[a] All compounds **4** had a band in each of the following ranges of the infrared spectrum (cm^{-1}, CCl_4): 1452–1467, 1380–1382, 1365–1368, 1276–1282, 1230–1238, 1195–1197, 1107–1115.

[b] The yield is a rough estimate only, because of the impure state of the product.

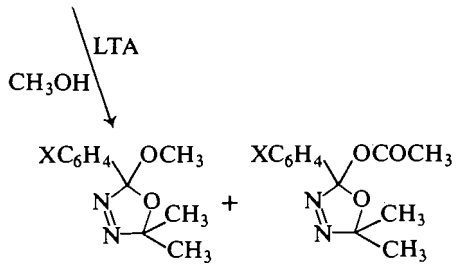
[c] In $CDCl_3$ with ref. CH_2Cl_2, δ 5.22.

[d] Peaks at δ 1.42 to δ 1.79 were assigned to methyl groups at C-2 and C-5 of a 1:1 mixture of *cis* and *trans* isomers. Signals at δ 2.75 and 3.17 were assigned to methoxy groups at C-2 in the isomers. The δ 2.75 signal was assigned to the isomer in which the 2-methoxy- and 5-(4-methoxyphenyl) substituents are *cis*. Signals from *p*-methoxy groups of the two isomers are overlapped at δ 3.72, where there is also a contribution from impurities, presumably 2-acetoxy analogues. The aryl region of the spectrum closely resembled that of **4***a* and is not listed. Integrals are listed relative to the four singlets of equal intensity which were assigned "3H".

[e] The singlet at δ 2.78, assigned to the 2-OCH_3 group *cis* to the 5-aryl group, was used as the reference for integration by assigning to it the value "3H".

[f] The reference signal for integration was that at δ 2.74 (see footnote *e*). The singlets at δ 1.44, 2.03, and 3.10 may arise from the products of decomposition of **5***c*. Those three signals remained intense in samples taken to completion of thermolysis.

[4] $(CH_3)_2C{=}NNHCOC_6H_4X$



4

coproducts, were destroyed by saponification (24–27, 31) and the residual methoxy compounds were purified by column chromatography (Experimental).

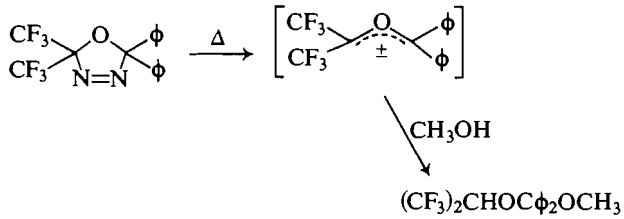
Compounds **5**, which were obtained by analogous oxidation of acetyl hydrazones of acetophenones, proved to be very difficult to obtain in pure form. Acyl hydrazones of acetophenones oxidize more slowly than do those of dialkyl ketones while, at the same time, the oxidation products from the former (2,5-dialkyl-5-aryl-2-alkoxyoxadiazolines) are somewhat more labile than those from the latter (5,5-dialkyl-2-alkoxyoxadiazolines). It was not possible, therefore, to find conditions for the preparation of **5** which did not lead to mixtures of **5**, starting material, and products from thermolysis of **5**. Moreover, the oxidative cyclizations gave **5** and the acetoxy analogue as mixtures of *cis/trans* isomers. Consequently, all experiments with **5** had to be carried out with materials of low purity (ca. 60–80%) and only three members of the series could be obtained at that level of purity. Table 1 lists the spectral data of compounds **4** and of mixtures containing **5**.

Attempts to prepare 5,5-diaryl-2-methoxy-2-methyl oxadiazolines (**6**), to avoid the problem of *cis/trans* isomeric mixtures, were even less rewarding. Acyl hydrazones of benzophenones are still less reactive toward lead tetraacetate than their acetophenone counterparts and the derived oxadiazolines (**6**) appear to be very labile. As a result, conditions which lead to formation of **6** also permitted their rapid thermolysis and no measurements at all could be made on **6**. Hoffmann and Luthardt have reported that the analogous 2,5- and 5,5-diaryl-2-acetoxyoxadiazolines decompose quite rapidly at 0°C (33).

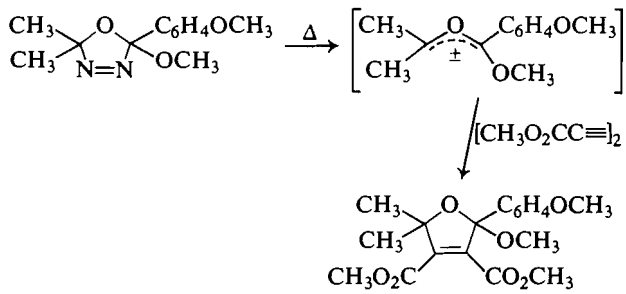
Thermolysis of oxadiazolines was followed by ^1H nmr spectroscopy using peak areas from the electronic integrator, normalized to that of an internal standard such as CH_2Cl_2. Good fits to the first order rate law were obtained, with correlation coefficients typically better than 0.998 for **4**. In the case of **5**, where the substrates were complex mixtures containing geometric isomers of **5**, geometric isomers of the corresponding 2-acetoxy compounds, and products from their decomposition during preparation of the sample, it was important to follow the decay of an appropriate signal in the ^1H nmr spectrum. Fortunately each of the mixtures containing **5***a*–**5***c* gave a distinctive signal (δ 2.75, 2.78, and 2.74, respectively), assignable to a methoxy group at C-2 shielded by a *cis* aryl group at C-5. The spectra of t_∞ samples were free of signals near δ 2.75. There was assurance, therefore, not only that what was being monitored was the concentration of a methoxyoxadiazoline and not that of an acetoxy analogue, but also that the measured rates pertained to the same geometric isomer of the family **5**.

Before beginning a discussion of the substituent and solvent effects on rates we turn briefly to the evidence for the existence of a carbonyl ylide intermediate in the thermolysis of 1,3,4-oxadiazolines. That evidence comes from the finding that oxiranes and/or enol ethers (22, 25, 32) are formed from an intermediate which can be diverted away from those products by methanol (22, 25, 34) and, in some cases, by reactive dipolarophiles (27, 32, 33*b*, 35). Moreover, the compounds resulting from interception of the intermediate have structures expected on the basis of the assumption that the intermediate is a carbonyl ylide, eqs. [5], [6].

[5]



[6]



Similar adducts have been obtained by trapping intermediates from non-oxadiazoline sources (36–40), including oxiranes, from which initial intermediates other than carbonyl ylides are particularly hard to imagine.

Oxadiazoline **4***a* had been decomposed earlier (27) in CD_3OD at 79.5°C. The absence of acetone, methyl *p*-methoxybenzoate, and 2-methoxy-2-(4-methoxyphenyl)-3,3-dimethyloxirane reported earlier (27) was noted also in the present study at 49.2°C. Similar results were obtained for other members of the family **4**.

Thermolysis of **4** in CCl_4 gave a complex mixture of products, some of which were not identified. For example, **4***c* gave acetone and methyl benzoate as major products, as well as isopropyl benzoate and at least five additional minor products. 2-Methoxy-2-phenyl-3,3-dimethyloxirane, the expected product of cyclization of a carbonyl ylide intermediate, was not found. That compound was synthesized independently and shown to be thermally stable at temperatures higher than those used for thermolysis of **4** (Experimental section). The fact that oxirane was not found among the products from **4***c*, under conditions that do not cause thermal ring opening of that oxirane, suggests at first that oxirane was not formed. Such a conclusion is probably not warranted, however, because of the possibility that one of the unidentified minor products (a trace amount of HCl for example) acts as a catalyst for ring opening of the oxirane.

Although compounds from the family **5** had not been studied previously, and ylide intermediates had therefore not been demonstrated for them specifically, it was possible to detect an ylide-derived product in the t_∞ samples. In the case of **5***b*, for example, the ^1H nmr spectrum of the thermolysis products

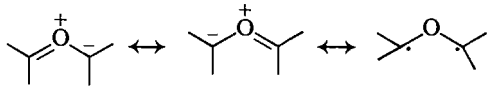
included a pair of doublets from vinylic protons (δ 4.8 and 4.3) and a quartet at low field (δ 6.5) characteristic of $H_2C{=}C(Ar)OCH(CH_3)OR$. Although it was not possible to determine whether that minor product had come from **5***b* (R = CH_3) or from the acetoxy analogues present as impurities (R = $COCH_3$), it does not really matter because the mechanistic analogy between 2-methoxy- and 2-acetoxyoxadiazolines is quite well established (24–27).

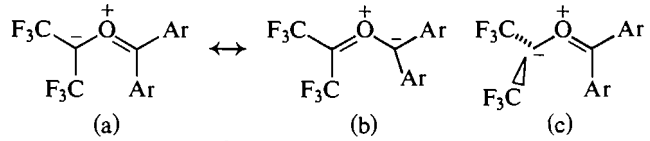
There is little doubt then that Δ^3-1,3,4-oxadiazolines, in general, undergo thermolysis via carbonyl ylide intermediates and the remaining mechanistic questions are whether the transition state for the rate-determining step involves one or two C—N bond scissions and whether that transition state is dipolar or diradical in character.

The results (Table 2) suggest that the extrusion of N_2 from 2-alkoxy-Δ^3-1,3,4-oxadiazolines may be a concerted process. Substitution of a phenyl group at either C-2 or C-5 leads to an enhanced thermolysis rate constant. Thus, at C-2 the enhancement factors are 3.6 in CCl_4 and 6.4 in CD_3OD at a temperature that is 30° lower than that used for the 2-methyl analogue. The true rate factors can be estimated by assuming that rate constants for **4** would double with every 10° increment in the temperature, for temperatures near 50°C. That assumption leads to estimates of 29 and 51 for the phenyl group effect at C-2, in CCl_4 and in CD_3OD, respectively. Similarly, the rate factor caused by phenyl-for-methyl substitution at C-5 is estimated to be 125. The most likely reason for those effects is that both the C-2 to N-3 and the N-4 to C-5 bonds break in the rate-determining step.[4]

The effects of *p*-substituents in aryl groups at C-2 and at C-5 (Table 2) are similar. In each case electron-withdrawing groups enhance the thermolysis rate constant, indicating that C-2 and C-5 become more electron-rich as the substrates pass from their ground states to the transition states. That is the result that would be expected from a mechanism involving an ylide-like transition state, as the following dipolar contributors to the ylide structure suggest. It was pointed out in the Introduction



that a previous study (22), with oxadiazoline **1** (eq. [2]), gave the opposite result. In that case the substituent effects indicated that the benzylic carbon became more positive in the transition state than it had been in the ground state. Although that result may appear to be at odds with a concerted mechanism leading to a carbonyl ylide intermediate, it can be rationalized within that mechanistic framework. A highly unsymmetric ylide like **2** might well have a charge distribution described largely by



(a) (b) (c)

[a] Water bath (49.20 ± 0.05°C) for compounds **4** and probe (45 ± 1°C) for compounds **5**.

[b] These values were taken to be the same as σ_p-values except for the NO_2 group, for which $\sigma_p = 0.78$, and the CF_3 group, for which $\sigma_p = 0.54$ (41). The correlation coefficients for the Hammett plot for **4**, using σ_p values, were 0.979 (CCl_4) and 0.978 (CD_3OD). Corresponding correlation coefficients from use of σ_p^--values were 0.995 and 0.998.

[c] At 79.5°C.

contributor (a), with only a small weighting accorded to contributor (b). Alternatively, the ground state of **2** could be twisted, like the 0°,90° conformation (c), in which also the aryl substituents would "see" the benzylic carbon as a positive site. Whatever the reason for the negative ρ-value of Shimizu and Bartlett (22), there is no doubt that the present results, indicating accumulation of *negative* charge at C-2 of **4** and at C-5 of **5** and thereby suggesting that, for each one, negative charge accumulates at *both ends* of the 1,3-fragment, are much more in keeping with expectations based on the classical valence bond structure of a simple carbonyl ylide.

Although the sense of charge redistribution that accompanies extrusion of nitrogen is unmistakable, the ρ-values are quite small[5,6] and it follows that relatively little negative charge develops at C-2 of **4** and at C-5 of **5**. This point is supported strongly by the solvent effects on rates of thermolysis of **4**. For all compounds **4** the rate constants for thermolysis in methanol were slightly smaller than those pertaining to CCl_4 solvent. Such a dependence is a common feature of the thermolysis kinetics of *cis* azo compounds (10, 42, 43). The explanation, in terms of preferential solvation of the polar ground state relative to solvation of the radical-pair-like transition state, can be invoked also for **4** and **5**. The oxadiazolines must have substantial local dipoles with the positive ends at C-2 and C-5, each of which bears an electron-withdrawing azo nitrogen and

[4] It would be desirable to determine rate constants for thermolysis of 2,5-diaryl-2-methoxyoxadiazolines, of course, to ascertain whether or not the aryl groups have additive effects. In view of our difficulties with the purification of **5** we hold out little hope of success for the preparation of 2,5-diaryl analogues in a pure state, using current methodology.

[5] For a list of ρ-values for reactions of known mechanism, see ref. 42. For example, displacement of Cl from 1-chloro-2-nitro-4-X benzenes by methoxide in methanol is correlated with σ^--values for X, with ρ (50°C) = 3.9.

[6] With only three points in hand, the ρ-value for **5** is not very reliable, of course.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.105 on 09/06/12
For personal use only.

one or two alkoxy groups. Since the dipole vectors from the azo and alkoxy substituents are additive, the oxadiazolines must be more polar than a simple *cis* azo compound and therefore at least as strongly solvated in polar media. Concerted loss of nitrogen from **4** or **5** would cause a larger reduction of substrate polarity than would the first step of a stepwise mechanism, in which one dipolar centre is effectively retained. The concerted mechanism therefore accommodates the solvent effect particularly well, especially if compensating polarity in the ylide product is poorly developed at the transition state.

In summary, the following description of the transition state appears to fit the information best. Both C—N bonds are partially severed and the C—O—C portion of the 5-membered ring has made some progress, by conrotatory motion, toward the 0°,0° ground state geometry of the carbonyl ylide product. Relatively little resonance stabilization, which requires full coplanarity if it is to be important, has accrued and, as a result, there is only a little ylide-like charge separation.

An alternative picture would have the transition state more product-like and would explain away the small ρ-value by invoking largely diradical character for the ylide itself, and therefore also for the transition state leading to it. Support for the view that many 1,3-dipoles are really more diradicaloid than dipolar comes from theory (44–46) and awaits experimental testing.

Experimental

2-Methoxy-2-(4-methoxyphenyl)-5,5-dimethyl-Δ^3-1,3,4-oxadiazoline **4***a*

To an ice-cold solution of lead tetraacetate (4.8 g, 10.8 mmol) in dry methanol (30 mL) was added acetone-N-(4-methoxybenzoyl)-hydrazone (2.0 g, 9.7 mmol), with stirring. When the yellow colour of the solution had been discharged, potassium hydroxide (pellets, 1 g) was added and the reaction mixture was stirred for 2 h at ice temperature. Much of the methanol was removed with a rotary evaporator without heating, water was added, and the aqueous solution/suspension was extracted with dichloromethane. After the extract had been dried over calcium chloride, the solvent was evaporated and the residue was chromatographed on basic alumina in a water-cooled column (ca. 10°C) using ether (5%) in hexane. The first fraction eluted was **4***a* (1.4 g, 59% yield); ms (ei mode, *m/z*): 135 ($CH_3OC_6H_4CO^+$), 107 ($CH_3OC_6H_4^+$), 92 ($C_6H_4O^+$); nmr spectra in Table 1.

2-Methoxy-5,5-dimethyl-2-(4-methylphenyl)-Δ^3-1,3,4-oxadiazoline **4***b*

The procedure described above for the preparation of **4***a* was followed. Oxidation of acetone-N-(4-methylbenzoyl)hydrazone afforded **4***b* in 55% yield; ms (ei mode, *m/z*): 150 ($CH_3C_6H_4CO_2CH_3^+$), 119 ($CH_3C_6H_4CO^+$), 91 ($C_7H_7^+$); nmr spectra in Table 1.

2-Methoxy-5,5-dimethyl-2-phenyl-Δ^3-1,3,4-oxadiazoline **4**c

This material was obtained in 47% yield by the procedure already described; ms (ei mode, *m/z*): 136 ($C_6H_5CO_2CH_3^+$), 105 ($C_6H_5CO^+$), 77 ($C_6H_5^+$); nmr spectra in Table 1.

2-(4-Chlorophenyl)-2-methoxy-5,5-dimethyl-Δ^3-1,3,4-oxadiazoline **4**d

Oxidation of acetone-*p*-chlorobenzoyl hydrazone as described above for analogues gave **4***d* in 55% yield; ms (ei mode, *m/z*): 141, 139 ($ClC_6H_4CO^+$); 113, 111 ($C_6H_4Cl^+$); nmr spectra in Table 1.

2-(4-Trifluoromethylphenyl)-2-methoxy-5,5-dimethyl-Δ^3-1,3,4-oxadiazoline **4**e

Compound **4***e* was obtained in 54% yield by the general procedure; ms (ei mode, *m/z*): 173 ($CF_3C_6H_4CO^+$), 145 ($CF_3C_6H_4^+$); nmr spectra in Table 1.

2-Methoxy-5,5-dimethyl-2-(4-nitrophenyl)-Δ^3-1,3,4-oxadiazoline **4**f

The general procedure afforded **4***f* in low yield (29%); ms (ei mode, *m/z*): 150 ($O_2NC_6H_4CO^+$), 104 ($C_6H_4CO^+$), 76 ($C_6H_4^+$); nmr spectra in Table 1.

2-Methoxy-5-(4-methoxyphenyl)-2,5-dimethyl-Δ^3-1,3,4-oxadiazoline **5**a *(*cis *and* trans *isomers containing 2-acetoxy analogues)*

p-Methoxyacetophenone-N-acetylhydrazone (1.0 g, 4.9 mmol) was added to an ice-cold solution of lead tetraacetate (3.02 g, 7.2 mmol, washed free of acetic acid with 30–60°C petroleum ether) in absolute methanol (50 mL). The resulting solution was placed in a freezer compartment (−33°C) where it was kept for 24 h. The solution was then kept at 0°C for 7 h, during which time it became colourless. A few pellets of KOH were added and stirring was continued, at 0°C, for 4 h more. A white precipitate was formed during that period. Cold water and cold dichloromethane were added and the resulting mixture was filtered through Celite. The methylene chloride layer was separated, washed with water, and dried in the refrigerator over $CaCl_2$. Evaporation of most of the solvent with a rotary evaporator and addition of $CDCl_3$ at room temperature gave a solution from which gas was evolved slowly (bubbles); ^{1}H nmr spectrum in Table 1.

2-Methoxy-2,5-dimethyl-5-phenyl-Δ^3-1,3,4-oxadiazoline **5**b *(*cis *and* trans *isomers containing 2-acetoxy analogues*

Oxidation of acetophenone-N-acetylhydrazone, by the procedure described above for preparation of **5***a*, gave a solution ($CDCl_3$) containing **5***b* from which gas was evolved at room temperature; ^{1}H nmr spectrum in Table 1.

5-(4-Bromophenyl)-2-methoxy-2,5-dimethyl-Δ^3-1,3,4-oxadiazoline **5**c *(*cis *and* trans *isomers containing 2-acetoxy analogues)*

Oxidation of *p*-bromoacetophenone-N-acetylhydrazone by the procedure described for preparation of **5***a* afforded a solution of crude **5***c* from which gas was evolved slowly at room temperature; ^{1}H nmr spectrum in Table 1.

Kinetics of thermolysis of **4**

An oxadiazoline **4** (20 mg) was dissolved in 0.5 mL of the solvent (CD_3OD or CCl_4) containing a small amount of CH_2Cl_2, which served as internal standard for integration. The solution was transferred to an nmr tube fitted with a ground glass joint and it was subjected to three cycles of freeze–pump–thaw degassing at 10^{-2} Torr (1 Torr = 133 Pa) before the tube was sealed.

Temperature was controlled with a water bath at 49.2 ± 0.05°C. The tube was withdrawn from the bath and chilled before an analysis of the contents by ^{1}H nmr spectroscopy. Time spent by a tube outside the bath, which included a brief period in the spectrometer probe at ca. 35°C, was not counted.

Progress of the reaction was followed by integrating the signal from the 2-methoxy substituent of the substrate and that from the internal standard. A plot of ln (relative integral) against time was linear. Typically, a reaction was followed to 80% or more of completion and each compound was thermolyzed at least twice in each solvent.

Kinetics of thermolysis of **5**

A solution of **5** in $CDCl_3$ containing CH_2Cl_2, which was prepared in order to acquire the ^{1}H nmr spectrum (see synthesis of **5***a*), was used directly for the kinetic studies. The sample was kept in the probe (T = 45°C), in a tightly-capped nmr tube, for the duration of the kinetic run (about two half-lives), during which time 14 to 20 readings were taken of the integral of the signal being monitored (**5***a*, δ 2.75; **5***b*, δ 2.78; **5***c*, δ 2.74) and of the integral of the signal from CH_2Cl_2. Correlation coefficients for plots of ln (relative integral) against time had the values 0.988, 0.996, and 0.994 for **5***a*, **5***b*, and **5***c*, respectively.

α-Bromoisobutyrophenone

Isobutyrophenone (1.48 g, 0.010 mol) in CCl_4 (10 mL) containing acetic acid (1 mL) was treated with Br_2 (1.60 g, 0.010 mol). Ether was added and the resulting solution was washed with aqueous sodium bicarbonate and with brine before it was dried over $MgSO_4$. Filtration, followed by evaporation of the solvents, left 2.27 g (98%) of crude

bromoketone: ^{1}H nmr (δ, CCl_4, TMS): 2.00 (s, 6H), 7.45 (m, 3H), 8.16 (m, 2H).

2-Methoxy-2-phenyl-3,3-dimethyloxirane

Following the procedure of Stevens and Dykstra (47) a solution of α-bromoisobutyrophenone (2.27 g, 0.010 mol) in methanol (15 mL) was heated to reflux and sodium methoxide (0.010 mol) in methanol (10 mL) was added. The resulting solution was refluxed for 10 min before it was poured onto ice. Extraction of the aqueous methanol with hexane, followed by drying and evaporation of the hexane, left the title compound (1.58 g, 90%) as an oil; ^{1}H nmr (δ, CCl_4, TMS): 0.97 (s, 3H), 1.47 (s, 3H), 3.17 (s, 3H), 7.36 (m, 5H). Singlets at δ 1.03, 1.20, 1.57, and 3.30, from impurities, accounted for about 8% of the total integral.

Thermal stability of 2-methoxy-2-phenyl-3,3-dimethyloxirane in benzene and in carbon tetrachloride

The oxirane described above (20 mg), dissolved in benzene (0.5 mL) and sealed into an nmr tube, was heated at 80°C in an oil bath for 96 h. The ^{1}H nmr spectrum at the end of the heating period was indistinguishable from that of the unheated sample, indicating that the oxirane is persistent at 80°C in benzene; ^{1}H nmr (C_6H_6 solvent, rel. C_6H_6 at δ 7.40): 1.10 (s, 3H), 1.76 (s, 3H), 3.33 (s, 3H), ArH obscured by solvent.

A similar sample, but containing also dimethyl acetylenedicarboxylate (56 mg) to test for reversible formation of ylide, was not altered after 96 h at 80°C as judged from the ^{1}H nmr spectrum.

An analogous sample of the oxirane in CCl_4 solvent that had been washed with bicarbonate, dried, and distilled, was not affected by heating for 100 h at 50°C or for 90 h at 80°C.

Acknowledgments

Financial support of this work, from the Natural Sciences and Engineering Research Council of Canada, is gratefully acknowledged. We extend thanks to Dr. P. A. Risbood for the synthesis of 2-methoxy-2-phenyl-3,3-dimethyloxirane and to Mr. E. Y. Osei-Twum for testing its thermal stability.

Received December 2, 1983

This paper is dedicated to Professor G. E. Dunn on the occasion of his 65th birthday

EDWARD G. JANZEN. Can. J. Chem. **62**, 1653 (1984).

The β-^{13}C and ^{15}N hyperfine splitting constants in the phenyl radical adduct of phenyl *tert*-butyl nitrone (PBN), diphenylmethyl *tert*-butyl aminoxyl, have been measured as a function of solvent and temperature.

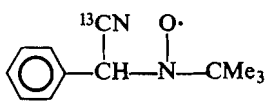
EDWARD G. JANZEN. Can. J. Chem. **62**, 1653 (1984).

Opérant à diverses températures et dans divers solvants, on a mesuré les constantes de couplage hyperfin du β-^{13}C et du ^{15}N des adduits du radical phényle avec la phényl *tert*-butyl nitrone (PBN) nommément le diphénylméthyl *tert*-butyl aminoxyle.

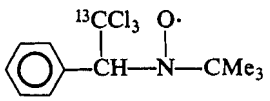
[Traduit par le journal]

Introduction

In previous publications the β-^{13}C hyperfine splitting constants (hfsc's) of the cyanyl (1) and trichloromethyl (2) radical adducts of phenyl *tert*-butyl nitrone (PBN) have been reported:

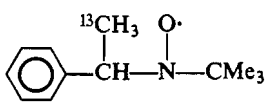


a_N = 15.02, a_β^H = 2.03, $a_\beta^{C\text{-}13}$ = 9.85 G
(in CH_3CN)



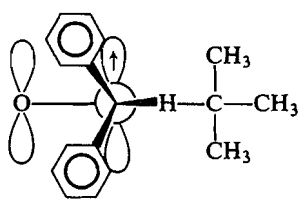
a_N = 14.10, a_β^H = 1.74, $a_\beta^{C\text{-}13}$ = 9.68 G
(in lipid or organic phase)

Since the β-^{13}C hfsc for the methyl adduct is considerably smaller (3), it was of interest to investigate the β-^{13}C hfsc



a_N = 14.6, a_β^H = 3.6, $a_\beta^{C\text{-}13}$ = 3.15 G
(in benzene)

for the phenyl adduct where the time-average conformation of the diphenylmethyl group is more readily assigned:



Experimental

Diphenylmethyl *tert*-butyl aminoxyl was prepared in an inert solvent (benzene or acetonitrile) by allowing phenylazotriphenylmethane to decompose in the presence of PBN under nitrogen (4) (overnight at room temperature or about 1 h at 50–70°C in a water bath):

$$(C_6H_5)_3CN_2C_6H_5 \rightarrow (C_6H_5)_3C\cdot + N_2 + C_6H_5\cdot$$

$$C_6H_5\cdot + PBN \rightarrow (C_6H_5)_2CHN(O\cdot)C(CH_3)_3$$

The solution was subsequently exposed to air to remove the signal due to the triphenylmethyl radicals:

$$2(C_6H_5)_3C\cdot + O_2 \rightarrow (C_6H_5)_3COOC(C_6H_5)_3$$

In order to obtain the spectrum in a different solvent, the solvent (benzene or acetonitrile) was evaporated and the new solvent added. Sample solutions were thoroughly purged with nitrogen to remove oxygen (15–20 min vigorous bubbling) before esr experiments were attempted.

An IBM ER200D-SRC spectrometer with an ASPECT data system was used. Although strong signals were obtained, the spectra were accumulated for display on the screen (3–5 scans were sufficient). The cursor was used to locate the maxima and minima of both the parent and satellite peaks (the latter at appropriately higher amplification of stored signal). Peak positions were calculated by computer and recorded in gauss by the printer.

The method used in calculating the hyperfine splittings is given below (see Figs. 1 and 2):

N-14, average of 8 spaces:
3T − 1T,3B − 1B,4T − 2T,4B − 2B,5T − 3T,5B − 3B,6T − 4T,6B − 4B

β-H, average of 6 spaces:
2T − 1T,2B − 1B,4T − 3T,4B − 3B,6T − 5T,6B − 5B

α-^{13}C, 2 × average of 6 spaces:
1T − 1S,1S − 2B,3T − 1S,1S − 4B,5T − 1S,1S − 6B

β-^{13}C, 2 × average of 6 spaces:
1T − OS,OS − 2B,3T − OS,OS − 4B,5T − OS,OS − 6B

N-15, sum of 2 spaces:
(4B − NF) + (NF − 3T)

The repeatability was better than ±0.005 G for N-14 and β-H hfsc's and better than ±0.05 G for α-C-13 and β-C-13 hfsc's. Because the high-field spacing is larger than the low-field spacing for the nitrogen triplet these measurements were averaged.

[1] All experimental work was peformed at the West Coast Customer Centre of IBM Instruments Inc., 40 W. Brokaw Rd., San Jose, CA 95110, U.S.A.

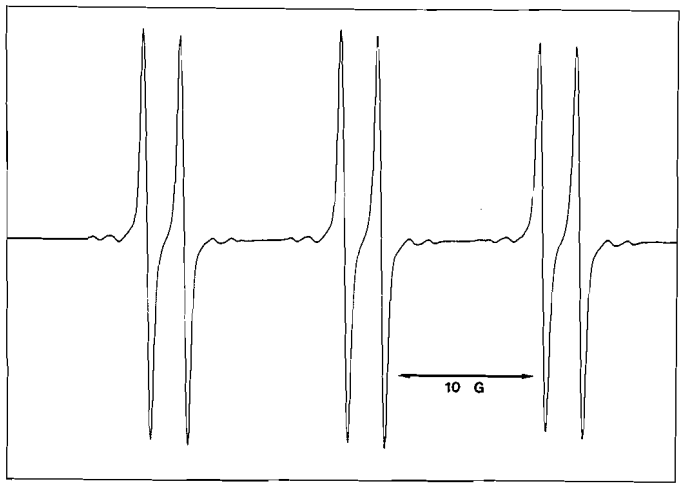

FIG. 1. Electron spin resonance spectrum of diphenylmethyl *tert*-butyl aminoxyl in acetonitrile at room temperature.

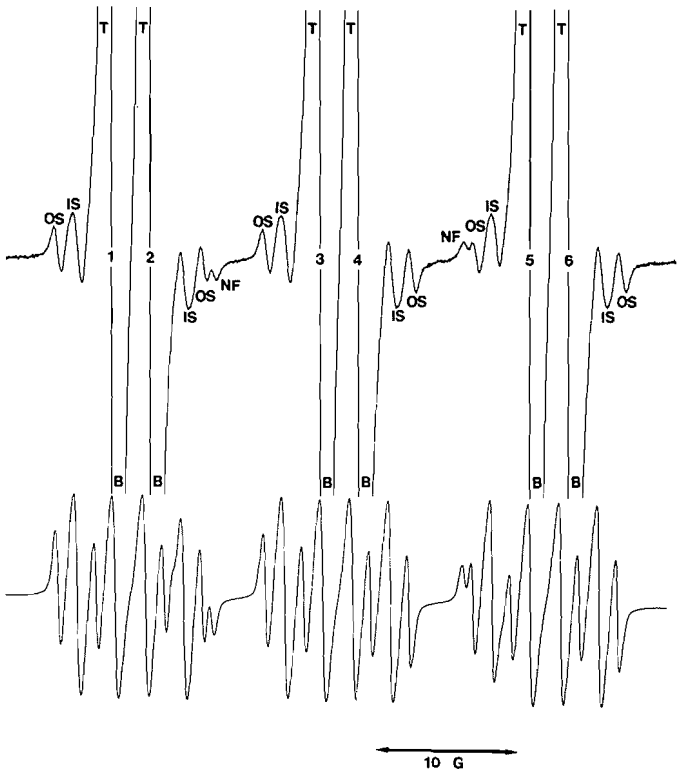

FIG. 2. Electron spin resonance spectrum from Fig. 1 at higher spectrometer gain with computer simulated esr spectrum of a mixture of two aminoxyls: one with N-14, β-H, β-C-13 and the other with N-15 and β-H only.

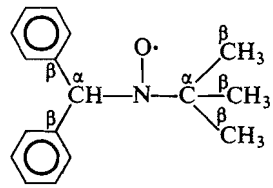
Results

A typical spectrum consisting of a triplet of doublets due to diphenylmethyl *tert*-butyl aminoxyl is shown in Fig. 1. Satellite peaks are clearly evident. At higher spectrometer gain (Fig. 2) these peaks are strong enough for accurate measurements. Intensity comparisons show that the outside peaks (OS) are due to 2 equivalent ^{13}C atoms and the "extra" two peaks in the spectrum are due to ^{15}N-hfs (marked NF). The OS peaks are assigned to the β-carbons of the phenyl groups of the diphenylmethyl group since the small dihedral angle of the carbon–phenyl bonds (~30° av.) should give the largest β-^{13}C hfsc in the molecule. The inside pair of satellites (IS) are due to 5 approximately equivalent ^{13}C atoms, namely the methyl groups of the *tert*-butyl function and the two α-carbon atoms attached to the nitroxyl nitrogen. This assignment is supported by the fact that in di-*tert*-butyl aminoxyl the α- and β-^{13}C hfsc's are almost the same (5), e.g. $a_{\alpha}^{C\text{-}13} = 4.38$, $a_{\beta}^{C\text{-}13} = 4.35$ G in benzene.

TABLE 1. Hyperfine splitting constants at room temperature



Solvent	$a_{N\text{-}15}$	$a_{N\text{-}14}$	a_{β}^{H}	$a_{\beta\text{-}\phi}^{C\text{-}13}$	$a_{\alpha}^{C\text{-}13}$	$\simeq a_{\beta\text{-}t\text{-}Bu}^{C\text{-}13}$
Hexane	—	14.25	2.10	7.38		—
Toluene	—	14.39	2.17	7.41		—
Benzene	20.37	14.41	2.19	7.41		4.63
Pyridine	20.48	14.59	2.44	7.46		4.86
Methylene chloride	—	14.72	2.69	7.43		—
Acetonitrile	20.65	14.72	2.72	7.50		4.88
Methanol	21.31	15.15	3.12	7.47		—
Water	22.39	16.02	4.23	7.65		—

The same spectrum could be obtained in various solvents, although the OS and NF peaks were sometimes overlapped (e.g. in hexane). On the other hand, the IS peak divided into two peaks in some solvents (e.g. in water) with an apparent intensity ratio of 2:3.

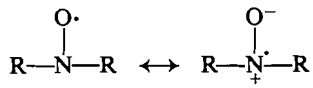
The splitting parameters obtained in eight solvents are given in Table 1. It is evident that all hyperfine coupling constants increase with increase in polarity of the solvent. This observation agrees with the data published for di-*tert*-butyl aminoxyl (5).

The hyperfine splitting constants of diphenylmethyl *tert*-butyl aminoxyl as a function of temperature in four solvents are given in Table 2. The N- and β-H hfsc's increase as a function of temperature in all solvents studied. In contrast, the β-^{13}C hfsc's decrease with increase in temperature in every solvent.

Discussion

In a previous publication (6) the solvent effect on the N- and β-H hfsc of diphenylmethyl *tert*-butyl aminoxyl was reported for 30 solvents. It was found that both the N- and β-H hfsc's increased approximately linearly with solvent polarity. Since the magnitude of the N-hfsc is itself a measure of the solvent polarity (7), the β-hfsc could be plotted against the N-hfsc and a good linear relationship was obtained.

A plot of both the β-H and the β-^{13}C-phenyl hfsc's against the N-hfsc is given in Fig. 3. The increase in β-H and β-^{13}C hfsc with increase in N-hfsc is attributable to the increase in spin density on the nitrogen atom of the nitroxyl function caused by the more polar solvent:



However, the change in β-^{13}C-phenyl hfsc with increase in polarity of solvent is much less than the change in the β-H hfsc

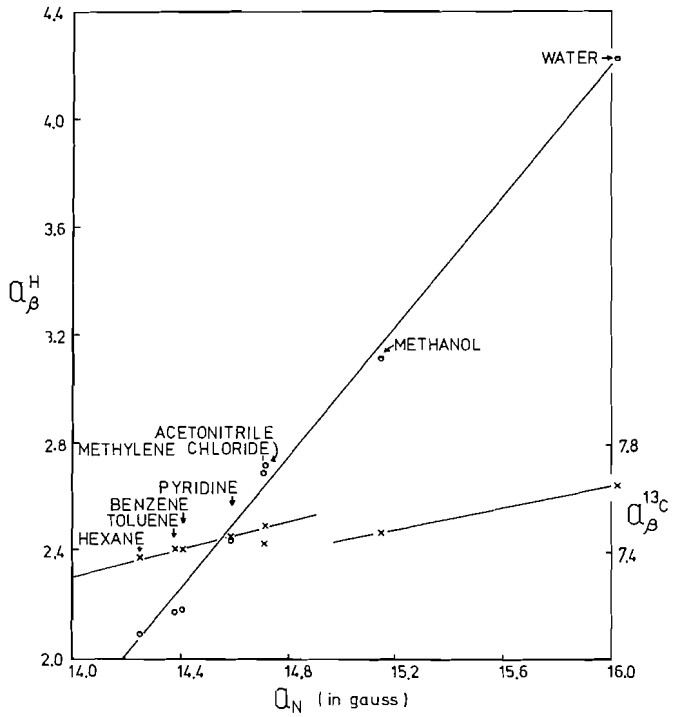

FIG. 3. Plot of a_β^H vs. a_N (in gauss) for diphenylmethyl *tert*-butyl aminoxyl in solvents indicated (left vertical); plot of a_β^{C-13} vs. a_N for same (right vertical).

when plotted against the N-hfsc. In addition there seems to be a discontinuity in the plot so that the points for the β-^{13}C-phenyl hfsc in the two protic solvents (methanol and water) seem to fall off the line marked by the other six solvents. This difference is small but has been seen in another example.[2]

If it is assumed that the Heller–McConnell equation applies for both the proton and the carbon atoms, the smaller values for the β-^{13}C hfsc's must be atrributable to the smaller magnitude of B in the case of carbon. This value can be calculated from the β-^{13}C hfsc in di-*tert*-butyl aminoxyl (5). (a_β^{C-13} = 4.50 G in CH_2Cl_2). If:

$$a_\beta^{C-13} = [B_0^{C-13} + B^{C-13} (\cos \theta_{C-13})^2]\rho_N$$

and $B_0^{C-13} \simeq$ zero, $(\cos \theta_{C-13})^2 \rightarrow \frac{1}{2}$ for freely rotating groups, and $\rho_N \simeq 0.45 \pm 0.05$, then $B^{C-13} = 20 \pm 2$. Then:

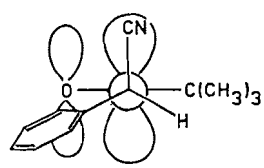
$$a_\beta^{C-13} \simeq 18\text{–}22 (\cos \theta)^2 \rho_N$$

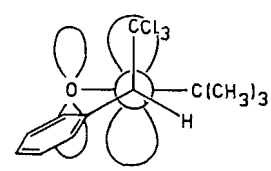
For aminoxyls:

$$a_\beta^{C-13} \simeq 7\text{–}11 (\cos \theta)^2 \text{ for } \rho_N = 0.40\text{–}0.50$$

As a check, the predicted value of a_β^{C-13} for the β-carbons of the phenyl groups of diphenylmethyl *tert*-butyl aminoxyl is about 5–8 gauss, assuming $\theta \simeq 30°$, which is in good agreement with experiment.

Using this value it is clear that in the cyanyl and trichloromethyl adducts, where $a_\beta^{C-13} \simeq 10$ gauss, the CN and CCl_3 groups must almost eclipse the *p*-orbital of the nitrogen atom of the nitroxyl function:[3]





On the other hand, the smaller β-^{13}C hfsc in the methyl adduct (3.15 gauss) must mean that the most stable time-average conformation is quite different. Thus from the equation

$$3.15 \simeq 20 \pm 2 (\cos \theta)^2 (0.45 \pm 0.05)$$

it is possible to estimate that $\theta_\beta^{C-13} = 53 \pm 4°$ for the methyl adduct of PBN.

[2] Unpublished results of C. M. DuBose.

[3] The β-^{13}C hfsc's for aminoxyls with polar groups in the β-position will be the subject of further publications.

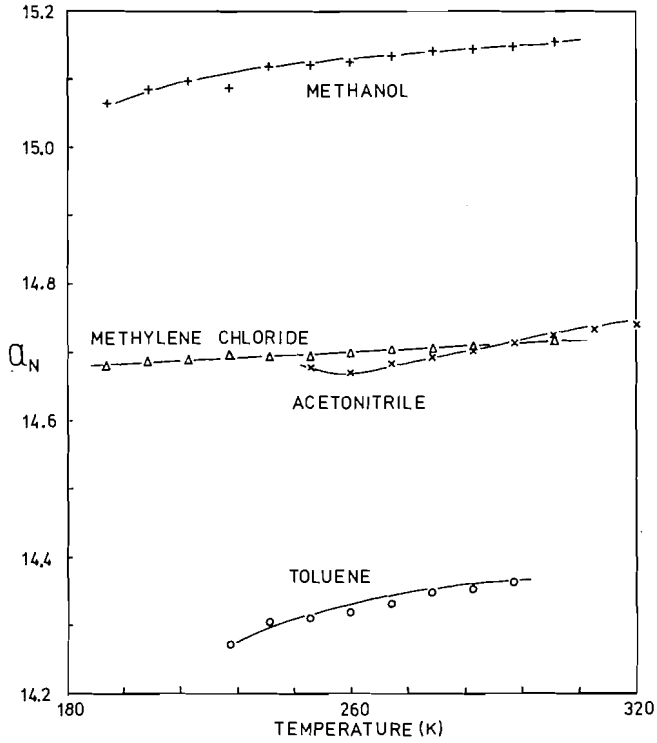

FIG. 4. Plot of a_N vs. temperature (K) for diphenylmethyl *tert*-butyl aminoxyl in four solvents (as indicated).

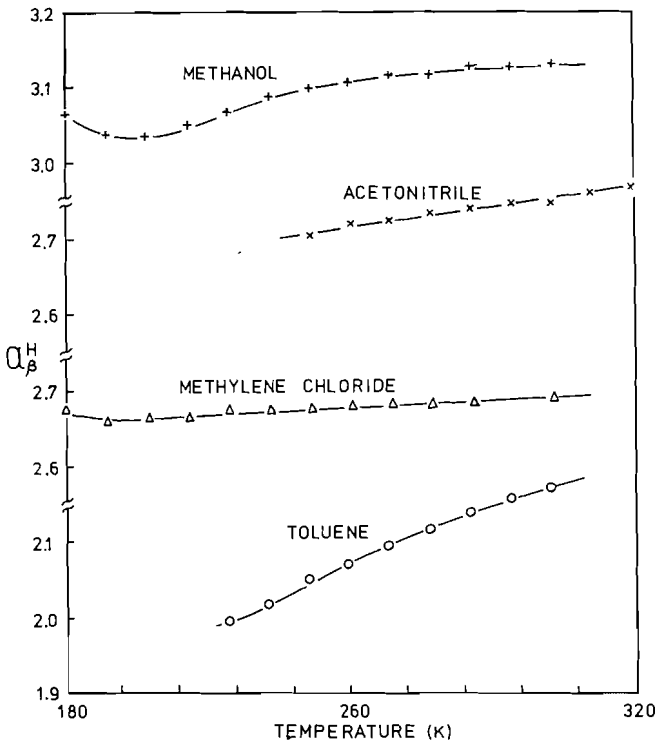

FIG. 5. Plot of a_β^H vs. temperature (K) for diphenylmethyl *tert*-butyl aminoxyl in four solvents (as indicated).

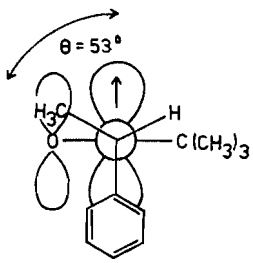

A plot of the N-hfsc as a function of temperature is shown in Fig. 4. The plots all show that the N-hfsc increases slightly with increase in temperature. Slight curvature may be present, which is in the same direction for methanol, methylene chloride, and toluene, but spectra due to slightly immobilized aminoxyls were obtained at low temperatures. According to Bullock and Howard (8), aminoxyls which are planar or almost planar show this temperature effect, i.e. the N-hfsc increases with increase in temperature. This is because, as the temperature is raised, the groups around the nitrogen atom spend more time above and below the $C_2NO\cdot$ plane. Thus the N-hfsc increases because the *s*-character of the orbital containing the unpaired electron is greater in a nonplanar nitroxyl function. However, Griller (9) has found that in some solvents (cyclopentane and ethanol) the change in N-hfsc for di-*tert*-butyl aminoxyl as a function of temperature can be attributed to volume change in the solvent.

A plot of the β-H hfsc as a function of temperature is given in Fig. 5. The β-H hfsc's increase with increase in temperature with different slopes as a function of solvent. The plot is almost flat for methylene chloride, whereas the slope is greatest for toluene and acetonitrile.

The increase in the β-H hfsc is expected with increase in temperature if the oscillation of the diphenylmethyl group is

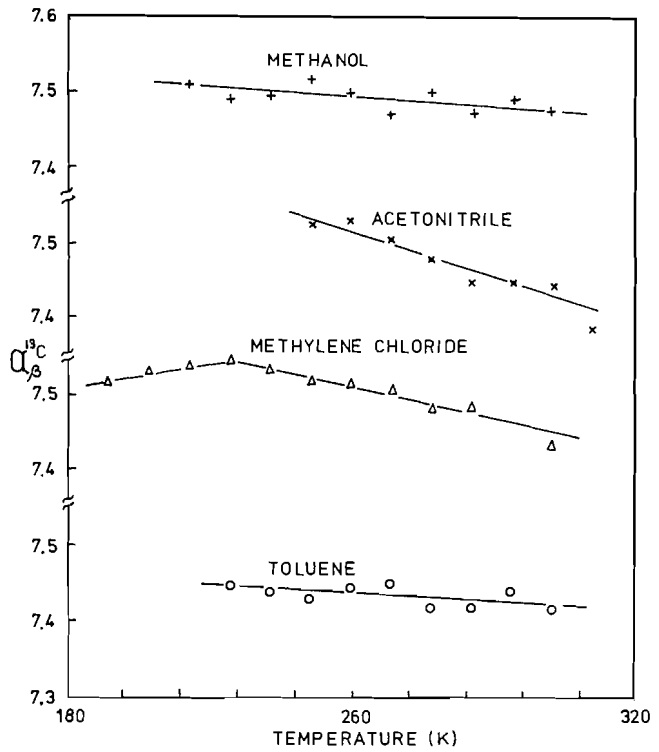

FIG. 6. Plot of $a_\beta^{C\text{-}13}$ vs. temperature (K) for diphenylmethyl *tert*-butyl aminoxyl in four solvents (as indicated).

increased at higher temperatures. This places the C—H bond above and below the eclipsing C—N bond at smaller dihedral angles to the *p*-orbital on nitrogen. Since the magnitude of deviation from planarity of the nitroxyl function also increases with increase in temperature, these motions may be correlated:

For personal use only.

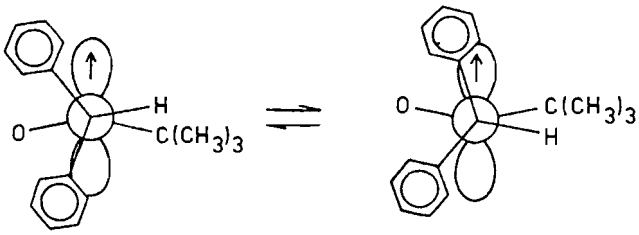

Figure 6 shows the plot of the β-^{13}C hfsc as a function of temperature. In each solvent the magnitude of the β-^{13}C hfsc decreases with increase in temperature. The slopes are different for each solvent but little, if any, curvature is found.

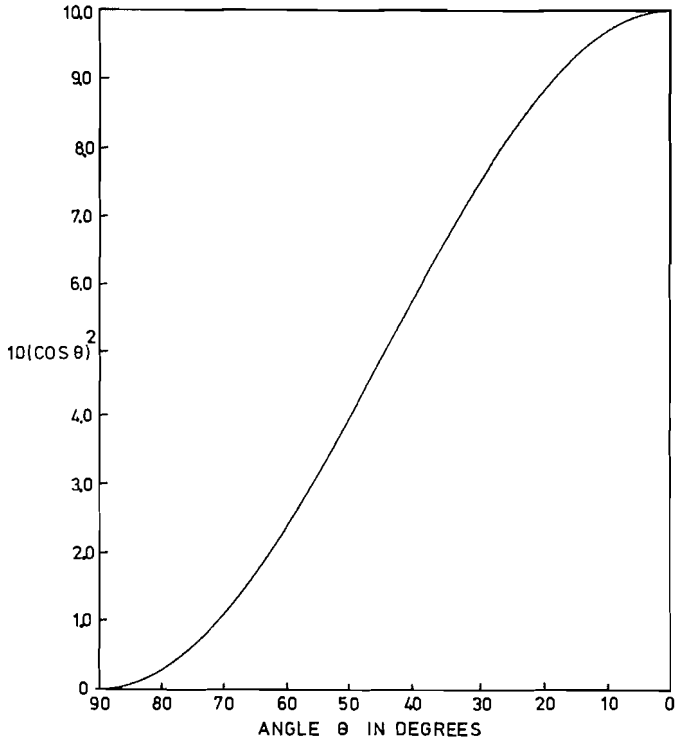
In order to account for the fact that the β-^{13}C hfsc decreases with increase in temperature, a plot of $(\cos\theta)^2$ as a function of θ should be considered:



It is expected that when $\theta < 45°$, larger oscillations will bring about smaller hfsc's, as found for the β-^{13}C hfsc's in diphenylmethyl *tert*-butyl aminoxyl. On the other hand, when $\theta > 45°$, increasing the temperature should lead to larger hfsc's, as found for the β-H hfsc's of the same aminoxyl as shown in Fig. 5. However, specific solvent effects seem to exist. The differences in the slopes of the plots of the β-H and β-C-13 hfsc's as a function of temperature in different solvents may be the result of small changes in θ from one solvent to another.[4]

In conclusion, the reported results indicate that the β-H and β-C-13 hfsc's in diphenylmethyl *tert*-butyl aminoxyl respond to solvent and temperature in predictable ways, i.e. both increase with increase in solvent polarity, and the β-H hfsc increases with increase in temperature while the β-C-13 hfsc decreases with increase in temperature. It is noteworthy that the effect of temperature on the hfsc's of diphenyl *tert*-butyl aminoxyl is *very* small, and in any case much smaller than the effect of solvent polarity.

Enthalpies of fusion and heat capacities for $H_2{}^{18}O$ ice and $H_2{}^{18}O$ tetrahydrofuran clathrate hydrate in the range 100–270 K[1]

Y. P. HANDA

Division of Chemistry, National Research Council of Canada, Ottawa, Ont., Canada K1A 0R9

Received January 10, 1984

Y. P. HANDA. Can. J. Chem. **62**, 1659 (1984).

Heat capacities between 100 and 270 K and enthalpies of fusion for $H_2{}^{18}O$ and tetrahydrofuran clathrate hydrate THF·16.9$H_2{}^{18}O$ have been determined using a heat flow calorimeter. The results are compared with the corresponding systems containing $H_2{}^{16}O$. The isotope effects on heat capacities, enthalpies of fusion, and temperature of fusion have been used to calculate ^{18}O fractionation factors, α, for the solid–liquid equilibrium in water and the hydrate. For $H_2{}^{18}O$, $\alpha = 1.0032 \pm 0.0007$ at 273.2 K and for THF·16.9$H_2{}^{18}O$, $\alpha = 1.0037 \pm 0.0006$ at 277.3 K.

Y. P. HANDA. Can. J. Chem. **62**, 1659 (1984).

Faisant appel à un calorimètre à écoulement de chaleur et opérant entre 100 et 270 K, on a déterminé les capacités calorifiques et les enthalpies de fusion du $H_2{}^{18}O$ et du clathrate THF·16,9$H_2{}^{18}O$. On a comparé les résultats à ceux obtenus avec les systèmes correspondants contenant du $H_2{}^{16}O$. On a utilisé les effets isotopiques sur les capacités calorifiques, les enthalpies de fusion et la température de fusion pour calculer les facteurs de fractionnement, α, du ^{18}O, pour l'équilibre solide–liquide dans l'eau et dans l'hydrate. Pour le $H_2{}^{18}O$ la valeur de $\alpha = 1{,}0032 \pm 0{,}0007$ à 273,2 K et pour le THF·16,9$H_2{}^{18}O$, $\alpha = 1{,}00037 \pm 0{,}0006$ à 277,3 K.

[Traduit par le journal]

Introduction

There have been several studies of deuterium isotope effect on the thermophysical properties of ice (1, 2) and clathrate hydrates (3, 4). The ^{18}O isotope effect on the thermal properties of these systems does not appear to have been reported in the literature. In this paper we make an experimental assessment of this effect for the systems $H_2{}^{18}O$–$H_2{}^{16}O$ and THF·16.9$H_2{}^{18}O$ –THF·16.9$H_2{}^{16}O$ where THF is tetrahydrofuran containing the ordinary oxygen. The results have also been used to calculate the ^{18}O fractionation factors in the two systems.

Experimental

Apparatus

An automated Tian-Calvet heat flow calorimeter (SETARAM, Model BT) operating under digital control was used in the temperature scanning mode using scan rates of 9 K h^{-1} for heat capacity measurements and 3 K h^{-1} for enthalpy of fusion measurements. The details of the calorimeter and the operating technique are given elsewhere (5). Heat capacities and enthalpies of fusion are precise to 0.5% and 0.3%, respectively, and temperatures of fusion to 0.05 K.

Samples

Normalized $H_2{}^{18}O$ was obtained from MSD Isotopes, Montreal, with specified composition of 97.17 atom% ^{18}O, 0.28 atom% ^{17}O, and 2.55 atom% ^{16}O. Ice was made from degassed water by slow freezing, followed by thermal annealing at 265 K for 24 h and at 80 K for 12 h.

Uninhibited THF was obtained from Anachemia. It was analysed using a Finnigan 4010 GC/MS and a Perkin Elmer 3920 gas chromatograph and found to be 99.9 mol% pure. It was used without further purification. A solution of composition THF·16.9$H_2{}^{18}O$ was prepared in the calorimeter cell from degassed components. The hydrate was prepared by cycling the temperature of the cell between 263 and 243 K at 24 h intervals for 7 days.

Results and discussion

Clathrate hydrates are non-stoichiometric compounds. In this paper, extensive thermodynamic properties of these compounds refer to that amount of the substance containing 1 mol of water.

Heat capacities

From the calorimetric runs, heat capacities for $H_2{}^{18}O$ and THF·16.9$H_2{}^{18}O$ in the range 100–270 K were obtained at 1 K intervals. By assuming that (*1*) our sample of water is an ideal solution of the three isotopic species $H_2{}^{16}O$, $H_2{}^{17}O$, and $H_2{}^{18}O$; (*2*) molar heat capacity of $H_2{}^{17}O$ is an arithmetic mean of molar heat capacities of $H_2{}^{16}O$ and $H_2{}^{18}O$; (*3*) C_p of water of natural isotopic composition is the same as that of pure $H_2{}^{16}O$, heat capacities pertaining to 100% ^{18}O content were calculated for water using present results and C_p data for ordinary water obtained with the same apparatus (5). Similarly C_p values for THF·16.9$H_2{}^{18}O$ pertaining to 100% ^{18}O content of water were obtained using present results and C_p data for THF·16.9$H_2{}^{16}O$ reported previously (5). For both systems, the correction for the ^{18}O content in the temperature range 100–270 K amounted to 0.4% or less.

The results at selected temperatures are given in Table 1. C_p values in the range 100–270 K (a total of 171 data points) were fitted to a smoothing polynomial by the method of least squares. Each data point was assigned unit weight. The choice of the number of parameters for the fit was based on the application of the *F*-test to the changes of the variance. For $H_2{}^{18}O$ the fit is

$$[1]\quad C_p/(\text{J K}^{-1}\text{ mol}^{-1}) = -0.934 + 0.2394\,(T/\text{K}) - 7.614 \times 10^{-4}\,(T/\text{K})^2 + 1.562 \times 10^{-6}\,(T/\text{K})^3$$

with a standard deviation of 0.12 J K^{-1} mol^{-1}. For THF·16.9$H_2{}^{18}O$ the fit is

$$[2]\quad C_p/(\text{J K}^{-1}\text{ (mol H}_2\text{O)}^{-1}) = 4.951 + 0.2375\,(T/\text{K}) - 9.363 \times 10^{-4}\,(T/\text{K})^2 + 2.274 \times 10^{-6}\,(T/\text{K})^3$$

with a standard deviation of 0.15 J K^{-1} (mol $H_2O)^{-1}$.

The results as represented by eqs. [1] and [2] are plotted in Fig. 1. For comparison, the heat capacities for $H_2{}^{16}O$ and THF·16.9$H_2{}^{16}O$ taken from our previous work (5) are also shown. For water, heat capacities of the ^{18}O system, $C_p{}^{18}$, are higher than that of the ^{16}O system, $C_p{}^{16}$, over the entire temperature range 100–270 K. The ^{18}O effect is 7% at 100 K, decreases with increase in temperature until at 200 K the effect

TABLE 1. Experimental heat capacities of ice and THF hydrate at selected temperatures

	C_p/(J K^{-1} (mol H_2O)$^{-1}$)	
T/K	$H_2{}^{18}O$	THF·16.9$H_2{}^{18}O$
100	16.93	21.83
110	18.31	22.85
120	19.57	23.92
130	20.82	24.99
140	21.98	25.84
150	23.08	27.32
160	24.26	28.29
170	25.58	29.43
180	26.54	30.74
190	27.76	31.83
200	29.00	33.00
210	30.38	34.50
220	31.48	36.13
230	32.93	37.56
240	34.35	39.39
250	35.59	41.35
260	37.15	43.00
270	39.69	46.26

is 2.5%. In the range 200–270 K, the effect remains constant at 2.5%.

From very precise measurements and extensive thermal conditioning of the samples, Haida *et al.* (2, 6) have shown that C_p of both H_2O and D_2O shows anomalous behavior in the region 100–140 K. This has been attributed to relaxation of the disordered configuration of the protons or deuterons in their respective lattices. Our C_p measurements on $H_2{}^{16}O$ and $H_2{}^{18}O$ also show a slight anomaly at around 115 K similar to the one observed for H_2O and D_2O. The magnitude of the anomaly is, however, within experimental precision. Such a result is expected in view of the limited thermal conditioning of our samples.

Due to the ice-like nature of clathrate hydrates (7), the ^{18}O isotope effect on the heat capacity of tetrahydrofuran hydrate will be expected to be similar to that in ice. However, as seen in Fig. 1, in the range 100–140 K, $C_p{}^{18}$ of THF hydrate is higher than its $C_p{}^{16}$ by only 1.6% and above 140 K the heat capacities of the two systems are virtually the same.

Enthalpies of fusion

The measured enthalpies of fusion, $\Delta_{fus}H$, were corrected to 100% ^{18}O content of water by making the same assumptions as in the case of heat capacities and using $\Delta_{fus}H^{16}$ for $H_2{}^{16}O$ and THF·16.9$H_2{}^{16}O$ reported previously (5). The correction in both systems amounted to 0.3%.

For $H_2{}^{18}O$ we obtained values of 6034.5 J mol^{-1} and 273.50 K for the enthalpy of fusion, $\Delta_{fus}H^{18}$, and fusion temperature, $T_{fus}{}^{18}$, respectively. The corresponding values for $H_2{}^{16}O$ are $\Delta_{fus}H^{16}$ = 6013.5 J mol^{-1} and $T_{fus}{}^{16}$ = 273.20 K as reported previously (5). The isotope effect on fusion temperature δT (= $T_{fus}{}^{18} - T_{fus}{}^{16}$) is 0.30 K and agrees well with literature value of (0.28 ± 0.02) K reported by Steckel and Szapiro (8). The isotope effect on the enthalpy of fusion δH (= $\Delta_{fus}H^{18} - \Delta_{fus}H^{16}$) is (21 ± 25) J mol^{-1}. From temperature dependences of the directly measured vapor pressure isotope effects in the solid and liquid phases Jakli and Staschewski (9) obtained for δH a value of −46 J mol^{-1}. Other literature values for δH quoted by Jakli and Staschewski (9) and also obtained from temperature dependences of vapor pressures are −42 and 33 J mol^{-1}. The present result tends to favor the latter value.

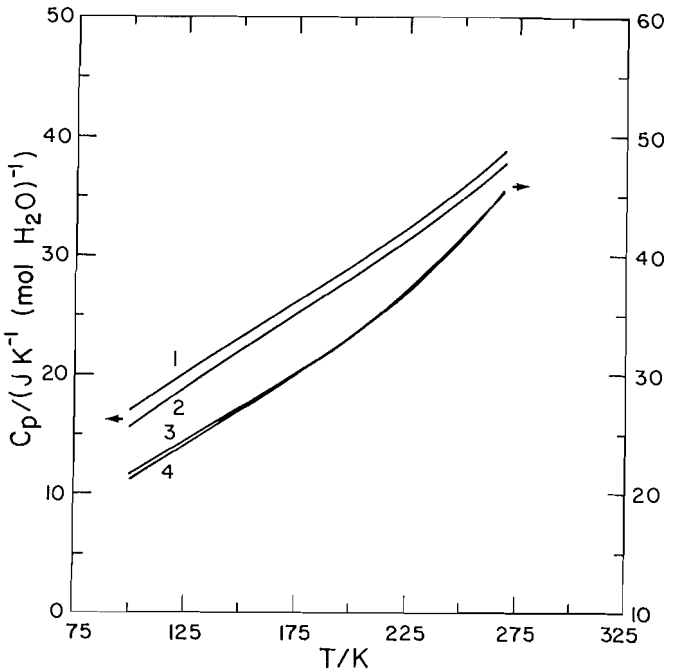

FIG. 1. Smoothed heat capacities vs. temperature for ice and tetrahydrofuran clathrate hydrate. Curve *1*: $H_2{}^{18}O$ from eq. [1]; curve *2*: $H_2{}^{16}O$ from ref. 5; curve *3*: THF·16.9$H_2{}^{18}O$ from eq. [2]; curve *4*: THF·16.9$H_2{}^{16}O$ from ref. 5. Curves *1* and *2* refer to the ordinate on the left and *3* and *4* to the ordinate on the right.

For THF·16.9$H_2{}^{16}O$ the values of $\Delta_{fus}H^{16}$ and $T_{fus}{}^{16}$ are 5526.6 J (mol H_2O)$^{-1}$ and 277.65 K, respectively. The corresponding values for THF·16.9$H_2{}^{16}O$ are 5842.3 J (mol H_2O)$^{-1}$ and 277.30 K (5), thus giving δT = 0.35 K and δH = −315.7 J (mol H_2O)$^{-1}$. As in the case of heat capacities, the isotope effect on the enthalpy of fusion for tetrahydrofuran hydrate is quite different than for ice.

Fractionation factors

Fractionation of $H_2{}^{18}O$ between the solid and the liquid phases can be represented by the hypothetical process

[3] $H_2{}^{16}O(s) + H_2{}^{18}O(l) \rightleftarrows H_2{}^{16}O(l) + H_2{}^{18}O(s)$

where s represents the solid phase and l the liquid phase. When $H_2{}^{18}O$ is present as the infinitely dilute component in $H_2{}^{16}O$ (as in the case of natural water) and assuming that $H_2{}^{18}O$ and $H_2{}^{16}O$ form ideal solutions both in the solid and the liquid phases, the fractionation factor, α, for reaction [3] at temperature T can be written as (10)

$$[4]\quad R \ln \alpha = \frac{1}{T}(\delta H - \Delta C_p \cdot \delta T) - \delta S + \Delta C_p \ln (T_{fus}{}^{18}/T_{fus}{}^{16})$$

where

$$[5]\quad \alpha = (x^{18}/x^{16})_s/(x^{18}/x^{16})_l$$

x being the mole fraction. In eq. [4], δS is the isotope effect on the entropy of fusion ($\delta S = \Delta_{fus}S^{18} - \Delta_{fus}S^{16}$) and ΔC_p is the difference between heat capacity of the liquid and solid phases. In the derivation of eq. [4] it has been assumed that $\Delta C_p{}^{18} = \Delta C_p{}^{16}$ and further that ΔC_p is constant between T and the fusion

temperature of the pure component. Equation [4] thus requires pure component properties only. For H_2O, ΔC_p = 37.7 J K^{-1} mol^{-1} at 273.2 K calculated by using the C_p values for liquid $H_2{}^{16}O$ as suggested by Kell (11) and for $H_2{}^{16}O$ ice extrapolated from the results reported previously (5). Substituting the various values in eq. [4] gives, for H_2O, $\alpha = 1.0032 \pm 0.0007$ at 273.2 K. The uncertainty in α was calculated assuming uncertainties of 1% in $\Delta_{fus}H$, 2% in ΔC_p, and 0.05 K in fusion temperatures. The major source of error in α is the uncertainty associated with fusion temperature. Our value of α compares well with the literature values of 1.0030 (12), 1.0028 ± 0.0001 (13), and 1.00268 ± 0.00003 (14) obtained by direct freezing experiments and values of 1.0035 ± 0.0003 (9), 1.0034 ± 0.0003 (15), and 1.0030 ± 0.0003 (16) obtained from vapor pressure isotope effects.

To calculate ΔC_p for THF hydrate, C_p for the solid phase was obtained by extrapolating the results for THF·$16.9H_2{}^{16}O$ reported previously (5) and for the liquid phase of the same composition calculated by using heat capacity of water (11), THF (17), and excess heat capacity for H_2O + THF (18) and assuming no temperature dependence for the excess heat capacity. For the THF hydrate ΔC_p = 41.9 J K^{-1} (mol $H_2O)^{-1}$ at 277.3 K. As in the case of water, substituting various values in eq. [4] and assuming negligible error in the composition of the hydrate, we obtain for THF hydrate $\alpha = 1.0037 \pm 0.0006$ at 277.3 K. The literature value for THF hydrate of same composition as the present is 1.00268 ± 0.00003 (14) obtained by direct freezing experiments.

Davidson *et al.* (14), using direct freezing technique, found α for ice and THF hydrate to be the same. In the present case, α for the THF hydrate at 277.3 K is slightly higher than α for ice at 273.3 K, though within the limits of precision of the results this claim is speculative at best. Stupin and Gurikov (4) found that the deuterium isotope effect on the thermal and electrical properties of clathrate hydrates depends on the nature of the hydrate former. It would be interesting to see if this is true of the ^{18}O fractionation factors also.

The synthesis, crystal and molecular structure of 1,1,3,3-tetramethylimidazolidinium diiodide methylene dichloride solvate, $(C_7H_{18}N_2)I_2 \cdot CH_2Cl_2$

MASOOD A. KHAN, CLOVIS PEPPE, AND DENNIS G. TUCK

Department of Chemistry, University of Windsor, Windsor, Ont., Canada N9B 3P4

Received May 19, 1983[1]

MASOOD A. KHAN, CLOVIS PEPPE, and DENNIS G. TUCK. Can. J. Chem. **62**, 1662 (1984).

A simple preparation of the title compound, its crystal structure, and nmr spectra are reported. The compound crystallizes in the space group $P2_1/n$, with a = 8.109(2) Å, b = 16.183(4) Å, c = 11.968(4) Å, β = 93.45(2)°, V = 1567.7(7) Å^{-3}, ρ = 1.987 g cm^{-3}, Z = 4 (MoK$_\alpha$, λ = 0.71069 Å). The structure was solved by the heavy atom method and refined to the final R = 0.0415 for 1261 "observed" reflections. The structure consists of five-membered cyclic $C_7H_{18}N_2^{2+}$ cations, iodide anions, and methylene dichloride molecules which are held loosely in the lattice.

MASOOD A. KHAN, CLOVIS PEPPE et DENNIS G. TUCK. Can. J. Chem. **62**, 1662 (1984).

On rapporte une préparation simple du composé mentionné dans le titre, de même que sa structure cristalline ainsi que son spectre rmn. Le composé cristallise dans le groupe d'espace $P2_1/n$, avec a = 8,109(2), b = 16,183(4), c = 11,968(4) Å, β = 93,45(2)°, V = 1567,7(7) Å^{-3}, ρ = 1,987 g/cm^{-3}, Z = 4 (MoK$_\alpha$, λ = 0,71069 Å). On a résolu la structure par la méthode des atomes lourds et on l'a affiné jusqu'à une valeur finale de R = 0,0415 pour les 1261 réflexions observées. La structure comporte des cations cycliques à cinq chaînons, $C_7H_{18}N_2^{2+}$, des anions iodures et des molécules de dichlorure de méthylène qui sont retenues d'une façon lâche dans la maille.

[Traduit par le journal]

Introduction

In a recent paper from this laboratory (1), we described the preparation and properties of solution of indium(I) halides (InX; X = Cl, Br, I) in mixtures of aromatic solvents and neutral bases. One reaction of particular interest corresponds to the oxidative insertion of the $In^{I}X$ (X = Cl, Br, I) solute species into the In^{III}—X bonds of indium trihalides (2). While studying these processes in a solvent system consisting of a mixture of toluene/methylene dichloride/*N,N,N′,N′*-tetramethyl-1,2-ethanediamine (tmen), we observed that tmen reacts slowly with CH_2Cl_2 to form 1,1,3,3-tetramethylimidazolidinium dichloride, $(C_7H_{18}N_2)Cl_2$. The reaction between InI and $InCl_3$ gave, *inter alia*, the crystalline diiodide derivative of the cyclic diammonium cation as the methylene dichloride solvate $(C_7H_{18}N_2)I_2 \cdot CH_2Cl_2$ (**1**).

Quaternisation reactions of *N,N,N′,N′*-tetramethyl-α,ω-diaminoalkanes with α,ω-dihaloalkanes have been previously studied in some detail (3, 4), since they lead to the formation of ionene polymers which are believed to have a sufficiently high positive charge concentration to produce organic materials of high electronic conductivity. In addition to the polymeric products, such reactions also produce cyclic diammonium compounds, and ring systems containing 5 to 14 atoms have been isolated, depending on the nature of the diamine and the dihaloalkane (4). The reaction of tmen with CH_2Br_2 was reported to give the bromide analogue of compound **1** (4), but to our knowledge similar reactions involving methylene dichloride have not been reported.

Experimental

Preparative

1,1,3,3-Tetramethylimidazolidinium dichloride

A total of 4 mL of tmen was added to 50 mL of CH_2Cl_2–toluene (1:1, v/v) and the solution kept at room temperature; the crystals which deposited after 3–15 days were shown to be $[C_7H_{18}N_2]Cl_2$. Found: Cl 35.1; calcd. 35.3. ^{1}H nmr (DCl solution, external TMS) 4.24 s, 6H; 5.10 s, 2H; 5.97 s, 1H.

1,1,3,3-Tetramethylimidazolidinium diiodide methylene dichloride solvate (1)

Equimolar quantities of InI and $InCl_3$ (5.0 mmol) were suspended in 50 mL of CH_2Cl–toluene (1:1, v/v) and cooled to −20°C under an atmosphere of dry nitrogen; tmen (4 mL) was then added and the temperature allowed to rise slowly to ambient (ca. 3 h). A clear yellow solution was obtained, and was kept at room temperature for one week, after which crystals of **1** began to deposit. The crystals were filtered and dried *in vacuo*. Found: I 56.4, calcd. 54.1. ^{1}H nmr (DCl solution, external TMS) 4.30 s, 6H; 5.13 s, 2H; 6.01 br, 2H; this last resonance is the apparent superposition of the coincident resonances from CH_2Cl_2 and the bridging $\overset{+}{N}$—CH_2—$\overset{+}{N}$ group of the cation.

X-ray studies

Crystals of the title compounds are colourless prisms. A crystal with approximate dimensions 0.12 × 0.18 × 0.23 mm was sealed in a thin-walled glass capillary and used for subsequent data collection on a Syntex $P2_1$ diffractometer (Table 1). Details of the procedure for data collections and processing were described elsewhere (5). Since crystal decomposition was rapid even in the capillary, variable scan speeds of 4.88–9.77°/min were used, and data collection was terminated at $2\theta_{max}$ = 40°. During the data collection, the averaged intensity decrease of three monitor reflections was 53%, and this was corrected for by applying a scale factor based on the averaged intensity decrease. The systematic absences ($0k0$, $k = 2n$; $h0l$, $h + l = 2n$) identified the space group as $P2_1/n$, a non-standard setting of $P2_1/c$ (C_{2h}^5, No. 14, with the equipoints $\pm(x, y, z)$ and $\pm(\frac{1}{2} + x, \frac{1}{2} - y, \frac{1}{2} + z)$). The data were corrected for Lorentz and polarization effects; absorption corrections could not be applied because of the rapid crystal decomposition.

The position of iodine atoms were obtained from a sharpened Patterson synthesis, and a difference Fourier map based on the iodine atoms gave the positions of all the remaining non-hydrogen atoms. The structure was refined anisotropically by full-matrix least-squares method and converged at R = 0.0487. At this stage, a difference map showed peaks at some plausible hydrogen atom locations. All hydrogen atoms were then included in the idealized positions, with C—H = 0.95 Å. After six more cycles of refinement convergence was achieved, with the final R = 0.0415 and the final R_w = 0.0469 for 1261 unique "observed" reflections. The function minimized during least-squares calculations was $\Sigma w(|F_o| - |F_c|)^2$ and a weighting scheme of the form $w = 1/[\sigma^2(F) + 0.001F^2]$ was employed. In the last cycle of refinement the largest shift/error ratio was 0.05. The final difference map had no features of any chemical significance, the

[a] The esd of the last digit is given in parentheses.

[b] U_{eq} is calculated from the refined anisotropic thermal parameters (deposited material) ($U_{eq} = (1/3)\sum_{i=1}^{3}(\text{rmsd})_i^2$, with rmsd values taken from the ORTEP output).

largest peak being 0.8 e Å^3 and close to I(2).

All calculations were done on the IBM 3031 computer. The programmes used during structural analysis include CHECK, PROC, ABSORB, SHELX, XANADU, and ORTEP (6). Scattering factors for all the non-hydrogen atoms, including anomalous dispersion correction terms for Cl and I ($\Delta f'$ and $\Delta f''$), were taken from ref. 7, and scattering factors for hydrogen atom were obtained from ref. 8.

Positional and thermal parameters are given in Table 2, and the bond distances and angle are listed in Table 3. Tables of observed and calculated structure factor amplitudes, anisotropic thermal parameters, and hydrogen atom coordinates are available as Supplementary Data.[2] Figure 1 shows the cation with the atomic numbering scheme, and Fig. 2 gives the unit cell packing; hydrogen atoms are omitted from Fig. 2 for the sake of clarity.

[2] A complete set of data is available, at a nominal charge, from the Depository of Unpublished Data, CISTI, National Research Council of Canada, Ottawa, Ont., Canada K1A 0S2.

Results and discussion

Preparative

Although methylene chloride is normally regarded as an unreactive solvent, it slowly quaternises both nitrogen sites of the tmen molecule, apparently by nucleophilic attack of the basic nitrogen at the carbon atom of CH_2Cl_2. This seems to be the first report on this reaction, although the use of such a process was mentioned before in the process of coagulation of polymers (9); no structural details were given in that publication. The unusual preparative route to the diiodide derivative can be regarded simply as exchange of the chloride anions of the initially formed dichloride salt with iodide ions from the indium–iodide compounds present in the solution. We attempted to prepare the diiodide salt of the cyclic cation from a reaction between equimolar quantities of tmen and CH_2I_2 in toluene. The ^{1}H nmr spectrum of the product isolated consists of a complex spectrum in the range 3.58–5.97 ppm from TMS (aq. DCl solution) suggesting the formation of a polymeric linear derivative as well as the cyclic dication.

Structural

The crystal structure of **1** consists of discrete dipositive cations, iodide anions, and loosely held CH_2Cl_2 solvent molecules (Fig. 1). Crystals of **1** are unstable because of the loss of

[a] Spectra of compound after loss of occluded CH_2Cl_2.

these solvent molecules from the lattice, and the proton nmr spectrum of the decomposed crystals showed the set of three singlets characteristic of the cyclic dication. The crystal instability encountered during data collection is therefore caused by the loss of the occluded solvent molecule rather than by decomposition of the dication.

Figure 2 shows the structure of the dication. The five-membered ring has the usual envelope conformation, as demonstrated by the torsion angles in Table 4. The plane is formed by the atoms N(1), N(2), C(2), and C(3) (maximum deviation, at C(3), 0.016(9) Å) and the C(1) atom is 0.61(9) Å out of plane. The dihedral angle between the planes N(1), C(1), C(2), and N(1), C(3), N(2), C(2) is 41.3°. The bond lengths in the dication are in agreement with literature values, with the exception of a significant shortening to 1.48(1) Å at C(1)—C(2).

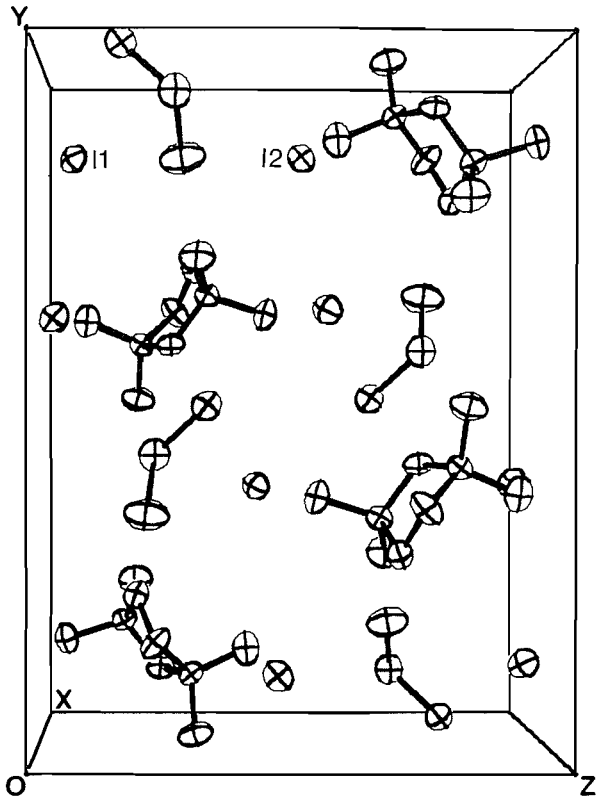

FIG. 2. The unit cell packing of $(C_7H_{18}N_2)I_2 \cdot CH_2Cl_2$, with hydrogen atoms omitted.

Similar values have been observed for this C—C bond length in molecules in which tmen acts as a bidentate ligand (10). The bond angles in the ring range between 103.0 and 106.3°, similar to the values reported for the dicarboxylic acid derivative of cyclopentane (11). There are no significant interionic interactions, the shortest such distance being 3.872(5) Å between I(1) and C(1). The C—Cl(1, 2) bond lengths, and the Cl—C—Cl angle in CH_2Cl_2 call for no comment.

Nuclear magnetic resonance spectroscopy

In view of the unusual C—C bond length in the dication, we re-examined the nmr spectra of the $C_7H_8N_2X_2$ salts, recording ^1H spectra in D_2O (c.f. DCl values reported in Preparative Section) and ^{13}C spectra in D_2O/dioxane. The results, relative to TMS in both cases, are shown in Table 5, which uses the atomic numbering scheme of Fig. 1 for identification. The ^1H results are similar to those reported for the 1,1,4,4-tetramethylpiperazonium cation (4), for which the N—CH_3 groups have the ^1H resonance at 3.4 ppm, and the ring CH_2 resonance at 4.05 ppm (from TMS). Analogous frequencies have been found for N-methyl cationic derivatives of quinucleodine (12). It therefore appears that the nmr spectrum of the dication is similar to those of related compounds, so that the relatively short C(1)—C(2) bond in the ring does not result in any unusual spectroscopic properties.

Diterpenoids from the brown alga *Dictyota binghamiae*

CHARLES PATHIRANA AND RAYMOND J. ANDERSEN[1]

Departments of Chemistry and Oceanography, University of British Columbia, Vancouver, B.C., Canada V6T 1W5

Received December 13, 1983

CHARLES PATHIRANA and RAYMOND J. ANDERSEN. Can. J. Chem. **62**, 1666 (1984).

Extracts of the brown alga *Dictyota binghamiae* contain three previously known and three new diterpenoids. The known compounds, pachydictyol A (**1**), dictyoxide (**7**), and the diacetal **16**, were identified by comparison of their spectral data with published values. The structures of the new diterpenoids, dictyol G acetate (**12**), dictyoxide A (**13**), and dictyotriol A diacetate (**15**), were proposed on the basis of their spectral data and the structures of acetate **12** and ether **13** were confirmed by chemical interconversion.

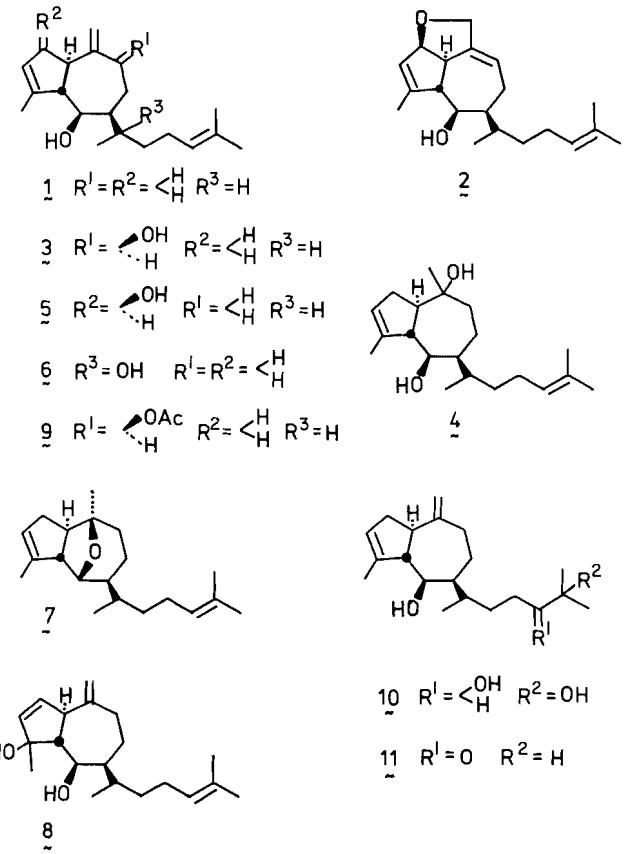
CHARLES PATHIRANA et RAYMOND J. ANDERSEN. Can. J. Chem. **62**, 1666 (1984).

Les extraits de l'algue brune *Dictyota binghamiae* contiennent trois diterpènes déjà connus et trois nouveaux. On a identifié les composés connus, le pachydictyol A (**1**), le dictyoxyde (**7**) et le diacétal **16** grâce à une comparaison de leurs données spectrales avec les valeurs rapportées dans la littérature. On a proposé des structures pour les nouveaux diterpènes, l'acétate de dictyol G (**12**), le dictyoxyde A (**13**) et le diacétate de dictyotriol A (**15**) en se basant sur leurs données spectrales et les structures de l'acétate **12** et de l'éther **13** ont été confirmées par une conversion chimique.

[Traduit par le journal]

Introduction

Species of brown algae belonging to the family *Dictyotaceae* have been a rich source of diterpenoids containing the perhydroazulene ring system. Pachydictyol A (**1**), which was isolated by Hirschfeld *et al.* (1) from *Pachydictyon coriaceum*, was the first member of this family to be reported. Subsequently a number of oxygenated derivatives of Pachydictyol A have been described. These include dictyol A (**2**), B (**3**), C (**4**), and D (**5**) isolated from the Mediterranean alga *Dictyota dichotoma* var *implexa* (2), dictyol E (**6**) and dictyoxide (**7**) isolated from *Dilophus ligulatus* (2*b*, 3), dictyotadiol (**8**) and dictyol B acetate (**9**) isolated from the British *Dictyota dichotoma* (4), and dictytriol (**10**) and dictyone (**11**) isolated from a Japanese collection of *Dictyota dichotoma* (5). We have examined extracts of *Dictyota binghamiae* which was collected subtidally in Barkley Sound, British Columbia and we wish to describe herein the isolation of three previously known and three new diterpenoids from the alga.



Results and discussion

Initial collections of *D. binghamiae* were dried in a convection oven at 50°C prior to powdering in a Wiley mill and soxhlet extraction with hexane. The crude hexane extract was fractionated by flash chromatography using a series of step gradients involving hexane, chloroform, and ethyl acetate. Fractions eluting with chloroform and chloroform – ethyl acetate mixtures contained the diterpenoids. Final purification of the individual compounds was achieved by radial thin layer chromatography and hplc. Later collections of *D. binghamiae* were extracted with methanol immediately after collection. The hexane soluble portion of the concentrated methanol extracts contained the diterpenoids, which were purified by radial tlc and hplc as before.

Five pure diterpenoids were obtained from the oven dried alga. Two previously known diterpenoids, pachydictyol A (**1**) and dictyoxide (**7**), were obtained as pale yellow oils. The spectral data for both substances were in excellent agreement with published values (1, 3).

Dictyol G acetate (**12**) was obtained as an optically active ($[\alpha]_D^{22}$ +50°) colorless oil from preparative reverse phase hplc. High resolution mass spectrometry showed that it had a molecular formula of $C_{22}H_{34}O_3$. Its ir spectrum contained hydroxyl (3500 cm^{-1}) and carbonyl (1725 cm^{-1}) absorption bands. A three-proton resonance at δ 2.02 (s) ppm in the ^1H nmr spectrum, and a significant fragment ion at *m/z* 286 ($M^+ - CH_3CO_2H$) in the mass spectrum, indicated the presence of an acetate ester. The ^1H and ^{13}C nmr spectra of acetate **12** also clearly indicated that it had the same substituted bicyclic ring system as pachydictyol A (**1**) (see Table 1) and thus the acetoxy substituent had to be attached to the side chain. A deshielded resonance at δ 5.57 ppm (dt, 1H, J = 8, 4 Hz) in the ^1H nmr spectrum of **12**, which was not present in the ^1H nmr spectrum

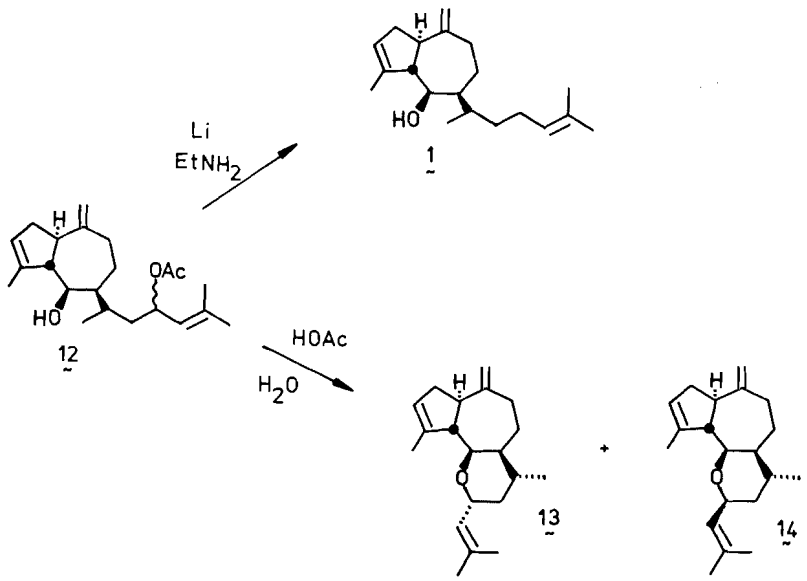

SCHEME 1

of pachydictyol A (**1**), could be assigned to a methine proton α to the acetoxy functionality. The chemical shift of the methine proton implied that it must also be allylic, and a double resonance experiment showed that it was spin coupled to the olefinic proton on C14 (δ 5.12, bd, J = 8 Hz). Thus the acetoxy functionality in **12** must be attached to C13. Reduction of dictyol G acetate (**12**) with lithium in ethylamine gave pachydictyol A (**1**) which was identical to an authentic sample by tlc and ^{1}H nmr comparison (see Scheme 1).

Dictyoxide A (**13**) was obtained as an optically active ($[\alpha]_D^{22}$ −5.6°) pale yellow oil that had the molecular formula $C_{20}H_{30}O$. Its ir spectrum showed an absence of either hydroxyl or carbonyl absorptions and its ^{13}C nmr spectrum contained two resonances at δ 79.5 and 68.6 ppm, appropriate for the carbon atoms of an ether functionality. Six additional carbon resonances at δ 152.0, 142.0, 133.5, 126.8, 124.9, and 106.8 ppm could be assigned to three olefin functionalities. Since the molecular formula of **13** requires six sites of unsaturation, we could conclude that it must be tricyclic. The ^{1}H nmr spectrum of **13** showed methyl resonances at δ 0.95 (d, 3H, J = 7 Hz), 1.65 (bs, 3H), 1.79 (bs, 3H), and 1.70 (bs, 3H) ppm that were virtually identical to those observed for the three olefinic and

one aliphatic methyl groups in pachydictyol A (**1**) (see Table 1). In addition, olefinic proton resonances at δ 5.37 (bs, 1H), 4.82 (bs, 1H), and 4.79 (bs, 1H) ppm were similar to those observed for their counterparts on C3 and C18 in **1**. The above evidence led to the hypothesis that dictyoxide **A** (**13**) had the same carbon skeleton as pachydictoyl A (**1**) but that the alcohol functionality in **1** was replaced by a cyclic ether in **13**. We assumed that one point of attachment of the cyclic ether was C6 and assigned a resonance at δ 3.74 ppm (dd, 1H, J = 10, 4 Hz) to the methine proton on that carbon. A downfield resonance at δ 4.45 ppm (ddd, 1H, J = 12, 8, 4 Hz) was assigned to a methine proton on the second ether carbon. This methine proton was shown via a double resonance experiment to be spin coupled to the olefinic proton on C14 (δ 5.20, bd, IH, J = 8 Hz) and hence C13 had to be the second point of attachment of the cyclic ether.

The constitution of dictyoxide A was confirmed by treatment of dictyol G acetate (**12**) with aqueous acetic acid which gave a 20% yield of **13** (see Scheme 1) and a very low yield of a second compound which was tentatively assigned the epimeric structure **14**. An analysis of the coupling constants observed for H13 and H12α in ether **13** revealed that the tetrahydropyran ring assumed a chair conformation and allowed us to assign the relative configuration at C13. H13 shows an 8-Hz vicinal coupling to H14, a 4-Hz axial, equatorial coupling to H12β and a 12-Hz axial, axial coupling to H12α. Therefore H13 must be axial and the vinyl residue must be equatorial. H12α appears as a quartet at δ 1.14 ppm with a 12-Hz coupling constant. It must therefore be coupled to H12β with a 12-Hz geminal coupling and to an axial proton on C11. Thus the C19 methyl must be equatorial and *cis* to the C13 vinyl substituent. Since the relative stereochemistry at C11 in pachydictyol A is known, we can conclude that dictyoxide A (**13**) adopts the conformation shown in Fig. 1. We were unable to adequately characterize the epimer **14** due to a very limited sample size, but its ^{1}H nmr spectrum was consistent with the proposed structure.

Dictyotriol A diacetate (**15**) was obtained as an optically active ($[\alpha]_D^{22}$ + 12.5°) colorless oil that had a molecular formula of $C_{24}H_{36}O_5$. Its ir spectrum showed hydroxyl (3450 cm^{-1}) and

FIG. 1.

carbonyl (1730 cm^{-1}) absorption bands. Two singlet methyl resonances at δ 2.06 and 2.07 ppm in the ^{1}H nmr of **15** indicated that it was a diacetate. The remainder of the ^{1}H nmr suggested that diacetate **15** had the same carbon skeleton as pachydictyol A (**1**) and that the $\Delta^{3,4}$, $\Delta^{10,18}$, $\Delta^{14,15}$, and C6 hydroxy functionalities were intact (see Table 1). Two resonances at δ 4.92 (m, 1H) and 5.59 (dd, 1H, J = 2, 6 Hz) ppm could be assigned to methine protons α to the acetoxy functionalities. This implied that the acetates were both esters of secondary alcohols, one of them allylic. Irradiation of the allylic methine proton (δ 5.50 ppm) did not change either the C3 or C14 olefinic proton resonances (δ 5.34 and 5.10 ppm) but it did simplify the H8α resonance to a broad doublet (δ 1.76 ppm, J = 15 Hz) and the H8β resonance to a doublet of doublets (δ 1.92 ppm, J = 15, 8 Hz). Decoupling further demonstrated a 1.5-Hz W coupling between H8α and H6, confirming the assignment of the former resonance. The allylic acetate must therefore be on C9 and it was assigned the α configuration because both the multiplicity and chemical shift of the α acetoxy methine proton were substantially different than those reported for dictyol B acetate (**9**) in which the C9 acetate is β (**9**: H9α, δ 5.16 ppm, t, J = 7 Hz (4)). The stereochemistry at C9 was confirmed by demonstrating a difference nOe in H5, H8β, and H8α when the H9 methine proton was irradiated.

Placement of the second acetoxy functionality on C12 followed from the fact that it had to be on a non-allylic secondary carbon which, according to decoupling experiments, was not vicinal to the C9 acetate. Further support for the positions of both acetoxy functionalities could be found in a ^{1}H 2D nmr COSY experiment (7) (see Fig. 2).[2] Clearly visible are the (14/13, 13′) and (12/13, 13′) off-diagonal peaks which would be expected if diacetate **15** contains a C12 acetoxy. It is also possible to follow the required coupling sequence from the C9 acetoxy α methine proton to the C6 carbinol methine proton. Thus starting at C9 we find the off-diagonal elements (9/8α), (9/8β), (7/8β), and (6/7).

The methanol extracted *D. binghamiae* was found to contain pachydictyol A (**1**), dictyoxide (**7**), dictyol G acetate (**12**), dictyotriol A diacetate (**15**), and **16**, a dimethoxy derivative of dictyodial (**17**) (6). A mixture of acetals **16**, which were epimeric at C19, have previously been reported from the Japanese alga *Pachydictyon coriaceum* (6). We isolated only a single epimer and we have not determined the configuration at C19. It appears that the diacetal **16** is an artifact formed from the reaction of dictyodial (**17**) with methanol. Our failure to find dictyoxide A (**13**) in the methanol extracted *D. binghamiae* also seems to indicate that it is an artifact formed from dictyol G acetate (**12**) during oven drying of the algae.

[2] Identification of the off-diagonal peaks in the COSY spectrum is made by listing the identities of the individual protons, that resonating downfield listed first.

Experimental

The ^1H and ^{13}C nmr spectra were recorded on Bruker WH 400 and WP80 spectrometers. TMS was used as an internal standard. Low resolution mass spectra where recorded on an AEI MS902 spectrometer and high resolution mass spectra were recorded on an AEI MS 50 spectrometer. The ir spectra were recorded on a Perkin–Elmer model 710 B spectrometer and optical rotations were measured on a Perkin–Elmer 141 polarimeter using a 1-dm cell. Melting points were obtained on a Fisher–Johns apparatus and values are uncorrected. Merck silica gel 230–400 mesh was used for flash chromatography, Merck silica gel PF 254 with $CaSO_4 \cdot 1/2\ H_2O$ Type 60 was used for radial tlc and a Whatman Magnum 9-ODS 3 column was used for preparative hplc. All chromatography solvents were hplc grade.

Collection data

Dictyota binghamiae was collected by hand using SCUBA (−3 to −5 m) in shallow bays off Dixon Island and Execution Rock in Barkley Sound, British Columbia.

Extraction and chromatography

Oven dried (50°C, 24 h) and powdered (Wiley mill) alga (135 g) was soxhlet extracted with hexane to give 2.3 g of crude oil after evaporation.

Methanol extracted alga was homogenized in an industrial blender with the solvent and extracted at room temperature for one to three days. The homogenate was filtered and the filtrate was evaporated *in vacuo* to give an aqueous suspension which was exhaustively extracted with hexane. Concentration of the hexane *in vacuo* gave a crude oil.

The crude hexane extracts were fractionated by step gradient flash chromatography using the following solvent sequence: (*i*) hexane; (*ii*) hexane/chloroform, 1:1; (*iii*) chloroform; (*iv*) chloroform/ethyl acetate, 9:1; (*v*) chloroform/ethyl acetate, 1:1. The chloroform eluted componenets from the flash chromatography were further purified by radial tlc (hexane/ethyl acetate, 95:5) to give crude samples of pachydictyol A (**1**), dictyoxide (**7**), and dictyoxide A (**13**) and a pure sample of diacetal **16**. Final purification of **1**, **7**, and **13** was accomplished by reverse phase hplc (**1** and **7**; water/acetonitrile, 20:80: **13**; water/ethanol, 20:80). The chloroform/ethyl acetate eluted components from the flash chromatography were further purified by radial tlc (hexane/ethyl acetate, 85:15) and reverse phase hplc (water/ethanol, 20:80) to give pure dictyol G acetate (**12**) and dictyotriol A diacetate (**15**).

Pachydictyol A (1): obtained as a pale yellow oil (ca. 0.013%); ir ($CHCl_3$): 3300, 3050–2850, 1460, 1400 cm^{-1}; ^1H nmr (400 MHz, $CDCl_3$) δ: 5.33 (br s, 1H), 5.12 (br t, 1H, J = 6 Hz), 4.75 (s, 1H), 4.74 (br s, 1H), 3.92 (br d, 1H, J = 8 Hz), 2.67 (q, 1H, J = 10 Hz), 2.62 (m, 1H), 2.49 (m, 1H), 2.32 (m, 1H), 1.81 (m, 3H), 1.69 (br s, 3H), 1.61 (br s, 3H), 1.00 (d, 3H, J = 7 Hz) ppm; ^{13}C nmr (100.6 MHz, $CDCl_3$) δ: 152.60, 141.48, 131.46, 124.81, 124.02, 107.15, 75.23, 60.58, 47.79, 46.24, 40.54, 35.17, 34.93, 34.01, 25.71, 25.66, 23.61, 17.66, 17.54, 15.80 ppm; ms m/z (rel. intensity): 288(M^+, 47), 270(19), 255(5), 203(20), 175(13), 159(56), 109(25), 91(32), 69(73), 41(100), 28(93). *Exact Mass* calcd. for $C_{20}H_{32}O$: 288.2454; found (hrms): 288.2453.

Dictyoxide (7): obtained as a pale yellow oil (ca. 0.008%). ^1H nmr (400 Hz, $CDCl_3$) δ: 5.50 (br s, 1H), 5.09 (t, 1H, J = 8 Hz), 3.97 (m, 1H), 2.63 (br d, 1H, J = 12 Hz), 2.41 (dt, 1H, J = 12, 6 Hz), 2.04 (m, 2H), 2.00–1.85 (m, 2H), 1.82–1.70 (m, 1H), 1.78 (br s, 3H), 1.68 (br s, 3H), 1.60 (br s, 3H), 1.65–1.45 (m, 5H), 1.37 (m, 1H), 1.25 (s, 3H), 1.10 (m, 1H), 0.90 (d, 3H, J = 7 Hz) ppm; ^{13}C nmr (100.6 MHz, $CDCl_3$) δ: 141.37, 130.57, 124.87, 123.66, 77.33, 74.19, 63.12, 61.30, 38.79, 38.38, 37.29, 34.51, 29.82, 26.32, 25.55, 22.23, 20.41, 17.63, 16.44, 15.91 ppm; ms m/z (rel. intensity): 288(M^+, 18), 270(5), 255(3), 207(16), 178(17), 159(14), 121(39), 107(46), 69(50), 55(36), 43(54), 41(64), 28(100). *Exact Mass* calcd. for $C_{20}H_{32}O$: 288.2454; found: 288.2465.

Dictyol G acetate (12): obtained as a colorless oil (ca. 0.015%); $[\alpha]_D^{22}$ +50.0° (*c* 0.13, $CHCl_3$); ir (film): 3500 (OH), 3100–2850, 1725 (C=O), 1460, 1386, 1250 cm^{-1}; ^1H nmr (400 MHz, $CDCl_3$) δ: 5.57 (dt, 1H, J = 4 Hz), 5.33 (br s, 1H), 5.12 (br d, 1H, J = 8 Hz), 4.75 (s, 1H), 4.73 (s, 1H), 3.93 (br d, 1H, J = 8 Hz), 2.70–1.45 (m, 12H), 2.02 (s, 3H), 1.82 (d, 3H, J = 1.0 Hz), 1.74 (d, 3H, J = 1.5 Hz), 1.72 (d, 3H, J = 1.3 Hz), 1.27 (m, 1H), 1.04 (d, 3H, J = 7 Hz) ppm; ^{13}C nmr (100.6 MHz, $CDCl_3$) δ: 170.48, 152.38, 141.36, 136.33, 124.51, 124.13, 107.21, 74.93, 70.58, 60.47, 48.03, 46.21, 40.45, 40.37, 33.99, 32.11, 25.62, 23.84, 21.25, 18.35, 18.12, 15.82 ppm; ms m/z (rel. intensity): 346(M^+), 286(30), 268(20), 186(26), 159(21), 145(16), 133(17), 120(35), 109(50), 91(21), 82(100), 69(21), 55(23), 43(40). *Exact Mass* calcd. for $C_{22}H_{34}O_3$: 346.2509; found (hrms): 346.2487.

Dictyoxide A (13): obtained as a pale yellow oil (ca. 0.010%); $[\alpha]_D^{22}$ −5.6° (*c* 0.16, $CHCl_3$); ir (film): 2980, 2920, 1620, 1520, 1470, 1350, 1240 cm^{-1}; ^1H nmr (400 MHz, $CDCl_3$) δ: 5.37 (br s, 1H), 5.20 (br d, 1H, J = 8 Hz), 4.82 (s, 1H), 4.79 (s, 1H), 4.45 (ddd, 1H, J = 12, 8, 4 Hz), 3.74 (dd, 1H, J = 10, 4 Hz), 2.75 (br t, 1H, J = 10 Hz), 2.62 (q, 1H, J = 9 Hz), 2.58–2.18 (m, 5H), 1.84 (m, 1H), 1.79 (br s, 3H), 1.70 (br s, 3H), 1.65 (br s, 3H), 1.70–1.50 (m, 3H), 1.14 (q, 1H, J = 12 Hz), 0.95 (d, 3H, J = 7 Hz) ppm; ^{13}C nmr (100.6 MHz, $CDCl_3$) δ: 151.95, 142.97, 133.46, 126.84, 124.90, 106.81, 79.49, 68.55, 53.59, 46.64, 45.53, 39.67, 34.34, 34.21, 29.45, 25.78, 25.09, 20.21, 18.34, 17.26 ppm; ms m/z (rel. intensity): 286(M^+), 268(23), 177(23), 159(20), 145(20), 120(40), 109(63), 91(40), 82(66), 69(57), 67(54), 43(49), 41(91), 28(100). *Exact Mass* calcd. for $C_{20}H_{30}O$: 286.2298; found (hrms): 286.2298.

Dictyotriol A diacetate (15): obtained as a colorless oil (ca. 0.031%); $[\alpha]_D^{22}$ +12.5° (*c* 0.11, $CHCl_3$); ir (film): 3450 (OH), 3050–2850, 1730–1700 (C=O), 1450, 1380, 1250, 1030, 1000, 980 cm^{-1}; ^1H nmr (400 MHz, $CDCl_3$) δ: 5.59 (dd, 1H, J = 2, 6 Hz), 5.34 (br s, 1H), 5.10 (s, 1H), 5.10 (t, 1H, J = 7 Hz), 5.03 (s, 1H), 4.92 (m, 1H), 3.87 (dd, 1H, J = 3, 8 Hz), 2.95 (br s, 1H), 2.79 (q, 1H, J = 10 Hz), 2.49 (m, 1H), 2.40–2.15 (m, 4H), 2.07 (s, 3H), 2.06 (s, 3H), 2.02 (dd, 1H, J = 3, 10 Hz), 1.92 (ddd, 1H, J = 2, 10, 15 Hz), 1.86 (m, 1H), 1.82 (m, 3H), 1.76 (dd, 1H, J = 6, 15 Hz), 1.70 (br s, 3H), 1.64 (br s, 3H), 0.94 (d, 3H, J = 7 Hz) ppm; ms m/z (rel. intensity): 404(M^+), 344(10), 284(23), 266(8), 157(35), 109(33), 69(42), 43(100). *Exact Mass* calcd. for $C_{24}H_{36}O_5$: 404.2564; found (hrms): 404.2570.

Diacetal 16: obtained as a pale yellow oil; ^1H nmr (400 MHz, $CDCl_3$) δ: 5.85 (d, 1H, J = 8 Hz), 5.45 (dd, 1H, J = 3, 12 Hz), 5.16 (s, 1H), 5.13 (t, 1H, J = 6 Hz), 5.08 (s, 1H), 3.38 (s, 3H), 3.32 (s, 3H), 3.07 (br dd, 1H, J = 12, 16 Hz), 2.64 (ddd, 1H, J = 3, 8, 16 Hz), 2.27 (br s, 1H), 2.21 (br d, 1H, J = 12 Hz), 2.05–1.85 (m, 5H), 1.72 (br s, 3H), 1.67 (br s, 3H), 1.60 (br s, 3H), 1.70–1.55 (m, 2H), 1.22 (q, 2H, J = 8 Hz), 0.99 (d, 3H, J = 7 Hz) ppm; ms m/z (rel. intensity): 348(M^+), 316(14), 284(18), 201(18), 159(57), 145(95), 109(90), 69(85), 41(100). *Exact Mass* calcd. for $C_{22}H_{36}O_3$: 348.2666; found (hrms): 348.2649.

Acid hydrolysis of dictyol G acetate (12)

Dictyol G acetate (**12**) (5 mg) was dissolved in aqueous HOAc (30%, 1 mL) with a few drops of CH_3CN and the reaction mixture was stirred at room temperature for 24 h. It was then freeze-dried and the products were separated by tlc (hexane/ethyl acetate 85:15) to give dictyoxide A (**13**) (0.9 mg, R_f 0.56) and its epimer (**14**). Compound **14**: ^1H nmr ($CDCl_3$, 400 MHz) δ: 1.16 (d, 1H, J = 7 Hz), 1.68 (s, 3H), 1.71 (s, 3H), 3.71 (dd, 1H, J = 4, 9 Hz), 4.22 (ddd, 1H, J = 12, 8, 4 Hz), 4.69 (bs, 2H), 5.14 (bd, 1H, J = 8 Hz), 5.35 (bs) ppm.

Li/EtNH$_2$ reduction of dictyol G acetate (12)

Dictyol G acetate (**12**) (20 mg) was dissolved in ethylamine (1.5 mL, anhydrous) and into that freshly cut Li was added in excess and stirred for 20 min. The solvent was then evaporated under vacuum and the products were separated by tlc (hexane/ethyl acetate, 95:5). The product, pachydictyol A (**1**) (2.9 mg) was identified by ^1H nmr and tlc.

A nuclear magnetic resonance study of the kinetics and equilibria for the oxidation of penicillamine and *N*-acetylpenicillamine by glutathione disulfide

DALLAS L. RABENSTEIN[1] AND YVON THERIAULT
Department of Chemistry, University of Alberta, Edmonton, Alta., Canada T6G 2G2

Received February 6, 1984

DALLAS L. RABENSTEIN and YVON THERIAULT. Can. J. Chem. **62**, 1672 (1984).

The kinetics and equilibria of the oxidation of penicillamine by glutathione disulfide to form, in the first step, penicillamine–glutathione mixed disulfide and glutathione and, in the second step, penicillamine disulfide and glutathione have been studied over the pH range 4–9 by ^{1}H nmr. The reactive species are found to be penicillamine with its amino group protonated and its thiol group deprotonated and glutathione disulfide and penicillamine–glutathione mixed disulfide with their two amino groups protonated. The rate and equilibrium constants for the first step are much larger than those for the second step, indicating a small tendency for penicillamine to form its symmetrical disulfide by thiol/disulfide exchange reactions. This and the smaller reducing power of penicillamine as compared to glutathione are attributed to steric hindrance from the methyl groups adjacent to the sulfur. The kinetics and equilibria of the oxidation of *N*-acetylpenicillamine by glutathione disulfide were studied at neutral pH. Conditional equilibrium and rate constants for the oxidation of penicillamine by glutathione disulfide at pH 7.4 are presented and discussed in terms of the metabolism of penicillamine.

DALLAS L. RABENSTEIN et YVON THERIAULT. Can. J. Chem. **62**, 1672 (1984).

Faisant appel à la rmn du ^{1}H et travaillant dans un intervalle de pH allant de 4 à 9, on a déterminé les cinétiques et les équilibres d'oxydation de la pénicillamine par le disulfure de glutathion qui, dans une première étape, conduit à la formation de glutathion et d'un sulfure mixte de pénicillamine et de glutathion et, dans une deuxième étape, donne le disulfure de pénicillamine et du glutathion. On a trouvé que les espèces réactives sont d'une part la pénicillamine dans laquelle le groupe amino est protoné et le groupe thiol est déprotoné et d'autre part le disulfure de glutathion et le disulfure mixte de pénicillamine et de glutathion dans lesquels les groupes amino sont protonés. Les constantes de vitesse et d'équilibre de la première étape sont beaucoup plus élevées que celles de la deuxième étape; ceci indique que la tendance de la pénicillamine à former son disulfure symétrique par des réactions d'échanges entre thiols et disulfures est faible. On attribue cette tendance et le pouvoir réducteur plus faible de la pénicillamine par rapport au glutathion, à l'encombrement stérique des groupes méthyles adjacents au soufre. On a étudié, à un pH neutre, les cinétiques et les équilibres d'oxydation de la *N*-acétylpénicillamine par le disulfure de glutathion. On présente des constantes de vitesse et d'équilibre conditionnels pour l'oxydation de la pénicillamine par le disulfure de glutathion à un pH de 7,4 et on en discute en fonction du métabolisme de la pénicillamine.

Introduction

The metabolism and biological functions of thiols depend to a large extent on the ease with which they are oxidized. There are several reactions by which they are oxidized in biological systems, including oxidation by disulfides via thiol/disulfide exchange as described by eqs. [1] and [2] (1, 2).

[1] $RSH + R'SSR' \rightleftarrows RSSR' + R'SH$

[2] $RSH + RSSR' \rightleftarrows RSSR + R'SH$

In this paper, we present the results of a ^{1}H nmr study of the oxidation of D-penicillamine (PSH, **1**) and *N*-acetyl-D,L-penicillamine (N-PSH) by glutathione disulfide (GSSG, **2**). PSH is widely used in medicine (3–6) for the treatment of Wilson's disease (7), heavy metal poisoning (8, 9), cystinuria (10), and rheumatoid arthritis (4). The primary pathway of PSH metabolism is via disulfide formation (3), and its pharmacological and therapeutic actions are largely explained by its ability to take part in thiol/disulfide exchange reactions (3, 5, 6). For example, the molecular basis for the treatment of cystinuria by PSH is the formation of the more soluble penicillamine–cysteine mixed disulfide from insoluble cystine by thiol/disulfide exchange (10). Also, the depolymerization and loss of serological activity of rheumatoid factor on reaction with PSH in vitro is by thiol/disulfide exchange involving disulfide bonds in rheumatoid factor (11).

Despite their importance, there have been few reports on the kinetics and equilibria of the oxidation of PSH by thiol/disulfide exchange reactions (5, 12, 13). In this study, we have obtained kinetic and equilibrium data for the reaction of PSH with GSSG and of GSH with PSSP over a wide range of solution pH by ^{1}H nmr. Resolved resonances are obtained for the various PSH-containing species, making it possible to characterize separately the two stepwise thiol/disulfide exchange reactions involved in the overall oxidation of thiol to disulfide. Results on the kinetics and equilibria for the reaction of N-PSH with GSSG at neutral pH are also reported. Glutathione disulfide was chosen for this study because it occurs naturally in biological systems (1, 2), it may be involved in the metabolism of PSH (5), and, with the cystine placed between two amino acid residues, it serves to a first approximation as a model for disulfide bonds in proteins.

Experimental

D-Penicillamine, glutathione, glutathione disulfide, and *N*-acetyl-

D,L-penicillamine were obtained from Sigma Chemical Co. D-Penicillamine disulfide was obtained from Aldrich Chemical Co. For most experiments, the thiols and disulfides were used as received. In several experiments, solutions of penicillamine were electrolyzed over a Hg pool electrode (14) to reduce traces (<1%) of penicillamine disulfide.

The pH measurements were made at 25°C with a Fisher Accumet pH meter equipped with a standard glass electrode and a fiber-tipped, saturated calomel reference electrode, or a microcombination electrode. The pH meter was calibrated with standard solutions having nominal pH values of 4.00, 7.00, and 10.00 at 25°C. The exact pH value of each standard solution was established, and checked periodically, by comparison with freshly prepared NBS pH standard solutions. In some of the experiments done in sealed nmr tubes, the pH was determined from the chemical shifts of resonances for the C2 and C4,5 hydrogens of imidazole, which was added to the solution as a pH indicator (15). The pH is related to the observed chemical shift, δ_{obs}, for C2H and C4,5H, respectively, by:

$$[3] \quad pH = 7.28 + \log\left(\frac{\delta_{obs} - 8.700}{7.7820 - \delta_{obs}}\right)$$

$$[4] \quad pH = 7.27 + \log\left(\frac{\delta_{obs} - 7.4892}{7.1380 - \delta_{obs}}\right)$$

Accurate pH values can be obtained from the imidazole chemical shifts over the pH range 6.3−8.3; at lower and higher pH values, the chemical shifts approach those of HIm^+ and Im, respectively, and are not sensitive to changes in pH.

The ^1H nmr spectra were measured at 200 MHz and 25°C on a Bruker WH-200 nmr spectrometer operating in the pulse/Fourier transform mode. The nmr spectra were obtained on aqueous solutions. To avoid the dynamic range problem, the water resonance was reduced in intensity by saturating it with a decoupler pulse applied at the water resonance frequency for 2 s prior to the observation pulse. The spectrometer was run in the unlocked mode because the magnet shows no detectable drift over the time required to obtain a spectrum. The ^1H chemical shifts were measured relative to the methyl resonance of *tert*-butanol (TBA), which was added to the solutions at a concentration of 0.001−0.01 *M*, depending on the thiol and disulfide concentrations. The chemical shifts are reported relative to the methyl resonance of sodium-2,2-dimethyl-2-silapentane-5-sulfonate (DSS); the resonance for TBA is 1.2397 ppm to high frequency from that of DSS. So that quantitative information could be obtained from resonance intensities, the repetition time was at least 5 times the longest T_1 of the methyl resonances of interest. The T_1 values of the methyl resonances were measured by the inversion−recovery method, and ranged from 0.3−1 s.

Solutions were prepared in water which had been purified by distilling it twice and then passing it through a Barnstead D8902 Ultrapure mixed bed ion-exchange resin. KCl (1 *M*) and EDTA (0.003 *M*) were added for ionic strength control and to complex traces of heavy metals which would catalyze the air oxidation of thiols (16). Previous studies have shown that EDTA has no effect on the rates of thiol/disulfide exchange (16). The solvent mixture was deoxygenated by bubbling with argon or nitrogen before addition of thiol to minimize oxidation by dissolved oxygen. Inert gas was also blown over the solution during adjustment of pH, and nmr tubes were flushed with the gas before transfer of an aliquot of solution to the tube. This method of solution preparation was satisfactory for solutions which came to equilibrium within a few hours after mixing of the thiol and disulfide. For those systems which reacted more slowly, the sample solution was degassed by taking the sample, in an nmr tube, through at least three freeze−pump−thaw cycles on a vacuum line. The nmr tube was then sealed while still on the vacuum line.

Several procedures were used to obtain the kinetic data. (*i*) In cases where the system came to equilibrium within a few hours and the pH was one at which resolved resonances are observed for the reactants and products, spectra were measured at preselected times while the sample remained continuously in the spectrometer. (*ii*) When the reaction was either too fast or the pH was one at which the resonances of interest were not resolved, aliquots were taken from a reaction vial as a function of time and quenched by lowering the pH to 0.5−2 with HCl. Spectra were measured for all the aliquots once the reaction was completed. (*iii*) When the reaction came to equilibrium very slowly, the sample was sealed in an nmr tube and stored at 25°C. Spectra were taken hourly, daily, or weekly as necessary to characterize the time course.

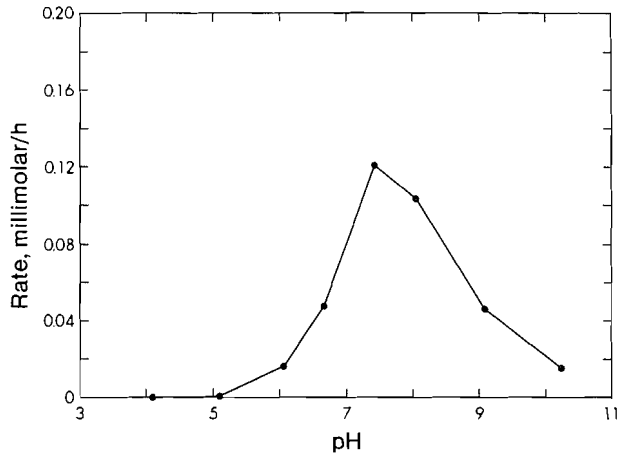

FIG. 1. Initial rate of air oxidation of PSH (0.0042 *M*) to PSSP as a function of pH.

Results

Air oxidation of penicillamine

Thiols are easily air oxidized to disulfides. Since air oxidation would lead to errors in the equilibrium and kinetic parameters measured for the thiol/disulfide exchange reactions, the air oxidation of PSH was studied. The procedure involved adjusting the pH of 0.0042 *M* PSH solutions to selected values in the pH range 4−10, placing aliquots in loosely stoppered vials, and then removing 0.5-mL portions for nmr analysis as a function of time for up to six days. The rate of decrease in PSH concentration was found to be dependent on solution pH, and independent of PSH and PSSP concentrations. The pH dependence of the initial rate is plotted in Fig. 1. As the pH is increased from 4, the initial rate increases, reaches a maximum at pH 7.5, and then decreases as the pH is increased further. The pH−rate profile in Fig. 1 is similar to that observed for the oxidation of GSH to GSSG (17). To test the efficiency of the freeze−pump−thaw technique for removing oxygen from sample solutions, a sealed tube containing a pH 8 solution (near the maximum in Fig. 1) of 0.060 *M* PSH was prepared by this procedure. After 10 days, no PSSP was detected in the ^1H nmr spectrum. After 33 days, approximately 3% of the PSH had been oxidized.

Penicillamine−glutathione disulfide nuclear magnetic resonance spectra

In Fig. 2 is shown the 200-MHz ^1H nmr spectrum of a solution prepared by reacting PSH with GSSG at pH 7.9 for 5 min, and then adjusting the pH to 4.06. The initial concentrations were 0.13 *M* PSH and 0.12 *M* GSSG. As is shown later, no PSSP is formed under these reaction conditions. The formation of PSSG is indicated by the appearance of an additional pair of methyl resonances in the 1.3−1.8 ppm region,[2]

[2]The chemical shifts of the ^1H resonances for the two methyl groups of PSH, and of PSSG, are different due to the asymmetric center at C_α.

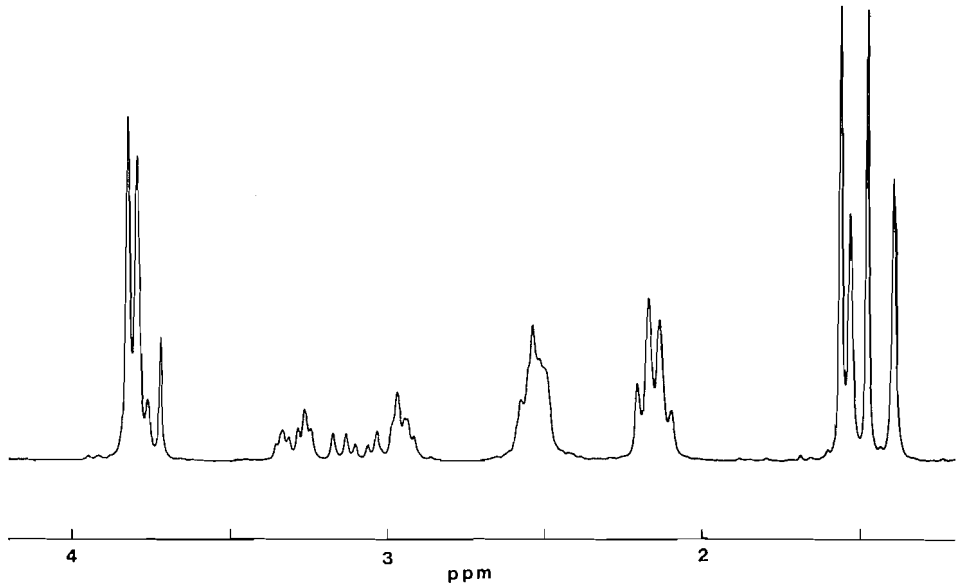

FIG. 2. 200-MHz ^{1}H nmr spectrum of mixture prepared by reacting 0.13 *M* PSH with 0.12 *M* GSSG.

and by additional resonances for C_α and C_β protons in the 3–4 ppm region. There is extensive overlap of resonances in the 3–4 ppm region, making it difficult to characterize the mixture using these resonances. However, the methyl resonances are singlets, and the resonances for the various penicillamine-containing species are reasonably well resolved over a wide range of pH, as shown in Figs. 3 and 4. The initial concentrations in the solution used to obtain the spectra in Fig. 3 were 0.02 *M* PSH, 0.01 *M* PSSP, 0.01 *M* GSSG, and 0.007 *M* TBA. The assignments were made by comparison with spectra obtained over the same pH range for solutions of PSH and PSSP. The chemical shift data plotted in Fig. 4 for PSH and PSSP were obtained from these experiments, while those for PSSG were obtained from spectra similar to those shown in Fig. 3. Since there is at least one resolved methyl resonance for each of the three penicillamine-containing species over a wide range of pH, these resonances were used to characterize the equilibria and kinetics of the oxidation of PSH by GSSG and of GSH by PSSP.

Penicillamine–glutathione thiol/disulfide exchange kinetics

The oxidation of PSH by GSSG takes place via two thiol/disulfide exchange reactions:

$$[5]\quad PSH_t + GSSG_t \underset{k_{2c}}{\overset{k_{1c}}{\rightleftharpoons}} PSSG_t + GSH_t$$

$$[6]\quad PSH_t + PSSG_t \underset{k_{4c}}{\overset{k_{3c}}{\rightleftharpoons}} PSSP_t + GSH_t$$

where k_{1c}–k_{4c} are conditional rate constants and $[PSH]_t$, $[PSSG]_t$, etc., represent the sums of the concentrations of the various protonated forms of PSH, PSSG, etc. at a particular pH. The rate of the second reaction is much slower than the first, and thus the kinetics of the two reactions were studied separately. The kinetics of the first reaction were studied over the pH range 4 to 9, using concentrations of reactants ranging from 0.0015 *M* to 0.024 *M*. Altogether, twenty kinetic experiments were performed by the methods described in the experimental section.

Typical time course spectra are shown in Fig. 5. The data at pH 3.96 indicate that, although thiol/disulfide exchange to form PSSG does take place, it is slow at this pH. However, there is no PSSP detected, even after 8 days. The second time course series in Fig. 5 indicates that the reaction of PSH with GSSG is somewhat faster at pH 6.61. Also, resonances due to PSSP are detected after 37 min. Comparison with time course spectra obtained for solutions of similar pH and concentration in degassed, sealed nmr tubes indicate this PSSP is formed by air oxidation. Rate constant k_{1c} was calculated from time course data taken before the appearance of PSSP.

The reaction of PSH with GSSG was found to be first order in the concentration of PSH and first order in the concentration of GSSG. The rate equation for the reaction represented by eq. [5] is:

$$[7]\quad \frac{d[PSSG]}{dt} = k_{1c}[PSH]_t[GSSG]_t - k_{2c}[PSSG]_t[GSH]_t$$

Rate constant k_{1c} was evaluated by fitting time course data by nonlinear least-squares calculations (18) to eq. [8], which is obtained from the integrated form of the rate expression for a second order, reversible reaction.

$$[8]\quad X = \frac{A_0B_0X_e\left(1 - \exp\left(\frac{k_{1c}t}{A}\right)\right)}{X_e(A_0 + B_0) - A_0B_0\left(1 + \exp\left(\frac{k_{1c}t}{A}\right)\right)}$$

where

$$[9]\quad A = \frac{X_e}{2A_0B_0 - X_e(A_0 + B_0)}$$

X and X_e are the concentrations of PSSG at time t and at equilibrium, and A_0 and B_0 the initial concentrations of PSH and GSSG. k_{1c} and X_e were both treated as unknowns in the nonlinear least-squares calculations. Typical time course data for the formation of PSSG at pH 3.96 and 9.01 are shown in Fig. 6. Values of k_{1c} = 0.0263 ± 0.0013 L/mol-min and $[PSSG]_e$ = 0.00779 ± 0.00020 *M* were obtained from the nonlinear least-squares fit of the pH 3.96 data; values of 146 ±

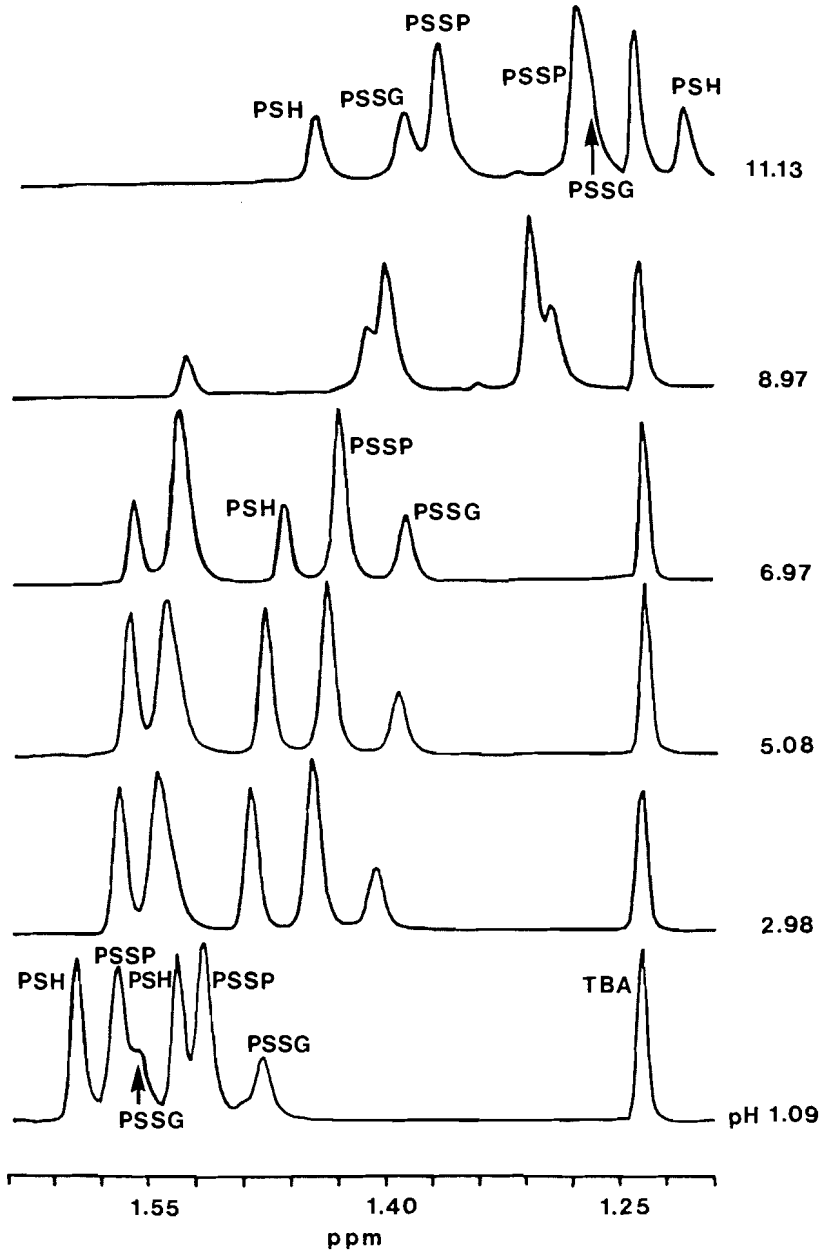

FIG. 3. Portions of the 200-MHz ^{1}H nmr spectra of a solution prepared from 0.02 *M* PSH, 0.01 *M* PSSP, 0.01 *M* GSSG, and 0.007 *M* TBA as a function of pH. The resonances are from methyl groups.

12 L/mol-min and 0.000761 ± 0.00004 *M* were obtained from the pH 9.01 data. The solid curves through the experimental points in Fig. 6 are the theoretical curves predicted by these parameters. The values obtained for k_{1c} from the twenty kinetic experiments are plotted in Fig. 7.

Thiol/disulfide exchange reactions proceed via the thiolate anion (19–27). There are two thiolate species possible for PSH: PS^-, in which the thiol group is deprotonated and the amino group protonated, and PS^{2-}, in which both groups are deprotonated. Both are present at low concentrations over the pH range 4–7; however, the dependence of their fractional concentrations on pH is different. The logarithms of their fractional concentrations (α), along with that of the form having both groups protonated (PSH^0), are plotted as a function of pH in Fig. 7. Over the pH range 4–7, the slope of the log α_{PSH^0} vs. pH plot is zero, that of the log α_{PS^-} vs. pH plot is one, and that of the log $\alpha_{PS^{2-}}$ vs. pH plot is two. The slope of the log k_{1c} vs. pH plot is one, indicating PS^- to be the reactive species.

There is also the possibility that the rate constant depends on the protonation state of GSSG. However, the pH dependence of log k_{1c} indicates that either the rate constant is the same for the various GSSG species present over the pH range studied or the fractional concentration of the GSSG species involved in the reaction is constant. Over this pH range, the fractional concentration of the species $GSSG^{2-}$, in which the four carboxylic acid groups are deprotonated and the two amino groups protonated, is nearly one while that of the other species varies over several orders of magnitude, indicating $GSSG^{2-}$ to be the predominant species involved.

The kinetics of the reaction of GSH with PSSP were studied over the pH range 5–8, either by following the time course for a reaction mixture in an nmr tube or by removing aliquots from a reaction vial as a function of time, quenching the reaction by lowering the pH, and then analyzing the mixture by nmr.

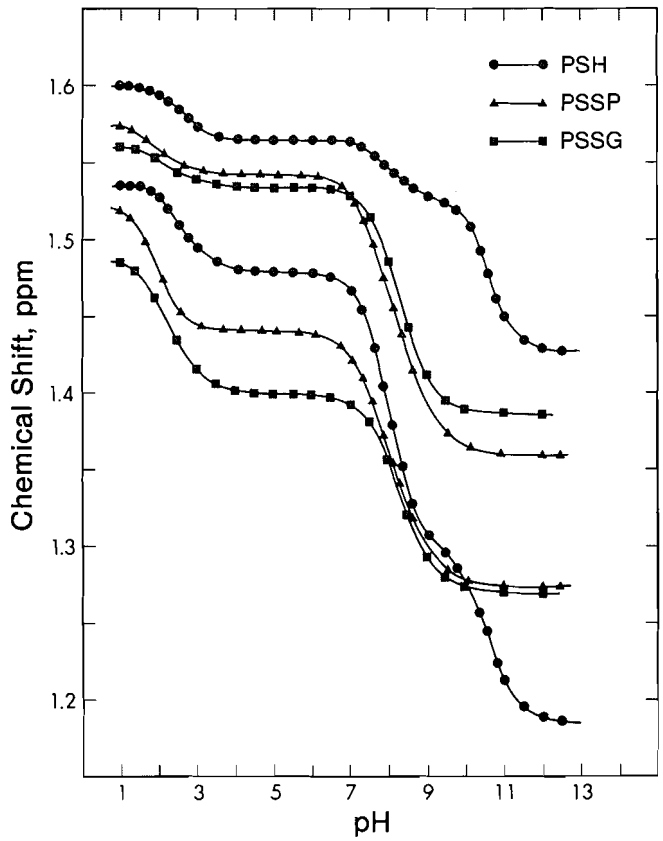

FIG. 4. pH dependence of the chemical shifts of the methyl resonances for PSH, PSSG, and PSSP.

Higher reactant concentrations (typically 0.1 *M*) were used due to the slowness of the reaction, and the length of time over which the progress of the reaction could be followed was limited to ~50 h due to air oxidation of thiols. The values obtained for k_{4c} were (pH, k_{4c}): 5.11, 0.00025 L/mol-min; 5.74, 0.00094 L/mol-min; 6.54, 0.0040 L/mol-min; 7.03, 0.0052 L/mol-min; 7.35, 0.012 L/mol-min; 8.03, 0.021 L/mol-min.

The general pH dependence of k_{4c} is similar to that observed for k_{1c}, and a comparison with the pH dependencies of the fractional concentrations of the various thiol-deprotonated forms of GSH indicates the thiol-deprotonated, amino-protonated form (GS^{2-}) to be the reactive species. Over this same pH range, PSSP is present predominantly in the amino-protonated form. Thus, the exchange reactions which occur are:

$$[10]\quad PS^- + GSSG^{2-} \underset{k_2}{\overset{k_1}{=}} PSSG^- + GS^{2-}$$

$$[11]\quad PS^- + PSSG^- \underset{k_4}{\overset{k_3}{=}} PSSP + GS^{2-}$$

where k_1–k_4 are pH independent rate constants.

Rate constant k_1 is related to the conditional rate constant k_{1c} by eq. [12].

$$[12]\quad k_{1c} = k_1\left(\frac{k_{a12}a_H}{a_H^2 + a_H K_{A2} + K_{A2}K_{A3}}\right)$$

where K_{A2} and K_{A3} are acid dissociation constants for PSH and a_H is calculated directly from the pH meter reading. k_{a12} is the microscopic acid dissociation constant for the deprotonation of the thiol group of the PSH species in which both the amino and thiol groups are protonated (28). A value of 190 ± 7 L/mol-min was obtained for k_1 by fitting the k_{1c} data at pH > 5 to eq. [12]. The solid line through the experimental points in Fig. 7 is the theoretical curve predicted by this value for k_1.

Rate constant k_4 was calculated from the values for k_{4c} using eq. [13].

$$[13]\quad k_{4c} = k_4\left(\frac{k_{a123}a_H}{a_H^2 + K_{A3}a_H + K_{A3}K_{A4}}\right)$$

where K_{A3} and K_{A4} are acid dissociation constants for GSH and k_{a123} is the microscopic acid dissociation constant for deprotonation of the thiol group from the carboxyl-deprotonated, amino- and thiol-protonated form of GSH (29). The value obtained for k_4 is 1.30 ± 0.34 L/mol-min.

Penicillamine–glutathione thiol/disulfide exchange equilibria

The equilibrium constants for the reactions represented by eqs. [10] and [11] are defined as:

$$[14]\quad K_1 = \frac{[PSSG^-][GS^{2-}]}{[PS^-][GSSG^{2-}]}$$

$$[15]\quad K_2 = \frac{[PSSP]^-[GS^{2-}]}{[PS^-][PSSG^-]}$$

where PS^- and GS^{2-} are the amino-protonated, thiol-deprotonated forms of PSH and GSH, and $GSSG^{2-}$, $PSSG^-$, and PSSP the amino-protonated forms of GSSG, PSSG, and PSSP. K_1 and K_2 were determined from the conditional (pH-dependent) equilibrium constants K_{1c} and K_{2c} for reactions [5] and [6]. K_1 and K_2 are related to K_{1c} and K_{2c} by:

$$[16]\quad K_1 = K_{1c}\frac{\alpha_1\alpha_2}{\alpha_3\alpha_4}$$

$$[17]\quad K_2 = K_{2c}\frac{\alpha_2\alpha_5}{\alpha_1\alpha_3}$$

where α_1 is the fraction of $PSSG_t$ that is in the form $PSSG^-$, α_2 the fraction of GSH_t that is GS^{2-}, α_3 the fraction of PSH_t that is PS^-, α_4 the fraction of $GSSG_t$ that is $GSSG^{2-}$, and α_5 the fraction of $PSSP_t$ that is in the form PSSP. α_1–α_5 can be calculated from the acid dissociation constants for the various species (30).[3]

K_{1c} and K_{2c} were determined over a wide range of solution conditions from the equilibrium concentrations of PSH_t, etc., which were determined from the intensities of the methyl resonances. First, the concentrations of PSH, PSSG, and PSSP, if present, were calculated from the initial PSH concentration and the relative areas of the methyl resonances, and then the concentrations of GSH and GSSG were obtained by difference. Equilibrium data were obtained from reactions carried out (*i*) in D_2O under an argon atmosphere, (*ii*) in H_2O under an argon atmosphere, and (*iii*) in H_2O in sealed nmr tubes which were degassed by the freeze–pump–thaw technique before sealing. The experiments in (*iii*) were found to be necessary for the measurement of K_{2c}, because the kinetics of the reaction represented by eq. [6] are slow and, at the long reaction times required to reach equilibrium, it was found that air oxidation

[3]For example, $\alpha_1 = [PSSG^-]/[PSSG]_t = a_H^2/(a_H^2 + K_{A4}a_H + K_{A4}K_{A5})$ where K_{A4} and K_{A5} are the last two acid dissociation constants for PSSG (30).

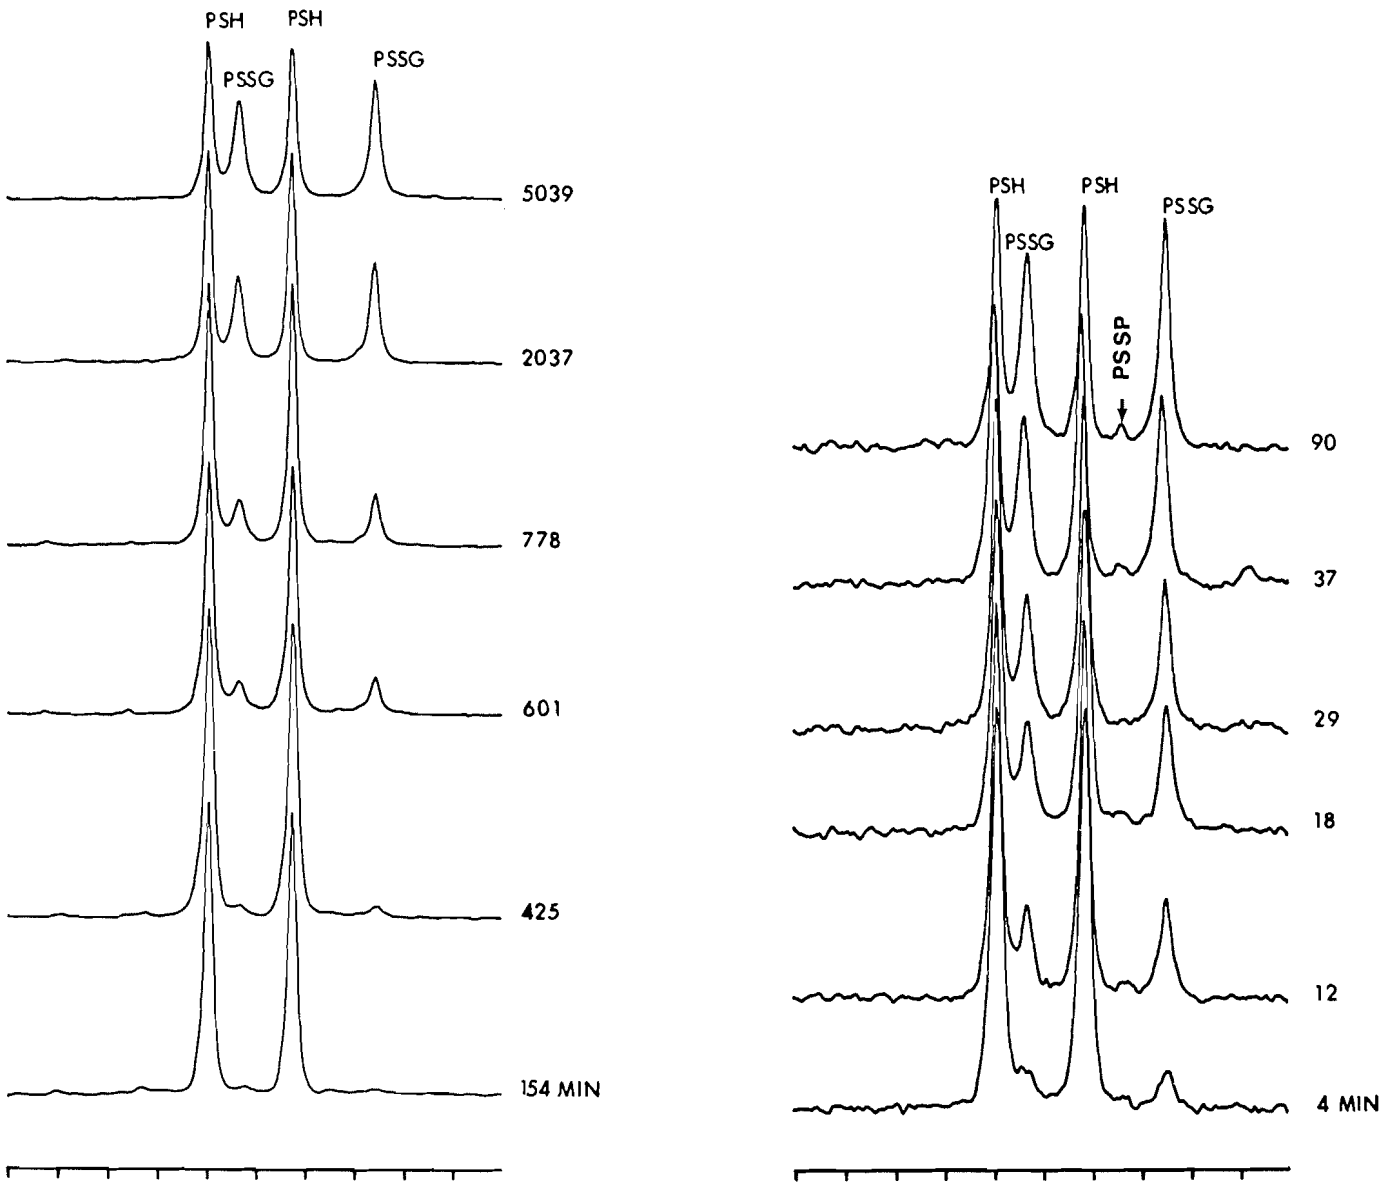

FIG. 5. 200-MHz ^{1}H nmr spectra obtained as a function of time for the reaction of PSH with GSSG. (Left) Initial concentrations of PSH and GSSG, 0.0160 *M*, pH = 3.96. (Right) Initial concentrations of PSH and GSSG, 0.00400 *M*, pH = 6.61.

of PSH and GSH leads to irreproducible results for K_{2c} in experiments (*i*) and (*ii*).

K_{1c} was measured at 15 pH values, covering the pH range 3.8−10.5, in experiment (*i*), at 9 pH values covering the pH range 7.2−10.0, in experiment (*ii*), and at 12 pH values covering the pH range 4.2−10.0 in experiment (*iii*). In experiments (*i*) and (*ii*), spectra were measured within 24 h of mixing the reactants. Beyond this time, PSSP and PSSG resonances increase due to air oxidation. The reaction represented by eq. [5] is sufficiently fast at the concentrations and pH values used that it has come to equilibrium within this time. However, the reaction represented by eq. [6] is much slower and has not reached equilibrium.

K_{2c} was measured as a function of pH in experiment (*iii*). To ensure that both reactions had come to equilibrium, spectra were measured for each of the solutions in sealed nmr tubes every few days for approximately one month.

A value of 0.56 ± 0.02 was calculated for K_1 and a value of 0.0143 ± 0.0014 for K_2 from the K_{1c} and K_{2c} values with eqs. [16] and [17]. With these values for K_1 and K_2 and the values determined for k_1 and k_4, k_2 and k_3 are calculated to be 340 ± 20 L/mol-min and 0.019 ± 0.005 L/mol-min respectively.

pH-independent equilibrium constants for the reactions written in terms of all the reactants and products in their fully deprotonated forms can also be calculated from the values for K_{1c} and K_{2c}. The values obtained are 34.8 ± 0.9 for the first reaction and 0.99 ± 0.10 for the second reaction.

N-*Acetylpenicillamine − glutathione disulfide reactions*

The kinetics and equilibria of the oxidation of *N*-acetyl-D,L-penicillamine (N-PSH) by GSSG were studied for comparison with the results obtained for the oxidation of PSH by GSSG. In Fig. 8 are shown ^{1}H nmr spectra for the penicillamine methyl protons in a solution containing N-PSH and GSSG at pH 6.58 as a function of time. One pair of resonances is observed for the two penicillamine methyl groups of N-PSH, whereas two pairs of resonances are observed for the N-PSH methyl groups in the mixed disulfide due to the two different

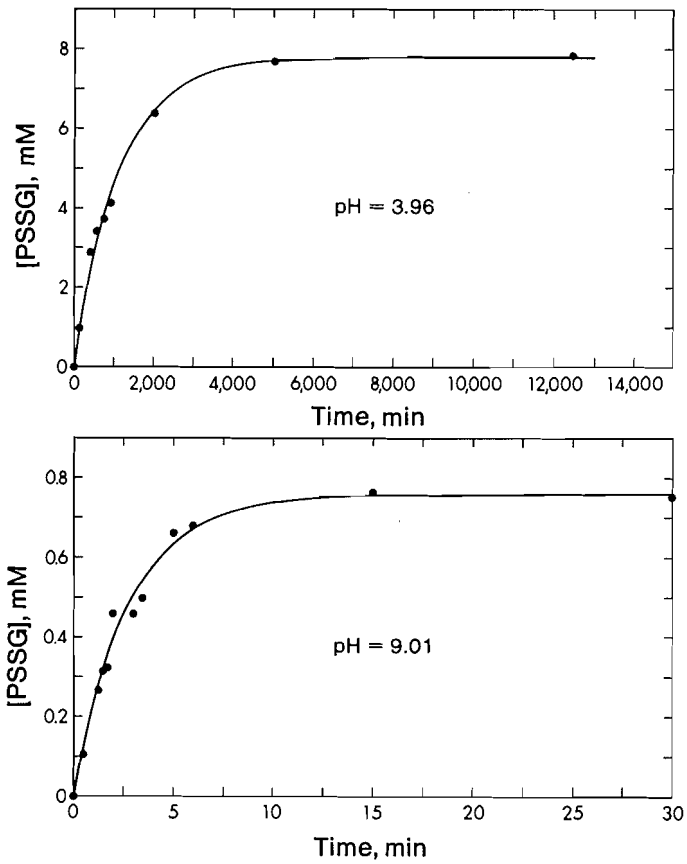

FIG. 6. Kinetic data for the formation of PSSG by reaction of PSH with GSSG at pH 3.96 and 9.01. At pH 3.96, the initial concentrations of PSH and GSSG were 0.0160 *M*. At pH 9.01, the initial concentrations were 0.00143 *M* PSH and 0.00137 *M* GSSG. The solid curves through the points are theoretical curves calculated with the rate parameters obtained from the data as described in the text.

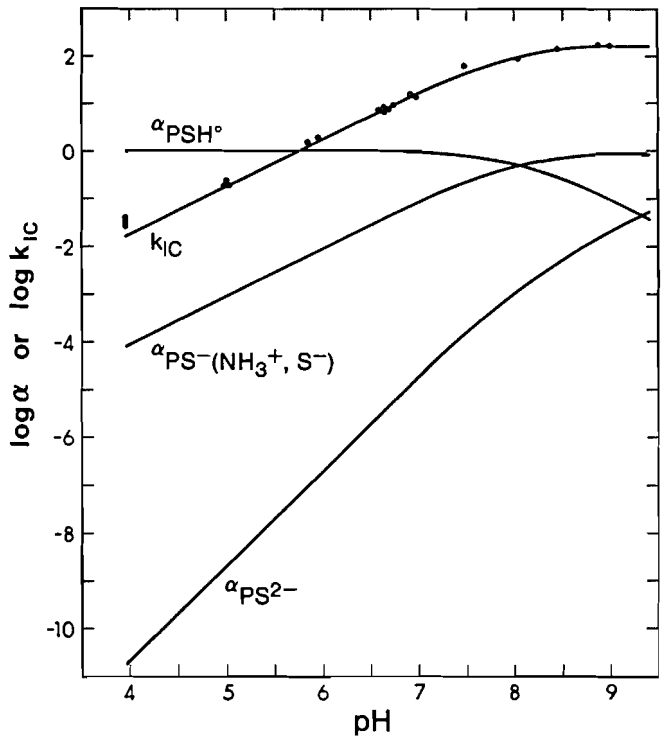

FIG. 7. The logarithm of the fractional concentrations (α) of the fully protonated (PSH^0), amino-protonated, thiol-deprotonated (PS^-), and amino-deprotonated, thiol-deprotonated (PS^{2-}) forms of PSH, and of the conditional rate constant k_{1c} as a function of pH. The solid curve through the experimental points is the theoretical curve predicted by the pH-independent rate constant k_1, as described in the text.

configurations which form: *N*-acetyl-D-penicillamine-glutathione mixed disulfide and *N*-acetyl-L-penicillamine-glutathione mixed disulfide.[4] Since the *N*-acetyl-D,L-penicillamine is a racemic mixture, the two pairs of resonances from the mixed disulfide are of equal intensity.

Using procedures similar to those described above, K_{1c}, defined by eq. [5], was found to be 2.55 ± 0.15 at pH 6.95, 2.60 ±0.13 at pH 7.44, and 2.79 ± 0.13 at pH 8.02. A value of 0.747 ± 0.012 L/mol-min was measured for the conditional rate constant k_{1c} at pH 6.58. Assuming the reactive species in the thiol/disulfide exchange reaction between N-PSH and GSSG at pH 6.58 to be the carboxyl and thiol-deprotonated form of N-PSH and the $GSSG^{2-}$ form of GSSG, a value of 3660 L/mol-min is calculated for rate constant k_1 from the value measured for k_{1c} at pH 6.58 and a pK_a of 10.27 for the thiol group of N-PSH (31). A pH-independent equilibrium constant cannot be calculated from the K_{1c} values because the acid dissociation constants of the mixed disulfide are not known.

Discussion

It is well established that thiol/disulfide exchange reactions are mechanistically simple S_N2 displacement reactions (19, 20), and that they proceed via the thiolate anion (19–27). For both PSH and GSH, there are two thiolate species possible, PS^- and GS^{2-}, in which the thiol group is deprotonated and the amino group protonated, and PS^{2-} and GS^{3-}, in which both groups are deprotonated. The pH dependence of the conditional rate constants indicate that PS^- and GS^{2-} are the reactive species.

Equations [10] and [11] describe the two steps in the oxidation of PSH by GSSG in terms of the species involved, and eq. [18] describes the overall reaction.

[18] $2PS^- - GSSG^{2-} \rightleftarrows PSSP + 2GS^{2-}$

The equilibrium constant for the overall reaction, K_3, is calculated to be 8.0×10^{-3} using the relation $K_3 = K_1K_2$. If the position of equilibrium in the two stepwise reactions was governed by random distribution, K_1 and K_2 would be 2 and 0.5 respectively, and K_3 would equal 1. The values obtained for K_1 and K_2 differ from these values by factors of ~4 and ~35 respectively. For comparison, Gorin and Doughty (27) reported values of $K_1 = 1.27$ and $K_2 = 0.27$ at pH 6.6 and 25°C for the reaction of cysteine with glutathione disulfide. Penicillamine differs from cysteine in that the thiol group of penicillamine is adjacent to two bulky methyl groups, which hinder its reactivity (5). The large difference between k_1 and k_3 indicates this is particularly true in the reaction of PS^- and PSSG, in which there also are two methyl groups adjacent to the specific disulfide sulfur at which the reaction occurs. The large difference between k_4 and k_2 suggests that the methyl groups also hinder the access of thiolate groups to the disulfide group of PSSP. Steric effects on thiol/disulfide exchange reac-

[4]The glutamic acid and cysteine residues in glutathione are both of the L-configuration.

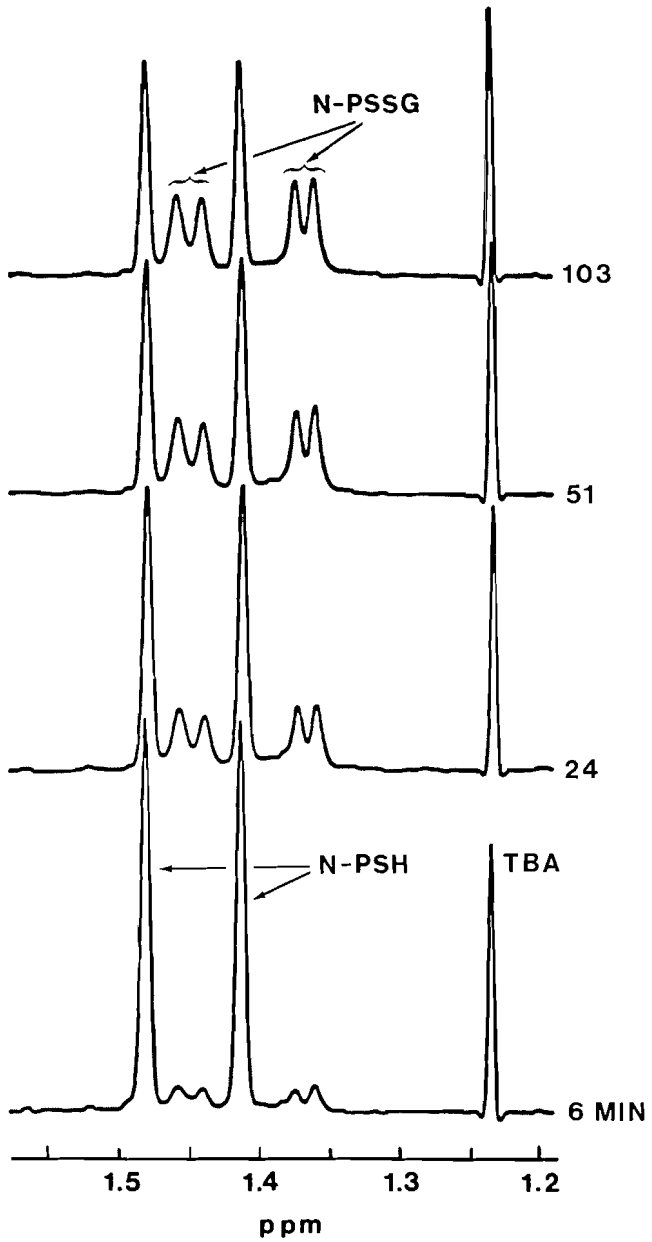

FIG. 8. Portions of the 200-MHz ^{1}H nmr spectra obtained as a function of time for the reaction of N-PSH with GSSG. Initial concentrations N-PSH = 0.0365 *M* and GSSG = 0.0348 *M*. TBA = 0.004 *M*, pH = 6.58. The resonances are from methyl groups.

tions have been observed previously for related systems. Equilibrium constants for thiol/disulfide exchange involving a series of alkyl thiols and disulfides differ from the statistically predicted values by a factor of 2 or less, except for the reaction of *tert*-butyl thiol with n-butyl *tert*-butyl mixed disulfide (32). Also, exchange equilibrium constants for the reaction of a series of 2-aminoethane thiols with 4,4′-dithiobis(benzenesulfonate) are near statistical values except for those having two methyl groups next to the thiol (26). Weber *et al.* found that the rate of reaction of GSH with RSSC, where R is an alkyl group and CS is cysteine, to form RSH and the cysteine–glutathione mixed disulfide is slowest when R is *tert*-butyl and isopropyl (33).

At physiological pH, thiol groups are almost completely protonated and the reactive thiol-deprotonated species PS^- and

k_{2c}	26.9 L/mol-min
k_{3c}	0.00047 L/mol-min
k_{4c}	0.012 L/mol-min

GS^{2-} represent a minor fraction of the total PSH and GSH. Also, since the pK_A's of the thiol groups of PSH and GSH are different, the fraction of PSH present as PS^- is different from the fraction of GSH present as GS^{2-}. Thus, at physiological pH, the conditional equilibrium and rate constants are different from the above values for K_1–K_3 and k_1–k_4. The conditional equilibrium and rate constants calculated from these values for a pH of 7.4 are listed in Table 1. The corresponding values for the reaction of N-PSH with GSSG at pH 7.4 are K_{1c} = 2.6, k_{1c} = 4.9 L/mol-min, and k_{2c} = 1.9 L/mol-min. This value for k_{1c} is less than that for PSH, even though k_1 is larger for N-PSH, because the fraction of the N-PSH in which the thiol group is deprotonated at pH 7.4 is less.

The small value for K_{2c} in Table 1 indicates that the tendency to form PSSP from the mixed disulfide is small. The small value for k_{3c} suggests that the PSSP found as a metabolite of penicillamine (3) is formed not by thiol/disulfide exchange but by other oxidation reactions. It has been proposed that, in cells, the nonenzymatic reduction of PSSP by GSH followed by the enzyme catalyzed reduction of GSSG to GSH is an efficient system for the reduction of PSSP (5). However, the small value obtained for k_{4c} in this study suggests that, once formed, reduction of PSSP by other thiols, including GSH and protein thiols, will be of minor importance in the metabolism of penicillamine.

The overall conditional equilibrium constant K_{3c} is related to the difference between the formal electrode potentials $E^{0\prime}$ of the GSSG/GSH and PSSP/PSH couples according to eq. [19].

$$[19]\quad E^{0\prime}_{GSSG/GSH} - E^{0\prime}_{PSSP/PSH} = \frac{RT}{nF} \ln K_{3c}$$

Values reported for $E^{0\prime}_{GSSG/GSH}$ are −0.205 V vs. the standard hydrogen electrode at 30°C and pH 7 (20) and −0.24 V at 40°C and pH 7 (34). Using the value given for K_{3c} in Table 1, $E^{0\prime}_{GSSG/GSH} - E^{0\prime}_{PSSP/PSH}$ is calculated to be −0.0378 V. For comparison, $E^{0\prime}_{GSSG/GSH} - E^{0\prime}_{CSSC/CSH}$, where CSSC is cystine, is reported to be in the range −0.013 to −0.018 V at pH 6.6–7.0 (21, 23, 27). The stepwise equilibrium constants for thiol/disulfide exchange indicate that the lower reducing power of PSH as compared to cysteine is due to the much smaller tendency of penicillamine to form its symmetrical disulfide from its unsymmetrical, mixed disulfides.

Etude du système acridine orange – poly(C) et de son interaction avec les complexes du palladium(II)

ROBERT MÉNARD ET MIKLOS ZADOR

Département de Chimie, Université de Montréal, C.P. 6210, Succ. A, Montréal (Qué.), Canada H3C 3V1

Reçu le 6 décembre 1983

ROBERT MÉNARD et MIKLOS ZADOR. Can. J. Chem. **62**, 1681 (1984).

Le complexe formé entre l'acridine orange (AO) et l'acide polycytidylique (poly(C)) a été étudié par spectrophotométrie et spectrofluorimétrie. Le complexe a été caractérisé par sa stoechiométrie, sa structure et les paramètres thermodynamiques de sa formation. Les résultats sont en accord avec une agrégation externe des molécules protonées de colorant le long de la chaîne du poly(C) chargée négativement et indiquent qu'environ deux molécules d'AO peuvent se fixer, par unité de nucléotide, au poly(C). La cinétique de la réaction de ce complexe avec un complexe de Pd(II) a été étudiée par la méthode du flux-stoppé. L'addition de (dien)Pd(II) au complexe AO–poly(C) conduit à la dissociation de celui-ci, due à la fixation du complexe de Pd(II) au site N3 de la base cytosine du poly(C). La constante de vitesse de libération de l'AO, extrapolée à une concentration d'AO nulle, correspond à la constante de vitesse pour la fixation du (dien)Pd(II) sur le poly(C). Ceci indique que l'AO peut être utilisé comme indicateur lors de cette réaction et permet de réaliser l'étude cinétique à des concentrations très faibles ($\leq 5 \times 10^{-6}$ *M*).

ROBERT MÉNARD and MIKLOS ZADOR. Can. J. Chem. **62**, 1681 (1984).

The complex formed between acridine orange (AO) and polycytidylic acid (poly(C)) was studied by spectrophotometry and spectrofluorometry. The complex was characterized by its stoichiometry, structure, and the thermodynamic parameters of its formation. The results are in agreement with an external aggregation of the protonated dye along the negatively charged poly(C) chain and indicate that approximately two AO molecules are bound per nucleotide unit of poly(C). The kinetics of the reaction between this complex and a Pd(II) complex was studied by the stopped-flow method. The addition of (dien)Pd(II) to the AO–poly(C) complex leads to the dissociation of the latter, due to fixation of the Pd(II) complex to the N3 site of the cytosine base of poly(C). The rate constant for the AO liberation, extrapolated at zero AO concentration, corresponds to the rate constant of Pd(II) fixation on poly(C). This indicates that AO can be used as an indicator for this reaction and allows kinetic studies at very low concentrations ($\leq 5 \times 10^{-6}$ *M*).

Introduction

L'acridine orange (AO) et la proflavine (PF) sont tous deux des agents mutagènes (1,2), ce qui est généralement attribué à leur interaction avec les acides nucléiques. L'activité biologique de ces colorants basiques et le fait que la plupart des dérivés de l'acridine sont fluorescents sont les raisons qui expliquent l'immense intérêt porté envers ces molécules. Plusieurs études ont été effectuées sur l'interaction entre les acridines et les acides nucléiques (3–7) ou d'autres polynucléotides et polyélectrolytes synthétiques (8–16).

Il existe principalement deux types de liaison entre l'AO (ou la PF) et les polynucléotides. Le premier type correspond à l'empilement des molécules de colorant le long de la chaîne, mais à l'extérieur des hélices (8). Le deuxième type implique l'intercalation du colorant entre deux paires de bases d'une double hélice (17). On observe aussi dans certains cas, comme en présence d'un polynucléotide à simple brin comme l'ADN dénaturé, une intercalation partielle (18). L'importance relative de ces complexes dépend de la structure du polymère (double hélice, simple hélice; natif, dénaturé), du rapport [polynucléotide]/[colorant], de la force ionique, etc.

Ce travail est consacré à l'étude de l'interaction entre un polynucléotide à simple brin, l'acide polycytidylique (poly(C)) et l'acridine orange. Cette interaction nous intéresse en vue de l'utilisation de l'AO comme indicateur lors de l'étude cinétique de réactions entre des polynucléotides et divers complexes d'ions métalliques tels ceux du Pd(II) et du Pt(II). La faible solubilité des polynucléotides ou des complexes formés est souvent la source de nombreux problèmes rencontrés lors de l'étude de ces réactions. L'utilisation d'un colorant fluorescent permettant de travailler à très faible concentration peut donc possiblement ouvrir la voie à de nombreuses études cinétiques quantitatives de ces systèmes.

La fluorescence de l'AO a déjà été utilisée avec succès pour étudier la réaction entre l'AO et l'ADN à des concentrations très basses (19). Dans le cas présent, l'AO est utilisé uniquement comme indicateur pour permettre la détermination des paramètres cinétiques de la réaction entre le poly(C) et des complexes du Pd(II). Pour vérifier la validité d'une telle méthode, la caractérisation du complexe AO–poly(C) et de son interaction avec le complexe du Pd(II) est indispensable.

Partie expérimentale

L'acridine orange (diméthylamino-3,6 acridine) a été obtenu sous forme de l'hydrochlorure de Eastman Kodak Co. et la proflavine (diamino-3,6 acridine) de Sigma Chemical Co. sous forme d'hémisulfate. L'AO et la PF ont été recristallisés plusieurs fois de mélanges méthanol–éther (~1:3) et éthanol–eau (1:1) respectivement.

L'acide polycytidylique (poly(C)) provenait de chez Sigma Chemical Co. et l'acide polyadénylique (poly(A)) de Miles Laboratories Inc. Tous deux sont des produits de haute pureté et furent utilisés sans purification supplémentaire. Le [(dien)PdCl]Cl (dien: diéthylènetriamine) a été synthétisé selon une méthode légèrement modifiée de celle décrite dans la littérature (20). Le complexe $[(dien)Pd(H_2O)](NO_3)_2$ a été préparé en précipitant les chlorures d'une solution de [(dien)PdCl]Cl sous forme de AgCl par addition de $AgNO_3$. Le précipité est retiré par filtration et la solution amenée à un volume connu.

L'AO et la PF sont photosensibles et peuvent en plus s'adsorber sur le verre et le quartz. Pour ces raisons, des précautions particulières ont été prises pour s'assurer de la fiabilité de nos résultats. Les solutions mères de colorant ont été conservées dans des bouteilles opaques en Teflon noir à 6°C. Dans ces conditions, les colorants étaient stables pendant plusieurs semaines. Les solutions diluées ont été fraîchement préparées et gardées à l'abri de la lumière. La verrerie normalement utilisée a été remplacée par du matériel de plastique. Les ballons jaugés, béchers et pipettes étaient en polypropylène et les cuvettes pour la spectrophotométrie en polystyrène transparent (Sarstedt Canada Inc.). Le seul contact avec du verre se produisait lors de

l'ajustement du pH où des électrodes en verre furent utilisées.

Les spectres d'absorption ont été enregistrés à l'aide d'un spectrophotomètre Perkin–Elmer modèle 552 tandis qu'un fluorimètre Fluorispec modèle SF-1 de Baird-Atomic Inc. a été utilisé pour les mesures de fluorescence. La cinétique des réactions entre le complexe AO–poly(C) et (dien)Pd(II) a été suivie par spectrophotométrie à flux-stoppé au moyen d'un Dionex modèle D-130 combiné à un système d'acquisition des données construit dans notre laboratoire (21). Les constantes de vitesse d'ordre deux ont été obtenues par traitement de moindres carrés de l'équation intégrée correspondante.

Toutes les mesures ont été effectuées à pH 7 et 25°C sauf lorsque spécifié autrement. Dans ces conditions, l'acridine orange est protoné (pK_a = 10,2) et les groupements phosphate des polynucléotides sont chargés négativement ($pK_a \approx 1$ (22)).

Résultats

L'étude spectrophotométrique montre que, comme pour la dimérisation, la fixation de l'AO sur le poly(C) s'accompagne de variations dans les spectres d'absorption et de fluorescence. Les spectres d'absorption pour l'AO seul et un présence de concentrations croissantes de poly(C) sont illustrés à la figure 1(a). On remarque l'absence de point d'isoabsorbance (isosbestique), ce qui indique la présence de plus de deux espèces en solution.

Dans le cas de l'AO seul (courbe 1) on observe deux maximums dans la région du visible: un premier à 492 nm attribué au monomère libre en solution et un deuxième, sous forme d'un épaulement à environ 465 nm, qui prédomine dans les solutions d'AO à concentration élevée, attribué au dimère $(AO)_2$ (5, 8, 23). Lors de l'addition de poly(C), ces bandes diminuent d'intensité (courbes 2–4), indiquant l'interaction avec le poly(C). A concentration en poly(C) élevée (courbe 4) on distingue clairement l'apparition d'une nouvelle bande vers 438 nm et on l'attribue à l'agrégation de l'AO sur la chaîne du poly(C) (5, 8). La position de cette bande exclue l'intercalation pour laquelle le maximum devrait se situer, d'après la littérature, vers 502 nm (7). L'addition du poly(C) à l'AO entraîne aussi une désactivation de fluorescence à 530 nm sans déplacement du maximum (Fig. 1(b)). L'intercalation conduirait plutôt à une augmentation de fluorescence (19).

Les variations d'absorbance ont été étudiées en fonction du rapport p = [poly(C)]/[AO] ([poly(C)] exprimée en mol L^{-1} d'unité de mononucléotide), de l'acidité et de la force ionique pour caractériser le complexe formé, notamment sa stoechiométrie, sa structure et les paramètres thermodynamiques de sa formation.

Premièrement, on remarque que le complexe AO–poly(C) est fortement influencé par la force ionique de la solution. L'absorbance à 492 nm de la solution contenant le complexe AO–poly(C), à un rapport p = 1,0, augmente considérablement lors de l'addition de $NaNO_3$ (ou de NaCl) (Fig. 2(a)). Ceci indique l'apparition d'AO libre provenant de la dissociation du complexe. Ce comportement est caractéristique aux complexes de type externe dont la formation est due aux interactions électrostatiques des ions positifs avec les sites phosphate de la chaîne chargés négativement (5, 8).

Un effet spécifique apparaît lors de l'addition d'ions Mg^{2+} à force ionique constante. Dans ce cas, la dissociation du complexe AO–poly(C) apparaît pour de petites quantités de $MgCl_2$ ajouté (~0,01 M) malgré une force ionique relativement élevée de 0,1 M (Fig. 2(b)). Cet effet est attribué à la fixation préférentielle (comparé aux ions Na^+) d'ions Mg^{2+} par les sites phosphate.

Comme on peut le voir sur la figure 2(c), l'addition du

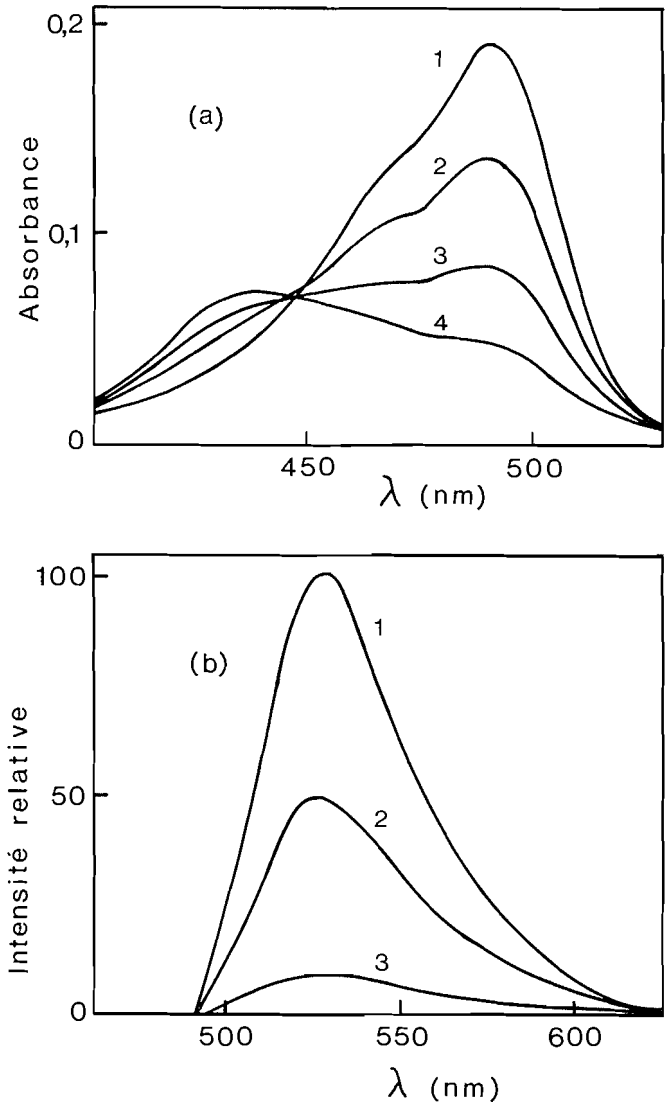

FIG. 1. Spectres d'absorption (a) et de fluorescence (b) de l'acridine orange à diverses concentrations de poly(C) ajouté. Conditions: (a) AO $5,0 \times 10^{-6}$ M, $NaNO_3$ 0,009 M, NaCl 0,001 M, pH 7, poly(C) ajouté: (1) 0, (2) $1,5 \times 10^{-6}$ M, (3) $2,5 \times 10^{-6}$ M, (4) $5,0 \times 10^{-6}$ M; (b) AO $1,0 \times 10^{-5}$ M, λ_{exc} = 490 nm, pH 7, poly(C) ajouté: (1) 0, (2) $5,0 \times 10^{-6}$ M, (3) $1,0 \times 10^{-5}$ M.

complexe (dien)$Pd(H_2O)^{2+}$ entraîne également la dissociation du AO–poly(C) et ceci à des concentrations beaucoup plus faibles ($<10^{-5}$ M). Cependant, dans ce dernier cas l'effet est indirect et provient de la fixation de (dien)Pd(II) sur le site N3 de la base cytosine. Il est connu que la fixation du (dien)Pd(II) se fait sur le site N3 dans le cas de la cytidine (24). Lors de cette réaction la bande à λ = 268 nm, correspondant au groupe cytosine, subit une augmentation d'intensité et un léger déplacement vers le rouge. Les mêmes phénomènes sont observés dans le cas du poly(C) et il est permis de supposer que le même site N3 soit impliqué. La fixation du (dien)Pd^{2+} conduit à la diminution du champ électrique de la chaîne phosphate chargée négativement et entraîne la libération de l'AO. Le même effet a été observé en fluorescence. Dans les deux cas, l'addition de concentrations suffisantes de (dien)$Pd(H_2O)^{2+}$ conduit au spectre de l'AO libre. Des tests effectués montrent que l'addition de (dien)Pd(II) n'influence pas les spectres d'absorption et de fluorescence de l'AO en absence de poly(C), ce qui indique

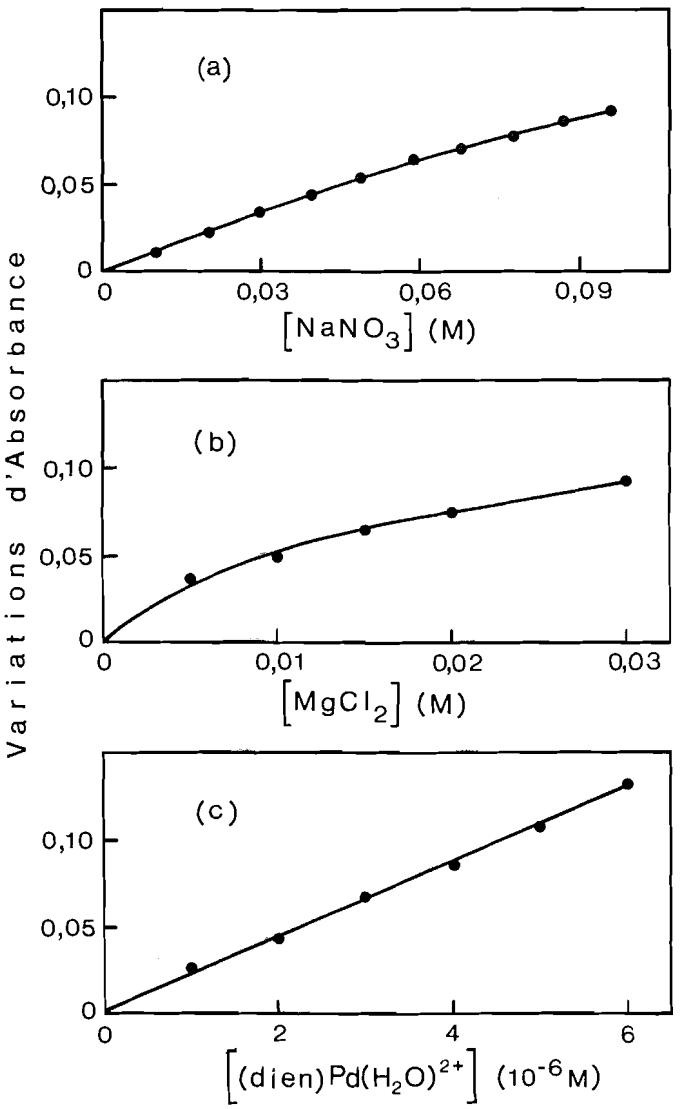

FIG. 2. Variations de l'absorbance à 492 nm du système AO–poly(C) lors de l'addition de $NaNO_3$ (a), $MgCl_2$ (b) et $[(dien)Pd(H_2O)](NO_3)_2$ (c). Conditions: (a) AO = poly(C) = $1{,}0 \times 10^{-5}$ *M*, pH 7; (b) AO = poly(C) = $1{,}0 \times 10^{-5}$ *M*, force ionique constante (0,1 *M*, ajustée avec $NaNO_3$), pH 7; (c) AO = poly(C) = $2{,}0 \times 10^{-5}$ *M*, force ionique constante (0,1 *M* $NaNO_3$), pH 7.

l'absence d'interaction Pd(II)–AO.

L'augmentation de l'acidité du milieu s'accompagne de l'augmentation de l'absorbance à 492 nm. A pH bas (<2) le spectre et l'absorbance correspondent à ceux de l'AO libre. La protonation du poly(C) au site N3 de la cytosine conduit donc, de la même façon que lors de la fixation du (dien)Pd(II), à la dissociation du complexe AO–poly(C). La courbe de titrage spectrophotométrique ne correspond pas à un équilibre acide–base simple. Les écarts se situent surtout entre pH 4 à 6 et peuvent être attribués à la formation de la double hélice du poly(C) semi-protoné.

Les variations d'absorbance en fonction du rapport *p* sont présentées à la figure 3. On observe une diminution graduelle d'absorbance jusqu'à $p \approx 1$, ensuite l'absorbance ne varie pratiquement plus. L'allure de la courbe montre qu'à l'addition des premières quantités de poly(C) ($p \leq 0{,}4$), la diminution d'absorbance est plus rapide que celle prévue pour un complexe, même très stable, de stoechiométrie 1:1. Par exemple,

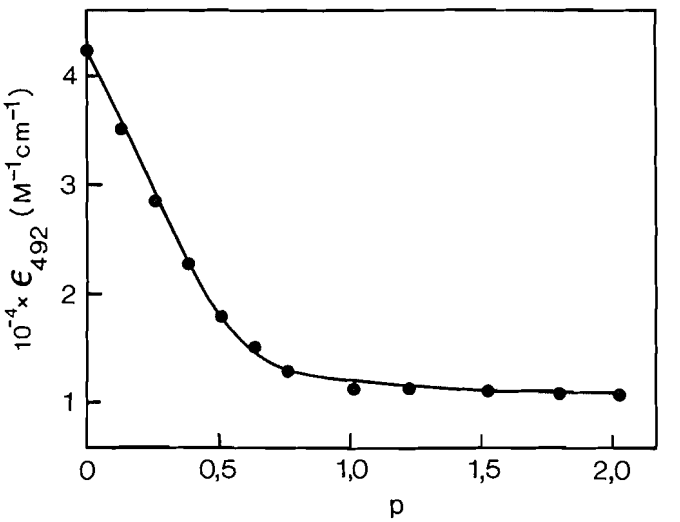

FIG. 3. Titrage spectrophotométrique à 492 nm de l'AO par le poly(C). Les points représentent les résultats expérimentaux et la ligne continue, la valeur calculée (voir texte). Conditions: AO $2{,}00 \times 10^{-5}$ *M*, NaCl 0,1 *M*, pH 7.

pour $p = 0{,}381$ l'absorbance est abaissée de 0,845 à 0,455 alors que pour le complexe 1:1 stable on calcule une valeur de 0,603. Ce phénomène est aussi visible sur les spectres de la figure 1(a). Ceci montre clairement qu'il y a plus d'une molécule d'AO fixée par unité de nucléotide dans ces conditions (excès de l'AO).

Les paramètres thermodynamiques de l'interaction AO–poly(C) ont été déterminés en utilisant le modèle de Schwarz (25) qui a été appliqué avec succès à l'interaction de colorants acridines avec l'acide L-glutamique (11, 12) et d'autres polyanions linéaires présentant des sites de liaison équivalents (14, 15).

D'après ce modèle, on représente par *g* le nombre de sites de liaison d'AO par unité de nucléotide du poly(C). Deux constantes d'équilibre sont utilisées, $K^{\ddagger}$ pour le processus de nucléation c.-à-d. fixation d'une molécule d'AO sur la chaîne et *K* pour le processus de croissance d'agrégat impliquant l'empilement de molécules d'AO sur des sites adjacents de façon coopérative. Le facteur de coopérativité *q* est défini par $q = K/K^{\ddagger}$. Cette coopérativité est due à l'interaction de molécules d'AO voisines, stabilise l'agrégat et favorise sa croissance. Ce phénomène est important dans le cas de l'AO tel que montré par sa constante de dimérisation élevée en solution aqueuse (12, 23).

Le titrage spectrophotométrique a été effectué pour des rapports [poly(C)]/[AO] assez petits ($p \leq 2$). Dans ces conditions, le système peut être décrit convenablement en utilisant seulement *K* et *g*. Les variations d'absorptivité molaire à $\lambda =$ 492 nm sont dues à des variations des fractions de chaque espèce en solution lors de l'addition du poly(C). L'additivité de l'absorbance et les bilans de matière des espèces en solution conduisent, d'après Schwartz *et al.* (11), à l'équation [1]:

$$[1] \quad \epsilon = \epsilon_{st} + (\epsilon_a - \epsilon_{st})\bar{\gamma}_a + 2(\epsilon_d - \epsilon_{st})K_d c_a^0 \bar{\gamma}_a^2$$

où ϵ, ϵ_a, ϵ_d, ϵ_{st}: absorptivités molaire expérimentale, du monomère libre, du dimère libre et du complexe AO–poly(C) respectivement; K_d: constante de dimérisation de l'AO; c_a^0: concentration totale d'AO; $\bar{c}_a$: concentration de monomère libre à l'équilibre; $\bar{\gamma}_a = \bar{c}_a/c_a^0$: fraction des molécules d'AO sous forme de monomère à l'équilibre.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.6 on 09/06/12
For personal use only.

La façon de déterminer les divers paramètres de cette équation ainsi que la valeur de g est légèrement différente des méthodes graphiques utilisées par Schwarz. En étudiant la dimérisation de l'AO en fonction de sa concentration, ϵ_a, ϵ_d et K_d peuvent être évalués. Des valeurs de $\epsilon_a = 57\,900$ L mol^{-1} cm^{-1}, $\epsilon_d = 5000$ L mol^{-1} cm^{-1} et $K_d = 1{,}5 \times 10^4\ M^{-1}$ ont été obtenues. La valeur de ϵ_{st} est déterminée sur la figure 3 en prenant $\epsilon_{st} = \epsilon$ pour $p \rightarrow \infty$, soit 10 400 L mol^{-1} cm^{-1}. Connaissant K_d et les valeurs des diverses absorptivités molaire on peut calculer $\bar{\gamma}_a$, par l'équation [1], pour diverses valeurs de p en utilisant les résultats expérimentaux.

On doit ensuite déterminer le paramètre g dont la connaissance est nécessaire pour l'obtention de la constante d'équilibre K. On peut obtenir g à partir de la variation de γ_a^*en fonction du rapport p. γ_a^* représente la fraction totale d'AO non-lié au polymère (monomère ou dimère libres) et est donné par l'équation [2]:

$$[2] \quad \gamma_a^* = \bar{\gamma}_a + 2K_d c_a^0 \bar{\gamma}_a^2$$

La loi de la conservation de la matière relie γ_a^* à p par l'équation [3]:

$$[3] \quad \gamma_a^* = 1 - \bar{\theta} g p$$

où $\bar{\theta}$: fraction des sites de liaison occupés par l'AO à l'équilibre. Comme en présence d'un grand excès d'AO (valeurs de p faibles) on tend vers $\bar{\theta} = 1$, on peut obtenir g comme la pente de la droite γ_a^* vs. p passant par les premiers points. Les résultats conduisent à $g = 2{,}05$ pour le système AO−poly(C). Cette valeur implique qu'il y a plus d'un AO qui se lie par unité de nucléotide sur le poly(C).

La détermination de la constante d'équilibre K a été effectuée par simulation à l'ordinateur. Cette constante est définie par l'équation [4].

$$[4] \quad K = \frac{\bar{c}_{st}}{\bar{c}_a \cdot \bar{c}_p}$$

où $\bar{c}_{st}$: concentration du complexe AO−poly(C) à l'équilibre; $\bar{c}_p$: concentration du poly(C) libre à l'équilibre. En remplaçant $\bar{c}_{st}$ et $\bar{c}_p$ par leurs valeurs en termes de $\bar{c}_a$ et en réarrangeant l'équation résultante, on obtient:

$$[5] \quad (2K_dK)\bar{c}_a^3 + (2K_d + K)\bar{c}_a^2 + (Kgc_p^0 + 1 - Kc_a^0)\bar{c}_a - c_a^0 = 0$$

où c_p^0: concentration totale de poly(C).

La méthode de simulation consiste à résoudre cette équation du troisième degré pour une valeur de K à diverses valeurs de c_p^0. Les valeurs de $\bar{c}_a$ et donc de $\bar{\gamma}_a$ ainsi obtenues sont introduites dans l'équation [1] ce qui conduit à la courbe calculée de ϵ vs. p. Celle-ci est ensuite comparée à l'ensemble des résultats expérimentaux. Différentes valeurs de K conduisent à des courbes différentes. Tel que montré par la figure 3, l'accord entre la courbe calculée et les points expérimentaux est excellent pour $K = 1{,}3 \times 10^6\ M^{-1}$. Des accords nettement moins bons sont obtenus pour des valeurs de K de $1 \times 10^6\ M^{-1}$ et $2 \times 10^6\ M^{-1}$ ce qui montre la sensibilité de la méthode.

L'interaction du poly(C) avec la proflavine a été étudiée de façon similaire. Comme l'interaction n'est pas suffisamment forte à une force ionique de 0,1 M, ces expériences ont du être effectuées à force ionique beaucoup plus basse (0,001 M). Les résultats sont donnés au tableau 1. Les valeurs de ϵ_d et K_d pour la proflavine ont été tirées de la littérature (11). Il n'est pas nécessaire de connaître avec précision ces deux paramètres à cause de la très faible quantité de dimère présent dans le cas de la PF dans ces conditions, dû à la faible valeur de K_d (~525 M^{-1}). A titre de comparaison, le complexe AO−poly(A) a aussi été étudié. Les résultats sont résumés au tableau 1.

TABLEAU 1. Paramètres thermodynamiques de divers systèmes colorant−polynucléotide

Système	μ (M)	g	K (M^{-1})
AO−poly(C)	0,1	2,05	$1{,}3\times10^6$
AO−poly(A)	0,1	1,40	$2{,}0\times10^6$
PF−poly(C)	0,001	1,15	$5{,}0\times10^6$

La cinétique de la réaction entre AO−poly(C) et le complexe de Pd(II) a ensuite été étudiée et comparée à la réaction entre le poly(C) et (dien)Pd(II) en absence d'AO. Dans ce deuxième cas, la réaction a été suivie en étudiant l'augmentation d'absorbance de la bande à $\lambda = 268$ nm du poly(C) lors de la fixation du complexe de Pd(II). Les concentrations de poly(C) et de (dien)Pd(II) étaient de $5 \times 10^{-5}\ M$ et $2{,}5 \times 10^{-5}\ M$ respectivement en absence d'AO et de $5 \times 10^{-6}\ M$ et $2{,}5 \times 10^{-6}\ M$ en présence de l'AO. Il est à noter que l'utilisation de l'AO permet de travailler à des concentrations 10 fois plus faibles qu'en absence de colorant. Ces mesures ont été faites en absorbance pour des raisons pratiques. On peut prévoir cependant qu'en utilisant la fluorescence de l'AO on pourrait descendre à concentration encore plus basse.

Ces réactions ont été étudiées à force ionique constante (μ = 0,1 M), pH 7 et à deux concentrations en ion chlorure différentes (0,001 M et 0,01 M). Le complexe de palladium est sous forme de (dien)Pd$(H_2O)^{2+}$ à très faible concentration en chlorure et sous forme de (dien)PdCl$^+$ en présence de concentrations en chlorure plus élevées. L'espèce (dien)Pd$(H_2O)^{2+}$ est plus réactive que le (dien)PdCl$^+$. Aucune réaction n'a été détectée entre les complexes de Pd(II) et l'AO. Les réactions sont représentées par les équations [6] et [7]:

$$[6] \quad \text{(dien)Pd(II)} + \text{poly(C)} \xrightarrow{k} \text{(dien)Pd(II)−poly(C)}$$

$$[7] \quad \text{(dien)Pd(II)} + \text{AO−poly(C)} \xrightarrow{k_{AO}} \text{(dien)Pd(II)−poly(C)} + \text{AO}$$

Les valeurs de k_{AO} obtenues sont légèrement plus faibles que les valeurs de k correspondantes et diminuent avec l'augmentation de la concentration de l'AO. Ceci est attribuable au fait que l'AO est chargé positivement et sa fixation sur le poly(C) neutralise les charges négatives du poly(C). L'interaction favorable entre le poly(C) négatif et le (dien)Pd(II) positif perd donc de l'importance lorsque la quantité d'AO fixé sur le poly(C) augmente ce qui conduit à une diminution de la vitesse de réaction. Cependant, une extrapolation linéaire à [AO] = 0 donne des valeurs de constante de vitesse très près de celles obtenues en absence d'AO. Ces valeurs sont données au tableau 2.

La constante de vitesse de la réaction entre (dien)Pd(II) et le poly(C) à pH 4,5 ne peut être déterminée à cause de la faible solubilité du produit à ce pH. Cependant, avec l'AO comme indicateur, la réaction a pu être étudiée. La constante de vitesse ainsi obtenue à pH 4,5 est environ 12 fois plus faible que pour la même réaction à pH 7 (900 M^{-1} s^{-1} à pH 4,5 vs. 11 000 M^{-1} s^{-1} à pH 7). Ceci est attribuable à deux facteurs principalement: (*i*) l'influence défavorable de la protonation sur les sites N3 et (*ii*) la structure secondaire particulière, à pH 4,5 (26), impliquant une double hélice due à la formation de ponts hydrogène

TABLEAU 2. Constantes de vitesse des réactions avec et sans indicateur

$[Cl^-]$ (M)	k^*_{AO} (M^{-1} s^{-1})	k (M^{-1} s^{-1})
0,001	$2,2(\pm0,4)\times10^4$	$2,3(\pm0,2)\times10^4$
0,010	$1,1(\pm0,1)\times10^4$	$1,0(\pm0,1)\times10^4$

*Les valeurs de k_{AO} sont extrapolées, comme décrit dans le texte.

entre les sites N3 protonés d'un brin et les sites non-protonés de l'autre.

Discussion

L'interaction du poly(C) avec l'acridine orange se décrit très bien en considérant uniquement la formation de complexes externes impliquant l'interaction électrostatique du colorant protoné avec les sites phosphate. La possibilité de contact étroit entre l'AO et les bases cytosine est à toute fin pratique à éliminer si on considère, d'une part, l'absence de la bande caractéristique de ce type d'interaction à $\lambda = 502$ nm dans le spectre d'absorbance et, d'autre part, l'absence d'exaltation de fluorescence à 530 nm caractéristique de l'intercalation. La désactivation de fluorescence observée a été, en général, reliée à la formation du complexe externe comme le sont l'hypochromicité et l'effet hypsochrome (blue shift) observés pour les mesures d'absorbance.

Ces phénomènes sont dus à la structure secondaire du poly(C), qui est à simple hélice et, en partie, au fait que les bases pyrimidiques, telle la cytosine, offrent un recouvrement moins favorable avec le colorant polyaromatique que les bases puriques.

L'influence de divers facteurs expérimentaux tels la force ionique, la présence d'ions Mg^{2+} et de complexes de Pd(II), indique que l'interaction est due, au moins en partie, à des forces de type électrostatique entre la chaîne chargée négativement et l'AO protoné chargé positivement.

Toutefois la valeur élevée des constantes d'équilibre, comparée à celles d'ions métalliques, montre qu'il y a un terme important dans l'énergie libre totale dû à l'interaction entre molécules de colorant voisines. Ceci produit un effet coopératif contribuant à renforcer l'interaction. Cette stabilisation supplémentaire est particulièrement importante dans le cas de l'AO qui possède une forte tendance à former des agrégats en solution. Ceci explique, par exemple, qu'il faut une concentration élevée d'ion Mg^{2+} ($\sim0,01$ M) pour déplacer significativement des sites phosphate l'AO qui est à une concentration de loin inférieure (10^{-5} M) même si, à cause de sa charge +2, le Mg^{2+} devrait avoir une interaction électrostatique plus forte que l'AO.

L'importance de l'interaction entre molécules de colorant sur la stabilité du complexe colorant–polynucléotide est aussi mise en évidence lors de l'étude du système PF–poly(C). La proflavine est un colorant qui a une constante d'équilibre de dimérisation beaucoup plus faible que l'AO. En conséquence, l'interaction de cycles voisins sur le poly(C) apporte peu de stabilité supplémentaire au complexe formé. Ceci explique qu'à une force ionique de 0,1 M, le complexe PF–poly(C) ne se forme pas tandis que dans le cas de l'AO il se forme facilement. Pour avoir un complexe PF–poly(C), il faut descendre à force ionique beaucoup plus faible (0,001 M) afin d'accroître la force de la liaison électrostatique et stabiliser ainsi le complexe.

La tendance à l'agrégation de l'AO se reflète aussi dans la valeur de g obtenue pour le système AO–poly(C). En effet, celle-ci indique qu'il y a environ deux molécules d'AO fixées par unité de nucléotide sur le poly(C). Cependant, pour le système AO–poly(A), à la même force ionique, une valeur de $g = 1,40$ a été obtenue. Ceci est dû au fait que la structure des polymères impliqués influence beaucoup la stoechiométrie des complexes formés.

Bradley et Wolf (8) ont déjà proposé que l'agrégation serait plus importante pour les polymères pouvant assumer des positions optimales, permettant une meilleure interaction entre les cycles de colorant voisins. La distance entre deux bases consécutives dans la direction de l'axe, à pH 7, est de 3.98 Å pour le poly(C) (27) et 3.5 Å pour le poly(A) (28). Ceci est une conséquence du fait que l'interaction d'empilement entre deux bases adénine est supérieure à celle entre deux cytosines à cause de la plus grande surface des bases puriques. Pour la même raison, le poly(C) est probablement aussi plus flexible que le poly(A) et peut, à cause de ces caractéristiques, accommoder un plus grand nombre de molécules d'AO le long de sa chaîne que le poly(A). En fait, les spectres visible sont aussi différents et la bande à 438 nm est absente dans le cas du poly(A) où seule la bande à $\lambda = 465$ nm apparaît. Ceci indique un mode de recouvrement différent, probablement moins important, dans le cas du poly(A).

Il est à noter que d'autres chercheurs ont obtenu une valeur de $g \approx 1$ pour le système AO–poly(A) en absence d'électrolyte ajouté, ce qui peut être expliqué par la répulsion trop importante de molécules voisines dans ces conditions. Nos résultats à force ionique élevée (0,1 M) ne peuvent pas être décrits en considérant une valeur de $g = 1$.

L'AO possède donc les propriétés recherchées au départ pour son utilisation comme indicateur. L'absorbance de ce colorant est assez élevée pour nous permettre de travailler à faible concentration ce qui est encore plus vrai lorsqu'on utilise la fluorescence. Il se lie au poly(C) avec un spectre d'absorbance et de fluorescence différents de ceux de l'AO libre en solution. En plus, le colorant protoné est inerte envers le palladium.

Lors de l'étude de la cinétique de la réaction entre le poly(C) et le complexe de Pd(II), par l'entremise de l'indicateur, on peut suivre les variations dans le spectre de l'AO en fonction du temps dues à sa libération. Cependant, l'étape lente du processus doit être la réaction du Pd(II) sur le poly(C) et non la dissociation du complexe AO–poly(C), ce qui a été démontré, étant donné que la valeur de la constante de vitesse extrapolée à [AO] = 0 (k_{AO}) est en accord avec celle obtenue sans indicateur. La formation et la dissociation du complexe AO–poly(C) sont trop rapides pour être observables par flux-stoppé et on peut prévoir que la fixation du (dien)Pd^{2+} sur le site N3 de la cytosine accélère encore la dissociation. Les polynucléotides à plusieurs brins, tels l'ADN, permettent l'intercalation de plusieurs colorants. Dans le cas du bromure d'éthidium, un colorant souvent utilisé, la formation du complexe intercalé est inhibée par les complexes du Pt(II) (29), ce qui est attribué à l'interaction de ceux-ci avec les sites azotés. Ce colorant peut également servir à l'étude de compétition avec des ions métalliques (30). Cependant, l'intercalation produit une perturbation des sites basiques de la double-hélice. Pour cette raison l'AO, formant un complexe externe, le seul observé dans le cas du poly(C) à simple brin, est un indicateur plus avantageux pour l'étude de la fixation d'ions métalliques sur les polynucléotides.

La précision de cette méthode faisant appel à l'AO (~10−20%) est suffisante pour étudier des variations importantes de réactivité tel qu'illustré par le changement dû à la protonation des sites N3 à pH 4.5. La méthode peut avoir des applications intéressantes dans la caractérisation cinétique de réactions impliquant des molécules peu solubles ou de celles se déroulant sans variation de propriété physique facilement mesurable.

Remerciements

The sulfohaloform reaction revisited and revised

JAMES CLAYTON BAUM, WILLIAM RAYNE HARDSTAFF, RICHARD FRANCIS LANGLER,[1] AND ANTHONY MAKKINJE
Department of Chemistry, Florida Institute of Technology, Melbourne, FL 32901, U.S.A.

Received November 20, 1983

JAMES CLAYTON BAUM, WILLIAM RAYNE HARDSTAFF, RICHARD FRANCIS LANGLER, and ANTHONY MAKKINJE. Can. J. Chem. **62**, 1687 (1984).

A study of the aqueous chlorinolyses of a series of benzylic dithioacetals along with related α-chlorobenzylic sulfides is reported. These results require a modification of our previously proposed sulfohaloform reaction, so that thionium ion intermediates which have at least one alkyl group on sp^2 carbon follow a different pathway.

JAMES CLAYTON BAUM, WILLIAM RAYNE HARDSTAFF, RICHARD FRANCIS LANGLER et ANTHONY MAKKINJE. Can. J. Chem. **62**, 1687 (1984).

On rapporte une étude sur la chloronolyse, en milieu aqueux, d'une série de dithioacétals benzyliques et des sulfures α-chlorobenzyliques apparentés. Pour expliquer ces résultats, il faut modifier le mécanisme de réaction sulfohaloformique que nous avons proposé antérieurement de façon à ce que les ions thionium intermédiaires qui portent au moins un groupe alkyle sur le carbone sp^2 suivent une voie différente.

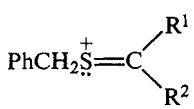
Introduction

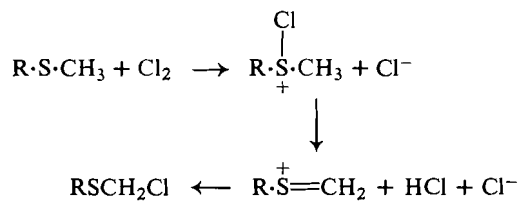
Some time ago, we published an examination of the pathway followed by dialkyl sulfides upon chlorinolysis in aqueous acetic acid (1). The study involved a detailed examination of sulfides and led to a proposed general pathway which we called the sulfohaloform reaction. We have subsequently carried out studies on the regiochemistry of the first step in aprotic media (2, 3) as well as an examination of steric effects in the cleavage step (4) in aqueous acetic acid.

The first step in the sulfohaloform pathway is believed to proceed as shown in Scheme 1. The proposed intermediacy of α-chloro-chlorosulfonium cations (derived from α-chloro-sulfides) in the sulfohaloform reaction rested on the following evidence: the chlorinolysis of the corresponding chlorine-free sulfoxides furnished different products from those obtained by chlorinolysis of the chlorine-free sulfides, thus ruling out sulfoxides as the first formed intermediates. The disturbing feature of the original proposal is the apparent inability of the thionium ion[2] intermediates, formed in the second step, to undergo hydrolysis.

We have subsequently developed benzylic sulfides as precursors for sulfonyl chlorides (8). While we did not establish whether aqueous chlorinolysis of benzylic sulfides proceeds by S_N1 dissociation of the intermediate chlorosulfonium cations or by the intermediacy of the corresponding sulfoxides with unimolecular dissociation of the corresponding oxochlorosulfonium cations, we did demonstrate that these reactions proceed without Pummerer rearrangement (see Scheme 1). We decided to generate benzylic thioniums ions, **A**, in order to determine whether they have any tendency to hydrolyze during exhaustive



A

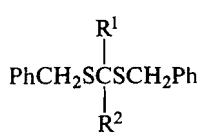


SCHEME 1

aqueous chlorinolyses. Such species, if hydrolyzed, would give rise to α-hydroxy sulfides which could dissociate to furnish phenylmethanethiol which would be transformed into phenylmethanesulfonyl chloride in aqueous acetic acid saturated with Cl_2. On the other hand, if they undergo exclusive nucleophilic attack by chloride ions, the intermediate α-chlorosulfide would be transformed into the corresponding α-chlorosulfonyl chloride and benzyl chloride (8).

Simple alkyl benzylic sulfides are ruled out as precursors since (*i*) they appear to undergo dissociation into sulfenyl chlorides and benzyl cations after chlorosulfonium cation formation (8), and (*ii*) any thionium ion intermediates would form by abstraction of a benzylic proton rather than abstraction of a proton from the alkylated α-carbon (2, 3).

To circumvent these problems we have decided to employ some dithioacetals, **B**, as precursors. Such substrates are



B

known to cleave pursuant to chlorosulfonium cation formation (9). The corresponding S-hydroxysulfonium sulfides are also known to dissociate in a parallel process (10). The expected mechanism for thionium ion formation is shown in Scheme 2.

Results and discussion

To begin our study of the simplest system, we have prepared and chlorinated benzyl chloromethyl sulfide, which gave results consistent with our previous report (8):

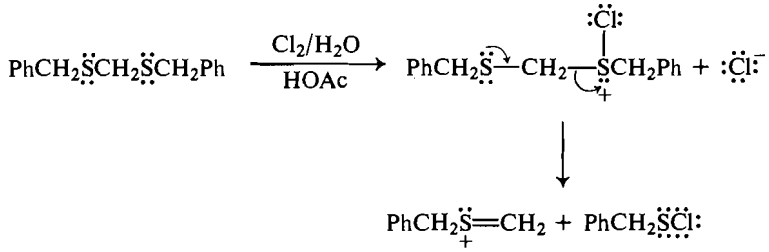
[1] Author to whom correspondence should be addressed.

[2] Durst *et al.* have called R·SO·CHR an oxosulfenium ion (5). We have called RSCHR a sulfenium ion (6) while Trost *et al.* call it a thionium ion (7). A referee of this paper has pointed out that the term sulfenium ion has also been applied to RS^+. To avoid confusion we shall refer to the first two species as oxothionium and thionium ions respectively.

TABLE 1. Chlorinolysis of 1 g $PhCH_2 \cdot S \cdot CHClCH_3$ (**6**)

Volume of Cl_2/H_2O* (mL)	Volume of Cl_2/HOAc† (mL)	Volume of HOAc (mL)	$(PhCH_2S)_2$ (%)	$(PhCH_2S)_2CHCH_3$ (%)	$PhCH_2SO_2Cl$ (%)	$PhCH_2Cl$ (%)	$PhCH_2OAc$ (%)
10	—	50	8.8	69.2	—	—	—
10	25	25	10.1	17.8	30.9	18.0	20.6
10	50	—	—	—	52.0	24.5	26.5

* H_2O was saturated with Cl_2 at ambient temperature.
† HOAc was saturated with Cl_2 at ambient temperature.



SCHEME 2

[1] $PhCH_2SH + CH_2O \xrightarrow{HCl} PhCH_2SCH_2Cl$ (**1**)

$\xrightarrow[HOAc]{Cl_2/H_2O} PhCH_2Cl$ (38%) + $ClCH_2SO_2Cl$ (54%) (**2**)

+ $PhCH_2SO_2Cl$ (9.4%) + $PhCH_2OAc$ (16%)

We have, subsequently, subjected bis(thiobenzyl)methane to exhaustive aqueous chlorinolysis which furnished the results shown in eq. [2]

[2] $(PhCH_2S)_2CH_2$ (**3**) $\xrightarrow[HOAc]{Cl_2/H_2O}$ $PhCH_2SO_2Cl$ (**4**) (38%)

+ $ClCH_2SO_2Cl$ (**2**) (53.6%) + $PhCH_2Cl$ (73.9%) + $PhCH_2OAc$ (9.8%)

The results shown in eq. [2] are in complete accord with our previous results on methyl sulfides as well as with our expectation that dithioacetals will dissociate to furnish thionium ions and sulfenyl chlorides following chlorosulfonium cation formation (*vide* Scheme 2). We note that these results (*i*) support our past proposal (1) that unsubstituted thionium ions react with chloride ions in preference to water molecules, (*ii*) offer further support to Wilson's proposal (11) that thionium ions are intermediates in the chlorinolyses of simple sulfides, and (*iii*) offer additional support to our contention (2) that thionium ions are unable to isomerize to the more stable regioisomeric thionium ions under normal conditions (2, 6).

We then chlorinated 1,1-bis(thiobenzyl)ethane **5** (eq. [3]) and α-chloroethyl benzyl sulfide **6** (eq. [4]).

[3] $(PhCH_2S)_2CHCH_3 + Cl_2/H_2O/HOAc \rightarrow 2\ PhCH_2SO_2Cl$
5 **4** (73%)

[4] $PhCH_2SCHClCH_3 + Cl_2/H_2O \xrightarrow{HOAc} PhCH_2SO_2Cl$
6 **4** (73.3%)

These results suggest the intermediacy of the thionium ion derived from **6** via unimolecular dissociation followed by hydrolysis *prior to* reaction with Cl_2. Since we were concerned that significant hydrolysis may have occurred before the introduction of Cl_2, and because we wished to learn more about the course of the conversion of **6** → **4**, we have undertaken a series of partial chlorinolyses of **6** in which chlorine was introduced *before* the sulfide. The results of this series of partial chlorinolyses are presented in Table 1, and show that α-alkyl-α-chlorosulfides dissociate to form chlorine-free thionium ions (in aqueous acetic acid) faster than they react with limited amounts of Cl_2 to furnish chlorosulfonium cations, clearly ruling out α-chloro-chlorosulfonium cations as principal intermediates in the chlorinolysis of dialkyl sulfides.

While it remains unclear whether α-chlorosulfides intervene in these reactions, it is clear that hydrolysis of the chlorine-free thionium ion is the principal pathway by which the reactions proceed.

To complete our study of these systems we have chlorinated the dithioketal **7** as depicted in eq. [5].

[5] $(PhCH_2S)_2C(CH_3)_2$ (**7**) $\xrightarrow[HOAc]{Cl_2/H_2O}$ 2 $PhCH_2SO_2Cl$ (**4**) (88%)

The change in behaviour of unalkylated thionium ions vs. alkylated thionium ions vis-à-vis hydrolysis could have been anticipated on the grounds that alkyl groups are more electron releasing than hydrogen atoms. In order to see whether selected thionium ions have gas phase stabilities which parallel their ease of formation in solution, or whether solvent effects must be invoked to rationalize the apparently greater facility of alkylated thionium ion formation, we have undertaken a modest MNDO study of the appropriate species **A**.[3]

[3] We intend the present MNDO study to supplement the one we have recently published (6).

TABLE 3. MNDO results on selected thionium ions

Thionium ion	ΔH_f (kcal/mol)	π Bond order CS	π Electron population S
$PhCH_2\overset{+}{S}=CH_2$	226.5	0.87	1.48
$PhCH_2\overset{+}{S}=CHCH_3$	211.7	0.82	1.53
$PhCH_2\overset{+}{S}=C(CH_3)_2$	202.2	0.78	1.57

MNDO calculations – method and results

Computations on a selected series of thionium ions and their corresponding sulfides were done using the MNDO (Modified Neglect of Differential Overlap) semi-empirical method described previously (6). Geometries were fully optimized except that the phenyl rings were constrained to be planar, with equal C—C bond lengths, C—H bond lengths, and 120° HCC and CCC bond angles.

The calculated heats of formation for the compounds studied are listed in Table 2. The ΔH_f's are consistent with our earlier results (6) except that the sulfide geometry is slightly more stable (0.2 kcal) with the Ph—C bond *trans*, instead of *cis*, to The $\overset{+}{S}$—CH_3 bond in benzyl methyl sulfide. This added stability for the phenyl-substituted sulfides increases with alkyl substitution. The important point is that the stability of the phenyl-substituted thionium ion increases with alkylation of the sp^2 carbon, as indicated by the decreasing ΔH_f's.

The CS π bond orders and π electron populations at S are tabulated for the thionium ions in Table 3. As the thionium ion stability increases, the π bond order decreases and the π electron population at S increases. These trends agree with our previous calculations (6) and indicate that the electron-releasing alkyl substituent is acting through the thionium ion π system to stabilize the system.

Mechanistic and pathway conclusions

The calculated ΔH_f values for the appropriate sulfides and the corresponding thionium ions (see Table 2) permit one to obtain $\Delta\Delta H_f$ values for the reaction shown in eq. [6] relative to the reaction in eq. [7].

[6] $ZYCHSCH_2PH \rightarrow ZYC = \overset{+}{S}CH_2Ph + \bar{H}$

[7] $CH_3SCH_3 \rightarrow CH_2 = \overset{+}{S}CH_3 + \bar{H}$

Calculated $\Delta\Delta H_f$ results, reflecting the impact on thionium ion energetics of progressively incoprorating methyl groups on sp^2 carbon, are presented in Table 2. These results indicate that solvent effects, while potentially important, do not need to be invoked to make calculated gas phase stabilities compatible with our solution phase results. The higher presumed inherent reactivity of **A** ($R^1 = R^2 = H$) over the other thionium ions, previously advanced to rationalize the preference for the unsubstituted thionium ion for chloride ions over water molecules, is compatible with our MNDO results. Scheme 3 presents our conclusions about the pathway followed by dialkyl sulfides upon exhaustive aqueous chlorinolysis.

The original version of the sulfohaloform reaction (1) was based on an extrapolation of detailed study of aqueous chlorinolyses of α-polychloromethyl sulfides and sulfoxides. The first intermediate for this reaction is shown in eq. [8] (X = Cl).

[8] $XCH_2SR \xrightarrow{Cl_2/H_2O} XCH_2\overset{\bar{O}}{\underset{|}{S}}R^+$

Since that time, similar behaviour has been observed for sulfides bearing an α-sulfonyl group (4) or two α-fluorine atoms (12). Parallel behaviour has also been suggested for sulfides bearing an α-carboxyl group (13). The intermediacy of the corresponding sulfoxide in the aqueous chlorinolysis of a sulfide is clearly the result of hydrolysis of the first formed chlorosulfonium cation (depicted in Scheme 1). The hydrolysis is evidently faster than the competing elimination reaction which would otherwise produce a thionium ion.

We conclude that aqueous chlorinolysis of sulfides is not as simple as originally proposed. The following facts have emerged: (*i*) highly electronegative substituents attached to an α-carbon in the sulfide substrate accelerate hydrolysis of the first formed chlorosulfonium chloride salt leading to formation of a sulfoxide, (*ii*) sulfides without strongly electronegative α-groups form thionium ions which react preferentially with the chloride counter ions leading to formation of an α-chlorosulfide, and (*iii*) the presence of inductive stabilizers (i.e., alkyl groups) on sp^2 carbon results in the intermediacy of thionium ions which hydrolyze. Scheme 4 presents this more complex array of pathways as The Revised Sulfohaloform Reaction.

Experimental

Aqueous chlorinolysis of 1

Crude benzyl chloromethyl sulfide (6.935 g) (14) was dissolved in glacial acetic acid (25 mL) and water (3 mL). Cl_2 (ca. 200 mL/min) was bubbled into the reaction mixture for 2 h. The reaction mixture was maintained between 20 and 30°C with an ice/water bath as necessary. Methylene chloride (100 mL) and water (50 mL) were added and the layers separated. The organic layer was washed with 2.5% w/v sodium hydroxide (two 50-mL aliquots). The organic layer was dried ($MgSO_4$) and concentrated, affording a crude mixture which contained phenylmethanesulfonyl chloride (0.728 g), chloromethanesulfonyl chloride (3.182 g), benzyl chloride (1.930 g), and benzyl acetate (0.970 g). The bulk of the phenylmethanesulfonyl chloride crystallized from the crude and was filtered off. It was shown to be identical to authentic material by ir, nmr, and tlc.

The filtered concentrated crude was chromatographed on silica gel (400 g) employing carbon tetrachloride elution (100-mL fractions). Fractions 12–18 were concentrated and combined, affording benzyl chloride which was identical to authentic material by nmr, ir, and tlc.

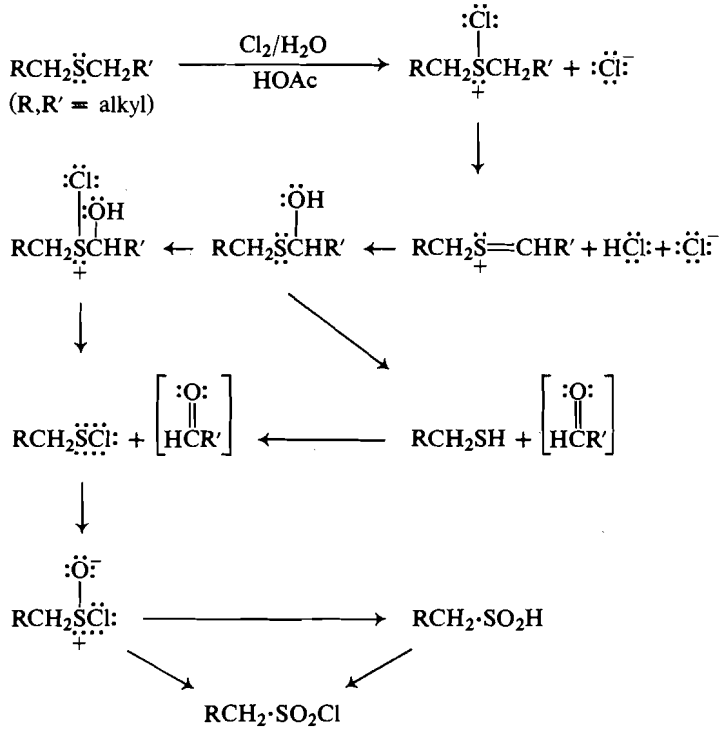

SCHEME 3

Fractions 37–40 were concentrated and combined, affording clean chloromethanesulfonyl chloride which was identical with authentic material by ir and nmr.

Aqueous chlorinolysis of ***3***

Bis(thiobenzyl)methane **3** (5.007 g) was suspended in glacial acetic acid (25 mL) and water (5 mL). The reaction mixture was chlorinated and worked up as described above. Phenylmethanesulfonyl chloride (1.394 g) crystallized from the crude and was shown to be identical with authentic material by mp, ir, and nmr.

The filtered concentrated crude mixture was rectified at reduced pressure, affording a mixture (bp 120–130°C/100 Torr) (1 Torr = 133.3 Pa) which contained chloromethanesulfonyl chloride (1.532 g), benzyl acetate (0.289 g), and benzyl chloride (1.729 g). The identity of the components was established by the addition of authentic compounds which, in each case, increased the intensity of the expected signals in the nmr spectrum of the mixture.

Aqueous chlorinolysis of ***5***

1,1-Bis(thiobenzyl)ethane **5** (5.002 g) was added to glacial acetic acid (25 mL) and water (5 mL). The reaction mixture was chlorinated and worked up as described above. The residue (5.050 g) was shown to be identical to authentic phenylmethanesulfonyl chloride by nmr, tlc, and mp.

Preparation of $PhCH_2SCH{=}CH_2$

Sodium metal (0.8025 g) was dissolved in refluxing 2-propanol (30 mL). A solution of $PhCH_2SCH_2CH_2Cl$ (6.038 g) (15) in 2-propanol (30 mL) was added and the reaction mixture refluxed for 1 h. Water (60 mL) was added and the resultant mixture washed with chloroform (four 60-mL portions). The combined organic layers were dried and concentrated. The residue was rectified at reduced pressure, affording clean benzyl vinyl sulfide (3.166 g, bp 52–56°C/0.4 Torr) which had ir ($CHCl_3$): 1585 cm^{-1}; nmr ($CDCl_3$) δ: 3.86 (2H, s), 5.20 (1H, d, J_{AX} ≃ 15 Hz), 5.26 (1H, d, J ≃ 11 Hz), 6.36 (1H, q, J_{AX} = 15 Hz, J_{BX} = 11 Hz); Cmr ($CDCl_3$) δ: 35.71, 111.01, 126.73, 128.10, 128.34, 131.66, 136.75; ms *m/e*: 150 (M^+, 28.6%) and 91 (100%).

Preparation of ***6***

Benzyl vinyl sulfide (5.006 g) was dissolved in carbon tetrachloride (50 mL). HCl (ca. 200 mL/min) was bubbled into the reaction mixture for 1 h. The solvent was evaporated and the residue rectified at reduced pressure, affording $PhCH_2SCHClCH_3$ (3.847 g, bp 92–93°C/0.9 Torr) which had nmr ($CDCl_3$) δ: 1.86 (3H, d), 3.90 (2H, s), 4.96 (1H, q), and 7.33 (5H, s); ms *m/e*: 188 (5.8%), 186 (M^+, 17.6%), 151 (25%), and 91 (100%).

Exhaustive aqueous chlorinolysis of ***6***

The chlorosulfide (5.0160 g) was added to glacial acetic acid (25 mL) and water (5 mL). The reaction mixture was chlorinated and worked up as described above. An nmr of the crude showed no observable α-chloroethanesulfonyl chloride present. The residue was crystallized from carbon tetrachloride, affording phenylmethanesulfonyl chloride (3.747 g) which was identical with authentic material by ir, nmr, mp, and mixture mp.

Controlled aqueous chlorinolysis of ***6***

A series of chlorinolyses of **6** were conducted. The results are presented in Table 1. Details below are provided for the second run.

Water (10 mL) was saturated with Cl_2 at ambient temperature. Glacial acetic acid (25 mL) was saturated with Cl_2 at room temperature. The chlorosulfide **6** (1.0084 g) was added to the Cl_2/H_2O, $HOAc/Cl_2$, and glacial acetic acid (25 mL) and the reaction mixture stirred at ambient temperature for 0.5 h. Water (50 mL) was added and the resultant mixture washed with chloroform (three 75-mL aliquots). The combined organic layers were washed with 2.5% w/v sodium hydroxide (four 50-mL aliquots). The organic layer was dried and concentrated, affording a residue which contained benzyl acetate (0.164 g), phenylmethanesulfonyl chloride (0.3116 g), benzyl chloride (0.1205 g), dibenzyl disulfide (0.066 g), and 1,1-bis(thiobenzyl)ethane (0.129 g).

The crude residue was chromatographed on silica gel (100 g) employing carbon tetrachloride elution (100-mL fractions). Fraction 4 contained benzyl chloride and dibenzyl disulfide. The presence of benzyl chloride was confirmed by the addition of authentic material and observing the change in intensity of the appropriate signals in the nmr spectrum of the mixture. Fraction 5 afforded clean dibenzyl disulfide which was identical to authentic material by ir, nmr, and tlc. Fractions 6–10 were combined and concentrated, affording

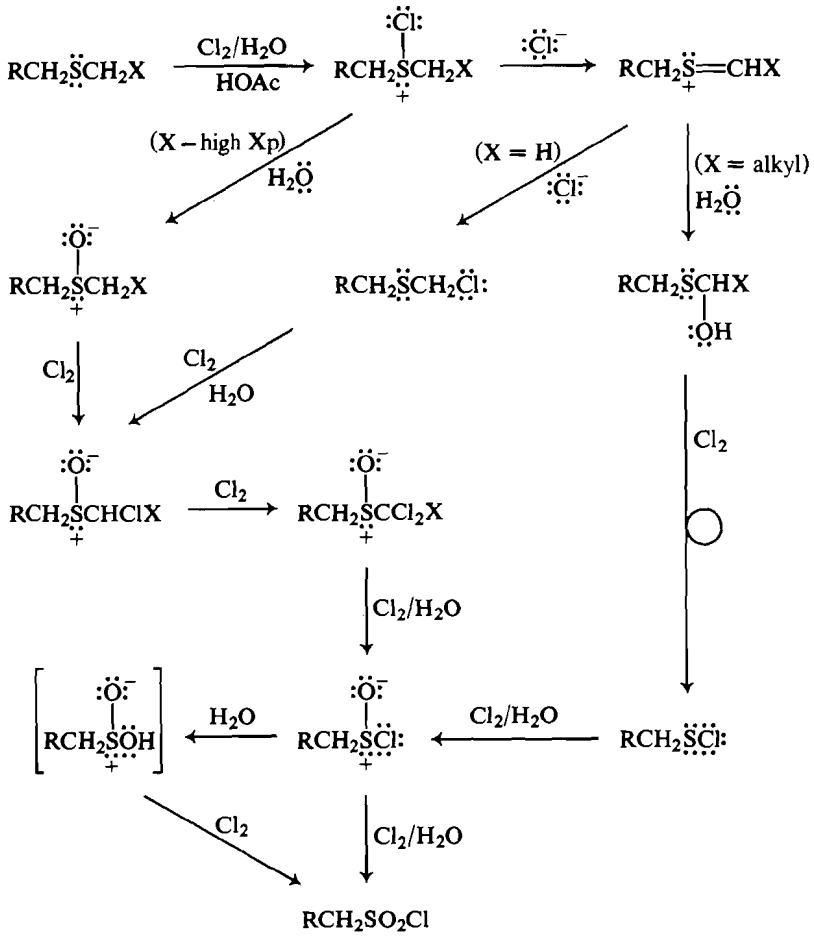

SCHEME 4. The revised sulfohaloform reaction

1,1-bis(thiobenzyl)ethane which was identical with authentic material by ir, nmr, and tlc. Fractions 13–18 were combined and concentrated, affording phenylmethanesulfonyl chloride which was identical to authentic material by ir, nmr, and tlc. Fraction 31 was combined with a final elution with diethyl ether (400 mL). Upon concentration of this eluent, benzyl acetate was obtained which was identical with authentic material by ir, nmr, and tlc.

Aqueous chlorinolysis of 7

2,2-Bis(thiobenzyl)propane (1.0190 g) was added to glacial acetic acid (50 mL) and water (10 mL). The reaction mixture was chlorinated and worked up as described above, furnishing clean crystalline phenylmethanesulfonyl chloride (1.1948 g).

Acknowledgments

The authors are indebted to Dr. J. H. Kim who ran the mass spectra and Dr. D. L. Hooper who ran the ^{13}C nmr spectrum. We are grateful to Mount Allison University for financial support in the early stages of the work and to the Florida Institute of Technology for financial support in the latter stages of the work and for the use of F.I.T. computing facilities.

Diffusion in aqueous solutions of sulfuric acid

DEREK G. LEAIST

Department of Chemistry, University of Western Ontario, London, Ont., Canada N6A 5B7

Received January 16, 1984

DEREK G. LEAIST. Can. J. Chem. **62**, 1692 (1984).

Diffusion of sulfuric acid in aqueous solution has been measured by a conductimetric technique at 25°C over the concentration range from 0.00035 to 0.2 mol dm^{-3}. At the lower end of this range, dissociation of bisulfate to sulfate and hydrogen ions produces a sharp increase in the rate of diffusion of the sulfuric acid component. Expressions are developed to predict the concentration dependence of the diffusion coefficient in terms of the mobilities of the diffusing ions and the degree of bisulfate dissociation. The treatment includes electrophoretic corrections that are derived from Onsager–Fuoss theory for the unsymmetrical, multi-ion electrolyte. At low concentrations where theory applies the observed diffusion coefficients are lower than the predicted values.

DEREK G. LEAIST. Can. J. Chem. **62**, 1692 (1984).

Opérant à 25°C et à des concentrations allant de 0.00035 à 0.2 mol dm^{-3} et faisant appel à une technique conductométrique, on a mesuré la diffusion de l'acide sulfurique en solution aqueuse. Aux concentrations les plus basses, la dissociation du bisulfate en ions sulfate et hydrogène provoque une importante augmentation de la vitesse de diffusion de l'acide sulfurique. On a mis au point des expressions qui permettent de prévoir l'effet de la concentration sur le coefficient de diffusion en fonction des mobilités des ions qui diffusent et du degré de dissociation du bisulfate. Le traitement comporte des corrections électrophorétiques que l'on a déduit de la théorie de Onsager–Fuoss relative aux électrolytes multi-ioniques non symétriques. Aux faibles concentrations où la théorie s'applique, les coefficients de diffusion observés sont plus faibles que les valeurs prévues.

Introduction

Industrial applications have prompted extensive inquiry into the physicochemical properties of aqueous solutions of sulfuric acid. Below 0.1 mol dm^{-3}, the properties of this system are complicated by the dissociation of bisulfate to sulfate and hydrogen ions. The purpose of this research is to establish the diffusional behavior of sulfuric acid at low concentrations where bisulfate dissociation is appreciable.

Previous studies (1–5) have shown that dissociation affects diffusion in two important ways. First, by increasing the number of dissolved particles per mol of solute, dissociation will increase the free energy gradient that drives the diffusion process. On the other hand, because a single species can move through the solution with less frictional resistance than two separate daughter species, dissociation will tend to reduce the overall mobility of the solute component. In the case of aqueous sulfuric acid, accurate activity data (6) are available for the evaluation of the first effect. In order that the second effect can be analyzed, we develop expressions for the mobility of the acid in terms of the degree of dissociation and the mobility of the diffusing ions.

At low concentrations, ionic mobilities can be estimated from limiting ionic conductivities with appropriate corrections for the well-known electrophoretic effect. Although convenient expressions can be developed to calculate these corrections for binary diffusion in solutions of strong electrolytes (7*a*, 8), the treatment of the electrophoretic effect in the case of a complex electrolyte such as sulfuric acid is significantly more difficult. For example, when three or more ionic species are present, we can no longer make the simplifying assumption that the diffusion velocities of the ions are identical. In this investigation we extend electrophoretic calculations to binary diffusion of an incompletely-dissociated, multi-ion electrolyte.

No diffusion measurements appear to have been made for aqueous sulfuric acid below 0.1 mol dm^{-3}. We report diffusion coefficients that were determined in this region by a conductimetric technique, and compare the results with values predicted by the equations which were developed.

Experimental

Savino and Vitagliano (10) have used Gouy interferometry to measure accurate diffusivities for aqueous sulfuric acid at concentrations from 0.1 to 4.8 mol dm^{-3}. Unfortunately, optical techniques are less reliable at lower concentrations. There, changes in the refractive index become too small to be measured with the required precision. Furthermore, the strong concentration dependence of the diffusion coefficient presents serious difficulties in the analysis of the interference patterns.

Procedure

The diffusion coefficients reported here were measured at 25°C by a conductimetric technique similar to the one developed by Harned and co-workers, especially for the study of dilute salt solutions (9,11). A syringe fitted with a long needle was used to introduce a small volume of sulfuric acid solution (0.1 to 0.5 mol dm^{-3}) into the bottom of a cylindrical chamber (1.270 cm diameter, 4.572 (±0.002) cm height) filled with conductivity water. As the acid diffused upward, its rate of diffusion was monitored by the change in the electrical conductance of the solution measured with pairs of small electrodes positioned at levels one-sixth of the distance from the top and bottom of the chamber. Conductance readings were taken for three consecutive days beginning one-and-a-half days after the introduction of electrolyte. By this time the concentration gradient along the column was very small. This helped to ensure that the measured diffusion coefficient corresponded to the differential value at the final cell concentration (9).

The diffusion cells used in this work were bored from a polypropylene rod. Platinum electrodes (1 mm diameter, cell constant ~10 cm^{-1}) were cemented with epoxy into holes drilled at the appropriate levels. The top of each chamber was sealed with a glass slide lubricated with a mixture of equal parts of Vaseline and Apiezon M grease. Further details of the equipment and procedure have been described (12).

Materials

Reagent grade sulfuric acid was used without further purification. Stock solutions of acid were made up from deionized, doubly-distilled water (conductivity 0.8×10^{-6} ohm^{-1} cm^{-1}). Concentrations of acid were determined by titration against standardized base.

Analysis of experimental data

Integration of the diffusion equation for restricted diffusion in a column of height a gives the Fourier expression (9)

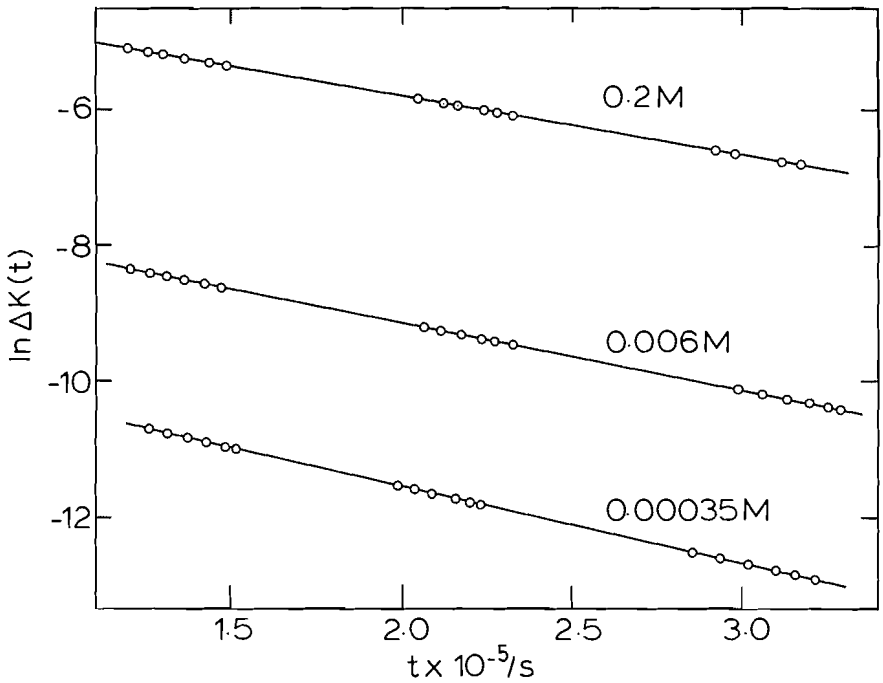

FIG. 1. Logarithm of the difference in conductance (in ohm^{-1}) plotted against the time for 0.2, 0.006, and 0.00035 mol dm^{-3} sulfuric acid.

$$[1] \quad \Delta c(t) = \sum_{n=1}^{\infty} A_n \sin(n\pi/2) \sin(n\pi/3) \exp(-n^2\pi^2 Dt/a^2)$$

for the difference in concentration between levels $a/6$ and $5a/6$ above the base of the column. D is the diffusion coefficient, t is the elapsed time since the introduction of electrolyte, and A_n are constants. The expression for $\Delta c(t)$ converges very rapidly; for $t \gtrsim a^2/20D$, only the first term in the series is significant.

$$[2] \quad \Delta c(t) = (\sqrt{3}A_1/2) \exp(-\pi^2 Dt/a^2)$$

In the present experiments, we followed $\Delta c(t)$ by measurement of the conductance difference defined by (9, 11, 12)

$$[3] \quad \Delta K(t) = (k_B/k_T)K_B(t) - K_T(t)$$

where $K_B(t)$ and $K_T(t)$ denote conductances measured at the bottom (B) and top (T) electrode positions, and k_B/k_T is the ratio of cell constants for the bottom and top pairs of electrodes. (This ratio is required to correct for imperfections in cell construction that lead to small discrepancies in electrode dimensions.) If diffusion is allowed to proceed until the concentration gradient in the cell is small, $\Delta K(t)$ will be proportional to $\Delta c(t)$. With this simplification, computation of D from conductance data is straightforward:

$$[4] \quad D = -\frac{a^2}{\pi^2} \frac{\mathrm{d} \ln \Delta K(t)}{\mathrm{d}t}$$

Calculations based on published conductivities for aqueous sulfuric acid (13) indicated that $\Delta K(t)$ is effectively proportional to $\Delta c(t)$ provided $t > 120\,000$ s. Conductance readings were taken at times long enough to satisfy this criterion; D values then were computed by least-squares analysis of the slope of $\ln \Delta K(t)$ plotted against t.

Results

Representative plots of $\ln \Delta K(t)$ against t are shown in Fig. 1. Over each three-day period during which conductivity readings were taken, the slope, and hence D, are constant within experimental error (±0.5%). This confirmed that $\Delta K(t)$ was proportional to $\Delta c(t)$, and also that the measured diffusion coefficients were in fact differential values.

The results of the diffusion measurements are recorded in column 4 of Table 1. At low concentrations the diffusion coefficient increases sharply as the bisulfate is converted to the more rapidly moving sulfate and hydrogen ions. Above 0.1 mol dm^{-3}, the present conductimetric data overlap the optical data of Savino and Vitagliano (10). Agreement between the two sets of data is very good, well within their combined uncertainties.

There was no evidence for adsorption of ions onto the walls of the diffusion cells. Indeed, the polypropylene cells worked well at concentrations as low as 0.00035 mol dm^{-3}, an order of magnitude lower than concentrations achieved in earlier studies of acid diffusion in which glass cells (14, 15) were used. Below this limit, however, it appeared that the density gradient was too small to fully stabilize the column of solution against convection for the required five day duration of the experiment.

Discussion

Aqueous sulfuric acid diffuses as H^+, HSO_4^-, and SO_4^{2-}, in proportions that vary with concentration. Because the rate of equilibration of the bisulfate dissociation reaction

$$HSO_4^- \rightleftarrows H^+ + SO_4^{2-}$$

is virtually instantaneous compared to the duration of a diffusion run, we can assume that the equilibrium of the reaction holds at each point along the diffusion path. In addition, the ionic flows must satisfy the requirement that the electric current vanishes for pure diffusion. In view of these dual constraints imposed on the three ionic flows, only one diffusional flow can be independent. Therefore, we may use the binary equations

$$[5] \quad J = -D\nabla c$$

$$[6] \quad J = -L\nabla\mu$$

to describe the isothermal diffusion of aqueous sulfuric acid. J, c, and μ refer to the molar flux, concentration (in mol per unit volume), and chemical potential of the H_2SO_4 component.

The transport coefficients D and L are related by $D = L\partial\mu/\partial c$. If we adopt the expression (6)

[a] These data obtained by the Gouy method (10).

[7] $\mu = \mu^0 + RT \ln (4c^3 y_{\pm}^3)$

for μ, we obtain

[8] $$D = 3RT\left(\frac{L}{c}\right)\left(1 + c\frac{\mathrm{d} \ln y_{\pm}}{\mathrm{d}c}\right)$$

where $y_{\pm}$ is the stoichiometric mean ionic activity coefficient on the molar concentration scale.

The term $c\,\mathrm{d} \ln y_{\pm}/\mathrm{d}c$ can be evaluated by the differentiation of Pitzer's equation (6) for the activity coefficient of aqueous sulfuric acid.[1] The thermodynamic factor $1 + c\,\mathrm{d} \ln y_{\pm}/\mathrm{d}c$ calculated in this manner takes values listed in the third column of Table 1. In column 2 are recorded values for the degree of dissociation of the bisulfate ion

[9] $\alpha = c_{SO_4^{2-}}/(c_{HSO_4^-} + c_{SO_4^{2-}})$

calculated[1] from

[10] $$K_{a2} = \frac{(1+\alpha)\alpha c}{1-\alpha}\frac{y_{H^+} y_{SO_4^{2-}}}{y_{HSO_4^-}} = 0.0105 \text{ mol dm}^{-3}$$

Below about 0.01 mol dm^{-3}, we see that the thermodynamic factor increases markedly as more bisulfate undergoes dissociation. Indeed, thermodynamics accounts for most of the concentration dependence of the diffusion coefficient in this region. If the electrolyte was fully ionized, the thermodynamic factor would of course be much less sensitive to concentration. In the case of a strong electrolyte such as aqueous calcium chloride, for example, $1 + c\,\mathrm{d} \ln y_{\pm}/\mathrm{d}c$ takes values 0.900, 0.929, and 0.947 at 0.005, 0.002, and 0.001 mol dm^{-3} (17, 18), while the corresponding values for aqueous sulfuric acid are 0.767, 0.833, and 0.879.

Also listed in Table 1 (column 5) are the values for L/c, the molar mobility of aqueous H_2SO_4, that were derived from the diffusion data by use of eq. [8]. It is of interest to note that the mobility of the acid actually decreases with the degree of dissociation, even though the highly mobile hydrogen ions are generated. As mentioned earlier, the reduced mobility is interpreted on the grounds that diffusion of H^+ and SO_4^{2-} is subject to more frictional resistance than diffusion of a single HSO_4^- species. As we will see later, this behavior is nearly masked by an exceptionally large electrophoretic effect.

In order to analyze diffusion of sulfuric acid in greater detail, we will use the expression derived by Creeth and Stokes (19) for the diffusion coefficient of an incompletely-dissociated 2:1 or 1:2 electrolyte

[11] $$D = 3\frac{\alpha(1+\alpha)D_1D_2 + (1-\alpha^2)D_1D_3 + \alpha(1-\alpha)D_2D_3}{(1+\alpha)D_1 + 4\alpha D_2 + (1-\alpha)D_3} \times \left(1 + c\frac{\mathrm{d} \ln y_{\pm}}{\mathrm{d}c}\right)$$

The D_i in the preceding equation refer to the diffusivities of the ions, which we number as follows: $H^+ = 1$, $SO_4^{2-} = 2$, and $HSO_4^- = 3$. As a first approximation, we will ignore the electrophoretic effect. As well, let us assume that the ionic diffusivities are independent of concentration and are given by their limiting values. Accurate values for the latter quantities can be calculated from conductivity data by the use of the relationship

[12] $$D_i^0 = \frac{RT}{F^2}\frac{\lambda_i^0}{z_i^2}$$

where R is the gas constant, T is the absolute temperature, F is the Faraday, λ_i^0 are the limiting ionic molar conductivities, and z_i are the ionic valencies. From the literature values (7*b*, 20–23) $\lambda_1^0 = 0.034981$, $\lambda_2^0 = 0.01600_4$, and $\lambda_3^0 = 0.00512$ m^2 ohm^{-1} mol^{-1}, we calculate $D_1^0 = 9.315 \times 10^{-9}$, $D_2^0 = 1.065 \times 10^{-9}$, and $D_3^0 = 1.363 \times 10^{-9}$ m^2 s^{-1}. Upon substitution of the

[1] Published densities (16) were used to convert the reported (6) molal activity coefficients γ_i to the molar activity coefficients y_i by the use of the relationship $y_i = m_i\rho_0\gamma_i/c_i$. m is sulfuric acid molality and ρ_0 is the density of the pure solvent.

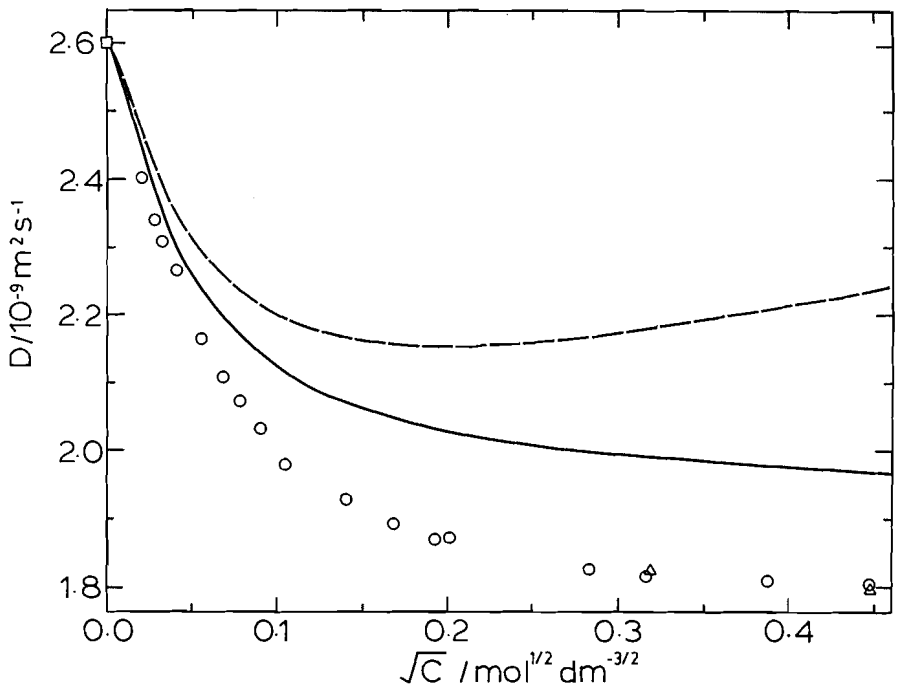

FIG. 2. Comparison of calculated diffusion coefficients with observed values for aqueous sulfuric acid at 25°C: dashed curve, eq. [11] without electrophoretic corrections; solid curve, eq. [11] with electrophoretic corrections; circles, present conductimetric data; triangles, optical data of Savino and Vitagliano (10).

limiting ionic diffusivities into eq. [11], the calculated D values shown by the dashed curve in Fig. 2 are obtained; the measured values are plotted as circles and triangles. At zero concentration, D is given by the limiting Nernst value for fully dissociated $2H^+ + SO_4^{2-}$

$$[13]\quad D^0 = \frac{3D_1^0 D_2^0}{D_1^0 + 2D_2^0} = 2.600 \times 10^{-9}\ \mathrm{m^2\ s^{-1}}$$

It is evident from Fig. 2 that the observed diffusion coefficients fall well below the dashed curve, even at the lowest concentrations accessible to the experiment. At low ionic strength, this discrepancy can be attributed to the neglect of the electrophoretic correction which appears to be large and negative for the system under discussion. At 0.01 mol dm^{-3}, for example, the observed diffusion coefficient is about 10% lower than the predicted value. Since one of the ions in the mixture (H^+) is considerably more mobile than the others, a negative electrophoretic effect is to be expected (see ref. 14 for the diffusion of aqueous hydrochloric acid). However, the size of the correction — an order of magnitude larger than corrections observed for other aqueous electrolytes (24) — is striking.

The theory developed by Onsager and Fuoss (25, 26) gives an accurate description of diffusion in binary solutions of strong 1:1 electrolytes at low ionic strength (7, 11, 14, 24). For higher-valency electrolytes, agreement between theory and experiment is only moderately good (7, 11). For the latter systems, however, the comparison is difficult to make, owing to the lack of accurate activity coefficients at low concentrations as well as uncertainties regarding the formation of ion-pairs.

Can the Onsager–Fuoss theory account for the diffusion behavior observed for dilute aqueous sulfuric acid? To answer this question we now turn to the problem of calculating electrophoretic corrections for binary diffusion in a solution of a complex, multi-ion electrolyte. Such electrolytes are invariably unsymmetrical. Therefore, following Robinson and Stokes (7*a*, 18), only the first-order corrections (proportional to $c^{1/2}$) will be included in the analysis since the higher-order terms imply an ionic distribution function that is inconsistent with the Poisson equation. Because of this limitation, good agreement is not to be expected. Nevertheless, the electrophoretic effect observed for aqueous sulfuric acid is large and unambiguous so that prediction of the effect for this system will constitute a clear test of theory.

In the limit of infinite dilution, the velocity v_i of a migrating ion is given by

$$[14]\quad v_i = \omega_i k_i$$

where ω_i is the limiting mobility

$$[15]\quad \omega_i = \lambda_i^0 / F z_i^2$$

and k_i is the force acting on the ion, which, in the case of pure diffusion, equals the negative gradient of the ion's electrochemical potential

$$[16]\quad k_i = -\nabla \tilde{\mu}_i$$

At non-zero concentrations, a force which would impart velocity v_i in the absence of ion–ion interactions actually produces a velocity $v_i + \Delta v_i$ where Δv_i is the electrophoretic contribution to the diffusion velocity. Provided Δv_i is small compared to v_i, the ionic diffusivities can be corrected for the effects of electrophoresis simply by multiplying each limiting ionic diffusivity by the factor $1 + (\Delta v_i / v_i)$. We obtain the expression

$$[17]\quad D_i = (1 + \delta_i) D_i^0$$

in which, for convenience, δ_i is an abbreviation for $\Delta v_i / v_i$ (7*a*).

According to the Onsager–Fuoss theory (24, 25), the δ_i values are given by

$$[18]\quad \delta_i = -\frac{\kappa}{6\pi\eta\omega_i} \sum_\sigma \frac{z_i u_\sigma}{z_\sigma} \left(\frac{k_\sigma}{k_i}\right)$$

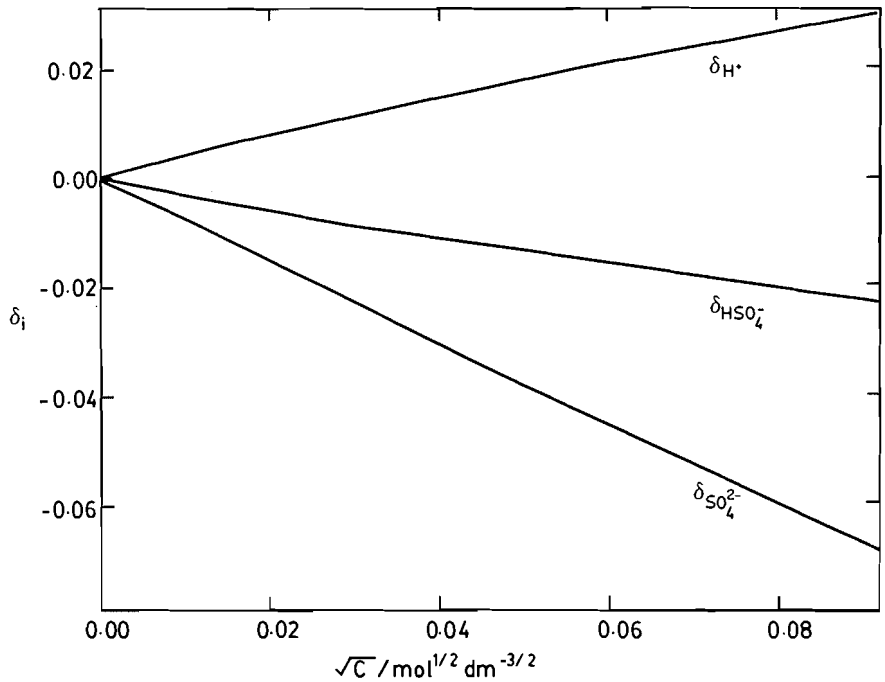

FIG. 3. Electrophoretic corrections plotted against the square root of the concentration.

where η is the viscosity of the pure solvent, u_σ stands for the fraction of the ionic strength contributed by ion σ

$$[19]\quad u_i = \tilde{c}_i z_i^2 / \sum_\sigma \tilde{c}_\sigma z_\sigma^2$$

and κ is the reciprocal Debye length given in the usual notation by

$$[20]\quad \kappa = \left[\frac{4\pi N e^2}{1000 \epsilon kT} \sum_\sigma \tilde{c}_\sigma z_\sigma^2\right]^{1/2}$$

In the preceding equations, $\tilde{c}_i$ refers to the concentration of ion i in mol per unit volume. The summations run over all ionic species present in solution.

For aqueous solutions of sulfuric acid, we have $\tilde{c}_1 = (1 + \alpha)c$, $\tilde{c}_2 = \alpha c$, and $\tilde{c}_3 = (1 - \alpha)c$ for H^+, SO_4^{2-}, and HSO_4^-, respectively. In order to compute the electrophoretic corrections, all that remains is to determine the force ratios k_σ/k_i that appear in eq. [18]. This is easily accomplished if we recall the constraints on the ionic flows, namely, local equilibrium of the dissociation reaction

$$[21]\quad \tilde{\mu}_3 = \tilde{\mu}_1 + \tilde{\mu}_2$$

and the electroneutrality requirement

$$[22]\quad \tilde{c}_1 \nu_1 = 2\tilde{c}_2 \nu_2 + \tilde{c}_3 \nu_3$$

From eqs. [21] and [22] we find

$$[23]\quad k_3 = k_1 + k_2$$

$$[24]\quad \tilde{c}_1 \omega_1 k_1 = 2\tilde{c}_2 \omega_2 k_2 + \tilde{c}_3 \omega_3 k_3$$

and hence

$$[25]\quad \frac{k_1}{k_2} = \frac{2\tilde{c}_2 \omega_2 - \tilde{c}_3 \omega_3}{\tilde{c}_1 \omega_1 - \tilde{c}_3 \omega_3}$$

$$[26]\quad \frac{k_2}{k_3} = \frac{\tilde{c}_1 \omega_1 - \tilde{c}_3 \omega_3}{\tilde{c}_1 \omega_1 + 2\tilde{c}_2 \omega_2}$$

$$[27]\quad \frac{k_3}{k_1} = \frac{2\tilde{c}_2 \omega_2 + \tilde{c}_1 \omega_1}{2\tilde{c}_2 \omega_2 - \tilde{c}_3 \omega_3}$$

The electrophoretic corrections δ_i are obtained by substitution of eqs. [25]–[27] into eq. [18]. In Fig. 3, δ_i values calculated in this manner for dilute sulfuric acid are plotted against the square root of the concentration. (The calculations are based on the values $\eta = 8.90 \times 10^{-4}$ kg m^{-1} s^{-1} for the viscosity and $\epsilon = 78.3$ for the dielectric constant of water at 25°C (7*c*).) When the corrected ionic diffusivities are substituted into eq. [11], we obtain the calculated values for the diffusion coefficient of sulfuric acid shown by the continuous curve in Fig. 2. As anticipated, inclusion of the electrophoretic corrections lowers the predicted diffusion coefficient. Although this brings the predictions into closer agreement with the experimental results, especially at the lower concentrations investigated, the observed electrophoretic effect is twice as large as the effect predicted by theory. This is true even at the very low concentrations ($\lesssim$0.005 mol dm^{-3}) where the theory is expected to apply (27, 28) and where complications arising from viscosity changes of the solutions are negligible. Without obvious reasons to dismiss the experimental results, we conclude that theory in its present form can provide only a qualitative description of diffusion in dilute solutions of sulfuric acid.

Values of the thermodynamic factor $1 + c\,\mathrm{d}\ln y_\pm/\mathrm{d}c$ and the limiting ionic conductances used to predict D are well established. On the other hand, values of α, the degree of dissociation of HSO_4^-, are not accurately known. Since the values of α used here were calculated from eq. [10], they depend on the values used for both the activity coefficient ratio $y_{H^+} y_{SO_4^{2-}}/y_{HSO_4^-}$ and K_{a2}. Because estimates of the activity coefficient of a divalent ion in a mixture are required, evaluation of the former is difficult. For K_{a2}, we used the value 0.0105 mol dm^{-3} recommended by Pitzer, Roy, and Silvester (6) in their comprehensive correlation of extensive emf and osmotic data. In another study, however, Covington, Dobson, and Wynne-

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.5 on 09/06/12
For personal use only.

Jones (29) determined $K_{a2} = 0.0106$. From conductance studies, Kerker (30) obtained $K_2 = 0.0102$, while Dunsmore and Nancollas (31) obtained $K_2 = 0.0105$. Young, Maranville, and Smith (32) determined the slightly higher value $K_{a2} = 0.0120$ from analysis of Raman spectra.

Uncertainties in the values of K_{a2} and $y_{H^+}y_{SO_4^{2-}}/y_{HSO_4^-}$ will lead to errors in the values we have used for α. If we have underestimated α, the calculated values of the mobility, then D will be too high. This might contribute to the poor agreement between theory and experiment shown in Fig. 2.

In order to examine this possibility in greater detail, consider the data point obtained at 0.001 mol dm^{-3} H_2SO_4. From Fig. 2, we see that the predicted value of D is about 2% higher than the observed value. If we repeat the calculation of D with a value of K_{a2} that is 10% larger than 0.0105 (or a value of $y_{H^+}y_{SO_4^{2-}}/y_{HSO_4^-}$ 10% smaller than the value recommended by Pitzer and Silvester), the value calculated for D will be only 0.4% lower than shown in Fig. 2. At 0.003 mol dm^{-3} where the observed D value is 3.5% below the predicted value, a 10% increase in K_a (or a 10% decrease in $y_{H^+}y_{SO_4^{2-}}/y_{HSO_4^-}$) will produce a 0.6% decrease in the predicted D value. Therefore, the discrepancy between theory and experiment is much too large to be explained by errors made in the values used for α.

Finally, it may be mentioned that Onsager and Fuoss (25) and Harned (24) have proposed that the second-order terms (proportional to $c \ln c$) be included in the calculation of electrophoretic corrections for unsymmetrical electrolytes, even though this procedure is known to be inconsistent (7*a*, 18). When we calculated the second-order correction for aqueous sulfuric acid, we found that it was large and *positive*. In fact, it practically cancelled out the first-order correction. Since inclusion of the second-order terms makes the discrepancy between theory and experiment significantly larger, the present investigation provides evidence that only first-order terms should be included in the treatment of the electrophoretic effect for unsymmetrical electrolytes.

Received October 31, 1983

AKHTAR OSMAN, RICHARD G. STEEVENSZ, DENNIS G. TUCK, HARRY A. MEINEMA, and JAN G. NOLTES. Can. J. Chem. **62**, 1698 (1984).

The compounds L_2M (M = Zn, Cd; L = 2-[(dimethylamino)methyl]phenyl ligand) are obtained by reacting MCl_2 with LiL. The organometallic halides have been prepared, either by a similar route (LZnCl), or by the direct electrochemical oxidation of cadmium metal in the presence of 1-bromo-2-[(dimethylamino)methyl]benzene (LCdBr). The latter can be converted to LCdMe or LCdPh. Proton nmr spectroscopy shows that both L_2Zn and L_2Cd undergo rapid intramolecular bond fission and formation at the M + NMe_2 site. For L_2Cd, studies of the Cd—C—C—H coupling show that the Cd—C_6H_5 bond undergoes rapid homo-exchange at room temperature.

AKHTAR OSMAN, RICHARD G. STEEVENSZ, DENNIS G. TUCK, HARRY A. MEINEMA et JAN G. NOLTES. Can. J. Chem. **62**, 1698 (1984).

On obtient les composés L_2M (M = Zn, Cd; L = ligand [(diméthylamino) méthyl]-2 phényl) en faisant réagir MCl_2 avec LiL. On a préparé les halogénures organométalliques soit par une route semblable (LZnCl) soit par l'oxydation électrochimique directe du cadmium métallique en présence de bromo-1 [(diméthylamino) méthyl]-2 benzène (LCdBr). On peut transformer ce dernier soit en LCdMe ou en LCdPh. La rmn du ^1H démontre que le L_2Zn ainsi que le L_2Cd subissent chacun des fissions et des formations de liaisons intramoléculaires rapides au niveau du site M+ NMe_2. Dans le cas du L_2Cd, les études du couplage Cd—C—C—H démontrent que la liaison Cd—C_6H_5 subit un échange homolytique rapide à la température ambiante.

[Traduit par le journal]

Introduction

Metal complexes of the potentially bidentate 2-[(dimethylamino)methyl]phenyl ligand (= L) have been the subject of a number of recent publications. Many of these compounds are derivatives of metals formally in a d^{10} configuration, such as tin(IV) (1), germanium(IV) (2), indium(III) (3, 4), thallium(III) (5), mercury(II) (6), and copper(I) (7). Particular attention has been paid to the coordination environment of the metal, both in the solid state (e.g., Sn (8), In (3), Cu (9)) and in solution (e.g. In (4), Hg (6), Cu (10)). We now report studies of ML_2 (M = Zn, Cd) and some related species.

Experimental

General

All reactions were carried out in an atmosphere of dry nitrogen. Solvents were purified and dried over sodium. Powdered zinc or cadmium chloride was dried at 150−160°C for 3−4 h. All other reagents were used as supplied.

Proton nmr spectra were recorded on JEOLCO C-60 HL or Varian EM-360 spectrometers at ambient temperature (30°C) unless otherwise stated. Infrared spectra were recorded on a Beckman IR-12 instrument using KBr cells. Mass spectra were obtained on a Varian MAT CH5 DF instrument, interfaced to an INCOS 2000 data system, and operating in either electron impact or field ionisation modes.

Metal analysis was by atomic absorption spectrophotometry.

Preparation of o-*lithio*-N,N′-*dimethylbenzylamine (LiL)*

A 5 mL portion (11 mmol) of *n*-butyllithium in hexane (2.24 mol L^{-1}) was added in one operation to 1.35 g (10 mmol) of *N*,*N*′-dimethylbenzylamine dissolved in diethyl ether (60 mL), all at room temperature. The reaction mixture was stirred for at least 18 h at room temperature before using the resultant yellow suspension of LiL in further preparative work.

Preparation of bis{2-[(dimethylamino)methyl]phenyl}zinc (L_2Zn)

Powdered anhydrous zinc chloride (0.68 g, 5.0 mmol) was slowly added over 2 h to a freshly prepared suspension of LiL (10 mmol) in 80 mL diethylether. The mixture was stirred for a further 4 h, insoluble material (LiCl) removed by filtration, and the solution phase concentrated. The addition of benzene to this concentrate removed any remaining traces of LiCl, after which the solution was again concentrated; petroleum ether (30−60°C) was then added with cooling to precipitate colourless crystals of $Zn[C_6H_4CH_2N(CH_3)_2\text{-}2]_2$. *Anal.* calcd.: Zn 19.6; found: Zn 19.2. ^1H nmr ($CDCl_3$/TMS) δ = 7.4−6.9 ppm, m (2.1H), C_6H_4; δ = 4.10 ppm, s (1.0H), NCH_2; δ = 2.62 ppm, s (3.1H), $N(CH_3)_2$.

Preparation of bis{2-[(dimethylamino)methyl]phenyl} cadmium (L_2Cd)

Anhydrous $CdCl_2$ (0.9 g, 0.50 mmol) was slowly (ca. 1.5 h) added to a freshly prepared suspension of 2-[(dimethylamino)methyl]phenyl lithium (10 mmol) in 60 mL of ether at room temperature. The mixture was then stirred for a further 3 h, by which time the reaction mixture contained a light grey suspension. The insoluble material was filtered off and the organic solution concentrated to a yellow oil. This oil was dissolved in 10 mL benzene and the murky solution filtered and again concentrated to a thick yellow liquid. The resulting oil was treated dropwise with 5−10 mL petroleum ether (30−60°C) and immediately cooled by rapid evaporation of a small portion of solvent *in vacuo*, which afforded white crystals of $Cd[C_6H_4CH_2N(CH_3)_2\text{-}2]_2$ which were collected, washed with cold petroleum ether (30−60°C), and dried *in vacuo*. Yield 0.3 g (16.0%). *Anal.* calcd.: Cd 29.5; found: Cd 29.0. ^1H nmr (C_6D_6/TMS) δ = 7.6−7.0 ppm, m (2.1H), C_6H_4; δ = 3.20 ppm, s (1.0H), NCH_2; δ = 1.93 ppm, s (3.0H), $N(CH_3)_2$.

Preparation of 2-[(dimethylamino)methyl]phenylzinc chloride (LZnCl)

Anhydrous $ZnCl_2$ (1.36 g, 10 mmol) was slowly added over 3 h to a suspension of 2-[(dimethylamino)methyl]phenyl lithium (10 mmol) in 100 mL diethylether. An exothermic reaction took place, requiring the reaction vessel to be cooled in an ice bath. The reaction mixture was stirred for 3−4 h, and then worked up using the procedures outlined above for ZnL_2. The yield of $ClZn[C_6H_4CH_2N(CH_3)_2\text{-}2]$ was 0.6 g (28%). *Anal.* calcd.: Zn 27.8, Cl 15.1; found: Zn 28.3, Cl 14.4.

^{1}H nmr ($CDCl_3$/TMS) δ = 7.6–6.9, m (1.9H), C_6H_4; δ = 3.98, s (1.0H), CH_2; δ = 2.50, s (3.0H), $N(CH_3)_2$.

Preparation of 1-bromo-2-[(dimethylamino)methyl]benzene (LBr)

1, α-dibromotoluene (CARE!) (48 g, 0.19 mol) was slowly added to a preheated (50°C) aqueous solution of dimethylamine (32 g, 0.71 mol, in 55 mL). The temperature was then held at 70°C for 2 h, after which a second 0.71 mol portion of 40% aqueous dimethylamine was added and the mixture heated for a further 3.5 h. The green–yellow organic layer was separated and the aqueous layer washed several times with benzene. The combined organic phase and benzene extracts were dried over anhydrous sodium sulphate, concentrated, and distilled, to yield $BrC_6H_4CH_2N(CH_3)_2$ as a colourless liquid (bp 60°C at 0.1 mm) (11). Yield 34.0 g (78%). ^{1}H nmr ($CDCl_3$/TMS) δ = 7.6–6.8, m (2.2H), C_6H_4; δ = 2.20 (3.0H), $N(CH_3)_2$.

Electrochemical preparation of 2-[(dimethylamino)methyl]-phenylcadmium bromide (LCdBr)

The electrochemical synthesis was carried out in the two-arm cell described in earlier papers (12, 13). The solution (see below) was placed in one arm, where it was repeatedly frozen, evacuated, and melted in order to remove all traces of oxygen. The degassed solution was then decanted *in vacuo* into the other arm, in which a piece of cadmium metal was suspended on a thin platinum wire entering the vessel through a Teflon plug situated in a standard taper neck. The cadmium then formed the anode of an electrochemical, non-aqueous cell; the cathode was a tungsten wire fused into the wall of the tube.

A solution of 1-bromo-2-[(dimethylamino)methyl]benzene (typically 1 g) in acetonitrile/benzene (ca. 8 mL; 2/1 v/v mixture) containing approximately 10 mg tetraethylammonium perchlorate was degassed in the manner described, and transferred to the electrochemical cells. The cadmium (ca. 5 g) was electrochemically oxidised for 5–6 h, during which time the white solid produced at the anode deposited in the bottom of the cell. The cell was opened, the solid collected by filtration under nitrogen, and the product washed with benzene and diethyl ether. In two separate experiments, 98 mg and 75 mg of cadmium were lost from the anode, and 186 mg and 154 mg of product obtained, representing yields of 65–70%. The product was $BrCd[C_6H_4CH_2N(CH_3)_2$-2], which is only slightly soluble in acetonitrile, chloroform, benzene, or acetone, and soluble in warm pyridine. *Anal.* calcd.: Cd 34.4, Br 24.5; found: Cd 34.7, Br 24.5.

Preparation of {2-[(dimethylamino)methyl]phenyl}methylcadmium (LCdMe)

LCdBr (100 mg, 0.34 mmol) was refluxed with an equimolar quantity of MeLi in 5 mL of benzene/diethyl ether (1/1 v/v) under nitrogen for 3–4 h with mechanical stirring. The white product thus formed was collected by filtration, washed several times with diethyl ether to remove residual LiBr, and dried *in vacuo*. Yield of $CH_3Cd[C_6H_4CH_2N(CH_3)_2$-2] 76 mg (84%). *Anal.* calcd.: Cd 43.0; found: Cd 41.9. The compound is insoluble in acetone, acetonitrile, or cold benzene, but slightly soluble in hot benzene; the insolubility prevented us from recording nmr spectra.

Preparation of {2-[(dimethylamino)methyl]phenyl}phenylcadmium (LCdPh)

Procedures similar to those just described, using PhLi (0.35 mmol) and LCdBr (107 mg, 0.33 mmol) yielded 95 mg of $C_6H_5Cd[C_6H_4N(CH_3)_2$-2]. Yield 89%. *Anal.* calcd.: Cd, 34.7; found: Cd 34.9. The solubilities of this compound are similar to those of the methyl analogue.

Results and discussion

Preparative

The preparation of L_2Zn and L_2Cd via the lithio derivative of the parent amine represents a logical extension of earlier syntheses of this type, and calls for little further comment. Three experimental points observed in the cadmium work are worth noting. Firstly, L_2Cd was obtained in pure form only when solid $CdCl_2$ was added to the organolithium suspension; addition in the reverse order causes the reaction to proceed in a less selective manner, as indicated by the isolation of various unidentifiable products whose presence caused difficulty in the purification of L_2Cd. Secondly, the particular cadmium halide chosen is important. Cadmium chloride was preferred, since the complete removal of LiCl could be achieved by the addition of benzene and subsequent filtration; when $CdBr_2$ was used, L_2Cd was contaminated with trace amounts of LiBr. Thirdly, pieces of grey material, presumed to be cadmium metal, were observed in the solution during the course of the reaction; analysis showed that the insoluble byproducts (theoretically CdX_2) contained up to 37.0% cadmium. This last observation is in keeping with the observed instability of the L_2Cd compound, which decomposes in air, and to a lesser extent in non-aqueous solvents.

The synthesis of LZnCl was accomplished by the reaction of $ZnCl_2$ with 1 mol of LiL. For LCdBr, we found it convenient to carry out a direct electrochemical synthesis, using anodic cadmium, to achieve what is effectively the insertion of the metal into the C—Br bond of 1-bromo-2-[(dimethylamino)-methyl]benzene. This process parallels earlier work on the direct synthesis of other RCdX compounds by electrochemical methods (14–17). The organocadmium compound LCdBr is a useful starting material for further synthetic work, exemplified by the synthesis of $LCdCH_3$ and $LCdC_6H_5$ from the reaction of LCdBr with the appropriate alkyl or aryl–lithium compounds.

Finally we note briefly a reaction which has yet to be explored in detail, and which depends on the reactivity of the phenyl-ring proton *ortho* to the $CH_2N(CH_3)_2$ group in $C_6H_5CH_2N(CH_3)_2$. The reactivity at this site is, of course, demonstrated by the smooth lithiation to give LiL (see above). When a solution of C_2H_5CdI in acetonitrile, prepared by the electrochemical oxidation of cadmium into a solution of C_2H_5I (14, 15) was reacted with HL, gas was evolved in accordance with the equation

$$[1] \quad C_2H_5CdI + HL \rightarrow C_2H_6 + LCdI$$

(wt. of C_2H_5CdI), calculated from cadmium dissolved, 0.36 g 1.34 mmol; vol. of gas collected, corrected to STP, 30.5 mL, 1.36 mmol and a colourless solid precipitated. Analytical results immediately after isolation of this solid. (*Anal.* calcd. for LCdI: Cd 30.1; I 34.0; found: Cd 30.6, I 34.5) confirmed the stoichiometry of reaction [1] but results 24 h later showed that subsequent decomposition had occurred. Despite this, the initial reaction [1] above suggests that alkane elimination between an organometallic halide RMX and LH may be a useful route to LMX compounds.

Nuclear magnetic resonance spectroscopy

The ^{1}H nmr spectra reported in the Experimental section serve to characterise the compounds in question. Benzene was the solvent of choice, both because of suitable solubilities and because some of the LZn and LCd complexes were found to undergo decomposition in CCl_4 and $CDCl_3$. We observed significant solvent shifts of the proton resonances between C_6D_6 and $CDCl_3$; for example, with L_2Cd, NCH_2 is found at 3.50 ($CDCl_3$) or 3.25 (C_6D_6) ppm, and NCH_3 at 2.31 ($CDCl_3$) or 1.93 (C_6D_6) ppm. Other 2-dimethylaminophenyl metal complexes show similar effects in these solvents (e.g. L_2InCl (4), LMe_2SnBr (1), and the origin of these solvent shifts has been discussed elsewhere (18)).

Nuclear magnetic resonance spectroscopy is a useful tool for obtaining information about the nature of the intramolecular

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.105 on 09/06/12
For personal use only.

coordination in LM compounds (19). The L_2M complexes (L = Zn, Cd) may occur as 2-, 3-, or 4-coordinate species. For L_2Zn at ambient temperatures, and for L_2Cd at 25°C and −50°C, both the NCH_2 and NCH_3 sets of protons give rise to singlets ($CDCl_3$ solution). These NCH_2 and NCH_3 moieties lack a molecular symmetry plane in a four-coordinate ML_2 complex, so that anisochronous resonances should be observed. The experimental observation that these resonances appear as singlets points to a rate-determining Cd—N bond dissociation which is fast on the nmr time-scale even at −50°C. Rapid pyramidal inversion at nitrogen clearly cannot take place while nitrogen is coordinate to the metal. That the equilibrium [2] should lie well

[2] 
to the right is not surprising, since the strain involved in the formation of a pseudo-tetrahedral MC_2N_2 kernel must be considerable for both zinc and cadmium, given that the bite angle N—M—C in related complexes has been found consistently to be close to 75° (e.g., 75.3° in Ph_2LSnBr (8), 73° in CpLTi (20), and 77 ° in L_2InCl (3)). Recently van Koten *et al.* (6) have used the chiral labelling technique (10) to show that the Hg—N coordination is stable on the nmr time scale at −70°C in LHgX compounds (X = Cl, OAc), but becomes labile at higher temperatures.

Although the ^1H nmr spectrum of L_2Cd gives little definitive information about the Cd—N coordination beyond the high lability of the bond, it does reveal an interesting dynamic effect in the Cd—C(aryl) bond. The phenyl/hydrogen atom *ortho* to this bond appears as a broad singlet (half-width ~20 Hz) at 24°C, but at −40°C one observes a triplet with satellites at a separation of 47 Hz, corresponding to the coupling of this proton with the cadmium isotopes ^{111}Cd (spin 1/2, 12.75%) and ^{113}Cd (spin 1/2, 12.76%), with J(Cd—C—C—H) similar to that reported for other organocadmium compounds (21). These satellites coalesce into the main peak at room temperature. Although we have not investigated this phenomenon in detail, it is compatible with ligand exchange between CdL_2 units which is slow on the nmr time scale at low temperatures.

[3] $CdL_2 + CdL_2^* \rightleftharpoons 2LCdL^*$

which is slow on the nmr time scale at low temperatures. Such homo-exchange has been extensively studied for dialkylcadmium compounds (21), but does not appear to have been observed previously for diaryl derivatives.

Mass spectrometry

As part of a programme of investigations into the mass spectrometric behaviour of organometallic compounds (22), we have recorded the electron impact (EI) and field desorption (FD) mass spectra of CdL_2, and for comparison the EI spectrum of LBr.

The dominant peak for LBr is at m/e = 170 + 172, corresponding to $C_7H_7Br^+$ (Br = 79 or 81); a variety of lower m/e values include strong peaks at 86($C_5H_{12}N^{+\cdot}$), 84($C_5H_{10}N^{+\cdot}$), and 28 ($C_2H_4^{+\cdot}$). The EI mass spectrum of CdL_2 shows no molecular ion, and the highest significant m/e values are at 135 ($LH^{+\cdot}$) and 134 (L^+). The most intense peak at m/e = 58($NC_3H_8^+$), with a significant intensity at m/e = 44($NC_2H_6^+$). The only cadmium-containing peaks are those in the region 110−114, corresponding to the various isotopic forms of $Cd^{+\cdot}$. The EI-induced decomposition of the CdL_2 complex and that of LBr clearly differ significantly.

The FD spectrum of CdL_2 reveals the ions formed in the low energy ionisation processes of this mode of mass spectrometry. No Cd^+ ions were detected, and m/e values up to ~800 were recorded. Such ions, which result from ionisation of aggregates, are not uncommon in FD mass spectrometry (22). More importantly, a series of ions at m/e = 378−386 clearly arise from the various isotopic forms of CdL_2^+. Other ions derived from the parent molecule correspond to $[CdL_2 - 2CH_3]^+$ and $[CdL_2 - N(CH_3)_2]^+$. The ions HL_2^+, $L_2CH_3^+$, $[L_2 - CH_3]^+$, $[CdL - CH_3]^+$, and $CdC_6H_5NCH_2^+$ are also prominent. The spectrum clearly does not give that small number of easily identifiable peaks which is generally an important advantage of the FDMS method. On the other hand, it does indicate the variety of stable positive ions which can be derived from CdL_2 by various transfer and abstraction processes.

The direct electrochemical synthesis of some thorium(IV) nitrate complexes

N. KUMAR AND DENNIS G. TUCK

Department of Chemistry, University of Windsor, Windsor, Ont., Canada N9B 3P4

Received January 30, 1984

N. KUMAR and DENNIS G. TUCK. Can. J. Chem. **62**, 1701 (1984).

The electrochemical oxidation of thorium in either nitric acid/tri-*n*-butyl phosphate (TBP) or dinitrogen tetroxide/ethyl acetate/acetonitrile media gives rise to non-aqueous solutions of thorium(IV) nitrate species. The only neutral adduct which could be obtained from HNO_3/TBP solution was $Th(NO_3)_4.8dmso$ (dmso = dimethylsulphoxide). Salts of $[Th(NO_3)_6]^{2-}$ with Et_4N^+, $[(bpyH)_3NO_3]^{2+}$, and $[(phenH)_3NO_3]^{2+}$ (bpy = 2,2′-bipyridine; phen = 1,10-phenanthroline) were also prepared by this route. Solutions in N_2O_4/EtOAc/CH_3CN yield $Th(NO_3)_4$, and neutral adducts with dmso, bpy, phen, Ph_3PO, and pyridine-*N*-oxide.

N. KUMAR et DENNIS G. TUCK. Can. J. Chem. **62**, 1701 (1984).

L'oxydation électrochimique du thorium soit dans l'acide nitrique/phosphate de tri-*n*-butyle (PTB) ou par le tétroxyde d'azote/acétate d'éthyle/acétonitrile conduit à la formation de nitrate de thorium(IV) en solutions dans des milieux non-aqueux. Le seul adduit neutre que l'on a pu obtenir à partir d'une solution de HNO_3/PTB est le $Th(NO_3)_4.8dmso$ (dmso = diméthylsulfoxyde). Utilisant cette méthode, on a aussi préparé les sels de $[Th(NO_3)_6]^{2-}$ avec les cations Et_4N^+, $[(bpyH)_3NO_3]^{2+}$ et $[(phenH)_3NO_3]^{2+}$ (bpy = bipyridine-2,2′; phen = phénanthroline-1,10). Des solutions dans le N_2O_4/EtOAc/CH_3CN conduisent au $Th(NO_3)_4$ et à des adduits neutres avec le dmso, la bpy, la phen, la Ph_3PO et la *N*-oxyde de la pyridine.

Introduction

In previous papers from this laboratory (1, 2), we have described the direct electrochemical synthesis of thorium(IV) and (II) halides, some neutral adducts, and anionic thorium(IV) halide complexes. As part of the continuing exploration of the application of the electrochemical oxidation of metals, we now report that solutions of thorium(IV) nitrate species and various solid derivatives can also be prepared in this manner.

Thorium metal is not attacked by aqueous nitric acid, and in fact is rendered impassive to oxidation by such treatment (3*a*). The route to the hydrates of thorium(IV) nitrate is via the hydroxide (3*b*). Anhydrous thorium(IV) nitrate has been prepared by dissolving $ThCl_4$ in ethyl acetate/dinitrogen tetroxide, followed by thermal decomposition of the N_2O_4 adduct so formed (5); thorium is not attacked by solutions of N_2O_4 in organic solvents (6). The method of direct electrochemical synthesis is based in part on the use of non-aqueous electrolyte phases (7), and we have found that thorium(IV) nitrate species can be prepared by carrying out the oxidation of the metal into solutions of dinitrogen tetroxide in ethyl acetate/acetonitrile mixtures, or into solutions of nitric acid in tri-*n*-butyl phosphate. This latter solvent system was selected because of its relevance to the solvent extraction methods commonly used in the industrial scale purification of heavy elements.

Experimental

Materials

Thorium metal, supplied in the form of rod (7.9 mm diameter, Alfa) was sliced into discs, 2–4 mm thick. Acetone was dried over anhydrous magnesium sulphate and molecular sieves, acetonitrile over phosphorus pentoxide, and ethyl acetate over calcium hydride. Dinitrogen tetroxide (Matheson) was dried by passing the gas over phosphorus pentoxide.

Tetraethylammonium nitrate was prepared by reacting equimolecular amounts of tetraethylammonium bromide and silver nitrate in aqueous solution. Tri-*n*-butyl phosphate (TBP) was purified by the method reported earlier (8). Other reagents were used without further purification. All experimental operations were performed in an atmosphere of dry nitrogen. All work was at room temperature (20°C) unless otherwise noted.

Thorium was determined by titration against solutions of EDTA, using Alizarin S as indicator (9). Nitrate was determined gravimetrically as nitron nitrate (10).

Infrared spectra were recorded as Nujol mulls on a Perkin Elmer IR-18 spectrophotometer in the range 100–4000 cm^{-1}.

Electrochemical oxidation with HNO_3/TBP

Equilibration of equal volumes of TBP and 10 *M* aqueous nitric acid yields an organic phase containing 3.6 mol L^{-1} HNO_3 (c.f. ref. 8). This solution was separated from the aqueous layer and used without further treatment in the electrochemical synthesis.

In a typical experiment, 50 mL of HNO_3/TBP was placed in a 100 mL tall-form beaker. A platinum foil (1 × 1 cm^2) served as the cathode; the anode was a thorium disc (1.14 g, 4.9 mmol) suspended on a platinum wire. A current of 10 mA was passed through this cell for 45 h, after which time it was found that 0.77 g of thorium had been removed from the anode (see Table 1 for details). The solution phase was filtered through a sinter to remove suspended particles of thorium; addition of organic solvents such as acetone, diethyl ether, or benzene to the resultant clear solution did not cause any precipitation. Heating resulted in the evolution of thick brown fumes, but again no precipitate was formed. The addition of certain ligands to the solution yielded either neutral or anionic thorium(IV) nitrate complexes.

Anionic complexes from HNO_3/TBP media

(*a*) A solution of tetraethylammonium nitrate (0.77 g, 4.2 mmol) in ethanol (5 mL) was added to an electrochemically prepared solution of thorium (0.41 g, 1.8 mmol) in 40 mL HNO_3/TBP (HNO_3 3.6 *M*). The white solid which precipitated immediately was collected, washed three times with diethyl ether, and dried *in vacuo*. Analysis (Table 2) and infrared spectroscopy identified this product as $(Et_4N)_2[Th(NO_3)_6]$.

(*b*) 2,2′-Bipyridine (bpy) (0.42 g, 3 mmol) in ethanol (10 mL) was added to a solution of thorium (0.15 g, 0.65 mmol) in HNO_3/TBP. The mixture was stirred for 2 h at room temperature, after which the volume was reduced *in vacuo*. The white product which precipitated was collected, washed (diethyl ether), dried, and recrystallised from acetone/toluene (1:1, v/v). The colourless crystals were shown analytically and by X-ray crystallography (11) to be $[(bpyH)_3NO_3][Th(NO_3)_6]$.

(*c*) A similar reaction with 1,10-phenanthroline (phen) yielded pale pink crystals analysed as $[(phenH)_3NO_3][Th(NO_3)_6]$.

Neutral complexes from HNO_3/TBP media

(*a*) Dimethylsulphoxide (2 g, 25 mmol) was added to a HNO_3/TBP

phase containing 0.15 g (0.6 mmol) thorium, and the mixture stirred for 4 h at room temperature. The precipitate which formed during this period was collected, washed with diethyl ether, and dried *in vacuo*. The product is the extremely hygroscopic $Th(NO_3)_4$.8dmso.

(*b*) We were unable to obtain any well-defined complexes on using urea, pyridine, triphenyl phosphine, or triphenylphosphine oxide under conditions similar to those used for dimethylsulphoxide. It seems probable that the high concentration of HNO_3 effectively prevented the formation of such complexes, and attempts were therefore made to run the electrochemical experiment at a lower concentration of HNO_3 by diluting the original HNO_3/TBP (3.6 *M*) solution. Acetone was found to be the most suitable diluent, but the addition of neutral complexing agents to such solutions did not yield adducts, the only exception again being in the case of dmso (see below).

Electrochemical oxidation with diluted HNO_3/TBP media

A solution (10 mL) of HNO_3/TBP (3.6 *M* HNO_3) was diluted with 65 mL of acetone, and this mixture then used as the electrolyte phase in the usual way. After completion of the electrolysis (Table 1), the reaction mixture was filtered, reduced in volume to 10 mL under reduced pressure, and treated with solid Na_2CO_3 (4 g) to neutralize any free nitric acid. The resultant solution was then stirred for 2 h with dmso (2 g) in acetone (50 mL). Addition of diethyl ether (30 mL) and pumping *in vacuo* produced a white precipitate of $Th(NO_3)_4$.6dmso, which was collected, washed with diethyl ether, and dried *in vacuo*.

Electrochemical oxidation with N_2O_4 solutions

The cell, a 100 mL tall-form beaker, contained 50 mL of ethyl acetate/acetonitrile (3:2 v/v). Dinitrogen tetroxide was condensed into this solution, cooled to 0°C, until (typically) 2 mL of liquid N_2O_4 (32 mmol) was present. Electrolysis under the conditions summarized in Table 1 caused oxidation of the thorium anode. The final solution phase was filtered (glass sinter) and the volume of the filtrate reduced to 10 mL. Addition of diethyl ether (40 mL) brought down a small quantity of white solid, which was removed by filtration. The resultant solution (*A*) was used for the preparation of $Th(NO_3)_4$ and a number of neutral adducts as described below.

Thorium tetranitrate

The solution *A* was concentrated slowly *in vacuo*, finally yielding an oily product. Repeated cycles of freezing (liquid nitrogen), pumping *in vacuo*, and melting gave a solid which was washed twice with diethyl ether; this product is the colourless, amorphous, and extremely hygroscopic $Th(NO_3)_4$.

Neutral adducts of $Th(NO_3)_4$

Solution *A* (10 mL) containing 0.4 g (1.7 mmol) thorium, as calculated from the weight loss of the anode, was diluted with acetonitrile to 50 mL. Addition of excess 2,2′-bipyridine (0.52 g, 3 mmol) was followed by stirring (2–3 h); the solution was concentrated to 5 mL, and benzene (15 mL) added to produce a pale pink precipitate which was collected by filtration, washed with ether (20 mL), and dried *in vacuo*. This product is $Th(NO_3)_4$.2bpy. Similar reactions with 1,10-phenanthroline yielded $Th(NO_3)_4$.2phen.

Triphenylphosphine oxide (TPPO) (1 g, 3.6 mmol) in acetonitrile (10 mL) was added to a sample of solution *A* (25 mL; 0.51 g Th, 2.2 mmol). The mixture was refluxed for 2 h, and excess solvent removed *in vacuo*, yielding a sticky solid which was recrystallised from hot benzene, when crystals of $Th(NO_3)_4$.2TPPO were obtained. With pyridine-*N*-oxide (pyNO) the refluxing was not necessary, and $Th(NO_3)_4$.8pyNO crystallised on concentrating the reaction mixture.

Results and discussion

Preparative

The electrochemical oxidation of thorium metal into either HNO_3/TBP or N_2O_4/EtOAc/MeCN is a straightforward process, yielding solutions of thorium(IV) which serve as the source of a number of anionic and neutral derivatives. The electrochemical efficiency, E_F, defined as moles of metal dissolved per Faraday of electricity, is ~0.2 mol F^{-1} for all systems studied. The electrochemical oxidation in those halide systems in which the products are thorium(IV) compounds is close to Faradaic behaviour (E_F = 0.25 mol F^{-1}), but values of E_F ~0.2 were found for β-diketonate systems (1). There is no other electrochemical work in nitrate media against which to compare the present results.

With TBP/HNO_3, the resultant highly acidic solutions of thorium(IV) yield salts of the anionic $[Th(NO_3)_6]^{2-}$ complex, even with the potentially bidentate neutral ligands bpy and phen. Protonation of these ligands gives salts of this anion with the unusual $[(bpyH)_3NO_3]^{2+}$ and $[(phenH)_3NO_3]^{2+}$ cations, one of which has been characterised by X-ray crystallography (11). A salt with the more conventional Et_4N^+ cation can also be obtained in this way, and there are a number of reports in the literature of salts with other cations, including diprotonated 1,10-phenanthroline (12). This last species was obtained in the present work via solutions of nitric acid.

Dimethylsulphoxide was the only neutral ligand to yield an adduct of $Th(NO_3)_4$ from such acidic media. With N_2O_4/organic solvent solutions, the electrochemical method provides a route to $Th(NO_3)_4$ itself, and to neutral complexes with both bidentate and monodentate ligands. The 1:2 adducts with triphenylphosphine oxide (12−14) and pyridine-*N*-oxide (15) are apparently identical to those reported by previous workers. The 1:8 adduct with dmso is different in stoichiometry from the compounds described in the literature (12, 16−18), but it may well be that reaction conditions affect the nature of the product, as evidenced by the preparation of both $Th(NO_3)_4$.8dmso and $Th(NO_3)_4$.6dmso from different media in the present work. The 1:2 adduct with 1,10-phenanthroline has been reported previously by Smith and Wassef (1). and the bpy compound extends this series.

Infrared spectroscopy

The vibrational spectra of the nitrate ion in the free state and in its various modes of ligation have been the subject of considerable discussion, and we follow the assignments by Hester and Grossman (19), Bullock (20), and Addison *et al.* (4). The results (Table 3) for $Th(NO_3)_4$ are similar to those reported by Ferraro and Walker (5). The remaining compounds show infrared absorptions similar to those given by Alvey, Bagnall, and Brown (16) and are accordingly formulated as complexes of covalent bidentate nitrate, a conclusion confirmed for $[(bpyH)_3NO_3][Th(NO_3)_6]$ by X-ray crystallography (11). In the case of $Th(NO_3)_4$.8dmso and $Th(NO_3)_4$.6dmso, bands at 840 and 1350 cm^{-1} have been taken to indicate the presence of ionic nitrate (16) in the lattice, in addition to that which is coordinated to the metal; the variation in stoichiometry with reaction conditions may well centre upon the competition between nitrate and dmso for the available coordination sites. The pyridine-*N*-oxide complex shows no evidence of coordinated nitrate, in agreement with the results published by Richard and Woollard (15).

The contributions made to these spectra by the neutral ligands are in keeping with results in the literature. ν(S=O) is at 950 or 960 cm^{-1} in $Th(NO_3)_4$.8dmso and $Th(NO_3)_4$.6dmso, respectively, ν(N=O) is at 1220 cm^{-1} in the pyNO complex, and ν(P=O) is at 1056 cm^{-1} in the Ph_3PO adduct. All the compounds show far infrared absorptions at 220 ± 20 cm^{-1}, attributed to ν(Th—O_2NO).

These results in general give little information on the actual coordination numbers at thorium in the compounds prepared. By analogy with $[Th(NO_3)_6]^{2-}$, the bpy and phen adducts likely involve twelve-coordinate thorium, but further work will be required to establish the coordination kernel in the other neutral adducts.

Synthesis and structural characterization of bis(tropolonatodimethylgallium), $[(C_7H_5O_2)Ga(CH_3)_2]_2$

STEVEN J. RETTIG, ALAN STORR, AND JAMES TROTTER

Department of Chemistry, University of British Columbia, 2036 Main Mall, Vancouver, B.C., Canada V6T 1Y6

Received October 26, 1983

STEVEN J. RETTIG, ALAN STORR, and JAMES TROTTER. Can. J. Chem. **62**, 1705 (1984).

Details of the synthesis, physical properties, and solid-state structure of $[(C_7H_5O_2)Ga(CH_3)_2]_2$ are reported. Crystals of bis(tropolonatodimethylgallium) are monoclinic, a = 10.2669(9), b = 9.3237(3), c = 10.8671(10) Å, β = 112.896(4)°, Z = 2, space group $P2_1/n$ (22°C, λ = 0.70930 Å). The structure was solved by conventional heavy-atom techniques and was refined by full-matrix least-squares procedures to R = 0.034 and R_w = 0.037 for 1746 reflections with $I \geq 3\sigma(I)$. The centrosymmetric binuclear dimer features five-coordinate gallium atoms having irregular trigonal bipyramidal coordination geometry and a planar four-membered Ga_2O_2 ring. Important bond lengths (corrected for libration) are Ga—O(equatorial) = 1.972(2), Ga—O(axial) = 2.025(2) and 2.551(2) Å, and Ga—C = 1.951(4) and 1.954(4) Å.

STEVEN J. RETTIG, ALAN STORR et JAMES TROTTER. Can. J. Chem. **62**, 1705 (1984).

On rapporte les détails relatifs à la synthèse, aux propriétés physiques et à la structure à l'état solide du $[(C_7H_5O_2)Ga[CH_3)_2]_2$. Les cristaux du bis(tropolonatodiméthylgallium) sont monocliniques, a = 10,2669(9), b = 9,3237(3), c = 10,8671(10) Å, β = 112,896(4)°, Z = 2, groupe d'espace $P2_1/n$ (22°C, λ = 0,70930 Å). On a résolu la structure par les techniques conventionnelles des atomes lourds et on l'a affiné par la méthode des moindres carrés (matrice complète) jusqu'à des valeurs de R = 0,034 et R_w = 0,037 pour 1746 réflexions avec $I \geq 3\sigma(I)$. Le dimère binucléaire centrosymétrique comporte des atomes de gallium penta-coordonnés possédant une géométrie de coordination bipyramidale trigonale irrégulière et un cycle plan à quatre chaînons de Ga_2O_2. Les longueurs de liaisons importantes (corrigées pour la libration) sont: Ga—O (équatorial) = 1,972(2), Ga—O(axial) = 2,025(2) et 2,551(2) Å et Ga—C = 1,951(4) et 1,954(4) Å.

Introduction

As part of our continuing study of compounds containing five-coordinate gallium atoms (1–6) we have synthesized and structurally characterized the compound bis(tropolonatodimethylgallium), $[(C_7H_5O_2)Ga(CH_3)_2]_2$. The choice of tropolone as the "active hydrogen" compound in this study was dictated by three considerations. Firstly, it was hoped to incorporate the tropolonato moiety in a mixed pyrazolyl gallate anionic ligand, secondly, we wished to extend our studies of five-coordinate gallium systems having three oxygen atoms in the coordination sphere about gallium and, finally, tropolone and its derivatives have been recently cited as antibiotic potentiators (7). Although the first objective was not fulfilled, the bis(tropolonatodimethylgallium) compound was isolated in high yield and shown to consist of dimer units in the solid state, displaying the familiar Ga_2O_2 central bridging unit and irregular trigonal bipyramidally coordinated gallium atoms. In dilute solution and in the gas phase, however, the compound exists solely as the monomeric species.

Experimental

Air-sensitive materials were handled in oxygen-free dry nitrogen. Tetrahydrofuran (THF) was dried by refluxing over sodium/benzophenone and used immediately following distillation. Tropolone (Aldrich) was used as supplied. Trimethylgallium was prepared as described earlier (8). 3,5-Dimethylpyrazole (pz″H) (Aldrich) and sodium hydride (Alfa) were used as supplied.

Attempted preparation of $Na^+[Me_2Gapz''(C_7H_5O_2)]^-$

$$Na^+[Me_3Gapz'']^- + C_7H_6O_2 \rightarrow Na^+[Me_2Gapz''(C_7H_5O_2)]^- + MeH$$

Trimethylgallium (2.156 g, 18.8 mmol) in THF was added to Napz″ (2.218 g, 18.8 mmol) (made from NaH + pz″H) in the same solvent. To the clear colorless solution of $Na^+[Me_3Gapz'']^-$ so formed was added tropolone (2.293 g, 18.8 mmol) in THF. An immediate formation of yellowish precipitate was observed. The mixture was refluxed for approximately 40 h and then filtered. The pale yellow solid precipitate was isolated and shown by elemental analysis to be sodium tropolonate, $Na^+C_7H_5O_2^-$. The soluble reaction product from the reaction was shown to be the $[Me_2Ga(\mu\text{-}pz'')]_2$ dimer (9).

Preparation of bis(tropolonatodimethylgallium), $[(C_7H_5O_2)Ga(CH_3)_2]_2$

Trimethylgallium (1.945 g, 16.96 mmol) in THF was added to tropolone (2.068 g, 16.95 mmol) in the same solvent. A vigorous evolution of methane occurred on mixing the two reactants. On cessation of gas evolution the solvent was removed under vacuum from the clear product solution. The solid obtained was recrystallized from benzene to yield colorless air-stable crystals of the product. *Anal.* calcd. for $[(C_7H_5O_2)Ga(CH_3)_2]_2$: C 48.93, H 4.98; found: C 48.61, H 5.16. ^1H nmr (C_6D_6, τ values refer to $\tau_{C_6H_6}$ = 2.84 ppm): 9.90 s ($GaMe_2$, 6), 6.32 t (J = 10 Hz, 1), 4.84 t (J = 10 Hz, 2), 2.84 d (J = 10 Hz, 2). The mass spectrum of the compound displayed weak signals due to the monomer parent ion $(C_7H_5O_2)Ga(CH_3)_2^+$ (= P^+) (4%), the strongest signals arising from the $P - Me^+$ ion (100%) and the $P - 2Me^+$ ion (13%). Mol. wt. calcd. for $(C_7H_5O_2)Ga(CH_3)_2$: 220.9; found (cryoscopy in benzene solution): 222.

X-ray crystallographic analysis of bis(tropolonatodimethylgallium)

A crystal bounded by the six faces (followed by their distances in mm from a common origin): ±(1 0 −1), 0.200, ±(0 1 1), 0.150, ±(1 −1 1), 0.138 was mounted in a general orientation. Unit-cell parameters were refined by least-squares on 2 sin θ/λ values for 25 reflections (2θ = 40–45°) measured on a diffractometer with Mo–$K\alpha$ radiation ($\lambda(K\alpha_1)$ = 0.70930, $\lambda(K\alpha_2)$ = 0.71359 Å). Crystal data at 22°C are:

$C_{18}H_{22}Ga_2O_4$ fw = 441.82

Monoclinic, a = 10.2669(9), b = 9.3237(3), c = 10.8671(10) Å, β = 112.896(4)°, V = 958.3(1) Å^3, Z = 2, ρ_c = 1.531 g cm^{-3}, F(000) = 448, μ(Mo − $K\alpha$) = 27.3 cm^{-1}. Absent reflections: $h0l$, $h + l$ odd, and $0k0$, k odd, uniquely indicate the space group $P2_1/n$ [nonstandard setting of $P2_1/c$, C_{2h}^5, No. 14, equivalent positions: ±(x, y, z; 1/2 − x, 1/2 + y, 1/2 − z)].

Intensities were measured with graphite-monochromated Mo − $K\alpha$ radiation on an Enraf-Nonius CAD4-F diffractometer. An ω–2θ scan at 1.18–10.06° min^{-1} over a range of (0.60 + 0.35 tan θ) degrees in ω (extended by 25% on both sides for background measurement) was employed. Data were measured to 2θ = 65°. The intensities of three

For personal use only.

check reflections, measured every 3600 s throughout the data collection, showed uniform decreases to final values 10% less than the initial values, the intensities being scaled accordingly. After data reduction,[1] an absorption correction was applied using the Gaussian integration method (10, 11). Transmission factors ranged from 0.353 to 0.524 for 184 integration points. Of the 3445 independent reflections measured, 1746 (50.7%) had intensities greater than $3\sigma(I)$ above background where $\sigma^2(I) = S + 2B + (0.04(S - B))^2$ with S = scan count and B = normalized background count.

The coordinates of the Ga atom were determined from the Patterson function and those of the O and C atoms from a subsequent difference map. After full-matrix least-squares refinement of the non-hydrogen atoms with anisotropic thermal parameters to $R = 0.063$, a difference map gave the positions of all 11 independent hydrogen atoms which were refined with isotropic thermal parameters in subsequent cycles of refinement. The scattering factors of ref. 12 were used for non-hydrogen atoms and those of ref. 13 for hydrogen atoms. Anomalous scattering factors from ref. 14 were used for the Ga atoms. The weighting scheme, $w = 1/\sigma^2(F)$ where $\sigma^2(F)$ is derived from the previously defined $\sigma^2(I)$, gave uniform average values of $w(|F_o| - |F_c|)^2$ over ranges of both $|F_o|$ and $\sin\theta/\lambda$ and was employed in the final stages of refinement. Reflections with $I < 3\sigma(I)$ were not included in the refinement. An isotropic Type I extinction correction (Thornley-Nelmes definition of mosaic anisotropy with a Lorentzian distribution) was applied (15–17). The final value of g was $5.8(5) \times 10^4$. Convergence was reached at $R = 0.034$ and $R_w = 0.037$ for 1746 reflections with $I \geq 3\sigma(I)$. For all 3445 reflections $R = 0.097$. The function minimized was $\Sigma w(|F_o| - |F_c|)^2$, $R = \Sigma||F_o| - |F_c||/\Sigma|F_o|$ and $R_w = (\Sigma w(|F_o| - |F_c|)^2/\Sigma w|F_o|^2)^{1/2}$.

On the final cycle of refinement the mean and maximum parameter shifts corresponded to 0.04 and 0.72σ, respectively. The largest shift was associated with the thermal parameter of H(2c). The mean error in an observation of unit weight was 1.575. A final difference map showed maximum fluctuations of $\pm 0.26(13)$ e Å^{-3}. The final positional and thermal parameters appear in Tables 1 and 5, respectively.[2] Measured and calculated structure factors have been placed in the Depository of Unpublished Data.[2]

The ellipsoids of thermal motion for the non-hydrogen atoms are shown in Fig. 1. The thermal motion has been analysed in terms of the rigid-body modes of translation, libration, and screw motion (18). The rms standard error in the temperature factors σU_{ij} (derived from the least-squares analysis) is 0.0015 Å^2. Analysis of the entire dimer indicated significant independent motion of the "$GaMe_2$" units. Independent analyses were carried out for two molecular fragments, the Ga coordination group and the tropolone moiety (rms $\Delta U_{ij} = 0.0016$ and 0.0017 Å^2, respectively). The appropriate bond distances have been corrected for libration (18, 19), using shape parameters q^2 of 0.08 for all atoms involved. Corrected bond lengths appear in Table 2 along with the uncorreeted values; corrected bond angles do not differ by more than 1σ from the uncorrected values given in Table 3. Intra-annular torsion angles defining the conformation of the tropolone ring are listed in Table 4. Bond lengths and angles involving hydrogen and a complete listing of torsion angles (tables 6–8) are included as supplementary material.[2]

*Here and elsewhere primed atoms are related to those in Table 1 by inversion through the centre of symmetry at 1/2, 1/2, 1/2.

Results and discussion

The title compound, bis(tropolonatodimethylgallium), represents the second example of a complex having a five-coordinate gallium centre which does not include nitrogen in the pentacoordination sphere about the metal atom (the Ga atom is coordinated to three oxygen and two carbon atoms). As with the salicylaldehydatodimethylgallium dimer, $(SalGaMe_2)_2$, the first such example (3), the present compound is not associated in either the gas phase or in dilute solution. Thus the mass spectrum of the compound gives no signals at m/e values higher than those corresponding to the monomer ion or its ions arising from predictable fragmentation patterns. In dilute benzene solution, molecular weight measurements indicate the monomer species to be present. The ^{1}H nmr pattern in C_6D_6, consisting of a singlet for the "$GaMe_2$" protons and a triplet: triplet:doublet pattern for the protons of the tropolonato moiety, is also consistent with a monomeric species in solution.

The solid state structure consists of well-separated dimeric units in which each five-coordinate Ga atom is in an irregular trigonal bipyramidal environment. Space group symmetry re-

[1]The computer programs used include locally written programs for data processing and locally modified versions of the following: ORFLS, full-matrix least-squares, and ORFFE, function and errors, by W. quires each dimer to possess a centre of symmetry. The dimerization occurs via the formation of a four-membered Ga_2O_2 ring in which each oxygen atom occupies an equatorial coordination site of one Ga atom and an axial site of the other. This type of dimerization has been noted for $(SalGaMe_2)_2$ (3), $(Me_2NCH_2CH_2OGaR_2)_2$ (R = H, Me) (5), and $[MeN(CH_2CH_2O)_2GaH]_2$ (6). The terminal tropolonato O atoms occupy the other axial positions while methyl groups complete the equatorial planes. The angle between the axial substituents, 149.99(8)°, is similar to the values of 150−152° found for the "ethanolamine" complexes (5, 6) in which five-membered chelate rings are also fused to the central Ga_2O_2 ring, but considerably smaller than the value of 164.4(1)° in $(SalGaMe_2)_2$ which contains six-membered chelate rings. The Ga atom is displaced by 0.2111(3) Å toward O(2) from the plane of the equatorial substituents. The system of five fused rings is planar to within 0.018(3) Å. The small but significant deviation from planarity arises in the tropolone ring which is significantly nonplanar (χ^2 = 84.6, maximum deviation 0.015(3) Å), the four-membered ring being exactly planar and the five-membered chelate ring being planar within experimental error (χ^2 = 7.5, maximum deviation 0.0035(21) Å).

The Ga—O distances[3] involving the bridging tropolonato O atom (1.972(2) and 2.551(2) Å for the equatorial and axial bonds, respectively) are significantly longer than those observed earlier for related molecules. In $(Me_2NCH_2CH_2OGaR_2)_2$ (R = H, Me) and $[MeN(CH_2CH_2O)_2GaH]_2$ which contain bridging alkoxide groups, the corresponding bond lengths are in the ranges 1.911(3)−1.960(8) Å and 2.018(2)−2.078(3) Å,

[3]Libration-corrected bond lengths (esd's assumed equal to those associated with the uncorrected values) are employed throughout the discussion and are compared with similarly treated distances except in the case of $(Me_2NCH_2CH_2OGaH_2)_2$ (5).

For personal use only.

respectively. The corresponding distances in $(SalGaMe_2)_2$ involving a bridging phenoxide moiety are 1.933(3) and 2.469(3) Å. The axial Ga—O bond to the terminal tropolonato O atom of 2.025(2) Å is similar to those quoted above for the bridging alkoxide groups and significantly shorter than the value of 2.127(3) Å for the aldehyde O atom in $(SalGaMe_2)_2$. A similar trend in B—O bond lengths has been noted for the tetrahedral tropolonato- (20), salicylaldehydato- (21), and aminoethanolatodiarylboron complexes (22–25). These findings are consistent with the known donor properties of these oxygen-containing ligands. The Ga—C distances are in good agreement with those reported earlier (1–6).

The observed geometry of the tropolonate ligand is intermediate between that in tropolone itself (26), in which there is partial localization of the double bonds, and the fully delocalized and symmetric structure such as that observed in the boron complex $(C_7H_5O_2)BPh_2$ (20). The structural inequivalence of the tropolonato oxygen atoms leads to a small alternation of bond lengths in the seven-membered ring (similar to that observed in the structure of $[(C_7H_5O_2)TlPh_2]_2$ (27)), although this can occur in the absence of structural differences as in the case of the square planar complex $(C_7H_5O_2)_2Cu$ (28) in which each ligand is bidentate and chelating. As expected,the two C—O distances differ significantly and both of these values (1.279(3) and 1.308(3) Å) are shorter than the mean C—O distance of 1.313(2) Å in the boron compound, consistent with relatively stronger O—B bonding than O—Ga bonding in these two tropolonate complexes. The shorter C—O bonds in the present structure are balanced by a significant lengthening of the unique C(3)—C(4) bond to 1.478(3) Å from the value of 1.446(2) Å in the boron compound. In tropolone itself, the C—O and unique C—C distances are 1.263(3), 1.333(3), and 1.454(4) Å, respectively. The average C—C distance for the remaining six tropolonato ring bonds is 1.388(13) Å compared to 1.385(26) Å in tropolone and 1.385(5) Å in the diphenylboron chelate. The mean short and long C—C bonds average 1.380(6) and 1.397(15) Å respectively, compared to corresponding values of 1.364(20) and 1.405(10) Å in tropolone (26).

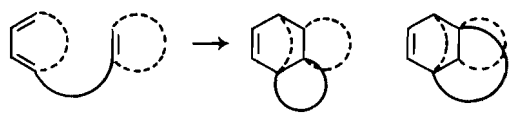
Introduction

The Diels–Alder reaction occupies a position of prominence in the arsenal of the synthetic organic chemist, as a consequence of its good yields, mild reaction conditions, high stereoselectivity, and predictability. However, several features of the intramolecular reaction are imperfectly understood, and further refinement is required if these cycloadditions are to be used with confidence at key stages of a total synthesis. Nevertheless, the synthetic potential of the intramolecular version of this reaction, in which the diene and dienophile are constrained in the same molecule, is considerable and in recent years has been applied to a variety of synthetic objectives with notable success (for reviews, see ref. 1). When the reacting components are themselves cyclic, and (or) have ring substituents, complex multicyclic arrays (Scheme 1) such as those contained in drugs and natural products can be constructed. Often the syntheses of molecules of this complexity are more difficult and lengthy by other routes.

In order to use these cycloadditions synthetically one must be able to predict the feasibility of the cyclization with various substitution patterns in both the reacting units themselves and the sidechain connecting them. An understanding of how these factors and related structural features influence the rate and stereoselectivity of the reaction is also essential. Recent studies by Boeckman and Ko (2) have shown that a fourfold change in rate is induced by sidechain geminal dimethyl functionality in the preparation of a tetrahydrohydrindan. The rate is also enhanced by conjugation of the dienophile with nitrile rather than ester although, as Roush *et al.* (3) have also found, the steric demands of the dienophile (*E* or *Z*) have little influence on the stereochemistry of the new rings. Sidechain substituents also play a key role in the cyclization of furans and several cases which fail to cyclize have been reported (4). In general, geminal substitution at the second carbon in the chain was required for the cycloaddition to proceed.

Among the diverse structures produced in nature the bridged sesquiterpenes longifolene (5) and sativene (copacamphene) (6) occupy a prominent position. Both have been the object of a variety of synthetic approaches (longifolene syntheses (7*a*) and sativene syntheses (7*b*)) and have served as a challenge for



SCHEME 1

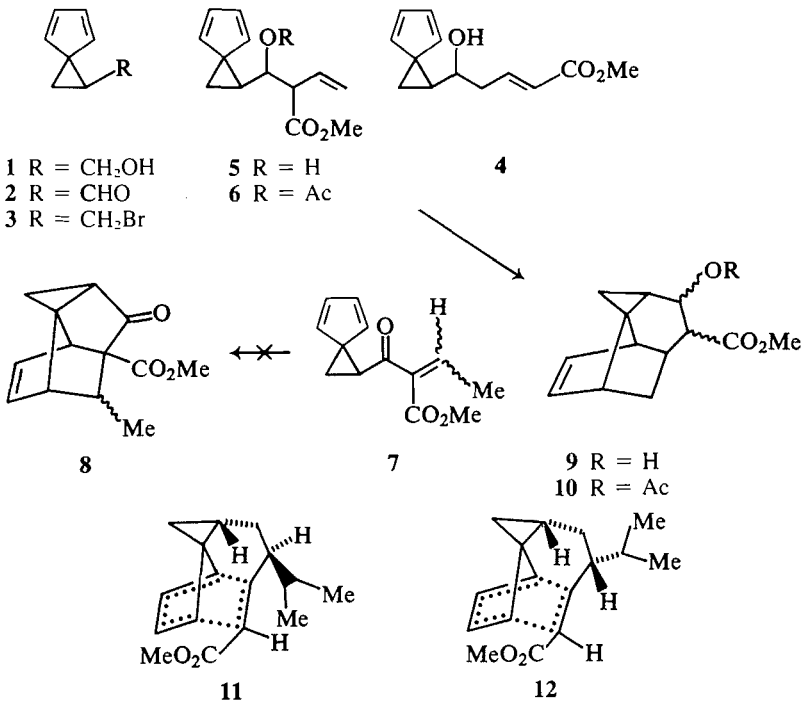
SCHEME 2

new synthetic methodology. Recently the interesting marine natural products sinularene (8) and 12-acetoxy sinularene (9) were isolated from soft corals and shown to possess a related bridged bicyclo[2.2.1]heptane skeleton.[1]

In principle these structures could be prepared using an intramolecular Diels–Alder reaction between a cyclopentadiene and an appropriately substituted sidechain. However, as an early approach to longifolene showed (11), the propensity of cyclopentadienes to undergo facile 1,5-sigmatropic rearrangement takes precedence (Scheme 2), and for this strategy to be successful either the rearrangement has to be blocked or the reaction must be conducted under conditions where cycloaddition can compete efficiently with rearrangement (for a successful intermolecular example, see ref. 12). Unfortunately, blocking the sigmatropic reaction is not necessarily straightforward since it has been found (13)[2] that even chlorine

[1] While this work was in progress two syntheses of sinularene were reported (10) and, since acceptance of this manuscript, 12-acetoxy-sinularene has also been prepared (26).

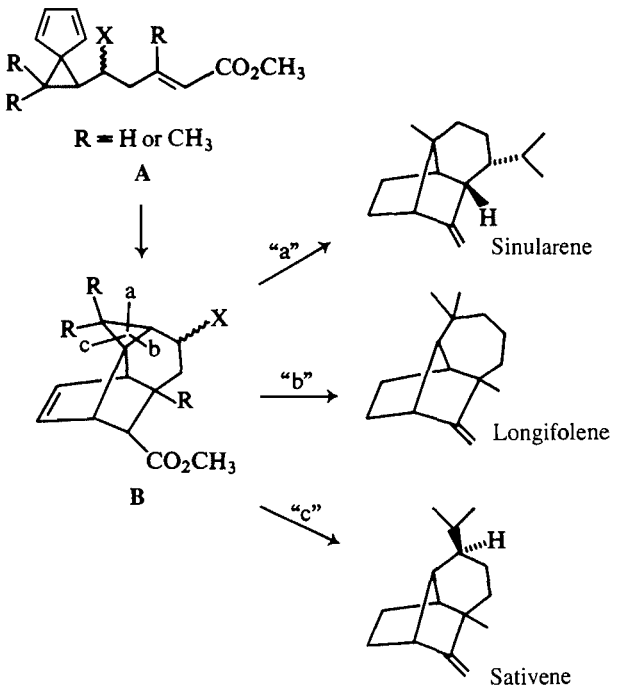
[2] In related studies we are examining the migratory aptitudes of 5-seleno and 5-thiocyclopentadienes in order to use these compounds and the stabilized anions derived from them for a variety of synthetic objectives. As we have pointed out elsewhere (25), an alternative solution employs a "brexane" intermediate followed by a ring expansion. This approach has been used by Snowden in a synthesis of sativene (see 7*b*).



migrates prior to cyclization in a related cyclopentadiene. Synthesis of a suitable spiro[2.4]heptadiene of type **A** should permit formation of the tetracyclic compound(s) **B** (described herein), since the sigmatropic rearrangement is blocked by the cyclopropane moiety, and with the appropriate substitution pattern controlled cyclopropane ring opening (hydrogenolysis, solvolysis, dissolving metal reductions, Lewis acid catalysis, etc.) should provide a general entry into the desired tricyclo[4.4.$0^{1,6}$.$0^{5,9}$]decane and tricyclo[5.4.$0^{1,7}$.$0^{6,10}$]undecane ring systems (Scheme 3) (see following paper).

Results and discussion

In order to bring these ideas to fruition, and as initial efforts to add diazocyclopentadiene to suitable olefins were not encouraging, the spiro-alcohol **1** was prepared from sodium cyclopentadiene and epichlorohydrin according to the procedure of Bangert and Boekelheide (14) and oxidized with active MnO_2 to the aldehyde **2** (83%). This aldehyde was rather unstable but could be briefly stored in solution at −20°C. In its ^{1}H nmr spectrum the aldehydic hydrogen appeared as a doublet, J = 5 Hz at δ 9.30, coupled to the tertiary cyclopropyl proton which gave rise to a complex multiplet at δ 2.87. The Grignard reagent derived from bromomethyl crotonate was next added to the aldehyde. In order to minimize self condensation the aldehyde was added dropwise during Grignard formation and the product could be isolated in 63% yield after chromatography. Crotyl Grignard reagents frequently afford a mixture of α- and γ-substitution products (15). In this instance a single regiochemical isomer was obtained. Vinyl groups usually display a characteristic ABC pattern in their ^{1}H nmr spectra at approximately δ 5 ppm. Although the appearance in this case was atypical (complex overlapping multiplet), the chemical shift was in the correct range, suggesting the structure was **5** rather than **4**.[3] Oxidation of **5** in dimethylsulfoxide containing di-



SCHEME 3

cyclohexyldicarbodiimide and trifluoroacetic acid provided a new ketone **7** whose spectral features were consistent with a conjugated system and confirmed the assignment of structure **5** to the triene. The ^{1}H nmr spectrum of **7** contained two overlapping vinyl methyl doublets at δ 1.82 and 1.89, J = 9 Hz, indicating, as did the methoxyl resonances at 3.64 and 3.70, that an ~1:1 mixture of E and Z isomers was present. The β-olefinic proton multiplet was shifted to low field 6.83, as expected for hydrogens on a conjugated double bond. Molecular models suggested that internal cyclization of this triene would be difficult in view of the contiguous sp^2 hybridized centres in the sidechain and the limited rotational freedom this

[3] Please note that this assignment differs from our preliminary communication and that the substituents were attached incorrectly to C_{11} rather than C_2 of the adducts (16).

imparts. This was confirmed experimentally. In contrast, the hydroxy-triene **5** underwent intramolecular cycloaddition (53%, 60% based on reacted triene) at 180°C in refluxing *p*-dichlorobenzene or, alternatively, in a sealed tube in toluene. This demonstrated the feasibility of this approach to the natural products but clearly a different substitution pattern was required.

In order to provide a direct route to sinularene it seemed appropriate to carry the isopropyl function in the sidechain. It appeared that this would introduce the interesting possiblity of controlling the stereochemistry of the isopropyl substituent as a consequence of steric interactions in the Diels–Alder transition state. It can be seen that the non-bonded interactions between the developing *exo* hydrogen and the isopropyl substituent are reduced in **12** compared to **11** and should clearly favour preferential cyclization to the required stereoisomer, although interaction between the bridgehead hydrogen and the isopropyl group in **12** may partially counteract this effect.

In order to test this possibility the desired triene ester **21** was synthesized in the following manner. Treatment of alcohol **1** with triphenylphosphine dibromide in acetonitrile afforded (73%) bromide **3** which was added to the dianion derived from methyl 5-methyl-3-oxo hexanoate (**13**) (17) to give the keto-ester **15**. Selective reduction of the ketone was achieved with sodium borohydride (70%) and the alcohol **17** converted to its acetate **18** under standard conditions with acetic anhydride in pyridine (88%). Direct dehydration of the alcohol with phosphorus oxychloride gave a mixture of α,β and β,γ unsaturated esters, a difficulty which was avoided when the diester **18** was treated with potassium *tert*-butoxide at room temperature for 50 min (18) to afford the triene **21** (82%). Unfortunately no conditions, thermal or Lewis acid catalysis, could be found to effect cyclization of **21** without decomposition of the sensitive spirocyclopentadiene moiety. In order to be certain a small amount of cyclized material was not overlooked, the diastereomers were separated by flash chromatography and studied individually, but cycloaddition did not occur.

In view of the fact that triene **5** cyclizes while **21** does not, it appears that both diastereomers of **21** experience adverse steric crowding during the attempted cycloaddition. Thus removal of the isopropyl substituent should facilitate cyclization. In an effort to learn more about these conformational effects, the unsubstituted triene **22** was synthesized by alkylation of the dianion of methyl acetoacetate with bromide **3** to give **16**. The double bond was introduced by reduction to the alcohol **19** followed by acetylation and elimination by the same procedure as utilized above. To our amazement, and disappointment, **22** showed no inclination to cyclize and after 65 h at 195°C in a sealed tube in toluene was recovered unchanged. The double bond is clearly conjugated since the dienophilic protons for **22** appear as separate signals, the β proton as a multiplet centred at δ 6.75, the α proton as a distorted doublet of triplets centred at δ 5.6.

Why does **5** undergo the desired cyclization while **21** and **22** do not? It appears that the alcohol **5** prefers a conformation in which the dienophile is folded underneath the cyclopentadiene

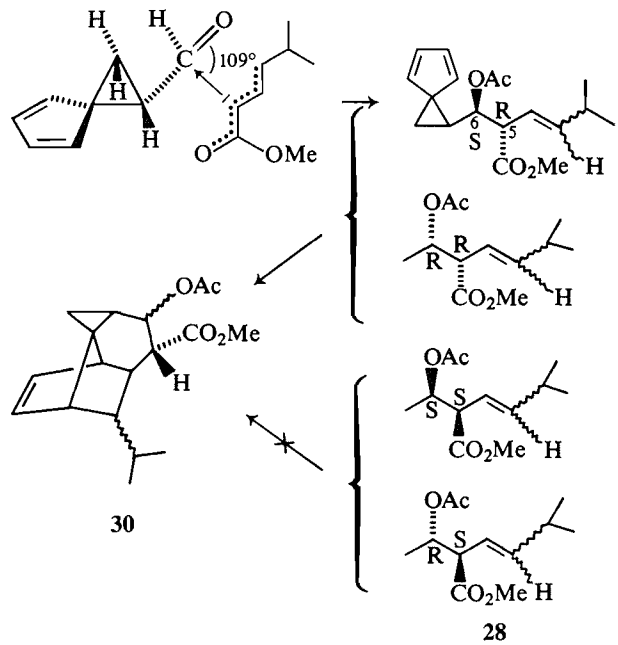
Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.40 on 09/06/12
For personal use only.

ring in an alignment which approximates that required for cycloaddition. Partial support for this contention is provided by the ^{1}H nmr spectrum of **5**, referred to above, in which the standard vinyl pattern appears to be affected by its proximity to the cyclopentadiene system. The hydroxyl function clearly exerts a beneficial influence but intramolecular hydrogen bonding with the ester cannot be the dominant factor since when the acetate **6**, prepared from **5**, was heated (175°C, 45 h, toluene, 66%), cyclization occurred even though the opportunity for hydrogen bonding was absent. This cycloaddition also proceeded readily under catalytic conditions with aluminum chloride at 23°C in dichloromethane for 3 h (75%).

Stereochemical influences of a similar type have been observed previously. For example, in the synthesis of patchouli alcohol it was found (19) that only one diastereomer of 1-(3-methyl-4-penten-1-yl)-2,6-trimethyl-2,5-cyclohexadien-1-ol would undergo an intramolecular Diels–Alder reaction and neither of them would cyclize unless a little potassium *tert*-butoxide was added! Unfortunately we have not uncovered a similar trick, and scrutiny of molecular models does not provide a reliable predictive guide to the relative ease of cyclization. In the above cases the approach of the reactive centres within the required 2.2 Å distance (20) seems readily achievable, but subtle conformational barriers intervene. Apparently the hydroxyl or acetoxy substituent holds the molecule in a folded conformation which either relieves a non-bonded interaction, although this is difficult to discern from models, or more likely the oxygen lone pair exerts a subtle but beneficial stereoelectronic effect of the barrier to cyclization is lowered and cycloaddition occurs before decomposition of the sensitive spiro-cyclopentadiene moiety. If this analysis is correct, then trienes such as **25** or **26** which contain the requisite sidechain hydroxyl function should exist preferentially in a folded conformation and undergo intramolecular cyclization. This has been shown to be the case for **26** and **28**.

Condensation of isovaleraldehyde with methyl (triphenylphosphoranylidene)acetate provided the unsaturated ester **23** (93%), which upon treatment with *N*-bromosuccinimide in refluxing carbon tetrachloride gave the allylic bromide **24** (80%). Grignard addition as outlined above with aldehyde **2** afforded a new triene. Generally bulky crotyl reagents and a sterically hindered carbonyl group favour the formation of the γ-substitution product. However, the ^{1}H nmr spectrum of this material contained no signals below the multiplets for the cyclopentadiene hydrogens, suggesting the product possessed structure **26**. This was confirmed by reducing the corresponding acetate **28** (H_2, 10% Pd/C, 2.5 atm., methanol) to the saturated ester **29**. Proton decoupling experiments established that the protons on the acetate and ester-bearing carbons were coupled to each other, a situation which could not have arisen from structure **27**. Additional support was provided in the 400-MHz spectrum of the triene acetate **28** obtained at the University of Alberta which revealed that the tertiary-isopropyl hydrogen was coupled to the neighbouring olefinic protons.

This condensation introduces two new chiral centres into the aldehyde **2** which is itself racemic. As illustrated for the *S*-aldehyde (Scheme 4), the Grignard can approach the carbonyl group from either the top or bottom face (shown) and in principle the ester function may be either *syn* or *anti* to the aldehydic hydrogen. It was anticipated that the Grignard reagent would be oriented on the same side as this hydrogen, partly because of the gorup's steric bulk, and, equally important, because the delocalized π system of the Grignard reagent



SCHEME 4

would likely align itself preferentially with the π system of the diene. Attack from the bottom thus generates the $C_6(S)C_5(R)$ triene whereas a topside approach will give the $C_6(R)C_5(R)$ diastereomer. Experimentally the coupled product was separated by flash chromatography into four diastereomers (~1:1:6:6), although the *E* and *Z* olefins could not be resolved. The major components, comprising 84% of the product, were assumed to be the C_6C_5 *SR* and *RR* isomers. The minor diastereomers refused to cyclize and direct cyclization (180°C, 24 h, *p*-dichlorobenzene, ~10%) of the major trienes was accompanied by extensive decomposition. However, the acetates **28** were more stable and cyclized cleanly (180°C, 24 h, 89% based on cyclized **28**) to the requisite tetracyclic diesters **30**. The formation of these adducts confirms the conclusions implied above since the fact that the minor *R,S* and *S,S* trienes failed to cyclize suggests that non-bonded interactions of the type depicted in **11** do play a dominant role.

The acetate cycloadditions (**28**, *R,R*; *S,R*) may also be catalyzed with $AlCl_3$ (1.1 equiv., 23°C, CH_2Cl_2 25%) under mild conditions, although polymerization competes. These results add to the growing list of intramolecular Diels–Alder reactions which may be catalyzed with Lewis acids (21), although unfortunately in all cases examined other catalysts ($EtAlCl_2$, $SnCl_4$, $FeCl_3$, $BF_3 \cdot Et_2O$, −78° to 23°C) promoted decomposition rather than cyclization. It should be noted that, for **28** and example **6** above, these cycloadditions differ from the normal situation in which the Lewis acid alters the electron density of the double bond by coordination with the dienophile. Instead, complexation with the oxygen and ester sidechain functionality resulted in a beneficial conformational bias which facilitated cyclization.

In conclusion, a C_5-oxygen substituent is essential for successful cyclization of these trienes, although further work is required to ascertain the exact origin of this effect, and whether an ester substituent plus both cyclopropane and diene units are essential. However, orbital proximity effects in rigid systems are well documented (22) and through space interactions of oxygen lone pair orbitals are known to influence conformer populations (23). These concepts are being applied to the syn-

thesis of sinularene and are currently being extended to an asymmetric synthesis of (+)-longifolene, commencing with ascorbic acid, utilizing the synthetically useful way we have developed of blocking the 1,5-sigmatropic rearrangement of cyclopentadienes, and taking advantage of the conditions described under which hydroxyl-bearing trienes undergo cycloaddition.

Experimental

Melting points were determined in capillary tubes with a Thomas–Hoover Uni-Melt apparatus or a Fischer–John's melting point apparatus and are uncorrected. Infrared spectra were recorded on a Perkin–Elmer 237B or 451 grating spectrophotometer, and were calibrated with the 2850 and 1601 cm^{-1} bands of polystyrene film. Ultraviolet spectra were recorded on a Perkin–Elmer 202 uv–visible spectrophotometer and were calibrated with the 279.4-nm band of a Holmium oxide filter. Proton magnetic resonance spectra were measured at 80 MHz with a Bruker model WP80 spectrometer employing a chloroform lock or at 60 MHz qith a Varian model EM-360 spectrometer. Signal positions are reported in ppm downfield from tetramethylsilane (δ scale) as an internal standard, the number of protons, multiplicity, coupling constants, and proton assignments are indicated in parentheses. Mass spectra were determined on a V.G. Micromass 7070 HS instrument using an ionization energy of 70 eV. Gas–liquid chromatograph analyses were conducted on a Hewlett Packard 402B gas chromatograph equipped with a column (3 m × 6 mm id) containing 1.5% OV-17 supported on Gas Chrom Q using helium as the carrier gas. Thin-layer chromatographic analyses were carried out on commercial precoated silica gel plates with fluorescent indicator (Eastman Kodak silica gel 13181). Preparative thin-layer chromatography was conducted on 20 × 20 cm glass plates coated with silica gel $PF_{254+366}$ type 60 (E. Merck). Flash chromatography used BDH silica gel Kieselgel 60, 230–400 mesh (24).

Solutions in organic solvents were dried over anhydrous magnesium sulphate and stripped of solvent with a Büchi rotary evaporator connected to a water aspirator. Unless otherwise indicated, all reactions were conducted under argon.

1-Carboxaldehydespiro[2.4]hepta-4,6-diene (2)

The spiro-alcohol **1** (12) (2 g, 18 mmol) was dissolved in dichloromethane (25 mL) – chloroform (50 mL) and freshly prepared active MnO_2 (30 g) added. The mixture was stirred under reflux for 12 h, cooled to room temperature, and diluted with ether (100 mL). The mixture was stirred for a further 15 min, filtered, the solid washed thoroughly with ether (250 mL), and the combined filtrate concentrated to afford the aldehyde **2** (1.8 g, 83%) as a pale yellow liquid: ir (KBr): 2825 (H—CO), 2720 (H—CO), 1704 (C=O) cm^{-1}; ^1H nmr (CCl_4) δ: 2.17 (2H, m, cyclopropyl H), 2.87 (1H, m, cyclopropyl H), 5.95 (1H, m, cyclopentadienyl H, C-4), 6.28 (1H, m, cyclopentadienyl H, C-7), 6.47 (2H, m, cyclopentadienyl H), 9.30 (1H, d, J = 5 Hz, H—CO).

The aldehyde was further characterized as its semicarbazone, mp 168–169°C (methanol–water). *Anal.* calcd. for $C_9H_{11}N_3O$: C 61.00, H 6.26, N 23.71; found: C 61.01, H 6.57, N 23.74.

1-Bromomethylspiro[2.4]hepta-4,6-diene (3)

Triphenylphosphine dibromide was prepared from triphenylphosphine (6.82 g, 26 mmol) suspended in dry acetonitrile (100 mL), stirred magnetically in a 250-mL round bottomed flask which was cooled in an ice bath during the dropwise addition of bromine (1.28 mL, 25 mmol). Pyridine (2.0 mL, 25 mmol) was added to the stirred white suspension, followed by the alcohol **1** (3.0 g, 24.6 mmol) to give a clear light yellow solution. Stirring was continued for a further 10 min at 0°C after addition was complete, and the solvent removed under reduced pressure. The dark orange residue so obtained was triturated with petroleum ether (3 × 100 mL), concentrated, and set at −20°C to precipitate triphenylphosphine oxide. Rapid column chromatography (sintered glass funnel packed with silica gel and elution with petroleum ether under water aspirator suction) afforded the bromide **3** (3.7 g, 81%); ^1H nmr (CCl_4) δ: 1.5–2.0 (2H, m, cyclopropyl H), 1.41 (1H, m, cyclopropyl H), 3.40 (2H, m, —CH_2—Br), 5.91 (2H, m, cyclopentadienyl H), 6.44 (2H, m, cyclopentadienyl H).

3-Carbomethoxy-4-hydroxy-4-(spiro[2.4]hepta-4,6-dien-1-yl)butene (5)

Magnesium (6 g, 247 mmol) was added to dry THF (300 mL) in a three-necked 1-L flask equipped with a paddle stirrer. Methyl 4-bromocrotonate (19.1 g, 107 mmol, Aldrich) in THF (100 mL) was added in small portions until the Grignard commenced, after which the remaining bromide and aldehyde **2** (8.7 g, 72.5 mmol) were added dropwise simultaneously. Once the vigorous reaction had subsided, the reaction was stirred for a further 2 h at room temperature and poured into saturated aqueous NH_4Cl solution (200 mL). After ether extraction (3 × 100 mL), the combined extracts were dried, concentrated, and purified by flash chromatography (20% ethyl acetate/petroleum ether). This initially afforded 3.8 g of product and rechromatography of the impure fractions yielded an additional 4.6 and 1.5 g for a total of 9.9 g (63%) of the triene alcohol **5**; uv (CH_3OH): 198 (ε = 6500), 224 (ε = 7500), 258 sh (ε = 2300) nm; ir (film): 3470 (br, OH), 1730 (C=O), 1643 (C=C) cm^{-1}; ^1H nmr (CCl_4) δ: 1.6–2.3 (3H, m, cyclopropyl H), 2.7–3.2 (1H, m, CH—C=), 3.63 (3H, s, OCH_3), 3.70 (1H, m, H—C—OH), 4.6–5.5 (3H, m, CH=CH_2), 5.88 (1H, m, cyclopentadienyl H), 6.28 (3H, m, cyclopentadienyl H). *Exact Mass* calcd. for $C_{13}H_{16}O_3$: 220.1099; found: 220.1101.

3-Carbomethoxy-4-(spiro[2.4]hepta-4,6-dien-1-yl)-2-buten-4-one (7)

The alcohol **5** (152 mg, 0.69 mmol) was dissolved in anhydrous DMSO (1.2 mL) and benzene (2.4 mL) contaning dicyclohexyldicarbodiimide (434 mg, 2.1 mmol, Aldrich) and pyridine (57 mg, 0.71 mmol). Trifluoroacetic acid (49 mg, 0.43 mmol) was added to the stirred solution and stirring was continued for 19 h at 22°C. Dicyclohexylurea was precipitated by the addition of ethyl acetate (10 mL), the mixture filtered, the residue washed with ethyl acetate, the combined filtrates washed with water (4 × 3 mL), dried over potassium carbonate, filtered, and concentrated. The residual brown oil was purified by tlc ($CHCl_3$) to give the keto-ester **7** as a yellow oil, 80 mg (53%); ir ($CHCl_3$): 1720 (C=O), 1685 (sh, C=O) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 1.82, 1.89 (3H, d, J = 9 Hz, =$CHCH_3$), 2.50 (1H, m, cyclopropyl H), 3.23 (1H, t, J = 7 Hz, cyclopropyl H by C=O), 3.64, 3.70 (3H, s, OCH_3), 5.95 (2H, m, cyclopentadienyl H), 6.35 (2H, m, cyclopentadienyl H), 6.83 (1H, m, J = 9 Hz, HMeC=).

3-Carbomethoxy-4-acetoxy-4-(spiro[2.4]hepta-4,6-dien-1-yl)butene (6)

The alcohol **5** (265 mg, 1.2 mmol) was dissolved in pyridine (5 mL) cooled to 0°C in an ice bath and acetic anhydride (2 mL) added. The reaction was stirred at room temperature for 15 h and poured onto ice/water. The aqueous solution was extracted with ether (2 × 50 mL), the combined extract washed with 3 *M* HCl, saturated aqueous sodium bicarbonate solution, brine, and dried. Purification by preparative tlc on silica gel (20% ethyl acetate/petroleum ether) gave the acetate **6** (255 mg, 82%); ir (film): 1745 (C=O), 1645 (C=C) cm^{-1}; ^1H nmr (CCl_4) δ: 1.3–2.3 (3H, m, cyclopropyl H), 1.95 (3H, s, CH_3—CO), 2.86 (1H, dd, J = 4, 9 Hz, HC—C=), 3.50, 3.53 (3H, s, OCH_3), 4.65 (1H, m, H—C—OAc), 4.8–5.6 (3H, m, CH=CH_2), 5.79 (1H, m, cyclopentadienyl H), 6.21 (3H, m, cyclopentadienyl H). *Exact Mass* calcd. for $C_{15}H_{18}O_4$: 262.1205; found: 262.1207.

2-Carbomethoxytetracyclo[5.4.0^{1,7}.0^{4,6}.0^{6,10}]undec-8-en-3-ol (9)

The triene alcohol **5** (3.8 g, 17.6 mmol) was placed in a 250-mL round bottom flask and solid *para*-dichlorobenzene (approximately 200 g) and boiling stones added. The reaction mixture was refluxed for 6 h and the solvent removed under reduced pressure. Flash chromatography (30% ethyl acetate/petroleum ether) of the remaining oil afforded 0.45 g of recovered triene and the tetracyclic alcohol **9** (2.0

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.40 on 09/06/12
For personal use only.

g, 60% based on reacted triene). Smaller scale runs were conducted in sealed tubes in toluene at 175°C for 5 h but yields were usually lower, 35–40%; ir (film): 3415 (br, OH), 1730 (C=O) cm^{-1}; ^1H nmr (CCl_4) δ: 0.49 (1H, m, cyclopropyl H), 1.0 (2H, m, cyclopropyl H), 1.6–2.0 (3H, m), 2.28 (2H, br s, bridgehead H), 2.71 (1H, d, J = 8.5 Hz, H—CCO_2CH_3), 3.50 (1H, m, H—C—OH), 3.61 (3H, s, OCH_3), 5.79 (1H, m, cyclopentadienyl H), 6.02 (1H, m, cyclopentadienyl H). *Exact Mass* calcd. for $C_{13}H_{16}O_3$: 220.1099; found: 220.1098.

*3-Acetoxy-2-carbomethoxytetracyclo[5.4.0^{1,7}.0^{4,6}.0^{6,10}]undec-8-ene (**10**)*

The triene acetate **6** (200 mg, 0.78 mmol) was dissolved in toluene (10 mL) flushed with argon and heated in a sealed tube at 175°C for 4.5 h. After the removal of the solvent under reduced pressure the product was purified by tlc (twice) (10% ethyl acetate/petroleum ether) to give 55 mg of recovered starting material and the tetracyclic acetate **10** (95 mg, 66% based on reacted triene); ir (film): 1740 (esters) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 0.39 (1H, m, cyclopropyl H), 1.18 (2H, complex, cyclopropyl H), 1.65 (2H, m, cyclohexyl H), 1.78 (1H, m), 2.01 (3H, s, $COCH_3$), 2.39 (2H, m, bridgehead H), 2.82 (1H, d, J = 8 Hz, H—C—CO_2CH_3), 3.64 (3H, s, OCH_3), 4.57 (1H, J = 7 Hz, H—C—OAc), 5.89 (1H, br m, cyclopentadienyl H), 6.15 (1H, br m, cyclopentadienyl H).

Cyclization proceeded in 75% yield in dichloromethane at 22°C (3 h) in the presence of $AlCl_3$ (1.2 equiv).

*Methyl 4-isopropyl-5-(spiro[2.4]hepta-4,6-dien-1-yl)-3-oxopentanoate (**15**)*

Methyl 5-methyl-3-oxohexanoate (**13**) (prepared from methyl acetoacetate and 2-iodopropane (17)) (1.4 g, 8.4 mmol) was added dropwise to a THF (25 mL) suspension of sodium hydride (598 mg, 60%) maintained at 0°C contained in a serum capped 100-mL flask equipped with pressure equalizing dropping funnel and magnetic stirring bar. After 10 min further stirring a hexane solution of *n*-butyllithium (6.5 mL, 14 mmol) was added dropwise creating a yellow–orange solution which was stirred at 0°C for a further 10 min. The bromide **3** (2.6 g, 14 mmol) dissolved in THF (5 mL) was added dropwise causing the colour of the dianion to fade and the reaction was slowly allowed to warm to room temperature (0.5 h). The reaction was cooled to 0°C, quenched with 3 *M* HCl (15 mL), ether (50 mL) added, and the reaction mixture poured into water/ether (1:1, 50 mL) and extracted with ether (2 × 50 mL). The combined extracts were washed with pH 7 buffer (3 × 20 mL), dried, and purified by flash chromatography (7.5% ethyl acetate/petroleum ether) to afford the keto-ester **15** (850 mg, 36%); ir (film): 1750 (CO_2CH_3), 1713 (C=O) cm^{-1}; ^1H nmr (CCl_4) δ: 0.93 (6H, overlapping singlets, $(CH_3)_2C$), 1.1–2.3 (7H, complex), 3.18, 3.29 (2H, s, OC—CH_2CO; 4.59, 4.87, s, enol H), 3.63, 3.69 (3H, s, OCH_3), 5.98 (2H, m, cyclopentadienyl H), 6.35 (2H, m, cyclopentadienyl H). *Exact Mass* calcd. for $C_{16}H_{22}O_3$: 262.1569; found: 262.1570.

*Methyl 5-(spiro[2.4]hepta-4,6-dien-1-yl)-3-oxopentanoate (**16**)*

Following the procedure outlined above, methyl acetoacetate (**14**) (4.6 g, 40 mmol, Eastman) was converted to its dianion and alkylated with the bromide **3** (3.7 g, 20 mmol) to give, after work-up and flash chromatography (15% ethyl acetate/petroleum ether), the keto-ester **16** (1.90 g, 43%); ir (film): 1748 (CO_2CH_3), 1718 (C=O) cm^{-1}; ^1H nmr (CCl_4) δ: 1.15–2.55 (7H, complex m), 3.19 (2H, s, OC—CH_2—CO), 3.59 (3H, s, OCH_3), 5.85 (1H, m, cyclopentadienyl H), 6.05 (1H, m, cyclopentadienyl H), 6.30 (2H, m, cyclopentadienyl H). *Exact Mass* calcd. for $C_{13}H_{16}O_3$: 220.1099; found: 220.1095.

*Methyl 4-isopropyl-3-hydroxy-5-(spiro[2.4]hepta-4,6-dien-1-yl)-pentanoate (**17**)*

The keto-ester **15** (2.09 g, 7.8 mmol) was dissolved in methanol (35 mL) and, after cooling to −40°C (CCl_4/solid CO_2 bath), sodium borohydride (300 mg) was added. The reaction was stirred at this temperature for 2 h and brine (25 mL) and water (25 mL) added. The solution was extracted with ether (4 × 40 mL), washed with brine, dried, and the alcohol-ester **17** obtained after flash chromatography (75% ethyl acetate/petroleum ether) (1.45 g, 70%); ir (film): 3500 (br, OH), 1735 (C=O) cm^{-1}; ^1H nmr (CCl_4) δ: 0.90 (6H, d, J = 6 Hz, $(CH_3)_2$—), 1.1–2.1 (7H, complex), 2.33 (2H, dm, J = 6 Hz, CH_2—CO), 2.77 (1H, br s, OH), 3.61 (3H, s, OCH_3), 3.95 (1H, br m, H—C—OH), 5.88 (1H, m, cyclopentadienyl H), 6.20 (3H, complex m, cyclopentadienyl H). *Exact Mass* calcd. for $C_{16}H_{24}O_3$: 264.1725; found: 264.1718.

In addition 0.45 g (22%) of a single diastereomer of the starting keto-ester **15** was separated, which was reduced separately and converted to the triene **21**.

*Methyl 3-hydroxyl-5-(spiro[2.4]hepta-4,6-dien-1-yl)pentanoate (**19**)*

The keto-ester **16** (1.9 g, 8.6 mmol) was reduced at −40°C using the procedure outlined above to afford, after flash chromatography (30% ethyl acetate/petroleum ether) the alcohol **19** (1.58 g, 83%); ir (film): 3425 (br OH), 1740 (C=O) cm^{-1}; ^1H nmr (CCl_4) δ: 1.2–2.0 (7H, complex), 2.20 (2H, br d, J = 6.5 Hz, CH_2—CO), 2.79 (1H, br s, OH), 3.61 (3H, s, OCH_3), 3.82 (1H, br m, H—C—OH), 5.85 (1H, dt, J = 5, 2 Hz, cyclopentadienyl H), 6–6.45 (3H, complex m, cyclopentadienyl H). *Exact Mass* calcd. for $C_{13}H_{18}O_3$: 222.1256; found: 222.1250.

*Methyl 4-isopropyl-3-acetoxy-5-(spiro[2.4]hepta-4,6-dien-1-yl)-pentanoate (**18**)*

Acetylation of the alcohol **17** (1.2 g, 4.5 mmol) was conducted with acetic anhydride – pyridine as outlined above to afford the diester **18** (1.22 g, 89%) after flash chromatography (15% ethyl acetate/petroleum ether); ir (film): 1747 (C=O) cm^{-1}; ^1H nmr (CCl_4) δ: 0.94 (6H, d, J = 6 Hz, $(CH_3)_2$—), 1.1–2.2 (7H, complex), 1.93 (3H, s, CH_3CO), 2.41 (2H, d, J = 6 Hz, CH_2—CO), 3.56 (3H, s, OCH_3), 5.17 (1H, br m, H—C—OAc), 5.99 (2H, m, cyclopentadienyl H), 6.29 (2H, m, cyclopentadienyl H). *Exact Mass* calcd. for $C_{18}H_{26}O_4$: 306.1830; found: 306.1842.

*Methyl 3-acetoxy-5-(spiro[2.4]hepta-4,6-dien-1-yl)pentanoate (**20**)*

Acetylation of the alcohol **19** (500 mg, 2.3 mmol) was conducted with acetic anhydride – pyridine as outlined above to give the diester **20** (560 mg, 94%) after flash chromatography (15% ethyl acetate/petroleum ether); ir (film): 1745 (C=O) cm^{-1}; ^1H nmr (CCl_4) δ: 1.1–2.0 (7H, complex), 1.92 (3H, s, CH_3—CO), 2.40 (2H, d, J = 6 Hz, CH_2—CO), 3.57 (3H, s, OCH_3), 5.96 (1H, m, H—C—OAc), 5.85 (1H, m, cyclopentadienyl H), 6.00 (1H, m, cyclopentadienyl H), 6.30 (2H, m, cyclopentadienyl H). *Exact Mass* calcd. for $C_{15}H_{20}O_4$: 264.1362; found: 264.1358.

*Methyl 4-isopropyl-5-(spiro[2.4]hepta-4,6-dien-1-yl)pentanoate (**21**)*

The acetate **18** (600 mg, 1.7 mmol) was dissolved in dry *tert*-butyl alcohol (2 mL). A freshly prepared 1 *M* solution of potassium *tert*-butoxide in *tert*-butyl alcohol (0.95 mL) was added dropwise to the stirred solution. After 1 h at room temperature the reaction was poured onto ice/water (30 mL), extracted with ether (2 × 50 mL), the combined extracts washed with water until neutral, dried, and purified by flash chromatography (7.5% ethyl acetate/petroleum ether) to give the triene **21** (335 mg, 82%); ir (film): 1727 (C=O), 1659 (C=C) cm^{-1}; ^1H nmr (CCl_4) δ: 0.86 (6H, d, J = 6.5 Hz, $(CH_3)_2C$), 1.0–2.2 (7H, br complex m), 3.58 (3H, s, OCH_3), 5.49 (1H, dd, J = 15, 8 Hz, C=CH—CO), 5.7–6.4 (4H, m, cyclopentadienyl H), 6.55 (1H, dd, J = 15, 8 Hz, CH=C—CO). In cyclization attempts the triene **21** decomposed above 215°C, and at room temperature in the presence of Lewis acids, while 65 h in xylene in a sealed tube at 200°C produced no cyclized product.

*Methyl 5-(spiro[2.4]hepta-4,6-dien-1-yl)pentanoate (**22**)*

Utilizing the analogous basic elimination procedure outlined above the acetate **20** was converted to the triene **22**. This triene **22** was recovered unchanged after 65 h at 195°C in a sealed tube in toluene; ir (film): 1727 (C=O), 1662 (C=C) cm^{-1}; ^1H nmr (CCl_4) δ: 1.25–2.4 (7H, complex), 3.60 (3H, s, OCH_3), 5.59 (1H, d t, J = 15, 7 Hz, C=CH—CO), 5.75–6.4 (4H, m, cyclopentadienyl H), 6.78 (1H, d t, J = 15, 7 Hz, CH=C—CO).

E-*Methyl 5-methyl-2-hexenoate (23)*

Isovaleraldehyde (1.0 g, 9.8 mmol, Aldrich) in dichloromethane (15 mL) was added to a tetrahydrofuran solution (15 mL) containing methyl(triphenylphosphorylidine)acetate (3.6 g, 10.8 mmol, Aldrich) and stirred under nitrogen at room temperautre for 1 h. After filtration, concentration, and trituration with petroleum ether the product was distilled, 90–91°C/20 Torr (1 Torr = 133.3 Pa), to give the ester **23**, (1.32 g, 95%); ir (film): 1722 (C=O), 1650 (C=O) cm^{-1}; ^1H nmr (CCl_4) δ: 0.90 (6H, d, J = 6.5 Hz, $(CH_3)_2$), 1.60 (1H, m, H—C$(CH_3)_2$), 2.01 (2H, m, J ~ 6 Hz, —CH_2—), 3.57 (3H, s, OCH_3), 5.60 (1H, d, J = 16 Hz, =CHCO), 6.71 (1H, dt, J = 16, 8 Hz, CH=C—CO).

E-*Methyl 5-methyl-4-bromo-2-hexenoate (24)*

N-Bromosuccinimide (1.38 g, 7.8 mmol, recrystallized, Fisher) was added to carbon tetrachloride (15 mL) followed by ester **23** (1.0 g, 7.0 mmol) in carbon tetrachloride (25 mL) and azoisobutylnitrile (0.010 g). The mixture was stirred under reflux for 18 h, filtered, concentrated, and the residue purified by distillation, bp 58–60°C/0.04 Torr, to give **24** (1.23 g, 78%); ir (film): 1722 (C=O), 1650 (C=O) cm^{-1}; ^1H nmr (CCl_4) δ: 0.90 (6H, d, J = 6 Hz, $(CH_3)_2C$), 1.95 (1H, m, J ~ 6 Hz, H—C$(CH_3)_2$), 3.68 (3H, s, OCH_3), 4.37 (1H, dd, J = 10, 6 Hz, H—C—Br), 5.80 (1H, d, J = 16 Hz, =CHCO), 6.67 (1H, dd, J = 10, 16 Hz, CH=C—CO). *Exact Mass* calcd. for $C_8H_{13}BrO_2$: 220.0098 and 222.0078; found: 220.0157 and 222.0074.

2-Methyl-5-carbomethoxy-6-hydroxy-6-(spiro[2.4]hepta-4,6-dien-1-yl)-3-hexene (26)

Magnesium (3.91 g, 163 mmol) was added to dry THF (150 mL) in a three-necked 500-mL flask equipped with a paddle stirrer. The bromo-ester **24** (19 g, 85.5 mmol) was added in small portions until the Grignard commenced, after which the remaining bromide and aldehyde **2** (9.79 g, 75 mmol) in THF (100 mL) were added dropwise simultaneously. Once the vigorous reaction had subsided the reaction was stirred for a further 2 h at room temperature and poured into saturated aqueous NH_4Cl solution (100 mL). After ether – ethyl acetate extraction (1 : 1, 3 × 100 mL), the combined extracts were dried, concentrated, and purified by flash chromatography (10% ethyl acetate/petroleum ether). This afforded a total yield of 17.96 g (91%) separated into the four C_6C_5 diastereomers as follows.

(a) *SS*,[4] 1.23 g (6.2%); ir (film): 3400–3500 (br, OH) 1725 (C=O) cm^{-1}; ^1H nmr (CCl_4) δ: 1.00 (6H, d, J = 6.5 Hz, $(CH_3)_2C$), 1.4–2.5 (4H, complex, cyclopropyl H, H—C$(CH_3)_2$), 3.21 (1H, m, CH—C=), 3.70 (3H, s, OCH_3), 3.78 (1H, br s, H—C—OH), 5.53 (2H, m, CH=CH), 6.00 (1H, m, cyclopentadienyl H), 6.38 (3H, m, cyclopentadienyl H).

(b) *RS*, 1.63, (8.3%); ir (film): 3400–3500 (br, OH), 1725 (C=O) cm^{-1}; ^1H nmr (CCl_4) δ: 0.99 (6H, d, J = 6.5 Hz, $(CH_3)_2C$), 1.5–2.5 (4H complex, cyclopropyl H, H—C$(CH_3)_2$), 3.20 (1H, m, CH—C=), 3.70 (3H, s, OCH_3), 3.81 (1H, br s, H—C—OH), 5.31–5.39 (2H, m, CH=CH), 6.01 (1H, m, cyclopentadienyl H), 6.40 (3H, m, cyclopentadienyl H).

(c) *SR*, 7.92 g (40.3%); ir (film): 3400–3500 (br, OH), 1735 (C=O), 1635 (sh, C=C) cm^{-1}; ^1H nmr (CCl_4) δ: 0.95 (6H, dd, J = 6.5 Hz, $(CH_3)_3C$—), 1.81 (2H, m, cyclopropyl H), 2.16 (2H, m, J = 6.5 Hz, cyclopropyl H, H—C$(CH_3)_2$), 2.85 (1H, m, CH—C=), 3.63 (3H, s, OCH_3), 3.80 (1H, dd, J = 4.9 Hz, H—C—OH), 5.30 (2H, m, CH=CH), 5.98 (1H, m, cyclopentadienyl H), 6.13 (1H, m, cyclopentadienyl H), 6.44 (2H, m, cyclopentadienyl H).

2-Methyl-5-carbomethoxy-6-acetoxy-6-(spiro[2.4]hepta-4,6-dien-1-yl)-3-hexene (28)

Acetic anhydride (1.08 g, 1 mL, 10.5 mmol) was added dropwise to a cold (0°C, external ice bath) solution of the appropriate alcohol **26** (1.0 g, 3.8 mmol) in dry pyridine (10 mL). The reaction mixture was stirred at 22°C for 12 h, poured into ice-cold 10% aqueous HCl – ether, the ether layer separated, washed with 10% aqueous hydrochloric acid, brine, dried, filtered, concentrated, and purified by flash chromatography (10% ethyl acetate/*n*-hexane) to give the individual acetates **28**, 1.06 g (91%); ir ($CHCl_3$): 1727 (C=O) cm^{-1}; (a) *SS*, ^1H nmr (CCl_4) δ: 0.91 (3H, s, CH_3), 1.03 (3H, s, CH_3), 1.78 (3H, s, CH_3CO), 3.09 (1H, br t, J ~ 7 Hz, CH—C=), 3.61 (3H, s, OCH_3), 4.79 (H, dd, J = 7, 8 Hz, CHOAc), 5.35 (2H, m, CH=CH), 5.90 (2H, m, cyclopentadienyl H), 6.23 (2H, m, cyclopentadienyl H); (b) *RS*, ^1H nmr (CCl_4) δ: 0.92 (3H, s, CH_3), 1.02 (3H, s, CH_3), 1.93 (3H, s, CH_3CO), 3.09 (1H, br t, J ~ 8 Hz, CH—C=), 3.61 (3H, s, OCH_3), 5.00 (1H, t, J = 8 Hz, CHOAc), 5.29 (2H, m, CH=CH), 5.81 (1H, m, cyclopentadienyl H), 6.10 (1H, m, cyclopentadienyl H), 6.28 (2H, m, cyclopentadienyl H). *Exact Mass* calcd. for $C_{18}H_{24}O_4$: 304.1674; found: 304.1642. (c) *SR*, ^1H nmr (CCl_4) δ: 0.86 (3H, s, CH_3), 1.00 (3H, s, CH_3), 1.99 (3H, s, CH_3CO), 2.80 (1H, m, CHC=), 3.62 (3H, s, OCH_3), 4.8–5.25 (3H, m, CHOAc, CH=CH), 5.84 (1H, m, cyclopentadienyl H), 6.25 (3H, m, cyclopentadienyl H). *Exact Mass* calcd. for $C_{18}H_{24}O_4$: 304.1674; found: 304.1666. (d) *RR*, ^1H nmr (CCl_4) δ: 0.84 (3H, s, CH_3), 0.94 (3H, s, CH_3), 2.00 (3H, s, CH_3CO), 3.10 (1H, dd, J ~ 8 Hz, CHC=), 3.59 (3H, s, OCH_3), 4.85–5.5 (3H, m, CHOAc, CH=CH), 5.89 (1H, m, cyclopentadienyl H), 6.35 (3H, m, cyclopentadienyl H); (400 MHz, $CDCl_3$) δ: 0.85, 0.89 (3H, d, J = 7 Hz, $(CH_3)_2$), 1.68 (1H, dd, J = 4.5, 8.5 Hz, cyclopropyl H), 1.84 (1H, dd, J = 4.5, 7.5 Hz, cyclopropyl H), 2.03 (1H, m, H—CMe_2), 2.08 (3H, s, CH_3CO), 2.16 (1H, m, cyclopropyl H), 3.22 (1H, br t, J ~ 2.9 Hz, CHC=), 3.66 (3H, s, OCH_3), 5.00 (1H, m, J = 2, 9, 16 Hz, HC=C), 5.18 (1H, dd, J = 1, 9 Hz, HC—OAc), 5.48 (1H, m, J = 1, 6, 16 Hz, C=CHiPr), 6.00 (1H, m, cyclopentadienyl H), 6.38 (1H, m, cyclopentadienyl H), 6.43 (1H, m, cyclopentadienyl H), 6.52 (1H, m, cyclopentadienyl H). Decoupling the isopropyl methyl signals revealed the location of the methine proton (2.03) which was itself coupled to the olefinic signal at 5.48. *Exact Mass* calcd. for $C_{18}H_{24}O_4$: 304.1674; found: 304.1661.

2-Pentyl-3-acetoxy-4-carbomethoxy-7-methyloctane (29)

Acetate **28** (0.5 g, 1.65 mmol) was dissolved in anhydrous methanol (25 mL), catalyst added (100 mg, 10% Pd/C), and the mixture placed in a Paar apparatus under 2.5 atm of hydrogen for 7 h. The catalyst was removed by filtration, washed with methanol, and the combined filtrate and methanol washings concentrated and subjected to flash chromatography (10% ethyl acetate/*n*-hexane) to give the diastersomeric esters **29**, 0.47 g (93%); ir (film): 1735 (esters) cm^{-1}; ^1H nmr (CCl_4) δ: 0.87, 0.99 (9H, overlapping doublets, J ~ 7 Hz, CH_3's), 2.02, (3H, s, CH_3CO), 2.53 (1H, m, CH—C=O), 3.67 (3H, s, OCH_3), 5.22 (1H, dd, J ~ 9 Hz, CHOAc). Decoupling experiments indicated that the signals at 2.53 and 5.22 were coupled to each other.

2-Carbomethoxy-11-isopropyltetracyclo[5.4.0^{1,7}.0^{4,6}.0^{6,10}]undec-8-en-3-acetate (30)

The triene acetate **28** (1.02 g, 3.35 mmol) was refluxed under nitrogen in *p*-dichlorobenzene (40 mL) for 20 h, the solvent removed under reduced pressure, and the residual oil purified by flash chromatography (4% ethyl acetate/*n*-hexane) to give the adduct **30**, 0.615 g (60%), and recovered triene **28**, 0.30 g (29%); ^1H nmr (CCl_4) δ: 0.39 (1H, m, J ~ 7 Hz, cyclopropyl H), 1.95 (3H, s, CH_3CO), 2.30 (2H, br s, bridgehead H), 2.84 (1H, d, J = 9 Hz, $CHCO_2Me$), 3.62 (3H, s, OCH_3), 4.57 (1H, t, J = 8.5 Hz, CHOAc), 5.98 (2H, br s, CH=CH). *Exact Mass* calcd. for $C_{18}H_{24}O_4$: 304.1674; found: 304.1672.

Alternatively the triene **28** (0.818 g, 2.69 mmol) was dissolved in

[4] These configurational assignments are tentative since the diastereomers have not been degraded to a compound of known absolute configuration.

dichloromethane (10 mL) and a solution (dichloromethane/ether, 2:1, 30 mL) of aluminium chloride (0.430 g, 3.22 mmol) added. The reaction mixture was stirred for 0.5 h, pyridine (3 mL) added, the solvent removed, and the residue purified by flash chromatography (10% ethyl acetate/*n*-hexane) to afford **30**, 0.205 g (25%).

The cyclization of the acetate isomers **28** was examined individually but only the C_6C_5 *RR* and *SR* diastereomers afforded the Diels–Alder adduct **30**.

Received January 9, 1984

SAMUEL K. ATTAH-POKU, KAZIMIERZ ANTCZAK, SANDRA J. ALWARD, and ALEX G. FALLIS. Can. J. Chem. **62**, 1717 (1984).

The reactivity of the tetracyclic cyclopropyl compounds **1**, **8**, **9**, **10**, and **15** has been investigated and general routes to the "sinularene" and "longifolene" skeletons developed. Hydrogenolysis cleaves the least substituted cyclopropane bond ("a") to give the tricyclo[4.4.0^{1,6}.0^{5,9}]decane (sinularene) ring systems **5** and **6**. Lithium–ammonia and zinc – zinc chloride reduction affords both tricyclic ketones **11** and **13** and **12** and **14** while chromium sulphate in 1 : 1 dimethyl formamide/water gives the tricyclo[5.4.0^{1,7}.0^{6,10}]undecene (longifolene) skeleton **14** exclusively (cleavage of bond "b") from ketone **9**.

SAMUEL K. ATTAH-POKU, KAZIMIERZ ANTCZAK, SANDRA J. ALWARD et ALEX G. FALLIS. Can. J. Chem. **62**, 1717 (1984).

On a étudié la réactivité des composés tétracycliques contenant des cyclopropyles, **1**, **8**, **9**, **10** et **15** et on a mis au point des voies d'accès générales aux squelettes "sinularène" et "longifolène". Par hydrogénolyse, on clive la liaison la moins substituée ("a") du cyclopropane et l'on obtient les systèmes tricyclo[4.4.0^{1,6}.0^{5,9}]décane (sinularène) **5** et **6**. La réduction par l'ammoniac et le lithium ou par le zinc et le chlorure de zinc fournissent les deux cétones tricycliques **11** et **13**, **12** et **14**; toutefois la réduction par le sulfate de chrome dans un mélange 1 : 1 de diméthylformamide/eau conduit exclusivement au squelette tricyclo[5.4.0^{1,7}.0^{6,10}]undécène (longifolène) **14** à partir de la cétone **9** (clivage de la liaison "b").

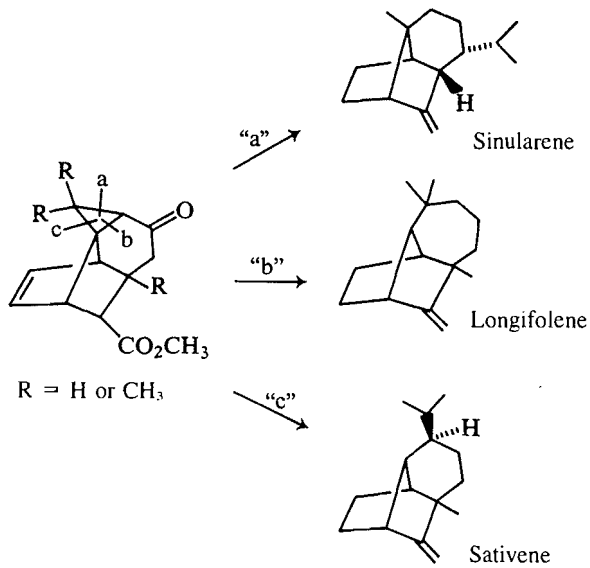
[Traduit par le journal]

Introduction

Controlled cleavage of cyclopropane intermediates provides a useful method for the total synthesis of multicyclic natural products and has been successfully employed in the stereocontrolled syntheses of (±) hinesol and (±) epihinesol (1), and (−)-acorenone B and (±) α-chamigrene (2). The preceding paper (3) outlines our general approach, using an intramolecular Diels–Alder sequence, to the tricyclic skeletons represented in nature by sinularene, longifolene, and sativene (copacamphene) (Scheme 1). This strategy requires, after construction of the appropriate tetracyclic precursor, selective cyclopropane bond cleavage (a, b, or c) to afford the desired tricyclic ring systems. The results of these studies, which permit controlled rupture of bond "a" or "b", are outlined below (4).[1]

Results and discussion

At the outset of this study it was anticipated that the strain inherent in the three-membered ring confined in the tetracyclo[5.4.0^{1,7}.0^{4,6}.0^{6,10}]undecene skeleton **1** would facilitate cleavage under a variety of conditions. In addition, during solvolysis procedures the presence of the double bond should help stabilize the presumed "C_7-norbornyl type" carbonium ion intermediates for a synthetic sequence leading to the "longifolene" ring system. Unfortunately, in practice neither of these objectives was experimentally feasible and treatment of the alcohol **1** or its tosylate (both epimers separately) under a variety of acidic and solvolytic conditions failed to provide ring-opened products in spite of related literature precedent (5). Similarly, reaction of the bromide with magnesium, lithium, and zinc salts did not afford the desired ring-opened olefins although these reactions proceed readily with less complex systems (6). Likewise, the phosphonate prepared from **1** underwent reduction with lithium napthalide but carbon–carbon bond cleavage did not result. Although disappointing, this latter result is not entirely surprising since the best success with this reagent has been achieved for cyclobutane ring fission (7).



SCHEME 1

It is well established that hydrogenolysis of cyclopropanes gives, as the predominant products, compounds which result from preferential cleavage of the least substituted bond (8). Treatment of alcohol **1** with hydrogen at 3 atm (1 atm = 101.3 kPa) in acetic acid in the presence of PtO_2 catalyst afforded a 90% yield of **5** resulting, as expected, from rupture of the least substituted bond "a", to give the tricyclo[4.4.0^{1,6}.0^{5,9}]decane (sinularene) compound as the only product.

In contrast to the general lack of reactivity of the compounds above, further activation of the cyclopropane unit, achieved by Jones' oxidation of the alcohol **1** to the cyclopropyl ketone **8**, provided a system very susceptible to cleavage. Hydrogenolysis occurred under mild conditions in methanol at room temperature using 10% Pd/C catalyst to give the "sinularene"

[1] Please note that the substituents in our preliminary communication were attached incorrectly to C_{11} rather than C_2 of the adducts.

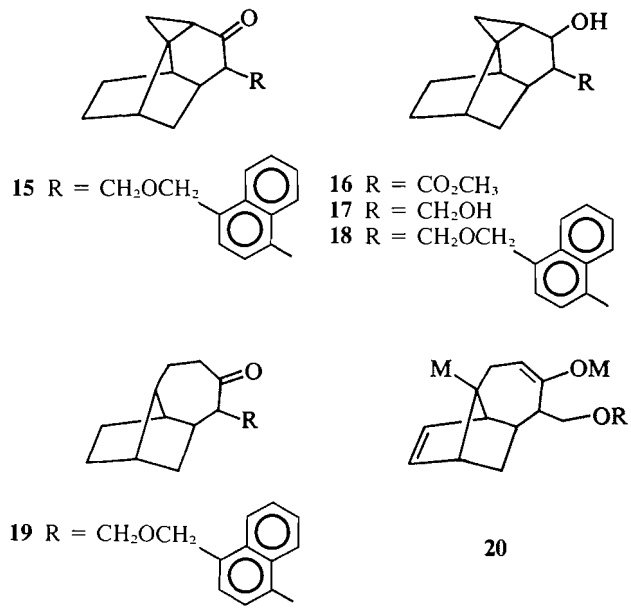
ketone **6** exclusively (95%).

Dissolving metal reductions of cyclopropyl ketones are subject to a variety of influences. Cleavage of the most substituted σ bond is frequently favoured, as this will afford the more thermodynamically stable carbanion intermediate although, in this case, it would involve the formation of a bridgehead carbanion. An important stereoelectronic factor concerns the relative orientation of the cyclopropane bonds and the carbonyl function. In general a preference is observed for cleavage of the cyclopropane bond which overlaps most efficiently with the π orbital of the carbonyl group (9). Molecular models imply that the difference between the least (a) and most substituted (b) bonds relative to the carbonyl is modest with a slight preference in favour of fission of "a" although a mixture of products is likely to result. In keeping with this analysis, lithium–ammonia reduction of **10**, in the presence of *tert*-butyl alcohol, afforded a mixture of the sinularene (74%) and longifolene (21%) type ketones **11** and **13**.

Often the metal and the solvent influence the course of these reactions and it was of interest to discover that zinc and chromium changed the above ratio. Treatment of **9** with zinc in methanol in the presence of zinc chloride (10) afforded the sinularene type ketone **12** (25%) as the minor and the longifolene type ketone **14** (75%) as the major products. The dominance of the longifolene product suggests that an intermediate salt of type **20**, in which the double bond plays a coordinating role, may be involved.

Solutions containing salts of chromium(II) ion are known to reduce conjugated enones under certain conditions (11, 12) but the reactions of cyclopropyl ketones under these conditions do not appear to have been investigated. Exposure of **9** to a solution of $CrSO_4$ in 2:1 dimethylformamide – water afforded the longifolene type ketone **14** (84%) as the only product. In contrast, the saturated ketone **15** gave a mixture of both **7** and **19** (20:80) under identical reaction conditions and reacted more slowly. It appears that the double bond exerts a beneficial influence in directing cleavage of the most substituted bond ("b"). Cyclopropyl methyl ketone reacted very sluggishly under these conditions to give a low yield of 2-pentanone, thus further establishing the importance of the double bond. It is



likely that a more active form of Cr(II), possibly as a diamine complex (12), will be required for chromium to be generally useful for cyclopropane cleavage. In keeping with mechanistic studies by House and Kinlock (12), an intermediate species such as **20**, in which the solvated chromium at the bridgehead is favourably disposed for interaction with the π system of the olefin, accounts for our results. In a related case, recent calculations (13) have indicated that the lithium in 7-lithionorbornadiene is strongly coordinated to the neighbouring π bond and bicyclic nickelocene complexes display similar stabilization (14).

The compounds required for this study were prepared from the intramolecular Diels–Alder adduct **1** (3). Lithium aluminum hydride reduction of ester **1** gave the diol **2** in which the primary alcohol group could be selectively protected with either 1-chloromethyl-4-methylnaphthalene or 1-chloropropane in the presence of sodium hydride to give **3** and **4** respectively. Jones' oxidation of the appropriate alcohols **1**, **3**, and **4** pro-

TABLE 1. Product distribution from reductive cyclopropane cleavage

Compound	Reagent	Products	
		"Sinularene type"	"Longifolene type"
1	$H_2/PtO_2/HOAc$ 3 atm	**5** (90%)	0
8	$H_2/Pd/C/MeOH$ 1 atm	**6** (95%)	0
10	$Li/NH_3/t$BuOH	**11** (74%)	**13** (21%)
9	$Zn/ZnCl_2/MeOH$	**12** (25%)	**14** (75%)
9	$CrSO_4/Zn$ DMF/H_2O	0	**14** (84%)
15	$CrSO_4/DMF/H_2O$	**7** (20%)	**19** (79%)

vided the ketones **8**, **9**, and **10**. Compound **15** was prepared in a similar manner from a sample of **1** in which the double bond was first saturated by hydrogenation over 10% Pd/C in methanol at room temperature to give **16**, followed by lithium aluminum hydride reduction to **17**, selective ether formation to give **18**, and Jones' oxidation.

As summarized in Table 1, these ring-opening studies allow controlled cyclopropane ring cleavage to either the tricyclo[4.4.$0^{1,6}$0^{5,9}]decane (sinularene) skeleton under hydrogenolysis conditions or to the tricyclo[5.4.$0^{1,7}$.$0^{6,10}$]undecane (longifolene) ring system using chromium sulphate. This methodology has laid the groundwork for our approach to the total synthesis of sinularene and we are currently engaged in further extensions of this chemistry via a total synthesis of chiral longifolene from ascorbic acid (Vitamin C).

Experimental

Melting points were determined in capillary tubes with a Thomas–Hoover Uni-Melt apparatus or a Fischer–John's melting point apparatus and are uncorrected. Infrared spectra were recorded on a Perkin–Elmer 237B or 451 grating spectrophotometer, and were calibrated with the 2850 and 1601 cm^{-1} bands of polystyrene film. Ultraviolet spectra were recorded on a Perkin–Elmer 202 uv–visible spectrophotometer and were calibrated with the 279.4-nm band of a Holmium oxide filter. Proton magnetic resonance spectra were measured at 80 MHz with a Bruker model WP80 spectrometer employing a chloroform lock or at 60 MHz with a Varian model EM-360 spectrometer. Signal positions are reported in ppm downfield from tetramethylsilane (δ scale) as an internal standard; the number of protons, multiplicity, coupling constants, and proton assignments are indicated in parentheses. Mass spectra were determined on a V.G. Micromass 7070 HS instrument using an ionization energy of 70 eV. Gas–liquid chromatographic analyses were conducted on a Hewlett Packard 402B gas chromatograph equipped with a column (3 m × 6 mm id) containing 1.5% OV-17 supported on Gas Chrom Q using helium as the carrier gas. Thin-layer chromatographic analyses were carried out on commercial precoated silica gel plates with fluorescent indicator (Eastman Kodak silica gel 13181). Preparative thin-layer chromatography was conducted on 20 × 20 cm glass plates coated with silica gel $PF_{254+366}$ type 60 (E. Merck). Flash chromatography used BDH silica gel Kieselgel 60, 230–400 mesh (15).

Solutions in organic solvents were dried over anhydrous magnesium sulphate and stripped of solvent with a Büchi rotary evaporator connected to a water aspirator. Unless otherwise indicated, all reactions were conducted under argon.

2-Carbomethoxy-5-methyltricyclo[4.4.$0^{1,6}$.$0^{5,9}$]decan-3-ol (5)

The cyclopropyl alcohol **1** (0.25 g, 1.1 mmol) (3) in acetic acid (20 mL), to which 10% PtO_2/C (10 mg) had been added, was placed in a Parr apparatus under 3 atm of hydrogen for 12 h at room temperature. The reaction mixture was diluted with ether (50 mL), filtered, and the filtrate neutralized with saturated aqueous sodium bicarbonate solution and extracted with ether. The ethereal extracts were washed with brine, dried, filtered, concentrated, and the product purified by flash chromatography (20% ethyl acetate/petroleum ether) to give **5** (0.225 g, 90%); ir ($CHCl_3$): 3480 (br, OH), 1716 (C=O) cm^{-1}; ^{1}H nmr (CCl_4) δ: 0.96 (3H, s, CH_3), 3.20 (1H, d, J = 7 Hz, H—C—CO_2Me), 3.60 (3H, s, OCH_3), 3.98 (1H, m, J ~ 6 Hz). *Exact Mass* calcd. for $C_{13}H_{20}O_3$: 224.1412; found: 224.1406.

2-Carbomethoxytetracyclo[5.4.$0^{1,7}$.$0^{4,6}$.$0^{6,10}$]undec-8-en-3-one (8)

The tetracyclic alcohol **1** (0.5 g, 2.7 mmol) was dissolved in acetone (25 mL) and Jones reagent (2 mL, prepared from chromium trioxide (7.0 g), H_2O (50 mL), and concentrated H_2SO_4 (6.1 mL)) added dropwise. The resulting mixture was stirred at room temperature for 15 min and sodium hydrosulfide added until the yellow colour discharged. The reaction mixture was filtered, and the filtrate concentrated to ~1 mL and extracted with ether. The ether extracts were washed with brine, dried, concentrated, and purified by flash chromatography (16% ethyl acetate/petroleum ether) to give the keto-ester **8** (0.439 g, 88%); ir (film): 1740 (CO_2CH_3), 1717 (C=O) cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 1.1–2.3 (6H, complex), 2.65 (2H, br s, bridgehead H), 3.53 (1H, br s, H—C—CO_2CH_3), 3.70 (3H, s, OCH_3), 6.13 (2H, br m, HC=CH). *Exact Mass* calcd. for $C_{13}H_{14}O_3$: 218.0943; found: 218.0944.

2-Carbomethyoxy-5-methyltricyclo[4.4.$0^{1,6}$.$0^{5,9}$]decan-3-one (6)

(a) *Oxidation of 5*

Jones reagent (1 mL) was added dropwise over 5 min to a stirred solution of the alcohol **5** (0.25 g, 1.2 mmol) in acetone (20 mL). Stirring was continued for a further 10 min, 2-propanol (1 mL) was added to consume excess oxidant, the reaction mixture concentrated, the residue (~2 mL) extracted with ether, the ethereal extracts washed with water, brine, dried, filtered, concentrated, and the product purified by flash chromatography (5% ethyl acetate/petroleum ether) to give the ketone **6** (0.175 g, 71%); ir ($CHCl_3$): 1733 (C=O), 1710 (C=O), 1640 (C=O), 1610 (C=O) cm^{-1}; ^{1}H nmr (CCl_4) δ: 1.03 (3H, s, CH_3), 3.06 and 3.29 (1H, d, J = 3 Hz, br s, $W_{1/2}$ = 4 Hz, H—C—CO_2CH_3), 3.65 (3H, s, OCH_3). *Exact Mass* calcd. for $C_{13}H_{18}O_3$: 222.1256; found: 222.1227.

(b) *Reduction of 8*

Hydrogenation of cyclopropyl ketone **8** (0.25 g, 1.1 mmol) was conducted in methanol (10 mL) using 10% Pd/C (20 mg) at atmospheric pressure and room temperature for 12 h. The reaction mixture was filtered, concentrated, and purified by flash chromatography (5% ethyl acetate/petroleum ether) to give ketone **6** (0.238 g, 95%).

2-Hydroxymethyltetracyclo[5.4.$0^{1,7}$.$0^{4,6}$.$0^{6,10}$]undec-8-en-3-ol (2)

The hydroxy-ester **1** (4.37 g, 19.7 mmol) (3) in ether (50 mL) was added dropwise to a cold (0°C), stirred, suspension of lithium aluminum hydride (2.24 g, 59 mmol, Aldrich) in ether (50 mL). After addition was complete the ice-bath was removed and the reaction mixture stirred at room temperature for 2 h, the ice bath replaced, and water (5 mL) added cautiously. This was followed by THF (200 mL) and anhydrous sodium sulfate; stirring was continued for 30 min, the mixture filtered, and the residue washed thoroughly with THF. The filtrates were concentrated and purified by flash chromatography on silica gel (60% ethyl acetate/petroleum ether) to give the diol **2** (3.63 g, 95%), mp 176–177°C; ^{1}H nmr ($CDCl_3$) δ: 0.47 (1H, m, cyclopropyl H), 0.74–2.4 (7H, complex), 3–4 (5H, complex, H—C—OH), 5.81 (1H, m, HC=C), 6.18 (1H, dd, HC=C, J = 3, 5 Hz).

2-(4-Methyl-1-methyloxynaphthyl)methyltetracyclo-[5.4.$0^{1,7}$.$0^{4,6}$.$0^{6,10}$]undec-8-en-3-ol (3)

The diol **2** (0.80 g, 4.2 mmol) in THF (10 mL) was added to a cold (0°C) stirred suspension of sodium hydride (0.50 g, 10.4 mmol, Aldrich, 60% dispersion in oil) in THF (10 mL). After 5 min hexamethylphosphoramide (5 mL, Aldrich) was added, followed by 1-(chloromethyl)-4-methylnapthalene (0.833 g, 4.4 mmol, Aldrich) in THF (5 mL), the ice bath was removed, and stirring continued at room

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.105 on 09/06/12
For personal use only.

temperature for 24 h. The ice bath was replaced, water (1 mL) added slowly, and the reaction mixture poured into cold (0°C) 10% aqueous hydrochloric acid and extracted with ether (2×). The combined extracts were washed with brine, dried, filtered, concentrated, and purified by flash chromatography (15% ethyl acetate/petroleum ether) to give the hydroxy-ether **3** (1.23 g, 85%) which was recrystallized from acetone/petroleum ether (1:10), mp 142–143°C; ir ($CHCl_3$): 3560 (sh, OH), 3575 (br, OH) cm^{-1}; ^1H nmr (CCl_4) δ: 0.35 (1H, m, cyclopropyl H), 0.6–2.3 (8H, complex), 2.59 (3H, s, CH_3—Ar), 3.04 (2H, m, H—C—OH, OH), 3.47 (2H, m, CH_2—O), 4.77 (2H, s, O—CH_2Ar), 5.72 (1H, m, CH=C), 6.00 (1H, m, CH=C), 7.16 (2H, m, Ar), 7.39 (2H, m, Ar), 7.90 (2H, m, Ar). *Exact Mass* calcd. for $C_{24}H_{26}O_2$: 346.1933; found: 346.1926.

2-(1-Oxypropyl)methyltetracyclo[5.4.0^{1,7}.0^{4,6}.0^{6,10}]undec-8-en-3-ol (4)

The diol **2** (0.749 g, 3.9 mmol) was converted to the hydroxypropyl ether **4** using sodium hydride and 1-chloropropane following the procedure outlined above. Flash chromatography of the product (20% ethyl acetate/*n*-hexane) afforded **4**, 630 mg (69%); ir ($CHCl_3$): 3475 (OH), 1050–1100 (C—O) cm^{-1}; ^1H nmr (CCl_4) δ: 0.38 (1H, m, cyclopropyl H), 0.88 (3H, t, J = 7 Hz, CH_3CH_2), 2.9–3.5 (5H, m, CH_2—O, HC—OH), 5.61 (1H, m, HC=), 5.94 (1H, m, HC=). Further elution (60% ethyl acetate/*n*-hexane) gave 135 mg (18%) of the unreacted diol **2**.

2-(4-Methyl-1-methyloxynaphthyl)methyltetracyclo-[5.4.0^{1,7}.0^{4,6}.0^{6,10}]undec-8-en-3-one (9)

Jones reagent (1.5 mL) was added dropwise over 10 min to a stirred solution of the alcohol **3** (0.50 g, 2.3 mmol) in acetone (50 mL). Stirring was continued for a further 5 min, 2-propanol was added until the yellow colour was discharged, the reaction mixture filtered, the residue washed with ether, the filtrate concentrated, and further ether added. The ethereal solution was washed with water, brine, dried, filtered, concentrated, and the product purified by flash chromatography (10% ethyl acetate/petroleum ether) to give **9** (0.348 g, 70%) which was recrystallized from carbon tetrachloride/petroleum ether, mp 135–136°C; ir ($CHCl_3$): 1704 (C=O) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 2.68 (3H, s, CH_3—Ar), 3.67 (2H, m, CH_2O), 4.89 (2H, s, O—CH_2Ar), 5.88 (1H, m, CH=C), 6.12 (1H, m, CH=C), 7.21 (2H, m, Ar), 7.43 (2H, m, Ar), 7.98 (2H, m, Ar). *Exact Mass* calcd. for $C_{24}H_{24}O_2$: 344.1776; found: 344.1781.

2-(1-Oxypropyl)methyltetracyclo[5.4.0^{1,7}.0^{4,6}.0^{6,10}]undec-8-en-3-one (10)

Oxidation of alcohol **4** (319 mg, 1.36 mmol) was accomplished as outlined above to give, after flash chromatography (15% ethyl acetate/*n*-hexane), the ketone **10**, 260 mg (82%); ir ($CHCl_3$): 1700 (C=O), 1115 (C—O) cm^{-1}; ^1H nmr (CCl_4) δ: 0.91 (3H, t, J = 7 Hz, CH_3CH_2), 2.55 (2H, br m, CH_2C=O), 3.14–3.74 (4H, m, CH_2—O), 5.97 (1H, m, HC=), 6.10 (1H, m, HC=C).

2-(4-Methyl-1-methyloxynaphthyl)methyl-5-methyltricyclo-[4.4.0^{1,6}.0^{5,9}]decan-3-one (7)

Hydrogenation of cyclopropyl ketone **9** (0.50 g, 1.45 mmol) was conducted in methanol/ethyl acetate (1:1, 50 mL) with 10% Pd/C (50 mg) at atmospheric pressure and 23°C for 12 h. Filtration, concentration, and flash chromatography (10% ethyl acetate/petroleum ether) afforded the ketone **7** (0.353 g, 70%); ir ($CHCl_3$): 1706 (C=O) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 0.81 (3H, s, CH_3), 2.62 (3H, s, CH_3Ar), 3.60 (2H, d, J = 7 Hz, —CH_2—O), 4.73 (2H, s, O—CH_2—Ar), 7.19 (2H, m, Ar), 7.38 (2H, m, Ar), 7.88 (2H, m, Ar). *Exact Mass* calcd. for $C_{24}H_{28}O_2$: 348.2089; found: 348.2083.

Zinc Reduction of Ketone 9

Zinc powder (78.5 mg, 1.2 mmol) and zinc chloride (16 mg, 0.12 mmol) were added to a methanol solution (5 mL) of the cyclopropyl ketone **9** (40 mg, 0.12 mmol) and stirred at 23°C for 18 h. Ethyl acetate (20 mL) was added, the mixture was filtered, concentrated, extracted with ether, the combined extracts washed with water, brine, dried, filtered, concentrated, and the product purified by flash chromatography (10% ethyl acetate/petroleum ether) to afford **14** (30 mg, 75%) and **12** (10 mg, 25%). Hydrogenation of the minor component **12** (10% Pd/C, MeOH, 23°C) gave **19**.

2-(4-Methyl-1-methyloxynaphthyl)methyltricyclo[5.4.0^{1,7}.0^{6,10}]-undec-8-en-3-one (14)

Chromium(II) sulfate (0.73 g, 1.6 mmol) and zinc powder (0.5 g, 7.7 mmol) were added to the cyclopropyl ketone **9** (49 mg, 0.14 mmol) in dimethylformamide/water (2:1) (13 mL) and stirred at room temperature for 1 h. Ether (20 mL) was added, the reaction mixture was filtered, the organic phase separated, washed with brine, dried, filtered, concentrated, and the product purified by flash chromatography (15% ethyl acetate/petroleum ether) to give ketone **14** (42 mg, 84%).

Alternatively the reduction was conducted in dimethylformamide–water (12:1) (13 mL) with added chromium(II) sulfate solution (5 mL, 0.02 *M*) for 1 h at room temperature and worked up as above to give **14** (40 mg, 80%); ir ($CHCl_3$): 1710 (C=O) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 2.64 (3H, s, CH_3Ar), 3.75 (2H, m, CH_2—O), 4.81 (2H, s, O—CH_2Ar), 5.84 (1H, m, CH=C), 6.14 (1H, m, CH=C), 7.19 (2H, m, Ar), 7.45 (2H, m, Ar), 7.97 (2H, m, Ar).

Lithium/ammonia reduction of ketone 8

A THF solution (5 mL) containing *tert*-butyl alcohol (240 mg, 3.25 mmol) and the cyclopropyl ketone **8** (150 mg, 0.65 mmol) was added to a stirred solution of lithium (45 mg, 6.5 mmol) in liquid ammonia at −78°C. After 1 h the carbon dioxide – acetone bath was removed and the reaction mixture warmed to room temperature (~1 h). Ether (30 mL) was added followed by methanol (2 mL) and water (10 mL), the reaction acidified with 10% aqueous hydrochloric acid, the mixture extracted with ether, the ether extracts washed with brine, dried, filtered, concentrated, and the products purified by flash chromatography (10% ethyl acetate/petroleum ether) to give the bridged cyclohexanone **11**, 112 mg (74%); ir ($CHCl_3$): 1700 (C=O) cm^{-1}; ^1H nmr (CCl_4) δ: 0.91 (3H, t, J = 7 Hz, CH_3—CH_2), 1.02 (3H, s, CH_3—C), 2–2.8 (6H, complex, bridgehead H, CH_2C=O), 3.40 (4H, m, CH_2—O), 6.01 (2H, br s, CH=CH), and the bridged cycloheptanone **13**, 32 mg (21%); ir ($CHCl_3$): 1695 (C=O) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 0.7–1.9 (10H, complex), 1.9–2.9 (6H, complex, bridgehead H, CH_2C=O), 3.48 (4H, m, CH_2—O), 5.94 (2H, br s, CH=CH).

2-(4-Methyloxynaphthyl)methyltetracyclo[5.4.0^{1,7}.0^{4,6}.0^{6,10}]-undecan-3-one (15)

Jones reagent (0.75 mL) was added dropwise over 5 min to a stirred solution of the alcohol **18** (0.25 g, 1.1 mmol) in acetone (25 mL). Stirring was continued for a further 5 min, 2-propanol (0.5 mL) was added to decompose excess oxidant, the reaction mixture concentrated, the residue extracted with ether, the ethereal extracts washed with water, brine, dried, filtered, concentrated, and the product purified by flash chromatography (10% ethyl acetate/petroleum ether) to afford the ketone **15** (0.199 g, 80%), mp 78–80°C; ir ($CHCl_3$): 1705 (C=O) cm^{-1}; ^1H nmr (CCl_4) δ: 2.53 (3H, s, CH_3—Ar), 3.38 (2H, m, CH_2—O), 4.65 (2H, s, OCH_2Ar), 7.05 (2H, m, Ar), 7.25 (2H, m, Ar), 7.78 (2H, m, Ar). *Exact Mass* calcd. for $C_{24}H_{26}O_2$: 346.1933; found: 346.1974.

Chromium reduction of cyclopropylketone 15

A solution of chromium(II) sulphate in water (5 mL, 0.02 *M*) was added dropwise to a DMF solution (10 mL) of the cyclopropylketone **15** (40 mg, 0.12 mmol) and the reaction stirred at 23°C for 4 h. The reaction mixture was extracted with ether, the combined extracts washed with water, brine, dried, filtered, concentrated, and the products purified by flash chromatography (10% ethyl acetate/petroleum ether) to give **7** (8.0 mg, 20%) and **19** (32 mg, 79%); ^1H nmr ($CDCl_3$) δ: 2.68 (3H, s, CH_3Ar), 3.3–3.9 (2H, m, CH_2—O), 4.91 (2H, s, OCH_2Ar), 7.30 (2H, m, Ar), 7.53 (2H, m, Ar), 8.07 (2H, m, Ar).

2-Hydroxymethyltetracyclo[5.4.0^{1,7}.0^{4,6}.0^{6,10}]undecan-3-ol (17)

The unsaturated hydroxy-ester **1** (0.50 g, 2.2 mmol) was hydrogenated in methanol (25 mL) containing 10% Pd/C (25 mg) at 23°C

for 4 h. The reaction mixture was diluted with ether (50 mL), filtered, concentrated, and purified by flash chromatography (20% ethyl acetate/petroleum ether) to give the saturated hydroxy-ester **16** (0.48 g, 95%); ir ($CHCl_3$): 3560 (OH), 3400–3500 (br sh, OH), 1725 (sh, C=O), 1705 (C=O) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 0.48 (1H, m, cyclopropyl H), 2.92 (1H, s, CH—CO_2Me), 3.57 (1H, m, H—C—OH), 3.69 (3H, s, OCH_3). The hydroxy-ester (0.44 g, 1.97 mmol) in ether (5 mL) was added dropwise to a stirred suspension of lithium aluminum hydride (0.224 g, 5.9 mmol) in ether (5 mL) at 0°C. Once addition was complete the ice-bath was removed and the reaction stirred at room temperature for 1.5 h, the reaction cooled, and water (0.5 mL) added carefully followed by anhydrous THF (20 mL) and anhydrous sodium sulphate. The mixture was stirred for a further 0.5 h, filtered, the residue washed thoroughly with THF, and the filtrate concentrated and purified by flash chromatography (60% ethyl acetate/petroleum ether) to give **17** (0.34 g, 90%); ir ($CHCl_3$): 3585 (OH), 3350–3450 (br, OH) cm^{-1}; ^1H nmr (CCl_4) δ: 0.59 (1H, m, cyclopropyl H), 3.73 (2H, br d, J = 5 Hz, CH_2—O), 4.45 (1H, br t, J = 4 Hz, HC—O).

2-(4-Methyl-1-methyloxynaphthyl)methyltetracyclo-[5.4.0^{1,7}.0^{4,6}.0^{6,10}]undecan-3-ol (18)

The diol **17** (0.80 g, 4.2 mmol) in THF (10 mL) was added to a cold (0°C) stirred suspension of sodium hydride (0.5 g, 10.4 mmol, Aldrich 60% dispersion in oil) in THF (10 mL). After 5 min hexamethylphosphoramide (5 mL, Eastman) was added, followed by 1-(chloromethyl)-4-methyl naphthalene (0.832 g, 4.4 mmol, Aldrich) in THF (5 mL), the ice bath was removed, and stirring continued at room temperature for 24 h. The ice bath was replaced, water (1 mL) added slowly, and the reaction mixture poured into cold (0°C) 10% aqueous hydrochloric acid and extracted with ether (2×). The combined extracts were washed with brine, dried, filtered, concentrated, and purified by flash chromatography (15% ethyl acetate/petroleum ether) to give the hydroxy-ether **18** (1.02 g, 70%); ir ($CHCl_3$): 3575 (sh, OH), 3450–3500 (OH) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 0.45 (1H, m, cyclopropyl H), 0.65–2.0 (12H, complex), 2.60 (3H, s, CH_3—Ar), 2.88 (1H, br, s, OH), 3.17 (1H, m, H—C—OH), 3.49 (2H, m, CH_2—O), 4.84 (2H, s, O—CH_2Ar), 7.16 (2H, m, Ar), 7.43 (2H, m, Ar), 7.96 (2H, m, Ar). *Exact Mass* calcd. for $C_{24}H_{28}O_2$: 348.2089; found: 348.2092.

Aqueous solutions of L-glutamine, L-asparagine, sodium L-glutamate, sodium L-aspartate, L-serine, and L-threonine were γ-irradiated in the presence of a spin trap, 2-methyl-2-nitrosopropane. Stable spin adducts produced in the irradiated solutions were analyzed by the spin-trap hplc–esr method. The spin adducts of the following short-lived radicals were found and identified: $H_2NCOCH_2\dot{C}H_2CHCOO^-$ (**1**), $H_2NCOCH_2CH_2\dot{C}(NH_3^+)COO^-$ and $H_2NCO\dot{C}HCH_2CH(NH_3^+)COO^-$ for L-glutamine; $H_2NCO\dot{C}HCH(NH_3^+)COO^-$ (**2**) for L-asparagine; $^-OOCCH_2CH_2\dot{C}HCOO^-$ (**3**) and $^-OOC\dot{C}HCH_2CH(NH_3^+)COO^-$ for sodium L-glutamate; $^-OOCCH_2\dot{C}HCOO^-$ (**4**) and $^-OOC\dot{C}HCH(NH_3^+)COO^-$ (**5**) for sodium L-aspartate; $HO\dot{C}HCH(NH_3^+)COO^-$ and $HOCH_2\dot{C}HCOO^-$ (**6**) for L-serine; $CH_3CH(OH)\dot{C}HCOO^-$ (**7**) and $\dot{C}H_2CH(OH)CH(NH_3^+)COO^-$ for L-threonine. The free radicals, **1**, **3**, **4**, **6**, and **7**, were due to the reaction of the hydrated electron (e_{aq}^-) with these amino acids and the other adducts were due to the attack of hydroxyl radical (·OH). The two diastereomeric pairs of spin adducts of the short-lived radicals, **2** and **5**, could be individually separated by the technique utilized.

NAOHISA IGUCHI, FUMIO MORIYA, KEISUKE MAKINO, SOUJI ROKUSHIKA et HIROYUKI HATANO. Can. J. Chem. **62**, 1722 (1984).

On a irradié des solutions aqueuses de L-glutamine, de L-asparagine, de L-glutamate de sodium, de L-aspartate de sodium, de L-sérine et de L-thréonine par des rayons γ en présence d'un capteur de spin, le méthyl-2 nitroso-2 propane. Faisant appel à la méthode de clhp–rpe des spin piégés, on a analysé les adduits de spin stables produits dans les solutions irradiées. On a trouvé et on a identifié les adduits de spin des radicaux suivants à courte vie: $H_2NCOCH_2CH_2CHCOO^-$ (**1**), $H_2NCOCH_2CH_2\dot{C}(NH_3^+)COO^-$ et $H_2NCO\dot{C}HCH_2CH(NH_3^+)COO^-$ pour la L-glutamine; $H_2NCO\dot{C}HCH(NH_3^+)COO^-$ (**2**) pour la L-asparagine; $^-OOCCH_2CH_2\dot{C}HCOO^-$ (**3**) et $^-OOC\dot{C}HCH_2CH(NH_3^+)COO^-$ pour le L-glutamate de sodium; $^-OOCCH_2\dot{C}HCOO^-$ (**4**) et $^-OOC\dot{C}HCH(NH_3^+)COO^-$ (**5**) pour le L-aspartate de sodium; $HO\dot{C}HCH(NH_3^+)COO^-$ et $HOCH_2\dot{C}HCOO^-$ (**6**) pour la L-sérine; $CH_3CH(OH)\dot{C}HCOO^-$ (**7**) et $\dot{C}H_2CH(OH)CH(NH_3^+)COO^-$ pour la L-thréonine. Les radicaux libres **1**, **3**, **4**, **6** et **7** proviennent de la réaction de l'électron hydraté (e_{aq}^-) avec ces acides aminés et les autres adduits proviennent d'une attaque du radical hydroxyle (·OH). La méthode utilisée permet de séparer individuellement les deux paires d'adduits de spin diastéréoisomères des radicaux de faible temps de vie, **2** et **5**.

[Traduit par le journal]

Introduction

Spin trapping (1–8) is the method by which short-lived radicals are converted into relatively stable aminoxyl radicals by reaction with diamagnetic compounds (spin traps). By means of this unique method, the assignment of the parent short-lived radicals can be made by analyzing the electron spin resonance (esr) spectra of the spin adducts produced. Since the introduction of this method, it has been intensively used to detect short-lived free radicals produced in aqueous solutions (9–12).

The combination of the spin trapping method, where 2-methyl-2-nitrosopropane is used as a spin trap, and high-performance liquid chromatography (hplc), by which individual spin adducts are isolated from their mixture solutions, has been utilized in order to assign each short-lived free radical produced in aqueous amino acid or peptide solutions by γ-radiolysis (13–19). This is because ionizing radiation is known to form a number of short-lived free radicals in aqueous solutions by the attack of highly reactive primary species such as hydrated electrons (e_{aq}^-) (20) and hydroxyl radicals (·OH) (21) which are generated from water, and in general, therefore, esr spectra obtained from the irradiated solutions by spin trapping are highly complicated. By the separation of the spin adducts followed by their esr analysis, a number of free radicals from the amino acids and peptides (glycine (16), L-alanine (16), L-valine (14), L-leucine (15), L-isoleucine (15), DL-methionine (13), L-proline (18), *trans*-4-hydroxy-L-proline (18), glycylglycine (17), glycyl-L-alanine (17), L-alanylglycine (19), L-alanyl-L-alanine (19), and so on), many of which had not been found before this combination was used, could be detected and assigned. In addition, the spin adducts produced in the irradiated aqueous MNP solution have been separated and assigned to the structures so that the identification of the spin adducts from amino acids and peptides can be made more unambiguous (22). It has also been demonstrated previously that some of the esr spectra from the amino acids and peptides showed extreme complexity due to the structural specificities of the spin adducts and that, in such cases, changes in the pH and D_2O replacement of the sample solution were useful for the unambiguous assignment. The hyperfine splittings (hfs) due to the atoms adjacent to functional groups such as amino or carboxyl groups were found to be changed by such treatments.

In the present study, amino acids with additional functional groups (L-glutamine, L-asparagine, L-glutamic acid, L-aspartic acid, L-serine, and L-threonine) were γ-irradiated in aqueous solutions, producing short-lived free radicals. These radicals were investigated by this combination hplc–esr method coupled with the changes in conditions of the sample solutions. Previously, only a few spin adducts from these amino acids could be assigned because of the high complexity of the obtained esr spectra arising from the overlapping of the esr components of several spin adducts present in the same sample

solution (10, 11). Therefore, it will be interesting if other unidentified free radicals from these amino acids can be analyzed by the method we have proposed. Also, since these amino acids are frequently located in the active center of various enzymes, such assignment is believed to be useful in understanding their inactivation caused by radiolysis.

Experimental

2-Methyl-2-nitrosopropane (MNP) used in this study was synthesized by the method proposed previously by Stowell (23). D_2O (99.8%) was obtained from E. Merck Co. Amino acids and all other reagents were purchased from Nakarai Chemicals (Kyoto, Japan). These compounds were used without further purification.

Aqueous MNP solutions (5 mg/mL) were prepared by stirring for 1 h at 45°C in the dark (22). L-glutamine (Gln), L-asparagine (Asn), L-serine (Ser), and L-threonine (Thr) (0.2 *M*) were dissolved into the MNP solutions. The sample solutions, with the exception of Asn, were cooled by ice and irradiated with ^{60}Co γ-rays at a dose rate of 4 kGy/h to a total dose of 3 kGy without deaeration. Aqueous solutions containing Asn were irradiated at room temperature. In the case of sodium L-glutamate (Na-Glu) and sodium L-aspartate (Na-Asp), saturated solutions were irradiated.

Immediately after the irradiation, the concentration of phosphoric ion in the irradiated solution was adjusted to 0.2 *M* by 2.0 *M* sodium phosphate buffer. A quantity of 1.0 mL (in the cases of Na-Glu and Na-Asp: 0.2 mL) of the solution was loaded on a 0.75 × 60 cm cation-exchange column (IEX-210SC of Toyo Soda). The high-performance liquid chromatograph used was a Toyo Soda HLC-803. The eluate was passed through ultraviolet uv (JASCO UVIDEC 100) and esr detectors and collected in the fraction tubes. The wavelength of the uv detector was 240 nm. The esr spectrometer was a JEOL PE-3X (X-band, 100-kHz field modulation). For the detection of radicals during chromatography, the magnetic field was fixed at the positions indicated by the vertical arrows, as shown in Fig. 1. The field modulation was used at a high amplitude of 1 mT to cover a wide range. A quartz flow cell (0.6-mm id) was fixed in the esr cavity. The eluent employed for the separation was 0.2 *M* Na_2HPO_4–Na_2HPO_4 buffer (pH 6.8). Each part in the chromatographic system was connected with 0.25-mm id Teflon tube. The chromatographic conditions were as follows: flow rate, ca. 0.3 mL/min (in the cases of Na-Glu and Na-Asp, ca. 0.1 mL/min); pressure, ca. 10 kg/cm^2; temperature, ca. 25°C. The esr spectra of the fractions containing the spin adducts were obtained at ca. 25°C in the dark. In some cases, the second derivative spectra (80 Hz modulation) were measured to obtain further information. The pH adjustment, which was employed to study the spectral changes depending on the pH of the solutions, was performed using dilute HCl or NaOH. Some of the fractions were lyophilized and then added to D_2O in order to determine the hyperfine splittings arising from the exchangeable hydrogens. Hyperfine splitting constants (hfsc's) were measured by using Mn^{2+} in MgO as a reference. The simulation of the esr spectra was achieved by using a JEOL JEC-980A minicomputer.

For other experimental details refer to previous works (13–19).

Results and discussion

By the method of combination of spin trapping with MNP and hplc separation of the resulting spin adducts, several individual esr spectra were obtained for each amino acid, and it was found that the parent radicals were produced by the deamination reaction due to the attack of e^-_{aq} or by the H-abstraction reaction caused by ·OH. The hfsc's obtained from the spectra and by the computer simulation are all listed in Table 1.

L-Glutamine

The esr spectrum obtained from the γ-irradiated aqueous solution containing Gln and MNP is shown in Fig. 1(a). The spectrum is composed of the several overlapping esr signals of the spin adducts, which are produced by the reactions of MNP with short-lived radicals from Gln as well as from MNP. By the chromatographic separation of this sample solution, five peaks (elution volumes: 9.8 mL, 14.8 mL, 16.8 mL, 18.0 mL, and 20.5 mL, respectively) were detected by esr. However, analyzable esr signals could not be obtained from the fractions of the second and fourth peaks. Figures 2(a)–(c) show the esr spectra obtained from the first, third, and fifth peaks, respectively.

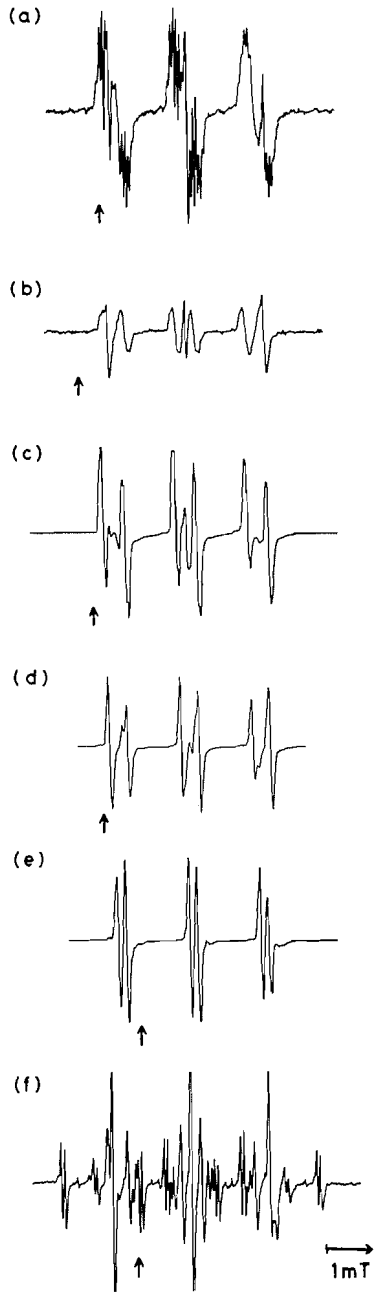

FIG. 1. Electron spin resonance spectra obtained from the γ-irradiated aqueous solutions of (a) Gln, (b) Asn, (c) Na-Glu, (d) Na-Asp, (e) Ser, and (f) Thr. During chromatography the magnetic fields were fixed at the positions indicated by the vertical arrows and the modulation amplitude was set to 1 mT. The esr settings are as follows: modulation amplitude, 0.02 mT; receiver gain, 5.0 × 10^2 for (a), (b), and (f), 1.0 × 10^2 for (c), (d), and (e); time constant, 0.03 s for (a), (b), (e), and (f), 0.01 s for (c) and (d); scan time, 8 min for (a), (b), (e), and (f), 4 min for (c) and (d).

TABLE 1. The hyperfine splitting constants (mT) of the spin adducts

Amino acid	Spin adduct	pH	a(N)	a(βH)	a(βN)	a(γN)	a(γN)	a(δH)

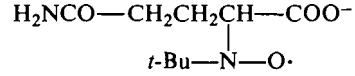
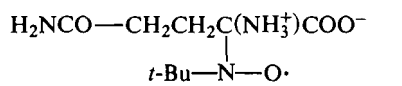
In the spectrum shown in Fig. 2(a), which was obtained from the fraction giving the first peak, each component of the primary triplet, which is due to the aminoxyl nitrogen, splits into 2 × 3 secondary lines due to a β-hydrogen and two equivalent γ-hydrogens. This spectrum was not changed at the alkaline pH. Consequently, this esr spectrum was assigned to the spin adduct (**1**), which is due to the reaction of the hydrated electron (e^-_{aq}) with the Gln, and called the deamino adduct.



1

The spectra produced by the fraction giving the third peak were measured in H_2O and D_2O, as shown in Figs. 3(a) and (b), respectively, where the $M_1 = 0$ components of each spectrum are represented. In D_2O, the second derivative of the spectrum was also obtained. The spectrum consists of 11 lines in H_2O whereas there are 10 lines in D_2O. The spectral change depending on the solvents indicates that the spectrum in H_2O involves hyperfine splittings due to at least one exchangeable hydrogen of the amino group or the amide group of the spin adduct. Also, a spectrum obtained in a basic solution (pH 11) was different from that at the neutral pH, which suggests the presence of the amino group near the aminoxyl group. The computer simulations for the esr spectra at neutral pH were carried out. In Figs. 3(a) and (b), the simulated spectra at pH 7 in H_2O and at pH 7 in D_2O are depicted, respectively, together with their original spectra. The parameters used for the simulations were as follows: a(βN) = 0.10 mT, a(γH-1) = 0.14 mT, a(γH-2) = 0.10 mT, a(γH) = 0.04 mT (three amino hydrogens) and Lorentzian peak-to-peak line width = 0.04 mT for the form in H_2O. In the case of the structure in D_2O, the values for the amino hydrogens were replaced by zero (the splitting constant due to a deuterium was too small to be observed, compared to that due to a hydrogen). The other values used were the same as those utilized for the form in H_2O. Consequently, the spectrum in Fig. 3(a) was assigned to the spin adduct **2**. The parent free radical of this adduct was formed by the attack of hydroxyl radical (·OH) to the Gln.



2

Figures 3(c) (in H_2O) and (d) (in D_2O) show the $M_1 = 0$ components of the esr spectra obtained from the fifth peak. The spectral pattern consisting of 2 × 6 lines in H_2O changed to 2 × 5 lines in D_2O. Assuming that the spectral change dependent on the solvent is due to the change in the splittings arising from one of the two exchangeable amide hydrogens (δ-hydrogens, (24)), the spin adduct in the fraction was assigned to the structure **3**. In order to make this assignment more unambiguous, computer simulation was made for the spectra shown in Figs.

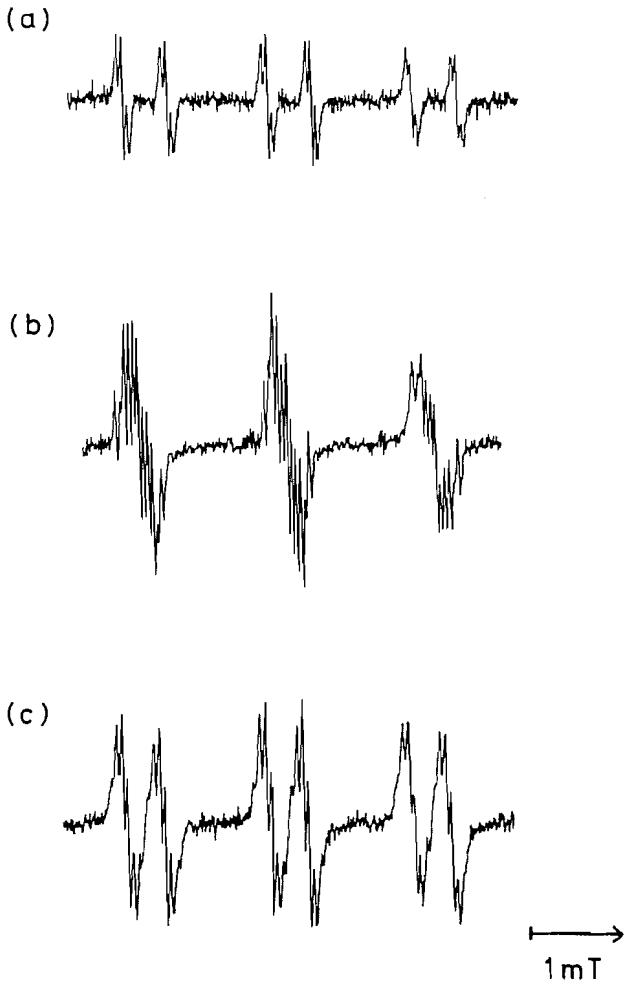

FIG. 2. Electron spin resonance spectra of the spin adducts from Gln. Figures (a)–(c) were obtained from the fractions giving the first, third, and fifth peaks in the esr chromatogram, respectively. The esr measurements were carried out at pH 6.8 in H_2O. The esr settings are as follows: modulation amplitude, 0.025 mT for (a) and (c), 0.02 mT for (b); receiver gain, 1.0×10^3; time constant, 0.1 s; scan time, 16 min.

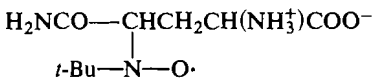

3

3(c) and 3(d) and good agreement between the spectra and the simulation spectra could be obtained. The esr parameters used for the simulation of the spectrum in H_2O were as follows: $a(\beta H) = 0.40$ mT, $a(\gamma H) = 0.06$ mT (2H), $a(\gamma N) = 0.06$ mT (amide nitrogen), $a(\delta H) = 0.06$ mT (amide hydrogen). The values used for the spectrum in D_2O were the same as those for the spectrum in H_2O except that the hfsc for the amide hydrogen was replaced by zero.

L-Asparagine

The esr spectrum shown in Fig. 1(b) was obtained from aqueous Asn solution with MNP just after the γ-irradiation. By chromatographic separation, three peaks (elution volumes were: 11.9 mL, 19.6 mL, and 27.4 mL, respectively) appeared in the esr chromatogram. The fractions of these peaks lead to the esr spectra shown in Figs. 4(a)–(c).

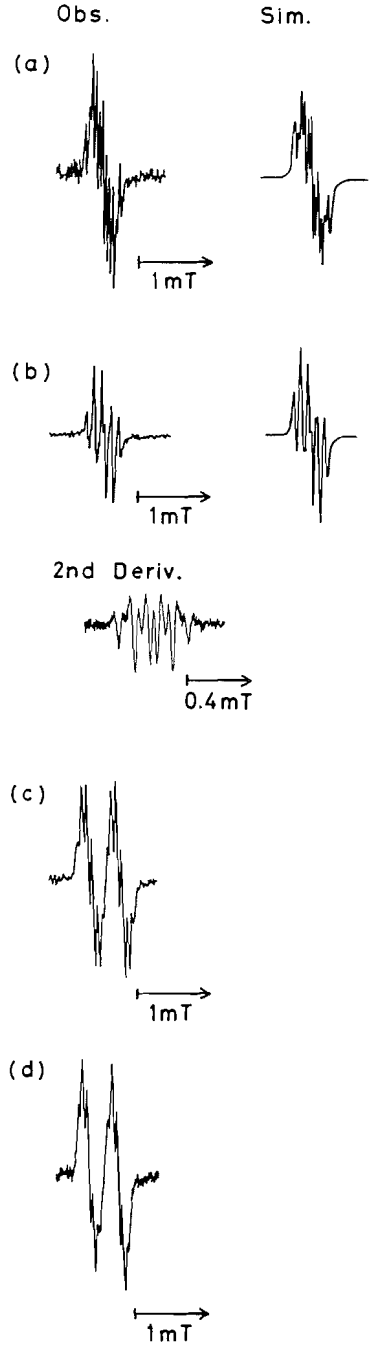

FIG. 3. (a) The $M_I = 0$ component of the esr spectrum in Fig. 2(b) and its simulation spectrum. The esr settings are as follows: modulation amplitude, 0.02 mT; receiver gain, 1.0×10^3; time constant, 0.1 s; scan time, 16 min. The esr parameters for the simulation spectrum refer to the text. (b) The $M_I = 0$ component (first and second derivatives at pH 6.8 in D_2O) of the esr spectrum of the spin adduct in Fig. 2(b) and the simulation for the first derivative. The esr settings are as follows: first derivative: modulation amplitude, 0.02 mT; receiver gain, 1.0×10^3; time constant, 0.3 s; scan time, 32 min; second derivative, modulation amplitude (100 kHz and 80 Hz), 0.02 mT; receiver gain (100 kHz), 1.0×10^4; receiver gain (80 Hz), 5.0; time constant, 1 s; scan time, 64 min. (c) The $M_I = 0$ component of the esr spectrum in Fig. 2(c). The esr settings are as follows: modulation amplitude, 0.025 mT; receiver gain, 1.0×10^3; time constant, 0.1 s; scan time, 16 min. (d) The $M_I = 0$ component (at pH 6.8 in D_2O) of the esr spectrum of the spin adduct in Fig. 2(c). The esr settings are as follows: modulation amplitude, 0.025 mT; receiver gain, 2.0×10^3; time constant, 1 s; scan time, 16 min.

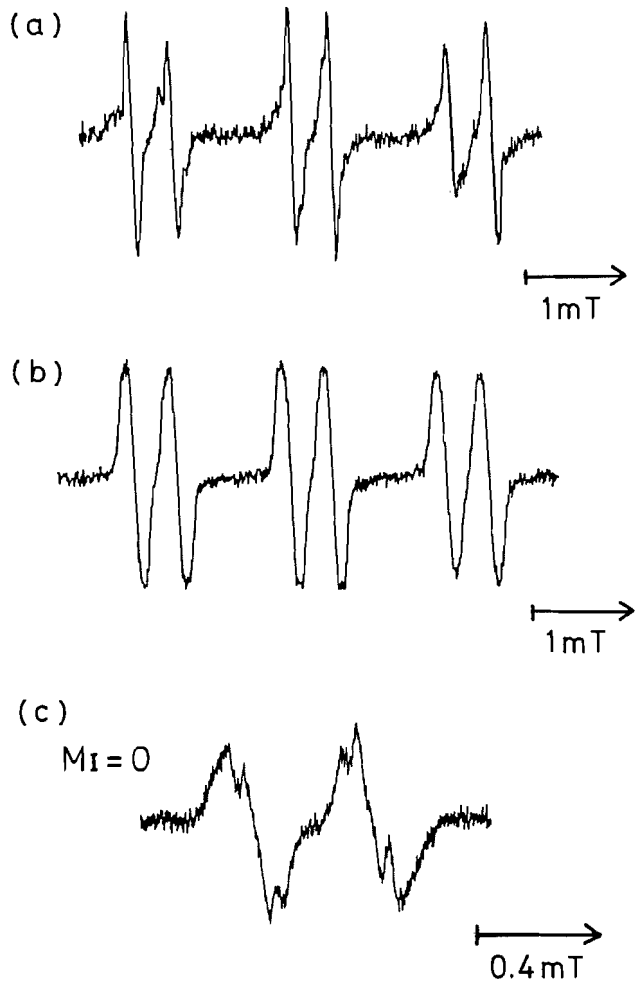

FIG. 4. Electron spin resonance spectra of the spin adducts from Asn. Figures (a) and (b) were obtained from the fractions giving the first and second peaks in the esr chromatogram, respectively. Figure (c) is the $M_I = 0$ component of expanded spectrum obtained from the third fraction. The esr measurements were carried out at pH 6.8 in H_2O for (a) and (b), while at pH 6.8 in D_2O for (c). The esr settings are as follows: modulation amplitude, 0.02 mT; receiver gain, 2.0×10^3 for (a), 1.0×10^3 for (b), 5.0×10^3 for (c); time constant, 1 s for (a), 0.3 s for (b), 3 s for (c); scan time, 64 min for (a), 32 min for (b), 128 min for (c).

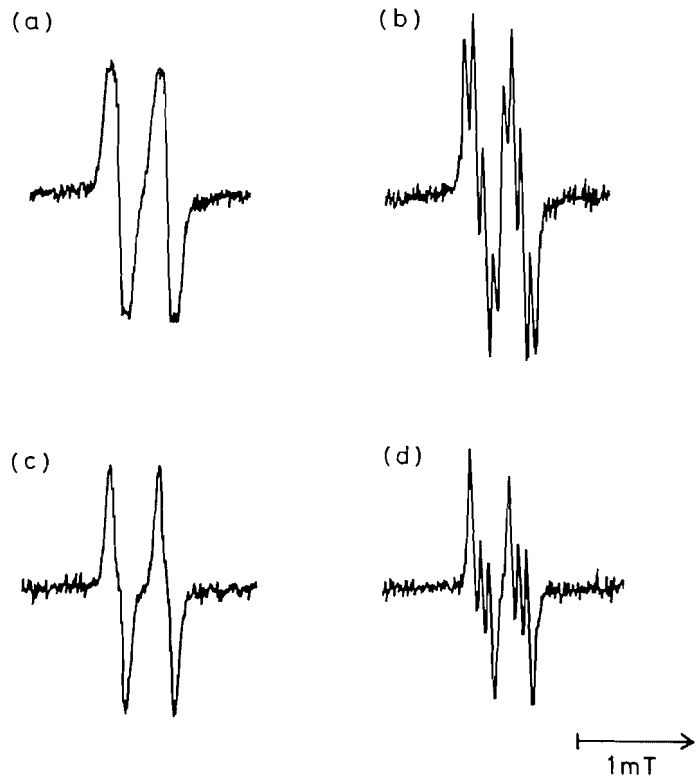

FIG. 5. The $M_I = 0$ components of the esr spectra of the spin adduct in Fig. 4(b) which were obtained at (a) pH 6.8 in H_2O, (b) pH 11.0 in H_2O, (c) pH 6.8 in D_2O, and (d) pH 11.0 in D_2O. The esr settings are as follows: modulation amplitude, 0.02 mT; receiver gain, 1.0×10^3 for (a), (c), and (d), 7.1×10^2 for (b); time constant, 0.3 s for (a), (c), and (d), 0.1 s for (b); scan time, 32 min for (a), (c), and (d), 16 min for (b).

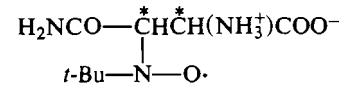
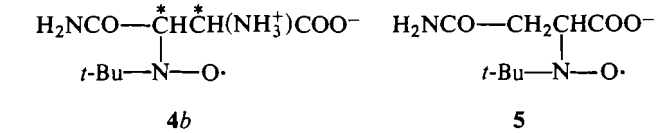
The spectrum represented in Fig. 4(a) (the first peak) consists of more than two spectra, so satisfactory identification could not be made. The spectrum shown in Fig. 4(b) (the second peak) is composed of only broad 3×2 lines. However, the spectra at pH 11 in H_2O and in D_2O involve further fine splittings as represented in Figs. 5(b) and 5(d). The esr spectrum at pH 11 in H_2O consists of two lines split into a quartet with an intensity ratio of 1:2:2:1, while the spectrum at pH 11 in D_2O has 2×3 secondary lines with an intensity ratio of 1:1:1. It is likely that the 4 secondary lines in the spectrum at pH 11 in H_2O are due to an amide nitrogen and one of two amide hydrogens, whereas the three lines appearing in the spectrum at pH 11 in D_2O are produced from only an amide nitrogen. Also, this marked spectral change caused by the pH variation indicates that this spin adduct retained the amino group. Consequently this spectrum was assigned to the spin adduct **4***a*.

The spectrum obtained from the third peak had a triplet split



4*a*

into doublets. The signal intensity of this spectrum was not enough to observe further splittings because of the low concentration of the adduct in the fraction. However, in the case of the spectrum in D_2O, secondary splitting of 2×3 lines could be observed as shown in Fig. 4(c). This result indicates that the adduct has a γ-nitrogen, or a γ-hydrogen and a γ-nitrogen whose hfsc is not equal to, but slightly different from, that of the γ-hydrogen, or two equivalent γ-hydrogens, as well as a β-hydrogen. This implies that the esr spectrum could be assigned to the structure **4***b* or **5**. In the case of the adduct **4***b*,



4*b* **5**

which can be produced by the H-abstraction from the Asn caused by ·OH attack, the γ-hfs is produced from a γ-hydrogen and a γ-nitrogen. The adduct **5** can be produced by the deamination reaction of Asn and the γ-hfs arises from two equivalent γ-hydrogens. Generally, deamino adducts of amino acids have a primary splitting $a(N) = 1.56$ or 1.57 mT, due to an aminoxyl nitrogen, while this adduct has a primary splitting

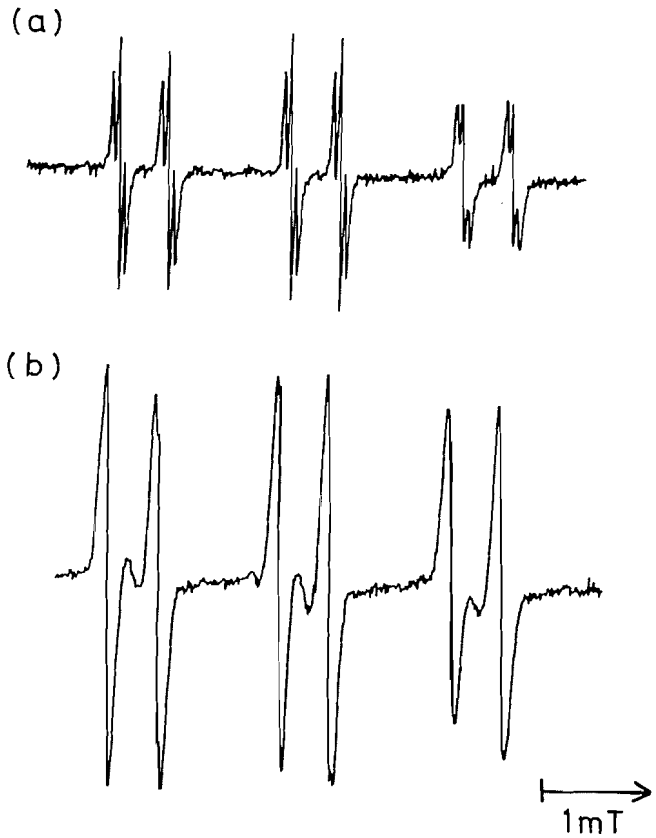

FIG. 6. Electron spin resonance spectra of the Na-Glu spin adducts obtained from the fractions giving the first (a) and second (b) peaks. They were observed at pH 6.8. The esr settings are as follows: modulation amplitude, 0.02 mT; receiver gain, 5.0×10^2; time constant, 0.1 s; scan time, 16 min.

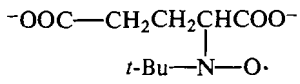
a(N) = 1.51 mT. In addition, adducts which do not have amino groups are eluted approximately at the void volume of the column, while this peak was eluted considerably late. Considering these facts, this spectrum was assigned to the adduct ***4b***. Since the structure ***4b*** is the same as ***4a***, these two species are diastereomeric spin adducts of each other (the carbon atoms asterisked are the chiral centers).

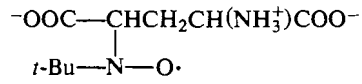
Sodium L-glutamate

The γ-irradiated aqueous Na-Glu solution containing MNP produced the esr spectrum shown in Fig. 1(c). The chromatographic separation of the solution at low flow rate of 0.1 mL/min gave two bands (elution volumes: 10.1 mL and 10.6 mL, respectively) in the esr chromatogram. The retention volumes of these bands are small. This is due to the existence of two carboxyl groups in the molecules. The spectra obtained from the fractions are shown in Figs. 6(a) and (b), respectively.

The spectrum shown in Fig. 6(a) (the first peak) has 2 × 3 secondary splitting due to a β-hydrogen and two equivalent γ-hydrogens. There are two possibilities for the assignment of the adduct. One possible structure is **6**. The other one is **7**. Since the observed spectra were not changed in the alkaline



6



7

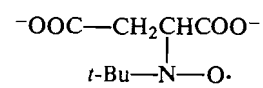
solution and since the adduct was eluted fast at the void volume, the spectra could be assigned to the adduct **6**, which does not have an amino group.

The spectrum in Fig. 6(b) (the second peak) consists of relatively broad 2 × 3 splittings. The hfsc's of the adduct are reversibly varied by the pH alteration as shown in Table 1 (at pH 1.6, 6.8, 12.0). The change in the alkaline pH range indicates the existence of an amino group in the adduct. Also, the large change in the acidic range implies that the adduct has a carboxyl group adjacent to the carbon on which there is a β-hydrogen of the adduct. The fast elution of this adduct may be due to the existence of the two carboxyl groups. Consequently, the spectrum was assigned to the spin adduct **7**. A little skew observed in the spectrum is probably due to the presence of some other radicals.

Sodium L-aspartate

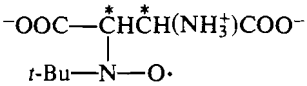
The esr spectrum represented in Fig. 1(d) was produced by the γ-irradiated Na-Asp solution. Figures 7(a)–(c) show the spectra obtained from the three peaks (elution volumes were: 10.9 mL, 11.3 mL, and 12.9 mL, respectively) appearing in the esr chromatogram. Those bands were also eluted fast.

The esr spectrum from the first peak (Fig. 7(a)), which appeared at the void volume, was not changed at the alkaline pH at all, indicating that the structure of the adduct is **8**.



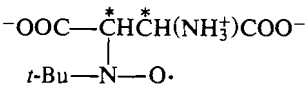
8

The spectrum obtained from the fraction of the second peak, which is shown in Fig. 7(b), consists of a secondary doublet due to a β-hydrogen. The hfs constants of the adduct are varied by the pH alteration as shown in Table 1 (pH 1.6, 6.8, and 11.0). Since this change of the hfsc's in the alkaline pH range indicates that this adduct has an amino group, this spectrum was assigned to the structure ***9a***. The splittings arising from a γ-hydrogen and γ-nitrogen could overlap to produce no fine structure.



9a

The fraction due to the third peak led to the spectrum shown in Fig. 7(c) and this spectrum was changed to that in Fig. 7(d) in D_2O. In both cases, the spectra consist of 2 × 2 secondary splittings due to a β-hydrogen and a γ-hydrogen. The difference of the line widths between the spectra implies that the spin adduct has amino hydrogens exchangeable to H_2O. The spectra were found to be reversibly changed in the acidic and alkaline pH ranges as well as the second peak. The structure of the adduct was assigned to ***9b***. Since ***9a*** and ***9b*** are the same, they



9b

are a pair of the diastereomeric spin adducts, which were eluted separately in the esr chromatogram.

L-Serine

The esr spectrum obtained from the γ-irradiated aqueous

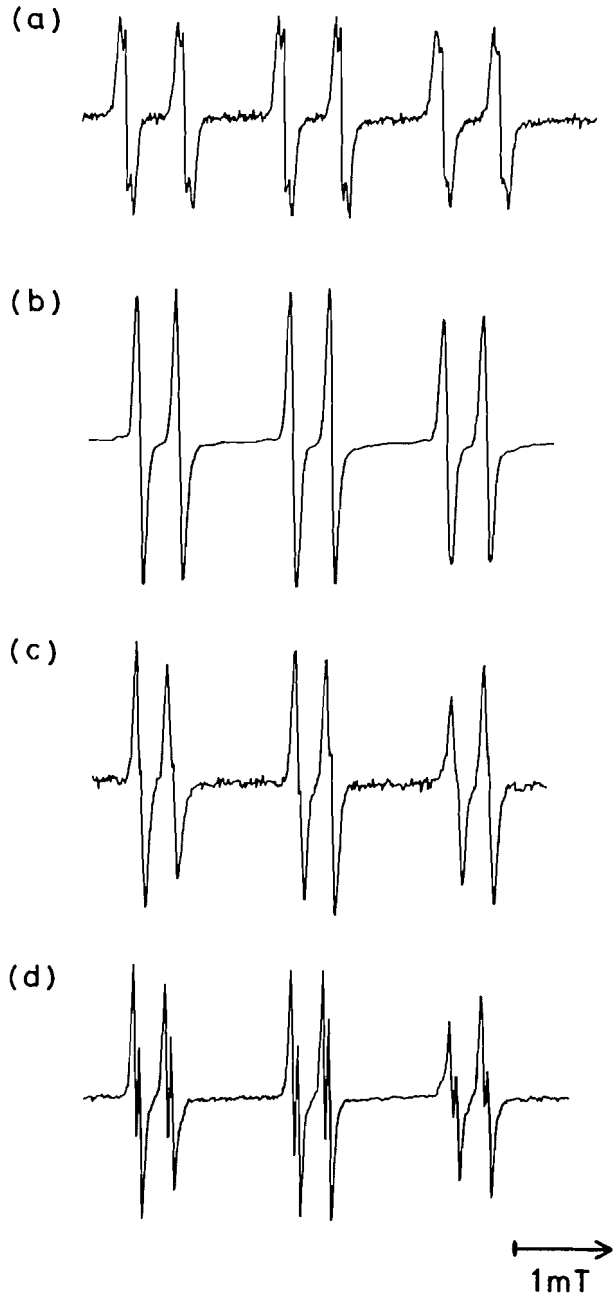


FIG. 7. Electron spin resonance spectra of the Na-Asp spin adducts obtained at pH 6.8 in H_2O from the fractions giving the first (a), second (b), and third (c) peaks. Figure (d) was obtained at pH 6.8 in D_2O from the third fraction. The esr settings are as follows: modulation amplitude, 0.02 mT; receiver gain, 5.0×10^2 for (a) and (c), 1.0×10^2 for (b), 2.5×10^2 for (d); time constant, 0.1 s for (a) and (c), 0.03 s for (b) and (d); scan time, 16 min for (a), 8 min for (b), (c), and (d).

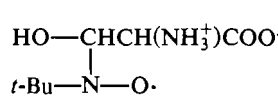
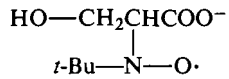
L-serine solution is shown in Fig. 1(e). The main component of the spectrum is composed of 3 × 2 lines and was assigned to the spin adduct **10**. This adduct was unstable, decaying with a half life of about 10 min.



10

The esr chromatogram obtained from this solution exhibited only one analyzable peak (elution volume: 11.9 mL). The spectrum from the peak is shown in Fig. 8(a). Since this is a typical spectrum of a deamino adduct, the structure of this adduct is **11**. The peak due to the adduct **10** did not appear in the chromatogram because the adduct was unstable on the column.

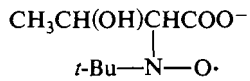


11

L-Threonine

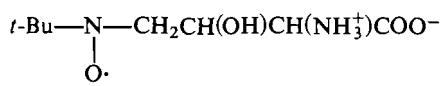
The esr spectrum of aqueous L-threonine solution just after the γ-irradiation is represented in Fig. 1(f). By the chromatographic analysis, two spin adducts (elution volumes: 12.1 mL and 18.2 mL) were detected. Their esr spectra are shown in Figs. 8(b) and (c).

The esr spectrum depicted in Fig. 8(b) (the first peak) was assigned to the structure **12**, which is a deamino adduct. Splitting due to a γ-hydrogen is not seen in the spectrum, probably because of the overlapping of two similar spectra arising from the existence of a pair of diastereomeric spin adducts.



12

The esr spectrum shown with its stick diagram in Fig. 8(c) was obtained from the fraction of the second peak. This spectral pattern, consisting of three sets of two sharp outer lines and two broad inner lines, is typical of a radical whose structure is *t*-Bu—N(O·)—CH_2—C*XYZ which has a methylene group between the chiral center and the aminoxyl group (25). Consequently, this spectrum was assigned to **13**.



13

In summary, by the spin-trap hplc–esr method, three, two, two, three, two, and two spin adducts were found to be produced from Gln, Asn, Na-Glu, Na-Asp, Ser, and Thr, respectively. The assignments were made more unambiguous by the observation of the spectral changes which were caused by changing the nature of the solutions. All of the spectral changes observed here were determined to be reversible. Some spin adducts detected in this study were not previously assigned unambiguously. In the present work, the relative spin adduct concentration in the radiolytic mixture could not be determined. Since spin adducts start decaying at a different rate immediately after the irradiation, although it is very slow, it seems to be quite difficult to estimate the concentration of each spin adduct even after the separation, although most of the spin adducts have been found to be more stable on the chromatographic column than in solution. Also, the facts that the chromatographic band widths of each spin adduct are not equal in most cases and that some chromatographic bands overlap with each other, so that esr measurments can not be performed

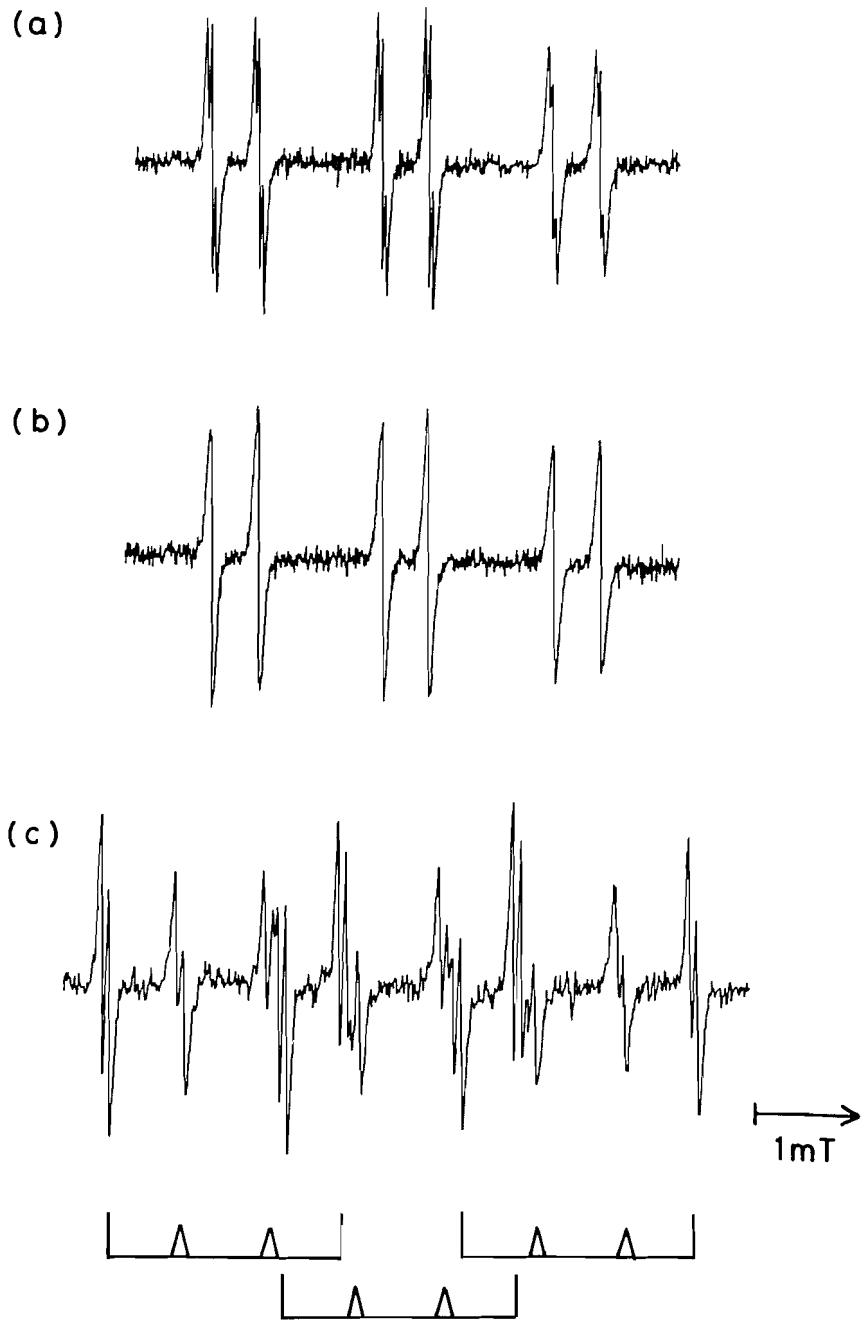

FIG. 8. Electron spin resonance spectra obtained at pH 6.8 from the spin adduct of Ser separated by hplc (a) and those of Thr ((b) and (c): the first and second peaks, respectively). The esr settings are as follows: modulation amplitude, 0.02 mT for (a) and (b), 0.04 mT for (c); receiver gain, 1.0×10^3 for (a) and (b), 3.2×10^3 for (c); time constant, 0.1 s for (a) and (b), 1 s for (c); scan time, 16 min for (a) and (b), 32 min for (c).

at the highest concentration of the spin adducts, prevent the estimation. However, this does not mean that a significant number of the spin adducts produced by the irradiation were left undetected. For instance, in the previous paper (15), all of the spin adducts produced by the H-abstraction from the possible carbons of L-isoleucine could be detected by the method. The estimation of the relative concentration remains as a problem we should overcome in the future. Also, the estimation of the parent short-lived radical concentration is a future problem, because the estimated relative concentration of the spin adduct involves both the reaction rate of each parent radical with a spin trap and the radiolytic yield of the parent radical.

Received January 23, 1984

VALERIE I. LANG and RICHARD D. DOEPKER. Can. J. Chem. **62**, 1731 (1984).

The gas-phase photolysis of 2-methyl-1,3-butadiene has been investigated using krypton (123.6 nm) resonance radiation. The observed neutral products of the primary decomposition were vinylacetylene, ethylene, acetylene, methylacetylene, propylene, allene, 2-methy-1-buten-3-yne, pentatriene/1-penten-3-yne, 1,3-butadiene, 2-butyne and butatriene, listed in decreasing order of concentration. There was also evidence of the presence of several radical fragments: CH_2/CH_3, C_2H_3, C_3H_3, and C_4H_5. Quantum yields for each of the products were determined in the photolysis of 2-methyl-1,3-butadiene, performed both in the presence and the absence of additives. Nitric oxide and oxygen were employed as radical scavengers, while hydrogen sulfide and hydrogen iodide were used as radical interceptors. Twelve primary, neutral molecule, reaction channels were proposed and the quantum efficiency assigned for each. The ionization efficiency of 2-methyl-1,3-butadiene was established as $n = 0.55$ at 10.03 eV. No products formed exclusively via an ion–molecule pathway were identified and therefore the fate of the $C_5H_8^+$ ion was not determined.

VALERIE I. LANG et RICHARD D. DOEPKER. Can. J. Chem. **62**, 1731 (1984).

Faisant appel à la radiation de résonance du krypton (123,6 nm), on a étudié la photolyse en phase gazeuse du méthyl-2 butadiène-1,3. La décomposition primaire donne, dans l'ordre décroissant de leur importance, les produits neutres suivants: vinylacétylène, éthylène, acétylène, méthylacétylène, propylène, allène, méthyl-2 butène-1 yne-3, pentatriène/pentène-1 yne-3, butadiène-1,3, butyne-2 et butatriène. On trouve également plusieurs fragments radicalaires CH_2/CH_3; C_2H_3; C_3H_3 et C_4H_5. On a déterminé les rendements quantiques de chacun des produits obtenus lors des photolyses du méthyl-2 butadiène-1,3 réalisées en présence et en l'absence d'additifs. On a utilisé l'oxyde nitrique et l'oxygène comme pièges de radicaux alors que le sulfure d'hydrogène et l'iodure d'hydrogène ont été utilisés comme intercepteurs de radicaux. On propose 12 voies réactionnelles primaires pour les réactions conduisant aux molécules neutres et on a calculé pour chacune d'elles l'efficacité quantique. On a établi que, pour une énergie de 10,03 eV, l'efficacité d'ionisation (n) du méthyl-2 butadiène-1,3 s'établit à 0,55. On n'a identifié aucun produit provenant uniquement d'une réaction ion–molécule et, par conséquent, on n'a pas déterminé le sort de l'ion $C_5H_8^+$.

Introduction

The ultraviolet photochemistry of 2-methyl-1,3-butadiene has been of interest to the Environmental Protection Agency (1, 2) since the volatile hydrocarbons were detected as a foliage emission in ambient forest atmopshere (3, 4). Smog chamber simulation using ultraviolet radiation at lower atmosphere sunlight wavelengths (between 290–380 nm) were undertaken by Arnts and Gay (1). They compared the oxidant-forming potential of naturally emitted terpenes and the hemiterpene isoprene with that of hydrocarbon emissions from autombile exhaust.

Srinivason and Boué (5, 6) studied the mercury $^3P_1$ (254 nm) sensitized isomerization of gas phase linear 1,3-diene to cyclopropane derivatives. At room temperature (25°C), the formation of 2,3-dimethylcyclopropene and 3,3-dimethylcyclopropene from 2-methyl-1,3-butadiene (isoprene) was a linear function with time, with the intercept at the origin. The photoisomerization of isoprene to these products was found to be a primary process.

Many of the photochemical reactions of 1,3-diene in general can be rationalized in terms of a diradical intermediate with a cyclopropane-like structure (5, 6*b*). In the case of 2-methyl-1,3-butadiene, formation of the diradical intermediate is followed by a 1,3-hydrogen shift to give the final products 3,3-dimethylcyclopropene and 2,3-dimethylcyclopropene. At a reaction pressure of 10 Torr, the two dimethylcyclopropenes thermally decompose to give 2-methylmethylenecyclopropane, 1,2-pentyne, 3-methyl-1-butyne, and one unidentified product. However, at 300 Torr, the only products were 2,3-dimethyl- and 3,3-dimethylcyclopropenes.

Prior to the present investigation, the photochemistry of 2-methyl-1,3-butadiene was studied between 147.0 nm and its absorption threshold (ca. 255 nm) by Collin *et al.* (7). When isoprene (2-methyl-1,3-butadiene) was irradiated with 230–255 nm photons ethylene, acetylene, propyne, allene, and 1,4-pentadiene were found. The radiation-produced yields decreased with increasing pressure. Stern–Volmer plots indicated that the photoexcited parent molecule produced by 230–255 nm radiation is collisionally stabilized at high pressures.

As the incident energy is increased with wavelengths of 174 and 163 nm less pressure dependency was observed, and at 147.0 nm none was found, within the pressure ranges used in the study. Eight primary reaction channels were proposed for the fragmentation of 2-methyl-1,3-butadiene at these three wavelengths. At 147.0 nm the products reported by Collin *et al.* (7) were methane, acetylene, ethylene, ethane, propylene, methylacetylene, allene, vinylacetylene, isobutene, and 2-methyl-1-buten-3-yne. Vinylacetylene was found to be the major product at 147.0 nm with a quantum yield of 0.66.

The most frequently quoted first ionization potential of 2-methyl-1,3-butadiene of 8.84 eV was reported by Watanabe *et al.* (8) and Franklin *et al.* (9). More recently Worley and Webb (10) have measured the ionization energy as 8.87 eV using photoelectron spectra of the diene. In the mass spectrum of isoprene obtained by Holmes (11), the appearance potentials were 8.84 eV for the $C_5H_8^+$ ion and 10.5 eV for the $C_5H_7^+$ ion.

Collin, Bertrand, and Gagnon (12) reported the ionization efficiencies of several unsaturated hydrocarbons at 123.6 nm (10.0 eV) and 104.8–106.7 nm (11.6–11.8 eV). At 10.03 eV, the ionization efficiencies (n) values were within limit $n < 0.27$ for monoolefins; $n = 0.30–0.45$ for diolefins; $n > 0.45$ for acetylenic type compounds. The reported ionization efficiency

of 2-methyl-1,3-butadiene was 0.33.

In the present study an attempt has been made to extend the work of Collin *et al.* (7) by investigating the vacuum-ultraviolet photochemistry of 2-methyl-1,3-butadiene above its ionization energy. This work attempts to evaluate the primary reaction channels at 123.6 nm and to examine the effect of ionization on the product distribution.

Experimental

Materials

2-Methyl-1,3-butadiene (isoprene), obtained from K and K Laboratories, was purified by vapor chromatography using a 25 ft., 30% (W/W) squalene on chromosorp P column operated at room temperature. Analysis of the resulting isoprene disclosed an impurity of 0.03% *trans*-2-butene. Low temperature trap-to-trap distillation techniques were used to purify HI, NO, H_2S, and CH_3I while other additives were obtained commercially and used without further purification.

Irradiation and analysis

The vacuum-ultraviolet photolysis was investigated at room temperature (25°C) in a standard static system using a 600 cm^3 reaction vessel and a titanium "gettered" krypton (123.6 nm) resonance lamp. A CaF_2 was used to filter out the dual 116.5 nm Kr resonance line. Irradiation procedures, including photoionization, and mercury photosensitized procedures have been reported previously (13). Analysis was performed by vapor chromatography (25 ft., 30% squalane at 60°C) equipped with a flame ionization detector.

Actinometry

The chemical actinometer used in this study was cyclopentene $\Phi_{C_2H_4} = 0.19$ (13*b*, 14). The ionization efficiency (n) of 0.16 was assumed for cyclopentene (13*b*, 14) at 123.6 nm. These two values were used to determine the quantum yields and the ionization efficiency of isoprene.

Results

The quantum yields of the products of the 123.6 nm photolysis of 2-methyl-1,3-butadiene are reported in Tables 1 and 2. The data are representative of those collected under a variety of experimental conditions. In the absence of additive, the product yield remained essentially constant when the amount of isoprene was varied between 0.5 and 5.0 Torr. As can be noted in Table 1, there was no pressure effect when samples of isoprene between 0.3 and 5.0 Torr were photolyzed in the presence of 10% NO or O_2, even with the addition of between 37 and 149 Torr of nitrogen.

Oxygen was not as useful a radical scavenger as NO in preventing ethane formation and in removing the C_5 radical species. Hydrogen iodide was found to be a more effective radical interceptor than hydrogen sulfide, as previously noted by Ausloos *et al.* (15). The optimum concentration for HI was 7% while varying the amount of H_2S from 5 to 15% did not improve its efficiency to any appreciable extent. However, the use of HI presented difficulties in quantifying the yields of certain products. At room temperature (25°C) and 30 min reaction times, a thermal addition reaction of HI to 2-methyl-1,3-butadiene produced 3-methyl-1-butene, 2-methyl-1-butene, and 2-methyl-2-butene. Collin (7) suggested also such a complication with two of the C_5H_{10} isomers which he based on an observation of Gorton and Walsh (16).

In order to investigate a possible H-atom mechanism for the formation of the C_5H_{10} isomers, the $Hg(^3P_1)$ sensitized photolysis of H_2 (16.5 Torr) in the presence of 2-methyl-1,3-butadiene (0.5 Torr) was performed. The products of this photolysis was 2-methyl-2-butene, 2-methyl-1-butene, and 3-methyl-1-butene given in decreasing order of importance. Further 123.6 nm studies were made in which the additive CH_3I (10%) was used to participate in a competitive reaction for the available H- atoms (17), thus reducing the yield of the C_5H_{10} compounds (Table 2).

The ionization energy of 2-methyl-1,3-butadiene 8.84 eV (18) is below the photon energy of the Kr (10.0 eV) resonance lamp. The ionization efficiency for isoprene was determined to be $n = 0.55 \pm 0.03$ at 123.6 nm. No products formed exclusively through an ion–molecule pathway were identified.

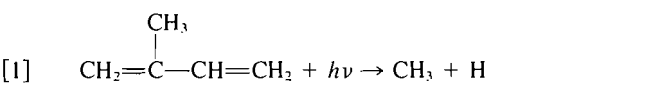
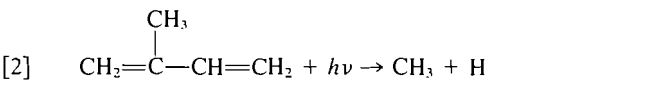
Discussion

The most abundant stable product in the 123.6 nm photolysis of 2-methyl-1,3-butadiene is vinylacetylene, $\Phi = 0.17$. Collin *et al.* (7) reported the highest quantum yield for vinylacetylene at 147.0 nm but with ethylene becoming the major product at both 163 nm and 174 nm. The cleavage of the methyl from the #2 carbon of the parent molecule and the elimination of a hydrogen atom from the #1 carbon results in the formation of vinylacetylene (reaction [1]). Similarly, the elmination of a hydrogen atom from the #3 carbon should lead to butatriene, $\Phi = 0.01$ (reaction [2])



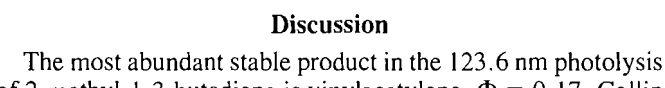
[1] $CH_2{=}C(CH_3){-}CH{=}CH_2 + h\nu \rightarrow CH_3 + H + HC{\equiv}C{-}CH{=}CH_2$



[2] $CH_2{=}C(CH_3){-}CH{=}CH_2 + h\nu \rightarrow CH_3 + H + H_2C{=}C{=}C{=}CH_2$

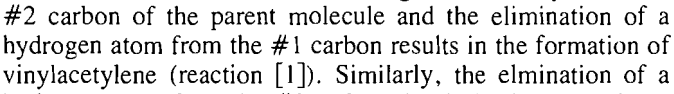
Since no pressure effect was observed in the formation of vinylacetylene or butatriene, it can be assumed that the elimination of both the hydrogen atom and the methyl radical must occur within the time of a few molecular vibrations. If it is assumed that reaction channels 1 and 2 are the only source of C_4H_4, then $\phi_1 = 0.17$ and $\phi_2 = 0.01$.

The elimination of the #1 methylene in conjunction with a carbon 3 to 4 hydrogen migration leads to the formation of 2-butyne (reaction [3]).



[3] $CH_2{=}C(CH_3){-}CH{=}CH_2 + h\nu \rightarrow CH_3{-}C{\equiv}C{-}CH_3 + CH_2$

1,3-Butadiene would result from a similar methylene elimination but coupled with a hydrogen atom migration from the methyl group to the #2 carbon (reaction [4]).

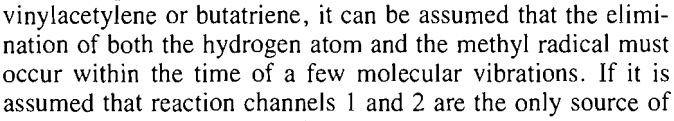


[4] $CH_2{=}C(CH_3){-}CH{=}CH_2 + h\nu \rightarrow CH_2{=}CH{-}CH{-}CH_2 + CH_2$

As is found in Table 1, the quantum yield for both 2-butyne and 1,3-butadiene are $\Phi_{C_4H_6\text{-yne}} = \Phi_{C_4H_6\text{-}1,3} = 0.01$. The primary quantum efficiencies for the reaction channels 3, and 4 are $\phi_3 = \phi_4 = 0.01$.

It is interesting to note that 1,2-butadiene was not found as a product in the NO or O_2 scavengered 123.6 nm photolysis. Although this product would result from a process involving a methylene elimination and a hydrogen 3 to 2 migration, it appears to be an unfavorable product.

The elimination of two hydrogen atoms (or molecular hydrogen) from the parent isoprene results in the formation of 2-methyl-1-butene-3-yne, $\Phi = 0.02$ via reaction channel [5].

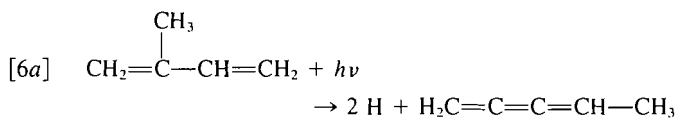


[5] $CH_2{=}C(CH_3){-}CH{=}CH_2 + h\nu \rightarrow CH_2{=}C(CH_3){-}C{\equiv}CH + 2\,H(H_2)$

Based on the formation of 2-methyl-1-buten-3-yne, the primary quantum efficiency for reaction channel is, $\phi_5 = 0.02$. If

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.105 on 09/06/12
For personal use only.

methyl migration should occur, pentatriene or 1-penten-3-yne may be produced (reaction [6]).

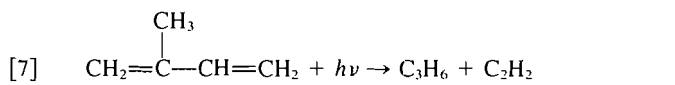


$$[6a]\quad CH_2{=}C(CH_3){-}CH{=}CH_2 + h\nu \rightarrow 2\,H + H_2C{=}C{=}C{=}CH{-}CH_3$$

$$[6b]\quad \rightarrow 2\,H + H_2C{=}CH{-}C{\equiv}C{-}CH_3$$

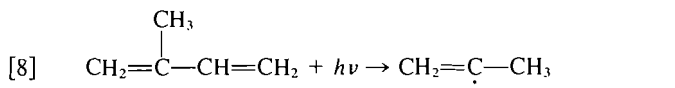
Analysis methods employed in this study were unable to distinguish between these two products. The primary quantum efficiency for reaction channel [6] should be equal to the scavengered quatum yield of these two C_5H_6 compounds, Table 1, $\phi_6 = 0.02$.

The appearance of propylene as a product even when scavengers are present, and the absence of a pressure effect, indicate that a primary process must exist leading to the formation of propylene. Hydrogen migration coupled with a carbon–carbon cleavage should lead to the formation of propylene and acetylene via reaction channel [7].



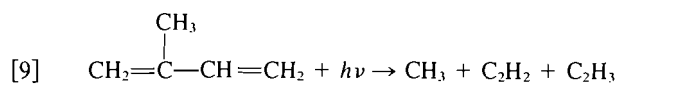
$$[7]\quad CH_2{=}C(CH_3){-}CH{=}CH_2 + h\nu \rightarrow C_3H_6 + C_2H_2$$

The fact that the propylene yield increased from 0.02 to 0.04 when HI or H_2S is introduced to the reaction system suggests the formation of a C_3H_5 radical. The fact that both H_2S and HI addition leads to the same quantum yield shows the C_3H_5 radical to be a vinyl radical (18), reaction [8].



$$[8]\quad CH_2{=}C(CH_3){-}CH{=}CH_2 + h\nu \rightarrow CH_2{=}\dot{C}{-}CH_3 + C_2H_2 + H$$

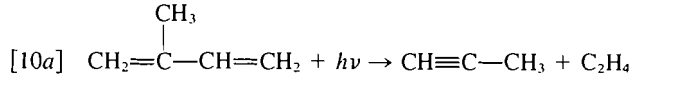
Considering both reaction channels [7] and [8], the quantum influence of each process is, $\phi_7 = \phi_8 \simeq 0.02$. It must be noted that the $\Phi_{C_3H_2} = 0.08$, independent of pressure and additive. Since only 0.04 is accounted for by reaction channels [7] and [8], a third source of acetylene must be present. A key to this process can be found in Table 2, where it can be noted that the quantum yield of ethylene increases by nearly 0.04 when HI or H_2S is present. ($\Phi_{C_2H_4} = 0.08$, W/NO; $\Phi_{C_2H_4} = 0.12$ W/HI or H_2S). A logical reaction channel then would appear to lead to the formation of acetylene and a vinyl radical. A methyl elimination and a carbon–carbon cleavage should result in the formation of acetylene and a vinyl radical, reaction [9].



$$[9]\quad CH_2{=}C(CH_3){-}CH{=}CH_2 + h\nu \rightarrow CH_3 + C_2H_2 + C_2H_3$$

If the total formation of acetylene can be limited to reaction channels [7], [8], and [9], then the quantum efficiency of reaction channel [9] would be $\phi_9 = 0.04$, which is comparable to the vinyl radical yield of $\Phi_{C_2H_3} = 0.04$.

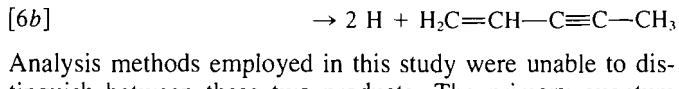
The elimination of molecular ethylene should result in the formation of methylacetylene or allene, depending on which hydrogen atom migrates, reaction [10].



$$[10a]\quad CH_2{=}C(CH_3){-}CH{=}CH_2 + h\nu \rightarrow CH{\equiv}C{-}CH_3 + C_2H_4$$

$$[10b]\quad \rightarrow CH_2{=}C{=}CH_2 + C_2H_4$$

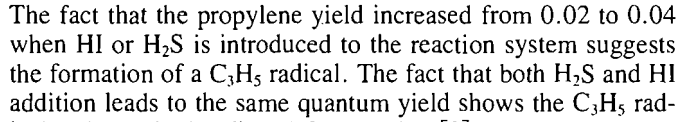
The quantum yield of ethylene is $\Phi_{C_2H_4} = 0.08$, while the yield of methylacetylene is $\Phi = 0.04$, and allene $\Phi = 0.02$ is $\Phi_{C_3H_4} = 0.06$. Assuming that reaction channel [10*a*] and [10*b*] are the only path for the formation of the C_3H_4 isomers, then $\phi_{10a} = 0.04$ and $\phi_{10b} = 0.02$. The excess quantum yield of 0.02 for ethylene suggests a reaction channel that simultaneously produces a propargyl radical with ethylene, reaction [11].



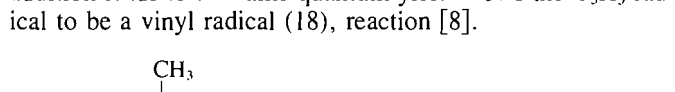
$$[11]\quad CH_2{=}C(CH_3){-}CH{=}CH_2 + h\nu \rightarrow C_2H_4 + C_3H_3 + H$$

Although there is no evidence of the C_3H_3 radical in this study, past studies in this laboratory have indicated that this species is not generally intercepted by H_2S nor HI. A maximum quantum efficiency for reaction [11] must be equal to the excess ethylene, or, $\phi_{11} = 0.02$.

Tables 1 and 2 reveal that the formation of 1,3-butadiene increases from 0.01 with NO present to a value of 0.05 when HI is added to the photolysis mixture likewise the fact that 1,2-butadiene is absent when NO is present shows a quantum yield of 0.01 when the radical interceptor HI is present. These observations are consistent with the formation of C_4H_5 radical systems. Two possible mechanisms could be postulated (reaction [12]).



$$[12a]\quad CH_2{=}C(CH_3){-}CH{=}CH_2 \rightarrow CH_2{=}\dot{C}{-}CH{=}CH_2 + CH_3$$



$$[12b]\quad CH_2{=}C(CH_3){-}CH{=}CH_2 \rightarrow C_4H_5 + H + CH_2$$

At present, there is no information available that

$$[13]\quad C_4H_5 + HI \rightarrow C_4H_6 + I$$

could distinguish between the two processes.

Considering the total methyl/methylene production of approximately $\Phi_{CH_3/CH_2} \simeq 0.31$ (Table 2), it is possible that the sum of the methyl/methylene formation (reactions [1]–[4], [9], and [12]) predicts a value of the total quantum yield for CH_3/CH_2 as

$$\begin{aligned}\Phi_{CH_3} &= \phi_1 + \phi_2 + \phi_3 + \phi_4 + \phi_9 + \phi_{12}\\ &= 0.17 + 0.01 + 0.01 + 0.01 + 0.04 + 0.05\\ &= 0.29\end{aligned}$$

This value is in good agreement with the experimental value of approximately 0.31.

It is apparent that the formation of 2-methyl-2-butene, 1-methyl-1-butene, and 1-methyl-3-butene were formed through a secondary process involving the addition of a hydrogen atom to a parent isoprene molecule (reactions [14] and [15]).

$$[14]\quad C_5H_8 + H\cdot \rightarrow C_5H_9\cdot$$

$$[15]\quad C_5H_9\cdot + RH \rightarrow C_5H_{10} + R\cdot$$

The total quantum yield for these three products in the presence of HI is $\Phi_{C_5H_{10}} = 0.42$, which is much greater than that predicted by the sum of all hydrogen atoms producing reaction channels, $\Phi_H = 0.30$. It must be recalled that HI addition to isoprene (7) leads to these products in a process that is *not* I_a-dependent, therefore this reported $\Phi_{C_5H_{10}} = 0.42$ value is completely unreliable.

[16]	$\rightarrow C_5H_8^+ + e^-$	0.55	—
		1.00	0.97

Summary and conclusion

The 123.0 nm photolysis of 2-methyl-1,3-butadiene may be described in 12 primary, neutral molecule, reaction channels and an ionization process, (reaction [16]).

[16] $C_5H_8 + h\nu \rightarrow C_5H_8^+ + e^-$

The quantum yields assigned through this study are summarized in Table 3 with an estimated accuracy of better than 10%. Although the neutral molecule decomposition of 2-methyl-1,3-butadiene is consistent with the investigation of Collin *et al.* (7), the ionization efficiency reported here $n = 0.55$ is considerably higher than reported by Collin (7), $n = 0.33$ at 123.6 nm.

The variation in the second hyperpolarisability of cyclobutane and cyclopentane through inversion, and an analysis of the contributions to this property

J. WAITE AND M. G. PAPADOPOULOS

Theoretical and Physical Chemistry Institute, National Hellenic Research Foundation, Vas. Constantinou 48, Athens 501/1, Greece

Received December 20, 1983

J. WAITE and M. G. PAPADOPOULOS. Can. J. Chem. **62**, 1736 (1984).

An extended basis CNDO-coupled-Hartree–Fock procedure has been used to determine the second hyperpolarisability of cyclobutane and cylopentane in both the puckered and planar forms. Analysis of the dependence of the hyperpolarisability on geometric elements (bond lengths, angles etc.) as well as its variation with change in configuration have been presented. The contribution of the multicenter interactions to the hyperpolarisability of C_4H_8 has been evaluated and its implications discussed.

J. WAITE et M. G. PAPADOPOULOS. Can. J. Chem. **62**, 1736 (1984).

On a utilisé une méthode CNDO avec base élargie-couplée à une procédure de Hartree–Fock pour déterminer la deuxième hyperpolarisabilité du cyclobutane et du cyclopentane tant dans leurs formes planes que plissées. On rapporte une analyse de la dépendance de l'hyperpolarisabilité sur les éléments géométriques (longueurs des liaisons, angles, etc) ainsi que sa variation avec des changements dans la configuration. On a évalué les contributions des interactions entre plusieurs centres sur l'hyperpolarisabilité du C_4H_8 et on discute de leurs implications.

[Traduit par le journal]

Introduction

The second hyperpolarisability is a molecular constant, describing the non-linear response of an atom or molecule to an electric field. It is defined by eq. [1]:

$$[1]\quad E(F) = E^{(0)} - \mu_\alpha F_\alpha - \frac{1}{2}\alpha_{\alpha\beta}F_\alpha F_\beta - \frac{1}{3!}\beta_{\alpha\beta\gamma}F_\alpha F_\beta F_\gamma - \frac{1}{4!}\gamma_{\alpha\beta\gamma\delta}F_\alpha F_\beta F_\gamma F_\delta - \ldots.$$

where $E(F)$ is the electronic energy of the molecule in the presence of the uniform electric field, F; $E^{(0)}$ is the unperturbed electronic energy; μ_α is the α component of the permanent dipole moment; $\alpha_{\alpha\beta}$ is the $\alpha\beta$ component of the polarisability; $\beta_{\alpha\beta\gamma}$ is the $\alpha\beta\gamma$ component of the first hyperpolarisability; $\gamma_{\alpha\beta\gamma\delta}$ is the $\alpha\beta\gamma\delta$ component of the second hyperpolarisability; and α, β, γ, δ are suffixes denoting cartesian components.

The importance of hyperpolarisabilities in the understanding of many non-linear processes and the design of materials with predefined properties has been discussed by many authors (1–6). However, it is noted that both the experimental and the theoretical evaluation of the second hyperpolarisability encounters difficulties (7, 8). A rigorous computational treatment of this property requires an accurate knowledge of the excited states which are currently available only for very small systems and even then with considerable effort (8). It is thus not surprising that rigorous *ab initio* methods have only been applied to H_2 (9, 10), HF (11–13), and H_2O (14). On larger systems, however, semiempirical methods have been employed (15–18). The level of approximations has been usually Hückel, CNDO, or INDO; while the electric field has been considered by some variant of FPT (Finite Perturbation Theory) or PT (Perturbation Theory).

One of the aspects which has not yet been treated systematically is the dependence of the average second hyperpolarisability, γ, on geometric elements (bond lengths, bond angles, etc.), for systems larger than H_2 (10). This is a matter of importance since the computed values which are determined employing fixed geometries are compared with experimental values that may be determined from conformational mixtures or rotationally averaged structures.

A question related to the rationalization and interpretation of both the theoretical and experimental hyperpolarisability results is the importance of multicenter interactions (that is interactions, which are essentially defined in terms of the charge cloud as a whole) as well as the extent to which the hyperpolarisability can be approximated by a sum of terms and interactions associated with specific parts of the molecule. The above stated problems have been investigated employing C_4H_8, its fragments, and C_5H_{10} as test models.

Method

We have employed a computational procedure (CHF–PT–EB–CNDO, for Coupled Hartree–Fock – Perturbation Theory – Extended Basis – Complete Neglect of Differential Overlap) which has successfully predicted the polarisabilities and hyperpolarisabilities of some alkanes (16), polyenes (17), and aromatics (18). This technique relies on (*a*) a CNDO (19) wave function formed from a properly optimized basis set, and (*b*) a self-consistent perturbation theory, that was developed by McWeeny and his co-workers, and which applies directly to the Fock–Dirac density matrix (20).

The following basis set has been used for the computations (16): C: $2s(1.625)$, $2p(1.625)$; and H: $1s(1.0)$, $2s(0.5)$, $2p(0.5)$. These atomic orbitals have been used to calculate α (the average polarisability) and γ of CH_4, C_2H_6 (four conformations), C_3H_6 and C_3H_8 (two conformations) wih average errors, in comparison to the experimental results, of 4.7% and 23.1% respectively (16). These data illustrate the aptitude of the employed basis set to satisfactorily reflect changes in polarisation induced by variation in geometry.

This observation is of importance because it demonstrates that both the first and second order correction to the density matrix are succesfully described and this allows one to think that the proposed values will have an error not exceeding 30% of an experimentally determined value, when it becomes available.

This is a reasonable degree of accuracy since the experimentally derived information may be uncertain due to dispersion (21), geometrical averaging and other effects by more than 20% (17).

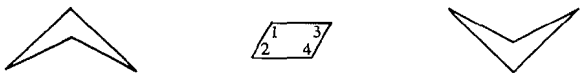

FIG. 1. Puckered and planar structures of cyclobutane which undergoes a rapid inversion between the two D_{2d} forms (23).

TABLE 1. Second hyperpolarisability of CH_2 in au as a function of the C—H bond length (R) and ∠HCH bond angle

	Hyperpolarisability[e]				
R (au)	90°	105.4°[a]	108°[d]	120°	145°
2.06	1843	1847	1847	1842	1787
2.08[a]	1887	1892	1892	1887	1831
2.10[b]	1949	1956	1956	1951	1893
2.14[c]	2045	2053	2054	2050	1988
2.20	2208	2221	2222	2220	2154
2.50	3302	3363	3370	3391	3320
3.00	6532	6854	6901	7085	7232

[a] These are the equilibrium bond lengths and angles found by *ab initio* (basis set: 4-31G) calculations for the singlet state of CH_2 (22).
[b] CH bond length in C_5H_{10} (24).
[c] CH bond length in C_4H_8 (27).
[d] ∠HCH in C_4H_8.
[e] The conversion factors for the unit of hyperpolarisability to SI and esu are: 1 au ≃ 0.503717×10^{-39} esu ≃ 0.623597×10^{-64} C^4 m^4 J^{-3}.

The average value of the second hyperpolarisability, γ, is given by (1):

$$[2] \quad \gamma = \frac{1}{5}(\gamma_{xxxx} + \gamma_{yyyy} + \gamma_{zzzz} + 2\gamma_{xxyy} + 2\gamma_{xxzz} + 2\gamma_{yyzz})$$

where x, y, and z denote cartesian components, and the individual tensors, $\gamma_{\alpha\alpha\beta\beta}$, are computed from the requisite perturbed density matrices (16, 17, 20) (Fig. 1).

Results and discussion

A. Dependence of γ on geometry elements

Cyclobutane and cyclopentane may be considered as made up of CH_2 units, while the general cycloalkane can be described by $(CH_2)_n$, where $n = 3, 4, 5, \ldots$. Thus we start our analysis by considering how the γ of CH_2 changes as a function of the C—H bond length and the bond angle ∠HCH.

The results of Table 1 show: (*a*) Variation of C—H(∠HCH = 105.4°, constant) from 2.06 au to 2.2 au leads to a maximum difference from the equilibrium value (C—H = 2.08 au, ∠HCH = 105.4° (22)) which is equal to 17.4%. It is further observed that γ increases with the bond length (Table 1). This can be rationalized by considering that lengthening of the bond makes the charge cloud more diffuse and thus more easy to polarise. (*b*) For variations of ∠HCH(C—H = 2.08 au, constant) γ has a maximum difference from the equilibrium value equal to 3.2%.

On the whole variation of the ∠HCH angle does not produce large effects on γ, which is shown to be more sensitive to the variation of the C—H bond length.

This finding implies that the variation of the internuclear distance has a larger effect on the rearrangement of the charge cloud, and in particular its outer regions, than the variation of the angle between the internuclear vectors. Further insight in the property change induced by structure variations is gained by considering the hyperpolarisability of the puckered and the planar configurations of C_4H_8 (23) and C_5H_{10} (24).

It is observed that the difference γ (puckered) − γ (planar) takes the values ≃ 2300 au and ≃ 1200 au for C_4H_8 and C_5H_{10}, respectively.

It is also noted that the difference α (puckered) − α (planar) takes the values 1.3 au and 0.7 au correspondingly.

Now, considering that α is proportional to the molecular volume, (18, 25), it appears that the larger hyperpolarisability of the puckered configuration with respect to that of the planar, for both C_4H_8 and C_5H_{10}, is associated with the larger volume. This is an interesting correlation because the second hyperpolarisability is thus associated with the volume — a well known property. Further, since this finding is in agreement with a similar observation in aromatic molecules (18), it seems that the molecular volume may be used as "thumb-rule" indicating, at least, the ordering of hyperpolarisabilities.

From the above variations of γ, induced by changes in the structure, the following are further noted. Firstly, for small changes of the bond length, like those which are normally found between assumed bond lengths and experimentally determined ones, the overall change in the molecular γ is usually less than 10% as computations on a large number of molecules have shown (16–18). This remark provides a justification for the use of standard geometric models at this level of approximation, where, on average, accuracy of around 30% is a worthy goal (17). Secondly, variation in γ induced by configuration changes are usually small. Thus fixed geometry models allow one to form a reasonably accurate estimate of the magnitude of experimental values, determined from mixtures of conformers, rotamers, etc.

B. An analysis of the contributions to γ

In order to evaluate the contribution of the multicenter interactions and the importance of considering the charge cloud as a whole we have approximated the second hyperpolarisability of a cycloalkane to a sum of (*a*) the values of the constituent CH_2 units, (*b*) the contributions due to all the pair wise interactions bonded and non-bonded, of these methylene units, γ_{pair}, and (*c*) a term, γ_{rem}, which gives a semi-quantitative measure of the multicenter interactions not included in the previous terms. This scheme is defined by the following equations:

$$[3] \quad \gamma = n\gamma_{CH_2} + \gamma_{int}$$

$$[4] \quad \gamma_{int} = \gamma_{pair} + \gamma_{rem}$$

where n is the number of CH_2 units from which the compound is constructed. In the analysis which follows we used for γ of CH_2 the value 2054 au (Table 1).

Application of eqs. [3] and [4], and the results in Table 2, give:

A. C_4H_8 (planar)

$4\gamma_{CH_2} = 8216$ au

$\gamma_{pair} = (4 \times 720 - 2 \times 670)$ au $= 1540$ au

$\gamma_{rem} = (14160 - 8216 - 1540)$ au $= 4404$ au

B. Fragment (123)

This fragment is defined in the footnote of Table 2.

$3\gamma_{CH_2} = 6162$ au

$\gamma_{pair} = (2 \times 720 - 670)$ au $= 770$ au

$\gamma_{rem} = (8650 - 6932)$ au $= 1718$ au

[c] Pair of methylene units defined from C_4H_8 (puckered).
[d] Geometry from ref. 27.
[e] Experimental value (28). The theoretical value (8650 au) has been calculated employing a geometry, that corresponds to the fragment of C_4H_8, and which is rather strained in comparison with the equilibrium geometry of cyclopropane to which the experimental value refers (16).
[f] Geometry is from ref. 24.
[g] Note: the numbers within parentheses denote the relevant CH_2 units of C_4H_8 (Fig. 1). For example (12) means the pair of methylene units — the numbers define the relevant carbon atoms — having the same spatial position as in the parent molecule.

C. C_4H_8 (puckered)

$$4\gamma_{CH_2} = 8216 \text{ au}$$

$$\gamma_{pair} = (4 \times 700 + 710 - 650) \text{ au} = 2860 \text{ au}$$

$$\gamma_{rem} = (16410 - 2860 - 8216) \text{ au} = 5334 \text{ au}$$

From the above results we note that: (*a*) The large contribution γ_{int} makes to the overall γ is a quantitative manifestation of the considerable changes, which are induced in the outer regions of the CH_2 charge clouds, when they merge to form a compound. An acceptable basis set has to be capable of reflecting this distortion of the charge. However, most basis sets, with constraints on the size, and which are optimized for energy, do not guarantee an adequate description of the molecular polarisation (26). Thus one of the most chemically satisfactory and computationally economical solutions is to optimize the A.O. set with respect to some judiciously chosen compounds for which the experimental values of γ are known in order to study other structurally similar molecules. This option is the cornerstone of our computational technique (16–18). (*b*) It is observed that $\gamma_{pair} \neq \gamma_{int}$. In fact γ_{rem} contributes 20% to the hyperpolarisability of the fragment (123), while it contributes 31% and 33% to the hyperpolarisability of the planar and puckered forms of C_4H_8, respectively. These large contributions demonstrate the importance of the multicenter contributions and more specifically underline the significance of treating the charge cloud as a whole, because otherwise large contributions may be lost. At this point it may be noted that one may manage to fit a series of hyperpolarisability results employing some bond or atom constants. However, it is to be stated that any model which is likely to promote our understanding has to give due consideration to the fact that the nonlinearity of the various functional groups greatly depends on their intra-molecular environment, (which has been amply demonstrated by the large contribution of γ_{rem} to γ) much more, in fact, than for the dipole moment or the polarisability, (16–18). This remark defines, also, an essential condition which has to be satisfied by an additivity scheme in order to be successful.

Conclusions

In this work we have presented the second hyperpolarisabilities of C_4H_8 and C_5H_{10} which are not currently available in the literature. These results were associated with an estimate of the error (30%), which is considered to be reasonable. A critical appraisal of standard geometric models, often employed in semiempirical calculations, as well as of fixed geometry models used to approximate values determined from experimental samples, has been presented. Further, the conformational change in the hyperpolarisability has been associated with the change in molecular volume. This correlation allows the ready comprehension of γ. It also points to a possible route for the evaluation of this property, from quantities easier to determine, by employing, perhaps, a scheme similar to that in ref. 18.

Analysis of the hyperpolarisability results for C_4H_8 demonstrates the importance of the multicenter interactions and illustrates that this non-linearity is most profitably approached as a property of the outer reaches of the charge cloud treated as a whole.

Etude par activation collisionnelle des ions $[C_4H_7O]^+$ provenant des ions penténols et méthylcetones $[C_5H_{10}O]^{\cdot+}$ métastables

G. Bouchoux et Y. Hoppilliard
Laboratoire de Synthèse Organique, Ecole Polytechnique, 91128 Palaiseau Cedex, France

et

R. Flammang, A. Maquestiau et P. Meyrant
Laboratoire de Chimie Organique, Université de l'Etat, 19, avenue Maistriau, 7000 Mons, Belgique

Reçu le 22 juin 1983[1]

G. Bouchoux, Y. Hoppilliard, R. Flammang, A. Maquestiau et P. Meyrant. Can. J. Chem. **62**, 1740 (1984).

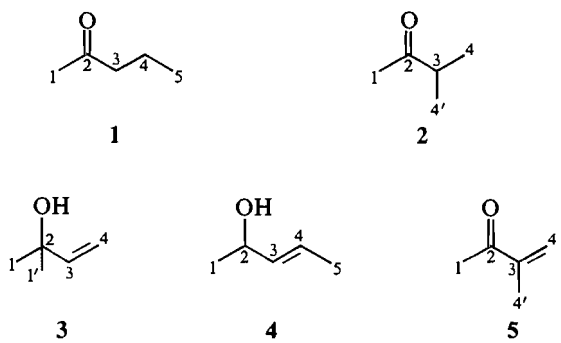
Les ions $[C_4H_7O]^+$ résultant de la perte de CH_3 à partir de la pentanone-2 (**1**), la méthyl-3-butanone (**2**), le méthyl-2-butène-3-ol-2 (**3**), le pentène-3-ol-2- (**4**) et le méthyl-3-butène-3-ol-2 (**5**) ont été étudiés par activation collisionnelle. Un spectromètre de masse à triple secteur a été utilisé afin de distinguer les ions fragments formés dans la source et dans la première région libre de champ. Les spectres de dissociations induites par collisions confirment ou éclairent les points suivants: (*i*) dans la source, l'élimination du CH_3 occupant la position 1 des molécules **1**−**5** conduit respectivement aux ions $[n\text{-}C_3H_7CO]^+$ (**a**), $[i\text{-}C_3H_7CO]^+$ (**b**), $[CH_3COHCHCH_2]^+$ (**c**), $[CH_3CHCHCHOH]^+$ (**d**) et $[CH_2C(CH_3)CHOH]^+$ (**e**), tandis que la perte de méthyle à partir de la chaîne produit compétitivement l'ion **c** pour les cinq précurseurs; (*ii*) en région libre de champ, les ions **1**, **3**, **4** et **5** conduisent à un même mélange de structures **a**, **b** et **c**, l'ion **2** conduit à l'ion acylium **b** de façon prépondérante. Les mécanismes et la thermochimie des réactions d'isomérisation des ions $[C_5H_{10}O]^{\cdot+}$ **1**−**5** sont discutés.

G. Bouchoux, Y. Hoppilliard, R. Flammang, A. Maquestiau, and P. Meyrant. Can. J. Chem. **62**, 1740 (1984).

The $[C_4H_7O]^+$ ions arising from 2-pentanone (**1**), 3-methylbutanone (**2**), 2-methylbut-3-en-2-ol (**3**), pent-3-en-2-ol (**4**), and 3-methylbut-3-en-2-ol (**5**) by methyl loss were studied by collisional activation. A triple sector (E/B/E) mass spectrometer was used to distinguish between fragment ion structures produced in the source and in the first field free region. The collision induced dissociations confirm or demonstrate that: (*i*) in the source, the methyl originally on the position 1 in compounds **1**−**5** is lost to give, respectively, $[n\text{-}C_3H_7CO]^+$ (**a**), $[i\text{-}C_3H_7CO]^+$ (**b**), $[CH_3COHCHCH_2]^+$ (**c**), $[CH_3CHCHCHOH]^+$ (**d**), and $[CH_2C(CH_3)CHOH]^+$ (**e**), while the methyl loss from the side chain gives, competitively, ion **c** for the five precursors; (*ii*) in the first field free region molecular ions **1**, **3**, **4**, and **5** produce an identical mixture of structures **a**, **b**, and **c**; the molecular ion **2** leads essentially to acylium ion **b**. The mechanisms and the thermochemistry of the isomerization path of **1**−**5** are discussed.

Introduction

L'élimination de CH_3 est la fragmentation principale des ions moléculaires $[C_5H_{10}O]^{\cdot+}$ métastables **1**−**5** (1−4), (Schéma 1); pour ces cinq exemples elle est en compétition avec la perte d'une molécule d'éthylène:

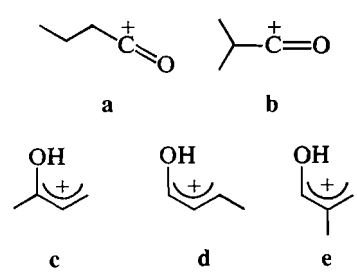


1 **2** **3** **4** **5**

Schéma 1

L'étude des spectres de masse des molécules **1**−**5** spécifiquement deutériées démontre que le radical méthyle éliminé provient aussi bien du groupement acétyle que de la chaîne propyle dans le cas de **1** (2) et **2** (3), du radical propényle pour les alcools **4** (4) et **5** (4) et du radical vinyle pour **3** (4).

Les mécanismes des réactions $[C_5H_{10}O]^{\cdot+} \rightarrow [C_4H_7O]^+ + CH_3^{\cdot}$ se produisant dans la source du spectromètre de masse ont alors été établis après examen des spectres de dissociations unimoléculaires des ions fragments $[C_4H_7O]^+$. Dans aucune des études citées, la structure des ions fragments formés en région libre de champ (RLC) n'a été directement établie. L'argumentation repose toujours sur l'utilisation du marquage isotopique et de ses conséquences sur le spectre de dissociation unimoléculaire de l'ion $M^{\cdot+}$ et sur les charactéristiques structurales des ions fragments formés dans la source. Le but du présent travail est tout d'abord d'apporter avec les spectres de collisions d'ions $[C_4H_7O]^+$ provenant de divers précurseurs, un nouveau moyen d'identification des structures **a**−**e** (Schéma 2) dont les décompositions unimoléculaires ont par ailleurs été décrites par Williams *et al.* (5) (pour **a**, **b**):



a **b** **c** **d** **e**

Schéma 2

Cette technique est ensuite utilisée sur les ions $[C_4H_7O]^+$ provenant de **1**−**5** dans la première région libre de champ d'un spectromètre de masse à triple secteur (E/B/E).

Ces résultats seront comparés aux données énergétiques associées aux réactions d'isomérisation et de dissociation des ions $[C_5H_{10}O]^{\cdot+}$ (**1**−**5**).

[a]Les intensités de pics ont été normalisées pour chaque massif en excluant la contribution des pics indiqués entre parenthèses (composantes unimoléculaires). Les participations globales de chaque massif au spectre complet sont les termes: ΣA, ΣB et ΣC; elles comprennent cette fois les pics placés entre parenthèses, elles sont rapportées à $\Sigma B = 1000$.

[b]Z = spectromètre de masse VG.ZAB.2F; M = spectromètre AEI.KRATOS.MS 902 modifié.

Resultats et discussion

1. *Spectres CID–MIKE*[2] *des ions a–e*

Les esters méthyliques **6** et **7** (Schéma 3) conduisent aux ions acylium **a** et **b** par simple rupture d'une liaison C—O. Les spectres MIKE des ions $[\mathbf{6}\text{-}OCH_3]^+$ et $[\mathbf{7}\text{-}OCH_3]^+$ ne comportent qu'un pic correspondant à l'élimination exclusive de CO (2), les énergies cinétiques $T_{0.5}$ sont très différentes (5) (respectivement 18 meV et 2 meV, VG.ZAB.2F) permettant de distinguer aisément les deux structures **a** et **b**.

Les ions **c**, **d** et **e** peuvent être formés soit par protonation des composés carbonylés **8**, **9** et **10**, soit par fragmentation des alcools **11**, **12** et **13** (Schéma 3). Les décompositions unimoléculaires des ions $[C_4H_7O]^+$ ainsi formés conduisent à deux pics *m/z* 53 ($-H_2O$) et *m/z* 43 ($-CO$ et $-C_2H_4$).

Le profil du pic $[C_4H_7O]^+ \rightarrow [C_2H_3O]^+ + C_2H_4$ est caractéristique de la structure de l'ion précurseur, "dish-topped" pour **c** ($T_{0.5}$ = 400 meV), "composite" pour **d**.

Les spectres CID–MIKE des ions $[C_4H_7O]^+$ formés dans la source à partir des molécules **6**–**13** sont rassemblés sur le tableau 1.

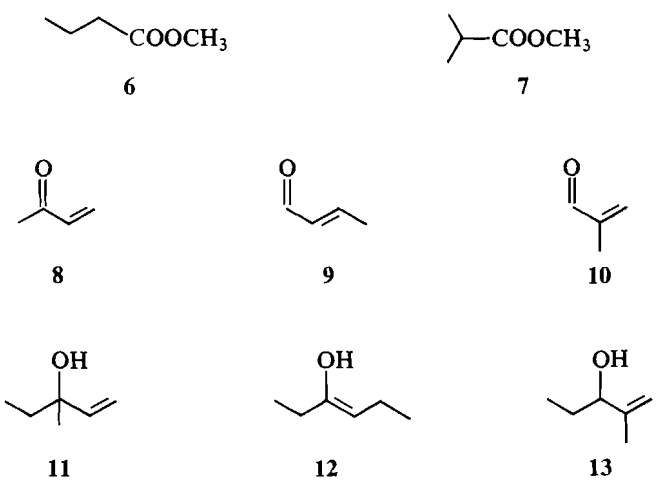

SCHÉMA 3

Le comportement des ions **a** et **b** est très largement dominé par l'élimination de 28 u.m.a. également observée sur les spectres MIKE. Parmi les fragmentations exclusivement induites par collisions, la présence pratiquement isolée du pic *m/z* 27 au coeur du massif C est caractéristique des ions acylium **a** et **b**. Seul **a** donne un pic *m/z* 29 appréciable et pour aucune des deux structures on ne détecte de pic *m/z* 31. Dans le massif B, on notera l'abondance particulière des ions *m/z* 42, ce pic surpasse *m/z* 39 dans le cas de **a**. Enfin dans la zone *m/z*

[2]On utilisera les acronymes anglosaxons MIKE (Mass Analysed Ion Kinetic Energy Spectra) et CID (Collision Induced Dissociations) – MIKE afin de désigner la technique expérimentale consistant à analyser, à l'aide d'un secteur électrique, les ions produits par la dissociation unimoléculaire (ou induite par collision) d'un ion précurseur sélectionné par un secteur magnétique (voir par exemple la référence 15).

TABLEAU 2. Spectre MIKE[a] de la pentanone 1,1,1,3,3-d_5

Fragment neutre éliminé	CH_3	CH_2D	CHD_2	CD_3	C_2H_4	C_2H_3D	$C_2H_2D_2$	C_2HD_3
Abondance (%)	65	27	18	70	43	100	47	8

[a]Mesures effectuées sur VG.ZAB.2F, 70 eV.

56−50 (A) la présence d'un pic intense m/z 56 est spécifique de l'ion **b**.

Les spectres des ions **c**, **d** et **e** sont assez différents de ceux des ions acylium, des pics nouveaux apparaissent (m/z 45, 31) ou prennent une plus grande importance (m/z 53, 51, 50, 29) et rendent identifiables les deux catégories d'ions $[C_4H_7O]^+$. La structure **c** se distingue par les intensités plus importantes des pics m/z 55 et m/z 27 au sein de leurs massifs respectifs. Les spectres des ions **d** et **e** présentent des massifs C et B extrêmement proches, la distinction entre ces deux structures est en revanche réalisable à partir des pics m/z 50−56 (le rapport m/z 55:m/z 51 est plus faible pour la structure **d**: 1,3 contre 2,5 pour **e** et 3,8 pour *c*), le pic m/z 53 domine cette région du spectre.

2. *Structure des ions $[C_4H_7O]^+$ provenant de 1 et 5*

2.1 *La pentanone-2 (1)*

La perte du méthyle occupant initialement la position 1 et celle d'un groupement CH_3 contenant trois hydrogènes de la chaîne propyle a été mise en évidence à partir des dérivés spécifiquement deutériés **1** 5,5,5-d_3 (1) et **1** 1,1,1,3,3-d_5 (2). Ces éliminations compétitives se produisent aussi bien dans la source qu'en région libre de champ du spectromètre de masse. Les ions fragments formés dans la source ont été identifiés par Krenmayr (2); à partir de **1** 1,1,1,3,3-d_5 l'élimination de CD_3 conduit à l'ion acylium **a** tandis que l'ion $[M - CH_3]^+$ correspond à **c**. Ces déductions sont basées sur le rapport des éliminations de CO et de $C_2(H,D)_4$ se produisant en première RLC d'un spectromètre à double focalisation Varian SM-IB.

Les spectres MIKE (VG.ZAB.2F) des ions $[M - CH_3]^+$ et $[M - CD_3]^+$ provenant de **1** 1,1,1,3,3-d_5 confirment les conclusions précédentes. L'ion $[M - CD_3]^+$ conduit exclusivement à $[C_3H_5D_2]^+$, le pic métastable est gaussien et sa largeur à mi-hauteur correspond à $T_{0.5}$ = 17 meV en accord avec la structure **a**.

L'ion $[M - CH_3]^+$ élimine essentiellement $C_2H_2D_2$, le pic métastable correspondant est large à sommet creux, ce profil est caractéristique ($T_{0.5}$ = 410 meV (3, 4, 6)) de la structure **c**.

Enfin le comportement de l'ion **1** 1,1,1,3,3-d_5 métastable est rapporté sur le tableau 2, un échange H/D non négligeable précède l'élimination de méthyle. On constate toutefois que les contributions des ions non échangés $[M - CH_3]^+$ et $[M - CD_3]^+$ prédominent et possèdent des valeurs comparables. Par analogie avec les fragmentations se déroulant dans la source, ces données peuvent s'interpréter par la formation compétitive d'ions **a** et **c**. L'échange partiel H/D constaté pour l'élimination de méthyle est accentué lorsque le fragment neutre expulsé est une molécule d'éthylène. La distribution $[M - C_2(H,D)_4]^{+\bullet}$ observée (Tableau 2) correspond à une répartition du type H_3D_3 sur laquelle on effectue un prélèvement de deux atomes (H_2HD/D_2 = 0,2:0,6:0,2). Cette observation, qui indique par conséquent que les échanges H/D qui précèdent l'élimination d'éthylène n'impliquent que les positions 1 et 5 (Schéma 4), est en accord avec les résultats de Beynon *et al.* (1) concernant le précurseur **1** 5,5,5-d_3:

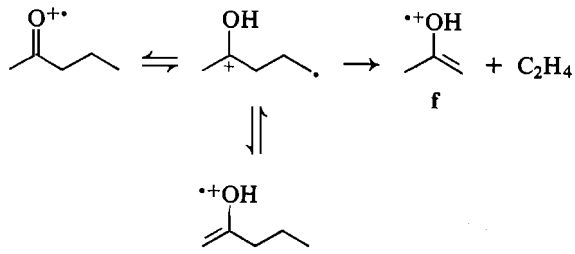

SCHÉMA 4

Les spectres CID−MIKE des ions $[1\text{-}CH_3]^+$ produits dans la source et en région libre de champ (Tableau 3) présentent de grandes similitudes. Par rapport au spectre de l'ion **a** ($[6\text{-}OCH_3]^+$, Tableau 1) on distingue une augmentation d'intensité des pics m/z 51 et 50, une abondance plus élevée du massif A et surtout l'apparition des pics m/z 45 et 31 qui trahissent la présence de la structure hydroxycarbénium **c** aussi bien parmi les ions $[1\text{-}CH_3]^+$ formés dans la source qu'en RLC. En RLC on constatera également un léger enrichissement du massif A en ions m/z 56 qui pourrait s'expliquer par l'apparition d'ions acylium **b**, à côté des structures **a** et **c** à partir de l'ion moléculaire **1** métastable.

Ajoutons enfin que l'évolution du rapport $[1a\text{-}CH_3]^+/[1a\text{-}CD_3]^+$ (0,4 en source et 0,9 en RLC) indique une plus large participation des ions de type **c** en RLC. Il se dégage de ces observations que les trajets de dissociation de **1** conduisant aux ions **a**, par simple fragmentation, et aux ions **b** et **c**, après isomérisation de l'ion moléculaire, possèdent des énergies critiques extrêmement proches.

2.2 *La méthyl-3-butanone (2)*

Il est établi que les ions de source $[2a\text{-}CD_3]^+$ et $[2a\text{-}CH_3]^+$ (**2***a*: 1,1,1,3-d_4 méthyl-3-butanone) sont, pour les premiers constitués d'un mélange d'ions **b** (majoritaire) et **e**, tandis que les seconds sont exclusivement des ions **c** (3).

Les ions $[2\text{-}CH_3]^+$ formés en source possèdent un spectre CID−MIKE très proche de celui de l'ion **b** ($[7\text{-}OCH_3]^+$, Tableau 1), la présence des pics m/z 45 et 31 témoigne de l'existence d'ions hydroxycarbénium **c**.

Un changement notable apparaît sur le spectre CID−MIKE des ions $[2\text{-}CH_3]^+$ formés en RLC, les pics m/z 45 et 31 disparaissent au profit de m/z 56: il ne subsiste pratiquement plus que la structure acylium **b** en RLC. Cette conclusion explique également la modification du rapport $[2a\text{-}CH_3]^+/[2a\text{-}CD_3]^+$ (0,5 dans la source contre 0,16 en RLC (3)). Il faut déduire de ce résultat que le processus de dissociation de l'ion **2** nécessitant le moins d'énergie est la simple élongation de la liaison C—C conduisant à **b** + $CH_3^\bullet$.

2.3 *Les penténols 3, 4 et 5*

On constate tout d'abord qu'aucune différence n'est décelable entre les spectres CID−MIKE des ions $[C_4H_7O]^+$ provenant de **3**, **8** et **11** dans la source (Tableaux 1 et 3): les ions $[3\text{-}CH_3]^+$ sont donc essentiellement des ions **c**. Ce résultat est en accord

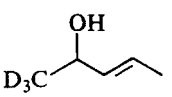
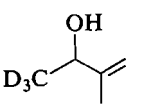
[a]Voir Tableau 1.

avec la formation pratiquement exclusive (95%) d'ions $[M - CD_3]^+$ à partir de **3***a* $(CD_3)_2COHCHCH_2$ (4) dans la source du spectromètre de masse. Dans le cas des précurseurs **4** et **5**, Zwinselman *et al.* (4) constatent que les ions de source $[M - CH_3]^+$ proviennent, pour ≈60% d'une élimination de CH_3 à partir de la chaîne propényle pour donner l'ion **c**, et pour ≈40% de la perte du méthyle occupant la position 1 conduisant ainsi aux ions **d** et **e**. Les spectres CID–MIKE des ions de source $[\mathbf{4}\text{-}CH_3]^+$ et $[\mathbf{5}\text{-}CH_3]^+$ sont assez proches, ils s'interprètent par l'existence de deux mélanges d'ions dominés par la structure **c** comme en témoigne en particulier la répartition des intensités de pics *m/z* 31–27 et la ressemblance étroite avec le spectre CID–MIKE de $[\mathbf{3}\text{-}CH_3]^+$. Les ions $[C_4H_7O]^+$ provenant des dérivés **4***a* et **5***a* permettent de contrôler l'identité du second constituant de chaque mélange d'ions $[\mathbf{4}\text{-}CH_3]^+$ et $[\mathbf{5}\text{-}CH_3]^+$:



4*a*



5*a*

Il existe un rapprochement certain entre les spectres CID–MIKE des ions de source $[\mathbf{4}a\text{-}CD_3]^+$ (Tableau 3) et **d** ($[\mathbf{12}\text{-}C_2H_5]^+$, Tableau 1) d'une part, et $[\mathbf{5}a\text{-}CH_3]^+$ (Tableau 3) et **e** ($[\mathbf{13}\text{-}C_2H_5]^+$, Tableau 1) d'autre part. Les spectres CID–MIKE des ions $[\mathbf{4}a\text{-}CH_3]^+$ et $[\mathbf{5}a\text{-}CH_3]^+$ sont identiques (Fig. 1); ils confirment la formation d'une structure commune de type **c** par élimination de CH_3 à partir de la chaîne propényle.

Les spectres d'activation collisionnelle apportent donc une confirmation aux conclusions de Zwinselman *et al.* (4) concernant les ions **3**, **4** et **5** de courte durée de vie ($\tau \leq 10^{-6}$ s).

En région libre de champ, **3***a* conduit à 75% d'ions $[M - CD_3]^+$ et 25% d'ions $[M - CH_3]^+$, ces pourcentages deviennent respectivement 65% et 35% pour les ions **4***a* et **5***a* métastables (4). On constate (Tableau 3) que les ions $[\mathbf{3}\text{-}CH_3]^+$, $[\mathbf{4}\text{-}CH_3]^+$ et $[\mathbf{5}\text{-}CH_3]^+$ formés en RLC possedent des spectres identiques. Ces trois spectres sont de plus assez semblables à celui des ions $[\mathbf{1}\text{-}CH_3]^+$ produits eux aussi en RLC. Compte tenu des résultats présentés lors de l'étude du composé **1**, il faut conclure ici à la production d'un mélange d'ions **a**, **b** et **c** à partir des penténols **3**, **4** et **5** métastables.

La composition du mélange peut être déduite des spectres des ions fragments issus de **4***a* et **5***a*. Les spectres CID–MIKE des ions $[\mathbf{4}a\text{-}CD_3]^+$ et $[\mathbf{5}a\text{-}CD_3]^+$ formés en RLC (Tableau 3) sont identiques. Par rapport aux spectres des ions de source, on constate le diminution importante des pics *m/z* 31, 50 et 51 et l'augmentation des pics *m/z* 56, 42 et 27 due à une très nette prédominance de structure acylium, un mélange d'ions **a** (majoritaires) et **b**.

Les ions $[\mathbf{4}a\text{-}CH_3]^+$ et $[\mathbf{5}a\text{-}CH_3]^+$ formés en RLC donnent des spectres CID–MIKE identiques entre eux et identiques à ceux qui ont été présentés sur la figure 1 pour les ions de source et dont la structure **c** est établie (4). Il ne fait donc aucun doute que l'élimination de méthyle à partir de la chaîne propényle conduit à l'ion **c**.

L'essentiel de la discussion précédente peut se résumer comme suit.

(a) Dans la source du spectromètre de masse, l'élimination du CH_3 occupant la position 1 des molécules **1**, **2**, **3**, **4** et **5** conduit respectivement aux ions **a**, **b**, **c**, **d** et **e** (ce dernier étant également formé à partir de **2**), tandis que, pour les cinq précurseurs, la perte de méthyle de la chaîne produit compétitivement l'ion **c**.

(b) En région libre de champ, les ions **1**, **3**, **4** et **5** conduisent à un même mélange d'ions **a**, **b** (minoritaire) et **c**; seul **2** possède un comportement distinct, la formation de l'ion acylium **b** étant prépondérante.

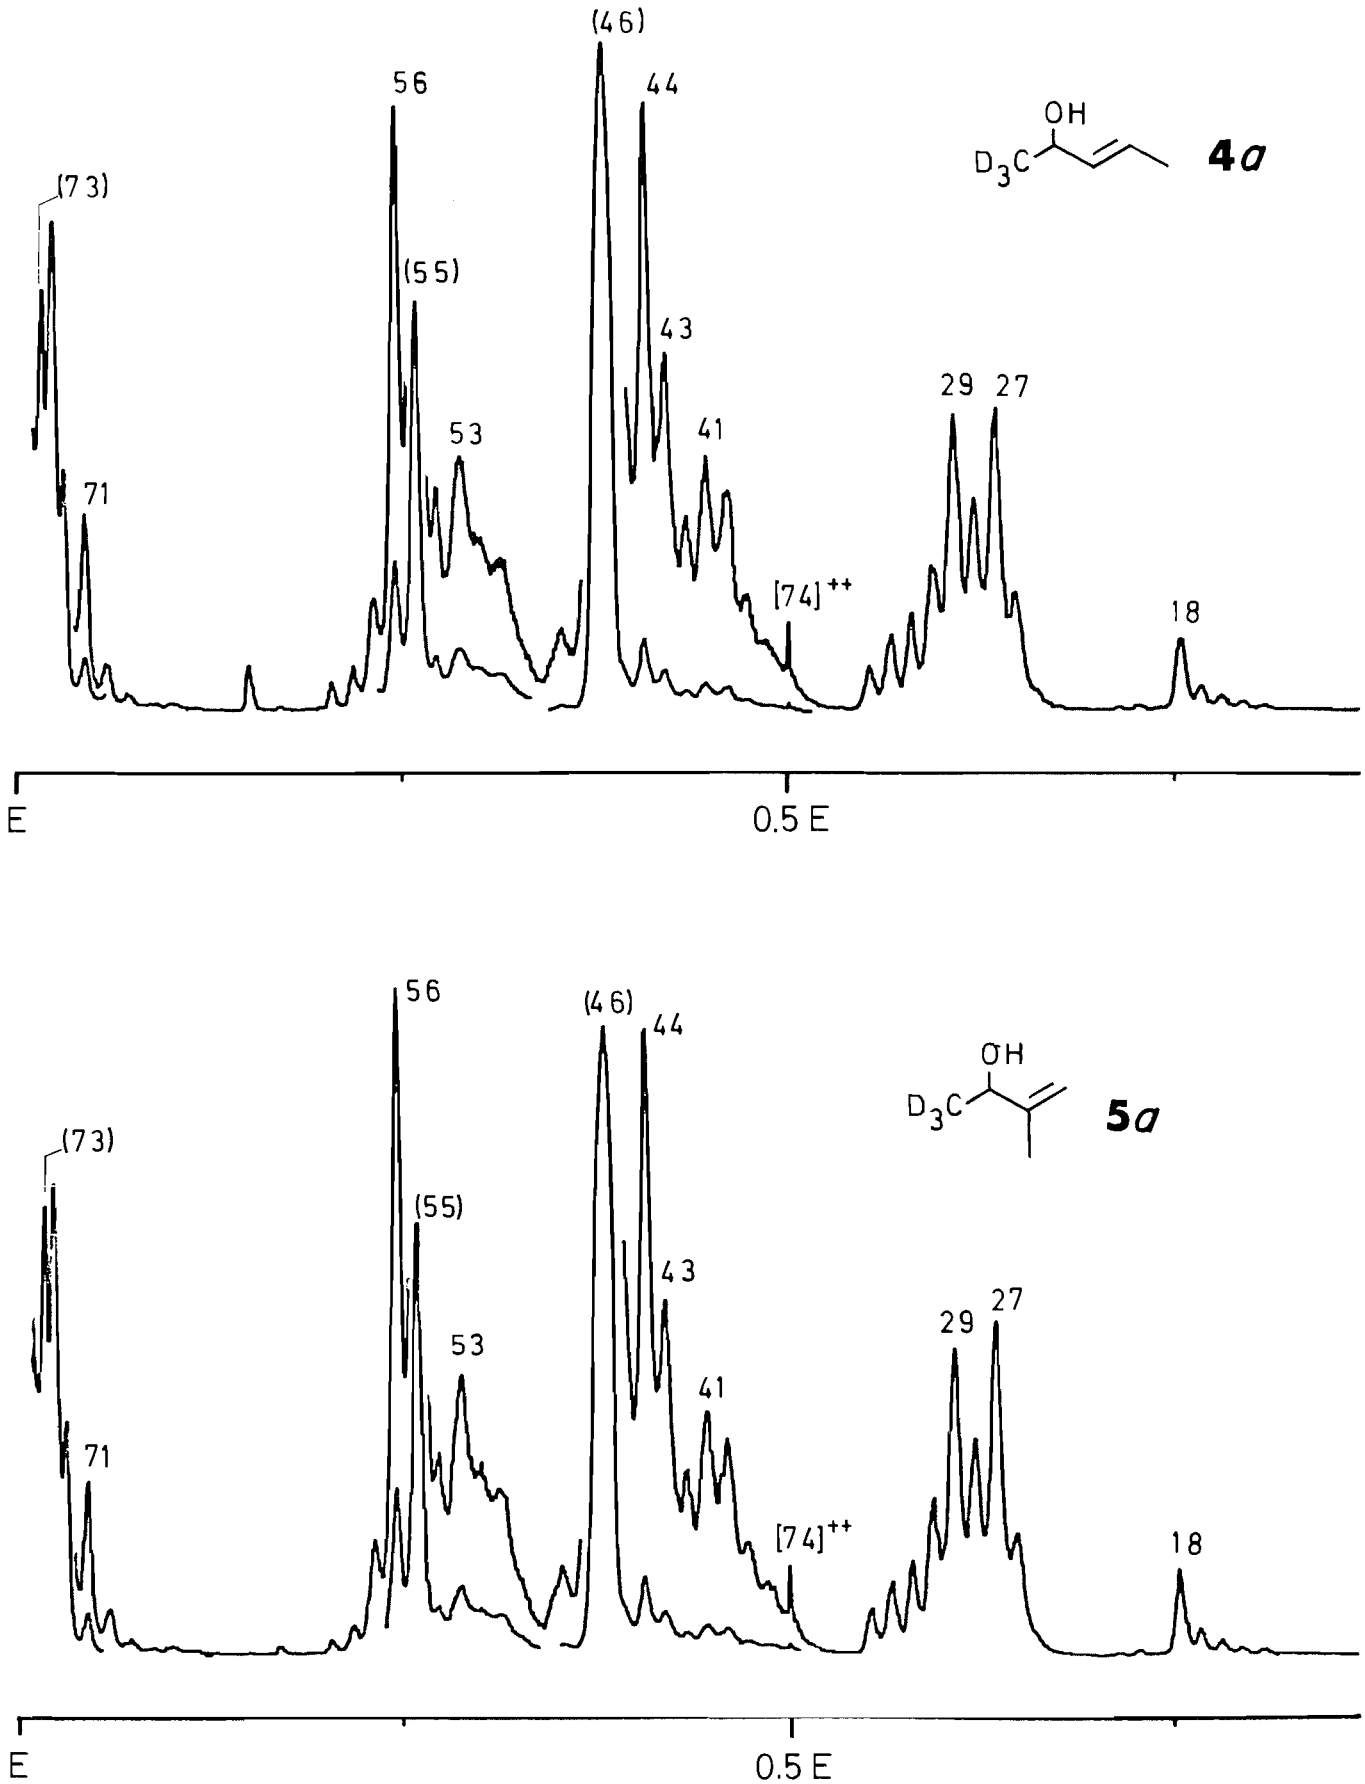

FIG. 1. Spectres CID–MIKE des ions $[\mathbf{4}a\text{-}CH_3]^+$ et $[\mathbf{5}a\text{-}CH_3]^+$ formés dans la source du spectromètre de masse MS.902.

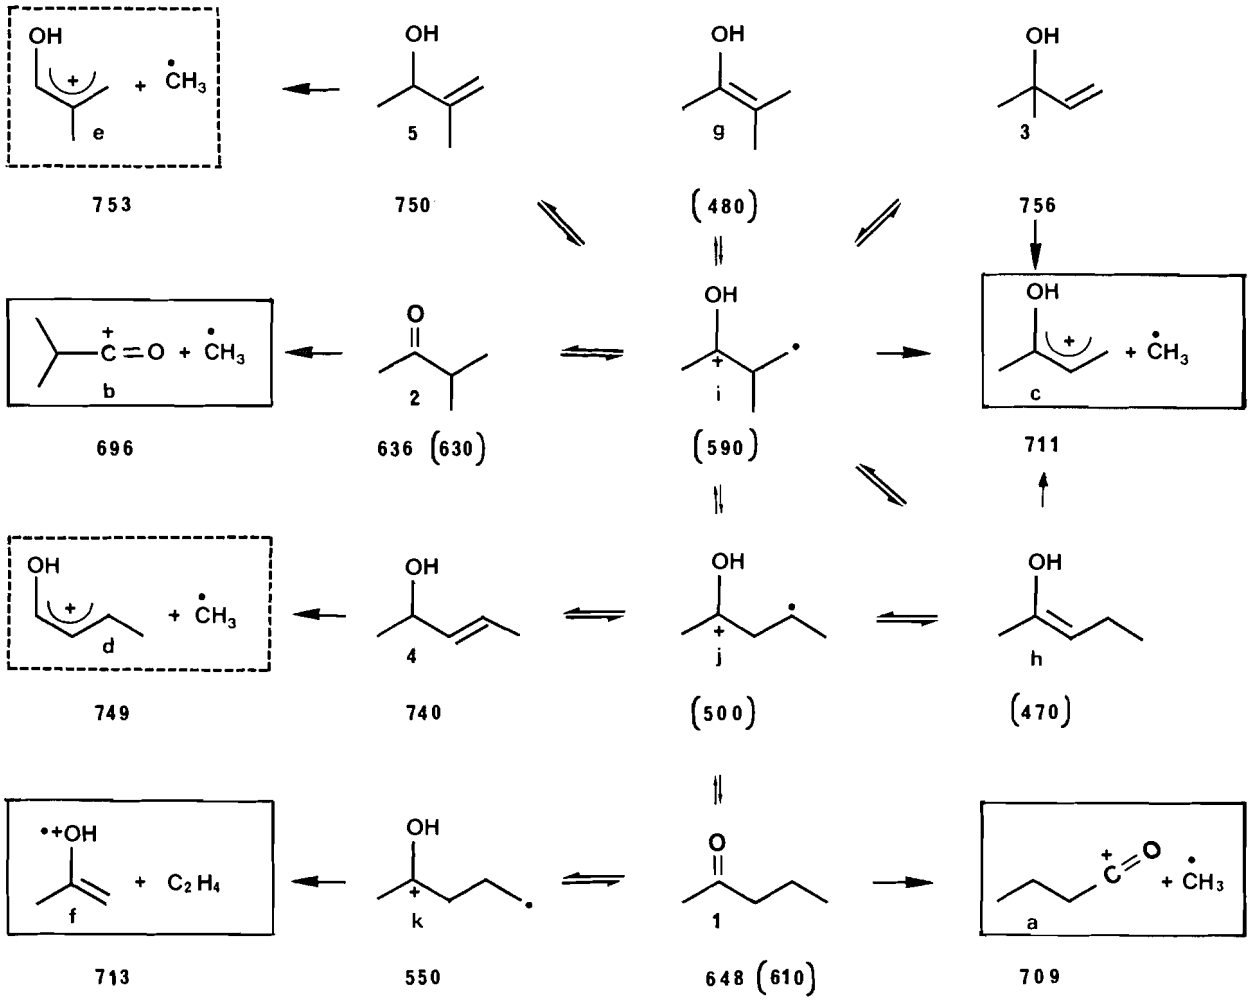

FIG. 2. Schéma d'isomérisation et de fragmentation des ions $[C_5H_{10}O]^{\cdot+}$. Les fragments encadrés d'un trait plein sont préférentiellement formés en RLC, les traits pointillés correspondent aux ions produits principalement dans la source. Les ΔH_f^0 sont exprimés en kJ mol^{-1} (entre parenthèses valeurs calculées par la méthode MINDO/3).

TABLEAU 4. Energies d'apparition (E.A. en eV) des principaux ions fragments issus de **6** et **7**[a]

	Précurseur	E.A. (m/z 71)	E.A. (m/z 74)	E.A. (m/z 87)
6	CO_2CH_3	10,8	[10,2]	10,8
7	CO_2CH_3	10,7	—	10,5

[a]Mesures effectuées sur Varian.MAT.CH5 par la méthode semi-logarithmique. Après calibration, l'échelle des énergies a été calée sur E.A. (m/z 74) = 10,2 eV (10), la reproductibilité des mesures est de l'ordre de 0,05 eV.

3. *Mécanismes et thermochimie*

L'observation des deux pics d'intensités voisines m/z 71 $[M - CH_3]^+$ et m/z 58 $[M - C_2H_4]^{\cdot+}$ sur les spectres MIKE des ions moléculaires **1**–**5** indique que les deux fragmentations possèdent des énergies critiques similaires. La thermochimie des ions **1**–**5** et de leurs dissociations conduisant à (**a**–**e**) + CH_3· (Schéma 2) et à **f** + C_2H_4 (Schéma 3) est connue (7–9). Les ΔH_f^0 des ions $[C_4H_7O]^+$ hydroxycarbénium proviennent de mesures d'affinités protoniques (7), les valeurs de ΔH_f^0 (**a**) et ΔH_f^0 (**b**) ont été déduites des énergies de photodissociation des ions moléculaires **1** et **2** (8). L'exactitude de ces deux derniers chiffres repose sur l'hypothèse de la formation exclusive des ions **a** et **b** au seuil thermodynamique en partant de **1** et **2**. Or il vient d'être établi que les ions **a** et **b** ne sont pas les seuls produits de l'élimination de CH_3 sous impact électronique à 70 eV.

Les ions **a** et **b** ont par conséquent été générés à partir des esters **6** et **7**. Les mesures d'énergie d'apparition consignées dans le tableau 4 conduisent aux estimations:

$$\Delta H_f^0 \text{ (a)} = 580 \pm 5 \text{ kJ mol}^{-1}$$

$$\Delta H_f^0 \text{ (b)} = 565 \pm 5 \text{ kJ mol}^{-1}$$

en utilisant ΔH_f^0 (**6**) = −451 kJ mol^{-1} (10), ΔH_f^0 (**7**) = −456 kJ mol^{-1} (chiffre obtenu en combinant ΔH_f^0 (**6**) et les incréments d'enthalpies des groupes n-C_3H_7 et iso-C_3H_7 (11)) et ΔH_f^0 (CH_3·) = 142 kJ mol^{-1}. Les valeurs obtenues ici sont très légèrement supérieures aux appréciations antérieures (ΔH_f^0 (**a**) = 567 kJ mol^{-1} et ΔH_f^0 (**b**) = 554 kJ mol^{-1} (8, 9)). Aucune correction aux mesures du tableau 4 n'a été effectuée en vue d'éliminer un déplacement cinétique compétitif éventuellement responsable de l'écart observé. Néanmoins ces chiffres confirment d'une part la plus grande stabilité de l'ion acylium ramifié **b**, et, d'autre part, l'extrême proximité des valeurs de ΔH_f^0 (**a**) et ΔH_f^0 (**c**) (569 ± 12 kJ mol^{-1} (7)).

La formation d'un ion $[\mathbf{3}\text{-}CH_3]^+$ de structure diméthylcétène protoné sur l'atome d'oxygène $[(CH_3)_2CCOH]^+$ (**1**) a été envisagée (4). Aucune donnée expérimentale ne permet de situer le ΔH_f^0 de cet ion, en revanche un calcul d'orbitales moléculaires a été entrepris. Ainsi les méthodes MINDO/3 (12) et MNDO (13) situent l'ion **1** 90 kJ mol^{-1} au-dessus de l'ion hydroxycarbenium **c**, la production de **1**, principalement en RLC, semble devoir être rejetée.

Un nombre restreint de réactions d'isomérisation des ions moléculaires **1**−**5** permet d'expliquer l'apparition des divers ions fragments **a**−**f** (Fig. 2). La formation des ions $[M - CH_3]^+$ de type **a** et **c** en compétition avec l'ion $[M - C_2H_4]^+$ de structure **f** à partir de **1**, **3**, **4** et **5** en RLC coïncide avec les valeurs identiques des ΔH_f^0 des produits de ces fragmentations, soit environ 710 kJ mol^{-1}. En conséquence, lorsque ces fragmentations sont globalement endothermiques, comme cela est le cas pour **1**, les réactions d'isomérisation correspondantes passent par des états de transition dont les ΔH_f^0 sont inférieurs à 710 kJ mol^{-1}. Il s'agit: de la migration 1,2 d'hydrogène (**h** ⇄ **j**); du transfert 1,2 du groupement CH_3COH (**i** ⇄ **j**) qui, à côté de l'enchaînement **i** ⇄ **h** ⇄ **j**, permet de rendre compte de l'isomérisation de la chaîne propyle avec un bilan énergétique plus favorable (14); et enfin des migrations 1,4 et 1,5 d'hydrogène (**1** ⇄ **j**, **1** ⇄ **k**).

On constate que l'état final de plus basse enthalpie, **b** + CH_3, n'est atteint de manière appréciable qu'à partir de l'ion moléculaire **2** métastable. Comme cela a été suggéré (3), ce comportement particulier s'explique par la présence d'une barrière d'isomérisation interdisant aux ions intermédiaires **i** (produits par **1**, **3**, **4** et **5**) l'accès à la structure **2**.

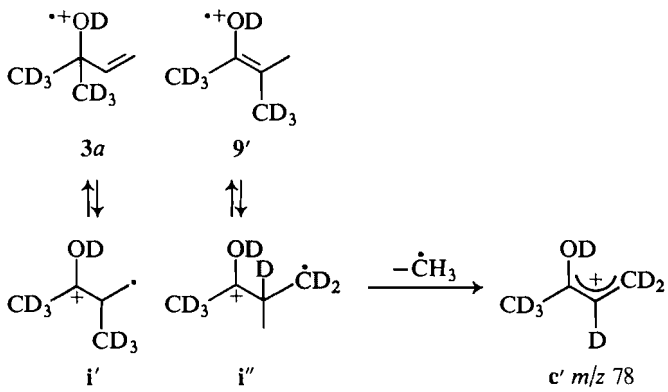

SCHÉMA 5

Ajoutons que l'isolement de **2** se traduit également par une moindre importance du pic m/z 58 sur le spectre MIKE de cet ion moléculaire (m/z 58: m/z 71 = 0,2 pour **2**, contre 0,6 pour les autres précurseurs **1**, **3**, **4** et **5**).

Le processus d'isomérisation **3** ⇄ **i** ⇄ **g** apporte une explication simple à l'élimination de CH_3 donnée en RLC partant de $[(CD_3)_2C(OD)CHCH_2]^{+\bullet}$ (4) (**3***a*) (Schéma 5). La formation d'un ion de type **c** est en effet attestée par les spectres CID−MIKE des ions $[\mathbf{3}\text{-}CH_3]^+$. Ajoutons que l'étape **3** ⇄ **i** autorise l'enchaînement d'isomérisation ultérieur conduisant à l'ion acylium **a** et à **f** + C_2H_4.

Partie expérimentale

Les spectres d'activation collisionnelle (gaz cible = hélium) des ions $[C_4H_7O]^+$ ont été relevés sur un spectromètre VG-ZAB-2F et sur un spectromètre AEI-MS.902.S modifié par l'adjonction d'un secteur électrique entre le secteur magnétique et le collecteur (E/B/E (15)). La tension d'accélération des ions a été réglée de façon à conférer une énergie cinétique voisine de 6,7 kV à tous les ions $[C_4H_7O]^+$ quelle que soit leur origine.

Les composés **1**−**5** et **8**−**10** sont d'origine commerciale tandis que **6** et **7** résultent d'une estérification. Les composés **11**, **13**, **4***a* et **5***a* sont issus de réactions de Grignard sur les cétones ou aldéhydes appropriés. La pentanone 1,1,1,3,3-d_5 a été obtenue après deux cycles d'échanges H/D dans $D_2O/BaCO_3$ (10%).

Total synthesis of *d,l*-coronafacic acid by an intermolecular Diels–Alder approach

HSING-JANG LIU AND MONTSE LLINAS-BRUNET
Department of Chemistry, University of Alberta, Edmonton, Alta., Canada T6G 2G2

Received February 27, 1984

HSING-JANG LIU and MONTSE LLINAS-BRUNET. Can. J. Chem. **62**, 1747 (1984).

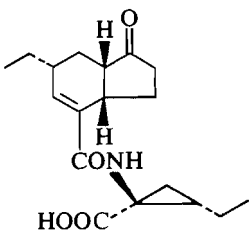
An efficient total synthesis of *d,l*-coronafacic acid (**2**) has been achieved from 4-cyclopentene-1,3-dione (**4**). The synthesis involves keto ester **7** as a key intermediate that is conveniently prepared by the Diels–Alder addition of enedione **4** to ethyl 4-ethyl-2,4-pentadienoate (**5**).

HSING-JANG LIU et MONTSE LLINAS-BRUNET. Can. J. Chem. **62**, 1747 (1984).

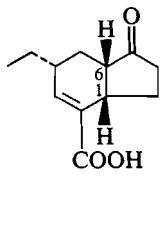
Utilisant la cyclopentène-4 dione-1,3 (**4**) comme produit de départ, on a réalisé une synthèse totale efficace de l'acide (*d,l*)-coronafacique (**2**). Le céto-ester **7**, l'intermédiaire clé dans cette synthèse, se prépare facilement par une addition de Diels–Alder de l'ènedione **4** sur l'éthyl-4 pentadiène-2,4 oate d'éthyle (**5**).

[Traduit par le journal]

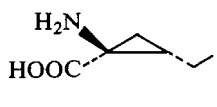
In 1977, Ichihara *et al.* (1) reported the isolation, from culture broth of *Pseudomonas coronafacience var. atropurpurea*, of a phytotoxic compound (2) named coronatine. These investigators were also able to rigorously establish the structure (1) and the absolute stereochemistry (3, 4) of the dextrorotatory phytotoxin as **1**. Hydrolysis of coronatine (**1**) gave (+)-coronafacic acid (**2**) and (+)-coronamic acid (**3**). Conversely, condensation of coronafacic acid (**2**) via the corresponding acid chloride and coronamic acid (**3**) gave rise to the parent molecule **1** (3). Coronafacic acid (**2**), which was found to be also present in the culture broth of the phytopathogenic bacterium (1), has been the subject of considerable synthetic activity and several total syntheses have been accomplished during the past few years (5). We wish to describe an efficient total synthesis of the racemic coronafacic acid (**2**) based on a fundamentally different approach.



1



2



3

As illustrated in Scheme 1, the synthesis began with a Diels–Alder reaction whereby the complete carbon framework of the target molecule was conveniently assembled. 4-Cyclopentene-1,3-dione (**4**) was chosen as the dienophile for its high dienophilicity and for its symmetry, as the use of unsymmetrical 2-cyclopentenones is expected to produce adducts such as **6** possessing the undesirable regiochemistry according to the *ortho* and *para* rules (6) governing the Diels–Alder reaction. In refluxing toluene, the cycloaddition of enedione **4** and ethyl 4-ethyl-2,4-pentadienoate (**5**) (7) proceeded smoothly to give a 67% yield of the crystalline adduct **7**,[1] mp 86–88°C. The nmr spectrum showed that the compound was completely enolized in chloroform solution and that the two stable enols were in a ratio of ca. 5:1.

Treatment of the lithium salt of diketone **7**, generated *in situ* using lithium hydride as a base, with phenyl dichlorophosphate and lithium chloride in tetrahydrofuran in the presence of a small amount of hexamethylphosphoramide[2] at room temperature overnight resulted in the formation of two isomeric chlorides **8** and **9** in 3:2 ratio and in a total yield of 64%. The two isomers were separated by high pressure liquid chromatography and their regiochemistry was individually assigned on the basis of the following observations. In the nmr spectrum, the C-1 proton of the major isomer appeared at δ 3.51 as a doublet of doublets of doublets of doublets with coupling constants of 7, 7, 2.5, and 2 Hz. This proton was shown by spin decoupling experiments to be coupled to the enone vinyl proton which appeared at δ 6.21 as a doublet with a small coupling constant of 2 Hz. On the other hand, the enone vinyl proton (doublet at δ 6.23) of the minor isomer was found to be coupled with a coupling constant of 2 Hz to the C-1 proton at δ 3.78 (ddd, $J = 7$, $J' = J'' = 2$ Hz).

The isomeric chlorides **8** and **9** were individually transformed to the desired keto ester **10** as follows. The conversion of **9** into **10** was straightforward; on hydrogenation in benzene in the presence of 5% palladium on carbon and sodium bicarbonate,[3] the former compound underwent selective reduction to give an 83% yield of keto ester **10** as a mixture of two stereoisomers (~9:1). For the transformation of **8** → **10**, initial studies were intended to proceed via the intermediacy of alcohol **11** that could be easily prepared by the reduction of **8** with sodium borohydride in ethanol. Unfortunately, alcohol **11** underwent extensive decomposition when treated with a variety of acids and with titanium tetrachloride and failed to give any detectable amount of the desired product **16**. To circumvent this difficulty, chloride **8** was subjected to the treatment with silver nitrate in hot methanol[4] and the resulting esters **12** and **13**, obtained in 82% yield and in ca. 9:1 ratio, were reduced with lithium aluminum hydride.[5] Acidic work-up using hydro-

[1]The assignment of its stereochemistry follows from the *endo*-rule and the *cis*-principle (6).

[2]This procedure was developed after several unsuccessful attempts were made to effect the transformation using known methods (8). We are currently examining the generality of this procedure for the conversion of β-dicarbonyl compounds to β-halo-α,β-unsaturated carbonyl compounds. Results will be reported elsewhere.

[3]When the catalytic hydrogenation reaction was carried out in the absence of sodium bicarbonate, a substantial amount of the fully saturated compound (dihydro derivative of **10**) was formed.

[4]When performed in ethanol, the reaction was very slow and gave a poor yield of ester **12**.

[5]Selective reduction of the enone carbonyl with sodium borohydride and with lithium tri-*tert*-butoxyaluminum hydride was attempted without much success.

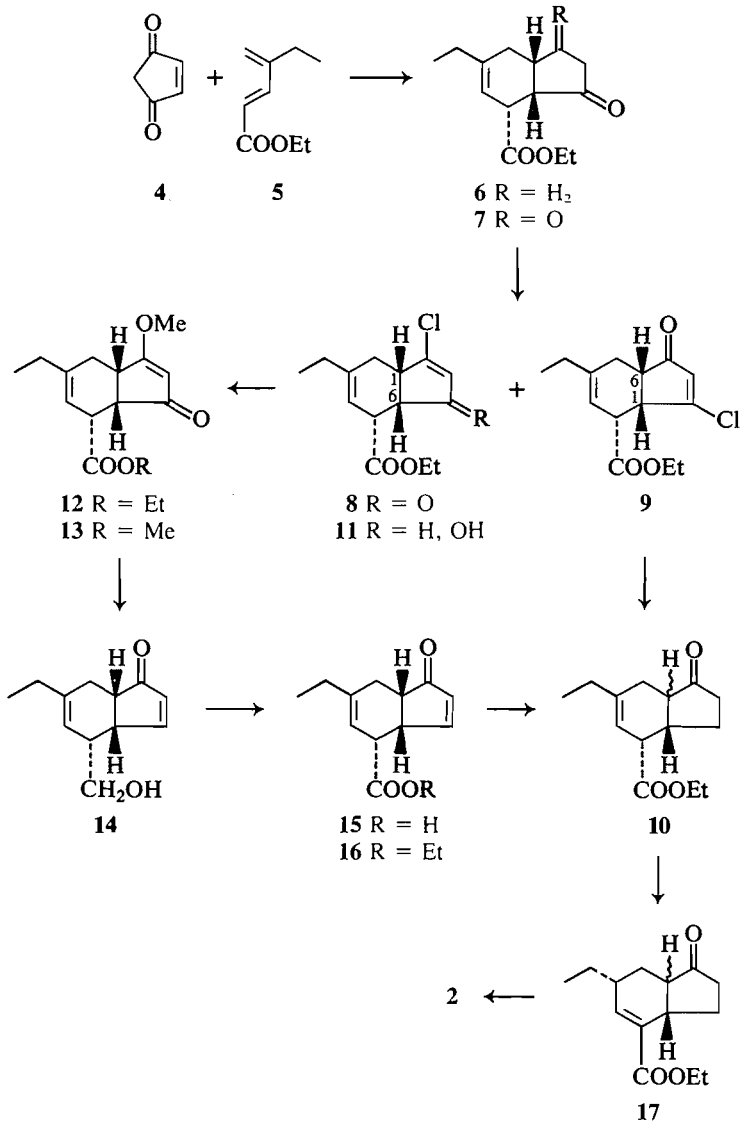

SCHEME 1

chloric acid gave a 70% yield of alcohol **14**. Jones oxidation of **14** followed by esterification of the resulting acid **15** with potassium carbonate and ethyl iodide in refluxing acetone (9) gave rise to enone ester **16** in 65% yield. Subsequent hydrogenation of this compound, carried out in ethyl acetate using 5% Pd/C as a catalyst, resulted in the selective saturation of the less substituted carbon–carbon double bond to furnish, in 92% yield, the epimeric keto esters **10** identical with those obtained previously from the minor chloride **9** (*vide supra*). Thus, by a total of seven operations, diketone **7** was converted to **10** in an overall yield of 35%.

To effect the isomerization of the double bond, the mixture of epimeric keto esters **10** was subjected to treatment with sodium ethoxide in ethanol at room temperature. Hydrolysis of the resulting α,β-unsaturated esters **17** (71% yield) in refluxing aqueous hydrochloric acid gave, in 73% yield, a solid material consisting of coronafacic acid (**2**) and its C-6 epimer[6] in ca. 4:1 ratio as determined by nmr analysis. Recrystallization of this solid material from ether–hexane gave pure *d,l*-coronafacic acid (**2**) (mp 121–125°C) identical in all respects with an authentic sample.

Experimental

General

Melting points were determined on a Kofler hot stage apparatus and are uncorrected. Elemental analyses were performed by the Microanalytical Laboratory of this department. Infrared spectra (ir) were recorded on a Nicolet 7-199 FT-IR spectrophotometer. Nuclear magnetic resonance spectra (nmr) were recorded on a Bruker WH-200 or WH-400 spectrometer and were obtained on solutions in deuteriochloroform with tetramethylsilane as internal reference. Mass spectra (ms) were recorded using A.E.I. model MS12 or MS50 mass spectrometers. Anhydrous magnesium sulfate was used for drying organic solutions.

2-Carbethoxy-4-ethylbicyclo[4.3.0]non-3-ene-7,9-dione (7)

A solution of 4-cyclopentene-1,3-dione (**4**) (290 mg, 3 mmol) and ethyl 4-ethyl-2,4-pentadienoate (**5**) (1.175 g, 7.6 mmol) in toluene (20 mL) was refluxed for 30 h under an atmosphere of nitrogen. The resulting solution was concentrated under reduced pressure. The residue was chromatographed on silica gel. Elution with a solution of 10%

[6]This compound was also isolated directly from the culture broth of *Pseudomonas coronafacience var. atropurpurea* (1). Its epimerization to **2** during the recrystallization of **2** and vice versa have been observed previously (1).

For personal use only.

petroleum ether in ethyl acetate gave diketone **7** (500 mg; 67% yield): mp 86–88°C (ether – petroleum ether); ms M^+ 250.1202 (calcd. for $C_{14}H_{18}O_4$: 250.1205). The compound existed completely in two enol forms (~5:1) in chloroform solution as indicated by the following spectral data: ir ($CHCl_3$ cast): 3440 (OH), 1730 (ester), 1642, and 1549 (β-hydroxy-α,β-unsaturated ketone) cm^{-1}; nmr: two sets of signals with the major at δ: 6.04 (br s, 1H, —OH), 5.58 (dd, 1H, J = 6, J' = 1 Hz, =CH—), 5.26 (s, 1H, =CHCO—), 4.24 (q, 2H, J = 7 Hz, —OCH_2—), 2.06 (q, 2H, J = 7 Hz, —CH_2CH_3), 1.34 (t, 3H, J = 7 Hz, —OCH_2CH_3), and 0.99 (t, 3H, J = 7 Hz, —CH_3) and the minor at δ: 6.04 (br s, 1H, —OH), 5.62 (d, 1H, J = 8 Hz, =CH—), 5.29 (s, 1H, =CHCO—), 4.29 (q, 2H, J = 7 Hz, —OCH_2—), 2.09 (q, 2H, J = 7 Hz, —CH_2CH_3), 1.36 (t, 3H, J = 7 Hz, —OCH_2CH_3), and 0.96 (t, 3H, J = 7 Hz, —CH_3). *Anal.* calcd. for $C_{14}H_{18}O_4$: C 67.17, H 7.25; found: C 67.01, H 7.07.

5-Carbethoxy-9-chloro-3-ethylbicyclo[4.3.0]nona-3,8-dien-7-one (8) and 2-carbethoxy-9-chloro-4-ethylbicyclo[4.3.0]nona-3,8-dien-7-one (9)

At 0°C, to a solution of diketone **7** (1.03 g, 4.1 mmol) in tetrahydrofuran (15 mL) under a nitrogen atmosphere, were added lithium hydride (43 mg, 5.4 mmol) and hexamethylphosphorous triamide (0.94 mL, 5.2 mmol) with stirring. After 10 min, phenyl dichlorophosphate (1.36 mL, 9.1 mmol) and lithium chloride (380 mg, 9 mmol) were added. The reaction mixture was stirred at room temperature for 16 h. Ice-cold water and dilute hydrochloric acid were added and the resulting mixture was extracted with chloroform. The extracts were washed with water, dried, filtered, and concentrated. Flash chromatography (10) of the residue on silica gel, eluting with 8% ethyl acetate in *n*-hexane, gave a 3:2 mixture (nmr analysis) of chlorides **8** and **9** (707 mg; 64% yield). The mixture was separated by preparative high pressure liquid chromatography on a Waters Associates Prep LC/System 500 using one silica gel cartridge and eluting with 7% ethyl acetate in *n*-hexane. Fractions were collected by shaving the leading and trailing edges of the single peak and recycling the central portion. The combined "leading edge" fractions were concentrated to give pure chloride **8** (178 mg); ir (neat): 1716 (ester and ketone) and 1591 (C=C) cm^{-1}; nmr δ: 6.21 (d, 1H, J = 2 Hz, =CHCO—), 5.53 (tdd, 1H, J = 7, J' = 2, J'' = 1 Hz, —CH=), 4.15, 4.13 (both q, 1H each, J = 7 Hz each, —OCH_2—), 3.61 (dd, 1H, J = 7, J' = 2 Hz, —CHCOO—), 3.51 (dddd, 1H, $J = J'$ = 7, J'' = 2,5, J''' = 2Hz, —CHCCl=), 3.23 (dd, 1H, J = 7, J' = 2 Hz, —CHCO—), 2.47 (ddd, 1H, J = 16, J' = 7, J'' = 2 Hz, —C*H*H—), 2.29 (dd, 1H, J = 16, J' = 2.5 Hz,—C*H*H—), 1.98, 1.96 (both dq, 1H each, J = 7, J' = 1 Hz each, —CH_2CH_3), 1.26 (t, 3H, J = 7 Hz, —OCH_2CH_3), and 0.94 (t, 3H, J = 7 Hz, —CH_3); ms: M^+ 270.0842 and 268.0865 (calcd. for $C_{14}H_{17}ClO_3$: 270.0837 and 268.0865). *Anal.* calcd. for $C_{14}H_{17}ClO_3$: C 62.55, H 6.38, Cl 13.20; found: C 62.50, H 6.58, Cl 12.89. The "trailing edge" fractions were combined and concentratd to give chloride **9** (196 mg); ir (neat): 1716 (ester and ketone) and 1593 (C=C) cm^{-1}; nmr δ: 6.23 (d, 1H, J = 2 Hz, =CHCO—), 5.43 (dd, 1H, J = 7, J' = 2 Hz, —CH=), 4.17 (q, 2H, J = 7 Hz, —OCH_2—), 3.78 (ddd, 1H, J = 7, $J' = J''$ = 2 Hz, —CHCCl=), 3.53 (dd, 1H, J = 7, J' = 2 Hz, —CHCOO—), 2.96 (ddd, 1H, $J = J'$ = 7, J'' = 4 Hz, —CHCO—), 2.32 (m, 2H, —CH_2—), 1.99 (q, 2H, J = 7 Hz, —CH_2CH_3), 1.28 (t, 3H, J = 7 Hz, —OCH_2CH_3), and 0.94 (t, 3H, J = 7 Hz, —CH_3); ms: M^+ 270.0850 and 268.0875 (calcd. for $C_{14}H_{17}ClO_3$: 270.0837 and 268.0865). The remaining material was recovered as a mixture of **8** and **9**.

2-Carbethoxy-4-ethylbicyclo[4.3.0]non-3-en-7-one (10) from chloride 9

To a solution of chloride **9** (48 mg, 0.18 mmol) in benzene (1.2 mL) were added sodium bicarbonate (15 mg, 0.18 mmol) and 5% Pd/C (4.8 mg). After stirring under an atmosphere of hydrogen for 4 h, the reaction mixture was filtered and concentrated. Flash chromatography of the residue on silica gel, eluting with 5% ethyl acetate in *n*-hexane, gave a mixture of epimeric keto esters **10** (35 mg; 83% yield); ir (neat): 1732 (ketone and ester) cm^{-1}; nmr δ: 5.44, 5.37 (both br s, ~1:9, total 1H, —CH=), 4.18 (q, 2H, J = 7 Hz, —OCH_2—), 1.33, 1.34 (both t, ~9:1, total 3H, J = 7 Hz each, —OCH_2CH_3), and 1.03 (t, 3H, J = 7 Hz, —CH_3); ms: M^+ 236.1410 (calcd. for $C_{14}H_{20}O_3$: 236.1413). *Anal.* calcd. for $C_{14}H_{20}O_3$: C 71.14, H 8.54; found: C 70.85, H 8.54.

5-Carbethoxy-3-ethyl-9-methoxybicyclo[4.3.0]nona-3,8-dien-7-one (12) and 5-carbomethoxy-3-ethyl-9-methoxybicyclo[4.3.0]nona-3,8-dien-7-one (13)

Chloride **8** (381 mg, 1.42 mmol) was dissolved in methanol (10 mL) under a nitrogen atmosphere in a flask wrapped in aluminum foil to exclude light. Silver nitrate (482 mg, 2.84 mmol) was introduced and the reaction mixture heated at 70°C for 19 h. Filtration and concentration gave the crude product which was subjected to flash chromatography on silica gel. Elution with 35% ethyl acetate in *n*-hexane gave ethyl ester **12** (276 mg; 74% yield); ir (neat): 1724 (ester), 1698 (ketone), and 1600 (C=C) cm^{-1}; nmr δ: 5.53 (tdd, 1H, J = 7, J' = 2, J'' = 1 Hz, —CH=), 5.32 (d, 1H, J = 1 Hz, =CHCO—), 4.16, 4.14 (both q, 1H each, J = 7 Hz each, —OCH_2—), 3.86 (s, 3H, —OCH_3), 3.62 (dd, 1H, J = 7 Hz, J' = 2 Hz, —CHCOO—), 3.33 (dddd, $J = J'$ = 7, J'' = 3, J''' = 1 Hz, —C*H*CH_2—), 3.15 (dd, 1H, J = 7, J' = 2 Hz, —CHCO—), 2.39 (ddd, 1H, J = 16, J' = 7, J'' = 2 Hz, —C*H*H—), 2.24 (dd, 1H, J = 16, J' = 3 Hz, —C*H*H—), 1.98, 1.96 (both dq, 1H each, J = 7, J' = 1 Hz each, —CH_2CH_3), 1.27 (t, 3H, J = 7 Hz, —OCH_2CH_3), and 0.94 (t, 3H, J = 7 Hz, —CH_3); ms: M^+ 264.1365 (calcd. for $C_{15}H_{20}O_4$: 264.1362). Further elution with the same solvent system gave methyl ester **13** (24 mg; 8% yield); ir (neat): 1735 (ester) 1695 (ketone), and 1598 (C=C) cm^{-1}; nmr δ: 5.56 (br d, 1H, J = 7 Hz, —CH=), 5.30 (s, 1H, =CHCO—), 3.83 (s, 3H, —OCH_3), 3.71 (s, 3H, —$COOCH_3$), and 0.93 (t, 3H, J = 7 Hz, —OCH_2CH_3); ms: M^+ 250.1210 (calcd. for $C_{14}H_{18}O_4$: 250.1205).

4-Ethyl-2-hydroxymethylbicyclo[4.3.0]nona-3,8-dien-7-one (14)

At −20°C, to a solution of esters **12** and **13** (11:1; 389 mg, 1.48 mmol) in ether (8 mL) under a nitrogen atmosphere was added lithium aluminum hydride (112 mg, 2.95 mmol). After stirring for 20 min, the reaction mixture was allowed to warm up to −5°C. Water (2 mL) was slowly added. The resulting mixture was acidified with 1 *N* hydrochloric acid, stirred at 0°C for 45 min, and extracted with methylene chloride. The organic solution was dried, filtered, and concentrated. Flash chromatography of the residue on silica gel, eluting with 45% ethyl acetate in *n*-hexane gave alcohol **14** (198 mg; 70% yield); ir (neat): 3425 (OH), 1704 (C=O), and 1585 (C=C) cm^{-1}; nmr δ: 7.64 (dd, 1H, J = 6, J' = 3 Hz, —C*H*=CHCO—), 6.17 (dd, 1H, J = 6, J' = 2 Hz, =CHCO—), 5.35 (d, 1H, J = 5 Hz, —CH=), 3.75, 3.69 (both dd, 1H each, J = 18, J' = 6 Hz each, —CH_2O—), 2.03 (q, 2H, J = 7 Hz, —CH_2CH_3), and 0.98 (t, 3H, J = 7 Hz, —CH_3); ms: M^+ 192.1143 (calcd. for $C_{12}H_{16}O_2$: 192.1150). *Anal.* calcd. for $C_{12}H_{16}O_2$: C 74.97, H 8.39; found: C 74.78, H 8.57.

2-Carboxy-4-ethylbicyclo[4.3.0]nona-3,8-dien-7-one (15) and 2-carbethoxy-4-ethylbicyclo[4.3.0]non-3,8-dien-7-one (16)

At 0°C, to a solution of alcohol **14** (131 mg, 0.68 mmol) in acetone (4 mL) was added dropwise 1 mL of 8 *N* Jones reagent (11) with stirring. After 1 h, the reaction mixture was diluted with water and extracted with ethyl acetate. Drying, filtration, and concentration gave 120 mg of acid **15** (ir ($CHCl_3$ cast): 3060 (acid), 1700 (acid and ketone), and 1590 (C=C) cm^{-1}). This compound, without purification, was dissolved in acetone (4 mL) and potassium carbonate (161 mg, 1.17 mmol) was added. The mixture was stirred at room temperature under a nitrogen atmosphere for 1 h and iodoethane

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.5 on 09/06/12
For personal use only.

(0.7 mL, 8.75 mmol) was then introduced. After heating at reflux for 16 h, the reaction mixture was poured into ice-cold water and extracted with methylene chloride. The organic solution was dried, filtered, and concentrated. Flash chromatography of the residue on silica gel, eluting with 8% ethyl acetate in *n*-hexane, gave enone ester **16** (103 mg; 65% yield from alcohol **14**); ir (CH_2Cl_2 cast): 1730 (ester), 1712 (ketone), 1590 (C=C) cm^{-1}; nmr δ: 7.62 (dd, 1H, J = 6, J' = 3 Hz, —C*H*=CHCO—), 6.26 (dd, 1H, J = 6, J' = 2 Hz, =CHCO—), 5.51 (dd, J = 7, J' = 2 Hz, —CH=), 4.22 (q, 2H, J = 7 Hz, —OCH_2—), 2.05 (q, 2H, J = 7 Hz, —CH_2CH_3), 1.31 (t, 3H, J = 7 Hz, —OCH_2CH_3), and 0.99 (q, 3H, J = 7 Hz, —CH_3); ms: M^+ 234.1256 (calcd. for $C_{14}H_{18}O_3$: 234.1256).

*Keto esters **10** from enone ester **16***

Enone ester **16** (85 mg, 0.36 mmol) was dissolved in ethyl acetate (3 mL) and 5% Pd/C (9 mg) was added. The mixture was stirred under an atmosphere of hydrogen at room temperature for 1 h. Filtration and concentration gave the crude product, which was purified by flash chromatography on silica gel. Elution with 5% ethyl acetate in *n*-hexane gave a mixture of keto esters **10** (78 mg; 92% yield) identical with that obtained previously from chloride **9**.

*2-Carbethoxy-4-ethylbicyclo[4.3.0]non-2-en-7-one (**17**)*

At 0°C, to a solution of keto esters **10** (35 mg, 0.15 mmol) in ethanol (1.5 mL) was added sodium hydride (80% oil dispersion; 10 mg, 0.33 mmol). After stirring at room temperature under a nitrogen atmosphere for 16 h, the reaction mixture was diluted with ice-cold water, acidified with dilute hydrochloric acid, and extracted with methylene chloride. The organic solution was dried, filtered, and concentrated. Flash chromatography of the residue on silica gel, eluting with 5% ethyl acetate in *n*-hexane, gave a mixture of epimeric esters **17** (25 mg; 71% yield); ir ($CHCl_3$ cast): 1742 (ketone), 1711 (ester), and 1642 (C=C) cm^{-1}; nmr δ: 6.98, 6.92 (2:5; both br s, total 1H, —CH=), 4.21 (m, 2H, —OCH_2—), 1.32, 1.27 (5:2; both t, total 3H, J = 7 Hz each, —OCH_2CH_3), 1.01, and 0.99 (5:2; both t, total 3H, J = 7 Hz each, —CH_3); ms: M^+ 236.1408 (calcd. for $C_{14}H_{20}O_3$: 236.1412). *Anal.* calcd. for $C_{14}H_{20}O_3$: C 71.16, H 8.53; found: C 71.14, H 8.53.

d,l-*Coronafacic acid (**2**)*

A solution of esters **17** (20 mg, 0.085 mmol) in 2.4 *N* aqueous hydrochloric acid (1.5 mL) was heated at reflux under a nitrogen atmosphere for 5.5 h. After cooling to room temperature, the resulting solution was diluted with water (2 mL) and extracted with ethyl acetate. The extracts were dried, filtered, and concentrated. Flash chromatography of the residue on silica gel, eluting with 40% ethyl acetate in *n*-hexane, gave 13 mg (73% yield) of a 4:1 (nmr integration) mixture of coronafacic acid (**2**) and its C-6 epimer. In the nmr spectrum, the vinyl proton of the latter compound appeared as a doublet of doublets (J = 4, J' = 2 Hz) at δ 7.12 in agreement with the reported value (1). Recrystallization of the mixture resulted in partial epimerization of the minor isomer to coronafacic acid (**2**) and gave 11 mg of the latter compound in crystalline form, mp 121–125°C. Concentration of the mother liquid gave 2 mg of a 1:1 mixture of **2** and its C-6 epimer. The ir, nmr, and mass spectra of the synthetic coronafacic acid were found to be identical with those of an authentic sample and displayed the following characteristic features: ir ($CHCl_3$ cast): 3040, 2634, 2532, 1685 (acid), 1741 (ketone), and 1634 (C=C) cm^{-1}; nmr δ: 7.06 (br s, 1H, —CH=) and 1.01 (t, 3H, J = 7 Hz, —CH_3); ms: M^+ 208.1104 (100%; calcd. for $C_{12}H_{16}O_3$: 208.1099).

Aliphatic diazo compounds. XIV. The synthesis of 7-substituted 3-diazo-2-norbornanones and the infrared and proton and carbon-13 nuclear magnetic resonance spectra of these diazo ketones and their precursors[1]

PETER YATES AND JOHN DAVID KRONIS
Lash Miller Chemical Laboratories, University of Toronto, Toronto, Ont., Canada M5S 1A1

Received December 14, 1983

PETER YATES and JOHN DAVID KRONIS. Can. J. Chem. **62**, 1751 (1984).

syn- and *anti*-7-Isopropyl-2-norbornanone (**5** and **6**) were prepared by catalytic hydrogenation of 7-isopropylidene-2-norbornanone; *syn*- and *anti*-7-benzhydryl-2-norbornane (**9** and **10**) were prepared in analogous fashion. Ketones **5** and **6** and *syn*- and *anti*-7-*tert*-butyl-2-norbornanone (**7** and **8**) were converted to the corresponding 3-diazo-2-norbornanones **1**–**4** via the monotosylhydrazones **44**–**47** of the corresponding α-diketones **40**–**43**. The ^1H and ^{13}C nmr spectra of **1**–**10**, **40**–**47**, and their precursors have been analyzed. The ^1H nmr spectra of the diazo ketones **1**–**4** have their C-1 and C-4 bridgehead proton signals shifted to higher and lower field, respectively, relative to the bridgehead signals of the corresponding diketones. The ^{13}C nmr spectra of all pairs of bicyclic epimers shown γ-*gauche* shielding effects by the 7-substituent at (sp^3) C-3 in the *syn* compounds and at C-5 and C-6 in the *anti* compounds. A converse effect is found at (sp^2) C-2 (and C-3 in the diketones). Comparison of the magnitude of the shielding effects of C-7 methyl, isopropyl, benzhydryl, and *tert*-butyl substituents gives evidence of δ deshielding effects at C-3 in the *syn* compounds and at C-5 and C-6 in the *anti* compounds by methyl substituents on C-8.

PETER YATES et JOHN DAVID KRONIS. Can. J. Chem. **62**, 1751 (1984).

On a préparé les isopropyl-7 norbornanones-2 *syn* et *anti* (**5** et **6**) par hydrogénation catalytique de l'isopropylidène-7 norbornanone-2; on a préparé les benzhydryl-7 norbornanones-2 *syn* et *anti* (**9** et **10**) d'une manière semblable. On a transformé les cétones **5** et **6** ainsi que les *tert*-butyl-7 norbornanones-2 *syn* et *anti* (**7** et **8**) en leurs diazo-3 norbornanones-2 correspondantes (**1**–**4**) par le biais des monotosylhydrazones **44**–**47** des α-dicétones correspondantes **40**–**43**. On a analysé les spectres rmn du ^1H et du ^{13}C des composés **1**–**10** et **40**–**47** et de leurs précurseurs. Dans les spectres rmn du ^1H des diazocétones **1**–**4**, les signaux des protons en tête de pont (C-1 et C-4) sont déplacés respectivement vers des champs plus haut et plus bas, par rapport aux signaux des protons dans les positions équivalentes des dicétones correspondantes. Les spectres rmn du ^{13}C de chacune des paires d'épimères bicycliques présentent tous des effets de blindage γ-*gauche*, dus aux substituants en position 7 et affectant la position C-3 (sp^3) des composés *syn* et les positions C-5 et C-6 des composés *anti*. On observe un effet inverse au niveau de C-2 (sp^2) (et de C-3 dans les dicétones). Une comparaison de l'amplitude des effets de blindage provoqués par les substituants méthyle, isopropyle, benzhydryle et *tert*-butyle en C-7 suggère que les substituants méthyles en C-8 provoquent des effets de déblindage δ en C-3 dans les composés *syn* et en C-5 et C-6 dans les composés *anti*.

In connection with our studies on the acid-catalyzed decomposition of α-diazo ketones (1, 2), we required pairs of 3-diazo-2-norbornanones with bulky *syn*- and *anti*-7 substituents. We describe here the synthesis of the diazo ketones **1**–**4**, prepared for this purpose, and discuss their ^1H and ^{13}C nmr spectra together with those of their precursors, which reveal features of intrinsic interest in addition to providing evidence for the structural assignments. We also discuss the synthesis and spectra of the *syn*- and *anti*-7-substituted 2-norbornanones **9** and **10**, which were not converted to the corresponding 3-diazo-2-norbornanones, but which are closely related to the 2-norbornanones **5**–**8** that were the precursors of **1**–**4**. In addition we include an account of the synthesis and spectra of the tricyclo[2.2.1.$0^{2,6}$]heptan-3-ones **11**–**14**, which were prepared from **1**–**4** for the purpose of comparison with products obtained by the acid-catalyzed decomposition of the latter.

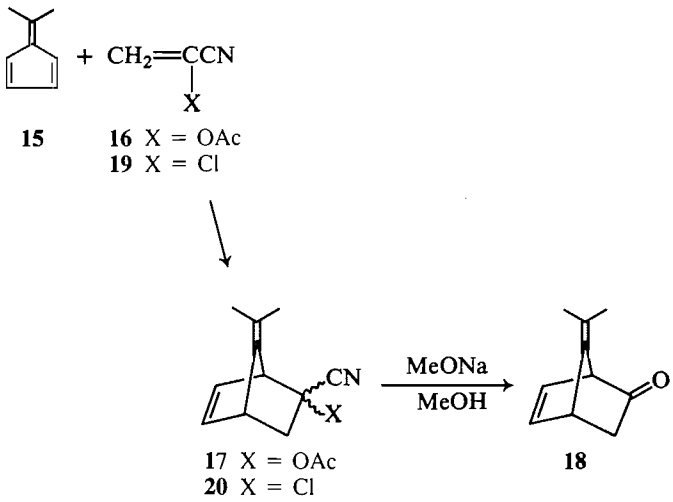
Synthesis of the 2-norbornanones and 3-diazo-2-norbornanones

A conceptually simple route to 7-substituted 2-norbornanones involves Diels–Alder addition of ketene to 5-substituted cyclopentadienes. In practice, this approach is complicated by several factors. First, the well-known tendency of ketene to participate in [2 + 2] rather than [4 + 2] cycloaddition reactions makes it necessary to use a ketene equivalent with subsequent conversion of the adduct to a carbonyl compound. Second, the 5-substituted cyclopentadienes very readily tautomerize to their 1- and 2-substituted isomers, which are usually highly favoured thermodynamically relative to the 5-substituted isomer (3). This problem is particularly acute in the case of relatively unreactive dienophiles, a class into which most ketene equivalents fall; however, Corey *et al.* (4) have successfully overcome it in some instances by the use of anhydrous cupric tetrafluoroborate as a catalyst for the Diels–Alder

[1] For part XIII, see ref. 1.

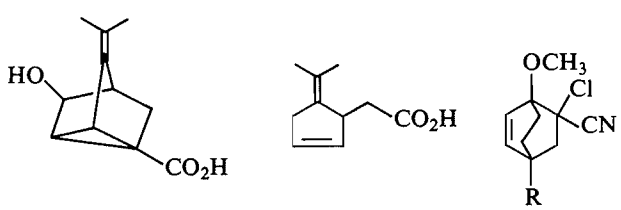


SCHEME 1

reaction, permitting the latter to be carried out at 0°C. Third, in reactions of this type one stereoisomer is often formed exclusively or predominantly (4, 5), making them impracticable for the synthesis of both *syn*- and *anti*-7-substituted 2-norbornanones.

We therefore adopted an approach based on earlier work by DePuy and Story (6), who carried out the Diels–Alder reaction of 6,6-dimethylfulvene (**15**) with the ketene equivalent 2-acetoxyacrylonitrile (**16**) to give the adducts **17**, which were converted to the dienone **18** with methanolic sodium methoxide (Scheme 1). Use of a fulvene rather than a cyclopentadiene as the diene obviates the problem of tautomerization and it appeared that **18** could serve as a source of both **5** and **6**. In fact when we prepared **18** by this method and hydrogenated it we obtained a product which was subsequently shown to be a mixture of **5** and **6**. However, this method was impracticable for the preparation of **5** and **6** on the large scale because of the high cost of 2-acetoxyacrylonitrile. We therefore undertook to develop an improved synthesis utilizing the very much more economical ketene equivalent, 2-chloroacrylonitrile (**19**). Reaction of **15** with an excess of **19** in benzene at 40°C for 51 days afforded an 82% yield of a mixture of the stereoisomeric α-chloro nitriles **20**; unfortunately, this reaction was not catalyzed by cupric tetrafluoroborate.

Attempted hydrolysis of this mixture with potassium hydroxide in dimethyl sulfoxide (7) resulted in the formation of a complex mixture of predominantly acidic products, which were not identified. They may include products of type **21***a*, whose formation has been observed in other cases (8, 9), but also include compounds containing vinyl hydrogen atoms, as shown by ^{1}H nmr spectroscopy. The latter could arise via Haller–Bauer cleavage (10) of the desired product **18** to acids of type **21***b* – a process that should be facilitated by the presence of two ethylenic double bonds in a β,γ relationship to the carbonyl group (*vide infra*).



21*a* **21***b* **22**

Evans *et al.* (11) have found that sodium sulfide nonahydrate in boiling ethanol can be used to effect the transformation of chloro nitriles of type **22** to the corresponding bicyclo-[2.2.2]octenones. To determine whether this procedure was likely to be applicable to the synthesis of bicyclo[2.2.1]hept-5-en-2-ones we prepared the chloro nitriles **23***a* and **23***b* by a modification of a known procedure (12); they were obtained as a 4:1 mixture, as shown by ^{1}H nmr spectroscopy (*vide infra*). Treatment of this mixture with sodium sulfide nonahydrate in boiling ethanol gave no 5-norbornen-2-one (**24**), but a 65% yield of a crystalline product, shown to be the chloro amide **25** by its spectra (see Experimental) and the fact that it is formed from a 4:1 mixture of **23***a* and **23***b*.

23*a* X = CN, Y = Cl
23*b* X = Cl, X = CN
24 X, Y = O

25

The synthesis of **5** and **6** was pursued by avoiding the intermediacy of the dienone **18** as shown in Scheme 2. The dienes **20** could be hydrogenated exclusively at the endocyclic double bond to give **26**, which on treatment with potassium hydroxide in dimethyl sulfoxide gave the ketone **27** in 80% yield. The fact that the hydrolysis reaction proceeds well in the case of **26** but not **20** lends strength to our earlier interpretation of its failure in the latter case. The high chemoselectivity in the partial hydrogenation of **20** contrasts with the low selectivity reported in the case of **18** (6); this must reflect steric inhibition of approach by the catalyst to the face of the exocyclic double bond that is *syn* to the *exo* chloro or cyano substituent.

Catalytic hydrogenation of the ketone **27** proceeded slowly and cleanly to give a 94% yield of a 3:2 mixture of the *syn* and *anti* ketones **5** and **6**, as determined by gas chromatographic analysis. These could not be separated by liquid chromatography but were separated by the exclusive precipitation of the *anti* isomer as its 2,4-dinitrophenylhydrazone (2,4-DNP) **28**. This selectivity was expected on the basis of the known high propensity of 2-norbornanones lacking a *syn*-7 substituent to undergo *exo* nucleophilic attack at the carbonyl group (13), and permits unambiguous assignment of stereochemistry to the individual epimers. The unchanged *syn* isomer was isolated from the filtrate in 89% recovery, while the *anti* isomer was obtained in 88% recovery by treatment of **28** with titanium chloride by the method of McMurry and Silvestri (14).[2]

The synthesis of the benzhydryl compounds **9** and **10** (Scheme 3) resembled that of their isopropyl analogues **5** and **6**. Reaction of 6,6-diphenylfulvene (**29**) with 2-chloroacrylonitrile gave a crystalline mixture of adducts **30**, which could again be hydrogenated exclusively at the endocyclic ethylenic double bond to give the dihydro compounds **31**. Hydrolysis of **31** with potassium hydroxide and dimethyl sulfoxide at room temperature for 48 h gave the ketone **32** as a minor product only; the major product was an acid, assigned structure **33** on the basis of its composition and spectra (see Experimental). The acid **33** is considered to arise by Haller–Bauer

[2] Since the initiation of this work the synthesis of mixtures of *syn*- and *anti*-7-*n*-alkyl-substituted 2-norbornanones from fulvenes and 2-chloroacrylonitrile has been reported in the patent literature (15).

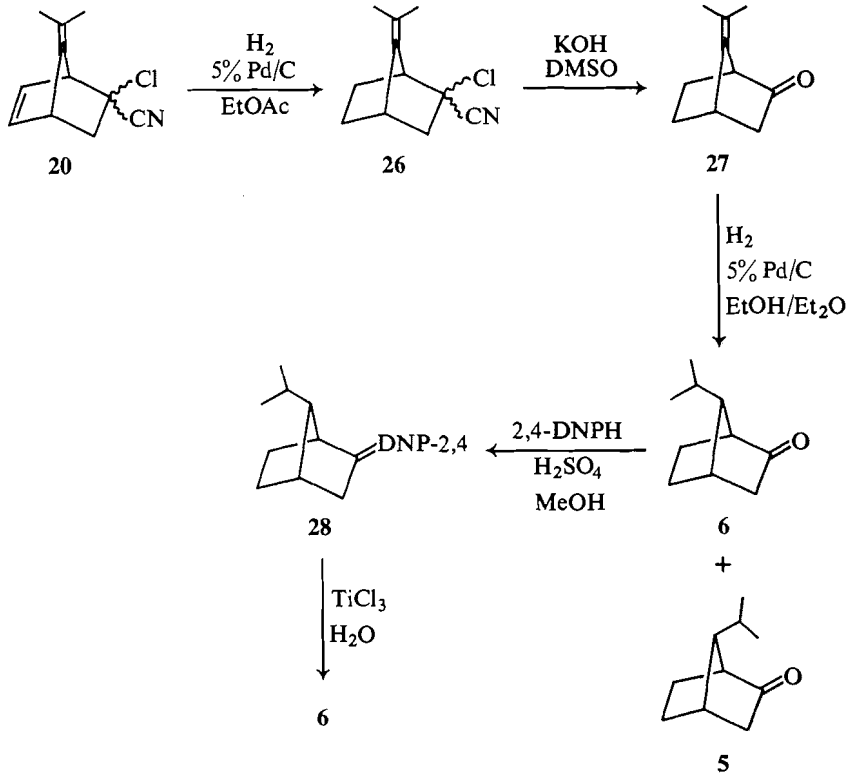
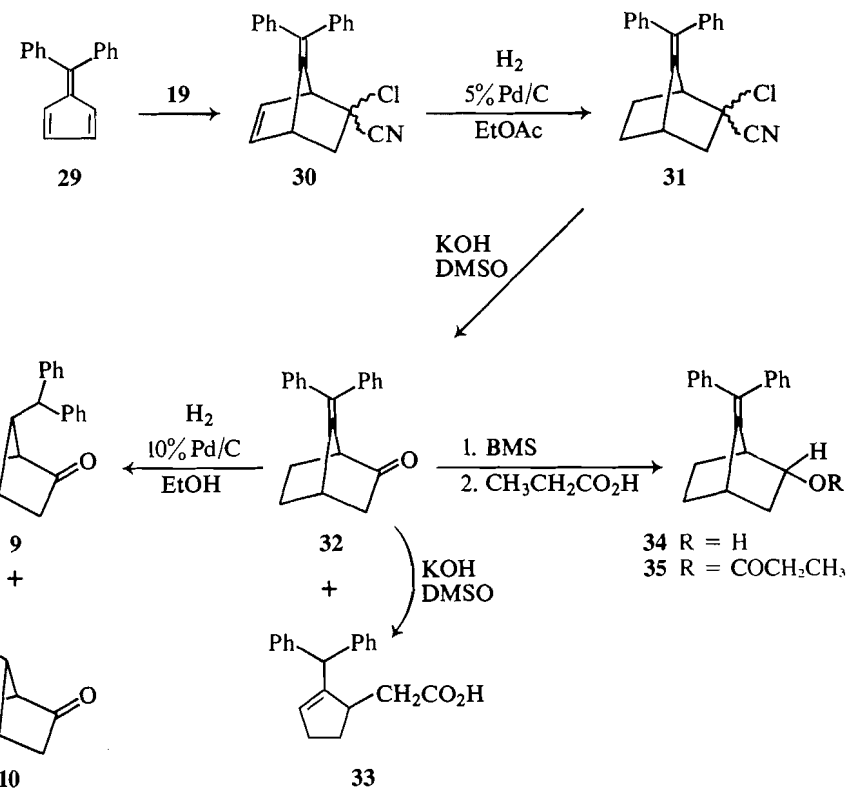


SCHEME 2



SCHEME 3

cleavage of the ketone **32**, as proposed above in the case of **18**; here facilitation of the cleavage is attributable to additional stabilization of the intermediate allylic anion by the phenyl substituents. That **32** can serve as the source of **33** was demonstrated by the fact that the latter is formed on treatment of **32** with potassium hydroxide and dimethyl sulfoxide. It was found possible to increase the yield of the desired product **32** to 86% by reducing the reaction time for the hydrolysis of **31** to 13 h. Catalytic hydrogenation of **32** gave a 92% yield of a mixture of the *syn* and *anti* ketones **9** and **10**, which in this case, unlike

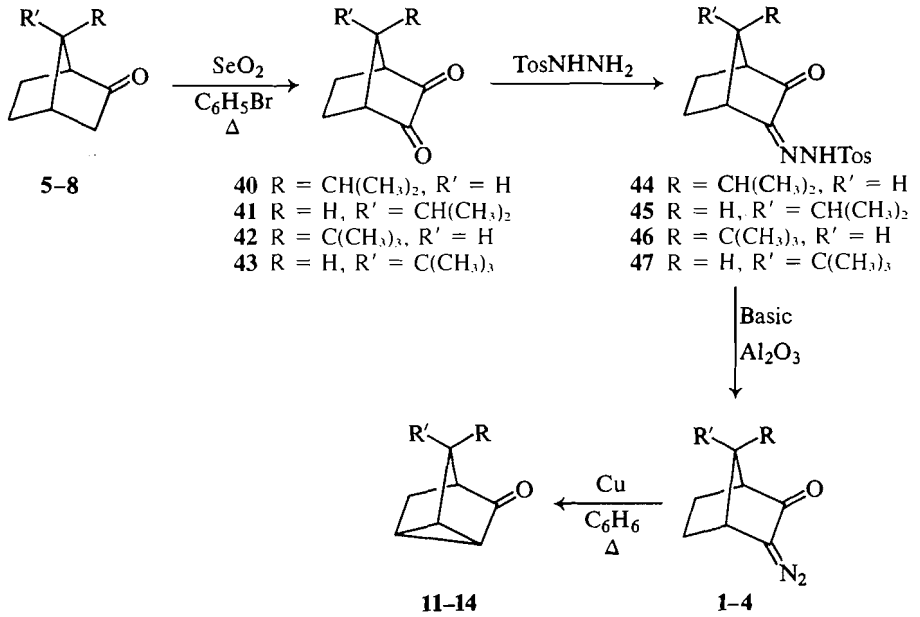

SCHEME 5

that of **5** and **6**, could be separated by liquid chromatography: individual stereochemical assignments were based on spectroscopic considerations (*vide infra*).

Initially, unexpected difficulties were encountered in the catalytic hydrogenation of **32** and the reduction of the ethylenic double bond by borane – methyl sulfide (BMS) (16) was investigated; it was anticipated that reduction of the carbonyl group would also occur, but considered that this could readily be regenerated. However, treatment of **32** with two equivalents of BMS in diglyme followed by protonolysis in boiling propionic acid gave **34**, in which only the carbonyl group had been reduced; this was accompanied by a minor product which is tentatively assigned structure **35**, the propionate of **34**.

The *tert*-butyl compounds **7** and **8** were prepared by oxidation of the alcohols **38** and **39**, respectively, with Jones reagent (Scheme 4). The alcohols were prepared from 7-*tert*-butylnorbornadiene (**36**) by the methods of Baird and Surridge (17), the only modification being hydroboration of *syn*-7-*tert*-butylnorbornene (**37**) with BMS rather than with 9-borabicyclo[3.3.1]nonane (9-BBN) – an expedient that gave an improved yield of **38**.

The general method used for the conversion of the 2-norbornanones **5**–**8** to the corresponding 3-diazo-2-norbornanones **1**–**4** was that of Scheme 5. A variety of conditions have been reported for the oxidation of ketones to α-diketones with selenium dioxide (18). In the cases studied here the best yields were obtained with the use of bromobenzene as solvent. The yields of the *anti*-7-substituted 2,3-norbornanediones **41** and **43** were lower than those of the *syn*-7 compounds **40** and **42**, presumably because of their greater susceptibility to further oxidation. Conversion of the α-diketones to their monotosylhydrazones **44**–**47** proceeded in good yield except in the case of the *syn*-*tert*-butyl compound, which gave a 45% yield. The *syn* compounds were obtained as their *Z* isomers, but the *anti* compounds were formed as mixtures of *Z* and *E* isomers, e.g., **45***Z* and **45***E*, which made recrystallization difficult. These mixtures could be converted to the single *Z* isomers by chromatography on silica gel. On one occasion **45***E* was iso-

45*E*

Infrared and ^{1}H nuclear magnetic resonance spectra

Selected signals in the ^{1}H nmr spectra of the α-chloro nitriles **20** and **30** together with those of **23** are given in Table 1. Paasivirta and Kuusisto (21) have reported ^{1}H nmr assignments for each of the epimers **23***a* and **23***b*, which they separated and individually identified. The structural and ^{1}H nmr spectroscopic assignments for **20***a*, **20***b*, **30***a*, and **30***b* were made by comparison of their spectra with those of **23***a* and **23***b*. The epimers **30***a* and **30***b* were separated by fractional crystallization; the epimers **20***a* and **20***b* could not be separated, but the ^{1}H nmr signals of the individual epimers were identified on the basis of their relative intensities. The differences of the chemical shifts of the H-1 protons of the epimeric pairs **23***a* and **23***b*, **20***a* and **20***b*, and **30***a* and **30***b* lie in the range 0.15–0.16 ppm, whereas the differences for the H-4 protons are much smaller (0.00–0.06 ppm), as expected. As a result the separation of the bridgehead proton signals ($\Delta\delta_{1,4}$) for **23***a*, **20***a*, and **30***a* lies in the range 0.35–0.40 ppm while for their epimers **23***b*, **20***b*, and **30***b*, $\Delta\delta_{1,4}$ = 0.24–0.28. Furthermore, while the *exo*-3 and *endo*-3 protons of **23***a*, **20***a*, and **30***a* give rise to distinct signals as the AM part of an AMX system and can be individually assigned on the basis of the magnitude of their coupling with the adjacent bridgehead proton (H-4), the corresponding protons of **23***b*, **20***b*, and **30***b* give rise to complex signals as the AB part of an ABX system. Cantello *et al.* (9) have used a similar analysis in assigning structure **48** to the major adduct (94%) from the reaction of spiro[2.4]hepta-4,6-diene with 2-chloroacrylonitrile. It is noteworthy that in all cases the *endo*-2-chloro-*exo*-2-cyano epimer is formed predominantly: **23** (4:1), **20** (3:1), **30** (2.5:1), **48** (16:1).

Salient features in the ir and ^{1}H nmr spectra of the 2-norbornanones **5**–**10** are given in Table 2. All of these ketones give rise to carbonyl-stretching bands at 5.71–5.72 μm, characteristic of five-membered cyclic ketones, and CH deformation bands at 7.05–7.09 μm, characteristic of the —CH_2CO— grouping; the compounds with isopropyl and *tert*-butyl substituents also give rise to CH deformation bands that are characteristic of these substituents. It is of interest that while the ir spectra of **5** and **6**, as for the other members of this series, show a single band in the carbonyl stretching region, the spectra of their unsaturated precursors **18** and **27** each show two bands at 5.72–5.73 (s) and 5.80–5.81 (w) μm.

Although the individual structural assignments for compounds **5** and **6** immediately follow from their difference in reactivity with 2,4-dinitrophenylhydrazine, and those for **7** and **8** from their methods of synthesis, those for **9** and **10** rest solely on comparison of their ^{1}H and ^{13}C nmr spectra. Doublets (J = 12 Hz) at δ 3.58 and 3.77 ppm are assigned to the $(C_6H_5)_2CH$ protons in the two compounds, and the compound with the higher field signal is considered to be the *syn*-7 isomer **9**, whose benzhydryl proton is expected to be shielded by the carbonyl group relative to the benzhydryl proton of **10** (22). The same effect may be invoked to account for the shielding of the *syn*-7-*tert*-butyl protons of **7** relative to those of **8**. Examination of molecular models suggests that the most favorable conformation for the benzhydryl group in **9** and **10** is of type **50**, in which the dihedral angle between the benzyhydryl CH bond and the C-7 CH bond approaches 180°, which is in accord with the observed 12-Hz coupling constants. It is expected that the isopropyl compounds **5** and **6** will adopt similar conformations, and this could account for the fact that the methyl signals of **5** are not upfield of those of **6**. It may be noted that in each case the methyl groups give rise to two doublets, reflecting their diastereotopism.

50

The ir spectra of the 2,3-norbornanediones **40**–**43** (Table 3) show two bands in the carbonyl-stretching region at 5.60–5.63 and 5.68–5.70 μm resulting from vibrational coupling, as has been observed previously for compounds of this type (23). In the ^{1}H nmr spectra of **40** and **41** the methyl proton signals appear as simple doublets, since the methyl groups in each compound are no longer diastereotopic. As in the case of the monoketones the *tert*-butyl methyl signal of the *syn* isomer **42** is shifted upfield relative to that of the *anti* isomer **43**, while there is no significant difference in the chemical shifts of the isopropyl methyl signals of **40** and **41**. Two-proton multiplets at δ 2.93–3.07 ppm in the spectra of **40**–**43** are assigned to the bridgehead protons (H-1,4) on the basis of earlier assignments for the bridgehead proton signals of 2,3-norbornanedione (**51**) (δ 3.06 ppm (24)), and related compounds (23).

The monotosylhydrazones **44**–**47** were normally isolated as their *Z* isomers. This stereochemical assignment is based on their ir and ^{1}H nmr spectra (Table 4). Strong intramolecular hydrogen bonding in these isomers results in sharp N—H stretching bands at 3.09–3.10 μm and carbonyl-stretching bands at 5.79–5.81 μm in their ir spectra. These spectra may be contrasted with the ir spectrum of the *E* isomer of **45** (*vide supra*), in which the NH stretching band is considerably broader and the carbonyl-stretching band appears at 5.70 μm. The intramolecular hydrogen bonding in the *Z* isomers is also vouchsafed by NH signals at δ 11.3–11.6 ppm in their ^{1}H nmr spectra (cf. **45***E*: δ 8.73 ppm).

The ir spectra of the α-diazo ketones **1**–**4** (Table 5) show the three characteristic strong bands associated with this functionality (25) at 4.83–4.84, 5.89–5.90, and 7.34–7.37 μm; in addition they all show a medium intensity band in the 9.1–9.3 μm region, which we have not assigned. Their ^{1}H nmr spectra show that one of the bridgehead proton signals is shifted downfield (Δδ 0.35–0.42 ppm) and the other upfield (Δδ −0.35 – −0.44 ppm) relative to the two equivalent bridgehead proton signals of the corresponding diketones **40**–**43**. An analogous effect has been observed previously for other 3-diazo-2-norbornanones (23) and the assignments made in the latter cases permit the assignment of the individual H-1 and H-4 signals given in Table 5. The diastereotopic relationship of the iso-

propyl methyl groups in **1** and **2** is readily apparent as in the case of **5** and **6** (in the case of the tosylhydrazones **44** and **45** the methyl signals were broad and poorly defined, presumably as a result of a reduced chemical shift difference between the methyl groups).

The ir and ^{1}H nmr spectra of the tricyclic ketones **11**–**14** are given in Table 6. In accord with expectation their carbonyl-stretching bands appear at shorter wavelength (Δλ 0.04–0.05 μm) than the corresponding bands of the bicyclic ketones **5**–**8**. Their methyl proton signals show analogous relationships to those of **5**–**8** and their chemical shifts are not greatly affected by the presence of the cyclopropane ring. Although most of the remaining signals give rise to overlapping multiplets, it is possible to make the assignments for H-2 given in Table 6, based on the coupling pattern of the signals and comparison with the spectra of related tricyclic ketones (26).

^{13}C Nuclear magnetic resonance spectra

Assignments for the signals in the ^{13}C nmr spectra of most of the compounds prepared in the present work are given in Tables 7–10. These assignments are based on comparison with the spectra of closely related compounds, single frequency off-resonance decoupled (sford) spectra, and consideration of well-established substituent effects.

The assignments were readily made in the case of the 2-norbornanones **5**–**8** on the basis of the extensive earlier work by Roberts (27) and Stothers (28, 29) and their co-workers on the spectra of such compounds. In Table 7 these assignments are compared with those for 2-norbornanone (**49**) (29) and *syn*-7- (**52**) and *anti*-7-methyl-2-norbornanone (**53**) (27), and in Table 8 the substituent effects of the 7-alkyl substituents are listed. The well-known γ-*gauche* shielding effect of the C-7 alkyl substituent at C-3 in all of the *syn*-7 compounds is readily apparent,[3] and to a lesser degree at C-5 and C-6 in the *anti*-7 isomers, with the interesting exception of C-5 in the *anti*-7-*tert*-butyl compound **8** (*vide infra*). Conversely, C-3 is deshielded by the 7-alkyl substituent in the *anti* isomers and C-5 and C-6 are deshielded in the *syn* isomers. This type of γ deshielding effect has been less commonly documented than the γ-*gauche*

[3] However, this effect is reversed at the carbonyl carbon (C-2) (*vide infra*).

[a] In $CDCl_3$; $\Delta\delta = {}^{C}\delta$ (7-substituted compound) − ${}^{C}\delta$ (unsubstituted compound).

shielding effect, but downfield γ shifts have been observed involving antiperiplanar axial substituents in compounds containing a fused or bridged cyclohexane ring (30, 31).

The consistent trends observed in the substituent effects in the spectra of compounds **5**–**8**, **52**, and **53** were applied to make individual stereochemical assignments for the benzhydryl compounds **9** and **10**. The results confirmed the assignments made on the basis of their ^{1}H nmr spectra and the chemical shift assignments and substituent effects for these compounds are also given in Tables 7 and 8. Comparison of all of these data shows that there is an attenuation of the γ-*gauche* effect of a 7-alkyl group at C-3 in the *syn* series and at C-5 and C-6 in the *anti* series, with increasing substitution on the γ carbon. Thus the shielding effects fall off in the order $CH_3 > CH(CH_3)_2 \simeq CH(C_6H_5)_2 \gg C(CH_3)_3$. This is attributable to a δ deshielding effect by these substituents, an effect that has been observed previously for hydroxyl substituents and attributed, at least in part, to steric interaction (32, 33). Since γ-*gauche* substituents produce upfield shifts and sterically interacting δ substituents produce small downfield shifts, the shielding effect of a *gauche tert*-butyl group is expected to be less than that of a *gauche* methyl group (34), as observed. In general the δ deshielding effect does not override the γ shielding effect of the isopropyl and *tert*-butyl groups at C-3, C-5, and C-6 in the present cases, except in the case of the negligible deshielding effect at C-5 of the *anti-tert*-butyl group in **8**. The δ effects are much larger for the *tert*-butyl group than the isopropyl and benzhydryl groups. If the effect is primarily steric in origin, this circumstance would be nicely accommodated by our earlier proposal of preferred conformations of type **50** for the latter groups. This interpretation must be treated with caution, since it is possible that the δ effect is not primarily steric in nature and devolves from removal of a γ hydrogen, in analogy to the proposal of Saunders and ApSimon and their co-workers that the γ effect arises from removal of a β hydrogen (30, 35).

Spectroscopic assignments for the unsaturated ketones **18**, **27**, and **32** prepared in the present work are included in Table 7, together with those for 5-norbornen-2-one (**24**) (36). The introduction of Δ^5 β,γ-unsaturation into 2-norbornanones has been observed previously to lead to shielding of the carbonyl carbon; it has also been observed that C-6 is shielded and C-5 is deshielded with respect to the corresponding olefins (29). These effects have been attributed in part to homoconjugation (37). Introduction of a second β,γ ethylenic bond as in **18** can be seen to lead to appreciable further deshielding of the carbonyl carbon, perhaps as a result of "cross-homoconjugation". The individual assignments for the olefinic carbon atoms of the exocyclic double bonds in **18**, **27**, and **32** were made in analogy to those for C-5 and C-6 in **24**.

The ^{13}C nmr spectral assignments for the diketones **40**–**43** and **51**, the tosylhydrazones **44**–**47**, and the diazo ketones **1**–**4**, **54**, and **55** (38) are also given in Table 7. In order to make the assignments for C-1(4) and C-7 for the diketones, the relative signal intensities were considered together with general trends observed in the spectra of the other classes of compounds; in each case the signal assigned to C-1(4) had a significantly higher intensity than that assigned to C-7.

The assignments of signals for the diazo ketones were facilitated by comparison with the chemical shift values for C-5 versus C-6 and C-1 versus C-4 in 4-methyl-3-diazocamphor (**55**) (38). The assignments for the tosylhydrazones were made in analogy to those for the other types of compounds. The carbonyl signals for all the compounds other than the monoketones in Table 7 are shifted by 15–17 ppm to higher field relative to their parent monoketones as a result of conjugative and inductive effects. The diazo carbon signals (C-3) of the diazo ketones appear at remarkably high field for the sp^2 carbon, as has been observed for other α-diazo ketones (38, 39), presumably as a result of the high electron density at this carbon (cf. **56***a*) and the partial triple bond nature of the C—N

56*a* **56***b*

bond (cf. **56***a* and **56***b*).

Similar γ and δ effects to those that have been described for the 2-norbornanone series are also apparent in the spectra of the diketones, tosylhydrazones, and diazo ketones (Table 8). It was noted earlier that the chemical shift relationships of the carbonyl carbons (C-2) of the *syn*-7 and *anti*-7 2-norbornanones do not follow those of the sp^3 carbons C-3,[4] C-5, and C-6. The same holds true of the other types of compounds in Table 8, the carbonyl carbon in each *anti*-7 compound being shielded relative to that in its *syn* isomer. The origin of this effect is unclear, since it is unknown whether it is associated with the hybridization, polarization, and (or) lack of hydrogen atoms at the carbonyl carbon. However, comparision of the carbonyl carbon shifts in the *syn*-7-isopropyl (and benzhydryl) compounds with those of the corresponding *syn*-7-*tert*-butyl compounds shows δ deshielding effects in the latter, albeit smaller than those observed at C-3.[4]

The ^{13}C nmr spectra of the tricyclic ketones **11**–**14** and the parent ketone **57** (40) are given in Table 9. The signals of the cyclopropyl carbons could not be individually assigned with rigour. In analogy with C-6 in the bicyclic ketones and their derivatives, C-7[5] in the tricyclic ketones is shielded in the *anti* compounds relative to the *syn* compounds and the carbonyl carbon is deshielded in the *syn* compounds relative to their *anti* isomers. Although the uncertainty of the individual cyclopropyl carbon assignments makes detailed comparison unfeasible, it is possible to conclude that none of the cyclopropyl carbon signals of the *anti*-5-*tert*-butyl compound are at higher field than those of its *syn*-5 isomer. Thus in these tricyclic systems, C-1, unlike C-5 in the bicyclic systems, is not shielded in the *anti*-5 relative to the *syn*-5 compound. This is attributable to the change in geometry and (or) hybridization when this carbon is incorporated into a cyclopropane ring.

The ^{13}C nmr spectra of the α-chloro nitriles previously referred to and of **58***a* and **58***b*, prepared by catalytic hydrogenation of the mixture of **23***a* and **23***b* (12), are given in Table 10. Both the cyano and chloro substituent effects are known for the *exo*- and *endo*-monosubstituted norbornene system (41). The assignments for the epimeric chloro nitriles **23***a* and **23***b* were made from their sford spectra and comparison of the calculated chemical shifts with the observed shifts. The assignments for the individual members of the other pairs of epimeric chloro nitriles then follow as in Table 10. In general the γ-*gauche* effect at C-6 and C-7 of the substituents at C-2 is consistent, irrespective of their sp^2 or sp^3 nature, with a 2-*exo*-chloro substituent shielding C-7 more than a 2-*exo*-cyano substituent; the only exception is in the case of the benzhydrylidene epimers **30***a* and **30***b* whose C-7 signals have identical chemical shifts. As expected from the work of Stothers *et al.* (29), the cyano carbon exhibits a configurationally dependent chemical shift with the *endo* cyano carbon shielded with respect to the *exo* cyano carbon for each pair of epimers.

Experimental[6]

Melting points were determined on a Fisher–Johns melting point apparatus and are uncorrected. The ir spectra were recorded in CCl_4 solution with a Perkin–Elmer 137 spectrometer, unless otherwise specified; bands are strong and sharp unless denoted as m (medium), w (weak), or br (broad). The ^1H and ^{13}C nmr spectra were recorded in $CDCl_3$ solution with Varian T-60 and Varian CFT-20 or XL-100 spectrometers, respectively. Mass spectra were recorded at 70 eV with a Bell and Howell CEC 21-490 single focussing mass spectrometer; exact mass measurements were made with an AE1-MS 902 double focussing mass spectrometer. Gas chromatographic (gc) analyses were carried out on a Varian Aerograph Series 2700 gas chromatograph, equipped with a flame ionization detector, and linked with a Varian CDS-111 integrator. The injector port temperature was 270°C, the detector temperature was 290°C, and the column tem-

[4] The effects at C-2 and C-3 in the diketones are of course identical owing to symmetry.
[5] See footnote 2 in Table 9.
[6] Spectroscopic data are given only where they supplement the data given in Tables 1–10.

perature was 110°C. The carrier gas was nitrogen at a flow rate of 30 mL/min. A 6-ft glass column (od 1/4 in., id 2 mm) packed with 3% OV-17 on 80/100 Chromosorb W(HP) was used. Solutions in organic solvents were dried over anhydrous Na_2SO_4 and the solvents were evaporated with a rotary evaporator at water aspirator pressure.

*6,6-Dimethylfulvene (**15**)*

6,6-Dimethylfulvene (**15**) was prepared according to the procedure of Freiesleben (43). A mixture of freshly distilled cyclopentadiene (89.57 g, 1.357 mol), acetone (78.82 g, 1.359 mol), and aqueous 40% methylamine (15.78 g, 0.2036 mol) was vigorously stirred for 4.5 h. The organic layer was separated, washed with water (2 × 60 mL) and saturated aqueous sodium chloride (60 mL), and fractionally distilled through a Vigreux column (46 cm), affording **15** (132 g, 92%) as a bright yellow liquid, bp 42°C (8 Torr) (lit. (43) bp 44–46°C (10 Torr)) (1 Torr = 133.3 Pa).

*7-Isopropylidenebicyclo[2.2.1]hept-5-en-2-one (**18**)*

The title compound **18** was prepared according to the procedure of DePuy and Story (6). Freshly distilled 2-acetoxyacrylonitrile (bp 60°C (10 Torr); 5.0 g, 45 mmol) was added dropwise with stirring over 1.5 h to 6,6-dimethylfulvene (10.0 g, 94 mmol). The solution was then heated at 55°C under a nitrogen atmosphere for 12 days. The excess dimethylfulvene was evaporated at reduced pressure with warming (40°C (0.04 Torr)) and the residue was triturated with cold pentane to give a yellow crystalline solid. Recrystallization from pentane afforded the single epimer *endo*-2-acetoxy-7-isopropylidenebicyclo-[2.2.1]hept-5-ene-*exo*-2-carbonitrile (**17***a*) (5.01 g, 51%); ir λ_{max}: 5.69, 6.95 (w), 7.43 (m), 7.59 (w), 8.18, 8.43 (w), 8.56 (m), 9.64 (m) μm; ^1H nmr δ: 1.57 (d, J = 13 Hz, 1H), 1.63 (s, 3H), 1.68 (s, 3H), 2.03 (s, 3H), 3.58 (dd, J = 13, 4 Hz, 1H), 3.45 (m, $W_{1/2}$ = 7 Hz, 1H), 4.21 (m, $W_{1/2}$ = 6 Hz, 1H), 6.07 (dd, J = 6, 3 Hz, 1H), 6.57 (dd, J = 6, 3 Hz, 1H).

The acetoxy carbonitrile **17***a* (2.0 g, 9.2 mmol) was stirred with 1 *N* methanolic sodium methoxide (17.7 mL) at ambient temperature for 3 h. Ice and water (60 mL) were added and the mixture was extracted with several portions of dichloromethane. The combined dichloromethane extracts were dried, filtered, and evaporated to give 7-isopropylidenebicyclo[2.2.1]hept-5-en-2-one (**18**). Distillation at 40°C (0.2 Torr) afforded **18** (680 mg, 50%) as a clear, colorless liquid (lit. (6) bp 46°C (0.3 Torr)); ir λ_{max}: 5.73, 5.81 (w), 7.31 (w), 8.98 (m) μm; ^1H nmr δ: 1.63 (s, 3H), 1.67 (s, 3H), 2.05 (m, $W_{1/2}$ = 4 Hz, 2H), 3.60 (m, $W_{1/2}$ = 13 Hz, 2H), 6.24 (m, $W_{1/2}$ = 11 Hz, 1H), 6.67 (dd, J = 6, 3 Hz, 1H).

*Hydrogenation of **18**. Formation of* syn- *and* anti-*7-isopropylbicyclo-[2.2.1]heptan-2-one (**5** and **6**)*

Compound **18** (962 mg, 6.50 mmol) was hydrogenated in a mixture of ethanol (5 mL) and ether (5 mL) over 5% Pd/C (15 mg) at ambient temperature and 1 atm (1 atm = 101.3 kPa) pressure until the uptake of hydrogen ceased (285 mL; 30.5 h). The mixture was filtered and the solvent was evaporated to give the crude product. Distillation at 106°C (15 Torr) afforded a mixture of epimers **5** and **6** (929 mg, 94%) as a clear, colorless liquid, bp 85°C (6 Torr), which was shown by gc and spectroscopic comparison to be identical to the mixture isolated from the hydrogenation of **27** (*vide infra*).

endo-*2-Chloro-7-isopropylidenebicyclo[2.2.1]hept-5-ene*-exo-*2-carbonitrile (**20**a) and* exo-*2-chloro-7-isopropylidenebicyclo-[2.2.1]hept-5-ene*-endo-*2-carbonitrile (**20**b)*

Freshly distilled **15** (bp 42°C (10 Torr); 97 g, 0.92 mol) was added dropwise with stirring to a solution of distilled 2-chloroacrylonitrile (bp 46°C (170 Torr); 129 g, 1.47 mol) in anhydrous benzene (200 mL). After the addition, the mixture was allowed to stand at 40°C in the dark under a nitrogen atmosphere for 51 days. The solvent and volatile components were evaporated and the resulting dark oil was distilled at 70°C (0.05 Torr) to give a clear, yellow liquid. Fractional distillation through a Vigreux column (12 cm) afforded a mixture of epimeric adducts **20***a* and **20***b*, bp 50°C (0.01 Torr), as a clear, pale yellow liquid (145 g, 82%) which solidified at −20°C. Crystallization from hexane gave a mixture of **20***a* and **20***b* as a white crystalline solid, mp 31–35°C; ir λ_{max}: 4.43 (w), 6.95, 7.31, 7.61 (m), 10.41, 11.41 (m) μm; *m/e*: 193 (1; M^+), 158 (5), 106 (100). *Anal.* calcd. for $C_{11}H_{12}ClN$: C 68.22, H 6.25, N 7.23, Cl 18.31; found: C 68.28, H 6.38, N 7.12, Cl 18.24. The adducts **20***a* and **20***b* were formed in a ratio of ~3:1 as determined by ^1H nmr spectroscopy.

*2-Chlorobicyclo[2.2.1]hept-5-ene-2-carbonitriles (**23**a and **23**b)*

The title compounds were prepared according to a modification of the procedure of Krieger (12). Freshly distilled cyclopentadiene (15.5

g, 235 mmol) was added dropwise with stirring to a solution of distilled 2-chloroacrylonitrile (41.0 g, 469 mmol) in anhydrous benzene (80 mL). After the addition the solution was allowed to stand at 40°C in the dark under a nitrogen atmosphere for 8 weeks. The volatile components of the mixture were evaporated and the residue was fractionally distilled affording a mixture of the epimeric adducts **23***a* and **23***b*, bp 32°C (0.01 Torr), as clear, colorless crystals (30.7 g, 85%), mp 38–41°C (lit. (12, 9) mp 45–47°C, 36–38°C). The adducts **23***a* and **23***b* were present in an ~4:1 ratio as determined by ^{1}H nmr spectroscopy (lit. (9) 4:1 ratio).

endo-2-*Chlorobicyclo[2.2.1]hept-5-ene*-exo-2-*carboxamide* (**25**)

A solution of the mixture of **23***a* and **23***b* (616 mg, 4.01 mmol) and sodium sulfide nonahydrate (963 mg, 4.01 mmol) in 95% ethanol (25 mL) was boiled under reflux overnight. The mixture was diluted with water and extracted with ether (4 × 25 mL). The combined ethereal extracts were washed with water and saturated aqueous sodium chloride, dried, filtered, and evaporated to give a white crystalline solid. Recrystallization from water afforded a single epimer **25** (447 mg, 65%) as white crystals, mp 114–115°C; ir λ_{max} ($CHCl_3$): 2.92 (w), 3.02 (w), 5.92, 6.36 (m), 7.40 (m) μm; ^{1}H nmr δ: 1.37–2.00 (m, 3H), 2.38–2.97 (m, 2H), 3.27 (m, 1H), 6.20 (dd, J = 5.5, 3 Hz, 1H), 6.32 (br s, 2H, absent after D_2O treatment), 6.40 (dd, J = 5.5, 2.5 Hz, 1H); ^{13}C nmr δ: 175.0 (s), 139.2 (d), 134.8 (d), 74.7 (s), 54.3 (d), 48.4 (t), 42.6 (d), 42.3 (t); m/e: 173 (2.5; $(M + 2)^+$), 171 (6; M^+), 66 (100). *Anal.* calcd. for $C_8H_{10}ClNO$: C 55.99, H 5.87, N 8.16, Cl 20.66; found: C 55.94, H 5.83, N 7.93, Cl 20.53.

endo-2-*Chloro-7-isopropylidenebicyclo[2.2.1]heptane*-exo-2-*carbonitrile* (**26**a) *and* exo-2-*chloro-7-isopropylidenebicyclo[2.2.1]heptane*-endo-2-*carbonitrile* (**26**b)

A mixture of **20***a* and **20***b* (80.0 g, 413 mmol) was hydrogenated in ethyl acetate (400 mL) over 5% Pd/C (6 g) at ambient temperature and 1 atm pressure until 1 equiv. of hydrogen was consumed (10.6 L; 19 h). Filtration followed by evaporation gave a yellow oil, which upon distillation at 65°C (0.01 Torr) afforded a mixture of **26***a* and **26***b* (78.7 g, 97%) as a clear, colorless liquid, which solidified at −20°C. Crystallization from hexane gave **26***a* as colorless crystals, mp 47.5–49°C; ir λ_{max}: 4.45 (w), 6.93 (m), 7.30 (m), 7.64 (w), 8.45 (w), 8.71 (m), 10.60 (m) μm; ^{1}H nmr δ: 1.34–2.78 (m), 1.74 (s), 1.78 (s), 3.14 (m); m/e: 197 (9; $(M + 2)^+$), 195 (26; M^+), 160 (24). *Anal.* calcd. for $C_{11}H_{14}ClN$: C 67.51, H 7.21, N 7.16, Cl 18.12; found: C 67.26, H 7.21, N 7.12, Cl 18.12.

7-Isopropylidenebicyclo[2.2.1]heptan-2-one (**27**)

A hot solution of potassium hydroxide (85.6%; 66.9 g, 1.023 mol) in water (30 mL) was added in one portion to a vigorously stirred solution of a mixture of **26***a* and **26***b* (51.3 g, 0.262 mol) in dimethyl sulfoxide (180 mL). The mixture was stirred in the dark under a nitrogen atmosphere for 15 h and then steam distilled until 1 L of distillate had been collected. The distillate was transferred to a separatory funnel with ether (100 mL). The layers were separated and the aqueous layer was extracted with ether (2 × 100 mL). The combined organic layers were washed with water (100 mL) and saturated aqueous sodium chloride (100 mL), dried, filtered, and evaporated to give the product. Distillation at 80°C (6 Torr) afforded **27** (31.5 g, 80%) as a clear, colorless liquid; ir λ_{max}: 5.72, 5.80 (w), 6.91 (w), 7.12 (w), 7.30 (w), 8.85 (w), 9.37 (w) μm; ^{1}H nmr δ: 1.67 (s, 3H), 1.73 (s, 3H), 1.30–2.73 (m, 6H), 3.08 (m, $W_{1/2}$ = 7 Hz, 2H); m/e: 150 (26; M^+).

syn- *and* anti-7-*Isopropylbicyclo[2.2.1]heptan-2-one* (**5** *and* **6**)

Compound **27** (46.4 g, 309 mmol) was hydrogenated in absolute ethanol (125 mL) and ether (125 mL) over 5% Pd/C (3 g) at ambient temperature and 1 atm pressure until the uptake of hydrogen ceased (7.5 L; 61.5 h). Filtration followed by evaporation gave the crude product, which upon distillation through a Vigreux column (12 cm) afforded a mixture of **5** and **6**, bp 85°C (6 Torr), as a clear, colorless liquid (44.3 g, 94%). Gas chromatographic analysis showed this to be a 3:2 mixture of *syn* (R_t = 3.6 min) and *anti* (R_t = 4.2 min) isomers.

Separation of syn- *and* anti-7-*isopropylbicyclo[2.2.1]heptan-2-one* (**5** *and* **6**)

(i) anti-7-*Isopropylbicyclo[2.2.1]heptan-2-one 2,4-dinitrophenylhydrazone* (**28**)

A solution of a mixture of **5** and **6** (70:30; 15.2 g, 100 mmol) in methanol (10 mL) was added in one portion to a filtered solution of 2,4-dinitrophenylhydrazine (6.90 g, 34.8 mmol) in methanol (140 mL) and concentrated sulfuric acid (9 mL). After 3 h at ambient temperature the mixture was cooled in ice and the resulting precipitate was collected by suction filtration through sintered glass and washed thoroughly with water until the washings were no longer acidic. The filtrate and washings were kept for procedure *(ii)* (*vide infra*). The orange solid was dissolved in a boiling mixture of absolute ethanol (1.1 L) and ether (500 mL). The solution was concentrated to a volume of 1.2 L and left at ambient temperature overnight. Cooling in ice afforded **28** (8.05 g) as a bright orange powder. Concentration of the mother liquor to a volume of 200 mL followed by cooling in ice afforded a further crop of product (1.24 g, 93% total based on *anti* isomer), mp 176–178°C; ir λ_{max}: 6.17 (m), 6.26 (m), 6.73 (w), 7.50, 7.14 (m) μm; ^{1}H nmr δ: 0.98 (d, J = 5 Hz, 6H), 1.13–2.43 (m, 8H), 2.57 (m, $W_{1/2}$ = 7 Hz, 1H), 2.91 (m, $W_{1/2}$ = 6 Hz, 1H), 7.88 (d, J = 10 Hz, 1H), 8.29 (dd, J = 10, 2.5 Hz, 1H), 9.08 (d, J = 2.5 Hz, 1H), 10.72 (br s, 1H); m/e: 332 (100; M^+). *Anal.* calcd. for $C_{16}H_{20}N_4O_4$: C 57.82, H 6.07, N 16.86; found: C 57.71, H 6.08, N 16.73.

(ii) syn-7-*Isopropylbicyclo[2.2.1]heptan-2-one* (**5**)

Pyruvic acid (1 g) was added to the filtrate from *(i)*. After 30 min the solution was combined with the water washings from *(i)* and water (800 mL) was added. The mixture was extracted with ether (4 × 150 mL). The combined ethereal extracts were washed with aqueous 4% sodium chloride (2 × 50 mL), dried, filtered, and evaporated to give an orange liquid (10.33 g). Distillation at 68°C (3 Torr) afforded **5** (9.52 g, 89%) as a clear, colorless liquid (gc analysis indicated the presence of <1% *anti* isomer); m/e: 152 (33; M^+), 109 (44). *Anal.* calcd. for $C_{10}H_{16}O$: C 78.90, H 10.59; found: C 78.56, H 10.58.

(iii) anti-7-*Isopropylbicyclo[2.2.1]heptan-2-one* (**6**)

An aqueous 20% solution of titanium trichloride (prepared in a glove box under a nitrogen atmosphere by the careful addition of titanium trichloride (Apache Chemicals) to degassed water; 500 mL, 648 mmol) was added slowly under a nitrogen atmosphere to a stirred solution of **28** (12.0 g, 36.1 mmol) in anhydrous 1,2-dimethoxyethane (600 mL). The mixture was stirred for 5 h and then steam distilled until 1.6 L of distillate had been collected. The distillate was extracted with dichloromethane (4 × 150 mL). The combined extracts were washed with saturated aqueous sodium chloride, dried, filtered, and evaporated to give the crude product (5.56 g). Distillation at 26°C (0.2 Torr) afforded **6** (4.82 g, 88%) as a clear, colorless liquid, which was 99.6% pure as shown by gc analysis (R_t = 4.4 min); m/e: 152 (29; M^+), 109 (44). *Anal.* calcd. for $C_{10}H_{16}O$: C 78.90, H 10.59; found: C 78.64, H 10.61.

syn-7-tert-*Butylbicyclo[2.2.1]heptan-2-one* (**7**)

syn-7-*tert*-Butylbicyclo[2.2.1]heptan-*endo*-2-ol (**38**) was prepared from *syn*-7-*tert*-butylnorbornene (**37**) by the method of Baird and Surridge (17) except that borane – methyl sulfide complex was used for the reduction of **37** rather than 9-borabicyclo[3.3.1]nonane (9-BBN).

To an ice-cold solution of **38** (3.89 g, 23.2 mmol) in acetone (50 mL) was added dropwise with stirring a solution of Jones reagent until an orange-brown color persisted. Isopropyl alcohol (5 drops) was added to give a green color, the mixture was filtered by suction, and the filtrate was evaporated to give a green oil. The oil was extracted with dichloromethane (2 × 20 mL) and the combined extracts were washed with aqueous 4% sodium bicarbonate, dried, filtered, and evaporated to give a pale green liquid (3.26 g). Distillation at 100°C (14 Torr) afforded **7** (3.12 g, 81%) as a clear, colorless liquid; ^{1}H nmr δ: 0.97 (s, 9H), 1.12–2.35 (m, 7H), 2.55 (m, 2H); m/e: 166 (50; M^+), 109 (93). *Anal.* calcd. for $C_{11}H_{18}O$: C 79.46, H 10.91; found: C 79.30, H 10.95.

anti-7-tert-*Butylbicyclo[2.2.1]heptan-2-one (8)*

To an ice-cold solution of *anti*-7-*tert*-butylbicyclo[2.2.1]heptan-*exo*-2-ol (**39**) (prepared by the procedure of Baird and Surridge (17); 1.98 g, 11.8 mmol) in acetone (45 mL) was added dropwise with stirring a solution of Jones reagent until an orange-brown color persisted. Isopropyl alcohol (5 drops) was added to give a green color, the mixture was filtered by suction, and the filtrate was evaporated to give a green oil. The oil was extracted with dichloromethane (2 × 15 mL). The combined extracts were dried over anhydrous sodium sulfate and a small amount of sodium bicarbonate, filtered, and evaporated to give an oil which crystallized at −20°C. Recrystallization from hexane at −20°C afforded **8** (1.42 g) as clear, colorless crystals. Evaporation of the mother liquor followed by sublimation at ambient temperature (0.01 Torr) with a Dry Ice – acetone condenser afforded further product (150 mg; 80% total), mp 30–32°C; ^{1}H nmr δ: 1.02 (s, 9H), 1.17–2.43 (m, 7H), 2.60 (m, 2H); *m/e*: 166 (27; M^+), 109 (59). *Anal.* calcd. for $C_{11}H_{18}O$: C 79.46, H 10.91; found: C 79.30, H 11.00.

6,6-Diphenylfulvene (29)

6,6-Diphenylfulvene (**29**) was prepared by a modification of the procedure of Wagner and Hunt (44) suggested by Poos *et al.* (45). To a warm solution of benzophenone (82.7 g, 454 mmol) in ethanolic sodium ethoxide (prepared by the addition of freshly cut sodium metal (10.4 g, 454 mmol) to anhydrous ethanol (325 mL)) was added freshly distilled cyclopentadiene (50.0 g, 757 mmol) slowly with stirring over 0.5 h under a nitrogen atmosphere. The mixture was stirred for a further 3 h and cooled in ice, and the resulting crystals were collected by suction filtration. Recrystallization from absolute ethanol afforded **29** (85.3 g, 82%) as large, red crystals, mp 76–78°C (lit. (44) mp 81–82°C).

7-Benzhydrylidene-endo-*2-chlorobicyclo[2.2.1]hept-5-ene*-exo-*2-carbonitrile (30*a*) and 7-benzhydrylidene*-exo-*2-chlorobicyclo-[2.2.1]hept-5-ene*-endo-*2-carbonitrile (30*b*)*

A solution of **29** (34.5 g, 150 mmol) in anhydrous benzene (150 mL) was added dropwise with stirring to a solution of distilled 2-chloroacrylonitrile (bp 46°C (170 Torr); 26.3 g, 301 mmol) in anhydrous benzene (100 mL). After the addition the mixture was allowed to stand at 40°C in the dark under a nitrogen atmosphere for 11 weeks. The volume of the solution was reduced to 25% of the original volume and the concentrate was cooled to 5°C. The tawny precipitate was collected by suction filtration and the filtrate was concentrated and cooled to give a further crop of product (32.2 g total, 68%). The crude product was treated with activated charcoal in boiling heptane. Gravity filtration of the hot solution followed by cooling of the filtrate afforded a white crystalline solid consisting of a mixture of **30***a* and **30***b* in a ratio of 2.5:1 as determined by ^{1}H nmr spectroscopy. The mixture was usually directly subjected to hydrogenation. Fractional crystallization of the mixture from absolute ethanol provided a pure sample of each adduct. Sublimation of *exo*-carbonitrile **30***a* at 90°C (0.005 Torr) afforded a white crystalline solid, mp 134–137°C; ir λ_{max}: 4.48 (w), 6.70 (m), 6.95, 7.57 (m), 9.35 (m), 9.71 (m), 10.36 μm; *m/e*: 319 (1; $(M + 2)^+$), 317 (3; M^+), 230 (100). *Anal.* calcd. for $C_{21}H_{16}ClN$: C 79.36, H 5.07, N 4.41, Cl 11.16; found: C 79.40, H 4.93, N 4.45, Cl 11.25.

Sublimation of *endo*-carbonitrile **30***b* at 90°C (0.005 Torr) afforded a white crystalline solid, mp 130–132°C; ir λ_{max}: 4.48 (w), 6.71, 6.94, 7.57, 9.32 (m), 9.46 (m), 9.72 (m), 10.22 (m) μm; *m/e*: 319 (0.5; $(M + 2)^+$), 317 (2; M^+), 230 (100). *Anal.* calcd. for $C_{21}H_{16}ClN$: C 79.36, H 5.07, N 4.41, Cl 11.16; found: C 79.22, H 5.10, N 4.57, Cl 11.09.

7-Benzhydrylidene-endo-*2-chlorobicyclo[2.2.1]heptane*-exo-*2-carbonitrile (31*a*) and 7-benzhydrylidene*-exo-*2-chlorobicyclo[2.2.1]heptane*-endo-*2-carbonitrile (31*b*)*

A mixture of **30***a* and **30***b* (3.18 g, 10.0 mmol) was hydrogenated in ethyl acetate (60 mL) over 5% Pd/C (125 mg) at ambient temperature and 1 atm pressure until one equivalent of hydrogen was consumed (240 mL; 2.25 h). Filtration followed by evaporation gave an oil which solidified under high vacuum affording a mixture of **31***a* and **31***b* (3.12 g, 98%). This was usually directly subjected to hydrolysis without further purification. An analytical sample of one of the epimers, considered to be **31***a*, was obtained by crystallization from heptane followed by sublimation at 80°C (0.005 Torr), as a white crystalline solid, mp 86–88°C; ir λ_{max} ($CHCl_3$): 4.50 (w), 5.12 (w), 5.28 (w), 5.52 (w), 5.72 (w), 6.24, 6.32 (w), 6.73 (m), 6.95, 7.59 (m), 8.73 (m), 9.28, 10.51, 11.03 (m), 11.47 (m) μm; ^{1}H nmr δ: 1.44–3.14 (m, 8H), 7.28 (m, 10H); *m/e*: 321 (29; $(M + 2)^+$), 319 (75; M^+), 284 (35). *Anal.* calcd. for $C_{21}H_{18}ClN$: C 78.86, H 5.67, N 4.38, Cl 11.08; found: C 79.14, H 5.85, N 4.33, Cl 11.08.

7-Benzhydrylidenebicyclo[2.2.1]heptan-2-one (32)

A hot solution of potassium hydroxide (86.3%; 1.51 g, 23.2 mmol) in water (1.5 mL) was added in one portion to a vigorously stirred solution of a mixture of **31***a* and **31***b* (2.50 g, 7.82 mmol) in dimethyl sulfoxide (20 mL). The mixture was stirred in the dark under a nitrogen atmosphere for 13 h, diluted with water (100 mL), and extracted with ether (6 × 50 mL). The combined ethereal extracts were washed with aqueous sodium bicarbonate (2 × 50 mL) and saturated aqueous sodium chloride (50 mL), dried, filtered, and evaporated to give **32** (1.84 g, 86%) as a yellowish-white foam. Sublimation at 75°C (0.01 Torr) gave a transparent gum which solidified on standing. Crystallization from methanol or hexane afforded **32** as a white crysalline solid, mp 100–102°C; ir λ_{max}: 5.71, 6.67 (w), 6.93 (w), 7.11 (w), 7.31 (w) μm; ^{1}H nmr δ: 1.43–2.71 (m, 6H), 3.19 (m, $W_{1/2}$ = 6 Hz, 2H), 7.23 (m, 10H); ^{13}C nmr δ: 211.7 (s), 143.6 (s), 131.6 (s), 53.4 (d), 48.0 (t), 38.0 (d), 27.0 (t), 24.0 (t); *m/e*: 274 (100; M^+). *Anal.* calcd. for $C_{20}H_{18}O$: C 87.56, H 6.61; found: C 87.44, H 6.65.

*Formation of (2-benzhydryl-2-cyclopentenyl)acetic acid (33) from 31*a *and 31*b

Hydrolysis of a mixture of **31***a* and **31***b* (45.6 g, 133 mmol) dissolved in dimethyl sulfoxide (400 mL) with a hot solution of potassium hydroxide (87.3%; 25.6 g, 399 mmol) in water (9 mL) for 48 h gave a very poor yield of ketone **32** after work-up as above. The original aqueous phase from the work-up was acidified with concentrated sulfuric acid and extracted several times with ether. The combined ethereal extracts were washed with water and saturated aqueous sodium chloride, dried, filtered, and evaporated to give a brown foam. The foam was applied to a Florisil plug and eluted with dichloromethane. Evaporation of the solvent followed by treatment with boiling hexane and cooling to −20°C afforded **33** as a white crystalline solid, mp 91–92°C; ir λ_{max}: 3–4 (br), 5.66 (w), 5.84, 6.69 (w), 6.89 (w), 7.10 (w) μm; ^{1}H nmr δ: 1.37–3.23 (m, 7H), 4.66 (m, $W_{1/2}$ = 5 Hz, 1H), 5.07 (m, $W_{1/2}$ = 5.5 Hz, 1H), 7.07 (m, 10H), 11.25 (br s, 1H); ^{13}C nmr δ: 179.6 (s), 148.1 (s), 143.2 (s), 141.3 (s), 130.4 (d), 128.9 (d), 128.5 (d), 128.1 (d), 126.6 (d), 126.2 (d), 51.6 (d), 43.1 (d), 38.1 (t), 30.7 (t), 30.5 (t); *m/e*: 292 (78; M^+), 232 (73). *Anal.* calcd. for $C_{20}H_{20}O_2$: C 82.16, H 6.90; found: C 82.04, H 6.90.

Formation of 33 from 32

A hot solution of potassium hydroxide (87.3%; 300 mg, 4.68 mmol) in water (0.5 mL) was added in one portion to a vigorously stirred solution of **32** (272 mg, 0.99 mmol) in dimethyl sulfoxide (8 mL). The mixture was stirred in the dark at ambient temperature under a nitrogen atmosphere for 36 h, diluted with water, and extracted several times with dichloromethane. The extracts were discarded, and the aqueous phase was acidified with concentrated sulfuric acid and extracted several times with dichloromethane. The combined extracts were dried, filtered, and evaporated to give an oil (202 mg). Sublimation at 110°C (0.01 Torr) afforded a glass (79 mg, 27%) which was shown to consist largely of **33** by ^{1}H nmr spectroscopic comparison.

syn- *and* anti-*7-Benzhydrylbicyclo[2.2.1]heptan-2-one (9 and 10)*

Compound **32** (2.15 g, 7.85 mmol) was hydrogenated in absolute ethanol (30 mL) over 10% Pd/C (60 mg) at ambient temperature and 1 atm pressure until the uptake of hydrogen ceased (200 mL; 48 h). Filtration followed by evaporation gave a mixture of **9** and **10** (2.00 g, 92%) as a colorless oil. The oil was applied to a column of silica gel (125 g) and eluted with benzene (20-mL fractions were collected).

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.5 on 09/06/12
For personal use only.

The majority of fractions contained a mixture of *syn* (R_f = 0.3) and *anti* isomers (R_f = 0.2). The final fractions consisted of only the *anti* isomer **10** (68 mg) which was purified further by sublimation at 65°C (0.025 Torr), affording a glass, followed by treatment with boiling hexane and cooling to −20°C to give **10** as a white crystalline solid, mp 80–82°C; ^{1}H nmr δ: 1.25–2.42 (m, 8H), 2.68 (br d, J = 12 Hz, 1H), 3.77 (d, J = 12 Hz, 1H), 7.23 (s, 5H), 7.26 (s, 5H); *m/e*: 276 (21; M^+). *Anal.* calcd. for $C_{20}H_{20}O$: C 86.92, H 7.29; found: C 86.88, H 7.35.

The fractions containing mixtures of isomers were combined and evaporated to give a colorless oil, which on treatment with boiling hexane and cooling to −20°C afforded the *syn* isomer **9** (522 mg) as a white crystalline solid, mp 130–131.5°C; ^{1}H nmr δ: 1.23–2.36 (m, 8H), 2.63 (br d, J = 12 Hz, 1H), 3.58 (d, J = 12 Hz, 1H), 7.13 (s, 5H), 7.19 (s, 5H); *m/e*: 276 (24; M^+). *Anal.* calcd. for $C_{20}H_{20}O$: C 86.92, H 7.29; found: C 86.78, H 7.26.

syn-7-*Isopropylbicyclo[2.2.1]heptane-2,3-dione* (**40**)

A mixture of **5** (8.00 g, 52.6 mmol) in distilled bromobenzene (bp 56°C (20 Torr); 180 mL) and powdered selenium dioxide (14.6 g, 132 mmol) was boiled under reflux with vigorous mechanical stirring under a nitrogen atmosphere. The reaction was monitored by examination of the ^{1}H nmr spectra of aliquots, which showed a signal at δ 3.02 attributed to the bridgehead protons of the product. After 39 h the yellow mixture was cooled and filtered through Celite with suction. The residual black selenium was washed well with benzene until the washings became colorless. Evaporation of solvent from the combined filtrate and washings under high vacuum left a red oil, which was treated with hot hexane (150 mL). Gravity filtration of the hot solution and cooling the filtrate to −20°C afforded **40** (6.04 g, 69%) as a bright yellow powder. Crystallization from hexane followed by sublimation at ambient temperature (0.005 Torr) gave yellow crystals, mp 88.5–90°C; ^{1}H nmr δ: 0.98 (d, J = 5 Hz, 6H), 1.12–2.55 (m, 6H), 3.02 (m, $W_{1/2}$ = 6.5 Hz, 2H); *m/e*: 166 (39; M^+), 123 (84). *Anal.* calcd. for $C_{10}H_{14}O_2$: C 72.26, H 8.49; found: C 72.15, H 8.52.

anti-7-*Isopropylbicyclo[2.2.1]heptane-2,3-dione* (**41**)

A mixture of **6** (2.00 g, 13.2 mmol) in distilled bromobenzene (bp 56°C (20 Torr); 130 mL) and powdered selenium dioxide (3.65 g, 32.9 mmol) was heated at 140°C with vigorous mechanical stirring under a nitrogen atmosphere. The reaction was monitored by examination of the ^{1}H nmr spectra of aliquots, which showed a signal at δ 2.93 attributed to the bridgehead protons of the product. After 21 h further selenium dioxide (1.4 g) was added. After a total of 33.5 h of heating, the yellow mixture was cooled and worked up as for **40** to give a red oil, which was treated with hot hexane (100 mL). Gravity filtration of the hot solution and cooling the filtrate to −20°C afforded **41** (912 mg) as bright yellow crystals. Evaporation of the mother liquor followed by two sublimations at ambient temperature (0.01 Torr) gave a further crop of product (254 mg; 53% total), mp 68.5–70°C; ^{1}H nmr δ: 0.98 (d, J = 5 Hz, 6H), 1.08–2.42 (m, 6H), 2.93 (m, $W_{1/2}$ = 6 Hz, 2H); *m/e*: 166 (28; M^+); 123 (22). *Anal.* calcd. for $C_{10}H_{14}O_2$: C 72.26, H 8.49; found: C 72.06, H 8.47.

syn-7-tert-*Butylbicyclo[2.2.1]heptane-2,3-dione* (**42**)

Compound **7** (4.00 g, 24.1 mmol) in distilled bromobenzene (bp 42°C (10 Torr); 125 mL) was oxidized with powdered selenium dioxide (6.69 g, 60.3 mmol) as in the case of **5**, with monitoring of a ^{1}H nmr signal at δ 0.94 attributed to the *tert*-butyl protons of the product. After 70 h, the yellow mixture on work-up as before gave a yellow solid, which was treated with hot hexane (75 mL). Gravity filtration of the hot solution and cooling the filtrate to −20°C afforded **42** (2.62 g) as bright yellow elongated plates. Concentration of the mother liquor and cooling to −20°C afforded a further crop of product (53 mg; 73% total), mp 97.5–99°C; ^{1}H nmr δ: 0.94 (s, 9H), 1.19–2.49 (m, 5H), 3.07 (m, $W_{1/2}$ = 7 Hz, 2H); *m/e*: 180 (14; M^+), 123 (80). *Anal.* calcd. for $C_{11}H_{16}O_2$: C 73.30, H 8.95; found: C 73.23, H 9.03.

anti-7-tert-*Butylbicyclo[2.2.1]heptane-2,3-dione* (**43**)

Compound **8** (2.41 g, 14.5 mmol) in distilled bromobenzene (170 mL) was oxidized with selenium dioxide (6.50 g, 58.6 mmol) as in the case of **6**, with monitoring of a ^{1}H nmr signal at δ 1.08 attributed to the *tert*-butyl protons of the product. After 25 h further selenium dioxide (1.00 g) was added. After a total of 41 h of heating, the yellow mixture was worked up as before to give a red oil. The oil was distilled in a Kugelrohr apparatus at 60°C (0.025 Torr) with cold water cooling of the receiver bulb to afford a yellow solid (1.51 g). Crystallization from hexane (25 mL) wih cooling to −20°C afforded **43** (800 mg) as a bright yellow powder. Concentration of the mother liquor and cooling to −20°C gave a further crop of product (288 mg). Further concentration of the mother liquor and cooling to −20°C gave a third crop, which after sublimation at ambient temperature (0.025 Torr) afforded a further 180 mg of product (49% total), mp 65–67°C; ^{1}H nmr δ: 1.08 (s, 9H), 1.46–2.54 (m, 5H), 3.05 (m, $W_{1/2}$ = 6.5 Hz, 2H); *m/e*: 180 (12; M^+), 123 (22). *Anal.* calcd. for $C_{11}H_{16}O_2$: C 73.30, H 8.95; found: C 73.11, H 8.88.

syn-7-*Isopropylbicyclo[2.2.1]heptane-2,3-dione, (Z)-monotosylhydrazone* (**44***Z*)

To a warm solution of **40** (3.00 g, 18.1 mmol) in glacial acetic acid (10 mL) was added in one portion a warm solution of *p*-toluenesulfonylhydrazine (3.37 g, 18.1 mmol) in glacial acetic acid (10 mL). After the mixture had stood at 5°C overnight, the crystals that had separated were collected by suction filtration and washed thoroughly with water, affording **44***Z* (5.18 g, 86%). Recrystallization from a mixture of methanol (40 mL) and acetonitrile (10 mL) gave greenish-yellow crystals, mp 166.5–168.5°C; ^{1}H nmr δ: 0.87 (br s, 6H), 0.97–2.26 (m, 6H), 2.43 (s, 3H), 2.73 (m, $W_{1/2}$ = 7 Hz, 1H), 2.97 (m, $W_{1/2}$ = 6 Hz, 1H), 7.24 (d, J = 8.5 Hz, 2H), 7.74 (d, J = 8.5 Hz, 2H), 11.49 (br s, 1H); *m/e*: 179 (26; $(M - C_7H_7SO_2)^+$), 150 (14). *Anal.* calcd. for $C_{17}H_{22}N_2O_3S$: C 61.05, H 6.63, N 8.38; found: C 60.96, H 6.65, N 8.27.

anti-7-*Isopropylbicyclo[2.2.1]heptane-2,3-dione, (Z)-monotosylhydrazone* (**45***Z*)

A solution of **41** (207 mg, 1.25 mmol) and *p*-toluenesulfonylhydrazine (232 mg, 1.25 mmol) in dry dichloromethane (15 mL) was boiled under reflux overnight. Evaporation of the solvent and examination of the ^{1}H nmr spectrum of the resulting yellow oil indicated the presence of a mixture of *Z*- and *E*-monotosylhydrazones. Application of the crude material to a plug of silica gel (15 g) and elution with dichloromethane converted the mixture to the single *Z* isomer. Evaporation of solvent gave a pale green oil which was treated wih boiling ether/hexane. Cooling to −20°C afforded **45***Z* (323 mg, 77%) as greenish-yellow crystals, mp 115–117°C; ^{1}H nmr δ: 0.89 (d, J = 4 Hz, 6H), 1.02–2.18 (m, 6H), 2.43 (s, 3H), 2.71 (m, $W_{1/2}$ = 8 Hz, 1H), 2.96 (m, $W_{1/2}$ = 6 Hz, 1H), 7.30 (d, J = 8.5 Hz, 2H), 7.80 (d, J = 8.5 Hz, 2H), 11.46 (br s, 1H); *m/e*: 179 (2; $(M - C_7H_7SO_2)^+$), 150 (14). *Anal.* calcd. for $C_{17}H_{22}N_2O_3S$: C 61.05, H 6.63, N 8.38; found: C 61.30, H 6.79, N 8.28.

anti-7-*Isopropylbicyclo[2.2.1]heptane-2,3-dione, (E)-monotosylhydrazone* (**45***E*)

To a warm solution of **41** (350 mg, 2.11 mmol) in glacial acetic acid (2.5 mL) was added in one portion a warm solution of *p*-toluenesulfonylhydrazine (393 mg, 2.11 mmol) in glacial acetic acid (2 mL). After the solution had stood overnight at ambient temperature, the solvent was evaporated and the resulting yellow oil was treated with hot methanol (6 mL). Cooling to −20°C gave **45***E* (138 mg, 20%) as a white powder, mp 155–158°C; ^{1}H nmr δ: 0.88 (d, J = 5 Hz, 6H), 1.03–2.18 (m, 6H), 2.43 (s, 3H), 2.69 (m, $W_{1/2}$ = 6.5 Hz, 1H), 3.28 (m, $W_{1/2}$ = 6 Hz, 1H), 7.38 (d, J = 8 Hz, 2H), 7.83 (d, J = 8 Hz, 2H), 8.73 (br s, 1H).

syn-7-tert-*Butylbicyclo[2.2.1]heptane-2,3-dione, (Z)-monotosylhydrazone* (**46***Z*)

A solution of **42** (540 mg, 3.00 mmol) and *p*-toluenesulfonylhydrazine (558 mg, 3.00 mmol) in dry methanol (12 mL) was boiled under reflux for 48 h. The mixture was cooled to −20°C and the crystals that separated were collected by suction filtration. Recrystallization from methanol afforded **46***Z* (464 mg, 45%) as greenish-yellow crystals, mp 147–148°C; ^{1}H nmr δ: 0.75 (s, 9H),

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.5 on 09/06/12
For personal use only.

1.25–2.18 (m, 5H), 2.42 (s, 3H), 2.74 (m, $W_{1/2}$ = 6 Hz, 1H), 3.03 (m, $W_{1/2}$ = 6 Hz, 1H), 7.30 (d, J = 8.5 Hz, 2H), 7.82 (d, J = 8.5 Hz, 2H), 11.57 (br s, 1H); *m/e*: 193 (2; $(M - C_7H_7SO_2)^+$). *Anal.* calcd. for $C_{18}H_{24}N_2O_3S$: C 62.04, H 6.94, N 8.04; found: C 62.15, H 7.09, N 8.07.

anti-7-tert-*Butylbicyclo[2.2.1]heptane-2,3-dione, (Z)-monotosylhydrazone (47Z)*

A solution of **43** (500 mg, 2.78 mmol) and *p*-toluenesulfonylhydrazine (517 mg, 2.78 mmol) in anhydrous benzene (60 mL) was boiled under reflux overnight in a 100-mL flask equipped with a Dean–Stark water separator. The solution was cooled and the solvent was evaporated to give a yellow oil which could not be crystallized. The oil was applied to a plug of silica gel (30 g) and eluted with dichloromethane. Evaporation of solvent gave a pale green oil which was treated with boiling ether/hexane. Cooling to −20°C afforded **47Z** (877 mg, 91%) as greenish-yellow crystals, mp 143–145°C; ^{1}H nmr δ: 1.02 (s, 9H), 1.17–2.30 (m, 5H), 2.45 (s, 3H), 2.81 (m, $W_{1/2}$ = 7 Hz, 1H), 3.08 (m, $W_{1/2}$ = 7 Hz, 1H), 7.32 (d, J = 8.5 Hz, 2H), 7.83 (d, J = 8.5 Hz, 2H), 11.34 (br s, 1H); *m/e*: 349 (4; $(M + 1)^+$), 193 (80; $(M - C_7H_7SO_2)^+$), 165 (15). *Anal.* calcd. for $C_{18}H_{24}N_2O_3S$: C 62.14, H 6.94, N 8.04; found: C 61.99, H 6.99, N 8.08.

Reaction of monotosylhydrazones 44Z–47Z with basic alumina. Preparation of α-diazo ketones 1–4

General procedure

A solution of vacuum-dried monotosylhydrazone (239 mg – 1.2 g, 0.687–3.6 mmol) in the minimum amount of dry dichlorethane (distilled from calcium hydride) was applied to a column (diameter 1.2 or 2 cm) of activated basic alumina (Fisher A 540; 23–100 g) packed in dichloromethane. The solution was adsorbed well into the column, which was left sealed overnight in the dark with 2 mL of solvent above the adsorption bed. Elution of the product with dichloromethane (100–300 mL) followed by evaporation of the solvent gave the diazo ketone as a bright yellow oil which solidified at −20°C.

3-Diazo-syn-7-*isopropylbicyclo[2.2.1]heptan-2-one (1)*

The yield of **1** was 96%. Sublimation at 40°C (0.01 Torr) gave bright yellow crystals, mp 57–58°C; ^{1}H nmr δ: 0.93 (d, J = 5 Hz, 3H), 0.99 (d, J = 5 Hz, 3H), 1.32–2.18 (m, 6H), 2.58 (m, $W_{1/2}$ = 7 Hz, 1H), 3.37 (m, $W_{1/2}$ = 5 Hz, 1H); *m/e*: 178 (25; M^+). *Anal.* calcd. for $C_{10}H_{14}N_2O$: C 67.39, H 7.92, N 15.72; found: C 67.50, H 7.93, N 15.80.

3-Diazo-anti-7-*isopropylbicyclo[2.2.1]heptan-2-one (2)*

The yield of **2** was 83%. Sublimation at ambient temperature (0.025 Torr) gave bright yellow crystals, mp 42–43°C; ^{1}H nmr δ: 0.88 (d, J = 5 Hz, 3H), 0.93 (d, J = 5 Hz, 3H), 1.02–2.15 (m, 6H), 2.57 (m, $W_{1/2}$ = 6 Hz, 1H), 3.30 (m, $W_{1/2}$ = 4.5 Hz, 1H); *m/e*: 178 (22; M^+). *Anal.* calcd. for $C_{10}H_{14}N_2O$: C 67.39, H 7.92, N 15.72; found: C 67.52, H 7.95, N 15.71.

syn-7-tert-*Butyl-3-diazobicyclo[2.2.1]heptan-2-one (3)*

The yield of **3** was 92%. Sublimation at ambient temperature (0.01 Torr) gave bright yellow crystals, mp 56–57°C; ^{1}H nmr δ: 1.01 (s, 9H), 1.22–2.48 (m, 5H), 2.63 (m, $W_{1/2}$ = 6.5 Hz, 1H), 3.42 (m, $W_{1/2}$ = 5 Hz, 1H); *m/e*: 192 (22; M^+). *Anal.* calcd. for $C_{11}H_{16}N_2O$: C 68.72, H 8.39, N 14.57; found: C 68.67, H 8.31, N 14.48.

anti-7-tert-*Butyl-3-diazobicyclo[2.2.1]heptan-2-one (4)*

Sublimation of the crude product at 32°C (0.025 Torr) afforded **4** (95%) as a bright yellow powder, mp 35–36°C; ^{1}H nmr δ: 1.00 (s, 9H), 1.42–2.42 (m, 5H), 2.70 (m, $W_{1/2}$ = 6 Hz, 1H), 3.47 (m, $W_{1/2}$ = 5 Hz, 1H); *m/e*: 192 (18; M^+). *Anal.* calcd. for $C_{11}H_{16}N_2O$: C 68.72, H 8.39, N 14.57; found: C 68.82, H 8.39, N 14.48.

Copper-catalyzed decomposition of α-diazo ketones 1–4. Preparation of tricyclic ketones 11–14

General procedure

To a solution of the α-diazo ketone (0.87 mmol) in anhydrous benzene (degassed by passage of argon for 30 min; 400 mL) in a 1-L flask that had been oven-dried and cooled under a stream of argon, was added powdered copper (Fisher, electrolytic metal, washed with ether and hexane, and vacuum dried prior to use; 9.8 g). The mixture was boiled gently under reflux with vigorous stirring under an argon atmosphere. The reaction was conveniently monitored by examination of the ir spectra of aliquots, which showed the disappearance of the band at 4.84 μm attributed to the diazo group of the starting material. After 5 h[7] the mixture was cooled and filtered, and the copper was washed well with benzene. Evaporation of the combined filtrate and washings afforded the tricyclic ketone as a highly volatile pale green liquid which was purified by distillation at 50°C (10 Torr) to afford a clear, colorless liquid in each case.

syn-5-*Isopropyltricyclo[2.2.1.0^{2,6}]heptan-3-one (11)*

The yield of **11** was 96%; ^{1}H nmr δ: 0.93 (d, J = 5 Hz, 3H), 1.04 (d, J = 5 Hz, 3H), 1.21 (t, J = 5 Hz, 1H), 1.32–2.15 (m, 7H); *m/e*: 150 (28; M^+), 107 (55), 79 (100). *Anal.* calcd. for $C_{10}H_{14}O$: C 79.96, H 9.39; found: C 79.80, H 9.44.

anti-5-*Isopropyltricyclo[2.2.1.0^{2,6}]heptan-3-one (12)*

The yield of **12** was 75%; ^{1}H nmr δ: 0.82 (d, J = 6 Hz, 3H), 0.99 (d, J = 6 Hz, 3H), 1.37 (t, J = 5.5 Hz, 1H), 1.68–2.13 (m, 7H); *m/e*: 150 (51; M^+), 107 (34), 79 (100). *Mol. Wt.* calcd. for $C_{10}H_{14}O$: 150.1044; found (ms): 150.1040.

syn-5-tert-*Butyltricyclo[2.2.1.0^{2,6}]heptan-3-one (13)*

The yield of **13** was 88%; ^{1}H nmr δ: 0.95 (s, 9H), 1.27 (t, J = 5 Hz, 1H), 1.58–2.05 (m, 6H); *m/e*: 164 (34; M^+), 107 (40), 79 (100). *Anal.* calcd. for $C_{11}H_{16}O$: C 80.44; H 9.82; found: C 80.13, H 9.95.

anti-5-tert-*Butyltricyclo[2.2.1.0^{2,6}]heptan-3-one (14)*

The yield of **14** was 65%; ^{1}H nmr δ: 0.98 (s, 9H), 1.43 (t, J = 5 Hz, 1H), 1.67–2.27 (m, 6H); *m/e*: 164 (46; M^+), 107 (88), 79 (100). *Mol. Wt.* calcd. for $C_{11}H_{16}O$: 164.1201; found (ms): 164.1202.

An improved synthesis of *m*-diazirinophenol

PIERRE LEBLANC AND GERHARD E. GERBER
Department of Biochemistry, McMaster University, Hamilton, Ont., Canada L8N 3Z5

Received July 27, 1983[1]

PIERRE LEBLANC and GERHARD E. GERBER. Can. J. Chem. **62**, 1767 (1984).

The published synthesis of phenolic diazirine was shown to result in products which were chlorinated during the hypochlorite oxidation while the desired unchlorinated product was lost during the usual work-up. A superior synthesis is described: inclusion of pyridine during the oxidation step prevents the chlorination; the desired volatile diazirine was isolated in good yield using silica gel and reverse phase high pressure liquid chromatography.

PIERRE LEBLANC et GERHARD E. GERBER. Can. J. Chem. **62**, 1767 (1984).

On a démontré que la méthode proposée dans la littérature pour la préparation de diazirine phénolique conduit d'une part, à la formation de produits qui ont été chlorés au cours de l'oxydation par l'hypochlorite alors que d'autre part, le produit non chloré désiré est perdu lors de la purification par les méthodes usuelles. On propose une synthèse supérieure qui implique l'inclusion de pyridine au cours de l'étape d'oxydation afin de prévenir la chloration; on a isole la diazirine volatile désirée avec de bons rendements en faisant appel à des chromatographies liquide à haute pression avec phase inversée et sur gel de silice.

Introduction

The phenolic diazirine group was introduced (1) as a potential photoactivable biological probe and has been incorporated into a number of biological systems (2–6). It has recently been attached to the ω-position in a series of tritiated fatty acids and these have been used to identify integral membrane proteins (6, 7) and to characterize the regions of such proteins which are buried within the hydrocarbon region of the bilayer (7). Further, we have shown that these fatty acid analogues can be biologically attached to the recently discovered (8, 9) membrane proteins which are normally acylated by fatty acids. These fatty acids thus afford photoaffinity derivatives of such membrane proteins (6, 7). Consequently, the *m*-diazirinophenolic group has a wide range of biological applications.

In the course of our synthesis of this probe by the published procedures (1, 6), we found that the yield of the desired diazirine was very low and that the products obtained were mostly chlorinated isomers. It had been suggested earlier (10) that removal of HCl generated during hypochlorite oxidations prevents the formation of chlorine and thus avoids chlorination. We therefore report a superior synthesis of the *m*-diazirinophenol, using pyridine to remove the generated HCl as the pyridinium hydrochloride salt.

Experimental

General

Dimethyl formamide (DMF) and methanol were hplc grade. The petroleum ether fraction used was the one boiling between 30–60°C. All other solvents used were reagent grade. Technical grades of both *m*-hydroxybenzaldehyde and chloromethyl methyl ether were purchased from Aldrich. *tert*-Butyl hypochlorite was freshly prepared and assayed as described (11). Thin layer chromatography (tlc) was carried out on silica gel using the following solvent systems: system A, diethyl ether – petroleum ether 1:1 (v/v); system B, diethyl ether – petroleum ether 1:4 (v/v). Elemental analyses were performed by Galbraith Laboratories, Knoxville.

Methoxymethylene ether of m-*hydroxy benzaldehyde (2)*

The *m*-hydroxy benzaldehyde (0.50 mol) was reacted at 0°C with 1.1 equivalent of sodium hydride in suspension in DMF. When the evolution of H_2 had stopped, an excess (0.55 mol) of chloromethyl methyl ether was added dropwise. The mixture was stirred at 0°C for 2 h and the resulting methoxymethylene ether obtained by vacuum distillation (62 g; 75%); bp 125–127°C at 4 Torr (1 Torr = 133.3 Pa); tlc: R_f 0.44 in system A; nmr δ (TMS): 3.23 (s, 3H, CH_3—O—), 4.97 (s, 2H, —O—CH_2—O—), 6.87–7.27 (m, 4H, aromatic), 9.53 (s, 1H, —C(=O)—H).

*1,3,5-Tri-(*m-*methoxymethylene phenyl ether)-2,4,6-triazabicyclo-[3.1.0]hexane (4)*

Chloramine was prepared by the cautious addition of *tert*-butyl hypochlorite (0.33 mol) to 10 *N* methanolic ammonia (280 mL) in a flask cooled by Dry Ice. The *m*-methoxymethylene benzaldehyde (**2**, 50 g) was added and the solution allowed to warm to room temperature during a reaction time of 36 h. The ammonia was allowed to evaporate and the solvent was removed by rotary evaporation under reduced pressure. The oily product was used directly without further characterization.

*Synthesis of 3-(*m-*methoxymethylene ether phenyl)-3*H*-diazirine in the absence of pyridine*

The triazabicyclohexane (**4**) prepared as described above starting with 30 g (0.18 mol) of the benzaldehyde (**2**) was an oily residue which was immediately dissolved in 40 mL of methanol and brought to 0°C. A solution of *tert*-butyl hypochlorite (0.09 mol) in *tert*-butyl alcohol (16 mL) was added dropwise and the reaction allowed to proceed for 2 h. Aliquots of the mixture were analyzed on hplc using a μ Bondapak C_{18} column with a solvent system consisting of 65% methanol–water. The mixture was poured into 1 L of a 10% solution of sodium metabisulfite and extracted 4 times with an equal volume of petroleum ether. The extracts were combined, subjected to silica gel chromatography using petroleum ether, and the fractions having absorbance at 360 nm were pooled. Evaporation of the ether afforded a yellow–green oil (1.95 g). The hplc analysis described in Fig. 2(a) identified products **5***a*, **5***b*, **5***c*, and **5***d* having retention times of 7.7, 11.5, 14.4, and 17.5 min respectively. Each of these components was obtained in pure form by preparative hplc on a μ Bondapak C_{18} column isocratically eluted with 55% methanol in water.

The peak eluting at 7.7 min (product **5***a*) was the desired diazirine (240 mg; 2%); ν_{max} (neat): 2930, 2860, 1605, 1580, 1490, 1450, 1400, 1350, 1320, 1278, 1250, 1210, 1150, 1080, 1030, 1000, 990, 920, 870, 770, 690 cm^{-1}; vis (cyclohexane), λ_{max}: 358 nm (ε 360); nmr δ (TMS): 1.98 (s, 1H, ), 3.38 (s, 3H, CH_3—O—), 5.03 (s, 2H, —O—CH_2—O—), 6.37–6.53 (m, 2H, aromatic),

[1]Revision received March 12, 1984.

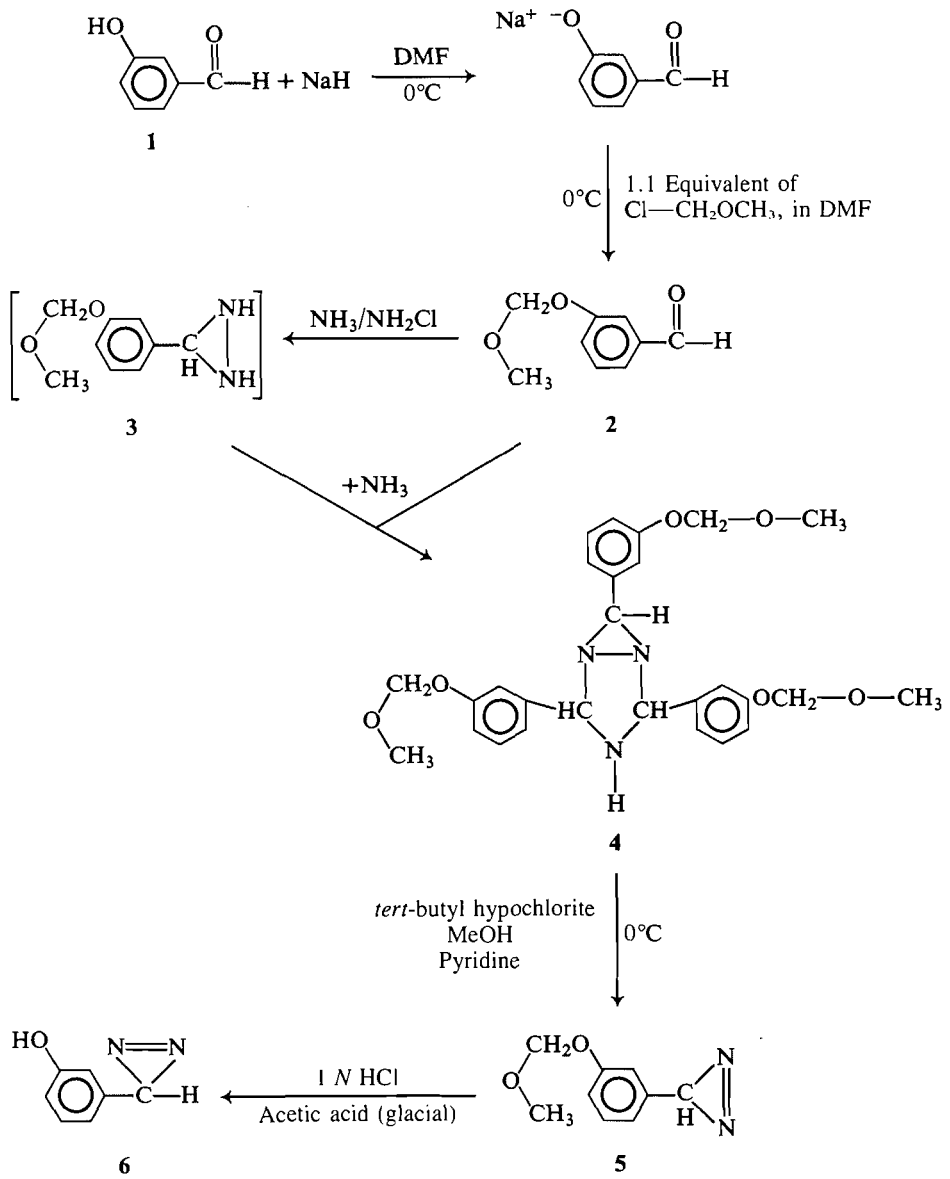

FIG. 1. Scheme for the synthesis of *m*-diazirinophenol.

6.83–7.23 (m, 2H, aromatic).

The peak observed on hplc, at 11.5 min (product **5***b*) was recovered as an oil (560 mg; 4.4%) and shown to be a chlorinated product; ν_{max} (neat): 2960, 2830, 1620, 1600, 1580, 1489, 1430, 1400, 1347, 1290, 1250, 1210, 1175, 1150, 1085, 1050, 1010, 980, 920, 815, 780, 750, 725, 625 cm^{-1}; vis (cyclohexane), λ max: 358 (ε 350); nmr δ (TMS): 2.03 (s, 1H, ), 3.52 (s, 3H, CH_3—O—), 5.20 (s, 2H, —O—CH_2—O—), 6.44 (dd, 1H, J_{ortho} = 8.2 Hz, J_{meta} = 2.0 Hz, aromatic), 6.75 (d, 1H, J_{meta} = 2.0 Hz, aromatic), 7.29 (d, 1H, J_{ortho} = 8.2 Hz, aromatic). *Anal.* calcd. for $C_9H_9N_2ClO_2$: C 50.83, H 4.27, N 13.17, Cl 16.67, O 15.05; found: C 51.27, H 4.70, N 11.20, Cl 17.78, O 14.86.

The peak eluting from hplc at 14.4 min (product **5***c*) was recovered as an oil (270 mg; 2.1%) and shown to be a chlorinated product; nmr δ (TMS): 2.54 (s, 1H, ), 3.50 (s, 3H, CH_3—O—), 5.24 (s, 2H, —O—CH_2—O—), 6.79 (dd, 1H, J_{ortho} = 6.8 Hz, J_{meta} = 2.5 Hz, aromatic), 7.06 (m, 2H, J_{ortho} = 6.8 Hz, J_{ortho} = 8.3 Hz, J_{meta} = 2.5 Hz, aromatic).

The peak observed on hplc at 17.5 min (product **5***d*) was recovered as an oil (700 mg; 5.5%) and shown to be a chlorinated product; ν_{max} (neat): 2930, 2860, 2830, 1620, 1600, 1571, 1475, 1425, 1400, 1345, 1305, 1278, 1238, 1210, 1170, 1150, 1140, 1080, 1060, 1010, 920, 870, 810, 640 cm^{-1}; vis (cyclohexane), λ_{max}: 358 (ε 289); nmr δ (TMS): 2.45 (s, 1H, ), 3.39 (s, 3H, CH_3—O—), 5.02 (s, 2H, —O—CH_2—O—), 5.90 (d, 1H, J_{meta} = 2.9 Hz, aromatic), 6.88 (dd, 1H, J_{ortho} = 8.8 Hz, J_{meta} = 2.9 Hz, aromatic), 7.25 (d, 1H, J_{ortho} = 8.8 Hz, aromatic). *Anal.* calcd. for $C_9H_9N_2ClO_2$: C 50.83, H 4.27, N 13.17, Cl 16.67, O 15.05; found: C 51.86, H 4.86, N 11.25, Cl 17.05, O 15.27.

*Synthesis of 3-(*m*-methoxymethylene ether phenyl)-3*H*-diazirine in the presence of pyridine*

The triazabicyclohexane (**4**), prepared as described above starting with 50 g (0.33 mol) of the benzaldehyde (**2**) was dissolved in 60 mL of methanol and brought to 0°C. After addition of pyridine (0.51 mol), *tert*-butyl hypochlorite (0.17 mol in 20.0 mL of *tert*-butyl alcohol) was added dropwise over a period of 10 min. The reaction was allowed to proceed for 2 h. The mixture was then processed as described above

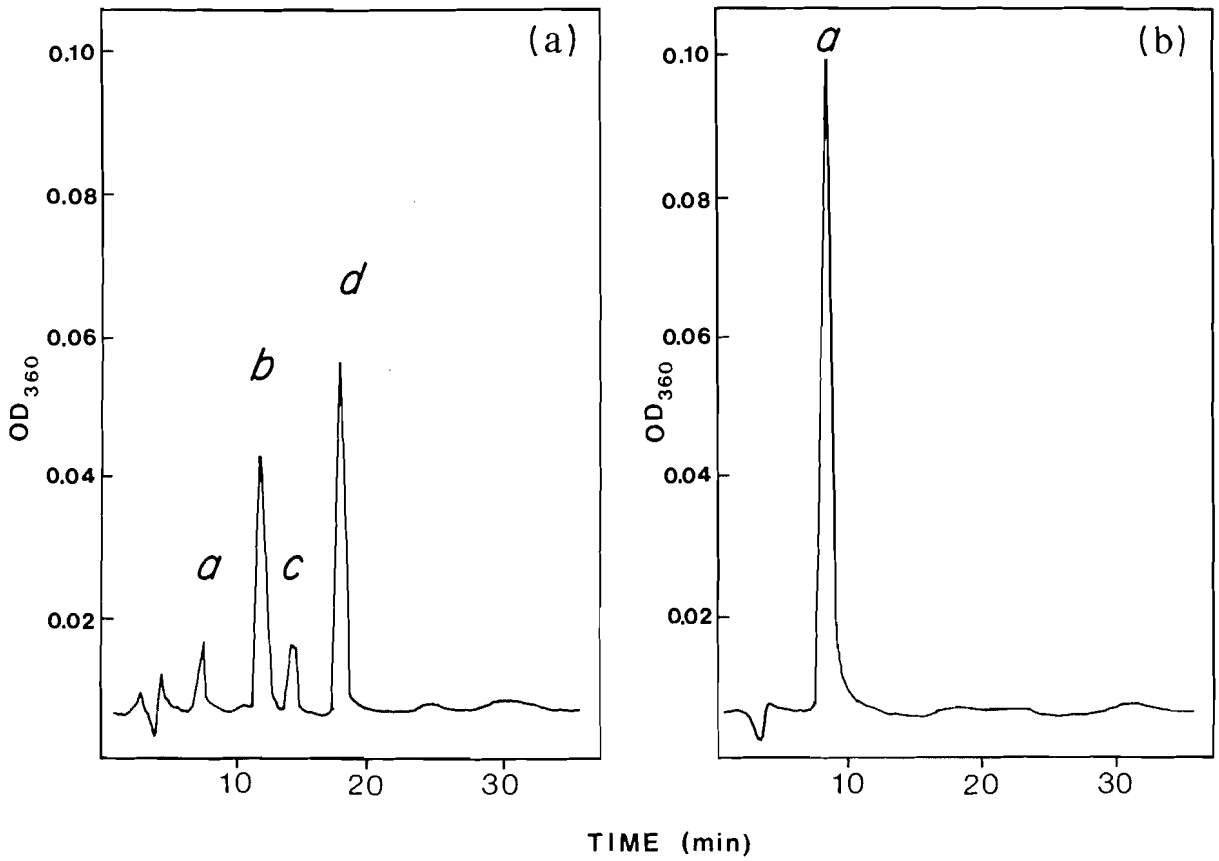

FIG. 2. High pressure liquid chromatographic analyses of the oxidation products (**5**) in the absence (a) and the presence (b) of pyridine. The reaction conditions were as described in the experimental section for the oxidation of the triazabicyclohexane. An aliquot (10 μL) of the reaction mixture was injected after 45 min, on a C_{18} reverse-phase hplc column using 65% methanol in water as an eluting solvent. The eluates were monitored using an ISCO detector equipped with a 340–365 nm filter.

For personal use only.

for the oxidation of the triazabicyclohexane (**4**) in the absence of pyridine. Final purification was achieved by preparative hplc on a μ Bondapak C_{18} column using 55% methanol–water as solvent. After extraction into diethyl ether and drying, a pale yellow–green oil was obtained (4.30 g; 24%); tlc: R_f 0.35 in system B; ν_{max} (neat): 2930, 2860, 1605, 1580, 1490, 1450, 1400, 1350, 1320, 1278, 1250, 1210, 1150, 1080, 1030, 1000, 990, 920, 870, 770, 690 cm^{-1}; vis (cyclohexane), λ_{max}: 358 nm (ε 360); nmr δ (TMS): 1.98 (s, 1H, ), 3.38 (s, 3H, CH_3—O—), 5.03 (s, 2H, —O—CH_2—O—), 6.37–6.53 (m, 2H, aromatic), 6.83–7.23 (m, 2H, aromatic). *Anal.* calcd. for $C_9H_{10}N_2O_2$: C 61.01, H 5.12, N 15.81, O 18.06; found: C 61.25, H 6.46, N 14.45, O 17.82, Cl none.

m-*Diazirinophenol* (*6*a)

The procedure was adapted from the one described (2). The dry diazirine (*5a*) (17 mmol) was dissolved in glacial acetic acid (51 mL); 1 *N* aqueous HCl (9.58 mL) was added and allowed to react for 2 h. The mixture was then transferred to 1.8 L of 1 *N* sodium bicarbonate and the crude *m*-diazirinophenol isolated by extraction into diethyl ether. The pure *m*-diazirinophenol generated was isolated by column chromatography on silica gel using petroleum ether and diethyl ether (95:5, v/v), followed by preparative hplc using an isocratic solvent system (25% methanol in water). The resulting unchlorinated phenolic diazirine was obtained as an oil (3.0 g, 90% yield); vis (cyclohexane), λ_{max}: 358 nm (ε 360); nmr δ (TMS): 1.98 (s, 1H, ), 5.47 (s, broad, 1H, arom-OH), 6.32 (dd, 1H, J_{meta} = 1.6 Hz, J_{meta} = 2.6 Hz, aromatic), 6.49 (ddd, 1H, J_{ortho} = 7.7 Hz, J_{meta} = 1.0 Hz, J_{meta} = 1.7 Hz, aromatic), 6.76 (ddd, 1H, J_{ortho} = 8.1 Hz, J_{meta} = 1.0 Hz, J_{meta} = 2.6 Hz, aromatic), 7.16 (t, 1H, J_{ortho} = 7.9 Hz, aromatic). *Anal.* calcd. for $C_7H_6N_2O$: C 62.88, H 4.51, N 20.88, O 11.93; found: C 61.98, H 4.36, N 16.40, O 13.13, Cl none.

Results and discussion

Our synthetic approach closely resembles that of Smith and Knowles (1) in that we form the triazabicyclohexane intermediate (**4**) prior to oxidative cleavage via *tert*-butyl hypochlorite (Fig. 1). Attempts at improving the yield of (*5a*) by other oxidation methods failed to produce a significant yield of the diazirine with *para*-substituted arylbicyclohexanes (1). The yields of the isolated *m*-diazirinophenol were typically in the range of 2–5% after oxidation of the triazabicyclohexane. We therefore studied the oxidation using hplc and the characteristic absorption at 360 nm of the diazirine to monitor the reaction, as shown in Fig. 2. The standard oxidation conditions resulted in a number of products as shown in Fig. 2(a). These products were isolated by preparative hplc and their nmr and vis spectra were determined. The small peak eluting at 7.7 min (Fig. 2(a)) contained product *5a* and had the nmr and vis characteristics expected for the desired diazirine. The products *5b*, *5c*, and *5d*, eluted at 11.5, 14.5, and 17.5 min respectively, had similar uv–vis spectra; however, their nmr spectra indicated the loss of an aromatic proton (3H aromatic for products *5b*, *5c*, and *5d*). Elemental analysis of these products was complicated by the fact that they were light- and heat-sensitive oils; however, the results unequivocally showed that these were all isomeric

*5*a*, *b*, *c*, and *d* are products from oxidation in absence of pyridine.
†6*a* is derived from oxidation in presence of pyridine.

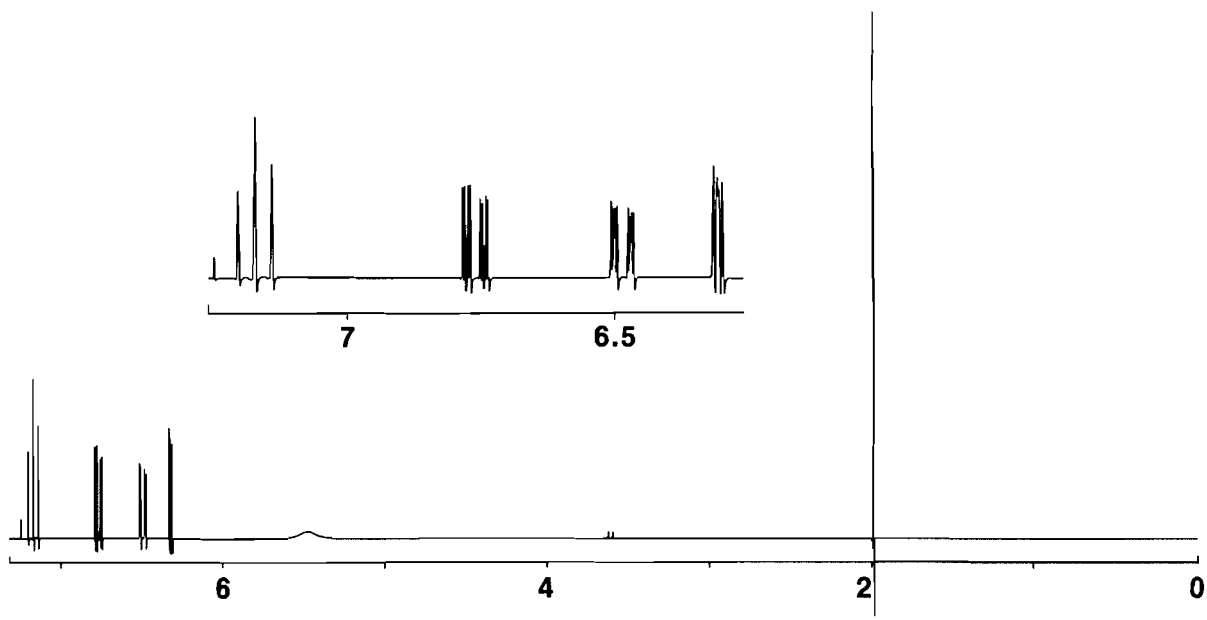

FIG. 3. The ^{1}H nmr spectrum ($CDCl_3$) of the unchlorinated *m*-diazirinophenol **6***a*.

forms of monochlorinated *m*-diazirinophenol.

Analysis of the nmr spectra using high resolution (250 MHz) nmr and spin decoupling indicated that products **5***b*, **5***c*, and **5***d* were chlorinated on the phenyl ring in positions R^2, R^1, and R^4 respectively (Table 1). It is of particular interest to note that chlorination in positions R^1 or R^4 (products **5***c* and **5***d* respectively) has a dramatic effect on the position of the adjacent diazirine proton while chlorination in position R^2 (product **5***b*) leaves this proton relatively unaffected compared to the unchlorinated compound. Furthermore the position of the *meta* proton at R^4 (when R^1 is chlorinated) or R^1 (when R^4 is chlorinated) is shifted to higher field, while the position of the proton at R^2 is shifted to lower field under these conditions. Detailed analysis of the nmr spectra of the chlorinated products enabled us to assign the position of the aromatic protons of the pure *m*-diazirinophenol (**6***a*) (see Fig. 3 for the nmr spectrum).

It was concluded that this chlorination was the result of the generation of Cl_2 during the hypochlorite oxidation. The formation of the diaziridine (**3**) generates HCl which is oxidized to Cl_2 by the hypochlorite, as had been suggested earlier (10). The pyridine traps the hydrochloric acid as the pyridinium hydrochloride salt and consequently avoids chlorination of the desired product. When the oxidation was performed in the presence of pyridine, the only diazirine-containing product

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.40 on 09/06/12
For personal use only.

formed was eluted in the region of the desired material on hplc, as shown in Fig. 2(b); the chlorinated products **5***b*, **5***c*, and **5***d* normally eluted at 11.5, 14.5, and 17.5 min respectively were entirely absent. The pyridine thus prevented the formation of undesired products and the yield of the desired phenyldiazirine (**5***a*) was greatly improved. Removal of the methoxy methylene group afforded the pure *m*-diazirinophenol (**6***a*).

It should also be noted that the isolated yield of the unchlorinated diazirine was affected by the work-up, since it was found to be volatile while the chlorinated isomers were not. Purification by fractional distillation was avoided due to the potentially explosive properties of the diazirine; the desired pure diazirine was therefore obtained by preparative hplc, extraction into diethyl ether, and drying under nitrogen. This procedure resulted in isolated yields of 24 to 30% of the desired diazirine.

It is interesting to note that in the unchlorinated *m*-diazirinophenol, the diazirine proton is observed at δ 1.98 while the position previously reported (6) was at δ 2.4. The compound actually reported in the literature therefore likely corresponded to the major chlorinated isomer (product **5***d*, Table 1). Our previous studies used the unchlorinated *m*-diazirinophenol isolated by hplc from the crude product obtained in the absence of pyridine (5). We have shown that fatty acid analogues synthesized using this diazirine are readily incorporated into phospholipids and proteins of mammalian cells in culture (5, 7). The failure of others (12) to observe biosynthetic utilization of these fatty acids may thus be due to their use of a chlorinated isomer. In order to use these probes for biological experiments it is clearly important to avoid the chlorination.

Polarographic redox potentials of diazotized polycyclic aromatic amines and the absolute electrode potentials[1]

RICHARD M. ELOFSON, FAHMI F. GADALLAH, KARLO F. SCHULZ, AND JAMES K. LAIDLER
Alberta Research Council, 11315 – 87 Avenue, Edmonton, Alta., Canada T6G 2C2

Received December 20, 1983

RICHARD M. ELOFSON, FAHMI F. GADALLAH, KARLO F. SCHULZ, and JAMES K. LAIDLER. Can. J. Chem. **62**, 1772 (1984).

The half-wave potentials ($E_{1/2}$) of polycyclic diazonium salts as well as those of the parent hydrocarbons, the corresponding aldehydes, and the nitro compounds, when plotted against the coefficient of the energy of either the lowest vacant orbital $-m_{m-1}$ or the coefficient of the highest occupied orbital $+m_m$ of the parent hydrocarbon tend toward the midpoint potential, E_m, equal to −0.31 V vs. sce as established by Parker. The polarographic results are correlated with ^{13}C nmr results with comments on solvation energies.

RICHARD M. ELOFSON, FAHMI F. GADALLAH, KARLO F. SCHULZ et JAMES K. LAIDLER. Can. J. Chem. **62**, 1772 (1984).

On a dressé un graphique mettant en opposition d'une part les potentiels à demi-vague ($E_{1/2}$) de sels de diazonium de dérivés polycycliques, de leurs hydrocarbures, des aldéhydes et des dérivés nitro correspondants et d'autre part le coefficient de l'énergie soit de l'orbitale basse vacante ($-m_{m-1}$) ou le coefficient de l'orbitale haute occupée ($+m_m$) de l'hydrocarbure de base. Ces courbes tendent vers un potentiel à mi-point, E_m, qui est égal à −0,31 V vs. sce tel qu'établi par Parker. On peut établir une corrélation entre les résultats polarographiques et les résultats de rmn du ^{13}C qui reflète sur les énergies de solvatation.

[Traduit par le journal]

Introduction

In 1969, we reported the results of our work on the effect of substituents on the half-wave reduction potentials of aryl diazonium tetrafluoroborates in the aprotic solvent sulfolane (1). These results produced a good Hammett plot [1]. Only one reversible, one electron-reduction wave was observed.

[1] $E_{1/2} = (0.229\sigma + 0.314)$ V vs. sce

These findings led to electrochemical techniques for arylations (2) and Pschorr reactions (3). The positive reduction potentials agree well with the strong electrophilicity of diazotized aromatic amines (4).

These studies have now been extended to include a number of diazotized polycyclic aromatic amines. The results are discussed in terms of the absolute scale of electrode potentials suggested by Parker (5), and by the molecular orbital theory.

Experimental

Experimental conditions were those previously described (1). However, a new polarograph (Princeton Applied Research Model 170) operating in the three electrode configuration was used. The diazonium salts were prepared from the corresponding amines by diazotization in dilute sulfuric acid. The diazotized amines were precipitated as the tetrafluoroborate salts and recrystallized repeatedly from dry methanol–ether mixtures. Because halide ions form complexes with diazonium cations at the mercury surface (a subsequent paper will elaborate on the nature of these complexes), halide ions must be rigourously excluded if meaningful results are to be obtained.

^{13}C nmr spectra were obtained using a Bruker WP80 spectrometer operating at 20.1 MHz. The corresponding amines were diazotized in the usual manner and, because of solubility considerations, converted to chloride salts which were examined in a 20% D_2O/H_2O mixture. The chemical shifts were established based on a measured chemical shift for methanol of 50.498 ppm at 5°C in a mixture of methanol in $CDCl_3$ and TMS. A spectra reference number based on methanol in 20% D_2O in H_2O was then established. The results were within 1 ppm for comparable compounds in the previous study (16).

Results

The half-wave potentials obtained for nine polycyclic diazonium salts are presented in Table 1. Figure 1 includes the data from Table 1 and a selection of half-wave potentials of polycyclic hydrocarbons, aldehydes (6), and a few nitro compounds (Table 2). The half-wave potentials of the nitro derivatives were also determined in this laboratory.

The potentials are plotted against the coefficient of the lowest vacant orbital $-m_{m+1}$ or the coefficient of the highest occupied orbital $+m_m$ of the parent hydrocarbon. Correlations *VI* and *VII* are the oxidation potentials of these hydrocarbons as determined by Lund (7) and by Parker (5), respectively. As may be seen from Fig. 1, these plots tend toward Parker's midpoint potential E_m of −0.31 V vs. sce as the energy coefficient of the parent hydrocarbon tends toward zero.

TABLE 1. Half-wave potentials of aryldiazonium salts*

Parent compound	$-E_{1/2}$ vs. sce (V)
Aniline	0.295

Discussion

Working with a platinum electrode in acetonitrile, Parker found that for alternate aromatic hydrocarbons (AAH) $E_{1/2(red)} + E_{1/2(oxid)}$ is equal to -0.31 V vs. sce. This result was interpreted to indicate that the solvation energy of all the anions and cations of the series were the same. This can hardly be true for the series of aldehydes, nitro compounds, and diazonium salts as described in Fig. 1, which would be expected to obey the Born equation (8) [2] where the symbols

$$[2] \quad (\Delta G^0) = (1 - 1/D)\, Ne^2/2r_c$$

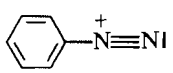
have the usual meaning and r_c is the mean effective radius of the ion. Since the degree of solvation is dependent on the mean diameter of the solute molecules, the solvation energy should be larger for smaller molecules. This fact would tend to increase either positive or negative slopes of the correlations in Fig. 1 to such an extent that all correlations might intersect at about -0.31 V vs. sce at the values of the energy coefficients equal to zero ($-m_{m+1}$ or $+m_m$ equals 0 for graphite by definition) if corrections could be made for solvation energies. In any event, these correlations lead us to support Parker's idea that the midpoint potential E_m is an important zero point against which to measure the energy change of an electrode reaction in organic systems. This is related to the "absolute" electrode potential as shown by Parker (5), where ϕ is the work function of graphite and equal to 4.39 V. This is shown in [3].

$$[3] \quad E_{absolute} = E_m - \phi$$

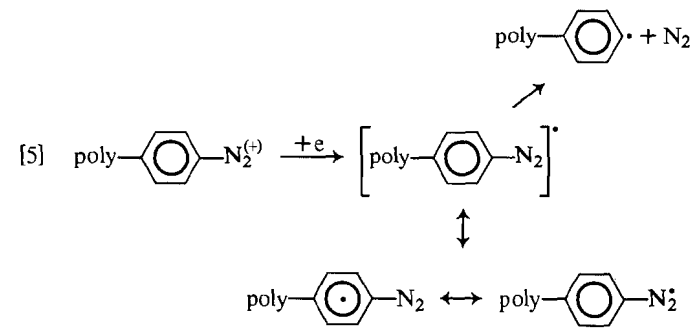
The first of the correlations in Fig. 1 was observed by Maccoll (9). He noted the linearity of the half-wave reduction potentials of polycyclic aromatic hydrocarbons plotted against the coefficient of the molecular orbital resonance integral in the expression for the lowest unoccupied orbital. This coefficient correlates with the maximum of the longest wave length electronic absorption spectra. In terms of the scale of Fig. 1, this became [4].

$$[4] \quad E_{1/2} = (2.368\, m_{m+1} - 0.924) \text{ V vs. sce}$$

This well-known correlation and prediction are to be expected of the classical formula proposed by Bamberger and by



Hantzsch (10), for the reduction of aryldiazonium salts suggests that the slope of the plot for polycyclic diazonium salts should also be positive according to [5].



However, this is not the case. Instead, the equation for correlation V in Fig. 1 is [6].

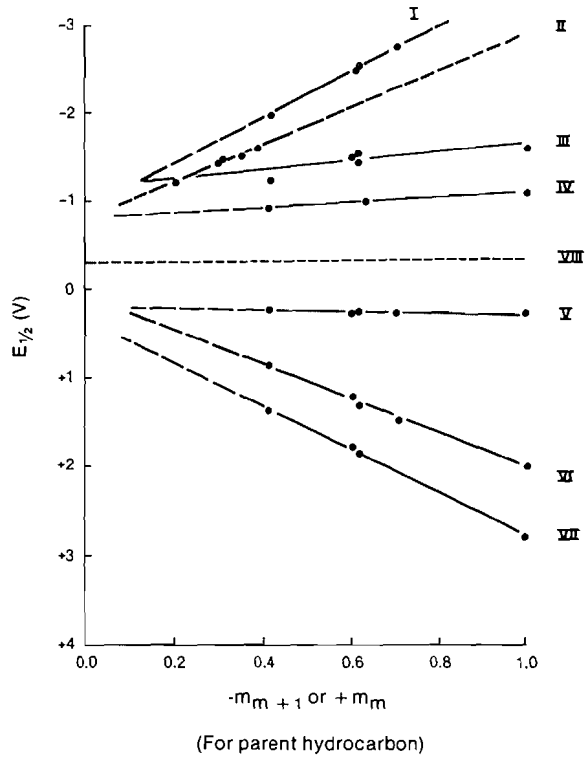


FIG. 1. *I*, $E_{1/2}$ vs. sce; polyArH $\xrightarrow{+e}$ polyArH($\dot{-}$) vs. $-m_{m+1}$ of parent hydrocarbon in aqueous dioxane, Hg electrode where applicable results agree with Parker, Pt electrode. *II*, $E_{1/2}$ vs. sce; polyArCHO $\xrightarrow{+e}$ vs. $-m_{m+1}$ of polyArCHO in 50% ethanol, Hg electrode. *III*, $E_{1/2}$ vs. sce; polyArCHO $\xrightarrow{+e}$ polyArCHO($\dot{-}$) vs. $-m_{m+1}$ of parent hydrocarbon in 50% ethanol, Hg electrode. *IV*, $E_{1/2}$ vs. sce; polyArNO$_2$ $\xrightarrow{+e}$ polyArNO$_2$($\dot{-}$) vs. $-m_{m+1}$ of parent hydrocarbon in sulfolane, Hg electrode. *V*, $E_{1/2}$ vs. sce; polyArN$_2^+$ $\xrightarrow{+e}$ polyArN$_2$(·) vs. $-m_{m+1}$ of parent hydrocarbon in sulfolane, Hg electrode. *VI*, $E_{1/2}$ vs. Ag$^+$; polyArH $\xrightarrow{-e}$ polyArH($\overset{+}{\cdot}$) vs. $-m_m$ of parent hydrocarbon in acetonitrile, Pt electrode (Lund). *VII*, $E_{1/2}$ vs. sce; polyArH $\xrightarrow{-e}$ polyArH($\overset{+}{\cdot}$) vs. $-m_m$ of parent hydrocarbon in acetonitrile, Pt electrode (Parker). *VIII*, E_m vs. sce; mid-point potential of aromatic hydrocarbons in acetonitrile (Parker).

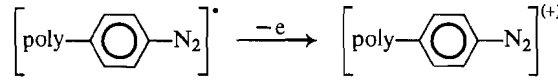
$$[6] \quad E_{1/2} = (-0.105\, m_{m+1} + 0.215) \text{ V vs. sce}$$

A correction for solvation factors would tend to increase the negativity of the slope, thus, correlation V may be taken as either midway between *I* and *VII* or closer to *VII* if solvation effects are considered.

Accepting the fact that this electrochemical system is reversible, V could be written as:



Va

and since the correlations *VI* or *VII* are written as oxidations for polyaromatics,

VI or *VII*

it seems reasonable that *VI* or *VII* might correlated with V. Alternatively, since polyaromatics are easier to oxidize than benzene, the reverse should follow, viz. the reduction of the highly oxidized benzene diazonium salt should release more energy (be more electrophilic) than polycyclic diazonium salts.

On the other hand, the reduction of aryldiazonium salts can be represented by [5], where correlation *I* should dominate. Combining *I* and *VI* or *VII*, the low negative slope of correlation *V* is not too surprising.

To further check the low slope of correlation *V*, ^{13}C nmr of a number of diazonium salts were determined. Many workers (11–15) have noted the shielding at the C_1 position of these salts increases when electron-donating groups are substituted in the ring, particularly in the *para* position. The results also correlate with σ or σ^+ and with $E_{1/2}$. This means that a decrease in the electrophilicity of a diazonium salt is due to increase in shielding at C_1. The relation between electrophilicity ($E_{1/2}$) and $^{13}C_1$ shielding (ppm) is shown in Table 3.

The equation for this correlation is given by:

$$[7] \quad E_{1/2} = (0.00650\delta - 0.452)\ \text{V}$$

with a correlation coefficient of 0.981. Or omitting *p*-phenyl from the correlation, the equation becomes

$$[7a] \quad E_{1/2} = (0.00665\delta - 0.467)\ \text{V}$$

These results indicate that the observed small negative slope of *V* is real.

In a recent study of *p*-substituted benzene diazonium salts (16), the equation was given by the relation

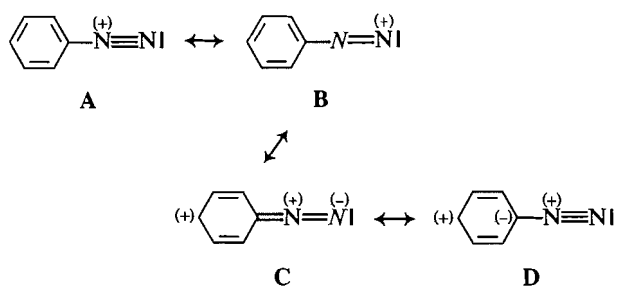
$$[8] \quad E_{1/2} = (0.0161\delta - 1.52)\ \text{V}$$

with a correlation coefficient of 0.982, where δ is the $^{13}C_1$ chemical shifts in ppm from TMS.

If the solvation effects of *p*-substituted benzene diazonium salts are assumed to be equal because of similar geometry, the slope of correlation *V* could reasonably be increased 2.42 times, as predicted earlier, to correct for the increase in mean diameter of the polycyclic diazonium salts. Also the scatter in the values of 1- and 2-naphthalene diazonium salts, Table 3, agree with the assumption that the diazonium moiety in the 2 position might be more solvated than that in the 1 position due to steric considerations.

The representation of diazonium salts shown in the conventional canonical structures **A**, **B**, **C**, and **D** (11) should be discussed in terms of correlation *V*. $^{13}C_1$ chemical shift rules out structure **C** as a significant contribution to the ground state (16).

[9]



A **B** **C** **D**

Also X-ray (17) evidence rules out the same structure (18). Structure **D** (11), in particular, accounts for the increased magnetic shielding as the electophilicity of the cation decreases, and also agrees with the fact that electrochemical reduction of the cation in aprotic solvents results in a one-electron transfer to yield the aryl radical and nitrogen as the only products. In terms of energy requirements, the compressed C_1—C_4 (18, 19) distance of 2.680 Å for the benzenediazonium cation ($E_{1/2}$ = 0.295 V) shown by X-ray measurements compared to 2.795 Å units in benzene is probably less pronounced in polycyclic aryldiazonium salts. Hence the energy gained by the addition of an electron, which should relieve this compression, would be less for the polycyclic structures. A recent determination of the C_1—C_4 distance in *p*-diethylamino benzene diazonium hexafluorophosphate of 2.77 Å units with $E_{1/2}$ equal to −0.095 V makes this point rather dramatically (20).

TABLE 3. Half-wave potentials and chemical shifts $^{13}C_1$ nmr of aryldiazonium chlorides in 20% D_2O

Diazonium salt of	$^{13}C_1$ chemical shift (ppm)	$-E_{1/2}$ vs. sce (V)
Benzene	115.2	0.295
p-Phenylbenzene	111.0	0.275
2-Naphthyl	109.5	0.260
1-Naphthyl	108.1	0.260
2-Anthracene	105.6	0.235
1-Anthracene	105.6	0.230
9-Phenanthrene	105.9	0.235

One further observation gained from Fig. 1: as the substituent constant becomes more positive, the slope of the correlation decreases until it becomes negative for the substituent —N_2^+, which has the highest known constant, +1.88 (15). The negative slope, as discussed earlier, correlates with a buildup of negative charge or increase in electron density as indicated by increased magnetic shielding C_1. The apparent inability of this charge to dissipate by hybridization, as indicated by lack of the resonance structure **C** in the ground state, may account for many of the unusual properties of diazonium salts.

Spectrophotometric study of the dissociation of *p*-nitroanilinium ion in a binary aqueous-dipolar aprotic solvent system (H_2O + acetonitrile) at 25°C: effect of the solvent

A. L. DE[1] AND T. K. DE

Department of Chemistry, Presidency College, Calcutta-700073, India

Received October 24, 1983

A. L. DE and T. K. DE. Can. J. Chem. **62**, 1776 (1984).

Thermodynamic dissociation constants ($_sK$) of *p*-nitroanilinium ion (BH^+) have been determined at 25°C in aqueous solutions containing 20, 40, 60, and 80 wt% acetonitrile (ACN) by spectrophotometric measurements. Standard Gibbs energies of transfer, ΔG_t^0(B) of *p*-nitroaniline (B) from water to other solvents have been evaluated from the measurement of solubilities at 25°C. Solvent effect on the dissociation of the acid (BH^+), $\delta(\Delta G^0) = 2.303RT[p(_sK) - p(_wK)]$, results in a characteristic minimum with a change in the solvent composition. The result in this protic – dipolar aprotic mixture (H_2O + ACN) has been compared with that in aqueous mixture of protic solvent (H_2O + ethylene glycol) available from literature. The solvent effect has been discussed in terms of the standard Gibbs energies of transfer ΔG_t^0 from water to aqueous mixtures of organic co-solvent of the uncharged base (B), the hydrochloride of the base (BHCl), and hydrochloric acid (HCl) and also in terms of the individual species involved in the dissociation process. The results indicate that solvent effect on dissociation is an involved process, guided by the combined effects of various types of solute–solvent interactions of the Brønsted acid and its conjugate base in addition to the relative solvent basicities.

A. L. DE et T. K. DE. Can. J. Chem. **62**, 1776 (1984).

Faisant appel à des mesures spectrophotométriques et opérant à 25°C, on a étudié la constante thermodynamique de dissociation ($_sK$) de l'ion *p*-nitroanilinium (BH^+) dans des solutions aqueuses contenant 20, 40, 60 et 80% en poids d'acétonitrile (ACN). Utilisant des mesures de solubilité à 25°C, on a évalué les énergies standard de dissociation de Gibbs ΔG_t^0(B) de la *p*-nitroaniline (B) dans l'eau et dans d'autres solvants. L'effet du solvant sur la dissociation de l'acide (BH^+): $\delta(\Delta G^0) = 2{,}303RT[p(_sK) - p(_wK)]$ conduit à un minimum caractéristique lorsqu'on change la composition du solvant. On a comparé les résultats obtenus à l'aide de ce mélange protique/aprotique dipolaire (H_2O + ACN) avec ceux obtenus antérieurement dans un mélange aqueux d'un solvant protique (H_2O + éthylèneglycol) et rapportés dans la littérature. On discute de l'effet du solvant en termes des énergies de transfert standard de Gibbs, ΔG_t^0, de l'eau à des mélanges aqueux de co-solvants organiques pour la base libre (B), pour son chlorhydrate (BHCl) et pour l'acide chlorhydrique (HCl); on discute aussi de l'effet du solvant en termes des espèces individuelles impliquées dans le processus de la dissociation. Les résultats indiquent que l'effet du solvant sur la dissociation est un processus complexe qui est guidé par l'effet combiné de divers types d'interactions soluté–solvant de l'acide de Brønsted et de sa base conjuguée en plus des basicités relatives du solvant.

Introduction

Dissociation constants of *p*-nitroanilinium ion (BH^+) were reported earlier in aqueous mixtures of protic solvents like ethylene glycol (EG) (1), methanol (2, 3), and acetic acid (4). This paper reports a study of the dissociation constants of *p*-nitroanilinium ion at 25°C in a series of aqueous mixtures of a dipolar aprotic solvent (5) acetonitrile (ACN), a solvent system of different nature. In contrast to previous studies, the contribution of the base *p*-nitroaniline (B) to the dissociation behaviour of the acid BH^+ in this solvent system was considered. This contribution was determined (1, 6) from measurement of the solubilities of the base in water as well as in various solvent mixtures.

Experimental

Purification (5) of ACN (L.R., B.D.H) and water, and the preparation (1) of solvents as well as solutions of HCl have been described earlier. *p*-Nitroaniline (AnalR) was purified by two crystallizations from aqueous ethanol (95% v/v) and then dried *in vacuo*. The dissociation constants ($_sK$) of *p*-nitroanilinium ion (BH^+) in the aqueous mixtures of ACN were determined spectrophotometrically using unbuffered solutions of HCl at different concentrations in a manner essentially similar to that described earlier (1, 2, 7–9). The $p(_sK)$ values were obtained by linear extrapolation of the plots of $p(_sK)'$ of eq. [1] against μ to $\mu = 0$

$$[1] \quad p(_sK)' = -\log m_{SH_2^+} - \log \frac{\alpha}{1-\alpha} = p(_sK) + \log \frac{\gamma_{SH_2^+}\gamma_B}{\gamma_{BH^+}} = p(_sK) + f(\mu)$$

where α and $(1 - \alpha)$ are the fractions of the indicator species present in the neutral form (B) and the ionic form (BH^+), respectively, and $m_{SH_2^+}$ is the effective molality of H^+ in the solution. A series of solution was prepared by adding weighed amounts of HCl solutions and the solvent to weighed amounts of the *p*-nitroaniline (B) solutions. The spectral absorbances were determined at 25 ± 0.2°C with a UNICAM SP 500 model spectrophotometer (England) with 1 cm quartz cells at 380 nm where the absorbance shows a maximum for the base form (2). The limiting absorbances of the acidic form at 380 nm, though small, were taken into account and the absorbance readings were corrected where necessary for the identical total concentration of the indicator (*p*-nitroaniline). The limiting absorbances (1, 2) of the acidic and basic forms of *p*-nitroaniline were measured in very concentrated HCl solutions (6 *M*) and in very dilute sodium hydroxide solutions (0.001 *M*). The values of $\alpha/(1 - \alpha) = (D - D_1)/(D_2 - D)$ were obtained from the optical densities, D_1, D_2, and D of the completely acid form (BH^+), completely base form (B), and the mixture of the two forms measured at an identical concentration of the indicator in the same cell. The molality of the *p*-nitroanilinium ion at equilibrium was negligibly small with respect to the molality of HCl, so that $-\log m_{SH_2^+}$ was virtually the same as that of $-\log m_{HCl}$ in most cases. The values of μ were taken to be equal to $m_{HCl}d_s$, where d_s is the density (5) of the solvent.

The standard Gibbs energies of transfer of the uncharged base, B, from water to aqueous mixtures of ACN were computed by the method described earlier (1, 6, 10), using the relation $\Delta G_t^0(B) = RT \ln (_wN_B/_sN_B)$ where $_wN_B$ and $_sN_B$ are the solubilities of the base in water and respective solvents (SH) on the mole fraction scale. Solubilities of B were determined at 25°C by the same method described earlier (1). As for uncharged solutes such as benzoic acid (11), tris(hydroxymethyl)aminomethane (1, 6), and nitroanilines (1, 8) in different

aquo-organic solvents, the validity of this relation depends on the assumption that the ratio of activity coefficients of the uncharged base in the saturated solutions in the mixed solvent and in water is unity.

Results

The values of $-\log [\alpha/(1-\alpha)]$, the molalities of HCl and the values of $p({}_sK)'$ are shown in Table 1. The $p({}_sK)$ values obtained in the different solvent mixtures are recorded at the bottom of the column of $p({}_sK)'$ in Table 1. The uncertainties in the $p({}_sK)$ values are of the order of ±0.005 unit. The solubilities of B and the $\Delta G_t^0(B)$ values at 25°C are recorded in Table 2. The maximum uncertainties in the $\Delta G_t^0(B)$ values are ±0.04 kJ mol^{-1}.

Discussion

As a basis for comparison (12) in different solvent mixtures, the $p({}_sK)$ values in the molal scale (Table 1) have been converted into the mole fraction scale, $p({}_sK)^N$, by the usual relation (13) and are recorded in Table 3. The solvent effect on the dissociation of BH^+ ion, $\delta(\Delta G^0)$ has been calculated (1, 8) using eq. [2]

$$[2] \quad \delta(\Delta G^0) = {}_s\Delta G^0 - {}_w\Delta G^0 = 2.303RT[p({}_sK)^N - p({}_wK)^N]$$

The values of $\delta(\Delta G^0)$ are recorded in Table 3.

Variation of $\delta(\Delta G^0)$ values with mol% ACN is shown in Fig. 1. For comparison, the corresponding variation in the water – ethylene glycol (H_2O + EG) solvent system obtained from literature (1) (Table 4) is also shown. In both cases the value of $\delta(\Delta G^0)$ decreases as the proportion of organic co-solvent increases and passes through a minimum, the decrease is greater in the case of H_2O + ACN. This indicates a greater solvent effect in the H_2O + ACN system as compared to that in H_2O + EG. The solvent effect can be expressed (1, 8, 14) in the form of eq. [3]

$$[3a] \quad \delta(\Delta G^0) = \Delta G_t^0(H^+) + \Delta G_t^0(B) - \Delta G_t^0(BH^+)$$

$$[3b] \quad = \Delta G_t^0(HCl) + \Delta G_t^0(B) - \Delta G_t^0(BHCl)$$

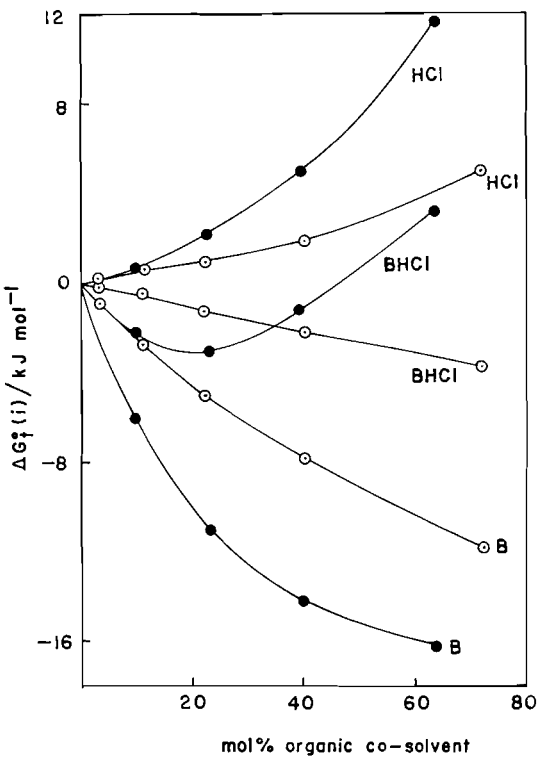

FIG. 2. Variation of $\Delta G_t^0(i)$ of some species in ACN + H_2O [●] and EG + H_2O [⊙] mixtures at 25°C. B = *p*-nitroaniline; BHCl = *p*-nitroanilinium chloride.

where ΔG_t^0(i) is the Gibbs energy change accompanying the transfer of one mole of species i from the standard state in water to the standard state in the solvent concerned, both on the mole fraction scale. The characteristic minimum in the $\delta(\Delta G^0)$ curve for a BH^+ type acid has been observed in aqueous mixtures of other protic solvents like acetic acid (4), methanol (3, 9), and the solvent effect in such cases are also smaller (not shown in Fig. 1) than that observed for the H_2O + ACN solvent system. The contribution of uncharged base was ignored in these cases and the result has been attributed to enhanced basicity of the media (4, 9, 15) resulting from a breakdown of the water structure. The contribution of base has been considered in the work by Bates *et al.* (6), Kundu *et al.* (1), and De (8, 10). The importance of the quantity ΔG_t^0(B) may be seen from Table 2.

Figure 2 illustrates the variation of ΔG_t^0(B) with mol% ACN. For comparison, the corresponding variation in H_2O + EG is also shown. There is an initial sharp decrease of ΔG_t^0(B) with mol% ACN followed by somewhat less downward trend. The values in H_2O + EG, however, decrease gradually with increase in mol% EG and are always much less negative compared to those in H_2O + ACN. The ΔG_t^0(B) values in H_2O + acetic acid (16) and H_2O + methanol (16) are also found to be much less negative. In the H_2O + EG system, the decrease in ΔG_t^0(B) has been primarily attributed (1) to the dispersion interaction of the benzene nucleus with the organic component of the solvent mixtures. In H_2O + ACN, the dispersion interaction also operates to stabilize B and this interaction possibly reaches saturation at around 0.3 mole fraction ACN, beyond which the rate of decrease in ΔG_t^0(B) falls significantly. As EG is a slightly more polarisable molecule than ACN (17) the dispersion interactions should be less in H_2O + ACN. However, the effect of forming a cavity may explain the large negative ΔG_t^0(B) values in H_2O + ACN. Since EG + H_2O are both hydroxylic solvents and because the activity of H_2O is unusually high in its mixture with ACN (18), it can be expected that H_2O + EG mixtures are more associated than H_2O + ACN mixtures. Consequently, it can be assumed that much less energy will be required to create a cavity for the accommodation of B in H_2O + ACN compared to that in H_2O + EG, thus making the cavity formation contribution to the total ΔG_t^0(B) for B more negative in the H_2O + ACN solvent system. This may explain the observed relative order of total ΔG_t^0(B) in these two solvent systems.

The values of ΔG_t^0(BHCl) calculated from eq. [3*b*] are recorded in Table 3. The ΔG_t^0(HCl) values required for calculation of ΔG_t^0(BHCl) were obtained from the literature (5, 19). The variation of ΔG_t^0(BHCl) and ΔG_t^0(HCl) (Table 3) with

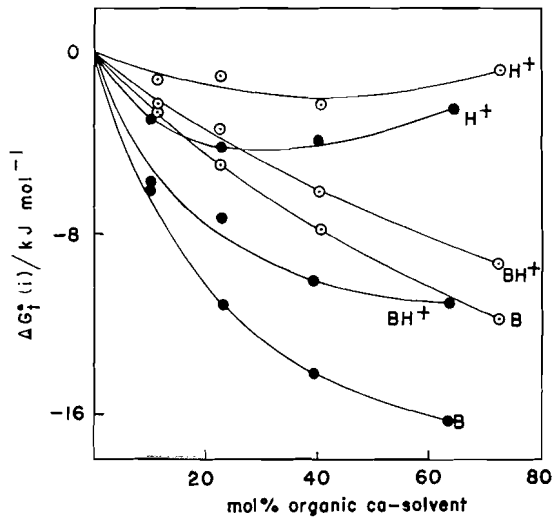

FIG. 3. Variation of $\Delta G_t^0(i)$ of some species in ACN + H_2O [●] and EG + H_2O [⊙] mixtures at 25°C; B = *p*-nitroaniline; BH^+ = *p*-nitroanilinium ion.

mol% ACN is shown in Fig. 2. For comparison, similar variations of ΔG_t^0(BHCl) and of ΔG_t^0(HCl) in H_2O + EG (Table 4) are also shown. It is observed that the ΔG_t^0(BHCl) value decreases sharply with the increase in mol% ACN at the beginning, passes through a minimum, and ultimately becomes positive. In contrast, the ΔG_t^0(BHCl) value decreases monotonically with the increase in mol% EG. The ΔG_t^0(HCl) value for both solvent systems increases with an increase in mol% organic co-solvent, but the rise in H_2O + ACN is greater at higher mol% ACN. Tables 3 and 4 show that the $\Delta G_t^0(B) - \Delta G_t^0$(BHCl) values for both solvent systems are increasingly negative with increase in mol% organic co-solvent and the minimum in $\delta(\Delta G^0)$ results from the increase in ΔG_t^0(HCl) and the simultaneous decrease of $\Delta G_t^0(B) - \Delta G_t^0$(BHCl) (vide eq. [3*b*]).

Equation [3*a*] shows that $\Delta G_t^0(B)$, $\Delta G_t^0(H^+)$, and $\Delta G_t^0(BH^+)$ are jointly responsible for the solvent effect. Values of $\Delta G_t^0(H^+)$ in the H_2O + EG system obtained by different extra-thermodynamic assumptions are available in the literature (20, 21); but since reference electrolyte (RE) method has proven to be the most sound, reasonable, and consistent (22, 23) we have utilized $\Delta G_t^0(H^+)$ values obtained by RE method for both solvent systems (5, 21) to calculate $\Delta G_t^0(BH^+)$ values which are given in Table 5. It is observed from Fig. 3 that the relative trend of $\Delta G_t^0(BH^+)$ in the two solvent systems are qualitatively similar to that of $\Delta G_t^0(B)$ and the reasons are probably similar to those advanced for the base. Comparison shows that the values of $\Delta G_t^0(BH^+)$ are less negative than those of $\Delta G_t^0(B)$ at every solvent composition in both the solvent systems. As the dielectric constant values of the solvents decrease with increase in concentration of organic co-solvent, the free energy transfer of BH^+ due to Born-type electrostatic interaction should be positive (24, 25) and this ion destabilizing effect acting in opposition should make $\Delta G_t^0(BH^+) > \Delta G_t^0(B)$.

The relative values of $\Delta G_t^0(H^+)$ in the two solvent systems have been described earlier (5). $\Delta G_t^0(H^+)$ may be taken as a measure of the basicity of the solvent SH with respect to that of water (1, 26). More negative values of $\Delta G_t^0(H^+)$ in H_2O + ACN (Table 5) results from the more extensive water structure breaking ability of ACN than EG, thereby releasing more "basic" monomeric water (26).

The solvent effect on the dissociation of *p*-nitroanilinium ion is found to be an involved process and is the combined effects of various types of solute–solvent interactions of the Brønsted acid and its conjugate base in addition to the relative solvent basicities.

Hydride transfer reactions. A kinetic study of oxidation of 2- and 3-methoxy-N-methylacridans by some π acceptors and a one-electron oxidant

ALLAN K. COLTER, PETER PLANK, JOHN P. BERGSMA, ROY LAHTI, ANDRÉ A. QUESNEL, AND A. GREGG PARSONS
Guelph–Waterloo Centre for Graduate Work in Chemistry, University of Guelph, Guelph, Ont., Canada N1G 2W1

Received January 9, 1984

ALLAN K. COLTER, PETER PLANK, JOHN P. BERGSMA, ROY LAHTI, ANDRÉ A. QUESNEL, and A. GREGG PARSONS. Can. J. Chem. **62**, 1780 (1984).

Relative rates of oxidation of N-methylacridan (**1***a*), 2-methoxy-N-methylacridan (**1***b*), and 3-methoxy-N-methylacridan (**1***c*) have been investigated as a probe of transition state structure in hydride transfer reactions. Oxidants investigated cover a 2×10^7-fold (with **1***a*) to 2×10^8-fold (with **1***c*) range of reactivity, and include the π acceptors 1,4-benzoquinone (BQ), *p*-chloranil (CA), 2,3-dicyano-1,4-benzoquinone (DCBQ), 7,7,8,8-tetracyanoquinodimethane (TCNQ), and tetracyanoethylene (TCNE) in acetonitrile (AN), BQ in 50:50 (v/v) AN–water, and the one-electron oxidant tris(2,2′-bipyridyl)cobalt(III), $Co(bipy)_3^{3+}$, in AN, all at 25°C. For all of the π acceptors except TCNE the order of reactivity, **1***c* > **1***b* > **1***a*, (DH) indicates a transition state resembling the corresponding acridinium ion product (D^+), while the order of reactivity with $Co(bipy)_3^{3+}$, **1***b* > **1***c* > **1***a*, indicates a transition state resembling the acridan radical cation ($DH^{+\cdot}$). The order of reactivity observed with TCNE, **1***b* ≈ **1***c* > **1***a*, is tentatively interpreted as indicating a transition state resembling the corresponding 9-acridanyl radical (D·).

ALLAN K. COLTER, PETER PLANK, JOHN P. BERGSMA, ROY LAHTI, ANDRÉ A. QUESNEL et A. GREGG PARSONS. Can. J. Chem. **62**, 1780 (1984).

On a étudié les vitesses relatives d'oxydation du N-méthylacridan (**1***a*), du méthoxy-2 N-méthylacridan (**1***b*) et du méthoxy-3 N-méthylacridan (**1***c*) comme méthode de déterminer la structure de l'état de transition lors de réactions de transfert d'hydrure. Les oxydants étudiés couvrent des intervalles de réactivité allant de 1 á 2×10^7 (pour le composé **1***a*) et jusqu'à 2×10^8 (pour le composé **1***c*); ils contiennent des accepteurs π comme la benzoquinone-1,4 (BQ), le *p*-chloranil (CA), la dicyano-2,3 benzoquinone-1,4 (DCBQ), le tétracyano-7,7,8,8 quinodiméthane (TCNQ) et le tétracyanoéthylène (TCNE) dans l'acétonitrile (AN), la BQ dans AN–eau (50:50, v/v) et finalement, un oxydant procédant par le biais d'un électron, le tris(bipyridyl-2,2′) cobalt(III), $Co(bipy)_3^{3+}$, dans AN; toutes ces oxydations ont été réalisées à 25°C. Pour tous les accepteurs π, à l'exception du TCNE, l'ordre de réactivité, **1***c* > **1***b* > **1***a*, (DH) indique que l'état de transition ressemble au produit, soit l'ion acridinium correspondant (D^+), tandis que l'ordre de réactivité observé avec le $Co(bipy)_3^{3+}$, **1***b* > **1***c* > **1***a*, indique que l'état de transition ressemble au cation radicalaire acridan ($DH^{+\cdot}$). On croit que l'ordre de réactivité observé avec le TCNE, **1***b* ≈ **1***c* > **1***a*, suggère l'existence d'un état de transition ressemblant au radical acridanyl-9 correspondant (D·).

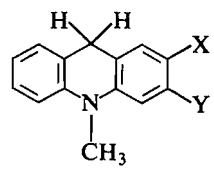
Introduction

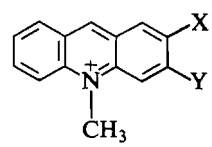
The mechanisms of hydride transfer reactions of nicotinamide coenzyme models continue to attract considerable interest (1,2, and references cited). The focus of much of the current interest and controversy is the experimental distinction between a one-step hydride transfer mechanism and stepwise mechanisms involving an initial single-electron transfer. This distinction, for oxidants capable of reacting as either a hydride or electron acceptor, has proven to be very elusive. Unambiguous evidence for radical intermediates in oxidation of dihydropyridine analogs by two-electron oxidants has been obtained only with oxidants of very high oxidizing strength (3). The spectrum of mechanisms possible for hydride transfer reactions is presently poorly defined, and for most particular examples it remains difficult to specify the mechanism with any confidence.

In an earlier study (1) we examined substituent effects in oxidation of a series of N-(substituted benzyl)acridans with three benzoquinone and two cyanomethylene π acceptors covering a 10^7-fold range of reactivity. The sensitivity of the rate to electronic substituent effects as measured by the Hammett ρ value showed a 2.2-fold variation with acceptor, but no clear pattern interpretable on the basis of a change in mechanism was discernible.

In this paper we report the results of an investigation of the relative rates of oxidation of N-methylacridan (NMA, **1***a*), 2-methoxy-N-methylacridan (2-MeO-NMA, **1***b*), and 3-methoxy-N-methylacridan (3-MeO-NMA, **1***c*) to the corresponding N-methylacridinium ions (**2***a*, *b*, and *c*) by the same five π acceptors and by the one-electron oxidant tris(2,2′-bipyridyl)cobalt(III), $Co(bipy)_3^{3+}$. This study was prompted by the following considerations: 2-MeO-NMA, because of the *para* relationship between two +R groups (4) (—N(H)—CH_3 and —O—CH_3), was expected to have a lower ionization energy than 3-MeO-NMA, in which these groups have a *meta*



1



2

a X = Y = H
b X = OCH_3, Y = H
c X = H, Y = OCH_3

relationship (5). However, because of the possibility of delocalization of the positive charge in **2***c* (but not in **2***b*) onto the methoxy group (structure **3**), 3-MeO-NMA should lose a hydride more easily than 2-MeO-NMA. Thus, in contrast to the

remote substituent effects in the N-benzylacridans, the response to substitution of H by methoxy at positions 2- and 3- was expected to depend strongly on whether the transition state more closely resembles the radical cation, $\mathbf{1}^{\ddagger}$, or the acridinium ion product, **2**.

Results

In order to obtain an experimental measure of the relative ease of one-electron oxidation of **1***a*, *b*, and *c*, the charge-transfer absorption maxima of their complexes with the π acceptors 1,3,5-trinitrobenzene (TNB) and 2,4,7-trinitro-9-fluorenone (TNF) were measured (Table 1). In all solutions containing both π donor and π acceptor, a broad maximum appeared to the long wavelength side of the separate donor and acceptor spectra. A more extensive investigation of several complexes of **1***a* (6) has established that the band at 507 nm in mixtures of **1***a* and TNB is a charge-transfer band. For complexes of a series of related donors with a common π acceptor the energy of the lowest-energy charge-transfer maximum is linearly related to the ionization energy (7) or to the standard one-electron oxidation potential (7, 8) of the donor.

The standard one-electron oxidation potential, $E^0(DH/DH^{\ddagger})$ for acridans or dihydronicotinamides cannot be measured accurately electrochemically because of the irreversibility of the oxidation on the time scale of the electrochemical measurements (9, 10). The initial one-electron oxidation of **1***a* is followed by irreversible loss of a proton to yield the N-methyl-9-acridanyl radical, which is rapidly oxidized by a second electron transfer to **2***a*. Cyclic voltammograms for **1***b* and **1***c* closely resemble those reported for **1***a*; anodic peak potentials (Table 1) measured under identical conditions again indicate that **1***b* should undergo a chemical one-electron oxidation more easily than **1***c*.

To obtain a measure of the relative stabilities of **2***a*, *b*, and *c* relative to **1***a*, *b*, and *c*, equilibrium constants, K_{R^+}, for pseudobase formation [1] (11) were measured for **2***a*, *b*, and *c*

[1] 
2 **4**

(as their iodide salts) (Table 2). With the methoxyacridinium salts **2***b* and *c* these determinations were complicated by disproportionation to the corresponding N-methylacridone (**5**) and N-methylacridan (**1**) at pH's above 10 (11, 12). This complication adds some uncertainty to the measured pK_{R^+} values (±0.08 p*K* units maximum) but not enough to affect the

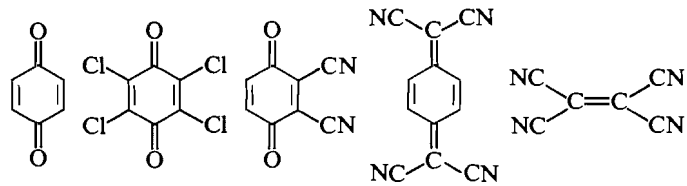
qualitative order of pK_{R^+} values or the conclusion that **1***c* should be a better hydride donor than **1***b*.

Rates of oxidation of **1***a*, *b*, and *c* by the π acceptors **6**–**10**



6, BQ **7**, CA **8**, DCBQ **9**, TCNQ **10**, TCNE

in acetonitrile (AN) and by 1,4-benzoquinone (BQ) in 50:50 (v/v) AN–water were measured at 25°C. In addition, rates of oxidation by the one-electron oxidant $Co(bipy)_3^{3+}$ (as the perchlorate salt) were measured in AN at 25°C.

Quantitative oxidation of **1** to **2** was confirmed by uv–visible spectral examination of reaction solutions for all oxidants except TCNQ, where the spectrum of **2** is masked by that of the radical anion reduction product, $TCNQ^{\cdot-}$. Isolation of **2***a* as the perchlorate or chloride salt in oxidation of **1***a* by all five π acceptors has been described earlier (6). The salts $\mathbf{2}b^+ClO_4^-$ and $\mathbf{2}c^+ClO_4^-$ are isolable in quantitative yield by oxidation of **1***b* and **1***c* by 2,3-dicyano-5,6-dichloro-1,4-benzoquinone (DDQ) following the procedure described earlier for NMA (6).

The corresponding reduction product of each π acceptor, A, is as described earlier (1, 6, 13) for oxidation of NMA, namely AH_2 from BQ + acetic acid, and $A^{\cdot-}$ + $0.5AH_2$ from DCBQ, TCNQ, and TCNE. CA leads to a mixture of $A^{\cdot-}$, AH^-, and AH_2 in AN but to 100% (±5%) AH_2 in AN – 0.1 *M* acetic acid (Experimental). The reduction products of the π acceptors, as well as the overall stoichiometry, depend on the extent to which the rapid reaction of the product of hydride transfer, AH^-, with unreacted acceptor ($2AH^- + A \rightleftharpoons AH_2 + 2A^{\cdot-}$) occurs, but shed no light on the mechanism of hydride transfer (1, 6, 13). With $Co(bipy)_3^{3+}$ 2 moles of Co(II), determined by spectrophotometric analysis as $CoCl_4^{2-}$, are formed per mole of **1** oxidized (Experimental). The stoichiometry is therefore as represented by [2], where DH is the hydride donor, **1**.

[2] $DH + 2Co(bipy)_3^{3+} \rightarrow D^+ + H^+ + 2Co(bipy)_3^{2+}$

[e] 0.1 M acetic acid added.
[f] 1×10^{-3} M 2,2′-bipyridyl added.

The kinetic results are summarized in Table 3. Rate measurements with all oxidants except CA and $Co(bipy)_3^{3+}$ were carried out under pseudo first-order conditions using a 30-fold or greater excess of oxidant. With CA and some of the $Co(bipy)_3^{3+}$ rates, lower molar ratios of oxidant to acridan were used and the data analyzed using the appropriate integrated second-order rate equation. A first-order dependence on both acridan and acceptor concentration is well established by this and earlier work (1, 6). Rate constants for **1***a* listed in Table 3 agree closely with those reported earlier except for DCBQ where the value reported earlier (6) is about 25% lower. Further investigations of $Co(bipy)_3^{3+}$ oxidations of acridans and dihydronicotinamides have been carried out and are in progress; the results will be reported separately.

Discussion

The reactivity pattern observed for $Co(bipy)_3^{3+}$ is consistent with a mechanism involving rate-determining electron transfer. By analogy with the mechanism of electrochemical oxidation of dihydropyridines (9, 10) the following mechanism is tentatively proposed:

$$DH + Co(bipy)_3^{3+} \underset{k_{-1}}{\overset{k_1}{\rightleftharpoons}} DH^{\ddagger} + Co(bipy)_3^{2+}$$

$$[3] \quad DH^{\ddagger} + bipy \xrightarrow{k_2} D^{\cdot} + bipyH^{+}$$

$$D^{\cdot} + Co(bipy)_3^{3+} \xrightarrow{fast} D^{+} + Co(bipy)_3^{2+}$$

If the main features of this mechanism are correct, k_2[bipy] must be much greater than k_{-1}[$DH^{\ddagger}$][$Co(bipy)_3^{3+}$] under the conditions of our measurements because a 20-fold increase in [bipy] (to 2×10^{-2} M) has no measurable effect on the rate.

The results of earlier studies of oxidations of NMA by π acceptors (6), particularly the variation of kinetic isotope effect with acceptor reactivity for structurally-related acceptors, are most easily accommodated by a one-step hydride transfer mechanism [4] or by a three-step electron–proton–electron mechanism [5] in which proton transfer is rate determining:

$$[4] \quad DH + A \rightarrow D^{+} + AH^{-}$$

$$[5] \quad DH + A \underset{k_{-1}}{\overset{k_1}{\rightleftharpoons}} DH^{\ddagger}A^{\cdot-} \xrightarrow[k_2]{slow} D{\cdot}AH{\cdot} \xrightarrow{fast} D^{+} + AH^{-}$$

We have argued earlier (1) that the radical cation – radical anion pair intermediate, $DH^{\ddagger}A^{\cdot-}$, of [5] is too high in energy to be an intermediate in oxidation of NMA by either BQ or CA in AN but that it cannot be excluded on this basis in oxidation of NMA by TCNQ, TCNE, or DCBQ. Indeed, successful trapping of the N-methyl-9-acridanyl radical (D·) in oxidation of NMA by DCBQ (3) is evidence that at least part of this reaction occurs by mechanism [5].

The transition state in [4] should be between DH (+A) and D^{+} (+AH^{-}) in structure and hence should reflect the energy of D^{+} (i.e., **2**) relative to DH (**1**). Values of K_R^{-1} (i.e., formation of D^{+} from **4**) from **2***a*, *b*, and *c*, relative to that of **2***a*, are, respectively, (1.0):11:50 in aqueous solution. Although the relative rates in Table 3 show some interesting and complex variations, it is clear that this pattern is maintained at least qualitatively for all of the π acceptors except TCNE. For four of the five π acceptors, therefore, D^{+} is a much better model for the transition state than $DH^{\ddagger}$.

The predictions of mechanism [5] are less clear. On the simplest level, the transition state should lie between $DH^{\ddagger}A^{\cdot-}$ and D·AH· in structure. Unfortunately we have no experimental model for the energy of D· relative to DH, though differences will surely be much smaller than the differences in the energies of $DH^{\ddagger}$ and D^{+} for the three systems compared. The relative rates of oxidation by TCNE appear to be at least consistent with [5].

Aside from the qualitative order of reactivities, two further points are worth noting. First, for the three benzoquinones, the effects of substitution increase in the order BQ < CA < DCBQ, that is, in order of increasing ease of reduction. Second, in oxidation by BQ, an increase in substituent effects is observed in changing from AN to 50:50 (v/v) AN–water solvent. Similar trends in more remote substituent effects were observed in oxidation of N-(substituted benzyl)acridans under identical conditions (1). At the same time, either an increase in acceptor strength or an increase in ion-solvating ability is accompanied by a decrease in the primary deuterium kinetic isotope effect in oxidation of NMA (6). Taken together, these results appear to require an increase in positive charge development with decreasing bond weakening. Such a trend is not in accord with the predicted changes in transition state structure along the reaction coordinate (i.e., the changes predicted by application of the Hammond postulate (14, 15)) for either mechanism [4] or mechanism [5]. If, however, bond breaking

and formation occur within a face-to-face charge-transfer complex (1, 6), increased acceptor electron affinity or ion solvation could result in increased π electron transfer from hydride donor to π acceptor in the transition state. Further work is required to test this idea, particularly to establish whether the observed pattern of substituent and isotope effects requires $\pi-\pi$ complexing.

Experimental

Melting points were measured in open capillary tubes and are uncorrected. Proton nmr spectra were measured using Varian T60 or A60 spectrometers. Chemical shifts are reported in δ units, with tetramethylsilane as internal standrad. Ultraviolet–visible spectra were obtained using Beekman 24 or Cary 118C spectrophotometers. Elemental microanalyses were performed by Guelph Chemical Laboratories, Guelph, Ontario. Electrochemical measurements were carried out by Mr. Henry J. Stronks using apparatus and methods described in the literature (16).

Reagents and solvents

BQ, CA, TCNE, TCNQ, DCBQ, and NMA were obtained and purified as previously described (6). $Co(bipy)_3(ClO_4)_3 \cdot 3H_2O$ was synthesized as described by Burstall and Nyholm (17). The recrystallized product was further purified by ion exchange chromatography on C-25-120 Sephadex cation exchange resin, eluting with aqueous NaCl. The complex was precipitated as the perchlorate salt by addition of $HClO_4$. *Anal.* calcd. for $C_{30}H_{24}O_{12}N_6Cl_3Co \cdot 3H_2O$: C 40.95, H 3.44, N 9.55; found: C 41.03, H 3.29, N 9.50. Borax buffers (pH 9.0–9.4), carbonate buffers (pH 9.6–11.8), phosphate buffers (pH 11.0–11.8), and potassium chloride – sodium hydroxide solutions (pH 12.0–12.6) used in the pK_{R^+} determinations were prepared from Fisher Scientific sodium hydroxide solutions, and Fisher Certified reagent grades sodium tetraborate, sodium bicarbonate, sodium dihydrogen phosphate, and potassium chloride, following Bates (18). Reagent grade acetonitrile was further purified for kinetic measurements as previously described (6).

2-Methoxy-N-methylacridan (2-MeO-NMA) was obtained in 90–100% crude yield by sodium borohydride reduction of 2-methoxy-N-methylacridinium iodide, as described for reduction of N-methylacridinium salts (6). One crystallization from methanol–water afforded material having mp 84.5–85.5°C and showing a single component by tlc analysis (silica gel); nmr ($CDCl_3$) δ: 3.33 (s, 3H, N—CH_3), 3.77 (s, 3H, OCH_3), 3.87 (s, 2H, 9-methylene), 6.7–7.5 (m, 7H, aromatic). *Anal.* calcd. for $C_{15}H_{15}NO$: C 79.97, H 6.71, N 6.22; found: C 80.27, H 6.72, N 6.24.

2-Methoxy-N-methylacridinium iodide was prepared by refluxing 2-methoxyacridine with an excess of methyl iodide in benzene solution (typically 1.8 mL of benzene per gram of acridine). The orange-red precipitate was washed with ether to yield the product in yields up to 80% of theory, mp 240–241°C (dec.); uv (acetonitrile) λ_{max}: 367 nm (log ϵ = 4.19). *Anal.* calcd. for $C_{15}H_{14}NOI$: C 51.30, H 4.02, N 3.99; found: C 50.98, H 4.05, N 3.84.

2-Methoxyacridine was prepared by a four-step procedure beginning with reaction of 2-chlorobenzoic acid with *p*-anisidine to form 4′-methoxydiphenylamine-2-carboxylic acid (19), followed by ring closure to 9-chloro-2-methoxyacridine using phosphorus oxychloride (20). Catalytic hydrogenation of 9-chloro-2-methoxyacridine following Albert's procedure for hydrogenation of 9-chloroacridine (21) led to 2-methoxyacridan in 95% yield. Crystallization from 95% ethanol led to about 75% recovery of material of mp 140–144°C (lit. (22) mp 139.6–140.5°C); nmr ($CDCl_3$) δ: 3.74 (s, 3H, OCH_3), 4.04 (s, 2H, 9-methylene), 5.8 (bs, 1H, N—H), 6.5–7.3 (m, 7H, aromatic). Finally, 2-methoxyacridan was oxidized to 2-methoxyacridine as follows. A solution of 2.88 g (1.17×10^{-2} mol) of *p*-chloranil in 140 mL of benzene was slowly added to a solution of 2.25 g (1.17×10^{-2} mol) of 2-methoxyacridan in 50 mL of benzene. Dry HCl gas was passed through the mixture until the brown precipitate turned yellow. The yellow 2-methoxyacridinium chloride was neutralized with aqueous sodium bicarbonate and extracted into 100 mL of chloroform. The chloroform extract was washed many times with aqueous sodium bicarbonate, dried over magnesium sulfate, filtered, and the chloroform removed by evaporation. The residue was crystallized from cyclohexane yielding 1.33 g (60%) of 2-methoxyacridine, mp 104–105°C (lit. (23) mp 104°C).

3-Methoxy-N-methylacridan (3-MeO-NMA) was prepared in 95% crude yield by reduction of 3-methoxy-N-methylacridinium iodide as described for 2-MeO-NMA. Crystallization from methanol led to product of mp 72.5–73.5°C; nmr ($CDCl_3$) δ: 3.38 (s, 3H, N—CH_3), 3.9 (s, 5H, OCH_3 and 9-methylene), 6.3–7.3 (m, 7H, aromatic). *Anal.* calcd. for $C_{15}H_{15}NO$: C 79.97, H 6.71, N 6.22; found: C 79.70, H 6.86, N 6.23.

3-Methoxy-N-methylacridinium iodide was prepared in 93% yield from 3-methoxyacridine as described for the 2-isomer, mp 231–233°C (dec.); uv (acetonitrile) λ_{max}: 366 nm (log ϵ = 4.45). *Anal.* calcd. for $C_{15}H_{14}NOI$: C 51.30, H 4.02, N 3.99; found: C 50.89, H 4.09, N 3.81.

3-Methoxyacridine was prepared by a four-step procedure analogous to that used for 2-methoxyacridine, beginning with reaction of 2-chlorobenzoic acid with *m*-anisidine to form 3′-methoxydiphenylamine-2-carboxylic acid (24) and ring closure to 9-chloro-3-methoxyacridine (20, 24, 25). Catalytic hydrogenation (21) led to 3-methoxyacridan in 96% yield. Crystallization from methanol led to product of mp 133.5–136°C; nmr ($CDCl_3$) δ: 3.79 (s, 3H, OCH_3), 4.01 (s, 2H, 9-methylene), 5.9 (bs, 1H, N—H), 6.2–7.3 (m, 7H, aromatic). 3-Methoxyacridine was obtained in 77% yield by *p*-chloranil oxidation of 3-methoxyacridan as described for 2-methoxyacridine. Purification by chromatography on neutral alumina led to product of mp 89–91°C (lit. (26) mp 89–90°C). Both 2-methoxyacridine and 3-methoxyacridine were also prepared in overall 40% yield from the 9-chloroacridines through the 9-(2-*p*-toluenesulfonylhydrazino)acridine following Albert and Royer (27).

Kinetic measurements

Kinetics of oxidation were measured spectrophotometrically using methods and instrumentation described earlier (1, 6). The progress of the reaction was followed at the N-methylacridinium ion maximum (357.5 nm for **2***a*, and 367 nm for **2***b*, *c*) for all oxidants except TCNQ, where the formation of $TCNQ^{\cdot-}$ was followed at 680 nm. To minimize errors in relative rates (Table 3), rates of oxidation of **1***a*, *b*, and *c* were compared using the same acceptor stock solution. Measurements were carried out under pseudo first-order conditions using a 30-fold or greater molar excess of acceptor with BQ, TCNQ, TCNE, DCBQ, and some of the Co(III) oxidations. With CA and most of the Co(III) rates, smaller molar ratios (2 to 30) of acceptor to donor were used and the data analyzed using the appropriate integrated second-order rate equation. For a reaction of stoichiometry represented by

$$DH + \alpha A \rightarrow D^+ + \alpha(AH^-, AH_2, \text{or } A^{\cdot-})$$

this equation is

$$[6] \quad k_2 t = \frac{1}{[A]_0 - \alpha[DH]_0} \ln \frac{[DH]_0([A]_0 - \alpha[D^+])}{[A]_0([DH]_0 - [D^+])}$$

where the symbol $[\,]_0$ refers to initial concentration, and α is the number of moles of acceptor consumed per mole of donor. Values of k_2 were obtained as $1/([A]_0 - \alpha[DH]_0)$ times the slope of a plot of $\ln([A]_0 - \alpha[D^+])/([DH]_0 - [D^+])$ vs. t. In terms of measured optical densities (OD) at $t = 0$, t, and ∞ this function takes the form $\ln\{(OD_\infty - OD_0)[A]_0 - \alpha(OD_t - OD_0)[DH]_0\}/(OD_\infty - OD_t)[DH]_0$. Such second-order plots, as well as first-order plots with large excesses of oxidant, A, were linear through at least 85% reaction. The value of α was established as 2 for the Co(III) oxidations and as 1 for oxidation by CA in AN – 0.1 *M* acetic acid (below). The second-order rate constant obtained in this way for oxidation of NMA with CA (11.8 M^{-1} s^{-1}) is in good agreement with the value obtained earlier (11.7 (6)) using pseudo first-order conditions.

The stoichiometric ratio α in oxidation of NMA with CA in AN is

between 1 and 1.5 as a result of incomplete reaction of the hydroquinone monoanion, AH^-, with unreacted acceptor, A (6):

$$2AH^- + A \rightleftharpoons AH_2 + 2A^{\cdot-}$$

However, this reaction can be suppressed by protonation of AH^-. In AN – 0.1 *M* acetic acid, spectrophotometric examination of reactions of a limiting concentration of CA with a two-fold molar excess of NMA established that under these conditions 1.00 mol of CA yields 1.00 ± 0.05 mol of D^+, i.e., that $\alpha = 1.00 \pm 0.05$.

The stoichiometric ratio in oxidation of the three donors by $Co(bipy)_3^{3+}$, measured by spectrophotometric analysis of reaction mixtures for Co(II) (as $CoCl_4^{2-}$) is 2.00 ± 0.05. The following experiment is typical. A 1.00 mL aliquot of $Co(bipy)_3(ClO_4)_3$-bipy solution (5.58×10^{-3} and 1.81×10^{-2} *M*, respectively) + 100 μL of NMA solution (2.56×10^{-3} *M*) was allowed to react for 22.5 h at 25°C, and diluted to 5.00 mL with 12 *M* aqueous HCl. The spectrum of the solution from 580–720 nm matched the published spectrum of $CoCl_4^{2-}$ (28). The optical density at the 681.5 nm maximum was 0.0564, corresponding to an apparent extinction coefficient of 551, assuming formation of 2 Co(II) per NMA. Similar measurements using 1.00 mL of 2.800×10^{-3} *M* $Co(bipy)_3(ClO_4)_2$ solution in place of the reaction mixture yielded an apparent molar extinction coefficient of 547 ± 14 at 681.5 nm. Beer's Law is obeyed (within ±5%) in the concentration range examined ($1 - 6 \times 10^{-4}$ *M*) and the analysis is unaffected by the presence of Co(III) salt. Similar results were obtained with 2-MeO- and 3-MeO-NMA. Although conversion of Co(II) to $CoCl_4^{2-}$ is incomplete in concentrated aqueous HCl (28), the apparent extinction coefficient is constant within ±5% for the solvent mixtures (ca. 1:50 (v/v) AN–HCl to ca. 2:25 (v/v) AN–HCl) examined.

Final absorbances were constant to 10–20 half-lives in all rates. The spectra of the reaction mixtures indicated quantitative (±5%) conversion of DH to D^+ with BQ, CA, TCNE, DCBQ, and $Co(bipy)_3^{3+}$ and production of the theoretical quantity of $TCNQ^{\cdot-}$ with TCNQ.

pK_{R^+} measurements

"Mixed" pK_{R^+} values (29) were determined by spectrophotometric measurement of $[DOH]/[D^+]$ in solutions of measured pH as previously described (1). Stock solutions of the iodide salts were ca. 7×10^{-4} *M*. The numbers of independent determinations averaged, the pH ranges, and analytical wavelengths were: $2a^+I^-$, 22, 9.228–11.196, 357.2 nm; $2b^+I^-$, 13, 9.596–11.911, 367.2 nm; $2c^+I^-$, 16, 10.386–12.176, 366.2 nm. Optical densities of solutions of the 2-MeO and 3-MeO salts in buffers of pH above 10 decreased significantly over a 5-min time period following the first measurement. Since the decreases were approximately linear with time over this period, initial optical densities were obtained by linear extrapolation of readings taken at 3, 4, 5, 6, and 7 min after the time of mixing. Optical densities of solutions in 0.1 *M* NaOH increased with time, extrapolating to approximately zero at zero time. Repeated spectral scans of solutions in aqueous NaOH and the basic buffers showed that the optical density changes are due to the well-documented disproportionation of the cation to the corresponding acridone and acridan (11, 12). Thus, absorption maxima appeared at 405 and 424 nm ($2b^+I^-$) and at 321, 376, and 390 nm ($2c^+I^-$), characteristic of the 2- and 3-methoxy-N-methylacridones (**5***b* and *c*), respectively (30). The disproportionation reactions were not investigated further. As a consequence of the uncertainties in measured optical densities, the pK_{R^+} values are considered to be uncertain to about ±0.08 (maximum range of measured values). Agreement between pK_{R^+} values measured at pH's where disproportionation is slow and values measured at higher pH's supports the validity of the procedure. Mixed pK_{R^+} values were corrected to zero ionic strength as previously described (1).

Radical ions in photochemistry. 15. The photosubstitution reaction between dicyanobenzenes and alkyl olefins

ROBERT M. BORG, DONALD R. ARNOLD,[1] AND T. STANLEY CAMERON
Department of Chemistry, Dalhousie University, Halifax, N.S., Canada B3H 4J3

Received August 18, 1983[2]

ROBERT M. BORG, DONALD R. ARNOLD, and T. STANLEY CAMERON. Can. J. Chem. **62**, 1785 (1984).

The photosubstitution (electron transfer) reaction between 1,4-dicyanobenzene (**1**) and 2,3-dimethyl-2-butene (**2**), which gives 1-(4-cyanophenyl)-2,3-dimethyl-2-butene (**3**) and 3-(4-cyanophenyl)-2,3-dimethyl-1-butene (**4**), has been extended to other dicyanobenzene–olefin mixtures. Substitution of a cyano group occurs when both **1** or 1,2-dicyanobenzene (**5**) are irradiated in acetonitrile solution, in the presence of **2** or cyclohexene (**16**). Under comparable conditions, 1,3-dicyanobenzene (**6**) failed to react. Little or no substitution was observed in any case when the olefin was methylpropene (**19**). The results for **1** and **5** are in agreement with empirical free energy calculations (Weller equation) for the electron transfer process which, however, fail to explain the general lack of reactivity of 1,3-dicyanobenzene. Phenanthrene (**11**) has been shown to photosensitize the photosubstitution reaction between dicyanobenzenes and **2**. Under these conditions the olefin reacts with **6** predominantly at the 4-position, resulting in overall substitution of a hydrogen atom. This reaction occurs regiospecifically, resulting in the formation of only one of the two possible isomeric side chains. The mechanistic details of these reactions have been substantiated by means of deuterium labelling studies. The aromatic nitriles also undergo photosubstitution by **2**, in acetonitrile–methanol solution, resulting in methanol-incorporated products. Whereas reaction with **1** or **5** results in substitution of a cyano group, **6** was observed to give isomeric dicyanocyclohexenes, resulting from initial reaction at the 4-position, followed by reduction. A detailed mechanism for this secondary photoreduction has been substantiated by deuterium labelling studies. The anomalous behaviour of 1,3-dicyanobenzene has been attributed to a difference in the reactivity of the radical anion.

ROBERT M. BORG, DONALD R. ARNOLD et T. STANLEY CAMERON. Can. J. Chem. **62**, 1785 (1984).

La réaction de photosubstitution (transfert d'électron) entre le dicyano-1,4 benzène (**1**) et le diméthyl-2,3 butène-2 (**2**), qui donne le (cyano-4 phényl)-1 diméthyl-2,3 butène-2 (**3**) et le (cyano-4 phényl)-3 diméthyl-2,3 butène-1 (**4**), est étendue à d'autres mélanges de dicyanobenzène et d'oléfines. Il se produit une substitution d'un groupe cyano lorsque soit le composé **1** ou le dicyano-1,2 benzène (**5**) sont irradiés, en solution dans l'acétonitrile, en présence du composé **2** ou du cyclohexène (**16**). Dans des conditions comparables, le dicyano-1,3 benzène (**6**) ne réagit pas. Lorsque l'oféfine est le méthylpropène (**19**), on n'observe pratiquement pas de substitution. Les résultats obtenus dans le cas des composés **1** et **5** sont en accord avec des calculs empiriques d'énergies libres (équation de Weller) pour le processus de transfert d'électron, qui n'explique cependant pas le manque général de réactivité du dicyano-1,3 benzène. On a montré que le phénanthrène (**11**) photosensibilise la réaction de photosubstitution entre les dicyanobenzènes et le composé **2**. Dans ces conditions, l'oléfine réagit principalement avec la position 4 du composé **6** et il en résulte, dans l'ensemble, une substitution nette d'un hydrogène. Cette réaction est régiospécifique et conduit uniquement à la formation de l'une des deux chaînes latérales possibles. Des études impliquant des marquages par le deutérium permettent de confirmer les détails mécanistiques de ces réactions. Les nitriles aromatiques, en solution dans des mélanges d'acétonitrile et de méthanol, subissent aussi des photosubstitutions par **2**; il y a formation de produits ayant incorporé du méthanol. Alors que la réaction des composés **1** ou **5** conduit à la substitution d'un groupe cyano, on a observé que le composé **6** donne des dicyanocyclohexènes isomères qui résultent d'une réaction initiale en position 4, suivie d'une réduction. Des études impliquant des marquages par du deutérium ont permis de confirmer le mécanisme détaillé de cette photoréduction secondaire. On attribue le comportement anormal du dicyano-1,3 benzène à la différence de réactivité de l'anion radical.

[Traduit par le journal]

Introduction

The photochemistry of aromatic nitriles in the presence of olefins has been an area of intense research activity during recent years (1). This is primarily due to the variety of potentially useful reactions that are known to occur, depending upon reaction conditions, such as solvent polarity and the oxidation or reduction potentials of the reactants. In nonpolar solvents, such as hexane, exciplex formation is predominant and often results in [2e+2e] cycloaddition to the nitrile bond (1*b*, *c*) or to the aromatic ring (1*a*, *f*, *h*). In more polar solvents, such as acetonitrile, full electron transfer can occur; radical ions are then the primary reactive species (1*d*, *e*, *g*; for a recent review on the reactions of radical ions generated photochemically, see ref. 2). These can react with one another, or with some other species in solution.

Several examples of the co-reaction of photochemically generated radical ion pairs have been reported (2), but few of these involve substitution of the nitrile function on the acceptor by an olefin (3–5). Recently we have described (1*c*) the photosubstitution reaction between 1,4-dicyanobenzene, (**1**), and 2,3-dimethyl-2-butene, (**2**), which gives the substituted benzonitriles, **3** and **4** (Fig. 1). Our interest in this reaction was renewed by an observation made during our recent studies into the photosensitized (electron transfer) [2e+4e] cycloaddition of phenylated olefins (6). We noticed that, while both 1,4- and 1,2-dicyanobenzene (**1** and **5** respectively) are good sensitizers of the reaction, on the other hand, in the presence of 1,3-dicyanobenzene, (**6**), no reaction was observed.[3] This behaviour is unusual because successful uses of **6** as a photosensitizer (electron transfer) have been reported in the literature (7). However, a similar trend in reactivity has been observed in the photosubstitution (electron transfer) of dicyanobenzenes by triethylamine (8). We wondered whether this anomalous be-

haviour would also be reflected in the reactivity of **6** towards photosubstitution by **2**. Furthermore, since the scope and limitations of this photosubstitution reaction have not yet been defined, and since products such as **3** and **4** are not readily accessible by more classical synthetic procedures, we decided the reaction warrants further study.

This paper, therefore, describes the results obtained when other dicyanobenzene–olefin mixtures are irradiated, as well as the dramatic improvement in the efficiency of the reaction through the use of photosensitization (electron transfer). The variation that results when a nucleophilic solvent such as methanol is used will also be discussed.

Results

Ultraviolet irradiation of a solution of 1,2-dicyanobenzene (**5**) and **2** in acetonitrile, through Pyrex ($\lambda > 280$ nm), resulted in a clear yellow solution from which the photosubstitution products, 1-(2-cyanophenyl)-2,3-dimethyl-2-butene (**7**) and 3-(2-cyanophenyl)-2,3-dimethyl-1-butene (**8**), were isolated by column chromatography. Under similar conditions, 1,3-dicyanobenzene (**6**) reacted very slowly to give only traces of the analogous 1,3-substituted products **9** and **10** (Fig. 1).

The photosubstitution reaction is quite inefficient (i.e. long irradiation times are required) when the cyanoaromatic is irradiated directly. A dramatic enhancement in efficiency was observed upon the addition of phenanthrene (**11**). Thus, for the reaction of 1,4-dicyanobenzene (**1**) with **2**, whereas the previously reported yields of the products **3** and **4** were 10% and 18% respectively (*1e*), in the presence of **11** these increased to 23% and 42%, and the irradiation time was shortened considerably (less than one-half). Similarly, yields of **7** and **8** were improved (Fig. 1). Phenanthrene recovery was generally better than 80%. Traces of the cyanated side-chain products **12** and **13** were also obtained. Use of naphthalene instead of **11** resulted in no significant enhancement in the rate of conversion, while the addition of anthracene was observed to slow down the reaction. Dinitrile **6** also reacts faster with **2** in the presence of **11**. However, in this case, the olefins **9** and **10** were not the major products. Instead, a colourless crystalline solid was isolated which was characterized as having the structure 1-(2,4-dicyanophenyl)-2,3-dimethyl-2-butene (**14**). Only this isomer was formed; no trace of **15** was detected (Fig. 2).

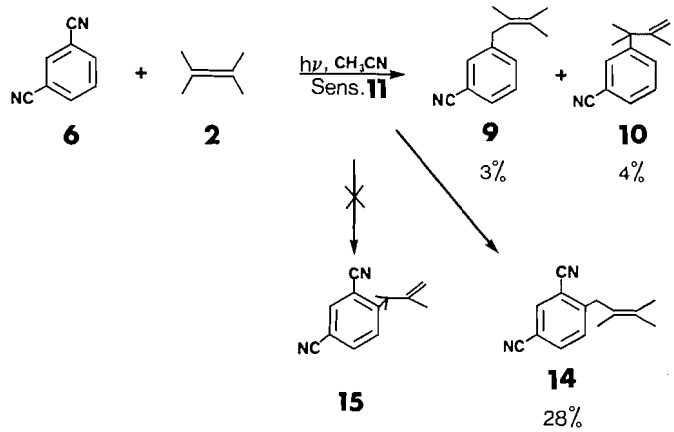

FIG. 2

The ultraviolet absorption spectra of all three dicyanobenzenes tail off at 300 nm. No reaction occurred if the irradiation was carried out through a long wavelength filter ($\lambda >$ 300 nm) unless **11** was present.

Both **1** and **5** reacted with cyclohexene (**16**) when irradiated in acetonitrile solution, but the transformation proceeded more slowly than with **2** as the olefin. Nevertheless, the photolysates were relatively clean and the desired photosubstitution products **17** and **18** (Fig. 3) were readily isolated by column chromatography. When **11** was used as a photosensitizer, the material balance of the reaction was improved in both cases. No reaction was observed between **6** and **16**, even in the presence of **11** and after prolonged irradiation.

All three dicyanobenzenes remained inert when irradiated in the presence of methylpropene (**19**) in acetonitrile solution. This was also the case in the presence of added **11**.

The photosensitized reactions illustrated in Figs. 1 and 2 were repeated with 2,3-dimethyl-2-butene-d_{12}. The substitution products were isolated and examined for deuterium incorporation by ^{13}C nmr spectroscopy.

Switching from pure acetonitrile as the solvent to a 3:1 mixture (by volume) of acetonitrile–methanol had the effect of accelerating the photolysis, which now proceeded with the incorporation of methanol in the products. Thus, the irradiation of **1** in the presence of **2** and **11**, followed by the usual work-up, afforded the ether **20** (Fig. 4) in 70% isolated yield. Similarly,

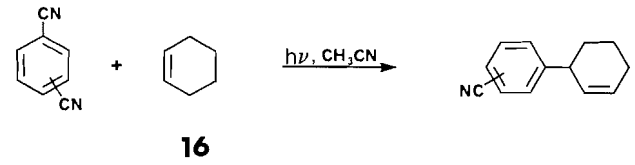

FIG. 3

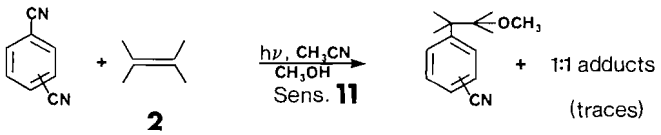

FIG. 4

the 1,2-substituted ether **21** was obtained in 45% yield from reaction of **5**. Control experiments established that these reactions proceeded in an identical fashion in the absence of **11**, except that longer irradiation times were required and yields were somewhat lower.

In the presence of methanol and **11**, the photo-induced reaction between **6** and **2** results in a complex mixture of products. Compound **22** (Fig. 5), analogous to the ethers **20** and **21**, was only a minor product. Instead, three isomeric crystalline compounds, **23–25** (Fig. 5), were obtained. The structure of these products rests firmly on the X-ray crystallographic analysis. Stereoscopic views of the molecules in the final structure are given in Fig. 6.

The relative ratios of these compounds was found to be dependent on the irradiation time. At low conversion (50%), yields of **23**, **24**, and **25** were 5%, 20%, and 26%, respectively. At higher conversion (75%), these figures changed to 0%, 7%, and 15%. Once again, in the absence of **11**, the reaction proceeded similarly, except that longer irradiation times were required, and a poorer material balance was obtained. The photolysis was also carried out with methanol-d_1 in the place of normal methanol. The products were isolated and analysed for deuterium incorporation by 360-MHz ^{1}Hmr spectroscopy.

The addition of methanol to the solvent has practically no effect on the efficiency of reaction between 1,4-dicyanobenzene (**1**) and methylpropene (**19**). However, prolonged irradiation does result in the formation of traces of the ether **26** (Fig. **7**). The addition of **11** results in the quenching of the formation of **26**. No trace of **27** could be detected. In view of the low yields obtained from this reaction, the photolyses involving **5** and **6** were not attempted.

Structural assignments

The structures assigned to the sixteen new compounds reported here (**7–10**, **12–14**, **17**, **18**, and **20–26**) are based predominantly on the ^{1}Hmr, ^{13}Cmr, infrared, and mass spectral data, as well as elemental analyses. The aliphatic region in the 80-MHz ^{1}Hmr spectra of **7** and **9** exhibits resonances corresponding to three vinyl methyl, and one vinyl methylene, groups. These are all broadened as a result of the homoallylic coupling typical of these systems (9). The isomers **8** and **10** show the ABX_3-type coupled system expected for the vicinal methylene (AB) at 4.8 ppm and methyl (X_3) at 1.7 ppm. The aromatic region in the ^{1}Hmr spectra of the four isomers is too complex at 80 MHz to allow conclusive deductions about substitution patterns to be made. However, the infrared spectra of these compounds are informative in this respect. The out-of-plane CH bending mode absorptions at 760 cm^{-1}, typical of 1,2-disubstituted aromatics (10), are prominent in the spectra of both **7** and **8** while, for **9** and **10**, bands at 790 cm^{-1} and 690 cm^{-1} are consistent with 1,3-disubstitution (10). The spectral data reported elsewhere (1*e*) for the corresponding 1,4-disubstituted isomers, **3** and **4**, render the above assignments more definitive.

Compound **14** was shown to have retained both cyano functions present in the starting material by the presence of two singlet resonances in the ^{13}Cmr spectrum at 117 and 116 ppm, typical of *sp*-hybridized carbon atoms in aromatic nitriles (11). Furthermore, the 360-MHz proton spectrum readily demonstrated the presence of an ABX system in the aromatic region with coupling constants that are consistent with 1,2,4-trisubstitution. The presence of a band of medium intensity at 860 cm^{-1} in the infrared spectrum confirmed this (10).

The cyclohexenylcyanobenzenes, **17** and **18**, were shown to be substituted at the 3-position of the cyclohexene ring (and not at the 1- or 4-position). In the mass spectra of **17** and **18**, a prominent peak at *m/e* 155 is indicative of a loss of 28 mass units, ethylene. This is consistent with 1- or 3-substitution, but not with 4-substitution. A weak absorption at 1650 cm^{-1} in the infrared spectrum, as well as no significant absorption above 290 nm in the ultraviolet spectrum, indicates a carbon–carbon double bond that is unconjugated with the aromatic ring. The presence of two vinyl protons, revealed by ^{1}Hmr and ^{13}Cmr spectroscopy, confirms that **17** and **18** are indeed 3-substituted cyclohexenes. Finally, 1,2- and 1,4-substitution on the aromatic ring is once again supported by infrared spectroscopy.

The proton magnetic resonances of the ethers **20–22** are predictably simple in the aliphatic region and the chemical shifts of the resonances compare favourably with those reported for similar compounds (1*d*, *g*). The mass spectra of all three isomers exhibit a weak peak at *m/e* 217, corresponding to an MH^+ ion, but no molecular ion. This behaviour is typical of ethers (12). The lower molecular mass region of the spectrum is dominated by the presence of an intense base peak at *m/e* 73. This may be attributed to cleavage of the side chain to give a stabilized cation as well as an also stable cyanocumyl radical; this is in good agreement with the proposed structure. It is interesting to note that while in the mass spectra of the aforementioned ethers the base peak occurs at *m/e* 73, for the similarly-structured compounds **12** and **13** (Fig. 1), the cyanocumyl cation at *m/e* 144 is the predominant ion, due to the relative instability of the alternative cyano-substituted cationic centre.

Cyclohexenes **23–25** were characterized conclusively by means of X-ray crystallography. Nevertheless, since a detailed mechanism for the formation of these compounds relies heavily on deuterium incorporation studies (*vide infra*), a complete analysis of the 360-MHz ^{1}Hmr spectra of these products was necessary. The spectral assignments are based primarily on

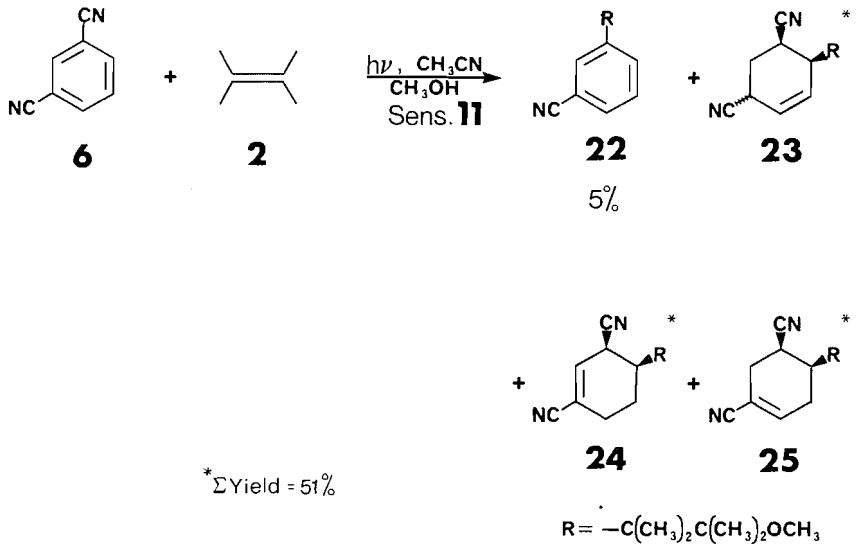

FIG. 5

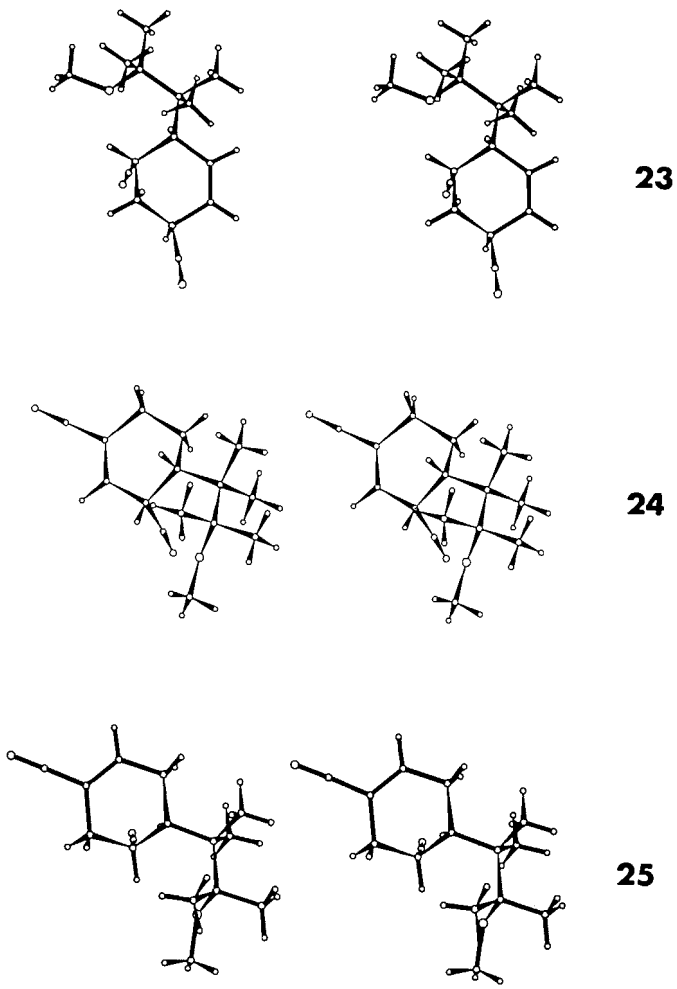

FIG. 6. Stereoscopic views of **23**, **24**, and **25**.

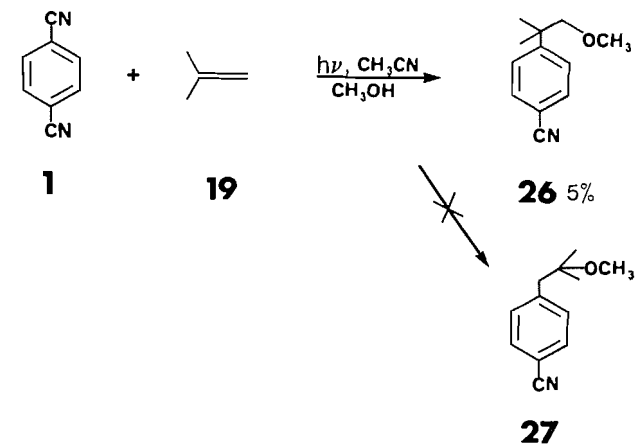

FIG. 7

X-ray data (supplementary material available). These data demonstrate that the bulky side chain present in **23**–**25** exists predominantly in an equatorial position.

The results for compound **23** will be presented here as an example. In compound **23**, since the side chain is in a pseudo-equatorial position (13), H_3 and H_6 are pseudo-axial, while H_5 is equatorial. The two high-field multiplets, centered at 2.50 and 2.09 ppm, are due to H_{4e} and H_{4a}, respectively. Analysis of these systems indicates a large coupling constant ($J_{4a,4e}$ = 13.3 Hz), typical of geminal coupling in six-membered rings (ref. 10, p. 275). The lower field resonance is assigned unambiguously to H_{4e} on the basis of the observed small coupling of 1.6 Hz magnitude with H_2. According to the X-ray data, H_{4e} and H_2 are in the correct orientation for this long-range "W-type" coupling (ref. 10, pp. 334–341). Having identified H_{4a}, $H_{3a'}$ can now easily be recognized at 3.7 ppm, due to the large coupling ($J_{3a',4a}$ = 11.9 Hz) associated with axial–axial vicinal coupling (ref. 10, p. 288). This is further substantiated by the observed small (<2 Hz) vicinal coupling, $J_{3a',2}$. Of the two remaining high field multiplets, H_{5e} is assigned to 3.42 ppm, since this resonance clearly is coupled to both H_{4e} and H_{4a}, as well as to $H_{6a'}$ ($J_{5e,6a'}$ = 3.8 Hz). This assignment seems even more reasonable on a chemical shift basis, since H_{5e} is geminal to a cyano substituent. All other coupling constants are also consistent with these assignments.

In the 360-MHz ^{1}Hmr spectrum of **23** prepared in methanol-d_1, positions 3 and 5 are completely deuterated, as is indicated clearly by the absence of the resonances assigned to $H_{3a'}$ and

H_{5e}. Furthermore, H_{4a} is also no longer visible, and the resonances due to H_1, H_2, $H_{6a'}$, and H_{4e} are now simplified considerably by the absence of the relevant spin–spin coupling.

A similar analysis of the 360-MHz ^{1}Hmr spectra of natural abundance and deuterated cyclohexenes **24** and **25** led to the deuterium substitution pattern assignments illustrated in Fig. 19.

A few other features in the spectral data of cyclohexenes **23**–**25** are worth mentioning. The infrared absorption spectra of **24** and **25** indicate the presence of two cyano stretching frequencies, corresponding to conjugated and unconjugated triple bonds. As expected, **23** shows only one such absorption at 2235 cm^{-1}. The mass spectra of these compounds are similar to those of the ethers **20**–**22** in that all three exhibit a weak MH^+ ion as well as an intense peak at *m/e* 73 which once again dominates the spectrum. However, fragments at *m/e* 115 and 84, presumably due to the methoxytetramethylethyl cation and tetramethylethyl radical cation, respectively, are now also quite prominent. Evidently, fragmentation of the entire side chain as a whole is preferred in the cyclohexenes, where the formation of a cyanocumyl radical is no longer feasible.

The ether **26** was distinguished from the regioisomeric form **27** on the basis of mass spectral and ^{13}Cmr data. The observed base peak at *m/e* 45 is indicative of cleavage at the side chain to give the methoxymethylene cation (as well as a cyanocumyl radical). Compound **27**, on the other hand, would be expected to give an intense peak at *m/e* 73, by analogy with the data presented for the above compounds. No such fragment was observed. An MH^+ ion at *m/e* 190 is also evident. Finally, the ^{13}Cmr magnetic resonances at 81.8 (t) and 39.4 (s) ppm are in agreement with those reported for compounds with the same side-chain composition as in **26** (15).

Photophysical studies

Rate constants for fluorescence quenching of the dicyanobenzenes by olefins **2**, **16**, and **19** were obtained from Stern–Volmer type plots of fluorescence intensity. These results are presented in Table 1. The singlet fluorescence lifetimes in degassed acetonitrile were obtained by a single photon counting technique. No exciplex emission could be detected during the quenching experiments, even at high concentrations of quencher.

The ultraviolet absorption and fluorescence emission spectra of the dicyanobenzenes, **1**, **5**, **6** and phenanthrene (**11**) in acetonitrile were measured. The emission spectra were normalized and the singlet energies of the compounds were estimated from the interesection of absorption and emission spectra. The results are presented in Table 2.

Discussion

Although the photosubstitution (electron transfer) of dicyanobenzenes by olefins is by no means a general reaction, the results just presented indicate that the method provides some synthetic utility, even in the low yield cases, since alternative synthesis of the products is not straightforward.

One of the most interesting observations to emerge from the results is the unique behaviour of 1,3-dicyanobenzene (**6**) when compared with the 1,2- and 1,4-isomers. Not only does **6** react at least ten times slower than **1** and **5** under comparable conditions, it also yields main products that are quite different. This anomalous behaviour is especially peculiar in the light of photophysical studies that show that all three isomers behave similarly.

Irradiations in acetonitrile solution

The mechanistic scheme previously proposed (1*e*) for the photosubstitution reaction in acetonitrile is outlined in Fig. 8. With reference to this scheme, the primary step in the reaction is excitation of the cyanoaromatic to the first excited singlet state. All three dicyanobenzenes absorb at wavelengths shorter than 300 nm and, under the conditions of the experiment (Pyrex, $\lambda > 280$ nm), they are expected to act as the principal absorbing species in solution. Upon encountering an olefin, electron transfer to the excited acceptor may occur, and the resulting radical ion pair is then able to proceed via the two mechanistic pathways depicted in the scheme. A similar mechanism is expected for reaction with cyclohexene (**16**), except that in this case only one product is, of course, possible.

Evidence for the involvement of the first excited singlet state of the dicyanobenzenes in the primary step of the reaction stems from the measured fluorescence lifetimes, and Stern–Volmer type plots. The quenching rate constants (Table 1) are all close to the diffusion-controlled limit[4] for acetonitrile solutions. This fluorescence quenching, combined with the fact that little or no reaction is observed when the irradiations are carried out in a nonpolar solvent (such as benzene) is strongly suggestive of an electron transfer mechanism.

The Weller (17) equation was used to estimate the free energy change associated with electron transfer from the olefins to the first excited singlet state of the dicyanobenzenes (Table 2). The calculations suggest that the transfer should be exergonic in all cases involving 2,3-dimethyl-2-butene (**2**) and cyclohexene (**16**), but unfavourable when methylpropene (**19**) is the donor. These values are consistent with the experimentally observed results for **1** and **5**, i.e. reasonably fast reaction with **2**, slower with **16**, and no reaction at all with **19**. However, they fail to explain why 1,3-dicyanobenzene (**6**) reacts so slowly when irradiated in the presence of **2** and, moreover, why it does not react at all with **16** since, in both cases, ΔG_{calc} is negative. It is conceivable that electron transfer to the first excited singlet of **6** is indeed occurring, especially in view of the diffusion-controlled quenching observed; but back electron transfer (18) is an efficient deactivation pathway. This process is probably the main reason for the low quantum yields frequently observed in photoreactions involving radical ion pairs generated in the singlet state (19).

A surprising feature of the data presented in Table 1 is the diffusion-controlled fluorescence quenching observed for all three dicyanobenzenes by methylpropene (**19**). In view of the observed lack of reaction and the positive values for ΔG_{calc} in the electron transfer step (Table 2), this result was unexpected. In these cases, a quenching mechanism other than full electron

[4] The limit is 1.7×10^{10} M^{-1} s^{-1} at 25°C using the Debye equation (16*a*): $k_d = 2 \times 10^5\ T/\eta$. At 25°C, η for acetonitrile = 0.345 cP (16*b*).

[b]The electron transfer process was irreversible. Value taken as 0.029 V before the cathodic peak potential (ref. 41).

[c]Estimated from the intersection of the ultraviolet absorption and fluorescence emission spectra.

[d]Calculated from the Weller equation (17). The oxidation potentials of **2** and **16** are +1.28 V and +1.98 V, respectively (cyclic voltammetry, vs. Ag, this work). The oxidation potential of **19** (+2.3 V) was estimated from the ionization potential using the equation $E^{ox}_{1/2} = 0.827$ I.P. − 5.40 V (ref. 14).

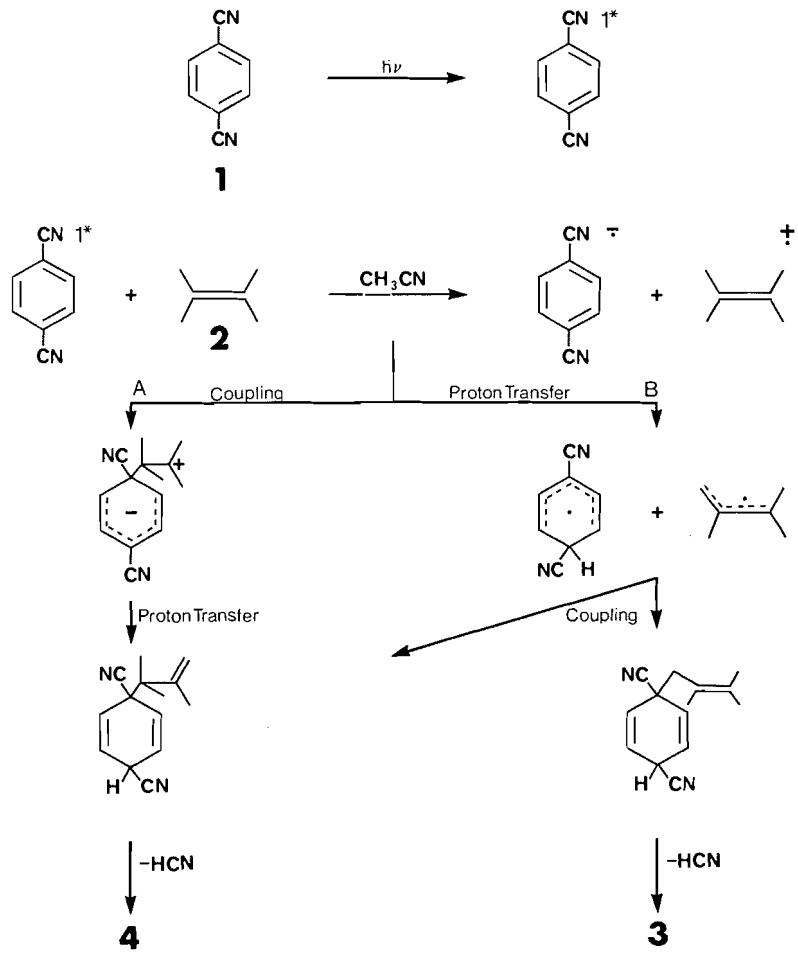

FIG. 8

transfer (e.g. exciplex formation) may be operative. The best evidence for the formation of an exciplex would be to observe emission from it. However, emission could not be detected from solutions of the dicyanobenzenes in acetonitrile, even when the fluorescence of these compounds was strongly quenched by any of the olefins investigated. Weak emission was observed when hexane was the solvent; especially when 1,3-dicyanobenzene (**6**) was the fluorophor and **2** was the quencher. It therefore seems plausible that ionic dissociation of the exciplexes in acetonitrile, followed by rapid back electron transfer, provides an efficient pathway for deactivation of the excited singlet state of the aromatic nitriles.

These photosubstitution reactions are generally inefficient, especially in the case of 1,3-dicyanobenzene (**6**). The use of phenanthrene (**11**) as a photosensitizer dramatically improved the efficiencies of some of the reactions, and material balances were enhanced. Other workers (4*a*, 7*a*, 20) have reported that **11**, as well as other aromatic hydrocarbons, act as sensitizers in photoreactions involving radical ion formation. They propose that the role these compounds play is that of a "radical

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/06/12
For personal use only.

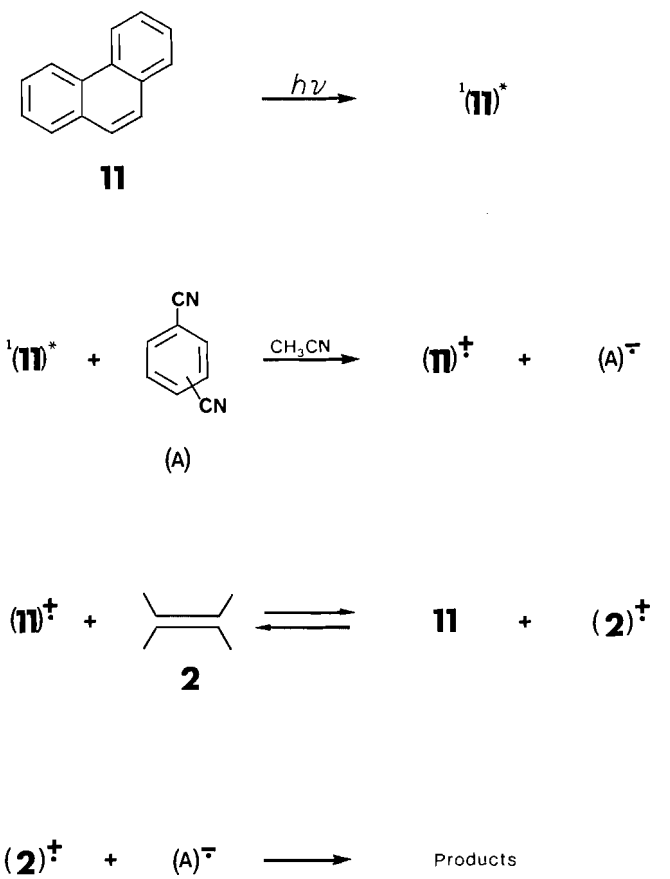

FIG. 9

cation transfer agent", as is depicted in Fig. 9, where the mechanistic scheme has been applied to the photosubstitution reaction.

According to the scheme, since **11** absorbs at longer wavelengths that the dicyanobenzenes, it now acts as the principle chromophore, resulting in the formation of the first excited singlet state (^{1}**11***). This then transfers an electron to ground state dicyanobenzene to form a radical ion pair which, in the polar acetonitrile solvent, leads to solvent separated ions. The encounter of the phenanthrene radical cation (**11**$^{\cdot+}$) with **2** could then result in a radical cation transfer. Such a transfer is feasible, but would be reversible, since **11** and **2** have similar oxidation potentials ($E^{ox}_{1/2}$ = +1.31 V and +1.28 V, respectively). This process has analogy in the well-known redox catalysis in organic electrochemistry (21). The resulting radical cation of **2** would then proceed to products according to the scheme given earlier (Fig. 8). Terms such as "co-sensitization" (20) or "redox photosensitization" (4*b*) have also been used to describe this mode of photosensitization.

There is ample evidence in the literature for the proposed electron transfer step between **11** and 1,4-dicyanobenzene (**1**). The radical cations of both pyrene (22) and **11** (7*a*) have been detected by means of laser flash photolysis in acetonitrile in the presence of **1**. Furthermore, Pac and co-workers (4*b*) have calculated the theoretical free energy change for the transfer process, using the Weller equation, and came to the conclusion that transfer from the excited singlet state of several aromatic hydrocarbons to **1** should be a highly favoured process. This was further substantiated by their observation that fluorescence from the hydrocarbons in polar solvents was quenched at the

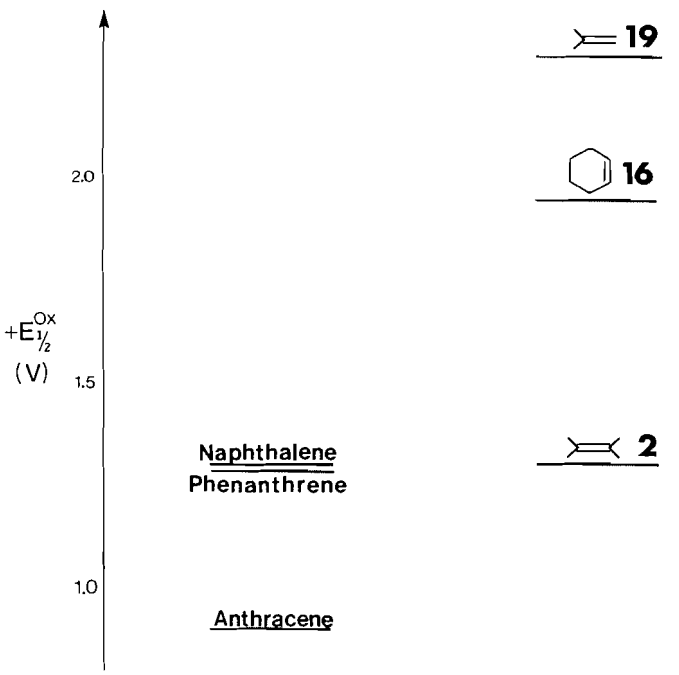

FIG. 10. The relative oxidation potentials of the aromatic hydrocarbons and the alkyl olefins.

diffusion-controlled rate by **1** (4*b*). Table 3 lists the calculated ΔG values for electron transfer from the excited singlet of phenanthrene (**11**) ($^1\Delta E_{0-0}$ = 346 kJ mol^{-1}) to the dicyanobenzenes. The values indicate that the above arguments should also apply to 1,2- and 1,3-dicyanobenzene.

Naphthalene and anthracene were also tried in the present system. Naphthalene neither sensitized nor quenched the reaction while anthracene slowed down the photolysis considerably. This, in spite of the fact that ΔG_{calc} for electron transfer to **1** from the first excited singlet of both hydrocarbons is negative (4*b*). The reason for this becomes clearer when one considers the relative oxidation potentials of these aromatic hydrocarbons compared to that of the olefins, as is illustrated in Fig. 10.

Reversible radical cation transfer to **2** or **16** is feasible from both phenanthrene (**11**) or naphthalene. However, since the main factor increasing the reaction efficiency is more effective use of light, naphthalene is not as useful a photosensitizer (electron transfer) as is phenanthrene. The absorption spectrum of **11** tails out to 360 nm while naphthalene does not absorb much above 330 nm. Since the anthracene molecule is an even longer-wavelength chromophore than **11**, it would be expected to be a more effective photosensitizer. However, as Fig. 10 indicates, transfer from the anthracene radical cation to the olefin is endothermic in all cases and this aromatic hydrocarbon

therefore acts as a quencher of the reaction. For the same reason, **11** does not photosensitize the reaction between 1,4-dicyanobenzene (**1**) and methylpropene (**19**) in acetonitrile solution, and actually quenches the formation of the ether **26** when **1** and **19** are irradiated in acetonitrile–methanol.

In most of the reported examples of related photosensitizations (4*a*, 7*a*, 20), the aromatic hydrocarbon was largely recovered after reaction. However, during the course of the irradiations described here some conversion (20%) of **11** to 9-cyanophenanthrene (**28**) and 9-cyano-9,10-dihydrophenanthrene (**29**) was observed. The formation of these side products can be explained by attack of cyanide ion on the radical cation of phenanthrene.

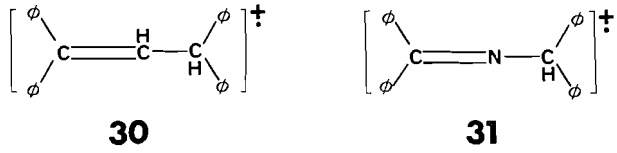
The photosensitized (electron transfer) cyanation of aromatic hydrocarbons has been well characterized by Pac and coworkers (7*b*). Formation of these derivatives provides further evidence for the involvement of the radical cation of **11** in the photosubstitution reaction, as well as demonstrating the presence of cyanide ion. Other evidence for the release of cyanide ion is the isolation of traces of **12** and **13** (Fig. 1). It seems likely that these compounds result from the nucleophilic interception of the radical cation of 2,3-dimethyl-2-butene (**2**) by cyanide ion. This point will be discussed in more detail below.

It was originally intended that the use of phenanthrene as a photosensitizer (electron transfer) would not only improve the yields and efficiencies of the photosubstitution reactions involving 2,3-dimethyl-2-butene (**2**) but that this would also result in a dramatic change in the ratio of products containing a terminal olefinic side chain (i.e. such as **4** and **8**, Fig. 1) to those containing the more heavily-substituted olefinic side chain (**3** and **7**). This was not so; within experimental error, no change in this ratio could be observed. Apparently, the final outcome of the photolysis is independent of whether the aromatic nitrile–olefin radical ion pair is formed in proximity or not. This is surprising, since one would expect that the use of phenanthrene to generate the radical cation of **2** would result in a different partitioning in the mechanistic pathway illustrated in Fig. 8. Presumably, less radical ion coupling (pathway A) would take place because $\mathbf{2}^{\cdot+}$ would deprotonate (to solvent) to form the relatively stable tetramethylallyl radical before encountering a dicyanobenzene radical anion molecule (pathway B).

A possible interpretation of these results is that the radical cation of **2** is in equilibrium with the allylic radical via deprotonation to the solvent. Thus, provided this equilibrium is established quickly enough, the same partitioning of product formation would be observed, both in the presence and absence of phenanthrene as a photosensitizer (electron transfer).

The deprotonation of $\mathbf{2}^{\cdot+}$ is a topic of particular interest. We have calculated a pK_a of $\mathbf{2}^{\cdot+}$ of around −4 in acetonitrile; deprotonation to this solvent might therefore be thermodynamically feasible (23). However, it is interesting to note that during studies of related systems involving **30**[5] and **31**[6] (Fig. 11), we found no evidence for the reversible deprotonation of these radical cations. The reason for this is not yet clear, and a thorough study of the kinetic versus thermodynamic acidities of these systems is continuing.

One further piece of experimental evidence pertaining to the mechanism of the photosubstitution reaction is available. In order to investigate the proposal that $\mathbf{2}^{\cdot+}$ protonates the radical



30 **31**

FIG. 11

anion of dicyanobenzene (pathway B, Fig. 8), irradiations were carried out in the presence of perdeutero-2,3-dimethyl-2-butene. Analysis of the products by ^{13}Cmr spectroscopy (see Experimental) indicated that *no deuterium was incorporated at any of the aromatic ring positions*. In the case of the 1,2- and 1,4-disubstituted products, **7** and **8**, and **3** and **4**, respectively, this can be explained if it is assumed that deuteration (protonation) via $\mathbf{2}^{\cdot+}$ occurs at the *ipso*-position, as illustrated in Fig. 8. Thus, elimination of DCN(HCN) would have to occur in the rearomatization step. However, this scheme cannot be applied to account for the lack of deuterium incorporation at the aromatic ring positions of **9** and **10**. This is because close inspection of the system involving 1,3-dicyanobenzene (**6**) reveals that protonation (deuteration) at positions other than *ipso* must occur if 1,3-disubstituted products are to be formed (Fig. 12).

The results just presented raise serious doubts about the details of the scheme originally proposed for the photosubstitution reaction (Fig. 8). This is even more so when one considers that it should be feasible to isolate intermediates such as the 1,4-cyclohexadienes proposed in the scheme. No such compounds were ever observed. It therefore seems necessary to invoke a mechanistic pathway that does not require protonation of the radical anion of dicyanobenzene by $\mathbf{2}^{\cdot+}$. Such a scheme (Fig. 13) involves a fast radical cation – allylic radical equilibrium. Two different processes then occur; radical ion coupling and loss of a proton and cyanide ion (not necessarily in that order) would result in the formation of terminal olefinic products. On the other hand, allylic radical – radical anion coupling, followed by loss of cyanide would give predominantly the tetrasubstituted olefins. This scheme can account for the product ratio being independent of the mode of formation of $\mathbf{2}^{\cdot+}$, as well as the fact that no deuterium is incorporated on the aromatic rings.

The formation of the trisubstituted product **14** (Fig. 2) is also accounted for, in part, by this mechanism. This compound probably results from coupling of the allylic radical with the radical anion of **6** at the 4-position of the aromatic ring, rather than at the 1-position. The intermediate anion thus generated would be stabilized by both cyano functions, thus explaining its preferential formation. Protonation would result in the 1,3-cyclohexadiene intermediate **32** (Fig. 14). The process would be analogous to the reaction of 9-cyanophenanthrene (**28**) with **2**, reported by Lewis and DeVoe (1*g*) (Fig. 15).

Two problems with the proposed overall mechanism now become apparent. If compound **32** was indeed an intermediate, instead of losing hydrogen cyanide to give the 1,4-substitution product **3**, it would have to be preferentially oxidized to **14** via some undetermined process. Since no amount of reduced material resulting from this was isolated, this result is not easily explained. Furthermore, attempts to isolate **32** failed. However, evidence pertaining to the existence of an intermediate such as **32** is provided by the results obtained when the photosubstitution reaction is carried out in a more nucleophilic solvent.

[5] D. D. M. Wayner and D. R. Arnold, unpublished results.
[6] J. Goodin and D. R. Arnold, unpublished results.

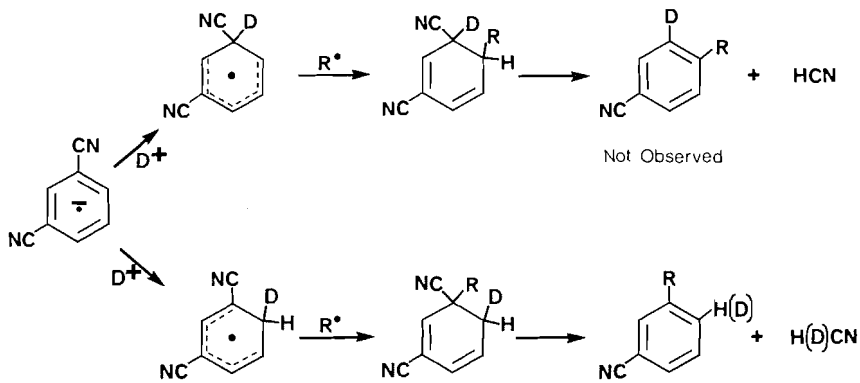


FIG. 12

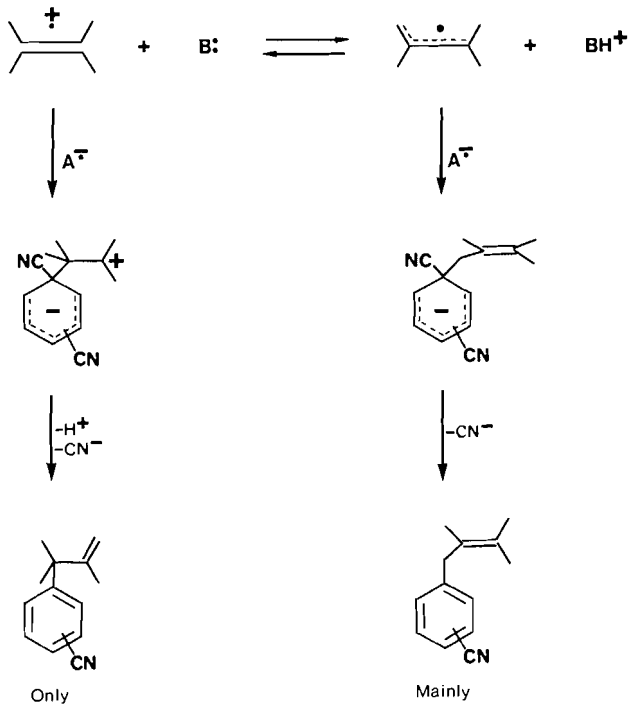

FIG. 13

Finally, another, and perhaps more serious, defect with the latest proposed scheme is that the terminal olefin **15** (Fig. 2) is never isolated. There is no apparent reason for this, since radical ion pair coupling at the 4-position of $\mathbf{6}^{\bullet+}$, followed by protonation, should lead to the same type of intermediate as **32**. At the present time, no reasonable explanation can be offered for the lack of formation of compound **15**. However, it is interesting to note that the observed regiospecificity, resulting in the predominant formation of **14** (and not **15**), has analogy in the 9-cyanophenanthrene system described above (Fig. 15).

Irradiation in acetonitrile–methanol

The mechanistic scheme proposed for the formation of the ethers **20** and **21** is shown below (Fig. 16).

The primary step is similar to that proposed for related systems (1*g*, 4*a*, 19), i.e., the photochemically generated radical cation of **2** is intercepted by the nucleophilic solvent to give the radical **33**. This couples with the radical anion of dicyanobenzene at the *ipso*-position. Loss of cyanide ion yields the observed products. The enhanced efficiencies (i.e. irradiation times were shorter, and material balances much improved) of formation of these ethers, when compared to the reactions observed in acetonitrile alone, are no doubt a result of "trapping" of the radical cation $\mathbf{2}^{\bullet+}$ by methanol, thus preventing energy-wasting back electron transfer from occurring.

It is interesting to compare the behaviour of the radical cation of **2** with that of aryl-substituted olefins, in the presence of methanol. We have previously reported (6*a*, 24) the photosensitized (electron transfer) *anti*-Markovnikov addition of alcohols to olefins such as 1,1-diphenylethylene (**34**). The proposed primary process in these reactions is the same as that illustrated in Fig. 16. However, following the interception of the olefinic radical cation by methanol, a divergence in behaviour is observed. Whereas **33** couples with the radical anion of the aromatic nitrile, the corresponding benzylic radical **35** is reduced by this radical anion and subsequent protonation of the resulting anion leads to the observed product, **36** (Fig. 17).

This difference in behaviour may be attributed to the relative ease of reduction of radical **35**, when compared to **33**. Breslow and co-workers (25) have provided approximate values for the reduction potentials of the benzyl and allyl radicals; these are $E^{red}_{1/2} = -1.0$ V and -1.2 V (vs. Ag), respectively. Unfortunately, the corresponding value for an alkyl radical is not available. However, since the reported gas-phase electron affinity of a benzyl radical (26*a*) is 85 kJ mol^{-1}, and the corresponding values for the allyl (26*a*) and methyl (26*b*) radicals are 53 and 8 kJ mol^{-1}, respectively, the reduction potential of the methyl radical can be estimated by extrapolation. The value is $E^{red}_{1/2} = -1.5$ V (vs. Ag). Thus, while it is considerably easier to reduce a benzyl radical than methyl, it should be feasible for dicyanobenzene ($E^{red}_{1/2} = -2.2$ to -2.0 V) to back electron transfer in every case. However, methyl radical has been considered here; a tertiary radical such as **33** is certainly less easily reduced.

Lewis and DeVoe (1*g*) have reported the formation of substantial amounts of the ethers **37***a* and **37***b* during the course of irradiations involving the generation of $\mathbf{2}^{\bullet+}$ in methanol. These are clearly the result of disproportionation of the radical **33**

37a **37**b

since these workers observed that **37***a* and **37***b* were formed in roughly equal amounts. Thus it appears certain that **37***b* does *not* arise via a pathway similar to that illustrated in Fig. 17.

The cyanated side-chain compounds, **12** and **13** (Fig. 1), are probably formed via an identical route to that shown in Fig. 16,

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/06/12

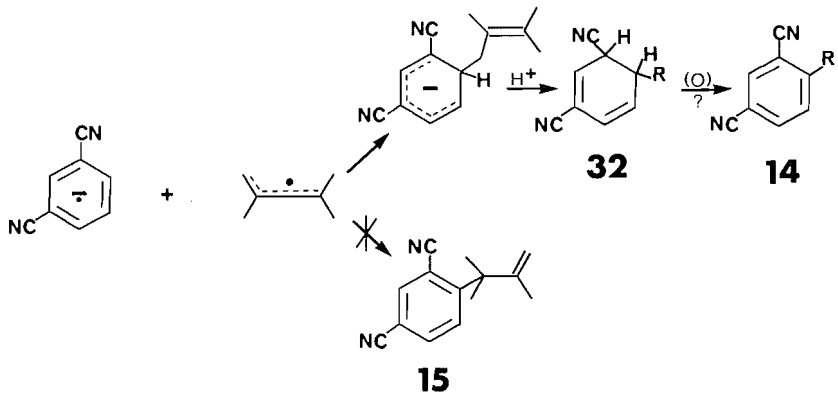

FIG. 14

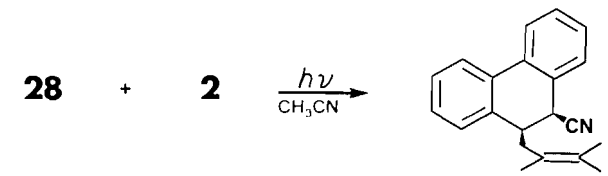

FIG. 15

except that the nucleophile is now cyanide ion, formed as a consequence of the photosubstitution reaction. Finally, it is noteworthy that while considerable amounts of 9-cyanophenanthrene (**28**) and 9-cyano-9,10-dihydrophenanthrene (**29**) were isolated from the phenanthrene-photosensitized reactions in acetonitrile solution, no trace of 9-methoxyphenanthrene or the 9-methoxydihydro derivative could be detected in the present system. Apparently the radical cation of phenanthrene (**11**) is not as susceptible to nucleophilic attack by methanol as by cyanide. This has been noted by others (4*b*) and is another added benefit to the synthetic potentiality of **11**. Obviously, however, photosensitization (electron transfer) by **11** cannot be used for the photocyanation of olefins (27).

When the irradiation of 1,3-dicyanobenzene (**6**) in the presence of **2** and **11** in acetonitrile–methanol solution was first attempted, it was expected that the major product would be **38**. This seemed like a logical prediction in view of the previous results. The eventual isolation of the cyclohexenes **23–25** as major products therefore came as a surprise since neither **1** nor **5** yielded analogous products. Compounds **23–25** are reduction products of the intermediates that would give **38**. A photochemical system such as dicyanobenzene–phenanthrene in a protic solvent is potentially a reducing medium for any substrates with a reduction potential low enough to be reduced by the dicyanobenzene radical anion (28). A few similar photochemical systems have been reported. Barltrop (29) has carried out extensive investigations on the photoreduction of aromatic systems in protic solvents, in the presence of triethylamine. Similar photoreductions (electron ttransfer) of 9-cyanophenanthrene (1*g*) and α-phenylcinnamonitrile (19) have been described in the literature.

The mechanistic scheme envisaged for the formation of cyclohexenes **23–25** is illustrated in Fig. 18. Coupling of the methoxytetramethylethyl radical **33** with $\mathbf{6}^{\bullet-}$ at the 4-position, followed by protonation, results in the 1,3-cyclohexadiene **39**. Two successive electron transfer – protonation steps to the latter would then result in the formation of the observed products.

The first electron transfer to **39** from the radical anion of **6** seems a reasonable step when one considers the reported reduction potential of crotonitrile ($E^{red}_{1/2} = -0.97$ V vs. Ag/Ag^+ in DMF) (30), a suitable model for **39**. Since the reduction potential of **6** is $E^{red}_{1/2} = -2.2$ V (Table 2), electron transfer from $\mathbf{6}^{\bullet-}$ to **39** is possible. This implies that electron transfer from the excited singlet of phenanthrene **11** is also a feasible process. However, control experiments established that **11** is not essential to the formation of **23–25**. Either this step does not occur or, more likely, both are operative.

In view of the protic solvent, it seems likely that protonation of the resulting radical anion of **39**, to give a radical, occurs rapidly. This radical, being stabilized by a cyano function and (or) being allylic, should also be reduced easily by $\mathbf{6}^{\bullet-}$ whenever such an encounter does occur. Protonation of the resulting anion would lead to the observed products.

The substitution pattern and stereochemistry of deuterium incorporation, is in good agreement with this scheme, Fig. 19. Formation of **23**, for example, would involve coupling of the methoxytetramethylethyl radical **33** with $\mathbf{6}^{\bullet-}$ at the 4-position to give a cyano-substituted cyclohexadienyl anion which would be protonated (deuterated) preferably from the side opposite to the bulky substituent. This establishes the *cis*-configuration in **39** that is retained in **23**, **24**, and **25**. Further reduction by two successive electron transfer/protonation (deuteration) steps would then follow. The stereochemical outcome of protonation (deuteration) in the latter two stages is dependent on the position of attack. Thus, protonation (deuteration) at positions that are γ, γ′, or δ to the bulky side chain would proceed via the expected (31) *axial* approach (thus resulting in *axial* deuterium incorporation). A similar result has been observed by McCullough *et al.* (1*d*). On the other hand, protonation (deuteration) cannot occur via axial attack at the carbon atom β′ to the side chain (i.e. *cis*), due to steric hindrance. *Equatorial* deuterium incorporation is therefore observed at this position (i.e. in compounds **24** and **25**, Fig. 19).

These deuterium incorporation results are therefore in good agreement with the overall mechanistic scheme proposed for the formation of compounds **23–25**. Furthermore, the inferred existence of cyclohexadiene **39** lends some credibility to the suggestion that the analogous compound **32** (Fig. 14) is a precursor to the trisubstituted product **14**.

The relative ratio of **23** to **25** was observed to be dependent on the irradiation time. Since no "scrambling" of deuterium over the ring positions in these compounds was observed, interconversion between the isomers (or intermediates leading to them) can be ruled out. The change in product ratios may then

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/06/12
For personal use only.

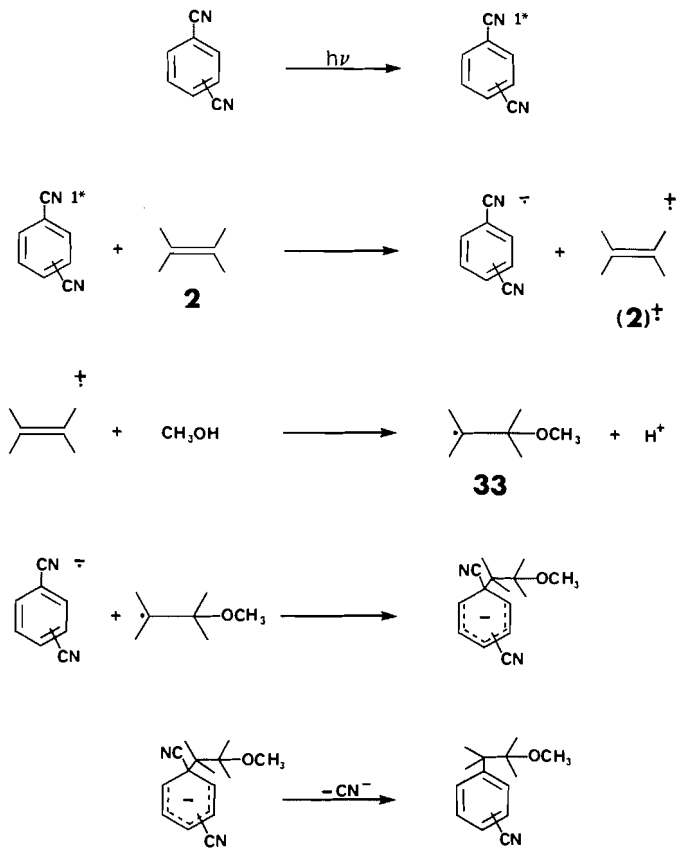

FIG. 16

be the result of secondary photolysis which leads to unidentified products. The incorporation of three atoms of deuterium per molecule is noteworthy since this indicates that methanol is the deuterating (protonating) species and that protonation via the radical cation of 2,3-dimethyl-2-butene (**2**) is not significant. Furthermore, *reduction involving hydrogen atom transfer must be of minor importance*. This result contrasts with that obtained by Mariano and colleagues (32) from their investigations into a secondary photoreduction step they observed during the photocyclization (electron transfer) of the pyridinium salt **40** (Fig. 20). The formation of **41** was rationalized in terms of a photoreduction (electron transfer) of the primary photoproduct, indolizidine (**42**). By means of deuterium studies, the authors came to the conclusion that *hydrogen atom transfer from the solvent plays an important part in the photoreduction process* (Fig. 21).

The difference between the two systems is not too surprising if one considers the electron affinity and reactivity of an allylic/cyano-stablized radical intermediate (Fig. 19) when compared to the radicaloid moiety **43**. Clearly, it is preferable for the latter species to abstract a hydrogen atom from the solvent, rather than undergo reduction to an α-amino anion. Therefore, methanol is not the reducing species in the 1,3-dicyanobenzene system being considered. Obviously, the formation of photoreduction products requires the genesis of an equivalent amount of oxidized material (such as formaldehyde (**44**) in Fig. 21). Such a compound was not identified. In view of the low material balance (50%) for this reaction, this is perhaps not too significant.

It is noteworthy that deuterium could not be detected in 1,3-dicyanobenzene (**6**) recovered from the irradiation in the presence of 2,3-dimethyl-2-butene (**2**) in acetonitrile – methanol-d_1. Thus, either the radical anion of **6** is not basic enough to be protonated by methanol, or such a process occurs irreversibly and leads to unidentified products. Finally, the lack of deuterium incorporation in the minor product **22** (Fig. 5), also isolated from the irradiation in acetonitrile – methanol-d_1, supports the mechanistic pathway shown in Fig. 16.

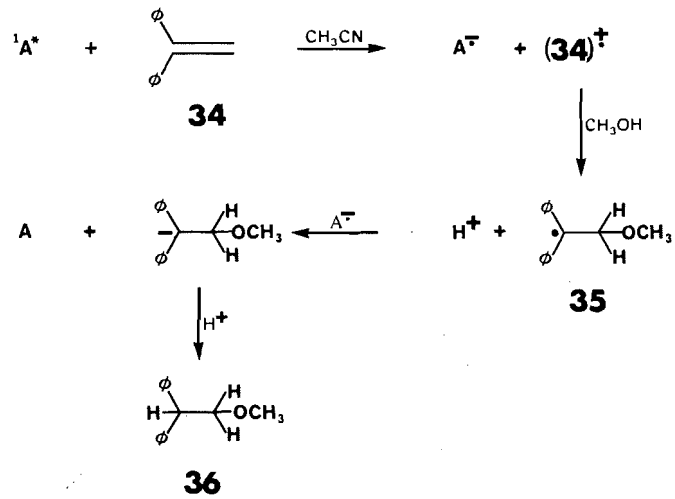

FIG. 17

The ether **26** (Fig. 7) was obtained by the irradiation of 1,4-dicyanobenzene (**1**) in the presence of **19** in acetonitrile–methanol solution. Formation of **26** is interesting because this compound results from competition between interception of the radical cation of **19** by solvent and back electron transfer in the radical ion pair. The latter process predominates in the absence

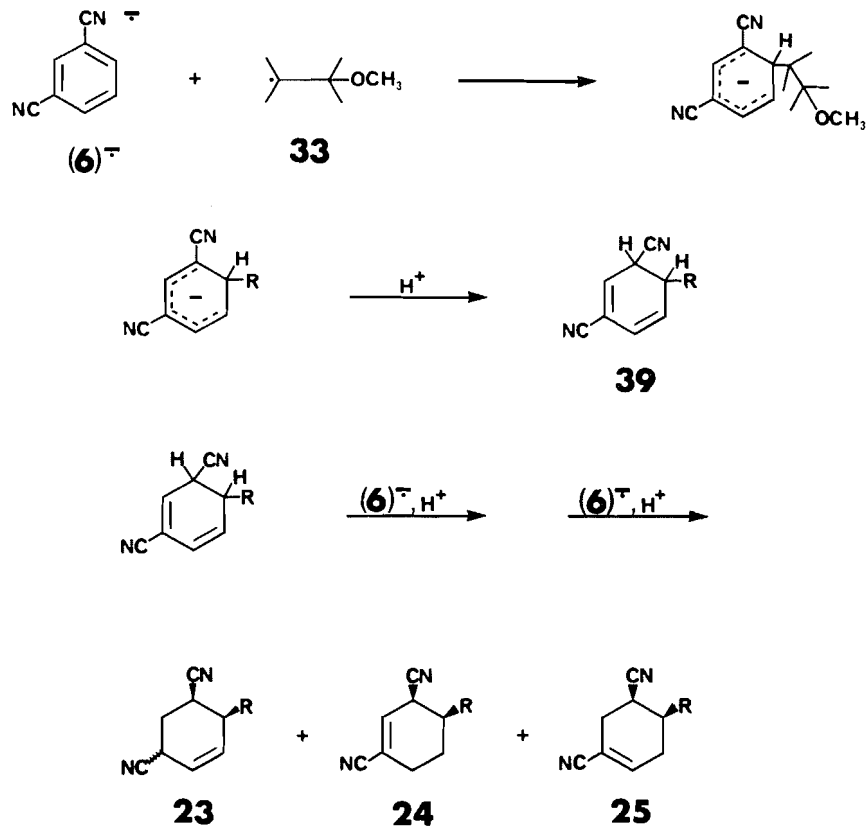

FIG. 18

of methanol and no reaction is then apparent. It is noteworthy that the observed regiospecificity (**27** was not detected, Fig. 7) has analogy in a related system (33), and provides evidence against a radical ion pair coupling (i.e. "zwitterion") mechanism occurring in methanol.

While some aspects of the mechanistic details of the photosubstitution (electron transfer) reaction still need clarification, the results clearly demonstrated the scope and limitations of the method. Efficient substitution is limited mainly to 1,2- and 1,4-dicyanobenzenes, but other polycyano-substituted aromatic hydrocarbons may also yield useful products. The use of phenanthrene as a photosensitizer has enhanced the scope of these reactions. The addition of methanol to the solvent not only renders the photolysis more efficient, but results in the incorporation of an ether function on the alkyl side chain which may serve as a useful "handle" in subsequent transformations.

The photosubstitution of dicyanobenzenes is limited to alkenes with an oxidation potential similar to, or less than, that of cyclohexene ($E^{ox}_{1/2} = +1.95$ V vs. Ag). Furthermore, the use of olefins that lead to a nonsymmetrical allylic-stabilized radical would increase the number of possible products, separation of which may not be a trivial problem.

One of the objectives of this work was to determine whether the anomalous behaviour of 1,3-dicyanobenzene (**6**), observed in other systems when compared to the 1,2- and 1,4-isomers, would also appear here. Clearly, this was the case once again and the anomaly may be attributed to a difference in the reactivity of the radical anion of **6**.

Evidence for this difference also stems from the electrochemical reduction of the dicyanobenzenes. The reduction of 1,2- and 1,4-dicyanobenzene (**5** and **1**) as electrochemically reversible, indicating their radical anions are stable within the time scale of the sweep. On the other hand, the reduction of 1,3-dicyanobenzene (**6**) is irreversible.

The irreversible electrolytic reduction of **6** in dimethylformamide (DMF) has also been reported by Baranski and Fawcett (34), who attributed the phenomenon to rapid reaction of an unstable radical anion, $\mathbf{6}^{\bullet -}$. However, Fraenkel and coworkers (35) have reported that the electron spin resonance (esr) spectrum of $\mathbf{6}^{\bullet -}$, generated electrochemically in DMF, was very persistent and thus the species causing it was quite stable. However, it was also observed that the signal was very weak when compared to that given by the radical anions of **5** and **1**, generated under identical conditions. Furthermore, the authors expressed less confidence in assigning the spectrum unequivocally to $\mathbf{6}^{\bullet -}$. There is, therefore, good reason to doubt whether this species was actually being observed. The radical anion of **6** has, however, been generated by alkali-metal reduction in tetrahydrofuran (36) and the measured electronic absorption spectrum was in good agreement with theoretical calculations. Similar results were obtained for **5** and **1**. Therefore all three dinitriles behave similarly under alkali-metal reduction conditions.

A possible interpretation of these results is that, in the electrochemical system, more than one electron is being transferred during the reduction of **6** (for example, to form the dianion), while true one-electron reduction is occurring in the chemical (as well as photochemical) system. This leads to the proposal that the radical anions of all three dicyanobenzenes can indeed be generated chemically, electrochemically, or photochemically, but the difference in the reactivity of $\mathbf{6}^{\bullet -}$, when compared to $\mathbf{5}^{\bullet -}$ or $\mathbf{1}^{\bullet -}$, causes this species to behave differently photochemically, and possibly to be further reduced in the electrochemical system. It is hoped that future photophysical,

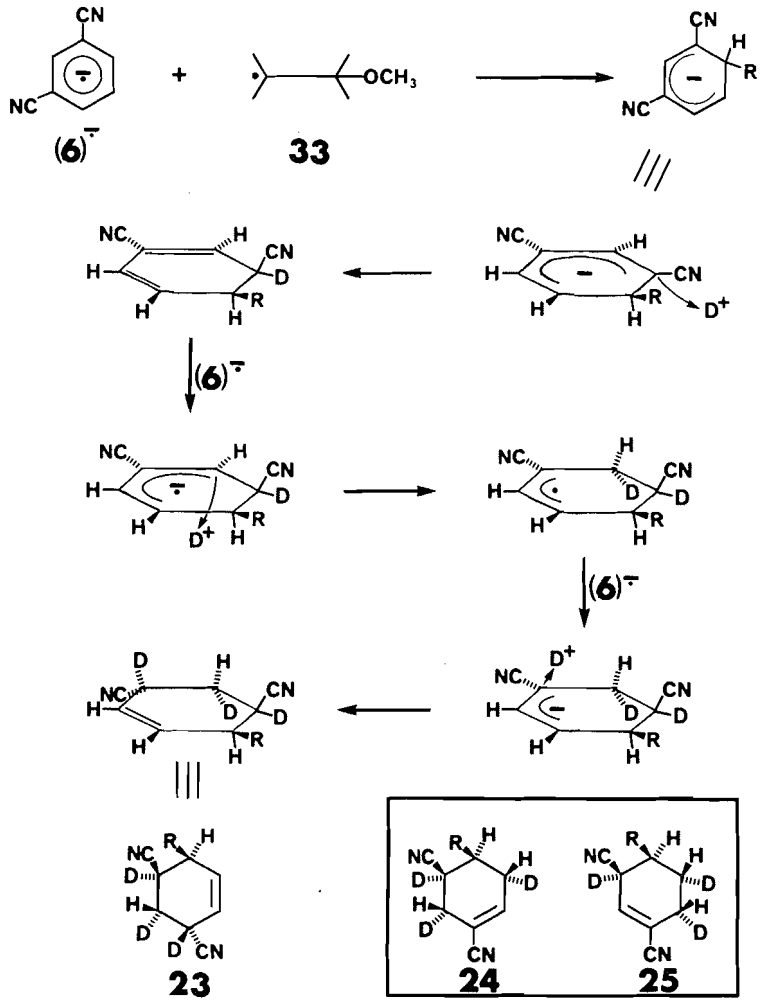

FIG. 19

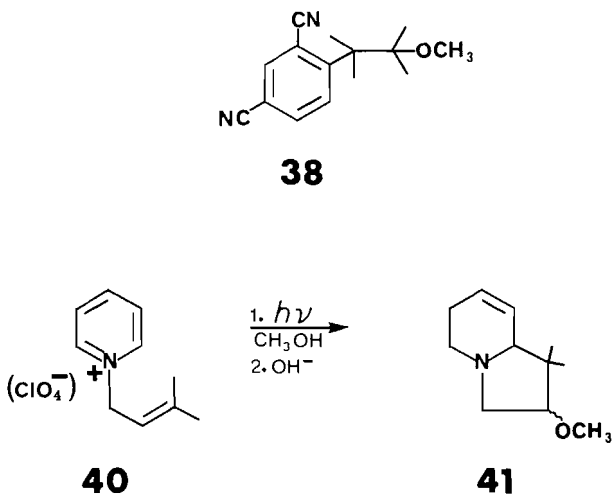

FIG. 20

electrochemical, esr spectral, and theoretical studies will shed some light on the reason(s) for this difference.

Experimental

General

Acetonitrile (Fisher, A.C.S. grade) for preparative work, as well as for photophysical and electrochemical studies, was purified by successive distillations from sodium hydride and phosphorous pentoxide, followed by passing through a basic alumina column and refluxing over calcium hydride and under nitrogen for 24 h, before distillation and storage over 3 Å molecular sieves. Dicyanobenzenes (Aldrich) were recrystallized four times from 95% ethanol and vacuum sublimed before use. 2,3-Dimethyl-2-butene (Aldrich 99+%) was used as received. Cyclohexene (Eastman) was passed through alumina and fractionally distilled before use. Methylpropene was obtained from Matheson and was of a minimum 99.8% purity. Methanol (Fisher, A.C.S. grade) was distilled and stored over 3 Å molecular sieves. Perdeutero-2,3-dimethyl-2-butene was prepared from the reaction between pinacol-d_{12} and triethyl orthoformate (37). The pinacol was synthesized by the reductive coupling of acetone-d_6 (Stohler Isotope Chemicals, 99.7% atom D), in the presence of magnesium (38).

All melting points are uncorrected. Elemental analyses were performed by Microanalysis Laboratories Limited, Toronto, Ontario, and agreed to within 0.3 of the calculated values for carbon and hydrogen and within 0.5 for nitrogen. Mass spectra were recorded on a Du Pont CEC Model 21-104 mass spectrometer, while accurate molecular ion masses were determined on a MAT Model 311A instrument.

X-ray data for the determination of structures was collected on an Enrauf–Nonius CAD-4 four circle diffractometer with automatic data collection utilizing a PDP8/a computer system (Digital Equipment Corporation). Subsequent computer operations were carried out on the Dalhousie Computer Centre's CYBER 170–720 (Control Data).

Infrared spectra were recorded on an air-purged Perkin–Elmer 180 grating spectrometer and are reported in wave numbers, calibrated against the 1602 cm^{-1} polystyrene absorption. Ultraviolet–visible absorption spectra were recorded on a Cary–Varian 219 spectrometer

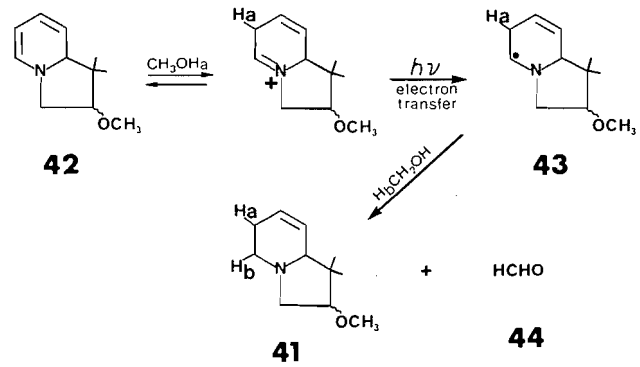

FIG. 21

and are reported in nanometers. The ^{1}Hmr and ^{13}Cmr spectra were obtained either on a Varian CFT-20 Fourier Transform nmr spectrometer or, where specified, on a Nicolet Model 360 NB spectrometer, coupled to an Oxford Instruments superconducting magnet and a Nicolet 192 kword data acquisition system. The solvents used were deuterochloroform or benzene-d_6. Tetramethylsilane or deuterochloroform were used as internal standards. Deuterium incorporation studies on compounds **23**–**25** were performed by ^{1}Hmr spectroscopy on the 360-MHz instrument. All other deuterium studies were carried out by ^{13}Cmr spectroscopy on a Varian XL-100 Fourier Transform nmr spectrometer, coupled to a Nicolet 1280 data system. Spectra were run in hexafluorobenzene/deuterochloroform (1:2) solution to which had been added 5 mg/mL chromium acetyl acetonate as a relaxation reagent. Spectra were acequired under total decoupling conditions from both ^{1}H and ^{2}H. Hexafluorobenzene was used as an internal standard (fluorine resonance). Chemical shifts were compared to those obtained for the natural abundance compounds under identical conditions. Differences of less than 0.4 ppm were considered as insignificant, i.e. deuterium substitution at that particular carbon atom was absent.

Measured oxidation and reduction potentials were obtained by cyclic voltammetry using a Princeton Applied Research Model 173 potentiostat/galvanostat, coupled to a Model 175 universal programmer. The working electrode was a platinum sphere, while the counter electrode was a platinum wire. A silver/silver nitrate (0.1 *M* in acetonitrile) electrode served as a reference potential. The electrolyte used was 0.1 *M* tetraethylammonium perchlorate (Eastman, recrystallized four times from 50% ethanol) in acetonitrile. The solutions were purged with dry nitrogen prior to each run, and a nitrogen atmosphere was maintained during the measurements. Substrate concentrations were typically 0.005 *M*. The voltammagrams were scanned at 20 mV s^{-1}, 100 mV s^{-1}, and 200 mV s^{-1}. The half-wave potentials were calculated as the average of the midpoints between the forward and reverse waves for the 100 mV s^{-1} scans. If the electron transfer process was not reversible, the half-wave was taken as 0.028 V before the anodic peak potential, or 0.029 V before the cathodic peak potential, at the 100-mV s^{-1} scan rate.

Fluorescence (emission) spectra were obtained on an Aminico–Bowman spectrophotofluorometer. Fluorescence quenching rate constants were obtained from Stern–Volmer type plots of fluorescence intensity, using a linear regression programme to estimate the best lines. Correlation coefficients (r^2) were always better than 0.99, except for the case of quenching by methylpropene (gaseous at room temperature) where values greater than 0.97 were considered acceptable. All solutions were degassed by four freeze–thaw cycles on a mercury-free vacuum line. Singlet energies were estimated from the intersection of the normalized absorption and emission spectra in acetonitrile. Singlet lifetime measurements were carried out on a Photochemical Research Associates single photon counting instrument. All photophysical and electrochemical measurements were carried out at room temperature.

Irradiations were carried out in 2-cm id Pyrex tubes using a General Electric Co. 1-kW medium pressure mercury lamp with a quartz cooling jacket immersed in a constant temperature bath at 10°C. Tube distance from the lamp was 6 cm. All samples were purged with nitrogen for 30 min prior to irradiation. Reaction mixtures were chromatographed on a low pressure liquid chromatography (lplc) system. This consisted of a Glenco Scientific Inc. glass column (2.5-cm id × 1 m), packed with 200 g of silica gel (Merck, 60 PF-254, for preparative layer chromatography) and coupled to a helium-pressurized solvent delivery system capable of near-linear solvent changes. The solvents used were distilled hexanes, changing gradually to distilled methylene chloride, followed by elution by the latter solvent alone. Fractions were monitored by an Instrumentation Specialities Co. Model UA-5 absorbance monitor (254 and 280 nm) and (or) by gas chromatography. Isolated compounds were further purified by lplc, as well as by several recrystallizations or by preparative gas chromatography.

Typically, 1 g (8 mmol) of the dicyanobenzene and 12 mmol of olefin (as well as 0.3 g (1.5 mmol) of phenanthrene where applicable) were dissolved in 25 mL of acetonitrile (or acetonitrile–methanol, 3:1 by volume) and irradiated. The course of the reactions was monitored by gas chromatography (gc) on a PYE Unicam Series 104 chromatograph equipped with a flame ionization detector. The column used was a 5 ft × 1/16 in. glass capillary packed with a 20% loading of SE-30 on Chromosorb W 60/80 mesh (Chromatographic Specialties Ltd.) with nitrogen as a carrier gas. When no further change was observed, solvent was removed by evaporation and the reaction mixture chromatographed as described earlier. All % yields reported are based on consumed dicyanobenzene.

The irradiation of 1,2-dicyanobenzene in the presence of 2,3-dimethyl-2-butene, in acetonitrile solution

Irradiation time: 140 h.

1-(2-Cyanophenyl)-2,3-dimethyl-2-butene (**7**): 0.10 g, 16%; ir (neat film), ν_{max}; 3070 (w), 2990 (m), 2920 (s), 2860 (m), 2225 (s), 1600 (m), 1485 (s), 1375 (m), 1125 (m), 760 (s), 700 (w); uv, λ_{max} (log ϵ_{max}), (hexane): 283 (3.16), 275 (3.10), 268 (sh, 2.93), 223 (3.96); ^{1}Hmr ($CDCl_3$), δ_{TMS}: 7.67–7.13 (m, 4H), 3.63 (s, br, 3H), 1.76 (s, br, 6H), 1.59 (s, br, 3H); ^{13}Cmr ($CDCl_3$), δ_{CDCl_3}: 144.9 (s), 132.6 (2 resonances, d), 128.7 (d), 127.8 (s), 126.2 (d), 124.1 (s), 118.0 (s), 112.8 (s), 38.2 (t), 20.6 (q), 20.5 (q), 18.1 (q); ms, 70 eV, *m/e* (relative intensity): 185 (M^+, 78), 171 (21), 170 (100), 143 (48), 142 (21), 116 (42). *Anal.* calcd. for **7**, $C_{13}H_{15}N$: C 84.28, H 8.16; found: C 84.11, H 8.09.

3-(2-Cyanophenyl)-2,3-dimethyl-1-butene (**8**): 0.11 g, 18%; ir (neat film), ν_{max}: 3070 (w), 2990 (s), 2225 (s), 1645 (m), 1600 (m), 1475 (s), 1445 (s), 1380 (m), 899 (s), 770 (s); uv, λ_{max} (log ϵ_{max}), (hexane): 282 (3.07), 270 (sh, 2.82), 226 (3.95); ^{1}Hmr ($CDCl_3$), δ_{TMS}: 7.60–7.25 (m, 4H), 5.03–4.99 (m, 1H, A part of an ABX_3 system, J_{AB} = 1.2 Hz, J_{AX} = 1.5 Hz), 4.85–4.83 (M, 1H, B part, J_{AB} = 1.2 Hz, J_{BX} = 0.5 Hz), 1.66 (m, 3H, X_3), 1.57 (s, 6H); ^{13}Cmr ($CDCl_3$), δ_{CDCl_3}: 151.6 (s), 149.9 (s), 135.2 (d), 132.3 (d), 126.8 (d), 126.2 (d), 118.9 (s), 112.6 (t), 111.7 (s), 44.5 (s), 27.9 (2 resonances, q), 20.0 (q); ms, 70 eV, *m/e* (relative intensity): 185 (M^+, 32), 170 (100), 144 (27), 143 (24), 142 (20), 129 (18), 116 (38). *Anal.* calcd. for **8**, $C_{13}H_{15}N$: C 84.28, H 8.16; found: C 84.51, H 8.32.

2-Cyano-3-(2-cyanophenyl)-2,3-dimethylbutane (**12**): traces; ir (neat film), ν_{max}: 3070 (w), 2990 (s), 2225 (sh, m), 2220 (s), 1595 (m), 1480 (br, s), 1460 (s), 1385 (s), 1375 (m), 1145 (s), 765 (s); uv, λ_{max} (log ϵ_{max}), (hexane): 282 (3.20), 274 (3.14), 270 (sh, 2.96), 266 (2.92), 234 (sh, 3.93), 226 (4.05); ^{1}Hmr ($CDCl_3$), δ_{TMS}: 7.78–7.60 (m, 4H), 1.78 (s, 6H), 1.38 (s, 6H); ^{13}Cmr ($CDCl_3$), δ_{CDCl_3}: 146.4 (s), 135.9 (d), 132.2 (d), 130.5 (d), 127.3 (d), 123.9 (s), 117.9 (s), 112.2 (s), 43.8 (s), 42.0 (s), 25.6 (q), 23.3 (q); ms, 70 eV, *m/e* (relative intensity): 212 (M^+, weak), 197 (M − 15, weak), 144 (100), 128 (5), 127 (3), 117 (15), 116 (45), 115 (10). *Exact Mass* of **12**: $C_{14}H_{16}N_2$ requires 212.13135; found: 212.13177. Recovered **5**: 0.29 g, 71% consumption.

The irradiation of 1,2-dicyanobenzene in the presence of 2,3-dimethyl-2-butene, in benzene solution

The above experiment was repeated with benzene as a solvent, in the place of acetonitrile. Monitoring by gas chromatography indicated

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/06/12
For personal use only.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/06/12
For personal use only.

that only traces of **7** and **8** were formed under these conditions, even after prolonged irradiation.

The irradiation of 1,2-dicyanobenzene and 2,3-dimethyl-2-butene in acetonitrile solution, in the presence of phenanthrene as a photosensitizer (electron transfer)

Irradiation time: 24 h. Recovered sensitizer **11**: 0.22 g, 73% recovery. Compound **7**: 0.30 g (21%). Compound **8**: 0.350 g (24%).

9-Cyanophenanthrene (**28**): 0.03 g; mp 107–108°C (ethanol) (lit. (39) mp 110°C). This compound also possessed an identical ^{1}Hmr spectrum to that reported in ref. 40.

9-Cyano-9-10-dihydrophenanthrene (**29**): 0.025 g; mp 85–85.5°C (ethanol/H_2O) (lit. (7*b*) mp 84–85°C). The ^{1}Hmr spectrum of this compound was identical to that reported in the literature (7*b*). Compound **12**: 0.15 g (9%). Recovered **5**: 0.0 g, 100% conversion.

The irradiation of 1,2-dicyanobenzene and 2,3-dimethyl-2-butene in acetonitrile solution, in the presence of phenanthrene; irradiation through a Corning CS-7-51 filter

In each of two nmr tubes (Pyrex, 5 mm) was placed a mixture of 25 mg (0.2 mmol) 1,2-dicyanobenzene (**5**), 25 mg (0.3 mmol) of 2,3-dicyanobenzene (**5**), 25 mg (0.3 mmol) of 2,3-dimethyl-2-butene (**2**), and 0.5 mL acetonitrile. To one tube was also added 7.5 mg (0.04 mmol) of phenanthrene (**11**). Both tubes were then irradiated simultaneously through a Corning CS-7-51 light filter (λ_{cutoff} = 300 nm). The course of the reactions was monitored by gc. It was observed that formation of **7** and **8** was fairly rapid in the tube containing the sensitizer. Little reaction was observed in the other tube.

Irradiation of 1,2-dicyanobenzene and 2,3-dimethyl-2-butene in acetonitrile solution, in the presence of various polynuclear aromatic hydrocarbons as photosensitizers (electron transfer)

In each of four nmr tubes (Pyrex, 5 mm) was placed a mixture of 25 mg (0.2 mmol) 1,2-dicyanobenzene (**5**), 25 mg (0.3 mmol) of 2,3-dimethyl-2-butene (**2**), and 0.5 mL acetonitrile. To tubes 2, 3, and 4 were added 0.04 mmol of anthracene, naphthalene, and phenanthrene (**11**), respectively. All four tubes were irradiated simultaneously and the formation of the substitution products, **7** and **8**, was monitored by gc. It was observed that, relative to tube number 1 (i.e. no photosensitizer), the rate of product formation was enhanced by phenanthrene, but was not affected by the presence of naphthalene. Considerable quenching of the reaction was observed in the tube containing anthracene.

Irradiation of 1,3-dicyanobenzene in the presence of 2,3-dimethyl-2-butene, in acetonitrile solution

Irradiation time: 14 days.

1-(3-Cyanophenyl)-2,3-dimethyl-2-butene (**9**) and *3-(3-cyanophenyl)-2,3-dimethyl-1-butene* (**10**): 0.03 g (15%) of a mixture that could not be separated by column chromatography. Separation was achieved by means of preparative gas chromatography on a 6 ft × 3/8 in. aluminum column, packed with Chromosorb W loaded with 20% SE-30 (190°C). The isomers were present in the ratio of **9**/**10** as 1:1.2. Isomer **9**: ir (neat film), ν_{max}: 2990 (m), 2910 (s), 2855 (m), 2225 (s), 1595 (w), 1560 (m), 1480 (m), 1430 (br, m), 1370 (m), 1115 (w), 790 (s), 730 (m), 685 (s); uv, λ_{max} (log ϵ_{max}), (hexane): 282 (3.09), 274 (3.05), 266 (sh, 2.88), 212 (4.11); ^{1}Hmr ($CDCl_3$), δ_{TMS}: 7.38 (br, 4H), 3.41 (br, 2H), 1.75 (br, 6H), 1.57 (br, 3H); ^{13}Cmr ($CDCl_3$), δ_{CDCl}: 142.4 (s), 132.9 (d), 131.7 (d), 129.4 (d), 128.9 (d), 127.2 (s), 124.8 (s), 119.1 (s), 112.2 (s), 39.5 (t), 20.5 (2 resonances, q), 18.2 (q); ms, 70 eV, *m/e* (relative intensity): 185 (M^+, 49), 171 (14), 170 (100), 143 (10), 142 (24), 116 (16). *Anal.* calcd. for **9**, $C_{13}H_{15}N$: C 84.28, H 8.16; found: C 84.11, H 8.08. Isomer **10**: ir (neat film), ν_{max}: 3080 (w), 2970 (s), 2225 (s), 1640 (m), 1595 (w), 1575 (m), 1480 (s), 1440 (m), 1415 (m), 1375 (m), 1360 (w), 1175 (m), 895 (s), 795 (s), 690 (s); uv, λ_{max} (log ϵ_{max}), (hexane): 281 (3.02), 273 (2.99), 266 (2.82), 230 (4.03), 226 (4.06), 220 (4.06); ^{1}Hmr ($CDCl_3$), δ_{TMS}: 7.58–7.41 (m, 4H), 5.01–4.92 (m, 2H), 1.49 (br, 3H), 1.42 (s, 6H); ^{13}Cmr ($CDCl_3$), δ_{CDCl_3}: 151.0 (s), 149.9 (s), 130.6 (d), 129.8 (d), 129.4 (d), 128.8 (d), 119.1 (s), 112.1 (s), 110.7 (d), 43.9 (s), 28.0 (2 resonances, q), 19.9 (q); ms, 70 eV, *m/e* (relative intensity): 185 (M^+, 31), 171 (14), 170 (100), 144 (23), 143 (16), 142 (30), 116 (38). *Anal.* calcd. for **10**, $C_{13}H_{15}N$: C 84.28, H 8.16; found: C 84.21, H 8.06. Recovered **6**: 0.7 g, 30% conversion.

Irradiation of 1,3-dicyanobenzene and 2,3-dimethyl-2-butene in acetonitrile solution, in the presence of phenanthrene as a photosensitizer (electron transfer)

Irradiation time: 7 days. Recovered sensitizer: 0.2 g, 67% recovery. Compounds **9** and **10**: 0.06 g (7%).

1-(2,4-Dicyanophenyl)-2,3-dimethyl-2-butene (**14**): 0.30 g (28%); mp 90–90.5°C (95% ethanol); ir (KBr), ν_{max}: 3110 (w), 3070 (m), 3040 (w), 2995 (m), 2920 (s), 2860 (m), 2230 (s), 1605 (m), 1490 (s), 1450 (br, m), 1400 (m), 1373 (m), 1160 (m), 910 (m), 880 (w), 860 (m), 830 (w); uv, λ_{max} (log ϵ_{max}) (ethanol): 293 (3.13), 283 (3.10), 275 (3.05), 234 (4.13); ^{1}Hmr (360 MHz, $CDCl_3$), δ_{TMS}: 7.91 (dd, 1H, A part of an ABX system, J_{AB} = 1.8 Hz, J_{AX} = 0.6 Hz), 7.78–7.75 (dd, 1H, B part centered at 7.77 ppm, J_{BX} = 8.2 Hz), 7.39–7.36 (dd, 1H, X part centered at 7.38), 3.69 (s, 2H), 1.78 (s, 3H), 1.76 (s, 3H), 1.60 (s, 3H); ^{13}Cmr ($CDCl_3$), δ_{CDCl_3}: 150.2 (s), 135.8 (d), 135.5 (d), 129.8 (d), 129.3 (s), 122.7 (s), 116.7 (s), 115.8 (s), 114.3 (s), 110.9 (s), 38.5 (t), 20.6 (q), 20.4 (q), 18.2 (q); ms, 70 eV, *m/e* (relative intensity): 210 (M^+, 43), 195 (100), 180 (9), 170 (41), 169 (27), 168 (23), 155 (30), 141 (20). *Anal.* calcd. for **14**, $C_{14}H_{14}N_2$: C 79.96, H 6.71; found: C 79.96, H 6.64. Recovered **6**: 0.36 g, 64% conversion.

Irradiation of 1,4-dicyanobenzene and 2,3-dimethyl-2-butene in acetonitrile solution, in the presence of phenanthrene as a photosensitizer (electron transfer)

Irradiation time: 35 h. Recovered sensitizer **11**: 0.23 g, 77% recovery. Compounds **3** and **4**: 0.85 g (23%, 42% respectively). The spectral data of these two main products have been presented elsewhere (ref. 1*e*). 9-Cyanophenanthrene (**28**), and 9-cyano-9,10-dihydrophenanthrene (**29**): traces. Recovered **1**: 0.11 g, 90% conversion.

2-Cyano-3-(4-cyanophenyl)-2,3-dimethylbutane (**13**): 0.07 g (5%); ir (KBr), ν_{max}: 3070 (w), 2980 (s), 2930 (m), 2225 (s), 1605 (m), 1510 (m), 1470 (m), 1460 (m), 1405 (m); 1385 (m), 1195 (w), 1145 (m), 1090 (m), 1020 (w), 840 (m), 680 (m); uv, λ_{max} (log ϵ_{max}), (ethanol): 279 (2.91), 271 (2.96), 267 (sh, 2.89), 260 (sh, 2.78), 238 (4.24), 231 (4.30); ^{1}Hmr ($CDCl_3$), δ_{TMS}: 7.61 (s, 4H), 1.54 (s, 6H), 1.24 (s, 6H); ^{13}Cmr ($CDCl_3$), δ_{CDCl_3}: 149.1 (s), 131.4 (d), 128.4 (d), 124.1 (s), 118.3 (s), 110.6 (s), 42.2 (s), 40.4 (s), 23.9 (q), 23.0 (q); ms, 70 eV, *m/e* (relative intensity): 212 (M^+, weak), 197 (M − 15, weak), 144 (100), 116 (43), 104 (9). *Exact Mass* of **13**: $C_{14}H_{16}N_2$ requires 212.13135; found: 212.13136.

Irradiation of 1,2-dicyanobenzene in the presence of cyclohexene, in acetonitrile solution

Irradiation time: 10 days.

3-(2-Cyanophenyl)cyclohexene (**17**): 0.18 g (31%); ir (neat film), ν_{max}: 3060 (w), 3020 (m), 2930 (s), 2855 (m), 2835 (w), 2220 (s), 1650 (w), 1595 (w), 1480 (m), 1445 (s), 1430 (w), 760 (s), 740 (w), 720 (m), 680 (w), 660 (m); uv, λ_{max} (log ϵ_{max}), (hexane): 283 (3.37), 274 (3.26), 270 (sh, 3.08), 268 (3.06), 223 (4.09); ^{1}Hmr ($CDCl_3$), δ_{TMS}: 7.64–7.24 (m, 4H), 6.00–5.67 (m, 2H), 3.90–3.80 (br, 1H), 2.33–1.41 (m, 6H); ^{13}Cmr ($CDCl_3$), δ_{CDCl_3}: 150.1 (s), 132.8 (d), 132.6 (d), 129.9 (d), 128.1 (d), 127.9 (d), 126.4 (d), 117.9 (s), 111.9 (s), 39.9 (d), 31.4 (t), 24.6 (t), 20.7 (t); ms, 70 eV, *m/e* (relative intensity): 183 (M^+, 100), 168 (42), 155 (50), 154 (50), 140 (35), 129 (22), 128 (28), 127 (28), 116 (28), 115 (35). *Anal.* calcd. for **17**, $C_{13}H_{13}N$: C 85.20, H 7.15; found, C 85.22, H 7.19. Recovered **5**: 0.58 g, 42% conversion.

Irradiation of 1,3-dicyanobenzene in the presence of cyclohexene, in acetonitrile solution

No reaction could be observed by gas chromatography, even after prolonged irradiation (18 days). The usual work-up afforded the starting material **6** only. Recovery was 0.7 g (70%).

Irradiation of 1,4-dicyanobenzene in the presence of cyclohexene, in acetonitrile solution

Irradiation time: 10 days.

3-(4-Cyanophenyl)cyclohexene (**18**): 0.28 g (31%); ir (neat film)

ν_{max}: 3020 (m), 2930 (s), 2860 (m), 2840 (m), 2225 (s), 1650 (w), 1605 (s), 1505 (s), 1445 (m), 1415 (m), 1300 (m), 900 (m), 880 (m), 830 (s); uv, λ_{max} (log ϵ_{max}), (hexane): 277 (2.47), 273 (2.62), 271 (2.60), 266 (2.79), 2.58 (2.70), 241 (4.24), 234 (4.29); ^{1}Hmr ($CDCl_3$), δ_{TMS}: 7.63–7.25 (AB quartet, centered at 7.44), 5.91–5.66 (m, 2H), 3.48–3.41 (br, 1H), 2.22–1.55 (m, 6H); ^{13}Cmr ($CDCl_3$), δ_{CDCl_3}: 152.1 (s), 132.0 (d), 129.4 (d), 128.4 (d), 128.3 (d), 118.9 (s), 109.7 (s), 41.7 (d), 32.1 (t), 24.7 (t), 20.7 (t); ms, 70 eV, *m/e* (relative intensity): 183 (M^+, 75), 155 (66), 140 (86), 130 (100), 116 (79), 102 (57). *Anal.* calcd. for **18**, $C_{13}H_{13}N$: C 85.20, H 7.15; found: C 84.89, H 6.89. Recovered **1**: 0.37 g, 63% conversion.

Irradiation of 1,4-dicyanobenzene and cyclohexene in acetonitrile solution in the presence of phenanthrene as a photosensitizer (electron transfer)

Irradiation time: 8 days. Recovered sensitizer **11**: 0.05 g, 17% recovery. Compound **18**: 0.26 g (56%).[7] 9-Cyanophenanthrene (**28**): 0.04 g. 9-Cyano-9,10-dihydrophenanthrene (**29**): 0.11 g. Recovered **1**: 0.69, 31% conversion.

Irradiation of 1,4-dicyanobenzene in the presence of methylpropene, in acetonitrile solution.

No reaction was observed between **1** and **19**, even after prolonged irradiation (10 days). The usual work-up resulted in the recovery (0.65 g, 65% recovery) of **1**. The same results were obtained when phenanthrene (**11**) was used as a photosensitizer (electron transfer).

The detection of exciplex emission from solutions of dicyanobenzene and 2,3-dimethyl-2-butene in hexane

To solutions of the dicyanobenzene (10^{-3} *M*) in hexane, in a 1-cm path-length fluorescence cell, was added 2,3-dimethyl-2-butene (**2**), in 1-μL portions, while the fluorescence (emission) spectrum of the cyanoaromatic was monitored simultaneously. Quenching of the fluorescence was observed in all three cases, together with the concurrent rise of a weak new emission maximum. The approximate position of this exciplex emission was 380 nm in the case of 1,2- and 1,4-dicyanobenzene, and 385 nm for the 1,3-dicyanobenzene/olefin system. Similar results were obtained when cyclohexene (**16**) or methylpropene (**19**) were the quenchers. However, the very low intensities of the exciplex emission rendered the determination of the emission maxima difficult.

Irradiation of 1,2-dicyanobenzene and 2,3-dimethyl-2-butene in acetonitrile–methanol solution, in the presence of phenanthrene as a photosensitizer (electron transfer)

Irradiation time: 22 h. Recovered sensitizer **11**: 0.15 g, 50% recovery. Compounds **7** and **8**: traces. 9-Cyanophenanthrene (**28**): 0.03 g. 9-Cyano-9,10-dihydrophenanthrene (**29**): 0.19 g.

3-(2-Cyanophenyl)-2-methoxy-2,3-dimethylbutane (**21**): 0.25 g (45%); ir (neat film), ν_{max}: 3070 (w), 2990 (s), 2960 (sh, s), 2830 (m), 2220 (s), 1595 (m), 1480 (s), 1375 (s), 1365 (m), 1155 (s), 1080 (s), 1065 (s), 760 (s); uv, λ_{max} (log ϵ_{max}), (hexane): 282 (3.09), 273 (3.08), 266 (sh, 2.87), 233 (sh, 3.90), 226 (4.01); ^{1}Hmr ($CDCl_3$), δ_{TMS}: 7.68–7.29 (m, 4H), 3.15 (s, 3H), 1.59 (s, 6H), 1.06 (s, 6H); ^{13}Cmr ($CDCl_3$), δ_{CDCl_3}: 149.8 (s), 135.4 (d), 130.7 (d), 130.3 (d), 125.8 (d), 119.9 (s), 113.7 (s), 78.5 (s), 48.7 (q), 47.2 (s), 25.2 (q), 19.5 (q); ms, 70 eV, *m/e* (relative intensity): 218 (MH^+, 2), 202 (63), 186 (69), 171 (21), 170 (46), 145 (19), 144 (67), 143 (42), 130 (71), 129 (27), 128 (38), 127 (19), 117 (27), 116 (100), 115 (46), 103 (27), 102 (33), 73 (intense, >300). *Anal.* calcd. for **21**, $C_{14}H_{19}NO$: C 77.38, H 8.81, N 6.45; found: C 77.26, H 8.76, N 6.38. X-ray data for ***25***

Monoclinic; a = 9.231 (1), b = 6.884 (2), c = 22.973 (3) Å; $\alpha = 90°$, $\beta = 101.946°$ (11), $\gamma = 90°$. Spacegroup $P2_1/C$, Z = 4; 1946 unique reflections of which 981 had $I > 3\sigma(I)$. The final refinement converged at R = 0.0333 (0.1104 on full data). MoKα, λ = 0.70926 Å, 20°C. (Supplemental material is available).

Irradiation of 1,3-dicyanobenzene and 2,3-dimethyl-2-butene in acetonitrile–methanol solution, in the presence of phenanthrene as a photosensitizer (electron transfer): irradiation for a prolonged period

The experiment described above was repeated except that a longer irradiation time was employed (5 days). The usual work-up afforded the following compounds. Recovered sensitizer **11**: 0.22 g, 73% recovery. 9-Cyanophenanthrene (**28**) and 9-cyano-9,10-dihydrophenanthrene (**29**): traces. Compound **22**: 0.06 g (5%). Recovered **6**: 0.28 g, 73% conversion. Compound **23**: traces. Compound **24**: 0.10 g (7%). Compound **25**: 0.21 g (15%).

Irradiation of 1,3-dicyanobenzene in the presence of 2,3-dimethyl-2-butene, in acetonitrile–methanol

Irradiation time: 14 days. Recovered **6**: 0.49 g, 51% conversion. Compound **23**: trace. Compound **24**: 0.05 g (5%). Compound **25**: 0.041 g (4%).

Irradiation of 1,4-dicyanobenzene in the presence of methylpropene, in acetonitrile–methanol solution

Irradiation time: 20 days.

2-(4-Cyanophenyl)-1-methoxy-2-methylpropane (**26**): 0.02 g (4%); ir (neat film), ν_{max}: 2970 (s), 2930 (s), 2870 (s), 2930 (m), 2920 (m), 2225 (s), 1605 (s), 1505 (s), 1395 (s), 1365 (m), 1200 (m), 1115 (s), 1095 (s), 960 (m), 835 (s); uv, λ_{max} (log ϵ_{max}), (hexane): 277 (2.60), 272 (2.66), 269 (sh, 2.65), 266 (2.73), 260 (sh, 2.61), 2.58 (2.63), 238 (4.20), 228 (4.26); ^{1}Hmr ($CDCl_3$), δ_{TMS}: 7.54–7.51 (4H, AB quartet), 3.40 (s, 2H), 3.28 (s, 3H), 1.32 (s, 6H); ^{13}Cmr ($CDCl_3$), δ_{CDCl_3}: 153.1 (s), 131.6 (d), 126.8 (d), 118.8 (s), 109.4 (s), 81.8 (t), 59.1 (q), 39.4 (s), 25.7 (q); ms, 70 eV, *m/e* (relative intensity): 190 (MH^+, 37), 159 (21), 144 (69), 143 (13), 128 (9), 116 (61), 115 (8), 104 (13), 89 (9), 45 (100). *Anal.* calcd. for **26**: $C_{12}H_{15}NO$: C 76.15, H 7.99, N 7.40; found: C 76.11, H 8.21, N 7.03.

No reaction was observed when the above irradiation was repeated in the presence of phenanthrene (**11**).

Structure–activity studies of β-carbolines. 2. Crystal and molecular structures of *N*-ethyl-3-carbamoyl-β-carboline

ALASTAIR K. S. MUIR AND PENELOPE W. CODDING[1]

Departments of Chemistry and Pharmacology and Therapeutics, University of Calgary, Calgary, Alta., Canada T2N 1N4

Received January 17, 1984

ALASTAIR K. S. MUIR and PENELOPE W. CODDING. Can. J. Chem. **62**, 1803 (1984).

The crystal and molecular structures of *N*-ethyl-3-carbamoyl-β-carboline, $C_{14}H_{13}N_3O$, a synthetic ligand of the benzodiazepine receptor are reported. The space group is $C2/c$ with $a = 16.220(4)$, $b = 7.728(4)$, $c = 19.623(6)$ Å, $\beta = 104.16(1)°$, $Z = 8$. The carboxyamide side chain assumes an extended conformation and is almost coplanar with the β-carboline skeleton. The observed molecular conformation is compared to the current model for the receptor binding site. Hydrogen bonding and aromatic ring stacking determine the molecular packing arrangement.

ALASTAIR K. S. MUIR et PENELOPE W. CODDING. Can. J. Chem. **62**, 1803 (1984).

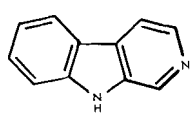
On rapporte les structures cristalline et moléculaire de la *N*-éthyl carbamoyl-3 β-carboline, $C_{14}H_{13}N_3O$, un ligand synthétique du récepteur benzodiazépine. Le groupe d'espace est $C2/c$ avec $a = 16{,}220(4)$, $b = 7{,}728(4)$, $c = 19{,}623(6)$ Å, $\beta = 104{,}16(1)°$, $Z = 8$. La chaîne latérale carboxyamide assume une conformation allongée et elle est pratiquement coplanaire avec le squelette de la β-carboline. On compare la conformation moléculaire observée avec le modèle couramment accepté pour le site de liaison du récepteur. L'arrangement de l'empilement moléculaire est déterminé par les liaisons hydrogènes et par l'entassement des noyaux aromatiques.

[Traduit par le journal]

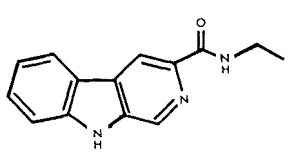
Introduction

Anti-anxiety drugs of the benzodiazepine family are heavily prescribed and hence are the subject of a large number of studies. In the past few years, a natural receptor for benzodiazepines has been identified in brain tissue (1). This finding motivated an extensive search for the endogenous ligand for the receptor. Of the many supposed ligands, several derivatives of β-carboline (**1**) have had the highest affinity for the benzodiazepine (BZD) receptor.

The β-carbolines (1) have been identified in brain tissue and in urine (2, 3); unfortunately, the actual derivatives that have been identified, 3-alkyl esters, are apparently formed in the isolation procedure. The actual endogenous congener of the 3-carboxy-β-carboline is still sought. Pharmacological tests indicate that some of the β-carbolines with affinity for the BZD receptor are antagonists of the action of the benzodiazepines and are therefore anxiogenic in nature. This finding leads to speculation that the physiological function of the BZD receptor involves alertness and other related attributes. The structure–activity data on these compounds show that the most active β-carbolines are unsaturated and uncharged (4–7); the most active synthetic structures are the 3-hydroxymethyl or 3-ethyl ester derivatives (6). It is possible that the natural side chain on C-3 is a link to a peptide; indeed, the β-carboline skeleton is related to tryptophan and may have similar biological origins.



1



2

To model this peptide link and to develop β-carbolines that are more resistant to enzymic hydrolysis, Coutts, Micetish, and co-workers (5) prepared 3-carboxamide derivatives of β-carboline for testing. In in vitro tests, these amides are less potent inhibitors of ^{3}H-flunitrazepam binding than the alkyl esters, but they still have significant activity. The amides may also have longer half-lives in vivo so that their effect may be comparable to the esters. These amide compounds are of interest because of the possibility of electron delocalization over the entire carboxyamide. This would change the charge density on the carbonyl oxygen atom. The hydrogen bonding capability of the side chain would then be different in amides from that in esters.

Since the β-carbolines and the benzodiazepines bind to the same receptor they must share at least some components of the same pharmacophoric unit. A model for β-carboline and benzodiazepine binding has been developed through distance geometry analysis (8); this method correlates binding free energies with patterns of atom–atom distances within average, rigid molecular structures. The binding site model developed from these considerations found 4 affinity sites and a restriction site for the β-carbolines. The binding site for the side chain in the 3 position did not reflect the variation in activity observed when that group is changed from ester to amide to hydroxymethyl; the binding was proposed to involve only the terminal methyl atom of the *ethyl* ester side chain.

In this work the three-dimensional structure of *N*-ethyl-3-carbamoyl-β-carboline (**2**) is described. The structure is examined with respect to the bonding of the carboxyamide group and the fit to the binding site model developed by Crippen (8). In an earlier paper (9), the structure of the most active of the saturated β-carbolines was reported, 3-carboxyltetrahydroharmane. (All of the saturated β-carbolines are less active than the unsaturated compounds.) The differences in the two types of molecular skeletons will be examined and related to their potential as ligands for the benzodiazepine receptor.

Experimental

A sample of the title compound was provided by R.T. Coutts and R.G. Micetish of the Faculty of Pharmacy, University of Alberta. The compound was crystallized by slow evaporation of a 50:50 mixture of ethanol and water. A colorless, rectangular crystal (0.15 × 0.20 ×

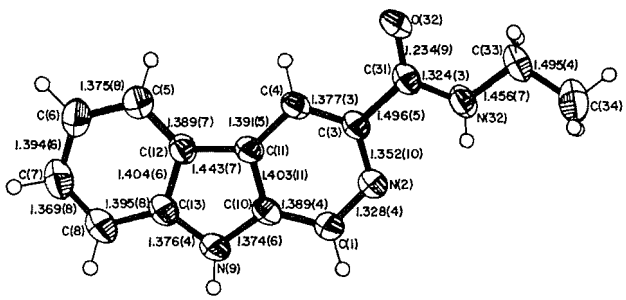

FIG. 1. The atomic labeling scheme and bond distances for the carbon, oxygen, and nitrogen atoms of *N*-ethyl-3-carbamoyl-β-carboline. The estimated standard deviations are in parenthesis. The drawing was made with the program ORTEP (24).

0.20 mm) was used for data collection on an Enraf Nonius CAD4F diffractometer with a graphite monochromator. Crystal data: $C_{14}H_{13}N_3O$ fw = 239.28 Monoclinic, $C2/c$, a = 16.220(4), b = 7.728(4), c = 19.623(6) Å, β = 104.16(1)°, V = 2385.0 Å^3, Z = 8, ρ_c = 1.333 g cm^{-3}, T = 20°C, MoKα, λ = 0.71069 Å, θ_{max} = 30°, 3472 unique reflections, 1133 observed, μ = 0.94 cm^{-1}. Lattice and space group determination and data collection procedures were as described previously (9). Lorentz and polarization corrections were applied.

The structure was solved using MULTAN 78 (10) and difference Fourier syntheses to complete the model. Full-matrix least-squares refinement of the coordinates and isotropic temperature factors converged to an R ($\Sigma||F_o| - |F_c||/\Sigma|F_o|$) value of 0.115. Successive difference Fourier syntheses then revealed the positions of the hydrogen atoms.

Hydrogen atoms were assigned isotropic thermal parameters that were 20% larger than those of the atom to which they were bonded and were included in the model; however, only their positional parameters were refined. The weighting scheme used in the refinement was $w = [[\sigma(F)]^2 + 0.001\ F^2]^{-1}$. The full-matrix least-squares refinement of the positional and anisotropic thermal parameters of the non-hydrogen atoms and the positional parameters of the hydrogen atoms converged with a maximum shift/error of 0.002, R = 0.032, and $R_w(\Sigma w(|F_o| - |F_c|)^2/\Sigma wF_o^2)^{1/2}$ = 0.038. The standard deviation of an observation of unit weight was 0.98; the largest peak in a final difference Fourier synthesis was 0.23 eÅ^{-3} and was associated with the C(11)—C(12) bond. The function minimized was $w(|F_o| - |F_c|)^2$ and the 2206 reflections used in the final refinement were the 1133 observed reflections and the 1073 unobserved reflections that had $F_c^2 > 2.5\sigma(I_o)$. Atomic coordinates are given in Table 1[2] with the atoms labeled as in Fig. 1. The bond distances for the carbon, nitrogen, and oxygen atoms are given in Fig. 1. The XRAY 76 system (11) of programs as used and the scattering factors were those of Cromer and Mann (12).

Results and discussion

Figure 1 shows the molecular structure of *N*-ethyl-3-carbamoyl-β-carboline. The carboxyamide side chain adopts an extended conformation as exemplified by the torsion angles: C(3)—C(31)—N(32)—C(33) = −177.0(2)° and C(31)—N(32)—C(33)—C(34) = 172.4(2)°. An *anti* arrangement of carbonyl oxygen atom (O(32)) and ring nitrogen atom (N(2)) across the C(3)—C(31) partial double bond is observed in this structure. Table 2 tabulates the N—C—C—O torsion angle for the 10 published examples of crystal structures containing a 2-carbamoylpyridine fragment and for this structure. In all but one case, the pyridinyl nitrogen atom is *anti* to the carbonyl oxygen atom; in the exception, α-picolinamide (15), the conformation deviates from this *antiperiplanar* conformation by only 18°. This consistent observation of one conformation for this fragment is important for the development of a model for the binding of β-carbolines to the benzodiazepine receptor because it has been established that activity is greatly dependent on the presence and the type of oxygen substituent on the carbon atom attached to the ring at C(3). The model for β-carboline binding that has been developed by distance constraint analysis (8) uses a different conformation for this group, i.e. *synclinal*, and this conformation has not been observed in any amide structure.

The ring system of the β-carboline nucleus is planar; the standard deviation for the 13 atom plane is 0.021 Å. The carboxyamide side chain lies approximately in this plane; the methyl carbon atom, C(34), shows the only significant deviation, 0.204 Å, from the plane. The carboxyamide group is also planar (σ = 0.003 Å) and the angle between the carboxyamide plane and the β-carboline is 0.6°. This coplanarity is evidence for an extensive delocalization of electrons throughout the entire π system of the β-carboline and carboxyamide group. In contrast, in the tetrahydroharmane molecule (9), the angle between the plane of the indole fragment and the carboxylic acid fragment was 58.9°.

The bond distances for the β-carboline ring are comparable to those found in other determinations of this unsaturated skeleton (21, 22) and are indicative of the aromatic nature of the ring system. The carboxyamide group shows the delocalization known to be typical of peptide linkages with distances C(31)—O(32) of 1.234(9) Å and for C(31)—N(32) of 1.324(3) Å. These values are also consistent with those observed in the other 10 examples of the 2-carbamoyl-pyridine fragment as shown in Table 2. In addition, the connecting C(3)—C(31) bond is considerably shortened, 1.496(5) Å, which suggests an overlap of the two π-systems. Both the bond distances and the overall planarity of the molecule are evidence for a delocalized π-system for the ring and carboxyamide por-

[2] Tables of the anisotropic thermal parameters, the bond angles for the non-hydrogen atoms, hydrogen atom parameters, and the observed and final calculated structure amplitudes are available, at a nominal charge, from the Depository of Unpublished Data, CISTI, National Research Council of Canada, Ottawa, Ontario, Canada K1A 0S2.

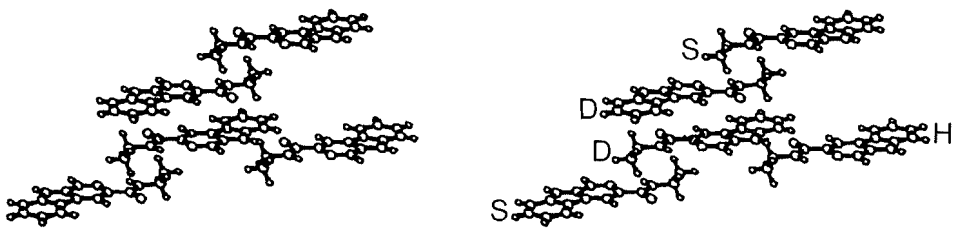

FIG. 2. A stereodrawing showing the close intermolecular contacts in the crystal. These are a dimer (D) contact, a side chain contact (S), and a hydrogen bond (H). The drawing was made with the program PLUTO (25).

tion of the side chain. Pharmacological testing has established that the fully aromatic β-carbolines are more active than their saturated congeners. Together, the two findings suggest that a π−π interaction with components of the receptor may play a role in the binding of these molecules. The delocalization of electrons into the side chain will change the energy of the π levels of the β-carboline and affect their possible interactions with portions of the receptor.

Often the intermolecular interactions in a crystal can be viewed as models for the types of forces that are important for binding to the receptor molecule (23). In this crystal, hydrogen bonding is one determinant of the packing. The bond is formed between molecules related by the face-centering of the crystal lattice; i.e., between N(9) and O(32) at $(1/2 + x, y - 1/2, z)$. This is shown in Fig. 2 as the contact between the lower molecule labeled D and the molecule labeled H. The bond is relatively weak, since the H(9)...O(32) distance is long at 1.96(2) Å, and the N(9)—H(9)...O(32) angle is 154(2)°. In paper 1 of this series (9) it was reported that the carboxylic acid derivative of β-carboline has extensive hydrogen bonding as part of the crystal environment. In both of these examples of 3-substituted β-carbolines, the oxygen atoms have functioned as hydrogen bond acceptors. Since it is known (6) that an oxygen-substituted side chain at position 3 of the β-carboline ring is necessary for maximal activity at the benzodiazepine receptor, it would appear that hydrogen-bond formation must be part of the interaction with the receptor. Rather surprisingly, the model developed by Crippen (8) does not include this site as a significant component of the binding features of these molecules.

Figure 2 shows some of the key features of the packing of the molecules of *N*-ethyl-3-carbamoyl-β-carboline. The molecules stack in dimers (labeled D) that are related by the inversion center at $(-1/2, -1/2, 0)$ and are separated by ca. 3.5 Å. The dimer stacks the carboxamide π-system over the π-system of the A ring of the β-carboline. The closest atom–atom distance is 3.464(8) Å from C(4) to N(2). The dimers are stacked in a ribbon through the operation of the center of symmetry at the cell origin. This dimer-to-dimer interaction places the carboxamide side chains in proximity, with the closest approach between C(33)—O(32) at 3.537(4) Å. In Fig. 2, this interaction is shown above and below the dimer by the molecules labeled S. The cell contains several ribbons that have a close contact of 3.74(1) Å between the methyl carbon atoms (C(34)) of the side chains in two neighboring ribbons, one at (x, y, z) and the other at $(1 - x, y, -z - 1/2)$. Close stacking of π-systems is

For personal use only.

important in this crystalline environment. The higher activity of unsaturated β-carboline derivatives and this packing arrangement are consistent with a $\pi-\pi$ interaction between these molecules and the benzodiazepine receptor.

In summary, analysis of this structure and the previous one in this series (9) has led to the identification of a hydrogen bond *acceptor* site as a part of the receptor binding features of β-carbolines. This site has not been identified in the model of β-carboline binding (8). In addition, analysis of the bonding and the crystalline environment of the title compound and like molecules has indicated that a single side chain conformation as well as electron delocalization and $\pi-\pi$ interactions are important in the unsaturated β-carboline amides.

Complexation par transfert de charge de la chlorpromazine en présence d'iode; action thyroïdienne sécondaire de cette molécule

ANNE-CATHERINE ABSIL, JACQUES BUXERAUD ET CLAUDE RABY

Laboratoire de Chimie Thérapeutique, Faculté de Médecine et de Pharmacie, 2, rue du Docteur Marcland, 87032 Limoges Cedex, France

Reçu le 30 septembre 1983[1]

ANNE-CATHERINE ABSIL, JACQUES BUXERAUD et CLAUDE RABY. Can. J. Chem. **62**, 1807 (1984).

L'interaction moléculaire entre l'iode et la chlorpromazine est étudiée par spectroscopie électronique. L'iode forme avec la chlorpromazine un complexe de transfert de charge, de stoechiométrie 1:1 et de type $n-\sigma$. Les valeurs de la constante de formation (K_c à 20°C = 3166 ± 19 L mol^{-1}), les paramètres thermodynamiques (ΔH^0 = −11,22 ± 0,11 kcal mol^{-1}; ΔS^0 = −22,29 ± 0,38 cal mol^{-1} K^{-1}) traduisent une forte interaction donneur−accepteur, comparable à celle obtenue avec les amines tertiaires. La constante de formation est comparée avec celles obtenues pour les molécules antithyroïdiennes. La chlorpromazine possèderait une activité sur l'hormonogénèse thyroïdienne.

ANNE-CATHERINE ABSIL, JACQUES BUXERAUD, and CLAUDE RABY. Can. J. Chem. **62**, 1807 (1984).

Molecular interaction between iodine and chlorpromazine is investigated by electron spectroscopy. Iodine forms a charge transfer complex with chlorpromazine, with 1:1 stoichiometry and of the $n-\sigma$ type. The values of the formation constant (K_c at 20°C = 3166 ± 19 L mol^{-1}) and thermodynamic parameters (ΔH^0 = −11.22 ± 0.11 kcal mol^{-1}, ΔS^0 = −22.29 ± 0.38 cal mol^{-1} K^{-1}) show a strong donor−acceptor interaction, comparable to that obtained with tertiary amines. The formation constant is compared to those obtained with antithyroid molecules. Chlorpromazine appears to have no effect on the intrathyroid cycle of iodine.

Introduction

Il est bien connu que les amines tertiaires, en particulier la triéthylamine, sont capables de former des complexes par transfert de charge avec l'iode. Ces complexes ont été étudiés qualitativement et quantitativement (1). La valeur de la constante de formation de complexe et les paramètres thermodynamiques ont permis de révéler une forte interaction donneur−accepteur.

Une étude semblable, effectuée sur les médicaments antithyroïdiens, a permis d'établir une corrélation entre les valeurs de constante K_c et l'activité antithyroïdienne (2). Cette relation structure−activité a permis de classer toutes les molécules antithyroïdiennes connues. La fixation de l'iode par formation de complexe serait donc un des mécanismes d'action des antithyroïdiens de synthèse.

La similitude d'action de la triéthylamine et des médicaments antithyroïdiens vis-à-vis de l'iode, nous a amené à nous intéresser aux nombreuses molécules médicamenteuses non antithyroïdiennes, mais possédant dans leur structure une fonction amine tertiaire. Il semble, en effet, intéressant d'étudier la formation de complexes entre de telles molécules et l'iode, afin de déterminer si ces molécules possèdent une activité antithyroïdienne secondaire méconnue à ce jour. Nous rapportons ici l'étude de l'interaction moléculaire chlorpromazine−iode. La chlorpromazine est un dérivé phénothiazinique à chaîne latérale portant un azote tertiaire permettant d'assimiler cette molécule à la famille chimique des amines tertiaires.

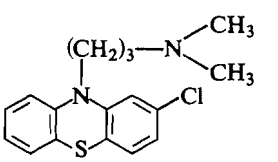
Partie expérimentale

Produits

L'iode est un produit suprapur bisublimé Merck 4763. Il est utilisé sans aucune purification et conservé à l'obscurité dans un dessiccateur contenant de l'anhydride phosphorique.

La chlorpromazine est un produit commercialisé sous forme de chlorhydrate. Ce chlorhydrate est transformé en base selon le procédé suivant: dans une ampoule à décanter, on introduit une prise d'essai exactement pesée, voisine de 0,30 g.

Après addition de 20 mL d'eau distillée et 10 mL de solution d'hydroxyde de sodium N, on pratique plusieurs extractions chloroformiques successives de la base ainsi libérée. Les phases chloroformiques sont recueillies et évaporées sous vide. La chlorpromazine base est purifiée par hplc; elle se présente sous la forme d'un produit huileux.



Chloro-3 (diméthylamino-3 propyl)-10 phénothiazine

Le solvant, tétrachlorure de carbone, est un produit Merck Uvasol pour spectroscopie utilisé sans aucune purification. Sa faible teneur en eau (maximum 0,01%) ne perturbe en aucun cas la formation du complexe chlorpromazine−iode.

Matériel

Les spectres électroniques sont enregistrés à l'aide d'un spectrophotomètre double faisceau Perkin−Elmer 554 uv−visible équipé d'un porte cuve thermostaté à effet Peltier (température contrôlée à ± 0,1°C). Les cuves utilisées sont en quartz, leur parcours optique est de 1 cm.

Protocole

Les solutions d'iode à des concentrations (M) de l'ordre de 10^{-4} sont préparées extemporanément par gravimétrie. Les différentes solutions de chlorpromazine sont préparées extemporanément par volumétrie à partir d'une solution mère obtenue par gravimétrie. Les solutions de complexes sont réalisées directement dans les cuves du spectrophotomètre en mélangeant 1,5 mL de solution de chlorpromazine et 1,5 mL de solution d'iode.

Les absorbances de ces solutions de complexe sont enregistrées immédiatement à différentes longueurs d'onde. De nouveaux spectres sont effectués après plusieurs heures de contact afin d'apprécier la stabilité du complexe chlorpromazine−iode.

Les paramètres thermodynamiques sont calculés en suivant l'évolution de l'absorbance d'une série de solutions en fonction de la température (10, 15, 20, 25, 30, 35 et 40°C). Les concentrations des solutions n'ont pas été corrigées dans cet intervalle de température

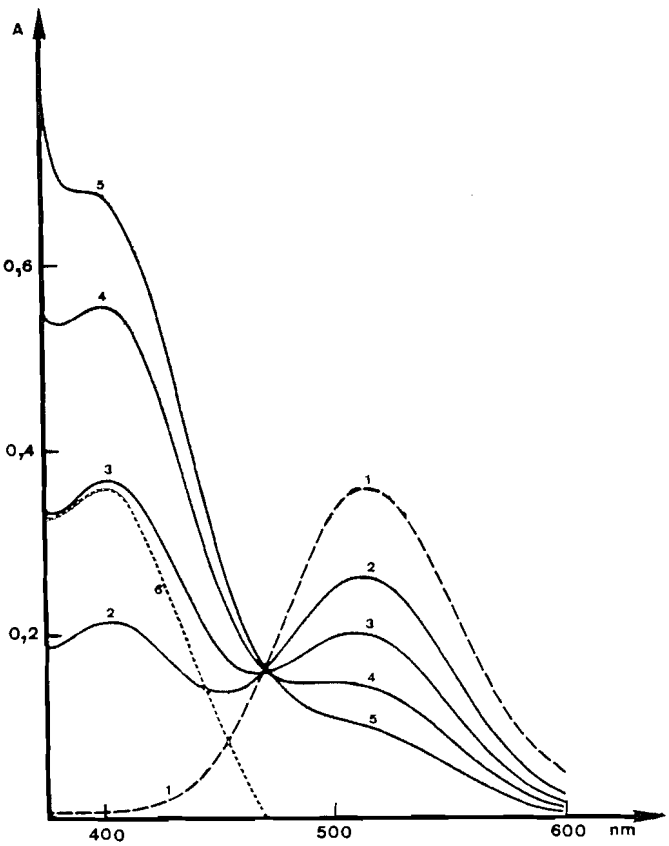

FIG. 1. Spectres d'absorption dans le visible du complexe chlorpromazine–iode (solvant tétrachlorure de carbone; température: 20 ± 0,1°C; cellules de quartz de 10 mm). La concentration de l'iode est fixée à $3{,}839 \times 10^{-4}$ *M*. Les concentrations (*M*) de la chlorpromazine sont: (1) 0; (2) $2{,}065 \times 10^{-4}$; (3) $4{,}13 \times 10^{-4}$; (4) $8{,}26 \times 10^{-4}$; (5) $1{,}377 \times 10^{-3}$. La courbe 6 représente l'absorption visible du complexe calculée pour la solution 3.

(Δ (°C) = 30). Après enrégistrement des absorbances de solutions de complexe à six températures, un retour à la température initiale permet de vérifier que les nouvelles absorbances lues restent inchangées par rapport aux absorbances initiales.

Résultats

Etude dans la région du visible

Aux concentrations utilisées variant de $0{,}207 \times 10^{-3}$ à $1{,}377 \times 10^{-3}$ *M*, le donneur est totalement transparent aux longueurs d'ondes étudiées, c'est à dire entre 420 et 515 nm.

L'adjonction d'une solution d'iode aux solutions de donneur entraîne une perturbation de la bande visible de l'iode à 515 nm: elle est déplacée vers les basses longueurs d'onde (effet hypsochrome) (fig. 1). Ces nouvelles bandes, "blue shifted bands", sont attribuées à la complexation de l'halogène, elles se recoupent en un point isobestique situé à 470 nm. Le pic du complexe est repéré à 405 nm en plaçant dans le faisceau de référence une cuve contenant une solution d'halogène à la même concentration que dans le complexe. L'enregistrement spectrophotométrique, à différentes températures, de la "blue shifted band" pour la solution de complexe montre que l'intensité de ces bandes décroit fortement avec une élévation de la température (fig. 2).

La stabilité des complexes est étudiée en réalisant de nouveaux enregistrements après 24 h. Il apparaît de nouvelles bandes d'absorption à 290 et 360 nm caractérisant la présence d'ions I_3^-. Les changements sont d'autant plus importants que

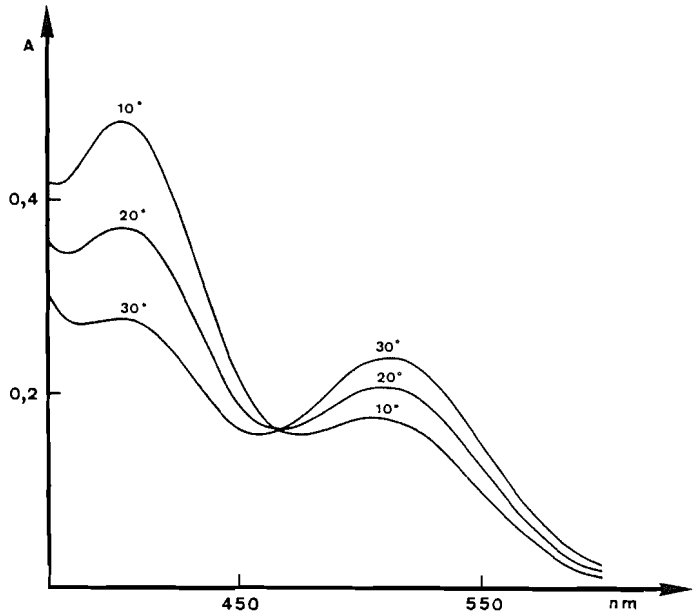

FIG. 2. Influence de la température sur la bande de l'iode complexé par la chlorpromazine dans CCl_4. Les concentrations en iode et en chlorpromazine sont respectivement: $3{,}839 \times 10^{-4}$ *M* et $4{,}13 \times 10^{-4}$ *M*.

les concentrations en donneur sont élevées.

L'étude mathématique de la transition $\pi_g \rightarrow \sigma_u$ de l'halogène, l'analyse des absorbances dans les spectres, l'existence d'un seul point isobestique, l'alignement parfait des points expérimentaux sur les droites de régression linéaire (fig. 3) confirment la présence d'un complexe de stoechiométrie 1:1. D'autre part, un contrôle matriciel de Liptay (3) à 420, 425, 430 et 435 nm a permis de s'assurer de la présence d'un seul complexe. Pour cela, les absorbances d'une série de solutions de complexes sont enregistrées. Une correction est apportée en soustrayant, pour chacune de ces absorbances lues, l'absorbance de l'iode non complexé calculée mathématiquement. Le donneur n'absorbant pas dans cette région, seule l'absorption due à l'iode est à soustraire.

$$[1] \quad A_{corr} = A_{obs} - \epsilon_{I_2}[I_2]$$

A_{corr} est l'absorbance corrigée du complexe, A_{obs} est l'absorbance du mélange donneur–iode, ϵ_{I_2} le coefficient d'absorption molaire de l'iode, $[I_2]$ la concentration d'iode non complexé, déterminée facilement à 515 nm (ϵ_{I_2} à 515 nm = 917 L mol^{-1}).

Les valeurs des absorbances corrigées du complexe ainsi obtenues pour différentes solutions à plusieurs longueurs d'onde sont disposées sous la forme d'une matrice. Cette matrice est ensuite normalisée sur la longueur d'onde 420 nm (tableau 1). En présence d'un seul complexe, toutes les colonnes sont égales aux erreurs expérimentales prés.

Pour déterminer les constantes de formation de complexe K_c et les coefficients d'absorption molaire ϵ_c la méthode de Benesi–Hildebrand–Scott (12, 13) n'a pu être utilisée, cette méthode s'appliquant lorsque les concentrations initiales en donneur sont très largement supérieures à celles de l'accepteur. L'équation [2] est donc utilisée (4, 11).

$$[2] \quad K_c = \frac{[C]}{([A_0] - [C])([D_0] - [C])}$$

où [C] est la concentration du complexe, $[A_0]$ la concentration

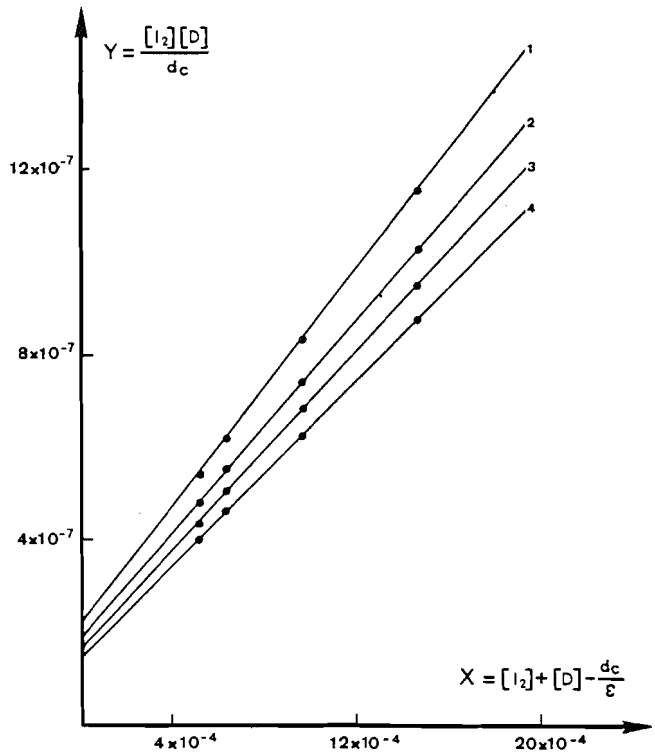

FIG. 3. Relation entre $[I_2][D]/d_c$ et $[I_2] + [D] - d_c/\epsilon_c$ pour le complexe chlorpromazine–iode à 20°C (solvant CCl_4, cuves quartz de 10 mm de parcours optique). Les droites de regression ont pour équation: (1) 435 nm, $Y = 6{,}551 \times 10^{-4} X + 2{,}093 \times 10^{-7}$ ($r = 0{,}999$); (2) 430 nm, $Y = 5{,}874 \times 10^{-4} X + 1{,}826 \times 10^{-7}$ ($r = 0{,}999$); (3) 425 nm, $Y = 5{,}338 \times 10^{-4} X + 1{,}676 \times 10^{-7}$ ($r = 0{,}999$); (4) 420 nm, $Y = 4{,}927 \times 10^{-4} X + 1{,}568 \times 10^{-7}$ ($r = 0{,}999$).

TABLEAU 1. Contrôle matriciel de Liptay effectué pour le complexe chlorpromazine–iode à 20°C

(a) Absorbances corrigées (A_{corr}) disposées sous forme de matrice*

λ (nm)	Sol. 1	Sol. 2	Sol. 3	Sol. 4
420	0,601	0,505	0,339	0,198
425	0,556	0,469	0,316	0,183
430	0,506	0,427	0,288	0,167
435	0,451	0,381	0,255	0,148

(b) Normalisation de cette matrice sur la λ 420 nm

	1	1	1	1
	0,925	0,928	0,932	0,934
	0,842	0,846	0,849	0,843
	0,750	0,754	0,752	0,747

*Les concentrations (M) des réactifs utilisées pour les 4 solutions sont: $[I_2]$ = constante = $3{,}889 \times 10^{-4}$; [chlorpromazine]: sol. 1 = $1{,}337 \times 10^{-3}$; sol. 2 = $8{,}260 \times 10^{-3}$; sol 3 = $4{,}130 \times 10^{-3}$; sol. 4 = $2{,}065 \times 10^{-4}$.

initiale de l'accepteur et $[D_0]$ la concentration initiale du donneur. Le terme [C] peut être remplacé par d_c/ϵ_c et conduire à l'éq. [3].

$$[3] \quad \frac{[A_0][D_0]}{d_c} = \left[[A_0] + [D_0] - \frac{d_c}{\epsilon_c}\right]\frac{1}{\epsilon_c} + \frac{1}{K_c\epsilon_c}$$

où la longueur d'onde étudiée d_c est l'absorbance du complexe seul, ϵ_c le coefficient d'absorption molaire du complexe et K_c la constante de formation du complexe. La résolution de l'éq. [3] par la méthode des moindres carrés nécessitant la connaissance de la valeur de ϵ_c fait appel à un procédé par itérations qui a été programmé sur ordinateur. La représentation graphique du terme $[A_0][D_0]/d_c$ en fonction de $[A_0] + [D_0] - d_c/\epsilon_c$ conduit à une droite de pente $1/\epsilon_c$ et d'intercept $1/K_c\epsilon_c$ (fig. 3). Les constantes de formation K_c et les coefficients d'absorption molaire ϵ_c du système chlorpromazine–iode sont rassemblés dans le tableau 2. Les valeurs obtenues (K_c à 20°C = 3166 ± 19 L mol^{-1}) sont en accord avec une forte interaction iode–chlorpromazine.

TABLEAU 2. Constantes de formation K_c et coefficients d'absorption molaire ϵ_c pour le complexe chlorpromazine–iode en solution dans le tétrachlorure de carbone à 10, 15, 20, 25, 30, 35 et 40°C

	435	897		1518

*Evaluation à partir de la bande visible du complexe par la méthode déjà décrite, à partir de 4 solutions de complexe chlorpromazine–iode. Pour chaque solution de complexe, la concentration d'iode est constante égale à $3{,}839 \times 10^{-4}$ M et la concentration du donneur varie ($0{,}207 \times 10^{-3}$ M; $0{,}413 \times 10^{-3}$ M; $0{,}826 \times 10^{-3}$ M et $1{,}377 \times 10^{-3}$ M).

Le coefficient d'absorption molaire du complexe ϵ_c à 405 nm, maximum d'absorption de la "blue shifted band" n'a pas pu être déterminé. En effet, l'absorbance encore non négligeable des ions I_3^- à 405 nm vient interférer avec l'absorbance du complexe dans la région du visible.

La représentation graphique de $R \ln K_c$ en fonction de $1/T$ conduit à une droite dont la pente donne la valeur de ΔH^0 et l'intercept celle de ΔS^0 (fig. 4). Les paramètres thermodynamiques, en accord avec la formation de complexes, sont rassemblés dans le tableau 3.

Etude dans la région de l'ultraviolet

L'absorption dans l'ultraviolet de la chlorpromazine à une concentration de $1{,}377 \times 10^{-5}$ M en solution dans le tétra-

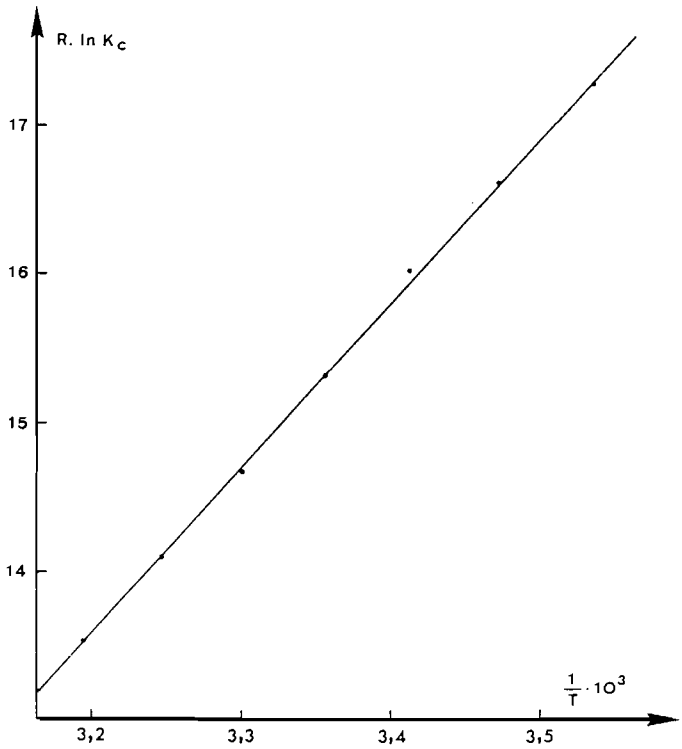

FIG. 4. Détermination des paramètres thermodynamiques du complexe chlorpromazine–iode. La droite de régression linéaire a pour équation $Y = 11{,}22\ X - 22{,}29$ ($r = 0{,}999$).

TABLEAU 3. Paramètres thermodynamiques obtenus pour les complexes chlorpromazine–iode et triéthylamine–iode

Paramètre	$[I_2]$ [Chlorpromazine]	$[I_2]$ [Triéthylamine]*
$-\Delta H^0$ kcal mol^{-1}	11,22±0,11	12,12±0,72
$-\Delta S^0$ cal mol^{-1} K^{-1}	22,29±0,38	−23,87±2,39
$-\Delta G^0$ kcal mol^{-1}	4,700±0,003 (à 293 K)	5,10±0,02 (à 293,5 K)

*Réference 1.

chlorure de carbone fait apparaître un pic principal à 259 nm (log ϵ = 4,43) et une large bande d'intensité plus faible dont le maximum est situé à 310 nm (log ϵ = 3,63).

La formation du complexe chlorpromazine–iode provoque des perturbations du spectre électronique ultraviolet avec apparition d'une nouvelle bande (fig. 5). Cette nouvelle bande est obtenue d'abord graphiquement en plaçant dans le faisceau de référence une concentration de donneur équivalente à celle se trouvant dans le complexe, puis mathématiquement en soustrayant l'absorption due à l'iode. Cette bande peut être déterminée avec plus de précision. En effet la détermination des concentrations en accepteur libre et en donneur libre est possible en faisant intervenir les constantes K_c obtenues dans le visible. Puis en soustrayant mathématiquement les absorptions respectives de l'iode et de la chlorpromazine non complexé, à partir de l'absorption lue directement pour la solution de complexe on obtient une nouvelle bande. Cette nouvelle bande est pratiquement identique à celle obtenue précédemment. Elle peut être attribuée à la bande de transfert de charge sur laquelle vient se superposer l'absorption due aux ions I_3^- à 290 nm lui donnant ainsi un aspect asymétrique.

Le maximum de la bande de transfert de charge est repéré à

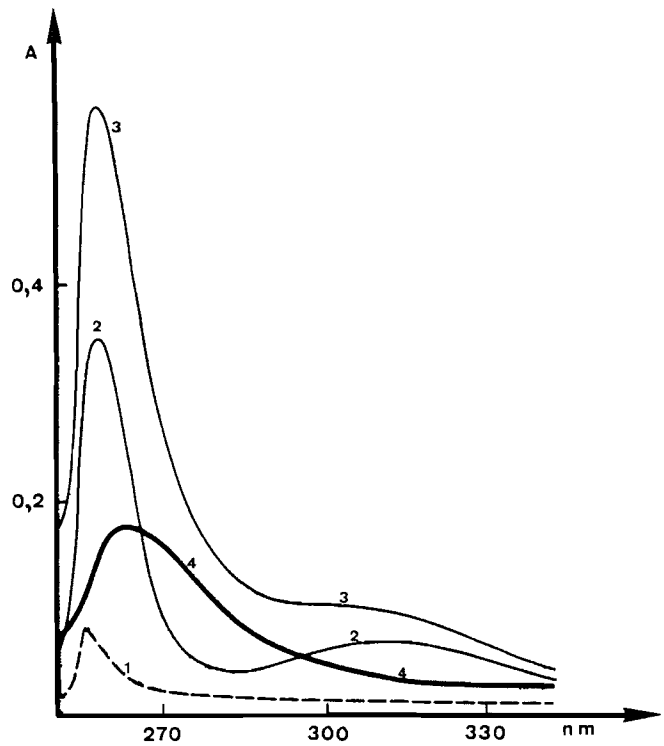

FIG. 5. Spectres d'absorption dans l'ultraviolet du complexe chlorpromazine–iode (solvant CCl_4; t: 20°C; cellules de quartz de 10 mm). Les concentrations (M) sont (1) I_2 3,839 × 10^{-4}; (2) chlorpromazine 1,377 × 10^{-5}; (3) I_2 3,839 × 10^{-4} et chlorpromazine 1,377 × 10^{-5}; (4) courbe d'absorption calculée du complexe.

264 ± 0,5 nm. Les relations de McConnell (5) et Hastings *et al.* (6) entre le potentiel d'ionisation et la fréquence du maximum de la bande de transfert de charge, permettent d'évaluer le potentiel d'ionisation de la chlorpromazine: $I_p \simeq 9{,}83 \pm 0{,}03$. Si la position du maximum d'absorption peut être repérée avec suffisamment de précision pour permettre d'évaluer le potentiel d'ionisation I_p de la chlorpromazine, par contre les absorbances de la bande de transfert de charge pour différentes concentrations ne peuvent pas être déterminées avec grande précision. En effet, l'absorption de la bande de transfert de charge se situe dans une région du spectre où absorbent aussi le donneur et les ions I_3^- formés lors de la réaction de complexation. Pour ces raisons il n'est pas possible d'entreprendre une étude thermodynamique à 264 nm. Un essai réalisé a fourni des résultats inexploitables signalés par l'obtention de coefficients de corrélation r très différents de 1 lors de la résolution de l'éq. [3] sur ordinateur.

Discussion

L'étude spectroscopique électronique confirme le caractère $n-\sigma$ des complexes iodés de transfert de charge obtenus avec la chlorpromazine. Ces complexes sont de stoechiométrie 1 : 1. Les résultats traduisent une forte interaction donneur–accepteur.

En accord avec Mulliken (7) et Popov et Deskin (8), la formation des ions I_3^- est due à la transformation d'un "outer complex" en un "inner complex" libérant des ions I^- qui viennent réagir avec l'iode moléculaire I_2 non complexé. Le schéma réactionnel est donné dans les équations [4]–[7].

[4] Chlorpromazine + $I_2 \rightleftarrows$ chlorpromazine $- I_2$

[6] Chlorpromazine $- I^+I^- \rightleftarrows$ [chlorpromazine $- I]^+ + I^-$ ("inner complex")

[7] $I^- + I_2 \rightleftarrows I_3^-$

La réaction selon l'éq. [5] se déroule lentement alors que les autres ont une cinétique rapide.

Les constantes K_c du complexe chlorpromazine–iode sont comparées avec celles obtenues pour la triéthylamine (1) et pour quelques molécules antithyroïdiennes (2) (tableau 4).

(*i*) La valeur de la constante K_c du complexe chlorpromazine–iode est particulièrement élevée et s'accorde avec les valeurs obtenues pour les amines tertiaires. Les paramètres thermodynamiques sont du même ordre de grandeur que ceux obtenus pour le complexe triéthylamine–iode (tableau 3). Il est donc raisonnable de penser que le transfert de charge s'effectue de la paire d'électrons libre portée par l'azote de la chaîne aminopropyle vers l'orbitale antiliante de l'iode.

(*ii*) La différence observée entre la valeur de K_c de la triéthylamine (K_c à 20,5°C = 6315 L mol^{-1}) et celle de la chlorpromazine (K_c à 20°C = 3166 L mol^{-1}) s'explique en examinant la structure tridimensionnelle de la molécule de chlorpromazine; la chaîne aminopropyle est repliée vers l'atome de chlore porté par le noyau phénothiazinique (9, 10), l'approche de l'iode vers l'azote tertiaire est donc gênée par encombrement stérique, ce qui se traduit par une diminution du caractère donneur de la chlorpromazine par rapport au caractère donneur attendu d'une amine tertiaire. Cette différence peut aussi secondairement s'expliquer par le fait que les complexes chlorpromazine–iode ont été étudiés dans CCl_4 alors que les complexes triéthylamine–iode ont été réalisés dans le *n*-heptane. Il est en effet bien connu que CCl_4 se comporte comme un accepteur vis-à-vis des amines (14). Bien que cette action soit très faible, CCl_4 est ici en très large excés et peut inhiber compétitivement de façon non négligeable la formation du complexe chlorpromazine–iode.

(*iii*) La chlorpromazine a, cependant, une constante supérieure à celle de la mercapto-2 thiazoline dont l'action antithyroïdienne est connue.

La chlorpromazine, grâce à son pouvoir de complexation de l'iode, pourraît donc perturber la synthèse des hormones thyroïdiennes et posséder une action antithyroïdienne secondaire. Une étude expérimentale chez le rat avec détermination des taux de T_3 et de T_4 et avec étude histologique des coupes de thyroïdes de rats traités par la chlorpromazine semble confirmer ce résultat.

Received December 13, 1983

NORBERT DE KIMPE, ROLAND VERHÉ, LAURENT DE BUYCK, and NICEAS SCHAMP. Can. J. Chem. **62**, 1812 (1984).

The effect of α-functionalization of a great variety of aldimines on the $^1J_{C-H}$ coupling constant at the sp^2 aldimine carbon has been determined. This comparative study includes α-*tert*-butyl, α-alkoxy-, α-phenyl-, α-hydroxy-, α-sulfenyl-, α,α-disulfenyl-, α-alkylamino-, α-chloro-, α,α-dichloro-, α-bromo-, α,α-dibromo-, and α,α,α-trichloroaldimines. Depending upon the α-heterofunctionalization the $^1J_{C-H}$ value for (*E*)-aldimines varied over a great range of about 150–178 Hz.

NORBERT DE KIMPE, ROLAND VERHÉ, LAURENT DE BUYCK et NICEAS SCHAMP. Can. J. Chem. **62**, 1812 (1984).

L'influence de la fonctionalisation en position α d'une grande varieté d'aldimines sur la valeur des constantes de couplage $^1J_{C-H}$ au niveau du sp^2-carbone de l'aldimine a été mesurée. Cette comparaison a été effectuée avec des aldimines α-*tert*-butylés, α-alkoxylés, α-phénylés, α-hydroxylés, α-sulfénylés, α,α-disulfenylés, α-alkylaminés, α-chlorés, α,α-dichlorés, α-bromés, α,α-dibromés et α,α,α-trichlorés. La grandeur de $^1J_{C-H}$ des (*E*)-aldimines varie de 150 à 178 Hz et dépend de la hétérofunctionalisation en position α du groupement imino.

Introduction

The influence of the relative stereochemistry of the nitrogen lone pair of electrons on the magnitude of spin coupling constants of proximate carbon atoms has already been studied in recent years. An important parameter related to this phenomenon is $^1J_{C-H}$, i.e. the coupling constant between a carbon atom and a hydrogen atom directly linked to it. According to a recent review on experimental and theoretical contributions in this field, the hybridization of the carbon atom plays a major role in determining the magnitude of this parameter (1). As a consequence, many classes of compounds containing the imino group —CH=N—, among others hydrazones, oximes, and simple imines (i.e. those derived from formaldehyde), have been studied theoretically in view of the influence of the nitrogen lone pair orientation on $^1J_{C-H}$ (2–4). Very few experimental data on this specific topic have been published, notably in the field of oximes (5). However, a very recent study added considerable experimental data to this subject by a study of the effect of the stereochemistry on $^1J_{C-H}$ at the sp^2 carbons of imino derivatives of aldehydes, i.e. aldoximes, aldohydrazones, and aldimines (6). The magnitudes of the coupling constant $^1J_{C-H}$ at the imino carbon of both *E* and *Z* isomers of the latter three classes of compounds have shown a consistently greater value, by about 20 Hz, for the *Z* isomer. In connection with a comprehensive study on the chemistry of α-halogenated imines (for review articles on the chemistry of α-haloimines, see ref. 7), we had occasion to study the coupling constant $^1J_{C-H}$ for a great variety of α-functionalized aldimines. Our results are discussed here and compared with the recent report of the configurational assignments of aldimines (6).

Results

Twenty-one aldimines, substituted at the α-position with various functional groups, including *tert*-butyl, phenyl and halogens (chlorine and bromine), hydroxy-, alkylthio-, alkoxy-, and alkylamino-groups, were synthesized. In addition, an α,β-unsaturated aldimine has been included in this series. The α-functionalized aldimines were prepared from aldehydes and chloral via the straightforward routes outlined in Scheme 1.

Coupling constants $^1J_{C-H}$ were measured from fully coupled spectra, obtained from 40% solutions of the aldimines in deuteriochloroform. The values, ranging between 151 and 178 Hz, are compiled in increasing order of magnitude in Table 1. The introduction of heteroatoms at the α-position of aldimines has a dramatic influence on the $^1J_{C-H}$ value. It should be stressed here that all aldimines, described by us, occurred as their *E*-stereoisomer, exclusively. This statement is based on accepted concepts of steric hindrance around an imino bond. For aldimines, there is an exclusive preference for the *E*-configuration at equilibrium (8). The barrier to *E*–*Z*-isomerization about the carbon–nitrogen double bond is very sensitive to the nature of the substituents. In some particular cases, such as for aldimines derived from *ortho*-disubstituted benzaldehydes or 9-anthrylaldehyde, a significant proportion of the *Z*-isomer has been detected at equilibrium in solution (8, 9). Such (*Z*)-aldimines may also be observed as transient intermediates after uv irradiation or may be prepared in certain cases after α-lithiation and α-alkylation by which the α-anion and the final product possess the *Z*-configuration (10). Tertiary aldimines, i.e. aldimines having an α-sp^3 carbon bearing no α-hydrogens, have not been found to show any trace of their *Z*-isomer. Because the ^{1}H nmr spectra of all our tertiary α-substituted aldimines showed only one stereoisomer (^{1}H nmr), it is reasonable to accept the *E*-stereochemistry. These findings agree with the recent study on this topic, in which no *Z*-isomer of pivaldimines (see Table 1; entry 1) could be produced or detected (6). The latter study revealed the $^1J_{C-H}$ coupling constant of (*E*)-*N*-(2,2-dimethyl-1-propylidene)isopropylamine (entry 1; Table 1) to be 150 Hz. We found a slightly higher value for α-*tert*-butylaldimines **14** and **15** (151 Hz), α,β-unsaturated aldimine **10** (153 Hz), α-alkylamino-, α-phenyl- and α-alkoxyaldimines **9**, **6**, and **11** (154.5 Hz, 155 Hz, and 155 Hz, respectively). A higher coupling constant $^1J_{C-H}$ was noticed for α-hydroxylated aldimine **16** (156.5 Hz) and α-sulfenylated aldimine **12** (158 Hz), but α,α-disulfenylated aldimines, α-chloro aldimines, and α-bromoaldimines showed

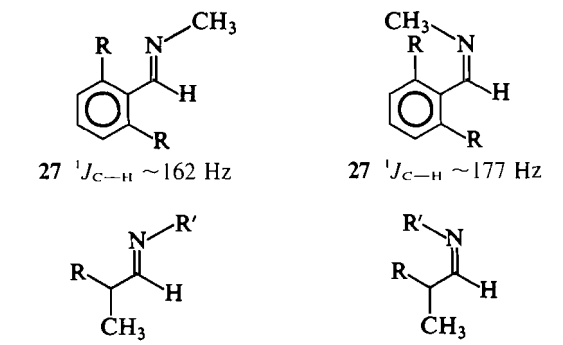
[d] This communication.
[e] Accuracy ±1 Hz.



SCHEME 2

a much higher coupling constant of 162.5 Hz. The greatest coupling constants were measured for α,α-dichloroaldimine **18**, α,α-dibromoaldimine **19**, and trichloroacetaldimines (**24**–**26**) whose $^1J_{C-H}$ values mounted to 171.5 Hz, 172.5 Hz, and 177.5–178 Hz, respectively. Thus there is a marked influence of the α-substitution on the $^1J_{C-H}$ value at the sp^2 carbon of aldimines. The increasing $^1J_{C-H}$ parallels to some extent an increasing electronegativity of the α-substituents, but plotting the $^1J_{C-H}$ values versus the Higgins electronegativities (19) of the α-heteroatoms did not reveal a significant relationship. On the contrary, the *N*-substituent (R) and the geminal α,α-dialkyl groups (R^1 and R^2) did not exert an important influence on the $^1J_{C-H}$ coupling constant. This is illustrated by comparison of the data of a series of five α-chloroaldimines **2**, **3**, **6**, **7**, and **8** (R^1, R^2 = Me or Et; R = iPr, cycloHex, or *t*Bu), whose $^1J_{C-H}$ coupling constants fall within a very narrow range between 162.3 and 162.7 Hz (all values in the table have been rounded off to 162.5 Hz). The same observation is noted for α,α,α-trichloroacetaldimines **24**–**26** whose $^1J_{C-H}$ values are only very slightly influenced by the *N*-substituent (R = iPr, cycloHex, *t*Bu). This phenomenon gains interest in view of the known $^1J_{C-H}$ values for (*E*) and (*Z*) aldimines. It has been generally found that the magnitude of $^1J_{C-H}$ at the aldimine sp^2-carbon is consistently greater for the *Z*-isomer with respect to the *E*-isomer. *o*,*o*-Disubstituted benzaldimines **27** have $^1J_{C-H}$ values of about 162 Hz and 177 Hz for the *E* and *Z*-isomers, respectively (8). On the other hand, propionaldimines or isobutyraldimines **28** showed $^1J_{C-H}$ coupling constants of 151–154 Hz for the *E* isomer and 170–171 Hz for the *Z* isomers (6). The unsubstituted and simplest aldimine, i.e. methyleneamine, was recently generated at low temperature and revealed $^1J_{C-H}$ coupling constants of 163.7 Hz and 172.9 Hz (11). These data are useful for establishing stereochemical assignments in aldimines provided that both stereoisomers are available. If not, the $^1J_{C-H}$ value does not provide any conclusive information regarding the stereochemistry of aldimines because the α-substitution (especially heteroatoms) plays a major role. It has been shown in this paper that tertiairy (*E*)-aldimines show a range of $^1J_{C-H}$ values which varies from about 150 to 178 Hz. This range entirely covers the range in which $^1J_{C-H}$ values for *E* and *Z* isomers of simple aldimines (e.g. **29**) are situated, therefore pointing to the care with which such figures should be handled.

Experimental

The ^{13}C nmr spectra were recorded using a Varian FT-80 nmr spectrometer, operating at 20 MHz. The coupling constants $^1J_{C-H}$ were obtained from fully coupled spectra, using 40% solutions of aldimines in deuteriochloroform. α-Functionalized aldimines were synthesized according to the following procedures. α-Chloroaldimines **2**, **3**, **6**, **7**, and **8** were prepared by chlorination (with *N*-chlorosuccinimide in CCl_4) of aldimines, obtained from condensation of aldehydes **1** with primary amines (12). α-Bromoaldimines **4** and **5** were synthesized in an analogous way using *N*-bromosuccinimide in CCl_4. This reaction required heating of the reactants in an oil bath at 50°C for an overnight period. After completion of the reaction (nmr monitoring), the precipitated succinimide was filtered off and the solvent evaporated *in vacuo*. α-Bromoaldimine **4** had a boiling point of 58–61°C/14 Torr (1 Torr = 133.3 Pa) (yield 62%), while the α-bromoaldimine **5** decomposed on distillation *in vacuo* and was therefore used as such (purity of at least 98%). α,β-Unsaturated aldimine **10** was obtained from dehydrochlorination of the chloro analogue of α-bromoaldimine **5** using sodium methoxide in methanol under reflux (12). α-Isopropoxyaldimine **11** was synthesized by silver-induced alcoholysis of α-bromoaldimine **4** with silver carbonate (1 molar equiv.) in dry isopropanol under reflux for 16 h. Aqueous work-up afforded solvolysis product **11** as the sole product (86% yield). α-Sulfenylated aldimine **12** was produced according to our previously published procedure (15). *N*-*tert*-butyl-α-(*N*-*tert*-butyl)aminoisobutyraldimine **9** was prepared by rearrangement of α-chloroaldimine **2** with methanol into the hydrochloride of α-*tert*-butylaminoisobutyraldehyde dimethyl acetal (12), after which the latter was hydrolyzed with 4 *N* hydrochloric acid (room temperature, 16 h) in a two-phase system with dichloromethane to afford α-*tert*-butylaminoisobutyraldehyde; this aldehyde was converted into the corresponding aldimine essentially according to our published method for the preparation of α-halogenated imines from α-halogenated carbonyl compounds using primary amines in the presence of

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.6 on 09/06/12
For personal use only.

titanium(IV) chloride (94% yield) (13). α-Phenylaldimine **13** was synthesized by Friedel–Crafts reaction of α-chloroaldimine **6** with $AlCl_3$ in benzene (14). α-*tert*-Butylated aldimines **14** and **15** were prepared by reaction of α-chloroaldimines **3** and **6** with *tert*-butyllithium in ether. The reaction mixtures were analyzed by preparative gas chromatography and afforded **14** and **15**, next to α-hydroxyaldimine **16** and coupling products, i.e. 1,4-diimines (see, for instance, footnote 1). α,α-Dichloroaldimine **18** and α,α-dibromoaldimine **19** were prepared from butanal as previously described (16, 17), except that the bromination to afford **19** required, preferentially, an overnight reaction time at 70°C. α,α-Disulfenylated aldimine **22** was obtained according to the following sequence: acidic hydrolysis of α,α-dichloroaldimine **18** afforded 2,2-dichlorobutanal **20** (16), which was converted into the protected α-ketoaldehyde **21** using sodium ethylthiolate in aqueous medium (18), after which compound **21** was transformed into α,α-disulfenylated aldimine **22** essentially according to our described procedure for the imination of α-halocarbonyl compounds (13).

N-(2,2,2-Trichloroethylidene)isopropylamine **24**, *N*-(2,2,2-trichloroethylidene)cyclohexylamine **25**, and *N*-(2,2,2-trichloroethylidene)-*tert*-butylamine **26** were prepared in analogy with the reported procedure for the synthesis of the *N*-*tert*-butyl derivative (13).

The chemical shifts (δ, $CDCl_3$) of the aldimine carbon (—*C*H=N)— of the various α-functionalized aldimines are as follows: compound **2**: 159.1 ppm; compound **3**: 162.0 ppm; compound **4**: 158.9 ppm; compound **5**: 158.6 ppm; compound **6**: 162.6 ppm; compound **7**: 162.1 ppm; compound **8**: 162.5 ppm; compound **9**: 166.1 ppm; compound **10**: 158.5 ppm; compound **11**: 162.1 ppm; compound **12**: 163.7 ppm; compound **13**: 166.3 ppm; compound **14**: 167.7 ppm; compound **15**: 168.5 ppm; compound **16**: 164.2 ppm; compound **18**: 157.5 ppm; compound **19**: 155.8 ppm; compound **22**: 157.1 ppm; compound **24**: 154.4 ppm; compound **25**: 154.5 ppm; compound **26**: 152.5 ppm.

Polarography of *n*-butylthioglycolate in aqueous media, methanol, and acetonitrile

K. C. GUPTA AND KALPANA K. SHARMA
Department of Chemistry, Govt. College, Kota (Raj.), India

Received August 19, 1983[1]

K. C. GUPTA and KALPANA K. SHARMA. Can. J. Chem. **62**, 1817 (1984).

The polarographic behaviour of *n*-butylthioglycolate (RSH) at the DME in aqueous media, methanol, and acetonitrile has been investigated in the presence of 0.1 *M* KNO_3 and 0.01% thymol. The effect of pH, concentration of RSH, and drop time on the wave characteristics and the mechanism of the reaction occurring at the surface of the mercury drop have been studied. Well-defined reversible and diffusion-controlled anodic waves were obtained in aqueous media (pH 4.2), 40% methanol (pH 3.22), and 40% acetonitrile (pH 2.96). Mathematical and analytical evidence was obtained to show that the anodic wave of RSH at a dropping mercury electrode in aqueous media, 40% methanol, and 40% acetonitrile is due to the formation of the mercury complex RSHg. The dissociation constant (p*K*) of the mercapto group in *n*-butylthioglycolate is 9.6 and the diffusion coefficient in the different media are 1.17×10^{-6} cm^2 s^{-1} (in aqueous media) 1.23×10^{-6} cm^2 s^{-1} (in 40% methanol), and 2.43×10^{-6} cm^2 s^{-1} (in 40% acetonitrile). The linearity of i_d with RSH concentration provides a rapid and precise method for the determination of RSH, down to 0.4 m*M* in aqueous media, methanol, and acetonitrile.

K. C. GUPTA et KALPANA K. SHARMA. Can. J. Chem. **62**, 1817 (1984).

On a examiné le comportement polarographique, au niveau de la goutte de mercure, du thioglycolate de *n*-butyle (RSH) en solution dans l'eau, le méthanol et l'acétonitrile, en présence de KNO_3 à 0,1 *M* et de thymol à 0,01%. On a étudié l'effet du pH, de la concentration du RSH et du temps de chute sur les caractéristiques de la vague et sur le mécanisme de la réaction se produisant à la surface de la goutte de mercure. En solutions dans l'eau (pH de 4,2), dans le méthanol (40% et pH de 3,22) ou dans l'acétonitrile (40% et pH de 2,96), on a obtenu des vagues anodiques réversibles bien définies et d'autres controlées par la diffusion. On a obtenu des données qui permettent de montrer que la vague anodique du RSH qui se produit au niveau de la goutte de mercure, dans l'eau et dans des solutions à 40% de méthanol ou à 40% d'acétonitrile, est due à la formation d'un complexe de mercure RSHg. La constante de dissociation (pK) du groupe thiol du thioglycolate de *n*-butyle est égale à 9,6 et les coefficients de diffusion dans les différents milieux sont $1,17 \times 10^{-6}$ (dans l'eau), 1.23×10^{-6} (dans le méthanol à 40%) et $2,43 \times 10^{-6}$ (dans l'acétonitrile à 40%) cm^2 s^{-1}. La linéarité de i_d avec la concentration de RSH fournit une méthode précise et rapide de déterminer la concentration de RSH, jusqu'à des concentrations de 0,4 m*M*, dans des milieux aqueux, méthanoliques ou d'acétonirile.

[Traduit par le journal]

Introduction

The electrochemical behaviour of thiols, alkyl thiols, and disulphides at DME has been the subject of several polarographic investigations (1–14). Because of the increasing significance of sulphur-containing organic compounds in pharmaceutical and industrial fields, a considerable interest on their electrochemical behaviour has been shown in the past two decades, but previous electrochemical studies are limited to polarographic investigations in aqueous media. In view of the important applications of *n*-butylthioglycolate and its interesting behaviour towards complex formation with heavy metal ions, it was considered worthwhile to investigate its polarographic behaviour at a dropping mercury electrode (dme) in aqueous and aqueous – non-aqueous media, which may provide an accurate method for its quantitative determination in semimicro amounts.

Experimental

Materials and methods

Reagents

n-Butylthioglycolate (Evan's Chemetics, Inc., New York) and AnalaR (BDH) reagents KNO_3, KCl, and NaOH, methanol, acetonitrile, etc., were used. Fresh solution of *n*-butylthioglycolate was prepared in 60% non-aqueous (methanol or acetonitrile) medium. Other stock solutions used were prepared in doubly-distilled air-free conductivity water. Reagent grade acetonitrile and methanol were used after further purification (15). Freshly prepared solutions were always used to avoid the effects of aging and air oxidation. Thymol 0.01% was used as maximum suppressor.

Apparatus

A Southern manual polarograph (Surrey, England) in conjunction with the thermostated cell was used for recording current voltage curves. An external saturated calomel electrode, connected to the cell by means of agar bridge (0.3% agar + 3.0% KNO_3), served as a reference electrode. The capillary characteristics measured in KNO_3 (μ = 0.1 *M*) at $E_{d.e.}$ = −0.1 V (sce) were m = 2.98 mg, t = 2.7 (h = 45 cm) and $m^{2/3}t^{1/6}$ = 2.4436 $mg^{2/3}$ $s^{-1/2}$.

For each polarographic measurement, the solution to be polarographed was prepared in a 25.0 mL volumetric flask by the addition of known volume of the standard stock solutions to give the required concentrations of the various contents in 25.0 mL with aqueous media or 40% v/v methanol or 40% v/v acetonitrile. The cell was kept immersed in an electrically maintained thermostat and the test solution was deaerated by a stream of hydrogen. A constant inert atmosphere was maintained over the solution throughout the experiment. The ncessary correction was made for residual current in determining all diffusion current data, Thymol (0.01%) was used as the maximum suppressor and 0.1 *M* KNO_3 as supporting electrolyte.

The pH measurements were made on cambridge bench pattern (null deflection type) pH meter.

Results and discussion

Preliminary experiments showed that *n*-butylthioglycolate produces anodic wave in aqueous media, 40% v/v methanol, and 40% v/v acetonitrile at pH values between 2.5 and 8. The effects of variation of pH, RSH concentration and drop time have been studied with a view to recognize the characteristics of the wave in order to determine the mechanism of the reaction at the drop surface. Electrolysis of RSH in well-buffered medium and then polarographic analysis of the electrolysed solution were carried out.

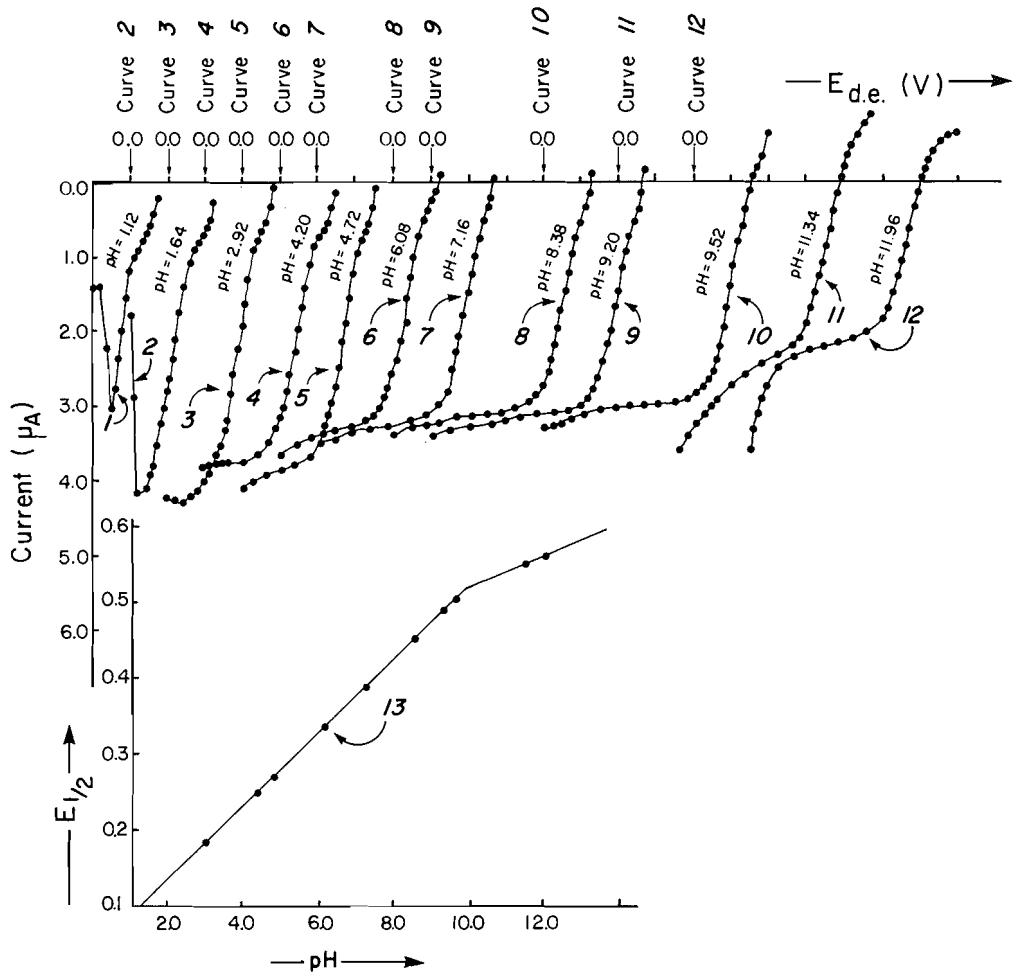

FIG. 1. Polarograms of 1.0 m*M* RSH at different pH values (curves *1*–*12*) in aqueous media, plot of $-E_{1/2}$ vs. pH (curve *13*).

Effect of pH

Polarograms of solution of 1 m*M* in *n*-butylthioglycolate at different pH values (clarks and lubs buffer) were recorded in aqueous media, 40% v/v methanol, and 40% v/v acetonitrile. The behaviour of the waves was not found to be considerably different in aqueous media (Fig. 1), 40% v/v methanol, and 40% v/v acetonitrile. It was found that reaction begins at −0.17 V and well-defined diffusion current region was not established, with the result that the waves are poorly defined below pH 2.5. However, as the pH increases the diffusion current plateau becomes more defined (curves *3*, *4*, *5*) and very well-defined anodic wave was obtained at pH 4.2 in aqueous media, at pH 3.22 in 40% v/v methanol, and at pH 2.96 in 40% v/v acetonitrile. It was observed that with the increase in pH, the waves not only start at more negative potential, but becomes irregular and irreversible in nature (curves *10*, *11*, *12*) in aqueous media. The residual current plateau disappeared in 40% v/v methanol and 40% v/v acetonitrile at pH beyond 4.5. The slow establishment of equilibrium may be regarded as the cause of irreversibility beyond certain pH in all the media studied.

The reversibility of the electrode reaction was tested by plotting log $(i_d - i)/i$ vs. $-E_{d.e.}$. The plot yielded a straight line with the slopes 0.0612 in aqueous media, 0.0603 in 40% v/v methanol and 0.0617 in 40% v/v acetonitrile within the pH range 2.5–8, producing logarithmic analysible waves. This indicates a one-electrode transfer process. The value of *n* in each of the media studied was determined by coulometric method (16) and was further checked by the De-Vries and Kroon methods (17) and found to be approximately one. All the subsequent studies were made at pH 4.20 in aqueous media, pH 3.22 in 40% methanol, and pH 2.96 in 40% acetonitrile.

Effect of concentration

Polarograms of solutions containing different concentrations of RSH (0.4–1.33 m*M*) + 0.1 *M* KNO_3 + 0.01% thymol at pH 4.2 in aqueous media, at pH 3.22 in 40% methanol, and at pH 2.96 in 40% acetonitrile were obtained. It was found that i_d/C are constant within experimental error and the mean values are 3.205 in aqueous media, 3.305 in 40% methanol, 4.617 in 40% acetonitrile. The ratio of i_d/C for methanolic-to-aqueous medium is 1.03 and acetonitrile-to-aqueous medium is 1.44. RSH can therefore be determined polarographically in 0.1 *M* KNO_3 and 0.01% thymol in aqueous, 40% v/v methanol, and 40% v/v acetonitrile.

Effect of Hg on pressure

A series of polarograms of solutions 1.0 m*M* in RSH + 0.1 *M* KNO_3 + 0.01% thymol in aqueous media (pH 4.2), 40% v/v methanol (pH 3.22), and 40% v/v acetonitrile (pH 2.96) were obtained for different heights of the mercury column. Well-defined anodic waves in aqueous media, 40% v/v methanol, and 40% v/v acetonitrile were obtained over the whole range. The constancy of i_d/h shows the diffusion-controlled nature of the wave.

Mechanism of electrode reaction

The electroxidation process indicated by the wave may involve the formation of mercurous mercaptide (one electron).

[1] $RSH + Hg \rightleftharpoons RSHg + H^+ + e^-$

or the formation of the disulphide (two electrons)

[2] $2RSH \rightleftharpoons RSSR + 2H^+ + 2e^-$

If these reactions are reversible, then the potential at any point on the wave at constant pH and 25°C should be given by

[3] $$E = E_{1/2} - 0.0591 \log \frac{i_d - i}{i}$$

for eq. [1] and

[4] $$E = E_{1/2} - \frac{0.0591}{2} \log \frac{(i_d - i)^2}{i}$$

for eq. [2].

If eq. [2] describes the wave, then a plot of $E_{d.e.}$ vs. log $(i_d - i)^2/i$ should yield straight line with a slope 0.0591/2 which is not found in the present case. On the other hand, if eq. [1] determines the wave, the plot of $E_{d.e.}$ vs. log $i_d - i/i$ should yield a straight line with a slope 0.0591, which has been found to be true for RSH in aqueous media, 40% methanol, and 40% acetonitrile in agreement with the one-electron transfer process. The values of n were further checked by other methods (16, 17).

It may therefore be inferred that the wave obtained with RSH in aqueous media, 40% methanol, 40% acetonitrile solution corresponds to the formation of mercurous mercaptide according to eq. [1]. In order to arrive at a definite reaction mechanism, solutions containing 1.0 m*M* RSH, 0.1 *M* KNO_3, and 0.01% thymol were electrolysed in different media, e.g., aqueous media (pH 4.2), 40% v/v methanol (pH 3.22), and 40% v/v acetonitrile (pH 2.96) at predetermined potentials from the respective limiting current value, in a completely inert atmosphere for 8 h. A portion of the electrolysed solution (in separate media) was then polarographed in buffered medium under identical pH values. In aqueous media, 40% methanol, and 40% acetonitrile, a cathodic wave was obtained (Figs. 2, 3, and 4, curve *2*), which corresponds to the reversible one-electron process. On passing H_2S through another portion of electrolysed solution, a black turbidity was obtained showing the presence of soluble mercury in electrolysed solution.

The presence of soluble mercury in the solution (electrolysed) was further determined by precipitating it as mercuric paraiodate (18). Further, when stationary platinum microelectrode was used, no anodic or cathodic wave was produced by RSH. This also shows that the mercury takes part in the electrode reaction. On the basis of these observations, the reaction mechanism as indicated by eq. [2] can be discarded.

In order to obtain more conclusive evidence, the following experiments were performed separately in aqueous media (pH 4.20), 40% methanol (pH 3.22), and 40% acetonitrile (pH 2.96). Solutions containing (*i*) 1.0 m*M* RSH + 0.5 m*M* $HgCl_2$; (*ii*) 1.0 m*M* RSH, (*iii*) 2.0 m*M* RSH + 0.5 m*M* $HgCl_2$, and (*iv*) chemically oxidised solution of RSH were polarographed in a buffered medium of identical pH values and similar conditions in the respective solvents. In aqueous media, 40% methanol, and 40% acetonitrile, solution *i* yielded a well-defined cathodie wave (Figs. 2, 3, and 4, curve *3*), which corresponds to one-electron reduction having $E_{1/2}$ similar to that of the anodic wave of RSH (Figs. 2, 3, and 4, curve *2*). Solution *iii*

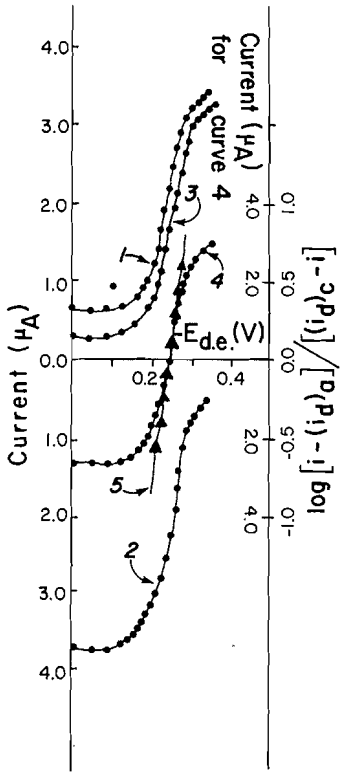

FIG. 2. Comparative anodic–cathodic $C-V$ curves of RSH and mercury–RSH complex in aqueous solution at pH 4.2. Curve *1*, 1.0 m*M* in RSH, electrolysed at large mercury pool electrode; curve 2, 1.0 m*M* in RSH; curve *3*, 1.0 m*M* in RSH + 0.5 m*M* in $HgCl_2$; curve *4*, 2.0 m*M* in RSH + 0.5 m*M* in $HgCl_2$; curve *5*, plot of $-E_{d.e.}$ vs. log $[i - (i_d)_a]/[(i_d)_c - i]$.

produced a composite wave of solution *i* and anodic wave of solution *ii*. The plot of $[i - (i_d)_a]/[(i_d)_c - i]$ for composite wave yielded a straight line with slope 0.0591 (in aqueous media), 0.0603 (in 40% methanol), 0.0624 (in 40% acetonitrile) (Figs. 2, 3, and 4, curve *5*). These observations clearly indicate that in the aqueous media, 40% methanol, and 40% acetonitrile, the anodic reaction is the anodic dissolution of mercury.

Conclusive experimental evidence was obtained by performing the following experiments with RSH and mercurous chloride. The solution containing (*i*) $HgCl_2$ and RSH in equimolar ratio and (*ii*) RSH solution saturated with Hg_2Cl_2 were polarographed under similar conditions. It was striking to note that the $C-V$ curves for the first solution showed large diffusion current at zero applied potential but the same value of slope and half-wave potential as that given by polarogram of solution *ii* and thus indicating the reduction of the same compound RSHg and the presence of the mercuric ions.

Kolthoff and co-workers (1, 4, 20, 25, and 26) considered the following reactions for the electrooxidation of mercaptan.

[5] $2RSH \rightleftharpoons RSSR + 2H^+ + 2e^-$

[6] $2RSH + Hg \rightleftharpoons Hg_2(RS)_2 + 2H^+ + 2e^-$

[7] $RSH + Hg \rightleftharpoons RSHg + H^+ + e^-$

They showed that a plot of $E_{d.e.}$ vs. log $(i_d - i)^2/i$ at 25°C should give a straight line with a slope of 0.059/2, if reactions [5] and [6] are involved (Fig. 5, curve *2*). On the other hand, if reaction [7] is involved, the plot of $E_{d.e.}$ vs. log $i_d - i/i$

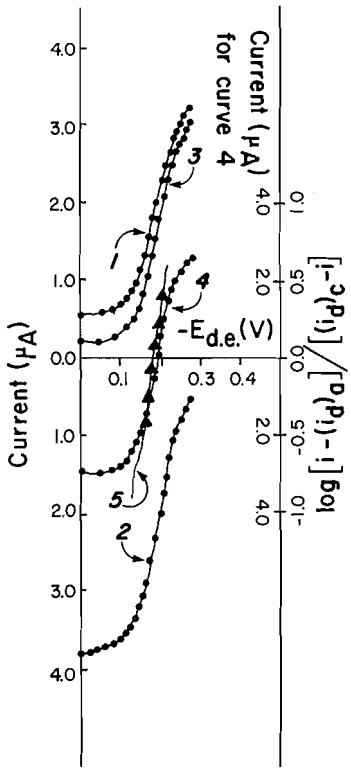

FIG. 3. Comparative anodic–cathodic $C-V$ curves of RSH and mercury–RSH complex in 40% v/v methanol at pH 3.22. Curve *1*, 1.0 m*M* in RSH, electrolysed at large mercury pool electrode; curve *2*, 1.0 m*M* in RSH; curve *3*, 1.0 m*M* in RSH + 0.5 m*M* in $HgCl_2$; curve *4*, 2.0 m*M* in RSH + 0.5 m*M* in $HgCl_2$; curve *5*, plot of $-E_{d.e.}$ vs. log $[i - (i_d)_a]/[(i_d)_c - i]$.

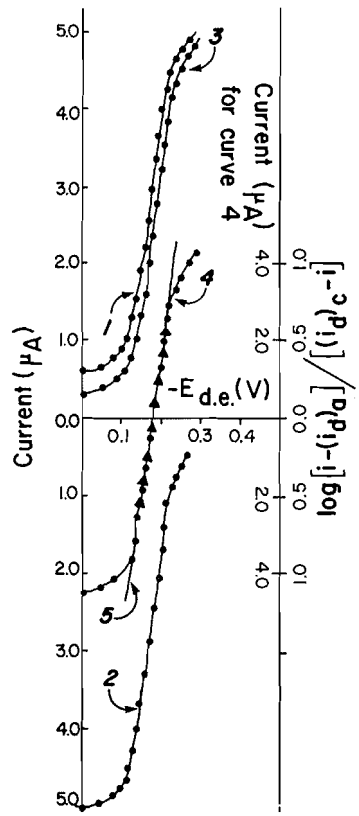

FIG. 4. Comparative anodic–cathodic $C-V$ curves of RSH and mercury–RSH complex in 40% v/v acetonitrile at pH 2.96. Curve *1*, 1.0 m*M* in RSH, electrolysed at large mercury pool electrode; cuve *2*, 1.0 m*M* in RSH; curve *3*, 1.0 m*M* in RSH + 0.5 m*M* in $HgCl_2$; curve *4*, 2.0 m*M* in RSH + 0.5 m*M* in $HgCl_2$; curve *5*, plot of $-E_{d.e.}$ vs. log $(i - (i_d)_a)/((i_d)_c - i)$.

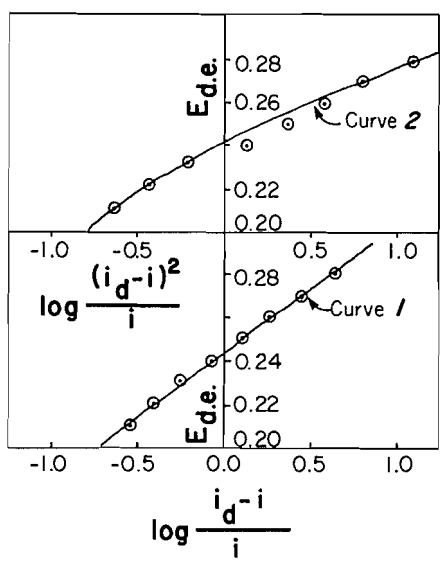

FIG. 5. Comparative plots of $E_{d.e.}$ vs. log $(i_d - i)/i$ (curve *1*) and $E_{d.e.}$ vs. log $(i_d - i)^2/i$ (curve *2*).

should give a straight line with a slope of 0.059. (Fig. 5, curve *1*). In the present case, it was found that only the analysis corresponding to reaction [7] yields a straight line with a slope equal to 0.059. Further, it was found that the half-wave potential remained constant when the RSH concentration varied from 1.33 to 0.4 m*M*. This constancy of half-wave potential is characteristic of eq. [7] but not of eqs. [5] and [6]. It may, therefore, be concluded that the anodic wave of RSH corresponds to the formation of mercurous mercaptide RSHg according to reaction [7]. This is in agreement with Kolthoff findings for cysteine and glutathione.

If this reaction is reversible the mercury in RSHg should be reversibly reducible at the dme. Experiments with RSH and mercurous chloride indicate that RSHg is not stable. In an attempt to prepare RSHg, when a solution of RSH is saturated with mercurous chloride, a whitish black precipitate, probably mixed precipitate of Hg_2Cl_2 and HgS, is obtained. Qualitative analysis of the insoluble portion showed that the presence of Hg^{2+} and polarographic analysis of the filtrate under identical conditions neither showed anodic wave nor cathodic wave except increased residual current. The formation of HgS and the absence of anodic or cathodic wave clearly reveal that mercurous chloride decomposes RSH, giving black precipitate of HgS, and that the complex RSHg is unstable.

The composite wave obtained with solution *iii* (Figs. 2, 3, and 4, curve *4*) containing RSH and $(RS)_2Hg$ has the same characteristics as the anodic wave of RSH. Figures 2, 3, and 4 give the current voltage curve of the composite wave (curve *4*) and the plot of log $[i - (i_d)_a]/[(i_d)_c - i]$ vs. $E_{d.e.}$ (curve *5*). The cathodic wave (Figs. 2, 3, and 4, curve *2*) of $(RS)_2Hg$ in the absence of RSH has the same characteristics as the composite wave mentioned above (that is, same slope (0.059) in the log plot and similar $E_{1/2}$). Experiments with $HgCl_2$ reveal that the cathodic wave results from the reduction of $(RS)_2Hg$ and it corresponds to the reduction of univalent mercury (Hg^+). The

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.105 on 09/06/12
For personal use only.

absence of any inflection of the composite wave (solution *iii*, curve *4*) and the identical characteristics of anodic wave given by RSH and cathodic wave by $(RS)_2Hg$ suggest that the anodic wave produced by RSH is reversible and the ultimate oxidation product is $(RS)_2Hg$. The controlled potential electrolysis studies indicate that the primary electrolysis product is quickly transformed to $(RS)_2Hg$. (cf. Kolthoff).

Thus RSH is not oxidised to RSSR at the dme but depolarizes the mercury with the formation of unstable RSHg, which changes rapidly into $(RS)_2Hg$. The wave due to $(RS)_2Hg$ corresponds to the reduction of univalent mercury apparently the reactions:

[8] $(RS)_2Hg + Hg \rightleftharpoons 2RSHg$

Similar behaviour was also observed by Saxena and Gupta (3, 5) for the other sulphydril compounds. The change in solution and diffusion coefficient have been reported to affect the shape of the wave, half-wave potential, and sometimes the electrode reaction as well (21–24).

Polarograms of 1.0 m*M* in RSH + 0.1 *M* KNO_3 + 0.01% thymol in varying aqueous media, methanol, and acetonitrile composition viz. 20, 40, 60, and 80% were also recorded in buffered media of identical pH values and similar conditions. The half-wave potentials were found to shift to the more positive potential and become irreversible in nature with increased concentration of organic solvents.

We may conclude that RSH in aqueous media, 40% methanol, and 40% acetonitrile is not oxidised to RSSR at the dme, but that it depolarizes the Hg with the formation of unstable RSHg. The reduction wave of $(RS)_2Hg$ corresponds to the reduction of univalent cation.

Protonation of the trisulphur trinitride ion, $S_3N_3^-$, with tetrafluoroboric acid yields the ring-contracted *S*-amino thiodithiazyl salt, $S_3N_2NH_2^+BF_4^-$. The crystal and molecular structure of this salt has been determined by X-ray diffraction. The crystals are triclinic, space group $P\bar{1}$, with $a = 5.445(2)$, $b = 7.346(3)$, $c = 9.473(5)$ Å, $\alpha = 85.89(4)$, $\beta = 83.92(3)$, $\gamma = 82.13(3)°$, $V = 372.6(4)$ Å^3, $D_c = 2.02$ g cm^{-3}, and $Z = 2$. The structure was solved by direct methods and refined by full-matrix least-squares procedures to give a final $R = 0.060$. The structure of the five-membered ring with a single exocyclic NH_2 group bonded to sulphur is discussed in relation to other S_3N_2NR derivatives. The reasons for the instability of six-membered rings of the type S_3N_3R are discussed in the light of MNDO molecular orbital calculations on an S_3N_3H model.

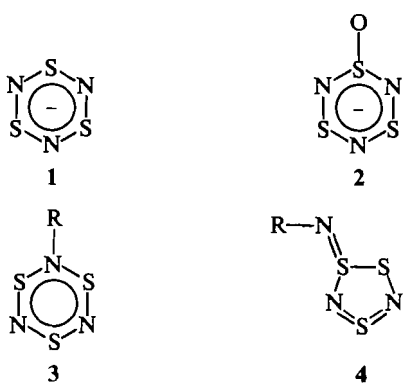
CLIFFORD G. MARCELLUS, RICHARD T. OAKLEY, A. WALLACE CORDES et WILLIAM T. PENNINGTON. Can. J. Chem. **62**, 1822 (1984).

La protonation de l'ion triniture de soufre $S_3N_3^-$ par l'acide tétrafluoroborique conduit au sel $S_3N_2NH_2^+BF_4^-$ comportant le cycle *S*-aminothiodithiazyle contracté. On a déterminé la structure du cristal et la structure moléculaire de ce sel par diffraction de rayons-X. Les cristaux appartiennent au groupe d'espace triclinique $P\bar{1}$, avec $a = 5,445(2)$, $b = 7,346(3)$, $c = 9,473(5)$ Å, $\alpha = 85,89(4)$, $\beta = 83,92(3)$, $\gamma = 82,12(3)°$, $V = 372,6(4)$ Å^3, $D_c = 2,02$ g cm^{-3} et $Z = 2$. On a résolu la structure par des méthodes directes et on l'a affinée par la méthode des moindres carrés (matrice entière) jusqu'à une valeur de $R = 0,060$. On discute de la structure du cycle à 5 chaînons portant un seul groupe NH_2 exocyclique lié au soufre en relation avec les structures d'autres dérivés S_3N_2NR. On discute des raisons de l'instabilité des cycles à 6 chaînons du type S_3N_3R à la lumière des calculs d'orbitales moléculaires MNDO sur un S_3N_3H modèle.

[Traduit par le journal]

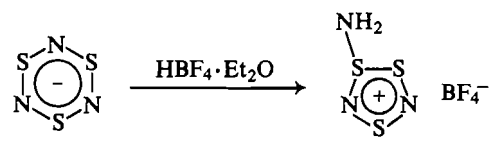
Introduction

The electronic structure of the trisulphur trinitride anion $S_3N_3^-$ has been a subject of recent discussion (1–5). While the possibility of symmetry breaking in the ground state has been suggested (2), the results of several spectroscopic (4) and theoretical (1, 3–5) studies have indicated that the species is best represented by the delocalized structure **1**. However, the threefold symmetry of the charge distribution can be lowered by chemical means. Thus the oxidation of $S_3N_3^-$ to $S_3N_3O^-$ (**2**) induces spectroscopic changes which reflect the splitting of the degenerate π^* H(ighest) O(ccupied) M(olecular) O(rbital) (6). Substitution at nitrogen by an electrophile (e.g. R^+) to produce **3** represents, at first sight, a correspondingly minor perturbation of the π-system of the anion. Nonetheless, while the existence of such species as **3** has been proposed on several occasions (7, 8), subsequent structural investigations have invariably revealed rearranged geometries based on the five-membered thiodithiazyl system **4** (9–12).



1 **2** **3** **4**

In order to investigate the apparent instability of derivatives such as **3** relative to **4**, we have examined the structural consequences of simple protonation of the $S_3N_3^-$ ion, using tetrafluoroboric acid. In this instance a rearrangement also occurs, the final product being the *S*-amino thiodithiazyl salt, $S_3N_2NH_2^+BF_4^-$ (reaction [1]). In the present paper we report the crystal and molecular structure of this salt and, using the S_3N_3H structure as a model system, present a molecular orbital interpretation of the electronic critera underlying the ring contraction process **3** to **4**. In our recent analysis of the structural consequences of the protonation of tetrasulphur tetranitride we demonstrated the importance of charge localization on the relative stabilities of different conformations of the eight-membered S_4N_4 ring (13). In the present paper these concepts are extended, and the subject of ring contraction in cyclic sulphur–nitrogen chemistry developed.



[1]

Experimental and theoretical procedures

Starting material

Tetrasulphur tetranitride S_4N_4 (14) and $PPN^+S_3N_3^-$ ($PPN^+ = [Ph_3P]_2N^+$) (15) were prepared according to published methods.

Tetrafluoroboric acid diethyl etherate was obtained commercially (Aldrich) and used without further purification. Methylene chloride (reagent grade) was dried by distillation from phosphorus pentoxide. Infrared spectra were recorded in Nujol mulls (CsI cell windows) using a Perkin-Elmer 467 grating spectrophotometer.

Preparation of $S_3N_2NH_2^+BF_4^-$

Method 1. An excess of $HBF_4 \cdot Et_2O$ (500 mg, 3.09 mmol) was added dropwise under an atmosphere of nitrogen to a solution of S_4N_4 (100 mg, 0.54 mmol) in 150 mL methylene chloride. The resulting deep red solution was left to stand at room temperature for 48 h, during which time the colour of the solution gradually faded to light orange, and canary yellow crystalline blocks were precipitated. The supernatant solution was decanted under nitrogen and the residual crystals washed with methylene chloride and dried *in vacuo*. The composition of these crystals was determined X-ray crystallography (*vide infra*) to be $S_3N_2NH_2^+BF_4^-$ (83 mg, 37 mmol). Infrared spectrum: 3340 (m, br), 3320 (m, br), 3070 (w), 1540 (m, br), 1250 (w), 1100–1000 (vs, br), 935 (s), 770 (w), 744 (ms), 520 (m), 470 (m, br), 380 (m).

Method 2. An excess of $HBF_4 \cdot Et_2O$ (500 mg, 3.09 mmol) was added dropwise under nitrogen to a solution of $PPN^+S_3N_3^-$ (500 mg, 0.74 mmol) in 15 mL methylene chloride. The resulting yellow solution was stored in a freezer at −20°C for one week, during which time canary yellow crystals were slowly produced. The supernatant liquid was decanted from these crystals, which were then washed with methylene chloride and dried *in vacuo*. The material was identified as $S_3N_2NH_2^+BF_4^-$ (124 mg, 0.55 mmol, 74%) by comparison of its infrared spectrum with that of a sample prepared from method 1.

X-ray analysis of $S_3N_2NH_2^+BF_4^-$

Crystals suitable for X-ray work were prepared by method 1 and sealed under argon in a glass capillary. All data were collected using an Enraf-Nonius CAD-4 diffractometer and graphite-monochromated Mo K_α (λ = 0.71073 Å) radiation. A least-squares calculation using the diffractometer settings for 25 carefully centred reflections with $22° < 2\theta < 34°$ gave the following cell dimensions (at 21°C): a = 5.445(2), b = 7.346(3), c = 9.473(5) Å, α = 85.89(4), β = 83.92(3), λ = 82.13(3)°, and V = 372.6(4) Å^3. For $S_3N_3H_2BF_4$ with mw = 227.03 and Z = 2, D_c = 2.02 g cm^{-3}, F_{000} = 224, and μ(MoKα) = 9.66 cm^{-1}.

The space group was verified by successful refinement in $P\bar{1}$ and our inability to get a better refinement in the non-centric group. A total of 3225 unique reflections were measured using $\theta-2\theta$ scans for 2θ from 2 to 70° (h = −8 to 8, k = −11 to 11, l = 0 to 15). The scan range was (1.0 + 0.35 tan θ) and the scan speeds varied from 4.0 to 20.1 deg min^{-1}. A total of 1725 reflections had $I < 3\sigma(I)$ and were considered unobserved. The intensities of three reflections (1 −1 5, −3 0 −3, 0 −4 0) which were measured periodically during the data collection varied less than 6.3% and thus indicated general crystal and electronic stability. No absorption correction was made.

The structure was solved by MULTAN 78 (16) followed by Fourier and least-squares techniques. The final full-matrix least-squares refinement based on F^2 included 108 parameters (positional and isotropic thermal parameters for hydrogen atoms) and had a parameter: reflection ratio of 1:14. The weighting scheme based on counting statistics (p = 0.07) gave no systematic variation $F/\sigma(F)$ as a function of F or sin θ. No secondary extinction correction was made. In the final cycle of refinement the maximum shift/error was 0.03, R = 0.060, R_w = 0.090, and GOF = 1.90. The final difference map had a maximum value of 0.82 e Å^{-3}. Neutral atom scattering factors corrected for real and imaginary anomalous dispersion corrections were used (17). The computer programmes used were those provided by the Enraf-Nonius SDP programme package.

Molecular orbital calculations

The M(odified) N(eglect) of D(iatomic) O(verlap) method (18) has been used by several groups for examining the electronic structures and molecular geometries of binary sulphur nitrides and related derivatives (13, 19–22). Although the method is somewhat deficient in assessing sulphur–sulphur interactions (23) it has, in several cases, been quite successful in predicting ground state geometries (e.g., S_4N_2 (19), S_3N^- (22), S_4N^- (20), $S_4N_4H^+$ (13)). In our studies on S_3N_3H and related systems we have used models with varying geometrical constraints. Numerical estimates of π-charge densities and bond orders (aps) (24) for S_3N_3H (**3**) refer to a calculation performed with full geometry optimization within the confines of C_{2v} symmetry. For the calculations related to the transformation from S_3N_3H to S_3N_2NH (i.e., **3** to **4**), no geometrical constraint was imposed save for the assumption of planarity within the five-atom SNSNS sequence. Numerical information pertaining to $S_3N_3^-$ were obtained from a calculation in which D_{3h} symmetry was imposed.[2]

Discussion

Preparation of $S_3N_2NH_2^+BF_4^-$

The reaction of $S_3N_3^-$ salts with electrophiles is known to produce ring-contracted products of the type **4** (25). Accordingly the acidification of a solution of $PPN^+S_3N_3^-$ in methylene chloride with tetrafluoroboric acid diethyl etherate affords a pale yellow microcrystalline precipitate of the salt $S_3N_2NH_2^+BF_4^-$ (reaction [1]). However, a more convenient route to this compound involves the protonation of S_4N_4 with $HBF_4 \cdot Et_2O$. This latter reaction, which we have previously used to prepare $S_4N_4H^+BF_4^-$, can be modified by using more dilute solutions to prevent the precipitation of the initially formed product. Under these conditions the red colour of the solution gradually fades to orange, and yellow crystalline blocks of $S_3N_2NH_2^+BF_4^-$ are slowly formed.[3] The mechanism of this secondary reaction is open to speculation, but we note the analogy between the present results and the production of related S_3N_2NR **4** derivatives via the reaction of S_4N_4 with acid anhydrides (7, 10, 27).

Crystal structure of $S_3N_2NH_2^+BF_4^-$

Crystals of this compound consist of $S_3N_2NH_2^+$ cations and BF_4^- anions interconnected by both hydrogen bonding and charge transfer interactions. An ORTEP drawing of a single cation and anion, indicating the atom numbering scheme, is given in Fig. 1. Figure 2 illustrates the packing of the ions in the unit cell, and Fig. 3 is an ORTEP drawing of a single cation and all of the atoms which are involved in hydrogen bonding

[2]It is worth noting that when the D_{3h} restriction was lowered to C_{2v}, no significant alteration was observed in the molecular orbital distributions.

[3]A yellow crystalline compound of unknown composition has been observed in the reaction of S_4N_4 with fluorosulphuric acid (ref. 26). We suggest that this material may be $S_3N_2NH_2^+SO_3F^-$.

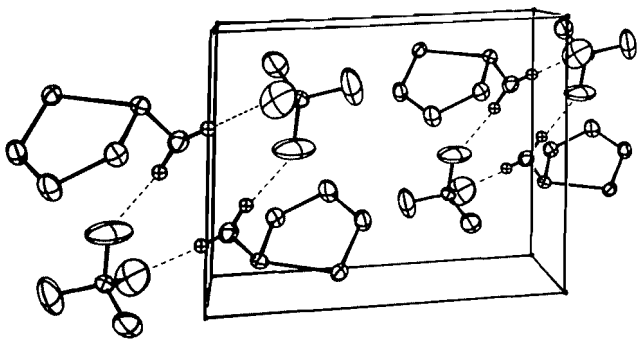

FIG. 2. Crystal packing for $S_3N_2NH_2^+BF_4^-$. The x axis is horizontal, the y axis vertical, and the origin is in the lower, left, rear corner.

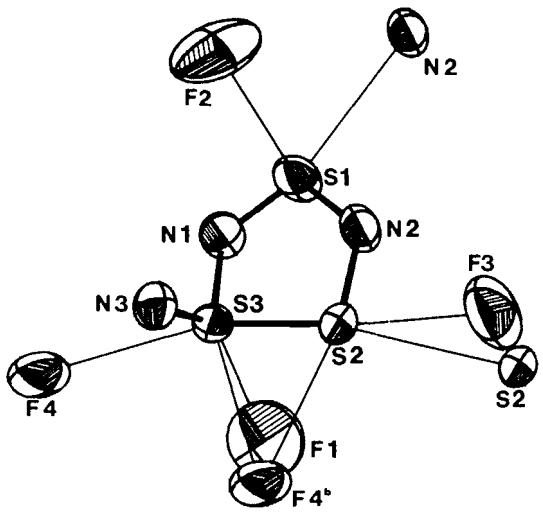

FIG. 3. ORTEP drawing (30% probability ellipsoids) of one $S_3N_2NH_2^+$ cation and all of the atoms involved in charge transfer interactions with it.

and charge transfer interactions with it. A listing of atom positions can be found in Table 1, while Table 2 provides bond distances and angles within each cation and anion. Table 3, providing temperature factors for the structure, and Table 4, which lists all the hydrogen bond and charge transfer interactions, have been deposited.[4]

Hydrogen bonds in the crystal are formed between the two hydrogen atoms of the amine group and fluorine atoms of two symmetry-related anions in the crystals (H1---F2 = 1.55(5) Å, F2 at symmetry transformation: $x - 1, y, z$; H2---F1 = 2.14(6) Å, F1 at symmetry transformation: $-x, 1 - y, -z$), forming a dimer of ion pairs about an inversion centre at $x = 0.5$, $y = 0.0$, and $z = 0.0$.

Charge transfer interactions (28) are also present, as in several related sulphur nitride salts, e.g., those of $S_3N_2^+$ (26), $S_4N_3^+$ (29). In the present case the most common interaction of this type involves transfer from a lone-pair type orbital on fluorine to an acceptor orbital (probably σ^*) on sulphur. Consistent with this interpretation all such contacts share three common features: they (*1*) are shorter than van der Waals' separations,[5] (*2*) are directed *trans* to an endocylic σ-bond (S—S or S—N), and (*3*) generate approximately tetrahedral angles with the primary covalent bonds to fluorine (i.e. B—F---S ~109°). Thus, the disulphide group of the cation is bridged by a fluorine atom (F4 at symmetry position $x - 1$, $y - 1, z$), the two S---F contacts being approximately *trans* to the S3—N1 and S2—N2 bonds. There are also interactions to these two sulphurs in directions colinear with the disulphide bond (S3---F4 of the anion at symmetry position $1 - x, 1 - y, -z$; S2---F3 of the anion at symmetry position $-x, 1 - y, 1 - z$). Finally there is a contact *trans* to the S3—N3 bond (S3---F1 of the anion at $x, y - 1, z$). For all of these interactions the primary covalent bond to the donor fluorine increases with the extent of charge transfer. For $S_3N_2NH_2^+BF_4^-$, the longest B—F bond (B—F4 = 1.342(5) Å) is almost 7σ's longer than the average of the other three B—F bonds, and involves the fluorine atom with the most numerous as well as the shortest charge transfer contacts.

*Atom numbering follows that shown in Fig. 1.
†Not reported.

In addition to the above anion–cation interactions, there are two cation–cation contacts which may also be of a charge transfer variety: N2 of a cation at $-x, 1-y, 1-z$ approaches S1 *trans* to the S1—N1 bond (N2---S1 = 3.222(4) Å), and there is a contact between S2 and the equivalent sulphur atom of a cation at $-x, -y, 1-z$ (S2---S2 = 3.642(2) Å).

The structure of the $S_3N_2NH_2^+$ cation

From a purely topological viewpoint, the molecular configuration of the $S_3N_2NH_2^+$ can be conveniently described as resulting from the insertion of an S—NH_2^+ group into the 6π-electron four-membered ring of disulphur dinitride.[6] The five-membered S_3N_2 ring is nearly planar, with the ring nitrogen atoms N1 and N2 displaced to opposite sides of the plane of the three sulphur atoms by 0.253(4) and 0.149(5) Å, respectively. The exocylic nitrogen atom lies 1.482(4) Å out of this plane to the side opposite N1.

The structures of a number of related five-membered S_3N_2NR rings have been determined (S_3N_2—NSO_2F, S_3N_2—$NCOCF_3$, S_3N_2—$NP_3N_3F_5$, S_3N_2—NSO_2NAsPh_3). A comparison of the S—S and S—N distances for all of these compounds, including $S_3N_2NH_2^+$, can be found in Table 5. The multiple bond character of the S—N bonds, the difference in bond lengths to S1 as opposed to S2 and S3, and the inequality of the S—N bonds to S1 are features which are common to all the S_3N_2X derivatives. The somewhat longer than normal S2—S3 bond and the lengthening of S3—N1 with respect to N2—S2 can be viewed as the result of a weakening caused by the mixing of a lone pair orbital on the exocylic nitrogen with the σ* orbitals associated with the S2—S3 and S3—N1 bonds (31). Certainly the near planarity of the S—NH_2 group in $S_3N_2NH_2^+$ (sum of angles at N3 equals 357°) and its orientation with respect to these bonds accommodates this interpretation.

*Molecular orbital analysis of the transformation **3** to **4***

Our major concern in the present study has been to understand the energetic preference for structures such as **4** over those such as **3**. Why should the latter be unstable with respect to ring contraction? Our strategy has been to carry out MNDO molecular orbital calculations on a series of model compounds based on S_3N_3H and $S_3N_3H_2^+$ formulas with the aim of evaluating the electronic factors which dictate the transformation of the **3** configuration into **4**.

*See ref. 24.

It is useful to begin the analysis by considering the consequences of the protonation of the $S_3N_3^-$ ring. Table 6 provides a charge and bond order breakdown for a model S_3N_3H molecule with C_{2v} symmetry. As expected, the electronic effects of protonating the $S_3N_3^-$ ion parallel those observed in $S_4N_4H^+$ (in C_{2v} symmetry). Electron density is drawn away from the protonated nitrogen through the N—H σ-bond, and the π-system "responds" by polarizing charge back onto the protonated nitrogen. Thus the π-charge at N(H) is larger (q_π = 1.94) than in $S_3N_3^-$ (q_π(N) = 1.67), while at the unperturbed nitrogens it is somewhat less (q_π = 1.47). Further information pertinent to the strength of the π-network can be obtained from an examination of the individual π-orbitals. Figure 4 illustrates the spatial and nodal properties of these orbitals. Like its parent anion $S_3N_3^-$, S_3N_3H is a 10π-electron system. The five occupied π-orbitals can be classified into three bonding ($1b_1$, $2b_1$, and $1a_2$) and two antibonding ($3b_1$ and $2a_2$) distributions. From

[6]The distributions of the π-like orbitals in S_3N_2X derivatives have been discussed by Gleiter and co-workers (30).

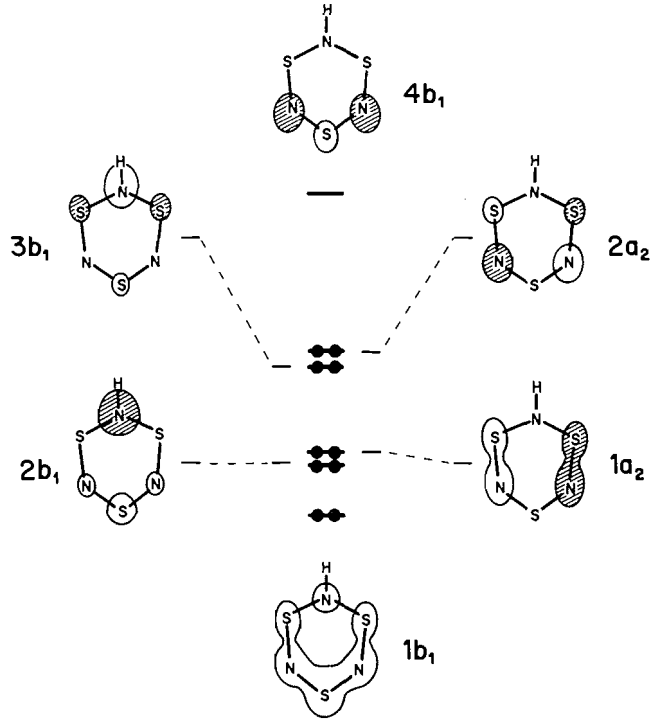

FIG. 4. Distributions and relative energies of the π-molecular orbitals (MNDO) for S_3N_3H (in C_{2v} symmetry). See Table 6 for eigenvalues.

an energetic standpoint the splitting of the formerly degenerate pairs of $S_3N_3^-$ ($2b_1$, $1a_2$ and $3b_1$, $2a_2$) is small. However, the π-bond orders, like the π-charge densities, are acutely sensitive to the electronegative perturbation caused by protonating the ring. As is indicated in Table 5, the $2b_1$ and $3b_1$ orbitals are polarized towards the protonated nitrogen, while the $1b_1$ is polarized away from it. The occupation of the $3b_1$ offsets the bonding contribution of the $2b_1$ orbital, and this effect, combined with the polarization of the $1b_1$ away from the S—N(H)—S region, leads to a weakened π-structure in the S—N(H)—S region and a strengthened S—N—S—N—S fragment. Thus the total π-bond orders (24) to the protonated nitrogen (0.00) are effectively nullified while those of the remaining S—N linkages are significantly larger (0.30, 0.31) than in $S_3N_3^-$ (0.11). In essence, the effect of protonation of $S_3N_3^-$ is to strengthen all the skeletal bonds save those to the protonated nitrogen. The latter are weakened to such an extent that some deformation is to be expected.

We have examined the energy consequences of a variety of deformations of the planar (C_{2v}) S_3N_3H model. Allowing the protonated nitrogen to move independently of the plane of the remaining five ring atoms (while the geometry at the N(H) atom is held planar) produces a chair-like conformation with a dihedral angle near 90°. The energy of this structure is ~5 kcal/mol lower than that of the C_{2v} structure. In order to simulate (and stimulate) the conversion of $S_3N_3H \rightarrow S_3N_2NH$ we performed a series of calculations in which the heat of formation was monitored as a function of d(S—S) (all other geometrical variables being optimized independently). Under these circumstances the six-membered ring structure remains the most stable until d(S—S) ≃ 2.2 Å, at which point the ring-contracted variation takes over (Fig. 5). We place little emphasis on the fact that the ring-contracted isomer **4** is predicted to be less stable (by ~20 kcal/mol) than the planar

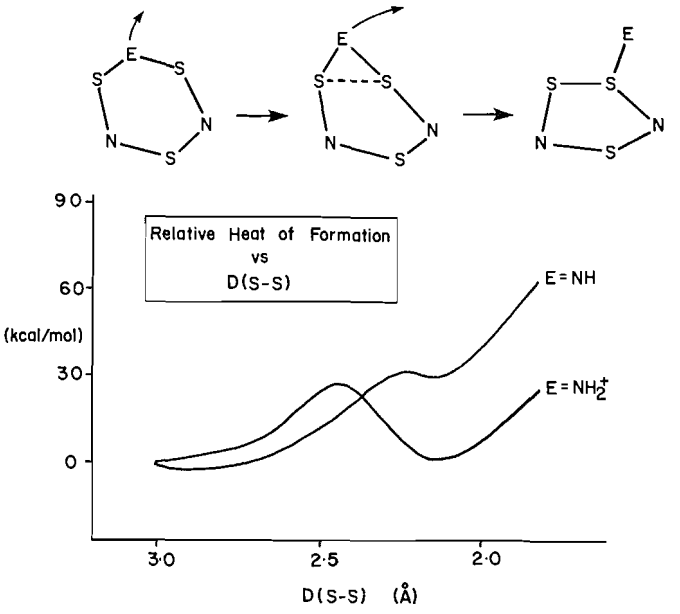

FIG. 5. Energy profile (MNDO) for the transformation of S_3N_3H and $S_3N_3H_2^+$ from six-membered to five-membered rings.

structure **3**. The discrepancy probably arises from the inadequacy of the MNDO method in assessing sulphur—sulphur interactions (23). However, we note that an analogous calculation performed on a model $S_3N_3H_2^+$ system produces a transformation **3** to **4** that is slightly exothermic (see Fig. 5). The activation energy calculated for the conversion of $S_3N_3H_2^+$ to $S_3N_2NH_2^+$ (~30 kcal/mol) probably represents a substantial overestimate of the true barrier to rearrangement. Low temperature nmr studies on the reaction of $S_3N_3^-$ with electrophiles may provide a means for measurement of this barrier.

Conclusion

It is well recognized that the π-networks of a planar binary sulphur nitrogen ring are weakened by the occupation of π* as well as π orbitals. Structural evidence on many compounds reveals that lattice forces alone are enough to cause significant molecular distortions (6). The protonation of S_4N_4 to $S_4N_4H^+$, and of $S_3N_3^-$ to S_3N_3H, effects stronger and more specific perturbations of the ring π-systems, resulting in extensive polarization of π* electron density into the skeletal bonds to the protonated nitrogens. The localized weakening of the cyclic frameworks can be alleviated in different ways; in $S_4N_4H^+$, the eight-membered ring puckers into a boat-like conformation, while in S_3N_3H a more drastic rearrangement, involving the cleavage of one of the weakened S—NH bonds, is observed. These two examples serve to illustrate that the polarizability of the π-systems of sulphur—nitrogen rings, coupled with the occupation of antibonding π-orbitals, leads to cyclic structures that will distort or even collapse upon coordination at nitrogen. The extensive chemistry of sulphur nitrides with Lewis acids and electrophiles should perhaps be interpreted in the light of these findings.

Crystal structure of 17,18,19-trisnorstemodan-3,13-dione

STEPHEN V. EVANS AND JAMES TROTTER
Department of Chemistry, University of British Columbia, Vancouver, B.C., Canada V6T 1Y6

Received September 27, 1983

STEPHEN V. EVANS and JAMES TROTTER. Can. J. Chem. **62**, 1828 (1984).

Crystals of the title compound, $C_{17}H_{24}O_2$, are monoclinic, $P2_1/c$, a = 10.395(2), b = 10.980(1), c = 13.181(3) Å, β = 113.55(1)°, Z = 4. The structure was solved by direct methods and refined by full-matrix least-squares to R = 0.051 for 1622 reflections with $I \geq 3\sigma(I)$. The molecule contains a tetracyclic system of three six-membered rings and one five-membered ring; the structure exhibits disorder of one C atom. Bond lengths and angles are normal.

STEPHEN V. EVANS et JAMES TROTTER. Can. J. Chem. **62**, 1828 (1984).

Les cristaux du composé du titre, $C_{17}H_{24}O_2$, sont monocliniques, $P2_1/c$, a = 10,395(2), b = 10,980(1), c = 13,181(3) Å, β = 113,55(1)°, Z = 4. On a résolu la structure par les méthodes directes et on a l'affinée par la méthode de moindres carrés (matrice entière) jusqu'à une valeur de R = 0,051 pour 1622 réflexions avec $I \geq 3\sigma(I)$. La molécule comprend une système tetracyclique, trois cycles de six membres et une cycle de cinq membres; et la structure présente la desordre de l'un des atomes de carbone. Les longeurs de liaisons et les angles sont normales.

Introduction

In a continuing research program aimed at the total synthesis of the structurally and physiologically interesting diterpenoid stemodin (**1**), a tetracyclic diketone possessing the stemodane carbon skeleton has been isolated (1). To establish the structure and stereochemistry conclusively before attempting conversion to (±)-stemodin, an X-ray analysis of the diketone has been undertaken, which proves structure **2**.

Experimental

Crystal data at 22°C:

$C_{17}H_{24}O_2$ fw = 260.38

Monoclinic, $P\ 2_1/c$, a = 10.395(2), b = 10.980(1), c = 13.181(3) Å, β = 113.55(1)°, Z = 4, V = 1379.1(5) Å^3, D_m = 1.26, D_c = 1.25 g cm^{-3}, $F(000)$ = 568, $\lambda(K\alpha_1)$ = 0.70930, $\lambda(K\alpha)$ = 0.71073 Å, μ = 0.9 cm^{-1}.

Intensity data were measured with Mo$K\alpha$ radiation (graphite monochromator) on an Enraf-Nonius CAD4-F diffractometer. An $\omega-2\theta$ scan was used, ω-scan angle (0.90 + 0.35 tan θ)° (extended by 25% on both sides for background measurement), scan speeds 1.55–10.06 deg min^{-1}, horizontal aperture (2.00 + tan θ) mm, vertical aperture 4 mm; three standard reflections showed no significant intensity variation during data collection. Cell parameters were refined by least-squares methods on sin θ values for 25 reflections with θ = 10–14° (the CAD4 procedure measures the peak profile and estimates the position of the α_1 peak).

A total of 3159 reflections were measured to θ = 27.5°, of which 1622 (51%) had $I \geq 3\sigma(I)$, where $\sigma^2(I) = S + 2B + [d(S - B)]^2$, with S = scan count and B = background count; previous experience indicated a value of 0.04 for d, and the appropriateness of this value was confirmed by the subsequent weighting scheme analysis. The intensities of the reflections fall off fairly rapidly with θ angle, presumably as a result of crystal quality (which might be affected by the disorder found in the structure). Most of the high angle reflections are weak, with only 30% of reflections in the range θ = 22–27.5°, but 70% of those in the range θ = 0–22°, having $I \geq 3\sigma(I)$. Lorentz and polarization factors but no absorption corrections were applied.[1]

The structure was solved by direct methods, and refined by full-matrix least-squares techniques; H atoms were located from a difference synthesis and included in the refinements, which converged to R = 0.047. Unusual geometry and large thermal anisotropy for the methylene carbon C(12) suggested disorder, which was treated by introducing two atomic positions C(12+) and C(12−) separated by about 0.67 Å, with isotropic thermal parameters and final occupancies

after refinement of 75% and 25%, respectively. A fully-occupied position H(12) corresponding to overlap of two partially-occupied hydrogen positions, one from C(12+) and one from C(12−), and the other 75% occupancy H(12+) were located; no difference map peak corresponding to the second 25% occupancy H(12−) was found, not surprisingly, and no contribution was included from this quarter-hydrogen atom. Ideally this description of the disorder should be extended to neighboring atoms C(13) (the C(12−)—C(13) bond

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.40 on 09/06/12
For personal use only.

length being rather poor) and to a smaller extent to C(11), C(9), C(14), etc. However, the reasonable anisotropic thermal parameters for these atoms, and the high correlation between the positional parameters of closely-spaced split atoms indicated that treatment of only C(12) as disordered is probably reasonably appropriate. The scattering factors of refs. 2 and 3 were used; the weighting scheme $w = 1/\sigma^2(F_0)$ gave uniform average values of $w(F_0 - F_c)^2$ over ranges of $|F_0|$ and $\sin\theta/\lambda$; the function minimized was $\sum w(F_0 - F_c)^2$, $R = \sum(F_0 - F_c)/\sum F_0$, $R_w = (\sum w(F_0 - F_c)^2/\sum wF_0^2)^{1/2}$. Final $R = 0.051$, $R_w = 0.064$ for 1622 reflections with $I \geq 3\sigma(I)$; the final R value of 0.051 for the disordered structure is slightly higher than that of 0.047 for the model with one C(12) position refined with large anisotropic thermal parameters; the disordered model is, however, more physically realistic. For all 3159 reflections to $\theta = 27.5°$, $R = 0.113$. The standard deviation in an observation of unit weight was 2.53; a final difference map showed maximum random fluctuations of ± 0.3 e Å^{-3}.

Final positional parameters are in Table 1, and thermal parameters, structure factors, and other material have been placed in the Depository of Unpublished Data.[2]

Discussion

The X-ray analysis has established the structure as **2** (Fig. 1). C(12) is disordered over two positions with 75:25 occupancies; the structural details in that region of the molecule are therefore less accurately defined. The three six-membered rings have chair conformations (with the 75% C(12+) position), considerably flattened and distorted as a result of the keto substituents and of the presence of the bridged ring system. The lower occupancy C(12−) position results in a shallow boat conformation for the C(9)—C(16) ring. The five-membered ring is best described as a half-chair, with C(9) and C(16) displaced in opposite directions from the C(8), C(15), C(14) plane.

Bond distances and angles (Table 2) are within normal ranges for such a condensed ring system. C(sp^3)—C(sp^3) = 1.505−1.563(3−5), mean 1.536, C(sp^3)—C(sp^2) = 1.476−1.506(4−5), mean 1.490 Å (omitting the distances involved in the less accurate C(12−) position), C=O = 1.205, 1.209(3) Å, angles at C(sp^3) = 101.5° at C(16), 104.6−117.6°, angles at C(sp^2) = 114.8−123.6°. Intermolecular distances correspond to van der Waals interactions.

Reactions of NO_2 and nitrite ion with organic radicals[1]

ALLEN JOHN ELLIOT[2] AND ANITA SANDRA SIMSONS[3]

Physical Chemistry Branch, Chalk River Nuclear Laboratories, Atomic Energy of Canada Limited Research Company, Chalk River, Ont., Canada, K0J 1J0

Received October 20, 1983

ALLEN JOHN ELLIOT and ANITA SANDRA SIMSONS. Can. J. Chem. **62**, 1831 (1984).

When deoxygenated aqueous sodium nitrate solutions containing an alcohol as a hydroxyl radical scavenger are irradiated, $G(NO_2^-)$ depends on the fraction of $\dot{O}H$ which forms 1-hydroxyalkyl radicals. This arises because $\dot{N}O_2$ is not reduced to nitrite by 2- or 3-hydroxyalkyl radicals.

Helium- and N_2O-saturated sodium nitrite solutions containing different organic hydroxyl radical scavengers were irradiated. Measurements of $G(-NO_2^-)$ showed that the radicals, $\dot{C}H_2OH$ and $\dot{C}H_2C(CH_3)_2OH$, do not react with the nitrite ion as rapidly as $CO_2^{\dot{-}}$ and $(CH_3)_2\dot{C}OH$. With the latter two radicals, nitric oxide is probably formed from the reaction with the nitrite ion.

ALLEN JOHN ELLIOT et ANITA SANDRA SIMSONS. Can. J. Chem. **62**, 1831 (1984).

Lorsqu'on irrarie des solutions aqueuses désoxygénées de nitrate de sodium contenant un alcool agissant comme piège radicalaire des hydroxyles, les valeurs de $G(NO_2^-)$ dépendent de la fraction des $H\dot{O}$ qui forment des radicaux hydroxyl-1 alkyles. Ceci est dû au fait que le $\dot{N}O_2$ n'est pas réduit en nitrite par les radicaux hydroxy-2 (ou -3) alkyles.

On a aussi irradié des solutions de nitrite de sodium saturées par de l'hélium et du N_2O et contenant divers pièges pour les radicaux hydroxyles organiques. Des mesures de $G(-NO_2^-)$ ont permis de montrer que, vis-à-vis l'ion nitrite, les radicaux $HO\dot{C}H_2$ et $HOC(CH_3)_2\dot{C}H_2$ ne réagissent pas aussi rapidement que les radicaux $CO_2^{\dot{-}}$ et $HO(CH_3)_2\dot{C}$. Avec les deux derniers radicaux, il se forme probablement de l'oxyde nitrique par réaction avec l'ion nitrite.

[Traduit par le journal]

Introduction

The aqueous free radical chemistry of the oxides of nitrogen has been studied extensively by photo- and radiation-chemical techniques (1–8). In operating nuclear reactors, nitric acid and nitrate ions are formed by radiation processes both in the annulus gases (9) and the coolant circuits (10) causing corrosion of metal components. Gadolinium nitrate is used as a neutron flux control agent in the moderator of CANDU reactors. In aqueous solutions, the important reactions involving the oxides of nitrogen have been identified along with their rate constants, but the effect of organic impurities on the radiolysis of nitrate systems has received less attention although these impurities may lead to problems such as excessive hydrogen production.

In radiation chemistry studies, the nitrate ion has been used extensively to measure the yield of the solvated electron, e_{aq}^-, in aqueous solution (11–19). In the irradiation of a nitrate solution containing a hydroxyl radical scavenger such as the formate ion (11–14) or an alcohol (11, 12, 15–18), $G(NO_2^-)$ is equated to $G(e_{aq}^-)$. On examination, the literature shows that, while similar, values of $G(NO_2^-)$ are different when different $\dot{O}H$ scavengers are used, e.g., formate ion, methanol, ethanol, and 2-propanol, even after allowing for their scavenging reactivities (12). In an earlier paper from this laboratory (11), it was also noted that when the hydroxyl scavenger was formate or 2-propanol, the yield of $G(NO_2^-)$ was not linear with dose suggesting that the nitrite ion was reacting with $CO_2^{\dot{-}}$ and $(CH_3)_2\dot{C}OH$. Henglein has reported that the nitrite ion is reduced by $(CH_3)_2\dot{C}OH$ (20).

An understanding of the role of organic radicals in nitrate and nitrite chemistry is also important in other areas; the use of the nitrate–nitrite redox couple as a store for photochemical energy (21) and also in the possible formation of carcinogenic nitrosoamines by free radical processes in the body from nitrite used as a food preservative (22). In this paper, we report on the reaction, in aqueous solutions, of $\dot{N}O_2$ and NO_2^- with radicals derived from the formate ion and from a series of alcohols.

Experimental

The solute chemicals (purchased from Fisher Scientific, Baker, Anachem and BDH) were all used as supplied except for *tert*-butanol (2-methyl-2-propanol) which was recrystallized. The solutions were prepared with triply distilled water. The pH was adjusted with perchloric acid for acid solutions; a phosphate buffer (3×10^{-3} mol dm^{-3}) for pH 7, and a borate buffer (3×10^{-3} mol dm^{-3}) for pH 9. The solutions were deoxygenated by bubbling with the appropriate UHP gas and irradiated in syringes. Nitrous oxide was first passed through a RIDOX (Fisher) column to remove any traces of oxygen.

The solutions were irradiated in an AECL Gammacell at a dose rate of approximately 2.2×10^{19} eV dm^{-3} s^{-1}. In some experiments a lower dose rate of 6.4×10^{17} eV dm^{-3} s^{-1} was obtained by irradiating the samples in a water-cooled lead block. In all experiments the nitrite ion was assayed as the product formed or the solute being removed. Its concentration was determined by the diazo-method (23) using an extinction coefficient at 540 nm of 52 860 mol^{-1} dm^3 cm^{-1} for solutions containing low concentrations of hydroxyl radical scavengers. Alcohols at high concentrations affected the final optical density in the nitrite assay so standard curves were prepared in these situations.

Results

(i) Sodium nitrate solutions

Helium-saturated solutions containing 2.5×10^{-3} mol dm^{-3} sodium nitrate were irradiated at pH 6.8 along with one of the hydroxyl scavengers: *tert*-butanol, 1-butanol, 1-propanol, 2-propanol, methanol, and the formate ion. As in earlier work from these laboratories (11), $G(NO_2^-)$ values shown in Fig. 1 are the values extrapolated to zero dose. With unbuffered solutions the $G(NO_2^-)$'s were the same, within experimental error, as those given in the figure. $G(NO_2^-)$ for the nitrate–methanol solution was also unchanged when irradiated at pH 9. In this study, except for *tert*-butanol, the concentration of the organic solute was sufficient to scavenge greater than 90% of the hydrogen atoms (24). With 0.1 mol dm^{-3} and 1.0 mol dm^{-3} *tert*-butanol, about 25% and 75%, respectively, of hydrogen

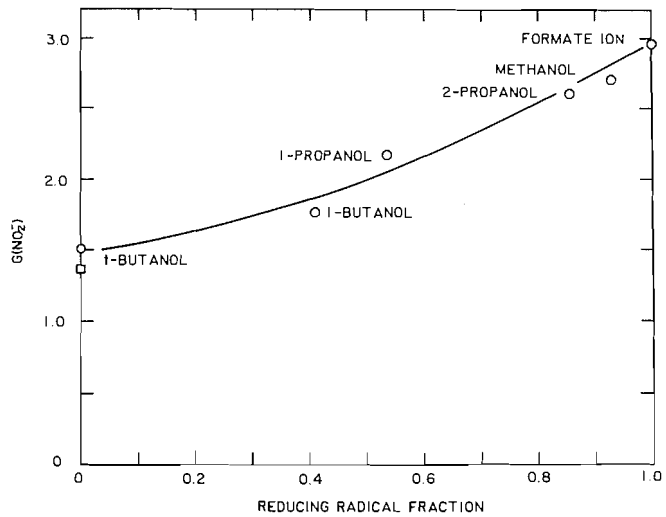

FIG. 1. $G(NO_2^-)$ as a function of the fraction of hydroxyl radicals forming reducing radicals for irradiated, helium saturated solutions containing 2.5×10^{-3} mol dm^{-3} $NaNO_3$ and 0.1 mol dm^{-3} (○) or 1 mol dm^{-3} (□) hydroxyl radical scavenger.

atoms were scavenged by the alcohol in competition with the nitrate ion. With the addition of 10^{-5} mol dm^{-3} copper(II) sulphate to 2.5×10^{-3} mol dm^{-3} sodium nitrate, 0.1 mol dm^{-3} *tert*-butanol solution, $G(NO_2^-)$ was reduced from 1.5 to 1.3.

(ii) Sodium nitrite solutions

Helium- and N_2O-saturated solutions containing sodium nitrite and various organic solutes (see Table 1) were irradiated at different pH's, dose rates, and solute concentrations. In these experiments the *G*-value for nitrite ion loss $G(-NO_2^-)$ was determined from 10–50% conversions of nitrite ion. The results are summarized in Table 1.

At pH 4.6, the formate solutions were self buffering, therefore the pH did not change during irradiation. However, at pH 4.6 with 2-propanol as the solute, the pH increased during the irradiation with the initial loss of protons, $G(-H^+)$, being about 1.3. In some experiments involving both helium- and N_2O-saturated solutions containing 0.1 mol dm^{-3} formate, NO was assayed for by the method described by Seddon and Sutton (25) but was not detected.

Henglein (20) reported that when a deoxygenated 10^{-3} mol dm^{-3} nitrite solution containing 0.2 mol dm^{-3} acetone and 0.4 mol dm^{-3} 2-propanol was irradiated, $G(-NO_2^-)$ was about 5. Since our results for 2-propanol solutions were all less than 2 (Table 1), Henglein's experiment was repeated at pH 6.8 and pH 9.4. The *G*-value for nitrite loss was 2.2 and 2.4, respectively.

(iii) Nitromethane solutions

The *G*-value for nitrite formation in a 10^{-4} mol dm^{-3} nitromethane solution, saturated with N_2O and irradiated at pH 9.5, was less than 0.2. When a helium-saturated 10^{-2} mol dm^{-3} nitromethane, 0.1 mol dm^{-3} sodium formate solution (pH 6.7) was irradiated, $G(NO_2^-)$ was less than 0.1.

Discussion

(i) Sodium nitrate solutions

A correlation exists between $G(NO_2^-)$ and the fraction of 1-hydroxyalkyl radicals formed by reaction of ·OH and ·H with the alcohol (26) present in the solution (Fig. 1). The fraction of CO_2^- formed from formate ions is taken as unity (26). These radicals are strong reducing agents and will be denoted as $\dot{R}_r$; the remaining 2- or 3-hydroxyalkyl radicals and alkoxy radicals formed will be denoted as $\dot{R}_{nr}$. In general terms, the radiolysis of deoxygenated nitrate–alcohol (or formate) solutions can be described by reactions [1]–[6].

$$[1] \quad NO_3^- + e_{aq}^- \xrightarrow{H_2O} \dot{N}O_2 + 2OH$$

$$[2] \quad RH + \dot{O}H, \dot{H} \rightarrow \dot{R}_r \text{ or } \dot{R}_{nr} + H_2O, H_2$$

$$[3] \quad \dot{N}O_2 + \dot{R}_r \rightarrow NO_2^- + R_r(-H)$$

$$[4] \quad \dot{N}O_2 + \dot{N}O_2 \rightleftharpoons N_2O_4$$

$$[5] \quad N_2O_4 + H_2O \rightarrow NO_2^- + NO_3^- + 2H^+$$

$$[6] \quad \dot{R}_r, \dot{R}_{nr} \rightarrow \text{Products}$$

Reaction [7] is too slow on the time scale of these experiments to contribute to the NO_2^- yield.

$$[7] \quad \dot{N}O_2 + \dot{R}_{nr} \rightarrow NO_2^- + R_{nr}(-H)$$

This is best illustrated by comparing $G(NO_2^-)$ for the scavengers formate and *tert*-butanol. With formate solutions, $G(NO_2^-)$ is equal to $G(e_{aq}^-)$, which indicates the strongly reducing radical CO_2^- (27) rapidly converts $\dot{N}O_2$ to NO_2^- in reaction [3]. With *tert*-butanol solutions, $G(NO_2^-)$ is approximately half $G(e_{aq}^-)$ so that reaction [7] involving the poor reducing 2-hydroxy radical cannot compete for $\dot{N}O_2$ (reaction [7]) against reactions [4] and [5] in the formation of NO_2^-. This results in two $\dot{N}O_2$ radicals forming one NO_2^- ion.

In one radiolysis experiment 10^{-5} mol dm^{-3} copper(II) sulphate was added to the 2.5×10^{-3} mol dm^{-3} sodium nitrate, 0.1 mol dm^{-3} *tert*-butanol solution to see if the copper(I) ion could reduce $\dot{N}O_2$ to NO_2^-. The copper(I) ion is formed by the overall reaction [8] from the 2-hydroxyalkyl radical (28, 29).

$$[8] \quad \dot{C}H_2—C(CH_3)_2OH + Cu^{2+} \rightarrow Cu^+ + \text{product}$$

As $G(NO_2^-)$ fell from 1.5 to 1.3 on addition of copper(II) ions, this indicates the reduction did not occur. This experiment was tried because, in the analogous iron system, the 2-hydroxy-*tert*-butanol radical was an inefficient reducing radical for the conversion of Fe(III) to Fe(II) whereas the copper(I) ion, formed by [8], was very effective (30).

Qualitatively, the results in Fig. 1 can be rationalized in terms of the fraction of strong reducing radicals formed in reaction [2] and the consequent pathways for NO_2^- formation. In reaction [3], each $\dot{N}O_2$ is converted to NO_2^- whereas by reactions [4] and [5], two $\dot{N}O_2$ are required to form one NO_2^-. However, quantitatively, for 2-propanol and methanol this explanation is not sufficient. The alcohol (or formate) concentration in these experiments is sufficient to scavenge most of the hydrogen atoms produced. Allowing for scavenging in the spur (12), in these solutions the sum of $G(\dot{O}H)$ and $G(\dot{H})$ is about four while $G(e_{aq}^-)$ is approximately three. This implies that in 2-propanol and methanol solutions, the number of 1-hydroxyalkyl radicals formed (reaction [2]) is in excess of the number of $\dot{N}O_2$ formed (reaction [1]). Hence $G(NO_2^-)$ in both cases should equal that in the formate solutions. However, this is not observed (Fig. 1) and the most likely explanation is that for these two alcohols reaction [3] cannot compete with reactions [4] and [6].

The computer code MAKSIMA CHEMIST (31) in conjunction with an optimizing routine was used to estimate values of k_3 for the formate, methanol, and 2-propanol scavengers based on reactions [1]–[6]. Most of the rate constants are known (11,

*Error ± 0.1.
†$[NO_2^-] = 10^{-3}$ mol dm^{-3}.

24, 28, 32). For 2-propanol solutions the bimolecular termination rate constant for $\dot{C}H_2CH(CH_3)OH$ ($\dot{R}_{nr}$) was assumed to be the same as for the $\dot{C}H_2C(CH_3)_2OH$ radical formed from *tert*-butanol (28) and the cross termination rate constant between $\dot{C}H_2CH(CH_3)OH$ and $(CH_3)_2\dot{C}OH$ was calculated as twice the root-mean-square of the symmetrical termination rate constants (33). For methanol, reaction [9] was added, with k_9 having a value of 2.6×10^5 mol^{-1} dm^3 s^{-1} (34).

[9] $CH_3OH + CH_3\dot{O} \rightarrow \dot{C}H_2OH + CH_3OH$

Assuming that for formate, $G(NO_2^-)$ was equal to $G(e_{aq}^-)$, k_3 was estimated to be $> 5 \times 10^9$, 1.1×10^9, and 1.0×10^9 mol^{-1} dm^3 s^{-1} for formate, 2-propanol, and methanol, respectively. A similar calculation for 0.1 mol dm^{-3} *tert*-butanol indicated that the rate constant for reaction of $\dot{C}H_2C(CH_3)_2OH$ with $\dot{N}O_2$ (i.e., reaction [7]) must be less than 5×10^4 mol^{-1} dm^3 s^{-1}.

(ii) Sodium nitrite solutions

In helium-saturated nitrite solutions where e_{aq}^- as well as the organic radical derived from the $\dot{H}$ and $\dot{O}H$ scavenger are present, the values of $G(-NO_2^-)$ are similar for all solutions (Table 1). The reaction of e_{aq}^- with the nitrite ion forms nitric oxide (reaction [10]) (2, 3).

[10] $NO_2^- + e_{aq}^- \rightarrow NO_2^{2-} \xrightarrow{H_2O} NO + 2OH^-$

The similarity of $G(-NO_2^-)$ for helium- and N_2O-saturated solutions containing either formate ions or 2-propanol suggests that $CO_2^{\dot{-}}$ and $(CH_3)_2\dot{C}OH$ also reduce nitrite ions to nitric oxide. For $(CH_3)_2\dot{C}OH$ this will probably involve an adduct nitro–anion radical (35) (reaction [11]) which then dissociates to form NO_2^{2-} followed by [12].

[11] $(CH_3)_2\dot{C}OH + NO_2^- \rightarrow \dot{\bar{O}}_2N{-}C(CH_3)_2OH \rightarrow NO_2^{2-} + (CH_3)_2CO + H^+$

[12] $NO_2^{2-} \xrightarrow{H_2O} NO + 2OH^-$

This mechanism is supported by the observation that $G(-H^+)$ was approximately equal to $G(-NO_2^-)$ in the irradiation of the nitrite solution containing 2-propanol at an initial pH of 4.6. The results from irradiated nitromethane solutions which will be discussed in the next section also support reactions [11] and [12].

The low $G(-NO_2^-)$ values for N_2O-saturated nitrite solutions containing methanol or *tert*-butanol indicate that $\dot{C}H_2OH$ and $\dot{C}H_2C(CH_3)_2OH$ do not react with the nitrite ion as efficiently as $(CH_3)_2\dot{C}OH$ and $CO_2^{\dot{-}}$ at the dose rate of our experiments.

In these solutions containing formate, nitric oxide is not observed and, in all solutions, the loss of nitrite is less than a third of the total yield of radicals formed. However, nitric oxide is known to react with free radicals (36, 37) to form nitroso-compounds which are themselves excellent free radical trapping agents (38). This suggests the nitric oxide and nitroso-compounds compete effectively against the nitrite ions for the organic radicals (R) through reactions [13]–[15].

[13] $\dot{R} + NO \rightarrow RNO$

[14] $\dot{R} + RNO \rightarrow R_2\dot{N}O$ or $R\dot{N}HO + R(-H)$

[15] $\dot{R} + R_2\dot{N}O$ or $RH\dot{N}O \rightarrow$ products

For the alcohol-derived radicals, the above reactions can account for the observed results; however, with $CO_2^{\dot{-}}$ the electron transfer reaction [16] may occur.

[16] $NO + CO_2^{\dot{-}} \rightarrow NO^- + CO_2$

The subsequent reaction of $CO_2^{\dot{-}}$ with NO^- or HNO ($pK \sim 4.7$) may account for the pH dependence of $G(-NO_2^-)$ observed in these solutions (2). The radical anion of NO is known to undergo a series of reactions involving $N_2O_2^-$, $N_3O_3^-$, etc. as intermediates (2, 3).

(iii) Nitromethane solutions

Reaction [11] postulates that $(CH_3)_2\dot{C}OH$ reacts with nitrite ion to form a nitro-radical anion which decomposes to form

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.40 on 09/06/12
For personal use only.

nitric oxide. Pulse radiolysis results (39) indicate that $HOCH_2NO_2^{\cdot-}$ (which would be formed by the reaction of $\dot{C}H_2OH$ and NO_2^-) decays by mixed first ($k \sim 80\ s^{-1}$) and second ($2k \sim 6 \times 10^6\ mol^{-1}\ dm^3\ s^{-1}$) order kinetics. The first order process (which would be the major process at our dose rates) was suggested to be the formation of the nitrite ion. The low $G(NO_2^-)$ (<0.2) observed in this study when the two nitro-anions formed in reactions [17] (40) and [18] (41) rules out this mode of decay.

$$[17]\quad \dot{O}H + CH_2{=}NO_2^- \xrightarrow{pH = 9.5} HOCH_2NO_2^{\cdot-}$$

$$[18]\quad e_{aq}^-,\ CO_2^{\cdot-} + CH_3NO_2 \xrightarrow{pH = 6.7} CH_3NO_2^{\cdot-}$$

The first order decay is most likely the formation of NO in reactions analogous to reactions [11] and [12]. The second order decay which probably entails the formation of a nitroso compound (reaction [19]) (41)

$$[19]\quad RNO_2^{\cdot-} + RNO_2^{\cdot-} \xrightarrow{2H^+} RNO + RNO_2 + H_2O$$

would not be important at the dose rates used in the nitrite solution irradiations.

Conclusions

The nitrate ion has been used extensively in radiation chemistry to measure $G(e_{aq}^-)$; however, it could be a poor choice since the measured product, the nitrite ion, can be formed by two processes depending on the radical formed from the $\dot{O}H$-scavenger. In one process $G(NO_2^-)$ equals $G(e_{aq}^-)$ (reaction [3]), while in the other $G(NO_2^-)$ is half $G(e_{aq}^-)$ (reactions [4] and [5]). The results in this paper indicate that $CO_2^{\cdot-}$ and 1-hydroxyalkyl radicals react with $\dot{N}O_2$ with rate constants greater than $10^9\ mol^{-1}\ dm^3\ s^{-1}$, whereas 2- or 3-hydroxyalkyl radicals and Cu^+ cannot reduce $\dot{N}O_2$ to the nitrite ion. The dependence of $G(NO_2^-)$ on dose for irradiated nitrite and formate (or 2-propanol) solutions can be attributed, at least in part, to the reaction of $CO_2^{\cdot-}$ and $(CH_3)_2\dot{C}OH$ with the nitrite ion.

The oxidation of alcohols by sodium ruthenate

DONALD G. LEE, LIGAYA N. CONGSON, UDO A. SPITZER, AND MERLE E. OLSON
Department of Chemistry, University of Regina, Regina, Sask., Canada S4S 0A2

Received June 27, 1983[1]

DONALD G. LEE, LIGAYA N. CONGSON, UDO A. SPITZER, and MERLE E. OLSON. Can. J. Chem. **62**, 1835 (1984).

The oxidation of 2-propanol and cyclobutanol by stoichiometric amounts of sodium ruthenate has been studied. Contrary to previously published speculations, it has been found that these reactions are not initiated by traces of perruthenate present as a contaminant in the ruthenate solutions. This conclusion is supported by both the kinetic rate law for the reaction and the products obtained from the oxidation of alcohols that would be expected to react differently with RuO_4^- and RuO_4^{2-}.

DONALD G. LEE, LIGAYA N. CONGSON, UDO A. SPITZER et MERLE E. OLSON. Can. J. Chem. **62**, 1835 (1984).

On a étudié l'oxydation du propanol-2 et du cyclobutanol par des quantités stoichiométriques de ruthénate de sodium. Contrairement aux spéculations publiées antérieurement, on a trouvé que cette réaction n'est pas initiée par des traces de perruthénate qui pourraient être présentes dans les solutions de ruthénate. Cette conclusion est basée à la fois sur la loi de la cinétique de la réaction et sur la nature des produits obtenus par oxydation des alcools qui devraient réagir différemment avec le RuO_4^- et le RuO_4^{2-}.

[Traduit par le journal]

Introduction

Sodium ruthenate may be used for the selective oxidation of primary and secondary alcohols containing carbon–carbon double bonds. The reaction has found application particularly in those cases where it is necessary to maintain basic conditions. A typical example of its use in this way appears in a recent report by Coates *et al.* in which they describe the oxidation of a number of unsaturated tricyclo lactones by alkaline RuO_4^{2-} (1). Oxidants which require neutral or acidic conditions cannot be used effectively for these reactions because the lactone ring remains closed under all but basic conditions and thus prevents oxidation of the incipient alcohol. On the other hand, the use of a number of other oxidants, such as permanganate, which function well under alkaline conditions is precluded because of their high reactivity with carbon–carbon double bonds. Other examples of the use of sodium ruthenate for the oxidation of unsaturated alcohols can also be found in the reports by Corey *et al.* (2), Nakano and Foglia (3), and Hall and co-workers (4). In addition Dauben and Cunningham have recently described the use of this reagent for the oxidation of a saturated hexacyclic alcohol (5).

In the above reactions, sodium ruthenate was prepared by the reduction of ruthenium tetroxide in aqueous sodium hydroxide solutions and used in stoichiometric quantities (6–8). However, Schroder and Griffith have also described a procedure for carrying out these reactions using catalytic quantities of ruthenium trichloride under alkaline conditions in the presence of a cooxidant, potassium persulphate (9). In these reactions it has been presumed that the cooxidant converted ruthenium(III) into RuO_4^{2-} which then oxidized the alcohols while being reduced to RuO_2. Ruthenium dioxide would then be reoxidized by cooxidant to RuO_4^{2-} and a cyclic process thus established. Dalton *et al.* have described the use of a similar process employing sodium periodate as the cooxidant for the oxidation of a number of unsaturated and saturated alcohols (10).

The exact mode of the reaction is somewhat difficult to determine because perruthenate, RuO_4^-, also forms when ruthenium tetroxide is reduced under basic conditions and Burke and Healy have pointed to the possibility that the active oxidant in these reactions might, in fact, be RuO_4^- (11). Because of the usefulness of these reactions in organic syntheses it is important to expose their mechanisms, with the expectation that greater understanding will lead to improved applications. Consequently, we have examined the stoichiometric reaction in an attempt to determine if perruthenate is also the active oxidant in the absence of a cooxidant. The results which we have obtained appear to suggest that this is not the case. Since similar products are obtained when a cooxidant is used, these results may also have implications for the catalytic reaction.

Experimental

Preparation of sodium ruthenate solutions

These solutions were prepared in three different ways. In one, ruthenium dioxide was oxidized to ruthenium tetroxide by either sodium hypochlorite or potassium periodate according to published procedures (12). The ruthenium tetroxide was then extracted into carbon tetrachloride, giving a bright yellow solution that was subsequently treated with a 1 *M* sodium hydroxide solution which reduced the RuO_4 to RuO_4^{2-} and extracted it into the aqueous layer (7). The solution of sodium ruthenate was separated and held at room temperature for at least 24 h to insure complete reduction to sodium ruthenate. Spectroscopic analysis of the solution showed that it did not contain detectable amounts of RuO_4 or RuO_4^- (13).

In a second approach RuO_2 was oxidized to RuO_4 by sodium periodate and then distilled on a stream of nitrogen into 1 *M* NaOH. After aging for 24 h this solution was found, within the limits of experimental detection, to contain only RuO_4^{2-} (13).

In a third approach RuO_2 was oxidized to RuO_4 by chromium trioxide in 1 *M* H_2SO_4 (14), extracted into carbon tetrachloride, and reduced to RuO_4^{2-} as described above.

Preparation of sodium perruthenate solutions

These solutions were also prepared by a controlled reduction of ruthenium tetroxide in cold aqueous sodium hydroxide solutions (8). Ruthenium tetroxide, prepared from the oxidation of ruthenium dioxide by sodium periodate, was carried on a stream by nitrogen into 0.3 *M* NaOH at −5°C. This solution was held at −5°C for 4 h and then extracted with 75 mL of carbon tetrachloride to remove any excess ruthenium tetroxide. The resulting green solution exhibited an absorption spectrum that was identical with that previously reported for sodium perruthenate (8).

Oxidation of cyclobutanol by sodium ruthenate

Cyclobutanol (7 mmol), prepared as previously described (15), was dissolved in 50 mL of a 0.9 *M* NaOH solution and a volume of sodium ruthenate solution containing sufficient oxidant to convert about 90% of the alcohol into ketone was added dropwise with stirring at room temperature. After 1 h the solution was gravity filtered, saturated with

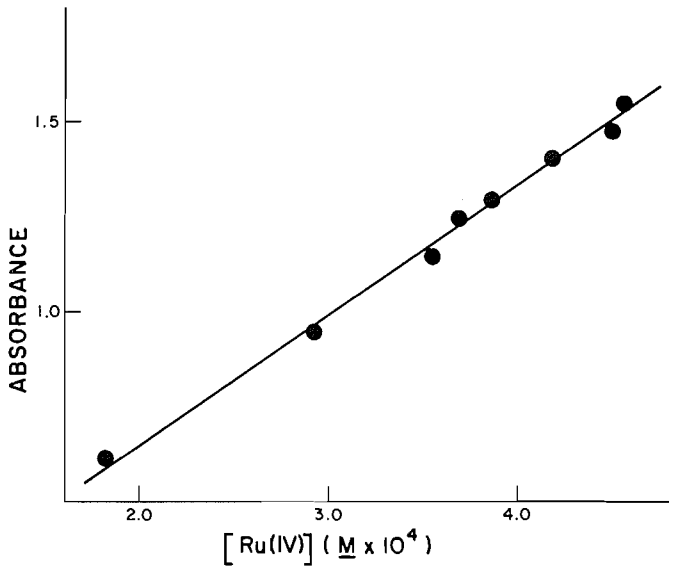

FIG. 1. Beer's Law plot for the reaction product. λ = 320 nm. Slope = 3370 M^{-1}. Intercept = −0.0090. r = 0.997. Temperature = 25.0 ± 0.1°C [NaOH] = 1.034 M.

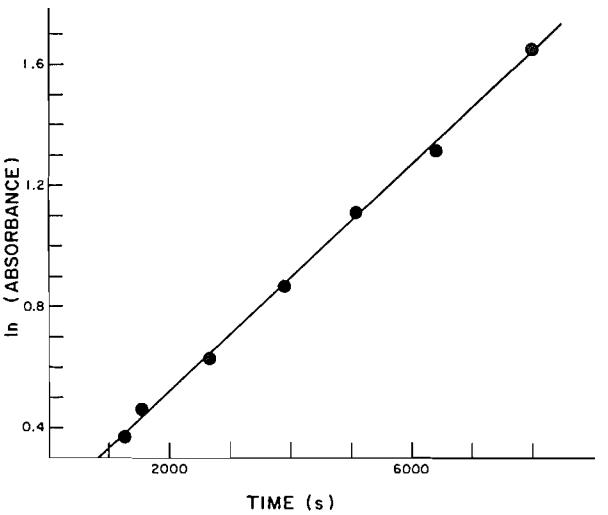

FIG. 2. Pseudo first order rate plot for the oxidation of 2-propanol by sodium ruthenate. λ = 464 nm. Temperature = 25.0 ± 0.1°C. [NaOH] = 0.951 M. [2-Propanol] = 4.16 × 10^{-3} M. r = 0.998.

sodium chloride, and extracted with eight 200-mL portions of diethyl ether. The ethereal extract was dried over anhydrous magnesium sulfate for 1 h, concentrated by rotary evaporation, and analyzed by gas chromatography. The only product detected was cyclobutanone.

Oxidation of cyclobutanol by sodium perruthenate

Two types of experiments were carried out; in one the initial reaction products which appeared to contain ruthenate ion were quenched with sodium arsenite, in the other the reaction was allowed to go to completion without external interference.

In the unquenched experiments cyclobutanol (7 mmol) in 50 mL of 0.3 M NaOH was allowed to react at −5°C with sufficient sodium perruthenate to oxidize 10−50% of the alcohol. The quenched reactions were carried out in a similar fashion with the exception that shortly after addition of oxidant the reaction was quenched with 50 mL of 0.3 M sodium arsenite. At the time of quenching the solution was a bright orange color characteristic of ruthenate ion.

When the reaction had gone to completion (as indicated by the complete disappearance of any orange color) the solution was filtered through a fine fritted filter and made acidic with sulfuric acid. Then 100 mL of a saturated solution of 2,4-dinitrophenylhydrazine in 2 M H_2SO_4 was added and allowed to react at room temperature for 24 h. The precipitate which formed was collected by filtration and dissolved in anhydrous chloroform. The filtrate was continuously extracted with ether for 48 h. The ether and chloroform solutions were combined, dried over $MgSO_4$ for 4 h and concentrated by rotary evaporation. The solid material that remained was then dissolved in a small amount of benzene, placed on an alumina column (activity III), and eluted with benzene. The bands were collected and the solvent was evaporated to yield a solid 2,4-dinitrophenylhydrazone.

In the unquenched reaction three bands were eluted. The fastest moving compound was identified as the product, cyclobutanone 2,4-dinitrophenylhydrazone, by comparison of the nmr and ir spectra (16) and melting points, 142−146°C (lit. (17) mp 147°C). The second (minor) compound was identified as acetone 2,4-dinitrophenylhydrazone from its melting point, 120−125°C (lit. (17) mp 128°C), and ir and nmr spectra. (Acetone was later shown, in a control experiment, to be present in small amounts in the solvent.) The last compound was found to be unreacted 2,4-dinitrophenylhydrazine.

Kinetics

The oxidation of 2-propanol was followed spectrophotometrically in two different ways, both of which gave rate constants that were identical within the limits of experimental uncertainty.

In the first approach, an excess of 2-propanol was added to a thermostated solution of RuO_4^{2-} and aliquots were periodically withdrawn, centrifuged to remove suspended RuO_2, and analyzed spectrophotometrically. The concentration of RuO_4^{2-} was determined by measurement of the absorbance at 464 nm (ε = 1960) (7). In a second approach, initial reaction rates were determined in the following way. Two milliliters of a ruthenate solution were added to a 1.0-cm cuvette which was in turn placed in the thermostated cell compartment of a Hewlett Packard 8450 A spectrophotometer. An excess of alcohol was added using a microliter syringe and the initial rate was determined by monitoring the increase in adsorbance at 320 nm. At this wavelength the product of the reaction (which appears to be a soluble form of ruthenium(IV) similar to the species formed during the electrochemical reduction of ruthenate (18)) conforms to Beer's Law with ε = 3370 (Fig. 1).

Although the reaction products were stable for several hours (as evidenced by the constancy of their uv−vis spectrum), ruthenium dioxide was observed to eventually precipitate. The abscissa in Fig. 1 is the concentration of product based on the assumption of a quantitative reduction of ruthenate to ruthenium(IV) oxide. The ordinate is the absorbance of the product at 320 nm before any ruthenium dioxide had precipitated.

Results

When the rate of reaction was determined by following the decrease in absorbance at λ_{max} 464 nm, linear plots of ln (absorbance) against time were obtained (Fig. 2). This indicates that the rate of reaction is first order with respect to ruthenate concentrations. When the reaction was followed by monitoring the increase in absorbance at 320 nm, the initial rates were found to be directly dependent on the concentrations of both ruthenate (Fig. 3) and 2-propanol (Table 1). This confirms that the reaction rate is first order with respect to ruthenate ion and demonstrates that it is also first order with respect to 2-propanol. The latter procedure was used for the remaining studies because the method of initial rates is known to be a more sensitive approach to kinetics (19) and because this procedure avoids the need to remove the sample from the thermostat for centrifuging before making absorbance measurements. The rate constants obtained from the use of ruthenate prepared in several different ways have been summarized in Table 1.

The yields of cyclobutanone obtainable from the oxidation of

cyclobutanol by sodium ruthenate and sodium perruthenate have been summarized in Table 2.

Discussion

Although most of the work described by Burke and Healy related to the catalytic reaction, they also presented some results which were taken to implicate RuO_4^- as the active oxidant in the stoichiometric reaction (11). It is as a test of this suggestion that our experiments have been conducted.

There are, in principle, two ways in which perruthenate could be produced in ruthenate solutions. The first of these is by disproportionation. This possibility can, however, be ruled out in the present case by the observation that the reaction rate is clearly first order in ruthenate concentration (Figs. 2 and 3). A reaction sequence initiated by disproportionation would require a higher order (6, 7).

As an alternative, small amounts of perruthenate could be formed from the oxidation of ruthenate by contaminants such as periodate or hypochlorite. Such compounds could easily be present in ruthenate solutions since they are used in its preparation. As described in the experimental section, ruthenium dioxide is first oxidized to ruthenium tetroxide by use of sodium periodate or sodium hypochlorite. The tetroxide is then extracted into carbon tetrachloride and reduced by treatment with aqueous base. Hence it is possible that IO_4^- or ClO^- could be carried along and be present in small amounts in the final RuO_4^{2-} solution. The reaction could then proceed by way of eq. [1]–[3].

$$[1]\quad 2RuO_4^{2-} + IO_4^- \rightarrow 2RuO_4^- + IO_3^-$$

$$[2]\quad RuO_4^- + R_2CHOH \rightarrow H_2RuO_4^- + R_2CO$$

$$[3]\quad H_2RuO_4^- + RuO_4^{2-} \rightarrow RuO_4^- + RuO_2$$

In order to determine if contaminants such as periodate could be important entities in the reaction scheme, we prepared

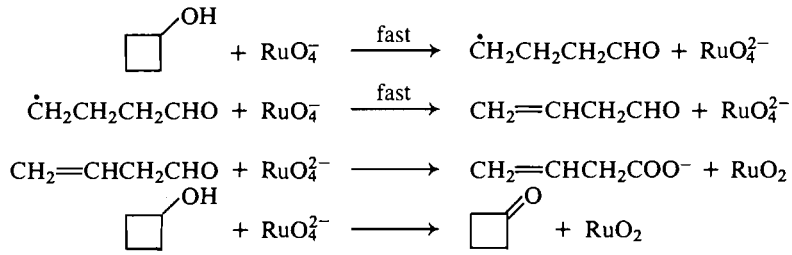
RuO_4^{2-} from RuO_4 that had been distilled (instead of extracted) from the solution in which it was formed. Ruthenate so prepared was found to react with 2-propanol at the same rate as that obtained by the more usual extraction procedures (Table 1).

Furthermore, if the sequence of reactions depicted in eqs. [1]–[3] is correct one would expect the reaction rate to be dependent on the amount of IO_4^- present. To test this possibility we added some sodium periodate to a solution of RuO_4^{2-} that had been prepared from distilled ruthenium tetroxide and observed spectrophotometrically the changes which occurred. As expected, some of the ruthenate was converted into perruthenate and the spectrum obtained was that of a mixture of the two (7). However, when 2-propanol was added the RuO_4^- was rapidly reduced to RuO_4^{2-} and the reduction of ruthenate then proceeded at the same rate as in those solutions which contained no periodate (Table 1).

Burke and Healy also found that ruthenate prepared using oxidants other than hypochlorite or periodate did not oxidize alcohols, with the exception of methanol. For example, they report that the use of chromic acid (which presumably would not extract into carbon tetrachloride and therefore would not be present to produce perruthenate) gave an unreactive form of ruthenate. However, in our hands, sodium ruthenate prepared by use of chromic acid reacted with 2-propanol at the same rate as all other samples of ruthenate (Table 1).

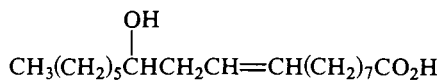
Further evidence which mitigates against the idea that perruthenate may be the active oxidant can be obtained from an examination of the products obtained in certain reactions. For example, although it is well known that perruthenate reacts rapidly with carbon–carbon double bonds (20), ruthenate solutions have often been used to oxidize unsaturated alcohols to

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.5 on 09/06/12
For personal use only.



SCHEME 1

the corresponding ketones in good yields (1, 2, 4, 10, 21). If the active oxidant was actually RuO_4^-, it is to be expected that cleavage reactions would produce serious amounts of by-products. For example, Nakano and Foglia have reported a study of the oxidation of ricinoleic acid, **1**, by both perruthenate and ruthenate (3). Perruthenate was found to give *only* cleavage products while ruthenate gave mainly the corresponding keto unsaturated acid and only minor amounts of cleavage products. If perruthenate was the active oxidant in both reactions, it is to be expected that a similar array of products should have been produced, assuming that the reaction mechanism is independent of the oxidant concentration.



1

It is also instructive to carefully examine the products obtained from the oxidation of cyclobutanol. This compound may be used to distinguish between one- and two-electron transfer oxidants (16, 22). With 1-electron transfer agents such as chromium(IV), cerium(IV), manganese(III), and vanadium(V), carbon–carbon bond cleavage occurs and non-cyclic products are obtained. With 2-electron oxidants such as chronium(VI) and (V) cyclobutanone is the major product. When cyclobutanol was oxidized by sodium ruthenate, cyclobutanone was obtained in nearly quantitative yields (Table 2). However, when it was oxidized by sodium perruthenate the maximum yield of cyclobutanone was 33%. Furthermore, the perruthenate reaction was observed to pass through two distinct, easily observable steps; in the first (rapid) stage RuO_4^- is reduced to RuO_4^{2-} which then reacts more slowly, giving ruthenium dioxide. When this second stage was eliminated by quenching the reaction with sodium arsenite at the appropriate time, very little or no cyclobutanone was obtained (Table 2). This clearly indicates that all of the cyclobutanone from the perruthenate oxidations is formed in the second (RuO_4^{2-}) stage and that RuO_4^- acts as a one-electron oxidant.

A reaction sequence that accounts for the formation of cyclobutanone in 33% yield from the oxidation of cyclobutanol by perruthenate is summarized in Scheme 1. The plausibility of the final two steps of this sequence is enhanced by the results of control experiments which showed that ruthenate ion reacts rapidly with crotonaldehyde and cyclobutanol to give crotonic acid and cyclobutanone, respectively.

Therefore, these results appear to indicate that perruthenate is not likely the active oxidant when sodium ruthenate is used in stoichiometric quantities to oxidize alcohols. However, it is possible that perruthenate could be involved in the catalytic reaction. In fact, there is a possibility that the importance of perruthenate for these reactions may be a function of pH, since it is stable in the pH region 7–12 but rapidly reduced to ruthenate in very basic solutions (23). Consequently one might anticipate its participation to be more significant under the conditions used by Burke and Healy (0.5 *M* KOH in aqueous acetone) than under those employed, for example, by Dalton *et al.* (10) for the selective oxidation of unsaturated alcohols (1 *M* aqueous NaOH).

One factual error in the paper by Burke and Healy (11) which we have noted is found on page 1096 where they claim that Lee and van den Engh (24) have reported an isotope effect, k_H/k_D, of 4.6 for the oxidation of 2-propanol by perruthenate. No such report exists. The isotope effect quoted is for the oxidation of 2-propanol by ruthenium tetroxide.

Treatment of methyl hydrogen decahydro-1,4:5.8-*exo,endo*-dimethanonaphthalene-4a,8a-dicarboxylate with lead tetraacetate in benzene – acetic acid replaces the carboxyl group by an acetoxy group. Hydrolysis of this product with 25% sulfuric acid at 130°C forms 8a-hydroxydecahydro-1,4:5,8-*exo,endo*-dimethanonaphthalene-4a-carboxylic acid **10**. The reaction between **10** and benzenesulfonyl chloride in pyridine containing triethylamine at 95°C produces *anti*-sesquinorbornene **1** in 34% yield. In the absence of triethylamine **1** is converted to the hydrochloride. The iodohydroperoxide of **1** is converted by silver acetate at 0°C to the diketone in a luminescent reaction. The 1,2-dioxetane could not be isolated. Decahydro-1,4:5,8-*exo,exo*-dimethanonaphthalene-4a,8a-dicarboxylic anhydride is converted slowly by methoxide ion in methanol at 150°C to the monomethyl ester which then undergoes demethylation. The isomeric *exo,endo* anhydride undergoes reaction readily with methoxide ion at 80°C.

KARL R. KOPECKY et ALAN J. MILLER. Can. J. Chem. **62**, 1840 (1984).

La réaction du décahydro-1,4:5,8 diméthano-*exo,endo* naphtalènedicarboxylate-4a,8a de méthyle et d'hydrogène avec le tétraacétate de plomb dans un mélange de benzène – acide acétique permet de remplacer le groupe carboxyle par un groupe acétoxyle. L'hydrolyse de ce produit, avec de l'acide sulfurique à 25% et à 130°C, conduit à l'acide hydroxy-8a décahydro-1,4:5,8 diméthano-*exo,endo* naphtalène carboxylique-4a **10**. La réaction du composé **10** avec le chlorure de benzènesulfonyle, à 95°C et dans de la pyridine contenant de la triéthylamine, conduit au sesquinorbornène-*anti*, **1**, avec un rendement de 34%. En l'absence de la triéthylamine, le composé **1** se transforme en chlorhydrate. Sous l'influence de l'acétate d'argent, à 0°C, l'iodohydropéroxyde du composé **1** se transforme en une dicétone par le biais d'une réaction luminescente. On ne peut pas isoler le dioxétane-1,2. A 150°C, l'ion méthylate dans le méthanol transforme lentement l'anhydride de l'acide décahydro-1,4:5,8 diméthano-*exo,exo* naphtalènedicarboxylique-4a,8a en ester monométhyllique qui subit alors une déméthylation. L'anhydridre isomère *exo,endo* réagit facilement avec l'ion méthylate à 80°C.

Introduction

It was concluded from the study (1) of a series of mono-, di-, and tricyclic-1,2-dioxetanes that C—C bond rotation was not required to accompany O—O bond rupture (2) in the thermolysis of these compounds. A study of the thermolysis of the dioxetane **2** of *anti*-sesquinorbornene **1** (3) might provide a further test of this conclusion. Examination of molecular models indicates that the perhydro-1,4:5,8-dimethanonaphthalene skeleton is very rigid. There would be no rotation about the C_{4a}—C_{8a} bond in **3**. The present paper reports an improved synthesis of **1**, some reactions of precursors to **1**, and the apparent instability of **2**.

Results and discussion

The decarboxylation of the diacid *anti*-**9** with lead tetraacetate or by electrolysis to give **1** proceeds in poor yield (3, 4). Other methods fail completely. A modified synthesis, Chart 1, produces **1** in about the same overall yield as reported (3), but allows the convenient preparation of gram quantities of the alkene in the last step. The essential goal in the modified route to **1** was the conversion of the anhydride *anti*-**6** to the β-hydroxy acid **10** as an apparently general method for the preparation of tetrasubstituted ethylenes from β-hydroxy acids has been reported (5). In fact the conversion is straightforward. Substitution of the carboxyl group in *anti*-**7** by an acetoxy group using lead tetraacetate proceeded in 65% yield. The usual result of the treatment of a tertiary carboxylic acid with lead tetraacetate is alkene formation (6), but this is precluded in the reaction of *anti*-**7**. Hydrolysis of **8** in refluxing aqueous sulfuric acid produced a nearly quantitative yield of **10**, whose structure is assured by its ready conversion back to **8** and to the desired alkene **1**.

The reaction between the β-hydroxy acid **10** and benzenesulfonyl chloride in pyridine required a temperature at least 55°C higher than that reported (5) before any decarboxylation occurred (gas evolution) and resulted in the formation of the hydrochloride **11** of **1**. A likely route to **11** would involve hydrochlorination of initially formed **1** by pyridinium hydrochloride. Inclusion of some triethylamine in the reaction mixture completely suppresses the formation of **11** and the alkene **1** was isolated in 35% yield when the reaction was conducted at 95°C. No decarboxylation at all occurred at 55°C.

The alkene **1** is readily converted to the hydrochloride **11** upon treatment with pyridinium hydrochloride in pyridine at 70°C. These are extremely mild conditions for hydrochlorination of an unactivated alkene. The π bond has an extremely low ionization potential, 7.90 eV, as determined by photoelectron spectroscopy (7), and this results in its facile hydrochlorination.

The compound **11** is remarkably stable considering that it is a tertiary chloride. Treatment of **11** with triethylamine in pyridine at 110°C for 8 h did not produce any alkene and **11** appeared not to have reacted at all. The hydrochloride **11** reacts very slowly with silver ion in methanol. At 20°C the solution slowly becomes turbid and some starting material is still left after several hours. Either there is steric hindrance to approach

CHART 1

of the reagents to the reaction sites in **11** or the corresponding carbocation is very unstable. Marked steric effects have been reported in reactions of other compounds with this hydrocarbon skeleton (3, 8, 9), but no instability of the carbocation has been noted.

An attempt to prove the structure of **11** by its conversion to the known (10) dihydro derivative of **1** resulted in another interesting reaction. There was no reaction between **11** and magnesium in ether but, when 1,2-dibromobutane was added to promote the reaction, **11** was converted to the alkene **1**. There was no evidence for the formation of any saturated hydrocarbon upon hydrolysis of the reaction mixture.

Some observations regarding the chemistry of other precursors to **1** and related compounds will now be described.

Relatively more *anti*-**5** than *syn*-**5** is formed when the Diels–Alder reaction between **4** and cyclopentadiene is conducted in solution at 80°C than in the silica gel catalyzed reaction at ~22°C (3). The ratios of *anti*-**5**/*syn*-**5** formed are

CHART 2

2.6:1 and 1.5:1, respectively. This ratio of products from the homogeneous reaction decreases from 2.8:1 to 2.2:1 as the temperature is increased from 50 to 110°C. These results suggest that the uncatalyzed reaction should result in a ~3:1 ratio of products at 20°C. There is no equilibration of *syn*-**5** to *anti*-**5** under the reaction conditions, as *syn*-**5** could be recovered unchanged after 8 h at 120°C.

The saturated anhydrides *syn*- and *anti*-**6** are very unreactive compounds. They are inert to alkoxide and methoxide ions at ambient temperatures and *syn*-**6** could not be hydrolyzed at all under a variety of conditions (3). There is a slow reaction between *syn*-**6** and methoxide ion in methanol at 150°C which produces, initially, the carboxylate ion of *syn*-**7** and then the dicarboxylate ion of *syn*-**9**. Demethylation of *anti*-**7** also occurs under these conditions. Demethylation probably results from nucleophilic attack of methoxide ion on the methyl group of the ester to form dimethyl ether, a reaction that was first observed some time ago (11). A more direct and probably easier hydrolysis of *syn*-**6** could probably be achieved by treatment with hydroxide ion in hot dimethyl sulfoxide. Hydrolysis of *anti*-**6** proceeds readily in this solvent at 70°C and also serves as a method of separating it from *syn*-**6** which is unreactive at this temperature. No attempt was made to hydrolyze *syn*-**6** at higher temperatures in this way. *Anti*-**7** is extremely difficult to hydrolyze. A slow hydrolysis occurs in the presence of aqueous hydroxide ion at 140°C.

The initial attempt to prepare the dioxetane **2** involved the photosensitized oxygenation of **1**, but **1** was found to be inert to singlet oxygen (3, 4).[3] The bromo- and iodohydroperoxides **14**, X = Br or I, of **1** were prepared and solutions of these compounds emitted light when treated with silver ion in the presence of fluorescers (a mixture of 9,10-dibromoanthracene DBA and 9,10-bis(phenylethynyl)anthracene BPEA). Luminescence from the iodohydroperoxide could be observed clearly at 0°C in a dark room and was quite bright at 20°C. Higher temperatures are required before luminescence from the bromohydroperoxide can be observed. However, the dioxetane **2** could not be isolated. If **2** is an intermediate in these reactions, it decomposes to the diketone **15** as soon as it is formed, even at 0°C. This was demonstrated by the immediate cessation of luminescence upon removal of silver acetate from a mixture also containing the iodohydroperoxide and fluorescers in dichloromethane at 0°C. No luminescence was observed when the resulting solution was quickly warmed to 25°C. Addition of some silver acetate to this solution at 20°C resulted in an immediate bright luminescence. Actually, the rigidity of the carbon skeletons of **2** and **3**, which would prevent rotation about the C_{4a}—C_{8a} bond, would tend to cause the O—O bond in **2** to be longer than the C—C bond of the dioxetane ring, much longer than the 1.48 Å as found in acyclic peroxides, and longer even than in some other strained 1,2-dioxetanes (12). The increased bond length in **2** would undoubtedly contribute to its instability and this would obscure any stabilizing effect, if there were any, of the lack of rotation about the C_{4a}—C_{8a} bond concurrent with the breaking of the O—O bond. If the luminescence results from decomposition of **2**, this is clearly the least stable tetraalkyl substituted dioxetane (13).

It was reported (4) that the energy of activation for thermolysis of **2** was ~25 kcal/mol. In view of the results just presented this value is clearly incorrect. Solutions of the bromohydroperoxide containing fluorescers become luminescent when heated to about 50°C in the absence of silver ions. The energy of activation reported was determined by measuring the intensity of the luminescence at different temperatures of benzene solutions of the bromohydroperoxide that had been treated with excess base in methanol for 20 min at 20°C. The energy of activation determined in this way thus represents the energy required to generate luminescence from the bromohydroperoxide in a process unassisted by silver ion or hydroxide ion, presumably via the dioxetane. The triplet/singlet ratio of excited states formed under these conditions was ~300:1.

Like **11**, the iodohydroperoxide **14**, X = I, is relatively unreactive toward silver ion. The reaction between the iodohydroperoxide of $\Delta^{9,10}$-octalin and silver acetate is complete within 5 min at 20°C (14), while mixtures of **14**, X = I, and silver acetate at 20°C glow clearly for more than 8 h. This corresponds to a reactivity difference of at least 100-fold.

Experimental

Melting points are uncorrected. Infrared spectra were taken on Perkin–Elmer 457 or 421 spectrometers. The ^{1}H nmr spectra were taken on a Varian A56/60 A analytical spectrometer. Mass spectra were taken on an AEI MS 50 mass spectrometer using an electron impact of 70 eV. Solutions were dried over $MgSO_4$. Elemental analyses were performed in the Microanalytical Laboratories in the Chemistry Department under the supervision of Mrs. Darlene Mahlow.

1,2,3,4,4a,5,8,8a-Octahydro-1,4:5,8-exo,exo-*dimethanonaphthalene-4a,8a-dicarboxylic anhydride and 1,2,3,4,4a,5,8,8a-octahydro-1,4:5,8*-exo,endo-*dimethanonaphthalene-4a,8a-dicarboxylic anhydride,* syn- *and* anti-*5*

A solution of 50.5 g (0.308 mol) of bicyclo[2.2.1]hept-2-ene-2,3-dicarboxylic anhydride (15) and 30 g (0.45 mol) cyclopentadiene in 300 mL toluene was heated at 80°C overnight in a pressure bottle, filtered, concentrated, and pentane added to the residue. A yield of 59.2 g (83%) of a mixture of *syn*- and *anti*-**5** crystallized. The product ratios from several reactions run at different temperatures were determined by integration of the ^{1}H nmr absorptions in C_6D_6 at δ 6.36 and 6.46, due to *anti*- and *syn*-**5**, respectively, of crude product mixtures before crystallization from which solvent was completely removed.

anti-*1,2,3,4,5,6,7,8-Octahydro-1,4:5,8-dimethanenaphthalene*, ***1***

A solution of 3.30 g (14.8 mmol) of **10**, 6.0 g (34 mmol) of benzenesulfonyl chloride, 6.6 g (65 mmol) of triethylamine, and 20 mL pyridine was heated at 95°C under argon for 6.5 h. Work-up (5) and chromatography of the neutral product (silica gel – pentane) gave 0.80 g (34%) of **1**, mp 64–65°C (lit. (3) mp 64–65°C).

*Conversion of **1** to **11***

A solution of 0.1 g of **1** and an excess of pyridinium hydrochloride in pyridine was heated overnight at 70°C. No **1** was left and only one product was formed (tlc) which was isolated as before and shown to be **11**; mp and mixture mp with authentic **11**, 85–87°C.

*Conversion of **11** to **1***

A mixture of 0.1 g of **11**, 0.1 g magnesium, and 2 mL ether was

treated with 0.1 g of 1,2-dibromobutane. After the exothermic reaction had subsided no starting material remained and only one product was formed (tlc) which was isolated as before and shown to be **1**; mp and mixture mp with authentic **1**, 64–65°C.

*4a-Hydroxyperoxy-8a-iodo-1,2,3,4,4a,5,6,7,8,8a-decahydro-1,4:5,8-*exo,endo*-dimethanonaphthalene,* ***14****, X = I*

To a stirred solution of 0.10 g (0.62 mmol) of **1** and 0.3 mL of 98% hydrogen peroxide in 5 mL ether at 0°C was added 0.120 g (0.32 mmol) of 1,3-diiodo-5,5-dimethylhydantoin. The mixture was stirred in subdued light for 5 min, 25 mL ether was added, and the resulting solution was shaken with ice water and with just enough aqueous bisulfite to leave the organic layer a light pink color. The organic layer was dried, concentrated at 0°C, and the residue quickly taken up in methylbutane. The pale yellow crystals which formed after 12 h at −78°C were recrystallized from methylbutane at −78°C, mp 55°C (dec.); ^{1}H nmr ($CDCl_3$) δ: 8.125 (s, 1H), 3.20 (m, 1H), 2.80 (m, 1H), 2.65–1.0 (series of m, 14H. This material is quite unstable and the crystals decompose rapidly at room temperature. The mp given is the highest of several determinations. It is stable for weeks in solution at −20°C.

anti-Tricyclo[6.2.1.^{1,8}1^{3,6}]dodecane-2,7-dione, ***15***

Method A

A solution of 20 mg **1** in 10 mL pentane at −70°C was treated with ozone. The residue remaining on evaporation of the pentane was suspended 10 mL ethanol together with 100 mg palladium on charcoal. This mixture was stirred for 30 h under hydrogen, warmed, and filtered. The ethanol was evaporated and the residue was sublimed at 120°C under 1 Torr to give 8 mg white crystals, mp 164–165°C; ir ν_{max} (Nujol): 1665, 1275, 855 cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 3.4–3.1 (m, 4H), 2.6–1.5 (series of m, 12H). *Anal.* calcd. for $C_{12}H_{16}O_2$: C 74.96, H 8.39; found: C 74.81, H 8.25.

Method B

A mixture of 15 mg of the iodohydroperoxide **14**, X = I, and 100 mg silver acetate in 2 mL dichloromethane was shaken in the dark at 22°C for 6 h and filtered. Solvent was removed to leave a small amount of residue whose ir and ^{1}H nmr spectra and R_f value on tlc were the same as those of **15** made by Method A.

Luminescence experiments

Samples of **1** were converted to the iodophydroperoxide **14**, X = I, as described above and to the bromohydroperoxide **14**, X = Br, by the usual procedure (1, 14). Crude solutions of these materials freed from hydrogen peroxide and dimethylhydantoin were used in the qualitative experiments described in the results and discussion section. A sample of the bromohydroperoxide **14**, X = Br, was treated with sodium hydroxide in methanol for 10 min at 20°C. The reaction mixture was poured into pentane, the pentane layer was washed with water, dried, concentrated to a small volume, and the residue taken up in benzene. The rate of decay of luminescence intensity from this material was measured in the usual way (14) using benzene solutions containing 10^{-2} *M* DBA and 10^{-4} *M* BPEA, as were triplet/singlet ratios using DBA and 9,10-diphenylanthracene (17).

The influence of hydrogen bonding on the character of N—H and C=O stretching modes in 2-thiopyrrole-1,2-dicarboximide

SHANKER RAM

Department of Physics, Indian Institute of Technology, Kanpur – 2080 016, India

Received August 24, 1983[1]

SHANKER RAM. Can. J. Chem. **62**, 1845 (1984).

The infrared spectra (200–4000 cm^{-1}) of 2-thiopyrrole-1,2-dicarboximide (TPH) in solid and solution forms have been measured as a function of temperature, and a direct correlation has been obtained between the two phases and the type and extent of hydrogen bonding. It is suggested that TPH exists as cyclic dimer in the solid state (below 310 K) and in dilute solutions by the formation of two equivalent hydrogen bonds. At the transition temperature, ~310 K, the cyclic dimer undergoes to the open-cyclic dimer and persists in this structure till 410 K. In addition, the thermodynamical functions ΔG^0, ΔH^0, and ΔS^0 have been estimated using the spectral data in solution.

SHANKER RAM. Can. J. Chem. **62**, 1845 (1984).

On a mesuré, en fonction de la température, les spectres infrarouges (200–4000 cm^{-1}) du thiopyrrole-2 dicarboximide-1,2 (TPH) sous forme solide et en solution; on a obtenu une corrélation directe entre les deux phases et le type ainsi que le degré de liaison hydrogène. On suggère que, à cause de la formation de deux liaisons hydrogènes équivalentes, le THP existe à l'état de dimère cyclique tant à l'état solide (à des températures inférieures à 310 K) qu'en solutions diluées. A une température de transition d'environ ~310 K, le dimère cyclique subit une ouverture de cycle qui le transforme en dimère ouvert, forme sous laquelle il persiste jusqu'à 410 K. De plus, en se basant sur les données spectrales en solution, on a évalué les fonctions thermodynamiques ΔG^0, ΔH^0 et ΔS^0.

[Traduit par le journal]

Introduction

Pyrrole and its derivatives constitute a broad class of organic molecules with both technological and biological relevance. Recently, Agarwala and co-workers (1, 2) have reported some sulfur derivatives of pyrrole and their properties of forming molecular complexes with metal ions in different oxidation states. These studies reveal certain very fascinating aspects of coordination chemistry, e.g., the formation of Co(II) diamagnetic complexes (3–6). 2-Thiopyrrole-1,2-dicarboximide (TPH) and *N*-carbonyl pyrrole thiocarboximide (CTPH) have been found to yield oxidized products when reacted with soft metal ions (1). With these interesting features, it seems worthwhile to study the vibrational structure and spectra correlations for these compounds and their complexes.

Infrared and Raman spectra of pyrrole and its deuterated analogue have been extensively studied (7, 8) in an attempt to provide a complete vibrational analysis of the fundamental bands. This type of spectral investigation is very limited for substituted pyrroles, especially when both C=O and C=S groups are present. In a previous report (9) we have given a brief vibrational analysis of the fundamental modes of TPH in the region 200–4000 cm^{-1}. The present paper is aimed to investigate the N—H and C=O stretching bands of this compound as a function of temperature in both solid and solution forms, and to study the role which these functional groups play in the formation of the cyclic dimer, an open cyclic dimer, and the free monomers.

Experimental

The 2-thiopyrrole-1,2-dicarboximide was prepared by the literature method (10) and was recrystallized several times in aqueous ethanol to give orange–red sample of mp 140°C. Its composition and purity (99.9%) were confirmed by chemical analysis in our microanalytical laboratory. The infrared spectra of polycrystalline sample using KBr pellets were measured at different temperatures between 80 to 410 K. The temperature (below 298 K) was varied using a Specac variable temperature cell fitted with an automatic temperature control unit and liquid nitrogen as coolant. The pellet mounted on the cold finger of the low-temperature cell was first cooled to liquid-nitrogen temperature and then allowed to warm with drops of liquid nitrogen dripping on the cold finger. This gave a control of the temperature which was monitored by a thermocouple placed in contact with the pellet. For high temperature (above 298 K) studies the pellet was mounted on a home-made heating block. The reported temperatures in both (low and high) measurements are believed to be accurate to within ± 2 K.

The spectra of TPH in CCl_4 solution were measured as a function of temperature (273 to 338 K) at a fixed concentration and as a function of concentration (15 to 0.5×10^{-3} mol L^{-1}) at a fixed temperature, using a NaCl liquid cell of 0.1 cm pathlength. The temperature of the solution was controlled to within ± 1 K using a water circulating bath.

All spectra were measured on a Perkin-Elmer Model 580 infrared spectrometer.

Results and discussion

In the approximation of a C_s molecular symmetry for TPH in its ground state, the 36 normal modes of vibration would be classified as $25a' + 11a''$. In the Mulliken notation (11), the vibrations from ν_1 to ν_{25} are planar (a') and those from ν_{26} to ν_{36} are non-planar (a'') with respect to the molecular plane. For the C_s point group, the permissible site symmetries in the crystal are C_1 and C_s. The exact crystal structure of TPH is not known but our vibrational analysis for the fundamental modes (9), where two factor group components for a' vibrations and only one component for a'' vibrations were observed, suggests four molecules in the crystal unit cell located at equivalent C_s sites. In the present course of investigation, we would confine our discussion only to the N—H stretching (ν_1) and C=O stretching (ν_5) modes with an emphasis on the role which these functional groups play in the formation of hydrogen bonds.

N—H stretching bands ν_1

Infrared spectrum of the solid sample in the N—H stretching region (2800–3500 cm^{-1}) is not very sensitive to temperature between 80 and 410 K. For comparison, Fig. 1 shows the results obtained at the two extreme temperatures, 80 and 410

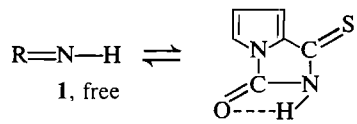
K. The broad band centred at about 3150 cm^{-1} includes three distinct bands of frequencies (relative integrated intensities) at 3210 (56), 3160 (78), and 3095 (52) cm^{-1} and thus indicates the presence of three different N—H stretching vibrations. The two sharper bands at 2912 and 2810 cm^{-1} are the C—H stretching vibrations of the pyrrole ring.

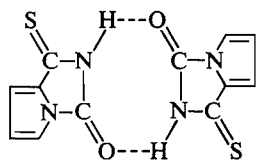
The spectrum of TPH in CCl_4 was measured as a function of temperature at a fixed concentration of 10.9×10^{-3} mol L^{-1} and as a function of concentration at a fixed room temperature (298 K). The results obtained at three temperatures (273, 298, and 338 K) are shown in Fig. 2. In solution, the N—H stretching bands are modified to show relatively sharp structure and all are shifted to higher frequency by about 230 cm^{-1} as compared to those in the solid. At a medium concentration of 10.9×10^{-3} mol L^{-1}, the spectrum shows four distinct bands centred at 3440, 3410, 3360, and 3320 cm^{-1}. At lower concentrations the intensities of the first two bands increase (though very little) in the same proportion but those of remaining two bands decrease continuously. The lowest frequency band (3320 cm^{-1}) disappears below $\sim 5 \times 10^{-3}$ mol L^{-1}. In our investigation, concentration could not be varied over a wide range as the solubility of TPH in CCl_4 is very small.

In a free molecule of TPH, the >N̈—H group links the >C=Ö group (a moderately stronger electron donor than the imide group) through a single valence bond. The two groups, being in very close vicinity of each other, may form both intra- and intermolecular hydrogen bonds via the H atom of imide group as shown below:

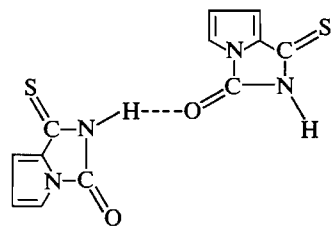


1, free

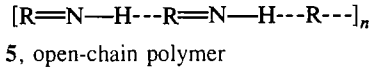
2, intra-bonded monomer



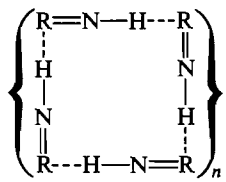
3, cyclic dimer



4, open-cyclic dimer



5, open-chain polymer



6, close-chain polymer

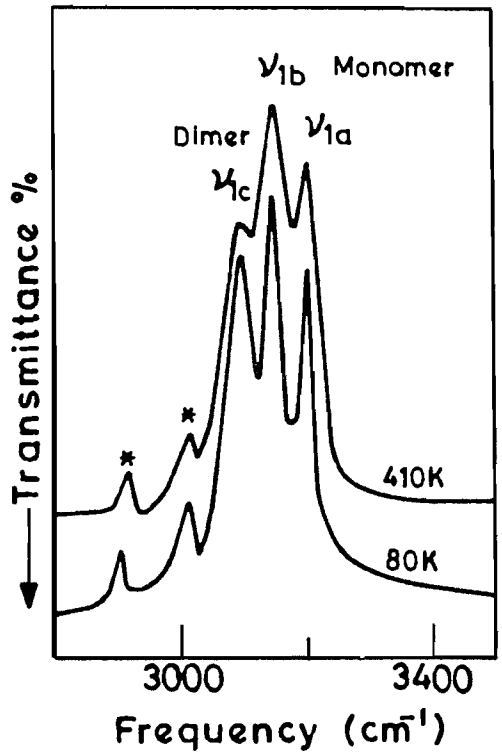


FIG. 1. N—H stretching region of TPH in pure solid phase. * C—H stretching bands.

where

R = 
and $n = 2, 3, 4, \ldots\ldots$; indicating dimer, trimer, and other high-order polymers. In addition, the N—H group through self-association may also form intermolecular hydrogen bonds but these are extremely weak to show any effect in conventional infrared spectroscopy (12).

The formation and nature of intra- and intermolecular hydrogen bonds of polyatomic molecules in solid, liquid, and solution forms are well established and may be seen everywhere (12–16). The main purpose of this work is not, therefore, to discuss the nature of the associated species for the molecule in question, but to interprate the spectra which have a converse bearing on the nature of association. The open-chain and close-chain polymers (structures **5** and **6**) would give almost the same results and are expected to appear only in concentrated solutions of inert solvents as CCl_4 (14, 16). The interbonded dimers (structures **3** and **4**) also appear in dilute (to $\sim 1 \times 10^{-3}$ mol L^{-1}) solutions. The intrabonded bands are usually not affected much by the intermolecular separation and thus persist in solution for every dilute concentration and also in the vapour phase. Moreover, the free monomer bands (structure **1**) are very sensitive of temperature as well as of concentration, and are expected to appear strongly in dilute solutions and the band intensity increases further as temperature increases.

If the two (cyclic and open-cyclic) dimer species of TPH do not exist simultaneously (as is usually accepted for large organic molecules (13–15, 17, 18) prior to the present work), the first three prominent structures **1**, **2**, **3** (or **4**) would give at least

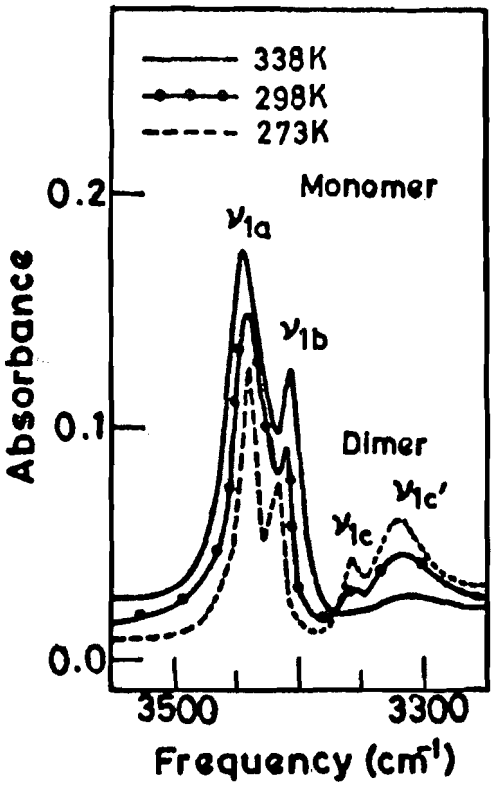

FIG. 2. N—H stretching region of TPH (in CCl_4 solution) at three different temperatures. Concentration = 10.9×10^{-3} mol L^{-1}.

four N—H stretching bands. Though Barnes *et al.* (12) have cited many examples of small inorganic molecules where both cyclic and open-cyclic dimers and other high-order polymers (trimer and tetramer) were also observed to exist simultaneously in equilibrium, the fact is that both species, in terms of vibrational bond frequencies, differ very little and identification is not so simple even if the concentration-dependence study is made in inert-gases using matrix isolation vibrational spectroscopy. Unfortunately, we do not have such sophisticated data but our investigation in CCl_4 solution also shows four different bands (see Fig. 2) which are designated as ν_{1a}, ν_{1b}, ν_{1c}, and $\nu_{1c'}$ in the order of decreasing frequency. The first two bands (ν_{1a} and ν_{1b}) are similar in structure and persist even in sufficiently dilute solutions. The intramolecular hydrogen bonding (structure **2**) usually produces very little frequency shift and therefore these two bands (which differ only by 20 cm^{-1}) are assigned to free and intrabonded N—H stretching modes, respectively. It is to be noted that in the solid state this difference is increased to ~50 cm^{-1}. The two dimeric bands ν_{1c} and $\nu_{1c'}$ are separated by ~35 cm^{-1} in solution but appear as a single band at 3095 cm^{-1} in the solid sample. These assignments are supported by the fact that the intensity of the monomer bands (ν_{1a} and ν_{1b}) increases and that of the dimer decreases as the temperature of the solution increases.

C=O stretching bands, ν_5

The evidence for intra- and intermolecular hydrogen bonds in TPH is more dramatic and clear from the C=O stretching bands, in which also the two dimeric bands (ν_{5c} and $\nu_{5c'}$) are well resolved in both the solid as well as the CCl_4 solutions (see Figs. 3 and 5).

In the spectrum of solid TPH, the relative intensity and separation of ν_{5a} (1774 cm^{-1}) and ν_{5b} (1760 cm^{-1}) are almost

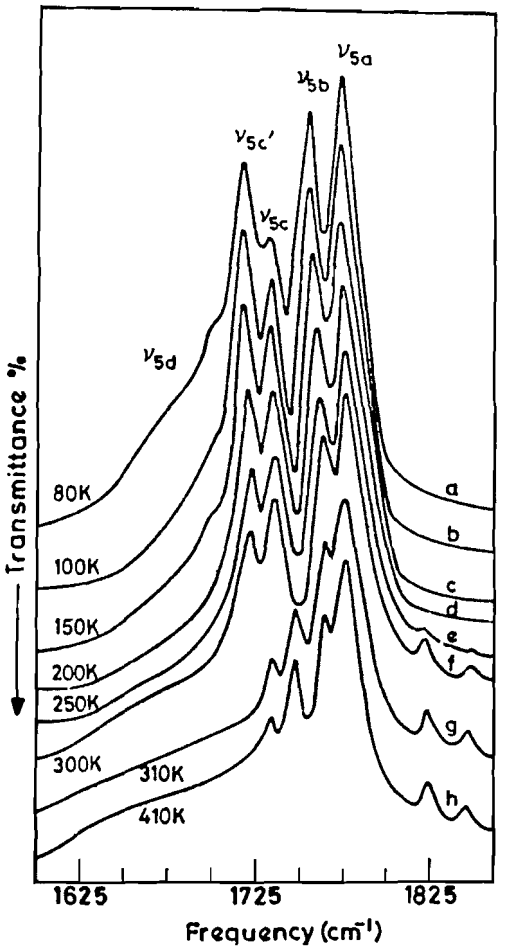

FIG. 3. The effect of temperature on the C=O stretching region of TPH in pure solid phase.

constant, though both shift by 4–10 cm^{-1} to higher frequency as the temperature rises from 80 to 410 K. On the other hand, of the two dimeric bands, ν_{5c} (1732 cm^{-1}) shows relatively lower intensity than $\nu_{5c'}$ (1717 cm^{-1}) at liquid nitrogen temperature. As temperature rises their relative intensity decreases continuously so that at 410 K, the ν_{5c} band becomes stronger than $\nu_{5c'}$, and at an intermediate temperature 250 K, both have nearly the same intensity. Moreover, the frequencies of both bands very slowly increase with temperature in the same manner from 80 to 300 K, show an abrupt increase of ~13 cm^{-1} at 310 K, and then remain constant up to 410 K. The frequency vs. temperature for these two bands is shown in Fig. 4. We believe that this indicates the presence of an open-cyclic dimer of TPH above 310 K, i.e., the C=O stretching vibrations of the open-cyclic dimer are at higher frequencies.

The solution spectra of C=O stretching region at three temperatures are shown in Fig. 5. The monomer bands are at 1796 (ν_{5a}) and 1784 (ν_{5b}) cm^{-1}, whereas those of the dimer are at 1770 (ν_{5c}) and 1764 ($\nu_{5c'}$) cm^{-1}. Both the dimer bands in dilute solutions most probably correspond to the cyclic dimer. However, the possibility of ν_{5c} and $\nu_{5c'}$ bands to belong to two different dimer species, i.e., ν_{5c} to open-cyclic dimer and $\nu_{5c'}$ to cyclic-dimer, may not be discarded. The spectra show an obvious increase in the monomer concentration and at the same time an appreciable decrease in the dimer concentration as the temperature increases from 273 to 338 K, and thus exactly resemble the spectra of N—H stretching vibration, as has been

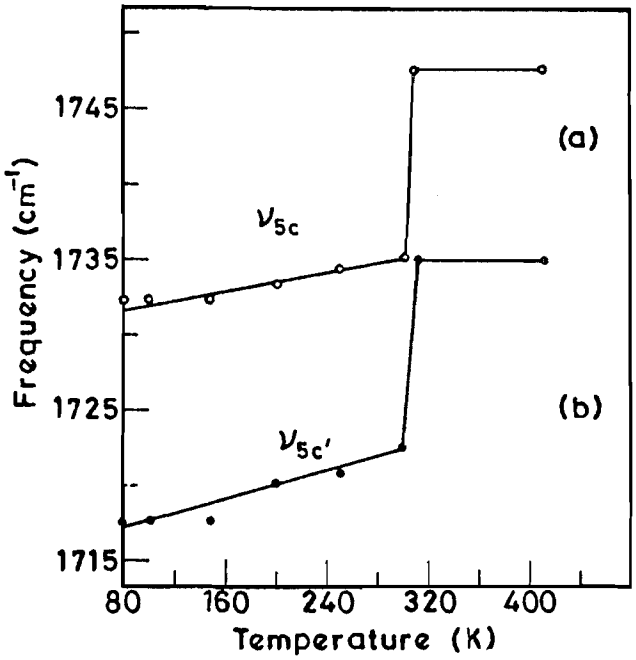

FIG. 4. C=O stretching bands of dimeric TPH vs. temperature (*a*) ν_{5c} and (*b*) $\nu_{5c'}$ bands.

discussed in the preceding section. The relatively weak and broad band centred at 1756 cm^{-1} indicates the features of a polymeric (structures **5** or **6**) C=O stretching vibration. Azima *et al.* (17) have also reported the similar results for the cyclic and open-cycle dimers existing in an equilibrium along with that of the monomer in *para*-substituted benzoic acids.

From the above observations it seems that the hydrogen bonds of TPH polymers are much stronger than those of the dimers, but it is not immediately obvious why the addition of a third (or more) unit should enhance so much the strength of the hydrogen bond which already links the first two. It occured to us that the dimers are open/cyclic chain systems with normal hydrogen bonds but that the polymers are cyclic with abnormally strong bonds derived from their special structure. There are good reasons why this should be so. If a $\rangle C{=}\ddot{O}$ group dissociates, the O^- ion is much more basic than before, and it is logical to regard the formation of a hydrogen bond which involves an extension of the C=O bond length as a step in this direction. An oxygen atom of a C=O group whose proton is engaged in a hydrogen bond should therefore be more basic than the original monomer. Similarly, the hydrogen atom of an $\rangle\ddot{N}H$ group, whose nitrogen is acting as a proton acceptor, can be expected to be more acidic than in the monomer. This must follow as the product is the same whichever end of a simple dimer is attacked by a third bonding unit. Now, it is quite understood that cyclic systems (structures **3** and **6**) will be especially enhanced in their bonding properties because of the increased acidity of the hydrogens and the increased basicity of the oxygens. Along this line and from the observations of the C=O stretching bands, we conclude that TPH forms the cyclic dimers in the solid state ($T < 310$ K) and in dilute solutions in CCl_4, but above the transition temperature 310 K, the structure most probably becomes open-cyclic. Bellamy *et al.* (17, 18) have also shown that the hydrogen-bond strengths of open-chain acid dimers of acetic (18) or oxalic acid (19) are appreciably lower than those of the corresponding cyclic forms.

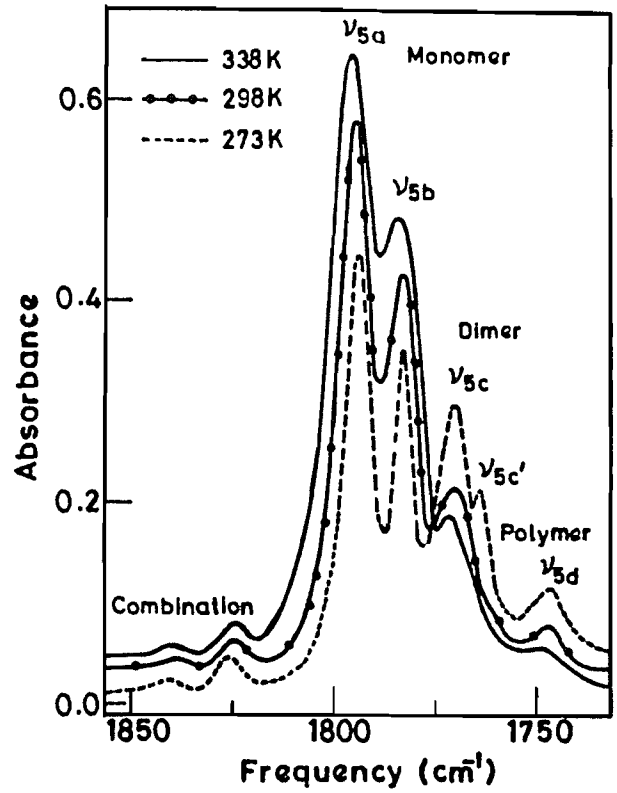

FIG. 5. The effect of temperature on the C=O stretching region of TPH in CCl_4 solution. Concentration = 10.9×10^{-3} mol L^{-1}.

Thermodynamic functions

If we assume that under our experimental conditions, the hydrogen bonding in TPH produces only the dimer and the intrabonded monomer, and that the Lambert–Beer law holds for all the three carbonyl bands, the maximum optical densities A_a, A_b, and A_c of the bands ν_{5a}, ν_{5b}, and ν_{5c} will be given by

$$[1]\quad A_a = \epsilon_a C_a l \qquad A_b = \epsilon_b C_b l \qquad A_c = \epsilon_c C_c l$$

where l is the cell length, C_a, C_b, and C_c are the concentrations of TPH present in the forms a, b, and c, respectively, and ϵ_a, ϵ_b, and ϵ_c are their respective molar extinction coefficients, each referred to one formula weight of TPH. The total concentration of TPH in the solution is

$$[2]\quad C = C_a + C_b + C_c$$

If we neglect the transformation b $\rightleftharpoons$ c, then for the chemical equilibrium, we may write

$$[3]\quad \begin{array}{ll} a \rightleftharpoons b & K_{ab} = [b]/[a] \\ a + a \rightleftharpoons c & K_{ac} = [c]/[a]^2 \end{array}$$

where K_{ab} and K_{ac} are the association constants for intrabonded monomer and interbonded dimer, respectively. In terms of K_{ab} and K_{ac}, eq. [2] becomes

$$\begin{aligned} C &= [a] + [b] + 2[c] \\ &= [a] + K_{ab}[a] + 2K_{ac}[a]^2 \end{aligned}$$

Substituting the value of $[a] = C_a$ from eq. [1], and dividing both sides by A_a/l, we get the final relation

$$[4]\quad \frac{lC}{A_a} = \frac{1}{\epsilon_a}(1 + K_{ab}) + \frac{2K_{ac}}{\epsilon_a^2}\frac{A_a}{l}$$

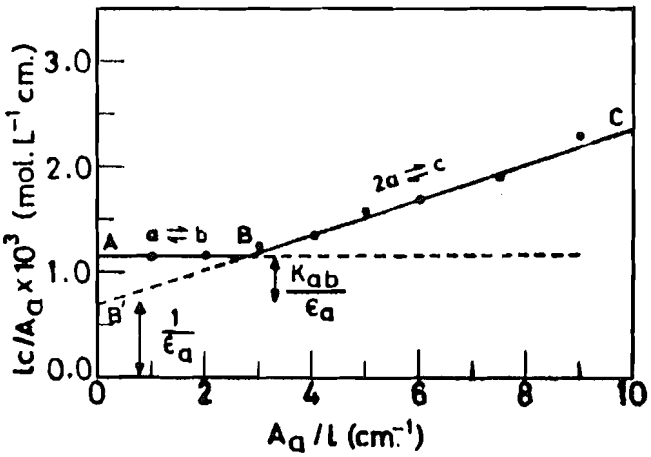

FIG. 6. Plot of lC/A_a vs. A_a/l for C=O stretching vibration of TPH in CCl_4 at 298 K. The AB curve represents a $\rightleftharpoons$ b equilibrium and that the BC curve 2a $\rightleftharpoons$ c equilibrium. The dotted lines are the extrapolated parts of the corresponding curves. $[c] = K_{ac}[a]^2 = 0$ for $A_a/l \leq 3$.

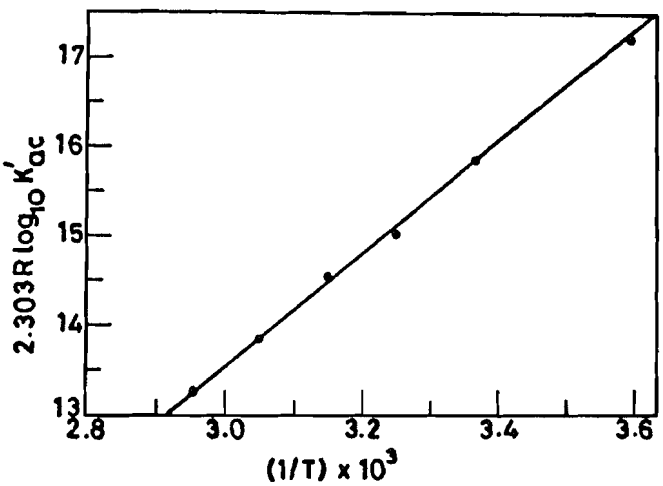

FIG. 7. Plot of $2.303R \log_{10} K'_{ac}$ vs. $1/T$ for TPH in CCl_4.

The free-monomer band ν_{5a} overlaps with the nearby intrabonded-monomer band ν_{5b}. As a result, the actual absorbance A_a would have somewhat a lower value than that read directly from the experimental peak height. This was estimated assuming that the observed doublet (of ν_{5a} and ν_{5b}) is the sum of two Lorentz curves with a slight contribution from the dimer bands. A plot of lC/A_a vs. A_a/l for the C=O stretching vibration of TPH is shown in Fig. 6. It seems reasonable to consider the plot to be linear in the two steps, AB and BC. The linearity of ABC between the points B and C indicates that in the medium of concentrated solutions of TPH in CCl_4, only the dimers and the free and intrabonded monomers are present, and the intrabonded monomers do not contribute to further hydrogen-bonded formations. Moreover, at sufficiently low concentrations, i.e., in region AB, the species existing in an equilibrium mixture are the free and the intrabonded monomers. The values of ϵ_a and K_{ac} were obtained from the intercept and the slope of the extrapolated straight line B'BC, and that of the constant K_{ab} from the difference of the intercepts of AB and B'C (i.e. OA—OB' = K_{ab}/ϵ_a) on the lC/A_a axis. The values so obtained at the room temperature are $\epsilon_a = 1430$ mol^{-1} L cm^{-1}, $K_{ac} = 0.27 \times 10^{-3}$ mol^{-1} L and $K_{ab} = 0.60$.

Assuming the ideal associated-solution model of prigogine (20) where the TPH monomer and dimer activities equal their mole fraction,

$$K'_{ac} = K_{ac}/V_0$$

in which V_0 is the molar volume of the solvent and K'_{ac} is the association constant in mole fraction unit. The standard free energy change, ΔG^0, for the formation of 1 : 1 complex is given by (21),

$$[5] \quad \Delta G^0_T = -RT \ln K'_{ac}$$

which, from the definition of $G = H - TS$, gives

$$[6] \quad 2.303\ R \log_{10} K'_{ac} = \Delta S^0 - \Delta H^0/T$$

The slope and the intercept of the plot $2.303R \log_{10} K'_{ac}$ vs. $1/T$, shown in Fig. 7, give directly the standard enthalphy ΔH^0 and the standard entropy ΔS^0 of complex formation. A least-squares analysis of these data gave $\Delta G^0_{298} = -4.75$ kcal/mol, $\Delta H^0 = -6.40$ kcal/mol, and $\Delta S^0 = -5.60$ cal/deg mol.

Acknowledgements

The author is very thankful to Professor H. D. Bist for his help and valuable discussions and to Dr. R. Saheb (Department of Chemistry) and Dr. J. S. Yadav (Department of Physics, Banaras Hindu University) for providing the sample and their infrared measurements. The financial support from the Department of Science and Technology, New Delhi, is gratefully acknowledged.

Thermochemical parameters for organic radicals and radical ions. Part 3. The relationship between bond dissociation enthalpy and radical stability in alkyl systems

A. MARTIN DE P. NICHOLAS AND DONALD R. ARNOLD[1]

Department of Chemistry, Dalhousie University, Halifax, N.S., Canada B3H 4J3

Received December 5, 1983

A. MARTIN DE P. NICHOLAS and DONALD R. ARNOLD. Can. J. Chem. **62**, 1850 (1984).

The relationship between radical stability and bond dissociation enthalpy (BDH) is reexamined. It is shown that relative stabilization energies of radicals are not equal to relative BDH values. *Net* stabilization energies of radicals, $SE^0[R^\cdot, RX]$ are defined relative to the R components of closed shell species RX (R(RX)). These components are chosen such that they contain the same (or, approximately the same) net charge as that of the radical ($R^\cdot$). The following results, relative to R = C_2H_5, were obtained: $R^\cdot$, $SE^0[R^\cdot, RX]$(kJ mol^{-1}) for X = R (i.e., the dimer RR), CH_3, and H; $CH_3^\cdot$, 23, 32, 37; n-$C_3H_7^\cdot$, −2, −2, −3; i-$C_3H_7^\cdot$, −9, −14, −19; *t*-$C_4H_9^\cdot$, −25, −32, −38. These results show that the methyl radical is more destabilized and the n-propyl-, i-propyl-, and *tert*-butyl radicals are more stabilized than is predicted from the corresponding relative BDH (R—X) values. The intrinsic C—H bond strengths of chosen alkanes are considered. Relative to the C—H bond in ethane, the bond in methane is found to be weaker by 8.12 kJ mol^{-1} and the primary and secondary bonds in propane and the tertiary bond in methyl propane are stronger by 2.56, 7.98, and 17.12 kJ mol^{-1} respectively.

A. MARTIN DE P. NICHOLAS et DONALD R. ARNOLD. Can. J. Chem. **62**, 1850 (1984).

On étudie de nouveau la relation existant entre la stabilité du radical et l'enthalpie de dissociation de la liaison (HDL). On montre que les énergies relatives de stabilisation des radicaux ne sont pas égales aux valeurs relatives de HDL. On a défini les énergies nettes de stabilisation des radicaux, $ES^0[R^\cdot, RX]$, par rapport aux composants R des espèces des couches complètes RX (R(RX)). On a choisi ces composants de telle sorte qu'ils contiennent la même (ou, approximativement la même) charge nette que celle du radical ($R^\cdot$). On a obtenu les résultats suivants, relatifs à R = C_2H_5: $R^\cdot$, $ES^0[R^\cdot, RX]$(kJ mol^{-1}) pour X = R (soit le dimère RR), CH_3 et H; $CH_3^\cdot$, 23, 32, 37; n-$C_3H_7^\cdot$, −2, −2, −3; i-$C_3H_7^\cdot$, −9, −14, −19; *t*-$C_4H_9^\cdot$, −25, −32, −38. Ces résultats montrent que le radical méthyle est plus déstabilisé et que les radicaux n-propyle, i-propyle et *tert*-butyle sont plus stabilisés que prévu à partir des valeurs relatives correspondantes de HBL (R—X). On considère les forces intrinsèques des liaisons C—H des alcanes choisis. Par rapport à la liaison C—H de l'éthane, on trouve que la liaison du méthane est 8,12 kJ mol^{-1} plus faible et les liaisons primaires et secondaires du propane et la liaison tertiraire du méthylpropane sont respectivement 2,56, 7,98 et 17,12 kJ mol^{-1} plus fortes.

[Traduit par le journal]

Introduction

Organic radicals are usually encountered as short-lived intermediates, rendering an accurate determination of their thermochemical parameters difficult. Most often, measured values have large uncertainties (1, 2). We have claimed previously that the presence of the effects of substituents on bond dissociation enthalpy (BDH) values cannot be attributed solely to the variation in the stability of the radicals (3). We have also suggested that a substituent scale ($\sigma_\alpha^\cdot$) based upon esr hyperfine coupling constants may reflect the component of energy that may be attributed to spin delocalization in benzyl radicals (3). In this work, we substantiate our claim that appropriate corrections (reflecting electronic effects in the R—H bonds) to relative BDH(R—H) values must be made before BDHs are used as an indication of radical stability. Simple hydrocarbon radicals are studied as representative examples. The results and conclusions are easily extended in principle to other classes of organic radicals.

Merits and ambiguities in current bond dissociation enthalpy schemes

The stability of two chemical systems can be compared only if they contain the same number of particles (electrons and nuclei, or atoms) (4, 5). For example, the free energy change, ΔG, in eq. [1], is a measure of the relative stability of the

[1] $$A + B \rightarrow C + D$$

products (C + D) with respect to the reactants (A + B). However, the stability of, say, D relative to B cannot be extracted from ΔG_1, (or ΔH_1) alone, unless the total energies of A and C are given. Moreover, even if the latter were known, individual bond contributions to the total energies of the participating species would be required before the relative importance of various factors governing the stability of one of the products (for example, a radical) can be defined in terms of one of the reactants.

The enthalpy change for the homolytic cleavage of the R—X

[2] $$RX \rightarrow R^\cdot + X^\cdot$$

bond in an organic molecule (RX) in the gaseous state, under standard conditions[2] is:

[3] $$\Delta H^0{}_2 = \Delta_f H^0(R^\cdot) + \Delta_f H^0(X^\cdot) - \Delta_f H^0(RX) = \mathrm{BDH(R—X)}$$

Equation [3] has been the basis for most definitions of the "stabilization energy" of radicals (2). This stabilization energy is conveniently derived from reactions conserving the number and nature of all chemical bonds ("isodesmic reactions" (6)).

The standard energy (or enthalpy) change $\Delta E^0{}_4$ (or $\Delta H^0{}_4$) has been defined as a measure of the interaction between X and Y (*vide infra*).

[4] $$X—Z—Y + H—Z—H \rightarrow X—Z—H + H—Z—Y$$

When Y = electron and Z = CH_2 reaction [4] yields:

[1] Author to whom all correspondence should be addressed.

[2] The standard heat of formation is symbolized by $\Delta_f H^0$ (and not $\Delta H^0{}_f$) as recommended by the IUPAC commission (5). In this paper, all species are considered in the gaseous state. However to simplify the notations used, the symbol "g" has been omitted.

[a] BDH values are given in Table 1.
[b] All values are in kJ mol^{-1}.

[5*a*] $X—CH_2^\cdot + H—CH_2—H \rightarrow X—CH_2—H + H—CH_2^\cdot$

[5*b*] $R^\cdot + CH_4 \rightarrow RH + CH_3^\cdot$

ΔH^0_{5b}, has been identified as the (de)stabilization energy (RE) of a chosen radical R$^\cdot$ (eq. [6]) (7).

[6] $RE\ (R^\cdot) = \Delta H^0_{5b} = BDH(CH_3—H) - BDH(R—H)$

For π-resonance delocalized radicals, Benson's definition of stabilization energy (SE), eq. [7], has been used (8*a*), where R_SCH_3 is the fully saturated compound analogous to $R_\pi CH_3$ (8, 9).

[7] $SE\ (R_\pi CH_2^\cdot) = BDH(R_SCH_2—H) - BDH(R_\pi CH_2—H)$

The BDH methods described above (eqs. [6] and [7]) assume that the relevant relative BDH values depend only on the stability of the radicals formed (2, 7–10). This suggests that the standard enthalpy change, ΔH^0_8, given by eq. [9] should not

[8] $R^\cdot_r + RZ \rightarrow R_rZ + R^\cdot$

vary with Z (10), where R_rZ is the molecule with respect to which relative BDH values {δ(BDH(R—Z))} are measured.

[9] $\Delta H^0_8 = BDH(R—Z) - BDH(R_r—Z) = \delta(BDH(R—Z))$

However, the variation in relative BDH values (δ(ΔH^0_8)) is given by the enthalpy change for reaction [10].[3]

[10] $R_rH + RX \rightarrow R_rX + RH$

[11] $\delta(\Delta H^0_8) = \Delta H^0_8\ (Z = X) - \Delta H^0_8\ (Z = H)$
$= \delta(BDH(R—X)) - \delta(BDH(R—H))$
$= \Delta_f H^0(R_rX) - \Delta_f H^0(RX) - \Delta_f H^0(R_rH) + \Delta_f H^0(RH)$
$= \Delta H^0_{10}$

The fact that δ(ΔH^0_8) is not zero does not indicate the absence (or presence) of radical stabilizing effects, because δ(ΔH^0_8) is independent of any $\Delta_f H^0$ (radical) value (11). Indeed, the limitations of the BDH method are illustrated in Tables 1, 2, and 3.

The involvement of substituent effects on the stability of undissociated molecules is also shown in Table 4, with reference to reaction [4]. In Fig. 1, we illustrate an example of how

[3] The use of the BDH method to estimate radical stability presupposes the absence of substituent effects on the stabilities of the parent undissociated molecules. This method actually assumes that ΔH^0_{10} is zero. In Table 3 we critically assess the validity of this assumption.

[a] Unless otherwise noted, ΔH^0_{10} was calculated using standard heats of formation (of species (involved) obtained from ref. 24*a*.
[b] Calculated using the standard heats of formation of $C_2H_5F(g)$ and $CH_3F(g)$ from ref. 8*b*.
[c] Uncertainty probably greater than 8 kJ mol^{-1}.

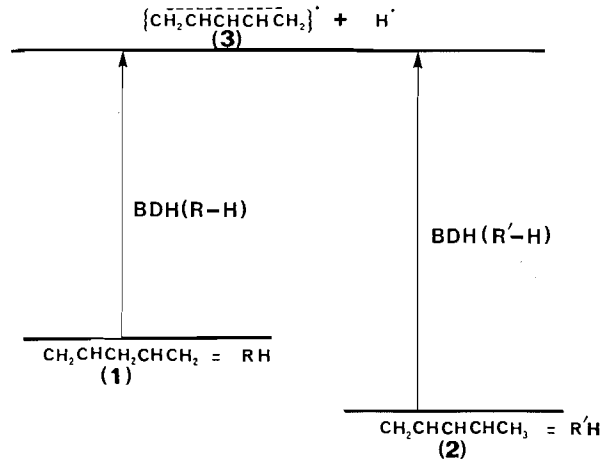

FIG. 1. A comparison of the bond dissociation enthalpies of 1,4-pentadiene (**1**) and 1,3-pentadiene (**2**). In fact, the difference in the BDH(R—H) values of **1** and **2** to give the same delocalized radical **3** has been attributed (2) to substituent effects on neutral closed shell species (i.e. extra stabilization of **2** due to its conjugated double bonds). However, the difference in the intrinsic bond strengths of the dissociated C—H bonds of **1** and **2** will also be a factor causing the unequal BDH values. It must be noted that this ambiguity will be present for all π-delocalized radicals that can be represented by at least two non-identical resonance forms.

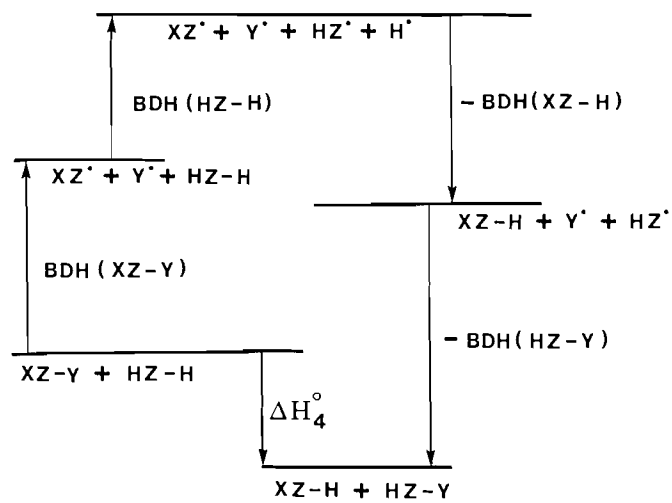

FIG. 2. A thermochemical cycle relating the enthalpy change in the isodesmic reaction [4] to BDH values of the participating species.

ambiguities can arise by equating relative BDH values to radical stability.

An analysis of the general isodesmic reaction (reaction [4])

Using the thermochemical cycle given in Fig. 2, the enthalpy change for reaction [4], ΔH^0_4, can be expressed by eq. [12], where δ(BDH(XZ—Y)) and δ(BDH(XZ—H)) are substituent effects on the BDH values of the Z—Y and Z—H bonds respectively. Equation [12]

$$[12] \quad \Delta H^0_4 = \mathrm{BDH(XZ—Y)} - \mathrm{BDH(HZ—Y)} - \mathrm{BDH(XZ—H)} + \mathrm{BDH(HZ—H)} = \delta(\mathrm{BDH(XZ—Y)}) - \delta(\mathrm{BDH(XZ—H)})$$

shows that for a fixed Y, ΔH^0_4 is a measure of only a relative interaction energy between X and Y with respect to X and H.

TABLE 4. The relative enthalpy of interaction [a,b] between two groups R and X ($\Delta H^0_{R/X}$ (kJ mol^{-1})) attached to a common moiety (CH_2) in the gas phase at 298.15 K

C_2H_3	0	—	−11.9 ± 4.4	−18.6 ± 2.5	−17.3 ± 2.1	−11.1 ± 0.8	−12.1 ± 1.4	−56.8 ± 8.4

[a] The standard enthalpy change at 298.15 K for the gas phase reaction $RCH_2H + HCH_2X \rightarrow RCH_2X + HCH_2H$.
[b] Calculated using standard heats of formation of species involved from ref. 24*a*.

This can also be readily seen by considering reaction [4], with Y = H, in which case $\Delta H^0_4 = 0$. It must be noted that the applicability of reaction [4] cannot be tested by the success or failure of any group additivity methods (8*b*) of obtaining the standard heat of formation of XZY from HZY, XZH, and HZH. This is because in these methods any type of interaction between X and H, say in XZH, is included in the group values for X(ZH) and ZH(X). Thus, the suitability of using reaction [4], when Y is simply an electron (or, alternatively, eq. [6]), to directly assess radical stability depends on the magnitude of the interaction between a substituent (X) and H in a molecule of the type XZH.

Factors governing bond dissociation energies

The bond dissociation energy (BDE) of a bond (C—X) at 0 K has been given by eq. [13], where ΔV is the bond potential energy (the energy needed to break the bond at 0 K when the

$$[13] \quad \mathrm{BDE(C{-}X)} = \Delta V + \Delta R + \Delta Z$$

fragments retain their valence state pertaining to bonding); ΔR is the energy change when fragments revert to the standard state at 0 K and ΔZ is the difference between the zero point energies before and after bond scission (12). Even if individual ΔV, ΔR, and ΔZ values can be estimated, the use of eq. [13] to obtain radical stabilities will be biased by effects on the parent species (C—X).

In an entirely different approach Leroy and co-workers (13) have estimated the stabilization energy (SE) of radical (or closed shell) species using

$$[14] \quad \mathrm{SE} = \Delta H_a - \Sigma N_{AB} E_{AB}$$

where ΔH_a is the heat of atomization of the species (radical or closed shell) and E_{AB}'s are standard bond energy terms derived from ΔH_a values of reference compounds. However, an unambiguous quantitative assessment of radical stability still cannot be made because it also requires an assumption regarding reference bonds.

The method

Charge effects on bond strengths

A bond by bond insight into the various factors contributing to the stability of hydrocarbons has been made possible by a suitable partitioning of the total energy of these species in terms of constituent bonds. Such an analysis in terms of electron distributions has been developed by Fliszár and co-workers (eqs. [15–19]) (14–22). Using this approach they have been able to calculate the energy of atomization, $\Delta_{at}E^*$, of several series of organic molecules at 0 K in the hypothetical vibrationless state, which shows good agreement with experiment (14–22)[4,5]. Equation [15] shows the relationship between $\Delta_{at}E^*$ and E_{ij}, where E_{ij} and E^*_{nb} give the energy contributions to $\Delta_{at}E^*$ from the iJ bond and the non-bonded interactions respectively.

$$[15] \quad \Delta_{at}E^* = \Sigma E_{ij} - E^*_{nb}$$

$$[16] \quad E_{ij} = E_{ij}(Q_i, Q_J)$$

$$[17] \quad E_{ij} = E^0_{ij} + \Delta Q_i(\partial E_{ij}/\partial Q_i)_{Q^0_i, Q^0_J} + \Delta Q_J(\partial E_{ij}/\partial Q_J)_{Q^0_i, Q^0_J}$$
$$= E^0_{ij} - \Delta q_i(\partial E_{ij}/\partial Q_i)_0 - \Delta q_J(\partial E_{ij}/\partial Q_J)_0$$

Equation [16] can be postulated, provided that for a given bond iJ the variations in Q_i and Q_J (the total electron population of the bond-forming atoms i and J respectively) due to changes in molecular environment are small. The E_{ij} terms can be expressed as standard E^0_{ij} terms (of eq. [17]) if eq. [16] is assumed (16). In eq. [17], Δq_i and Δq_J are net (i.e., $Z - Q$) atomic charges relative to standard charges q^0_i and q^0_J. By defining E_{CC} and E_{CH} with respect to the ethane CC and CH bonds and, consequently, q_C and q_H expressed relative to the net atomic charges of C and H of ethane, application of eq. [17] gives:

$$[18] \quad E_{CC} = E^0_{CC} + a_{CC}(\Delta q_{C_i} + \Delta q_{C_J})$$

$$[19] \quad E_{CH} = E^0_{CH} + a_{CH}\,\Delta q_C + a_{HC}\,\Delta q_H$$

In these equations a_{CC}, a_{CH}, and a_{HC} represent the appropriate $-(\partial E_{ij}/\partial Q_i)_0$ values of eq. [17]. *The significance of eqs. [15]–[19] is that the individual bond contributions to the differences in the relative stability of two species can be determined, if the required* a_{ij} *and* Δq *values are known (14–21).*

Useful information about charge effects on intrinsic bond strengths[6] has been obtained from the application of eqs. [15]–[19] to a variety of organic molecules. Studies by Fliszár and co-workers (14) of linear and branched paraffins and compounds containing chair or boat cyclohexane rings have given the following a_{ij} values[7,8,9] in the units kJ mol^{-1} me^{-1}: a_{HC} =

[4] The energy of atomization is symbolized by $\Delta_{at}E$ as recommended by the IUPAC commission (5).

[5] $\Delta_{at}E^* = \Sigma_i n_i[\Delta_f H^0(A_i) - 5RT/2] + \mathrm{ZPE} + (H_T - H_0) - \Delta_f H^0$ (molecule) (22).

[6] By "intrinsic" is meant the contribution of that bond to the energy of atomization of the molecule.

[7] For more details on the calculation of the a_{ij} terms see refs. 14, 19, and 20.

[8] Charge–energy relationships (eqs. [16]–[19]) are valid for small perturbations (in the order of millielectrons).

[9] The unit of charge is expressed in millielectrons and symbolized by me (14).

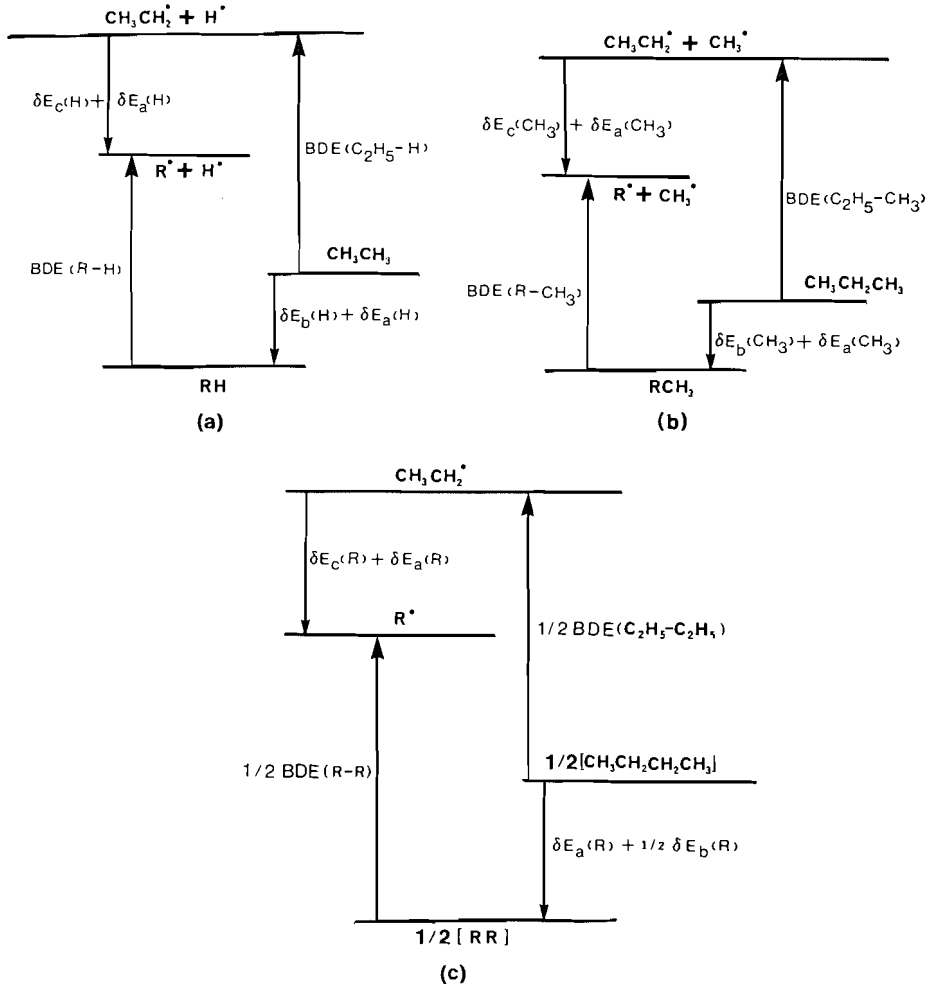

FIG. 3. A schematic representation of substituent effects on an open-shell species (CH_3CH_2) and closed shell species (CH_3CH_2X), at 0 K, in the hypothetical vibrationless state, where non-bonded interactions have been ignored. (a) X = H (b) X = CH_3 (c) X = C_2H_5. $-\delta E_a(X) = E^0\{R(RX)\} - E^0\{C_2H_5(C_2H_5X)\}$; $-\delta E_b(X) = SE^0(C^*/X)$; $-\delta E_c(X) = SE^0[R^\cdot, RX]$.

2.64, a_{CH} = 1.03, and a_{CC} = 2.04. These values indicate that 0.001 electron (= 1 me) added to hydrogen ($\Delta q_H = -1$ me) stabilized a CH bond by 2.64 kJ mol^{-1}, whereas 1 me added to carbon had a stabilizing effect of 1.03 and 2.04 kJ mol^{-1} on a CH and a CC bond, respectively (14). *Thus, any electron enrichment on a carbon atom, at the expense of the electron population at the hydrogen atoms of a CH bond in these alkanes, results in a gain in molecular stability but a concomitant weakening of that CH bond.*

The relationship between charges on atoms and stabilities provides a method of estimating substituent effects on the intrinsic C—H and C—C bond strengths of several types of organic molecules (RX) independent of the standard heat of formation of the corresponding radicals ($\Delta_f H^0(R^\cdot)$ and $\Delta_f H^0(X^\cdot)$). Next we apply this approach to assess changes in the intrinsic C—H and C—C bond strengths of a few representative alkanes. These estimations then enable the calculation of relative net stabilization energies of alkyl radicals via the use of appropriate BDH values (*vide infra*).

Relative net stabilization energies of a radical ($SE^0[R^\cdot, RX]$)

Consider the isodesmic reaction[10]

[20] $C^*(R^1R^2R^3)X + CH_3CH_2^\cdot \rightarrow [C^*(R^1R^2R^3)]^\cdot + CH_3CH_2X$

all participating species being in their hypothetical vibrationless state at 0 K. The energy change, ΔE^0_{20}, can be expressed in terms of BDE values:

[21*a*] $\Delta E^0_{20} = BDE(R—X) - BDE(CH_3CH_2—X)$

If we neglect non-bonded interactions (E^0_{nb}), from Fig. 3(a) and (b) it is clear that ΔE^0_{20}, is given by

[21*b*] $\Delta E^0_{20} = -\delta E_c(X) - \delta E_a(X) + \delta E_b(X) + \delta E_a(X)$
$= SE^0[R^\cdot, RX] - SE^0(C^*/X)$

In eq. [21*b*], $-\delta E_a(X)$ is the energy of the R component of RX, measured relative to the C_2H_5 component of C_2H_5X. Thus $-\delta E_C(X)$ is a measure of the stability of the R moiety as a radical with reference to it being a part of RX (in this paper, the R component of RX is denoted by R(RX)), and $SE^0[R^\cdot, RX]$, is referred to as a *net* stabilization energy because it is measured with reference to R(RX). Values of $-\delta E_b(X)$ (= $SE^0(C^*/X)$), are measures of the stabilization energy of the C*/X interaction in RX relative to that in C_2H_5X. Hence, it is clear that ΔE^0_{20} depends not only on effects of R^1, R^2, and R^3 (R^1, R^2, and R^3 are alkyl groups or hydrogen) on the stability of $R^\cdot$ relative to $C_2H_5^\cdot$, $SE^0[R^\cdot, RX]$, but also on $SE^0(C^*/X)$.

[10] X is a fixed group (alkyl group or hydrogen) for the series of R groups considered, where R = $C^*(R^1R^2R^3)$.

Under standard conditions, the enthalpy change for eq. [20], ΔH^0_{20} is related to $SE^0[R^\cdot, RX]$ by:

$$[22a] \quad SE^0[R^\cdot, RX] = \Delta H^0_{20} + SE^0(C^*/X) + (\Delta E^0_{nb})_{20} - \Delta(ZPE + H_T - H_0)_{20}$$

Values of $\Delta(ZPE + H_T - H_0)$ for isodesmic reactions are generally expected to be small. To a first approximation, by neglecting such effects and $(\Delta E^0_{nb})_{20}$, eq. [22*a*] simplifies to:

$$[22b] \quad SE^0[R^\cdot, RX] = \Delta H^0_{20} + SE^0(C^*/X)$$

For X = H or CH_3, the neglect of $(\Delta E^0_{nb})_{20}$ will not lead to any serious error because $\Delta E^0_{nb}(RX)$ values have been shown to be small (14, 23).

Notice that the radical R$^\cdot$ and the reference state, R(RX), contain the same number of atoms and approximately[11] the same net charge; hence their total energies or atomization energies will reflect their relative stabilities. However, the structure and charge distribution of the reference states, R(RX) (and hence $SE^0[R^\cdot, RX]$), can vary.

To test the magnitude of this variation, three types of reference states (R(RX); X = H, CH_3, and R) have been studied.

Case (i): X = H

Substitution of X = H in eq. [22*b*] gives eq. [23], where $SE^0(C^*/H^*)$ is the substituent effect on the intrinsic C*—H* bond of RH*. Equation [23] expresses $SE^0[R^\cdot, RH]$ in terms of known BDH(R—H) values and $SE^0(C^*/H^*)$ which can be calculated using eqs. [19] and [24].

$$[23] \quad SE^0[R^\cdot, RH] = \Delta H^0_{20}(X = H) + SE^0(C^*/H^*)$$

$$[24] \quad SE^0(C^*/H^*) = SE^0(C^*—(H^*)) + SE^0(H^*—(C^*)) = a_{C^*H^*}[\Delta q_{C^*}] + a_{H^*C^*}[\Delta q_{H^*}]$$

In eq. [24] $a_{C^*H^*}[\Delta q_{C^*}]$ and $a_{H^*C^*}[\Delta q_{H^*}]$ are the respective contributions to the stabilization of the C*—H* bond ($SE^0(C^*/H^*)$), from changes in the charges (in the units of me) on the C* and H* atoms relative to the carbon and hydrogen atoms of ethane. Similar equations can be developed to assess $SE^0(C^*/H^*)$ values in carbonyl compounds (19), ethers (19), and ethylenes (20).

Case (ii) X = CH_3

Substitution of X = CH_3 in eq. [22*b*] gives:

$$[25] \quad SE^0[R^\cdot, RCH_3] = \Delta H^0_{20}(X = CH_3) + SE^0(C^*/CH_3)$$

where $SE^0(C^*/CH_3)$ is the substituent effect on the interaction between C* and the whole CH_3 group (eq. [26]). Equation [25] expresses $SE^0[R^\cdot, RCH_3]$ in terms of known BDH(R—CH_3) values and $SE^0(C^*/CH_3)$, which can be calculated using eq. [26]. In eq. [26] $SE^0(Y—(Z))$ symbolizes the substituent effect on the stabilization of the Y—Z bond due to changes in the charges on the atom Y. Δq_Y symbolizes the charge on atom Y relative to that on the same atom (Y) when R = C_2H_5. Thus, (C^*/CH_3) involves the interactions in one C—C bond and three C—H bonds.

$$[26] \quad SE^0(C^*/CH_3) = SE^0\{C^*—(C)\} + SE^0\{C—(C^*)\} + 3SE^0\{C—(H)\} + 3SE^0\{H—(C)\} = a_{C^*C}[\Delta q_{C^*}] + a_{CC^*}[\Delta q_C] + 3a_{CH}[\Delta q_C] + 3a_{HC}[\Delta q_H] = a_{CC}[\Delta q_{C^*}] + 3a_{HC}[\Delta q_H] + (a_{CC} + 3a_{CH})[\Delta q_C]$$

Case (iii): X = R

The need for considering terms such as $SE^0(C^*/X)$ in eqs. [23] and [25] implies the presence of, and the variation in, charge on X (and hence R(RX)). Thus, the choice of reference state in defining radical stability using eqs. [21], [23], and [25] will be biased by this charge effect. Such charge effects can be overcome by choosing the reference state, R(RR), where $q_{R(RR)}$ is zero by symmetry. To define $SE^0[R^\cdot, RR]$, let us consider the following isodesmic reaction:

$$[27] \quad 1/2\,[C^*(R^1R^2R^3)]_2 + CH_3CH_2^\cdot \rightarrow [C^*(R^1R^2R^3)]^\cdot + 1/2\,[CH_3CH_3]_2$$

all participating species being in their hypothetical vibrationless state at 0 K.[12] ΔE^0_{27} depends not only on the effects of R^1, R^2, and R^3 (R^1, R^2, and R^3 are alkyl groups or hydrogen) on the stability of R$^\cdot$ relative to the $C_2H_5^\cdot$, $SE^0[R^\cdot, RR]$, but also on $SE^0(C^*/C^*)$ (eqs. [28] and [29]), the stabilization of the central C*—C* bond in RR relative to that in $CH_3CH_2CH_2CH_3$ (i.e. the central C—C bond in n-butane). This is illustrated in Fig. 3(c). In eq. [28] the symbolism adopted (at 0 K) is the same as in eq. [21]. Thus the descriptions of terms in eq. [21] are also applicable to eq. [28]. The standard enthalpy change for eq. [27], ΔH^0_{27}, is related to $SE^0[R^\cdot, RR]$ by:

$$[28] \quad \Delta E^0_{27} = 1/2[BDE(R—R) - BDE(CH_3CH_2—CH_2CH_3)] = SE^0[R^\cdot, RR] - 1/2\,SE^0(C^*/C^*)$$

$$[29a] \quad SE^0[R^\cdot, RR] = \Delta H^0_{27} + 1/2SE^0(C^*/C^*) + \delta(\Delta E^0_{nb})_{27} - \Delta(ZPE + H_T - H_0)_{27}$$

Values of $\Delta(ZPE + H_T - H_0)$ for isodesmic reactions are small and can be neglected in a first approximation. $(\Delta E^0_{nb})_{27}$ may not be small (for example when R = *t*-Bu (15)), but, if neglected, simplifies eq. [29*a*] to:

$$[29b] \quad SE^0[R^\cdot, RR] = \Delta H^0_{27} + 1/2\,SE^0(C^*/C^*)$$

Equation [29*b*] expresses $SE^0[R^\cdot, RR]$ in terms of known BDH(R—R) values and $SE^0(C^*/C^*)$ which can be calculated using eq. [30], where Δq_{C^*} is the charge on the C* atom of RR relative to that in RR(R = C_2H_5).

$$[30] \quad SE^0(C^*/C^*) = 2\,SE^0\{C^*—(C^*)\} = 2\,a_{CC}[q_{C^*}(RR) - q_{C^*}(n\text{-}C_4H_{10})] = 2\,a_{CC}[\Delta q_{C^*}]$$

Variation of $SE^0[R^\cdot, RX]$ with choice of X

The variation in $SE^0[R^\cdot, RX]$, for X = CH_3 and X = R (with reference to X = H), can be represented by;

$$[31a] \quad \delta(SE^0[R^\cdot, RX]) = SE^0[R^\cdot, RCH_3] - SE^0[R^\cdot, RH]$$

$$[31b] \quad \delta'(SE^0[R^\cdot, RX]) = SE^0[R^\cdot, RR] - SE^0[R^\cdot, RH]$$

Substitution of eqs. [23], [25], and [29*b*] in eq. [31] yields:

[11] The radical R$^\cdot$ is electrically neutral. But R(RX), where X ≠ R, will usually have a small net charge (q_R). For the alkanes, the magnitude of this charge is in the order of 1–10 me (see Table 9).

[12] Note that eq. [27] and eq. [20] are related by: [27] = 1/2([20](X = R) + [20](X = C_2H_5)).

$$[32a]\quad \delta(SE^0[R^\cdot, RX]) = \Delta H^0_{20}[(X = CH_3) - (X = H)] + SE^0(C^*/CH_3) - SE^0(C^*/H) = \delta(\Delta H^0_{20}) + \delta(SE^0(C^*/X))$$

$$[32b]\quad \delta'(SE^0[R^\cdot, RX]) = \Delta H^0_{27} - \Delta H^0_{20}(X = H) + 1/2\ SE^0(C^*/C^*) - SE^0(C^*/H)$$

In eq. [32] $\Delta(ZPE + H_T - H_0)$ and $\delta(\Delta E^0)_{nb}$ terms have been ignored. Although individual ΔH^0_{20} or ΔH^0_{27} values have large uncertainties (~8 kJ mol^{-1}), their difference or $\delta(\Delta H^0_{20})$ values are known more precisely (uncertainty < 1 kJ mol^{-1}) (Table 3). Thus, the differences in the $SE^0[R^\cdot, RX]$ values can be calculated using eqs. [32*a*] and [32*b*].

While individual $\Delta(ZPE + H_T - H_0)$ values for eqs. [20] and [27] are not readily calculated, their differences can usually be obtained (22). Similarly, differences in ΔE^0_{nb} values are generally estimable (14, 23). Using eqs. [21] and [29*a*], the differences in the $SE^0[R^\cdot, RX]$ values can be expressed by:

$$[33a]\quad \delta(SE^0[R^\cdot, RX]) = \delta(\Delta H^0_{20}) + \delta(SE^0(C^*/X)) - \Delta(ZPE + H_T - H_0)_{20}[(X = CH_3) - (X = H)] + (\Delta E^0_{nb})_{20}[(X = CH_3) - (X = H)]$$

$$[33b]\quad \delta'(SE^0[R^\cdot, RX]) = [\Delta H^0_{27} - \Delta H^0_{20}(X = H)] + 1/2\ SE^0(C^*/C^*) - SE^0(C^*/H) - \Delta(ZPE + H_T - H_0)_{27} + \Delta(ZPE + H_T - H_0)_{20}[X = H] + (\Delta E^0_{nb})_{27} - (\Delta E^0_{nb})_{20}[X = H]$$

From Fig. 3, it is clear that for any X the total substituent effect on the stability of a radical is a constant. Consequently, by assuming $E^0_{nb}[R(RX)]$ and $E^0_{nb}[R(RH)]$ are equal, eq. [34] is obtained.

$$[34]\quad \delta E_a(CH_3) + SE^0[R^\cdot, RCH_3] = \delta E_a(H) + SE^0[R^\cdot, RH] = \delta E_a(R) + SE^0[R^\cdot, RR]$$

The differences $\delta[E_a(CH_3) - E_a(H)]$ and $\delta[E_a(R) - E_a(H)]$ can be estimated by considering the charges on the atoms of the $R(RCH_3)$ and R(RR) relative to that in R(RH).

$$[35a]\quad \delta[E_a(CH_3) - E_a(H)] = \delta E_a(CH_3) - \delta E_a(H) = [E_a(CH_3) - E_a(H)]_R - [E_a(CH_3) - E_a(H)]_{C_2H_5}$$

$$[35b]\quad \delta[E_a(R) - E_a(H)] = [E_a(R) - E_a(H)]_R - [E_a(C_2H_5) - E_a(H)]_{C_2H_5}$$

$$[36]\quad -(E_a(X) - E_a(H))_R = \Sigma_i[(n_{C_i}a_{CC} + n_{H_i}a_{CH})\,\Delta q_{C_i}] + \Sigma_j[a_{HC}\Delta q_{H_j}] = \Sigma_i[(n_{C_i}a_{CC} + n_{H_i}a_{CH} - a_{HC})\,\Delta q_{C_i}] + a_{HC}\{q[R(RX)] - q[R(RH)]\}$$

In eq. [36] n_{C_i} and n_{H_i} are the number of carbon and hydrogen atoms attached to C_i; Δq_{C_i} and Δq_{H_j} are charges on the *i* carbon and *j* hydrogen atom of R(RX) relative to R(RH).

From eqs. [34]–[36] an expression for the $\delta(SE^0[R^\cdot, RX])$ values is obtained;

$$[37a]\quad \delta(SE^0[R^\cdot, RX]) = \delta\{E_a(CH_3) - E_a(H)\}$$

$$[37b]\quad \delta'(SE^0[R^\cdot, RX]) = \delta\{E_a(R) - E_a(H)\}$$

Results and discussion

The stabilization energy of a radical must be an invariant quantity. Tables 1 and 2 clearly show, that relative BDH values cannot be directly equated to radical stability. For example, by considering the C—OH bond cleavage it might be concluded that the stabilities of the simple alkyl radicals are in the order, $i\text{-}C_3H_7^\cdot \simeq t\text{-}C_4H_9^\cdot < C_2H_5^\cdot$. This is a complete reversal in the order of stability, $C_2H_5^\cdot < i\text{-}C_3H_7^\cdot < t\text{-}C_4H_9^\cdot$, obtained by considering C—H bond cleavage.

It might be argued that the relatively poor correlation of BDH values (when X is an electronegative atom or group) in Table 1 is due to the uncertainty in some of the data used in the analysis. However, it must be noted that a good correlation in the BDH data is a necessary but not a sufficient criterion to propose that relative BDH (R—X) values are a suitable measure of radical stability. The differences obtained in Table 2 are independent of the standard enthalpy of formation of any radical species and are equal to the ΔH^0_{10} values in Table 3. Most of these values have uncertainties that are smaller than the differences in Table 2 (24). The ambiguities in the order of stabilities inferred from Table 2 are a result of neglecting effects on the parent undissociated molecules of these radicals (see Table 4). Thus, even when more accurate determinations of BDH values are available, they will not change the apparent discrepancies in the values in Table 2 and may not significantly improve the correlation in Table 1.

The poor correlation obtained in the BDH values when X is an electronegative atom is not surprising (Table 1).[13] This is because the polarity of the $C^{\delta+}\text{---}X^{\delta-}$ bond will certainly affect the strength of the other bonds in the molecule. On dissociation of the C—X bond the effects of X on R will be absent. In addition, an X that had a partial negative charge when attached to R leaves as a neutral species. Thus, in the radical state, the R component will have to accommodate the excess electrons. Furthermore, there will be effects on the C—X bond (and, where X contains more than one atom, there will be an effect on the individual bonds in X) from the groups attached to (CX). One of the reasons for the poor correlation in Table 1 and the large ΔH^0_4 values, when X = OH, is possibly because of effects on the O—H bond.

The relatively better correlation, when X = alkyl, is probably due to the fact that substituent effects on RX are very similar in nature when X is an alkyl group or a hydrogen atom. *However, Table 2 clearly shows that even when X = alkyl the magnitude of relative BDH values changes appreciably relative to X = H.* Alternatively, it can be suggested that, due to the variation in the relative BDH values, only RH be used to define radical stability. However, such an a priori choice is unjustified, unless the effects of substituents on the intrinsic R—H bond strengths are known.

Studies by Fliszár and co-workers have shown that charge effects are the dominant factor influencing the stabilities of alkanes (14). From Table 5 it is evident that such effects can be as large as −17 kJ mol^{-1} for the tertiary C—H bond in 2-methyl propane. These effects are a result of the variation in the charges on both atoms (carbon and hydrogen) involved in the bond. In the alkanes studied, except for the primary C—H bond in propane, the variation of charge on hydrogen had a greater effect ($a_{HC}\Delta q_{H^*}$) than the corresponding variation on

carbon ($a_{CH}\Delta q_{C^*}$). From Table 5 we see that the C—H bond in methane is 8 kJ mol^{-1} weaker than in ethane. The primary and secondary C—H bonds of propane and the tertiary C—H bond of 2-methyl propane are found to be, respectively, 2.6, 8.0, and 17 kJ mol^{-1} more stable than the C—H bond of ethane.

Charge effects on the total interaction between a methyl group and the carbon atom at the point of attachment for selected alkanes are given in Table 6. These values show that there is a greater contribution to the total effect from charge variations on the carbon atoms than from those on the hydrogen atoms. It is also evident that the C* atom shows a greater effect in the C/CH_3 system compared to the C/H system. This is partly because $a_{CC} > a_{CH}$. The substituent effects observed on the C/CH_3 interaction is in the same order as the C/H interaction, but greater in magnitude. The variation in the relative BDH values observed for the C—CH_3 and C—H cleavages is partly due to differences in $SE^0(C^*/CH_3)$ and $SE^0(C^*/H)$ values. The $SE^0[R^\cdot, RX]$ values obtained after the appropriate BDH values have been corrected for C/H, C/CH_3, and C/C interactions are given in Table 7.

From Table 7 it is evident that, for a given $R^\cdot$, $SE^0[R^\cdot, RX]$ varies with the choice of reference state. The uncertainties in the individual $SE^0[R^\cdot, RX]$ values depend to a large extent on the error in the BDH values used to calculate ΔH^0_{20} or ΔH^0_{27}. Before discussing the relative merits of using the various $SE^0[R^\cdot, RX]$ values calculated to define radical stability, the reasons for their differences must be given careful consideration. The charge contribution to the energy differences be-

tween reference states is given in Table 8. These values show that for a given R the stabilities of the reference states are in the order R(RR) > R(RCH_3) > R(RH). This order arises because of the differences in the net charges of the reference states (Table 9).[14]

A radical, R$^\bullet$ is electrically neutral. However, Table 9 shows that q[R(RH)] and q[R(RCH_3)] have non-zero values with the exception of q[CH_3(C_2H_6)]. The closer a reference R component R(RX) is to neutrality, the more suitable it is to be used to define radical stability. This is because if q[R(RX)] is not negligible, then R(RX) and R$^\bullet$ do not have the same net charge, and their energies are not directly comparable. The rationale behind choosing R(RX) to define radical stability was to use a reference state having the identical arrangement of atoms and same net charge as R$^\bullet$ and in addition have an *inert* unpaired electron. All these conditions are met in R(RR), where q[R(RR)] is zero for all R by symmetry. R(RH) and R(RCH_3) have the limitation of having a slight deficiency in the electronic charge. Thus, conceptually the SE^0[R$^\bullet$, RR] values are the best parameters that can be used to define radical stability.

It must be noted that these SE^0[R$^\bullet$, RR] values also include stabilization due to change in hybridization (ΔR of eq. [13]). The ΔR term will include stabilization due to changes in one electron, two-electron, and nonbonded interactions. It is also interesting to consider to what extent a radical in the hypothetical sp^3 hybridized state can be stabilized. This can be obtained from[15]

$$[38] \quad SE^0[R^\bullet(sp^3), RR] = SE^0[R^\bullet, RR] - [\Delta R(R^\bullet) - \Delta R(C_2H_5^\bullet)]$$

Relative to the ethyl radical in the sp^3 state, the following SE^0[R$^\bullet$ (sp^3), RR] values in kJ mol^{-1} are obtained: CH_3, 21; i-C_3H_7, −7; t-C_4H_9, −22. These values indicate that, even in an sp^3 hybridized state, radicals are stabilized. However, the origin of this stabilization is not apparent from this study.

The dependence of the relative stabilization energies of radicals on the chosen reference state is described by δ(SE^0[R$^\bullet$, RX]) and δ'SE^0[R$^\bullet$, RX]) values in Table 10. The advantage of this approach is that these differences (δ(SE^0[R$^\bullet$, RX]) values) can be calculated independent of any $\Delta_f H^0$ (radical) values (which introduce large uncertainties). The differences in the values calculated using eqs. [32] and [33] are due to, respectively, the neglect and inclusion of (ZPE + $H_T - H_0$) and E^0_{nb} terms in the computations. The fair agreement between the two equations suggests that SE^0[R$^\bullet$, RX] calculated (eqs. [23], [25], and [28]) are reliable. However, the SE^0[R$^\bullet$, RR] value for R = i-C_3H_7 and t-C_4H_9 must be used with caution because the required (ZPE + $H_T - H_0$) and E^0_{nb} values are known with less certainty (15). Thus, the SE^0[R$^\bullet$, RR] values for these R groups may be in error. The close agreement between δ(SE^0[R$^\bullet$, RX]) (or δ') values calculated using eqs. [32] and [37] indicates the internal consistency in using linear charge–energy relationships to estimate SE^0[R$^\bullet$, RX] values.

Conclusions

The relationship between radical stability and bond dissociation enthalpies involves several factors that need careful consideration.[16] It is shown that relative BDH values cannot be directly equated to radical stability. The net stabilization energy of a radical R$^\bullet$ can be defined relative to the same R group; when present in a closed shell species RX(X is an alkyl group or hydrogen) R(RR) is found to be the most suitable reference state because (like a radical R$^\bullet$) it is electrically neutral.

SE^0[R$^\bullet$, RX] values indicate that the methyl radical is more destabilized and that the n-propyl, iso-propyl, and *tert*-butyl radicals are more stabilized, relative to the ethyl radical, than suggested from the corresponding BDH(R—X) values. This results from differences in the total C/X interactions (defined independent of any radical species) of RX as a function of R.

Finally, we have attempted to analyse critically methods of assessing radical stability, with the hope that a clearer understanding of the behaviour of these reactive species will ensue.

[14] In Table 9, the net charges of the R components RH, RCH_3, and RC_2H_5 are compared. The charges of R(RH) range from 9.05 me (the value for R = methyl) to 17.02 me (R = *tert*-butyl). The charges of R(RCH_3) and R(RC_2H_5) are of a much smaller magnitude.

[15] ΔR values were obtained from ref. 13*b*.

[16] The SE^0[R$^\bullet$, RX] values obtained in this work do not agree with the SE values reported by Leroy (13). A major reason for these differences is the use of different reference C—C (E(C—C)) and C—H (E(C—H)) bond energies and the assumption, made by Leroy, of a constant E(C—C) value for all alkanes. This work is based on the intrinsic bond energies obtained by Fliszár and co-workers for ethane: E(C—C) = 292 kJ mol^{-1}; E(C—H) = 448.1 kJ mol^{-1}. However, Leroy's work is based on E(C—C) = 355.8 kJ mol^{-1}, obtained by using an empirical scheme suggested by Laidler (25). The assumption that E(C—C) is constant is an obvious drawback of the Laidler scheme (26). In addition, the neglect of charge effects on Fajan's bond energy terms by Leroy can introduce serious error. It is noted that SE values for radicals derived from eq. [14] are measured relative to closed shell species.

TABLE 10. The variation in the relative net stabilization energies[a] of a radical R$^{\cdot}$, (SE^0[R$^{\cdot}$, RX]), with reference state[b] R(RX)

[a] All values are in kJ mol^{-1}.
[b] R components of RH, RCH_3, and RR.
[c] $\delta(\Delta H^0_{20})$ values have been obtained from Table 3.
[d] The required (ZPE + $H_T - H_0$) and E^0_{nb} values have been obtained from refs. 14, 15, 16, and 22.
[e] From Table 8.
[f] The differences in ΔH^0 values have been obtained using $\Delta_f H^0$ values from ref. 24*a*.

It is stressed that, with available data, a definite separation of radical and charge contributions to the stability of an open-shell species is not possible.

At present, Fliszár's method of assessing charge effects on bond strengths cannot be extended to the benzenoid systems. Alternatively, a molecular orbital approach can be used. This will be the topic of the following paper (27).

Thermochemical parameters for organic radicals and radical ions. Part 4. The relationship between bond dissociation enthalpy and radical stability in benzenoid systems

A. MARTIN DE P. NICHOLAS AND DONALD R. ARNOLD[1]

Department of Chemistry, Dalhousie University, Halifax, N.S., Canada B3H 4J3

Received December 5, 1983

A. MARTIN DE P. NICHOLAS and DONALD R. ARNOLD. Can. J. Chem. **62**, 1860 (1984).

It is shown that isodesmic reactions used to assess interaction energies between substituents (X and Y) in benzenoid compounds have not been corrected for X/H and Y/H interactions. Excellent linear Mulliken charge – interaction energy relationships are established for *meta*- and *para*-substituted toluenes. These studies illustrate the relative importance of σ- and π-effects on a quantitative basis. The ρ-values obtained show an equal importance of π-effects in *meta*- and *para*-substituted toluenes. The signs of the ρ(π)-values confirm the presence of resonance type π-interactions. The role of ring hydrogens in σ-type interactions cannot be assessed from this study. At present, BDH values in benzenoid systems cannot be corrected such that they can be used to define radical stability. ^{13}C chemical shifts are found not to correlate wih isodesmic interaction energies. The application of ^{13}C chemical shifts is limited by the inability to independently relate these shifts to σ- and π-effects.

A. MARTIN DE P. NICHOLAS et DONALD R. ARNOLD. Can. J. Chem. **62**, 1860 (1984).

On montre que les réactions isodesmiques utilisées pour déterminer les énergies d'interaction entre les substituants (X et Y) dans les composés benzénoïdes ne sont pas corrigées pour les interaction X/H et Y/H. Dans les cas des toluènes *méta* et *para*-substitués, on a établi d'excellentes relations linéaires entre la charge de Mulliken et l'énergie d'interaction. Ces études illustrent l'importance relative des effets σ et π sur une base quantitative. Les valeurs de ρ obtenues montrent que les effets π ont une égale importance dans les toluènes substitués en positions *para* et *méta*. Les signes des valeurs de ρ(π) confirment la présence d'interactions de résonance de type π. A partir de cette étude, on ne peut pas déterminer le rôle des hydrogènes cycliques dans des interactions de type σ. Pour le moment, on ne peut pas corriger les valeurs BDH des systèmes benzénoïdes de façon à pouvoir les utiliser pour définir la stabilité de radicaux. On trouve qu'il n'y a pas de corrélation entre les déplacements chimiques du ^{13}C et les énergies d'interaction isodesmiques. L'application des déplacements chimiques du ^{13}C est limitée par l'incapacité de relier d'une façon indépendante ces déplacements aux effets σ et π.

Introduction

In the preceding paper (1), a study of the relationship between the stability of an alkyl radical R$^{\bullet}$ and BDH(R—X) *g* values enabled us to define the net stabilization energy of a radical R$^{\bullet}$, (SE^0[R$^{\bullet}$, RX]), with reference to the R component of RX. This study has now been extended to benzylic systems. Here we show that the BDH value for the benzylic C—H bond of a toluene is not a true measure of the stability of the corresponding benzyl radical. We also discuss the difficulties of estimating SE^0[R$^{\bullet}$, RX] in benzenoid systems.

The substituent effect on the stability of a benzyl radical will depend on the extent of interaction between a substituent and the $CH_2^{\bullet}$ group. The interaction energy between two substituents X and Y attached to a benzene ring has been estimated (2) using the isodesmic reaction:

[1] $C_6H_5X + C_6H_5Y \rightarrow XC_6H_4Y + C_6H_6$

Applying Y = H to reaction [1] it is evident that interaction energies measured using this reaction are only relative to interactions between X (and Y) and the appropriate ring hydrogens. The X/Y interactions can be understood by considering ΔH^0_{I} values in terms of relative BDH values (1).

[2] $\Delta H^0_{\text{I}} = \delta[\text{BDH}(XC_6H_4—)H] - \delta[\text{BDH}(XC_6H_4—)Y]$

Alternatively, if the X/H interaction ($\Delta H^0_{X/H}$) and the Y/H interaction ($\Delta H^0_{Y/H}$) can be estimated, the interaction enthalpy between X and Y ($\Delta H^0_{X/Y}$) will be given by eqs. [3] and [4]. In eq. [4] the X/Y interaction is represented as a substituent effect.

[3] $\Delta H^0_{X/Y} = \Delta H^0_{\text{I}} + \Delta H^0_{X/H} + \Delta H^0_{Y/H} - \Delta H^0_{H/H}$

[4] $\delta(\Delta H^0_{X/Y}) = \Delta H^0_{\text{I}} + \delta(\Delta H^0_{X/H})$

From eqs. [1]–[4] it is evident that $\Delta H^0_{X/H}$ values must be known before eq. [1] can be used to determine the stability of a benzyl radical.

In this study we demonstrate the presence of substituent effects on X/Y interactions in benzenoid systems using standard heats of formation ($\Delta_f H^0$) of mono- and disubstituted benzenes in the gas phase (3, 4). *Ab initio* MO calculations are used to obtain Mulliken charge – energy relationships in benzenoid systems and to demonstrate the presence of substituent effects on the benzylic C—H bond of substituted toluenes. The toluenes are of special interest, because they have been used as reference states for assessing benzyl radical stability (5).

The toluenes studied represent five groups. Substituents were studied at both the *meta* and *para* positions. These substituents were chosen only to illustrate the presence of charge related interactions between groups attached to a benzene nucleus, and not with a view of establishing an overall picture of such effects.[2]

The following classification was made:

(*i*) H (unsubstituted toluene), representing a σ-donating[3] and π-noninteracting group.

(*ii*) CH_3, representing a π- and σ-donating[3] group.

[1] Author to whom all correspondence should be addressed.

[2] For a recent review of studies on substituent interactions in benzenoid systems using *ab initio* MO calculations and Perturbation MO theory approach, see ref. 2.

[3] The H and CH_3 groups are classified as σ-donors because $q_\sigma(H) < 0$ and $q_\sigma(CH_3) < 0$ (2). This classification is valid within the framework of the Mulliken charge analysis which has been adopted in this work.

TABLE 1. Relative interaction enthalpies, $-\Delta H^0_1$ (kJ mol^{-1}) for the interaction between X and Y (relative to X and H, and Y and H) for the isodesmic reaction [1] in the gas phase at 298.15 K

Charge effects in benzenoid systems

The charge–energy relationships were studied with two objectives: first, to investigate whether charge and energy were linearly correlated; second, to assess the energetics of the interactions between a substituent and ring hydrogens of monosubstituted benzenes.

Fliszár's method of assessing intrinsic CH bond strengths in terms of charge distributions can be extended in principle to benzenoid systems (6). However, at present the relevant data necessary for such an analysis of these systems is not available.[5] In this paper, the relationship between relative interaction energies (i.e. interaction between substituents and C(ring)—CH_3 group relative to the C(ring)—H group), Mulliken charges on atoms, and ^{13}C chemical shifts in substituted toluenes have been studied. The significance of such a study is that it is a test of the existence of a linear charge–energy or chemical shift – energy relationship in these systems.

The studies of cyclic and acyclic alkanes (6), ethers (7), ethylenes (8), and carbonyl compounds (7) by Fliszár and coworkers have revealed linear ^{13}C nmr chemical shift – calculated atomic charge relationships. They have also shown that these charges are at variance with Mulliken charges derived from *ab initio* MO calculations. The Mulliken population analysis (9) has been found to contain assumptions that can lead to unrealistic results (10).[6] However, Mulliken charges can be used in all cases where carbon forms the same number and type of bonds, because any anticipated error due to an incorrect assignment of overlap populations (e.g. for C—H) cancels in this type of comparison. In fact, linear relationships between STO-3G Mulliken charges (using standard geometries) and ^{13}C chemical shift data have been reported in several benzenoid systems, where the substituent is far removed from the site on which the charge is sampled (11). In this study, the effect of partial geometry optimizations at the STO-3G level on such a charge–shift relationship in monosubstituted benzenes will be investigated.

Satisfactory correlations between Mulliken charges and substituent constants (σ) in benzenoid systems have been reported (11). For reasons that will become clear, we have chosen relative interaction energies rather than σ-values to investigate the presence of linear Mulliken charge – energy and chemical shift – energy relationships.

Results and discussion

The proximity of R and X in a molecule of the type RCH_2X (and the fact that they are bonded to the same atom) is one of the reasons for the large relative interaction energies observed in alkyl systems (1). However, even in *meta*- and *para*-disubstituted benzenes, where the interacting groups are far removed from one another, significant interactions are observed (Table 1).[7] For example, values for the relative interaction between two cyano groups are 14.2 and 8.6 kJ mol^{-1}, respectively, for the *meta* and *para* derivatives. These values clearly show significant interactions between two cyano groups and (or) between a cyano group and hydrogen atoms (CN/H) at these positions. The (CN/H) interaction has to be considered because ΔH^0_1 values in Table 1 are measured relative to X/H and Y/H interactions.

The X/COOH interactions are particularly interesting because the Hammett σ-scale is based on the dissociation of these benzoic acids (12). From Table 1 it is clearly seen that for the benzoic acids, when X = NH_2 and Cl, significant interactions exist both at the *meta* and *para* positions (and when X = I at the *para* position). These are total group effects; at present no separation into contributions from individual bonds in the CO-

[4] It is noted that a σ- and π-separation of charge cannot be made for the methoxy toluenes within the Mulliken framework (2).

[5] S. Fliszár, private communication.

[6] For a discussion on the limitation of the Mulliken scheme see ref. 6 (and ref. 32 therein).

[7] Albeit, the uncertainty in some cases is as large as the corresponding interaction enthalpy.

[a] One of the C—H bonds in the CH_3 group is assumed to be coplanar with the benzenoid ring.
[b] A model CH_3 group (r_{CH} = 1.09 Å and ∠HCH = 109.47 Å) was used.
[c] One of the C—H bonds in the CH_3 group is in a plane perpendicular to the benzenoid ring.
[d] The O—C bond in the OCH_3 group is assumed to be coplanar with the benzenoid ring.

OH group is not possible. The importance of such a separation is that it will indicate the presence (or absence) of a substituent effect in the benzoic acids that may not exist in the ionized state.[8] The interactions are significant even with alkyl groups (X = OH, Z = C_2H_5) and thus can be expected to be general. The significance of these results is that kinetically derived substituent constants reflect interactions in a transition state (or intermediate) relative to a reference state that is also subject to substituent interactions. Undoubtedly the interactions on the reference state will be smaller than on any ionized state or highly polar transition state, but may be large enough (not to be disregarded) when effects on nonionized open or closed shell states are considered. Thus, ΔE^0_I values (rather than σ-values) have been used in this work to investigate the relationship between interaction energies and charges on atoms (or chemical shifts).

Substituent effects on the stability of benzyl radicals is a topic of interest to us (13). In the BDH method, these stabilities are assessed relative to the toluenes. Here we have attempted to study the energetics of the interaction between substituents and the methyl group in toluenes using *ab initio* MO calculations at the STO-3G level (Table 2).[9] These interaction energies (ΔE^0_I) were calculated by considering the appropriate isodesmic reaction (reaction [1]).

In an isodesmic reaction, the formal bond types are conserved on both sides of the equation. This has the advantage that systematic errors inherent in the minimum STO-3G basis set calculations tend to cancel (18). Thus, a fair confidence can be placed in the calculated ΔE^0_I values, although some of the properties of an individual species computed at the STO-3G level may not agree with experiment. For example, while Table 3 shows that, except for the methoxy substituent, the STO-3G equilibrium geometries agree with experiment, Table 4 indicates deviations between STO-3G and experimental dipole moments.

Table 5 clearly shows the presence of significant interactions between substituents (especially the cyano group) and the methyl (and (or) hydrogen atom) group. Similar results have been obtained in the *ab initio* MO study of several series of disubstituted benzenes at the STO-3G level using standard geometries (2). However, at present the dissection of these effects in terms of individual bond contributions of the methyl group is not possible. *Thus, BDH values cannot be corrected to yield substituent effects on the stability of a benzyl radical.*

A major drawback in estimating $SE^0[R^\cdot, RX]$ values (1) has been the inability to determine the charges on atoms in these systems. Table 6 shows that performing partial geometry optimizations does not affect the linear ^{13}C chemical shift – Mulliken charge relationships that have been established previously (11). However, a complete description of charge effects in benzenoid systems requires a separation into σ- and π-contributions. At present, such a dissection of ^{13}C chemical shift values cannot be made. Thus, the usefulness of chemical shift values to establish shift–charge or shift–energy relationships is limited, and it is not surprising that the correlation between ^{13}C chemical shifts and energy is poor (Table 7). In Tables 8–10, the feasibility of using *ab initio* MO calculations, at a minimum STO-3G level, to establish charge–energy relationships is studied.

The Mulliken charges and π-overlap populations given in Tables 8 and 9 show that the donation (or withdrawal) of σ- or π-charges by a substituent to (or from) the ring is changed only slightly in the toluenes compared to the benzenes. Thus, the charge contributions of X to the stability of the toluene relative to the benzene will depend on the different sensitivities of the methyl group and the hydrogen atom to the charge effects of X. If the stabilizing effect of X was independent of Y (including H atoms), $\delta(\Delta E^0_{X/Y})$ would be equal to $\delta(\Delta E^0_{X/H})$ and ΔE^0_I would be zero (eq. [4]). However, ΔE^0_I values in Table 5 show significant interactions between substituents and the *meta*- and *para*-methyl groups (and (or) hydrogen atoms). In Table 10 the importance of charge effects in these interactions is investigated.

In an extensive and incisive study of substituent interactions in substitued benzenes, Pross and Radom (2) outlined factors governing the stability of disubstituted benzenes, and reached qualitative conclusions about σ- and π-interactions. Their study indicated that the dominant σ-effects were the lowering (or raising) of the energy levels of the ring orbitals by a deshielding (or shielding) process caused by σ-acceptors (or donors). It was also found that σ-effects cause changes to π*-energy levels and hence affect π-charges. The π-effects (especially in the *para* position) were found to be dominated by resonance type interactions. In this study the relationship between interaction energies and σ- and π-charges is investigated on a quantitative basis. Results in Table 10 support the above conclusions reached in the study by Pross and Radom (2).

It is clear from Table 10 that a linear Mulliken charge – energy relationship has been established for both *meta*- and *para*-substituted toluenes. However, it must be noted that the linear charge–energy relationship obtained for the disubstituted benzenes does not, in any way, indicate the absence (or presence) of a substituent interaction with the *meta* or *para* hydrogen in the monosubstituted benzene. It can only be con-

[8] If such interactions are present, σ-values will partly reflect stabilization (or destabilization) of the undissociated acid.

[9] Standard single determinant MO theory was used. The *ab initio* MO calculations described were obtained by the use of the GAUSSIAN 76 program (14) on a Control Data CYBER 170-220 system. The closed shell, spin-restricted (RHF) procedure was employed (15) to compute the energies of the mono- and disubstituted benzenes. The minimal STO-3G basis set (16) was used. Partial geometry optimizations, subject to imposed symmetry constraints, were applied. A standard phenyl ring with hexagonal symmetry was assumed in every case (17). r_{CC} = 1.38669 Å and r_{CH} = 1.08258 Å (STO-3G values for benzene, ref. 17).

cluded that, if both types of interactions do exist, they are well correlated. A closer examination of the correlation data in Table 10 enables a better understanding of these interactions.

From Table 10 it is seen that the best correlations are obtained for the three-parameter equations involving $q_\sigma(X)$, $q_\sigma(Y)$, and $q_\pi(X)$ (or $q_\pi(X)\cdot q_\pi(Y)$). Table 9 shows that $q_\pi(Y)$ varies only slightly throughout the series. Thus, we are unable to conclude whether $q_\pi(X)$ or $[q_\pi(X)\cdot q_\pi(Y)]$ is better as one of the parameters describing the linear correlation between charges and energies.

The positive $[\rho_\pi(X)\cdot\rho_\pi(Y)]$ or the negative $\rho_\pi(X)$ values indicate that π-acceptors interact favourably with the π-donating methyl group. This type of π-resonance interaction is found to be equally important with the *meta*-substituents as for the *para*-substituents. There can also be π-type interactions between substituents and the π-electrons of the ring in monosubstituted benzenes. However, such interactions will also be present in the toluenes and will differ from the benzenes due to the π-effect of the methyl group.

A few general conclusions can be made about σ-effects. Table 10 shows $\rho_\sigma(Y) > 0$ and $\rho_\sigma(X) < 0$. A positive $\rho_\sigma(Y)$ value indicates that any substituent that decreases $q_\sigma(Y)$ will stabilize the CH_3/X interaction relative to the H/X interaction. As expected from the shielding–deshielding process described above, σ-acceptors decrease and σ-donors increase $q_\sigma(Y)$. However, π-effects are also found to affect these σ-interactions. Thus, while $q_\sigma(F) > q_\sigma(CN)$, $q_\sigma(CH_3)$ for the cyano toluenes is more negative than that of the corresponding fluoro toluenes. The lithium substituent (with $q_\sigma(X) < 0$) makes $q_\sigma(Y) > 0$. Both $\rho_\sigma(Y)$ and $\rho_\sigma(X)$ values indicate that the Li/CH_3 interaction is destabilizing relative to the Li/H interaction (as is observed in Table 10). This is an unusual case, where the contribution to ΔE^0_1 is positive (destabilizing) for a σ-donor/σ-acceptor pair. A possible explanation for this phenomenon is that lithium forces electrons from the ring to the methyl group and causes a destabilization. Alternatively, it is also possible that the positive ΔE^0_1 values, for X = *m*-Li or *p*-Li, are due to a greater stabilizing Li/H interaction relative to the Li/CH_3 interaction. This would imply that hydrogen is either a weaker σ-donor than methyl or it is a σ-acceptor that will interact favourably with lithium. Such a conclusion is at variance with the Mulliken analysis, which indicates that hydrogen is a fairly strong σ-donor and should not interact favourably with the σ-donating groups like lithium.

Table 10 also shows that the constants in eq. [6] are not zero. These small values may be a reflection of the interaction be-

[a] $q_\sigma(m\text{-H})$ and $q_\sigma(p\text{-H})$ are the total σ charges donated by the ring hydrogens at the *meta* and *para* positions respectively.
[b] $q_\sigma(X)$ and $q_\pi(X)$ are the total σ and π charges, respectively, donated by the substituent X.
[c] π(Ph—X) is the Mulliken overlap population of the adjacent π-type *p*-orbitals in the bond joining X to the ring.
[d] Average of two values for the different types of *meta* hydrogens.

tween CH_3/H in toluene relative to H/H benzene. However, a definite conclusion cannot be made from this study involving such a limited number of substituents.

It is likely that nonlinear charge effects exist and can be studied using parameters such as $q_\pi(X)/[1 + \epsilon q_\pi(Y)]$ and $q_\sigma(X)/[1 + \epsilon q_\sigma(Y)]$ (19). However, the limited data in this work does not warrant such an attempt.

Conclusions

The present work shows that *ab initio* MO calculations, even at the minimum STO-3G level, can provide a quantitative analysis of interactions in benzenoid systems. Relative interaction energies between a substituent and the methyl group in *meta*- and *para*-substituted toluenes are found to be linearly related to Mulliken σ- and π-charges. Further work needs to be done to

determine whether these linear relationships are generally applicable. We hope that the present approach of analysing ΔE^0_1 values in terms of q_σ and q_π values will stimulate further work in this area. The use of chemical shift values to establish a shift–energy relationship is limited by the inability to separate σ- and π-effects on δ values.

At present, $SE^0_{C^*/X^*}$ values (1) for benzenoid systems cannot be estimated, because the problem of establishing reliable atomic charges has not been overcome. Thus, at present, BDH values or isodesmic interaction energies (ΔE^0_1) cannot be used to estimate the stability of benzyl radicals.

Limiting low-pressure rate constant for the stepladder model of a thermal unimolecular reaction

H. O. PRITCHARD AND S. R. VATSYA

Centre for Research in Experimental Space Science, York University, Downsview, Ont., Canada M3J 1P3

Received January 4, 1984

H. O. PRITCHARD and S. R. VATSYA. Can. J. Chem. **62**, 1867 (1984).

An explicit formula for the rate constant of a thermal unimolecular reaction with stepladder relaxation probabilities, together with the corresponding eigenvector, are derived; a comment is also made about the limiting behaviour of the incubation time for such a reaction.

H. O. PRITCHARD et S. R. VATSYA. Can. J. Chem. **62**, 1867 (1984).

On a déduit une formule explicite de la constante de vitesse d'une réaction thermique unimoléculaire à probabilités de relaxation par paliers, de même que les vecteurs eigen correspondant; on commente de plus sur le comportement limitant du temps d'incubation d'une telle réaction.

Introduction

Some years ago, Yau derived an analytic formula for the rate constant of a bimolecular reaction in which the internal relaxation consisted of stepladder (i.e. nearest-neighbour) processes, and for which there was only one state which was capable of being transformed into products (1); this formula was applied successfully to semiquantitative discussions of the ionisation of H atoms (2) and of the dissociation of H_2 molecules (3). With trivial modification, this formula can be used to give the rate constant for a thermal unimolecular reaction at its second order limit, provided that the activation processes are nearest-neighbour only, and that there is only one reactive state above the threshold (4). Since the rate of a unimolecular reaction at its low-pressure limit is strictly independent of the decay rate constants for the reactive states (5), it was easily shown by numerical experiment (6) that a minor modification of Yau's formula gave the correct eigenvalue for a stepladder thermal unimolecular reaction at this limit, regardless of the number of reactive states above the threshold. In this paper, we derive an analytic formula for this rate constant — for which hitherto there have only been available a series of steady-state approximations (7) — and also the corresponding eigenvector; the latter is important because it leads directly to the population distribution during the steady phase of the reaction, and also to the incubation time (4).

Preliminaries

Let $\mathbf{Q}$ be the tridiagonal relaxation matrix, with elements $[\mathbf{Q}]_{ji} = q_{ij}$ corresponding to the rate constant for conversion from grain (or state) i to grain (or state) j at unit pressure ($P = 1$); $q_{ij} = 0$ unless $j = i \pm 1$. The thermal unimolecular rate constant is the smallest eigenvalue γ_0 of the matrix $-[p\mathbf{Q} - \mathbf{D}]$, where $\mathbf{D}$ is a diagonal matrix of the decay rate constants d_j for the reactive grains (or states). The matrix $\mathbf{Q}$ is unsymmetric, but may be symmetrised by a similarity transformation constructed from the detailed balancing relationships, to give

$$[1] \quad \mathbf{R} = -\mathbf{E}^{-1/2}\,[p\mathbf{Q} - \mathbf{D}]\,\mathbf{E}^{1/2} = [p\mathbf{A} + \mathbf{D}]$$

where $[\mathbf{E}]_{ij} = \delta_{ij}\tilde{n}_j$, and $\tilde{n}_j$ is the equilibrium population of grain (or state) j at the temperature in question. Let the eigenvector of $\mathbf{A}$ corresponding to its zero eigenvalue be $\mathbf{S}_0$; the elements $(\mathbf{S}_0)_j = \tilde{n}_j^{1/2}$. Also let the notation (,) denote the scalar product of two vectors, and $p_j = \mathbf{S}_j(\mathbf{S}_j, \ )$ are the eigenprojections of $\mathbf{A}$ corresponding to the eigenvalues λ_j. For further details relating to this formulation, see ref. 4.

The limiting low-pressure rate constant

Let the grains (or states) be labelled by the index i, $0 \le i \le n-1$, with i_0 denoting the last one below the reactive threshold. We note that γ_0 is a fixed point of $\chi(x)$ given by (8)

$$[2] \quad \frac{1}{\chi(x)} = (\mathbf{S}_0, [p\mathbf{A} + \mathbf{D} - (1 - p_0)x]^{-1}\mathbf{S}_0)$$

and $\chi(0)$ is an excellent (upper bound) approximation to γ_0 for the entire pressure range. From eq. [4] of ref. 8, $\chi(0)$ is given by

$$[3] \quad \frac{P}{\chi(0)} = -\sum_{i=0}^{n-1}\sum_{j=1}^{n-1}\sum_{k=0}^{j}\frac{\tilde{n}_i^{1/2}\alpha_i\tilde{n}_k^{1/2}\alpha_k}{\alpha_j\alpha_{j+1}A_{j,j+1}} = -\sum_{j=0}^{n-1}\frac{1}{\alpha_j\alpha_{j+1}A_{j,j+1}}\left(\sum_{i=0}^{j}\tilde{n}_i^{1/2}\alpha_i\right)^2$$

where $A_{n-1,n} = A_{n,n-1} = 1/P$, $\alpha_0 = 1$, $\alpha_1 = -A_{00}/A_{01}$, ..., and $\alpha_{i+1} = -[A_{i,i-1}\alpha_{i-1} + (A_{ii} + d_i/P)\alpha_i]/A_{i,i+1}$, $i = 1, 2, \ldots, (n-1)$. (Notice that the elements $A_{n-1,n}$, $A_{n,n-1}$ are not part of the original nth order matrix; they arise from extending the original matrix as described in ref. 8.) It is clear that

$$\alpha_j = \tilde{n}_j^{1/2}/\tilde{n}_0^{1/2},\ j = 0, 1, \ldots, (i_0 + 1)$$

and $\alpha_{i_0+1}/\alpha_{i_0+2} \xrightarrow[P \to 0]{} 0$. Further,

$$\frac{\alpha_j}{\alpha_{j+1}} = \frac{-PA_{j,j+1}}{PA_{jj} + d_j + PA_{j,j-1}\alpha_{j-1}/\alpha_j} \quad \text{for each } j$$

Let $(n-1) \ge j \ge (i_0 + 2)$ if $\alpha_{j-1}/\alpha_j \xrightarrow[P \to 0]{} 0$, then $\alpha_j/\alpha_{j+1} \xrightarrow[P \to 0]{} 0$. Since $\alpha_{i_0+1}/\alpha_{i_0+2} \xrightarrow[P \to 0]{} 0$, it follows that $\alpha_j/\alpha_{j+1} \xrightarrow[P \to 0]{} 0$ for all $(i_0 + 1) \le j \le (n-1)$.

Since

$$\frac{\alpha_i\alpha_k}{\alpha_j\alpha_{j+1}} = \frac{\alpha_j}{\alpha_{j+1}}\prod_{l=1}^{j-i}\frac{\alpha_{i+l-1}}{\alpha_{i+l}}\prod_{m=1}^{j-k}\frac{\alpha_{k+m-1}}{\alpha_{k+m}} \qquad i, k \le j$$

$$\frac{\alpha_i\alpha_k}{\alpha_j\alpha_{j+1}} \xrightarrow[P \to 0]{} 0 \text{ for } (n-1) \ge j \ge i_0 + 1 \text{ and } j \ge i, k$$

It then follows from [3] that

$$[4]\quad \gamma_0 = P\left(\sum_{j=0}^{i_0} t_j\right)^{-1}$$

$$\text{where } t_j = -\left(\sum_{i=0}^{j} \tilde{n}_i\right)^2 \Big/ \tilde{n}_j^{1/2}\tilde{n}_{j+1}^{1/2}A_{j,j+1}$$

The expression for t_j can be simplified a little further, since

$$A_{ij} = -\tilde{n}_i^{-1/2}Q_{ij}\tilde{n}_j^{1/2} = -\tilde{n}_i^{-1/2}q_{ji}\tilde{n}_j^{1/2}, \qquad i \neq j$$

giving finally that

$$t_j = \left(\sum_{i=0}^{j} \tilde{n}_i\right)^2 \Big/ \tilde{n}_j q_{j,j+1}$$

The examination of activation bottlenecks and their effect on the low-pressure unimolecular rate becomes a simple matter with this expression (6); in fact, [4] is quite similar to the earlier steady-state approximations, but the expression for the t_j is different.

The corresponding eigenvector

An eigenvector ψ_0 of $[p\mathbf{A} + \mathbf{D}]$ corresponding to the eigenvalue γ_0 is given by

$$\psi_0 = \gamma_0[p\mathbf{A} + \mathbf{D} - \gamma_0(1 - p_0)]^{-1}\mathbf{S}_0$$

where ψ_0 is normalised so that $(\psi_0, \mathbf{S}_0) = 1$. The vector ψ_0 is approximated by $\bar{\psi} = \chi(0)[p\mathbf{A} + \mathbf{D}]^{-1}\mathbf{S}_0$ to the same degree of accuracy as is γ_0 by $\chi(0)$. Now, from the results in the preceding section, we can write

$$[5]\quad f_i = \lim_{P \to 0} (p[p\mathbf{A} + \mathbf{D}]^{-1}\mathbf{S}_0)_i$$

$$= -\sum_{j=1}^{i_0} \frac{\tilde{n}_i^{1/2} \sum_{k=0}^{j} \tilde{n}_k}{\tilde{n}_j^{1/2}\tilde{n}_{j+1}^{1/2}A_{j,j+1}}, \qquad i \leq i_0$$

$$= 0, \qquad i > i_0$$

where f_i are the elements of the un-normalised vector; the elements of the normalised vector are simply

$$[6]\quad (\bar{\psi}_0)_i = \gamma_0 f_i/P$$

Apart from the different normalisation, this is the same eigenvector as that derived by Brau (9).

Incubation times

It was found recently that for a shock-wave heating process from a low starting temperature, the incubation time (τ_{inc}) for a strong-collision thermal reaction becomes independent of the pressure at the low-pressure limit (10). Intuitively, this is an unphysical result; its existence, however, renders it necessary to prove that in reactions not governed by the strong-collision relaxation rates, the relation $P\tau_{inc}$ = constant still holds, as is usually assumed to be the case in experimental systems. As a beginning, we do this here for the stepladder model of a unimolecular reaction at the low-pressure limit. To the same degree of approximation as γ_0 is approximated by $\chi(0)$, an excellent approximation $\bar{\tau}_{inc}$ to (4, 11)

$$\tau_{inc} = \frac{1}{\gamma_0} \ln [(\mathbf{E}^{-1/2}\mathbf{n}(0),\psi_0)/(\psi_0,\psi_0)]$$

is given by

$$[7]\quad P\bar{\tau}_{inc} = \frac{P}{\chi(0)} \ln \frac{(\mathbf{E}^{-1/2}\mathbf{n}(0),[p\mathbf{A} + \mathbf{D}]^{-1}\mathbf{S}_0)}{\chi(0)(\mathbf{S}_0,[p\mathbf{A} + \mathbf{D}]^{-2}\mathbf{S}_0)}$$

where $\mathbf{n}(0)$ is the starting distribution, taken to be 1, 0, 0, ... for a shock-wave heating from a low starting temperature. Straightforward substitution of [6] into [7] yields

$$[8]\quad \lim_{P \to 0} (P\bar{\tau}_{inc}) = \bar{\gamma}(0)^{-1} \ln (f_0/F\tilde{n}_0^{1/2})$$

where $F = \bar{\gamma}(0) \sum_{i=0}^{i_0} f_i^2$ and $\bar{\gamma}(0) = \lim_{P \to 0} \gamma_0/P$.

This results leads to two conclusions. First, like the limiting rate constant, the incubation time for the stepladder case is also independent of the numerical values of the decay rate constants; this is already known, see e.g. equation (5.2) of ref. 12. Second, since γ_0/P is a constant at the low-pressure limit, the right-hand side of [8] is a constant; hence $P\bar{\tau}_{inc}$ is a constant, as we wished to show.

Department of Chemistry, University of British Columbia, 2036 Main Mall, Vancouver, B.C., Canada V6T 1Y6

Received January 18, 1984

KEITH D. GALLICANO, NORMAN L. PADDOCK, STEVEN J. RETTIG, and JAMES TROTTER. Can. J. Chem. **62**, 1869 (1984).

The synthesis and physical properties of $[(\eta^3\text{-Me(MeNPMe)}_4)\text{Mo(CO)}_3]\text{I}$ are reported. Crystals of (η^3-nonamethylcyclotetraphosphazanium-*P*,*P*,*P*)tricarbonylmolybdenum(0) iodide – acetonitrile (1:1) are orthorhombic, a = 13.1938(4), b = 13.7847(5), c = 29.281(2) Å, Z = 8, space group *Pcab*. The structure was solved by Patterson and Fourier techniques and was refined by full-matrix least-squares procedures to R = 0.030 and R_w = 0.034 for 2388 reflections with $I \geq 3\sigma(I)$. The structure consists of discrete cations, anions, and solvent molecules. The complex cation has approximate mirror symmetry in the solid state, the Mo atom being coordinated to three phosphazane P atoms and three carbonyl ligands in a distorted octahedral arrangement. Important bond lengths (corrected for libration) are: Mo—P = 2.483(2), 2.439(2), and 2.474(2), mean Mo—C = 1.984(3), mean P—N = 1.710(11) for coordinated P and 1.669(5) Å for quaternized P. The stronger bonding of the cationic ligand to the metal relative to that of the neutral species $(CH_3NPCH_3)_4Mo(CO)_3$, and the strengthening of the ring bonds in both molecules relative to $(CH_3NPCH_3)_4$, are discussed in terms of *d*-orbital contraction.

KEITH D. GALLICANO, NORMAN L. PADDOCK, STEVEN J. RETTIG et JAMES TROTTER. Can. J. Chem. **62**, 1869 (1984).

On rapporte la synthèse et les propriétés physiques du $[(\eta^3\text{-Me(MeNPMe)}_4)\text{Mo(CO)}_3]\text{I}$. Les cristaux de l'iodure-acétonitrile (1:1) du (η^3-nonaméthylcyclotétraphosphazanium-*P*,*P*,*P*)tricarbonylmolybdène(0) sont orthorhombiques, a = 13,1938(4), b = 13,7847(5), c = 29,281(2) Å, Z = 8, groupe d'espace *Pcab*. On a résolu la structure par les techniques de Patterson et Fourier et on l'a affinée par la méthode des moindres carrés (matrices complètes) jusqu'à des valeurs de R = 0,030 et R_w = 0,034 pour 2388 réflexions avec $I \geq 3\sigma(I)$. La structure comporte des cations, des anions et des molécules de solvant qui sont indépendantes. A l'état solide, la symétrie du cation complexe est approximativement celle d'un mirroir alors que l'atome de Mo est coordonné à trois atomes de P des phosphazanes et à trois ligands carbonyles dans un arrangement octaédrique déformé. Les longueurs de liaison importantes (corrigées pour la libration) sont: Mo—P = 2,483(2), 2,439(2) et 2,474(2), Mo—C (moyenne) = 1,984(3), P—N = 1,710(11) (moyenne pour le P coordonné) et 1,669(5) Å (moyenne pour le P quaternaire). C'est à des contractions dues à des orbitales *d* qu'on attribue le fait que la force de la liaison ligand cationique–métal est plus forte que celle impliquant l'espèce neutre $(CH_3NPCH_3)_4Mo(CO)_3$ ainsi que le renforcissement des liaisons du cycle dans chacune de ces deux molécules par rapport au $(CH_3NPCH_3)_4$.

Introduction

An earlier paper (1) described the preparation of the complex $(CH_3NPCH_3)_4Mo(CO)_3$, **1**, and its crystal and molecular structure. Its methiodide can be prepared either from the complex or by reaction of the methiodide of the ligand with molybdenum hexacarbonyl. We have determined its structure to see what effect the positive charge has on the geometry and electron distribution.

Experimental

The compound $[(\eta^3\text{-Me(MeNPMe)}_4)\text{Mo(CO)}_3]\text{I}$, **2** (Fig. 1), was prepared by heating a mixture of **1** and an excess of methyl iodide in tetrahydrofuran under reflux for 4 h. After a further 18 h stirring at room temperature, the pale brown precipitate was filtered off, washed with acetonitrile, and crystallized from hot acetonitrile as pale green–yellow blocks of the monosolvate $[(\eta^3\text{-Me(MeNPMe)}_4)\text{-Mo(CO)}_3]\text{I}\cdot\text{MeCN}$, (**3**). *Anal.* calcd. for $C_{14}H_{30}IMoN_5P_4O_3$: C 25.4, H 4.6, N 10.6, I 19.1; found: C 25.6, H 4.6, N 10.6, I 18.9. The mass spectrum of **2** (70 eV) shows peaks corresponding to the stepwise loss of three CO's, with the characteristic isotopic distribution of Mo, the peak of highest m/e being at 480 (M^+ – MeI). ν_{CO} (cm^{-1}) 1946; 1856, 1836. ^1H nmr spectrum (δ, CD_3OD, int. TMS), 1.76 (3H, doublet, J ~ 6.5 Hz, P(2)), 2.02 (6H, broad, P(1), P(3)), 2.43 (3H, doublet, J ~ 12.5 Hz, P(4)), 2.72 (3H, doublet, J ~ 14.5 Hz, P(4)), 2.96 (6H, quintet, J ~ 4.5 Hz, N(1), N(2)), 3.27 (6H, doublet split into virtual triplets, J ~ 10 Hz, 2Hz, N(3), N(4)).

X-ray crystallographic analysis of **3**

A crystal bounded by the six faces (followed by their distances in mm from a common origin): ±(0 0 1), 0.040, (−1 −1 2), 0.138, (−1 1 2), 0.100, (1 −1 2), 0.100, (1 1 0), 0.153 was mounted in a general orientation. Unit-cell parameters were refined by least-squares on 2 sin θ/λ values for 25 reflections (2θ = 28–40°) measured on a diffractometer with Mo-$K\alpha$ Radiation ($\lambda(K\alpha_1)$ = 0.70930, $\lambda(K\alpha_2)$ = 0.71359 Å). Crystal data at 22°C are:

$C_{14}H_{30}IMoN_5P_4O_3$ fw = 663.16

Orthorhombic, a = 13.1938(4), b = 13.7847(5), c = 29.281(2) Å, V = 5325.4(5) Å^3, Z = 8, ρ_c = 1.654 g cm^{-3}, $F(000)$ = 2624, μ(Mo-$K\alpha$) = 18.9 cm^{-1}. Absent reflections: $0kl$, l odd, $h0l$, h odd, and $hk0$, k odd uniquely indicate the space group *Pcab* (non-standard setting of *Pbca*, D_{2h}^{15}, No. 61, equivalent positions: ±(x, y, z; $-x$, 1/2 − y, 1/2 + z; 1/2 − x, 1/2 + y, $-z$; 1/2 + x, $-y$, 1/2 − z)).

Intensities were measured with graphite-monochromated Mo-$K\alpha$ radiation on an Enraf-Nonius CAD4-F diffractometer. An ω–2θ scan at 1.26–10.06° min^{-1} over a range of (0.65 + 0.35 tan θ) degrees in

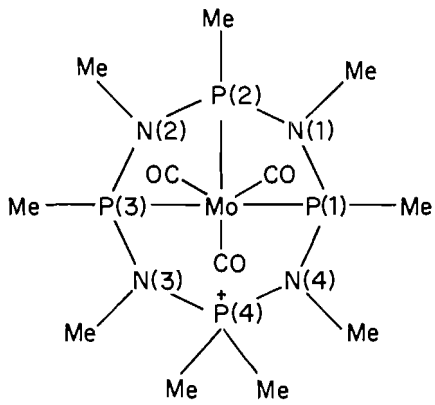

FIG. 1. Bond diagram of the cation **2**.

For personal use only.

ω (extended by 25% on both sides for background measurement) was employed. Data were measured to $2\theta = 55°$. The intensities of three check reflections, measured every 3600 s throughout the data collection, showed uniform decreases of 4.5%, the data being scaled accordingly. After data reduction,[1] an absorption correction was applied using the Gaussian integration method (2, 3). Transmission factors ranged from 0.564 to 0.920 for 98 integration points. Of the 6108 independent reflections measured, 2388 (39.1%) had intensities greater than $3\sigma(I)$ above background where $\sigma^2(I) = S + 2B + (0.04(S - B))^2$ with S = scan count and B = normalized background count. It should be noted that most reflections with 2θ less than 40° were observed but at higher angles most were very weak. The data were collected to 55° in order to maximize the number of observations. Using a 2σ cutoff would have added only 59 reflections.

The coordinates of the I and Mo atoms were determined from the Patterson function and those of the remaining non-hydrogen atoms from a subsequent difference map. After full-matrix least-squares refinement of the non-hydrogen atoms with anisotropic thermal parameters to $R = 0.040$, a difference map revealed the positions of nearly all hydrogen atoms which were included in subsequent cycles of refinement as fixed atoms in idealized positions (based on the observed positions with C—H = 0.98 Å and $U_H = 1.2U_C$), recalculated after each least-squares cycle. The scattering factors of ref. 4 were used for non-hydrogen atoms and those of ref. 5 for hydrogen atoms. Anomalous scattering factors from ref. 6 were used for the I, Mo, and P atoms. The weighting scheme, $w = 1/\sigma^2(F)$ where $\sigma^2(F)$ is derived from the previously defined $\sigma^2(I)$, gave uniform average values of $w(|F_o| - |F_c|)^2$ over ranges of both $|F_o|$ and $\sin\theta/\lambda$ and was employed in the final stages of refinement. Unobserved reflections were not included in the refinement. Convergence was reached at $R = 0.030$ and $R_w = 0.034$ for 2388 reflections with $I \geq 3\sigma(I)$. The function minimized was $\Sigma w(|F_o| - |F_c|)^2$, $R = \Sigma||F_o| - |F_c||/\Sigma|F_o|$ and $R_w = (\Sigma w(|F_o| - |F_c|)^2/\Sigma w|F_o|^2)^{1/2}$.

On the final cycle of refinement the mean and maximum parameter shifts corresponded to 0.015 and 0.09σ respectively. The mean error in an observation of unit weight was 1.340. A final difference map showed no unusual features, the largest residual peak being 0.66 e Å^{-3} near the Mo atom. The final positional and thermal parameters appear in Tables 1 and 6,[2] respectively. Measured and calculated structure factors have been placed in the Depository of Unpublished Data.[2]

The ellipsoids of thermal motion for the non-hydrogen atoms are shown in Fig. 2. The thermal motion has been analysed in terms of the rigid-body modes of translation, libration, and screw motion (7). The rms standard error in the temperature factors σU_{ij} (derived from the least-squares analysis) is 0.0042 Å^2. Analysis of the entire cation (rms $\Delta U_{ij} = 0.0115$ Å^2) indicated significant independent motion of the carbonyl O atoms. A second analysis, excluding the three O atoms, gave rms $\Delta U_{ij} = 0.0051$ Å^2 and physically reasonable derived parameters. The appropriate bond distances have been corrected for libration (7, 8), using shape parameters q^2 of 0.08 for all atoms involved. Corrected bond lengths appear in Table 2 along with the uncorrected values; corrected bond angles do not differ by more than 1σ from the uncorrected values given in Table 3. Intra-annular torsion angles defining the conformations of phosphazane and chelate rings are listed in Table 4. Calculated hydrogen coordinates and thermal parameters (Table 5) are included as supplementary material. A complete list of torsion angles (Table 7) has also been deposited.

[1] The computer programs used include locally written programs for data processing and locally modified versions of the following: ORFLS, full-matrix least-squares, and ORFFE, function and errors, by W. R. Busing, K. O. Martin and H. A. Levy; FORDAP, Patterson and Fourier syntheses, by A. Zalkin; ORTEP II, illustrations, by C. K. Johnson.

[2] The structure factor table, Table 6 (anisotropic thermal parameters), and other material mentioned in the text are available, at a nominal charge, from the Depository of Unpublished Data, CISTI, National Research Council of Canada, Ottawa, Ont., Canada K1A 0S2.

Results and discussion

The ^{1}H nmr spectrum shows that quaternization strengthens the molecule, in that it is no longer fluxional in solution. It also provides a qualitative proof of the structure. The methyl groups at P(1), P(2), P(3), N(3), and N(4) are deshielded, relative to those in the uncomplexed quaternary iodide (9); those at N(1) and N(2) are unchanged. The two methyl groups at the quaternary centre are now differentiated (a distinction from the uncomplexed quaternary), and their shielding is increased, presumably a diamagnetic effect of the neighboring carbonyl group C(2)—O(2) (Fig. 2). The C≡O stretching frequencies, in comparison with those of the neutral complex (1) show that quaternization leads to a slight strengthening of these bonds.

The detailed geometry of the neutral and cationic complexes is in fact strikingly similar, except in two regions. Both molecules have an approximate plane of symmetry and, for the discussion, the corresponding dimensions are averaged. A large part of the earlier discussion (1) still applies. From the neutral to the quaternary complex, C≡O (mean[3]) decreases insignificantly from 1.154(3) to 1.147(6) Å (though the difference parallels $\delta\nu$ (C≡O)), Mo—C is unchanged at 1.984(3) Å, and the mean C—Mo—C angle increases, again insignificantly, from 90.7(20) to 91.2(17)°. Within the segments P(1)N(1)P(2)N(2)P(3), there is hardly any variation between the two structures. The differences appear near the quaternization centre and in the Mo—P bonds. Electron with-

[3] Here and elsewhere in this report mean values refer to weighted means with rms deviations from the mean in parentheses.

drawal at P(4) increases the ring angles at P(4) from 107.1(1) to 113.9(2)°, at N(3) and N(4) from 111.6(5) to 120.4(5)°, shortens the bonds P(4)—N(3) and P(4)—N(4) from 1.735(7) to 1.669(5) Å, and lengthens slightly the next bonds N(3)—P(3) and N(4)—P(1) from 1.698(8) to 1.722(7) Å. The effect of electron withdrawal is seen also in the sum of the angles at N(3), N(4), which increases from 357.6 to 359.9°. The remaining ring bonds are not changed significantly, but the effective transmission of a partial positive charge to P(1), P(3), and (to a smaller extent) to P(2) is shown by the lengths of the Mo—P(1), Mo—P(3) bonds, reduced from 2.525(12) to 2.479(5) Å, and of Mo—P(2), reduced from 2.467(1) to 2.439(2) Å, the reduction resulting from increased back-donation Mo→P, least at the remote phosphorus atom. Electron release from molybdenum is evidently competitive with that from nitrogen, since the mean sum of angles at N(1), N(2) decreases slightly on quaternization from 358.1 to 356.1°.

Phosphorus can use its *d*-orbitals for bonding if they are sufficiently contracted (10), and, because of the smaller effective nuclear charge, such interactions are expected to be weaker for P(III) than for P(V), for which they are well established. In fact, and as discussed earlier for $(MeNPMe)_4$ (1), nitrogen as a ligand is sufficiently electronegative to induce significant *d*-orbital bonding, even in a neutral molecule. The strength of such bonding is increased by the attachment of acceptor groups, as seen in the variation of mean P—N bond lengths:

$(MeNPMe)_4$, 1.722 Å (11); **1**, 1.711 (1); **3**, 1.699 (this work). The effect of the $Mo(CO)_3$ group is nearly the same as that of Me^+, since in the dication $(MeNPMe)_4Me_2^{2+}$ the mean P—N length is 1.700 Å (9). Similar effects have been found in the pair of structures of $P(NMeNMe)_3P$ (12) and of $OP(NMeNMe)_3PO$ (13), in $P_4(NMe)_6$ and its thioderivatives (14) and its monomethiodide (15), which shows a distinct contraction of the P—N bonds at the quaternized phosphorus atom; the photoelectron spectra of some of these compounds have been interpreted as showing that the formal lone pairs on nitrogen make appreciable contribution to the bonding (16).

A more detailed analysis is possible. Because the angles near P(4) differ in the neutral (**1**) and cationic (**3**) complexes, the differences in bond length cannot be taken as a direct measure of differences in bond strength. The endo- and exo-angles at P(4) are related almost exactly as they would be for hybrids formed from *s*- and *p*-orbitals, and it seems a good approximation to assume that the ring geometry reflects the σ-hybridization state of the ring atoms directly. The method of ref. 17 can then be used to estimate the bond length contractions arising from *d*-orbital interactions; they are arbitrarily classed as π-contractions, even though there is no strict molecular symmetry operation to which they can be referred. We can draw the following conclusions. (*1*) The π-contractions in **3** (mean 0.055 Å) are significant, but small compared to those in phosphazenes (up to 0.16 Å), in which formal π-bonding is required. (*2*) The large reduction in the lengths of the ring bonds from P(4), relative to **1**, results mainly from the change in σ-hybridization, no doubt induced by the d_π-bonding. The π-contraction in these bonds (0.023 Å relative to **1**) is offset by an almost equal π-extension in the adjacent bonds. (*3*) The situation at the phosphorus atoms coordinated to molybdenum is more complex, and strictly requires a deeper analysis. However, it is clear from the shortening of the P—Mo bonds that the effect of the charge on the quaternary centre is relayed at least to P(1), P(3). These bonds are strengthened partly at the expense of the local rings bonds, but, as a result of the increase in the *d*-population at phosphorus by back-donation from molybdenum, the π-contractions in the ring bonds (mean 0.067 Å) are nevertheless greatest in this region. If the *d*-orbitals at phosphorus were not contracted by the charge of the Me^+, then shortening of the P—Mo bonds would be expected to be accompanied by lengthening of the local P—N bonds.

Received February 22, 1984

WARREN KENNETH MUSKER, PARMINDER S. SURDHAR, RIZWAN AHMAD, and DAVID A. ARMSTRONG. Can. J. Chem. **62**, 1874 (1984).

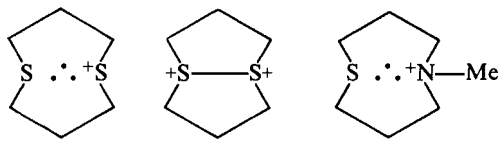
The one electron oxidant $\cdot Br_2^-$ reacts with 5-methyl-1-thia-5-azacyclooctane (**4**) in aqueous solution at high pH with an overall rate constant of $\sim 2 \times 10^8\ M\ s^{-1}$. The radical intermediate produced has a broad maximum at 500 nm with $\epsilon = 2400\ M^{-1}\ cm^{-1}$ and at pH 10 decays with a first order rate constant of $2.3 \pm 0.3 \times 10^4\ s^{-1}$, first half-life of 30 ± 5 μs. Its characteristics do not correspond to those of the >S∴Br or >S∴$^+$S< species reported by Asmus and co-workers. The species appears to be the same as the cation radical reported earlier in the one electron oxidation of **4** in acetonitrile. This species is considered to have an >S∴$^+$N< type structure, which provides transannular stabilization.

WARREN KENNETH MUSKER, PARMINDER S. SURDHAR, RIZWAN AHMAD et DAVID A. ARMSTRONG. Can. J. Chem. **62**, 1874 (1984).

En solution aqueuse et à des pH élevés, l'oxydant à un électron $\cdot Br_2^-$ réagit avec le méthyl-5 thia-1 aza-5 cyclooctane (**4**); la constante globale de la vitesse de la réaction est d'environ $2 \times 10^8\ M\ s^{-1}$. L'intermédiaire radicalaire qui se forme présente une large bande d'absorption autour de 500 nm avec un $\epsilon = 2400\ M^{-1}\ cm^{-1}$; à un pH de 10, il se décompose avec une constante de vitesse du premier ordre de $2{,}3 \pm 0{,}3 \times 10^4\ s^{-1}$ et une première demi-vie de 30 ± 5 μs. Ses caractéristiques ne correspondent pas à celles rapportées par Asmus et ses collaborateurs pour les espèces >S∴Br ou >S∴$^+$S<. Il semble que les espèces impliquées soient les mêmes que celles rapportées antérieurement dans l'oxydation de **4** par un électron dans l'acétonitrile. On considère que cette espèce possède une structure du type >S∴$^+$N< qui permet une stabilisation transannulaire.

[Traduit par le journal]

Mechanisms of oxidation and reduction of sulphur-containing molecules are of importance in many areas of chemistry (1, 2) and biochemistry (3). Previous studies have indicated that intramolecular nucleophilic assistance can facilitate both one (4, 5) and two electron oxidations (1, 6, 7) of compounds, such as disulphides and thioethers. In recent studies of mesocyclic dithia compounds in nonaqueous solvents oxidation has been shown to produce cation radicals (**1**) and dications (**2**), which are stabilized by transannular interactions



1 **2** **3**

between the sulphur atoms (8, 9). A relatively long-lived N—S bonded cation radical (**3**) and the corresponding dication have also been prepared in nonaqueous media from the mesocyclic aminothioether, 5-methyl-1-thia-5-azacyclooctane (**4**) (10). A N—S interaction similar to that shown in **3** has been considered as a possible step in the mechanism of the one electron oxidation of methionine (4). However, although species similar to **1** have been studied extensively in aqueous media (11–15), direction observation of an >S∴$^+$N< intermediate under those conditions has not thus far been reported. Here we report the characteristics of an intermediate produced in the one electron oxidation of **4** by $\cdot Br_2^-$ in aqueous solution.

The compound **4** was prepared and purified as previously described (10). Required amounts were weighed out on a microbalance and made up in 50-mL volumetric flasks in solutions of phosphate buffer and 0.33 *M* KBr. After thorough purging with N_2O, they were flushed into a 1-cm optical cuvette and subjected to 2-μs pulses of 1.5-MeV electrons. The electron accelerator has already been described (16) and the techniques are well established (17). Experiments were performed at 23 ± 2°C.

Pulse radiolysis of N_2O-saturated solutions of 0.03 *M* KBr produces $6.0 \times 10^{-6}\ M$ $\cdot Br_2^-$ anion complexes per krad of absorbed radiation (17). This species has a strong peak ($\epsilon = 9900 \pm 600\ M^{-1}\ cm^{-1}$) at 360 nm (18). In the absence of a reactant it undergoes second order decay with $2k = 3.6 \times 10^9\ M^{-1}\ s^{-1}$ (19). However, in the presence of 3 to $8 \times 10^{-4}\ M$ **4** at pH 10, the 360-nm peak decayed in a pseudo first order process, with a lifetime which varied inversely with the concentration of **4**. An example of that decay is seen in Figs. 1a and b. In contrast, the absorbance at and above 500 nm, where $\cdot Br_2^-$ absorbs only weakly, exhibited growth over the initial ~10 μs and then decay (Fig. 1c). Spectra 5 μs and 44 μs after

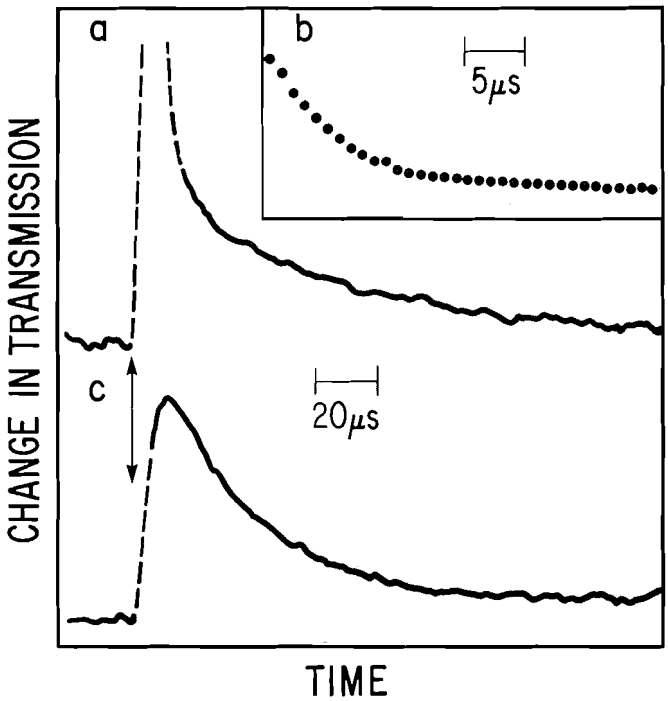

FIG. 1. Changes in transmission as a function of time for 0.8 m*M* 5-methyl-1-thia-5-azacyclooctane (**4**) in 0.03 *M* KBr with 10 m*M* phosphate buffer at pH 10. Wavelength = 360 nm for (a) and (b), and 640 nm for (c). Arrows indicate start of 2-μs electron pulse for (a) and (c). Trace (b) commences 1 μs after pulse ends and the ordinate scale sensitivity is one fifth of that of (a) and (c).

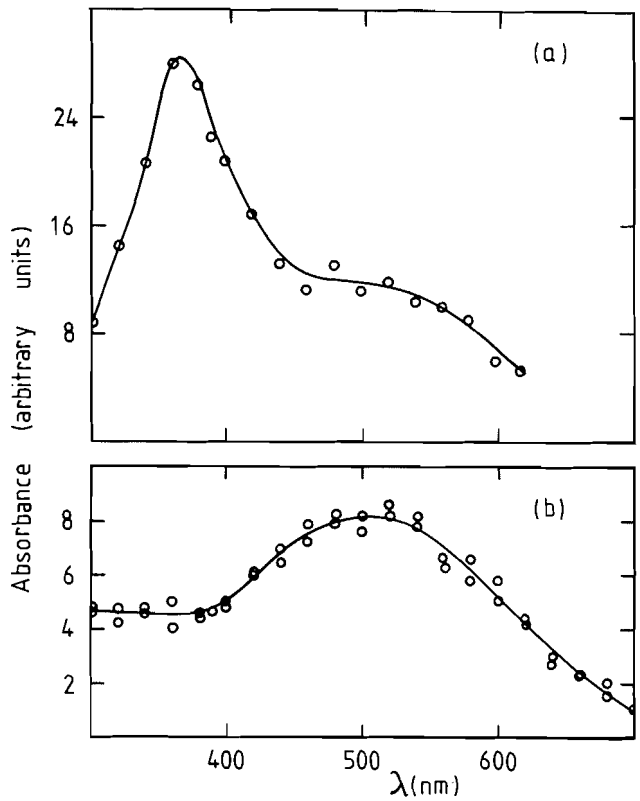

FIG. 2. Absorbance of transient species in buffered (pH 10) solutions of **4** in KBr as a function of wavelength at 5 μs(a) and 44 μs after start of 2-μs pulse. Concentration of **4** was 0.03 m*M* in (a) and 0.4 to 0.8 m*M* in (b).

the start of the electron pulse are shown in Fig. 2.

Beyond three half-lives for the 360-nm decay the spectrum shape above 400 nm was independent of time and corresponded to the line in Fig. 2b. This spectrum, which decayed at pH 10 with a first order rate constant of 2.0 to 2.6 × 10^4 s^{-1}, must correspond to a long-lived transient B formed in the reaction of $\cdot Br_2^-$ and **4**. The intensity of the absorbance due to B and its lifetime were independent of the concentration of **4** over the range 0.4 to 0.8 m*M*. Correction for the first order decay leads to an extinction coefficient of about 2400 M^{-1} cm^{-1} at the 500-nm peak.

Asmus and co-workers (14, 15) have reported the formation of $\rangle S\therefore Br$, three-electron bonded complexes in reactions of thioethers and $\cdot Br_2^-$. These are characterized by absorption maxima at 400 nm and absorbance coefficients of ~7000 M^{-1} cm^{-1}. Also the following equilibria (12–15):

[1] $\rangle S\therefore Br + S\langle \rightleftharpoons \rangle S\therefore {}^+S\langle + Br^-$

[2] $\rangle S\therefore Br \rightleftharpoons \rangle S^{\ddagger} + Br^-$

[3] $\rangle S\therefore {}^+S\langle \rightleftharpoons \rangle S^{\ddagger} + S\langle$

have been observed in a series of thioethers with $K_1 \simeq 1.5$ (14), $K_2 \simeq 1 \times 10^{-3}$ (14), and $K_3 \simeq 1 \times 10^{-3}$ (11, 12). The monomer ($\rangle S\cdot^+$) and dimer ($\rangle S\therefore {}^+S\langle$) cations have $\lambda_{max} \simeq 300$ and $\simeq 480$ nm with $\epsilon_{max} \simeq 1600$ and 6000 M^{-1} cm^{-1} respectively.

Clearly the absorbance maximum of the present transient does not correspond with $\rangle S\therefore Br$ or $\rangle S\cdot^+$. It is closest to that of the dimer cations. However, the absorbance coefficient of 2400 M^{-1} cm^{-1} is much smaller. In addition, with $K_3 = 0.3$ to 1 × 10^{-3} for typical sulphides, the intensity of absorbance should differ by a factor of about two for concentrations of 0.4 and 0.8 m*M* and this was not seen. Thus the species appears to be monomeric. Based on the chemical and esr evidence of the previous study of the oxidation of **4** in acetonitrile solution (10), its structure probably involves transannular stabilization as in **3**. The oxidation of **4** to **3** can be accounted for by the overall reaction:

[4] $\cdot Br_2^- + \mathbf{4} \rightarrow 2Br^- + \mathbf{3}$

which assumes any $\rangle S\therefore Br$ species to be short-lived. The pseudo first order half-lives of $\cdot Br_2^-$ decay correspond to $k_4 \sim 2 \times 10^2$ M^{-1} s^{-1}.

The first order decay of B was found to be enhanced at high pH, a feature which suggests that proton transfer to OH^- or buffer is a dominant mode. This type of decay is also important in cyclic-dithia cation monomers (13). It is interesting to note that the first order half-lives and extinction coefficients of these ions decrease as the wavelength of the maximum absorption increases (13). The half-life and extinction coefficient of B resemble those of 2,5-dithiahexane (ϵ 2500 M^{-1} cm^{-1}, $t_{1/2} \cong 30$ μs), but the value of λ_{max} for that cation system is significantly different (570 nm). Thus the optical properties of B differ significantly from those of species containing sulphur only.

Electrochemical evaluation of electron acceptor materials

R. O. LOUTFY, C. K. HSIAO, B. S. ONG, AND B. KEOSHKERIAN
Xerox Research Centre, 2660 Speakman Drive, Mississauga, Ont., Canada L5K 2L1

Received September 11, 1983[1]

This paper is dedicated to Professor Paul de Mayo on the occasion of his 60th birthday

R. O. LOUTFY, C. K. HSIAO, B. S. ONG, and B. KEOSHKERIAN. Can. J. Chem. **62**, 1877 (1984).

The electrochemical half-wave reduction potential ($E_{1/2}$) of 33 electron acceptor molecules in dry methylene chloride has been measured by cyclic voltammetry (CV) at a mercury electrode. The differences in $E_{1/2}$ values for the reversible reduction to the corresponding anion radicals reflect the electronic influence of the substituent at different ring positions.

The measurements of the half-wave reduction potentials provided a convenient method for determining the conducting energy levels of the electron relay molecules in condensed media. Repetitive potential cycle measurements provided information on the chemical stability and cyclability of the intermediate anion radicals formed during electron transport processes.

R. O. LOUTFY, C. K. HSIAO, B. S. ONG et B. KEOSHKERIAN. Can. J. Chem. **62**, 1877 (1984).

Opérant dans le chlorure de méthylène anhydre et faisant appel à la voltamétrie cyclique au niveau d'une électrode à mercure, on a mesuré le potentiel de réduction électrochimique à demi-vague ($E_{1/2}$) de 33 molécules électroacceptrices. Les différences entre les valeurs de $E_{1/2}$ pour la réduction réversible conduisant aux anions radicalaires correspondants reflètent l'influence électronique des substituants fixés en diverses positions du cycle.

La mesure de potentiels de réduction à demi-onde s'avère donc une méthode convenable de déterminer les niveaux d'énergie de conduction des molécules qui transmettent des électrons en milieu condensé. Des mesures répétitives de cycle de potentiel fournissent de l'information sur la stabilité chimique et la cyclabilité des anions radicalaires intermédiaires formés au cors de processus de transfert d'électron.

Introduction

Electrochemical reduction potential of many aromatic electron acceptor (A) molecules containing one or more nitro (NO_2) or cyano (CN) groups have been reported in the literature (1–6). These reduction potential measurements were performed in order to determine the electron affinity (EA) of these compounds and its dependence on the molecular structure. Recently, considerable interest has been generated in electron acceptor molecules as a means of obtaining one-dimensional conducting charge transfer complexes (7); stabilization of semiconductors (8): electron relays (9), and electron transporting layers for xerographic applications (10–13). The latter, in particular, has stimulated considerable research activity. Attempts were made to correlate the xerographic discharge characteristics of molecularly doped polymer systems and the electron affinity of the acceptor compound (3, 14, 15). It was found that charge carrier mobility and trapping depend on the energy level of the molecular species involved and the electrochemical stability of the intermediate radical ion (3).

In the present work we have examined the electrochemical properties of a large number of electron acceptor compounds to determine their electron conducting level; the stability of the intermediate radical anions, and the rate of electron exchange. In this study we have used the cyclic voltammetric technique, which is capable of rapidly observing the redox behaviour of molecules over a wide potential range. The electrode potential at which the compound undergoes reduction can be rapidly located using the CV method. A very important aspect of cyclic voltammetry is its ability to generate the reduced electron acceptor molecule in the first potential scan:

$$[1] \quad A + e \rightarrow A^{\dot{-}}$$

and then probe the species ($A^{\dot{-}}$) fate on the second and subsequent scans. As such, it is a powerful probe for monitoring stability and cyclability of electron acceptor molecules. In addition, from the dependence of the shape of cyclic voltammogram on potential scan rate it is possible to determine quantitatively the heterogeneous rate of electron transfer (k_s):

$$[2] \quad A + e \overset{k_s}{\rightleftarrows} A^{\dot{-}}$$

The versatility of cyclic voltammetry, combined with its simplicity, makes CV a useful characterization tool for the evaluation of electron acceptor compounds.

Experimental

A. Materials

Synthesis of new electron acceptor compounds are described in ref. 15. Others were commercially available or were synthesized by published techniques. The chemical structure of the electron acceptor materials studied is given in Table 1. Generally, six series of compounds were examined: (*i*) substituted fluoren-9-one derivatives; (*ii*) substituted 9,9-di(alkyl)fluorenes; (*iii*) substituted 9-fluorenylidenemalononitriles; (*iv*) substituted benzylidene malononitriles; (*v*) substituted benzophenone malononitriles; and (*vi*) arylidene-2-indan-1,3-diones. Methylene chloride Caledon Spectral grade was stored over 4A molecular sieves. Tetrabutylammonium perchlorate, TBAP (recrystallized from ethanol/water) was dried in a vacuum oven overnight.

B. Measurements

All measurements were made using PAR 174A polarographic analyzer connected to PAR 175 universal programmer. The current–voltage curves were recorded on a Houston Instruments 2000 X–Y recorder. Experiments were performed using PAR model 303 static mercury drop electrode assembly. The system is equipped with a hanging-mercury-drop working electrode, an aqueous Ag/AgCl, sat. KCl reference electrode, and a platinum wire auxiliary electrode. A 0.1 *M* tetrabutylammonium perchlorate (TBAP) in dry methylene chloride (spectral grade) was used as an indifferent electrolyte. The solutions of 1 m*M* of the electron acceptor compounds were deaerated using dry argon gas and reductions were carried out under a blanket of argon. Methylene chloride was chosen as the solvent for a number of reasons. It is an excellent, yet relatively inert, solvent for a wide variety of organic compounds. It has an exceptionally wide potential

[a] In V, vs. Ag/AgCl.

window for the appropriate redox measurements, it is aprotic, it is the common coating solvent of transport layers, and it has a low dielectric constant. Solvent-induced shifts in $E_{1/2}$ have been discussed by a number of workers (16) and may include contributions from differences in liquid junction potential, ion pairing effects, and interactions of the solvent with the species undergoing the redox reaction. These difficulties can be avoided in principle by referring all measurements to the reversible half-wave potential of a redox couple which does not interact with solvent and is, therefore, unaffected by a change in solvent, 7,7,8,8-tetracyanoquinodimethane (TCNQ) which was shown to have a reduction potential of +0.29 V vs. Ag/AgCl, KCl in methylene chloride was used as internal standard to minimize possible experimental artifacts. Furthermore, it was previously shown (3) that $E_{1/2}$ of fluorenones correlate with Gutmann's donor number (17), which measures the ability of a solvent to donate electrons. Methylene chloride has very low donor number and thus $E_{1/2}$ in that solvent is expected to be free of solvent effect. We also found little difference in $E_{1/2}$'s of 2,4,7-trinitrofluorenone, **5**, measured in methylene chloride or acetonitrile.

Results

Cyclic voltammetry

The compounds studied are shown in Table 1 and their cyclic voltammetric behaviour is discussed below. The compounds are divided into six groups according to their structure.

*Fluoren-9-ones, **1–9***

Many polynitrofluorenones have been prepared before and their electrochemical behaviour has been extensively studied (3). The solubility of these compounds in common organic solvents and in polymers is usually very low. To solve this problem, i.e., to increase the solubility of nitrofluorenones, alkyl and/or *n*-butoxycarbonyl (CO_2Bu) groups were introduced into the fluorenone rings. The electrochemical behaviour of these new compounds was studied and compared with previous data. Table 2 summarizes our electrochemical results on eight fluorenone derivatives. The half-wave reduction potential of the parent compound fluoren-9-one **1** appears at −1.3 V vs. Ag/AgCl in CH_2Cl_2. This value is above the reduction potential of oxygen in the same media and therefore, this material will not be a suitable electron transporter in most applications since the oxygen will act as an electron trap. Substitution of a proton in **1** by a *n*-butoxylcarbonyl (CO_2Bu) group shifts the reduction potential anodically by ~0.12 V, while nitro group substitution shifts $E_{1/2}$ by ~0.28 V for each NO_2 group as

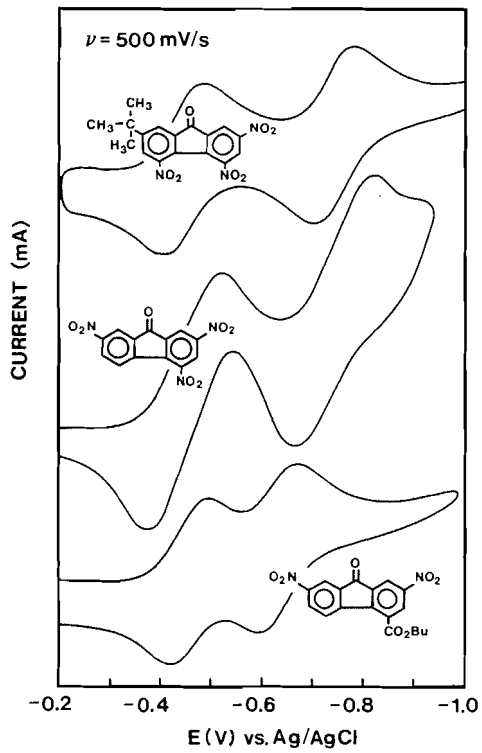

FIG. 1. Cyclic voltammograms of substituted fluorenones in CH_2Cl_2 at Hg electrode vs. Ag/AgCl, KCl.

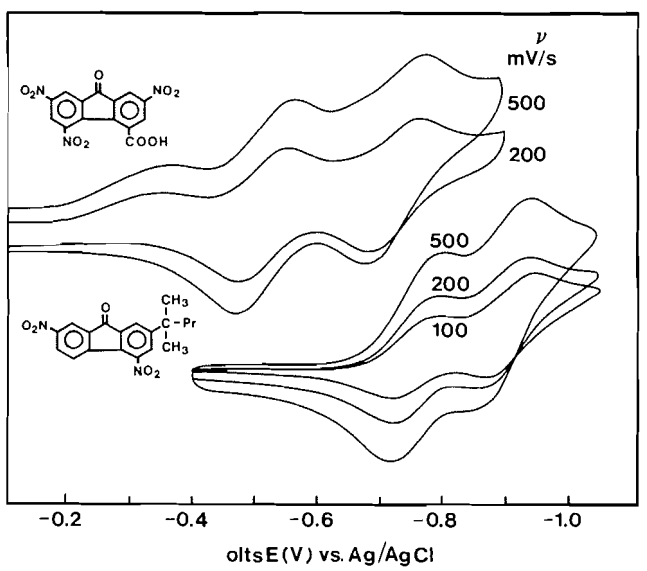

FIG. 2. The CV behavior of tri- and tetra-substituted fluorenones.

indicated in Table 2. Figures 1 and 2 show typical cyclic voltammograms of several of these new compounds along with that of 2,4,7-trinitro fluorenone (TNF), **5** (the best known electron-acceptor compound). Each compound in the series exhibits two reversible one-electron reduction waves separated by ~0.3 V. The reduction potential of the *t*-butyl trinitrofluorenone, **6** (−0.44 V), is identical to that of TNF, **5** (−0.42 V). They also display similar electron mobility. However, **6** is much more soluble than TNF in common solvents. The dinitrobutoxycarbonylfluorenone, **7** is reduced at a slightly more cathodic potential (−0.55 V) than TNF **5** (−0.42 V) reflecting the weaker electronic influence of the CO_2Bu com-

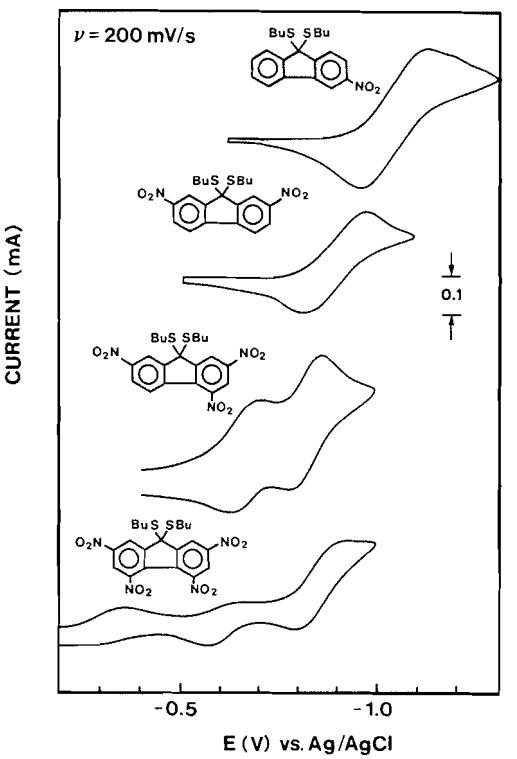

FIG. 3. CV of nitro-9,9-bis(*n*-butylthio)fluorenes.

pared to a NO_2 group. The 2-alkyl 4,7-dinitrofluorenone, **4**, exhibits reversible reduction at −0.76 V, which is 0.34 V cathodic of TNF.

The CV of all fluorenone derivatives show a reversible response, with separation of 70 mV between cathodic and anodic peak potentials, independent of scan rate between 10–200 mV/s, indicating a kinetically uncomplicated diffusion-controlled reduction to the corresponding radicals which are stable within the time scale of the cyclic voltammetric experiment. The only fluorenone derivative which exhibits an irreversible first-reduction wave is 4-carboxyl-2,5,7-trinitrofluorenone, **8**, as shown in Fig. 2. This can be attributed to the protonation of the radical anion by protons of the carboxyl groups.

*9,9-Bis(*n*-butylthio)nitrofluorenones,* ***10–14***

These compounds are derived from the corresponding fluorenone via thioketalization. The compounds exhibit intramolecular charge transfer from the sulfur to the nitrofluorene moiety and display electron mobilities that are higher than that of TNF (15). Figure 3 shows the CV of the mono, di, tri, and tetranitro-9,9-bis(*n*-butylthio)fluoreneone, **11–14**. All exhibit reversible one-electron reduction waves. The reduction potential shifts anodically by ~0.2 V per nitro group. The $E_{1/2}$'s range from −1.02 V for the mononitro to −0.33 V for the tetranitro compound, a shift of approximately 0.70 eV. These materials appear to have good solubility and electrochemical stability; however, xerographically the tetranitro derivative displays high dark decay while the others display heavy bulk trapping of charges. The electron drift mobility (μ_e) measured xerographically (11, 14) for these compounds appears to increase as the electron affinity of the molecule increases. The electrochemical data are summarized in Table 3.

Dialkyl-2,4,5,7-tetranitrofluorene-9,9-dipropionates, ***15–16***

These compounds exhibit four one-electron reversible reduc-

tion waves as shown in Fig. 4 and summarized in Table 4.

The first reduction wave occurs at −0.36 V independent of the alkyl group (ethyl **15** or butyl **16**), which is about 0.22 V cathodic of tetranitrofluorenone, **8**, reduction. Although these materials display reasonable solubility in common solvents and polymers, their electron mobility is very low.

9-Fluorenylidenemalononitriles, 17–20

This series of compounds displays a reduction potential ranging from −0.69 V to +0.11 V, i.e., span over a 0.80 eV in potential energy. All exhibit two reversible one-electron reduction waves. The first reduction potential of the parent compound 9-fluorenylidenemalononitrile, **17**, appears at −0.69 V vs. Ag/AgCl and shifts anodically by 0.2 V for each nitro group substitution. Table 5 summarizes the electrochemical results for the polysubstituted fluorenylidene malononitriles. Figure 5 shows a typical cyclic voltammogram of the representative samples of the series. All showed a clean reversible redox couple with peak separations ($E_p^C - E_p^a$) of about 70 mV, indicating a diffusion-controlled reduction to the corresponding radical anion. The radical anion formed at the working electrode has an intense orange–red color. The (nitro-9-fluorenylidene) malononitriles, **18–20**, although better electron acceptors than TNF, **5**, xerographically show high dark decay (in poly vinyl carbazole, PVK matrices).

Benzophenonemalononitriles, 21–22

These compounds are synthesized from the condensation of the benzophenones with malononitrile. The CV of these materials show reversible one-electron reduction. It is interesting to compare the reduction potential of the benzophenone malononitrile, **21** ($E_{1/2} = -1.15$ V), and that of 9-fluorenylidene malononitrile, **17** ($E_{1/2} = -0.69$ V). The CV of both compounds is shown in Fig. 6. Anodic shift of over 0.45 V results from rigidizing the two benzene rings of benzophenone into a fluorene. The 4,4′-dinitrobenzophenone malononitrile, **22**, is quite insoluble in most common solvents and exhibits reduction potential at −0.58 V vs. Ag/AgCl.

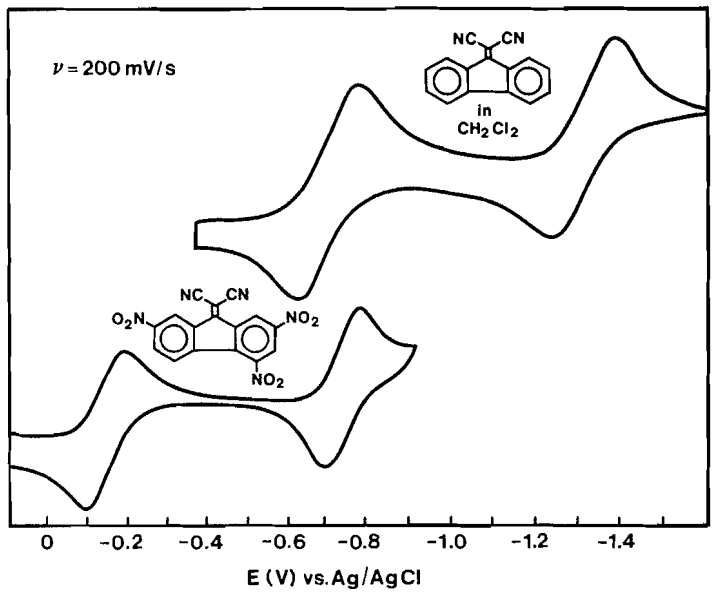

FIG. 5. CV of representative 9-fluorenylidene malononitrile.

Benzylidene malononitriles, 23–30

The synthesis of these compounds involves condensation of the benzaldehyde derivatives with malononitrile. All except the *p-N,N*-dimethyl aminobenzylidene malononitrile, **23**, display irreversible one-electron reduction waves as shown in Fig. 7. The reduction peak potential E_p^c shifts cathodically by 60 mV for a 10-fold increase in scan rate, indicating an irreversible charge transfer involving one-electron and an electron-transfer coefficient, $\beta = 0.5$. The irreversibility can be associated with the presence of the vinylic proton. Displacing the vinylic proton by a phenyl restores reversibility. The terphthalylidene malononitriles, **29** and **30**, show quasi-reversible reduction waves at −0.53 and −0.81 V, respectively. These compounds form very stable radical anions with intense purple color.

2-Arylidene indan-1,3-dione, 31–33

The CV wave of 2-benzylidene indan-1,3-dione, **31**, is a quasi-reversible two-electron reduction, while the CV wave of **32** and **33** is a reversible one-electron reduction as shown in Fig. 7. The electrochemical results for compounds **21** to **33** is shown in Table 6.

Discussion

The electron affinities from electrochemical reduction potential

The energy of the electron conducting level of a molecule in condensed media, A_c, is linked with the gas phase electron affinity A_g via

$$[3] \quad A_c = A_g - P_c^-$$

where P_c^- is the solid medium polarization energy, which can be given by

$$[4] \quad P_c^- = -\left(1 - \frac{1}{n^2}\right)\frac{e^2}{2r}$$

where n^2 is the optical dielectric constant of the medium and r is the effective radius of the radical ion A^-. The gas phase electron affinity, A_g, of a molecule is related to the solution half-wave reduction potential according to

$$[5] \quad A_g = E_{1/2} + P_s^- + E_{RE}$$

Where P_s^- is the differential real solvation energy of the radical anion and E_{RE} is the free energy of electron in the reference electrode vs. an electron in vacuum ($E_{Ag/AgCl} = 4.70$ eV). The solvation energy for a negative ion, P_s^- can be given by:

$$[6] \quad P_s^- = -\frac{e^2}{2r}\left(1 - \frac{1}{\epsilon}\right) - FX_S$$

where ϵ and X_S are the dielectric constant and surface potential of the solvent. Combining eqs. [3] and [5] gives

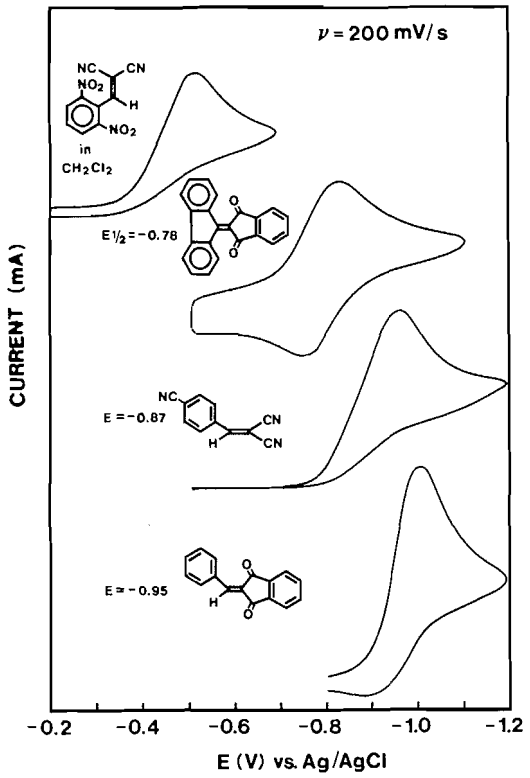

FIG. 7. CV of benzylidene malononitriles and indandiones.

[7] $A_c = E_{1/2} + E_{RE} - (P_c^- - P_s^-)$

The molecular energy levels of electron acceptors in various media are depicted in Fig. 8. Many attempts have been made to correlate A_g and $E_{1/2}$. In most of these correlations the solvation energies of widely different electron acceptors were assumed to be constant. Briegleb (1) found $A_g = E_{1/2} + 1.41$; Chen and Wentworth (5) reported $A_g = E_{1/2} + 2.49 \pm 0.26$; and Lyons and Palmer (6) used $A_g = E_{1/2} + 2.0$. All these linear correlations between A_g and $E_{1/2}$ were obtained in spite of the fact that it is unreasonable to expect that the solvation energy of small molecules such as tetracyanoethylene can be equal to

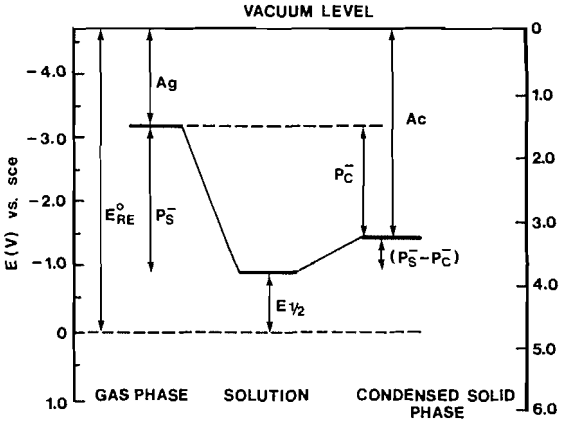

FIG. 8. Molecular energy level scheme for electron conducting level in various media.

that of the relatively larger aromatic hydrocarbons such as anthracene. It is not unreasonable, however, to expect the solvation energy to vary linearly with $E_{1/2}$, i.e., $P_s^- = -(aE_{1/2} + b)$. Thus, A_g can be related to $E_{1/2}$ via

[8] $A_g = (1 - a)E_{1/2} + (4.7 - b)$

where a and b are constants. To determine the value of these constants an empirical correlation between A_g and $E_{1/2}$ was used. The gas phase electron affinity of only a few molecules is known accurately. Recently, Lyons and Palmer (6) accurately measured A_g of tetracyanoethylene by photodetachment experiments to be 2.37 eV. Table 7 lists the best known A_g and $E_{1/2}$ values of a few organic molecules. Figure 9 shows the correlation between A_g and $E_{1/2}$ for the series of molecules listed in Table 7. The least-square fit of the linear correlation shown in Fig. 9 can be given by the eq. [9]:

[9] $A_g = 0.81E_{1/2} + 2.10$

The values of the constants a and b are 0.19 and 2.6 eV, respectively. By using the one-electron reduction potential in Tables 2 to 6, the gas phase electron affinities of the compounds studied here may then be obtained and are listed. Substituting the values of A_g, $E_{1/2}$, and E_{RE} (4.70 eV) into eq. [5], the solvation energies P_s^- can be obtained and are also listed in the tables.

The energy of the electron conducting level of an electron acceptor molecule in polymeric solid-solution can be obtained

[a]The correlation between $E_{1/2}$ and A_g gives $A_g = 0.81E_{1/2} + 2.10$.
[b]$P_s^- = A_g - E_{1/2} - 4.70$.
[c]$P_c^- \simeq 0.86P_s^-$.
[d]$A_C = A_g - P_c^- \simeq E_{1/2} + 4.38$; $A_C = 1.2A_g + 1.81$.
[e]References 18–20.

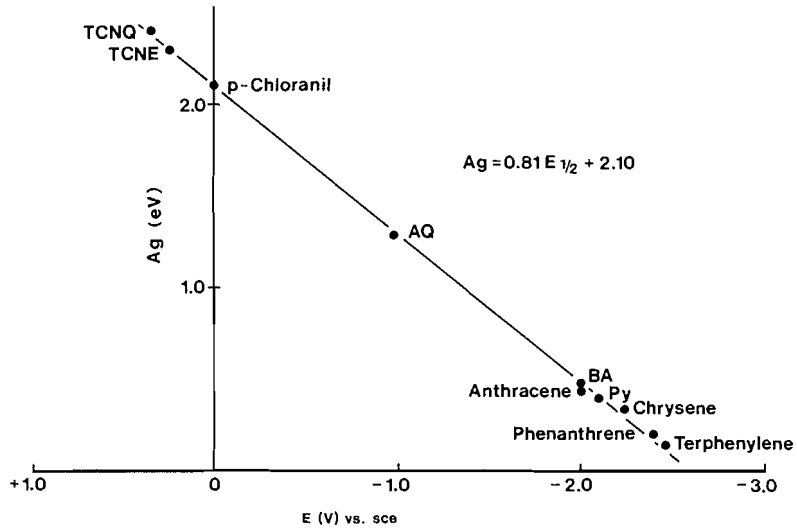

FIG. 9. Correlation between the gas phase electron affinity A_g and the solution half-wave reduction potential of some organic molecules.

using eq. [3], if the value of P_c^- is known. From eqs. [4] and [6], it was found that $P_c^- \simeq 0.86\ P_s^-$. Substituting in eq. [7], using $P_c^- \simeq 0.86\ P_s^-$ and $P_s^- = -(0.19E_{1/2} + 2.6)$ gives

$$[10] \quad A_c \simeq E_{1/2} + 4.38$$

and

$$[11] \quad A_c = 1.2\ A_g + 1.81$$

Using the one-electron reduction potential in Tables 3 to 6, the energy of the electron conducting level of the compounds studied in solid-matrix may thus be obtained and are listed in the tables. The values of A_c of the compound studied varied from 3.0 to 4.44 eV.

Tetracyanoethylene (TCNE) and hexacyanobutadiene has an A_c value of 4.60 and 4.93 eV, respectively. These materials are among the strongest electron-accepting molecules. TNF and **17** has an A_C value of 3.92 and 3.66 eV, which places their accepting level slightly above the conduction band of a −Se (4.0 eV).

The gas phase electron affinity of TNF, **5**, is 1.76 eV, previous estimates have been 2.17 (1), 2.07 (3), 2.1 (5), 1.7 (6), and 1.7 eV (4). The discrepancy is mainly due to the fact that in all previous studies solvation energies of various radical anions were assumed to be constant, while in our study we assumed that P_s^- varies linearly with $E_{1/2}$.

Conclusion

Cyclic voltammetry was used to electrochemically evaluate a series of 33 electron acceptor molecules. The one-electron half-wave reduction potentials were used to determine the electron conducting levels of these materials in various media.

Determination of amphetamine, cocaine, and heroin vapour pressures using a dynamic gas blending system and gas chromatographic analysis[1]

A. H. LAWRENCE,[2] L. ELIAS, AND M. AUTHIER-MARTIN[3]

Unsteady Aerodynamics Laboratory, National Aeronautical Establishment, National Research Council of Canada, Ottawa, Ont., Canada K1A 0R6

Received January 16, 1984

This paper is dedicated to Professor Paul de Mayo on the occasion of his 60th birthday

A. H. LAWRENCE, L. ELIAS, and M. AUTHIER-MARTIN. Can. J. Chem. **62**, 1886 (1984).

A dynamic gas blending system was used to generate controlled vapour concentrations of amphetamine, cocaine, or heroin. An adsorption – thermal desorption – gas chromatographic procedure was developed and used to measure the output vapour concentrations. The vapour pressure of amphetamine at 20°C was determined, and vapour pressures as a function of temperature have been measured for cocaine and heroin.

A. H. LAWRENCE, L. ELIAS et M. AUTHIER-MARTIN. Can. J. Chem. **62**, 1886 (1984).

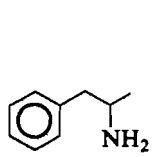
On a utilisé un système dynamique pour produire des concentrations controlées d'amphétamine, de cocaïne ou d'héroïne en phase gazeuse. On a mis au point une méthode d'adsorption – désorption thermique – chromatographie gazeuse permettant de mesurer la production de concentrations de vapeur. On a déterminé la tension de vapeur de l'amphétamine, à 20°C, et on a mesuré les tensions de vapeur, en fonction de la température, de la cocaïne et de l'héroïne.

[Traduit par le journal]

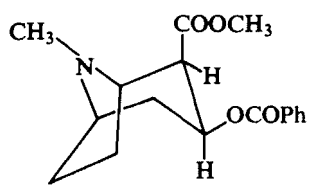
Introduction

The measurement of the vapour pressure of amphetamine, cocaine, and heroin is an integral part of the continuing effort to develop a highly specific and sensitive technique for the detection of these drugs of abuse. This laboratory has been successful previously in the development of vapour-sensing techniques for the detection of hidden explosives (1).

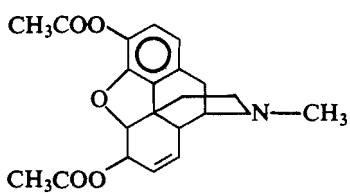
Amphetamine (**I**), cocaine (**II**), and particularly heroin (**III**), in the free-base form are relatively nonvolatile compounds at ambient conditions, and vapour pressure data for these chemicals have not been determined.



I



II



III

The methods of measuring vapour pressure may be classified into two types: static and dynamic, depending on whether the test sample is in a closed system (static), or whether the generated vapour is transported with a carrier stream and the resulting concentration determined (dynamic).

In this work, a dynamic gas-blending system was employed to produce controlled vapour concentrations of amphetamine, cocaine, or heroin. The technique, in brief, is to saturate a flowing gas stream with the narcotic vapour by passage of the stream over the test sample. The vapourized chemical is collected in a solid adsorber sampling tube and then thermally desorbed and analyzed by gas chromatography (gc) using a nitrogen-selective detector. The gc peak area can be related to the amount of compound collected and to the concentration in the flowing stream. A similar procedure was used to measure the vapour pressures of DNT, TNT, and ethylene glycol dinitrate (2).

Experimental

Chemicals

d-Amphetamine sulfate (BDH lot 30603-35403), benzoylmethylecgonine (cocaine) (May & Baker, L64305), and diacetylmorphine (heroin) (T & H Smith EV9022-29) were obtained from Health and Welfare Canada. Amphetamine free base was extracted from the sulfate salt following the procedure described by Predmore and Christian (3). Tenax-GC (35–60 mesh) was obtained from Supelco Inc., Ultra Bond PEGS (80–100 mesh) from Alltech Associates.

Stock solutions ($\sim 10^{-6}$ g/μL) were prepared by dissolving 15 to 25 mg of the drugs in acetone (50 cm^3). Standard hexane solutions were prepared by the appropriate dilution of the stock solutions. The concentration of the standard solutions were amphetamine, 6×10^{-9} g/μL; cocaine, 1.3×10^{-9} g/μL; and heroin, 3×10^{-9} g/μL. All solvents used were distilled-in-glass grade from Caledon.

Solid adsorber sampling tubes

The adsorbent tubes used in this study were constructed of glass tubing 75 mm × 6.3 mm od with a restriction in the middle. For the collection of amphetamine, the tube contained a small amount (ca. 30 mg) of Tenax-GC. The adsorbent was held in place with small plugs of silanized glass wool. For the collection of cocaine and heroin, the tube contained a platinum plug (80 mesh, 7×1.5 cm^2, ~0.5 g) coated with OV-17 (1% in chloroform). All tubes were conditioned for several hours at 250°C in a nitrogen stream at a flow rate of 50 cm^3/min. Before use a chromatogram was recorded to check the purity of each adsorber. Neither peaks nor baseline drift were observed for adsorbers conditioned as above, and stored for up to 2 days. The collection efficiency of the tubes was determined following a previous test procedure (4) and the tubes were found to be 90–95% efficient under the experimental conditions used.

Continuous-flow trace vapour source

A continuous stream of laboratory compressed air containing a

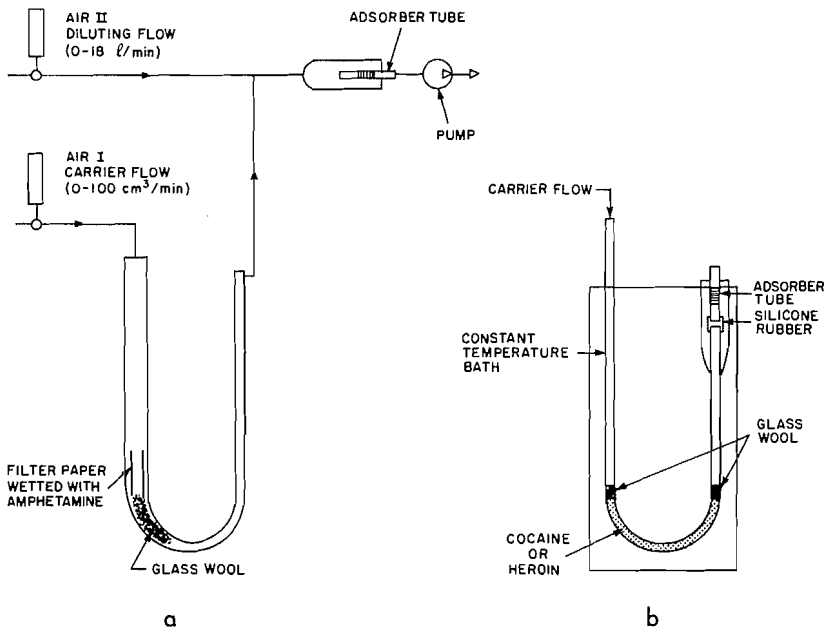

FIG. 1. Continuous-flow trace vapour source.

constant concentration of drug vapour was generated by a continuous-flow trace vapour source developed in this laboratory (5). The trace vapour generator, employing dynamic dilution of vapours of amphetamine, is shown schematically in Fig. 1*a*. For proper sampling, the flow rate of vapour exiting the source was maintained at twice or greater than the sampling rate. A diaphragm pump (Fisher Scientific Instruments) was used for sampling. Amphetamine, which is a liquid at room temperature, was placed in the U-tube on a strip of filter paper wetted with about 200 mg of the substance.

Due to the low vapour pressure of cocaine and heroin, dynamic dilution was not necessary with these compounds (i.e., Air II = 0), and at temperatures above ambient, a much simpler device was used (Fig. 1*b*). Purified air flows at an adjustable rate through the U-tube filled with crystalline cocaine or heroin immersed in a thermostated bath, and carries the vapours directly to the adsorber tube. The connection between the adsorber and the U-tube is also immersed in the temperature-controlled bath. The above design has the advantage of keeping the vapours at the selected temperature until they reach the sorbent material, thus reducing vapour losses. The junction between the source and the adsorber was made with a piece of silicone rubber tubing. After collecting a vapour sample, the adsorber was disconnected from the U-tube and attached to the gas chromatograph for analysis.

Gas chromatographic analysis

A Varian 1400 gas chromatograph equipped with a nitrogen–phosphorus thermionic specific detector (TSD) was used for the experimental work described in this paper. The gc was modified to accommodate a two-stage adsorber system. The second adsorber contained a small amount ca. 30 mg of Ultra Bond PEGS, and is incorporated in the instrument. After sampling, the solid adsorber sampling tube (adsorber I) was connected to the gas chromatograph. The collected vapours were removed by heating, and flushed with a carrier gas stream to the smaller adsorber (adsorber II) from which they were subsequently thermally desorbed for injection into the chromatographic column. A six-port switching valve provided the various functions involved in the analysis as indicated in Fig. 2 and was maintained at 210°C to avoid condensation. The signal from the detector was recorded on a Hewlett Packard 3390A strip chart reporting integrator. The recorded drug peak area was compared with that of a drug standard solution deposited with a syringe directly on adsorber I, and analyzed in the same manner as an air sample. Amphetamine, cocaine, and heroin were successfully chromatographed under the conditions given in Table 1.

Results and discussion

Vapour pressure of amphetamine

The collection efficiency of the Tenax adsorber was tested by measuring the vapour concentration as a function of the sampling flow rate over the range 200 to 500 cm^3/min. The carrier flow and the diluting flow were maintained at 2.1 cm^3/min and 15.7 L/min, respectively. The sampling time was 60 s. The plot of the measured vapour concentration at the sampling port of the vapour source as a function of the sampling rate was found to be linear with a correlation coefficient of 0.996. The vapour source was tested by measuring the equilibrium vapour concentration as a function of the diluting flow. The carrier flow was maintained at a sufficiently low level (2.1 cm^3/min) to permit saturation with the vapour of the amine (deviation from equilibrium conditions was observed at a carrier flow > 7 cm^3/min). The sampling rate was 200 cm^3/min.

Under conditions where the static equilibrium vapour pressure above the sample is nearly maintained, the concentration C in the air stream at the sampling port is simply the equilibrium vapour concentration C_0 of amphetamine reduced by the appropriate dilution ratio according to the equation:

$$[1] \quad C = C_0 \left(\frac{f}{f + F}\right)$$

f is the flow rate of the carrier air and F is the diluting air entering the mixing manifold, the ratio $f/(f + F)$ being the dilution factor. The diluted vapour concentrations were measured experimentally by analyzing the adsorber tubes gas chromatographically as described above. The equilibrium vapour concentrations were calculated from eq. [1]. Measured values of C and the derived values of C_0 are presented in Table 2; the constancy of C_0 indicates a proper vapour generator performance. The vapour pressure of amphetamine at 20°C calculated from the equilibrium concentration data using the ideal gas law was found to be $2.4 \pm 0.2 \times 10^{-1}$ Torr.

Vapour pressures of cocaine and heroin

In a similar procedure, the effect of carrier flow rate on reaching equilibrium conditions was determined by varying the air flow from 50 to 150 cm^3/min through the vapour source

(Fig. 1*b*) containing cocaine at 20°C. The measured cocaine concentration was found to be independent of the air carrier flow rate over this range. Measurements made with heroin showed no differences in vapour concentrations when the carrier flow rate was varied from 20 to 95 cm^3/min at 63°C. Accordingly, the air carrier flow rates used for generating cocaine and heroin equilibrium vapour concentrations were 100 cm^3/min and 35 cm^3/min, respectively. Equilibrium vapour concentrations were generated from 21 to 41°C for cocaine and from 51 to 66°C for heroin, and measured chromatographically as described above. Vapour pressure data were calculated using the ideal gas law. Each data set was plotted as log P vs. $1/T$ according to eq. [2] and treated by the weighted least-square method.

$$[2] \quad \log P = A - B/T$$

P is the vapour pressure expressed in Torr, A and B are the intercept and slope, respectively, and T is the temperature in degrees Kelvin. The results obtained are summarized in Table 3.

TABLE 2. Diluted and equilibrium vapour concentrations of amphetamine*

Dilution factor	f (cm^3/min)	F (L/min)	Measured C(g/L)	Calculated C_o(g/L)
0.00021	2.1	9.9	$3.8\pm0.3\times10^{-7}$	1.8×10^{-3}
0.00013	2.1	15.7	$2.5\pm0.2\times10^{-7}$	1.9×10^{-3}

*Temperature, 20°C.

TABLE 3. Vapour pressure constants for cocaine and heroin*

Compound	No. of data pts	A	B	σ_A	σ_B	Correlation coefficient
Cocaine	18	13.02	5884	0.50	147.4	0.995
Heroin	16	16.20	7549	0.62	209.8	0.999

*Log $P = A - B/T$.

In conclusion, the selectivity of the nitrogen/phosphorus detector together with the advantages of the two-stage preconcentration technique (4) renders the dynamic method described above a simple, inexpensive, and sensitive technique for the determination of the vapour pressure of relatively nonvolatile nitrogen-containing compounds.

The adsorption of the cationic dye rhodamine 6G by montmorillonite (Wyoming bentonite) and laponite (synthetic hectorite) was studied by visible and fluorescent spectroscopy and by X-ray diffraction methods. Adsorption of the dye takes place by the mechanism of cation exchange. X-ray data indicate that the adsorbed cationic dye is located in the interlayer spaces of both minerals. It was found that adsorption prevents the dimerization of the dye, and gives rise to red shifts of the principal absorption band of the dye. A study of the effect of varying concentration of dye or clay on the location and intensity of this band proved to be useful in determining the adsorption capacity of the clay. The observed spectral changes are linked to surface polarity and to clay flocculation. At concentrated suspensions of montmorillonite, an additional weak absorption shoulder is obtained at 470–490 nm, which may be attributed to aggregated dye molecules, probably trapped within the cavities of book-house structured flocs. Due to steric hindrance rhodamine 6G does not give π interactions with the oxygen plane of the silicate layer. Therefore the adsorption of the dye by expanding clay minerals does not give rise to metachromasy. Fluorescence of the adsorbed dye is reported: it is red shifted and quenched relative to aqueous solutions. The use of fluorescence spectra to determine the saturation point is described, and aging and ultrasonic effects on spectral features are presented and discussed.

Faisant appel à la diffraction des rayons-X et à la spectroscopie visible et de fluorescence, on a étudié l'adsorption du colorant cationique rhodamine 6G par la montmorillonite (bentonite du Wyoming) et par la laponite (hectorite synthétique). L'adsorption du colorant se fait par un mécanisme impliquant un échange de cations. Les données de rayons-X indiquent que, dans le cas de chacun des deux minéraux, le colorant cationique est adsorbé dans les espaces interstitiels. On a trouvé que l'adsorption empêche la dimérisation du colorant. A la suite de l'adsorption, la principale bande d'adsorption du colorant se déplace vers le rouge. Une étude de l'effet d'un changement de concentration du colorant ou de l'argile sur la position et l'intensité de cette bande s'avère un outil utile pour déterminer la capacité d'adsorption de l'argile. Les changements spectraux observés sont liés à la polarité de la surface et à la floculation de l'argile. Pour des suspensions concentrées de montmorillonite, on observe une adsorption supplémentaire faible qui apparaît comme un épaulement à 470–490 nm et que l'on peut attribuer à une aggrégation de molécules de colorant qui sont probablement emprisonnées dans les cavités des flocons. La rhodamine 6G, à cause de l'encombrement stérique, n'a pas d'interactions π avec le plan d'oxygènes de la couche de silicate. Par conséquent, l'adsorption du colorant par la dilatation des minéraux argileux ne provoque pas de métachromasie. On rapporte la fluorescence du colorant adsorbé: par opposition à son comportement en milieux aqueux, il y a déplacement vers le rouge et un piégeage. On décrit une méthode de déterminer le point de saturation qui fait appel à l'utilisation des spectres de fluorescence. On rapporte et on discute des effets ultrasoniques et du vieillissement sur les caractéristiques spectrales.

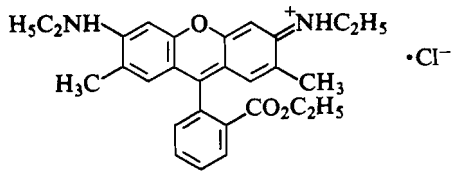
Introduction

As part of our interest in the use of photoprocess at solid (1, 2) and liquid (3) interfaces as probes for studying these environments, we have investigated the electronic absorption and emission spectra of rhodamine 6G (R6G, **1**) adsorbed on clays in aqueous suspensions. Two smectite minerals were chosen: montmorillonite (Wyoming bentonite) and laponite (synthetic hectorite).



1

The xanthenes comprise a family of fluorescent dyes, with wide applications such as laser dyes (4), photosensitizers (5), and singlet oxygen generators (6). Spectroscopic properties of adsorbed xanthene dyes have been investigated on surfaces of various solid materials such as porous (2*b*, 2*d*, 7) and nonporous (8–11) silica type glasses, semiconductors (10, 12–14), various surface-hydroxylated materials (14), crystals of polycyclic aromatic hydrocarbons (15), silver islands (16), and gold films (8).

Organometallic fluorescent dyes adsorbed on clays have been studied by Van-Damme and co-workers (e.g. ref. 17) and by DellaGuardia and Thomas (e.g. ref. 18) as part of their interest in the applications of photo-redox reactions in organized media.

In previous publications from our laboratory the adsorption of two cationic dyes by montmorillonite was described (1*a*, *b*): methylene blue and acridine orange. The adsorption of these dyes takes place by the mechanism of cation exchange which is reflected by the spectroscopic phenomenon of metachromasy, i.e., the appearance of a new blue shifted band. From those studies it was concluded that metachromasy resulted from π interactions between the oxygen planes of the clay and the aromatic rings of the organic dye. Such π-interaction cannot occur in R6G due to steric hindrance; in this molecule the phenyl ring is sterically constrained to be roughly perpendicular to the planar xanthene group (19). It was therefore expected that if our suggested mechanism of meta-

[1]Authors to whom correspondence should be addressed.
[2] M. Richter Fellow.

chromasy (1) is correct, the adsorption of R6G by smectites should not lead to metachromasy. In the present study we show that this is indeed the case. We also show that the study of electronic absorption and emission spectra of the clay/R6G associates provides information not only on the adsorbed dye itself, but also on saturation ratios, on the structural aspects of the clay suspensions, and on the polarity of the surface.

Experimental

1. Chemicals

R6G (Aldrich) was twice recrystallized from ethanol. The resulting crystals showed a single point on tlc and were fluorescent. Elemental analysis showed the recrystallized material to be of 98.8% purity. Laponite XLG (a synthetic Na-hectorite) was from Laporte Industries Inc., WY. Bentonite (Na-montmorillonite) was supplied by Wards Natural Science Establishment, Inc. It was ground to 80 mesh. Quartz was separated by sedimentation. Clay suspensions of 1% by weight were used as stock suspensions. An aqueous solution of 4.2×10^{-4} *M* R6G was used as a stock solution and kept in the dark in order to avoid photodecomposition.

2. Adsorption and sample preparation

The desired amount of clay was transferred from the concentrated stock suspension into a 25 mL flask, and diluted with triple-distilled water to less than 25 mL. After thorough shaking, the desired amount of dye from the dye stock-solution was added dropwise, and the volume filled to 25 mL. The reverse order of addition is not recommended, since this may cause heavy dye coating on the first added clay particles.

3. Absorption and emission spectra

Absorption and emission spectra were recorded immediately after the preparation of the clay–dye suspension. Absorption spectra were also recorded after aging periods of 1 and 6 days. Some of the aged suspensions were exposed to ultrasonic agitation for 10 min and their visible spectra then recorded. Aliquots of the various aged suspensions were separated by centrifuging on an A. B. Ljungberg spot-test centrifuge and the spectra taken on a Bausch and Lomb spectrophotometer model 2000 and on a Cary 219 (Varian) spectrophotometer. Fluorescence measurements (excitation and emission) were performed on a SLM-Aminco model 4800 Spectrofluorimeter, using 1 mm quartz cells in a front face set up.

4. X-ray diffraction

Oriented samples of R6G treated clay were prepared by drying the suspensions on glass slides. X-ray diffraction patterns were obtained on a Philips Diffractometer using monochromatic CuK_α radiation. Diffractions were also determined after 6 days in an oven at 195°C.

Results

1. Cation exchange

The adsorption of R6G by montmorillonite and laponite takes place largely by a cation exchange mechanism. Exchangeable metallic cations are released into the solution when the clay is equilibrated with R6G. Some representative data are presented in Table 1.

TABLE 1. Metallic cations (in mequiv./100 g clay) released into an equilibrated suspension of montmorillonite and laponite treated with 85 m*M* R6G per 100 g clay

Cation	Montmorillonite	Laponite
Na	97	71
K	4	0.3
Mg	53*	140*

*High values for Mg may be due to the presence of peptized clay in the supernatant.

2. Spectral changes in adsorbed R6G

It is well documented that xanthene dyes tend to dimerize at concentrations as low as 10^{-4} *M* via π interactions. This is usually reflected by the appearance of metachromatic absorption bands (20). For R6G, the monomeric absorption maximum at 525 nm (band α) in dilute solutions (Fig. 1*A*) is accompanied by a blue-shifted new band at 498 nm (band β) at high concentrations (Fig. 2).

The most striking change in the absorption spectrum that R6G undergoes upon adsorption on laponite and montmorillonite is the disappearance of the dimeric band β accompanied by an increase in the intensity of band α, indicating the dissociation of dimers into a monomeric adsorbed species (Fig. 2). Band α is red shifted upon adsorption (Fig. 1). This spectral change is described in detail in the next section.

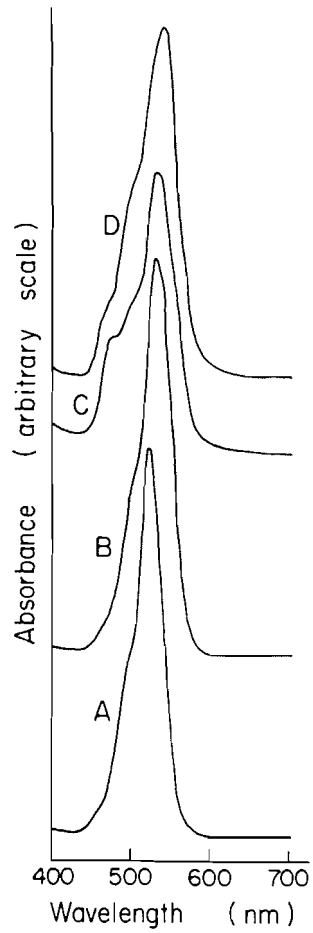


FIG. 1. Absorption spectra of 1.7×10^{-5} *M* R6G in: *A*, aqueous solution; *B*, 0.02% laponite suspension; *C*, 0.02% montmorillonite suspension; *D*, 0.002% montmorillonite suspension.

A new band (band γ) appears as a shoulder at 470–490 nm in the spectrum of R6G adsorbed on montmorillonite (Fig. 1*C*) but not on laponite (Fig. 1*B*). This strongly blue-shifted band appears only for clay concentrations higher than 0.01%, and its intensity increases with dye coverage up to a point which is slightly above the saturation ratio. Beyond this point, the excess dye causes clay peptization. At low clay concentrations, e.g., 0.002%, band γ is not apparent at any dye/clay ratio (Fig. 1*D*).

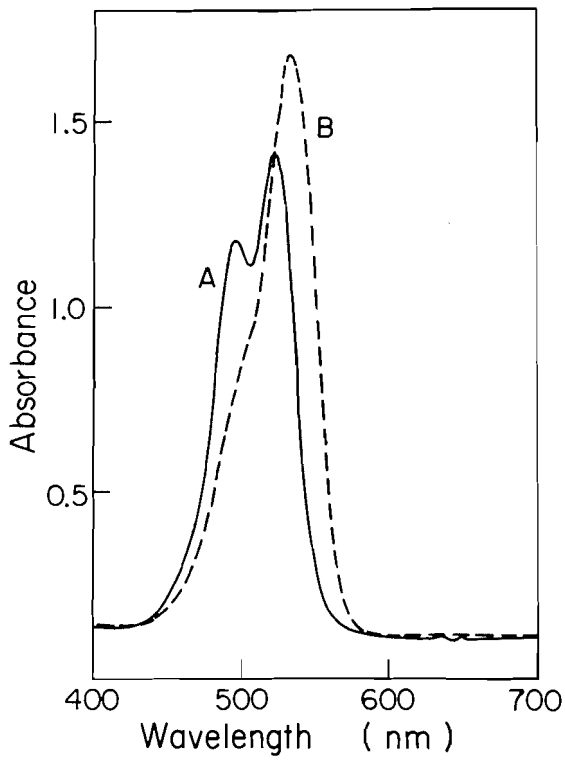

FIG. 2. Absorption spectra of aqueous solutions of R6G: *A*, 2.1×10^{-4} *M*; *B*, 2.1×10^{-4} *M* in the presence of laponite (0.05%). A similar effect is apparent in the case of montmorillonite.

3. Determination of saturation point from analysis of band α

A series of montmorillonite− and laponite−R6G suspensions was prepared using a constant amount of R6G (1.7×10^{-5} *M*) and increasing amounts of clay mineral. Visible and fluorescence spectra of the suspensions were recorded. Figure 3*a* shows the effect of the clay concentration in the suspension on the location of band α in the absorption spectrum of the dye. As indicated in the figure, adsorption on both clays causes a red shift in band α. Maxima are obtained when the ratios between the dye and the clay are equal to 60 and 45 m*M* dye per 100 g montmorillonite and laponite, respectively. At this stage band α is located at 545 and 538 nm in the spectra of montmorillonite− and laponite−R6G suspensions, respectively. The supernatant obtained after the separation of the clay fraction from the suspension by centrifugation shows that up to the stage where maximum wavelength shift is obtained, some of the dye remains in the supernatant, whereas at lower dye/clay ratios the dye is totally adsorbed by the clay. The presence of free R6G in the supernatant is deduced from the location of band α at 525 nm. The saturation point can be also detected in a plot of absorption intensity of a fixed dye amount vs. amount of added clay (Fig. 3*b*). Here the absorption intensities for laponite and montmorillonite are at *minima*, and are slightly shifted with respect to the positions of the maxima in Fig. 3*a*. This shift is significant, and will be discussed below.

The saturation ratios were then cross-checked by changing the dye concentration, and keeping the clay concentration fixed (0.002% and 0.02%). As seen from Fig. 4*a* for the 0.002% case, indeed the same saturation ratios are obtained as in Fig. 3. Similar results were obtained for the 0.02% concentration. A rather complicated curve described the change in absorption maxima as a function of added dye (Fig. 4*b*). This

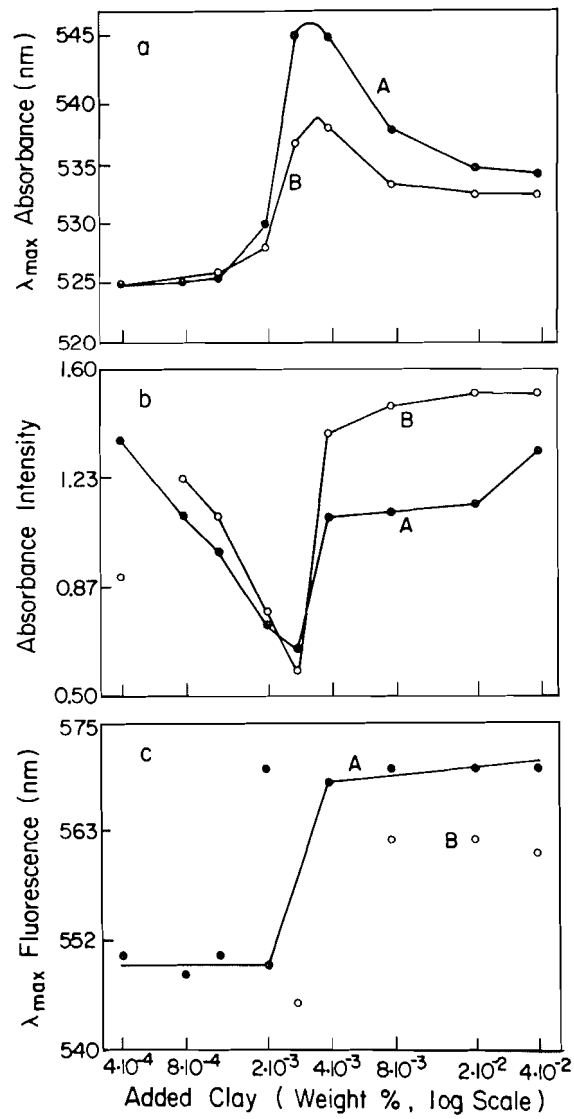

FIG. 3. The effect of added clay mineral on (*a*) the location of band α; (*b*) the absorption intensity of band α; (*c*) the fluorescence maxima, all at a fixed R6G concentration of 1.7×10^{-5} *M*. *A*, montmorillonite; *B*, laponite.

behaviour may reflect (see below) changes in the structure of the colloidal suspension.

4. Determination of saturation point from fluorescence spectra

The effect of clay concentration in the clay−R6G suspension on the fluorescence spectrum was investigated. In solution, the emission band of the dye is quite intense. Upon adsorption of the dye by the clay, the fluorescence intensity decreased substantially. Consequently, as long as there is free R6G in the solution, the recorded spectrum is governed by the features of the aqueous soluble dye molecules (λ_n = 550 nm). When the dye is completely adsorbed by the added clay, so that free dye − molecules do not interfere, a substantial red shift in the emission is revealed; 569 nm and 563 nm for montmorillonite and laponite, respectively (Fig. 5). Excitation spectra of the adsorbed dye are shown in Fig. 5 as well; the maxima of these spectra were close to within 0−2 nm to the absorption maxima. The shoulders in the emission and excitation spectra of R6G−montmorillonite are located at positions of non-adsorbed dye. The abrupt change in fluorescence properties across the saturation point is indicated in Fig. 3*c*.

5. The effect of aging and ultrasound on flocculation

The above series of clay/R6G suspension with fixed (0.02%) clay concentration and changing amounts of dye was subjected to aging for various periods, and the absorption spectra were then recorded. The results are summarized in Tables 2 and 3. As indicated in the tables, values obtained after the aging periods are lower than those obtained for the fresh systems. The batches which showed lowering in absorbance appeared to be flocculated. During the aging period the suspensions were kept in the dark in order to avoid photodecomposition of the organic dye. It seems therefore that flocculation which occurred during the aging period is the principal reason for the decrease in absorbance.

The aged suspensions were centrifuged for 10 min and the spectra of the supernatants were recorded. The supernatants may contain the soluble dye cation which was not adsorbed by the clay, and peptized clay coloured by the adsorbed dye. The first absorbs at 525 nm, whereas the latter absorbs at higher values (Figs. 3, 4). The difference between the absorbances of the original suspension and of the supernatant can give an indication as to the degree of flocculation of the organo-clay (Tables 2, 3). From the tables it can be seen that flocculation increases with increasing amounts of organic material up to a certain amount, and then decreases. The highest degree of flocculation is obtained when the of R6G in the clay suspension is slightly above the saturation point of the clay.

To examine this assumption, some of the aged suspensions were deflocculated by ultrasonic treatment. The recorded spectra showed a considerable increase in the absorbance of band α (Tables 2 and 3). In some cases the absorbance values recorded after the ultrasonic treatment were even higher than the original values recorded for the fresh suspensions. This increase may reflect better peptization achieved by the ultrasonic treatment.

6. X-ray studies

Oriented specimen of clay samples treated with various amounts of R6G were examined by X-ray diffraction at ambient conditions and after being dried at 195°C for 6 days (Table 4). The thermal treatment of natural Wyoming bentorite or laponite results in a dehydration process, leading to a *c* spacing of 1.0 nm. On the other hand, in the presence of R6G only minor effects of the thermal treatment on the *c* spacing due to dehydration were observed. From these results it may be concluded that the *c* spacing is principally controlled by the presence of the organic dye in the interlayer space.

Discussion

1. The disappearance of band β and its consequences on the question of metachromasy in clay minerals

The metachromatic appearance of band β in R6G aqueous solutions has been studied recently by Arbeloa *et al.* (19). From spectroscopic considerations, and from investigation of molecular models, they proposed a structure for the dimer of R6G which leads to metachromasy. According to the suggested structure, two xanthene moieties form parallel planes held together by π interactions and separated by 0.56 nm, with a twist angle of 76°. This angle is caused by the steric hindrance between the two *ortho* ethyl benzoate substituents, which are roughly perpendicular to the xanthene planes. As described above, upon adsorption on the clays band β disappears, and the monomeric band α increases in intensity. This was interpreted as dimer dissociation upon adsorption.

In contradistinction, metachromasy occurs during adsorption of either methylene blue or acridine orange even when the interlayer spacing of the clay mineral is insufficient for dye aggregation (1). As mentioned in the Introduction, it has been suggested that metachromasy in these systems is due to interactions between the oxygen plane of the aluminosilicate layer and the π electron orbitals of the dye–cation. Whereas a twisting angle in R6G can compensate for the steric hindrance of the benzoic acid substituents in the dimer in solution, such compensation is impossible between the oxygen plane and the xanthene moiety. Therefore, not only is there no metachromasy due to adsorbed aggregates of R6G, there is also no metachromasy due to *monomeric* adsorption, as was the case for methylene blue and acridine orange. It seems to us that these observations strengthen the hypothesis that metachromasy of dyes adsorbed into the interlayers of expandable smectites originate from monomeric adsorption and adsorbate/adsorbant π interactions, and not, as suggested by Bergmann and O'Konski (21), from adsorbed aggregates. According to the adsorbed-aggregates hypothesis, band β should have been seen also in the case of R6G adsorbed on clays.

2. Band γ and the book-house structure of montmorillonite

We do, however, think that there is a very small degree of aggregation on high concentration montmorillonite suspensions as reflected by the weak shoulder at 474 nm (Fig. 1, band γ). This band is located at a wavelength shorter than band β, suggesting that it represents "sandwiched" adsorbed aggregates of more than two R6G molecules. Another possibility is that band γ represents solvated dimers in solutions trapped within "book-house" structures (24). This quasimicellar arrangement may cause a local effect of increase in concentration as reported for micelles (22). Since the intensity of this band is very weak in comparison to that of band α, it seems that only a very small fraction of the R6G molecules undergo this type of aggregation.

In the very dilute suspension the platelets of montmorillonite are initially well dispersed. In the more concentrated suspension the platelets form face-to-face associations (tactoids). When the clay flocculates, as the result of the treatment with R6G, card-house and book-house structures are obtained in dilute and concentrated suspensions, respectively. It seems that the book-house structure is essential for this type of metachromasy, so that dye aggregates form in the vacancies between the tactoids which participate in the floc. Indeed, in laponite, which does not show a tendency to form book-house structures, this type of metachromasy was not detected at any of the concentrations used.

3. Band α as an indicator of surface polarity and of flocculation

Changes in intensity and location of band α as the concentrations of dye or clay vary were described in Figs. 3 and 4. From Fig. 3*a* and 4*a* it is clear that the higher the surface coverage, the larger is the red shift in band α. Even at low degree of coverages the adsorbed molecule is red-shifted relative to R6G in water. The fact that the location of band α changes gradually with change of degree of coverage is an indication to a gradual and even distribution upon adsorption and not to clustered adsorption. A possible sequence of events is first, a gradual coverage of isolated plates, followed by tactoids build up, and then adsorption into the interlayer spacing. We suggest that the gradual change in location is an indication for the gradual change in average local polarity: as more dye molecules are adsorbed, the local environment gradually changes to less polar and becomes more hydrophylic. Indeed, red shifts in R6G were observed when water was substituted by a less polar solvent (23). Consequently, the red shift observed even at low coverages may be interpreted as reflecting surface polarity which is not as high as that of water. This observation is in agreement with the known hydrophobicity of the oxygen plane of the clay (24). Interestingly, in the case of acridine orange, which forms strong π interactions with the oxygen plane, the gradual change in the location of band β is to the *blue* as concentration increases (1*c*). This is a con-

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.105 on 09/06/12
For personal use only.

sequence of gradual water removal from the oxygen plane which enables stronger interaction between the positive π electron cloud of the dye and the clay plane. The opposite trend in spectral shifts for the two dyes is a further indication for the lack of π interactions in R6G.

Figure 4*b* shows clearly local minima of absorption intensities, just after the saturation point is reached. A similar phenomenon is the slight shift in the minima of Fig. 3*b* compared to the maxima of Fig. 3*a*. Supernatant analyses (Tables 2, 3) and simple observation of the samples reveal that flocculation becomes prominent for a certain small range of excess dye beyond the saturation point. The decrease in absorption intensity is therefore very similar to the known effect deviation from Beer–Lambert law upon aggregation. As further indicated in Figs. 3, 4, flocculation ceases above a certain excess of dye. At these higher dye concentrations, the organic material apparently acts as a dispersing agent, causing efficient peptization of the clay. The sensitivity of band α to aging or ultrasonic treatment follows similar lines, i.e., it reflects the clay/dye suspension structures from large flocs down to a fine colloid.

4. Fluorescence quenching and red shift

The quenching of the fluorescence upon adsorption is due to iron impurities in the clays. This well-known phenomenon has been elegantly studied recently by Van-Damme *et al.* (25). Indeed, for laponite which contains less iron (25) the quenching is less severe, as could be judged from relative intensities at the same low concentration coverages. Other possible mechanisms for fluorescence-quenching are intermolecular sequences of energy transfers which act as an energy sink, or simply inner filter-effects within the flocs. In fact, the large difference in fluorescence intensities and maxima between adsorbed and non-adsorbed dye (Fig. 3*c*) suggests the use of this type of spectral analysis for determining the saturation ratios. The red shifts in the fluorescence maxima probably reflect, as discussed above, the reduced polarity of the surface compared to an aqueous hydration shell.

A comparative study of other laser-dyes is in progress, parts of which will be reported soon.

Internal rotation in [*p*-(dialkylamino)benzylidene]malononitriles

A. SAFARZADEH-AMIRI

Photochemistry Unit, Department of Chemistry, The University of Western Ontario, London, Ont., Canada N6A 5B7

Received February 10, 1984

This paper is dedicated to Professor Paul de Mayo on the occasion of his 60th birthday

A. SAFARZADEH-AMIRI. Can. J. Chem. **62**, 1895 (1984).

The dynamic structures of [*p*-(dialkylamino)benzylidene]malononitriles have been investigated by ^{1}H nmr, and the kinetic and thermodynamic parameters for the partial rotation of the malononitrile moiety were obtained and those of the dialkylamino group were estimated. The rate of rotation of the above rotors were found to be of the order of $\sim 10^4$ s^{-1} and $\sim 10^7$ s^{-1}, respectively.

A. SAFARZADEH-AMIRI. Can. J. Chem. **62**, 1895 (1984).

Faisant appel à la rmn du ^{1}H, on a étudié les structures dynamiques de [*p*-(dialkylamino)benzylidène]-malonontriles; on a pu déterminer les paramètres thermodynamiques pour la rotation partielle de l'unité malononitrile et l'on a évalué ceux du groupe dialkylamino. On a trouvé que les vitesses de rotation des rotors mentionnés ci-dessus sont respectivement de l'ordre de 10^{-4} s^{-1} et de 10^{-7} s^{-1}.

Introduction

Dynamic nmr spectroscopy is now a standard tool for investigating hindered rotations with activation energies in the range of 20 to 125 kJ/mol. The barrier to rotation is either due to steric hindrance, partial double bond character, or both. Disubstituted benzenes of the type D—Ph—A, where D is an electron donor and A is an electron acceptor moiety (such as *para*-substituted anilines) are examples of molecules where both partial double bond character and steric hindrance could provide an appreciable barrier to rotation around the D—Ph and/or Ph—A bonds (1).

[*p*-*N*,*N*-(Dialkylamino)benzylidene]malononitriles (compounds **1** to **3**) are D—Ph—A type molecules (see Fig. 1) with interesting photophysical properties (2–5). Their absorption and fluorescence emission spectra are solvent polarity dependent and their fluorescence quantum yields are solvent viscosity dependent. These properties make them suitable fluorescent probes to investigate, (*i*) the effective polarity and the microviscosity of micellar environments (5), and (*ii*) the relationship between the limiting conversion and temperature in polymerization processes (4), etc. These molecules, therefore, were of interest to us as possible means of characterizing silica gel surface modification in the presence and absence of additives and as a function of heat treatment.

The fluorescence decay times of compounds **1** to **3** in ordinary solvents were esimated to be 3–10 ps (2), and their fluorescence quantum yields were determined to be ca. (1–3) $\times 10^{-3}$ (2–4). The low quantum yield of emission and fast decay times were attributed to the rotation of the dialkylamino or malononitrile moieties (2–4). Thus, the rotation of the dialkylamino group in compound **1** was estimated to be of the order of 10^{11} s^{-1} in the excited state (2, 3). In order to obtain an estimate of the rate of rotation of both the dialkylamino and the malononitrile moieties, we have investigated the temperature dependence of the dynamic structure of these molecules in the ground state by ^{1}H nmr spectroscopy. The results are presented in this paper. The kinetic parameters of the ground state enable us to draw some conclusions about the excited state dynamics, in so far as the rotation around the partial double bonds D—Ph and Ph—A are concerned. Our conclusion differs from those reached from fluorescence studies.

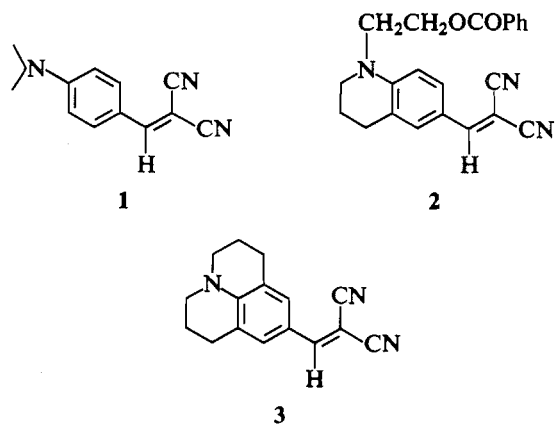

FIG. 1. Structures of [*p*-(dialkylamino)benzylidene]malononitriles.

Experimental

Compounds **1** and **3** were the generous gift of Dr. R. O. Loutfy (Xerox Research Centre, Canada) and were prepared and purified as described before (2). The deuteriated solvents were from Aldrich Chem. Co.

Perdeuteriotetrahydrofuran, THF-d_8, was kept over sodium and was transferred to the nmr tube by distillation and was sealed all in vacuum. Nuclear magnetic resonance spectra were obtained with a Varian XL-100 spectrometer equipped with a variable temperature probe in the pulsed Fourier-transform mode. The temperature was measured with a stationary thermocouple junction which was immersed in toluene in a reference nmr tube. The accuracy of the temperature measurements is estimated to be ca. ±2°C. The kinetic parameters were obtained by line shape analysis using the iterative DNMR 5 program (QCPE No. 365, Indiana University).

Results and discussion

Figure 2 shows the proton nmr spectra at room temperature of compounds **1** and **3** in THF-d_8 and acetone-d_6, respectively. From the signal intensities and by comparison with other systems of similar structure (6), all signals can be readily assigned. The aromatic protons in compound **3** display a single sharp line at room temperature and an AB doublet ($\delta\nu$ = 94 ± 2 Hz) below −66°C. The aromatic protons of compounds **1** are an AB quartet ($\delta\nu$ = 107 ± 2 Hz, J = 9 Hz) at room temperature, each of which splits into a doublet at sufficiently low temperature.

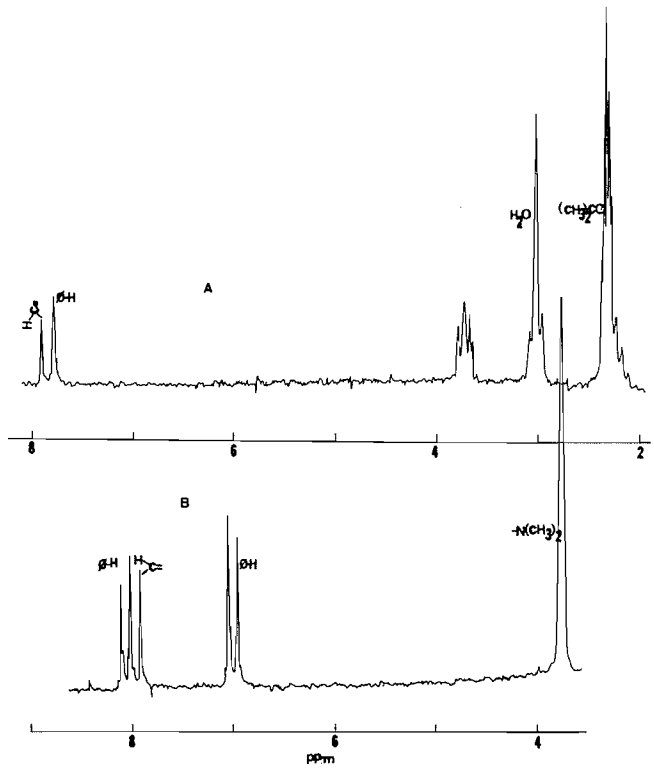

FIG. 2. ^{1}H nmr spectra at room temperature of (*A*) compound **3** in THF-d_8 and (*B*) compound **1** in acetone-d_6.

The protons *ortho* to the amino group become a singlet below ca. −87°C, and then change to a quartet below −90°C, and those *meta* to the amino group become a singlet below about −65°C, an AB doublet below −74°C, and finally become an AB quartet below about −90°C. Figure 3 shows the temperature dependence of the aromatic protons of compounds **1** and **3** in THF-d_8 and acetone-d_6, respectively. Each proton signal becomes narrower as the temperature is decreased. From the temperature dependence of the aromatic proton signals, the rate of rotation of the malononitrile moieties are obtained over a temperature range of 25−30°C. From these rates and the absolute rate theory for internal rotation (7), the enthalpies and the entropies of activation are obtained. These kinetic parameters are given in Table 1 and the plots of ln (k/T) vs. $1/T$, where k is the rate of rotation and T is the absolute temperature, are shown in Fig. 4. Also given in Table 1 are the chemical shifts of the non-equivalent aromatic protons, the coalescence temperatures (T_c), the free energies of activation at T_c, and the rates of rotation at 25°C.

It is appropriate at this point to discuss the nature of the barrier to rotation in these compounds. The conformational energies of compounds **1**−**3** are expected to be dependent on the dihedral angle, θ, between the aromatic ring and the malononitrile moiety. This dependence is due to the steric interaction between the aromatic hydrogens *ortho* to the malononitrile and the nitrile groups, as well as the partial double bond character of the Ph—A bond. Both CNDO/2 MO and *ab initio* calculations performed on (4-hydroxybenzylidene)malononitrile (HBMN) and its anionic form (6) predict that: (*i*) the planar conformation (θ = 0) is quite unstable with a large energy barrier to rotation, (*ii*) the twisted structure (θ = 40−60° depending on the nature of calculation) is the most stable conformation, and (*iii*) there is a small energy barrier for rotating beyond θ = 90° for the malononitrile moiety and that this barrier is higher for anionic HBMN than the neutral molecule. On the basis of these data, it is not unreasonable to assume that compounds **1**−**3** would also have an energy profile similar to HBMN, although with different energy barriers (at θ = 90°) and with a stable twisted conformation. The observed barrier in compounds **1** and **3**, therefore, are due to partial rotation of the malononitrile moiety beyond 90°, because of the partial double bond character of the Ph—A bond.

The ionization potential of the dialkylamino group in compound **1** is greater than that in compound **3** and the ground state dipole moments of compounds **1** and **3** are 8.7 D and 9.4 D (14), respectively. Thus, one would expect that the Ph—A bonds in compound **3** would possess more double bond character as compared with compound **1** and consequently, the barrier to partial rotation in compound **3** should be greater than that in compound **1**. However, the data given in Table 1 show that the enthalpies and free energies (at the coalescence temperature) of activation are the same for both compounds within experimental error. The use of two solvents with different viscosities can not account for the apparent equality of the barriers to partial rotation in the two compounds because the temperature coefficients of the two solvents are very similar (905 K for THF and 935 K for acetone obtained from the variation of viscosity with temperature (8, 9)). Association of solvent−solute molecules could account for the apparent equality of the enthalpies and free energies of activation at T_T (10). This effect is also ruled out on the basis of the following observations. The ($S_1 \leftarrow S_0$) absorption and the ($S_1 \rightarrow S_0$) fluorescence band shapes in benzene do not change with addition of polar solvents (such as methanol). Addition of polar solvents leads only to hypsochromic and bathochromic shifts of the absorption and emissions spectra, respectively, without affecting their band widths (3). The same effect is also observed in solvents of increasing polarity. Lowering the temperature would cause a hypsochromic shift of the fluorescence spectra without affecting the band width (2). The difference in the activation parameters of the two compounds is, therefore, expected to be small and could not be measured by this technique.

Measurements of the barrier to rotation (or rate of rotation) of the dimethylamino group in compound **1** was not possible. However, it is not expected to differ much from that of the malononitrile moiety. A lower limit of this barrier could be established from the available literature data. The barrier to rotation of the dimethylamino group in *p*-dimethylaminobenzonitrile (DMABN) was obtained from the data provided by Mackenzie and MacNicol (11) and is ~30.5 kJ/mol (at 133 K). The rate of rotation of the dimethylamino moiety in DMABN is of the order of $\sim 3 \times 10^7$ s^{-1} at 25°C. The dipole moment of DMABN is 7.6 ± 0.2 D (12), which is 1.1 D smaller than that of compound **1**. Thus the barrier to rotation of the dimethylamino moiety in **1** is expected to be greater than 31 kJ/mol (at 133 K) and its rate of rotation smaller than 3×10^7 s^{-1} at 25°C.

The barrier to partial rotation for the malononitrile moiety of (3,5-di-*tert*-butyl-4-hydroxybenzylidene)malononitrile (DBHBMN) is 31.3 ± 1.0 kJ/mol at T_c (in diethyl-d_{10}-ether) (6*c*) and for the vinyl moiety of styrene in both gas and solution phase is ~7.44 ± 0.08 kJ/mol at room temperature (13). The temperature coefficients of diethylether (834 K) (9) is slightly smaller than those of THF and acetone, and may account for part of the excess activation energies of the hindered rotation in compounds **1** and **3** as compared to their phenolic counterpart. However, the bulk of the energy differences could be ac-

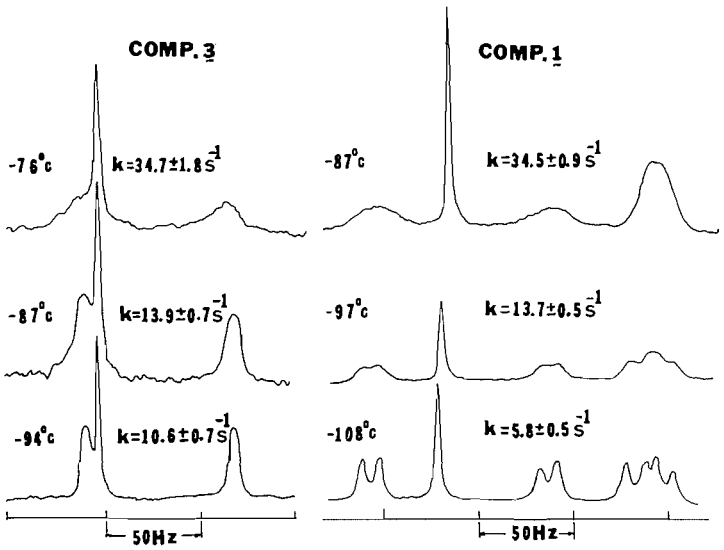

FIG. 3. ^{1}H nmr spectra of compounds **1** and **3** as a function of temperature.

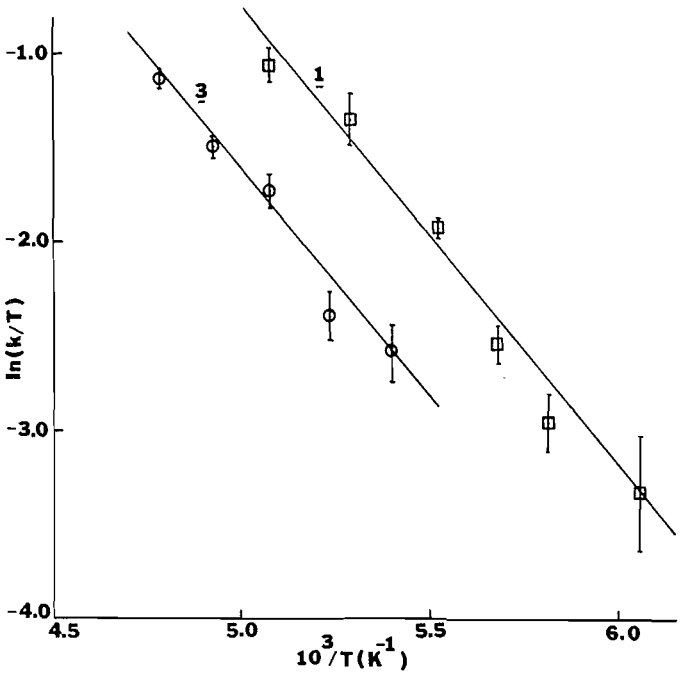

FIG. 4. Eyring plots for the process of internal rotation about the Ph—A bond.

counted for by considering the differences in their dipole moments. The dipole moment of DBHBMN is not known, but it can be estimated from the data provided by Kuder *et al.* (14) and was found to lie in the range of $6.74\ D < \mu_g < 7.54\ D$. This is lower than the corresponding values for compounds **1** and **3** by at least 1.2−1.9 D. Differences of ca. 5 kJ/mol for free energies of activation between the *p*-methoxy- and *p*-dimethylamino-substituent of both benzaldehyde and acetophenone have been reported (10). The much lower barrier to rotation for the vinyl group of styrene as compared to those of the malononitrile moieties in compounds **1** and **3** is due to the negligible dipole moment of styrene (13).

The dipole moments of compounds **1** and **3** in the first excited electronic state are approximately three and two times (2) greater than the ground state values, respectively. The highly polarized excited state was assigned to an intramolecular charge-transfer state (2). This assignment is consistent with the observed spectral properties of these compounds as a function of solvent polarity and electron donating ability of the dialkylamino groups. Further support is obtained by comparison with other systems of similar properties (15). It was pointed out earlier that the barrier to partial rotation around the Ph—A bond is due to the partial double bond character (i.e. resonance structure **II** in Scheme 1) of the Ph—A bond (10). It is also established that the first excited electronic states of compounds **1**−**3** are of intramolecular charge-transfer type. Thus, the resonance form **II** is expected to be the major contributor to the

For personal use only.

excited-state electronic charge distribution (16, 17), amongst other possible resonance structures. Other factors being the same, the barrier to rotation is a measure of the double bond character. On the basis of the foregoing discussion, the double bond character of the D—Ph and Ph—A bonds in the first electronic excited state is greater than the ground state in compounds **1** and **3**. Therefore, both the malononitrile and the dimethylamino moieties are expected to have a rate of rotation at room temperature less than ca. 10^4 s^{-1} and $\sim 10^7$ s^{-1}, respectively. These results are in vast disagreement with those estimated from the fluorescences studies (3, 5). The discrepancy lies in the interpretation of the fluorescence data and the mechanism of the excited state relaxation of these compounds. The decay dynamics of these compounds will be the subject of a forthcoming paper.

In conclusion, we have been able to obtain the kinetic and thermodynamic parameters of the malononitrile moiety in compounds **1** and **3** and to estimate the corresponding values for the dimethylamino group in compound **1**. It was shown that the rate of rotation of the dimethylamino and malononitrile moieties are $\leq 10^7$ s^{-1} and $\sim 10^4$ s^{-1} in the ground state, respectively, and should be less than those in the first electronic excited state.

NOTE ADDED IN PROOF: The σ_p^- value for the malononitrile moiety is 1.20 (18). Using this value of σ_p^- and the data provided in ref. 11, we obtain $\Delta G^{\ddagger} \simeq 33.0$ kJ mol^{-1} and $k_r \simeq 10^7$ s^{-1} (at 25°C).

Acknowledgements

The author would like to thank Professor Paul de Mayo for his encouragements, critical and constructive comments and allowing me to carry out this work, Dr. S. K. Wong for helpful discussions, Dr. R. O. Loutfy for samples of the compounds used in this work, and Mr. A. Draper for some of the spectral measurements. Last but not least he thanks Professor W. F. Reynolds for his constructive criticism.

Stereoselectivity of C(3)-methylation of camphor and derivatives

JOHN H. HUTCHINSON AND THOMAS MONEY
Department of Chemistry, The University of British Columbia, Vancouver, B.C., Canada V6T 1Y6

Received March 2, 1984

This paper is dedicated to Professor Paul de Mayo on the occasion of his 60th birthday

JOHN H. HUTCHINSON and THOMAS MONEY. Can. J. Chem. **62**, 1899 (1984).

Contrary to general expectations, kinetic methylation of camphor, 9-bromocamphor, or 9,10-dibromocamphor produces the 3-*exo*-methyl derivative as the major product.

JOHN H. HUTCHINSON et THOMAS MONEY. Can. J. Chem. **62**, 1899 (1984).

Contrairement à ce qui est généralement attendu, la méthylation cinétique du camphre, du bromo-9 camphre ou dibromo-9,10 camphre conduit principalement au dérivé méthylé en position 3-*exo*.

[Traduit par le journal]

For personal use only.

In connection with our general investigations (1) on the use of (+)-camphor (**1**) or (−)-camphor as chiral starting materials in the enantiospecific synthesis of terpenoids and steroids, we required reaction conditions which would enable us to alkylate camphor and its halogen derivatives stereoselectively at the C(3)-position. Although the literature contains many examples of camphor alkylation the stereochemistry of the C(3)-monoalkyl derivatives is not clearly described (2−6). In our initial investigations we established that addition of (+)-camphor (**1**) to LDA (1 mole equivalent) in THF 0°C followed by treatment with excess methyl iodide for 30 min provided a product (70−85% yield) which was shown by nmr (400 MHz) and capillary glc to be a mixture (~4:1)[1] of 3-*exo*-methylcamphor (**2**) (δ 1.20, d, J = 7.5 Hz)[2] and 3-*endo*-methylcamphor (**3**) (δ 1.06, d, J = 7.5 Hz).[2] Flash chromatography (7) on silica provided pure (+)-3-*exo*-methylcamphor (**2**) as a crystalline solid (mp 50−54°C; δ ($CDCl_3$, 400 MHz), 0.85 (3H, s), 0.90 (3H, s), 0.93 (3H, s), 1.21 (3H, d, J = 7.5 Hz), 1.85 (1H, d, J = 4 Hz), 1.95 (1H, q, J = 7.5 Hz). Treatment of the kinetic mixture (4:1) of 3-*exo*-methylcamphor (**2**) and its C(3)-*endo*-epimer (**3**) with refluxing sodium methoxide in methanol or acetic acid/hydrochloric acid provides a mixture (9:1 by 270 MHz nmr) in which 3-*endo*-methylcamphor (**3**) is the major steroisomer. Subsequent low temperature crystallization of this product from pentane provided pure (+)-3-*endo*-methylcamphor (**3**) as a crystalline solid (mp 37−39°C; δ ($CDCl_3$, 400 MHz), 0.87 (3H, s), 0.90 (3H, s), 1.00 (3H, s), 1.06 (3H, d, J = 7.5 Hz), 1.98 (1H, t, J = 4.5 Hz), 2.48 (1H, pentet[3] J = 4.5 Hz and 7.5 Hz)). The above information leads us to conclude that previous reports (2−6) on the synthesis of (+)-3-methylcamphor (mp 38−39°C) refer to the 3-*endo*-methyl isomer (**3**) prepared under thermodynamic conditions.

C(3)-Methylation of (+)-9-bromocamphor (**4**) (8) can also be accomplished in a similar fashion to provide a product whose nmr spectrum (400 MHz) and capillary glc indicated that it was a mixture of 9-bromo-3-*exo*-methylcamphor (**5**) and 9-bromo-3-*endo*-methylcamphor (**6**)[4] in a ratio of ~1.7:1.

[1]Since some equilibration could have occurred during "kinetic methylation" the true kinetic ratio may be greater than observed.

[2]Comparable assignments have been reported for 3-*exo*- and 3-*endo*-methyl groups in norcamphor derivatives (9−11).

[3]Partially coalesced quartet of doublets.

[4]This compound can also be prepared in 50% yield by treating 3-*endo*-methylcamphor (**3**) with bromine in chlorosulfonic acid for 24 hours (13).

SCHEME 2

Subsequent equilibration with HCl/HOAc provided the *endo*-methyl isomer (**6**) as a major component of the mixture (*endo* : *exo* ~10 : 1). When (+)-9,10-dibromocamphor (**7**) was methylated (LDA/MeI) as described, above the product was a mixture (~1.7 : 1) of 9,10-dibromo-3-*exo*-methylcamphor (**8**) and the 3-*endo*-methyl epimer (**9**).[5] Equilibration with acid (HCl/HOAc) provided 9,10-dibromo-3-*endo*-methylcamphor (**9**) as the major product (*endo* : *exo* = ~6 : 1). The latter compound is an important intermediate in our current efforts to develop a stereoselective route from camphor to the steroids.

In contrast to the kinetic *exo*-stereoselectivity described above, C(3)-methylation of 3-methylcamphor displays *endo*-stereoselectivity, i.e., sequential treatment of 3-methylcamphor, (**2**) + (**3**), with LDA in THF at 0°C followed by addition of trideuteromethyl iodide provided a product (~60% yield) which was shown, by ^1H nmr spectroscopy, to be a mixture (~3.4 : 1) of 3-*exo*-methyl-3-*endo*-trideuteromethylcamphor (**10**) and its epimer (**11**).[6]

Other investigations have shown that bicyclo[2,2,1]heptan-2-one (norcamphor) (**13**) (9) and 5,6-dehydroketones (**14***a*,*b*) (10*a*,*b*) undergo kinetic *exo*-methylation while the related 5,6-dehydroketones (**15***a*–*e*) (10*c*–*e*, 11), having a C(7)-*syn*-methyl group, undergo exclusive *endo*-methylation (Scheme 2). In addition, it has been reported that 5-ketobornyl methyl ether (**16**) can be converted exclusively to the corresponding 3-*exo*-allyl derivative (12).

The combined results described above indicate that kinetic *endo*-methylation of bicyclo[2,2,1]heptan-2-ones will occur if (*a*) the compound has a C(7)-*syn* alkyl group and lacks C(5)/C(6)-*endo* hydrogens or (*b*) the compounds has C(7)-*syn* and C(3) alkyl substituents. Correspondingly kinetic C(3)-*exo* alkylation will be preferred if the bicyclic ketone has a C(7)-*syn* alkyl group and C(5)/C(6)-*endo* hydrogens or substituents. When the difference in stereoselectivity between the methylation of camphor (**1**) and the 5,6-dehydro-10-norcamphor derivatives (**15***a*–*e*) (Scheme 2) is considered in conjunction with their structural differences, we are prompted to conclude that the presence or absence of the C(5)-*endo*-hydrogen is a significant factor in determining the stereochemical outcome of reactions of the corresponding enolate ions. The presence of an *endo* methoxy substituent in the epicamphor derivate (**16**) (12) presumably plays a similar but more effective role in directing the electrophilic reagent (in this case allylbromide) to the *exo* position.

While we do not have a convincing explanation for the kinetic stereoselectivity revealed by our investigations it is relevant to note that the reaction of camphor enol trimethylsilyl ether (**17**) with bromine (13), Eschenmoser's salt (15), ozone (16, 17),[7] or diborane (18, 19) provides a considerable proportion of the thermodynamically less stable C(3)-*exo*-product (cf. Scheme 3). The exception is the reaction with singlet oxygen (**17**) which provides a mixture (94 : 6) of 3-*endo*-trimethylsilylperoxycamphor and its C(3)-epimer. It has been suggested (17) that the difference in stereoselectivity between the reactions with ozone and singlet oxygen is due to the fact that O_3 reacts, in a polar fashion, at the end of the enolate double bond while $^1O_2$ adds to the least hindered *endo* face in a [2+2] cycloaddition process.

Experimental

Unless otherwise stated, the following are implied. Melting points (mp) were determined on a Kofler micro heating stage and are uncorrected. The capillary glc analysis was carried out on a Hewlett-Packard 5880A gas chromatograph employing a flame ionization detector and using a W.C.O.T. narrow bore (0.21 mm × 50 m or 12 m) Carbowax 20 M column. Helium was used as the carrier gas. The 270 MHz ^1H nmr spectra were recorded on a 270 MHz instrument constructed from a Bruker console, a Nicolet computer Model 293 A with a Diablo disk and a 270 MHz superconducting magnet supplied by Oxford Instruments. The 400 MHz ^1H spectra were recorded on a Bruker WH-400 instrument. Signal positions are given in delta (δ) with tetramethylsilane (TMS) as internal reference and signal multiplicity and integrated areas are indicated in parentheses. The solvent used was deuteriochloroform. Infrared spectra were recorded on a Perkin-Elmer 137 spectrophotometer and optical rotations were measured using a Perkin-Elmer model 141 polarimeter. Low resolution mass spectra were obtained using a Varian/Mat model CH4B mass spectrometer and high resolution mass spectra using a Kratos MS50 instrument. Microanalysis were performed by Mr. P. Borda, Microanalytical Laboratory, University of British Columbia, Vancouver.

*(+)-3-*Exo-*methylcamphor (2)*

(+)-Camphor (4.0 g, 26 mmol) was added to a freshly prepared solution of lithium diisopropylamide (25 mmol) in dry THF (30 mL) at 0°C under argon and the enolate allowed to form over 0.5 h. Methyl iodide (6.5 mL, 105 mmol) was then added and the reaction stirred for a further 0.5 h before being quenched with 1 *N* hydrochloric acid. The mixture was extracted with ether and the combined ether extracts washed with water three times and dried over anhydrous magnesium sulphate. Removal of the solvent yielded a pale yellow oil (4.28 g) which partially crystallized on standing. Capillary glc analysis of the

[5]By analogy with the reported conversion of 3,9-dibromocamphor to 3,9,10-tribromocamphor (1*a*) we attempted to prepare 9,10-dibromo-3-*endo*-methylcamphor (**9**) by treating 9-bromo-3-*endo*-methylcamphor (**6**) with bromine in chlorosulfonic acid. However, under these reaction conditions, **6** is isomerized to 9-bromo-6-*endo*-methylisofenchone (**12***a*) which undergoes partial bromination to furnish an additional compound, presumably structure **12***b*. Structure **12***a* has been confirmed by X-ray crystallographic analysis (14).

[6]The structural assignments for **10** and **11** were made by comparing the C(3)-methyl chemical shift with that observed for 3-*endo*- and 3-*exo*-methylcamphor.

[7]Reference 16 describes reaction of camphor *tert*-butyldimethylsilyl enol ether with ozone.

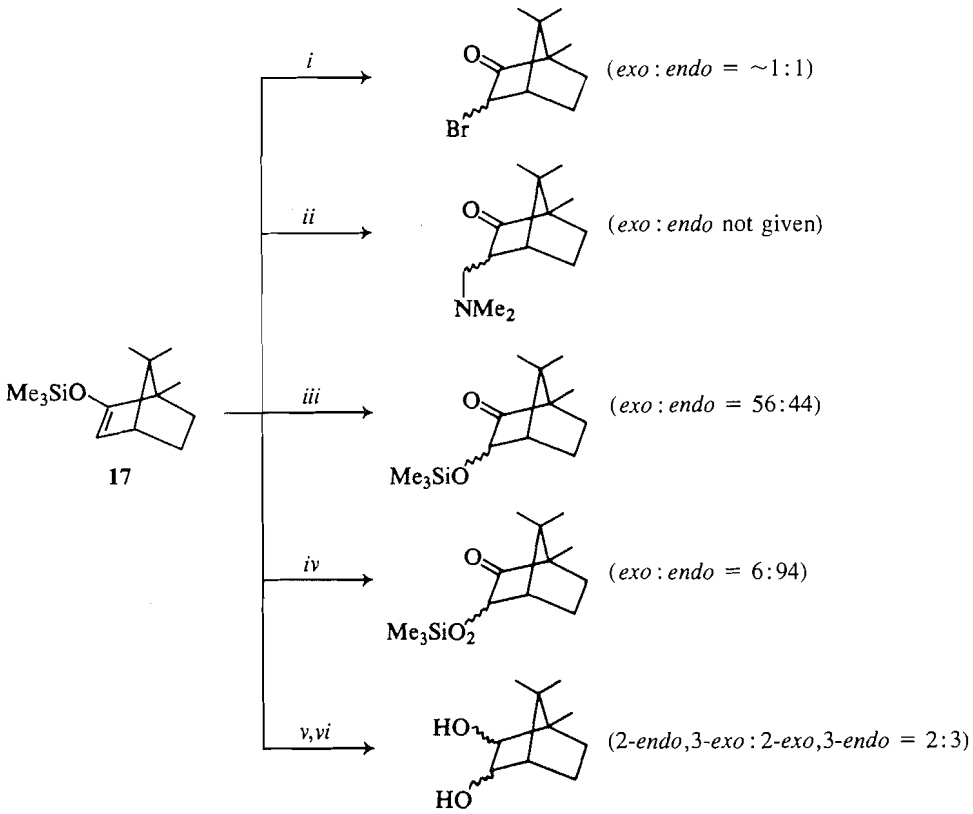

SCHEME 3. *i*, Br_2:dioxane/C_5H_5N; *ii*, $Me_2N^+ = CH_2I^-/CH_2Cl_2$; *iii*, O_3/CH_2Cl_2/MeOH; *iv*, $^1O_2$/CCl_4; *v*, BH_3:THF; *vi*, H_2O_2/HO^-.

crude product indicated the ratio of 3-*exo*- to 3-*endo*-methylcamphor to be in the range 3.4−3.8:1.

Purification by column chromatography (silica gel; petroleum ether) (30−60°C)/(ether 50:1) afforded starting material (0.603 g) and a mixture of 3-*exo*- and 3-*endo*-methylcamphor (3.16 g 72%; 85% yield based on recovered starting material). Nuclear magnetic resonance (400 MHz) and capillary glc analysis showed the ratio of 3-*exo*- to 3-*endo*-methylcamphor to be 3.4−3.8:1.

A sample of pure 3-*exo*-methylcamphor (**2**) was obtained by re-chromatographing the above mixture using the same conditions. The fractions containing pure 3-*exo*-methylcamphor (monitored by capillary glc) were combined and sublimed to provide 3-*exo*-methylcamphor (**2**) as a white crystalline solid, mp 50−54°C: $[\alpha]_D$ +71.4° (*c*, 0.57, MeOH); ν_{max} ($CHCl_3$) 2970, 1740 cm^{-1}; δ ($CDCl_3$, 400 MHz), 0.85 (3H, s), 0.90 (3H, s), 0.93 (3H, s), 1.21 (3H, d, J = 7.5 Hz), 1.85 (1H, d, J = 4 Hz), 1.96 (1H, q, J = 7.5 Hz); *m/e* (relative intensity): 166 (M^+, 32), 123 (40), 108 (51), 95 (100), 83 (83); M.W. calcd. for $C_{11}H_{18}O$: 166.1358; found (high resolution mass spectrometry): 166.1358. *Anal.* calcd. for $C_{11}H_{18}O$: C 79.47, H 10.91; found; C 79.50, H 10.86.

*(+)-3-*Endo-*methylcamphor (3)*

A mixture of 3-*exo*- and 3-*endo*-methylcamphor (239 mg) in glacial acetic acid/conc. hydrochloric acid (2 mL, 9:1) was heated at 80°C for 6 h. The solution was diluted with water, extracted with ether, and the extract washed with sodium bicarbonate solution and then with water. Removal of the dried solvent yielded a white crystalline product (231 mg, 97%). Capillary glc and 270 MHz nmr showed that the ratio of 3-*exo*- to 3-*endo*-methylcamphor was ~1:9.

Low temperature crystallization (CO_2/acetone bath) from pentane provided pure 3-*endo*-methylcamphor (**3**), mp 37−39°C lit. (5) mp 38−39°C; $[\alpha]_D$ +25.4° (*c*, 2.5, MeOH), lit. (5) $[\alpha]_D$ +27.3° (*c*, 10.0, EtOH); ν_{max} ($CHCl_3$): 2975, 1735 cm^{-1} nmr ($CDCl_3$. 400 MHz), δ 0.87 (3H, s), 0.90 (3H, s), 1.00 (3H, s), 1.06 (3H, d, J = 7.5 Hz), 1.98 (1H, t, J = 4.5 Hz), 2.48 (1H, pentet,[3] J = 4.5 Hz and 7.5 Hz); *m/e* (relative intensity): 166 (M^+, 37), 123 (37), 108 (63), 95 (100), 83 (70). M.W. calcd. for $C_{11}H_{18}O$: 166.1358; found (high resolution mass spectrometry): 166.1362. *Anal.* calcd. for $C_{11}H_{18}O$: C 79.47, H 10.91; found: C 79.50, H 10.88.

*(+)-9-Bromo-3-*exo-*methylcamphor (5)*

(+)-9-Bromocamphor (**4**) (2.0 g, 8.7 mmol) was added to a freshly prepared solution of lithium diisopropylamide (8.2 mmol) in dry THF (9.8 mL) at 0°C under argon and the enolate allowed to form over 0.5 h. Methyl iodide (2.2 mL, 34.6 mmol) was then added and the reaction stirred for a further 0.5 h before being quenched with 1 *N* hydrochloric acid. After the normal work up, removal of solvent yielded a pale yellow solid (2.04 g).

Purification by column chromatography (silica gel; petroleum ether) (30−60°C)/(ether 50:1)) afforded starting material (0.471 g) and 9-bromo-3-methylcamphor (1.49 g, 70%; 92% based on recovered starting material) as a mixture of epimers. 400 MHz nmr of this product showed the ratio of the 3-*exo*- to 3-*endo*-methyl epimer to be ~1.7:1. Repeated recrystallization of the mixture of epimers from petroleum ether (30−60°C) afforded pure (+)-9-bromo-3-*exo*-methylcamphor (**5**), mp 115−116°C; $[\alpha]_D$ +158.4°C (*c*, 0.125, CH_2Cl_2); ν_{max} ($CHCl_3$): 2980, 1745 cm^{-1}; δ ($CDCl_3$, 270 MHz), δ 0.96 (3H, s), 1.02 (3H, s), 1.23 (3H, d, J = 8 Hz), 2.04 (1H, q, J = 8 Hz), 2.25 (1H, d, J = 4 Hz), 3.19 (d) and 3.57 (d) (2H, AB quartet, J = 10 Hz); *m/e* (relative intensity); 244/246 (M^+, 15), 186/188 (38), 165 (15), 137 (59), 123 (29), 107 (100), 95 (100); M.W. calcd. for $C_{11}H_{17}OBr$: 246.0442/244.0462; found (high resolution mass spectrometry): 246.0449/244.0456. *Anal.* calcd. for $C_{11}H_{17}OBr$: C 53.89, H 6.99, Br 32.59; found: C 53.87, H 6.98, Br 32.48.

*(+)-9-Bromo-3-*endo-*methylcamphor (6)*

An epimeric mixture of (+)-9-bromo-3-methylcamphor (1.03 g) in glacial acetic acid (19 mL) and conc. hydrochloric acid (1 mL) was heated at 80°C for 16 h. Work up in the usual way provided white solid (1.02 g, 99%) which was shown by nmr (400 MHz) to be a mixture of 3-*exo*- to 3-*endo*-methyl epimers in the ratio ~1:9.5.

The major isomer, (+)-9-bromo-3-*endo*-methylcamphor (identical

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.5 on 09/06/12

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.5 on 09/06/12
For personal use only.

to an authentic sample[4]) displayed the following characteristics: mp 104–106°C; $[\alpha]_D$ +69.4° (*c*, 0.39, MeOH); ν_{max} ($CHCl_3$): 2975, 1740 cm^{-1}; nmr ($CDCl_3$, 400 MHz), δ 0.92 (3H, s), 1.02 (3H, s), 1.07 (3H, d, *J* = 7.0 Hz), 2.37 (1H, t, *J* = 4 Hz), 2.45 (1H, pentet,[3] *J* = 4.0 and 7.0 Hz), 3.23 (d) and 3.65 (d) (2H, AB quartet, *J* = 10 Hz); *m/e* (relative intensity): 244/246 (M^+, 38), 186/188 (100), 165 (36). M.W. calcd. for $C_{11}H_{17}OBr$: 246.0442/244.0462; found (high resolution mass spectrometry): 246.0444/244.0466. *Anal.* calcd. for $C_{11}H_{17}OBr$: C 53.89, H 6.99, Br 32.59; found: C 53.66, H 7.12, Br 32.38.

*(+)-9,10-Dibromo-3-*exo*-methylcamphor (8)*

(+)-9,10-Dibromocamphor (**7**) (0.908 g, 2.9 mmol) was added to a freshly prepared solution of lithium diisopropylamide (2.78 mmol) in THF (3.3 mL) at 0°C under argon. Methyl iodide (0.72 mL, 11.6 mmol) was added after 15 min and the reaction quenched with 1 *N* hydrochloric acid after a further 0.5 h. Work up in the usual fashion yielded a pale yellow solid (875 mg) which, on column chromatography (silica gel; petroleum ether) (30–60°C)/(ether 50:1), gave starting material (512 mg) and an epimeric mixture of (+)-9,10-dibromo-3-methylcamphor (318 mg, 34%). Capillary glc and 400 MHz nmr showed the ratio of 3-*exo*- to 3-*endo*-methyl epimers to be ~1.7:1. The major isomer, (+)-9,10-dibromo-3-*exo*-methylcamphor (**8**), was obtained after repeated recrystallization from methanol, mp 84–85.5°C; $[\alpha]_D$ +102.0° (*c*, 0.20, CH_2Cl_2); ν_{max} ($CHCl_3$): 2975, 1740 cm^{-1}; δ ($CDCl_3$, 400 MHz), δ 1.11 (3H, s), 1.24 (3H, d, *J* = 8 Hz), 2.09 (1H, q, *J* = 8 Hz), δ 2.34 (1H, d, *J* = 4 Hz), 3.45 (d) and 3.67 (d) (2H, AB quartet, *J* = 12 Hz), 3.49 (d) and 3.63 (d) (2H, AB quartet, *J* = 10 Hz); *m/e* (relative intensity): 243/245 (M^+ – Br, 40), 235/237 (23), 163 (17), 135 (100); M.W. calcd. for $C_{11}H_{16}OBr_2$: 325.9527/323.9547/321.9567; found (high resolution mass spectrometry): 325.9540/323.9572/321.9566. *Anal.* calcd. for $C_{11}H_{16}OBr_2$: C 40.77, H 4.98, Br 49.31; found: C 40.56, H 5.04, Br 49.20.

*(+)-9,10-Dibromo-3-*endo*-methylcamphor (9)*

An epimeric mixture of (+)-9,10-dibromo-3-methylcamphor (1.49 g) in glacial acetic acid (27 mL) and conc. hydrochloric acid (3 mL) was heated at 80°C for 16 h. Work up in the usual way afforded a crystalline product (1.34 g, 90%) which was shown by capillary glc and 400 MHz nmr, to be a mixture of 3-*exo*- to 3-*endo*-methyl epimers in the ratio of ~1:6.

Repeated crystallization from methanol afforded pure (+)-9,10-dibromo-3-*endo*-methylcamphor (**9**), mp 62.5–63°C; $[\alpha]_D$ +46.7° (*c*, 0.30, CH_2Cl_2); ν_{max} ($CHCl_3$) 2980, 1735 cm^{-1}; δ ($CDCl_3$, 400 MHz), δ 1.11 (3H, d, *J* = 8 Hz), 1.15 (3H, s), 2.43–2.54 (2H, m), 4.44 (d) and 4.66 (d) (2H, AB quartet, *J* = 12 Hz), 4.60 (d) and 4.74 (d) (2H, AB quartet, *J* = 10 Hz). *m/e* (relative intensity): 322/324/326 (M^+, 0.8/1.7/0.6), 243/245 (44), 215/217 (24), 163 (19), 135 (100); M.W. calcd. for $C_{11}H_{16}OBr_2$: 325.9527/323.9547/321.9567; found (high resolution mass spectrometry): 325.9512/323.9558/321.9562. *Anal.* calcd. for $C_{11}H_{16}OBr_2$: C 40.77, H 4.98, Br 49.31; found: C 40.65, H 4.92, Br 49.23.

3-Methyl-3-trideuteriomethylcamphor (10 + 11)

(+)-3-Methylcamphor (0.693 g, 4.17 mmol) dissolved in dry THF (9 mL) was added to a freshly prepared solution of lithium diisopropylamide (5.13 mmol) in THF (9 mL) at 0°C under argon. After 45 min d_3-methyl iodide (0.68 mL, 10.7 mmol) was added and the reaction quenched with 1 *N* hydrochloric acid 1 h later. Work up in the usual way afforded a yellow oil (0.737 g) which, on column chromatography (silica gel; petroleum ether (30–60°C)/(ether 50:1)), gave starting material (0.24 g) and 3-methyl-3-trideuteriomethylcamphor, 0.476 g (62%; 95% based on recovered starting material), as a mixture of epimers (**10** + **11**). 400 MHz nmr showed the ratio of the 3-*exo*- (**10**) to 3-*endo*-methyl (**11**) epimers to be ~3.4:1. ν_{max} ($CHCl_3$) 1740 cm^{-1}. M.W. calcd. for $C_{12}H_{17}D_3O$: 183.1703; found (high resolution mass spectrometry): 183.1703; δ ($CDCl_3$, 400 MHz), 0.91 (3H, s), 1.00 (3H, s), 1.03 (0.7H, s, C(3)-*endo*-methyl), 1.19 (2.3H, s, C(3)-*exo*-methyl).

The vapour phase thermolyses at 400°C of three *gem*-dimethylated 2-cyclohexenones **1, 2**, and **3** were studied to determine the effect of blocking the direct conversion of these substrates to aromatic systems. In all three reactions it is proposed the major pathway taken was enolization followed by elimination of methane to yield a substituted phenol. This elimination reaction proceeded more readily with **2** than with either **1** or **3**, and HMO calculations which are consistent with this order of reactivity are presented. A general mechanistic scheme is proposed to account for the products formed and it is necessary to include a [1,5] sigmatropic methyl shift to explain the formation of at least one product in each thermolysis.

G. L. LANGE, M. J. NYE, V. A. PEREIRA, V. STRATTON et T. YURKEVICH. Can. J. Chem. **62**, 1903 (1984).

Dans le but de déterminer l'effet de bloquage de la transformation directe de ces substrats en produits aromatiques, on a étudié la thermolyse en phase vapeur à 400°C de trois cyclohexène-2 ones *gem*-diméthylées (**1**, **2**, et **3**). Dans chacune de ces trois réactions, on suggère que la voie de réaction principale est une énolisation suivie par une élimination de méthane qui conduit à un phénol substitué. Cette réaction d'élimination se produit plus facilement avec **2** qu'avec soit **1** ou **3**; on présente des calculs d'orbitales moléculaires suivant Hückel qui sont en accord avec cet ordre de réactivité. On propose un schéma général pour le mécanisme de la réaction qui tient compte des produits formés; il est nécessaire d'introduire une transposition sigmatropique [1,5] du méthyle pour expliquer la formation d'au moins un produit dans chaque thermolyse.

In a previous study we investigated the vapour phase thermolyses at 400°C of a number of mono- and di-alkylated 2-cyclohexenones and showed that the major products were alkylated benzenes and phenols (1). The formation of these products can be explained by enolization of the carbonyl group followed by [1,5] sigmatropic hydrogen shifts and/or loss of a molecule of H_2O, H_2, or RH. We felt it would be of interest to examine the thermolysis of a series of *gem*-dimethylated 2-cyclohexenones where the conversion to the aromatic ring was blocked by these substituents without the involvement of [1,5] sigmatropic methyl shifts or elimination of methane. It was also of interest to discover if the thermolyses of these cyclohexenones bear any resemblance to the thermolysis of 5,5-dimethyl-1,3-cyclohexadiene in which Spangler and Boles (2) observed both [1,5] sigmatropic shifts and eliminations. The three compounds 4,4-dimethyl- (**1**), 3,5,5-trimethyl- (**2**), and 3,6-6-trimethyl-2-cyclohexenone (**3**) were chosen for our study because they have *gem*-dimethyl substitution at the 4-, 5-, and 6-positions, respectively. In this paper we report our results of the thermolysis of these substrates, suggest a general mechanism for the formation of the products, and offer an explanation for the relative reactivities of the three compounds.

Experimental

Instrumentation

Infrared (ir) spectra were recorded on a Beckman Acculab 6 spectrophotometer, proton magnetic resonance (nmr) spectra on a Varian T-60 spectrometer with TMS ($\delta = 0.0$) as internal standard, and mass spectra on a VG Micromass 7070F spectrometer coupled to a gas chromatography unit (gc–ms) equipped with a 6 ft × 0.25 in. 5% Carbowax 20M column.

Gas chromatographic (gc) analyses and collections were performed on an Aerograph Autoprep Model A-700 using the following columns: column A, 8 ft × 0.25 in. 20% Carbowax 20M on Chromosorb W-HP A/W DMCS 80/100 mesh; column B, 6 ft × 0.25 in. 20% DEGS on Chromosorb W 60/80 mesh; column C, 6 ft × 0.25 in. 20% OV-1 on Chromosorb W-HP 80/100 mesh. In the analysis of the products the areas of all peaks on the gc tracings were determined by triangulation and the areas were not corrected for differences in the thermal response of the detector. The values reported are an average of at least two runs for each substrate.

*Preparation of substrates **1**, **2**, and **3** and gas chromatography standards*

4,4-Dimethyl-2-cyclohexenone (**1**) was prepared by acid-catalyzed annelation of isobutyraldehyde and methyl vinyl ketone (3), 3,5,5-trimethyl-2-cyclohexenone (isophorone) (**2**) was commercially available, and 3,6,6-trimethyl-2-cyclohexenone (**3**) was prepared from **1** by reaction with methyllithium followed by oxidation with pyridinium chlorochromate (4).

The following is a list of the compounds which were available in our laboratory and were used for gc comparison with the thermolysis products: benzene; toluene; *o*-, *m*-, and *p*-xylenes; 1,3,5-(mesitylene), 1,2,3- and 1,2,4-trimethylbenzenes; phenol; *o*-, *m*-, and *p*-cresols; 2,3-, 2,4-, 2,5-, 2,6-, 3,4-, and 3,5-dimethylphenols; 2,3,5-, 2,3,6-, and 2,4,6-trimethylphenols.

Thermolyses and product identification

The thermolyses were conducted at 400 ± 2°C for 20 h in an evacuated (<0.02 Torr) 650-mL Pyrex reactor similar to that previously described (5). The substrates **1, 2**, and **3** were purified by vacuum distillation immediately prior to reaction, and the sample size was 0.40 g for each run. The products were distilled into a cold finger cooled in liquid N_2 and then were analyzed by gc. The crude distillation recoveries were always high as very little tar formation was evident in any of the thermolyses. The gc peaks were identified by coincident retentions with known samples on two or three columns, by the peak enhancement method, by gc–ms analysis, and in some instances by preparative gc collection and spectral analysis. No attempt was made to analyze for gaseous products such as methane. Schemes 1, 2, and 3 give a detailed product distribution obtained as described above for thermolysis of the three substrates. In the gc tracings of each of the thermolyses there were a number of small unknown peaks and these have been included in the unidentified products total.

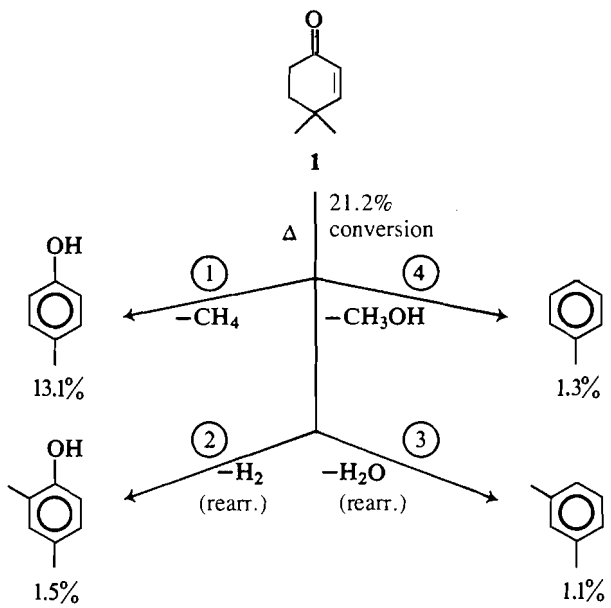
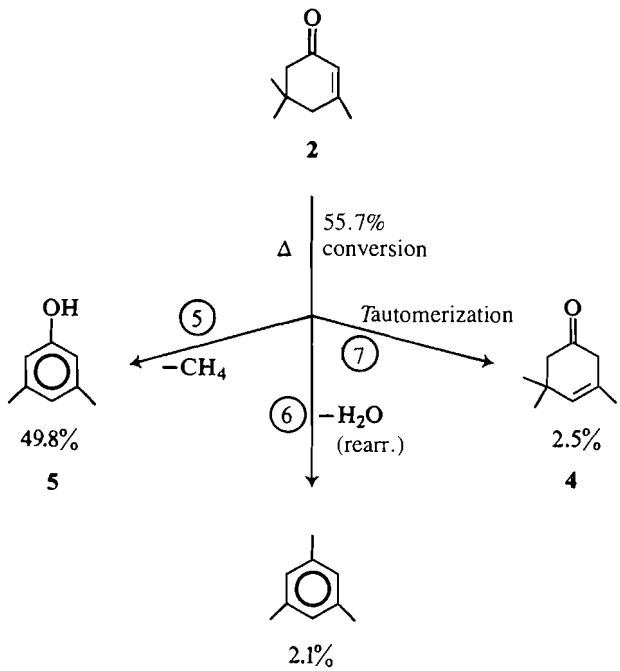
[2]Revision received December 6, 1983.



Unidentified products = 4.2%

SCHEME 1



Unidentified products = 1.3%

SCHEME 2

Gas chromatographic collection of peaks

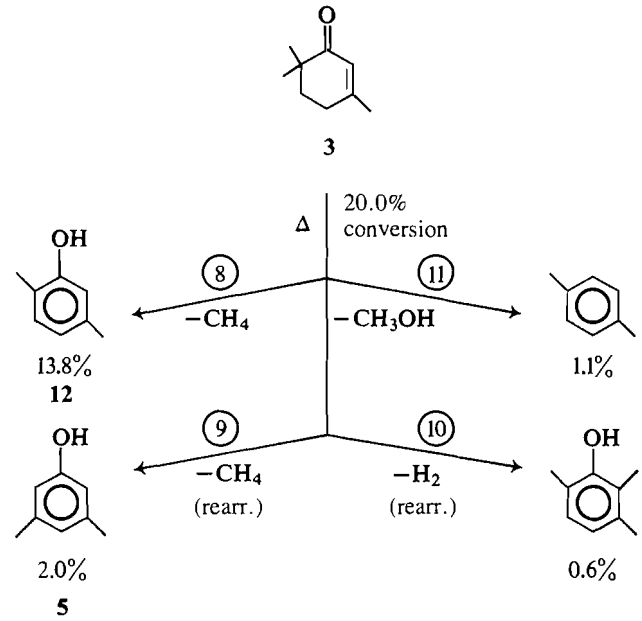
Following is a list of the peaks that were collected by preparative gc (column A) and an indication of how each peak was analyzed.

Thermolysis of 1

The major peak eluted after **1** was collected and its ir and nmr spectra suggested it was a mixture. This peak was resolved into its two components, *p*-cresol and 2,4-dimethylphenol, on column C.

Thermolysis of 2

The peak between mesitylene and **2** was collected and found to have spectral data consistent with 3,5,5-trimethyl-3-cyclohexenone (**4**): ir(CCl_4): 1715 cm^{-1}; nmr was the same as that previously reported (6); mass spectrum *m/e* (rel. int.): 138 (M^+, 64), 123(59), 96(100), 95(66), 71(79). The major peak appearing considerably after **2** was also collected and found to have mp and ir and mass spectra identical to an authentic sample of 3,5-dimethylphenol (**5**).



Unidentified products = 2.5%

SCHEME 3

Thermolysis of 3

All three phenolic products had retention times considerably longer than **3** and the major of these was isolated and identified as 2,5-dimethylphenol (**12**) by comparison of its mp and its ir and mass spectra with an authentic sample. A second phenol, which appeared at a longer retention time than **12**, had properties identical to 3,5-dimethylphenol (**5**). A minor peak which appeared as a shoulder on the front side of the peak for **12** was not isolated but its mass spectrum and gc behaviour unambiguously identified it as 2,3,6-trimethylphenol. On polar gc columns such as columns A and B it was found that phenols with methyl substituents at the 2- or 2- and 6-positions were eluted before other isomers, presumably because these alkyl groups reduced or shielded the interaction of the phenolic hydroxyl group with the polar gc phase. This explains why 2,3,6-trimethylphenol elutes before either of the dimethylphenols (**5** or **12**) and also why **12** elutes before **5**. Of course, on a non-polar column such as C, which separates on the basis of boiling points, the trimethylphenols are eluted *after* the dimethylphenols.

Molecular orbital calculations

The standard HMO method with Jacobian optimization by computer (7) was used to calculate the relative energies of the various species. Regarding coulomb integrals, α was used for all carbon atoms and $\alpha + 2$ for OH groups, and the resonance integrals (β') of partial σ or π bonds were calculated from the partial bond order (p) using the very approximate empirical relation $\beta' = \beta\sqrt{p}$. Further explanation is given in the discussion.

Results and discussion

Schemes 1, 2, and 3 summarize the results of the thermolyses of **1**, **2**, and **3** under vapour phase conditions at 400°C for 20 hours. Along with an arrow directed to each product in these schemes is a circled number and an indication of the nature of the reaction involved in the formation of that product. The types of reactions observed in this work and in our previous study (1) are listed below together with examples of each.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.6 on 09/06/12

Type of reaction	No. of reaction (or reference)
(*i*) Isomerization	(7), (1)
(*ii*) Loss of H_2	(1)
(*iii*) Loss of H_2 with rearrangement	(2), (3), (10)
(*iv*) Loss of RH	(1), (5), (18), (1)
(*v*) Loss of RH with rearrangement	(9)
(*vi*) Loss of H_2O	(1)
(*vii*) Loss of H_2O with rearrangement	(3), (6)
(viii) Loss of ROH	(11)
(*ix*) Loss of ROH with rearrangement	(4)

These nine reaction types involve only three reaction processes: *isomerization*, *rearrangement*, and *elimination*. In order to arrive at an overall reaction mechanism let us consider each of these processes in turn. *Isomerization* was observed in the conversion of **2** to the unconjugated enone **4** and was also seen in the thermolysis of 3-methyl-2-cyclohexenone (1). The generally accepted mechanism of isomerization of unsaturated ketones involves the formation of enol intermediates in acid or base catalyzed reactions, and the same route may be involved in the thermal isomerizations, with the enolization occurring on the surface of the glass vessel (5). The postulation of surface involvement avoids the objection that Woodward–Hoffmann rules (8) prohibit facile unimolecular enolization, and the observation that addition of glass chips increases the rate of the thermolysis of cyclohexenones (1) lends experimental support to this proposal. Regarding the *rearrangement* process, enolization of substrates **1**, **2**, or **3** leads to a substituted 1,3-cyclohexadiene, a system which is known to undergo [1,5] sigmatropic shifts of hydrogen or alkyl groups below 400°C (2), and hence a mechanism for the rearrangements is apparent. Concerning the *elimination* process, consideration of the Woodward–Hoffmann symmetry rules (8) is a key issue. Although reactions violating these rules cannot be dismissed, we took the view that if Woodward–Hoffmann allowed routes are available they will be of lower energy and hence preferred. Also, we have assumed these transformations to be intramolecular as no products of intermolecular disproportionation (i.e., transfer of H_2, CH_4, H_2O, or CH_3OH) were observed. 1,3-Cyclohexadienes are formally allowed to give benzenes via a Möbius [2 + 2] elimination which involves inversion of one of the two centres being eliminated. As a check of this statement, the Hückel orbital energies were calculated for different points along the reaction coordinate (9) for the [2 + 2] elimination and these are shown in Diagram 1(a) for the mechanism involving one inversion and in 1(b) for no inversions. A high energy process involving crossover of HOMO and LUMO orbitals is clearly seen for 1(b). Hence 1,2-elimination of CH_4, H_2O, or CH_3OH is allowed whereas loss of H_2 by a unimolecular process is prohibited since the *s* orbital of hydrogen is not capable of inversion. In order to explain the observed loss of H_2 without violating the Woodward–Hoffmann rules, it is necessary for the reaction to proceed via 1,4-cyclohexadiene precursors, which can easily arise from observed nonconjugated enones (e.g. **4**) by enolization. This type of reaction has been observed to occur for 1,4-cyclohexadiene itself below 400°C (10), and is presumed to proceed by the allowed Hückel [2 + 4] elimination mechanism.

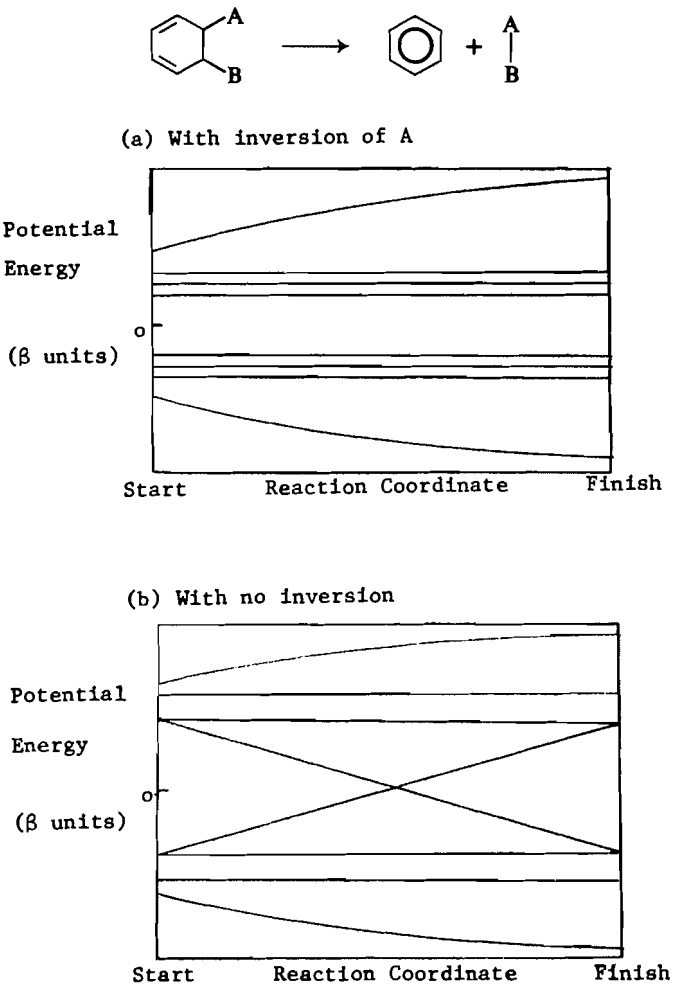

DIAGRAM 1
Orbital following diagram for reaction

Combining the above concepts leads to the general mechanism for thermolysis of cyclohexenones shown in Scheme 4. This mechanistic scheme explains the occurrence of all products reported in this paper (except for the formation of **5** from **3**) and in the previous paper from this laboratory (1), and most of the products predicted using this scheme are actually observed. Furthermore, in most cases the formation of non-observed products involves more steps, particularly methyl shifts, than the observed products involve, and may therefore be formed at lower rates. An illustration of the above argument is the observation of loss of methanol from **3** (three steps with no methyl shifts based on Scheme 4) in contrast to the non-observation of loss of water from **3** (five steps with one methyl shift). In the case of **2**, all of the thermolysis products predicted by the scheme were observed. The product distributions are best explained if the relative rates of reaction are: elimination > hydrogen shifts > methyl shifts (a comparison of hydrogen vs. methyl shifts has been reported (11)).

With respect to alternative mechanisms, a free radical process was ruled out since intermolecular products were not ob-

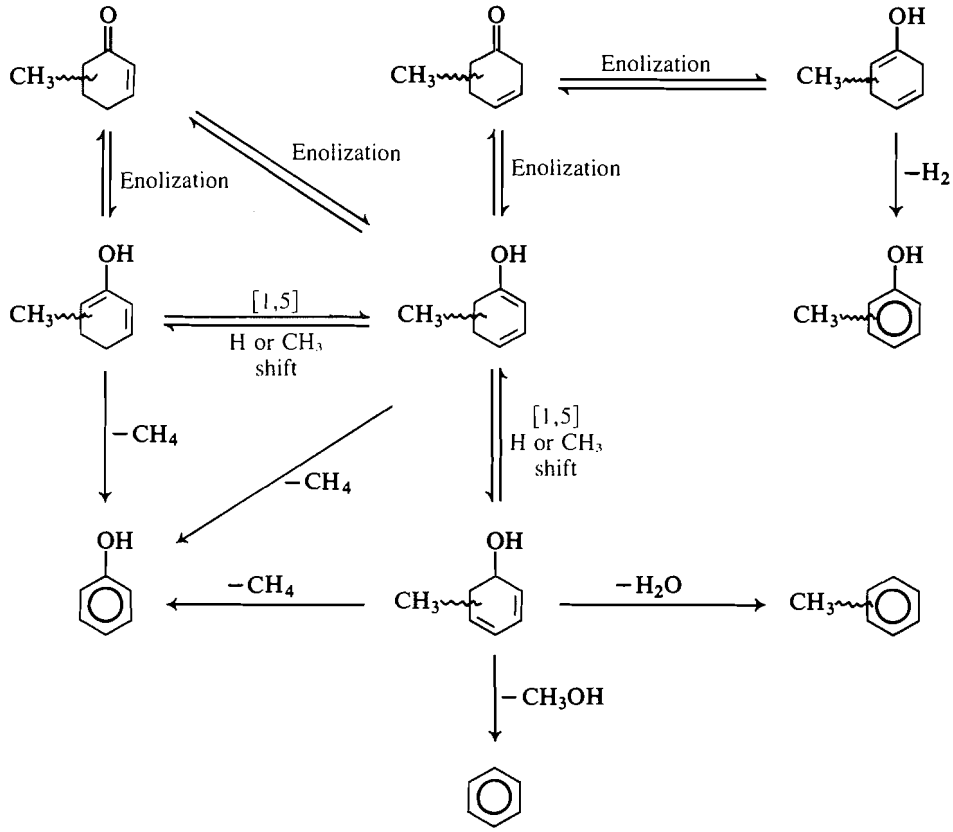
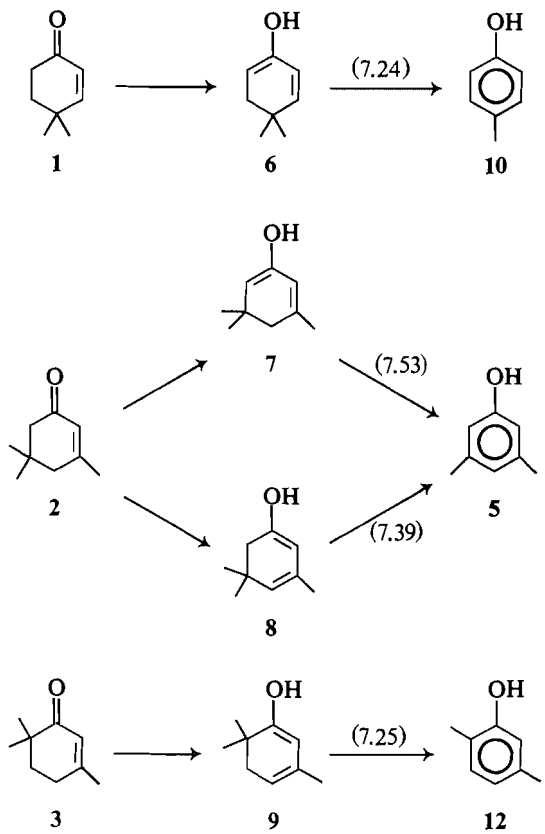


SCHEME 4

served. Schiess and Dinkel (12) have proposed a mechanism involving an electrocyclic ring opening followed by a sigmatropic hydrogen shift and then an electrocyclic ring closing to explain the rearrangements of certain *gem*-disubstituted 1,3-cyclohexadienes, but this mechanism would not explain the formation of many of our products including **5**. Spangler and Boles' paper on *gem*-dialkylated 1,3-cyclohexadienes (2) proposes a mechanism involving [1,5] shifts analogous to ours, and their observed rearrangements and eliminations of CH_4 and H_2 are entirely explicable using Scheme 4.

One distinctive feature of the three thermolyses is the significantly greater conversion of **2** to products (55.7%) as compared with **1** and **3** (21.2 and 20.0%, respectively). Also, in each instance the major product (49.8% for **2** vs. 13.1 and 13.8% for **1** and **3**, respectively) was formed by loss of CH_4, so an explanation was sought for this preferred elimination pathway. The proposed mechanisms for loss of CH_4 based on Scheme 4 are shown in Scheme 5, including two alternatives for the transformation of **2**. The glass chips experiment (1) suggests that enolization of the starting ketones is the rate determining step. If this is entirely true, it would simply be necessary to explain why **2** enolizes faster than **1** or **3**, but it is not apparent why this should be the case. In fact, it would seem more likely that either **2** and **3** would enolize the fastest as they *both* form linearly conjugated dienols (**8** and **9**) or, alternatively, **1** and **2** would enolize the fastest as *both* form cross-conjugated dienols (**6** and **7**). A solution to this problem may be that the second step, the [2 + 2] Möbius elimination, is of similar rate to the enolization and may contribute to the rate determination. In order to test this theory, Hückel Molecular Orbital (HMO) calculations were carried out to estimate the relative energies of the transition states for the elimination reactions of **1**, **2**, and **3**, based on



SCHEME 5. Routes for conversion of enones to phenols (relative stabilization energies of transition states in β units for loss of methane are shown in brackets).

13 (radical pair) **14** (concerted)

15 (1 : 1 blend of **13** and **14**)

SCHEME 6. Transition states for elimination of methane from 5-methyl-1,3-cyclohexadiene showing bond orders.

the reasonable assumption (13) that this step is a blend of a purely free radical mechanism involving the transition state **13** and a purely concerted mechanism involving the transition state **14** (for the calculations a 1 : 1 blend was chosen). Stated in another way, this means that the C—C bond is pictured as breaking ahead of the C—H bond. The resulting transition state is depicted as **15** (Scheme 6), and this is the basic structure for the transition state envisioned during elimination of methane from **6**, **7**, **8**, and **9**, except that the location of the hydroxyl substituents is different for each of these. The relative energies of each of these transition states were calculated, and the results are given in Scheme 5. The larger values indicate higher stabilization, lower energy barrier, and hence faster rate of reaction, so that the relative rates of formation of the products should be **5** > **10** and **12**, which is compatible with our observations. Appreciable alteration of the bond orders in the transition state does not affect the relative calculated energies sufficiently to nullify the argument. An alternative explanation suggested by a referee for the faster thermolysis of **2** relative to **1** and **3** is that reaction of **2** is faster because of the presence of two product-forming enols.

In conclusion, thermolysis of *gem*-dimethylated 2-cyclohexenones **1**, **2**, and **3** at 400°C yields as the major product in each case a phenol, which is formed by loss of methane from the corresponding enol tautomer. The elimination reaction proceeds to a much greater extent with enone **2** than with **1** or **3** and HMO calculations of the relative energies of the transition states in going from the intermediate enols to the phenols predict this order of reactivity. [1,5] Sigmatropic methyl shifts from the enols account for at least one product in each thermolysis. The formation of all products isolated (except for **5** from **3**) may be explained by assuming three processes are operative: enolizations, [1,5] sigmatropic shifts, and eliminations (Scheme 4).

Received December 16, 1983

This paper is dedicated to Professor Paul de Mayo on the occasion of his 60th birthday

ROBERT M. CORY, LESTER P. J. BURTON, DOMINIC M. T. CHAN, FRED R. MCLAREN, MARY H. RASTALL, and RICHARD M. RENNEBOOG. Can. J. Chem. **62**, 1908 (1984).

Insertion of a carbon atom into a methyl cyclohexene, leading in a single synthetic step to a bicyclo[3.2.1.$0^{2,7}$]octane by carbene addition to the double bond and carbene insertion into a methyl C—H bond, has been accomplished by treating the cyclohexene with carbon tetrabromide and methyllithium at low temperatures. This new bicycloannulation method has been employed in a total synthesis of ishwarane (**1**), the naturally occurring parent hydrocarbon of the ishwarane class of tetracyclic sesquiterpenes. Although this reaction was not successful with various possible precursors of ishwarone (**2**), this natural product was prepared in low yield by a two-step version of the carbon atom insertion bicycloannulation (CAIB) procedure involving addition of bromoform-derived dibromocarbene to the octalone (**5**) followed by treatment of the resulting dibromocyclopropane (**56**) with methyllithium. The same two-step sequence was also successful in the first synthesis of norishwarane (**20**), the hydrocarbon comprising the bare ring system of the ishwarane sesquiterpenoids. The Diels–Alder synthesis used in the preparation of the octalin precursor (**18**) of norishwarane could not be used for the terpenes themselves because of the lack of dienophilic reactivity of the required cyclohexenone (**7**). A regioselective Diels–Alder equivalent sequence was therefore developed, consisting of conjugate addition of lithium di(3-methyl-3-butenyl)cuprate (**42**) to 2,3,4-trimethylcyclohex-2-en-1-one (**7**), epoxidation, base-catalyzed cyclization of the resulting epoxide (**47**) to a mixture of primary and tertiary alcohols (**50** and **49**, respectively), and dehydration of **49** to give **5**. In the case of ishwarane, the octalin precursor (**62**) was synthesized by conjugate addition of lithium dimethylcuprate to octalone **59**, addition of methyl magnesium bromide to the resulting decalone (**60**) to give octalol **61**, and dehydration.

ROBERT M. CORY, LESTER P. J. BURTON, DOMINIC M. T. CHAN, FRED R. MCLAREN, MARY H. RASTALL et RICHARD M. RENNEBOOG. Can. J. Chem. **62**, 1908 (1984).

En faisant réagir le cyclohexène avec le tétrabromure de carbone et le méthyllithium à basse température, on a réalisé l'insertion d'un atome de carbone dans le méthylcyclohexène; on a ainsi obtenu en une seule étape le bicyclo[3.2.1.$0^{2,7}$]octane par l'addition de carbène sur la double liaison et par une insertion de carbène dans une liaison C—H du méthyle. On a utilisée cette nouvelle méthode de bicycloannellation dans une synthèse totale de l'ishwarane (**1**), l'hydrocarbure naturel parent des sesquiterpènes tétracycliques de la classe de l'ishwarane. Bien que cette réaction n'aie pas pu être appliquée avec succès à divers précurseurs possibles de l'ishwarone (**2**), on a préparé ce produit naturel avec un faible rendement en faisant appel à une version en deux étapes de la méthode de bicycloannellation par insertion d'un atome de carbone (BIAC) impliquant une addition d'un dibromocarbène, provenant du bromoforme, sur l'octalone (**5**), puis une réaction du dibromocyclopropane (**56**) qui en résulte avec du méthyllithium. On a aussi utilisé cette méthode avec succès pour réaliser la première synthèse du norishwarane (**20**), l'hydrocarbure comportant le système cyclique de base du sesquiterpène ishwarane. Dû au faible caractère diènophile de la cyclohexènone (**7**) requise, on ne peut pas se servir de la synthèse de Diels–Alder pour la synthèse des terpènes eux-mêmes, même si cette synthèse peut être utilisée pour la préparation de l'octaline (**18**) précurseur du norishwarane. On a donc mis au point une série de réactions régiosélectives équivalentes à la réaction de Diels–Alder qui comprend une addition conjuguée du di(méthyl-3 butényl-3) cuprate de lithium (**42**) sur la triméthyl-2,3,4 cyclohexène-2 one-1 (**7**), une époxydation, une cyclisation, catalysée par les bases, de l'époxyde (**47**) formé qui conduit à un mélange d'alcools primaire et tertiaire (respectivement **50** et **49**) et finalement une déshydratation de l'alcool **49** permet d'aboutir au composé **5**. Dans le cas de l'ishwarane, on a préparé son précurseur, l'octaline (**62**), par une addition conjuguée de diméthylcuprate de lithium sur l'octalone **59**, suivie d'une addition de bromure de méthylmagnésium sur la décalone obtenue (**60**) qui permet d'obtenir l'octalol (**61**) dont la déshydration permet d'accéder au produit désiré.

Introduction

Ishwarane (**1**) (1), a tetracyclic sesquiterpene, is found in an interesting variety of tropical plants which seem to have little else in common: *Aristolochia indica* L. (Aristolochiaceae)[2] (2), *Cymbopetalum penduliflorum* (Dunal) Baill. (Annonaceae)[3] (3), and *Bixa orellana* L. (Bixaceae)[4] (7). A small family of

[1]Author to whom correspondence should be addressed.

[2]This is the so-called Indian birthwort, the roots of which have been used for centuries in India as a folk remedy for snake and insect bites and a variety of other complaints. The name ishwarane for the sesquiterpene is derived from the Kanada name for this plant, *ishwari beru* (4). The extract of the roots has recently been found to have potent contraceptive properties, and the active principles have been isolated and characterized (5).

[3]The "ear flower" of the ancient peoples of Mexico, still used as a spice for flavouring food and beverages in Guatemala, is obtained from this tree, which occurs in the mountains of Guatemala and southern Mexico (6).

[4]The lipstick tree, cultivated widely throughout the tropical and subtropical areas of the world, is the source of annatto, an important natural food dye used in the colouration of butter, cheese, and margarine. In ancient times the Aztecs added it (along with the flavouring agent from *C. penduliflorum*) to the world's first chocolate beverage (*xocoatl*) to colour it red (15).

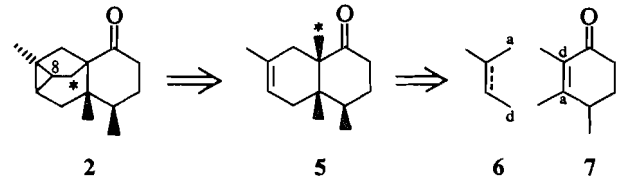
sesquiterpenoids,[5] of which ishwarane is the parent hydrocarbon, comprises ishwarone (**2**) (8) and ishwarol (**3**) (9) (both congeners of ishwarane in *A. indica*), and 3-oxoishwarane (**4**) (10) (from *A. debillis*). Because of the unusual polycyclic structure of these molecules, they have attracted the attention of a number of synthetic organic chemists, and total syntheses of ishwarane (11–13), ishwarone (13, 14), and ishwarol (13) have been reported. We now wish to describe in detail our own total syntheses of ishwarane and ishwarone.[6]

From a synthetic standpoint, the strategically central structural moiety of the ishwarane terpenes is the tricyclo-[3.2.1.$0^{2,7}$]octane system containing rings B, C, and D.[7] Our plan (Scheme 1) was based on the retrosynthetic removal of a single carbon atom (C-8) from that portion of the ishwarone framework,[8] resulting in a significant simplification of structure and leaving behind an octalone system (**5**), the construction of which would, on the most naive level, be a simple matter using the Diels–Alder strategy. Unfortunately, however, on the basis of the lack of dienophilic reactivity observed (19) for 2,3-dimethylcyclohexenone, cyclohexenone **7** would not be expected to react at all with isoprene.[9] Nonetheless, the ready availability of cyclohexenone **7** led us to propose an *equivalent* of the Diels–Alder synthesis employing a *polarized* isoprene synthon of type **6**, having either an intact or a latent double bond (*vide infra*).[10]

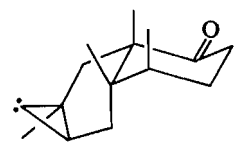
Provided an efficient procedure could be devised for the insertion of the carbon atom into the octalone **5** in the desired fashion, one would have in hand an extremely concise route to a fairly complex terpene structure. In the absence of functional groups other than the olefin and carbonyl in **5** with which to activate this intermediate toward attack by an appropriate reagent, the only viable approach along these lines (Scheme 2) is via a carbon atom equivalent capable of acting as a dicarbene synthon, sequentially adding to the olefin to form the cyclopropane (ring D) and inserting into a C—H bond of a specific methyl group (pro-C-9). In order for this to be of synthetic



2 **5** **6** **7**

SCHEME 1. Retrosynthetic analysis of ishwarone.

utility, the normal preference for attack on the less hindered convex face of the *cis* octalone (25) must obtain so that the reagent adds stereoselectively to the β side of the olefin, and, equally important, intramolecular insertion of the intermediate cyclopropylidene (**8**) must occur regioselectively, so that little or no insertion into the other angular methyl group or any of the ring C—H bonds takes place. The latter condition was expected to be fulfilled by the fact that conformation **8** should be the preferred one, due to an unfavourable 1,3-diaxial interaction between methyl groups in the other chair conformer (**9**),[11] and by the fact that in conformer **8** the carbene and the



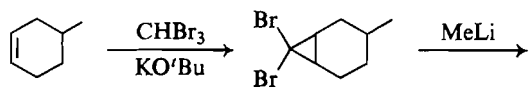
9

methyl into which insertion is desired are within bonding distance of each other.[12] In spite of these encouraging considerations, however, it was apparent from the outset that a source of naked carbon atoms woud not be synthetically useful for this purpose in light of the high reactivity and low selectivity of this simplest of all organic reactive intermediates (29). We therefore sought a less direct means of accomplishing the desired carbon atom insertion.

Results and discussion

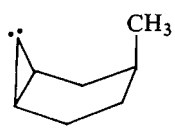
Model studies

As we began our work in this area, we were spurred on by the important observation by Paquette *et al.* (30) that applica-



10 **11**

12 **13** **14**



15

[5]For a review of the chemistry of the eremophilane sesquiterpenes, including the ishwarane family, see ref. 16.

[6]For preliminary accounts of portions of this work see refs. 11, 14, and 17. An attempted, but unsuccessful, synthesis of ishwarone has also been reported (18).

[7]This ring system is also present in another sesquiterpene, cycloseychellene (20), and in the trachylobane (21) and helifulvane (22) series of diterpenoids. For an alternative approach to the rapid construction of this system, see our synthesis of trachyloban-19-oic acid (23) and ref. 12*a*.

[8]Since ishwarone has been converted to ishwarane by Wolff–Kishner reduction (8*a*), any synthesis of the former constitutes a formal synthesis of the latter.

[9]We have confirmed this under a variety of conditions.

[10]For annulations via a related conjunctive reagent see ref. 24.

[11]This interaction costs approximately 3.7 kcal mol^{-1} (15.5 kJ mol^{-1}) (26).

[12]Interestingly, this plan would have been rejected by the computer-assisted design program LHASA on the grounds that a bond to a cyclopropane ring is not a strategic one (27). For a related violation of this rule see ref. 28.

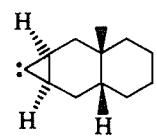
SCHEME 3. Synthesis of norishwarane.

tion of Moore's bicyclobutane synthesis (31)[13] to 4-methylcyclohexene (**10**) via the dibromocyclopropanes **11** led not only to the expected ring C—H insertion products **12** and **13**, but also to the parent tricyclo[3.2.1.$0^{2,7}$]octane (**14**), resulting from *methyl* C—H insertion, surprisingly, as the major product.[14] Furthermore, it was deduced on the basis of mass balance considerations that this tricyclooctane must have been the *exclusive* product from debromination of *cis*-**11**, while the other two products were derived only from the *trans* dibromide. Methyl insertion was explained by involving kinetic control, in which the *proximity* of the carbenoid[15] and methyl groups in the *cis* axial conformer **15** outweighed all other factors, including the greater nucleophilicity of secondary C—H bonds[16]. Thus, our prediction that ring C—H insertion should not be a problem seemed to be confirmed by this experiment, and carbon atom insertion via a dibromocyclopropane intermediate appeared to be a viable approach to the ishwarane structure.

Accordingly, a model study (Scheme 3) was carried out to test the accommodation of the Moore sequence to the requirement that initial attack on the octalone **5** must be on its β face. In this we followed the plan of Scheme 1, where all structures were simplified by lacking one or more methyl groups. Thus, when the *cis* octalin **18**, prepared by Lewis acid-catalyzed Diels–Alder reaction (19) of 2-methylcyclohex-2-enone (**16**) with 1,3-butadiene followed by Wolff–Kishner reduction of the resulting octalone **17**, was treated with bromoform and aqueous sodium hydroxide under phase-transfer conditions (35), the dibromocarbene adduct **19** was produced in 48% yield. Contrary to expectations, however, this appeared to be a mixture of α and β diastereomers by gas chromatographic analysis, which showed two overlapping peaks in a ratio of about 2:1,[17] in spite of the fact that only one methyl singlet was visible in the ^{1}H nmr spectrum. On reaction of this mixture with methyllithium at −10°C there were obtained three debromination products in a total yield of 77%, of which two could not be separated from each other. Although the latter material could not be completely characterized due to the fact that it was a mixture, the presence of two methyl singlets at δ 0.77 and 0.91 (ca. 2:1 ratio) in its ^{1}H nmr spectrum indicated that *both* of the components had resulted from *ring* C—H insertion rather than methyl C—H insertion. The third product, however, which was produced in 28% yield, lacked a singlet in its ^{1}H nmr spectrum, as expected for methyl insertion, and this compound was therefore assigned the structure of the desired product, norishwarane (**20**), possessing the complete ring system of ishwarane itself (**1**) but divested of the three methyl groups of the natural product.[18] As in the case of the Paquette study (30), mass balance considerations led us to tentatively propose that while the two ring C—H insertion products were derived only from the undesired α dibromocarbene adduct (concave attack on octalin **18**), norishwarane (**20**) was the exclusive product from intramolecular insertion of cyclopropylidene (**21**) (corresponding to **8**). These conclusions, on



21

the other hand, would appear to imply that the preferred attack of dibromocarbene on octalin **18** is from the (presumably more hindered) concave face of the olefin, a seemingly untenable inference. For this reason, it is believed that at least a portion of one or both of the ring C—H insertion products was derived from the β dibromocyclopropane. Possible factors responsible for this observation, which contradicts Paquette's findings for the simpler 4-methylcyclohexene adduct, are discussed below.

Whatever the causes of the mixed results of this model study, the production of even some of the desired norishwarane was at least encouraging, and a means of inserting the carbon atom in a *single* step, as opposed to the two-step sequence required

[13]For recent applications of this procedure see ref. 32.

[14]Other instances of preferential insertion into primary C—H bonds have been reported (33). This amounts, in this case, to insertion of the cyclopropylidene into a δ C—H bond. For other examples see ref. 34.

[15]For recent work on the elucidation of the nature of this intermediate see ref. 36. For a review of the chemistry of lithium halocarbenoids see ref. 37.

[16]For a recent discussion of the selectivity of the insertion of cyclopropylidenes into C—H bonds see ref. 38.

[17]A 0.2 in × 10 ft copper column packed with 10% SE-30 on Diatoport S was employed at 200°C.

[18]For further proof of this structure by ^{13}C nmr see ref. 39.

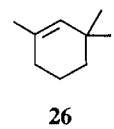
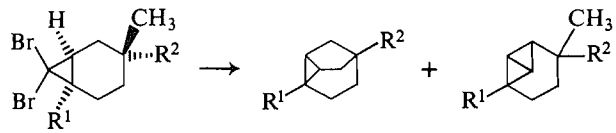
SCHEME 4. Carbon atominsertion model study.

by the Moore procedure, was devised to avoid the isolation and purification of the heat sensitive dibromocyclopropane intermediate. Our one-step method is based on the Skattelbøl allene synthesis (40)[19], in which an olefin is converted to the corresponding allene by insertion of a carbon atom between the two carbons of the olefinic double bond. This procedure involves treatment of the olefin with carbon tetrabromide and excess methyllithium at low temperatures, thus generating dibromocarbene by lithium–bromine exchange[20] and converting the resulting dibromocyclopropane *in situ* to the cyclopropylidine, which collapses to the allene. Encouraged by the fact that an excess of cyclohexene had previously been found to give a low yield of the corresponding dibromocyclopropane on reaction with carbon tetrabromide and *n*-butyllithium at −50°C (42), we chose to investigate the use of carbon tetrabromide as a carbon atom equivalent for insertion into cyclohexenes in a single step. In order to allow for the maximum chance of success, a cyclohexene having a methyl substituent on at least one of the olefinic carbons was desirable in view of the higher reactivity toward dichlorocarbene offered by methylcyclohexene over cyclohexene itself (43)[21]. Such a substrate would have the added advantage of having an olefinic group identical in structure to that of the proposed ishwarone precursor, **5**. Furthermore, a cyclohexene having *two* methyl groups at the 4-position, so that *cis* and *trans* dibromocyclopropanes are not possible, would not suffer from any lack of stereoselectivity of the dibromocarbene addition, as do addition to 4-methylcyclohexene and, apparently, octalin **18**.

Accordingly, the substrate chosen for the model study of the one-step carbon atom insertion was 1,5,5-trimethylcyclohexene (**22**), which was obtainable (47) from isophorone as an 85:15 mixture with 1,3,3-trimethylcyclohexene (**26**).[22] Initially, the Moore two-step procedure was tested on this material to serve as a benchmark for comparison with the proposed one-step method (Scheme 4). Thus, treatment of the olefinic mixture of **22** and **26** with bromoform and aqueous base under the same conditions as for octalin **18** (35) gave a 45% yield of dibromocyclopropane **23**, while the more hindered olefin **26** was recovered unchanged. Debromination of **23** with methyllithium at −10°C produced not one product, as expected on the basis of Paquette's earlier report on 4-methylcyclohexene, but *two* tricyclic hydrocarbons: only a 21% yield of the expected tricyclo[3.2.1.$0^{2,7}$]octane **24** and a surprising 33% yield of the



26



27 28 29

(**a**, R' = Me, R^2 = H; **b**, R' = H, R^2 = Me; **c**, R' = Me, R^2 = Me)

tricyclo[4.1.0.$0^{2,7}$]heptane **25** (yields determined by gas chromatographic analysis).[23] Paquette and Taylor (49) have since found similar behavior for the dibromocyclopropanes **27**, which provide mixtures of tricyclooctane **28** and tricycloheptane **29** on reaction with methyllithium. Both we (50) and these authors have ascribed this increased tendency toward *ring* C—H insertion (vis-à-vis *cis*-**11**) at least partly to a ponderal effect in which additional substituents slow down the rate of conformational interconversion of the intermediate cyclopropylidenes to such an extent that ring C—H insertion becomes competitive with the faster methyl C—H insertion. The latter, however, can only occur when the methyl into which insertion is possible is oriented axially (as in **15**). The behaviour of the dibromocyclopropane (**19**) derived from octalin **18** can be attributed to the same sort of competition between C—H insertion and conformational mobility. In fact, it is the parent 4-methylcyclohexene-derived dibromocyclopropane **11** which is the anomaly, such that ring flipping is apparently *faster* than ring C—H insertion in the intermediate cyclopropylidene (**15**), thus allowing methyl insertion to take over completely. At any rate, these results did not deter us from the pursuit of our goal since, as mentioned above, the conformation shown for the proposed intermediate cyclopropylidene **8** was expected to greatly predominate.

Suitable conditions for the *one*-step conversion of cyclohexene **22** to the carbon atom insertion products **24** and **25** were found after a number of unsuccessful experiments, and it appears on the basis of these results that the reaction is quite sensitive to temperature and concentration. For example, when a solution of cyclohexene **22** and an equimolar amount of carbon tetrabromide in diethyl ether at −78°C was treated with an equimolar amount of methyllithium, and the mixture was stirred at that temperature for 1.5 h and then allowed to warm to 0°C, followed by addition of a *second* equimolar quantity of methyllithium, the tricyclic products **24** and **25** were obtained in 17% and 39% yields (by gas chromatographic analysis), respectively. These yields were, even at this level of development, a significant improvement over the overall yields from the Moore two-step procedure (9% and 15%, respectively), but further increases were observed when a more dilute solution in diethyl ether was used, amounts of carbon tetrabromide and methyllithium were *doubled*, and the second addition of methyllithium was carried out at −30°C instead of 0°C. Under these optimum conditions (17) not only the total yield of carbon atom insertion products, but also the relative proportion of the desired tricyclooctane (**24**) was increased, such that **24** and **25**

[19]For more recent applications of this reaction see ref. 41.

[20]For the determination of the structure of the intermediates in this reaction by ^{13}C nmr see refs. 36 and 44.

[21]Methylcyclohexene is 8.43 times more reactive than cyclohexene toward dichlorocarbene generated from chloroform and potassium *tert*-butoxide, as quoted in ref. 45. Although the sensitivity of dibromocarbene to electronic effects (greater reactivity toward more electron-rich olefins) is somewhat attenuated by steric hindrance, relative to the chlorine analogue, this factor is not so important as to override the electronic one in the cases studied thus far (46).

[22]These olefins, commonly known as α- and β-cyclogeraniolene, occur in the defense secretions of the major soldiers of the African termite *Ancistrotermes cavithorax* (48).

[23]For spectral data establishing the structure of these compounds see refs. 17 and 39.

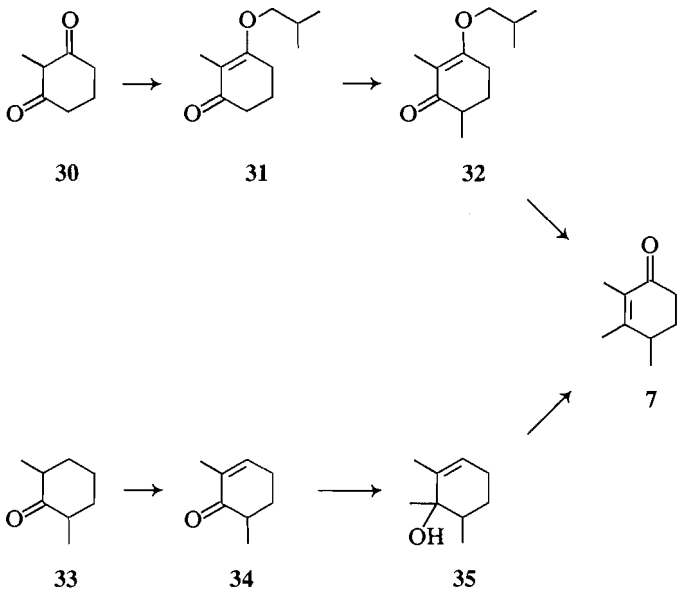


SCHEME 5. Synthesis of 2,3,4-trimethylcyclohexenone.

were obtained in a combined yield of 80%, containing *equal* amounts of the two isomers. Thus our one-step method is, at least in this case, far superior to the Moore two-step sequence, being much more convenient and providing a greater than 300% enhancement in the yield of the ishwarane model compound, **24**. This new synthetic method, which accomplishes the insertion of a single carbon atom into a molecule by addition to a C—C double bond and insertion into a C—H bond in one smooth operation, thereby forming a tricyclic system from a monocyclic one, will hereafter be referred to as *carbon atom insertion bicycloannulation* (CAIB).[24]

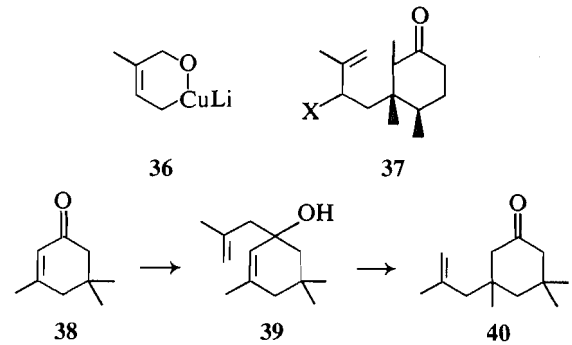
Total synthesis of ishwarone

Although cyclohexenone **7** (53) (Scheme 1) had been prepared from Hagemann's ester (54), the low yield of this process (16%) dictated a search for a more efficient route. We therefore explored two relatively new methods which held out the promise of higher yields (Scheme 5). The first of these, based on a sequence suggested by Stork and Danheiser (55), involved kinetically controlled methylation of enol ether **31** to give **32**, which was then converted to cyclohexenone **7** by addition of methyllithium and hydrolysis.[25] The overall yield from the relatively expensive dione, **30**, was a respectable 74%. However, a more economical approach proved to be by way of the allylic oxidation method of Dauben and Michno (56). Thus, chlorination–dehydrochlorination (57) of 2,6-dimethylcyclohexenone (**33**), followed by addition of methyllithium to the resulting cyclohexenone, **34**, provided allylic alcohol **35**, which without purification was directly converted to cyclohexenone **7** by PCC oxidation. In this case the overall yield of **7** from cyclohexenone **33** was 48%, but the greater convenience and less expensive materials used for this sequence made it the method of choice for large scale preparations of **7**.

[24]To the best of our knowledge, only one other type of CAIB has been reported, the Katz-Cheung bicycloannulation of aromatic and other conjugated carbanions (51). For recent applications of this highly useful reaction see ref. 52.

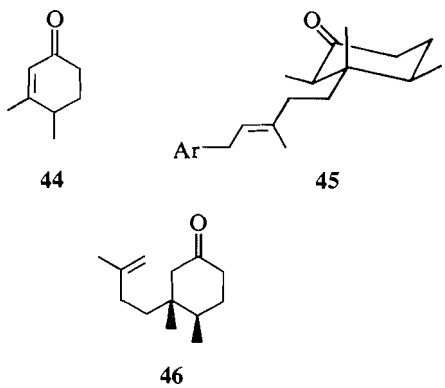
[25]Following our preliminary publication in which this synthesis was described (14), the same route to enol ether **32** was reported by Piers *et al.*, and experimental details have been provided by them (58).

A suitable chemical realization of synthon **6** (Scheme 1) having an intact double bond might be the complex organocuprate **36**, in which the alkoxide moiety is present in the



capacity of a latent leaving group (59). Athough it is even conceivable that such a conversion of cyclohexenone **7** to octalone **5** could be carried out in a single pot, where the initial conjugate addition of the organocopper moiety would be followed by addition of a sulfonyl chloride and *in situ* formation of a sulfonate leaving group, our experiments with model compounds did not prove sufficiently promising to justify a full investigation of any version of this plan.

However, a less direct implementation of the protocol embodied in synthon **6** was ultimately successful (Scheme 6).[26] The organocuprate **42** (R = $CH_2CH_2C(CH_3)CH_2$) was prepared without incident from homoallyl iodide **41** (64) by addition of *tert*-butyllithium at −78°C followed by copper(I) iodide at −50°C.[27] Addition of cyclohexenone **7** to the resulting solution in diethyl ether at −45°C and aqueous work-up gave a 45% yield (60% based on consumed **7**) of the keto-olefin, **43**, after chromatography on alumina. Athough this product appeared to be a mixture of epimers by nmr, the major component is believed to have the stereochemistry shown. This assumption is based partly on the previously known preference for attack of organocuprates on 3,4-dimethylcyclohexenone (**44**) to give the



[26]An alternative approach would have involved an allylic precursor, **37**, which was intended to undergo an internal S_N2' ($S_{cN'}$) reaction (60) on treatment with base. Unfortunately, this plan was thwarted at an early stage when it was found in a model study that the anionic oxy-Cope rearrangement (61) of the tertiary allylic alcohol, **39**, prepared from isophorone (**38**) and allyl magnesium chloride, gave mainly isophorone and only a 14% yield of the desired ketone, **40**. The primary pathway of this reaction is thus a β hydroxy olefin cleavage (62) and this has also been observed by Evans *et al.* as a side reaction in some of their anionic oxy-Cope rearrangements with compounds closely related to allylic alcohol **39** (63).

[27]For recent applications employing this same cuprate see ref. 65.

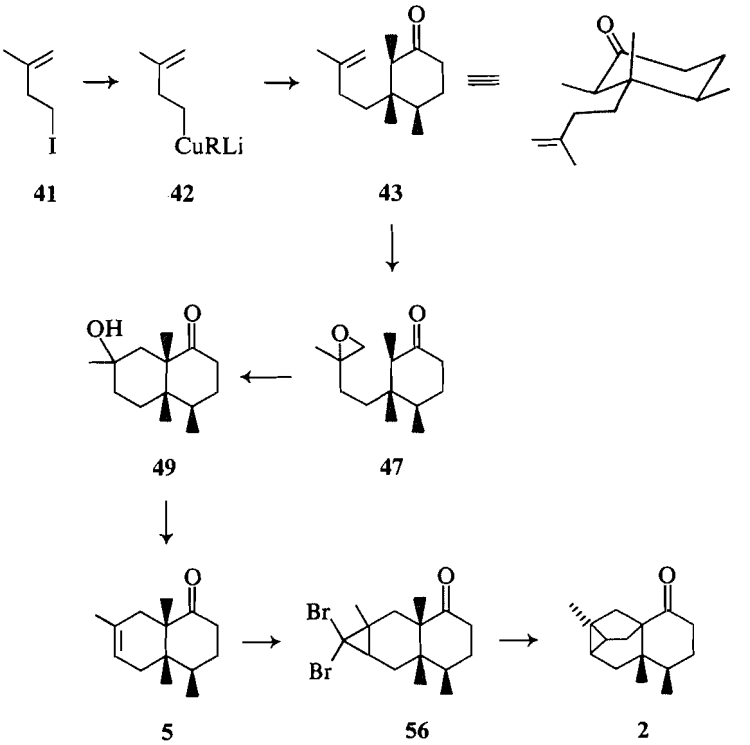

SCHEME 6. Total synthesis of ishwarone.

adduct having *cis* methyl groups with high stereoselectivity (66, 67), and partly on the occurrence of a high field singlet absorption in the nmr at δ 0.57 attributable to an axial methyl at C-3 shielded by the carbonyl group (cf. the microbial metabolite **45**, in which the corresponding absorption appears at δ 0.55 (68)). An attempt to develop a more efficient synthesis of keto-olefin **43** via trapping of the intermediate enolate from addition of **42** to cyclohexenone **44** with methyl iodide (69) produced only the adduct, **46**, none of the desired methylation being observed. Similar lack of success has been obtained in closely related studies by Mori and Fujioka with the same substrate (70).

Epoxidation of keto-olefin **43** with *m*-chloroperbenzoic acid was not accompanied by any detectable amounts of lactones resulting from Baeyer–Villiger oxidation, giving the desired keto-epoxide (**47**) as a mixture of diastereomers.[28] Direct treatment of this mixture, without purification, with potassium *tert*-butoxide in *tert*-butyl alcohol at reflux provided a crude mixture of keto-alcohols which, as a solution in cyclohexane, was subjected to dehydration with 50% aqueous sulfuric acid (25*a*). The major product of these reactions (38% from keto-epoxide **47**) was shown to be a 4.3:1 mixture of the desired octalone, **5**, and its position isomer, **48**, by spectrosopic analysis and ultimate conversion of **5** to ishwarone (**2**). It therefore follows that the major product of the base-catalyzed cyclization was keto-alcohol **49** (presumably as a mixture of diastereomers). However, this compound was accompanied by minor quantities of keto-alcohol **50**, which survived the dehydration conditions used here as a result of its being a primary alcohol. It was therefore convenient to wait until this stage for purification of the intermediates, since octalone **5** was easily separated from keto-alcohol **50** by chromatography on alumina. Although, in the absence of definite information as to the stereochemistry of keto-alcohols **49** and **50** and their precursors, it is not possible to speculate on the factors responsible for the observed low regioselectivity for attack of the enolate moiety of intermediate **51** on the primary carbon of the epoxide moiety, the formation of the five-membered ring of **50** by attack on the tertiary carbon of the epoxide was not surprising in light of previous studies of epoxide – keto-enolate cyclizations (25*a*, 66, 71). However, it is worthy of note that the analogous cyclization of the epoxy-lactam **52** with sodium hydride in benzene has been reported to form exclusively a six-membered ring, giving hydroxy-lactam **53** (72).

With the obtention of octalone **5** the Diels–Alder equivalent

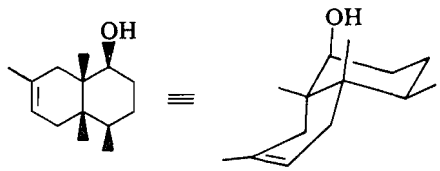
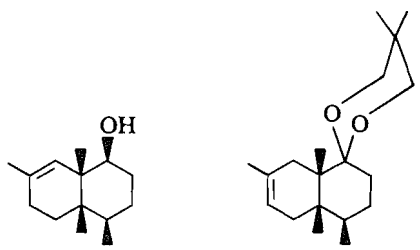
sequence, which represents overall addition of isoprene to cyclohexenone **7** in a specific regiochemical and stereochemical sense, was complete. It remains to be seen how general this process will be in view of the mixture of products obtained in the epoxide cyclization, but the loss of almost half of the material through formation of the side product, **50**, was not so discouraging as to deter us from our goal. Accordingly, the stage was now set for the proposed CAIB of octalone **5**, which was designed to give ishwarone (**2**) in a single step. In spite of the presence of the carbonyl group and the potential for addition of methyllithium or other carbanionic intermediates to it during the application of our new CAIB method, we were led to believe that protection of the ketone function would not be necessary by a report from Sydnes and Skattebøl (73) describing the reaction of methyllithium with dibromocyclopropyl ketones to give exclusively C—H insertion products resulting from bromine–lithium exchange, none of which involved attack at the carbonyl group.[29] Nevertheless, treatment of octalone **5**[30] with carbon tetrabromide and methyllithium under the conditions established in the model studies gave only intractable material.

Accordingly, although the reasons for the failure of the CAIB were not understood, it was decided that the carbonyl group of octalone **5** should be reduced to the alcohol in the hope that the resulting octalol, **54**, would undergo the desired CAIB to give ishwarol (**3**). Reduction of the mixture of octalones **5** and **48** with lithium aluminium hydride gave a mixture of octalols **54** and **55**, the ^{1}H nmr spectrum of which showed a



54



55 **57**

triplet (J = 3Hz) at δ 3.37 for the carbinol C—H, indicating an axial hydroxyl group for the major component, **54**. Since the spectrum of ishwarol (**3**) exhibits a very similar absorption, and it has been obtained by hydride reduction of ishwarone (**2**) (8*a*, 9), it was apparent that attack of the hydride had occurred on the α side of the octalone, away from the hindering methyl groups, as expected. Thus, it can be concluded that **54** has the conformation shown, and, assuming the corresponding intermediate carbenoid in the CAIB adopts an analogous one, intramolecular C—H insertion should occur at the desired methyl group as in Scheme 2. Again, however, attempted CAIB with **54** under our standard conditions failed to produce any identifiable materials.[31]

It would thus appear that our CAIB method is considerably more limited than we had hoped, and that the success or failure of carbon atom insertion with methyllithium – carbon tetrabromide is dependent to a large extent on the structure of the olefinic reactant and other functional groups present. Be that as it may, there was still a chance that the two-step procedure involving bromoform/base followed by lithium–bromine exchange with the resulting dibromocyclopropane could convert our intermediate octalone, **5**, to ishwarone and (or) the corresponding octalol, **54**, to ishwarol. In the latter case, reaction of the octalol with bromoform and aqueous base under the same phase-transfer conditions used for octalin **18** gave a crude tarry product, the nmr of which indicated that the alcohol group was no longer present.[32] Ketones, on the other hand, are generally somewhat less reactive under these conditions than alcohols are (78, 79), and treatment of the mixture of octalones **5** and **48** with bromoform and aqueous sodium hydroxide in the presence of tributylamine (80) gave dibromocyclopropane **56** mixed with unreacted **48**, as expected. When this crude mixture was treated with methyllithium in ether at −10°C, and the crude products were subjected to gas chromatographic analysis, a small amount of material having the same retention time as that of authentic ishwarone (**2**)[33] was collected. This proved to be a mixture, but preparative thick-layer chromatography enabled the separation of a minute amount of material having spectroscopic properties (^{1}H and ^{13}C nmr) identical with those of the authentic ishwarone. Athough the yield of this reaction, and therefore of the overall total synthesis, was very low, the synthesis from the cyclohexanedione, **30**, or the cyclohexenone, **33**, consisted of only nine steps, comparing favourably, in length, at least, with the previously reported synthesis of racemic ishwarone, which required some 19 steps from cyclohexenone **44** (13).

Total synthesis of ishwarane

In spite of the failure of our CAIB method in the synthesis of ishwarone, we were confident that the procedure would be

[29]More recently, mixed results have been obtained with other dibromocyclopropyl ketones (74). For a review of the generation and reactions of carbenes and carbenoids having neighbouring heteroatoms see ref. 75. Adding further complexity to this subject, it has been found that bromolithiocyclopropanes can be induced to add intermolecularly to ketones and aldehydes (76). It thus would appear that the course of reaction which a given substrate takes is dependent to a large extent on its structure and the conditions. In any case the carbonyl group of octalone **5** is a very hindered one, and no interference with the CAIB was expected from it.

[30]The mixture of octalones **5** and **48** was used due to the difficulty in separating these isomers and in the expectation that **48** would be unreactive, as was the analogous olefin, **26**.

[31]Mixed results have been obtained regarding the reactivity of hydroxyl groups under the conditions of alkyllithium-induced bromine–lithium exchange in dibromocyclopropanes (75, 77). Protection of the carbonyl group of octalone **5** as the ketal (**57**) also failed to enable the CAIB.

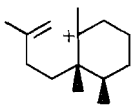
[32]Although phase transfer catalyzed addition of dibromocarbene to the double bond of olefinic alcohols can usually be accomplished without interference, reaction of dibromocarbene and dichlorocarbene with alcohols is known to give a variety of products, most based on "deoxidation" to carbocations (78). We have also demonstrated that cyclohexanol gives 7,7-dibromonorcarane under the same conditions, presumably by way of cyclohexyl cation and dibromocarbene addition to cyclohexene resulting from loss of a proton from the carbocation.

[33]We are greatly indebted to Dr. P. C. Parthasarathy, C.I.B.A.–Geigy Research Centre, Bombay, for generous samples of ishwarone and ishwarane.

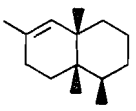
Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.105 on 09/06/12
For personal use only.

viable for the corresponding hydrocarbon since it seemed reasonable to assume that the difficulties which prevented us from using it for ishwarone and ishwarol were somehow associated with the presence of the functional groups, and since our model studies, which were carried out on hydrocarbons (e.g. **22**), had already proven the utility of the CAIB methodology. Although the octalin, **62** (Scheme 7), required for a CAIB synthesis of ishwarane (**1**) could conceivably have been prepared from octalone **5** by Wolff–Kishner reduction, the length of the sequence leading to **5** as well as the loss of considerable material at the epoxide cyclization stage dictated a search for more efficient possibilities for the synthesis of the octalin.[34]

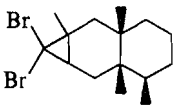
The ultimately successful plan (Scheme 7),[35] involved conjugate addition of a methyl group to the octalone, **59**, which has also been employed in two other syntheses of ishwarane (12), followed by addition of a methyl group to the carbonyl of the resulting decalone, and dehydration. When the octalone, **59**, obtainable stereoselectively by the elegant method of Boeckman *et al.* (83)[36] was treated with lithium dimethylcuprate – dimethyl sulfide complex (84), the desired decalone, **60**, was obtained in 77% yield. The assignment of the *cis* stereochemistry to this decalone was based on the eventual success of the total synthesis as well as literature precedent (25*c*, 81*h*). Addition of methyl magnesium iodide gave a mixture of tertiary alcohols, **61**, which, without purification, was dehydrated



58



63



64

as for the analogous ishwarone intermediate, **49**, providing an 87% yield of a 1:1 mixture of octalins **62** and **63**. Although these isomers could not be separated, as was the case with octalone **48**, octalin **63** has the more hindered olefinic group and thus would not be expected to react with dibromocarbene in the next step.

With octalin **62** in hand, the stage was set for the application

SCHEME 7. Total synthesis of ishwarane.

of our CAIB reaction, and, indeed, treatment of the mixture of octalins **62** and **63** with carbon tetrabromide and methyllithium under the standard conditions gave a mixture of isomeric hydrocarbons from which ishwarane (**1**), identical with an authentic sample,[33] was separated in 20% yield using gas chromatography[37]. Thus, the total synthesis of ishwarane was accomplished in remarkably few steps, namely four from octalone **59**, compared with 12 steps for the Hagiwara synthesis (12*a*) and 10 steps for the Kelly synthesis (12*b*). Unfortunately, the nature of the side products of the CAIB step are not known, since they could not be separated from each other, but it is clear that ishwarane was formed in fairly good yield from octalin **62**, in view of the fact that a 40% yield of octalin **63** was recovered from the reaction.

In summary, the CAIB method that we have developed for the synthesis of the tricyclo[3.2.1.$0^{2,7}$]octane ring system seems to be useful only in cases in which (a) the cyclohexene substrate bears an alkyl substituent on the double bond and (b) there are no interfering functional groups in the substrate, ketone and alcohol groups being the two which we have shown to be detrimental. In the proper cases, limited though they may be, it is clear that CAIB can save a tremendous amount of time and materials over more traditional, multistep procedures.

Experimental

General

All reactions were conducted under a positive pressure of argon. Ethyl ether (when used as a reaction solvent), tetrahydrofuran, and 1,2-dimethoxyethane were distilled from sodium–benzophenone, diisopropylamine and *tert*-butyl alcohol were distilled from calcium hydride, and hexamethylphosphoramide was distilled from 13× molecular sieves. Methyllithium (in ethyl ether), *n*-butyllithium (in hexane), and *tert*-butyllithium (in pentane) were obtained from Ventron. These solutions were titrated (85) with 2-butanol in xylene (bipyridyl indicator) before use.

Preparative thick-layer chromatography was performed on precoated E. Merck silica gel GF (2 mm thick) on glass plates. Ethyl acetate was used to extract the separated components from the silica gel. Gas chromatography was carried out by using 1.5% OV-101 on Chromosorb G (100/120 mesh) in a 0.2 in. × 6 ft stainless-steel column with a helium flow rate of 60 mL/min unless otherwise noted.

[34]Although one could argue that a total synthesis of ishwarane is a redundant exercise at this point,[8] the unsatisfactory yield of the last step in our synthesis of ishwarone and a desire to put our new CAIB method to good use were sufficient reasons to approach ishwarane via octalin **62**.

[35]An alternative approach would have involved a carbocation–olefin cyclization (81) of tertiary carbocation **58** followed by loss of a proton to give **62**. Unfortunately, however, this plan was thwarted at an early stage by the fact that when cyclohexenone **16** was treated with lithium dimethyl cuprate in diethyl ether at 0°C, the solvent was replaced by 1,2-dimethoxyethane, and the resulting solution of enolate was treated with iodo alkene **41**, the major product isolated was that of simple conjugate addition, 2,3-dimethylcyclohexenone, very little alkylation of the enolate having taken place. This undesired result can be attributed at least in part to β elimination from the homoallylic iodide, **41**, (thus providing a source of protons for ketonization of the enolate) under the highly basic conditions of the reaction, although other workers have reported no problems with the same alkylating reagent and related carbanionic substrates (64, 82).

[36]This octalone was prepared, in the early stages of our work, by the method of Kelly and Zamecnik (12*c*), but we later found the more selective Boeckman sequence to be somewhat more satisfactory. We are most grateful to Yousry M. A. Naguib for the preparation of sufficient quantities of octalone **59**.

[37]In one small-scale experiment, probably due to loss of methyllithium during addition, the intermediate dibromocyclopropane, **64**, was isolated and could be completely characterized. It appeared to be a mixture of diastereomers, indicating that the addition of dibromocarbene to the octalin was non-stereoselective (cf. addition to octalin **18**) and presumably accounting for at least some of the side products accompanying the formation of ishwarane in the C—H insertion step.

For personal use only.

Nuclear magnetic resonance (nmr) spectra were recorded on a Varian Model HA-100 or Model XL-100 spectrometer, and proton and carbon-13 chemical shifts are reported in parts per million (δ) downfield from internal tramethylsilane. Infrared (ir) spectra were obtained on a Perkin–Elmer Model 621 spectrophotometer, and mass spectra (ms) were determined on a Varian MAT Model 311A spectrometer employing an ionizing voltage of 70 eV. Melting and boiling points are uncorrected.

Cis-9-Methyl-2-octalin (18)

A solution of 22.3 g (0.136 mmol) of octalone **17** (19) and 150 mL of hydrazine hydrate (99%) in 750 mL of diethylene glycol was heated at 120°C for 11 h. After the resulting solution had been allowed to cool, 94 g of potassium hydroxide was dissolved in it, and the temperature of the oil bath was slowly raised to 210°C over 1 h during which water was removed in a flow of argon and condensed. The mixture was then heated at 210°C for 3 h, cooled, and poured into water. The aqueous phase was extracted with petroleum ether (boiling range 30–60°C) and the combined extracts were washed with water and saturated aqueous sodium chloride and dried over anhydrous sodium sulfate. The aqueous distillate carried over in the initial heating with hydroxide was worked up in the same manner, and the resulting extracts were combined with the others. The solvent was removed by distillation through a Vigreux column, and the residue was distilled to give 12.0 g (59%) of the octalin (**18**); bp 55–58°C/6 Torr (1 Torr = 133.32 Pa) nmr as previously reported (86).

*2,3-(Dibromomethano)-9-methyl-*cis*-decalin (19)*

To a solution of 2.00 g (13.3 mmol) of octalin **18**, 2.33 mL (6.74 g, 26.7 mmol) of bromoform, 27 mg of benzyltriethylammonium chloride, and 0.054 mL of ethanol was added dropwise, with stirring and cooling, 6.7 mL of 50% aqueous sodium hydroxide over 10 min, while the temperature of the mixture was maintained at 40–45°C. The mixture was stirred vigorously for 3 h at 40–45°C, during which 1.5 mL of methylene chloride was added to prevent the emulsion from becoming too thick, and it was then partitioned between 50 mL of water and 25 mL of methylene chloride. The aqueous phase was extracted with methylene chloride (2 × 25 mL), and the combined extracts were washed with 25 mL of water; 25 mL of 5% aqueous hydrochloric acid, another 25 mL of water, and 25 mL of saturated aqueous sodium chloride and dried over anhydrous sodium sulfate. The solvent was evaporated under reduced pressure, and the residue was subjected to bulb-to-bulb distillation to give 2.06 g (48%) of dibromocyclopropane **19** as a colorless oil; bp 75°C/0.05 Torr; ^{1}H nmr (CCl_4) δ: 0.93 (s, 3H); ms *m/e* (relative intensity): 41(51), 55(48), 67(62), 81(100), 95(48), 109(70), 123(40), 135(29), 149(65), 161(37), 210(10), 212(19), 214(9), 305(15), 307(31), 309(15), 320(5, M^+), 322(11, M^+), 324(5, M^+); high resolution ms, *m/e* calcd. for $C_{12}H_{18}Br_{12}$: 321.9755; found: 321.9799.

Norishwarane (20)

To a solution of 1.54 g (4.8 mmol) of dibromocyclopropane **19** in 8.5 mL of ethyl ether at −10°C was added dropwise, with stirring 3.7 mL of 1.5 *M* methyllithium (5.5 mmol) over 2.5 h. After the resulting yellow solution had been stirred at −10°C for an additional 30 min, followed by 1 h of stirring at room temperature, it was recooled to 5°C and 10 mL of water was added dropwise, with stirring. The aqueous phase was extracted with 10 mL of ethyl ether and the combined extracts were washed with 10 mL of saturated aqueous sodium chloride and dried over anhydrous sodium sulfate. The solvent was removed by distillation through a Vigreux column, and bulb-to-bulb distillation of the residue gave 0.60 g (77%) of colorless oil; bp 70°C/5 Torr. This material was then subjected to preparative gas chromatography,[38] which gave two peaks at 32 min and 39 min with relative areas of 64% and 36%, respectively. The first of these appeared to be a 2:1 mixture of two isomers of norishwarane resulting from ring C—H insertion as judged from its nmr and ms data; ^{1}H nmr ($CDCl_3$) δ: 0.77 (s, larger of the two singlets), 0.91 (s), 1.82 (d, J = 12 Hz); ^{13}C nmr ($CDCl_3$) δ: 5.1, 7.0, 11.5, 13.8, 18.6, 19.1, 22.2, 22.4, 22.9, 23.0, 26.3, 27.3, 27.5, 27.6, 27.7, 29.9, 30.4, 30.5, 32.1, 34.9, 37.8, 38.0, 38.8, 41.0, 42.1, 53.6; high resolution, ms, *m/e* calcd. for $C_{12}H_{18}$: 162.1409; found 162.1411. The component with a retention time of 39 min was norishwarane (**20**); ir (CCl_4): 3040 cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 0.62 (m, 1H), 1.97 (d, J = 11.5 Hz, 1H); ^{13}C nmr ($CDCl_3$) δ: 13.1, 16.7, 17.7, 23.9, 26.4, 26.6, 29.9, 32.1, 37.2, 39.2, 40.2, 41.6; ms *m/e* (relative intensity): 67(25), 79(61), 95(70), 108(25) 120(76), 133(40), 147(18), 162(100, M^+); high resolution ms, *m/e* calcd. for $C_{12}H_{18}$: 162.1409; found: 162.1408.

1,3,3-Trimethyl-7,7-dibromobicyclo[4.1.0]heptane (23)

To a mixture of 4.0 g (32 mmol) of bromoform, 2.0 g (16 mmol) of 1,5,5-trimethylcyclohexene (**22**) (47) (containing 15% of the isomer, 1,3,3-trimethylcyclohexene, **26**), and 0.032 g of benzyltriethylammonium chloride was added dropwise, with stirring, 8 mL of 50% aqueous sodium hydroxide over 10 min, keeping the temperature in the range 40–45°C by means of a cold water bath. Stirring was continued at this temperature for 3 h, and the mixture was then poured into 250 mL of water. The aqueous phase was extracted with methylene chloride and the combined extracts were washed with water, dilute aqueous hydrochloric acid, and more water and dried over anhydrous sodium sulfate. The solvent was removed by distillation, and distillation of the residue gave 1.8 g (45%) of dibromocyclopropane **23**: bp 60°C/0.25 Torr; ir (CCl_4): 1370, 1390 cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 0.85 (s, 6H), 1.45 (s, 3H); ms *m/e* (relative intensity): 55(65), 69(100), 84(89), 91(50), 107(27), 123(71), 135(65), 147(15), 159(24), 173(24), 199(18), 215(33), 226(18), 281(11), 296(5, M^+).

1,5-Dimethyltricyclo[3.2.1.0^{2,7}]octane (24) and 1,3,3-trimethyltricyclo[4.1.0.0^{2,7}]heptane (25)

To a solution of 1.0 g (3.5 mmol) of dibromocyclopropane **23** in 6 mL of ethyl ether at −10°C was added dropwise, with stirring, 2.6 mL (3.9 mmol) of a 1.5 *M* solution of methyllithium in ethyl ether over 2 h. Stirring was continued for 1 h after the addition was complete, and 6 mL of water was then added. The organic layer was washed with saturated aqueous sodium chloride, dried over anhydrous sodium sulfate, and concentrated by distillation. The residue was subjected to preparative gas chromatography, and yields of 21% for **24** and 33% for **25** were determined using *trans*-decalin as internal standard; spectral data as previously reported (17).

2,3,4-Trimethylcyclohex-2-en-1-one (7)

(a) To a solution of 32.5 g (0.166 mol) of 3-isobutoxy-2,6-dimethylcyclohex-2-en-1-one (**32**) (14, 58) in 300 mL of ethyl ether at 0–4°C was added dropwise, with stirring, 130 mL of 1.5 *M* methyllithium (0.195 mol) over 2 h. After the solution had been allowed to stir at room temperature for 13 h, 1.15 L of 5% aqueous hydrochloric acid was added slowly, and the resulting mixture was stirred vigorously for 3.5 h. The aqueous phase was extracted with petroleum ether (boiling range 30–60°C) and the combined extracts were washed with saturated aqueous sodium bicarbonate and saturated aqueous sodium chloride and dried over anhydrous sodium sulfate. The solvent was evaporated under reduced pressure, and the remaining yellow oil was distilled to give 20.0 g (87%) of enone **7**; bp 103–108°C/15 Torr (lit. (54) bp 93–98°C/8 Torr); ir and nmr as previously reported (53); ms *m/e* (relative intensity): 67(77), 81(55), 96(95), 110(59), 123(23), 138(100, M^+); high resolutions ms, *m/e* calcd. for $C_9H_{14}O$: 138.1045; found: 138.1047.

(b) To a solution of 50.5 g (0.40 mol) of 2,6-dimethylcyclohexanone in 200 mL of carbon tetrachloride was added dropwise, with stirring and cooling with a room temperature water bath, 35.5 mL (59.4 g, 0.44 mol) of sulfuryl chloride in 60 mL of carbon tetrachloride over 75 min, while the evolved hydrogen chloride and sulfur dioxide were removed with an aspirator trap. After the mixture had been stirred for an additional 2 h, it was washed with water (3 × 60

[38]A 0.2 in. × 10 ft copper column packed with 10% SE-30 on Diatoport S was employed at 135°C.

For personal use only.

mL), saturated aqueous sodium bicarbonate (2 × 60 mL), and 60 mL of saturated aqueous sodium chloride and dried over anhydrous sodium sulfate and anhydrous magnesium sulfate. The solvent was distilled off using a Vigreux column, first at atmospheric pressure and then at aspirator pressure, to give the crude chloro ketone which was used directly for the next step. This material was combined with 10.4 g (0.245 mol) of lithium chloride in 100 mL of *N,N*-dimethylformamide, and the mixture was heated at 100°C for 50 min, after which it was cooled to room temperature and added to a mixture of 400 mL of ethyl ether and 400 mL of 2.5% aqueous sulfuric acid. The resulting mixture was stirred vigorously for 4 h, and the aqueous phase was saturated with sodium chloride and extracted with ethyl ether (1 × 100 mL and 3 × 70 mL). The combined extracts were washed with saturated aqueous sodium bicarbonate (2 × 100 mL) and saturated aqueous sodium chloride (2 × 100 mL) and dried over anhydrous sodium sulfate and anhydrous magnesium sulfate. The solvent was removed by distillation through a Vigreux column, and the residue was distilled to give 39.9 g (80%) of 2,6-dimethylcyclohex-2-en-1-one (**34**); bp 71–82°C/15–16 Torr (lit. (87) bp 72–74°C/13 Torr); nmr and ms as reported previously (88).

To this lot of enone **34** in 400 mL of ethyl ether at −78°C was added dropwise, with stirring, 176 mL of 1.95 *M* methyllithium (0.34 mol) over 1.25 h. The mixture was allowed to warm to room temperature and stirred for 4.5 h, after which 200 mL of water was added dropwise, with stirring, and the mixture was allowed to stand overnight. The aqueous phase was extracted with ethyl ether (2 × 200 mL), and the combined extracts were washed with water (2 × 400 mL) and dried over anhydrous sodium sulfate and anhydrous magnesium sulfate. The solvent was evaporated under reduced pressure, and the residual crude alcohol was used without purification for the next step. To a suspension of 77.66 g (0.36 mol) of pyridinium chlorochromate (PCC) in 540 mL of methylene chloride was added, all at once, 25.3 g of the crude alcohol in 180 mL of methylene chloride, and the mixture was stirred for 2 h. The mixture was then diluted with 750 mL of ethyl ether, the solution was decanted, and the black insoluble residue was washed with ethyl ether (1 × 300, 2 × 250, and 1 × 200). The combined extracts were divided into two equal portions, each of which was washed with 5% aqueous sodium hydroxide (2 × 750 mL), 750 mL of 5% aqueous hydrochloric acid, and saturated aqueous sodium bicarbonate (2 × 400 mL) and dried over anhydrous sodium sulfate. The solvent was evaporated under reduced pressure, and the remaining orange oil was distilled to give 15.7 g (60%) of enone **7**.

*2,3,4-Trimethyl-3-(3-methyl-3-butenyl)cyclohexanone (**43**)*

To a solution of 5.32 g (27.1 mmol) of 4-iodo-2-methyl-1-butene (**41**) in 20 mL of ethyl ether at −78°C was added dropwise, with stirring, 25 mL of 1.7 *M tert*-butyllithium (42.5 mmol) over 20 min. After the mixture had been allowed to stir at −78°C for an additional 30 min, the Dry Ice – acetone bath was replaced by a Dry Ice – aqueous calcium chloride bath at −50°C, and 2.71 g (14.7 mmol) of copper(I) iodide was added all at once. The resulting grey suspension was stirred at −40 to −50°C for 3.5 h, after which 1.60 g (11.6 mmol) of 2,3,4-trimethylcyclohex-2-en-1-one (**7**) in 20 mL of ethyl ether was added dropwise, with stirring, over 20 min. After 3 h of stirring at −45°C the mixture was quenched by the addition of 10 mL of saturated aqueous sodium bicarbonate and poured into a mixture of 40 mL of ethyl ether and 60 mL of 10% aqueous ammonium hydroxide. The aqueous phase was extracted with ethyl ether and the combined extracts were washed with 10% aqueous ammonium hydroxide, water, and saturated aqueous sodium chloride, and dried over anhydrous magnesium sulfate. The solvent was evaporated under reduced pressure leaving an oil which was subjected to open column liquid chromatography on activity III neutral alumina. The fractions eluted with 1% ethyl acetate in hexane gave 1.1 g (45% yield) of oily ketone **43**, while 2% ethyl acetate in hexane gave 0.47 g of the starting ketone (**7**). The yield of **43** based on consumed **7** was thus 60%; ir (CCl_4): 1715, 1645, 896 cm^{-1}; ^1H nmr (CCl_4) δ: 0.57 (s, 3H), 0.84 (d, J = 7 Hz, 3H), 0.90 (d, J = 7 Hz, 3H), 1.71 (bs, 3H), 4.63 (bs, 2H); ms *m/e* (relative intensity): 55(68), 69(82), 97(96), 139(100), 163(9), 208(10, M^+); high resolution ms, *m/e* calcd. for $C_{14}H_{24}O$: 208.1827; found: 208.1825.

*3-(3,4-Epoxy-3-methylbutyl)-2,3,4-trimethylcyclohexanone (**47**)*

To a solution 1.04 g (5.0 mmol) of enone **43** in 30 mL of methylene chloride at 0°C was added dropwise, with stirring, 1.12 g (5.5 mmol) of 85% *m*-chloroperbenzoic acid in 25 mL of methylene chloride over 45 min. After the mixture had been allowed to stir for 9 h at room temperature, 75 mL of methylene chloride was added, and the solution was washed with 10% aqueous sodium bisulfite, 5% aqueous sodium hydroxide, water, and saturated aqueous sodium chloride, and dried over anhydrous magnesium sulfate. The solvent was evaporated under reduced pressure to give 1.11 g of a light yellow oil which was a sufficiently pure mixture of diastereomers for use in subsequent reactions; ir (CCl_4): 1715 cm^{-1}; ^1H nmr (CCl_4) δ: 0.58 (s, 3H), four doublets (J = 7 Hz) at 0.85, 0.87, 0.92, and 0.93 (combined 6H), 1.43 (s, 3H), 2.67 (bs, 2H); ms *m/e* (relative intensity): 43(43), 49(81), 55(41), 67(42), 84(100), 96(65), 110(42), 111(42), 123(19), 138(77), 139(88), 154(10), 163(3), 196(2), 208(2), 224(1, M^+); high resolution ms, *m/e* calcd. for $C_{14}H_{24}O_2$: 224.1776; found: 224.1772.

*4,7,9,10-Tetramethyl-6-octal-1-one (**5**), 4,7,9,10-tetramethyl-7-octal-1-one (**48**), and 7-hydroxymethyl-1,2,6,7-tetramethylbicyclo[4.3.0]nonan-5-one (**50**)*

To a solution of 1.11 g (5.0 mmol) of the crude mixture of epoxyketones (**47**) in 6 mL of *tert*-butyl alcohol was added 23 mL of a solution of potassium *tert*-butoxide (26 mmol) freshly prepared by reaction of 1.11 g of potassium with 25 mL of *tert*-butyl alcohol at 50°C. The resulting orange solution was refluxed for 14 h, after which 15 mL of water was added, and the bulk of the solvent was evaporated under reduced pressure. The remaining orange gum was partitioned between 100 mL of water and 80 mL of ethyl ether, and the aqueous phase was extracted with two 50-mL portions of ethyl ether. The combined extracts were washed with water and saturated aqueous sodium chloride, and dried over anhydrous sodium sulfate. The solvent was evaporated under reduced pressure to give 1.3 g of a mixture of keto-alcohols as a crude yellow oil which was used for the next step without purification. To a solution of the above crude product in 20 mL of cyclohexane was added 17 mL of 50% aqueous sulfuric acid, and the mixture was stirred vigorously for 0.5 h. The mixture was then partitioned between ethyl ether and water, and the aqueous phase was neutralized with solid sodium carbonate and extracted with ethyl ether. The combined extracts were washed with saturated aqueous sodium bicarbonate and saturated aqueous sodium chloride, and dried over anhydrous magnesium sulfate, anhydrous sodium sulfate, and potassium carbonate. The solvent was evaporated under reduced pressure, giving a yellow oil which was subjected to open column liquid chromatography on 32 g of activity III alumina, eluting first with hexane, then with 1% ethyl acetate in hexane, and finally with pure ethyl acetate. Fractions eluted with ethyl acetate – hexane gave 0.39 g (38%) of a 4.3:1 mixture (analysis of integration of the olefinic proton signals in the nmr) of octalones **5** and **48** as a light yellow oil; ir (CCl_4): 1708 cm^{-1}; ^1H nmr (CCl_4) δ (relative LIS (for **5** only) with added $Eu(fod)_3$ in brackets): 0.66[2.2] (s, 3H), 0.82[1.0] (d, J = 7 Hz, 3H), 0.92[4.1] (s, 3H), 1.63[0.6] (bs, 3H), 4.99 and 5.28[0.9] (m, width at half-height 4 Hz and 11 Hz, respectively, combined 1H, vinyl protons for **48** and **5**, respectively); ms *m/e* (relative intensity): 55(71), 67(74), 79(68), 91(82), 107(100), 121(87), 163(74), 173(34), 188(11), 191(11), 206(45, M^+); high resolution ms, *m/e* calcd. for $C_{14}H_{22}O$: 206.1670; found 206.1668. A small amount of nearly pure **48** was isolated from an early fraction; ir (CCl_4): 1708 cm^{-1}; ^1H nmr (CCl_4) δ: 0.66 (s, 3H), 0.88 (d, J = 7 Hz, 3H), 0.94 (s, 3H), 1.64 (bs, 3H), 4.99 (m, 1H). Fractions eluted with pure ethyl acetate gave 0.34 g of a yellow oil (ca. 80% pure by ^1H nmr) from which pure keto-alcohol **50** could be isolated as a very light yellow oil by preparative gas chromatography (140°C); ir (CCl_4): 3425, 1687, 1055 cm^{-1}; ^1H nmr (CCl_4) δ: 0.97 (s, 3H), 0.99 (d, J = 7 Hz, 3H) 1.11 (s, 3H), 1.17 (s, 3H), 3.25 (d, J = 12 Hz, 1H), 3.67 (d, J = 12 Hz, 1H); ms *m/e*

(relative intensity): 55(10), 67(18), 81(14), 95(20), 109(35), 121(20), 139(100), 163(19), 175(7) 191(5), 206(3), 224(1, M^+); high resolution ms, *m/e* calcd. for $C_{14}H_{24}O_2$: 224.1776; found: 224.1776.

*4,7,9,10-Tetramethyl-6-octal-1-ol (**54**) and 4,7,9,10-tetramethyl-7-octal-1-ol (**55**)*

To a suspension of 30 mg (0.79 mmol) of lithium aluminum hydride in 1.0 mL of ethyl ether at 0°C was added dropwise, with stirring, 0.117 g (0.57 mmol) of a 4.3:1 mixture of octalones **5** and **48** in 1.0 mL of ethyl ether, followed by 1.5 mL of ethyl ether. The mixture was allowed to warm to room temperature and stirred for 24 h, after which 0.030 mL of water was added followed by 0.045 mL of 10% aqueous sodium hydroxide and 0.90 mL of water. The resulting suspension was filtered, the solid was washed with ethyl ether, and the filtrate was extracted with ethyl ether. The combined extracts were washed with saturated aqueous sodium chloride and dried over anhydrous sodium sulfate. The solvent was evaporated under reduced pressure to give 0.100 g (85%) of a light yellow oil; ir (CCl_4): 3640, 3510(b) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 1.54 (bs, 3H), 3.37 (t, J = 3 Hz, 1H), 4.80 (small m, 1H, vinyl of **55**), 5.14 (m, 1H, vinyl of **54**); high resolution ms, *m/e* calcd. for $C_{14}H_{24}O$: 208.1827; found: 208.1828.

*Racemic ishwarone (**2**)*

To a solution of 0.104 g (0.50 mmol) of a 4.3:1 mixture of octalones **5** and **48**, 0.060 mL (0.173 g, 0.69 mmol) of bromoform and ca. 3 mg of tributylamine in 0.065 mL of methylene chloride was added dropwise, with stirring, 0.17 mL of 50% aqueous sodium hydroxide. The mixture was stirred vigorously and heated at 40–50°C for 115 h, during which time small amounts of methylene chloride were added occasionally to replace that lost due to evaporation. The cooled mixture was partitioned between ethyl ether and water, and the aqueous phase was neutralized with 50% aqueous sulfuric acid and extracted with ethyl ether. The combined extracts were washed with 5% aqueous hydrochloric acid and saturated aqueous sodium chloride and dried over anhydrous sodium sulfate. The solvent was evaporated under reduced pressure, leaving a brown oil which was subjected to preparative thick-layer chromatography using carbon tetrachloride. The dibromocyclopropane **56** was isolated as a yellow oil containing unreacted octalin **48**; ^1H nmr ($CDCl_3$) δ: 0.80 (s), 0.87 (d, J = 7 Hz), 1.10 (s), 1.52 (s); high resolution ms, *m/e* calcd. for $C_{15}H_{22}Br_2O$: 378.0017; found: 378.0027. To a solution of this mixture of **56** and **48** in 1.5 mL of ethyl ether at −10°C was added dropwise, with stirring, over 2 h, 0.25 mL (0.40 mmol) of 1.6 *M* methyllithium diluted with 1.5 mL of ethyl ether. The mixture was allowed to warm slowly to room temperature and was partitioned between ethyl ether and water. The aqueous phase was extracted with ethyl ether, and the combined extracts were washed with saturated aqueous sodium chloride and dried over anhydrous sodium sulfate. The solvent was evaporated under reduced pressure and the residual oil was subjected to preparative gas chromatography,[39] and the peak having a retention time corresponding to that of authentic ishwarone was collected and subjected to preparative thick-layer chromatography on alumina using 5% ethyl ether in cyclohexane. The band having the same R_f value as that of authentic ishwarone was extracted with ethyl acetate, and the solvent was evaporated under reduced pressure to give 1.5 mg (2%) of an oil, the ^1H and ^{13}C nmr spectra of which were identical to those of authentic ishwarone (**2**); ^1H nmr ($CDCl_3$) δ: 0.56 (m, 1H), 0.73 (s, 3H), 0.87 (d, J = 6.5 Hz, 3H), 1.15 (s, 3H); ^{13}C nmr (CD_2Cl_2) δ: 15.8, 17.9, 19.4, 19.7, 21.7, 22.7, 28.1, 30.7, 34.9, 38.0, 38.9, 39.7 39.8 (the quaternary carbon resonance observed at 58.6 in the spectrum of authentic ishwarone could not be discerned above the noise in the spectrum of the synthetic material due to the small amount available, and the signal due to the carbonyl carbon was not looked for). A 270 MHz ^1H nmr spectrum[40] of natural ishwarone was also obtained, and all resonances could be assigned, partly by decoupling ($CDCl_3$) δ: 0.56 (m, 1H, C-7 cyclopropyl), 0.73 (s, 3H, C-15 tertiary methyl), 0.87 (d, $J_{4,14}$ = 6.5 Hz, 3H, C-14 secondary methyl), 0.94 (dd, $J_{7,8}$ = 7.5 Hz, $J_{8,9\alpha}$ = 3 Hz, 1H, C-8 cyclopropyl), 1.15 (s, 3H, C-13 tertiary methyl), 1.35 (d, $J_{9\alpha,9\beta}$ = 12.5 Hz, 1H, C-9 βH), 1.42 (qd, $J_{2\alpha,3\beta} = J_{3\alpha,3\beta} = J_{3\beta,4}$ = 13.5 Hz, $J_{2\beta,3\beta}$ = 4 Hz, 1H, C-3 βH), 1.59 (dd, $J_{6\alpha,6\beta}$ = 14 Hz, $J_{6\beta,7}$ = 4 Hz, 1H, C-6 βH), 1.73 (dddd, $J_{3\alpha,3\beta}$ = 13.5 Hz, $J_{2\alpha,3\alpha}$ = 6.5 Hz, $J_{2\beta,3\alpha}$ = 4 Hz, $J_{3\alpha,4}$ = 2 Hz, 1H, C-3 αH), 1.86 (d, $J_{12\alpha,12\beta}$ = 12 Hz, 1H, C-12 βH), 1.90 (dd, $J_{6\alpha,6\beta}$ = 14 Hz, $J_{6\alpha,7}$ = 2 Hz, 1H, C-6 αH), 1.99 (dd, $J_{9\alpha,9\beta}$ = 12.5 Hz, $J_{8,9\alpha}$ = 3 Hz, 1H, C-9 αH), 2.13 (dqd, $J_{3\beta,4}$ = 13.5 Hz, $J_{4,14}$ = 6.5 Hz, $J_{3\alpha,4}$ = 2 Hz, 1H, C-4), 2.22 (dt, $J_{2\alpha,2\beta}$ = 13.5 Hz, $J_{2\beta,3\alpha} = J_{2\beta,3\beta}$ = 4Hz, 1H, C-2 βH), 2.25 (d, $J_{12\alpha,12\beta}$ = 12 Hz, 1H, C-12 αH), 2.46 (td, $J_{2\alpha,2\beta} = J_{2\alpha,3\beta}$ = 13.5 Hz, $J_{2\alpha,3\alpha}$ = 6.5 Hz, 1H, C-2 αH).

*5β,9β,10β-Trimethyl-2-decalone (**60**)*

To a solution of 10.7 g (52 mmol)) of the copper(I) bromide – dimethyl sulfide complex (84) and 70 mL of dimethyl sulfide in 70 mL of ethyl ether was added dropwise, with stirring, 64 mL of 1.6 *M* methyllithium (96 mmol), followed by 6.83 g (38 mmol) of octalone **59** (83) in 10 mL of ethyl ether. After the yellow suspension had been stirred for 4 h, the mixture was partitioned between petroleum ether (boiling range 30–60°C) and aqueous ammonium hydroxide (buffered to pH 8 with ammonium chloride). The aqueous phase was extracted with petroleum ether, and the combined extracts were washed with water and saturated aqueous sodium chloride and dried over anhydrous sodium sulfate. The solvent was evaporated under reduced pressure, and the residual oil was distilled to give 5.8 g (77%) of decalone (**60**); bp 80°C/0.02 Torr; ir (CCl_4): 1713 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 0.88 (m, 9H, methyl, not resolved), 3.05 (bd, J = 14 Hz, 1H); ms *m/e* (relative intensity): 55(100), 67(90), 81(60), 95(38), 110(44), 123(44), 179(15), 194(29); high resolution ms, *m/e* calcd. for $C_{13}H_{22}O$: 194.1671; found: 194.1669.

*2,5β,9β,10β-Tetramethyl-2-octalin (**62**) and 2,5β,9β,10β-tetramethyl-1-octalin (**63**)*

To a solution of methylmagnesium bromide (prepared from 0.35 g (14 mmol) of magnesium turnings and 0.95 mL (2.16 g, 15 mmol) of methyl iodide in 4.3 mL of ethyl ether) was added dropwise, with stirring, 1.1 g (5.7 mmol) of decalone **60** in 14.2 mL ethyl ether over 2.5 h. After the mixture had been stirred for 3h, the mixture was quenched with aqueous ammonium chloride, and the aqueous phase was extracted with ethyl ether. The combined extracts were evaporated under reduced pressure to give 1.02 g (85%) of crude gummy decalol **61**, which was used directly for the next step, but which could be purified by preparative thick-layer chromatography on silica gel using 10% ethyl acetate in cyclohexane; ir (CCl_4): 3615, 3490 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 0.76 (s, 3H), 0.76 (d, J = 6.5 Hz, 3H), 1.08 (s, 3H), 1.21 (s, 3H), 2.12 (bd, J = 15 Hz, 1H). To a solution of 0.90 g (4.3 mmol) of the crude decalol in 18 mL of cyclohexane was added 14 mol of 50% aqueous sulfuric acid, and the two-phase mixture was stirred vigorously for 2 h and then partitioned between 25 mL of ethyl ether and 25 mL of water. The aqueous phase was extracted with ethyl ether (3 × 25 mL) and the combined extracts were washed with 50 mL of saturated aqueous sodium bicarbonate, 50 mL of water, and 50 mL of saturated aqueous sodium chloride and dried over anhydrous sodium sulfate. The solvent was evaporated under reduced pressure to give 0.69 g (87%) of a 1:1 mixture of octalins **62** and **63**, which could not be separated; ir (CCl_4): 1670 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 0.77 (s, 3H), 0.80 (d, J = 6.5 Hz, 3H) 0.84 (s, 3H), 1.64 (bs, 3H), 4.98 and 5.21 (broad singlets for **63** and **62**, respectively, 1H); ms *m/e* (relative intensity): 55(29), 67(34), 79(28), 91(30), 109(100), 124(33), 177(9), 192(9, M^+); high resolution, ms, *m/e* calcd. for $C_{14}H_{24}$: 192.1878; found: 192.1880.

*Racemic ishwarane (**1**)*

To a solution of 0.40 g (2.1 mmol) of octalins **62** and **63** and 1.38 g (4.2 mmol) of carbon tetrabromide in 14 mL of ethyl ether at −78°C was added dropwise, with stirring, 2.3 mL of 1.8 *M* methyllithium (4.2 mmol) over 1 h, and the resulting yellow solution was

[39]A 0.2 in. × 6 ft stainless-steel column packed with 5% OV-101 on 80/100 mesh Chromosorb W was employed at 150°C.

[40]Recorded on a Bruker Model WH-270 spectrometer at the University of Wisconsin, Madison.

For personal use only.

stirred at −78°C for 45 min. The mixture was then allowed to warm to −30°C over 1.75 h, during which time the color changed from yellow to black. While the temperature of the mixture was maintained at −30°C, an additional 2.3 mL of 1.8 *M* methyllithium (4.2 mmol) was added dropwise, with stirring, over 45 min, and the black mixture was stirred at −30°C for an additional hour, after which it was allowed to warm to 0°C over 1 h. At this point 10 mL of water was added dropwise, with stirring, and the aqueous phase was extracted with petroleum ether (2 × 25 mL). The combined extracts were washed with 50 mL of water and 50 mL of saturated aqueous sodium chloride and dried over anhydrous sodium sulfate. The solvent was evaporated under reduced pressure, and the residual oil was subjected to preparative thick-layer chromatography on silica gel using hexane, followed by preparative gas chromatography,[41] which gave four peaks: retention time (relative area, amount collected, identity) 20 min (40%, 11 mg, unreacted octalin **63**), 22 min (21%, 4 mg, unreacted octalin **62**), 26 min (19%, 6 mg, unidentified isomer or isomers of ishwarane; high resolution ms, *m/e* calcd. for $C_{15}H_{24}$: 204.1878; found: 204.1879), and 31 min (20%, 10 mg, racemic ishwarane). The latter material was found to have ^1H and ^{13}C nmr spectra which were identical to those of authentic ishwarane (**1**); ^1H nmr ($CDCl_3$) δ: 0.48 (m, 1H), 0.75 (d, J = 6.5 Hz, 3H), 0.80 (s, 3H), 1.14 (s, 3H), 1.88 (bd, J = 12 Hz, 1H), 2.09 (bd, J = 12 Hz, 1 H); ^{13}C nmr ($CDCl_3$) δ: 16.6, 16.7, 19.9, 20.3, 22.4, 23.0, 23.9, 30.9, 33.6, 34.7, 35.7, 35.8, 38.7, 39.3, 44.0; high resolution ms, *m/e* calcd. for $C_{15}H_{24}$: 204.1878; found: 204.1877. A 270 MHz ^1H nmr spectrum[40] of natural ishwarane was also obtained ($CDCl_3$) δ: 0.47 (m, 1H, C-7 cyclopropyl), 0.74 (d, $J_{4,14}$ = 6.4 Hz, 3H, C-14 secondary methyl), 0.79 (s, 3H, C-15 tertiary methyl), 1.00 (d, $J_{9\alpha,9\beta}$ = 11.2 Hz, 1 H, C-9 βH), 1.14 (s, 3H, C-13 tertiary methyl), 1.51 (dd, $J_{6\alpha,6\beta}$ = 14 Hz, $J_{6\beta,7}$ = 4 Hz, 1H, C-6 βH), 1.68 (dd, $J_{6\alpha,6\beta}$ = 14 Hz, $J_{6\alpha,7}$ = 2 Hz, 1H, C-6 αH), 1.87 (d, $J_{12\alpha,12\beta}$ = 12 Hz, 1H, C-12 βH), 2.09 (d, $J_{12\alpha,12\beta}$ = 12 Hz, 1H, C-12 αH).

Synthesis of anthracyclinones. Part 1. Regioselective alkylation of 5-hydroxyquinizarin

LAURENCE M. HARWOOD, LESLIE C. HODGKINSON, JAMES K. SUTHERLAND,[1] AND PATRICK TOWERS
Chemistry Department, The Victoria University of Manchester, Manchester, England M13 9PL

Received November 9, 1983

This paper is dedicated to Professor Paul de Mayo on the occasion of his 60th birthday

LAURENCE M. HARWOOD, LESLIE C. HODGKINSON, JAMES K. SUTHERLAND, and PATRICK TOWERS. Can. J. Chem. **62**, 1922 (1984).

Condensation of *leuco*-5-hydroxyquinizarin with aldehydes under Marschalk conditions (sodium hydroxide − water) gives 2-alkyl-5-hydroxyquinizarins with high regioselectivity, while the 3-alkyl compounds are obtained under Lewis conditions (piperidinium acetate − isopropanol). Reaction of the quinone with nitronate anions in methanol yields 2-alkyl derivatives exclusively.

LAURENCE M. HARWOOD, LESLIE C. HODGKINSON, JAMES K. SUTHERLAND et PATRICK TOWERS. Can. J. Chem. **62**, 1922 (1984).

La condensation de la *leuco* hydroxy-5 quinizarine avec les aldéhydes, en utilisant les conditions de Marschalk (hydroxyde de sodium et eau), conduit aux alkyl-2 hydroxy-5 quinizarines avec une grande régiosélectivité; toutefois, si on utilise les conditions de Lewis (acétate de pipéridinium et isopropanol), on obtient les composés alkylés en position 3. La réaction de la quinone avec les anions nitronates dans le méthanol conduit exclusivement aux dérivés alkylés en position 2.

Our choice of the readily available 5-hydroxyquinizarin (**1**) as a starting point for the synthesis of the aglycones of the anthracycline antibiotics daunomycin and carminomycin (*1*) necessitated the development of methods for the regioselective substitution of **1** at C-2 and (or) C-3. Prior work by Marschalk *et al.* (2) had shown that aldol condensation between *leuco*-quinizarin (**12**) and aldehydes was an effective method for the preparation of 2-alkylquinizarins. Brockmann and Müller (3) carried out Marschalk condensations with *leuco*-5-hydroxy-quinizarin (**13**) and presented evidence for some regioselectivity in favour of C-2.

We first examined the Marschalk condensation of propionaldehyde with the *leuco*-compound **13** and obtained the 2-propyl derivative (**2**). The structure of **2** was established by conversion to the tri-*O*-methyl ether which was cleaved with $KOBu^t-H_2O$ using Hodge's method (4) to give, after methylation of the acidic products with CH_2N_2, *m*-methoxybenzoic acid methyl ester (22%) and the ester **14** (28%). An authentic sample of the ester **14** was synthesized starting with propionylation of 1,4-dimethoxybenzene followed by Clemmensen reduction to 2-*n*-propyl-1,4-dimethoxybenzene; Friedel−Crafts acetylation followed by hypochlorite oxidation and esterification gave material identical with the degradation product. Reaction of the *leuco*-compound **13** with propionaldehyde in isopropanol containing piperidinium acetate (conditions described by Lewis (5)) gave predominantly the 3-propylquinone (**3**). Since we have not found any chromatographic system which will separate the 2- and 3-propyl isomers it is necessary to convert the product to the tri-*O*-methyl ethers to determine isomeric purity; these isomers can be separated by tlc. Degradation of the tri-*O*-methyl ether of **3** by the Hodge procedure was much more complex than in the previous case but did yield *m*-methoxybenzoic acid (9%) and the ester **15** (6%). The tri-*O*-methyl ethers of **2** and **3** show minor differences in their ^1H nmr spectra which we have found to be present in other isomeric pairs. We believe these differences are reliable enough to allow assignment of structures. In the 2-alkyl series the proton resonates at δ_H 7.00 with the methoxyl singlets at 3.94, 3.91, and 3.83 while in the 3-alkyl series the 2-proton absorbs at 6.82 and the methoxyls at 3.94, 3.90, and 3.88. Table 1 summarizes the isomer ratios obtained with a variety of aldehydes using the two alkylation methods.

We have no definitive experiments pertaining to the origin of the regioselectivity in these reactions; however, titration of *leuco*-5-hydroxyquinizarin indicates that in dilute alkaline

[d]No 3-alkylation.

solution the bulk species present is a monoanion. This is the likely species present under the conditions of the Marschalk condensation. If the predominant anion present is **16**[2] then the kinetically active species must arise by proton abstraction from position 2 which will generate an enolate stabilized by hydrogen bonding; no such stabilization is available to the enolate arising from proton abstraction from position 3, since the hydrogen bond is stabilizing the oxyanion. Under the Lewis conditions the kinetically reactive species may well be **17**[3] derived from the neutral *leuco*-compound to give, by proton abstraction from position 3, a more stable enolate than that derived from position 2 due to more extensive hydrogen bonding.

With the regioselectivity of the reactions established we turned to the problem of introducing side-chains containing functional groups. Table 1 shows that α-, γ-, and δ-hydroxyaldehydes can be used successfully. Krohn and Radeloff (6) have defined conditions where a wide variety of aldehydes have been successfully condensed with *leuco*-quinizarin and the reaction intercepted at the aldol stage to give 2-(1-hydroxyalkyl)quinizarins after aerial oxidation; we have found this method to be an excellent one using *leuco*-quinizarin but not generally applicable to the 5-hydroxy derivative. However, the protocol described by Shaw and co-workers (7) is an effective method using *leuco*-5-hydroxyquinizarin (**13**). Reaction of 2,3-epoxybutanal with **13** under controlled conditions gave a compound formulated as **18** (ν_{max}: 1665, 1625 cm^{-1}; δ_H: 12.32 (1H, s), 11.93 (1H, s), 7.56 (1H, dd, J = 8.0 and 1.3 Hz), 7.22 (1H, t, J = 8.0 Hz), 7.00 (1H, dd, J = 8.0 and 1.3 Hz), 6.98 (1H, s), 4.93 (1H, td, J = 8.0 and 3.0 Hz), 4.40 (1H, qd, J = 8.0 and 3.0 Hz), 3.72 (1H, bs), 3.17 (2H, m), 1.22 (3H, d, J = 8.0 Hz)). On oxidation with pyridinium chlorochromate a methyl ketone was formed (ν_{max}: 1730, 1660, 1620 cm^{-1}; δ_H: 5.26 (1H, t, J = 7 Hz), 3.45 (2H, d, J = 7 Hz), 2.38 (3H, s)).

The conditions of the Marschalk condensation are not compatible with the presence of certain functionalities in the aldehyde; in particular, leaving groups β to the aldehyde function do not survive. In an effort to define milder conditions for the aldol condensation we attempted to prepare an enamine from *leuco*-quinizarin (**12**); to our surprise, reaction of **12** with pyrrolidine in refluxing toluene gave 1-hydroxyanthraquinone in excellent yield. Application of these conditions to *leuco*-5-hydroxyquinizarin yielded 1,5-dihydroxyanthraquinone. We formulate this reaction as shown in Scheme 1. At lower temperatures amines did not react with *leuco*-quinizarin, but quinizarin (produced by adventitious oxidation) gave amino derivatives. This was confirmed by reaction of quinizarin with pyrrolidine, piperidine, and benzylamine to give the amines of the type **19**. Since a likely mechanism of formation of these compounds is nucleophilic addition followed by aerial oxidation, we investigated the reactions of the quinizarins with carbanions.

23

Reaction of 5-hydroxyquinizarin with an excess of 1-nitropropane and half that concentration of sodium methoxide in methanol gave the 2-propyl compound **2** in excellent yield. By conversion to the trimethyl ether it was shown, within our detection limits, to be uncontaminated with any of the 3-isomer. 2-Nitropropane and nitromethane gave similar results; in the latter case prolonged reaction gave 2,3-dimethyl-5-hydroxyquinizarin. Reaction with 1,4-dinitrobutane gave the tetracycle **20**, and the ethylene acetal of 4-nitrobutan-2-one produced **9**. We postulate that the regioselectivity is determined in the addition of the nitronate anion to the *unionized* 5-hydroxyquinizarin to give the more stable 3-enolate. In support of this suggestion, no reaction occurs when enough base is present to convert both quinizarin and nitroalkane to their respective anions. Similar arguments can be used to account for regioselectivity in an electron transfer mechanism. When the reaction with 1-nitropropane is carried out in 95% ethanol the likely intermediate **23** can be trapped by water to give, after aerial oxidation, the hydroxypropyl compound **11**.[4]

[2]The huge difference in acidity between 2-acyl-1-naphthols and 2-acyl-1,8-naphthalenediols was established during the structure determination of terramycin (8).

[3]Selective formation of the 3,4-enamine as intermediate instead of **17** was considered but rejected in the expectation that the adduct would undergo aromatization either to the 3-hydroxyalkyl-1,5-dihydroxyanthraquinone (see later) or to the 3-alkyl-1,5-dihydroxy-4-pyrrolidinylanthraquinone. However, the electrophile in the reaction might well be the immonium salt of the aldehyde.

[4]This reaction was discovered by Mr. A. Kumar in these laboratories.

In order to test some of the later stages of our proposed synthesis we carried out some model experiments. The alcohol **5** could be oxidized to the aldehyde with pyridinium chlorochromate without oxidation of the quinizarin ring. Dithionite reduction of the aldehyde under Marschalk conditions gave the tetracycle **20**. Hydrolysis of the acetal **9** generated the ketone which, under Marschalk conditions, gave a mixture of **21** and **22**; dithionite reduction of **21** gave **22**.

Experimental

All samples on which accurate mass measurements were determined show a single spot on tlc.

2-n-Propyl-5-hydroxyquinizarin (2)

5-Hydroxyquinizarin (512 mg) was dissolved in 5% NaOH–H_2O and the blue solution adjusted to pH 10 with 10% HCl–H_2O. After warming to 40°C under a N_2 atmosphere a solution of Na_2CO_3 (2 g) and $Na_2S_2O_4$ (1 g) in H_2O (20 mL) was added until the orange *leuco*-anion was formed. Propionaldehyde (348 mg) in H_2O (10 mL) was added over 30 min and the mixture boiled with reflux for 2 h. Heating then ceased and air was passed through the solution for 15 min. After acidification with 10 *M* HCl the precipitate was filtered off, washed with H_2O, dried, and extracted with boiling $CHCl_3$ (4 × 20 mL). The $CHCl_3$ extract was dried and evaporated to give a red solid which on recrystallization from CCl_4 gave the *propyl derivative* (**2**) (300 mg), mp 187–190°C; λ_{max} (EtOH): 233 (40 000), 253 (24 500), 292 (7 800), 466 (9 700), 481 (11 400), 493 (13 000), 514 (9 500), and 527 nm (9 000); δ_H: 1.03 (3H, t, J = 7.5 Hz), 1.73 (2H, m), 2.72 (2H, t, J = 7.5 Hz), 7.09 (1H, s), 7.24 (1H, dd, J = 8 and 1.3 Hz), 7.63 (1H, t, J = 8 Hz), 7.82 (1H, dd, J = 8 and 1.3 Hz), 12.18 (1H, s), 12.25 (1H, s), 13.46 (1H, s). *Anal.* calcd. for $C_{17}H_{14}O_5$: C 68.5, H 4.7%; found: C 68.3, H 4.7%.

The following 2-substituted 5-hydroxyquinizarins were prepared from the aldehydes indicated, in a similar way.

2-(5′-Hydroxypentyl) (**4**) from 5-hydroxypentanal (43%), mp 187–191°C (CCl_4). *Anal.* calcd. for $C_{19}H_{18}O_6$: C 66.7, H 5.3%; found: C 66.4, H 5.4%.

2-(4′-Hydroxybutyl) (**5**) from 4-hydroxybutanal (44%) (CCl_4), mp 195–199°C (CCl_4). *Anal.* calcd. for $C_{18}H_{16}O_6$: C 65.9, H 4.9%; found: C 66.0, H 4.9%.

2-(2′-Hydroxyethyl) (**7**), from hydroxyacetaldehyde (50%) mp >300°C. $C_{16}H_{12}O_6$ requires M^+: 300.0634; found: 300.0629.

2-(2′-Methyl-3′-furyl)methyl (**8**) from 2-methylfuran-3-carboxaldehyde (72%), mp 215–218°C (CCl_4). *Anal.* calcd. for $C_{20}H_{14}O_6$: C 68.6, H 4.0%; found: C 68.6, H 4.0%.

2-Ethyl- from acetaldehyde (67%), mp 125–128°C (Me_2CO). *Anal.* calcd. for $C_{16}H_{12}O_5$: C 67.6, H 4.3%; found: C 67.9, H 4.4%.

2-(2′-Methylpropyl) from 2-methylpropanal (63%), mp 196–199°C (Me_2CO). *Anal.* calcd. for $C_{18}H_{16}O_5$: C 69.2, H 5.2%; found: C 69.6, H 5.6%.

The ether (**18**) from 2,3-epoxybutanal (80%), mp >205°C (dec.) (CCl_4). $C_{18}H_{14}O_6$ requires M^+: 326.0790; found: 326.0785.

Oxidation of **18** with pyridinium chlorochromate gave a ketone, mp >180°C (dec.). ν_{max}: 1720 cm^{-1}; δ_H: 2.40 (3H, s), 3.45 (2H, d, J = 7 Hz), 5.28 (1H, t, J = 7 Hz), 12.11 (1H, s), 12.54 (1H, s).

2-(Cyclopent-3′-enyl)methyl from cyclopent-3-ene carboxaldehyde (42%), mp 199–201°C (sublimation). *Anal.* calcd. for $C_{20}H_{16}O_5$: C 71.4, H 4.8%; M^+: 336.0998; found: C 71.3, H 4.8%; M^+: 336.0991.

2-n-Propyl-1,4,5-trimethoxyanthracene-9,10-dione

2-*n*-Propyl-5-hydroxyquinizarin (**2**) (122 mg) was boiled with reflux in dimethoxyethane (15 mL) containing NaH (400 mg of 50% dispersion in oil) and MeI (1 g) for 12 h. Addition of Et_2O, filtration, and evaporation of solvent gave a brown paste which was washed with pentane, 2 *M* HCl, and extracted with Et_2O. Removal of solvent gave a gum which was purified by plc on silica gel GF254 eluting with EtOAc–Et_2O (5:3) to give the *ether* (58 mg), mp 49–52°C; δ_H: 1.00 (3H, t, J = 7.5 Hz), 1.66 (2H, m), 2.66 (2H, t, J = 7.5 Hz), 3.83 (3H, s), 3.91 (3H, s), 3.94 (3H, s), 6.98 (1H, s), 7.00 (1H, dd, J = 8 and 2 Hz), 7.46 (1H, t, J = 8 Hz), 7.61 (1H, dd, J = 8 and 2 Hz). $C_{20}H_{20}O_5$ requires M^+: 340.1310; found: 340.1304.

Cleavage of 2-n-propyl-1,4,5-trimethoxyanthracene-9,10-dione

The ether (56 mg) in dimethoxyethane (15 mL) containing KOBu′ (250 mg) and H_2O (12 mg) was boiled with reflux under a N_2 atmosphere for 4 h. Brine (20 mL) was added and the solution extracted with Et_2O (2 × 30 mL). Acidification of the aqueous layer, extraction with EtOAc, and concentration of the dried extract gave a gum which was treated with CH_2N_2–Et_2O. Removal of solvent gave a gum which was resolved by plc on silica gel GF254 by eluting with pentane–Et_2O (4:3) into methyl 3-methoxybenzoate (6 mg) (identical to an authentic specimen) and *methyl 2,5-dimethoxy-4-n-propylbenzoate* (11 mg); δ_H: 0.96 (3H, t, J = 7.5 Hz), 1.62 (2H, m), 2.57 (2H, t, J = 7.5 Hz),, 3.69 (3H, s), 3.71 (6H, s), 6.65 (1H, bs), 7.27 (1H, s). $C_{13}H_{18}O_4$ requires M^+: 238.1205; found: 238.1205.

Synthesis of methyl 2,5-dimethoxy-4-n-propylbenzoate

1,4-Dimethoxybenzene (2.76 g) and propionic acid (2.22 g) were dissolved in polyphosphoric acid (120 mL) and the solution stirred at 70°C for 2 h. H_2O (100 mL) was cautiously added and the mixture extracted with Et_2O (2 × 100 mL). The ethereal layer was washed with saturated $NaHCO_3$–H_2O, H_2O, dried, and concentrated to give *2-propionyl-1,4-dimethoxybenzene* (3.69 g) as a low melting (ca. 8°C) solid. *Anal.* calcd. for $C_{11}H_{14}O_3$: C 68.0, H 7.3%; found: C 68.2, H 7.3%. An amalgam was prepared from $HgCl_2$ (150 mg), Zn dust (2 g) in 10 *M* HCl (5 mL) was added to the ketone (970 mg) suspended in H_2O (20 mL), and the mixture boiled with reflux for 5 h. During this time 10 *M* HCl was added in portions (5 × 1 mL). After 18 h at ambient temperature the mixture was extracted with Et_2O (3 × 15 mL), the extract washed with saturated $NaHCO_3$–H_2O, H_2O, dried, and concentrated to give a brown oil which on bulb-to-bulb distillation gave *2,5-dimethoxy-1-n-propylbenzene* (430 mg). *Anal.* calcd. for $C_{11}H_{16}O_2$: C 73.3, H 9.0%; found: C 73.7, H 9.0%. The ether (400 mg) in CS_2 (10 mL) was slowly added to powdered $AlCl_3$ (355 mg) in CS_2 (20 mL) at 0°C. After 17 h the mixture was poured on to ice and 10 *M* HCl (1 mL) added. Extraction with Et_2O (3 × 15 mL) gave, after washing with H_2O, drying, and concentration, an oil which was chromatographed on silica gel; elution with pentane–Et_2O (3:1) gave starting ether (149 mg) and *2,5-dimethoxy-4-n-propylacetophenone*, mp 38–39°C (pentane). *Anal.* calcd. for $C_{13}H_{18}O_3$: C 70.3, H 8.1%; found: C 70.7, H 8.1%. The ketone (30 mg) in dioxan (0.3 mL) was added to 5% NaOCl–H_2O (15 mL) and 10% NaOH–H_2O (1 mL). After heating for 2 h on a steam bath, the cooled solution was extracted with Et_2O and the aqueous layer acidified and extracted with EtOAc (3 × 10 mL). Drying and concentration of the EtOAc extract gave a gum which was treated with CH_2N_2–Et_2O. Preparative layer chromatography of the product on silica GF254 and elution with pentane–Et_2O (4:3) gave methyl 2,5-dimethoxy-4-*n*-propylbenzoate identical with the material obtained from degradation of the ether by nmr, ir, and mass spectroscopy and tlc.

3-n-Propyl-1,4,5-trihydroxyanthraquinone

leuco-5-Hydroxyquinizarin (**13**) (1.087 g) was suspended in EtOH (70 mL) and the mixture warmed to 60°C under a N_2 atmosphere. Propanal (3.6 g) was added, followed by piperidinium acetate (665 mg) in EtOH (5 mL). After boiling with reflux for 3 h, the cooled solution was carefully acidified with 5 *M* HCl. The red precipitate was filtered off, dried (828 mg), and recrystallized from CH_2Cl_2 to give the *3-n-propylquinone* (**3**) (744 mg), mp 193°C. *Anal.* calcd. for $C_{17}H_{14}O_5$: C 68.5, H 4.7%; found: C 67.9, H 4.4%.

1-Hydroxyanthraquinone

leuco-Quinizarin (**12**) (242 mg) in PhMe (150 mL) was refluxed under a N_2 atmosphere in a Dean-Stark apparatus. Pyrrolidine (71 mg) in PhMe (20 mL) was added and the solution boiled with reflux until no more H_2O separated (ca. 4 h). The solid obtained after evaporation of solvent was extracted with hot Me_2CO (3 × 50 mL). Evaporation of the Me_2CO extracts gave a dark yellow solid which was extracted with hot CCl_4 (3 × 50 mL). Evaporation of this extract and recrystallization of the residue from Me_2CO gave the quinone (186 mg),

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.4 on 09/06/12
For personal use only.

mp 194–195°C.

Similar reaction of *leuco*-5-hydroxyquinizarin gave 1,5-dihydroxyanthraquinone.

When Et_2O was substituted for $PhCH_3$ the *amine* **19** was obtained, mp 219–220°C (CCl_4): λ_{max}: 223 (19 000), 235 (16 300), 281 (15 000), 513 (8 700), 545 (15 700), 577 nm (11 500); δ_H: 14.65 (1H, s), 14.28 (1H, s), 8.2 (2H, m), 7.4 (2H, m), 5.93 (1H, s), 3.6 (4H, m), 1.95 (4H, m). $C_{18}H_{15}NO_4$ requires M^+: 309.1001; found: 309.1000. This product was shown to arise from quinizarin produced by oxidation of the *leuco*-compound.

Reactions of 5-hydroxyquinizarin with nitronate anions

5-Hydroxyquinizarin (256 mg) was suspended in EtOH (100 mL) and a NaOEt solution (*ex.* 112 mg Na and 20 mL EtOH) added, forming a blue solution. 1-Nitropropane (890 mg) was added and the solution boiled with reflux until no starting quinone remained (ca. 24 h). The cooled solution was acidified with 10 *M* HCl, extracted with $CHCl_3$, and the dried extract concentrated to give a red solid which, on recrystallization from CCl_4, gave the propyl compound (**2**) (197 mg) identical to that previously prepared and confirmed to be the 2-isomer by conversion to the trimethyl ether.

The following 2-substituted 5-hydroxyquinizarins were prepared in the same manner from the nitro compound indicated.

2-Me (70%), mp 216–218°C (Me_2CO) from $MeNO_2$.

2-Pr^i (53%), mp 187–189°C (Me_2CO) from Pr^iNO_2. $C_{17}H_{14}O_5$ requires M^+: 298.0841; found: 298.0833.

2-$(CH_2)_2C(OCH_2)_2Me$ (66%), mp 194–195°C (CCl_4) from $MeC(OCH_2)_2(CH_2)_2NO_2$. *Anal.* calcd. for $C_{20}H_{18}O_7$: C 64.9, H 4.9%; found: C 64.9, H 4.9%.

2,3-$(CH_2)_4$ (47%), mp sublimes ca. 220°C.

*Preparation of the tetracycle (**20**)*

The alcohol **5** (74 mg) in CH_2Cl_2 (25 mL) was added to a stirred suspension of pyridinium chlorochromate (150 mg) in CH_2Cl_2 (20 mL). After 2 h the mixture was filtered through Celite, after the addition of Et_2O (50 mL). The residues were washed with Et_2O (3 × 15 mL). The combined filtrates were shaken with 5% $NaHCO_3$–H_2O (2 × 30 mL), 1 *M* HCl (30 mL), and then 5% NaOH–H_2O. Acidification of the latter extract and extraction with CH_2Cl_2 (2 × 25 mL) gave the *aldehyde* (44 mg), mp 171–175°C; ν_{max}: 1720 cm^{-1}; δ_H: 9.8 (1H, t, J = 1.5 Hz). *Anal.* calcd. for $C_{18}H_{14}O_6$: C 66.3, H 4.3%; found: C 66.0, H 4.7%.

The aldehyde (31 mg) in 1% NaOH–H_2O (20 mL) was warmed to 90°C and 5% $Na_2S_2O_4$–H_2O added until the blue colour was discharged. After 5 h at 90°C a current of air was passed through the cooled solution for 5 min. Acidification with 1 *M* HCl, extraction with CH_2Cl_2, and drying and concentration of the extract gave the *tetracycle* **20** (24 mg), mp sublimes ca. 220°C. *Anal.* calcd. for $C_{18}H_{14}O_5$: C 69.7, H 4.6%; M^+: 310.0841; found: C 69.5, H 4.7%; M^+: 310.0839.

*2-(1′-Hydroxypropyl)-5-hydroxyquinizarin (**11**)*

5-Hydroxyquinizarin (512 mg) was suspended in 95% EtOH–H_2O (200 mL) and NaOEt in 95% EtOH (*ex.* Na 230 mg and 20 mL solvent) added. After boiling with reflux for 24 h, the cooled solution was acidified with 10% HCl–H_2O and extracted with $CHCl_3$ (3 × 25 mL). Concentration of the dried solution gave the *alcohol* **11** (320 mg), mp 216°C ($CHCl_3$); δ_H: 14.03 (1H, s), 13.46 (1H, s), 13.29 (1H, s), 7.83 (1H, dd, J = 8 and 1.8 Hz), 7.65 (1H, t, J = 8 Hz), 7.41 (1H, t, J = 0.6 Hz), 7.25 (1H, dd, J = 8 and 1.8 Hz), 4.91 (1H, bd, J = 5.6 Hz), 1.78 (2H, m), 0.94 (3H, t, J = 8 Hz). $C_{17}H_{14}O_6$ requires M^+: 314.0790; found: 314.0785.

*Hydrolysis of acetal (**9**)*

The acetal **9** (370 mg) was dissolved in hot Me_2CO (150 mL) and 5% HCl–H_2O (70 mL) added. After 10 h at ambient temperature the Me_2CO was removed *in vacuo* and the solid recrystallized from $CHCl_3$–pentane to give the *ketone* **10** (287 mg), mp 189–190°C; ν_{max}: 1720 cm^{-1}; δ_H: 2.99 (2H, t, J = 8.2 Hz), 2.84 (2H, t, J = 8.2 Hz), 2.18 (3H, s). $C_{18}H_{14}O_6$ requires M^+: 326.0790; found: 326.0781.

*Cyclization of the ketone (**10**)*

The ketone (163 mg) was dissolved in 5% NaOH–H_2O (70 mL) under a N_2 atmosphere and $Na_2S_2O_4$ (500 mg) in H_2O (20 mL) added. After $\frac{1}{2}$ h at 80°C the mixture was acidified and extracted with $CHCl_3$. Concentration of the dried extract gave a solid which on crystallization from $CHCl_3$–pentane gave a fraction rich in **21**, while the mother liquours contained mainly **22**. Complete separation could be effected by sublimation at 150°C/0.01 Torr (1 Torr = 133.32 Pa) when the sublimate was found to be the *cyclopentane* **22** (92 mg), mp 187–189°C; δ_H: 1.04 (3H, d, J = 8.5 Hz). $C_{18}H_{14}O_5$ requires M^+: 310.0841; found: 310.0838. The residue was found to be the *cyclopentene* **21** (54 mg), mp 193–196°C; δ_H: 2.46 (3H, bs), 6.50 (1H, m). $C_{18}H_{12}O_5$ requires M^+: 308.0684; found: 308.0674. Reduction of **21** with $Na_2S_2O_4$ under the reaction conditions formed **22** in quantitative yield.

A new route to the *cis–anti–cis* triquinane ring system. The synthesis of 4,4-dimethyltricyclo[6.3.0.0^{2,6}]undecan-3-one via β-enolate rearrangement[1]

HEMANT A. PATEL AND J. B. STOTHERS
Department of Chemistry, University of Western Ontario, London, Ont., Canada N6A 5B7

Received March 9, 1984

This paper is dedicated to Professor Paul de Mayo on the occasion of his 60th birthday

HEMANT A. PATEL, and J. B. STOTHERS. Can. J. Chem. **62**, 1926 (1984).

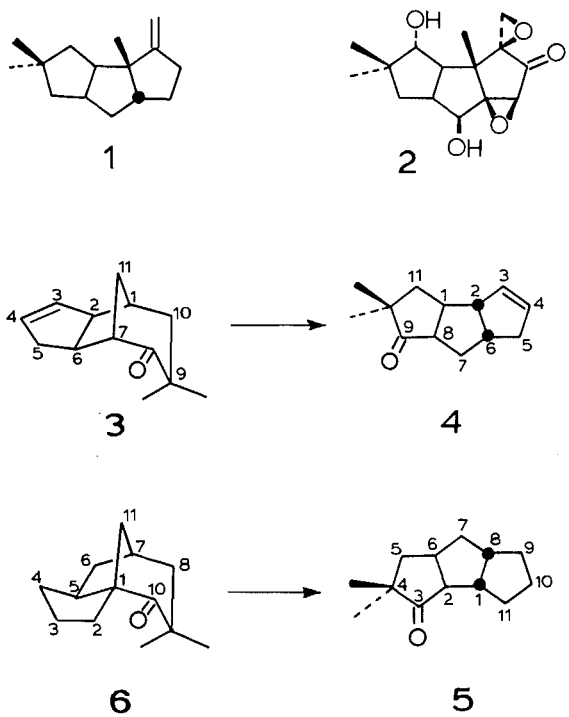
A synthesis of *cis*, *anti*, *cis*-4,4-dimethyltricyclo[6.3.0.0^{2,6}]undecan-3-one is described in which the key step is β-enolate rearrangement of 9,9-dimethyltricyclo[5.3.1.0^{1,5}]undecan-10-one proceeding with retention of configuration. The required [5.3.1.0^{1,5}] ketone was prepared in six steps from tricyclo[5.2.1.0^{1,5}]dec-8-ene. This sequence constitutes a new route to the tricyclo[6.3.0.0^{2,6}]undecane ring system characteristic of the hirsutane sesquiterpenes. The ^{13}C data for several tricyclic derivatives are reported.

HEMANT A. PATEL, et J. B. STOTHERS. Can. J. Chem. **62**, 1926 (1984).

On décrit une synthèse de la diméthyl-4,4 tricyclo[6.3.0.0^{2,6}]undécanone-3 *cis*, *anti*, *cis* dans laquelle l'étape déterminante est une transposition β-énolique de la diméthyl-9,9 tricyclo [5.3.1.0^{1,3}]undécanone-10 qui se produit avec une rétention de configuration. On a préparé la cétone [5.3.1.0^{1,5}] requise en six étapes à partir du tricyclo[5.2.1.0^{1,5}]décène-8. Cette série de réaction constitue une nouvelle voie permettant de préparer le système tricyclo[6.3.0.0^{2,6}]undécane qui est caractéristique des sesquiterpènes hirsutanes. On rapporte les données de la rmn du ^{13}C pour plusieurs dérivés tricycliques.

[Traduit par le journal]

The discovery and characterization of several naturally occurring compounds having the linearly fused tricyclopentanoid ring system of *cis*, *anti*, *cis*-tricyclo[6.3.0.0^{2,6}]undecane, such as hirsutene (**1**) and coriolin (**2**), have attracted considerable interest since many of these materials exhibit anti-tumor and (or) antibiotic activity (1). An array of synthetic routes to **1**, **2**, and congeners has been described (2) including, from this laboratory (3), a sequence leading to **1** which utilizes a stereocontrolled β-enolate rearrangement for the generation of the ring system. The key step is the conversion of **3** → **4**[2] via proton abstraction from C-11 in **3** with the stereochemistry of the subsequent rearrangement constrained to give the correct configuration at C-8 in **4**. Through our interest in the potential of homoenolate rearrangement for the generation of less accessible polycyclic carbon skeletons, we have investigated other possible routes to the [6.3.0.0^{2,6}] system. In this report, we wish to describe the formation of 4,4-dimethyltricyclo-[6.3.0.0^{2,6}]undecan-3-one (**5**) in reasonable yield by β-enolization of 9,9-dimethyltricyclo[5.3.1.0^{1,5}]undecan-10-one (**6**).[2]



The required tricyclic ketone **6** was prepared from the known epoxide **7** (4) as outlined in Scheme 1. After heating **7** under reflux with lithium triethyl borohydride ("Super Hydride") in THF (5), the product was oxidized with alkaline peroxide to furnish a 85:15 mixture of alcohols **8** and **9** which were separable by flash chromatography (6). Pyridine – chromic acid oxidation (7) of **8** furnished the corresponding ketone **10***a* in high yield. The generation of the homologous ketone **12** via cyclopropanation of the silyl enol ether of **10***a* followed by homoketonization failed, in sharp contrast to the behavior of the isomeric **11***a* which is readily transformed to **14** by this route (8). Each of several attempts, under a variety of conditions, gave a complex mixture of unidentified products. As an alternative, the Tiffeneau–Demjanov ring expansion (9) was examined and found to be satisfactory although less efficient because of the concomitant formation of the unwanted isomer **13**. Treatment of **10***a* with trimethylsilyl cyanide (10) gave the trimethylsilyl cyanohydrin ether **10***b*, which was reduced to the β-aminoalcohol **10***c* with lithium aluminium hydride. Reaction of **10***c* with nitrous acid furnished a 2:1 mixture of ketones **12** and **13** which were separated by flash chromatography. The overall yield for the ring expansion of **10***a* → **12** and **13** was 80%. Ketones **12** and **13** were easily distinguished by their ^{13}Cmr spectra since the quaternary carbon signals appeared at 66.1 and 52.6 ppm, respectively. The 13.5 ppm downfield shift of this signal in **12** is readily attributed to the α-carbonyl group. The identity of these ketones was confirmed by carrying alcohol **9** through the same series of reactions to a 64:36 mixture of two ketones in 74% yield. These two ketones were separated

[1]Part 110 in the series ^{13}Cmr studies; for Part 109 see ref. 8.

[2]With the skeletal rearrangement, a different numbering scheme is required as indicated in the formulas.

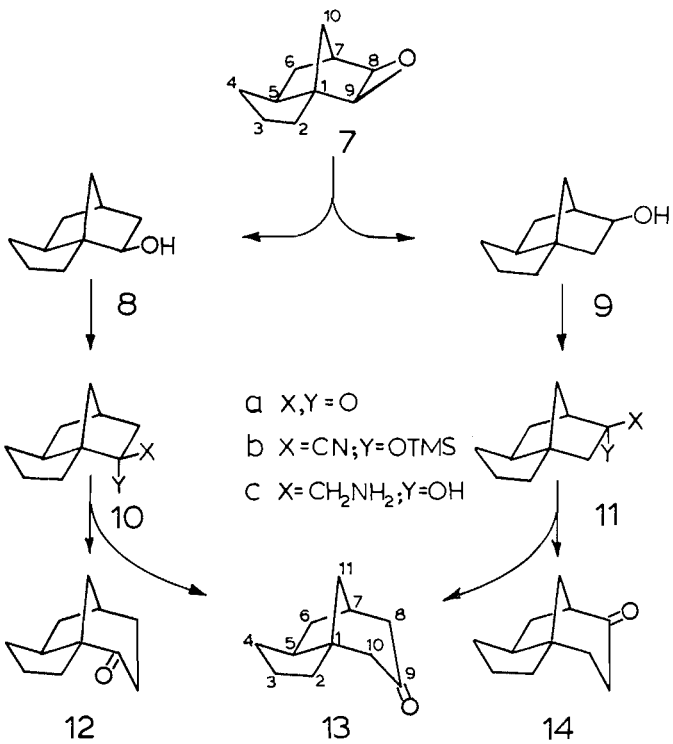
[b]Assignments obtained from 2D INADEQUATE spectra.



SCHEME 1

by flash chromatography and the major ketone was found to be identical (ir, ^{1}Hmr, ^{13}Cmr, ms) to the known **14** (8). The spectral properties of the minor ketone were the same as those for **13**. Dimethylation of **12** with sodamide – ether – methyl iodide gave the required **6** in 69% yield.

As part of their characterization, the ^{13}Cmr spectra of **6**, **7**, and **10**–**13** were recorded and the shielding data are collected in Table 1. The assignments for the [5.2.1.$0^{1,5}$] derivatives followed from the observed trends throughout the series with due regard for the expected substituent effects and by comparison with the previously reported data for **8**, **9**, and **11***a* (8). In addition, unequivocal assignments for the 8,8-dimethyl derivative of **10***a*, available from another project, were obtained from its two-dimensional, double quantum coherence spectrum (11). Similarly, the 2D INADEQUATE spectra for **6**, **12**, and **13** furnished definitive assignments as listed in Table 1.

Having **6** in hand, we were able to examine its behavior under typical homoenolization conditions. From our earlier study of the simpler 3,3-dimethylbicyclo[3.2.1]octan-2-one under such conditions (12), we could anticipate β-proton abstraction to occur at either, or both, C-5 and -11 to generate, in principle, β-enolates **15** and **16**, respectively. Subsequent cleavage of these β-enolates via mode b (Scheme 2) would lead to the formation of **6** and **5**, respectively. It is significant that, in either case, cleavage b must occur with retention of configuration at the carbon picking up the proton (C-1 in the original skeleton). Although the majority of examples of β-enolate cleavage, for which the stereochemistry has been examined, proceed primarily with inversion of configuration, there are some systems which exhibit a high degree of retention (13). In the present cases of **15** and **16**, inversion of configuration for cleavage via b would lead to a *trans* ring junction in the resulting ketones, each of which is a substituted [3.3.0] system. However, in the parent [3.3.0] system, the *trans* arrangement is disfavored by ca. 6 kcal/mol relative to the *cis* (14). Thus, retention of configuration upon cleavage of **15** and **16** would be expected. It may be noted that for **15** cleavage by either a or b should proceed with retention and that mode b merely constitutes a racemization pathway for **6**. In the case of **16**, cleavage a must proceed with inversion and b with retention.

Treatment of **6** with *t*-BuO^-/*t*-BuOH at 185°C for extended reaction times gave a neutral fraction in 69% yield which was isolated by ether extraction. This fraction consisted of two ketones in a ratio of ca. 1:2; the minor component of the mixture was shown to be **6** after separation by flash chromatography. The major ketonic product was found to be isomeric having the molecular formula $C_{13}H_{20}O$, by precise mass measurement, and to contain a five-membered ring ketone according to its carbonyl absorption (1730 cm^{-1} ($CHCl_3$), δ_c 225.1). Thus the compound could be assigned structure **5** arising by proton abstraction at C-11 in **6** to form **16**, or an equivalent β-enolate, which is cleaved with protonation occurring at C-1 with retention of configuration thereby generating the *cis*-1,8 ring junction in the *cis*, *anti*, *cis* [6.3.0.$0^{2,6}$] skeleton, which is the ring system of the hirsutanes. To confirm this structural assignment, **5** was converted to the corresponding hydrocarbon **17** by Wolff–Kishner reduction (15) in 80% yield. The same hydrocarbon **17** (by ir, ^{1}Hmr, ^{13}Cmr) was found to arise by Wolff–Kishner reduction of a mixture of **18** (1*b*) and its 5-oxo isomer. The latter mixture had been syn-

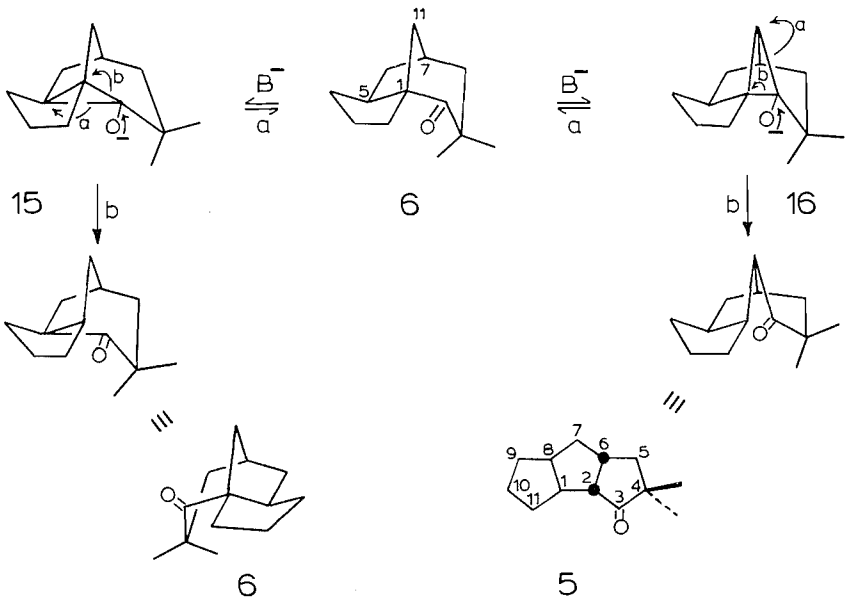
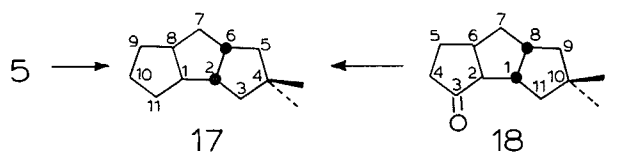
For personal use only.



SCHEME 2



thesized in our sequence leading to hirsutene (**1**) (3).

With the identification of ketone **5** we have established a second route via β-enolate rearrangement to the tricyclo-[6.3.0.$0^{2,6}$]undecane ring system. In this case, the required configuration at C-6 and -8 in **5** is present at the outset (C-5 and -7 in **6**), while the constraints of the ring system govern the stereochemistry at C-1 and -2 leading to the desired *cis*, *anti*, *cis* arrangement of the three cyclopentane rings. It may be noted that, in contrast to the route to the hirsutanes via **4** (3), the rearrangement of **6** → **5** places oxygen at the appropriate carbon in the dimethylated ring of the system for the coriolin family of compounds. Thus this sequence may be capable of adaption for the synthesis of these derivatives and their analogs. Further studies directed toward this goal are in hand.

Experimental

Melting points and boiling points are uncorrected. Thin layer chromatography (tlc) was done on Kiesel gel 60 F_{254} plates and flash chromatography (fc) columns were prepared as described in the literature (6). Tetrahydrofuran (THF) and ether were distilled from Na/benzophenone just before use. Pyridine and *tert*-butyl alcohol were distilled from CaH_2 and stored over 4A molecular sieves. The following compounds were prepared by known methods and gave satisfactory physical and spectral data: pent-4-en-1-ol (16), pent-4-enylcyclopentadienes (4), and **7** (4).

Infrared spectra were recorded with a Beckman 4250 spectrophotometer. Mass spectra were obtained on a Varian MAT-311A system at 70 eV (direct inlet). Routine ^{1}Hmr spectra were recorded on a Varian T-60 instrument while data for pure samples were obtained with a Varian XL-200 spectrometer. The latter instrument was used to record the ^{13}C spectra (50.3 MHz) and comparison of the fully decoupled spectra with those obtained with either the APT (17) or INEPT (18) sequences served to identify the methyl, methylene, methine, and quaternary signals. The 2D INADEQATE spectra (11) were obtained with the CCC2D pulse sequence of the XL software using a 2048 × 128 data point matrix transforming 2048 and 512 points, respectively, with the following sweep widths in both domains: 2000 (**13**), 2200 (**6** and **12**), and 2500 Hz (8,8-Me_2-**10***a*). The ^{13}C data are collected in Table 1.

exo-*Tricyclo[5.2.1.$0^{1,5}$]decan-9-ol (8)*

To a stirred solution of $LiEt_3BH$ in THF (20 mL, 1.0 *M*, 0.02 mol) under N_2 was added **7** (1.5 g, 0.01 mol) in THF (3.0 mL) at room temperature and the solution heated under reflux for 15 h. After cooling, excess reagent was destroyed by the addition of cold water (1 mL) before adding aqueous NaOH (10 mL, 3 *M*). After the cautious slow addition of H_2O_2 (10 mL, 30%) and MeOH (10 mL), the reaction mixture was stirred at room temperature for 24 h. Upon saturation of the mixture with solid NaCl, the THF layer was separated and the aqueous layer extracted with Et_2O (3 × 50 mL). The combined extracts were dried over $MgSO_4$ and then the solvent was evaporated to furnish a mixture of **8** and **9** (1.38 g, 91%) in a 85:15 ratio which was separable by fc (Et_2O – petroleum ether, 30:70). Alcohol **8** (1.5 g): mp 35–36°C; alcohol **9** (0.2 g): mp 47–49°C (lit. (4) mp 45–49°C).

*Tricyclo[5.2.1.$0^{1,5}$]decan-9-one (10*a*)*

Alcohol **8** was added to a stirred solution of CrO_3 (3.0 g, 0.03 mol) in pyridine (4.74 g, 0.06 mol) and methylene chloride (75 mL) at room temperature and the stirring continued for 1.5 h. After decantation of the liquid from the black residue, it was washed sequentially with aqueous NaOH (2 × 50 mL, 10%), aqueous HCl (50 mL, 10%), aqueous $NaHCO_3$, and water, before drying over $MgSO_4$. Upon evaporation of the solvent, the desired ketone (0.67 g, 88%) was isolated, bp 56°C/0.8 Torr (1 Torr = 133.3 Pa).

Tricyclo[5.3.1.$0^{1,5}$]undecan-10-one (12)

Trimethylsilylcyanide (0.73 g, 7.4 mmol) was added to a stirred mixture of **10***a* (1.0 g, 6.7 mmol) and $ZnBr_2$ (10 mg) under N_2 at room temperature and the stirring continued for 24 h. Removal of excess reagents afforded **10***b* (1.6 g, 96%); ir ($CHCl_3$): 2220 cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 0.25 (s, 9H, Me_3Si), 1.1–2.47 (complex absorption).

Cyanohydrin **10***b* in THF (3 mL) was added to a stirred suspension of LAH (0.54 g, 1.42 mmol) in THF (25 mL) under N_2 and the mixture heated under reflux for 12 h before destruction of the excess LAH by the addition of cold water. The precipitate was removed by filtration, washed with ether, and the washings added to the THF solution before drying over $MgSO_4$. Evpoaration of the solvent afforded aminoalcohol **10***c* (1.12 g, 97%); ir ($CHCl_3$): 3440 cm^{-1}.

The total product **10***c* was dissolved in acetic acid (2.5 mL) and water (14 mL); to this solution was added a solution of $NaNO_2$ (0.87 g, 12.6 mmol) in water (5 mL) at 0°C. After stirring at 0°C for

3.5 h, the solution was allowed to stir overnight at room temperature before the product was extracted with ether (3 × 50 mL). The extracts were washed with H_2O, 10% $NaHCO_3$, and H_2O before drying over $MgSO_4$. Evaporation of the solvent gave a yellow oil which was distilled to yield a 2:1 mixture of **12** and **13** as a colorless liquid (0.87 g, 80% overall yield). The ketones were separated by fc (ether − petroleum ether, 10:90). Ketone **12**: bp 64°C/0.2 Torr; ir ($CHCl_3$): 1700 cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 0.97−2.67 (complex absorption): ms, *m/e* (relative intensity): 164 (M^+, 40), 135 (87), 120 (100), 107 (39), 93 (22), 92 (18), 79 (60). *Exact Mass* calcd. for $C_{11}H_{16}O$: 164.12011; found: 164.12012. Ketone **13**: bp 64°C/0.2 Torr: ir ($CHCl_3$): 1710 cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 0.97−2.77 (complex absorption); ms, *m/e* (relative intensity): 164 (M^+, 100), 134 (45), 121 (50), 106 (26), 95 (23), 81 (34), 79 (32). *Exact Mass* calcd. for $C_{11}H_{16}O$: 164.12011; found 164.12012.

Tricyclo[5.3.1.0^{1,5}]undecan-9-one (13)

Ketone **11***a* (130 mg, 0.87 mmol), prepared in 86% yield from **9** according to the procedure described above for **10***a*, was converted to the silyloxy cyanohydrin **11***b*, thence to **11***c*, and was treated with nitrous acid in a manner exactly analogous to that described above for **10***a*; **11***b* and *c* were characterized by their ^{13}Cmr spectra (see Table 1). This sequence furnished a 64:36 mixture of two ketones (105 mg, 74% overall yield) which were readily separated by fc; the major component was identical to the previously reported **14** (8) and the minor product was **13**, exhibiting the same properties as those listed above.

9,9-Dimethyltricyclo[5.3.1.0^{1,5}]undecan-10-one (6)

To a stirred suspension of $NaNH_2$ (832 mg, 21.3 mmol) in Et_2O (40 mL) under N_2 was added, over 5 min, **12** (700 mg, 4.27 mmol) in Et_2O (5 mL) at room temperature and the mixture was refluxed for 3.5 h. After cooling, methyl iodide (3.64 g, 25.6 mmol) was added slowly and the mixture refluxed overnight before a second addition of MeI (606 mg, 4.27 mmol). After refluxing for 2.5 h, the mixture was cooled and diluted with water (25 mL). The ether layer was separated and the aqueous layer extracted with ether (4 × 25 mL). The combined extracts were washed with water, dried over $MgSO_4$, and concentrated to provide **6** (560 mg, 69%) as a colorless liquid, bp 2°C/0.1 Torr; ir ($CHCl_3$): 1692 cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 1.135 (s, 3H, Me), 1.197 (s, 3H, Me), 1.27−2.07 (complex absorption, 11H), 2.36 (m, 2H), 2.50 (m, 1H); ms, *m/e* (relative intensity): 192 (M^+, 46), 177 (20), 135 (100), 121 (33), 120 (42), 107 (98), 96 (21), 79 (55). *Exact Mass* calcd. for $C_{13}H_{20}O$: 192.15141; found: 192.15172.

cis, anti, cis-*4,4-Dimethyltricyclo[6.3.0.0^{2,6}]undecan-3-one (5)*

A solution of **6** (137 mg, 0.713 mmol) in *t*-BuO^-/*t*-BuOH (2.7 mL, H_2O content: 266 μg/mL; prepared from potassium metal (0.111 g) and *t*-BuOH (2.7 mL) was prepared under N_2 and quickly transferred to a predried, thick-walled glass tube (capacity ~30 mL), degassed and sealed under vacuum (~0.1 Torr) before heating to 185°C for 460 h. After cooling, the reaction mixture was diluted with water (10 mL) and the neutral product isolated by ether extraction (3 × 20 mL). The extracts were washed with water, dried over $MgSO_4$, and the solvent evaporated to afford a yellow oil which was subjected to fc (ether − petroleum ether, 5:95) to furnish recovered starting material **6** (29 mg) and the new ketone **5** (61 mg, 56% based on recovered **6**); ir ($CHCl_3$): 1730 cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 1.027 (s, 3H, Me), 1.090 (s, 3H, Me), 1.25−1.97 (complex absorption, 11H), 2.50 (m, 2H), 2.77 (m, 1H); ^{13}Cmr ($CDCl_3$) δ_c: 225.1 (C=O), 24.9, 25.7 (2 × Me), 25.7, 32.8, 34.1, 39.3, 42.4 (5 × CH_2), 39.5, 43.2, 47.8, 59.4 (4 × CH), 47.0 (quat. C); ms, *m/e* (relative intensity): 192 (M^+, 100), 163 (26), 136 (50), 124 (26), 111 (30), 108 (45), 79 (79), 67 (31). *Exact Mass* calcd. for $C_{13}H_{20}O$: 192.15141; found: 192.15142.

cis, anti, cis-*4,4-Dimethyltricyclo[6.3.0.0^{2,6}]undecane (17)*

A mixture of **5** (27 mg, 0.14 mmol), hydrazine hydrate (70 mg, 1.4 mmol), KOH (118 mg, 2.11 mmol), and diethylene glycol (0.6 mL) was placed in a thick-walled glass tube; the tube was sealed and heated at 182°C for 60 h. After cooling and dilution with H_2O (5 mL), the reaction mixture was extracted with ether (3 × 10 mL) and the extracts washed with H_2O before drying over $MgSO_4$. Evaporation of the ether gave an oil which was passed through a short column (1 × 5 cm) of SiO_2 (eluent: *n*-pentane, 30 mL) to furnish **17** (20 mg, 80%) as a colorless liquid; ^{1}Hmr ($CDCl_3$) δ: 0.85 (s, 3H, Me), 1.00 (s, 3H, Me), 1.0−2.8 (complex absorption, 16H); ^{13}Cmr ($CDCl_3$) δ_c: 28.1, 29.9 (2 × CH_3), 25.8, 32.0, 33.3, 39.8, 48.1, 49.0 (6 × CH_2), 44.0, 44.2, 50.9, 52.1 (4 × CH), 41.2 (quat. C); ms, *m/e* (relative intensity): 178 (M^+, 10), 163 (42), 122 (100), 95 (26), 93 (31), 81 (49), 67 (33). *Exact Mass* calcd. for $C_{13}H_{22}$: 178.17215; found: 178.17227.

Repetition of the preceding procedure with a mixture (21 mg, 0.109 mmol) of **18** (1*b*) and its 5-oxo isomer (8) gave hydrocarbon **17** (13 mg, 65%).

A synthesis of (+)-aphidicol-15-ene

RONALD B. KELLY, G. SANKAR LAL, GOPALA GOWDA, AND RABINDRA N. REJ
Department of Chemistry, University of New Brunswick, P.O. Box 5050, Saint John, N.B., Canada E2L 4L5

Received March 14, 1984

This paper is dedicated to Professor Paul de Mayo on the occasion of his 60th birthday

RONALD B. KELLY, G. SANKAR LAL, GOPALA GOWDA, and RABINDRA N. REJ. Can. J. Chem. **62**, 1930 (1984).

A stereospecific synthesis of (+)-aphidicol-15-ene is described. Pursuing a concept successfully applied to our total synthesis of stemarin and the stemodane diterpenoids, the C/D ring system was elaborated by functional group manipulation and rearrangement of a 6-hydroxybicyclo[2.2.2]octan-2-one system.

RONALD B. KELLY, G. SANKAR LAL, GOPALA GOWDA et RABINDRA N. REJ. Can. J. Chem. **62**, 1930 (1984).

On décrit une synthèse stéréospecifique du (+)-aphidicolène-15. Faisant appel à un concept utilisé avec succès lors de nos synthèses totales des diterpénoïdes stémarine et stémodane, on a élaboré le système cyclique C/D grâce à la manipulation des groupes fonctionnels et à une transposition du système hydroxy-6 bicyclo[2.2.2] octanone-2.

More than four years ago (ref. 1, see also ref. 2) we conceived the possibility of constructing the C/D ring systems of stemarin (**1**), the stemodane diterpenoids (e.g. **2**), and aphidicolin (**3**) by stereospecific rearrangement of a common 6-hydroxybicyclo[2.2.2]octan-2-one system represented by **4**. This concept was an efficient feature of total syntheses of stemarin (**1**)(1), and of 2-desoxystemodinone (**2***a*) and stemodinol (**2***b*)(2,3); we now wish to describe its application to a stereospecific synthesis of (+)-aphidicol-15-ene (**5**), a derivative of aphidicolin (**3**)(4).[1] This synthesis was undertaken as a model, relative to a projected total synthesis of aphidicolin.

The keto alcohol **6**, formerly encountered as an intermediate in our synthesis of (+)-2-desoxystemodinone (**2***a*)(3), served also as an intermediate in the present synthesis. This intermediate, prepared from podocarpic acid (3), is the enantiomer represented by **6** and leads to the enantiomer **5** derived from aphidicolin (4).

In preparation for the rearrangement of the bicyclic system of **6** to that of **5**, it was necessary to reduce the secondary hydroxyl group to a methylene group and convert the keto

group to an appropriate leaving group. The former task was accomplished efficiently by Barton's procedure (6). Thus, the keto alcohol was converted in 87% yield into the *S*-methyldithiocarbonate **7**. Reduction of **7** with $NaBH_4$ afforded, in 90% yield, the alcohol **8**. The stereospecific reduction of the keto group of **7** to the required epimer **8** is attributable to the "propeller" effect of the bulky dithiocarbonate group. The alcohol **8** was converted in 97% yield into the benzoate **9**. Reduction of the latter with tri-n-butyltin (6) followed by hydrolysis of the benzoate **10** afforded (75% from **9**) the alcohol **11**.

The alcohol **11** was converted into the tosylate **12** in which the tosylate group, serving as a leaving group, has the correct stereo-alignment for rearrangement via migration of bond (m) and elimination of a proton (Y). The tosylate **12**, on heating for 2 h at 60°C in DMSO containing methyl sulfinyl carbanion, underwent the anticipated rearrangement to give (+)-aphidicol-15-ene (**5**) (4) in 60% yield (cf. refs. 1–3). The synthetic diterpene had properties (mp, ir and nmr spectra) identical with (+)-aphidicol-15-ene derived from aphidicolin (4).

Experimental

Instrumentation, methods, and materials

Proton nmr were recorded in $CDCl_3$ on a Varian T-60 instrument; chemical shifts are expressed in ppm (δ values) relative to TMS as an internal standard. Unless otherwise stated, ir spectra were recorded as $CHCl_3$ solutions with a Perkin–Elmer 297 instrument. The ms were recorded on a Vacuum Generator UG-ZAB-1F instrument. Melting points were determined on a Fisher–Johns apparatus and are uncorrected.

Silica gel G-60 was used for column chromatography and silica gel GF-240 for tlc (E. Merck, Darmstadt). Petroleum ether refers to the fraction with boiling point range 30–60°C. Brine refers to a saturated solution of NaCl.

Keto S-methyldithiocarbonate 7

The following reaction sequence was carried out under a nitrogen atmosphere.

A solution of 155 mg of the keto alcohol **6** in 5 mL of THF was treated with 37 mg of NaH and 2 mg of imidazole, then refluxed for 3 h. After cooling, 0.20 mL of CS_2 was added to the reaction solution and refluxing was continued for 30 min. The reaction solution was again cooled and, after the addition of 0.10 mL of CH_3I, refluxing was continued for a further 30 min. The cooled reaction solution was treated with 0.05 mL of acetic acid, then diluted with 25 mL of water. The aqueous mixture was extracted with three 50-mL portions of CH_2Cl_2. The extracts were washed with 25 mL of 0.05 *M* HCl, 25 mL of saturates $NaHCO_3$, and, finally, with 25 mL of water. The aqueous washings were extracted with two 50-mL portions of CH_2Cl_2 and the extracts were combined, dried over $MgSO_4$, and evaporated *in vacuo*. Chromatography of the residue on 20 g of silica gel in petroleum ether-ether afforded 175 mg (87%) of **7**, mp 128°C; ir (Nujol): 1715 (ketone) cm^{-1}; nmr δ: 0.88 and 0.92 (3-proton singlets, tertiary methyls), 1.01 (s, 6H, superimposed signals for two tertiary methyls), 2.51 (s, 3H, SCH_3), and 5.70 (dd, 1H, *H*COCSSCH$_3$). *Anal.* calcd. for $C_{22}H_{34}S_2O_2$: C 66.96, H 8.68; found: C 67.03, H, 8.52%.

Reduction of keto S-methyldithiocarbonate 7 to 8

A solution of 130 mg of **7** in 5 mL each of ether and methanol was cooled to −10°C, treated with 50 mg of $NaBH_4$, and stirred at −10°C for 1 h. The reaction solution was diluted with 25 mL of brine and the aqueous mixture was extracted with two 50-mL portions of ether. Evaporation of the combined, dried ($MgSO_4$) extracts and chromatography of the residue on 10 g of silica gel in petroleum ether – ether afforded 118 mg (90%) of **8** as an oil; ir: 3580 (OH) cm^{-1}; nmr δ: 0.85 (s, 6H, superimposed signals for two tertiary methyls), 0.91 and 0.98 (3-proton singlets, tertiary methyls), 2.55 (s, 3H, SCH_3), 3.60 (m, 1H, *H*COH), and 5.51 (m, 1H, *H*COCSSCH$_3$).

This compound was further characterized as the benzoate (*vide infra*).

Benzoate 9

A solution of 100 mg of **8** and 0.3 mL of benzoyl chloride in 1 mL of pyridine was kept at −5°C for 4 h. The reaction mixture was diluted with 50 mL of ether and the resulting solution was washed with 25 mL of saturated $NaHCO_3$, 25 mL of 0.05 *M* HCl, and 25 mL of water. The aqueous washings were extracted with two 50 mL portions of ether. The combined ether extracts were dried ($MgSO_4$) and evaporated *in vacuo*. Chromatography of the residue on 40 g of silica gel in petroleum ether – ether afforded 122 mg (97%) of the benzoate **9**, mp 194°C; ir: 1710 (ester) cm^{-1}; nmr δ: 0.85 and 0.88 (3-proton singlets, tertiary methyls), 0.97 (br s, 6H, superimposed signals for two tertiary methyls), 2.61 (s, 3H, SCH_3), 4.98 (m, 1H, *H*OBz), 5.67 (m, 1H, *H*COCSSCH$_3$), and 7.45 and 8.12 (br m, 5H, aromatic protons). *Anal.* calcd. for $C_{29}H_{40}S_2O_3$: C 69.56, H 8.05; found: C 68.99, H 8.19%.

Alcohol 11

The following reaction sequence was carried out under a nitrogen atmosphere.

A solution of 342 mg of the benzoate **9** in 11 mL of toluene was added over 1 h to a refluxing solution of 0.56 mL of tri-n-butyltin hydride in 17 mL of toluene. Refluxing was continued for 33 h during which time 0.20-mL portions of tri-n-butyltin hydride were added after 10, 22, and 25 h. The solvent was evaporated *in vacuo* and the residue was filtered through a column of 50 g of silica gel in petroleum ether – ether (1:1). Evaporation of the eluant afforded a crude product (**10**) which was refluxed in 58 mL of 1 *M* ethanolic KOH for 1 h. The solvent was evaporated *in vacuo* and 50 mL of water was added to the residue. The product was extracted from the aqueous mixture into three 50-mL portions of CH_2CL_2. The extracts were dried over $MgSO_4$ and evaporated *in vacuo*. Chromatography of the residue over 40 g of silica gel in petroleum ether – ether afforded 148 mg (75%) of **11** as an oil; ir: 3620 (OH) cm^{-1}; nmr δ: 0.78 and 0.90 (3-proton singlets, tertiary methyls), 0.84 (s, 6H, superimposed signals for two tertiary methyls), and 3.56 (br m, 1H, *H*COH).

(+)-aphidicolin-15-ene

A solution of 55 mg of the alcohol **11** in 1.1 mL of pyridine was treated with 134 mg of *p*-toluenesulfonyl chloride and left at 3°C for 72 h. The solution was diluted with 5 mL of ice water and extracted with three 50-mL portions of ether. The ether extracts were washed with 50 mL each of cold 2 *M* HCl and cold water. The combined extracts were dried (K_2CO_3) and evaporated *in vacuo* to give 86 mg of tosylate **12**, which was used immediately for the next reaction.

A solution of 86 mg of the tosylate **12** in 12 mL of DMSO was treated with 0.6 mL of a 0.5 *M* DMSO solution of methyl sulfinyl carbanion (7). The resulting solution was stirred under nitrogen for 2 h at 60°C, cooled, treated with 1 mL of water and diluted with 50 mL of ether. The ether solution was washed with three 30-mL portions of brine, followed by two 30-mL portions of water, and the aqueous washings were extracted with five 50-mL portions of ether. Evaporation of the combined, dried ($MgSO_4$) extracts and chromatography of the residue on 10 g of silica gel in pentane afforded 31 mg (60%) of aphidicol-15-ene **5**, mp 101–103°C (lit. (4) mp 101–105°C). *Mol. Wt.* calcd. for $C_{20}H_{32}$: 272.2504; found (ms): 272.2514. The spectral properties (ir and nmr) of the synthetic diterpene **5** were identical to spectra for aphidicol-15-ene derived from aphidicolin.

Base catalysis as an alternative explanation for an apparent deuterium solvent isotope effect in the photochemical reactions of α,β-unsaturated esters[1]

ALAN C. WEEDON

Photochemistry Unit, Department of Chemistry, The University of Western Ontario, London, Ont., Canada N6A 5B7

Received January 19, 1984

This paper is dedicated to Professor Paul de Mayo on the occasion of his 60th birthday

ALAN C. WEEDON. Can. J. Chem. **62**, 1933 (1984).

An apparent deuterium solvent isotope effect upon the photochemical reactions of the α,β-unsaturated esters ethyl 3,4,4-trimethyl-2-pentenoate, **1**, and ethyl 3,4-dimethyl-2-pentenoate, **4**, is re-examined; it is concluded that the changes in reaction rate can be attributed to interception of the reaction intermediates (photochemically produced dienols) by basic impurities present in the solvent used. This conclusion is used to explain the apparently anomalous photochemistry of esters **1** and **5** in non-deuterated solvents. The results described also exemplify the use of a base to enhance the efficiency and to alter the direction of deconjugation in the photochemical conversion of α,β-unsaturated esters to their β,γ-unsaturated isomers.

ALAN C. WEEDON. Can. J. Chem. **62**, 1933 (1984).

On a réétudié un effet isotopique apparent de solvants deutérés sur les réactions photochimiques des esters α,β-non saturés, triméthyl-3,4,4 pentène-2 oate de méthyle (**1**) et diméthyl-3,4 pentène-2 oate de méthyle (**4**); on en conclut que les changements dans les vitesses de réactions peuvent être attribués à l'interception des intermédiaires réactionnels (des diénols produits photochimiquement) par des impuretés basiques présentes dans le solvant utilisé. On utilise cette conclusion pour expliquer la photochimie apparemment anormale des esters **1** et **5** dans des solvants qui ne sont pas deutérés. Les résultats décrits servent aussi d'exemples pour démontrer l'utilité d'une base pour augmenter l'efficacité et pour modifier la direction de la déconjugaison lors de la transformation photochimique d'esters α,β-non saturés en leurs isomères β,γ-non saturés.

[Traduit par le journal]

Introduction

Direct irradiation of α,β-unsaturated esters with ultraviolet light results in *E*–*Z* isomerization around the double bond with a quantum efficiency of the order of 5–10% (1). If the ester possesses hydrogen substituents at the 4-position oriented *syn* with respect to the ester function, then these can be abstracted in competition with *E*–*Z* isomerization to yield a dienol intermediate which can reketonize by protonation at the 2-position to give a β,γ-unsaturated ester (Scheme 1). This photoenolization reaction has been shown to proceed via the singlet excited state (2), and may be regarded as a photochemically allowed antarafacial 1,5-sigmatropic hydrogen shift. The formation of β,γ-unsaturated esters by this pathway has frequently been observed (3–8) and has been proposed as a synthetic route to these compounds (9).

One of the earliest reports concerning this reaction described an exception (10); ultraviolet light irradiation of ethyl 3,4,4-trimethyl-2-pentenoate, **1**, in diethyl ether resulted in formation of the cyclopropane derivative **2** rather than the expected product, the β,γ-unsaturated ester **3**, which would be formed following photoenolization. This result is especially surprising in view of the relative bond energies of the C—H bonds undergoing cleavage and because formation of **2** proceeds via δ rather than the normally preferred γ-hydrogen abstraction. A later report from the same laboratory (11) described the irradiation of **1** in methanol, and in this solvent the products were the cyclopropane derivative **2** along with the β,γ-unsaturated ester **3**. The chemical yield of the latter was, however, found to be erratic, varying from 2% to 30–40%. Subsequent work (12) revealed that when the reaction was performed in methanol-O-*d* the product ratio was dramatically altered with the β,γ-unsaturated ester **3** being formed in 90–95% yield. A remarkable deuterium solvent isotope effect was also found with the esters **4**, **5**, and **6** (12): when **4** was irradiated in methanol, **7** was the major product along with small amounts of the alternative deconjugated isomer **8**; however, when the reaction was carried out in methanol-O-*d* the two β,γ-unsaturated esters were found to be formed in comparable amounts. In contrast to the results obtained with **1**, the use of a deuterated solvent with **4** resulted in an enhanced chemical yield of the product obtained from cleavage of the

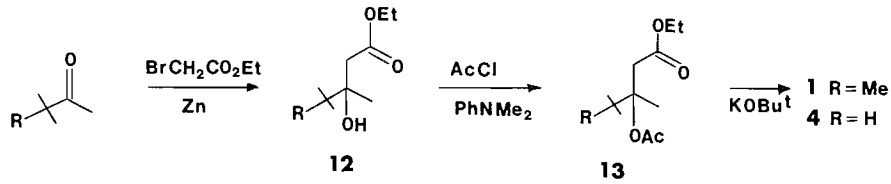

SCHEME 2

stronger C—H bond, rather than the weaker as was observed with **1**. In the case of ester **5**, irradiation in methanol-O-*d* enhanced the chemical yield of the β,γ-unsaturated ester **9** and with ester **6** the yield of **10** was enhanced relative to **11**.

Recently in this laboratory the photoenolization and photodeconjugation reaction has been investigated for α,β-unsaturated ketones and esters in the presence of weak organic bases (13–15), and the results of these studies suggest that the photochemically formed dienol can reketonize by two competing pathways; the dienol can isomerize back to the α,β-unsaturated carbonyl compound, by way of a thermally allowed suprafacial 1,5-sigmatropic hydrogen shift, or it can be intercepted by a base to give the β,γ-unsaturated isomer. In view of these results it seemed that the apparent deuterium solvent isotope effects described above could be a result of the presence in the solvents of species capable of intercepting the photochemically produced dienols and catalysing their conversion to the β,γ-unsaturated products. Described here are the results of a study designed to investigate this possibility.

Results

The esters **1** and **4** were prepared as shown in Scheme 2 by base catalysed elimination of the acetates prepared from the Reformatsky hydroxy esters **12**. This procedure has been developed by Fung *et al.* (16) and readily yields large quantities of the α,β-unsaturated esters, predominantly in the thermodynamically more stable *E*-geometry, and with minimal contamination by the β,γ-unsaturated isomers.

The esters **1** and **4** were irradiated with ultraviolet light of wavelength 254 nm as 0.1 *M* solutions in diethyl ether, methanol, and methanol-O-*d* in both the presence and absence of a weak organic base, under conditions such that the esters adsorbed all of the incident light. The base used, 1,2-dimethylimidazole, was chosen because it is soluble in the solvents used, adsorbs very weakly at 254 nm, and is insufficiently strong to catalyse reconjugation of the β,γ-unsaturated ester products or attack the ester functions as a nucleophile. The quantum yields measured in each reaction are shown in Tables 1 and 2, and the progress of typical reactions in Figs. 1 and 2.

Irradiation of ester **1** in diethyl ether resulted in relatively rapid (ϕ = ca. 0.1) *E*–*Z* isomerization to give a photostationary state with *E*–**1** and *Z*–**1** present in the ratio 74:26, respectively. Continued irradiation resulted in slow loss of **1** (ϕ = 0.0084), with the cyclopropane **2** being formed as the major product (10). Also formed, but at a ten-fold slower rate, was the β,γ-unsaturated isomer of the starting material, ester **3**. At complete conversion the esters **2** and **3** were present in 76% and 8% yields, respectively, along with small amounts of two further products which were isolated and identified as the *d,l* and *meso* forms of 1,2-diethoxybutane from ^{1}H nmr and mass spectroscopic evidence. These last products, which account for the missing 16% of the starting material, are presumed to arise from inefficient abstraction of hydrogen from the solvent by either photo-excited esters, or by radicals formed from photolysis of the esters.[2]

Irradiation of ester **1** in methanol also resulted in the rapid formation of a photostationary state (27.5% *Z*–**1**) followed by subsequent production of the cyclopropane **2** at a rate similar to that in diethyl ether (Table 1); however, the chemical yield of **2** was suppressed to 36% at complete conversion due to competitive formation of the deconjugated ester **3**, which was produced at a three-fold faster rate in this solvent, resulting in a chemical yield of 25% at complete conversion.

Very similar results were obtained when methanol-O-*d* was used as solvent; the quantum yield of formation of **2** was found to be the same as in methanol within the experimental error of

[2] When esters **1** and **4** were irradiated in methanol, or methanol-O-*d*, similar losses of material were observed, but the extra products were not isolated or identified. The losses by this route in the faster reactions did not exceed ca. 3%, but in the slower reactions (i.e., in absence of added base) were as high as 30%. In all reactions, the quantum yield of disappearance of ester to unidentified products by this route was approximately constant at 0.005.

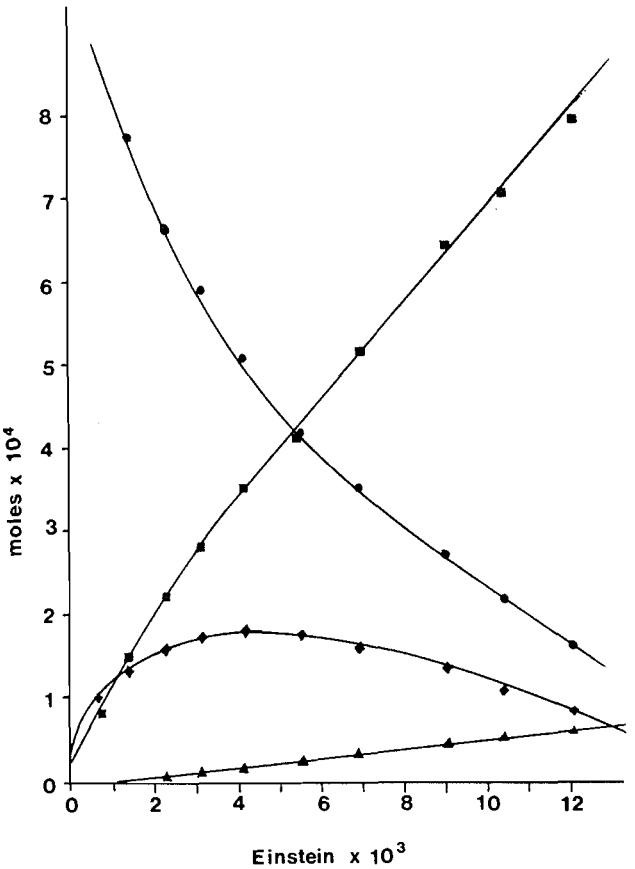

FIG. 1. Plot of reaction mixture composition against amount of light absorbed for the irradiation of 10.00 mL of a 0.100 *M* solution of ester **1** in methanol containing 1,2-dimethylimidazole (1.73×10^{-2} *M*). ●, *E*–**1**; ◆, *Z*–**1**; ■, **3**; ▲, **2**.

the determination, while the quantum yield of formation of **3** was slightly increased in deuterated solvent (Table 1).

Addition of catalytic amounts of 1,2-dimethylimidazole to solutions of **1** in diethyl ether, methanol, or methanol-O-*d* resulted in a large increase in the rate of formation of **3**, while the rate of formation of **2** increased only slightly (Table 1). The course of a typical reaction in methanol is shown in Fig. 1; very similar results were observed in methanol-O-*d* and diethyl ether. As can be seen in Fig. 1, irradiation produces fast *E*–*Z* isomerization of **1**, as was observed in the absence of base, but now deconjugation to **3** also occurs at a comparable rate with the result that the position of the photostationary state between *E*–**1** and *Z*–**1** is shifted from 27.5% *Z*–**1** in the absence of base to 33% with base present. Subsequent to attainment of the photostationary state, the rate of formation of **2** and **3** becomes zero order and the quantum yield of formation of **3** at this point is an order of magnitude greater than the yield when base was absent. When diethyl ether was used as solvent, the increase in rate of formation of **3** following addition of base was even greater, with the quantum yield of formation of **3** rising by a factor of 70. In both methanol and methanol-O-*d* the addition of base resulted in chemical yields at complete conversion of 7% for **2** and 92% for **3**.

The photochemistry of ester **4** followed a parallel course and Fig. 2 shows the progress of a reaction in methanol; initial rapid *E*–*Z* isomerization and formation of a photostationary state are followed by formation of ethyl 3,4-dimethyl-3-pentenoate, **7**. Production of *Z*–**4** and **7** was accompanied by slower formation of ethyl 3-methylene-4-methylpentanoate, **8**. The quantum yields are shown in Table 2, and the chemical yields at complete conversion were 6% for **8** and 58% for **7**. When a catalytic quantity of 1,2-dimethylimidazole was added to the irradiation mixture, the rate of formation of **7** was increased slightly, the position of the photostationary state was perturbed, and the rate of formation of **8** was increased by a factor of ten to a rate similar to that for the formation of **7**. In constrast to the previously reported work (12), *identical* results were obtained when the irradiations were performed in methanol-O-*d*.

Discussion

The previously published work on the photochemistry of the esters **1** and **4** found that use of a deuterated solvent exerted a large effect upon the rate of deconjugation (12). In the study reported here this effect was not found; in the case of ester **4** identical results were obtained in methanol-O-*d* and methanol, while with **1** a slight increase in the quantum efficiency of deconjugation was noted when methanol-O-*d* was used. However, the previously observed behaviour could be obtained if a weak base was added to the solvents.

In the previously published work, the possibility that impurities could cause the observed apparent isotope effect was considered, but discounted on the grounds that methanol-O-*d* prepared by different routes gave the same results, and deliberate addition of acid did not produce a rate change (12). In the work described here the methanol-O-*d* was prepared by additon of deuterium oxide to excess sodium methoxide followed by distillation. Two batches were prepared; one was used for the experiments with ester **1** and the other for experiments with ester **4**. The slight rate enhancement observed in this work for ester **1** but not for ester **4** may reflect the relative purities of the two samples of deuterated solvent.

The effect of addition of base can be understood in terms of the mechanism of the photoenolization and deconjugation reaction proposed in a previous publication from this laboratory (15) and outlined in Schemes 3 and 4 for esters **1** and **4**.

For ester **1** irradiation of *E*–**1** produces *Z*–**1** which when present in sufficient quantity can itself absorb light and either isomerize back to *E*–**1** or undergo intramolecular hydrogen abstraction from the δ-position to yield the biradical **16**.[3] This in turn can couple to give enol **17** whose only fate can be acid or base catalysed reketonization to **2**. In competition with isomerization around the double bond, photo-excited *E*–**1** can undergo intramolecular hydrogen abstraction to yield dienol **14**. As this is a singlet excited state process (2, 11), a biradical need not be an intermediate on the reaction pathway and the formation of **14** may be regarded as a photochemical 1,5-sigmatropic hydrogen shift proceeding antarafacially. In the absence of a base **14** reverses rapidly to *E*–**1**, by a thermal 1,5-sigmatropic hydrogen shift, this time proceeding suprafacially; if base is present, either as an impurity or deliberately added, **14** can be intercepted and converted to the dienolate **15** which on C-protonation can yield **1** and **3**. In the absence of added base the formation of **3** is inefficient, but is faster in methanol; this

[3] A referee has suggested that *E*–**1** and *Z*–**1** may react from a common excited state. However, if this were the case no induction period would be observed prior to the formation of products derived from *Z*–**1**. Such an induction period was observed, as shown in Fig. 1, and has been observed in the photochemistry of other esters (see refs. 2 and 11), suggesting that the *singlet* excited states of *E* and *Z* α,β-unsaturated esters are distinct.

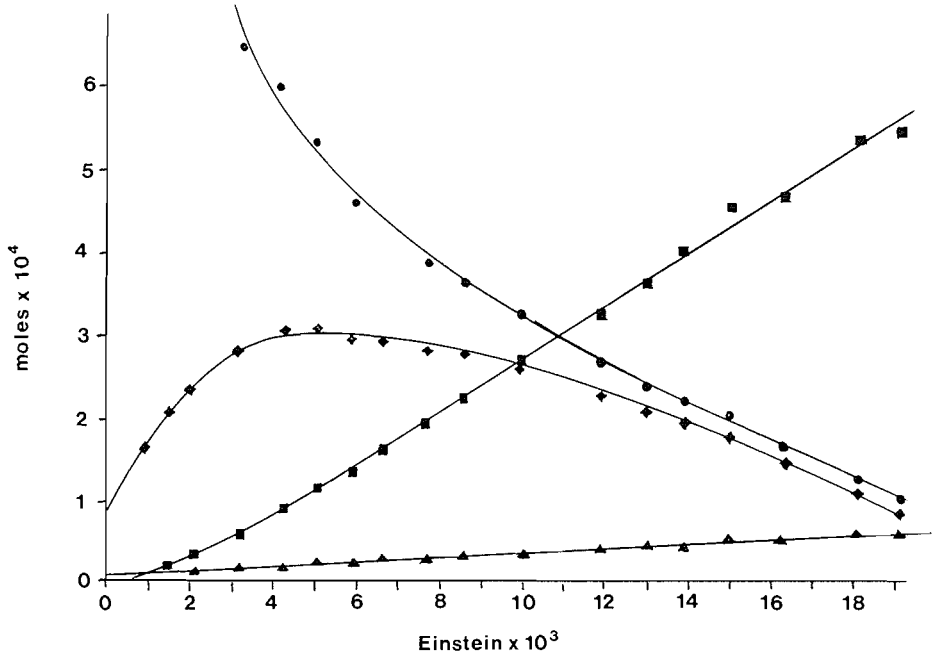

FIG. 2. Plot of reaction mixture composition against amount of light absorbed for the irradiation of 10.00 mL of a 0.100 *M* solution of ester **4** in methanol. ●, *E*–**4**; ◆, *Z*–**4**; ■, **7**; ▲, **8**.

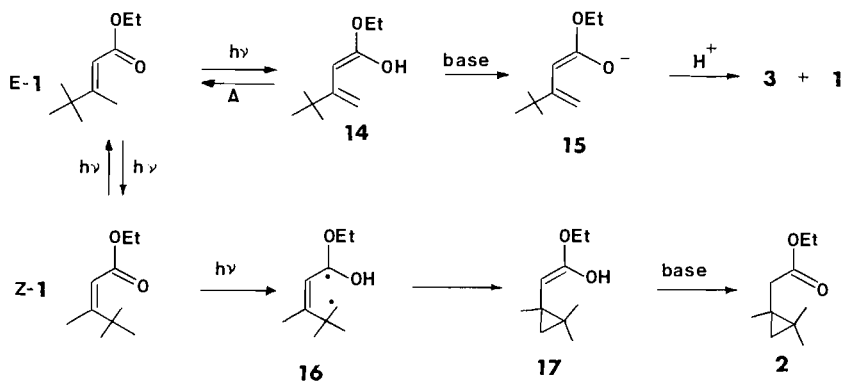


SCHEME 3

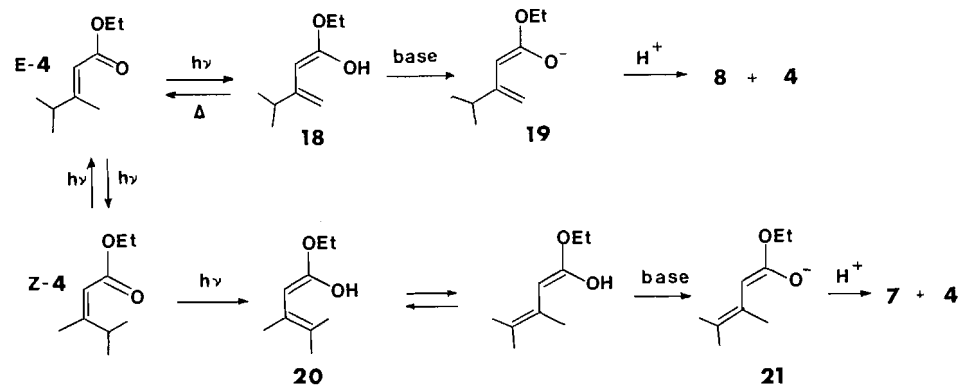
may reflect the relative purities of these solvents or the relative basicities of ether and methanol if the solvent is acting as the base, or it may reflect the lower solvating power of ether which would destabilize **15** and decrease its rate of formation relative to the rate of thermal reversal of **14** to *E*–**1**.[4]

This mechanism suggests that the quantum yield of formation of **2** from *Z*–**1** should not be affected by the addition of base. As can be seen in Table 1, this appears not to be the case as the quantum yield of formation of **2** is increased slightly by the presence of base; this can be understood in terms of a shift in the position of the photostationary state towards *Z*–**1** when base is present, which increases the rate of light absorption by *Z*–**1**. The change in photostationary state composition is caused by removal of *E*–**1** to give **3** at a rate comparable to *E*–*Z* isomerization.

For ester **4** the quantum yield of deconjugation is increased greatly by addition of base for the β,γ-unsaturated ester **8**, but only slightly for **7**. The mechanism which accounts for this is shown in Scheme 3. Irradiation of *E*–**4** yields *Z*–**4** which, after an induction period during which its concentration builds up to a level at which it can absorb light, undergoes photoenolization to give dienol **20** in the *cis* conformation of the diene. Bond rotation allows adoption of the more stable *trans* conformation by relieving the unfavorable steric interaction between the hydroxyl and isoproylidene functions. Adoption of the *trans* conformation slows reversion of **20** to *Z*–**4** and allows base impurities or weakly basic solvent to compete effectively by catalysing reketonization of **20** to give **7** via dienolate **21**. The very small effect of addition of base upon the quantum yield of formation of **7** suggests that the rate of conversion of **20** to **7** via **21** is fast compared to thermal reversion of **20** to **4**; it is possible that all of **20** undergoes base catalysed reketonization with no reversion to **4**, and that the observed rate enhancement with base is derived from a shift in the photostationary state towards *Z*–**4** caused by depletion of *E*–**4** to give **8**, as was described for **2**.

In competition with double bond isomerization, *E*–**4** can photoenolize to **18** which is fixed in the *cis* conformation be-

[4] A referee has suggested that the greater efficiency of deconjugation in polar solvents may reflect hydrogen bonding of the dienol which would inhibit the thermal reversion of **14** to *E*–**1**.



SCHEME 4

cause of destabilization of the *trans* conformation by the bulky isopropyl substituent. This being the case, thermal reversion of **18** to *E*–**4** via a 1,5-sigmatropic hydrogen shift is fast relative to conversion to **8** via **19** unless a high enough concentration of base is present to intercept **18** and convert it to **19**. Thus the yield of **8** is low unless sufficient base is present.

The reported photochemistry of ester **6** can be explained in an identical manner. It was observed (12) that irradiation of **6** in methanol gave **11** only, but that in methanol-O-*d* the yield of **10** was enhanced. This is reasonable if the dienol produced by irradiation of *E*–**6** reverts to *E*–**6**, while the dienol from *Z*–**6** is forced into a *trans* conformation by the bulky γ-substituent and undergoes base catalysed reketonization to **11**. In methanol-O-*d* higher levels of basic impurities can intercept the dienol from *E*–**6** prior to reversion and so the yield of **10** is enhanced.

Conclusions

The effect of a deuterated solvent upon the efficiencies of the photochemical reactions of esters **1** and **4** can be accounted for in terms of basic impurities present in the methanol-O-*d* used and is not due to the presence of deuterium. The observations described also explain the anomalous behaviour of esters **1** and **5** in non-deuterated solvents. In the case of **1**, δ-hydrogen abstraction in *Z*–**1** of a non-allylic hydrogen appears to proceed with similar efficiency to γ-hydrogen abstraction of an allylic hydrogen in *E*–**1**, as indicated by the relative chemical yields of **2** and **3**. However, addition of base demonstrates that the true rate of γ-hydrogen abstraction in *E*–**1** is greater than the rate of δ-hydrogen abstraction in *Z*–**1**. In the case of **5**, irradiation in methanol leads to products derived from fragmentation following abstraction of the cyclopropyl methine and not to the deconjugated ester **9**, apparently indicating a faster rate of abstraction for a hydrogen bound to a cyclopropyl ring than a primary allylic C—H (12). This would be the expected result if the dienol formed from *E*–**5** reverts efficiently to **5** rather than undergoing base catalysed reketonization to yield **9**, and leads to the prediction that **9** would be a major product if base were present. In fact, when **5** was irradiated in methanol-O-*d* (12) the yield of **9** was increased, and in view of the results described here this can be ascribed to basic impurities in the deuterated solvent.

The observations reported here support the previously proposed (15) mechanism for base catalysed deconjugation of α,β-unsaturated carbonyl compounds. They also extend the synthetic utility of photochemical deconjugation as a useful procedure for the preparation of β,γ-unsaturated carbonyl compounds by demonstrating how the efficiency and yield of deconjugation, and the direction of deconjugation in non-symmetrically β,β-disubstituted α,β-unsaturated carbonyl compounds can be modified by addition of base.

Experimental

Preparation of E*-ethyl 3,4,4-trimethyl-2-pentenoate,* **1**

Ethyl 3-hydroxy-3,4,4-trimethylpentanoate (**12**, R = Me) was prepared in 36% yield by the Reformatsky reaction between pinacolone and ethyl bromoacetate (17, 18). Compound **12** (R = Me) (10 g, 0.053 mol), N,N-dimethylaniline (7 g, 0.058 mol), and acetyl chloride (4.4 g, 0.056 mol) were dissolved together in chloroform (30 mL) and the solution was refluxed for 9 h after which time gc (5% SE 30, 120°C) of a worked-up sample indicated complete reaction. The reaction mixture was poured into excess dilute sulphuric acid (100 mL) and extracted with two portions of ether (75 mL, 25 mL). The organic extracts were dried ($MgSO_4$ + Na_2CO_3) and evaporated to yield an oil which on distillation gave the acetate **13** (R = Me), 7.74 g (63%), bp 80–82°C/0.6 Torr (1Torr = 133.3 Pa); ^{1}H nmr ($CDCl_3$, 60 MHz): 1.01 (9H, s), 1.21 (3H, t, *J* = 7 Hz), 1.59 (3H, s), 2.01 (3H, s), 2.9 (2H, m), 4.02 (2H, q, *J* = 7 Hz) ppm.

The acetate **13** (R = Me) (7.74 g, 0.0337 mol) was dissolved in dry *tert*-butanol (15 mL) and added over 5 min to a stirred solution of potassium *tert*-butoxide in *tert*-butanol (50 mL of a 1.03 *M* solution). The solution became warm during the addition and a white gelatinous precipitate began to form when half of the acetate had been added. At completion of the addition the mixture was stirred for 15 min, poured into water (200 mL), and extracted with ether (100 mL, 2 × 50 mL). The organic phases were combined, dried ($MgSO_4$), and evaporated to give an oil which was distilled to give 3.58 g (63%) of **1**, bp 97°C/19 Torr (lit. (18) 65°C/6 Torr; ^{1}H nmr ($CDCl_3$, 60 MHz): 1.12 (9H, s), 1.31 (3H, t, *J* = 7 Hz), 2.20 (3H, d, *J* = 1 Hz), 4.15 (2H, q, *J* = 7 Hz), 5.72 (1H, q, *J* = 1 Hz). From the gc (10% OV101, 100°C) the prepared sample was 96% *E*–**1**, 3% *Z*–**1**, and 1% deconjugated isomer **3**.

Preparation of Z*-ethyl 3,4,4-trimethyl-2-pentenoate,* **1**

A sample of the *Z* isomer was prepared for gc calibration as follows.

E-ethyl 3,4,4-trimethyl-2-pentenoate, **1** (0.2265 g), was irradiated in pentane (10 mL) using a low pressure mercury lamp for 2 h after which time gc (5% SE30, 110°C) indicated that the mixture consisted of 26% *Z*–**1** and 74% *E*–**1**. The pentane was evaporated and the residue was separated by gc (10% OV101, 100°C) to give *Z*–**1** (30 mg) which had ^{1}H nmr ($CDCl_3$, 60 MHz): 1.19 (9H, s), 1.28 (3H, t, *J* = 7 Hz), 1.81 (3H, d, *J* = 1 Hz), 4.10 (2H, q, *J* = 7 Hz), 5.58 (1H, q, *J* = 1 Hz) ppm.

Preparation of ethyl 2-(1′,2′,2′-trimethylcyclopropyl)acetate, **2**

A sample of **2** was prepared for gc calibration as follows.

Ester **1** (0.194 g) was dissolved in ether (10 mL) and irradiated in quartz to complete conversion (gc; 5% SE30, 100°C) using a low pressure mercury lamp. The ether was distilled off through a short

Vigreux column and the residue was separated by gc (10% OV101, 100°C) to give 2,3-diethoxybutane (12 mg) as the more volatile component and the cyclopropane ester **2** (67 mg). The 2,3-diethoxybutane was isolated as a mixture, presumed to be the *d,l* and *meso* isomers and had ^{1}H nmr ($CDCl_3$): 1.0–1.3 (12H, m), 3.2–3.7 (6H, m) ppm; *m/e*: 146, 73, 45. *Mol. Wt.* calcd. for $C_8H_{18}O_2$: 146.1307; found: 146.1300. For the cyclopropane ester **2**, ^{1}H nmr ($CDCl_3$, 100 MHz): 0.22 (1H, d, J = 4.5 Hz), 0.32 (1H, d, J = 4.5 Hz), 1.11 (6H, s), 1.15 (3H, s), 1.26 (3H, t, J = 7 Hz), 2.24 (1H, d, J = 15.5 Hz), 2.49 (1H, d, J = 15.5 Hz), 4.16 (2H, q, J = 7 Hz) ppm.

Preparation of ethyl 4,4-dimethyl-3-methylenepentanoate, 3

A sample of **3** was prepared for gc calibration as follows.

Ester **1** (0.198 g) and 1,2-dimethylimidazole (0.016 g) were dissolved in ether (10 mL) and irradiated in quartz to complete conversion (gc; 5% SE30, 100°C) using a low pressure mercury lamp. The ether was evaporated and the residue separated by gc (10% OV101, 100°C) to give **3** (0.092 g); ^{1}H nmr ($CDCl_3$, 100 MHz): 1.07 (9H, s), 1.26 (3H, t, J = 7 Hz), 3.06 (2H, d, J = 1 Hz), 4.16 (2H, q, J = 7 Hz), 4.90 (1H, d, J = 1 Hz), 5.07 (1H, s) ppm.

Preparation of E*-ethyl 3,4-dimethyl-2-pentanoate, 4*

Ethyl 3,4-dimethyl-3-hydroxypentanoate, **12** (R = H), was prepared by the Reformatsky reaction between 3-methyl-2-butanone and ethyl bromoacetate in 72% yield and had bp 120°C/50 Torr; ^{1}H nmr ($CDCl_3$, 100 MHz): 0.90 (3H, d, J = 6.5 Hz), 0.94 (3H, d, J = 6.5 Hz), 1.16 (3H, s), 1.28 (3H, t, J = 7 Hz), 1.77 (1H, septet, J = 6.5 Hz), 2.37 (1H, d, J = 15 Hz), 2.55 (1H, d, J = 15 Hz), 3.60 (1H, exchanges with D_2O), 4.18 (2H, q, J = 7 Hz) ppm.

The hydroxy ester **12** (R = H) was converted to the acetoxy ester **13** (R = H) as follows.

Compound **12** (R = H) (31.2 g, 0.179 mol), N,N-dimethylaniline (25.0 g, 0.207 mol), and acetyl chloride (15.0 g, 0.191 mol) were refluxed together in chloroform (50 mL) for 2.5 h after which time gc (5% SE30, 120°C) of a worked-up sample indicated that the reaction was complete. The reaction mixture was washed with excess dilute sulphuric acid and dried (Na_2CO_3 + K_2CO_3). The chloroform was evaporated and the residual oil distilled through a 12-in Vigreux column to yield acetate **13** (R = H), 34 g (88%), bp 80°C/1.2 Torr which had ^{1}H nmr ($CDCl_3$, 100 MHz): 0.93 (6H, d, J = 7 Hz), 1.25 (3H, t, J = 7 Hz), 1.43 (3H, s), 1.99 (3H, s), 2.40 (1H, septet, J = 7 Hz), 2.86 (1H, d, J = 14 Hz), 3.05 (1H, d, J = 14 Hz), 4.13 (2H, q, J = 7 Hz) ppm.

The acetate **13** (R = H) (20 g, 0.093 mol) was dissolved in *tert*-butanol (15 mL) and added over 5 min to a stirred solution of potassium *tert*-butoxide in *tert*-butanol (prepared from 4.6 g, 0.12 mol K and 100 mL *tert*-butanol). Following completion of the addition the solution, which had become warm and precipitated a gelatinous white solid, was stirred for 15 min, poured into water (250 mL), and extracted with ether (200 mL, 2 × 100 mL). The extracts were combined, dried ($MgSO_4$), and evaporated, and the residual oil was distilled through a 12-in Vigreux column to give **4**, 7.7 g (53%), bp 100°C/37 Torr (lit. (20) bp 80°C/20 Torr). The gc analysis (10% OV101, 100°C) of the sample of **4** prepared indicated that it consisted of 90% *E*–**4**, 9% *Z*–**4**, 0.7% ethyl 4-methyl-3-methylenepentanoate, **8**, and 0.3% ethyl 3,4-dimethyl-3-pentenoate, **7**. For *E*–**4**, ^{1}H nmr ($CDCl_3$, 60 MHz): 1.1 (6H, d, J = 7 Hz), 1.3 (3H, t, J = 7 Hz), 2.1 (3H, d, J = 1 Hz), 2.4 (1H, septet, J = 7 Hz), 4.2 (2H, q, J = 7 Hz), 5.73 (1H, broad, s) ppm.

Preparation of ethyl 3,4-dimethyl-3-pentanoate, 7

A sample of **7** was prepared for gc calibration as follows.

Ethyl 3,4-dimethyl-2-pentenoate, **4** (0.167 g), was dissolved in diethyl ether (10 mL) and irradiated using light of wavelength 254 nm until gc (10% OV101, 100°C) indicated no starting material remained. The ether was evaporated and the residual oil was purified by gc (20% Carbowax 20 M, 110°C) to give **7**, 0.100 g as a colourless oil; ^{1}H nmr ($CDCl_3$, 60 MHz): 1.23 (3H, t, J = 7 Hz), 1.77 (9H, s), 3.05 (2H, s), 4.10 (2H, q, J = 7 Hz) ppm.

Preparation of ethyl 3-methylene-4-methylpentanoate, 8

A sample of **8** was prepared for gc calibration as follows.

Ethyl 3,4-dimethyl-2-pentenoate, **4** (0.165 g), and 1,2-dimethylimidazole (0.018 g) were dissolved in diethyl ether (10 mL) and irradiated using light of wavelength 254 nm until gc (10% OV101, 100°C) indicated no starting material remained. The ether was evaporated and the residual oil was purified by gc (10% UCON LB 550X, 100°C) to give **7**, 0.070 g, and **8**, 0.041 g, as colourless oils. For **8**, ^{1}H nmr ($CDCl_3$, 60 MHz): 1.04 (6H, d, J = 8 Hz), 1.24 (3H, t, J = 7 Hz), 2.0–2.6 (1H, m), 3.04 (2H, s), 4.01 (2H, q, J = 7 Hz), 4.86 (1H, s), 4.93 (1H, s) ppm.

Irradiations

Irradiations were performed using a low pressure mercury lamp housed in a quartz tube which was immersed into the solution to be irradiated in such a manner that all of the emitted light entered the solution. Since the lamp became warm during operation (ca. 40°C) the solution being irradiated was placed in a bath maintained at 21° ± 0.5°C.

Quantum yields were determined by performing the irradiations on solutions containing a non-light-absorbing, inert internal standard and monitoring the progress of the reactions with time by gas chromatography using 10% OV101 on Chromosorb at 100°C for **4** and 120°C for **1**. Internal standards used were dimethylsuccinate for **1** and n-pentylacetate for **4**.

The light source was calibrated following each irradiation using azoxybenzene as an actinometer according to the procedure developed by Bunce *et al.* (21).[5] Solutions of azoxybenzene (0.035 *M*) in 95% ethanol were irradiated to 5% conversion; 1.00-mL aliquots were withdrawn periodically during the irradiations and diluted to 10.00 mL with 5% KOH in 95% ethanol. The amount of O-hydroxy azoxybenzene formed was determined from the absorbance of these solutions at 454 nm assuming an extinction coefficient of 7600, and the light intensity was calculated assuming a quantum yield of 0.017 for the conversion of azoxybenzene to O-hydroxyazobenzene. The lamp output in all irradiations performed in this work was (1.16 ± 0.06) × 10^{-6} Einsteins s^{-1}.

Synthesis of 3-isoxazolols revisited. Diketene and β-ketoesters as starting materials

NIELS JACOBSEN, HANS KOLIND-ANDERSEN, AND JENS CHRISTENSEN

Research and Development Departments, Cheminova Ltd., P.O. Box 9, DK-7620 Lemvig, Denmark

Received January 24, 1984

This paper is dedicated to Professor Paul de Mayo on the occasion of his 60th birthday

NIELS JACOBSEN, HANS KOLIND-ANDERSEN, and JENS CHRISTENSEN. Can. J. Chem. **62**, 1940 (1984).

3-Isoxazolols can be made in good yields from β-ketoesters or diketene and hydroxylamine, provided that pH is kept at about 10 throughout the reaction, and that the reaction mixture is quenched with an excess of strong mineral acid. This suppresses the formation of 5-isoxazolones, which are otherwise normally the main products of the reaction.

NIELS JACOBSEN, HANS KOLIND-ANDERSEN et JENS CHRISTENSEN. Can. J. Chem. **62**, 1940 (1984).

On peut préparer les isoxazolols-3 avec de bons rendements en utilisant de l'hydroxylamine et des β-cétoesters ou dicétènes comme produits de départ à condition de maintenir le pH à environ 10 pendant toute la réaction et de piéger le mélange réactionnel avec un excès d'acide minéral fort. Cette précaution supprime la possibilité de formation des isoxazolones-5, qui sont autrement les produits principaux de la réaction.

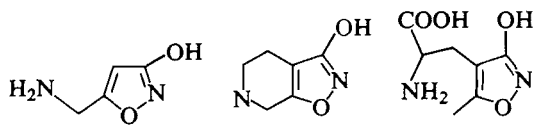
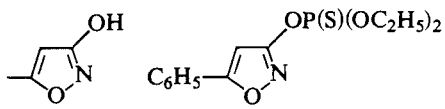
Introduction

In recent years much interest has been given to the 3-isoxazolol moiety, which is contained in a variety of physiologically active compounds. Thus the naturally occurring alkaloid muscimol **1** is an in vivo active mimetic of the neurotransmitter γ-aminobutyric acid (GABA) (1).



1 **2** **3**

The synthetic analogue THIP, **2**, is a very potent GABA receptor agonist and, as it is relatively nontoxic, it is of considerable pharmacological interest (1). The compound AMPA, **3**, has been pointed out as an agonist of glutamic acid, and has powerful pharmacological effects after local injection into various brain areas of the rat (2). A rather simple molecule, 5-methyl-3-isoxazolol **4**, has been commercialized under the names Tachigaren or Hymexazol. It is a soil fungicide and a growth promoter (3). Also the contact insecticide Karphos **5**



4 **5**

contains the 3-isoxazolol moiety (4). A general and economical synthetic method for this interesting class of compounds is therefore desirable.

Although one of the most direct routes to 3-isoxazolols would appear to be the reaction of a β-ketoester (or diketene) with hydroxylamine, this method is unsuitable in most cases, largely because of preferential formation of 5-isoxazolones. This is particularly the case when 2-unsubstituted β-ketoesters are employed (5–8). Thus, it has been claimed that **4** cannot be prepared by direct condensation of hydroxylamine with acetoacetic esters or diketene (ref. 9, and references therein). As a consequence, these compounds are usually prepared from protected β-ketoesters or by entirely different methods (3, 9–11). Some 2-substituted β-ketoesters (e.g. ethyl 2-methylacetoacetate, **6**) have, however, been shown to yield 3-isoxazolols (5), although these were originally described as 5-isoxazolones (8). Jacquier *et al.* (12–14) made a detailed investigation of the reaction of β-ketoesters and hydroxylamine under alkaline conditions. They demonstrated that in the few cases where 3-isoxazolols were formed in substantial amounts (5, 15), their formation depended on rapid acidification of the reaction mixture with a large excess of concentrated hydrochloric acid, whereas only 5-isoxazolones were formed upon slow acidification to pH 3–5. These authors suggested hydroxamic acids **7** and oximes **8** as discrete intermediates for 3-isoxazolols and 5-isoxazolones, respectively.

7 **8**

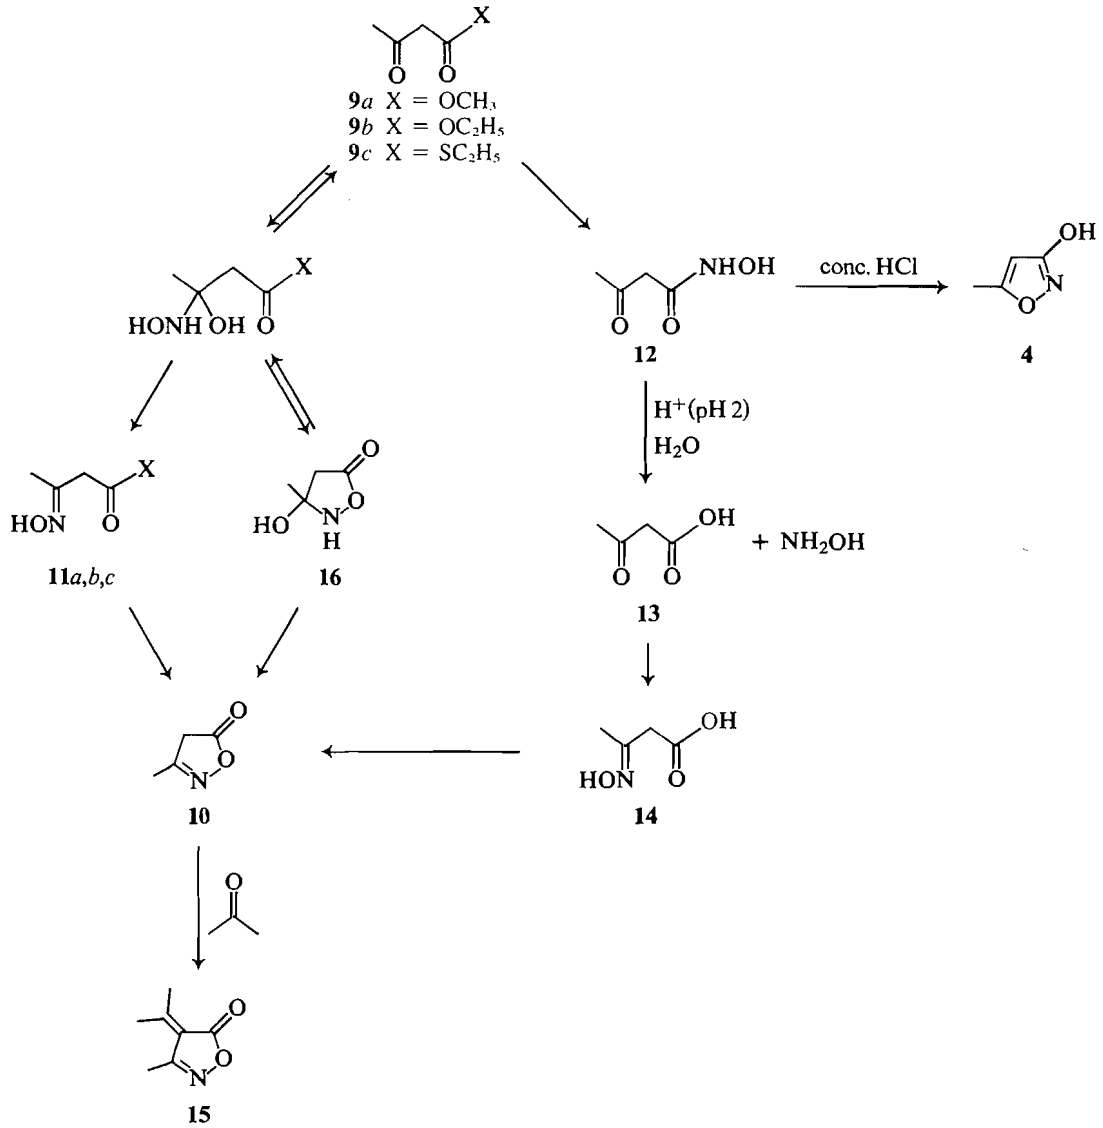
It seemed likely that the ratio of **7** to **8** and hence the total outcome of the reaction would be greatly influenced by the pH of the reaction mixture. The subject of the present paper is an investigation of the pH dependence of this reaction, which, combined with the "acidification brusque" of Jacquier *et al.*, ultimately led to a practical synthesis of 3-isoxazolols from β-ketoesters or diketene.

Results and discussion

Due to the economic importance of **4** and the availability and low price of methyl acetoacetate **9***a*, reaction of the latter with hydroxylamine was first investigated in detail. Addition of **9***a* to an aqueous solution of one equivalent of hydroxylamine hydrochloride, neutralized with 0.5 molar equivalents of sodium carbonate, and quenching the reaction mixture with a tenfold molar excess of concentrated hydrochloric acid gave 3-methyl-5-isoxazolone **10** as the main product. Only traces of **4** were detected.

When, however, the hydroxylamine hydrochloride solution was buffered with a twofold excess of sodium carbonate (ph 10–11) prior to the addition of **9***a* an approximately equimolar mixture of **4** and **10** resulted, whereas substituting the carbonate with bicarbonate (pH ~8) led to the formation of **10** only.

We therefore investigated the dependence on pH of the for-



SCHEME 1

mation of **4** by running the reaction at constant pH values using a pH-stat with 2 *N* sodium hydroxide as the modifying reagent. In each case the reaction mixture was poured into a large excess of concentrated hydrochloric acid and the yield of **4** determined by hplc after continuous extraction with methylene chloride. The optimum pH for the formation of **4** was found to be 9–10, giving a yield of 70%. At pH 8.5 or 10.5 the yield is already reduced, at pH 8 it is below 40%, and at pH 11 it is below 50%.

At pH = 10, which is intermediate between the pK_a value of the hydroxylammonium ion (5.9) (10, 16) and hydroxylamine (13.7) (10) respectively, the dominant species is the neutral hydroxylamine molecule. This species has its nucleophilicity centered on the nitrogen atom (10), whose attack on **9***a* could lead to either the oxime **11***a* or the hydroxamic acid **12**. Formation in alkaline solution of **10** via **11***b* is well documented (17, 18), and **11***a* could be isolated from the reaction buffered by bicarbonate upon extraction with methylene chloride prior to the acidification. When treated with concentrated hydrochloric acid **11***a* was transformed into **10** exclusively. Thus **11***a* cannot be an intermediate in the formation of **4**. Lowering the pH from 10, it therefore seems likely that enhanced oxime formation can account for the decrease in yield of **4**. Around pH 10 the hydroxamic acid **12** could be suggested as the main intermediate, leading upon very rapid acidification to **4**, whereas moving towards higher pH would cause an increasing participation of deprotonated hydroxylamine (NH_2O^-). This species has its nucleophilicity located mainly on the oxygen atom (10), which could lead to the formation of different intermediates incapable of forming **4**. Our attempts to isolate the hydroxamic acid **12** have remained unsuccessful and, to our knowledge, only one hydroxamic acid of this type has been described (**7**, R = Ph, R′ = CH_3 (14)).

Quenching of the reaction mixture with excess strong acid is crucial for obtaining high yields of **4**. Diminution of the amounts of acid led to a decrease in the yield of **4** accompanied by an increase in the yield of **10**. When the mixture from the reaction at pH 10 was brought to pH 2 by dropwise addition of concentrated hydrochloric acid, only approximately 1% **4** could be detected. Instead, a 85% yield of **10** was obtained, compared to the 70% yield of **4** obtained by rapid acidification.

Since the sum of these yields exceeds 100%, at least part of the mass of **4** and **10** must be derived from a common precursor. Our data do not allow definite assignment of a structure to this precursor, but if it were the hydroxamic acid **12**, formation of **10** requires breaking of the C—N bond in **12**. Thus hydrolysis of **12** would lead to acetoacetic acid **13**, which under the

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.5 on 09/06/12

For personal use only.

weakly acidic conditions could react with the liberated hydroxylamine to form an oxime **14** and, subsequently, **10**. It is known that hydroxamic acids can be hydrolysed (19). The results of the different modes of acidification would thus reflect perturbations of the balance between cyclization and hydrolysis of **12**.

The condensation product **15** (18, 20) between **10** and acetone is formed as a minor by-product in all the reactions. The acetone required for the formation of **15** can originate from several sources, e.g. via decarboxylation of **13**. The reaction pathways discussed are depicted in Scheme 1. When ethyl acetoacetate **9***b* or diketene were used instead of **9***a* under optimum conditions for the formation of **4**, almost identical yields were obtained (Table 1), whereas ethyl thiolacetoacetate **9***c* gave a mixture of **4** (15%) and **10** (40%), probably reflecting formation of **10** via the carbinolamine intermediate **16** (16), a pathway which is not operative for **9***b* (17). The reaction of **9***b* and ketene had similar pH profiles to that of **9***a*, with an optimum around pH 10.

Using the same reaction conditions, several β-ketoesters were reacted with hydroxylamine, and the results are found in Table 1. In several examples (**4**, **23**, **26**, **28**, **38**, and, presumably, **20**) 3-isoxazolols, which were not previously accessible by this method, have been obtained, whereas in other examples (**17**, **34**) substantial increases in the yield of 3-isoxazolols were obtained compared to those reported in the literature. Most of the 5-isoxazolones are unstable under our reaction and work-up conditions, so the yields given for these compounds must be interpreted with care.

Using 2-carbethoxycyclopentanone **40** as substrate, the reaction failed completely, and cyclopentanone oxime was the only product isolated. In spite of the apparent formation of **20** from 2-carbethoxycyclohexanone **19**, all attempts to transform the structural analogue **41** into **42**, a precursor of THIP **2** (22), failed. Only the 5-isoxazolone **43** was isolated. The previously unknown compound **28** seems well suited as a starting material for the synthesis of AMPA **3**.

43

Experimental

Melting points were obtained with a Büchi 510 Melting Point Determinator and are uncorrected. The ir spectra were recorded on a Perkin–Elmer 177 grating spectrophotometer. The 60 mHz ^{1}Hmr spectra were obtained with a JEOL JNM-PMX 60 spectrometer. Peak positions are δ values in ppm downfield from TMS. The uv spectra were recorded on a Shimadzu UV-240 spectrophotometer. The pH-stat consisted of a Radiometer PHM 82 standard pH meter equipped with a titrator TTT 80 loaded with 2 *N* sodium hydroxide, a magnetic valve Type MNV I D, and a GK 2403 C electrode. The gc and hplc equipment was Hewlett–Packard 5840A and 1084B, respectively.

Reaction of β-ketoesters or diketene with hydroxylamine. General procedure

Hydroxylammonium chloride (0.20 mol) was dissolved in approximately 100 mL of 2 *N* sodium hydroxide to achieve a solution of pH 10.0. This solution was cooled to 0–5°C (20°C in the case of **30** and **33**) and vigorously stirred while the β-ketoester (0.20 mol) was added during 30 min, keeping pH at 10.0 ± 0.2 by means of the pH-stat. Stirring was continued for about 30 min at pH 10. At this point approximately 100 mL of 2 *N* sodium hydroxide had been added. The mixture was then poured into 150 mL ice-cooled concentrated hydrochloric acid and the mixture left overnight at room temperature. In some cases the 3-isoxazolols crystallized from this mixture, but in most cases the products were isolated by continuous extraction with methylene chloride.

In the case of **9***a*, *b* or diketene as substrates, the pH dependence was determined using the general procedure, only varying the pH.

*Methyl acetoacetate oxime **11**a*

To a solution of sodium bicarbonate (40 g) in 300 mL of water was added hydroxylammonium chloride (16 g, 0.23 mol) followed by methyl acetoacetate **9***a* (23 g, 0.20 mol). After 80 min the mixture was extracted with three 150-mL portions of methylene chloride. After drying and evaporation of the methylene chloride, the residue was bulb-to-bulb distilled at 150°C/0.05 Torr (1 Torr = 133.3 Pa) to give **11***a* (8.5 g) as a colourless oil; ^{1}Hmr ($CDCl_3$) δ: 1.97 (s, 3H), 3.27 (s, 2H), 3.72 (s, 3H), 9.6 (broad s, 1H). *Anal.* calcd. for $C_5H_9NO_3$: C 45.80, H 6.92, N 10.68; found: C 45.96, H 6.78, N 10.86.

*4,5,6,7-Tetrahydro-1,2-benz-3-isoxazolol, **20** and 4,5,6,7-tetrahydro-2,1-benzisoxazolin-3-one, **21***

The product from the standard procedure using 2-carbethoxycyclohexanone **19** as substrate was a crystalline solid (25.4 g), whose mp (90.5–93°C) did not change significantly after repeated recrystallization from MeOAc. From spectroscopic data, a 2:1 mixture of **20** and **21** may be proposed; uv (EtOH) λ_{max}: 218 and 256 nm; ^{1}Hmr ($CDCl_3$) δ: 1.3–3.0 (m, 8H), 3.1 (dd, 1H, **21**), 11.3 (s, 1H, **20**). *Anal.* calcd. for $C_7H_9NO_2$: C 60.42, H 6.52, N 10.07, O 22.99; found: C 59.74, H 6.49, N 10.21, O 23.00.

*5-Isopropyl-3-isoxazolol, **23** and 3-isopropyl-5-isoxazolone, **24***

The compound **23** crystallized spontaneously from the reaction mixture after acidification, yield 46%, mp (heptane) 45–46°C. Extraction of the filtrate gave a mixture of **23** and **24** in 21 and 16% yield, respectively (gc).

*5-Propyl-3-isoxazolol, **26***

The crude methylene chloride extract contained **26**, corresponding to a yield of 59% (gc). Crystallization from H_2O and heptane, successively, gave **26**, mp 43–44°C.

*4-(2-Hydroxyethyl)-5-methyl-3-isoxazolol, **28***

The general procedure was followed, using 2-acetylbutyrolactone **27** as substrate, and, upon cooling the methylene chloride extract to 0°C, **28** crystallized in 48% yield, mp (MeOH) 167–169°C. The mother liquor contained **27**, 24% yield, and 5-hydroxy-2-pentanone, 24% yield (gc). Data of **28**: uv (EtOH) λ_{max} (log ε): 225 (3.1) nm; ir (KBr) ν_{max}: 3180, 2940, 2810, 1660, 1520, 1390, 1350, 1330, 1245, and 1050 cm^{-1}; ^{1}Hmr ($CDCl_3$ + DMSO-d_6) δ: 2.33 (s, 3H), 2.53 (t, J = 7.0 cps, 2H), 3.77 (t, J = 7.0 cps, 2H), 7–9 (broad signal, 2 × OH). *Anal.* calcd. for $C_6H_9NO_3$: C 50.34, H 6.34, N 9.79; found: C 50.26, H 6.41, N 9.76.

*5-tert-Butyl-3-isoxazolol, **38** and 3-tert-butyl-5-isoxazolone, **39***

The crude product from the general procedure contained **38** and **39**, corresponding to yields of 73 and 22%, respectively, (nmr). Separation by fractional crystallization from aqueous methanol gave the pure compounds: **38**, mp 99–101°C; uv (EtOH) λ_{max} (log ε): 207 (3.8) nm; ir (KBr) ν_{max}: 3400, 2960, 1615, 1530, 1455, 1365, 1345, and 1270 cm^{-1}; ^{1}Hmr (DMSO-d_6) δ: 1.25 (s, 9H), 5.65 (s, 1H), 10.5

An efficient synthesis of pterosin C and other pterosins

KAM-MUI EVA NG AND TREVOR C. MCMORRIS
Department of Chemistry, University of California, San Diego, La Jolla, CA 92093, U.S.A.

Received January 13, 1984

This paper is dedicated to Professor Paul de Mayo on the occasion of his 60th birthday

KAM-MUI EVA NG and TREVOR C. MCMORRIS. Can. J. Chem. **62**, 1945 (1984).

A versatile synthetic route to pterosins, sesquiterpenoid indanones present in bracken, *Pteridium aquilinum*, has been developed. The route is exemplified by the synthesis of (2*S*,3*S*)-pterosin C by Friedel–Crafts bisacylation of the methyl ether of 2-(2,6-dimethylphenyl)ethanol with methylmalonyl chloride. Demethylation of the resulting 1,3-indandione and reduction with zinc and acetic acid in the presence of acetic anhydride and sodium acetate afforded a mixture of racemic *cis* and *trans* isomers of pterosin C diacetate, which was hydrolysed to the corresponding pterosins. Separation and resolution via the *S*-(+)-α-phenylbutyric esters gave (2*S*,3*S*)-pterosin C and (2*R*,3*R*)-pterosin C. Other pterosins were prepared as racemates from the 1,3-indandione.

KAM-MUI EVA NG et TREVOR C. MCMORRIS. Can. J. Chem. **62**, 1945 (1984).

On a développé une voie de synthèse versatile conduisant aux ptérosines, les indanones sesquiterpéniques présentes dans le *Pteridium aquilinum*. Un exemple de cette nouvelle voie est la synthèse de la ptérosine C (2*S*,3*S*) en faisant appel à une bis acylation suivant Friedel et Crafts de l'éther méthylique du (diméthyl-2,6 phényl)-2 éthanol avec le chlorure de méthylmalonyle. La déméthylation de l'indanedione-1,3 qui en résulte et sa réduction par le zinc et l'acide acétique en présence d'anhydride acétique et d'acétate de sodium conduit à un mélange racémique des isomères *cis* et *trans* du diacétate de ptérosine C, qui peut être hydrolysé en ptérosines correspondantes. La séparation et la résolution grâce aux esters de l'acide *S*-(+)-α-phénylbutyrique conduit aux ptérosines C (2*S*,3*S*) et (2*R*,3*R*). Partant de l'indanedione-1,3, on a préparé d'autres ptérosines sous forme de racémiques.

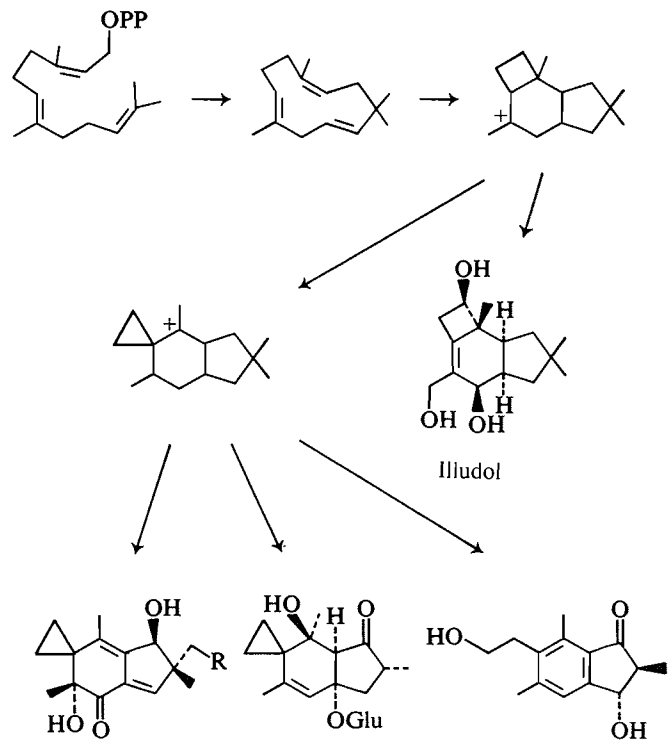
[Traduit par le journal]

The pterosins are a large group of sesquiterpenes and norsesquiterpenes first isolated from bracken fern, *Pteridium aquilinum*, in Japan (1). These compounds have since been found to occur widely in ferns (2) and they are also present in certain fungi of the class Basidiomycetes, e.g., *Fomes annosus*, *Fomitopsis insularis*, and *Cyathus bulleri* (3).

The structures of the pterosins indicate that they are derived from farnesyl pyrophosphate via the same protoilludane precursor which was proposed for the basidiomycete metabolites illudin-S and illudol nearly twenty years ago (Scheme 1) (4). It is interesting to note that pterosins sometimes occur together with compounds closely related to illudin-S or to illudol. An unstable norsesquiterpene glucoside, ptaquiloside, was recently isolated from bracken and it was readily converted to pterosin B by mild acid or base treatment (3, 5). This suggests that some of the pterosins may actually be formed from unstable precursors during isolation.

We first encountered the pterosins during our investigation of the male reproductive organ inducing substance antheridiogen A, in cultures of gametophytes of bracken fern (6). Chromatography of ethyl acetate extracts of the culture filtrates gave fractions which had high activity in the biological assay for antheridiogen A. These fractions contained ponasterone A, ecdysterone, and perhaps other ecdysones as well as a number of pterosins, two of which were tentatively identified as pterosin C and pterosin L (7). However, the antheridiogen has not yet been characterized.

During the past ten years there have been several reports on the biological properties of various pterosins. Natori and coworkers (2*a*, *b*) isolated these compounds in their search for carcinogens present in bracken. None of the pterosins was found to be carcinogenic although some did show cytotoxicity to HeLa cells (2*a*). Kobayashi and Koshimizu reported that several of the pterosins produce cytotoxic effects on the ciliate, *Paramecium caudatum*, and also induced abnormal development of the urchin embryos (8). Pterosins B and O have been



SCHEME 1

isolated from the fern *Pteris inequalis* and shown to be active against *Bacillus subtilis* (9). The 3β-D-glucoside of (2*S*,3*S*)-pterosin C, "wallichoside", has been isolated from *Pteris wallichiana* which grows in the Himalayas. It is reported to be active against *Staphylococcus aureus* (2*d*). Pterosin Z and related sesquiterpene, calomelanolactone, have been isolated

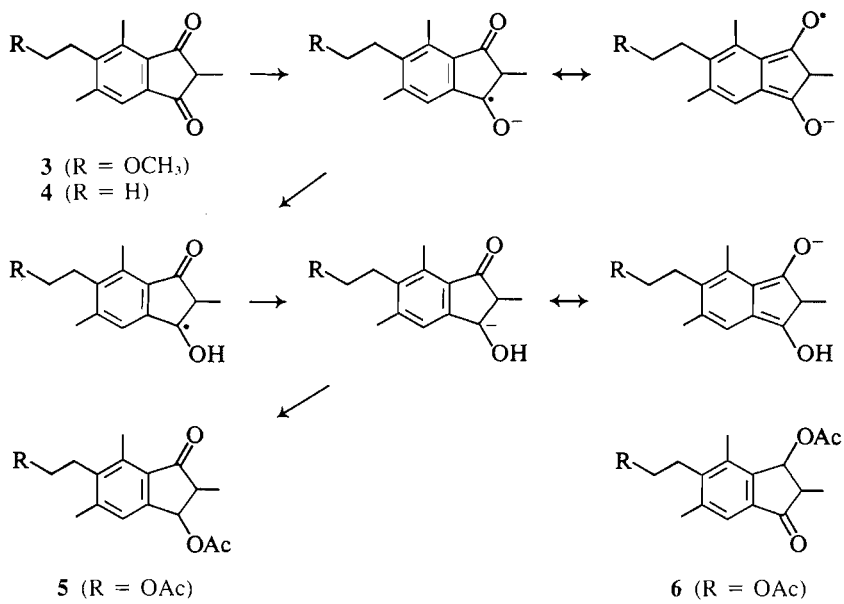


SCHEME 2

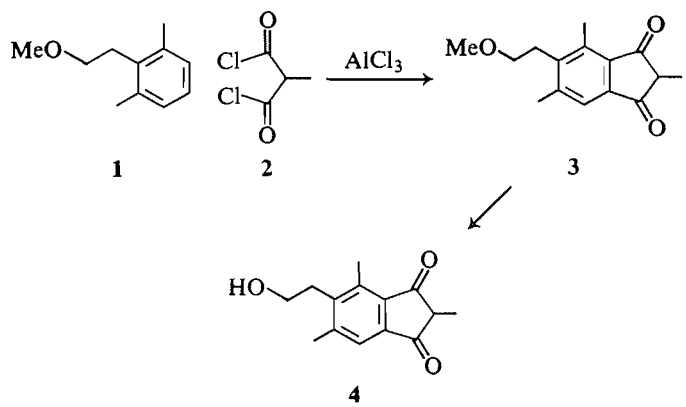
from "silver fern" *Pityrogramma calomelanos* L. which is used in Guyana for treatment of venereal diseases (2*e*).

Bracken itself is widely distributed throughout the temperate zone. It has been known from the end of the last century that the fern contains a toxin which is capable of producing a fatal hemorrhagic syndrome in cattle when they feed on the plant. Evans *et al.* (10) were the first to describe the fundamental lesions leading to the condition, severe damage of the bone marrow with consequent loss of cellular elements in the blood, together with aplasia of the intestinal mucosa resulting in loss of function and ulceration. The toxin, which can be extracted from the fronds with hot ethanol or water, has not yet been identified. However, the purified toxin extract contained a number of known organic compounds including pterosin B and its glucoside pteroside B.

Because of the possible link between bracken toxin and the pterosins, we were encouraged a few years ago to develop an efficient method for making these compounds. This would provide enough material for a thorough evaluation of their biological properties. Pterosins are present only in minute amounts in ferns and their isolation is tedious. The syntheses of pterosins E (11), B, D, H (12), Z, I, and F (7) have been reported but none of the methods appeared to be readily adaptable to large scale preparation of all the pterosins.

In this paper we describe a new method which is simple and efficient and has been employed for the preparation of many pterosins. The key step is Friedel–Crafts bisacylation of the methyl ether of 2-(2,6-dimethylphenyl)ethanol (**1**) with methylmalonyl chloride (**2**) to form the pure 1,3-indandione (**3**) in a yield of 73%.

Optimum conditions were as follows. Aluminum chloride was added gradually during 3 h to a solution of the acid chloride and benzene derivative (1.5:1 molar ratio) in refluxing carbon disulfide. Three moles of catalyst to every one mole of acid chloride were used, the third mole, presumably, being necessary because of complex formation of the catalyst with the ether oxygen. Total reaction time was about 7 h. This bisacylation reaction was developed many years ago by Freund and Fleischer and has proved to be a valuable method for introducing 3-carbon units as new rings (13).



Cleavage of the methyl ether in **3** to give the corresponding alcohol (**4**) was achieved in 91% yield by treatment with 48% hydrobromic acid in acetic acid.

Another unusual reaction employed in our synthesis was the selective reduction of the 1,3-indandione (**4**) to the diacetoxyindanone (**5**) by means of zinc and acetic acid in the presence of acetic anhydride and sodium acetate (14). The product contained the *cis* and *trans* isomers of **5** (64%, ratio of *cis* to *trans*, 1:2) and the regioisomer **6** (16%). The latter was readily separated from **5** by chromatography.

Two features of this reaction deserve comment. One is that the indanone carbonyl is not reduced by zinc and acetic acid. The reduction of the indandione may well proceed via the radical anion shown (Scheme 2) for which an isoindene resonance structure is possible. Protonation and further reduction followed by protonation gives, after acetylation, the observed product. The second feature is the regioselectivity which is probably the result of steric hindrance of one of the carbonyl groups by the *peri* methyl group.

Acid hydrolysis (5% sulfuric acid, dioxane 1:4, 45°C) of the diacetate **5** gave pterosin C (**7**) as a mixture of *cis* and *trans* isomers (1:2). Mild base treatment (sodium bicarbonate in water–tetrahydrofuran) of **5** caused elimination of the secondary acetoxy group, giving the bright yellow indenone (**8**). The indenone was also obtained by acid hydrolysis at higher tem-

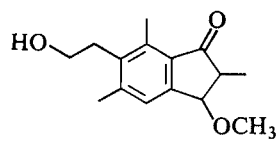
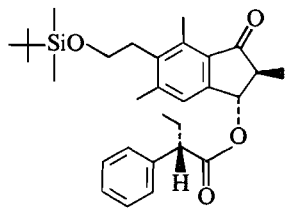
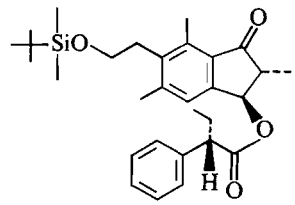
8 R = OH
14 R = OCH_3



9



10



11

peratures (>45°C). When the diacetate **5** was treated with aqueous sodium bicarbonate in excess methanol the methoxy derivative (**9**) was formed in high yield. Presumably, elimination of the acetoxy group occurred, followed by Michael reaction of the resulting indenone with methanol. The high reactivity of indenone to nucleophiles has been noted previously by Lacy and Smith (14).

All four pterosin C isomers have been isolated from bracken, the 2*R*,3*R* isomer and 2*S*,3*R* isomer (as its glucoside at the primary hydroxyl) from rhizomes, and the 2*R*,3*S* and 2*S*,3*S* isomers from fronds (15). The *cis* and *trans* isomers can be readily distinguished by their nmr spectra. In the spectrum of the *cis* isomers (2*S*,3*R* and 2*R*,3*S*). The C2 methyl appears as a doublet at δ 1.17 (J = 7 Hz) and the C3 proton as a doublet at δ 5.09 (J = 7 Hz). In the spectrum of the *trans* isomers the corresponding signals are δ 1.29 (J = 7 Hz) and δ 4.70 (J = 3 Hz). The ratio of *cis* to *trans* isomers varied from one isolate to another. This may have been due partly to the ready epimerization at C2. Thus treatment of 2*S*,3*R*-pterosin C with 2% sodium hydroxide in methanol gave a mixture containing mainly the *trans* isomer (2*R*,3*R*).

The cd (circular dichroism) curves of mixtures of *cis* and *trans* isomers exhibited nearly the same ellipticity values irrespective of the ratio of *cis* to *trans* (16). A mixture with ratio of 2*R*,3*S*:2*S*,3*S* = 1:2 had $[\theta]_{326}$ +20 688 and for the ratio 1:4, $[\theta]_{326}$ +22 939. A sample of pterosin C isolated from rhizomes was a mixture of the 2*S*,3*R* and 2*R*,3*R* isomers (ratio 1:4) and had $[\theta]_{330}$ −12 320. Thus the sign of the cd curves is apparently determined by the configuration at C3 regardless of the configuration at C2.

Our synthetic mixture of *cis* and *trans* pterosin C could be separated only by hplc using a reverse phase column. In order to resolve the enantiomers, the mixture (*cis* and *trans*) was first treated with *tert*-butyldimethylsilyl chloride, dimethylaminopyridine, and triethylamine to form the monosilylether. Treatment of this compound with *S*-(+)-α-phenylbutyric acid, dimethylaminopyridine, and dicyclohexylcarbodiimide gave the corresponding ester which was mainly *trans* isomer (**10** and **11**). Apparently, during these reactions epimerization occurred at C2, leading to the more stable product. Separation of the diastereomeric esters was accomplished by hplc. The cd curve of isomer **10** showed $[\theta]_{331.5}$ +26 496 while that of isomer **11** showed $[\theta]_{330.5}$ −24 812. The isomers could also be distinguished by their 360-MHz nmr spectra. Thus the signal for the C4 aromatic proton in **10** appeared at δ 6.68 while that for the C4 proton in **11** appeared at δ 7.02, indicating a preferred conformation for **10** in which the C4 proton is shielded by the aromatic ring of the *S*-(+)-α-phenylbutyric ester. The absolute configuration assigned to isomer **10** followed from its conversion to 2*S*,3*S* pterosin C by treatment with acetic acid – water–tetrahydrofuran (2:1:1) followed by 5% aqueous sulfuric acid – dioxane (2:5) at 80°C.

Glu = 
The synthesis of other pterosins as racemates from the key intermediate indandione (**3**) was readily achieved by means of well-known reactions. In the following discussion the pterosins are arranged in three groups: (1) norsesquiterpenoid skeleton; (2) sesquiterpenes containing a *gem* dimethyl group; and (3) sesquiterpenes containing a hydroxymethyl at C2.

Pterosin O. Reduction of indandione (**3**) in a similar way to reduction of (**4**) described earlier gave the 3-acetoxy indanone derivative which, on treatment with base, afforded the corresponding indenone. Catalytic hydrogenation with 5% Pd on

carbon in ethyl acetate then gave pterosin O (mp 45–46°C) (17).

Pterosin B. This compound (mp 109–110°C) (8, 17) was obtained from pterosin O by demethylation with 48% hydrobromic acid in acetic acid.

Pterosin F. A mixture of pterosin B and triphenylphosphine in carbon tetrachoride was refluxed for 3 h. Work-up of the reaction yielded pterosin F in 79% yield (mp 69–70°C) (8, 17).

Pterosin E. This compound (mp 149–150°C) (11, 17) was obtained by oxidation of pterosin B wih Jones reagent.

Pterosin J. Treatment of the indandione (4) with triphenylphosphine in carbon tetrachloride afforded the corresponding chloro analogue (87%) which, on reduction similar to that of **4**, gave pterosin J acetate and isopterosin J acetate (4:1, overall yield 86%). Separation of the isomers by chromatography followed by gentle acid hydrolysis of the major isomer gave pterosin J, mp 120–121°C (17) (85%).

Pterosin I. Methylation of pterosin O with methyl iodide and potassium *tert*-butoxide in *tert*-butanol gave an 89% yield of pterosin I (mp 59–60°C) (8, 12).

Pterosin Z. Demethylation of pterosin I with hydrobromic acid in acetic acid afforded pterosin Z (mp 89–90°C) (8, 12, 17).

Pterosin H. Displacement of the hydroxyl of pterosin Z by chloride gave pterosin H (mp 87–88°C). (8, 12).

Pterosin D. Methylation of indandione (**3**) with methyl iodide and sodium hydride in benzene gave 5-(β-methoxy)ethyl-2,2,4,6-tetramethyl-1,3-indandione in 89% yield. Treatment of this compound with 48% hydrobromic acid in acetic acid yielded the corresponding alcohol which was reduced in a similar way to the reduction of **4**. Pterosin D diacetate and isopterosin D diacetate were obtained in the ratio of 7:3 (overall yield 86%). Acid hydrolysis of the diacetate furnished pterosin D (mp 183–184°C) (17).

Pterosins V, A, and *K.* These compounds were obtained by hydroxymethylation of pterosins O, B, and F respectively. Only pterosin K was obtained crystalline (mp 85–86°C) (17).

Pterosin L. Hydroxymethylation of indandione **4** followed by reduction as for **4** gave a mixture of pterosin L triacetate and isopterosin L triacetate in a ratio of 4:1. Acid hydrolysis of the major triacetate yielded pterosin L (70%, mp 147–149°C) (17) and *epi* pterosin L (21%, mp 80–81°C) (17).

Biological studies on some of the pterosins and related indandiones and indenones will be reported in another paper.

Experimental

Melting points were determined on a Kofler hot stage apparatus and are uncorrected. Spectra were obtained on the following instruments: JEOL CFT-100, ^{13}C nmr, 25.34 MHz; Pye–Unicam SP 3-200 and Perkin–Elmer PE 281B, ir; Finnigan 4021, gc–ms DS; Perkin–Elmer 550, uv; Varian EM 390, ^{1}H nmr, 90 MHz. In cases where indicated, a 360-MHz nmr spectrometer with highly modified Varian HR-220 console, an Oxford magnet, and a Nicolet 1180-E computer system were used. The nmr (^{1}H) spectra were taken in $CDCl_3$ (except where indicated) with Me_4Si as internal standard. For ^{13}C nmr spectra, peak positions were assigned relative to the $CHCl_3$ resonances at 78.16, 76.90, and 75.62 ppm as well as the DMSO resonances at 42.12, 41.28, 40.43, 39.60, 38.77, 37.92, and 37.07 ppm. The uv spectra were taken in methanol. Elemental analysis were performed by Galbraith Laboratories, Knoxville, Tennessee.

Column chromatography was carried out with silica gel (230–400 mesh) and thin layer chromatography with silica gel 60 F-245 plates (E. Merck Laboratories).

Dry tetrahydrofuran (THF) was prepared by heating the reagent grade liquid at reflux over potassium in a circulating still. Benzene, methylene chloride, and carbon disulfide were distilled from powdered calcium hydride.

In the work-up of reactions, the solutions containing the products were dried over anhydrous magnesium sulfate, filtered, and concentrated under reduced pressure prior to chromatography.

2,6-Dimethylbromobenzene

To a magnetically stirred suspension of 2,6-dimethylaniline (50 mL, 0.41 mol) in 140 mL of 48% HBr, was added a solution of $NaNO_2$ (30 g, 0.43 mol) in 100 mL water. The temperature was kept below 10°C during the addition. When the diazotization was complete (KI–starch paper test positive), copper bronze (2 g) was added and the mixture was warmed on a steam bath until evolution of N_2 began. The flask containing the mixture was removed from the bath to moderate the reaction. When the evolution of N_2 slowed, the flask was warmed again until evolution of N_2 ceased. The mixture was then steam distilled. The organic layer was washed with 10% NaOH solution, brine, and then dried. Distillation of the organic liquid gave 35 g (47% yield) of 2,6-dimethylbromobenzene (bp 40°C/0.5 Torr) (1 Torr = 133.3 Pa). It was further purified by filtering the hexane solution through a column of alumina; nmr (^{1}H, CCl_4) δ: 2.30 (s, 6), 6.97 (s, 3); nmr (^{13}C) δ: 138.0 (s), 127.9 (d), 127.4 (s), 126.4 (d), 23.7 (q); ms *m/z* (relative intensity): 186 (M^+ + 2, 26), 184 (M^+, 29), 105 (100).

2-(2,6-Dimethylphenyl)ethanol

To a three-necked 1-L flask equipped with a reflux condenser, a dropping funnel, and a sealed stirrer was added 2,6-dimethylbromobenzene (25 g, 0.14 mol) in 140 mL dry THF followed by magnesium turnings (3.62 g, 0.15 mol). When the spontaneous reaction had ceased the mixture was refluxed for 30 min. The water condenser was replaced by a Dry Ice condenser. A well-cooled solution of ethylene oxide (20 mL) in dry THF (50 mL) was added during 5 min, then the mixture was refluxed for 3 h. After cooling, the dark colored oil was added to ice water and concentrated HCl (10 mL). The two layers were separated and the aqueous phase was extracted with ether (twice). The combined organic phases were washed with brine, then dried. 2-(2,6-Dimethylphenyl)ethanol was isolated by distillation (bp 95°C/0.6 Torr). The liquid product (17.52 g, 87%) crystallized on cooling. Recrystallization from hexane gave colorless needles, mp 59–60°C (lit. (18) mp 62.5–63°C); ir (film): 3300, 1470, 1035 cm^{-1}; nmr (^{1}H, CCl_4) δ: 2.27 (s, 6), 2.80 (t, J = 7 Hz, 2), 3.57 (t, J = 7 Hz, 2), 6.87 (s, 3); nmr (^{13}C) δ: 136.3 (s), 134.4 (s), 127.8 (d), 125.8 (d), 60.8 (t), 32.6 (t), 19.6 (q); ms *m/z*: 150 (M^+, 51), 132 (3), 119 (100).

Methyl 2-(2,6-dimethylphenyl)ethyl ether (1)

A mixture of the above alcohol (17.52 g, 0.12 mol), tetrabutylammonium iodide (3 g, 8.12 mmol), 50% NaOH solution (40 mL), and hexane (250 mL) was stirred at room temperature for 0.5 h. Dimethylsulfate (60 mL) was added during 0.5 h and the mixture was refluxed for 15 h. It was acidified with saturated NH_4Cl solution and extracted with ether (three times). The extract was washed with brine, dried, and distilled to give methyl 2-(2,6-dimethylphenyl)ethyl ether (**1**), 18 g, bp 55°C/0.6 Torr, (94% yield); ir (film): 2880, 1100 cm^{-1}; nmr (^{1}H) δ: 2.23 (s, 6), 2.80 (t, J = 7 Hz, 2), 3.20 (s, 3), 3.33 (t, J = 7 Hz, 2), 6.83 (s, 3); nmr (^{13}C) δ: 136.5 (s), 134.7 (s), 127.9 (d), 125.9 (d), 71.1 (t), 58.3 (q), 29.9 (t), 19.7 (q); ms *m/z*: 164 (M^+, 19), 150 (9), 132 (18), 119 (100).

Methylmalonyl chloride (2)

To a solution of diethyl methylmalonate (50 g, 0.29 mol) in absolute ethanol (200 mL) was added a solution of KOH in absolute ethanol (38 g in 200 mL) with stirring during 1 h. Stirring was continued at room temperature overnight. The salt was filtered off, washed with anhydrous ether, and dried *in vacuo*. To the cooled solution of the salt (ice bath) in water (50 mL) was added gradually concentrated HCl solution (40 mL). It was extracted three times with ether and the extract was washed with brine, dried, and the solvent was removed, leaving 33.4 g methylmalonic acid (99% yield), mp 132–132.5°C; nmr (^{1}H, CD_3OD) δ: 1.40 (d, J = 7 Hz, 3), 3.41 (q,

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.5 on 09/06/12
For personal use only.

J = 7 Hz, 1), 5.73 (br s, disappeared on adding D_2O, 2).

A mixture of diacid (30 g, 0.25 mol) and thionylchloride (100 mL) was warmed at 55–60°C for 4 h. Distillation then yielded methylmalonyl chloride (**2**) (31.5 g, 81%), bp 45°C/0.5 Torr; nmr (^{1}H, CCl_4) δ: 1.63 (d, J = 7 Hz, 3), 4.25 (q, J = 7 Hz, 1).

5-(β-Methoxy)ethyl-2,4,6-trimethyl-1,3-indandione (3)

To a solution of methyl 2-(2,6-dimethylphenyl)ethyl ether **1** (14.1 g, 0.09 mol) and methylmalonyl chloride (21.4 g, 0.14 mol) in carbon disulfide (50 mL) was added portionwise $AlCl_3$ (55 g, 0.41 mol) during a period of about 3 h. The mixture was refluxed for 4 h more, then added to crushed ice and the whole extracted three times with chloroform. The combined extract was washed with brine, dried, and the solvent removed, leaving a residue which on chromatography with 5% ethyl acetate in benzene gave the indandione **3**, 15.5 g (73% yield), mp 86.5–87.5°C (from ether–hexane); uv λ_{max} nm (log ε): 203 (4.66), 235 (5.06), 256 (4.59), 266 (4.59), 315 (3.66); ir (KBr): 1740, 1700, 1590 cm^{-1}; nmr (^{1}H) δ: 1.32 (d, J = 7 Hz, 3), 2.50 (s, 3), 2.73 (s, 3), 2.93 (q, J = 7 Hz, 1), 3.07 (t, J = 7 Hz, 2), 3.33 (s, 3), 3.48 (t, J = 7 Hz, 2), 7.57 (s, 1); nmr (^{13}C) δ: 201.6 (s), 200.6 (s), 145.2 (s), 144.9 (s), 140.2 (s), 137.1 (s), 121.4 (d), 70.4 (t), 58.3 (q), 48.8 (d), 29.5 (t), 21.0 (q), 13.9 (q), 10.1 (q); ms m/z: 246 (M$^+$, 60), 231 (11), 201 (100).

5-(β-Hydroxy)ethyl-2,4,6-trimethyl-1,3-indandione (4)

A solution of indandione **3** (8.8 g, 0.04 mol) in glacial acetic acid (80 mL) and 48% hydrobromic acid (40 mL) was heated at 100°C for 4 h. The solution was concentrated under reduced pressure, then extracted three times with chloroform. The extract was washed with saturated $NaHCO_3$ solution (twice), brine, and dried. Removal of solvent and chromatography with 30% ethyl acetate in benzene gave the alcohol **4**, 7.51 g (91%), mp 103–106°C (from ether–hexane); ir (KBr): 3360, 1740, 1700, 1590, 1050 cm^{-1}; nmr (^{1}H) δ: 1.32 (d, J = 7 Hz, 3), 2.55 (s, 3), 2.77 (s, 3), 2.97 (q, J = 7 Hz, 1), 3.17 (t, J = 7 Hz, 2), 3.87 (t, J = 7 Hz, 2), 7.67 (br s, 1); nmr (^{13}C) δ: 202.1 (s), 201.3 (s), 145.6 (s), 145.1 (s), 140.4 (s), 137.5 (s), 137.3 (s), 121.8 (d), 60.8 (t), 49.0 (d), 32.4 (t), 21.3 (q), 14.3 (q), 10.4 (q); ms m/z: 232 (M$^+$, 77), 217 (34), 201 (100).

Pterosin C diacetate (5) and isopterosin C diacetate (6)

To a stirred mixture of indandione **4** (513 mg, 2.21 mmol), acetic acid (20 mL), acetic anhydride (20 mL), and anhydrous sodium acetate (1.74 g) was added zinc dust (3.02 g) during 15 min. Stirring was continued for 24 h at 45°C, after which the mixture was filtered. Acetic acid was added to the solid and the combined filtrate and washings were concentrated under reduced pressure. The semi-solid product was dissolved in a mixture of ethyl acetate (50 mL) and brine (50 mL). The organic layer was washed with brine, then the solvent was removed and the residue was chromatographed with 5% ethyl acetate in benzene to give pterosin C diacetate **5** (400 mg, oil), a mixture of **5** and **6** (80 mg), and **6** (88 mg). Total yield was 80%. Spectral data for **5** (mixture of *cis* and *trans* isomers 1:1) were as follows: ir (film): 1735, 1710, 1600, 1240, 1220 cm^{-1}; nmr (^{1}H) *trans* isomer, δ: 1.28 (d, J = 8 Hz, 3), 2.00 (s, 3), 2.08 (s, 3), 2.47 (s, 3), 2.67 (s, 3), 2.50–2.80 (m, 1), 3.00 (t, J = 8 Hz, 2), 4.07 (t, J = 8 Hz, 2), 5.73 (d, J = 3 Hz, 1), 7.17 (s, 1); *cis* isomer, δ: 1.07 (d, J = 8 Hz, 3), 2.00 (s, 3), 2.03 (s, 3), 2.47 (s, 3), 2.67 (s, 3), 2.50–2.80 (m, 1), 3.00 (t, J = 8 Hz, 2), 4.07 (t, J = 8 Hz, 2), 6.17 (d, J = 7 Hz, 1), 7.23 (s, 1); ms m/z: 318 (M$^+$, 3), 258 (15), 216 (100), 198 (67), 185 (31). Spectral data for **6** (mixture of *cis* and *trans* isomers 3:7) included: ir ($CHCl_3$): 1720, 1710, 1600, 1240 cm^{-1}; nmr (^{1}H) *trans* isomer, δ: 1.28 (d, J = 8 Hz, 3), 1.97 (s, 3), 2.05 (s, 3), 2.30 (s, 3), 2.43 (s, 3), 2.50–2.90 (m, 1), 3.00 (t, J = 8 Hz, 2), 4.10 (t, J = 8 Hz, 2), 5.87 (br s, 1), 7.33 (s, 1); *cis* isomer, δ: 1.05 (d, J = 8 Hz, 3), 1.97 (s, 3), 2.05 (s, 3), 2.30 (s, 3), 2.43 (s, 3), 2.50–2.90 (m, 1), 3.00 (t, J = 8 Hz, 2), 4.10 (t, J = 8 Hz, 2), 6.45 (d, J = 7 Hz, 1), 7.33 (s, 1); ms m/z: 318 (M$^+$, 1), 276 (28), 258 (67), 216 (100), 201 (64), 198 (55).

Pterosin C 7

A solution of pterosin C diacetate **5** (352 mg, 1.11 mmol) in dioxane (20 mL) and dilute sulfuric acid (5%, 5 mL) was warmed at 45°C for 10 h. The cooled solution was extracted with chloroform (three times) and the extract was washed with brine and dried. Removal of the solvent and chromatography of the residue with 5% methanol in chloroform gave pterosin C **7** as a mixture of *cis* and *trans* isomers 1:2 (234 mg, 90%). Recrystallization from ethyl acetate gave white needles, mp 160–162°C (lit. (17) mp 153–156°C, lit. (15) mp 162–164°C, lit. (3*c*) mp 160–162°C); uv λ_{max} nm (log ε): 212 (4.78), 255 (4.45), 297 (3.60); ir (KBr): 3400, 1670, 1590, 1020 cm^{-1}; nmr (^{1}H, 360 mHz) *trans* isomer, δ: 1.29 (d, J = 7 Hz, 3), 2.47 (s, 3), 2.64 (s, 3), 2.50–2.90 (m, 1), 3.00 (t, J = 7 Hz, 2), 3.63 (t, J = 7 Hz, 2), 4.70 (d, J = 3 Hz, 1), 7.37 (s, 1); *cis* isomer, δ: 1.17 (d, J = 7 Hz, 3), 2.47 (s, 3), 2.64 (s, 3), 2.50–2.90 (m, 1), 3.00 (t, J = 7 Hz, 2), 3.63 (t, J = 7 Hz, 2), 5.09 (d, J = 7 Hz, 1), 7.37 (s, 1); nmr (^{13}C, DMSO) *trans* isomer, δ: 2.05.0 (s), 153.5 (s, 144.0 (s), 136.9 (s), 135.4 (s), 130.7 (s), 124.3 (d), 73.7 (d), 59.8 (t), 53.2 (d), 32.1 (t), 20.9 (q), 13.3 (q), 12.7 (q); *cis* isomer, δ: 207.9 (s), 154.1 (s), 144.0 (s), 137.2 (s), 136.8 (s), 130.6 (s), 125.4 (d), 67.9 (d), 59.8 (t), 47.8 (d), 32.1 (t), 20.9 (q), 13.4 (q), 10.4 (q); ms m/z: 234 (M$^+$, 46), 219 (10), 203 (100). *Anal.* calcd. for $C_{14}H_{18}O_3$: C 71.77, H 7.74; found: C 71.60, H 7.74.

6-(β-Hydroxy)ethyl-2,5,7-trimethyl-3-methoxy-1-indanone

A solution of pterosin C diacetate **5** (94 mg, 0.4 mmol) in methanol (5 mL) and saturated $NaHCO_3$ solution (1 mL) was stirred at room temperature for 20 h. It was extracted with ether (three times), and the extract was washed with brine and dried. Removal of the solvent yielded crude product (63 mg) which was 15% 6-(β-hydroxy)ethyl-2,5,7-trimethyl-1-indenone **8**: nmr (^{1}H) δ: 1.77 (d, J = 1.5 Hz, 3), 2.30 (s, 3), 2.50 (s, 3), 3.00 (t, J = 7 Hz, 2), 3.73 (t, J = 7 Hz, 2), 6.60 (s, 1), 6.93 (q, J = 1.5 Hz, 1) and 85% 6-(β-hydroxy)ethyl-2,5,7-trimethyl-3-methoxy-1-indanone **9** (mixture of *cis* and *trans* isomers 1:3): nmr (^{1}H) *trans* isomer, δ: 1.33 (d, J = 7 Hz, 3), 2.45 (s, 3), 2.67 (s, 3), 3.00 (t, J = 7 Hz, 2), 3.53 (s, 3), 4.43 (d, J = 3 Hz, 1), 7.33 (s, 1); *cis* isomer, δ: 1.27 (d, J = 7 Hz,, 3), 2.45 (s, 3), 2.67 (s, 3), 3.00 (t, J = 7 Hz, 2), 3.47 (s, 3), 4.73 (d, J = 7 Hz, 1), 7.33 (s, 1).

6-(β-tert-Butyldimethylsilyloxy)ethyl-3-hydroxy-2,5,7-trimethyl-1-indanone

A mixture of pterosin C **7** (1.18 g, 5.0 mmol), *tert*-butyldimethylsilylchloride (2.19 g, 10 mmol), 4-dimethylaminopyridine (98 mg, 0.8 mmol), triethylamine (1 mL), and dichloromethane (30 mL) was stirred at room temperature for 4 h, saturated NH_4Cl solution was added, and the mixture was extracted with chloroform (three times). Chromatography of the product with 25% ethyl acetate in hexane gave the bis-*tert*-butyldimethylsilyl ether (322 mg, 17%), and the desired mono-*tert*-butyldimethylsilyl ether (1.15 g, 83%) as an oil. (The reaction was 79% complete.) Spectral properties for the mono-*tert*-butyldimethylsilyl ether (mixture of *cis* and *trans* isomers 1:1) were as follows: ir (film): 3400, 1710, 1600 cm^{-1}; nmr (^{1}H) *trans* isomer, δ: 0.00 (s, 6), 0.85 (s, 9), 1.30 (d, J = 7 Hz, 3), 2.43 (s, 3), 2.63 (s, 3), 2.40–2.80 (m, 1), 2.97 (t, J = 7 Hz, 2), 3.70 (t, J = 7 Hz, 2), 4.77 (d, J = 3 Hz, 1), 7.33 (s, 1); *cis* isomer, δ: 0.00 (s, 6), 0.85 (s, 9), 1.20 (d, J = 7 Hz, 3), 2.43 (s, 3), 2.63 (s, 3), 2.40–2.80 (m, 1), 2.97 (t, J = 7 Hz, 2), 3.70 (t, J = 7 Hz, 2), 5.20 (d, J = 6 Hz, 1), 7.33 (s, 1); ms m/z: 291 (M$^+$ − C_4H_9, 100), 261 (60), 243 (2), 217 (4), 199 (4). Spectral data for the bis-*tert*-butyldimethylsilyl ether included: ir (film): 1700, 1590 cm^{-1}; nmr (^{1}H) δ: 0.00 (s, 6), 0.06 (s, 6), 0.70 (s, 9), 0.78 (s, 9), 1.13 (d, J = 7 Hz, 3), 2.26 (s, 3), 2.52 (s, 3), 2.30–2.70 (m, 1), 2.86 (t, J = 7 Hz, 2), 3.50 (t, J = 7 Hz, 2), 4.60 (d, J = 3 Hz, 1), 7.00 (s, 1); ms m/z: 463 (M$^+$, 3), 447 (5), 405 (96), 349 (17), 331 (12), 289 (28), 215 (31), 199 (60).

Esterification of pterosin C tert*-butyldimethylsilyl ether with S-(+)-α-phenylbutyric acid*

A mixture of the *tert*-butyldimethylsilyl ether of pterosin C (568 mg, 1.63 mmol), *S*-(+)-α-phenylbutyric acid (282 mg, 1.72 mmol), and 4-dimethylaminopyridine (20 mg, 0.16 mmol) in dichloromethane (10 mL) was stirred under N_2 at 0°C. Dicyclohexyl-

For personal use only.

carbodiimide (382 mg, 1.85 mmol) was added to the mixture, which was stirred at 0°C for 30 min, then at room temperature for 8 h. It was filtered and the filtrate was washed with saturated $NaHCO_3$ solution, 1% $KHCO_3$ solution, and finally with brine. Removal of the solvent and chromatography of the residue with 2.5% ethyl acetate in hexane gave the *trans* isomer of the desired ester (366 mg), a mixture of *trans* and *cis* isomers (283 mg), and the *cis* isomer (93 mg) for a total yield of 95% (ratio of *trans* to *cis*, 4:1). The *trans* isomer was actually a mixture of two diastereomers **10** and **11**. They were only partially separated by hplc on a μ Porasil column with 2% ether in hexane. However, on recycling the effluent from the column six times, complete separation of the diastereomers was achieved. The more polar isomer **10** gave a positive cd curve, $[\theta]_{331.5}$ +26 496; ir (film): 1710, 1700 cm^{-1}; nmr (^1H, 360 MHz) δ: 0.00 (s, 6), 0.79 (s, 9), 0.88 (t, J = 7 Hz, 3), 1.30 (d, J = 7 Hz, 3), 1.79 (m, 1), 2.06 (m, 1), 2.25 (s, 3), 2.40–2.60 (m, 1), 2.59 (s, 3), 2.88 (t, J = 7 Hz, 2), 3.46 (t, J = 7 Hz, 1), 3.60 (t, J = 7 Hz, 2), 5.80 (d, J = 3 Hz, 1), 6.68 (s, 1), 7.28 (br s, 5); ms m/z: 437 ($M^+ - C_4H_9$, 10), 273 (20), 199 (100). The less polar isomer **11** had $[\theta]_{330.5}$ −24 812; nmr (^1H, 360 MHz) δ: 0.00 (s, 6), 0.79 (s, 9), 0.87 (t, J = 7 Hz, 3), 1.20 (d, J = 7 Hz, 3), 1.79 (m, 1), 2.06 (m, 1), 2.35 (s, 3), 2.30–2.50 (m, 1), 2.59 (s, 3), 2.90 (t, J = 7 Hz, 2), 3.44 (t, J = 7 Hz, 1), 3.61 (t, J = 7 Hz, 2), 5.80 (d, J = 3 Hz, 1), 7.02 (s, 1), 7.23 (br s, 5).

Pterosin C-3-(+)-α-phenylbutyrate

A solution of the *trans* isomer of the ester **10** (14.5 mg, 0.03 mmol) in acetic acid – THF–water (3:1:1, 10 mL) was stirred at room temperature for 12 h. It was extracted with ether (three times). The extract was washed with brine, the solvent was removed, and the residue was chromatographed with 30% ethyl acetate in hexane to give 2*S*,3*S*-pterosin C-3-(+)-α-phenylbutyrate (10.6 mg, 97%). Spectral properties included: ir (film): 3400, 1730, 1700, 1600 cm^{-1}; nmr (^1H, 360 MHz) δ: 0.93 (t, J = 7 Hz, 3), 1.34 (d, J = 7 Hz, 3), 1.82 (m, 1), 1.85 (m, 1), 2.29 (s, 3), 2.40–2.60 (m, 1), 2.64 (s, 3), 3.00 (t, J = 7 Hz, 2), 3.51 (t, J = 7 Hz, 1), 3.72 (t, J = 7 Hz, 2), 5.84 (d, J = 3 Hz, 1), 6.73 (s, 1), 7.31 (br s, 5); ms m/z: 380 (M^+, 2), 234 (12), 217 (83), 185 (25). The other diastereomer **11** was treated as above and gave the 2*R*,3*R* alcohol; nmr (^1H, 360 MHz) δ: 0.93 (t, J = 7 Hz, 3), 1.25 (d, J = 7 Hz, 3), 1.82 (m, 1), 1.85 (m, 1), 2.40 (s, 3), 2.30–2.50 (m, 1), 2.64 (s, 3), 3.00 (t, J = 7 Hz, 2), 3.51 (t, J = 7 Hz, 1), 3.72 (t, J = 7 Hz, 2), 5.84 (d, J = 3 Hz, 1), 7.08 (s, 1), 7.27 (br s, 5).

(2S,3S)-Pterosin C and (2R,3R)-pterosin C

Separate solutions of the α-phenylbutyrate esters (10.6 mg, 0.027 mmol) in 5% aqueous sulfuric acid – dioxane (2:5, 14 mL) were stirred at 80°C for 48 h. They were extracted with chloroform (three times), and the extracts were washed with brine and dried. Removal of the solvent and chromatography of the residue with 5% methanol in chloroform gave optically active 2*S*,3*S*-pterosin C and 2*R*,3*R*-pterosin C (5 mg, 71% for each isomer). The cd curves showed $[\theta]_{323.5}$ +23 070 and $[\theta]_{329.5}$ −16 692 respectively.

3-Acetoxy-6-(β-methoxy)ethyl-2,5,7-trimethyl-1-indanone and its regioisomer 3-acetoxy-5-(β-methoxy)ethyl-2,4,6-trimethyl-1-indanone

Zinc dust (50 g, 0.77 mol) was added to a solution of indandione **3** (9.2 g, 0.04 mol) and sodium acetate (30 g, 0.37 mol) in acetic acid (150 mL) and acetic anhydride (150 mL). The mixture was stirred at 50°C for 12 h and then filtered. The solids were washed with acetic acid and the combined filtrate and washings were concentrated under reduced pressure to give a sticky solid. It was dissolved in a mixture of ethyl acetate (150 mL) and brine (150 mL), the organic phase was separated, washed with brine, and dried. Removal of solvent and chromatography of the residue with 5% ethyl acetate in benzene gave the desired indanone (6.06 g, oil), the regioisomer (1.51 g), and a mixture of the two (1.10 g). Total yield was 80%. The indanone was a 1:1 mixture of the *cis* and *trans* isomers: ir (film): 1730, 1700, 1590, 1200, 1100 cm^{-1}; nmr (^1H) *trans* isomer, δ: 1.27 (d, J = 7 Hz, 3), 2.05 (s, 3), 2.37 (s, 3), 2.57 (s, 3), 2.93 (t, J = 7 Hz, 2), 3.23 (s, 3), 3.37 (t, J = 7 Hz, 2), 5.70 (d, J = 3 Hz, 1), 7.15 (s, 1); *cis* isomer, δ: 1.06 (d, J = 7 Hz, 3), 2.00 (s, 3), 2.37 (s, 3), 2.57 (s, 3), 2.93 (t, J = 7 Hz, 2), 3.23 (s, 3), 3.37 (t, J = 7 Hz, 2), 6.12 (d, J = 7 Hz, 1), 7.17 (s, 1); ms m/z: 290 (M^+, 22), 248 (32), 230 (95), 215 (31), 203 (87), 185 (100). The regioisomer was a 1:4 mixture of *cis* and *trans* isomers: ir (film): 1730, 1700, 1600, 1230, 1100 cm^{-1}; nmr (^1H) *trans* isomer, δ: 1.37 (d, J = 7 Hz, 3), 2.17 (s, 3), 2.35 (s, 3), 2.43 (s, 3), 3.05 (t, J = 7 Hz, 2), 3.37 (s, 3), 3.52 (t, J = 7 Hz, 2), 5.97 (br s, 1), 7.43 (br s, 1); *cis* isomer, δ: 1.13 (d, J = 7 Hz, 3), 2.17 (s, 3), 2.35 (s, 3), 2.43 (s, 3), 3.05 (t, J = 7 Hz, 2), 3.37 (s, 3), 3.52 (t, J = 7 Hz, 2), 6.57 (d, J = 7 Hz, 1), 7.43 (br s, 1); ms m/z: 290 (M^+, 2), 248 (30), 230 (100), 215 (31), 203 (22).

6-(β-Methoxy)ethyl-2,5,7-trimethyl-1-indenone

A solution of the acetoxy indanone from above (1.60 g, 5.5 mmol) in 10% potassium hydroxide solution (10 mL) and tetrahydrofuran (20 mL) was refluxed for 2 h. It was cooled and extracted with ether (three times). The combined ether extracts were washed with brine, dried, and the solvent removed, leaving a residue which was chromatographed with 2% ethyl acetate in benzene to give 968 mg of the indenone (76%), a bright yellow compound, mp 72–73°C; uv λ_{max} nm (log ε): 206 (4.32), 246 (4.92), 328 (3.72); ir (film): 1680, 1590, 1100 cm^{-1}; nmr (^1H) δ: 1.80 (d, J = 1.5 Hz, 3), 2.27 (s, 3), 2.50 (s, 3), 2.87 (t, J = 7 Hz, 2), 3.33 (s, 3), 3.40 (t, J = 7 Hz, 2), 6.53 (s, 1), 6.90 (q, J = 1.5 Hz, 1); nmr (^{13}C) δ: 199.7 (s), 143.3 (s), 142.0 (s), 141.3 (d), 137.1 (s), 135.8 (s), 135.7 (s), 125.6 (s), 121.6 (d), 71.1 (t), 58.5 (q), 28.9 (t), 20.6 (q), 12.9 (q), 9.9 (q); ms m/z: 230 (M^+, 20), 215 (1), 201 (27), 185 (100).

Pterosin O

A solution of the above indenone (1.72 g, 7.48 mmol) in ethyl acetate (50 mL) was shaken in an atmosphere of hydrogen with 5% palladium/charcoal (~500 mg) until there was no further uptake of hydrogen (~1 h). The mixture was filtered through Celite. The Celite was eluted with ethyl acetate and the combined filtrates on removal of solvent gave a quantitative yield of pterosin O (1.74 g), mp 45–46°C (from hexane; lit. (17) mp 45–46°C); ir (film): 1690, 1595, 1100 cm^{-1}; nmr (^1H, CCl_4) δ: 1.17 (d, J = 7 Hz, 3), 2.33 (s, 3), 2.30–2.70 (m, 1), 2.60 (s, 3), 2.80–3.60 (m, 2), 2.93 (t, J = 7 Hz, 2), 3.27 (s, 3), 3.37 (t, J = 7 Hz, 2), 7.07 (br s, 1); nmr (^{13}C) δ: 209.1 (s) 151.7 (s), 143.5 (s), 136.9 (s), 134.6 (s), 131.5 (s), 125.1 (d), 70.8 (t), 58.0 (q), 41.9 (d), 33.2 (t), 28.5 (t), 20.6 (q), 16.0 (q), 12.9 (q); ms m/z: 232 (M^+, 27), 217 (40), 187 (100).

Pterosin B

A solution of pterosin O (1.07 g, 4.6 mmol) in 48% hydrobromic acid (30 mL) and acetic acid (60 mL) was warmed at 100°C for 4 h. The solution was concentrated under reduced pressure and then extracted with ether (three times). The combined extracts were washed with brine, dried, and chromatographed with 30% ethyl acetate in benzene to give pterosin B (879 mg, 88%), mp 109–110°C (from chloroform–hexane; lit. (8) mp 107–109°C, lit. (17) mp 109–110°C, lit. (2*d*) mp 89–91°C); ir (film): 3420, 1670, 1590, 1040 cm^{-1}; nmr (^1H) δ: 1.27 (d, J = 7 Hz, 3), 2.17 (br s, exchangeable, 1), 2.44 (s, 3), 2.68 (s, 3), 2.50–2.70 (m, 2), 3.00 (t, J = 7 Hz, 2), 3.24 (dd, J = 7.5, 16.5 Hz, 1), 3.75 (t, J = 7 Hz, 2), 7.10 (s, 1); nmr (^{13}C) δ: 210.3 (s), 152.3 (s), 144.2 (s), 137.6 (s), 134.7 (s), 131.8 (s), 125.4 (d), 61.2 (t), 42.3 (d), 33.6 (t), 31.7 (t), 21.1 (q), 16.3 (q), 13.5 (q); ms m/z: 218 (M^+, 39), 203 (81), 187 (100).

Pterosin F

A mixture of pterosin B (879 mg, 4.0 mmol), carbon tetrachloride (20 mL), and triphenylphosphine (1.56 g, 5.96 mmol) was heated and the resulting solution was refluxed for 3 h. It was cooled, hexane (50 mL) was added, and the mixture was stirred for 15 min. The precipitate of triphenylphosphine oxide was filtered off and washed with hexane (50 mL). The combined filtrate and washings were combined, the solvent removed, and the residue chromatographed with 2.5% ethyl acetate in hexane to give 753 mg (79%) of pterosin F, mp 69–70°C (from hexane, lit. (17) mp 66–67°C, lit. (8) mp 65–68°C); ir (film): 1690, 1595 cm^{-1}; nmr (^1H, CCl_4) δ: 1.20 (d, J = 7 Hz, 3),

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.5 on 09/06/12
For personal use only.

2.40 (s, 3), 2.30–2.70 (m, 2), 2.60 (s, 3), 3.13 (m, 3), 3.47 (m, 2), 7.00 (br s, 1); nmr (^{13}C) δ: 209.6 (s), 152.7 (s), 143.6 (s), 137.4 (s), 134.3 (s), 132.0 (s), 125.6 (d), 42.3 (d), 41.8 (t), 33.6 (t), 32.0 (t), 20.9 (q), 16.3 (q), 13.3 (q); ms *m/z*: 238 (M^+ + 2, 13), 236 (M^+, 43), 221 (9), 201 (100), 187 (97).

Pterosin E

An excess of Jones reagent was added dropwise to a solution of pterosin B (314 mg, 1.44 mmol) in acetone cooled in ice water. It was diluted with ether and filtered through Celite. Removal of the solvent from the filtrate gave pterosin E which was recrystallized from carbon tetrachloride, yield 300 mg (90%), mp 149–150°C (lit. (17) mp 160–162°C, lit. (11) mp 151–153°C); ir (film): 3500–2400, 1710, 1690, 1590 cm^{-1}; nmr (^{1}H) δ: 1.27 (d, J = 7 Hz, 3), 2.39 (s, 3), 2.30–2.70 (m, 2), 2.65 (s, 3), 3.25 (dd, J = 7.5, 16.5 Hz, 1), 3.78 (s, 2), 7.13 (s, 1); nmr (^{13}C) δ: 210.1 (s), 176.6 (s), 153.4 (s), 144.2 (s), 138.1 (s), 131.9 (s), 131.0 (s), 125.5 (d), 42.3 (d), 33.9 (t), 33.7 (t), 21.2 (q), 16.3 (q), 13.6 (q); ms *m/z*: 232 (M^+, 64), 217 (46), 187 (100).

5-(β-Chloro)ethyl-2,4,6-trimethyl-1,3-indandione

This compound was prepared from indandione **4** (1.51 g, 6.49 mmol) in the same way as the preparation of pterosin F from pterosin B. Yield 1.28 g (87%), mp 114–115°C (from hexane); ir (film): 1725, 1690, 1590 cm^{-1}; nmr (^{1}H, CCl_4) δ: 1.27 (d, J = 7 Hz, 3), 2.50 (s, 3), 2.70 (s, 3), 2.95 (q, J = 7 Hz, 1), 3.20 (m, 2), 3.50 (m, 2), 7.53 (br s, 1); nmr (^{13}C) δ: 201.9 (s), 201.0 (s), 145.3 (s), 143.9 (s), 140.9 (s), 137.5 (s), 122.1 (d), 49.1 (d), 41.3 (t), 32.5 (t), 21.2 (q), 14.3 (q), 10.5 (q); ms *m/z*: 252 (M^+ + 2, 15), 250 (M^+, 49), 215 (66), 201 (100).

Pterosin J acetate and isopterosin J acetate

Reduction of the above indandione (990 mg, 3.94 mmol) in the same way as for the reduction of **4** gave, after chromatography with 2% ethyl acetate in benzene, 540 mg of pterosin J acetate (a 1:1 mixture of *cis* and *trans* isomers), 150 mg of the regioisomer (a 1:4 mixture of *cis* and *trans* isomers), and 310 mg of a mixture of all the four isomers (total yield 86%). Spectral properties for pterosin J acetate included: ir (film): 1730, 1710, 1700, 1590, 1220 cm^{-1}; nmr (^{1}H, CCl_4) *trans* isomer, δ: 1.37 (d, J = 7 Hz, 3), 2.17 (s, 3), 2.47 (s, 3), 2.70 (s, 3), 2.40–3.00 (m, 1), 3.23 (m, 2), 3.60 (m, 2), 5.91 (d, J = 3 Hz, 1), 7.33 (br s, 1); *cis* isomer, δ: 1.17 (d, J = 7 Hz, 3), 2.13 (s, 3), 2.47 (s, 3), 2.70 (s, 3), 2.40–3.00 (m, 1), 3.23 (m, 2), 3.60 (m, 2), 6.35 (d, J = 6 Hz, 1), 7.37 (br s, 1); ms *m/z*: 296 (M^+ + 2, 6), 294 (M^+, 18), 252 (77), 237 (57), 234 (83), 203 (94), 199 (71), 185 (100). Spectral properties for isopterosin J acetate included: ir (film): 1730, 1720, 1710, 1600, 1230 cm^{-1}; nmr (^{1}H, CCl_4) *trans* isomer, δ: 1.37 (d, J = 7 Hz, 3), 2.12 (s, 3), 2.35 (s, 3), 2.45 (s, 3), 2.30–3.00 (m, 1), 3.25 (m, 2), 3.62 (m, 2), 5.98 (br s, 1), 7.50 (br s, 1); *cis* isomer, δ: 1.13 (d, J = 7 Hz, 3), 2.12 (s, 3), 2.35 (s, 3), 2.45 (s, 3), 2.30–3.00 (m, 1), 3.25 (m, 2), 3.62 (m, 2), 6.57 (d, J = 7 Hz, 1), 7.50 (br s, 1); ms *m/z*: 254 (M^+ + 2 − CH_2CO, 16), 252 (M^+ − CH_2CO, 53), 237 (75), 234 (100), 219 (25), 217 (34), 203 (15), 199 (81), 185 (59).

Pterosin J

Acid hydrolysis of pterosin J acetate (200 mg, 0.69 mmol) was carried out in the same way as that for pterosin C diacetate. The yield of pterosin J after chromatography with 30% ethyl acetate in benzene was 147 mg (85%), a 2:3 mixture of *cis* and *trans* isomers, mp 120–121°C (from benzene–hexane; lit. (17) mp 136–137°C); ir (film): 3400, 1690, 1595 cm^{-1}; nmr (^{1}H) *trans* isomer, δ: 1.30 (d, J = 8 Hz, 3), 2.43 (s, 3), 2.63 (s, 3), 2.40–2.80 (m, 1), 3.17 (m, 2), 3.53 (m, 2), 4.73 (d, J = 3 Hz, 1), 7.37 (s, 1); *cis* isomer, δ: 1.20 (d, J = 8 Hz, 3), 2.43 (s, 3), 2.63 (s, 3), 2.40–2.80 (m, 1), 3.17 (m, 2), 3.53 (m, 2), 5.20 (d, J = 6 Hz, 1), 7.37 (s, 1); nmr (^{13}C) *cis* isomer, δ: 207.5 (s), 153.3 (s), 144.5 (s), 137.2 (s), 136.8 (s), 131.2 (s), 125.4 (d), 69.5 (d), 48.1 (d), 41.8 (t), 32.1 (t), 21.1 (q), 13.8 (q), 10.1 (q); *trans* isomer, δ: 205.1 (s), 152.7 (s), 144.4 (s), 136.9 (s), 136.4 (s), 131.5 (s), 124.4 (d), 75.2 (d), 53.6 (d), 41.8 (t), 32.1 (t), 21.1 (q), 13.8 (q), 12.9 (q); ms *m/z*: 254 (M^+ + 2, 13), 252 (M^+, 40), 237 (29), 203 (100).

Pterosin I

A solution of pterosin O (1.16 g, 5.0 mmol) in *tert*-butanol (10 mL) was added dropwise to potassium *tert*-butoxide (3.26 g, 30 mmol) in *tert*-butanol (2 mL). The mixture was stirred at room temperature for 15 min, then methyl iodide (10 mL) was added and the mixture was kept overnight. It was acidified (diluted hydrochloric acid) and extracted with ether. The extract was dried, the solvent removed, and the residue chromatographed with 10% ethyl acetate in hexane to give pterosin I (1.1 g, 89%), mp 59–60°C (from hexane, lit. (12) mp 61–62°C, lit. (8) mp 60–63°C, lit. (17) mp 56–57°C); ir (film): 1690, 1600 cm^{-1}; nmr (^{1}H, CCl_4) δ: 1.17 (s, 6), 2.30 (s, 3), 2.63 (s, 3), 2.80 (s, 2), 2.93 (t, J = 7 Hz, 2), 3.27 (s, 3), 3.40 (t, J = 7 Hz, 2), 7.03 (br s, 1); nmr (^{13}C) δ: 211.2 (s), 150.5 (s), 143.7 (s), 137.5 (s), 134.7 (s), 130.4 (s), 125.3 (d), 70.8 (t), 58.1 (q), 44.9 (s), 41.2 (t), 28.5 (t), 25.1 (q), 20.7 (q), 13.0 (q); ms *m/z*: 246 (M^+, 25), 231 (45), 201 (100).

Pterosin Z

This compound was prepared by demethylation of pterosin I (576 mg, 2.34 mmol) in the same way as described for preparation of pterosin B. Purification by chromatography with 30% ethyl acetate in benzene gave a (493 mg) 90% yield of pterosin Z, mp 89–90°C (from ether–hexane; lit. (17) mp 86–88°C, lit. (12) mp 93–93.5°C, lit. (8) mp 87–89°C); ir (film): 3400, 1680, 1590, 1040 cm^{-1}; nmr (^{1}H) δ: 1.10 (s, 6), 2.37 (s, 3), 2.60 (s, 3), 2.73 (s, 2), 2.93 (t, J = 7 Hz, 2), 3.63 (t, J = 7 Hz, 2), 4.07 (br s, exchangeable, 1), 6.97 (br s, 1); nmr (^{13}C) δ: 212.3 (s), 151.1 (s), 144.3 (s), 138.0 (s), 134.8 (s), 130.7 (s), 125.6 (d), 61.2 (t), 45.4 (s), 41.5 (t), 31.7 (t), 25.3 (q), 21.1 (q), 13.5 (q); ms *m/z*: 232 (M^+, 35), 217 (96), 201 (100).

Pterosin H

This compound was prepared from pterosin Z (294 mg, 1.27 mmol) in a similar way to that for pterosin F, though the reflux time was 17 h. It was purified by chromatography with 2.5% ethyl acetate in hexane, yielding pterosin H 195 mg, 74% (83% conversion), mp 87–88°C (from hexane; lit. (8) mp 87–88°C, lit. (12) mp 87.5–88°C); ir (film): 1690, 1590 cm^{-1}; nmr (^{1}H) δ: 1.17 (s, 6), 2.40 (s, 3), 2.67 (s, 3), 2.80 (s, 2), 3.13 (m, 2), 3.50 (m, 2), 7.05 (br, s, 1); nmr (^{13}C) δ: 211.8 (s), 151.6 (s), 143.8 (s), 138.0 (s), 134.5 (s), 128.5 (s), 125.9 (d), 45.5 (s), 41.9 (t), 41.6 (t), 32.1 (t), 25.4 (q), 21.0 (q), 13.5 (q); ms *m/z*: 252 (M^+ + 2, 18), 250 (M^+, 56), 235 (91), 215 (100), 201 (71).

5-(β-Methoxy)ethyl-2,2,4,6-tetramethyl-1,3-indandione

A solution of indandione **3** (250 mg, 1.0 mmol) in benzene (10 mL) was added dropwise to a stirred suspension of 50% sodium hydride (135 mg, 2.8 mmol) in benzene (2 mL). After a further 30 min, excess methyl iodide (10 mL, 0.16 mol) was added dropwise and the mixture was refluxed for 24 h. Water was added and the mixture was extracted with chloroform (three times). The combined extracts were dried, the solvent was removed, and the residue was chromatographed with 5% ethyl acetate in benzene, yielding the product as an oil (235 mg, 89%); ir (film): 1720, 1690, 1580, 1100 cm^{-1}; nmr (^{1}H) δ: 1.25 (s, 6), 2.50 (s, 3), 2.77 (s, 3), 3.10 (t, J = 7 Hz, 2), 3.33 (s, 3), 3.50 (t, J = 7 Hz, 2), 7.63 (br s, 1); nmr (^{13}C) δ: 205.5 (s), 204.6 (s), 145.7 (s), 145.4 (s), 138.9 (s), 137.8 (s), 135.7 (s), 122.2 (d), 70.7 (t), 58.6 (q), 49.8 (s), 29.8 (t), 21.3 (q), 20.3 (q), 14.3 (q); ms *m/z*: 260 (M^+, 56), 245 (11), 230 (13), 215 (100).

5-(β-Hydroxy)ethyl-2,2,4,6-tetramethyl-1,3-indandione

This compound was prepared by demethylation of the preceding methyl ether (235 mg, 0.90 mmol) in the same way as for pterosin B. Purification by chromatography with 30% ethyl acetate in benzene gave a (206 mg) 93% yield of the product, mp 108–109°C (from ether; lit. (17) mp 111°C); ir (film): 3400, 1720, 1690, 1580, 1030 cm^{-1}; nmr (^{1}H) δ: 1.25 (s, 6), 1.70 (br s, exchangeable, 1), 2.53 (s, 3), 2.77 (s, 3), 3.13 (t, J = 7 Hz, 2), 3.83 (t, J = 7 Hz, 2), 7.67 (br s, 1); nmr (^{13}C) δ: 205.4 (s), 204.7 (s), 145.8 (s), 138.7 (s), 137.9 (s),

Pterosin D diacetate and isopterosin D diacetate

The above indandione (206 mg, 0.84 mmol) was reduced in a similar way to that used in the preparation of pterosin C diacetate, but the reaction temperature was 75°C and the time was 40 h. Purification of the product by chromatography with 5% ethyl acetate in benzene gave pterosin D diacetate (179 mg, oil), isopterosin D diacetate (51 mg), and a mixture of the two compounds (8 mg). Total yield was 86%. Spectral properties for pterosin D diacetate included: ir (film): 1720, 1700, 1590, 1230 cm^{-1}; nmr (^1H, CCl_4) δ: 1.00 (s, 3), 1.20 (s, 3), 1.97 (s, 3), 2.07 (s, 3), 2.43 (s, 3), 2.63 (s, 3), 3.00 (t, J = 7 Hz, 2), 4.07 (t, J = 7 Hz, 2), 5.80 (s, 1), 7.17 (br s, 1); nmr (^{13}C) δ: 207.9 (s), 170.7 (s), 170.6 (s), 148.3 (s), 144.8 (s), 137.9 (s), 136.7 (s), 130.5 (s), 125.5 (d), 77.5 (d), 62.3 (t), 49.6 (s), 27.9 (t), 24.1 (q), 21.0 (q), 20.7 (q), 19.5 (q), 13.6 (q); ms *m/z*: 332 (M^+, 12), 290 (54), 272 (2), 230 (100). Spectral properties for isopterosin D diacetate included: ir (film): 1730, 1710, 1700, 1600, 1240, 1220 cm^{-1}; nmr (^1H, CCl_4) δ: 1.00 (s, 3), 1.20 (s, 3), 1.97 (s, 3), 2.03 (s, 3), 2.30 (s, 3), 2.43 (s, 3), 3.03 (t, J = 7 Hz, 2), 4.10 (t, J = 7 Hz, 2), 6.00 (s, 1), 7.37 (s, 1); nmr (^{13}C) δ: 207.8 (s), 170.5 (s), 170.4 (s), 145.2 (s), 142.3 (s), 139.8 (s), 135.7 (s), 133.6 (s), 122.7 (d), 77.8 (d), 62.0 (t), 49.2 (s), 29.1 (t), 24.8 (q), 20.6 (q), 20.3 (q), 18.3 (q), 14.4 (q); ms *m/z*: 332 (M^+, 1), 290 (43), 272 (26), 230 (31), 215 (42).

Pterosin D

Acid hydrolysis of pterosin D diacetate (119 mg, 0.36 mmol) in the same way as for pterosin C diacetate gave, after chromatography with 5% methanol in chloroform, an 88% yield of pterosin D (78 mg), mp 183–184°C (from chloroform–methanol; lit. (17) mp 189–190°C); ir (film): 3300, 1670, 1580, 1090 cm^{-1}; nmr (^1H, CD_3OD) δ: 1.07 (s, 3), 1.20 (s, 3), 2.47 (s, 3), 2.63 (s, 3), 2.98 (t, J = 7 Hz, 2), 3.63 (t, J = 7 Hz, 2), 4.73 (s, 1), 7.37 (br s, 1); nmr (^{13}C, DMSO) δ: 209.0 (s), 152.7 (s), 144.2 (s), 137.2 (s), 136.1 (s), 129.4 (s), 124.9 (d), 75.3 (d), 59.8 (t), 50.9 (s), 32.2 (t), 23.0 (q), 21.0 (q), 20.6 (q), 13.5 (q); ms *m/z*: 248 (M^+, 77), 233 (69), 217 (100), 199 (79).

Pterosin A

A solution of pterosin B (594 mg, 2.7 mmol) in THF (10 mL) was added dropwise to a suspension of sodium hydride (50% dispersion, 270 mg, 5.6 mmol) in THF and the mixture was stirred at room temperature for 30 min. Formaldehyde solution (37%, 10 mL) was added and the mixture was then refluxed for 12 h. Work-up included addition of water, extraction with chloroform, and chromatography with 5% methanol in chloroform. The yield of pterosin A was quantitative (673 mg). Attempts at crystallization were not successful; ir (film): 3400, 1680, 1590, 1020 cm^{-1}; nmr (^1H, 360 MHz) δ: 1.21 (s, 3), 1.76 (br s, exchangeable, 1), 2.43 (s, 3), 2.66 (s, 3), 2.74 (d, J = 17 Hz, 1), 3.00 (t, J = 7 Hz, 2), 3.05 (d, J = 17 Hz, 1), 3.59 (d, J = 10 Hz, 1), 3.74 (t, J = 7 Hz, 2), 3.77 (d, J = 10 Hz, 1), 7.11 (s, 1); nmr (^{13}C, DMSO) δ: 218.5 (s), 152.2 (s), 144.2 (s), 136.7 (s), 135.6 (s), 131.8 (s), 125.7 (d), 66.8 (t), 60.1 (t), 51.2 (s), 36.2 (t), 32.2 (t), 21.0 (q), 13.4 (q); ms *m/z*: 248 (M^+, 51), 233 (43), 217 (70), 203 (52), 199 (60), 187 (100).

Pterosin K

A solution of pterosin F (474 mg, 2 mmol) in 10% potassium hydroxide in methanol (50 mL) was stirred at room temperature for 30 min, then aqueous formaldehyde (37%, 20 mL) was added and the solution was refluxed for 90 min. It was then cooled and extracted with chloroform (three times) and the combined extracts washed with brine. Removal of solvent and chromatography of the residue with 15% ethyl acetate in benzene gave pterosin K (497 mg, 93%), mp 85–86°C (from hexane; lit. (17) mp 85–87°C); ir (film): 3400, 1680, 1590 cm^{-1}; nmr (^1H) δ: 1.13 (s, 3), 2.40 (s, 3), 2.61 (s, 3), 2.66 (d, J = 17 Hz, 1), 3.11 (d, J = 17 Hz, 1), 3.23 (m, 2), 3.43 (m, 2), 3.53 (d, J = 11 Hz, 1), 3.76 (d, J = 11 Hz, 1), 7.11 (br s, 1); nmr (^{13}C) δ: 211.1 (s), 152.6 (s), 144.0 (s), 137.4 (s), 134.2 (s), 131.4 (s), 125.7 (d), 67.2 (t), 50.7 (s), 41.6 (t), 36.3 (t), 31.7 (t), 20.7 (q), 20.6 (q), 13.3 (q); ms *m/z*: 268 (M^+ + 2, 27), 266 (M^+, 76), 251 (18), 248 (10), 235 (100), 231 (19).

Pterosin V

A solution of pterosin O (354 mg, 1.5 mmol) in methanolic potassium hydroxide was treated with formaldehyde solution in the same way as in the preparation of pterosin K. Purification by chromatography with 15% ethyl acetate in benzene gave pure pterosin V (374 mg, 93%); ir (film): 3420, 1670, 1590, 1100 cm^{-1}; nmr (^1H) δ: 1.15 (s, 3), 2.40 (s, 3), 2.63 (s, 3), 2.66 (d, J = 17 Hz, 1), 2.97 (t, J = 7 Hz, 2), 3.15 (d, J = 17 Hz, 1), 3.35 (s, 3), 3.43 (t, J = 7 Hz, 2), 3.53 (d, J = 11 Hz, 1), 3.78 (d, J = 11 Hz, 1), 7.10 (s, 1); nmr (^{13}C) δ: 211.1 (s), 152.0 (s), 144.2 (s), 137.4 (s), 134.6 (s), 131.2 (s), 125.4 (d), 70.8 (t), 67.2 (t), 58.1 (q), 50.6 (s), 36.2 (t), 28.4 (t), 20.7 (q), 20.5 (q), 13.2 (q); ms *m/z*: 262 (M^+, 82), 247 (77), 231 (55), 217 (35), 200 (57), 199 (100).

5-(β-Hydroxy)ethyl-2-hydroxymethyl-2,4,6-trimethyl-1,3-indandione

A solution of indandione **4** (1.71 g, 7.4 mmol) in 10% potassium hydroxide in methanol (100 mL) was stirred at room temperature for 30 min, then aqueous formaldehyde (37%, 50 mL) was added and the solution was refluxed for 90 min. It was neutralized with 10% hydrochloric acid and the solution was then extracted with chloroform (three times). The extract on work-up, which included chromatography with 5% methanol in chloroform, gave 1.22 g (63%) of the desired hydroxymethyl compound, mp 150–152°C (from ethyl acetate); ir (KBr): 3400, 1740, 1700, 1590, 1050 cm^{-1}; nmr (^1H, CD_3OD) δ: 1.00 (s, 3), 2.43 (s, 3), 2.62 (s, 3), 2.96 (t, J = 7 Hz, 2), 3.67 (t, J = 7 Hz, 2), 3.90 (s, 2), 7.37 (s, 1); nmr (^{13}C, DMSO) δ: 207.6 (s), 144.2 (s), 137.2 (s), 135.8 (s), 131.2 (s), 124.6 (d), 65.6 (t), 60.0 (t), 55.8 (s), 32.3 (t), 21.1 (q), 18.7 (q), 13.7 (q); ms *m/z*: 264 (M^+, 19), 246 (68), 233 (79), 231 (44), 218 (65), 215 (99), 202 (30), 201 (57), 187 (100).

Pterosin L triacetate and isopterosin L triacetate

The above indandione (1.22 g, 4.7 mmol), acetic acid (50 mL), acetic anhydride (50 mL), sodium acetate (3.8 g), and zinc dust (6.1 g) was stirred at 75°C for 40 h. Work-up in a similar way to that for the preparation of pterosin C diacetate gave pterosin L triacetate (865 mg), a mixture of pterosin L triacetate and isopterosin L triacetate (84 mg), and isopterosin L triacetate (419 mg), The total yield was 75%. Spectral properties for pterosin L triacetate (oil, a 7:3 mixture of *cis* and *trans* isomers) included: ir (film): 1730, 1720, 1700, 1590, 1220, 1210, 1030 cm^{-1}; nmr (^1H) *trans* isomer, δ: 1.00 (s, 3), 2.00 (s, 3), 2.07 (s, 3), 2.11 (s, 3), 2.47 (s, 3), 2.67 (s, 3), 3.03 (t, J = 7 Hz, 2), 4.00–4.40 (m, 4), 6.17 (s, 1), 7.20 (br s, 1); *cis* isomer, δ: 1.27 (s, 3), 1.83 (s, 3), 2.00 (s, 3), 2.07 (s, 3), 2.47 (s, 3), 2.67 (s, 3), 3.03 (t, J = 7 Hz, 2), 4.00–4.40 (m, 4), 5.97 (s, 1), 7.20 (br s, 1): ms *m/z*: 390 (M^+, 12), 348 (10), 347 (7), 288 (66), 287 (30), 228 (100). Spectral properties for isopterosin L triacetate (a mixture of isomers *cis/trans* 1:2) included: ir (film): 1730, 1710, 1700, 1590, 1240, 1220, 1020 cm^{-1}; nmr (^1H) *trans* isomer, δ: 1.10 (s, 3), 1.82 (s, 3) 1.93 (s, 3), 2.03 (s, 3), 2.22 (s, 3), 2.27 (s, 3), 3.03 (t, J = 7 Hz, 2), 4.00–4.40 (m, 4), 6.20 (s, 1), 7.40 (br s, 1); *cis* isomer, δ: 0.93 (s, 3), 1.82 (s, 3), 1.93 (s, 3), 2.00 (s, 3), 2.22 (s, 3), 2.27 (s, 3), 3.03 (t, J = 7 Hz, 2), 4.00–4.40 (m, 4), 6.32 (s, 1), 7.40 (br s, 1); ms *m/z*: 390 (M^+, 4), 348 (16), 347 (7), 330 (7), 288 (34), 287 (39).

Pterosin L and epi *pterosin L*

A solution of pterosin L triacetate (153 mg, 0.39 mmol), a mixture of two isomers, was hydrolysed in a similar way to that of pterosin C diacetate (but at 50°C for 15 h). Work-up, which included chromatography with 10% methanol in chloroform, gave pterosin L, the *cis* isomer, (72 mg, 70%) and *epi* pterosin L, the *trans* isomer, (22 mg, 21%). Properties of pterosin L included: mp 147–149°C (from benzene; lit. (17) mp 139–141°C); ir (KBr): 3350, 1670, 1590 cm^{-1}; nmr (^1H, $CDCl_3$ and CD_3OD) δ: 1.17 (s, 3), 2.47 (s, 3), 2.67 (s, 3), 3.00 (t, J = 7 Hz, 2), 3.63 (t, J = 7 Hz, 2), 3.78 (s, 2), 4.87 (s, 1), 7.37 (br s, 1); nmr (^{13}C, DMSO) δ: 207.5 (s), 153.4 (s), 144.1 (s), 137.1 (s), 135.6 (s), 131.1 (s), 124.5 (d), 75.4 (d), 65.3 (t), 59.8 (t), 55.7 (s), 32.2 (t), 21.0 (q), 18.5 (q), 13.5 (q); ms *m/z*: 264 (M^+, 14), 246

(9), 233 (43), 215 (53), 203 (75), 185 (100). Properties of *epi* pterosin L included: mp 80–81°C (from benzene; lit. (17) mp 86–89°C); ir (KBr): 3400, 1695, 1685, 1600 cm^{-1}; nmr (^1H, $CDCl_3$ and CD_3OD) δ: 1.00 (s, 3), 2.48 (s, 3), 2.67 (s, 3), 3.00 (t, J = 7 Hz, 2), 3.60 (d, J = 10 Hz, 1), 3.67 (t, J = 7 Hz, 2), 3.85 (d, J = 10 Hz, 1), 5.20 (s, 1), 7.41 (br s, 1); nmr (^{13}C, DMSO) δ: 208.4 (s), 154.3 (s), 144.3 (s), 137.1 (s), 135.9 (s), 130.7 (s), 125.1 (d), 70.0 (d), 64.9 (t), 60.0 (t), 56.4 (s), 32.3 (t), 21.0 (q), 16.0 (q), 13.7 (q).

This article is dedicated to Professor Paul de Mayo on the occasion of his 60th birthday

JOEL R. CHRISTENSEN and WILLIAM REUSCH. Can. J. Chem. **62**, 1954 (1984).

A facile preparation of 6,9,9-trimethylbicyclo[5.3.0]deca-1,6-dien-3-one (**6**) from 2,5,5-trimethylcyclohexane-1,3-dione is described. Enolate reactions of **6** do not yield norcaradiene products, but proceed in the conventional manner (e.g., α-methylation and O-silylation). Nucleophilic addition reactions at the carbonyl function, and epoxidation of the γ,δ double bond are also observed. Under a variety of conditions, singlet oxygen reacts with the diene moiety in **6** to give both endoperoxide (**13**) and ene reaction (**14**) products in roughly equal amounts. The endoperoxide rearranges to cyclic hemiketal (**15**) on treatment with base.

JOEL R. CHRISTENSEN et WILLIAM REUSCH. Can. J. Chem. **62**, 1954 (1984).

On décrit une préparation simple de la triméthyl-6,9,9 bicyclo[5,3,0] décadiène-1,6 one-3 (**6**) à partir de la triméthyl-2,5,5 cyclohexanedione-1,3. Les réactions énoliques du composé **6** ne conduisent pas à des dérivés du norcaradiène; elles donnent plutôt les produits conventionnels (soit l'α-méthylation et la O-sylilation). On a aussi observé des réactions d'addition nucléophile sur la fonction carbonyle et une époxydation de la double liaison γ,δ. L'oxygène singulet réagit, sous diverses conditions, avec la portion diénique du composé **6** pour donner des quantités à peu près égales de l'endoperoxyde **13** et du produit **14** qui provient d'une réaction ene. Sous l'influence des bases, l'endoperoxyde se transpose en un hémicétal cyclique (**15**).

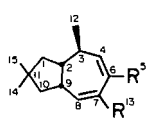
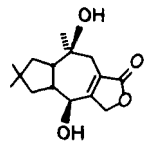
Introduction

Sesquiterpenes belonging to the lactarane family, such as velleral (**1*a***), vellerolactone (**1*b***), and lactaroruffin A (**2**), represent an interesting variation of the perhydroazulene skeleton in natural products (cf. guaianolides and pseudo-guaianolides). Over a dozen such compounds have been isolated from Basidomycetes fungi, and the chemistry of these humulene-derived terpenes has been reviewed (1).





2

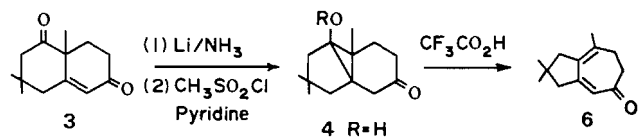
1a $R^5 = R^{13} = CHO$

1b $R^5 = CO$, $R^{13} = CH_2O$ (γ-lactone)

Total syntheses of velleral, vellerolactone, and pyrovellerolactone (an isomer of **1*b***) have been reported by Magnusson's group in Lund, Sweden (2). Their construction of the perhydrozaulene skeleton was accomplished by a [2+2] cycloaddition of dimethyl acetylenedicarboxylate to an enamine derivative of 2,7,7-trimethylbicyclo[3.3.0]octan-3-one, followed by electrocyclic opening of the resulting fused-cyclobutene ring. In this paper we describe an efficient synthesis of the 5,13-bisnorlactarane **6**, which we believe offers an alternative approach for the total synthesis of lactarane sesquiterpenes. We also present a survey of reactions which bear on the potential usefulness of **6** as a synthetic intermediate.

Results and discussion

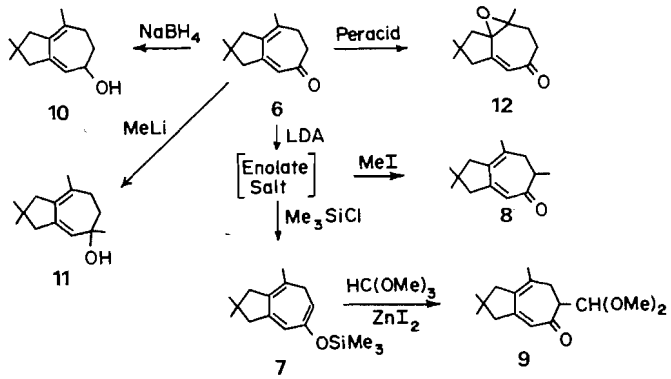
Robinson annulation of methyldimedone gave the bicyclic enedione **3** in good yield (3). Dissolving metal reduction of **3** proceeded smoothly to a fused cyclopropanol (4) which was converted to a mesylate derivative **5** without purification. Solvolysis of **5** in trifluroacetic acid yielded dienone **6**, our lactarane precursor, in greater than 60% overall yield from **3**.



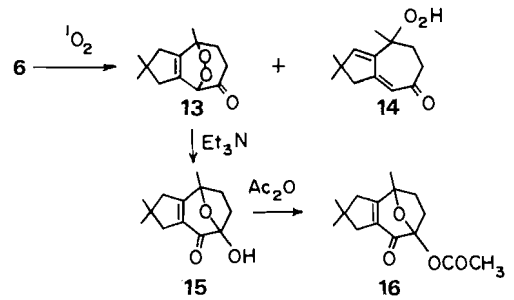
3 4 R=H 5 R=SO_2CH_3 6

Although the disposition of functional groups in **6** is such that structural elaboration should be possible, certain questions concerning the chemical behavior of this intermediate needed to be answered. Foremost among these addressed was the potential valence bond isomerism that might perturb reactions of enolate derivatives of **6**, as in the case of eucarvone (5). In the event, treatment of **6** with lithium diisopropylamide (LDA) generated a lithium enolate, which reacted rapidly with trimethylsilyl chloride to give the O-silylated product **7**, and sluggishly with methyl iodide to give the α-methylation product **8** (Scheme 1). The corresponding sodium enolate (from the action of sodium hydride on **6**) proved to be more reactive than the lithium enolate with weak electrophiles such as ethyl formate, but the resulting **6**-hydroxymethylene product was obtained only in poor yield. Fortunately, the corresponding dimethyl acetal **9** could be prepared in good yield by Lewis-acid promoted alkylation of **7** with trimethyl orthoformate (6). In light of these findings, we conclude that enolate reactions of **6**, unlike those of eucarvone, show no tendency to give norcaradiene products.

In other experiments with **6** (Scheme 1) we determined that the carbonyl function gave 1,2-addition reactions with methyllithium and cerium(III)-doped borohydride (7), and that the γ,δ double bond was epoxidized selectively on treatment with peracid. Acid-catalyzed reaction of **6** with ethylene glycol gave a mixture of diene–ketal derivatives, which were hydrolyzed back to **6**. This mixture of unsaturated ketals was not separated



SCHEME 1



SCHEME 2

or characterized in an unambiguous fashion.

The last aspect of the chemical behavior of **6** that we chose to study in this survey concerned its reactions with singlet oxygen. Lactaroruffin A (**2**) and several other lactarane sesquiterpenes have *cis*-hydroxyl groups at C-3 and C-8, and an endoperoxide derivative of **6** seemed to be an ideal intermediate for the construction of such compounds (8). The desired endoperoxide, **13**, should result from a [4+2] cycloaddition of singlet oxygen to the diene moiety of **6**; however, competing ene reactions often occur at highly-substituted double bonds, and may be a problem in this case. In the event, hematoporphyrin-sensitized photooxidation of **6** in acetone solution gave a 1.2:1 mixture of **13** and a single ene product **14** in over 90% yield (Scheme 2). A similar photooxidation of dienols **10** and **11** gave complex mixtures of ene products and very little endoperoxide, indicating that the electron-withdrawing influence of the carbonyl function in **6** not only facilitates the cycloaddition reaction, but also favors one of the four possible ene products (that involving the most nucleophilic double bond). All our efforts to increase the **13**/**14** ratio by changing the sensitizer, the solvent, or the reaction temperature resulted in small to moderate decreases in this ratio. In particular, the 0.67 ratio observed for hematoporphyrin or tetraphenylporphine-sensitized reactions in carbon tetrachloride solution was surprising, since recent work by Matsumoto and Kuroda indicated that endoperoxide formation should be enhanced in this solvent (9). When the temperature of the reaction mixture was lowered to 0°C, this ratio decreased further to 0.44.

A number of reductive transformations of endoperoxides that might be useful in transforming **13** to a saturated *cis*-diol have been described (8,10). Unfortunately, our attempts to react **13** with diimide or palladium and hydrogen resulted in complex mixtures of unidentified products. These failures were counterbalanced, however, by a facile base-catalyzed rearrangement of **13** to the bridged hemiketal **15**. This compound and its acetate derivative (**16**) appear to offer good opportunities for selective reduction reactions but, except for their lack of reaction with diimide, these possibilities have not been tested. Obviously, the usefulness of such a study is diminished by our inability to suppress the ene reaction during singlet oxygen addition to **6**. If the selectivity of this reaction cannot be improved, or if alternative routes to intermediates such as **15** cannot be devised (possibly via epoxide **12**), applications of **6** to lactarane sesquiterpene sysnthesis will be limited.

Experimental

The ir spectra were recorded on a Perkin–Elmer 237B grating spectrophotometer. The ^{1}H nmr spectra were taken in $CDCl_3$ solution on either a Varian T-60 or a Bruker 250-MHz spectrometer and are calibrated in ppm downfield from Me_4Si as an internal standard. The ^{13}C nmr spectra were obtained with a Varian CFT-20 spectrometer or with the Bruker 250-MHz instrument. Mass spectra were taken with a Finnigan 4000 gc/ms spectrometer. The uv spectra were recorded on a Unicam SP-800 spectrophotometer. Melting points were measured on either a Hoover–Thomas apparatus (capillary tube) or on a Reichert hot-stage microscope and are uncorrected.

Microanalyses of C and H were performed by Spang Microanalytical Laboratories, Eagle Harbor, MI.

With the exception of the singlet oxygen reactions, all reactions were conducted under nitrogen or argon with solvents purified by distillation from suitable drying agents.

Preparation of mesylate **5**

Ammonia (1 L) was condensed in a dry, 2 L, three-neck, round bottom flask containing 75 mL of tetrahydrofuran (THF), and equipped with a mechanical stirrer, an addition funnel, and a Dry Ice condenser. Lithium wire (1.02 g, 147 mmol) was dissolved in the ammonia, followed by dropwise addition of a solution of 12.0 g (59.3 mmol) of **3** (3) in 150 mL THF. This solution was stirred for 0.5 h, and was then quenched by careful addition of approximately 3 g of ammonium chloride. After the cooling bath was removed, the ammonia was evaporated under nitrogen and the residue was diluted with 500 mL ether, washed with water, and dried over sodium sulfate. Evaporation of the ether gave 11.9 g of a yellow oil, which by ^{1}H nmr analysis still contained ca. 6% of enedione **3**. This crude cyclopropanol (**4**) was dissolved in 35 mL of cold pyridine and added to a solution of 7.0 mL (90 mmol) of freshly-distilled methanesulfonyl chloride in 35 mL of pyridine, containing 0.5 g of 4-(*N*,*N*-dimethylamino) pyridine. After being stirred overnight, this mixture was poured into 400 mL of ice water, and extracted twice with 500-mL portions of ether. The combined ether layers were washed successively with 2% hydrochloric acid, saturated sodium bicarbonate solution, and then dried. Evaporation of the solvent gave a solid, which was triturated with cold ether and filtered, yielding 11.0 g of **5**, mp 101 – 103°C (dec.) Characteristic properties of **5** are: infrared $\bar{\nu}_{max}$ ($CHCl_3$): 1715 cm^{-1}; ^{1}H nmr methyl signals at δ: 1.0 (3H,s), 1.16(6H,s), 3.08(3H,s) ppm; ^{13}C nmr ($CDCl_3$) δ: 14.2, 25.9, 27.2, 30.8, 33.1, 35.5, 35.6, 39.4, 40.5, 45.1, 45.2, 46.9, 81.0, 211.5 ppm; mass spectrum (70 eV) *m/e* (rel. intens.): 286(5), 271(5), 207(55), 189(100), 175(20), 165(92), 147(54), 123(40). *Anal.* calcd. for $C_{14}H_{22}O_4S$: C 58.71, H 7.74; found C 58.54, H 7.75.

6.9.9-Trimethylbicyclo[5.3.0]deca-1,6-dien-3-one (**6**)

A solution of 2.0 g (7.0 mmol) of **5** in 20 mL of trifluroacetic acid was stirred for 0.5 h at room temperature, poured into 100 mL of water, and extracted with 100 mL of ether. The ether extract was washed with 100-mL portions of aqueous sodium bicarbonate until gas evolution ceased, and was then dried. Evaporation of the solvent, followed by chromatography of the residue (silica gel, 25% ethyl acetate/hexane) gave 1.18 g (91%) of **6**, a light yellow oil. Characteristic properties of **6** are: infrared $\bar{\nu}_{max}$ ($CHCl_3$): 1630, 1590 cm^{-1}; λ_{max} (95% EtOH): 315 nm (ε = 6250); ^{1}H nmr ($CDCl_3$) δ: 1.05 (6H,s),

1.92 (3H,s), 2.2 – 2.7 (8H,m), 6.0 (1H, br s) ppm; ^{13}C nmr ($CDCl_3$) δ: 22.4, 27.0 $(CH_3)_2$, 29.3, 35.4, 39.4, 46.3, 51.4, 122.8, 134.4, 142.5, 158.0, 198.5 ppm; mass spectrum (70eV) *m/e* (rel. intens.): 190(96), 175(26), 162(49), 147(95), 119(33), 106(96), 105(56), 91(100), 77(24). *Anal.* calcd. for $C_{13}H_{18}O$: C 82.06, H 9.54; found: C 81.92, H 9.47.

3-Trimethylsilyloxy-6,9,9-trimethylbicyclo[5.3.0]deca-1,3,6-triene (7)

A solution of LDA in THF was prepared by first reacting diisopropyl amine (2.6 mmol) with n-butyllithium (2.4 mmol) in 5 mL of hexane, removing the solvent and excess amine at reduced pressure, and finally dissolving the resulting white solid in 2.5 mL of THF. The LDA solution was cooled to 0°C and a solution of **6** (418 mg, 2.2 mmol) in 1 mL THF was then added. After a 10-min reaction period, 0.32 mL (2.4 mmol) of trimethylsilyl chloride was introduced, the reaction mixture was stirred for 5 min. and the solvent was removed. The residue was dissolved in 20 mL of pentane, filtered, and then evaporated to give 536 mg (93%) of pure **7** as a volatile yellow oil. Characteristic properties of **7** are: infrared $\bar{\nu}_{max}$: 1620, 1250 cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 0.16 (9H,s), 1.03 (6H,s), 1.85 (3H,br s), 2.2 – 2.4 (6H,m), 4.58 (1H,br t, J = 4 Hz), 5.95 (1H,br s) ppm; ^{13}C nmr ($CDCl_3$) δ: 0.7, 21.9, 29.1 $(CH_3)_2$, 31.7, 37.8, 46.1, 50.7, 98.3, 121.7, 127.9, 135.6, 148.3, 150.8 ppm; mass spectrum (70 eV) *m/e* (rel. intens.): 262(87), 261(55), 247(100), 73(51). Parent ion isotope ions calcd. for $C_{16}H_{26}OSi$: P + 1, 22.88; P + 2, 5.03; found: (corrected for P – 1 contributions): P + 1, 23.89; P + 2, 5.57.[1]

4,6,9,9-Tetra methylbicyclo[5.3.0]deca-1,6-dien-3-one (8)

A solution of 0.13 g (0.7 mmol) of **6** in 1 mL THF was added to a cold solution of LDA (0.8 mmol) in 2.2 mL THF (prepared as above). After stirring this mixture for 10 min, 140 mg (1.0 mmol) of methyl iodide was added and this solution was refluxed for 30 min. The cooled reaction mixture was then diluted with ether (30 mL), washed successively with water and brine, and dried. Evaporation of the solvent followed by chromatography of the residue (silica gel, 20% ethyl acetate/hexane) gave 120 mg (82%) of **8** as a yellow oil. Characteristic properties of **8** are: infrared $\bar{\nu}_{max}$ ($CHCl_3$): 1630, 1590 cm^{-1}; λ_{max} (95% EtOh): 315 nm (ε = 6100); ^{1}H nmr ($CDCl_3$) δ: 1.04 (6H,s) 1.06 (3H,d, J = 7.5 Hz), 1.91 (3H,s), 2.2 – 2.7 (7H,m), 5.98 (1H, br s) ppm; mass spectrum (70 eV) *m/e* (rel. intens.): 204(4), 189(3), 176(7), 161(8), 149(15), 147(27), 129(100), 119(11), 112(34), 105(15). *Anal.* calcd. for $C_{14}H_{20}O$: C 82.30, H 9.87; found: C 82.15, H 9.76.

4-Dimethoxymethyl-6,9,9-trimethylbicyclo[5.3.0]deca-1,6-dien-3-one (9)

To a solution of 0.97 g (3.67 mmol) of **7** in 20 mL of dry trimethylorthoformate was added 1.28 g (4.0 mmol) of zinc iodide. This mixture was stirred for 1 h, diluted with 100 mL of ether, washed with 100-mL portions of water and brine, and dried. Evaporation of the solvent followed by chromatography (silica gel, 25% ethyl acetate/hexane) gave 0.86 g (85%) of **9** as a yellow oil. Characteristic properties of **9** are: infrared $\bar{\nu}_{max}$ ($CHCl_3$): 1645, 1585 cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 1.03 (3H,s), 1.05 (3H,s), 1.92 (3H,s), 2.2 – 2.9 (7H,m), 3.35 (3H,s), 3.38 (3H,s), 4.80 (1H,d, J = 7 Hz), 6.0 (1H,br s) ppm; ^{13}C nmr ($CDCl_3$) δ: 23.6, 27.8, 27.9, 31.3, 36.5, 47.1, 50.8, 52.2, 54.1, 54.3, 102.6, 123.2, 135.5, 141.5, 158.6, 198.0 ppm; mass spectrum (70 eV) *m/e* (rel. intens.): 264(3), 249(3), 232(11), 217(4), 189(5), 115(15), 75(100).

6,9,9-Trimethylbicyclo[5.3.0]deca-1,6-dien-3-ol (10)

To 4.6 mL (1.84 mmol) of a 0.4 *M* solution of cerium(III) chloride in methanol was added 0.35 g (1.84 mmol) of **6** followed by 69.3 mg (1.8 mmol) of sodium borohydride. After stirring the reaction mixture for 5 min, it was treated with ice water and extracted with ether. The washed and dried ether extracts were evaporated, and chromatography (silica gel, 40% ethyl acetate/hexane) yielded 280 mg (80%) of **10** as a colorless oil. Characteristic properties of **10** are: infrared $\bar{\nu}_{max}$ (neat): 3350 (broad), 1625 cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 0.97 (3H,s), 1.00 (3H,s), 1.78 (3H,s), 1.5 – 2.4 (9H,m), 4.32 (1H,m), 5.65 (1H,br d, J = 4 Hz) ppm; ^{13}C nmr ($CDCl_3$) δ: 23.2, 27.8, 28.0, 30.9, 33.4, 35.8, 48.3, 51.8, 69.1, 123.9, 133.2, 136.5, 142.3 ppm; mass spectrum (70 eV) *m/e* (rel. intens.): 192(33), 177(57), 174(34), 159(67), 149(20), 105(16), 91(100), 79(64), 77(86).

3,6,9,9-Tetramethylbicyclo[5.3.0]deca-1,6-dien-3-ol (11)

A stirred solution of **6** (90 mg, 0.47 mmol) in 1.5 mL of ether was cooled to −78°C, and to this was added 0.34 mL (0.51 mmol) of a 1.5 *M* solution of methyl lithium in ether. The reaction mixture was then warmed to room temperature, stirred 1 h, and quenched with saturated ammonium chloride solution. The ether layer was washed with brine, dried (Na_2SO_4), and evaporated. Chromatography (silica gel, 25% ethyl acetate/hexane) gave 75 mg (77%) of **11** as a pale yellow oil. Characteristic properties of **11** are: ^{1}H nmr ($CDCl_3$) δ: 0.96 (3H,s), 0.98 (3H,s), 1.30 (3H,s), 1.76 (3H,s), 1.5 – 2.5 (9H,m), 5.54 (1H,br s) ppm; mass spectrum (70 eV) *m/e* (rel. intens.): 206(16), 191(30), 188(72), 173(100), 163(45), 107(23). *Anal.* calcd. for $C_{14}H_{22}O$: C 81.50; H 10.75; found: C 81.23, H 10.70.

6,7-Epoxy-6,9,9-trimethylbicyclo[5.3.0]deca-1-en-3-one (12)

A solution of 4.8 g (25 mmol) of **6** in 100 mL chloroform was treated with 10.1 g (50 mmol) of 85% *m*-chloroperoxybenzoic acid. This solution was stirred for 1 h and then washed successively with aqueous sodium sulfite, sodium bicarbonate, and brine. Evaporation of the dried chloroform solution followed by chromatography of the residue (silica gel, 25% ethyl acetate/hexane) gave 4.1 g (80%) of **12** as a clear oil. Characteristic properties of **12** are: infrared $\bar{\nu}_{max}$ ($CHCl_3$): 1660, 1200 cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 1.08 (3H,s), 1.15 (3H,s), 1.44 (3H,s), 1.6 – 2.9 (8H,m), 6.03 (1H,br s) ppm; ^{13}C nmr ($CDCl_3$) δ: 21.4, 27.4, 27.6, 28.1, 36.2, 36.8, 46.9, 51.1, 65.6, 69.2, 127.6, 159.7, 200.9 ppm; mass spectrum (70 eV) *m/e* (rel. intens.): 206(62), 191(27), 163(30), 150(97), 149(100), 135(65), 121(13), 107(30). *Anal.* calcd. for $C_{13}H_{18}O_2$: C 75.69, H 8.79; found: C 75.51, H 8.74.

Reaction of 6 with singlet oxygen

A solution of 190 mg (1.0 mmol) of **6** and 10 mg of hematoporphyrin in 15 mL of acetone was irradiated by a 200-W incandescent light while oxygen was slowly bubbled through the solution. From time to time acetone was added to the reaction solution to replace that lost by evaporation. After 10 h the irradiation was stopped and the reaction solution was evaporated, leaving 230 mg of a solid residue. Chromatography of this residue (silica gel, 50% ethyl acetate/hexane) gave 110 mg (49%) of **13**, mp 67.5 – 68°C, and 93 mg (42%) of **14**, mp 133.5 – 134.5°C.

Characteristic properties of **13**: infrared $\bar{\nu}_{max}$ ($CHCl_3$): 1716 cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 1.08 (3H,s), 1.18 (3H,s), 1.33 (3H,s), 1.9 – 3.3 (8H,m), 4.78 (1H,s) ppm; ^{13}C nmr ($CDCl_3$) δ: 22.3, 29.4, 29.9, 36.7, 37.3, 38.9, 46.8, 47.9, 82.7, 85.6, 131.1, 145.0, 202.9 ppm; mass spectrum (70 eV) *m/e* (re. intens.): 223(M + 1, 15), 222(1.3), 207(10), 206(28), 205(50), 195(8), 179(29), 178(79), 177(71), 164(100), 163(75), 149(25), 145(23), 135(93), 121(79), 107(57). *Anal.* calcd. for $C_{13}H_{18}O_3$: C 70.24, H 8.16; found: C 70.31, H 8.22.

Characteristic properties of **14**: infrared $\bar{\nu}_{max}$ ($CHCl_3$): 3535 (sharp), 3250 (broad), 1610 (broad) cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 1.15 (3H,s), 1.17 (3H,s), 1.52 (3H,s), 1.9 – 3.0 (7H,m), 5.88 (1H,br s), 6.63 (1H,s) ppm; ^{13}C nmr ($CDCl_3$) δ: 24.7, 28.0 (overlapping signals), 31.2, 37.1, 42.4, 49.7, 81.6, 120.6, 143.2, 158.5, 161.3, 201.2 ppm; mass spectrum (70 eV) *m/e* (rel. intens.): 223(M + 1, 7), 222(14), 207(11), 206(16), 205(8), 189(91), 177(43), 163(34), 161(100), 149(30), 147(64), 145(32), 133(35), 121(27), 119(62), 107(34), 105(59). *Anal.* calcd. for $C_{13}H_{18}O_3$: C 70.24, H 8.16; found: C 70.34, H 8.21.

[1]Because of its volatility, conventional microanalysis of **7** was not attempted. Although high-resolution mass spectrometry was not available to us, we believe the characteristic isotope distribution of natural silicon makes the P + 1 and P + 2 measurement particularly informative.

*1-Hydroxy-5,5,8-trimethyl-11-oxatricyclo[6.2.1.0^{3,7}]undec-3(7)-en-2-one (**15**)*

To a solution of 100 mg (0.45 mmol) of **13** in 5 mL of methylene chloride was added 4.5 mg of triethylamine. This solution was stirred for 1 h and the solvent and amine were removed under vacuum. The resulting solid (100 mg) was crystallized from ethyl acetate/hexane to give pure **15**, mp 106 − 108°C (>90% yield). Characteristic properties of **15** are: infrared $\bar{\nu}_{max}$ ($CHCl_3$): 3500, 1685, 1620, 1200 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 1.08 (3H,s), 1.18 (3H,s), 1.52 (3H,s), 1.8 − 2.7 (8H,m), 4.55 (1H,br s, exchange D_2O); ^{13}C nmr ($CDCl_3$) δ: 21.5, 29.0, 29.4, 32.1, 33.7, 39.2, 42.9, 47.5, 80.9, 103.7, 132.5, 171.3, 195.0 ppm; mass spectrum (70 eV) *m/e* (rel. intens.): 222(28), 207(2), 189(1), 178(20), 163(100), 136(21), 135(50), 121(33), 119(13), 107(34). *Anal.* calcd. for $C_{13}H_{18}O_3$: C 70.24, H 8.16; found: C 69.92, H 8.16.

An acetate derivative **16** was prepared from **15** by treatment with acetic anhydride in pyridine containing DMAP. This derivative, mp 112−113°C, exhibited the following properties: infrared $\bar{\nu}_{max}$ ($CHCl_3$): 1750, 1690, 1620, 1210 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 1.06 (3H,s), 1.19 (3H,s), 1.56 (3H,s), 2.18 (3H,s), 1.6 − 2.7 (8H,m) ppm; ^{13}C nmr ($CDCl_3$): fifteen peaks; mass spectrum (70 eV): molecular ion at *m/e* 264 amu. *Anal.* calcd. for $C_{15}H_{20}O_4$: C 68.16, H 7.62; found: C 68.23, H 7.66.

The formation and hydrolytic cleavage of substituted benzalacetones

J. PETER GUTHRIE,[1] JOHN COSSAR, AND KATHLEEN F. TAYLOR
Department of Chemistry, University of Western Ontario, London, Ont., Canada N6A 5B7

Received January 24, 1984

This paper is dedicated to Professor Paul de Mayo on the occasion of his 60th birthday

J. PETER GUTHRIE, JOHN COSSAR, and KATHLEEN F. TAYLOR. Can. J. Chem. **62**, 1958 (1984).

The base catalyzed aldol condensation of acetone and benzaldehyde, as well as two substituted benzaldehydes, has been reinvestigated in both the formation and cleavage directions. Microscopic rate and equilibrium constants have been deduced from the experimental data in a fashion consistent with the rigorously correct integrated rate law. The values so obtained are as follows: (substituent, rate constants, equilibrium constants); H: $k'_{12} = 3.2 \times 10^{-4}\ M^{-1}\ s^{-1}$, $k'_{21} = 7.5 \times 10^{-3}\ M^{-1}\ s^{-1}$, $k'_{23} = 1.4 \times 10^{-2}\ M^{-1}\ s^{-1}$, $k''_{32} = 0.17\ M^{-2}\ s^{-1}$; $K_{12} = 0.042$, $K_{32} = 12.\ M^{-1}$, $K_{overall} = 286.$; *p*-MeO: $k'_{12} = 1.6 \times 10^{-4}\ M^{-1}\ s^{-1}$, $k'_{21} = 1.3 \times 10^{-2}\ M^{-1}\ s^{-1}$, $k'_{23} = 3 \times 10^{-2}\ M^{-1}\ s^{-1}$, $k''_{32} = 0.047\ M^{-2}\ s^{-1}$; $K_{12} = 0.012$, $K_{32} = 1.6\ M^{-1}$, $K_{overall} = 131.$; *p*-NO_2: $k'_{12} = 1.8 \times 10^{-3}\ M^{-1}\ s^{-1}$, $k'_{21} = 1.3 \times 10^{-2}\ M^{-1}\ s^{-1}$, $k'_{23} = 1.6 \times 10^{-2}\ M^{-1}\ s^{-1}$, $k''_{32} = 3.8\ M^{-2}\ s^{-1}$; $K_{12} = 0.14$, $K_{32} = 235.\ M^{-1}$, $K_{overall} = 1730.$

J. PETER GUTHRIE, JOHN COSSAR et KATHLEEN F. TAYLOR. Can. J. Chem. **62**, 1958 (1984).

On a étudié de nouveau la condensation aldolique, catalysée par les bases, de l'acétone, du benzaldéhyde ainsi que de deux benzaldéhydes substitués, tant du point de vue de la condensation que du point de vue du clivage des produits. Pour obtenir les constantes d'équilibre et de vitesse microscopique à partir des donnés expérimentales, on a utilisé une méthode qui est en accord avec la loi intégrée de vitesse qui est rigoureusement correcte. On a ainsi obtenu les valeurs suivantes: (substituant, constantes de vitesse, constante d'équilibre); H: $k'_{12} = 3{,}2 \times 10^{-4}\ M^{-1}\ s^{-1}$, $k'_{21} = 7{,}5 \times 10^{-3}\ M^{-1}\ s^{-1}$, $k'_{23} = 1{,}4 \times 10^{-2}\ M^{-1}\ s^{-1}$, $k''_{32} = 0{,}17\ M^{-2}\ s^{-1}$; $K_{12} = 0{,}042$, $K_{32} = 12\ M^{-1}$, $K_{global} = 286$; *p*-MeO: $k'_{12} = 1{,}6 \times 10^{-4}\ M^{-1}\ s^{-1}$, $k'_{21} = 1{,}3 \times 10^{-2}\ M^{-1}\ s^{-1}$, $k'_{23} = 3{,}0 \times 10^{-2}\ M^{-1}\ s^{-1}$, $k''_{32} = 0{,}047\ M^{-2}\ s^{-1}$; $K_{12} = 0{,}012$, $K_{32} = 1{,}6\ M^{-1}$, $K_{global} = 131$; *p*-NO_2: $k'_{12} = 1{,}8 \times 10^{-3}\ M^{-1}\ s^{-1}$, $k'_{21} = 1{,}3 \times 10^{-2}\ M^{-1}\ s^{-1}$, $k'_{23} = 1{,}6 \times 10^{-2}\ M^{-1}\ s^{-1}$, $k''_{32} = 3{,}8\ M^{-2}\ s^{-1}$; $K_{12} = 0{,}14$, $K_{32} = 235\ M^{-1}$, $K_{global} = 1730$.

[Traduit par le journal]

Introduction

We have reported a study (1) of the equilibrium constants for aldol condensation reactions. One of the few cases for which a full kinetic analysis had been reported was that of benzalacetone (4-phenyl-3-buten-2-one), which had been studied by Noyce and Reed (2). On further examination of their paper it was realized that the analysis was flawed, among other things involving a violation of microscopic reversibility. Since we consider it important to have a reliable set of rate and equilibrium constants for a set of simple aldol reactions and need such data for an examination of rate equilibrium correlations for the aldol reaction, we have reinvestigated the retroaldol reactions of some simple benzalacetones.

Results and discussion

The retroaldol reaction of benzalacetone can be followed spectrophotometrically; when benzalacetone, as a solution in acetonitrile, is injected into aqueous sodium hydroxide solution there is a smooth disappearance of the absorbance at 291 nm, which follows a simple first-order rate law. Thus one can see no sign of the two stages which are believed to be essential for this reaction; eq. [1]

[1] $$\mathrm{Ph{-}CH{=}CH{-}CO{-}CH_3} \underset{k_{21}}{\overset{k_{12}}{\rightleftarrows}} \mathrm{Ph{-}CHOH{-}CH_2{-}CO{-}CH_3}$$

$$\mathrm{Ph{-}CHOH{-}CH_2{-}CO{-}CH_3} \underset{k_{32}}{\overset{k_{23}}{\rightleftarrows}} \mathrm{Ph{-}CHO + CH_3{-}CO{-}CH_3}$$

The two phases of the reaction are quite apparent when the ketol, 4-phenyl-4-hydroxy-2-butanone, is injected into aqueous sodium hydroxide solution; the absorbance at 291 nm first rises and then, about 100 times more slowly, falls again: see Fig. 1. The rate of the slow fall in absorbance is essentially identical to the rate of disappearance of the absorbance of benzalacetone when the latter is used to initiate reaction. Analysis of the two-phase kinetics data permits evaluation of the rate constants. For the cleavage reactions of benzalacetones or ketols, where a low concentration of aldol product undergoes retroaldol cleavage, the rate of the second-order aldol formation process, k_{32}, is negligible. A rigorous solution of the kinetics equations is possible following the procedure described in Moore and Pearson (3), and leads to eq. [2] which gives the absorbance as a function of time.

[2] $$A = A_\infty + \alpha \exp(-\lambda_2 t) + \beta \exp(-\lambda_3 t)$$

where A = absorbance; $\lambda_{2,3} = (p \pm q)/2$; $p = k_{12} + k_{21} + k_{23}$; $q = (p^2 - k_{12}k_{23})^{1/2}$. When kinetics of benzalacetone formation are studied, all four rate constants are necessary, but the rigorously correct rate law still follows eq. [2], although now $p = k_{12} + k_{21} + k_{23} + k_{32}$ and $q = (p^2 - (k_{12}k_{23} + k_{32}k_{12} + k_{32}k_{21}))^{1/2}$. The initial rapid phase of the reaction is observed as a lag before the absorbance begins to rise: see Fig. 2.

When reaction starts with benzalacetone,

$$\alpha = C_1^0 k_{12}\epsilon_1(\lambda_2 - k_{23})\{1 - \epsilon_2\lambda_2/\epsilon_1(\lambda_2 - k_{23}) + \epsilon_3 k_{23}/\epsilon_1(\lambda_2 - k_{23})\}/\lambda_2(\lambda_2 - \lambda_3)$$

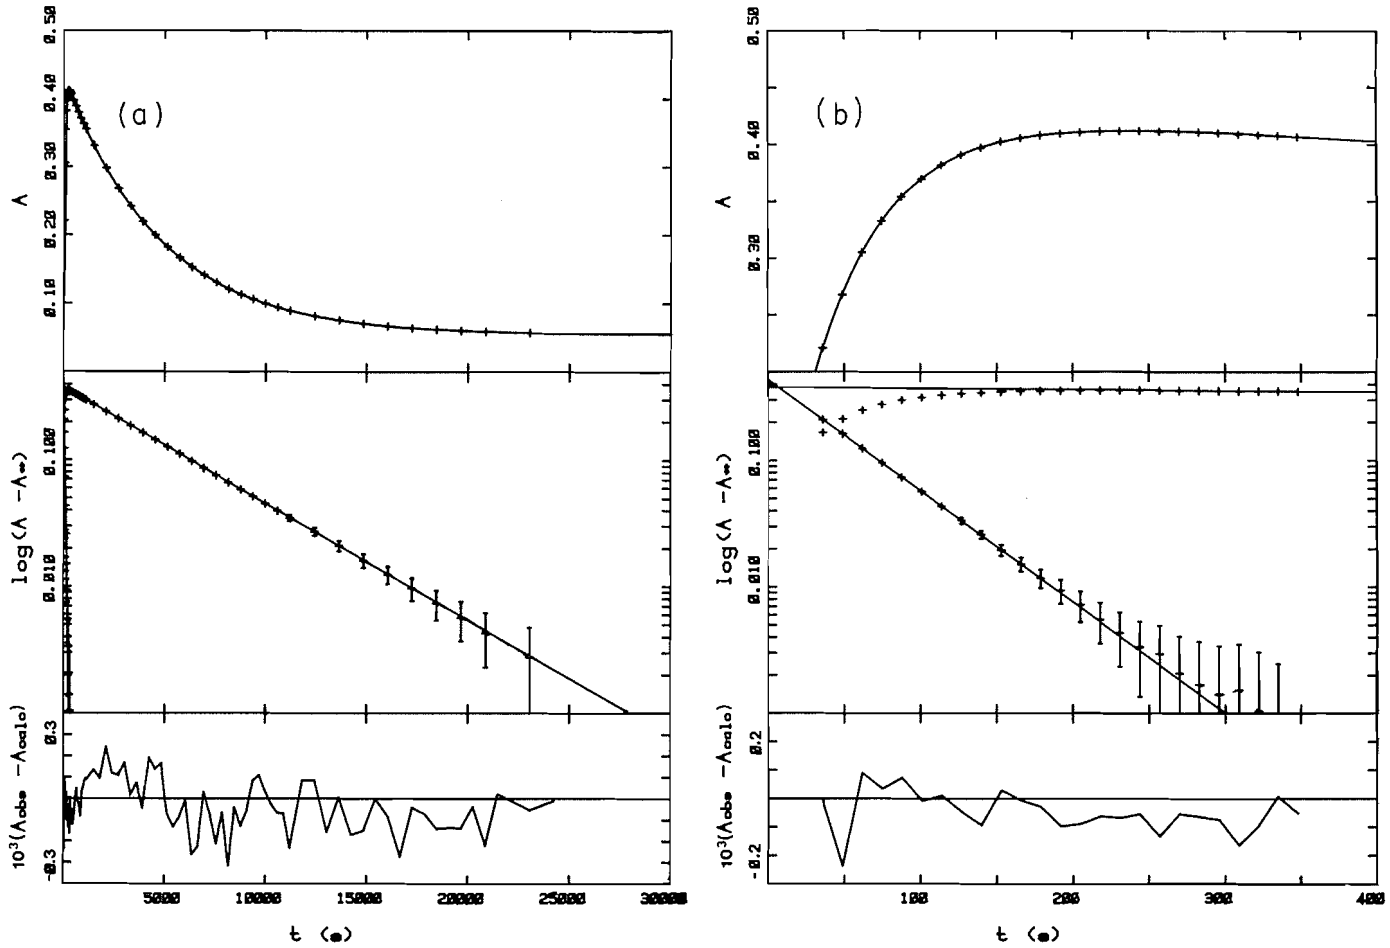

FIG. 1. Retroaldol reaction of 4-hydroxy-4-phenyl-2-butanone. Absorbance as a function of time for the reaction of 6.3×10^{-6} *M* ketol in 1 *M* NaOH.

$$\beta = C_1^0 k_{12}\epsilon_1(k_{23} - \lambda_3)\{1 - \epsilon_2\lambda_2/\epsilon_1(k_{23} - \lambda_3) - \epsilon_3 k_{23}/\epsilon_1(k_{23} - \lambda_3)\}/\lambda_3(\lambda_2 - \lambda_3)$$

When reaction starts with the ketol,

$$\alpha = C_2^0 k_{21}\epsilon_1\{-1 + \epsilon_2(\lambda_2 - k_{12})/\epsilon_1 k_{21} - \epsilon_3 k_{23}(\lambda_2 - k_{12})/\epsilon_1 k_{21}\lambda_2\}/(\lambda_2 - \lambda_3)$$

$$\beta = C_2^0 k_{21}\epsilon_1\{1 - \epsilon_2(\lambda_3 - k_{12})/\epsilon_1 k_{21} + \epsilon_3 k_{23}(\lambda_3 - k_{12})/\epsilon_1 k_{21}\lambda_3\}/(\lambda_2 - \lambda_3)$$

where, in either case, ϵ_1 = extinction coefficient for benzalacetone; ϵ_2 = extinction coefficient for the ketol; ϵ_3 = extinction coefficient for the products (benzaldehyde plus acetone); and C_i^0 = initial concentration of benzalacetone ($i = 1$) or ketol ($i = 2$). When reaction starts with benzaldehyde plus acetone (acetone in excess),

$$\alpha = C_3^0 k_{32}\{\epsilon_3(\lambda_2 - k_{12} - k_{21}) + \epsilon_2(k_{12} - \lambda_2) + \epsilon_1 k_{21}\}/\lambda_2(\lambda_2 - \lambda_3)$$

$$\beta = C_3^0 k_{32}\{\epsilon_3(k_{21} + k_{12} - \lambda_3) + \epsilon_2(\lambda_3 - k_{12}) - \epsilon_1 k_{21}\}/\lambda_3(\lambda_2 - \lambda_3)$$

where C_3^0 = initial concentration of benzaldehyde, and the concentration of acetone has been absorbed into k_{32}, now a pseudo first-order rate constant.

These equations can be usefully simplified by noting that ϵ_1, $\epsilon_3 \gg \epsilon_2$, so that for reaction starting with benzalacetone:

$$\alpha \cong C_1^0 k_{12}\{\epsilon_1\lambda_2 - k_{23}(\epsilon_1 - \epsilon_3)\}/\lambda_2(\lambda_2 - \lambda_3)$$

$$\beta \cong C_1^0 k_{12}\{(\epsilon_1 - \epsilon_3)k_{23} - \epsilon_3\lambda_3\}/\lambda_3(\lambda_2 - \lambda_3)$$

for reaction starting with the ketol:

$$\alpha \cong C_2^0\{-\lambda_2(k_{21}\epsilon_1 + k_{23}\epsilon_3) + k_{12}k_{23}\epsilon_3\}/\lambda_2(\lambda_2 - \lambda_3)$$

$$\beta \cong C_2^0\{\lambda_3(k_{21}\epsilon_1 + k_{23}\epsilon_3) - k_{12}k_{23}\epsilon_3\}/\lambda_3(\lambda_2 - \lambda_3)$$

and for reactions starting with benzaldehyde and excess acetone:

$$\alpha \cong C_3^0 k_{32}\{\epsilon_3(\lambda_2 - k_{12}) - (\epsilon_3 - \epsilon_1)k_{21})\}/\lambda_2(\lambda_2 - \lambda_3)$$

$$\beta = C_3^0 k_{32}\{\epsilon_3(k_{12} - \lambda_3) + (\epsilon_3 - \epsilon_1)k_{21}\}/\lambda_3(\lambda_2 - \lambda_3)$$

For reactions starting with the ketol the individual rate constants may now be calculated using:

$$k_{23} = (\epsilon_1(\lambda_2 + \lambda_3) - \lambda_2\epsilon_3 - ((\lambda_2 - \lambda_3)\beta/C_2^0) \pm((\epsilon_1(\lambda_2 + \lambda_3) - \lambda_2\epsilon_3 - (\lambda_2 - \lambda_3)\beta/C_2^0)^2 - 4(\epsilon_1 - \epsilon_3)\epsilon_1\lambda_2\lambda_3)^{\frac{1}{2}})/2(\epsilon_1 - \epsilon_3)$$

$$k_{21} = \lambda_2 + \lambda_3 - k_{23} - \lambda_2\lambda_3/k_{23}$$

$$k_{12} = \lambda_2\lambda_3/k_{23}$$

λ_3 can also be expressed by the steady state rate equation,

[3] $\lambda_3 \cong k_{12}k_{23}/(k_{21} + k_{23})$

which can also be derived from the above rigorous solution

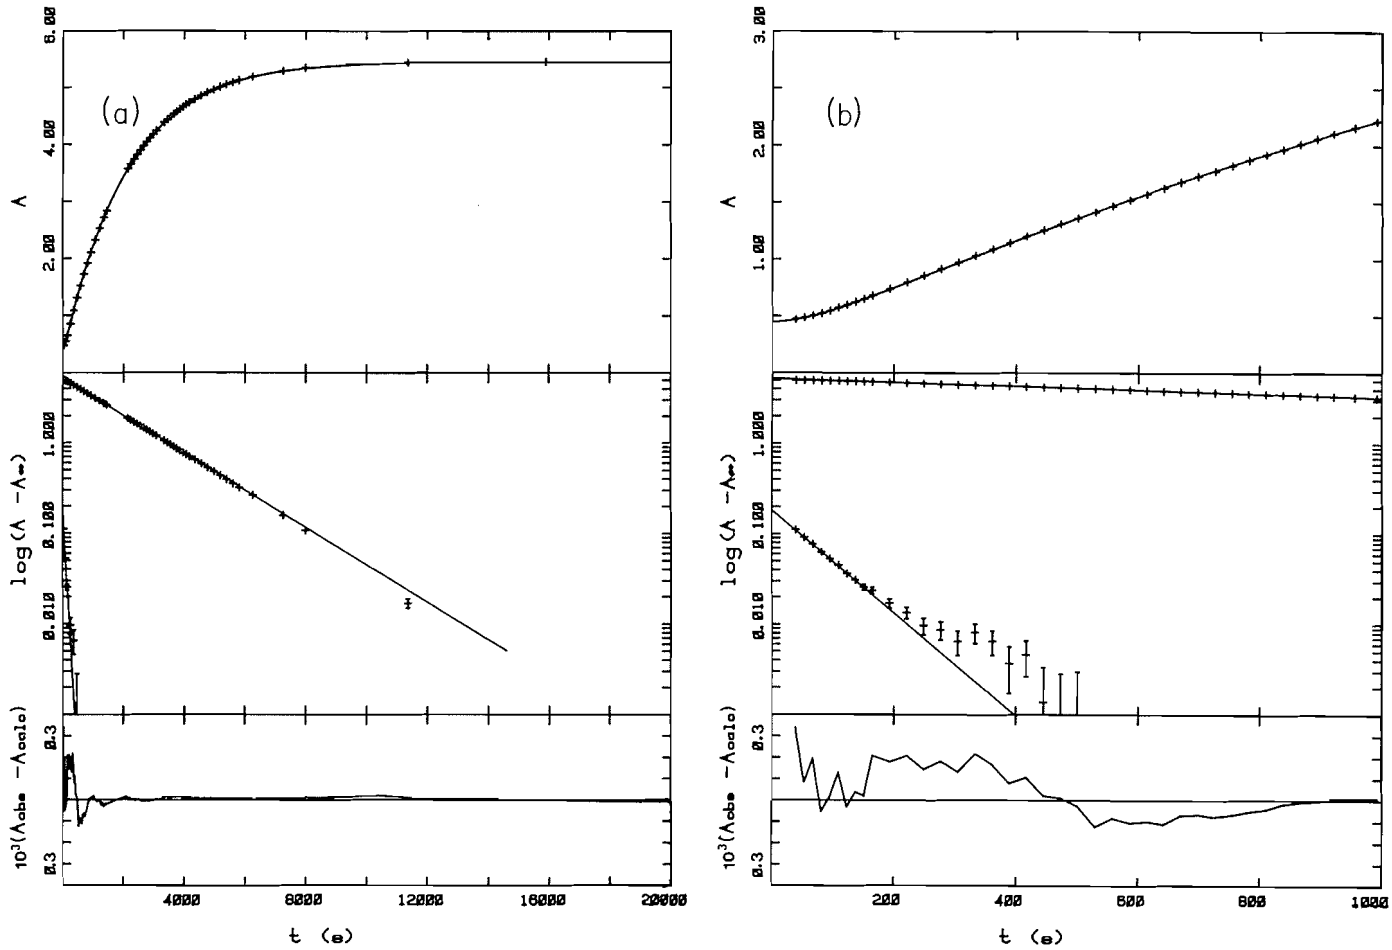

FIG. 2. Formation of 4-(*p*-methoxyphenyl)-3-buten-2-one, starting with 0.107 *M* acetone and 6.75×10^{-6} *M* *p*-methoxybenzaldehyde in 0.3 *M* NaOH.

when $k_{12} \ll k_{21}$, k_{23} (as it is for the present reaction). There is an ambiguity as to which of the quadratic solutions is the physically meaningful one. In the present case the ambiguity is easily resolved by comparison with the results of the unambiguous analysis of the kinetics of the benzalacetone formation kinetics discussed below. Alternatively we could carry out a first approximation solution, making the further simplifying assumption that $\epsilon_1 \gg \epsilon_3$ (which is not really correct in the present case) and apply the reasoning used for 3-methyl-2-butenal (4).

For kinetics where only the second phase was studied, we used the steady state expression for λ_3, eq. [3], and the ratio k_{21}/k_{23} derived from the analysis of biphasic kinetics to calculate k_{12}. For kinetics where only the first phase was studied, we used the approximate equation for α given above with the further simplifications, justified by the results from the analysis of biphasic kinetics, that $k_{23} \gg \lambda_3$ and $\lambda_2 \gg \lambda_3$ to obtain:

$$|\alpha| \cong C_2^0(\epsilon_3 k_{23} + \epsilon_1 k_{21})/\lambda_2$$

$$\lambda_2 \cong k_{21} + \lambda_{23}$$

These can easily be solved for k_{21} and k_{23}. For kinetics at high NaOH concentrations, where the reactions are faster, we felt that β was the better defined parameter.

Table 1 shows the results of applying this analysis to the experimental data for benzalacetone and the corresponding ketol. The individual rate constants show the expected first-order dependence upon the hydroxide concentration. The equilibrium constant for addition of water to the enone, K_{12}, may be showing a slight dependence upon $[OH^-]$. There is a corresponding slight dependence upon $[OH^-]$ for the second-order rate constants, k'_{12}. This effect is small, amounting to as much as 12% in k'_{12} or 25% in K_{12}. There is no obvious mechanistic path by which k_{12} could show a second-order dependence upon $[OH^-]$, and it seems unlikely that Na^+ ion is exerting a catalytic effect. We suspect that this behavior represents an artifact, and have taken average values for the rate and equilibrium constants. The rate constant ratio k_{23}/k_{21} describing the partitioning of the ketol intermediate is independent of the concentration of hydroxide; the weighted average value is 1.18 ± 0.28. It should be noted that the value of this ratio corresponds to nearly equal amounts of ketol undergoing cleavage or loss of water. Errors reported for the microscopic rate constants are based on propagation of error calculations (5) carried out using simple BASIC programs.

The final rate constant needed to describe the system, k_{32}, is obtained by studying the formation reaction, starting with solutions of benzaldehyde plus acetone. In this case the reaction remains simple because the condensation of acetone with benzaldehyde is much more favorable than the condensation of acetone with acetone. The reaction is carried out with low and limiting concentrations of benzaldehyde. The apparent rate constants determined in these experiments are found in Table 2.

For these kinetics there was a slight lag before the absorbance began to increase, which allowed least-squares fitting to a double exponential expression. It is possible to carry out the analysis to obtain microscopic rate constants using only the directly measured rate constants by taking advantage of the concentration dependence of the pseudo first-order rate constant k_{32}, which is a function of acetone concentration. One plots $\lambda_2 + \lambda_3$ and $\lambda_2\lambda_3$ vs. the acetone concentration and obtains from the plot of $\lambda_2 + \lambda_3$: slope = k'_{32} and intercept = $k_{23} + k_{12} + k_{21}$, and from the plot of $\lambda_2\lambda_3$: slope = $k'_{32}(k_{21} + k_{12})$ and intercept = $k_{23}k_{12}$, where k_{32} is the pseudo first-order rate constant and k'_{32} is the corresponding second-order rate constant, k_{32}/[acetone]. From these four equations, the four rate constants can be determined. This is the preferred method whenever the formation kinetics show both phases of the reaction so that the two apparent rate constants can be determined with satisfactory precision. The rate constants so obtained are found in Table 3.

The total change in absorbance, (α + β), as a function of acetone concentration depends upon the change in extinction coefficient from benzaldehyde to benzalacetone, and the equilibrium constant. These parameters can be extracted by fitting to the equation:

$$\epsilon_{app} = \Delta\epsilon/(1 + 1/K[\text{acetone}])$$

When this is done we obtain $\Delta\epsilon = 1.90 \times 10^4$ (expected 1.88×10^4), and $K = 460. \pm 63$. Examination of a plot of the data shows that our experiments were done at acetone concentrations leading to extensive conversion, so that Δε is expected to be precise, but K is not.

For *p*-methoxybenzalacetone, we studied the kinetics of the retroaldol reaction of 4-hydroxy-4-(*p*-methoxyphenyl)-2-butanone, and also of the formation reaction starting with *p*-methoxybenzaldehyde and acetone. In the cleavage reaction the two kinetic phases were well marked, but in the formation kinetics it was necessary to go to relatively high acetone concentrations to make the fast phase significant and to have k_{32} make a significant contribution to λ_2. The kinetics of the cleavage reaction were analyzed as described above, leading to the microscopic rate constants in Tables 1 and 3. The kinetics of

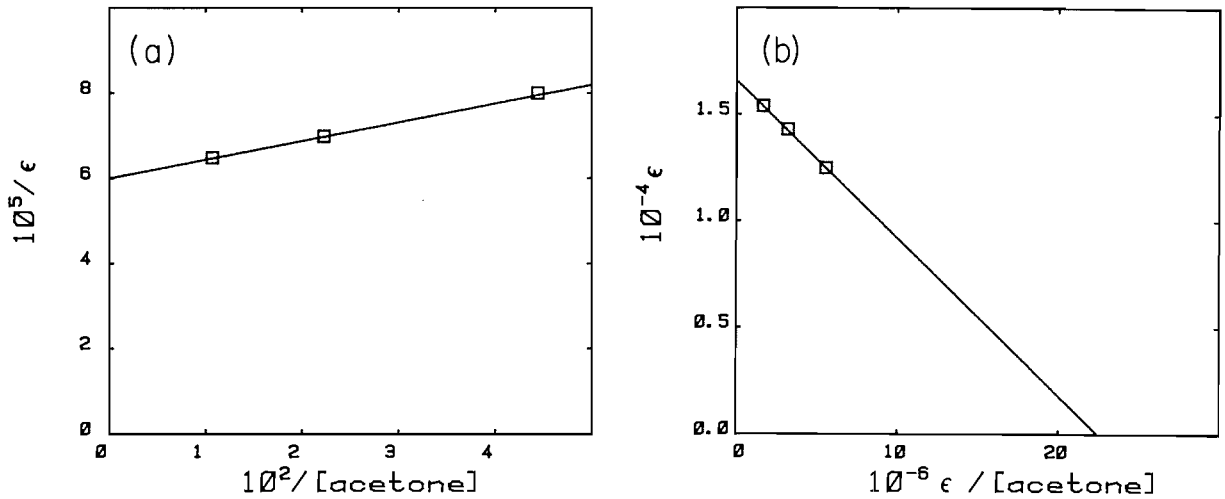

FIG. 3. Plots allowing evaluation of $\Delta\epsilon$ and K for formation of 4-(*p*-nitrophenyl)-3-buten-2-one. (a) Plot of $1/\epsilon_{app}$ vs. 1/(acetone). (b) ϵ_{app} vs. ϵ_{app}/[acetone].

the formation reactions, Table 2, were analyzed as for benzalacetone, leading to the rate constants in Table 3. Although the runs at lower acetone concentrations led to stable infinity points, the experiment at 1.07 M acetone showed a slow upward drift in the infinity value. We attribute this to self condensation of the acetone. The least-squares fit used a double exponential equation with an extra term linear in time to allow for this drift. The dependence of the total absorbance change upon acetone concentration leads to $\Delta\epsilon = (2.38 \pm 0.06) \times 10^4$ (expected 2.30×10^4) and $K = 93 \pm 10\ M^{-1}$.

For the cleavage reactions of 4-phenyl-3-buten-2-one, 4-hydroxy-4-phenyl-2-butanone, and 4-hydroxy-4-(*p*-methoxyphenyl)-2-butanone, we studied some reactions at lower ionic strength (0.01 or 0.1 M) as well as at 1.0 M. Although the observed rate constants did vary, by about 10%, clearly the reaction is not very sensitive to ionic strength.

For *p*-nitrobenzaldehyde we studied only the formation kinetics; the two phases were well marked, so the analysis was straightforward. The apparent rate constants are found in Table 2 and the derived microcopic rate constants are found in Table 3. From the dependence of the apparent extinction coefficient upon acetone concentration we obtained $\Delta\epsilon = (1.67 \pm 0.001) \times 10^4$ and $K = 1160. \pm 10.$

The value of the equilibrium constant derived from the dependence of the final absorbance upon the acetone concentration is quite different from that deduced from the kinetics, and the errors calculated by least squares are impressively small. However, it should be borne in mind that there were only three points so that a statistical method can give a spuriously low standard deviation if the points happen to fall on a line. More important is the question of why the two values differ so much. Since the analysis involved (frequently carried out using double reciprocal plots) is of some generality, arising in equilibrium studies, enzyme kinetics, and photochemistry, it is perhaps worthwhile to point out some things which have been learned in enzymology (6). The normal double reciprocal plot, see Fig. 3(a), where $1/\epsilon_{app}$ is plotted against 1/[acetone], because the ordinate and abscissa are defined from zero to infinity, can easily look better than it deserves. Seeing the three points falling on a line one could think that slope and intercept are both well defined, although careful examination would show that if the true errors in the *y*-values were 10% the slope would be almost indistinguishable from zero. It is harder to fool oneself using a plot such as Fig. 3(b), where ϵ_{app} is plotted against ϵ_{app}/[acetone], because now the coordinates are only defined between the *x*- and *y*-intercepts of the line, all larger or smaller abscissa values having no physical significance. (Such a plot is analogous to the Eadie plot (7, 8) used in enzymology.) Since the entire allowed range of the plot is shown, it is easier to see how well the data cover this range. The *y*-intercept is $\Delta\epsilon$ and the slope is $-1/K$; the *x*-intercept is $K\Delta\epsilon$. It is more apparent from Fig. 3(b) than from Fig. 3(a) that the data define $\Delta\epsilon$ well but do not define K. In fact the experiments were designed to evaluate K from the kinetics and not from the equilibrium absorbance.

TABLE 4. Comparison of rate constants for benzalacetone with literature results[a]

Rate constant	Value: Ref. 2	Value: This work[b]
a. Benzalacetone cleavage		
$10^4 \times \lambda_3/[OH^-]$	2.26±0.03	2.00±0.12

TABLE 5. Hammett slopes for rate and equilibrium constants

Rate constant	ρ	Equilibrium constant	ρ
k'_{12}	0.98±0.02	K_{12}	0.86±0.23
k'_{21}	0.14±0.17	K_{32}	1.88±0.22
k'_{23}	−0.15±0.22	$K_{overall}$	1.03±0.04
k''_{32}	1.76±0.03		

principal source of the discrepancy is the assumption in ref. 2 that the rate of the retroaldol reaction is given by k_{12} (k_4 in the notation of ref. 2) rather than by the steady state expression given above.

The aromatic aldehydes are partially converted to their hydroxide adducts in NaOH solutions. The equilibrium constants are: H, 0.18 M^{-1}; p-NO_2, 13.3 M^{-1} (9). For benzaldehyde (and even more so for p-methoxybenzaldehyde, for which the equilibrium constants will be even smaller) the correction is trivial except at high [OH^-], and would only be 20% at 1 N NaOH. For p-nitrobenzaldehyde the correction is more serious, amounting to a factor of 2.33 at 0.1 N NaOH. This correction was made to the values in Table 4, and the corrected data were used for Hammett correlations.

The dependence of the rate and equilibrium constants upon Hammett σ can be examined: see Table 5.

The rate-determining step for the condensation reaction, k_{32}, is the carbon−carbon bond-forming step, and not proton abstraction from acetone, because the observed reaction rate is slower than the known rate of enolate formation. The post equilibrium for this addition is a proton transfer from solvent to the alkoxide ion corresponding to the ketol, and should be very fast.

In marked contrast, there is a possible ambiguity as to the rate-determining step for the k_{12} process, because the immediate product is an enolate ion which must either protonate on carbon or expel hydroxide ion. If the carbon protonation rate constant is the same as for acetone, then it is probably fast relative to expulsion of hydroxide ion, but if there is steric hindrance leading to a slower rate of reprotonation, then the two paths could occur at competitive rates. This can be seen by estimating the equilibrium constant for the actual addition step:

$$Ph—CH=CH—CO—CH_3 + OH^- \rightleftharpoons Ph—CHOH—CH=C(O^-)—CH_3$$

so that the rate constant for expulsion of hydroxide can be calculated from the known rate of the overall addition reaction. We assume that the basicity of the ketone is similar to that of acetone ($pK_a \cong 19$ (10)); from the value of K_{12} we deduce that for the actual addition step, $K = 4 \times 10^{-7}$, and the rate constant for the expulsion of hydroxide is 750 s^{-1}. If the rate of protonation is even ten-fold slower than that for acetone, it would be ca. 10^3 s^{-1}, and both steps would be partly rate determining.

Experimental

Materials

Benzaldehyde and p-methoxybenzaldehyde were redistilled before use. p-Methoxybenzaldehyde was stored as the crystalline solid (lit. (11) mp 2.5°C) in a refrigerator. p-Nitrobenzaldehyde was recrystallized from diethyl ether; mp 105−106°C (lit. (11) mp 106°C). Benzalacetone was prepared following Drake and Allen (12); mp 39.2−40.5°C (lit. (12) mp 40−42°C). 4-Hydroxy-4-phenyl-2-butanone was prepared following Noyce and Reed (13); mp 37.0−37.2°C (lit. (13) mp 34−36°C; (14) mp 38°C. 4-Hydroxy-4-(p-methoxyphenyl)-2-butanone was made following the procedure of Noyce and Reed (13) except that purification of the initial crude distillate was by two-fold bulb-to-bulb distillation in vacuum followed by crystallization from ether − petroleum ether; mp 42.5−43°C (lit. (13) mp 40°C). 4-(p-Methoxyphenyl)-3-buten-2-one was prepared by the procedure of Drake and Allen (12); mp 72.5−73.6°C (lit. (12) mp 72−74°C). Acetone and acetonitrile were spectrophotometric grade.

Extinction coefficients were determined for the wavelengths used for kinetics. Benzalacetone: 2.2×10^4 at 291 nm. 4-Hydroxy-4-phenyl-2-butanone: 36 at 291 nm. Benzaldehyde: 3320 at 291 nm. 4-(p-Methoxyphenyl)-3-buten-2-one: 2.37×10^4 at 320 nm. 4-Hydroxy-4-(p-methoxyphenyl)-2-butanone: 38 at 320 nm. p-Methoxybenzaldehyde: 735 at 320 nm. Acetone: 0.12 at 320 nm. p-Nitrobenzaldehyde: 3200 at 308 nm. Acetone: 0.72 at 308 nm.

Methods

The procedure for kinetics was as previously described (15, 4). Reactions were followed at λ_{max} for the substituted benzalacetone. Most kinetics were carried out in 10-cm cells, so that low concentrations, assuring complete solubility, could be employed.

Calculations

Least-squares calculations were carried out using a Xitan microcomputer and FORTRAN or BASIC programs written for the purpose. Plots similar to Figs. 1 and 2 were prepared for each run. The residual plots were frequently not the random scatter about the zero line which should be seen for a good fit. The absolute values of the weighted residuals were in all cases small, being less than 0.001 absorbance. In the case of Fig. 2 it was clear that the fit was imperfect, but the worst deviation corresponds to an unweighted error of 0.004 at an overall absorbance of 1.2 for a relative error of 0.5%. Thus the fit can be considered satisfactory, as is shown by the plot of absorbance vs. time.

Conformational and steric effects on regioselectivity in the Baeyer–Villiger reaction

VINOD DAVE, J. B. STOTHERS, and E. W. WARNHOFF
Department of Chemistry, University of Western Ontario, London, Ont., Canada N6A 5B7

Received February 27, 1984

This paper is dedicated to Professor Paul de Mayo on the occasion of his 60th birthday

VINOD DAVE, J. B. STOTHERS, and E. W. WARNHOFF. Can. J. Chem. **62**, 1965 (1984).

The Baeyer–Villiger oxidation of six β,β,γ-trisubstituted cyclopentanones and cyclohexanones leads to preferential migration of the α-carbon relative to the α′-carbon by a factor of 1.5–4:1. The origin of the preference is suggested to be steric and is ascribed to the greater relief of non-bonded interactions as the α—β bond lengthens in going to the transition state. Thus, in the carbonyl addition intermediate the 1,3-diaxial-like interaction between the hydroxyl and the closest γ-carbon is diminished to a greater extent when the α-carbon migrates relative to the α′-carbon.

VINOD DAVE, J. B. STOTHERS et E. W. WARNHOFF. Can. J. Chem. **62**, 1965 (1984).

L'oxydation selon Baeyer–Villiger de six cyclopentanones et cyclohexanones β,β,γ-substituées conduit d'une façon préférentielle (rapport de 1,5–4:1) à la migration du carbone α par rapport au carbone α′. On croit que cette préférence est d'origine stérique et on l'attribue à une plus grande réduction d'interactions non-liées lorsque la liaison α—β s'allonge au moment de passer à l'état de transition. Lors de l'addition intermédiaire sur le carbonyle, il se développe une interaction de type 1,3-diaxial entre l'hydroxyle et le carbone en γ le plus rapproché; cette interaction diminuerait plus lors de la migration du carbone α que lorsque le carbone α′ migre.

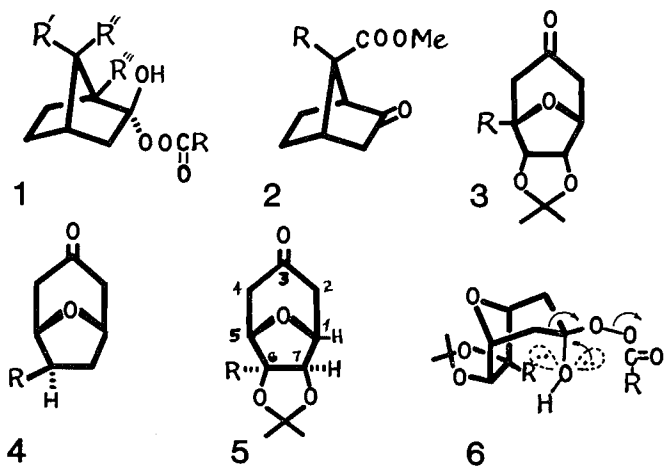
Recently there has been renewed interest in the migratory selectivity exhibited in Baeyer–Villiger reactions of cyclic ketones (1–16). This revival is due partly to new attempts to separate and understand further the factors that influence the regioselectivity of the reaction, and partly to the discovery of "naturally occurring Baeyer–Villiger products", the plant growth regulating brassino steroids (17–30).

The earlier general conclusion that the α-carbon better able to stabilize positive charge migrates preferentially has long been known to be an oversimplification (31). While recent work (1, 4, 9, 17) has provided complementary evidence for the operation of an electronic effect, in that nearby electron-withdrawing groups retard the migration of an α-carbon, nevertheless in a number of cases the electronic effect has been overridden by other factors. In fact, merely changing the peroxyacid/solvent combination can affect the lactone product ratio drastically (5, 6, 15, 31). Steric or conformational effects on the relative energies of the transition states for the two possible migrations to oxygen can also dictate the lactone ratio, as is apparently the case under some conditions for 7-*syn* substituted norbornanones in which the enforced *endo* addition of peroxyacid (→**1**, e.g. camphor) allows a chair-like transition state for CH_2 migration to be of lower energy than the boat-like transition state for migration of the electronically favored tertiary or quaternary bridgehead (6, 16). However, even here other factors may intervene since the effect is reversed if the 7-*syn*-substituent is COOMe as in **2** (2).



Noyori *et al.* (1, 9, 10) have used three series of highly oxygenated C-nucleoside structures **3**, **4**, and **5** to probe electronic and steric effects systematically, **3** and **4** presumably responding only to electronic effects and **5** only to γ-steric effects. In seven differently substituted examples of **5**, the carbonyl α-CH_2 more remote from R was found to migrate preferentially by a factor of 2–3:1. A complex rationalization for the observation was offered (see **6**) involving *exo* addition of peroxyacid, antiperiplanar orientation of the migrating α-carbon and the peroxide bond, the necessity of a stereoelectronic push by an *anti*-aligned non-bonding electron pair on the OH, and repulsion between the hydroxyl hydrogen and the R group (1, 32). We now present several Baeyer–Villiger reactions for which the last part of this rationale is irrelevant, and in which the product ratio is apparently determined by differential relief of conformational crowding in going to the two possible migratory transition states.

Our interest in Baeyer–Villiger regioselectivity began some time ago with examination of how remote a substituent could be and still affect the migration ratio in rearrangements of 3-keto 5α- and 5β-steroid derivatives (11, 14). With the most convenient and reliable analytical method – integration of appropriate ^{13}Cmr signals – it was found that only when polar substituents got as close as C-6 or C-5, i.e. γ or β with respect to the carbonyl group, was the migratory ratio much different from ~1:1. Not surprisingly, with such a high degree of symmetry in the vicinity of the chair cyclohexanone carbonyl group, the migratory potential of both α-CH_2 groups is essentially the same in the absence of nearby perturbing groups.

In the light of this work, the reported reactions of several *A*-nor-5α- and 5β-steroid 2-ketones seemed anomalous (33–35). For example, both 5α- and 5β-*A*-norcholestan-2-one were reported to give only the 2-oxa-3-one lactones **13** and **14** with peroxybenzoic or trifluoroperoxyacetic acids (33, 34). Whilst these ketones are not so symmetrical near the carbonyl group as the cholestan-3-ones, there is no obvious structural

[a] In ppm from internal TMS for $CDCl_3$ solutions, similar values in parentheses may be interchanged. In these compounds C-15 to C-18 and C-20 to C-27 absorb at 24.2, 28.2, 56.3, 12.1, 35.7, 18.7, 36.1, 23.8, 39.5, 28.0, 22.6, 22.8 ppm, respectively.
[b] *A*-Nor-5β-cholestane.

feature which would tip the balance completely in favor of migration of C-1. Therefore these reactions were reinvestigated. Pure specimens of the two *A*-nor-2-ketones **7** and **8** were prepared (see Experimental) and their Baeyer–Villiger oxidations carried out with *m*-chloroperoxybenzoic acid (MCPBA) in chloroform. The product from the 5α-ketone **7** gave a single tlc spot, whereas that from the 5β-ketone **8** gave two overlapping tlc spots. Contrary to previous reports (33–35) it was evident from both the ^{1}Hmr and ^{13}Cmr spectra that both products were mixtures, but in each mixture the ratio of lactones was distinctly different from 1 : 1. Structural assignment to the pairs of lactones was obvious from the ^{1}Hmr signals of the O—CH_2 group. The C-1 methylene of the major products **13** and **14** was a sharp AB pattern while the C-4 methylene of the minor products **19** and **20** was broadened by coupling with the C-5 hydrogen (see Fig. 1).

The ^{13}Cmr spectra confirmed these assignments and permitted analysis by integration of appropriate signals (see Experimental). The major lactones **13** and **14** had the lower field O—CH_2 signals at δ 81.1 and 75.3, respectively, while the

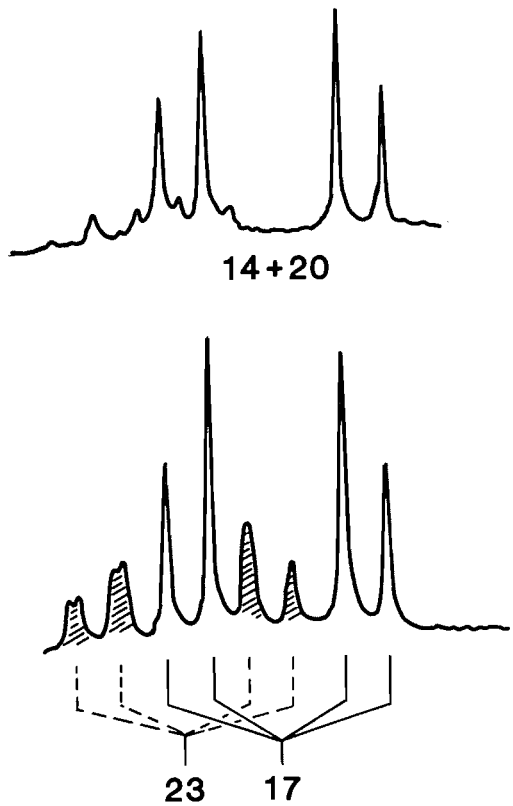

FIG. 1. The O—CH_2 region of the ^{1}Hmr spectra of the Baeyer–Villiger oxidation products of 5β-*A*-norcholestan-2-one (**8**) (upper trace) and *cis*-9-methyl-2-hydrindanone (**11**) (lower trace).

minor lactones had the O—CH_2 absorption at higher field δ 71.0 and 70.0, respectively.[1] Integration gave a lactone ratio **13**:**19** of 80:20 from the 5α-*A*-nor-2-ketone **7** and a ratio **14**:**20** of 79:21 from the 5β-*A*-nor-2-ketone **8**. With trifluoroperoxyacetic acid the 5α-ketone **7** gave a **13**:**19** ratio of 70:30, only slightly different from the *m*-chloroperoxybenzoic acid result. Thus C-1 had migrated preferentially by a substantial amount in each case.

Such regioselectivity seemed likely to originate in a conformational or steric effect, and additional ketones were rearranged in hope of defining the cause. It was not necessary to have a cyclopentanone to observe the effect. Oxidation of 5α-cholestan-2-one (**9**) with MCPBA/$CHCl_3$ gave a 75:25 mixture of two lactones which could be separated by thick layer chromatography. The less polar major component had a sharply defined four-line O—CH_2 ^{1}Hmr pattern at δ 3.87 and δ 4.23 (J = 13 Hz) while the minor component had an ill-defined multiplet centered at δ 4.20. In the ^{13}C spectrum the major lactone had the lower field O—CH_2 signal at δ 76.0 compared to the minor lactone O—CH_2 peak at δ 68.8. Therefore, the major lactone was again the product **15** of C-1 migration.

Finally, two bicyclic analogs of the preceding ketones were oxidized to test further the generality of the regioselectivity. *cis*-10-Methyl-2-decalone **10** ⇄ **10A** on treatment with MCPBA/$CHCl_3$ afforded two lactones separated on tlc. The major lactone **16** again had the sharper O—CH_2 ^{1}Hmr pattern superimposed on the more lumpy pattern of the minor isomer **22**. In the ^{13}Cmr spectrum only the O—CH_2 from the major lactone **16** was visible as a broadened (by conformational averaging?) peak at δ 74.1 (cf. 76.0 in **15**). Integration of the well-separated CH_3 signals in the ^{1}Hmr spectrum gave a **16**:**22** ratio of 81:19.

cis-9-Methyl-2-hydrindanone **11** ⇄ **11A** on reaction with MCPBA/$CHCl_3$ also produced two lactones separable by tlc. The major lactone **17** had the sharper O—CH_2 ^{1}Hmr pattern (see Fig. 1) separated from the broader pattern of the minor isomer. In the ^{13}Cmr spectrum the O—CH_2 from the major isomer **17** was at δ 75.6 and at 71.9 from the minor isomer **23**. The lactone ratio (60:40) from comparison of the intensity of these ^{13}Cmr signals agreed well with that (62:38) obtained by integration of the O—CH_2 peaks in the ^{1}Hmr spectrum. The regioselectivity had been somewhat reduced, but the major lactone was still the product of C-1 migration.

To the above five examples may be added a sixth from the literature, the dimethylhydrindanone **12**, which on Baeyer–Villiger oxidation with MCPBA/CH_2Cl_2 gave a lactone ratio **18**:**24** of 77:23 (8).

The consistent pattern of all these results suggests a common basis for the observed regioselectivity favoring migration of C-1. The only structural difference to distinguish the α- from the α′-CH_2 of each ketone is the methyl group which is closer to C-1 in each compound. Its *electronic* effect on the migratory ratio would be negligible, as shown by the 53:47 ratio of lactones from example **3**(R=CH_3) of Noyori *et al.* (1, 9). However, the *steric* effect of this methyl group is not symmetrically disposed toward both the α- and the α′-CH_2, and this fact can account for the regioselectivity.

For the two A/B *trans*-fused ketones the preferred conformations will be those shown in **7** and **9**. For two of the four A/B *cis*-fused ketones there is a single preferred conformation **8** and **12**, but for the other two *cis*-fused ketones there are two conformations of comparable energy **10** ⇄ **10A** and **11** ⇄ **11A**.[2] On the usual assumption that the lowest energy transition states for rearrangement will result from the peroxyacid adding to the less hindered carbonyl face, the tetrahedral addition intermediates which undergo rearrangement will be **7B** – **12B** plus **10B′** and **11B′**.[3] These would be expected to rearrange with the *anti* orientation of an α- or α′-CH_2 and the peroxide bond. Inspection of Dreiding models reveals that for either potential migration in each of the ketones it is possible to have a hydroxyl lone pair of electrons aligned *anti* to the migrating CH_2 for a "stereoelectronic push" *without* the hydroxyl H being crowded into the CH_3, CH_2, or CH marked in the **B** series of formulas. Consequently, the final postulate of Noyori *et al.* (1, 32) (repulsion between hydroxyl H and the nearby group prevents oxygen lone pair alignment for one migration) does not apply to the present cases.[4] Nor can it be suggested for the four cyclopentanones **7**, **8**, **11**, and **12** that migration of the CH_2 leading to a chair-like transition state is the preferred path (6, 16), because for all four the preferred C-1 migration leads to a twist boat-like transition state.

[1] This order of signals is expected since C-1 is bonded to a tertiary center while C-4 is adjacent to a secondary carbon.

[2] The B-ring methyl group in **12** would be axial in a conformation corresponding to **11A** and therefore would be about 1.7 kcal/mol higher in energy relative to **12**.

[3] For **11B′** both sides of the molecule have an encumbering group, and the two addition intermediates are probably of about the same energy.

[4] The stereochemistry of **6** forces the OH and substituent R closer together in Noyori's series of rigid molecules than in the present six examples.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.40 on 09/06/12
For personal use only.

A consistent explanation for all six of these reactions is simply that that CH_2 migrates preferentially which leads to a greater relief of repulsive steric interactions at the transition state. Migration of C-1 in each case will lead (by lengthening the C-1—C-2 bond) to the greater reduction of the 1,3-diaxial-like crowding of the OH with the indicated CH_3, CH_2, or CH in structures **7B**–**12B**, **10B'**, **11B'**.[5] In this view, it would not be surprising that the hydrindanone **11** ⇄ **11A** with the ambiguous intermediate **11B'** would show the least regioselectivity. It remains to be seen whether this pronounced selectivity will be found with even simpler monocyclic ketones.

Finally it should be emphasized that the regioselectivity observed with ketones **7**–**12** is in just the opposite sense from that reported by Noyori *et al.* for ketones **5**. This reversal is apparently caused by the closer approach of OH and R in **6** which, according to Noyori *et al.*, would affect differently (by hydroxyl H—R repulsion) the ability of the hydroxyl O to offer stereoelectronic help to the two potential migrating groups.[6]

Experimental

General

Melting points were determined on a Reichert–Kofler microscope hotstage and are corrected. The ir spectra were recorded on a Beckman Acculab 4 instrument with $CHCl_3$ solutions. The ^{1}Hmr spectra were recorded on Varian T-60 and XL-100 spectrometers with $CDCl_3$ solutions containing Me_4Si. The ^{13}Cmr spectra were taken with $CDCl_3$ solutions on a Varian XL-200 instrument. Exact masses were determined on a MAT 311A mass spectrometer. Optical rotations were determined with $CHCl_3$ solutions on a Rudolph Model 80 polarimeter.

Unless otherwise stated, peroxyacid reactions were worked up by evaporating the $CHCl_3$, dissolving he residue in ether, and then washing the solution successively with 5% aqueous KI, 5% aqueous $Na_2S_2O_3$, saturated aqueous $NaHCO_3$, and saturated aqueous NaCl before drying with anhydrous $MgSO_4$ and evaporation of solvent at aspirator vacuum on a rotating evaporator. Camag DF-5 silica gel was used for thick and thin layer chromatography. Unless otherwise specified, preparative thick plates were 20 × 20 cm and held 20 g of silica gel. The MCPBA was from the Aldrich Co.

Oxidation of A-*nor*-5α-*cholestan*-2-*one* (**7**)

(a) Ketone **7** was prepared by the pyrolysis of 2,3-seco-5α-cholestane-2,3-dioic acid (36) and was shown to be pure by its ^{13}Cmr spectrum. A solution of 50 mg (0.134 mmol) of ketone **7** and 111 mg (0.48 mmol) of MCPBA (75%) in 1.5 mL of $CHCl_3$ was allowed to stand at room temperature for 2 days. Work-up gave 50 mg (96%) of colorless solid which gave a single tlc spot more polar than **7**. The ^{1}Hmr and ^{13}Cmr spectra were taken. The reaction was repeated on a 25-mg scale with the same results.

(b) To a stirred (magnetic bar) solution of 15 mg (0.26 mmol) of 60% H_2O_2 and 55 mg of trifluoroacetic anhydride in 0.5 mL of $CHCl_3$ was added 15 mg of Na_2HPO_4 followed by a solution of 25 mg (0.067 mmol) of ketone **7** in 0.5 mL of $CHCl_3$. The reaction mixture was stirred at room temperature for 24 h. Work-up afforded 23 mg (88%) of colorless solid which gave a single tlc spot more polar than **7**. The ^{1}Hmr and ^{13}Cmr spectra were taken (cf. the oxidation of **7** in ref. 33).

The lactone mixtures from the above three preparations were combined and recrystallized thrice from CH_3OH to give 35 mg of pure major lactone **2-oxa-5α-cholestan-3-one** (**13**) as colorless plates, mp 125–133°C, mp 130–132°C (capillary); $[\alpha]_D^{24}$ +14.7° (*c*, 1.93 in $CHCl_3$) (lit. (34) mp 134–136°C, lit. (33) mp 134–135°C, $[\alpha]_D$ +20° (*c*, 1.1 in $CHCl_3$)); ir: 1720 cm^{-1}; ^{1}Hmr δ: 3.92 and 4.22 (2H, AB, J = 11 Hz, OCH_2); M^+ calcd. for $C_{26}H_{44}O_2$: 388.3341; found: 388.3340. The ^{13}Cmr spectrum contained 24 peaks with the 28.0 and 39.5 ppm absorptions corresponding to two carbons each. The ^{13}Cmr spectrum of the minor lactone **19** was obtained by subtracting the peaks of the major isomer from the ^{13}Cmr spectrum of the lactone mixture. For determination of the lactone ratio the following ^{13}Cmr peaks were integrated (14): C-18, C-19, C-1 (**13**), C-4 (**19**), C-9.

A-*Nor*-5β-*cholestan*-2-*one* (**8**)

To a mixture of 7 mg of PtO_2 (Johnson and Matthey) and 1.0 mL of glacial HOAc saturated with hydrogen was added a solution of 43 mg of *A*-nor-5β-cholest-3-en-2-onc (37, 38) in 1.0 mL of glacial HOAc. The reaction was stirred (magnetic bar) at room temperature for 12 h. The catalyst was removed by filtration, and the filtrate was concentrated to leave 43 mg of viscous oil. Thin layer chromatography (hexanes–EtOAc, 90:10) indicated some overreduction to alcohol. The product was dissolved in 2.0 mL of CH_2Cl_2 and oxidized with 20 mg of $PyH^+ClCrO_3^-$ for 2 h. The CH_2Cl_2 soluble material was chromatographed on a 10-g plate developed with hexanes–EtOAc (90:10). The band at R_f 0.37 yielded 26 mg of colorless granules of **A-nor-5β-cholestan-2-one** (**8**), mp 99–103°C (lit. (37) mp 102–103°C); ir: 1740 cm^{-1}; ^{1}Hmr: no absorption between δ 2.5–8; M^+ calcd. for $C_{26}H_{44}O$: 372.3392; found: 372.3390. The ^{13}Cmr spectrum contained 26 peaks with no trace of any absorption from the 5α-epimer **7**.

The tlc band moving with the solvent front gave 7 mg of crystalline **A-nor-5β-cholestane**, mp 48–50°C; M^+ calcd. for $C_{26}H_{46}$: 358.3599; found: 358.3595.

Oxidation of A-*nor*-5β-*cholestan*-2-*one* (**8**)

A solution of 25 mg (0.067 mmol) of ketone **8** and 55 mg (0.24 mmol) of MCPBA (75% peroxyacid) in 1.0 mL of $CHCl_3$ was allowed to stand at room temperature for 43 h. Work-up gave 25 mg (96%) of oily solid whose tlc (hexanes–EtOAc, 80:20) revealed two overlapping spots more polar than **8** in a ratio of ~85:15; ir: 1725 cm^{-1}; ^{1}Hmr: see Fig. 1. For determination of the lactone ratio the following ^{13}Cmr peaks were integrated (14): C-1, C-4, and C-5 of each lactone.

The lactone mixture was chromatographed on a 10-g plate developed four times in hexanes–EtOAc (80:20). The lower band at R_f 0.59 yielded 9.5 mg of pure **2-oxa-5β-cholestan-3-one** (**14**), mp 123–125°C after recrystallization from MeOH (lit. (34) mp 125–128°C); ir: 1725 cm^{-1}; ^{1}Hmr δ: 3.76 and 4.22 (2H, AB, J = 12 Hz, O—H_2C-1); M^+ calcd. for $C_{26}H_{44}O_2$: 388.3341; found: 388.3336. The ^{13}Cmr spectrum contained 24 peaks with the absorption at δ 39.5 corresponding to three carbons.

Oxidation of 5α-*cholestan*-2-*one* (**9**)

A solution of 25 mg (0.065 mmol) of ketone **9** (39) and 55 mg (0.24 mmol) of MCPBA (75%) in 1.2 mL of $CHCl_3$ was allowed to stand at room temperature for 5 days. Since tlc still indicated some unreacted **9**, 21 mg (0.095 mmol) more of MCPBA was added, and the reaction was allowed to proceed for 2 days more. Work-up gave 24 mg (92%) of colorless solid whose tlc (hexanes–EtOAc, 90:10) showed two spots more polar than **9**. For determination of the lactone ratio the following ^{13}Cmr peaks were integrated: C-1 (**21**), C-5, C-9, C-18, and C-19. C-1 in **15** was too close to $CDCl_3$ absorption to be used for integration.

The above reaction was repeated on 72 mg more of the ketone **9**, and the combined product (98 mg) from the two reactions was chromatographed on a thick plate developed four times in hexanes–EtOAc (80:20).

[5] In ref. 8 it was suggested that preferential migration of C-1 in **12B** was "presumably due to a relief of eclipsing interactions involving the substituents at C-9, C-1, C-2" (C-2, C-3, and C-3a according to the numbering in ref. 8). Actually, each of the two bonds involved is more staggered than eclipsed. Also C-1 migration leads to a twist boat conformation whose "partially-eclipsed" bonds would be of higher energy than the staggered bonds of the chair conformation that would result from migration of C-3.

[6] The basis for structural assignment to the pairs of lactones from compound **5** was the Δδ (0.20–0.44) for H—C-7 in the ^{1}Hmr spectra (1), the isomer absorbing at lower field being assigned the structure with H—C-7 in the *deshielding* region of the nearby ether oxygen in the chair conformation of the lactone ring, while the isomer absorbing at higher field has H—C-7 in the *shielding* zone of the carbonyl π-bond in the chair conformation of the lactone ring.

The upper band at R_f 0.60 afforded 39 mg of solid major lactone. Three recrystallizations from MeOH gave 33.8 mg of colorless plates of **2-oxa-A-homo-5α-cholestan-3-one** (**15**), mp 133–135°C; $[\alpha]_D^{23}$ −19.3° (*c*, 1.87 in $CHCl_3$); ir: 1725 cm^{-1}; ^{1}Hmr δ: 2.62 (2H, m, O=C—H_2C-4), 3.87 and 4.23 (2H, AB, J = 13 Hz, O—H_2C-1); M^+ calcd. for $C_{27}H_{46}O_2$: 402.3497; found: 402.3480.

The lower band at R_f 0.55 yielded 15.8 mg of colorless solid minor lactone. Three recrystallizations from MeOH gave 10 mg of colorless plates of **3-oxa-A-homo-5α-cholestan-2-one** (**21**), mp 136–141°C; ir: 1720 cm^{-1}; ^{1}Hmr δ: 2.37 and 2.86 (2H, AB, J = 13 Hz, O=C—H_2C-1) and 4.20 (2H, m, O—H_2C-4); M^+ calcd. for $C_{27}H_{46}O_2$: 402.3497; found: 402.3491.

Oxidation of cis-*10-methyl-2-decalone* (***10***)

The starting ketone **10**, ir: 1700 cm^{-1}, was prepared by the CuBr - catalyzed addition of CH_3MgI to $\Delta^{1,9}$-2-octalone (40, 41) and was shown to be pure by its ^{13}Cmr spectrum δ: 28.4 (CH_3), 22.2, 25.1, 27.1, 28.2, 37.8, 38.0, 49.1 (7 × CH_2), 40.4 (CH), 38.6 (quat. C), 213.1 (C=O). A solution of 35 mg (0.21 mmol) of **10** and 96 mg (0.42 mmol) of MCPBA (75%) in 1.5 mL of $CHCl_3$ was allowed to stand at room temperature for 2 days. Work-up afforded 35 mg (91%) of colorless oil; ir: 1725 cm^{-1}; ^{1}Hmr δ: 1.01 (s, CH_3 of major lactone), 1.11 (s, CH_3 of minor lactone), 3.87 and 4.19 (AB, J = 13 Hz, O—H_2C-1 of major lactone); ^{13}Cmr δ: 21.9, 22.1, 24.0, 25.2 (CH_3), 27.4, 27.7, 27.9, 30.7 (b), 31.6, 33.9 (quat. C), 36.5, 42.3 (b), 74.1 (b), 175.8 (C=O). Thin layer chromatography in benzene–ether (85:15) with three developments revealed two spots more polar than **10** in the ratio of ~70:30. M^+ of the mixture calcd. for $C_{11}H_{18}O_2$: 182.1307; found: 182.1306.

Oxidation of cis-*9-methyl-2-hydrindanone* (***11***)

The ketone **11**, ir: 1745 cm^{-1}, was prepared by the method of Lansbury and Nienhouse (42) and was shown to be pure by its ^{13}Cmr spectrum δ: 26.6 (CH_3), 21.8, 22.0, 26.4, 34.1, 42.6, 51.6 (6 × CH_2), 41.3 (CH), 37.8 (quat. C), 219.8 (C=O). A solution of 30 mg (0.20 mmol) of **11** and 138 mg (0.60 mmol) of MCPBA (75%) in 1.5 mL of $CHCl_3$ was allowed to stand at room temperature for 2.5 days. Work-up gave 25 mg (74%) of pale yellow oil whose tlc (benzene–ether, 95:5) showed a single spot more polar than **11**; ir: 1720 cm^{-1}; ^{1}Hmr (see Fig. 1) δ: 3.89 and 4.35 (AB, J = 11.5 Hz, O—H_2C-1 of major lactone), 4.15 and 4.59 (AB part of ABX, J_{AB} = 11.5 Hz, O—H_2C-4 of minor lactone); M^+ calcd. for $C_{10}H_{16}O_2$: 168.1150; found: 168.1150; ^{13}Cmr δ (major lactone): 24.3 (CH_3), 75.6 (O—H_2C-1), 21.3, 23.1, 28.4, 32.4, 33.0 (5 × CH_2), 37.3 (CH), 31.4 (quat. C), 171.3 (C=O); (minor lactone): 28.6 (CH_3), 71.9 (O—H_2C-4), 21.5, 24.8, 25.8, 37.2, 37.8 (5 × CH_2), 39.2 (CH), 32.2 (quat. C), 171.3 (C=O).

^{13}C Nuclear magnetic resonance spectra

The ^{13}Cmr spectra were recorded at 50.3 MHz and comparison of the fully decoupled spectra with those obtained with either the APT (43) or INEPT (44) sequences served to identify the methyl, methylene, methine, and quaternary signals. Unequivocal assignments for **7** were obtained from its 2D INADEQUATE spectrum (45) using the CCC2D pulse sequence of the XL software with a 2048 × 128 data point matrix transforming 2048 and 512 points, respectively, with a 2400-Hz sweep width in both domains. The ^{13}C data are collected in Table 1. It has been demonstrated previously (see ref. 14, pp. 1558 and 1563) that integration of proton-decoupled ^{13}Cmr signals is accurate and reproducible with the large rigid steroid molecules under non-saturating conditions.

Received January 23, 1984

This paper is dedicated to Professor Paul de Mayo on the occasion of his 60th birthday

JÜRG E. HOLENSTEIN, ALBERT STOESSL, HEINZ KERN, and J. B. STOTHERS. Can. J. Chem. **62**, 1971 (1984).

The structure of the phytotoxin marticin **7***a* has been confirmed on the basis of ^{1}H and ^{13}Cmr data for the methyl ester **7***c*, but these and other considerations have led to a revision of the stereochemistry assignable to the isomeric isomarticin from **7***b* to **13**. Incorporation of [1,2-$^{13}C_2$]- and [2-$^{13}C_1$]-acetates into **7***a*, isolated as **7***c*, has established a heptaketide origin for its fusarubin (**1**) moiety, and the tricarboxylic acid cycle as the biogenetic source of the remaining C_3 fragment, only the first three turns of the cycle making significant contributions.

JÜRG E. HOLENSTEIN, ALBERT STOESSL, HEINZ KERN et J. B. STOTHERS. Can. J. Chem. **62**, 1971 (1984).

Faisant appel à la rmn du ^{1}H et du ^{13}C de l'ester méthylique **7***c*, on a confirmé la structure de la phytotoxine marticine, **7***a*; toutefois, ces données et d'autres considérations nous ont amené à reviser la stéréochimie que l'ont doit attribuer à l'isomarticine isomère, de **7***b* à **13**. Des unités acétates, marquées au [1,2-$^{13}C_2$]- et au [2-$^{13}C_1$], ont été incorporées au **7***a*, qui a été isolé sous forme de **7***c*, et ont permis d'établir que l'origine de sa portion fusarubine (**1**) est un heptacétide alors que la source biogénétique du fragment résiduel en C_3 est le cycle de l'acide tricarboxylique; toutefois, seuls les trois premiers tours du cycle contribuent d'une façon importante.

[Traduit par le journal]

Species of the fungal genus *Fusarium* produce naphthazirinoid pigments, several of which have received much attention because of their antibiotic, insecticidal, and phototoxic properties (1–5) and non-host-specific phytotoxicity (2, 6–10). Biogenetically, some eighteen of these compounds, exemplified by fusarubin (**1**) and javanicin (**2**), are heptaketides; at least one, norjavanicin (**3**), is a non-exceptional norheptaketide; another, novarubin (**4**) (2, 5) is either a rearranged heptaketide or a norheptaketide with an extra, C_1-pool derived hydroxymethyl group. Bikaverin (**5***a*) and its 0-demethyl derivative norbikaverin (**5***b*) are probably nonaketides (11). Excellent experimental evidence for an acetate–polymalonate origin has been adduced for **2** by Gatenbeck and Bentley (12) and similarly, for **1** and **3**, by Kurobane *et al.* (13) and McCulloch *et al.* (5). The two latter studies demonstrated that **1** and **3** are formed non-enzymically from the congeneric dihydrofusarubins (**6***a*, *b*) which must, therefore, be regarded as the true fungal metabolites.[4] Two further naphthazirins, marticin and isomarticin, for which structures **7***a* and *b* have been assigned (15) are congeneric with **1**–**4**, **6***a* and *b* in certain *Fusarium* strains (2, 6, 10, 14) but differ in the presence of an additional C_3 chain, attached to C-14 of **1**. This feature may be significant for structure–activity and virulence relations, because the two compounds appear to be the most phytotoxic of the group (2, 6, 10), and, clearly, is also of considerable biogenetic interest. Early time–sequence studies (16) had suggested that **7***a* and *b* might be precursors of their congeners, which would accordingly be derived by degradative reactions. If this is correct, the marticins would presumably be derived from nonaketides by the loss of one carbon. It is therefore relevant that nonaketides, while relatively rare as fungal products (17; see also ref. 18), are, in fact, well known as metabolites of *Fusarium* species; viz., zearalenone (**8**) and several derivatives from *F. roseum*, and the more immediately pertinent bikaverin (**5***a*) and norbikaverin (**5***b*) from *F. oxysporum* and the related *Gibberella fujikuroi* (18). Despite this, a nonaketide origin of the marticins is difficult to reconcile with the "rule" that "the uncyclized residues from the methyl ends of polyketide chains are never shorter than residues from the carboxyl end of the chain" (17), and also with the proven intermediacy of the dihydrofusarubins in the formation of **1** and **3** (5, 13). For these reasons, an alternative hypothesis was suggested (7), according to which the marticins would be biosynthesized by addition of a C_3 unit to a heptaketide precursor.

To distinguish between these two, mutually exclusive possibilities, we have studied the incorporation of [1,2-$^{13}C_2$]- and [2-$^{13}C_1$]-acetate into the marticins. The results, as briefly reported in a preliminary communication (19), unambiguously demonstrate a heptaketide origin for the marticins and, in addition, implicate the tricarboxylic acid (Krebs) cycle as the source of the extra C_3 fragment. These results are discussed here in greater detail, with, in addition, comments on the structures and stereochemistries of the marticins.

The marticins were first examined in detail by Hardegger and Pfiffner and the results of their extensive chemical and spectroscopic studies, published only in thesis form (15), led to the assignment of structures **7***a* and *b* to marticin and isomarticin,

respectively. The two compounds are obtained from the acid portion of the fungal extract as a difficultly separable mixture in which the thermodynamically less stable isomarticin predominates. Treatment of either marticin or isomarticin with methanolic HCl, however, gives marticin methyl ester as the major (>90%) product (15). Since only relatively small quantities of material were available in the present work, the crude acidic product was esterified to render marticin methyl ester **7***c* isolable by crystallization. This material was found to be identical (ir, mp, ^{1}Hmr) with that reported by Pfiffner (15).

The ^{13}Cmr spectrum of **7***c* contained signals consistent with the previously assigned structure. In the sp^2 region, the following signals appeared (δ_C): two quinonoid carbonyls, 180.3, 186.7; a carboxyl, 170.9; three aryl carbons bearing oxygen, 154.3, 156.9, 160.8; a single aryl C—H, 110.1; and four fully substituted aryl carbons, 108.4, 110.1, 135.1, 137.7. The coincidence of the two signals at 110.1 was confirmed by examination of the proton-coupled spectrum. In the sp^3 region, the spectrum contained signals for a quaternary carbon, 96.3; two methoxyls, 52.4, 56.9; two carbinyl carbons, 65.3, 67.2; two methylenes, 30.7, 32.5; and one methyl carbon, 29.0.

Comparison of the ^{13}Cmr spectrum of **7***c*-$^{13}C_x$, obtained from the incorporation experiments with [1,2-$^{13}C_2$]-acetate, with that for natural **7***c* readily revealed that seventeen of the nineteen carbons were enriched, the exceptions being the two methoxyl carbons, as expected. Each of the signals for the labelled carbons was accompanied by ^{13}C satellites arising from spin coupling between adjacent labelled centres demonstrating the pairwise incorporation of carbons in intact acetate units for C-1 through C-14. Since each of these seven coupling constants is different, the pairwise assignments were straightforward as set out in **9**, in which the heavy bonds indicate intact acetate incorporation, with the *J* values given in parentheses. The absorption patterns for C-15, -16, and the carboxyl carbon also contained ^{13}C satellites. With the exception of the methyl and carboxyl absorptions, the patterns for all labelled centres exhibited detectable ^{13}C satellites of the satellites, undoubtedly owing to the relatively high probability of incorporation of enriched acetate units into adjacent sites during the limited period of active uptake of exogenous acetate (13). The intensities of the satellite signals relative to that of the central signal for C-1 through C-14 indicated a ^{13}C enrichment level of ca. 2%. For C-15, -16, and the carboxyl carbon the enrichment level was distinctly lower, ca. 1%. Prominent satellites with J = 68 Hz for C-16 and the carboxyl carbon indicated that incorporation of an intact acetate unit occurred. The C-16 pattern also contained less intense satellites with J = 35 Hz due to coupling with C-15, confirming its enrichment. Although C-16 and the carboxyl carbon thus arise largely from an intact acetate unit, the C_3 cannot be part of an initially formed nonaketide chain without a somewhat improbable rearrangement involving the extrusion of one carbon atom. If no rearrangement is involved, the results are compatible with the derivation of **7***c* from a fusarubin (or precursor) skeleton which gains a C_3 unit derived, most probably, from a metabolite of the tricarboxylic acid cycle into which acetate readily enters in the required manner. In particular, it was predictable for this case that the incorporation of [2-$^{13}C_1$]-acetate via citrate would result in a high probability of labelling of both C-15 and C-16, which would be revealed by readily observable coupling of these two nuclei.

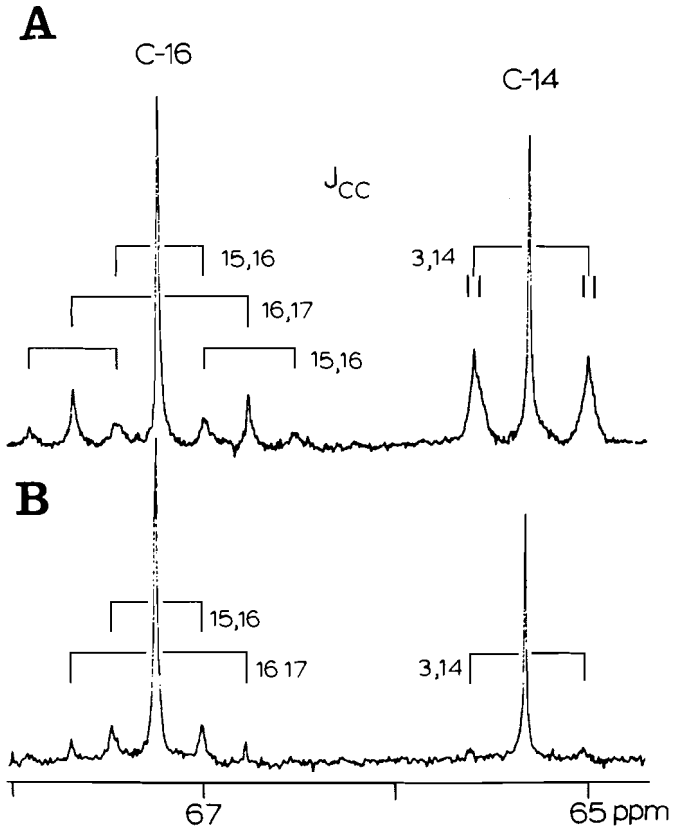

FIG. 1. The carbinyl carbon (C-14 and -16) absorptions in the 75.4-MHz spectra of (A) 7*c*-$^{13}C_x$ and (B) 7*c*-$^{13}C_y$ (see text). The origins of the one-bond, $^{13}C—^{13}C$ couplings are indicated; $J_{15,16}$ = 35.2 Hz, $J_{16,17}$ = 68.2 Hz, $J_{3,14}$ = 44.5 Hz. The broadening of these satellites for C-14 in (A) arises from geminal $^{13}C—^{13}C$ coupling with C-2, -4, and -12 in the variously labelled moieties of this enriched sample.

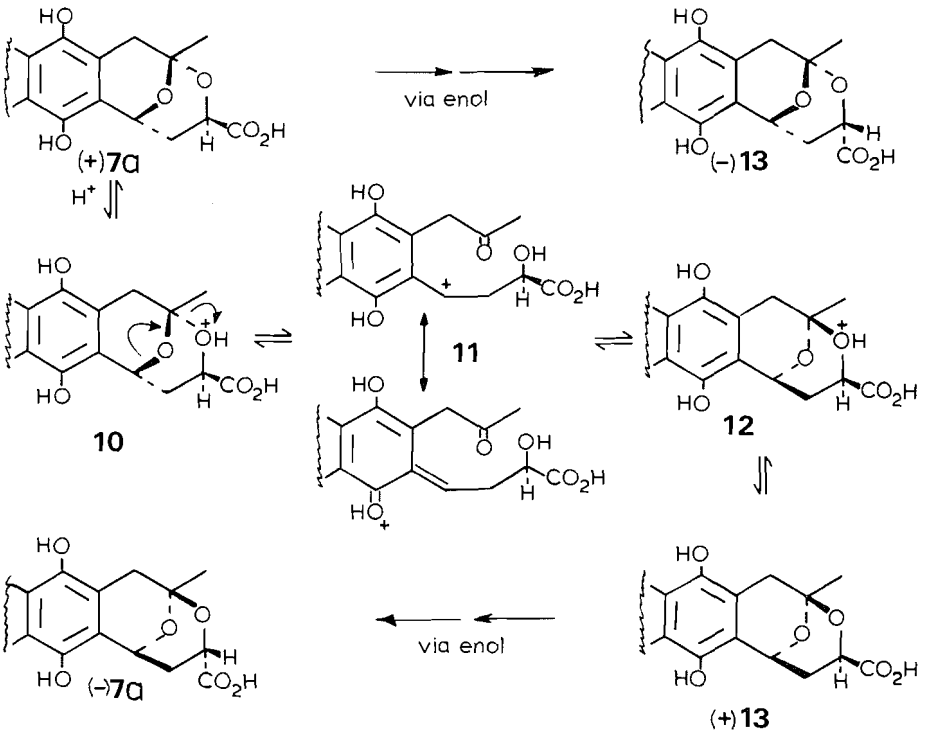
Setting out from this consideration, cultures of the fungus were supplemented with [2-$^{13}C_1$]-acetate and the ^{13}Cmr spectrum of the isolated 7*c*-$^{13}C_y$ was recorded. The intensities of the signals for the alternate carbons in the fusarubin portion of the molecule were significantly enhanced as were those for C-15, -16, and the carboxyl carbon. These data confirm the assignments shown in **9**, clearly distinguishing between C-1 and -4 and between C-5 and -8. Thus, the original structural assignment by Pfiffner was confirmed. It may be noted that in the thesis (15) there was some doubt regarding the placement of the aryl methoxyl group but the spectra of the labelled metabolites establish its bonding to C-7. Most importantly for our purpose, however, the absorption for both C-15 and C-16 in 7*c*-$^{13}C_y$ contained prominent ^{13}C satellites, J = 35 Hz, indicating a high level of incorporation of acetate into a Krebs cycle precursor in which the methyl carbons of two acetate units are directly bonded. In addition, the C-16 pattern has less intense satellites, with J = 68 Hz, which match those found for the carboxyl carbon, C-17. To illustrate the differences in the C-16 patterns for the two labelled metabolites, 7*c*-$^{13}C_x$ and 7*c*-$^{13}C_y$, the carbinyl regions of the spectra are shown in Fig. 1. Weak satellites (J = 44 Hz) were also apparent for C-14 in the spectrum of 7*c*-$^{13}C_y$; in fact each of the signals for the enriched centres in 7*c*-$^{13}C_y$ exhibited similar weak satellite peaks and each of the patterns for the protonated carbons contained a closely spaced pair of satellites, $J \sim 4$ Hz, arising from geminal $^{13}C—^{13}C$ coupling. As noted above, this is undoubtedly owing to the relatively high probability of incorporation of enriched acetate units into adjacent sites during the limited period of active uptake.

We turn now to a more detailed consideration of the argument that C-15 through C-17 are derived from acetate via one to several turns of the Krebs cycle. Such incorporations have been observed previously in ^{13}Cmr biosynthetic studies (20). A detailed mathematical analysis of the flux of [2-$^{13}C_1$]-acetate into primary Krebs cycle metabolites in perfused rat hearts was published very recently (21), after our work had been completed. In another, similar but mathematically less explicit study, also published very recently (22), the incorporation of [2-$^{13}C_1$]-acetate into citrate and glutamate by *Saccharomyces cerevisiae* was followed on a time basis; a particularly interesting feature which emerged from this is that after the relatively brief interval of ca. 4 h, a steady state is reached. in which glutamate is markedly labelled in the 2,3,4- and the 1,2,3,4-positions whereas 4-, 2,4-, 3,4-, and 1,3,4-labelled glutamate decreases from initially modest to very low concentrations.

With respect to the results for 7*c*, it is salient to recall, in addition, that the 2- and 3-positions of succinate are equivalent in the operation of the Krebs cycle (16, 23). Thus, unlabelled, pool-derived oxaloacetate will condense with [**1**,**2**-$^{13}C_2$]-acetate to give citrate, which will furnish in succession [**4**,**5**-$^{13}C_2$]-oxoglutarate, [**1**,**2**-$^{13}C_2$]-succinate, and, hence, equal amounts of [**1**,**2**-$^{13}C_2$]- and [**3**,**4**-$^{13}C_2$]-oxaloacetate in the first turn of the cycle. The bold face numbers indicate paired labels arising through uptake of an intact doubly labelled acetate unit. Degradative condensation of these or other intermediates of the cycle (but most probably that of oxaloacetate) with a heptaketide precursor will lead to two different labelled species of marticin, one labelled at C-15 and one with paired labels at C-**16**, -**17**. On the second turn of the cycle, condensation of [**1**,**2**-$^{13}C_2$]- and [**3**,**4**-$^{13}C_2$]-oxaloacetate with [**1**,**2**-$^{13}C_2$]-acetate will furnish [3,**4**,**5**-$^{13}C_3$]- and [**1**,**2**,**4**,**5**-$^{13}C_4$]-2-oxoglutarate and, hence, [**1**,**2**,3-$^{13}C_3$]- and [**1**,**2**,4-$^{13}C_3$]-succinate, respectively. This would lead to marticin labelled at C-15 and -16, C-15 and -17, C-**16**, -**17**, and C-15, -**16**, -**17** with the four species accruing in a 1 : 1 : 1 : 1 ratio. However, the second turn of the cycle will also involve natural acetate. Thus [2-$^{13}C_1$]- and [3-$^{13}C_1$]-2-oxoglutarate will be produced, leading to [1-$^{13}C_1$]- and [2-$^{13}C_1$]-succinate which will give rise to one unlabelled and three monolabelled species (C-15, C-16, and C-17) of marticin. A third turn of the cycle, with [**1**,**2**-$^{13}C_2$]-acetate as well as with natural acetate, can give rise to nine different labelled species, allowing for the distinction between C-**16**, -**17** and C-16, -17 and between C-15, -**16**, -**17** and C-15, -16, -17, by 32 possible routes. Thus, labelled acetate will lead by two routes each to the labelling patterns C-15, C-15, -16, C-15, -17, and C-15, -16, -17, and by four routes each to C-**16**, -**17** and C-15, -**16**, -**17**. Unlabelled acetate will lead by two routes each to the patterns C-16, C-17, C-16, -17 and by four to C-15. The relative magnitudes of the contributions from the various turns of the cycle, and those from unlabelled acetate in the second and third turns, cannot be readily predicted nor quantitated from the available experimental data. However, the intensities of the observed satellites (Fig. 1A) indicate that the 16, 17-doubly labelled species are about four times as abundant as their 15, 16-labelled counterparts and this indicates that the contributions from the first turn were predominant.

The incorporation of [2-$^{13}C_1$]-acetate into the C-15, -16, -17



SCHEME 1

fragment of marticin will proceed via the Krebs cycle in a manner analogous to that described by Dickinson *et al.* (22)[5] with the important difference that intermediates of the cycle are withdrawn for marticin formation before a steady state is attained. The first turn through the tricarboxylic acid cycle with [2-$^{13}C_1$]-acetate will produce [2-$^{13}C_1$]-succinate and, consequently, marticin monolabelled at C-15 and at C-16 in a 1:1 ratio. The second turn with [2-$^{13}C_1$]-acetate will provide marticin labelled at C-16, at C-15, -17, and at C-15, -16 in a ratio of 1:1:2, while the second turn utilizing natural acetate will produce unlabelled and the three possible monolabelled species in a ratio of 1:1:1. The third turn of the cycle with both [2-$^{13}C_1$]-acetate and natural acetate leads to all seven possible labelling combinations for the three pertinent carbons. Of the thirty-two routes via oxaloacetate, there are six which lead to each of the following species: unlabelled, monolabelled at C-15 and at C-16, and dilabelled at C-15, -16, while there are two routes to each of the C-15, -17 and C-16, -17 dilabelled species and the trilabelled material. Clearly the enrichment of C-15 and C-16 will be expected to exceed that for C-17. This is the situation observed; for the C-16 pattern in Fig. 1B the intensity of the satellites with $J = 35$ Hz is about three times greater than that for the satellites with $J = 68$ Hz. As mentioned previously, the immediate precursor for marticin production is probably a C_4 Krebs cycle metabolite, oxaloacetate being the most favored mechanistically but its prior decarboxylation to pyruvate cannot be excluded.

While the ^{13}C results confirm the original structural assignment for marticin methyl ester as **7***c* and thereby **7***a* for marticin itself, these data do not provide definitive information on the stereochemistry of these compounds and the original stereochemical assignments appear open to question. Pfiffner (15) established that marticin ($[\alpha]_D$ +132°), isomarticin ($[\alpha]_D$ +26°), and their methyl esters are optically active; furthermore, the ord curves for marticin and its methyl ester are essentially superimposable and in an approximate mirror-image relationship with those for all isomarticin derivatives, even though all $[\alpha]_D$ values are positive. The mixture of marticin and isomarticin isolated from the fungal extract contains predominantly the less stable isomarticin, but on brief heating with methanolic HCl, the mixture is converted largely to marticin methyl ester. In one experiment Pfiffner heated 1.5 g of pure isomarticin with MeOH/HCl and obtained 1.3 g of marticin methyl ester after recrystallization, while fractional crystallization of the mother liquors gave 39 mg of pure isomarticin methyl ester. The isomerization of isomarticin was ascribed, without explanation, to epimerization at C-16, presumably by enolization. Tatum and Baker (14) have accepted this assignment and in fact ascribe the 16-*S* and 16-*R* configurations to marticin and isomarticin, respectively, with no additional evidence but merely noting that isomarticin is converted to marticin "when cleaning up on tlc". Both groups have apparently overlooked the fact that an acetal is much more labile under acidic conditions than a hydrogen α to a carboxy group. Consideration of the behavior of the marticin system under acidic conditions must take account of the consequences of simple acid catalyzed cleavage and reclosure of the acetal function.

To examine the situation in detail, Scheme 1 has been constructed in which we have arbitrarily labelled one of the marticin enantiomers as (+)-**7***a*. Its protonation will lead to **10** which will readily ketonize to give **11** in which the carbonium ion centre is not only benzylic but *o*-hydroxybenzylic! Reclosure on the opposite face of the carbonyl group will furnish **12**, deprotonation of which gives (+)-**13** as in the scheme. The sequence (+)-**7***a* → (+)-**13** inverts the configuration at C-12 and -14 while the configuration at C-16 is unchanged. It is to

[5] It should be noted that their flow chart for ^{13}C isotopomer distribution for incorporation of [2-^{13}C]-acetate on sequential terms of the cycle does not include condensation with natural abundance acetate.

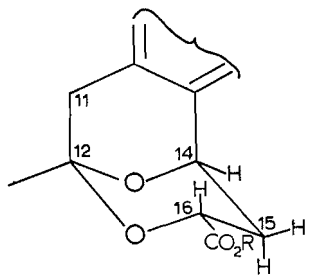
be noted that in the scheme, enolization at C-16 transforms (+)-**7***a* to (−)-**13**, the enantiomer of **13** produced by acetal cleavage and reclosure, while enolization of (+)-**13** will produce (−)-**7***a*. The much greater probability of acetal cleavage under acidic conditions than enolization necessitates the conclusion that the facile isomerization of isomarticin to marticin involves inversion at C-12 and -14 with no change in configuration at C-16, contrary to the earlier suggestion (15).

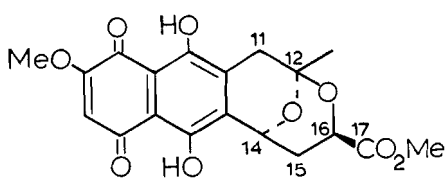
With regard to the stereochemical assignments for marticin, an examination of the ^{1}Hmr data should be informative and, to this end, the proton spectrum of **7***c* was recorded. Although Pfiffner utilized proton spectroscopy extensively throughout the original investigation (15), he did not provide a complete ^{1}H data set for marticin methyl ester. The proton spectra of marticin and isomarticin were reported by Tatum and Baker (14) very recently, while our own studies were in progress. Unfortunately, however, the latter authors did not provide all of the coupling constant data. Furthermore, data *tabulated* for their "more stable" isomer agree better with those for Pfiffner's less stable material and their results for their "less stable" acid agree closely with our data for the more stable ester. In addition, their assignments for the carbinyl protons in each isomer require reversal.

Nevertheless the proton data provide a clear distinction between the two isomers on the following grounds. The carbinyl protons give rise to doublets of doublets owing to vicinal coupling to the 15-methylene protons. For H-14, δ 5.44, the couplings are 1.7 and 5.2 Hz, while for H-16, δ 4.376, J = 3.0 and 12.2 Hz; the absorptions for H-14 and H-16 were conclusively identified by a heteronuclear correlation spectrum since the signals for C-14 and -16 were unequivocally distinguished by the spectra of the labelled samples described earlier. The eight-line patterns for each of the 15-protons were at δ 2.387 (axial H-15), J = 5.2, 12.2, 13.4 Hz and δ 1.956, J = 1.7, 3.0, 13.4 Hz (equatorial H-15). These coupling constants agree remarkably well with those found for a series of 2-alkyl-1,3-dioxanes (24) in which the vicinal interactions ($J_{4,5}$) were found to be 12.4–12.5 (4_{ax}, 5_{ax}), 2.6 (4_{ax}, 5_{eq}), 5.0 (4_{eq}, 5_{ax}), 1.3 Hz (4_{eq}, 5_{eq}) and the geminal coupling $J_{5_{ax},5_{eq}}$ = 13.3 Hz. Since the 2-alkyl-1,3-dioxanes undoubtedly adopt chair conformations, it follows that the ketal ring of marticin and its methyl ester is

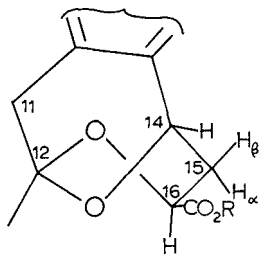


14

also a chair as in **14**, corresponding to **7***a* (Scheme 1). Isomarticin is, therefore, **13** and its methyl ester **15**, for which the



15



16

favored conformation can be represented as the twist-boat **16**. Fortunately, Pfiffner (15) reported the following data for isomarticin methyl ester: H-14, δ 5.33, J = 2.0, 9.0 Hz; H-15, δ 2.14, J = 2.0, 8.5, 13.5 Hz; H-15, δ 2.71, J = 6.0, 9.0, 13.5 Hz; H-16, δ 4.53, J = 6.0, 8.5 Hz. The results are entirely compatible with structure **15** existing in conformation **16**. It can be mentioned that the proton spectra of the O-methyl derivatives of the marticin and isomarticin methyl esters were fully described in Pfiffner's thesis and the data accord very well with the results for the esters themselves. The 11-methylene proton patterns found for the marticin and isomarticin series offer a clear distinction between the two since δ_{AB} for these patterns is $\leq$ 0.15 ppm for marticin and derivatives while $\delta_{AB} \geq$ 0.4 ppm for the isomarticin series. For example, **7***c* has δ_A 3.097, δ_B 2.992, J_{AB} = 20 Hz and **15**, δ_A 3.13, δ_B 2.68, J_{AB} = 18.5 Hz (15).

We conclude from all of these data that marticin methyl ester is **7***c* (or enantiomer) and isomarticin methyl ester is **15** (or enantiomer) rather than **7***b* as had been previously claimed.

Experimental

Reference samples of isomarticin, fusarubin, javanicin, and novarubin were available from earlier work (2, 10). Sodium [1,2-$^{13}C_2$]- and [2-$^{13}C_1$]-acetate, as well as $CDCl_3$ were purchased from MSD Isotopes, Pointe Claire – Dorval. The ^{1}H spectra were determined on a Varian XL-200 spectrometer with solutions of 5–10 mg/0.4 mL of $CDCl_3$. The ^{13}C spectra were obtained with a Varian XL-300 instrument at 75.4 MHz (28° pulses, 3-s rep rate with 18-kHz sweep widths and 60 000 points with 64K transforms) using the same solutions as those employed for the proton spectra; comparison of the decoupled spectra with those obtained by the INEPT sequence identified the methyl, methylene, methine, and quaternary carbons. A coupled spectrum of **7***c* was obtained with gated decoupling (17% duty cycle) to aid the initial assignments. A ^{13}C—^{1}H correlation experiment was done using the HETCOR sequence of the XL software (25) to permit definitive assignments for the two methylene and the two carbinyl absorptions. For this purpose, a 2048 × 256 data matrix with a 4800-Hz spectral width for ^{13}C and 1200-Hz width for ^{1}H, transforming 2048 and 512 points, respectively, was employed.

The fungal organism used was *Fusarium martii* App. et Wr. var. *pisi* F.R. Jones, strain F1.1 from the collection at the Institut für Phytomedizin, ETH, Zurich, and was routinely maintained on malt agar (10). Shake cultures on Raulin medium (80 mL/200 mL Delong flask) were grown at 27°C (the temperature requirement being critical) and harvested by filtration, usually after 5–7 days, when the culture media were dark purple. The mixture of metabolites extracted from the acidified filtrates (a few drops of concentrated HCl to pH 3) by EtOAc (2 × 1 vol) was separated into acidic and neutral fractions by distribution between $NaHCO_3$ (1 *M*, 3 × 100 mL) and EtOAc (4 × 100 mL), essentially as described by Pfiffner (15). The $NaHCO_3$ extracts were acidified (concentrated HCl) and reextracted with EtOAc (2 × 1 vol) to give a product containing isomarticin (**7***b*) as major component, together with smaller quantities of marticin (**7***a*) and fusarubin (**1**) (tlc). The crude acidic product was methylated by brief boiling with methanolic HCl (15), crude crystalline marticin methyl ester separating on standing at room temperature for 1–2 days. The pure

component was obtained by repeated recrystallizations with MeOH/$CHCl_3$.

Incorporation of [1,2-$^{13}C_2$]-acetate

Fifteen cultures of the fungus were injected with [1,2-$^{13}C_2$]-acetate (99% ^{13}C; 0.093 *M*, 4 mL/culture) when the culture media had turned orange-yellow (66 h after inoculation). The addition was repeated after a further 24 h and the cultures were harvested another 24 h thereafter. Methylation of the acidic product gave 20 mg of crude **7***c*, mp 150–210°C, which afforded 10 mg of pure compound, mp 236–238°C, after two recrystallizations. This sample was enriched by ca. 2% according to ^{13}Cmr analysis.

Incorporation of [2-$^{13}C_1$]-acetate

Twelve fungal cultures were treated analogously with [2-$^{13}C_1$]-acetate (99% $^{13}C_1$; 0.096 *M*, 4 mL/culture) 67 h and, again, 91 h after inoculation, and harvested 24 h thereafter. Methylation of the acidic metabolic product and recrystallization of the crude methyl ester (17 mg) gave pure **7***c* (7.8 mg), mp 238–240°C.

Vinylogous nucleophilic catalysis. Tertiary amine promoted hydrolysis of 1-alkene-1-sulfonyl chlorides[1]

JAMES FREDERICK KING, JOHN HENRY HILLHOUSE, AND STANISŁAW SKONIECZNY[2]
Department of Chemistry, University of Western Ontario, London, Ont., Canada N6A 5B7

Received February 2, 1984

This paper is dedicated to Professor Paul de Mayo on the occasion of his 60th birthday

JAMES FREDERICK KING, JOHN HENRY HILLHOUSE, and STANISŁAW SKONIECZNY. Can. J. Chem. **62**, 1977 (1984).

We present evidence that the reactions of ethenesulfonyl chloride (**1**) and *trans*-1-propene-1-sulfonyl chloride (**3**) with water in the presence of pyridine, trimethylamine, and a number of other tertiary amines proceed primarily by way of an initial vinylogous substitution reaction to form the cationic sulfene, $R_3^+NCHRCH{=}SO_2$, which subsequently reacts with water either by addition (and deprotonation) to form the betaine $R_3^+NCHRCH_2SO_3^-$, or by vinylogous substitution (and deprotonation) to give the alkenesulfonate anion, $CHR{=}CHSO_3^-$ (R = H or CH_3). Formation of the latter represents the first well-supported example of vinylogous nucleophilic catalysis. These conclusions are drawn from kinetic and product composition observations, including (*a*) α-monodeuteration in the betaine and lack of deuteration of the ethenesulfonate ($CH_2{=}CHSO_3^-$) from the reaction in D_2O, (*b*) rate lowerings of up to 2000-fold for 2- (and 6-) substituted pyridines from those expected from Brønsted-type relationships shown by "unhindered" pyridine bases, (*c*) lack of a kinetic solvent isotope effect in the reaction of **1** with 3-cyanopyridine, (*d*) a lower rate of reaction of **3** vs. **1** not directly correlated with product composition, and (*e*) formation of similar product mixtures from either **1** or $Pyr^+CH_2CH_2SO_2Cl\ Cl^-$ (**18***a*) with aqueous pyridine. For the initial formation of the sulfene, $R_3^+NCH_2CH{=}SO_2$, the available evidence does not distinguish between a two-step mechanism via an intermediate zwitterion and a closely related concerted reaction, but for the further reaction of the sulfene a process involving a zwitterionic intermediate common to both products is favoured. For the reaction of **1** or **3** in the absence of tertiary amines evidence is presented for a direct displacement on sulfur mechanism leading to the alkenesulfonate anion, plus a small proportion (up to 15%) of formation of the 2-hydroxy-1-alkanesulfonate anion by way of the sulfene $HOCHRCH{=}SO_2$ (R = H or CH_3).

JAMES FREDERICK KING, JOHN HENRY HILLHOUSE et STANISŁAW SKONIECZNY. Can. J. Chem. **62**, 1977 (1984).

On rapporte des données qui suggèrent que la réaction du chlorure d'éthènesulfonyle (**1**) et du chlorure de propène-1 sulfonyle-1 *trans* (**3**) avec de l'eau, en présence de pyridine, de triméthylamine et d'un certain nombre d'autres amines tertiaires, se produit principalement par le biais d'une réaction initiale de substitution vinylogue conduisant à la formation du sulfène cationique $R_3^+NCHRCH{=}SO_2$, qui réagit ensuite avec de l'eau soit par une addition (et une déprotonation) pour former la bétaïne $R_3^+NCHRCH_2SO_3^-$ soit par une substitution vinylogue (et une déprotonation) pour donner l'anion alcènesulfonate, $CHR{=}CHSO_3^-$ (R = H ou CH_3). La formation de ce dernier composé représente le premier exemple bien documenté d'une catalyse nucléophile vinylogue. On tire ces conclusions en se basant sur les données cinétiques et sur des observations relatives à la composition du produit; en particulier sur le fait que (*a*) si on effectue la réaction dans le D_2O, il y a α-monodeutération de la bétaïne alors qu'il n'y a pas de deutération de l'éthènesulfonate ($CH_2{=}CHSO_3^-$) dans les mêmes conditions; (*b*) pour les pyridines substituées en position 2 (et 6), les vitesses de réaction sont jusqu'à 2000 fois plus faibles que celles prévues, par des relations de type Brønsted, pour des pyridines "non encombrées"; (*c*) il n'y a pas d'effet isotopique cinétique du solvant lors de la réaction du composé **1** avec la cyano-3 pyridine; (*d*) la différence dans les vitesses de réactions des composés **3** vs. **1** n'est pas reliée avec la composition du produit; et (*e*) dans un milieu de pyridine aqueuse, il y a formation du même mélange réactionnel que le produit de départ soit le composé **1** ou **18***a* ($Pyr^+CH_2CH_2SO_2Cl\ Cl^-$). Dans le cas de la formation initiale du sulfène, $R_3^+NCH_2CH{=}SO_2$, les données disponibles ne permettent pas de faire la distinction entre un mécanisme en deux étapes impliquant un zwitterion intermédiaire et une réaction concertée qui lui est très semblable; toutefois pour tenir compte de la réaction subséquente du sulfène, on favorise un processus qui implique un zwitterion intermédiaire commun aux deux produits. Dans le cas de la réaction des composés **1** ou **3**, en l'absence d'amines tertiaires, on présente des données suggérant l'existence d'un mécanisme par déplacement direct au niveau du soufre qui conduit à l'anion alcènesulfonate aux côtés d'une faible quantité (jusqu'à 15%) de l'anion hydroxy-2 alcanesulfonate-1, qui se forme par l'intermédiaire du sulfène $HOCHRCH{=}SO_2$ (R = H ou CH_3).

[Traduit par le journal]

Introduction

There are two accepted general mechanisms for hydrolysis of alkanesulfonyl chlorides, or, more generally, for reactions of the following type

$$RSO_2Z + Nu^{(-)} \rightarrow RSO_2Nu + Z^{(-)}$$

wherein Z is a leaving group (nucleofuge), and $Nu^{(-)}$ a nucleophile: (*i*) a direct displacement on the sulfur atom (DDS mechanism) (2–11, and refs. cited), and (*ii*) an elimination–addition process going by way of an intermediate sulfene ($R'R''C{=}SO_2$) (12–16). Direct displacement, which may be a single reaction or involve two consecutive direct displacements in a nucleophilic catalysis mechanism, is observed in reactions of arenesulfonyl chlorides (2–7) and related species (10, 11), and presumably with derivatives of alkanesulfonic acids lacking an α-hydrogen. Elimination–addition, on the other hand, is the usual pathway for reactions of alkanesulfonyl chlorides and the like that have an α-hydrogen, in such common preparative reactions as the formation of alkanesulfonate esters by reaction of the alkanesulfonyl chloride with an alcohol and a tertiary amine (12–14); the direct displacement is observed, however, in the simple uncatalyzed hydrolysis and alcoholysis

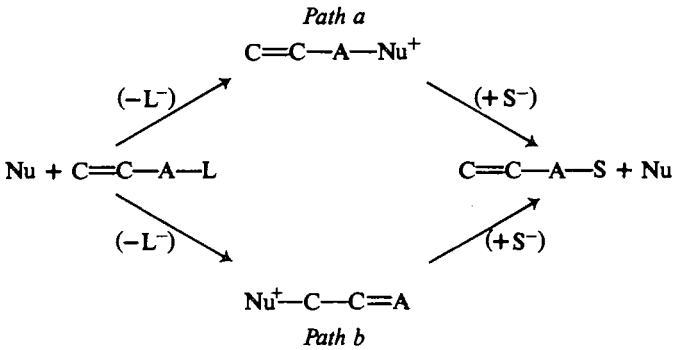


SCHEME 1

of alkanesulfonyl chlorides and other reactions as well (6, 8, 12–14, 16).

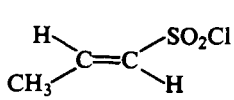
Upon considering the reactions of ethenesulfonyl chloride (**1**) it became evident that previous knowledge was not sufficient to predict its mode of reaction with any confidence. Two mechanistic questions in particular appeared to have especial mechanistic interest; (*i*) is the cumulated sulfene (**2**) formed from **1** and, if so, how does it react, or, alternatively, (*ii*) if **1**

$CH_2{=}CHSO_2Cl$ $CH_2{=}C{=}SO_2$

1 **2**

is subject to nucleophilic attack, does the reaction occur at the sulfur or vinylogously at C-2? The two possible pathways considered in question (*ii*) are illustrated in Scheme 1 for the simplest form of the general substitution without rearrangement. As we show in this paper, the simple tertiary amine-promoted hydrolysis of ethenesulfonyl chloride does, in fact, proceed by a "*path b*" mechanism. In preliminary communications (17, 18) we have already outlined this and a related study of the corresponding reaction with alcohols in a nonpolar medium, and used the terms "S_N2' catalysis" and "vinylogous nucleophilic catalysis" for the "*path b*" process. The former description, though brief, appears to convey an unintended implication that the reaction is necessarily concerted, and we therefore now use the less connotative term "vinylogous nucleophilic catalysis". Our first experiments and communication (17) investigated esterification in nonpolar media, but subsequent work on the hydrolysis has provided a system which, because it is simpler in its chemistry and easier to study kinetically, now appears to be the logical starting point for a detailed presentation of the mechanism of the reaction; the esterification reactions will be discussed in a subsequent paper.

Prior to the present study comparatively little work had been published on the reactions of hydroxylic reagents with ethenesulfonyl chloride (**1**) and its companion in our work, *trans*-1-propene-1-sulfonyl chloride (**3**). Most previous reports



3

(19–22) described essentially synthetic investigations of **1**, including a valuable study (21) of the formation of betaines by reaction with tertiary amines in glacial acetic acid and certain other media. Two kinetic studies have been reported (8*b*, 23); the former concluded that the cation $CH_2{=}CHSO_2^+$ was probably not an intermediate in the ethanolysis of **1** and ascribed the ten-fold increase in its rate of ethanolysis (relative to saturated analogues) to inductive withdrawal by unsaturation, while the latter investigation tentatively pointed to the possibility of conjugation in the transition state for the solvolysis of **3** in aqueous dioxan. Truce and Campbell (13) noted that reaction of **3** with triethylamine and methyl and ethyl alcohols gave both the rearranged and unrearranged esters and suggested that the former arose from vinylsulfene ($CH_2{=}CHCH{=}SO_2$) and the latter from the sulfonylammonium ion ($CH_3CH{=}CHSO_2N^+Et_3$). Remarkably, however, the products of simple hydrolysis of neither **1** nor **3** seem to have been described.

Results and discussion

Hydrolysis of 1 and 3 without amines. Products and kinetics

At pH 4.0 (pH-stat) **1** gave the expected ethenesulfonic acid (**4**) in 90% yield, along with a 10% yield of a second product identified as 2-hydroxyethanesulfonic acid (**5**). At pH 10.5 and 10.8 there seemed to be slightly more **5** (15% and 13%, as the

$CH_2{=}CHSO_2Cl + H_2O \rightarrow CH_2{=}CHSO_3H$

1 **4**

$+ HOCH_2CH_2SO_3H$

5

salt). The presence of potassium chloride up to 0.5 *M* had no effect on the composition of the reaction product at pH 4.0. Similar reaction of **3** gave at high pH (11.5 and 12.7) the salt of the propenesulfonic acid (**6**) with a small amount of that of the hydroxyacid (**7**) (5%), but there was not sign of **7** (<2%) visible in the ^{1}Hmr spectrum of the product of reaction at pH 4.0.

$CH_3CH{=}CHSO_2Cl + H_2O \rightarrow CH_3CH{=}CHSO_3H$

3 **6**

$CH_3CHOHCH_2SO_3H$

7

The rates of hydrolysis of **1** and **3** at 25.0°C were determined by the pH-stat technique over the pH range 3.0 to 10.75 or 11.0 (in 0.1 *M* KCl containing 0.2% of 1,2-dimethoxyethane (DME)). Plots of log k_ψ (where k_ψ is the pseudo-first-order rate constant for hydrolysis) vs. pH showed the familiar hockey-stick pattern (Fig. 1) corresponding to the equation $k_\psi = k_1 + k_{OH}[OH^-]$; k_1 and k_{OH} values for the reactions of **1** and **3** are listed in Table 1.[3]

In D_2O at apparent pH's (i.e. meter readings) of 3.4 and 5.0 we observed k_1 values for **1** of 8.48×10^{-4} s^{-1} and 8.68×10^{-4} s^{-1}, and so obtained a kinetic solvent isotope effect, $(k_1)_H/(k_1)_D$, of 1.54 at 25°C. The ^{1}Hmr spectrum of the product at the kinetic concentrations showed mostly undeuterated **4** (90% yield, <5% deuterated) plus a little monodeuterated **5**, $HOCH_2CHDSO_3H$ (10% yield, >90% mono D).

[3] Complete set of tables giving observed first-order rate constants, product composition, and reaction conditions (5 tables) is available, at a nominal charge, from the Depository of Unpublished Data, CISTI, National Research Council of Canada, Ottawa, Canada, K1A 0R6.

TABLE 1. Rate constants[a] for the reaction of some alkene- and arene-sulfonyl chlorides with water and hydroxide at 25.0°C[b]

R	10^3k_1 (s^{-1})	10^3k_{1S} (s^{-1})	10^3k_{1C} (s^{-1})	k_{OH} (M^{-1} s^{-1})	$k_{(OH)S}$ (M^{-1} s^{-1})	$k_{(OH)C}$ (M^{-1} s^{-1})
CH_2=CH (**1**)	1.32 ± 0.07[c]	1.2	0.1	124 ± 10	107	17
CH_3CH=CH (**3**)	1.22 ± 0.08[d]	1.2	<0.02	37 ± 4	35	~2
C_6H_5[e]	3.06	(3.06)	—	40.4	(40.4)	—
p-$CH_3C_6H_4$[e]	3.00	(3.00)	—	16.1	(16.1)	—

[a] k_1 and k_{OH} are the experimental first- and second-order rate constants for reaction with H_2O and OH^-, respectively; k_{1S} and k_{1C} are calculated from $k_1 = k_{1S} + k_{1C}$ and k_{1S}/k_{1C} = the ratio of **4** to **5** (or of **6** to **7**) in the product at pH 4.0; similarly $k_{(OH)S}$ and $k_{(OH)C}$ are from $k_{OH} = k_{(OH)S} + k_{(OH)C}$ and $k_{(OH)S}/k_{(OH)C}$ = the ratio of **4** to **5** (or of **6** to **7**) in the product at pH 10.5 to 12.7 (see discussion in text).

[b] In 0.1 M aqueous KCl (plus 0.2% 1,2-dimethoxyethane) for **1** and **3**, 0.05 M KCl for $C_6H_5SO_2Cl$ and p-$MeC_6H_4SO_2Cl$.

[c] Values of k_1 for **1** at other temperatures are 8.86×10^{-5} at 1.0, 5.14×10^{-4} at 17.3, 2.91×10^{-3} at 35.0, 7.18×10^{-3} at 45.0, and 3.47×10^{-2} s^{-1} at 60.0°C (see also Table S1); these, after conversion to second-order rate constants (by dividing by 55.5 M), gave $\Delta H^{\ddagger} = 17.5 \pm 2$ kcal mol^{-1} and $\Delta S^{\ddagger} = -21 \pm 8$ cal K^{-1} mol^{-1} (maximum errors as estimated by Wiberg's method (24)).

[d] At 1.0°C k_1 for **3** is 8.1×10^{-5} s^{-1}; $\Delta H^{\ddagger} = 17.5 \pm 3$ kcal mol^{-1} and $\Delta S^{\ddagger} = -21 \pm 10$ cal K^{-1} mol^{-1} (also from second-order rate constants).

[e] Reference 3.

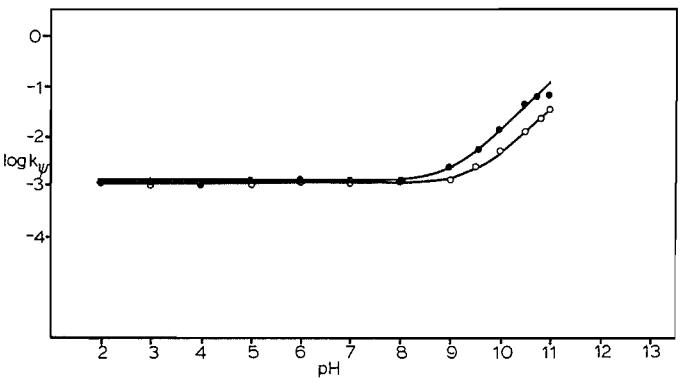

FIG. 1. pH–rate profile for the hydrolysis (in 0.1 M KCl containing 0.2% DME at 25.0°C) of ethenesulfonyl chloride (**1**) (closed circles) and *trans*-1-propene-1-sulfonyl chloride (**3**) (open circles). The points are experimental and the lines calculated from $\log k_\psi = \log (1.32 \times 10^{-3} + 124[OH^-])$ for **1** and $\log k_\psi = \log (1.22 \times 10^{-3} + 37[OH^-])$ for **3**.

4.0	0.13	5.5	0.79[d]	0.80
5.0	0.16	5.0	0.85	0.85

[a] Initial concentration of **1**, 1.6×10^{-2} M.

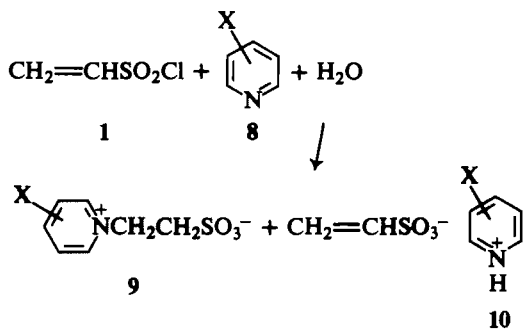
[b] B_T = [B] + [BH^+].

[c] Betaine fractions: experimental betaine fraction, q = (yield of betaine)/(yield of betaine plus alkenesulfonate anion); yields were determined by ^{1}Hmr integration, except as otherwise noted; corrected betaine fraction, q', refers to the fraction of betaine produced in the amine-induced reaction only; $q' = q\,(1 + k_1/k_B[B])$.

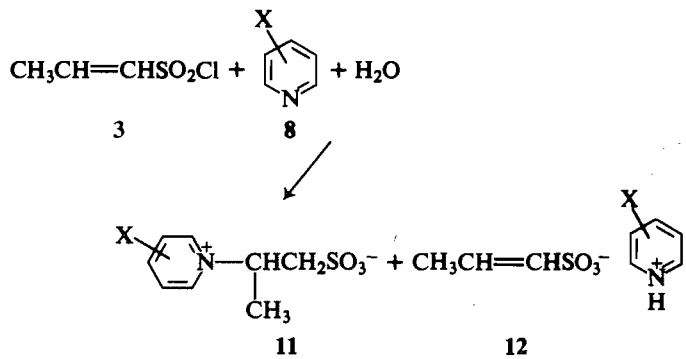
[d] Determined by weighing betaine obtained after isolation via the deionization procedure.

*Reactions of **1** and **3** with pyridine bases in aqueous 0.1 M KCl*

In the presence of pyridine, reaction of **1** in 0.1 M KCl is much accelerated and gives mostly the betaine (**9**, X = H) along with the salt (**10**, X = H) (and the pyridinium chloride).



Passage of the reaction product through a deionizing resin removed the salts and the product so obtained was identified as **9** (X = H) by comparing with an authentic specimen (21). The fraction of betaine (**9**, X = H) in the reaction product was determined either by ^{1}Hmr integration or by weighing the product obtained after deionization, and the results given as "betaine fraction", q, in Table 2. Within the experimental uncertainty of these procedures (about ± 0.05) q is unaffected by change in pH or in the concentration of either the pyridine or the pyridinium ion; control experiments showed that the products are stable to the conditions of reaction and work-up. Similar treatment of *trans*-1-propene-1-sulfonyl chloride (**3**) gave the betaine (**11**, X = H) (56%) and the propenesulfonate salt (**12**, X = H) (44%). In D_2O at apparent pH 3.4, **1** gave the



monodeuterated betaine, $Pyr^+CH_2CHDSO_3^-$ (75% yield, >95% monodeuterated) and undeuterated ethenesulfonate anion, CH_2=$CHSO_3^-$ (25% yield).

As shown in Fig. 2, the pseudo-first-order rate constants for

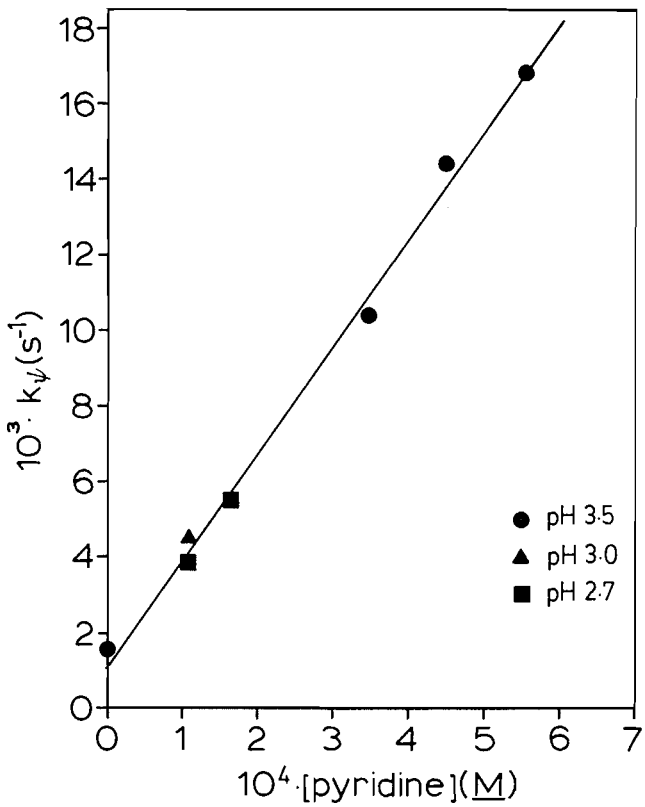

FIG. 2. Dependence of the observed pseudo-first-order rate constant on pyridine concentration in the reaction of **1** with pyridine in aqueous 0.1 *M* KCl (plus 0.2% DME) at 25.0°C; the points are experimental, the line that obtained from least squares: $k_\psi = 1.03 \times 10^{-3} + 28[B]$.

reaction **1** with pyridine in the pH range 2.7–3.5 obey the simple expression,

$$k_\psi = k_l + k_B[B]$$

with k_B, the second-order rate constant for the reaction of **1** with pyridine, equal to $28 \pm 3\ M^{-1}\ s^{-1}$; **3** behaved similarly with $k_B = 1.5 \pm 0.2\ M^{-1}\ s^{-1}$.

The rate constants were determined for an array of substituted pyridine bases (see Table 3). As may be seen from Fig. 3, a Brønsted plot (k_B vs. pK_a') for the reaction of **1** at 25.0°C with the "unhindered" bases – i.e. those with substituents in only the 3 or 4 positions – gave a good straight line ($r = 0.993$), corresponding to the equation $\log k_B = 0.32\ pK_a' - 0.22$. The same pattern was found with **3** at 25.0°C and **1** at 45.0°C: the values of β_{nuc}, the slope of the line for the "unhindered" bases, were respectively 0.31 for **1** at 45.0°C and 0.30 for **3** at 25.0°C. The "hindered" bases (those with 2- or both 2- and 6-substitution) invariably showed a lower value of k_B than predicted by this expression. It would seem reasonable to ascribe this deviation to the steric effect of the substituent(s) in the 2 (and 6) position(s)[4] and, with the aim of enabling a quantitative discussion of this effect, we define for the "hindered" bases a steric factor $SF = k/k_{predicted}$, in which k is

[4] The specific rates of the Menschutkin reaction of methyl iodide with 2- (and 6-) substituted pyridines show similar deviations from the Brønsted correlation of "unhindered" bases; this deviation has been assigned to steric effects (26, 27) and quantitatively correlated with steric parameters (28).

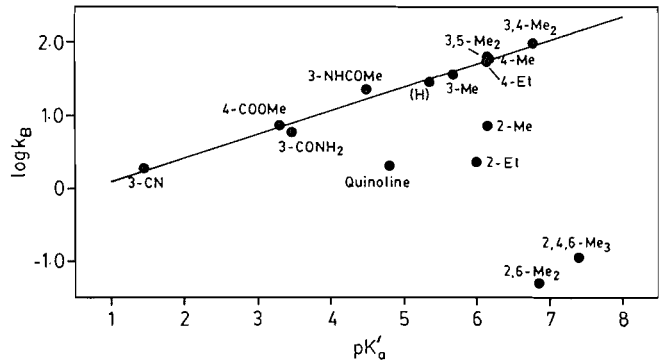

FIG. 3. Brønsted plot of the reaction of pyridine bases with ethenesulfonyl chloride (**1**). The points are experimental, the line is that of the expression, $\log k_B = 0.322\ pK_a' - 0.219$, obtained by linear regression ($r = 0.994$) from the k_B values for the "unhindered" bases, i.e. those lacking substituents in the 2 or 6 positions.

simply the experimental value of the rate constant for the particular "hindered" base, and $k_{predicted}$ is given by $\log k_{predicted} = \beta pK_a' + C$, where pK_a' refers to the same "hindered" base and β and C are obtained from the Brønsted plot of $\log k$ vs. pK_a' for the "unhindered" bases; SF is thus conveniently given by

$$\log SF = \log k - \beta pK_a' - C$$

In this form steric retardation is indicated by $SF < 1$, steric acceleration by $SF > 1$, and no steric effect at all (as, by definition, with the "unhindered" bases) by $SF = 1.0$. These steric factors are specific to both the particular base and the particular reaction; their function here is simply to separate steric and electronic factors as an aid in assessing the reasonableness of different possible mechanisms. Since we mention more than one kind of steric factor in this paper we attach a subscript that distinguishes the origin of each, e.g. SF_B is the steric factor for the reaction of hindered tertiary amines with **1** and **3**, as determined from k_B's. It should be noted specifically that SF_B does not give an absolute measure of the total steric effect in a reaction but rather the *difference* between the steric effect in the transition state for the reaction of the amine with **1** (or **3**) and the steric effect in the comparison species, i.e. the hydrated ammonium cation, on the assumption that electronic effects are not changed by the difference in steric effects.

The steric factors listed in Table 3 for reaction of **1** (at 25.0°C) point to steric retardations varying from eight-fold for 2-picoline to about two thousand-fold for 2,6-lutidine, while for the reaction of **3** the steric factors follow a similar pattern with invariably somewhat greater retardations.

For the reaction of **1** with 3-cyanopyridine in D_2O at 25.0°C (apparent pH 4.0) k_B was found to be $1.95\ M^{-1}\ s^{-1}$, giving a kinetic solvent isotope effect (KSIE), $(k_B)_H/(k_B)_D$, of 1.0.

The fraction of betaine in the reaction product (q in Tables 2 and 4) varied considerably with substitution. Where possible, the product composition was determined under conditions in which $k_B[B]/k_l > 20$, i.e. in which >95% of the product was formed in the base-induced reaction. With slow reacting or poorly soluble amines, however, this was not always feasible and with these reactions in particular the value of q describes a product from both the base-promoted and simple hydrolysis processes. To enable comparison of betaine fractions only from the amine-induced reactions, a "corrected" betaine fraction, q', and a product ratio, p, were calculated (see footnote *a*, Table 2). Again, to separate steric and electronic effects, we define

Benzo[b]	4.80	—	2.0	—	—	—	9.4×10^{-2}	—	0.074	5.8×10^{-2}

[a] Titrimetric pK_a values determined in 0.1 *M* aqueous KCl.

[b] For the "unhindered bases", $\log k_B = 0.322\ pK'_a - 0.219$ for **1** at 25.0°C ($r = 0.994$); at 45.0°C $\log k_B = 0.327\ pK'_a + 0.307$ ($r = 0.989$), and for **3** at 25.0°C $\log k_B = 0.302\ pK'_a - 1.344$ ($r = 0.992$). For some of the "hindered" amines, e.g. 2-picoline and especially 2,6-lutidine, the values of k_B are substantially lower than those reported in our communication (18); this arises because these amines, though originally judged pure (by ^{1}Hmr and vpc), were found on inspection of the betaines produced under kinetic conditions to contain significant amounts of much faster reacting impurities. We therefore adopted the careful purification and stringent purity tests described in the Experimental.

[c] The "steric factor", SF_B, for the "hindered" bases is given by: $\log SF_B = \log k_B - \beta_{nuc} pK'_a - C$; β_{nuc} and C are given in footnote *b* for the appropriate reaction, and k_B and pK'_a are listed in the table. SF_B is assigned as 1.0 for the "unhindered" bases (see text).

[d] Estimated from a literature value (25) for pure water by adding a small (estimated) correction (0.06) for the change to 0.1 *M* KCl.

[e] No detectable catalytic effect ($k_\psi = 1.0 \times 10^{-3}$ s^{-1}) at pH 8.0, total base 5.16×10^{-2} *M* ([B] = 4.8×10^{-2} *M*).

[a] As defined in Table 2, footnote *c*; q values from ^{1}Hmr integration unless otherwise noted.
[b] The product ratio, p, is the ratio of **10** to **9** (or **12** to **11**) and is given by $(1 - q')/q'$.
[c] For the "unhindered" bases and **1** $\log p = 1.056 - 0.305\ pK_a'$ ($r = 0.987$); SF_p values are from $\log SF_p = \log p - 1.056 + 0.305\ pK_a'$.
[d] For the "unhindered" bases and **3**, $\log p = 1.422 - 0.300\ pK_a'$ ($r = 0.994$); SF_p values are from $\log SF_p = \log p - 1.422 + 0.300\ pK_a'$.
[e] For q and individual q' values see Table 2.
[f] Mean value of those in Table 2.
[g] Determined from weight of product after deionization.

another steric factor, SF_p, from the product ratio, p, following the pattern detailed above. The values of SF_p are listed in Table 4 and are notably limited in range compared to SF_B's. As may also be seen from Table 4, both greater steric "bulk" and a low pK_a' of the amine favour a larger value of p, i.e. the greater proportion of the alkenesulfonate salt (**10** or **12**) in the product of the amine-induced reaction.

The reaction of 1 and 3 with tertiary alkylamines

We have also looked at the reaction of **1** and **3** with some simple saturated tertiary amines in the same medium (0.1 *M* aqueous KCl containing 0.2% DME), and found the rates to be measurable at 1.0°C when very low concentrations of the free amine were used. As is shown in Table 5, the reaction product is a mixture of the betaine (**13**) and the tertiary ammonium alkenesulfonate (**14**), plus the chloride salt as well:

$$R_3N + R'CH{=}CHSO_2Cl$$

1 R′ = H
3 R′ = CH_3

$$R_3\overset{+}{N}CHCH_2SO_3^- + R_3\overset{+}{N}H\ R'CH{=}CHSO_3^- + R_3\overset{+}{N}H\ Cl^-$$

$$\begin{matrix} & & \\ & R' & \end{matrix}$$

13 **14**

a R′ = H
b R′ = CH_3

As with the pyridine bases, the essentially constant values of q' with each base (Table 5) show that change in pH, or the concentration of the base or the conjugate acid of the base does not alter the composition of the product from the reaction of the aqueous amines with **1** or **3**.

Table 6 gives the k_B, average q', and p values for these reactions at 1.0°C. The k_B's show two effects: (*i*) the 30-fold greater rate for quinuclidine vs. trimethylamine indicates that in the absence of significant steric differences a stronger base reacts faster than a weaker, and (*ii*) the successive lowering of k_B as methyl groups are replaced by ethyl or isopropyl, even though accompanied by increasing base strength, points to significant steric effects in these reactions as well. In order to separate steric from electronic factors, we follow the method already described for the pyridine bases by making the reasonable assumption that trimethylamine and quinuclidine show very similar steric effects, and that these may be expected to be the smallest possible such effects for tertiary alkylamines, i.e. that among such amines these two are the "unhindered" members of the class. The specific rates for these two bases therefore provide the basis for a Brønsted-type expression for "unhindered" tertiary alkylamines, which makes it possible to calculate steric factors, SF_B, for the other tertiary amines; these are listed in Table 6 along with the analogously obtained values for SF_p, the steric factor derived from the product ratio, p. Although any Brønsted expression based on only two points must be regarded as very approximate, the basic validity of this procedure is supported not only by the arguments given above but also by the consistency of the parameters so obtained. The Brønsted exponents from the k_B's are 0.37 for **1** and 0.41 for **3**, values in accord with each other and in the general range found for the corresponding reactions of the pyridine bases

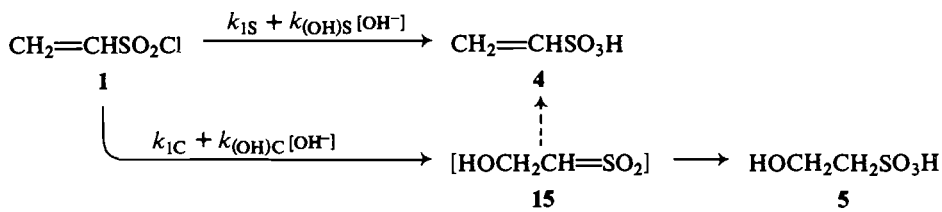
[a] Titrimetric pK_a values determined in 0.1 *M* aqueous KCl at 1.0°C.
[b] $B_T = [B] + [BH^+]$.
[c] Terms defined in Table 2, footnote *c*; q values were determined by weighing the betaine obtained after deionization, except as otherwise noted.
[d] Determined by ^{1}Hmr integration.
[e] No sign of any betaine after deionization.
[f] Peaks tentatively ascribable to the betaine (~3% yield) were observed in the product of deionization; no authentic sample of the betaine has been prepared and its stability to the work-up not proved; the values of q, q', and also p and SF_p (Table 6) are therefore tentative.



SCHEME 2

(0.32 and 0.30, respectively). The greater difference in Brønsted exponents from p values, i.e. 0.5 for **1** vs. 0.3 for **3** (footnotes *d* and *e*, Table 6) is due at least in part to experimental uncertainty; the former value in particular, because it derives from p for the reaction of **1** with quinuclidine in which the small amount of the salt (**14**) is difficult to determine accurately, is only a rough number (±0.2). The SF_B values, as might be expected, show a progression from a very small steric effect (SF_B = 0.77) with dimethylethylamine to the 900-fold steric effect with diisopropylethylamine. As was noted already with the pyridine bases, (*i*) the steric effect of a particular base (triethylamine in this case) is more pronounced in its reaction with **3** than with **1**, and (*ii*) the steric effects for the attack of the amine (shown by SF_B) are larger than in product formation (as shown by SF_p).

In D_2O at apparent pH 10.0, trimethylamine gave the monodeuterated betaine, $Me_3\overset{+}{N}CH_2CHDSO_3^-$ (>90% mono D), and undeuterated ethenesulfonate salt (<5% deuteration on the anion); similarly, diisopropylethylamine in D_2O–DME (80:20) at pH (meter reading) 9.0 (under conditions in which the presence of the amine increased the pseudo-first-order rate constant by a factor of 2.9) also gave the ethenesulfonate salt with no sign of deuteration on the anion.

Mechanisms. First considerations

For the reaction of **1** or **3** with water in the absence of amines, our observations are nicely consistent with a direct displacement on sulfur (DDS) mechanism in which most of the reactions occur by attack of water or hydroxide ion on the sulfonyl sulfur to produce **4** (or **6**).[5]

The small amount of 2-hydroxyethanesulfonic acid (**5**) formed by reaction of **1** at both high and low pH points to the hydroxysulfene (**15**) as an intermediate as indicated in Scheme 2; **15** is presumably formed in acidic medium by attack of water, with attack of hydroxide ion becoming important above pH ~9. Postulation of the intermediacy of **15** raises the possibility that at least some of the ethenesulfonic acid (**4**) may arise from **15** (as shown by the broken arrow in Scheme 2); this, of course, would be a form of vinylogous nucleophilic catalysis. As we have described elsewhere (31), however, we have pre-

[5] The present study is not primarily concerned with the detailed mechanism of the DDS process, but if, as has been suggested by Williams and co-workers (29, 30), hydroxide ion reacts with aryl sulfonic esters with concerted extrusion of aryloxide anion, then it would seem likely that expulsion of the relatively nucleofugal chloride ion from **1** or **3** is also concerted.

[a] As defined in Table 3, footnote *c*; the Brønsted-type expressions from the reactions of the "unhindered" bases Me_3N and quinuclidine are, for **1**, $\log k_B = 0.368\ pK'_a - 0.250$, and for **3**, $0.409\ pK'_a - 2.852$.
[b] Average of those in Table 5.
[c] The product ratio, p, is the ratio of **14** to **13**, and is given by $(1 - q')/q'$.
[d] From $\log SF_p = \log p - 4.47 + 0.48\ pK'_a$ (cf. Table 4, footnote *d*).
[e] From $\log SF_p = \log p - 3.61 + 0.29\ pK'_a$.
[f] Approximate value only, owing to small catalytic effect (7% and 17% increases in k_ψ for reactions at pH 8.0 and 8.5, $B_T = 0.08\ M$).
[g] See footnote *f*, Table 5.

pared 2-hydroxyethanesulfonyl chloride ($HOCH_2CH_2SO_2Cl$) and seen clear signs of the formation of **15** therefrom, and concluded that **15** gives **5** with little or no **4**, thereby excluding the route **1** → **15** → **4**.

It is therefore reasonable to infer that **4** (and also **6**) arises by the DDS mechanism and **5** (and **7**) by way of the sulfene resulting from attack on C-2, in each case by reaction with either water or hydroxide ion. On this basis, by simply taking the proportions of **4** and **5** (or **6** and **7**) we may factor the experimental rate constants k_I and k_{OH} into k_{IS} and k_{IC}, and $k_{(OH)S}$ and $k_{(OH)C}$ values,[6] as defined in Scheme 2 and listed in Table 1. Note that k_{IS} is the same for **1** and **3** within experimental uncertainty (1.2×10^{-3} s^{-1}), whereas $k_{(OH)S}$ for **1** is about three times that for **3**. A similar effect of methyl substitution in reaction with water and hydroxide ion (in a presumed DDS reaction) is seen by comparing the k_I and k_{OH} values for benzenesulfonyl and *p*-toluenesulfonyl chlorides reported by Rogne (3) and listed in Table 1.

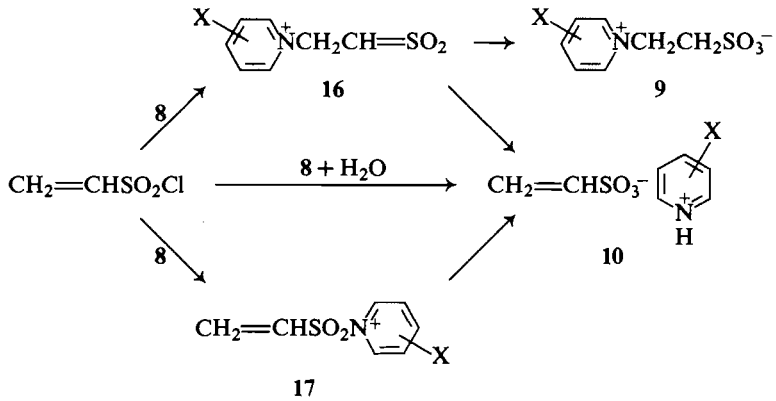
In contrast with those reactions which involve attack of water on the sulfur atom, those in which water bonds to C-2 with ultimate formation of the sulfene (e.g. **15**) are evidently sensitive to the presence of the methyl group, with k_{IC} being at least five times greater for **1** than for **3**. This result is consistent with modest steric interference by the methyl group to attack at C-2; a similar effect is probably influencing attack of hydroxide as well, though here the steric and electronic effects are hard to sort out.

Also in full accord with this mechanistic picture are the results of the experiments carried out in deuterium oxide. The absence of deuterium in the ethenesulfonate (**4**) clearly shows that it cannot have been formed by way of the cumulated sulfene (**2**), while the presence of one (and only one) deuterium in the 2-hydroxyethanesulfonate is fully consistent with its formation from **15**. The kinetic solvent isotope effect (KSIE), k_H/k_D, of 1.54 is close to those reported by Robertson and Laughton for the hydrolyses of methanesulfonyl chloride (1.58 at 20.0°C) and benzenesulfonyl chloride (1.58 at 10.0°C) (32).

Tertiary amine bases completely alter the reaction, the major product with pyridine bases in most cases being the betaine (**9** or **11**). As initially suggested by Le Berre *et al.* (21) the simplest route to the betaine (**9**) is via the sulfene (**16**) (Scheme 3); the formation in D_2O of monodeuterated betaine, $Pyr^+CH_2CHDSO_3^-$, accords with this picture. The origin of the ethenesulfonate salt (**10**), however, is not as easily settled, with three possible pathways shown in Scheme 3. The first of these, **1** → **16** → **10** is a vinylogous nucleophilic catalysis (VNC) mechanism, the second, **1** → **10**, is a general base-catalyzed DDS reaction, and the third, **1** → **17** → **10**, is a conventional nucleophilic catalysis (CNC) process. A further possible route, that via the cumulated sulfene (**2**), is readily dismissed by the observation of undeuterated ethenesulfonate anion $CH_2{=}CHSO_3^-$ from the reaction in D_2O.

Two pieces of evidence combine to provide a convincing case against the general base-catalyzed DDS mechanism. First is the observation that the presence of a 2-substituent in the pyridine base consistently retards the reaction. This effect is quantitatively characterized by the steric factor, SF_B, (see Table 3), which for the "hindered" bases is always less than one and in some cases less than 10^{-3}, corresponding to retardations

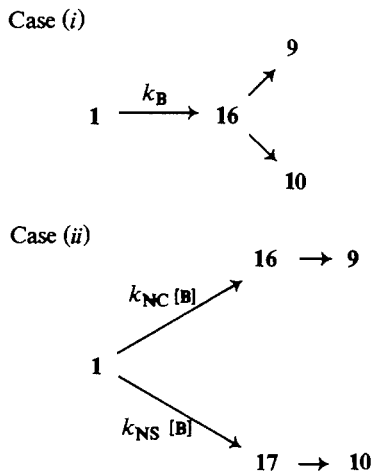
[6] The additional subscripts S and C indicate the site of nucleophilic attack, sulfur or carbon, respectively.



SCHEME 3

of more than a thousand times. Such a sizeable deviation from the Brønsted-type expression obeyed by the "unhindered" bases is much more readily accommodated by a nucleophilic catalysis mechanism than a general-base process (33). Second, the lack of a KSIE in the reaction of **1** with 3-cyanopyridine is also more easily reconciled with nucleophilic catalysis than general base promotion (33). 3-Cyanopyridine was chosen as the base for investigation of the KSIE primarily because it gives the largest proportion of **10** (~80%) of any of the "unhindered" bases and hence any KSIE in the formation of **10** would be readily apparent from the simple measurement of the KSIE for the overall transformation to a mixture of **9** and **10**.[7]

Distinguishing rigorously between vinylogous and conventional nucleophilic catalysis is, however, a little more difficult. It is perhaps helpful to consider separately the two extreme mechanisms for formation of the alkenesulfonate salt **10** (or **12**); i.e. (*i*) the salt is formed exclusively by VNC, or (*ii*) **10** (or **12**) is produced entirely by CNC. The two limiting pictures may thus be summarized for the overall reaction of **1** as follows:



With case (*i*) the measured k_B is simply the rate constant for the rate-determining attack of the amine on **1** with formation of **16**, while *p* provides information about the subsequent fate of **16**, being simply the ratio of the rate of formation of the betaine **9** (or **11**) to that of the salt **10** (or **12**). With the case (*ii*) mechanism, however, k_B is the sum of two rate constants, $k_{NC} + k_{NS}$, where k_{NC} refers to attack on carbon to form the sulfene (e.g. **16**) and k_{NS} to formation of the sulfonylammonium salt[6] (e.g. **17**); q' then describes the fraction of attack at carbon and $(1 - q')$ the fraction of attack on sulfur. On this basis, then

$$k_{NC} = q'k_B \text{ and } k_{NS} = (1 - q')k_B$$

and one may easily assemble an array of k_{NC} and k_{NS} values from those for k_B and q' given in Table 4. At this point we may examine the trends and variations in the respective sets of parameters for case (*i*) and for case (*ii*), to see if we can decide which is the more reasonable mechanism.

The values of k_{NC} and k_{NS} for **1** and **3** with the "unhindered" bases show good to mediocre correlations with pK_a', with linear regression giving the following: for **1**, $\log k_{NC} = 0.45\ pK_a' - 0.49$ and $\log k_{NS} = 0.14\ pK_a' + 0.04$ ($r = 0.996$ and 0.91, respectively), while for **3**, $\log k_{NC} = 0.49\ pK_a' - 2.63$ and $\log k_{NC} = 0.18\ pK_a' - 1.16$ ($r = 0.995$ and 0.96). Following the established procedure we can also calculate steric factors for the "hindered" bases from the k_{NC} and k_{NS} values for attack on C-2 and on the sulfur. This analysis reveals three points. (*a*) We note that k_{NS} for **1** is always greater than that for **3** by factors varying from 7.3 to 29 and averaging 12.4; this contrasts with the corresponding reaction with water (also a neutral nucleophile), in which **1** and **3** react at the *same* rate ($k_{1S} = 1.2 \times 10^{-3}$ s^{-1} for each, see Table 1). (*b*) On comparing the reactions of the only "hindered" bases for which we have results for reaction with both **1** and **3**, viz. 2-picoline and quinoline, we note that the steric factors determined from the k_{NS} values for reaction with **1** differ from those with **3**; for 2-picoline the steric factor is 0.4 with **1** and 0.1 with **3**, and for quinoline it is 0.2 with **1** and 0.08 with **3**. By way of comparison, k_{NC} values give steric factors of 0.08 and 0.03 for 2-picoline with **1** and **3**, respectively, and 0.08 and 0.06 for the corresponding quinoline reactions. Interpretation of these results in terms of the case (*ii*) mechanism presents the following odd situation: we have two substrates which differ only in that the differentiating group is attached directly to one reaction centre (C-2) and well removed from the other (the sulfur atom), and yet not only do we see a change in steric factor for the reaction at the remote centre on changing substrates, but also this change in steric factor is actually greater than that for the reaction at C-2, the substituent-bearing site. (*c*) Further, we note an anomaly of a different kind. The Brønsted exponent, β_{nuc}, for the putative DDS reaction (from k_{NS} values) is respectively 0.14 and 0.18. This contrasts with $\beta_{nuc} = 0.45$ reported by Rogne (34) for the reaction of benzenesulfonyl chloride (34) with pyridine bases under fairly similar conditions (0.05 *M* aqueous KCl, 25.0°C). If, as we have reason to believe, the benzenesulfonyl chloride

[7] The general base-catalyzed reaction is not necessarily excluded for *all* of the reactions in this study, see footnote 9.

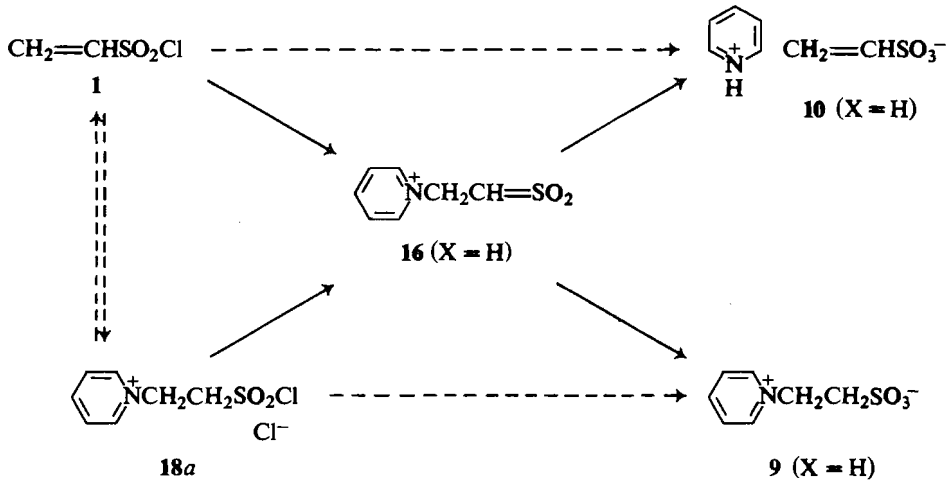
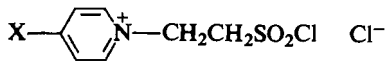


SCHEME 4

reaction is indeed a CNC process, then it is difficult to see how such different β_{nuc} values are compatible with such similar reactions. When taken with the two additional points above, it is clear that the case (*ii*) mechanism presents serious difficulties.

Similarly we find that our results for the reactions of saturated tertiary alkylamines with **1** and **3** also lead to difficulties when interpreted in terms of the case (*ii*) mechanism. From the k_{NS} values, particularly, we note the following. (*a*) For the reaction of **1** with quinuclidine k_{NS} is about the same (or, if anything, smaller) than that with trimethylamine, implying a Brønsted exponent of zero (or possibly lower) for the attack of these amines at a sulfonyl sulfur; this, of course, is quite different from $\beta_{nuc} = 0.45$, already mentioned, for the attack of pyridine bases on arenesulfonyl chlorides (34). (*b*) The k_{NS} values for **1** are substantially greater than those for **3**, by factors of 49, >285, and 15 for Me_3N, Et_3N, and quinuclidine, respectively.[8] We can remove the somewhat remote possibility that these differences reflect significant electronic effects by extracting steric factors, SF_{NS}, (from k_{NS} values for the three amines as already described); the SF_{NS} so obtained are 0.07 for the reaction of triethylamine with **1** and <0.005 for that with **3**. Such an increase in steric retardation of the reaction at sulfur of more than 14-fold on going from **1** to **3** seems difficult to explain and begs an alternative explanation.

Analysis of the kinetic and product composition data on the basis of the case (*i*) mechanism, on the other hand, gives apparently reasonable values both for the Brønsted exponents (0.30 and 0.32 for the pyridine bases and 0.37 and 0.41 for the saturated amines, as given above) and also for the rate constant ratios deduced from *p* discussed later in this paper. We were thus led to conclude that the above results argued strongly against the CNC process and in favour of the VNC mechanism for formation of **10** (and **12** and **14** also). But, since the latter was an unprecedented mechanism, we felt that further evidence would be desirable, and to this end we turned to one of the classic arguments of chemistry, viz., that a postulated intermediate, however generated, must give the same products under the same conditions. As our source of **16**, the presumed intermediate from **1**, we turned to the chlorosulfonylammonium salt **18***a*, which had already been prepared by Dr. Sheena Loosmore in these laboratories.



18
a **X = H**
b **X = Me**

Preparation and reactions of N-*(2-chlorosulfonylethyl)pyridinium chloride (18*a)

The salt (**18***a*) was prepared simply by adding a methylene chloride solution of **1** to a solution of pyridinium chloride and collecting the crystals. The mode of synthesis, taken with (*i*) satisfactory elemental analyses and (*ii*) appropriate ^{1}Hmr and infrared spectra (see Experimental), suffices to identify this material as **18***a*. Similar reaction of **1** and 4-picolinium chloride gave crystalline **18***b*.

Reaction of **18***a* with pyridine in 0.1 *M* aqueous KCl at pH 4.0 gave an 83:17 ratio of the betaine (**9**, X = H) and the ethenesulfonate salt (**10**, X = H). The concentration of pyridine in this reaction ($B_T = 0.5$ *M*, [B] = 0.021 *M*) was such that virtually all (99%) of the product would be expected to arise from the amine-induced reaction, and hence to a fair approximation $q = q' = 0.83$. On comparison with q' values given in Table 2 it is clear that the value from **18***a* is indistinguishable from those from **1**. In D_2O (0.1 *M* in KCl) at apparent pH 4.0, **18***a* and pyridine ($B_T = 2.5$ *M*) gave a mixture containing monodeuterated betaine (>95% $PyrCH_2CHDSO_3^-$) and undeuterated ethenesulfonate salt, corresponding to $q = 0.76$. Ethenesulfonyl chloride (**1**) in 0.1 *M* KCl in D_2O at apparent pH 3.4 ($B_T = 0.5$ *M*) gave similarly monodeuterated betaine and undeuterated salt with $q = 0.70$. With the 4-picoline analogue (**18***b*), similar reaction with 4-picoline ($B_T = 0.62$ *M*) gave the betaine (**9**, X = 4-Me) and the ethenesulfonate salt (**10**, X = 4-Me) in a 92:8 ratio: q' for 4-picoline (Table 2) is 0.88. Scheme 4 summarizes pathways consistent with these observations. To the extent that the products from **18** and **1** differ at all, the former appear to show more betaine (**9**) and the latter more of the salt (**10**), as would be expected from incursion of a small proportion of the DDS

[8] For comparison we note, in addition to those in Table 1, the following rate constants: (*a*) for solvolysis at 25.0°C in H_2O–dioxane (20:80) $MeSO_2Cl$ 14.8×10^{-6}, $EtSO_2Cl$ 13.0×10^{-6}, $PrSO_2Cl$ 11.2×10^{-6}, and Bu^iSO_2Cl 7.49×10^{-6} s^{-1} (35); (*b*) for reaction in methanol of $PhSO_2Cl$ and *p*-$MeC_6H_4SO_2Cl$, respectively, with pyridine (at 25.0°C) 2.51×10^{-2} and 2.06×10^{-2} M^{-1} s^{-1} (36), and with aniline (at 35.0°C) 10.6×10^{-2} and 7.85×10^{-2} M^{-1} s^{-1} (9). The effect of replacing a hydrogen by a methyl group is small in each case.

20 **21**

reaction (either uncatalyzed or general base catalyzed) shown by the horizontal dotted arrows in Scheme 4, but in the light of similarity of the products from **1** and **18** we conclude that the reactions shown by the horizontal dotted arrows are at most only minor contributors (<3%) to the reactions of **1** or **18** with aqueous pyridine bases under our conditions.

The two vertical dotted arrows in Scheme 4 describe the conversion of **1** to **18** and vice versa, two essentially trivial processes which could also, however, lead to common products from **1** and **18**. The first of these, **1** → **18***a*, is easily excluded by the results already described for the reaction in D_2O, the products of which were undeuterated ethenesulfonate salt (**10**) and the monodeuterated betaine. If **1** were indeed to form **18***a*, then in D_2O it would have to be largely monodeuterated, i.e. $Pyr^+CH_2CHDSO_2Cl\ Cl^-$ (**19**), which in turn would be expected to give some α-dideuterated betaine. We have, in fact, prepared a sample of **19** and found that it does give such products; their absence in the product of the reaction of **1** in D_2O therefore excludes the reaction **1** → **18** in the conversion to **9** and **10**.

The alternative possibility, **18***a* → **1**, was excluded by preparing **20**, by using pyridinium-d_5 chloride in place of ordinary pyridinium chloride. Reaction of **20** with ordinary pyridine (>200-fold excess) in water gave the betaine-d_5 (**21**) and **10** (81% and 19%, respectively). Any conversion of **18** to **1** would simply mix a little pyridine-d_5 with a much larger amount of ordinary pyridine and further reaction of the **1** so obtained would give almost entirely **9** (X = H) rather than **21**. Since even a small amount (<5%) of **9** (X = H) would have been readily seen by ^{1}Hmr, we conclude that there is no significant formation of **1** from **18** either, and hence that none of the reactions indicated by dotted arrows in Scheme 4 are important in the reaction of **1** or **18** with aqueous pyridines. We conclude that the hitherto unrecognized vinylogous nucleophilic catalysis mechanism must be regarded as the only important pathway consistent with our observations on the conversion of **1** to **10** and **3** to **12**. In the light of the evident similarity of these reactions to those of the saturated tertiary amines, it seems highly likely that the latter reactions leading to **14** also proceed by way of the VNC route.[9]

Further mechanistic points

(a) The sulfene formation

More detailed consideration raises the two additional questions of the mechanisms of formation and trapping of the sulfene (**16**). Extensive study of the generation of sulfenes by way of elimination reactions from alkanesulfonyl chlorides, aryl alkanesulfonates, and alkyl α-disulfones (12–16, 37, 38), has shown some of these reactions to proceed via α-sulfonyl carbanions (E1cB reactions, both reversible and irreversible) and some also very likely by a concerted elimination process in which there is a sizeable buildup of negative charge on the α-carbon in the transition state (E1cB-like E2). With this in mind it would appear likely that reaction of **1** with tertiary amines might also take place either by way of the analogue of the discrete carbanion, namely the zwitterion **22** (Z = Cl), or

$$R_3\overset{+}{N}CH_2\bar{C}HSO_2Z$$

22

in a one-step concerted but nonsynchronous displacement in which there is a considerable accumulation of negative charge on C-1. It should be noted that the conformation of the putative zwitterionic intermediate (**22**, Z = Cl) in which the chlorine and nitrogen atoms are *syn* to each other has a particularly favourable arrangement leading to stabilization of the lone pair of electrons by the anomeric effect (39–42).[10] This conformation is very close to that expected for the transition state of a concerted (but not necessarily fully synchronous) *syn* S_N2' displacement and, in the light of the extensive studies on allylic systems which have concluded that the favoured stereochemistry with uncharged nucleophiles is also *syn* (44–47, and refs. cited), we find it particularly easy to imagine, for the formation of **16** from **1**, a family of closely related mechanisms with very similar geometry and differing only in the extent by which C—N bond formation precedes S—Cl bond breakage. From the evidence for considerable buildup of negative charge on the α-carbon in sulfene formation from phenylmethanesulfonyl chloride (48), we are inclined to expect a considerable negative charge on C-1 in the **1** → **16** conversion, but whether or not this actually leads to formation of **22** (Z = Cl) as a discrete intermediate, we are unable to determine at this stage.

(b) Trapping of the sulfene

In contrast to formation of the sulfene (**16**), however, trapping of **16** shows features which incline us in favour of a stepwise mechanism as shown in Scheme 5. Formation of two

[9] The value of SF_p for the reaction of **1** with diisopropylethylamine is tentative (see Table 5, footnote *f*) but, if real, would seem sufficiently different from the other SF_p values listed in Tables 4 and 6 as to suggest that the observed weakly catalytic effect of the base may not derive from VNC at all but rather from another process, e.g. general base catalysis, a process in which steric factors are less important than nucleophilic catalysis (33); reaction in D_2O–DME (80:20) showed no sign of deuterium uptake in the ethenesulfonate anion, showing that the cumulated sulfene (**2**) could not be an intermediate even with this highly hindered amine.

[10] The influence of the ammonio group in stabilizing the negative charge in **22**, though smaller than that of the sulfonyl function, would appear to be considerable. Thomas and Stirling (43) estimate that hydrogen exchange in sulfones of the type $PhSO_2CH_2CH_2Z$ proceeds about 10^8 times faster when Z = Me_3N^+ than when Z = H (with EtONa in EtOH at 25°C). Although we know of no experimental demonstration of the geometrical requirements of this stabilization of negative charge, it seems highly likely from the obvious similarity of the $\bar{C}—CN^+R_3$ system to those that show the anomeric effect that an effect of this magnitude should have similar origins and the corresponding preferred periplanar orientation of the free electron pair and the C—N bond.

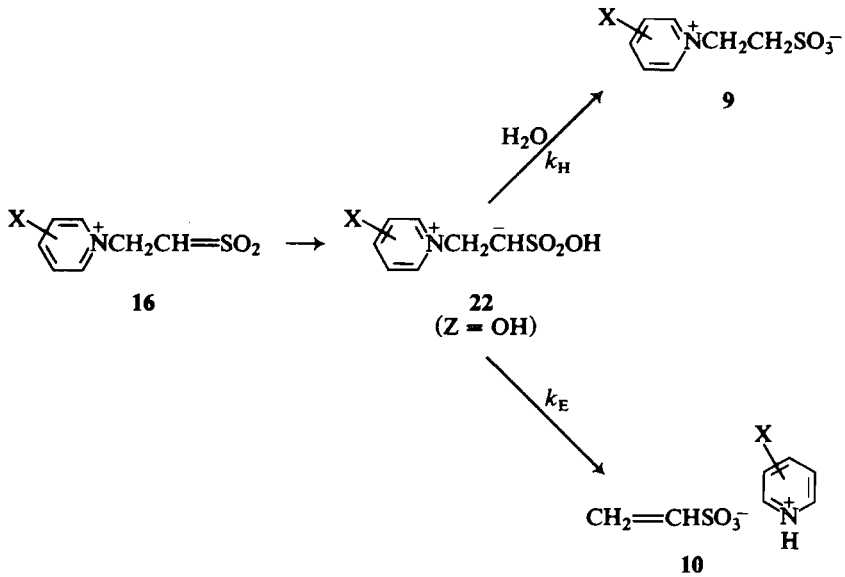

SCHEME 5

products (e.g. **9** and **10**) from a common species requires that that species (**22**, Z = OH, in this case) be a discrete intermediate and the product ratio (**10**/**9** = p, see Table 4) therefore reflect the relative rates of the unimolecular elimination to form **10** and proton uptake to give **9**. From our observation that the product ratio is insensitive to change in either pH or the concentration of pyridine or pyridinium ion (see Table 2, compare also Table 5), it would appear that the proton required to form **9** comes from neither H_3O^+ nor the pyridinium ion and so must be provided by the water, as shown. The ratio of the two rate constants is simply given by the product ratio, i.e. $p = k_E/k_H$. A plot of log p for the reaction of **1** vs. the pK_a of the unhindered pyridine bases gives a fair straight line corresponding to the expression $-0.31\ pK_a' + 1.05$, while for the corresponding reaction of **3** we obtain, similarly, $-0.31\ pK_a' + 1.42$ (with $r = 0.984$ and 0.994, respectively). The similarity of the slopes of these lines points to very similar charge development in the transition states for trapping of **16** and the sulfene from **3**. The difference in product ratios from **1** and **3** is therefore evidently associated with the vertical displacement of these parallel lines, which is reasonably assigned to a two- to three-fold steric acceleration of elimination by the methyl group. The deviations of p for the "hindered" bases from the pattern of the "unhindered" bases are given in Table 4 by the SB_p values, which, in full accord with this steric acceleration picture, are all greater than 1.0.

The mechanism in Scheme 5 is also consistent with the lower proportion of betaine (73 ± 3%) formed in D_2O than in H_2O (82 ± 2%). If we make the reasonable assumption that the kinetic solvent isotope effect for formation of **10** from **22** (Z = OH) is negligible, then this difference can be ascribed largely to a primary kinetic isotope effect in the trapping of **22** (Z = OH) to form the betaine (**9**). The kinetic isotope effect so obtained (1.7 ± 0.5) agrees with the value (1.9 ± 0.1) observed in these laboratories for the competitive trapping of sulfene (from methanesulfonyl chloride and triethylamine) with a mixture of H_2O and D_2O (J. D. Lock, unpublished observations). We note, on the basis of the mechanism in Scheme 5, that these observations define a rather narrow range for the rate of the protonation of **22** (Z = OH) by water and hence of the elimination to form **10** as well. This may be seen as follows. The specific rate of protonation of $(PhSO_2)_2CH^-$ with H_3O^+ (at 25°C, in 0.1 M aqueous HCl) is reported to be $2.1 \times 10^{10}\ M^{-1}\ s^{-1}$ (49), and it is likely that for the same reaction of **22** (Z = OH), which must be a stronger base, the rate constant will also be $>10^{10}\ M^{-1}\ s^{-1}$; at pH 3.0 the pseudo-first-order rate constant will thus be $>10^7\ s^{-1}$ and, since this reaction is not in evidence, the postulated reaction with water must be faster yet, i.e. have a rate constant $>10^8\ s^{-1}$. At the same time, however, both the protonation and the elimination, though very fast, show (*a*) a hydrogen isotope effect, and (*b*) normal β and SF_p values, thereby indicating that these processes are not in general occurring at the maximum rates, which are controlled by vibration or solvent-relaxation limits and at which such selectivity would be expected to disappear.

Instead of the mechanism in Scheme 5, however, it is also possible to imagine a pathway in which the two products **9** and **10** are formed from **16** by two quite separate processes. For example, attack on the sulfene (**16**) in a conformation in which the ammonio group and the attacking molecule of water are more or less *syn* to each other might permit a concerted displacement to form **10**, whereas reaction of the sulfene **16** in another conformation might well lead to the betaine (**9**). A concerted *trans* elimination is also conceivable but, to the extent that the S_N2' displacement on **16** would be expected to follow the pattern of the S_N2' reaction of neutral nucleophiles with simple allylic systems (as mentioned above), the *syn* process is the more likely. Inspection of molecular models suggests that such a *syn* orientation of nucleophile and nucleofuge will lead to increasing nonbonding repulsions with increase in the number and size of the 2- (and 6-) substituents, and hence, if the nucleophilic displacement step determines the rate of formation of **10** relative to **9**, then this picture predicts that p will decrease as the "size" of the amine increases. It is evident from Table 4, however, that this is contrary to experiment, with the "larger" bases giving *larger* values of p. The discussion in this paragraph has assumed that interconversion of the conformations of **16** is fast relative to their further reaction; the alternative possibility in which the conformational interconversion is relatively slow is also conceivable, but would appear unlikely since it does not readily account for the kinetic isotope effect (1.7 ± 0.5) noted above.

We therefore conclude that the simplest mechanism consistent with our observations on both the pyridine bases and the saturated tertiary amines is that shown in Scheme 5, in which trapping of the cationic sulfene (e.g. **16**) proceeds in a two-step process via a discrete zwitterionic intermediate (**22**). It is tempting to extend this picture and to suggest that trapping of neutral sulfenes in hydroxylic media to form sulfonic acids or esters takes place analogously, i.e. by way of the corresponding discrete intermediate carbanion.

(c) Related work and comments

Finally, we recall that in our communications (17, 18) we pointed to the likelihood that vinylogous nucleophilic catalysis would show up in other systems, and we are gratified to note that this prediction would appear to have been fulfilled for the α,β-unsaturated carbonyl system by the reports of Inoue and Bruice (50, 51) describing their work on what they term an "extended E1cB mechanism" in the hydrolysis of *p*-nitrophenyl 2-cyano-3-(*p*-methoxyphenyl)propenoate.[11] These authors, in addition to reporting their own studies, comment on the mechanism of the formation of the sulfene (**16**), stating that they "believe that this reaction also proceeds by the stepwise mechanism as is shown in this paper (i.e. nucleophilic attack of pyridine on the double bond to yield a carbanion (betaine) followed by departure of the leaving group (chloride))" (51). Inoue and Bruice do not detail the basis of this comment but if, as seems possible, it is influenced by their experience with their own system in which the leaving group is *p*-nitrophenoxide, than it may be appropriate to recall the differences that have been noted in sulfene formation by elimination when the leaving group, Z, in $PhCH_2SO_2Z$ is changed. With Z = *p*-nitrophenoxy the reaction is $(E1cB)_R$ or $(E1cB)_I$ depending on reaction conditions and with Z = 2-chloro-4-nitrophenoxy the mechanism was found to be clearly $(E1cB)_I$ (37, 38); but with Z = Cl the situation is less clear (53), though published evidence favours an E1cB-like E2 process (48). As we have already noted, we feel that the question of stepwise vs. concerted formation of **16** cannot be settled with the evidence at hand, and the belief announced by Inoue and Bruice (51), though possibly correct, is at present without visible scientific basis.

Experimental

Proton magnetic resonance (^{1}Hmr) spectra were recorded using Varian T-60, HA-100, and XL-100 spectrometers; unless otherwise stated, all δ values reported were recorded from spectra obtained on the XL-100 or HA-100 spectrometers; ^{13}Cmr spectra were determined on a Varian XL-200 instrument. Spectra of deuterochloroform (Merck, Sharp and Dohme Ltd.) and nitromethane-d_3 (Aldrich, 99 at.% D) solutions were calibrated with tetramethylsilane (TMS, Merck, Sharp and Dohme), those in deuterium oxide (D_2O, Merck, Sharp and Dohme) with either sodium 3-(trimethylsilyl)propionate (TSP, Aldrich) or sodium 3-(trimethylsilyl)propanesulfonate (DSS, Aldrich). Infrared (ir) spectra were recorded on Perkin–Elmer 621 or Beckman 4250 spectrometers using sodium chloride or potassium bromide cells; all ir spectra were calibrated with a polystyrene reference film. All melting points were obtained on a Gallenkamp melting point apparatus, and are uncorrected. Refractive indices were determined on a thermostatically controlled Bausch and Lomb Abbé refractometer.

1,2-Dimethoxyethane (DME) (Eastman) and methylene chloride (Fisher) were dried by distillation from calcium hydride (Fisher) and stored over molecular sieves (3 Å grade 564, 8–12 mesh). All other solvents and reagents used were reagent grade and used as supplied unless otherwise specified. Rexyn 300 (H-OH) deionizing resin (Fisher) was used as supplied, usually in excess. Standard sodium hydroxide and hydrochloric acid solutions were prepared volumetrically from sodium hydroxide solution concentrate, *N*/1 or *N*/10 (Fisher). For a few kinetic determinations the titrant used was prepared from sodium hydroxide electrolytic pellets (Fisher); identical rate constants were obtained from titrant solutions prepared by either method.

Methylene chloride and ether extracts were dried over anhydrous magnesium sulfate (Fisher, certified grade) prior to evaporation. The spinning band distillation apparatus was a Nester/Faust model NFT50 (Nester/Faust Manufacturing Corp., Newark, Delaware) equipped with a 24-in. Teflon spinning band.

Ethenesulfonyl chloride (**1**) was prepared from 2-chloroethanesulfonyl chloride and triethylamine (54) and further purified by fractional distillation under reduced pressure (1.5 Torr, bp 25°C; (1 Torr = 133.3 Pa)) using the spinning band apparatus. The ^{1}Hmr ($CDCl_3$) spectrum showed an ABC multiplet which was reproduced within experimental uncertainty on computer simulation with the following parameters: δ_A 6.25 (H *trans* to SO_2Cl), δ_B 6.54 (H *cis* to SO_2Cl), δ_C 7.04 (CH); J_{AB} = −1.4 Hz, J_{AC} = 9.3 Hz, J_{BC} = 16.1 Hz); ir (CH_2Cl_2) ν_{max}: 3115 (w), 3075 (m), 1380 (vs), 1170 (vs), 980 (s), 940 (m), 650 (s) cm^{-1}; n_D^{20} 1.4681 (lit. (19), n_D^{20} 1.4686). *trans*-1-Propene-1-sulfonyl chloride (**3**) prepared from 2-chloropropane-1-sulfonyl chloride (55) by the method of Rondestvedt and Chang (56) consistently showed in the ^{1}Hmr spectrum (*a*) an ABX_3 pattern consistent (computer simulation) with δ_A 7.14, δ_B 6.80, δ_X 2.05, J_{AB} 14.9, J_{AX} 7.1, and J_{BX} −1.7 Hz, the *trans* stereochemistry being assigned from the large J_{AB}, and (*b*) the presence of a second set of signals at (T-60) 2.2 ("d", 3H), 6.0 (m, 1H), and 6.3 ppm ("s", 1H), J_{XY} = 2 Hz, attributed to the presence of a small amount (about 3 to 10% in different preparations) of 1-propene-2-sulfonyl chloride. Spinning band distillation (15 Torr, bp ~70°C) gave a clean material showing only the above signals assigned to **3** in the ^{1}Hmr spectrum and the following peaks in the ir (CH_2Cl_2), ν_{max}: 3060 (w), 1635 (m), 1435 (m), 1375 (vs), 1295 (w), 1170 (s), 945 (s), 805 (s) cm^{-1}.

3,4-Dimethylpyridine, 3,5-dimethylpyridine, 4-methylpyridine, 4-ethylpyridine, 3-methylpyridine, methyl 4-pyridinecarboxylate, and pyridine were obtained commercially and were all fractionally distilled at atmospheric pressure before use. 3-Carbamoylpyridine (nicotinamide) was recrystallized from benzene (mp 128–129°C, lit. (57) mp 128°C). Commercial samples of 2-ethylpyridine, 2-methylpyridine, and quinoline were purified through their picrate salts and fractionally distilled (57–59). 2,6-Dimethylpyridine and 2,4,6-trimethylpyridine were treated with 5 mol% of dimethyl sulfate overnight; the mixture was filtered and fractionally distilled. 3-Ethanamidopyridine was prepared from 3-aminopyridine and acetic anhydride (60) and recrystallized (benzene), mp 133–134.5°C; lit. (60) mp 133°C. 3-Cyanopyridine was made from nicotinamide with P_2O_5 and purified by vacuum distillation; mp 49.5–51°C, lit. (61) mp 50–51°C.

The purity of the hindered pyridines was checked by performing a reaction with the base and ethenesulfonyl chloride (**1**), using initial sulfonyl chloride concentrations at or near those employed in the kinetic runs. The ^{1}Hmr spectra of the crude reaction products (occasionally the crude products were treated with Rexyn 300 (H-OH) deionizing resin to remove all ions except the betaine) were then compared with ^{1}Hmr spectra of authentic samples of the pyridine betaines; the base was deemed sufficiently pure when no signals due to betaines other than the one corresponding to the pyridine employed were visible.

[11] We are, however, surprised by Inoue and Bruice's suggestion that conversion of the enolate to the ketene requires that the enolate assume an "energetically unfavorable conformation... wherein the delocalization energy of the enolate anion system is lost" (51). Such a twisting of the carbon–carbon double bond of the enolate would seem to us to be so "unfavorable" as to be impossible, and it is puzzling that the authors do not indicate why they prefer this unlikely process to the straightforward extrusion of aryloxide with the assistance of the appropriately oriented electron pair on the enolate (charged) oxygen as described by Farrar and Williams (52).

Quinuclidine (Aldrich) was recrystallized from petroleum ether and stored under nitrogen. Trimethylamine was used as supplied by Eastman Kodak Company. All other aliphatic tertiary amines were dried over CaH_2 and freshly distilled.

*Preparation of substituted pyridine betaines from ethenesulfonyl chloride (**1**) and* trans-*1-propene-1-sulfonyl chloride (**3**)*

The substituted pyridine betaines were prepared according to the method of Le Berre *et al.* (62) in glacial acetic acid. The reactions of **1** were worked up after 2–3 h at room temperature, the last traces of acetic acid being removed by azeotroping with toluene. The residue was recrystallized from 95% alcohol unless otherwise specified. The yields of betaines (**9**) obtained in this manner were in the range 50–90%, depending upon the nucleophilicity of the base employed (hindered pyridines generally gave lower yields, sometimes <50%). For the reaction with **3**, the reactions were usually allowed to stand at room temperature overnight before work-up. The elemental analyses (where the compound was previously unknown) and the physical properties of these compounds are given in Tables 7 and 8.

Preparation of the betaines of the aliphatic amines

To a mixture of triethylamine (5 g, 50 mmol) and water (15 mL) stirred in an ice bath, 2-hydroxyethanesulfonyl chloride (31) (1.735 g, 12 mmol) was added dropwise slowly and the contents stirred for 0.5 h at room temperature. The solution was then extracted four times with methylene chloride (25-mL portions), and the aqueous phase was concentrated to ~5 mL under reduced pressure and passed through a column of deionization resin (Rexyn 300 (H-OH), Fisher). 2-(*N,N,N*-Triethylammonio)ethanesulfonate was obtained as a colorless crystalline solid (341 mg, 13.5%) and recrystallized from 95% ethanol, mp 294–296°C (dec.). All spectroscopic data were identical with those reported earlier (31).

Reactions of 2-hydroxyethanesulfonyl chloride with diethylmethylamine, dimethylethylamine, trimethylamine, and quinuclidine were carried out in the same manner with yields of 19, 23, 28.5, and 34%, respectively. Similarly, 1-propene-1-sulfonyl chloride (**3**) gave betaines with trimethylamine and quinuclidine in 8.5% and 17.5% yields, respectively. Analytical and spectroscopic data for these betaines are summarized in Table 9.

*Procedure for determining the products of the uncatalysed solvolyses of ethenesulfonyl chloride (**1**) and* trans-*1-propene-1-sulfonyl chloride (**3**) at 25.0°C*

A solution of the sulfonyl chloride in ~0.5 mL DME (sufficient to give an initial concentration of the sulfonyl chloride in the range $1.6 \times 10^{-3} - 2.9 \times 10^{-2}$ *M*) was injected into a stirred solution of potassium chloride in water or D_2O (50 mL) at 25.0°C at the desired pH. The pH was maintained until the addition of titrant had stopped. For those reactions performed above pH 7, the reaction was then neutralized to pH 7 with dilute HCl solution. The solvent was then evaporated to dryness, and the composition of the residue determined by integration of the peaks corresponding to the methylene protons of the hydroxyalkanesulfonate anion and the characteristic vinyl protons of the alkenesulfonate anion. The product from one run (at pH 4.0; starting with 0.20 g, 1.6 mmol, of ethenesulfonyl chloride) was dissolved in hot water (5 mL) and *S*-benzylthiuronium chloride (0.32 g, 1.6 mmol) in water (5 mL) added. The crystalline precipitate was recrystallized from 95% alcohol, mp 145–146.5°C; reported (64) for benzylthiuronium ethenesulfonate, mp 145–146°C.

*General procedure for determining the product composition for reactions of **1** and **3** with substituted pyridines in water containing 0.1* M *potassium chloride*

The reaction products (and their relative proportions) for the reactions at 25°C of **1** and **3** with substituted pyridines were determined using initial concentrations of sulfonyl chloride in the range $1.0 - 16 \times 10^{-3}$ *M*. Where possible, a sufficient amount of the substituted pyridine base was employed in these reactions to ensure pseudo-first-order conditions, and to exceed the uncatalysed hydrolysis reaction of **1** or **3** by a factor of at least 50 (so that the relative proportions of the products would not be subject to large corrections for the presence of any alkenesulfonate anion derived from the uncatalysed hydrolysis reaction). After completion of the reaction, the pH was normally raised to at least one pH unit above the apparent pK_a of the substituted pyridine, and the solution extracted with ether. Evaporation of the aqueous layer gave a residue the ^{1}Hmr spectrum (D_2O) of which was compared with authentic spectra of the pyridine betaines **9** and **11** and alkenesulfonate anions **10** and **12**. Integration of the methylene protons of the betaine and the olefinic protons of the alkenesulfonate anion gave the relative proportions of the products expressed as the "betaine fraction", or q value (q = % betaine/(% betaine + %alkenesulfonate anion)) (see Tables 2 and 4); these were also corrected for the generation of any alkenesulfonate anion derived from any uncatalysed hydrolysis reaction and listed as the q' values.

For the specific case of the reaction of **1** with pyridine the betaine was isolated and identified as follows. Ethenesulfonyl chloride (**1**) (0.065 g, 0.52 mmol) was allowed to react with a solution of pyridine (1.0 mL, 125 mmol) in water (50 mL) containing potassium chloride (0.400 g, 5.36 mmol) at 25.0°C and pH 4.0. After the reaction was judged to be complete, the pH was raised to 7.0 and the aqueous solution extracted several times with ether. The aqueous layer was then evaporated to dryness, dissolved in 1–2 mL of water, and passed down a column containing Rexyn 300 (H-OH) deionizing resin. Evaporation of the eluant gave **9** (X = H) as a colorless residue (80 mg) which was recrystallized from 95% alcohol. The mp, mixture mp (255–257°C), and the ^{1}Hmr spectrum (D_2O) of this material were identical with those of an authentic specimen of **9** (X = H) (21).

Kinetic determinations

The pH-stat apparatus has been described (31). A typical rate measurement was carried out by injecting (from a 100-μL syringe) a 100-μL aliquot of a solution of **1** or **3** in dry DME into the reaction solution (50 mL of water containing 0.40 g of KCl, plus amine where appropriate) previously brought to the desired pH and temperature; initial concentrations of the sulfonyl chloride were in the range $4 \times 10^{-4} - 3 \times 10^{-3}$ *M*. The rate of reaction was followed by recording the volume of sodium hydroxide solution with time. Due care was taken to avoid very low pH's and buffered solutions. Half-lives varied from 0.25 min to several hours, with most in the range 0.5 – 10 min. The slopes of the best straight line fit for a plot of log $(V_\infty - V_t)$ vs. time gave the (pseudo) first-order rate constant. The concentrations of free base used to obtain k_B from k_ψ from the amine reactions were calculated from the apparent pK_a' values of the amines obtained from the half-neutralization point from a titration of the base with 1.0 *M* HCl in 0.1 *M* KCl, with appropriate correction for hydrolysis for bases with pK_a's below 4.0.

*Composition of the products of the reaction of the saturated tertiary amines with **1** and **3** in 0.1* M *aqueous KCl*

(a) ^{1}H magnetic resonance identification

Ethenesulfonyl chloride (**1**) (55 mg, 0.435 mmol) was dissolved in dry DME (0.5 mL) and 30 μL of the solution was injected into a triethylamine solution (50 mL, 0.08 *M* triethylamine, 0.1 *M* KCL in H_2O, 1°C). The pH was maintained constant (pH = 7.5) in a pH-stat apparatus with 0.1 *M* sodium hydroxide titrant. About every 20 min (roughly 3–4 half-lives) another 30 μL of the ethenesulfonyl chloride solution was added till the addition was completed. Reaction was judged complete when no further addition of titrant was observed during 10 min (total 8.70 mL of titrant was used; calculated for 2 equiv of the substrate, 8.70 mL). The pH then was raised to ca. 11.3 and the aqueous solution extracted three times with ether (100-mL portions), neutralized with 1 *M* HCl, and water evaporated. The solid residue was dissolved in D_2O; the ^{1}Hmr spectrum indicated that the reaction products consist of only two compounds: the ethenesulfonate salt (**14**, R = Et, R′ = H) and the triethyl betaine (**13**, R = Et, R′ = H) (54% and 46% as judged from integration of the peaks at 5.80–6.90 ppm and 1.25–1.35 ppm, respectively).

(b) Isolation of the betaines

Ethenesulfonyl chloride (**1**) (70.5 mg, 0.557 mmol) dissolved in dry DME (0.8 mL) was hydrolyzed in the presence of triethylamine as

described above. The aqueous solution containing hydrolysis product was concentrated and passed through the Rexyn 300 (H-OH). A crystalline product, 53.5 mg, was isolated, the mp and ^{1}Hmr and ^{13}Cmr spectra of which were identical with those of authentic *N,N,N*-triethylammonium-2-ethanesulfonate (**13**, R = Et, R′ = H). The yield of the betaine (46%) was identical to that determined by ^{1}Hmr integration.

All other betaines obtained in the hydrolysis reactions were isolated and identified in the same manner and the yields (expressed as *q* values) are summarized in Tables 5 and S4). In the case of the reaction of **1** in the presence of *N,N*-diisopropylethylamine and of **3** in the presence of triethylamine no betaines were isolated by this procedure, even with the total amounts of starting material doubled.

Preparation and reactions of N-*(2-chlorosulfonylethyl)pyridinium chloride (**18**a)*

Ethenesulfonyl chloride (**1**) (1.7 g, 13.4 mmol) was added dropwise over 1 min to freshly prepared pyridine hydrochloride (1.6 g, 14 mmol) dissolved in dry methylene chloride (20 mL). The immediately formed colorless precipitate was filtered in the cold and washed with pentane, yield 2.4 g (72%); mp 103–105°C; ir (Nujol) ν_{max}: 1640 (m), 1495 (m), 1376 (s), 1168 (s), 835 (w), 775 (m), 667 (s) cm^{-1}; ^{1}Hmr (CD_3NO_2) δ: 5.02 (t, 2H), 5.57 (t, 2H), 8.26 (m, 2H), 8.76 (t, 1H), 9.40 (d, 2H). *Anal.* calcd. for $C_7H_9Cl_2NO_2S$: C 34.72, H 3.75, Cl 29.28, N 5.79, S 13.22; found: C 34.97, H 4.03, Cl 29.32, N 5.71, S 13.09.

The sulfonyl chloride (**18***a*) (90 mg, 0.37 mmol) was added to an aqueous solution (50 mL) of KCl (0.400 g, 5.36 mmol) at pH 4.0 (pH-stat, 1.0 *M* NaOH) and 25.0°C. After 1 h the solvent was evaporated and the residue investigated by ^{1}Hmr spectroscopy, which indicated the presence of **9** (X = H) (88%) and **10** (X = H) (12%). Under the same conditions **18***a* (X = H) (0.15 g, 5.6 mmol) with pyridine (2.0 mL, 24.8 mmol) as above gave, after acidification to pH 7.5 and washing with ether and evaporation of the water, a product shown by ^{1}Hmr to contain **9** (X = H) (83%) and **10** (X = H) (17%).

In D_2O (50 mL, 0.1 *M* KCl, no pyridine) **18***a* (X = H) (38 mg, 0.16 mmol) similarly gave pyridine betaine **9** (X = H) (86%) (~80% $Pyr^+CH_2CHDSO_3^-$, ~20% $Pyr^+CH_2CH_2SO_3^-$) and **10** (X = H) (14%, undeuterated). In the presence of pyridine (10 μL) in D_2O (50 mL, with KCl, 0.400 g) as before, the ^{1}Hmr of the product showed **9** (X = H) (75%, >95% $Pyr^+CH_2CHDSO_3^-$) and **10** (X = H) (25%, undeuterated).

Preparation and reactions of deuterated N-*(2-chlorosulfonylethyl)-pyridinium chlorides **19** and **20***

Pyridine deuterochloride (400 mg, 3.4 mmol), prepared by bubbling DCl gas (generated by addition of oxalyl chloride to D_2O) into a solution of pyridine in benzene, was dissolved in dry CH_2Cl_2 (10 mL) and **1** (0.5 mL, 5.4 mmol) was added dropwise over 1 min. The immediately formed colorless precipitate of **19** was collected by filtration in the cold, washed with CH_2Cl_2, and used as such (500 mg, 60%); the ^{1}Hmr spectrum (DMSO-d_6) indicated >64% α-monodeuteration (—$CHDSO_2Cl$). Sulfonyl chloride **19** (150 mg, 0.62 mmol) was added to a stirred solution of pyridine (1.0 mL, 12.5 mmol) and KCl (400 mg, 5.36 mmol) in D_2O (50 mL) at pH (meter reading) 3.4 and 25.0°C in the pH-stat, with the pH maintained constant with 2.5 *M* NaOD in D_2O. After 1 h the pH was adjusted to 7.0 and the mixture worked up as before. The ^{1}Hmr spectrum (D_2O) of the residue showed the presence of partially deuterated pyridinoethanesulfonate and ethenesulfonate anion (product ratio 75:25), with the relative areas of the ^{1}Hmr signals due to the protons on C-1 and C-2 being, respectively, 0.5:2.0 and 0.6:2.0.

Pyridine-d_5 hydrochloride (550 mg, 4.58 mmol), freshly prepared as above from pyridine-d_5 (Merck, Sharp and Dohme) and gaseous HCl in CH_2Cl_2 (15 mL), with **1** (575 mg, 4.54 mmol) as above except that the precipitate was washed with pentane, gave **20** (470 mg, 42%); ^{1}Hmr (T-60, CD_3NO_2) δ: 5.0 (m, 2H) and 5.3 (m, 2H) with no signals in the range 8–10 ppm. This material (**20**, 160 mg, 0.65 mmol) was added to a stirred solution of pyridine (2.0 mL, 24.9 mmol) and KCl (400 mg, 5.36 mmol) in water (50 mL) at pH 4.0 and 25.0°C in the pH-stat with 0.1 *M* NaOH as titrant. After 2 h the pH was adjusted to 7.5 and worked up as above; the ^{1}Hmr spectrum (D_2O) showed the presence of the betaine (**21**) and ethenesulfonate salt (**10**) (relative proportions 81:19), plus peaks in the range 8–10 ppm ascribable to the pyridinium cation ($C_5H_5\overset{+}{N}H$). Further washing with ether (×5) removed all signs of this ion, leaving the characteristic peaks due to **21** and **10** with no absorption at all in the range (8.0–10.5) expected for the aromatic hydrogens in **9** (R = H); passage through a deionizing resin removed the olefinic signals due to **10**, leaving only the strong upfield triplets of **21** with no sign of aromatic hydrogens.

*Preparation and reactions of 4-methyl-*N-*(2-chlorosulfonylethyl)-pyridinium chloride (**18**b)*

Freshly prepared 4-picoline hydrochloride (1.0 g, 7.7 mmol) in dry CH_2Cl_2 (20 mL) and **1** (1.0 g, 7.9 mmol) as with preparation of **20**, gave **18***b* (1.5 g, 76%), mp 80–85°C (sealed tube); ir (CH_2Cl_2) ν_{max}: 3025 (w), 2940 (w), 2860 (w), 1640 (m), 1560 (w), 1475 (w), 1380 (s), 1168 (s), 1035 (w), 820 (w) cm^{-1}; ^{1}Hmr (T-60, CD_3NO_2) δ: 2.7 (s, 3H), 5.0 (t, 2H), 5.5 (t, 2H), 8.0 (d, 2H), 9.1 (d, 2H). A solution of **18***b* in D_2O after standing for 1 h at room temperature showed peaks in the ^{1}Hmr appropriate to the betaine (**9**, X = 4-Me) (>95%) plus a small amount of ethenesulfonate; no sign of deuteration of either product was evident. Sulfonyl chloride **18***b* (100 mg, 3.9 mmol) was added to a solution of 4-picoline (3.0 mL, 31 mmol) and KCl (400 mg, 5.36 mmol) in water (50 mL) at pH 4.0 and 25.0°C, in the pH-stat as above. Work-up after 15 min gave a product shown by ^{1}Hmr to consist of **9** (X = 4-Me) and **10** (X = 4-Me) in the ratio 92:8.

*Ethenesulfonyl chloride (**1**) with tertiary amines in D_2O: reaction products*

(a) Pyridine

A solution of **1** (29 mg, 0.23 mmol) in dry DME (0.5 mL) was injected into a stirred solution of pyridine (2.0 mL, 24.8 mmol) and KCl (400 mg) in D_2O (50 mL) at 25.0°C and pH (meter reading) 3.4, maintained in the pH-stat with 1.2 *M* NaOD in D_2O. After 15 min the pH (reading) was adjusted to 7.0 and the mixture worked up as above. The ^{1}Hmr spectrum (D_2O) of the material so obtained showed the presence of the betaine and ethenesulfonate anion with the ratio ~70:30; the latter showed no sign of deuterium incorporation, whereas the betaine was estimated (by comparison of the integrals of the peaks at 3.5 and 5.0 ppm) to be >90% $Pyr^+CH_2CHDSO_3^-$ (with a small amount of **9**, R = H).

(b) Trimethylamine

The hydrolysis of ethenesulfonyl chloride (**1**) (27 mg, 0.21 mmol) in D_2O was carried out using a solution in DME (1.0 mL, dried) under similar conditions as those for kinetic measurements: 1°C, pH-stat, pH reading = 10.0, ~0.1 *M* NaOD as a titrant, with 30-μL portions of the DME solution injected to ~0.2 *M* NMe_3 solution in D_2O (40 mL, maximum substrate concentration ~1.6×10^{-4} mol/L) at 5-min intervals. The excess of NMe_3 was then extracted with ether, the solvents evaporated to dryness, and the residue dissolved in D_2O. The ^{1}Hmr spectrum showed that the characteristic A_2B_2 pattern of the undeuterated betaine with its two multiplets of equal area at 3.4–3.6 ppm and 3.7–3.9 ppm was distinctly altered, as expected for conversion largely to $Me_3\overset{+}{N}CH_2CHDSO_3^-$, with the integral of the high field component reduced in area to approximately half of the low field part of the signal; the characteristic peaks of $CH_2{=}CHSO_3^-$ were observed from 5.8–6.9 ppm; we also noted two small 1:1:1 triplets centred around 5.9 and 6.1 ppm, indicating that a small part (~5%) of the ethenesulfonate anion was α-deuterated ($CH_2CDSO_3^-$).

Control experiments

Experiments were carried out showing that: (*a*) sodium ethenesulfonate give no H–D exchange in D_2O at pH (meter readings) 3.4 for 100 min or pH 10.5 for 30 min at 25.0°C followed by work-up, (*b*) the ratio of **9** to **10** is unchanged on standing for 2 h at pH 4.0 followed by work-up, (*c*) the ratio of **9** to **10** in the product obtained on carrying out the reaction of **1** in the presence of added sodium ethenesulfonate corresponds to that of the reaction plus the added ethenesulfonate (and hence the product mixture is not an equilibrium

mixture), and (*d*) sodium hydroxyethanesulfonate gives no H–D exchange on carbon in 0.08 *M* NaOD in D_2O at room temperature for 2 h followed by work-up. Further details may be found elsewhere (65).

Reaction of ethenesulfonyl chloride (1) in D_2O–DME (80:20) without and with diisopropylethylamine

Ethenesulfonyl chloride (50 mg, 0.4 mmol) was dissolved in DME (4.5 mL, dried) and 50 μL of this solution was injected into aqueous DME (25 mL, DME/D_2O 20:80 v/v) at pH (meter reading) 9.0 and maintained at constant pH in the pH-stat apparatus with ~0.1 *M* NaOD in D_2O at 25°C. About every 15 min (ca. 4 half-lives) another 50 μL of the solution was added till the hydrolysis was completed (the concentration of starting material never exceed 1.8×10^{-4} *M*). The solution was then neutralized, and solvent evaporated and the residue dissolved in D_2O. The ^{1}Hmr spectrum did not show any incorporation of deuterium (i.e. <5%) into the ethenesulfonate. (In other experiments, however, where concentration of free **1** exceeded 5×10^{-4} *M*, the presence of deuterium in ethenesulfonate was observed (at 5.86 and 6.07 ppm); it seemed to increase with the increase of concentration of the substrate.)

In a similarly carried out experiment, except for the presence of *N*,*N*-diisopropylethylamine in the D_2O solution ($B_T = 0.265$ *M*, conditions in which k_ψ was 2.9 times that without the amine) did not produce any incorporation of deuterium.

Photochemical and mass spectrometric transformation of gibberellenic acid to 9-epiallogibberic acid

HUSSAIN K. AL-EKABI AND GHAZI A. W. DERWISH
Chemistry Department, College of Science, University of Baghdad, Adamyia, Baghdad, Iraq

Received February 6, 1984

This paper is dedicated to Professor Paul de Mayo on the occasion of his 60th birthday

HUSSAIN K. AL-EKABI and GHAZI A. W. DERWISH. Can. J. Chem. **62**, 1996 (1984).

Gibberellenic acid (**2**) reacted thermally in a modified immersion photochemical reactor, to give an intermediate triene (**3**). This triene then isomerized photochemically, via suprafacial [1,3]-hydrogen migration, to 9-epiallogibberic acid (**5**). On the other hand, comparison of the positive mass spectra of gibberellenic acid (**2**), allogibberic acid (**4**), and 9-epiallogibberic acid (**5**) showed that gibberellenic acid underwent electron impact fragmentation to the triene **3** cation. This cation then rearranged through suprafacial [1,3]-hydrogen migration to the 9-epiallogibberic acid (**5**) cation.

HUSSAIN K. AL-EKABI et GHAZI A. W. DERWISH. Can. J. Chem. **62**, 1996 (1984).

L'acide gibbérellènique (**2**), traité dans un réacteur photochimique à immersion modifié, subit une réaction thermique conduisant à l'intermédiaire triène (**3**) qui s'isomérise alors par un processus photochimique, via une migration [1,3] suprafaciale d'hydrogène, pour conduire à l'acide 9-épiallogibbérique (**5**). Par ailleurs, une comparaison des spectres de masse positives des acides gibbérellènique (**2**), allogibbérique (**4**) et 9-épiallogibbérique (**5**) a permis de montrer que l'acide gibbérellènique subit une fragmentation, sous impact électronique, conduisant au cation triénique **3**. Ce cation se transpose alors, par le biais d'une migration [1,3] suprafaciale d'hydrogène, pour conduire au cation de l'acide 9-épiallogibbérique (**5**).

For personal use only.

Gibberellic acid (**1**) is known to be the most biologically active in most circumstances among the gibberellins (1). It decomposes thermally in aqueous solutions to gibberellenic acid (**2**) (2–4), which is also thermally unstable in aqueous solution, giving allogibberic acid (**4**) in 80% yield and 10% of 9-epiallogibberic acid (**5**) (2–4). Pryce (4) proposed a mechanism (Scheme 1) in which **2** decomposes thermally to the intermediate triene **3**, which then rearranges, through a solvent exchange process, to **4**. Neither a photochemical nor an electron impact fragmentation study of **2** has been carried out. We wish to report now on (a) the thermal and subsequent photochemical rearrangement of **2** to 9-epiallogibberic acid (**5**), and (b) electron impact fragmentation of **2** to the **5** cation. Furthermore, the work is also aimed at presenting evidence that **2** is the first step in the fragmentation of **1**.

Results and discussion

(a) *Thermal and subsequent photochemical rearrangement of 2 to 5*

An aqueous solution of **2** (λ_{max} = 253 nm) at 25–30°C is fairly stable, and irradiation at this temperature under argon in Pyrex produced no reaction. However, according to Pryce (4), an aqueous solution of **2** is thermally reactive at about 100°C, giving the intermediate triene **3** (λ_{max} = 326 nm). An experiment was therefore designed to follow the subsequent photochemical behaviour of the thermally formed triene. An immersion photochemical reactor (Applied Photophysics Ltd., Model RQ 100) was used with some modifications, which led to simultaneous heating and irradiation (above 300 nm) of the sample (see Experimental). After 30 min irradiation in water the starting material was consumed and a product identified as 9-epiallogibberic acid (**5**) precipitated in good yield. When the reaction was repeated in D_2O (Merck 99.7^{2}H) as the solvent, **5** was formed which, in contrast to the experiment described by Pryce (4), contained no deuterium at C-9, as indicated by nmr (experimental error ±10%).

In both experiments (thermal (4) and thermal–photochemical) the first step should be the formation of the intermediate triene (**3**). The fate of this triene then depends on the conditions, reflecting the different symmetry properties of a triene in its ground and first excited state. Thus, in accordance with orbital symmetry rules, a mechanism is proposed (Scheme 2) in which the triene undergoes photochemically suprafacial

[1,3]-hydrogen migration to give 9-epiallogibberic acid (**5**) in a high yield (90%).

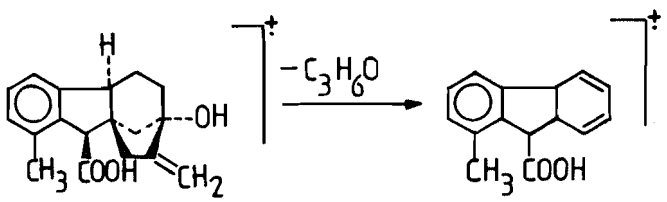
(b) *Electron impact fragmentation of* ***1*** *to the* ***5*** *cation*

The positive ion mass spectrum of **2** showed the expected molecular ion peak at *m/e* 346 (Fig. 1). The base peak at *m/e* 284 indicates that aromatization of ring A is favoured.

In order to identify the origin of the base peak, the positive ion mass spectra of **4** and **5**, which are the expected aromatic derivatives of **2**, were measured (Figs. 2 and 3). They showed indeed the base peaks at *m/e* 284.

Although the three spectra have much the same fragmentation pattern below *m/e* 284, the ion peak of *m/e* 226 exhibits significant differences. While it is the second most intense peak of **4**, it is much less intense in **2** and **5**. It can be considered as a key peak in distinguishing between **4** and **5** by mass spectroscopy.

Voigt *et al.* (5) attributed the 226 peak to the loss of a C_3H_6O



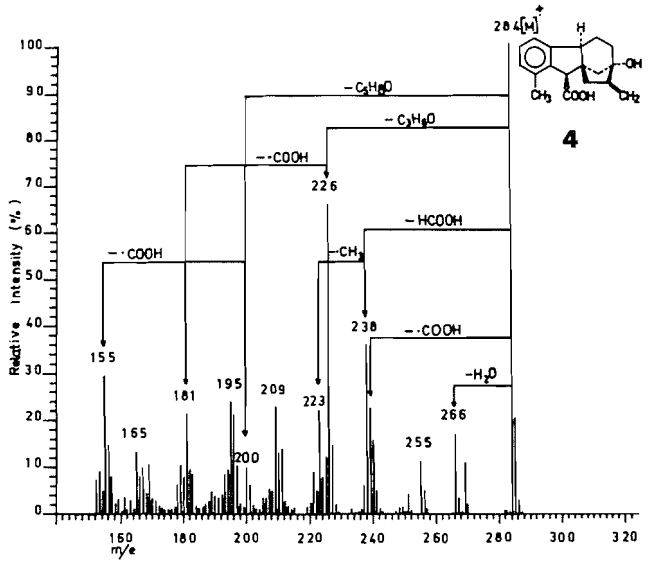


FIG. 2. 70-eV Mass spectrum of allogibberic acid **4**.

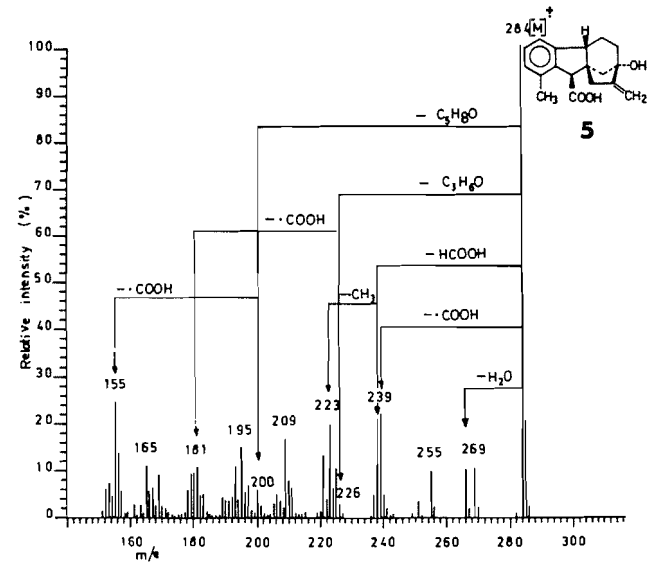

FIG. 3. 70-eV Mass spectrum of epiallogibberic acid **5**.

unit from the molecular ion peak *m/e* 284 of **4** as follows:

The extremely low intensity of the peak in **5** may be explained by stereochemical considerations of **4** and **5**. According to the stereomodel, ring D should have a normal envelope conformation in **5** but a much more twisted envelope in **4**. The latter conformation may facilitate the loss of a C_3H_6O unit and thus produce another π-system contributing to the stability of the proposed cation.

In view of the similarity of the mass spectra of **2** and **5** below *m/e* 284, it seems reasonable to conclude that the base peak in **2** originates from the fragmentation of **2** to the **5** cation. Thus, the aromatization of ring A involves the loss of water to give an ion peak at *m/e* 328. This is followed by elimination of carbon dioxide to yield the triene ion, which then rearranges (as in the photochemical reaction) to the corresponding aromatic ion of *m/e* 284 (9-epiallogibberic acid cation **5**; Scheme 2). If this were not the case, a highly intense peak at *m/e* 226 would appear in the spectrum of **2**. The results led us to reinvestigate the positive ion mass spectrum of gibberellic acid

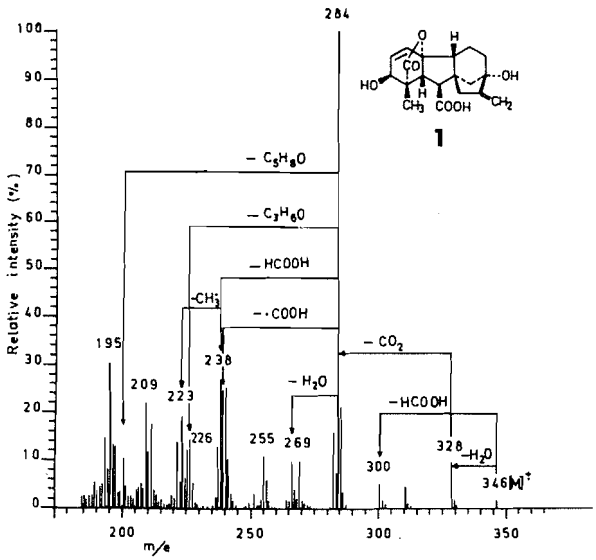

FIG. 4. 70-eV Mass spectrum of gibberellic acid **1**.

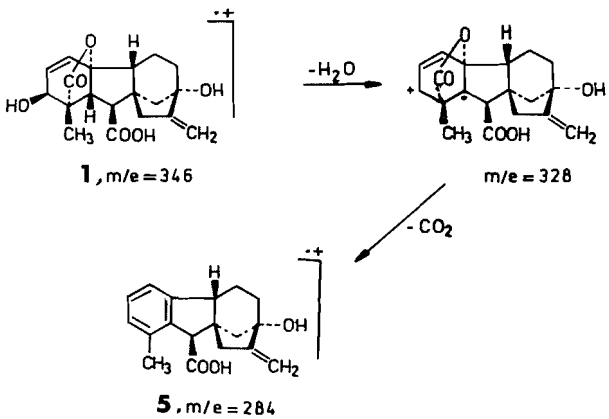

SCHEME 3

(Fig. 4), which again shows, as in **2**, the expected molecular ion peak at *m/e* 346. However, its intensity is about three times higher than that of **2**. The base peak at *m/e* 284 indicates that aromatization of ring A is favoured.

The close similarity of the mass spectra of **1** and **2** and the higher intensity of the molecular ion peak of **1** may suggest that **2** is the first step in the fragmentation of **1**. Incidentally, **2** is the first aqueous decomposition product of **1** (2–4). Alternatively, a fragmentation pathway of **1** to **5** without passing through the intermediate **2** is also possible (Scheme 3).

Experimental

Ultraviolet (uv) spectra were run in MeOH and infrared (ir) spectra were taken in Nujol. Varian A-60 and Bruker WH 200 spectrometers were used to record the ^{1}H nmr spectra. The spectra were run in pyridine-d_5 solution, with HMDS as an internal standard. Mass spectra were taken on a Varian CH5 instrument (70 eV) (source temperature 150–200°C).

The photolysis was carried out on a modified immersion photochemical reactor (Applied Photophysics, Ltd. Model RQ 100). Thus, a single-wall Pyrex immersion well instead of the double-wall quartz was used to hold the medium pressure mercury lamp (125 W). The lamps could thus act as a convenient heat source as well as a light source ($\lambda > 300$ nm). Practically, the solution started to boil 5 min after switching on the lamp. Thus a solution of 500 mg of **2** in 100 mL of doubly distilled water was irradiated under argon and reflux conditions. After about 30 min the starting material was consumed, as indicated by tlc, and a product precipitated. The latter was separated (450 mg), recrystallized from methanol–water as prisms, mp 245°C, and was identified, on the basis of the physical constants, as 9-epiallogibberic acid (**5**) (4); uv λ_{max}: 266 nm, ϵ_{max} = 350 L mol^{-1} cm^{-1}; ir: aromatic band at 1600 cm^{-1} instead of the original conjugated C=C band at 1655 cm^{-1}; nmr (pyridine-d_5): no olefinic ring A protons, 3 adjacent aromatic protons at δ: 7.26 (1H, t, J = 7.3 Hz), 7.15 (1H, d, J = 7.4 Hz) and 7.06 (1H, d, J = 7.4 Hz), 4.02 (H-6, s), and 3.88 (H-9, d, J = 5 Hz); ms: molecular ion peak at *m/e* 284.

Gibberellic acid **1** (Fluka) was used after several recrystallizations from MeOH–H_2O. Gibberellenic acid **2** was prepared from **1** according to the procedures of Moffat (6).

Surface photochemistry: ^{13}C enrichment by photolysis on silica gel[1]

LINDA J. JOHNSTON AND S. KING WONG

Photochemistry Unit, Department of Chemistry, The University of Western Ontario, London, Ont., Canada N6A 5B7

Received February 10, 1984

This paper is dedicated to Professor Paul de Mayo on the occasion of his 60th birthday

LINDA J. JOHNSTON and S. KING WONG. Can. J. Chem. **62**, 1999 (1984).

The enrichment of the ^{13}C isotope by partial photolysis of dibenzyl ketone on silica gel has been demonstrated. The ^{13}C enrichment is substantial and is parallel to the increase in the probability of geminate radical recombination on a silica surface as compared with that in solution. A substantial ^{13}C enrichment was also observed for the rearranged starting material, 1-phenyl-4′-methylacetophenone. The single-stage isotope separation factors are different for the two ketones although both are isomers derived from the same benzyl–phenylacetyl radical pairs.

LINDA J. JOHNSTON et S. KING WONG. Can. J. Chem. **62**, 1999 (1984).

On a démontré qu'il se produit un enrichissement de l'isotope ^{13}C lors de la photolyse partielle de la dibenzylcétone sur du gel de silice. L'enrichissement en ^{13}C est important et il augmente avec l'augmentation de la probabilité de recominaison du radical geminé sur la surface de la silice par opposition à la probabilité en solution. On a aussi observé un enrichissement important en ^{13}C dans le produit de départ transposé, la phényl-1 méthyl-4′ acétophénone. Même si les deux cétones sont des isomères dérivés de la même paire de radicaux benzyl–phénylacétyles, les facteurs de séparation isotopique pour une étape sont différents.

Virtually all methods of isotope enrichment are based upon differences in mass or related properties. However, in 1971, Lawler and Evans (1) predicted that, according to the radical pair theory for magnetic polarization (2, 3), the separation of isotopes based upon differences in their magnetic moments rather than their masses should be possible. In 1976 the observation of Buchachenko *et al.* (4*a*) of ^{13}C enrichment during the photolysis of dibenzyl ketone confirmed that magnetic effects could lead to isotope separation. Since then there have been a number of investigations of the influence of magnetic isotope and magnetic field effects on radical reactions (4–8).

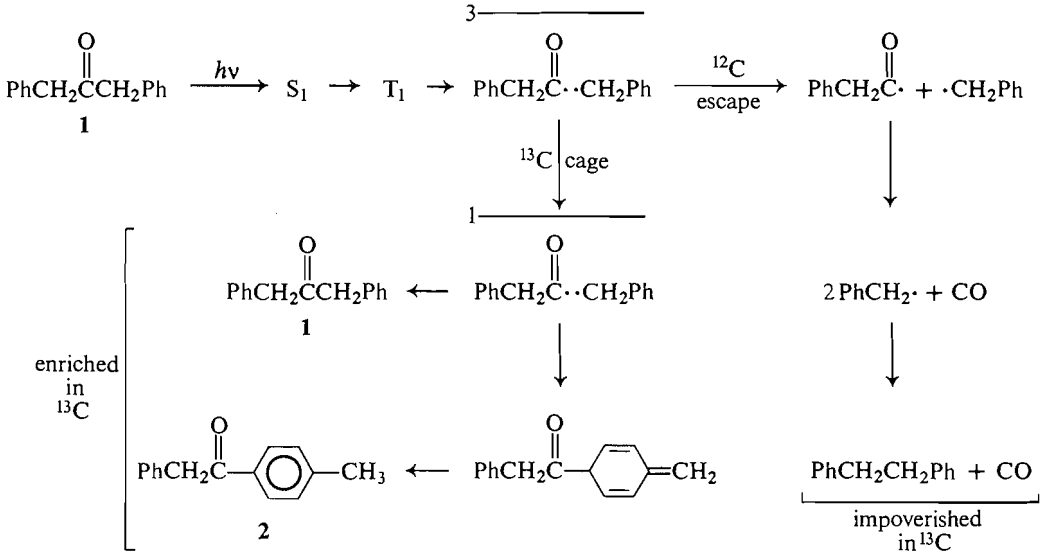
A geminate radical pair in solution may undergo a number of processes: intersystem crossing (isc), diffusional separation, recombination to produce products or regenerate starting materials, or transformation to a new radical pair. A basic premise of the radical pair theory is the postulate that the chemical behaviour of a radical pair may be influenced by the spin of magnetic nuclei through the electron-nuclear hyperfine coupling (hfc) isc interaction. Since the hfc interaction is one of the major mechanisms for isc in radical pairs containing magnetic nuclei, the presence of such nuclei will increase the isc rate, particularly when the hfc constants are large. For example, a triplet radical pair containing a magnetic isotope with a large hfc constant (e.g., ^{13}C) will undergo more rapid isc than will the same triplet pair containing a nonmagnetic isotope (^{12}C). If isc to a singlet radical pair followed by cage recombination competes with diffusional separation and nongeminate reaction of the radicals, then the cage products are expected to be enriched in the magnetic isotope while the escape products will be impoverished.

The ^{13}C enrichment which occurs during the photolysis of dibenzyl ketone, **1**, (4, 6, 7) can be explained in terms of Scheme 1. Excitation followed by rapid isc produces a short-lived triplet which undergoes α cleavage to generate a triplet phenylacetyl–benzyl radical pair (9, 10). In solution this radical pair decays by either recombination to generate starting material or diffusional separation (10). Decarbonylation of the free phenylacetyl radicals occurs and the benzyl radicals combine to yield dibenzyl. The original acyl–benzyl radical pairs containing ^{13}C nuclei will undergo more rapid isc to a singlet pair than will those containing ^{12}C nuclei, while more of the radicals containing ^{12}C will escape from their original partners. Therefore, the cage products, regenerated **1** (and its isomer, 1-phenyl-4′-methylacetophenone, **2**, when formed (6)) will be enriched in ^{13}C. The free radical products will, on the other hand, contain more ^{12}C than did the original starting material.

Small amounts of ^{13}C enrichment have been observed in **1** recovered after partial photolysis in solution (4, 6, 7); the value for α, the single-stage enrichment parameter, was ~1.04 in benzene (6*a*). Pines and co-workers (7) concluded from their investigations of temperature and solvent viscosity effects that the enrichment efficiency was strongly dependent on viscosity with maximum effects at intermediate viscosities. Turro and co-workers (6) have reported substantial increases in enrichment for photolysis of **1** in aqueous micellar solutions: α_{CO} (**1**) ≃ 1.35, α_{CH} (**1**) ≃ 1.18, and α'_{CO} (**2**) ≃ 1.26, where α′ refers to the single stage enrichment parameter for **2** and the subscripts refer to the position of the ^{13}C enrichment. The larger enrichment at the carbonyl rather than the methylene carbon was consistent with the hfc constants (6*d*) for ^{13}C at the various positions. The efficient ^{13}C enrichment in micelles has been attributed to the restricted space in which the radical pair finds itself (6); the micelle is thought to provide a boundary which prevents the radical pair from diffusing apart and allows more time for hfc-induced isc to occur. Decarbonylation, rather than diffusion (as in solution), was proposed as the competing escape mechanism for the triplet radical pair in a micelle.

Substantial enrichment (α = 1.66) was also reported for **1** photolysed on a surface prepared by chemically bonding a hydrocarbon layer to the surface of silica gel (11). The authors suggested that the synthetic monolayer surface was analogous to a micelle in providing an artificial "reflecting boundary" which led to an enhanced magnetic isotope effect. However, it appeared more likely that the above results were a reflection of the silica gel surface properties rather than the micelle-like properties of the synthetic monolayer surface, since a number of studies have indicated that radical mobility is restricted on

[1] Publication No. 317 from the Photochemistry Unit, Department of Chemistry, The University of Western Ontario.



SCHEME 1

silica surfaces (12–16). For example, limited translational motion has been shown to precede recombination of a singlet radical pair generated on silica gel by the photo-Fries rearrangement (12). A greater amount of movement has been reported for both benzyl (13) and cyanopropyl (14) radical pairs on silica gel. Similarly, some surface mobility has been observed for radical pairs generated by photolysis of azocumene (15*a*) and diacyl peroxides (15*b*) on silica gel. Evidence for restriction of the mobility of adsorbed radicals has been provided by the observation of previously undetected reaction pathways in the photolysis of benzoin methyl ether on silica gel (16).

Efficient ^{13}C enrichment requires that diffusional separation of the radical pair be sufficiently slow that hfc-induced isc can compete, but not so slow that the rates of isc of all radical pairs are the same, regardless of whether or not they contain ^{13}C or ^{12}C. The slower escape of a radical from its original geminate partner on silica gel, as compared to solution, suggested that the silica gel surface should provide a suitable environment for the observation of substantial amounts of ^{13}C enrichment. The present study of ^{13}C enrichment on silica gel was, therefore, undertaken with the intention of searching for conditions for optimization of ^{13}C enrichment and of obtaining further information concerning the mechanism of the magnetic isotope effect in restricted environments and the diffusional motion of radicals on a surface.

Data analysis

Since the amount of enrichment depends on the extent of conversion, it is useful to express the results in terms of a single-stage isotope separation factor, α, (17) which is independent of conversion and thus allows comparison of isotope separation efficiencies for different experiments. Bernstein (17) has shown that, for competitive, first-order reactions of isotopically different species, the residual unreacted starting material becomes exponentially enriched in the slower reacting isotope. This may be applied to the competitive $^{12}C/^{13}C$ reactions in the photolysis of dibenzyl ketone, as shown by Turro *et al.* (6*a*). Since molecules containing ^{13}C proceed to products at a slower rate (i.e., more geminate recombination to regenerate starting material occurs for ^{13}C radical pairs) than do those containing ^{12}C, the residual unreacted ketone will become enriched in ^{13}C.

The parameter α is defined as the single-stage separation (17) and may be computed from the measured quantities, S, the overall separation factor, and f, the fractional conversion. These are defined for carbon isotopes in eqs. [1] and [2], where the subscripts 0 and f refer to concentrations in the initial and recovered material.

$$[1] \quad S = \frac{[^{12}C]_0[^{13}C]_f}{[^{12}C]_f[^{13}C]_0}$$

$$[2] \quad f = 1 - \frac{[^{12}C]_f + [^{13}C]_f}{[^{12}C]_0 + [^{13}C]_0}$$

The magnitude of α is then obtained from eq. [3] which can, for most purposes, be approximated by eq. [5].

$$[3] \quad \log S = \frac{\alpha - 1}{\alpha}\left[\log\left(\frac{1 + SR_0}{1 + R_0}\right) - \log(1 - f)\right]$$

$$[4] \quad R_0 = \frac{[^{13}C]_0}{[^{12}C]_0}$$

$$[5] \quad \log S = \frac{\alpha - 1}{\alpha}[-\log(1 - f)]$$

In practice, α can be evaluated directly from [3] or [5] for each experiment or can be computed from the slope ($(\alpha - 1)/\alpha$) of a plot of $\log S$ versus $-\log(1 - f)$.

The above method for obtaining enrichment efficiencies cannot be used to express isotope separation efficiencies for products formed in the reaction. When dibenzyl ketone is photolysed in either micelles (6) or on silica gel (18), an isomeric product, 1-phenyl-4′-methylacetophenone, **2**, is produced. This isomer is formed by geminate recombination of the initial radical pair and is thus expected to be formed more often from ^{13}C ketone molecules than from ^{12}C molecules. Any isomer formed is not diluted by a large pool of unreacted, unenriched material, as is the case for regenerated dibenzyl ketone. As a result, the ^{13}C enrichment, as measured by S, is much higher for **2** than for **1** at low conversions but increases more slowly with increasing conversion. The increase in S for **2** with conversion

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.105 on 09/06/12
For personal use only.

occurs because the ketone from which **2** is formed is being constantly enriched in ^{13}C as the reaction progresses.

In principle, measurement of S for **2** at very low conversions for which the ^{13}C enrichment for **1** is negligible can yield directly the single-stage enrichment parameter, α', for **2**. Kraeutler and Turro (*6d*) obtained α' by plotting log S against $-\log(1-f)$ for **2** and extrapolating to zero conversion. The physical meaning of the plot is not clear and a considerable number of points at low conversion are required to obtain α' in this way. Therefore, a method based upon the overall separation factor, S, for **1** (i.e., the variation in $^{13}C/^{12}C$ ratios for **1** throughout the photolysis was developed for the calculation of α' for **2** in the present experiments.

The single-stage enrichment parameter α' for **2** may be defined as shown in eq. [6] where k_{13} and k_{12} are the rate constants

$$[6] \quad \alpha' = \frac{k_{13}}{k_{12}}$$

for the formation of ^{13}C and ^{12}C **2**, respectively. The rate of formation of **2** depends on the concentration of **1**; integration

$$[7] \quad \frac{d[^{13}C_2]}{dt} = k_{13}[^{13}C_1]$$

of both sides of eq. [7], followed by a change of variable (from time to conversion, f) and substitution for $[^{13}C_1]$, as outlined in the Appendix, yields the following expression:

$$[8] \quad [^{13}C_2]_{total} = k_{13}C_0 \int_0^f \left(\frac{SR_0}{1+SR_0}\right)(1-f)\,df$$

A similar expression is obtained for $[^{12}C_2]_{total}$:

$$[9] \quad [^{12}C_2]_{total} = k_{12}C_0 \int_0^f \left(\frac{1}{1+SR_0}\right)(1-f)\,df$$

After evaluation of the integrals in eqs. [8] and [9], the relative amounts of $^{13}C/^{12}C$ for **2** may be used to evaluate k_{13}/k_{12} which, from [6], is equivalent to α'. The integration is done numerically using the known values of α and f to obtain S.

Results and discussion

Carbon 13 enriched ketone was used as the starting material for all measurements of ^{13}C enrichment resulting from photolysis of dibenzyl ketone, **1**. Analysis of the $^{13}C/^{12}C$ ratios was more accurate if enriched material was used; several preliminary experiments had indicated that there was considerable error in the mass spectral analysis if unenriched ketone was used. Dibenzyl ketone was prepared (19) from ^{13}C-labelled phenylacetic acid (90% ^{13}C in the carbonyl) and was mixed with an appropriate amount of natural abundance **1** to give ketone which contained 25% ^{13}C in the carbonyl position. All reported α values, therefore, refer to enrichment at the carbonyl and have been corrected for the natural abundance ^{13}C content at other positions.

^{13}C enrichment on silica gel

Substantial ^{13}C enrichment was observed in both **1** and its isomer, **2**, recovered after partial photolysis of **1** on silica gel. The mass spectral results obtained for an experiment at 84.3% conversion are shown in Fig. 1: the intensity at m/e 211 relative to that at 210 was greater for recovered **1** than for the starting material. The ^{13}C contents of recovered **1** and **2** were 30.4% and 35.6%, respectively, from the mass spectral intensities. These results were confirmed by nmr analysis of the two ketones. The methylene protons of both show signals that

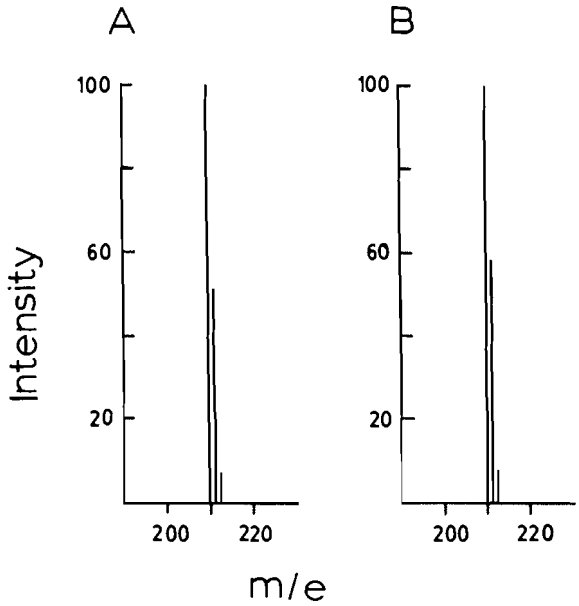


FIG. 1. Mass spectral intensities for **1** (25% $^{13}C{=}O$) before photolysis (A) and after photolysis to 84.3% conversion (B).

are a combination of a singlet due to a ^{12}C carbonyl and a doublet centred at the same chemical shift, the latter arising from the ^{13}C carbonyl. Integration of the singlet and the two satellites allowed determination of the ^{13}C content at the carbonyl; values determined by nmr integration agreed well with those determined mass spectrally.

The ^{13}C contents in **1** and **2** recovered after photolysis on silica gel at 20°C are listed in Table 1. As expected, the ^{13}C content of ketone **1** increased steadily with conversion. The calculated values for α, the single-stage enrichment factor, ranged from 1.12 to 1.18; the average was 1.14. The lower α values obtained at higher conversions may result from the over-irradiation of enriched ketone caused by inhomogeneous photolysis on the silica gel surface. This explanation is substantiated by the fact that lower α values ($\alpha < 1.04$) were obtained for experiments carried out to >98% conversion. The α values of ~1.18 for the lower conversion appear, therefore, to provide a more reliable measure of the ^{13}C enrichment efficiency on the silica gel surface. An α value of 1.13 was calculated from the slope of a plot of log S versus $-\log(1-f)$ (Fig. 2) for the data in Table 1 (20°C experiments).

Comparison of the results obtained under various experimental conditions (Table 1) showed that the ^{13}C enrichment was not affected by the water content of the silica gel or by the method of sample mixing. Lowering the photolysis temperature had little effect on α; at −55°C the observed enrichments (Table 1) were similar to those obtained at 20°C, although the α values were slightly higher for dry silica gel than for undried silica.

For isomer **2** the ^{13}C content was, as expected, already quite high at low conversion and did not increase very rapidly thereafter. For example, at 20°C the 33.0% ^{13}C content at 29.9% conversion increased to only 35.6 at 84.3% conversion (Table 1). Values of α' were all ~1.5 for **2** recovered after photolysis of **1** at 20°C on silica gel. As for ketone **1**, the enrichment for **2** at room temperature was not affected by either the dryness of the silical gel or the method of sample mixing. However, in contrast to results obtained for **1**, changing the photolysis temperature from 20°C to −55°C substantially decreased the en-

richment efficiency for **2** ($\alpha' \sim 1.1$ at −55°C).

The above results indicate that, as predicted, photolysis of **1** on dry silica gel does yield substantial ^{13}C enrichments in recovered ketones **1** and **2**. The observed α values for **1** are larger than those in solution ($\alpha \sim 1.04$ (6*a*)) but enrichment occurs less efficiently on the surface than it does in a micellar environment ($\alpha \sim 1.3$ (6) and the present work reported below). The α′ values for **2** on the surface are, however, larger than those in micelles.

^{13}C enrichment on other surfaces

Ketone **1** was photolysed on several other types of surfaces to determine their effect upon ^{13}C enrichment. The results are summarized in Table 2. First, **1** recovered after photolysis on a smaller particle size (6 μm rather than 0.2–0.5 mm) silica gel showed an enrichment ($\alpha \sim 1.13$) similar to that already observed. Second, photolysis of **1** on neutral alumina also gave a similar α value (~1.1); however, the situation on alumina may

[d] −55°C.

be more complex than that on silica gel since the product recovery as dibenzyl was only ~20% for the former. Isomer **2** was not detected among the reaction products when **1** was photolysed on either 6-μm silica or on alumina. This suggests that a particular surface site may be instrumental in permitting the formation of **2** during the photolysis on silica gel.

Third, **1** was photolysed on silica gel on which decanol had been coadsorbed at ~55% monolayer coverage, based upon calculated molecular areas. The values obtained for both α and α′ at 20°C and at −55°C were not appreciably different from those for silica gel in the absence of decanol. Comparison of the present results for silica gel and silica gel plus decanol with those of Epling and Florio (11) suggest that it is the silica gel surface, not the bound hydrocarbon layer, which is responsible for the enhanced ^{13}C enrichment efficiency. It seems unlikely that the hydrocarbon layer makes the surface "micelle-like" as has been suggested (11). Radicals on a hydrocarbon layer would be expected to be more mobile than those attached directly to silica gel and would be less likely to produce ^{13}C enriched material via the geminate recombination pathway. Although a higher α value was obtained in the previous study (11), it should be noted that this reflects the total enrichment at all carbons and is, consequently, expected to be higher than the present α values for carbonyl enrichment.

TABLE 3. ^{13}C enrichment for **1** and **2** recovered after photolysis of **1** in aqueous potassium dodecanoate

$\bar{N}$	Conversion	α	α′
0.34[a]	98.0	1.19	1.73
0.43[a]	34.7	1.28	1.20
0.43[a]	39.2	1.19	1.23
1.17[b]	94.4	1.24	1.67
1.24[b]	54.7	1.37	1.20

[a][Surfactant] = 0.16 *M*.
[b][Surfactant] = 0.08 *M*.

^{13}C enrichment in micelles

For comparison with earlier work in micelles (6) and for correlation with our work on cage recombination (13), ^{13}C enriched dibenzyl ketone was photolysed in aqueous potassium dodecanoate. Our previous experimental results on the photolysis of an unsymmetrically substituted dibenzyl ketone in micelles showed that there is a strong dependence of geminate formation of dibenzyl on the average number of molecules per micelle $\bar{N}$ (13). The probability of geminate combination decreases from 92% to 51% when $\bar{N}$ is changed from 0.35 to 0.85. The present work was, therefore, designed to investigate the effect of variations in $\bar{N}$ on the ^{13}C enrichment efficiency. It might be expected that the ^{13}C enrichment efficiency would decrease with an increase of $\bar{N}$ since the rapid escape of radicals from their geminate partners is thought to be responsible for the low α values in solution. The results shown in Table 3 indicate that α and α′ values for the recovered ketones are not particularly sensitive to $\bar{N}$. The high α′ values at high conversion could be due to photolysis of **2** and its further enrichment by recombination to regenerate itself; the lower yields of **2** obtained at >80% conversion support this hypothesis. The observed enrichments are comparable to those reported by Turro and co-workers in other micelle systems (6).

The insensitivity of ^{13}C enrichment to changes in $\bar{N}$ was unexpected. In fact there may be a slight trend opposite to the expected one of more free radical combination products when $\bar{N}$ is increased. It seems obvious now that the behaviour of the benzyl–benzyl radical pair is not directly correlated to that of the benzyl–phenylacetyl radical pair, which is the reaction intermediate responsible for the magnetic isotope enrichments of **1** and **2**. For instance, one expects that the average initial interradical separation for the two radical pairs will be different; this separation is crucial for both radical escape by diffusion and for ^{13}C enrichment by recombination.

Further discussions

Consideration of α values for **1** on a variety of surfaces and in micelles indicates that both environments are effective in enhancing the ^{13}C enrichment. Since restrictions on the diffusion of the initial radical pair appear to be important in the enrichment process, the results suggest that the silica gel surface provides a slightly less restricted environment than does a micelle. The dibenzyl ratios obtained upon photolysis of unsymmetrical dibenzyl ketones also indicate more restriction of radical motion by micelles than by the silica surface. However, the differences are much greater in the latter case. This is reasonable if the lifetimes of the radical pairs are considered. The acyl–benzyl radical pair involved in the ^{13}C enrichment process has a shorter lifetime than the benzyl radical pair and the surface will be much more effective in localizing this shorter-lived radical pair. On the other hand, since radical exit from a micelle is relatively slow (10^5–10^6 s^{-1} (20)), the micelles can effectively localize both radical pairs until recombination occurs.

Substantially higher enrichments were observed for isomer **2** than for **1** at 20°C on silica gel. Different efficiencies had also been observed for the two ketones in micelles (6). Both **1** and **2** are derived from the same initial radical pair and one would expect α and α′ values to be the same. The differences in enrichment must be a reflection of differences in the rates of processes leading to each ketone. While the initial state of the primary radical pair must be identical, the final states leading to products **1** and **2** must be different. The developing singlet character and the geometric positions of the radicals within the radical pair before coupling are the deciding factors. The present theories of CIDNP have only considered radicals as hard spheres without structures. Apparently the structure of the individual components of the radical pair and their relative positions can affect the ^{13}C enrichment efficiency, and rotation should also be considered.

The different temperature dependence of α and α′ may be understood within this context. While α values for **1** are much less sensitive to temperature variations, α′ values for **2** decreased considerably at lower temperature on silica gel. Turro has also obtained different temperature dependences for α and α′ in micelles (6). The precise nature of the structure of the radical pair and its dynamics of motion as related to the electron-nuclear hfc induced intersystem crossing is at present unclear. More detailed studies of the ^{13}C enrichment of **1** and **2** are required for better understanding.

Experimental

Apparatus

Proton nmr spectra were recorded on either a Varian T-60 (60 MHz) or an XL-100 (100 MHz) spectrometer. Gas chromatography – mass spectrometry was done on a Varian 1400 gas chromatograph interfaced with a Varian MAT 311 A mass spectrometer and data system. Gas chromatography was done on a Varian 2400 instrument equipped with a flame ionization detector, a temperature programmer, and a 5 ft × 1/4 in. glass column packed with 10% SE 30 on Chromosorb W. Operating conditions were as follows: carrier gas, helium, 40 mL/min; injector, 225°C; column, 170°C; detector, 250°C. Irradiations were carried out with either a 1000-W XBO high pressure xenon lamp in a Photochemical Research Associates lamp housing or a 450-W Hanovia medium pressure mercury lamp.

Materials

Silical gel (35–70 mesh, Merck, cat. no. 7733) was used as received or dried as outlined below. Silica gel, 6-μm particle size, was used as received. Alumina, neutral (Fisher, Brockmann Activity 1) was dried for 12 h at 200°C, 0.1 Torr (1 Torr = 133.3 Pa), and was stored in a desiccator until used. Methylene chloride (Fisher spectrograde) was refluxed over P_2O_5 and distilled directly before use for adsorption of compounds onto dry silica gel, but was used as received for adsorption of compounds onto undried silica or other surfaces. Water for micelle solutions was triply distilled (second distillation from potassium permanganate). All other solvents were reagent grade and were used as received. Decanol was distilled before use. Potassium dodecanoate was prepared form dodecanoic acid and potassium hydroxide and purified by recrystallization from methanol. Dibenzyl ketone (ICN Pharmaceutical) was recrystallized from ether (at −78°C) or petroleum ether (40–60°C), mp 30.5–32°C. ^{13}C labelled dibenzyl ketone was prepared by the method of Coan and Becker (19) from phenylacetic acid (90% $^{13}C{=}O$, Merck, Sharp and Dohme), and was purified by bulb-to-bulb distillation followed by crystallization from 40–60°C petroleum ether, mp 32.5–33.5°C.

Photolysis of 1 on silica gel

Dibenzyl ketone was adsorbed on silica gel (4.77×10^{-4} mol/g) from a methylene chloride solution. When the ketone was to be adsorbed on silica gel dried at 200°C at $\leq$ 1 Torr for $\geq$ 5 h, the previously described method and apparatus were used (18). For samples on silica gel which had not been predried, a methylene chloride solution of **1** was added to a preweighed silica sample in a round bottom flask. After solvent removal by evacuation, the sample was transferred to an irradiation cell and evacuated for ~15 min at 1 Torr. All samples were then degassed to 10^{-5} Torr by 3 or more freeze–thaw cycles at liquid nitrogen temperatures. Dry, deoxygenated nitrogen was then added to the sample tube before it was sealed. The samples were rotated and irradiated with a 1000-W xenon lamp. The light was focused on one end of a 16-mm quartz light pipe and the sample was rotated under the other end. During irradiation the samples were cooled with either cold running water (20°C) or by immersion in a methanol – Dry Ice bath (−78°C).

The adsorbed materials were removed from the silica gel by extraction with 100 mL of diethyl ether. The ether solution was concentrated and analyzed by gc after the addition of a known amount of eicosane as an internal standard. Calibration curves were constructed for **1**, **2**, and **3**; the average of three or more injections was used for each determination. Dibenzyl always accounted for ≥90% of the photolysed ketone. Yields of **2** were typically from 2–4%.

For samples containing coadsorbed decanol, the decanol was adsorbed first, followed by **1**. The samples were prepared as described above using undried silica gel.

Photolysis of 1 in micelles

An appropriate amount of **1** was added to a solution of potassium dodecanoate in triply distilled water and the mixture was sonicated for 1–2 h to dissolve the ketone completely. The solution was then transferred to an irradiation vessel and degassed by purging with nitrogen for 30 min. All samples were stirred and irradiated through Pyrex with a 450-W Hanovia medium pressure mercury lamp. After photolysis, the sample was diluted to <0.02 *M* (i.e., below the cmc) and was extracted three times with ether. The formation of emulsions during the extraction procedure was minimized by the addition of sodium chloride to the aqueous phase. The combined ether layers were washed once with 10% Na_2CO_3 and once with water and were dried over anhydrous $MgSO_4$. The extract was concentrated and analyzed by gc as previously described. Dibenzyl accounted for ~90% of the photolysed ketone. Yields of **2** were from 6–10% for most experiments but decreased to 1–2% at >90% conversion.

^{13}C analyses

1 and **2** were separated from the photolysis mixtures by preparative chromatography on silica gel plates using 10% ethyl acetate in petroleum ether as eluent. The ^{13}C content in the recovered ketones was then determined by gc/ms. A Varian 1400 gas chromatograph interfaced with a Varian MAT311A mass spectrometer and a Varian data system was used. A standard sample of **1** (25% $^{13}C{=}O$) was always analyzed before samples of recovered **1** were run. Comparison of the ^{13}C calculated for the standard with that determined mass spectrally allowed correction of the data for instrumental variations. For **1** the relative intensities of the molecular ion peaks at *m/e* 210 and 211 were used. Since **2** gave a very weak molecular ion, the ^{13}C content was determined from the mass fragment peaks at *m/e* 119 and 120. The mass spectral intensities for both ketones were corrected for the natural abundance distributions of ^{13}C at other than the carbonyl, ^{2}H, and ^{17}O. Separation factors, *S*, were then calculated from the corrected intensities and used to evaluate α and α' values.

Appendix

Integration of [7] yields [10], which may be rewritten as

$$[10] \quad [^{13}C_2]_{total} = k_{13} \int_0^t [^{13}C_1]\, dt$$

[11] after the appropriate change of variable from time to conversion, *f*. The $[^{13}C_1]$ at a particular conversion, *f*, may be

$$[11] \quad [^{13}C_2]_{total} = k_{13} \int_0^f [^{13}C_1]\, df$$

expressed as shown in [12] where C_0 is the initial total [**1**] and the fraction $^{13}C_1$ is determined as shown below:

$$[12] \quad [^{13}C_1]_f = (\text{fraction } ^{13}C_1)_f\,(1 - f)C_0$$

$$[13] \quad (\text{fraction } ^{13}C_1)_f = \frac{^{13}C_f}{^{13}C_f + {}^{12}C_f}$$

$$[14] \quad = \frac{SR_0}{1 + SR_0}$$

$$[15] \quad [^{13}C_1]_f = \frac{SR_0}{1 + SR_0}\,(1 - f)C_0$$

substitution of [15] in [11] yields

$$[16] \quad [^{13}C_2]_{total} = k_{13}\int_0^f \frac{SR_0}{1 + SR_0}\,(1 - f)C_0\,df$$

A similar set of operations gives $[^{12}C_2]_{total}$ as expressed in eq. [9].

Coumarin–nucleotide base pairs. Ultraviolet absorption, fluorescence, and photochemical study

GRAŻYNA WENSKA AND STEFAN PASZYC
Faculty of Chemistry, A. Mickiewicz University, Poznań, Poland

Received January 6, 1984

This paper is dedicated to Professor Paul de Mayo on the occasion of his 60th birthday

GRAŻYNA WENSKA and STEFAN PASZYC. Can. J. Chem. **62**, 2006 (1984).

Bichromophoric compounds containing a nucleotide base and coumarin linked with a polymethylene chain have been synthesized. A hypochromic effect was observed for adenine–coumarin pairs in contrast to the thymine containing compound. The fluorescence intensity of coumarin when bound into these systems was found to be significantly reduced. It has also been demonstrated that excitation energy is transferred from adenine or thymine to the coumarin moiety. Intermolecular dimerization of coumarin residues was observed upon irradiation of an adenine–coumarin pair.

GRAŻYNA WENSKA et STEFAN PASZYC. Can. J. Chem. **62**, 2006 (1984).

On a synthétisé des composés à deux chromophores contenant un nucléotide et une coumarine reliés par une chaîne polyméthylène. Par opposition à ce qui est observé avec le composé semblable contenant de la thymine, on a observé un effet hypsochrome avec les paires adénine–coumarine. On a observé que l'intensité de la fluorescence de la coumarine liée à ces systèmes est considérablement réduite. On a aussi démontré que l'énergie d'excitation est transféré de l'adénine ou de la thymine vers la portion coumarine. Lors de l'irradiation d'une paire adénine–coumarine, on a observé une dimérisation intermoléculaire des résidus de la coumarine.

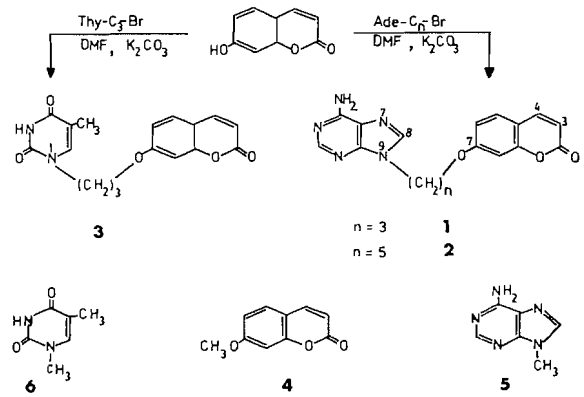
Introduction

Furocoumarins (psoralens) and some simple coumarins form weak complexes with nucleic acids in the ground state by intercalation of planar furocoumarin chromophores between the base pairs of nucleic acids. It has been suggested that aromatic ring stacking, hydrogen bonding, and hydrophobic and van der Waals forces are involved in the interaction of furocoumarins and nucleic acids. The intercalated molecule can form a covalent bond with a nucleic acid base upon irradiation with ultraviolet (uv) light and photomodifications of nucleic acids appear to be responsible for observed biological effects (1, 2).

In order to get more insight into an interaction process and a photoreaction between respective chromophores, synthesis of bichromophoric compounds which serve as spectroscopic models may be carried out. This approach has been used recently to study the ring–ring stacking interaction and photocycloaddition of psoralen and thymine (3, 4).

We have prepared bichromophoric compounds containing adenine or thymine linked by a polymethylene chain with 7-oxycoumarin. The aim of this work is to study the ring–ring interactions between pyrimidine (thymine) or purine (adenine) bases and coumarin in the absence of the complicating factors present in the nucleic acid – furocoumarin complex (eg. hydrogen bonding). The intramolecular interactions could be detected in these systems by both absorption and emission spectroscopy. The results of such studies can be useful in the explanation of the origin of spectral changes resulting from complexation of coumarin in biological systems.

In this paper we present our results of uv absorption and fluorescence studies. The photochemistry of an adenine–coumarin pair was also of interest. Although it has been generally accepted that coumaryl compounds react mainly with thymine, there is experimental evidence that 8-methoxypsoralen can photochemically add to adenine (1).



SCHEME 1

Results and discussion

The compounds CouO-C_3-Ade (**1**),[1] CouO-C_5-Ade (**2**), and CouO-C_3-Thy (**3**) were synthesized according to Scheme 1. Thus 7-hydroxycoumarin was treated with 9-(3-bromopropyl)-adenine (Ade-C_3-Br) or 9-(5-bromopentyl)adenine (Ade-C_5-Br) in DMF solution in the presence of anhydrous K_2CO_3 to afford **1** and **2** respectively. Similar reaction of 1-(3-bromopropyl)thymine (Thy-C_3-Br) led to compound **3**. The ω-bromoalkyl derivatives of adenine and thymine were prepared as described previously (5, 6). We attempted the synthesis of **1**, **2**, and **3** starting from α-(7-oxycoumarinyl)ω-bromoalkane as a common intermediate, but difficulties occurred in the purification of this precursor, probably because of its lability. The reference compounds CouO-CH_3 (**4**), Ade-CH_3 (**5**), and Thy-CH_3 (**6**) were also prepared.

The compounds **1**, **2**, and **3** were examined by uv absorption

[1]Abbrevations used: Ade – aden-9-yl; Thy – thym-1-yl; CouO – 7-oxycoumarinyl; C_3, C_5 – n-propyl, n-pentyl.

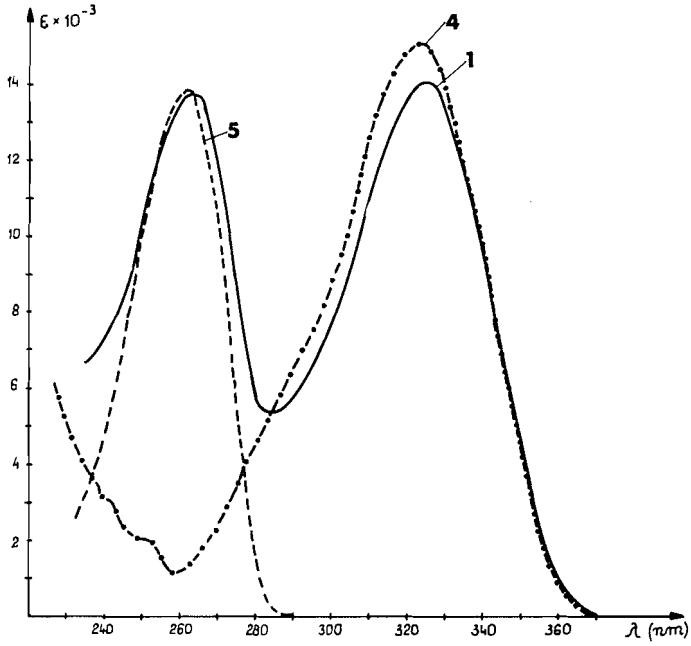


FIG. 1. Ultraviolet absorption spectra of **1** (———), **4** (–·–·–), and **5** (– – –) in water.

spectroscopy. This technique has been used to detect ground state complex formation of coumarins and psoralens with DNA (2). A bathochromic shift and a decrease in uv absorption had been observed in the spectrum of 5,7-dimethoxycoumarin as a result of intercalation into DNA (7). Similar but much smaller effects were observed for the coumarin chromophore in the synthesized compounds **1**, **2**, and **3**. Quanitatively, the spectral shape of the uv absorption bands of each compound closely resembles an equimolar mixture of its constituent monomers (Fig. 1).

Linking of the 7-oxycoumarin moiety to a nucleic acid base through the polymethylene chain caused only a small red shift (ca. 3 mm) of the near uv band of the former. Quantitatively, a reduction in band intensities compared to the sum of the absorption intensities of the component monomers was observed for aqueous solutions of the synthesized bichromophoric compounds. This loss of intensity is usually described by percent hypochromism (*%H*) and Table 1 shows the values calculated for the nucleotide base (adenine or thymine) and coumarin absorption bands of **1**, **2**, and **3**. The uv spectra were determined at a concentration low enough to avoid any intermolecular association (see Experimental). Hypochromism is common for systems which are stacked with chromophores one on the top of the other and has been widely used to assess intramolecular stacking in various bichromophoric systems (3, 4, 8, 9).

The appreciable hypochromism exhibited by CouO-C_3-Ade (**1**) in water indicates that at least a fraction of the molecules were in a stacked (folded) conformation in the ground state. CouO-C_5-Ade (**2**) is stacked to a lesser degree. Lengthening of a chain linking two chromophores reduces the *%H* value, as has been found previously for other systems (8, 10). The very weak hypochromic effect exhibited by CouO-C_3-Thy (**3**) in water probably indicates that the interactions between coumarin and thymine are weaker than those between coumarin and adenine. Water plays an important role in the interaction process because a reduced hypochromism or even hyperchromism was observed in methanol (Table 1). Methanol has been shown to destroy the stacking of bases in nucleic acids (11).

TABLE 1. Computed percent hypochromism (*%H*)

Compound	Water		Methanol
	238–300 nm[a]	300–370 nm[b]	300–370 nm[b]
CouO-C_3-Ade (**1**)	9.8±0.8[c]	7.0±1.0	1.7±1.0
CouO-C_5-Ade (**2**)	7.3±0.2	4.4±0.2	−5.3±1.0
CouO-C_3-Thy (**3**)	2.0±0.5	−0.1±0.4	−0.6±0.4

[a]Absorption is mainly due to adenine or thymine.
[b]Coumarin is the sole absorbing chromophore.
[c]The values calculated from three determinations were in this range.

In addition, CouO-C_3-Ade (**1**) showed essentially no hypochromism in dimethylsulfoxide which is known to disfavour stacking between intercalating molecules and nucleic acid base pairs (12). Whereas thymine and adenine display only a very weak fluorescence at room temperature ($\Phi_n \sim 10^{-4}$) (13), 7-methoxycoumarin does emit under these conditions (14). Fluorescence emission spectra of CouO-C_3-Ade (**1**), CouO-C_5-Ade (**2**), CouO-C_3-Thy (**3**), and CouO-CH_3 (**4**) were recorded in water and in methanol. Figure 2 shows the emission spectra in water measured for samples of equal optical density. The excitation wavelength was 324 nm, i.e. only the coumarin moiety was excited.

The fluorescence spectra of **1**, **2**, and **3** showed the same shape as that of **4** in the same solvent. The fluorescence quantum efficiencies for **4** in water and in methanol, relative quantum efficiencies (see Experimental), and maximum emission wavelengths are given in Table 2. In water, the fluorescence intensity of coumarin bound into the CouO-C_3-Ade (**1**), CouO-C_5-Ade (**2**), and CouO-C_3-Thy (**3**) systems was found to be sensitive to the environment (attached nucleotide base) and considerably less than that of CouO-CH_3 (**4**) itself. This reduction in intensity is certainly due to intramolecular quenching of the coumarin fluorescence by the neighbouring nucleotide base. The fluorescence quenching is consistent with the existence of a portion of the molecules **1**, **2**, **3** in folded or stacked conformations which are nonfluorescent. In the ground state the presence of such folded forms in aqueous solution follows from the calculated *%H* values, at least in the case of **1** and **2**. Although *%H* calculated for CouO-C_3-Thy (**3**) in aqueous solution is near zero, the fluorescence quantum yield for **3** is only 30% of the value found for CouO-CH_3 (**4**). It should be pointed out, however, that hypochromism is dependent both on π-orbital overlap and the relative orientation of transition moments and, as has been shown previously (10), zero hypochromism does not necessarily mean that there are no ground state stacked conformations. Moreover, in molecules like **1**, **2**, and **3**, in which intramolecularly complexed forms are in dynamic equilibrium with open forms, the observed quenching of the fuorescence may arise not only from a ground state complexation (static quenching), but also from a quenching occurring during the excited state lifetime (dynamic quenching) (8). Better understanding of the role of static quenching in observed fluorescence quenching must await fluorescence lifetime determinations. The relative fluorescence quantum yields for **1**, **2**, and **3** are much higher in methanol, indicating very little or no quenching. The fluorescence intensity of 5,7-dimethoxycoumarin in the presence of DNA has been shown to be significantly diminished by static quenching, i.e. the fluorescence lifetime remained unchanged (7, 15).

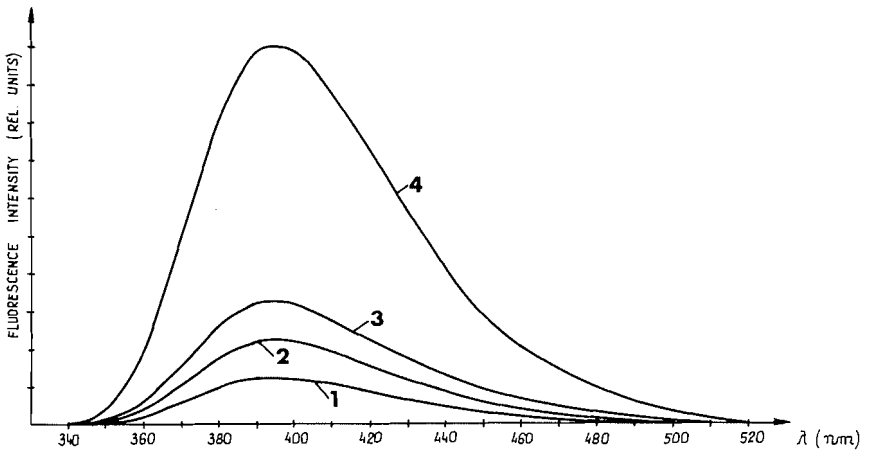

FIG. 2. Fluorescence spectra of **1**, **2**, **3**, and **4** in water; λ_{ex} = 324 nm.

TABLE 2. Relative quantum efficiencies[a,b]

Compound	Water[c]	Methanol[d]
CouO-C_3-Ade (**1**)	0.12	0.81
CouO-C_5-Ade (**2**)	0.22	1.44
CouO-C_3-Thy (**3**)	0.32	1.01

[a]The values had a reproducibility of ±10%.
[b]Excitation 324 nm.
[c]Relative to 7-methoxycoumarin (**4**) in water, fluorescence max 393 nm (corr). Φ_n = 0.16 (quinine sulfate as a standard).
[d]Relative to **4** in methanol, fluorescence max 388 nm (corr). Φ_n = 0.02 (quinine sulfate as a standard).

Fluorescence studies of **1**, **2**, and **3** have also revealed that light energy absorbed in the adenine or thymine part of the molecules is transferred to the fluorescent coumarin moiety. Excitation energy transfer was demonstrated by a comparison of corrected fluorescence excitation and absorption spectra (Figs. 3 and 4). The absorption spectrum of CouO-C_3-Thy (**3**) is almost identical to that of an equimolar mixture of the single chromophores (negligible $\%H$, Table 1) but their fluorescence excitation spectra differ considerably (Fig. 3).

The excitation spectrum of the mixture of Thy-CH_3 (**6**) and CouO-CH_3 (**4**) is superimposable upon that of **4**, indicating no energy transfer. However, an additional peak in the region where thymine absorbs appears in the excitation spectrum of **3**. Energy transfer, although less efficient, was demonstrated also for CouO-C_3-Ade (**1**) and CouO-C_5-Ade (**2**), (Fig. 4). This energy transfer process was further indicated by the observed dependency of the relative fluorescence quantum efficiencies of **1**, **2**, and **3** on excitation wavelength. These values are constant at $\lambda_{ex} > 300$ nm, where only coumarin absorbs the light, and are presented in Table 2 for λ_{ex} = 324 nm. At $\lambda <$ 300 nm, where nucleotide base and coumarin were simultaneously excited, the relative fluorescence efficiencies (determined as described in the experimental section) increased. The respective values are 1.43, 1.07, and 0.65 for **3** at λ_{ex} = 260, 270, and 280 nm and 0.42 for **1** and 0.44 for **2** at λ_{ex} = 260 nm.

The energy transfer efficiency T can be determined from these measurements using the equation derived by A. Kawski and co-workers (16) for systems in which the absorption of the macromolecule is a sum of the absorption of single chromophores. Thus the energy transfer efficiency for CouO-C_3-Thy

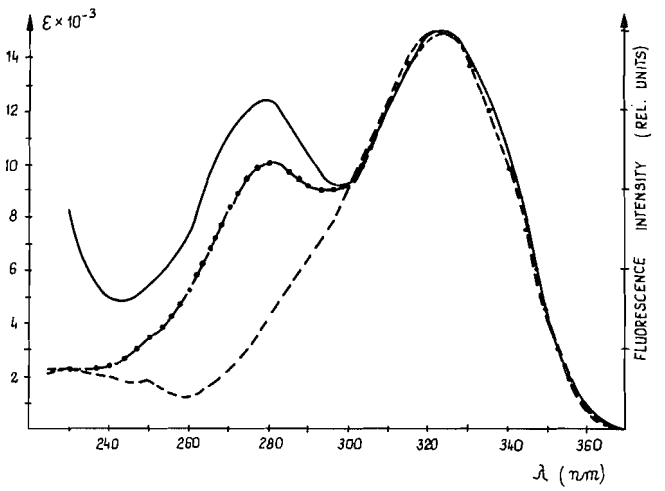

FIG. 3. Absorption spectrum of **3** (——); corrected excitation spectrum of **3** (–·–·–); corrected excitation spectrum of **4** + **6** (– – –). Solvent: water; fluorescence at 393 nm was monitored.

(**3**) (negligible $\%H$, Table 1) was calculated, e.g. for λ_{ex} = 260 nm;

$$T = \left[\frac{\text{rel.fluoresc. efficiency for } \mathbf{3}\ (\lambda_{ex} = 260\text{ nm})}{\text{rel.fluoresc. efficiency for } \mathbf{3}\ (\lambda_{ex} = 324\text{ nm})} - 1\right] \times \frac{A_{260\,nm} \text{ of } \mathbf{4}}{A_{260\,nm} \text{ of } \mathbf{6}}$$

where A is the absorbance. The value of T for **3** calculated for λ_{ex} = 260, 270, 280 nm was found to be 0.60.

Photochemistry of CouO-C_5-Ade (**2**) was also investigated. This compound was chosen because a chain with at least five methylene units is necessary to allow the superposition of the $C^3{=}C^4$ coumarin and $N^7{=}C^8$ adenine reactive bonds. This imidazole part of adenine has been shown to be involved in formation of a photocycloadduct with thymine (17). Since **2** was only sparingly soluble in water, a solution in methanol ($c = 3 \times 10^{-4}$ M) was used. Analysis of the product mixture showed, however, that intermolecular photodimerization of coumarin residues was dominant. The major product was isolated and assigned the dihydroxy diester structure, **7** (Scheme 2). Analysis of uv absorption and ^{1}H nmr spectra of the photoproduct and starting CouO-C_5-Ade (**2**) led to the conclusion that adenine remained intact in **7**.

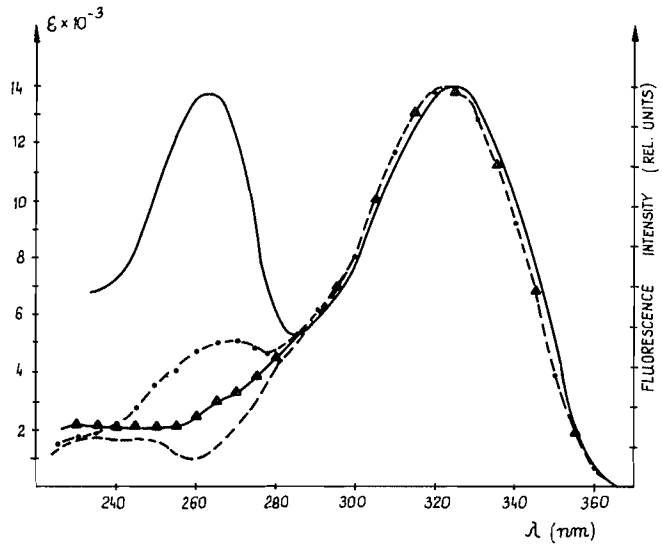

FIG. 4. Absorption spectrum of **1** (——); corrected excitation spectra of **1** (–·–·–), **2** (–▲–▲–), and **4** + **5** (– – –). Solvent: water; fluorescence at 393 nm was monitored.

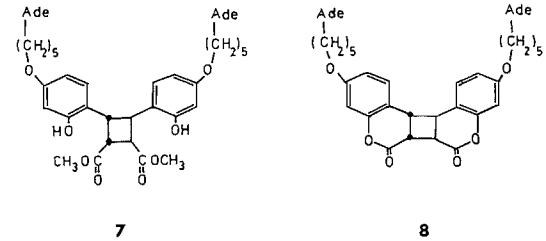
The ^{1}H nmr spectrum of **7** shows no pyrone double bond protons but instead new signals are observed in a spectral region typical for cyclobutane protons. It was not possible to establish the configuration of **7** on the basis of the ^{1}H nmr spectrum because of overlapping cyclobutane and pentamethylene bridge proton signals. However, a comparison of the low field part of the absorption of cyclobutane protons with that of the four possible coumarinic acid photodimers suggests the *anti* head-to-head configuration for **7** (18). This assignment is in accord with literature data. Dependence of the photodimer distribution on the solvent polarity and coumarin concentration has been observed (19). Photolysis of a dilute methanolic solution of coumarin (10^{-2} *M*) has been reported to give *anti* head-to-head and *syn* head-to-head dimers in the ratio of 13:1. However, only the dihydropyrone ring of the former opened easily in methanol (20). One of the minor photoproducts was tentatively assigned as the cyclobutane photodimer **8** on the basis of its properties. It converts to **7** in the presence of methanol and splits to give back CouO-C_5-Ade (**2**) after reirradiation with λ = 254 nm. On the other hand, **2** was not recovered from **7** although the irradiation with λ = 254 nm is accompanied by appearance of a low intensity band at λ > 300 nm.

Experimental

All melting points are uncorrected. The ir spectra were run on a Perkin-Elmer 580 and uv absorption spectra were recorded on a Zeiss Specord M-40 spectrophotometer. The ^{1}H nmr spectra were determined on Varian A-60 (60 MHz) and JEOL FX 90 Q (90 MHz) spectrometers using tetramethylsilane as internal standard. The mass spectra were determined using a JEOL D-100 spectrometer at an ionization potential of 70 eV. Microanalyses were performed using a Perkin–Elmer Elemental Analyzer 240. Doubly distilled water, methanol, and dimethylsulfoxide (spectroscopic grade, Merck) were used as solvents.

Electronic absorption

Quantitative measurements were made using 6×10^{-5} *M* solutions of bichromophoric compounds **1**, **2**, and **3** and constituent monomers (reference compounds) **4**, **5** and **6** in water, methanol, and dimethylsulfoxide. Spectra were determined in 10-mm cells. In the case of



SCHEME 2

CouO-C_5-Ade (**2**) in water, because of solubility limitation, a 9×10^{-6} *M* solution was used and absorption measured in 50-mm cells. Percentages of hypochromism (%*H*) were determined by quantitative comparison of absorption spectra of bichromophoric compounds with the summation of the spectra of reference compounds as described earlier (6). Oscillator strengths $f = 4.32 \times 10^{-9} \times \int \epsilon(\tilde{\nu}) d\tilde{\nu}$ were computed from absorption spectra using Simpson's rule.

Fluorescence measurements

Uncorrected emission spectra were recorded on a Perkin–Elmer MPF-3 spectrofluorometer. Relative fluorescence quantum efficiencies were determined by integration and comparison of uncorrected emission spectra of the compounds **1**, **2**, and **3** with that of **4** when exciting at λ > 300 nm (coumarin solely absorbs) or an equimolar mixture of reference compounds: **4** + **5** or **4** + **6** at λ_{ex} < 300 nm. Both the solution of bichromophoric compound and the mixture of reference compounds had equal optical density at the exciting wavelength. Fluorescence spectra used for these determinations were not corrected for photomultiplier response and monochromator efficiency because only coumarin fluorescence was observed. Corrected fluorescence emission and excitation spectra were recorded on a Perkin–Elmer MPF-44 spectrofluorometer. Fluorescence quantum efficiencies for **4** in water (pH 6.5) and in methanol were measured from corrected spectra using quinine sulfate as a standard (0.1 *N* H_2SO_4, Φ_{fl} = 0.55 (21)). Optical densities of the samples (10-mm cells) for fluorescence studies were ≤ 0.05, i.e. concentrations of the solutions were in the range of $2.2-6.8 \times 10^{-6}$ *M*.

Materials

The following compounds had been described previously: 9-(3-bromopropyl)adenine, 9-(5-bromopentyl)adenine (5), 1-methylthymine (22), 9-methyladenine (23), 7-methoxycoumarin (24). All these materials have been synthesized in this work by alkylation of a heterocycle with an appropriate 1,ω-dibromoalkane or methyl iodide in DMF solution in the presence of K_2CO_3. 1-(3-Bromopropyl)thymine has been synthesized by the method described in ref. 6.

Synthesis of CouO-C_3-Ade (1), CouO-C_5-Ade (2) and CouO-C_3-Thy (3)

All the compounds were synthesized following the same general procedure. In a typical experiment a solution of 256 mg (1 mmol) of 9-(3-bromopropyl)adenine in 30 mL of dry dimethylformamide was added dropwise to a suspension of 162 mg (1 mmol) of 7-hydroxycoumarin and 152 mg (1.1 mmol) of anhydrous potassium carbonate in 10 mL of dimethylformamide. The mixture was stirred overnight at room temperature. After filtration, solvent was removed from the filtrate *in vacuo* and the yellow residue treated with methanol–isopentane mixture. The resulting suspension was filtered to collect the crude **1**. Crude products were chromatographed on silica gel (ethyl acetate – methanol, 3:1) and finally crystallized from aqueous methanol.

7-[3-(Aden-9-yl)propyloxy]coumarin (1)

Yield: 55%; mp 200°C; uv (H_2O): 263 nm (13 700), 325 nm (13 800); ^{1}H nmr (DMSO-d_6)δ: 8.1 (s, 2, Ade^{2}H and Ade C^{8}H), 7.9 (d, *J* = 10 Hz, 1, CouC=C^{4}H), 7.7–7.4 (m, 1, phenyl H), 7.2 (br s, 2, NH_2), 7.0–6.8 (m, 2, phenyl H), 6.2 (d, *J* = 10 Hz, 1, CouC=C^{3}H), 4.5–3.9 (m, 4, NCH_2 and OCH_2), 3.3–3.1 (m, 2, CCH_2C); ms *m/e* (rel int %): M^+ 337 (34), 192 (14), 176 (100), 175

(6), 162 (8), 149 (92), 135 (42), 134 (14). *Anal.* calcd. for $C_{17}H_{15}N_5O_3$: C 60.5, H 4.5, N 20.8; found: C 60.2, H 4.5, N 20.9.

7-[5-(Aden-9-yl)pentyloxy]coumarin (2)

Yield: 67%; mp 223°C; uv (H_2O): 264 nm (14 400), 325 nm (14 100); ^{1}H nmr (TFA)δ: 8.7 (s, 2, Ade C^2H and Ade C^8H), 8.1 (d, 1, CouC=C^4H), 7.7–7.4 (m, 1, phenyl H), 7.2–6.9 (m, 2, phenyl H), 6.5 (d, 1, CouC=C^3H), 4.9–4.5 and 4.4–4.0 (2t, 4, NCH_2 and OCH_2), 1.7–2.4 (m, 6, $C(CH_2)_3C$); ms *m/e* (rel int %): M^+ 365 (10), 337 (3), 220 (6), 204 (52), 191 (100), 190 (59), 176 (27), 175 (9), 162 (27), 149 (77), 135 (42), 134 (9). *Anal.* calcd. for $C_{19}H_{19}N_5O_3$: C 62.4, H 5.2, N 19.2; found: C 62.6, H 5.4, N 19.0.

7-[3-(Thym-1-yl)propyloxy]coumarin (3)

Yield: 30%; mp 228–229°C; uv (H_2O): 278 nm (12 300), 324 nm (15 000); ^{1}H nmr (TFA)δ: 8.0 (d, 1, CouC=C^4H), 7.7–7.4 (m, 2, ThyC^6H and phenyl H), 7.2–6.9 (m, 2, phenyl H), 6.6 (d, 1, CouC=C^3H), 4.5–4.0 (m, 4, NCH_2 and OCH_2), 2.6–2.2 (m, 2, CCH_2C), 2.0 (s, 3, CH_3); ms *m/e* (rel int %): M^+ 328 (6), 189 (1), 175 (1), 167 (100), 139 (12), 134 (3). *Anal.* calcd. for $C_{17}H_{16}N_2O_5$: C 62.2, H 4.9, N 8.5; found: C 61.9, H 5.0, N 8.4.

Irradiation of 2

A high-pressure mercury lamp TQ 150 (Original Hanau) cooled with water was used as a light source. This was immersed in a Pyrex reactor provided with an additional jacket filled with a 2-mm layer of the filter solution. A 1-mm layer of the filter solution (sodium bromide and lead acetate (24)) had optical densities >3, 1.0, 0.40, and 0.18 at 313, 324, 330, and 335 nm respectively. Compound **2** (427 mg) was dissolved in 3.5 L of methanol ($c = 3 \times 10^{-4} M$). A portion (130 mL) of the solution was placed in the reactor and deoxygenated by bubbling nitrogen 1 h before and during the irradiation. Irradiation was performed until 60% of starting material reacted (2 h) as judged from the uv spectrum. Chromatography over silica gel (ethyl acetate – methanol, 5:1) gave 189 mg of the mixture of dimers **7** and **8** and unidentified material. The products were further separated on a silical gel column. Elution with chloroform–methanol – acetic acid (140:7.5:2.5) gave 136 mg of **7** (50% yield based on **2** reacted); 25 mg of homogeneous material (free of **7**), which yielded the mixture of **7** and the other product upon standing in methanol, was also obtained.

Photoproduct 7

Ultraviolet (CH_3OH): 237 nm (21 000), 263 nm (28 000), shoulder 285 nm (7000); ir (KBr): 3430, 3340, 3180, 2950, 2870, 1725, 1640, 1615, 1600, 1520, 1475, 1435, 1415, 1290, 1250, 1170, 1030, 835, 800 cm^{-1}; ^{1}H nmr (DMSO-d_6)δ: 8.2 (s, 4, Ade C^2H and Ade C^8H), 7.2 (br s, 4, NH_2), 6.3–7.0 (m, 6, phenyl H), 6.2 (br s, 2, OH), 4.8–4.4 (m, 2, cyclobutyl H), 4.3–3.3 (m, 10, cyclobutyl H and OCH_2, NCH_2), 3.3 (s, 6, OCH_3), 2.0–1.3 (m, 12, $C(CH_2)_3C$); ms *m/e* (rel int %): 204 (4), 191 (73), 190 (46), 176 (11), 162 (18), 149 (60), 148 (100), 145 (5), 135 (51), 134 (54), 133 (16). *Anal.* calcd. for $C_{40}H_{46}N_{10}O_8$: C 60.4, H 5.8, N 17.6; found: C 60.1, H 5.7, N 17.4.

Structures of rengyol, rengyoxide, and rengyolone, new cyclohexylethane derivatives from *Forsythia suspensa* fruits

KATSUYA ENDO AND HIROSHI HIKINO
Pharmaceutical Institute, Tohoku University, Aoba-yama, Sendai, Japan

Received January 23, 1984

This paper is dedicated to Professor Paul De Mayo on the occasion of his 60th birthday

KATSUYA ENDO and HIROSHI HIKINO. 1984. Can. J. Chem. **62**, 2011 (1984).

Three new C_6-C_2 natural alcohols, rengyol (**1**), rengyoxide (**2**), and rengyolone (**3**), have been isolated from *Forsythia suspensa* fruits, along with a novel glycoside, forsythoside E (**4**), a new sugar ester, 4-caffeoylrutinose, and a known quinol glucoside, cornoside (**5**). Chemical and spectroscopic studies have established the structures of these new constituents.

KATSUYA ENDO et HIROSHI HIKINO. 1984. Can. J. Chem. **62**, 2011 (1984).

On a isolé trois nouveaux alcools naturels en C_6—C_2 des fruits de la *Forsythia suspensa*, soit le rengyol (**1**), le rengyoxide (**2**) et la rengyolone (**3**); on a aussi isolé de la même source un nouveau glycoside, le forsythoside E (**4**), un nouvel ester d'un sucre, le caféoyl-4 rutinose, et un glucoside connu du quinol, le cornoside (**5**). Des études chimiques et spectroscopiques ont permis d'établir les structures de ces nouveaux constituants.

[Traduit par le journal]

For personal use only.

Forsythia suspensa Vahl (Oleaceae) is an important original plant of the crude drug "rengyo" (Forsythiae Fructus) which has been used for antiinflammatory, diuretic, drainage, and antidotal purposes in Oriental medicine. The crude drug has also been known to exhibit antibacterial activity, and we have recently disclosed that the principal antibacterial constituent of the crude drug originating from the fruits of *F. suspensa* is the glycoside, forsythoside A (**6**), which occurs also in the leaves of the same plant (1). We have also revealed that the fruits of *F. suspensa* contain other antibacterial glycosides, forsythoside C (**7**) and forsythoside D (**8**), in addition to D-glucose, L-rhamnose, and rutinose (2).

In a continuation of our chemical and pharmacological study of this crude drug, the fruits of *F. suspensa*, we have now isolated three new natural alcohols, rengyol (**1**), rengyoxide (**2**), and rengyolone (**3**), having an unusual nonaromatic C_6—C_2 carbon skeleton presumably derived from phenylpropanoids, together with a new glycoside, forsythoside E (**4**), a new sugar ester, 4-caffeoylrutinose, and a known glucoside, cornoside (**5**). This report deals with the structure determination of these new constituents.

Rengyol (**1**), mp 124°C, $[\alpha]_D$ +0.08°, analyzed for $C_8H_{16}O_3$ and displayed ion peaks at *m/e* 161.1206 ($C_8H_{17}O_3$: 161.1203) and 142.0992 ($C_8H_{14}O_2$: 142.0992) in its high resolution mass spectrum. The ^{13}C nmr spectrum of rengyol exhibited three signals (δ 58.7, 69.7, 69.9) assignable to the carbon substituted with an oxygen. Since the number of these carbon atoms was the same as that of the oxygen atoms present in the molecule, all oxygen atoms were expected to constitute hydroxyl groups. In fact, rengyol yielded the diacetate (**1***a*) on acetylation with acetic anhydride in pyridine and the dibenzoate (**1***b*) on benzoylation with benzoyl chloride in pyridine. The former was acetylated further to the triacetate (**1***c*) by acetic anhydride and 4-dimethylaminopyridine in triethylamine, while on controlled reaction with acetic anhydride in ethanolic pyridine, rengyol yielded the monoacetate (**1***d*). These results substantiated that three hydroxyl groups existed in rengyol (**1**) and they suffered from different degrees of steric hindrance. The ^1H nmr spectra of the diacetate (**1***a*) and the dibenzoate (**1***b*) revealed the presence of a primary acyloxyl group (δ 4.24, 2H triplet, *J* 7 Hz for **1***a*; δ 4.54, 2H triplet, *J* 7 Hz for **1***b*), adjacent to a methylene group, and a secondary acyloxyl group (δ 4.66, 1H quintet, *J* 6.5 Hz for **1***a*; δ 4.98, 1H quintet, *J* 6.5 Hz for **1***b*). The corresponding signals for rengyol (**1**) were observed at δ 3.74 (2H triplet, *J* 7 Hz) and 3.53 (1H broad quintet, *J* 6.5 Hz), while those for the triacetate (**1***c*) and the monoacetate (**1***d*) appeared at δ 4.10 (2H triplet, *J* 7 Hz), 4.69 (1H m), and δ 4.27 (2H triplet, *J* 7 Hz), 3.61 (1H multiplet), respectively.

The ^{13}C nmr spectrum of rengyol exhibited only six carbon signals, indicating the presence of two pairs of equivalent methylene groups (δ 31.6, 2C triplet; 36.0, 2C triplet) (Table 1). The absence of optical activity as well as the structural features described above suggested that three hydroxyl groups were situated in a plane of symmetry. Hence, the presence of a cyclohexane system substituted with a β-hydroxyethyl group and two hydroxyl groups at the C-1 and C-4 positions was deduced. The configuration of the secondary hydroxyl group at the C-4 position was assigned to be equatorial, based on the half-height width, $W_{1/2}$ 20 Hz, of the multiplet signals for the axially oriented C-4 methine hydrogen of the

2*c*: $R^1=R^2=H$, $R^3=(OCH_3)_2$

2*d*: $R^1=R^2=Ac$, $R^3=(OCH_3)_2$

triacetate (**1***c*, δ 4.69) and the monoacetate (**1***d*, δ 3.61), although the coupling constants and the half-height width of the corresponding methine signals in rengyol (**1**) and its diesters (**1***a* and **1***b*) were not informative because of the virtual coupling. This assignment was supported further by the result of an empirical calculation of the carbon-13 shielding. Thus the observed resonance at δ 69.7 for the C-4 carbon of rengyol was in good accordance with the calculated value, δ 69.4, for 1-alkyl substituted *cis*-1,4-cyclohexanediol, but clearly different from the value, δ 64.0, for the *trans* isomer (3). Consequently, the stereostructure of rengyol has been concluded to be **1**, provided that the substituent with a higher conformational energy, the β-hydroxyethyl group, assumes the more stable equatorial configuration.

Rengyoxide (**2**), $[\alpha]_D$ +0.16°, exhibited ion peaks at *m/e* 158 (M) in its mass spectrum, corresponding to the molecular formula, $C_8H_{14}O_3$. The ^1H nmr spectrum of rengyoxide resembled that of rengyol (**1**) and displayed the signal compatible with a primary hydroxyl group (δ 3.77, 2H triplet, *J* 7 Hz) that was next to a methylene group (δ 1.80, 2H triplet), but lacked the signal assignable to a secondary hydroxyl group. The ^{13}C nmr spectrum of rengyoxide was also similar to that of rengyol (**1**) and showed only six carbon signals, suggesting the presence of two pairs of equivalent methylene groups (δ 28.6, 2C triplet; 34.7, 2C triplet) in addition to one primary and one tertiary carbon-oxygen bond (δ 58.8, 1C triplet; 70.3, 1C singlet) (Table 1). Elemental composition of rengyoxide indicated the presence of two degrees of unsaturation in the structure. Since infrared and ^{13}C nmr spectra of rengyoxide did not exhibit any signal assignable to an olefinic group or a carbonyl group, it was expected to contain one oxide ring in a cyclohexyl group. The resonance signal at δ 100.2 (singlet) in the ^{13}C nmr spectrum was thus assigned to a geminally dioxygenated carbon. The absence of optical activity as well as the structural features described above suggested that the structure of rengyoxide corresponded to the 4-dehydro derivative of rengyol existing almost exclusively in the hemiketal form by intramolecular interaction with a hydroxyl group.

In coincidence with this view, reaction of rengyoxide (**2**) with acetic anhydride in pyridine at room temperature yielded, as a sole product, the monoacetate (**2***a*), which, however, was esterified further by acetic anhydride in triethylamine with the aid of 4-dimethylaminopyridine affording the diacetate (**2***b*). On the other hand, treatment of rengyoxide with methanolic hydrogen chloride at room temperature produced the dimethyl ketal (**2***c*), which in turn was transformed into the corresponding diacetate (**2***d*) by acetic anhydride and 4-dimethylaminopyridine in triethylamine. Moreover, the reaction of rengyoxide with sodium borohydride in aqueous methanol resulted in almost exclusive formation of only one epimeric alcohol, which was identified as rengyol (**1**) itself. Reversibly, Collins oxidation of the rengyol monoacetate (**1***d*) yielded the corresponding dehydro derivative (**2***a*), identical to the rengyoxide monoacetate, which on alkaline hydrolysis generated rengyoxide (**2**). These reactions, as well as the interconversions of rengyol (**1**) and rengyoxide (**2**), rigorously established the nature and location of the oxygen functions in the molecule, and consequently the structure of rengyoxide has been established as represented by the formula **2**.

Rengyolone (**3**), $[\alpha]_D$ +0.26°, exhibited ion peaks at *m/e* 154 (M) corresponding to the molecular formula $C_8H_{10}O_3$. The ultraviolet and ^1H nmr spectra of rengyolone revealed the presence of an oxymethylene group (δ 4.02, 2H triplet, *J* 7 Hz) adjacent to a methylene group (δ 2.27, 2H multiplet), an oxymethine group (δ 4.24, 1H double doublet with doubling, *J* 6, 5, and 1.5 Hz) next to another methylene group (δ 2.64, 1H double doublet, *J* 17 and 6 Hz; 2.73, 1H double doublet, *J* 17 and 5 Hz), and an α,β-unsaturated carbonyl group (λ_{max} 227 nm; δ 5.95, 1H doublet, *J* 10 Hz; 6.74, 1H double doublet, *J* 10 and 1.5 Hz). The existence of a long-range coupling (*J* 1.5 Hz) between the signals at δ 6.74 and 4.24 indicated that the corresponding hydrogens were situated in quasi equatorial orientation. Although rengyolone exhibited a broad absorption at 3420 cm^{-1} in its infrared spectrum, it was recovered unchanged from a reaction with acetic anhydride in pyridine at room temperature overnight, showing the presence of a hydroxyl group which was in a hindered position. This structural information, as well as the carbon-13 shieldings (Table 1), led to the stereostructure **3** for rengyolone, and the spectral data of rengyolone were in good agreement with those of the substance derived from *p*-hydroxyphenylethanol by photosensitized oxygenation (4). Since rengyolone (**3**) shows no cd (circular dichroism) absorption, it is regarded as a racemic mixture.

Forsythoside E (**4**), $[\alpha]_D$ −35.3°, showed ion peaks at *m/e* 501 (M+K), 485 (M+Na), and 463 (M+H) in its field desorption mass spectrum, corresponding to the molecular formula $C_{20}H_{30}O_{12}$. The ultraviolet and ^1H nmr spectra of forsythoside

5

E indicated the presence of a secondary methyl group (δ 1.25, 3H doublet, *J* 6 Hz), a benzylic methylene group (δ 2.77, 2H triplet, *J* 7 Hz), two anomeric methine groups (δ 4.27, 1H doublet, *J* 8 Hz; 4.74, 1H doublet, *J* 1.5 Hz), and a trisubstituted phenyl group (λ_{max} 282 nm; δ 6.4−6.9, 3H multiplet). From this information, forsythoside E was regarded as the decaffeoyl derivative of forsythoside A (**6**). In fact, on mild alkaline hydrolysis with sodium hydroxide in aqueous methanol, forsythoside A (**6**) yielded methyl caffeoate (2) and decaffeoylforsythoside A (**4**), $[\alpha]_D$ −39.9°, which was found identical to forsythoside E.

4-Caffeoylrutinose, $[\alpha]_D$ −8.0°, displayed an ion peak at 512 (M+Na+1) in its field desorption mass spectrum, reflecting the molecular formula $C_{21}H_{28}O_{13}$. The ultraviolet and ^{1}H nmr spectra of this substance revealed the presence of a secondary methyl group (δ 1.19, 3H doublet, *J* 6.5 Hz), an anomeric methine group (δ 4.59, 1H doublet, *J* 1.5 Hz) and a caffeoyl group (λ_{max} 328 nm; δ 6.7−7.1, 3H multiplet; 6.26, 1H doublet, *J* 16 Hz; 7.56, 1H doublet, *J* 16 Hz). Further, the presence of another anomeric methine group in equilibrium was indicated by a pair of signals at δ 4.52 (doublet, *J* 8 Hz) and 5.08 (broad singlet), totalling one hydrogen equivalent. Alkaline hydrolysis of this substance with sodium hydroxide as above yielded methyl caffeoate and rutinose (2), proving that this substance was a caffeoyl ester of rutinose. The acyl group was allocated to the C-4 position of the glucosyl group based on a detailed analysis of the ^{13}C nmr spectrum (2,3). Thus the new sugar ester has been characterized as 4-caffeoylrutinose.

Cornoside (**5**), $[\alpha]_D$ −10.5°, exhibited ion peaks at *m/e* 316 (M) in its field desorption mass spectrum, corresponding to the molecular formula $C_{14}H_{20}O_8$. The ultraviolet and ^{1}H nmr spectra of this substance disclosed the presence of a methylene group (δ 2.05, 2H triplet, *J* 7 Hz), an anomeric methine group (δ 4.23, 1H doublet, *J* 7 Hz), and an α,β-unsaturated carbonyl group (λ_{max} 224 nm; δ 6.11, 2H doublet, *J* 10 Hz; 7.01, 2H doublet, *J* 10 Hz). The characteristic chemical shift of the carbonyl resonance (δ 185.8, singlet) in its ^{13}C nmr spectrum, in addition to the presence of two equivalent olefinic groups (δ 127.0, 2C doublet; 153.6, 2C doublet) and a quaternary carbon (δ 68.2, singlet) (Table 1), demonstrated that this substance had a *para*-quinol type partial structure (5). The ^{13}C nmr spectrum also indicated the presence of a β-glucosyl group. Consequently, the sugar derivative was considered to be cornoside (**5**) (6), and in fact, the physicochemical data presented above agreed well with the reported values (6).

Experimental

Melting points are uncorrected. The nmr spectra were run at 100 MHz (^{1}H) and 25 MHz (^{13}C). Chemical shifts (δ) are reported in ppm from internal TMS and coupling constants (*J*) given in Hz. Abbreviations: s = singlet, d = doublet, t = triplet, q = quartet, m = multiplet.

Isolation of the constituents

The methanol extract (109 g) of *F. suspensa* fruits (1.0 kg) was extracted successively with AcOEt and BuOH in the presence of water, yielding the AcOEt soluble fraction (45 g), BuOH soluble fraction (21 g), and water soluble fraction (25 g), respectively.

The BuOH fraction (16 g) was then placed on a column of polyamide (Wako Polyamide C-200, 300 g) and eluted with 20% water−MeOH (800−1200 mL) to give a fraction (3.26 g) that was further fractionated on Sephadex LH-20 (Pharmacia, 350 mL) with MeOH, yielding a crystalline substance, rengyol (**1**, 1.1 g): colourless prisms (MeOH), mp 123−124°C, $[\alpha]_D$ +0.08° (*c* 1.21, MeOH); ^{1}H nmr (CD_3OD) δ: 3.53 (1H broad quintet, *J* 6.5), 3.74 (2H t, *J* 7); ms *m/e*: 142 (M − H_2O), 115 (M − C_2H_4OH). *Anal.* calcd. for $C_8H_{16}O_3$: C 59.97, H 10.07; found: C 59.34, H 10.08.

The mother liquid (850 mg) of recrystallization of **1** was chromatographed on silica gel (Merck Kiesel gel 60, 30 g) and eluted with 3% MeOH−$CHCl_3$ to afford the crude rengyoxide fraction (60 mg) that was purified by repeated chromatography to give rengyoxide (**2**): colourless oil, $[\alpha]_D$ +0.16° (*c* 1.66, MeOH); ^{1}H nmr (CD_3OD) δ: 1.80 (2H t, *J* 7), 3.77 (2H t, *J* 7); ms *m/e*: 158 (M), 140 (M − H_2O), 130 (M − CO).

The crude rengyol fraction (1.65 g) of the Sephadex LH-20 chromatography mentioned above was again applied on a Sephadex LH-20 column and eluted with MeOH to yield the following constituents.

Rengyolone (**3**, 120 mg): colourless oil, $[\alpha]_D$ +0.26° (*c* 1.14, MeOH); uv λ_{max} (MeOH) nm: 227; ir ($CHCl_3$) cm^{-1}: 3420, 1680; ^{1}H nmr ($CDCl_3$) δ: 2.27 (2H m), 2.64 (1H dd, *J* 6, 17), 2.73 (1H dd, *J* 5, 17), 4.02 (2H t, *J* 7), 4.24 (1H ddd, *J* 1.5, 5, 6), 5.95 (1H d, *J* 10), 6.74 (1H dd, *J* 1.5, 10) ms *m/e*: 154 (M), 137 (M − OH), 110 (M − C_2H_4OH).

Cornoside (**5**, 26 mg): colourless oil, $[\alpha]_D$ −10.5° (*c* 0.26, MeOH); uv λ_{max} (MeOH) nm: 224; ^{1}H nmr (CD_3OD) δ: 2.05 (2H t, *J* 7), 4.23 (1H d, *J* 7), 6.11 (2H d, *J* 10), 7.01 (2H d, *J* 10); ^{13}C nmr (pyridine-d_5) δ: 104.5 (d, C-1′), 75.0 (d, C-2′), 78.3 (d, C-3′), 71.5 (d, C-4′), 78.3 (d, C-5′), 62.6 (t, C-6′) for the β-glucosyl group. Data for the aglycone part is given in the Table 1.

Continued elution of the above polyamide column, for the BuOH-solubles of the crude drug extract, with 20% water − MeOH (1200−2400 mL) yielded, after purification by repeated chromatography (Sephadex LH-20/MeOH), the following constituents.

Forsythoside E (**4**, 35 mg): a pale yellow amorphous solid, $[\alpha]_D$ −35.3° (*c* 0.41, MeOH); uv λ_{max} (MeOH) nm: 282; ^{1}H nmr (CD_3OD) δ: 1.25 (1H d, *J* 6), 2.77 (2H t, *J* 7), 4.27 (1H d, *J* 8), 4.74 (1H d, *J* 1.5), 6.4−6.9 (3H m); ^{13}C nmr (pyridine-d_5) δ: 130.3 (s, C-1), 117.2 (d, C-2), 146.7 (s, C-3), 145.2 (s, C-4), 116.4 (d, C-5), 120.4 (d, C-6), 36.2 (t, C-7), 71.2 (t, C-8) for the aglycone; 104.4 (d, C-1′), 74.8 (d, C-2′), 78.3 (d, C-3′), 71.6 (d, C-4′), 76.8 (d, C-5′), 68.0 (t, C-6′) for the glucosyl group; and 102.2 (d, C-1″), 72.5 (d, C-2″), 72.0 (d, C-3″), 73.7 (d, C-4″), 69.6 (d, C-5″), 18.5 (q, C-6″) for the rhamnosyl group; fd−ms *m/e*: 501 (M+K), 485 (M+Na), 463 (M+H).

4-Caffeoylrutinose (28 mg): a pale yellow amorphous solid, $[\alpha]_D$ −8.0° (*c* 0.20, MeOH); uv λ_{max} (MeOH) nm: 245, 295, 328; ^{1}H nmr (CD_3OD) δ: 1.19 (3H d, *J* 6.5), 4.59 (1H d, *J* 1.5), 4.52 (d, *J* 8) and 5.08 (broad s) totalling 1H, 6.26 (1H d, *J* 16), 6.7−7.1 (3H m), 7.56 (1H d, *J* 16); ^{13}C nmr (pyridine-d_5) δ: 126.6 (s, C-1″), 115.6 (d, C-2″), 147.4 (s, C-3″), 151.7 (s, C-4″), 116.5 (d, C-5″), 122.0 (d, C-6″), 146.1 (d, C-7″), 114.6 (d, C-8″), 167.0 (s, C-9″) for the caffeoyl group; 93.8 (d, C-1), 74.0 (d, C-2), 72.6 (d, C-3), 73.1 (d, C-4), 70.0 (d, C-5), 67.5 (t, C-6) for the α-glucosyl group; 98.7 (d, C-1), 76.6 (d, C-2), 74.6 (d, C-3), 72.6 (d, C-4), 75.7 (d, C-5), 67.4 (t, C-6) for the β-glucosyl group; 102.1 (d, C-1′), 72.6 (d, C-2′), 71.9 (d, C-3′), 73.9 (d, C-4′), 69.6 (d, C-5′), 18.4 (q, C-6′) for the rhamnosyl group; fd−ms *m/e*: 512 (M+Na+1).

*Rengyol diacetate (**1**a)*

Rengyol (**1**, 80 mg) was treated with acetic anhydride (1 mL) in pyridine (5 mL) at room temperature overnight. The mixture was then worked up as usual and the product purified by column chromatography (silica gel/5% MeOH − $CHCl_3$) to afford the diacetate (**1***a*, 92 mg): colourless oil; ir ($CHCl_3$) cm^{-1}: 3530, 1725; ^{1}H nmr

($CDCl_3$) δ: 1.81 (2H t, *J* 7), 2.03 (3H s), 2.04 (3H s), 4.24 (2H t, *J* 7), 4.66 (1H quintet, *J* 6.5); ms *m/e*: 245 (M+1), 227 (M − OH), 184 (M − AcOH), 157 (M − C_2H_4OAc).

*Rengyol dibenzoate (**1**b)*

Rengyol (**1**, 50 mg) was allowed to react with benzoyl chloride (1.0 mL) in pyridine (10 mL) at room temperature overnight. Usual work-up of the reaction mixture followed by chromatographic purification (silica gel/$CHCl_3$) afforded the dibenzoate (**1***b*, 105 mg): colourless prisms (ether), mp 113°C; ir (KBr) cm^{-1}: 3590, 1715, 1698; ^1H nmr ($CDCl_3$) δ: 2.00 (2H t, *J* 7), 4.54 (2H t, *J* 7), 4.98 (1H quintet, *J* 6.5), 7.3−8.1 (10H m); ms *m/e*: 369 (M+1), 351 (M − OH), 245 (M − C_6H_5COOH), 219 (M − $C_2H_4OCOC_6H_5$).

*Rengyol triacetate (**1**c)*

Rengyol diacetate (**1***a*, 50 mg) was treated with acetic anhydride (0.5 mL) and 4-dimethylaminopyridine (50 mg) in triethylamine (2 mL) at room temperature overnight. The reaction mixture was concentrated under vacuum, and the residue was subjected to column chromatography (silica gel/$CHCl_3$ and silica gel/ether) to yield the triacetate (**1***c*, 45 mg): colourless oil; ir ($CHCl_3$) cm^{-1}: 1725; ^1H nmr ($CDCl_3$) δ: 2.02 (3H s), 2.03 (3H s), 2.05 (3H s), 2.25 (2H t, *J* 7), 4.10 (2H t, *J* 7), 4.69 (1H m); ms *m/e*: 227 (M − OAc), 199 (M − C_2H_4OAc).

*Rengyol monoacetate (**1**d)*

Rengyol (**1**, 200 mg) was dissolved in EtOH (2 mL) and pyridine (10 mL). Acetic anhydride (4 mL) was added to the solution in small portions for two days under stirring at room temperature. The reaction mixture was then worked up as usual, followed by column chromatography (silica gel/5% MeOH − $CHCl_3$) to give the starting compound **1** (53 mg), the diacetate (**1***a*, 40 mg), and the monoacetate (**1***d*, 171 mg): ^1H nmr ($CDCl_3$) δ: 2.06 (3H s), 3.61 (1H m), 4.27 (2H t, *J* 7); ms *m/e*: 142 (M − AcOH), 124 (M − AcOH − H_2O).

*Rengyoxide monoacetate (**2**a)*

Rengyoxide (**2**, 20 mg) was esterified with acetic anhydride (0.5 mL) in pyridine (5 mL) at room temperature overnight followed by work-up as above to give the monoacetate (**2***a*, 20 mg): colourless oil; ir ($CHCl_3$) cm^{-1}: 3480, 1710; ^1H nmr ($CDCl_3$) δ: 1.93 (2H t, *J* 7), 2.07 (3H s), 4.31 (2H t, *J* 7); ms *m/e*: 201 (M+1), 183 (M − OH), 140 (M − AcOH), 122 (M − AcOH − H_2O).

*Rengyoxide diacetate (**2**b)*

Rengyoxide monoacetate (**2***a*, 6 mg) was treated with acetic anhydride (0.3 mL) and 4-dimethylaminopyridine (5 mg) in triethylamine (2 mL) at room temperature overnight. The reaction mixture was worked up as before to yield the diacetate (**2***b*, 4 mg): colourless oil; ir ($CHCl_3$) cm^{-1}: 1735, 1720; ^1H nmr ($CDCl_3$) δ: 2.03 (3H s), 2.05 (3H s), 2.35 (2H t, *J* 7), 4.16 (2H t, *J* 7); ms *m/e*: 183 (M − OAc), 155 (M − C_2H_4OAc).

*Rengyoxide dimethyl ketal (**2**c)*

Rengyoxide (**2**, 20 mg) was treated with 5% HCl − MeOH (5 mL) at room temperature overnight. The reaction mixture was then neutralized with $NaHCO_3$, followed by concentration, to yield a residue that was purified by column chromatography (silica gel/10% MeOH − $CHCl_3$) to afford the dimethyl ketal (**2***c*, 15 mg): colourless oil; ^1H nmr ($CDCl_3$) δ: 1.74 (2H t, *J* 7), 3.13 (3H s), 3.19 (3H s), 3.88 (2H t, *J* 7); ms *m/e*: 205 (M+1), 173 (M − OCH_3).

*Rengyoxide dimethyl ketal diacetate (**2**d)*

Rengyoxide dimethyl ketal (**2***c*, 10 mg) was treated with acetic anhydride (0.5 mL) and 4-dimethylaminopyridine (5 mg) in triethylamine (2 mL) at room temperature overnight, followed by the usual work-up as before, to afford the diacetate (**2***d*, 7 mg): colourless oil; ^1H nmr ($CDCl_3$) δ: 2.02 (6H s), 2.27 (2H t, *J* 7), 3.14 (3H s), 3.19 (3H s), 4.10 (2H t, *J* 7); ms *m/e*: 257 (M − OCH_3), 228 (M − AcOH).

*Sodium borohydride reduction of rengyoxide (**2**)*

Rengyoxide (**2**, 5 mg) was dissolved in 50% water − MeOH (10 mL) and was treated with $NaBH_4$ (large excess) at room temperature for 3 h. The reaction mixture was then acidified with Amberlite IR-120 (Rohm and Haas, H^+ form) and concentrated to dryness. The residue was redissolved, followed by repeated concentration with water and methanol to give the crystalline product (5 mg): mp 122°C; ^1H nmr (CD_3OD) δ: 3.51 (1H m), 3.72 (2H t, *J* 7), which was identical to rengyol (**1**) in spectroscopic and chromatographic behaviour.

*Transformation of rengyol (**1**) into rengyoxide (**2**)*

Rengyol monoacetate (**1***d*, 50 mg) was oxidized with Collins reagent (excess) in CH_2Cl_2 (30 mL) overnight at room temperature. The reaction mixture was then worked up as usual and the product purified by column chromatography (silica gel/AcOEt) to afford the dehydro derivative (**2***a*, 39 mg): ^1H nmr ($CDCl_3$) δ: 1.93 (2H t, *J* 7), 2.07 (3H s), 4.31 (2H t, *J* 7), which was found identical chromatographically as well as spectroscopically to rengyoxide monoacetate. The oxidation product was then hydrolysed with 5% NaOH in 50% water − MeOH (10 mL) to give its deacetyl product (**2**): ^1H nmr (CD_3OD) δ: 1.81 (2H t, *J* 7), 3.79 (2H t, *J* 7), which was identified as rengyoxide.

*Transformation of forsythoside A (**6**) into forsythoside E (**4**)*

Forsythoside A (**6**, 100 mg) was hydrolysed with 5% NaOH in 50% water − MeOH (20 mL) overnight at room temperature under a nitrogen atmosphere. The mixture was neutralized with Amberlite IR 120 (H^+ form) and concentrated to dryness. The residue was partitioned with water and AcOEt. The organic layer yielded methyl caffeoate (18 mg): mp 150°C; ^1H nmr (CD_3OD) δ: 3.74 (3H s), 6.23 (1H d, *J* 16), 6.6−7.1 (3H m), 7.52 (1H d, *J* 16), while the aqueous layer afforded the decaffeoylforsythoside A (**4**, 25 mg): $[\alpha]_D$ −39.9° (*c* 0.14, MeOH); ^1H nmr (CD_3OD) δ: 1.26 (3H d, *J* 6), 2.79 (2H t, *J* 7), 4.28 (1H d, *J* 8), 4.78 (1H d, *J* 1.5), 6.4−6.8 (3H m), which was found identical to forsythoside E in chromatographic and spectroscopic characteristics.

Alkaline hydrolysis of 4-caffeoylrutinose

4-Caffeoylrutinose (9 mg) was dissolved in MeOH (10 mL) and treated with 2% NaOH in 50% water − MeOH (2 mL) under a nitrogen atmosphere overnight at room temperature. The reaction mixture was then neutralized with Amberlite IR 120 (H^+ form), followed by partitioning with water and AcOEt to give, as the organic extract, methyl caffeoate: ^1H nmr (CD_3OD) δ: 3.75 (3H s), 6.22 (1H d, *J* 16), 6.6−7.1 (3H m), 7.52 (1H d, *J* 16), and, from the aqueous fraction, rutinose: ^1H nmr (CD_3OD) δ: 1.26 (3H broad d, *J* 6), 4.46 (d, *J* 8) and 5.15 (broad s) 1H in total, 4.46 (1H, broad s).

The compound O-(4-iodophenyl)choline iodide has been synthesized using iodine-125, iodine-127, and iodine-131 by diazonium salt and melt exchange procedures. Radiochemical yields of approximately 2% and 56%, respectively, were obtained. The biodistribution of this compound in mice was analyzed in order to determine its potential as a myocardial imaging agent. Selective myocardial concentration was observed at 5 min post-injection, with a heart-to-blood ratio of 18:1.

DUNCAN H. HUNTER, YOLANDA ZEA PONCE, G. WILLIAM BROWN, MICHAEL J. CHAMBERLAIN, ALBERT A. DRIEDGER et GARY MORRISSEY. Can. J. Chem. **62**, 2015 (1984).

On a synthétisé l'iodure de la O-(iodo-4 phényl) choline marquée à l'iode-125, à l'iode-127 et à l'iode-131 en faisant appel soit à un processus impliquant un sel de diazonium soit à des échanges à l'état fondu. Pour chacune de ces méthodes, les rendements radiochimiques sont respectivement de 2% et 56%. Afin de déterminer le potentiel de ce composé comme agent pouvant créer des images du myocarde, on a analysé la biodistribution de ce composé dans les souris. On a déterminé les concentrations sélectives au niveau du myocarde 5 min après les injections et avec un rapport coeur/sang de 18:1.

Introduction

Variations in regional myocardial blood flow can be detected by external imaging of radiotracer distributions in the myocardium, after intravenous injection. Thallous-201 ion is the current radionuclide of choice (1), but it has the disadvantages of being costly, of having suboptimal energy emmissions, and of requiring long study times during which the distribution may change. In tracer studies the initial distribution is blood flow limited and therefore a number of compounds may be considered as myocardial perfusion agents regardless of the mechanism of their concentration in the tissue.

Since iodine-123 is less expensive than thallous-201 ion, the development of an iodine-labelled myocardial imaging agent seemed attractive. Bioactive quaternary ammonium compounds are taken up by heart tissue by mechanisms which may or may not be receptor specific (2) and, when radiolabelled, are potentially useful as heart imaging agents. In pursuit of such agents, we were attracted to certain choline derivatives.

Benzoyl choline derivatives have been recently investigated (3) as myocardial imaging agents and have proven somewhat successful. While the ester **1** hydrolyzes too readily to permit accumulation, this is not the case for the amide **2**. An ether analog **3** should also be resistant to hydrolysis.

The 4-iodophenyl derivative **3** of choline can be labelled by a diazonium salt procedure. Alternatively, a direct exchange of iodide ion for aromatic iodide is another route to the labelled compound, provided that the specific activity is not critical.

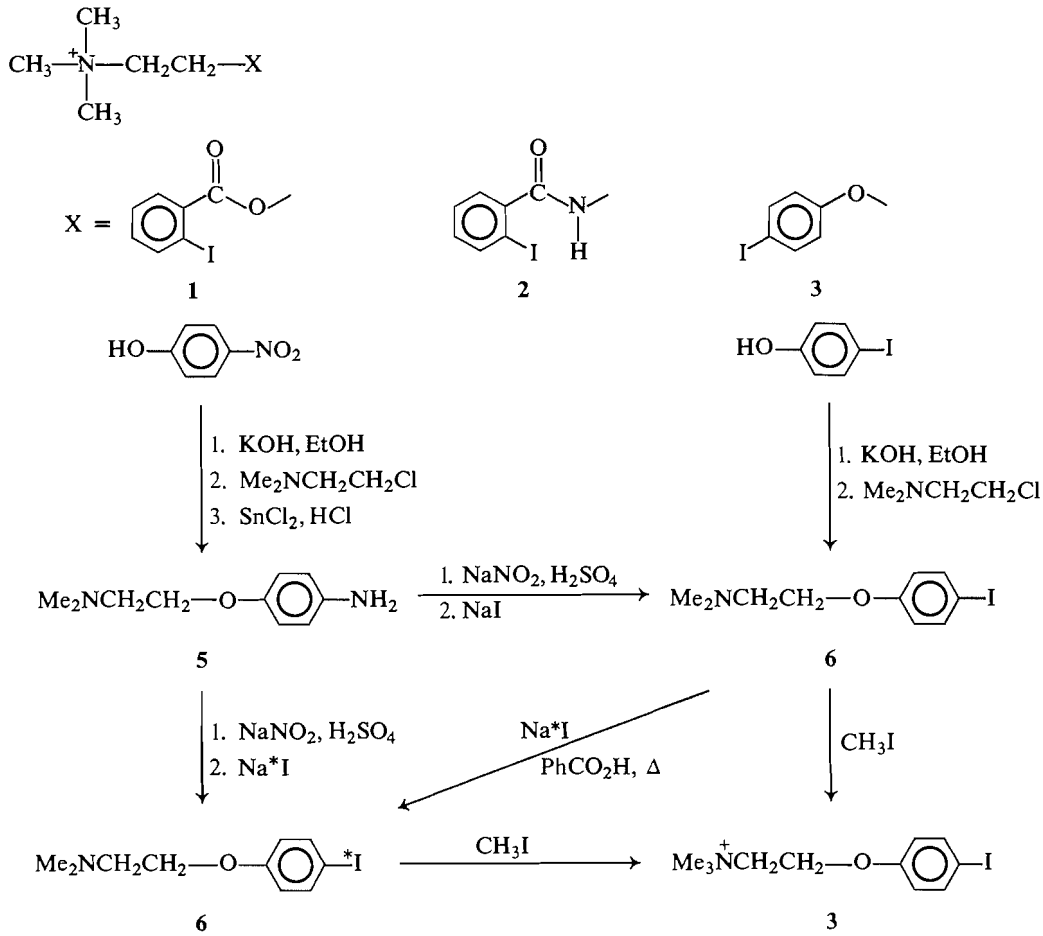
The position of the radioiodide within the molecule may affect both the labelling procedure and the biological distribution. From considerations of receptor specificity, an *ortho* halogen may produce undesirable steric effects. Further, it has been noted that nicotinic activity is more pronounced with *meta* halogen substitution than with the *para* analog (4). With the hope of minimizing such activity, the 4-iodo compound was prepared.

Results and discussion

As illustrated in the preparative scheme, several independent routes to the iodine-labelled quaternary ammonium salt **3** were investigated. The final step in each case involved reaction of the amine **6** with excess methyl iodide. Even with radioiodine-labelled **6**, this methylation requires only a few minutes and yields directly a saline solution of **3**. Using [^{125}I]-**6**, a sample of [^{125}I]-**3** was obtained in about 95% radiochemical yield and showed only one radioactive spot on tlc with an R_f corresponding to **3**.

As shown, the preparation of the radioiodine-labelled amine **6** was attempted both by a diazonium salt procedure (5) and by the direct exchange of **6**. The diazonium salt procedure using [^{125}I]-NaI gave very low radiochemical yields even with added carrier ([^{127}I]-NaI) to increase the overall iodide ion concentration. For example, with a 10,000-fold excess of [^{127}I]-NaI, a radiochemical yield of 2% was obtained. Consequently, the direct exchange of **6** with radioiodide in molten benzoic acid (6) was investigated. Treatment of 1 mg of **6** with [^{131}I]-NaI at 165°C for 1 h resulted in a 56% radiochemical yield. The **6** prepared in both these ways showed the same chromatographic behaviour as **6** that had been characterized by spectroscopic techniques.

This surprisingly facile and efficient exchange between iodide ion and aryl iodide seems to be fairly general and does not require a ring activated to nucleophilic substitution. A variety of solvents and conditions have been reported for iodide ion – aryl iodide exchange; neat liquid at 100–185°C (3, 7); acetamide at 140–180°C (8); benzoic acid at 170°C (6); and water at 100–150°C (9). We have found that, for **6**, thorough re-



moval of water is essential for efficient exchange using benzoic acid. While the mechanism of this process is in doubt ($S_{RN}1$?) (10), it is worth noting that there seems to be no production of the *ortho* or *meta* iodo analogues during the exchange process. A simple equilibration does not seem to be involved, since the exchange stops short of the anticipated equilibrium value and further heating does not lead to further exchange.

The time needed to convert the amino compound **5** into the ammonium salt **3** or to exchange **6** and convert it to **3** is about 2 h, which should be short enough to extend its use to iodine-123, which has a half-life of 13.3 h.

Biodistribution studies (Table 1) in mice showed rapid uptake in the myocardial tissue, with a maximum value of 20% of the injected dose per gram of tissue at 5 min post-injection. This percentage decreased continually from 5 min onward, dropping substantially in the heart between 15 and 30 min post injection. The only other organs showing significant amounts of radioactivity were the liver (21%) and the lungs (13%). Liver radioactivity decreased more slowly, as did the radioactivity in the other organs sampled. Blood radioactivity was always very low and increased somwhat as the study progressed, contrasting with the drop of radioactivity in the other organs.

From Table 2 it can be seen that the optimal time for imaging in mice as judged by heart/lung and heart/liver ratios would be within 5 to 15 min post-injection. In contrast, the amide **2** showed optimal ratios nearer to 30 min post-injection (3).

In considering the application of this to human imaging, interspecies variation must be borne in mind together with the shorter time scale often seen for physiological processes in smaller animals (11).

TABLE 1. Biodistribution of [^{125}I]-O-(4-iodophenyl)choline in mice

	% Uptake per gram of tissue: average of 4 mice ± S.D.			
Organ	5 min	15 min	30 min	60 min
Blood	1.1 ± 0.3	1.2 ± 0.2	1.4 ± 0.3	1.5 ± 0.2
Heart	19.9 ± 2.1	17.9 ± 1.6	6.0 ± 3.0	4.6 ± 1.0
Lung	13.1 ± 3.7	10.0 ± 0.4	4.1 ± 0.5	3.8 ± 1.0
Liver	20.6 ± 1.9	13.9 ± 1.4	11.1 ± 1.5	9.6 ± 3.0
Spleen	6.6 ± 1.9	6.4 ± 0.2	4.6 ± 0.6	5.8 ± 0.9
Muscle	1.9 ± 1.0	1.8 ± 0.3	1.2 ± 0.1	1.2 ± 0.4
Bone	3.0 ± 0.9	2.5 ± 0.3	1.6 ± 0.1	1.6 ± 0.5

Although in vitro protein binding experiments showed relatively high plasma protein binding (65%), very little of the compound was present in the blood at any time during the study. Since significant amounts of radioactivity resided in the heart, it would appear that the affinity of [^{125}I]-**3** for the heart tissue was much greater than that for the plasma protein component of the blood.

The present work involving radiolabelling with [^{125}I]-NaI and [^{131}I]-NaI has led to **3**, with specific activities of about 7.4 GBq/mmol (0.2 Ci/mmol) from the diazonium salt procedure and 148 MBq/mmol (4 mCi/mmol) for the melt exchange technique. Work is in progress to augment the specific activities from both these procedures in order to obtain material for experiments in receptor localization.

Biodistribution studies using the 4-iodo compound have shown significant uptake in the myocardium of mice at 5–15

TABLE 2. Selected organ ratios

Time (min)	Heart/blood ratio	Heart/lung ratio	Heart/liver ratio
5	18	1.5	1.0
15	15	1.8	1.3
30	4.3	1.5	0.5
60	3	1.2	0.5

min post-injection, with favourable heart/lung and heart/blood ratios at these times. At present the *meta* and *ortho* iodinated phenyl analogs are being investigated to improve labelling yield, specific activity, and biodistribution.

Experimental

Materials and methods

Melting points reported are uncorrected, elemental analyses were performed commercially (Guelph Chem. Labs. Ltd., Guelph, Ontario), and gas chromatography separations were accomplished with a 6-ft stainless steel column packed with 10% Carbowax-20M on Chromosorb P. The iodide-125 and iodide-131 were obtained commercially (C.E. Frosst and Co., Kirkland, P.Q.) as aqueous solutions of sodium iodide with concentrations of about 1.85 GBq/mL (50 mCi/mL). Radioactivity was assayed in a dose calibrator and in an automatic γ counter.

*1-Dimethylamino-2-(4-nitrophenoxy)ethane (**4**)*

A solution of potassium hydroxide (5.16 g, 0.1 mol) in 30 mL absolute ethanol was added to a solution of 4-nitrophenol (14 g, 0.1 mol) in 20 mL absolute ethanol. The orange-yellow potassium 4-nitrophenoxide salt was filtered, washed with a few milliliters of cold absolute ethanol, and air dried. Yield, 14.3 g (81%).

To a cooled solution of 2-dimethylamino ethylchloride hydrochloride (12.6 g, 0.09 mol) in 40 mL water, a solution of sodium hydroxide (4.2 g, 0.1 mol) in 20 mL water was added. The reaction mixture was saturated with solid sodium chloride and extracted with five 30-mL portions of toluene. The toluene fractions were combined and dried over potassium hydroxide pellets. The dried toluene solution was added to a suspension of potassium 4-nitrophenoxide (14 g, 0.08 mol) in 80 mL toluene and refluxed overnight.

After cooling, the reaction mixture was filtered and the filtrate concentrated on a rotary evaporator. A brown oily residue was obtained (13.1 g, 78%). Proton nmr (chloroform-*d*) δ: 2.25 (s, 6H, CH_3), 2.65 (t, 2H, CH_2), 4.10 (t, 2H, CH_2), 6.9 (d, 2H, aromatic H), 8.10 (d, 2H, aromatic H).

About 1 g of the crude product was purified as its hydrochloride salt by recrystallization from 2-propanol (mp 166–167°C). Infrared (ir) (Nujol): 1510 cm^{-1} (s, NO_2), 1330 cm^{-1} (s, NO_2), 1300 cm^{-1} (m, C—O—C). The proton nmr spectrum (DMSO-d_6) was consistent with its structure; δ: 2.80 ppm (s, 6H, CH_3), 3.50 (t, 2H, CH_2), 4.50 (t, 2H, CH_2), 7.10 (d, 2H, aromatic H), 8.10 (d, 2H, aromatic H).

*1-Dimethylamino-2-(4-aminophenoxy)ethane (**5**)*

Compound **4** (11 g, 0.052 mol) was added slowly, with stirring, to a solution of concentrated hydrochloric acid (80 mL) and stannous chloride dihydrate (47.2 g, 0.2 mol). After stirring at 0°C for 30 min, and then at room temperature overnight, the reaction mixture was made basic by addition of a very concentrated sodium hydroxide solution until all stannous hydroxide redissolved.

The resulting mixture was extracted with dichloromethane (4 × 100 mL). After washing with water (100 mL), drying, and solvent evaporation, a dark brown oil was left as residue. Recrystallization from petroleum ether (30–55° bp) gave pale yellowish needles, mp 51–52°C; yield: 7.72 g, 82%; ^{1}Hmr (chloroform-*d*) δ: 2.25 (s, 6H, CH_3), 2.60 (t, 2H, CH_2), 3.37 (s, 2H, NH_2), 3.90 (t, 2H, CH_2), 6.50 (m, 4H, aromatic H). *Exact Mass* determination calcd. for $C_{10}H_{16}N_2O$: 180.126; found (ms): 180.126.

*1-Dimethylamino-2-(4-iodophenoxy)ethane (**6**)*

(a) From 4-iodophenol

Reaction of potassium hydroxide (13 g, 22.7 mmol) with 4-iodophenol (5 g, 22.7 mmol) in 20 mL of absolute ethanol at room temperature left the 4-iodophenoxide salt as a yellowish oil after solvent evaporation. This salt was refluxed overnight with a 50-mL toluene solution of 2-dimethylaminoethylchloride prepared from the hydrochloride (3.3 g, 22.7 mmol) as described above.

After cooling and filtration, solvent removal on a rotary evaporator yielded 6.4 g of a crude oil which was converted to its hydrochloride by bubbling dry hydrochloric acid into an ether solution. Yield: 5.88 g, 79%; mp 186–187°C; ^{1}Hmr (dimethylsulfoxide-d_6) δ: 2.8 (s, 6H, CH_3), 3.42 (t, 2H, CH_2), 4.34 (t, 2H, CH_2), 6.76 (d, 2H, aromatic H), 7.52 (d, 2H, aromatic H).

(b) *From **5** using the diazonium salt method*

*(i) [^{127}I]-**6***

A 1.02-g (5.7 mmol) sample of **5** in 25 mL of 50% sulfuric acid at 0°C was reacted with a 1.17-g (17 mmol) solution of sodium nitrite in 3 mL of water. After about 10 min at 0°C, urea (0.7 g, 12 mmol) was added to destroy any excess nitrite. After bubbling had ceased (~10 min), a solution of sodium iodide (8.5 g, 57 mmol) and sodium sulfite (2.9 g, 23 mmol) in 30 mL of water was added. After 10 min at 0°C, 10 min at ambient temperature, and about 6 min heating at 80°C, the reaction was worked up by first making basic with sodium hydroxide.

Extraction with methylene chloride followed by a water wash, drying with sodium sulfate, and solvent evaporation left a dark solid residue. Filtration of an ether solution of this residue through a short column of neutral alumina yielded 0.21 g of a red oily product. This was further purified by tlc on alumina using ether as the eluent to yield 0.18 g (11%) of a material showing identical tlc and gc behaviour, as well as identical ^{1}Hmr and ir spectra, to the material from *p*-iodophenol. *Anal.* calcd. for $C_{10}H_{14}NOI$: C 41.25, H 4.85, N 4.81, I 43.59; found: C 41.29, H 4.85, N 5.0, I 43.01. *Exact Mass* determination: calcd. for $C_{10}H_{14}NOI$: 291.011; found (ms): 291.011. A mp of the hydrochloride of this material and a mixture mp with the hydrochloride of **6** from *p*-iodophenol were identical.

*(ii) [^{125}I]-**6***

Following the procedure described above, 2 mg (11 μmol) of **5** in 100 μL of 50% sulfuric acid was reacted with sodium nitrite (2.3 mg in 40 μL, 33 μmol). Urea (1.5 mg, 25 μmol) was added after 10 min at 0°C and, when bubbling had ceased, sodium iodide-125, 92.5 MBq (2.5 mCi in 50 μL) was added, followed by 40 μL of a solution of sodium iodide-127 (3.0 mg, 20 μmol) and sodium sulfite (1.0 mg, 8 μmol). After the usual extractive work-up, a material showing the same R_f on tlc as the authentic sample prepared above, with an activity of 50 μCi (2% yield), was isolated. This material was used without further purification for the synthesis of O-(4-iodophenyl)choline iodide.

(c) *[^{131}I]-**6** from **6** using a melt exchange method*

In a typical experiment, 1 mg of [^{127}I]-**6** and 3 mg of benzoic acid were dissolved in 0.2 mL of absolute ethanol in a 1-mL multi-dose vial. Approximately 80 μL (192 μCi) of [^{131}I]-NaI solution, 92.5 MBq (2.5 mCi/mL); was added and, after cooling in a Dry Ice – acetone mixture, the solvents were removed on a rotary evaporator.

The vial was then sealed with a rubber septum and aluminum cap and the solid mixture heated in an oil bath at 165°C for 60 min. After alkalinization and extraction with portions of methylene chloride, and washing and drying of the combined extracts, the radioactivity in the CH_2Cl_2 layer was 5.18 MBq (140 μCi) (73%). The CH_2Cl_2 was reduced in volume and used for tlc purification on alumina/ether against [^{127}I]-**6**.

The [^{131}I]-**6** was recovered from the tlc plate by extraction with methanol, filtered, and the solvent evaporated to yield purified[^{131}I]-**6**, 3.96 MBq, (107 μCi; 56% incorporation).

*O-(4-iodophenyl)choline iodide (**3**)*

(a) *From [^{127}I]-**6***

To 44 mg (0.15 mmol) of **6** dissolved in 3 mL chloroform, at room temperature, was added a solution of 440 mg (3.1 mmol) methyl

iodide in 2 mL chloroform. The reaction mixture was stirred for 30 min at room temperature. The excess methyl iodide and chloroform were evaporated and the white crystals left were washed with three portions (3–5 mL each) of chloroform and air dried.

The crystals were redissolved in methanol, filtered, and the solvent evaporated, yielding 62 mg of **3** as white crystals (95%), mp (dec.) 246°C; ^{1}Hmr (dimethylsulfoxide-d_6) δ: 3.2 (s, 9H, $^+$N $(CH_3)_3$), 3.8 (t (br), 2H, CH_2), 4.45 (t (br), 2H, CH_2), 6.84 (d, 2H, aromatic H), 7.60 (d, 2H, aromatic H). *Anal.* calcd. for $C_{11}H_{17}NOI_2$: C 30.51, H 3.96, N 3.23, I 58.61; found: C 30.66, H 3.98, N 3.25, I 58.32.

(b) *From [^{125}I]-6 or [^{131}I]-6*

The 1.85-MBq (50 μCi) sample of [^{125}I]-**6** prepared as previously described was dissolved in 2 mL chloroform and excess methyl iodide (20–30 mg) was added. The mixture was refluxed for 30 min (65–70°C). After cooling, the chloroform layer was transferred to a 12-mL centrifuge tube and the reaction flask washed twice with 0.5 mL saline solution. The saline portions were added to the chloroform and thoroughly mixed. After separation of the two layers had occurred, the saline was carefully recovered and transferred to a 3-mL screw cap vial and its radioactivity assayed: 1.81 MBq (about 49 μCi).

The saline solution of [^{125}I]-**3** was later diluted, filtered through a millipore filter, and used for the biodistribution studies.

This material showed tlc (alumina; CH_3CN/H_2O 9:1) behaviour identical to the [^{127}I]-**3** material characterized above.

Biodistribution studies

White Swiss mice were initially anaesthetized with an intraperitoneal injection of sodium pentobarbital (80 mg/kg body weight) and then received a 0.1-mL intravenous tail injection of 93 MBq (2.5 μCi) of [^{125}I]-**3**. Four mice were sacrificed by cardiac puncture/exsanguination at each post-injection period of 5, 15, 30, and 60 min. Selected organs were washed, patted dry, and weighed, along with the blood samples. Tissues and injection standards were subsequently assayed for radioactivity. Results were expressed as percent uptake per gram of wet tissue.

Protein binding

The in vitro binding of **3** to human serum proteins was determined by adding 100-μL aliquots of [^{125}I]-**3** to 1 mL of plasma in each of four centrifuge tubes. At 5, 15, 30, and 60 min, 100 μL of the plasma – [^{125}I]-**3** mixture was added to duplicate tubes containing 1 mL of 10% trichloroacetic acid, followed by centrifugation.

The supernatant was removed and, after washing the pellet with normal saline, the combined supernatant washings and the pellets were assayed for radioactivity. 66% of [^{125}I]-**3** was found bound at 5 and 15 min, 65% at 30 and 60 min.

Une synthèse hautement stéréosélective de dienes conjugués (*E*)

R. Bloch, J. Abecassis et D. Hassan

Laboratoire des Carbocycles, ERA 316, Bâtiment 420, Université de Paris-Sud, 91405 Orsay Cedex, France

Reçu le 3 janvier 1984

Cet article est dédié au Professeur Paul de Mayo à l'occasion de son 60ème anniversaire

R. Bloch, J. Abecassis et D. Hassan. Can. J. Chem. **62**, 2019 (1984).

Une méthode générale de préparation de dienes conjugués terminaux de stéréochimie (*E*) a été développée par thermolyse éclair de dihydro-2,5 thiophènedioxides-1,1 monosubstitués, eux-mêmes engendrés par réaction de rétro Diels–Alder. Ce procédé permet d'obtenir des dienes conjugués fonctionnels (alcools, esters. . .) ou non avec une excellente pureté stéréochimique (en général supérieure à 98%). L'application à la synthèse du dodécadiène-9,11 yl-1 acétate (*E*), le composant principal de la phéromone sexuelle de *Diparopsis castanea* montre l'intérêt et l'efficacité de cette méthode.

R. Bloch, J. Abecassis, and D. Hassan. Can. J. Chem. **62**, 2019 (1984).

A general method for the preparation of (*E*) terminal conjugated dienes was developed by the flash thermolysis of 2-substituted 2,5-dihydrothiophene-1,1-dioxides generated by a retro Diels–Alder reaction. This process allows the obtention of conjugated dienes, bearing or not a functionality (alcohols, esters), with an excellent stereoisomeric purity (in general higher than 98%). An application to the synthesis of (*E*)-9,11-dodecadien-1-yl acetate, the major component of the sex pheromone of *Diparopsis castanea*, shows the generality and the efficacy of this method.

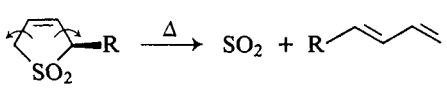
Introduction

La préparation stéréosélective de dienes conjugués a pris une importance croissante durant ces quelques dernières années. Deux raisons principales semblent être à l'origine de ce regain d'intérêt: (*i*) la présence d'un enchaînement diénique conjugué de stéréochimie bien précise dans de nombreux composés naturels et en particulier dans les phéromones sexuelles d'insectes (pour une revue voir la référence 1); (*ii*) l'utilisation croissante des réactions de Diels–Alder intra- ou intermoléculaires pour la synthèse totale de molécules complexes (2).

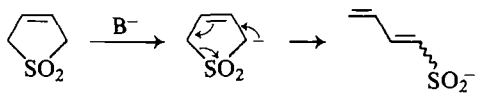
Plusieurs méthodes de synthèse stéréosélective des dienes-1,3 ont été récemment décrites soit par réactions de Wittig modifiées (3), soit par couplage croisé d'un dérivé organométallique vinylique et d'un halogénure vinylique de stéréochimies bien définies (4), soit encore par ouverture thermique concertée de cyclobutènes substitués (5). Ces différentes méthodes sont en général difficilement applicables à la préparation de dienes fonctionnels. Dans ce mémoire est exposée la mise au point d'une méthode générale de préparation hautement stéréosélective de dienes conjugués (*E*) par extrusion thermique de SO_2 à partir de dioxides de dihydro-2,5 thiofènes (ou sulfolènes) **1**, eux-mêmes engendrés par une réaction de rétro Diels–Alder.

Il a été en effet montré il y a quelques années (6) que la thermolyse des sulfolènes monosubstitués **1** conduit, par extrusion de SO_2 selon un processus concerté disrotatoire, à des dienes conjugués **2** de stéréochimie *E* d'excellente pureté stéréoisomérique et avec d'excellents rendements:



1 **2** (*E*) > 99,5%

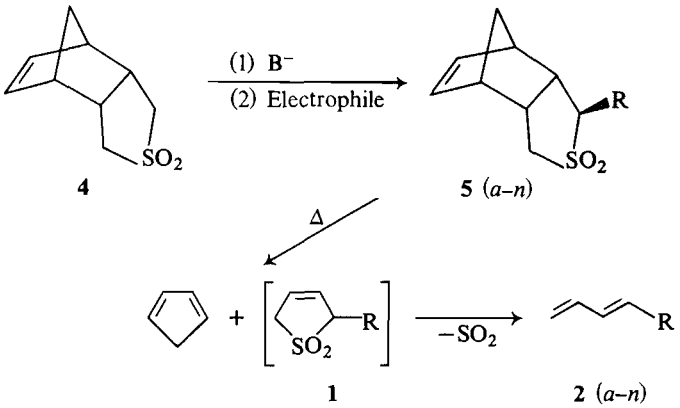
Pourtant ce procédé très simple n'a pas été développé, probablement en raison de la difficulté d'obtention des sulfolènes convenablement substitués **1**. En particulier, la substitution directe du sulfolène parent **3** est rendue délicate[1] par l'ouverture facile du cycle en milieu basique (7):



3

Cependant, après protection de la double liaison, il devrait être possible d'engendrer un anion stable qui, après réaction avec des électrophiles variés suivie de la régénération de la double liaison conduirait aux sulfolènes **1** puis aux dienes **2**. La sulfone tricyclique **4** paraît être un synthon intéressant dans un tel processus pour les raisons suivantes. (*i*) Le groupe protecteur étant thermiquement labile, son élimination par une réaction de rétro Diels–Alder ainsi que l'extrusion de SO_2 peuvent s'effectuer en une seule étape. (*ii*) En raison de la structure tricyclique rigide de la molécule, la face *endo* du cycle hétéroatomique à cinq chaînons est très encombrée: une attaque sélective des électrophiles par la face *exo* devrait conduire à l'introduction stéréocontrolée des substituants. (*iii*) Enfin l'anion de la sulfone **4** peut entrer en réaction non seulement avec des halogènures d'alkyle mais aussi avec différents électrophiles (aldéhydes, cétones, esters . . .) pour donner des précurseurs de dienes conjugués fonctionnels de stéréochimie *E*.

La méthode que nous avons développée est donc décrite par le schéma suivant:[2]



4 **5** (*a–n*) **1** **2** (*a–n*)

[1] Cependant, par utilisation de conditions opératoires très précises, l'alkylation directe du sulfolène **3** a pu être effectuée avec des rendements de 15 à 33% par rapport au sulfolène mis en réaction: voir les références 8 et 9.

[2] Une partie de ce travail a fait l'objet de notes préliminaires: voir la référence 10.

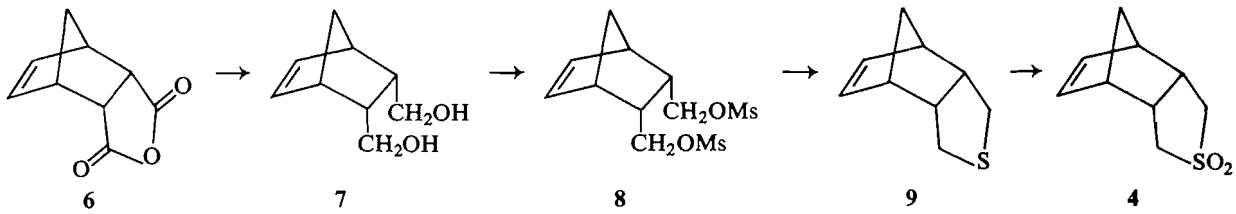
Résultats et discussion

(a) *Préparation de la sulfone tricyclique 4*

Une méthode simple et à haut rendement de préparation de cette sulfone était nécessaire. La réaction directe de Diels–Alder entre le cyclopentadiène et le sulfolène **3** n'a pu être effectuée même en présence de catalyseurs (acides de Lewis, SiO_2). La sulfone **4** a donc été synthétisée par modifications d'une méthode décrite par Photis et Paquette (11) selon le schéma suivant:



6 **7** **8** **9** **4**

L'adduit **6** du cyclopentadiène et de l'anhydride maléique est réduit en diol **7** par l'hydrure de lithium-aluminium dans le THF à reflux. Ce diol est ensuite transformé en dimésylate **8** par action de deux équivalents de chlorure de méthane sulfonyle en présence de pyridine. Le sulfure **9** est obtenu avec d'excellents rendements par réaction du dimésylate **8** avec une solution aqueuse de sulfure de sodium dans les conditions de transfert de phase en utilisant l'aliquat 336 comme agent de transfert (12). Finalement le sulfure est oxydé en sulfone par action d'une solution aqueuse méthanolique d'oxone ($2KHSO_5$, K_2SO_4, $KHSO_4$). Contrairement à ce qui avait été décrit sur d'autres substrats (13) nous avons obtenu à température ambiante une proportion non négligeable d'époxydation de la double liaison. Cette époxydation est supprimée en effectuant la réaction à une température inférieure à 0°C. La sulfone **4** a pu ainsi être obtenue avec un rendement global de 50–55% par rapport à l'adduit **6**.

(b) *Action des électrophiles sur la sulfone 4*

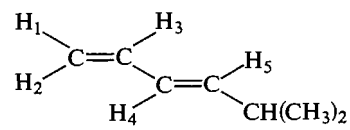
Le traitement de la sulfone **4** en solution dans le THF anhydre avec un équivalent de nBuLi à −78°C, suivi de l'addition de 1,1 équivalent de réactif électrophile et hydrolyse après retour à la température ambiante fournit les sulfones monosubstituées **5**(*a–n*) avec les rendements reportés dans le tableau 1.

Dans de nombreux cas (**5***b–e*, **5***i* et **5***j*) les sulfones monosubstituées sont accompagnées de la sulfone de départ et de sulfones α,α′-disubstituées. Il faut noter que les rendements et les proportions relatives de ces trois produits ne sont pas affectés par la présence de HMPT dans le milieu ou par la nature de l'halogène ($C_5H_{11}I$ ou $C_5H_{11}Br$), mais par contre dépendent de l'encombrement stérique des substituants introduits. Ainsi, la proportion de sulfone dialkylée est très faible lors de l'alkylation avec un halogénure secondaire tel que l'iodure d'isopropyle. La réaction de la sulfone **4** avec le chloroformiate d'éthyle est limitée par la formation d'un anion en α du groupe ester et si le rendement en **5***f* est excellent par rapport à l'électrophile, il ne peut dépasser 50% par rapport à la sulfone **4** mise en réaction, alors que l'action des esters avec la sulfone **4** conduit aux cétones **5** (*l–n*) avec d'excellents rendements.

Dans tous les cas, la rmn du proton et la chromatographie en phase gazeuse sur colonne capillaire couplée à la spectrométrie de masse montrent qu'un seul stéréoisomère **5** est formé. Il s'agit très probablement de l'isomère où le groupe R est en position *exo*, provenant d'une attaque de l'électrophile par la face la moins encombrée.

(c) *Thermolyse des sulfones 5*

Les thermolyses ont été effectuées en phase vapeur avec un temps de contact dans la zone chaude de l'ordre de 10 à 50 ms (pour une description de l'appareillage voir la référence 14). Il a été nécessaire de chauffer à 650°C pour obtenir une conversion totale des sulfones **5**. Dans ces conditions, les sulfolènes **1** intermédiaires perdent spontanément SO_2 pour conduire directement aux dienes conjugués **2** en général avec d'excellents rendements. Les dienes conjugués terminaux n'étant pas séparables en chromatographie en phase vapeur conventionnelle même sur colonne capillaire,[3] leur pureté stéréoisomérique a été déterminée par résonance magnétique nucléaire soit du proton, soit du carbone 13. Dans la grande majorité des cas (voir tableau 1) un seul stéréoisomère a pu être décelé dans les spectres de rmn ^{13}C des dienes obtenus et leur pureté stéréoisomérique a donc été estimée supérieure à 98% (limite de précision de l'appareillage). La stéréochimie *E* des dienes **2** qui découle directement de leur mode de formation (6) a pu être vérifiée: dans le cas du pentadiène-1,3 **2***a* par comparaison de son spectre de rmn ^1H avec celui d'un échantillon authentique; dans le cas du nonadiène-1,3 **2***b* par comparaison de son spectre de rmn ^{13}C avec celui d'un mélange de nonadiène-1,3 *E* + *Z* obtenu par réaction de Wittig, en particulier par comparaison des déplacements chimiques des carbones allyliques (16): 32,7 ppm pour l'isomère *E* et 27,9 ppm pour l'isomère *Z*; enfin dans le cas du méthyl-5 hexadiène-1,3 **2***k* par une analyse de son spectre de rmn ^1H à 400 MHz et en particulier par la détermination des constantes de couplage:



$J_{H_1H_2}$ = 2 Hz
$J_{H_1H_3}$ = 10,5 Hz
$J_{H_2H_3}$ = 17 Hz
$J_{H_3H_4}$ = 10,5 Hz
$J_{H_4H_5}$ = 15 Hz

La moins bonne stéréosélectivité observée lors de l'obtention des dienes **2***d* (R = $SiMe_3$) et **2***e* (R = $SnMe_3$) peut être expliquée par les plus grandes longueurs de liaison C—Si et

[3] Les dienes conjugués terminaux peuvent être cependant séparés en chromatographie en phase vapeur sur des supports enrobés d'une phase stationnaire de cristaux liquides nématiques (15). Nous avons cependant observé que les stéréoisomères des cétones dièniques sont facilement séparables tant par chromatographie en phase vapeur que par chromatographie sur colonne.

TABLEAU 1. Synthèse stéréosélective de diènes conjugués (*E*)

Préparation des sulfones **5**			Thermolyse		
Electrophile	Produit obtenu	Rendement(%)[a]	Diènes obtenus	Rendemen(%)[a]	Pureté stéréoisomérique[b]
ICH_3	**5***a*	85	**2***a* 	85	>95
IC_5H_{11}	**5***b*	65	**2***b* 	90	>98
	**5***c*	67	**2***c* 	71	>98
$ClSiMe_3$	**5***d*	84	**2***d* 	89	96
$ClSnMe_3$	**5***e*	76	**2***e* 	25	85
$ClCO_2Et$	**5***f*	47	**2***f* 	80	>98
$CH_3COCH_2CH_2CH_3$	**5***g*	95	**2***g* 	73	>98
	5*h*	77	**2***h* 	78	>98
CH_3CH_2CHO	**5***i*	56	**2***i* 	77	>98
C_4H_9CHO	**5***j*	52	**2***j* 	73	>98
$ICH(CH_3)_2$	**5***k*	72	**2***k* 	80	>98
CH_3CO_2Et	**5***l*	72	**2***l* 	85	>98
$CH_3(CH_2)_3CO_2Et$	**5***m*	77	**2***m* 	91	>98
	**5***n*	76	**2***n* 	45	>98

[a] Les rendements et les puretés stéréoisomériques sont données pour des produits purs isolés par distillation ou par chromatographie sur colonne.
[b] Déterminée par rmn ^{13}C ou rmn ^1H.

C—Sn qui permettent un deuxième mode d'ouverture disrotatoire des sulfolènes **1**.[4]
