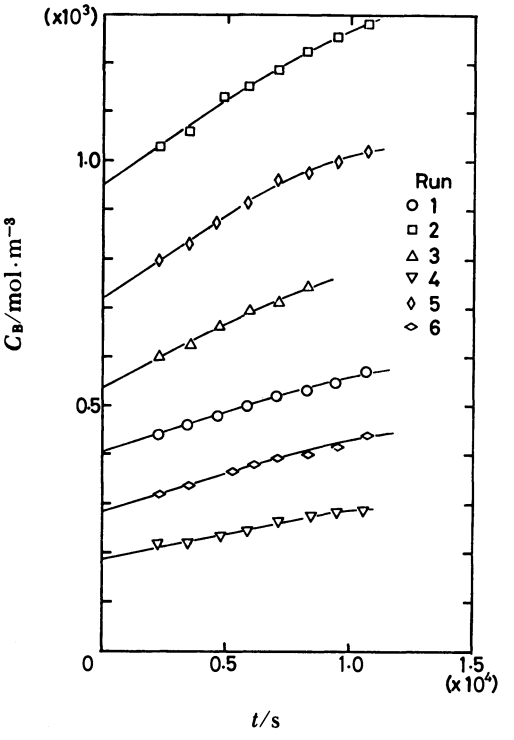

Fig. 3. Concentration of Q as a function of time. Run numbers refer to the experimental run given in Table 4.

1 kg of catalyst is given by Eq. 2.

$$-r = v(C_{Bi} - C_B)/W \quad (2)$$

A description of the experimental conditions for Co(II)TPPS/PAS/Alumina 1 is given in Table 4.

After the reaction system reached to pseudo-steady state, Q concentration (C_B) was monitored at appropriate time intervals. Figure 3 shows the C_B as a function of time for Runs 1—6 for example, and the corresponding reaction rates ($-r$) are plotted vs. time

Table 4. Experimental Conditions for the Kinetic Study of the Reversion of Q Catalyzed by 1[a)]

Run	$C_{Bi}\times10^{-3}$ mol·m^{-3}	$W\times10^{3}$ kg	$v\times10^{7}$ m^3·s^{-1}	T °C	Catalyst

16	1.12	0.78	1.78	25.0	Fresh
17	0.39	0.78	1.73	25.0	Fresh
18	1.24	0.74	1.79	25.0	Fresh
19	0.78	0.75	1.80	25.0	Fresh
20	0.54	0.83	1.73	25.0	Fresh
21	1.24	0.74	2.09	25.0	Reactivated (Used in Run 18)
22	0.55	0.73	1.81	25.0	Reactivated (Used in Run 20)
23	1.26	0.73	1.80	25.0	Reactivated (Used in Run 21)

a) Values C_{Bi}, W, and v refer to symbols in Fig. 2, (see text).

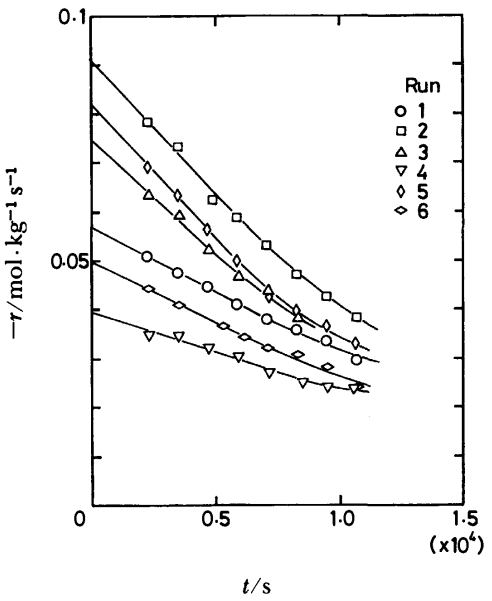

Fig. 4. Reaction rate as a function of time. Run numbers refer to the experimental run given in Table 4.

in Fig. 4. The decrease in the reaction rate arises from the partial loss of activity of the catalyst. The value r_0 estimated by extrapolation at t=0 was adopted as a reaction rate for the corresponding Q concentration C_{B0}. Plots of $-r_0$ vs. C_{B0} are shown in Fig. 5 for three different temperatures. If the reaction were first order with respect to Q the plots should be linear. The plots shown in Fig. 5 can be expressed by equations indicated in the same figure for each temperature. The equations can be correlated to Langmuir-Hinshelwood type rate expression

$$-r = kKC_B/(1 + KC_B) \quad (3)$$

Kinetic constant k mol·kg^{-1} s^{-1} and absorption constant K m^3·mol^{-1} were obtained from experimental correlation shown in Fig. 5 and are summarized in Table 5. Figure 6 shows Arrhenius Plots for k and K which gave temperature dependences of these values as indicated in the same figure. Thus, reaction rate of the reversion of Q to NBD catalyzed by **1** can be written as following.

$$-r = \frac{0.406\exp(-2062/T)C_B}{1 + 1.01 \times 10^{-3}\exp(213/T)C_B} \quad (4)$$

In the case of Co(II)DPIX/PAS/Alumina (**2**-B), the similar experiments gave qualitatively the same results as the case of **1**. The kinetic profiles for **2**-B are shown in Table 5, and the rate expression is

$$-r = \frac{0.539\exp(-1832/T)C_B}{1 + 1.58 \times 10^{-4}\exp(593/T)C_B} \quad (5)$$

The retension of the catalytic activity of **2**-B after

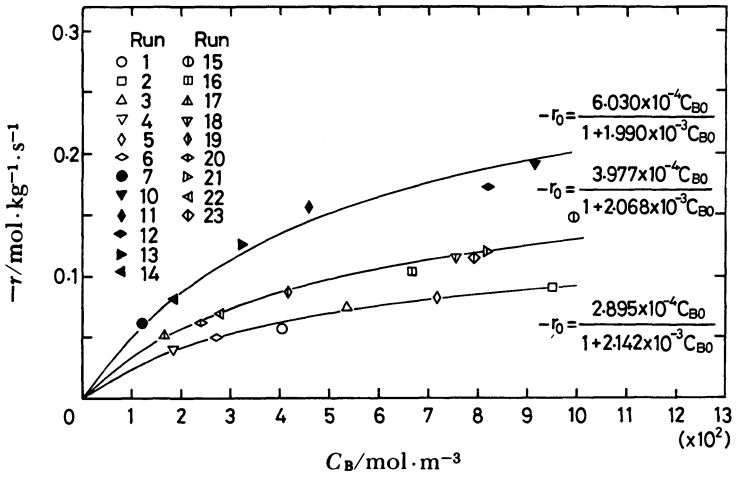

Fig. 5. Plots of reaction rates vs. Q concentration at t=0. Run numbers correspond to the experimental conditions given in Table 4. Upper curve is for 42.0 °C (Runs 7—14), middle curve for 25.0 °C (Runs 15—23) and bottom curve for 11.0 °C (Run 1—6).

Table 5. Kinetic Parameters for the Reversion of Q to NBD Catalyzed by Co(II)TPPS/PAS/Alumina (**1**) and Co(II)DPIX/PAS/Alumina (**2-B**)[a)]

Catalyst	Temp	k	10^3K	E_a	ΔH
	°C	$\mathrm{mol\cdot kg^{-1}\cdot s^{-1}}$	$\mathrm{m^3\cdot mol^{-1}}$	$\mathrm{kJ\cdot mol^{-1}}$	$\mathrm{kJ\cdot mol^{-1}}$
	11.0	0.135	2.14		
1	25.0	0.192	2.07	18.9	−1.77
	42.0	0.303	1.99		
	11.0	0.714	1.24		
2-B	20.0	0.833	1.20	20.2	−4.93
	40.0	1.51	1.04		

a) k and K refer to the symbols in Eq. 3. E_a is energy of activation obtained based on an Arrhenius plots for k and ΔH heat of adsorption for K.

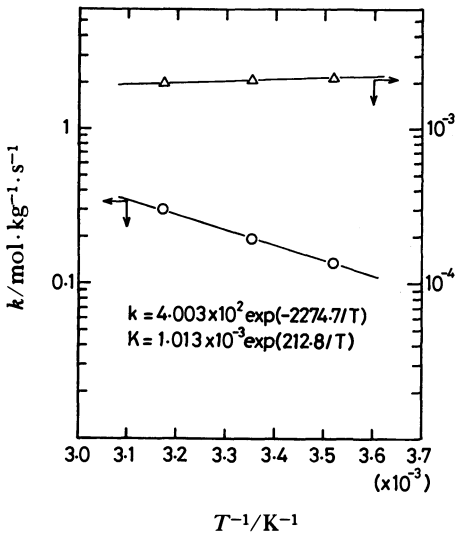

Fig. 6. Arrhenius plots for the kinetic constant k and adsorption constant K given in Table 5 for the Co(II)TPPS/PAS/Alumina catalyzed reversion of Q.

repeated use was examined by an isothermal (30±1 °C) batch reactor according to the method described by King and Sweet.[9)] A 0.17 g charge of catalyst **2-B** (6.6×10^{-4} mol·L^{-1} Co) was examined for loss of activity upon repeated recycling using 10 mL of 0.1 mol·L^{-1} Q in pentane. After five times batch of repeated use, ca. 40% loss of activity was observed while they reported ca. 50% loss of activity when 0.107 g of their polystyrene-anchored Co(II)TPP (8.1×10^{-4} mol·L^{-1} Co) was used. The deactivation of catalytic activity was examined quantitatively based on the kinetic studies by the use of the isothermal recycle reactor. For this purpose, fractional activity (a) is defined as

$$a = -r(C_B,t)/-r(C_B,0) \quad (6)$$

where $-r(C_B,0)$ is the initial rate expressed by Eq. 4 or Eq. 5 corresponding to the fresh catalyst, and $-r(C_B,t)$ denotes the reaction rate corresponding to catalyst which has worked for t s being exposed in Q solution of the concentration C_B. Numerical treatments

Table 6. Values, α and β, in Eq. 7 Characterizing the Retension of Activities of Catalysts **1** and **2-B**

Catalyst	Temperature °C	$10^3\alpha$	$10^6\beta$
1	11	31	2.9
1	20	31	3.3
2-B	11	3.7	0.27
2-B	20	3.7	0.27
2-B	40	16	1.1

afforded the expression of the fractional activity as a function of C_B and t

$$a = \exp[(-\beta C_B/1 + \alpha C_B)t] \quad (7)$$

where the values, α and β, for **1** and **2-B** at various temperatures are reported in Table 6.

Although the mechanism of the loss of activity is not clear, Eq. 7 indicates that Q molecule should be included in the mechanism. King and Sweet reported[9] that the loss in catalytic activity of their polystyrene-anchored Co(II)TPP arised from partial oxidation of the cobalt metal, and they demonstrated that the loss could be partially regenerated by the treatment with a strong reducing agent. In our case of cobalt(II) porphine anchored on PAS/Alumina, the decrease in the activity could be regenerated by heating the used catalyst at 200 °C in vacuo. In the Runs 21 and 22 seen in Table 4, used catalysts reactivated by this method were employed. As shown in Fig. 5 the plots for these runs is on the line obtained for the runs with fresh catalysts, which indicates the complete recovery of the catalytic activity. Even in the case of Run 23 in which the catalyst used has experienced two times reactivations, an almost complete regeneration of the catalytic activity was observed. The same reactivation procedure was effective for Co(II)DPIX/PAS/Alumina. These results indicate that the loss of catalytic activity of **1** and **2** should be due to fouling which arises from a kind of reaction of Q molecule and which can be eliminated by heating in vacuo.

A Bench-Scale Examination of Energy-Releasing Process, Q→NBD, Catalyzed by Co(II)DPIX/PAS/Alumina, 2-B. The feature of the heat-releasing process based on the reversion of Q catalyzed by **2-B** was examined by using a bench scale fixed bed reactor. A schematic of the flow system is shown in Fig. 7. The reactor was made of Pyrex glass, 2 cm in inner diameter and 70 cm in length, and packed with solid catalyst **2-B** of ca. 200 cm^3 in volume. Measurement of the axial temperature distribution in the reactor was made by the twenty thermocouples fixed at the axis of the reactor. Isooctane solution of Q at room temperature was introduced into the reactor by means of a roller pump. Table 7 lists the experimental conditions and the physical properties of the solution.

Table 7. Experimental Conditions and Physical Properties of Isooctane Solution of Q

Flow rate	$0.157\,cm\cdot s^{-1}$ a)
Solution	
Q concentration	$1.09\,mol\cdot L^{-1}$ b)
Mean value of heat capacity at constant pressure	$2.28\,J\cdot g^{-1}\cdot K^{-1}$ c)
Density	$0.793\,g\cdot cm^{-3}$
Heat of reversion of Q	$96.2\,kJ\cdot mol^{-1}$ d)

a) Superficial velocity. b) Initial concentration. c) Heat capacity of isooctane at 55 °C was employed. d) Determined by a microcalorimetry of the isomerization catalyzed by $Rh_2Cl_2(NBD)_2$.

At the experimental conditions, both conversions and temperature rise were close to equilibrium. That is, Q in the inlet solution was isomerized to NBD during the flow through the catalyst bed with a concomitant evolution of heat and with no detectable by-products. Conversion at the exit of the reactor was unity, and maximum temperature rise was 58.5 °C which agrees well with the adiabatic temperature rise calculated based on the values in Table 7.

Figure 8 shows the axial temperature profiles along the reactor. With increasing distance Z, the temperature T rapidly increases and reaches a constant value. This system could conceivably have external mass transport resistance with Damköhler number being 11.5 at 40 °C. Therefore one-dimensional heterogeneous model accounting for interfacial gradient was used to predict the longitudinal distribution of temperature in the adiabatic fixed bed.[14] Here, the rate expression, Eq. 5, includes the internal mass transfer resistance. Although measurements show a little larger rate of the catalyst deactivation, they are well represented by the solid lines.

Conclusion

Polyaminesulfone modified alumina beads adsorbed cobalt(II) porphine derivatives possessing acidic group through ionic linkages, which provides an very easy method to immobilize cobalt(II) porphines on solid support. Using cobalt(II) tetrakis(*p*-sulfonatophenyl)porphine and cobalt(II) deuteroporphyrin, the method provides active catalysts for the valence isomerization of Q to NBD. The catalysts reveal prominent properties; high activity, small deactivation rate and moreover ability of regeneration of activity by heating the catalyst at 200 °C in vacuo. Furthermore, the distribution of the active species in the catalyst particle is restricted to a thin layer on the surface of the support. The catalyst showed strong resistivity against temperature (250 °C).

The reaction rate of the catalyzed isomerization of Q

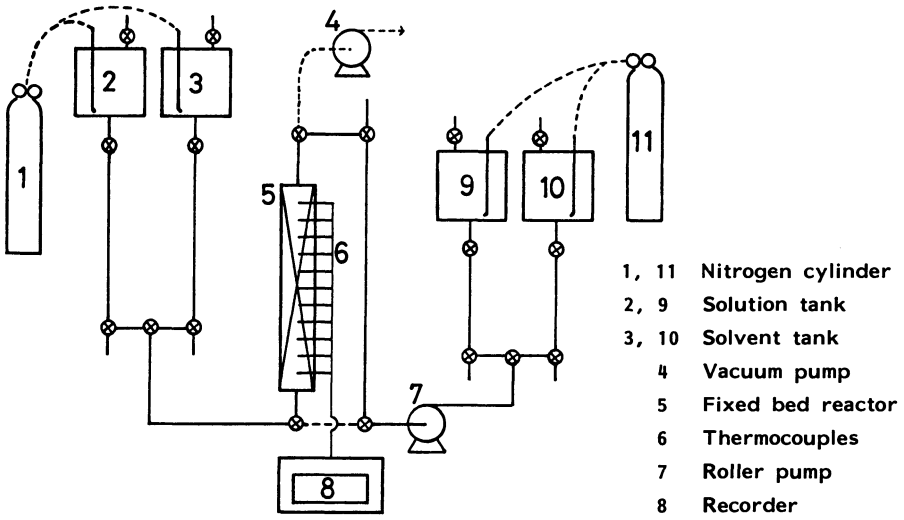

Fig. 7. Schematic of flow system.

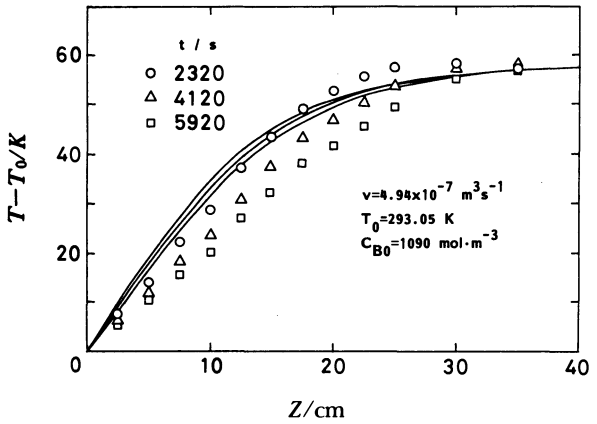

Fig. 8. Temperature profiles along the axis of the fixed bed reactor (**5**, Fig. 7) for the energy releasing process catalyzed by Co(II)DPIX/PAS/Alumina.

obeys Langmuir-Hinshelwood type rate expression. In a bench scale test, the catalysts revealed efficient activities to evolve heat rapidly upon contact with Q. The relatively large particle size of the catalyst and correspondingly the small pressure drop when packed in a column is presumably a preferable property in practical process. Furthermore, the catalysts did not swell up upon contact with any solvent.

Experimental

Materials. Polyaminesulfone-A (PAS) and activated alumina beads (Sumitomo Alumi NKH-1) were offered by Nittobo Co. Ltd. and Sumitomo Aluminium Smelting Co. Ltd., respectively. Deuteroporphyrin IX was prepared from protohemin according to the method of Fischer.[15] Incorporation of cobalt(II) was performed by the method of Yamamoto.[16] Pyridine was distilled over KOH under argon. Quadricyclane was prepared by a modification of King's method.[9] Pentane and isooctane used in kinetic studies were guaranteed grade commercially available and were used without further purification.

Analytical Method. Gas chromatographic analyses were carried out on a GC system composed of a Shimadzu GC-7A with TCD detector and a Shimadzu Chromatopac C-E1B. A Pyrex glass column, 5 mm in inner diameter and 1 m in length, was packed with Silicone DC-550. Helium was used as a carrier with flow rate of 50 mL·min^{-1}. Treatment of the packed column with five times injections of 50 μL triethylamine followed by baking out for 3 h at 150 °C eliminated the isomerization of Q in the column. Samples were analyzed using an injector temperature of 120 °C and a column temperature of 70 °C.

Sodium Tetrakis(*p*-sulfonatophenyl)porphinatocobalt(II) Complex (Co(II)TPPS, 4). A solution of 9.95 g (8 mmol) of sodium tetrakis(*p*-sulfonatophenyl)porphine and 1.99 g (8 mmol) of cobalt acetate in 100 mL of DMF was refluxed for 5 min. After cooling the reaction mixture, addition of benzene afforded 10 g (98%) of **4**.

PAS Modified Alumina Beads. To a 1 L solution of polyaminesulfone-A (PAS, **3**) (mean MW=2×10^5, Nittobo Co. LTD.) in water (10 wt%) was added 200 g of activated alumina beads (mean diameter of 3 mm, Sumitomo Aluminium Smelting Co. Ltd., NKH-1). The mixture was stood for 12 h with occasional swirling. Separation of the beads by filtration with a stainless steel net, air-drying at 100 °C for 2 days and drying at 80 °C in vacuo for 3 h afforded 245 g of the PAS modified alumina beads, PAS/Alumina.

Co(II)TPPS/PAS/Alumina (1). A two-necked round-bottomed flask equipped with a septum rubber stopper and three way valve was charged with a 190 g of PAS/Alumina, air in the flask was replaced with argon by means of a pump and argon balloon. To this was added a solution of 9.12 g (7.2 mmol) of **4** in a 2 L of degassed methanol by means of a canalation by positive argon pressure using a teflon tubing with 3 mm in inner diameter. The mixture was stood for 2 days under positive argon pressure with occasional swirling. After 2 days the color of the cobalt(II) porphine of the supernant was disappeared almost completely. The catalyst beads were filtered under nitrogen atmosphere and dried for

6 h at 120 °C in vacuo to give 174 g of the title catalyst. The catalyst was stocked under positive argon pressure.

Co(II)DPIX/PAS/Alumina (2). A solution of 0.75 g (1.3 mmol) of cobalt(II) deuteroporphyrin (Co(II)DPIXCo, **5**) in 160 ml of dry pyridine degassed by freeze and pumping was introduced onto a 69 g of PAS/Alumina beads under argon atmosphere. After the color of the cobalt(II) porphyrin was disappeared from the supernant, the beads were separated by filtration under argon and dried for 5 h at 150 °C in vacuo to give 70 g of **2** of batch-A. Batch-B, C, and D of **2** were prepared by similar manner. The specific quantities of materials and the solvent employed in the preparation of each batch are shown in Table 1.

Scanning Electron Microscopy and Wavelength Dispersive X-Ray Microanalysis. Scanning electron microscopy and the wavelength dispersive X-ray microanalysis on catalyst **1** were simultaneously carried out by the use of a JXA-733 of JOEL Co. Ltd. The specimen for the analysis of the cross section of the bead was prepared by dividing a bead into two hemispheres.

Measurements of Catalytic Activities and Studies on the Recycling Catalytic Run. A reaction cell of 20 mL in volume mantled with a jacket was equipped with a magnetic stirring bar and a septum rubber stopper. Thermostated water was circulated through the jacket in order to regulate the temperature of the reaction cell. The cell was charged with a weighed catalyst (ca. 70 mg) under argon atmosphere and was added a Q solution in pentane being set at reaction temperature by a syringe and the timing begun. Samples of the reaction solution (10 μL) were withdrawn for GC analyses. The initial sample was withdrawn at 30 s with subsequent samples at 120 s intervals, and more than 15 samples were analyzed.

The recycling study was carried out in a similar manner. At the end of the reaction period (more than 90% conversion), the reaction solution was decanted. The employed catalyst was washed two times with 5 mL of pentane and was dried up for 5 min under reduced pressure before using it for the next catalytic run.

Kinetic Studies Using an Isothermal Recycle Reactor. A schematic illustration of a recycle reactor is shown in Fig. 2. As shown in Table 4, around 1 g of catalyst was charged in the batch of the reactor. The whole system was immersed in a water bath thermostated at desired temperature. Solution of Q in isooctane was introduced into the reactor with precise control of the flow rate. In the experimental runs, recycling ratio γ was set above 67 so that the reactor could be treated as an ideal CSTR.[13] The superficial velocity in the catalyst fixed bed reactor above 4.2 $cm \cdot s^{-1}$ was employed in order to eliminate external diffusion resistance.[17] Samples of the reaction solution were withdrawn at the exit of the reactor and were analyzed on a GC system. After the reaction system reached to pseudo-steady state samplings were carried out at such time intervals indicated in Fig. 4.

Bench Scale Examination of the Catalytic Energy-Releasing Process on Co(II)DPIX/PAS/Alumina 2-B. A schematic of the flow system is shown in Fig. 7. The apparatus was made of teflon except a glass reactor and a rubber (Biton) tubing in pump. Each tank was 5 L in volume and the pipeline which connects a reactor with tanks was 6 mm in diameter. Feed was introduced into the reactor by means of a roller pump which provides very precise control of flow rate over the range of 120—1200 $mL \cdot h^{-1}$. A cylindrical reactor was used, which is made of Pyrex glass, 2 cm in inner diameter and 70 cm in length. The reactor was packed with **2-B** of 200 cm^3 in volume. The active catalytic portion was contained between inert fore and aft sections of glass beads. The reactor was thermally insulated from its surroundings with asbestos. The twenty copper-constantan thermocouples were fixed at the axis of the reactor to measure the axial temperature distribution in the reactor. A hybrid recorder was used to record the outputs of the thermocouples. The concentrations of both Q and NBD were measured with a GC. Isooctane was used as a solvent.

In operation, feed at room temperature (20.1 °C) was introduced into the reactor by means of a roller pump at a constant flow rate. The solvent feed was initially passed through the reactor, establishing a steady flow. Once steady flow was achieved a three way valve was switched, sending the solution stream through the reactor. Temporal changes in temperature were measured by the thermocouples and samplings of the solution were made at the exit of the reactor. Their compositions were analyzed with the GC. During the experiments, the solution and solvent in tank has been bubbling by nitrogen gas from a cylinder to prevent a polymerization of NBD by dissolved oxygen. Reaction periods of about 1—2 h were employed. Table 7 lists the experimental conditions and the physical properties of the solutions.

Interactions of $CoCl_2$ with K{M(OPr^i)$_6$} in 1:2 molar ratio in Pr^{i}OH and C_6H_6 result in products with the composition [Co{M(OPr^i)$_6$}$_2$] (M=Nb or Ta) in quantitative yields. Interchange reactions of these isopropoxide derivatives with alcohols of varying steric bulk (e.g., MeOH, EtOH, Pr^{n}OH, Bu^{n}OH, and Bu^{t}OH, or Am^{t}OH) yield derivatives of composition, [Co{M(OR)$_6$}$_2$] (R=Me, Et, Pr^n, and Bu^s); [Co{M(OPr^i)$_3$(OBu^s)$_3$}$_2$]; [Co{M(OPr^i)$_5$(OBu^t)}$_2$] and [Co{M(OPr^i)$_2$(OR)$_4$}$_2$] (R=Bu^t or Am^t). All these novel compounds have been characterized by elemental analyses and molecular weight determinations as well as by infrared, visible spectral and magnetic studies.

In contrast to the well-known chemistry of alkoxy derivatives of earlier transition metals,[1,2] alkoxides of later transition metals have received only scanty attention possibly due to their insolubility and polymeric nature. One of the fascinating developments in the alkoxide chemistry of later '3d' metals (including cobalt) has been the synthesis[3] of soluble, monomeric, volatile, bimetallic alkoxides, [M{Al(OR)$_4$}$_n$] (where n=3, when M=Cr(III), Fe(III) and n=2, when M=Co(II), Ni(II), Cu(II)) in our laboratories. The {Al(OR)$_4$}$^-$ has proved to be an excellent ligand and depicts an interesting variation in its ligating behavior; e.g., it acts as a bidentate ligand towards Cr(III),[4] and Fe(III),[5] but it exhibits a tridentate ligating behavior with Co(II)[6] and Cu(II);[7] and with Ni(II),[8] an ambidentate (both bi- and tri-) behavior has been observed. By contrast, bimetallic alkoxide derivatives containing both early and later d-block elements bridged by alkoxy groups have been much less studied. These bimetallic alkoxides could be expected to find useful applications (i) as homogeneous catalysts,[9] (ii) in ceramic industry[10] and (iii) in organic syntheses. In view of the above, we report herein some aspects of bimetallic alkoxide derivatives of cobalt(II) containing Co(μ-OR)$_3$M (M=Nb or Ta) bridging units.

Experimental

General. Stringent precautions were taken to exclude atmospheric moisture from the glasswares, solvents and the reagents were purified by literature methods prior to use.

Anhydrous $CoCl_2$ was prepared by heating the hydrated $CoCl_2 \cdot 6H_2O$ in a current of dry HCl gas and analyzed. Analysis for $CoCl_2$: Found: Co, 45.41; Cl, 54.59; Calcd: Co, 45.39; Cl, 54.61%.

Niobium and tantalum isopropoxides were prepared[11] by passing dry NH_3 gas in a solution of their pentachlorides (Fluka) in isopropyl alcohol.

Cobalt in bimetallic derivatives was estimated gravimetrically[12] as [Co(C$_5$H$_5$N)$_4$](NCS)$_2$ and niobium (tantalum) was estimated as oxide. From the solution of the bimetallic alkoxides in hydrochloric acid, hydrated niobium (tantalum) oxide is first precipitated with only slight excess of aqueous ammonia and cobalt is then precipitated as [Co(C$_5$H$_5$N)$_4$](NCS)$_2$ by addition of NH_4SCN followed by pyridine to the filtrate. Blank determinations with known solutions showed that niobium (tantalum) tends to be about 2% higher and cobalt about 1—2% lower under these conditions.

Alcohols were determined by an oxidimetric method.[13]

The infrared spectra were recorded in the range 4000—400 cm^{-1} on a Perkin-Elmer 557 spectrometer using Nujol mull. The visible spectra have been recorded on a Pye-Unicam SP8-100 spectrophotometer. The magnetic susceptibilities were measured on a Gouy balance using Hg[Co(NCS)$_4$] as standard. The magnetic moments, μ_{eff}, were calculated by the expression: $\mu_{eff}=2.84\sqrt{\chi_M^{Corr} \cdot T}$ (where χ_M^{Corr} is the molar susceptibility corrected for the diamagnetism of the constituent atoms by the use of Pascal's constants). Helium gas compressor was used for low temperature susceptibility measurements. Molecular weights were determined cryoscopically.

Syntheses and Reactions. Methods of synthesis of [Co{M(OPr^i)$_6$}$_2$] derivatives and some of their typical reactions are described briefly below. The amount of chemicals used in each reaction, the yield of the product, the elemental analyses and other details are given in Table 1.

A. Preparation of [Co{M(OPr^i)$_6$}$_2$] (M=Nb or Ta). A weighed amount of K{M(OPr^i)$_6$} in benzene (40 cm^3) was added to a suspension of $CoCl_2$ in Pr^{i}OH (30 cm^3). The reaction mixture was refluxed for≈5 h and precipitated KCl was removed by filtration. The excess of solvent was distilled out and the concentrate kept at room temperature; purple-red crystalline solid [Co{M(OPr^i)$_6$}$_2$] crystallized out. The product was further recrystallized unchanged either from Pr^{i}OH-PhH or hexane.

B. Reactions of [Co{M(OPr^i)$_6$}$_2$]. (i) With Excess of MeOH (at Room Temperature). To a benzene solution of [Co{M(OPr^i)$_6$}$_2$], an excess of MeOH was added. The reaction mixture was stirred for≈6 h, during which the color changed from purple-red to violet. After removal of the volatiles under reduced pressure a violet colored solid product of composition, [Co{M(OMe)$_6$}$_2$] was isolated, which could be recrystallized unchanged from hexane.

(ii) With Excess of EtOH (at Room Temperature). EtOH was added to a benzene solution of [Co{Ta(OPr^i)$_6$}$_2$] and stirred for≈6 h at room temperature. The solvent was removed under reduced pressure to yield a violet red solid

a) Yield of the crystallized product and molecular weight of $[Co\{Nb(OPr^i)_6\}_2]$, Found: 901; Calcd (954) and for $[Co\{Ta(OPr^i)_6\}_2]$ Found: 1015; Calcd (1130). b) Reaction was carried out at room temperature. c) Reaction was carried out in refluxing C_6H_6 (without azeotropic removal of Pr^iOH). d) Reaction was carried out in refluxing C_6H_6 with azeotropic removal of Pr^iOH. e) Stoichiometric yield in parenthesis.

product of composition $[Co\{Ta(OPr^i)_2(OEt)_4\}_2]$.

(iii) With EtOH, Pr^{n}OH, and Bu^{n}OH in Refluxing Benzene. Interaction of a benzene solution of $[Co\{M(OPr^i)_6\}_2]$ with excess of EtOH followed by refluxing for≈6 h, resulted the change in color from purple red to violet. Removal of the solvent under reduced pressure afforded a solid of composition $[Co\{M(OEt)_6\}_2]$ which could be purified unchanged by recrystallization from hexane.

Derivatives of *n*-propyl and butyl alcohols were prepared similarly.

(iv) With Excess of Bu^{s}OH at Room Temperature. An excess of *s*-butyl alcohol was added to a benzene solution of $[Co\{Ta(OPr^i)_6\}_2]$ and the resulting reaction mixture was stirred for≈6 h. The removal of the solvent produced a violet solid of composition $[Co\{Ta(OPr^i)_3(OBu^s)_3\}_2]$.

(v) Reaction with Bu^{s}OH in Refluxing Benzene. To a benzene solution of $[Co\{Ta(OPr^i)_6\}_2]$ *s*-butyl alcohol was added and the reaction mixture was refluxed for ≈6 h. The removal of the solvent under reduced pressure afforded a violet red solid product of composition, $[Co\{Ta(OPr^i)_2(OBu^s)_4\}_2]$.

(vi) With Excess of Bu^{s}OH (Azeotropically). To a solution of $[Co\{Nb(OPr^i)_6\}_2]$ in benzene an excess of *s*-butyl alcohol was added and reaction mixture was refluxed for ≈6 h during which the liberated isopropyl alcohol was collected and estimated. After complete removal of the isopropyl alcohol, the solvent was stripped off under reduced pressure to afford a violet red solid $[Co\{Nb(OBu^s)_6\}_2]$.

(vii) With Excess of Bu^{t}OH (in Refluxing Benzene). To a benzene solution of $[Co\{Nb(OPr^i)_6\}_2]$ *t*-butyl alcohol

was added and refluxed for ≈6 h. After removal of the solvent under reduced pressure and drying a violet red solid product of composition, $[Co\{Nb(OPr^i)_5(OBu^t)\}_2]$ was obtained.

(viii) With Excess of Bu^tOH/Am^tOH (Azeotropically). $[Co\{Nb(OPr^i)_6\}_2]$ was dissolved in benzene and excess of *t*-butyl alcohol was then added. The reaction mixture was continued to reflux for ≈25 h, with continuous removal of the liberated isopropyl alcohol. When the liberation of isopropyl alcohol ceased off, the volatiles were removed and the product was dried under reduced pressure to afford violet red solid of composition, $[Co\{Nb(OPr^i)_2(OBu^i)_4\}_2]$.

A similar procedure was employed for the preparation of $[Co\{Ta(OPr^i)_2(OAm^t)_4\}_2]$.

Results and Discussion

Bis(hexaisopropoxy) derivatives $[Co\{M(OPr^i)_6\}_2]$ (M=Nb or Ta) have been synthesized by the reactions of anhydrous cobalt(II) chloride with $K\{M(OPr^i)_6\}$ in 1 : 2 molar ratio in Pr^iOH and C_6H_6:

$$CoCl_2 + 2K\{M(OPr^i)_6\} \xrightarrow[\text{reflux}]{Pr^iOH\text{-}PhH} [Co\{M(OPr^i)_6\}_2] + 2\ KCl\downarrow$$

Products from the above reactions have been isolated in quantitative yields and purified by recrystallization either from Pr^iOH–PhH or hexane. These bimetallic isopropoxides are purple red crystalline solids and depict monomeric behavior (cryoscopically) in benzene. On heating even under reduced pressure, these appear to disproportionate into the corresponding volatile isopropoxide, $M(OPr^i)_5$ and non-volatile, $\{Co(OPr^i)_2\}_n$.

Alcoholysis reactions of these bimetallic isopropoxides $[Co\{M(OPr^i)_6\}_2]$ with different alcohols have shown interesting results. The extent of substitution reactions vary with experimental conditions and the bulk of the reacting alcohol; these are indicated by the following equations:

$$[Co\{M(OPr^i)_6\}_2] + 12\ \underset{\text{(excess)}}{MeOH} \xrightarrow{rt} [Co\{M(OMe)_6\}_2] + 12\ Pr^iOH\uparrow \quad (1)$$

$$[Co\{Ta(OPr^i)_6\}_2] + 8\ \underset{\text{(excess)}}{EtOH} \xrightarrow{rt} [Co\{Ta(OPr^i)_2(OEt)_4\}_2] + 8\ Pr^iOH\uparrow \quad (2)$$

$$[Co\{M(OPr^i)_6\}_2] + 12\ \underset{\text{(excess)}}{ROH} \xrightarrow[\text{reflux}]{PhH} [Co\{M(OR)_6\}_2] + 12\ Pr^iOH\uparrow \quad (3)$$

$$[Co\{Ta(OPr^i)_6\}_2] + 6\ \underset{\text{(excess)}}{Bu^sOH} \xrightarrow[\text{stirred at rt}]{PhH} [Co\{Ta(OPr^i)_3(OBu^s)_3\}_2] + 6\ Pr^iOH\uparrow \quad (4)$$

$$[Co\{Ta(OPr^i)_6\}_2] + 8\ Bu^sOH \xrightarrow[\text{reflux}]{PhH} [Co\{Ta(OPr^i)_2(OBu^s)_4\}_2] + 8\ Pr^iOH\uparrow \quad (5)$$

However, Reaction 5 also could be pushed to completion if the liberated isopropyl alcohol is removed azeotropically with benzene:

$$[Co\{Nb(OPr^i)_6\}_2] + 12\ \underset{\text{(excess)}}{Bu^sOH} \xrightarrow[\text{reflux}]{PhH} [Co\{Nb(OBu^s)_6\}_2] + 12\ Pr^iOH\uparrow \quad (6)$$

Reactions of $[Co\{Ta(OPr^i)_6\}_2]$ with an excess of *t*-butyl alcohol in benzene at room temperature showed no evidence of reaction. However, when the reactions were carried out in refluxing benzene without azeotropic removal of isopropyl alcohol, two moles of isopropyl alcohol could be replaced and the analyses of the product corresponded to the formulae $[Co\{Nb(OPr^i)_5(OBu^t)\}_2]$:

$$[Co\{Nb(OPr^i)_6\}_2] + 2\ Bu^tOH \xrightarrow[\text{reflux}]{PhH} [Co\{Nb(OPr^i)_5(OBu^t)\}_2] + 2\ Pr^iOH\uparrow \quad (7)$$

Further, the reactions of $[Co\{Nb(OPr^i)_6\}_2]$ with an excess of *t*-butyl alcohol in benzene under azeotropic conditions gave only mixed derivative of composition $[Co\{Nb(OPr^i)_2(OBu^t)_4\}_2]$ even after ≈25 h of fractionation:

$$[Co\{Nb(OPr^i)_6\}_2] + 8\ \underset{\text{(excess)}}{Bu^tOH} \xrightarrow[\text{reflux}]{PhH} [Co\{Nb(OPr^i)_2(OBu^t)_4\}_2] + 8\ Pr^iOH\uparrow \quad (8)$$

The reactions with Am^tOH were slower in comparison to Bu^tOH and required ≈30 h of fractionation to yield product of the composition $[Co\{Ta(OPr^i)_2(OAm^t)_4\}_2]$.

The above alcoholysis experiments indicate that the ease of replacement of isopropoxy groups in $[Co\{M(OPr^i)_6\}_2]$ decreases with the size and ramification of the alkyl group. The extent of replacement increases under refluxing conditions. However, even when attempt is made to shift the equilibrium by continuous removal of Pr^iOH, the reactions can not be pushed to completion with tertiary alcohols.

These alcoholysis results as well as physico-chem-

ical (magnetic and spectroscopic) properties described later can be explained on the basis of the plausible structure (Fig. 1) for these bimetallic species.

On making actual models of the above structures, it becomes apparent that out of the three bridging alkoxy groups per niobium (tantalum) atom, one would be in a rather strained state; this is reflected in the alcoholysis results, where four of the six isopropoxy groups per niobium (tantalum) atom tend to behave differently from the remaining two. Further steric crowding around niobium (tantalum) atoms in derivatives like $[Co\{(OPr^i)_2(OBu^t)Nb(OBu^t)_3\}_2]$ appears to hinder any further alcoholysis with excess tertiary alcohol, but in the corresponding less crowded structures as in $[Co\{(OPr^i)_2(OBu^n)Nb(OBu^n)_3\}_2]$, further replacement with excess Bu^nOH could be expected and is actually observed.

All these new bimetallic cobalt(II) alkoxides are colored (purple-red/violet) solids which are highly soluble in organic solvents such as benzene, carbon tetrachloride and hexane, but these exhibit lower solubility in parent alcohols except the methoxide derivatives which are highly soluble in methanol also. It may be pertinent to note that whereas the methoxides of most of the metals (e.g., Al, Ga, Ti, and Zr) are insoluble in organic solvents, methoxides of niobium and tantalum are quite readily soluble possibly due to their monomeric nature.

Infrared Spectral Studies. The infrared spectra (in the range 4000—400 cm^{-1}) of these new bimetallic alkoxides exhibited structurally significant absorption bands[1,14-16] (Table 2) at 1180—900 cm^{-1} for $\nu_{(C-O)M}$ and at 610—510 cm^{-1} for $\nu_{(M-O)}$ (M=Nb or Ta) and at 480—410 cm^{-1} for $\nu_{(Co-O)}$.

Table 3. Visible Spectral[a] Data of Bimetallic Alkoxide of Cobalt(II) with Nb(V) or Ta(V)

S. No.	Compound	$^4T_{1g}(F) \xrightarrow{\nu_3} {}^4T_{1g}(P)$ $10^{-3}\nu_{max}/cm^{-1}$
1	$[Co\{Nb(OPr^i)_6\}_2]$[b]	18.0, 19.3 (sh)
2	$[Co\{Ta(OPr^i)_6\}_2]$	(i) 18.0, 19.8 (sh) (ii) 18.5 (Pyridine)

9	$[Co\{Ta(OPr^i)_2(OBu^t)_4\}_2]$	17.8, 19.7 (sh)

a) All spectra recorded in benzene unless otherwise indicated. b) Only in the case of $[Co\{Nb(OPr^i)_6\}_2]$ (see the text), an additional band was observed at $14.9\times10^3 cm^{-1}$, which can be ascribed to $^4T_{1g}(F) \xrightarrow{\nu_2} {}^4A_{2g}(F)$.

Visible Spectral Studies. The visible spectra of cobalt(II) bimetallic derivatives studied herein showed a multiple band (asymmetric) (Table 3) in the region 17.8×10^3 cm^{-1} which may assigned[17,18,20] as $^4T_{1g}(F) \xrightarrow{\nu_3} {}^4T_{1g}(P)$ transition and the shoulder on the higher frequency side in the region 19.5×10^3 cm^{-1} being assigned to spin forbidden transitions to doublet states derived from the free ion ^2G and ^2H terms, which are characteristic of octahedral geometry.[17,19] The $^4A_{2g}(F) \xleftarrow{\nu_2} {}^4T_{1g}(F)$ transition is not normally

observed in most of the cobalt(II) derivatives, being formally a two electron transition. However, only the spectrum of $[Co\{Nb(OPr^i)_6\}_2]$ in visible region did show a very weak band at 14.9×10^3 cm^{-1} (sh) possibly due to the ν_2 transition.

The value of Dq for $[Co\{Nb(OPr^i)_6\}_2]$ has been calculated to be 795 cm^{-1} by using Underhill and Billing equation[21] and the ligand $\{Nb(OPr^i)_6\}^-$ can be placed in the following spectrochemical order:

$$\underset{(649)}{Br^-} < \underset{(764)}{Cl^-} < \underset{(795)}{\{Nb(OPr^i)_6\}^-} < \underset{(920)}{H_2O} < \underset{(1020)}{NH_3}$$

The nephelauxetic ratio (β) is 0.71 for $[Co\{Nb(OPr^i)_6\}_2]$ which is less than that (0.85) for $\{Co(H_2O)_6\}^{2+}$ ion, indicating a more covalent nature of the bimetallic derivative.

Magnetic Studies. For high spin octahedral cobalt(II) derivatives, magnetic moment values are expected to lie in the range of 4.7—5.3 BM, depending upon the extent of orbital contribution.[22] The room temperature magnetic moment values for new cobalt(II) bimetallic derivatives are in the range 5.01 ± 0.11 BM (Table 2), which are in agreement with the values reported for cobalt(II) in octahedral geometry.

The variable temperature data for $[Co\{Ta(OPr^i)_6\}_2]$ have been measured in the temperature range 14.4—295 K; the calculated values of χ_M (including correction of 545×10^{-6} CGS) are 200340 (16.4), 180490 (17.8), 152700 (21.0), 132860 (25.2), 113670 (28.8), 75960 (43.6), 36930 (86.6), 23700 (134), 10930 (295), with temperatures in parenthesis. The plot of $1/\chi_M^{Corr}$ versus T is a straight line obeying the Curie-Weiss law. The magnetic moment values increase slightly (from 5.07 to 5.28 BM) with decrease of temperature (from 295 to 16.4 K) resulting in a positive value of θ and showing the presence of weak cooperative phenomenon.

We wish to thank Prof. S. Mitra, Tata Institute of Fundamental Research, Bombay (India) for providing facilities for magnetic susceptibility measurements. The authors are grateful to Department of Science and Technology (Govt. of India), New Delhi for financial assistance in the form of a research project.

Adsorption of Xenon in the Zeolitic Pore in the Henry's Law Region of the Isotherms

Toshihisa YOSHIDA*, Jun-ichi KOIZUMI, and Yoshio AKAI†
Faculty of Education, Saitama University, Urawa 338
†The Central Research Laboratory, Idemitsu Kosan Co. Ltd., Sodegaura-machi, Chiba 292-01
(Received July 9, 1987)

Synopsis. The isotherms and the ^{129}Xe NMR spectra of Xe adsorbed on HY and USY zeolites of faujasite structure were measured. There were two kinds of Xe species, which could be distinguished as one trapped on the internal surface of the supercage and the other freely mobile in the supercage.

Zeolites with their specific and rather well-defined structure show some interesting properties related to the adsorption of gases in the intense potential fields, which exist in cavities of molecular dimensions; this causes an increased intermolecular solid-gas interaction, even in the case of nonpolar gases such as xenon.

In recent years, much effort has been devoted to investigations of adsorption in restricted geometries, such as zeolite structure. It has been proposed that the adsorption of various gasses on activated charcoals and zeolites (5A and 13X) is a superimposed two-site Langmuir adsorption.[1] In the following studies of the adsorption of xenon, the experimental results in zeolitic pore (H-ferrierite) have been fully analyzed by statistical thermodynamics.[2] The ^{129}Xe NMR study of xenon adsorbed on Y zeolites has also revealed characteristic properties of a faujasite structure.[3]

We have now observed the interesting behavior of xenon adsorbed on zeolites (faujasite) in the Henry's law region of the adsorption isotherms. This note is therefore, devoted to the elucidating of the behavior of xenon adsorbed on Y zeolites. The isotherms and the ^{129}Xe NMR spectra of xenon adsorbed on HY and USY zeolites were measured and compared.

Experimental

Commercial synthetic NaY zeolites (Union Showa, Japan) were used. HY zeolite was prepared from NaY type. USY zeolite (Si/Al_2=22.7) was prepared from HY type by dealuminations, steaming and leaching with acid. Before the xenon was adsorbed on the zeolites, these were pretreated for 4 h at 400 °C under vacuum (10^{-5} Torr[4]). The adsorption isotherms of xenon (99.5%) were measured on a volumetric apparatus at −78 °C. NMR absorptions of ^{129}Xe adsorbed on the samples were observed by using FX-90Q (FT-NMR; JEOL, Japan) at a frequency of 24.785 MHz and a magnetic field of 21.1 kG (1G=10^{-4}T) with D lock. The radio frequency field pulse was repeated every second, which was sufficiently long compared to the relaxation time. The reference signal, 24.7850 MHz of ^{129}Xe was taken as that of Xe gas at 5 atm in the presence of about 5% of oxygen as a paramagnetic impurity.[3] All resonance signals of ^{129}Xe adsorbed on zeolites were obtained after 2000 accumulations and shifted to higher frequency relative to the reference.

After the xenon had been adsorbed on each zeolite and the NMR tubes had been sealed at −78 °C, the ^{129}Xe NMR spectra were observed at −78 °C (for HY zeolite, 31.5 Torr of xenon and for USY one, 37.3 Torr of xenon at each adsorption equilibrium) and by cooling to −100 °C (for HY one and for USY one), respectively.

Results and Discussion

The adsorption isotherms of xenon adsorbed on HY (empty circles) and USY (crosses) zeolites at −78 °C are shown in Fig. 1. The amounts of xenon adsorption are proportional to the pressure in the Henry's law region of the isotherms, but these change to a different linear dependence at higher adsorption pressure. These isotherms are at first convex towards the pressure axis at these adsorption equilibria and have an inflection point. The interesting and strange results obtained here are similar to those observed by Aristov, et al.[5] They considered that localized and non-localized xenon adsorptions often co-exist on crystals of zeolites LiX and NaX. These features of the

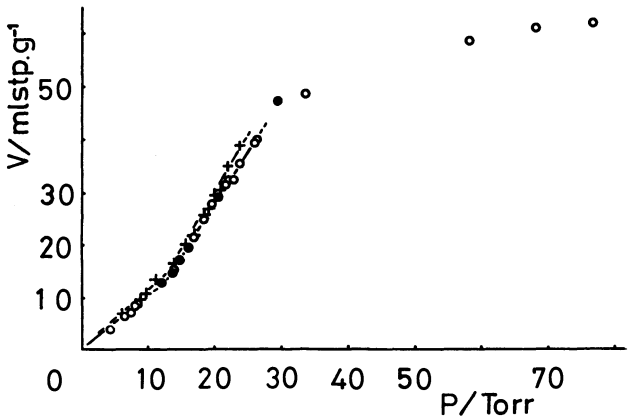

Fig. 1. The amounts for xenon adsorbed vs. pressures of the adsorption equilibrium at −78 °C on HY (circles; ○ for the adsorption, ● for the desorption) and USY zeolites (crosses).

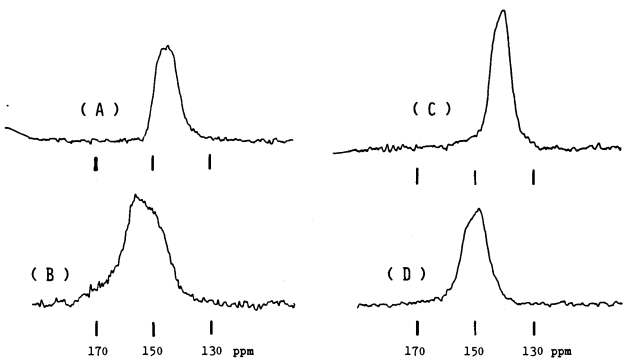

Fig. 2. ^{129}Xe NMR spectra of xenon adsorbed, on HY zeolite at −78 °C under 31.5 Torr of xenon at the adsorption equilibrium (A) and then cooled to −100 °C (B), and on USY zeolite at −78 °C under 37.3 Torr of xenon (C) and also cooled to −100 °C (D), respectively.

isotherms can also be interpreted by a superimposed two-site Langmuir model.[1] The data obtained were highly reproducible. No hystereses of these isotherms were observed, that is, the amount adsorbed for xenon in the adsorptive process equals strictly that in the desorptive one at the same equilibrium pressure, shown by full circles in Fig. 1. From this, it follows that the xenon adsorption occurs in intense potential fields, not by pore filling.[6] The isosteric differential heat of adsorption, q_{iso} of xenon was 16—18 kJ mol^{-1} in the Henry's law region of the isotherms on HY and USY zeolites, different from the heat of vaporization of xenon 12.6 kJ mol^{-1}.[7]

Figure 2 shows the ^{129}Xe NMR spectra of xenon adsorbed at −78 °C and −100 °C, on HY and USY zeolites. Each ^{129}Xe line shape is characteristic in width and suggests it consists of two signals. The NMR signal of ^{129}Xe adsorbed on zeolite shifts increasingly with increasing the xenon pressure at the adsorption equilibrium. When the ^{129}Xe NMR spectra were observed by cooling the NMR tubes to −100 °C, the two NMR signals in Fig. 2 (B) or (D) could be clearly separated into one peak, 146 or 148 ppm and another, 152 or 158 ppm shifted to the reference, respectively.

The distinguishable differences between the two NMR signals and between two heats of xenon adsorption corresponded to each NMR signals are extremely small. The relaxation time for the higher field signal and for the other were approximately 10 and 70 ms, respectively. Comparatively speaking, the xenon species adsorbed and corresponding to the higher field signal is considered to be strongly trapped on the internal surface of the supercage and the other to be freely mobile in the supercage of the faujasite structure. We deduce therefore, that the higher field signal for our NMR spectra appeared at lower xenon densities (within 7—9 xenon atoms/unit cell) must be due to the interactions between a xenon atom and the internal surface of the supercage. Another lower field signal appeared at higher xenon densities is also deduced to be caused by mutual interactions between xenon atoms in the supercage.[3] This conclusion agrees perfectly with that of the superimposed two-site Langmuir model.[1]

The superimposed two-site Langmuir model was not based on spectroscopical evidence. Here we propose this supporting evidence based on the NMR signals of ^{129}Xe adsorbed on zeolites. We infer the adsorption states of Xe adsorbed on HY zeolite are comparatively similar to those on USY one.

The Crystal Structure of the Gold(III) Complex, Tribromo(dibenzyl sulfide)gold(III)

Kazuhiro TAKAHASHI* and Katsuo KATO†
Electrotechnical Laboratory, 1-1-4 Umezono, Tsukuba, Ibaraki 305
†National Institute for Research in Inorganic Materials, 1-1 Namiki, Tsukuba, Ibaraki 305
(Received April 30, 1987)

Synopsis. The crystal structure of tribromo(dibenzyl sulfide) gold(III) has been determined. The crystal belongs to the triclinic system, with a=7.002(1), b=7.949(1), c=17.244(2) Å, α=88.83(1), β=79.52(1), and γ=66.35(1)°, with the space group $P\bar{1}$ and with Z=2. The complex has a square-planar coordination geometry with 3BrlS donor atoms. The bond lengths of the three Au-Br coordinations are in the range of 2.41—2.43 Å.

Since the gold complexes of dibenzyl sulfide (DBS) were first reported by Herrmann,[1] more than ten species of gold(I), gold(III), and mixed-valence gold(I)-gold(III) complexes have been synthesized and characterized.[2]

We have begun to study the structures and electronic states of a series of halogen-gold-DBS ternaly complexes, taking special interest in the coordination mode of the alkyl sulfide and the correlation between the structure and the valence of the gold ion.[3] However, the molecular structures of most of the gold-DBS complexes have not yet been revealed. Though detailed structural studies of the above compounds are much to be desired, the crystal structure determinations of only two DBS-gold(I) complexes have thus far been reported.[4]

In order to obtain details of the molecular structure and the coordination mode of DBS, we have in this study prepared good single crystals of the gold(III) compound, [$AuBr_3$(DBS)], and determined its molecular structure by the use of the X-ray diffraction method.

Experimental

The [$AuBr_3$(DBS)] was prepared by Brain's method.[2] The deep brown prismatic crystals were obtained by recrystallization from a 1,2-dibromoethane/diethyl ether solution (Found: C, 25.62; H, 2.10%) at ca. 5 °C. The intensity data were collected at room temperature with a Rigaku AFC-3 four-circle diffractometer using graphite monochromated Mo $K\alpha$ radiation (λ=0.71073 Å). The unit cell parameters were determined from 47 reflections with $15<2\theta<30°$.

Crystal Data: $C_{14}H_{14}SBr_3Au$, M=651.0; triclinic; space group $P\bar{1}$; a=7.002(1), b=7.949(1), c=17.244(2) Å, α=88.83(1), β=79.52(1), γ=66.35(1)°, V=863.0(2) Å^3; D_m=2.47 (by floatation), D_c=2.51 g cm^{-3}; Z=2; μ=130 cm^{-1}; crystal size 0.1×0.2×0.2 mm^3. A total of 5039 reflections were collected by the ω scan ($2\theta\leqq30°$) and ω-2θ scan techniques ($30\leqq2\theta\leqq60°$), with a 2θ scan rate for 4° min^{-1}, and by monitoring 5 check reflections after each 50 measurements. The check reflections showed a max. 14.2% (on F_o) intensity drop during the course of the data collection. The intensity data were corrected for Lorents-polarization effects, decay, and absorption using 10 crystal faces.[5] 3866 independent reflections with $|F_o|\geqq3\sigma(|F_o|)$ were used for the structure analysis. The structure was solved by the direct method, and was then refined by the full-matrix least-squares procedure. Anisotropic thermal parameters were adopted for the non-hydrogen atoms. Fourteen hydrogens were placed at the calculated positions and were included in the last cycle of the final refinements with B_{eq}=8.0 Å^2 (fix). The final $R_1(=\sum||F_o|-|F_c||/\sum|F_o|)$ and $R_2(=\{\sum||F_o|-|F_c||^2/\sum|F_o|^2\}^{1/2})$ values are 0.041 and 0.043, respectively. All the calculations were carried out on a FACOM M-340S computer at the NIRIM, using UNICS III computing systems.[6] The final atomic positional and isotropic thermal parameters of the non-hydrogen atoms are given in Table 1.††

Results and Discussion

An ORTEP drawing of the complex molecule is shown in Fig. 1. Table 1 lists the final atomic coordinates of the non-hydrogen atoms.

As is shown in Fig. 1, the Au atom is four-coordinated, with the square-planar coordination geometry normally observed in mononuclear Au(III) complexes. The square plane consists of three bromine atoms and the sulfur atom of DBS. The

†† Lists of structure factors, the anisotropic thermal parameters, the coordinates of the hydrogen atoms, the bond distances and angles, and the results of the least-squares plane calculations are deposited at the office of the Chemical Society of Japan as Document No. 8775.

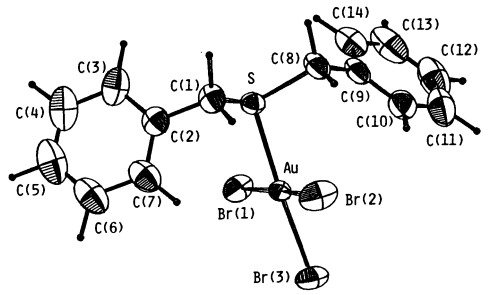

Fig. 1. ORTEP drawing of the molecule with atom numbering scheme for non-hydrogen atoms(thermal ellipsoids are drawn at 50% probability level). Hydrogen atoms are drawn at an arbitraty small size. Selected interatomic distances(l/Å) and angles(ϕ/°) around the coordination sphere of Au are: Au-Br(1) 2.418(1), Au-Br(2) 2.425(1), Au-Br(3) 2.419(2), Au-S 2.349(3), Br(1)-Au-Br(2) 175.78(5), Br(1)-Au-Br(3) 90.54(4), Br-(1)-Au-S 86.88(6), Br(2)-Au-Br(3) 90.21(5), Br(2)-Au-S 92.70(6), Br(3)-Au-S 174.78(7).

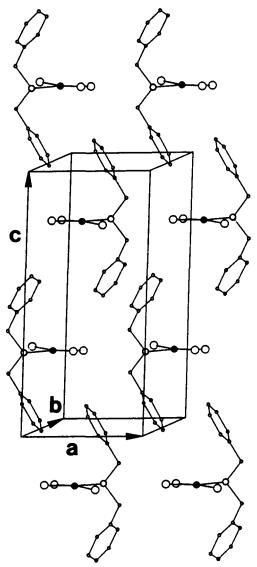

Fig. 2. Perspective view of the crystal structure.

deviations of the Au and donor atoms from the least-squares plane (through Br(1), Br(2), Br(3), and S) are less than 0.1 Å. The bond lengths of the three Au-Br coordinations are in the range from 2.418 to 2.425 Å, and Au-S is 2.349(3) Å. The values of the Au-Br bonds fall within the range observed for the previously reported gold(III) tribromide complexes (2.40—2.47 Å).[7] The Au-S bond length could not be compared with those of other sulfide-coordinated gold(III) complexes because of the lack of any structural study of similar complexes. The dihedral angles of coordination bonds across the Au atom are in the 86—93° range, deviating slightly from the ideal angle, 90°. These results indicate that the first coordination sphere of Au is little affected sterically by the bulky benzyl groups of DBS.

In the case of trihalogeno(phosphine)gold(III) complexes, which possess a coordination structure similar to that of [$AuBr_3$(DBS)], the Au–halogen bond trans to the Au–P bond is appreciably longer than the other two Au–halogen bonds (ca. 0.05 Å). This is due to the strong trans influence of the coordinated phosphine.[7] In the present complex, however, no such strong effect of the trans ligand DBS is observed on the Au–Br(3) bond. The above remarkable difference in the effect from the trans donor species, phosphine and sulfide, seems to reflect the order of the electronegativities of coorddinated sulfur and phosphorus atoms in each ligand (Phosphine<Au^{3+} (2.7)[8]<DBS).

The crystal structure of [$AuBr_3$(DBS)] is shown in Fig. 2. The significant intermolecular distances less than 3.5 Å are: Br(1)-Br(2)(symmetry code: $x+1$, $y-1$,z; 3.460(2) Å), C(11)-C(12)($-x$,$-y$,$2-z$; 3.44(2) Å) and C(12)-C(12)($-x$,$-y$,$2-z$; 3.38(3) Å). In the crystal structure of the two-coordinated gold(I)-DBS complex, [AuBr(DBS)], the short intermolecular distance of Au^+–Au^+ (3.30 Å) is observed.[4] No such adjacency of gold atoms is observed in the crystal structure of [$AuBr_3$(DBS)](the shortest distance of Au^{3+}–Au^{3+} (x,y,$z+1$); 7.002(1) Å).

One of the present authors(KT) wishes to express his thanks to Dr. Hiroshi Tanino, Dr. Takafumi Yao, and Dr. Takehiko Ishiguro(ETL) for their continuous interest and encouragement.

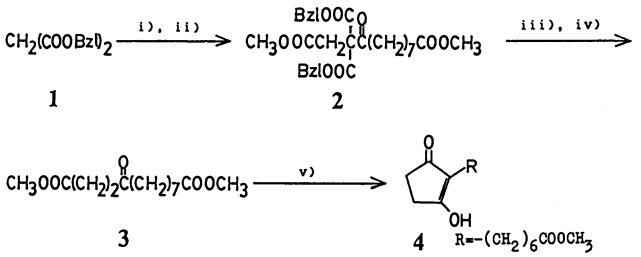
An Improved Synthesis of Methyl 7-(2-Hydroxy-5-oxo-1-cyclopentenyl)heptanoate

Hirokazu NAORA,* Takashi OHNUKI, and Asao NAKAMURA
Applied Research Dept., Central Laboratories, Ajinomoto Co., Inc.,
1-1, Suzuki-cho, Kawasaki, Kanagawa 210
(Received May 13, 1987)

Synopsis. Methyl 7-(2-hydroxy-5-oxo-1-cyclopentenyl)-heptanoate, which is a valuable synthon for prostanoids, was prepared in a good yield from dibenzyl malonate via three steps.

A polymeric prostaglandin, PGB_X, with biochemical and physiological properties very different from those of any other prostaglandin derivatives, was first synthesised by Polis et al.[1] PGB_X has such biological properties as restoring the oxidative phosphorylation of isolated degraded rat liver mitochondria in vitro and increasing in survival after otherwise lethal episodes of myocardial ischemia in monkeys and hypocia in dogs in vivo.[2] PGB_X is an oligomeric mixture (4—6 monomer units) of the 15-dehydro-PGB_1 methyl ester. The total syntheses of PGB_1 or its equivalents have already been known,[3] and methyl 7-(2-hydroxy-5-oxo-1-cyclopentenyl)heptanoate (**4**) is a key intermediate in all cases. **4** is a valuable synthon not only for PGB_1 but also for other prostanoids, for other synthetic intermediates for primary prostaglandins can easily be derived from **4**.[4] We thought that a simple method of preparing a large quantity of **4** would be of significant synthetic and pharmaceutical interest and so started to investigate it.

We modified Bowmann's general method of ketone synthesis[5] and obtained **4** from dibenzyl malonate in a short time and in a good yield. In our method, **4** was prepared in only three steps because the tetraester **2**, which is difficult to prepare by Bowmann's method, was obtained in a single step.



1 2 3 4

i) NaH, $BrCH_2CO_2CH_3$ ii) NaH, $CH_3O_2C(CH_2)_7COCl$ iii) H_2, Pd/C iv) Δ v) $NaOCH_3$

Tetraester **2** was prepared from dibenzyl malonate (**1**) in one pot by base-promoted alkylation with methyl bromoacetate, followed by acylation with methyl 8-chloroformyloctanoate. The crude yield of this one pot reaction was 92% from dibenzyl malonate (**1**). Although the tetraester **2** was used in the next step without further purification, it can be purified by silica-gel column chromatography if necessary. The structure of **2** was elucidated by means of the spectroscopic data.

Thermal decarboxylation after the removal of the benzyl groups of the tetraester **2** gave the keto diester[3] **3** in a 58% yield. This step was achieved by hydrogenolysis in mixture of 10% palladium on charcoal and by subsequent thermal decomposition under reflux in ethyl alcohol. All the spectroscopic data of **3** support its structure.

The keto diester **3** was cyclized with sodium methoxide to give methyl 7-(2-hydroxy-5-oxo-1-cyclopentenyl)heptanoate[3,4] (**4**) in a 94% yield. The IR and NMR spectra of **4** were identical with those of an authentic sample.[3]

Experimental

Dimethyl 3-Bis(benzyloxycarbonyl)-4-oxo-1,12-dodecanedioate (2). A solution of 40 g of dibenzyl malonate (**1**: Aldrich No. 16040-7) in 100 ml of benzene was added to a suspension of 3.36 g (0.14 mol) of sodium hydride in 400 ml of benzene dropwisely. Benzene (200 ml) was then added to the reaction mixture, after which it was gently heated to reflux. After 15 min, a solution of 21.6 g (0.14 mol) of methyl bromoacetate in 100 ml of benzene was added at 50 °C, and then the reaction mixture was heated under reflux for 90 min.

The resultant mixture was added dropwise to a suspension of 3.36 g (0.14 mol) of sodium hydride in 400 ml of benzene with stirring at room temperature. The reaction mixture was kept at 50 °C for 30 min during the evolution of hydrogen gas and then heated under reflux for 15 additional min.

At 50 °C, to the stirred mixture was added a solution of 30.8 g (0.14 mol) of methyl 8-chloroformyloctanoate in 100 ml of benzene dropwisely. The mixture was then cooled to room temperature after refluxing for 2 h. The organic materials were extracted with 1000 ml of ether, and the ethereal layer was washed with 500 ml of water, 300 ml of aq. sat. $NaHCO_3$, 500 ml of water (three times), and brine, and then dried over $MgSO_4$. The removal of the solvents and volatile components under 0.4 mmHg (1 mmHg=133.322 Pa) at 160 °C for 2 h gave 70 g of crude **2** in a 92% yield. Crude **2** can be used for the next step without further purification. Column chromatography (LiCroprep Si 60; hexane–ethyl acetate=3:1) gave pure **2**: ^1H NMR (90 MHz, chloroform-d_1, TMS) δ=7.29 (br., 10H), 5.16 (s, 4H), 3.66 (s, 3H), 3.58 (s, 3H), 3.13 (s, 2H), 2.55 (t, J=7.5 Hz, 2H), 2.27 (t, J=7.5 Hz, 2H), 1.4—1.8 (br., 4H), and 1.0—1.4 (br., 6H); IR (film) 2940, 2850, 1735, 1455, and 1440 cm^{-1}; MS (LREI) 540 (M^+), 509 (M−MeO), 508 (M−MeOH), 477 (M−MeO−MeOH), and 449 (M−Bzl); (HREI) Found: m/z 540.2347. Calcd for $C_{30}H_{36}O_9$: M, 540.2336.

Dimethyl 4-Oxo-1,12-dodecanedioate[3] (3). The hydrogenolysis of 25.5 g (0.047 mol) of **2** was carried out in 150 ml of 95% ethyl alcohol with hydrogen gas at atmospheric pressure over 2 g of 10% palladium on charcoal for 24 h. After the removal of the catalyst by filtration, the reaction mixture was heated under reflux for 2 h. The resultant

product was distilled at 159—160 °C (0.7 mmHg) to give 7.47 g of **3** in a 58% yield: ^{1}H NMR (100 MHz, chloroform-d_1, TMS) δ=3.63 (s, 6H), 2.80—2.08 (m, 8H), and 1.80—1.05 (m, 10H); IR (KBr) 2940, 2850, 1740, 1710, and 1440 cm^{-1}.

Methyl 7-(2-Hydroxy-5-oxo-1-cyclopentenyl)heptanoate[3,4] (4). Dimethyl 4-oxo-1,12-dodecanedioate (**3**: 2.72 g; 10 mmol) in 20 ml of dry toluene was added dropwise to a suspension of 20 mmol of sodium methoxide in 50 ml of dry toluene under reflux. The reaction mixture was then heated under reflux for 30 min, followed by the azeotropic removal of the generating methyl alcohol for 2 h. After it had then been cooled to room temperature, the resultant mixture was diluted with 20 ml of water and acidified with 1 M HCl (1 M=1 mol dm^{-3}) between pH 1 and pH 2. The organic materials were extracted with 20 ml of ethyl acetate twice. The organic layer was washed successively with equal volumes of 1 M HCl, water, and brine. The subsequent removal of the solvents gave 2.26 g (94% yield) of **4**: ^{1}H NMR (90 MHz, chloroform-d_1, TMS) δ=4.75—4.0 (br., 1H), 3.66 (s, 3H), 2.66 (br., 4H), 2.75—1.95 (m, 4H), and 1.9—1.0 (m, 8H); IR (KBr) 2910, 2860, and 1740 cm^{-1}.

A Facile Synthesis of 4*H*-Cyclopenta[*def*]phenanthrene

Masahiro MINABE,* Masaaki YOSHIDA, and Tokuei TAKAYANAGI
Department of Industrial Chemistry, Faculty of Engineering, Utsunomiya University, Ishiicho, Utsunomiya 321
(Received July 15, 1987)

Synopsis. A facile and cheap method for synthesis of 4*H*-cyclopenta[*def*]phenanthrene was achieved from fluorene as the starting material via di-*t*-butylfluorene.

In order to learn how to facilely obtain 4*H*-cyclopenta[*def*]phenanthrene (**1**) is one of the important reasons for studing the chemistry of **1**.[1] About ten procedures have been proposed for the synthesis of **1**; usually pyrene[2] and diphenic acid[3] are used as the starting materials in more facile methods. The preparation from tetralin is cheap but needs a long sequence.[4]

We wish to report here on a convenient, cheap method to make **1** from fluorene (**2**).

Hydrocarbon **2** is known to react with electrophile, mainly at the 2,7-positions, accompanied by a minor amount of the 2,5-positional isomer. For the preparation of the 4-substituted fluorene, it is necessary to block the 2,7-positions by the positional protecting group. The *t*-butyl group is convenient for the protection;[5] the synthesis of 4-bromofluorene by this method has been reported by Kajigaeshi et al.[6]

The sequence of the preparation of **1** from **2** is summarized in Scheme 1. We first planned to make 4-iodofluorene via **4e**;[6] however, trans-*t*-butylations of **4e** and **7** were difficult. The second plan, to convert **4e** into **4f**, was not effective due to the low yield. The final design was a route through **4a**.[6] The chloromethylation of **3** using chloromethyl methyl ether in the presence of titanium tetrachloride gave **4a** in a good yield accompanied by the formation of dimeric **8**. The conversion of **4a** to **4c**[6] was furnished by a treatment of potassium cyanide in DMF to give **4b**[6] followed by acidic hydrolysis to form **4c** in good yields, respectively.

The ring closure of the acid chloride **4d** gave the phenol **5** which was so unstable as to change into reddish materials containing the quinone. Crude **5** was submitted to a reduction using hydriodic acid-red phosphorus in acetic acid, giving a mixture of **1**, **6a**, and maybe **6b**. The mixture was directly treated with aluminium chloride in toluene, yielding expected hydrocarbon **1**.

This procedure can give **1** from **2** via 8-steps in a total yield of 12—13%, and be facile comparable to the method from diphenic acid[3] (40—50% yield through 10-steps). However, the available diphenic acid is more costly (more than three times) than commercial fluorene. The preparation is the most facile and cheap way to obtain **1** within the established procedures.

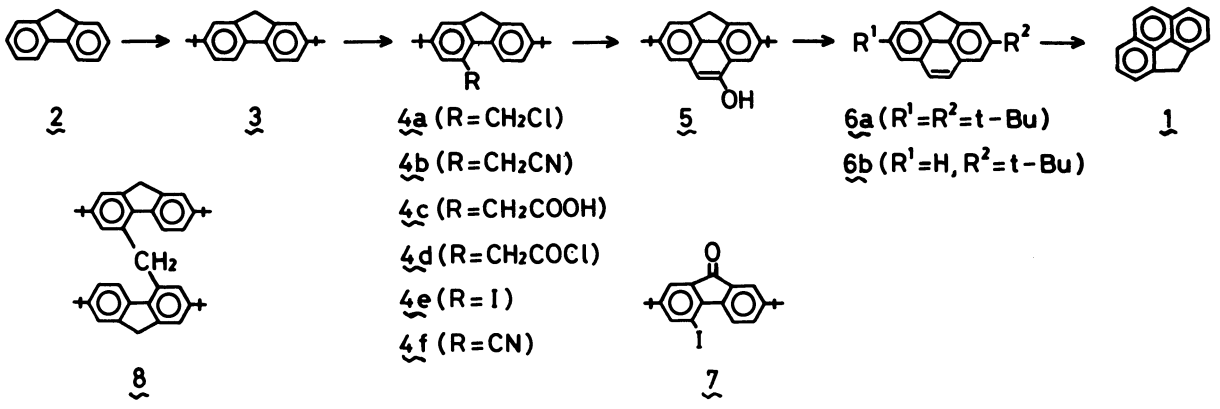
Experimental

All the melting points are uncorrected. The ^{1}H NMR spectra were measured using Varian VXR-300 or Jeol JNM C-60 HL spectrometers in $CDCl_3$ using TMS. The IR (KBr-pellet), UV data (cyclohexane), and MS spectra were recorded on Jasco IR-G, Shimadzu UV-180 and Hitachi M-80 spectrometers, respectively.

Compounds **3** and **4e** were synthesized according to a method similar to that given in the literature.[6] ^{1}H NMR of **4e**, δ=1.35 (9H, s) 1.38 (9H, s), 3.87 (2H, s), 7.47—7.56 (3H, m), 7.80 (1H, s), and 8.66 (1H, d, J=8.5 Hz).

Trans-*t*-butylation of 4e. A mixture of **4e** (808 mg, 2 mmol) and $AlCl_3$ (200 mg, 1.5 mmol) in toluene (20 ml) was stirred at 50 °C for 6 h; only **2** was isolated from the resulting mixture: 73.2 mg (22%); mp 112—114 °C.

2,7-Di-*t*-butyl-4-iodo-9-fluorenone (7). A mixture of **4e** (2.02 g, 5 mmol) and $KMnO_4$ (4.42 g, 28 mmol) in acetone (100 ml) was stirred at room temperature for 10 h. After decomposition with aqueous $NaHSO_3$, the resulting mixture was extracted with benzene and chromatographed on a SiO_2 column. The yellow eluate was evaporated to give 1.85 g (89%) of **7**: mp 140.5—141.5 °C (hexane); IR, 1710 cm^{-1}; ^{1}H NMR, δ=1.32 (9H, s), 1.34 (9H, s), 7.58 (1H, dd, J=8.1, 2.0 Hz), 7.69 (1H, d, J=1.7 Hz), 7.73 (1H, d, J=2.0 Hz), 7.82 (1H, d, J=1.7 Hz), and 8.41 (1H, d, J=8.1 Hz); UV, λ_{max} 410 (log ε 3.01), 336 (3.00), 305 (3.62), 274 (4.74), 264 (4.68), and 240 (4.40); MS, m/z 418 (M^+) and



Scheme 1.

403. Found: C, 60.11; H, 5.29%. Calcd for $C_{21}H_{23}OI$: C, 60.29; H, 5.06%.

A mixture of **7** (418.5 mg, 1 mmol) and $AlCl_3$ (540 mg, 4 mmol) in toluene (10 ml) was stirred at 70 °C for 40 h, but no specific material was obtained except **7** (262 mg, 62%, mp 139.5—141.5 °C).

4-Cyano-2,7-di-*t*-butylfluorene (4f). A mixture of **4e** (809 mg, 2 mmol), KCN (263 mg, 4 mmol), and CuCN (361 mg, 4 mmol) in DMF (10 ml) was refluxed for 17 h. The mixture was extracted with benzene, washed with dil. HCl, successively with water, dried, and chromatographed on SiO_2 giving **4f** (110 mg, 20%); mp 192—193 °C (hexane); IR, 2250 cm^{-1}; ^1H NMR, δ=1.37 (9H, s), 1.38 (9H, s), 3.88 (2H, s), 7.49 (1H, dd, J=8.1, 1.8 Hz), 7.60—7.61 (2H, m), 7.74 (1H, s), and 8.29 (1H, d, J=8.1 Hz); UV, λ_{max} 329 (log ε 4.24), 316 (4.15), 273 (4.37), and 241 (4.27); MS, m/z 303 (M^+) and 270. Found: C, 86.92; H, 8.09; N, 4.43%. Calcd for $C_{22}H_{25}N$: C, 87.14; H, 8.24; N, 4.62%.

4-Chloromethyl-2,7-di-*t*-butylfluorene (4a).[6] To a mixture of **3** (2.78 g, 10 mmol) in CS_2 (100 ml), there was added chloromethyl methyl ether (2.30 ml, 30 mmol), and successively added $TiCl_4$ (1.30 ml, 11.6 mmol) for 5 min with ice-cooling. Upon stirring for 2 h at the temperature, the reaction was quenched by pouring into ice-water, and the organic layer was evaporated and purified by sublimation in vacuo to yield **4a** (2.84 g, 87%); mp 98.5—99.5 °C (lit,[6] mp 90—93 °C); UV, λ_{max} 310 (log ε 4.05) and 273 (4.34); ^1H NMR,[6] δ=1.38 (9H, s), 1.39 (9H, s), 3.89 (2H, s), 5.00 (2H, s), 7.31 (1H, s), 7.46 (1H, d, J=8.3 Hz), 7.54 (1H, s), 7.59 (1H, s), and 7.90 (1H, d, J=8.3 Hz).

The residue of sublimation afforded **8**: mp 230—231 °C; IR, 1260 cm^{-1}; ^1H NMR, δ=1.18 (18H, s), 1.34 (18H, s), 3.95 (4H, s), 4.87 (2H, s), 7.00 (2H, s), 7.23—7.26 (2H, m), 7.46 (2H, s), 7.59 (2H, s), and 7.64 (2H, d, J=8.0 Hz); MS, m/z 568 (M^+), 553, and 269. Found: C, 90.83; H, 9.37%. Calcd for $C_{43}H_{52}$: C, 90.79; H, 9.21%.

4-Cyanomethyl-2,7-di-*t*-butylfluorene (4b).[6] A solution of **4a** (655 mg, 2 mmol) in DMF (20 ml) was stirred at room temperature with KCN (260 mg, 4.0 mmol) in H_2O (0.35 ml) for 24 h. Upon decomposition with dil. HCl, the residue was extracted with benzene and chromatographed on SiO_2 to give 530 mg (84%) of **4b**: mp 187—188 °C (lit,[6] mp 186—187 °C); UV, λ_{max} 304 (log ε 4.07), 292 (4.11), 285 (4.29), and 274 (4.44).

2,7-Di-*t*-butyl-9*H*-fluorene-4-acetic acid (4c).[6] A solution of **4b** (318 mg, 1 mmol) in AcOH (10 ml) was refluxed with conc. H_2SO_4 (0.8 ml) and H_2O (0.8 ml) for 3.5 h. Upon dilution with H_2O, the precipitate was recrystallized from benzene–cyclohexane to give **4c** (298 mg, 89%): mp 178—179 °C (lit,[6] mp 177—178 °C); UV, λ_{max} 335 (log ε 2.66), 305 (4.01), 293 (4.05), 285 (4.30), and 273 (4.45).

2,6-Di-*t*-butyl-4*H*-cyclopenta[*def*]phenanthren-8-ol (5) through Acid Chloride 4d. A mixture of **4c** (170 mg, 0.5 mmol) in $SOCl_2$ (5 ml) was refluxed for 30 min giving oily **4d**: IR, 1792 cm^{-1}; ^1H NMR, δ=1.39 (18H, s), 3.87 (2H, s), 4.55 (2H, s), and 7.13—7.54 (5H, m).

The above oil was added dropwise into a mixture of $AlCl_3$ (100 mg, 8 mmol) in $C_2H_4Cl_2$ (10 ml) at −8 °C, and the resulting mixture was stirred for 2 h giving 119 mg (75%) of **5**: mp>200 °C; IR, 3420 cm^{-1}; ^1H NMR, δ=1.45 (18H, s), 4.19 (2H, s), 6.94 (1H, s), 7.36 (1H, s), 7.50 (1H, s), 7.69 (1H, s), and 7.96 (1H, s).

The alcohol **5** was easily decomposed into red by standing for a few hour, and was failed to measure of the elemental analysis: the main portion may be 2,6-di-*t*-butyl-4*H*-cyclopenta[*def*]phenanthrene-8,9-dione (IR, 1671 cm^{-1}; MS, m/z 332, 318).

Reduction of 5. Carboxylic acid **4c** (340 mg, 1.0 mmol) was converted into **5** by a method similar to above; the resulting crude **5** was dissolved in AcOH (50 ml) and refluxed with HI (57%, 10 ml) and red phosphorus (1.0 g) for 90 h. Upon the usual treatment, a part of the resulting mixture was submitted GLPC (5% Dexsil 300 GC on Chromosorb, 1.0 Kg cm^{-2}, 230 °C): **1** (retention time 2.4 min, 8%) and **6a** (14.2 min, 31%) were confirmed by comparison with the authentic specimens. The major peak (6.3 min, 56%) might correspond to the monoalkylated compound **6b**.

The separation of the residual part of the mixture gave small amount of 2,6-di-*t*-butyl-4*H*-cyclopenta[*def*]phenanthrene (**6a**): mp 224—225 °C; IR, 1342 and 1210 cm^{-1}; ^1H NMR, δ=1.51 (18H, s), 4.31 (2H, s), 7.76 (2H, s), and ca. 7.8 (4H, s); MS, m/z 302 (M^+), 288, and 287. (Found: C, 91.80; H, 8.29%. Calcd for $C_{23}H_{26}$: C, 91.33; H, 8.67%.)

4*H*-Cyclopenta[*def*]phenanthrene (1). Acid **4c** (672 mg, 2 mmol) was treated in a way similar to the above, yielding a mixture of **6a**, **6b**, and **1**. The reaction mixture was dried, dissolved in toluene (40 ml), and stirred with $AlCl_3$ (36 mg, 0.3 mmol) at room temperature for 1.5 h giving 104 mg (27% based on **4c**) of **1**, mp 114—115 °C. This is identical in all respects with the authentic specimen.

We are grateful to Professor Takashi Toda, Utsunomiya University for his encouragement.

Active and Selective Transports of Alkali Metal Ions through Hydrophobic Membrane

Takashi HAYASHITA,* Kiyotaka TEDO, Takeo YAMABE, and Manabu IGAWA
Department of Applied Chemistry, Faculty of Engineering, Kanagawa University, Rokkakubashi, Kanagawa-ku, Yokohama 221
(Received August 1, 1987)

Synopsis. The active and selective transport of alkali metal ions coupled with proton permeation, were observed through a dense hydrophobic membrane. The flux of alkali metal ions increased with the decrease in the degree of hydration. The behavior can be comprehended in terms of the asymmetrical permeabilities of ions through the hydrophobic membrane.

Active and selective transport phenomena have been intensively studied as models of biological membranes and with a view to the practical application in industry.[1,2] Active transport has been observed through a liquid membrane containing ionophore[3–5] and an artificial membrane with containing ion-exchange groups.[6–8] We wish to report herein the findings that a dense hydrophobic membrane are also revealed active and selective transport for alkali metal ions. Such specific transport, depending on the hydrophobic environment, is considered to play an important role in artificial and biological membranes.

Experimental

A thin and dense hydrophobic membrane was prepared by coating a fluorocarbon polymer (FEP-120 dispersion, purchased from the Dupont Co.) on a "fluoropore", porous support membrane (FP-010, obtained from the Sumitomo Electric Co., Ltd.; pore size, 0.1 μm), followed by melting at 300 °C.[9,10] The SEM studies indicated that the thickness of the polymer layer on the membrane surface was about 6 to 8 μm. A homogeneous and dense layer was formed on the support membrane.[9] The coating density of the membrane used in this experiment was 0.79 mg cm^{-2}.

The dialysis experiments were carried out with a cell in which 100 mL of an aqueous solution containing 1 mmol dm^{-3} of alkali metal salts (L-side) and 100 mL of an aqueous solution containing equimolar amounts of alkali metal salts in addition to 0.1 mol dm^{-3} additive salts for producing active transport (R-side) were circulated separately into two chambers divided by the hydrophobic membrane.[11] The change in the concentration of the metal ions with time in both chambers was measured by means of an atomic-absorption spectrophotometer (Shimadzu AA-630-02).

The transport number was determined with two glass cells separated by a membrane and equipped with calomel electrodes. A metal sulfate solution of a different concentration (0.01—0.001 mol dm^{-3}) was circulated in each cell.[12]

Results and Discussion

Figure 1 shows the change in the concentration of the alkali metal ions and the pH changes on the L-side and the R-side through the hydrophobic membrane. The concentration of potassium ions on the R-side increased with the decrease in the pH on the L-side. The permeation flux of sodium ions was low

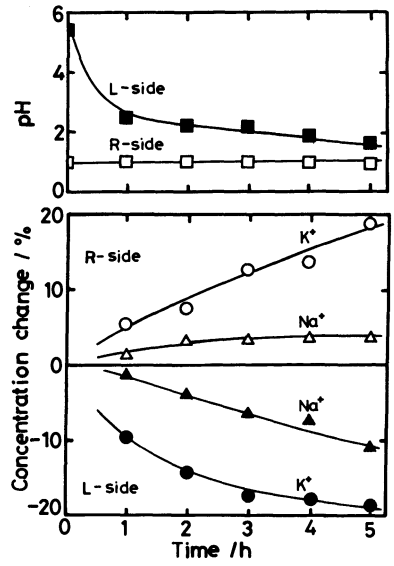

Fig. 1. Time-transport curves of Na^+, K^+ and pH through the hydrophobic membrane. L-side soln.: $[Na_2SO_4]=[K_2SO_4]=1$ mmol dm^{-3} (closed symbols). R-side soln.: $[Na_2SO_4]=[K_2SO_4]=1$ mmol dm^{-3}, $[H_2SO_4]=0.1$ mol dm^{-3} (open symbols).

compared with that of potassium ions. These results indicate that the selective and active transport of the alkali metal ions occurred coupled with the proton permeation. The behavior can be explained as a consequence of the asymmetrical permeabilities of the cations and the anion through the membrane, because the hydrophobic membrane repels the penetration of highly hydrated ions. It should be noted that some permeation lags were observed in this system. That is, the increment of alkali metal ions in the R-side solution were somewhat low compared with the decreasing degree of the L-side solution. This suggests that the rate of ion-exchange migration in the membrane was slower than that of distribution into the membrane.

These selectivities were only observed through a dense hydrophobic membrane. When the support membrane before coating was used as a barrier, an osmotic flow of water occurred and stable measurements could not be attained. To prevent such an osmotic flow, a coating density of at least 0.5 mg cm^{-2} was needed. The measurements are also considered to be difficult in the case of excess coating because of the low diffusibility of ions in the dense hydrophobic region of the membrane. Therefore, an appropriate amount of coating density (0.5—1.0 mg cm^{-2}) was required in these measurements.

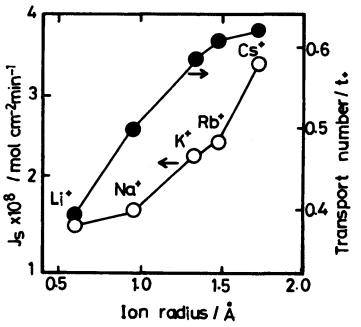

Fig. 2. Effect of ion radius on ion flux and transport number of permeate cations. ○: Ion flux (which were measured in the single component systems). L-side soln.: $[M_2SO_4]$=1 mmol dm^{-3}. R-side soln.: $[M_2SO_4]$=1 mmol dm^{-3}, $[H_2SO_4]$=0.1 mol dm^{-3}. ●: Transport number through the hydrophobic membrane.

Table 1. Effects of Additive Species on the Ion Flux[a)]

Additive	$J\times10^8$/mol cm^{-2} min^{-1} K$^+$	Na$^+$	J_{K^+}/J_{Na^+}
H_2SO_4	2.38	0.69	3.4
HCl	1.39	0.79	1.8
NH_4Cl	0.20	0.27	0.7
LiCl	−0.55	−0.26	2.1

a) Measurements were carried out in the Na$^+$, K$^+$ binary system. L-side soln.: $[Na_mX]=[K_mX]$=1 mmol dm^{-3}. R-side soln.: $[Na_mX]=[K_mX]$=1 mmol dm^{-3}, [Additive]=0.1 mol dm^{-3} (X=Cl$^-$ or SO_4^{2-}, m=1 or 2).

The effect of the ion radius of alkali metal ions on the ion flux, as calculated from the initial change in the concentration on the R-side, is shown in Fig. 2. The measurements were carried out in a single-component system. The hydration degree of an ion is known to decrease with the increase in the ion radius.[13)] From the figure, the flux of metal ions is seen to increase with the decrease in the hydration degree. In a hydrophobic environment, a low-hydrated ion is considered to be more permeable. These differences in permeability depending on the hydration degree are also proved by the values of the transport numbers for the cations. As may be seen from the figure, the transport number of cations increased with the decrease of hydration degree, similarly with the propensity of the ion flux (Fig. 2).

The effect of additive species in producing the active transports is shown in Table 1. As the proton has a high permeability because of the different permeation mechanism (the transport number of protons through the membrane (t_{H^+}) was 0.69 for H_2SO_4), which is known as a proton-jump mechanism coupled with water molecules,[14)] the metal ions were effectively transported couples with proton permeation. However, when a cation with a low membrane permeability, such as the lithium ion, was used as the additive, the flux depending on the antiport mechanism decreased significantly, while, on the contrary, the symport permeation of alkali metal ions, coupled with the permeation of chloride anions, was found to occur. These results also indicate that asymmetrical permeabilities of ions through the hydrophobic membrane are the cause of these specific permeations.

In conclusion, the selective and active transport of alkali metal ions was found to be attained through a dense hydrophobic membrane prepared by coating a fluorocarbon polymer on a support membrane. We consider that the hydrophobic membrane is a useful model for studing an ion channel consisting of a hydrophobic environment. Further studies of these specific permeations for other ionic solutes are in progress.

12) The transport number of the cation (t_+) was determined using the following equation:

$$E = \left(\left(\frac{1}{z_+} - \frac{1}{z_-}\right)t_+ + \frac{1}{z_-}\right)\frac{RT}{F}\ln\frac{a_R}{a_L}$$

Here, E is the membrane potential; z represents the ionic charge; R, T, and F are the gas constant, the absolute temperature, and the faraday constant respectively and a_R and a_L are the salt activities of the R-side and L-side solutions respectively.

Heats of Solution and Viscosity *B* Coefficients for Some Cyclic Mono- and Bis(quaternary ammonium) Salts

Kunio TAMAKI,* Takeshi KITAZAWA, and Misako ASADA
Department of Chemistry, Yokohama City University, Kanazawa-ku, Yokohama 236
(Received May 27, 1987)

Synopsis. Heats of solution and viscosity *B* coefficients, for cyclic mono(quaternary ammonium) salts, $(CH_3)_2N(CH_2)_nBr$ (n=4—6) and cyclic bis(quaternary ammonium) salts,  (n=1—3) in water were measured, and the effect of structural changes in the solvent water upon the dissolution of both series of electrolytes is discussed.

In previous papers,[1,2] the balance of ionic hydration and hydrophobic hydration in aqueous solutions of *N,N'*-polymethylenebis(trimethylammonium) dibromides and alkyltrimethylammonium bromides was discussed on the basis of the change in the heat capacity upon dissolution in water and the temperature dependence of the viscosity *B* coefficients in aqueous solutions.

Noguchi and Rembaum[3-5] reported that, in the course of the synthetic studies of polyelectrolytes by the Menschutkin reaction between *N,N,N',N'*-tetramethyl-α,ω-alkanediamines $(CH_3)_2N(CH_2)_xN(CH_3)_2$ (I) and α,ω-dibromoalkanes $Br(CH_2)_yBr$ (II), syntheses of polyelectrolytes were unsuccessful when the reaction systems with small values of x's and/or y's were carried out, and various linear and cyclic mono- and diammonium salts of low molecular weights were isolated. It seems that it would be of interest to study the solution properties of these low molecular weight compounds in water. We selected some cyclic mono(quaternary ammonium) salts $(CH_3)_2N(CH_2)_nBr$ (n=4—6; which will be abbreviated as NC_n[6]) and cyclic bis(quaternary ammonium) salts  (n=1—3; which will be abbreviated as NC_nC_2N[7]) from the products reported by Noguchi and Rembaum.[3-5] The experimental results will be reported on the heats of solution and the viscosity *B* coefficients of aqueous solutions of these five-, six-, and seven-membered cyclic mono- and bis(quaternary ammonium) salts in this paper.

Experimental

All the salts were prepared by the reaction of ditertiary amines (I) with dibromides (II) in acetonitrile at room temperature according to the procedure described by Noguchi and Rembaum.[3-5] After the solvent had been removed, the salts were purified several times by recrystallization from suitable solvents. The reaction system and the solvents for recrystallization are summarized in Table 1. As NC_1C_2N was obtained in poor yield by the method of Noguchi and Rembaum,[4] the iodide salt of NC_1C_2N was prepared by the reaction of *N*-methylpyrrolidine with methyl iodide in ethanol,[8] the product was then converted to the bromide salt using the anion-exchange resin. All the salts were dried in vacuo at room temperature for several days, and then analyzed for bromide ion by argentometric titration. The salts were found to have a purity greater than 99.3%. Water was triply distilled. The solutions were made by weight.

Table 1. Reaction System and the Solvents for Recrystallization

Compound	x-y Reaction	Solvent
NC_4	2-1	EtOH–water (12:1)
NC_5	1-2	EtOH–water (5:1)
NC_6	2-3	EtOH–water (7:1)
NC_1C_2N	1-4	EtOAc–EtOH (1:1)
NC_2C_2N	1-5	EtOAc–EtOH (1:1)
NC_3C_2N	1-6	EtOAc–EtOH (2:1)

The heats of solution were measured at 15, 25, and 35 °C using a twin isoperibol calorimeter, TIC-2C, of the Tokyo Riko Co., Ltd., by a method similar to that described in a previous paper.[9]
