Efficient cleavage of the C(1)—C(2) bond in 9,10-dibromocamphor (**3**) provides a chiral intermediate (**5**) that can be used in a new enantiospecific synthesis of estrone.

JOHN H. HUTCHINSON et THOMAS MONEY. Can. J. Chem. **65**, 1 (1987).

Le clivage efficace de la liaison C(1)—C(2) du dibromo-9,10 camphre (**3**) fournit un intermédiaire chiral (**5**) qui peut être utilisé dans une nouvelle synthèse énantiospécifique de l'estrone.

Recent research in our laboratory has shown that (+)-camphor (**1**)[1] can be converted to (+)-9,10-dibromocamphor (**3**) (2*a*,*b*) and that the latter compound undergoes facile, efficient ring cleavage (1*b*, 2*c*,*d*, 5*g*) with base to provide monocyclic bromoacid (**4**) or hydroxyacid (**5**) in >90% yield. The development of an enantiospecific synthesis[2] of estrone[3] from the monocyclic hydroxyacid **5** or its enantiomer is described below and outlined in Scheme 1.

In our initial studies we recognized that bromoacid **4** (2*c*,*d*) could represent ring D and part of ring C of (−)-estrone **20** and that the exocyclic double bond in **4** could be regarded as the eventual precursor of the 17-keto group. Our investigations also made us aware of the tendency of the exocyclic double bond in **4** to undergo acid-catalyzed isomerization to the thermodynamically more stable endocyclic position (6). This isomerization would, of course, greatly diminish the synthetic usefulness of bromoacid **4** or hydroxyacid **5** and thus it was necessary to avoid prolonged acidic conditions during the synthetic sequence until oxidative cleavage of the exocyclic double bond had been accomplished. Initially we considered the possibility of constructing the *trans*-C,D hydrindane ring system in estrone by intramolecular alkylation of the bromoketone **6** derived from bromoacid **4**. However, this proved to be only partially successful since reaction of **6** with LDA/HMPA at −78°C provided a mixture of the desired bicyclic ketone **9** and a monocyclic hydroxyketone **7**, which was presumably formed by hydrolysis of the intermediate bicyclic enol ether **10**. A molecular model of the kinetic enolate derived from bromoketone **6** indicates that there is some strain involved in achieving the proper trajectory for the desired 6-(enolendo)-*exo*-tet cyclization (7) and therefore the 6-*exo*-tet cyclization (*O*-alkylation) leading to enol ether **10** becomes a viable alternative (7–9).

The disappointing results described above prompted us to consider an alternative route to the C,D ring system of estrone, which involved the intermediacy of hydroxyacid **5** (2*c*) derived directly from (+)-9,10-dibromocamphor (**3**). As shown in Scheme 1, conversion of hydroxyacid **5** to hydroxyketone **7** followed by oxidation to ketoaldehyde **8** and subsequent intramolecular aldol condensation provided the *trans*-bicyclic dienone **11** in ~40% overall yield. The remaining task in the synthesis was construction of the A, B ring system of estrone, and our initial attempts to accomplish this by alkylation of dienone **11** with *m*-methoxyphenethyl iodide were unsuccessful in spite of reasonable analogy (10). A similar difficulty has been reported by other research groups (11, 12) when they tried to use *m*-methoxyphenethyl iodide as alkylating agent and is presumably due to the tendency of this compound to undergo elimination rather than substitution. We decided, therefore, to construct rings A and B by adaptation of a previous approach described by Cohen and co-workers (13), i.e., conjugate addition of *m*-methoxybenzylmagnesium chloride to an exocyclic bicyclic enone system. The intermediate trienone **13** required for this purpose was synthesized by heating dienone **11** with Brederick's reagent ($Bu^tOCH(NMe_2)_2$) (14–18) followed by DIBAL reduction of the intermediate vinylogous amide **12**. However, all attempts to achieve regiospecific conjugate addition of *m*-methoxybenzylmagnesium chloride to trienone **13** in the presence or absence of CuI or CuII salts (13*b*, 19) gave mixtures of 1,2 and 1,4 addition products.

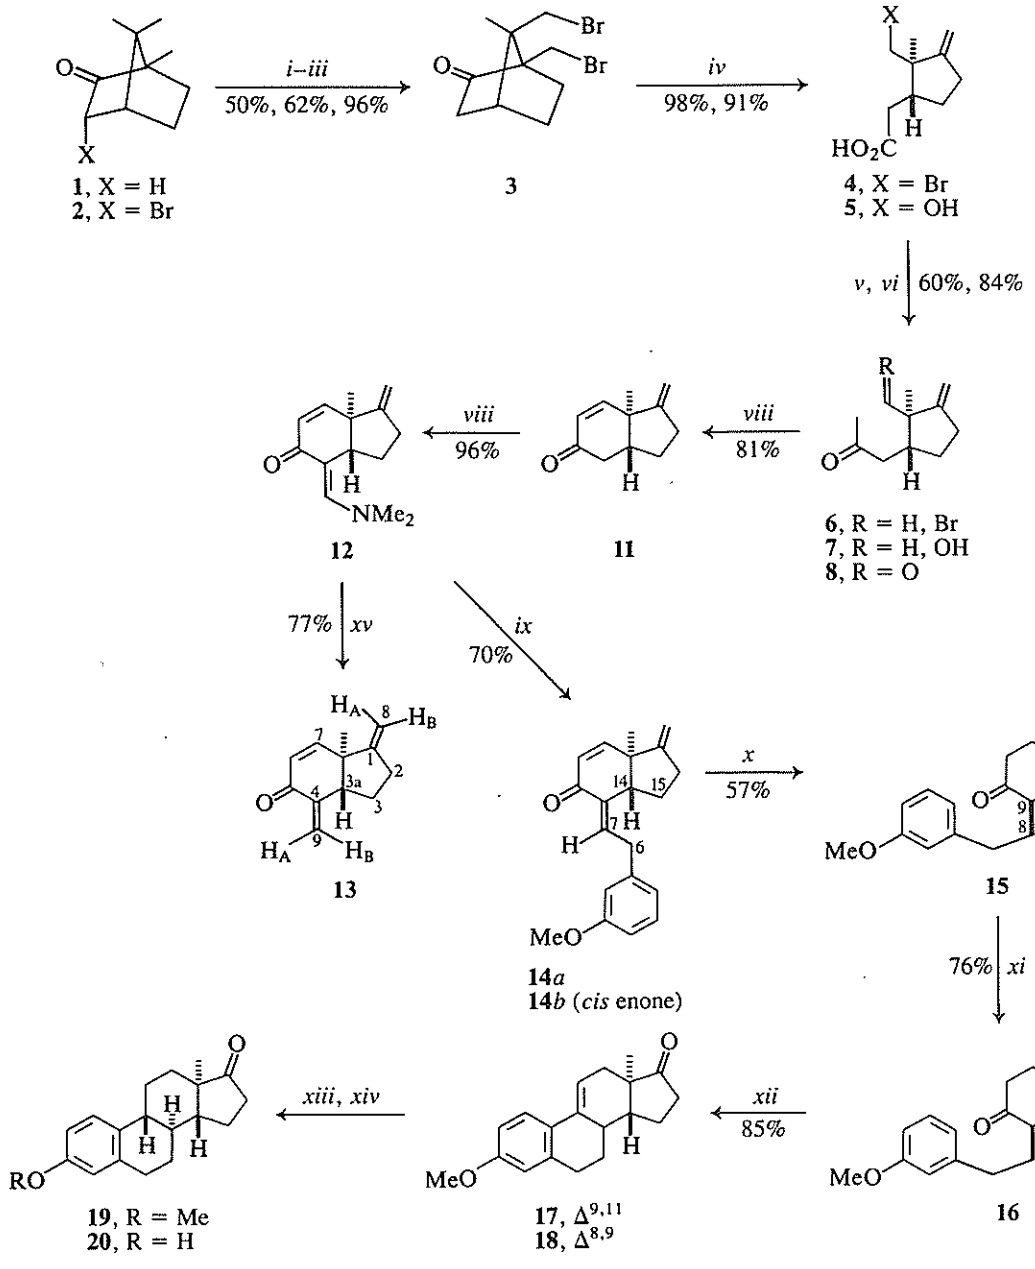
The failure of this approach prompted us to consider conjugate addition of *m*-methoxybenzylmagnesium chloride to the vinylogous amide **12**. This type of reaction was first reported by Benary (20), who found that conjugate addition of Grignard reagent to vinylogous amides followed by acid hydrolysis provides α,β-unsaturated ketones. Since then similar reactions have been described by other research groups (21, 22). In the event, treatment of vinylogous amide **12** with *m*-methoxybenzylmagnesium chloride provided trienones **14***a*,*b* in ~70% yield. The major product (**14***a*) (~90%) and minor product (**14***b*) (~10%) were identified as *trans*- and *cis*-trienones respectively by nOe (nuclear Overhauser effect) difference spectra. For example, irradiation at the chemical shift (δ 6.94) of the C(7) vinyl proton in *trans*-trienone **14***a* produced positive enhancement for protons at C(6) (steroid numbering), while irradiation of the corresponding proton (δ 5.85) in the *cis*-trienone **14***b* resulted in enhancement of the C(6), C(14), and C(15) proton signals.

The stereoselectivity of conjugate addition of Grignard reagent to the *trans*-vinylogous amide (stereochemistry assumed by analogy with similar systems (16, 21*a*)) can be explained (Scheme 2) by the smaller steric interactions in the rotamer

[1]The development of elegant synthetic routes from camphor to various steroid systems has been described by the late Professor R. V. Stevens and co-workers (1).

[2]We define enantiospecific synthesis as one in which readily available enantiomeric starting materials provide enantiomeric products. The term "stereospecific synthesis" is defined (3) as one in which stereoisomeric starting materials (which, of course, include geometric isomers) provide stereoisomeric products and therefore would also include all enantiospecific syntheses.

[3]Syntheses of estrone published up to the end of 1981 have been reviewed in ref. 4; syntheses of estrone since 1982 include those in ref. 5.



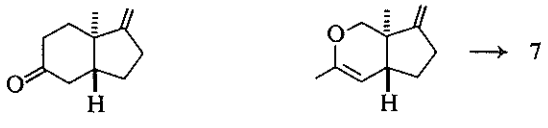
i $Br_2/ClSO_3H/1$ h; *ii* $Br_2/ClSO_3H/5$ days; *iii* Zn/HOAc/Et_2O/0°C; *iv* KOH/DMSO/H_2O/24 h; *v* MeLi/THF; Me_3SiCl; 1 *N* HCl; *vi* PDC/CH_2Cl_2/20°C/24 h; *vii* 2 *N* NaOH/MeOH/0°C/5 min; MsCl/Et_3N/DMAP; DBU; *viii* Bu^{t}OCH$(NMe_2)_2$/heat; *ix* *m*-$CH_3OC_6H_4CH_2MgCl/Et_2O$; *x* $Li/NH_3/Et_2O$; *xi* O_3/CH_2Cl_2; Me_2S; *xii* HCl/HOAc; *xiii* H_2/Pd; *xiv* BBr_3/CH_2Cl_2; *xv* DIBAL/THF

SCHEME 1

(**22***a*) of the intermediate enolate adduct (**21**) that leads to the major product (**14***a*).

The final stages of the synthetic route involved stereoselective reduction of trienone **14***a* with Li/NH_3 in ether, followed by ozonolysis to provide the known diketone **16** (23) in ~50% overall yield. Subsequent cyclodehydration of diketone **16** with concentrated HCl/HOAc (24) at 0°C led to a mixture (97:3) of (−)-9,11-dehydroestrone methyl ether **17** (5*b*, 23, 25, 26) and the $\Delta^{8,9}$ isomer **18** (5*b*, 25*b*, 26, 27) in ~85% yield. Finally, catalytic hydrogenation (Pd/C) of **17** (5*b*, 23, 25*b*) gave (−)-estrone methyl ether **19**, which was demethylated with boron tribromide (28) to provide (−)-estrone **20** having ir, nmr (400 MHz), and mass spectra identical to those of authentic (+)-estrone.[4]

To obtain natural (+)-estrone would of course require the use of (−)-3-bromocamphor in the reaction sequence. This can be obtained inexpensively by oxidizing (−)-borneol to (−)-camphor (29) followed by bromination in acetic acid (30). The commercial availability of (+)-3-bromocamphor (**2**), however, prompted us to conduct our investigations in the *ent*-series.



9 **10**

[4]The synthesis of estrone shown in Scheme 1 was presented at the International Symposium on the Chemistry of Natural Products in Edmonton, Alberta, June 23–26, 1985.

Experimental

Melting points (mp) were determined on a Kofler micro heating stage and are uncorrected. Infrared spectra were recorded on a Perkin–Elmer 137 spectrophotometer and optical rotations were made on a Perkin–Elmer 141 polarimeter. The ^{1}H nmr spectra were recorded on Bruker WH-400, Bruker WP-80, or Nicolet–Oxford H-270 instruments. Signal positions are given in delta (δ) with tetramethylsilane (TMS) as internal reference (except for compounds containing trialkylsilyl groups where TMS was used as an external reference). The integrated areas and signal multiplicities are indicated in parentheses. Low resolution mass spectra were determined on a MAT CH-4 spectrometer and high resolution spectra were recorded on a Kratos MS-50 spectrometer. Gas–liquid chromatography was performed on a Hewlett–Packard model 5830A gas chromatograph with a 6 ft × 1/8 in. column (3% OV-17) or a Hewlett–Packard model 5880A gas chromatograph using 50 or 12 m × 0.2 mm columns (Carbowax 10M). Column chromatography was done using Merck silica gel 60 (230–400 MHz) and thin-layer chromatography (tlc) utilizing silica gel HLF5 UV254 (Analtech) or silica gel 1B2-F (Baker-flex) sheets. Microanalyses were performed by Mr. P. Borda, Microanalytical Laboratory, University of British Columbia.

Bromoketone (6)

Methyllithium (2.43 mL, 3.0 mmol; 1.25 *M* solution in ether) was added to a solution of the bromoacid (**4**) (2*c*) (250 mg, 1.0 mmol) in tetrahydrofuran (10 mL, 0°C). After 2 h, freshly distilled trimethylsilyl chloride (2.54 mL, 20 mmol) was added and the solution warmed to room temperature over 45 min (31). Hydrochloric acid (1 *N*) was added and the solution extracted 3 times with ether. The organic phase was washed twice with water, dried over $MgSO_4$, and the solvent removed to give a pale yellow oil (241 mg).

Column chromatography on silica gel using distilled toluene as eluant gave the bromoketone **6** as a colorless oil (173 mg, 70%); $[\alpha]_D$ −48.3° (*c* 0.4, MeOH); ν_{max} ($CHCl_3$): 1715, 1650, 890 cm^{-1}; δ ($CDCl_3$, 400 MHz): 1.05 (3H, s), 1.24 (1H, m), 1.95 (1H, m), 2.18 (3H, s), 2.26 (1H, dd, *J* = 16 Hz, 10 Hz), 2.31–2.45 (2H, m), 2.54 (1H, m), 2.68 (1H, dd, *J* = 16 Hz, 4 Hz), 3.39 (d) and 3.47 (d) (2H, AB quartet, *J* = 10 Hz), 4.84 (1H, br s), 4.99 (1H, br s); *m/e* (relative intensity): 246/244 (M^+, 0.1/0.1), 231/229 (0.6/0.6), 188/186 (26/27), 165 (10), 109 (23), 107 (100), 93 (26), 91 (23). *Mol. Wt.* calcd. for $C_{11}H_{17}O$ ($M-Br$)$^+$: 165.1279; found (high resolution mass spectrometry): 165.1280.

Hydroxyketone (7)

The hydroxyacid **5** (2*c*) (5.0 g, 27.2 mmol) in dry tetrahydrofuran (250 mL) at 0°C under argon was treated with methyllithium (200 mL, 200 mmol; 1 *M* solution in ether) over 30 min. After 1 h at 0°, the reaction was warmed to room temperature and left to stir overnight. Trimethylsilyl chloride (52 mL, 408 mmol; freshly distilled) was added slowly (**care**!) and after 10 min the solution was treated with hydrochloric acid (1 *N*; 100 mL) for 30 min. The solution was then made basic with potassium hydroxide (2 *N*) and extracted twice with ether. The ether layers were washed with 2 *N* potassium hydroxide (twice), then water, dried ($MgSO_4$), and the ether removed to yield the crude hydroxyketone **7** (3.60 g). It was found that the best overall yield of the ketoaldehyde (**8**) was obtained by oxidizing this crude material without purification. Isolation of a portion of the crude product was achieved by flash chromatography on silica gel (petroleum ether/ether 2:1) to yield pure hydroxyketone **7**; ν_{max} (film): 3420, 1705, 1650, 885 cm^{-1}; δ ($CDCl_3$, 400 MHz): 0.84 (3H, s), 1.28 (1H, m), 1.90 (1H, m), 2.09 (1H, br s, exchangeable with D_2O), 2.17 (3H, s), 2.32 (1H, m), 2.32 (1H, dd, *J* = 16 Hz, 8.5 Hz), 2.45 (2H, m), 2.60 (1H, dd, *J* = 16 Hz, 5 Hz), 3.36 (d) and 3.52 (d) (2H, AB quartet, *J* = 11 Hz), 4.82 (1H, t, *J* = 2.5 Hz), 5.00 (1H, t, *J* = 2 Hz); *m/e* (relative intensity): 182 (M^+, 0.4), 151 (11), 109 (35), 95 (15), 94 (100), 93 (30), 89 (34). *Mol. Wt.* calcd. for $C_{11}H_{18}O_2$: 182.1307; found (high resolution mass spectrometry): 182. 1297.

Acidification of the combined aqueous phases with 6 *N* hydrochloric acid and extraction with ether (×3), then washing the ether layers with water, gave (after drying and evaporation) a white solid (1.16 g). Chromatography on Florisil (elution with ether) afforded starting material **5** (754 mg).

Oxidation of the crude hydroxyketone[5] **7** (3.4 g, ~18.7 mmol) was carried out with pyridinium dichromate (14 g, 37.4 mmol) in dichloromethane (200 mL) at room temperature under argon for 24 h. The usual work-up provided a crude oil (3.16 g). Column chromatography (silica gel; petroleum ether/ether 5:1) gave the keto aldehyde **8** (2.21 g, 48% yield over 2 steps); $[\alpha]_D$ −22.2° (*c* 0.315, CH_2Cl_2); ν_{max} ($CHCl_3$): 2725, 1720, 1650, 900 cm^{-1}; δ ($CDCl_3$, 400 MHz): 1.03 (3H, s), 1.42 (1H, m), 2.0 (1H, m), 2.13 (3H, s), 2.34–2.57 (4H, m), 2.73 (1H, 6-line multiplet), 4.75 (1H, t, *J* = 2.5 Hz), 5.09 (1H, t, *J* = 2 Hz), 9.31 (1H, s); *m/e* (relative intensity): 151 (12), 109 (32), 95 (15), 94 (100), 93 (30), 79 (37). *Mol. Wt.* calcd. for $C_{11}H_{16}O_2$ − CHO: 151.1123; found (high resolution mass spectrometry): 151.1131. *Anal.* calcd. for $C_{11}H_{16}O_2$: C 73.30, H 8.95; found: C 73.05, H 9.00.

Hydrindienone (11)

Sodium hydroxide (2 *N*, 50 mL) was added to a cooled (0°C) solution of ketoaldehyde **8** (1.6 g, 8.9 mmol) in methanol (50 mL). after 1 min, tlc indicated the reaction was complete and the mixture was poured into brine and carefully treated with 6 *N* hydrochloric acid until neutral. After extracting with ether (×5), the combined ether layers were washed with brine, dried, and concentrated *in vacuo* to give crude aldol product as a pale yellow solid (1.75 g); ν_{max} (film): 3450 (br), 1705, 1650, 890 cm^{-1}; δ ($CDCl_3$, 80 MHz): 1.08 (3H, s), 4.00 (1H, dd, *J* = 20 Hz, 12 Hz), 4.82 (1H, m), 5.38 (1H, m); *m/e* (relative intensity): 180 (M^+, 0.9), 120 (3), 91 (99), 79 (100).

The crude aldol product (1.75 g) was converted to the corresponding mesylate (methanesulphonyl chloride, 1.8 mL; triethylamine, 4.4 mL; 4-dimethylaminopyridine, 0.4 g; dichloromethane, 60 mL; argon; 24 h), which was then treated with 1,5-diazabicyclo[5.4.0]undec-5-ene (DBU) (1.3 g, 8.9 mmol) in dry dichloromethane (50 mL) for 45 min. The solution was diluted with dichloromethane, washed successively with 1 *N* hydrochloric acid and water (twice), dried, and evaporated to provide the dienone **11** (1.21 g, 84%) as a white crystalline solid that was sufficiently pure for further reactions. Low temperature recrystallization of this material from pentane provided pure dienone **11**, mp 60.5–61.5°C (sealed tube); $[\alpha]_D$ −13.5° (*c* 0.17, CH_2Cl_2); ν_{max} ($CHCl_3$): 1670, 1665, 890 cm^{-1}; δ ($CDCl_3$, 400 MHz): 1.03 (3H, s), 1.57 (1H, m), 1.81 (1H, m), 2.17 (1H, m), 2.41 (1H, dd, *J* = 17 Hz, 14 Hz), 2.41 (1H, m), 2.58 (1H, dd, *J* = 17 Hz, 4.5 Hz),

[5]Oxidation of the pure hydroxyketone **7** provided ketoaldehyde **8** in 81% yield.

2.58 (1H, m), 4.87 (1H, t, J = 2 Hz), 4.92 (1H, t, J = 2.5 Hz), 5.90 (1H, d, J = 10 Hz), 7.30 (1H, d, J = 10 Hz); m/e (relative intensity): 162 (M^+, 14), 147 (22), 120 (100), 105 (37), 91 (47), 77 (33). *Mol. Wt.* calcd. for $C_{11}H_{14}O$: 162.1045; found (high resolution mass spectrometry): 162.1042. *Anal.* calcd. for $C_{11}H_{14}O$: C 81.44, H 8.70; found: C 81.22, H 8.78.

*Vinylogous amide (**12**)*

Dienone **11** (280 mg, 1.73 mmol) and *tert*-butoxybis(dimethylamino)methane (14) (870 mg) were stirred at 70°C for 6 h. Water was added and the solution extracted with dichloromethane. The combined organic extracts were washed with water, dried, and concentrated to provide the vinylogous amide **12** as a brown oil (386 mg). This material was used without any further purification; ν_{max} (film): 1640, 1610, 1560, 890, 820 cm^{-1}; δ ($CDCl_3$, 270 MHz): 0.90 (3H, s), 1.60 (1H, m), 1.81 (1H, m), 2.45 (1H, m) and 2.55 (1H, m), 3.05 (6H, s), 4.89 (1H, t, J = 2 Hz), 4.93 (1H, t, J = 2.5 Hz), 5.90 (1H, d, J = 9.5 Hz), 6.21 (1H, s), 6.98 (1H, d, J = 9.5 Hz); m/e (relative intensity): 217 (M^+, 100), 202 (99), 200 (13), 85 (51), 84 (44), 83 (75), 73 (68), 72 (43). *Mol. Wt.* calcd. for $C_{14}H_{19}ON$: 217.1467; found (high resolution mass spectrometry): 217.1467.

*Trienone (**13**)*

To a cold (−78°C) solution of the vinylogous amide **12** (377 mg, 1.69 mmol) in tetrahydrofuran (10 mL) under an argon atmosphere was added diisobutylaluminum hydride (DIBAL) (1.75 mL, 1.75 mmol; 1 *M* solution in hexane). The reaction was stirred for 3 h (−78°C to room temperature), then ammonium chloride solution (10 mL) was added and stirring continued for a further 10 h. The mixture was partitioned between ether and 1 *N* hydrochloric acid. The aqueous layer was extracted twice more with ether and the combined ether extracts washed with water (×3), dried, and the solvent removed. A pale yellow oil resulted, which was subjected to chromatography on silica gel (petroleum ether/ether 24:1) to provide the trienone (225 mg, 1.29 mmol, 76%); $[\alpha]_D$ +123.2° (c 0.41, CH_2Cl_2); ν_{max} (film): 1675, 1660, 1630, 885, 840 cm^{-1}; δ ($CDCl_3$, 400 MHz): 0.94 (3H, s), 1.80 (1H, 9-line multiplet; C(3)-H), 1.94 (1H, m; C(3)-H); 2.52 (1H, m; C(2)-H), 2.64 (1H, m; C(2)-H), 2.82 (1H, dddd, J = 12 Hz, 6 Hz, 2.5 Hz, 2.5 Hz; C(3a)-H), 4.89 (1H, dd, J = 2 Hz, 2 Hz; C(8)-H_B), 4.94 (1H, dd, J = 2.5 Hz, 2.5 Hz; C(8)-H_A), 5.21 (1H, ddd, J = 2.5 Hz, 1.5 Hz, 0.75 Hz; C(9)-H_B), 6.03 (1H, dd, J = 10 Hz, 0.75 Hz; C(6)-H), 6.13 (1H, dd, J = 2.5 Hz, 1.5 Hz; C(9)-H_A), 7.35 (1H, d, J = 10 Hz; C(7)-H). Irradiation at δ 5.2 (C(9)-H_B) causes the following signals to collapse: δ 6.13 (C(9)-H_A) to a doublet (J = 2.5 Hz); 6.03 (C(6)-H) to a doublet (J = 10 Hz); and δ 2.82 (C(3a)-H) to a ddd (J = 12 Hz, 6 Hz, 2.5 Hz). Irradiation at δ 2.52 (C(2)-H) causes both δ 4.89 (C(8)-H_B) and 4.94 (C(8)-H_A) to collapse to doublets (J = 2 Hz and 2.5 Hz respectively). Similarly, irradiation at δ 2.64 (C(2)-H) gives doublets at δ 4.89 and δ 4.94 (J = 2 Hz and 2.5 Hz respectively). Irradiating δ 1.94 (C(3)-H) causes 2.82 to become a ddd (J = 12 Hz, 2.5 Hz, 2.5 Hz), and irradiation at δ 1.80 (C(3)-H) causes 2.82 to collapse to a broad singlet. The nOe difference experiments provided the following results: (i) irradiation at δ 1.80 (C(3)-H), enhancement at δ 2.64 (C(2)-H) and 5.21 C(9)-H_B; (ii) irradiation at δ 2.82 (C(3a)-H), enhancement at δ 1.94 (C(3)-H) and 2.52 (C(2)-H); (iii) irradiation at δ 7.35 (C(7)-H), enhancement at δ 4.94 C(8)-H_A). m/e (relative intensity): 174 (M^+, 100), 159 (50), 146 (19), 145 (21), 131 (42), 105 (18), 91 (36). *Mol. Wt.* calcd. for $C_{12}H_{14}O$: 174.1045; found (high resolution mass spectrometry). 174.1049.

*Benzyltrienone (**14**a,b)*

m-Methoxybenzyl chloride (32) (1.74 g, 11.1 mmol) in ether (20 mL) was added to magnesium turnings (534 mg, 22.2 mmol) at a rate that maintained a vigorous reflux. A further 20 mL of ether was added and the solution refluxed for 30 min and then cooled to room temperature. A 1-mL aliquot was removed, added to water, and titration with 0.05 *N* hydrochloric acid using phenolphthalein as indicator indicated that the Grignard solution was 0.425 *M*.

To vinylogous amide **12** (680 mg, 3.08 mmol) in dry ether (40 mL) at −78°C under argon was added a solution of *m*-methoxybenzylmagnesium chloride (9 mL, 3.8 mmol). After 40 min the cold bath was removed and the reaction warmed at room temperature over 30 min. The solution was then transferred via cannula to a rapidly stirred solution of ammonium chloride. Extraction with ether (×3) and work-up in the usual way provided a pale yellow oil (973 mg) that, on column chromatography (silica gel: petroleum ether/ether 12:1), gave a mixture of *meta*-methylanisole and 1,2-di-(3-methoxyphenyl)ethane (144 mg) followed by the *cis* enone (**14***b*) (61 mg, 7%) as a colourless oil; $[\alpha]_D$ −34.6 (c 0.24, MeOH); ν_{max} (film): 1670, 1630, 1605, 1590, 1495, 890 cm^{-1}; δ ($CDCl_3$, 400 MHz): 0.95 (3H, s), 1.67–1.86 (2H, m), 2.48 (1H, m), 2.60 (1H, m), 2.82 (1H, m; C(14)-H), 3.80 (3H, s), 3.93–4.08 (2H, m; C(6)-H), 4.89 (1H, t, J = 2 Hz), 4.94 (1H, t, J = 2.5 Hz), 5.85 (1H, ddd, J = 7.5 Hz. 7.5 Hz, 2.5 Hz; C(7)-H), 6.00 (1H, d, J = 10 Hz), 6.73–6.85 (3H, m), 7.21 (1H, t, J = 8 Hz), 7.24 (1H, d, J = 10 Hz). In an nOe difference experiment irradiation at δ 5.85 gives a positive enhancement at δ 1.67–1.86, δ 2.82, and δ 3.93–4.08; m/e (relative intensity): 294 (M^+, 100), 279 (36), 173 (32), 135 (24), 121 (41), 91 (28). *Mol. Wt.* calcd. for $C_{20}H_{22}O_2$: 294.1620; found (high resolution mass spectrometry): 294.1625.

Elution with petroleum ether/ether (2:1) provided the *trans*-enone **14***a* (595 mg, 66%) as a colourless oil; $[\alpha]_D$ +24.5° (c 0.2, MeOH); ν_{max} (film): 1680, 1660, 1620, 1600, 1590, 1495, 890 cm^{-1}; δ ($CDCl_3$, 400 MHz): 1.04 (3H, s), 2.18 (1H, 9-line multiplet), 2.29 (1H, m), 2.48 (1H, m), 2.66 (1H, m), 2.90 (1H, m; C(14)-H), 3.60 (1H, ddd, J = 16 Hz, 8 Hz, 2 Hz; C(6)-H), 3.70 (1H, ddd, J = 16 Hz, 8 Hz, 1 Hz; C(6)-H), 3.78 (3H, s), 4.94 (1H, t, J = 2 Hz), 4.98 (1H, t, J = 2.5 Hz), 6.04 (1H, d, J = 10 Hz), 6.72–6.81 (3H, m), 6.94 (1H, ddd, J = 8 Hz, 8 Hz, 2.5 Hz; C(7)-H), 7.22 (1H, t, J = 7.5 Hz), 7.30 (1H, d, J = 10 Hz). Decoupling the proton at δ 6.94 (C(7)-H) simplifies signals at δ 3.70, 3.60, and 2.90. The nOe difference experiment: irradiation at δ 6.94 gave enhanced signals at δ 6.72–6.81 and δ 3.60–3.70; m/e (relative intensity): 294 (M^+, 100), 279 (53), 173 (99), 171 (34), 160 (38), 145 (40), 135 (38), 134 (31), 121 (69), 115 (35), 91 (70), 77 (43). *Mol. Wt.* calcd. for $C_{20}H_{22}O_2$: 294.1620; found (high resolution mass spectrometry): 294.1625.

*Enone (**15**)*

To a solution of lithium (45 mg, 9.1 mmol) in ammonia (30 mL) under argon was added the trienone **14***a* (102 mg, 0.34 mmol) in ether (7 mL). After 2 h, the ammonia was removed and saturated ammonium chloride solution was added. The mixture was extracted with ether (×3) and the ether layers washed twice with water, dried, and the solvent removed to provide a pale yellow oil (100 mg). Subsequent chromatography on silica gel (petroleum ether/ether 10:1) afforded enone **15** (40.6 mg), followed by a mixture of starting material **14***a* and an unknown dihydro derivative (32.2 mg). This mixture was subjected to the same reduction conditions described above (lithium, 20 mg; ammonia, 20 mL; ether, 5 mL; 30 min) and the product, after chromatography, provided a further quantity of the desired enone **15** (18.1 mg) (58.7 mg total, 57% combined yield); $[\alpha]_D$ −28.6° (c 0.405, MeOH); ν_{max} (film): 1705, 1660, 1600, 1590, 1490, 880 cm^{-1}; δ ($CDCl_3$, 400 MHz): 1.09 (3H, s), 1.51 (1H, m), 1.61–1.76 (3H, m), 1.82 (1H, m), 1.93 (1H, m), 2.00 (1H, ddd, J = 13 Hz, 7 Hz, 2 Hz), 2.30–2.67 (6H, m), 2.73 (1H, 8-line multiplet), 3.80 (3H, s), 4.68 (1H, t, J = 2.5 Hz), 4.73 (1H, t, J = 2 Hz), 6.70–6.81 (3H, m), 7.19 (1H, t, J = 8 Hz); m/e (relative intensity): 298 (M^+, 27), 164 (35), 134 (100), 122 (29), 121 (37), 94 (82), 91 (29). *Mol. Wt.* calcd. for $C_{20}H_{26}O_2$: 298.1933; found (high resolution mass spectrometry): 298.1928.

*Diketone (**16**)*

Ozone was bubbled through a cold (−78°C) solution of the enone **15** (143.9 mg, 0.48 mmol) in dry methanol (25 mL). At the first sign of a pale blue colour, the flow of ozone was stopped and the system purged with oxygen until colourless. Dimethylsulphide (1 mL) was added and the reaction allowed to warm to room temperature. After 3 h the solvent was removed *in vacuo* and the crude product (202.5 mg) purified by flash chromatography (petroleum ether/ether 2:1) to provide pure diketone (**16**) (110.6 mg, 76%) as a viscous oil; $[\alpha]_D$ −77.2° (c 0.47, MeOH); ν_{max} (film): 1740, 1710, 1605, 780, 695 cm^{-1} (lit. (23) ν_{max} (film): 1740, 1710, 1600, 780, 690 cm^{-1}; lit (25*a*) ν_{max} (film): 1740, 1715, 1600, 1585 cm^{-1}); δ ($CDCl_3$, 400 MHz): 1.13 (3H, s),

1.62–1.80 (3H, m), 1.86 (1H, ddd, J = 13 Hz, 12.5 Hz, 5.5 Hz), 1.94–2.09 (3H, m), 2.21 (1H, 6-line multiplet), 2.41–2.62 (5H, m), 2.76 (1H, m), 3.80 (3H, s), 6.71–6.83 (3H, m), 7.19 (1H, t, J = 8 Hz); m/e (relative intensity): 300 (M^+, 9), 135 (14), 134 (100), 122 (12). *Mol. Wt.* calcd. for $C_{19}H_{24}O_3$: 300.1726; found (high resolution mass spectrometry): 300.1730.

(−)-9,11-Dehydroestrone methyl ether (17) and (−)-8,9-dehydroestrone methyl ether (18)

Ketone **16** (57.4 mg, 0.19 mmol) was dissolved in ether (1 mL) and a mixture of glacial acetic acid/concentrated hydrochloric acid (10:1) (2 mL) at 0°C. After 2 h, the reaction was poured into brine and extracted with ether. The ether layers were washed with sodium bicarbonate solution, brine (twice), dried ($MgSO_4$), and evaporated to yield a white crystalline solid (53.5 mg) that, on column chromatography (silica gel; petroleum ether/ether 4:1), provided the tetracyclic products **17** and **18** (45.8 mg, 85%) in the ratio 97:3 (capillary glc, OV-101, 200°C).[6] Recrystallization from methanol provided pure (−)-9,11-dehydroestrone methyl ether **17**, mp 143–145.5°C (lit. (5*b*) mp 143–144°C, lit. (25*a*) mp 142.5–144°C); $[\alpha]_D$ −284° (*c* 0.208, $CHCl_3$) (lit. (5*b*) $[\alpha]_D$ −288.20 (*c* 0.5, dioxane) and, for the enantiomer, lit. (5*b*) $[\alpha]_D$ +288.7° (*c* 0.479, dioxane), lit. (25*a*) $[\alpha]_D$ +290.0° (*c* 0.5, $CHCl_3$)); ν_{max} ($CHCl_3$) 1735, 1610, 1500 cm^{-1}; δ ($CDCl_3$, 400 MHz): 0.95 (3H, s), 1.47 (1H, m), 1.68 (2H, m), 2.10–2.40 (6H, m), 2.54 (1H, m), 2.83–3.00 (2H, m), 3.80 (3H, s), 6.14 (1H, m; C(11)-H), 6.63 (1H, d, J = 3 Hz; C(4)-H), 6.73 (1H, dd, J = 8 Hz, 3 Hz; C(2)-H), 7.54 (1H, d, J = 8 Hz; C(1)-H); m/e (relative intensity): 282 (M^+, 100), 267 (49), 249 (19), 225 (30), 224 (36), 211 (22). *Mol. Wt.* calcd. for $C_{19}H_{22}O_2$: 282.1620; found (high resolution mass spectrometry): 282.1618. *Anal.* calcd. for $C_{19}H_{22}O_2$: C 80.82, H 7.85; found: C 80.71, H 7.88.

(−)-Estrone methyl ether (19)

Dehydroestrone methyl ether (38.4 mg; **17**:**18** 93:7), palladium-on-charcoal (10% catalyst, 13.1 mg), and methanol (8 mL) were stirred under an atmosphere of hydrogen for 2 h (23). The solution was diluted with ether, filtered through a pad of Celite, and the solvent removed to yield a white crystalline solid (35.0 mg). Capillary glc analysis (OV-101, 220°C) showed this to be two compounds, estrone methyl ether **19** and an unidentified by-product[7] in the ratio 65:35. Recrystallization from methanol provided pure (−)-estrone methyl ether **19** (18.2 mg, 47%), mp 167.5–170°C (lit. (13*b*) mp 164–167°C); $[\alpha]_D$ −149.2° (*c* 0.126, dioxane) (lit. (13*b*) $[\alpha]_D$ +153.98° (*c* 1.0, dioxane) for enantiomer); ν_{max} ($CHCl_3$): 1735, 1620, 1500 cm^{-1}; δ ($CDCl_3$, 400 MHz): 0.91 (3H, s; C(18)-methyl), 1.35–1.70 (6H, m), 1.93–2.20 (4H, m), 2.26 (1H, m), 2.40 (1H, m), 2.50 (1H, dd, J = 20 Hz, 8 Hz), 2.90 (2H, m), 3.78 (3H, s), 6.66 (1H, d, J = 3 Hz), 6.73 (1H, dd, J = 8 Hz, 3 Hz), 7.21 (1H, d, J = 8 Hz); m/e (relative intensity): 284 (M^+, 100), 199 (56), 186 (24), 160 (32). *Mol. Wt.* calcd. for $C_{19}H_{24}O_2$: 284.1775; found (high resolution mass spectrometry): 284.1775. The synthetic material was found to be identical (tlc, ir, ^1H nmr, and ms) to an authentic sample of (+)-estrone methyl ether prepared from (+)-estrone.

(−)-Estrone (20)

Boron tribromide (11.5 L, 0.12 mmol) was added to a solution of (−)-estrone methyl ether **19** (31.3 mg, 0.11 mmol) in dichloromethane (2 mL) at −78°C under argon (28). The cold bath was removed and after 30 min the reaction mixture was added to ice and brine. Dilution with dichloromethane followed by extraction with 2*N* potassium hydroxide solution, acidification of the aqueous layer, extraction with chloroform, and removal of solvent provided a crude product that, on titration with petroleum ether/ether, afforded (−)-estrone **20** (16 mg, 54%); ν_{max} ($CHCl_3$): 3600 (sharp), 3350 (br), 1735, 1610 cm^{-1}; δ ($CDCl_3$, 400 MHz): 0.90 (3H, s), 1.38–1.70 (6H, m), 1.93–2.28 (5H, m), 2.38 (1H, m), 2.50 (1H, dd, J = 19 Hz, 9 Hz), 2.86 (2H, m), 4.69 (1H, br s), 6.59 (1H, d, J = 3 Hz), 6.64 (1H, dd, J = 8 Hz, 3 Hz), 7.15 (1H, d, J = 8 Hz); m/e (relative intensity): 270 (M^+, 100), 185 (47), 172 (38), 146 (40). The synthetic (−)-estrone was found to be identical (tlc, ir, ^1H nmr, and ms) with authentic (+)-estrone (Sigma Chemical Co.).

(+)-Estrone methyl ether (ent-*19*)

(+)-Estrone (*ent*-**20**) (108 mg, 0.4 mmol; Sigma Chemical Co.), potassium hydroxide (100 mg, 1.79 mmol), methanol (6 mL), water (2 mL), and dimethyl sulphate (0.6 mL, 6.3 mmol) were stirred for 24 h. The mixture was added to ammonium hydroxide solution, extracted with ether, and the ether layers washed with potassium hydroxide solution (2 *N*) followed by washing with water. The dried solution was evaporated to provide a white crystalline solid (113 mg), which was crystallized from acetonitrile to give pure (+)-estrone methyl ether (*ent*-**19**), mp 170–173°C (lit. (13*b*) mp 164–167°C); $[\alpha]_D$ +154.0° (*c* 1.02, dioxane) (lit. (13*b*) $[\alpha]_D$ +153.98° (*c* 1.0, dioxane)).

[6]When the reaction was carried out at room temperature the ratio of **17** to **18** was found to be 3.7:1 by integration of the C(18)-methyl resonances in the 400-MHz ^1H nmr spectrum. (−)-9,11-Dehydroestrone methyl ether **17** has the C(18)-methyl at δ 0.94 (25*b*, 26) while the (−)-8,9-dehydroestrone methyl ether **18** has the C(18)-methyl resonance at δ 0.90 (26, 27).

[7]Analysis of the crude product by glc–ms (DB-17 column, 220°C) showed the by-product to be isomeric with (−)-estrone methyl ether; m/e (relative intensity): 284 (M^+, 100), 199 (38), 186 (15), 160 (24). It seems reasonable to assume that this compound is the 9α-isomer (23, 33) of **19**.

Metabolites of the honey mushroom, *Armillaria mellea*

WILLIAM A. AYER and JOHN B. MACAULAY
Department of Chemistry, University of Alberta, Edmonton, Alta., Canada T6G 2G2

Received March 26, 1986

This paper is dedicated to Dr. O. E. (Ted) Edwards

WILLIAM A. AYER and JOHN B. MACAULAY. Can. J. Chem. **65**, 7 (1987).

The fungus *Armillaria mellea* (Vahl ex. Fr.) Kummer is responsible for severe losses in timber and fruit production.The metabolites isolated when certain strains of this fungus are grown in liquid culture have been identified as diterpenoid acids possessing the abietane (**1**) and pimarane (**2**) skeletons. These compounds, known collectively as resin acids, have not been reported previously from a fungal source. In addition to the resin acids dehydroabietic acid (**3**), pimaric acid (**4**), isopimaric acid (**5**), and sandaracopimaric acid (**6**), three additional acids, levopimaric acid *endo*-peroxide (**7**), 7-oxodehydroabietic acid (**9**), and 7-oxo-15-hydroxydehydroabietic acid (**10**) were obtained. On one occasion three orange pigments, austocystin F (**11**), averufin (**12**), and averufanin (**13**), all previously known fungal metabolites, were isolated.

WILLIAM A. AYER et JOHN B. MACAULAY. Can. J. Chem. **65**, 7 (1987).

Le champignon *Armillaria mellea* (Vahl ex. Fr.) Kummer est responsable de pertes importantes dans l'industrie du bois et dans la production des fruits. On a identifié les métabolites qui ont été isolés lorsqu'on fait croître certaines souches de ce champignon dans des milieux de cultures liquides; il s'agit de diterpénoïdes possédant des squelettes de l'abiétane (**1**) et du pimarane (**2**). Ces composés sont connus collectivement comme des acides résiniques; leur production à partir de champignons n'avait pas été rapportée jusqu'à maintenant. En plus des acides résiniques, déhydroabiétique (**3**), pimarique (**4**), isopimarique (**5**) et sandaracopimarique (**6**), on a aussi obtenu trois acides additionnels, soit le peroxide-*endo* de l'acide lévopimarique (**7**), l'acide oxo-7 déhydroabiétique (**9**) et l'acide oxo-7 hydroxy-15 déhydroabiétique (**10**). À une occasion, on a aussi isolé trois pigments oranges, l'austocystine F (**11**), l'avérufine (**12**) et l'avérufanine (**13**), qui sont tous des métabolites de champignons qui étaient connus antérieurement.

[Traduit par la revue]

Introduction

The fungus commonly regarded as *Armillaria mellea* (Vahl ex. Fr.) Kummer, also known as shoe string root rot (the fruiting body is the "honey mushroom"), is a vigorous pathogen of many commercially important types of trees (1). Larch, cedar, willow, walnut, and apple trees are all very susceptible to attack by this fungus. Fir, oak, and birch, although frequently attacked, show fewer adverse effects. The fungus invades the healthy tree via the roots. Sheets of white mycelium develop just beneath the outer bark as the fungus spreads. The mycelium may completely girdle small trees and shrubs. This girdling, combined with extensive damage to the root system, deprives the leaves of water, and the tree wilts and dies (1, 2). *A. mellea* has been reported to produce antibacterial and antifungal metabolites (3, 4). Previous examinations of the metabolites produced by the fungus have yielded the sesquiterpenoid orsellinates of armillol (4*a*), a neoilludol derivative (4*a*), and melleolide (4*b*). Ergosterol (5), unsaturated analogues of ergosterol (5), and polysaccharides (6) also have been reported. In this paper we report the isolation of metabolites afforded by three strains (NFRC-621, 624, and 631) of this fungus, indigenous to western Canada, when they are grown in liquid culture.

Among the metabolites, several are diterpenoid carboxylic acids possessing the abietane (**1**) and pimarane (**2**) skeletons. These compounds have not been reported previously from a fungal source (7). They are known collectively as resin acids and are the major constituents of resin exuded by coniferous trees. Some resin acids are known to display antibiotic, antifungal, and antilarval activity (8). In addition, three orange pigments, all previously known fungal metabolites, have been isolated and identified.

Liquid still cultures of *A. mellea* were grown on either 10% (v/v) clarified V-8 juice solution containing 1% (w/v) glucose or on potato dextrose broth. After a growth period of between 34 and 92 days, the mycelial mat was removed by filtration, and the culture broth was extracted with chloroform. The mycelium was separately subjected to Soxhlet extraction with chloroform or methanol. The crude broth metabolites were separated by chromatography over silica gel to give four major components, dehydroabietic acid (**3**) and three isomeric compounds, pimaric acid (**4**), isopimaric acid (**5**), and sandaracopimaric acid (**6**). The more polar fractions of the crude extract afforded three additional metabolites, levopimaric acid *endo*-peroxide (**7**), 7-oxodehydroabietic acid (**9**), and 7-oxo-15-hydroxydehydroabietic acid (**10**). On one occasion[1] one of the strains (NFRC-631) produced orange pigments in both the broth and mycelial extracts. Chromatography over silica gel afforded three compounds, austocystin F (**11**), averufin (**12**), and averufanin (**13**) (also known as avermutin).

Discussion

Metabolites **3–6** initially were obtained as a mixture after preliminary separation of the crude broth extract. Mass spectroscopy (ms) indicated that the mixture was composed of compounds of molecular weight 302 ($C_{20}H_{30}O_2$) and 300 ($C_{20}H_{28}O_2$). The infrared (ir) spectrum of the mixture shows broad OH absorption (3300–2400 cm^{-1}) and strong carbonyl absorption (1692 cm^{-1}) indicative of carboxylic acids. Esterification with diazomethane converted all four components to the corresponding methyl esters (the ir spectrum reveals no OH absorption, while the carbonyl peak is shifted to 1720 cm^{-1}). The ^1H nuclear magnetic resonance (nmr) spectrum of the mixture of esters is virtually identical with that of the acids except for the appearance of methyl singlets at δ 3.63, 3.66, and 3.67. Hydrogenation (H_2, 10% Pd/C) of the mixture of acids resulted in the uptake of four atoms of hydrogen by the $C_{20}H_{30}O_2$ components but left the $C_{20}H_{28}O_2$ compound

[1]This result was not reproducible, thus the production of the orange pigments due to a contamination by another fungus cannot be ruled out.

unchanged. The acids **3–6** were further separated by careful chromatography over silica gel impregnated with silver nitrate.

Inspection of the ^{1}H nmr spectrum reveals that the $C_{20}H_{28}O_2$ component contains a 1,2,4-trisubstituted benzenoid nucleus and that one of the substituents is an isopropyl group. Thus the three aromatic protons (δ 6.87, 6.98, 7.14) possess *ortho* (J = 8 Hz), *ortho* and *meta* (J = 8, 1.75 Hz), and *meta* (J = 1.75 Hz) couplings respectively. Three benzylic protons are evident, two as a multiplet centred at δ 2.90 and an isopropyl methine appearing at δ 2.82 (septet, J = 7 Hz). The ir spectrum shows absorptions for a carboxylic acid at 3200–2400 cm^{-1} (OH) and 1692 cm^{-1} (C=O). The fragmentation pattern of the mass spectrum is indicative of an abietane (**1**) skeleton (as judged by comparison with mass spectra of other compounds that possess the abietane framework). Comparison (thin-layer chromatography (tlc), ^{1}H nmr, and ir) with an authentic sample showed that this component is dehydroabietic acid (**3**). The optical rotation ([α]$_D$ +54°) confirmed the absolute configuration (9).

The isomeric $C_{20}H_{30}O_2$ compounds could not be completely separated. One component, **4**, was obtained in pure form, while **5** and **6** were isolated as an inseparable mixture. The ^{1}H nmr spectra of all three components show an AMN splitting pattern in the region δ 4.8–5.9 characteristic of a vinyl group. This suggested that compounds **4–6** possess the pimarane skeleton **2**, which is closely related biogenetically to the abietane skeleton **1**. The presence of an additional olefinic proton (see Table 1) indicated that each of the three components possesses a trisubstituted (nuclear) carbon–carbon double bond. The equatorial disposition of the carboxyl group in the three compounds is confirmed (10) by the C—O stretch (1244 cm^{-1}) in the ir spectra of the corresponding methyl esters (formed by treatment of the acids with diazomethane). It has been observed (11) that the ir frequency of the out-of-plane C—H bend of the vinyl group in pimarane-type structures is particularly diagnostic with respect to the relative stereochemistry of the vinyl and methyl groups attached to C-13. Thus a 914 cm^{-1} absorption in the ir spectrum of the methyl ester of **4** indicates a β-vinyl substituent

TABLE 1. ^{1}H nuclear magnetic resonance data of olefinic protons in **4–6**

Compound	Proton	δ (ppm)	Multiplicity	J (Hz)
4	H_A	5.72	dd	17.5, 10.5
	H_B	4.96	dd	10.5, 2
	H_C	4.91	dd	17.5, 2
	Nuclear H	5.15	bs	—
5	H_A	5.81	dd	17.5, 10.5
	H_B	4.87	dd	10.5, 1.5
	H_C	4.93	dd	17.5, 1.5
	Nuclear H	5.33	bd	5
6	H_A	5.78	dd	17.5, 10.5
	H_B	4.89	dd	10.5, 1.5
	H_C	4.91	dd	17.5, 1.5
	Nuclear H	5.22	bs	—

group while the mixture of the methyl esters of **5** and **6** shows absorption at 909 cm^{-1}, suggesting an α-vinyl substituent. These data led to the assignment of the three isomers as pimaric (**4**), isopimaric (**5**), and sandaracopimaric (**6**) acids respectively. Identification was confirmed by comparison (tlc, ^{1}H nmr) with authentic samples.

Compound **7** contains a carboxyl function that can be methylated (diazomethane), resulting in a shift of the carbonyl frequency in the ir spectrum from 1692 cm^{-1} to 1720 cm^{-1}. In the ^{1}H nmr spectrum, a septet at δ 2.50 (J = 7 Hz) again suggests an isopropyl group and thus the abietane skeleton. It is noteworthy that the methyl groups of the isopropyl unit in **7** give rise to two well-separated doublets, δ 1.08 and 1.12 (J = 7 Hz), indicating that the environments of the two methyls differ more than in **3**, where the isopropyl methyl doublets overlap (δ 1.22, J = 7 Hz). Compound **7** has one olefinic proton appearing as a singlet at δ 5.87. Since the isopropyl methine is allylic (δ 2.50), the singlet nature of the olefinic proton indicates a $\Delta^{13,14}$ double bond with C-8 fully substituted. The appearance of signals at

δ 76.9 (s) and δ 74.6 (d) in the ^{13}C nmr spectrum indicates the presence of two oxygenated sp^3 carbons. This, coupled with the fact that the base peak in the mass spectrum (m/z 302) corresponds to the loss of a molecule of oxygen, suggested that **7** might be the *endo*-peroxide of levopimaric acid (**8**). Comparison of the methyl ester of **7** with an authentic sample confirmed the identity. Although the *endo*-peroxide is not an auto-oxidation product (12) of levopimaric acid (**8**), the presence of light and a photosensitizing substance in the crude extract (13) may bring about the incorporation of molecular oxygen in the homoannular diene component of **8**.

7-Oxodehydroabietic acid (**9**) was obtained in the flash chromatography fractions eluting after the acids **3–6**. The ^1H nmr spectrum reveals three aromatic protons with a coupling pattern similar to that of **3**, although at somewhat lower field. A benzylic isopropyl methine proton appears at δ 2.92 (septet, J = 7 Hz), but the C-7 benzylic protons of **3** are absent. A ketonic carbon is evident in the ^{13}C nmr spectrum at δ 198.4. In addition to the carboxyl carbonyl at 1695 cm^{-1} in the ir spectrum, an unsaturated ketone appears at 1685 cm^{-1}. The two carbonyl bands become better resolved (1727 and 1684 cm^{-1}) when the acid is esterified (diazomethane). The ultraviolet spectrum indicates the presence of an aromatic ketone (217 (ε 10 500), 255 (ε 7700), 304 (ε 1830) nm). Comparison of the spectroscopic data with literature values (23) for methyl 7-oxodehydroabietate confirmed the identity. This uv-active compound may be an artifact since upon standing dehydroabietic acid gives a number of auto-oxidation products, including **9** (14).

The identity of 7-oxo-15-hydroxydehydroabietic acid (**10**) was established from the ^1H nmr, ir, and mass spectra, and by comparison with the spectral data of **3** and **9**. Thus, the three aromatic protons with the coupling pattern found in the C-ring of **3** appear again in **10**. As in **9**, these three protons are deshielded relative to **3**. Both the C-7 methylene and the benzylic isopropyl proton of **3** are absent in **10**, while two methyl singlets appear at δ 1.60 and 1.61. Thus the ketone and hydroxyl groups are assigned to C-7 and C-15, respectively. Although 15-hydroxy compounds are not among the reported (14) auto-oxidation products of **3**, the fact that benzylic auto-oxidation may give rise to **9** suggests that **10** also may be an artifact.

The pigment austocystin F (**11**) was obtained as orange crystals, mp 232–234°C. The molecular formula $C_{17}H_{10}O_7$ was established by high resolution mass spectroscopy. The ir spectrum shows an OH band at 3480 cm^{-1}, and absorption at 1663 and 1645 cm^{-1} characteristic of the γ-pyrone unit. The ^1H nmr spectrum shows three protons exchangeable with D_2O, two hydrogen-bonded phenolic protons that appear as singlets at δ 11.80 and 12.38, and an alcoholic proton at δ 2.88. A 1,2,3-trisubstituted aromatic system is apparent from the coupling of the aromatic protons at δ 6.80, 6.89, and 7.59. The low-field position of the latter proton, which shows two *ortho* couplings, indicates its location *para* to an electron-withdrawing substituent. Protons at δ 5.73 and 6.58 are coupled (J = 2.75 Hz). The small coupling constant and the large difference in their chemical shifts indicate they are located on a highly polarized *Z*-olefin. This suggested the presence of the *bis*-dihydrofuran moiety, typical of the aflatoxins (15). Such a structure also accounts for two low-field singlets at δ 6.44 and 6.46. One is a methine deshielded by two ethereal oxygens while the other is assigned to the isolated aromatic proton at C-4. Thus the alcoholic OH must be the other ring junction substituent. The linear nature of the fused pentacyclic system follows from the chemical shift (δ 6.44 or 6.46) of the proton at C-11 (16). Comparison (tlc, ir) with an authentic sample of austocystin F confirmed the identity of the metabolite as well as the *cis* fusion of the dihydrofuran rings. Austocystin F has been isolated previously as a member of a series of austocystins produced by *Aspergillus ustus* (16).

Averufin (**12**) and averufanin (**13**) were found to cocrystallize from chloroform. The mixture appeared homogeneous by tlc and could not be separated.[2] The mixture was shown to be composed of two components by chemical ionization mass spectroscopy, which gives M + 1 peaks at m/z 369 (100%) and 371 (78%). In conjunction with the high resolution mass spectrum, the molecular formulae were established as $C_{20}H_{16}O_7$ (368) and $C_{20}H_{18}O_7$ (370). The ir spectrum reveals OH (3380 cm^{-1}) as well as unsaturated carbonyls (1669 and 1622 cm^{-1}). That the latter of these is a quinone carbonyl hydrogen-bonded to two *peri*-phenolic groups is indicated by the appearance of singlets in the ^1H nmr spectrum ($CDCl_3$) at δ 12.34 (1H) and 12.51 (1H). In acetone-d_6 + D_2O the spectrum shows two aromatic protons, displaying mutual *meta* coupling (2 Hz) at δ 6.58 and 7.13, and an isolated aromatic proton at δ 7.03. These data give rise to the anthraquinone partial structure **14**.

Acetylation (acetic anhydride – pyridine) of the mixture afforded products that were separated by preparative tlc. Mass spectral analysis shows these to be a tetraacetate ($C_{28}H_{26}O_{11}$) arising from the component of molecular weight 370, and a triacetate ($C_{26}H_{22}O_{10}$) formed from the compound of molecular weight 368. The ^1H nmr spectrum of the triacetate possesses a multiplet at δ 5.29 (1H) and a singlet at δ 1.56 (3H). These features helped establish the structure of averufin (**12**) as the parent compound of the triacetate. The identity was confirmed by comparison (tlc, ir, ms) with an authentic sample.

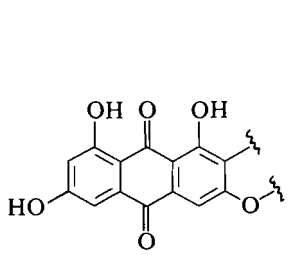
The location of an hydroxyl at C-3 in **13** follows from the magnitude (Δ ppm = 0.79) of the downfield shift of H-4 upon acetylation (18). Such a large change can be attributed to the acetylation of both *ortho* and *para* phenolic hydroxyls. In **12** H-4 experiences a downfield shift of only 0.41 ppm, due to acetylation of the *para* OH substituent. The ^1H nmr spectrum of **13** contains signals at δ 1.31 (3H, d, J = 6 Hz), 3.8 (1H, m), and 5.13 (1H, dd, J = 11.5, 2.25 Hz), suggesting a methyl substituted tetrahydropyran ring, which accounts for the single remaining degree of unsaturation. Acetylation (acetic anhydride – pyridine) of an authentic sample of averufanin afforded a product identical (tlc, ir) with the tetraacetate of the compound in hand.

A thorough examination of the mycelial extracts afforded several steroidal compounds, ergosterol peroxide (**15**), sitostanol (**16**), and β-sitosterol (**17**). The presence of the saturated compound (**16**) in the sample of **17** was indicated by the mass spectrum, which shows a peak of 19% intensity at m/z 416 (M^+ of **16**), whereas an intensity of only 5% would be anticipated for the M + 2 peak of m/e 414 (M^+ of **17**).

Saturated fatty acids possessing 18, 20, 22, and 24 carbon atoms were present in the mycelial extract. Triglycerides were also isolated, which upon basic hydrolysis (10% KOH (w/v)) yielded a mixture of saturated fatty acids (having 16 and 18 carbons) and the unsaturated fatty acid linoleic acid (**18**).

Fifteen distinct species (five in Europe and ten in North

[2]In our hands, averufin and averufanin could not be separated by tlc using the method of Berger and Jadot (17). Observed R_f values were significantly lower than those reported and no separation was obtained.



14

17

18

America) of the *A. mellea* complex have been identified (19). The three strains employed in this study are "biological species I" of Anderson and Ullrich (19) or the closely related "foothills type" of Mallett (20). They correspond to a taxonomic species *Armillaria ostoyae* (Romagn.) Herink (= *A. obscura* (Persoon) Herink), one of the species recognized within the *Armillaria mellea* complex in recent years (21). Thus it is possible that the species used in this study has not been examined previously for its metabolites, while reported metabolites of *A. mellea* (broad sense), including those of Oduro *et al.* (3*a*) may have been isolated from one or more of the other species. The strains studied in this investigation are parasitic on pine and spruce, themselves producers of resin acids, but the media used in this study (V-8 juice, potato dextrose) do not contain resin acids. The biological significance of this observation is not clear to us. However, it is interesting to note that in conifers large amounts of resin are exuded through the bark at the point of infection and the area of resinosis increases as the fungus spreads in the bark (2*a*). As noted previously, resin acids hitherto have not been identified as fungal metabolites.

Experimental

General

High resolution electron impact mass spectra (hreims) were recorded on an AEI MS-50 mass spectrometer. Unless diagnostically significant, only those peaks with intensity of >30% of the base peak are recorded. Chemical ionization mass spectra (cims) were obtained using an AEI MS-12 mass spectrometer with ammonia as the reagent gas. The data were processed in DS-55 and Nova-4 computers. Fourier transform infrared (Ftir) spectra were recorded as $CHCl_3$, CH_2Cl_2, or CH_3OH casts on a Nicolet 7199 FTIR interferometer. Single scan infrared (ir) spectra were recorded on a Perkin Elmer 297 spectrometer. Nuclear magnetic resonance (nmr) spectra (^1H and ^{13}C) were obtained on Bruker WH-200 or WH-400 spectrometers with an Aspect 2000 computer system. Tetramethylsilane was used as the internal standard. Ultraviolet (uv) spectra were obtained on a Unicam SP 1700 spectrophotometer and optical rotations on a Perkin Elmer 141 polarimeter. Melting points are uncorrected and were determined on Zeitz–Wetzlar and Thomas Model 40 melting point apparatus. Macherey Nagel silica gel 60 (less than 200 mesh) was used for column chromatography. Fractions were collected with a Buchler Fracto Mette 200 fraction collector. E. Merck silica gel 60 (230–400 mesh) was used for flash chromatography. Preparative thin-layer chromatography (ptlc) was carried out on Terochem silica gel G containing a trace of electronic phosphor (General Electric), 20 × 20 cm, 10 × 20 cm, or 5 × 20 cm plates, 0.35 mm thickness. Analytical thin-layer chromatography (tlc) was carried out on glass plates (75 × 25 or 75 × 50 mm) coated with the same adsorbent as ptlc, or on E. Merck precoated plates of silica gel 60 F-254. Analytical tlc plates with adsorbed silver nitrate ($AgNO_3$) were prepared by dipping the precoated plates into a solution of 20% (w/v) $AgNO_3$ in H_2O–CH_3OH, 1:1 (stored in the dark) for several seconds, then drying with a heat gun. The plates were used immediately. Unless otherwise indicated, R_f values are for single elutions. Ultraviolet active materials were detected by visualization under a uv lamp (254 or 350 nm). The plate (only a thin vertical band in the case of ptlc) was then sprayed with a solution of 10% or 30% sulphuric acid and charred on a hot plate. Unless specified, all solvents, with the exception of ether, hexane, and tetrahydrofuran, were distilled prior to use. Skellysolve B refers to Skelly Oil Company light petroleum, bp 62–70°C.

Fungal strains

The strains of *Armillaria mellea* used in this study were obtained from Dr. Y. Hiratsuka, Northern Forest Research Centre (NFRC), Edmonton. They were collected from the following host trees in British Columbia. Slant tube cultures of these strains were transferred to potato dextrose agar (PDA) slant tubes, which were kept as stock cultures at 4°C.

Strain	Host	Rhizomorph type*
NFRC-621	Lodgepole pine	Modified *A. bulbosa*
NFRC-624	Ponderosa pine	*A. mellea*
NFRC-631	White spruce	No rhizomorphs

*As determined by K. Mallett.

Still cultures of the fungus were initiated by inoculation into 1-L Fernbach flasks charged with sterile culture medium (either a 10% (v/v) solution of clarified V-8 juice containing 1% (w/v) glucose or potato dextrose broth (PDB)). The flasks were stoppered with foam rubber plugs covered loosely with aluminum foil. Growth periods were from 34 to 92 days.

Bioassays

The resin acids **3–7** and **9** show mild (0.5–2 mm zones of inhibition) antibiotic activity against *Staphylococcus aureus*, *Streptococcus pyogenes*, and *Klebsiella pneumoniae* at a concentration of 1% (w/v) (3.4% (w/v) for **7**). Antibiotic activity of resin acids against *S. aureus* has been reported previously (8*a*–*c*).

In vitro bioassays of the resin acid mixture **3–6** (1–5% (w/v) concentration) showed inhibition of *Fomes annosus*, *F. roseus*, and *F. pini*. A plug of *A. mellea* NFRC-621 also inhibited the growth

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 80.58.250.72 on 09/07/12
For personal use only.

of *F. roseus* in vitro. Resin acids have been reported to inhibit the mycelial growth of *F. annosus* (8*d*).

The resin acid mixture **3–6** was also found to inhibit the growth of lodgepole pine seedlings at a concentration of 0.1% (w/v).

Extraction of the metabolites

The culture mixture was separated into broth and mycelium by filtration through cheesecloth. The culture broth was extracted with chloroform (ca. equal volume). The chloroform extracts contained emulsions, and vacuum filtration through Celite facilitated the separation of organic and aqueous phases. The chloroform was dried over sodium sulphate and evaporated *in vacuo* to afford the crude metabolites. Although yields of crude metabolites varied with different growth periods, the resin acids (*vide infra*) were produced consistently by all three strains. The mycelium was extracted with chloroform or methanol in a Soxhlet extractor. The organic extract was dried over sodium sulphate and concentrated to dryness.

*Isolation of dehydroabietic acid (**3**), pimaric acid (**4**), isopimaric acid (**5**), and sandaracopimaric acid (**6**)*

The crude broth metabolites of strain NFRC-621 (1.8 g) were subjected to flash chromatography (chloroform – ethyl acetate – acetic acid, 94:5:1) to afford 0.547 g of a mixture of compounds **3–6**. A 40-mg sample of the mixture was applied to a 20 × 20 cm ptlc plate and developed 12 times with Skellysolve B – ethyl acetate – acetic acid, 98:2:1. Careful scraping of the lower edge of the band corresponding to the mixture and elution from the silica gel yielded 3.2 mg of impure **3**. This sample was further purified by ptlc on a 5 × 20 cm plate using the same solvent system as above and eluting five times, followed by scraping and elution to give **3**, pure as judged by multiple-elution tlc on silver nitrate-impregnated silica gel, using both protic and aprotic solvent systems.

A 90-mg sample of the mixture **3–6** was chromatographed on 10 g of silica gel that had been thoroughly mixed with 2 g powdered silver nitrate. The column (1.5 cm diameter) was wrapped in aluminum foil. Fractions (5 mL) were collected from elution with chloroform – Skellysolve B, 50:50, then 75:25 (each for approximately one column volume), then 100% chloroform to fraction 175, and finally chloroform – ethyl acetate, 98:2, to fraction 260.

Fractions 30–69 gave 31 mg of impure **3**. Further purification by flash chromatography (chloroform – ethyl acetate, 98:2) afforded 19 mg of **3**, mp 162–168°C (CH_3OH–H_2O) (lit. (9) mp 171–172°C); $[\alpha]_D$ +54° (*c* 1.9, 95% EtOH) (lit. $[\alpha]_D^{25}$ +61° (95% EtOH); tlc: R_f 0.6 (Skellysolve B – ethyl acetate – acetic acid, 75:25:1), R_f 0.72 (chloroform – ethyl acetate – acetic acid, 97:2:1, 3×, silver nitrate-impregnated silica gel); Ftir (CH_2Cl_2 cast): 3200–2400 (b), 2950, 2925, 2865, 1692 cm^{-1}; uv (CH_3OH): 220 (ε 2180), 268 (ε 630), 276 (ε 600) nm; ^1H nmr ($CDCl_3$) δ: 1.0–1.9 (7H, m), 1.23 (6H, d, J = 7 Hz, C-15 2 × CH_3), 1.25 (3H, s, C-10 CH_3), 1.29 (3H, s, C-4 CH_3), 2.24 (1H, dd, J = 12.5, 2 Hz), 2.30 (1H, bd, J = 12.5 Hz), 2.82 (1H, septet, J = 7 Hz, C-15 H), 2.90 (2H, m, C-7 CH_2), 6.87 (1H, d, J = 1.75 Hz, C-14 H), 6.98 (1H, dd, J = 8, 1.75 Hz, C-12 H), 7.14 (1H, d, J = 8 Hz, C-11 H); ^{13}C nmr ($CDCl_3$) δ: 16.3, 24.0 (2 C's), 25.2 (CH_3); 18.6, 21.9, 30.1, 36.9, 38.1 (CH_2); 33.5, 44.7, 124.0, 124.2, 127.0 (CH); 37.0, 47.5, 134.8, 145.8, 146.9 (C); 185.0 (C=O); hreims, m/z calcd. for $C_{20}H_{28}O_2$ (M^+): 300.2089; found: 300.2093 (30), 285 (100), 239 (74).

Fractions 95–169 from the above chromatography of 90 mg of the mixture **3–6** afforded 3.3 mg of **4**, mp 200–208°C (95% EtOH) (lit. (22) mp 212°C); tlc R_f 0.65 (chloroform – ethyl acetate – acetic acid, 97:2:1, 3×, silver nitrate-impregnated silica gel); Ftir ($CHCl_3$ cast): 3600–2400(b), 2925, 2870, 2850, 1695 cm^{-1}; ^1H nmr ($CDCl_3$): see Table 1; δ: 0.80 (3H, s, C-10 CH_3), 0.8–1.8 (13H, m), 1.02 (3H, s, C-13 CH_3), 1.23 (3H, s, C-4 CH_3), 1.95 (1H, dd, J = 12.5, 2.5 Hz), 2.13 (1H, m), 2.29 (1H, m); ^{13}C nmr ($CDCl_3$) δ: 15.0, 16.7, 29.4 (CH_3); 18.0, 18.9, 25.1, 35.3, 35.6, 37.0, 38.1, 116.4 (CH_2); 48.7, 51.4, 128.4, 147.2 (CH); 37.8, 38.6, 47.3, 137.9 (C); 185.8 (C=O); hreims, m/z calcd. for $C_{20}H_{30}O_2$ (M^+): 302.2246; found: 302.2243 (49), 287 (69), 167 (37), 121 (100), 91 (31).

The later fractions from the above chromatography of 90 mg of the mixture **3–6** gave 40 mg of impure **5** and **6**. After this sample was subjected twice more to flash chromatography (Skellysolve B – ethyl acetate – acetic acid, 95:5:1, and chloroform – ethyl acetate, 9:1, respectively) a trace of **4** was still present by tlc (silver nitrate). The remainder (17 mg) was subjected to flash chromatography (chloroform – ethyl acetate – acetic acid, 97:2:1) on silica gel (2.4 g) thoroughly mixed with powdered silver nitrate (0.6 g) to give 5 mg of **5** and **6**, appearing as a single spot by tlc: R_f 0.52 (chloroform – ethyl acetate – acetic acid, 97:2:1, 3×, silver nitrate-impregnated silica gel); ^1H nmr ($CDCl_3$): see Table 1; δ: 0.85 (s, C-10 CH_3 of **6**), 0.87 (s, C-10 CH_3 of **5**), 0.91 (s, C-13 CH_3 of **5**), 1.05 (s, C-13 CH_3 of **6**), 1.1–2.0 (m), 1.22 (s, C-4 CH_3 of **6**), 1.28 (s, C-4 CH_3 of **5**); hreims, m/z calcd. for $C_{20}H_{30}O_2$ (M^+): 302.2246; found: 302.2250 (100), 287 (47), 273 (29), 257 (27), 241 (34), 187 (30), 105 (31), 91 (33).

*Esterification of **3–6***

An excess of diazomethane in ether was added to a magnetically stirred solution of **3–6** (28 mg; tlc: R_f 0.67 (Skellysolve B – ethyl acetate – acetic acid, 75:25:1); ir ($CHCl_3$): 3400–2400(b), 1690 cm^{-1}) dissolved in ether (1 mL). Evaporation to dryness gave a colourless oil (28 mg), tlc: R_f 0.82 (Skellysolve B – ethyl acetate – acetic acid, 75:25:1); ir ($CHCl_3$): 1720 cm^{-1}; cims, m/z: 334 (M + 18 for esters of **4–6**), 332 (M + 18 for ester of **3**), 317 (M + 1 for esters of **4–6**), 315 (M + 1 for ester of **3**).

Similarly 2.5 mg of purified **4** was esterified to give methyl pimarate; tlc: R_f 0.67 (chloroform – ethyl acetate – acetic acid, 97:2:1, 2×, silver nitrate-impregnated silica gel); Ftir ($CHCl_3$ cast): 2918, 2849, 1728, 1244, 914 cm^{-1}.

*Chromatography of the methyl esters of **3–6***

The mixture of esters (47 mg) was subjected to column chromatography over neutral alumina (36.4 g; Woelm, ICN Pharmaceuticals), mixed thoroughly with powdered silver nitrate (7.3 g). The column (1.5 cm diameter) was wrapped in aluminum foil and eluted with hexane (7 fractions, 8 mL), hexane–ether, 98:2 (to fraction 38), and finally hexane–ether, 95:5. Methyl dehydroabietate (methyl ester of **3**) and methyl pimarate (methyl ester of **4**) eluted together; however, methyl isopimarate and methyl sandaracopimarate (6 mg; methyl esters of **5** and **6** respectively) eluted in fractions 67–88; tlc: R_f 0.44 (Skellysolve B – ethyl acetate, 90:10, silver nitrate-impregnated silica gel); Ftir ($CHCl_3$ cast): 3080 (w), 2950, 2920, 2865, 2845, 1728 (s), 1637 (w), 1244, 909 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 0.83 (s), 0.86 (s), 0.90 (s), 1.04 (s), 1.1–2.0 (m), 1.20 (s), 1.26 (s), 3.65 (s), 3.67 (s), 4.86 (dd, J = 10.5, 1.5 Hz), 4.88 (dd, J = 10.5, 1.5 Hz), 4.90 (dd, J = 17.25, 1.5 Hz), 4.92 (dd, J = 17.25, 1.5 Hz), 5.21 (bs), 5.31 (dd, J = 7.5, 1.5 Hz), 5.77 (dd, J = 17.25, 10.5 H), 5.80 (dd, J = 17.25, 10.5 Hz); cims, m/z: 334 (M + 18).

*Hydrogenation of **3–6***

The mixture **3–6** (10 mg) was dissolved in dry ethyl acetate (9 mL) and activated 10% palladium on charcoal (102 mg) was added. The mixture was pressurized with hydrogen (15 psi; 1 psi = 6.9 kPa) and shaken in a Parr hydrogenator for 24 h at room temperature. The catalyst was removed by filtration through Celite. Evaporation of the filtrate *in vacuo* afforded 10 mg of a colourless solid; tlc: R_f 0.56 (Skellysolve B – ethyl acetate – acetic acid, 75:25:1) ir ($CHCl_3$ cast): 3400–2400(b), 1695 (s) cm^{-1}; cims, m/z: 324 (M + 18 for hydrogenation products of **4–6**), 318 (M + 18 for unchanged **3**).

Isolation of levopimaric acid endo-*peroxide (**7**)*

The crude broth metabolites of strain NFRC-631 (0.74 g) were subjected to flash chromatography (chloroform – ethyl acetate, 9:1, to fraction 16, then chloroform – ethyl acetate – acid, 97:2:1, to fraction 21, and 94:5:1 to fraction 25). Elution was continued with Skellysolve B – ethyl acetate, 3:1 (100 mL), 1:1 (100 mL), and ethyl acetate (100 mL). A 389-mg fraction (eluting with chloroform – ethyl acetate – acetic acid (97:2:1) after **3–6**) contained **7** and was further purified by flash chromatography (chloroform – ethyl acetate – acetic acid, 97:2:1) to give **7** (269 mg); tlc: R_f 0.43 (chloroform–acetone – acetic acid, 89:10:1, 5×); Ftir ($CHCl_3$ cast): 3600–2400 (b), 2955, 2935, 2870, 1692 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 0.56 (3H, s, C-10 CH_3), 0.9–2.4 (14H, m), 1.08 and 1.12 (2 × 3H, d, J = 7 Hz, C-15 CH_3), 1.15 (3H, s, C-4 CH_3), 2.50 (1H, septet, J = 7 Hz, C-15 H), 4.61 (1H, m, C-12

For personal use only.

H), 5.87 (1H, s, C-14 H), 9.0 (1H, bs, COOH); ^{13}C nmr ($CDCl_3$) δ: 15.1, 16.2, 20.1, 20.3 (CH_3); 16.9, 21.6, 24.9, 32.0, 36.1, 36.6 (CH_2); 31.0, 48.8, 50.0, 74.6, 124.6 (CH); 36.8, 46.8, 76.9, 149.0 (C); 184.9 (C=O); hreims, m/z calcd. for $C_{20}H_{30}O_4$ (M^+): 334.2144; found: 334.2149 (18), 319 (14), 316 (18), 302 (100), 291 (18), 285 (21), 275 (25), 245 (51), 146 (37), 121 (56), 113 (32), 107 (32), 105 (38), 93 (38), 91 (58).

Esterification of levopimaric acid endo*-peroxide (7)*

Treatment of **7** (12 mg) with excess diazomethane in ether overnight at room temperature yielded 12 mg of the methyl ester upon evaporation to dryness; tlc: R_f 0.56 (chloroform–acetone – acetic acid, 89:10:1, 5×); ir ($CHCl_3$): 2950, 2875, 1720, 1300–1190 (b) cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 0.58 (3H, s), 0.9–2.4 (14H, m), 1.10 (3H, d, J = 7 Hz), 1.14 (3H, d, J = 7 Hz), 1.17 (3H, s), 2.5 (1H, septet), 3.70 (3H, s), 4.62 (H, m), 5.89 (1H, s); hreims, m/z calcd. for $C_{21}H_{32}O_4$ (M^+): 348.2300; found: 348.2302 (9), 333 (5), 316 (100), 146 (48), 121 (70), 91 (36).

Isolation of 7-oxodehydroabietic acid (9)

Flash chromatography of the crude broth metabolites of strain NFRC-621 (*vide supra*) afforded impure **9** in fractions eluting with chloroform – ethyl acetate – acetic acid, (94:5:1) after the fractions containing the mixture **3–6**. This material (153 mg) was further subjected to flash chromatography (chloroform – ethyl acetate 94:6, containing 3 drops acetic acid per 10 mL) to give impure **9** (37 mg). Preparative tlc (chloroform – ethyl acetate, 90:10, 5×) yielded, after careful scraping and elution, 12 mg of **9**, $[\alpha]_D$ −3° (*c* 1.56, 95% EtOH); tlc: R_f 0.23 (Skellysolve B – ethyl acetate – acetic acid, 85:15:1); Ftir ($CHCl_3$ cast): 3500–2400 (b), 2955, 2930, 2870, 1695, 1685 cm^{-1}; uv (CH_3OH): 217 (ε 10 500), 255 (ε 7700), 304 (ε 1830) nm; ^{1}H nmr ($CDCl_3$) δ: 0.8–1.9 (4H, m), 1.234 and 1.237 (2 × 3H, d, J = 7 Hz, C-15 2 × CH_3), 1.26 (3H, s, C-4 CH_3), 1.34 (3H, 3H, s, C-10 CH_3), 2.36 (2H, bd, J = 13 Hz), 2.49 and 2.70 (2 × 1H, d, J = 14 Hz, C-6 H_{eq} and C-5 H), 2.76 (1H, dd, J = 14 Hz, C-6 H_{ax}), 2.92 (1H, septet, J = 7 Hz, C-15 H), 7.29 (1H, d, J = 8 Hz, C-11 H), 7.41 (1H, dd, J = 8, 2 Hz, C-12 H), 7.87 (1H, d, J = 2 Hz, C-11 H); ^{13}C nmr ($CDCl_3$) δ: 16.2, 23.65, 23.69, 23.76 (CH_3); 18.2, 36.7, 37.2, 37.8 (CH_2), 33.6, 43.8, 123.4, 125.3, 132.5 (CH); 29.7, 46.4, 130.9, 147.0, 153.0 (C); 182.1, 198.4 (C=O); hreims, m/z calcd. for $C_{20}H_{26}O_3$ (M^+): 314.1882; found: 314.1883 (58), 299 (35), 253 (100), 211 (26).

Esterification of 7-oxodehydroabietic acid (9)

An excess of diazomethane in ether was added to a magnetically stirred solution of **9** (4.5 mg) in $CHCl_3$ (2 mL) and the reaction mixture was stirred for 15 min at room temperature. Evaporation to dryness afforded 4.5 mg of the methyl ester; $[\alpha]_D$ +2° (*c* 4.5, 95% EtOH) (lit. (23) $[\alpha]_D$ +7.9° (EtOH)); tlc: R_f 0.41 (Skellysolve B – ethyl acetate – acetic acid, 85:15:1); Ftir ($CHCl_3$ cast): 2955, 2936, 2868, 1727 (s), 1684 (s), 1608 (w), 1250 cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 0.8–1.9 (5H, m), 1.255 (6H, d, J = 7 Hz, C-15 2× CH_3), 1.27 (3H, s, C-4 CH_3), 1.35 (3H, s, C-10 CH_3), 2.36 (2H, m), 2.73 (2H, m), 2.93 (1H, septet, J = 7 Hz, C-15 H), 3.66 (3H, s, OCH_3), 7.29 (1H, d, J = 8 Hz, C-11 H), 7.40 (1H, dd, J = 8, 2 Hz, C-12 H), 7.87 (1H, d, J = 2 Hz, C-14 H); hreims, m/z calcd. for $C_{21}H_{28}O_3$ (M^+): 328.2038; found: 328.2037 (66), 313 (6), 253 (100).

Isolation of 7-oxo-15-hydroxydehydroabietic acid (10)

The polarity of the eluent in the flash chromatography of the crude broth metabolites of strain NFRC-621 (*vide supra*) was increased to chloroform – ethyl acetate – acetic acid, 84:15:1 after 31 fractions. A polar fraction (210 mg) containing **10** was further subjected to flash chromatography (Skellysolve B – ethyl acetate – acetic acid, 70:30:1, to fraction 18, then 65:35:1; sample dissolved in chloroform). Fractions 29–34 gave 12 mg of material, which was further purified by flash chromatography (chloroform–acetone – acetic acid, 90:10:1) to afford pure **10** (3 mg); tlc: R_f 0.4 (chloroform–acetone – acetic acid, 89:10:1, 3×); Ftir ($CHCl_3$ cast): 3600–2400 (b), 2970, 2930, 2867, 1696 (b), 1237, 756 cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 0.8–1.9 (5H, m), 1.29 (3H, s, C-10 CH_3), 1.37 (3H, s, C-4 CH_3), 1.60 and 1.61 (2 × 3H, s, C-15 2 × CH_3), 2.38 (2H, bd, J = 11 Hz), 2.49 and 2.58 (2 × 1H, d, J = 12.5 and 12.25 Hz respectively, C-6 H_{eq} and C-5 H), 2.74 (1H, dd, J = 12.5, 12.25 Hz, C-6 H_{ax}), 7.39 (1H, d, J = 8.5 Hz, C-11 H), 7.77 (1H, dd, J = 8.5, 2.25 Hz, C-12 H), 8.09 (1H, d, J = 2.25 Hz, C-14 H); hreims, m/z calcd. for $C_{20}H_{26}O_4$ (M^+): 330.1831; found: 330.1826 (3), 315 (100), 312 (3), 269 (8).

Isolation of austocystin F (11)

Flash chromatography of the crude broth metabolites of strain NFRC-631 (*vide supra*) gave 109 mg of material containing **3–6** as well as **11–13** in fractions eluting with chloroform – ethyl acetate – acetic acid. This sample was further purified by flash chromatography (Skellysolve B – ethyl acetate – acetic acid, 92:7:1; sample dissolved in chloroform) to afford **3–6**, then Skellysolve B – ethyl acetate – acetic acid (87:12:1) coeluted **12** and **13**, and Skellysolve B – ethyl acetate – acetic acid (79:20:1) gave **11**. Recrystallization from toluene provided **11** (2 mg, mp 232–234°C (lit. (16) mp 230–233°C); $[\alpha]_D$ −180° (*c* 1.1, pyridine) (lit. (16) $[\alpha]_D^{22}$ −244° (*c* 0.91, pyridine)); tlc: R_f 0.35 (Skellysolve B – ethyl acetate – acetic acid, 85:15:1, 3×); Ftir (CH_2Cl_2 cast): 3480 (b), 1663, 1645, 1606, 1491 cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 2.88 (1H, bs, C-3a OH), 5.73 (1H, d, J = 2.75 Hz, C-3 H), 6.44 and 6.46 (2 × 1H, s, C-11 H and C-12a H), 6.58 (1H, d, J = 2.75 Hz, C-2 H), 6.80 (1H, d, J = 8.25 Hz, C-7 H), 6.89 (1H, d, J = 8.25 Hz, C-9 H), 7.59 (1H, t, J = 8.25 Hz, C-8 H), 11.80 (1H, s, C-4 OH), 12.38 (1H, s, C-6 OH); hreims, m/z calcd. for $C_{17}H_{10}O_7$ (M^+): 326.0426; found: 326.0423 (58), 297 (100), 271 (15).

Isolation of averufin (12) and averufanin (13)

The amounts of **12** and **13** from the broth extract of strain NFRC-631 (*vide supra*) were too small for identification purposes. Soxhlet extraction (chloroform) of the mycelium of the same growth of NFRC-631 mentioned above provided 7.2 g of crude metabolites. A portion (3.3 g) was subjected to flash chromatography (sample dissolved in chloroform), eluent Skellysolve B – ethyl acetate, 93:7 (750 mL), then Skellysolve B – ethyl acetate, 85:15 (750 mL), then chloroform—methanol, 99:1 (500 mL), then chloroform–methanol, 98:2 (750 mL), and finally chloroform–methanol, 95:5 (500 mL). Fraction 24 (eluting with Skellysolve B – ethyl acetate, 85:15) afforded orange crystals upon concentration and cooling to ca. 5°C. The crystalline material (23 mg) was a mixture of **12** and **13**; tlc: R_f 0.50 (Skellysolve B – ethyl acetate – acetic acid, 85:15:1, 3×); R_f 0.20 (chloroform – ethyl acetate, 98:2, 3×); Ftir ($CHCl_3$ cast): 3380 (b), 1669 (w), 1622, 1399, 1268, 1258, 1156, 751 cm^{-1}; ^{1}H nmr (acetone-d_6 + D_2O) δ: 1.1–2.1 (m), 1.24 (<3H, d, J = 6.5 Hz, C-5′ CH_3 of **12**), 3.73 (<1H, m, C-5′ H of **13**), 5.04 (<1H, dd, J = 11.5, 2.25 Hz, C-1′ H of **13**), 5.22 (<H, d, J = 2.75 Hz, C-1′ H of **12**), 6.58 (1H, d, J = 2 Hz, C-7 H), 7.03 (1H, s, C-4 H), 7.13 (1H, d, J = 2 Hz, C-5 H); hreims, m/z calcd. for $C_{20}H_{18}O_7$ (M^+ for **13**): 370.1052; found: 370.1040 (17); m/z calcd. for $C_{20}H_{16}O_7$ (M^+ for **12**): 368.0896; found: 368.0891 (57), 350 (22), 325 (89), 310 (100), 297 (71), 286 (58); cims, m/z: 386 (M + 18 for **12**), 371 (M + 1 for **13**), 369 (M + 1 for **12**).

Acetylation of averufin (12) and averufanin (13)

Acetic anhydride (1.0 mL) and pyridine (1.0 mL) were added to the mixture of **12** and **13** (3.5 mg) and the reaction mixture was stirred for 18 h at room temperature. The solvents were evaporated *in vacuo* and the crude products were separated by preparative tlc (chloroform–methanol, 99:1) to give averufin triacetate (1.3 mg), mp 205–210°C (Skellysolve B – benzene) (lit. (24) mp 210–214°C): $[\alpha]_D$ −25° (*c* 2.2, $CHCl_3$) (lit. (24) $[\alpha]_D$ −15° ($CHCl_3$)); tlc: R_f 0.45 (chloroform–methanol, 99:1, 2×); Ftir (CH_2Cl_2 cast): 1770, 1677, 1662, 1600, 1346, 1325, 1197 cm^{-1}; ^{1}H nmr (acetone-d_6) δ: 1.6–2.2 (6H, m), 1.56 (3H, s, C-5′ CH_3), 2.37, 2.40, and 2.44 (3 × 3H, s, 3 × $COCH_3$), 5.29 (1H, m, C-1′ H), 7.39 (1H, d, J = 3 Hz, C-7 H), 7.51 (1H, s, C-4 H), 7.93 (1H, d, J = 3 Hz, C-5 H); hreims, m/z calcd. for $C_{26}H_{22}O_{10}$ (M^+): 494.1213; found: 494.1211 (10), 452 (61), 410 (100), 368 (49), 352 (84), 340 (32), 325 (77), 310 (99), 309 (56), 297 (69), 286 (34), 285 (41), 281 (37).

The above mentioned ptlc also gave 0.5 mg of averufanin tetra-

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 80.58.250.72 on 09/07/12
For personal use only.

acetate; tlc: R_f 0.29 (chloroform–methanol, 99:1, 2×); Ftir ($CHCl_3$ cast): 2920, 2850, 1776, 1677, 1595, 1367, 1324, 1183 cm^{-1}; ^1H nmr (acetone-d_6) δ: 1.15 (3H, d, J = 6 Hz, C-5′ CH_3), 1.6–2.3 (6H, m), 2.37, 2.40, 2.41, and 2.44 (4 × 3H, s, 4 × $COCH_3$), 3.8 (1H, m, C-5′ H), 4.93 (1H, m, C-1′ H), 7.41 (1H, d, J = 2.25 Hz, C-7 H), 7.89 (1H, s, C-4 H), 7.94 (1H, d, J = 2.25 Hz, C-5 H); hreims, m/z calcd. for $C_{28}H_{26}O_{11}$ (M^+): 538.1475; found: 538.1475 (8), 496 (42), 478 (24), 454 (73), 436 (11), 412 (76), 394 (28), 352 (42), 300 (27), 299 (38), 297 (31), 172 (50), 57 (100).

Averufanin tetraacetate was also prepared from authentic averufanin for comparative purposes, using the same procedure described above for the mixture of **12** and **13**.

*Isolation of ergosterol peroxide (**15**)*

The crude mycelial extract (0.94 g) from strain NFRC-621 was subjected to flash chromatography. Elution with chloroform gave a fraction (86 mg) that was further chromatographed (Skellysolve B – ethyl acetate, 85:15; changed to 75:25 after 11 fractions) to provide impure **15** (16 mg). Preparative tlc (chloroform–methanol, 97:3, 3×) afforded **15** (5 mg), which was recrystallized from ether–hexane, mp 178–181°C (lit. (25) mp 181.5–183°C). The compound was identical (tlc, ftir, ^1H nmr) with an authentic sample.

Analysis of other mycelial extracts by tlc showed **15** to be produced by strains NFRC-624 and 631 as well. Although not isolated in pure form, ergosterol was also shown to be present in the mycelial extracts of NFRC-624 by comparative tlc with an authentic sample.

*Isolation of sitostanol (**16**) and β-sitosterol (**17**)*

Flash chromatography of the crude mycelial extract of strain NFRC-624 (0.82 g) afforded 30 mg from fractions eluting with Skellysolve B – ethyl acetate (75:25). Preparative tlc of this material (Skellysolve B – ethyl acetate, 85:15, 4×) yielded a mixture of **16** and **17** (6 mg), which was recrystallized from methanol–ether (mp 136–138°C) (lit. (26) mp 136–137°C); tlc: R_f 0.37 (Skellysolve B – ethyl acetate, 85:15, 3×); Ftir ($CHCl_3$ cast): 3600–3100 (b), 2955, 2930, 2865, 1465, 1375, 1057 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 0.66 and 0.69 (2s, C-10 CH_3 of **16** and **17**), 0.7–2.4 (m), 0.81–0.87 (m, C-13 CH_3 of **16**, C-25 2 × CH_3 and C-28 CH_3 of **16** and **17**), 0.90–0.95 (2d, J = 7 Hz, C-20 CH_3 of **16** and **17**), 1.03 (s, C-13 CH_3 of **17**), 3.52 (bs, C-3 H of **16** and **17**), 5.38 (m, C-6 H of **16**); hreims, m/z calcd. for $C_{29}H_{52}O$ (M^+ for **16**): 416.4018; found: 416.4005 (19); m/z calcd. for $C_{29}H_{50}O$ (M^+ for **17**): 414.3861; found: 414.3871 (73), 401 (6), 399 (19), 396 (30), 303 (32), 159 (30), 145 (40), 133 (32), 121 (33), 119 (33), 109 (33), 107 (62), 105 (41), 95 (67), 93 (46), 91 (36), 81 (74), 69 (62), 57 (82), 55 (100).

Isolation of fatty acids and triglycerides

Flash chromatography of the crude mycelial extracts of strain NFRC-631 (see isolation of **12** and **13**) afforded crude triglycerides (531 mg) in fractions 4–5. These were further purified by flash chromatography (Skellysolve B – ethyl acetate, 95:5) to give mixed triglycerides (370 mg) as a colourless liquid; tlc: R_f 0.68 (Skellysolve B – ethyl acetate – acetic acid, 85:15:1, 2×); Ftir ($CHCl_3$ cast): 3005 (w), 2925, 2850, 1745, 1465, 1163 cm^{-1}.

From several fractions of the above flash chromatography of the NFRC-631 mycelial extract, a mixture of fatty acids crystallized upon concentration, mp 59–61°C; Ftir ($CHCl_3$ cast): 3300–2400 (b), 2915, 2850, 1697 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 0.88 (3H, t, J = 7 Hz, CH_3—$(CH_2)_n$—), 1.26 (s, CH_3—$(CH_2)_n$—CH_2CH_2CO—), 1.63 (2H, quintet, J = 7.5 Hz, —CH_2—CH_2—CO—), 2.35 (2H, t, J = 7.5 Hz, —CH_2—CO); cims, m/z: 386 (M + 18 for lignoceric acid (C24)), 358 (M + 18 for behenic acid (C22)), 330 (M + 18 for arachic acid (C20)), 302 (M + 18 for stearic acid (C18)).

Hydrolysis of triglycerides

A solution of triglycerides (158 mg) in tetrahydrofuran (4 mL) and 10% (w/v) potassium hydroxide (2 mL) was stirred overnight at room temperature. After evaporation of the tetrahydrofuran *in vacuo*, the solution was acidified (5 *N* hydrochloric acid) and extracted with chloroform (5 × 20 mL). The combined chloroform extracts were washed with water (3 × 25 mL) and brine (3 × 25 mL) and dried over sodium sulphate. Filtration and evaporation afforded crude hydrolysis products (96 mg). Crystallization from ethyl acetate gave mixed fatty acids (11 mg), mp 55–57°C; cims, m/z: 302 (M + 18 for stearic acid (C18)), 198 (M + 18 for linoleic acid (18)), 274 (M + 18 for palmitic acid (C16)).

The remainder of the hydrolysis products was subjected to flash chromatography (Skellysolve B – ethyl acetate – acetic acid (gradient), 94:5:1 to 89:10:1 to 84:15:1) to afford additional fatty acids (62 mg); ir ($CHCl_3$): 3500–2400 (b), 1930, 2860, 1706 cm^{-1}; ^1H nmr ($CDCl_3$): δ: 0.88 (m, CH_3—$(CH_2)_n$—), 1.26 (m, CH_3—$(CH_2)_n$—CH_2CH_2CO—), 1.64 (m, —CH_2—CH_2—CO), 2.05 (m, —CH_2—CH=CH— of **18**), 2.36 (t, J = 7.5 Hz, —CH—CO), 2.79 (t, J = 6 Hz, —CH=CH—CH_2—CH=CH— of **18**), 5.35 (m, —CH=CH— of **18**), 9.7 (bs, —COOH); hreims, m/z calcd. for $C_{18}H_{36}O_2$ (stearic acid) (M^+): 284.1715; found: 284.1714 (8); m/z calcd. for $C_{18}H_{32}O_2$ (linoleic acid) (**18**) (M^+): 280.2402; found: 280.2400 (10); m/z calcd. for $C_{16}H_{32}O_2$ (palmitic acid) (M^+): 256.2402; found: 256.2403 (20).

Acknowledgements

We gratefully acknowledge the financial support of the Natural Sciences and Engineering Research Council of Canada in the form of operating grants (W.A.A.) and scholarships (J.B.M.). We thank Dr. Y. Hiratsuka, Northern Forest Research Centre, Edmonton, for bringing this problem to our attention and for providing cultures of *A. mellea*, Dr. K. Mallett for mycological information on the strains used in this study, and A. Szenthe for carrying out the later culture growths. For kindly providing authentic samples we wish to thank Dr. O. E. Edwards and Dr. E. Wenkert for pimaric, isopimaric, and sandaracopimaric acids; Dr. R. Vleggaar for austocystin F; Dr. J. C. Vederas for averufin; and Dr. A. Castonguay for averufanin.

Bullerone, a novel sesquiterpenoid from *Cyathus bulleri* Brodie[1]

WILLIAM A. AYER AND ROBERT H. MCCASKILL
Department of Chemistry, University of Alberta, Edmonton, Alta., Canada T6G 2G2

Received May 21, 1986

This paper is dedicated to Dr. O. E. (Ted) Edwards

WILLIAM A. AYER and ROBERT H. MCCASKILL. Can. J. Chem. **65**, 15 (1987).

The structure of bullerone (**3**), a minor metabolite of the bird's nest fungus *Cyathus bulleri* Brodie, has been determined by a combination of chemical and spectroscopic methods. The possible biogenesis of bullerone, a new skeletal class of sesquiterpenoid, is discussed.

WILLIAM A. AYER et ROBERT H. MCCASKILL. Can. J. Chem. **65**, 15 (1987).

Faisant appel à des méthodes tant chimiques que spectroscopiques, on a déterminé la structure de la bullérone (**3**), un métabolite mineur du champignon *Cyathus bulleri* Brodie des nids d'oiseaux. On discute des diverses possibilités de biogénèse de la bullérone qui, du point de vue du squelette, appartient à une nouvelle classe de sesquiterpénoïdes.

[Traduit par la revue]

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 80.58.250.72 on 09/07/12
For personal use only.

Recently we reported (2) that the bird's nest fungus *Cyathus bulleri* Brodie, when grown in liquid culture, elaborates a series of humulene derived metabolites of which cybrodol (**1**) is representative. Subsequently, we described (3) the isolation and structural elucidation of the biogenetically unique sesquiterpenoid nidulol (**2**) from the same source. We report herein the structure of bullerone (**3**),[2,3] a minor metabolite of this fungus. Bullerone represents a new skeletal type of sesquiterpenoid.

Bullerone ($C_{15}H_{18}O_3$)[4] was obtained as a light yellow oil that resisted all attempts to induce crystallization. The functionality of bullerone was determined in the following manner. Bullerone shows infrared (ir) absorption in the carbonyl region at 1752 cm^{-1} and does not show hydroxyl absorption. The ^{13}C nmr spectrum of bullerone shows only one carbonyl signal at δ 214.4. Bullerone is thus a keto diether and the ketone is most likely located in a five-membered ring. Reduction of bullerone with sodium borohydride in methanol gave a complex reaction mixture from which bullerol (**4**, $C_{15}H_{20}O_3$, ir 3420 cm^{-1}) was isolated in 20% yield. Recourse to the method of Luche (4) (sodium borohydride, methanol, ceric chloride) gave bullerol in 88% yield. The carbinol proton and carbon of bullerol are evident in the ^1H nmr (δ 3.26) and ^{13}C nmr (δ 84.7) spectra, respectively. Acetylation (acetic anyhydride, pyridine) of bullerol afforded the acetyl derivative **5** ($C_{17}H_{22}O_4$, ir 1742 cm^{-1}) in which the characteristic secondary alcohol acetylation shift of 1.50 ppm is observed for the carbinol proton (δ 4.76) in the ^1H nmr spectrum.

In the olefinic carbon region of the ^{13}C nmr spectrum of **3** four signals are evident, two of which (δ 121.9, 132.9) correspond to carbons bearing hydrogen while the remaining pair (δ 134.1, 144.9) represent fully substituted carbons. Thus bullerone possesses two double bonds and is therefore tetracyclic. In the ^1H nmr spectrum of **3**, two vinylic protons ($CDCl_3$, δ 5.58, 5.62; C_6D_6, δ 5.14, 5.35) mutually coupled by 1.5 Hz are observed. This coupling constant is too small to arise from a vicinal arrangement (5) but may be rationalized in terms of a conjugated diene in which the hydrogens are in a 1,4 *anti* relationship, as in **3** (ref. 5, pp. 341–342). The presence of a conjugated diene is substantiated by the ultraviolet (uv) spectrum (CH_3OH) of **3**, which shows bands at 215 (ε 2800), 250 (ε 3300), and 342 nm (ε 600) assigned respectively to the ketone n–π* end absorption, the conjugated diene chromophore, and (likely) an uv-active impurity, since bullerone was isolated as a light yellow oil. The uv spectrum of **4** (CH_3OH) shows only one absorption band at 246 nm (ε 3500), in good agreement with the calculated value (6) of 244 nm.

The singly oxygenated carbon region of the ^{13}C nmr spectrum of **3** has two signals (δ 77.6, 77.7) assigned[5] to fully substituted and methylene carbons respectively. Consistent with this, the ^1H nmr spectrum of **3** shows the presence of a geminate pair of

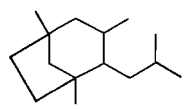
5 R = CH_3CO



6

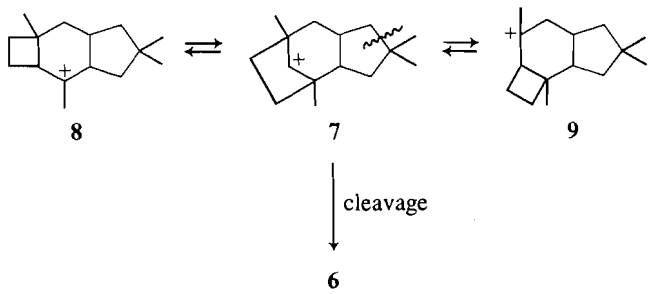
[1]Part 20 in the series: Metabolites of bird's nest fungi. For Part 19, see ref. 1.

[2]The numbering reflects the systematic name for bullerone: 1,4,10-trimethyl-6,14-dioxa-13-oxotetracyclo[8.2.1.$1^{4,7}$.$0^{2,8}$]-tetradeca-2,8-diene.

[3]To facilitate a concise presentation, the evidence will be presented in terms of the adduced structure. No stereochemistry is implied for **3**.

[4]Because of the small amounts available, all molecular formulas were established by high resolution mass spectrometry. Chemical ionization mass spectrometry was used to confirm the molecular weights.

[5]The multiplicities of all ^{13}C nmr signals were determined by single frequency off-resonance decoupling.



SCHEME 1

protons (δ 3.43, 3.84) mutually coupled by 6 Hz. The acetal function of **3** is revealed by a ^{13}C nmr signal at δ 101.3 arising from a carbon bearing a hydrogen and bonded to two oxygens. This hydrogen appears as a singlet at δ 5.62 in the ^1H nmr spectrum of **3**. No coupling is observed between H-7 and H-9 in accord with an allylic angle of nearly 0° (ref. 5, p. 316). The nmr parameters of the hydrogens and carbons associated with the acetal function are in accord with model compounds (7). Efforts to chemically characterize the acetal system of **3** were unsuccessful. Thus exposure to boron trifluoride etherate in methanol (2 days, 25°C) gave only recovered starting material, as did treatment with methanol saturated with hydrogen chloride (2 days, 25°C). When the latter reaction mixture was heated under reflux overnight an intractable mixture resulted.

Bullerone has three methyl groups (^1H nmr: δ 1.16, 1.19, 1.50; ^{13}C nmr: δ 15.2, 17.2, 20.2) all bonded to fully substituted carbons. The remaining four protons of bullerone appear in the ^1H nmr spectrum as an isolated spin system of four single-proton triple doublets (δ 1.70, 1.82, 1.90, 2.11) whose complexity and chemical shifts are consistent with contiguous methylene groups flanked by fully substituted carbons as per C-11 and C-12 of **3**.

The carbinol proton of **4** is coupled only to vinyl proton H-9 (δ 5.45) by 1.5 Hz. Since bullerone is clearly not an α,β-unsaturated ketone, these two protons cannot be vicinal and thus the carbonyl carbon of bullerone must be flanked by fully substituted carbons. Inspection of models of **3** and **4** indicates that hydride reduction of **3** from the less hindered face of the carbonyl would place the carbinol hydrogen of **4** in a four-bond "w" relationship to H-9, thus explaining the coupling between these protons. With the connectivity between the cyclopentanone fragment and the diene component thus indicated, insertion of the remaining structural elements (methyls, acetal, contiguous methylenes) into the partial structure thus derived leads to **3** as the only structure that is not subject to very severe bond angle strain.

We make no stereochemical assignment for bullerone, although of the two possible relative stereoisomers, that in which the C-5, O-6 bridge is *syn* rather than *anti* with respect to the carbonyl is somewhat more likely since we do observe pyridine-induced chemical shifts of 0.04 and 0.10 ppm for the C-5 hydrogens of **4**. This could indicate that the environment of one of these hydrogens is influenced somewhat by the C-13 hydroxyl. Lack of material precluded further studies to confirm the assignment.

The mass spectral fragmentation pattern of **3** shows loss of formaldehyde (presumably C-5 and O-6) and carbon monoxide (carbonyl carbon) leading to a base peak at *m/e* 188. Bullerol (**4**) loses formaldehyde (*m/e* 218), then ethylene (*m/e* 190), followed by CH_3 (*m/e* 175, 100%) or OH (*m/e* 173, 89%).

The carbon skeleton (**6**)[6] of bullerone, to the best of our knowledge, is unprecedented. It appears to be derived from a cation (**7**) that was proposed as an intermediate connecting the sterpurane system **8** (8) with the *proto*-illudane system **9** (Scheme 1).[7] It is significant that *C. bulleri* appears to be producing metabolites derived from cations **7**, **8**, and **9**. Thus nidulol (**2**) is likely derived from **8**, cybrodol (**1**) from **9**, and bullerone (**3**) from **7**. Interestingly, derivation of skeleton **6** from **7** requires the same bond cleavage as that which gives rise to cybrodol (**1**) from **9**.

Experimental

Cyathus bulleri was cultured and worked up as previously described (2). All solvents were distilled prior to use. Skellysolve B refers to Skelly Oil Company light petroleum, bp 62–70°C. Macherey Nagel silica gel (<80 μm) was used for column chromatography. Analytical thin-layer chromatography (tlc) was carried out on glass plates (75 × 25 or 75 × 50 mm) coated (0.3 mm) with silica gel G (E. Merck, Darmstadt) containing 1% electronic phosphor (General Electric, Cleveland). Materials were detected by visualization under an ultraviolet lamp. The plate was then sprayed with a solution of vanillin (1%) in concentrated sulfuric acid and carefully charred with a heat gun.

Mass spectra (ms) were recorded on a A.E.I. MS-50 mass spectrometer coupled to a DS 50 computer or a A.E.I. MS-9 mass spectrometer (chemical ionization). Data is reported as *m/e* (relative intensity) and, unless diagnostically significant, peaks with intensities less than 20% of the base peak are omitted. Infrared (ir) spectra were recorded on a Nicolet 7199 FT interferometer and ultraviolet (uv) spectra on a Unicam SP 1700 uv spectrophotometer. The ^1H nmr spectra were measured on a Varian HA-100 spectrometer interfaced to a Digilab FTS/NMR-3 data system or a Bruker WH-400 spectrometer. The ^{13}C nmr spectra were measured on a Bruker HFX-90 spectrometer interfaced to a Nicolet 1085 computer. All nuclear magnetic resonance measurements employed tetramethylsilane (TMS) as an internal standard.

Isolation of bullerone (3)

The crude neutral fungal extract (1.6 g) described previously (2) showed a prominent red spot (vanillin, H_2SO_4 visualization) on tlc at R_f 0.75 (eluent benzene–ether, 1:1). The extract was chromatographed over Sephadex LH-20 (100 g, 7-mL fractions) with fractions 42 and 43 (195 mg) containing the material responsible for the red spot. Silica gel chromatography (Skellysolve B – chloroform, 1:1; 10 g of silica gel) of this crude material afforded bullerone (18 mg) as a yellow oil; uv (CH_3OH) λ_{max}: 215 (ε 2800), 250 (ε 3300), 342 nm (ε 600); ir ($CHCl_3$ cast): 1752, 1645, 1605, 1450, 1375, 1340, 1315, 1295, 1235, 1195, 1090, 1080, 1020, 1000, 990, 940, 910, 840 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 1.16 (3H, s), 1.19 (3H, s), 150 (3H, s), 1.70 (1H, ddd (6.8, 10.8, 12.0 Hz)), 1.82 (1H, ddd (3.6, 12.0, 12.0 Hz)), 1.90 (1H, ddd (6.8, 12.0, 12.8 Hz)), 2.11 (1H, ddd, (3.6, 10.8, 12.8 Hz)), 3.43 (1H, d (6 Hz)), 3.84 (1H, d (6 Hz)), 5.58 (1H, d (1.5 Hz)), 5.62 (1H, d (1.5 Hz)), 5.62 (1H, s); (C_6D_6) δ: 0.99 (3H, s), 1.16 (6H, s), 1.3–1.7 (4H, m), 3.29 (1H, d (6 Hz)), 3.60 (1H, d (6 Hz)), 5.14 (1H, d (1.5 Hz)), 5.35 (1H, d (1.5 Hz)), 5.69 (1H, s); ^{13}C nmr ($CDCl_3$) δ: 15.2, 17.2, 20.0 (CH_3); 33.5, 35.1, 77.7 (CH_2); 101.3, 121.9, 132.9 (CH); 47.2, 49.6, 77.6, 134.1, 144.9, 214.4 (C); ms *m/e* calcd. for $C_{15}H_{18}O_3$ (M^+): 246.1255; found: 246.1245 (49), 231 (16), 218 (20), 216 (34), 203 (24), 201 (20), 188 (100), 173 (25), 160 (28), 145 (22), 128 (21). Chemical ionization (NH_3) ms shows peaks at *m/e* 247 (*M* + 1) and 264 (*M* + 18).

Sodium borohydride – ceric chloride reduction of bullerone (3)

Sodium borohydride (5 mg) was added to a stirred solution of bullerone (**3**, 25 mg) and ceric chloride hexahydrate (353 mg) in

[6]We propose the trivial name bullerane for skeleton **6**.

The extrusion of sulfur from thiepins and benzothiepins, a reaction leading to the formation of benzenes and naphthalenes, respectively, is well documented (1, 2). The extrusion of sulfur from a heterocyclic system containing both nitrogen and sulfur in the same ring has also been reported. It was shown that indoles were formed from 4*H*-3,1-benzothiazines on prolonged heating (3) but reactions of this type are rare. Here we report the novel formation of isoquinolines when 3-aryl-2-carbomethoxy-4,5-dihydro-1,4-benzothiazepines were oxidized with *N*-chlorosuccinimide (NCS).

The benzothiazepines used in this investigation were prepared by established methods (see Scheme 1). Szabo *et al.* (4) have reported the reaction of thiophenol (**1**) with the hydroxymethylamides (**2***a* and **2***b*) yielding the amides (**3***a* and **3***b*). Treatment of the amides with $POCl_3$ led to the formation of the 2-aryl-4*H*-1,3-benzothiazines (**4***a* and **4***b*). It was shown (5, 6) that the latter reacted with chloroacetyl chloride in the presence of triethylamine yielding the β-lactams (**5***a* and **5***b*) and that the β-lactams rearranged to 4,5-dihydro-1,4-benzothiazepines (**6***a* and **6***b*) in the presence of sodium methoxide in methanol. We prepared **6***a*, **6***b*, and the analogue **6***c* by the methods described (4–6). The spectroscopic properties of **6***c* and of the intermediates leading to it closely resemble those of the previously reported **6***a* and **6***b* and their precursors and do not merit discussion.

The treatment of **6***a*, **6***b*, and **6***c* with *N*-chlorosuccinimide in diethyl ether gave the corresponding 6,7-dimethoxy-3-aryl-4-carbomethoxyisoquinolines (**9***a*, **9***b*, and **9***c*). The three isoquinolines were identified by their spectroscopic properties of which the ^1H nmr spectra were most revealing. The three compounds have in common two aromatic methoxy signals appearing in the region of δ 4.0 and one ester methoxy signal near δ 3.70. Each compound shows three signals in the aromatic region associated with the protons at C-1, C-5, and C-8 of the isoquinoline ring system. The signal for C-1 appears in all three compounds near δ 9.2. The aromatic protons and other signals associated with the aryl group at C-3 of the isoquinoline ring are in accord with the nature and number of substituents on the aromatic ring. Other spectroscopic data also support the assigned structures.

We conclude that the reaction with NCS proceeds by halogenation at nitrogen followed by elimination of HCl to yield the transient benzothiazepines **7** and that subsequent elimination of sulfur through intermediates **8** provides the isoquinolines **9**.[3] 1,4-Benzothiazepines, to our knowledge, have not been reported in the literature so that there is no precedent for the sulfur extrusion reaction reported in this system. However, 1-benzothiepins (ref. 1 and references therein) have been extensively studied and are known to eliminate sulfur with ease, leading to formation of naphthalenes. It is generally considered that episulfides such as **8** are intermediates in the extrusion pathway of benzothiepins and thiepins (1, 2). The ease of sulfur elimination is a function of structure, but half-lives of less than 1 h (1, 2) have been reported. The fact that we did not observe intermediates **7** suggests that benzothiazepines decompose during work-up of the reaction mixture.

The substituted isoquinolines prepared in this study have not been previously reported. They are potentially useful intermediates for the synthesis of several classes of isoquinoline alkaloids of which the protoberberines, the benzophenanthridines, and the 3-arylisoquinolines are specific examples (7).

Experimental

The ^1H nmr spectra were recorded on a Bruker AM500 at 500 MHz and the ^{13}C nmr spectra on the same instrument at 125.8 MHz. The samples were dissolved in $CDCl_3$ using tetramethylsilane (TMS) as internal standard; chemical shifts are reported in ppm (δ) downfield from TMS. The symbols, s (singlet), d (doublet), t (triplet), q (quartet), m (multiplet), and br (broadened), are used to report the multiplicity and shape of the signals. EI mass spectra were recorded either on a VG Micro Mass 7070F or a VG ZAB E mass spectrometer at an ionizing voltage of 70 eV. Infrared spectra were recorded on a Perkin–Elmer 283 infrared spectrometer. Melting points were determined using a Gallenkamp apparatus and are uncorrected. *N*-hydroxymethylpiperonylamide **2***c* was prepared by a modification of a literature procedure (8). Compounds **6***a* and **6***b* were prepared as described (4, 6, 8). Thin-layer chromatography was performed using Polygram Sil G/UV_{254} or Polygram Aloxn/UV_{254} plates. The homogeneity of

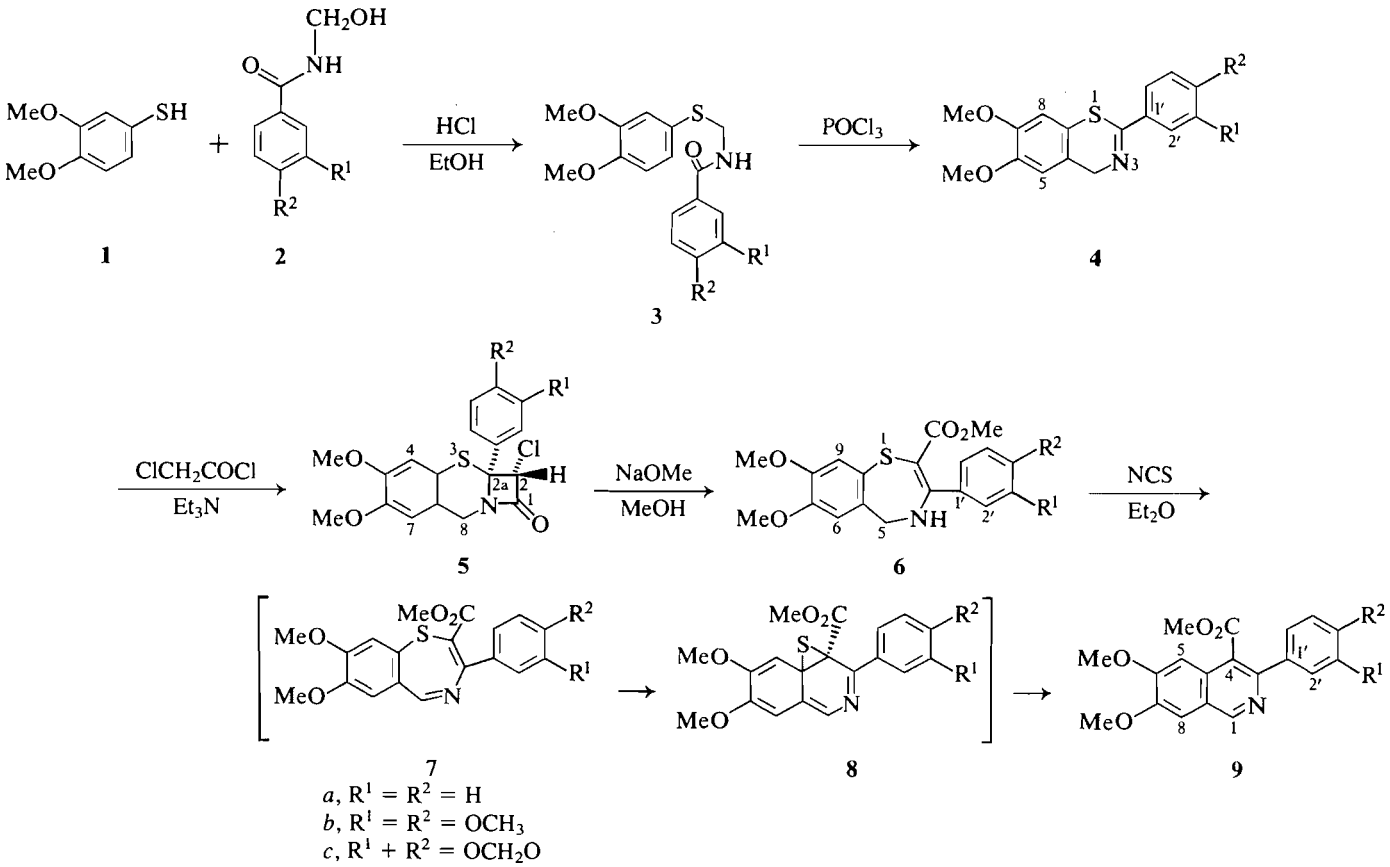
[3]An alternative route to intermediate **7** has been suggested by a referee, namely, that chlorination may occur initially at sulfur, and that HCl and H^+ may be eliminated subsequently.



SCHEME 1

the products was established on the basis of chromatographic and spectroscopic (^{1}H nmr, ^{13}C nmr, and mass spectral) examination.

*6,7-Dimethoxy-2-(3',4'-methylenedioxyphenyl)-4*H*-1,3-benzothiazine (4c)*

Preparation of N*-(3,4-dimethoxyphenylthiomethyl)-piperonylamide (3c)*

A solution of 3,4-dimethoxythiophenol (**1**) (8.5 g, 0.05 mol) and *N*-(hydroxymethyl)-piperonylamide (**2***c*) (9.75 g, 0.05 mol) in EtOH was treated with 5 mL of a saturated solution of HCl in EtOH. The solution was maintained at room temperature for 3 h after which the crystalline product (14.8 g, 88.2%) was separated by filtration and recrystallized from EtOH, mp 108–109°C; ^{1}H nmr (500 MHz) $CDCl_3$ δ: 3.82 (3H, s, OMe), 3.86 (3H, s, OMe), 4.77 (2H, apparent d, J = 6.2 Hz, CH_2), 6.01 (2H, s, OCH_2O), 6.42 (1H, br s, NH), 6.80 (2H, m, Ar H's), 7.04 (2H, m, Ar H's), 7.20 (2H, m, Ar H's); ms (EI), m/z (%): 347(2) $M^{+\bullet}$, 177 (2), 170 (53), 169 (20), 155 (13), 149 (100), 121 (34).

Conversion of **3**c *to* **4**c

A mixture of **3***c* (6.94 g, 0.02 mol) and $POCl_3$ (10 mL) was heated on a boiling water bath for 1 h. The mixture was cooled to room temperature and ice was added to decompose the excess $POCl_3$. The solution was then neutralized with sodium carbonate, extracted with benzene, and the extract dried over anhydrous Na_2SO_4. The benzene solution was filtered, evaporated, and the residue taken up in 20 mL of hot EtOH. The crystals (3.12 g, 47.2%) that separated melted at 169–170°C after recrystallization from methanol; ^{1}H nmr (500 MHz, $CDCl_3$) δ: 3.89 (3H, s, OCH_3), 3.90 (3H, s, OCH_3), 4.72 (2H, s, C-4 H's), 6.03 (2H, s, OCH_2O), 6.85 (1H, s, C-5 or C-8 H), 6.87 (1H, s, C-8 or C-5 H), 6.86 (1H, d, J = 8.2 Hz, C-5' H), 7.55 (1H, d, J = 1.7 Hz, C-2' H), 7.63 (1H, q, J = 8.2 and 1.7 Hz, C-6' H); ^{13}C nmr (125.8 MHz), $CDCl_3$ δ: 55.4 (C-4), 56.4 (2 × OCH_3), 102.0 (OCH_2O), 108.3, 109.7, 110.4, 121.1, 123.6, 123.8, 148.4, 149.1, 149.4, 151.2 (aromatic and imine C-atoms);[4] ms (EI), m/z (%): 329 (15) $M^{+\bullet}$, 182 (100), 167 (56), 147 (3), 146 (5), 139 (4). *Mol. Wt.* calcd. for $C_{17}H_{15}NO_4S$: 329.0721; found (hrms): 329.0720.

cis*-2-Chloro-2,2a-dihydro-5,6-dimethoxy-2a-(3',4'-methylenedioxy)-1*H*,8*H*-azeto[2,1-b][1,3]benzothiazin-1-one (5*c*)*

A solution of compound **4***c* (1.645 g, 0.005 mol) in benzene (30 mL) was treated with chloroacetyl chloride (0.60 g). The mixture was heated to boiling under reflux and a solution of triethylamine (0.60 g) in benzene (30 mL) was added dropwise, with stirring, over a period of 1 h. The crystalline $Et_3\overset{+}{N}H\ Cl^-$ that separated was removed by filtration. The benzene filtrate was evaporated to dryness and the residue taken up in ethanol. The colorless crystals (1.88 g, 94%) were collected by filtration and melted at 141–142°C. ir (ν_{max} cm^{-1}), 1790; ^{1}H nmr (500 MHz, $CDCl_3$) δ: 3.83 (3H, s, OMe), 3.84 (3H, s, OMe), 4.26 and 4.90 (2H, ABq, J = 16.3 Hz, C-8 H's), 5.07 (1H, s, C-2 H), 5.98 (2H, s, OCH_2O), 6.66 (1H, s, C-4 or C-7 H), 6.67 (1H, s, C-4 or C-7 H), 6.78 (1H, d, J = 8.3 Hz, C-5' H), 6.93 (1H, q, J = 8.3 and 1.8 Hz, C-6' H), 6.94 (1H, apparent s, C-2' H); ms (EI), m/e (%): 405 (14) $M^{+\bullet}$, 369 (18), 329 (5), 182 (100), 167 (73), 147 (28), 146 (42). *Mol. Wt.* calcd. for $C_{19}H_{16}NO_5S^{35}Cl$: 405.0438; found (hrms): 405.0443.

2-Carbomethoxy-4,5-dihydro-7,8-dimethoxy-3-[3',4'-methylenedioxyphenyl]-1,4-benzothiazepine (6c)

A solution of compound **5***c* (0.405 g, 0.001 mol) in MeOH (10 mL) was treated with sodium methoxide (0.054 g, 0.001 mol) and the mixture heated under reflux for 3 h. Water was added to the cooled solution and the mixture extracted with $CHCl_3$. The extract was dried, evaporated, and the residue dissolved in MeOH. The crystals (0.334 g, 84%), which separated on standing, melted at 170–171°C.

[4]There are 10 signals for the 13 sp^2 hydridized C atoms of **4***c*, indicating that three pairs of C atoms have similar resonances.

The conversion of podocarpic acid to hexahydrophenalene derivatives: an approach to the synthesis of edulone A[1]

ROBERT H. BURNELL[2] AND JEAN-MARC DUFOUR
Chemistry Department, Université Laval, Québec (Qué.), Canada G1K 7P4

Received April 21, 1986

This paper is dedicated to Dr. O. E. (Ted) Edwards

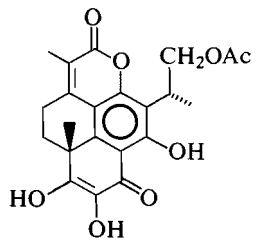
ROBERT H. BURNELL and JEAN-MARC DUFOUR. Can. J. Chem. **65**, 21 (1987).

To test the feasibility of a biogenetically inspired synthesis of edulone A **1**, podocarpic acid **3***a* has been transformed into a substituted hexahydrophenalene **16***b*. The critical steps involve introduction of a double bond into the A ring, cleavage by ozone, and, after suitable manipulation, an epoxy-arene cyclization. A second product from this cyclization is an octahydrophenaleno[1,9-*bc*]furan **17**.

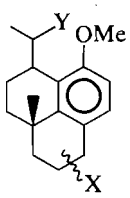
ROBERT H. BURNELL et JEAN-MARC DUFOUR. Can. J. Chem. **65**, 21 (1987).

Afin de vérifier que notre plan de synthèse de l'édulone A **1** inspiré d'une biosynthèse est réalisable, nous avons transformé l'acide podocarpique **3***a* en un hexahydrophénalène substitué **16***b*. Les étapes critiques de la synthèse impliquent l'introduction d'une insaturation dans le cycle A, l'ouverture de ce cycle par l'ozone et la cyclisation de la chaîne ainsi obtenue sur le cycle aromatique via l'époxyde **15**. De plus, nous avons isolé un second produit de cette cyclisation, soit l'octahydrophénalèno[1,9-*bc*]furanne **17**.

Edulone A **1** was isolated from *Plectranthus edulis* (1) and is unusual in that this 2[*H*]-1-oxapyrene skeletal type of diterpene is unknown elsewhere. When the accepted structure was proposed by Eugster and co-workers (1), they also suggested a logical biogenesis involving cleavage of the C4—C5 bond of a normal tricyclic diterpene intermediate, appropriate oxidations, and cyclization of the resulting long sidechain to the relevant positions on the C ring (C11 and the oxygen at C12). For some time our interests (2) have been the elaboration of complex structures starting from commercially affordable chiral materials, for instance podocarpic acid **3***a*. We felt that a biogenetically inspired approach to the laboratory synthesis of edulone A merited investigation and in a preliminary study we wished to test the feasibility of transforming methyl *O*-methyl podocarpate **3***b* into the model hexahydrophenalene system **2** (in which X and Y could be virtually any functional group). Since the absolute stereochemistry at the quaternary carbon C10 of podocarpic acid will be preserved throughout the transformations, this could be used to induce a stereoselective edulone sythesis later.



1



2

The rupture of the C4—C5 bond in methyl *O*-methyl podocarpate **3***b* under laboratory conditions, which is critical to the project, would be considerably easier if one of the substituents at C4 were sacrificed. To this end a conjugated enone function was introduced by the known DDQ[2] oxidation of the B ring (3) to give **4***a* and the ester moiety was then replaced by hydrogen using organic bases such as *quinuclidinol*-3, DBU, or DBN[3] (4), affording the demethoxycarbonylated enone **4***b*. The yield in the DDQ oxidation was only moderate since the crude product was very discolored and required repeated chromatography, so we actually used a longer but more manageable route when larger quantities of **4***b* were needed. The steps involved were: benzylic oxidation to the aromatic ketone **5***a* (5) and then bromination using copper bromide (6) to afford the 6-bromo derivative **5***b*, which was both dehydrobrominated and demethoxycarbonylated by treatment with DBU.

To open the A ring it was necessary to shift the double bond and, after unsuccessfully trying to do this by formation of the ketal or by reducing the enol acetate, we found the best method was the deconjugation of the enone **4***b* by potassium *tert*-amylate (7), which gave the β,γ-enone **6** in high yield. This reaction must be performed in a rigorously inert atmosphere. Sodium borohydride reduction of **6** leads to the homoallylic alcohol **7** and the A ring was then opened by cleavage of the double bond with ozone. Cautious work-up gave a product that was partly the β-hydroxy ketone **8** but, as anticipated, the latter dehydrated almost spontaneously; we therefore found it expedient to isolate only the conjugated enone **9**, by stirring the material in dichloromethane containing acetic acid until tlc showed the presence of but one product. The ring B double bond was easily hydrogenated to the diketone **10** in which the two carbonyls should show markedly different reactivity due to the sterically imposing quaternary carbon adjacent to the ring ketone. The reduction of the enone **9** afforded a second product that turned out to be the hydroxy ketone **13***a* (see later).

Since we needed to retain a function in the B ring while transforming the sidechain, it was necessary to provide adequate protection, which was achieved in the following manner. Mild conditions (ethylene glycol, BF_3-etherate at −9°C) (8) afforded the monoketal **11** with barely a trace of the diketal. The remaining hindered carbonyl was then reduced with lithium aluminium hydride, giving exclusively the hydroxy compound **12***a*. After acetylation to **12***b*, the ketal residue was hydrolysed to give the acetoxy ketone **13***b*, which proved to be identical

[1]The structure of edulone A has been revised very recently, see ref. 12.

with the product obtained by acetylating the hydroxy ketone **13***a* referred to above.

Using the copper bromide technique (6), the ketone **13***b* was brominated selectively at the methylene group to afford **13***c*, which, when reduced with sodium borohydride, afforded only a 15% yield of the bromohydrin **14** since the major part of the product had precociously formed the mixture of stereoisomeric epoxides **15**. Cyclization of the latter was promoted by stannic chloride (9) and gave rise to the tricyclic hexahydrophenalene alcohol **16***a* (58%), which, for easier characterization, was oxidized (10) to the methyl ketone **16***b* (thus eliminating some of the diastereomeric possibilities). A second product, also obtained from the cyclization, was shown to be the tetracyclic dihydrobenzofuran **17** (38%). The distribution of products was not altered by lowering the temperature of the cyclization reaction, which suggests that the stereochemistry of the epoxide dictates the outcome of the process. Examination of molecular models does not immediately reveal which of the four epoxides should suffer subsequent cyclization but it seems likely that the terminal methyl, arising from the electrophilic opening of the epoxide, forces the still complexed potential hydroxyl residue close to the aromatic methoxyl residue to provoke the ready cyclization.

These model results assured us that an approach to the synthesis of edulone A based on Eugster's suggested biosynthetic pathway has a good chance of success. Our efforts are now directed towards preparing, from podocarpic acid, the suitably functionalized aromatic starting material for the total synthesis.

Experimental

Unless otherwise stated, the conditions and instruments used to characterize the products were the following: melting points, Electrothermal, uncorrected; ultraviolet spectra, ethanol solutions (log ε in parentheses), Hewlett Packard 8450A; infrared spectra, solids as KBr pellets, others as carbon tetrachloride solutions, Beckman 4250 and Perkin Elmer 457; proton magnetic resonance spectra, deuteriochloroform solutions, TMS internal standard, (multiplicity, integrated peak areas, and, where important, coupling constants and assignments in parentheses: D_2O infers that resonances were no longer detectable after shaking the solution for a few minutes with deuterium oxide), Bruker HX 90 and Varian XL-200; carbon-13 magnetic resonance spectra, deuteriochloroform solutions, TMS internal standard, Bruker WP 80; the peaks were assigned after recording the ^{1}H-decoupled and the off-resonance spectra, by comparison with the spectra of the many similar compounds previously described (2*a*–*d*) and by calculation using standard empirical parameters (11); mass spectra, Hewlett Packard 5992; high resolution mass spectra were recorded on an AEI MS30. Elemental analyses were by Galbraith Laboratories, Knoxville, Tenn.

Dry column chromatography (abbreviated dry col chrom) implies the use of Merck Kieselgel 60F (70–230 mesh) in Nylon foil tubing and development with either hexane – ethyl acetate or carbon tetrachloride – ethyl acetate (proportions determined by prior thin-layer chromatography using Machery–Nagel precoated plastic sheets).

9-Oxo-6-methoxy-1,4a(S)-dimethyl-2,3,4,4a,9,10-hexahydrophenanthrene (6)

Potassium (15.1 g) was added to *tert*-amyl alcohol (500 mL) in small amounts and the resulting solution was refluxed for 12 h under argon. The conjugated enone **4***b*, prepared as described in the literature (3, 4) (6.59 g), was added to the cooled amylate solution and the mixture was stirred at room temperature for 48 h. The solution changed color to become red and finally almost black. Under cooling, the reaction was neutralized with 10% acetic acid (300 mL, added rapidly) and the whole was then poured into saturated sodium bicarbonate solution, extracted with ether, dried over magnesium sulfate, evaporated, and chromatographed (silica gel, CCl_4 with 10% EtOAc). This afforded the deconjugated enone **6** (4.73 g; 72%) as a pale yellow solid, mp

114–118°C; uv: 226 (10 700), 278 (11 400), and 287 (10 300) nm; ir: 1680, 1600, and 790 cm^{-1}; ^1H nmr δ: 1.45 (s, Me-C10), 1.68 (s br, Me-C4), 3.29 and 3.63 (ABq, J = 18 Hz, H_2-C6), 3.86 (s, Me-O), 6.82 (dd, J = 2.5 and 9 Hz, H-C13), 6.89 (d, J = 2.5 Hz, H-C11), and 7.97 (d, J = 9 Hz, H-C14); ms m/z: 256 (20, M^+), 242 (14), 241 (100), 223 (8), 213 (9), 211 (7), and 198 (6). *Exact Mass* calcd. for $C_{17}H_{20}O_2$: 256.1464; found (hrms): 256.1462 (base peak calcd. for $C_{16}H_{17}O_2$: 241.1229; found: 241.1246, $M^+ - CH_3$); ^{13}Cmr, see Table 1.

6-Methoxy-9(S)-hydroxy-1,4a(S)-dimethyl-2,3,4,4a,9,10-hexahydrophenanthrene (7)

To the ketone **6** (4.66 g) in methanol (100 mL) was added sodium borohydride (0.73 g) in small portions. After stirring the solution for 3 h, it was poured into water and extracted with ether. The yellow solid obtained by evaporation was chromatographed (silica gel, CCl_4 with 10% EtOAc) to give the homoallylic alcohol **7** (4.35 g; 93%); ir: 3450, 1600, and 1570 cm^{-1}; ^1H nmr δ: 1.47 (s, Me-C10), 1.77 (s br, $w_{1/2}$ = 3 Hz, Me-C4), 3.18 (dd, J = 12 and 6 Hz, H_{eq}-C6), 3.93 (s, Me-O), 4.75 (dd, J = 11 and 6 Hz, H-C7), 6.73 (dd, J = 7.5 and 2.5 Hz, H-C13), 6.79 (d, J = 2.5 Hz, H-C11), and 7.50 (dd, J = 7.5 and 1 Hz, H-C14); ms m/z: 258 (18, M^+), 243 (34), 240 (17), and 225 (100); ^{13}Cmr, see Table 1.

Ozonolysis of the homoallylic alcohol 7

A solution of the alcohol **7** (1.72 g) in dichloromethane (500 mL) was cooled to −78°C and a current of oxygen containing about 3% ozone was bubbled through for 20 min. Dimethyl sulfide was added (5 mL) and the solution was allowed to warm to room temperature when a saturated solution of potassium iodide (30 mL, aqueous) and acetic acid (5 mL glacial) was added. The mixture was stirred for 45 min and then washed with saturated sodium thiosulfate solution. The organic phase was dried ($MgSO_4$), evaporated, and the residue purified by dry col chrom (silica gel, CCl_4 with 15% EtOAc) to give enone **9** (762 mg; 42%) and the β-hydroxy ketone **8** (575 mg; 30%). The latter was quantitatively converted to the enone by taking it up in dichloromethane containing a trace of glacial acetic acid and stirring at room temperature. The enone **9** was a colorless oil; uv: 221 (16 000), 245 (13 700), and 342 (12 300) nm; ir: 3005, 1710, 1650, 1620, and 1605 cm^{-1}; ^1H nmr δ: 1.38 (s, Me-C10), 2.02 (s, Me-C=O), 2.28 (t, J = 7 Hz, CH_2—C=O), 3.89 (s, Me-O), 6.07 (d, J = 9.5 Hz, H-C6), 6.82 (dd, J = 8 and 2.5 Hz, H-C13), 6.99 (d, J = 2.5 Hz, H-C11), 7.29 (d, J = 8 Hz, H-C14), and 7.42 (d, J = 9.5 Hz, H-C7); ms m/z: 272 (4, M^+), 214 (2), and 188 (100). *Exact Mass* calcd. for $C_{17}H_{20}O_3$: 272.1412; found (hrms): 272.1411 (base peak calcd. for $C_{12}H_{12}O_2$: 188.0837; found: 188.0821); ^{13}Cmr, see Table 1.

Catalytic hydrogenation of the enone 9

The enone **9** (762 mg) in ethyl acetate (30 mL) was shaken with 10% palladium on charcoal (100 mg) under hydrogen at 40 psi (1 psi = 6.9 kPa) during 1 h. After filtering the catalyst and evaporating the solvent, the residue was purified by dry col chrom (silica gel, CCl_4 with 25% EtOAc) affording, as the less polar product, *1-(4'-oxopentyl)-2-oxo-7-methoxy-1(R)-methyl-1,2-dihydronaphthalene* ***10*** (479 mg; 63%) as a viscous oil; uv: 220 (20 000), 280 (6 000), and 287 (5 400) nm; ir: 1705, 1605, and 1570 cm^{-1}; ^1H nmr δ: 1.38 (s, Me-C10), 2.06 (s, Me-C=O), 2.33 (t, J = 7 Hz, CH_2—C=O), 2.62 (dd, J = 7.5 and 6 Hz, H-C7), 2.66 (dd, J = 7.5 and 5.5 Hz, H-C7), 2.99 (2H, dd, J = 11.5 and 5.5 Hz, H_2-C6), 3.84 (s, Me-O), 6.77 (dd, J = 8 and 3 Hz, H-C13), 6.88 (d, J = 3 Hz, H-C11), and 7.13 (d, J = 8 Hz, H-C14); ms m/z: 274 (25, M^+), 256 (60), 216 (2), 189 (100), and 175 (11). *Exact Mass* calcd. for $C_{17}H_{22}O_3$: 274.1569; found (hrms): 274.1578 (base peak calcd. for $C_{12}H_{13}O_2$: 189.0916; found: 189.0889); ^{13}Cmr, see Table 1.

The chromatogram afforded a more polar compound, *1-(4'-oxopentyl)-2-hydroxy-7-methoxy-1(R)-methyl-1,2-dihydronaphthalene* ***13***a, as a slightly yellow oil (229 mg; 30%); ir (film): 3460, 1700, and 1605 cm^{-1}; ^1H nmr δ: 1.24 (s, Me-C10), 2.11 (s, Me—C=O), 3.13 (br s, OH, D_2O), 3.81 (s, Me-O), 3.94 (m, H-C5), 6.63 (dd, J = 8 and 3 Hz, H-C13), 6.80 (d, J = 3 Hz, H-C11), and 6.97 (d, J = 8 Hz, H-C14); ms m/z: 276 (8, M^+), 258 (4, $M - H_2O$), 243 (3), 200 (4), 186 (4), and 173 (64). *Exact Mass* calcd. for $C_{17}H_{24}O_3$: 276.1726; found (hrms): 276.1729 (base peak calcd. for $C_{12}H_{13}O$: 173.0966; found: 173.0968). Acetylation of this alcohol ***13****a* using acetic anhydride – pyridine gave an acetate, which is described later; ^{13}Cmr, see Table 1.

Monoketalization of the diketone 10

The diketone **10** (203 mg) was dissolved in dichloromethane (20 mL) containing ethylene glycol (5 mL) and the solution cooled to −9°C (ice; isopropanol). Boron trifluoride etherate (0.4 mL) was added and stirring was continued for 5 h, after which the reaction mixture was poured into water and extracted with dichloromethane. After washing, drying, and evaporating, the residue was chromatographed over silica gel (hexane:EtOAc 6:4) to give the ketal **11** (198 mg; 84%: *1-(4',4'-ethylenedioxypentyl)-7-methoxy-1(R)-methyl-2-tetralone)*, as a colorless oil; uv: 220 (8 600), 279 (2 800), and 286 (2 500) nm; ^1H nmr δ: 1.22 and 1.41 (2s, Me-C), 3.89 (s, Me-O), 3.92 (m, 4H, —OCH_2CH_2O—), 6.74 (dd, J = 8 and 3 Hz, H-C13), 6.87 (d, J = 3 Hz, H-C11), and 7.08 (d, J = 8 Hz, H-C14); ms m/z: 318 (1.2), 303 (1.4), 190 (60), 161 (16), and 87 (100). *Exact Mass* calcd. for $C_{19}H_{26}O_4$: 318.1831; found (hrms): 318.1815; ^{13}Cmr, see Table 1.

Reduction of ketone 11

Lithium aluminium hydride (14 mg) was added slowly to a solution of ketone **11** (72 mg) in dry ether (20 mL). After 12 h of stirring, the excess hydride was decomposed by adding water and the product was obtained by extraction into ether. Chromatography of the crude material (silica gel, CCl_4 with 25% EtOAc) afforded the alcohol ***12****a* (64 mg; 88%: *1-(4',4'-ethylenedioxypentyl)-7-methoxy-2-hydroxy-1(R)-methyl-1,2,3,4-tetrahydronaphthalene)*, colorless oil; ir: 3380, 1605, and 1565 cm^{-1}; ^1H nmr δ: 1.25 and 1.28 (2s, Me-C), 2.30 (br s, OH, D_2O), 3.79 (s, Me-O), 3.92 (br s, —OCH_2CH_2O—), arom. protons at 6.72 (dd, J = 8 and 2.5 Hz), 6.91 (d, J = 2.5 Hz), and 7.04 (d, J = 8 Hz); ms m/z: 320 (1.1), 258 (10), 200 (5), 188 (10), 174 (15), 173 (23), and 158 (15). *Exact Mass* calcd. for $C_{19}H_{28}O_4$: 320.1988; found (hrms): 320.1983 (also calcd. for $C_{12}H_{14}O$: 174.1045; found: 174.1034); ^{13}Cmr, see Table 1.

The alcohol ***12****a* (290 mg) was acetylated by stirring at room temperature for 18 h in pyridine (25 mL) containing acetic anhydride (11 mL). The reaction was stopped by pouring the mixture into ice/water and the product was extracted into ether, which was then well washed. The residue was chromatographed over silica gel (hexane:EtOAc 8:2) to give the acetate ***12****b* (293 mg; 89%: *1-(4',4'-ethylenedioxypentyl)-2(R)-acetoxy-7-methoxy-1(R)-methyl-1,2,3,4-tetrahydronaphthalene)*, as a colorless oil; ir: 1730, 1605, 1565, and 1240 cm^{-1}; ^1H nmr δ: 1.28 and 1.29 (2s, Me-C), 2.08 (s, Me—C=O), 3.83 (s, Me-O), 3.96 (br s, —OCH_2CH_2O—), 5.12 (dd, J = 6 and 3.5 Hz, H-C5), arom. protons at 6.67 (dd, J = 8 and 3 Hz), 6.83 (d, J = 3 Hz), and 6.99 (d, J = 8 Hz); ms m/z: 362 (5, M^+), 347 (2), 302 (2), 240 (6), 225 (9), 200 (10), 173 (26), and 87 (100). *Exact Mass* calcd. for $C_{21}H_{30}O_5$: 362.2093; found (hrms): 362.2092; ^{13}Cmr, see Table 1.

*Hydrolysis of the ketal 12*b

Aqueous hydrochloric acid (15 mL of 2%) was added to a solution of the ketal ***12****b* (290 mg) in THF (40 mL). After stirring at room temperature for 15 h, the reaction mixture was poured into water and extracted with ether. After washing, drying, and evaporating, the residue was chromatographed over silica gel (hexane:EtOAc 8:2) to give the ketone ***13****b* (231 mg; 91%: *1-(4'-oxopentyl)-2(R)-acetoxy-7-methoxy-1(R)-methyl-1,2,3,4-tetrahydronaphthalene)*, as a colorless oil; ir: 1730, 1715, 1610, 1570, and 1240 cm^{-1}; ^1H nmr δ: 1.26 (s, Me-C10), 2.08 and 2.09 (2s, acetate and methyl ketone), 2.38 (t, J = 6.4 Hz, CH_2—C=O), 2.79 (2H, m, H_2-C7), 3.77 (s, Me-O), 5.00 (dd, J = 8.3 and 3.2 Hz, C*H*—OAc), 6.66 (dd, J = 8.3 and 2.5 Hz, H-C13), 6.77 (d, J = 2.2 Hz, H-C11), and 6.96 (d, J = 8.3 Hz, H-C14); ms m/z: 318 (2.1, M^+), 258 (5.3), 200 (7.2), 191 (11.4), 185 (14.2), 173 (100), and 158 (19.7). *Exact Mass* calcd. for $C_{19}H_{26}O_4$: 318.1831; found (hrms): 318.1827 (also calcd. for $C_{17}H_{22}O_2$ (M^+ −

[b]The carbon atoms are always numbered as a function of their "origin" in the abieta-8,11,13-triene skeleton.
[c]Some of the signals are "doubled" due to the presence of diastereomers.

CH_3COOH): 258.1620; found: 258.1616 and, for base peak, calcd. for $C_{12}H_{13}O$: 173.0966; found: 173.0949); ^{13}Cmr, see Table 1.

Bromination of the methyl ketone ***13****b*

The methyl ketone **13***b* (229 mg) was dissolved in a mixture of chloroform and ethyl acetate (12.5 mL of each), and cupric bromide (209 mg) was added. The mixture was refluxed for 18 h with efficient stirring, cooled, filtered, and evaporated. Chromatography (silica gel, CCl_4 with 10% EtOAc) allowed the isolation of some starting material (36 mg) and then the bromo-ketone **13***c* (222 mg; 78%, which rises to 92% if the recovery of the starting material is considered); ir: 1725; 1605, and 1570 cm^{-1}; ^{1}H nmr δ: 1.30 (s, Me-C10), 2.12 (s, O—CO—CH_3), 2.36 (s, methyl ketone), 3.87 (s, Me-O), 4.24 (m, —C*H*—Br), 5.11 (dd, J = 5.5 and 4.5 Hz, —C*H*—OAc), aromatic protons at 6.71 (dd, J = 8 and 2.5 Hz, 6.78 (d, J = 2.5 Hz), and 7.03 (d, J = 8 Hz); ms m/z: 398 and 396 (0.4, M^+), 257 (9.5), 213 (7.8), 191 (13.1), 187 (13.5), 174 (20.1), 173 (100), and 158 (32.4). *Exact Mass* calcd. for $C_{19}H_{25}O_4Br$: 398.0916 and 396.0936; found (hrms): 398.0914 and 396.0914; ^{13}Cmr, see Table 1.

Borohydride reduction of the α-bromo-ketone ***13****c*

To the bromo-ketone **13***c* (84 mg) in methanol (20 mL) was added sodium borohydride (13 mg) and the mixture was stirred at room temperature for 3 h. After diluting with water, the crude product was extracted into ether and the residue purified by dry col chrom (CCl_4 with 10% EtOAc) affording two products:

Epoxide ***15***, colorless oil (50 mg; 75%); ir: 1735, 1610, and 1575 cm^{-1}; ^{1}H nmr δ: 1.23 (d, J = 7 Hz, Me-CH), 1.28 (s, Me-C10), 2.08 (s, acetate), 3.82 (s, Me-O), 5.03 (dd, J = 5.5 and 4 Hz, C*H*—OAc), 6.70 (dd, J = 8 and 3 Hz, H-C13), 6.83 (d, J = 3 Hz, H-C11), and 7.05 (d, J = 8 Hz, H-C14); ^{13}Cmr, see Table 1.

Bromohydrin ***14***, colorless oil (13 mg; 15%); ir: 1725, 1610, and 1575 cm^{-1}; ^{1}H nmr δ: 1.27 (d, J = 7 Hz, Me—C*H*(OH)-), 1.30 (s, Me-C10), 2.10 (s, acetate), 3.82 (s, Me-O), 5.03 (dd, J = 5 and 4 Hz, C*H*—OAc), aromatic protons at 6.72 (dd, J = 8 and 2.5 Hz), 6.87 (d, J = 2.5 Hz), and 7.05 (d, J = 8 Hz); ms m/z: 400 and 398 (0.1, M^+), 241 (3.6), 225 (2.8), 213 (3.9), 191 (16.1), 185 (16.6), 173 (100), 171 (16.7), 158 (27.6), and 145 (8.6); ^{13}Cmr, see Table 1.

Cyclization of epoxide ***15***

To the epoxide **15** (50 mg) in dichloromethane (40 mL, anhydrous) was added stannic chloride dissolved in dichloromethane (0.3 mL of 1 *M*) and the mixture was then refluxed for 90 min. The cooled solution was poured into ice/water and extracted with more dichloromethane. Evaporation gave a mixture of two products (tlc), which were separated by dry col chrom (CCl_4 with 10% EtOAc):

Alcohol ***16****a*, colorless oil (29 mg; 58%: *4-(1'-hydroxyethyl)-7(*R*)-acetoxy-3-methoxy-6a(*R*)-methyl-4,5,6,6a,7,8-hexahydro[1*H*]phenalene)*; ir: 3450, 1730, 1610, and 1595 cm^{-1}; ^{1}H nmr δ: 1.15 (s, Me-C), 1.28 (br s, $w_{1/2}$ = 6 Hz, Me—CH(OH)—), 1.95 (s, acetate), 3.83 (s, Me-O), 5.03 (m, C*H*—OAc), 6.73 (d, J = 8 Hz, H-C13) and 7.03 (d, J = 8 Hz, H-C14).

Benzodihydrofuran ***17***, colorless oil (18 mg; 38%: *5(*R*)-acetoxy-2,4a(*R*)-dimethyl-2,2a,3,4,4a,5,6,7-octahydrophenaleno[1,9-*bc*]furan)*; ir: 1730, 1630, and 1600 cm^{-1}; ^{1}H nmr δ: 1.16 (s, Me-C), 1.61 (d, J = 6 Hz, Me-CH), 1.97 (s, acetate), 4.52 (m, Me—C*H*-O-), 5.19 (dd, J = 3.5 and 3 Hz, C*H*—OAc), 6.46 (d, J = 8 Hz, H-C13), and 6.78 (d, J = 8 Hz, H-C14); ms m/z: 286 (11.6, M^+), 243 (1.1), 227 (12.7), 226 (66.2), 212 (16.7), 211 (88.7), 193 (23), 183 (36), and 171 (30.3). *Exact Mass* calcd. for $C_{18}H_{22}O_3$: 286.1569; found (hrms): 286.1555.

Oxidation of alcohol ***16****a*

Pyridinium dichromate (37 mg) was added to a solution of the alcohol **16***a* (29 mg) in dichloromethane (10 mL). After vigorous stirring for 22 h the reaction mixture was diluted with ether and the precipitated solids removed by filtration. The brownish oil obtained by evaporation was purified by dry col chrom (CCl_4 with 25% EtOAc), which afforded the methyl ketone **16***b* (24 mg; 84%: pale yellow oil); ir: 1722 (br) cm^{-1}; ^{1}H nmr δ: 1.18 and 1.25 (2s, Me-C), 1.96 (s, CH_3—C=O), 2.14 and 2.20 (2s, $OCOCH_3$), 2.88 (m, 2H, H_2-C7), 3.73 and 3.74 (2s, Me-O), 3.94 (m, 1H, H-C3), 5.02 (t, J = 2.9 Hz, *H*—C—OAc), 6.68 (dd, J = 8.3 and 2.5 Hz, H-C14), and 7.00 (dd, J = 8.3 and 0.95 Hz, H-C13); ms m/z: 316 (9.6, M^+), 273 (9.5, M − 43), 256 (7.6), 213 (87.5), 198 (10.0), 187 (10.8), 185 (12.8), 171 (100), and 165 (12.8). *Exact Mass* calcd. for $C_{19}H_{24}O_4$: 316.1675; found (hrms): 316.1669.

The formylacetate synthon. Studies related to the synthesis of the penam and oxapenam ring systems

SAUL WOLFE AND ROMAN Z. STERZYCKI
Department of Chemistry, Queen's University, Kingston, Ont., Canada K7L 3N6

Received May 29, 1986

This paper is dedicated to Dr. O. E. (Ted) Edwards

SAUL WOLFE and ROMAN Z. STERZYCKI. Can. J. Chem. **65**, 26 (1987).

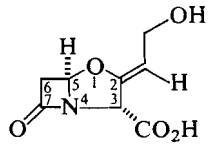
Methyl penicillanate has been synthesized by condensation of D-penicillamine with three different variations of the synthon RO_2CCH_2CHO, followed by esterification of the resulting 4-carboxythiazolidine-2-acetic acid ester, removal of R, and Mukaiyama ring closure. The conditions for the synthesis of an analogous 4-carboxyoxazolidine-2-acetic acid ester, containing an *N*-benzoyl protecting group, have been worked out. The condensation of threonine with diethinylketone does not lead directly to a vinylogous oxapenam.

SAUL WOLFE et ROMAN Z. STERZYCKI. Can. J. Chem. **65**, 26 (1987).

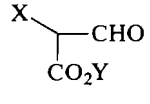
On a réalisé la synthèse du pénicillanate de méthyle en procédant à une condensation de la D-pénicillamine avec trois variations différentes du synthon RO_2CCH_2CHO, suivie d'une estérification de l'ester de l'acide carboxy-4 thiazolidine acétique-2 qui en resulte, d'une élimination du groupement R et d'une cyclisation selon la méthode de Mukaiyama. On a aussi mis au point les conditions permettant de réaliser la synthèse d'un ester analogue de l'acide carboxy-4 oxazolidine acétique-2 contenant un groupement protecteur *N*-benzoyle. La condensation de la thréonine avec la diéthinylcétone ne conduit pas directement à la formation de l'oxapénam vinylogue.

[Traduit par la revue]

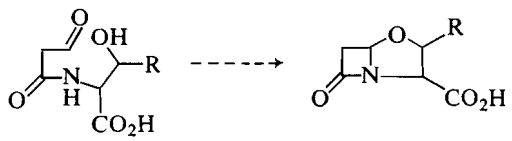
The biosynthesis of clavulanic acid (**1**) proceeds via a 5-carbon precursor (most probably L-ornithine (1)) and a 3-carbon precursor (most probably 3-hydroxypropionate (2, 3)). Since the bridgehead carbon atom (C5) of clavulanic acid is a masked aldehyde, and the 3-carbon moiety formylacetate (**2**, X = Y = H) has the required oxidation level, the condensations depicted in **3** and **4** could have biomimetic relevance. However,



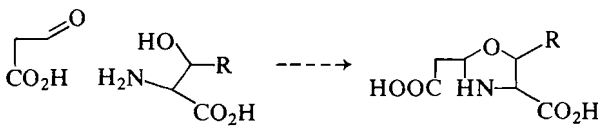
1



2

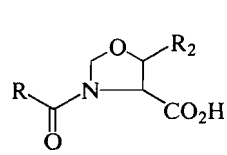


3

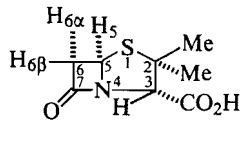


4

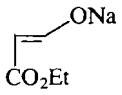
monocyclic oxazolidine-4-carboxylic acids are not stable in aqueous solution below pH 7, and can be characterized only following N-acylation (**5**) (4). In addition, although formylacetic acid (malonaldehydic acid) is a known biochemical substrate (5), it must be prepared *in situ*, in dilute aqueous solution, and used rapidly. Accordingly, a realization of **3** or **4** will require attention to two problems: the development of an effective equivalent to formylacetate, and the development of conditions or protecting groups to stabilize an appropriately substituted monocyclic oxazolidinecarboxylic acid at an intermediate stage of a synthetic sequence. This manuscript is



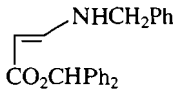
5



6



7



8

concerned with **4**, and reports a solution to the first problem, exemplified by a successful synthesis of methyl penicillanate, and a partial solution to the second.

Like clavulanic acid, penicillanic acid (**6**) contains a formylacetate skeleton at C5—C7 but, in this case, the condensation of a mercaptoamino acid with an aldehyde leads to a chemically stable *thia*zolidine-4-carboxylic acid (6). Indeed, Sheehan's celebrated total synthesis of penicillin (7) begins with the condensation of the aldehyde **2** (X = phthalimido, Y = *tert*-butyl) with D-penicillamine. However, despite this precedent, a synthesis of **6** from the parent aldehyde **2** (X = Y = H) or its equivalent has not yet been completed (8).

Following Vanderhaeghe and co-workers (8*a*), we first examined the reaction of D-penicillamine with the synthons **7** (9) and **8**. Since the enamine **8** is obtained easily by addition of benzylamine to benzhydryl propiolate (**9**), it was then realized (correctly (8*b*)) that **9** may condense with penicillamine without prior activation.

Table 1 summarizes reactions of penicillamine with **7**, **8**, and **9** to form the thiazolidines **10**, as approximately 1:1 mixtures of C5 epimers.[1] Vanderhaeghe and co-workers had found that the epimers of the ethyl ester **10***a* could not be separated by chromatography on a Lobar RP8 column. In the present work, complete separation of C5 epimers was possible on a Lobar

[1]Penicillin numbering is employed. See **6**.

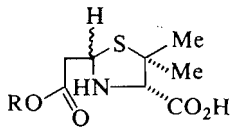
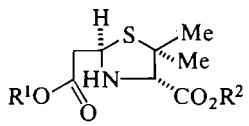
TABLE 1. Condensation of D-penicillamine with various formylacetate equivalents

Reactant	Solvent	Time (h)	Additional reagents (equiv.)	Product (% yield)
7	EtOH–H_2O (1:1)	16	None	**10***a* (10)
	H_2O (pH 6)	40	*p*-TsOH (1)	**10***a* (18)
8	THF–H_2O (1:1)	16	Na_2CO_3 (1)	(0)
	EtOH–H_2O (1:1)	16	None	**10***b* (47)
	DMF–H_2O (1:1)	16	HCl (1.5)	**10***b* (51)
	DMF–H_2O (2:1)	16	*p*-TsOH (1)	**10***b* (80)
	DMF–H_2O (3:2)	16	*p*-TsOH (1)	**10***b* (85)
9	DMF	16	None	**10***b* (56)

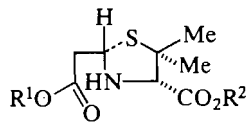
LiChroprep Si60 column, following esterification of **10***b* to **11** (**11***a,b*: CH_2N_2, 2:1 methylene chloride – methanol (10); **11***c,d*: *p*-nitrobenzyl bromide – triethylamine – acetonitrile). The esters **11** could be deprotected selectively at C7,[1] using 98% formic acid (11), to give C3-protected[1] thiazolidineacetic acids **12**.



10*a*: R = Et
b: R = $CHPh_2$



11*a*: $R^1 = CHPh_2$; $R^2 = CH_3$
c: $R^1 = CHPh_2$; R^2 = *p*-nitrobenzyl



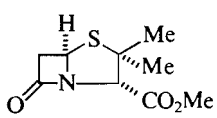
11*b*: $R^1 = CHPh_2$; $R^2 = CH_3$
d: $R^1 = CHPh_2$; R^2 = *p*-nitrobenzyl

12*a*: R^1 = H; $R^2 = CH_3$
c: R^1 = H; R^2 = *p*-nitrobenzyl

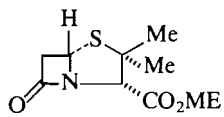
12*b*: R^1 = H; $R^2 = CH_3$
d: R^1 = H; R^2 = *p*-nitrobenzyl

Cyclization to the penam ring system was pursued with the methyl esters **11***a,b* and **12***a,b*, under four sets of conditions: (*A*) PhMgBr (on **11***a,b*) (12); (*B*) benzotriazolyl *N*-oxytrisdimethylaminophosphonium hexafluorophosphate (BOP) (on **12***a,b*) (13); (*C*) methanesulfonyl chloride – potassium bicarbonate – tetrabutylammonium bisulfate under phase transfer conditions (on **12***a,b*) (14); (*D*) triphenylphosphine – 2-mercaptopyridine disulfide – acetonitrile (on **12***a,b*) (15).

The Mukaiyama phase transfer procedure (*C*) led to 20% isolated yields of the 5*R*-penicillanate **13**, and the 5*S*-penicillanate **14**. The Ohno method (*D*) afforded only 2% isolated



13



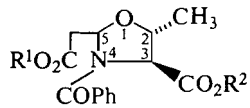
14

yields of penicillanates; this compares to the 8–9% yields obtained with this procedure in the parent system lacking a carboxyl group (8*b*). Grignard cyclization (*A*) produced less than 1% of penicillanates; and the BOP reagent (*B*) gave no β-lactam containing products.

The ^{1}Hmr spectrum of **14**, but not **13**, shows long-range coupling (1.4 Hz) between H3 and H6β. This confirms the configurational assignment for this compound and, therefore, that of its thiazolidineacetic acid precursor. In each of **11–14**, H3 is at higher field when it is *cis* to H5 (16).

Sulbactam (penicillanic acid sulfone) is a potent β-lactamase inhibitor (17). Although the β-lactam forming step of the present synthesis proceeds in low yield, it is reproducible, and the sequence is easily accomplished and applicable to syntheses of ^{14}C-labelled analogs of Sulbactam and its C5 epimer.

Following these exploratory studies, condensation reactions of **7–9** were reexamined, with L-threonine or its methyl ester as the substrate in place of D-penicillamine. With the conditions of the earlier oxazolidine synthesis as a precedent (4), the salt **7** was allowed to react with threonine in water, and the reaction mixture was then benzoylated (PhCOCl, $NaHCO_3$, acetone). Exhaustive chromatography was necessary to obtain the oxazolidine **15***a*, in only 8% yield.



15*a*: R^1 = Et; R^2 = H
b: $R^1 = Ph_2CH$; $R^2 = CH_3$

The enamine **8** is a crystalline compound, but its ^{1}Hmr spectrum in chloroform solvent changes with time, from that of the *E*-isomer (7.61 ppm, 1H, q, 8.0, 14.0 Hz, =CHN; 4.92 ppm, 1H, d, 14.0 Hz, =CHC) to that of a 1:3 *E*:*Z* mixture (*Z*-isomer: 6.70 ppm, 1H, q, 8.0, 14.0 Hz, =CHN; 4.72 ppm, 1H, d, 8.0 Hz, =CHC). This spectral information facilitated the structural determination of the complex mixture of products formed initially in the reactions of **8** and **9** with threonine.

Treatment of threonine with **8** (DMF–H_2O, 3:2), at room temperature, followed by benzoylation (PhCOCl, $NaHCO_3$, acetone) and esterification (CH_2N_2) of the acidic fraction, led to a 2:1 adduct (A_1) (38%), *which did not contain a benzoyl group*. Under slightly different conditions (DMF–H_2O, 3:2, 1 equiv. *p*-TsOH, then benzoylation and esterification as above), a different 2:1 adduct (A_2) (48%) could be isolated, and *this also lacked a benzoyl group*. The same adducts were obtained, but in lower yields, when the condensations were carried out with the synthon **9**.

The adduct A_1 was found to have the formula $C_{37}H_{35}NO_7$, and its mass spectrum contained a series of peaks corresponding to successive loss of Ph_2CH, CO_2, CH_2, and CO. The ^{1}Hmr spectrum featured an *E*-enamine vinyl moiety. Structure **16** is assigned to A_1; its configuration at C5[1] is uncertain, because only one epimer was isolated.

The adduct A_2 has two sets of vinyl protons (7.88, 4.62 ppm, J = 13.5 Hz; and 4.95 ppm, 4.54 ppm, J = 17.0 Hz), and it is assigned the acyclic structure **17**.

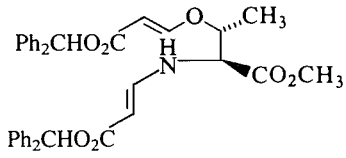
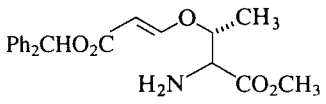
16



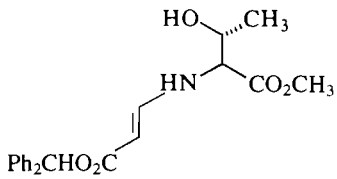
17

Treatment of the oxazolidine **16** with benzoyl chloride (CH_2Cl_2–*pyridine*) led to loss of the enamine moiety, and formation of the *N*-benzoyloxazolidine **15***b* as a single epimer, mp 123–124°C. The ^{1}Hmr spectrum of this compound was consistent with the structure assigned and, in addition, showed the expected evidence for restricted rotation about the amide bond (4).

Reaction of the methyl ester of threonine with **9** (CH_3CN, 20°C, 48 h) led to **16** (42%). However, this compound was not formed when *pyridine* was present in the reaction mixture (18). Instead, a mixture of three compounds (tlc) was produced, whose ^{1}Hmr spectrum was interpretable in terms of **17**–**19**.



18

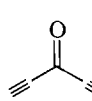


19

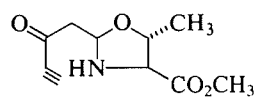
Addition of benzoyl chloride transformed this complex mixture to a single crystalline substance, the *N*-benzoyloxazolidine **15***b*.

The nitrogen atom of a 4-carboxyoxazolidine-2-acetic acid derivative thus seems to be an effective nucleophile for Michael addition reactions. It was therefore considered that the incorporation of two ethinyl acceptor groups into the same molecule, as in diethinylketone (**20**), might lead, via **21**, to a vinylogous oxapenam **22** (19).

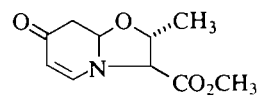
The ketone **20** was synthesized by oxidation (MnO_2) of diethinylcarbinol (20). Condensation of **20** with the methyl ester of threonine in ether or ether–acetonitrile led to the same major product, isolable in 38–48% yield. This product did not contain an RCH_2CO moiety. Its infrared spectrum featured acetylene (2095 cm^{-1}), ester (1730 cm^{-1}), and enamine (1620 cm^{-1}) absorptions. The ^{1}Hmr spectrum confirmed the presence of a *Z*-enamine and an ethinyl group, with the ethinyl signal indicating the presence of a 2:1 mixture of isomers. The product is assigned structure **23**, a mixture of epimers at C5. The formation of **23** can be understood in terms of oxazolidine formation onto the carbonyl group of **24**, in preference to the cyclization **24** → **21**. Attempts to obtain a 1:1 adduct, by use of an excess of **20** in this reaction, have not been successful.



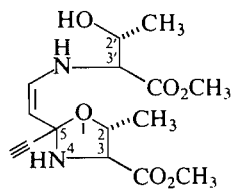
20



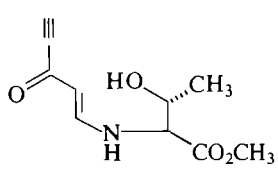
21



22



23



24

In summary, a strategy for bicyclic azetidinone synthesis, based on the formylacetate synthon, has been applied successfully to obtain a penam, and to reach the first (condensation) intermediate of a projected extension to an oxapenam. Whether such intermediates can be carried further will require the development of an appropriate alternative to benzoyl at the acylation stage.

Experimental

Solvents were routinely distilled before use, dried as required by standard methods (21), and stored over molecular sieves. Analytical thin-layer chromatography (tlc) was performed on precoated Merck silica gel 60 F-254 plates, with aluminium backing. Merck 60 mesh silica gel was used for column chromatography. High performance liquid chromatography used Merck prepacked Lobar columns, and a Fluid Metering Inc. model RP-SY pump and model PD-60-LF pulse dampener. The ^{1}Hmr spectra were recorded at 200 MHz or 400 MHz. Mass spectra were obtained on an AEI-MS 3074/DS 50 instrument. Analyses are by Galbraith Laboratories, Knoxville, TN.

Ethyl formylacetate sodium salt (7) (9)

Sodium hydride (50% in mineral oil, 24 g, 0.5 mol) was washed with ether under dry nitrogen, dried, and suspended in ether (100 mL), to which ethanol (23 g, 0.5 mol) was added dropwise, with stirring. After the addition was complete, more ether (50 mL) was added, and the mixture was cooled to −15°C. Then a mixture of ethyl acetate (44 g, 0.5 mol) and ethyl formate (37 g, 0.5 mol) was added with stirring, at such a rate as to maintain the temperature below −10°C. When this addition was complete, the mixture was allowed to warm to room temperature, cooled to −5°C, and filtered under nitrogen. The salt was washed with dry ether, dried, and stored under nitrogen.

Benzhydryl propiolate (9)

A solution of diphenyldiazomethane (5.92 g, 30 mmol) in methylene chloride (75 mL) was added dropwise, with stirring, to a solution of propiolic acid (2.1 g, 30 mmol) in methylene chloride (25 mL). When the reaction was complete, the solvent was removed, and the residue was purified by chromatography on silica gel (6% ethyl acetate in hexane).

Benzhydryl 2-N-benzylacrylate (8)

A solution of benzhydryl propiolate (6.7 g, 28.4 mmol), in ether (50 mL), was cooled to 0°C, and benzylamine (3.04 g, 28.4 mmol) was added dropwise. The product crystallized slowly, and was collected after 18 h, washed with ether, and dried (6.3 g, 65%), mp 122–123°C; ^{1}Hmr ($CDCl_3$) δ: 8.14 (1H, bm, NH), 7.46–7.16 (15H, m), 7.61 (1H, q, 8.0, 14.0, =CHN), 6.94 (1H, s), 4.92 (1H, d, 14.0, =CHC), 4.16 (2H, d, 5.5). *Anal.* $C_{23}H_{21}NO_2$: C, H, N.

Reaction of penicillamine with 7

The salt **7** (276 mg, 2 mmol), D-penicillamine (149 mg, 1 mmol), and *p*-toluenesulfonic acid (380 mg, 2 mmol) were dissolved in water (3 mL), the pH was adjusted to 6.0 with KH_2PO_4, and the solution was stirred at room temperature for 50 h. The mixture, containing some precipitated material, was then diluted with water, acidified to pH 2, and extracted with ether. This extract was dried and evaporated. The residue was crystallized from ether–hexane to give 53 mg (18%) of **10***a*, mp 132–133°C; ^{1}Hmr ($CDCl_3$) δ: 5.18 (0.5H, t, H5), 4.99 (0.5H, t, H5), 4.17 (2H, q), 4.01 (0.5H, s, H3), 3.83 (0.5H, t, H3), 3.20–2.71 (2H, m), 1.64 (3H, br s), 1.32 (3H, br s), 1.23 (3H, t). Mass spectrum, M^+.

Reaction of penicillamine with 8

p-Toluenesulfonic acid hydrate (2.32 g, 12.2 mmol) and D-penicillamine (1.79 g, 12.0 mmol) were dissolved in water (7 mL) and DMF (3 mL). To this solution, with stirring, was added a solution of the enamine (4.2 g, 12.2 mmol) in DMF (12 mL). The clear solution was stirred for 18 h, and some insoluble material was then removed by filtration. The filtrate was diluted with ether and extracted with 5% sodium carbonate. The aqueous extract was washed thoroughly with

ether, and then layered with ether and acidified with 6 *N* HCl. The ether extract was dried and evaporated to give 3.7 g (80%) of the product **10***b*. 5*S*-epimer, ^{1}Hmr (acetone-d_6) δ: 7.48–7.17 (10H, m), 6.89 (1H, s), 4.97 (1H, t, H5), 3.67 (1H, s, H3), 3.28–2.77 (2H, m), 1.61 (3H, s,) 1.23 (3H, s); 5*R*-epimer, ^{1}Hmr (acetone-d_6) δ: 7.48–7.17 (10H, m), 6.88 (1H, s), 5.20 (1H, t, H5), 3.88 (1H, s, H3), 1.61 (3H, s), 1.28 (3H, s).

Reaction of penicillamine with ***9***

D-Penicillamine (449 mg, 3 mmol) was suspended in DMF (15 mL), and a solution of benzhydryl propiolate (850 mg, 3.6 mmol) in DMF (15 mL) was added. The mixture was stirred at room temperature for 5 days, and then diluted with 5% sodium carbonate and extracted exhaustively with ethyl acetate. The aqueous phase was then layered with ethyl acetate and acidified to pH 2.5. Evaporation of the dried organic phase gave 643 mg (56%) of **10***b*, which crystallized upon trituration with methylene choride, mp 134–136°C. *Anal.* $C_{21}H_{23}NO_4S$: C, H, N.

Conversion of ***10***b *to the methyl esters* ***11***a *and* ***11***b

The acid **10***b* (a 1:1 mixture of epimers at C5) (870 mg, 2.3 mmol) was added to 2:1 methylene chloride – methanol (20 mL), and treated with excess ethereal diazomethane. After 30 min, the residual diazomethane was destroyed by addition of silica gel. The product was extracted from the silica gel with methanol. After removal of the solvent, the ester was chromatographed (Lobar, 10% acetone–hexane) to yield **11***b* (312 mg), followed by **11***a* (300 mg); **11***a*, ^{1}Hmr ($CDCl_3$) δ: 7.34 (10H, s, Ph), 6.92 (1H, s, $CHPh_2$), 5.16 (1H, t, 6.0 Hz, H5), 3.78 (4H, s, CH_3 + H_3), 3.34 (1H, br s, NH), 2.97 (1H, q, 6.0, 12.0 Hz, H6), 2.75 (1H, q, 6.0, 12.0 Hz, H6), 1.63 (3H, s), 1.22 (3H, s); **11***b*, ^{1}Hmr ($CDCl_3$) δ: 7.32 (10H, br s, Ph), 6.90 (1H, s, $CHPh_2$), 4.93 (1H, br t, 5.0 Hz, H5), 3.75 (3H, s, CH_3), 3.60 (1H, s, H3), 3.27 (1H, br, NH), 2.97 (1H, d, 5.0 Hz, H6), 1.63 (3H, s, CH_3), 1.14 (3H, s, CH_3).

Conversion of ***10***b *to the* p*-nitrobenzyl esters* ***11***c,d

The acid **10***b* (1.75 g, 4.7 mmol) and *p*-nitrobenzyl bromide (1.02 g, 4.7 mmol) were dissolved in acetonitrile (10 mL), triethylamine (0.735 mL, 5.3 mmol) was added, and the mixture was refluxed under nitrogen for 2 h. The mixture was then cooled, diluted with methylene chloride (50 mL), and extracted exhaustively with brine. After drying and evaporation, a portion of the product (total 2.3 g, 93%) was purified by chromatography (Lobar, 10% ethyl acetate – hexane) to separate the esters; **11***c*, ^{1}Hmr ($CDCl_3$) δ: 8.24 (2H, d, 8.5 Hz), 7.53 (2H, d, 8.5 Hz), 7.32 (10H, s, Ph), 6.88 (1H, s, $CHPh_2$), 5.26 (2H, s, CH_2Ar), 5.13 (1H, t, 6 Hz, H5), 3.78 (1H, br s, H3), 3.46 (1H, br s, NH), 2.90 (1H, dd, 6.0, 15.0 Hz, H6), 2.72 (1H, dd, 6.0, 15.0 Hz, H6), 1.56 (3H, s, CH_3), 1.13 (3H, s, CH_3); **11***d*, ^{1}Hmr ($CDCl_3$) δ: 8.24 (2H, d, 9.0 Hz), 7.54 (2H, d, 5.0 Hz), 7.34 (10H, s, Ph), 6.91 (1H, s, $CHPh_2$), 5.29 (2H, s, CH_2Ar), 4.92 (1H, dt, 5.5, 11.5 Hz, H5), 3.62 (1H, t, 11.5 Hz, NH), 3.53 (1H, d, 11.5 Hz, H3), 3.02 (1H, q, 5.5, 16.0 Hz, H6), 2.91 (1H, q, 5.5, 16.0 Hz, H6), 1.59 (3H, s, CH_3), 1.06 (3H, s, CH_3).

Conversion of ***11***a *into* ***12***a

The diester **11***a* (65 mg, 0.16 mmol) was dissolved in 98% formic acid (1 mL), and the solution was left at room temperature for 3 h, and then freeze-dried. The residue was dissolved in water, extracted with ethyl acetate (5 × 1 mL), and freeze-dried again; ^{1}Hmr ($CDCl_3$) δ: 4.90 (1H, t, 6.0 Hz, H6), 3.76 (3H, s, CH_3), 3.75 (1H, s, H3), 2.87 (2H, d, 6.0 Hz), 1.64 (3H, s, CH_3), 1.23 (3H, s, CH_3).

Conversion of ***12***a *into methyl* 5R*-penicillanate (****13****)*

The substrate (130 mg, 0.56 mmol), potassium bicarbonate (240 mg, 2.4 mmol), and tetra-*n*-butylammonium bisulfate (30 mg) were dissolved in water (5 mL). Then chloroform (10 mL) was added, followed, all at once, by a solution of methanesulfonyl chloride (137 mg, 1.2 mmol), in chloroform (15 mL). The mixture was stirred at room temperature for 18 h and then partitioned between ether and water. The organic layer was dried and evaporated, and the residue was purified by column chromatography (20–30% ethyl acetate – hexane) to yield the penam (24 mg, 20%); ^{1}Hmr ($CDCl_3$) δ: 5.31 (1H, q, 2.0, 3.8 Hz, H5), 4.48 (1H, s, H3), 3.78 (3H, s, CH_3), 3.58 (1H, q, 3.8, 16.8 Hz, H6α), 3.08 (1H, q, 2.0, 16.8 Hz, H6β), 1.68 (3H, s, CH_3), 1.48 (3H, s, CH_3).

Conversion of ***12***b *into methyl* 5S*-penicillanate (****14****)*

The reaction was carried out as described for **13**; ^{1}Hmr ($CDCl_3$) δ: 5.09 (1H, q, 2.1, 4.2 Hz, H5), 3.83 (3H, s, CH_3), 3.78 (1H, d, 1.4 Hz, H3), 3.44 (1H, dq, 1.4, 4.2, 16.1 Hz, H6β), 3.21 (1H, q, 2.1, 16.1 Hz, H6α), 1.65 (3H, s, CH_3), 1.52 (3H, s, CH_3).

Reaction of threonine with ***7***

L-Threonine (119 mg, 1 mmol) and the salt **7** (138 mg, 1 mmol) were dissolved in water (2 mL); the solution was stored for 3 days at 4°C and then treated with a solution of benzoyl chloride (141 mg, 1 mmol) in acetone (1 mL), with addition of $NaHCO_3$ (1 g) to maintain the pH above 7. After 2 h, the mixture was diluted with water and extracted with ether. This extract was discarded. The aqueous phase was acidified to pH 1, and extracted successively with ether and ethyl acetate. The combined organic extracts were dried and evaporated to yield 135 mg of material, which (tlc, 80:1:4 butanone – acetic acid – water) was a mixture of at least six products. This mixture was chromatographed (Lobar, 1:1 ethyl acetate – hexane, followed by 3:1 ethyl acetate – hexane, followed by ethyl acetate). The fifth substance eluted was identified as the oxazolidine **15***a*, 24 mg (8%); ^{1}Hmr ($CDCl_3$) δ: 7.44 (2H, m, Ar), 7.31 (3H, br s, Ar), 5.07 (1H, br s, H5), 4.19 (2H, q, 6 Hz, CH_2), 4.02 (1H, d, 6.0 Hz, H3), 3.72 (1H, dq, 6.0, 6.0 Hz, H2), 2.60 (1H, m, H6), 2.27 (1H, m, H6), 1.15 (3H, d, 6.0 Hz, CH_3), 0.89 (3H, t, 6.0 Hz, CH_3).

Reaction of threonine with ***8****. Preparation of* ***16***

A solution of L-threonine (119 mg, 1 mmol) in water (2 mL) was treated dropwise with a solution of the enamine **8** (343 mg, 1 mmol) in DMF (3 mL). The mixture was stirred in an ice bath for 3 h, and was then left overnight at 4°C. Then sodium bicarbonate (1 g) was added, followed by a solution of benzoyl chloride (140 mg, 1 mmol) in acetone (3 mL). The next day, the mixture was diluted with water (50 mL), extracted exhaustively with ether, and then acidified to pH 2. Extraction with ether, followed by drying and evaporation, afforded an acidic fraction, which was converted to the methyl ester with ethereal diazomethane. The product was isolated by chromatography (Lobar, 10% ethyl acetate – hexane), 230 mg (38%); ^{1}Hmr ($CDCl_3$) δ: 7.59 (1H, d, 13.5 Hz, =CHN), 7.34 (20H, Ph), 6.93 (2H, s, $CHPh_2$, $CHPh_2$), 5.57 (1H, dd, 4.5, 7.5 Hz, H5), 4.73 (1H, d, 13.5 Hz, =CHC), 4.50 (1H, dq, 6.0, 6.0 Hz, H2), 3.80 (1H, d, 6.0 Hz, H3), 3.78 (3H, s, CH_3), 2.97 (1H, dd, 4.5, 15.3 Hz, H6), 2.87 (1H, dd, 7.5, 15.3 Hz, H6), 1.39 (3H, d, 6.0 Hz, CH_3); ms, *m/z*: 605 (M^+), 448 (M − Ph_2CH), 404, 390, 362. *Anal.* $C_{37}H_{35}NO_7$: C, H, N.

Reaction of threonine with ***8****. Preparation of* ***17***

The reaction was carried out as described above, except that the initial mixture also contained *p*-toluenesulfonic acid hydrate (190 mg, 1 mmol). The product was eluted with 20% ethyl acetate – hexane; ^{1}Hmr ($CDCl_3$) δ: 8.7 (1H, br), 7.88 (1H, d, 13.5 Hz), 7.32 (10H, br), 7.29 (10H, d), 6.88 (2H, s), 4.95 (1H, d, 17.0 Hz), 4.62 (1H, d, 13.5 Hz), 4.54 (1H, d, 13.5 Hz), 3.76 (1H, dq, 6.0, 8.1 Hz), 3.65 (1H, d, 6.0 Hz), 3.63 (3H, s), 1.40 (3H, d, 8.1 Hz).

Conversion of ***16*** *into the* N*-benzoyloxazolidine* ***15***b

The enamine **16** (350 mg, 0.58 mmol) was dissolved in CH_2Cl_2 (7 mL), and pyridine (49 mg, 0.62 mmol) was added. After 1 h, benzoyl chloride (241 mg, 1.72 mmol) was added. The reaction mixture was stirred at room temperature for 4 h, and the solvent was then removed. The residue was chromatographed (Lobar, 30% ethyl acetate – hexane) to yield **15***b* (219 mg, 80%), mp 123–124°C (ethyl acetate – hexane); ^{1}Hmr ($CDCl_3$) δ: 7.43 (5H, Ph), 7.32 (10H, Ph), 6.90 (1H, $CHPh_2$), 6.05 (1H, br d, 9.0 Hz, H5), 4.50 (1H, dq, 5.4, 5.4 Hz, collapses to a doublet J = 5.4 Hz upon irradiation at 1.35 ppm, H2), 4.20 (1H, br, H3), 3.71 (3H, s, CH_3), 3.19 (1H, br, H6), 2.97 (1H, dd, 9.0, 15.0 Hz, collapses to a doublet J = 15.0 Hz upon irradiation at 6.05 ppm, H6), 1.35 (3H, d, 5.4 Hz, CH_3); ms, *m/z*:

473 (M^+). *Anal.* $C_{28}H_{27}NO_6$, C, H, N. The H3 and H5 protons and one of the H6 protons show temperature-dependent broadening, characteristic of restricted rotation about the amide bond (4).

*Formation of **16** in the reaction of **9** with threonine methyl ester*

The methyl ester of L-threonine (386 mg, 2.90 mmol) was suspended in acetonitrile (10 mL), and treated with a solution of **9** (700 mg, 2.97 mmol) in acetonitrile (5 mL). The mixture was stirred at room temperature for 48 h, filtered to remove 250 mg of insoluble material, and evaporated to give 832 mg of crude product. This was purified by chromatography (20% → 50% ethyl acetate – benzene) to yield **16** (370 mg, 42% based on threonine), identified by comparison with the aforementioned material.

*Reaction of **9** with the methyl ester of threonine in the presence of pyridine*

A solution of **9** (344 mg, 1.46 mmol) in acetonitrile (2 mL), was added during 1 h to a suspension of the methyl ester of L-threonine (194 mg, 1.46 mmol) in acetonitrile (3 mL), containing pyridine (115 mg, 1.46 mmol). During the addition the reaction mixture turned yellow and then orange, and a white semicrystalline precipitate then formed slowly. This was collected after 10 h (55 mg), and the filtrate was evaporated to dryness. The tlc of the precipitate and the residue were similar (3 spots). The ^{1}Hmr spectra in $CDCl_3$, acetone-d_6, and DMSO-d_6 showed varying proportions of **17** and two other enamines. Treatment of the residue with benzoyl chloride (204 mg) in 1:1 methylene chloride – pyridine (4 mL) effected quantitative conversion to a single product, **15***b*.

Reaction of diethinylketone with the methyl ester of threonine

Diethinylcarbinol (450 mg, 5.6 mmol) was dissolved in 1,1,2,2-tetrachloroethane (4 mL), and added dropwise under nitrogen to a suspension of activated manganese dioxide (5 g) in the same solvent (6 mL). The mixture was stirred, gradually warmed to 50°C, and evacuated (1 Torr; 1 Torr = 133.3 Pa). The distillate was collected in two traps, ice–water and Dry Ice – ethanol. The contents of the Dry Ice – ethanol trap were used in the following experiment. The methyl ester of L-threonine (140 mg, 1.05 mmol) was suspended in ether (10 mL), diethinylketone (80 mg, 1.02 mmol) was added, and the reaction mixture was stirred at room temperature for 1 week. The solvent was then removed, and the residual oil was chromatographed (Lobar, 35:10:55 ethyl acetate – methanol–hexane) to yield the main product; ^{1}Hmr ($CDCl_3$) δ: 8.37 (1H, br, NH), 6.85 (1H, q, 7.1, 12.5 Hz, collapses to a doublet, J = 12.5 Hz upon irradiation at 5.38 ppm, =CHN), 6.50 (1H, br, NH), 5.38 (1H, d, 7.1 Hz, =CHC), 4.73 (1H, dd, 2.2, 8.5 Hz, H3), 4.44 (1H, dq, 2.2, 8.4 Hz, collapses to a doublet, J = 2.2 Hz upon irradiation at 1.29 ppm, H2), 4.32 (1H, dq, 3.6, 8.7 Hz, collapses to a doublet J = 3.6 Hz upon irradiation at 1.29 ppm, H2′), 3.85 (3H, s, CH_3), 3.84 (3H, s, CH_3), 3.77 (1H, dd, 3.6, 8.5 Hz, H3′), 3.11 + 3.06 (1H, s + s, ≡CH), 1.84 (1H, br, OH), 1.29 (6H, d, 8.5 Hz, CH_3).

This paper is dedicated to Dr. O. E. (Ted) Edwards

J. APPA RAO, K. RAVICHANDRAN, G. J. O'MALLEY, and M. P. CAVA. Can. J. Chem. **65**, 31 (1987).

The formal synthesis of aklavinone and the first synthesis of 4,11-dideoxy-α-rhodomycinone are described. Oxidative decyanation of the tetracyclic nitrile to the corresponding ketone using a strong base (LDA) constitutes an important strategy in the synthesis of both these compounds.

J. APPA RAO, K. RAVICHANDRAN, G. J. O'MALLEY et M. P. CAVA. Can. J. Chem. **65**, 31 (1987).

On décrit la synthèse formelle de l'aklavinone ainsi que la première synthèse de la didéoxy-4,11 α–rhodomycinone. La décyanation oxydante du nitrile tétracyclique, sous l'influence d'une base forte (LDA), constitue une stratégie importante dans la synthèse de chacun de ces deux composés.

Recently we reported (1) the conversion of some simple hydroxyanthraquinone dye intermediates into the tetracyclic ketonitriles **8** and **14**; a tandem Michael vicarious aromatic substitution reaction on the enones **7** and **13** formed the key step of the synthetic sequence.

We now report the use of **8** to complete a new formal synthesis of aklavinone (**1**), as well as the elaboration of **14** to afford the first synthesis of 4,11-dideoxy-α-rhodomycinone (**6**).

Synthesis of aklavinone

As part of the continuing search for new anthracyclines that may show decreased side effects and (or) increased antitumor activity relative to daunomycin and adriamycin, much interest has focused on aclacinomycin A (2). Since microbiological methods permit the transformation of the aglycon, aklavinone (**1**), to aclacinomycin A, significant efforts have been expended on the synthesis of **1** (3).

The research described in this section emanated from our search for a method to convert nitrile **8** into the versatile intermediate 4,6-dihydroxy-9-ethyl-7,8,9,10-tetrahydronaphthacenetrione **12**, which has already found use as a late stage precursor to aklavinone, as well as a potential starting material for the synthesis of other 11-deoxyanthracyclinones such as decarbomethoxyaklavinone **2** (4) and β_1-citromycinone **3** (5).

We envisaged that the ketone functionality of **8** would be troublesome to maintain since it would contribute a driving force for the aromatization of the "A" ring. Hence the removal of this functionality seemed advantageous. The carbonyl group could be reduced directly using triethylsilane/TFA (6) to afford **10** (46%), although a better yield (~80%) was obtained by conversion of **8** to the dithioketal **9** and subsequent reduction using tri-*n*-butyltin hydride (7).

We first expected that the anionic oxygenation of **10** to ketone **11** would succeed using a mild base such as K_2CO_3 in DMSO (8). However, varying the temperature from room temperature to 100°C and prolonging the oxidation time for 72 h failed to afford the required product. Changing the base to NaH and (or) *t*-BuOK, together with varying the oxygenation temperature, also proved futile.

The only success in obtaining **11** required the use of the strong base LDA (lithium diisopropylamide) (1.5 equiv.) and dry oxygen (9). Compound **11** was easily demethylated in the conventional way ($AlCl_3/CH_2Cl_2$) to obtain **12**; both **11** and **12** were identical in all respects (tlc, ^{1}Hmr, mp, ms) with authentic samples.[2]

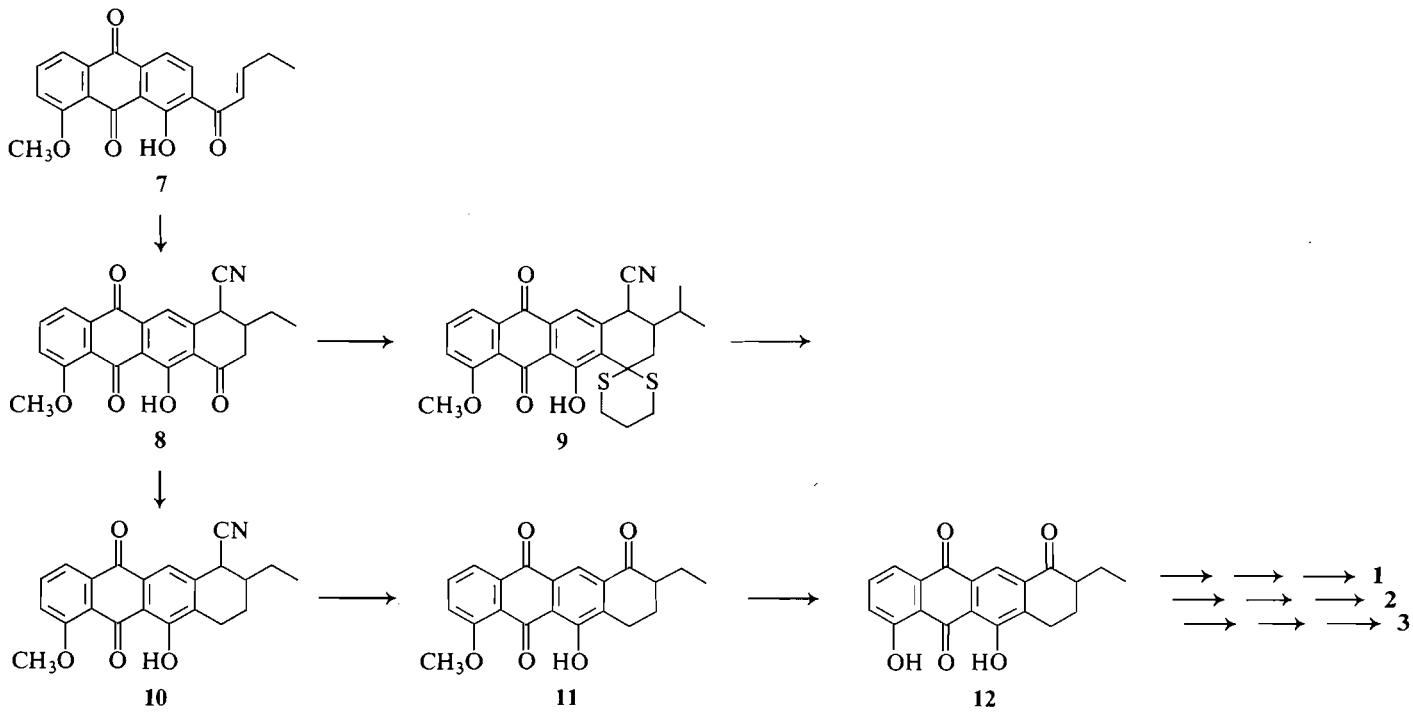
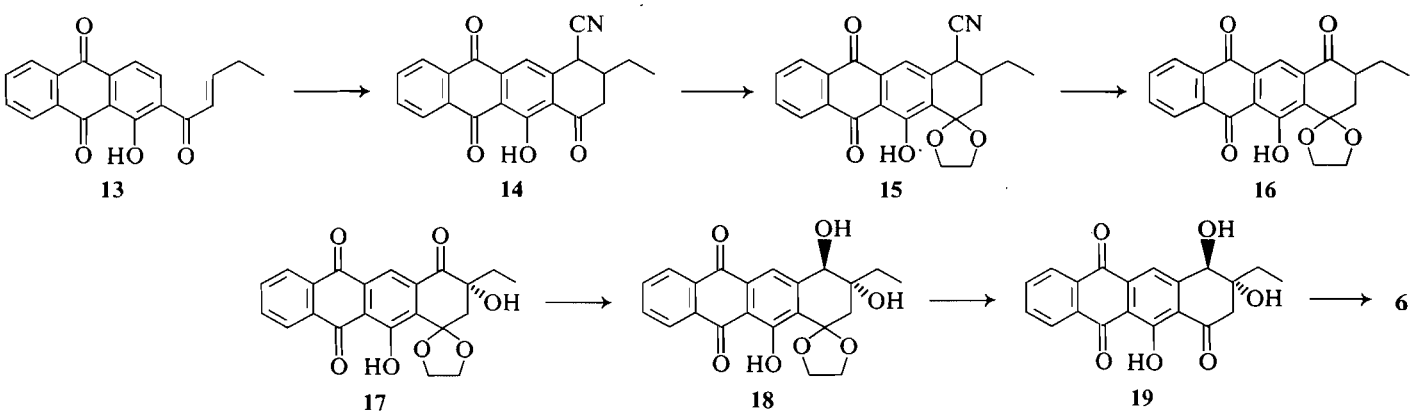


SCHEME 1



SCHEME 2

Since **12** has been previously converted to aklavinone (3*a*,*b*), decarbomethoxyaklavinone (4), and β_1-citromycinone (5), our route to this versatile intermediate by a conceptually different approach constitutes new formal syntheses of these anthracyclinones.

Synthesis of 4,11-dideoxy-α-rhodomycinone

The rhodomycinones (**4**) are the principal aglycones of the aminoglycoside antibiotics of the rhodomycin group produced by various strains of streptomyces (10). Several elegant studies have been described, aimed at the synthesis of these molecules (11). Recently 4,11-dideoxy-2-hydroxy-β-rhodomycinone (**5**) (12), has been synthesized: this compound comprises of a hybrid analog of 2-hydroxyaklavinone and β-rhodomycinone. We now report the first synthesis of 4,11-dideoxy-α-rhodomycinone (**6**), a structure that constitutes a hybrid analog of 4-deoxyaklavinone and α-rhodomycinone.

Earlier we synthesized (1) the ketonitrile **14** by a two-step sequence in 56% overall yield from the enone **13**. However, treatment of the enone **13** with $PhSCH_2CN$ improved the yield of **14** to 72% in a single-step operation.

Unlike in the aklavinone synthesis, we decided to keep the carbonyl function intact at the 7 position in the ketonitrile **14**; hence, this was protected as the ethylene ketal **15** in 76% yield. Oxidative decyanation of **15** using LDA as described in the previous section conveniently provided the requisite ketone **16**. Enolate hydroxylation of the ketone **16** with oxodiperoxymolybdenum(pyridine)hexamethylphosphoramide (MoOPH) (13) gave the α-hydroxyketone **17** in 60% yield. Reduction of the carbonyl group in **17** was accomplished with sodium cyanoborohydride at pH 5 to afford the desired 9,10-*trans* diol **18** in 80% yield; the remainder was the *cis* isomer, which could be eliminated by chromatography followed by crystallization.

Cleavage of the ketal function by 5% HCl proceeded smoothly to afford **19** in 68% yield. Reduction of the C-7 carbonyl of **19** with an excess (10 equivalents) of $NaCNBH_3$ at pH 5 provided **6** together with its isomer, albeit in modest yield due to extensive aromatization of the "A" ring. The separation of these isomers was easily achieved using benzeneboronic acid/PTS (14) to provide the desired *trans* isomer as a yellow solid, mp 238–240°C (dec.).

In conclusion, we have completed a new formal synthesis

of aklavinone, as well as the first synthesis of 4,11-dideoxy-α-rhodomycinone, using the oxidative decyanation of fully constructed tetracyclic molecules derived from simple hydroxyanthraquinone precursors.

Experimental

Melting points were determined on a Thomas–Hoover apparatus and are uncorrected. The ^{1}H nmr spectra were obtained on a Bruker 250 FT instrument using $CDCl_3$ as solvent and Me_4Si as an internal standard; shifts are expressed in δ units. Infrared (ir) spectra were obtained on a Perkin–Elmer 781 grating spectrophotometer using polystyrene film as a standard; absorbances are expressed in units of cm^{-1}. Mass spectra were determined on a V-G 70-70 Micromass. Thin-layer chromatographic plates were obtained from JT Baker Chemical Co. (Si 250 F). Products were detected by viewing under an uv source and (or) exposing to I_2 vapours. All organic extracts were washed and dried over anhydrous Na_2SO_4 prior to filtration and evaporation.

4-Methoxy-6-hydroxy-9-ethyl-10-cyano-7,8,9,10-tetrahydronaphthacene-dione ***10***

Method A

To a stirred solution of the keto nitrile **8** (100 mg, 0.26 mmol) and triethylsilane (150 mg, 1.3 mmol) in CH_2Cl_2 (15 mL) at 0°C, was added trifluoroacetic acid (0.2 mL, 2.34 mmol). After stirring at 0°C for 1 h, the reaction mixture was gradually warmed to room temperature and left overnight. The contents were poured over crushed ice, extracted with methylene chloride, and washed thoroughly with $NaHCO_3$. Column chromatography followed by crystallization (95% EtOH) afforded **10** (45 mg, 0.124 mmol, 46%), mp 192–194°C (dec.); nmr: 1.03 (t, 3H, J = 7.4 Hz), 1.62 (m, 1H), 1.82–2.04 (m, 2H), 2.20–2.38 (m, 1H), 2.42–2.60 (m, 1H), 2.86–2.94 (m, 1H), 3.10–3.24 (m, 1H), 3.78 (d, 1H, J = 9.1 Hz), 4.10 (s, 3H), 7.40 (d, 1H, J = 7.5 Hz), 7.70 (t, 1H, J = 7.5 Hz), 13.50 (s, 1H); ms: 362 (32), 351 (92), 250 (18), 69 (100). *Mol. Wt.* (high resolution ms) calcd. for $C_{22}H_{19}O_4N$: (M^+ + 1), 362.1350; found: 362.0242.

Method B

To a stirred solution of the ketonitrile **8** (100 mg, 0.26 mmol), 1,3-propanedithiol (66.6 mg, 0.53 mmol), and trimethylsilyl chloride (50 mg, 0.53 mmol) in a flame-dried, nitrogen flushed flask containing CH_2Cl_2 (15.0 mL) was added 1 drop of trimethylsilyl triflate. After stirring at room temperature for 20 min, the dark green solution was diluted with H_2O (100 mL). This was extracted with methylene chloride, dried over anhydrous Na_2SO_4, and evaporated to dryness. Chromatography (silica gel, hexane – ethyl acetate 2:1) provided **9** (106 mg, 0.23 mmol, 85%) as an *unstable* light orange solid, ((mp 138–140°C); nmr: 1.09–1.15 (m, 3H), 2.14–2.19 (m, 2H), 2.66–2.90 (m, 2H), 3.04–3.30 (m, 6H), 3.85 (d, 1H, J =9.1 Hz), 4.18 (s, 3H), 7.40 (d, 1H, J = 7.5 Hz), 7.70 (t, 1H, J = 7.5 Hz), 7.64 (s, 1H), 14.6 (s, 1H); ms: 465 (0.5), 423 (4.6), 361 (100), 343 (15.8), 332 (69.9)), which was immediately refluxed in *dry* benzene (15.0 mL) containing tri-*n*-butyltin hydride (296 mg, 1.02 mmol) and AIBN (catalyst, 20 mg). After 3 h the solvent was removed under reduced pressure, extracted with methylene chloride, washed several times with water, dried over anhydrous Na_2SO_4, and finally evaporated to dryness. Chromatography (silica gel, hexane–EtOAc 3:1) followed by crystallization (95% EtOH) afforded **10** (77 mg, 0.21 mmol, 94%), which was identical in all respects with the sample obtained by Method A.

*7,8-Dihydro-4-methoxy-6-hydroxy-9-ethyl-5,10,12(9*H*)-naphthacenetrione* ***11***

To a solution of 0.152 mmol of lithium diisopropylamide in 3.0 mL of anhydrous THF at −78°C under a nitrogen atmosphere was added a solution of **10** (50 mg, 0.138 mmol) in 2 mL THF and 0.5 mL HMPA. Dry O_2 was bubbled (250 mL/min) into the lithionitrile solution for 1 h at −78°C. The reaction was quenched with 6.0 mL of 1 *M* aqueous $NaHSO_3$ solution and stirred at 0°C for 1. After further stirring at room temperature for 30 min, the reaction mixture was diluted with ether, washed successively with water, 1 *M* NaOH solution, water, and brine, and dried over anhydrous Na_2SO_4. Chromatography of the crude product followed by crystallization (95% EtOH) afforded **11** (27 mg, 0.77 mmol, 55%), mp 224–225°C (lit. (*3a*) mp 224–225°C); nmr: 1.03 (t, 3H, J = 7.4 Hz), 1.60 (quintet, 1H, J = 7.4 Hz), 1.82–2.04 (m, 2H), 2.30–2.40 (m, 1H), 2.42–2.51 (m, 1H), 2.85–2.94 (m, 1H), 3.17–3.24 (m, 1H), 7.30 (d, 1H, J = 7.5 Hz), 7.70 (t, 1H, J = 7.5 Hz), 7.84 (d, 1H, J = 7.5 Hz), 8.37 (s, 1H), 13.42 (s, 1H); ms: 350 (3.1), 256 (14.1), 149 (50.5), 57 (100). This substance was identical in all respects with an authentic sample.[2]

4,6-Dihydroxy-9-ethyl-7,8,9,10-tetrahydronaphthacenetrione ***12***

To a suspension of anhydrous $AlCl_3$ (100 mg, excess) in 15 mL of dry CH_2Cl_2 was added a solution of ketone **11** (25 mg, 0.07 mmol) in CH_2Cl_2 (2.0 mL) at room temperature under N_2. After 24 h, all solvent was removed under reduced pressure; 5% HCl (2.0 mL) and saturated brine (15 mL) were added and stirred further for 1 h. This was extracted with ether (2 × 15 mL) dried over anhydrous Na_2SO_4, evaporated, and crystallized (CH_2Cl_2/ether/hexane) to afford **12** (18 mg, 0.05 mmol, 75%); mp 203–204°C (lit. (*3a,b*) mp 203–204°C, 204–205°C); nmr: 1.03 (t, 3H, J = 7.4 Hz), 1.60 (quintet, 1H, J = 7.4 Hz), 1.88–2.03 (m, 2H), 2.29–2.38 (m, 1H), 2.44–2.51 (m, 1H), 2.85–2.94 (m, 1H), 3.17–3.24 (m, 1H), 7.29 (d, 1H, J = 7.5 Hz), 7.70 (t, 1H, J = 7.5 Hz), 7.84 (d, 1H, J = 7.5 Hz), 8.37 (s, 1H), 12.0 (s, 1H), 12.46 (s, 1H); ms: 336 (5.9), 252 (2.5), 123 (8.3), 81 (48.4), 69 (100). This substance was identical in all respects with an authentic sample.[2]

*10-Cyano-9,10-dihydro-9-ethyl-6-hydroxy-5,7,12(8*H*)-naphthacenetrione* ***14***

To a suspension of 200 mg (4.36 mmol) of NaH (60% dispersion in oil) in 20 mL of DMF, 0.375 mL (2.18 mmol) of $PhSCH_2CN$ was added under nitrogen with stirring. After 15 min, 500 mg (1.64 mmol) of the enone **13** was added in one lot. The reaction mixture was stirred at room temperature for 3 h and was poured onto ice (50 g) containing 2 mL of acetic acid. The mixture was extracted with CH_2Cl_2 (100 mL), washed with water (2 × 50 mL), dried (Na_2SO_4), and the solvent evaporated. The residue was chromatographed over silica gel (3:1 hexane:ethyl acetate) to give, after crystallization from benzene, the cyanoketone **14** (400 mg, 1.16 mmol, 72%) as yellow crystalline solid, mp 205–206°C (lit. (1) mp 205–206°C); nmr: 1.07–1.14 (t, 3H, J = 7.4 Hz), 1.59–1.83 (m, 2H), 2.37–2.42 (m, 1H), 2.75–2.96 (m, 2H), 4.29–4.30 (d, 1H, J = 3.6 Hz), 7.84–7.86 (m, 3H), 8.26–8.35 (m, 2H), 13.97 (s, 1H); ms: 346 (M^++1, 100), 345 (33), 289 (37), 205 (4), 177 (5), 150 (4), 113 (8), 84 (11). *Mol. Wt.* (high resolution ms) calcd. for $C_{21}H_{15}NO_4$; 345.0966; found: 345.1187.

10-Cyano-9-ethyl-7,7-ethylenedioxy-6-hydroxy-7,8,9,10-tetrahydro-5,12-naphthacenedione ***15***

A mixture of 500 mg (1.45 mmol) of the cyanoketone **14,** 0.1 mL (1.8 mmol) of ethyleneglycol, and 25 mg of *p*-toluenesulfonic acid in 50 mL of benzene was refluxed for 2 h under nitrogen with azeotropic removal of water. The reaction mixture was cooled, washed successively with 10% $NaHCO_3$ solution (25 mL), water (2 × 25 mL), dried (Na_2SO_4), and solvent removed. The residue was chromatographed over silica gel (4:1 hexane:ethyl acetate) to afford, after crystallization from CH_2Cl_2–MeOH, the cyanoketal **15** (420 mg, 1.08 mmol, 76%) as bright yellow crystals, mp 224–226°C; nmr: 1.05–1.11 (t, 3H, J = 7.3 Hz), 1.56–1.71 (m, 2H), 2.04–2.17 (m, 3H), 4.07–4.49 (m, 5H), 7.74 (s, 1H), 7.81–7.86 (m, 2H), 8.27–8.34 (m, 2H), 13.64 (s, 1H); ms: 390 (M^+ + 1, 57), 389 (M^+, 11), 347 (21), 346 (88), 334 (24), 333 (100). *Mol. Wt.* (high resolution ms) calcd. for $C_{23}H_{19}NO_5$: 389.1257; found: 389.1250.

*9-Ethyl-6-hydroxy-7,8-dihydro-7,7-ethylenedioxy-5,10,12 (9*H*)-naphthacenetrione* ***16***

LDA was prepared from 0.25 mL (1.87 mmol) of diisopropylamine and 0.75 mL of 2.5 *M n*-BuLi in 10 mL of THF at −78°C. Cyanoketal **15** (250 mg, 0.625 mmol) dissolved in 10 mL of THF was added at −78°C. After stirring for 30 min, dry oxygen was bubbled through the solution for 2 h at −78°C. The reaction mixture was brought to 0°C and 2.5 mL of 1 *M* stannous chloride in 2 *M* HCl was added. After 30 min, the reaction mixture was extracted with CH_2Cl_2 (100 mL), and washed with 1 *N* NaOH (50 mL). The aqueous solution was acidified with acetic acid and extracted with CH_2Cl_2 (100 mL). The organic

phase was washed with water (2 × 50 mL), dried, and solvent removed. The residue was chromatographed over silica gel (4:1 hexane:ethyl acetate) to afford, after crystallization from CH_2Cl_2–MeOH, the ketone **16** (165 mg, 0.43 mmol, 68%) as reddish brown crystals, mp 212–214°C; ir: 1710 (C=O), 1685 and 1640 (quinone C=O); nmr: 1.01–1.08 (t, 3H, J = 7.4 Hz), 1.54–1.77 (m, 1H), 1.95–2.05 (m, 1H), 2.11–2.23 (m, 1H), 2.33–2.40 (dd, 1H, J = 13.9 and 4.3 Hz), 2.81–1.91 (m, 1H), 4.13–4.58 (m, 4H), 7.80–7.89 (m, 2H), 8.29–8.37 (m, 2H), 8.38 (s, 1H), 13.58 (s, 1H); ms: 379 (M^+ + 1, 100), 378 (M^+, 36), 335 (41), 307 (66), 294 (88), 138 (20). *Mol. Wt.* (high resolution ms) calcd. for $C_{22}H_{18}O_6$: 378.1110; found: 378.1135.

6,9-Dihydroxy-7,8-dihydro-9-ethyl-7,7-ethylenedioxy-5,10,12(9H)-naphthacenetrione **17**

LDA was prepared from 0.17 mL (1.2 mmol) of diisopropylamine and 0.51 mL of 2.5 *M n*-BuLi in 10 mL of THF at −78°C. A solution of 150 mg (0.4 mmol) of the ketone **16** in 10 mL of THF was added at −78°C. After 30 min, 210 mg (0.48 mmol) of MoOPH was added with vigorous stirring. After stirring the reaction mixture at −78°C for 1 h, it was slowly brought to room temperature over a period of 1 h and stirred for another 2 h. The contents were poured onto ice (50 g) containing 2 mL of acetic acid, extracted with CH_2Cl_2 (75 mL), washed with water (2 × 25 mL), dried (Na_2SO_4), solvent evaporated, and the residue was chromatographed over silica gel (3:1 hexane:ethyl acetate) to furnish, after crystallization from CH_2Cl_2–MeOH, the α-hydroxyketone **17** (94 mg, 0.24 mmol, 60%) as reddish brown needles, mp 226–227°C; ir: 1710 (C=O), 1680 and 1640 (quinone C=O); nmr: 0.86–0.92 (t, 3H, J = 7.2 Hz), 1.82–1.86 (m, 2H), 2.33–2.66 (ABq, 2H, J =14.4 Hz), 3.74 (s, 1H), 4.21–4.51 (m, 4H), 7.84–7.87 (m, 2H), 8.30–8.34 (m, 2H), 8.36 (s, 1H), 13.57 (s, 1H); ms: 395 (M^+ + 1, 100), 394 (M^+, 34), 377 (28), 338 (16), 294 (27), 293 (22), 85 (41), 83 (57). *Mol. Wt.* (high resolution ms) calcd. for $C_{22}H_{18}O_7$: 394.1050; found: 394.1008.

9-Ethyl-7,7-ethylenedioxy-7,8,9,10-tetrahydro-6,9,10-trihydroxy-5,12-naphthacenedione **18**

To a solution of 100 mg (0.25 mmol) of the α-hydroxyketone **17**, in CH_2Cl_2 (10 mL) and MeOH (10 mL), was added acetic acid (~1 mL) to give a solution of pH 5. $NaBH_3CN$ (0.32 g, 0.5 mmol) was added and the solution stirred at room temperature for 36 h. Solvent was removed under reduced pressure, the residue was dissolved in CH_2Cl_2 (25 mL), washed with water (3 × 25 mL), dried, and the residue, after removal of the solvent, was chromatographed over silica gel (2:1 hexane: ethyl acetate) to afford, after crystallization from benzene, **18** (80 mg, 0.20 mmol, 80%) as yellow needles, mp 228–230°C (dec.); nmr: 1.02–1.08 (t, 3H, J = 7.4 Hz), 1.56–1.60 (m, 2H), 2.00–2.06 and 2.43–2.49 (ABq, 2H, J = 14.5 Hz), 2.25–2.27 (d, 1H, J = 5.0 Hz), 2.93 (s, 1H), 4.19–4.48 (m, 4H), 4.62–4.64 (d, 1H, J = 5.0 Hz), 7.81–7.84 (m, 2H), 7.93 (s, 1H), 8.28–8.33 (m, 2H), 13.63 (s, 1H); ms: 397 (M^+ + 1, 40), 396 (2), 379 (28), 334 (43), 278 (25), 116 (18), 91 (100), 79 (25), 72 (32), 70 (44). *Mol. Wt.* (high resolution ms) calcd. for $C_{22}H_{20}O_7$: 396.1210; found: 396.1179.

9,10-Dihydro-9-ethyl-6,9,10-trihydroxy-5,7,12(8H)-naphthacenetrione **19**

To a solution of the ketal **18** (60 mg, 0.15 mmol) in 5 mL of THF, 2 mL of 5% HCl was added while cooling in ice and the mixture stirred for 90 min. Solvent was removed under reduced pressure, the residue was taken up in CH_2Cl_2 (25 mL), washed with water (2 × 25 mL), and dried (Na_2SO_4). Removal of the solvent gave yellowish brown solid, which on chromatographic purification over silica gel (1:1 hexane:ethyl acetate) furnished, after crystallization from benzene, **19** (40 mg, 0.11 mmol, 66%) as yellow solid, mp 205–210°C (dec.); nmr: 1.00–1.06 (t, 3H, J = 7.4 Hz), 1.54–1.63 (m, 2H), 1.81–1.93 (m, 1H), 2.69 (s, 1H), 2.73–2.79 and 3.14–3.21 (ABq, J = 17.1 Hz), 4.89 (s, 1H), 7.81–7.85 (m, 2H), 8.05 (s, 1H), 8.25–8.35 (m, 2H), 13.89 (s, 1H); ms: 353 (M^+ + 1, 32), 352 (4), 335 (66), 334 (100). *Mol. Wt.* (high resolution ms) calcd. for $C_{20}H_{16}O_6$: 352.0950; found: 352.0932.

4,11-Dideoxy-α-rhodomycinone **6**

To a solution of **19** (50 mg, 0.142 mmol) in CH_2Cl_2 (10 mL) and MeOH (10 mL) was added acetic acid (~1 mL) to give a solution of pH 5. $NaBH_3CN$ (90 mg, 1.42 mmol) was added and the solution stirred at room temperature for 3 h. Solvent was removed under reduced pressure, the residue was dissolved in CH_2Cl_2 (25 mL), washed with water (3 × 25 mL), dried (Na_2SO_4), and the residue after evaporation of the solvent was chromatographed over silica gel (1:1 hexane:ethyl acetate) to give a mixture of triols (10 mg, 0.028 mmol, 20%) as yellow solid. The solid was dissolved in a mixture of benzene (10 mL) and CH_2Cl_2 (10 mL), and benzeneboronic acid (6 mg) and PTS (2 mg) were added. The solution was stirred at room temperature for 24 h, and was then washed with 5% aqueous $NaHCO_3$ solution (10 mL), dried (Na_2SO_4), solvent evaporated, and the residue chromatographed over silica gel (1:1 hexane:ethyl acetate) to afford, after crystallization from hexane CH_2Cl_2, **6** (6 mg, 0.017 mmol, 12%) was yellowish powder, mp 238–240°C (dec.); nmr: 1.03–1.10 (t, 3H, J = 7.4 Hz), 1.80–1.88 (m, 2H), 2.22–2.31 (m, 1H), 2.45–2.49 (m, 1H), 4.55 (bs, 1H), 5.29–5.32 (m, 1H), 7.66–7.95 (m, 2H), 8.16 (s, 1H), 8.18–8.45 (m, 2H), 13.39 (s, 1H); ms: 355 (M^+ + 1, 10), 354 (14), 349 (42), 336 (24), 319 (45), 318 (19), 303 (20), 302 (18), 278 (17), 264 (24), 224 (14), 207 (17), 199 (27), 181 (14), 175 (26), 151 (21), 133 (24), 113 (100). *Mol. Wt.* (high resolution ms) calcd. for $C_{20}H_{18}O_6$: 354.1100; found: 354.1065.

Two new tetranortriterpenoids, trijugins *A* (**1**) and *B* (**3**), isolated from the leaves of *Heynea trijuga* (Meliaceae), have been shown to be derivatives of methyl angolensate but with a novel carbon skeleton having a contracted ring C. The structures were assigned on the basis of detailed ^1H and ^{13}C nuclear magnetic resonance spectroscopic examination including 2D long-range δ_C/δ_H correlation and homonuclear ^1H nuclear Overhauser effect difference experiments.

On a démontré que deux nouveaux tétranortriterpénoïdes, les trijugines *A* (**1**) et *B* (**3**), isolés des feuilles du *Heynea trijuga* (Meliaceae) sont des dérivés de l'angolensate de méthyle qui possèdent toutefois un nouveau squelette carboné comportant un cycle C ayant subi une contraction. On a attribué les structures en se basant sur un examen détaillé des spectres rmn du ^1H et du ^{13}C comportant des corrélations δ_C/δ_H 2-D et à longue distance ainsi que des expériences de différences d'eOn ^1H homonucléaire.

[Traduit par la revue]

Introduction

Previous work (1) on the leaves of *Heynea trijuga* Roxb., which are bitter and known to possess tonic properties, resulted in the isolation of 24-methylenecycloartane-3β,21-diol and heynic acid. We have now examined the more polar fractions of the extract and have obtained two new tetranortriterpenoids, trijugins *A* and *B*, which have been shown to have the novel structures **1** and **3** respectively and which represent a new skeletal type of compound.

Results and discussion

Trijugin *A* (**1**), $C_{29}H_{34}O_{11}$ (*m/z* 498.1893 (M^+ − HOAc)), mp 265–266°C, $[\alpha]_D^{30}$ −32.5° (*c* 2.0 in $CHCl_3$), ir (KBr) ν_{max}: 3450, 1742, 1702 cm^{-1}, has ^1H and ^{13}C resonances (see Tables 1 and 2) for four tertiary methyl groups, a secondary acetate with abnormally highly shielded methyl protons (δ_H 1.75), a carbomethoxyl, an exomethylene, a ketonic carbonyl, a ring D lactone, a β-substituted furan, and four further oxygen-bearing carbons, two secondary, one quaternary (δ_C 88.4), and one a ketal or hemiketal (δ_C 108.4). These signals together with two methylenes, two methine, and three quaternary carbon atoms account for all the carbon and all but one of the hydrogen atoms. Hence there is one hydroxyl group, but this is not acetylated under normal conditions. Trijugin *A* is therefore bicarbocyclic with two oxygen bridges and the above features suggest it is a derivative of methyl angolensate (**2**) (2). The signal at δ_C 108.4 is then assigned to the hemiketal carbon of a cyclic hemiketal involving a secondary oxygen function.

Further insight was obtained from ^1H nOe (nuclear Overhauser effect) difference and 2D COSY experiments. Support for a methyl angolensate type of structure comes from the observation of ^1H resonances for an ABX system associated with 2H-2 and H-1, and an isolated AB quartet arising from 2H-15. The large geminal coupling constants of the C-2 and C-15 methylene protons are consistent with their situation α to carbonyl groups. The ring D lactone terminus H-17, identified by its coupling to H-21 of the furan, shows a large nOe (8%) from the secondary acetate methine proton (δ_H 5.84); this implies that the acetate is attached α to C-12, consistent with the high shielding of its methyl protons. H-12 is coupled (4.2 Hz) to a proton at δ_H 3.06. This coupling must be vicinal and the proton must be H-11 since the alternative, a ^4J W-interaction

[a]In ppm relative to internal $CHCl_3$ at δ 7.25 for solutions in $CDCl_3$ run at 200.13 MHz. Multiplicities and splittings (Hz) are given in brackets.

between H-12 and H-9, would require an α-H at C-12 and is inconsistent with the nOes observed between H-11 and H-12 (both 3%), and H-12 and H-17 (8 and 5%). H-11 couples allylically to the exomethylene protons. This fact is significant and indicates that we are not dealing with a normal ring B-cleaved tetranortriterpenoid but with one containing a cyclopentanoid ring C. This conclusion is supported by several nOes. Thus the resonance for H-11 is enhanced (6%) by irradiation of 3H-18 but not of 3H-19. The spatial relationships are therefore different from the normal methyl angolensate type of structure, where H-9 is equatorial in ring C and remote from C-18 but *gauche* to C-19, and where H-9 and 2H-30 are coplanar. Complementary results for methyl angolensate (to be published) confirm these conclusions. The remaining coupled ^{1}H spin system consists of the secondary terminus of the cyclic hemiketal H-6 coupled to H-5, both with large nOes (6%) from {3H-28}. Hence the hemiketal carbon is C-9. The large nOe (7%) of the hemiketal hydroxyl proton from {3H-19} agrees with this assignment and shows that the configuration of C-9 is *S*. The large nOe (13%) of H-6 from {H-5} means that the coupling involved (8.3 Hz) arises from a *syn* rather than an *anti* relationship and that the configuration of C-6 is *R* as in related compounds (3). These data lead to structure **1** for trijugin *A*.

Definitive assignments of all the ^{13}C resonances and confirmation of the structure were achieved using 2D δ_C/δ_H correlation experiments. 2D One-bond δ_C/δ_H correlation permitted the assignments of all the protonated carbons including the tertiary methyl groups. Prior identification of the ^{1}H resonances of the tertiary methyl groups was effected using small *J* 2D COSY, which revealed the ^4J couplings between 3H-28 and 3H-29 and between H-17 and 3H-18. The quaternary carbons were assigned on the basis of the 2D long-range δ_C/δ_H correlations listed in Table 3. The hemiacetal carbon has long-range correlations with H-6 (^3J via oxygen), H-11 (^2J), H-12 (^3J), and 3H-19 (^3J), which support its assignment as C-9. In contrast C-12 exhibits long-range correlations with H-11 (^2J) and 3H-18 (^3J). C-11 correlates with 2H-30 (^3J) but not with 3H-19.

It is clear from the spectroscopic properties of trijugin *B* (**3**), $C_{27}H_{32}O_9$ (*m/z* 500.2066 (M^+)), mp 230–231°C, $[\alpha]_D^{30}$ −15° (*c* 2.0 in $CHCl_3$), ir (KBr) ν_{max}: 3 450, 1 730, 1 685 cm^{-1}, that it is closely related to trijugin *A* (**1**). The ^{1}H and ^{13}C nmr data (Tables 1 and 2) show all the same features except for a secondary hydroxyl group instead of an acetate at C-12, a ketone instead of a cyclic hemiketal at C-9, and a second proton at C-6 (J_{gem} 17.8 Hz). Acetylation of trijugin *B* (**3**) afforded the acetate **4**, mp 222°C, ir (CCl_4) ν_{max}: 1 750, 1 710, 1 694 cm^{-1}, *m/z* 542.2156. The acetate protons are again shielded (δ_H 1.81), consistent with their position at C-12, and the five-membered ring C was established for compound **4** by evidence similar to that for compound **1**. Irradiation of 3H-18 gave a 4% nOe at H-11, and the H-12, {H-17} nOe was 6%. The C-9 ketone was confirmed by 2D long-range δ_C/δ_H correlations (Table 3) to H-11, H-12, and 3H-19. Thus trijugin *B* has structure **3**.

Trijugins *A* (**1**) and *B* (**3**) represent a new skeletal type of tetranortriterpenoid. The contraction of ring C may occur by a pinacol–pinacolone rearrangement of a 9,11-dihydroxy precursor. The structural elucidation of trijugins *A* and *B* provides another illustration of the use of 2D long-range δ_C/δ_H correlation in the solution of structural problems and for definitive assignment of nonprotonated carbons, although in this case nOe difference experiments provided the vital clues to the new tetranortriterpenoid skeleton. Spectroscopically the distinction between the new cyclopentanoid and the normal six-membered ring C is rather subtle and with acetate **4**, for example, the data obtained initially pointed towards structure **5**. Several tetranortriterpenoids with multiple oxygenation of ring C are known (3) and it is clear that in future more

[a]Standard 2D δ_C/δ_H correlation experiments giving heteronuclear decoupling in both dimensions and performed (4), with phase-cycling to achieve quadrature detection in both dimensions (5); the fixed delay for coherence transfer was 40 ms and the fixed delay for refocussing of transverse ^{13}C magnetisation was 20 ms.

[b]It was not possible to distinguish between the α and β positions because of the 2nd-order character of 2H-15: the correlation observed corresponded to the inner lines of the AB quartet, which are not resolved in the 2D experiment.

detailed examination of such compounds will be necessary than has been the norm in the past. Subsequent to this work we ourselves have found that the ekebergolactones (3) also possess the cyclopentanoid ring C (to be published).

Experimental

All mps are uncorrected. Acme's silica gel (100–200 mesh) was used for column chromatography. Separations were monitored by tlc (silica gel G).

Isolation

The leaves of *H. trijuga* Roxb. (syn. *Trichilia connaroides* (W. & A.) Bentilezen) were collected at Pune, India, in May and identified by Mr. S. Usman Ali, Assistant Director, Jawaharlal Nehru Ayurvedic Medicinal Plants Garden and Herbarium, Pune. A specimen (Reg. No. 275) has been deposited at the Herbarium of the Captain Srinivasa Murti Drug Research Institute.

Dried, powdered leaves (2 kg) were defatted with *n*-hexane and then extracted with $CHCl_3$ in the cold for 48 h. The residue (30 g), after removal of the solvent, was chromatographed over a column of silica gel (600 g). The column was eluted with *n*-hexane, benzene, and $CHCl_3$ followed by mixtures of $CHCl_3$–EtOAc. $CHCl_3$–EtOAc (19:1) yielded 24-methylenecycloartane-3β,21-diol (300 mg) (1) while $CHCl_3$–EtOAc (9:1) gave heynic acid (600 mg) (1). Elution with 15% EtOAc–$CHCl_3$ (200 mL) and removal of solvent afforded a green mass, which on further chromatography over silica gel and crystallization from acetone–*n*-hexane gave *trijugin A* (**1**) (300 mg), mp 265–266°C. *Anal.* calcd. for $C_{29}H_{34}O_{11}$: C 62.4, H 6.1%; found: C 62.8, H 6.3. The product obtained on elution with 20% EtOAc–$CHCl_3$ (300 mL) was rechromatographed over silica gel and crystallized from acetone–*n*-hexane to give *trijugin B* (**3**) (350 mg), mp 230–231°C. *Exact Mass* calcd. for $C_{27}H_{32}O_9$: 500.2046; found (*m/z*): 500.2066.

Acetate 4

Trijugin *B* (**3**) (100 mg) in dry pyridine (1 mL) was treated with acetic anhydride (2 mL) at room temperature for 12 h. The usual work-up, followed by filtration through a short column of silica gel and crystallization from acetone–*n*-hexane, afforded the *acetate* **4** (80 mg) mp 222°C. *Exact Mass* calcd. for $C_{29}H_{34}O_{10}$: 542.2152; found (*m/z*): 542.2156.

The oxidation of sulfonhydrazides with benzeneseleninic acid provides an efficient and convenient preparation of selenosulfonates. Se-Phenyl *p*-tolueneselenosulfonate was also produced in good to excellent yield from the reaction of *p*-toluenesulfonhydrazide with PhSeCl, $PhSeBr_3$, or $PhSeCl_3$. Sulfonhydrazides react with sulfenyl halides or with $PhSBr_3$ to produce thiosulfonates in generally high yield. The treatment of *p*-toluenesulfonhydrazide with benzenetellurinic acid, $PhTeCl_3$, or $PhTeBr_3$ afforded only diphenyl ditelluride and not the corresponding tellurosulfonate.

THOMAS G. BACK, SCOTT COLLINS et M. VIJAYA KRISHNA. Can. J. Chem. **65**, 38 (1987).

L'oxydation des sulfonhydrazides par l'acide benzènesélénique s'avère une méthode efficace et intéressante de préparer des sélénosulfonates. On a aussi préparé le *p*-toluènesélénosulfonate de Se-phényle avec un rendement de bon à excellent en faisant réagir la *p*-toluènesulfonhydrazide avec le PhSeCl, le $PhSeBr_3$ ou le $PhSeCl_3$. Les sulfonhydrazides réagissent avec les halogènures de sulfényles ou avec le $PhSBr_3$ pour conduire aux thiosulfonates, généralement avec des rendements élevés. La réaction de la *p*-toluènesulfonhydrazide avec l'acide benzènetellurinique, le $PhTeCl_3$ ou le $PhTeBr_3$ ne conduit qu'au ditellurure de diphényle et non pas au tellurosulfonate correspondant.

Introduction

Selenosulfonates (RSO_2SeR') are stable, crystalline, odourless compounds, which were first reported by Foss (1) in 1947. They were then almost completely ignored until quite recently, when we and others began an investigation of their electrophilic (2) and free-radical (2–8) additions to olefins (2–4), allenes (5), acetylenes (6, 7), and diazomethane (8). The synthetic utility of these processes, collectively named "selenosulfonations", has now been firmly established and the need for a convenient source of the required selenosulfonates is evident.

Previously, a few selenosulfonates had been obtained by the reactions of areneselenenyl bromides with sulfinates (eq. [1]) (1, 9). However, the scope of this method and its limitations were never clearly established. We now report several new procedures for preparing diverse selenosulfonates from readily available sulfonhydrazides via their oxidations with benzeneseleninic acid ($PhSeO_2H$) or from their reactions with selenenyl halides or trihalides. The similar syntheses of the well-known corresponding sulfur analogues, the thiosulfonates (RSO_2SR') (for lead references, see ref. 11), using sulfenyl halides or sulfur trihalides are also described. While this work was in progress (preliminary communication, ref. 10), Gancarz and Kice (3*b*, 12) reported a related preparation of selenosulfonates from the oxidation and sulfinic acids with benzeneseleninic acid (eq. [2]).

[1] $ArSeBr + Ar'SO_2^- \rightarrow Ar'SO_2SeAr + Br^-$

[2] $2ArSO_2H + PhSeO_2H \rightarrow ArSO_2SePh + ArSO_3H + H_2O$

Results and discussion

The oxidations of several types of hydrazo compounds with seleninic acids and anhydrides have been investigated previously (13, 14). In particular, *N*-acylhydrazines are known to afford selenoesters (eq. [3]), as well as other products, depending on the conditions (15). It appeared reasonable that, by analogy, the oxidation of sulfonhydrazides with benzeneseleninic acid ($PhSeO_2H$) should produce the desired selenosulfonates via eq. [4].

[3] $RC(=O)NHNH_2 + PhSeO_2H \longrightarrow RC(=O)SePh + N_2 + 2H_2O$

[4] $RS(=O)_2NHNH_2 + PhSeO_2H \longrightarrow RS(=O)_2SePh + N_2 + 2H_2O$

1

Our results are summarized in Table 1, which indicates that generally high yields of Se-phenyl areneselenosulfonates (**1**, R = aryl) are available via the process shown in eq. [4]. Both electron-donating and electron-withdrawing substituents are tolerated on the arylsulfonyl group. The method is also applicable to alkaneselenosulfonates, as illustrated by the methane derivative (**1**, R = Me), obtained in 65% yield (entry 9, Table 1).

Typically, the sulfonhydrazide in dichloromethane is added dropwise to benzeneseleninic acid in the same solvent at 0°C. Vigorous evolution of nitrogen occurs and the product is isolated by evaporation of the solvent, followed by crystallization of the yellow or red residue, generally from methanol. In some instances (entries 1 and 4) it was more expedient to employ methanol as the reaction solvent instead of dichloromethane, as the product then crystallized directly from the reaction medium in a high state of purity. This procedure therefore constitutes an exceptionally rapid, convenient, and efficient preparation of selenosulfonates.

A plausible mechanism for the oxidation is shown in Scheme 1. Seleninylation of the sulfonhydrazide is followed by selenoxide elimination to produce the corresponding azene **2** and benzeneselenenic acid (PhSeOH). Further reaction of these two

intermediates is expected to furnish the selenadiazene **3**, from which nitrogen extrusion affords the desired selenosulfonate.[4]

We also investigated the reactions of *p*-toluenesulfonhydrazide with benzeneselenenyl chloride (PhSeCl), phenylselenium tribromide ($PhSeBr_3$), and phenylselenium trichloride ($PhSeCl_3$), in each case affording Se-phenyl *p*-tolueneselenosulfonate (**1**, R = *p*-tolyl) in high yield. The reactions were carried out in dichloromethane at 0°C in the presence of pyridine to remove HCl or HBr. When PhSeCl was employed, 3 molar equivalents of the reagent were required and, unfortunately, the simultaneous formation of one mole of diphenyl diselenide (PhSeSePh) necessitated the chromatographic isolation of the selenosulfonate (eq. [5]).

A plausible mechanism for the above process is given in Scheme 2, which invokes the same intermediates **2** and **3** as in

[5] 
the oxidation of sulfonhydrazides with $PhSeO_2H$ as shown in Scheme 1.

The undesired formation of PhSeSePh in the preceding reaction prompted us to examine the use of selenium trihalides instead of PhSeCl, with the expectation that the higher oxidation state of the selenium atom (Se(IV) vs. Se(II)) would result in the stoichiometry shown in eq. [6], thus avoiding the unwanted diselenide by-product.

Phenylselenium tribromide (16) was prepared *in situ* by adding 3 molar equivalents of bromine to PhSeSePh in dichloromethane. The subsequent addition of the sulfonhydrazide and

$$ArSO_2NHNH_2 + PhSeCl + Py \longrightarrow [ArSO_2NHNHSePh] + Py{\cdot}HCl$$

$$[ArSO_2NHNHSePh] + Py \longrightarrow [ArSO_2N{=}NH] + PhSe^- {}^+PyH$$
2

$$[ArSO_2N{=}NH] + PhSeCl + Py \longrightarrow [ArSO_2N{=}NSePh] + Py{\cdot}HCl$$
2 **3**

$$[ArSO_2N{=}NSePh] \longrightarrow ArSO_2SePh + N_2$$
3

$$PhSe^- {}^+PyH + PhSeCl \longrightarrow PhSeSePh + Py{\cdot}HCl$$

(Ar = *p*-tolyl)

SCHEME 2

[4] A referee has pointed out that nitrogen extrusion from **2** would produce a sulfinic acid (RSO_2H), which could react with PhSeOH (or PhSeCl in Scheme 2) to produce the selenosulfonate **1** without the intermediacy of **3**. Indeed, this variation cannot be ruled out on the basis of the available evidence, as indicated previously (29).

TABLE 2. Preparation of thiosulfonates

$$RSO_2NHNH_2 \xrightarrow[R'SBr_3]{R'SCl \text{ or } R'SBr \text{ or}} RSO_2SR'$$

Entry	R of sulfonhydrazide[a]	Sulfur halide reagent (mmol)[b]		Isolated yield of RSO_2SR' (%)
1		PhSBr	(3)	65[c]
2		PhSCl	(3)	79[c]
3		$CH_3(CH_2)_4SCl$	(3)	88[c]
4		$PhCH_2SCl$	(3)	89[c]
5		$PhSBr_3$	(1)	42[d]

[a]All reactions were performed in CH_2Cl_2 at 0°C, using 1 mmol of sulfonhydrazide.
[b]The reagents were prepared *in situ* by adding Br_2 or SO_2Cl_2 to the corresponding disulfides in the presence of a catalytic amount of Et_3N.
[c]An approximately equimolar amount of R'SSR' was also produced.
[d]*p*-Toluenesulfonyl bromide was also isolated in 20% yield.

[6] 
pyridine afforded the expected selenosulfonate in 60% yield. Closer scrutiny of the reaction mixture revealed the accompanying formation of *p*-toluenesulfonyl bromide, which was isolated in 21% yield. It therefore appears that the selenium tribromide functions as a brominating agent[5] as well as a selenenylating agent in this reaction. Similar results were obtained with $PhSeCl_3$, which was also generated *in situ* from the diselenide and sulfuryl chloride (17). In this case an improved yield of the selenosulfonate (83%) was realized and only a small quantity of *p*-toluenesulfonyl chloride (11%) was produced. The use of selenium halide reagents therefore comprises an alternative approach to the synthesis of selenosulfonates, although the need for the removal of by-products renders the method less convenient than the oxidation of sulfonhydrazides with $PhSeO_2H$.

We also wished to determine whether similar procedures would permit the preparation of the synthetically useful thiosulfonates (RSO_2SR', **4**) (11), and the, as yet unreported, tellurosulfonates (RSO_2TePh, **5**). We first attempted to react *p*-toluenesulfonhydrazide with *p*-toluenesulfinic acid (by analogy to eq. [4]); however, no reaction was observed, indicating that the sulfinic acid is a considerably less powerful oxidant than $PhSeO_2H$ in this process. On the other hand, the treatment of several sulfonhydrazides with 3 molar equivalents of sulfenyl chlorides or bromides in the presence of pyridine afforded high yields of the desired thiosulfonates, as indicated in Table 2. As in the case of the selenium series (ca. eq. [5]), the products were accompanied by the formation of an equimolar amount of the corresponding disulfides. The use of phenylsulfur tribromide ($PhSBr_3$) proved less satisfactory (entry 5, Table 2), affording only 42% of the thiosulfonate (cf. eq. [6]) as well as 20% of *p*-toluenesulfonyl bromide.

Attempts to react *p*-toluenesulfonhydrazide with benzenetellurinic acid ($PhTeO_2H$) (19), phenyltellurium trichloride ($PhTeCl_3$) (20), or phenyltellurium tribromide ($PhTeBr_3$) (20) all failed to afford significant quantities of the corresponding tellurosulfonate RSO_2TePh (**5**, R = *p*-tolyl). In each case diphenyl ditelluride (PhTeTePh) was the only major tellurium-containing product that could be isolated.

These experiments demonstrate that sulfonhydrazides can be used as convenient precursors of both selenosulfonates and thiosulfonates, but not of tellurosulfonates.

Experimental

Melting points were obtained on an A. H. Thomas hot-stage apparatus and are uncorrected. Spectroscopic data were recorded on the following instruments, ir: Perkin–Elmer 467 or Nicolet 5DX FTIR; ^1H nmr: Hitachi Perkin–Elmer R24B or Varian XL200; ms: Varian MAT CH5 or Kratos MS80. All nmr spectra were obtained in $CDCl_3$ solution with internal TMS as the standard unless otherwise indicated. Elemental analyses were performed by Dr. W. S. Lin (University of Calgary) or by Guelph Chemical Laboratories.

Benzeneseleninic acid, diphenyl diselenide, and benzeneselenenyl chloride were purchased from the Aldrich Co. and used without further purification. Sulfonhydrazides were obtained from commercial sources except for the following compounds, which were prepared by literature methods: 4-methoxybenzenesulfonhydrazide (21), 3-, 4-, and 2,4-dinitrobenzenesulfonhydrazides (22), and methanesulfonhydrazide (23). Diphenyl ditelluride (24) and phenyltellurium trihalides (20) were obtained by published procedures. Benzenetellurinic acid (19) was prepared by the hydrolysis of $PhSeBr_3$, according to a known general method (25). Diphenyl, di-*n*-amyl, and dibenzyl disulfides, as well as all other required reagents, were purchased commercially and purified by standard methods as necessary.

[5]It has been reported that selenium trihalides are in equilibrium with the corresponding selenenyl halides and free halogen (18), as in the following example: $PhSeBr_3 \rightleftharpoons PhSeBr + Br_2$.

Preparation of selenosulfonates via the oxidation of sulfonhydrazides with $PhSeO_2H$ (see Table 1)

Se-Phenyl p-*tolueneselenosulfonate (entries 1 and 2)*

p-Toluenesulfonhydrazide (18.6 g, 100 mmol) in 75 mL of methanol was added dropwise over ca. 15 min to a suspension of benzeneseleninic acid (18.9 g, 100 mmol) in 75 mL of methanol at 0°C. Vigorous evolution of nitrogen was observed. The solution gradually turned clear yellow and towards the end of the addition a yellow precipitate formed. After cooling at −5°C overnight, the product was filtered to afford 27.65 g of the title compound, mp 77–78°C (lit. (26) mp 77–79°C.). The concentrated mother liquor provided a second crop of 2.25 g, mp 70–73°C. Total yield: 96%.

When the reaction was repeated with 20 mmol of each reactant in dichloromethane, the yield of the selenosulfonate was 92% after evaporation *in vacuo* and recrystallization from methanol, mp 79.5–80°C.

Se-Phenyl benzeneselenosulfonate (entry 3)

The procedure of entry 2 was followed to afford 88% of the title compound, mp 56–58°C (lit. (9) mp 51°C).

Se-Phenyl 2,4,6-trimethylbenzeneselenosulfonate (entry 4)

The procedure of entry 1 was followed to afford 91% of the title compound, mp 75–76°C (from methanol); ir ($CHCl_3$): 1315, 1133 cm^{-1}; ^1H nmr (60 MHz) δ: 7.55–7.25 (m, 5H), 6.82 (s, 2H), 2.31 (s, 6H), 2.29 (s, 3H); mass spectrum, *m/e*: 340 (M^+, ^{80}Se), 338 (M^+, ^{78}Se). *Anal.* calcd. for $C_{15}H_{16}O_2SSe$: C 53.07, H 4.76, S 9.46; found: C 53.40, H 4.87, S 9.58.

Se-Phenyl 4-methoxybenzeneselenosulfonate (entry 5)

The procedure of entry 2 was followed to afford 83% of the title compound, mp 79–80°C (from methanol); ir (Nujol): 1316, 1139 cm^{-1}; ^1H nmr (60 MHz) δ: 7.60–7.25 (m, 7H), 6.82 (d, J = 9 Hz, 2H), 3.88 (s, 3H); mass spectrum, *m/e*: 328 (M^+, ^{80}Se), 326 (M^+, ^{78}Se). *Anal.* calcd. for $C_{13}H_{12}O_3SSe$: C 47.69, H 3.70, S 9.80; found: C 47.85, H 3.85, S 10.19.

Se-Phenyl 3-nitrobenzeneselenosulfonate (entry 6)

3-Nitrobenzenesulfonhydrazide (108 mg, 0.50 mmol) was added in portions over 15 min to $PhSeO_2H$ (104 mg, 0.55 mmol) in 10 mL of dichloromethane. The solvent was removed *in vacuo* and the residue was separated by preparative tlc on silica gel with 20% chloroform–benzene to furnish 139 mg (82%) of the title compound, mp 125–127°C (from methanol); ir (KBr): 1545, 1350, 1320, 1145 cm^{-1}; ^1H nmr (60 MHz) δ: 8.42 (dt, J = 8, 2 Hz, 1H), 8.21 (t, J = 2 Hz, 1H), 7.85 (dt, J = 8, 2 Hz, 1H), 7.65–7.20 (m, 6H); mass spectrum, *m/e*: 343 (M^+, ^{80}Se), 341 (M^+, ^{78}Se). *Anal.* calcd. for $C_{12}H_9NO_4SSe$: C 42.12, H 2.65, N 4.09, S 9.37; found: C 41.76, H 2.64, N 4.00, S 9.24.

Se-Phenyl 4-nitrobenzeneselenosulfonate (entry 7)

4-Nitrobenzenesulfonhydrazide (0.87 g, 4.0 mmol) was added in portions over 15 min to $PhSeO_2H$ (0.76 g, 4.0 mmol) in 75 mL of dichloromethane. After stirring for several additional minutes, a small amount of insoluble material was filtered, the filtrate was concentrated, and the product crystallized upon addition of hexane to give 1.14 g (83%), mp 143–145°C; ir (KBr): 1528, 1351, 1308, 1134 cm^{-1}; ^1H nmr (60 MHz) δ: 8.28 (d, J = 8 Hz, 2H), 7.65 (d, J = 8 Hz, 2H), 7.41 (br s, 5H); mass spectrum, *m/e*: 343 (M^+, ^{80}Se), 341 (M^+, ^{78}Se). *Anal.* calcd. for $C_{12}H_9NO_4SSe$: C 42.12, H 2.65, N 4.09, S 9.37; found: C 42.30, H 2.59, N 4.11, S 9.61.

Se-Phenyl 2,4-dinitrobenzeneselenosulfonate (entry 8)

The preceding procedure was followed to afford 68% of the title compound, mp 147–150°C (from dichloromethane–hexane); ir (Nujol): 1566, 1540, 1362, 1344, 1319, 1135 cm^{-1}; ^1H nmr (60 MHz, DMSO-d_6) δ: 8.91 (d, J = 3 Hz, 1H), 8.55 (dd, J = 8, 3 Hz, 1H), 7.61 (d, J = 8 Hz, 1H), 7.55 (m, 5H); mass spectrum, *m/e*: 388 (M^+, ^{80}Se), 386 (M^+, ^{78}Se). *Anal.* calcd. for $C_{12}H_8N_2O_6SSe$: C 37.20, H 2.08, N 7.24, S 8.18; found: C 38.12, H 2.30, N 7.35, S 8.37. Attempts at further purification by crystallization resulted in decomposition.

Se-Phenyl methaneselenosulfonate (entry 9)

The procedure of entry 2 was followed to afford 65% of the title compound, mp 88–90°C (from methanol); ir ($CHCl_3$): 1330, 1131 cm^{-1}; ^1H nmr (60 MHz, CCl_4) δ: 7.80 (m, 2H), 7.46 (m, 3H), 3.18 (s, 3H); mass spectrum, *m/e*: 236 (M^+, ^{80}Se), 234 (M^+, ^{78}Se). *Anal.* calcd. for $C_7H_8O_2SSe$: C 35.73, H 3.43, S 13.64; found: C 35.87, H 3.59, S 13.48.

Reaction of p-*toluenesulfonhydrazide with PhSeCl*

The sulfonhydrazide (186 mg, 1.00 mmol) in 2 mL of dichloromethane was added dropwise to a solution of PhSeCl (574 mg, 3.00 mmol) and pyridine (0.24 mL, 3 mmol) in 4 mL of dichloromethane at 0°C. After 15 min, the mixture was concentrated *in vacuo* and separated by flash chromatography on silica gel. Diphenyl diselenide was eluted with hexane and elution with 60% dichloromethane–hexane afforded 300 mg (96%) of Se-phenyl *p*-tolueneselenosulfonate (**1**, R = *p*-tolyl), mp 76–78°C.

Reaction of p-*toluenesulfonhydrazide with $PhSeBr_3$*

Bromine (77 μL, 1.5 mmol) in 2 mL of dichloromethane was added dropwise to a solution of PhSeSePh (157 mg, 0.50 mmol) in 2 mL of dichloromethane at 0°C and stirring was continued for 1.5 h. A solution of the sulfonhydrazide (186 mg, 1.00 mmol) and pyridine (0.24 mL, 3 mmol) in 3 mL of dichloromethane was then added to the $PhSeBr_3$ solution at 0°C. The mixture was concentrated and flash chromatographed over silica gel. A small amount of PhSeSePh was removed with hexane, followed by elution of *p*-toluenesulfonyl bromide (50 mg, 21%) with 30% dichloromethane–hexane, mp 90–93°C (lit. (27) mp 93–94°C), identified by its ir and mass spectra. Further elution with 40% dichloromethane–hexane afforded 188 mg (60%) of the selenosulfonate **1** (R = *p*-tolyl), mp 74–76°C.

Reaction of p-*toluenesulfonhydrazide with $PhSeCl_3$*

Sulfuryl chloride (0.12 mL, 1.5 mmol) was added to PhSeSePh (157 mg, 0.50 mmol) in 1 mL of dichloromethane at 0°C and stirring was continued for 0.5 h. The $PhSeCl_3$ thus produced was then treated with the sulfonhydrazide and pyridine as in the preceding procedure to afford 21 mg (11%) of *p*-toluenesulfonyl chloride, identical to an authentic sample, and 257 mg (83%) of the selenosulfonate **1** (R = *p*-tolyl), mp 77–78°C.

Preparation of thiosulfonates from sulfonhydrazides and sulfur halides (see Table 2)

S-*Phenyl* p-*toluenethiosulfonate (entries 1, 2, and 5)*

Bromine (77 μL, 1.5 mmol) in 2 mL of dichloromethane was added to PhSSPh (327 mg, 1.50 mmol) in 2 mL of dichloromethane at 0°C. After several minutes, *p*-toluenesulfonhydrazide (186 mg, 1.00 mmol) and pyridine (0.24 mL, 3.0 mmol) in 3 mL of dichloromethane was added to the sulfenyl bromide solution. The mixture was concentrated and separated by flash chromatography to furnish 257 mg (118% based on the expected formation of 1.0 mmol) of PhSSPh (eluant: hexane), 48 mg (20%) of *p*-toluenesulfonyl bromide (eluant: 20% dichloromethane–hexane), mp 92–93°C, identical to the sample prepared from the sulfonhydrazide and $PhSeBr_3$, and 172 mg (65%) of the title compound, mp 75–76°C (lit. (28) mp 75–76°C), with an ir spectrum as reported in the literature (28).

In a second experiment, sulfuryl chloride (0.12 mL, 1.5 mmol) was added to PhSSPh (327 mg, 1.5 mmol) in 1 mL of dichloromethane containing a trace of triethylamine at 0°C. After several minutes, the sulfonhydrazide and pyridine were added to the resulting sulfenyl chloride as in the above procedure. Flash chromatography in the same manner provided 230 mg (105% based on the expected formation of 1.0 mmol) of PhSSPh and 209 mg (79%) of the title compound, mp 73–75°C.

In a third experiment, bromine (77 μL, 1.5 mmol) in 2 mL of dichloromethane was added to PhSSPh (109 mg, 0.50 mmol) in 2 mL of dichloromethane at 0°C. The addition of the sulfonhydrazide and pyridine to the resulting $PhSBr_3$ solution, and subsequent flash chromatography, were performed as in the preceding two procedures. The products thus obtained were 48 mg (20%) of *p*-toluenesulfonyl bromide, mp 92°C, and 111 mg (42%) of the title compound, mp 73–75°C.

S-n-*Amyl 2,4,6-trimethylbenzenethiosulfonate (entry 3)*

The procedure of entry 2 was followed to afford 88% of the title compound as a colourless oil, bp 132–134°C (0.2 Torr; 1 Torr =

133.3 Pa) by short-path distillation; ir (film): 1602, 1325, 1141, 1047, 1033, 853, 714, 645 cm^{-1}; ^1H nmr (200 MHz) δ: 6.97 (s, 2H), 3.03 (t, $J = 7$ Hz, 2H), 2.70 (s, 6H), 2.31 (s, 3H), 1.6 (m, 2H), 1.3 (m, 4H), 0.83 (t, $J = 7$ Hz, 3H); mass spectrum, m/e: 286 (M^+). *Anal.* calcd. for $C_{14}H_{22}O_2S_2$: C 58.74, H 7.69, S 22.37; found: C 58.54, H 7.83, S 22.23.

S-Benzyl 4-methoxybenzenethiosulfonate (entry 4)

The procedure of entry 2 was followed to afford 89% of the title compound as a colourless oil, bp 185–188°C (0.25 Torr) by short-path distillation; ir (film): 1593, 1496, 1326, 1263, 1137, 1080, 1024, 834, 802, 701, 660 cm^{-1}; ^1H nmr (200 MHz) δ: 7.78 (d, $J = 9$ Hz, 2H), 7.23 (m, 5H), 6.92 (d, $J = 9$ Hz, 2H), 4.25 (s, 2H), 3.88 (s, 3H); mass spectrum, m/e: 294 (M^+). *Anal.* calcd. for $C_{14}H_{14}O_3S_2$: C 57.14, H 4.76, S 21.76; found: C 57.14, H 4.85, S 21.83.

Attempted preparation of tellurosulfonates

The reaction of *p*-toluenesulfonhydrazide with $PhTeO_2H$, $PhTeBr_3$, and $PhTeCl_3$ was performed in both methanol and dichloromethane, with and without the presence of pyridine. In each case flash chromatography on silica gel afforded 55–60% of diphenyl ditelluride, identical to an authentic sample. The only other tellurium-containing products were either insoluble or highly polar, and were not isolated.

Synthesis of 11- and 12-membered rings by a direct cyclization method

DENIS BRILLON AND PIERRE DESLONGCHAMPS[1]

Laboratoire de synthèse organique, Département de chimie, Faculté des sciences, Université de Sherbrooke, Sherbrooke (Qué.), Canada J1K 2R1

Received May 1, 1986

This paper is dedicated to Dr. O. E. (Ted) Edwards

DENIS BRILLON and PIERRE DESLONGCHAMPS. Can. J. Chem. **65**, 43 (1987).

The malonate anion intramolecular displacement of propargylic or allylic chlorides, and of primary bromide, in eleven- and twelve-carbon chains containing either two, one, or no unsaturation centers leads to the corresponding 11- and 12-membered ring compounds in good yield under conditions of medium dilution.

DENIS BRILLON et PIERRE DESLONGCHAMPS. Can. J. Chem. **65**, 43 (1987).

Le déplacement intramoléculaire de bromure primaire et de chlorures allyliques ou propargyliques par l'anion malonate de chaînes de onze et douze carbones contenant soit deux, une ou aucune insaturation conduit aux composés cycliques à 11 et 12 membres correspondants, avec d'excellents rendements dans des conditions de dilution moyenne.

The study of the conformation and the chemical reactivity of medium and large carbocyclic and heterocyclic rings containing various functional groups and substituents is an interesting area of research that has so far been essentially unexplored.[2,3] The discovery of reliable direct methods of cyclization for the preparation of these macrocyclic compounds is an important step in starting such a study.

We have recently reported (1) that 10-membered rings can be obtained in good yield by a direct method of cyclization at 10^{-2} and 10^{-3} molar solutions (not high dilution) provided that the aliphatic chains contain two unsaturation centers (double or triple bond). The success of this method was due to the presence of the unsaturation centres, which diminish the number of degrees of freedom of the chain and which eliminate, at the same time, most of the transannular steric interactions (the two main factors that render macrocyclization difficult).

Since previous studies on cyclization of aliphatic saturated chains have shown generally the difficulty of preparing C-9 to C-12 membered rings (with a drop in yield for C-10) (4), we have undertaken a study of 11- and 12-membered ring formation via the above strategy and we wish to report this work.[4]

Cyclization reactions were carried out for the C-11 and C-12 acyclic precursors **1***a* and **1***b* (Scheme 1), which have two unsaturation centers (either a triple bond or a double bond (*cis* or *trans*)), and which can yield either the corresponding cyclic monomers (**2***a* and **2***b*) or dimers (**3***a* and **3***b*) in competition with the polymerization process. The cyclization of the C-11 and C-12 acyclic precursors **4***a* and **4***b* containing only one unsaturation center (a triple bond) was also studied. Similarly, the cyclization of the C-11 and C-12 saturated precursors **5***a* and **5***b* was also carried out to confirm the validity of our approach. In competition with the polymerization process, compounds **4***a,b* and **5***a,b* can yield either their corresponding cyclic monomers (**6***a,b* and **7***a,b* respectively) or dimers (structures not shown).

An interesting synthetic route for the preparation of all the C-11 and C-12 precursors, starting with simple acetylene derivatives, was found, and is summarized in Schemes 2–4. The C-6 and C-7 acetylenic key intermediates **8***a* and **8***b* were prepared as described in Scheme 2. Using these two intermediates, the corresponding C-6 and C-7 intermediates having a *cis* olefin (**9***a* and **9***b*), a *trans* olefin (**10***a* and **10***b*), or no unsaturation (**11***a* and **11***b*) were prepared as shown in Scheme 3. The same scheme summarizes also the conversion of the C-6 and C-7 key intermediates **8***a*, **8***b*, **9***a*, **9***b*, **10***a*, and **10***b* respectively into the C-11 and C-12 doubly unsaturated aliphatic precursors **1***a* and **1***b* [A–A, A–T, A–C, T–T, T–C, and C–C] (A = acetylene, T = *trans* olefin, and C = *cis* olefin). It also describes the preparation of the mono-unsaturated C-11 and C-12 aliphatic chains **4***a* and **4***b* (containing one triple bond) from the saturated C-6 and C-7 intermediates **11***a* and **11***b*, as well as the formation of the fully saturated C-11 and C-12 aliphatic chains **5***a* and **5***b* obtained respectively from the catalytic hydrogenation of **4***a* and **4***b*.

The general strategy for the preparation of the unsaturated C-11 and C-12 aliphatic chains **1***a*, **1***b*, **4***a*, and **4***b* from the C-6 and C-7 aliphatic chains is further detailed in Scheme 4: alkylation of intermediates **8**–**11** (*a* or *b*) with an appropriate alkylating agent (*cis* or *trans* 1,4-dichloro-2-butene or 1,4-dichloro-2-butyne) gave the corresponding chlorides **14***a* and **14***b*. SN_2 displacement of these chlorides with dimethyl malonate gave the THP-malonates **15***a* and **15***b*. Acid hydrolysis then provided the primary alcohol malonates **16***a* and **16***b*, which were then respectively converted into the C-11 and C-12 allylic or propargylic chlorides **1***a* and **1***b* [A–A, A–T, A–C, T–T, T–C, and C–C] as well as the primary bromides **4***a* and **4***b*.

The reactions of cyclization were performed at 2×10^{-2} and 2×10^{-3} molar dilution and not high dilution. The results are summarized in Tables 1 and 2 for the 11- and 12-membered rings respectively. The monomers and dimers are readily separated by column chromatography. All the cyclic monomers (except for **2***a* [T–T]) and dimers are crystalline compounds. For all new substances, the spectra (ir, 250-MHz and 80-MHz ^{1}H nmr, ^{13}C nmr, and high resolution mass spectra) were in complete agreement with the assigned structures. The corresponding ^{1}H nmr, ^{13}C nmr, and mass spectral characteristics and melting points for the cyclic compounds are listed in Table 3.

As previously observed with C-10 aliphatic chains (1), dimerization always competes effectively with the polymerization process, even at 10^{-2} *M*. At 10^{-3} *M*, the monomers are generally produced in a yield greater than 60% except for **2***a* [C–C] (54%), **2***a* [T–T] (32%), **2***a* [A–T] (44%), and **2***b* [C–T] (38%). Better yields of monomers are obtained in the C-12 series except for **2***b* [C–T] and **2***b* [A–A]. The increase in yield of monomer on passing from the saturated chain to the monoacetylene and to the bisacetylene is clearly seen in the

C-12 series (29, 39, and 79%), but is much more dramatic in the C-11 series (2, 40, and 87%). This must be a consequence of the transannular steric interactions, which must be more important in the C-11 than in the C-12 series. Further analysis of these results requires detailed molecular modeling studies.

In conclusion, the above results fully illustrate the use of unsaturation in the chain to obtain good yield in macrocyclization processes. We have also studied the cyclization of 13- and 14-membered rings and these results are reported in the following publication (13).

Experimental

Proton nmr spectra ($CDCl_3$) were recorded on Bruker WP-80 and WM-250 instruments. The ^{13}C nmr spectra were recorded on a Bruker WM-250 instrument. Infrared (ir) spectra were recorded on a Perkin–Elmer 681 spectrophotometer ($CHCl_3$). Mass spectra (ms) and peak matching assays were obtained using a VG Micromass ZAB-1F mass spectrometer. Vapor phase chromatographic (vpc) analysis was performed on a Hewlett–Packard 5710A gas chromatograph with flame ionization detection (capillary column OV-101, 25 m). Melting points were determined on a Reichert apparatus. For flash chromatography, silica gel Kiesel gel 60 (230–400 mesh ASTM) from Merck was used.

All reactions were carried out under an argon atmosphere. Ground anhydrous potassium carbonate was used for cyclization reactions. Tetrahydrofuran was dried by distilling over sodium/benzophenone, whereas *N,N*-dimethylformamide was dried over calcium hydride, followed by decantation and distillation under reduced pressure. All reagents were distilled prior to use: 1,4-dichloro-2-butyne (Aldrich) was thus obtained in 99% purity (vpc analysis), *cis*-1,4-dichloro-2-butene in 95% purity, and *trans*-1,4-dichloro-2-butene in 85% purity (contaminated with *cis* isomer) from distillation.

Purification of trans-*1,4-dichloro-2-butene*

Freshly distilled *trans*-1,4-dichloro-2-butene (150 mL) was kept in a closed addition funnel for 16 h at −15°C (freezer). The remaining liquid (found to be a 1:2 mixture of *cis* and *trans* isomers from vpc

analysis) was removed and the remaining crystals were washed twice with 10 mL of diethyl ether precooled to −30°C. After warming to 25°C and removal of solvent under vacuum, 62 g of 98.5% pure *trans* isomer was obtained (contaminated with 1.4% of *cis* isomer).

General Procedure 1:

Propargyl alcohol tetrahydropyranyl ether ***17***

To a stirred solution of dihydropyran (45.5 g, 0.542 mol) and trifluoroacetic acid (0.15 g, 1.3 mmol) in dichloromethane (200 mL), was added over a 30-min period a solution of propargyl alcohol (26.8 g, 0.514 mol) dissolved in dichloromethane (50 mL). After 18 h of stirring, the mixture was distilled under vacuum to afford compound **17** as a liquid (66.9 g, 93%); bp 54–56°C (3 Torr; 1 Torr = 133.3 Pa); ir: 3280, 2115, and 1025 cm^{-1}; ^{1}H nmr δ: 1.30–1.80 (6H, m, C—$(CH_2)_3$—C), 2.38 (1H, t, J = 2.4 Hz, —C≡C—H), 3.45–4.00 (2H, m, —OCH_2—, cyclic), 4.22 (2H, d, J = 2.3 Hz, —OCH_2—C≡C—), 4.80 (1H, m, —O_2CH—).

*5-[(Tetrahydro-2*H*-pyran-2-yl)oxy]-3-pentyn-1-ol (****18****)*

To a stirred solution of **17** (3.00 g, 21.4 mmol), hexamethylphosphoramide (1.14 mL, 6.40 mmol), and triphenylmethane (1 mg) dissolved in diethyl ether (30 mL) and tetrahydrofuran (12 mL), was added *n*-butyllithium (1.6 *M* in hexanes) until the coloration change from yellow to orange at −40°C. Neat ethylene oxide (2.2 mL, 43 mmol) was added at 25°C through the septum and the reaction mixture was stirred for 30 h. Diethyl ether (200 mL) was added and the organic phase was washed twice with brine/water (4:1) (50 mL), dried on sodium sulfate, and evaporated to give crude alcohol **18** as an oil (4.08 g, 103%); ir: 3620, 3200–3600, 1025 cm^{-1}; ^{1}H nmr δ: 1.60 (6H, m, —$C(CH_2)_3$C—), 2.07 (1H, m, —OH), 2.47 (2H, m, —CCH_2C≡C—), 3.40–4.00 (4H, m, —CH_2O—), 4.22 (2H, m, THPOCH_2—), 4.77 (1H, m, —O_2CH—).

General Procedure 2:

Bromide ***19****a from alcohol* ***18***

To a solution of alcohol **18** (4.08 g crude), carbon tetrabromide

(9.50 g, 28.6 mmol, 1.15 equiv.), and pyridine (0.4 mL) in dichloromethane (70 mL) at 0°C, was added rapidly a solution of triphenylphosphine (8.13 g, 30.9 mmol, 1.3 equiv.) in dichloromethane (10 mL). The solution was stirred 1 h at 0°C, then left overnight at 25°C. The solvent was evaporated, followed by the addition of dichloromethane (10 mL) and hexanes (150 mL), filtration, and evaporation. Bromide **19***a* was obtained as an oil (3.48 g, 66% from **17**) by flash chromatography (hexanes/ethyl acetate 15:1); ir: 2240, 1018 cm^{-1}; ^1H nmr δ: 1.30–1.80 (6H, m, —$C(CH_2)_3C$—), 2.65–2.90 (2H, m, —$CCH_2C{\equiv}C$—), 3.43 (2H, t, J = 6 Hz, —CH_2Br), 3.40–4.00 (2H, m, —OCH_2—, cyclic), 4.24 (2H, m, —$OCH_2C{\equiv}C$—), 4.80 (1H, m, —O_2CH—); ms m/e: 247 (MH^+).

*1-Bromo-6-[(tetrahydro-2H-pyran-2-yl)oxy]-4-hexyne (**19**b)*

To a solution of acetylene **17** (10.0 g, 71.4 mmol), hexamethylphosphoramide (1.25 mL, 7.0 mmol), and triphenylmethane (3 mg) in tetrahydrofuran (200 mL) was added *n*-butyllithium (1.6 *M* in hexane) at −40°C until the color of the solution passed from yellow to orange. To this solution was added distilled 1,3-dibromopropane (36 mL, 356 mmol) and the mixture was refluxed for 28 h. To the cooled solution was added diethyl ether (200 mL) and the organic phase was washed with water (3 × 50 mL) and dried over sodium sulfate. Volatile materials were evaporated and pure bromide **19***b* was obtained from a Kugelrohr distillation (65–75°C at 0.015 Torr) (15.0 g, 83%); ir: 2200, 1020 cm^{-1}; ^1H nmr δ: 1.30–1.80 (6H, m, —$C(CH_2)_3C$—), 2.03 (2H, m, —CH_2CH_2Br), 2.42 (2H, m, —CH_2—$CH_2C{\equiv}C$—), 3.50 (2H, t, J = 6 Hz, —CH_2Br), 3.40–4.00 (2H, m, —OCH_2—, cyclic), 4.23 (2H, m, —$C{\equiv}C$—CH_2O—), 4.78 (1H, m, —O_2CH—); ms m/e: 261 (MH^+).

General Procedure 3:

*Malonate **8**a from **19**a*

To a solution of bromide **19***a* (3.43 g, 13.9 mmol) and dimethyl malonate (7.9 mL, 69.2 mmol) in tetrahydrofuran (55 mL) and *N,N*-dimethylformamide (18 mL) at room temperature (r.t.), was added sodium hydride (1.01 g, 25.2 mmol, 60% in mineral oil). The solution was refluxed for 1.5 h. Hexane (20 mL) and water (100 mL) were then added at r.t. The aqueous phase was washed with a 1:1 mixture of diethyl ether and hexane (2 × 30 mL). Combined organic phases were dried on sodium sulfate. The solvents were evaporated and volatile materials distilled at 90°C (oil bath temperature) at 1 Torr. Compound **8***a* was obtained pure by flash chromatography (ethyl acetate/dichloromethane/hexanes 1:2:7) (3.78 g, 91%); ir: 1732 cm^{-1}; ^1H nmr δ: 1.61 (6H, m, —$C(CH_2)_3C$—), 1.95–2.40 (4H, m, —$C{\equiv}C$—$(CH_2)_2$—), 3.35–4.00 (3H, m, —$CH(CO_2Me)_2$ and —OCH_2—, cyclic), 3.74 (6H, s, CH_3), 4.24 (2H, m, —$C{\equiv}CCH_2O$—), 4.78 (1H, m, —O_2CH—); ms m/e: 299 (MH^+).

*Methyl 2-carbomethoxy-8-[(tetrahydro-2H-pyran-2-yl)oxy]-6-octynoate (**8**b)*

To a solution of bromide **19***b* (15.0 g, 57.4 mmol) and dimethyl malonate (33.6 mL, 294 mmol) in a 1:1 mixture of tetrahydrofuran and *N,N*-dimethylformamide (220 mL) was added potassium carbonate (40.6 g, 294 mmol). The mixture was heated at 90°C for 15 h. Hexane (100 mL) was then added at r.t. The mixture was filtered on Celite, the solvents were evaporated, and the volatile materials removed by Kugelrohr distillation (30°C, 0.02 Torr). The crude residue was dissolved in diethyl ether (250 mL) and washed with a 5% aqueous solution of sodium bicarbonate (3 × 50 mL). The organic phase was dried on magnesium sulfate and evaporation of solvents afforded pure malonate **8***b* as an oil (17.5 g, 98%); ir: 1740 cm^{-1}; ^1H nmr δ: 1.30–1.80 (8H, m, —$C(CH_2)_3$—C and —$CH_2CH_2CH_2C{\equiv}C$—), 1.80–2.30 (4H, m, —$CH_2CH_2CH_2C{\equiv}C$—), 3.38 (1H, t, J = 6 Hz, —$CH(CO_2Me)_2$), 3.40–4.00 (2H, m, —OCH_2—, cyclic), 3.73 (6H, s, CH_3), 4.22 (2H, m, —$C{\equiv}CCH_2O$—), 4.78 (1H, m, —O_2CH—); ms m/e: 313 (MH^+).

General Procedure 4:

cis-*Alkene **9**a from **8**a*

Malonate **8***a* (2.8 g, 9.4 mmol) was dissolved in cyclohexane (10 mL) and ethyl acetate (2 mL) under argon. Lyndlar catalyst ($Pd/CaCO_3/PbO$ from Aldrich) (0.5 g) was added and this mixture was stirred for 44 h under hydrogen (1.03 atm; 1 atm = 101.3 kPa). The solution was filtered, then evaporated to give pure *cis*-alkene **9***a* (2.8 g, 99.5%); ir: 1736 cm^{-1}; ^1H nmr δ: 1.40–1.80 (6H, m, —$C(CH_2)_3C$—), 1.90–2.20 (4H, m, —$CH_2CH_2C{=}C$—), 3.30–4.30 (5H, m, —$CH(CO_2Me)_2$ and —OCH_2—), 3.73 (6H, s, CH_3), 4.60 (1H, m, —O_2CH—), 5.30–5.80 (2H, m, —HC=CH—); ms m/e: 301 (MH^+).

*Methyl (Z)-2-carbomethoxy-8-[(tetrahydro-2H-pyran-2-yl)oxy]-6-octenoate (**9**b)*

Following procedure 4: Malonate **8***b* (3.00 g, 9.61 mmol) gave, under an hydrogenation pressure of 1.00 atm, alkene **9***b* (2.90 g, 96%); ir: 1740 cm^{-1}; ^1H nmr δ: 1.20–2.25 (12H, m, C—CH_2—C), 3.20–4.30 (5H, m, —$CH(CO_2Me)_2$ and —OCH_2—), 3.72 (6H, s, CH_3), 4.60 (1H, m, —O_2CH—), 5.25–5.80 (2H, m, H—C=C—H); ms m/e: 315 (MH^+).

General Procedure 5:

*Alcohol **12**a from **8**a*

Malonate **8***a* (2.35 g, 7.88 mmol) was dissolved in methanol (18 mL) containing pyridinium *p*-toluenesulfonate (170 mg, 0.67 mmol). This solution was refluxed for 1.5 h, and methanol was evaporated under vacuum. The residue was dissolved in methylene dichloride (5 mL) and filtered on silica gel (hexanes/dichloromethane/ethyl acetate 2:2:1) until complete recovery of alcohol **12***a*, which was obtained as a colorless oil (1.68 g, 99.5%); ir: 3600 and 1732 cm^{-1}; ^1H nmr δ: 1.90 (1H, m, —OH), 2.00–2.40 (4H, m, —CH_2CH_2—), 3.57 (1H, t, J = 6 Hz, —$CH(CO_2Me)_2$), 3.74 (6H, s, CH_3), 4.23 (2H, m, —CH_2OH); ms m/e: 215 (MH^+).

General Procedure 6:

trans-*Allylic alcohol **13**a*

A solution of chromous chloride was prepared by the slow addition, under an argon stream, of chrome powder (3.34 g, 64.2 mmol, 325 mesh from Aldrich) to a 8:9 mixture of degassed water and concentrated hydrochloric acid (15 mL) at 10°C. After 45 min of stirring, deoxygenated water (80 mL) was added, followed by sodium acetate (2.50 g, 30.5 mmol) and sodium sulfate (4.40 g, 30.9 mmol). Alcohol **12***a* (1.68 g, 7.84 mmol), dissolved in deoxygenated *N,N*-dimethylformamide (30 mL), was added to the chromous solution and stirred for 45 h at 25°C. The reaction mixture was extracted with diethyl ether (7 × 50 mL), dried on sodium sulfate, and evaporated. The alcohol **13***a* was purified by flash chromatography (ethyl acetate/dichloromethane/hexanes 1:2:2) (1.30 g, 77%); ir: 1732 cm^{-1}; ^1H nmr δ: 1.26 (1H, m, —OH), 2.07 (4H, m, —CH_2CH_2—), 3.39 (1H, t, —$CH(CO_2Me)_2$), 3.74 (6H, s, CH_3), 4.10 (2H, m, —CH_2O—), 5.67 (2H, m, —HC=CH—); ms m/e: 217 (MH^+).

*Methyl (E)-2-carbomethoxy-7-[(tetrahydro-2H-pyran-2-yl)oxy]-5-heptenoate (**10**a)*

Following procedure 1: Alcohol **13***a* (370 mg, 1.72 mmol) was transformed into **10***a*, which was purified by flash chromatography (ethyl acetate/dichloromethane/hexanes 1:2:7) (466 mg, 91%); ir: 1732 cm^{-1}; ^1H nmr δ: 1.40–1.80 (6H, m, C—$(CH_2)_3$—C), 2.06 (4H, m, —$C{=}CCH_2CH_2$—), 3.30–4.30 (5H, m, —$CH(CO_2Me)_2$ and —CH_2O—), 3.73 (6H, s, CH_3), 4.62 (1H, m, —O_2CH—), 5.64 (2H, m, —HC=CH—); ms m/e: 301 (MH^+).

*Methyl (E)-2-carbomethoxy-8-hydroxy-6-octenoate (**13**b)*

The malonate **8***b* was converted directly into alcohol **13***b* via a modification of procedure 6: the malonate **8***b* (2.00 g, 6.37 mmol) was heated for 4 h at 60°C under the conditions of procedure 6 without using sodium acetate. Then sodium acetate (1.80 g, 21.9 mmol) was added at 25°C and, after 36 h, the alcohol **13***b* was isolated (1.23 g, 84%); ir: 1733 cm^{-1}; ^1H nmr δ: 1.30–2.20 (6H, m, —$(CH_2)_3$—), 3.36 (1H, t, —$CH(CO_2Me)_2$), 3.73 (6H, s, CH_3), 4.10 (2H, m, —CH_2O—), 5.66 (2H, m, —HC=CH—); ms m/e: 231 (MH^+).

*Methyl (E)-2-carbomethoxy-8-[(tetrahydro-2H-pyran-2-yl)oxy]-6-octenoate (**10**b)*

Following procedure 1: Malonate **10***b* (1.55 g, 92%) was obtained from alcohol **13***b* (1.23 g, 5.35 mmol); ir: 1740 cm^{-1}; ^1H nmr δ: 1.30–2.20 (12H, m, C—CH_2—C), 3.36 (1H, t, J = 6 Hz, —$CH(CO_2Me)_2$),

[a]For notation: C (*cis*), T (*trans*), A (Acetylene).
[b]"E" refers to the ester group (CO_2Me).
[c]Only for monomers; mass spectra for dimers; calculated values in parentheses.
[d]Recrystallized sample ($CHCl_3$/hexanes).
[e]Unrecrystallized sample.

3.40–4.30 (4H, m, —OCH_2—), 3.73 (6H, s, CH_3), 4.62 (1H, m, —O_2CH—), 5.64 (2H, m, H—C=C—H); ms *m/e*: 315 (MH^+).

General Procedure 7:

Saturated malonate ***11****a from* ***8****a*

Malonate **8***a* (1.80 g, 6.04 mmol) was dissolved under an argon atmosphere in a 5:1 mixture of cyclohexane and ethyl acetate (12 mL). To this solution was added 5% palladium on charcoal (100 mg) and the solution was stirred under hydrogen (1.0 atm) until gas uptake ceased. The solution was filtered on Celite and the solvents removed to give crude malonate **11***a* (1.81 g, 99%); ir: 1731 cm^{-1}; ^{1}H nmr δ: 1.20–2.05 (14H, m, C—CH_2—C), 3.20–4.10 (5H, m, —$CH(CO_2Me)_2$ and —OCH_2—), 3.73 (6H, s, CH_3), 4.56 (1H, m, —O_2CH—); ms *m/e*: 303 (MH^+).

*Methyl 2-carbomethoxy-8-[(tetrahydro-2*H*-pyran-2-yl)oxy]-octanoate (****11****b)*

Following procedure 7: Crude malonate **11***b* (3.15 g, 100%) was obtained from acetylene **8***b* (3.11 g, 9.97 mmol); ir: 1740 cm^{-1}; ^{1}H nmr δ: 1.10–2.00 (16H, m, C—CH_2—C), 3.10–4.10 (5H, m, —$CH(CO_2Me)_2$ and —OCH_2—), 3.74 (6H, s, CH_3), 4.55 (1H, m, —O_2CH—); ms *m/e*: 317 (MH^+).

General Procedure 8:

*Methyl (*Z*)-2-carbomethoxy-2-[(*Z*)-4-chloro-2-butenyl]-7-[(tetrahydro-2*H*-pyran-2-yl)oxy]-5-heptenoate (****14****a [C–C])*

A mixture of malonate **9***a* (1.30 g, 4.33 mmol) and sodium hydride (207 mg, 5.20 mmol, 60% in mineral oil) in tetrahydrofuran (18 mL) was refluxed for 30 min. (Z)-1,4-Dichloro-2-butene (2.3 mL, 21.6 mmol)

was added at 25°C and the mixture refluxed for 30 min. The solution was cooled to 0°C, followed by the addition of 10% aqueous ammonium chloride (20 mL) and extraction with diethyl ether (3 × 50 mL). The organic phases were dried on sodium sulfate, evaporated, and purified by flash chromatography (ethyl acetate/dichloromethane/hexanes 1:2:8) to afford compound **14***a* [C–C] (1.49 g, 89%) as an oil; ir: 1730 cm^{-1}; ^1H nmr δ: 1.63 (6H, m, C—$(CH_2)_3$—C), 1.97 (4H, m, —CH_2—CH_2—$C(CO_2Me)_2$—), 2.68 (2H, m, —C=$CCH_2C(CO_2Me)_2$—), 3.40–4.20 (4H, m, —OCH_2—), 3.78 (6H, s, CH_3), 4.15 (2H, m, —CH_2Cl), 4.59 (1H, m, —O_2CH—), 5.30–5.80 (4H, m, H—C=C—H); ms *m/e*: 389 (MH^+).

Methyl (Z),(Z)-*2,7,7-tricarbomethoxy-12-[(tetrahydro-2*H*-pyran-2-yl)oxy]-4,10-dodecadienoate (**15**a [C–C])*

Following procedure 3, compound **14***a* [C–C] (1.48 g, 3.8 mmol) was transformed into the malonate **15***a* [C–C] (1.71 g, 92%); ir: 1732 cm^{-1}; ^1H nmr δ: 1.30–1.70 (6H, m, C—$(CH_2)_3$—C), 1.95 (4H, m, —CH_2—CH_2—), 2.65 (4H, m, —C=$CCH_2C(CO_2Me)_2$—), 3.25–4.20 (5H, m, —$CH(CO_2Me)_2$ and —OCH_2—), 3.71, 3.73 (12H, s, CH_3), 4.59 (1H, m, —O_2CH—), 5.20–5.65 (4H, m, H—C=C—H); ms *m/e*: 485 (MH^+).

General Procedure 9:

Methyl (Z),(Z)-*2,7,7-tricarbomethoxy-12-hydroxy-4,10-dodecadienoate (**16**a [C–C])*

Malonate **15***a* [C–C] (1.70 g, 3.51 mmol) was dissolved in methanol (5 mL) containing pyridinium *p*-toluenesulfonate (77 mg, 0.31 mmol) and this solution was stirred at r.t. for 2 days, followed by removal of volatile materials under vacuum. Methanol (10 mL) was added and this solution was stirred for 1 day, followed by evaporation of solvent. The crude oil was filtered on silica gel using ethyl acetate/dichloromethane/hexanes 1:2:2 as eluent and this method afforded alcohol **16***a* [C–C] (1.37 g, 98%) as a pure oil; ir: 3400 (weak), 1732 cm^{-1}; ^1H nmr δ: 1.60 (1H, m, —OH), 1.97 (4H, m, —CH_2CH_2—), 2.66 (4H, m, —C=C—$CH_2C(CO_2Me)_2$), 3.40 (1H, t, —$CH(CO_2Me)_2$), 3.75, 3.76 (12H, s, CH_3), 4.14 (2H, m, —CH_2O—), 5.20–5.70 (4H, m, H—C=C—H); ms *m/e*: 401 (MH^+).

General Procedure 10:

Methyl (Z),(Z)-*2,7,7-tricarbomethoxy-12-chloro-4,10-dodecadienoate (**1**a [C–C])*

To a solution of **15***a* [C–C] (1.36 g, 3.40 mmol), lithium chloride (287 mg, 6.90 mmol), and 2,4,6-collidine (671 μL, 5.45 mmol) in *N,N*-dimethylformamide (35 mL) at 0°C, was added methanesulfonyl chloride (396 μL, 5.45 mmol). This solution was stirred for 2 h at 0°C, 1 h at 25°C, poured onto ice-water (400 mL), and extracted with a mixture of diethyl ether/hexanes 1:1 (4 × 80 mL). The organic phase was dried on sodium sulfate and evaporated. Purification of the resulting oil by flash chromatography, using ethyl acetate/dichloromethane/hexanes 1:2:4 as eluent, afforded compound **1***a* [C–C] as an oil (1.18 g, 83%); ir: 1735 cm^{-1}; ^1H nmr δ: 1.98 (4H, m, —CH_2CH_2—), 2.70 (4H, m, C=$CCH_2C(CO_2Me)_2$—), 3.41 (1H, t, —$CH(CO_2Me)_2$), 3.73, 3.75 (12H, s, CH_3), 4.10 (2H, m, —CH_2Cl), 5.30–5.70 (4H, m, H—C=C—H); ms *m/e*: 419 (MH^+).

General Procedure 11:

(Z),(Z)-*1,1,6,6-Tetracarbomethoxy-3,8-cycloundecadiene* (**2**a *[C–C])* and (Z),(Z),(Z),(Z)-*1,1,6,6,12,12,17,17-octacarbomethoxy-3,9,14,20-cyclodocosatetraene* (**3**a *[C–C])*

To a solution of **1***a* [C–C] (204 mg, 0.489 mmol) in tetrahydrofuran and *N,N*-dimethylformamide (1:1) (24 mL) was added potassium carbonate (330 mg, 2.40 mmol). This mixture was refluxed (oil bath at 90°C) for 45 h, then cooled, and hexane (10 mL) was added followed by filtration on Celite. The solvents were removed under reduced pressure and the residue purified by flash chromatography (ethyl acetate/dichloromethane/hexanes in successive ratios of 1:2:6, 1:2:4, and 1:2:3) to give monomer **2***a* [C–C] (29.4 mg, 15.7%) and dimer **3***a* [C–C] (53.1 mg, 28.4%). Both compounds were recrystallized in a minimum amount of chloroform, followed by addition at 25°C of excess hexanes and cooling to −15°C for a few hours (see Table 3 for melting point); ir of **2***a*: 1730, 1290, 1210 cm^{-1}; ir of **3***a*: 1735, 1230 cm^{-1}.

Methyl (Z)-*2-carbomethoxy-2-[(*E*)-4-chloro-2-butenyl]-7-[(tetrahydro-2*H*-pyran-2-yl)oxy]-5-heptenoate (**14**a [C–T])*

Following procedure 8: Compound **9***a* (1.203 g, 4.01 mmol) was reacted with (*E*)-1,4-dichloro-2-butene (2.1 mL, 20 mmol) to afford **14***a* [C–T] as an oil (1.24 g, 80%); ir: 1730 cm^{-1}; ^1H nmr δ: 1.62 (6H, m, C—$(CH_2)_3$—C), 1.94 (4H, m, —CH_2CH_2—), 2.71 (2H, m, C=$CCH_2C(CO_2Me)_2$—), 3.30–4.00 (2H, m, —CH_2O—, cyclic), 3.73 (6H, s, CH_3), 4.00–4.15 (4H, m, —CH_2Cl and —OCH_2C=C—), 4.61 (1H, m, —O_2CH—), 5.45–5.75 (4H, m, H—C=C—H); ms *m/e*: 389 (MH^+).

Methyl (E),(Z)-*2,7,7-tricarbomethoxy-12-[(tetrahydro-2*H*-pyran-2-yl)oxy]-4,10-dodecadienoate (**15**a [C–T])*

Following procedure 3: Chloride **14***a* [C–T] (1.23 g, 3.17 mmol) gave **15***a* [C–T] (1.51 g, 99%); ir: 1732 cm^{-1}; ^1H nmr δ: 1.61 (6H, m, C—$(CH_2)_3$—C), 1.90 (4H, m, —CH_2CH_2—), 2.54 (4H, m, —C=$CCH_2C(CO_2Me)_2$), 3.40 (1H, t, —$CH(CO_2Me)_2$—), 3.40–4.00 (2H, m, —CH_2O—, cyclic), 3.71, 3.74 (12H, s, CH_3), 4.13 (2H, m, —O—CH_2—C=C—), 4.61 (1H, m, —O_2CH—), 5.53 (4H, m, H—C=C—H); ms *m/e*: 485 (MH^+).

Methyl (E),(Z)-*2,7,7-tricarbomethoxy-12-hydroxy-4,10-dodecadienoate (**16**a [C–T])*

Following procedure 9: Compound **15***a* [C–T] (1.5 g, 3.1 mmol) gave alcohol **16***a* [C–T] (1.24 g, 100%); ir: 3300–3700, 1730 cm^{-1}; ^1H nmr δ: 1.80–1.90 (5H, m, —OH and —CH_2CH_2—), 2.58 (4H, m, —C=$CCH_2C(CO_2Me)_2$—), 3.41 (1H, t, —$CH(CO_2Me)_2$), 3.71 (12H, s, CH_3), 4.15 (2H, m, —CH_2O—), 5.50 (4H, m, H—C=C—H); ms *m/e*: 401 (MH^+).

Methyl (E),(Z)-*2,7,7-tricarbomethoxy-12-chloro-4,10-dodecadienoate (**1**a [C–T])*

Following procedure 10: Chloride **1***a* [C–T] (1.11 g, 86%) was obtained from the alcohol **16***a* [C–T] (1.23 g, 3.07 mmol); ir: 1730 cm^{-1}; ^1H nmr δ: 1.94 (4H, m, —CH_2CH_2—), 2.60 (4H, m, —C=$CCH_2C(CO_2Me)_2$), 3.40 (1H, t, —$CH(CO_2Me)_2$), 3.72 (12H, s, CH_3), 4.05 (2H, m, —CH_2Cl), 5.3–5.7 (4H, m, —HC=CH—); ms *m/e*: 419 (MH^+).

(E),(Z)-*1,1,6,6-Tetracarbomethoxy-3,8-cycloundecadiene* (**2**a *[C–T])* and (E),(Z),(E),(Z)-*1,1,6,6,12,12,17,17-octacarbomethoxy-3,9,14,20-cyclodocosatetraene* (**3**a *[C–T])*

Following procedure 11: After 20 h of treatment chloride **1***a* [C–T] (198 mg, 0.474 mmol) afforded **2***a* [C–T] (38.1 mg, 21%) and **3***a* [C–T] (83.1 mg, 45.8%); ir of **2***a*: 1730, 1280, 1180 cm^{-1}; ir of **3***a*: 1730, 1250 cm^{-1}.

Methyl (E)-*2-carbomethoxy-2-[*(E)*-4-chloro-2-butenyl]-7-[(tetrahydro-2*H*-pyran-2-yl)oxy]-5-heptenoate (**14**a [T–T])*

Following procedure 8: Using (*E*)-1,4-dichloro-2-butene: compound **10***a* (1.58 g, 5.27 mmol) gave chloride **14***a* [T–T] (1.71 g, 84%); ir: 1731 cm^{-1}; ^1H nmr δ: 1.59 (6H, m, C—$(CH_2)_3$—C), 1.97 (4H, m, —CH_2CH_2—), 2.63 (2H, m, C=$CCH_2C(CO_2Me)_2$), 3.40–4.20 (6H, m, —CH_2Cl and —OCH_2—), 3.72 (6H, s, CH_3), 4.61 (1H, m, —O_2CH—), 5.64 (4H, m, —HC=CH—); ms *m/e*: 389 (MH^+).

Methyl (E),(E)-*2,7,7-tricarbomethoxy-12-[(tetrahydro-2*H*-pyran-2-yl)oxy]-4,10-dodecadienoate (**15**a [T–T])*

Following procedure 3: Chloride **14***a* [T–T] (1.71 g, 4.41 mmol) gave **15***a* [T–T] (2.06 g, 97%); ^1H nmr δ: 1.62 (6H, m, C—$(CH_2)_3$—C), 1.94 (4H, m, —CH_2CH_2—), 2.54 (4H, m, C=$CCH_2C(CO_2Me)_2$), 3.40 (1H, t, —$CH(CO_2Me)_2$), 3.30–4.20 (4H, m, —OCH_2—), 3.70, 3.74 (12H, s, CH_3), 4.63 (1H, m, —O_2CH—), 5.2–5.7 (4H, m, —HC=CH—); ms *m/e*: 485 (MH^+).

Methyl (E),(E)-*2,7,7-tricarbomethoxy-12-hydroxy-4,10-dodecadienoate (**16**a [T–T])*

Following procedure 9: Compound **15***a* [T–T] (1.45 g, 3.00 mmol)

gave **16***a* [T–T] (1.17 g, 98%); ir: 3600–3200, 1740, 1733 cm^{-1}; ^1H nmr δ: 1.66 (1H, m, —OH), 1.92 (4H, m, $—CH_2CH_2—$), 2.57 (4H, m, $—C{=}CCH_2C(CO_2Me)_2—$), 3.40 (1H, t, $—CH(CO_2Me)_2$), 3.71, 3.75 (12H, s, CH_3), 4.11 (2H, m, $—CH_2O—$), 5.40–5.80 (4H, m, —HC=CH—).

Methyl (E),(E)-*2,7,7-tricarbomethoxy-12-chloro-4,10-dodecadienoate (1*a *[T–T])*

Following procedure 10: Alcohol **16***a* [T–T] (1.16 g, 2.91 mmol) gave chloride **1***a* [T–T] (0.826 g, 68%); ir: 1739, 1730 cm^{-1}; ^1H nmr δ: 1.92 (4H, m, $—CH_2CH_2—$), 2.55 (4H, m, $—C{=}C—CH_2C(CO_2Me)_2$), 3.38 (1H, t, $—CH(CO_2Me)_2$), 3.70, 3.73 (12H, s, CH_3), 4.03 (2H, m, $—CH_2Cl$), 5.30–5.75 (4H, m, H=C=CH—); ^{13}C nmr δ: 26.6, 31.5, 31.7, 35.9 (CH_2), 44.9 (CH_2Cl), 51.6 ($—CH(CO_2Me)_2$), 52.3, 52.4 (CH_3), 57.3 ($—(CH_2)_2C(CO_2Me)_2$), 126.7, 127, 130.2, 134.2 (C=C), 169.0, 171.2 (C=O); ms *m/e*: 419 (MH^+).

(E),(E)-*1,1,6,6-Tetracarbomethoxy-3,8-cycloundecadiene (2*a *[T–T]) and* (E),(E),(E),(E)-*1,1,6,6,12,12,17,17-octacarbomethoxy-3,9,14,20-cyclodocosatetraene (3*a *[T–T])*

Following procedure 11: At 2×10^{-3} *M*, chloride **1***a* [T–T] (187 mg, 0.447 mmol) gave the monomer **2***a* [T–T] (60% pure from vpc analysis) (88.5 mg, 52%) and dimer **3***a* [T–T] (64.6 mg, 38%); ir of **2***a*: 1728, 1241 cm^{-1}; ir of **3***a*: 1730, 1273, 1200, 1138 cm^{-1}.

*Methyl 2-carbomethoxy-2-[(Z)-4-chloro-2-butenyl]-7-[(tetrahydro-2H-pyran-2-yl)oxy]-5-heptynoate (14*a *[A–C])*

Following procedure 8: Malonate **8***a* (1.13 g, 3.79 mmol) gave chloride **14***a* [A–C] (1.294 g, 88%); ir: 1731 cm^{-1}; ^1H nmr δ: 1.40–1.80 (6H, m, $—C(CH_2)_3C—$), 2.20 (4H, m, $—CH_2CH_2—$), 2.72 (2H, bd, $C{=}CCH_2C(CO_2Me)_2—$), 3.40–3.90 (2H, m, $—OCH_2—$, cyclic), 3.72 (6H, s, CH_3), 4.07 (2H, bd, $—CH_2Cl$), 4.21 (2H, m, $THPOCH_2—$), 4.76 (1, m, $—O_2CH—$), 5.35–5.95 (2H, m, —HC=CH—); ms *m/e*: 387 (MH^+).

Methyl (Z)-*2,7,7-tricarbomethoxy-12-[(tetrahydro-2*H*-pyran-2-yl)oxy]-4-dodecen-10-ynoate (15*a *[A–C])*

Following procedure 3: In tetrahydrofuran as solvent, compound **14***a* [A–C] (1.28 g, 3.32 mmol) gave malonate **15***a* [A–C] (1.30 g, 80%); ir: 1732 cm^{-1}; ^1H nmr δ: 1.64 (6H, m, $C—(CH_2)_3—C$), 2.17 (4H, m, $—CH_2CH_2—$), 2.68 (4H, m, $C{=}CCH_2C(CO_2Me)_2$), 3.30–3.90 (3H, m, $—CH_2O—$, cyclic and $—CH(CO_2Me)_2$), 3.72, 3.74 (12H, s, CH_3), 4.20 (2H, m, $THPOCH_2—$), 4.77 (1H, m, $—O_2CH—$), 5.40 (2H, m, —HC=CH—); ms *m/e*: 481 (MH^+).

(Methyl (Z)-*2,7,7-tricarbomethoxy-12-hydroxy-4-dodecen-10-ynoate (16*a *[A–C])*

Following procedure 9: Compound **15***a* [A–C] (1.29 g, 2.69 mmol) gave **16***a* [A–C] (1.06 g, 99%); ir: 3610 (weak), 1731 cm^{-1}; ^1H nmr δ: 1.63 (1H, m, —OH), 2.17 (4H, m, $—CH_2CH_2—$), 2.70 (4H, m, $—C{=}CH_2C(CO_2Me)_2—$), 3.40 (1H, t, $—CH(CO_2Me)_2$), 3.73, 3.74 (12H, s, CH_3), 4.22 (2H, m, $—CH_2O—$), 5.40 (2H, m, —HC=CH—); ms *m/e*: 399 (MH^+).

Methyl (Z)-*2,7,7-tricarbomethoxy-12-chloro-4-dodecen-10-ynoate (1*a *[A–C])*

Following procedure 10: Compound **16***a* [A–C] (1.05 g, 2.64 mmol) gave chloride **1***a* [A–C] (0.910 g, 83%); ir: 1732 cm^{-1}; ^1H nmr δ: 2.16 (4H, m, $—CH_2CH_2—$), 2.65 (4H, m, $—C{=}CCH_2C(CO_2Me)_2$), 3.39 (1H, t, $—CH(CO_2Me)_2$), 3.72, 3.74 (12H, s, CH_3), 4.11 (2H, m, $—CH_2Cl$), 5.38 (2H, m, —HC=CH—); ms *m/e*: 417 (MH^+).

(Z)-*1,1,6,6-Tetracarbomethoxy-3-cycloundecen-8-yne (2*a *[A–C])* and (Z),(Z)-*1,1,6,6,12,12,17,17-octacarbomethoxy-3,14-cyclodocosadien-9,20-diyne (3*a *[A–C])*

Following procedure 11: Chloride **1***a* [A–C] (250 mg, 0.6 mmol) gave, after 15 h, **2***a* [A–C] (107 mg, 46.8%) and dimer **3***a* [A–C] (67.0 mg, 29.3%); ir of **2***a*: 1730, 1285, 1230 cm^{-1}; ir of **3***a*: 1732, 1290 cm^{-1}.

*Methyl 2-carbomethoxy-2-[(E)-4-chloro-2-butenyl]-7-[(tetrahydro-2H-pyran-2-yl)oxy]-5-heptynoate (14*a *[A–T])*

Following procedure 8: Using *trans*-1,4-dichloro-2-butene, compound **8***a* (1.15 g, 3.86 mmol) gave **14***a* [A–T] (1.34 g, 90%); ir: 1732 cm^{-1}; ^1H nmr δ: 1.62 (6H, m, $—C(CH_2)_3C—$), 2.17 (4H, m, $—CH_2CH_2—$), 2.65 (2H, m, $—C{=}CCH_2C(CO_2Me)_2—$), 3.40–3.90 (2H, m, $—CH_2O—$, cyclic), 3.73 (6H, s, CH_3), 4.02 (2H, m, $—CH_2Cl$), 4.20 (2H, m, $THPOCH_2—$), 4.77 (1H, m, $—O_2CH—$), 5.66 (2H, m, —HC=CH—); ms *m/e*: 387 (MH^+).

Methyl (E)-*2,7,7-tricarbomethoxy-12-[(tetrahydro-2*H*-pyran-2-yl)oxy]-4-dodecen-10-ynoate (15*a *[A–T])*

Following procedure 3: Using tetrahydrofuran as solvent, chloride **14***a* [A–T] (1.33 g, 3.44 mmol) gave malonate **15***a* [A–T] (1.38 g, 83%); ir: 1730 cm^{-1}; ^1H nmr δ: 1.62 (6H, m, $—C(CH_2)_3C—$), 2.12 (4H, m, $—CH_2CH_2—$), 2.55 (4H, m, $—C{=}CCH_2C(CO_2Me)_2$), 3.40 (1H, t, $—CH(CO_2Me)_2$), 3.40–4.00 (2H, m, $—OCH_2—$, cyclic), 3.71, 3.74 (12H, s, CH_3), 4.2 (2H, m, $—CH_2OTHP$), 4.77 (1H, m, $—O_2CH—$), 5.43 (2H, m, —HC=CH—); ms *m/e*: 399 ($M^+ - THP$).

Methyl (E)-*2,7,7-tricarbomethoxy-12-hydroxy-4-dodecen-10-ynoate (16*a *[A–T])*

Following procedure 9: Compound **15***a* [A–T] (1.36 g, 2.82 mmol) gave alcohol **16***a* [A–T] (1.12 g, 100%); ir: 1732 cm^{-1}; ^1H nmr δ: 1.67 (1H, m, —OH), 2.12 (4H, m, $—CH_2CH_2—$), 2.57 (4H, m, $—C{=}CCH_2C(CO_2Me)_2$), 3.40 (1H, m, $—CH(CO_2Me)_2$), 3.72, 3.74 (12H, s, CH_3), 4.20 (2H, m, $—CH_2OH$), 5.45 (2H, m, —HC=CH—); ms *m/e*: 399 (MH^+).

Methyl (E)-*2,7,7-tricarbomethoxy-12-chloro-4-dodecen-10-ynoate (1*a *[A–T])*

Following procedure 10: Alcohol **16***a* [A–T] (1.11 g, 2.79 mmol) gave **1***a* [A–T] (0.94 g, 81%); ir: 1732 cm^{-1}; ^1H nmr δ: 2.13 (4H, m, $—CH_2CH_2—$), 2.55 (4H, m, $—C{=}CCH_2C(CO_2Me)_2$), 3.39 (1H, t, $—CH(CO_2Me)_2$), 3.72, 3.74 (12H, s, CH_3), 4.12 (2H, m, $—CH_2Cl$), 5.40 (2H, m, —HC=CH—); ms *m/e*: 417 (MH^+).

(E)-*1,1,6,6-Tetracarbomethoxy-3-cycloundecen-8-yne (2*a *[A–T])* and *(E),(E)-1,1,6,6,12,12,17,17-octacarbomethoxy-3,14-cyclodocosadien-9,20-diyne (3*a *[A–T])*

Following procedure 11: After 18 h and at 2×10^{-3} *M*, the chloride **1***a* [A–T] (166 mg, 0.4 mmol) gave the monomer **2***a* [A–T] (68.0 mg, 45%) and **3***a* [A–T] (10.3 mg, 7%, 85% pure estimated from ^{13}C nmr); ir of **2***a*: 1730, 1229 cm^{-1}; ir of **3***a*: 3040, 1730, 1235 cm^{-1}.

*Methyl 2-carbomethoxy-2-(4-chloro-2-butynyl)-7-[(tetrahydro-2*H*-pyran-2-yl)oxy]-5-heptynoate (14*a *[A–A])*

Following procedure 8: Using 1,4-dichloro-2-butyne, malonate **8***a* (1.4 g, 4.7 mmol) gave **14***a* [A–A] (1.36 g, 75%); ir: 1733 cm^{-1}; ^1H nmr δ: 1.62 (6H, m, $—C(CH_2)_3C—$), 2.27 (4H, m, $—CH_2CH_2—$), 2.89 (2H, t, J = 2.5 Hz, $—C{\equiv}CCH_2C(CO_2Me)_2—$), 3.40–4.00 (2H, m, $—CH_2O—$, cyclic), 3.75 (6H, s, CH_3), 4.08 (2H, t, J = 2.5 Hz, $—CH_2Cl$), 4.21 (2H, m, $—C{\equiv}CCH_2O—$), 4.78 (1H, m, $—O_2CH—$); ms *m/e*: 385 (MH^+).

*Methyl 2,7,7-tricarbomethoxy-12-[(tetrahydro-2*H*-pyran-2-yl)oxy]-4,10-dodecadiynoate (15*a *[A–A])*

Following procedure 3: Using tetrahydrofuran as solvent, chloride **14***a* [A–A] (1.29 g, 3.36 mmol) gave compound **15***a* [A–A] (1.23 g, 76%); ir: 1740, 1732 cm^{-1}; ^1H nmr δ: 1.40–1.70 (6H, m, $—C(CH_2)_3C—$), 2.22 (4H, m, $—CH_2CH_2—$), 2.76 (4H, m, $—C{\equiv}CCH_2C(CO_2Me)_2$), 3.35–4.00 (3H, m, $—CH(CO_2Me)_2$ and $—OCH_2—$, cyclic), 3.72, 3.75 (12H, s, CH_3), 4.19 (2H, m, $—C{\equiv}CCH_2O—$), 4.76 (1H, m, $—O_2CH—$); ms *m/e*: 481 (MH^+).

*Methyl 2,7,7-tricarbomethoxy-12-hydroxy-4,10-dodecadiynoate (16*a *[A–A])*

Following procedure 5: Malonate **15***a* [A–A] (1.22 g, 2.54 mmol) at 50°C gave alcohol **16***a* [A–A] (0.947 g, 94%) as an oil containing some impurities; ir: 1735 cm^{-1}; ^1H nmr δ: 1.57 (1H, m, —OH), 2.24 (4H, m, $—CH_2CH_2—$), 2.79 (4H, m, $—C{\equiv}CCH_2C(CO_2Me)_2$), 3.52 (1H, t, $—CH(CO_2Me)_2$), 3.73, 3.77 (12H, s, CH_3), 4.21 (2H, m, $—CH_2O—$); ms *m/e*: 397 (MH^+).

*Methyl 2,7,7-tricarbomethoxy-12-chloro-4,10-dodecadiynoate (**1**a [A–A])*

Following procedure 10: Alcohol **16***a* [A–A] (0.937 g, 2.37 mmol) gave chloride **1***a* [A–A] (0.73 g, 75%) as an oil; ir: 2240, 1740 cm^{-1}; ^1H nmr δ: 2.24 (4H, m, $—CH_2CH_2—$), 2.77 (4H, m, $—C{\equiv}CCH_2C(CO_2Me)_2—$), 3.51 (1H, t, $—CH(CO_2Me)_2$), 3.73, 3.77 (12H, s, CH_3), 4.11 (2H, m, $—CH_2Cl$); ms *m/e*: 415 (MH^+).

*1,1,6,6-Tetracarbomethoxy-3,8-cycloundecadiyne (**2**a [A–A]) and 1,1,6,6,12,12,17,17-octacarbomethoxy-3,9,14,20-cyclodocosatetrayne (**3**a [A–A])*

Following procedure 11: After 14 h, chloride **1***a* [A–A] (169 mg, 0.408 mmol) gave monomer **2***a* [A–A] (81.1 mg, 53%) and dimer **3***a* [A–A] (36.0 mg, 24%); ir of **2***a*: 1730, 1232 cm^{-1}; ir of **3***a*: 1730, 1295 cm^{-1}.

*Methyl 2-carbomethoxy-2-[4-chloro-2-butynyl)-7-[(tetrahydro-2H-pyran-2-yl)oxy]-5-heptanoate (**14**a [A])*

Following procedure 8: Crude malonate **11***a* (1.40 g, 4.65 mmol) gave chloride **14***a* [A] as an impure oil (0.975 g, 54%); ir: 1732 cm^{-1}; ^1H nmr δ: 1.30–2.20 (14H, m, $—C(CH_2)_3C—$ and $C—(CH_2)_4—C$), 2.87 (2H, t, J = 2.5 Hz, $—C{\equiv}CCH_2C(CO_2Me)_2—$), 3.20–4.00 (4H, m, $—OCH_2—$), 3.74 (6H, s, CH_3), 4.08 (2H, t, J = 2.5 Hz, $—CH_2Cl$), 4.55 (1H, m, $—O_2CH—$); ms *m/e*: 389 (MH^+).

*Methyl2,7,7-tricarbomethoxy-12-[(tetrahydro-2H-pyran-2-yl)oxy]-4-dodecynoate (**15**a [A])*

Following procedure 3: Compound **14***a* [A] (0.955 g, 2.46 mmol) gave **15***a* [A] (0.983 g, 83%) as an oil; ir: 1735 cm^{-1}; ^1H nmr δ: 1.30–2.10 (14H, m, $—C(CH_2)_3C—$ and $—C(CH_2)_4C—$), 2.77 (4H, m, $—C{\equiv}CCH_2C(CO_2Me)_2$), 3.20–4.10 (5H, m, $—CH(CO_2Me)_2$ and $—OCH_2—$), 3.72, 3.76 (12H, s, CH_3), 4.56 (1H, m, $—O_2CH—$); ms *m/e*: 485 (MH^+).

*Methyl 2,7,7-tricarbomethoxy-12-hydroxy-4-dodecynoate (**16**a [A])*

Following procedure 5: Compound **15***a* [A] (0.983 g, 2.03 mmol) gave, after 2.5 h, alcohol **16***a* [A] (0.786 g, 98%); ir: 1732 cm^{-1}; ^1H nmr δ: 1.10–2.20 (9H, m, —OH and $—C(CH_2)_4C—$), 2.76 (4H, m, $—C{\equiv}CCH_2C(CO_2Me)_2$), 3.30–3.70 (3H, m, $—CH(CO_2Me)_2$ and $—OCH_2—$), 3.72, 3.76 (12H, s, CH_3); ms *m/e*: 401 (MH^+).

*Methyl 12-bromo-2,7,7-tricarbomethoxy-4-dodecynoate (**4**a)*

Following procedure 2: Alcohol **16***a* [A] (0.786 g, 1.76 mmol) gave, after flash chromatography (ethyl acetate/dichloromethane/hexanes 1:2:4), bromide **4***a* (0.704 g, 77%); ir: 2350, 1732 cm^{-1}; ^1H nmr δ: 1.00–2.10 (8H, m, $—C(CH_2)_4C—$), 2.76 (4H, m, $—C{\equiv}CCH_2C(CO_2Me)_2$), 3.40 (2H, t, J = 6 Hz, $—CH_2Br$), 3.50 (1H, m, $—CH(CO_2Me)_2$), 3.72, 3.76 (12H, s, CH_3); ms *m/e*: 463 (MH^+).

*1,1,6,6-Tetracarbomethoxy-3-cycloundecyne (**6**a) and 1,1,6,6,12,12,17,17-octacarbomethoxy-3,14-cyclodocosadiyne* (dimer)

Following procedure 11: After 44 h bromide **4***a* (166.4 mg, 0.359 mmol) gave **6***a* (58.6 mg, 42%) and dimer (25.2 mg, 18%) at 2×10^{-3} *M*; ir of **6***a* 1732, 1460, 1270 cm^{-1}; ir of dimer: 1733, 1285, 1120 cm^{-1}.

General procedure 12:

*Methyl 12-bromo-2,7,7-tricarbomethoxy-dodecanoate (**5**a)*

Bromide **4***a* (454 mg, 0.983 mmol) was dissolved in cyclohexane (10 mL) and ethyl acetate (2 mL) under argon. Platinum(IV) oxide (25 mg) and sodium sulfate (100 mg) were added at 25°C and the mixture was stirred under a hydrogen atmosphere for 3 h. The solution was filtered on Celite and the solvents were evaporated under vacuum to give **5***a* (448 mg, 98%); ir: 1730 cm^{-1}; ^1H nmr δ: 1.00–2.10 (16H, m, $—CCH_2C—$), 3.33 (1H, t, $—CH(CO_2Me)_2$), 3.38 (2H, t, J = 6 Hz, $—CH_2Br$), 3.70, 3.73 (12H, s, CH_3); ms *m/e*: 467 (MH^+).

*1,1,6,6-Tetracarbomethoxy-cycloundecane (**7**a) and 1,1,6,6,12,12,17,17-octacarbomethoxy-cyclodocosane* (dimer)

Following procedure 11: After 48 h, bromide **5***a* (172 mg, 0.369 mmol) gave monomer **7***a* (4.8 mg, 3%) and dimer (3.5 mg, 2%) at 2×10^{-3} *M*; ir of **7***a*: 1728, 1250, 1192 cm^{-1}; ir of dimer: 1730, 1230 cm^{-1}.

*Methyl (Z)-2-carbomethoxy-2-[(Z)-4-chloro-2-butenyl]-8-[(tetrahydro-2H-pyran-2-yl)oxy]-6-octenoate (**14**b [C–C])*

Following procedure 8: Compound **9***b* (1.37 g, 3.4 mmol) gave chloride **14***b* [C–C] (1.49 g, 85%); ir: 1732 cm^{-1}; ^1H nmr δ: 1.25–2.30 (12H, m, $—C(CH_2)_3C—$), 2.70 (2H, m, $—C{=}CCH_2C(CO_2Me)_2$), 3.30–4.00 (6H, m, $—CH_2Cl$ and $—OCH_2—$), 3.72 (6H, s, CH_3), 4.60 (1H, m, $—O_2CH—$), 5.30–5.90 (4H, m, $—HC{=}CH—$); ms *m/e*: 403 (MH^+).

*Methyl (Z),(Z)-2,7,7-tricarbomethoxy-13-[(tetrahydro-2H-pyran-2-yl)oxy]-4,11-tridecadienoate (**15**b [C–C])*

Following procedure 3: Compound **14***b* [C–C] (1.48 g, 3.67 mmol) gave the malonate **15***b* [C–C] (1.77 g, 97%); ir: 1730–1740 cm^{-1}; ^1H nmr δ: 1.30–2.10 (12H, m, $—C(CH_2)_3C—$), 2.61 (4H, m, $—C{=}CCH_2C(CO_2Me)_2$), 3.37 (1H, t, $—CH(CO_2Me)_2$), 3.30–4.00 (2H, m, $—OCH_2—$, cyclic), 3.71, 3.74 (12H, s, CH_3), 4.14 (2H, m, $THPOCH_2—$), 4.63 (1H, m, $—O_2CH—$), 5.30–5.70 (4H, m, $—HC{=}CH—$); ms *m/e*: 499 (MH^+).

*Methyl (Z),(Z)-2,7,7-tricarbomethoxy-13-hydroxy-4,11-tridecadienoate (**16**b [C–C])*

Following procedure 9: Compound **15***b* [C–C] (1.76 g, 3.53 mmol) gave alcohol **16***b* [C–C] (1.43 g, 98%); ir: 3200–3600, 1730 cm^{-1}; ^1H nmr δ: 1.2–2.1 (7H, m, —OH and $—(CH_2)_3—$), 2.63 (4H, m, $—C{=}CCH_2C(CO_2Me)_2$), 3.38 (1H, t, $—CH(CO_2Me)_2$), 3.71, 3.74 (12H, s, CH_3), 4.17 (2H, m, $—CH_2O—$), 5.20–5.70 (4H, m, $—HC{=}CH—$); ms *m/e*: 415 (MH^+).

*Methyl(Z),(Z)-2,7,7-tricarbomethoxy-13-chloro-4,11-tridecadienoate (**1**b [C–C])*

Following procedure 10: Alcohol **16***b* [C–C] (1.42 g, 3.43 mmol) gave chloride **1***b* [C–C] (1.27 g, 86%); ir: 1730–1745 cm^{-1}; ^1H nmr δ: 1.30–2.20 (6H, m, $—(CH_2)_3—$), 2.72 (4H, m, $—C{\equiv}CCH_2C(CO_2Me)_2—$), 3.37 (1H, t, $—CH(CO_2Me)_2$), 3.70, 3.73 (12H, s, CH_3), 4.12 (2H, m, $—CH_2Cl$), 5.25–5.70 (4H, m, $—HC{=}CH—$); ms *m/e*: 433 (MH^+).

*(Z),(Z)-1,1,6,6-Tetracarbomethoxy-3,8-cyclododecadiene (**2**b [C–C] and (Z),(Z),(Z),(Z)-1,1,6,6,13,13,18,18-octacarbomethoxy-3,10,15,22-cyclotetracosatetraene (**3**b [C–C])*

Following procedure 11: After 24 h, the chloride **1***b* [C–C] (184 mg, 0.427 mmol) gave the monomer **2***b* [C–C] (50.1 mg, 29.1%) and **3***b* [C–C] (70.4 mg, 40.9%); ir of **2***b*: 1731, 1271, 1060 cm^{-1}; ir of **3***b*: 1730, 1136, 1103 cm^{-1}.

*Methyl (Z)-2-carbomethoxy-2-[(E)-4-chloro-2-butenyl]-8-[(tetrahydro-2H-pyran-2-yl)oxy]-6-octenoate (**14**b [C–T])*

Following procedure 8: Using *trans*-1,4-dichloro-2-butene, compound **9***b* (1.33 g, 4.26 mmol) gave chloride **14***b* [C–T] (1.38 g, 81%); ir: 1733 cm^{-1}; ^1H nmr δ: 1.10–2.10 (12H, m, $—C(CH_2)_3C—$), 2.67 (2H, m, $—C{=}CCH_2C(CO_2Me)_2$), 3.40–4.00 (2H, m, $—OCH_2—$, cyclic), 3.72 (6H, s, CH_3), 4.00–4.15 (4H, m, $—CH_2Cl$ and $THPOCH_2—$), 4.62 (1H, m, $—O_2CH—$), 5.30–5.70 (4H, m, $—HC{=}CH—$); ms *m/e*: 403 (MH^+).

*Methyl (E),(Z)-2,7,7-tricarbomethoxy-13-[(tetrahydro-2H-pyran-2-yl)oxy]-4,11-tridecadienoate (**15**b [C–T])*

Following procedure 3: Compound **14***b* [C–T] (1.37 g, 3.40 mmol) gave **15***b* [C–T] (1.54 g, 91%); ir: 1730 cm^{-1}; ^1H nmr δ: 1.20–2.10 (12H, m, $—(CH_2)_3—$), 2.59 (4H, m, $—C{=}CCH_2C(CO_2Me)_2$), 3.38 (1H, t, $—CH(CO_2Me)_2$), 3.40–4.00 (2H, m, $—OCH_2—$, cyclic), 3.70, 3.74 (12H, s, CH_3), 4.10 (2H, m, $THPOCH_2—$), 4.61 (1H, m, $—O_2CH—$), 5.30–5.70 (4H, m, $—HC{=}CH—$); ms *m/e*: 499 (MH^+).

*Methyl (E),(Z)-2,7,7-tricarbomethoxy-13-hydroxy-4,11-tridecadienoate (**16**b [C–T])*

Following procedure 9: Compound **15***b* [C–T] (1.52 g, 3.06 mmol) gave alcohol **16***b* [C–T] (1.29 g, 100%); ir: 3620, 1730 cm^{-1}; ^1H nmr δ: 1.10–2.20 (7H, m, —OH and $—(CH_2)_3—$), 2.52 (4H, m, $—C{=}CCH_2C(CO_2Me)_2$), 3.37 (1H, t, $—CH(CO_2Me)_2$), 3.69, 3.73 (12H, s, CH_3), 4.17 (2H, m, $—CH_2O—$), 5.10–5.80 (4H, m, $—HC{=}CH—$); ms *m/e*: 415 (MH^+).

Following procedure 11: After 22 h chloride **1***b* [A–T] (185.9 mg,

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 80.58.250.72 on 09/07/12
For personal use only.

0.432 mmol) gave monomer **2***b* [A–T] (100 mg, 59%) and dimer **3***b* [A–T] (39.5 mg, 23%); ir of **2***b*: 1730, 1251, 1135 cm^{-1}; ir of **3***b*: 1740, 1730, 1180–1260 cm^{-1}.

*Methyl 2-carbomethoxy-2-[4-chloro-2-butynyl)-8-[(tetrahydro-2*H*-pyran-2-yl)oxy]-6-octynoate (**14**b [A–A])*

Following procedure 8: Using 1,4-dichloro-2-butyne, malonate **8***b* (1.14 g, 3.66 mmol) gave **14***b* [A–A] (1.09 g, 75%); ir: 1731 cm^{-1}; ^{1}H nmr δ: 1.30–2.40 (12H, m, C—$(CH_2)_3$—C), 2.87 (2H, t, J = 3 Hz, —C≡C$CH_2C(CO_2Me)_2$), 3.40–4.00 (2H, m, —OCH_2—, cyclic), 3.74 (6H, s, CH_3), 4.10 (2H, t, J = 3 Hz, —CH_2Cl), 4.22 (2H, m, THPOCH_2—), 4.78 (1H, m, —O_2CH—); ms m/e: 399 (MH^+).

*Methyl2,7,7-tricarbomethoxy-13-[(tetrahydro-2*H*-pyran-2-yl)oxy]-4,11-tridecadiynoate (**15**b [A–A])*

Following procedure 3: Chloride **14***b* [A–A] (1.08 g, 2.70 mmol) gave malonate **15***b* [A–A] (0.99 g, 74%) by performing the reaction in tetrahydrofuran; ir: 1735 cm^{-1}; ^{1}H nmr δ: 1.25–2.40 (12H, m, C—$(CH_2)_3$—C), 2.76 (4H, m, —C≡C$CH_2C(CO_2Me)_2$), 3.35–3.90 (3H, m, —$CH(CO_2Me)_2$ and —OCH_2—, cyclic), 3.72, 3.76 (12H, s, CH_3), 4.23 (2H, m, THPOCH_2—), 4.79 (1H, m, —O_2CH—); ms m/e: 411 (M^+ − THP).

*Methyl 2,7,7-tricarbomethoxy-13-hydroxy-4,11-tridecadiynoate (**16**b [A–A])*

Following procedure 9: Malonate **15***b* [A–A] (0.98 g, 1.98 mmol) gave alcohol **16***b* [A–A] (0.81 g, 100%); ir: 1734 cm^{+1}; ^{1}H nmr δ: 1.20–1.60 (3H, m, —OH and $(CH_2)_2CH_2$—), 1.80–2.40 (4H, m, $(CH_2)_2CH_2$—), 2.76 (4H, m, —C≡C$CH_2C(CO_2Me)_2$), 3.52 (1H, m, —$CH(CO_2Me)_2$), 3.73, 3.78 (12H, s, CH_3), 4.25 (2H, dt, J = 8 Hz and 3 Hz, —CH_2—O); ms m/e: 411 (MH^+).

*Methyl 2,7,7-tricarbomethoxy-13-chloro-4,11-tridecadiynoate (**1**b [A–A])*

Following procedure 10: Alcohol **16***b* [A–A] (800 mg, 1.95 mmol) gave chloride **1***b* [A–A] (0.76 g, 91%); ir: 1738 cm^{-1}; ^{1}H nmr δ: 1.20–1.60 (2H, m, —$(CH_2)_2CH_2$—), 1.90–2.40 (4H, m, $(CH_2)_2CH_2$), 2.77 (4H, m, —C≡C$CH_2C(CO_2Me)_2$—), 3.51 (1H, m, —$CH(CO_2Me)_2$), 3.73, 3.77 (12H, s, CH_3), 4.14 (2H, t, J = 3 Hz, —CH_2Cl); ms m/e: 429 (MH^+).

*1,1,6,6-Tetracarbomethoxy-3,8-cyclododecadiyne (**2**b [A–A]) and 1,1,6,6,13,13,18,18-octacarbomethoxy-3,10,15,22-cyclotetracosatetrayne (**3**b [A–A])*

Following procedure 11: Chloride **1***b* [A–A] (162 mg, 0.380 mmol) after 15 h gave the monomer **2***b* [A–A] (71.5 mg, 48%) and dimer **3***b* [A–A] (17.3 mg, 12%); ir of **2***b*: 1736, 1250, 1080 cm^{-1}; ir of **3***b*: 1736, 1292, 910 cm^{-1}.

*Methyl 2-carbomethoxy-2-(4-chloro-2-butynyl)-8-[(tetrahydro-2*H*-pyran-2-yl)oxy]-octanoate (**14**b [A])*

Following procedure 8: Using 1,4-dichloro-2-butyne, compound **11***b* (2.09 g, 6.61 mmol) gave **14***b* [A] as an impure oil (2.06 g, 77.5%); ir: 1732 cm^{-1}; ^{1}H nmr δ: 1.20–2.20 (16H, m, C—CH_2—C), 2.86 (2H, t, J = 3 Hz, C≡C$CH_2C(CO_2Me)_2$), 3.20–3.90 (4H, m, —OCH_2C—), 3.73 (6H, s, CH_3), 4.08 (2H, t, J = 3 Hz, —CH_2Cl), 4.55 (1H, m, —O_2CH—); ms m/e: 403 (MH^+).

*Methyl2,7,7-tricarbomethoxy-13-[(tetrahydro-2*H*-pyran-2-yl)oxy]-4-tridecynoate (**15**b [A])*

Following procedure 3: Chloride **14***b* [A] (2.05 g, 5.1 mmol) gave malonate **15***b* [A] (1.93 g, 76%) as an oil; ir: 1733 cm^{-1}; ^{1}H nmr δ: 1.20–2.20 (16H, m, C—CH_2—C), 2.75 (4H, m, C≡C$CH_2C(CO_2Me)_2$), 3.20–4.00 (5H, m, —$CH(CO_2Me)_2$ and —OCH_2—), 3.71, 3.75 (12H, s, CH_3), 4.55 (1H, m, —O_2CH—); ms m/e: 499 (MH^+).

*Methyl 2,7,7-tricarbomethoxy-13-hydroxy-4-tridecynoate (**16**b [A])*

Following procedure 9: Compound **15***b* [A] (1.92 g, 3.85 mmol) gave alcohol **16***b* [A] (1.52 g, 95%); ir: 3300–3600, 1732 cm^{-1}; ^{1}H nmr δ: 1.20–2.10 (11H, m, —OH and —$(CH_2)_5$—), 2.76 (4H, m, C≡C$CH_2C(CO_2Me)_2$), 3.30–3.80 (3H, m, —CH_2O— and —$CH(CO_2Me)_2$), 3.71, 3.76 (12H, s, CH_3); ms m/e: 415 (MH^+).

*Methyl 13-bromo-2,7,7-tricarbomethoxy-4-tridecynoate (**4**b)*

Following procedure 2: Alcohol **16***b* [A] (1.51 g, 3.65 mmol) gave bromide **4***b* (1.45 g, 83%); ir: 1731 cm^{-1}; ^{1}H nmr δ: 1.20–2.10 (10H, m, —$(CH_2)_5$—), 2.77 (4H, m, C≡C$CH_2C(CO_2Me)_2$), 3.40 (2H, t, J = 6 Hz, —CH_2Br), 3.51 (1H, m, —$CH(CO_2Me)_2$), 3.72, 3.76 (12H, s, CH_3); ms m/e: 477 (MH^+).

*1,1,6,6-Tetracarbomethoxy-3-cyclododecyne (**6**b) and 1,1,6,6,13,13,18,18-octacarbomethoxy-3,15-cyclotetracosadiyne* (dimer)

Following procedure 11: After 48 h, bromide **4***b* (205.6 mg, 0.432 mmol) gave monomer **6***b* (63.4 mg, 37%) and dimer (33.5 mg, 19%); ir of **6***b*: 1732, 1247, 1108 cm^{-1}; ir of dimer: 1730, 1282, 1200 cm^{-1}.

*Methyl 13-bromo-2,7,7-tricarbomethoxy-tridecanoate (**5**b)*

Following procedure 12: The compound **4***b* (597 mg, 1.25 mmol) gave **5***b* (598 mg, 99%); ir: 1729 cm^{-1}; ^{1}H nmr δ: 1.20 and 1.83 (18H, m, C—CH_2—C), 3.31 (1H, t, —$CH(CO_2Me)_2$), 3.36 (2H, t, J = 6.5 Hz, —CH_2Br), 3.68, 3.71 (12H, s, CH_3); ms m/e: 481 (MH^+).

*1,1,6,6-Tetracarbomethoxy-cyclododecane (**7**b) and 1,1,6,6,13,13,18,18-octacarbomethoxy-cyclotetracosane* (dimer)

Following procedure 11: After 40 h, compound **5***b* (199.6 mg, 0.415 mmol) gave monomer **7***b* (46.6 mg, 28%) and dimer (estimated to be 50% pure by ^{1}H nmr) (18.1 mg, 11%); ir of **7***b*: 1730, 1472, 1276 cm^{-1}; ir of dimer: 1728, 1460, 1172 cm^{-1}.

DENIS BRILLON and PIERRE DESLONGCHAMPS. Can. J. Chem. **65**, 56 (1987).

The malonate anion intramolecular displacement of propargylic or allylic chlorides, and primary bromide, in thirteen- and fourteen-carbon chains containing either two, one, or no unsaturation sites, yields the corresponding 13- and 14-membered ring compounds under conditions of medium dilution.

DENIS BRILLON et PIERRE DESLONGCHAMPS. Can. J. Chem. **65**, 56 (1987).

Le déplacement intramoléculaire de bromure primaire et de chlorures allyliques ou propargyliques par l'anion malonate de chaînes de treize et quatorze carbones contenant soit deux, une ou aucune insaturation conduit aux composés cycliques à 13 et 14 membres correspondants, dans des conditions de dilution moyenne.

For personal use only.

We have recently published (1) a simple and good method for the preparation of 10-membered rings by direct cyclization, under conditions of medium dilution, of C-10 aliphatic chains containing two sites of unsaturation (double or triple bonds). In the preceding publication (2) we reported a similar study on the cyclization of C-11 and C-12 aliphatic chains. In this report, we wish to disclose an analogous study on the cyclization of C-13 and C-14 aliphatic chains.[2]

We have studied the cyclization of the C-13 and C-14 aliphatic chains **1***a* and **1***b*, which can yield, beside polymerization, either the corresponding cyclic monomers (**2***a* and **2***b*) or dimers (**3***a* and **3***b*) (Scheme 1). The two unsaturations in the chain can be (two of) a *cis* (C), a *trans* (T) olefin, and (or) an acetylene (A). The following combinations were studied: **1***a* or **1***b* -[C–C], -[C–T], -[T–T], -[A–C], -[A–T], and -[A–A]. The cyclization of C-13 and C-14 aliphatic precursors containing only one unsaturation center, an acetylene, i.e. compounds **4***a* and **4***b*, was also studied. Similarly, the cyclization of the fully saturated C-13 and C-14 chains **5***a* and **5***b* was also carried out. These compounds (**4***a*, *b* and **5***a*, *b*) can yield the corresponding cyclic monomers (**6***a*, *b* or **7***a*, *b* respectively) and dimers (structures not shown), or undergo polymerization.

The various C-13 and C-14 aliphatic precursors were obtained by a route (Schemes 2–4) similar to that used for the preparation of the C-11 and C-12 aliphatic chains (2). Scheme 2 describes the preparation of the C-8 and C-9 acetylenic key intermediates **8***a* and **8***b*. The C-8 and C-9 key intermediates having a *cis* olefin (**9***a* and **9***b*), a *trans* olefin (**10***a* and **10***b*), or no unsaturation (**11***a* and **11***b*) were prepared from the acetylenic intermediates **8***a* and **8***b* (Scheme 3). The same scheme summarizes also the conversion of the C-8 and C-9 key intermediates **8***a*, **8***b*, **9***a*, **9***b*, **10***a*, **10***b*, **11***a*, and **11***b* respectively into the C-13 and C-14 doubly unsaturated aliphatic precursors **1***a* and **1***b* [A–A, A–T, A–C, T–T, T–C, and C–C]. It also describes the preparation of the C-13 and C-14 monoacetylenic chains **4***a* and **4***b* (via **11***a* and **11***b*) as well as that of the saturated chains **5***a* and **5***b* obtained from the hydrogenation of **4***a* and **4***b* respectively.

The preparation of the various C-13 and C-14 aliphatic chains from the C-8 and C-9 key intermediates (**8***a*, *b*, **9***a*, *b* **10***a*, *b*, and **11***a*, *b*) is further detailed in Scheme 4: Alkylation of intermediates **8**–**11** (*a* or *b*) with an appropriate alkylating agent (*cis* or *trans* 1,4-dichloro-2-butene or 1,4-dichloro-2-butyne) gave the corresponding chlorides **14***a* and **14***b*. SN_2 displacement of these unsaturated chlorides with dimethyl malonate gave the THP-malonates **15***a* and **15***b*. Acid hydrolysis then gave the primary alcohol malonates **16***a* and **16***b*, which were then respectively transformed into the C-13 and C-14 allylic and propargylic chlorides **1***a* and **1***b* [A–A, A–T, A–C, T–T, T–C, and C–C] as well as the monoacetylenic primary bromides **4***a* and **4***b*.

The cyclization reactions (K_2CO_3/DMF–THF, 90°C) were carried out at 2×10^{-2} and 2×10^{-3} molar dilution, not high dilution, and are presented in Tables 1 and 2 for the C-13 and C-14 aliphatic chains respectively. The cyclic monomers and dimers are readily separated by column chromatography and are all crystalline, except for the monomer **2***b* [C–C]. For all new substances, the spectra (ir, 250-MHz and 80-MHz ^{1}H nmr, ^{13}C nmr, and high resolution mass spectra; low resolution mass spectra were obtained for the dimers) were in complete agreement with the assigned structure. The corresponding ^{1}H nmr, ^{13}C nmr, and mass spectral characteristics and melting points for the cyclic compounds are listed in Table 4.

In most cases, at 10^{-2} *M*, the formation of monomer plus dimer competes effectively with polymerization and, at 10^{-3} *M*, formation of monomer is the main process. During the cyclization of the bromides (**4***a*, *b* and **5***a*, *b*), better yields of monomers were obtained if cesium carbonate was used in addition to potassium carbonate. Under those conditions, cyclization is faster and the formation of a secondary product (a formate resulting from DMF displacement of bromides) was negligible.

The increase in yield on passing from the saturated chain, the monoacetylene, and the bisacetylene is important (44, 53, and 89%) in the C-13 series, but much less in the C-14 series (66, 55, and 76%). Low yields of monomers observed in the cyclization of **1***a* [C–T] (20%), **1***a* [T–T] (45%), **1***b* [T–T] (20%), and **1***b* [A–T] (41%) show that in the C-13 and C-14 series the presence of unsaturation (especially *trans* olefin) can even decrease the yield, by comparison with the cyclization of the monoacetylenes and the fully saturated chains. Somewhat surprisingly, the C-14 series gave lower yields than the C-13 series except for the cyclization of saturated chains **5***b* and **1***b* [C–T].

A comparison of yields obtained at 10^{-3} *M* for monomers and

dimers with aliphatic chain length from C-10 to C-14 is made in Table 3. The results are in agreement with previous studies on saturated systems, which indicate easier formation of monomers from C-13 and C-14 chains, in comparison with C-10, C-11, and C-12 chains (10). This table also shows clearly that, generally, the introduction of unsaturation in the chain is much more important for a good yield in the C-10, C-11, and C-12 than in the C-13 and C-14 series. In addition, much better yields

SCHEME 3

are obtained when an acetylenic grouping is present in the chains, and *cis* olefins appear to increase the yield better than *trans* olefins.

In conclusion, these results show clearly that C-10 to C-14 membered rings can be obtained in good yield by a direct cyclization method under conditions of medium dilution. A detailed molecular modeling study of the above result is necessary to understand further the factors that influence these macrocyclization reactions.

Experimental

Proton nmr spectra were recorded in $CDCl_3$ on Bruker WP-80 and WM-250 instruments. The ^{13}C nmr spectra were recorded on a Bruker WM-20 instrument. The infrared (ir) spectra were taken on a Perkin–Elmer 681 spectrophotometer ($CHCl_3$). The mass spectra (ms) and peak matching assays were obtained using a VG Micromass ZAB-1F mass spectrometer. Vapor phase chromatographic (vpc) analyses were carried out on a Hewlett–Packard 5710A gas chromatograph with a flame ionization detector (capillary column OV-101, 25 m). Melting points were determined on a Reichert apparatus. For flash chromatography, the silica gel Kieselgel-60 (from Merck) was used.

All reactions were carried out under an argon atmosphere. Tetrahydrofuran was dried by distilling over sodium/benzophenone whereas *N,N*-dimethylformamide was dried over calcium hydride followed by decantation and distillation under reduced pressure. Ground anhydrous potassium carbonate was used for cyclization reactions.

(E) and (Z)-1,4-Dichloro-2-butene and acetylene **17**

The same samples that were prepared in the preceding work (2) were used.

General procedure 1:

Bromide **18***a from* **17**

To a stirred solution of **17** (10.0 g, 71.3 mmol), triphenylmethane (3 mg), and hexamethylphosphoramide (1.25 mL, 7.0 mmol) in tetrahydrofuran (200 mL), at −40°C, was added *n*-butyllithium (1.6 *M* in hexanes) until the coloration of the solution changed from yellow to dark yellow. Then 1,4-dibromobutane (77.0 g, 356 mmol) was added and the solution was refluxed for 30 h. Diethyl ether (250 mL) was added after cooling and the organic phase was washed with 10% aqueous sodium chloride (3 × 50 mL), dried on sodium sulfate, and evaporated. The remaining volatile materials were removed by Kugelrohr distillation (35°C at 0.02–0.08 Torr) and similarly pure bromide **18***a* was obtained by heating at 85–90°C (0.005–0.01 Torr) (16.5 g, 86%); ^{1}H nmr δ: 1.25–2.40 (12H, m, —C(CH$_2$)$_3$C—), 3.43 (2H, t, J = 7 Hz, —CH$_2$Br), 3.40–3.95 (2H, m, —OCH$_2$—, cyclic), 4.24 (2H, m, THPOCH$_2$—), 4.79 (1H, bs, —O$_2$CH—); ms m/e: 275 (MH$^+$).

*1-Bromo-8-[(tetrahydro-2*H*-pyran-2-yl)oxy]-6-octyne (***18***b)*

Following procedure 1: Using 1,5-dibromopentane (82.0 g, 356 mmol), acetylene **17** (10.0 g, 71.3 mmol) gave bromide **18***b* (16.9 g, 82%), which was obtained as a pure oil by a Kugelrohr distillation (100–110°C at 0.005 Torr); ir: 3008, 2230, 1020 cm^{-1}; ^{1}H nmr δ:

1.20–2.00 (12H, m, C—$(CH_2)_3$—C, cyclic and $BrCH_2$—$(CH_2)_3$—), 2.24 (2H, m, —C≡CCH_2—C), 3.41 (2H, t, *J* = 7 Hz, —CH_2Br), 3.40–4.00 (2H, m, —OCH_2—, cyclic), 4.24 (2H, m, THPOCH_2—), 4.80 (1H, bs, —O_2CH—); ms *m/e*: 289 (MH^+).

General procedure 2:

*Malonate 8*a *from 18*a

A stirred mixture of bromide **18***a* (16.5 g, 61.3 mmol), dimethyl malonate (40.0 mL, 306 mmol), and potassium carbonate (42.0 g, 306 mmol) in tetrahydrofuran (110 mL) and *N,N*-dimethylformamide (110 mL) was heated at 80°C for 15 h. The mixture was cooled and hexane (150 mL) was added, followed by filtration through a Celite pad and removal of solvents under reduced pressure. The residue was dissolved in a (1:1) mixture of diethyl ether/hexane (350 mL), washed with 10% aqueous sodium bicarbonate (60 mL), dried on sodium sulfate, and the solvents were evaporated. The volatile materials were removed by Kugelrohr distillation at 40°C (0.02 Torr) to afford pure malonate **8***a* as an oil (18.7 g, 96%); ir: 1760–1740 cm^{-1}; ^{1}H nmr δ: 1.20–2.30 (14H, m, C—$(CH_2)_3$—C and C—$(CH_2)_4$—C), 3.33 (1H, t, *J* = 6 Hz, —$CH(CO_2Me)_2$), 3.40–4.00 (2H, m, —OCH_2—, cyclic), 3.70 (6H, s, CH_3), 4.20 (2H, m, THPOCH_2—), 4.76 (1H, bs, —O_2CH—); ms *m/e*: 340 (M^+).

*Methyl 2-carbomethoxy-10-[(tetrahydro-2*H*-pyran-2-yl)oxy]-8-decynoate (8*b*)*

Following procedure 2: Bromide **18***b* (16.9 g, 58.5 mmol) gave malonate **8***b* (19.8 g, 99%); ir: 2251, 1730 cm^{-1}; ^{1}H nmr δ: 1.20–2.30 (16H, m, C—$(CH_2)_5$—C and C—$(CH_2)_3$—C), 3.25–4.00 (3H, m, —$CH(CO_2Me)_2$ and —OCH_2—, cyclic), 3.70 (6H, s, CH_3), 4.20 (2H, m, THPOCH_2—), 4.76 (1H, bs, —O_2CH—); ms *m/e*: 341 (MH^+).

General procedure 3:

*(Z)-Alkene 9*a *from 8*a

Lindlar's catalyst (Pd/$CaCO_3$/PbO from Aldrich (300 mg) was added under an argon atmosphere to a solution of **8***a* (2.8 g, 8.1 mmol) in ethyl acetate (3 mL) and cyclohexane (13 mL). This mixture was then carefully stirred under hydrogen (1.00 atm (1 atm = 101.3 kPa) at the end) until the hydrogen uptake ceased. The mixture was filtered through a Celite pad and the filtrate evaporated to afford **9***a* as an oil (2.81 g, 100%); ir: 1730 cm^{-1}; ^{1}H nmr δ: 1.20–2.20 (14H, m, C—$(CH_2)_4$—C and C—$(CH_2)_3$—C), 3.35 (1H, t, *J* = 6 Hz, —$CH(CO_2Me)_2$), 3.35–4.00 (2H, m, —OCH_2—, cyclic), 3.73 (6H, s, CH_3), 4.14 (2H, m, THPOCH_2—), 4.61 (1H, bs, —O_2CH—), 5.55 (2H, m, —HC=CH—); ms *m/e*: 329 (MH^+).

*Methyl (Z)-2-carbomethoxy-10-[(tetrahydro-2*H*-pyran-2-yl)oxy]-8-decenoate (9*b*)*

Following procedure 3: Malonate **8***b* (3.0 g, 9.4 mmol) gave **9***b* (3.0 g, 99%); ir: 1731 cm^{-1}; ^{1}H nmr δ: 1.10–2.20 (16H, m, C—$(CH_2)_5$—C and C—$(CH_2)_3$C), 3.35 (1H, t, *J* = 6.5 Hz, —$CH(CO_2Me)_2$), 3.40–4.00 (2H, m, —OCH_2—, cyclic), 3.74 (6H, s, CH_3), 4.15 (2H, m, THPOCH_2—), 4.62 (1H, bs, —O_2CH—), 5.56 (2H, m, —HC=CH—); ms *m/e*: 343 (MH^+).

General procedure 4:

*Alcohol 12*a *from 8*a

Malonate **8***a* (2.04 g, 6.20 mmol) and pyridinium *p*-toluenesulfonate (170 mg, 0.680 mmol) were dissolved in methanol (15 mL). This solution was heated at 50°C for 1.5 h. After evaporation of methanol under reduced pressure, the residual oil was purified on a silica gel column with ethyl acetate/dichloromethane/hexanes (1:2:2) as eluent. The evaporation of solvents afforded crude alcohol **12***a* as an oil (1.53 g, 99.5%); ^{1}H nmr δ: 1.25–2.35 (9H, m, C—$(CH_2)_4$—C and —OH), 3.38 (1H, t, *J* = 6 Hz, —$CH(CO_2Me)_2$), 3.75 (6H, s, CH_3), 4.2 (2H, dt, *J* = 6 and 2.5 Hz, —OCH_2—); ms *m/e*: 243 (MH^+).

General procedure 5:

*Alcohol 13*a *from 12*a

To a solution of chromous chloride (80 mL) (see ref. 2) was added sodium sulfate (3.30 g, 23.2 mmol), sodium acetate (1.90 g, 23.1 mmol), and alcohol **12***a* (1.53 g, 62.2 mmol) dissolved in deoxygenated *N,N*-dimethylformamide (27 mL). This mixture was stirred at room temperature for 36 h, followed by extraction with diethyl ether (5 × 60 mL). The organic phase was dried over sodium sulfate and evaporated. The residual oil was purified by flash chromatography (ethyl acetate/dichloromethane/hexanes (1:2:2)) to afford the pure alcohol **13***a* as an oil (1.38 g, 92%); ir: 3600, 1732 cm^{-1}; ^{1}H nmr δ: 1.20–1.60 (5H, m, —OH and —$CH_2(CH_2)_2CH_2$—), 1.70–2.20 (4H, m, —$CH_2(CH_2)_2CH_2$—), 3.25 (1H, t, *J* = 6.5 Hz, —$CH(CO_2Me)_2$), 3.74 (6H, s, CH_3), 4.08 (2H, m, —OCH_2—), 5.68 (2H, m, —HC=CH—); ms *m/e*: 245 (MH^+).

General procedure 6:

*(E)-Alkene 10*a *from 13*a

Trifluoroacetic acid (0.05 mL) was added at room temperature to a solution of alcohol **13***a* (1.37 g, 5.52 mmol) and dihydropyran (0.66 mL, 7.2 mmol) in dichloromethane (20 mL). The reaction mixture was stirred at 25°C for 18 h. Dichloromethane was evaporated under reduced pressure and the residual oil was purified by flash chromatography (ethyl acetate/hexanes 1:5) to afford the compound **10***a* (1.77 g, 96%); ir: 1732 cm^{-1}; ^{1}H nmr δ: 1.20–2.20 (14H, m, C—$(CH_2)_3$—C and C—$(CH_2)_4$—C), 3.20–4.30 (5H, m, —$CH(CO_2Me)_2$, —OCH_2—), 3.73 (6H, s, CH_3), 4.61 (1H, bs, —O_2CH—), 5.63 (2H, m, —HC=CH—); ms *m/e*: 329 (MH^+).

*Methyl 2-carbomethoxy-10-hydroxy-8-decynoate (12*b*)*

Following procedure 4: Malonate **8***b* (2.00 g, 5.78 mmol) gave alcohol **12***b* as a crude oil; ir: 3610, 1732 cm^{-1}; ^{1}H nmr δ: 1.25–2.35 (11H, m, C—$(CH_2)_5$—C, —OH), 3.37 (1H, t, —$CH(CH_2Me)_2$),

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 80.58.250.72 on 09/07/12
For personal use only.

3.74 (6H, s, CH_3), 4.20 (2H, dt, J = 3 and 7 Hz, —CH_2O—); ms m/e: 257 (MH^+).

*Methyl (*E*)-2-carbomethoxy-10-hydroxy-8-decenoate (**13**b)*

Following procedure 5: Crude alcohol **12***b* afforded purified alcohol **13***b* (1.36 g, 91% from **8***b*); ir: 1730 cm^{-1}; ^1H nmr δ: 1.20–2.20 (11H, m, C—$(CH_2)_5$—C and —OH), 3.35 (1H, t, —$CH(CO_2Me)_2$), 3.73 (6H, s, CH_3), 4.24 (2H, m, —CH_2O—), 5.65 (2H, m, —HC=CH—); ms m/e: 259 (MH^+).

*Methyl (*E*)-2-carbomethoxy-10-[(tetrahydro-2*H*-pyran-2-yl)oxy]-8-decenoate (**10**b)*

Following procedure 6: Alcohol **13***b* (1.43 g, 5.42 mmol) gave malonate **10***b* (1.79 g, 95%); ir: 1732 cm^{-1}; ^1H nmr δ: 1.10–2.20 (16H, m, C—$(CH_2)_3$—C and C—$(CH_2)_5$—C), 3.20–4.30 (5H, —$CH(CO_2Me)_2$ and —OCH_2—), 3.73 (6H, s, CH_3), 4.63 (1H, bs, —O_2CH—), 5.60 (2H, m, —HC=CH—); ms m/e: 343 (MH^+).

General procedure 7:

*Malonate **11**a from **8**a*

The catalyst 5% palladium on activated carbon (90 mg) was added under argon to a solution of malonate **8***a* (3.10 g, 8.95 mmol) in cyclohexane (10 mL) and ethyl acetate (2 mL). This mixture was then stirred under hydrogen (1.00 atm) until no more hydrogen uptake was observed. The solution was filtered through a Celite pad and the evaporation of solvents afforded crude malonate **11***a* (3.13 g, 100%) (impure from tlc analysis); ir: 1733 cm^{-1}; ^1H nmr δ: 1.10–2.00 (18H, m, C—$(CH_2)_6$—C and C—$(CH_2)_3$—C), 3.20–4.00 (5H, m, —$CH(CO_2Me)_2$, —OCH_2—), 3.71 (6H, s, CH_3), 4.50 (1H, bs, —O_2CH—); ms m/e: 331 (MH^+).

*Methyl 2-carbomethoxy-10-[(tetrahydro-2*H*-pyran-2-yl)oxy]-decanoate (**11**b)*

Following procedure 7: Alkyne **8***b* (2.10 g, 5.83 mmol) gave crude malonate **11***b* (2.13 g, 100%); ir: 1732 cm^{-1}; ^1H nmr δ: 1.15–2.00 (20H, m, C—$(CH_2)_7$—C and C—$(CH_2)_3$—C), 3.15–4.00 (5H, m, —$CH(CO_2Me)_2$ and —OCH_2—), 3.66 (6H, s, CH_3), 4.49 (1H, bs, —O_2CH—); ms m/e: 345 (MH^+).

General procedure 8:

*Methyl (Z)-2-carbomethoxy-2-[(Z)-4-chloro-2-butenyl]-9-[(tetrahydro-2*H*-pyran-2-yl)oxy]-7-nonenoate (**14**a [C–C])*

To a stirred solution of **9***a* (1.36 g, 4.15 mmol) in tetrahydrofuran (18 mL) was added sodium hydride (190 mg, 60% in mineral oil, 4.77 mmol) and this mixture was refluxed for 20 min. After cooling, (*Z*)-1,4-dichloro-2-butene (2.0 mL, 20 mmol) was added and the solution was heated under reflux for 20 min, cooled to 0°C, followed by addition of diethyl ether/hexanes (1:1) (100 mL). The organic phase was washed with 10% aqueous ammonium chloride (10 mL) and dried over sodium sulfate. After filtration and evaporation of solvents under reduced pressure, the residual oil was purified by flash chromotography (ethyl acetate/dichloromethane/hexanes 1:2:7) to afford chloride **14***a* (1.42 g, 82%) as an oil; ir: 1730 cm^{-1}; ^1H nmr δ: 1.10–2.20 (14H, m, C—$(CH_2)_3$—C and C—$(CH_2)_4$—C), 2.66, 2.75 (2H, d, J = 7 Hz, —C=$CCH_2C(CO_2Me)_2$—), 3.30–4.25 (6H, m, —OCH_2— and —CH_2Cl), 3.73 (6H, s, CH_3), 4.61 (1H, bs, —O_2CH—), 5.60 (4H, bm, —HC=CH—); ms m/e: 417 (MH^+).

General procedure 9:

*Methyl (Z),(Z)-2,7,7-tricarbomethoxy-14-[(tetrahydro-2*H*-pyran-2-yl)oxy]-4,12-tetradecadienoate (**15**a [C–C])*

To a stirred solution of **14***a* [C–C] (1.41 g, 3.38 mmol) and dimethyl malonate (2.2 mL, 16.9 mmol) in tetrahydrofuran (14 mL) and *N*,*N*-dimethylformamide (4 mL), was added sodium hydride (354 mg, 60% in mineral oil, 8.8 mmol). This solution was heated under reflux for 1.5 h, then cooled to room temperature. Water (50 mL) was added and the aqueous phase was extracted with a 1:1 mixture of diethyl ether/hexanes (3 × 80 mL). The combined organic phases were dried over sodium sulfate, filtered, and concentrated under reduced pressure (1 Torr (133.3 Pa), 90°C). The crude oil was then purified by flash chromatography (ethyl acetate/dichloromethane/hexanes 1:2:4) to afford **15***a* [C–C] (1.70 g, 98%) as an oil; ir: 1731 cm^{-1}; ^1H nmr δ: 1.10–2.20 (14H, m, C—$(CH_2)_4$—C and C—$(CH_2)_3$—C), 2.70 (4H, m, C=$CCH_2C(CO_2Me)_2$—), 3.30–4.00 (3H, m, —$CH(CO_2Me)_2$ and —OCH_2—, cyclic), 3.70, 3.73 (12H, s, CH_3), 4.14 (2H, m, THPOCH_2—), 4.61 (1H, bs, —O_2CH—), 5.20–5.70 (4H, m, —HC=CH—); ms m/e: 513 (MH^+).

General procedure 10:

*Methyl (Z),(Z)-2,7,7-tricarbomethoxy-14-hydroxy-4,12-tetradecadienoate (**16**a [C–C])*

The malonate **15***a* [C–C] (1.69 g, 3.3 mmol) and pyrdinium *p*-toluenesulfonate (100 mg, 0.4 mmol) were stirred in methanol (10 mL) for 24 h at room temperature. The solvent was evaporated, the volatile materials removed under vacuum, and methanol (5 mL) was added. The solvent was evaporated after 24 h, and the crude oil was filtered on silica gel (ethyl acetate/dichloromethane/hexanes (1:2:2)) to afford alcohol **16***a* [C–C] (1.38 g, 97%) as an oil; ir: 3620, 1730 cm^{-1}; ^1H nmr δ: 1.10–1.60 (5H, m, —OH, —$CH_2(CH_2)_2CH_2$—), 2.70–3.30 (4H, m, —$CH_2(CH_2)_2CH_2$—), 2.63 (4H, m, —C=$CCH_2C(CO_2Me)_2$), 3.37 (1H, t, J = 6 Hz, —$CH(CO_2Me)_2$), 3.71, 3.74 (12H, s, CH_3), 4.18 (2H, t, J = 6 Hz, —CH_2O—), 5.10–5.80 (4H, m, —HC=CH—); ms m/e: 429 (MH^+).

General procedure 11:

*Methyl (Z),(Z)-2,7,7-tricarbomethoxy-14-chloro-4,12-tetradecadienoate (**1**a [C–C])*

To a solution of the alcohol **16***a* [C–C] (1.36 g, 3.18 mmol), *s*-collidine (0.78 mL, 5.1 mmol), and lithium chloride (340 mg, 8.1 mmol) in *N*,*N*-dimethylformamide (25 mL) at 0°C, was added methanesulfonyl chloride (0.46 mL, 8.1 mmol). This solution was stirred 1 h at 0°C, then 2 h at room temperature, and finally poured into water (at 0°C) and extracted with diethyl ether/hexanes (1:1) (5 × 60 mL). The combined organic phases were dried over sodium sulfate and the solvents were evaporated. The residual oil was purified by flash chromatography (ethyl acetate/dichloromethane/hexanes, 1:2:4) to afford chloride **1***a* [C–C] (1.08 g, 77%) as an oil; ir: 1730 cm^{-1}; ^1H nmr δ: 1.00–1.60 (4H, m, —$CH_2(CH_2)_2CH_2$—), 1.70–2.30 (4H, m, —$CH_2(CH_2)_2$—(CH_2—), 2.63 (4H, m, C=$CCH_2(CO_2Me)_2$), 3.37 (1H, t, J = 7 Hz, —$CH(CO_2Me)_2$), 3.71, 3.73 (12H, s, CH_3), 4.03, 4.11 (2H, d, J = 6 Hz, —CH_2Cl), 5.20–5.70 (4H, m, —HC=CH—); ms m/e: 447 (MH^+).

General procedure 12:

*(Z),(Z)-1,1,6,6-Tetracarbomethoxy-3,8-cyclotridecadiene (**2**a [C–C]) and (Z),(Z),(Z),(Z)-1,1,6,6,14,14,19,19-octacarbomethoxy-3,8,16,21-cyclohexacosatetraene (**3**a [C–C])*

Chloride **1***a* [C–C] (185 mg, 0.450 mmol) was dissolved in tetrahydrofuran (11 mL) and *N*,*N*-dimethylformamide (11 mL) containing potassium carbonate (330 mg, 2.40 mmol) and the reaction mixture was heated at 90°C for 42 h. The solution was cooled and hexane (20 mL) was added. After filtration through a Celite pad, the solvents were removed by distillation under reduced pressure and the residual solid was purified by flash chromatography (ethyl acetate/dichloromethane/hexanes in successive ratios of 1:2:7, 1:2:4, 1:2:3) to afford monomer **2***a* [C–C] (118 mg, 70%, 95% pure from vpc analysis) and dimer **3***a* [C–C] (18.6 mg, 11%). Dimer **3***a* was recrystallized from chloroform/hexanes at −15°C. Monomer **2***a* was recrystallized from a (5:1) hot mixture of methanol/chloroform; ir of **2***a*: 3012, 1735, 1220 cm^{-1}; ir of **3***a*: 2955, 1733, 1200 cm^{-1}.

*Chloride **14**a [C–T] from **9**a*

Following procedure 8: Using (*E*)-1,4-dichloro-2-butene, malonate **9***a* (1.28 g, 3.9 mmol) gave **14***a* [C–T] (1.24 g, 76%); ir: 1731 cm^{-1}; ^1H nmr δ: 1.10–2.20 (14H, m, C—$(CH_2)_3$—C and C—$(CH_2)_4$—C), 2.63 (2H, m, C=CCH_2—$C(CO_2Me)_2$), 3.30–4.30 (6H, m, —OCH_2— and —CH_2Cl), 3.71 (6H, s, CH_3), 4.62 (1H, m, —O_2CH—), 5.60 (4H, m, —HC=CH—).

*Malonate **15**a [C–T] from **14**a [C–T]*

Following procedure 9: Chloride **14***a* [C–T] (1.23 g, 2.95 mmol) gave **15***a* [C–T] (1.40 g, 93%); ir: 1730, 1740 cm^{-1}; ^1H nmr δ:

—$CH_2(CH_2)_2CH_2$—), 2.57 (4H, m, C=$CCH_2C(CO_2Me)_2$), 3.38 (1H, t, J = 7.5 Hz, —$CH(CO_2Me)_2$), 3.70, 3.73 (12H, s, CH_3), 4.10 (2H, d, J = 7 Hz, —CH_2Cl), 5.28–5.72 (4H, m, —HC=CH—); ms m/e: 447 (MH^+).

(E),(Z)-1,1,6,6-Tetracarbomethoxy-3,8-cyclotridecadiene (2a [C–T]) and (E),(Z),(E),(Z)-1,1,6,6,14,14,19,19-octacarbomethoxy-3,8,16,21-cyclohexacosatetraene (3a [C–T]) from 1a [C–T]

Following procedure 12: Chloride **1***a* [C–T] (158 mg, 0.354 mmol) gave, after 62 h, monomer **2***a* [C–T] (15.3 mg, 10.5%, estimated to be 75% pure from ^{13}C nmr analysis; no vpc analysis was possible due to decomposition during analysis) and dimer **3***a* [C–T] (68.3 mg, 46.9%); ir of **2***a*: 1729, 1212 cm^{-1}; ir of **3***a*: 1732, 1202 cm^{-1}.

Chloride 14a [T–T] from 10a

Following procedure 8: Using (*E*)-1,4-dichloro-2-butene, malonate **10***a* (1.59 g, 4.86 mmol) gave **14***a* [T–T] (1.59 g, 79%); ir: 1731 cm^{-1}; ^1H nmr δ: 1.00–2.20 (14H, m, C—$(CH_2)_4$—C and C—$(CH_2)_3$—C), 2.67 (2H, m, C=$CCH_2C(CO_2Me)_2$), 3.30–4.40 (6H, m, —OCH_2— and —CH_2Cl), 3.71 (6H, s, CH_3), 4.61 (1H, m, —O_2CH—), 5.65 (4H, bm, —HC=CH—); ms m/e: 417 (MH^+).

Malonate 15a [T–T] from 14a [T–T]

Following procedure 9: Compound **14***a* [T–T] (1.58 g, 3.8 mmol) gave **15***a* [T–T] as an oil; ir: 1733 cm^{-1}; ^1H nmr δ: 1.10–2.20 (14H, m, C—$(CH_2)_4$—C and C—$(CH_2)_3$—C), 2.60 (4H, m, C=$CCH_2C(CO_2Me)_2$), 3.38 (1H, t, —$CH(CO_2Me)_2$), 3.70 and 3.74 (12H, s, CH_3), 3.40–4.20 (4H, m, —OCH_2—), 4.61 (1H, bs, —O_2CH—), 5.41 and 5.66 (4H, 2 m, —HC=CH—); ms m/e: 429 (MH^+ − THP).

Alcohol 16a [T–T] from 15a [T–T]

Following procedure 10: Malonate **15***a* [T–T] gave **16***a* [T–T] (1.43 g, 88% from **14***a* [T–T]); ir: 3610, 1728 cm^{-1}; ^1H nmr δ: 1.00–2.20 (9H, m, —OH and C—$(CH_2)_4$—C), 2.58 (4H, m, C=$CCH_2C(CO_2Me)_2$), 3.38 (1H, t, —$CH(CO_2Me)_2$), 3.69, 3.73 (12H, s, CH_3), 4.09 (2H, m, —CH_2O—), 5.40 and 5.64 (4H, 2 m, —HC=CH—); ms m/e: 429 (MH^+).

Chloride 1a [T–T] from 16a [T–T]

Following procedure 11: Alcohol **16***a* [T–T] (1.42 g, 3.32 mmol) gave chloride **1***a* [T–T] (1.26 g, 85%); ir: 1730 cm^{-1}; ^1H nmr δ: 1.00–2.20 (8H, m, C—$(CH_2)_4$—C), 2.60 (4H, m, C=CCH_2—$C(CO_2Me)_2$), 3.38 (1H, t, —$CH(CO_2Me)_2$), 3.70 and 3.73 (12H, s, CH_3), 3.99 (2H, d, J = 5 Hz, —CH_2Cl), 5.40 and 5.62 (4H, 2 m, —HC=CH—); ms m/e: 447 (MH^+).

(E),(E)-1,1,6,6-Tetracarbomethoxy-3,8-cyclotridecadiene (2a [T–T]) and (E),(E),(E),(E)-1,1,6,6,14,14,19,19-octacarbomethoxy-3,8,16,21-cyclohexacosatetraene (3a [T–T]) from 1a [T–T]

Following procedure 12: Chloride **1***a* [T–T] (188 mg, 0.420 mmol) gave, after 60 h, monomer **2***a* (24.1 mg, 14%) and dimer **3***a* (70.3 mg, 40.8%); ir of **2***a*: 1731, 1205–1225 cm^{-1}; ir of **3***a*: 1730, 1279, 1200 cm^{-1}.

Chloride 14a [A–C] from 8a

Following procedure 8: Malonate **8***a* (1.43 g, 4.39 mmol) gave compound **14***a* [A–C] 0.97 g, 54%); ir: 1736 cm^{-1}; ^1H nmr δ: 1.10–2.20 (14H, m, C—$(CH_2)_4$—C and C—$(CH_2)_3$—C), 2.80 (2H, d, J = 6 Hz, —C=$CCH_2C(CO_2Me)_2$—), 3.30–4.00 (2H, m, —OCH_2—, cyclic), 3.72 (6H, s, CH_3), 4.10 (2H, d, J = 5 Hz, —CH_2Cl), 4.22 (2H, m, THPOCH_2—), 4.78 (1H, bs, —O_2CH—), 5.61 (2H, bm, —HC=CH—).

Malonate 15a [A–C] from 14a [A–C]

Following procedure 9: Chloride **14***a* [A–C] (0.96 g, 2.31 mmol) gave malonate **15***a* [A–C] (0.98 g, 77%); ir: 1733 cm^{-1}; ^1H nmr δ: 1.10–2.40 (14H, m, C—CH_2)$_4$—C and C—$(CH_2)_3$—C), 2.65 (4H, m, C=$CCH_2C(CO_2Me)_2$), 3.37 (1H, t, —$CH(CO_2Me)_2$), 3.40–4.00 (2H, m, —OCH_2—, cyclic), 3.71, 3.74 (12H, s, CH_3), 4.22 (2H, m, THPOCH_2—), 4.77 (1H, bs, —O_2CH—), 5.40 (2H, m, —HC=CH—).

Alcohol 16a [A–C] from 15a [A–C]

Following procedure 10: Compound **15***a* [A–C] (0.97 g, 1.9 mmol) gave alcohol **16***a* [A–C] (0.81 g, 100%); ir: 3300–3620, 1730 cm^{-1}; ^1H nmr δ: 1.40, 1.87, 2.22 (9H, 3 m, —OH and C—$(CH_2)_4$—C), 2.65 (4H, m, C=$CCH_2C(CO_2Me)_2$), 3.38 (1H, t, —$CH(CO_2Me)_2$), 3.71, 3.74 (12H, s, CH_3), 4.26 (2H, dt, J = 1.5 and 4.5 Hz, $HOCH_2$—), 5.40 (2H, bm, —HC=CH—).

Chloride 1a [A–C] from 16a [A–C]

Following procedure 11: Alcohol **16***a* [A–C] (0.800 g, 1.88 mmol) gave the precursor **1***a* [A–C] (0.64 g, 77%); ir: 1730 cm^{-1}; ^1H nmr δ: 1.26, 1.51, 1.85 (6H, m, —$(CH_2)_3C(CO_2Me)_2$—), 2.24 (2H, tt, J = 2.3 and 7 Hz, —C≡CCH_2—$(CH_2)_3$—), 2.66 (4H, m, —C=CCH_2—), 3.37 (1H, t, J = 7.5 Hz, —$CH(CO_2Me)_2$), 3.71, 3.74 (12H, s, CH_3), 4.13 (2H, t, J = 2.3 Hz, —CH_2Cl), 5.38 (2H, bm, —HC=CH—); ms m/e: 445 (MH^+).

(Z)-1,1,6,6-Tetracarbomethoxy-3-cyclotridecen-8-yne (2a [A–C]) and (Z),(Z)-1,1,6,6,14,14,19,19-octacarbomethoxy-3,16-cyclohexacosadiene-8,21-diyne (3a [A–C])

Following procedure 12: After 36 h, chloride **1***a* [A–C] (125.1 mg, 0.28 mmol) gave monomer **2***a* [A–C] (105 mg, 91.4%) and dimer **3***a* [A–C] (5.7 mg, 5%); ir of **2***a*: 1730, 1075 cm^{-1}; ir of **3***a*: 1732 cm^{-1}.

Chloride 14a [A–T] from 8a

Following procedure 8: Compound **8***a* (1.35 g, 4.13 mmol) and (*E*)-1,4-dichloro-2-butene gave **14***a* [A–T] (1.28 g, 75%); ir: 1732 cm^{-1}; ^1H nmr δ: 1.10–2.40 (14H, m, C—$(CH_2)_3$—C and C—$(CH_2)_4$—C), 2.65 (2H, m, C=$CCH_2C(CO_2Me)_2$), 3.30–4.00 (2H, m, —OCH_2—, cyclic), 3.72 (6H, s, CH_3), 3.97 (2H, d, —CH_2Cl), 4.22 (2H, m, THPOCH_2—), 4.77 (1H, bs, —O_2CH—), 5.65 (2H, m, —HC=CH—).

Malonate 15a [A–T] from 14a [A–T]

Following procedure 9: Chloride **14***a* [A–T] (1.27 g, 3.07 mmol) gave compound **15***a* [A–T] (1.51 g, 97%); ir: 1735 cm^{-1}; ^1H nmr δ: 1.10–2.40 (14H, m, C—$(CH_2)_4$—C and C—$(CH_2)_3$—C), 2.60 (4H, m, —C=CCH_2—), 3.38 (1H, t, —$CH(CO_2Me)_2$), 3.30–4.00 (2H, m, —OCH_2—, cyclic), 3.70, 3.73 (12H, s, CH_3), 4.22 (2H, m, THPOCH_2—), 4.78 (1H, bs, —O_2CH—), 5.40 (2H, m, —HC=CH—).

Alcohol 16a [A–T] from 15a [A–T]

Following procedure 10: Malonate **15***a* [A–T] (1.50 g, 2.94 mmol) gave **16***a* [A–T] (1.23 g, 99%); ir: 3620, 1735 cm^{-1}; ^1H nmr δ: 1.10–2.35 (9H, m, —OH and C—$(CH_2)_4$—C), 2.58 (4H, m, —C=CCH_2—), 3.39 (1H, t, —$CH(CO_2Me)_2$), 3.70, 3.74 (12H, s, CH_3), 4.23 (2H, dt, —CH_2O—), 5.40 (2H, m, —HC=CH—).

Chloride 1a [A–T] from 16a [A–T]

Following procedure 11: Alcohol **16***a* [A–T] (1.22 g, 2.87 mmol) gave chloride **1***a* [A–T] (0.945 g, 74%); ir: 1730 cm^{-1}; ^1H nmr δ: 1.26, 1.50, 1.81 (6H, 3 m, —$(CH_2)_3C(CO_2Me)_2$), 2.23 (2H, tt, J = 2.3 and 7 Hz, —C≡CCH_2—$(CH_2)_3$—), 2.58 (4H, m, —C=C—CH_2—), 3.38 (1H, t, J = 7.6 Hz, —$CH(CO_2Me)_2$), 3.70, 3.73 (12H, s, CH_3), 4.13 (2H, t, J = 2.4 Hz, —CH_2Cl), 5.25–5.60 (2H, m, —HC=CH—); ms m/e: 445 (MH^+).

(E)-1,1,6,6-Tetracarbomethoxy-3-cyclotridecen-8-yne (2a [A–T]) and (E),(E)-1,1,6,6,14,14,19,19-octacarbomethoxy-3,16-cyclohexacosadiene-8,21-diyne (3a [A–T])

Following procedure 12: Chloride **1***a* [A–T] (156 mg, 0.35 mmol) gave, after 42 h, monomer **2***a* [A–T] (86.8 mg, 61%) and **3***a* [A–T] (33.7 mg, 23.5%); ir of **2***a*: 1730, 1095 cm^{-1}; ir of **3***a*: 1732, 1282 cm^{-1}.

Chloride 14a [A–A] from 8a

Following procedure 8: 1,4-Dichloro-2-butyne and malonate **8***a* (1.39 g, 4.26 mmol) gave **14***a* [A–A] (1.57 g, 90%); ir: 1736 cm^{-1}; ^1H nmr δ: 1.10–2.35 (14H, m, C—$(CH_2)_3$—C and C—$(CH_2)_4$—C), 2.90 (2H, t, J = 2.5 Hz, C≡$CCH_2C(CO_2Me)_2$—), 3.30–4.00 (2H, m, —OCH_2—, cyclic), 3.74 (6H, s, CH_3), 4.09 (2H, t, J = 2.5 Hz, —CH_2Cl), 4.22 (2H, m, THPOCH_2—), 4.79 (1H, bs, —O_2CH—); ms m/e: 413 (MH^+).

Malonate ***15***a *[A–A] from* ***14***a *[A–A]*

Following procedure 9: Compound ***14a*** [A–A] (1.56 g, 3.79 mmol) gave ***15a*** [A–A] (1.82 g, 95%); ir: 1736 cm^{-1}; ^1H nmr δ: 1.10–2.40 (14H, m, C—$(CH_2)_4$—C and C—$(CH_2)_3$—C), 2.60–2.80 (4H, m, —C≡C—CH_2—$C(CO_2Me)_2$), 3.3–4 (3H, m, —$CH(CO_2Me)_2$ and —OCH_2—, cyclic), 3.72, 3.77 (12H, s, CH_3), 4.24 (2H, m, $THPOCH_2$—), 4.78 (1H, bs, —O_2CH—); ms *m/e*: 508 (M^+).

Alcohol ***16***a *[A–A] from* ***15***a *[A–A]*

Following procedure 10: Compound ***15a*** [A–A] (1.81 g, 3.56 mmol) gave ***16a*** [A–A] (1.49 g, 99%); ir: 1730 cm^{-1}; ^1H nmr δ: 1.10–2.40 (9H, m, —OH and C—$(CH_2)_4$—C—), 2.77 (4H, m, C≡$CCH_2C(CO_2Me)_2$), 3.53 (1H, t, —$CH(CO_2Me)_2$), 3.73, 3.77 (12H, s, CH_3), 4.21 (2H, dt, *J* = 2 and 7 Hz, —CH_2O—); ms *m/e*: 425 (MH^+).

Chloride ***1***a *[A–A] from* ***16***a *[A–A]*

Following procedure 11: Alcohol ***16a*** [A–A] (1.48 g, 3.49 mmol) gave ***1a*** [A–A] (1.27 g, 82%); ir: 1735 cm^{-1}; ^1H nmr δ: 1.10–2.40 (8H, m, C—$(CH_2)_4$—C), 2.78 (4H, m, —C≡$CCH_2C(CO_2Me)_2$—C), 3.50 (1H, m, —$CH(CO_2Me)_2$), 3.73–3.77 (12H, s, CH_3), 4.13 (2H, t, *J* = 2 Hz, —CH_2Cl); ms *m/e*: 443 (MH^+).

*1,1,6,6-Tetracarbomethoxy-3,8-cyclotridecadiyne (***2***a [A–A]) and 1,1,6,6,14,14,19,19-octacarbomethoxy-3,8,16,21-cyclohexacosatetrayne (***3***a [A–A])*

Following procedure 12: Chloride ***1a*** [A–A] (233 mg, 0.527 mmol) gave ***2a*** [A–A] (144 mg, 67%) and ***3a*** [A–A] (38 mg, 18%); ir of ***2a***: 1735, 1280 cm^{-1}; ir of ***3a***: 1738, 1200 cm^{-1}.

Chloride ***14***a *[A] from* ***11***a

Following procedure 8: 1,4-Dichloro-2-butyne and malonate ***11a*** (1.60 g, 4.85 mmol) gave ***14a*** [A] (1.42 g, 70%); ir: 2250, 1732 cm^{-1}; ^1H nmr δ: 1.10–2.20 (18H, m, C—$(CH_2)_3$—C and C—$(CH_2)_6$—C), 2.85 (2H, m, C≡$CCH_2C(CO_2Me)_2$), 3.30–4.10 (4H, m, —OCH_2—), 3.72 (6H, s, CH_3), 4.08 (2H, m, —CH_2Cl), 4.56 (1H, bs, —O_2CH—).

Malonate ***15***a *[A] from* ***14***a *[A]*

Following procedure 9: Compound ***14a*** [A] (1.41 g, 3.39 mmol) gave ***15a*** [A] (1.40 g, 85%); ir: 1735 cm^{-1}; ^1H nmr δ: 1.00–2.15 (18H, m, C—$(CH_2)_3$—C and C—$(CH_2)_6$—C), 2.75 (4H, bs, —C≡$CCH_2C(CO_2Me)_2$), 3.20–4.10 (5H, m, —$CH(CO_2Me)_2$, —OCH_2—), 3.70, 3.75 (12H, s, CH_3), 4.56 (1H, bs, —O_2CH—).

Alcohol ***16***a *[A] from* ***15***a *[A]*

Following procedure 10: Compound ***15a*** [A] (1.39 g, 2.71 mmol) gave ***16a*** [A] (1.12 g, 97%); ^1H nmr δ: 1.10–1.70 (11H, m, —OH and —$(CH_2)_5$—$C(CO_2Me)_2$—), 1.95 (2H, m, —CH_2CH_2O—), 2.76 (4H, bs, —C≡CCH_2—), 3.30–3.90 (3H, m, —OCH_2— and —$CH(CO_2Me)_2$), 3.71, 3.76 (12H, s, CH_3).

General procedure 13:

Bromide ***4*** *from* ***16*** *[A]*

*Methyl 14-bromo-2,7,7-tricarbomethoxy-4-tetradecynoate (***4***a)*

The alcohol ***16a*** [A] (1.115 g, 2.60 mmol) and carbon tetrabromide (1.0 g, 3.0 mmol) were dissolved in dichloromethane (15 mL) at 0°C. To this solution was rapidly added a solution of triphenylphosphine (0.900 g, 3.39 mmol) in dichloromethane (5 mL). The solution was stirred for 2 h at 0°C, and for 10 h at room temperature. The solvents were evaporated under vacuum and the solid residue was dissolved in a minimum amount of dichloromethane and purified by flash chromatography (ethyl acetate/dichloromethane/hexanes, 1:2:4) to afford ***4a*** (1.14 g, 89%) as an oil; ir: 1730 cm^{-1}; ^1H nmr δ: 1.31 (8H, m, —$(CH_2)_4$—$CH_2C(CO_2Me)_2$), 1.86 (4H, m, —$CH_2(CH_2)_4CH_2C(CO_2Me)_2$—), 2.74 (4H, bs, —C≡$CCH_2$—), 3.39 (3H, bt, —$CH_2Br$ and —$CH(CO_2Me)_2$), 3.70, 3.74 (12H, s, CH_3); ms *m/e*: 491 (MH^+).

1,1,6,6-Tetracarbomethoxy-3-cyclotridecyne ***6***a *and 1,1,6,6,14,14,19,19-octacarbomethoxy-3,16-cyclohexacosadiyne* (dimer)

Following procedure 12: After 40 h, bromide ***4a*** (172 mg, 0.349 mmol) gave at 2×10^{-3} *M* the monomer ***6a*** (78.6 mg, 54.8%) and dimer (18.7 mg, 13%); ir of ***6a***: 1736, 1060 cm^{-1}; ir of dimer: 2935, 1736, 1203 cm^{-1}.

General procedure 14:

Bromide ***5*** *from* ***4***

*Methyl 14-bromo-2,7,7-tricarbomethoxytetradecanoate (***5***a)*

To a solution of ***4a*** (551 mg, 1.11 mmol) dissolved in ethyl acetate (10 mL) was added sodium sulfate (100 mg) and platinum(IV) oxide (25 mg) under an argon atmosphere. This mixture was stirred for 2 h under a hydrogen atmosphere, then filtered through a Celite pad. Evaporation of solvents afforded bromide ***5a*** (549 mg, 99%) as an oil; ir: 1731 cm^{-1}; ^1H nmr δ: 0.90–1.50 and 1.50–2.10 (20H, m, —$(CH_2)_6$—$C(CO_2Me)_2$—$(CH_2)_4$—), 3.31 (1H, t, *J* = 7 Hz, —$CH(CO_2Me)_2$), 3.38 (2H, t, *J* = 7 Hz, —CH_2Br), 3.68, 3.70 (12H, s, CH_3); ms *m/e*: 495 (MH^+).

*1,1,6,6-Tetracarbomethoxycyclotridecane (***7***a) and 1,1,6,6,14,14,19,19-octacarbomethoxycyclohexacosane* (dimer)

Following procedure 12: At 2×10^{-3} *M*, bromide ***5a*** (171 mg, 0.345 mmol) gave, after 44 h, monomer ***7a*** (60.6 mg, 42.5%) as an impure solid. Another run in the presence of a 4:1 mixture of potassium carbonate and cesium carbonate (250 mg) gave, after 16 h, monomer ***7a*** (57.8% and 54.1%); ir of ***7a***: 2932, 1730, 1179 cm^{-1}. No dimer was detected from mass spectral (ms) analysis.

Chloride ***14***b *[C–C] from* ***9***b

Following procedure 8: Malonate ***9b*** (1.41 g, 4.12 mmol) gave ***14b*** [C–C] (1.19 g, 67%); (no spectral data available).

Malonate ***15***b *[C–C] from* ***14***b *[C–C]*

Following procedure 9: Compound ***14b*** [C–C] (1.19 g, 2.77 mmol) gave ***15b*** [C–C] (1.08 g, 75%); ir: 1730–1740 cm^{-1}; ^1H nmr δ: 1.00–2.15 (16H, m, C—$(CH_2)_5$—C and C—$(CH_2)_3$—C), 2.63 (4H, m, —C=$CCH_2C(CO_2Me)_2$), 3.25–4.25 (5H, m, —$CH(CO_2Me)_2$ and —OCH_2—), 3.70, 3.73 (12H, s, CH_3), 4.61 (1H, m, —O_2CH—), 5.20–5.70 (4H, m, —HC=CH—).

Alcohol ***16***b *[C–C] from* ***15***b *[C–C]*

Following procedure 10: Compound ***15b*** [C–C] (1.07 g, 2.04 mmol) gave ***16b*** [C–C] (0.901 g, 100%); ir: 1736 cm^{-1}; ^1H nmr δ: 1.28 (7H, m, —OH, —$CH_2(CH_2)_3CH_2$—), 1.95 (4H, m, —CH_2—$(CH_2)_3CH_2$—), 2.63 (4H, m, C=$CCH_2C(CO_2Me)_2$), 3.37 (1H, t, —$CH(CO_2Me)_2$), 3.71, 3.74 (12H, s, CH_3), 4.25 (2H, t, *J* = 5 Hz, —CH_2O—), 5.20–5.70 (4H, m, —HC=CH—).

Chloride ***1***b *[C–C] from* ***16***b *[C–C]*

Following procedure 11: Alcohol ***16b*** [C–C] (890 mg, 2.01 mmol) gave chloride ***1b*** [C–C] (785 mg, 85%); ir: 1731 cm^{-1}; ^1H nmr δ: 1.18, 1.35, 1.85, 2.10 (10H, 4 m, —$C(CH_2)_5C$—), 2.66 (4H, m, C=$CCH_2C(CO_2Me)_2$), 3.36 (1H, t, *J* = 7.6 Hz, —$CH(CO_2Me)_2$), 3.70, 3.73 (12H, s, CH_3), 4.08 (2H, m, —CH_2Cl), 5.38, 5.61 (4H, 2 m, —HC=CH—); ms *m/e*: 461 (MH^+).

*(Z),(Z)-1,1,6,6-Tetracarbomethoxy-3,8-cyclotetradecadiene (***2***b [C–C]) and (Z),(Z),(Z),(Z)-1,1,6,6,15,15,20,20-octacarbomethoxy-3,8,17,22-cyclooctacosatetraene (***3***b [C–C])*

Following procedure 12: After 58 h, chloride ***1b*** [C–C] (142.7 mg, 0.31 mmol) gave monomer ***2b*** [C–C] (101 mg, 77.1%, 90% pure from vpc analysis) and ***3b*** [C–C] (4.9 mg, 3.7%); ir of ***2b***: 1730, 1100 cm^{-1}; ir of ***3b***: 1732, 975 cm^{-1}. The monomer could not be recrystallized or purified.

Chloride ***14***b *[C–T] from* ***9***b

Following procedure 8: Malonate ***9b*** (1.41 g, 4.14 mmol) and (*E*)-1,4-dichloro-2-butene gave compound ***14b*** [C–T] (1.41 g, 79%); ^1H nmr δ: 1.00–2.20 (16H, m, C—$(CH_2)_3$—C and C—$(CH_2)_5$—C), 2.63 (2H, m, —C=$CCH_2C(CO_2Me)_2$), 3.20–4.00 (2H, m, —OCH_2—, cyclic), 3.71 (6H, s, CH_3), 3.99 (2H, m, —CH_2Cl), 4.17 (2H, m, $THPOCH_2$—), 4.61 (1H, bs, —O_2CH—), 5.63 (4H, m, —HC=CH—).

Malonate ***15***b *[C–T] from* ***14***b *[C–T]*

Following procedure 9: Chloride ***14b*** [C–T] (1.41 g, 3.28 mmol) gave compound ***15b*** [C–T] (1.55 g, 90%); ir: 1735 cm^{-1}; ^1H nmr δ:

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 80.58.250.72 on 09/07/12
For personal use only.

1.10–2.20 (16H, m, C—$(CH_2)_3$—C and C—$(CH_2)_5$—C), 2.59 (4H, m, C=$CCH_2C(CO_2Me)_2$), 3.25–4.00 (3H, m, —$CH(CO_2Me)_2$ and —OCH_2—, cyclic), 3.70, 3.73 (12H, s, CH_3), 4.15 (2H, m, THPOCH_2—), 4.62 (1H, bs, —O_2CH—), 5.50 (4H, m, —HC=CH—).

Alcohol ***16***b *[C–T] from* ***15***b *[C–T]*

Following procedure 10: Compound ***15****b* [C–T] (1.54 g, 2.93 mmol) gave alcohol ***16****b* [C–T] (1.28 g, 99%); ir: 3620, 1731 cm^{-1}; ^1H nmr δ: 1.28, 1.90 (11H, 2 m, —OH and C—$(CH_2)_5$—C), 2.59 (4H, m, C=$CCH_2C(CO_2Me)_2$—), 3.39 (1H, t, —$CH(CO_2Me)_2$), 3.70, 3.73 (12H, s, CH_3), 4.18 (2H, t, —CH_2O—), 5.50 (4H, m, —HC=CH—).

Chloride ***1***b *[C–T] from* ***16***b *[C–T]*

Following procedure 11: Alcohol ***16****b* [C–T] (1.27 g, 2.88 mmol) gave chloride ***1****b* [C–T] (1.10 g, 87%); ir: 1735 cm^{-1}; ^1H nmr δ: 1.13–1.34 (2H and 4H, 2 m, —$CH_2(CH_2)_3$—CH_2—), 1.80, 2.08 (4H, 2 m, —$CH_2(CH_2)_3CH_2$—), 2.58 (4H, m, C=$CCH_2C(CO_2Me)_2$), 3.37 (1H, t, J = 7.7 Hz, —$CH(CO_2Me)_2$), 3.70, 3.73 (12H, 2 s, CH_3), 4.08 (2H, m, —CH_2Cl), 5.40, 5.61 (4H, 2 m, —HC=CH—); ms m/e: 461 (MH^+).

*(E),(Z)-1,1,6,6-Tetracarbomethoxy-3,8-cyclotetradecadiene (****2****b [C–T]) and (E),(Z),(E),(Z)-1,1,6,6,15,15,20,20-octacarbomethoxy-3,8,17,22-cyclooctacosatetraene (****3****b [C–T])*

Following procedure 12: After 60 h, chloride ***1****b* [C–T] (123 mg, 0.376 mmol) gave ***2****b* [C–T] (32 mg, 20%) and dimer ***3****b* [C–T] (60.6 mg, 38%); ir of ***2****b*: 1732, 1278 cm^{-1}; ir of ***3****b*: 1730, 1239 cm^{-1}. The monomer was recrystallized in hot methanol, followed by addition of hexanes and cooling at 0°C.

Chloride ***14***b *[T–T] from* ***10***b

Following procedure 8: (*E*)-1,4-Dichloro-2-butene and malonate ***10****b* (1.39 g, 4.06 mmol) gave chloride ***14****b* [T–T] (1.29 g, 74%); ir: 1731 cm^{-1}; ^1H nmr δ: 1.10–2.15 (16H, m, C—$(CH_2)_3$—C and C—$(CH_2)_5$—C), 2.63 (2H, m, —C=$CCH_2C(CO_2Me)_2$—), 3.30–4.30 (6H, m, —CH_2O—, CH_2Cl), 3.72 (6H, s, CH_3), 4.61 (1H, bs, —O_2CH—), 5.65 (4H, m, —HC=CH—); ms m/e: 431 (MH^+).

Malonate ***15***b *[T–T] from* ***14***b *[T–T]*

Following procedure 9: Chloride ***14****b* [T–T] (1.27 g, 2.95 mmol) gave ***15****b* [T–T] (1.52 g, 98%); ir: 1730 cm^{-1}; ^1H nmr δ: 1.25, 1.64, 2.03 (16H, 3 m, C—$(CH_2)_3$—C and C—$(CH_2)_5$—C), 2.60 (4H, m, C=$CCH_2C(CO_2Me)_2$), 3.38 (1H, t, —$CH(CO_2Me)_2$), 3.70, 3.74 (12H, s, CH_3), 3.40–4.20 (4H, m, —OCH_2—), 4.63 (1H, bs, —O_2CH—), 5.41 and 5.64 (4H, 2 m, —HC=CH—); ms m/e: 527 (MH^+).

Alcohol ***16***b *[T–T] from* ***15***b *[T–T]*

Following procedure 10: Compound ***15****b* [T–T] (1.51 g, 2.87 mmol) gave ***16****b* [T–T] (1.265 g, 100%); ir: 1731 cm^{-1}; ^1H nmr δ: 1.10–1.60, 1.60–2.20 (11H, 2 m, —OH and C—$(CH_2)_5$—C), 2.59 (4H, m, C=$CCH_2C(CO_2Me)_2$), 3.38 (1H, t, —$CH(CO_2Me)_2$), 3.69, 3.79 (12H, s, CH_3), 4.07 (2H, m, —CH_2O—), 5.39, 5.65 (4H, 2 m, —HC=CH—); ms m/e: 443 (MH^+).

Chloride ***1***b *[T–T] from* ***16***b *[T–T]*

Following procedure 11: Alcohol ***16****b* [T–T] (1.26 g, 285 mmol) gave ***1****b* [T–T] (1.08 g, 83%); ir: 1735 cm^{-1}; ^1H nmr δ: 1.27 and 1.85 (6H and 4H, 2 m, C—$(CH_2)_5$—C), 2.59 (4H, m, C=$CCH_2C(CO_2Me)_2$), 3.38 (1H, t, —$CH(CO_2Me)_2$), 3.69, 3.73 (12H, 2 s, CH_3), 4.02 (2H, d, J = 5 Hz, —CH_2Cl), 5.40, 5.64 (4H, 2 m, —HC=CH—); ms m/e: 461 (MH^+).

*(E),(E)-1,1,6,6-Tetracarbomethoxy-3,8-cyclotetradecadiene (****2****b [T–T]) and (E),(E),(E),(E)-1,1,6,6,15,15,20,20-octacarbomethoxy-3,8,17,22-cyclooctacosatetraene (****3****b [T–T])*

Following procedure 12: Chloride ***1****b* [T–T] (173 mg, 0.377 mmol) gave, after 60 h, the monomer ***2****b* [T–T] (12.5 mg, 7.9%, 85% pure from vpc analysis) and ***3****b* [T–T] (47.2 mg, 31%). The monomer was purified by recrystallization in a 4:1 mixture of acetone/water followed by cooling at 0°C; ir of ***2****b*: 1730, 1230, 970 cm^{-1}; ir of ***3****b*: 1730, 1197, 971 cm^{-1}.

Chloride ***14***b *[A–C] from* ***8***b

Following procedure 8: Malonate ***8****b* (1.52 g, 4.47 mmol) gave ***14****b* [A–T] (1.66 g, 87%); ir: 1730, 1021 cm^{-1}; ^1H nmr δ: 1.00–2.30 (16H, m, C—$(CH_2)_3$—C and C—$(CH_2)_5$—C), 2.70 (2H, bd, J = 6 Hz, —C=$CH_2C(CO_2Me)_2$), 3.30–4.00 (2H, bm, —OCH_2—, cyclic), 3.72 (6H, s, CH_3), 4.08 (2H, d, J = 6 Hz, —CH_2Cl), 4.23 (2H, q, THPOCH_2—), 4.79 (1H, bs, —O_2CH—), 5.60 (2H, bm, —HC=CH—).

Malonate ***15***b *[A–C] from* ***14***b *[A–C]*

Following procedure 9: Compound ***14****b* [A–C] (1.65 g, 3.85 mmol) gave ***15****b* [A–C] (2.00 g, 100%); ir: 1735 cm^{-1}; ^1H nmr δ: 1.00–2.40 (16H, m, C—$(CH_2)_3$—C and C—$(CH_2)_5$—C), 2.63 (4H, m, C=$CCH_2C(CO_2Me)_2$), 3.25–4.00 (3H, m, —OCH_2—, cyclic and —$CH(CO_2Me)_2$), 3.71, 3.74 (12H, s, CH_3), 4.23 (2H, q, THPOCH_2—), 4.79 (1H, bs, —O_2CH—), 5.40 (2H, bm, —HC=CH—).

Alcohol ***16***b *[A–C] from* ***15***b *[A–C]*

Following procedure 10: Compound ***15****b* [A–C] (1.995 g, 3.81 mmol) gave alcohol ***16****b* [A–C] (1.66 g, 99%); ir: 3300–3620, 1720–1750 cm^{-1}; ^1H nmr δ: 1.40–1.76, 2.20 (11H, 3 m, —OH and C—$(CH_2)_5$—C), 2.63 (4H, m, —C=$CCH_2C(CO_2Me)_2$), 3.39 (1H, t, J = 7.5 Hz, —$CH(CO_2Me)_2$), 3.71, 3.74 (12H, s, CH_3), 4.22 (2H, dt, J = 2 and 6 Hz, —CH_2O—), 5.40 (2H, bm, —HC=CH).

Chloride ***1***b *[A–C] from* ***16***b *[A–C]*

Following procedure 11: Alcohol ***16****b* [A–C] (1.65 g, 3.75 mmol) gave ***1****b* [A–C] (1.59 g, 92%); ir: 1731 cm^{-1}; ^1H nmr δ: 1.15, 1.26, 1.38, 1.84, 2.21 (10H, 5 m, C—$(CH_2)_5$—C), 2.63 (4H, m, —C=$CCH_2C(CO_2Me)_2$), 3.36 (1H, t, J = 7.5 Hz, —$CH(CO_2Me)_2$), 3.69, 3.73 (12H, s, CH_3), 4.12 (2H, t, J = 2.3 Hz, —CH_2Cl), 5.35 (2H, m, —HC=CH—); ms m/e: 459 (MH^+).

*(Z)-1,1,6,6-Tetracarbomethoxy-3-cyclotetradecen-8-yne (****2****b [A–C]) and (Z),(Z)-1,1,6,6,15,15,20,20-octacarbomethoxy-3,17-cyclooctacosadiene-8,20-diyne (****3****b [A–C])*

Following procedure 12: Chloride ***1****b* [A–C] (184.9 mg, 0.404 mmol) after 38 h gave ***2****b* [A–C] (135.5 mg, 79.6%) and dimer ***3****b* [A–C] (3.3 mg, 1.9%); ir of ***2****b*: 1730, 1047 cm^{-1}; ir of ***3****b*: 1730, 1100 cm^{-1}.

Chloride ***14***b *[A–T] from* ***8***b

Following procedure 8: (*E*)-1,4-Dichloro-2-butene and malonate ***8****b* (1.50 g, 4.49 mmol) gave ***14****b* [A–T] (1.59 g, 84%) as an impure oil; ir: 1732 cm^{-1}; ^1H nmr δ: 1.16, 1.40, 1.53, 1.85 (8H, 4 m, —$(CH_2)_4$—$C(CO_2Me)_2$), 2.21 (2H, tt, J = 7 and 2.1 Hz, —C≡CCH_2C—), 2.64 (2H, d, J = 6.3 Hz, C=$CCH_2C(CO_2Me)_2$), 3.52 and 3.84 (2H, 2 m, —OCH_2—, cyclic), 3.72 (6H, s, CH_3), 3.99 (2H, d, J = 5.9 Hz, —CH_2Cl), 4.24 (2H, q of t, J = 12.3 and 2.1 Hz, THPOCH_2—), 4.81 (1H, bt, —O_2CH—), 5.64 (2H, bm, —HC=CH—); ms m/e: 429 (MH^+).

Malonate ***15***b *[A–T] from* ***14***b *[A–T]*

Following procedure 9: Compound ***14****b* [A–C] (1.58 g, 3.73 mmol) gave ***15****b* [A–T] (1.73 g, 88%); ir: 1736 cm^{-1}; ^1H nmr δ: 1.15, 1.28, 1.52, 1.80, 2.20 (10H, 5 m, C—$(CH_2)_5$—C), 2.57 (4H, m, C=$CCH_2C(CO_2Me)_2$), 3.37 (1H, t, J = 7.5 Hz, —$CH(CO_2Me)_2$), 3.50 and 3.84 (2H, 2 m, —OCH_2—, cyclic), 3.69, 3.73 (12H, s, CH_3), 4.23 (2H, q of t, J = 11.9 and 2.2 Hz, THPOCH_2—), 4.79 (1H, bt, —O_2CH—), 5.40 (2H, bm, —HC=CH—); ms m/e: 525 (MH^+).

Alcohol ***16***b *[A–T] from* ***15***b *[A–T]*

Following procedure 10: Compound ***15****b* [A–T] (1.73 g, 3.30 mmol) gave alcohol ***16****b* [A–T] (1.41 g, 98%); ir: 1732 cm^{-1}; ^1H nmr δ: 1.18, 1.40, 1.48, 1.82 (9H, 4 m, —OH and —$(CH_2)_4$—$C(CO_2Me)_2$), 2.20 (2H, t of t, J = 6.1 and 2.1 Hz, —C≡CCH_2C—), 2.58 (4H, m, C=$CCH_2C(CO_2Me)_2$), 3.39 (1H, t, J = 7.4 Hz, —$CH(CO_2Me)_2$), 3.70, 3.74 (12H, s, CH_3), 4.25 (2H, d of t, J = 6 and 2.2 Hz, —CH_2O—), 5.40 (2H, bm, —HC=CH—); ms m/e: 441 (MH^+).

Chloride ***1***b *[A–T] from* ***16***b *[A–T]*

Following procedure 11: Alcohol ***16****b* [A–T] (1.4 g, 3.21 mmol)

gave chloride **1***b* [A–T] as an oil (1.29 g, 88%); ir: 1736 cm^{-1}; ^1H nmr δ: 1.15, 1.37, 1.48, 1.81 (8H, 4 m, —$(CH_2)_4C(CO_2Me)_2$—), 2.21 (2H, t of t, J = 5.7 and 2.2 Hz, —C≡CCH_2C—), 2.58 (4H, m, C=$CCH_2C(CO_2Me)_2$), 3.38 (1H, t, J = 7.5 Hz, —$CH(CO_2Me)_2$), 3.70, 3.73 (12H, s, CH_3), 4.14 (2H, t, J = 2.3 Hz, —CH_2Cl), 5.4 (2H, bm, —HC=CH—); ms m/e: 459 (MH^+).

*(*E*)-1,1,6,6-Tetracarbomethoxy-3-cyclotetradecen-8-yne (***2**b *[A–T]) and (*E*),(*E*)-1,1,6,6,15,15,20,20-octacarbomethoxy-3,17-cyclooctacosadien-8,22-diyne (***3**b *[A–T])*

Following procedure 12: Chloride **1***b* [A–T] (152 mg, 0.332 mmol) gave, after 38 h, monomer **2***b* [A–T] (15.2 mg, 10.8%, 85% pure from vpc analysis) and dimer **3***b* [A–T] (34.2 mg, 28.4%). The monomer was purified from recrystallization in hot methanol; ir of **2***b*: 1735, 1035 cm^{-1}; ir of **3***b*: 1733, 1198 cm^{-1}.

*Chloride **14**b [A–A] from **8**b*

Following procedure 8: 1,4-Dichloro-2-butyne and malonate **8***b* (1.37 g, 4.03 mmol) gave **14***b* [A–A] (1.57 g, 91%); ir: 1733 cm^{-1}; ^1H nmr δ: 1.10–2.30 (16H, m, C—$(CH_2)_3$—C and C—$(CH_2)_5$—C), 2.90 (2H, m, —C≡$CCH_2C(CO_2Me)_2$), 3.77 (6H, s, CH_3), 3.30–4.00 (2H, m, —OCH_2—, cyclic), 4.12 (2H, t, J = 3 Hz, —CH_2Cl), 4.27 (2H, m, THPOCH_2—), 4.84 (1H, bs, —O_2CH—); ms m/e: 426 (M^+).

*Malonate **15**b [A–A] from **14**b [A–A]*

Following procedure 9: Compound **14***b* [A–A] (1.56 g, 3.66 mmol) gave **15***b* [A–A] (1.76 g, 92%); ir: 1734 cm^{-1}; ^1H nmr δ: 1.10–2.30 (16H, m, C—$(CH_2)_3$—C and C—$(CH_2)_5$—C), 2.78 (4H, m, —C≡$CCH_2C(CO_2Me)_2$—), 3.41 (1H, —$CH(CO_2Me)_2$), 3.30–4.00 (2H, m, —OCH_2—, cyclic), 3.73, 3.75 (12H, s, CH_3), 4.25 (2H, m, THPOCH_2—), 4.82 (1H, bs, —O_2CH—); ms m/e: 522 (M^+).

*Alcohol **16**b [A–A] from **15**b [A–A]*

Following procedure 10: Compound **15***b* [A–A] (1.75 g, 3.75 mmol) gave **16***b* [A–A] (1.4 g, 95%); ir: 1733 cm^{-1}; ^1H nmr δ: 1.00–2.40 (11H, m, —OH and C—$(CH_2)_5$—C), 2.78 (4H, m, C≡$CCH_2C(CO_2Me)_2$), 3.40 (1H, t, —$CH(CO_2Me)_2$), 3.73, 3.78 (12H, s, CH_3), 4.25 (2H, d of t, J = 6 and 2 Hz, —CH_2O—); ms m/e: 439 (MH^+).

*Chloride **1**b [A–A] from **16**b [A–A]*

Following procedure 11: Compound **16***b* [A–A] (1.39 g, 3.17 mmol) gave **1***b* [A–A] (1.13 g, 78%); ir: 1734 cm^{-1}; ^1H nmr δ: 1.00–2.40 (10H, 2 m, C—$(CH_2)_5$—C), 2.78 (4H, m, C≡$CCH_2C(CO_2Me)_2$), 3.52 (1H, —$CH(CO_2Me)_2$), 3.72, 3.78 (12H, s, CH_3), 4.20 (2H, t, J = 5 Hz, —CH_2Cl); ms m/e: 457 (MH^+).

*1,1,6,6-Tetracarbomethoxy-3,8-cyclotetradecadiyne (***2**b *[A–A]) and 1,1,6,6,15,15,20,20-octacarbomethoxy-3,8,17,22-cyclooctacosatetrayne (***3**b *[A–A])*

Following procedure 12: Chloride **1***b* [A–A] (204 mg, 0.448 mmol) after 15 h gave **2***b* [A–A] (75.4 mg, 40%) and **3***b* [A–A] (47 mg, 24.9%); ir of **2***b*: 1732, 1230, 1132 cm^{-1}; ir of **3***b*: 1735, 1201 cm^{-1}.

*Chloride **14**b [A] from **11**b*

Following procedure 8: Malonate **11***b* (1.67 g, 4.85 mmol) and 1,4-dichloro-2-butyne gave chloride **14***b* [A] (1.65 g, 79%); ir: 1736 cm^{-1}; 250-MHz ^1H nmr δ: 1.31 (6H, m, $C(CH_2)_3$—C, cyclic), 1.16, 1.45–1.95, 2.02 (14H, 3 m, C—$(CH_2)_7$—C), 2.87 (2H, t, J = 2.3 Hz, C≡$CCH_2C(CO_2Me)_2$), 3.38 and 3.72 (2H, 2 d of t, J = 9.6 and 6.6 Hz, —OCH_2—, acyclic), 3.50 and 3.88 (2H, 2 m, —OCH_2—, cyclic), 3.74 (6H, s, CH_3), 4.09 (2H, t, J = 2.3 Hz, —CH_2Cl), 4.57 (1H, bt, —O_2CH—); ms m/e: 431 (MH^+).

*Malonate **15**b [A] from **14**b [A]*

Following procedure 9: Compound **14***b* [A] (1.65 g, 3.84 mmol) gave malonate **15***b* [A] (1.71 g, 85%) as an oil; ir: 1738 cm^{-1}; ^1H nmr δ: 1.30 (6H, m, C—$(CH_2)_3$—C), 1.11, 1.55–1.89, 1.96 (14H, 3 m, C—$(CH_2)_7$—C), 2.74 (4H, m, —C≡CCH_2—), 3.38 and 3.72 (1H and 1H, 2 d of t, J = 9.6 and 6.7 Hz, —OCH_2— acyclic), 3.50, 3.88 (2H, 2 m, —OCH_2—, cyclic), 3.52 (1H, m, —$CH(CO_2Me)_2$), 3.72, 3.76 (12H, s, CH_3), 4.57 (1H, bt, —O_2CH—); ms m/e: 527 (MH^+).

*Alcohol **16**b [A] from **15**b [A]*

Following procedure 10: Compound **15***b* [A] (1.71 g, 3.25 mmol) gave alcohol **16***b* [A] (1.43 g, 99%); ir: 3630, 1735 cm^{-1}; ^1H nmr δ: 1.11, 1.30, 1.56, 1.96 (2, 9, 2, and 2H, 4 m, —OH and C—$(CH_2)_7$—C), 2.75 (4H, m, —C≡CCH_2—), 3.51 (1H, t, J = 7.5 Hz, —CH—$(CO_2Me)_2$), 3.63 (2H, t, J = 6.5 Hz, —CH_2O—), 3.71, 3.76 (12H, s, CH_3); ms m/e: 443 (MH^+).

*Bromide **4**b from **16**b [A]*

Following procedure 13: Alcohol **16***b* [A] (1.42 g, 3.20 mmol) gave bromide **4***b* (1.46 g, 91%); ir: 1733 cm^{-1}; ^1H nmr δ: 1.12, 1.31, 1.42, 1.85, 1.97 (2, 6, 2, 2, and 2H, 5 m, C—$(CH_2)_7$—C), 2.74 (4H, m, —C≡CCH_2—), 3.40 (2H, t, J = 5.8 Hz, —CH_2Br), 3.51 (1H, t, J = 7.5 Hz, —$CH(CO_2Me)_2$), 3.72, 3.76 (12H, s, CH_3); ms m/e: 505 (MH^+).

*1,1,6,6-Tetracarbomethoxy-3-cyclotetradecyne (**6**b) and 1,1,6,6,15,15,20,20-octacarbomethoxy-3,17-cyclooctacosadiyne* (dimer)

Following procedure 12: Bromide **4***b* (85.9 mg, 0.170 mmol) in the presence of a 7:1 mixture of potassium carbonate and cesium carbonate (230 mg) gave, after 30 h, **6***b* (39.1 mg, 53.9%) and dimer (10.5 mg, 14.5%); ir of **6***b*: 1738, 1279, 1118 cm^{-1}; ir of dimer: 1737, 1466, 1200–1230 cm^{-1}.

*Bromide **5**b from **4**b*

Following procedure 14: Bromide **4***b* (0.925 g, 1.82 mmol) dissolved in ethyl acetate (12 mL) and cyclohexane (12 mL) gave **5***b* after 5 h (0.915 g, 98%); ir: 1733 cm^{-1}; ^1H nmr δ: 1.05–1.5 (14H, m, —CH_2—$(CH_2)_5$—CH_2—CH_2Br and —$(CH_2)_2CH_2CH(CO_2Me)_2$—), 1.86 (8H, m, —CH_2CH_2Br and —$CH_2C(CO_2Me)_2$—), 3.34 (1H, t, J = 7.6 Hz, —$CH(CO_2Me)_2$), 3.40 (2H, t, J = 6.8 Hz, —CH_2Br), 3.70, 3.73 (12H, s, CH_3); ms m/e: 509 (MH^+).

*1,1,6,6-Tetracarbomethoxycyclotetradecane (**7**b) and 1,1,6,6,15,15,20,20-octacarbomethoxycyclooctacosane* (dimer)

Following procedure 12: Bromide **5***b* (165.9 mg, 0.326 mmol) in the presence of a 4:1 mixture of potassium carbonate and cesium carbonate (500 mg) gave, after 16 h, monomer **7***b* (91.9 mg, 65.7%), dimer (6.5 mg, 4.6%), and a saturated formate ester (3.4%; 13.5% in absence of cesium carbonate); ir of **7***b*: 1730, 1260, 1120 cm^{-1}; ir of dimer: 1736, 1200–1230 cm^{-1}.

Synthesis of cedranoid sesquiterpenes. III. Functionalization at carbon 4[1]

PETER YATES, D. JEAN BURNELL,[2] VERNON J. FREER,[3] AND JEFFERY F. SAWYER
Lash Miller Chemical Laboratories, University of Toronto, Toronto, Ont., Canada M5S 1A1

Received June 16, 1986

This paper is dedicated to Dr. O. E. (Ted) Edwards

PETER YATES, D. JEAN BURNELL, VERNON J. FREER, and JEFFERY F. SAWYER. Can. J. Chem. **65**, 69 (1987).

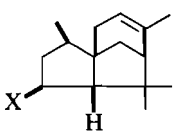
Dimethyl 6,6-dimethyl-5,7-dioxobicyclo[2.2.2]oct-2-ene-2,3-dicarboxylate (**8**) on irradiation in acetophenone gives dimethyl 6,6-dimethyl-4,7-dioxotricyclo[3.2.1.$0^{2,8}$]octane-1,8-dicarboxylate (**13**), which on treatment with lithium dimethylcuprate followed by monodecarbomethoxylation gives methyl 4,4-*endo*-8-trimethyl-3,6-dioxo-*cis*-bicyclo[3.3.0]octane-1-carboxylate (**17**). Similar irradiation of dimethyl 4,6,6-trimethyl-5,7-dioxobicyclo[2.2.2]oct-2-ene-2,3-dicarboxylate (**24**) and its 7,7-ethylenedioxy derivative (**25**) followed by treatment with DBU and concentrated H_2SO_4, respectively, gives dimethyl 3-hydroxy-4,4,8-trimethyl-6-oxo-*cis*-bicyclo[3.3.0]-octa-2,7-diene-1,2-dicarboxylate (**30**). This, on acetylation, reduction with $NaBH_4/CeCl_3$, methanolysis, monodecarbomethoxylation, and hydrogenation, gives methyl *endo*-6-hydroxy-4,4-*endo*-8-trimethyl-3-oxo-*cis*-bicyclo[3.3.0]octane-1-carboxylate (**38**), while on reduction with Li/NH_3 followed by monodecarbomethoxylation it gives a methyl 6-hydroxy-4,4-*exo*-8-trimethyl-3-oxo-*cis*-bicyclo[3.3.0]octane-1-carboxylate (**33**).

PETER YATES, D. JEAN BURNELL, VERNON J. FREER et JEFFERY F. SAWYER. Can. J. Chem. **65**, 69 (1987).

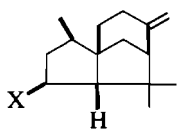
L'irradiation du diméthyl-6,6 dioxo-5,7 bicyclo[2.2.2]octène-2 dicarboxylate-2,3 de diméthyle (**8**) dans l'acétophénone conduit au diméthyl-6,6 dioxo-4,7 tricyclo[3.2.1.$0^{2,8}$]octane dicarboxylate-1,8 de diméthyle (**13**) qui, par une réaction avec du diméthylcuprate de lithium suivie d'une monodécarbométhoxylation, conduit au triméthyl-4,4,8-*endo* dioxo-3,6 bicyclo[3.3.0]octane-*cis* carboxylate-1 de méthyle (**17**). Des irradiations semblables du triméthyl-4,6,6 dioxo-5,7 bicyclo[2.2.2]octène-2 dicarboxylate-2,3 de diméthyle (**24**) et de son dérivé éthylènedioxy-7,7 (**25**), suivies par des traitements respectifs avec de la DBU et du H_2SO_4 concentré, conduisent à l'hydroxy-3 triméthyl-4,4,8 oxo-6 bicyclo[3.3.0]octadiène-2,7-*cis* dicarboxylate-1,2 de diméthyle (**30**). Ce composé, soumis à une acétylation, une réduction par le $NaBH_4/CeCl_3$, une méthanolyse, une monodécarbométhoxylation et une hydrogènation, conduit à l'hydroxy-6-*endo* triméthyl-4,4,8-*endo* oxo-3 bicyclo[3.3.0]octane-*cis* carboxylate-1 de méthyle (**38**) alors que sa réduction par Li/NH_3, suivie d'une monodécarbométhoylation, conduit à un hydroxy-6 triméthyl-4,4,8-*exo* oxo-3 bicyclo[3.3.0]octane-*cis* carboxylate-1 de méthyle (**33**).

[Traduit par la revue]

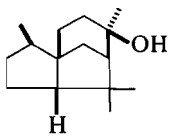
The cedranoid sesquiterpenes have the tricyclo[5.3.1.$0^{1,5}$]undecane ring system. The simplest members of the series are α-cedrene (**1**), β-cedrene (**2**), and cedrol (**3**).[4] Two members, α-biotol (**4**) and β-biotol (**5**), have been shown to have a hydroxyl substituent at C-4 (4).



1 X = H
4 X = OH



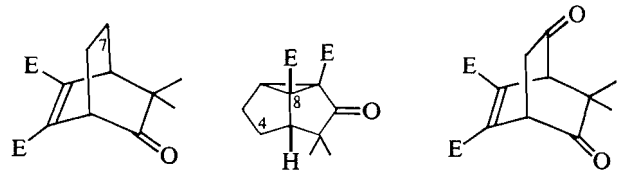
2 X = H
5 X = OH



3

In continuation of our synthetic studies in this series (1, 2) we report now on work directed towards the incorporation of an oxygen function at C-4. Our general approaches have included the photosensitized oxa-di-π-methane rearrangement of bicyclo[2.2.2]octenone **6** to the tricyclo[3.2.1.$0^{2,8}$]octenone **7**. We have used an analogous route in the present work with the introduction of an oxygen substituent at C-7 in **6**, which places the corresponding substituent at C-4 in **7**. Accordingly the diketone **8** was synthesized by the route shown in Scheme 1.

Oxidation of 5,5-dimethyl-2-cyclohexen-1-one (**9**) (5) under the somewhat arcane conditions described in the patent literature (6) for the corresponding oxidation of isophorone (3,5,5-trimethyl-2-cyclohexen-1-one) gave enedione **10** (7). This was



6 **7** (E = CO_2Me) **8**

treated with an excess of isopropenyl acetate and dimethyl acetylenedicarboxylate (DMAD) and a catalytic amount of *p*-toluenesulfonic acid to give the Diels–Alder adduct (**12**) of DMAD and the acetoxy diene **11** without isolation of the latter (cf. ref. 8). Attempted purification of **12** by chromatography on silica led to partial hydrolysis to **8**, but the ^1H nmr spectrum of **12** could be shown to be in accord with expectation by

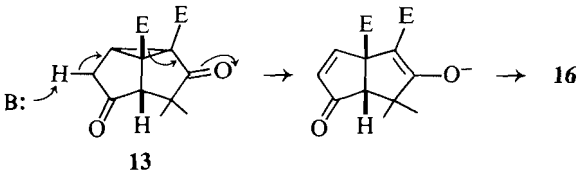
SCHEME 3

comparison of the spectrum of the mixture of **8** and **12** with that of **8**. Deliberate conversion of **12** to **8** was effected by methanolysis with methanolic sodium methoxide.

Because of the likelihood that the dione **8** would give a mixture of oxa-di-π-methane products on photosensitized reaction, attempts were made initially to convert it selectively to a monoacetal by treatment with ethylene glycol and *p*-toluenesulfonic acid. However, ^{1}H nmr spectroscopy and tlc showed that the product was a mixture of both monoacetals, the diacetal, and starting material. The photosensitized reaction of the dione **8** itself was therefore examined. This gave a single product in 95% yield that was shown (*vide infra*) to be the desired tricyclic diketone **13**, derived by an oxa-di-π-methane rearrangement involving the C-5 carbonyl group, rather than **14**, involving the C-7 carbonyl group (Scheme 2).[5]

Reaction of **13** with lithium dimethylcuprate in ether gave two products. (Scheme 3). The ir spectrum (λ_{max} 5.78, 6.01, 6.16 μm) and ^{1}H nmr spectrum (δ 0.92 (d, J = 7 Hz, 3H), 10.78 (br s, 1H)) of the major product (67%) led to the assignment to it of a gross structure corresponding to **15**. Its relative configuration at C-8 was established by its decarbomethoxylation by the method of Krapcho and Lovey (9) to give **17**, whose relative configuration was independently determined (*vide infra*). The minor product (20%) is assigned structure **16**. Its α,β-unsaturated, five-membered cyclic ketone and enolized β-keto ester moieties are apparent from its ir and ^{1}H nmr spectra (λ_{max} 5.88, 5.98, 6.13, 6.29 μm; δ 6.13 (d, J = 6 Hz, 1H), 7.92 (d, J = 6 Hz, 1H), 10.46 (br s, 1H)). It is considered to

[5]The origin of the remarkable selectivity in this reaction is uncertain and is under investigation; ADDED IN PROOF: cf. ref. 20.

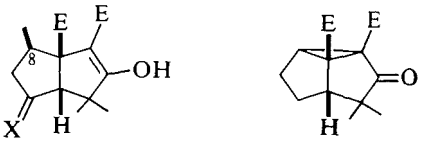


(E = CO_2Me)

SCHEME 4

arise from **13** via removal of a proton from C-7 by a species in the cuprate reagent (10) and opening of the cyclopropane ring to give the anion of the β-keto ester system (Scheme 4) (or by a Lewis-acid-catalyzed variant of this reaction). This type of pathway was confirmed by the demonstration that treatment of **13** with DBU in dichloromethane for 10 min at room temperature gives **16** in 98% yield. The formation of **16** from the photoproduct from **8** establishes that the latter has structure **13**, since an analogous product could not be formed from **14**.

It had been hoped that reaction of lithium dimethylcuprate with **13** would give the *exo* C-8 methyl product **18** rather than the *endo* epimer **15**, in analogy with the reaction of this reagent with **19** to give **20** in our earlier work on the synthesis of cedrene (1). The difference may be directly due to the presence of the carbonyl group at C-4 in **13** or to the formation of **15** by conjugate addition to **16** rather than homoconjugate addition to **13**. Indeed, reaction of **16** with lithium dimethylcuprate was observed to give **15**. It has been postulated that these two types of addition can proceed by different mechanisms (11), and they thus may follow different stereochemical courses. In any event compound **15** has the wrong relative configuration at C-8 for eventual elaboration to the biotols **4** and **5** and, since there appeared to be no simple method for epimerization at C-8, it was necessary to pursue a different approach.



(E = CO_2Me)

This involved the incorporation of what was to become the C-8 methyl group of **18** earlier in the synthesis. Oxidation of isophorone to the enedione **21** was effected under the conditions used for the oxidation of **9** to **10** (6, 7). In a run where the crude product was worked up with aqueous sodium hydroxide, a by-product was isolated whose elemental composition and spectra are in accord with the assignment to it of structure **22** (7). This is considered to arise by base-catalyzed condensation of **21** with **23**, formed by over-oxidation of isophorone,[6] followed by aromatization of the resulting cyclohexadiene ring by air oxidation.

Compound **21** was converted to the dione **24** by a reaction sequence analogous to that of Scheme 1. Unlike its analogue **8**, **24** could be converted selectively to a monoacetal by treatment

[6]S. Ito and M. Matsumoto (quoted in ref. 12) have oxidized the 3-methyl group of isophorone to a formyl group with O_2/$FeCl_3$. D. J. Burnell, R. Grewal, and P. Yates (unpublished results) have observed the formation of both this product and 3,3,5-trimethyl-5-cyclohexene-1,2,4-trione on oxidation of isophorone with selenium dioxide in dioxane.

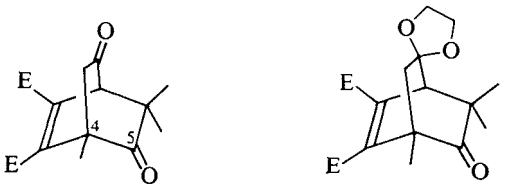
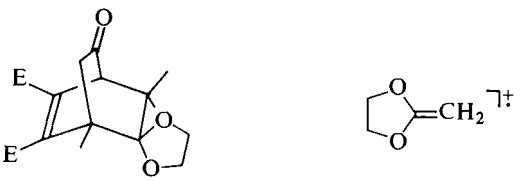
21 22 23

with ethylene glycol and *p*-toluenesulfonic acid. This is assigned structure **25** rather than **26** for the following reasons: (*i*) Its ^{1}H nmr spectrum has the bridge methylene and bridgehead methine proton signals at δ 2.06 and 3.29, respectively, showing that these protons are not on carbon atoms adjacent to the remaining carbonyl group (cf. the chemical shifts for the protons in the spectrum of **24**, δ 2.34 and 3.85), and (*ii*) the presence in the mass spectrum of the monoacetal of a strong peak with *m/z* 86 that can be assigned to the fragment ion **27**, which is readily derivable from **25**, but not from **26**. The selectivity in the monoacetalization of **24** relative to **8** can be attributed to increased steric hindrance to acetalization of the C-5 carbonyl group because of the presence of the C-4 methyl group.



24 25



26 27

Photosensitized rearrangement of **25** gave the tricyclo-octane derivative **28** (Scheme 5). It was planned to convert **28** to the dione **29** and then treat this with base to give **30**. Attempts to convert the acetal function of **28** to a ketone by hydrolysis in the presence of *p*-toluenesulfonic acid or pyridinium *p*-toluenesulfonate (13) or by treatment with triphenylcarbenium tetrafluoroborate (14) were unsuccessful, and so we had to resort to dissolution of **28** in concentrated sulfuric acid followed by quenching in ice-water. This led to the direct conversion of **28** to **30**, presumably via **29**. Longer reaction times with sulfuric acid led to yet another desired transformation, that of **30** by decarbomethoxylation to **31**, which could also be prepared from **30** by the method of Krapcho and Lovey (9). It was subsequently found that the unprotected dione **24**, like the dione **8**, gave a single product (94%) on photosensitized rearrangement that was shown to be **29**[5] by its conversion to **30** on treatment with 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU).

It was now necessary to reduce the ethylenic double bond of **31** stereoselectively to give a product with an *exo* methyl group at C-8. Since dissolving metal reductions of α,β-unsaturated ketones often lead to the more stable product (15), the reduction of **31** with lithium in liquid ammonia was investigated. This led to the production of compounds **32** and **33** (Scheme 6), in low yields. The gross structures of these products followed from their spectra (each showed a three-proton doublet in its ^{1}H nmr spectrum). In contrast, hydrogenation of **31** over platinum yielded only **17** (89%). This suggested the *endo* configuration at C-8 shown in **17**, but it was still not possible to assign unambiguously the relative stereochemistry at this center.

Since eventually it would be necessary to build the third ring of the biotols by selective reaction at C-3, we next investigated the selective reduction of the C-6 ketone group of the 3,6-diones **32** and **17**, but this could not be achieved with either sodium borohydride or aluminum isopropoxide, and was also unsuccessful in the case of their enolized precursor **30**. However, protection of the hydroxyl group of **30** by conversion with acetic anhydride, triethylamine, and 4-(dimethylamino)pyridine (DMAP) (16) to the enol acetate **34**, followed by reduction with sodium borohydride and cerous chloride heptahydrate in methanol,[7] gave the C-6 hydroxy compound **35** (Scheme 7). Removal of the acetyl group by methanolysis yielded the β-keto ester **36**. Interestingly, this was the only methyl 4,4-dimethyl-3-oxobicyclo[3.3.0]octane-2-carboxylate of the many encountered in our present and earlier (1, 2) work that was isolated as the unenolized form.[8] Decarbomethoxylation of **36** in the usual manner (9) gave **37**. This on treatment with hydrogen over platinum gave **38**, whose relative stereochemistry was established by X-ray crystallographic analysis to be that shown.[9]

Establishment of the relative configuration at C-6 in **38** leads immediately to the assignment of the corresponding relative configuration shown for compounds **35**, **36**, and **37**. More importantly, the now-established relative configuration at C-8 in **38** together with the observation that **38** is oxidized by pyridinium dichromate (18) to **17** leads to the unambiguous assignment of the *endo* configuration to the secondary methyl group in **17** (Scheme 8). This in turn leads to the assignment of the *exo* configuration for the C-8 methyl group in **32**, which can only differ from **17** by its configuration at C-8. Furthermore, since oxidation of **33** with pyridinium dichromate gives **32**, the former also can be assigned a structure with an *exo* C-8 methyl group (Scheme 8).

Thus in the hydrogenation of the ethylenic double bonds of **31** and **37** over platinum, addition of hydrogen occurs exclusively from the *exo* face of the bicyclo[3.3.0]oct-7-ene system and reduction of the ketone group of **34** with sodium borohydride/cerous chloride occurs in the same stereochemical sense. Preference for reaction on the convex, *exo* face rather than the concave, *endo* face of bicyclo[3.3.0]octane derivatives has been observed previously for similar reactions. However, it was previously uncertain in the present cases whether this stereoselectivity would be operative in the presence of the carbomethoxy substituent C-1.

When reduction of **31** was effected with lithium/ammonia, products (**32** and **33**) with *exo* C-8 methyl groups were obtained (Scheme 6). Since the corresponding methyl group of the biotols has the *exo* configuration, it was clear that we would have to resort to dissolving metal reduction of the C-7—C-8 double bond of a bicyclo[3.3.0]oct-7-ene derivative to obtain the correct relative configuration at C-8. However, as the yields of **32** and **33** from **31** were very low, it was necessary

[7]Gemal and Luche (17) have shown that conditions of this type favor 1,2 rather than 1,4 reduction of enones.

[8]This may be the result of hydrogen bonding between the *endo* C-6 hydroxyl group and the C-2 carbomethoxyl group, if the latter has the *endo* configuration.

[9]The details of this analysis will be published elsewhere.

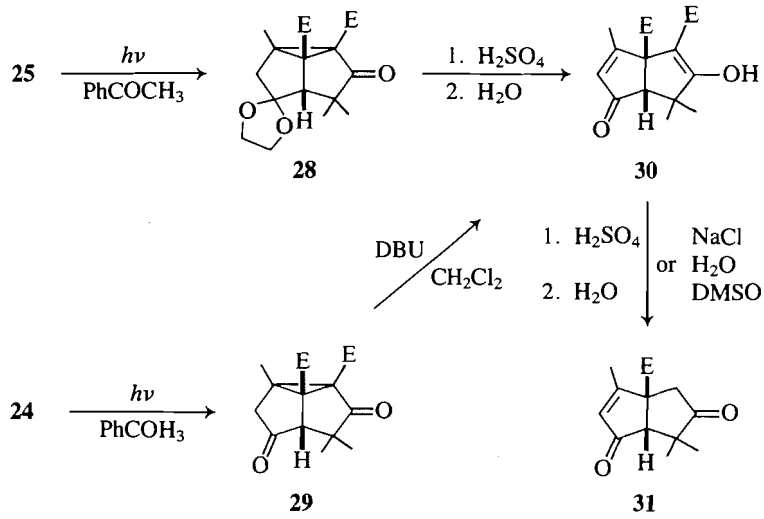
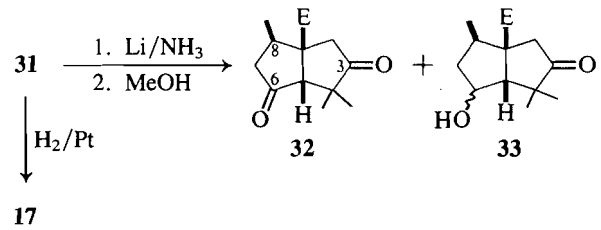


SCHEME 5



SCHEME 6

to modify this route, which was done by carrying out the lithium/ammonia reduction on **30**, the precursor of **31**. The major product (40%) was an alcohol, which was shown to be **39** by decarbomethoxylation in the usual manner to give **33**. Compound **18** was also formed in the reduction of **30** (Scheme 9).

Thus the *exo* C-8 methyl series can be entered more efficiently in this way, although additional work is needed to further improve the yields, which should be possible since the second product, **18**, from the reduction of **30** also has an *exo* C-8 methyl group. The relative configuration of the C-6 hydroxyl group cannot be assigned unambiguously on the basis of available data. However, this is not critical because, if it is found that the hydroxyl group in **33** has the undesired *endo* configuration, routes are available for inversion at C-6 (cf. ref. 19 and references cited therein).

Experimental

Melting points were determined on a Fisher-Johns apparatus and are uncorrected. The uv spectra were taken in CH_3OH solution and the ir spectra in CCl_4 solution, unless otherwise stated; ir bands are strong unless specified as medium (m) or weak (w) and are sharp unless specified as broad (br). The ^1H nmr spectra were taken in $CDCl_3$ solution at 60 MHz, unless specified to have been taken at 200 MHz. The ^{13}C nmr spectra were taken in $CDCl_3$ solution; chemical shifts were determined by recording the spectra in the proton noise-decoupled mode; the recorded multiplicities were determined from spectra obtained in the single frequency off-resonance decoupled mode.

Diethyl ether and tetrahydrofuran were freshly distilled from benzophenone sodium ketyl and were introduced to the reaction vessel (flame-dried under a flow of nitrogen) through a rubber septum via syringe. Other solvents used for work-ups or chromatography were either distilled or were of ACS Reagent Grade quality. Solutions were concentrated on a rotary evaporator under water aspirator pressure and subsequently under high vacuum provided by a two-stage vacuum pump. Liquid ammonia was dried and distilled from sodium.

Ultraviolet irradiations were conducted in a Rayonet Srinivasan–Griffin photochemical reactor equipped with 11 low-pressure RPR lamps. Solutions were degassed with a stream of nitrogen or argon for 0.3–1 h prior to irradiation.

*5,5-Dimethyl-2-cyclohexen-1-one (**9**)*

A solution of 5,5-dimethylcyclohexane-1,3-dione (dimedone; 2.80 g, 0.0206 mol) and tosylhydrazine (3.83 g, 0.0206 mol) in anhydrous methanol (50 mL) containing concentrated sulfuric acid (3 drops) was stirred at room temperature for 18 h under nitrogen. The methanol was

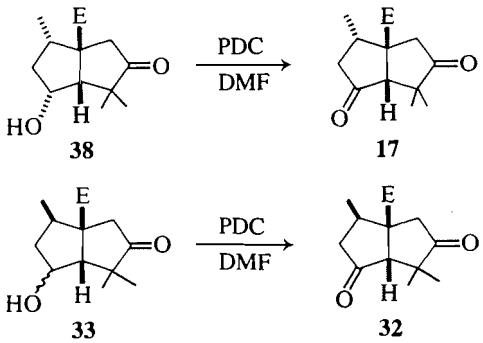

SCHEME 8

removed, potassium carbonate (22.1 g, 0.160 mol) and distilled water (250 mL) were added, and the solution was heated to steam distil the product. The distillate was saturated with sodium chloride and extracted with ether (3 × 30 mL). The organic extracts were washed with saturated brine (2 × 20 mL) and dried over Na_2SO_4. The ethereal solution was concentrated to give **9** as a yellow oil. Purification was accomplished by column chromatography on silica with hexanes/ethyl acetate (4:1 v/v) as the eluent to give **9** (1.28 g, 0.0103 mol, 50%) as a colorless oil; ir λ_{max}: 5.93 μm; ^{1}H nmr δ: 1.07 (s, 6H), 2.20 (m, 2H), 2.27 (s, 2H), 6.00 (dt, J = 10, 2 Hz, 1H), 6.83 (dt, J = 10, 4 Hz, 1H).

*5,5-Dimethyl-2-cyclohexene-1,4-dione (**10**)*

Compound **9** (4.0 g, 0.032 mol) was added to phosphomolybdic acid (0.0148 g, 0.0089 mmol), potassium dichromate (0.0018 g, 0.006 mmol), and cupric sulfate pentahydrate (0.0071 g, 0.045 mmol). The reaction mixture was stirred and maintained at 100°C while air was blown into it through a gas delivery frit at a flow rate of 300 mL/min. Consumption of starting material was complete after 84 h. The viscous black mixture was extracted with ether (100 mL) and the extract was washed with distilled water (4 × 50 mL) and saturated brine (2 × 50 mL). The ethereal solution was dried over $MgSO_4$ and concentrated. The residual oil was distilled (0.5 Torr (1 Torr = 133.3 Pa), 90°C) to give **10** (2.66 g, 0.019 mol, 60%) as a clear, yellow, mobile oil. Crystallization of this oil from hexanes and cooling with ice gave **10** as yellow plates, mp 39.0–39.5°C; ir λ_{max}: 5.89 μm; ^{1}H nmr δ: 1.38 (s, 6H), 2.83 (s, 2H), 6.75 (s, 2H); ^{13}C nmr δ: 25.6 (q), 45.0 (s), 51.3 (t), 139.0 (d), 139.8 (d), 197.5 (s), 202.6 (s); ms *m/z*: 138 (30%). *Exact Mass* calcd. for $C_8H_{10}O_2$: 138.0681; found: 138.0687. *Anal.* calcd. for $C_8H_{10}O_2$: C 69.54, H 7.30; found: C 69.41, H 7.31.

Compound **10** has been prepared previously in 32% yield by oxidation of **9** with *tert*-butyl hydroperoxide and palladium(II) catalysts (12).

*Dimethyl 7-acetoxy-6,6-dimethyl-5-oxobicyclo[2.2.2]octa-2,7-diene-2,3-dicarboxylate (**12**)*

A solution of compound **10** (0.211 g, 1.53 mmol), freshly distilled dimethyl acetylenedicarboxylate (1.42 g, 10.0 mmol), and hydroquinone (3 mg) in isopropenyl acetate (5 mL) was stirred at 25°C for 0.5 h under nitrogen, after which *p*-toluenesulfonic acid (20 mg) was added and the solution was boiled at reflux for 96 h. The isopropenyl acetate and excess dimethyl acetylenedicarboxylate were distilled under water aspirator pressure to leave crude **12**. Chromatography on silica with dichloromethane/ethyl acetate (17:3 v/v) as the eluent gave **12** as a clear yellow oil contaminated with **8** (total combined weight of both materials was 0.466 g), indicating some of **12** underwent hydrolysis on the silica column; ir λ_{max}: 5.72 (br) μm; ^{1}H nmr δ: 1.12 (s, 3H), 1.30 (s, 3H), 2.67 (s, 3H), 3.87 (s, 3H), 3.90 (s, 3H), 3.97 (d, J = 2 Hz, 1H), 4.37 (d, J = 6 Hz, 1H), 6.20 (dd, J = 6, 2 Hz, 1H).

*Dimethyl 6,6-dimethyl-5,7-dioxobicyclo[2.2.2]oct-2-ene-2,3-dicarboxylate (**8**)*

A solution of compound **12** (0.466 g, 1.45 mmol) in methanol (50 mL) containing sodium methoxide (50 mg, 0.926 mmol) was stirred at room temperature for 1 h. The reaction mixture was treated with glacial acetic acid (2 drops) and concentrated. The crude product was redissolved in dichloromethane and the solution was passed through a small plug of neutral alumina and concentrated to give **8** (0.304 g, 1.09 mmol, 75%) as a yellow oil. Purification was accomplished by flash chromatography with hexanes/ethyl acetate (85:15 v/v) as eluent to give **8** as colorless crystals, mp 101.5–102°C; uv λ_{max} (ε) 219 (2 750), 252 (2 800), 307 (850) nm; ir λ_{max}: 5.75 (br) μm; ^{1}H nmr δ: 1.35 (s, 3H), 1.40 (s, 3H), 2.45 (d, J = 3 Hz, 2H), 3.56 (s, 1H), 3.83 (s, 6H), 3.87 (t, J = 3Hz, 1H); ^{13}C nmr δ: 24.7 (q), 25.2 (q), 33.9 (t), 41.7 (s), 50.5 (d), 52.8 (q), 63.5 (d), 136.0 (s), 138.1 (s), 163.8 (s), 164.5 (s), 203.8 (s), 209.2 (s); ms m/*z*: 280 (1%). *Exact Mass* calcd. for $C_{14}H_{16}O_6$: 280.0947; found: 280.0964. *Anal.* calcd. for $C_{14}H_{16}O_6$: C 59.99 H 5.75; found: C 60.06, H 5.81.

*Dimethyl 6,6-dimethyl-4,7-dioxotricyclo[3.2.1.0^{2,8}]octane-1,8-dicarboxylate (**13**)*

A solution of compound **8** (2.14 g, 7.64 mmol) in freshly distilled acetophenone (25 mL) was degassed with nitrogen for 30 min and then irradiated at 350 nm for 32 h in a Pyrex tube. The acetophenone was removed by distillation at 0.5 Torr. The residual solid was recrystallized from hexanes/ethyl acetate (3:1 v/v) to give **13** (2.04 g, 7.28 mmol, 95%) as colorless prisms, mp 112.5–113.5°C; ir λ_{max}: 5.70 (br) μm; ^{1}H nmr (200 MHz) δ: 0.95 (s, 3H), 1.36 (s, 3H), 2.24 (d, J = 20 Hz, 1H), 2.65 (ddd, J = 20, 7, 3 Hz, 1H), 3.17 (d, J = 3 Hz,

1H), 3.33 (d, J = 7 Hz, 1H), 3.77 (s, 3H), 3.80 (s, 3H); ^{13}C nmr δ: 17.4 (q), 25.9 (q), 33.8 (t), 36.4 (d), 46.8 (s), 52.9 (q), 53.3 (q), 54.1 (s), 55.9 (s), 58.8 (d), 164.9 (s), 168.4 (s), 207.0 (s), 210.8 (s); ms m/z: 280 (5%). *Exact Mass* calcd. for $C_{14}H_{16}O_6$: 280.0947; found: 280.0956. *Anal.* calcd. for $C_{14}H_{16}O_6$: C 59.99, H 5.75; found: C 60.18, H 5.86.

*Dimethyl 3-hydroxy-4,4-*endo*-8-trimethyl-6-oxo-*cis*-bicyclo[3.3.0]oct-2-ene-1,2-dicarboxylate (**15**)*

A solution of methyllithium – lithium bromide complex in ether (1.53 *M*; 0.96 mL, 1.47 mmol) was added over 20 min to a cold (0°C) slurry of cuprous iodide (0.142 g, 0.747 mmol) in ether (8 mL) under nitrogen. After 1 h a solution of compound **13** (0.100 g, 0.355 mmol) in ether (4 mL) was added over 30 min. The reaction mixture was stirred at 0°C for 5 h and was then siphoned into cold 10% hydrochloric acid (20 mL). The mixture was filtered through Celite. The filtrate was separated and the aqueous phase was extracted with ether (2 × 10 mL). The organic phases were combined and washed with saturated aqueous sodium bicarbonate (5 mL), 1 *M* aqueous sodium thiosulfate (5 mL), and saturated brine (2 × 5 mL). The organic extract was dried over $MgSO_4$ and concentrated to give a yellow oil (0.096 g) containing **15** and **16.**

The ^{1}H nmr spectrum of the oil showed that the ratio of **15** and **16** was 3:1. Chromatography of the mixture with hexanes/ethyl acetate (3:1 v/v) as the eluent gave **15** (0.064 g, 0.219 mmol, 67%) as a colorless solid, mp 102–103.5°C; ir λ_{max}: 5.78, 6.01 (m), 6.16 (m) μm; ^{1}H nmr (200 MHz) δ: 0.92 (d, J = 7 Hz, 3H), 1.18 (s, 3H), 1.35 (s, 3H), 2.02 (dd, J = 17, 8 Hz, 1H), 2.51 (d, J = 2 Hz, 1H), 2.60 (ddd, J = 17, 7.5, 2 Hz, 1H), 3.10 (m, $W_{1/2}$ = 10 Hz, 1H), 3.71 (s, 3H), 3.77 (s, 3H), 10.78 (br s, 1H); ^{13}C nmr δ: 17.6 (q), 21.6 (q), 29.1 (q), 34.2 (d), 46.0 (s), 47.3 (t), 51.4 (q), 52.6 (q), 60.5 (s), 62.6 (d), 98.1 (s), 170.1 (s), 175.4 (s), 181.6 (s), 214.3 (s); ms m/z: 296 (21%). *Exact Mass* calcd. for $C_{15}H_{20}O_6$: 296.1254; found: 296.1243.

Compound **16** (*vide infra*) (20%) was also isolated during chromatography.

*Dimethyl 3-hydroxy-6-oxo-4,4-dimethyl-*cis*-bicyclo[3.3.0]octa-2,7-diene-1,2-dicarboxylate (**16**)*

A solution of compound **13** (0.099 g, 0.354 mmol) in dichloromethane (4 mL) containing 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU; 0.4 mL) was stirred at 25°C under nitrogen. After 10 min the reaction mixture was treated with 10% hydrochloric acid (5 mL). The mixture was extracted with ethyl acetate (2 × 25 mL). The extract was washed with 10% hydrochloric acid (2 × 5 mL), distilled water (2 × 5 mL), and saturated brine (2 × 5 mL), dried over $MgSO_4$, and concentrated to give a yellow oil. Crystallization of the oil from hexanes/ethyl acetate (3:1 v/v) gave **16** (0.097 g, 0.343 mmol, 98%) as colorless plates, mp 119.5–120.5°C; ir λ_{max}: 3.33 (br, w), 5.88, 5.98, 6.13, 6.29 μm; ^{1}H nmr δ: 1.23 (s, 3H), 1.50 (s, 3H), 2.70 (s, 1H), 3.80 (s, 3H), 3.90 (s, 3H), 6.13 (d, J = 6 Hz, 1H), 7.92 (d, J = 6 Hz, 1H), 10.46 (br s, 1H); ^{13}C nmr δ: 22.0 (q), 28.9 (q), 45.6 (s), 51.7 (q), 52.8 (q), 59.6 (d), 61.7 (s), 99.5 (s), 133.1 (d), 163.4 (d), 168.6 (s), 173.0 (s), 180.9 (s), 206.2 (s); ms m/z: 280 (16%). *Exact Mass* calcd. for $C_{14}H_{16}O_6$: 280.0947; found: 280.0950. *Anal.* calcd. for $C_{14}H_{16}O_6$: C 59.99, H 5.75; found: C 60.13, H 5.84.

Treatment of compound **16** with lithium dimethylcuprate under similar conditions gave **15** in 62% yield.

*Methyl 4,4-*endo*-8-trimethyl-3,6-dioxo-*cis*-bicyclo[3.3.0]octane-1-carboxylate (**17**)*

A mixture of compound **15** (0.0451 g, 0.190 mmol) and sodium chloride (0.96 mg, 0.016 mmol) was stirred and heated (112°C) in reagent grade dimethyl sulfoxide (4 mL) containing added water (30 μL) for 18 h under nitrogen. The mixture was diluted with distilled water (5 mL) and extracted with ether (2 × 10 mL). The combined organic extracts were washed with distilled water (2 × 5 mL) and saturated brine (2 × 5 mL), dried over $MgSO_4$, and concentrated to give a yellow oil. Purification of the oil was accomplished by column chromatography on silica with hexanes/ethyl acetate (4:1 v/v) as the eluent, giving **17** (0.0255 g, 0.107 mmol, 56%) as a colorless oil. Crystallization of the oil from pentane/dichloromethane provided **17** as colorless plates, mp 70.5–71°C; ir λ_{max}: 5.65, 5.71 μm; ^{1}H nmr (200 MHz) δ: 1.08 (s, 3H), 1.09 (s, 3H), 1.10 (d, J = 5 Hz, 3H), 2.04 (dd, J = 13.5, 17.5 Hz, 1H), 2.41 (d, J = 19 Hz, 1H), 2.51 (ddd, J = 17.5, 7, 1.5 Hz, 1H), 2.79 (m, 1H), 2.93 (m, $W_{1/2}$ = 4 Hz, 1H), 3.10 (dd, J = 19, 2 Hz, 1H), 3.78 (s, 3H); ^{13}C nmr δ: 14.9 (q), 21.3 (q), 27.1 (q), 35.6 (d), 38.3 (t), 45.2 (t), 49.2 (s), 52.8 (q), 54.9 (s), 64.9 (d), 175.4 (s), 213.3 (s), 217.8 (s); ms m/z: 238 (35%). *Exact Mass* calcd. for $C_{13}H_{18}O_4$: 238.1200; found: 238.1199. *Anal.* calcd. for $C_{13}H_{18}O_4$: C 65.53, H 7.61; found: C 65.54, H 7.69.

*2,6,6-Trimethyl-2-cyclohexene-1,4-dione (**21**)*

3,5,5-Trimethyl-2-cyclohexen-1-one (isophorone; 250 g, 1.81 mol) was added to phosphomolybdic acid (4.0 g, 2.2 mmol), potassium dichromate (0.081 g, 0.28 mmol), and cupric sulfate pentahydrate (0.346 g, 1.39 mmol). The reaction mixture was stirred and maintained at 90–95°C while air was blown into it through a gas delivery frit at a flow rate of 300 mL/min. Consumption of starting material was complete after 100 h. The black mixture was extracted with ether (300 mL) and the extract was washed with distilled water (3 × 50 mL) and saturated brine, dried over $MgSO_4$, and concentrated. The residual liquid was distilled (20 Torr, 99–101°C) to give **21** (152.7 g, 1.01 mol, 56%) as a pale yellow liquid; ir λ_{max}: 5.96 μm; ^{1}H nmr δ: 1.25 (s, 6H), 2.02 (br s, 3H), 2.74 (s, 2H), 6.54 (m, $W_{1/2}$ = 3.5 Hz, 1H); ms m/z: 152 (3%).

In an experiment in which the crude product was treated with aqueous base, a by-product, **22** (2,2,6,6-tetramethylanthracene-1,4,5,8(2*H*,3*H*,6*H*,7*H*)-tetraone), was obtained as yellow flakes, mp 224.5–225°C; uv λ_{max} (ε): 238 (58 000), 262 (40 000), 324 (3 000) nm; ir λ_{max}: 5.87 μm; ^{1}H nmr δ: 1.33 (s, 12H), 3.00 (s, 4H), 8.73 (s, 2H); ^{13}C nmr δ: 25.5 (q), 45.8 (s), 51.8 (t), 126.8 (d), 137.1 (s), 138.6 (s), 194.4 (s), 199.5 (s); ms m/z: 298 (72%). *Exact Mass* calcd. for $C_{18}H_{18}O_4$: 298.1205; found: 298.1219. *Anal.* calcd. for $C_{18}H_{18}O_4$: C 72.45, H 6.09; found: C 72.42, H 6.17.

*Dimethyl 4,6,6-trimethyl-5,7-dioxobicyclo[2.2.2]oct-2-ene-2,3-dicarboxylate (**24**)*

A solution of compound **21** (26.67 g, 0.178 mol), freshly distilled dimethyl acetylenedicarboxylate (25.32 g, 0.178 mol), and hydroquinone (0.167 g, 1.52 mmol) in isopropenyl acetate (20.20 g, 0.202 mol) was stirred at 25°C for 0.5 h under nitrogen. After 30 min *p*-toluenesulfonic acid was added and the solution was heated to 91°C for 48 h. The excess isopropenyl acetate was removed by distillation under water aspirator pressure to leave a solid. This was repeatedly recrystallized from a mixture of hexanes and ethyl acetate to give dimethyl 7-acetoxy-4,6,6-trimethyl-5-oxobicyclo[2.2.2]octa-2,7-diene-2,3-dicarboxylate (49.49 g, 0.148 mol, 83%) as colorless crystals; ir λ_{max} ($CHCl_3$): 5.75 (br) μm; ^{1}H nmr δ: 1.07 (s, 3H), 1.20 (s, 3H), 1.43 (s, 3H), 2.18 (s, 3H), 3.80 (s, 6H), 3.88 (d, J = 3 Hz, 1H), 5.79 (d, J = 3 Hz, 1H); ^{13}C nmr δ: 13.2 (q), 21.1 (q), 26.3 (q), 26.5 (q), 39.7 (s), 52.0 (q), 52.4 (s), 52.6 (q), 57.3 (d), 113.0 (d), 136.2 (s), 147.6 (s), 157.0 (s), 163.3 (s), 166.0 (s), 167.5 (s), 206.6 (s).

A solution of the above product (0.250 g, 0.744 mmol) and sodium methoxide (0.010 g, 0.185 mmol) in methanol (10 mL) was stirred at room temperature for 1 h under nitrogen. Concentrated glacial acetic acid (2 drops) was added and the solution was concentrated to give a yellow oil. The oil was dissolved in dichloromethane, and the solution was passed through a short plug of neutral alumina and concentrated. Repeated crystallization of the residue from hexanes/ethyl acetate (4:1 v/v) gave **24** (0.182 g, 0.618 mmol, 83%) as large colorless plates, mp 82–83°C; uv λ_{max} (ε): 216 (3 270), 251 (3 040), 307 (817) nm; ir λ_{max}: 5.78 (br), 6.12 (m) μm; ^{1}H nmr δ: 1.16 (s, 6H), 1.31 (s, 3H), 2.26 (d, J = 19 Hz, 1H), 2.42 (d, J = 19 Hz, 1H), 3.78 (s, 1H), 3.81 (s, 3H), 3.85 (s, 3H); ^{13}C nmr δ: 13.9 (q), 24.9 (q), 25.0 (q), 41.1 (t), 41.6 (s), 52.5 (s), 52.5 (q), 52.8 (q), 61.0 (d), 130.8 (s), 146.6 (s), 162.7 (s), 165.3 (s), 204.7 (s), 210.0 (s); ms m/z: 294 (6%). *Anal.* calcd. for $C_{15}H_{18}O_6$: C 61.22, H 6.16; found: C 61.22, H 6.15.

*Dimethyl 7,7-ethylenedioxy-4,6,6-trimethyl-5-oxobicyclo[2.2.2]oct-2-ene-2,3-dicarboxylate (**25**)*

Ethylene glycol (10 mL) and *p*-toluenesulfonic acid (50 mg) were added to a solution of compound **24** (6.02 g, 0.021 mol) in dry benzene (100 mL) under nitrogen. The mixture was boiled at reflux for 40 h in a Dean–Stark apparatus. After cooling, the mixture was concentrated, the residual oil was dissolved in ether (60 mL), and the solution was washed with 5% aqueous sodium hydroxide (2 × 10 mL), distilled water (2 × 10 mL), and saturated brine (2 × 10 mL). The ethereal layer was dried over $MgSO_4$ and concentrated. Repeated crystallization of the residual oil from a mixture of hexanes and ethyl acetate gave **25** (6.40 g, 0.019 mol, 92%) as colorless plates, mp 88–89°C; ir λ_{max}: 5.71 (br), 6.08 (w) μm; ^{1}H nmr (200 MHz) δ: 1.07 (s, 3H), 1.21 (s, 3H), 1.32 (s, 3H), 2.06 (s, 2H), 3.29 (s, 1H), 3.79 (s, 3H), 3.81 (s, 3H), 3.85–4.00 (m, 4H), ^{13}C nmr δ: 14.0 (q), 25.0 (q), 27.6 (q), 41.3 (s), 43.5 (t), 50.8 (d), 51.2 (s), 51.9 (q), 52.2 (q), 63.4 (t), 64.4 (t), 111.4 (s), 135.3 (s), 142.7 (s), 163.5 (s), 165.9 (s), 212.1 (s); ms *m/z*: 338 (4%). *Anal.* calcd. for $C_{17}H_{22}O_7$: C 60.35, H 6.55; found: C 60.47, H 6.54.

*Dimethyl 4,4-ethylenedioxy-2,6,6-trimethyl-7-oxotricyclo[3.2.1.0^{2,8}]octane-1,8-dicarboxylate (**28**)*

A solution of compound **25** (6.40 g, 0.019 mol) in freshly distilled acetophenone (20 mL) was degassed with nitrogen for 15 min and then irradiated at 350 nm for 96 h in a Pyrex tube. The acetophenone was removed by distillation at 0.5 Torr. The residual solid was recrystallized from hexanes/ethyl acetate (3:1 v/v) to give **28** (6.03 g, 0.018 mol, 94%) as colorless prisms, mp 112–113°C; uv λ_{max} (ε): 216 (3 125), 248 (3 660), 304 (570) nm; ir λ_{max} ($CHCl_3$): 5.75, 5.80 μm; ^{1}H nmr (200 MHz) δ: 1.14 (s, 3H), 1.23 (s, 3H), 1.59 (s, 3H), 1.83 (d, *J* = 14 Hz, 1H), 1.95 (dd, *J* = 14, 3 Hz, 1H), 2.81 (d, *J* = 3 Hz, 1H), 3.74 (s, 3H), 3.78 (s, 3H), 3.81–4.00 (m, 4H); ^{13}C nmr δ: 17.1 (q), 18.0 (q), 27.7 (q), 41.9 (t), 42.4 (s), 50.8 (s), 52.2 (q), 52.4 (q), 53.6 (s), 55.5 (d), 57.6 (s), 62.2 (t), 66.1 (t), 118.4 (s), 164.8 (s), 168.9 (s), 210.0 (s); ms *m/z*: 338 (5%). *Anal.* calcd. for $C_{17}H_{22}O_7$: C 60.35, H 6.55; found: C 60.42, H 6.57.

*Dimethyl 3-hydroxy-4,4,8-trimethyl-6-oxo-*cis*-bicyclo[3.3.0]octa-2,7-diene-1,2-dicarboxylate (**30**)*

A solution of compound **28** (6.03 g, 0.018 mol) in concentrated sulfuric acid (20 mL) was stirred for 10 min. The reaction mixture was poured into an ice–water mixture and extracted with ether (4 × 50 mL). The combined organic layers were washed with distilled water (3 × 25 mL), saturated aqueous sodium bicarbonate (3 × 50 mL), and saturated brine (3 × 25 mL). The ethereal layer was dried over $MgSO_4$ and concentrated to give a yellow oil. Repeated crystallization of this oil from hexanes/ethyl acetate (3:1 v/v) gave **30** (5.11 g, 0.017 mol, 98%) as colorless plates, mp 122–123°C; ir λ_{max}: 3.40 (br, w), 5.73, 5.87, 6.02, 6.19 μm; ^{1}H nmr (200 MHz) δ: 1.14 (s, 3H), 1.39 (s, 3H), 2.19 (d, *J* = 1.5 Hz, 3H), 2.73 (s, 1H), 3.73 (s, 3H), 3.82 (s, 3H), 5.92 (q, *J* = 1.5 Hz, 1H), 10.9 (br s, 1H); ^{13}C nmr δ: 17.8 (q), 22.0 (q), 28.9 (q), 45.2 (s), 51.5 (q), 52.7 (q), 62.7 (d), 63.9 (s), 98.6 (s), 132.2 (d), 169.4 (s), 172.8 (s), 178.1 (s), 183.0 (s), 204.8 (s); ms *m/z*: 294 (6%). *Anal.* calcd. for $C_{15}H_{18}O_6$: C 61.22, H 6.16; found: C 61.11, H 6.19.

Treatment of compound **30** with concentrated sulfuric acid for 18 h under otherwise similar conditions gave **31** in 95% yield.

*Dimethyl 2,6,6-trimethyl-4,7-dioxotricyclo[3.2.1.0^{2,8}]octane-1,8-dicarboxylate (**29**)*

A solution of compound **24** (0.489 g, 1.66 mmol) in freshly distilled acetophenone (5 mL) was degassed with nitrogen for 20 min and then irradiated at 350 nm for 144 h in a Pyrex tube. The acetophenone was removed by distillation at 0.5 Torr. The residual oil was crystallized from a mixture of pentane and dichloromethane to give **29** (0.440 g, 1.49 mmol, 90%) as a colorless crystalline solid, mp 111.5–112.5°C; ir λ_{max}: 5.70, 5.75 μm; ^{1}H nmr δ: 0.97 (s, 3H), 1.37 (s, 3H), 1.68 (s, 3H), 2.47 (br s, 2H), 3.20 (br s, 1H), 3.93 (s, 6H); ^{13}C nmr δ: 16.4 (q), 17.1 (q), 25.5 (q), 40.5 (s), 43.4 (t), 47.2 (s), 52.3 (q), 52.5 (q), 55.3 (s), 56.3 (s), 60.0 (d), 164.0 (s), 167.5 (s), 207.4 (s), 209.9 (s); ms *m/z*: 294 (1%). *Exact Mass* calcd. for $C_{15}H_{18}O_6$: 294.1098; found: 294.1125.

Treatment of compound **29** with DBU under conditions similar to those used for the conversion of **13** to **16** gave **30** in 89% yield.

*Methyl 4,4,8-trimethyl-3,6-dioxo-*cis*-bicyclo[3.3.0]oct-7-ene-1-carboxylate (**31**)*

A mixture of compound **30** (0.095 g, 0.323 mmol) and sodium chloride (0.029 g, 0.501 mmol) was stirred in reagent grade dimethyl sulfoxide (4 mL) containing added water (50 μL) and heated to 80°C for 11 h under nitrogen. After cooling, the mixture was diluted with distilled water and extracted with ether (3 × 25 mL). The combined ethereal extracts were washed with distilled water (2 × 10 mL) and saturated brine. The organic layer was dried over $MgSO_4$ and concentrated to give a brown oil. The oil was passed through a silica plug with hexanes/ethyl acetate (4:1 v/v) as the eluent to give **31** (0.064 g, 0.269 mmol, 83%) as a colorless oil; ir λ_{max}: 5.72, 5.83, 6.12 (m) μm; ^{1}H nmr (200 MHz) δ: 1.07 (s, 3H), 1.25 (s, 3H), 2.09 (d, *J* = 1 Hz, 3H), 2.54 (d, *J* = 19 Hz, 1H), 2.93 (s, 1H), 3.42 (d, *J* = 19 Hz, 1H), 3.78 (s, 3H), 6.03 (q, *J* = 1 Hz, 1H); ^{13}C nmr δ: 15.4 (q), 20.1 (q), 27.0 (q), 40.7 (t), 48.0 (s), 52.7 (q), 57.0 (s), 61.9 (d), 131.8 (d), 172.4 (s), 174.9 (s), 204.6 (s), 215.7 (s); ms *m/z*: 236 (1%). *Exact Mass* calcd. for $C_{13}H_{16}O_4$: 236.1044; found: 236.1049.

*Reduction of compound **31** with lithium and ammonia. Formation of compounds **32** and **33***

Lithium (90.4 mg) was added to liquid ammonia (100 mL) and the mixture was stirred for 45 min to ensure complete dissolution. A solution of compound **31** (0.84 g) in dry tetrahydrofuran (10 mL) was added by syringe. After 10 min solid ammonium chloride (3 g) was added and the ammonia was allowed to evaporate. Water (200 mL) was added to the residue and the mixture was extracted with ether (4 × 75 mL) to give a brown oil (0.63 g). Flash chromatography with 3:1 hexanes – ethyl acetate gave a very low yield of compound **32** in the early fractions, which was identified by comparison with the product obtained by oxidation of compound **33** (*vide infra*).

In another run compound **31** (60 mg) in dry tetrahydrofuran was added to liquid ammonia (10 mL), followed by lithium (12 mg). Within 1 min the solution became dark blue and methanol (2.5 mL) was added rapidly, followed by ammonium chloride (1 g). Work-up as before gave a brown oil, which on flash chromatography with 2:1 hexanes – ethyl acetate gave a low yield of compound **33**, identified by comparison with product obtained by decarbomethoxylation of compound **39** (*vide infra*).

*Conversion of compound **31** to compound **17***

Compound **31** (0.523 g, 2.22 mmol) was hydrogenated at 3 atm (1 atm = 101.3 kPa) in ethyl acetate (30 mL) over platinum (formed from platinum oxide *in situ*; 0.040 g) for 16.5 h. The catalyst was filtered and the filtrate was concentrated to give a yellow oil. Purification was accomplished by chromatography on silica with hexanes/ethyl acetate (3:1 v/v) as the eluent and subsequent crystallization from hexanes/ethyl acetate (3:1 v/v) with cooling to give **17** (0.474 g, 1.99 mmol, 89%) as colorless plates, mp 70.5–71°C. The spectroscopic data for the product were identical with those reported for compound **17** prepared by decarbomethoxylation of **15** (*vide supra*).

*Dimethyl 3-acetoxy-4,4,8-trimethyl-6-oxo-*cis*-bicyclo[3.3.0]octa-2,7-diene-1,2-dicarboxylate (**34**)*

A solution of compound **30** (1.62 g, 5.51 mmol) in acetic anhydride (16 mL) and triethylamine (2 mL) containing 4-(dimethylamino)pyridine (0.005 g, 0.04 mmol) was stirred at room temperature under nitrogen for 16 h. The reaction mixture was treated with distilled water (15 mL) and extracted with ethyl acetate (3 × 20 mL). The combined organic extracts were washed with water (3 × 25 mL), saturated aqueous sodium bicarbonate (2 × 25 mL), and saturated brine (2 × 20 mL). The solution was dried over $MgSO_4$ and concentrated to give a brown solid. Crystallization from hexanes/ethyl acetate

For personal use only.

(3:1 v/v) gave **34** (1.46 g, 4.35 mmol, 79%) as a colorless crystalline solid, mp 124.5–125°C; ir λ_{max}: 5.57 (m), 5.73, 5.83, 6.04 (w), 6.16 (w) μm; ^{1}H nmr δ: 1.07 (s, 3H), 1.37 (s, 3H), 2.22 (m, 3H), 2.28 (s, 3H), 2.78 (s, 1H), 3.77 (s, 6H), 6.02 (m, 1H); ^{13}C nmr δ: 17.7 (q), 20.4 (q), 21.4 (q), 28.6 (q), 46.0 (s), 51.3 (q), 52.4 (q), 61.0 (d), 64.7 (s), 115.5 (s), 132.7 (d), 162.5 (s), 166.0 (s), 166.5 (s), 171.7 (s), 177.3 (s), 204.1 (s); ms *m/z*: 336 (2%). *Anal.* calcd. for $C_{17}H_{20}O_7$: C 60.71, H 5.99; found: C 60.86, H 6.02.

Dimethyl 3-acetoxy-endo-*6-hydroxy-4,4,8-trimethyl*-cis-*bicyclo[3.3.0]-octa-2,7-diene-1,2-dicarboxylate (35)*

Compound **34** (0.193 g, 0.575 mmol) and cerous chloride hexahydrate (0.217 g, 0.613 mmol) were added to methanol (10 mL) and the mixture was stirred for 10 min at room temperature. Sodium borohydride (0.0271 g, 0.715 mmol) was added in one portion to the resulting solution and stirring was continued for 3 h. The pH was adjusted to neutrality with 10% hydrochloric acid before the mixture was concentrated on the rotary evaporator to yield a yellow oil. The crude material was extracted with ether (2 × 30 mL). The extracts were combined and washed with distilled water (2 × 10 mL) and saturated brine (2 × 20 mL). The solution was dried over $MgSO_4$ and concentrated to give **35** as an oil (0.145 g, 0.429 mmol, 75%); ir λ_{max}: 2.95 (w), 5.59, 5.75, 5.78, 6.00 (w), 6.13 (w) μm; ^{1}H nmr δ: 1.20 (s, 3H), 1.33 (s, 3H), 1.78 (m, $W_{1/2}$ = 5 Hz, 3H), 2.12 (br, 1H), 2.27 (s, 3H), 2.71 (d, J = 7 Hz, 1H), 3.65 (s, 6H), 4.67–4.98 (m, $W_{1/2}$ = 13 Hz, 1H), 5.73 (m, $W_{1/2}$ = 6 Hz, 1H); ^{13}C nmr δ: 14.8 (q), 20.4 (q), 20.7 (q), 27.5 (q), 46.1 (s), 51.0 (q), 52.1 (q), 60.9 (s), 66.8 (d), 75.3 (d), 117.2 (s), 134.0 (d), 142.3 (s), 163.1 (s), 167.3 (s), 167.9 (s), 174.1 (s); ms *m/z*: 338 (1%). *Exact Mass* calcd. for $C_{17}H_{22}O_7$: 338.1365; found: 338.1366.

Dimethyl endo-*6-hydroxy-4,4,8-trimethyl-3-oxo*-cis-*bicyclo[3.3.0]oct-7-ene-1,2-dicarboxylate (36)*

A mixture of compound **35** (0.118 g, 0.349 mmol) and potassium carbonate (0.025 g, 0.181 mmol) in methanol (6 mL) was stirred for 2.5 h under nitrogen. The reaction was quenched with 10% aqueous hydrochloric acid (3 mL) and the mixture was concentrated. The residual oil was extracted with ether (2 × 20 mL) and the combined extracts were dried over $MgSO_4$. The ethereal solution was concentrated to give a colorless oil. Purification of the oil was accomplished by flash chromatography on silica with dichloromethane/ethyl acetate (9:1 v/v) as the eluent to give **36** (0.088 g, 0.297 mmol, 85%) as a colorless solid, mp 102.5–104°C; ir λ_{max}: 3.03 (w), 5.68, 5.79 (br), 6.03 (w), 6.13 (w) μm; ^{1}H nmr δ: 1.00 (s, 3H), 1.40 (s, 3H), 1.57 (m, 3H), 1.77 (br s, 1H), 2.88 (d, J = 6 Hz, 1H), 3.75 (s, 3H), 3.80 (s, 3H), 4.41–4.77 (m, 1H), 4.63 (s, 1H), 5.97 (m, 1H); ms *m/z*: 296 (5%).

Methyl endo-*6-hydroxy-4,4,8-trimethyl-3-oxo*-cis-*bicyclo[3.3.0]oct-7-ene-1-carboxylate (37)*

A mixture of compound **36** (0.340 g, 1.15 mmol) and sodium chloride (0.117 g, 2.00 mmol) was stirred in reagent grade dimethyl sulfoxide (4 mL) containing added water (40 μL) and heated to 80°C for 14 h under nitrogen. After cooling, the mixture was diluted with distilled water and extracted with ethyl acetate (2 × 25 mL). The combined organic extracts were washed with distilled water (2 × 25 mL) and saturated brine (2 × 25 mL) before being dried over $MgSO_4$. The solution was concentrated to yield a clear yellow oil. Flash chromatography of the oil on silica with chloroform/ethyl acetate (4:1 v/v) as the eluent gave **37** (0.271 g, 1.14 mmol, 99%) as a colorless crystalline solid, mp 123.5–124.5°C; ir λ_{max}: 2.99 (br, w), 5.75 μm; ^{1}H nmr δ: 0.98 (s, 3H), 1.30 (s, 3H), 1.44 (d, J = 5 Hz, 1H), 1.70 (m, $W_{1/2}$ = 3 Hz, 3H), 2.18 (d, J = 19 Hz, 1H), 2.87 (d, J = 6 Hz, 1H), 3.36 (d, J = 19 Hz, 1H), 3.73 (s, 3H), 4.58–4.98 (m, $W_{1/2}$ = 10 Hz, 1H), 5.62–5.80 (m, $W_{1/2}$ = 6 Hz, 1H); ^{13}C nmr δ: 14.0 (q), 18.7 (q), 26.1 (q), 42.7 (t), 48.6 (s), 52.6 (q), 60.5 (s), 61.3 (d), 75.7 (d), 130.8 (d), 148.3 (s), 175.7 (s), 217.8 (s); ms *m/z*: 238 (6%). *Exact Mass* calcd. for $C_{13}H_{18}O_4$: 238.1200; found: 238.1203.

Methyl endo-*6-hydroxy-4,4*-endo-*8-trimethyl-3-oxo*-cis-*bicyclo[3.3.0]-octane-1-carboxylate (38)*

Compound **37** (0.0677 g, 0.284 mmol) was hydrogenated at atmospheric pressure in ethyl acetate (12 mL) over platinum (formed from platinum oxide *in situ;* 0.010 g) for 50 min. The catalyst was filtered and the filtrate was concentrated to give a colorless oil. Purification was accomplished by flash chromatography on silica with chloroform/ethyl acetate (4:1 v/v) as the eluent and crystallization from pentane containing 5–10% dichloromethane to yield **38** (0.0622 g, 0.259 mmol, 91%) as colorless crystals, mp 122.5–123°C; ir λ_{max}: 3.00 (br, w), 5.72, 5.78 μm; ^{1}H nmr (200 MHz) δ: 0.89 (s, 3H), 1.14 (d, J = 7.5 Hz, 3H), 1.25 (s, 3H), 1.53 (ddd, J = 14.0, 2.5, 1.0 Hz, 1H), 1.55 (br, 1H), 2.32 (ddd, J = 14.0, 10.5, 3.5 Hz, 1H), 2.57 (qdd, J = 10.5, 7.5, 2.5 Hz, 1H), 2.72 (d, J = 19.5 Hz, 1H), 2.85 (d, J = 3.5 Hz, 1H), 3.03 (d, J = 19.5 Hz, 1H), 3.74 (s, 3H), 4.38 (m, $W_{1/2}$ = 6.5 Hz, 1H); ^{13}C nmr δ: 19.5 (q), 25.7 (q), 39.2 (t), 41.7 (d), 44.1 (t), 48.0 (s), 52.5 (q), 56.3 (s), 63.5 (d), 75.1 (d), 179.1 (s), 220.1 (s); ms *m/z*: 240 (6%). *Exact Mass* calcd. for $C_{13}H_{20}O_4$: 240.1361; found: 240.1361. *Anal.* calcd. for $C_{13}H_{20}O_4$: C 64.98, H 8.39; found: C 64.54, H 8.27.

Oxidation of compounds 33 and 38 to compounds 32 and 17

A solution of compound **33** (0.050 g, 0.208 mmol) and pyridinium dichromate (0.118 g, 0.313 mmol) in anhydrous *N,N*-dimethylformamide (5 mL) was stirred for 18 h under nitrogen at room temperature. The reaction mixture was extracted with ethyl acetate (2 × 10 mL) and the extract was washed with distilled water (3 × 5 mL) and saturated brine (3 × 5 mL), dried over $MgSO_4$, and concentrated. The residual oil was chromatographed on silica with hexanes/ethyl acetate (3:1 v/v) as the eluent to yield **32** (0.030 g, 0.126 mmol, 61%) as a colorless oil; ^{1}H nmr (200 MHz) δ: 1.03 (s, 3H), 1.08 (d, J = 6.5 Hz, 3H), 1.21 (s, 3H), 2.23 (m, 1H), 2.39–2.47 (m, 2H), 2.61 (d, J = 19 Hz, 1H), 2.91 (s, 1H), 3.12 (d, J = 19 Hz, 1H), 3.76 (s, 3H). *Anal.* calcd. for $C_{13}H_{18}O_4$: C 65.53, H 7.61; found: C 65.34; H 7.69.

Oxidation of compound **38** under similar conditions gave **17**.

Dimethyl 3,6-dihydroxy-4,4-exo-*8-trimethyl*-cis-*bicyclo[3.3.0]oct-2-ene-1,2-dicarboxylate (39)*

Lithium wire (36 mg, 5.2 mg-atom) was added to a stirred solution of **30** (0.514 g, 1.75 mmol) in anhydrous tetrahydrofuran (15 mL) and ammonia (50 mL) under nitrogen. After 20 min the reaction was quenched with methanol (3 mL), solid ammonium chloride was added, and the ammonia was allowed to evaporate. Saturated aqueous ammonium chloride (15 mL) was added and the layers were separated. The aqueous phase was extracted with ethyl acetate (2 × 10 mL). The combined organic layers were washed with distilled water (3 × 10 mL), saturated brine (3 × 10 mL), dried over $MgSO_4$, and concentrated. The residual oil was chromatographed on silica with dichloromethane/ethyl acetate (20:3 v/v) as the eluent to give **39** (40%); ir λ_{max}: 2.75 (w), 5.77 (br), 6.04 (br), 6.21 μm; ^{1}H nmr δ: 1.12 (s, 3H), 1.12 (d, J = 6 Hz, 3H), 1.30 (s, 3H), 1.53–2.27 (m, 4H), 2.50 (d, J = 9 Hz, 1H), 3.70 (s, 3H), 3.80 (s, 3H), 4.12 (m, $W_{1/2}$ = 26 Hz, 1H), 10.90 (br s, 1H); ^{13}C nmr δ: 16.0 (q), 18.9 (q), 28.3 (q), 40.7 (t), 43.8 (d), 44.2 (s), 51.1 (q), 51.6 (q), 61.0 (s), 64.8 (d), 73.9 (d), 102.5 (s), 170.8 (s), 175.7 (s), 180.5 (s); ms *m/z*: 298 (3%). *Exact Mass* calcd. for $C_{15}H_{22}O_6$: 298.1410; found: 298.1434.

The presence of both compounds **39** and **18** in the crude product was demonstrated by its decarbomethoxylation to both **33** and **32** (*vide infra*).

Decarbomethoxylation of compound 39 to compound 33

A mixture of compound **39** (0.090 g, 0.302 mmol) and sodium chloride (0.010 g, 0.171 mmol) in reagent grade dimethyl sulfoxide (4 mL) containing added distilled water (30 μL) was stirred and heated (80°C) for 24 h under nitrogen. The mixture was diluted with distilled water (10 mL) and extracted with ethyl acetate (2 × 10 mL). The combined organic extracts were washed with distilled water (4 × 5 mL) and saturated brine (2 × 5 mL), and dried over $MgSO_4$. The solution was concentrated to give **33** as an oil (0.049 g, 0.204 mmol, 68%); ^{1}H nmr (200 MHz) δ: 0.98 (d, J = 6.5 Hz, 3H), 1.07 (s, 3H), 1.14

(s, 3H), 1.75 (m, 2H), 2.18 (m, 1H), 2.20 (d, J = 19 Hz, 1H), 2.5 (br, exchangeable with D_2O, 1H), 2.67 (d, J = 6.5 Hz, 1H), 3.25 (d, J = 19 Hz, 1H), 3.78 (s, 3H), 4.04 (m, $W_{1/2}$ = 10 Hz, 1H); ^{13}C nmr δ: 14.9 (q), 19.1 (q), 28.2 (q), 43.2 (t), 44.2 (d), 45.0 (t), 48.1 (s), 52.1 (q), 55.3 (s), 63.8 (d), 74.2 (d), 176.3 (s), 219.8 (s); ms m/z: 240 (6%). Exact Mass calcd. for $C_{13}H_{20}O_4$: 240.1356; found: 240.1354.

When a sample of the crude product mixture from the lithium/ammonia reduction of **30** was similarly decarbomethoxylated, the ^1H nmr spectrum of the product showed the presence of both **33** and **32**.

Acknowledgments

We thank Mr. N. Plavac for obtaining the 200-MHz ^1H nmr spectra and the Natural Sciences and Engineering Research Council of Canada for financial support.

(Trialkylstannyl)copper(I) reagents: preparation and reaction with α,β-unsaturated carbonyl systems. Preparation of β-trialkylstannyl α,β-unsaturated ketones

EDWARD PIERS, HOWARD E. MORTON, AND J. MICHAEL CHONG
Department of Chemistry, University of British Columbia, 2036 Main Mall, University Campus, Vancouver, B.C., Canada V6T 1Y6

Received May 16, 1986

This paper is dedicated to Dr. O. E. (Ted) Edwards

EDWARD PIERS, HOWARD E. MORTON, and J. MICHAEL CHONG. Can. J. Chem. **65**, 78 (1987).

Reaction of Me_3SnLi with 1 equivalent of $CuBr \cdot Me_2S$, PhSCu, $Me_2(MeO)C—C\equiv C—Cu$, or CuCN in tetrahydrofuran (THF) affords the (trimethylstannyl)copper(I) reagents $Me_3SnCu \cdot Me_2S$ (**1**) and $[Me_3SnCuY]Li$ (Y = PhS (**2**), $Me_2(MeO)C—C\equiv C$ (**4**), CN (**5**)), respectively. Similarly, treatment of a THF solution of Me_3SnLi with 0.5 equivalent of $CuBr \cdot Me_2S$ provides $(Me_3Sn)_2CuLi$ (**3**), while reaction of *n*-Bu_3SnLi with PhSCu (1 equivalent) gives [*n*-$Bu_3SnCuSPh]Li$ (**6**). Reagents **2** and **6** readily transfer (in a conjugate sense) the R_3Sn group to conjugated enones (e.g. **7–9**) and structurally simple enoates (e.g. **10**), but do not react with β,β-disubstituted α,β-unsaturated esters (e.g. **11–13**). Reaction of reagent **2** with the enone **26** under "normal" conditions produces, in addition to the expected ketone **28**, a significant amount of the double conjugate addition product **30**. A similar result is obtained with ethyl propenoate (**27**). However, reaction of **26** and **27** with reagent **2** in the presence of acetic acid provides cleanly and efficiently the "simple" conjugate addition products **28** and **29**, respectively. Reagent **1** does not react, or reacts very sluggishly, with α,β-unsaturated carbonyl compounds. β-Trialkylstannyl α,β-unsaturated ketones (e.g. **37–46**) can be produced smoothly and efficiently by reaction of the corresponding β-iodo enones (e.g. **32–36**) with reagents **2** (or **1**) and **6**.

EDWARD PIERS, HOWARD E. MORTON et J. MICHAEL CHONG. Can. J. Chem. **65**, 78 (1987).

Les réactions du Me_3SnLi avec un équivalent de $CuBr \cdot Me_2S$, de PhSCu, de $Me_2(MeO)C—C\equiv C—Cu$ ou de CuCN, dans le tétrahydrofuranne (THF), conduisent respectivement aux réactifs de (triméthylstannyl)cuivre(I) suivants : $Me_2SnCu \cdot Me_2S$ (**1**), $[Me_3SnCuY]Li$ (Y = Phs (**2**), $Me_2(MeO)C—C\equiv C$ (**4**) ou CN (**5**). De la même manière, la réaction d'une solution de THF de Me_3SnLi avec 0,5 équivalent de $CuBr \cdot Me_2S$ conduit au $(Me_3Sn)_2CuLi$ (**3**) alors que la réaction du *n*-Bu_3SnLi avec le PhSCu (1 équivalent) conduit au [*n*-$Bu_3SnCuSPh]Li$ (**6**). Les réactifs **2** et **6** transfèrent facilement (d'une façon conjuguée) le groupement R_3Sn aux énones conjuguées (comme **7–9**) et aux énoates simples d'un point de vue des structures (comme **10**); toutefois, ils ne réagissent pas avec les esters α,β-non-saturées portant deux substituants en position-β,β (comme les composés **11–13**). La réaction de **2** avec l'énone **26**, utilisant des conditions "normales", conduit à une quantité importante du produit **30** provenant d'une double addition conjuguée, en plus de la cétone **28** attendue. Des résultats semblables ont été obtenus avec le propènoate d'éthyle (**27**). Toutefois, la réaction des composés **26** et **27** avec le réactif **2**, en présence d'acide acétique, conduit d'une façon propre et efficace aux produits **28** et **29** provenant d'une addition conjuguée «simple». Le réactif **1** ne réagit pas, ou ne réagit que très lentement, avec les composés carbonylés portant une insaturation en α,β. On peut obtenir les cétones α,β-non-saturées portant un groupement trialkylstannyle en position β (comme **37–46**) d'une façon douce et efficace en faisant réagir les β-iodo énones correspondantes (comme **32–36**) avec les réactifs **2** (ou **1**) et **6**.

Introduction

Over the past two decades, organocopper reagents derived from the interaction of alkyl-lithium, alkenyl-lithium, and (or) related Grignard reagents with copper(I) salts have become well established in organic synthesis (1). Indeed, carbocuprates of various types and constitutions have been found to react efficiently with a wide range of electrophilic substrates and it is difficult to overestimate the importance of these reactions, particularly as methods for forming carbon–carbon bonds.

Recently, cuprate reagents derived from anions other than carbanions have been prepared and have found increasing use in organometallic synthesis. In this connection, the elegant work of Fleming and co-workers (2; see also ref. 3) on the preparation and use of silyl-cuprate reagents deserves explicit mention. The formation of germyl-cuprates from triethyl- and triphenylgermyl-lithium has also been reported (4).

Recently, we initiated investigations into the preparation and chemical reactivity of (trialkylstannyl)copper species, a new class of organometallic reagents first prepared in our laboratory. Our work thus far has focussed mainly on the reactions of these reagents with a variety of electrophilic substrates, and some of the results of these studies have been published in preliminary form (5; see also ref. 6). We report herein (*a*) the preparation of (trimethylstannyl)copper(I)-dimethyl sulfide (**1**), the (trimethylstannyl)cuprate reagents **2–5**, and lithium (phenylthio)(tri-*n*-butylstannyl)cuprate (**6**); (*b*) a study of the reaction of reagents **1**, **2**, and **6** with α,β-unsaturated ketones and esters; and (*c*) the use of reagents **1**, **2**, and **6** for the conversion of β-iodo α,β-unsaturated ketones into the corresponding β-trialkylstannyl enones, a hitherto unknown class of organostannane compounds.

Results and discussion

(a) Preparation of the (trialkylstannyl)copper(I) reagents 1–6

Reaction of trimethylstannyl-lithium[1] with 1.0 or 0.5 equivalents of cuprous bromide – dimethyl sulfide complex (8) in

$Me_3SnCu \cdot Me_2S$	$[Me_3SnCuY]Li$
1	**2** Y = SPh
	3 Y = $SnMe_3$
[*n*-$Bu_3SnCuSPh]Li$	**4** Y = $C\equiv C—C(OMe)Me_2$
6	**5** Y = CN

[1]Trimethylstannyl-lithium and tri-*n*-butylstannyl-lithium were prepared by reaction of hexamethylditin and hexa-*n*-butylditin with 1.0 equivalent of methyl-lithium and *n*-butyl-lithium, respectively. See ref. 7.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 190.90.36.8 on 09/07/12
For personal use only.

cold (−48°C), dry tetrahydrofuran (THF) provided solutions of reagents **1** and **3**, respectively. Similarly, the cuprate reagents **2**, **4**, and **5** were prepared by addition of 1.0 equivalent of solid phenylthiocopper(I) (9), 3-methoxy-3-methyl-1-butynylcopper(I) (10), or cuprous cyanide, respectively, to cold solutions of trimethylstannyl-lithium[1] in dry THF. Lithium (phenylthio)(tri-*n*-butylstannyl)cuprate (**6**) was obtained in analogous fashion by reaction of tri-*n*-butylstannyl-lithium[1] with phenylthiocopper(I) (9) in THF at −20°C.

The formulations shown in **1**–**6** are not meant to imply actual structures, but are used for convenience and to show stoichiometry. These formulas are, of course, analogous to those commonly used to represent alkylcuprate reagents.[2] It is interesting to note that THF solutions of reagents **1**–**4** and **6** are dark red in color, while solutions of the cyanocuprate **5** are bright orange.

Although the preparation of reagents **1**–**6** is relatively straightforward, it is important to discuss a number of details. In analogy with alkylcuprates, the (trialkylstannyl)copper(I) reagents are thermally unstable and are sensitive to oxygen. Therefore, it is imperative to maintain relatively low reaction temperatures (certainly ≤ room temperature) and to carefully exclude oxygen from the reaction mixtures. An explicit study regarding the relative stabilities of **1**–**6** was not carried out, but on the basis of observations made during the course of our work with these species, it appears that the phenylthiocuprates **2** and **6** and the cyanocuprate **5** are somewhat more stable than reagents **1**, **3**, and **4**.

For the preparation of reagents **1** and **3**, it is best to use white, recently prepared (8) cuprous bromide – dimethyl sulfide complex. Furthermore, we have found that, although phenylthiocopper(I) (9) remains a uniform yellow color even after storage (ambient temperatures, argon atmosphere) for periods of time greater than one year, the phenylthiocuprates **2** and **6** did not form consistently when the phenylthiocopper(I) used was more than about six months old. In a similar vein, the cuprate reagent **4** should be prepared within a few days of preparing 3-methoxy-3-methyl-1-butynylcopper(I) (10). For the formation of the cyanocuprate **5**, purification of commercially available cuprous cyanide is not necessary.

(b) Reaction of reagents 1, 2, and 6 with α,β-unsaturated carbonyl compounds

It is well known that the reactivity patterns of alkyl-lithium reagents are notably different from those of alkylcuprates (1). For example, reaction of alkyl-lithiums with α,β-unsaturated carbonyl compounds normally results in direct attack of the alkyl group on the carbonyl carbon (1,2-addition). In contrast, alkylcuprate reagents of various types and constitutions usually transfer the alkyl group to the β carbon of conjugated enones and enoates (1,4-addition) (1).

Still has shown (7) that reaction of trimethylstannyl-lithium with 2-cyclohexen-1-ones *in diethyl ether* results largely in 1,2-addition products. However, treatment of α,β-unsaturated ketones and esters with Me_3SnLi *in THF or THF–hexamethylphosphoramide (HMPA)* provides conjugate addition products in high yields. (7). Interestingly, these reactions take place rapidly even at −78°C. Thus, although both alkyl-lithiums and trialkylstannyl-lithiums are highly reactive reagents, their reactivity patterns with respect to enones and enoates are not entirely analogous.

TABLE 1. Reaction of trialkylstannyl reagents with α,β-unsaturated ketones and esters

Entry	Substrate	Reagent (equiv.)	Reaction conditions[a]	Product (yield, %)[b]
1	**7**	Me_3SnLi		**14** (93)[c]
2	**7**	**1** (1.3)	A	**14** (trace)[d]
3	**7**	**2** (1.3)	B	**14** (76)
4	**7**	**6** (1.5)	C	**15** (69)
5	**8**	Me_3SnLi		**16** (96)[c]
6	**8**	**1** (1.3)	A	**16** (32)[e]
7	**8**	**2** (2.0)	B	**16** (91)
8	**8**	**6** (1.5)	C	**17** (78)
9	**9**	Me_3SnLi		**18** (77)[c]
10	**9**	**1** (1.3)	A	**18** (—)[d]
11	**9**	**2** (2.0)	B	**18** (69)
12	**9**	**6** (1.5)	C	**19** (64)
13	**10**	Me_3SnLi (1.1)	D	**20** (71)
14	**10**	**1** (1.3)	A	**20** (trace)[d]
15	**10**	**2** (1.1)	B	**20** (67)
16	**10**	**6** (1.5)	C	**21** (74)
17	**11**	Me_3SnLi (1.1)	D	**22** (74)
18	**11**	**2** (1.3)	B	**22** (—)[d]
19	**12**	Me_3SnLi		**23** (80)[c]
20	**12**	**2** (1.3)	B	**23** (—)[d]
21	**13**	Me_3SnLi (1.1)	D	**24** (75)
22	**13**	**2** (1.3)	B	**24** (—)[d]

[a]A: THF, −48°C, 2 h; −20°C, 1 h; room temperature, 1 h. B: THF, −20°C, 15 min; room temperature, 1 h. C: THF, −78°C, 1 h; −20°C, 1 h; room temperature, 1 h. D: THF, −78°C, 15 min.

[b]Yields from the experiments described herein refer to isolated, purified material.

[c]Taken from ref. 7.

[d]Starting material was recovered in high yield.

[e]The diketone **25** was also produced (24% yield) in this reaction (see text).

It might be expected that (trialkylstannyl)copper(I) reagents would also transfer, in a conjugate sense, the R_3Sn group to α,β-unsaturated carbonyl compounds.[3] Furthermore, it was of interest to compare the reactivity of these reagents with that of the "parent" trialkylstannyl-lithium species. Therefore, we investigated initially the reactions of reagents **1**, **2**, and **6** with a number of representative α,β-unsaturated ketones (**7**–**9**) and esters (**10**–**13**), and compared the results obtained with those derived from reaction of these substrates with trimethylstannyl-lithium. The results of this study are summarized in Table 1.

A number of points should be made with respect to the data given in Table 1. In terms of its ability to transfer conjugatively the trimethylstannyl group to α,β-unsaturated carbonyl systems, lithium (phenylthio)(trimethylstannyl)cuprate (**2**) was found to be less reactive than Me_3SnLi. Thus, reagent **2** readily transformed the enones **7**–**9** and methyl (*E*)-2-butenoate (**10**) into the corresponding 1,4-addition products **14**, **16**, **18**, and **20**, respectively (Table 1, Entries 3, 7, 11, 15). However, the cuprate **2** failed to react with ethyl 3-methyl-2-butenoate (**11**) or with the β,β-disubstituted enoates **12** and **13** (Entries 18, 20,

[2]For very interesting recent work regarding the constitutions of various cuprate reagents derived by interaction of methylcopper(I) and varying amounts of methyl-lithium, see ref. 11. See also ref. 12.

[3]Hudec (13) reported that treatment of two 2-cyclohexen-1-one derivatives with a "black" THF solution of trimethylstannyl-lithium in the presence of a *catalytic amount* of cuprous iodide provided the corresponding conjugate addition products. However, in view of Still's work (7), it is not clear that the CuI catalyst played a significant role in these transformations.

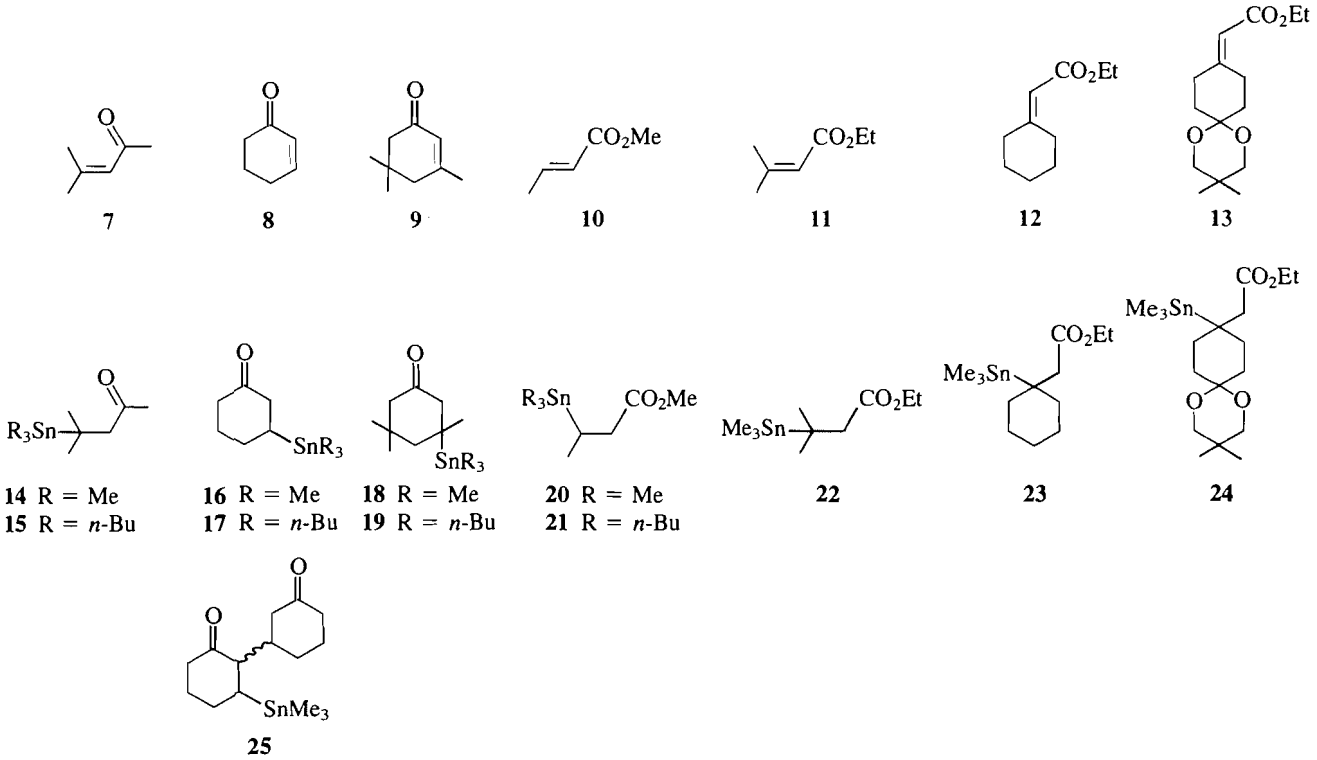

CHART 1

22). In each case, a high proportion of the starting material was recovered. In contrast, trimethylstannyl-lithium smoothly and efficiently converted all of the substrates **7**–**13** into the corresponding conjugate addition products (Entries 1, 5, 9, 13, 17, 19, 21).

Lithium (phenylthio)(tri-*n*-butylstannyl)cuprate (**6**) evidently has reactivity similar to that of the trimethylstannyl analog **2**. Thus, reaction of the substrates **7**–**10** with **6** provides the tri-*n*-butylstannyl derivatives **15**, **17**, **19**, and **21**, respectively, in good yields (Entries 4, 8, 12, 16).

The results summarized in Table 1 also show that (trimethylstannyl)copper(I)-dimethyl sulfide (**1**) is relatively unreactive towards α,β-unsaturated carbonyl compounds. In fact, treatment of the substrates **7**, **9**, and **11** with reagent **1** did not produce any products; in each case, starting material was recovered in high yield (Entries 2, 10, 14). On the other hand, reaction of 2-cyclohexen-1-one (**8**) with **1** (Entry 6) provided a low yield (32%) of 3-trimethylstannylcyclohexanone (**16**). Also produced in this reaction, in 48% yield, was the diketone **25**. Thus, although reagent **1** does transfer the Me_3Sn group to the β carbon of enone **8**, conjugate addition of the enolate anion thus formed to a second molecule of **8** is competitive with the initial addition.

The problem of "double" conjugate addition is also observed in the reactions of trimethylstannyl-lithium and the cuprate reagent **2** with the structurally simple substrates 3-buten-2-one (**26**) and ethyl propenoate (**27**) (see Chart 2 and Table 2). Thus, treatment of **26** and **27** with 1 equivalent of Me_3SnLi (−78°C, THF) provided, in each case, a mixture of mono-addition (**28**, **29**, respectively) and di-addition (**30**, **31**, respectively) products (Table 2, Entries 1 and 3). Similarly, reaction of the enone **26** with reagent **2** afforded products **28** (27%) and **30** (37%) (Entry 2), while an analogous transformation involving the enoate **27** gave a low yield (18%) of the diester **31** as essentially the only volatile product.

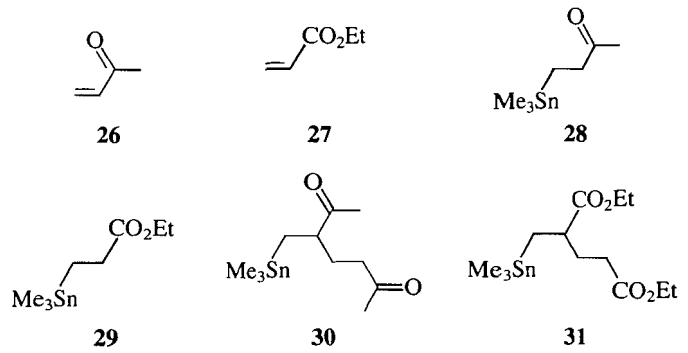

CHART 2

Interestingly, however, it was found that the reactions of **26** and **27** with the cuprate reagent **2** can be controlled experimentally so as to produce good yields of the conjugate addition products **28** and **29**. Thus, treatment of **26** with reagent **2** (1.3 equivalents) *in the presence of 1.3 equivalents of acetic acid* provided the ketone **28** in 77% yield (Entry 5).[4] Under these conditions, only trace amounts of the diketone **30** was formed. Evidently, conjugate addition of cuprate reagent **2** to the enone **26** is considerably faster than protonation (destruction) of **2** by acetic acid. Furthermore, protonation (HOAc) of the initially formed enolate anion (from **26** + **2**) is relatively fast compared with a second conjugate addition reaction (to produce **30**). In similar fashion, treatment of a cold THF solution of reagent **2** (4 equivalents) with a mixture of ethyl propenoate (**27**) and acetic acid (2 equivalents) afforded the mono-ester **29** in 70% yield (Entry 6).

The results just described revealed an interesting and import-

[4]Reaction of the enone **26** with trimethylstannyl-lithium in the presence of acetic acid gave only trace amounts of the conjugate addition product **28**.

TABLE 2. Reaction of Me_3SnLi and $[Me_3SnCuSPh]Li$ (**2**) with 3-buten-2-one (**26**) and ethyl propenoate (**27**)

Entry	Substrate	Reagent (equiv.)	Reaction conditions[a]	Products (yield, %)[b]
1	**26**	Me_3SnLi (1.0)	A	**28** (43), **30** (31)
2	**26**	**2** (1.3)	B	**28** (27), **30** (37)
3	**27**	Me_3SnLi (1.0)	A	**29** (20), **31** (29)
4	**27**	**2** (1.3)	B	**29** (trace), **31** (18)
5	**26**	**2** (1.3)	B[c]	**28** (77), **30** (trace)
6	**27**	**2** (4.0)	B[d]	**29** (70), **31** (trace)

[a]A: THF, −78°C, 1 h. B: THF, −78°C, 30 min; −20°C, 1 h; room temperature, 30 min.

[b]Yields refer to isolated, purified products.

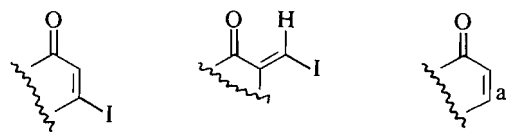
[c]HOAc (1.3 equiv.) was added along with the substrate **26** to a solution of reagent **2**.

[d]HOAc (2.0 equiv.) was added along with the substrate **27** to a solution of reagent **2**.

ant characteristic of (trialkylstannyl)cuprate reagents. Unlike the "parent" trialkylstannyl-lithiums, the corresponding copper(I) species are relatively weak bases in THF.[5] This property not only allows one to perform successfully transformations such as **26** → **28** and **27** → **29**, but proved to be important in subsequent investigations concerning the use of these reagents in synthesis (5).

(c) Reaction of reagents 1, 2, and 6 with β-iodo α,β-unsaturated ketones

Recent work in our laboratory (14) has shown that β-iodo α,β-unsaturated ketones (15) (general formulas **A**, **B**) serve as excellent synthetic equivalents of unsaturated a^3 synthons of general structures **C** and **D**, respectively. In connection with an investigation (16) aimed at employing β-iodo enones as synthetic equivalents of the unsaturated d^3 synthons **E** and **F** we



wished to convert substances of general structures **A** and **B** into the corresponding β-trialkylstannyl α,β-unsaturated ketones.

Treatment of 3-iodo-2-cyclohexen-1-one (**32**) (see Chart 3) with 1 equivalent of trimethylstannyl-lithium in THF at −78°C for 1 h afforded a mixture (gas–liquid chromatographic analysis) of starting material **32** (42%), the desired enone **37** (32%), the di-addition product **47** (15%), and a number of minor constituents. Pure samples of **37** and **47** were obtained by preparative gas–liquid chromatography and these substances were fully characterized. In general, this reaction was not very reproducible and attempts to increase the yield of **37** by varying reaction conditions proved to be unfruitful.

In contrast, reaction of the iodo enone **32** with 1.1 equivalents of lithium (phenylthio)(trimethylstannyl)cuprate (**2**) in THF (−20°C to room temperature) gave 3-trimethylstannyl-2-cyclohexen-1-one (**37**) in 86% yield (see Table 3, Entry 1). In similar fashion, the cuprate reagent **6** smoothly converted substrate **32** into the tri-*n*-butylstannyl derivative **38** (81%, Table 3, Entry 2). Both reactions were clean and none of the corresponding di-addition products (e.g. **47**) could be detected in the materials initially isolated.

Similar transformations involving the β-iodo enones **33–36** and the cuprate reagents **2** and **6** were carried out and the results are summarized in Table 3 (Entries 3–10). Although the conversions of **32–35** into the β-trialkylstannyl enones **37–44** were generally clean and efficient, the corresponding transformations of (*E*)-2-(iodomethylene)cyclohexanone (**36**) into **45** and **46** were not entirely reproducible. The yields of isolated, purified products obtained from several reactions varied considerably (~35–80% for **45** and 45–70% for **46**). In general, best results were obtained when the crude reaction products were subjected to chromatography on silica gel prior to bulb-to-bulb distillation.

The stereochemistry of products **45** and **46** was assigned on the basis of the following comparisons. In the ^1H nmr spectra of compounds **48** and **49** (see Chart 4), the olefinic protons resonate at δ 5.6 and 6.62, respectively (17). On the other hand, the olefinic protons adjacent to the methyl group in (*E*)-2-heptene (**50**) and to the Me_3Sn function in (*E*)-1-trimethylstannyl-1-hexene (**51**) give rise to signals at δ 5.40 and 5.92 (18), respectively. Thus, replacing the methyl substituent on the double bond of **50** by a trimethylstannyl group (cf. **51**) causes a downfield shift of about 0.5 ppm for the adjacent olefinic proton. Analysis of the data given above would lead one to predict that the alkene protons of **45** and **46** should resonate at approximately δ 7.1 (~6.6 + ~0.5). In fact, the olefinic protons in question exhibit triplets (J = 2 Hz) at δ 7.03 (**45**) and δ 7.04 (**46**). These values provide excellent evidence for the stereochemical assignments.

The reactions of β-iodo enones with other (trimethylstannyl)copper(I) reagents were also examined. For example, reaction of **32** with $Me_3SnCu \cdot Me_2S$ (**1**) in THF (−48°C to room temperature) provided **37** in excellent yield (Table 3, Entry 11).[6] In similar fashion, the β-iodo enones **34–36** were converted efficiently into the corresponding products **41**, **43**, and **45**, respectively (Table 3, Entries 12–14). The yields of these reactions were comparable to those obtained from reaction of **32** and **34–36** with the cuprate reagent **2**. Furthermore, reaction of **36** with **1** (to produce **45**) was found to be much more reproducible than the corresponding transformation involving **36** and the cuprate reagent **2**.

It was also found that reaction of 3-iodo-2-methyl-2-cyclopenten-1-one (**35**) with reagent **1** under conditions identical with those used for the iodo enones **32** and **34** gave, in addition to the desired product **43**, a significant amount of starting material. However, addition of HMPA to the reaction mixture improved the efficiency of this conversion (Table 3, Entry 13).

[5]Similar observations were made independently by Cox and Wudl (see the last citation in ref. 6).

[6]The β-iodo enone **32** could also be converted efficiently into **37** by reaction with the bis(trimethylstannyl)cuprate **3** or the cyanocuprate **5**. However, since two equivalents of Me_3SnLi are required to prepare one equivalent of **3**, it seems clear that the mixed cuprates **2** and **5** or the (trimethylstannyl)copper(I) reagent **1** are the preferred reagents. Thus far, most of our work has employed reagents **1** and **2**.

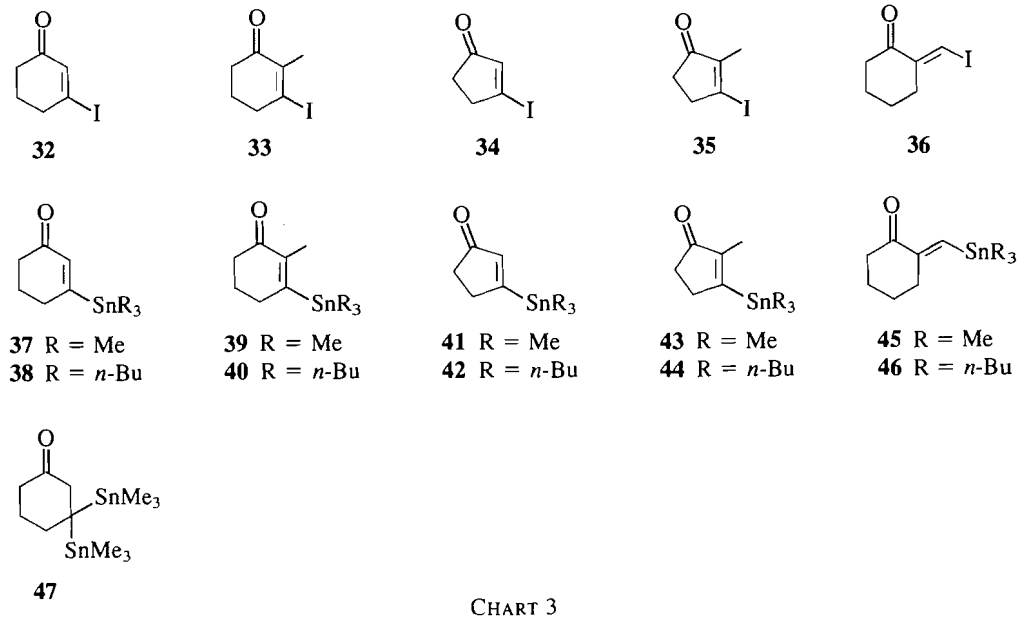


CHART 3

TABLE 3. Preparation of β-trialkylstannyl α,β-unsaturated ketones

Entry	Substrate	Reagent (equiv.)	Reaction conditions[a]	Product (yield, %)[b]

[a]A: THF, −20°C, 15 min; room temperature, 30 min. B: THF, −48°C, 2 h; −20°C, 1 h; room temperature, 1 h. C: THF, −48°C, 2 h.

[b]Yields refer to isolated, purified products.

[c]In this reaction, HMPA was added to the reaction mixture prior to addition of the β-iodo enone **35**.

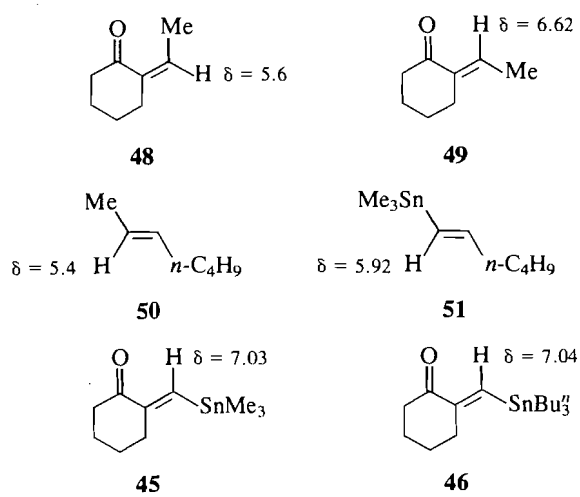

CHART 4

TABLE 4. Longest wavelength π→π* ultraviolet absorption bands of β-trialkylstannyl α,β-unsaturated ketones (methanol solution)

Entry	Compound	λ_{max}, nm (ε)
β-Trimethylstannyl α,β-unsaturated ketones		
1	**37**	236 (12 000)
2	**39**	250 (14 300)
3	**41**	233 (15 200)
4	**43**	242 (15 800)
5	**45**	246 (8 300)
β-Tri-*n*-butylstannyl α,β-unsaturated ketones		
6	**38**	242 (10 900)
7	**40**	256 (12 000)
8	**42**	235 (12 100)
9	**44**	246 (13 200)
10	**46**	250 (7 400)

(d) Ultraviolet spectra of β-trialkylstannyl α,β-unsaturated ketones

Prior to the work described herein, cyclic β-trialkylstannyl α,β-unsaturated ketones were unknown. Therefore, it was of interest to record the ultraviolet spectra of compounds **37**–**46** to determine the effect of β R_3Sn groups on the position of the longest wavelength π→π* absorption band of the enone system. The data are recorded in Table 4.

The π→π absorption maxima of the "parent" enones 2-cyclohexen-1-one, 2-cyclopenten-1-one, and 2-(methylene)cyclohexanone appear at 226, 218, and 231 nm, respectively. The data given in Table 4 show that a β Me_3Sn group causes a significant bathochromic shift (10–15 nm) in the position of the absorption maxima (Entries 1, 3, 5). As expected (19), introduction of an α methyl group results in a further shift to longer wavelengths (Entries 2,4). Similar trends are seen with β-tri-*n*-butylstannyl enones, although the bathochromic shifts (16–19 nm, Entries 6,8,10) associated with the *n*-Bu_3Sn group are consistently larger than those related to the Me_3Sn group. Finally, it is interesting to note that the molar absorptivities of the β-trimethylstannyl enones are consistently greater than those of the tri-*n*-butylstannyl analogs.

Experimental

General information

Melting points and distillation temperatures, which refer to short path (Kugelrohr) distillations, are uncorrected. Ultraviolet (uv) spectra were measured with a Cary 15 spectrophotometer. Infrared (ir) spectra were recorded on Perkin Elmer models 710 or 710B spectrophotometers and were calibrated using the 1601 cm^{-1} band of polystyrene film. Proton nuclear magnetic resonance (^1H nmr) spectra were recorded at 80 MHz (Bruker WP-80 spectrometer) or at 100 MHz (Varian Associates HA-100 or XL-100 spectrometers). Signal positions are given in δ units and were measured relative to the chloroform signal (δ 7.25). The tin–proton coupling constants (J_{Sn-H}) are given as an average of the ^{117}Sn and ^{119}Sn values. High resolution mass spectra were recorded with Kratos/AEI MS50 or MS 902 mass spectrometers. For compounds containing trialkylstannyl groups, molecular mass measurements were based on ^{120}Sn. Microanalyses were performed in the Microanalytical Laboratory of the University of British Columbia.

Note: All reactions described below were carried out under an atmosphere of dry argon in carefully dried glassware.

Trimethylstannyl-lithium

To a cold (−20°C), stirred solution of hexamethylditin in dry THF (~10 mL per mmol of $Me_3Sn–SnMe_3$) was added a solution of methyl-lithium (1.0 equiv.) in ether. The mixture was stirred at −20°C for 15 min to afford a pale yellow solution of trimethylstannyl-lithium.

Tri-n-butylstannyl-lithium

To a cold (0°C), stirred solution of hexa-*n*-butylditin in dry THF (~10 mL per mmol of the ditin) was added a solution of *n*-butyl-lithium (1.0 equiv.) in hexane. The mixture was stirred at 0°C for 15 min to afford a yellow solution of tri-*n*-butylstannyl-lithium.

Lithium (phenylthio)(trimethylstannyl)cuprate (2)

To a cold (−20°C), stirred solution of trimethylstannyl-lithium (0.75 mmol) in 10 mL of dry THF was added in one portion solid phenylthiocopper(I) (132 mg, 0.75 mmol). The slurry was stirred at −20°C for 15 min to afford a dark red solution of the cuprate reagent **2**.

Lithium (phenylthio)(tri-n-butylstannyl)cuprate (6)

To a cold (−20°C), stirred solution of tri-*n*-butylstannyl-lithium (0.55 mmol) in 7 mL of dry THF was added in one portion solid phenylthiocopper(I) (97 mg, 0.55 mmol). The mixture was stirred at −20°C for 15 min to produce a dark red solution of the cuprate reagent **6**.

Lithium bis(trimethylstannyl)cuprate (3)

To a cold (−48°C), stirred solution of trimethylstannyl-lithium (1.1 mmol) in 10 mL of dry THF was added in one portion solid cuprous bromide – dimethyl sulfide complex (117 mg, 0.55 mmol). The mixture was stirred at −48°C for 20 min to afford a dark red solution of the cuprate reagent **3**.

Lithium (3-methoxy-3-methyl-1-butynyl)(trimethylstannyl)cuprate (4)

To a cold (−48°C), stirred solution of trimethylstannyl-lithium (0.39 mmol) in 5 mL of dry THF was added, in one portion, solid (3-methoxy-3-methyl-1-butynyl)copper(I) (63 mg, 0.39 mmol). The mixture was stirred at −48°C for 15 min to afford a dark red solution of the cuprate reagent **4**.

Lithium (cyano)(trimethylstannyl)cuprate (5)

To a cold (−78°C), stirred solution of trimethylstannyl-lithium (0.39 mmol) in 5 mL of dry THF was added, in one portion, solid cuprous cyanide (35 mg, 0.39 mmol). The mixture was stirred at −78°C for 5 min and at −48°C for 15 min to afford a bright orange solution of the cuprate reagent **5**.

(Trimethylstannyl)copper(I)-dimethyl sulfide (1)

To a cold (−48°C), stirred solution of trimethylstannyl-lithium (0.65 mmol) in 5 mL of dry THF was added, in one portion, solid cuprous bromide – dimethyl sulfide complex (113 mg, 0.65 mmol). The mixture was stirred at −48°C for 10 min to give a dark red solution of the cuprate reagent **1**.

Preparation of β-trialkylstannyl ketones and esters

(a) General procedure A

To a cold (−20°C), stirred solution of lithium (phenylthio)(trimethylstannyl)cuprate (**2**) (1.1–2.0 equiv.) in dry THF (10 mL) was added a solution (THF, ~1 mL) of the appropriate α,β-unsaturated ketone or ester (0.58–1.5 mmol). The reaction mixture was stirred at −20°C for 15 min and at room temperature for 1 h. Methanol (~0.2 mL) and diethyl ether (~30 mL) were added and the mixture was stirred at room temperature for several minutes. The resulting yellow slurry was filtered through a short column of Florisil (10 g, 100–200 mesh). The column was eluted with 50 mL of diethyl ether. Removal of the solvent from the combined eluate, followed by bulb-to-bulb distillation of the residual oil, gave the product(s).

(b) General procedure B

To a cold (−78°C), stirred solution of lithium (phenylthio)(tri-*n*-butylstannyl)cuprate (**6**) (1.3–1.5 equiv.) in dry THF (10 mL) was added a solution (THF, ~1 mL) of the α,β-unsaturated ketone or ester (0.67–1.0 mmol). The reaction mixture was stirred at −78°C for 1 h, at −20°C for 1 h, and at room temperature for 1 h. Methanol (~0.2 mL) and diethyl ether (~30 mL) were added and work-up was carried out as described in procedure A, above. The crude, undistilled product was subjected to column chromatography on 20 g of silica gel. Elution of the column with 1:9 diethyl ether – petroleum ether gave initially a mixture of tetra-*n*-butylstannane and hexa-*n*-butylditin. Further elution, followed by concentration of the appropriate fractions and bulb-to-bulb distillation of the residue, afforded the product(s).

(c) General procedure C

To a cold (−78°C), stirred solution of trimethylstannyl-lithium (1.0–1.1 equiv.) in dry THF (10 mL) was added a solution (THF, ~1 mL) of the α,β-unsaturated ketone or ester (0.5–1.5 mmol). After the reaction mixture had been stirred at −78°C for the appropriate length of time, methanol (~0.5 mL) and diethyl ether (~30 mL) were added. The mixture was allowed to warm to room temperature and then was filtered through a column of Florisil (10 g, 100–200 mesh). The column was eluted with 50 mL of diethyl ether. Removal of the solvent from the combined eluate and bulb-to-bulb distillation of the residual oil gave the product(s).

4-Methyl-4-trimethylstannyl-2-pentanone (14)

Following general procedure A, 4-methyl-3-penten-2-one (**7**) (57 mg, 0.58 mmol) was allowed to react with 0.75 mmol of the cuprate reagent **2** in 11 mL of dry THF. Work-up and distillation (air-bath temperature 40–47°C/0.3 Torr (1 Torr = 133.3 Pa), receiver cooled to −78°C) afforded 116 mg (76%) of the ketone **14**. An analytical sample, prepared by preparative tlc on silica gel (developing solvent 2:98 diethyl ether – petroleum ether), exhibited ir (film): 1713, 765 cm^{-1}; ^1H nmr δ: −0.02 (s, 9H, J_{Sn-H} = 50 Hz), 1.06 (s, 6H, J_{Sn-H} = 62 Hz), 2.10 (s, 3H), 2.49 (s, 2H, J_{Sn-H} = 66 Hz). *Anal.* calcd. for $C_9H_{20}OSn$: C 41.11, H 7.67; found: C 41.10, H 7.70. *Exact Mass* calcd. (M^+ −15): 249.0301; found: 249.0288.

4-Methyl-4-tri-n-butylstannyl-2-pentanone (15)

Following general procedure B, 4-methyl-3-penten-2-one (**7**) (66 mg, 0.67 mmol) was allowed to react with 1.0 mmol of the cuprate reagent **6** in 11 mL of dry THF. Work-up, followed by column chromatography of the crude product and distillation (air-bath temperature 120–128°C/0.2 Torr) of the oil obtained from the appropriate fractions, gave 181 mg (69%) of the ketone **15**. An analytical sample, obtained by preparative tlc on silica gel (developing solvent 2:98 diethyl ether – petroleum ether), exhibited ir (film): 1718 cm^{-1}; ^1H nmr δ: 0.62–1.64 (m, 27H), 1.04 (s, 6H), 2.03 (s, 3H), 2.44 (s, 2H, J_{Sn-H} = 64 Hz). *Anal.* calcd. for $C_{18}H_{38}OSn$: C 55.55, H 9.84; found: C 55.66, H 9.74.

3-Trimethylstannylcyclohexanone (16)

(a) Via general procedure A

2-Cyclohexen-1-one (**8**) (66 mg, 0.68 mmol) was allowed to react with 1.36 mmol of the cuprate reagent **2** in 11 mL of dry THF. Work-up, followed by distillation (air-bath temperature 75–90°C/0.2 Torr) of the crude product, gave 162 mg (92%) of the ketone **16** (one spot by tlc and one peak by glc). This material exhibited ir (film):

1712, 770 cm^{-1}; ^1H nmr δ: −0.02 (s, 9H, J_{Sn-H} = 51 Hz), 1.40–2.15 (m, 5H), 2.15–2.54 (m, 4H). *Exact Mass* calcd. for $C_9H_{18}OSn$: 262.0380; found: 262.0394.

(b) Via reaction of 2-cyclohexen-1-one (8) with (trimethylstannyl)copper(I)-dimethyl sulfide (1)

To a cold (−48°C), stirred solution of the copper reagent **1** (0.65 mmol) in 5 mL of dry THF was added a solution of the enone **8** (48 mg, 0.50 mmol) in dry THF (0.5 mL). The reaction mixture was stirred at −48°C for 2 h, at −20°C for 1 h, and at room temperature for 1 h. Saturated aqueous ammonium chloride (pH 8, 5 mL) and diethyl ether were added and the mixture was stirred for several minutes. The layers were separated and the organic phase was washed with saturated aqueous ammonium chloride (pH 8) and dried ($MgSO_4$). Removal of the solvent gave a yellow oil that, on the basis of glc analysis, consisted of a mixture (~1:1) of 3-trimethylstannylcyclohexanone (**16**) and 2-(3-ketocyclohexyl)-3-trimethylstannylcyclohexanone (**25**). These substances were separated by distillation. Ketone **16** (42 mg, 32%) exhibited spectral data identical with those given above.

The diketone **25** (43 mg, 48%; distillation temperature 148–159°C/0.09 Torr) exhibited ir (film): 1705, 775 cm^{-1}; ^1H nmr δ: 0.02 (s, 9H, J_{Sn-H} = 51 Hz), 1.30–2.66 (br diffuse m, 17H). *Exact Mass* calcd. for $C_{15}H_{26}O_2Sn$: 358.0955; found: 358.0964.

3-Tri-n-butylstannylcyclohexanone (17)

Reaction of 2-cyclohexen-1-one (**8**) (64 mg, 0.67 mmol) with the cuprate reagent **6** (1.0 mmol) in 11 mL of dry THF was carried out via general procedure B. Work-up, followed by column chromatography of the crude product and distillation (air-bath temperature 165–169°C/0.2 Torr) of the desired material, gave 202 mg (78%) of the ketone **17**; ir (film): 1710 cm^{-1}; ^1H nmr δ: 0.76–1.02 (m, 15H), 1.08–2.08 (m, 17H), 2.08–2.48 (m, 4H). *Exact Mass* calcd. for $C_{18}H_{36}OSn$: 388.1786; found: 388.1791.

3,5,5-Trimethyl-3-trimethylstannylcyclohexanone (18)

Following general procedure A, 3,5,5-trimethyl-2-cyclohexen-1-one (**9**) (94 mg, 0.68 mmol) was allowed to react with the cuprate reagent **2** (1.36 mmol) in 11 mL of dry THF. Work-up afforded a yellow oil, which consisted (glc analysis) of the starting material **9** and the β-trimethylstannyl ketone **18** in a ratio of 7:93, respectively. Distillation (air-bath temperature 80–93°C/0.06 Torr) afforded 52 mg (69%) of the ketone **18** (homogeneous by tlc and glc analyses); ir (film): 1712, 750 cm^{-1}; ^1H nmr δ: 0.07 (s, 9H, J_{Sn-H} = 49 Hz), 1.00, 1.07 (s, s, 3H each), 1.28 (s, 3H, J_{Sn-H} = 64 Hz), 1.59 (d, 1H, J = 15 Hz), 1.91 (d, 1H, J = 15 Hz), 2.11–2.18 (unresolved m, 3H), 2.54 (d, 1H, J = 14 Hz). *Exact Mass* calcd. for $C_{12}H_{24}OSn$: 304.0849; found: 304.0870.

3,5,5-Trimethyl-3-tri-n-butylstannylcyclohexanone (19)

This compound was prepared, via general procedure B, by reaction of the enone **9** (92 mg, 0.67 mmol) with 1.0 mmol of the cuprate reagent **6** in 11 mL of dry THF. Work-up, column chromatography of the crude product, and distillation (air-bath temperature 169–177°C/0.2 Torr) of the desired material yielded 185 mg (64%) of the ketone **19**. The later substance was homogeneous by tlc and glc analyses and exhibited ir (film): 1711 cm^{-1}; ^1H nmr δ: 0.81–0.97 (m, 15H) 1.01, 1.06, 1.34 (s, s, s, 3H each), 1.20–1.56 (m, 12H), 1.64 (d, 1H, J = 13 Hz), 1.98 (d, 1H, J = 13 Hz), 2.10–2.38 (m, 3H), 2.61 (d, 1H, J = 13 Hz). *Exact Mass* calcd. for $C_{21}H_{42}OSn$: 430.2258; found: 430.2264.

4-Trimethylstannyl-2-butanone (28)

(a) Via general procedure C

Following general procedure C, 3-buten-2-one (**26**) (70 mg, 1 mmol) was allowed to react with 1.0 mmol of trimethylstannyl-lithium in 11 mL of THF at −78°C for 1 h. Work-up afforded a yellow oil, which was subjected to column chromatography on 2.7 g of silica gel. Elution of the column with petroleum ether (~10 mL) gave hexamethylditin. Further elution with diethyl ether (~12 mL) provided a colorless oil, which, on the basis of a glc analysis, consisted of a mixture of the ketone **28** and the diketone **30** in a ratio of about 3:1, respectively.

Distillation (air-bath temperature 98–110°C/35 Torr) of the oil afforded 102 mg (43%) of the ketone **28**; ir (film): 1710, 767 cm^{-1}; ^1H nmr δ: −0.02 (s, 9H, J_{Sn-H} = 52 Hz), 0.83 (t, 2H, J = 7.5 Hz, J_{Sn-H} = 54 Hz), 2.08 (s, 3H), 2.60 (t, 2H, J = 7.5 Hz, J_{Sn-H} = 58 Hz). *Anal.* calcd. for $C_7H_{16}OSn$: C 35.79, H 6.87; found: C 35.78, H 6.95.

Distillation (air-bath temperature 110–120°C/0.35 Torr) of the remaining oil gave 47 mg (31%) of the diketone **30**; ir (film): 1708, 770 cm^{-1}; ^1H nmr δ: 0.06 (s, 9H, J_{Sn-H} = 52 Hz), 0.81 (dd, 1H, J = 13, 8 Hz), 0.98 (dd, 1H, J = 13, 7 Hz), 1.54–1.96 (m, 2H), 2.09, 2.11 (s, s, 3H each), 2.34–2.37 (m, 2H), 2.49–2.64 (m, 1H). *Anal.* calcd. for $C_{11}H_{22}O_2Sn$: C 43.32, H 7.27; found: C 43.36, H 7.30.

(b) Via reaction of 3-buten-2-one with the cuprate reagent 2

To a cold (−78°C), stirred solution of the cuprate reagent **2** (2.0 mmol) in 10 mL of dry THF was added a solution of 3-buten-2-one (**26**) (105 mg, 1.5 mmol) in dry THF (1 mL). The red solution was stirred at −78°C for 30 min, at −20°C for 1 h, and at room temperature for 30 min. Saturated aqueous ammonium chloride (0.2 mL) and diethyl ether (30 mL) were added. Further work-up as described in general procedure A, followed by column chromatography of the residual oil as described in (*a*), above, gave a colorless oil. Analysis (glc) of this material showed that it consisted of a mixture of the ketone **28** and the diketone **30**, in a ratio of about 2:1, respectively. Separation of these substances by distillation gave 96 mg (27%) of **28** and 85 mg (37%) of **30**. The spectral properties of these compounds were identical with those reported above.

(c) Via reaction of 3-buten-2-one with the cuprate reagent 2 in the presence of acetic acid

To a cold (−78°C), stirred solution of the cuprate reagent **2** (2.0 mmol) in 10 mL of dry THF was added, dropwise, a solution of 3-buten-2-one (**26**) (105 mg, 1.5 mmol) and glacial acetic acid (120 mg, 2.0 mmol) in dry THF (1 mL). The red solution was stirred at −78°C for 30 min and at −20°C for 1 h. The cooling bath was removed and, after 20 min, saturated aqueous ammonium chloride (0.2 mL) and diethyl ether (30 mL) were added. Further work-up (see general procedure A) and column chromatography of the crude material on silica gel as described in (*a*), above, afforded a colorless oil. This material consisted of a mixture of the ketone **28** and the diketone **30** in a ratio of 97:3, respectively. Distillation (air-bath temperature 90–100°C/30 Torr) provided 271 mg (77%) of 4-trimethylstannyl-2-butanone (**28**). The spectral properties of this material were identical with those reported above.

Methyl 3-trimethylstannylbutanoate (20)

(a) Via general procedure A

Following general procedure A, methyl (*E*)-2-butenoate (**10**) (68 mg, 0.68 mmol) was allowed to react with the cuprate reagent **2** (0.75 mmol) in 11 mL of dry THF. Work-up and distillation (air-bath temperature 41–50°C/0.2 Torr; receiver cooled to −78°C) of the crude product gave 122 mg (67%) of the ester **20**, which exhibited ir (film): 1738, 1202, 770 cm^{-1}; ^1H nmr δ: 0.02 (s, 9H, J_{Sn-H} = 51 Hz), 1.17 (d, 3H, J = 7 Hz, J_{Sn-H} = 68 Hz), 1.30–1.62 (m, 1H), 2.50 (d, 2H, J = 7 Hz), 3.66 (s, 3H). *Anal.* calcd. for $C_8H_{18}O_2Sn$: C 36.27, H 6.85; found: C 36.64, H 6.94.

(b) Via general procedure C

Reaction of methyl (*E*)-2-butenoate (**10**) (68 mg, 0.68 mmol) with 0.75 mmol of trimethylstannyl-lithium in 11 mL of dry THF for 5 min (general procedure C), followed by work-up and bulb-to-bulb distillation of the crude product, gave 108 mg (71%) of the ester **20**. The spectral properties of this material were identical with those given above.

Methyl 3-tri-n-butylstannylbutanoate (21)

Following general procedure B, methyl (*E*)-2-butenoate (**10**) (100 mg, 1 mmol) was allowed to react with 1.3 mmol of the cuprate reagent **6** in 11 mL of dry THF. Work-up, followed by column chromatography of the crude product and distillation (air-bath temperature 110–115°C/0.25 Torr) of the desired material, afforded 287 mg (74%) of the ester **21**. An analytical sample, obtained by preparative tlc on silica gel (developing solvent 2:98 diethyl ether – petroleum ether),

exhibited ir (film): 1738, 1200 cm^{-1}; ^1H nmr δ: 0.81–0.95 (m, 15H), 1.21 (d, 3H, J = 7 Hz, J_{Sn-H} = 60 Hz), 1.26–1.37 and 1.41–1.53 (m, m, 12H), 1.57–1.68 (m, 1H), 2.45 (dd, 1H, J = 15, 9 Hz), 2.55 (dd, 1H, J = 15, 7 Hz), 3.69 (s, 3H). *Anal.* calcd. for $C_{17}H_{36}O_2Sn$: C 52.20, H 9.28; found: C 52.46, H 9.21.

Ethyl 3-methyl-3-trimethylstannyl-2-butenoate (22)

Following general procedure C, ethyl 3-methyl-2-butenoate (**11**) (87 mg, 0.68 mmol) was allowed to react with trimethylstannyl-lithium (0.75 mmol) in 11 mL of dry THF at −78°C for 15 min. Work-up and distillation (air-bath temperature 115–123°C/25 Torr) of the crude product gave 147 mg (74%) of the ester **22**, which exhibited ir (film): 1733, 760 cm^{-1}; ^1H nmr δ: 0.01 (s, 9H, J_{Sn-H} = 50 Hz), 1.12 (s, 6H, J_{Sn-H} = 61 Hz), 1.24 (t, 3H, J = 7 Hz), 2.32 (s, 2H, J_{Sn-H} = 67 Hz), 4.11 (q, 2H, J = 7 Hz). *Exact Mass* calcd. for $C_{10}H_{22}O_2Sn$: 282.9781; found: 282.9792.

Ketal ester 24

Following general procedure C, the α,β-unsaturated ester **13** (134 mg, 0.5 mmol) was allowed to react with 0.53 mmol of trimethylstannyl-lithium in 11 mL of dry THF at −78°C for 15 min. Work-up and distillation (air-bath temperature 130–150°C/0.07 Torr) of the crude product gave 162 mg (75%) of the ketal ester **24**, which exhibited ir (film): 1730, 1097, 758 cm^{-1}; ^1H nmr δ: 0.03 (s, 9H, J_{Sn-H} = 60 Hz), 0.94 (s, 6H), 1.21 (t, 3H, J = 7 Hz), 1.42–2.04 (diffuse m, 8H), 2.49 (s, 2H, J_{Sn-H} = 74 Hz), 4.08 (q, 2H, J = 7 Hz). *Exact Mass* calcd. for $C_{18}H_{34}O_4Sn$: 434.1479; found: 434.1495.

Ethyl 3-trimethylstannylpropanoate (29)

(a) Via general procedure C

Ethyl propenoate (**27**) (150 mg, 1.5 mmol) was allowed to react with 1.5 mmol of trimethylstannyl-lithium in 11 mL of dry THF at −78°C for 1 h. Work-up gave a yellow oil, which was subjected to column chromatography on 2.7 g of silica gel. Elution with petroleum ether (10 mL) gave hexamethylditin. Further elution with diethyl ether (12 mL) produced a colorless oil, which was shown (glc analysis) to consist of a mixture of the ester **29** and the diester **31** in a ratio of about 3:2, respectively.

Distillation (air-bath temperature 100–118°C/30 Torr) of the oil afforded 80 mg (20%) of the ester **29**, which exhibited ir (film): 1732, 775 cm^{-1}; ^1H nmr δ: 0.01 (s, 9H, J_{Sn-H} = 52 Hz), 0.95 (t, 2H, J = 8 Hz), 1.21 (t, 3H, J = 7 Hz), 2.47 (t, 2H, J = 8 Hz, J_{Sn-H} = 59 Hz), 4.12 (q, 2H, J = 7 Hz). *Anal.* calcd. for $C_8H_{18}O_2Sn$: C 36.27, H 6.85; found: C 36.56, H 6.81.

Distillation (air-bath temperature 100–118°C/0.3 Torr) of the remaining oil produced 81 mg (29%) of the diester **31**, which exhibited ir (film): 1727, 772 cm^{-1}; ^1H nmr δ: 0.03 (s, 9H, J_{Sn-H} = 53 Hz), 0.93–1.06 (m, 2H), 1.21 (t, 6H, J = 7 Hz), 1.63–2.03 (m, 2H), 2.08–2.43 (m, 2H), 2.43–2.73 (m, 1H), 4.09 (q, 4H, J = 7 Hz). *Anal.* calcd. for $C_{13}H_{26}O_4Sn$: C 42.77, H 7.18; found: C 42.41, H 7.03.

(b) Via reaction of ethyl propenoate (27) with the cuprate reagent 2 in the presence of acetic acid

To a cold (−78°C), stirred solution of the cuprate reagent **2** (2 mmol) in 10 mL of dry THF was added, dropwise, a solution of ethyl propenoate (**27**) (50 mg, 0.5 mmol) and glacial acetic acid (60 mg, 1.0 mmol) in dry THF (1 mL). The red mixture was stirred at −78°C for 30 min and at −20°C for 1 h. After removal of the cooling bath, the mixture was stirred for 30 min and then was treated with saturated aqueous ammonium chloride (0.2 mL) and diethyl ether (30 mL). Work-up as described in general procedure A, followed by column chromatography of the crude product as described in (*a*), above, gave a colorless oil. Analysis (glc) of this material showed that it was composed of a mixture of the ester **29** and the diester **31** in a ratio of 93:7, respectively. Distillation (air-bath temperature 105–110°C/38 Torr) of the oil provided 92 mg (70%) of the ester **29**, which exhibited spectral data identical with those reported above.

Preparation of β-trialkylstannyl α,β-unsaturated ketones

(a) General procedure D

To a cold (−20°C), stirred solution of the cuprate reagent **2** (0.75 mmol) in 10 mL of dry THF was added a solution of the appropriate β-iodo α,β-unsaturated ketone (0.57–0.68 mmol) in 1 mL of dry THF. The dark red mixture was stirred at −20°C for 15 min and at room temperature for 30 min. Methanol (0.2 mL) and diethyl ether (30 mL) were added and the mixture was stirred for several minutes. The resulting yellow slurry was filtered through a short column of Florisil (10 g, 100–120 mesh). The column was eluted with 50 mL of diethyl ether. Removal of the solvent from the combined eluate, followed by bulb-to-bulb distillation of the residual oil, gave the desired β-trimethylstannyl enone.

(b) General procedure E

To a cold (−48°C), stirred solution of (trimethylstannylcopper(I)-dimethylsulfide (**1**) (0.65 mmol) in 5 mL of dry THF was added a solution of the appropriate β-iodo α,β-unsaturated ketone (0.5 mmol) in 0.5 mL of dry THF. The dark red solution was stirred at −48°C for 2 h, at −20°C for 1 h, and at room temperature for 1 h. Saturated aqueous ammonium chloride (pH 8, 5 mL) and diethyl ether (30 mL) were added and the mixture was stirred for several minutes. The organic layer was separated, washed with saturated aqueous ammonium chloride, and dried ($MgSO_4$). Removal of the solvent, followed by bulb-to-bulb distillation of the crude product, gave the desired β-trimethylstannyl enone.

(c) General procedure F

To a cold (−20°C), stirred solution of the cuprate reagent **6** (0.55–0.65 mmol) in 10 mL of dry THF was added a solution of the appropriate β-iodo α,β-unsaturated ketone (0.5 mmol) in 0.5 mL of dry THF. The mixture was stirred at −20°C for 15 min and at room temperature for 30 min. Methanol (0.2 mL) and diethyl ether (30 mL) were added and the mixture was stirred at room temperature for several minutes. The yellow slurry was filtered through a short column of Florisil (10 g, 100–200 mesh) and the column was eluted with a further 50 mL of diethyl ether. Removal of the solvent from the combined eluate gave a yellow oil, which was subjected to column chromatography on 20 g of silica gel. Elution of the column with a 1:9 mixture of diethyl ether – petroleum ether gave initially a mixture of tetra-*n*-butyltin and hexa-*n*-butylditin and then the desired β-tri-*n*-butylstannyl enone. Distillation (air-bath) of this material provided the pure product.

3-Trimethylstannyl-2-cyclohexen-1-one (37)

(a) Via reaction of the β-iodo enone 32 with trimethylstannyl-lithium

To a cold (−78°C), stirred solution of trimethylstannyl-lithium (0.5 mmol) in 10 mL of dry THF was added a solution of 3-iodo-2-cyclohexen-1-one (**32**) (111 mg, 0.5 mmol) in 0.25 mL of dry THF. The orange solution was stirred at −78°C for 1 h. Saturated aqueous ammonium chloride (5 mL) and diethyl ether (30 mL) were added and the mixture was allowed to warm to room temperature. The organic layer was separated, washed with brine, and dried ($MgSO_4$). Removal of the solvent, followed by distillation (air-bath temperature 65–69°C/0.15 Torr) of the residual oil, afforded a mixture (100 mg) that, on the basis of a glc analysis, was composed of the starting material **32** (~42%), 3-trimethylstannyl-2-cyclohexen-1-one (**37**) (~32%), and 3,3-bis(trimethylstannyl)cyclohexanone (**47**) (~15%), along with minor unidentified substances. A pure sample of each of the major components was obtained by preparative glc.

The enone **37** exhibited ir (film): 1670, 1582, 766 cm^{-1}; ^1H nmr δ: 0.17 (s, 9H, J_{Sn-H} = 54 Hz), 1.82–2.14 (m, 2H), 2.28–2.66 (m, 4H), 6.22 (t, 1H, J = 2 Hz, J_{Sn-H} = 64 Hz). *Anal.* calcd. for $C_9H_{16}OSn$: C 41.75, H 6.23; found: C 41.75, H 6.22. *Exact Mass* calcd.: 260.0223; found: 260.0216.

The ketone **47** exhibited mp 50–51°C; ir ($CHCl_3$): 1701 cm^{-1}; ^1H nmr δ: 0.04 (s, 18H, J_{Sn-H} = 49 Hz), 1.76–2.18 (m, 4H), 2.18–2.46 (m, 2H), 2.67 (br s, 2H). *Anal.* calcd. for $C_{12}H_{26}OSn_2$: C 34.02, H 6.19; found: C 34.08, H 6.26.

(b) Via general procedure D

Following general procedure D, the cuprate reagent **2** (0.75 mmol) was allowed to react with the β-iodo enone **32** (151 mg, 0.68 mmol) in 11 mL of dry THF. Work-up and distillation (air-bath temperature 65–80°C/0.09 Torr) of the crude product provided 153 mg (86%) of

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 190.90.36.8 on 09/07/12
For personal use only.

the β-trimethylstannyl enone **37**, which showed spectral data identical with those given above.

(c) Via general procedure E

Following general procedure E, 0.65 mmol of the (trimethylstannyl-copper(I) reagent **1** was allowed to react with the β-iodo enone **32** (111 mg, 0.5 mmol) in 5.5 mL of dry THF. Work-up and distillation (air-bath temperature 71–79°C/0.1 Torr) of the crude product gave 129 mg (84%) of the enone **37**.

*3-Tri-*n*-butylstannyl-2-cyclohexen-1-one (38)*

Following general procedure F, the cuprate reagent **6** (0.55 mmol) was allowed to react with the β-iodo enone **32** (111 mg, 0.5 mmol) in 10.5 mL of dry THF. Work-up, followed by column chromatography of the crude product on silica gel and distillation (air-bath temperature 150–158°C/0.2 Torr) of the desired crude product, afforded 157 mg (81%) of the enone **38**. This material exhibited ir (film): 1672, 1575 cm^{-1}; ^1H nmr δ: 0.78–1.05 (m, 15H), 1.08–1.70 (m, 12H), 1.82–2.14 (m, 2H), 2.30–2.60 (m, 4H), 6.22 (t, 1H, J = 2 Hz, J_{Sn-H} = 57 Hz). *Anal.* calcd. for $C_{18}H_{34}OSn$: C 56.13, H 8.90; found: C 56.22, H 9.00. *Exact Mass* calcd.: 386.1632; found: 386.1632.

2-Methyl-3-trimethylstannyl-2-cyclohexen-1-one (39)

Following general procedure D, 0.75 mmol of the cuprate reagent **2** was allowed to react with the β-iodo enone **33** (160 mg, 0.68 mmol) in 11 mL of dry THF. Work-up and distillation (air-bath temperature 58–69°C/0.07 Torr) of the resultant crude product yielded 158 mg (84%) of the β-trimethylstannyl enone **39**, which exhibited ir (film): 1665, 1595, 760 cm^{-1}; ^1H nmr δ: 0.22 (s, 9H, J_{Sn-H} = 54 Hz), 1.78–2.08 (m, 2H), 1.86 (t, 3H, J = 1.8 Hz), 2.32–2.56 (m, 4H). *Exact Mass* calcd. for $C_{10}H_{18}OSn$: 274.0378; found: 274.0374.

*2-Methyl-3-tri-*n*-butylstannyl-2-cyclohexen-1-one (40)*

Following general procedure F, the cuprate reagent **6** (0.65 mmol) was allowed to react with the β-iodo enone **33** (118 mg, 0.5 mmol) in 10.5 mL of dry THF. Work-up, column chromatography of the crude product on silica gel, and distillation (air-bath temperature 160–163°C/0.2 Torr) of the oil thus obtained gave 157 mg (79%) of the β-tri-*n*-butylstannyl enone **40**. This material exhibited ir (film): 1677, 1590 cm^{-1}; ^1H nmr δ: 0.75–1.09 (m, 15H), 1.11–1.63 (m, 12H), 1.88 (t, 3H, J = 2 Hz), 1.72–2.14 (m, 2H), 2.28–2.62 (m, 4H). *Exact Mass* calcd. for $C_{19}H_{36}OSn$: 400.1788; found: 400.1801.

3-Trimethylstannyl-2-cyclopenten-1-one (41)

(a) Via general procedure D

The cuprate reagent **2** (0.75 mmol) was allowed to react with the β-iodo enone **34** (141 mg, 0.68 mmol) in 11 mL of dry THF. Work-up and distillation (air-bath temperature 60–72°C/0.17 Torr) of the crude product gave 138 mg (83%) of the β-trimethylstannyl enone **41**, which exhibited ir (film): 1685, 1558, 762 cm^{-1}; ^1H nmr δ: 0.25 (s, 9H, J_{Sn-H} = 56 Hz), 2.23–2.35 (m, 2H), 2.73–2.90 (m, 2H), 6.37 (t, 1H, J = 2.3 Hz, J_{Sn-H} = 33 Hz). *Exact Mass* calcd. for $C_8H_{14}OSn$: 247.0145; found: 247.0143.

(b) Via general procedure E

Reaction of the (trimethylstannyl)copper(I) reagent **1** (0.65 mmol) with the β-iodo enone **34** (104 mg, 0.50 mmol) in 5.5 mL of dry THF, followed by work-up and distillation (air-bath temperature 65–71°C/0.15 Torr) of the crude product, provided 98 mg (80%) of the enone **41**. The spectral properties of this material were identical with those given above.

*3-Tri-*n*-butylstannyl-2-cyclopenten-1-one (42)*

Following general procedure F, the cuprate reagent **6** (0.55 mmol) was allowed to react with the β-iodo enone **34** (104 mg, 0.5 mmol) in 10.5 mL of dry THF. Work-up, column chromatography of the crude product on silica gel, and distillation (air-bath temperature 150–154°C/0.2 Torr) of the desired material gave 141 mg (76%) of the enone **42**. This material exhibited ir (film): 1705, 1555 cm^{-1}; ^1H nmr δ: 0.76–1.18 (m, 15H), 1.18–1.72 (m, 12H), 2.24–2.39 (m, 2H), 2.76–2.96 (m, 2H), 6.40 (t, 1H, J = 2 Hz), J_{Sn-H} = 29 Hz). *Anal.* calcd. for $C_{17}H_{32}OSn$: C 55.02, H 8.69; found: C 54.79, H 8.70. *Exact Mass* calcd.: 372.1475; found: 372.1488.

2-Methyl-3-trimethylstannyl-2-cyclopenten-1-one (43)

(a) Via general procedure D

The cuprate reagent **2** (0.75 mmol) was allowed to react with the β-iodo enone **35** (151 mg, 0.68 mmol) in 11 mL of dry THF. Work-up and distillation (air-bath temperature 65–73°C/0.2 Torr) of the crude oil produced 144 mg (82%) of the β-trimethylstannyl enone **43**, which exhibited ir (film): 1690, 1601, 765 cm^{-1}; ^1H nmr δ: 0.26 (s, 9H, J_{Sn-H} = 56 Hz), 1.83 (t, 3H, J = 2 Hz), 2.28–2.40 (m, 2H), 2.56–2.76 (m, 2H). *Exact Mass* calcd. for $C_9H_{16}OSn$: 260.0224; found: 260.0234.

(b) Via reaction of the β-iodo enone 35 with (trimethylstannyl)copper(I)-dimethyl sulfide (1)

To a cold (−48°C), stirred solution of the (trimethylstannyl)copper(I) reagent **1** (0.65 mmol) in 5 mL of dry THF was added, sequentially, hexamethylphosphoramide (2 mL) and a solution of the β-iodo enone (111 mg, 0.50 mmol). The red solution was stirred at −48°C for 2 h, at −20°C for 1 h, and at room temperature for 1 h. Work-up as described in general procedure E, followed by distillation (air-bath temperature 63–75°C/0.2 Torr) of the crude product, provided 105 mg (82%) of the β-trimethylstannyl enone **43**. The spectra of this material were identical with those summarized above.

*2-Methyl-3-tri-*n*-butylstannyl-2-cyclopenten-1-one (44)*

Following general procedure F, 0.65 mmol of the cuprate reagent **6** was allowed to react with the β-iodo enone **35** (110 mg, 0.5 mmol) in 10.5 mL of dry THF. Work-up, followed by column chromatography of the crude product on silica gel and distillation (air-bath temperature 158–164°C/0.2 Torr) of the oil thus obtained, yielded 152 mg (79%) of the enone **44**. This material exhibited ir (film): 1702 cm^{-1}; ^1H nmr δ: 0.70–1.18 (m, 15H), 1.18–1.67 (m, 12H), 1.84 (t, 3H, J = 2 Hz), 2.28–2.42 (m, 2H), 2.58–2.80 (m, 2H). *Anal.* calcd. for $C_{18}H_{34}OSn$: C 56.13, H 8.90; found: C 56.37, H 9.00. *Exact Mass* calcd.: 386.1632; found: 386.1609.

(E)-*2-(Trimethylstannylmethylene)cyclohexanone (45)*

(a) Via general procedure D

The cuprate reagent **2** (0.75 mmol) was allowed to react with the β-iodo enone **36** (134 mg, 0.57 mmol) in 11 mL of dry THF. Work-up produced a red oil, which was purified by preparative tlc on silica gel (developing solvent 1:9 diethyl ether – petroleum ether). Distillation (air-bath temperature 80–90°C/0.17 Torr) of the oil thus obtained gave 120 mg (77%) of the β-trimethylstannyl enone **45**, which exhibited ir (film): 1687, 1577, 775 cm^{-1}; ^1H nmr δ: 0.17 (s, 9H, J_{Sn-H} = 56 Hz), 1.63–2.05 (m, 4H), 2.27–2.64 (m, 4H), 7.03 (t, 1H, J = 2 Hz, J_{Sn-H} = 68 Hz.) *Exact Mass* calcd. for $C_9H_{15}OSn$ (M^+-15): 259.0145; found: 259.0142.

(b) Via general procedure E

Reaction of the β-iodo enone **36** (118 mg, 0.5 mmol) with the trimethylstannylcopper(I) reagent **1** (0.65 mmol) in 5.5 mL of dry THF at −48°C for 2 h afforded, after work-up, purification of the crude product by preparative tlc, and distillation of the desired material, 102 mg (75%) of the β-trimethylstannyl enone **45**. The spectra of this material were identical with those summarized above.

(E)-*2-(Tri-*n*-butylstannylmethylene)cyclohexanone (46)*

Following general procedure F, the cuprate reagent **6** (0.55 mmol) was allowed to react with the β-iodo enone **36** (118 mg, 0.5 mmol) in 10.5 mL of dry THF. Work-up, column chromatography of the crude product on silica gel, and distillation (air-bath temperature 160–171°C/0.2 Torr) of the oil thus obtained produced 136 mg (69%) of the enone **46**. This material exhibited ir (film): 1690, 1581 cm^{-1}; ^1H nmr δ: 0.77–1.13 (m, 15H), 1.17–1.66 (m, 12H), 1.66–2.00 (m, 4H), 2.38–2.68 (m, 4H), 7.04 (t, 1H, J = 2 Hz, J_{Sn-H} = 62 Hz). *Exact Mass* calcd. for $C_{19}H_{36}OSn$: 400.1788; found: 400.1763.

β-Lactams. XII.
A study of the synthesis of N-unsubstituted β-lactams, and of 4-styryl monobactams

DENISE DUGAT, GEORGE JUST, AND SOUMYA SAHOO
Department of Chemistry, McGill University, Montreal, P.Q., Canada H3A 2K6

Received April 29, 1986

This paper is dedicated to Dr. O. E. (Ted) Edwards

DENISE DUGAT, GEORGE JUST, and SOUMYA SAHOO. Can. J. Chem. **65**, 88 (1987).

A few types of amines XNH_2 were investigated for the formation of β-lactams via the cycloaddition of the corresponding Schiff bases with azidoacetyl chloride. Among the β-lactams formed, only the *N-p,p'*-dimethoxybenzhydryl compounds could be transformed to N-unsubstituted azetidinones by removal of the N-substituent with ceric ammonium nitrate. Conversion of those N-unsubstituted intermediates to 3-acylated monobactams was studied in the 4-styryl series.

DENISE DUGAT, GEORGE JUST et SOUMYA SAHOO. Can. J. Chem. **65**, 88 (1987).

Dans le but de déterminer leur abilité à former des β-lactames, on a étudié la cycloaddition d'un certain nombre de bases de Schiff, dérivées de quelques types d'amines XNH_2, avec le chlorure d'azidoacétyle. Parmi les β-lactames qui se sont formées, seuls les composés *N-p,p'*-diméthoxybenzhydryles ont pu être transformés, sous l'influence du nitrate d'ammonium cérique, en azétidones ne portant pas de substituants sur le N. Dans la série des dérivés styrylés en position 4, on a étudié la conversion de ces intermédiaires ne portant pas de substituants sur le N en monobactames acylés en position 3.

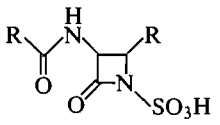
Introduction

We have been interested for some time in the synthesis of monocyclic β-lactams in which ring strain imparted by a second ring in classical β-lactams such as penicillins and cephalosporins was replaced by strain induced by electron withdrawal (1).

Recently, a new class of antibiotics was discovered (2, 3): the monobactam **A** in which this electronic strain is created by *N*-sulfonation of a monocyclic β-lactam.



A

Subsequently, powerful antibiotics were developed by chemical modification of **A** (4, 5). The required β-lactam nucleus has been synthesized by conversion of 6-amino penicillanic acid (5), by cyclization of the appropriate threonine derivative (6) or α,β-diaminocarboxylic acids (7), or by cycloaddition of azidoacetyl chloride with a Schiff base of type **2** and **3** where X is a group that can be subsequently removed without the destruction of the β-lactam ring. Examples of this last approach were mentioned in recently published papers. Thus 2-(phenylselenenyl)ethylamine (8), *p*-anisidine (9), and threonine (10) have been used as the amine from which Schiff bases were derived. The removal of the N-substituents was effected respectively by elimination and oxidative hydrolysis (8), by ceric ammonium nitrate (CAN) oxidation (9), and by oxidation with an excess of Jones reagent (10).

We would like to report our results in this field, which indicate that only certain types of amines may be used for the formation of β-lactams via the cycloaddition reaction pioneered by Bose *et al.* (11) and developed by Doyle *et al.* (12).

In a second part, we describe our studies of the synthesis of 4-styryl monobactams, since some 4-styryl monocyclic β-lactams[1] had shown weak antibacterial properties.

[1]G. Just, W. Y. Liu, and A. Ugolini. Unpublished results.

Results and discussion

Formation of unsubstituted β-lactams

The prototype aldehydes used for this investigation were acetaldehyde and cinnamaldehyde; the amines covered the range described (**1***a*–**1***i*).

The first two amines investigated, hydroxylamine **1***a* and its *O*-benzyl derivative **1***b*, where the X group can be removed by known methods (14), formed oximes **2***a,b* and **3***a,b*; neither of these underwent cycloaddition with azidoacetyl chloride.

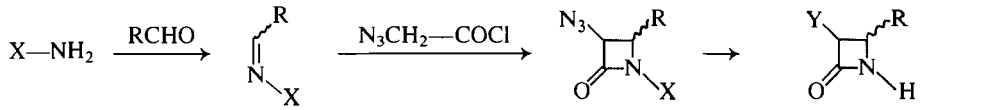
Next, we investigated trityl amine **1***c* and *tert*-butyldimethylsilylamine **1***d* where the X group might be removed by hydrogenolysis or tetra-*n*-butylammonium fluoride; neither amine formed a Schiff base, even under forcing conditions.

The next two amines investigated, trimethylsilylethylamine **1***e* (prepared from vinyltrimethylsilane according to Kabalka *et al.* (15)) and allylamine **1***f*, were found to be too reactive for Schiff base formation with acetaldehyde; they reacted smoothly with cinnamaldehyde to generate the corresponding Schiff bases **3***e,f*, which upon reaction with azidoacetyl chloride gave the *cis* β-lactams **5***e,f* in good yield. However, the removal of the trimethylsilylethyl group in **5***e*, using a variety of conditions recently described by Lipshutz *et al.* (16), failed. Similarly, the removal of the allyl group in **5***f*, using $(Ph_3P)_3RhCl$, according to Laguzza and Ganem (17), was also unsuccessful.

We finally investigated *l*-methylphenylcarbinyl amine **1***g*, benzhydrylamine **1***h*, and *p,p'*-dimethoxybenzhydrylamine **1***i*. All three gave Schiff bases **2***g,h,i* and **3***g,h,i* in excellent yield. Cycloaddition of these with azidoacetyl chloride led in good yields to *cis*-styryl β-lactams **5***g,h,i* and *trans*-methyl β-lactams **4***g,h* (12), except in the case of Schiff base **2***i*, which gave in moderate yield the *cis* β-lactam **4***i*.

Hydrogenolysis using a variety of catalysts did not effect the removal of the X group in **4***g,h,i* and **5***g,h,i*. The *p,p'*-dimethoxybenzhydryl group of **4***i* and **5***i* could be removed in 75% yield by means of ceric ammonium nitrate using a modification of the described conditions (9) (overall from **1**, **6**: 13.5%, **7**: 44%).

We have no explanation for the formation of **4***i* in the *cis* configuration rather than the expected *trans* arrangement.



X—NH_2	Imines		β-Lactams	
	R = CH_3	R = styryl	R = CH_3	R = styryl
a X = OH	**2***a*	**3***a*	—	—
b X = OCH_2Ph	**2***b*	**3***b*	—	—
c X = CPh_3	—	—	—	—
d X = $SiMe_2t$-Bu	—	—	—	—
e X = $CH_2CH_2SiMe_3$	—	**3***e*	—	**5***e cis*
f X = $CH_2CH{=}CH_2$	—	**3***f*	—	**5***f cis*
g X = CHMePh	**2***g*	**3***g*	**4***g trans*	**5***g cis*
h X = $CHPh_2$	**2***h*	**3***h*	**4***h trans*	**5***h cis*
i X = $CH(p\text{-}C_6H_4OMe)_2$	**2***i*	**3***i*	**4***i cis*	**5***i cis*

Due to the low yield of **6**, further work was carried out only on 4-styryl β-lactam **7**.

Selective reduction of the azide function in the presence of the styryl group was effected either by catalytic hydrogenation, using nickel boride (18) as catalyst, or by treatment with triphenyl phosphine, followed by aqueous hydrolysis of the resulting iminophosphorane (19), giving amine **8**.

4-Styryl-monobactams

Acylation of **8** with phenylacetyl chloride provided **11** (yield 51%), which was transformed to the *N*-potassium sulfonate **12***b* by sulfonation of **11** with the pyridine – sulfur trioxide complex in pyridine (20), followed by extraction of the sulfonic acid as its tetra-*n*-butylammonium salt **12***a*; passage through an ion-exchange resin gave the potassium salt **12***b* in 48% yield from **11**.

A synthesis of **18***c*, in which the styryl β-lactam **10** was acylated with the aminothiazolylcarboxylic acid **14**, a side chain similar to that used of the highly active aztreonam, has been described in a patent of the Squibb Institute (21), but no information was given concerning its antibacterial activity. We report here two other routes leading to **18***c*.

For personal use only.

The first approach reproduces the sequence condensation–sulfonation as developed above for **12***b*. Thus, reaction of **8** with the trityl-amino acid **13** was carried out in CH_2Cl_2/DMF using *N*-ethoxycarbonyl-2-ethoxy-1,2-dihydroquinoline (EEDQ) (22) as coupling agent (yield of **15**: 62%), and gave better yields than dicyclohexylcarbodiimide (DCC) and *N*-hydroxybenzotriazole. The sulfonation reaction, which required more forcing conditions than before, due to solubility problems, was carried out in DMF/pyridine directly on the trityl-amino β-lactam **15** or on its deprotected amino analogue **16**. Deblocking of the trityl group of **15** and **17** was performed by refluxing for 7 h in a methanolic solution of formic acid. The pyridinium sulfonate **18***a* obtained in both cases could not be isolated and purified as before as its *N*-butylammonium salt **18***b*, because of the low solubility of **18***b* in organic solvents; it was directly converted to potassium salt **18***c* by means of potassium 2-ethyl hexanoate (23), and was obtained with greater purity and better yield in the first sequence (path A) (**15** → **17** → **18**: yield 75%) than in the second one (path B) (**15** → **16** → **18**: yield 50%).

β-Lactam sulfonic salt **18***c* could also be obtained, albeit in lower yield and purity, by another approach involving a modification of the peptide synthesis from an azide and a carboxylic acid, a reaction pioneered by Vilarrasa and co-workers (24) and recently developed by Roberts and co-workers (25). Thus, the tetrabutylammonium salt of 3-azido β-lactam **9***a*, generated from **7** in the conditions previously used, was treated with triphenylphosphine in THF–DMF to form the zwitterion intermediate **19**, which partially precipitated during the reaction (24). Heating of the crude mixture in the presence of carboxylic acid **14** afforded **18***b* contaminated with side products that were difficult to remove. Passage through an ion-exchange resin gave **18***c*.

All compounds reported gave good interpretable nmr and mass spectra. Positive-ion fast atom bombardment mass spectra of **18***c* and aztreonam (26) were compared; both are characterized by the following fragments: MK^+, MH^+, $MH^+ - SO_3$, $MH^+ - HSO_3NCHR$ (**18***c*: R = styryl; aztreonam: R = Me), and 126 ($C_4H_4N_3S$).

None of the monobactamates **9***b*, **12***b*, and **18***c* showed notable antibacterial activity when tested against a panel of Gram positive and negative bacteria. The presence of a 4-styryl group seemed to decrease the intrinsic activity of those compounds, especially of aminothiazolyl methoxyimino monobactam **18***c* as compared to its 4-methyl analogue (4, 5).

This result may be explained by either a steric effect, where the antibacterial activity decreases for side chains larger than ethyl (5, 13), or, as suggested by Cimarusti,[2] by the increased lipophilicity of the aromatic ring at an inappropriate binding site.

Experimental

Thin-layer chromatography was performed on Merck Silica Gel 60 F_{254} aluminum-backed plates. Flash chromatography was done with Woelm silica (32–63 μm) using predistilled solvents. Melting points were determined on a Gallenkamp block and are uncorrected. Infrared spectra were run on a Perkin–Elmer 297 spectrophotometer. Nuclear magnetic resonance spectra were recorded on Varian T-60, T-60A, XL-200, and XL-300 spectrometers. Mass spectra were taken on an LKB-9000 and FAB mass spectra on a VG-analytical mass spectrometer.

[2]Personal discussions during the XIth European Heterocyclic Colloquium, Ferrara, Italy, October 1985.

Amines

Trityl amine ***1***c *and* tert-*butyldimethylsilylamine* ***1***d

To a solution of trityl chloride (1.114 g, 4 mmol) or *tert*-butyldimethylsilylchloride (602 mg, 4 mmol) in ether at −50°C was added ether (80 mL) previously saturated by ammonia (at −78°C). After stirring overnight until elimination of excess ammonia, the solvent was removed *in vacuo* to afford the corresponding amines in 90% yield.

Trimethylsilylethylamine ***1***e (ref. 15)

To a solution of vinyltrimethylsilane (900 mg, 9 mmol) in THF (3 mL) was added under nitrogen, at −5°C, BH_3–THF (3 mmol, 3 mL of a 1 *M* solution). The solution was stirred for 2 h and allowed to warm to 10°C. Then, to the organoborane (3 mmol), cooled again to 0°C, was added dropwise under nitrogen aqueous solutions of ammonium hydroxide (3 mmol) and sodium hypochlorite (3.3 mmol). The mixture was stirred for 15 min and allowed to warm to 10°C. The reaction mixture was extracted with ether (3 × 10 mL). The organic layers were combined, washed with brine, and dried on $MgSO_4$. Removal of the solvent gave the expected amine (yield: 65%); ^{1}H nmr (60 MHz, $CDCl_3$) δ: 0.1 (s, 9H, $SiMe_3$), 0.80–1.3 (m, 2H, $SiCH_2$), 1.9 (br s, 2H, NH_2), 3.0 (m, 2H, CH_2—N).

p,p′-*Dimethoxybenzhydrylamine* ***1***i

To a solution of *p,p′*-dimethoxybenzhydrol (1.22 g, 5 mmol) in dry CH_2Cl_2 (100 mL) at −50°C, under nitrogen, was added dropwise mesylchloride (0.87 mL, 1.145 g, 10 mmol) and triethylamine (2.78 mL, 2.20 g, 20 mmol). The mixture was stirred for ½ h and allowed to warm up to −20°C maximum. As shown by tlc, the alcohol was rapidly converted into its mesylate. The reaction mixture was then cooled again to −50°C and THF (100 mL), previously saturated by ammonia (at −78°C), was added. After stirring overnight, the solvents were removed *in vacuo* and replaced with ether (200 mL). The solution was washed with 1 *N* HCl solution (3 × 20 mL); the aqueous layer was then made slightly basic with aqueous sodium hydroxide and extracted several times with ether. The organic extract was dried on $MgSO_4$ and stripped of solvent under reduced pressure to afford the desired amine, which was essentially pure by tlc analysis; yield: 70%; ^{1}H nmr (60 MHz, $CDCl_3$) δ: 2.3 (br s, 2H, NH_2), 3.8 (s, 6H, $2OCH_3$), 5.1 (s, 1H, CH), 7.0 (AB spectra, 8H, 2φ, J = 8.0 Hz, $\Delta\nu$ = 25 Hz).

Schiff bases ***2***a,b,g,h,i, ***3***a,b,e,f,g,h,i

All the Schiff bases were prepared in a similar manner and used without purification. The following is a representative procedure.

A solution of the amine **1***i* (1.21 g, 5 mmol) in dry CH_2Cl_2 (50 mL) was treated with magnesium sulfate (2.4 g, 20 mmol) and cooled to −20°C under a nitrogen atmosphere. Freshly distilled acetaldehyde (660 mg, 15 mmol) or cinnamaldehyde (660 mg, 5 mmol) was added dropwise. The mixture was stirred for 2 h, filtered, and evaporated to give a crude material that was directly used for the next reaction.

2*i*: yield: 90%; ^{1}H nmr (60 MHz, $CDCl_3$) δ: 1.95 (d, 3H, CH_3, J = 5.0 Hz), 3.7 (s, 6H, $2OCH_3$), 5.35 (br s, 1H, CH), 7.0 (AB spectra, 8H, 2φ, J = 9.0 Hz, $\Delta\nu$ = 21 Hz), 7.85 (q, 1H, CH=, J = 5.0 Hz).

3*i*: yield: 78%; ^{1}H nmr (60 MHz, $CDCl_3$) δ: 3.9 (s, 6H, $2OCH_3$), 5.45 (br s, 1H, CH), 6.8–7.5 (m, 15H, 3φ + C*H*=C*H*), 8.1 (br s, 1H, *H*C=N).

Azido β-lactams ***4***g–i, ***5***e–i

All β-lactams were prepared in an identical manner. To a solution of Schiff base (2 mmol) and triethylamine (292 μL, 212 mg, 2.1 mmol) in dry CH_2Cl_2 (10 mL) at −30°C, under nitrogen, was added dropwise a solution of azidoacetyl chloride (263 mg, 2.2 mmol) in CH_2Cl_2 (10 mL). The reaction mixture, after stirring for 1 h, was allowed to warm up to 0°C, washed with brine, dried on $MgSO_4$, and evaporated. The crude material was purified by flash chromatography and obtained in approximately 75% yield except for compound **4***i* (yield: 20%); ir ($CHCl_3$) ν_{max}: 2100 (N_3), 1750–1760 (CO β-lactam) cm^{-1}.

Compound *trans* **4***g*: ^{1}H nmr (60 MHz, $CDCl_3$) δ: 1.2 and 1.3 (2d, 3H, CH—*CH*$_3$, J = 6.5 Hz), 1.65 and 1.8 (2d, 3H, CHPh—*CH*$_3$, J = 8.0 Hz), 3.4 (dg, 1H, C*H*Me, J = 6.5, 2.0 Hz), 4.1 (d, 1H, C*H*N_3, J = 2.0 Hz), 4.4—5.1 (m, 1H, C*H*MePh), 7.3 (s, 5H, φ).

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 80.58.250.72 on 09/07/12
For personal use only.

Compound *trans* **4***h*: ^{1}H nmr (60 MHz, $CDCl_3$) δ: 1.2 (d, 3H, $CHCH_3$, J = 6.5 Hz), 3.5 (dg, 1H, CHMe, J = 6.5, 2.0 Hz), 4.2 (d, 1H, CHN_3, J = 2.0 Hz), 6.0 (s, 1H, $CHPh_2$), 7.3 (s, 10H, 2φ).

Compound *cis* **4***i*: ^{1}H nmr (60 MHz, $CDCl_3$) δ: 1.6 (d, 3H, $CHCH_3$, J = 6.0 Hz), 3.8 (s, 6H, $2OCH_3$), 4.1 (dg, 1H, CHMe, J = 6.0, 5.0 Hz), 4.7 (d, 1H, CHN_3, J = 5.0 Hz), 5.7 (s, 1H, $CH(\phi OMe)_2$), 6.7–7.2 (m, 8H, 2φ).

Compound *cis* **5***e*: ^{1}H nmr (60 MHz, $CDCl_3$) δ: 0.2 (s, 9H, $SiMe_3$), 0.8–1.6 (m, 2H, CH_2—Si), 3.2–3.8 (m, 2H, N—CH_2), 4.6 (dd, 1H, CH—CH=, J = 9.0, 5.5 Hz), 5.0 (d, 1H, CHN_3, J = 5.5 Hz), 6.1–7.1 (m, 2H, CH=CH), 7.6 (s, 5H, φ).

Compound *cis* **5***f*: ^{1}H nmr (60 MHz, $CDCl_3$) δ: 3.4–4.3 (m, 2H, N—CH_2), 4.45 (dd, 1H, CH—CH=, J = 9.0, 5.5 Hz), 4.85 (d, 1H, CHN_3, J = 5.5 Hz), 5.1–6.9 (m, 5H, 3CH= and CH_2=), 7.4 (s, 5H, φ).

Compound *cis* **5***g*: ^{1}H nmr (60 MHz, $CDCl_3$) δ: 1.8 and 1.95 (2d, 3H, CHφ—CH_3, J = 8.0 Hz), 4.1 (dd, 1H, CH—CH=, J = 9.5, 5.0 Hz), 4.5–5.1 (m, 2H, CHMePh + CHN_3), 6.2–7.2 (m, 12H, 2φ + CH=CH).

Compound *cis* **5***h*: ^{1}H nmr (60 MHz, $CDCl_3$) δ: 4.3 (dd, 1H, CH—CH=, J = 9.0, 5.5 Hz), 4.7 (d, 1H, CHN_3, J = 5.5 Hz), 6.0 (s, 1H, $CHPh_2$), 6.1–6.7 (m, 2H, CH=CH), 6.9–7.3 (m, 15H, 3φ).

Compound *cis* **5***i*: ^{1}H nmr (60 MHz, $CDCl_3$) δ: 3.7 and 3.8 (2s, 6H, $2OCH_3$), 4.4 (dd, 1H, CH—CH=, J = 9.0, 5.0 Hz), 4.8 (d, 1H, CHN_3, J = 5.0 Hz), 5.8–6.5 (m, 3H, $CH(\phi\text{-}OMe)_2$ + CH=CH—), 6.7–7.3 (m, 13H, 3φ).

3-Azido N-unsubstituted β-lactams ***6*** *and* ***7*** (ref. 9)

Both β-lactams **6** and **7** were prepared in an identical manner from the corresponding *N*-dimethoxybenzhydryl compounds **4***i* and **5***i*, using the following procedure. A solution of *N*-dimethoxybenzhydryl azetidinone (1 mmol) in acetonitrile (10 mL) was cooled at 0°C and treated with a solution of ceric ammonium nitrate (CAN) (1.64 g, 3 mmol) in water (5 mL) over 5 min. The reaction was stirred at −5° to 0°C for 45 min and diluted with 40 mL of water. The mixture was extracted with ethyl acetate (3 × 15 mL). The organic extracts were washed with 5% sodium bicarbonate (30 mL) and the aqueous extracts back-washed with ethyl acetate (10 mL). The combined organic solutions were washed with 10% sodium sulfite (until the aqueous layer remained colorless), 5% sodium bicarbonate (5 mL), and brine. The resulting solution was swirled over charcoal for 30 min; sodium sulfate was added and the mixture was filtered through Celite. Removal of the solvent yielded a crude material, which was purified by flash chromatography (ethyl acetate – hexane: 30:70) to afford the N-unsubstituted β-lactams in approximately 75% yield.

Compound **6**: ir ($CHCl_3$) ν_{max}: 3400 (NH), 2930 (CH), 2840 (CH_3), 2100 (N_3), 1760 (CO β-lactam) cm^{-1}; ^{1}H nmr (60 MHz, $CDCl_3$) δ: 1.5 (d, 3H, CH_3, J = 6.0 Hz), 4.2 (dq, 1H, CHMe, J = 6.0, 5.0 Hz), 4.8 (dd, 1H, CHN_3, J = 5.0, 1.0 Hz), 6.7 (br d, 1H, NH, J = 1.0 Hz).

Compound **7**: mp 100–102°C (lit. (9) mp 103–105°C); ir ($CHCl_3$) ν_{max}: 3410 (NH), 2920 (CH), 2100 (N_3), 1775 (CO β-lactam), 1650 (w, C=C) cm^{-1}; ^{1}H nmr (60 MHz, $CDCl_3$) δ: 4.5 (dd, 1H, CH—C=, J = 7.5, 5.5 Hz), 4.8 (dd, 1H, CHN_3, J = 5.5, 1.5 Hz), 6.2 (dd, 1H, —CH=CHφ, J = 16.0, 7.5 Hz), 6.5 (d, 1H, CH=CHφ, J = 16.0 Hz), 6.95 (br d, 1H, NH, J = 1.5 Hz), 7.4 (m, 5H, φ).

3-Amino β-lactam ***8***

(a) Method 1

To nickel acetate (249 mg, 1 mmol), in a 2-necked flask equipped with a septum, was added 2 mL of 95% ethanol. The flask was connected to the hydrogenation apparatus and was flushed with hydrogen. The catalyst was produced by injecting 2 mL of a 0.5 *M* solution of sodium borohydride in 95% ethanol to the rapidly stirred solution of nickel acetate. The reaction vessel was reflushed with hydrogen. Hydrogenation was then initiated by introducing 214 mg (1 mmol) of azido β-lactam **7** in 2 mL ethanol via the septum. The reaction was stopped after 2 h, just before that the absorbed quantity of hydrogen was larger than the liberated quantity of nitrogen. The reaction mixture was then filtered through Celite, the ethanol removed under reduced pressure, and the residue diluted in acetone. The solution was filtered again and evaporated. The crude compound was purified on aluminium oxide (eluant: $CHCl_3$–MeOH, 98:2) to give 56 mg of pure β-lactam **8** (yield 30%); ir ($CHCl_3$) ν_{max}: 3420 (NH, NH_2), 2930 (CH), 1760 (CO β-lactam), 1600 (w, C=C) cm^{-1}; ^{1}H nmr (200 MHz, $CDCl_3$) δ: 1.8 (br s, 2H, NH_2), 4.4–4.5 (m, 2H, CH—CH), 6.22 (dd, 1H, CH=CHφ, J = 16.0, 6.5 Hz), 6.4 (s, 1H, NH), 6.65 (d, 1H, =CHφ, J = 16.0 Hz), 7.25–7.41 (m, 5H, φ); ms (70 eV) *m/e*: 188 (85, M^+), 187 (64), 145 (103, H_2N—CH—CH—CH=$CH\phi^+$), 144 (163), 143 (35), 133 (110), 132 (1000, $M^+ - H_2NCHCO + 1$), 117 (96), 116 (64), 115 (374), 91 (75), 72 (131), 57 (124, H_2N—CH—CO), 51 (150), 43 (60, CONH).

(b) Method 2

To a solution of azido β-lactam **7** (214 mg, 1 mmol) in dry THF (10 mL) was added, under nitrogen and at room temperature, triphenylphosphine (288 mg, 1.1 mmol). After 2 h stirring, 2 or 3 equivalents of water were added and the reaction mixture was stirred overnight. The solvent was then evaporated and the residue dissolved in acetone (5 mL). *para*-Toluenesulfonic acid (209 mg, 1.1 mmol) was added and the solution stirred again for 3 h. The precipitate was filtered and washed with 1 mL of acetone to give 188 mg of the *para*-toluenesulfonate salt of β-lactam **8** (yield: 52%); mp 198–200°C; ir (KBr) ν_{max}: 3400 (NH_3), 2930 (CH), 1750 (CO β-lactam), 1610 (C=C), 1030 (SO_3), 1000, 955 cm^{-1}; ^{1}H nmr (200 MHz, DMSO-d_6) δ: 2.04 (s, 3H, CH_3), 4.48 (dd, 1H, CH—C=, J = 7.5, 5.0 Hz), 4.62 (d, 1H, H_3N—CH, J = 5.0 Hz), 6.34 (dd, 1H, CH=CHφ, J = 16.0, 7.5 Hz), 6.78 (d, 1H, =CHφ, J = 16.0 Hz), 7.04–7.46 (m, 9H, 2φ), 8.42 (br s, 3H, NH_3), 8.85 (s, 1H, NH β-lactam).

4-Styryl 3-azido 2-oxo 1-azetidine sulfonic acid ***9*** (ref. 20)

(a) Tetrabutylammonium salt ***9***a

A solution of 3-azido β-lactam **7** (214 mg, 1 mmol) in 3 mL of pyridine was heated under nitrogen to 80°C, and 477 mg (3 mmol) of pyridine – sulfur trioxide complex added. The mixture, which quickly became homogeneous, was stirred for 2 h and then poured into 35 mL of 0.5 *N* KH_2PO_4. The resulting solution was extracted with CH_2Cl_2 (2 × 10 mL) and EtOAc (1 × 10 mL); the organic extracts were back-washed with phosphate solution (4 × 10 mL). The combined aqueous layers were then treated with 355 mg (1.05 mmol) of tetrabutylammonium hydrogen sulfate (TBAHS) and extracted with methylene chloride (1 × 20 mL and 2 × 10 mL). The organic extract was dried on $MgSO_4$ and concentrated to yield the desired tetra-*n*-butylammonium salt, which was essentially pure by tlc analysis ($CHCl_3$–MeOH, 9:1); yield: 80%; ir (film) ν_{max}: 2960, 2930 and 2875 (CH_3, CH_2), 2100 (N_3), 1770 (CO β-lactam), 1485, 1465, 1380, 1265, 1050 (SO_3), 790, 760 cm^{-1}; ^{1}H nmr (200 MHz, $CDCl_3$) δ: 0.95 (t, 12H, $4CH_3$, J = 7.3 Hz), 1.40 (m, 8H, 4 × CH_2—Me), 1.57 (m, 8H, $4CH_2$), 3.19 (m, 8H, $4NCH_2$), 4.65 (d, 1H, N_3—CH—, J = 5.7 Hz), 4.80 (dd, 1H, CH—C=, J = 5.7, 7.9 Hz), 6.28 (dd, 1H, CH=CHφ, J = 15.9, 7.9 Hz), 6.85 (d, 1H, CH=CHφ, J = 15.9 Hz), 7.25 (m, 5H, φ); ms (70 eV) *m/e*: 242 (1000, NBu_4), 243 (200).

(b) Potassium salt ***9***b

A solution of tetra-*n*-butylammonium salt (148 mg, 0.28 mmol) in distilled water – methanol (3:1) was applied to a column of ion exchange resin (12 mL) (Dowex: 50 × 8-200) previously charged in K^+ ions with a 1 *N* KCl solution. Elution was made with distilled water. The eluate was freeze-dried to give 44 mg of the desired potassium salt as a yellow powder (yield: 50%); ir (KBr) ν_{max}: 3460 (br, OH), 2100 (N_3), 1765 (CO β-lactam), 1615 (C=C), 1245 and 1050 (SO_3), 970, 755, 695, 650 cm^{-1}; ^{1}H nmr (200 MHz, DMSO-d_6) δ: 4.65 (dd, 1H, CH—C=, J = 7.8, 5.6 Hz), 5.12 (d, 1H, N_3—CH—, J = 5.6 Hz), 6.22 (dd, 1H, —CH=CHφ, J = 16.1, 7.8 Hz), 6.8 (d, 1H, CH=CHφ, J = 16.1 Hz), 7.33 (m, 5H, φ); ms *m/e* (negative FAB): 293 (814, M − K), 265 (161, M − K − N_2), 252 (137), 210 (710, $O_3SNC_9H_8$), 185 (225), 161 (170), 153 (433), 145 (185), 122 (1000,

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 80.58.250.72 on 09/07/12

O_3SNCO); *m/e* (positive FAB): 371 (244, M + K), 332 (71, M), 261 (118), 247 (102), 242 (1000), 168 (457), 158 (496), 142 (275).

4-Styryl 3-phenylacetamido 2-azetidinone ***11***

To a solution of amino β-lactam **8** (34 mg, 0.18 mmol) and pyridine (43 mg, 0.54 mmol) in dry methylene chloride (4 mL) was added dropwise at 0°C, under nitrogen, a solution of phenylacetyl chloride (40 mg, 0.25 mmol) in dry methylene chloride (1 mL). After the addition was complete, the solution was stirred for 3 h, washed with pH 4.5 buffer solution, 5% $NaHCO_3$ solution, and brine. The organic layer was dried on $MgSO_4$ and evaporated. The solid that precipitated was washed with chloroform to give 28 mg (51%) of pure compound, mp 210°C; ir (KBr) ν_{max}: 3280 (NH), 1770 (CO β-lactam), 1660 (CO amide), 1600 (w, C=C), 1540, 1190, 970, 750, 690 cm^{-1}; ^1H nmr (200 MHz, CD_3COCD_3) δ: 3.5 (AB spectra, 2H, CH_2, J = 12.7 Hz, $\Delta\nu$ = 15.5 Hz), 4.47 (ddd, 1H, C*H*—C=, J = 7.0, 5.5, 0.8 Hz), 5.31 (ddd, 1H, NH—C*H*, J = 9.5, 5.5, 1.0 Hz), 6.17 (dd, 1H, —C*H*=CHφ, J = 16.0, 7.0 Hz), 6.71 (dd, 1H, —CH=C*H*φ, J = 16.0, 0.8 Hz), 7.0 (m, 5H, φ), 7.2 (m, 5H, φ), 7.50 (d, 1H, NH β-lactam, J = 1.0 Hz), 7.76 (d, 1H, NH amide, J = 9.5 Hz); ms (70 eV) *m/e*: 306 (1.5, M^+), 289 (5), 263 (15, M^+ − CONH), 188 (19), 187 (20), 175 (23, M^+ − PhCH= − CH—CH—NH), 171 (855), 132 (1000, M^+ − $PhCH_2CONHCHCO$ + 1), 119 (15, $PhCH_2CO$), 115 (309).

4-Styryl 3-phenylacetamido 2-oxo 1-azetidine sulfonic acid ***12*** (ref. 20)

(*a*) *Tetrabutylammonium salt* ***12a***

Tetrabutylammonium salt ***12a*** was prepared from **11** (15 mg, 0.05 mmol) following the procedure described for ***9a***. Yield: 57%; ir ($CHCl_3$) ν_{max}: 3420 (NH), 2960, 2940, 2880 (CH_3, CH_2), 1760 (CO β-lactam), 1670 (CO amide), 1600 (C=C), 1460, 1265 and 1050 (SO_3) cm^{-1}; ^1H nmr (200 MHz, $CDCl_3$) δ: 0.92 (t, 12H, $4CH_3$, J = 7.3 Hz), 1.40 (m, 8H, 4 × CH_2—Me), 1.60 (m, 8H, $4CH_2$), 3.22 (m, 8H, $4NCH_2$), 3.50 (s, 2H, CH_2φ), 4.85 (dd, 1H, C*H*—C=, J = 6.7, 5.9 Hz), 5.33 (dd, 1H, NH—C*H*—, J = 9.7, 5.9 Hz), 5.98 (d, 1H, NH, J = 9.7 Hz), 6.20 (dd, 1H, C*H*=CHφ, J = 16.0, 6.7 Hz), 6.75 (d, 1H, CH=C*H*φ, J = 16.0 Hz), 7.0 (m, 5H, φ), 7.3 (m, 5H, φ); ms *m/e* (positive FAB): 629 (13, MH_2^+), 332 (138), 307 (35, MH_2^+ − NBu_4 − SO_3), 302 (103), 272 (161), 258 (172), 242 (1000, NBu_4), 240 (1000), 212 (63, $HSO_3NC_9H_8$ + H^+), 142 (CH_2NBu_2), 123 (115, HSO_3NCO).

(*b*) *Potassium salt* ***12b***

Potassium salt ***12b*** was prepared from ***12a*** (11 mg, 0.017 mmol) as described for ***9b***. However, in the present case the tetrabutylammonium salt was dissolved in distilled water – methanol (1:1). Elution of the ion-exchange resin was made first with a MeOH–H_2O (1:1) solution, then distilled water. The eluate was partially evaporated *in vacuo* and freeze-dried to afford 6 mg of potassium salt. Yield: 83%; ir (KBr) ν_{max}: 3485, 3310 (NH), 1760 (CO β-lactam), 1660 (CO amide), 1600 (C=C), 1540, 1295, 1240, 1050 and 1040 (SO_3) cm^{-1}; ^1H nmr (200 MHz, DMSO-d_6) δ: 3.38 (AB spectra, 2H, CH_2, J = 12 Hz, $\Delta\nu$ = 16 Hz), 4.53 (dd, 1H, C*H*—C=, J = 8.4, 5.7 Hz), 5.13 (dd, 1H, NH—C*H*, J = 9.4, 5.7 Hz), 6.31 (dd, 1H, C*H*=CHφ, J = 16.0, 8.4 Hz), 6.60 (d, 1H, CH=C*H*φ, J = 16.0 Hz), 6.95–7.40 (m, 10H, 2φ), 8.92 (d, 1H, NH, J = 9.4 Hz).

4-Styryl 3[[(2-trityl-amino 4-thiazolyl)(methoxyimino)acetyl]amino] 2-azetidinone ***15***

To a solution of (2-trityl-amino 4-thiazolyl)(methoxyimino) acetic acid **13** (443 mg, 1 mmol) in dry CH_2Cl_2 (5 mL) was added dropwise, at 0°C under nitrogen, a solution of EEDQ (296 mg, 1.2 mmol) in CH_2Cl_2 (5 mL). The mixture was stirred for 1 h. Simultaneously, to a solution of *para*-toluenesulfonate salt of β-lactam **8** (360 mg, 1 mmol) in 6 mL CH_2Cl_2–DMF (4:1) was added dropwise, at 0°C under nitrogen, triethylamine (167 μL, 121 mg, 1.2 mmol). The mixture was allowed to warm up to 25°C over 1 h and was then added dropwise to the first solution at 0°C. After stirring overnight, the precipitate was filtered and washed with 1 mL CH_2Cl_2 to give 380 mg of trityl β-lactam **15** (yield: 62%); mp 235°C; ir (KBr) ν_{max}: 3410 (w, NH β-lactam), 3280 (br, NH), 1780 (CO β-lactam), 1670 (CO amide), 1590 (C=C) cm^{-1}; ^1H nmr (200 MHz, DMSO-d_6) δ: 3.6 (s, 3H, OCH_3), 4.4 (dd, 1H, C*H*—C=, J = 8.0, 5.0 Hz), 5.22 (dd, 1H, NH—C*H*—, J = 9.0, 5.0 Hz), 6.1 (dd, 1H, C*H*=CHPh, J = 16.0, 8.0 Hz), 6.34 (s, 1H, S—C*H*=), 6.6 (d, 1H, =C*H*Ph, J = 16.0 Hz), 7.26 (m, 20H, $4C_6H_5$), 8.48 (s, 1H, NH β-lactam), 8.78 (s, 1H, ϕ_3C—N*H*), 9.24 (d, 1H, NH amide, J = 9.0 Hz); ms (70 eV) *m/e*: 614 (9, M^+ + 1), 483 (9, M^+ − φCH=CH—NH + 1), 244 (1000, ϕ_3CH), 243 (195, ϕ_3C), 223 (110), 207 (235), 205 (101), 183 (128), 165 (167), 153 (104), 131 (147, C_6H_5—CH=CH—CH—NH), 115 (387).

4-Styryl 3[[(2-amino 4-thiazolyl)(methoxyimino)acetyl]amino] 2-azetidinone ***16***

Trityl β-lactam **15** (306 mg, 0.5 mmol) in 40 mL methanol – formic acid (2:1) was refluxed for 7 h. After evaporation of the solvent, the crude material was washed with chloroform (3 × 2 mL) and MeOH (1 × 1 mL) to give 173 mg (93%) of amino β-lactam **16**; mp 226–229°C; ir (KBr) ν_{max}: 3400 (NH β-lactam), 3300, 3200 (NH_2), 1770 (CO β-lactam), 1660 (CO amide), 1590 (C=C) cm^{-1}; ^1H nmr (200 MHz, DMSO-d_6) δ: 3.6 (s, 3H, OCH_3), 4.46 (dd, 1H, C*H*—C=, J = 8.0, 5.0 Hz), 5.26 (dd, 1H, NH—C*H*—, J = 9.0, 5.0 Hz), 6.26 (dd, 1H, C*H*=CHφ, J = 16.0, 8.0 Hz), 6.4 (s, 1H, S—C*H*=), 6.64 (d, 1H, C*H*φ, J = 16.0 Hz), 7.13 (s, 2H, NH_2), 7.24–7.44 (m, 5H, φ), 8.5 (s, 1N, NH β-lactam), 9.26 (d, 1H, NH amide, J = 9.0 Hz); ms (70 eV) *m/e*: 371 (3, M^+), 328 (3, M^+ − CONH), 240 (M^+ − PhCH=CH—CHNH), 210 (169), 181 (182), 156 (209, $C_5H_6N_3OS$), 131 (346, C_6H_5—CH=CH—CH—NH), 130 (1000), 126 (218, $C_4H_4N_3S$), 125 (349), 115 (224), 103 (230), 84 (307), 43 (353, CHNO).

4-Styryl 3-[[(2-amino 4-thiazolyl)(methoxyimino)acetyl]amino] 2-oxo 1-azetidine sulfonic acid, potassium salt ***18c***

(a) Method 1 (path A)

A solution of trityl-amino azetidinone **15** (184 mg, 0.3 mmol) in 2 mL pyridine–DMF (1:1) was heated under nitrogen to 80°C, and 215 mg (1.35 mmol) of pyridine – sulfur trioxide complex was added. The mixture was stirred at 80°C for 15 h until tlc showed no more starting material. Evaporation of the solvents *in vacuo* afforded **17** as a crude material; ir ($CHCl_3$) ν_{max}: 3500–2500 (br), 1770 (CO β-lactam), 1385, 1255 (SO_3), 1100, 1050 (SO_3), 920, 760, 730 cm^{-1}; ^1H nmr (60 MHz, $CDCl_3$) δ: 3.7 (s, 3H, OCH_3), 4.5–5.2 (m, 2H, N—C*H*—C*H*—), 6.1–7.0 (m, 3H, 3CH=), 7.2 and 8.0 (m, φ).

Crude **17** was dissolved in 16 mL methanol – formic acid (3:1); the solution was refluxed for 7 h and evaporated to dryness. The residue was washed with chloroform (5 × 2 mL), dissolved in methanol (0.5 mL), and 2 mL of potassium 2-ethyl hexanoate (0.5 *M* in ethyl acetate) was added. The slurry was cooled to 0°C, filtered, washed with ethyl acetate, and dried to give 105 mg of potassium salt ***18c***; yield ~ 75–80%; mp 200°C (dec.); pH = 4.5; ir (KBr) ν_{max}: 3650–2800 (br), 1770 (CO β-lactam), 1670 (CO amide), 1635, 1535, 1250 (SO_3), 1130 (strong), 1050 (SO_3), 980, 620 cm^{-1}; ^1H nmr (300 MHz, DMSO-d_6) δ: 3.9 (s, 3H, OCH_3), 4.64 (dd, 1H, C*H*—CH=, J = 8.0, 5.0 Hz), 5.3 (dd, 1H, NH—C*H*—, J = 10.0, 5.0 Hz), 6.37 (dd, 1H, C*H*=CHφ, J = 16.0, 8.0 Hz), 6.45 (s, 1H, S—C*H*=), 6.68 (d, 1H, C*H*φ, J = 16.0 Hz), 7.25 (br s, 2H, NH_2), 7.29–7.5 (m, 5H, φ), 9.2 (d, 1H, NH, J = 10.0 Hz); ms *m/e* (positive FAB): 529 (55, MH^+ + K), 528 (151, MK^+), 490 (151, MH^+), 452 (82), 451 (94, MH^+ − K), 410 (166, MH^+ − SO_3), 390 (121), 359 (272), 353 (121), 343 (91), 329 (70, MH^+ − KSO_3NCO), 321 (145), 279 (151, MH^+ − $HSO_3NC_9H_8$), 242 (1000), 240 (91, 279 − K), 165 (424, $C_4H_4N_3S$ + K), 126 (575, $C_4H_4N_3S$), 91 (363, $C_6H_5CH_2$).

(b) Method 1 (path B)

A solution of amino β-lactam **16** (93 mg, 0.25 mmol) in 1.5 mL pyridine–DMF (1:2) was heated under nitrogen to 80°C and 159 mg (1 mmol) of pyridine – sulfur trioxide complex was added. The mixture was stirred at 80°C for 10 h. Evaporation of the solvents *in vacuo* gave a crude material, which was washed with chloroform (5 × 1.5 mL) and dissolved in methanol (0.5 mL). A solution of potassium 2-ethyl hexanoate in ethyl acetate (1.5 mL, 0.5 *M*) was added. The slurry was cooled to 0°C, filtered, and dissolved in distilled water (1 mL). The

aqueous solution was washed with ethyl acetate (2 × 0.5 mL), partially evaporated *in vacuo*, and freeze-dried to afford 62 mg of potassium salt **18***c* as a white powder (yield: 51%).

(c) Method 2 (refs. 24, 25)

To a solution of triphenylphosphine (208 mg, 0.8 mmol) in 1.5 mL THF–DMF (2:1) was added a solution of 3-azido *N*-sulfonyl β-lactam **9***a* (390 mg, 0.73 mmol) in 1 mL THF. The mixture was stirred for 1 h at room temperature. A light precipitate of zwitterion **19** appeared during the reaction; ir (KBr) ν_{max}: 3480 (br), 3080, 2895, 2790, 1780 (CO β-lactam), 1590 (C=C), 1480, 1440, 1290, 1230 (SO_3), 1180, 1120, 1050 (SO_3), 990 cm^{-1}; ^1H nmr (300 MHz, DMSO-d_6) δ: 4.44 (m, 1H, C*H*—CH=), 4.88 (br s, 1H, N—C*H*), 6.48 (m, 2H, C*H*=), 7.4–8.1 (m, 22H); ms *m/e* (positive FAB): 551 (6, MNa^+), 529 (14, MH^+), 450 (12), 449 (27, $MH^+ - SO_3$), 406 (10, $MH^+ - HSO_3NCO$), 332 (20), 318 (10, $MH^+ - HSO_3C_9H_8$), 262 (47, $P\phi_3$), 242 (1000), 142 (322), 91 (57), 90 (161).

Thereupon, a solution of amino-thiazolyl acid **14** (147 mg, 0.73 mmol) in 2 mL THF–DMF (1:1) was added to the above solution and the mixture was heated to 50°C for 8 h. The solution was then cooled, filtered, and evaporated *in vacuo* to afford 500 mg of crude *N*-butylammonium salt **18***b*; ir (film) ν_{max}: 3380 (br), 2940, 2880 (CH_3, CH_2), 1750 (CO β-lactam), 1640 (CO amide), 1460, 1240 and 1040 (SO_3), 880, 750 cm^{-1}; ^1H nmr (300 MHz, $CDCl_3$) δ: 1.05 (t, 12H, $4CH_3$, J = 7.3 Hz), 1.5 (m, 8H, $4CH_2Me$), 1.7 (m, 8H, $4CH_2$), 3.34 (m, 8H, $4CH_2N$), 3.40 (s, 3H, OCH_3), 4.8–5.5 (m, 2H, C*H*—C*H*), 6.35–7.8 (m, 11H, φ, 3CH=, NH_2, NH); ms *m/e* (positive FAB): 332 (14, 240 + G), 242 (1000, NBu_4), 240 (72, $MH^+ - NBu_4$—$HSO_3NC_9H_8$), 165 (9, $C_4H_4N_3S$ + K), 142 (287, CH_2NBu_2), 126 (8, $C_4H_4N_3S$), 100 (46), 98 (40), 91 (9).

The *N*-butylammonium salt **18***b* was dissolved in distilled water – methanol (2:1) and the solution was applied to a column of ion-exchange resin (12 mL) (Dowex 50 × 8-200) previously charged in K^+ ions with a 1 *N* KCl solution. Elution was made first with a MeOH–H_2O solution (1:1) and then distilled water. The eluate was washed with chloroform (2 × 0.5 mL) to remove the small amount of unexchanged *N*-butylammonium salt (18 mg). The aqueous layer was partially evaporated *in vacuo* and freeze-dried to afford 36 mg of potassium salt **18***c* in 11% overall yield from **9***a*.

This paper is dedicated to Dr. O. E. (Ted) Edwards

TAKEHIRO SANO, JUN TODA, NOBUTERU MAEHARA, and YOSHISUKE TSUDA. Can. J. Chem. **65**, 94 (1987).

Total synthesis of *dl*-coccuvinine **1***a* and *dl*-coccolinine **2***a*, "abnormal-type" erythrinan alkaloids lacking the C(16) O-function at the aromatic ring, was effectively achieved by using the Diels–Alder reaction of dioxopyrroline. Isoquinolinopyrrolinedione **6***a*, a key dienophile, was synthesized via the tetrahydroisoquinoline **5***a*, which was prepared by Bischler–Napieralski cyclization of the amide **4***a* at the unactivated position. The Diels–Alder adduct **7***a* of 1,3-bis(trimethylsilyloxy)-butadiene with **6***a* with converted stereoselectively into these alkaloids in short steps.

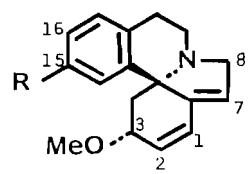
TAKEHIRO SANO, JUN TODA, NOBUTERU MAEHARA et YOSHISUKE TSUDA. Can. J. Chem. **65**, 94 (1987).

Faisant appel à une réaction de Diels–Alder de la dioxopyrroline, on a effectivement réalisé la synthèse totale de la (*dl*)-coccuvinine (**1***a*) et de la (*dl*)-coccolinine (**2***a*), des alcaloïdes de l'érythrinane d'un «type anormal» et qui ne portent pas de fonction oxygénée en position C(16) du cycle aromatique. On a synthétisé l'isoquinolinopyrrolinedione (**6***a*), un diénophile clé, par le biais de la tétrahydroisoquinoléine **6***a* qui a été préparée par une cyclisation de Bischler–Napieralski de l'amide **4***a* vers la position qui n'est pas activée. L'adduit de Diels–Alder **7***a* du bis(triméthylsilyloxy)-1,3 butadiène avec le composé **6***a* peut être transformé stéréosélectivement dans les deux alcaloïdes par des étapes courtes.

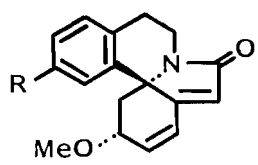
[Traduit par la revue]

Introduction

Coccuvinine **1***a*, the alkaloid isolated from *Cocculus laurifolius* DC. (Menispermaceae), is an "abnormal-type" erythrinan alkaloid in the sense that it contains no oxygen function at the C(16) position (1). Coccolinine **2***a* is the 8-oxo derivative of **1***a*. This non-basic lactam alkaloid was also isolated from the same plant (2). The synthesis of "abnormal-type" erythrinan alkaloids is of interest because of their biological activity, such as hypotensive and neuromuscular blocking action (3). We wish to report in detail the total synthesis of *dl*-coccuvinine **1***a* and *dl*-coccolinine **2***a*.



1



2

a: R=OMe, b: R=H

We have recently developed a new effective synthetic route to the erythrinan alkaloids using Diels–Alder reaction of isoquinolinopyrrolinedione with 1,3-*O*-disubstituted butadiene as a key step (4–6). This method provides a short synthesis of these alkaloids, if the isoquinoline ring closure occurs at the *meta* position with respect to the methoxy group on the aromatic ring. Ju-ichi *et al.* (7), who accomplished the first total synthesis of the abnormal-type erythrinan alkaloids by the method developed by Mondon *et al.* (8, 9), solved this problem by the introduction of an ethoxycarbamide group at the C(16) position as a regioselective *para*-directing group. Eventually this function was replaced with hydrogen after ring closure. However, this conversion itself requires several additional steps, thus lowering the total yield. Therefore, to further prove the efficiency of our method of erythrinan alkaloid synthesis, we have chosen these alkaloids as target molecules.

Total synthesis of dl-*coccuvinine and* dl-*coccolinine*

Condensation of 2-(4-methoxyphenyl)-ethylamine **3***a* with methyl chloroformylacetate afforded the amide **4***a* in good yield. As anticipated, the isoquinoline ring closure of **4***a* was very difficult. Treatment of **4***a* with phosphorus oxychloride under reflux afforded the tetrahydroisoquinoline **5***a* in only 3% yield. No starting material was recovered. Heating of **4***a* with polyphosphate ester (PPE) (10) in chloroform under reflux for 18 h afforded **5***a* in 15% yield together with an appreciable amount of the starting material (22%). Increase of the reaction time (48 h) resulted in greater decomposition of **5***a*, thus lowering the yield of **5***a* (9%). A fairly good result, although not optimized, was obtained by heating **4***a* in PPE without solvent for 18 h. Under these conditions **5***a* was formed in 34% yield and the starting material recovered in 33% yield. Since the starting material can be recycled, the net yield of **5***a* was calculated to be 51%. Condensation of **5***a* with oxalyl chloride provided the isoquinolinopyrrolinedione **6***a* in 78% yield. The structure of the dioxopyrroline moiety was readily characterized by the visible absorption band at 430 nm (11). Thus the key intermediate **6***a* was obtained from the commercially available amine **3***a* in 38% overall yield.

The Diels–Alder reaction of **6***a* with 1,3-trimethylsilyloxy-butadiene proceeded in a regio- and stereoselective manner. Thus, heating of **6***a* with the diene in toluene at 130°C for 20 min afforded the adduct **7***a* in 71% yield. The stereochemical assignment of the C(1) OTMS group as having the *endo* configuration results from comparison of the nmr spectrum of **7***a* with those of the adducts reported in the previous papers

[1]For part 16 see ref. 6. This paper also constitutes Part XXXIX of Dioxopyrrolines.

(6, 12). Reduction of **7***a* with lithium borohydride at −63°C occurred selectively at the C(7) keto group and treatment of the resulting alcohol with hydrochloric acid afforded the enone **8***a* in 56% yield. Removal of the methoxycarbonyl group at the C(6) position was effected by heating **8***a* with magnesium chloride in DMSO (13), giving rise to the dienone **10***a* with concomitant dehydration of the C(7) OH group in 32% yield. Substitution of the C(7) OH by a good leaving group markedly improved this step. Thus mesylation of **8***a* and demethoxycarbonylation of the resulting mesylate **9***a* under similar conditions produced **10***a* in 72% yield.

Meerwein–Ponndorf reduction of **10***a* occurred stereoselectively at the C(3) ketone to give the α-alcohol **11***a* and the β-alcohol **12***a* in 76 and 18% yields, respectively. Methylation of **11***a* with methyl iodide in the presence of a phase transfer catalyst afforded *dl*-coccolinine **2***a* in 93% yield. Reduction of **2***a* with aluminum hydride generated by lithium aluminum hydride, and aluminum chloride in THF occurred site-selectively at the C(8) lactam carbonyl group to furnish *dl*-coccuvinine **1***a* in 93% yield. The identity of **1***a* and **2***a* with authentic samples was confirmed by their spectral comparison. Thus, the total synthesis of *dl*-coccuvinine was effectively accomplished in 10 steps, proceeding in 6–7% overall yield from the commercially available amine **3***a*.

Synthesis of 15-demethoxycoccuvinine

Because of physiological interest, we have synthesized 15-demethoxycoccuvinine **1***b*, an unnatural erythrinan compound that lacks an O-function at the aromatic ring. The synthesis was achieved via the same route starting from phenylethylamine. Bischler–Napieralski cyclization of the amide **4***b*, using PPE as a condensing reagent as described above, afforded the tetra-

For personal use only.

hydroisoquinoline **5***b* in 47% yield. The subsequent reactions proceeded in similar manner and afforded *dl*-15-demethoxycoccuvinine **1***b* in a comparable yield.

Experimental

Unless otherwise stated, the following procedures were adopted. Melting points were taken on a Yanagimoto hot-stage apparatus and are uncorrected. Organic extracts were dried over anhydrous Na_2SO_4 and concentrated *in vacuo*. Column chromatography was performed on silica gel (Wakogel C-200). Thin-layer chromatographic (tlc) analyses were carried out by using silica gel plates (Merck precoated plates, silica gel 60F-254). Infrared spectra were taken in Nujol mulls with a Hitachi 260-10 spectrometer, and are given in cm^{-1}. Ultraviolet spectra were recorded in dioxane solution with a Hitachi 200-10 spectrophotometer. Proton nuclear magnetic resonance spectra were taken in $CDCl_3$ solution with tetramethylsilane (TMS) as an internal standard on a JEOL JNM-FX100 (FT-NMR; 100 MHz) spectrometer.

*General procedure for condensation reaction of arylethylamine **3** with methyl chloroformylacetate*

A solution of methyl chloroformylacetate (1.2 equiv. of **3**) in CH_2Cl_2 (50 mL) was added dropwise to a mixed solution of arylethylamine **3** in CH_2Cl_2 (100 mL) and 10% K_2CO_3 (1.2 equiv.) at 0°C, and stirring was continued for 1 h. The reaction mixture was neutralized with 5% HCl and the organic layer was washed with water, dried, and evaporated. Crystallization of the residue gave the amide **4**.

*Methoxycarbonylaceto-2-(4-methoxyphenyl)ethylamide (**4**a)*

Compound **4***a* (7.96 g, 96%) was prepared from **3***a* (5.00 g), mp 88–89°C, as colorless needles from AcOEt; ir ν_{max}: 3260, 1740, 1630 cm^{-1}; ^{1}Hmr δ: 2.77 (t, J = 7 Hz, 2H, $ArCH_2$—), 3.28 (s, 2H, —$COCH_2CO$—), 3.47 (t, J = 7 Hz, $>NCH_2$—), 3.72 (s, 3H, $COOCH_3$), 3.79 (s, 3H, OCH_3), 6.85 (d, J = 9 Hz, 1H, ArH), 7.14 (d, J = 9 Hz, 1H, ArH). *Mol. Wt.* calcd. for $C_{13}H_{17}NO_4$: 251.1156; found (ms): 251.1143.

*Methoxycarbonylaceto-2-phenylethylamide (**4**b)*

Compound **4***b* (16.1 g, 88%) was prepared from **3***b* (10 g), mp 65–67°C, as colorless needles from AcOEt; ir ν_{max}: 3230, 1740, 1640 cm^{-1}; ^{1}Hmr δ: 2.83 (t, J = 7 Hz, 2H, $ArCH_2$—), 3.48 and 3.61 (d, J = 7 Hz, each 1H, $>NCH_2$—), 3.71 (s, 3H, $COOCH_3$), 7.24 (m, 5H, ArH). *Mol. Wt.* calcd. for $C_{12}H_{15}NO_3$: 221.1050; found (ms): 221.1033.

*General procedure for Bischler–Napieralski reaction of nonactivated amide **4***

A mixture of **4** and polyphosphate ester (PPE) (20 times the amount of **4**) was heated at 80°C for the appropriate time (18 h for **4***a* and 40 h for **4***b*). After the excess of PPE was decomposed with ice water, the solution was basified with 10% K_2CO_3 and extracted with $CHCl_3$. The extract was washed with water, dried, and evaporated. The residue was chromatographed on silica gel using $CHCl_3$ as eluent to give the isoquinoline **5**.

*(Z)-7-Methoxy-1-methoxycarbonylmethylidene-1,2,3,4-tetrahydroisoquinoline (**5**a)*

Compound **5***a* (1.60 g, 34%) was obtained from **4***a* (5.00 g) as a pale yellow oil; ir ν_{max}: 3300, 1650 cm^{-1}; ^{1}Hmr δ: 2.77 (t, J = 7 Hz, 2H, $ArCH_2$—), 3.39 (t, J = 7 Hz, 2H, $>NCH_2$—), 3.69 (s, 3H, $COOCH_3$), 3.78 (s, 3H, OCH_3), 5.12 (s, 1H, $>C$=$CHCO$—), 6.9–7.1 (m, 3H, ArH). *Mol. Wt.* calcd. for $C_{13}H_{15}NO_3$: 233.1052; found (ms): 233.1059.

The starting amide **4***a* (1.70 g, 33%) was recovered from the column chromatography.

*(Z)-1-Methoxycarbonylmethylidene-1,2,3,4-tetrahydroisoquinoline (**5**b)*

Compound **5***b* (2.20 g, 47%) was obtained from **4***b* (5.08 g) as a pale yellow oil; ir($CHCl_3$) ν_{max}: 3300, 1650 cm^{-1}; ^{1}Hmr δ: 2.81 (t, J = 6 Hz, 2H, $ArCH_2$—), 3.42 (m, 2H, $>NCH_2$—), 3.68 (s, 3H, $COOCH_3$), 5.15 (s, 1H, $>C$=$CHCO$—), 7.39 (m, 4H, ArH).

The starting amide **4***b* (709 mg, 14%) was recovered from the column chromatography.

*General procedure for condensation reaction of **5** with oxalylchloride*

Oxalylchloride (1.1 equiv. of **5**) was added dropwise to a solution of **5** in anhydrous ether (50 mL) at 0°C under stirring, and the stirring was continued for one additional hour. The precipitate was collected by filtration and chromatographed on silica gel, using $CHCl_3$ as eluent, to give the dioxopyrroline **6**.

*8-Methoxy-1-methoxycarbonyl-2,3-dioxo-2,3,5,6-tetrahydropyrrolo[2,1-a]isoquinoline (**6**a)*

Compound **6***a* (892 mg, 78%) was obtained from **5***a* (930 mg), mp 181–185°C, as red prisms from AcOEt; ir ν_{max}: 1760, 1730, 1680 cm^{-1}; uv (dioxane, 25°C) λ_{max} (ε): 220 (15 800), 300 (12 600), 383 (4 900), 425 (4 100; sh); ^{1}Hmr δ: 3.03 (t, J = 6 Hz, 2H, $ArCH_2$—), 3.81 (t, J = 6 Hz, 2H, $>NCH_2$—), 3.87 (s, 6H, $COOCH_3$ and OCH_3), 7.17 (dd, J = 3 and 9 Hz, 1H, ArH), 7.29 (d, J = 9 Hz, 1H, ArH), 8.08 (d, J = 3 Hz, 1H, ArH). *Mol. Wt.* calcd. for $C_{15}H_{13}NO_4$: 287.0794; found (ms): 287.0797.

*1-Methoxycarbonyl-2,3-dioxo-2,3,5,6-tetrahydropyrrolo[2,1-a]isoquinoline (**6**b)*

Compound **6***b* (1.15 g, 61%) was obtained from **5***b* (1.5 g), mp 203–206°C, as red prisms from AcOEt; ir ν_{max}: 1760, 1720, 1700 cm^{-1}; ^{1}Hmr δ: 3.10 (t, J = 4 Hz, 2H, $ArCH_2$—), 3.84 (t, J = 4 Hz, 2H, $>NCH_2$—), 3.88 (s, 3H, $COOCH_3$), 7.53 (m, 4H, ArH). *Mol. Wt.* calcd. for $C_{14}H_{11}NO_4$: 257.0687; found (ms): 257.0687.

*General procedure for Diels–Alder reaction of **6** with 1,3-bis(trimethylsilyloxy)-1,3-butadiene*

A solution of **6** and the diene (5 equiv. of **6**) in toluene (10 mL) was heated at 130°C for 20 min in a sealed tube. The solution was concentrated to dryness to give a residue, which was triturated with *n*-hexane to give the adduct **7**.

(4R, 4aR*, 13bR*)-12-Methoxy-4a-methoxycarbonyl-5,6-dioxo-2,4-bis(trimethylsilyloxy)-4,4a,5,6,8,9-hexahydro-1H-indolo[7a,1-a]isoquinoline (**7**a)*

Compound **7***a* (256 mg, 71%) was prepared from **6***a* (200 mg), mp 144–146°C, as colorless prisms from EtOAc–*n*-hexane; ir ν_{max}: 1780, 1740, 1720, 1660 cm^{-1}; ^{1}Hmr δ: 0.05 and 0.12 (each s, 9H, $Si(CH_3)_3$), 2.90 (s, 3H, $COOCH_3$), 3.59 (s, 3H, OCH_3), 5.12 (d, J = 6 Hz, 1H, $>CHOTMS$), 5.25 (d, J = 6 Hz, 1H, C=CH—), 6.60–7.20 (m, 3H, ArH). *Mol. Wt.* calcd. for $C_{25}H_{35}NO_7Si_2$: 517.1952; found (ms): 517.1958.

(4R, 4aR*, 13bR*)-4a-Methoxycarbonyl-5,6-dioxo-2,4-bis(trimethylsilyloxy)-4,4a,5,6,8,9-hexahydro-1H-indolo[7a,1-a]isoquinoline (**7**b)*

Compound **7***b* (780 mg, 67%) was prepared from **6***b* (617 mg), mp 155–158°C, as colorless prisms from EtOAc; ir ν_{max}: 1760, 1710, 1650 cm^{-1}; ^{1}Hmr δ: 0.11 (s, 18H, 2 × $Si(CH_3)_3$), 2.83 (s, 3H, $COOCH_3$), 5.12 (d, J = 5 Hz, 1H, $>CHOTMS$), 5.22 (d, J = 5 Hz, 1H, C=CH—), 7.02 (m, 4H, ArH). *Mol. Wt.* calcd. for $C_{24}H_{35}NO_6Si_2$: 487.1844; found (ms): 487.1824.

*General procedure for reduction of **7** with $LiBH_4$*

A mixture of **7** and $LiBH_4$ in anhydrous THF was stirred for 20 min at −60°C under an argon atmosphere. The mixture was diluted with Et_2O, washed with saturated NaCl solution and water, dried, and evaporated. The residue in 5% HCl–THF (1:1) (10 mL) was heated on a water bath for 1 h. The mixture was extracted with $CHCl_3$, washed with water, dried, and evaporated. Recrystallization of the residue gave the enone **8**.

(2R,13bR*)-2-Hydroxy-12-methoxy-6-oxo-2,6,8,9-tetrahydro-1*H*-indolo[7a,1-a]isoquinoline (**12**a)*

Compound **12***a* (9 mg, 18%) was prepared from **10***a* (50 mg), mp 83–85°C, as colorless prisms from Et_2O; ir ν_{max}: 3300, 1640 cm^{-1}; ^{1}Hmr δ: 2.11 (dd, J = 5 and 14 Hz, 1H, H-1′), 2.73 (br d, J = 14 Hz, 1H, H-1′), 3.75 (s, 3H, C_{12}-OCH_3), 4.47 (br t, J = 5 Hz, 1H, —CH—OH), 6.01 (s, 1H, —COCH=C—), 6.29 (dd, J = 5 and 10 Hz, 1H, —CH=CH—CH(OH)—), 6.78 (dd, J = 3 and 8 Hz, ArH), 6.91 (d, J = 10 Hz, 1H, —CH=CH—CH(OH)—), 6.93 (d, J = 3 Hz, 1H, ArH), 7.20 (d, J = 8 Hz, 1H, ArH).

(2S,13bR*)-2-Hydroxy-6-oxo-2,6,8,9-tetrahydro-1*H*-indolo[7a,1-a]isoquinoline (**11**b)*

Compound **11***b* (81 mg, 83%) was prepared from **10***b* (97 mg), mp 196–198°C, as colorless prisms from MeOH; ir ν_{max}: 3350, 1650 cm^{-1}; ^{1}Hmr δ: 4.12 (m, 1H, —CHOH), 5.96 (s, 1H, —COCH=C—), 6.25 (d, J = 10 Hz, 1H, H-4′), 6.80 (dd, J = 3 and 10 Hz, 1H, H-3′), 7.12 (m, 4H, ArH). *Mol. Wt.* calcd. for $C_{16}H_{15}NO_2$: 253.1101; found (ms): 253.1088.

(2R,13bR*)-2-Hydroxy-6-oxo-2,6,8,9-tetrahydro-1*H*-indolo[7a,1-a]isoquinoline (**12**b)*

Compound **12***b* (13 mg, 13%) was prepared from **10***b* (97 mg), mp 75–77°C, as colorless prisms from Et_2O; ir ν_{max}: 3200, 1670, 1650 cm^{-1}; ^{1}Hmr δ: 4.46 (t, J = 5 Hz, 1H, —CHOH), 6.02 (s, 1H, H-5′), 6.28 (dd, J = 5 and 10 Hz, 1H, H-3′), 6.93 (d, J = 10 Hz, 1H, H-4′), 7.27 (m, 4H, ArH). *Mol. Wt.* calcd. for $C_{16}H_{15}NO_6$: 253.1101; found (ms): 253.1076.

Synthesis of dl*-coccolinine (**2**a) and* dl*-15-demethoxycoccolinine (**2**b)*

A mixture of **11***a* (50 mg), CH_3I (280 mg), Et_4NBr (210 mg), and KOH (99 mg) in anhydrous THF (10 mL) was stirred for 18 h at room temperature. The mixture was diluted with water and extracted with $CHCl_3$. The extract was washed with water, dried, and evaporated. Recrystallization of the residue from MeOH gave *dl*-coccolinine **2***a* (49 mg, 93%) as colorless prisms, mp 152–154°C; ir ν_{max}: 1670, 1610 cm^{-1}; ^{1}Hmr δ: 2.82 (dd, J = 4 and 12 Hz, 1H, H-4′), 3.34 (s, 3H, OCH_3), 3.74 (s, 3H, OCH_3), 3.90 (m, 1H, —CHOMe), 6.03 (s, 1H, —COCH=C—), 6.30 (d, J = 9 Hz, 1H, H-1′), 6.70–7.30 (m, 3H, ArH), 6.79 (d, J = 9 Hz, 1H, H-2′). *Mol. Wt.* calcd. for $C_{18}H_{19}NO_3$: 297.1365; found (ms): 297.1365.

The ir and ^{1}Hmr spectra were identical with those of natural coccolinine. The difference in melting point of *dl*-coccolinine from

that reported (lit. (7) mp 179–180°C) might be attributable to the presence of dimorphic forms.

Similarly, a solution of **11***b* (67 mg) in anhydrous THF (10 mL) was treated with CH_3I (600 mg) in the presence of Et_4NBr (210 mg) and KOH (80 mg). Working up as described above, *dl*-demethoxycoccolinine **2***b* (65 mg, 95%) was obtained as colorless needles from AcOEt, mp 165–168°C; ir ν_{max}: 1675 cm^{-1}; ^{1}Hmr δ: 1.74 (d, J = 12 Hz, 1H, H-4′), 2.82 (dd, J = 5 and 12 Hz, 1H, H-4′), 3.33 (s, 3H, OCH_3), 3.99 (m, 1H, H-3′), 6.02 (s, 1H, H-8′), 6.30 (d, J = 10 Hz, 1H, H-1′), 6.88 (dd, J = 2 and 10 Hz, 1H, H-2′). *Mol. Wt.* calcd. for $C_{17}H_{17}NO_2$: 267.1257; found (ms): 267.1255.

Synthesis of dl-*coccuvinine (**1**a) and* dl-*15-demethoxycoccuvinine (**1**b)*

An ethereal solution of excess AlH_3 (prepared from $LiAlH_4$:$AlCl_3$ = 3:1) was added to a solution of **2***a* (60 mg) in anhydrous THF (15 mL) at room temperature under an argon atmosphere. The reaction mixture was stirred for a further 2 h. The mixture was basified with 10% NH_4OH and extracted with $CHCl_3$. The extract was washed with water, dried, and evaporated to give *dl*-coccuvinine **1***a* (52 mg, 91%) as a colorless oil (picrate, yellow prisms from EtOH, mp 166–167°C); ^{1}Hmr δ: 1.90 (t, J = 11 Hz, 1H, H-4′), 2.52 (dd, J = 5.5 and 11 Hz, 1H, H-4′), 3.31 (s, 3H, OCH_3), 3.73 (s, 3H, OCH_3), 3.96 (m, 1H, H-3′), 5.72 (s, 1H, H-7′), 5.99 (d, J = 10 Hz, H-1′), 6.56 (dd, J = 2 and 10 Hz, 1H, H-2′), 6.70 (d, J = 2.7 Hz, 1H, ArH), 6.81 (dd, J = 2.7 and 8.0 Hz, 1H, ArH), 7.08 (d, J = 8.0 Hz, 1H, ArH).

The ir and ^{1}Hmr spectra were identical with those of natural coccuvinine.

Similarly, **2***b* (50 mg) in anhydrous THF (13 mL) was reduced with excess AlH_3 as described above to give 15-demethoxycoccuvinine **1***b* (44 mg, 93%) as a colorless oil (picrate, yellow prisms from EtOH, mp 191–193°C); ^{1}Hmr δ: 1.84 (t, J = 11 Hz, 1H, H-4′), 2.54 (dd, J = 6 and 11 Hz, 1H, H-4′), 3.29 (s, 3H, OCH_3), 3.85 (m, 1H, H-3′), 5.71 (s, 1H, H-7′), 5.97 (d, J = 10 Hz, 1H, H-1′), 6.55 (dd, J = 2 and 10 Hz, 1H, H-2′), 7.14 (m, 5H, ArH).

Acknowledgement

We are grateful to Professor M. Ju-ichi, Mukogawa Women's University, for providing the spectral data of coccolinine and coccuvinine.

^{13}C Nuclear magnetic resonance spectroscopy in the elucidation of structures of diterpenoid alkaloids[1]

BALAWANT S. JOSHI, JOHN K. WUNDERLICH, AND S. WILLIAM PELLETIER[2]

Institute for Natural Products Research and the School of Chemical Sciences, The University of Georgia, Athens, GA 30602, U.S.A.

Received May 28, 1986

This paper is dedicated to Dr. O. E. (Ted) Edwards

BALAWANT S. JOSHI, JOHN K. WUNDERLICH, and S. WILLIAM PELLETIER. Can. J. Chem. **65**, 99 (1987).

^{13}C Nuclear magnetic resonance spectroscopy is an exceptionally useful tool for the structure determination of diterpenoid alkaloids. A detailed study of the ^{1}H and ^{13}C nmr spectra of aconitine and 3-deoxyaconitine has permitted definite assignments to all the carbon atoms of the molecule. Chemical shift revisions have been suggested for certain carbon atoms of the C_{19}-diterpenoid alkaloids. Chemical examination of *Aconitum columbianum* Nutt. ssp. *columbianum*, *A. forrestii* Stapf, *Delphinium tatsienense* Franch., and *D. vestitum* Wall. resulted in the isolation of several new C_{19}-diterpenoid alkaloids. The structure derivation of those alkaloids was based mainly on ^{13}C nmr spectroscopic evidence.

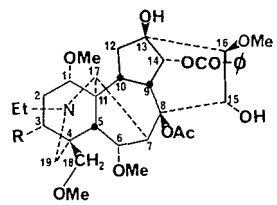
BALAWANT S. JOSHI, JOHN K. WUNDERLICH et S. WILLIAM PELLETIER. Can. J. Chem. **65**, 99 (1987).

La spectroscopie rmn du ^{13}C est un outil d'une utilité exceptionnelle pour déterminer la structure des alcaloïdes diterpéniques en C_{13}. Une étude détaillée des spectres rmn du ^{1}H et ^{13}C de l'aconitine et de la déoxy-3 aconitine a permis d'attribuer d'une façon définitive tous les déplacements de tous les atomes de carbone de la molécule. Des revisions des déplacements chimiques ont été suggérées pour certains atomes de carbone d'alcaloïdes diterpéniques en C_{19}. Un examen des produits chimiques contenus dans les sources naturelles suivantes *Aconitum columbianum* Nutt. ssp. *columbianum*, *A. forrestii* Stapf, *Delphinium tatsienense* Franch. et *D. vestitum* Wall. a permis d'isoler plusieurs nouveaux alcaloïdes diterpéniques en C_{19}. Les structures de ces alcaloïdes ont été déterminées en se basant principalement sur des données de la rmn du ^{13}C.

[Traduit par la revue]

To date, the structures of about 175 naturally occurring C_{19}-diterpenoid alkaloids have been reported and a large majority of these structures have been elucidated during the last ten years (1). The structure determination of these complex alkaloids has largely been possible because of the developments in isolation methods (2) and advances in spectroscopic techniques, e.g. proton nmr, carbon-13 nmr, high resolution mass spectra, and X-ray analysis. However, by far the most useful technique for the structure elucidation of these alkaloids has been the application of ^{13}C nmr spectroscopy. By a systematic study of more than 100 naturally occurring C_{19}-diterpenoid alkaloids and their derivatives, we have accumulated a data base that has proved very useful in the derivation of structures of newly isolated alkaloids.

Jones and Benn made the initial contribution to ^{13}C nmr spectroscopy of diterpenoid alkaloids (3). In 1976, Pelletier and Djarmati studied the ^{13}C nmr spectra of various closely related aconitine-type alkaloids and suggested assignments of all the carbon atoms making use of substituent effects (4). Undoubtedly, these data on the ^{13}C chemical shifts of various functional groups in C_{19}-diterpenoid alkaloids have been useful in structure determination of newly isolated alkaloids. Although errors in assignment may be averaged out over a large number of compounds having similar structural features, and the correct structure may be derived in the case of new alkaloids, the assigned chemical shifts may not be absolutely correct. We therefore undertook a detailed study of the ^{13}C nmr chemical shift assignments for the well-known alkaloid aconitine (**1***A*). A variety of methods were used to obtain the ^{1}H and ^{13}C nmr assignments, with the major emphasis on the use of the 2-D nmr technique (5). The assignments of the acetyl and benzoyl groups have been well studied and there is no doubt about these values.



1*A* R=OH Aconitine

1*B* R=H 3-Deoxyaconitine

First, homonuclear proton decoupling experiments were carried out and then $^{1}H-^{1}H$ correlated (COSY) 2-D experiments, without and with the addition of pyridine, to note the dispersion of some signals. A summary of the results of the COSY experiment is given in Table 1. A slice through the data-matrix at δ 4.88 showed two off-diagonal elements: a doublet of doublets at δ 2.90 and a doublet at δ 3.33. The correlation with the doublet at δ 3.33 can best be attributed to "*w*" coupling between H-14 and H-16. A slice taken at δ 2.90 showed as an off-diagonal element, a doublet at δ 4.88 (H-14) and a doublet of doublets of doublets at δ 2.33. Assuming that H-9 appears at δ 2.9, the signal at δ 2.33 should be assigned to H-10. A slice taken at δ 4.48 showed, as off-diagonal elements, a doublet at δ 4.39 and a doublet at δ 3.33. Based on earlier evidence, since H-16 appears at δ 3.33, the signal at δ 4.48 must be assigned to H-15 and the doublet at δ 4.39 should be due to C(15)—OH. By this process most of the proton assignments were made as shown in Table 1. These ^{1}H nmr assignments are essentially in agreement with the reported values of Katz and Rudin for aconitine (6).

A C/H correlation experiment was performed on aconitine without the addition of pyridine. The quaternary carbon resonances will not appear since the experiment relies on a polarization transfer step to observe the C/H correlation. A slice taken at the downfield carbon resonance at 90.1 ppm showed a correlation with the H-16 resonance at δ 3.33, indicating that the signal at 90.1 should be assigned to C(16). Similarly, the signal

[a]NOTE: For Tables 1, 2, and 3 the 2D-nmr spectra were taken on a JEOL FX-270 MHz instrument using JEOL FAFT-84 2D software. Aconitine (90 mg) and 3-deoxyaconitine (79.8 mg) were dissolved in 0.5 mL or 1 mL of $CDCl_3$ for 5-mm or 10-mm (od) nmr tubes, respectively. All chemical shifts are reported in ppm (δ) relative to internal tetramethylsilane; s: singlet, d: doublet, t: triplet, q: quartet, br: broad, m: multiplet.

[a]See NOTE, Table 1.

83.4 ppm was assigned to C(6) as it was correlated with H-6, appearing at δ 4.04. Using the same approach, assignments were made for C(1), C(3), C(14), C(15), C(17), and C(18) (Table 2). The signals at 48.9 and 47.0 ppm showed correlation with the methylene proton resonances of an *N*-ethyl group and C(19), respectively. The methine carbons appearing at 46.9, 44.8, and 44.2 ppm were correlated with H-5, H-7, and H-9 resonating at 2.1, 2.84, and 2.9, respectively. The doublet at 40.9 ppm was assigned to C(10) as it showed an overlap with the H-10 resonance at δ 2.33. The remaining chemical shifts for C(2) and C(12) were assigned to the signals appearing at 33.9 and 35.9 ppm, respectively.

The DIFNOE (difference nuclear Overhauser enhancement) technique was used for assigning the methoxyl protons. Irradiation at δ 3.76 gave four enhanced signals, due to H-15, 15-OH, 13-OH, and H-16, suggesting that the δ 3.76 signal belongs to the 16′-methoxyl group. The C/H correlation shows that the signal at 61.1 ppm can be assigned to the 16′-methoxyl. The remaining three methoxyls were similarly assigned (Table 3).

These investigations provided accurate ^{13}C chemical shift assignments for all the carbon atoms of aconitine. Table 4 shows a comparison of the previously assigned values (4) and the revised chemical shift assignments. By a similar set of experiments, the ^{1}H and ^{13}C chemical shifts of 3-deoxyaconitine (**1B**) were derived (Table 4).

On the basis of published data of the ^{13}C nmr spectra of more than 160 C_{19}-diterpenoid alkaloids and their derivatives, we have prepared a table indicating the general chemical shift ranges of all the carbon atoms (1). These data are only approximations but are useful in studying the structures of newly isolated alkaloids.

Even when correct structures may be derived on the basis of these chemical shift values, the individual carbon atoms could have been assigned incorrectly. One such error has been noticed in the chemical shift assignments for C(10) and C(13). For most of the alkaloids, the higher field resonance appearing in the range 37–43 ppm has been ascribed to C(10) and the lower field signal around 43–46 ppm to C(13), when neither of these carbons bears an oxygen function. It is well established that within a group of closely related compounds, a given substituent produces remarkably similar effects on the shielding of the carbons at or near the site of substitution. Thus, when a hydrogen is replaced by a hydroxyl group, a downfield shift of about 7–8 ppm is observed on the β carbon (β-effect) and an upfield shift of 2–4 ppm on the γ carbon (γ-effect).

These generalized β- and γ-effects are not observed in the published chemical shifts of C(10) and C(13) in closely related C_{19}-diterpenoid alkaloids; e.g. placement of a hydroxyl at C(9) in monticoline (**2**) leads to a related alkaloid ranaconine (**3**). The chemical shifts for C(10) and C(13) in monticoline (**2**) have

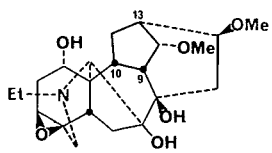
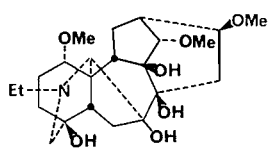
[a,b]Values may be interchanged.

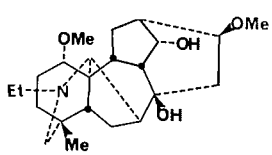
been assigned the values 37.1 and 42.0 ppm, respectively (7). In ranaconine (**3**), C(10) and C(13) have been assigned 37.5 and 51.1 ppm (8), which point to a downfield shift of 0.4 ppm on C(10) (β-effect) and a downfield shift of 9.1 ppm on C(13) (γ-effect). Similarly, the published values for sachaconitine (**4**) (9) and lappaconine (**5**) (10) indicate an upfield shift of 1.1 ppm on C(10) and a downfield shift of 4.9 ppm on C(13) when C(9) is substituted with a hydroxyl group contrary to the expected β- and γ-effects. If the presently assigned values of C(10) and



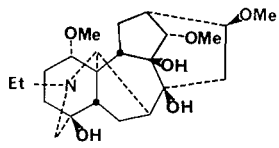
2 Monticoline



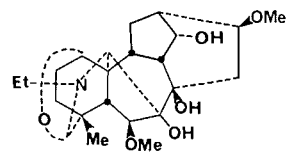
3 Ranaconine



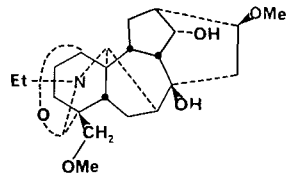
4 Sachaconitine



5 Lappaconine



6 Gadesine



7 Nevadenine

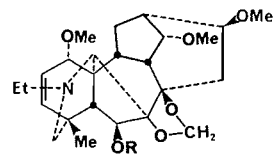
C(13) are reversed, then the expected β- and γ-effects are observed. We have therefore suggested that the earlier assigned chemical shifts for C(10) and C(13) of many of the C_{19}-diterpenoid alkaloids should be reversed, assigning the downfield signal occurring around 43–46 ppm to C(10) and the upfield signal around 37–43 ppm to C(13) (11).

Another assignment that needs to be corrected in the literature is that of C(1) and C(19) in gadesine (**6**) (1, 12), nevadenine (**7**) (13), and other alkaloids containing a 1,19-oxygen bridge. The low field signals at 89.0 and 87.6 ppm respectively in **6** and **7** should be assigned to C(19) and the upfield signals at 68.3 and 69.4 ppm should be assigned to C(1) for these compounds instead of the reversed assignments reported. The C(19) signal generally appears in the range 52.0–52.5 ppm when it does not bear an oxygen function. When it does, a downfield shift of around 40 ppm would be expected and C(19) should show a signal around 90 ppm (14).

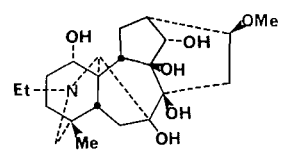
Recent examples of our application of ^{13}C nmr spectroscopy in the field of diterpenoid alkaloid structure elucidation include the following:

Alkaloids of Delphinium tatsienense *Franch.*

From the roots of *Delphinium tatsienense* Franch., a Chinese medicinal plant, more than ten alkaloids were isolated and their structures determined mainly on the basis of ^{13}C nmr spectroscopy. Tatsiensine, $C_{27}H_{39}NO_7$, an amorphous alkaloid, was formulated as **8** on the basis of ^1H nmr and ^{13}C nmr evidence (15). The structure of tatsinine (**9**), $C_{22}H_{35}NO_6$, mp 132–

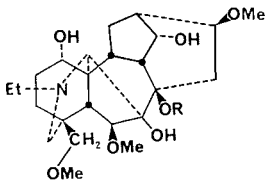


8 R=Ac Tatsiensine



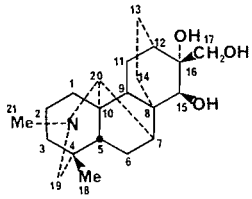
9 Tatsinine

133°C, was proposed solely on the basis of ^{13}C nmr spectral data (16). This structure has recently been confirmed by an X-ray crystal structure determination (17). The isolation and structure determination of another amorphous alkaloid, $C_{25}H_{41}NO_7$ (**10**), designated as deltatsine, was based on ^1H nmr and ^{13}C nmr spectroscopic data and a chemical correlation with delcosine (**11**) (18). The other C_{19}-diterpenoid alkaloids from *D. tatsienense,* whose structures were determined by ^{13}C nmr spectra, were browniine, delcosine, lycoctonine, and the C_{20}-diterpenoid alkaloids ajaconine, hetisine, and hetisinone (15). A C_{20}-diterpenoid alkaloid, $C_{21}H_{33}NO_3$, mp 181–182°C, isolated from

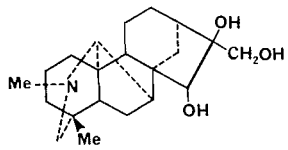


10 R=Me Deltatsine

11 R=H Delcosine



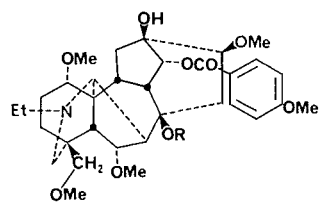
12 Dictyzine



13

this plant, was shown to be identical with dictyzine (**12**), first obtained from *D. dictyocarpum* DC. The structure **13** proposed for this alkaloid based on chemical studies (19) was revised to **12** from an X-ray crystal structure determination (20). We derived the structure of this alkaloid from its ^{13}C nmr spectrum, which showed the following signals ($CDCl_3$; TMS): C(1) 40.2t, C(2) 20.8t, C(3) 27.7[a]t, C(4) 34.4s, C(5) 44.2d, C(6) 26.6[a]t, C(7) 36.2d, C(8) 42.0s, C(9) 52.8d, C(10) 45.6s, C(11) 21.9t, C(12) 42.8d, C(13) 23.1t, C(14) 26.6[a]t, C(15) 86.7d, C(16) 79.8s, C(17) 59.8t, C(18) 23.6q, C(19) 67.8t, C(20) 73.5d ppm ([a] these values may be interchanged).

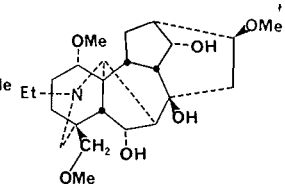
From the roots of another Chinese medicinal plant, *Aconitum forrestii* Stapf, we had isolated two new C_{19}-diterpenoid alkaloids forestine (**14**) and foresticine (**15**) together with three known alkaloids chasmanine, talatizamine, and yunaconitine (21). These alkaloids were isolated from the crude alkaloid fraction obtained at pH 8 and the structures were derived mainly on ^{13}C nmr spectroscopic evidence. From the alkaloidal fraction taken at pH 5–6, we have isolated four new alkaloids acoforine (**16**), acoforesticine (**17**), acoforestine (**18**), and acoforestinine (**19**), besides crassicauline A (**20**) and yunaconitine (**21**).



14 R=H Forestine

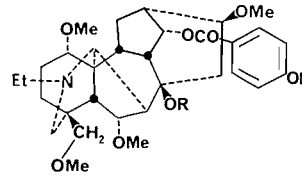
18 R=Et Acoforestine

20 R=Ac Crassicauline A



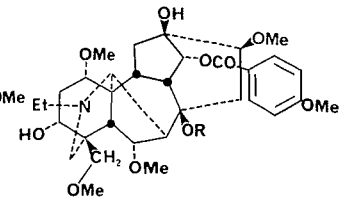
15 Foresticine

Except for acoforestine, mp 203–204°C, the three alkaloids **16**, **17**, and **19** are amorphous. The structures of all these alkaloids were derived from their ^{13}C nmr spectral data and correlation studies. Acoforine (**16**) was shown to be identical with 14-acetylcolumbidine, prepared from columbidine (*vide infra*). When acoforesticine (**17**) was acetylated with acetic anhydride and *p*-toluenesulfonic acid it gave the known alkaloid foresaconitine (vilmorrianine C) (**22**). Heating crassicauline A (**20**) with ethanol in a sealed tube at 130°C afforded acoforestine (**18**). As the structure of **20** was based only on spectral and chemical evidence, an X-ray crystal structure determination of acoforestine was carried out, confirming the structure proposals **18** and **20** for these alkaloids (22).



17 R=H Acoforesticine

22 R=Ac Foresaconitine



19 R=Et Acoforestinine

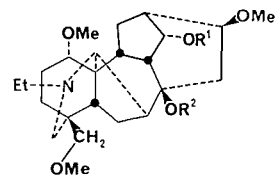
21 R=Ac Yunaconitine

C_{19}-Diterpenoid alkaloids containing a methoxyl or an ethoxyl group at C(8) have been reported in the literature, e.g. alkaloid A, ambiguine, puberaconitidine, septentrionine, columbidine. The question as to whether these alkaloids containing an alkoxyl group at C(8) are artefacts or are present in the plants cannot be answered with certainty until the extraction procedures are repeated, avoiding the use of methanol and ethanol during the isolation.

The conversion of the 8-acetoxy group in C_{19}-diterpenoid alkaloids to afford the 8-alkoxy compounds can be considered as a Grob type fragmentation, when the free electron pair on the nitrogen atom is oriented periplanar with respect to the Cβ,Cγ bond that undergoes cleavage (23).

Aconitum columbianum Nutt. ssp *columbianum*, growing in the Western parts of the USA, afforded the known alkaloids cammaconine, deltaline, dictyocarpine, talatizamine (**23**), 8-*O*-methyl talatizamine, and a new alkaloid columbidine (**24**) (11). The structures of all the alkaloids were derived mainly on the basis of ^{13}C nmr spectral data.

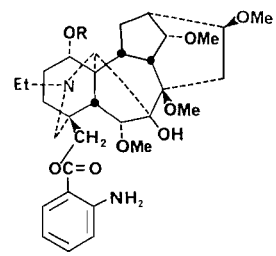
Delphinium vestitum Wall., growing in the Western Himalayas, was found to contain two closely related alkaloids delvestine (**25**) and delvestidine (**26**), the structures of which



16 R^1=Ac; R^2=Et Acoforine

23 R^1=R^2=H Talatizamine

24 R^1=H; R^2=Et Columbidine



25 R=H Delvestine

26 R=Me Delvestidine

were based on ^{13}C nmr spectroscopic data and correlation with gigactonine and lycoctonine, respectively (24).

In summary, our work indicates that a data bank of ^{13}C nmr spectra of C_{19}-diterpenoid alkaloids is valuable in deriving structures of newly isolated compounds of this class. Also, in the case of amorphous alkaloids, where an X-ray crystal structure determination is not possible, ^{13}C nmr spectroscopy is a very useful tool for derivation of structure.

Synthesis of tricyclic azetidinones by intramolecular free radical cyclization

GEORGE JUST[1] AND GUERINO SACRIPANTE
Department of Chemistry, McGill University, Montreal, P.Q., Canada H3A 2K6

Received June 6, 1986

This paper is dedicated to Dr. O. E. (Ted) Edwards

GEORGE JUST and GUERINO SACRIPANTE. Can. J. Chem. **65**, 104 (1987).

The synthesis of strained tricyclic azetidinones was achieved by free radical cyclization of N-substituted azetidinones involving a tributyltin hydride/AIBN mediated chain reaction. The 5-*exo* cyclization led to benzo carbapenems **10**, **12**, and **13**, which were relatively unstable in solution. The 6-*exo* mode, however, afforded stable benzo carbacephems **20**, **22**, **24**, and **25**.

GEORGE JUST et GUERINO SACRIPANTE. Can. J. Chem. **65**, 104 (1987).

On a réalisé la synthèse d'azétidinones tricycliques tendues en faisant appel à une cyclisation radicalaire d'azétidinones N-substituées qui implique une réaction en chaîne provoquée par le couple hydrure de tributylétain/AIBN. La cyclisation *exo*-5 conduit aux benzo carbapénèmes **10**, **12** et **13** qui sont relativement instables en solution. Toutefois, dans le mode *exo*-6, les cyclisations conduisent aux benzo carbacéphèmes **20**, **22**, **24** et **25** stables.

[Traduit par la revue]

Introduction

Since the discovery of the antibacterial drug thienamycin, **1**, numerous modifications of its carbapenem structure have been carried out to determine the effect of the ring size on biological activity (1). Our interests in preparing nonclassical tricyclic azetidinones (2) prompted us to investigate the stabilities of the more strained tricyclic benzo carbapenem ($n = 0$) or carbacephem ($n = 1$) of type **2**. The syntheses of carbapenems or carbacephems were previously achieved by ionic methods. In view of the known instability of tricyclic carbacephems towards acids and nucleophilic reagents, we sought a free radical method for their synthesis (3).

As suitable precursors for the intramolecular free radical annelation yielding **2**, the radicals were generated either β ($n = 0$) or γ ($n = 1$) to the nitrogen atom of the azetidinone **3**, and a phenyl substituent (R^1) was chosen so that the *exo* mode of addition should be favoured over the *endo* process. Similar free radical cyclizations yielding bicyclic azetidinones have been described elsewhere (4, 5).

Results and discussion

The *cis*-azido azetidinones were prepared by known methods (2) involving the condensation of an appropriate Schiff base with azidoacetyl chloride in the presence of equimolar amounts of triethylamine. Reduction of the azide substituent using hydrogen sulfide and triethylamine followed by acylation of the amine intermediate with phenylacetyl chloride and triethylamine gave fair to good yields of the expected amido azetidinones **4**–**8**.

Free radical cyclization of **4** (0.02 *M* in refluxing benzene), with slow addition of tributyltin hydride and catalytic AIBN over a 20-h period under an inert atmosphere, gave the reduction product **9** (15%), tricyclic azetidinone **10** (5%), and the azepinone **11** (35%), together with some starting material, after separation using a neutral silica hplc column. The configuration of **10** was assigned, based on its coupling constant of 8 Hz (J_{H4-H5}), by analogy with diastereomers **20** and **26** discussed below. When this tricyclic benzo carbapenam **10** was placed in an nmr tube ($CDCl_3$), it decomposed within a week, and **11** was isolated as the major product. Due to the instability of **10** in solution, the free radical annelation of **4** was repeated using 1.5 equiv. of tributyltin hydride over a shorter period of time (3 h). After evaporation of the solvent, the crude residue was redissolved in carbon tetrachloride, and **10** precipitated as colorless crystals (24%). The infrared spectrum of **10** displayed the azetidinone carbonyl frequency at 1805 cm^{-1}, which is considerably higher than for less strained bicyclic azetidinones such as cephalosporanic acid (1765 cm^{-1}). The decomposition of **10** to **11** most likely resulted via proton abstraction at C5 with a double bond formation at C4—C5 and ring opening at the C4—N position to give **11**, which is closely related to diazepam (see arrows, **10**). To avoid this decomposition, we decided to carry out the next experiment on a propargyl azetidinone **5**, where the resulting product **12**/**13** lacks the C5 proton.

Thus, the free radical cyclization of **5** gave two tricyclic azetidinones **12** and **13** in a 4:3 ratio as a crystalline mixture (31%), mp 140–145°C. Also, the reduction product **14** (27%), some starting material, and several decomposition products were obtained. The mixture of **12** and **13** did not survive chromatography using various types of silica and only **13** was recovered partially when neutral silica gel was used. Attempts to recrystallize this mixture also failed, giving decomposition in solution within a few days. From this decomposed mixture was isolated the azepinone **15**, which most likely resulted via proton abstraction at C3 forming a double bond at C3—C4 and ring opening at N—C4 of the azetidinone rings **12** and **13**. The infrared spectra of **12** and **13** showed the azetidinone carbonyl frequency vibration at 1824 cm^{-1}.

Since the benzo carbapenems obtained were found to be unstable in solution, we next investigated the formation of the somewhat less strained benzo carbacephems **2** ($n = 1$). Desilylation of **6**–**8** using tetrabutylammonium fluoride, followed by bromination of the corresponding alcohol with triphenylphosphine/carbon tetrabromide, gave good yields of the bromo azetidinones **16**, **17**, and **18** respectively.

Free radical cyclization of **16** gave some reduction product **19** and 65% tricyclic benzo carbacephem, mp 256°C, exclusively, as the less crowded diastereomer **20**. The infrared spectrum showed the azetidinone carbonyl absorption at 1755 cm^{-1}. This tricyclic product resulting from a 6-*exo* addition was found to be highly stable in solution. Similarly, free radical cyclization of **17** gave the reduction product **21** and a good yield of the analogous tricyclic azetidinone **22** (70%), mp 273°C, which displayed the infrared carbonyl vibration at 1770 cm^{-1}.

FIG. 3

Hydrogenolysis of **22** using palladium on charcoal in DMF afforded an almost quantitative yield of the tricyclic phenol **23**, which displayed the carbonyl frequency at lower wave numbers, 1715 cm^{-1}, due to H-bonding of the phenol proton with the azetidinone carbonyl. The presence of the azetidinone was proven by silylation with Me_3SiCl/Et_3N, which gave a product for which the azetidinone frequency reverted to its expected position at 1773 cm^{-1}. In both of the above cyclizations, no diastereomer of **20**/**22** or 7-*endo* cyclization product was detected.

The free radical cyclization of **18** gave the 6-*exo* intramolecular cyclization products as a 1:1 mixture of geometic isomers

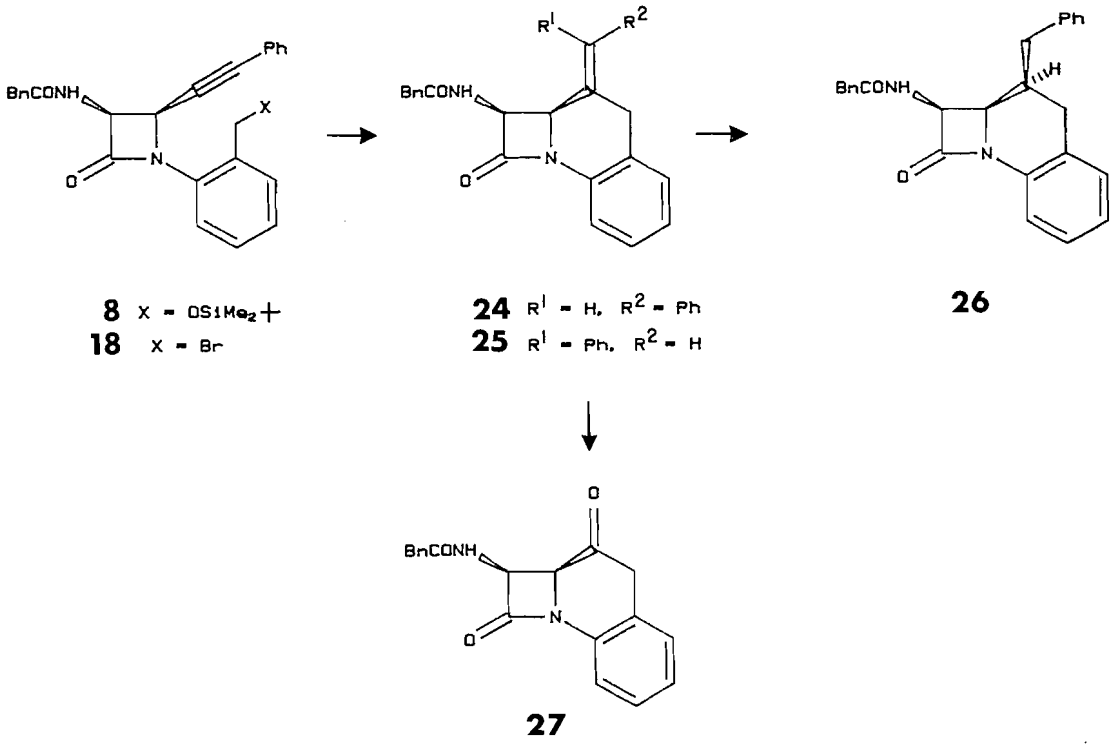

FIG. 4

in over 75% combined yield. These tricyclic azetidinones **24** and **25** were easily separated by flash chromatography and their structures assigned unambiguously by nOe (nuclear Overhauser effect) nmr experiments. The tricyclic azetidinones **24** and **25**, mp 189 and 196°C respectively, were found to be soluble in most organic solvents and stable in solution. Interestingly, the more sterically crowded *Z* isomer **25** displayed a slightly higher azetidinone carbonyl frequency at 1753 cm^{-1}, as compared to 1748 cm^{-1} for **24**. Hydrogenation of either **24** or **25**, using platinum black as catalyst, reduced the exocyclic double bond from the less hindered side to give the more crowded tricyclic benzo carbacephem **26** as the only product, mp 236–237°C. The coupling constant between H-4 and H-5 was found to be 3 Hz, distinctly smaller than for its diastereomer **20** (10 Hz). The infrared spectrum showed the carbonyl frequency at 1768 cm^{-1}, which was, not surprisingly, 13 wave numbers higher than its less constrained diastereomer **20**. Finally, a mixture of **24** and **25** was ozonolyzed to give the corresponding ketone **27** in good yield. Its infrared spectrum showed the azetidinone frequency at 1793 cm^{-1} and the ketone absorption at 1722 cm^{-1}. This ketone was considerably less stable than its olefinic precursor, and slowly decomposed on silica gel.

Overall, the infrared data indicate a trend of higher instability as the azetidinone carbonyl frequency increases from 1755 to 1824 cm^{-1}. The reactions carried out establish the usefulness of a radical process for the carbon–carbon bond formation in strained azetidinone. These free radical reactions also give good stereochemical control in the intramolecular cyclization onto an olefinic bond.

Experimental

The nmr spectra were recorded on a Varian XL-200 or XL-300 spectrometer using TMS as internal standard, and the assignments were determined unambiguously by decoupling, nOe, or 2D experiments when necessary. The infrared spectra were recorded on Perkin Elmer 297 or Nicolet FT 7000 ir spectrometers. Mass spectra (ms) were obtained on MP 5984A or LKB 9000 mass spectrometers, ion source 250°C and 70 eV electron impact, direct inlet (unless otherwise stated); *m/z* (assignment, relative intensity). Melting points were determined on a Gallenkamp block and are uncorrected. Column chromatography was performed using Woelm Silica, 32–63 μm size, and the hplc separations were performed using an Altex Ultrasphere-Si column.

The *cis*-azetidinones **4**, **5**, and **8** were prepared by a procedure as described for **6** (2*a*) and **7** (2*b*).

Bromo azetidinone 4

Prepared in 78% yield from its corresponding azide; mp 138–139°C; ir (KBr) ν_{max}: 3300 (NH), 1771 (azetidinone), 1654 (amide); ^1H nmr ($CDCl_3$) δ: 3.51 (s, 2H, CH_2), 5.31 (dd, 1H, C3-H, J = 5.3, 8), 5.45 (dd, 1H, C4-H, J = 5.4, 8), 5.9 (dd, 1H, C5-H, J = 8, 16), 6.15 (d, 1H, N-H, J = 8), 6.52 (d, 1H, C6-H, J = 16), 7.03–7.51 (m, 14H, Ar-H); ^{13}C nmr ($CDCl_3$) δ: 43.4 (CH_2), 59.9 (C3), 63.4 (C4), 117–136 (20 C, C5, C6 and Ar-C), 165.7 (C2), 171.4 (amide carbonyl); ms (150°C): 460/462 (M^+, 0.6), 284 ($M^+ - C_{10}H_9NO_2$, 32), 263 ($M^+ - C_{18}H_{17}NO$, 38.8), 197 (40.7), 171 (72.6), 145 (67.6), 91 (100). *Mol. Wt.* (high resolution ms) calcd. for $C_{25}H_{21}O_2N_2Br$: 460.0783; found: 460.0799.

Free radical cyclization of 4

Tributyltin hydride (170 mg, 0.55 mmol), AIBN (catalytic amount), and dry benzene (3 mL) were added to azetidinone **4** (213 mg, 0.46 mmol) and dry benzene (20 mL) at reflux temperature during 20 h (syringe pump) under an inert atmosphere. The mixture was cooled to room temperature and the solvent removed. The residual yellow oil was dissolved in acetonitrile (30 mL), washed with hexane (3 × 30 mL), and the solvent removed. High performance liquid chromatography (hplc) using isopropanol/hexane (1:5) as eluent gave starting material (same spectroscopic data as **4**) and the following products:

Reduction product **9** (15%); ir (KBr) ν_{max}: 1765 (azetidinone), 1657 (amide); ^1H nmr ($CDCl_3$) δ: 3.56 (s, 2H, CH_2), 4.95 (dd, 1H, C4-H, J = 5, 8), 5.53 (dd, 1H, C3-H, J = 5, 8), 5.98 (dd, 1H, C5-H, J = 8, 16), 6.61 (d, 1H, C6-H, J = 16), 7.01–7.44 (m, 16H, N-H and Ar-H).

Tricyclic benzo carbapenem **10** (5%); mp 121°C: ir (KBr) ν_{max}: 3305 (NH), 1805 (azetidinone), 1664 (amide); ^1H nmr ($CDCl_3$) δ: 2.95 (dd, 1H, C6-Hb, J = 13.8, 18), 3.18 (dd, 1H, C6-Ha, J = 6.2, 13.8), 3.34–3.45 (m, 1H, C5-H), 3.45 (dd, 2H, CH_2, J = 4, 16), 4.32 (dd,

1H, C4-H, J = 5, 8), 5.39 (dd, 1H, C3-H, J = 5, 8), 5.73 (d, 1H, N-H, J = 8), 7.05–7.32 (m, 14H, Ar-H); ms (260°C): 382 (M^+, 100), 337 ($M^+ - 45$, 56), 247 ($M^+ - BnCONH_2$, 96), 207 ($M^+ - C_{10}H_9NO_2$, 53.1). *Mol. Wt.* (high resolution ms) calcd. for $C_{25}H_{22}N_2O_2$: 382.1681; found: 382.1734.

Azepinone **11** (35%); ir (KBr) ν_{max}: 3290 (NH), 1680 (lactam), 1657 (amide); ^{1}H nmr ($CDCl_3$) δ: 3.63 (s, 2H, CH_2CO), 4.31 (dd, 2H, CH_2Ar, J = 3, 5), 4.56 (d, 1H, C4-H, J = 5.2), 5.68 (dd, 1H, C3-H, J = 5, 6), 6.78 (d, 1H, N-H, J = 6), 6.93–8.0 (m, 15H, Ar-H); ms (111°C): 382 (M^+, 0.23), 291 ($M^+ - Bn$, 0.3), 207 ($M^+ - C_{10}H_9NO_2$, 31.3), 206 (24.4), 130 (100).

Repeating the above cyclization, except adding 1.5 equiv. of tributyltin hydride over a 3-h period, gave a precipitate, after evaporation of the solvent and trituration of the corresponding residue with carbon tetrachloride. The crystals were filtered off and washed with hexane to give **10** (24%) as colorless crystals, with identical spectroscopic data as before.

Bromo azetidinone 5

Prepared in 71% yield from its corresponding azide; mp 151–152°C as colorless crystals; ir (KBr) ν_{max}: 2280 (C≡C), 1741 (azetidinone), 1647 (amide); ^{1}H nmr ($CDCl_3$) δ: 3.65 (s, 2H, CH_2), 5.48 (d, 1H, C4-H, J = 5.4), 5.75 (dd, 1H, C3-H, J = 5.4, 9), 6.78 (d, 1H, N-H, J = 9), 7.11–7.6 (m, 14H, Ar-H); ^{13}C nmr ($CDCl_3$) δ: 43.46 (CH_2), 53.62 (C4), 59.22 (C3), 81.34 (C5); 90.07 (C6), 118–133 (18C, Ar-C), 165.5 (C2), 171.22 (amide carbonyl); ms (195°C): 458/460 (M^+, 5.7), 283/285 ($M^+ - C_{10}H_9NO_2$, 20.8), 175 ($M^+ - 283$, 5.7).

Free radical cyclization of 5

Tributyltin hydride (150 mg, 0.5 mmol), AIBN (cat.), and dry benzene (1 mL) were added to azetidinone **5** (193 mg, 0.42 mmol) and dry benzene (20 mL) at reflux temperature during 5 h (syringe pump) under an inert atmosphere. The mixture was cooled to room temperature and the solvent removed. The residue was dissolved in acetonitrile (30 mL), washed with hexanes (3 × 30 mL), and the solvent removed. Trituration of the residue with carbon tetrachloride/acetonitrile gave the tricyclic azetidinones **12** and **13** as a yellow precipitate (4:3 ratio respectively, 31%), mp 140–145°C. From the filtrate was isolated starting material (5%), reduction product **14** (11%), and the azepinone **15** (27%), after separation by column chromatography using ethyl acetate/hexane as eluent (1:1).

Tricyclic azetidinone **12**; ^{1}H nmr ($CDCl_3$) δ: 3.60 (dd, 1H, CH_2, J = 2.5, 17), 5.79 (dd, 1H, C3-H, J = 5.9, 9.2), 6.00 (d, 1H, N-H, J = 9.2), 6.32 (d, 1H, C6-H, J = 2.5), 7.07–7.54 (m, 14H, Ar-H); ^{13}C nmr ($CDCl_3$) δ: 43.42 (CH_2), 58.34 (C4), 62.13 (C3), 126.01 (C6), 122–144 (Ar-C and C5), 171.00 (C1), 175.87 (amide carbonyl).

Tricyclic azetidinone **13**; ^{1}H nmr ($CDCl_3$) δ: 3.06 (dd, 2H, CH_2, J = 17, 34), 5.51 (dd, 1H, C4-H, J = 3.3, 6), 5.66 (d, 1H, N-H, J = 10), 6.10 (dd, 1H, C3-H, J = 6, 10), 6.99 (d, 1H, C6-H, J = 3.3), 7.07–7.54 (m, 14H, Ar-H); ^{13}C nmr ($CDCl_3$) δ: 42.79 (CH_2), 58.02 (C4), 61.86 (C3), 123.42 (C6), 122–144 (Ar-C and C5), 170.32 (C2), 175.77 (amide carbonyl); ir of **14** and **15** (KBr) ν_{max}: 3290–3310 (NH), 1824 (azetidinone), 1640–1647 (amide).

Reduction product **14**; ir (KBr) ν_{max}: 3300 (NH), 1745 (azetidinone), 1649 (amide); ^{1}H nmr ($CDCl_3$) δ: 3.65 (s, 2H, CH_2), 5.03 (d, 1H, C4-H, J = 5), 5.72 (dd, 1H, C3-H, J = 5, 8), 6.26 (d, 1H, N-H, J = 8), 7.05–7.59 (m, 15H, Ar-H); ms (111°C) chemical ionization, isobutane: 381 ($M^+ + 1$, 22.1), 363 ($M^+ - BnCO$, 15.8), 353 (381 − CO, 10.1), 206 ($M^+ - C_{10}H_9NO_2$, 100), 176 ($M^+ - 206$, 65.7).

Azepinone **15**; ^{1}H nmr ($CDCl_3$) δ: 4.19 (s, 2H, CH_2CO), 6.86–7.50 (m, 11H, Ar-H and C=CH), 8.85 (bs, 1H, NH).

Bromo azetidinone 8

Prepared in 49% yield from its corresponding azide; mp 123–124°C (colorless crystals); ir (KBr) ν_{max}: 3210 (NH), 1768 (azetidinone), 1645 (amide); ^{1}H nmr ($CDCl_3$) δ: 0.048 and 0.056 (s, 6H, $SiMe_2$), 0.907 (s, 9H, *tert*-butyl), 3.67 (s, 2H, CH_2CO), 5.18 (2, 1H, C4-H, J = 8), 5.7 (s, 2H, CH_2O), 5.71 (dd, 1H, C3-H, J = 5, 10), 6.3 (d, 1H, N-H, J = 10), 7.1–7.5 (m, 14H, Ar-H); ms (175°C): 524 (M^+, 0.1) 467 (M^+ − *tert*-butyl, 1.9), 349 ($M^+ - C_{10}H_9NO_2$, 1.7), 292 (M^+ − C2C3 − *tert*-butyl, 26.1).

Silyl azetidinone 16

Tetrabutylammonium fluoride (4.69 g, 17 mmol) and THF (5 mL) were added to azetidinone **6** (5.0 g, 9.5 mmol) and 150 mL of dry THF at 0°C under a nitrogen atmosphere. After 30 min, water (2 mL) was added and the solvent removed. The residue was then purified by flash chromatography using ethyl acetate/hexane (1:1) as eluent to give the alcohol as colorless crystals (72%); mp 174–175°C; ir (KBr) ν_{max}: 1756 (azetidinone), 1660 (amide); ^{1}H nmr (DMSO-d_6) δ: 3.34 (s, 2H, CH_2CO), 4.52–4.56 (bs, 1H, O-H), 4.53 (s, 2H, CH_2—O), 4.82 (dd, 1H, C4-H, J = 5, 86), 5.25 (dd, 1H, CH_3-H, J = 5, 8), 6.05 (dd, 1H, C5-H, J = 8, 16), 6.40 (d, 1H, C6-H, J = 16), 6.8–7.28 (m, 19H, Ar-H), 8.26 (d, 1H, N-H, J = 8); ms (230°C): 410 ($M^+ - 2H^+$, 2.6), 333 (410 − Ph, 3.3), 320 ($M^+ - Bn - H^+$, 50.1).

To the above alcohol (700 mg, 1.7 mmol) and dry methylene chloride (100 mL) at 0°C under a nitrogen atmosphere were added carbon tetrabromide (560 mg) followed by slow addition of triphenylphosphine (430 mg, 1.97 mmol). After 3 h of stirring, the solution was allowed to warm up to room temperature, and purified by column chromatography using ethyl acetate/hexane (1:3) to give the azetidinone **16** as colorless crystals (62.5%) after recrystallization from ethyl acetate/hexane; mp 123–124°C; ir (KBr) ν_{max}: 3310 (NH), 1744 (azetidinone), 1644 (amide); ^{1}H nmr ($CDCl_3$) δ: 3.60 (s, 2H, CH_2—O), 4.72 (dd, 2H, CH_2Br, J = 10.4, 22), 5.02 (dd, 1H, C4-H, J = 5, 8.2), 5.55 (dd, 1H, C3-H, J = 5, 8), 6.08 (dd, 1H, C5-H, J = 8.2, 16), 6.38 (d, 1H, N-H, J = 8), 6.64 (d, 1H, C6-H, J = 16), 7.1–7.34 (m, 14H, Ar-H); ms (305°C): 474/476 (M^+, 4/3.9), 395 ($M^{+\bullet} - Br^\bullet$, 33), 394 ($M^+ - HBr$, 100), 317 ($M^+ - Ph - HBr$, 70.5), 275 ($M^+ - HBr - BnCO$, 43.7), 220 ($M^{+\bullet} - C_{10}H_9NO_2 - Br^\bullet$, 45), 263 ($M^+ - C_{18}H_{17}NO$, 17).

Silyl azetidinone 17

Prepared as described for **16**. The alcohol was obtained in 65% yield from **9** as colorless crystals, mp 163°C; ^{1}H nmr ($CDCl_3$) δ: 3.50 (s, 2H, CH_2CO), 4.12 (dd, 1H, O-H, J = 4, 8), 4.64 and 4.82 (dd, 2H, CH_2—O, J = 8, 12 and 4, 12), 5.08 (s, 1H, $PhCH_2Ar$), 5.13 (dd, 1H, C4-H, J = 5, 8), 5.24 (dd, 1H, C3-H, J = 5, 8), 6.07 (dd, 1H, C5-H, J = 8, 16), 6.40 (d, 1H, C6-H, J = 16), 6.80 (d, 1H, N-H, J = 8), 6.9–7.39 (m, 13H, Ar-H); ms (200°C): 518 (M^+, 0.1), 343 ($M^+ - C_{10}H_9NO_2$, 0.9), 263 ($M^+ - C_{15}H_{13}NO_3$, 42.7), 175 ($M^+ - NC_4$, 3.0).

Azetidinone **17** was obtained as colorless crystals in 81% yield from the above alcohol; mp 145–146°C; ir (KBr) ν_{max}: 3270 (NH), 1758 (azetidinone), 1656 (amide); ^{1}H nmr ($CDCl_3$) δ: 3.56 (s, 2H, CH_2CO), 4.66 (dd, 2H, CH_2Br, J = 10, 10.1), 5.05 (s, 2H, $PhCH_2Ar$), 5.12 (dd, 1H, C4-H, J = 5, 8), 5.41 (dd, 1H, C3-H, J = 5.8), 5.96 (bd, 1H, N-H, J = 8), 6.09 (dd, 1H, C5-H, J = 8, 16), 6.42 (d, 1H, C6-H, J = 16), 6.88–7.39 (m, 18H, Ar-H); ms (285°C): 580/582 (M^+, 0.8/0.7), 501 ($M^{+\bullet} - Br$, 38.4), 500 ($M^+ - HBr$, 100), 423 ($M^+ - HBr - Ph$, 30), 381 ($M^+ - HBr - BnCON$, 19.9).

Silyl azetidinone 18

Prepared as described for **17**. The alcohol was obtained in 51% yield from **8** as colorless crystals; mp 184–185°C; ir (KBr) ν_{max}: 3305 (NH), 1768 (azetidinone), 1650 (amide); ^{1}H nmr (DMSO-d_6) δ: 3.29 (s, 1H, O-H), 3.61 (s, 2H, CH_2CO), 4.69 (s, 2H, CH_2—O), 5.23 (d, 1H, C4-H, J = 5), 5.50 (dd, 1H, C3-H, J = 5, 8), 7.08–7.46 (m, 15H, Ar-H and N-H); ms (208°C) chemical ionization, isobutane: 411 ($M^+ + 1$, 19.4), 319 ($M^+ + 1 - C_{10}H_9NO_2$, 9.1). *Mol. Wt.* (high resolution ms (208°C)) calcd. for $C_{26}H_{22}N_2O_3$: 410.1629; found: 410.1685.

Azetidinone **18** was obtained in 63% yield from the above alcohol as colorless crystals; mp 135–136°C; ir (KBr) ν_{max}: 3290 (NH), 1755 (azetidinone), 1666 (amide); ^{1}H nmr ($CDCl_3$) δ: 3.69 (s, 2H, CH_2CO), 4.64 (dd, 2H, CH_2Br, J = 10, 18), 5.21 (d, 1H, C4-H, J = 5), 5.75 (dd, 1H, C3-H, J = 5, 8), 6.30 (d, 1H, N-H, J = 8), 7.05–7.51 (m, 14H, Ar-H); ms (195°C): 472/474 (M^+, 0.3), 343 ($M^{+\bullet} - Br^\bullet$, 1.8), 392 ($M^+ - Bn$, 1.8), 392 ($M^+ - HBr$, 5.8), 218 ($M^{+\bullet} - Br^\bullet - C_{10}H_9NO_2$, 56.8), 217 (41.2), 175 (28.2).

Tricyclic benzo carbacephem ***26***

To a mixture of azetidinones **24** (10 mg) and **25** (10 mg), ethyl acetate (5 mL), and ethanol (3 mL) was added platinum black (3 mg). The mixture was stirred overnight at room temperature under a hydrogen atmosphere, was then filtered off, and the solvent removed. The residue was purified by flash chromatography using ethyl acetate/hexane as eluent to give, after recrystallization from chloroform/carbon tetrachloride, the tricyclic azetidinone **26** as colorless crystals (25%); mp 237°C; ir (KBr) ν_{max}: 3305 (NH), 1768 (azetidinone), 1641 (amide); ^{1}H nmr ($CDCl_3$) δ: 1.91–2.04 and 2.36–2.65 (m, 5H, C5-H, C6-H, and C7-H), 3.65 (dd, 2H, CH_2CO, J = 2.5, 6), 4.25 (dd, 1H, C4-H, J = 3, 5), 5.41 (dd, 1H, C3-H, J = 5, 6), 6.01 (d, 1H, N-H, J = 6), 6.7–7.5 (m, 14H, Ar-H); ms (220°C): 396 (M^+, 2.1), 305 (M^+ − Bn, 1.7), 277 (M^+ − BnCO, 23.1), 262 (M^+ − $BnCONH_2$, 20), 222 (M^+ + H − $C_{10}H_9NO_2$, 14.2), 175 (14.4). *Mol. Wt.* (high resolution ms) calcd. for $C_{26}H_{24}O_2N_2$: 396.1837; found: 396.1758.

Tricyclic ketoazetidinone **27**

A mixture of azetidinones **24** (10 mg) and **25** (10 mg), methanol (2 mL), and dichloromethane (2 mL) at −78°C was ozonized for 5 min. The light blue solution was stirred for 15 min, and a stream of nitrogen was passed through the solution for 15 min. Dimethylsulfide (excess) was added and the mixture left overnight at room temperature. The solvents were removed and the residue purified by column chromatography using ethyl acetate/hexane (1:1) to give the ketone **27** as a yellow **oil (75% yield)**; ir (neat) ν_{max}: 3160 (NH), 1793 (azetidinone), 1722 (ketone), 1647 (amide); ^{1}H nmr ($CDCl_3$) δ: 3.55 (dd, 1H, C6-Ha, J = 1.8, 22), 3.56 (s, 2H, CH_2CO), 4.06 (d, 1H, C6-Hb, J = 22), 4.06 (dd, 1H, C4-H, J = 1.8, 5.7), 4.74 (dd, 1H, C3-H, J = 5.7, 7.2), 6.05 (d, 1H, N-H, J = 7.2), 7.17–7.39 (m, 9H, Ar-H); ms (148°C) chemical ionization, isobutane: 321 (M^+ + 1, 48.4), 320 (M^+, 2.7), 319 (14.7), 304 (321 − 17, 38.8), 303 (321 − 18, 48.3), 176 (14.6), 146 (M^+ + 1 − $C_{10}H_9NO_2$, 100).

Stereochemistry of 3-carboxylated 2,5-dihydrothiophene formation[1,2]

JOHN M. MCINTOSH AND IVY E. E. HAYES[3]
Department of Chemistry, University of Windsor, Windsor, Ont., Canada N9B 3P4

Received May 20, 1986

This paper is dedicated to Dr. O. E. (Ted) Edwards

JOHN M. MCINTOSH and IVY E. E. HAYES. Can. J. Chem. **65**, 110 (1987).

The preparation of 2-carboxylated-1,3-dienes from carbomethoxy vinylphosphonates and 2-mercaptocarbonyl compounds has been shown to give stereoisomeric mixtures. This may be due to the formation of stereoisomers of the intermediate 2,5-dihydrothiophenes and (or) to the occurrence of both modes of disrotatory sulfur dioxide elimination.

JOHN M. MCINTOSH et IVY E. E. HAYES. Can. J. Chem. **65**, 110 (1987).

On démontre que la préparation de diènes-1,3 portant un groupement carboxyle en position-2, effectuée à partir de carbométhoxy vinylphosphonates et de composés mercapto-2 carbonyles, conduit à des mélanges de stéréoisomères. Ce résultat peut être dû à formation de stéréoisomères des dihydro-2,5 thiophènes intermédiaires et (ou) à la présence de chacun des deux modes d'éliminations disrotatoires du dioxyde de soufre.

Some time ago we described the reaction of 2-mercaptoaldehydes and ketones (**1**) with vinylphosphonium salts as a preparative route to substituted 2,5-dihydrothiophenes (DHT's) (**3**) (2). This Michael–Wittig sequence was shown to afford products that were predominantly the *cis* 2,5-disubstituted stereoisomers when the 3-substituent was small (R′ = H), but increasing amounts of the *trans*-isomer were formed as the steric bulk of the ring substituents increased (3). These results were rationalized on the basis of a model (**2**) in which the substitutents were preferentially on the side opposite the bulky triphenylphosphine moiety. Oxidation of the DHT to the sulfone, followed by thermolysis, led to the disrotatory (4) elimination of sulfur dioxide and the formation of a 1,3-diene in a regiospecific and stereoselective manner by the formal joining of two vinyl moieties (Scheme 1).

In subsequent work it was shown that vinylphosphonates (**4**) bearing an α-carbomethoxy group afforded excellent yields of 3-carboxylated DHT's (**6**) and, after oxidation and thermolysis, 2-carbomethoxy-1,3-dienes **8** (Scheme 2) (5). In view of the potential applications of compounds of type **8** to natural product syntheses (6), an examination of the stereochemistry of the DHT formation and decomposition was deemed to be worthwhile and this brief report deals with that aspect of the reaction.

It is known that the attack of the anion of a phosphonate, like that of a phosphorane, on a carbonyl group is a reversible process (7). Thus the isomeric distribution of DHT's should reflect the thermodynamic stabilities of the intermediate **5** that is undergoing irreversible decomposition. Comparison of the intermediate **2** (Scheme 1), in which a hydrogen is attached to the phosphorus-bearing carbon atom (α-substituted vinylphosphonium salts do not give DHT products (8)), with **5** (Scheme 2), in which a carbomethoxy group is in this position, suggests that the tendency toward the formation of the *cis* 2,5-disubstituted isomers should be lowered in the latter case.

Two vinylphosphonates (**4***a* and **4***b*) were utilized with one 2-mercaptoaldehyde (**1***a*) and two 2-mercaptoketones (**1***b*, *c*) giving five DHT's (**6***a–e*) with varying substitution patterns, two of which can exist in only one stereoisomeric form. The products and their yields are shown in Table 1, and Table 2 summarizes the spectroscopic data for the new compounds. As was found with the noncarboxylated DHT's (2), it was not possible to separate the stereoisomers by either thin-layer chromatography (tlc) or gas chromatography (gc). In addition, the spectra, although confirming the presence of stereoisomeric mixtures in many cases, could not be used to unambiguously determine isomer ratios. In an attempt to circumvent this problem, the DHT's were oxidized to the corresponding sulfones **7** (2), and thermolysis to the dienes **8** under two conditions was studied. Direct injection into a gas chromatograph (inlet temperature 270°C) led to the elution of the component dienes. Integration of the peaks led to the isomer ratios. Alternatively, decomposition of the sulfones in refluxing toluene for varying lengths of time gave the same dienes, but in ratios that were, in some cases, time dependent. Because separation of the components on a preparative basis was not achieved, the stereochemistry of each component is uncertain. However, the number of components and the time dependence of their abundance gives information regarding the stereochemistry of the DHT's and also of the cheletropic sulfur dioxide elimination reaction.

The results of the diene decompositions are presented in Table 3. From these data, the following conclusions can be drawn. The two sulfones (**7***a* and **7***b*) that can exist in only one stereoisomeric form both give two dienes. Collection of the mixture and reinjection into the gas chromatograph gave the same peaks in the same ratios, establishing that, at least in these cases, no diene isomerization was occurring under these "direct decomposition" conditions. If it is assumed that the presence of the 3-carbomethoxy group does not affect the stereochemical nature of the sulfur dioxide elimination, it can be stated that both modes of disrotatory ring opening are occurring. The initial product favors the *Z*-isomer but prolonged heating causes equilibration toward the more stable *E* form. In the case of **7***c*, two sulfone stereoisomers are possible but only two dienes are expected since the cyclohexene double bond must be *cis*. In this case, a 1:1 mixture of two dienes is obtained under direct decomposition conditions and this ratio does not change on prolonged heating, a result which can be rationalized either on the basis of equal amounts of the two sulfone stereoisomers or on very rapid equilibration of the two isomers. In the final two instances (**7***d* and **7***e*), two sulfone isomers and four diene components are possible, but only three of the latter are formed.

4*b*	iPr	**1***c*	Me	Me	**6***e*	31	**7***e*	69

[a]Reference 5*a*.

Prolonged heating of these does not significantly alter the component ratios. In the absence of definitive identification of the diene component stereochemistry, it is not possible to unambiguously determine the stereochemical composition of the sulfone mixtures. However, at best, **7***d* is a 9:1 mixture and, at worst (the more likely scenario), a 3:1 mixture. Similar considerations apply to **7***e*.

In conclusion, the following can be stated. The presence of a 3-carbomethoxy group significantly and negatively affects the stereochemical outcome of the use of DHT's for 1,3-diene synthesis. This may be due to steric influences in the transition state for DHT formation, which gives larger *trans*/*cis* ratios than when vinylphosphonium salts are used, and (or) to significant interactions in the transition state for sulfur dioxide elimination, which allows both modes of disrotatory ring opening to occur. The overall result is that, although assembly of the carbon skeleton of the 2-carbomethoxy-1,3-diene system remains facile, stereochemical control of the process is not feasible.

Experimental

Infrared spectra were obtained on a Perkin Elmer Model 180 instrument or a Nicolet 5:DX (FT) instrument in $CHCl_3$ solution (unless otherwise noted) and are reported in cm^{-1}. The ^1H nmr spectra were obtained on a Varian EM360 or Bruker WP-80 instrument in $CDCl_3$ solution and the chemical shift values are relative to internal TMS as standard. Gas chromatographic analyses were performed on a Varian Model 3700 instrument using a helium flow rate of 1 cm^3/s. The injector port temperature was 270°C and the columns used were 10 ft × 0.25 in. 20% SE-30 on Chromosorb W or 50 cm × 0.125 in. 5% OV-101 on Chromosorb W.

Starting materials

Mercaptoaldehyde **1***a* was purchased in the form of its dimer (1,4-dithiane-2,5-diol); compounds **1***b* (9), **1***c* (10), and **4***a* (5*a*) were prepared according to literature procedures.

*Methyl 2-diethylphosphono-4-methyl-2-pentenoate (4*b*)*

To a stirred solution of isobutyraldehyde (11.97 g, 0.166 mol) and diethyl phosphonoacetate (6.99 g, 0.033 mol) in 250 mL of dry benzene was added a mixture of 1.5 mL acetic acid and 0.5 g of piperidine. The solution was heated at reflux under a Dean–Stark water separator for 55 h, at which time gc analysis indicated the reaction was complete. The solvent was evaporated and the residue distilled to give 7.39 g (90%) of **4***b* as a mixture of diastereomers; bp 97–105°C (0.5 Torr; 1 Torr = 133.3 Pa). *Anal.* calcd. ($C_{11}H_{21}O_5P$): C 49.99, H 8.01; found: C 50.23, H 7.84.

General procedure for dihydrothiophene preparation and oxidation

To a refluxing, nitrogen-blanketed suspension or solution of **1** (0.033 mol) in 250 mL of CH_2Cl_2 containing 5.3 g of Et_3N was added dropwise a solution of 0.02 mol of vinyl phosphonate **4** in 50 mL of CH_2Cl_2. After 14–24 h the reaction was complete, as shown by gc analysis. The solution was cooled, washed with water (2 × 200 mL), 5% HCl (2 × 150 mL), dried, and evaporated to give the crude dihydrothiophene as a yellow oil. Chromatography (neutral alumina, activity grade I) using 1:1 petroleum ether:ether as eluant eluted the pure DHT in the first 300 mL. Yields of products are given in Table 1 and physical and spectroscopic data in Table 2. Analytical data for new compounds are given in Table 4.

Oxidation to the sulfones 7 was accomplished according to the literature procedure (5*a*). In the case of **6***e*, oxidation was incomplete even with several equivalents of peracid and the sulfone was contaminated with small amounts of sulfoxide (ir and mass spectra). DHT sulfoxides are known to decompose nonstereospecifically but at much

higher temperatures than sulfones (11), and this mixture was used directly in the thermolysis experiments.

Sulfone thermolyses

Injection of sulfones into the injection port of a gas chromatograph (neat or in solution) effected elimination of SO_2, and the dienes were eluted. Flask thermolyses were performed by suspending the sulfone in dry toluene and heating at reflux under nitrogen until tlc indicated the absence of starting material. The solvent was removed by distillation and the residue chromatographed on silica gel using 20% petroleum ether in ether. The collected fractions of dienes were combined and analyzed by gc. Results of all thermolyses are given in Table 3. The mass spectra (field desorption) and ir and nmr spectra of the diene mixtures indicated that only the expected dienes were present, but were not interpretable in terms of the stereochemistry of the components.

Received Received June 4, 1986

This paper is dedicated to Dr. O. E. (Ted) Edwards

KAZIMIERZ ANTCZAK, JOHN F. KINGSTON, ALEX G. FALLIS, and ALFRED W. HANSON. Can. J. Chem. **65**, 114 (1987).

Stereoselective total syntheses of (±)-sinularene and (±)-5-epi-sinularene are described. The sequence employs a "blocked" cyclopentadiene in which the cyclopropane unit also serves as a latent methyl group. Thus intramolecular [4 + 2] cycloaddition of the substituted methyl spiro[2.4]hepta-4,6-dien-1-yl-2-pentenoate **13***c* affords 5-benzyloxy-6-isopropyl-8-carbomethoxytetracyclo[5.4.$0^{1,7}$.$0^{2,4}$.$0^{2,9}$]undec-10-ene (**14***c*), which after selective hydrogenolysis generates the tricyclo[4.4.$0^{1,6}$.$0^{2,8}$]decane (sinularene) ring system. Removal of the secondary hydroxyl function by elimination and hydrogenation ($Ph_3P/CCl_4/CH_3CN$; H_2/Pd/C), reduction of the methyl ester ($LiAlH_4$), and introduction of the exocyclic double bond (acetate pyrolysis, 550°C) completes the synthesis of (±)-sinularene in 12 steps from aldehyde **7**. A parallel series of reactions employing the isopropyl triene epimer **13***a* affords (±)-5-epi-sinularene. X-ray analyses of the triene **13***a* and the adduct **14***a* are also reported.

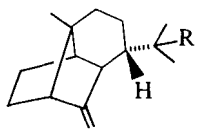
KAZIMIERZ ANTCZAK, JOHN F. KINGSTON, ALEX G. FALLIS et ALFRED W. HANSON. Can. J. Chem. **65**, 114 (1987).

On décrit les synthèses stéréosélectives du (±)-sinularène et du (±)-épi-5 sinularène. Ces synthèses impliquent l'utilisation d'un cyclopentadiène «bloqué» dans lequel l'unité cyclopropane sert aussi de groupement méthyle latent. Ainsi, la cycloaddition intramoléculaire [4 + 2] du spiro[2.4]heptadiène-4,6 yl-1 pentène-2 oate de méthyle substitué (**13***c*) conduit au benzyloxy-5 isopropyl-6 carbométhoxy-8 tétracyclo[5.4.$0^{1,7}0^{2,4}0^{2,9}$]undécène-10 (**14***c*) qui, après hydrogénolyse sélective, conduit au système cyclique tricyclo[4.4.$0^{1,6}0^{2,8}$]décane du sinularène. L'enlèvement de la fonction hydroxyle secondaire, par le biais d'une élimination suivie d'une hydrogénation ($Ph_3P/CCl_4/CH_3CN$; H_2/Pd/C), suivie d'une réduction de l'ester méthylique ($LiAlH_4$) et de l'introduction de la double liaison exocyclique (pyrolyse de l'acétane, 550°C) complètent la synthèse du (±)-sinularène, en 12 étapes à partir de l'aldéhyde **7**. Une série de réactions parallèles, appliquée au triène portant un groupement isopropyle de stéréochimie épimère **13***a*, conduit au (±)-épi-5 sinularène. On rapporte aussi des études par diffraction des rayons-X qui ont été effectuées sur le triène **13***a* ainsi que sur l'adduit **14***a*.

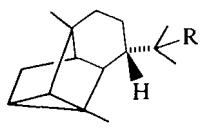
[Traduit par la revue]

Introduction

Marine invertebrates are a rich source of secondary metabolites and in recent years have afforded a broad cross section of interesting terpenoid skeletons (1). The coelenterates, particularly, have provided an array of new sesquiterpenes including the structurally unusual hydrocarbon (−)-sinularene (**1**). Sinularene was isolated from the alcyonacean soft coral *Sinularia mayi* and its structure established in 1977 by X-ray analysis (2, 3). More recently, the related esters 12-acetoxysinularene (**2**) and 12-acetoxycyclosinularene (**4**) were obtained from a



1 R = H
2 R = OAc



3 R = H
4 R = OAc

closely related stoloniferan soft coral *Claularia inflata* (4). To the best of our knowledge the corresponding parent hydrocarbon cyclosinularene (**3**) still awaits discovery.

The synthesis of natural products continues to play a significant role in the development of modern organic chemistry and thus, not surprisingly, these structures have attracted considerable attention as synthetic targets. Three total syntheses of (±)-sinularene have been reported. The first by Collins and Wege utilized a Wagner–Meerwein rearrangement, followed by intramolecular alkylative ring closure (5). Subsequently Oppolzer *et al.* employed an intramolecular "magnesium-ene" reaction as the key step (6) and, more recently, have also prepared 12-acetoxysinularene by this procedure (7). Coincident with the completion of our own work (8), Piers and Jung described an efficient Cope rearrangement sequence to the bicyclo[3.2.1]octane nucleus, followed by intramolecular alkylation to generate sinularene (9).

Results

(a) Synthetic plan (see Scheme 1)

Our own approach is based on an intramolecular Diels–Alder reaction sequence, a reaction in which there is considerable current interest and which has recently been applied to a number of natural product syntheses with notable success (10–13). The route selected, outlined briefly in retrosynthetic fashion in Scheme 1, utilizes the cyclopropane ring present in the spiro[2.4]heptatriene system **6** to block the normally dominant 1,5 sigmatropic rearrangement of cyclopentadienes. This cyclopropyl unit subsequently serves as a source of latent functionality to generate the requisite tertiary methyl group from the tetracyclic Diels–Alder adduct of type **5** by selective cyclo-

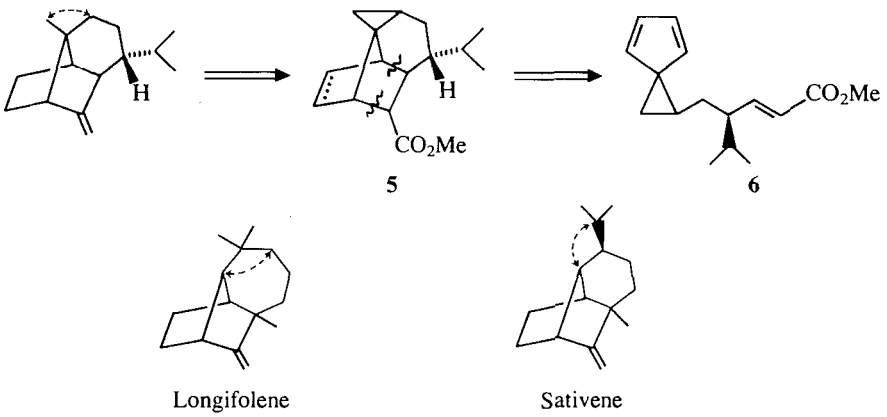

SCHEME 1

propane bond cleavage to provide a direct entry into the tricyclo[4.4.$0^{1,6}$.$0^{2,8}$]decane ring system possessed by sinularene. This strategy thus requires, in a retrosynthetic sense, the construction of a bond between the tertiary methyl group and the neighbouring methylene position (arrows) prior to double disconnection of the "bicyclo[2.2.1]heptane" nucleus. In the forward, synthetic direction the cyclopropane step corresponds to the reverse of an intramolecular alkylation. We have described earlier the general potential of this strategy for the eventual total synthesis of longifolene (14, 15) and sativene (16, 17) by controlled cleavage of the other cyclopropane bonds with suitably substituted precursors (arrows) (18).

(b) Preparation of hydroxy-ester 8 (see Figure 1)

Our initial intention to utilize triene **6** directly was thwarted by the discovery that it would not cyclize and that a C5 oxygen substituent was essential to ensure that the desired intramolecular cycloaddition proceeded as required (19). In addition, carrying the isopropyl function in the sidechain seemed advantageous so the correct stereochemistry could be established at an early stage. These considerations indicated that the substituted triene **13** (Scheme 2) was a desirable intermediate target, as it possessed these features as well as containing all 15 carbon atoms required for the natural product.[4]

The substituted triene **13** was elaborated from a series of condensations commencing with the aldehyde **7**, which was prepared by oxidation of the corresponding primary alcohol (20, 21) with active manganese dioxide (19). The initial aldol condensation of **7** with the anion derived from methyl 3-methylbutyrate and lithium diisopropylamide (LDA) was conducted at −78°C in tetrahydrofuran (THF). This led to a 47:30:14:2 mixture (based on isolated yields, total yield 93%) of the hydroxy-ester stereoisomers **8** (Fig. 1). The major isomer **8***c* (47%) arose from preferential attack of the *E*(O) enolate, as illustrated in **9**, on the aldehyde carbonyl from the less hindered direction and was assigned the (2*S**,3*S**,1′*S**)-configuration based on its conversion to (±)-sinularene.[4] The (2*R**,3*S**,1′*S**)-stereochemistry of the isomer **8***a* (30%) followed from the X-ray-difraction analysis described below and its conversion to (±)-5-epi-sinularene. Experimentally the chromatographic behaviour of the 14% component **8***b* and that of the **8***c* hydroxy-ester were very similar and thus it was more efficient to separate these compounds at the ether-alcohol stage (i.e., **11**, Scheme 2). In principle, the 2,3-*anti* selectivity of this coupling could be further enhanced if the conditions were altered to afford the *E*(O) enolate preferentially using modified aldol conditions (22). This has not been examined in the present instance due to our desire to have access to the various isomeric trienes **13***a–c*, in order to learn more about their cycloaddition behaviour and the unusual stereoelectronic effects of oxygen substituents in this series.

(c) Preparation of Diels–Alder adducts 14 (see Scheme 2)

The following set of parallel reactions converted the individual diastereomers **8** into the (4*R**,5*R**,1′*S**)-triene **13***c*, the (4*S**,5*R**,1′*S**)-triene **13***a*, and the (4*R**,5*S**,1′*S**)-triene **13***b*. The secondary alcohol **8** was protected as its benzyl ether in 80% yield upon generation of the alkoxide with sodium hydride in dimethoxyethane (DME) and alkylation with benzyl bromide. The resulting ether-ester **10** was reduced with lithium aluminum hydride in 95% yield to the primary alcohol **11**. Oxidation of **11** with pyridinium dichromate gave the aldehyde **12**, which was subjected to Wittig condensation with methyl (triphenylphosphoranylidene)acetate in refluxing tetrahydrofuran. In contrast to our earlier experience with **6**, these conditions resulted in simultaneous cyclization of triene **13***c* to the tetracyclic ester **14***c* in 72% overall yield. This implied a cycloaddition yield of approximately 95% and dramatically illustrated the beneficial influence of the C5 oxygen substituent.

In similar fashion the (4*S**,5*R**,1′*S**)-triene **13***a* also cyclized at 67°C (THF), although recycling was required since at this temperature the initial Diels–Alder reaction stopped at 50% completion. This implied that an equilibrium was established. However, this does not appear to be the exact explanation, since there was no evidence (^{1}H nmr) for any triene formation when a sample of the adduct **14***a* was heated in refluxing THF for 8 h, and cyclization at a higher temperature (110°C, toluene) failed to improve the cycloaddition yield beyond 50%. In contrast to the behaviour of **13***c* and **13***a*, the related isomeric (4*R**,5*S**,1′*S**)-triene **13***b* failed to cyclize to a detectable extent even in refluxing *o*-dichlorobenzene (180°C).

(d) Conversion of 14 into (±)-sinularene and (±)-5-epi-sinularene (see Scheme 2)

The direct preparation of the desired tetracyclic adducts **14***c* and **14***a* now permitted the introduction of the latent methyl functionality by hydrogenolysis. As expected from our pre-

[4]All the compounds described are racemic but only the enantiomers leading to the natural configuration of sinularene and 5-epi-sinularene are illustrated. The relative stereochemistries are indicated commencing with the *S** isomer of aldehyde **7** from which the (4*R**,5*R**,1′*S**)-triene **13***c* and sinularene were prepared. Thus rotation of the (4*S**,5*R**,1′*S**)-triene **13***a* affords the X-ray conformation in Fig. 3 and ring closure leads to **14***a* (Fig. 2).

For natural series: (a) $LiAlH_4$, ether, 0°C, 1 h, 95%; (b) PDC, CH_2Cl_2, 21°C, 24 h, 64%; (c) $Ph_3P{=}CHCO_2Me$, THF, 67°C, 12 h, 76%; (d) THF, 67°C, 12 h, 95%; (e) H_2, 10% Pd/C, 50 psi, MeOH, 21°C, 24 h, 85%; (f) Ph_3P/CCl_4, CH_3CN, 21°C, 24 h, 97%; (g) H_2, 10% Pd/C, 1 atm, MeOH, 21°C, 48 h, 99%; (h) $LiAlH_4$, ether, 0°C, 0.5 h, 99%; (i) Ac_2O/pyridine, 4°C, 15 h, 99%; (j) 550°C, flow, 77%.

SCHEME 2

liminary studies of related cyclopropyl ketones (18), hydrogenolysis of **14** in the presence of 10% Pd/C at 50 psi (1 psi = 6.9 kPa) cleaved the least substituted cyclopropane bond exclusively, with concomitant removal of the benzyl function and hydrogenation of the double bond to give the hydroxy-ester **15***c* in 85% yield. Originally we intended to convert the secondary alcohol function into a halide substituent for subsequent hydride displacement and ester reduction in the next step. However, attempted conversion of **15***c* into a secondary bromide with triphenylphosphine dibromide afforded a significant amount of the olefin **16***c*, accompanied by unreacted alcohol and only a trace of the desired bromide. Elimination is

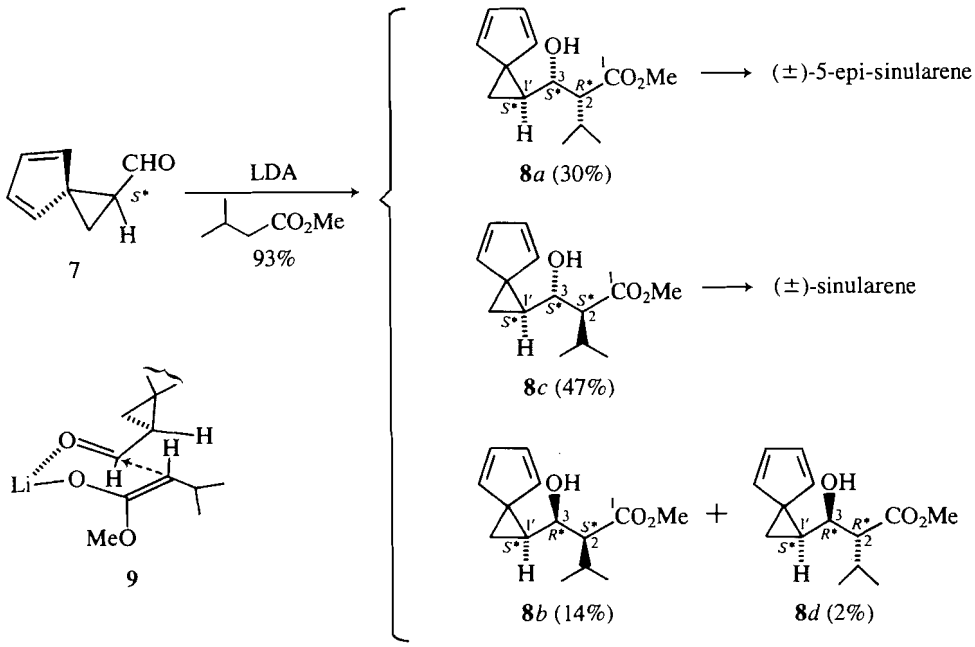

FIG. 1.

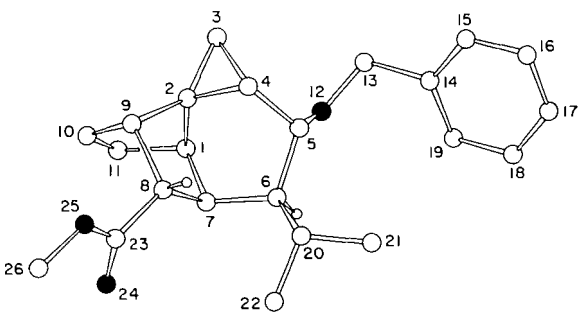

FIG. 2. A view of the adduct **14***a* ((4*S**,5*R**,6*S**)-5-benzyloxy-6-isopropyl-8-carbomethoxytetracyclo[5.4.$0^{1,7}$.$0^{2,4}$.$0^{2,9}$]undec-10-ene); H-atoms are shown only where they help in visualizing the stereochemistry. Here and in Fig. 3, C and O atoms are represented by open and solid circles, and H atoms by smaller open circles.

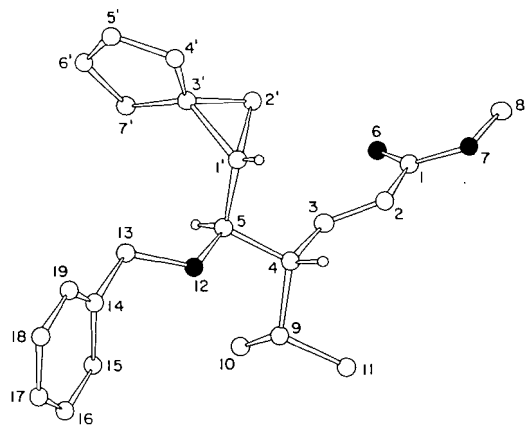

FIG. 3. A view of the triene **13***a* (4*S**,5*R**,1′*S**)-4-isopropyl-5-benzyloxy-5-(spiro[2.4]hepta-4,6-dien-1-yl)-2-pentenoate); H-atoms (assumed positions) are shown only where they help in visualizing the stereochemistry.

known to accompany substitution in these cases (23) and, by conducting the reaction at 21°C in acetonitrile with triphenylphosphine/carbon tetrachloride, the single ester-olefin **16***c* was obtained in 97% yield. The ^{13}C nmr spectrum contained only two olefinic carbon signals at δ 135.3 and 128.9, confirming that there was none of the more highly substituted double bond isomer **17** present. This result is consistent with a facile *trans* diaxial elimination from **15***c* in which inversion of the secondary alcohol has occurred to give the axial chloride prior to the elimination with loss of the axial methylene proton. In the epi series two antiperiplanar axial hydrogens are available in the halide intermediate, and consequently both olefins **16***a* and **17** are produced (~1:1).

Hydrogenation of **16***c* (H_2, 10% Pd/C, CH_3OH, 1 atm (101.3 kPa), 99%) provided the saturated ester **18***c* directly. It is important that pressure be avoided during this hydrogenation to avoid partial double bond isomerization and subsequent epimerization of the isopropyl substituent due to hydrogenation from the less hindered, back side of the molecule. In the epi series, similar hydrogenation of **16***a* and **17** afforded the ester **18***a* as the predominant product. Unfortunately, the selectivity in the hydrogenation of **17** was not quite complete and the product was accompanied by a small amount of the natural isomer, which was separated by chromatography.

Completion of the synthesis now required the conversion of the ester functionality into a double bond. The esters **18** were reduced quantitatively with lithium aluminum hydride to the primary alcohols **19** but, unfortunately, direct introduction of the exocyclic methylene using either selenoxide elimination or dehydrobromination proved impractical. Therefore, the acetate **20***c* was prepared (Ac_2O, pyridine, 99%) and (±)-sinularene was obtained in 77% yield via pyrolysis of this acetate in a flow apparatus at 550°C (5, 6). The sesquiterpene possessed spectral features (^{1}H nmr, ir, ms) identical to those published for the natural product (3) and completed a direct stereoselective synthesis of (±)-sinularene in 22% overall yield from the major aldol diastereomer **8** (9% from **7**). It required 14 steps from cyclopentadiene (12 from **7**), the same ultimate starting material as employed in the syntheses of both refs. 5 and 6. In parallel

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 80.58.250.72 on 09/07/12
For personal use only.

fashion, pyrolysis of the **20***a* acetate afforded (±)-5-epi-sinularene in 85% yield.

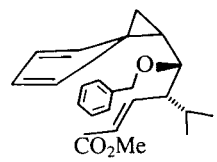
Discussion

In spite of considerable recent attention, the subtle substituent effects governing intramolecular Diels–Alder reactions are still imperfectly understood (10, 11, 19, 24–30). The key cycloaddition steps in the syntheses above were diastereospecific and were clearly dominated by the presence of the benzyl ether substituent and its orientation. Molecular models suggested that the steric bulk of this substituent in the (4*R**,5*S**,1′*S**)-triene **13***b* was sufficient to impede the close approach of the diene and dienophilic components as required for cyclization. As illustrated in **22**, a particularly favourable conformation results from the π stacking of the cyclopentadiene, phenyl, and dienophilic units in a series of parallel planes, which precludes cycloaddition and indicates that the barrier to cyclization will be large. Transition state interactions of a related type were encountered during the total synthesis of patchouli alcohol (31). In that instance only the diastereomer **23** underwent Diels–Alder cycloaddition due to the nonbonded interaction in the methyl epimer. More recently, the steric interaction between a vinyl bromide (29) or vinyl silane (30) substituent and an allylic ether group (benzyl or methoxymethyl) has been employed, to encourage enhanced levels of diastereoselection due to cyclization from a conformation resembling **24** in which this interaction is minimized, rather than other possible diastereomeric arrangements.

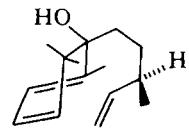
It is of fundamental interest that this sort of steric limitation was not present in triene **6**, which lacks a benzyloxy substituent and yet also failed to cyclize (19)! The exact role of the C5 oxygen substituent awaits further clarification but it is likely that this group alters the conformation of the triene to one in which the diene is positioned near the cyclopentadiene ring in an alignment that facilitates the cycloaddition. Fortunately, in the present study the **13***a* triene and its adduct **14***a* were crystalline and thus permitted the determination of the interatomic distances in the crystalline state. The crystal structure analyses confirm the proposed formulations and establish unambiguously the stereochemistries of these compounds.

The critical C_1—C_7 and C_9—C_8 distances (adduct numbering) between the reacting olefinic centres in the triene are 4.78 and 6.01 Å respectively. In the adduct **14***a* these new bonds (1.560 and 1.586 Å) are longer than average, a characteristic that appears to be common in spiro adducts of a similar type (32). Recent theoretical calculations (33–35) for the cycloaddition of butadiene to ethylene support a synchronous C_s Diels–Alder transition structure in which bond formation is concerted, although it seems likely that highly substituted intramolecular cases are represented more accurately by a twist-asynchronous model (27). The separation of the diene and the dienophile in these cases is approximately 2.2 Å. It is apparent from Fig. 3 and molecular models that rotation of the sidechain about the C1′—C5 bond relieves any interaction between the phenyl and cyclopentadiene rings and places the dienophile in close promimity to the diene.

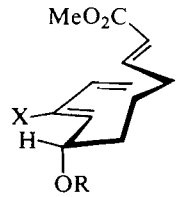
To ascertain if the observed rate enhancement due to the presence of the oxygen substituent adjacent to the diene is a general phenomenon we have conducted a competitive experiment between the spiro-dienes **25** and **26** and *N*-phenylmaleimide. However, it was found that they react at comparable rates at 21°C, indicating that in this instance the hydroxyl function



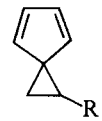
22



23



24
X = Br, $SiMe_3$
R = Bzl, MOM



25 R = H
26 R = CH_2OH

does not exert a significant beneficial influence.[5] In related studies, we are conducting *ab initio* calculations on less substituted spirotrienes to ascertain the effect that varying the C5 substituent has on the energy minima.[6] At present we have insufficient data, both theoretical and experimental, to draw an unambiguous conclusion on the origin of this steric and (or) stereoelectronic effect. As a referee has indicated, the fact that Diels–Alder additions to **25** and **26** proceed at similar rates implies that the steric bulk of the benzyloxy group, rather than an electronic influence, is the dominant factor. Nevertheless this effect played a crucial role in the success of these syntheses and has set the stage for the extension of these concepts and procedures to related targets, such as 12-acetoxysinularene (4, 7) and (+)-longifolene, utilizing this intramolecular Diels–Alder – cyclopropane ring-opening strategy.

Experimental

Melting points were determined in capillary tubes with a Thomas–Hoover Uni-Melt apparatus or on a Fisher–Johns melting point apparatus, and are uncorrected. Infrared spectra were recorded on a Perkin–Elmer 237B or 451 grating spectrophotometer, and were calibrated with the 2850 and 1601 cm^{-1} bands of polystyrene film. Ultraviolet spectra were recorded on a Perkin–Elmer 202 uv–visible spectrophotometer and were calibrated with the 279.4-nm band of a Holmium oxide filter. Proton magnetic resonance spectra were measured at 80 MHz with a Bruker WP80 spectrometer employing a chloroform lock, at 60 MHz with a Varian EM 360 spectrometer, or at 400 MHz (at the University of Alberta) with a Bruker WH 400 spectrometer. Signal positions are reported in ppm downfield from tetramethylsilane (δ scale) as an internal standard; multiplicity, the number of protons, coupling constants, and proton assignments are indicated in parentheses. Mass spectra were determined on a V.G. Micromass 7070 HS instrument using an ionization energy of 70 eV. A Picker four-circle diffractometer was used for crystallographic measurements.

Thin-layer chromatographic analyses were carried out on commercial precoated silica gel plates with fluorescent indicator (Eastman Kodak silica gel 13181). Preparative thin-layer chromatography was conducted on 20 × 20 cm glass plates coated with silica gel $PF^{254+366}$ type 60 (E. Merck). Flash chromatography using BDH silica gel Kieselgel 60, 230–400 mesh, was employed for all column chromatography.

Petroleum ether refers to a fraction with boiling range 30–60°C.

Anhydrous diethyl ether (ether), tetrahydrofuran (THF), dimethoxyethane (DME), and dioxane were obtained by distillation from lithium aluminium hydride or potassium/benzophenone. Absolute ethanol and methanol were dried by distillation from magnesium. Dry hexamethylphosphoramide (HMPA), dimethylformamide (DMF), dimethyl sulfoxide (DMSO), and diisopropylamine were prepared by distillation from calcium hydride. Solutions in organic solvents were dried over anhydrous magnesium sulphate and stripped of solvent with a Buchi rotary evaporator connected to a water aspirator. Unless otherwise indicated all reactions were conducted under an atmosphere of dry nitrogen.

Parallel reactions were conducted on the same scale in both the sinularene and epi-sinularene series and are grouped under the single compound name.

Methyl 3-hydroxy-2-isopropyl-3-(spiro[2.4]hepta-4,6-dien-1-yl)propanoate (8)

Methyl isovalerate (13 g, 0.115 mol) in THF (20 mL) was added dropwise to a THF solution maintained at −78°C with an external, solid carbon dioxide/acetone bath, containing lithium diisopropylamide (LDA, prepared from 2.6 *M* *n*-butyllithium solution (Aldrich, 65.4 mL, 0.17 mol) and diisopropylamine (16.8 mL, 0.12 mol) in THF (250 mL) at −78°C). The reaction mixture was stirred for 0.5 h and the aldehyde **7** (19) (12 g, 0.1 mol) in THF (20 mL) added dropwise. After stirring for a further 10 min at −78°C, the cooling bath was removed and replaced by an ice bath. Once the reaction mixture had reached 0°C it was quenched with saturated aqueous ammonium chloride solution and extracted with diethyl ether (3×). The combined ether extracts were dried, filtered, concentrated, and the residue purified by chromatography (petroleum ether/diethyl ether; 3:1) to afford the hydroxy-ester **8** as three separate fractions; **8***a*, 7.32 g (30%), recrystallized from dichloromethane/hexane, mp 59–60°C; ir (film): 3570 (OH), 3430 (sh, OH), 1725 (C=O), 1635 (w, C=C) cm^{-1}; ^1H nmr (CCl_4) δ: 0.99 (d, 3H, *J* = 6.5 Hz, CH_3CH), 1.01 (d, 3H, *J* = 6.5 Hz, CH_3CH), 1.52 (d, 1H, *J* = 2 Hz, OH), 1.80 (m, 2H, $HCMe_2$, cyclopropyl H), 2.09 (m, 1H, *J* = 6 Hz, HC—C=O), 2.45 (m, 2H, cyclopropyl H), 3.58 (m, 1H, H-C—OH), 3.62 (s, 3H, OCH_3), 6.00 (m, 1H, cyclopentadienyl H), 6.21 (m, 1H, cyclopentadienyl H), 6.46 (m, 1H, cyclopentadienyl H), 6.58 (m, 1H, cyclopentadienyl H). *Exact Mass* calcd. for $C_{14}H_{20}O_3$: 236.1412; found: 236.1399.

Hydroxy-esters **8***b* and **8***c*, 15.1 g (64%); ir (film): 3400 (br, OH), 1725 (C=O) cm^{-1}; ^1H nmr (CCl_4) δ: 0.89 (d, 6H, *J* = 7 Hz, $(CH_3)_2CH$), 1.6–2.5 (m, 5H), 3.25 (d, 1H, *J* ~5 Hz, OH), 3.54 (s, 3H, OCH_3), 3.75 (m, 1H, H-C—OH), 5.9–6.5 (m, 4H, cyclopentadienyl H). *Exact Mass* calcd. for $C_{14}H_{20}O_3$: 236.1412; found: 236.1420.

Hydroxy-ester **8***d*, 0.47 g (2%); ir (film): 3510 (OH), 1730 (C=O), 1625 (w, C=C) cm^{-1}; ^1H nmr (CCl_4) δ: 1.00 (dd, 6H, *J* = 6.5, $(CH_3)_2CH$), 1.5–2.5 (m, 6H), 3.65 (m, 1H, H-C—OH), 3.70 (s, 3H, OCH_3), 5.99 (m, 1H, cyclopentadienyl H), 6.26 (m, 1H, cyclopentadienyl H), 6.46 (m, 2H, cyclopentadienyl H). *Exact Mass* calcd. for $C_{14}H_{20}O_3$: 236.1412; found: 236.1372.

Methyl 3-benzyloxy-2-isopropyl-3-(spiro[2.4]hepta-4,6-dien-1-yl)propanoate (10)

The hydroxyester **8** (4.72 g, 0.02 mol) in dimethoxyethane (DME, 5 mL) was added dropwise to a suspension of sodium hydride (0.8 g, 0.02 mol, 60% oil dispersion, Aldrich) in DME (15 mL) maintained at 0°C with an external ice bath. Tetrabutylammonium iodide (150 mg) was added after hydrogen evolution had ceased (approximately 0.5 h), followed by benzyl bromide (3.9 g, 0.023 mol, Aldrich). The resulting mixture was stirred at 0°C for approximately 4 h (monitored by tlc) until no hydroxy-ester remained. The reaction was quenched by careful dropwise addition of saturated aqueous ammonium chloride, the mixture was extracted with ether (3×), the combined ether extracts dried and concentrated, and the products purified by chromatography (5% ethyl ether/petroleum ether) to give the ester **10***a* 5.02 g (77%) recrystallized from ether/hexane, mp 81.5–82.5°C; ir (CCl_4): 1735 (C=O) cm^{-1}; ^1H nmr (CCl_4) δ: 0.94 (d, 6H, *J* = 6.5 Hz, $(CH_3)_2CH$), 1.57 (m, 2H, cyclopropyl H), 1.8–2.7 (m, 3H), 3.46 (m, 1H, HCOBzl), 3.58 (s, 3H, OCH_3), 4.05 (s, 2H, H_2COBzl), 5.97 (m, 1H, cyclopentadienyl H), 6.39 (m, 3H, cyclopentadienyl H), 7.11 (s, 5H, phenyl H).

Ether-esters **10***b* and **10***c*, 5.35 g (82%); ir (film): 1735 (C=O) cm^{-1}; ^1H nmr (CCl_4) δ: 0.92 (overlapping d's, 2 × 6H, $(CH_3)_2CH$'s), 3.48 and 3.53 (s, 2 × 3H, OCH_3), 4.58 (m, 2 × 2H, H_2COBzl's), 5.98 (m, 2 × 1H, cyclopentadienyl H's), 6.35 (m, 2 × 3H, cyclopentadienyl H's), 7.19 (s, 2 × 5H, phenyl H's).

3-Benzyloxy-2-propyl-3-(spiro[2.4]hepta-4,6-dien-1-yl)propanol (11)

The benzyloxy-ester **10** (5.28 g, 0.015 mol) dissolved in diethyl ether (25 mL) was added dropwise to an ether solution (100 mL) of lithium aluminium hydride (0.6 g) maintained at 0°C with an external ice bath. The reaction mixture was stirred for a further hour after addition was complete and the excess lithium aluminium hydride destroyed by dropwise addition of ethyl acetate. This was followed by the addition of aqueous 20% sodium tartrate solution (150 mL) and extraction with ether (4×). The combined ether extracts were dried, filtered, and concentrated. The product was purified by chromatography (petroleum ether/diethyl ether; 3:1) to give the alcohol **11***a*, 4.20 g (94%); ir (film): 3380 (br, OH) cm^{-1}; ^1H nmr (CCl_4) δ: 0.96 (d, 6H, *J* = 6.5 Hz, $(CH_3)_2CH$), 3.00 (br s, 1H, OH), 3.56 (m, 3H, CH_2OH, HCOBzl), 4.06 (s, 2H, CH_2Ph), 5.91 (m, 1H, cyclopentadienyl H), 6.31 (m, 3H, cyclopentadienyl H), 7.05 (s, 5H, phenyl H).

Alcohol **11***b*, 0.94 g (21%); ir (film): 3490 (OH) cm^{-1}; ^1H nmr (CCl_4) δ: 0.90 (d, 6H, *J* = 6.5 Hz, $(CH_3)_2CH$), 3.54 (m, 3H, CH_2OH, HCOBzl), 4.54 (AB system, 2H, *J* = 12 Hz, OCH_2Ph), 5.95 (m, 2H, cyclopentadienyl H), 6.35 (m, 2H, cyclopentadienyl H), 7.20 (s, 5H, phenyl H).

Alcohol **11***c*, 3.40 g (76%); ir (film): 3400 (br, OH) cm^{-1}; ^1H nmr (CCl_4) δ: 0.85 (d, 6H, *J* = 6.5 Hz, $(CH_3)_2CH$), 2.62 (br s, 1H, OH), 3.51 (m, 3H, CH_2OH, HCOBzl), 4.55 (AB system, 2H, *J* = 12 Hz, OCH_2Ph), 5.95 (m, 2H, cyclopentadienyl H), 6.33 (m, 2H, cyclopentadienyl H).

3-Benzyloxy-2-isopropyl-3-(spiro[2.4]hepta-4,6-dien-1-yl)propanal (12)

The primary alcohol **11** (4.47 g, 0.015 mol) was dissolved in dichloromethane (50 mL) and added to pyridinium dichromate (PDC, 9.4 g, 0.08 mol) contained in dichloromethane (100 mL). The reaction mixture was stirred for 24 h at 21°C, diluted with diethyl ether, and filtered through magnesium sulfate. The residue obtained after concentration was purified by chromatography (petroleum ether/diethyl ether; 10:1) to give the aldehyde **12***a*, 2.66 g (60%); ir (film): 3070 (HC=C), 3035 (HC=C), 2630 (HC=O), 1722 (C=O) cm^{-1}; ^1H nmr (CCl_4) δ: 1.02 (d, 3H, *J* = 6.5 Hz, CH_3CH), 1.08 (d, 3H, *J* = 6.5 Hz, CH_3CH), 1.5–2.5 (m, 5H), 3.94 (dd, 1H, *J* = 6, 8 Hz, HCOBzl), 4.24 (s, 2H, OCH_2Ph), 6.11 (m, 1H, cyclopentadienyl H), 6.40 (m, 1H, cyclopentadienyl H), 6.54 (m, 2H, cyclopentadienyl H), 7.27 (s, 3H, phenyl H), 7.36 (m, 1H, *o*-phenyl H), 7.62 (m, 1H, *o*-phenyl H), 9.78 (d, 1H, *J* = 3 Hz, HC=O).

Aldehyde **12***b*, 2.84 g (64%); ir (film): 3070 (HC=C), 3035 (HC=C), 2735 (HC=O), 1720 (C=O) cm^{-1}; ^1H nmr (CCl_4) δ: 0.84 (d, 3H, *J* = 6.5 Hz, CH_3CH), 0.92 (d, 3H, *J* = 6.5 Hz, CH_3CH), 1.7–2.5 (m, 5H), 3.57 (dm, 1H, *J* = 8 Hz, HCOBzl), 4.67 (AB system, 2H, *J* = 12 Hz, OCH_2Ph), 5.95 (m, 2H, cyclopentadienyl H), 6.39 (m, 2H, cyclopentadienyl H), 7.26 (s, 5H, phenyl H), 9.60 (d, 1H, *J* = 3 Hz, HC=O).

Aldehyde **12***c*, 2.84 g (64%); ir (film): 3075 (HC=C), 3035 (HC=C), 2725 (HC=O), 1722 (C=O) cm^{-1}; ^1H nmr (CCl_4) δ: 0.93 (d, 3H, *J* = 6.5 Hz, CH_3CH), 1.03 (d, 3H, *J* = 6.5 Hz, CH_3CH), 1.7–2.4 (m, 5H), 3.82 (dd, 1H, *J* = 5.5, 8 Hz, HCOBzl), 4.68 (AB system, 2H, *J* = 12 Hz, OCH_2Ph), 6.10 (m, 2H, cyclopentadienyl H), 6.45 (m, 2H, cyclopentadienyl H), 7.30 (s, 3H, phenyl H), 7.46 (m, 1H, *o*-phenyl H), 7.78 (m, 1H, *o*-phenyl H), 9.42 (d, 1H, *J* = 3 Hz, HC=O).

*Methyl 5-benzyloxy-4-isopropyl-5-(spiro[2.4]hepta-4,6-dien-1-yl)-2-pentenoate (**13**) and 5-benzyloxy-6-isopropyl-8-carbomethoxy-tetracyclo[5.4.0^{1,7}.0^{2,4}.0^{2,9}]undec-10-ene (**14**)*

The aldehyde **12** (2.96 g, 10 mmol) was dissolved in THF (10 mL), mixed with methyl (triphenylphosphoranylidene)acetate (4 g, 12 mol, Aldrich) in THF (50 mL), and stirred under reflux for 12 h. The solution was concentrated and the product purified by chromatography (5% diethyl ether/petroleum ether) to give the triene **13***a*, 1.41 g, (40%), recrystallized from hexane, mp 76–77°C; ir ($CHCl_3$): 3050 (HC=C), 3035 (HC=C), 1715 (C=O), 1655 (C=C) cm^{-1}; ^{1}H nmr ($CDCl_3$) 400 MHz, δ: 0.87 (d, 3H, J = 6.5 Hz, CH_3CH), 0.88 (d, 3H, J = 6.5 Hz, CH_3CH), 1.64 (dd, 1H, J = 4.5, 7 Hz, cyclopropyl H), 1.75 (dd, 1H, J = 4.5, 8.5 Hz, cyclopropyl H), 2.10 (dd, 1H, J = 8.5 Hz, cyclopropyl H), 2.26 (m, 1H, J ~ 7 Hz, $HC(CH_3)_2$), 2.37 (m, 1H, HCC=C), 3.58 (dd, 1H, J = 7, 8.5 Hz, HCOBzl), 3.75 (s, 3H, CH_3O), 4.25 (AB system, 2H, J = 11.5 Hz, OCH_2Ph), 5.78 (d, 1H, 15.5 Hz, C=CHC=O), 6.09 (dt, 1H, J = 2, 5 Hz, cyclopentadienyl H), 6.37 (dt, 1H, J = 2, 5 Hz, cyclopentadienyl H), 6.54 (ddt, 2H, J = 1.5, 5 Hz, cyclopentadienyl H), 6.88 (dd, 1H, J = 11, 15.5 Hz, HC=CC=O), 7.28 (m, 5H, phenyl H); and the Diels–Alder adduct **14***a* 1.76 g (50%), recrystallized from diethyl ether, mp 115–116°C; ir ($CHCl_3$): 3065 (HC=C), 1730 (C=O) cm^{-1}; ^{1}H nmr ($CDCl_3$) 400 MHz δ: 0.47 (dt, 1H, J = 5.5, 8.5 Hz, cyclopropyl H-CC—OBzl), 0.90 (d, 3H, J = 6.5 Hz, CH_3CH), 0.92 (d, 3H, J = 6.5 Hz, CH_3CH), 1.09 (t, 1H, J = 5.5 Hz, cyclopropyl H), 1.21 (dd, 1H, J = 5.5, 8.5 Hz, cyclopropyl H), 1.46 (br septet, 1H, J ~ 6.5 Hz, $HC(CH_3)_2$), 1.88 (dd, 1H, J = 5.5, 11 Hz, *endo*-H-C), 2.33 (dd, 1H, J = 2.5, 5.5 Hz, *exo*-H-CCOOCH$_3$), 2.39 (br s, 1H, $W_{1/2}$ = 7 Hz, H-C*i*Pr), 2.51 (m, 1H, $W_{1/2}$ = 9 Hz, bridgehead H), 2.58 (dd, 1H, J = 2.5, 4.5 Hz, bridgehead H), 3.62 (s, 3H, CH_3O), 3.74 (d, 1H, J = 5.5 Hz, HCOBzl), 4.43 (AB system, 2H, J = 12 Hz, OCH_2Ph), 6.05 (dm, 1H, J ~ 0.5, 2.5, 5.5 Hz, HC=C), 6.26 (dm, 1H, J ~ 1, 3, 5.5 Hz, HC=C), 7.29 (m, 5H, phenyl H).

Alternatively, a solution of the triene **13***a* (1.41 g) in THF (50 mL) was refluxed for 12 h. Concentration followed by chromatography (5% diethyl ether/petroleum ether) afforded the tetracyclic ester **14***a* in 45% yield, accompanied by uncyclized triene (50%), which was recycled; the combined total yield from aldehyde **12***a* was 72%.

Triene **13***b*, 3.41 g (97%), recrystallized from dichloromethane/hexane, mp 101–103°C; ir (CCl_4): 3070 (HC=C), 3030 (HC=C), 1725 (C=O), 1655 (C=C) cm^{-1}; ^{1}H nmr ($CDCl_3$) 400 MHz δ: 0.77 (d, 3H, J = 6.5 Hz, CH_3CH), 0.88 (d, 3H, J = 6.5 Hz, CH_3CH), 1.4–2.2 (m, 5H), 3.47 (dd, 1H, J = 2, 8 Hz, HCOBzl), 3.66 (s, 3H, OCH_3), 4.68 (AB system, 2H, J = 12 Hz, OCH_2Ph), 5.10 (d, 1H, J = 16 Hz, C=CHC=O), 6.05 (m, 2H, cyclopentadienyl H), 6.50 (m, 2H, cyclopentadienyl H), 6.92 (dd, 1H, J = 10, 16 Hz, HC=CC=O), 7.31 (s, 5H, phenyl H). Cyclization did not occur in separate experiments for 24 h in refluxing THF, toluene, xylene, and *o*-dichlorobenzene.

Triene **13***c* cyclized spontaneously under the Wittig reaction conditions to the adduct **14***c*; 2.52 g (72%, from aldehyde); ir (film): 3070 (HC=C), 3035 (HC=C), 1735 (C=O) cm^{-1}; ^{1}H nmr ($CDCl_3$) 400 MHz δ: 0.46 (m, 1H, J ~ 5 Hz, cyclopropyl H), 0.84 (d, 3H, J = 6.5 Hz, CH_3CH), 1.00 (d, 3H, J = 6.5 Hz, CH_3CH), 1.25 (m, 2H, cyclopropyl H), 2.06 (m, 2H, $HCCOOCH_3$, HC*i*Pr), 2.85 (m, 2H, bridgehead H), 3.61 (m, 1H, HCOBzl), 3.62 (s, 3H, OCH_3), 4.61 (AB system, 2H, J = 12 Hz, OCH_2Ph), 6.09 (t, 2H, J = 1 Hz, HC=CH), 7.33 (s, 5H, phenyl H).

*7-Carbomethoxy-5-isopropyl-2-methyltricyclo[4.4.0^{1,6}.0^{2,8}]decan-4-ol (**15**)*

The tetracyclic ester **14** (1.76 g, 5 mol) dissolved in methanol (25 mL) was mixed with 10% Pd/C (200 mg) and hydrogenated in a Parr apparatus at 50 psi for 24 h at 21°C. The catalyst was removed by filtration, washed with diethyl ether, and the product purified by chromatography (petroleum ether/diethyl ether; 3:1) to give the hydroxy-ester **15***a*, 1.08 g (81%), recrystallized from hexane, mp 87–88°C; ir (CCl_4): 3400 (br, OH), 1725 (C=O) cm^{-1}; ^{1}H nmr (CCl_4) δ: 0.78 (d, 3H, J = 6.5 Hz, CH_3CH), 1.00 (s, 3H, CH_3C), 1.00 (d, 3H, J = 6.5 Hz, CH_3CH), 2.34 (m, 1H, bridgehead H), 2.65 (m, 1H, *exo*-H-CCOOCH$_3$), 2.96 (br s, 1H, OH), 3.63 (s, 3H, OCH_3), 3.83 (m, 1H, HCOH). *Exact Mass* calcd. for $C_{16}H_{26}O_3$: 266.1882; found: 266.1884.

Hydroxy-ester **15***c*, 1.13 g (85%); ir (film): 3375 (br OH), 1730 (C=O) cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 0.82 (d, 3H, J = 6.5 Hz, CH_3CH), 0.91 (d, 3H, J = 6.5 Hz, CH_3CH), 0.96 (s, 3H, CH_3), 2.05 (d, 1H, J = 3 Hz, bridgehead H), 2.25 (s, 1H, OH), 2.63 (m, 1H, *exo*-H-CCOOCH$_3$), 3.52 (m, 1H, HCOH), 3.55 (s, 3H, OCH_3); ^{13}C nmr ($CDCl_3$) δ: 18.60, 20.91, 21.25, 22.79, 24.67, 29.37, 40.82, 41.16, 42.01, 46.88, 48.59, 51.24, 55.26, 58.33, 67.73, 175.39. *Exact Mass* calcd. for $C_{16}H_{26}O_3 - H_2O$: 248.1786; found: 248.1776.

*7-Carbomethoxy-5-isopropyl-2-methyltricyclo[4.4.0^{1,6}.0^{2,8}]dec-3-ene (**16**)*

The hydroxy ester **15** (120 mg, 0.45 mmol) was dissolved in anhydrous acetonitrile (1 mL) and triphenyl phosphine (157 mg, 0.6 mmol), carbon tetrachloride (92 mg, 0.6 mmol), and pyridine (80 mg) added. The reaction mixture was stirred for 24 h at 21°C, concentrated, and the product purified by chromatography (5% diethyl ether/petroleum ether) to give the alkene **16***a* and its positional isomer **17**, ~1:1, 96 mg (93%); ir (film): 3035 (HC=C), 1740 (C=O) cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 3.60 (s, 6H, OCH_3), 5.08 (m, 1H, HC=C), 5.50 (m, 2H, HC=CH), ^{13}C nmr ($CDCl_3$) δ: 117.6, 128.5, 134.7, 156.2, 174.7, 175.8. *Exact Mass* calcd. for $C_{16}H_{24}O_2$: 248.1776; found: 248.1777.

Olefin **16***c*, 100 mg (97%); ir (film): 3030 (HC=C), 1735 (C=O) cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 0.90 (d, 3H, J = 6.5 Hz, CH_3CH), 0.93 (d, 3H, J = 6.5 Hz, CH_3CH), 0.99 (s, 3H, CH_3C), 2.15 (m, 2H), 2.30 (m, 1H), 2.56 (m, 1H), 3.60 (s, 3H, OCH_3), 5.50 (br s, 2H, HC=CH). ^{13}C nmr ($CDCl_3$) δ: 18.0, 21.3, 21.5, 23.5, 24.6, 41.8, 43.0, 50.5, 51.4, 52.4, 53.4, 128.9, 135.3, 175.9. *Exact Mass* calcd. for $C_{15}H_{24}O_2$: 248.1776; found: 248.1816.

*7-Carbomethoxy-5-isopropyl-2-methyltricyclo[4.4.0^{1,6}.0^{2,8}]decane (**18**)*

A methanol solution of olefin ester **16** (1.24 g, 5 mmol) was hydrogenated in the presence of 10% Pd/C (100 mg) in a Parr apparatus at 21°C at atmospheric pressure. (Under pressure (30–50 psi) the reaction requires ~8 h, but the double bond undergoes partial isomerization, resulting in epimerization of the isopropyl group, which is avoided at atmospheric pressure although the reaction is much slower, 24–48 h.) The catalyst was removed by filtration, washed thoroughly with ether, the combined washings and filtrate dried, and the solvent removed to give the saturated ester **18***a*, 1.23 g (98%); ir (film): 1735 (C=O) cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 0.92 (triplet-like, 9H, overlapping CH_3's), 2.60 (m, 1H, bridgehead H), 2.72 (m, 1H, $HCOOCH_3$), 3.57 (s, 3H, OCH_3). ^{13}C nmr ($CDCl_3$) δ: 20.00, 20.77, 25.13, 25.73, 30.77, 33.59, 43.42, 44.70, 46.33, 47.78, 49.92, 50.94, 175.22.

Ester **18***c*, 1.24 g (99%); ir (film): 1735 (C=O) cm^{-1}; ^{1}H nmr (CCl_4) δ: 0.84 (s shoulder, 3H, CH_3C), 0.93 (overlapping d's, 6H, J = 6.5 Hz, CH_3CH), 2.72 (m, 1H, $HCOOCH_3$), 3.57 (s, 3H, OCH_3). *Exact Mass* calcd. for $C_{16}H_{26}O_2$: 250.1933; found: 250.1936.

*7-Hydroxymethyl-5-isopropyl-2-methyltricyclo[4.4.0^{1,6}.0^{2,8}]decane (**19**)*

The ester **18** (0.5 g, 2 mmol) in diethyl ether (5 mL) was added dropwise to an ether suspension (20 mL) of lithium aluminium hydride (76 mg, 2 mmol) maintained at 0°C with an external ice bath. The reaction was stirred at this temperature for 0.5 h, ethyl acetate added dropwise followed by aqueous 20% sodium potassium tartrate (10 mL), and the aqueous layer extracted with ether (3 × 10 mL). The combined ether extracts were dried, concentrated, and the product purified by chromatography (diethyl ether/petroleum ether) to give the alcohol **19***a*, 435 mg, (98%); ir (film): 3350 (br, OH) cm^{-1}; ^{1}H nmr (CCl_4) δ: 0.90 (9H, overlapping CH_3's), 2.18 (m, 1H, *exo*-H), 3.40 (d, 2H, J = 16 Hz, CH_2O), 3.93 (s, 1H, OH).

Alcohol **19***c*, 440 mg (99%); ir (film): 3350 (br, OH) cm^{-1}; ^{1}H nmr (CCl_4) δ: 0.98 (9H, overlapping CH_3's), 2.80 (s, 1H, OH), 3.47

(d, 2H, J = 16 Hz, CH_2O). *Exact Mass* calcd. for $C_{15}H_{26}O$: 222.1984; found: 222.1999.

*7-Acetoxymethyl-5-isopropyl-2-methyltricyclo[4.4.0^{1,6}.0^{2,8}]decane (**20**)*

The alcohol **19** (444 mg, 2 mmol) was dissolved in pyridine (3 mL) and acetic anhydride (0.76 mL, 8 mmol) was added. The reaction mixture was maintained at 4°C for 15 h, diluted with diethyl ether, and poured into ice acidified with a few drops of concentrated hydrochloric acid. The resulting mixture was extracted with diethyl ether (3×), the combined ether extracts washed with aqueous 10% sodium bicarbonate solution and then with brine, dried, and concentrated. The product was purified by chromatography (petroleum ether/diethyl ether; 5:1) to give the acetate **20***a*, 523 mg (99%); ir (film): 1745 (C=O) cm^{-1}; ^{1}H nmr (CCl_4) δ: 0.90 (9H, overlapping CH_3's), 1.94 (s, 3H, CH_3C=O), 3.90 (d, 2H, J = 15 Hz, CH_2O); ^{13}C nmr ($CDCl_3$) δ: 19.97, 21.08, 22.45, 23.98, 25.61, 26.72, 29.96, 33.72, 39.96, 46.20, 46.37, 46.88, 48.34, 50.47, 66.79, 171.6.

Acetate **20***c*, 525 mg (99%); ir (film): 1740 (C=O) cm^{-1}; ^{1}H nmr (CCl_4) δ: 0.94 (9H, overlapping CH_3's), 1.92 (s, 3H, CH_3C=O), 3.91 (d, 2H, J = 16 Hz, CH_2OAc); ^{13}C nmr ($CDCl_3$) δ: 20.40, 20.91, 25.52, 30.90, 32.10, 39.96, 46.20, 46.54, 46.80, 47.82, 49.79, 66.53, 170.4.

*(±)-5-Epi-sinularene (**21**) and (±)-sinularene (**1**)*

The acetate **20** (200 mg, 0.76 mmol) was dissolved in benzene (2 mL) and injected, under a stream of nitrogen, into a Pyrex tube (14 × 60 cm, packed with glass helices) preheated to 550°C and attached to a receiver that was cooled to −78°C with an external solid carbon dioxide/acetone bath. Once injection of the sample was complete it was followed by two further aliquots of benzene (2 mL) and the collected material was concentrated and purified by chromatography (petroleum ether) to give (±)-5-epi-sinularene, 130 mg (85%); ir (film): 3070 (H-C=C), 1658 (C=C), 877 (C=C) cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 0.82 (d, 3H, J = 6.5 Hz, CH_3CH), 0.89 (s, 3H, CH_3C), 0.96 (d, 3H, J = 6.5 Hz, CH_3CH), 2.08 (br s, 1H, allylic *endo*-H), 2.38 (br s, 1H, allylic bridgehead H), 4.52 (br s, 1H, H-C=C), 4.80 (br s, 1H, H-C=C); ^{13}C nmr ($CDCl_3$) δ: 20.65, 21.34, 24.92, 26.55, 29.02, 31.93, 34.84, 47.31, 48.08, 49.62, 51.24, 52.86, 102.2, 159.2. *Exact Mass* calcd. for $C_{15}H_{24}$: 204.1878; found: 204.1898.

(±)-Sinularene (**1**), 119 mg (77%); ir (film): 3070 (H-C=C), 1665 (C=C), 875 (C=C) cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 0.90 (d, 3H, J = 6 Hz, CH_3CH), 0.92 (d, 3H, J = 6 Hz, CH_3CH), 0.92 (s, 3H, CH_3C), 4.59 (br s, 1H, H-C=C), 4.79 (br s, 1H, H-C=C); ^{13}C nmr ($CDCl_3$) δ: 20.74, 21.51, 22.36, 26.03, 29.02, 30.22, 31.67, 42.95, 48.42, 49.19, 50.22, 53.29, 101.2, 162.9. *Exact Mass* calcd. for $C_{15}H_{24}$: 204.1878; found: 204.1875.

Sinularene and epi-sinularene can be separated by plc using isooctane as the eluent on Beckman silica gel$_{PF\,254}$ treated with 20% silver nitrate.

Crystallography

(4S,5R*,6S*)-5-Benzyloxy-6-isopropyl-8-carbomethoxytetracyclo[5.4.0^{1,7}.0^{2,4}.0^{2,9}]undec-10-ene (**14**a)*

All procedures at nominal 22°C, using Ni-filtered CuKα radiation. Unit-cell constants from least-squares analysis of diffractometer angles of a number of well-centered reflections (α_1 component) of large Bragg angle. The intensities of the accessible independent reflections were measured using θ–2θ scans, with analysis of individual reflection profiles (36). The standard deviations of the intensities were evaluated from counting statistics. Absorption corrections were deemed to be unnecessary, and were not applied. The structure solution was by direct methods (MULTAN 78) (37). Refinement was by block-diagonal least squares, minimizing $\Sigma w\Delta F^2$, where $1/w = \sigma^2(F_o) + kF_o^2$. Hydrogen atoms were initially located in physically reasonable positions (C—H = 1.08 Å) or located in a ΔF synthesis. The parameters refined were scale factor, secondary extinction coefficient g (38), atomic coordinates, and temperature factors (anisotropic for C and O). Refinement was terminated when all parameter shifts were acceptably small. The final ΔF synthesis revealed no detail inconsistent with the proposed structure.

TABLE 1. Atomic coordinates (e.s.d.'s) and equivalent isotropic B value (B_{eq}, Å^2) for (4*S**,5*R**,6*S**)-5-benzyloxy-6-isopropyl-8-carbomethoxytetracyclo[5.4.0^{1,7}.0^{2,4}.0^{2,9}]undec-10-ene (**14***a*) (H-atoms omitted)

[a]In this and the following table, B_{eq} is the arithmetic mean of the principal axes of the thermal ellipsoid.

Methyl (4S,5R*,1'S*)-4-isopropyl-5-benzyloxy-5-(spiro[2,4]hepta-4,6-dien-1-yl)-2-pentenoate (**13**a)*

Except where noted, same procedures as for **14***a*. The specimen was extremely small, and poorly diffracting. It was not possible to observe reflections for which 2θ ≥ 100°C. Therefore, in measuring the cell constants, α_1–α_2 overlap problems were avoided by using the K_β components of lower-angle reflections. Refinement was hindered by the low yield of observable reflections and by severe thermal motion (or disorder) of the benzene ring. (The carbon atoms of this ring must be regarded as poorly resolved.) The methyl H atoms of the carbomethoxy group could not be located; H atom parameters were not refined, nor was the secondary extinction coefficient g.

The atomic coordinates for both structures are given in Tables 1 and 2, and selected bond lengths in Tables 3 and 4. The computer programs and the source of the atomic scattering factors are identified in the references (36–39). Supplementary data[7] include H-atom coordinates, temperature factors, all bond lengths, and structure factors.

Directed *ortho* metalation reactions. Convergent synthesis of "angular" anthracyclinones ochromycinone and X-14881 C[1]

K. KATSUURA AND V. SNIECKUS[2]

Guelph–Waterloo Centre for Graduate Work in Chemistry, University of Waterloo, Waterloo, Ont., Canada N2L 3G1

Received June 16, 1986

This paper is dedicated to Dr. O. E. (Ted) Edwards

K. KATSUURA and V. SNIECKUS. Can. J. Chem. **65**, 124 (1987).

Convergent syntheses of the benz[*a*]anthraquinone natural products X-14881 C (**2***c*) and ochromycinone (**2***d*) have been achieved using aromatic directed metalation strategies. Key steps involve (a) the condensations of dilithiated *cis*-tetralol (**13***a*) with the aldehydo *o*-anisamide **14** and of methoxymethyl protected aldehyde **17***b* with lithiated *o*-anisamide (**18**) to give, after acid-catalyzed cyclization, the phthalide **16**, and (b) the regiospecific hydroxyselenylation of anthraquinone **22** to provide the hydroxyselenide **23**.

K. KATSUURA et V. SNIECKUS. Can. J. Chem. **65**, 124 (1987).

Faisant appel à des stratégies de métalations orientées par les groupements aromatiques, on a réalisé des synthèses convergentes des produits naturels X-14881 C (**2***c*) et ochromycinone (**2***d*) de la série des benz[*a*]anthraquinones. Les étapes clés impliquent: (a) les condensations du tétralol-*cis* dilithié (**13***a*) avec l'aldéhydo *o*-anisamide (**14**) ainsi que de l'aldéhyde **17***b*, protégé par un groupement méthoxyméthyle, avec la *o*-anisamide lithiée (**18**) qui conduisent toutes les deux au phtalide **16** après une cyclisation acido-catalysée; et (b) l'hydroxysélénylation régiospécifique de l'anthraquinone **22** qui conduit à l'hydroxysélénide **23**.

For personal use only.

The benz[*a*]anthraquinones (**1**) constitute a distinct class of antibiotic substances isolated from cultures of several strains of *Streptomyces* (2). Represented by several ring A oxidation states, levels of oxygenation, and functional group complexity (e.g. tetrangulol (**1**) (2*a*), rabelomycin (**2***a*) (2*b*), X-14881 A (**3**) (2*e*)), this group of structural "angular" analogues of the anthracyclinones (3) has been shown to exhibit weak antibacterial (2*b*, 2*d*), enzyme inhibitory (2*c*), and antitumor (2*d*) activity. Synthesis of the benz[*a*]anthraquinone antibiotics is limited to a classical route to tetrangulol (**1**) (4) and an interesting convergent construction of the non-naturally occurring 3-deoxyrabelomycin (**2***b*) (5) based on regioselectively generated anionic 1-tetralol chromium tricarbonyl complex intermediates (6). We detail herein the first total syntheses of X-14881 C (**2***c*) and ochromycinone (**2***d*) by a strategy which originated with our general anthraquinone synthesis (7) and which focusses on the application of *ortho* metalated benzamide (8) and **uncomplexed** 1-tetralol (6) intermediates.

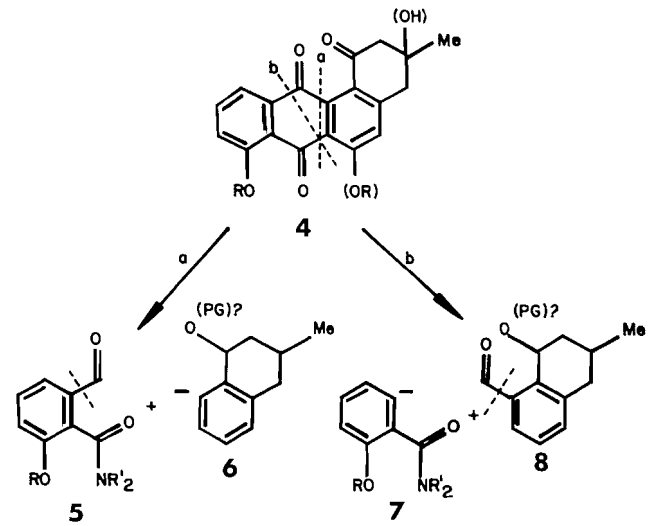
Maximum synthetic convergence to the benz[*a*]anthraquinone skeleton **4** is gained by dissections a and b (Scheme 1) leading to fragments **5**, **6** and **7**, **8** respectively. These retro-



SCHEME 1

synthetic paths are mutually interactive in that aldehydes **5** and **8** are obtainable from **7** and **6** respectively by reaction with DMF. The question of necessity to protect the 1-tetralol function was considered to be best answered by experimentation. Of the two approaches, route a proved to be the more efficient.

The tetralone derivative **12** (Scheme 2), obtained by unexceptional chemistry (see experimental section), was reduced to a *cis–trans* mixture of tetralols **13***a*, *b* (**13***a* major) according to a reported procedure (9). Since the isomers had been separated and fully characterized (9), the opportunity to test stereochemical effects involving a benzyl alcohol directed *ortho* metalation group was presented for the first time (6, 10). Dilithiation of the *cis* isomer (**13***a*) using *n*-BuLi/TMEDA complex in refluxing Et_2O followed by D_2O quench at 0°C resulted in 86% d_1 incorporation, while metalation and deuteration of the *trans* isomer (**13***b*) under essentially identical conditions gave only 24% d_1 incorporation (nmr analysis). This distinct stereochemical consequence, perhaps the result of better coordinative stabilization in the planar dilithiated species

SCHEME 3

derived from the *cis* isomer, provided persuasive evidence that further metalation reactions be effected on pure **13***a*.

The *cis*-isomer (**13***a*) (Scheme 3) was thus dilithiated as before and the resulting species was coupled at −45°C with the amide aldehyde **14**, derived in high yield from lithiated *N*,*N*-diethyl *o*-anisamide by reaction with DMF (11). The conditions for this coupling to give optimum yields of product were achieved after considerable experimentation.

As previously encountered for related systems (7), manipulation and purification of the intermediate amide alcohol **15** proved to be problematical. Therefore, **15** was treated directly with TsOH in refluxing benzene to give the phthalide alcohol **19***a* (42%) and the corresponding dehydrated product **16** (4%) as a stereoisomeric nonhomogeneous material. Chromium trioxide – pyridine oxidation of **19***a* to the keto phthalide **19***b* followed by zinc hydrogenolysis in basic solution produced the keto benzoic acid **20**. Friedel–Crafts cyclization directly to the anthrone corresponding to X-14881 C (**2***c*) was unsuccessful using TFAA (7) or concentrated sulfuric acid, undoubtedly due in part to the deactivated nature of the aromatic ring. These failures and the possibility of the Hayashi rearrangement under more vigorous Lewis acid catalyzed conditions (12) forced a reexamination of the conditions for the TsOH-catalyzed lactonization of the intermediate **15**. When the solvent was

a: R = H, OH
b: R = O

changed to toluene, the olefin phthalide **16** was obtained in high yield, a result also observed by Uemura *et al.* in a similar system (6). This finding and the expected minor effect of the double bond in the projected Friedel–Crafts reaction changed the strategy to one incorporating a functional group conversion step at the terminal stage of the synthesis.

The alternate convergent strategy to **16** (route b, Scheme 1) was initiated by dimetalation and formylation of **13***a* to give, in quantitative yield, the formyl tetralol **17***a*. Protection of the secondary alcohol with the popular methoxymethyl group, followed by coupling with **18** at −78°C and acid-catalyzed cyclization, furnished the same phthalide **16** in substantially lower overall yield (58%) than that obtained by condensation of **13***a* with **14**.

Zinc-mediated hydrogenolysis (7) of **16** (Scheme 4) led to the benzoid acid **21** (93%), which upon sequential TFAA-catalyzed Friedel–Crafts reaction and aerial oxidation in the presence of Triton B (13) afforded the dihydrobenz[*a*]anthraquinone **22**. Regiospecific C-1 hydroxylation of **22** using the well-documented hydroxymercuration method (14) failed. However, the Nicolaou procedure of selenohydroxylation with phenylselenylphthalimide (15*a*) afforded the required product **23**. Compound **23** was also prepared by Clive's phenylselenyl chloride procedure (15*b*) in comparable yield. Although the assigned regiochemistry was in agreement with the ^{1}H nmr data (δ 3.87, 1H, br t, C-2 H; 4.84, 1H, d, J = 4 Hz, D_2O-exchangeable; 5.34, 1H, dd, J = 4, 2.5 Hz, C-1 H), it was deduced only after correlation of synthetic X-14881 C (**2***c*) with the natural product. The *trans* stereochemistry was tentatively assigned on the basis of the generally accepted *trans* mode addition of selenium electrophiles to simple olefin systems (16). The small coupling constant, J = 2.5 Hz, for C-1 H suggests *cis* (17) or *trans*-diaxial relationship between the hydroxyl and phenylselenyl groups. We prefer the latter assignment on the basis of the accepted mechanism of addition (16) and the recent evidence that the PhSe group prefers axial orientation in both *cis* and *trans* cyclohexanone derivatives (18). A mechanistic rationalization (Scheme 5) for the formation of **23** involves assistance in the delivery of acetate to the benzylic carbon by initial coordination with the quinone oxygen. The stereochemistry of **23** is, of course, inconsequential to the synthetic end result (**2***c*, **2***d*).

Adoption of the standard excess Ph_3SnH conditions (19) on **23** to reductively cleave the C—Se bond resulted in the formation of the olefin **22**, presumably by thermal dehydration of the deselenylated intermediate. However, when hydroxy selenide **23** was first subjected to CrO_3 oxidation and the intermediate selenyl ketone was treated with Ph_3SnH, X-14881 C (**2***c*) was obtained cleanly and in good yield. Synthetic **2***c* was shown to be identical with the natural product by comparison of physical and spectral data with those reported in the literature (2*e*). Demethylation using $AlCl_3$ afforded ochromycinone (**2***d*) whose identity with the natural product (20) was similarly established. Direct comparison of ochromycinone acetate (**2***e*) with an authentic sample further established identity of the two materials.

To conclude, syntheses of X-14881 C (**2***c*) and ochromycinone (**2***d*) have been completed in 21% overall yield and 8–9 steps based on compound **9** and consideration of the higher yield sequences. This work demonstrates the viability of coupling aromatic directed *ortho* metalation reactions (8) for regiospecific and convergent construction of these substituted benz[*a*]anthraquinone antibiotics and invites further application of this strategy in organic synthesis (21).

Experimental

Melting points were measured on a Büchi SMP-20 apparatus and are uncorrected. The ^{1}H nmr spectra were recorded on a Bruker WP-80 spectrometer in deuteriochloroform using tetramethylsilane as an internal standard unless otherwise stated. The ir spectra were determined on a Perkin–Elmer 983 spectrometer. Mass spectra were recorded on a high resolution CH-7 spectrometer. Column chromatog-

raphy was performed with Silica Gel 60 (Merck, 230–400 mesh) or aluminum oxide (Aldrich, neutral). The phrase "standard work-up" refers to washing of the organic phase with water, drying over $MgSO_4$, filtration, and evaporation under reduced pressure.

*Ethyl 3-methyl-4-(1,3-dithiopropano)-4-phenylbutyrate (**11**a) from **9***

To a stirred solution of **9** (23.04 g, 118 mmol) in dry THF (350 mL) was added dropwise a solution of *n*-BuLi (78 mL, 118 mmol, 1.5 *M* solution) at −78°C under nitrogen. After stirring 1 h at −78°C, the solution was treated with ethyl crotonate (14.8 mL, 119 mmol). The resulting mixture was stirred for 1 h at −78°C and treated with aqueous NH_4Cl solution. The mixture was concentrated to ca. 200 mL and extracted with ether. Standard work-up gave an oil, which upon distillation afforded 28.58 g (78%) of ethyl 3-methyl-4-(1,3-dithiopropano)-4-phenylbutyrate (**11***a*) as a pale yellow oil, bp 160–180°C/0.03 Torr (1 Torr = 133.3 Pa); ir (neat) ν_{max}: 1730 cm^{-1}; ^1H nmr δ: 0.98 (3H, d, *J* = 6.5 Hz), 1.20 (3H, t, *J* = 7 Hz), 1.60–3.20 (9H, m), 4.07 (2H, q, *J* = 7 Hz), 7.10–8.00 (5H, m); ms *m/e* (rel. intensity): 310 (4, M^+), 195 (49), 84 (61).

Hydrolysis of **11***a* (20% aqueous NaOH–EtOH, reflux) furnished in 90% yield *3-methyl-4-(1,3-dithiopropano)-4-phenylbutyric acid*, mp 137–138°C (EtOAc); ir (Nujol) ν_{max}: 1711 cm^{-1}; ^1H nmr δ: 1.00 (3 H, d, *J* = 6 Hz), 1.80–3.10 (9H, m), 7.20–7.50 (3H, m), 7.85–8.00 (2H, m); ms *m/e* (rel. intensity): 282 (11, M^+), 195 (100). *Anal.* calcd. for $C_{14}H_{18}O_2S_2$: C 59.53, H 6.43, S 22.70; found: C 59.58, H 6.56, S 22.98.

*Ethyl 3-methyl-4-phenylbutyrate (**11**b) from **10***

To an ice-cooled solution of *p*-toluenesulfonyl chloride (53.0 g, 0.28 mol) in dry pyridine (230 mL) was added **10***a* (38.2 g, 0.25 mol) (22), and the reaction mixture was stirred overnight at room temperature. Concentration to remove pyridine was followed by acidification (dilute HCl) and extraction with Et_2O. Standard work-up furnished a colorless syrup of the tosylate; ^1H nmr δ: 0.88 (3H, d, *J* = 7 Hz), 1.90–2.90 (3H, m), 2.44 (3H, s), 3.86 (2H, d, *J* = 5.5 Hz), 7.00–7.85 (9H, m).

A stirred suspension of the above tosylate and powdered NaCN (11.6 g, 0.24 mol) in methyl cellosolve (270 mL) was refluxed for 2.5 h under nitrogen. After removal of the solvent, the reaction mixture was diluted with Et_2O and the heterogeneous mixture was filtered. Standard work-up followed by distillation gave 33.4 g (82%) of the nitrile as a colorless oil, bp 80–92°C/0.14 Torr (lit. (23) bp 100–105°C/1.5 Torr); ir (neat) ν_{max}: 2246 cm^{-1}; ^1H nmr δ: 1.11 (3H, d, *J* = 6.5 Hz), 1.90–2.30 (3H, m), 2.66 (2H, d, *J* = 6.5 Hz), 7.10–7.40 (5H, m); ms *m/e* (rel. intensity): 159 (100, M^+).

A stirred mixture of the above nitrile (1.00 g, 6.3 mmol) and concentrated H_2SO_4 (2 mL) in 95% EtOH (5 mL) was refluxed for 18 h. The reaction mixture was poured into ice-water and extracted with ether. The extract was washed with aqueous $NaHCO_3$ solution and subjected to the standard work-up to give 1.08 g (83%) of a pale yellow oil, which was shown to be identical with **11***b* obtained as described below by comparison of ^1H nmr and ir spectra.

*3-Methyl-1-tetralone (**12**)*

A stirred suspension of **11***a* (14.19 g, 45.8 mmol) and Raney-Ni (W-7, 50 g) in absolute EtOH (200 mL) was refluxed for 2 h. After removal of the catalyst and the solvent, the residue was dissolved in $CHCl_3$. Standard work-up gave 10.10 g of *ethyl 3-methyl-4-phenylbutyrate* (**11***b*) as a colorless oil; ir (neat) ν_{max}: 1730 cm^{-1}; ^1H nmr δ: 0.90–1.32 (6H, m), 2.15–2.65 (5H, m), 4.10 (2H, q, *J* = 7 Hz), 7.10–7.30 (5H, m).

A stirred mixture of the crude ester (**11***b*) and 75% H_2SO_4 (50 mL) was heated at 100°C for 8 h. The reaction mixture was poured into ice-water and extracted with $CHCl_3$. Standard work-up gave material that was distilled to afford 5.79 g (79%) of **12** as a pale yellow oil bp 80–90°C/0.14 Torr (lit. (24) bp 94–96°C/0.3 Torr); ^1H nmr δ: 1.13 (3H, d, *J* = 6 Hz), 2.10–3.10 (5H, m), 7.15–7.60 (4H, m), 8.02 (1H, dd, *J* = 1.5 and 7.5 Hz).

Cis- *and* trans-*3-methyl-1-tetralol (**13**a, **13**b)*

The method of Mitsui *et al.* (9) was adopted. To an ice-cooled stirred solution of the tetralone **12** (6.75 g, 42.0 mmol) in a mixture of *i*-PrOH (60 mL) – water (6 mL) was added $NaBH_4$ (1.50 g, 39.0 mmol) in one portion. The reaction mixture was stirred at room temperature for 44 h and evaporated to a slurry, which was diluted with water and extracted with $CHCl_3$. The extract was washed with H_2O, dried ($MgSO_4$), and evaporated to dryness to give a colorless solid (16.82 g, quantitative). Recrystallization from Et_2O–hexane gave 5.21 g (76%) of colorless needles of the *cis*-tetralol **13***a*, mp 95–96°C (lit. (9) mp 96.5–98°C); nmr (acetone-d_6) δ: 4.80 (dd, *J* = 6.3, 10.6 Hz) (9).

By fractional crystallization of the mother liquor of several reduction experiments from Et_2O–hexane, the *trans*-tetralol **13***b* was obtained, mp 110.5–112°C (lit. (9) mp 113–115°C); nmr (acetone-d_6)δ: 4.81 (t, 1H, *J* = 3.1 Hz) (9).

Lithiation of the cis-*tetralol **13**a*

To a stirred solution of **13***a* (110 mg, 0.68 mmol) and TMEDA (0.21 mL, 1.39 mmol) in dry ether (10 mL) was added *n*-BuLi solution (1.2 mL, 1.68 mmol, 1.40 *M* solution) and the mixture was refluxed for 5 h under nitrogen. The resulting red solution was quenched with MeOD (0.5 mL) at 0°C. The reaction mixture was stirred for 1 h at room temperature, treated with aqueous NH_4Cl solution, and concentrated. The resulting aqueous solution was extracted with Et_2O and the extract was washed with dilute HCl. Standard work-up gave 110 mg (quantitative) of **13***a* as a colorless solid whose ^1H nmr spectrum (acetone-d_6) showed 86% d_1 incorporation by comparison of aromatic and C-Me and C1-H integrations.

Lithiation of the trans-*tetralol **13**b*

Lithiation and deuteration of **13***b* was carried out under conditions identical to those described for **13***a*. From **13***a* (144 mg, 0.89 mmol), TMEDA (0.3 mL, 1.99 mmol), and *n*-BuLi (1.8 mL, 2.63 mmol, 1.46 *M* solution) in anhydrous Et_2O (25 mL), there was obtained after the identical work-up but with chromatography (silica gel, 30% EtOAc–hexane eluent), 130 mg (90%) of **13***b* whose ^1H nmr spectrum (acetone-d_6) showed, by appropriate integration, 24% d_1 incorporation.

*Phthalide **16** from* cis-*tetralol **13**a*

To a stirred solution of **13***a* (7.80 g, 48.1 mmol) and TMEDA (14.6 mL, 96.9 mmol) in dry ether (700 mL) was added a solution of *n*-BuLi (75 mL, 109.5 mmol, 1.46 *M* solution) under argon and the mixture was refluxed for 6 h. To the resulting red solution was added dropwise a solution of **14** (11) (11.00 g, 46.8 mmol) in dry ether (10 mL) at −45°C with stirring. The reaction mixture was stirred overnight at ambient temperature, treated with aqueous NH_4Cl solution, and washed with dilute HCl. Standard work-up gave crude amide alcohol **15** as a solid.

A solution of crude **15** and TsOH (6.80 g, 35.8 mmol) in toluene (800 mL) was refluxed for 18 h with azeotropic removal of water. The reaction mixture was washed with aqueous $NaHCO_3$ solution and subjected to standard work-up. The residue was chromatographed (silica gel, 40% EtOAc–hexane eluent) to give 11.04 g (77%) of **16**; ir (Nujol) ν_{max}: 1764 cm^{-1}; ^1H nmr δ: 1.14 (3H, d, *J* = 6 Hz), 2.50–3.00 (3H, m), 4.00 (3H, s), 6.42 (1H, br d, *J* = 10 Hz), 6.70–7.70 (8H, m); ms *m/e* (rel. intensity): 306 (34, M^+), 273 (35), 83 (100).

*Phthalide **16** from methylenemethoxy* cis-*tetralol aldehyde **17**b*

To a stirred solution of TMEDA (0.18 mL, 1.2 mmol) and *s*-BuLi (1.0 mL, 1.3 mmol, 1.27 *M* solution) in dry ether (15 mL) was added a

solution of *N,N*-diethyl *o*-anisamide (207 mg, 1.0 mmol) (11) in anhydrous Et_2O (2 mL) at −78°C under argon and the mixture was stirred for 1 h. The resulting milky suspension was quenched with a solution of **17***b* (227 mg, 1.0 mmol) in dry ether (3 mL) and the mixture was stirred overnight at ambient temperature. The solution was treated with aqueous NH_4Cl solution and concentrated. The residue was acidified with dilute HCl and extracted with Et_2O. Standard work-up gave 443 mg of a pale yellow syrup.

A mixture of the crude product and TsOH (240 mg) in toluene (60 mL) was refluxed for 6 h. The reaction mixture was washed with aqueous $NaHCO_3$ solution and subjected to standard work-up to give material that was chromatographed (ptlc, silica gel) to give 193 mg (65%) of a colorless solid. This solid was shown to be identical with compound **16** prepared above, by comparison of ^1H nmr and ir spectra.

*3-Methyl-8-formyl-*cis*-1-tetralol (17*a*)*

A mixture of **13***a* (1.01 g, 6.2 mmol), TMEDA (1.9 mL, 12.6 mmol), and a solution of *n*-BuLi (12.7 mL, 17.8 mmol, 1.40 *M*) in dry Et_2O (70 mL) was refluxed for 6 h under argon. The resulting red solution was quenched with DMF (2.4 mL, 31.1 mmol) at 0°C. The reaction mixture was stirred overnight at ambient temperature and treated with aqueous NH_4Cl solution. The Et_2O layer was washed with dilute HCl and subjected to standard work-up to give a colorless syrup. Chromatography (silica gel, 25% EtOAc–hexane) gave 1.18 g (quantitative) of **17***a* as a colorless syrup; ir (neat) ν_{max}: 3396, 1679 cm^{-1}; ^1H nmr δ: 1.12 (3H, d, J = 6 Hz), 1.30–2.80 (5H, m), 4.76 (1H, br s, exchangeable with D_2O), 5.20 (1H, t, J = 8 Hz), 7.20–7.80 (3H, m), 10.05 (1H, s); ms (20 eV) m/e: 190.0984 (M^+) (calcd. for $C_{12}H_{14}O_2$: 190.0990).

Methylenemethoxy cis*-1-tetralol aldehyde **17**b*

A mixture of **17***a* (0.75 g, 4.0 mmol), diisopropylethylamine (2.6 mL, 15.0 mmol), and chloromethyl methyl ether (2.3 mL, 30.3 mmol) in dry THF (40 mL) was stirred for 7 days at room temperature. The reaction mixture was evaporated to dryness and the residue was dissolved in water. The solution was acidified (dilute HCl) and extracted with Et_2O. The extract was washed with brine and worked up in the standard manner to give a residue that was chromatographed (silica gel, 15% EtOAc–hexane) to give 0.82 g (89%) of **17***b* as a colorless syrup; ir (neat) ν_{max}: 1690 cm^{-1}; ^1H nmr δ: 1.14 (3H, d, J = 6 Hz), 1.30–2.80 (5H, m), 3.40 (3H, s), 4.81 (2H, s), 5.39 (1H, t, J = 7 Hz), 7.20–7.80 (3H, m), 10.31 (1H, s); ms (20 eV) m/e (rel. intensity): 189 (100, $M^+ - CH_2OMe$), 172 (71).

*Phthalide alcohol **19**a*

A mixture of **13***a* (4.35 g, 26.9 mmol), TMEDA (8.3 mL, 55.1 mmol), and *n*-BuLi solution (41.0 mL, 62.3 mmol, 1.52 *M*) in dry Et_2O (400 mL) was refluxed for 6 h under argon. The resulting red solution was treated with a solution of **14** (6.34 g, 27.0 mmol) (11) in dry Et_2O (20 mL) at −40°C with stirring. The reaction mixture was stirred overnight at ambient temperature and treated with aqueous NH_4Cl solution. The Et_2O layer was washed with dilute HCl and worked up in standard manner to give crude material used directly in the following reaction.

A solution of the crude product and TsOH (1.28 g, 6.7 mmol) in benzene (350 mL) was refluxed for 8 h. The reaction mixture was washed successively with aqueous $NaHCO_3$ solution and worked up in the standard manner to give a residue that was chromatographed (silica gel, 20% EtOAc–hexane eluent) to give 0.84 g (19%) of the tetralol **13***a*. Elution with 30% EtOAc–hexane gave 0.36 g (4%) of a colorless solid, which was identified as **16** by comparison of ^1H nmr and ir spectra. Elution with 60% EtOAc–hexane gave a yellow syrup, which was crystallized from MeOH to give 3.65 g (42%) of **19***a* as colorless prisms, mp 195–197°C; ir (Nujol) ν_{max}: 3466, 1736 cm^{-1}; ^1H nmr δ: 1.14 (3H, d, J = 6 Hz), 1.20–3.00 (5H, m), 2.67 (1H, d, J = 5.5 Hz, exchangeable with D_2O), 3.99 (3H, s), 5.28 (1H, m, convertible into t, J = 7 Hz by D_2O exchange), 6.60–7.70 (7H, m); ms m/e (rel. intensity): 306 (100, $M^+ - H_2O$). *Anal.* calcd. for $C_{20}H_{20}O_4$: C 74.06, H 6.21; found: C 73.82, H 6.47.

*Phthalide ketone **19**b*

Cornforth's reagent (25) (5 mL, prepared from CrO_3 (1.0 g), H_2O (1 mL), and pyridine (10 mL)) was added to a stirred solution of **19***a* (681 mg, 2.1 mmol) in pyridine (15 mL) and the mixture was stirred at room temperature for 16 h. *i*-PrOH (1 mL) was added, the reaction mixture was diluted with EtOAc, and the whole was filtered. The filtrate was concentrated and the residue was dissolved in EtOAc. The solution was washed with dilute HCl and subjected to standard work-up to give a colorless foam. Crystallization from Et_2O gave 618 mg (91%) of **19***b* as colorless prisms, mp 140–154°C; ir (Nujol) ν_{max}: 1758, 1672 cm^{-1}; ^1H nmr δ: 1.18 (3H, d, J = 5 Hz), 2.10–3.20 (5H, m), 4.00 (3H, s), 6.80–7.70 (7H, m); ms m/e (rel. intensity): 322 (100, M^+). *Anal.* calcd. for $C_{20}H_{18}O_4$: C 74.52, H 5.63; found: C 74.30, H 5.74.

*Keto benzoic acid **20***

A suspension of **19***b* (244 mg, 0.76 mmol) and zinc powder (3.0 g) in 10% NaOH solution (30 mL) was refluxed for 24 h with stirring. After filtration, the reaction mixture was washed with Et_2O, acidified with dilute HCl, and extracted with Et_2O. The extract was washed with brine, dried, and concentrated. The residue was chromatographed (silica gel, 70% EtOAc–hexane eluent) to give 133 mg (54%) of **20**. Crystallization (toluene) gave colorless needles, mp 139.5–140°C; ir (Nujol) ν_{max}: 1696 cm^{-1}; ^1H nmr δ: 1.08 (3H, d, J = 5.5 Hz), 2.00–3.20 (5H, m), 3.85 (3H, s), 4.52 (2H, s), 6.40–7.50 (6H, m), 9.61 (1H, br s, exchangeable with D_2O); ms m/e (rel. intensity): 280 (10, $M^+ - CO_2$), 143 (100%). *Anal.* calcd. for $C_{20}H_{20}O_4$: C 74.06, H 6.21; found: C 73.82, H 6.43.

*Ene benzoic acid **21***

A stirred suspension of **16** (327 mg, 1.1 mmol) and zinc powder (4.0 g) in 10% NaOH solution (40 mL) was refluxed for 24 h. The reaction mixture was subjected to filtration. The filtrate was washed with Et_2O, acidified with dilute HCl, and extracted with $CHCl_3$. Crystallization (EtOAc–hexane) gave colorless prisms, mp 169.5–171°C; ir (Nujol) ν_{max}: 1706 cm^{-1}; ^1H nmr δ: 1.04 (3H, d, J = 6 Hz), 2.30–3.00 (3H, m), 3.92 (3H, s), 4.20 (2H, s), 5.87 (1H, dd, J = 10 and 2.5 Hz), 6.50–7.40 (7H, m); ms m/e (rel. intensity): 308 (18, M^+), 143 (100). *Anal.* calcd. for $C_{20}H_{20}O_3$: C 77.90, H 6.54; found: C 77.70, H 6.60.

*Anthraquinone **22***

A mixture of **21** (2.79 g, 9.1 mmol) and trifluoroacetic anhydride (20 mL) in dry CH_2Cl_2 (75 mL) was refluxed for 4 h under argon. The reaction mixture was concentrated to dryness and the residue was used immediately for the next step.

A stream of oxygen was bubbled through a stirred solution of the above residue and 30% Triton B (15 mL) in MeOH (180 mL) for 2 h at room temperature. After removal of the solvent, the reaction mixture was dissolved in $CHCl_3$ and subjected to standard work-up to give material that was chromatographed (silica gel, 20% EtOAc–hexane eluent) to give 2.31 g (84%) of **22**. This was crystallized (MeOH–$CHCl_3$) to furnish red needles, mp 172–172.5°C; ir (Nujol) ν_{max}: 1664 cm^{-1}; ^1H nmr δ: 1.14 (3H, d, J = 6 Hz), 2.50–3.00 (3H, m), 4.04 (3H, s), 6.25 (1H, dd, J = 10 and 2.5 Hz), 7.20–8.20 (6H, m); ms m/e (rel. intensity): 304 (100, M^+), 289 (88). *Anal.* calcd. for $C_{20}H_{16}O_3$: C 78.93, H 5.30; found: C 79.19, H 5.54.

*Hydroxyselenide **23***

*Method a (15*a)*

The *N*-phenylselenophthalimide (N-PSP) reagent was prepared as follows: To a stirred suspension of potassium phthalimide (500 mg, 2.7 mmol) in dry CH_2Cl_2 (10 mL) was added phenylselenenyl chloride (500 mg, 2.6 mmol) and the mixture was filtered to give N-PSP reagent (0.26 *M*) as a colorless solution.

To a stirred solution of **22** (39 mg, 0.13 mmol) and TsOH (10 mg, 0.05 mmol) in CH_2Cl_2 saturated with water (20 mL) was added the N-PSP reagent (0.6 mL, 0.17 mmol) at room temperature. After 15 h, the reaction mixture was treated with additional N-PSP reagent (1.0 mL, 0.26 mmol) and the mixture was stirred for a total of 84 h at

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 80.58.250.72 on 09/07/12
For personal use only.

room temperature. The resulting solution was diluted with Et_2O and washed with aqueous NaOH solution. Standard work-up followed by chromatography (silica gel, 30% EtOAc–hexane eluent) gave 52 mg (85%) of **23** as a yellow-brown solid; ir ($CHCl_3$) ν_{max}: 3504, 1664 cm^{-1}; ^1H nmr δ: 1.31 (3H, d, J = 6 Hz), 2.60–3.10 (3H, m), 3.87 (1H, br t), 4.05 (3H, s), 4.84 (1H, d, J = 4 Hz, exchangeable with D_2O), 5.34 (1H, dd, J = 4 and 2.5 Hz, convertible into d, J = 2.5 Hz by D_2O exchange), 7.10–7.90 (9H, m), 8.21 (1H, d, J = 8 Hz).

Method b (15 b)

To a stirred solution of **22** (2.50 g, 8.22 mmol) and anhydrous sodium acetate (2.40 g, 29.3 mmol) in HOAc (50 mL) and dry CH_2Cl_2 (25 mL) was added phenylselenenyl chloride (5.26 g, 27.4 mmol) and the mixture was stirred for 4 days at room temperature. After removal of solvent, the reaction mixture was dissolved in $CHCl_3$ and the resulting solution was washed with aqueous $NaHCO_3$ solution. Standard work-up gave a reddish-yellow syrup. The crude product was treated with 10% K_2CO_3 solution (70 mL) in THF (70 mL) and MeOH (70 mL) and the whole was refluxed for 4 h. The reaction mixture was concentrated and the resulting aqueous mixture was extracted with $CHCl_3$. Standard work-up followed by chromatography (alumina; 35% EtOAc–hexane eluent) gave 3.50 g (89%) of a yellow solid, which was identified as **23** by comparison of ir and ^1H nmr spectra and tlc with the product obtained by Method a).

X-14881 C (2c)

A mixture of **23** (945 mg, 1.98 mmol) and Cornforth's reagent (25) (5 mL), prepared as described in the synthesis of **19***b*, in pyridine (15 mL) was stirred for 18 h at room temperature. *i*-PrOH (1 mL) was added and the mixture was concentrated. The residue was treated with $CHCl_3$ and the resulting mixture was subjected to filtration. The filtrate was washed with dilute HCl. Standard work-up and chromatography (alumina, $CHCl_3$ eluent) gave 682 mg (72%) of the ketoselenide as a yellow solid; ir ($CHCl_3$) ν_{max}: 1697, 1667 cm^{-1}.

A solution of the ketoselenide (640 mg, 1.35 mmol), triphenyltin hydride (1.46 g, 4.15 mmol), and azobisisobutyronitrile (8 mg) in dry benzene (50 mL) was refluxed for 1 day under argon. The reaction mixture was concentrated to half of the initial volume and chromatographed (alumina, 20% EtOAc–hexane eluent) to give 27 mg (7%) of **22**, identical by ir and ^1H nmr comparison with material obtained above.

Elution (35% EtOAc–hexane) gave 288 mg (67%) of X-14881 (**2***c*). Crystallization ($CHCl_3$–MeOH) gave orange needles, mp 236–237°C (lit. (2*e*) mp 235°C (dec.)), which was shown to be identical with an authentic sample by comparison of ir, ^1H nmr, uv, and mass spectra provided by Dr. H. Maehr.

Further elution (30% $CHCl_3$–EtOAc) gave 147 mg (23%) of the starting ketoselenide as a yellow solid.

Ochromycinone (2 d)

A mixture of **2***c* (74 mg, 0.23 mmol) and anhydrous $AlCl_3$ (307 mg, 2.30 mmol) in dry CH_2Cl_2 (35 mL) was stirred for 4 h at room temperature. Ice-water was added and the mixture was extracted with $CHCl_3$. Standard work-up followed by chromatography (silica gel, $CHCl_3$ eluent) gave 70 mg (99%) of *ochromycinone* (**2***d*). Crystallization (MeOH) gave yellow prisms, mp 168–169°C (lit. (20) mp 152–153°C),[3] shown to be identical with natural ochromycinone by comparison of its ir, ^1H nmr, and uv spectra with those provided by Prof. J. H. Bowie.

Ochromycinone acetate (2e)

To an ice-cooled solution of **2***d* (73 mg, 0.24 mmol) in dry pyridine (10 mL) was added Ac_2O (3 mL) and the mixture was stirred overnight at room temperature. The reaction mixture was concentrated and the residue was dissolved in $CHCl_3$. Standard work-up gave 82 mg (99%) of **2***e*. Crystallization (EtOAc) afforded yellow prisms, mp 175–176°C (J. H. Bowie, personal communication, mp 170.5–171.5°C); ir (KBr) ν_{max}: 1768, 1708, 1672 cm^{-1}; ^1H nmr δ: 1.20 (3H, d, J = 5.5 Hz), 2.48 (3H, s), 2.50–3.10 (5H, m), 7.37 (1H, dd, J = 1.5 and 8 Hz), 7.51 (1H, d, J = 8 Hz), 7.78 (1H, t, J = 8 Hz), 8.11 (1H, dd, J = 1.5 and 8 Hz), 8.21 (1H, d, J = 8 Hz); ms m/e (rel. intensity): 348 (4, M^+), 306 (77), 263 (100).

Compound **2***e* was shown to be identical by ir and uv comparison, and by mixture mp determination with an authentic sample of ochramycinone acetate provided by Prof. J. H. Bowie.

[3]The mp discrepancies are probably due to impurities present in the originally isolated ochromycinone: J. H. Bowie, personal communication, March 13, 1984.

Acknowledgements

We gratefully acknowledge the financial support of NSERC Canada and Merck Frosst Canada. We thank E. G. Doadt for experimental work, which pointed the way towards the successful synthesis; Dr. M. Uemura, Osaka City University for a preprint of ref. 5 and beneficial discussion; and Dr. H. Maehr for spectral data of X-14881 C. Prof. J. H. Bowie kindly provided spectral data of ochromycinone, a sample of ochromycinone acetate, and much encouragement.

This paper is dedicated to Dr. O. E. (Ted) Edwards

REGINA ARNOLD, GABOR FODOR, CLIFFORD GEORGE, and ISABELLA KARLE. Can. J. Chem. **65**, 131 (1987).

The structure of the Michael adduct of L-ascorbic acid (**1**) to methyl vinyl ketone was established as 2-(3-oxobutyl)-3-oxo-L-gulonolactone⟨3,6⟩hemiketal (**3**). In aqueous solution **3** is prone to undergo base- or acid-promoted degradations. 1-(2-Furyl)-1,4-pentanedione was isolated from the acidic product mixture. Under strictly anhydrous acid-catalyzed conditions, if a suitable nucleophile like ethanol is present, the tricyclic ethyl ketal **6***b* forms. In the absence of a nucleophile, the unexpected self-condensation of **3** occurs leading to cyclo-trimer **7**, the structure of which was established by X-ray crystallography. Trimer **7**, held together via ketal bridges, is converted quantitatively into the tricyclic methyl ketal **6***a* in methanolic hydrogen chloride. Mechanisms are proposed for the formation of **6***a* and *b* or **7**.

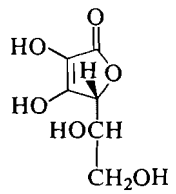
REGINA ARNOLD, GABOR FODOR, CLIFFORD GEORGE et ISABELLA KARLE. Can. J. Chem. **65**, 131 (1987).

On a établi que le produit d'addition de Michael de l'acide L-ascorbique (**1**) sur la méthyl vinyl cétone est le (oxo-3 butyl)-2 oxo-3 L-gulonolactone⟨3,6⟩hémicétal (**3**). En solution aqueuse, le composé **3** est sujet à subir des dégradations sous l'influence tant des acides que des bases. On a isolé la (furyl-2)-1 pentanedione-2,4 du mélange des produits obtenus en milieu acide. En milieu acide strictement anhydre et en présence d'un nucléophile approprié, comme l'éthanol, il se forme l'éthyl cétal tricyclique **6***b*. En l'absence d'un nucléophile, il se produit une auto-condensation surprenante du composé **3** qui conduit au cyclo-trimère **7** dont la structure a été établie par diffraction des rayons-X. Sous l'influence du chlorure d'hydrogène en milieu méthanolique, le trimère **7**, qui est retenu ensemble par des ponts cétals, se transforme quantitativement en méthyl cétal tricyclique **6***a*. On propose des mécanismes pour la formation des composés **6***a* et *b* ou du composé **7**.

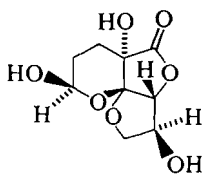
[Traduit par la revue]

Introduction

L-Ascorbic acid (**1**) has been found recently to act as a Michael carbanion donor towards α,β-unsaturated aldehydes and ketones (1). The reaction with acrolein leads to the tricyclic hemiacetal lactone **2**. The homologous aldehydes methacrolein



1



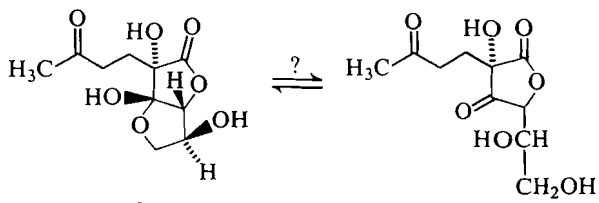
2

and crotonaldehyde likewise give tricyclic adducts (2). In contrast, addition of **1** to methyl vinyl ketone yields the bicyclic lactone **3**. More recently the list of Michael acceptors has been extended to include cyclic enones and also benzoquinone monoepoxide (3).

The L-ascorbic acid – methyl vinyl ketone adduct 2-(3-oxobutyl)-3-oxo-L-gulonolactone⟨3,6⟩hemiketal (**3**) attracted our attention early because of its potential synthetic utility as a chiral intermediate. The tautomer of **3**, namely the monocyclic diketo lactone **4**, appeared to be set up for an intramolecular aldol condensation in a Robinson annulation sequence.

Although there was no spectral evidence that **4** is present in neutral solution, its transient existence under base- or acid-catalyzed conditions was envisaged. This working hypothesis prompted us to expose adduct **3** to various reaction conditions.

[1]Author to whom correspondence may be addressed.



3 **4**

It soon became clear that the idea of using **3** in a Robinson annulation had to be abandoned. In return, however, we learned what conditions promote the degradation of **3**, and we discovered that **3** can undergo a remarkable self-condensation (preliminary paper, ref. 4). These and other aspects of the chemistry of **3** will be the subject of this paper.

Results and discussion

Adduct **3** is a hydrophilic molecule and therefore readily soluble in protic solvents. One of our first findings was that in such an environment bases as well as acids promote the degradation of **3**. In 1% ethanolic potassium hydroxide the lactone opens up to the carboxylic acid, which is subsequently decarboxylated. This degradation was proven by the spectral evidence that the products had lost the lactone functionality. Degradation of the structurally related 2-*C*-benzyl ascorbic acid was reported earlier (5).

The acid-promoted degradation was studied in more detail. Thus it was shown that **3** decarboxylates in dilute hydrochloric acid; the reaction proceeds rapidly on heating to 80°C. One neutral component, 1-(2-furyl)-1,4-pentanedione (**5**) was isolated. Its ir and nmr characteristics were in accord with literature values for **5** reported by Severin and König (6). The pathway

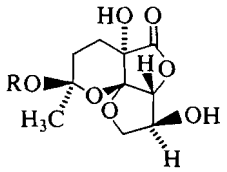
5

from **3** to **5** can be rationalized by a straightforward mechanism (2). Our results are in line with the known degradation of piptosidin (*7a*), a natural product that is structurally similar to **3**. Also, the slow spontaneous degradation of **3** in aqueous solution should be mentioned. Compound **5** was shown (by tlc) to be present in an "aged" solution of **3**.

No ascorbic acid (**1**) was detected in these experiments, proving that the Michael addition of **1** to methyl vinyl ketone is not reversible, unlike the formation of ascorbigen by C-2 alkylation of **1** with 3-(hydroxymethyl)-indole (8).

The impact of catalytic amounts of acids in an anhydrous medium was studied next. We found that the lactone ring of **3** remains intact, but two unexpected condensation reactions occur. None of the transformations that are to be described involve tautomer **4**. Therefore the existence of **4** as a reactive intermediate was ruled out.

When compound **3** and a trace of *p*-toluenesulfonic acid were refluxed in a benzene–ethanol mixture under strictly anhydrous conditions (azeotropic removal of water), a crystalline product was isolated from the reaction mixture, namely the tricyclic ethyl ketal **6***b*. The methyl ketal **6***a* had been prepared earlier (1) when **3** was exposed to glycosidation conditions, i.e., 2% methanolic hydrogen chloride. One should rationalize why methyl or ethyl ketal formation at C-3 of adduct **3** is not observed. This ketalization would require a puckered bridgehead carbonium ion at the transition state. In contrast, the carbonyl group in the 3-oxobutyl side chain is less restricted to participate in mixed ketalization. However, methyl glycoside formation at C-3 has been reported for R = benzyl (5) and R = skatyl (3-methylindolyl) (8), where intramolecular ketalization with the substituent at C-2 is excluded.



6*a*, R = CH_3
6*b*, R = C_2H_5

The mechanism for the formation of the tricyclic ethyl ketal **6***b* involves continuous removal of water, which shifts the overall reaction irreversibly towards the C-3′ carbonium ion, which is then captured by an intramolecular stereospecific attack of the C-3 hemiketal hydroxyl upon one face of the planar ion at C-3′. We did not observe the formation of diastereoisomers of either **6***a* or **6***b*.

The intramolecular ketalization depends upon the presence of a reactive nucleophile. Therefore it was deemed of interest to study the behavior of **3** with no external nucleophile present. Upon refluxing a suspension of **3** in benzene under anhydrous conditions in the presence of an acid catalyst, a crystalline product formed. It was practically insoluble in all common solvents except methylene chloride. In further experiments methylene chloride was used as the solvent of choice.

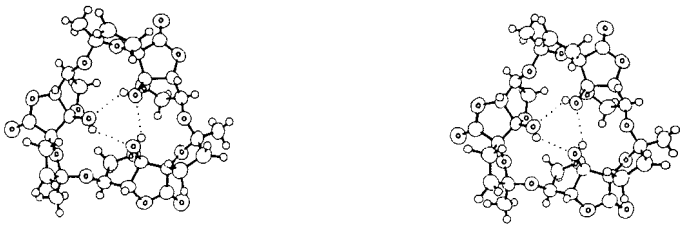


FIG. 1. Stereodiagram of **7** from experimental coordinates determined by X-ray diffraction. Thermal ellipsoids enclose 50% probability.

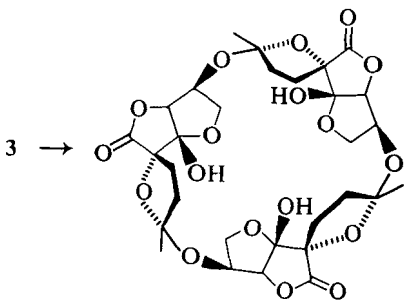
The spectral and chemical properties of the new compound were controversial. The ir spectrum showed only one carbonyl band at a position (1800 cm^{-1}) that is unusually high for a lactone absorption. The keto carbonyl, present in **3**, disappeared. Several osmometric molecular weight determinations gave high (≥500) but inconsistent values. Therefore the possibility of an intermolecular reaction had to be considered. However, the mass spectrum showed no M^+ peak in that order of magnitude (highest peak: *m/e* 228). Furthermore, the ^{13}C nmr spectrum showed ten resonances; hence the number of carbons of **3** was preserved. The chemical shifts also indicated that the skeleton of **3** did not undergo a drastic structural change. The ^1H nmr spectrum (60 MHz) confirmed a methyl singlet at δ 1.65, a singlet at δ 4.50, comparable to the C-4 proton in **3**, and only one hydroxyl proton resonance. Unlike results for compound **3**, resonances of uncertain multiplicities were found up- and downfield of the C-4 proton singlet. The data suggested, however, that the unknown compound was a symmetrical oligomer.

X-ray analysis revealed a highly symmetrical crown-like structure (Fig. 1). This remarkable macrocycle **7**, itself com-



7

posed of nine rings, is the product of a self-condensation of **3**. Now the ten peaks in the proton decoupled ^{13}C nmr spectrum were readily assigned (Fig. 2). The highest peak in the mass spectrum corresponds to the M^+ peak of the monomeric unit of **7**. We were able to obtain a high resolution (600 MHz) ^1H nmr spectrum of **7**, the downfield portion of which clearly shows the coupling pattern of the C-4, C-5, and C-6 protons (Fig. 3). The geminal protons H-6 and H-6′ are separated by 1.0 ppm, because H-6′ is deshielded by the tetrahydrofuryl oxygen of the adjacent monomeric unit. This "through space" effect reflects the spatial arrangement of the nine rings and the overall conformational rigidity of **7**. The integrated intensity of the C-4 proton was consistently less than expected. A small increase in the height of the singlet was observed when one of the C-2′ protons was selectively irradiated. These observations suggest a nuclear Overhauser effect (nOe). However, the percentage of intensity increase was not determined. Scale models show that

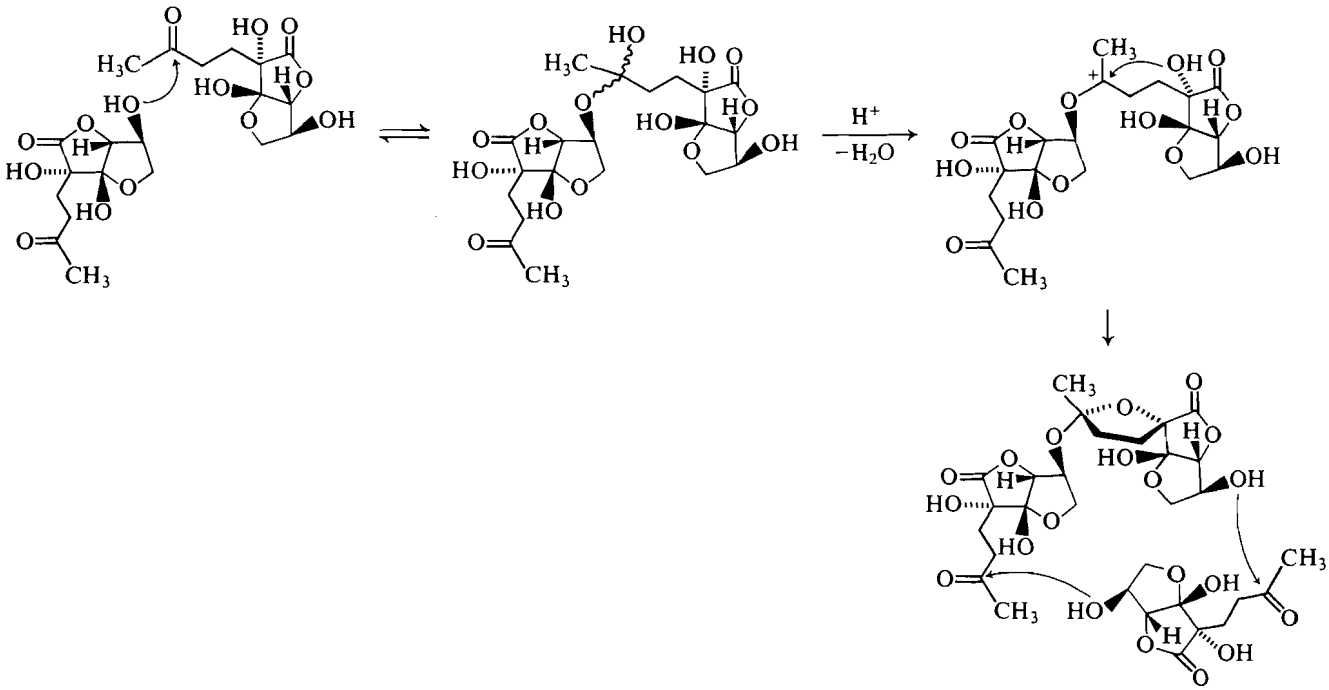

SCHEME 1

the protons in question are very closely situated, a prerequisite for the nOe.

The self-condensation (cyclo-trimerization) of **3** occurs almost quantitatively. Yields of 90% were reproducible with no polymeric by-products. The solvent dependency was demonstrated when ketolactone **3** failed to trimerize in anhydrous tetrahydrofuran under comparable conditions (acid catalysis, reflux, presence of molecular sieves 4Å to remove water if formed). Thus only anhydrous aprotic solvents that are unable to participate in hydrogen bonding to the hydroxyls of **3** promote this self-condensation.

Any reaction mechanism for **7** should be viewed under the premise that the solvent prompts the hydrophilic monomer as well as oligomeric intermediates to "curl up" during the reaction sequence. Thereby the spatial prerequisite for the successful cyclo-trimerization of **3** can be achieved. As a first step, reversible hemiketal formation may occur intramolecularly with either the C-2 or the C-3 hydroxyl, or intermolecularly with the C-5 hydroxyl of another molecule of **3**. We propose in Scheme 1 that the latter hemiketal is preferentially and irreversibly dehydrated, thus linking two molecules of **3**. An intramolecular reaction involving the C-3 hydroxyl appears to be prevented on steric grounds. This view was supported by examining a Dreiding model of the assumed dimeric carbonium ion intermediate. The C-2 hydroxyl, however, can approach the carbonium ion without steric restrictions. The intramolecular ketalization has to be stereospecific, for only the "right" configuration at the ketal carbon allows the self-condensation to proceed and ultimately leads to the cyclo-trimer **7**. In keeping with the carbohydrate derived name for the parent molecule **3**, we chose the following name for trimer **7**: tris⟨3′,5⟩ketal of 2-(3′-oxobutyl)-3-oxo-L-gulonolactone⟨2,3′⟩hemiketal⟨3,6⟩hemiketal.

A drawback of this nomenclature is that the spiro junction of **7** is not mentioned explicitly. The atom numbering scheme used in the discussion of the X-ray analysis is somewhat different to avoid ambiguities. As for the spiro junction, piptosidin, a spirodilactone (*7a,b*), attracted our attention, since its skeleton is strikingly similar to the monomeric unit of **7**.

The trimer **7** is held together via ketal bridges. For that reason, the otherwise very stable substance was expected to be sensitive to acid. Furthermore, if our mechanistic ideas are correct, the acid-catalyzed breakdown of **7** should lead, in the presence of a nucleophile, to the respective tricyclic ketal (**6**). We found that transketalization in methanolic hydrogen chloride yields the methyl ketal **6***a* quantitatively.

The cyclo-trimer **7** is a lipophilic molecule but the three inwardly oriented hydroxyls should render the cavity hydrophilic. Crown ethers exhibit comparable features, although on a simpler structural level. It was an intriguing thought to use **7** as a macrocyclic ligand for metal ions. Initial experiments designed to probe the idea gave only negative results.

The Dreiding model of **7** is somewhat misleading with respect to the size of the cavity in the macrocycle, because the model is conformationally flexible. The X-ray structure analysis revealed after the final refinement that the hydroxyl hydrogens participate in hydrogen bonding within the trimer. As a result, the molecule is locked into one conformation in which the oxygens of the three hydroxyls occupy fixed position at the corners of an equilateral triangle (2.76(1) Å). In this conformation there is no cavity that could accommodate a guest cation.

Experimental

Melting points were determined on a Electrothermal melting point apparatus and are uncorrected.

Infrared spectra were recorded on a Beckman IR 10 or IR 8 spectrometer. For measurements in solution a pair of matched cells (NaCl) with a pathlength of 0.11 mm was used.

The ^{1}H nmr spectra were recorded on a Varian EM-360 (60 MHz) spectrometer or on a Varian CFT-20 spectrometer equipped with a proton probe at 80 MHz. The 600-MHz nmr data were obtained at the Carnegie–Mellon NMR Center for Biomedical Studies in Pittsburgh. Tetramethylsilane was used as internal standard. The ^{13}C nmr spectra were taken on a Varian CFT-20 spectrometer at 20 MHz. For deuterium oxide as a solvent, *p*-dioxane was the internal standard.

A Perkin–Elmer Model 141 M polarimeter was used for the optical rotation measurements.

Mass spectra were obtained on a Finnigan 4021 mass spectrometer with an INCOS data system. The ionizing voltage was 70 eV unless otherwise indicated.

Elemental analyses and osmometric molecular weight determinations were performed by Galbraith Laboratories, Inc., Knoxville, Tennessee.

2-(3-Oxobutyl)-3-oxo-L-gulonolactone⟨3,6⟩hemiketal (**3**) was prepared following the published procedure (1). Benzene was dried by distillation from sodium metal. The 2% w/v methanolic hydrogen chloride solution was prepared by passing dry hydrogen chloride gas through methanol that had been dried by treatment with magnesium metal, and subsequent distillation. The acid content was determined by titration with a standard 0.10 *M* sodium hydroxide solution.

Degradation of compound **3** *in acidic medium. Isolation of 1-(2-furyl)-1,4-pentanedione (***5***)*

A solution of 1.1 g (4.5 mmol) of adduct **3** in 100 mL 1 *M* hydrochloric acid was prepared in a flask fitted with a thermometer and an adapter for gas outlet. The solution was stirred and slowly heated to 80°C, while the evolving carbon dioxide was collected in a graduated cylinder. After 40 min the desired temperature was reached and the expected gas volume (110 mL) had been collected. The distinctly yellow solution was allowed to cool to room temperature and extracted with chloroform (2 × 40 mL). Thin-layer chromatography (tlc) (silica, ethyl acetate) revealed at least three unresolved components of R_f's <0.31 and one component of R_f 0.59. The combined extracts were shaken with 5 mL of 0.5 *M* sodium hydroxide solution and subsequently washed with 20 mL water. The basic aqueous layer turned bright yellow at first, then became brown, and was discarded. The almost colorless chloroform solution was dried ($MgSO_4$) and checked by tlc. Only the component of R_f 0.59 (silica, ethyl acetate) was present. After removal of chloroform the residue, a yellow mobile oil, was kept *in vacuo* for several hours. The oily product (208 mg, 28%) was identified as 1-(2-furyl)-1,4-pentanedione (**5**); ir (in $CHCl_3$): 1720 (s, C=O), 1680 (vs, furoyl C=O) cm^{-1}; ^1H nmr ($CDCl_3$, 80 MHz) δ: 2.21 (s, 3H), 2.98 (m, A_2B_2 system, 4H), 6.53 (dd, 1H), 7.21 (d, $J \simeq$ 4 Hz, 1H), 7.58 (unresolved d, 1H); ^{13}C nmr ($CDCl_3$): 29.9, 32.1, 36.7, 112.2, 117.0, 146.4, 152.5, 187.7, and 206.9 ppm.

These spectral characteristics are in agreement with data reported in the literature (6).

Preparation of the tricyclic ethyl ketal lactone **6**b

To 4 g (16.3 mmol) of adduct **3** a mixture of dry benzene (90 mL) and absolute ethanol (30 mL) was added, together with a catalytic amount of *p*-toluenesulfonic acid. The flask was equipped with a Dean and Stark moisture test receiver allowing the continuous removal of water. The suspension was stirred and heated to reflux, whereupon the solid dissolved. After 12 h at reflux the pale yellow reaction mixture was cooled to room temperature before the solvents were evaporated. The residue, a yellow viscous liquid, was stirred vigorously, while the flask was immersed in an ice bath until a crystalline solid precipitated. After being kept in the cold for several hours the crystalline mass was diluted with dry benzene, the crystals were filtered off, washed with a small amount of cold absolute ethanol, and dried *in vacuo* at 78°C. First crop: 1.1 g of pure **6***b*. The mother liquor was concentrated and subjected to the same work-up sequence three more times. The combined crops afforded 3 g (67%) of ethyl ketal **6***b*. Recrystallization from ethyl acetate gave large transparent prisms and plates; mp 145–147°C; $[\alpha]_D^{25}$ +53.9 ± 0.3° (*c* 1, methanol); ir (KBr): 3500 (s, sh, O—H), 3330 (s, O—H), 3000–2950 (m, C—H), 1730 (vs, lactone C=O) cm^{-1}; ir (1.5% w/w in $CHCl_3$): ~3500 (m, br, O—H), 3000–2900 (m, C—H), 1730 (vs, sh, lactone C=O) cm^{-1}; ^1H nmr (DMSO-d_6, 60 MHz) δ: 1.24 (t, 3H), 1.40 (s, 3H), 1.5–2.3 (m, 4H), 3.7–4.4 (q and m, 5H), 4.43 (s, ~1H); D_2O exchangeable resonances: δ 5.35 (b, d, 1H) and 5.75 (s, 1H); ^{13}C nmr (D_2O): 14.2, 23.4, 31.2, 35.2, 63.6, 73.1, 75.5, 77.6, 86.6, 112.8, 114.9, and 173.3 ppm; ^{13}C nmr (DMSO-d_6): 13.9, 23.7, 31.1, 34.9, 60.4, 71.9, 74.8, 76.3, 85.8, 110.0, 114.1, and 171.2 ppm; ms (20 eV) *m/e*: 274 (M^+ peak), 246, 213, 186, 173, 158, 141, 113, 99, 85, and 59 (base peak). *Anal.* calcd. for $C_{12}H_{18}O_7$: C 52.55, H 6.57, O 40.88; found: C 52.63, H 6.70, O 40.61.

*Self-condensation of 2-(3-oxobutyl)-3-oxo-L-gulonolactone⟨3,6⟩hemiketal (***3***)*

Adduct **3** (2 g, 8.1 mmol) was suspended in 100 mL methylene chloride in a flask equipped with a moisture test receiver (recycle type). To prevent reentry of water traces during recycling of the solvent the receiver was charged with molecular sieves 4Å. A catalytic amount (15–25 mg) of *p*-toluenesulfonic acid was added; the suspension was stirred and heated to reflux. After about 7 h the reaction mixture had become homogeneous. The pale yellow solution was allowed to cool to room temperature and evaporated to dryness. The residue, a crystalline yellowish solid, was suspended in 30 mL cold 95% ethanol and stirred vigorously (~30 min). The white crystals were filtered and dried *in vacuo* at 78°C. Cyclo-trimer **7** (1.67 g, 90%) was obtained. Recrystallization from methylene chloride gave small white needles. Recrystallization from methylene chloride with a trace of absolute ethanol afforded long transparent needles, among which were single crystals suitable for X-ray analysis, mp 240–242°C dec. (sealed capillary tube); $[\alpha]_D^{25}$ +57.1 ± 0.3° (*c* 0.5, methylene chloride); ir (KBr): 3400 (s, O—H), 2980–2860 (w, C—H), 1800 (vs, lactone C=O) cm^{-1}; ^1H nmr (CD_2Cl_2, 600 MHz) δ: 1.58 (s, 9H), 1.98 (m, 6H), 2.15 (m, 3H), 2.68 (m, 3H), 4.04 (dd, J = 10.7 and 4.8 Hz, 3H), 4.43 (s, <3H), 4.59 (d, J = 4.8 Hz, 3H), 5.04 (d, J = 10.7 Hz, 3H), 5.53 (s, 3H, hydroxyl protons); ^{13}C nmr (CD_2Cl_2): 21.7, 30.9, 39.6, 74.5, 76.7, 86.0, 86.9, 106.9, 111.6, and 173.5 ppm; ms *m/e*: 228 (M^+, monomeric unit), 127, 110, 82, 71, 55, and 43 (base peak, CH_3—C≡O). Molecular weight (osmometry): 495–570. *Anal.* calcd. for $C_{30}H_{36}O_{18}$: C 52.63, H 5.26, O 42.11; found: C 52.55, H 5.50, O 41.85. *Note*: The decomposition point of **7** is not a reliable physical constant. Depending on the rate of heating and whether an open or sealed capillary was used, the decomposition was found to start as low as 228°C, or as high at 250°C.

X-Ray crystallographic analysis of compound **7** *(tris⟨3′,5⟩ketal of 2-(3′-oxobutyl)-3-oxo-L-gulonolactone⟨2,3′⟩hemiketal⟨3,6⟩hemiketal)*

A clear 0.70 × 0.12 × 0.10 mm crystal was mounted in a general orientation. Unit cell parameters were refined from 24 centered reflections ($16° < 2\theta < 54°$) on an automated diffractometer with a graphite incident beam monochromater. Crystal data are

$C_{10}H_{12}O_6$ fw 228.20

Hexagonal, space group $P6_3$ (C_6^6, No. 173), $a = b = 18.997(3)$, $c = 5.691(1)$ Å, $\gamma = 120.0°$, $V = 1778.7(6)$ Å^3, $Z = 6$, $\rho c = 1.278$ gm cm^{-3}, $\mu = 8.80$ cm^{-1}, $F(000) = 720$ (22°C; CuKα, $\lambda = 1.54178$ Å). Reflection condition $000l = 2n$.

Intensities were measured on a Nicolet R3M diffractometer in the $\theta/2\theta$ mode with scan width of $(2.0 + \Delta_{\alpha 1\alpha 2})°$. The scan rate was a function of the count rate (4°/min minimum, 30°/min maximum). The range of hkl was: $-17 \leq h \leq 20$, $-20 \leq k \leq 17$, $0 \leq l \leq 7$ with $(\sin\theta/\lambda)_{max} = 0.54$. The intensities of the 3 check reflections 210, 631, and 203 were monitored every 60 reflections and showed a maximum random variation of 3.2% over the data collection. In total, 4242 reflections were measured, 1464 unique, with 1434 observed with $|F_o| > 3\sigma|F_o|$. The value of $R_{int} = \Sigma|F - \langle F\rangle|/\Sigma F = 0.02$ from merging equivalent data. The data were corrected for Lorentz and polarization, but not for absorption, effects.

The structure was solved by direct methods (9), and refined using the program SHELXTL (10). In the "block cascade" least squares the function minimized was $\Sigma w(|F_o| - |F_c|)^2$ where $w = 1/[\sigma^2(|F_o|) + g(F_o)^2]$, and $g = 0.0003$ for this work. The 149 parameters refined include the C and O coordinates, anisotropic thermal parameters, and atom positions for the hydroxyl hydrogen. All other hydrogens were fixed in idealized positions with isotropic thermal parameters fixed at 1.1 times the value of the atom to which they are bonded. The final R values were $R = 0.042$ and $wR = 0.054$ for the 1434 independent reflections, with maximum and mean shift-to-error ratio $\Delta/\sigma = 0.32$ and 0.09, respectively. The mean error in the observation of unit

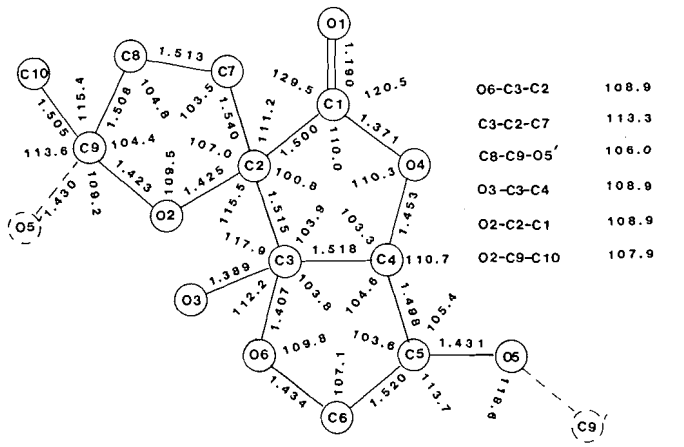

FIG. 4. Bond distances (esd's ≈ 0.004 Å) and bond angles (esd's ≈ 0.3°) for **7**.

weight was 2.02 and the final difference Fourier excursions were +0.27 and −0.34 e/Å^3.

Table 1 lists fractional coordinates for the C and O atoms as well as the equivalent isotropic thermal parameters.[2] The bond distances and angles are given in Fig. 4. The molecular geometry of the trimer is shown in the stereodiagram, Fig. 1. The asymmetric unit is linked by ketal bridges about the 3-fold axis to form a trimer with the three portions of the molecule related by symmetry operations (x, y, z), ($1.0 - y$, $1.0 + x - y$, z), and ($-x + y$, $1.0 - x$, z).

The absolute configuration of **7** is based on the chirality of L-ascorbic acid as referenced to the chiral centers of **7**. The fused lactone-furanose rings are twisted about their common bond with torsion angles C2—C3—C4—C5 = −147.5(2)° and O6—C3—C4—O4 = 82.2(2)°. This portion of the molecule has nearly the same molecular geometry as the L-ascorbic acid derivatives previously reported (1, 11): the cyclic hemiacetal of 2-(3-oxopropyl)-3-oxo-L-gulonolactone⟨3,6⟩hemiketal (**2**) and 2-(5-methyl-2-furyl)-3-oxo-L-gulonolactone⟨3,6⟩hemiketal. The respective torsion angles are −139.3(4)° and 89.8(4)° for **2**, and −140.3(4)° and 87.0(5)° for the latter. Orientation of the methyltetradydrofuryl ring at the spiro junction is described by torsion angles C(4)—C(3)—C(2)—C(7) = 85.9(3)° and C(4)—C(3)—C(2)—O(2) = 150.1(2)°.

Intermolecular contacts (trimer–trimer) in this compound are at normal van der Waals separations. The nearest approaches are H(4)--H(6B)′ = 2.26(1) Å, H(8B)--H(10B)′ = 2.39(1) Å, and O(4)--H(4)′ = 2.63(1) Å.

Within the trimer, intramolecular hydrogen bonding occurs between the hydroxyls. O(3) acts as a donor to one of its symmetry equivalents and as an acceptor from the other symmetrically equivalent hydroxyl oxygen within the trimer, as do each of the equivalent hydroxyl oxygens. The H--O and O--O distances and O--H—O angles are 2.17(4) Å, 2.76(1) Å, and 138.2(4.5)°. Near approaches within the trimer occur at H(6A)--O(2)′ = 2.56(1) Å and H(6A)--O(6)′ = 2.57(1) Å.

Atomic scattering factors are from the International Tables for X-ray Crystallography, 1974.

Preparation of the tricyclic methyl ketal ***6a*** *from the cyclo-trimer* ***7***

Trimer **7** (1.5 g, 2.2 mmol) was suspended in 120 mL anhydrous methanol that contained 2% hydrogen chloride. The suspension was stirred at room temperature in a flask fitted with a drying tube ($CaSO_4$). After 5 h a clear, colorless solution was obtained. The hydrochloric acid was neutralized with the stoichiometric amount of solid silver carbonate (8.8 g). Silver chloride was removed by suction filtration, and the filtrate was dried (Na_2SO_4). After an additional filtration with Celite the methanol was evaporated to near dryness. The residue was a clear, colorless syrup. Scratching with a glass rod induced crystallization immediately. The flask was kept in the cold for some time before the crystals were washed with a small portion of cold anhydrous ether and dried *in vacuo*. The crystalline product (mp 153–154°C) was shown to be pure methyl ketal ***6a***; yield 1.72 g (100%); ms (20 eV) m/e: 260 (M^+ peak), 232, 199, 172, 159, 141, 99, 85, and 59 (base peak).

Other spectral and chemical data of ***6a*** have been reported previously (1).

A reinvestigation of the major product from the Schmidt reaction on camphor has led to the assignment of the structure as 1,9,9-trimethyl-3-oxo-2,8-diazabicyclo[3.3.1]nonane (**5**). The structure has been established by high-field proton and carbon-13 nuclear magnetic resonance, as well as degradation to the imine ester **4**. Confirmation of the structure of **5** was achieved by X-ray crystallography. Compound **5**, $C_{10}H_{18}N_2O$, crystallized in space group $P2_1/a$ with a = 14.934(1) Å, b = 10.973(1) Å, c = 12.341(1) Å, β = 92.0°, and Z = 8. The relatively rare *cis* amide linkage is present in the molecule. In addition to the amino amide **5**, the Schmidt reaction on camphor leads to small amounts of the tetrazole **8** and the imine nitrile **9**.

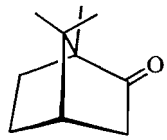
NORMAN R. HUNTER, M. ZAFAR KHAN, KIRK MARAT, OSSAMA A. L. EL-KABBANI et LOUIS T. J. DELBAERE. Can. J. Chem. **65**, 137 (1987).

Un réexamen du produit principal de la réaction de Schmidt effectuée sur le camphre a permis d'établir que sa structure est le triméthyl-1,9,9 oxo-3 diaza-2,8 bicyclo[3.3.1]nonane (**5**). On a établi cette structure en se basant sur ses spectres de rmn du ^1H et du ^{13}C ainsi que sur le fait que sa dégradation conduit à l'imine ester **4**. On a confirmé la structure **5** par diffraction des rayons-X. Le composé **5**, $C_{10}H_{18}N_2O$, cristallise dans le groupe d'espace $P2_1/a$ avec a = 14,934(1), b = 10,973(1) et c = 12,341(1) Å, β = 92,0° et Z = 8. Dans cette molécule, on retrouve une liaison amide-*cis* qui est relativement rare. En plus de l'amide aminé **5**, la réaction de Schmidt effectuée sur le camphre conduit aussi à de faibles quantités du tétrazole **8** et du nitrile aminé **9**.
[Traduit par la revue]

Introduction

Since the first report by Karl F. Schmidt (1) on the reaction of hydrazoic acid on carbonyl compounds in the presence of a mineral acid, this reaction has been carried out on a variety of organic compounds including alkenes and carbonyl compounds (2). Bridged bicyclic ketones have been studied in the Schmidt reaction. This reaction, which involves the insertion of nitrogen into the bicyclic system, yields bicyclic lactams as the major product (3). Occasionally some cleavage products are also obtained. In some cases, where excess hydrazoic acid is used, tetrazoles are also isolated. Schmidt has claimed the isolation of the tetrazole **1** in 20% yield from the reaction of hydrazoic acid on camphor (4). It has also been reported that in an attempt to prepare α-camphidone **2** by the reaction of camphor with sodium azide in the presence of concentrated sulfuric acid, less than 1% yield of **2** was obtained (5). The major product from this reaction (approximately 30%) had a mp of 178–180°C and was assigned the structure of the urea **3**.

Recently we reexamined this product using carbon-13 nuclear magnetic resonance spectroscopy. The spectrum showed a downfield absorption at 173.8 ppm, which is characteristic of an amidic carbonyl and not the carbonyl of a urea. This observation led us to reinvestigate the reaction of camphor under Schmidt reaction conditions and to reconsider the structure previously assigned to the major product.



Camphor

Results and discussion

Structure of the major product

The Schmidt reaction on camphor was carried out using two different orders of addition of reagents. Either sodium azide (2.1 equiv.) was added slowly to the rapidly stirred mixture of *dl*-camphor, chloroform, and concentrated sulfuric acid or, alternatively, concentrated sulfuric acid was added slowly to the rapidly stirred mixture of *dl*-camphor, chloroform, and sodium azide (2.1 equiv.). Identical work-up (see Experimental) gave almost the same yield of the major product regardless of the order of addition of reagents. The yield of the major product obtained over a number of trials varied from 30 to 42%. (The best conditions for this reaction are given in the experimental section.) The yields for this exothermic reaction were lowest

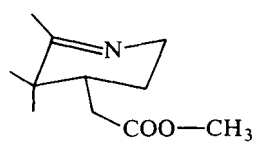
when the temperature was controlled at room temperature or lower, and in such cases a large amount of unreacted camphor was recovered. Other products that were isolated in low yields will be discussed later. The mass spectrum of the major product showed a molecular ion peak at m/z 182, indicating an even number of nitrogen atoms. The proton magnetic resonance (90 MHz) spectrum showed two different deuterium exchangeable protons, one at 5.90 ppm and the other at 1.60 ppm. The infrared spectrum showed NH stretching of secondary amines at 3310 cm^{-1} and 3285 cm^{-1}, N—H stretching for amides at 3180 cm^{-1}, carbonyl stretching (amide band I) at 1662 cm^{-1} and (amide band II) at 1640–1655 cm^{-1}. The carbon-13 nuclear magnetic resonance (22.63 MHz) spectrum (broad band proton decoupled) showed 10 peaks. The Fourier transform polarization transfer (proton decoupled INEPT) technique (6) was used to assign the carbon-13 chemical shifts (in ppm) to methine, methylene, methyl, and quaternary carbons as 71.8 (quaternary), 37.9 (methine), 37.4 (methylene), 35.9 (methylene), 35.8 (quaternary), 28.5 (methylene), 24.0 (methyl), 23.1 (methyl), and 22.9 (methyl). The peak at 173.8 ppm was assigned to an amidic carbon atom.

To assign a new structure to this major product (hereafter called the amino amide), it was mixed with 3% HCl in methanol (prepared by the addition of acetyl chloride to methanol) and heated at reflux for 3 days. The product obtained after work-up was a clear liquid, bp 85–90°C at 0.4 Torr (1 Torr = 133.3 Pa) (74% yield). The infrared spectrum showed absorption for ester and imine functional groups. The proton magnetic resonance (90 MHz) spectrum showed a singlet at 3.65 ppm (3 H's) (—CO—O—Me), a double doublet at 1.91 ppm (3 H's), and two singlets at 1.15 ppm (3 H's) and 0.97 ppm (3 H's). The mass spectrum showed a parent ion at m/z 197.

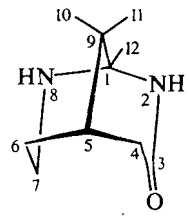
The high resolution proton magnetic resonance (400 MHz) spectrum (Fig. 1*a*) of this hydrolysis product (cf. Table 1 for chemical shifts, assignments, and couplings) established the structure of the imine ester as **4**. The methyl group attached to the C2 carbon of **4** absorbs at 1.922 ppm and is coupled to two protons on C6 through long range coupling showing a double doublet (three-bond couplings of 1.6 and 2.0 Hz).

The values for the chemical shifts and coupling constants given in Table 1 were obtained from the spectrum simulated on an Amdal 470 computer (LAME–LAOCOON program). The experimental and simulated spectra are shown in Fig. 1*b*. The carbon-13 magnetic resonance spectral data (broad band proton decoupled, and proton decoupled INEPT) and assignments are shown in Table 2.

Since only amino amide **5** would give rise to the imine ester **4**, the structure of the amino amide from the Schmidt reaction on camphor is therefore assigned as **5**. This assignment of structure **5** was confirmed by the high resolution proton magnetic resonance (400 MHz) spectrum studies (Fig. 2*a*). The chemical shifts, assignments, and coupling constants are given in Table 3. Again the values for the chemical shifts and coupling constants were taken from the simulated spectrum obtained on an Amdal 470 computer (LAME–LAOCOON program). The experimental and simulated spectra of **5** are shown in Fig. 2*b*. The carbon-13 spectral assignments for **5** are given in Table 2.



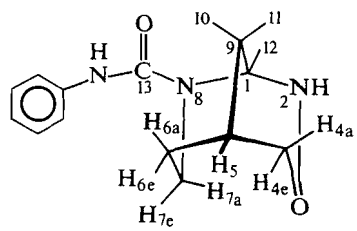
4



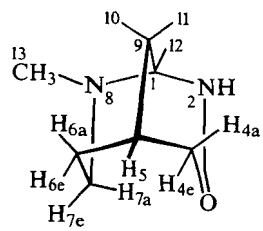
5

Proton decoupled INEPT was used to assign all carbons except the two methylenes C4 and C7. Carbon–proton shift mapping (Fig. 3) was used to distinguish between these two methylenes. The downfield absorption at 37.4 ppm was assigned to C7 and the upfield absorption at 35.9 ppm was assigned to C4.

To confirm that one nitrogen atom is amidic and the other a secondary amine, the N8 phenylcarbamoylamino derivative **6** and the N8 methyl derivative **7** were prepared by standard procedures (see Experimental).



6



7

Based on the proton and carbon-13 magnetic resonance studies of the amino amide as well as its derivatives and degradation product, it is clear that the structure of the amino amide obtained from the Schmidt reaction on camphor is that of compound **5**. An X-ray analysis further confirmed this assignment.

X-Ray crystallographic confirmation of amino amide 5

X-Ray results and discussion

Table 4 illustrates the bond lengths and angles determined for the two molecules in the crystallographic asymmetric unit. These two molecules are related by an appropriate noncrystallographic center of symmetry present at approximately (0.19, 0.25, 0.61). A perspective drawing of the two molecules is given in stereo in Fig. 4 (11).

The average values for the bond angles around the *cis* amide bond, C4—C3—O3, N2—C3—O3, N2—C3—C4, C1—N2—C3 are 120.3(2), 121.8(2), 118.0(2), 126.2(2)°, respectively. The average bond distances N2—C3, C1—N2

for the two molecules have values of 1.335(3) and 1.489(3) Å respectively. On the other hand the bond angles around a *trans* amide bond have values of 121, 122, 117, and 120° with corresponding bond distances of 1.32 and 1.45 Å, respectively (12). The N2—C3 average distance of 1.335(3) Å is similar to the bond distance of 1.32 Å in *trans* peptide bonds, which shows that there is also double bond character for this bond in compound **5**. The average C1—N2 distance of 1.489(3) Å represents a single bond and may be compared with the other single C—N bonds of compound **5**, C1—N8 and C7—N8, which have average bond distances of 1.465(3) and 1.454(4) Å, respectively, for molecules A and B. Furthermore the bond angles C1—N8—C7 and N8—C7—C6 for the two molecules have average values of 114.4(2) and 109.3(2)°, respectively.

Table 5 shows the torsion angles involving non-hydrogen atoms in the two molecules. The six-membered ring C9—C1—N2—C3—C4—C5 has a distorted chair conformation due to the *cis*-amide bond at N2—C3 in molecules A and B. This amide bond is not strictly planar (planar within 0.04 and 0.11 Å in molecules A and B, respectively) with the C1—N2—C3—C4 torsion angles being −6.7 and 15.4° for molecules A and B, respectively. The six-membered ring C1—C9—C5—C6—C7—N8 has a chair conformation in the two molecules. The torsion angles calculated for this ring in the two molecules are listed in Table 5.

There are two intermolecular hydrogen bonds between these molecules, O3(b)...N2(A) = 3.103(6), O3(B)...H(N2A) = 2.26(3) Å, angle N2(A)—H...O3(B) = 168(3)° and O3(A)...N2(B) = 2.864(6), O3(A)...H(N2B) = 1.97(3) Å, angle N2(B)—H...O3(A) = 172(3)°. The thermal parameters for the non-hydrogen atoms, the hydrogen atom parameters, and the structure amplitude table for **5** are available from the Depository of Unpublished Data.[5]

Other products from the Schmidt reaction on camphor

Other minor products that were obtained and identified from the Schmidt reaction on camphor are α-camphidone **2**, the tetrazole **8**, and the imine nitrile **9**.

(a) α-Camphidone 2

This compound was isolated from the acidic reaction mixture (along with the tetrazole **8**) in 5.3% yield and had a melting point range of 242–244°C. The infrared spectrum showed absorptions for N—H stretch and imidic carbonyl stretch. The mass spectrum showed the parent ion peak at m/z 167. The proton magnetic resonance (90 MHz) spectrum showed the amidic N—H proton resonance at 5.90 ppm (1H, m). The protons at the 4a and 4e positions were coupled to the amidic proton (^3J = 1–2 Hz). This coupling was confirmed by examination of an N—H decoupled proton magnetic resonance (90 MHz) spectrum where the coupling of H4a and H4e to the amidic N—H was removed. The carbon-13 magnetic resonance (broad band decoupled, and proton decoupled INEPT) data and assignments are given in Table 2. The lactam **2** has previously been reported as a product from the Schmidt reaction on camphor in only 1% yield (5).

(b) Tetrazole 8 (see Scheme 1)

This tetrazole, obtained in 1% yield, is N-bridge substituted and is different from the tetrazole **1** claimed by Schmidt as the major product from camphor (4). The structure of tetrazole **1**, assigned by Schmidt, was supported only by its elemental analysis and melting point (242–243°C). The tetrazole isolated by us, and assigned structure **8**, melts over the range 245–247°C in a sealed tube. The mass spectrum of **8** shows a parent ion at m/z 192. In addition, nitrogen is readily lost from the parent ion to give a fragment ion at m/z 164. The assignment of structure **8**, rather than structure **1**, to this tetrazole is based largely on its proton magnetic resonance spectrum. At 90 MHz the spectrum showed a double-double-doublet centered at 3.15 ppm for proton H4a (^2J(4a,4b) = −17 Hz, ^3J(4a,5) = 3.1 Hz, and ^4J(4a,6a) = 1.5 Hz) and a double-doublet centered at 2.95 ppm for proton H4b (^2J(4b,4a) = −17 Hz, ^3J(4b,5) = 2 Hz). A singlet at 1.78 ppm (3 H) is assigned to the hydrogens of the C11 methyl group, which are deshielded by the ring current of the tetrazole ring. A singlet at 0.81 ppm (3 H) is assigned to the hydrogens on the shielded methyl group C10. The chemical shifts of H4a and H4b, at 3.15 and 2.95 ppm respectively, are more upfield than one would predict from the corresponding hydrogens adjacent to N3 in tetrazole **1** (13). The carbon-13 magnetic resonance (broad band decoupled, and proton decoupled INEPT) data and assignments for **8** are shown in Table 2.

(c) Imine nitrile 9 (see Scheme 1)

This compound (bp 65°C at 0.1 Torr) was isolated in 1% yield from the mother liquors of the recrystallization of amino amide **5**. The infrared spectrum of **9** showed absorptions for nitrile and imine functional groups. The proton magnetic resonance (90 MHz) spectrum showed a double-doublet at 1.88 ppm (3 H) due to the protons on the C9 methyl group. This methyl group is coupled to H6a and H6b as in the imine ester **4** obtained from amino amide **5**. (All the proton couplings of imine nitrile **9** were very similar to those of imine ester **4**. The major difference in the proton magnetic resonance spectrum of these compounds was in the chemical shifts for the protons at C4 in the side chain.) The carbon-13 nmr (broad band decoupled, and proton decoupled INEPT) data and assignments are shown in Table 2.

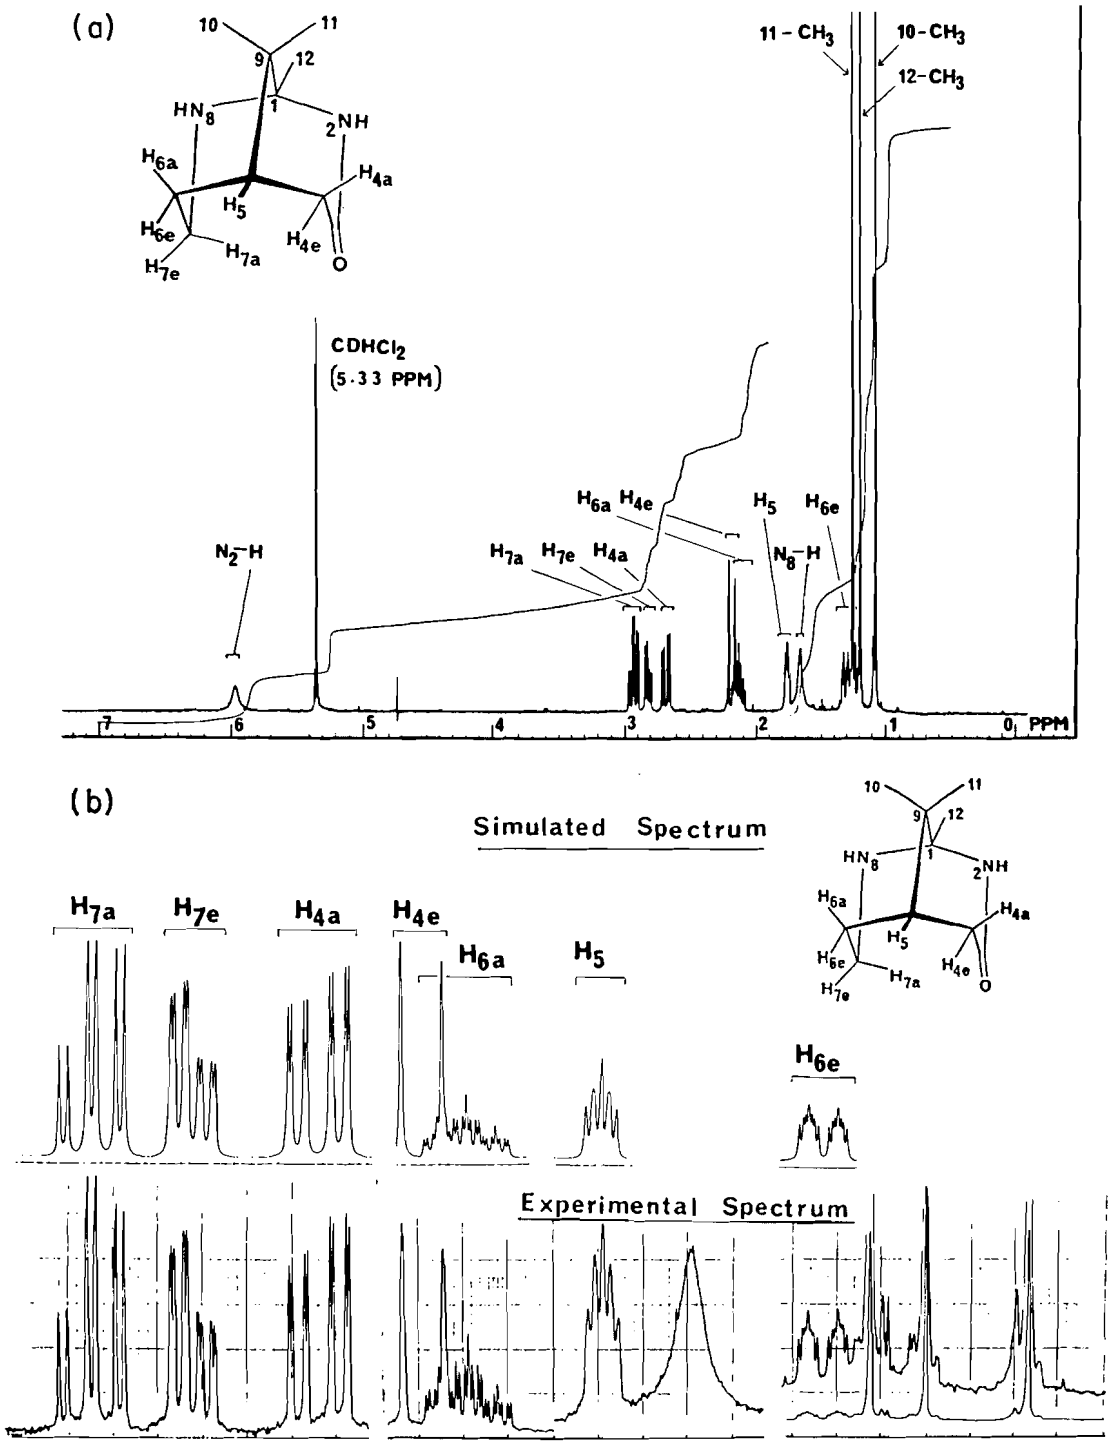

FIG. 2. (*a*) The ^{1}H nmr spectrum (400 MHz) of amino amide **5**. (*b*) The ^{1}H nmr spectrum of amino amide **5**; top: simulated spectrum; bottom: experimental spectrum (400 MHz).

Here also, with the exception of the C4 carbon, the chemical shifts are similar for both compounds **4** and **9**.

Mechanistic discussion

The mechanism established for the formation of the major product **5** will be discussed in a separate paper. However, the formation of the product **9** and the regioisomeric nitrogen insertion products **2** and **8**, though low in yield, is worthy of mechanistic comment at this stage. We suggest the simultaneous action of five different mechanisms to explain the formation of products **2**, **5**, **8**, and **9**.

We believe that, initially, camphor adds one mole of hydrazoic acid to generate the intermediate protonated azidohydrin **11** (Scheme 1). Molecular models show that the attack of hydrazoic acid on the carbonyl carbon of camphor should occur from the *endo* face due to hindrance of the *exo* face by the *syn*-7 methyl group. Nucleophilic attack at a ketonic carbonyl group requires the attainment of a 110° angle of Nu-C=O at the time of attack (14). This angle is only favourable in the case of camphor when attack is from the *endo* face. Attack of hydrazoic acid on the ketonic carbon of norcamphor (15) and of peracid during the Baeyer–Villiger oxidation of norcamphor (16) and fenchone

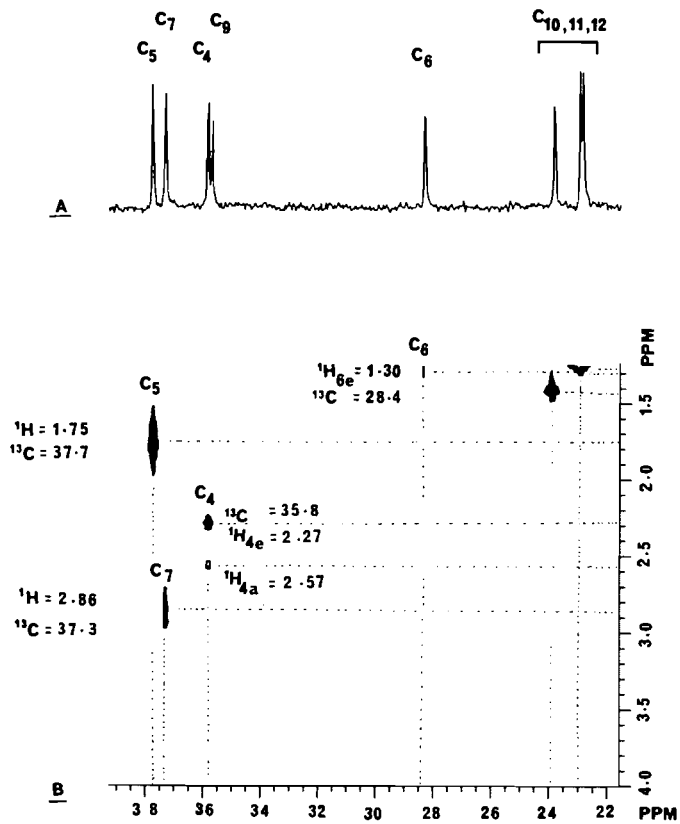

FIG. 3. *A*: The ^{13}C nmr spectrum of amino amide **5** (C1 at 71.8 ppm and C3 at 173.8 ppm not shown). *B*: Carbon–proton shift map.

(17) is believed to take place from the *exo* face because of the absence of the *syn*-7 methyl group. Based on the relative percentage yield of the amino amide **5**, we infer that most of the protonated azidohydrin **11** undergoes cleavage (Scheme 2) to generate the intermediate α-campholenoamide **16**. One mole of hydrazoic acid then adds to **16** to ultimately produce the amino amide **5**. Experimental support for this conclusion will be presented in a separate paper. In addition, some of the protonated azidohydrin **11** rearranges with methylene migration to nitrogen to produce α-camphidone **2** (*vide infra*). The isolation of compounds **8** and **9** indicates that some of the intermediate **11** dehydrates to generate the iminodiazonium ion **12***a*, which is analogous to camphor oxime **12***b*. The iminodiazonium ion **12***a* then rearranges in two ways to produce **8** and **9**: (*i*) Bridgehead carbon migration to nitrogen leading to the intermediate iminium ion **13**, which then adds one mole of hydrazoic acid to yield the tetrazole **8** (13*b*). (Iminium ion **13** may also lead to **10**. This type of cleavage between the bridgehead carbon and the imine carbon of the iminium ion has been suggested for the iminium ion formed during the Schmidt reaction of *cis*-8-methylhydrindan-1-one (13*b*) (*vide infra*).) (*ii*) Cleavage between the bridgehead carbon and imine carbon leads to α-campholenonitrile **10**. This type of cleavage has been observed for camphor oxime **12***b* (18) and fenchone oxime (19). α-Campholenonitrile **10** then reacts with one mole of hydrazoic acid to produce the iminonitrile **9**. (α-Campholenonitrile **10** was not isolated during any of the trials.)

Roberts and co-workers (20*a*) have established the configuration of camphor oxime as having the OH group *anti* to the bridgehead carbon. This assignment has been confirmed by an X-ray crystallographic study (20*b*).[6] For the present argument it is assumed that the iminodiazonium ion **12***a* and the camphor oxime **12***b* are isosteric since the iminodiazonium ion is larger than OH. It is known (21) that iminodiazonium ion intermediates rearrange according to the rule of *anti*-migration which also operates in the Beckmann rearrangement. *anti*-Migration of the bridgehead carbon to nitrogen for **12***a* would result in the iminium ion **13**, which in principle should lead to the 2-azalactam **15** and, in the case of reaction with a second mole of hydrazoic acid, the tetrazole **8**. The isolation of **8** and the absence of **15** can be explained by the fact that the excess hydrazoic acid present would react very rapidly with iminium ion **13** to produce the tetrazole **8**. The small amount of water present would not compete effectively for the iminium ion **12**. (It is known that tetrazoles cannot be produced under Schmidt reaction conditions (13*b*) from the corresponding lactams.) The same arguments can be applied to the iminium ion **14**, which

C7—N8—C1—C9	−66.1	63.0

would be produced if camphor iminodiazonium ion has the configuration with the iminodiazonium ion *syn* to the bridgehead carbon. Since tetrazole **1** was not isolated, as would be expected if the iminium ion **14** had formed, the formation of **2** probably proceeds directly from rearrangement of the protonated azidohydrin **12**. This rearrangement is analogous to that proposed by Krow and Szezepanski (22) for the formation of α-camphidone from reaction of camphor with hydroxylamine-*O*-sulfonic acid.

Similar to the rearrangement of **11** to **2**, the methylene migration during the rearrangement of other intermediate protonated azidohydrins and the intermediates formed by the attack, from the *endo* face, of peracids on camphor have been explained by considering different factors. Murray *et al.* (23), while determining the structure of steroidal D-ring lactones, have tried to identify the electronic factors involved in the Baeyer–Villiger oxidation of camphor. They suggested that the migration of the tertiary bridgehead carbon involves a high-energy transition state of the boat form (Scheme 3), while migration of the methylene carbon involves a lower energy transition state of the chair form.

Di Maio and Permutti (13*b*) have suggested the simultaneous action of two mechanisms to explain the formation of regioisomeric nitrogen insertion products obtained during the Schmidt reaction on *cis*-8-methyl hydrindan-1-one (Scheme 4).

The first mechanism proposed by Di Maio and Permutti involves the stereospecific migration of bridgehead carbon *anti* to the leaving group in the intermediate (Scheme 4) to form the iminium ion **B**, which then undergoes either ring opening to yield the corresponding nitrile or attack by excess hydrazoic acid to give the corresponding tetrazoles. The second mechanism was based upon the relative boat–chair conformational strain energies, as proposed by Murray *et al.* (23), to explain the formation of the isoquinoline-type lactam **D**. The formation of lactam **D** would be favoured by the chair transition state obtained during migration of the methylene group as indicated in structure **C**. If the relative boat–chair conformational strain energies are a factor during the rearrangement of intermediates produced in the Baeyer–Villiger reaction and the Schmidt reaction of bridged bicyclic ketones, then the formation of α-camphidone **2** from **11** can be explained on precisely the same basis. As indicated by the arrows in **11** (Scheme 1), the migration of the methylene group would result in the formation of **2** via a transition state with an energetically favoured chair conformation. The bridgehead migration of **11** to produce **15** (which we have not detected) would occur via the less favourable boat transition state.

Sauers and Beisler (17) have observed mainly methylene migrated products from the Baeyer–Villiger oxidation of *syn* 7-chloronorcamphor and *syn* 7-bromonorcamphor because the predominently *endo* attack of the peracid leads to chair conformations in the transition state. To rationalize their observations, as well as those of others (24), they considered forces that might work in opposition to both electronic and boat–chair conformational interactions in the transition state. The conformation of the leaving group would not be an important factor provided it is able to attain *trans*-coplanarity with either of the possible migrating groups (25). These authors proposed that an extra factor, associated with the torsional strain caused by the eclipsed nonbonded interactions between substituents on C2 and the hydrogens on C3, is involved in these

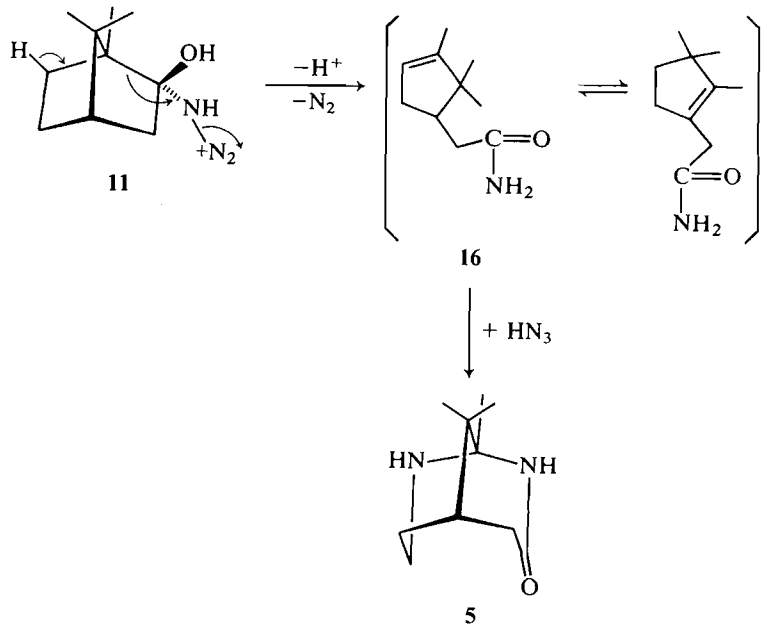
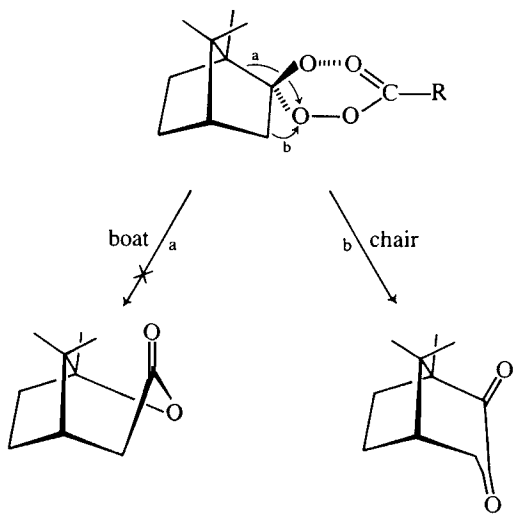
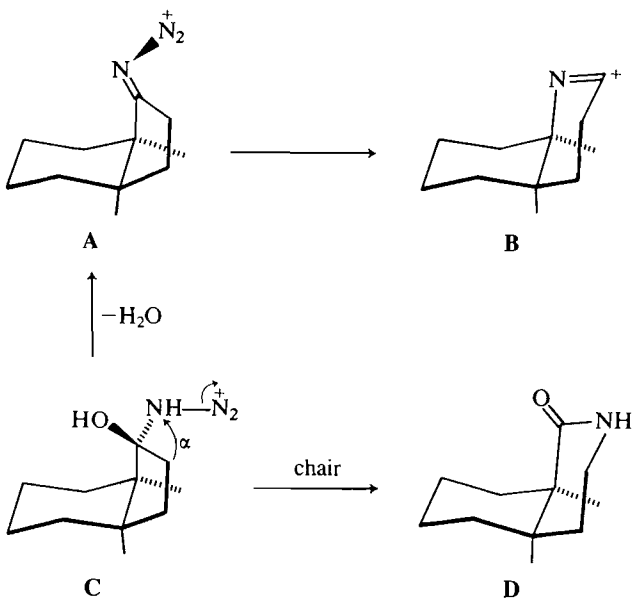


SCHEME 2



SCHEME 3



SCHEME 4

migrations. The similar nonbonded interaction between substituents on C2 and the bridgehead carbon are much less severe since the dihedral angles involved are approximately 44° (H1 with the C2 *exo* substituent) and 79° (H1 with the C2 *endo* substituent). Thus migration of the C2—C3 bond would proceed with considerable relief of eclipsing strain. Sauers and Beisler concluded that migration of the C2—C3 bond during the Baeyer–Villiger reaction of bicyclic ketones will always be favoured by torsional factors regardless of the substitution or orientation of the hydroxy-perester function. Such a rationalization was used to predict the migration of the C2—C3 bond in fenchone under peracid oxidation conditions (17). In the case of fenchone, the electronic effects are essentially equal and the competition is between formation of the boat form and relief of torsional strain. The major product (approximately 60%) was the one predicted on the latter basis.

We could apply the same arguments to the case of protonated azidohydrin **11** where there would be torsional strain caused by the eclipsed nonbonded interactions between the substituents on C2 and the hydrogens on C3. Migration of the C2—C3 bond, yielding **2**, would proceed with greater relief of eclipsing strain. It appears that the two effects of (*i*) forces due to the energetically favoured chair conformation and (*ii*) the greater relief of torsional strain caused by the eclipsed nonbonded interactions between substituents on C2 and C3 operate concurrently to cause migration in the same direction during the C2—C3 bond migration of protonated azidohydrin **11** to produce **2**. However, considering the 3-way rearrangement of **11** and the 2-way rearrangement of iminodiazonium ion **12***a*, and also the C1—C2 bond or C2—C3 bond migration or ring opening observed by other workers during the Schmidt or Beckmann reactions on bridged bicyclic ketones, it will be very difficult to predict the products of a ring enlargement owing to the different factors involved.

We could not detect or isolate compounds **15** or **1**, which would be produced from the intermediates **13** and **14**, respectively. The total yield of the identified products **2**, **5**, **8**, and **9** from the Schmidt reaction on camphor is approximately 50%. Since no unreacted camphor was recovered from the reaction under *optimum conditions* (see Experimental), it is apparent that the other product(s) obtained must be water soluble. Attempts

to obtain identifiable products from the aqueous layer have so far been unsuccessful. It is probable that some of the lactam produced (**2** or **15**) undergoes hydrolysis to water soluble amino acids prior to work-up of the Schmidt reaction. Because of the relatively low material balance it is not possible to draw definitive conclusions about the migratory ratios involved in the total reaction of hydrazoic acid with camphor.

Experimental

Melting points were determined using a precalibrated Thermopan (Kofler hot stage) melting point apparatus or, in the case of a sealed tube melting point, a Canlab–Gallenkamp apparatus. Infrared spectra were recorded on a Unicam SP 1000 spectrophotometer. Mass spectra were recorded using a Finnigan 1015 mass spectrometer under electron-impact at 70 eV ionization voltage, and on a high resolution A.E.I. model MS 50 mass spectrometer (hrms). Proton magnetic resonance spectra were recorded on a Varian EM-360 (60 MHz), a Bruker WH 90 (90 MHz), or a Bruker WH 400 (400 MHz) spectrometer. Carbon-13 nuclear magnetic resonance spectra were obtained on a Bruker WH 90 (at 22.63 MHz) spectrometer equipped with a NIC 1180 computer, 293 A′ pulse programmer, homebuilt phase shifter, and NTL FT software. Analytical thin-layer chromatography (tlc) was performed on sheets precoated with silica gel 60 F(254) (EM reagents) of 0.2 mm thickness. Spots were detected under uv light or visualized in an iodine chamber. Silica gel Kieselgel 60 (230–400 mesh ASTM) was used in columns for flash chromatography. All solvent evaporations were carried out on rotary evaporators.

X-Ray experimental

Colorless crystals of compound **5** were obtained as rods elongated along the *b* axis exhibiting the forms [100], [010], and [001]. The crystal data are given in Table 6. The systematically absent reflections that occurred for the crystal were $h0l$; $h = 2n + 1$ and $0k0 = 2n + 1$. This is consistent with the monoclinic space group $P2_1/a$.

Quantitative data collection was carried out on an Enraf–Nonius CAD4F diffractometer with an $\omega/2\theta$ scan. Observational weights (7) for the reflections were derived from the formula $W = (2I)^2/F_o^2(T + (0.02I)^2 + r^2B)$, where I is the net intensity, F_o is the observed structure amplitude, T is the total peak count, B is the sum of the background counts, and r is the ratio of the peak-scan time to the total background counting time ($r = 2$ for this data). Lorentz and polarization corrections were applied.

X-Ray diffraction data collected on the crystal were processed by using the XRAY76 system (8). The observed structure amplitudes were then converted into normalized structure factors, E values, by using a Wilson plot (9). The overall B was 3.4 Å^2. The structure was solved by employing the MULTAN80 package of computer programs (10). Both figures of merit, ABSFOM and RESID, were used to choose the best set of phases used in the structure determination; ABSFOM was 1.0700 and RESID had a value of 13.08.

The positions of the non-hydrogen atoms of the molecule were determined from a calculated E map. Least-squares isotropic refinement gave an R value of 0.148. Anisotropic refinement was then carried out and gave an R value of 0.109. The positions of the hydrogen atoms were located by using a difference Fourier map. Finally, full-matrix least-squares refinement of anisotropic temperature factors for the non-hydrogen atoms and isotropic refinement for the hydrogen atoms converged to an R index of 0.042. The largest shift/error value for the coordinates of the non-hydrogen atoms was 0.38 and the average shift/error for all of the parameters was 0.12 for the final cycle of refinement. The final atomic parameters are given in Table 7. The DEC 2060 computer at the University of Saskatchewan was used to carry out all crystallographic computations.

Schmidt reaction on camphor

(a) Amino amide ***5***

d,l-Camphor (30.4 g, 0.2 mol) was dissolved in chloroform (400 mL). Concentrated H_2SO_4 (100 mL) was then added. To this rapidly stirred two-phase system, sodium azide (27.0 g, 0.41 mol) was added in small portions over a period of 3.25 h. During this addition

the temperature of the reaction mixture remained above 35°C and occasionally reached 50°C. The reaction mixture was stirred for an additional 3.5 h and then placed in the freezer overnight. The upper $CHCl_3$ layer was decanted from the thick yellow gum at the bottom of the flask. This yellow gum was diluted with ice-water (600 g) and stirred for 5 min before extraction with $CHCl_3$ (1 × 200 mL). This $CHCl_3$ extract was reserved for later work-up (see below). The acidic aqueous layer was adjusted to pH 10 with 60% NaOH solution and then extracted with $CHCl_3$ (3 × 150 mL). These combined $CHCl_3$ extracts were dried with anhydrous Na_2SO_4 and then evaporated to dryness on the rotary evaporator. The semisolid obtained was crystallized from ethyl acetate to give 14.3 g (39.4%) of pure compound, mp 181–183°C (sealed tube); ir (Nujol) cm^{-1}: 3310 (m) and 3285 (m) (NH stretch of amine), 3180 (m) (NH stretch of amide), 1662 (s) (C═O, amide band I), 1655–1640 (s) (amide band II). The carbon-13 nmr and proton nmr (400 MHz) data and assignments are given in Tables 2 and 3 respectively. Mass spectra *m/z*: 182 (38) (M^+), 167 (10) (M − (CH_3)), 139 (23) (M − (NH═C═O)), 114 (46), 101 (98), 98 (77) (139 − (CH_2CH═CH_2)) 82 (100) (98 − (NH_2)). *Exact Mass* calcd. for $C_{10}H_{18}N_2O$: 182.1419; found (hrms, 100%): 182.1420. This compound was assigned the structure of the amino amide **5**.

The mother liquor saved from the crystallization of the amino acid **5** was concentrated on the rotary evaporator and the product obtained was chromatographed on a silica gel column (10 in. × 1.5 in.). Sixty-four fractions (10 mL) were collected using $CHCl_3$–EtOH (20:1) as the eluting system. A white solid (mp 181–182°C in sealed tube), 0.995 g, 2.7%, was obtained from fractions 30–62. This material was identified as the amino amide **5** by ir, nmr, and mass spectra.

(b) Imine nitrile 9

Fractions 15–21 from above were combined and concentrated. A brown liquid (0.548 g) was obtained. This product was purified by treatment with activated charcoal and rechromatography on silica gel with $CHCl_3$. The tlc pure fraction (R_f 0.38 in $CHCl_3$–EtOH (10:1, v:v)) collected was distilled at 65°C oil bath temperature (0.1 Torr) to give 0.315 g of colourless liquid, ir (thin film) cm^{-1}: 2240 (m) (CN), 1651 (s) (C═N); ^{1}H nmr (90 MHz) in $CDCl_3$, δ: m centred at 3.54 (2H, H6a, H6e), dd at 2.44 (1H, H) [^2J(7, 7*) = 16.5 Hz, ^3J(7, 4a) = 4.0 Hz], dd at 2.08 (1H, H7*) [^2J(7*, 7) = −16.6 Hz, ^3J(7*, 4a) = 9.5 Hz], dd at 1.88 (3H, C9 methyl) [^5J(Me, 6a) = 1.9 Hz, ^5J(Me, 6e) = 1.6 Hz], m at 1.97–1.41 (3H, H4a, H5a, H5e), s at 1.13 (3H) and s at 0.97 (3H) due to C10 and C11 methyls. The carbon-13 nmr (proton decoupled and proton decoupled INEPT) data and assignments are given in Table 2. Mass spectra *m/z*: 164 (18) (M^+), 149 (2) (M − (CH_3)), 124 (16) (M − (CH_3—C═N—CH_2—CH_2)), 83 (100) (124 − (CH_3—CN)), 68 (47) (83 − (CH_3)), 55 (76) (83 − (CH_2═CH_2)). This mass fragmentation pattern is analogous to that of the imine ester **4** (see below).

(c) Tetrazole 8 and α-camphidone 2

The chloroform extract of the acidic aqueous layer (see Sect. (*a*) above) was washed with water, dried, and concentrated. A white solid (4.44 g) was obtained. Thin-layer chromatography with CH_2Cl_2–CH_3OH (100:2, v:v) showed two spots (R_f 0.75 and 0.44). This white solid was chromatographed on a silica gel column using CH_2Cl_2–CH_3OH (100:2, v:v) as eluant.

(i) Tetrazole 8

Fractions 18 and 19 from the above chromatography were combined and concentrated to give a white crystalline solid (0.349 g) that was pure by tlc. After recrystallization from ethyl acetate the product had mp 245–247°C (sealed tube); ir (thin film) cm^{-1}: 1520 (m) (C═N of tetrazole ring), 1417 (s) (C—N stretch); ^{1}H nmr (90 MHz) in $CDCl_3$, δ: ddd at 3.15 (1H, H4a) [^2J(4a, 4b) = 17 Hz, ^3J(4a, 5) = 3.1 Hz, ^4J(4a, 6a) = 1.5 Hz], dd at 2.95 (1H, H4b) [^2J(4b, 4a) = −17 Hz, ^3J(4b, 5) = 2 Hz], set of multiplets from 2.42 to 1.92 (4H, H5, H6a, H7a, H7b), s at 1.78 (3H, C11 methyl), m at 1.60 to 1.33 (1H, H6b), s at 1.16 (3H, C9 methyl), and s at 0.81 (3H, C10 methyl). The carbon-13 nmr (proton decoupled and proton decoupled INEPT) data and assignments are given in Table 2. Mass spectra *m/z*: 192 (8) (M^+), 164 (5) (M − (N_2)), 163 (10) (164 − (H)), 149 (20) (164 − (CH_3)), 124 (15), 109 (9) (149 − (CH_2—CN)), 108 (25) (109 − (H)), 107 (33) (108 − (H)), 97 (79), 82 (100) (M − (N_2)). *Anal.* calcd. for $C_{10}H_{16}N_4$: C 62.47, H 8.39, N 29.14; found: C 62.35, H 8.39, N 29.12.

(ii) α-Camphidone 2

Fractions 23–36 from the above chromatography were combined and evaporated to dryness to yield a white solid, which was recrystallized from ethyl acetate (1.76 g, 5.3%) (mp 242–244°C in a sealed tube). Thin-layer chromatography showed that this product was pure; ir (Nujol) cm^{-1}: 3310 (w), 3220 (m) and 3090 (w) (all N—H stretchings), 1667 (s) (C═O); ^{1}H nmr (90 MHz) in $CDCl_3$, δ: broad m centred at 5.90 (1H, N3 H), dddd at 3.44 (1H, H4a) [^2J (4a, 4e) = −11.1 Hz, ^3J(4a, 5) = 3.5 Hz, ^3J(4a, NH) = 1–2 Hz, ^4J(4a, 6a) = 1.6 Hz], ddd at 2.99 (1H, H4e) [^2J(4e, 4a) = −11.1 Hz, ^3J(4e, 5) = 2 Hz), ^3J(4e, NH) = 2.0 Hz], set of m at 2.22 to 1.42 (5H, H5, H6a, H6b, H7a, H7b), 3 s at 1.10 (3H), 1.04 (3H), and 0.96 (3H) (C9, C10, and C11 methyls); NH-decoupled ^{1}H nmr (90 MHz) in $CDCl_3$, δ: ddd at 3.46 (1H, H4a) [^2J(4a, 4e) = 11.1 Hz, ^3J(4a, 5) = 3.5 Hz, ^4J(4a, 6a) = 1.6 Hz], dd at 3.01 (1H, H4e) [^2J(4a, 4e) = 11.1 Hz, ^3J(4e, 5) = 2.0 Hz], no N—H absorption, and the rest of the spectrum similar to the NH coupled spectrum. The carbon-13 magnetic resonance (proton decoupled and proton decoupled INEPT) data and assignments are given in Table 2. Mass spectra *m/z*: 167 (61) (M^+), 152 (97) (M − (CH_3)), 139 (6) (M − (CO)), 138 (15) (139 − (H)), 124 (27) (M − (HN═C═O)), 98 (94) (M − (Me_2C═CH—CH_2)), 69 (100) (Me_2C═CH—CH_2), 55 (73) (69 − (CH_2)).

Imine ester 4

Acetyl chloride (12 g) was slowly added to methanol (240 mL) over a period of 0.5 h (26). Amino amide **5** (2.0 g, 0.11 mol) was added and this solution was heated under reflux for 3 days while the reaction was monitored by tlc. The reaction mixture was concentrated to dryness and the solid obtained was dissolved in water (30 mL). This aqueous solution was made basic (pH 9–10) with dilute sodium bicarbonate solution and extracted with $CHCl_3$ (3 × 30 mL). The combined $CHCl_3$ extracts were dried with sodium sulfate and evaporated to dryness. A clear liquid (2.08 g) was obtained. After distillation (bp 85–90°C at 0.4 Torr), 1.60 g (74%) of a colourless liquid was obtained; tlc: R_f 0.55 in $CHCl_3$–EtOH (10:1, v:v); ir (thin film) cm^{-1}: 1745 (s) (O═C—OCH_3), 1655 (s) (C═N); ^{1}H nmr data (400 MHz) are given in Table 1. Carbon-13 nmr (proton decoupled and proton decoupled INEPT) data and assignments are given in Table 2. Mass spectra *m/z*: 197 (15) (M^+), 182 (11) (M − (CH_3)), 166 (12) (M − (OCH_3)), 138 (8) (M − (CO—OCH_3)), 128 (47) (Me_2C═CH—CH_2COOCH_3), 124 (47) (M − (CH_2—$COOCH_3$)), 96 (77), 69 (100). *Exact Mass* calcd. for $C_{11}H_{19}NO_2$: 197.1416; found (hrms, 64.8%): 197.1419.

N8-Phenylcarbamoylamino amide 6

A benzene solution (50 mL) of phenyl isocyanate (0.81 g, 0.006 mol) was added to a benzene solution (50 mL) of the amino amide **5** (1.09 g, 0.006 mol). Within 2 min a white solid started to appear. The mixture was stirred for an additional 16 h. The white solid suspended in the solution was filtered off, washed with fresh benzene (15 mL), and dried under suction (yield 1.78 g). This highly polar compound was recrystallized from EtOAc–MeOH (3:1, v:v) to give 1.07 g (60%) of **6**; mp 163–165°C; ir (Nujol) cm^{-1}: 3330 (m), 3200 (m) and 3080 (m) (all N—H stretch), 1675 (s) (C═O, urea), 1645 (s) (C═O, amide), 1595 (s) (C═C, aromatic); ^{1}H nmr (90 MHz) in DMSO-d_6, δ: br s at 8.18 (^{1}H, N14 proton), set of m at 7.46–6.80 (5H, aromatic), br m at 6.10 (H, N2 proton), m at 3.22–2.73 (3H, H7a, H7e, H4a), sets of m at 2.40–1.50 (3H, H4e, H6a, H5), m at 1.32–1.04 (1H, H6e), three s at 1.23 (3H), 0.92 (3H), and 0.80 (3H) (C10, C11, and C12 methyls). The spectrum also shows a br s at 8.38 (OH of methanol), s at 3.31 (H_2O from recrystallization and DMSO-d_6 solvent), s at 3.12 (CH_3 of methanol). The CH_3 and OH of methanol integrate for 0.85 mol of methanol of crystallization. Mass spectra *m/z*: 301 (3) (M^+), 286 (3) (M − (CH_3)), 209 (5) (M − (Ph—NH)), 182 (33) (M − (Ph—N═C═O)), 167 (11) (182 − (CH_3)), 139 (22) (182 − (NH═C═O)), 119 (100) (Ph—N═C═O), 101 (76), 98 (54) (139 − (CH_2—CH═CH_2)), 93 (74) (Ph—NH_2), 82 (72) (98 − NH_2). *Anal.* calcd. for $C_{17}H_{23}N_3O_2 \cdot 0.85\,CH_3OH \cdot 0.5\,H_2O$: C 63.50, H 8.18, N 12.45; found: C 63.84, H 8.05, N 12.31. The carbon-13 nmr

(proton decoupled and proton decoupled INEPT) data and assignments are given in Table 2. (The INEPT experiments also demonstrated the presence of methanol by the observance of a peak at 48.26 ppm.)

N8-Methylamino amide **7**

(*a*) Amino amide **5** (3.62 g, 0.02 mol) was dissolved in methylene chloride (50 mL). Magic Methyl® (97% methyl fluorosulphonate) (1.90 mL, 0.022 mol) was added to this solution over a period of 10 min (27). A white precipitate began forming immediately after the addition of the methyl fluorosulphonate. After stirring at room temperature for an additional 1.5 h, the methylene chloride was decanted from the white solid that had formed. This product was washed with cold methylene chloride (5 mL) and then suspended in 35 mL of methylene chloride. A 1 *N* solution of sodium hydroxide (30 mL) was added to the organic solution and the mixture was stirred for 5 min while the white solid dissolved. After separation of the two layers, the aqueous layer was extracted with chloroform (3 × 20 mL). The combined organic extracts were dried with sodium sulphate and evaporated to dryness. The white solid that remained was recrystallized from ethyl acetate to give 2.73 g (70%) of compound **7**; tlc: R_f 0.5 in $CHCl_3$–EtOH (10:1, v:v); mp 150–150°C; ir (Nujol) cm^{-1}: 3188 (m) (NH stretch), 1672–1664 (s) (C=O, amide band I overlapped by amide band II); ^1H nmr (90 MHz), δ: dd at 2.67 (^1H, H4a) [^2J(4a, 4e) = −18 Hz, ^3J(4a, 5) = 7 Hz], sets of m at 2.65–2.36 (2H, H7a, H7e), d at 2.22 (1H, H4e) [^2J(4e, 4a) = −18 Hz] overlapped by a br m at 2.32–1.94 (1H, H6a), s at 2.16 (3H, N8 methyl), m at 1.72 (1H, H5), m at 1.45–1.25 (1H, H6e), s at 1.24 (6H), and s at 1.08 (3H) (C10, C11, and C12 methyls). Carbon-13 nmr (proton decoupled, and proton decoupled INEPT) data and assignments are given in Table 2. Mass spectra *m/z*: 196 (100) (M^+), 181 (22) (M − (CH_3)), 153 (44) (M − (HN=C=O)), 138 (56) (181 − (HN=C=O) or 153 − (CH_3)), 127 (58), 124 (50) (138 − (CH_2)), 112 (96), 110 (89). *Exact Mass* calcd. for $C_{11}H_{20}N_2O$: 196.1576; found (hrms, 100%): 196.1578. *Anal.* calcd. for $C_{11}H_{20}N_2O$: C 67.31, H 10.27, N 14.27; found: C 66.78, H 10.38, N 14.13.

(*b*) A methanol solution of amino amide **5** (3.0 g, 0.0165 mol) and MeI (7.5 g, 0.0532 mol) was heated for 3 days at oil-bath temperature of 55–62°C in a pressure bottle. The hot solution was then filtered under gravity and the methanol removed to leave a pale yellow solid. Recrystallization from methanol/pentane (1:1, v:v) gave a white hydroiodide salt (3.55 g). The filtrate from this salt was diluted with water and made basic (pH 12) with dilute NaOH. Extraction with $CHCl_3$ (2 × 30 mL) gave, after drying and evaporation, a yellowish solid (0.65 g, 20% crude). The hydroiodide salt from above was converted to the free base by dissolving it in water, adjusting to pH 10 with dilute NaOH, and extraction with $CHCl_3$ (3 × 60 mL). After drying and evaporation to dryness, the combined $CHCl_3$ extracts yielded a white solid (1.86 g, 58% crude). The two solids were identified as the *N*-methyl amino amide **7** by ir, ms, and ^1H nmr. *N*-Methylamino amide **7** could also be prepared by reacting the amino amide **5** and MeI in isopropyl alcohol at room temperature but the yield of recrystallized product was only 37%.

Chemical constituents of *Lansium anamallayanum* Bedd.

K. K. PURUSHOTHAMAN, A. SARADA, AND A. SARASWATHY
Captain Srinivasa Murti Drug Research Institute for Ayurveda, Arumbakkam, Madras-600106, India

Received May 12, 1986

This paper is dedicated to Dr. O. E. (Ted) Edwards

K. K. PURUSHOTHAMAN, A. SARADA, and A. SARASWATHY. Can. J. Chem. **65**, 150 (1987).

Several triterpenoids and steroids have been isolated from *Lansium anamallayanum* Bedd. The leaves yielded an unknown triterpene lansitriol and four new steroids, lansisterone *E* **1**, lansisterone *Z* **2**, lansisterol B, and lansisterol A **3**. From the bark, a new triterpene lactone designated as lansilactone **4** was isolated. Structures for compounds **1**, **2**, **3**, and **4** have been proposed as 3β,4β-dihydroxy-17(20)-*cis* 5α-pregna-16-one; 3β,4β-dihydroxy-17(20)-*trans* 5α-pregna-16-one; 24-methylene 3β,4β,7β, 20-tetrahydroxy cholest-5-ene, and 25,26,27-lanostane trisnorlactone.

K. K. PURUSHOTHAMAN, A. SARADA et A. SARASWATHY. Can. J. Chem. **65**, 150 (1987).

On a isolé plusieurs triterpènoïdes et stéroïdes du *Lansium anamallayanum* Bedd. Les feuilles ont fourni un triterpène inconnu, le lansitriol, ainsi que quatre nouveaux stéroïdes, la lansistérone-(E) (**1**), la lansistérone-(Z) (**2**), le lansistérol B et le lansitérol A (**3**). À partir de l'écorce, on a isolé une nouvelle lactone triterpénique que l'on a appelé lansilactone (**4**). On propose que les structures des composés **1**, **2**, **3** et **4** sont respectivement celles de la dihydroxy-3β,4β 17(20)-*cis* 5α-pregnanone-16; de la dihydroxy-3β,4β 17(20)-*trans* 5α-pregnanone-16; du méthylène-24 tétrahydroxy-3β,4β,7β,20 cholestène-5 et de la lanostane trisnor-25,26,27 lactone.

From the leaves of *Lansium anamallayanum* Bedd. (Meliaceae), syn: *Reinwardtiodendron anamallayanum* (Bedd) Saldanha (1), we have isolated five new compounds: lansitriol, lansisterone *E* (**1**), lansisterone *Z* (**2**), lansisterol B, and lansisterol A (**3**). The bark yielded a new triterpene lactone, lansilactone (**4**). Both the bark and the leaves yielded, as well, α-amyrin acetate, *n*-octacosanol, α-amyrin, and β-sitosterol.

Lansisterone E *(1)*

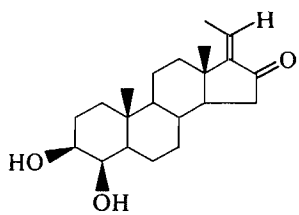
Lansisterone *E* (**1**), mp 205°C, $[\alpha]_D^{30}$ −130°C (*c* 1, in chloroform), $C_{21}H_{32}O_3$ (M^+ 332), ir ν_{max}: 3425 (hydroxyls), 1725, 1660 cm^{-1} (α,β-unsaturated five-membered ketone), answered the Libermann Burchard test characteristic of steroids. The formation of a diacetate showed the presence of two hydroxyls. All three oxygens of the molecule were accounted for by these functionalities. The ^1H nmr spectrum more precisely settled the position of the α,β-unsaturated moiety. There were signals for three methyls, two of them were tertiary and the other a vinylic methyl at δ 1.85 (d, 3H, C=C(H)CH_3). There was one olefinic proton as a quartet at δ 6.5, showing that the vinylic methyl and the vinylic proton are attached to the same carbon.

The two hydroxyls present in the compound are vicinal, as **1** readily underwent cleavage by periodate to yield the corresponding dialdehyde. Of the two aldehyde protons, one appeared as a triplet (δ 9.74) and the other as a doublet (δ 9.86) in the ^1H nmr.

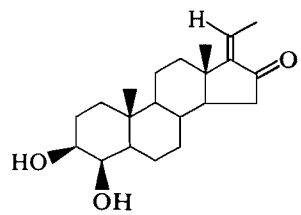
In the ^1H nmr of **1**, there was a proton at δ 3.75 as a multiplet, having one diaxial and two axial–equatorial interactions. Both the multiplicity and the chemical shift were in agreement for the 3β-hydroxyl. The H4 appeared as dd at δ 3.98 (J_{3-4} = 3.5 Hz and J_{4-5} = 3.5 Hz), which could be ascribed to the equatorial H4 proton. Therefore the 4-hydroxyl is axial. The coupling constant of H4–H5 was further deduced by irradiation at δ 3.75, which reduced the H4 double doublet into a doublet (3.5 Hz), which agrees with H4 equatorial and H5 axial coupling. The compound, therefore, belongs to the 5α-pregnane series, which is found to occur abundantly in nature. Lansisterone *E* is assigned structure 3β,4β-dihydroxy-17(20)-*cis* 5α-pregna-16-one (**1**). The ^{13}C nmr measurements were in agreement with the structure.

Lansisterone Z *(2)*

During the course of acetylation of **1**, two acetates were formed. One isomer of the acetate $C_{25}H_{36}O_5$, mp 176°C, was assigned from its ^1H nmr spectrum as the acetate corresponding to **1**. The other isomer, mp 193°C, had, as a distinguishing feature, the olefinic hydrogen appearing as a quartet at δ 5.75 instead of at δ 6.50 as observed in the diacetate of **1**. In **1**, the vinylic hydrogen is deshielded due to the proximity of the carbonyl. In **2**, this hydrogen is disposed away from the carbonyl and therefore appeared at higher field. So the acetate having mp 193°C corresponds to the *Z* isomer (**2**). The lansisterone *Z* (**2**) itself was not separated from the crude extract but its presence could be detected spectroscopically.



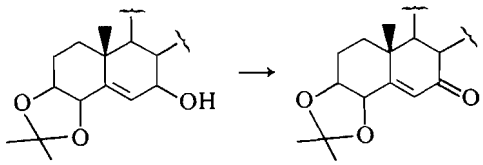
1



2

Lansisterol A (3)

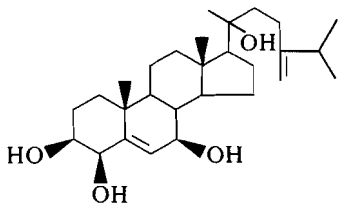
Lansisterol A, mp 130°C, $[\alpha]_D^{30}$ −107°C (*c* 2, in chloroform), $C_{28}H_{46}O_4$ (M^+ 446), had three secondary and one tertiary hydroxyl groups, δ 64.82 (d), 71.84 (d), 78.49 (d), and 74.92 (s) and δ H 3.58 (H3), 3.93 (H7), and 4.15 (H4) shifted to, in the triacetate, δ H 4.85, 5.05, and 5.52 (three hydroxy methines), δ C 156.2 (s) and 106.22 (t) and δ H 4.72 (2H), an exomethylene, and δ C 146.55 (s) and 129.48 (d) and δ H 5.83 (H6), trisubstituted double bond, and gave a positive colour test for steroids. The compound is tetracarbocyclic. The tertiary nature of one hydroxyl was further proved by the ir spectrum of the triacetate, which still retained the hydroxyl absorption at 3480 cm^{-1}. There were five methyls at δ H 0.88 (s, 3H, —CH_3), 1.0 (s, 3H, —CH_3), 1.1 and 1.2 (s, 3H, each, isopropyl *methyls*), and 1.3 (s, 3H, —CH_3). The absorption at 1.3 should correspond to a methyl group attached to an oxygen-bearing carbon (C20). The presence of a CH_2—$C(CH_2)$—$CH(CH_3)_2$ moiety in the side chain was concluded from the



infrared and mass spectra, 1660, 890 (exomethylene), 1389, 1385 cm^{-1} (isopropyl group) and the mass fragment of 83 amu. Lansisterol A underwent periodate oxidation to give a dialdehyde without loss of a carbon atom. Of the two aldehyde protons, one was a triplet (δ 9.60) and the other a singlet (δ 9.35) and the corresponding hydroxy methines, which disappeared, were δ 3.58 (H3) and 4.15 (H4). The chemical shifts of the two hydroxy methines suggested that H4, H7 were allylic. Lansisterol A formed an acetonide that was smoothly oxidized to an α,β-unsaturated ketone (ν_{max} 1672 cm^{-1} and λ_{max} 235 nm).

An examination of the chemical shifts and the multiplicities of ^1H nmr of lansisterol A, the acetonide, and the corresponding ketone indicated that in **3** the signal at 3.93 corresponds to H7.

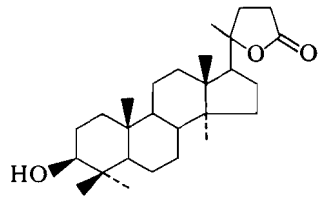
Double irradiation studies on the triacetate of **3** confirmed the various proton assignments and their configurations. Irradiation of the H7 proton at δ 5.05 (dd, J_{6-7} = 4.5 Hz, J_{7-8} = 7.5 Hz) collapsed the H6 signal at 5.95 (d, J_{6-7} = 4.5 Hz) to a singlet. Irradiation of the H3 proton at δ 4.85 (m) similarly collapsed the H4 proton at 5.52 (d, J_{3-4} = 4.5 Hz) to a singlet and irradiation of the H6 proton at 5.95 (d, J_{6-7} = 4.5 Hz) collapsed the H7 (dd) at 5.05 to a doublet of 7.5 Hz. From the foregoing experiments and the observed multiplicities (2), the structure for lansisterol A is proposed as 24-methylene 3β,4β,7β,20-tetrahydroxy cholest-5-ene (**3**).



3

Lansilactone (4)

Lansilactone, $C_{27}H_{44}O_3$, ir ν_{max}: 3450 (hydroxyl), 1750 (γ-lactone) cm^{-1}, gave a colour reaction for triterpene with tin and thionyl chloride. The ^1H nmr showed six C-methyls at δ 0.82, 0.84, 0.89, 0.92, 0.95, and 1.35; the last signal indicated that the methyl is attached to a carbon carrying the lactonic oxygen. Formation of such a lactone by the elimination of three carbon atoms from the side chain had been earlier reported by Beillmann and Ourisson (3) while suggesting a structure for diterocarpol trisnorlactone. Lansilactone formed a monoacetate; the shift of hydroxy methine was in agreement with 3β-hydroxyl. Further confirmation of the 3β-hydroxyl was obtained by observing the chemical shift of 4α,α-dimethyls in the ^1H nmr of the ketone taken in $CDCl_3$, and the shift (0.36 ppm) by the addition of 30% benzene was in agreement with the reported value (0.33 ppm (4)). Diterocarpol trisnorlactone, which belongs to the dammarane series, and lansilactone, though having identical molecular formulae and functional groups, were not found to be identical by direct comparison. On biogenetic grounds and in conformity with the lanostane series, lansilactone is assigned structure **4**.



4

Experimental

Melting points are uncorrected and were determined in open-ended capillaries and expressed in degrees centigrade. Thin-layer chromatographic analyses were performed on silica gel-G (Mira chem), plates developed by ceric sulphate. Known compounds have been identified by their mp, mmp, ir, and specific rotation. Infrared spectra were obtained on a Perkin–Elmer 337 instrument using KBr pellets, and the uv spectra were recorded in methanol solution on a Pye–Unicam 1800 uv spectrophotometer. The ^1H nmr spectra were recorded on a Varian-XL 100 at 100 MHz or on an EM 390 90-MHz spectrometer with TMS as internal standard. The ^{13}C nmr spectra were recorded at 25.2 MHz. The chemical shifts are expressed as δ ppm.

Leaves and bark of *Lansium anamallayanum* Bedd. were collected at Bhimashankar, State of Maharashtra, India during the month of July 1981, shade dried, and coarsely powdered. Specimens of these samples were kept in the herbarium of this Institute under the registry number 277.

The coarsely powdered leaves (1.5 kg) were extracted successively with *n*-hexane, chloroform, and alcohol. Each extraction was carried out in an aspirator bottle by the cold percolation method for a period of 72 h. The solvents were removed (up to 80%) by distillation of a water bath at room temperature and then *in vacuo*. The hexane and chloroform extracts showed similar spots on tlc, so they were combined. The combined extract (26.5 g) was chromatographed over silica gel (Acme 100–200 mesh, 1:22) which was eluted with solvents of increasing polarity in the order hexane, hexane–benzene, benzene, chloroform, and ethyl acetate. The hexane eluate after removal of the waxy material afforded *n*-octacosanol and a gum, which on crystallization using methanol gave α-amyrin (250 mg).

Benzene-eluted fractions on concentration resulted in the isolation of β-sitosterol (0.85 g).

Isolation of lansitriol

The column was then eluted with chloroform and the eluted material was further chromatographed through a column of neutral alumina (Acme) using hexane, benzene, chloroform, and ethyl acetate and their mixtures. The residue obtained from the chloroform–ethyl acetate (20:1) eluates crystallized from benzene to give lansitriol (200 mg), mp 178°C; $[\alpha]_D^{30}$ +35° (*c* 1, in chloroform); ν_{max}: 3400, 1030 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 0.33 and 0.55 (d, 1H each, *J* = 5 Hz, cyclopropane protons), 0.78 (s, 3H, CH_3), 0.88 (s, 3H, CH_3), 0.94 (s, 6H, 2 × CH_3), 1.13 (s, 3H, CH_3), 1.19 (s, 6H, 2 × CH_3), and 3.3 (m, 2H, C*H*—OH); ^{13}C nmr ($CDCl_3$) δ: 79.64 (s), 78.84 (s), 73.23 (d); *m/z*: 460, 447, 427, 409, 399, 320, 315, 255, 241, 229, 227, 215, 203, 202, 191, 189, 177, 175, 173, 171, 163, 162, 161, 159, 157, 149, 145, 135, 134, 133, 131, 127, 121, 119, 95, 71, 69, 67, 59 (100%), 55, 43, 41. *Anal.* calcd. for $C_{30}H_{52}O_3$: C 78.25, H 11.31; found: C 78.50, H 11.15.

Isolation of lansisterol B

Fractions eluted with chloroform – ethyl acetate (10:1) were combined and crystallized from alcohol to give lansisterol B (130 mg), mp 238°C; ν_{max}: 3400, 1075, 965, 895 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 0.98 (s, 6H, 2 × CH_3), 1.06 (s, 3H, CH_3), 1.13 (d, 6H, 2 × CH_3), 2.56 (d, 1H, $W_{1/2}$ = 4.5 Hz), 3.36 (m, 1H, C*H*—OH), 4.0 (dd, *J* = 8.5 Hz and 4.5 Hz, 1H), 4.25 (m, 1H, C*H*—OH), 4.85 (d, 2H, *J* = 6.5 Hz, exomethylene), 5.3 (bd, 1H, olefinic proton). *Anal.* calcd. for $C_{28}H_{44}O_3$: C 78.50, H 10.28; found: C 78.56, H 10.21.

Isolation of lansisterone E *(1) and lansisterone* Z *(2)*

Eluates of a mixture of chloroform and ethyl acetate (1:1) were

For personal use only.

combined and rechromatographed over a short column of neutral alumina. Crystallization of the solid from chloroform–benzene gave **1** (240 mg), mp 205°C; $[\alpha]_D^{30}$ −130° (*c* 1, in chloroform); ν_{max}: 3425, 1725, 1660 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 0.82 (s, 3H, C*H*$_3$), 1.0 (s, 3H, C*H*$_3$), 1.85 (d, 3H, C=C(H)C*H*$_3$), 3.75 (m, 1H, C*H*—OH, H3), 3.98 (dd, J_{3-4} = 3.5 Hz and J_{4-5} = 3.5 Hz, 1H, C*H*—OH, H4), 6.5 (q, 1H, C=C(*H*)CH$_3$, olefinic proton); ^{13}C nmr ($CDCl_3$) δ: 37.9 (t), 33.5 (t), 69.0 (d), 69.2 (d), 40.5 (d), 12.4 (t), 36.2 (t), 34.2 (d), 50 (d), 37.0 (s), 20.7 (t), 31.8 (t), 43.4 (s), 53.9 (d), 38.1 (t), 206.7 (s), 147.9 (s), 13.2 (q), 17.6 (q), 129.3 (d), 27.40 (q); *m/z*: 332, 317, 314, 299, 281, 234, 216, 201, 191, 190, 175, 161, 149, 147, 143, 135, 133, 123, 121, 119, 109, 107, 106, 105, 95, 94, 93, 90, 83 (100%), 81, 80, 79 (81.22%), 78, 77, 69, 67, 65, 57, 55 (73.21%), 34. *Anal.* calcd. for $C_{21}H_{32}O_3$: C 75.91, H 9.64; found: C 75.85, H 9.64.

The presence of lansisterone *Z* (**2**) was indirectly concluded during acetylation of **1** (see later).

Isolation of lanisterol A (3)

Ethyl acetate fractions from the main column yielded a gum, which on crystallization from dilute acetone afforded **3** (600 mg), mp 138°C; $[\alpha]_D^{30}$ −107° (*c* 2, in chloroform); ν_{max} (CCl_4): 3450, 1660, 1389, 1385, 890 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 0.88 (s, 3H, 18-C*H*$_3$), 1.0 (s, 3H, 19-C*H*$_3$), 1.1 (s, 3H, —CH(C*H*$_3$)CH$_3$), 1.2 (s, 3H, —CH(CH$_3$)C*H*$_3$), 1.3 (s, 3H, 21-C*H*$_3$), 3.58 (m, 1H, —C*H*—OH, H3), 3.98 (m, 1H, —C*H*—OH, H7), 4.15 (m, 1H, C*H*, —OH, H4), 4.72 (d, 2H, *J* = 6 Hz, exomethylene), 5.83 (d, 1H, *J* = 5 Hz, olefinic proton, H6). The ^{13}C nmr spectrum taken in $CDCl_3$ and CD_3COCD_3 showed a singlet at 156.2 (C24), a triplet at 106.22 (C28), a singlet at 146.55 (C5), a doublet at 129.48 (C6), a singlet at 74.92 (C21), and three doublets at 78.49, 71.84, and 64.82 (C4, C7, and C3) respectively. Mass spectra *m/z*: 446, 428, 390, 349, 313, 295, 270, 173, 159, 157, 147, 145, 135, 133, 131, 129, 123, 121, 119, 109, 107, 105, 97, 95, 93, 91, 83, 81, 79, 77, 69, 67, 55, 43, 28 (base). *Anal.* calcd. for $C_{28}H_{46}O_4$: C 75.34, H 10.55; found: C 75.28, H 10.60.

Later fractions of ethyl acetate yielded a gummy material containing a few crystals. The crystals were washed with methanol and recrystallized from absolute alcohol to get sitosterol-3β-glucopyranoside (200 mg), mp 288°C. It was hydrolysed to get β-sitosterol, mp 131°C.

Isolation of lansilactone (4)

The coarsely powdered bark (1.5 kg) of *Lansium anamallayanum* Bedd. was extracted by the cold percolation method. The hexane and chloroform extracts were combined and chromatographed over silica gel (1:22). The column was eluted with solvents in the order hexane, benzene, chloroform, and ethyl acetate and their mixtures.

Hexane eluates yielded α-amyrin acetate. Material obtained from hexane–benzene mixtures was identified as *n*-octacosanol and α-amyrin. Fractions eluted with benzene gave β-sitosterol. Benzene–chloroform (1:1) and chloroform fractions were combined and rechromatographed and the chloroform eluate on crystallization with benzene–hexane afforded lansilactone (4) (200 mg), mp 239°C; $[\alpha]_D^{30}$ +20° (*c* 1, in chloroform); ν_{max}: 3450, 2920, 1750, 1450, 1380, 1270, 1255, 1080, 945 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 0.82, 0.84, 0.89, 0.92, 0.95, and 1.35, each (s, 3H, C*H*$_3$), and 3.4 (t, 1H, —C*H*—OH, H3); ^{13}C nmr ($CDCl_3$) δ: 176.8 (s), 90.13 (s), 75.8 (d). *Anal.* calcd. for $C_{27}H_{44}O_3$: C 77.90, H 10.58; found: C 78.40, H 10.20.

Acetylation of 1

Lansisterone *E* (70 mg) in pyridine (2 mL) was treated with freshly distilled acetic anhydride (3 mL) and the mixture was heated for 3 h on a water bath. The product was worked up in the usual way and then purified on silica gel. The material (40 mg) eluted with hexane crystallized from hexane (minimum) giving the diacetate (35 mg), mp 176°C; ^1H nmr δ: 0.88 (s, 3H, C*H*$_3$), 0.98 (s, 3H, C*H*$_3$), 1.93 (d, *J* = 7 Hz, 3H, C=C(H)C*H*$_3$), 2.06 (s, 3H, —O—CO—C*H*$_3$), 2.12 (s, 3H, —O—CO—C*H*$_3$), 4.97 (bm, 1H, —C*H*—OAc, H3), 5.28 (dd, *J* = 3 and 4 Hz, 1H, —C*H*—OAc, H4), 6.5 (q, 1H, C=C(*H*)CH$_3$, olefinic proton); ^{13}C nmr ($CDCl_3$) δ: 206.23 (s), 170.38 (s), 170.30 (s), 147.78 (s), 130.10 (d), 69.90 (d), 69.2 (d), 53.85 (d), 49.93 (d), 43.32 (s), 39.42 (d), 39.42 (t), 37.83 (t), 37.16 (s), 36.15 (t), 33.48 (d), 32.27 (t), 31.61 (t), 27.14 (q), 21.21 (q), 21.09 (q), 20.64 (t), 17.63 (q), 13.15 (q), 12.5 (t); *m/z*: 416, 402, 401 (100%), 356, 314, 299, 296, 281, 177, 175, 163, 161, 159, 149, 145, 136, 135, 133, 131, 123, 121, 119, 117, 109, 107, 105, 95, 93, 91, 83, 81, 79, 76, 67, 55, 53. *Anal.* calcd. for $C_{25}H_{36}O_5$: C 72.11, H 8.65; found: C 72.04, H 8.53.

Isolation of lansisterone Z (2) acetate

The column on further elution yielded yet another 20 mg of a compound that showed a different spot. The product was further rechromatographed and gave **2** acetate. Subsequently further runs of acetylation were carried to separate the acetate in a pure form, which was crystallized from alcohol, mp 193°C; ν_{max} (CCl_4): 1744, 1722 (enone), 1650 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 0.9 (s, 6H, 2 × CH$_3$), 1.88 (s, 6H, 2 × —O—CO—C*H*$_3$), 2.08 (s, 3H, 21-C*H*$_3$), 4.98 (m, 1H, —C*H*—OAc, H3), 5.30 (dd, *J* = 3 and 4 Hz, 1H, C*H*—OAc, H4), 5.75 (q, 1H, C=C(*H*)CH$_3$); ^{13}C nmr ($CDCl_3$) δ: 208.46 (s), 170.38 (s), 170.30 (s), 148.21 (s), 130.10 (d), 69.90 (d), 69.20 (d), 54.07 (d), 49.43 (d), 43.24 (s), 39.42 (d), 39.42 (t), 37.83 (t), 37.2 (s), 35.62 (t), 33.82 (d), 32.27 (t), 31.61 (t), 27.14 (q), 27.21 (q), 21.09 (q), 20.64 (t), 19.65 (q), 14.04 (q), 12.50 (t). *Anal.* calcd. for $C_{25}H_{30}O_5$: C 72.11, H 8.65; found: C 72.04, H 8.7.

Periodate oxidation of 1

Lansisterone *E* (40 mg) in methanol (2 mL) was treated with potassium metaperiodate solution (100 mg in 2 mL of water) and kept aside for 24 h. Methanol was removed *in vacuo*. Water was added and the product extracted into chloroform. Removal of the solvent by distillation gave the dialdehyde gum (25 mg), ^1H nmr ($CDCl_3$) δ: 9.74 (t, 1H, —CH$_2$—C*H*O), 9.86 (d, 1H, —CH—C*H*O). *Anal.* calcd. for $C_{21}H_{30}O_3$: C 76.37, H 9.14; found: C 76.20, H 9.04.

Acetonide of 1

A suspension of **1** (40 mg) and anhydrous copper sulphate (200 mg) in anhydrous acetone (10 mL) was refluxed on a water bath for 24 h. This suspension was filtered and evaporation of the filtrate gave the acetonide gum (25 mg). *Anal.* calcd. for $C_{24}H_{36}O_5$: C 71.29, H 8.91; found: C 71.35, H 8.85.

Jones oxidation of 1

Lansisterone *E* (85 mg) in dry acetone (3 mL) was oxidized with Jones reagent with constant shaking for 5 min at room temperature. The excess reagent was destroyed by adding methanol, diluted with water, and extracted with chloroform. The product was absorbed on silica gel. Elution with benzene yielded ketone (60 mg), which was crystallized from benzene–hexane (55 mg), mp 251°C; ^1H nmr (CD_3OD) δ: 0.85 (s, 3H, C*H*$_3$), 1.02 (s, 3H, —C*H*$_3$), 1.84 (d, *J* = 7 Hz, 3H, C=C(H)C*H*$_3$), and 6.46 (q, 1H, C=C(*H*)CH$_3$); ^{13}C nmr (CD_3OD) δ: 208.43 (s), 174.94 (s), 177.31 (s) for carbonyl carbons; *m/z*: 328, 303, 287, 243, 241, 219, 218, 201, 135, 131, 129, 128, 123, 122, 121, 119, 109, 108, 107, 105, 95, 93, 92, 91 (100%), 83, 81, 79, 77, 69, 67, 65, 55, 53. *Anal.* calcd. for $C_{21}H_{28}O_3$: C 76.83, H 8.54; found: C 76.75, H 8.34.

Acetylation of 3

Compound **3** (100 mg) was acetylated in pyridine (3 mL) and acetic anhydride (2 mL) by heating on a water bath. After 2.5 h, reaction was completed. The product (60 mg) obtained after the usual work-up was crystallized from dichloromethane and alcohol; ν_{max}: 3480, 2930, 1740, 1720, 1460, 1370, 1240, 1038, 890 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 0.85 (s, 3H, 18-C*H*$_3$), 1.0 (s, 3H, 19-C*H*$_3$), 1.08 (s, 3H, —CH(C*H*$_3$)CH$_3$), 1.15 (s, 3H, —CH(CH$_3$)C*H*$_3$), 1.30 (s, 3H, C(OH)—C*H*$_3$), 1.98 (s, 3H, —O—COC*H*$_3$), 2.04 (s, 6H, 2 × O—COC*H*$_3$), 4.72 (d, *J* = 6 Hz, 2H, exomethylene), 4.85 (m, 1H, —C*H*—OAc, H3), 5.05 (dd, J_{6-7} = 4.5 Hz and J_{7-8} = 7.5 Hz, 1H, C*H*—OAc, H7), 5.52 (d, J_{4-3} = 4.5 Hz, 1H, C*H*—OAc, H4), and 5.95 (d, J_{6-7} = 4.5 Hz, H6, olefinic proton); ^{13}C nmr ($CDCl_3$) δ: 170.32 (s), 170.19 (s), 169.65 (s), 156.20 (s), 143.82 (s), 128.28 (d), 106.29 (t), 74.98 (s), 74.92 (d), 72.12 (d), 67.41 (d), 57.84 (d), 49.14 (d), 43.29 (d), 42.50 (s), 42.24 (t), 39.17 (t), 36.90 (s), 36.26 (t), 35.09 (d), 33.91 (d), 28.79 (t), 26.11 (q), 23.53 (t), 22.37 (t), 22.27 (t), 21.90 (q), 21.88 (q), 21.25 (q), 21.18 (q), 21.01 (q), 19.97 (t), 13.72 (q), 13.06 (q). *Anal.* calcd. for $C_{34}H_{52}O_7$: C 71.34, H 9.09; found: C 71.41, H 9.13.

Acetonide of 3

A mixture of **3** (120 mg) and anhydrous copper sulphate (3 g) in permanganate-distilled acetone (4 mL) was refluxed on a water bath for 3 days. It was diluted with acetone and filtered, then purified by chromatography (100 mg), mp 202°C; ^{1}H nmr ($CDCl_3$) δ: 0.85 (s, 3H, 18-CH_3), 0.97 (s, 3H, 19-CH_3), 1.04 (s, 6H, —CH(CH_3)CH_3), 1.16 (s, 3H, —C(OH)—CH_3), 1.29 (s, 6H, C(CH_3)CH_3), 3.6 (m, 1H, —C*H*—O—(O)C(Me)Me, H3), 3.95 (m, 1H, C*H*—OH, H7), 4.15 (d, J_{4-3} = 4.5 Hz, 1H, C*H*—O—(O)C(Me)Me, H4), 4.72 (d, J = 6 Hz, 2H, exomethylene), and 5.85 (d, J_{6-7} = 4.5 Hz, 1H, olefinic proton). *Anal.* calcd. for $C_{31}H_{50}O_4$: C 76.54, H 10.29; found: C 76.46, H 10.35.

Acetylation of 3 acetonide

Lansisterol A acetonide (50 mg) was acetylated in pyridine – acetic anhydride (1:1) by heating on a water bath for 2 h. Crystals (40 mg) from benzene–hexane, mp 169°C; ν_{max}: 3500, 2950, 1750, 1380, 1250, 1065, 1055, 1020, 930, 890 cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 0.8 (s, 3H, 18-CH_3), 0.9 (s, 3H, 19-CH_3), 1.03 (s, 3H, —CH(CH$_3$)CH_3), 1.1 (s, 3H, —CH(CH_3)CH$_3$), 1.2 (s, 3H, —C(OH)—CH_3), 1.3 (s, 3H, —O—(O)C(CH_3)CH$_3$), 1.53 (s, 3H, —O—(O)C(CH$_3$)CH_3), 2.07 (s, 3H, —O—CO—CH_3), 4.17 (m, 1H, —C*H*—O—C(Me)Me), 4.43 (dd, J_{6-7} = 4.5 Hz and J_{7-8} = 7.8 Hz, —C*H*—OAc, H7), 4.72 (d, J = 6 Hz, 2H, exomethylene), 5.06 (d, J_{4-3} = 4.5 Hz, 1H, —C*H*—O—C(Me)Me, H4), 5.9 (d, J_{6-7} = 4.5 Hz, olefinic proton, H6). *Anal.* calcd. for $C_{33}H_{52}O_5$: C 74.96, H 9.85; found: C 74.85, H 9.60.

Jones oxidation of 3 acetonide

Compound **3** acetonide (50 mg) was oxidized with Jones reagent as before to get the product (35 mg), mp 163°C; ν_{max}: 3450, 2925, 1672, 1380, 1105, 890 cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 0.9 (s, 3H, 18-CH_3), 1.0 (s, 3H, 19-CH_3), 1.08 (s, 6H, —CH(CH_3)CH_3), 1.33 (s, 3H, C(CH$_3$)CH$_3$), 1.55 (s, 3H, —O—(O)C(Me)Me), 4.3 (m, 1H, C*H*—O—(O)C(Me)Me, H3), 4.54 (d, J_{4-3} = 5 Hz, 1H, C*H*—O—(O)C(Me)Me, H4), 4.72 (d, J = 6 Hz, 2H, exomethylene), and 5.9 (s, 1H, olefinic proton, H6). *Anal.* calcd. for $C_{31}H_{48}O_4$: C 76.85, H 9.92; found: C 76.79, H 9.83.

Periodate oxidation of 3

Lansisterol A (240 mg) in alcohol (5 mL) was treated with sodium metaperiodate solution (120 mg in 3 mL of water) and set aside for 24 h. Alcohol was removed at room temperature and the product extracted into ether as gum (120 mg); ν_{max} ($CHCl_3$): 1720, 1090, 860 cm^{-1}; λ_{max} (EtOH): 232 nm; λ_{max} (NaOH): 215 nm; ^{1}H nmr ($CDCl_3$) δ: 0.8 (s, 3H, 18-CH_3), 0.9 (s, 3H, 19-CH_3), 1.0 (s, 3H, —CH(CH_3)CH$_3$), 1.06 (s, 3H, —CH(CH$_3$)CH_3), 1.25 (s, 3H, —C(OH)—CH_3), 3.2 (m, 2H, —CH_2 protons), 4.15 (m, 1H, C*H*—OH, H7), 4.70 (d, J = 6 Hz, exomethylene), 6.82 (t, 1H, olefinic proton, H6), 9.35 (s, 1H, CC*H*O), and 9.60 (t, 1H, —CH$_2$C*H*O). *Anal.* calcd. for $C_{28}H_{42}O_4$: C 76.04, H 9.50; found: C 76.15, H 9.39.

Acetylation of 4

Lansilactone (80 mg) was acetylated in pyridine (3 mL) and acetic anhydride (2 mL) by heating on a water bath for 2 h, and then worked up in usual way affording **4** acetate as crystals from hexane (60 mg), mp 179°C; ^{1}H nmr ($CDCl_3$) δ: 0.84 (s, 3H, CH_3), 0.86 (s, 6H, 2 × CH_3), 0.92 (s, 3H, CH_3), 0.97 (s, 3H, CH_3), 1.35 (s, 3H, ), 1.96 (s, 3H, —OCO—CH_3), and 4.65 (t, 1H, —C*H*—OAc, H3). *Anal.* calcd. for $C_{29}H_{46}O_4$: C 75.98, H 10.04; found: C 75.86, H 10.13.

Jones oxidation of 4

Lansilactone (60 mg) dissolved in acetone was shaken with 6 drops of Jones reagent for 15 min, worked up, and crystallized from alcohol (38 mg), mp 182°C; ν_{max}: 2900, 1750, 1695 cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 0.9 (s, 3H, CH_3), 0.95 (s, 3H, CH_3), 1.0 (s, 3H, CH_3), 1.05 (s, 6H, 2 × CH_3), and 1.35 (s, 3H,  ; ^{1}H nmr ($CDCl_3$ and benzene) δ: 0.84 (s, 3H, 4β-CH_3), 0.9 (s, 3H, CH_3), 0.95 (s, 3H, CH_3), 1.0 (s, 3H, CH$_3$), 1.20 (s, 3H, 4α-CH_3), and 1.35 (s, 3H, ). *Anal.* calcd. for $C_{27}H_{42}O_3$: C 78.25, H 10.14; found: C 78.15, H 10.21.

Spiro(bicyclo[2.2.2]octane-2,1′-[2,4]cyclopentadiene) (**3**) has been synthesized in ten steps, and its Diels–Alder cycloadditions, both thermal and catalysed, have been studied with a variety of *Z*-ethylenic dienophiles. No significant differences in facial stereoselectivity were observed. This suggests that, in the *exo* region, the distance between the addends at the transition state is approximately the same in all the cases studied.

D. Jean Burnell, H. Bruce Goodbrand, Stephanie M. Kaiser et Zdenek Valenta. Can. J. Chem. **65**, 154 (1987).

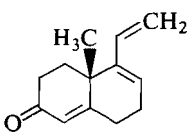
On a synthétisé le spiro(bicyclo[2.2.2]octane[2,4]cyclopentandiène-2,1′) (**3**) en dix étapes et on a étudié la nature de ses cycloadditions de Diels–Alder, tant thermiques que catalysées, avec divers diénophiles portant un groupement éthyléniques *Z*. On n'a pas observé de différences remarquables dans les stéréosélectivités faciales. Ceci suggère que, dans la région *exo* de l'état de transition, les distances entre les réactifs sont approximativement les mêmes dans tous les cas étudiés.

[Traduit par la revue]

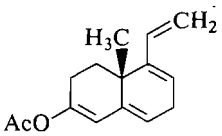
Introduction

Facial (*syn–anti*) stereoselectivity in a Diels–Alder reaction involving a plane-nonsymmetric diene is dependent on the different steric interactions which an incoming dienophile encounters as it approaches either face of the diene. In most instances, the major product is the one resulting from addition to the less hindered face (1). However, in some cases facial stereoselectivity is governed by what might loosely be called "electronic" effects. Dramatic examples are the well-documented contrasteric additions of 5-heterosubstituted cyclopentadienes (2). Furthermore, dienes fused to some bridged systems give major addition products that have been rationalized in terms of electronic effects (3).

In the course of total syntheses of steroids we found that significant changes in facial selectivity could be accomplished by seemingly modest alterations in the structure of the diene-bearing molecule. Thus, whereas addition of a dienophile to **1** was predominantly *syn* to the methyl group (4), addition to **2**



1



2

was predominantly *anti* to the methyl group (5). We believed that this difference could be explained largely in terms of steric effects; however, a perusal of the literature revealed that there has been little systematic study of steric control of facial selectivity in the Diels–Alder reaction.

Purely synthetic considerations were not the only reason for the initiation of a study of facial selectivity. Frontier orbital theory has been used by Sustmann (6*a*) and by Houk (6*b*) to explain orientation in Diels–Alder additions. To rationalize the increase in *endo* stereoselectivity in catalysed reactions and the heightening of asymmetric induction with chiral dienophiles in the presence of Lewis acid catalysts, Houk and Strozier (6*c*), in an extension of the frontier orbital theory to catalyzed additions,

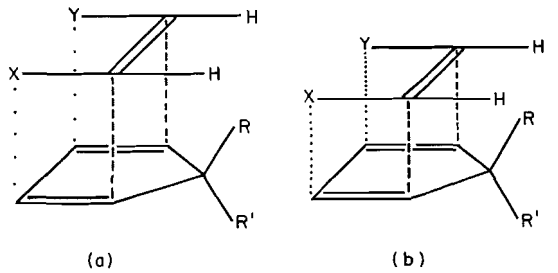


FIG. 1. The transition state structures of the additions of less reactive dienophiles (a) and of more reactive or catalysed dienophiles (b), with the same plane-nonsymmetric diene, are illustrated. According to the tight-transition-state hypothesis, in (b) secondary orbital interactions (dotted lines) are stronger, resulting in a shorter distance between the addends, which implies that the distance between the dienophile and the point of plane-nonsymmetry is also shorter in (b).

invoked the idea of a "tighter" transition state as a consequence of much stronger (attractive) secondary orbital interactions. In other words, they postulated that at the transition state the addends may be significantly closer together in a catalysed reaction than in the corresponding thermal reaction. The idea of a "tighter" transition state has been extended to explain why relatively reactive dienophiles, such as maleic anhydride and *N*-phenylmaleimide, tend to react thermally with greater *endo* stereoselectivity than less reactive dienophiles, such as methyl acrylate and 3-buten-2-one (7).

We expected that reactions of plane-nonsymmetric dienes might provide valuable clues to the geometry of the Diels–Alder transition state. This was based on the following reasoning: The two faces of a plane-nonsymmetric diene present different amounts of steric hindrance toward an incoming dienophile, while the magnitude of these steric interactions at the transition state should be a function of the distance between interacting centres. If the tight-transition-state hypothesis is correct, then with a given plane-nonsymmetric diene the catalysed reactions (with the tightest transition states) should be the most sensitive to the different amounts of steric repulsion presented by the two faces of the diene (Fig. 1). Therefore, catalysed reactions should give the greatest facial (*syn–anti*) stereoselectivity, followed by relatively thermally-reactive dienophiles, followed by less thermally-reactive dienophiles.

We chose the cyclopentadiene derivative **3** as our test diene for the following reasons:

(*i*) It avoids the potential problem of significant electronic effects which heteroatoms or additional π-orbitals might present.[3]

(*ii*) Although **3** is plane-nonsymmetrical, it does have a plane of symmetry perpendicular to the diene moiety; regioisomeric mixtures can, therefore, not be produced.

(*iii*) Steric interactions should preclude the formation of *exo* addition products; therefore only *syn-anti* stereoisomerism should be observed in the adducts.

(*iv*) It is fairly rigid, which avoids conformational ambiguities. In fact, the steric difference between the two faces is analogous to the difference in steric hindrance between the methyl groups of 5,5-dimethylcyclopentadiene **4** with its methyl groups "frozen" in two different conformations.

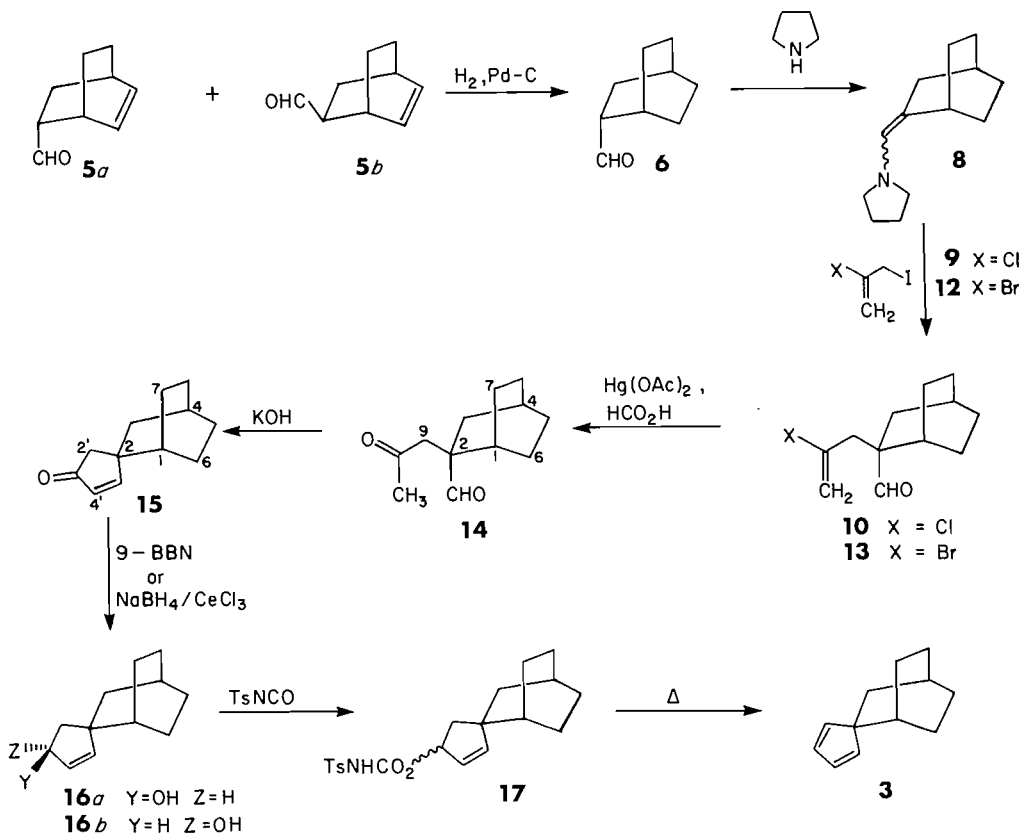
The synthesis of, and the details of our Diels–Alder study with, the diene **3** are presented here. The cycloaddition results have been published in preliminary form (9).

Synthesis of the diene

Our strategy for the construction of **3** was to form the bicyclo[2.2.2]octanyl moiety by a Diels–Alder reaction, then to build the five-membered ring by paralleling methodology developed by Martin and co-workers (10). The synthesis is shown in Scheme 1.

The cycloaddition of 1,3-cyclohexadiene to acrolein could be effected in yields of up to 77% by heating the reactants in a Carius tube as described by Krantz and Lin (11) followed by vacuum distillation to remove some troublesome polymeric material. A better thermal procedure involved heating the reactants for several days in a high-pressure hydrogenation apparatus under an argon atmosphere. Yields of up to 94% were achieved, with very little, or no, polymer. These thermal procedures provided the *endo* and the *exo* adducts, **5***a* and **5***b* respectively, in a ratio of about 9:1. Alternately, catalysis of the Diels–Alder reaction by the introduction of tin(IV) chloride (in dichloromethane at −78°C) gave exclusively the *endo* adduct **5***a*, but polymerization of the acrolein resulted in a yield of only 71%.

Hydrogenation of the adduct(s) yielded the aldehyde **6** in excellent yield. However, overhydrogenation was surprisingly facile, yielding not the corresponding alcohol, but the symmetrical ether **7**. Indeed, prolonged hydrogenation of **6** provided a respectable yield of **7**. This ether must arise by hydrogenolysis



SCHEME 1

[3]Calculations have suggested that 5-methylcyclopentadiene is a system in which there is very little π-orbital perturbation by the methyl group (8).

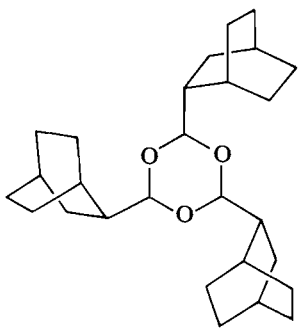
7

of an intermediate hemiacetal formed by attack of the alcohol onto unreduced aldehyde **6**.

Slow addition of the aldehyde **6** to a solution of pyrrolidine in benzene gave the enamine **8** in high yield,[4] but prolonged heating of a solution of **8** with 2,3-dibromo-1-propene in acetonitrile provided no alkylated material. Fortunately, the enamine **8** would slowly attack 2-chloro-3-iodo-1-propene (**9**) to give, following hydrolysis of the intermediate immonium salt and vacuum distillation, the chloro-aldehyde **10** in 60% yield.

A significant amount of **6** was always recovered, even if the alkylation was allowed to proceed for five days with a large excess of **9**. Continued heating of the pot residue after vacuum distillation of **10** resulted in the sublimation of a white powder. The ^{13}C nmr spectrum of this material (which was evidently relatively pure) showed that the compound had a high degree of symmetry. It was interesting to note that the proton noise-decoupled spectrum contained a perfect triplet (1:2:1) centred at δ 104.5. The spectral evidence pointed towards a cyclic trimer **11**. Because the aldehyde **6** was racemic, trimer **11** must have



11

been a mixture of two pairs of enantiomers *RRR/SSS* and *RRS/RSS* in ratio of 1:3, respectively, by random attachment. The *RRS/RSS* forms might give rise to two signals for the *s*-trioxane carbons (ratio 2:1), whereas the *RRR/SSS* form should give just one. Thus the "triplet" signal in the ^{13}C nmr spectrum could be explained (assuming that all three substituents on the *s*-trioxane ring were equatorial). Not unexpectedly, thin-layer chromatography (tlc) of **11** on silica gel gave only one spot that corresponded to the carboxylic acid to which **6** readily oxidizes in air.

Alkylation of the enamine **8** with the bromo-iodide **12** gave a marginally better yield (67%) of product **13** in a four-day reaction.

Whereas mercury(II) acetate with boron trifluoride etherate (10) or trifluoroacetic acid proved completely ineffective in the transformation of **10** to the keto-aldehyde **14**, with formic acid (12) the yield of **14** was very good. Cyclization of **14** to the enone **15** proceeded cleanly with potassium hydroxide in ethanol. This two-step conversion was much better (89%) than direct conversion of **10** to **15** with cold sulphuric acid, which was a very capricious reaction. Much of the product of the latter process was isomeric with **15**; column chromatography was required to isolate the desired enone, which, even in one of the better runs, was obtained in only 21% yield. Welch *et al.* (13) have reported similar results with this direct conversion reaction.

The ketone of **15** could be reduced in high yield by 9-borabicyclo[3.3.1]nonane (9-BBN) in dry tetrahydrofuran (14) to a mixture of epimeric alcohols **16***a* and **16***b*. However, this procedure was relatively long (involving column chromatography) compared to the extremely simple procedure consisting of sodium borohydride reduction of **15** in the presence of hydrated cerium(III) chloride (15). Again, a mixture of epimers **16***a* and **16***b* was obtained, in a ratio of about 55:45, respectively.[5]

Attempted dehydration of this mixture of alcohols using tosyl chloride, mesyl chloride, and thionyl chloride gave mainly rearranged materials. Hoping to avoid cationic intermediates, we formed the carbamates **17** with *para*-toluenesulphonylisocyanate (17). Subsequent pyrolysis in a Kugelrohr apparatus yielded crude diene **3** along with sulphonamide and a few minor contaminants. A more convenient procedure was merely to add the isocyanate to a benzene solution of the alcohols, then to heat this mixture under reflux for a few days. To have very pure materials for the Diels–Alder study, the product was chromatographed very carefully. We obtained an 81% yield of **3** containing no impurities detectable by tlc, ^1H nmr, or ^{13}C nmr spectroscopy. The latter spectrum demonstrated that no rearrangement had taken place: only two olefinic signals were evident and, of the remaining six resonances, two were doubled in size as expected for a symmetric molecule.

The overall yield of diene **3** from 1,3-cyclohexadiene was 37% via the chloro-aldehyde **10** and 40% via the bromo-aldehyde **13**.

Diels–Alder reactions

To avoid possible complications arising from solvent effects (18) we chose dichloromethane as the solvent for all the Diels–Alder reactions. Thermal reactions with maleic anhydride, *N*-phenylmaleimide, and *para*-benzoquinone were heated under reflux for 12 h. The less reactive dienophiles (dimethyl maleate, acrolein, methyl acrylate, and 3-buten-2-one) required much longer reaction times with a large excess of dienophile. The crude products of these slower reactions were freed of excess dienophile and secondary products by preparative tlc. (To confirm that no significant amount of adduct had been overlooked, the silica gel remaining on each plate was extracted; the ^1H nmr spectra of the extracts displayed no signals attributable to the desired adducts.)

Catalysed reactions were carried out with three dienophiles using one equivalent of boron trifluoride etherate as the Lewis acid catalyst. Rate enhancement was obvious; the reactions were complete within a few hours at −78°C.

The adduct mixtures were analysed by high-field ^1H nmr, and signals for a major and a minor adduct were seen in every case. The signals arising from the bicyclo[2.2.1]heptene moieties were found downfield of the signals due to the unfunctionalized bicyclo[2.2.2]octane moieties. The latter resonances were generally poorly resolved, even at 360 MHz, and in the upfield region the signals due to the minor adducts could not be

[4]Addition of pyrrolidine to the aldehyde **6** gave inconsistent results.

[5]This was estimated by integration of the ^{13}C nmr spectrum of the mixture with suppression of the nuclear Overhauser enhancements, obtained by a gated decoupling experiment. The δ-*syn* effect (16) of the hydroxyl group was used to show that the major isomer was **16***a* and the minor one was **16***b*.

TABLE 1. Diels–Alder adducts obtained by reaction with **3**

Dienophile	Adducts		Thermal reaction[a]		Catalysed reaction[b]	
	Type I	Type II	Yield (%)	Type I/Type II	Yield (%)	Type I/Type II
Maleic anhydride	**18***a*	**18***b*	95	86:14	71	90:10
N-Phenylmaleimide	**19***a*	**19***b*	100	86:14	98	93: 7
para-Benzoquinone	**20***a*	**20***b*	100	86:14	95	89:11
Dimethyl maleate	**21***a*	**21***b*	80	89:11	—	—
Acrolein	**22***a*	**22***b*	85	86:14	—	—
Methyl acrylate	**23***a*	**23***b*	83	88:12	—	—
3-Buten-2-one	**24***a*	**24***b*	61	89:11	—	—

[a]In boiling dichloromethane (40°C). Thus, for the thermal reaction with *N*-phenylmaleimide the $\Delta\Delta G^{\ddagger}$ is 1.1 kcal/mol.
[b]With one equivalent of BF_3 etherate in dichloromethane at −78°C. The $\Delta\Delta G^{\ddagger}$ of the catalysed reaction with *N*-phenylmaleimide is 1.0 kcal/mol.

discerned. The major to minor adduct ratios were determined by integration of all the well-separated pairs of downfield signals. (We estimated the precision to be ±5%.)

Although the signals due to the bicyclo[2.2.1]heptene moieties could be assigned with reasonable confidence based on chemical shifts and couplings, we verified our assignments with spin-decoupling experiments (19). Coupling constants in the minor adducts were very similar to those in the major adducts. In both cases there was appreciable coupling between the proton on the carbon α to the carbonyl group(s) and the vicinal bridgehead proton(s); therefore in both cases the α-protons must have been *exo* with respect to the bicyclo[2.2.1]heptene moiety (20). Hence, in every case the adducts differed from each other only in the configuration of the spiro junction (Fig. 2), i.e. one adduct (Type I) must have resulted by *endo* addition to the face of the diene moiety of **3** *syn* to the C-3 methylene, and the other adduct (Type II) was the result of *endo* addition to the face of the diene moiety of **3** *syn* to the C-1 methine.

As expected, the protons nearest the carbonyl group(s) showed the largest chemical shift changes when deuterochloroform was replaced with perdeuterobenzene as the nmr solvent. Dramatically moving upfield were signals that decoupling experiments showed were due to the two C-3 protons of the bicyclo[2.2.2]octane moieties of the major adducts (only). This, along with a careful comparison of the relative chemical shifts (major versus minor) (19), implied that *every* major adduct was the Type I adduct, with the bicyclo[2.2.2]octane C-3 methylene *syn* to the carbonyl(s). This was demonstrated unequivocally by careful irradiation of the α-proton resonance of the major adduct with maleic anhydride (**18***a*). This resulted in an 11% nuclear Overhauser enhancement of the C-3 methylene signal as measured from a difference spectrum.[6]

The adduct yields and the Type I to Type II ratios for all additions are given in Table 1. All the dienophiles should provide the same steric interaction with **3**. That is, during cycloaddition, each dienophile projects two hydrogens towards the bicyclo[2.2.2]octane moiety of **3**. We found very little difference in the facial stereoselectivity between dienophiles. Furthermore, the effect of Lewis acid catalysis on the facial selectivity was not significant.

Before attempting to rationalize these results it seemed prudent to resolve the question of kinetic versus thermodynamic control. Regardless of the substantial precedent for kinetically

FIG. 2. Two modes of *endo*-addition in diene **3**. The Type I adduct results from addition to the face of the cyclopentadienyl ring *syn* to the C-3 methylene of the bicyclo[2.2.2]octane moiety. The Type II adduct results from addition to the opposite diene face, i.e., *syn* to the C-1 methine of the bicyclo[2.2.2]octane moiety.

controlled reactions in Diels–Alder cycloadditions involving nonheterocyclic dienes, the fact that our product ratios were so similar suggested that these ratios might have been the result of equilibrating conditions. The major adduct (**18***a*) from the cycloaddition with maleic anhydride was isolated by multiple recrystallization. A solution of this very pure Type I adduct was heated under reflux for two days, after which we could find no evidence of isomerization to **18***b*. Furthermore, heating a

[6]We thank Dr. Thomas T. Nakashima, Department of Chemistry, University of Alberta, for kindly running this experiment on a Bruker WH-400 instrument.

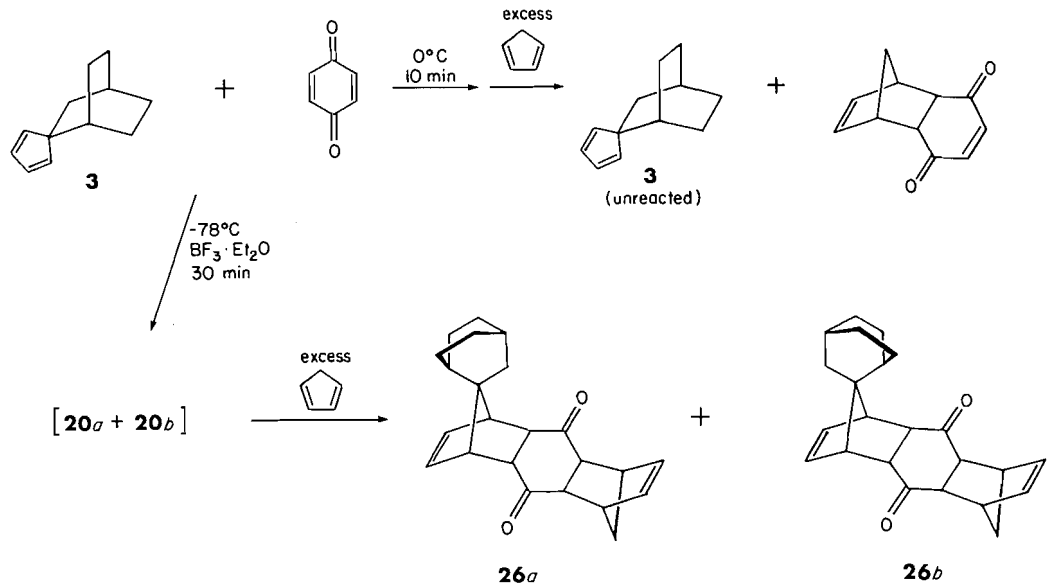
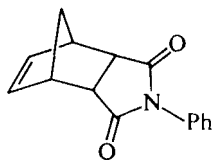


SCHEME 2

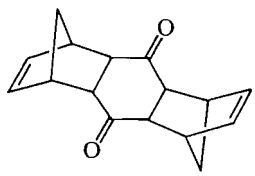
solution of **19***a* and **19***b* with a large excess of cyclopentadiene failed to produce any cyclopentadiene adduct **25**.

We knew from competitive experiments that diene **3**, like 5,5-dimethylcyclopentadiene **4** (21), is much less reactive than cyclopentadiene. We used this fact to prove that our so-called catalysed reactions were indeed taking place efficiently at



25

−78°C (Scheme 2). Thus, without the catalyst, **3** did not react appreciably with *para*-benzoquinone even at 0°C. However, at −78°C in the presence of boron trifluoride etherate, cycloaddition of **3** to *para*-benzoquinone was efficient and, after quenching the reaction with excess cyclopentadiene, the double-adducts **26***a* and **26***b* were obtained. (Had **3** not reacted readily at −78°C the cyclopentadiene double adduct **27** (22) would have been the result.)



27

Discussion

All the dienophiles used in this study were mono- or *cis*-disubstituted ethylenes. The nmr data showed that both the major (Type I) and the minor (Type II) adducts resulted by *endo* addition. Therefore, with every dienophile studied we expected that the important steric interactions would be between a pair of (*cis*) hydrogens on the incoming dienophile and plane-nonsymmetric substituents in the *exo* region of diene **3** as shown in Fig. 2. The hydrogens of the C-1 methine and the C-3 methylene of **3** are situated between 2 and 2.2 Å from the plane of the diene moiety. This is the distance between addends at the Diels–Alder transition state, as determined by *ab initio* calculations (23, 24). As **3** was much less reactive than cyclopentadiene, steric interactions were indeed very important and therefore it seemed resonable to assume that these interactions must have governed the observed facial stereoselectivity. Nevertheless, the data in Table 1 show that there was very little, if any, correlation between the inherent reactivity of the system and the stereoselectivity; i.e., the Type I to Type II ratios were roughly constant. This is clearly *not* what would be expected considering the tight-transition-state hypothesis.

During cycloaddition with diene **3**, the dienophiles experienced steric interactions in the *exo* region of the transition-state structure. In contrast, the experimental data that led to the formulation of the tight-transition-state hypothesis involved *endo*-controlled phenomena. Furthermore, our previous studies (4, 5), in which different *syn–anti* ratios were observed for thermal and catalysed reactions, employed dienes (**1** and **2**) that were plane-nonsymmetrical in the *endo* region.

All these data are consistent with the following hypothesis, which emphasizes the degree of rehybridization at the reacting centres rather than the actual distance between the addends. Isotope effects have suggested that the Diels–Alder transition state is very early on the reaction coordinate (25), but obviously some rehybridization of the reacting centres from sp^2 to sp^3 must be evident at the transition state. This is borne out by *ab initio* calculations of the butadiene plus ethylene reaction (23, 24). The simplest rationalization for the data in Table 1 is that the distance between the sterically interacting atoms must be roughly constant for all the reactions studied. This implies that the angles ϕ_3 and ϕ_4, in the *exo* region of the generic Diels–Alder transition-state structure shown in Fig. 3, are roughly constant (regardless of the reactivity of the dienophile). On the other hand, we might expect the angles ϕ_1 and ϕ_2, in the *endo* region of Fig. 3, to be significantly smaller with more reactive dienophiles because they generally have stronger attractive interactions between the secondary, ultimately non-reacting, centres (6*c*, 7, 26).

As originally postulated (6*c*), the tight-transition-state hypothesis seems somewhat at variance with Hammond's postulate (27). Intuitively, one would expect that, if anything, the more reactive systems should be *further* apart at the transition state! Figure 3 serves to illustrate that, in fact, the more reactive

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 190.90.36.8 on 09/07/12
For personal use only.

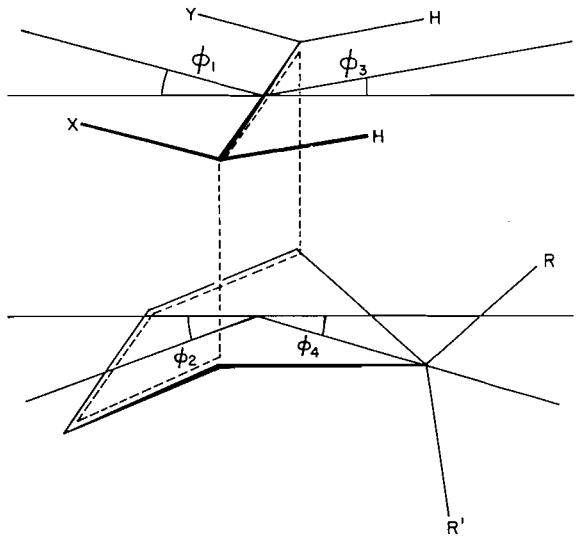


FIG. 3. Diels–Alder transition-state geometry.

systems are more reactant-like in that at the transition state of a reaction involving a more reactive dienophile the addends are flatter, i.e. more sp^2, than at the transition state of a reaction involving a less reactive dienophile.

The hypothesis outlined above is, of course, predicated on the assumption that the observed facial stereoselectivity was governed by steric factors. In our communication (9) we mentioned that signals corresponding to C-1 and C-3 in the ^{13}C nmr spectrum of **3** were found significantly upfield of their expected positions. We conjectured that this might be symptomatic of appreciable hyperconjugation of various σ-orbitals of the bicyclo[2.2.2]octane moiety with the diene π-orbital(s). This, in turn, suggested that electronic factors might be important in controlling the facial stereoselectivity of **3**, just as Gleiter, Paquette, Vogel, and others (3) have proposed for isodicyclopentadiene and related systems.[7] We should therefore mention here the result of recent calculations. Evaluation of the steric interactions in an MM2 model for the addition of ethylene to **3** gave reasonable agreement with the ratios in Table 1. This is consistent with steric factors being dominant in determining facial stereoselectivity with **3**.[8]

In the course of steroid syntheses we encountered instances in which substituted benzoquinones reacted with significantly better regioselectivity than other dienophiles (28). Hence, we were particularly interested to see whether *para*-benzoquinone would react in a different manner when compared to nonquinonoid dienophiles of similar reactivity. Table 1 shows that *para*-benzoquinone reactions, be they thermal or catalysed, gave the same *syn–anti* ratios as reactions with maleic anhydride and *N*-phenylmaleimide.[9] Thus, it appears that the "anomalous" quinone behavior is not related to significant differences in the geometry of the *exo* region of its Diels–Alder transition-state structures.

In conclusion, we have demonstrated that facial stereoselectivity, when governed by steric interactions in the *exo* region, is insensitive to dienophile reactivity. The implication is that the transition-state geometry is fairly constant in the *exo* region.

Experimental

Melting points (mp) were determined on a Kofler hot stage and are uncorrected. Ultraviolet (uv) spectra were obtained with a Beckman Model 25 spectrophotometer. Infrared (ir) spectra were recorded on a Perkin–Elmer 727B spectrophotometer in $CHCl_3$ solution. Routine ^1H nuclear magnetic resonance (nmr) spectra were obtained at 60 MHz (Varian T-60) in $CDCl_3$ solution, unless otherwise noted. Some spectra were also recorded at 200 MHz (Varian XL-200), 220 MHz, and 360 MHz (via Mr. Alan Lee, Department of Medical Genetics, University of Toronto). Routine ^{13}C nmr spectra were obtained on a Varian CFT-20 or a Bruker WP-80 instrument in $CDCl_3$ solution. Chemical shifts are given in ppm downfield of the tetramethylsilane internal reference. Standard abbreviations apply, but *apparent* multiplicities are usually reported. (In many instances the actual coupling is very complicated.) Signal multiplicities for ^{13}C nmr data refer to single-frequency off-resonance decoupled (SFORD) spectra. Considerable signal overlap was encountered in the ^{13}C nmr SFORD spectra of some compounds; this was overcome by simple spin-echo experiments. Low resolution electron impact mass spectra (ms) were provided by a Hitachi Perkin–Elmer RMU-6D instrument (70 eV). High resolution spectra were run by Dr. A. M. Hogg, Department of Chemistry, University of Alberta, on an AEI MS-50 spectrometer. Microanalyses were by Dr. F. Pascher, Mikroanalytisches Laboratorium, Bonn, and Mr. H. Seguin, National Research Council, Ottawa. Unless otherwise specified, reactions were performed under an atmosphere of dry nitrogen or argon. Solvents were distilled or were of A.C.S. Reagent Grade quality. Aqueous solutions are implied by saturated NaCl, $NaHCO_3$, etc.

*(1RS,2RS,4RS)- and (1RS,2SR,4RS)-5-bicyclo[2.2.2]octene-2-carboxaldehyde (**5**a and **5**b)*

(a) Thermal reaction

1,3-Cyclohexadiene[10] (39.1 g, 0.488 mol), freshly distilled acrolein (60.0 mL, 0.898 mol), and hydroquinone (approximately 100 mg) were placed in a Parr Series 4000 high pressure hydrogenation apparatus attached to an argon cylinder. Over a period of 5 h the pressure and temperature were increased to 194 atm and 85°C. After 60 h the reaction mixture was allowed to cool to room temperature (11 h), and the pressure was released. The product was removed from the reaction vessel with CH_2Cl_2. Rotary evaporation followed by vacuum distillation (bp 42–50°C/0.5 Torr; 1 Torr = 133.3 Pa) afforded 62.6 g (94%) of a 9:1 mixture (by ^1H nmr spectroscopy) of the *endo*- and *exo*-addition products, ***5a*** and ***5b*** respectively.

(b) Catalysed reaction

A stirred solution of 1,3-cyclohexadiene[10] (23.0 g, 0.287 mol) in CH_2Cl_2 (625 mL), containing a very small amount of hydroquinone, was cooled in a Dry Ice – acetone bath. Tin(IV) chloride (144 mL of a 1 *M* solution in CH_2Cl_2) was introduced, and freshly distilled acrolein (43.7 g, 0.780 mol) was added over a period of 2 h, then stirred for an additional 4 h. (Initially the reaction mixture was bright yellow, but it gradually became paler and more turbid.) The mixture was allowed to warm to room temperature, and water (230 mL) was added slowly. The CH_2Cl_2 layer was washed with saturated $NaHCO_3$, water, and saturated NaCl, then dried (Na_2SO_4) and concentrated by rotary evaporation. The viscous residue was distilled under vacuum (bp 54–58°C/0.4 Torr) to provide pure ***5a*** (27.8 g, 71%). For ***5a***: ir ν_{max}:

[7]For an alternative explanation of the facial stereoselectively of isodicyclopentadiene see ref. 24.

[8]F. K. Brown, K. N. Houk, D. J. Burnell, and Z. Valenta. Manuscript in preparation.

[9]Competitive experiments with cyclopentadiene as the diene in dichloromethane solution at room temperature gave the following relative reaction rates: maleic anhydride, 8.6; *N*-phenylmaleimide, 6.1; and *para*-benzoquinone, 1.0. Our results were similar to, but not identical with, the following relative rates reported by Sauer (18) for the same reactions in dioxane (20°C): maleic anhydride, 6.1; *N*-phenylmaleimide, 7.7; and *para*-benzoquinone, 1.0.

[10]The 1,3-cyclohexadiene was prepared by free-radical bromination of cyclohexene (*N*-bromosuccinimide, *hν*, 2.5 h; 69%) followed by dehydrobromination (quinoline, heating to 150°C while fractionally distilling the product; 79%) (29). We found this to be somewhat superior to the Organic Syntheses procedure (30).

2945, 2880, 2835 and 2740 (both m, aldehyde C—H), 1720, 1380, and 910 cm^{-1}; ^1H nmr δ: 9.44 (d, J = 1.5 Hz, 1H), 6.32 (ddd, J = 1.7, 6.4, 8.6 Hz, 1H) and 6.09 (ddd, J = 1.8, 6.3, 8.6 Hz, 1H) in an AB relationship, 2.45–3.1 (m, 3H), and 1.1–1.9 (m, 6H). For **5***b*: ^1H nmr δ: 9.77 (br s, 1H).

*Bicyclo[2.2.2]octane-2-carboxaldehyde (**6**)*

A solution of **5***a* and **5***b* (11.3 g, 83.2 mmol) in ethyl acetate (50 mL) was hydrogenated in the presence of 10% Pd on charcoal (1.0 g) for 1 h at 3.4 atm (1 atm = 101.3 kPa) on a Parr apparatus. After filtration through Celite, evaporation of the solution *in vacuo* provided **6** (11.5 g, 100%); bp 90°C/14 Torr: ir ν_{max}: 2945, 2875, 2830 and 2735 (both m, aldehyde C—H), and 1720 cm^{-1}; ^1H nmr δ: 9.73 (s, 1H), 2.3–2.7 (br m, 1H), and 1.3–2.3 (m, 12H) including two large pseudosinglets at δ 1.50 and 1.65.

*Di(bicyclo[2.2.2]octane-2-methylyl)ether (**7**)*

A solution of **5***a* and **5***b* (26.8 g, 0.197 mol) in ethyl acetate (60 mL) was hydrogenated in the presence of 10% Pd on charcoal (3.5 g) for 74.5 h at 5 atm. Filtration and evaporation yielded 23.8 g of a 3:4 mixture of **6** and **7**. A relatively pure sample of **7** was obtained by precipitation from cold ethyl acetate followed by preparative tlc; ir ν_{max}: 2920, 2870, and 1090 cm^{-1}; ^1H nmr δ: 3.32 (d, J = 7 Hz, 4H) and 1.35–2.1 (m) including a large pseudosinglet at δ 1.58; ^{13}C nmr δ: 74.7 (t, C-9), 35.9 (d, C-2), 30.6 (t, C-3), 27.2 (t, C-7), 26.2 (t, C-5), 25.6 (t, C-8), 25.3 (d, C-1), 24.5 (d, C-4), and 20.9 (t, C-6).

*2-(Pyrrolidinomethylene)-bicyclo[2.2.2]octane (**8**)*

A solution of pyrrolidine (100 mL) in dry benzene (1000 mL) was heated under reflux as a solution of **6** (35.0 g, 0.253 mol) in benzene (200 mL) was added over 5 h; evolved water was removed by means of a Barrett water separator. Reflux was maintained for a further 14 h. Rotary evaporation of the benzene and excess pyrrolidine left a red-brown residue, which was distilled under vacuum to provide **8** (46.0 g, 95%), bp 100°C/0.55 Torr; ir ν_{max}: 3200 (br), 1710, 1660, 1455, and 1360 cm^{-1}; ^1H nmr δ: 5.68 (t, 1H), 3.03 (br t, 4H), 2.39 (br t, 2H), and 1.4–2.0 (m, 14H); ms m/z (%): 191 (100, M^+), 190 (15), 162 (79), 148 (29), 123 (21), 122 (68), 120 (23), 109 (36), 94 (21), 93 (29), 91 (32), 84 (33), 81 (63), 80 (67), 79 (44), 77 (25), 70 (36), 69 (21), 67 (63), 57 (36), 55 (40), 44 (82), 43 (38), and 41 (69).

*2-Chloro-3-iodo-1-propene (**9**)*

Sodium iodide (425 g, 2.84 mol) was added to a solution of 2,3-dichloro-1-propene (174 g, 1.57 mol) in spectral-grade acetone (1.5 L). After heating under reflux for 3.5 h,[11] the mixture was cooled and water and ether were introduced. The organic layer was washed with $NaHSO_3$, water, and saturated NaCl, then dried ($MgSO_4$) and evaporated to yield essentially pure **9** (290 g, 91%), bp 101–102°C; ^1H nmr δ: 5.60 (br d, 1H), 5.32 (d, J = 1.6 Hz, 1H), and 4.11 (s, 2H).

*2-(2-Chloro-2-propenyl)-bicyclo[2.2.2]octane-2-carboxaldehyde (**10**)*

The chloro-iodide **9** (290 g, 1.43 mol) was added dropwise to a stirred solution of **8** (71.4 g, 0.373 mol) in dry acetonitrile (approx. 1.8 L). The reaction mixture was heated under reflux for 5 days. Following rotary evaporation of most of the acetonitrile, the residue was stirred for several hours with 560 mL of a water–THF mixture (1:1). The volume was reduced by about one third by rotary evaporation, and this was extracted with ether. The organic solution was washed with 5% HCl, 10% $Na_2S_2O_3$, 10% $NaHCO_3$ and saturated NaCl, then dried ($MgSO_4$), and the solvent was evaporated. The residue was distilled under vacuum; the initial fractions were unreacted **9** and aldehyde **6**, followed by the desired chloro-aldehyde **10** (47.6 g, 60%), bp 99–104°C/0.3 Torr, which, when stored in a freezer, slowly crystallized to provide pale yellow crystals, mp 30–33°C; ir ν_{max}: 2950, 2875, 1720, 1640, and 890 cm^{-1}; ^1H nmr δ: 9.63 (s, 1H), 5.24 (d, J = 1.5 Hz, 1H), 5.10 (br d, 1H), 2.73 (br s, 2H), 2.4 (m, 1H), 2.2 (m, 1H), and 1.2–2.0 (10H); ^{13}C nmr, see Table 2. Remaining in the distillation flask, and subliming slowly as a white powder, was *2,4,6-tri(bicyclo[2.2.2]octan-2-yl)-1,3,5-trioxane* (**11**): ir ν_{max}: 2930, 2855, 1720 (w), 1350, and 1085 cm^{-1}; ^1H nmr δ: 4.77 (br d, J = 7 Hz, 3H), and 1.2–2.1 (39 H), mostly in the form of one large pseudosinglet centred at δ 1.53; ^{13}C nmr δ: 104.7, 104.5 and 104.3 (1:2:1, doublets, —O—CH—O—), 40.0 (d, C-2), 28.3 (t, C-3), 26.8 (t, C-7), 26.1 (t, C-5), 25.4 (t, C-8), 24.0 (d, C-4), 23.8 (d, C-1), and 21.5 (t, C-6). *Anal.* calcd. for $C_{27}H_{42}O_3$: C 78.21, H 10.21; found: C 77.65, H 9.99.[12]

*2-Bromo-3-iodo-1-propene (**12**)*

Sodium iodide (8.78 g, 58.5 mmol) was added to a solution of 2,3-dibromo-1-propene (6.50 g, 32.5 mmol) in spectral-grade acetone (19 mL). After heating under reflux for 4 h, the mixture was cooled and water and ether were introduced. The dark purple organic layer was washed with dilute $NaHSO_3$, then saturated NaCl, dried ($CaCl_2$), and evaporated to yield **12** as a colourless liquid (6.09 g, 76%); ^1H nmr δ: 6.03 (br d, 1H), 5.88 (d, J = 2 Hz, 1H), and 4.23 (s, 2H).

*2-(2-Bromo-2-propenyl)-bicyclo[2.2.2]octane-2-carboxaldehyde (**13**)*

The enamine **8** (0.50 g, 2.6 mmol) was added to a solution of **12** (6.1 g, 25 mmol) in dry acetonitrile (50 mL). After heating under reflux for 4 days, the solvent was removed by rotary evaporation, and the residue was worked up as for **10**. Unreacted **12** was removed by vacuum distillation in a Kugelrohr apparatus leaving crude **13** as the residue (0.45 g, 67%), bp 104°C/0.18 Torr; ^1H nmr δ: 9.67 (s, 1H), 5.53 (br s, 2H), 2.91 (br s, =CBr-CH_2-, 2H), 2.4 (m, 1H), 2.2 (m, 1H), and 1.2–2.0 (10 H).

*2-(2-Oxopropyl)-bicyclo[2.2.2]octane-2-carboxaldehyde (**14**)*

*(a) From the chloro-aldehyde **10***

Mercury(II) acetate (13.1 g, 41.2 mmol) was added to a solution of **10** (8.77 g, 41.2 mmol) in 98% formic acid (175 mL). After stirring for 19.5 h at 23°C, the reaction mixture was poured into saturated NaCl (1000 mL), which was extracted with ether. The organic solution was washed with water and saturated NaCl, then dried ($MgSO_4$) and evaporated to provide essentially pure **14** (7.42 g, 93%). Recrystallization of a portion of this from CH_2Cl_2–CH_3OH gave colourless plates, mp 40.5–42°C; ir ν_{max}: 2945, 2875, 2730 (w), 1720 (very strong), 1365, and 1165 cm^{-1}; ^1H nmr δ: 9.80 (s, 1H), 2.98 (slightly broadened

[11]Prolonged heating of the reaction mixture, as advocated by Letsinger and Traynham (31), produces an appreciable amount of a second product, tentatively identified as 2,5-dichloro-1,5-hexadiene; ^1H nmr δ: 5.18 (br s) and 2.60 (br s).

[12]Purification of this cyclic trimer is problematic. Our attempts resulted in the production of *more* of the major contaminant, *bicyclo[2.2.2]octane-2-carboxylic acid*. (The monomer **6** is very susceptible to aerial oxidation.)

For personal use only.

s, 2H), 2.5 (m, 1H), 2.3 (m, 1H), 2.13 (s, 3H), and 1.2–2.0 (10H) mainly in the form of a large, broad pseudodoublet, $J \simeq 4$ Hz, centred at δ 1.47; ^{13}C nmr, see Table 2; ms m/z (%): 194 (6, M^+), 166 (25), 136 (44), 108 (24), 81 (21), 80 (26), 79 (33), 43 (100), and 41 (21).

(b) From the bromo-aldehyde ***13***

The procedure was very similar to the above. The bromo-aldehyde **13** (0.454 g, 1.77 mmol) and mercury(II) acetate (0.564 g, 1.77 mmol) in 98% formic acid (9.0 mL), stirred for 22 h at 23°C, ultimately provided **14** in a 92% yield (0.420 g).

*Spiro(bicyclo[2.2.2]octane-2,1'-[4]cyclopenten-3-one) (**15**)*

(a) From the keto-aldehyde ***14***

A solution of **14** (4.46 g, 22.9 mmol) in 6% ethanolic KOH (200 mL) was heated under reflux for 1.5 h, after which the reaction mixture was poured into water, and the product was extracted into ether. The organic solution was washed with 5% HCl, water, and saturated NaCl, then dried ($MgSO_4$) and evaporated to provide the cyclic enone **15** (3.85 g, 95%), mp 30–31.5°C; bp 89°C/0.4 Torr; ir ν_{max}: 2945, 2870, 1710, 1680, and 1590 cm^{-1}; uv λ_{max} (hexane): 220.7 nm (ε 8600); ^{1}H nmr δ: 7.67 (d, J = 6 Hz, 1H), 5.98 (d, J = 6 Hz, 1H), 2.55 (d, J = 18 Hz, 1H) and 2.22 (d, J = 18 Hz, 1H) as an AB quartet, and 1.2–2.0 (12H) mostly in the form of one large broad peak at δ 1.67; ^{13}C nmr, see Table 2; ms m/z (%): 176.1201 (76, M^+), 148.1252 (34, $C_{11}H_{16}^+$), 95.0497 (100, $C_6H_7O^+$), 94.0418 (21, $C_6H_6O^+$), 80.0626 (28, $C_6H_8^+$), and 67.0555 (35, $C_5H_7^+$). *Anal.* calcd. for $C_{12}H_{16}O$: C 81.77, H 9.15; found: C 81.64, H 9.11.

(b) Directly from the chloro-aldehyde ***10***

A solution of **10** (1.92 g, 9.03 mmol) in CH_2Cl_2 (5 mL) was added slowly to 20 mL of ice-bath cooled, concentrated H_2SO_4. Within a few minutes the reaction mixture became deep red. Stirring was continued for 8 h with gradual warming to room temperature. The reaction mixture was poured onto crushed ice and repeatedly extracted with CH_2Cl_2. The combined organic solutions were washed with 10% $NaHCO_3$ and saturated NaCl, dried ($MgSO_4$), and evaporated. The residue was chromatographed on a silica gel HF (65 g) column eluted with hexane containing an increasing proportion of ethyl acetate to provide pure **15** (0.332 g, 21%).

*(2RS,3'RS)- and (2RS,3'SR)-spiro(bicyclo[2.2.2]octane-2,1'-[4]cyclopenten-3-ol) (**16**a and **16**b)*

(a) By reduction with 9-BBN

A solution of 9-BBN (Aldrich; 8.00 mmol) in dry THF (35 mL) was added over a period of 30 min to an ice-bath cooled solution of **15** (1.39 g, 7.87 mmol) in dry THF (approximately 200 mL). The reaction mixture was stirred at this temperature for an additional 3.5 h, then at room temperature for 11.5 h. Approximately 0.5 mL of CH_3OH was added, then all the solvent was removed by rotary evaporation, and pentane (200 mL) was added. 2-Aminoethanol (0.5 mL) was added, producing a greenish gum; the pentane was decanted, and the gum was reextracted with fresh pentane (2 × 50 mL). After evaporation of the pentane, the combined extracts were chromatographed on a silica gel HF (40 g) column eluted with hexane, containing an increasing proportion of ethyl acetate, to provide a nearly 1:1 mixture of the epimeric alcohols **16***a* and **16***b* (1.31 g, 93%).

(b) By reduction with $NaBH_4$–$CeCl_3$

To an ice-bath cooled solution of **15** (6.54 g, 37.1 mmol) in CH_3OH (300 mL) was added solid $CeCl_3 \cdot 7H_2O$ (B.D.H; 13.8 g, 37.1 mmol). After stirring for 5 min, $NaBH_4$ (2.00 g, 52.8 mmol) was added in small portions over a period of 5 min. Water (100 mL) was added, and the mixture was reduced in volume to approximately one third by rotary evaporation. This was extracted with ether. The organic extract was washed with water and saturated NaCl, dried ($MgSO_4$), and evaporated to yield 6.32 g (96%) of a mixture of **16***a* (56% of product) and **16***b* (44% of product); ir ν_{max}: 3615, 3470 (br), 2940, 2865, and 1620 (w) cm^{-1}; ^{1}H nmr δ: 6.05 (d, J = 5 Hz, 1H), 5.75 (br d, J = 5 Hz, $W_{1/2}$ of each line ≃ 3.5 Hz, 1H), 4.8 (br m, 1H), 3.1 (concentration dependent, 1H), 1.8–2.6 (m, 2H, C-5'H_2), and 1.1–2.0 (12H) mainly as a broad pseudosinglet at δ 1.61; ^{13}C nmr of both isomers, see Table 2; ms m/z (%): 178.1358 (77, M^+, $C_{12}H_{18}O^+$ requires 178.1358), 160.1251 (20, $C_{12}H_{16}^+$), 135.1175 (25, $C_{10}H_{15}^+$), 96.0572 (73, $C_6H_8O^+$), 95.0498 (100, $C_6H_7O^+$), 93.0702 (20, $C_7H_9^+$), 91.0550 (26, $C_7H_7^+$), 83.0500 (22, $C_5H_7O^+$), 82.0423 (27, $C_5H_6O^+$), 81.0704 (32, $C_6H_9^+$), 80.0627 (39, $C_6H_8^+$), 79.0552 (47, $C_6H_7^+$), 77.0397 (20, $C_6H_5^+$), and 67.0555 (33, $C_5H_7^+$).

N-para-*Toluenesulphonylspiro(bicyclo[2.2.2]octane-2,1'-[4]cyclopenten-3-yl)carbamate (**17**)*

A mixture of **16***a* and **16***b* (2.06 g, 11.6 mmol) and *para*-toluenesulphonylisocyanate (2.28 g, 11.6 mmol) in dry benzene (50 mL) was stirred at room temperature overnight. The benzene was evaporated to yield **17** as a white powder (4.34 g, 100%); ^{1}H nmr δ: 7.6–8.4 (very br, 1H, NH), 7.92 (d, J = 8 Hz, 2H), 7.30 (br d, J = 8 Hz, 2H), 6.12 (br d, J = 6 Hz, 1H), 5.62 (br d, J = 6 Hz, 1H), 5.6 (br m, 1H), 2.45 (br s, 3H), and 0.9–2.3 (14H) including a large broad pseudosinglet at δ 1.53.

*Spiro(bicyclo[2.2.2]octane-2,1'-[2,4]cyclopentadiene) (**3**)*

(a) By pyrolysis of ***17***

The carbamate **17** (4.30 g, 11.4 mmol) was heated to 130°C under vacuum (approximately 0.2 Torr) in a Kugelrohr apparatus. Initially, a yellow liquid was evolved, followed by a white solid. Column chromatography of the distillate on silica gel HF (30 g), eluted with hexane – ethyl acetate (15:1) provided the diene **3** as a colourless liquid (1.46 g, 80%).

(b) Without isolation of ***17***

para-Toluenesulphonylisocyanate (6.75 g, 34.2 mmol) was added to a solution of **16***a* and **16***b* (6.09 g, 34.2 mmol) in dry benzene at 23°C. The mixture was warmed to reflux. After 20 h an additional 1.5 g of *para*-toluenesulphonylisocyanate was added; then after a further 14 h under reflux the solvent was evaporated. The resulting gum was dissolved in a 1:1 mixture of dry CH_3OH and hexane. Addition of a few drops of water separated the layers, and the methanolic layer was reextracted with hexane. The combined hexane extracts were evaporated, and the residue was chromatographed on a silica gel HF (40 g) column, eluted with hexane – ethyl acetate (20:1) to yield pure diene **3** as a colourless liquid (4.45 g, 81%), bp 65°C/0.1 Torr; uv λ_{max} (hexane): 205.0 nm (ε 1200) and 258.2 nm (ε 1100); ^{1}H nmr 360 MHz in $CDCl_3$ [60 MHz in C_6D_6] δ: 6.505 [6.48] (m, $W_{1/2}$ = 8.5 Hz, 2H, C-2'H and C-5'H) and 6.160 [6.17] (m, $W_{1/2}$ = 8.5 Hz, 2H, C-3'H and C-4'H) as an AA'XX' [AA'BB'] spin system, and 0.8–2.1 [1.0–2.2] (complex signals, 12H) appearing mainly as a very large pseudosinglet at δ 1.72 [1.53] at 60 MHz; ^{13}C nmr, see Table 2; ms m/z (%): 160.1252 (100, M^+, $C_{12}H_{16}^+$ requires 160.1252), 132.0933 (29, $C_{10}H_{12}^+$), 131.0860 (43, $C_{10}H_{11}^+$), 117.0704 (46, $C_9H_9^+$), 91.0549 (45, $C_7H_7^+$), 81.0707 (23, $C_6H_9^+$), 80.0632 (37, $C_6H_8^+$), 79.0554 (31, $C_6H_7^+$), and 67.0557 (24, $C_5H_7^+$).

Diels–Alder additions to ***3***

The Diels–Alder study used pure diene **3** and commercially available dienophiles, which in all cases were further purified. In order that the ratio of adducts be undisturbed, in most instances 360-MHz ^{1}H nmr spectra were run on the crude reaction mixtures, which usually contained a small amount of unreacted dienophile. Other spectra were taken on adduct mixtures from which impurities had been removed. Adduct ratios, which were determined by integration of the 360-MHz nmr, and percentage yields are reported in Table 1.

Addition of maleic anhydride ***3***

(a) Thermal reaction

Maleic anhydride (122.2 mg, 1.246 mmol) was added to solution of **3** (195.8 mg, 1.222 mmol) in CH_2Cl_2 (10 mL). The mixture was heated under reflux for 12 h. Rotary evaporation provided an off-white powder (300.4 mg) composed of **18***a* (major) and **18***b* (minor) (respectively, *(2s,3'aR,4'S,7'R,7'aS)-* and *(2r,3'aR,4'S,7'R,7'aS)-3'a,4',7',7'a-tetrahydro-1',3'-dioxospiro(bicyclo[2.2.2]octane-2,8'-[4,7]methanoisobenzofuran))*.

(b) Catalysed reaction

The diene **3** (288.9 mg, 1.803 mmol) was added to a stirred solution of maleic anhydride (187.9 mg, 1.907 mmol) in CH_2Cl_2 (8 mL) cooled

[a]Assignments are in accordance with SFORD and (or) spin echo data. However, signals of similar chemical shift with the same multiplicity should be considered interchangeable.

[b]Adducts are numbered as in Fig. 2. Although this is not always in accordance with strict IUPAC rules, it does allow convenient comparison of signals.

in a Dry Ice – acetone bath, followed quickly by addition of 220 μL (1.80 mmol) of freshly distilled BF_3 etherate. After 10 h the reaction mixture was allowed to warm to room temperature, and water (10 mL) was introduced. The organic solution was washed with water, saturated $NaHCO_3$, and saturated NaCl, then evaporated to yield a mixture of **18***a* (major) and **18***b* (minor) as a yellow powder (332.4 mg). Repeated (×6) recrystallization of the product from CH_2Cl_2 – ethyl acetate afforded a small amount of pure **18***a*, mp 172–175°C (sub.); ir ν_{max}: 1810 (m), 1775 (s), 1075, and 905 cm^{-1}; ^1H nmr 360 MHz in $CDCl_3$ [200 MHz in C_6D_6] δ: 6.235 [5.76] (t, J = 2.0 Hz, 2H), 3.676 [2.78] (dd, J = 1.5, 2.9 Hz, 2H, H α to C=O), 3.169 [2.54] (quintet, $W_{1/2}$ = 6 Hz, 2H, [2.2.1] bridgehead H), 1.855 [1.44] (br t, $W_{1/2}$ = 7 Hz, 1H, [2.2.2] C-1H), 1.685 [1.33] (distorted br q, $W_{1/2}$ = 10 Hz, 1H, [2.2.2] C-4H), 1.377 [0.65] (br d, J = 3.2 Hz, 2H, [2.2.2] C-$3H_2$), and remaining signals unresolved 1.35–1.55 [0.95–1.33]; ^{13}C nmr in $CDCl_3$, see Table 3 (100 MHz in C_6D_6 δ: 171.8 (2C), 135.2 (2C), 69.9, 52.6 (2C), 46.0 (2C), 34.7, 26.2, 25.9, 25.0 (2C), and 23.7 (2C)); ms m/z (%): (M^+ not apparent), 230.1305 (8, $C_{15}H_{18}O_2^+$), 185.1331 (100, $C_{14}H_{17}^+$), 117.0704 (12, $C_9H_9^+$), 104.0627 (12, $C_8H_8^+$), 91.0549 (17, $C_7H_7^+$), and 81.0706 (11, $C_6H_9^+$). *Anal.* calcd. for $C_{16}H_{18}O_3$: C 74.40, H 7.02; found: C 74.26, H 6.94. For **18***b* (determined from mixture): ^1H nmr 360 MHz in $CDCl_3$ δ: 6.272 (t, J = 2 Hz, 2H), 3.555 (dd, J = 1.5, 2.9 Hz, 2H, H α to C=O), and 3.225 (quintet, $W_{1/2}$ = 6 Hz, 2H, [2.2.2] bridgehead H); ^{13}C nmr, see Table 3.

Addition of N-*phenylmaleimide to* **3**

(a) Thermal reaction

N-Phenylmaleimide (54.0 mg, 0.312 mmol) was added to a solution of **3** (50.0 mg, 0.312 mmol) in CH_2Cl_2 (3 mL). The mixture was heated under reflux for 12 h. Rotary evaporation yielded a pale yellow powder (103.6 mg) composed of **19***a* (major) and **19***b* (minor) (respectively, *(2s,3′aR,4′S,7′R,7′aS)-* and *(2r,3′aR,4′S,7′R,7′aS)-3′a,4′,7′,7′a-tetrahydro-1′,3′-dioxo-2′-phenylspiro(bicyclo[2.2.2]octane-2,8′-[4,7]methanoisoindole))*.

(b) Catalysed reaction

A solution of **3** (40.5 mg, 0.253 mmol) in CH_2Cl_2 (4 mL) was cooled in a Dry Ice – acetone bath; *N*-phenylmaleimide (43.9 mg, 0.253 mmol) was added, followed immediately by 31 μL (≡ 0.25 mmol) of BF_3 etherate. After stirring for 2 h, the solution was allowed to attain room temperature slowly. The red-brown reaction mixture was added to ether (25 mL), which was washed with saturated NaCl, then dried ($MgSO_4$) and evaporated to afford an off-white solid (82.7 mg) composed of **19***a* (major) and **19***b* (minor); ir ν_{max}: 2930 (m), 2860 (w), 1710, 1600, 1380, 1050, and 1010 cm^{-1}; ^1H nmr of **19***a* 360 MHz in $CDCl_3$ [60 MHz in C_6D_6] δ: 7.12–7.46 [7.0–7.5] (5H), 6.178 [5.93] (t, J = 2.0 Hz, 2H), 3.542 [2.93] (dd, J = 1.5, 2.8 Hz, 2H, H α to C=O), 3.195 [2.85] (m, $W_{1/2}$ = 6 Hz, 2H, [2.2.1] bridgehead H), 1.88 [1.67] (m, 1H, [2.2.2] C-1H), 1.68 (m, 1H, [2.2.2] C-4H), [0.95] (br, $W_{1/2}$ = 6 Hz, 2H, [2.2.2] C-$3H_2$), and remaining signals 1.3–1.6 [1.0–1.5] mainly in the form of a large pseudosinglet at δ 1.45 [1.25]; ^1H nmr of **19***b* 360 MHz in $CDCl_3$ δ: 6.214 (t, J = 2.0 Hz, 2H), 3.429 (dd, J = 1.6, 2.7 Hz, 2H, H α to C=O), and 3.243 (m, $W_{1/2}$ = 6 Hz, 2H, [2.2.1] bridgehead H); ^{13}C nmr of **19***a* and **19***b*, see Table 3; ms (of the mixture of **19***a* and **19***b*) m/z (%): 333.1730 (100, M^+), 186.1407 (12, $C_{14}H_{18}^+$), 119.0370 (10, $C_7H_5NO^+$), 104.0628 (38, $C_8H_8^+$), 95.0858 (10, $C_7H_{11}^+$), 92.0622 (12, $C_7H_8^+$), 91.0548 (17, $C_7H_7^+$), 79.0549 (11, $C_6H_7^+$), and 78.0472 (10, $C_6H_6^+$). Multiple recrystallization of the product from CH_3OH provided colourless crystals, which sublimed above 200°C, recondensing as beautiful plates, mp 227°C. *Anal.* calcd. for $C_{22}H_{23}NO_2$: C 79.25, H 6.95, N 4.20; found: C 79.34, H 6.99, N 4.31.

Addition of para-*benzoquinone to* **3**

(a) Thermal reaction

The procedure was the same as for the *N*-phenylmaleimide addition; 33.7 mg (0.312 mmol) of *para*-benzoquinone and 50.0 mg (0.312 mmol) of **3** provided 83.7 mg of an off-white solid[13] composed of **20***a* (major) and **20***b* (minor) respectively, *(2s,1′R,4′S,4′aR,8′aS)-* and *(2r,1′R,4′S,4′aR,8′aS)-1′,4′,4′a,8′a-tetrahydrospiro(bicyclo[2.2.2]octane-2,9′-[1,4]methanonaphthalene)-5′,8′-dione)*.

(b) Catalysed reaction

BF_3 etherate (145 μL, 1.17 mmol) was added to a stirred solution of *para*-benzoquinone (126.5 mg, 1.170 mmol) in CH_2Cl_2 (25 mL) cooled in a Dry Ice – acetone bath. This was followed by addition of

[13]Attempts to recrystallize this adduct mixture from a number of common solvents resulted in the production of a significant amount of very sparingly soluble material, which did not appear to be either photocyclized or aromatized.

a solution of **3** (187.2 mg, 1.168 mmol) in CH_2Cl_2 (approximately 2 mL). After stirring for 6 h, the reaction mixture was allowed to attain room temperature slowly. The mixture was poured into approximately 75 mL of ether, and this solution was washed with saturated $NaHCO_3$ and saturated NaCl, then dried (Na_2SO_4) and evaporated to provide a pale brown solid[13] (297.1 mg) composed predominantly of the adducts **20***a* (major) and **20***b* (minor); ir ν_{max}: 2930, 2870, and 1670 cm^{-1}; ^1H nmr of **20***a* 220 MHz in $CDCl_3$ [360 MHz in C_6D_6] δ: 6.64 [6.099] (s, 2H, olefinic H of enedione), 6.04 [5.715] (t, J = 2.0 Hz, 2H, [2.2.1] olefinic H), 3.40 [2.812] (dd, J = 1.4, 2.3 Hz, 2H, H α to C=O), 3.25 [3.035] (m, 2H, [2.2.1] bridgehead H), 1.82 [1.612] (m, $W_{1/2}$ = 8 Hz, 1H, [2.2.2] C-1H), 1.69 [1.400] (m, $W_{1/2}$ = 9.5 Hz, 1H, [2.2.2] C-4H), [0.91] (br d, J = 2 Hz, 2H, [2.2.2] C-3H_2), and remaining signals 1.3–1.75 (1.1–1.35), in $CDCl_3$ mainly in the form of one large pseudosinglet at δ 1.43; ^1H nmr of **20***b* 220 MHz in $CDCl_3$ [360 MHz in C_6D_6] δ: 6.63 [6.093] (s, 2H, olefinic H of enedione), 6.07 [5.781] (t, J = 2.0 Hz, 2H, [2.2.1] olefinic H), [3.068] (m, 2H, [2.2.1] bridgehead H), and [2.633] (m, 2H, H α to C=O); ms (of the mixture of **20***a* and **20***b*) m/z (%): 268.1465 (50, M^+, $C_{18}H_{20}O_2^+$ requires 268.1463), 240.1514 (100, $C_{17}H_{20}O^+$), 160.1252 (18, $C_{12}H_{16}^+$), 131.0496 (23, $C_9H_7O^+$), 117.0704 (20, $C_9H_9^+$), 104.0628 (19, $C_8H_8^+$), and 91.0548 (31, $C_7H_7^+$).

Thermal addition of dimethyl maleate to 3

A large excess of dimethyl maleate (0.5 mL) was added to a solution of **3** (30.9 mg, 0.193 mmol) in CH_2Cl_2 (4 mL), and the mixture was heated under reflux for 72 h. The solvent was evaporated, and the residue was purified by preparative tlc to yield 47.2 mg (80%) of a semisolid composed of **21***a* (major) and **21***b* (minor) (respectively, *dimethyl (1*R,*2*S,*3*R,*4*S,*7*s)- and *dimethyl (1*R,*2*S,*3*R,*4*S,*7*r)-*spiro(bicyclo[2.2.1]hept-5-ene-7,2'-bicyclo[2.2.2]octane)-2,3-dicarboxylate;* ir ν_{max}: 2935, 2865, 1740, 1605, 1165, and 1020 cm^{-1}; ^1H nmr of **21***a* 360 MHz in $CDCl_3$ [360 MHz in C_6D_6] δ: 6.175 [6.215] (t, J = 1.9 Hz, 2H), 3.613 [3.429] (s, 6H), 3.427 [3.233] (m, $W_{1/2}$ = 4 Hz, H α to C=O), 2.836 [2.646] (m, $W_{1/2}$ = 5 Hz, [2.2.1] bridgehead H), 1.905 [1.850] (m, $W_{1/2}$ = 7.5 Hz, 1H, [2.2.2] C-1H), 1.644 [1.380] (m, $W_{1/2}$ = 9 Hz, 1H, [2.2.2] C-4H), [0.961] (br d, J = 3 Hz, 2H, [2.2.2] C-3H_2), and remaining signals 1.34–1.5 [1.1–1.35], in $CDCl_3$ mainly in the form of a large pseudosinglet at δ 1.41; ^1H nmr of **21***b* 360 MHz in $CDCl_3$ [360 MHz in C_6D_6] δ: 6.211 [6.285] (t, J = 1.9 Hz, 2H), 3.601 [3.415] (s, 6H), 3.323 [3.120] (m, $W_{1/2}$ = 4 Hz, 2H, H α to C=O), 2.921 [2.733] (m, $W_{1/2}$ = 5.5 Hz, 2H [2.2.1] bridgehead H), and [0.907] (m, 1H, [2.2.2] C-1H ?); ^{13}C nmr of **21***a* and **21***b*, see Table 3; ms (of the mixture of **21***a* and **21***b*) m/z (%): 304.1674 (8, M^+), 273.1486 (17, $C_{17}H_{21}O_3^+$), 244.1465 (100, $C_{16}H_{20}O_2^+$), 185.1333 (95, $C_{14}H_{17}^+$), 146.0580 (17, $C_6H_{10}O_4^+$), 117.0704 (18, $C_9H_9^+$), 113.0240 (23, $C_5H_5O_3^+$), and 91.0549 (24, $C_7H_7^+$). A small amount was recrystallized from CH_3OH. *Anal.* calcd. for $C_{18}H_{24}O_4$: C 71.03, H 7.95; found: C 70.85, H 7.93.

Thermal addition of acrolein to 3

A large excess of acrolein (approximately 1 mL) was added to a solution of **3** (42.0 mg, 0.262 mmol) in CH_2Cl_2 (4 mL), and the mixture was heated under reflux for 48 h. The solvent was evaporated, and the oily product was purified by preparative tlc to yield a white solid (48.0 mg, 85%) composed of **22***a* (major) and **22***b* (minor) (respectively, *(1*RS,*2*RS,*4*RS,*7*SR)- and *(1*RS,*2*RS,*4*RS,*7*RS)-*spiro(bicyclo[2.2.1]hept-2-ene-7,2'-bicyclo[2.2.2]octane)-2-carboxaldehyde);* ir ν_{max}: 2930, 2870, 2710 (w), and 1710 cm^{-1}; ^1H nmr of **22***a* 360 MHz in $CDCl_3$ [360 MHz in C_6D_6] δ: 9.509 [9.335] (d, J = 2.1 [1.6] Hz, 1H, CHO), 6.124 [5.810] (dd, J = 3.2, 5.9 Hz, 1H, C-5H), 5.902 [5.636] (dd, J = 2.9, 5.9 Hz, 1H, C-6H), 2.996 [2.575] (dddd, J = 2.1 [1.6], 3.7, 3.9, 8.6 Hz, 1H, C-2H), 2.910 [2.473] (m, $W_{1/2}$ = 7.5 Hz, 1H, C-1H), 2.597 [2.192] (br t, $W_{1/2}$ = 8 Hz, 1H, C-4H), 2.064 [1.703] (ddd, J = 3.7, 8.6, 12.4 Hz, 1H, C-3$_{exo}$H), 1.827 [1.753] (m, $W_{1/2}$ = 7.5 Hz, 1H, [2.2.2] C-1H) 1.636 [1.460] (m, $W_{1/2}$ = 8.5 Hz, 1H, [2.2.2] C-4H), 1.455[14] [1.374[14]] (dd, J = 3.9, 12.4 Hz, 1H, C-3$_{endo}$H), [1.054 and 0.993] (second-order doublets with much additional coupling, J_{gem} = 13.8 Hz, 2H, [2.2.2] C-3H_2), and remaining signals 1.25–1.6 [1.2–1.45]; ^1H nmr of **22***b* 360 MHz in $CDCl_3$ [360 MHz in C_6D_6] δ: 9.501[14] [9.312] (d, J = 2.0 [1.7] Hz, 1H, CHO), 6.159 [5.869] (dd, J = 3.2, 5.9 Hz, 1H, C-5H), 5.944 [5.699] (dd, J = 2.8, 5.9 Hz, 1H, C-6H), 2.91[14] [2.56[14]] (m, 1H, C-1H), 2.90[14] [2.440[14]] (dddd, J = 2.0 [1.7], 3.7, 3.9, 8.6 Hz, 1H, C-2H), 2.690 [2.289] (br t, $W_{1/2}$ = 8 Hz, 1H, C-4H), and 1.952 [1.566] (ddd, J = 3.7, 8.6, 12.3 Hz, 1H, C-3$_{exo}$H); ^{13}C nmr of **22***a*, see Table 3; ms (of the mixture of **22***a* and **22***b*) m/z (%): 216.1513 (13, M^+, $C_{15}H_{20}O^+$ requires 216.1513), 187.1488 (16, $C_{14}H_{19}^+$), 160.1248 (10, $C_{12}H_{16}^+$), 131.0860 (8, $C_{10}H_{11}^+$), 117.0704 (9, $C_9H_9^+$), 109.1019 (100, $C_8H_{13}^+$), 91.0549 (18, $C_7H_7^+$), 79.0552 (18, $C_6H_7^+$), and 67.0554 (46, $C_5H_7^+$).

Thermal addition of methyl acrylate to 3

A large excess of methyl acrylate (approximately 1 mL) was added to a solution of **3** (25.3 mg, 0.158 mmol) in CH_2Cl_2 (2.5 mL). The mixture was heated under reflux for 5 days. The solvent and excess dienophile were evaporated, and the residue was subjected to preparative tlc to yield 32.3 mg (83%) of white needles composed of **23***a* (major) and **23***b* (minor) (respectively, *methyl (1*RS,*2*RS,*4*RS,*7*SR)- and *methyl (1*RS,*2*RS,*4*RS,*7*RS)-*spiro(bicyclo[2.2.1]hept-5-ene-7,2'-bicyclo[2.2.2]octane)-2-carboxylate);* ir ν_{max}: 2935, 2865, 1715, and 1165 cm^{-1}; ^1H nmr of **23***a* 360 MHz in $CDCl_3$ [360 MHz in C_6D_6] δ: 6.118 [5.987] (dd, J = <0.5,[15] 3.2, 5.8 Hz, 1H, C-5H), 5.832 [5.891] (dd, J = <0.5,[15] 2.9, 5.8 Hz, 1H, C-6H), 3.621 [3.375] (s, 3H, OCH_3), 3.055 [2.911] (dt, J = 3.8, 3.9, 8.8 Hz, 1H, C-2H), 2.848 [2.836] (m, $W_{1/2}$ = 8 Hz, J = <0.5, 1, 2.9, 3.8 Hz,[15] 1H, C-1H), 2.511 [2.230] (m, $W_{1/2}$ = 8 Hz, J = <0.5, 1, 3.2, 3.7 Hz,[15] 1H, C-4H), 2.059 [1.907] (ddd, J = 3.7, 8.8, 12.2 Hz, 1H, C-3$_{exo}$H), 1.812 [1.846] (m, $W_{1/2}$ = 7 Hz, 1H, [2.2.2] C-1H), 1.619 [1.459] (m, $W_{1/2}$ = 8 Hz, 1H, [2.2.2] C-4H), 1.43[14] [1.645] (dd, J = 3.9, 12.2 Hz, 1H, C-3$_{endo}$H), [1.089] (multiplets with J_{gem} = 14 Hz, 2H, [2.2.2] C-3H_2), and remaining signals 1.3–1.6 [1.2–1.45]; ^1H nmr of **23***b* 360 MHz in $CDCl_3$ [360 MHz in C_6D_6] δ: 6.144[14] [6.039] (dd, J = 3.2, 5.6 Hz, 1H, C-5H), 5.872 [5.953] (dd, J = 2.6, 5.6 Hz, 1H, C-6H), 3.614 [3.366] (s, 3H, OCH_3), 2.953[14] [2.763] (dt, J = 3.9, 3.9, 8.7 Hz, 1H, C-2H), 2.934[14] [2.90[14]] (m, 1H, C-1H), 2.602 [2.333] (m, $W_{1/2}$ = 8 Hz, C-4H), 1.947 [1.777] (ddd, J = 3.9, 8.7, 12.2 Hz, 1H, C-3$_{exo}$H), and [1.64[14]] (dd, 1H, C-3$_{endo}$H); ^{13}C nmr of **23***a*, see Table 3; ms (of the mixture of **23***a* and **23***b*) m/z (%): 246.1616 (100, M^+, $C_{16}H_{22}O_2^+$ requires 246.1620), 187.1473 (39, $C_{14}H_{19}^+$), 186.1409 (71, $C_{14}H_{18}^+$), 109.1018 (53, $C_8H_{13}^+$), 105.0706 (25, $C_8H_9^+$), 104.0630 (29, $C_8H_8^+$), 91.0544 (31, $C_7H_7^+$), 79.0544 (33, $C_6H_7^+$), 77.0391 (20, $C_6H_5^+$), and 67.0556 (27, $C_5H_7^+$).

Thermal addition of 3-buten-2-one to 3

A large excess of 3-buten-2-one (approximately 1 mL) was added to a solution of **3** (44.1 mg, 0.275 mmol) in CH_2Cl_2 (4 mL). The mixture was heated under reflux for 7 days. The solvent and excess dienophile were evaporated, and the residue was subjected to preparative tlc to yield 38.8 mg (61%) of a white semisolid composed of **24***a* (major) and **24***b* (minor) (respectively, *(1*RS,*2*RS,*4*RS,*7*SR)- and *(1*RS,*2*RS,*4*RS,*7*RS)-*2-acetylspiro(bicyclo[2.2.1]hept-5-ene-7,2'-bicyclo[2.2.2]octane));* ir ν_{max}: 2930, 2865, 1700, 1600 (w), 1350, 1055, and 1015 cm^{-1}; ^1H nmr of **24***a* 360 MHz in $CDCl_3$ [360 MHz in C_6D_6] δ: 6.084 [5.910] (dd, J = 3.2, 5.9 Hz, 1H, C-5H), 5.767 [5.644] (dd, J = 2.9 [2.6], 5.9 Hz, 1H, C-6H), 3.050 [2.636] (ddd, J = 3.8 [3.7], 4.0 [5.2], 8.5 [7.0] Hz, 1H, C-2H), 2.869 [2.583] (m, $W_{1/2}$ = 8 [7] Hz, 1H, C-1H), 2.515 [2.228] (m, $W_{1/2}$ = 8.5 [8] Hz, 1H, C-4H), 2.119 [1.744] (s, 3H, $COCH_3$), 1.895 [1.69[16]] (ddd, J = 3.8, 8.5, 12.3 Hz, 1H, C-3$_{exo}$H), 1.818 [1.831] (m, $W_{1/2}$ = 7 Hz, 1H, [2.2.2] C-1H), 1.641 [1.510] (m, $W_{1/2}$ = 8 Hz, 1H, [2.2.2] C-4H), 1.508[14] [1.69[16]] (dd, J = 4.0, 12.3 Hz, 1H, C-3$_{endo}$H), [1.15 and 1.09] (second-order doublets with much additional coupling, J_{gem} =

[14]Partially or completely overlapped signal.

[15]Couplings determined with the aid of spin decoupling experiments.

[16]In C_6D_6 these protons have essentially the same shift, resulting in a very complicated 2H signal.

Reactivity of **3** *versus cyclopentadiene*

A solution of **3** (19.2 mg, 0.120 mmol) and freshly cracked cyclopentadiene (7.7 μL ≡ 0.093 mmol) in C_6D_6 (approximately 0.5 mL) was rapidly mixed in an nmr tube with a solution of *para*-benzoquinone (12.9 mg, 0.119 mmol) in C_6D_6 (0.5 mL). The ^{1}H nmr spectra taken at intervals showed reaction of all the cyclopentadiene with the dienophile within a few minutes, but at the same time there was no detectable production of **20***a*. However, after 2.5 h much of the remaining *para*-benzoquinone had reacted with **3** to provide mainly **20***a*. After 24 h the amount of diene **3** in solution had not decreased significantly.

Reactivity of **3** *at 0°C*

A solution of **3** (11.3 mg, 0.070 mmol) in CH_2Cl_2 (5 mL) was cooled in an ice bath as *para*-benzoquinone (7.6 mg, 0.070 mmol) was added. After 10 min approximately 30 mg of cyclopentadiene was added, and the solution was allowed to attain room temperature. The solvent and excess cyclopentadiene were evaporated. The ^{1}H nmr spectrum of the product showed that it consisted solely of unreacted **3** and of cyclopentadiene adduct.

This mixture was redissolved in CH_2Cl_2 (3 mL) and cooled again in an ice bath. One drop of BF_3 etherate was added followed quickly by *para*-benzoquinone (7.2 mg). The mixture was stirred for 4 min before a large excess of cyclopentadiene was added. The mixture was added to water. The organic layer was dried (Na_2SO_4) and evaporated. The ^{1}H nmr spectrum of the product showed signals attributable to the double adducts **26***a* and **26***b* (*vide infra*), but no trace of **3** or of **20***a*.

Reactivity of **3** *at −78°C in the presence of a Lewis acid*

A solution of **3** (50.0 mg, 0.312 mmol) in CH_2Cl_2 (4 mL) was cooled in a Dry Ice – acetone bath; BF_3 etherate (38.5 μL, 0.313 mmol) was added, followed quickly by a solution of *para*-benzoquinone (33.7 mg, 0.312 mmol) in CH_2Cl_2 (approximately 1 mL). The mixture was stirred at −78°C for 30 min, and the cyclopentadiene (0.35 μL, 4.2 mmol) was added at once. The solution was allowed to warm above 0°C, then it was diluted with ether, and this solution was washed (×2) with saturated NaCl. Evaporation of the solvent provided a yellow solid the ^{1}H nmr spectrum of which was consistent with a mixture of **26***a* and **26***b*, but there were no signals corresponding to **3**, **20***a*, the cyclopentadiene adduct, or the double cyclopentadiene adduct **27**.

Attempts at thermal equilibration

(a) Of pure **18***a*

A solution of pure (by 400-MHz ^{1}H and 100-MHz ^{13}C nmr) adduct **18***a* in CH_2Cl_2 was heated under reflux for 48 h, then the solvent was evaporated. In the 400-MHz ^{1}H nmr spectrum of the product, only signals due to **18***a* were apparent, i.e. not even a trace of **18***b* could be detected.

(b) Of **19***a and* **19***b with cyclopentadiene*

A solution of adducts **19***a* and **19***b* and a large excess of freshly-cracked cyclopentadiene in CH_2Cl_2 was heated under reflux for 15.5 h, then the solvent was evaporated. The ^{1}H nmr spectrum of the product revealed that no cyclopentadiene adduct **25** had formed. (What remained was unchanged **19***a* and **19***b*.)

Double addition of para*-benzoquinone to* **3** *and cyclopentadiene*

A stirred solution of **3** (50.0 mg, 0.312 mmol) in CH_2Cl_2 (3 mL) was cooled in a Dry Ice – acetone bath. BF_3 etherate (38.4 μL, 0.312 mmol) and *para*-benzoquinone (33.7 mg, 0.312 mmol) were added, and the mixture was stirred for 6 h. Freshly cracked cyclopentadiene (27.5 μL, 0.312 mmol) was added, and the mixture was stirred for a further 20 min, after which the mixture was allowed to attain room temperature. Ether was added, and the organic solution was washed with saturated NaCl, dried ($MgSO_4$), and evaporated to yield 101.0 mg of a pale yellow solid composed of **26***a* (major) and **26***b* (minor) (respectively, *(2s,1'R,4'S,4'aR,5'S,8'R,8'aS,9'aS,10'a*R- and *(2r,1'R,4'S,4'aR,5'S,8'R,8'aS,9'aS,10'aR)-1',4',4'a,5',8',-8'a,9'a,10'a-octahydrospiro(bicyclo[2.2.2]octane-2,11'-[1,4][5,8]dimethanoanthracene)-9',10'-dione)* and small amounts of **20***a* and **20***b*. Crystallization from ethyl acetate – CH_2Cl_2 provided colourless crystals; ir ν_{max}: 2930, 2870, and 1685 cm^{-1}; ^{1}H nmr of **26***a* 60 MHz in $CDCl_3$ [360 MHz in C_6D_6] δ: 6.20 [5.998] (t, J = 1.8 Hz, 2H, C-6'H + C-7'H), 6.07 [5.895] (t, J = 1.9 Hz, 2H, C-2'H + C-3'H), 3.39 [3.181] (m, $W_{1/2}$ = 4.5 Hz, 2H, C-5'H + C-8'H), 3.0[14] [2.943] (m, $W_{1/2}$ = 5 Hz, 2H, C-1'H + C-4'H), 3.0[14] [2.793] (m, $W_{1/2}$ = 5 Hz, 2H, C-4'aH + C-9'aH), 2.9[14] [2.592] (m, $W_{1/2}$ = 5 Hz, 2H, C-8'aH + C-10'aH), [1.729] (m, $W_{1/2}$ = 8 Hz, 1H, [2.2.2] C-1H), [1.392] (m, $W_{1/2}$ = 9.5 Hz, 1H, [2.2.2] C-4H), [1.159] (d of very small t, J_{gem} = 9 Hz, 1H, C-12'*s*H), [0.938] (br d, J = 2 Hz, 2H, [2.2.2] C-3H_2), [0.783] (br d, J_{gem} = 9 Hz, 1H, C-12'*r*H), and remaining signals unresolved 1.1–2 [1.1–1.35]; ^{1}H nmr of **26***b* [360 MHz in C_6D_6] δ: [5.982] (t, J = 2.0 Hz, 2H, C-2'H + C-3'H), and [3.02] (m, 2H, C-1'H + C-4'H), with the majority of signals being partially or completely overlapped with signals due to **26***a*; ^{13}C nmr of **26***a*, see Table 3; ms (of mixture of **26***a* and **26***b*) *m/z* (%): 334.1929 (1.5, M^+), 268.1463 (53, $C_{18}H_{20}O_2^+$), 240.1514 (100, $C_{17}H_{20}O^+$), 160.1251 (42, $C_{12}H_{16}^+$), 160.0524 (17, $C_{10}H_8O_2^+$), 131.0860 (20, $C_{10}H_{11}^+$), 131.0497 (24, $C_9H_7O^+$), 117.0704 (28, $C_9H_9^+$), 109.1020 (22, $C_8H_{13}^+$), 104.0628 (23, $C_8H_8^+$), 91.0549 (46, $C_7H_7^+$), 82.0062 (67, $C_4H_2O_2^+$), 79.0550 (25, $C_6H_7^+$), 67.0554 (26, $C_5H_7^+$), and 66.0479 (31, $C_5H_6^+$). *Anal.* calcd. for $C_{23}H_{26}O_2$: C 82.60, H 7.84; found: C 82.43, H 7.83.

*(1*R*,4*S*,4a*R*,5*S*,8*R*,8a*S*,9a*S*,10a*R*)-1,4,4a,5,8,8a,9a,10a-octahydro[1,4],[5,8]dimethanoanthracene (27)*[17]

Cyclopentadiene (2.5 mL) was added to a solution of *para*-benzoquinone (1.02 g, 9.44 mmol) in CH_2Cl_2 (approximately 50 mL). The mixture was heated under reflux for 60 h. After evaporation of the solvent, the residue was crystallized from CH_2Cl_2–ether–pentane yielding colourless crystals (1.77 g, 78%), mp 165–166.5°C (lit. (22, 32) mp 157°C; ir ν_{max}: 2980, 2930, 2860, and 1685 cm^{-1}; ^{1}H nmr 60 MHz in $CDCl_3$ [360 MHz in C_6D_6] δ: 6.22 [5.928] (t, J = 1.8 Hz, 4H), 3.37 [3.119] (m, $W_{1/2}$ = 4.5 Hz, 4H), 2.88 [2.503] (br t, $W_{1/2}$ = 4 Hz, 4H), 1.45 [1.117] (dt, J = 2, 9.6 Hz, 2H, C-11H + C-12H *syn* to double bonds), and 1.31 [0.743] (br d, J = 9.6 Hz, 2H, C-11H + C-12H *anti* to double bonds (20)); ms *m/z* (%): 240 (12, M^+), 212 (12), 174 (48), 146 (11), 91 (10), and 66 (100).

Thermolysis of geminal diazides: a novel route to 1,3,4-oxadiazoles

WILLIAM OGILVIE[1] AND WERNER RANK[2]

Department of Chemistry, Laurentian University, Ramsey Lake Road, Sudbury, Ont., Canada P3E 2C6

Received July 8, 1986

This paper is dedicated to Dr. O. E. (Ted) Edwards

WILLIAM OGILVIE and WERNER RANK. Can. J. Chem. **65**, 166 (1987).

The geminal diazides ethyl α,α-diazidoacetoacetate and α,α-diazidobenzoylacetate were prepared from the corresponding dibromo precursors by nucleophilic azide displacement. Thermolysis of the diazido compounds led to the formation of 2,5-disubstituted 1,3,4-oxadiazoles in high yield.

WILLIAM OGILVIE et WERNER RANK. Can. J. Chem. **65**, 166 (1987).

Utilisant les dérivés dibromés correspondants comme précurseurs et faisant appel à des réactions de déplacements nucléophiles par des azotures, on a préparé les dérivés diazidés géminés, α,α-diazidoacétoacétate et α,α-diazidobenzoylacétate d'éthyle. La thermolyse des composés diazidés conduit à la formation, avec de très bons rendements, d'oxadiazoles-1,3,4 disubstitués dans les positions 2 et 5.

Interest in azido compounds stems partially from their potential for thermal and photolytic decomposition to highly reactive nitrenes. Depending on the structure and on conditions, the nitrenes rearrange to more stable products where a major stabilization process may lead to the formation of azomethines (1). Thus nitrenes may undergo 1,2-hydrogen shifts leading to the formation of imines, or alkyl and aryl shifts leading to the formation of N-substituted azomethines. Less commonly observed is the migration of an acyl group from carbon onto nitrogen, leading to the formation of *N*-acyl imines (2–4). In some cases the evidence for the intermediacy of *N*-acyl imines is indirect. An intermediate *N*-acyl imine has been postulated in the thermolytic conversion of the geminal diazide 2,2-diazido-1,3-indandione to a tetrazole derivative (3) (eq. [1]).

[1] 
Diazide *N*-Acylimine Tetrazole

The photolytic decomposition of dimethyl diazidomalonate provides another example of this nature (5). To further explore the structural requirements for acyl migration onto nitrogen we chose to study the thermolysis of ethyl α,α-diazido-acetoacetate and -benzoylacetate.

To undertake this study we first had to synthesize these two hitherto unknown geminal diazides. For this purpose ethyl acetoacetate and ethyl benzoylacetate were first brominated to the known dibromo derivatives **1***a* (6) and **1***b* (7). Nucleophilic displacement of halogen by the azide ion was achieved when the dibromo derivatives were treated with sodium azide in dimethyl formamide. Fractional distillation[3] gave pure ethyl α,α-diazidoacetoacetate (**2***a*) and pure ethyl α,α-diazidobenzoylacetate (**2***b*) in yields of 76% and 63%, respectively. The structural identity of the diazido derivatives was established from their spectral and microanalytical data. An ir absorption characteristic for the azido group was observed at 2135 cm^{-1} for **2***a* and at 2130 cm^{-1} for **2***b*.

Thermolysis of the two diazido compounds gave in each case one major product, which proved to be a 2,5-disubstituted 1,3,4-oxadiazole (Scheme 1). This complex rearrangement is not only of synthetic utility as a good route to 1,3,4-oxadiazoles, but also has mechanistic significance in that it presents an example of acyl migration to nitrogen.

When ethyl α,α-diazidoacetoacetate was heated in refluxing dry xylene under a N_2 atmosphere the ir azide absorption at 2135 cm^{-1} disappeared completely after 2 h. Flash chromatography through silica gel gave a crude material (94%) that proved to be almost pure 2-carboxyethyl-5-methyl-1,3,4-oxadiazole (**3***a*) according to its ^{1}Hmr spectrum. Further purification by Kugelrohr distillation and recrystallization gave 76% of pure 1,3,4-oxadiazole **3***a*. The ir absorption at 1745 cm^{-1}, the ^{1}Hmr signals at 4.60 (2H, q) and 1.50 (3H, t), as well as the ^{13}Cmr signals at 166.18, 63.45, and 14.08 supported the presence of an ethyl carboxylate function. Medium ir absorption bands at 1565 and 1540 cm^{-1} were attributed to the presence of two C=N bonds. These spectral data supported the structure of the 2,5-disubstituted 1,3,4-oxadiazole **3***a*. However, the possibility of an isomeric 1,2,4-oxadiazole structure (Scheme 2) could not be excluded unequivocally, either mechanistically or on the basis of the spectral data. It was therefore decided to prove the structure of the thermolytic product by an independent synthesis (Scheme 1). For this purpose 5-methyltetrazole (**4**) was prepared from acetonitrile and covalent aluminum azide, in analogy to a procedure reported by Behringer and Kohl (8). The tetrazole so obtained was acylated with oxalyl chloride mono-

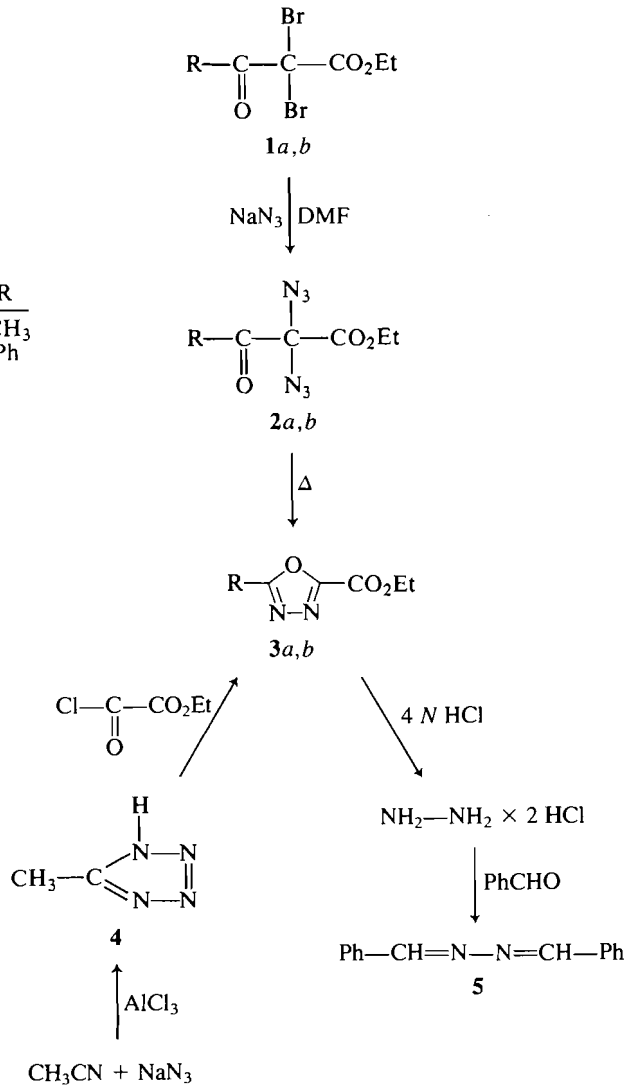
[3]Attention should be drawn to the potentially hazardous nature of azides (5). In our laboratory no difficulties were encountered when they were handled in solution or when small amounts were distilled under reduced pressure. However, proper caution should be exercised at all times.



SCHEME 1

ethyl ester in refluxing xylene, in analogy to a method described by Huisgen *et al.* (9). The 2-carboxyethyl-5-methyl-1,3,4-oxadiazole obtained by this route melted at 45°C and had ir and ^{1}Hmr spectral data identical to those of the thermolytic oxadiazole.

In a further experiment the thermolytic oxadiazole **3***a* was hydrolyzed with refluxing 4 *N* hydrochloric acid. The residue obtained upon evaporation was reacted with benzaldehyde to give crystalline benzalazine (**5**), which was identified by a mixture melting point with authentic benzalazine (10). Since in benzalazine the nitrogen atoms are linked to each other, the thermolytic oxadiazole **3***a* must have the 1,3,4-oxadiazole rather than the 1,2,4-oxadiazole structure.

Thermolysis of ethyl α,α-diazidobenzoylacetate **2***b* in refluxing xylene under a N_2 atmosphere showed complete conversion of the starting material after 2 h by the absence of an ir absorption band at 2130 cm^{-1}. Evaporative work-up followed by medium pressure column chromatography gave recrystallized 2-carboxyethyl-5-phenyl-1,3,4-oxadiazole **3***b* (83%) with a melting point of 72–73°C. This melting point as well as the uv spectral data were in agreement with the data reported in the literature (9). The ir absorption at 1740 cm^{-1}, the ^{1}Hmr signals at 4.53 (2H, q) and 1.43 (3H, t), as well as the ^{13}Cmr signals at 166.42, 63.50, and 14.12 confirmed the presence of an ethyl carboxylate function. The remaining ^{13}Cmr data of 1,3,4-oxadiazole **3***b* at 156.57 and 154.41 were comparable to the data of the 1,3,4-oxadiazole **3***a* at 157.11 and 154.41.

Mechanistic considerations

Upon thermolysis, both diazido compounds **2***a* and **2***b* followed the same reactivity pattern, leading to the formation of 1,3,4-oxadiazoles **3***a* and **3***b* in excellent yields (Scheme 2). Although no intermediates could be isolated, we would like to propose that initially the diazido compound probably loses one molar equivalent of nitrogen to form a nitrene. Subsequent migration of the acyl group onto nitrogen leads then to the formation of an azidoazomethine intermediate.[4]

Alternatively, the negatively charged azido nitrogen may attack the electrophilic carbonyl carbon. A subsequent rearrangement with concomitant loss of one molar equivalent of nitrogen may then lead to the formation of the same azidoazomethine intermediate.

Azidoazomethines usually isomerize readily to tetrazoles in a reversible reaction (11). Loss of a second molar equivalent of nitrogen from either the azidoazomethine directly or from the tetrazole might lead to the diazir-2-ene, which finally rearranges to the 2,5-substituted 1,3,4-oxadiazole. Huisgen and Blaschke (12) considered such a diazirene intermediate as a possibility in the formation of 1,3,4-oxadiazoles in both the photolytic and thermolytic reaction of ethyl azidoformate with nitriles. Since in our case no intermediates have been isolated or spectrally detected, these mechanistic considerations are speculative. However, the correctness of an initial acyl migration onto nitrogen can be assumed.

Experimental

Infrared (ir) spectra were obtained with a Perkin–Elmer spectrometer, model 735B, using chloroform as solvent. Ultraviolet (uv) spectra of ethanolic solutions were measured on a Hitachi Perkin–Elmer double beam spectrometer, model 124-0031. Proton magnetic resonance (^{1}Hmr) spectra were recorded with a Varian T-60 spectrometer and ^{13}C magnetic resonance (^{13}Cmr) spectra were recorded with a Bruker WP-80 FT spectrometer. The chemical shift data are quoted in δ units and refer to solutions in deuterochloroform using tetramethylsilane as internal reference. Thin-layer chromatography (tlc) was performed on precoated silica gel GF Redi Plates (Fisher Scientific Co.). Preparative layer chromatography (plc) was carried out on 20 × 20 cm glass plates precoated with silica gel Sil G-100 UV_{254} (Brinkmann Instruments, Inc.). Column chromatography was done under medium pressure with silica gel G-type 60 (E. Merck) as adsorbent, or by gravity flow using silica gel (60–200 mesh) "Baker Analyzed Reagent" (J. T. Baker Chemical Co.). Unless otherwise stated, anhydrous sodium sulfate was used for drying organic solutions. Solvents were usually removed on a rotary evaporator at reduced pressure using bath temperatures of 30–40°C. Melting points and boiling points are uncorrected.

*Ethyl α,α-dibromoacetoacetate (**1**a)*

To a vigorously stirred mixture of ethyl acetoacetate (13.0 g, 0.10 mol) and water (25 mL) was added dropwise (2 h) bromine (33.6 g, 0.2 mol) at room temperature. After additional stirring for 1 h methylene chloride (50 mL) was added. The organic phase was then separated, washed with water (3×), and dried. Evaporation of the solvent gave a yellow oil, which was purified by fractional distillation to give ethyl α,α-dibromoacetoacetate (20.7 g, 72%), $bp_{1.6}$ 83–84°C; $n_D^{20} = 1.4988$.

[4]It should be noted that there was no evidence of migration of the carboxyethyl group onto nitrogen.

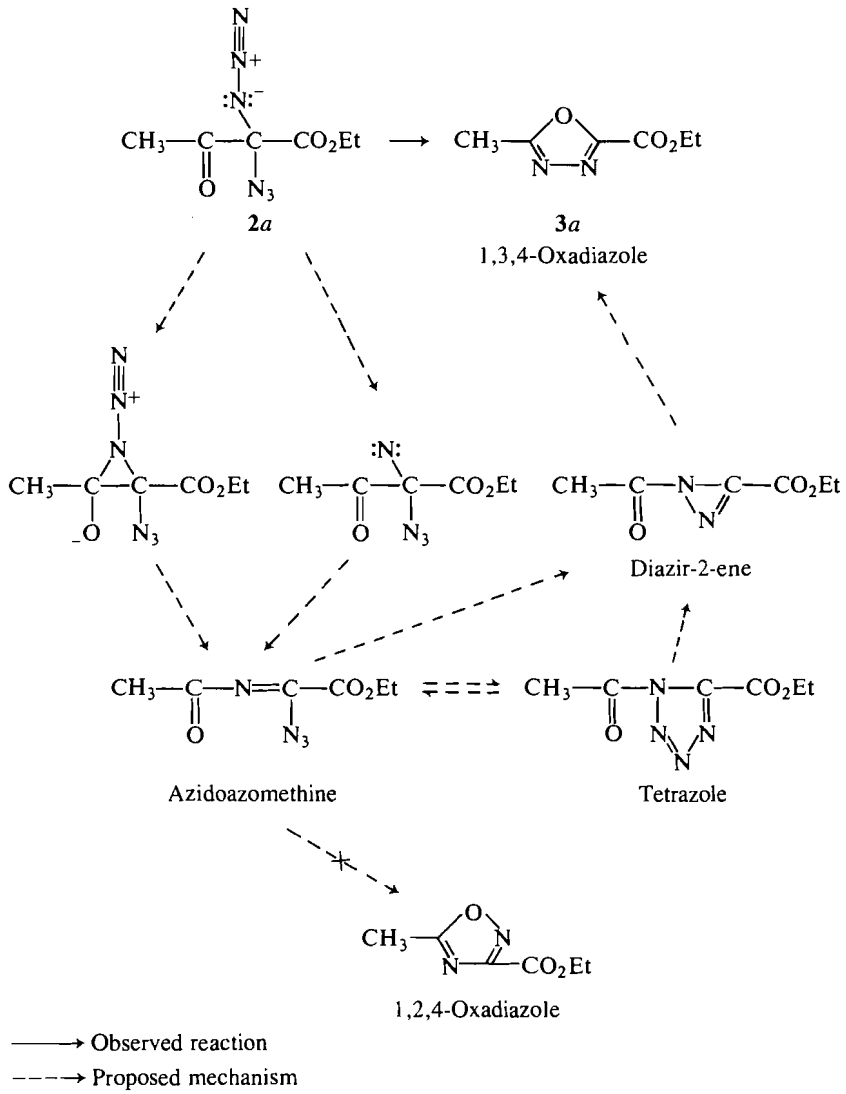

SCHEME 2

Ethyl α,α-dibromobenzoylacetate (1b)

To a refluxing solution of ethyl benzoylacetate (19.2 g, 0.1 mol) in carbon tetrachloride (100 mL), bromine (33.6 g, 0.21 mol) was added gradually (1.5 h). After additional reflux for 1 h the solvent was removed and the residue was distilled to give ethyl α,α-dibromobenzoylacetate (23.5 g, 67%), $bp_{0.3}$ 121–124°C; $n = 1.5705$ (lit. (7) bp_1 153–154°C; $n_D^{20} = 1.5703$).

Ethyl α,α-diazidoacetoacetate (2a)

To an ice cold solution of ethyl α,α-dibromoacetoacetate (14.4 g, 0.05 mol) in dimethylformamide (50 mL), sodium azide (7.15 g, 0.11 mol) was added portionwise during 30 min. After the reaction mixture reached room temperature, stirring was continued for another hour. Then water (100 mL) was added and the ester extracted with ether (2 × 50 mL). The combined ether extracts were washed with water (50 mL) and with brine (50 mL). After drying and evaporation of the solvent a yellowish liquid (9.6 g) was obtained. Fractional distillation (footnote 3) gave pure ethyl α,α-diazidoacetoacetate (8.1 g, 76%) with $bp_{0.8}$ 69–72°C and $n_D^{20} = 1.4627$. Spectral data corroborated the structural assignment; ir ν_{max}: 2135, 1740, 1715 cm^{-1}; ^{1}Hmr: 4.41 (2H, q, J = 7 Hz), 2.31 (3H, s), 1.38 (3H, t, J = 7 Hz). *Anal.* calcd. for $C_6H_8N_6O_3$: C 33.96, H 3.80, N 39.61; found: C 34.21, H 3.98, N 39.30.

Ethyl α,α-diazidobenzoylacetate (2b)

Ethyl α,α-dibromobenzoylacetate (14.0 g, 0.04 mol) was reacted as above with sodium azide. Extractive work-up followed by fractional distillation (footnote 3) gave pure ethyl α,α-diazidobenzoylacetate (6.9 g, 63%) with $bp_{0.1}$ 105–115°C and $n_D^{20} = 1.5395$. Spectral data supported the structural assignment; ir ν_{max}: 2130, 1745, 1700 cm^{-1}; ^{1}Hmr: 7.2–8.0 (5H, m), 4.18 (2H, q, J = 7 Hz), 1.13 (3H, t, J = 7 Hz). *Anal.* calcd. for $C_{11}H_{10}N_6O_3$: C 48.18, H 3.68, N 30.64; found: C 48.32, H 3.85, N 30.29.

2-Carboxyethyl-5-methyl-1,3,4-oxadiazole (3a)

(a) Thermolysis of ethyl α,α-diazidoacetoacetate (2a)[5,6]

A solution of diazide **2a** (1 g, 47 mmol) in sodium-dried xylene (3 mL) was heated to reflux under a N_2 atmosphere. An ir spectrum after 2 h indicated the complete disappearance of the azide signal at 2135 cm^{-1}. A crude purification of the products was achieved by putting the reaction mixture on a short column of silica gel (5 g, 60–200 mesh). Elution with cyclohexane removed the xylene. Subsequent elution with ethyl acetate gave a brownish viscous material (690 mg), which proved to be almost pure 2-carboxyethyl-5-methyl-1,3,4-oxadiazole according to the ^{1}Hmr spectrum. Kugelrohr distillation by heating this material up to 130°C at a pressure of 0.1 Torr (1 Torr =

[5]The above experiment was scaled up to 5 g of diazide **2a** without any difficulties.

[6]When the thermolysis was carried out in refluxing toluene instead of xylene the reaction was much slower. After a reaction time of 13 h the reaction mixture consisted of about 40% diazide **2a** and 60% oxadiazole **3a**.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 190.90.36.8 on 09/07/12
For personal use only.

133.3 Pa) furnished white crystalline oxadiazole **3***a* (556 mg, 75%). Recrystallization from ether/cyclohexane gave pure oxadiazole **3***a* with a melting point of 45°C. Spectral data were in agreement with the structural assignment; ir ν_{max}: 1745, 1565, 1540 cm^{-1}; uv λ_{max} (EtOH): 218 nm (ε 8000); ^{1}Hmr: 4.60 (2H, q, J = 7 Hz), 2.73 (3H, s), 1.50 (3H, t, J = 7 Hz); ^{13}Cmr: 166.18, 157.11, 154.41, 63.45, 14.08, 11.21. *Anal.* calcd. for $C_6H_8N_2O_3$: C 46.15, H 5.16, N 17.94; found: C 46.07, H 5.09, N 17.81.

*(b) Independent synthesis of 2-carboxyethyl-5-methyl-1,3,4-oxadiazole (3*a*)*

Oxadiazole **3***a* was prepared through acylation of 5-methyl tetrazole **4** in analogy to a reaction described by Huisgen *et al.* (9).

5-Methyltetrazole (4)

In analogy to a method developed for the synthesis of other tetrazoles (8), sodium azide (48.75 g, 0.75 mol) was added to a solution of acetonitrile (10.25 g, 0.25 mol) in dry tetrahydrofuran (50 mL). To this suspension was added a solution of aluminum trichloride (35 g, 0.26 mol) in dry tetrahydrofuran (250 mL). This reaction mixture was heated to reflux for 25 h, then cooled to room temperature and stirred for 1 h with 10% hydrochloric acid (50 mL). The mixture was then evaporated to dryness. Extraction of the residue with hot acetone gave an oil that crystallized upon standing. Recrystallization from chloroform gave pure 5-methyl tetrazole (7.2 g, 34.3%) with a melting point of 143°C (lit. (9) mp 143°C).

*Oxadiazole 3*a

To a solution of 5-methyl tetrazole (168 mg, 2 mmol) in dry xylene (10 mL) was added oxalylchloride monoethyl ester (316 mg, 2.5 mmol). After reflux for 1 h, tlc indicated the absence of starting tetrazole **4***a* and the formation of a new major product with a polarity equaling that of the thermolytic oxadiazole **3***a*. Evaporative work-up gave a viscous residue (247 mg) that was purified by plc to give pure 2-carboxyethyl-5-methyl-1,3,4-oxadiazole (194 mg, 62%), which after recrystallization from cyclohexane melted at 45°C. Identical ir and nmr spectra for the oxadiazoles generated by the two different routes proved the identity of the products.

Hydrolysis of 2-carboxyethyl-5-methyl-1,3,4-oxadiazole

The oxadiazole **3***a* (156 mg, 1 mmol) was hydrolyzed with refluxing 4 *N* hydrochloric acid (5 mL) during 3 h. The reaction mixture was then evaporated, followed by several coevaporations with ethanol to furnish a white, solid residue (91 mg). An ir spectrum in Nujol indicated the absence of any carbonyl absorption. An aqueous solution of this residue formed a voluminous precipitate with a solution of silver nitrate. These properties suggested that this material was hydrazine hydrochloride, which was confirmed by its conversion to benzalazine **5**. For this purpose a solution of the above residue (65 mg) and of sodium acetate (200 mg) in water (5 mL) was reacted with benzaldehyde (5 drops) in methanol (2 mL). Upon gentle warming of this mixture (heat gun, 10 min) a yellow precipitate formed. After cooling, the precipitate was filtered off, washed thoroughly with water, and dried to yield benzalazine **5** (108 mg, 84%). The melting point of 92°C and mixture melting point of 92°C established the identity of this material with authentic benzalazine (lit. (10) mp 93°C).

*2-Carboxyethyl-5-phenyl-1,3,4-oxadiazole (3*b)

A solution of diazide **2***b* (5.0 g, 18 mmol) in sodium-dried xylene (15 mL) was heated to reflux under a N_2 atmosphere. The progress of the reaction was monitored by ir and after 2 h there was no longer a detectable azide absorption at 2130 cm^{-1}. Evaporation of the solvent, followed by oil pump evacuation, left a liquid residue that was purified by medium pressure column chromatography to give a major product. Recrystallization from ethanol/cyclohexane afforded pure 2-carboxyethyl-5-phenyl-1,3,4-oxadiazole (3.3 g, 83%) with a melting point of 72–73°C. Spectral data supported the structural assignment; ir ν_{max}: 1740, 1605, 1540 cm^{-1}; uv λ_{max} (EtOH): 265 nm (ε 20 540); ^{1}Hmr: 7.33–8.23 (5H, m), 4.53 (2H, q, J = 7 Hz), 1.43 (3H, t, J = 7 Hz); ^{13}Cmr: 166.42, 156.57, 154.41, 63.50, 14.12. *Anal.* calcd. for $C_{11}H_{10}N_2O_3$: C 60.55, H 4.62, N 12.84; found: C 60.28, H 4.60, N 12.98. Literature (9) mp 71°C and λ_{max} (EtOH): 266 nm (ε 19 540).

Biosynthesis of lupanine: incorporation of [3,3-$^2H_2$]cadaverine

THOMAS HEMSCHEIDT AND IAN D. SPENSER[1]
Department of Chemistry, McMaster University, Hamilton, Ont., Canada L8S 4M1

Received June 19, 1986

This paper is dedicated to Dr. O. E. (Ted) Edwards

THOMAS HEMSCHEIDT and IAN D. SPENSER. Can. J. Chem. **65**, 170 (1987).

The mode of incorporation of ^2H from [3,3-$^2H_2$]cadaverine into lupanine (**2**) and 13α-hydroxylupanine (**3**) in *Lupinus angustifolius* was determined by ^2H nmr spectroscopy. Lupanine carried deuterium at positions 4α, 4β, 8α, 8β, 13α, and 13β. These six sites were approximately equally enriched. Similarly, 13α-hydroxylupanine carried label approximately equally at five sites, 4α, 4β, 8α, 8β, and 13β. [3,3-$^2H_2$]Cadaverine was prepared by borodeuteride reduction in D_2O of the *p*-toluenesulfonylhydrazone of *N*-benzoylpiperid-4-one, followed by degradation of the resulting *N*-benzoyl[4,4-$^2H_2$]piperidine into 1,5-dibromo[3,3-$^2H_2$]pentane, conversion into 1,5-diphthalimido[3,3-$^2H_2$]pentane, and acid hydrolysis.

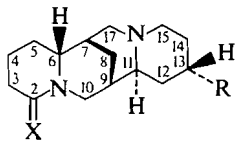
THOMAS HEMSCHEIDT et IAN D. SPENSER. Can. J. Chem. **65**, 170 (1987).

Faisant appel à la rmn du ^2H, on a déterminé le mode d'incorporation du ^2H de la [3,3-$^2H_2$]cadavérine dans la lupanine (**2**) et dans l'hydroxy-3α lupanine (**3**) dans le *Lupinus angustifolius*. La lupanine porte des atomes de deutérium dans les positions 4α, 4β, 8α, 8β, 13α et 13β. Les taux d'enrichissement de chacun de ces sites sont approximativement égaux. De la même manière, l'hydroxy-13α lupanine porte des quantités a peu près égales de marqueurs dans les positions 4α, 4β, 8α, 8β et 13β. On a préparé la [3,3-$^2H_2$]cadavérine en procédant à une réduction de la *p*-toluènesulfonylhydrazone de la *N*-benzoylpipéridone-4 par le borodeutêrure dans le D_2O, suivie d'une dégradation de la *N*-benzoyl [4,4-$^2H_2$]pipéridine qui en résulte en dibromo-1,5[3,3-$^2H_2$]pentane, d'une conversion en diphtalimido-1,5[3,3-$^2H_2$]pentane et finalement d'une hydrolyse acide.

[Traduit par la revue]

Introduction

Cadaverine, derived by decarboxylation from L-lysine (1), is a key intermediate in the biosynthesis of the lupine alkaloids. Label from [1-^{14}C]cadaverine is incorporated into specific sites of the tetracyclic $C_{15}N_2$ lupine alkaloids, sparteine (**1**) (2, 3), lupanine (**2**) (4–6), and 13α-hydroxylupanine (**3**) (4, 7). Each



1 R = H, X = H_2
2 R = H, X = O
3 R = OH, X = O

of these sites contained approximately one-sixth of the total activity of the intact alkaloid. Experiments with stable isotopes revealed the entire regiochemistry of the incorporation of label from [1-^{13}C]cadaverine. In (−)sparteine (**1**) (8, 9), in (+)lupanine (**2**) (10, 11), and in 13α-hydroxylupanine (**3**) (10), each of the six C-atoms adjacent to nitrogen (C-2, -6, -10, -11, -15, -17) are equally enriched with ^{13}C. Thus, three cadaverine-derived C_5 units supply the carbon skeleton of the $C_{15}N_2$ alkaloids.

Furthermore, the mode of incorporation of intramolecularly doubly labelled [1-^{13}C,1-^{15}N]cadaverine (8–11) shows that each of the two nitrogen atoms enters the alkaloids as part of an intact cadaverine-derived C—N fragment, (N-1,C-2 and N-16,C-15, respectively).

Thus, two cadaverine-derived C_5N units supply the outer C_5N units (N-1,C-2 to C-6 and N-16,C-15 to C-11, respectively), whereas a cadaverine-derived C_5 unit supplies the central C_5 chain, C-17,C-7 to C-10, of the alkaloids. That this central chain cannot originate from a cadaverine-derived C_5 unit with C_{2v} symmetry is shown by the mode of incorporation of label from [2-^{14}C]- and [6-^{14}C]-Δ^1-piperideine (12).

These two compounds are equivalent to 5-amino[1-^{14}C]pentanal and 5-amino[5-^{14}C]pentanal, respectively, i.e., they represent labelled C_5N units that are derivable from cadaverine but lack C_{2v} symmetry. [2-^{14}C]-Δ^1-Piperideine delivers radioactivity into C-6, C-17, and C-11, but not into C-2, C-10, or C-15 of lupanine, whereas [6-^{14}C]-Δ^1-piperideine delivers label into C-2, C-10, and C-15 of lupanine, but not into C-6, C-17, or C-11. These findings suggest that the same cadaverine-derived C_5N precursor that supplies the outer rings, N-1,C-2 to C-6 and N-16,C-15 to C-11, also supplies the inner C_5 chain, and that nitrogen is lost from this segment at a late stage of biosynthesis.

Whereas experiments with [1-^{13}C,1-^{15}N]cadaverine have clarified the regiochemistry of incorporation, tracer work with chirally deuteriated samples of [1-$^2H_1$]cadaverine have shed light on stereochemical aspects of the biosynthetic events that occur in the vicinity of the nitrogen atoms of sparteine and lupanine (11, 13, 14).

Despite the wealth of tracer evidence that has been accumulated, intermediates between cadaverine and the alkaloids have not been unequivocally identified or generally accepted and the biosynthetic steps leading from cadaverine into the alkaloids are currently the subject of controversy. Several biogenetic hypotheses are under consideration (12, 15–17) and have been scrutinized in recent texts (18) and reviews (17, 19, 20).

In an attempt to add to the evidence that might lead to a clearer understanding of the steps on the biosynthetic route from cadaverine into the alkaloids, we have studied the incorporation of label from [3,3-$^2H_2$]cadaverine into lupanine and 13α-hydroxylupanine in *Lupinus angustifolius*.

Results and discussion

[3,3-$^2H_2$]Cadaverine carries deuterium at the only site within the molecule that is not affected, directly or indirectly, by the reactivity of the nitrogen atom and at the only site that is proprochiral (Caabb) rather than prochiral (Caabc).

Loss of deuterium or protium, as the case may be, on the route from [1,1-$^2H_2$]- or (*S*)- and (*R*)-[1-$^2H_1$]cadaverine into sparteine or lupanine (11, 13, 14) is the inevitable consequence of the process that converts cadaverine into the biosynthetic C_5N

intermediate, presumably free or bound $NH_2—\overset{5}{C}H_2—\overset{4}{C}H_2—\overset{3}{C}H_2—\overset{2}{C}H_2—\overset{1}{C}HO$, and loss of deuterium or protium, as the case may be, on the route from [2,2-$^2H_2$]- or (*S*)- and (*R*)-[2-$^2H_1$]cadaverine is the necessary consequence of keto–enol or imine–enamine equilibration of this intermediate (e.g., $NH_2—\overset{5}{C}H_2—\overset{4}{C}H_2—\overset{3}{C}H_2—\overset{2}{C}H_2—\overset{1}{C}H{=}NH \rightleftarrows NH_2—\overset{5}{C}H_2—\overset{4}{C}H_2—\overset{3}{C}H_2—\overset{2}{C}H{=}\overset{1}{C}H—NH_2$), and the distribution of label within the alkaloids from [1-^{2}H]- and [2-^{2}H]cadaverines thus throws light mainly on the early, pre-alkaloid stages of the pathway. Distribution within the alkaloids of deuterium from [3,3-$^2H_2$]cadaverine, on the other hand, may expose stereochemical events that take place at a later stage of biosynthesis, after ring formation has taken place and the proprochiral site of the precursor, containing homotopic protons, has been transformed into prochiral sites, containing diastereotopic protons.

Label from [3,3-$^2H_2$]cadaverine can be predicted to enter C-4, C-8, and C-13 of the $C_{15}N_2$ alkaloids. If, at any one of these sites, there is nonequivalent deuterium enrichment at the α and β position, then a chiral event must have taken place at this site in the course of biosynthesis. If, at any one of these sites, deuterium enrichment at the α and the β positions is identical, then an intact CH_2 (or CD_2) unit from C-3 of the substrate has survived at that site.[2]

[3,3-$^2H_2$]Cadaverine was prepared in five steps from commercially available *N*-benzoylpiperid-4-one. The *p*-toluenesulfonylhydrazone of the piperidone was reduced to *N*-benzoyl[4,4-$^2H_2$]piperidine with sodium borodeuteride in a solution of tetrahydrofuran containing 20% (v/v) D_2O. Reaction with a mixture of bromine and phosphorus tribromide (21) cleaved the piperidine derivative to yield 1,5-dibromo[3,3-$^2H_2$]pentane, which was then converted into 1,5-diphthalimido[3,3-$^2H_2$]pentane, i.e., *N*,*N*′-diphthaloyl[3,3-$^2H_2$]cadaverine. Acid hydrolysis gave the dihydrochloride of [3,3-$^2H_2$]cadaverine. The overall yield of deuterocadaverine with respect to sodium borodeuteride was 9.5%.

The ^{2}H nmr spectrum of the deuteriated sample of *N*,*N*′-diphthaloylcadaverine shows a major and a minor signal. The major signal, at δ 1.31 ppm (relative signal area 4) is due to deuterium at C-3. Since the ^{1}H nmr spectrum of the sample does not exhibit a signal at this chemical shift, the sample is fully deuteriated at this position. The minor signal appears at δ 1.65 (relative signal area 1). This signal is due to deuterium at the C-2 and C-4 atoms. Each of four spin-equivalent hydrogen atoms at these two positions carried 5% deuterium. The ^{1}H nmr spectra of the labelled samples of diphthaloylcadaverine and cadaverine dihydrochloride confirm the presence of deuterium at C-2, -4, in that in each case the relative signal area of the upfield triplet (δ 1.64, 1.80, respectively), due to the four hydrogen atoms of the two β-carbons, is 10% smaller than that of the downfield triplet (δ 3.60, 3.15, respectively), due to the four hydrogen atoms on the α-carbons.

The deuterium at C-2, -4 was introduced into the positions adjacent to the hydrazone carbon atom of *N*-benzoylpiperid-4-one *p*-toluenesulfonylhydrazone by proton–deuteron exchange, in the course of the reduction. The presence of this small but

[2]The possibility that biochemical events might have taken place, which, in entirely nonstereospecific manner, remove and then replace each of the diastereotopic protons to an equal extent, is regarded as too remote to be considered within the context of the biosynthetic route to a product with four or five chiral and 11 or 10 or 9 prochiral centres.

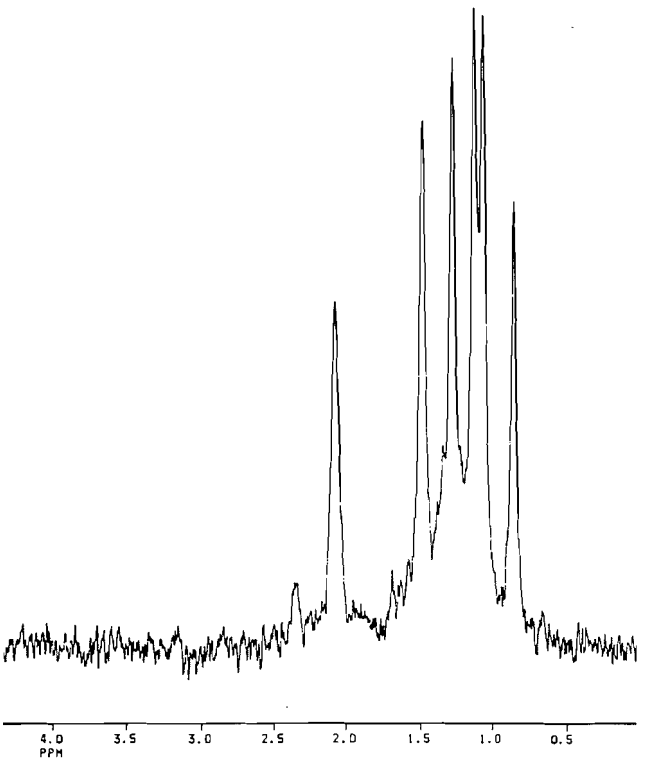

FIG. 1. The ^{2}H nmr spectrum (76.8 MHz) of a deuterium enriched sample of lupanine isolated from *L. angustifolius* after administration of [3,3-$^2H_2$]cadaverine. Lupanine (53 mg) in benzene (0.66 mL); 3000 scans. The spectrum was recorded in the Fourier mode on a Bruker AM 500 spectrometer, in a 5-mm tube, with the natural abundance signal of the solvent as internal reference, 45° pulses, 16 K data points, 4.8 s acquisition time.

significant amount of deuterium at C-2, -4 (5% at each of four hydrogen atoms) in the [3,3-$^2H_2$]cadaverine, nevertheless does not substantially interfere with the interpretation of the results of the tracer experiment.

An aqueous solution of the labelled cadaverine dihydrochloride (100 mg in 100 mL) was administered to 100 six-weeks-old plants of *Lupinus angustifolius* by infusion through cotton wicks over a period of a week. Lupanine (53 mg) and 13α-hydroxylupanine (71 mg) was then isolated by standard procedures (22).

The ^{2}H nmr spectra of the two alkaloids are shown in Figs. 1 and 2.

Direct entry of label from [3,3-$^2H_2$]cadaverine into the alkaloids would be expected to lead to deuteriation at C-4, C-8, and C-13. As expected, six deuterium signals appear in the spectrum of lupanine (Fig. 1) and five in that of 13α-hydroxylupanine (Fig. 2). The specific incorporation (100 × (deuterium enrichment per C_5 unit of alkaloid)/(deuterium enrichment of precursor)) of [3,3-$^2H_2$]cadaverine into lupanine (1.3%) and 13-hydroxylupanine (0.11%) was determined by comparing the signal area due to natural abundance deuterium in the solvent with the signal areas of the two signals due to deuterium at carbon-8 of each alkaloid. The signals were assigned on the basis of heteronuclear 2D COSY spectra of nonenriched samples of the two alkaloids, and on the basis of chemical deuteriation studies.[3]

Complete (24) and partial (25, 26) assignments of the signals due to the protons at C-4 (24, 25), C-8 (24–26), and C-13 (24)

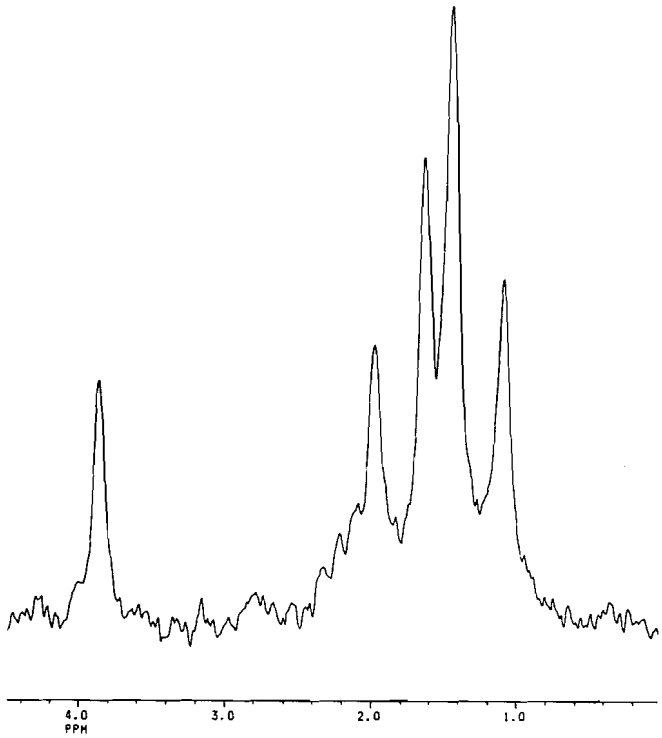

FIG. 2. The ^2H nmr spectrum (76.8 MHz) of a deuterium enriched sample of 13α-hydroxylupanine isolated from *L. angustifolius* after administration of [3,3-$^2H_2$]cadaverine. 13α-Hydroxylupanine (71 mg) in dichloromethane (0.65 mL); 15 520 scans. The spectrum was recorded in the Fourier mode on a Bruker AM 500 spectrometer, in a 5-mm tube, with the natural abundance signal of the solvent as internal reference, 45° pulses, 16 K data points, 4.8 s acquisition time.

of lupanine and due to the protons at C-8 (25) and the proton at C-13 (25) of 13α-hydroxylupanine, based on homonuclear 2D COSY and 2D *J*-resolved nmr spectra (24), and by application of an Europium shift reagent (25), and of homonuclear INDOR spectroscopy (26), have been published.

The six signals in the ^2H nmr spectrum of lupanine derived from [3,3-$^2H_2$]cadaverine are due to the three pairs of diastereotopic deuterons, at C-4 (δ 1.12, 1.28), at C-8 (δ 0.84, 2.08), and at C-13 (δ 1.06, 1.49) (Fig. 1). The weak signal at δ 2.44 ppm is at a chemical shift assigned to one of the hydrogens at C-3, i.e., the C atom adjacent to the lactam carbonyl group. Deuterium enrichment at this position is to be expected due to the presence of 5% ^2H within each of the four hydrogen atoms at C-2 and C-4 of the labelled substrate (see above). The strong background noise of deuterium in the region δ 1.0–1.6 is, similarly, due to this additional labelling, which would be expected to reside at C-5, -7, -9, -12, and -14. All ten hydrogen atoms at these centers resonate in this region of the spectrum. The deuterium signals due to the three pairs of deuterium atoms, at C-4, C-8, and C-13, clearly emerge from the background. Within the limits of error, the deuterium enrichment is the same at each of the two members of each of the three pairs. It follows that in the course of biosynthesis the CH_2 group at C-3 of cadaverine has maintained its integrity on the route to C-4, C-8, and C-13 of the alkaloids. Thus, no hidden biochemical event has occurred at any of these sites. This finding disposes of a biogenetic scheme (16) that includes, as essential steps, loss of a hydrogen from C-8 (either by deprotonation or by dehydrogenation) and reintroduction of a hydrogen, at the same site, in a subsequent step.

The ^2H nmr spectrum of 13α-hydroxylupanine (Fig. 2) shows a distribution of ^2H analogous to that in lupanine. Since deuterium enrichment in 13α-hydroxylupanine was lower[4] than enrichment in lupanine from the same experiment, the signal-to-noise ratio in the spectrum, Fig. 2, is less favourable than in the spectrum of Fig. 1. Nonetheless, five deuterium-enriched sites are evident, two pairs at C-4 (δ 1.43, 1.63) and C-8 (δ 1.08, 1.97) and the β-hydrogen at C-13 (δ 3.86).

As in Fig. 1, and for the same reason, there is again a significant background of deuterium in the region, δ 1.0–2.2, of the spectrum. Nevertheless, the conclusion is confirmed that the integrity of the CH_2 group at C-3 of the precursor is preserved on the route into C-4 and C-8 of 13α-hydroxylupanine. The fact that deuterium is maintained at the 13β site of 13α-hydroxylupanine (δ 3.86) shows that introduction of oxygen at C-13 does not proceed by way of a carbonyl intermediate.

Experimental

Synthesis of [3,3-$^2H_2$]cadaverine

N-*Benzoylpiperid-4-one*-p-*toluenesulfonylhydrazone*

N-Benzoylpiperid-4-one (5.8 g, 28.6 mmol) was dissolved in ethanol (30 mL), *p*-toluenesulfonylhydrazide (6.3 g, 35 mmol) was added, and the solution was boiled 1 h under reflux. The product crystallized on cooling and was recrystallized from ethanol, mp 186°C (dec.); yield 9.53 g (90%); ir (KBr) cm^{-1}: 3250 (NH), 1635 (CO), 1420, 1330, 1160, 1030; ^1H nmr ($CDCl_3$, 90 MHz) δ: 2.45 (s(br), 7H, CH_3 and H-4, -5), 3.65 (s(br), 4H, H-2, -6), 7.25–7.90 (AB q, *J* 8 Hz, 4H, tosyl), 7.50 (s, 5H, phenyl); ^{13}C nmr ($CDCl_3$, 127 MHz) δ: 170.8 (CO), 156.6 (CN), 143.8, 135.4, 135.2, 129.9, 129.4, 128.5, 127.9, 126.7 (aromatic C atoms), 47.3, 44.9, 42.2, 40.8, 34.3, 33.0, 27.8, 26.9 (piperidine ring C atoms), 21.5 (CH_3); ($^2H_6$-DMSO, 127 MHz, 50°C) δ: aromatic C atoms unchanged, 40–46 (br), 33.2, 27.6, 20.8 (CH_3) ppm;[5] ms (DCI, NH_3): 389 (14%, M + 1 + NH_3), 372 (46%, M + 1), 216 (50%, M^+ minus CH_3—C_6H_4—SO_2), 188 (100%, M^+ minus CH_3—C_6H_4—SO_2NN), 105 (22%, C_6H_5CO). *Anal.* calcd. for $C_{19}H_{21}N_3O_3S$: C 61.4, H 5.7, N 11.3%; found: C 61.1, H 5.9, N 11.2%.

[4]There are several possible explanations for the observation that the level of deuterium enrichment within 13α-hydroxylupanine is lower than that within lupanine. Among these are the following: (*a*) The plant may contain a larger store of preformed 13α-hydroxylupanine than of preformed lupanine. Newly biosynthesized 13α-hydroxylupanine would then be more highly diluted with preformed natural abundance material than newly biosynthesized lupanine. (*b*) 13α-Hydroxylupanine may be formed from lupanine. Further experimentation is required to distinguish among these possibilities.

[5]The ^{13}C nmr spectrum of *N*-benzoylpiperid-4-one *p*-toluenesulfonylhydrazone in $CDCl_3$ at room temperature exhibits eight broad lines between δ 27 and 47 ppm. At elevated temperature (50°C) these eight signals collapse into two sharp lines together with a broad signal between δ 40 and 46 ppm. It is suggested that eight, instead of the expected two, lines for the α- and β-carbon atoms of the piperidine nucleus appear as a consequence of the existence, at room temperature, of two stereoisomers of the *p*-toluenesulfonylhydrazone, in which the benzoyl and the *p*-toluenesulfonyl groups are, respectively, *syn* and *anti*. In either of these isomers the two α-carbon atoms and the two β-carbon atoms of the piperidine nucleus are nonequivalent, so that the piperidine nucleus of each isomer gives rise to four carbon signals. At elevated temperature, fast equilibration of the isomers occurs by restored rotation of the benzoyl group, as a result of which the eight signals collapse to yield a broad signal due to the α-carbons and two lines due to the two nonequivalent β-carbon atoms.

N-Benzoyl[4,4-$^2H_2$]piperidine

The above *p*-toluenesulfonylhydrazone (3.7 g, 10 mmol) was dissolved in a mixture of dry tetrahydrofuran (40 mL) and ^2H_2O (99.8% at.% ^2H, 10 mL). The solution was refluxed 30 min under dry nitrogen, cooled, and concentrated *in vacuo*. The residual suspension was extracted with dichloromethane (3 × 35 mL) and the combined organic extracts were washed with ^2H_2O (10 mL), dried (Na_2SO_4), and evaporated *in vacuo*. The residual foam was dissolved in dry tetrahydrofuran (40 mL), ^2H_2O (10 mL) was added, the mixture was refluxed 30 min, and then cooled to 0°C. Sodium borodeuteride (820 mg) was added in small portions with vigorous stirring over 15 min. The mixture was refluxed gently for 18 h and was then cooled and concentrated *in vacuo*. The residue was extracted with chloroform (3 × 25 mL), the combined organic extracts were washed with water (2 × 25 mL) and saturated sodium chloride (25 mL), dried (Na_2SO_4), and evaporated.

Bulb-to-bulb distillation of the residue (80°C air-bath temperature, 0.005 Torr (1 Torr = 133.3 Pa)), gave *N*-benzoyl[4,4-$^2H_2$]piperidine as a yellowish oil. Yield: 1.29 g (68%); ^1H nmr ($CDCl_3$, 90 MHz) δ: 1.65 (s(br), 4H, H-3, -5), 3.50 (s(br), 4H, H-2, -6), 7.40 (s, 5H, phenyl); ^{13}C nmr ($CDCl_3$, 22.63 MHz) δ: 170.3 (CO), 136.6, 128.9, 128.4, 126.8 (phenyl), 47.0 (br, α-C), 43.0 (br, α-C), 25.9 (β-C).

1,5-Dibromo[3,3-$^2H_2$]pentane (cf., ref. 21)

N-Benzoyl[4,4-$^2H_2$]piperidine (1.29 g, 6.8 mmol) was mixed at 0°C with phosphorus tribromide (1.7 g, 6.4 mmol). After 10 min, bromine (1.0 g, 6.1 mmol) was added dropwise at 0°C with vigorous stirring. The flask was connected to a bulb-to-bulb distillation apparatus, which was flushed with nitrogen gas and connected to a pump. The mixture was distilled by raising the temperature of the air bath slowly to 160°C at 20 Torr. The distillate was collected over 2 h in a trap cooled with Dry Ice/acetone. The distillate was mixed with crushed ice (2 g), ice-cold hydrobromic acid (48%, w/v, 8 mL) was added, and the mixture was then refluxed under nitrogen 4 h at 110°C with vigorous stirring. After cooling, the reaction mixture was extracted with dichloromethane (2 × 25 mL). The combined organic extracts were washed with water (3 × 50 mL), with saturated sodium bicarbonate solution (3 × 50 mL), and with saturated sodium chloride (50 mL), dried (Na_2SO_4), and evaporated. The residue was used in the subsequent reaction without further purification.

1,5-Diphthalimido[3,3-$^2H_2$]pentane

The dark-brown product of the previous reaction was dissolved in dry dimethylformamide (15 mL), potassium phthalimide (5.5 g, 30 mmol) was added, and the mixture was heated 36 h at 90°C under nitrogen with vigorous stirring. The reaction mixture was cooled, filtered, and the solids were extracted repeatedly with hot chloroform (3 × 75 mL). The filtrate and the chloroform extracts were combined and washed in turn with water (100 mL), dilute sodium hydroxide (0.3 *M*, 3 × 100 mL), water (100 mL), and saturated sodium chloride solution (50 mL), dried (Na_2SO_4), and concentrated. 1,5-Diphthalimido[3,3-$^2H_2$]pentane, i.e., *N,N'*-diphthaloyl[3,3-$^2H_2$]cadaverine, crystallized on addition of methanol; mp 181–183°C (lit. (23) mp 186°C); yield 0.7 g (29% with reference to *N*-benzoylpiperidine); ^1H nmr ($CDCl_3$, 90 MHz) δ: 7.74–7.62 (m, 8H, phthaloyl), 3.60 (t, 4H, *J* 7.1 Hz), 1.64 (t, 3.6H, *J* 7.0 Hz); ^2H nmr ($CHCl_3$, 76.8 MHz) δ: 1.31 (s, rel. area 4), 1.65 (s, rel. area 1).

[3,3-$^2H_2$]Cadaverine dihydrochloride

1,5-Diphthalimido[3,3-$^2H_2$]pentane (0.36 g, 1 mmol) and concentrated hydrochloric acid (3 mL) were heated in a sealed tube 8 h at 180°C. On cooling, the reaction mixture was diluted with water, solids were filtered off and washed with water, and the aqueous filtrate repeatedly evaporated from water. The solid residue was recrystallized from ethanol yielding [3,3-$^2H_2$]cadaverine dihydrochloride as hygroscopic needles. Yield 130 mg (90%); ^1H nmr (D_2O, 90 MHz) δ: 3.15 (t, *J* 7 Hz, 4H), 1.80 (t, *J* 7 Hz, 3.6H).

Administration of [3,3-$^2H_2$]cadaverine to Lupinus angustifolius *plants and isolation of alkaloids*

Plants of *Lupinus angustifolius* were grown from seed in the greenhouse and were used for the feeding experiment with [3,3-$^2H_2$]cadaverine 6 weeks after germination.

Tracer solution (100 mg [3,3-$^2H_2$]cadaverine dihydrochloride in 100 mL glass-distilled water) was administered by wick to 100 plants over 5 days (20 mL/day). The plants were allowed to grow for a further 3 days before being harvested.

Lupanine and 13α-hydroxylupanine were isolated and purified by conventional methods (22). The plant material (1050 g) was dried 12 h at 50°C and was then ground and extracted 16 h in a Soxhlet extractor with methanol. The extract was evaporated and the residue partitioned between chloroform (100 mL) and hydrochloric acid (3% v/v, 25 mL). The aqueous phase was washed with chloroform (2 × 100 mL), filtered through Celite, and concentrated *in vacuo*. The solution was then neutralized by addition of solid potassium carbonate, made strongly alkaline with concentrated potassium hydroxide (50% w/v), and the alkaloids extracted into dichloromethane. The extract was dried (K_2CO_3) and evaporated *in vacuo*. The residue was dissolved in dilute hydrochloric acid (3% v/v, 3 mL), the solution was extracted with ether, neutralized by addition of solid potassium carbonate, basified with potassium hydroxide solution (50% w/v), and extracted with ether–dichloromethane (1:1, 3 × 5 mL). The organic extract was dried (Na_2SO_4) and evaporated and the residue taken through one more acid–base cycle. The alkaline solution so obtained was mixed with kieselguhr (7 g); the mixture was kept 30 min at room temperature and was then added to a column containing kieselguhr (7 g) moistened with potassium hydroxide solution (50% w/v, 5 mL). The column was eluted first with petroleum ether (30–60°C, 125 mL) to yield lupanine (53 mg), and then with dichloromethane to yield 13α-hydroxylupanine (71 mg).

Acknowledgments

This investigation was supported by a grant from the Natural Sciences and Engineering Research Council of Canada. We thank Thelma Leech, Greenhouse Supervisor, McMaster University, for providing facilities for this work.

This paper is dedicated to Dr. O. E. (Ted) Edwards

JÁNOS SZABÓ, GÁBOR BERNÁTH, ÁGNES KATÓCS, LAJOS FODOR, and PÁL SOHÁR. Can. J. Chem. **65**, 175 (1987).

The reaction of sodium 3,4-dimethoxythiophenolate (**1**) with 2-bromoethylamine (**2**) gave 2′-aminoethyl-3,4-dimethoxyphenyl sulfide hydrochloride (**3**). Ring closure of the acyl derivatives **4***a–c* with phosphoryl chloride furnished the 2,3-dihydro-1,4-benzothiazepines **5***a–c*. In a reaction competing with the cyclization, the acid amides **4** decomposed to 2′-chloroethyl-3,4-dimethoxyphenyl sulfide (**7**) and the corresponding nitrile. A few derivatives (**8–10**) of **5***c* were prepared. Sodium borohydride reduction of **5***b*, *c* yielded the 2,3,4,5-tetrahydro-1,3-benzothiazepines **11***a*, *b*. With substituted acetyl chlorides, compounds **5***c* and **10** were converted to the β-lactam derivatives **12***a–f* and **13**, the configurations and conformations of which were determined by nmr spectroscopy; under similar reaction conditions the analogous compounds **5***a*, *b* gave the enamides **14**, **15**, and **16**.

JÁNOS SZABÓ, GÁBOR BERNÁTH, ÁGNES KATÓCS, LAJOS FODOR et PÁL SOHÁR. Can. J. Chem. **65**, 175 (1987).

La réaction du diméthoxy-3,4 thiphénolate de sodium (**1**) avec la bromo-2 éthylamine (**2**) conduit au chlorhydrate du sulfure d'amino-2 éthyle et de diméthoxy-3,4 phényle (**3**). La cyclisation des dérivés acyles **4***a–c* avec le chlorure de phosphoryle conduit aux dihydro-2,3 benzothiazépines-1,4 **5***a–c*. Les amides acides **4** subissent en même temps une réaction de décomposition qui conduit au sulfure de chloro-2 éthyle et de diméthoxy-3,4 phényle (**7**) et au nitrile correspondant. On a préparé quelques dérivés (**8–10**) de **5***c*. La réduction des composés **5***b*, *c* par le borohydrure de sodium conduit aux tétrahydro-2,3,4,5 benzothiazépines-1,3 **11***a*, *b*. À l'aide de chlorures d'acétyles substitués, on a pu transformer les composés **5***c* et **10** en dérivés β-lactames **12***a–f* et **13** dont on a déterminé les configurations et les conformations en faisant appel à la rmn; dans des conditions semblables, les composés analogues **5***a*, *b* conduisent aux énamides **14**, **15** et **16**.

[Traduit par la revue]

Introduction

Many researchers have dealt with the syntheses of 3-oxo, 5-oxo, and 3,5-dioxo derivatives of 1,4-benzothiazepines, but there are only a few publications (2–9) relating to the preparation of 2,3- and 3,4-dihydro- or 2,3,4,5-tetrahydro-1,4-benzothiazepines containing no carbonyl group. Only a single procedure, following a different pathway, was found in the literature for the synthesis of a β-lactam derivative of 1,4-benzothiazepine (10).

We earlier reported the syntheses of 4,5-dihydro-1,4-benzothiazepine and 4,5-dihydro-1,4-benzothiazepin-3(2*H*)-one derivatives (8, 9, 11). In the present work, convenient preparations of suitably substituted 2,3-dihydro- and 2,3,4,5-tetrahydro-1,4-benzothiazepines and the syntheses of their β-lactam and other derivatives are described.

Syntheses

The reaction of sodium 3,4-dimethoxythiophenolate (**1**) with 2-bromoethylamine (**2**) gave 2′-aminoethyl-3,4-dimethoxyphenyl sulfide, which was isolated as the hydrochloride **3**. With acid anhydrides or acid chlorides, compound **3** was converted to the acid amides **4***a–c*. Heating of the latter with $POCl_3$ furnished the benzothiazepine derivatives **5***a–c* (Scheme 1) in poor yields, since a competitive reaction, probably via disintegration of the intermediary imide chloride **6**, gave rise mainly to the decomposition products 2′-chloroethyl-3,4-dimethoxyphenyl sulfide (**7**) and the corresponding nitrile. Compound **7** and benzonitrile, formed simultaneously with the cyclization of the acid amide **4***c*, were isolated from the reaction mixture. A definitive synthesis of compound **7** was its preparation from sodium 3,4-dimethoxythiophenolate and 1,2-dichloroethane (Scheme 1).

A few characteristic derivatives were prepared from **5***c*, such as the methiodide **8** with methyl iodide, the sulfoxide **9** with $NaIO_4$, and the sulfone **10** with $KMnO_4$. Reduction of **5***b* and **5***c* with $NaBH_4$ furnished the corresponding tetrahydro-1,4-benzothiazepines **11***a*, *b* (Scheme 2).

Analogously to the cycloaddition reactions of imines with acid chlorides, **5***c* gave the β-lactams **12***a–f*. It was found that, except for one case, only one of the diastereomers was formed; thus, the reactions were regio- and stereospecific. However, when **5***c* and 2-chloro-2-phenylacetyl chloride were reacted in the presence of TEA (triethylamine), both stereoisomers **12***e* and **12***f* were isolable (Scheme 3).

The β-lactam **13** obtained from the benzothiazepine dioxide **10** by treatment with phenylacetyl chloride was identical with the compound formed from the β-lactam **12***a* by oxidation with peracetic acid (Scheme 4).

Compound **5***a* with benzoyl chloride and, analogously, **5***b* with dichloroacetyl chloride or benzoyl chloride in the presence of TEA gave the enamides **14**, **15**, and **16**, respectively (Scheme 5), similar to the reactions of 1-alkyl-3,4-dihydroisoquinolines and 4-alkyl-2*H*-1,3-benzothiazines (12, 13). Further investigations relating to these compounds are in progress.

Spectroscopic evidence of structures

The ir and ^1H and ^{13}C nmr data supporting the structures of

the new compounds are given in the Experimental; those of the β-lactams are listed in Tables 1–3.

In the ^1H nmr spectrum of the sulfone analog **10**, the two methylene groups give a singlet of 4H intensity. Thus, the two methylene groups appear to be isochronous in $CDCl_3$ solution, owing to the practically identical substituent effects of the sp^2 nitrogen and the sulfone group. The chemical equivalence of both pairs of methylene protons indicates a rapid interconversion of the thiazepine ring.

The ArH-9 signal of **11***b* shows a very marked upfield shift (−0.5 ppm) as compared with the value for the starting compound **5***c*. This shift is a consequence of the anisotropic shielding of the phenyl substituent (14*a*) attached to the saturated hetero ring, confirming the preference for a conformation in which the ArH-9 atom is situated "above" the plane of the phenyl ring and near to it. This conformation is also indicated by the upfield shift of the C-8 methoxy signal.

The configurations of the C-1 and C-10 atoms in the β-lactams **12***a–f* and **13** remain to be elucidated; this is hampered by the fact that the thiazepine ring may assume several conformations, differing according to the substitution.

In determining the steric structures of the diastereomeric pair **12***e–f*, it is helpful to start with the ^1H nmr data, since there are

13	14.5	14.5	11.8	3.2	2.9	3.2

no significant differences either in the ir frequencies or in the chemical shifts of the carbon resonance signals. On the other hand, in the ^1H nmr spectrum of **12***f* both methoxy signals and also the H-6 and H-9 singlets, mainly one of each, reveal very considerable upfield shifts. The two larger shifts amount to about −0.5 and −1.0 ppm. This is indicative of a configuration and conformation in which the C-10 phenyl ring, occupying different positions in the diastereomers, has come near to the methoxy groups. This steric structure is possible only when the C-1 and C-10 phenyl rings are in the *trans* position, i.e. if the relative configuration is 1*R*,10*S* (1*S*,10*R*). Further evidence for this is given in the spectrum of **12***e* by the higher shielding of some of the aromatic hydrogens, indicating that the two rings in this compound are nearer to each other, i.e. in the *cis* position relative to the β-lactam ring. In view of the data listed in Table 1, **12***b* and **12***f* have analogous structures (the C-1 phenyl and C-10 phenoxy groups are in the *trans* position), whereas the structures of the β-lactams **12***a*,*c*,*d* and **13** are identical with that of isomer **12***e*.

Information about the conformations is obtained primarily from the vicinal proton–proton coupling constants of the methylene groups (Table 2). As shown by molecular models,

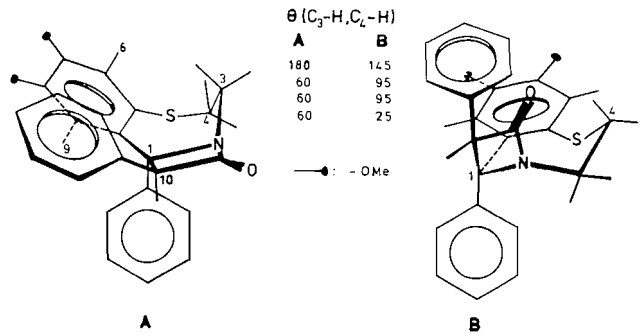

FIG. 1. The possible conformations of compounds **12***a–c* (A) and **12***d–f* (B), respectively.

two sterically favored, relatively stable conformations are possible (Fig. 1). In one of these (**A**), the thiazepine ring is in a boat-like form; the β-lactam ring is attached *quasi-equatorially*, and the dihedral angles of the methylene hydrogens are about 180, 60, 60, and 60°. In the other conformation (**B**), there is a chair-like seven-membered heterocycle (in which C-1 and C-4 are situated out of the plane of the other five atoms constituting the ring), and a *quasi-axially* annelated β-lactam ring is coupled

[i]These assignments are due to α and β effects of the SO_2 substituent.

to it. (The C-H,C-H dihedral angles of the C-3 and C-4 methylene groups are approximately 145, 95, 95, and 25°.) In this more strained skeletal structure, the substituent in the position *trans* to the C-1 phenyl group is sterically favored. The distance between H-9 and the C-1 phenyl group is increased. It is therefore obvious that compounds **12***d–f* have the **B** conformation, whereas for the analogs **12***a*,*c* and **13**, which have no C-10 substituent in the position *trans* to the C-1 phenyl group, the preferred conformation is the boat-like form **A**. In **12***b*, with *trans* C-1 and C-10 substituents in the postulated configuration, the phenoxy group can avoid steric hindrance through rotation about the C_{10}—O—C_{aryl} chain. Consequently, the predominant conformer is **A**. This is indicated by the higher value of the ^3J(H-3′,H-4′) coupling constant and the lower value of its ^3J(H-3,H-4) counterpart in compounds **12***a–c* and **13**.

Evidence of the conformational difference is furnished by the switchover of the relative chemical shifts of the methylene proton pairs. In **12***a–c* and **13** the usual relations δ H-3*e* > δ H-3′*a* and δ H-4*e* < δ H-4′*a* were observed (it is characteristic of sulfur-containing saturated heterocycles (14*b*) that the sequence of shifts of the C-4 methylene hydrogens is opposite in direction to that for the cyclohexane derivatives, i.e. the *equatorial* proton is more shielded than its *axial* counterpart); in the C-10 disubstituted analogs, just the opposite sequence is found. This is probably due to the anisotropic effect of the β-lactam ring, which increases the shielding around H-4′*a* and decreases it around H-3*e*, the chair-like conformation of the thiazepine ring. The assignments given in Table 1 are based partly on a consideration of the expected substituent effects, and partly on the magnitudes of the coupling constants.

The preferred conformations of compounds **14–16** are supported by the broadening and downfield shifts of some of the ^1H nmr signals. In the spectrum of **14**, the C-8 methoxy signal is found at 3.63 ppm, upfield by about 0.25 ppm in comparison with the average shifts in the other compounds. The ArH-9 singlet is at 6.22 ppm, i.e. in the same direction, but with a very markedly larger shift and broadened. This strongly suggests a predominant conformation in which the benzoyl group is near to the C-8 methoxy group and the ArH-9 atom. In one of the rotamers, the aromatic ring exerts an anisotropic shielding effect on this group and atom; this is the reason why the upfield shifts appear, while the broadening of the signal is caused by the slow interconversion of the rotational isomers. In this conformation, the ethylidene group is *quasi-axial* relative to the hetero ring; in the *N*-benzoyl substituent, the phenyl ring and the amide group are not coplanar. This is evidenced by the observation that the signals of the phenyl *ortho* hydrogens are not separated in the downfield direction from the signals of the *meta* and *para* protons, as generally occurs in benzoyl compounds, due to the anisotropic effect of a coplanar carbonyl group (14*c*).

The conformation of **15** is analogous to that of **14**; the relative positions of the benzylidene ring to the C-8 methoxy group and to the ArH-9 atom are also quite similar; accordingly, similar upfield shifts of these signals are found, and there is a broadening of the latter, due to the hindered amide rotation.

The combined anisotropic effect of the two phenyl groups in compound **16** results in anomalous upfield shifts of the corresponding signals; that of the 8-methoxy group is found at 3.13 ppm, i.e. shifted by about −0.8 ppm as compared with the usual value for these compounds; the very broad ArH-9 signal is at 5.50 ppm, the chemical shift being about 1.5 ppm smaller

For personal use only.

than the average. This is evidence of the analogous conformation; at the same time the *E*-configuration about the olefin bond in compounds **15** and **16** is shown, in which the phenyl ring of the benzylidene group is situated in the direction of the fused veratryl ring, and the olefin hydrogen toward the benzoyl group.

Experimental

The ir spectra were run in KBr discs on a Perkin–Elmer 125 (**3**, **4***a–c*, **5***c*, **8–10**, **11***b*, and **15**) or an Aspect 2000 computer-controlled Bruker IFS-113v-FT spectrometer (all other compounds).

The nmr spectra were recorded in 5- or 10-mm tubes at room temperature on a Varian EM-60 (**3**, **4***a–c*, **5***a–c*, **8**, **11***b*, and **15**) or a Bruker WM-250 (all others) instrument (^{1}H) at 60 and 250 MHz, respectively, and on a WP-80-SY FT spectrometer controlled by an Aspect 2000 computer at 20.14 MHz (^{13}C) in $CDCl_3$ or DMSO-d_6 solution, using the deuterium signal to the solvent as the lock and TMS as internal reference. The most important measuring parameters for the FT mode were as follows: sweep width: 5 kHz; pulse width: 1 (^{1}H) or 3.5 (^{13}C) μs (ca. 20° or 30° flip angle); acquisition time 1.64 s; number of scans: 16 or 2^{10}–2^{16}; computer memory: 16K; Lorentzian exponential multiplication for signal-to-noise enhancement (LB 0.7 or 1.0 Hz) and complete proton noise decoupling (ca. 1.5 W) for ^{13}C measurements were applied.

DEPT experiments (16) were performed (for compounds **12***b*, *c*, *e*, *f* and **13**) in a standard way (17), using only the θ = 135° pulse to separate the CH/CH_3 and CH_2 lines phase "up" and "down", respectively. Typical acquisition data were number of scans: 128–2048 K; relaxation delay for proton 3 s; 90° pulse width: 10.8 and 22.8 μs for ^{13}C and ^{1}H, respectively. The estimated value for J(C,H) resulted in a 3.7 ms delay for polarization.

Spectral data on the β-lactams **12***a–f* and **13** are given in Tables 1–3; parameters on the other structures are listed separately below.

Melting points are uncorrected.

2'-Aminoethyl-3,4-dimethoxyphenyl sulfide hydrochloride **3**

Sodium 3,4-dimethoxythiophenolate (19.22 g; 100 mmol) was added to a solution of 2-bromoethylamine (12.4 g; 100 mmol) in dry benzene (100 mL). The mixture was stirred and refluxed for 1 h, then extracted with 5% NaOH solution (50 mL), and the benzene phase was dried (Na_2SO_4) and evaporated to dryness. The residue was dissolved in ethanol (15 mL) and ethanol (20 mL) saturated with HCl was added. Compound **3** precipitated as colorless crystals (18.48 g; 74%), mp 175–176°C (EtOH); ir: ν N^+H: 3200–2300, ≈1990 cm^{-1}; ^{1}H nmr (D_2O): CH_2: 3.30 s (4H); OCH_3: 3.90 s (6H); ArH-5: 6.90 d (8 Hz, 1H); ArH-2,6: ≈7.1 m (2H). *Anal.* calcd. for $C_{10}H_{16}NO_2S$: C 48.09, H 6.46, N 5.61; found: C 48.11, H 6.85, N 5.22%.

2'-Acetaminoethyl-3,4-dimethoxyphenyl sulfide **4**a

Compound **3** (2.5 g; 10 mmol) was refluxed in acetic anhydride for 2 h. The mixture was poured into water and extracted with benzene. The extract was washed with dilute Na_2CO_3 solution and then with dilute H_2SO_4 and water, dried (Na_2SO_4), and evaporated. The residue was crystallized from CCl_4 to give colorless needles (1.66 g; 65%), mp 82–83°C. *Anal.* calcd. for $C_{12}H_{17}NO_3S$: C 56.44, H 5.53, N 5.49; found: C 56.59, H 5.72, N 5.60%.

3,4-Dimethoxyphenyl-2'-phenylacetaminoethyl sulfide **4**b

Compound **3** (2.5 g; 10 mmol) was dissolved in ice-water (20 g) and, with continuous stirring, phenylacetyl chloride (2 mL) and then a solution of NaOH (1.1 g NaOH in 5 mL of water) were added dropwise. The mixture was extracted with benzene, and the extract was dried (Na_2SO_4) and evaporated. The residue crystallized. Recrystallization from methanol gave colorless needles (2.92 g; 88%), mp 99–100°C. *Anal.* calcd. for $C_{18}H_{21}NO_3S$: C 65.23, H 6.39, N 4.23; found: C 65.62, H 6.73, N 4.29%.

2'-Benzoylaminoethyl-3,4-dimethoxyphenyl sulfide **4**c

Compound **3** (2.5 g; 10 mmol) was dissolved in pyridine (10 mL). Benzoyl chloride (1.7 mL) was added with stirring, and the mixture was allowed to stand for 30 min. It was then poured into ice-cold dilute H_2SO_4 and the crystals that separated were collected by filtration (2.85 g; 90%); colorless prisms, mp 108–109°C (MeOH); ir: ν NH: 3310 (**4***a*), 3270 (**4***b*), 3380 (**4***c*); amide-I: 1635, 1640, 1650 cm^{-1}; ^{1}H nmr: $COCH_3$ (**4***a*): 1.93 s (3H); SCH_2: 2.95 t (2H, **4***a*), 2.90 t (2H, **4***b*), 3.03 t (2H, **4***c*); NCH_2: 3.45, 3.35, 3.60 q (2H); $PhCH_2$ (**4***b*): 3.50 s (2H); OCH_3: 3.83, 3.86 2s (2 × 3H, **4***a*), 3.80 s (6H, **4***b*), 3.78 s (6H, **4***c*); NH: ≈6.2 br s (1H, **4***a*), ≈6.1 br s (1H, **4***b*), ≈7.0 m (overlapped with the ArH, **4***c*); ArH-5: 6.78, 6.75, 6.75 d (8 Hz, 1H); ArH-2: 6.90, 6.85, 6.93 d (2 Hz, 1H); ArH-6: 6.95, 6.90, 6.98 dd (1H); Ar (Ph): 7.20 ≈s (5H, **4***b*); ArH-3',5' (Ph): ≈7.4 m (3H); ArH-2',6' (Ph): ≈7.7 m (2H, **4***c*). *Anal.* calcd. for $C_{17}H_{19}NO_3S$: C 64.33, H 6.03, N 4.41; found: C 64.01, H 6.17, N 4.70%.

2,3-Dihydro-7,8-dimethoxy-5-methyl-1,4-benzothiazepine **5**a

A mixture of compound **4***a* (10.2 g; 40 mmol) and $POCl_3$ (15 mL) was heated on a steam bath for 1 h. The reaction mixture was decomposed in ice-water, made alkaline with Na_2CO_3, and extracted with benzene. The extract was reextracted with 10% HCl (100 mL). The acid phase was neutralized with Na_2CO_3 and extracted with benzene. After drying (Na_2SO_4), the benzene solution was evaporated. The pale-yellow oily residue was dissolved in ethanol, and **5***a* was precipitated from the solution as yellow crystals of the picrate (1.55 g; 8.3%), mp 195–197°C (dec.). The base liberated from the picrate was a pale-yellow, slowly crystallizing oil. Recrystallization from petroleum ether yielded a product melting at 100–102°C, in all respects identical with the compound synthesized in a different way (2).

5-Benzyl-2,3-dihydro-7,8-dimethoxy-1,4-benzothiazepine **5**b

A mixture of **4***b* (2.31 g; 10 mmol) and $POCl_3$ (3 mL) was heated on a steam bath for 1 h. The mixture was treated with ice-water, made alkaline with Na_2CO_3, and extracted with benzene. The organic phase was dried (Na_2SO_4) and concentrated. The residue was dissolved in ethanol (2 mL) and **5***b*·HCl was precipitated, by the addition of ethanol saturated with HCl, as pale-yellow crystals (0.32 g; 14.7%), mp 195–196°C. *Anal.* calcd. for $C_{18}H_{20}ClNO_2S$: C 61.79, H 5.76, Cl 10.14; found: C 62.18, H 6.09, Cl 10.66%.

The *picrate* was prepared as yellow crystals (EtOH), mp 197–199°C (dec.).

The base liberated from **5***b*·HCl was a viscous oil. *Anal.* calcd. for $C_{18}H_{19}NO_2S$: C 68.98, H 6.11, N 4.47; found: C 69.10, H 6.35, N 4.60%.

2,3-Dihydro-7,8-dimethoxy-1,4-benzothiazepine **5**c *and 2'-chloroethyl-3,4-dimethoxyphenyl sulfide* **7**

Compound **4***c* (9.51 g; 30 mmol) and $POCl_3$ (11 mL) were heated in a steam bath for 3 h. The mixture was poured into ice-water (150 mL) and extracted with benzene. The extract was dried (Na_2SO_4) and the solvent was evaporated. Fractional distillation of the oily residue in a water-pump vacuum gave benzonitrile (1.55 g), and 2'-chloroethyl-3,4-dimethoxyphenyl sulfide (3 g); $n_\alpha^{20°}$ 1.5816. *Anal.* calcd. for $C_{10}H_{13}ClO_2S$: C 51.60, H 5.63, Cl 15.24; found: C 51.76, H 5.53, Cl 15.45%.

The acidic aqueous solution was made alkaline and extracted with benzene. After drying (Na_2SO_4), the solvent was evaporated and the residue was crystallized from ethanol to give colorless prisms of **5***c* (3.3 g; 36.7%), mp 167–168°C. *Anal.* calcd. for $C_{17}H_{17}NO_2S$: C 68.20, H 5.73, N 4.68; found: C 69.09, H 6.03, N 4.89%.

The *picrate* crystallized from ethanol as a yellow product, mp 238–240°C (dec.); ^{1}H nmr: $COCH_3$ (**5***a*): 2.36 s (3H); CH_2: 3.50 s (4H, **5***a*), 3.47, and 3.56 2m (2 × 2H, **5***b*), ≈3.65 AA'BB'-type m (4H) with close A and B parts (**5***c*); OCH_3: 3.90 s (6H, **5***a*), 3.73 and 3.84 2s (2 × 3H, **5***b*), 3.73 and 3.82 2s (2 × 3H, **5***c*); $PhCH_2$ (**5***b*): 4.01 s (2H); ArH-6: 6.80, 6.95, 7.08 s (1H); ArH-9: 7.00, 6.63, 6.60 s (1H); ArH(Ph): 7.1–7.3 m (5H, **6***b*), 7.2–7.7 m (5H, **5***c*). *Anal.* calcd. for $C_{23}H_{20}N_4O_9S$: C 52.27, H 3.82, N 10.60; found: C 52.02, H 3.88, N 10.66%.

2'-Chloroethyl-3,4-dimethoxyphenyl sulfide **7**

3,4-Dimethoxythiophenol (1.7 g; 10 mmol) was dissolved in 1,2-dichloroethane (10 mL). The solution was refluxed under a nitrogen protecting atmosphere while a solution of $NaOCH_3$ (10 mmol)

in methanol (10 mL) was added dropwise. The mixture was refluxed for 3 h. It was then diluted with water and extracted with $CHCl_3$. The extract was washed with $NaHCO_3$ solution, dried (Na_2SO_4), and evaporated. The oily residue was distilled, in the vacuum of a water pump, on an air bath at 125°C. The product was a colorless oil (1.6 g; 70%), $n_\alpha^{20°}$ 1.5808, in all properties identical with compound **7** isolated from the reaction mixture in the preparation of **5***c*; ^{1}H nmr: CH_2: 3.11, 3.58 AA'BB'-type m (4H); OCH_3: 3.87, 3.88 2s (2 × 3H); ArH-5: 6.81 d (8.5 Hz, 1H); ArH-2: 6.97 d (2.0 Hz, 1H); ArH-6: 7.03 dd (1H); ^{13}C nmr: SCH_2: 38.0; $ClCH_2$: 42.4; OCH_3: 56.01, 56.05; C(Ar)-2: 112.3; C(Ar)-5: 116.4; C(Ar)-1: 125.1; C(Ar)-6: 125.4; C(Ar)-3,4: 149.5, 149.6.

2,3-Dihydro-7,8-dimethoxy-4-methyl-5-phenyl-1,4-benzothiazepinium iodide ***8***

Compound **5***c* (0.75 g; 2.5 mmol) was dissolved in CH_3CN (5 mL). CH_3I (0.4 mL) was added and the mixture was refluxed for 1 h. On cooling, crystals of **8** separated (0.72 g; 65.5%). Recrystallization from CH_3CN gave a product with mp 204–205°C (dec.); ^{1}H nmr: N^+CH_3: 3.67 s (3H); OCH_3: 4.00, 4.05 2s (2 × 3H); CH_2: ≈4.05 (overlapped by the OCH_3 singlets), 4.45, AA'BB'-type m (4H); ArH-9: 6.60 s (1H); ArH-6: 7.20 s (1H); ArH(Ph): ≈7.65 m (5H). *Anal.* calcd. for $C_{18}H_{20}INO_2S$: C 48.99, H 4.57, N 3.17; found: C 48.80, H 4.82, N 3.16%.

2,3-Dihydro-7,8-dimethoxy-5-phenyl-1,4-benzothiazepine 1-oxide ***9***

A solution of **5***c* (1 g; 3.3 mmol) in methanol (40 mL) was stirred at room temperature for 3 days with a solution of $NaIO_4$ (0.7 g) in water (10 mL). After dilution with water, the precipitate was filtered off. Recrystallization from methanol (3 mL) gave colorless prisms (0.67 g; 63.8%), mp 157–158°C; ir: ν SO: 1065 cm^{-1} (the strongest band of the ir spectrum); ^{1}H nmr: CH_2: 3.10 dd (1H), 3.44 dt (1H), ≈4.1 (1H, overlapped by one of the OCH_3 singlets), 4.63 dt (1H); OCH_3: 3.83, 4.07 2s (2 × 3H); ArH-9: 6.75 s (1H); ArH-3′,5′ (Ph): 7.4 m (3H); ArH-6: 7.53 s (1H); ArH-2′,6′ (Ph): 7.60 ≈d (2H). *Anal.* calcd. for $C_{17}H_{17}NO_3S$: C 64.74, H 5.44, N 4.44; found: C 64.56, H 5.67, N 4.19%.

The *picrate*, yellow crystals from ethanol, had mp 210–211°C (dec.). *Anal.* calcd. for $C_{23}H_{20}N_4O_{10}S$: C 50.73, H 3.70, N 10.29; found: C 50.89, H 3.98, N 10.58%.

2,3-Dihydro-7,8-dimethoxy-5-phenyl-1,4-benzothiazepine 1,1-dioxide ***10***

Compound **5***c* (1 g; 3.3 mmol) was dissolved in a mixture of dioxan (5 mL) and acetic acid (5 mL). A solution $KMnO_4$ (3 g) in water (20 mL) was added, in portions, to the stirred mixture and stirring was continued for 1 h. H_2O_2 was added dropwise until dissolution of the MnO_2 was complete. The solution was diluted with water (100 mL), made alkaline with Na_2CO_3, and stirred for 1 h more. It was then extracted with benzene, and the extract was dried (Na_2SO_4) and evaporated to dryness. The residue was crystallized from a small amount of ethanol as colorless prisms (0.6 g, 54.5%), mp 162–164°C; ir: ν_{as} SO_2: 1315; ν_s SO_2: 1125 cm^{-1}; ^{1}H nmr: OCH_3: 3.79, 4.01 2s (2 × 3H); CH_2: 3.88 s (4H); ArH-9: 6.68 s (1H); ArH-3′,5′ (Ph): 7.40 m (3H); ArH-6: 7.58 s (1H); ArH-2′,6′ (Ph): 7.62 d (2H). *Anal.* calcd. for $C_{17}H_{17}NO_4S$: C 61.61, H 5.17, N 4.23; found: C 61.20, H 5.24, N 4.48%.

Picrate: yellow crystals from ethanol, mp 245–246°C (dec.). *Anal.* calcd. for $C_{23}H_{20}N_4O_{11}S$: C 49.28, H 3.60, N 10.00; found: C 49.08, H 3.85, N 9.91%.

5-Benzyl-7,8-dimethoxy-2,3,4,5-tetrahydro-1,4-benzothiazepine ***11****a*

Compound **5***b*·HCl (0.35 g; 1 mmol) was dissolved in methanol (25 mL). $NaBH_4$ (0.5 g) was added in portions, and the mixture was allowed to stand overnight. After the addition of water (0.5 mL), the mixture was evaporated to dryness and extracted with ether. The ethereal extract was concentrated and a solution of HCl in ether was added to precipitate **11***a*·HCl as colorless crystals (0.29 g; 82.6%), mp 110–112°C. *Anal.* calcd. for $C_{18}H_{22}ClNO_2S$: C 61.44, H 6.30, Cl 10.08, N 3.98; found: C 61.11, H 6.60, Cl 10.38, N 3.68%.

The base **11***a* liberated from the hydrochloride was a viscous oil; ^{1}H nmr: NH: 1.80 s (1H); SCH_2: 2.68 m (2H); CH_2(Ph): 3.0–3.2 m (2H); NCH_2: 3.3–3.4 m (2H); NCH: 4.59 dd (9.6 and 5.6 Hz, 1H); ArH-9: 6.77 s (1H); ArH-6: 7.08 s (1H); ArH(Ph): ≈7.25 ≈s (5H); ^{13}C nmr: C-4: 35.4; C-3: 40.0; CH_2Ph: 49.9; OCH_3: 55.9 (two overlapping lines); C-1: 61.4; C-6: 111.2; C-9: 117.0; C-4′: 126.0; C-5a: 126.9; C-3′,5′: 128.2; C-2′,6′: 128.9; C-9a: 139.2; C-1′: 140.3; C-7: 147.1; C-8: 148.5. *Anal.* calcd. for $C_{18}H_{21}NO_2S$: C 68.54, H 6.71, N 4.44; found: C 68.70, H 6.95, N 4.20%.

7,8-Dimethoxy-5-phenyl-2,3,4,5-tetrahydro-1,4-benzothiazepine ***11****b*

Compound **5***c* (1.5 g; 5 mmol) was dissolved in methanol (50 mL). $NaBH_4$ (1 g) was added in small portions, and the mixture was left to stand overnight. Water (1 mL) was then added, and the mixture was evaporated to dryness and extracted with benzene. The extract was concentrated, whereupon the residue crystallized to give colorless prisms (1.45 g; 96%), mp 145–146°C (from methanol); ir: ν NH: 3340 cm^{-1} (weak); ^{1}H nmr: NH: 1.70 s (1H); CH_2: ≈2.7 m (2H), ≈3.4 m (2H, overlapped by one of the OCH_3 singlets); OCH_3: 3.50, 3.82 2s (2 × 3H); NCH: 5.60 s (1H); ArH-9: 6.10 s (1H); ArH-6: 7.05 s (1H); ArH(Ph): 7.30 ≈s (5H). *Anal.* calcd. for $C_{17}H_{19}NO_2S$: C 67.74, H 6.35, N 4.65; found: C 67.41, H 6.57, N 4.79%.

The **11***b*·HCl was precipitated from benzene with ether containing HCl; mp 102–105°C. *Anal.* calcd. for $C_{17}H_{20}ClNO_2S$: C 60.43, H 5.97, Cl 10.49, N 4.15; found: C 60.27, H 6.27, Cl 10.52, N 4.16%.

General procedure for preparation of β-lactams **12***a–f and* **13**

The appropriate acid chloride (5 mmol) was added to a solution of **5***c* (1.5 g; 5 mmol) in benzene (30 mL). The mixture was refluxed and, with continuous stirring, TEA (0.5 g; 5 mmol) in benzene (30 mL) was added dropwise during 1 h. The crystalline TEA·HCl was removed by filtration, the filtrate was evaporated, and the residue was crystallized from ethanol to yield colorless crystals (cf. Table 4).

Separation of diastereomers **12***e and* **12***f*

The reaction was effected according to the general procedure. The residue was dissolved in ethanol and, after the mixture had stood for 3 h, the precipitated crystals of **12***e* were collected by filtration. The mother liquor was stored in a refrigerator at 5°C overnight, whereupon compound **12***f* crystallized.

Synthesis of compounds **13** *by oxidation of* **12***a*

Compound **12***a* (1.40 g; 3.3 mmol) was dissolved in acetic acid (20 mL); peracetic acid (15 mL) was added, and the solution was left to stand overnight. The crystals (1.07 g; 71.3%) that separated on dilution with water were filtered off and recrystallized from ethanol; the colorless product had mp 239–240°C and was in all respects identical with compound **13** prepared from **10**.

4-Benzoyl-2,3-dihydro-7,8-dimethoxy-5-methylene-1,4-benzothiazepine ***14***

A solution of TEA (1.01 g; 10 mmol) in benzene (20 mL) was added to **5***a*·HCl (1.75 g; 5 mmol) and, with constant stirring, a solution of benzoyl chloride (0.70 g; 5 mmol) in benzene (20 mL) was added. Stirring was continued for 1 h more. After removal of the TEA·HCl by filtration, the filtrate was evaporated to dryness. The residue crystallized slowly. It was suspended in petroleum ether and filtered off to yield the product (0.35 g; 20.6%), which was recrystallized from benzene; mp 140–142°C; ir: amide-I: 1647, ν C=C(H_2): 1622, ν (=CH_2): 864, 792 cm^{-1}; ^{1}H nmr: SCH_2: 3.23 ≈t (5.8 Hz, 2H); OCH_3: 3.63, 3.84 2s (2 × 3H); NCH_2: 4.21 ≈t (2H); =CH_2: 5.24, 5.38 2 × ≈s (2 × 1H); ArH-9: 6.22 s (1H, broadened due to hindered rotation of the *N*-benzoyl group); ArH-6: 6.76 s (1H); ArH(Ph) ≈7.3 m (5H); ^{13}C nmr: C-4: 31.8; C-3: 50.4; OCH_3: 55.8 (two overlapping lines); C-6: 112.9; =CH_2: 113.3; C-9: 116.0; C-5a: 125.2; C-2′,6′ and C-3′,5′: 127.3, 127.4; C-4′: 129.0; C-1′: 130.5; C-9a: 136.7; C-1 and C-8: 147.3 (two overlapping lines); C-7: 148.9; C=O: 170.8. *Anal.* calcd. for $C_{19}H_{19}NO_3S$: C 66.84, H 5.61, N 4.10; found: C 66.56, H 5.90, N 4.32%.

5-Benzylidene-7,8-dimethoxy-4-dichloroacetyl-2,3-dihydro-1,4-benzothiazepine ***15***

TEA (1.01 g; 10 mmol) in benzene (20 mL) was added to **5***b*·HCl (1.75 g; 5 mmol). With constant stirring, a solution of dichloroacetyl

Total synthesis of a proposed structure of isohimachalone[1]

HSING-JANG LIU AND ERIC N. C. BROWNE[2]
Department of Chemistry, The University of Alberta, Edmonton, Alta., Canada T6G 2G2

Received May 21, 1986

This paper is dedicated to Dr. O. E. (Ted) Edwards

HSING-JANG LIU and ERIC N. C. BROWNE. Can. J. Chem. **65**, 182 (1987).

A proposed structure **5** of the naturally occurring sesquiterpene ketone isohimachalone has been synthesized by a route using the unique Diels–Alder chemistry developed in our laboratory. The product has been shown to be non-identical with the natural material by comparison of spectral data, a result which has been implied by the work of an independent group using direct methods. Spectroscopic differences between our synthetic material and the natural and closely related products are discussed.

HSING-JANG LIU et ERIC N. C. BROWNE. Can. J. Chem. **65**, 182 (1987).

Utilisant la chimie unique de Diels–Alder qui a été développé dans notre laboratoire, on a synthétisé le composé **5** dont la structure avait été proposée pour la cétone sesquiterpénique naturelle isohimachalone. Une comparaison des données spectrales a permis de démontrer que le produit obtenu n'est pas identique avec le produit naturel; ce résulte a déjà été suggéré par le travail d'un groupe indépendant qui a utilisé des méthodes directes. On discute des différences observées dans les spectres du produit de synthèse, du produit naturel et d'autres produits qui leur sont fortement apparentés.

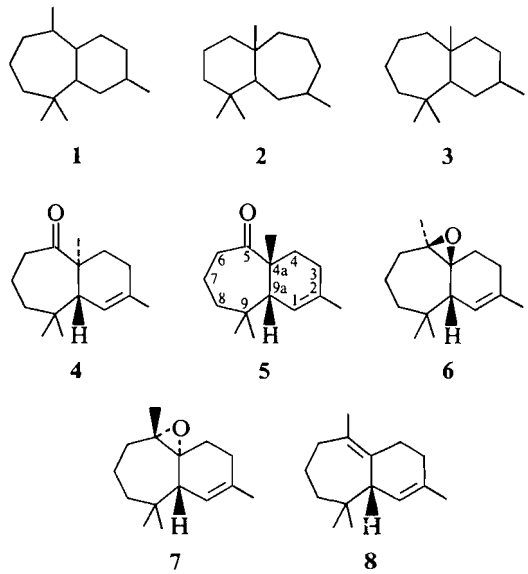
Introduction

As described by us in a previous paper (1), the himachalane class of naturally occurring sesquiterpenes represented by skeleton **1** has grown significantly since the first examples were reported (2, 3). In the 1970's two other very closely related skeletal types were disclosed. The allohimachalane skeleton **2** is characteristic of two compounds isolated by Dev and co-workers (4–6) while the related isohimachalane skeleton **3** is characteristic of two reported compounds. Teisseire first reported the isolation (7) from *Cedrus atlantica* of a ketone to which he has assigned the *trans*-fused structure **4** (8). Dev later reported (4) the isolation from *Cedrus deodara* Loud. of a ketone to which he originally assigned *cis*-fused structure **5** and which he named isohimachalone.

It has been suggested (8) that *trans*-ketone **4** arises by a rearrangement of the epoxide **6**. One or both of the epimeric epoxides **6** and **7** are reportedly (9) auto-oxidation products of β-himachalene **8**, and so conceivably the *cis*-fused structure could arise by a similar rearrangement of the naturally occurring epoxide **7**. Both epimeric epoxides **6** (7, 10, 11) and **7** (10) have been shown to occur naturally. The allohimachalane skeleton **2** would arise in a similar fashion by migration of a different carbon–carbon bond in these same epoxide intermediates **6** and **7**.[3]

Recently, a collaborative effort of Dev and Clardy and co-workers (14, 15) using X-ray analysis has resulted in revision of the stereochemistry of himachalol from **9** (16) to **10**. Consequently, the structures of a number of related natural products whose stereochemistries were logically derived from that of himachalol must also be revised, in particular that of the non-naturally derived (17) β-himachalene oxide originally assigned in 1977 (9) as **7**, which now stands corrected to **6**. By implication (ref. 14, footnote 6), although not specifically stated in that paper, this general revision includes the structure of



isohimachalone,[4] the stereochemistry of which was assigned after partial synthesis from β-himachalene via the 6,7-epoxide. This implied revision of the structure of isohimachalone to *trans*-fused structure **4** confirms an earlier independently reached conclusion of this group (18) that the *cis*-compound **5** could not be identical with that of the reported naturally occurring material by either group.

A number of different synthetic approaches to the himachalane skeleton **1** have been reported (19–24). Our own group has achieved the synthesis of α-(**11**) and β-himachalene (**8**) by a unique Diels–Alder approach (1). We wish at this time to report our synthesis of the *cis*-fused compound **5** using the unique Diels–Alder chemistry previously developed by this group. Spectroscopic differences between **5** and the natural product will be demonstrated, which support the implication of the Dev/Clardy group's results.

A modern synthetic scheme should be designed to achieve the rapid assembly of the target carbon skeleton in an intermediate containing functional groups that require only simple modifica-

16

tions to give the synthetic target. On this basis, keto ester **12** prepared by Diels–Alder addition of isoprene to dienone ester **13** (1) offers a suitable key intermediate for synthesis of the isohimachalane skeleton **3**. Reduction to saturated ketone **14** followed by conversion of the carbomethoxyl substituent to an angular methyl group would give ketone **15**, which requires only homologation of the A ring and isomerization of the double bond to give *cis*-ketone **5**.

A similar approach could be applied to the synthesis of *trans*-ketone **4** (isohimachalone). Starting with the *cis*-fused ketone **15**, isomerization of the double bond and epimerization of the ring junction could give *trans*-fused ketone **16**, which, after homologation of the A ring, would give the ketone **4** (isohimachalone). The synthesis of *cis*-ketone **5** has been achieved and found to be not identical with naturally occurring isohimachalone. The synthesis of *trans*-ketone **4** is under study and the progress in this study will be reported in a future publication.

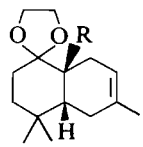
Results and discussion

For the proposed synthesis of *cis*-ketone **5** the previously reported saturated keto-ester **14** (1), obtained by hydrosilylation/hydrolysis of keto ester **12** was used as the key intermediate. Conversion of the carbomethoxyl group of **14** to an angular methyl group required protection of the ketone prior to the reduction step. Thus ketone **14** was treated with ethylene glycol and *p*-toluenesulfonic acid in refluxing benzene for 47 h and a ketal was obtained in 93% yield to which structure **17** was tentatively assigned.

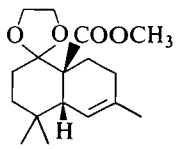
To ascertain that the acidic ketalization conditions had not also caused migration of the double bond to give ketal **18**, the ketal group was removed by treatment with *p*-toluenesulfonic acid in acetone for 14 days. A single product was obtained in quantitative yield (based on recovery of 46% of the starting ketal), which was identical by ^1H nmr, ir, and tlc analysis with the original keto ester **14**. The production of un-isomerized keto ester **14** from the very mild transketalization conditions indicated that the ketalization of **14** had occurred without migration of the double bond and that **17** was the structure of the product obtained.

Conversion of the carbomethoxy group of **17** to a methyl group required reduction of the ester to the alcohol **19**, followed by attachment of a leaving group and further reduction to give the methyl derivative **20**. The ester **17** was easily reduced with lithium aluminum hydride in ether to give alcohol **19** in 92% yield.

The further reduction of the hydroxymethylene group of **19** to an angular methyl required the use of a derivative that could be reduced without steric interference from the adjacent neopentyl center. It has been shown (25) that tetramethyl phosphorodiamidate (TMPDA) derivatives of alcohols can be reduced to hydrocarbons with lithium in ethylamine/tetrahydrofuran/*tert*-butyl alcohol. Such TMPDA derivatives of sterically hindered alcohols are, however, difficult to prepare directly from reaction of the alcohol with tetramethylphosphorodiamidic chloride. This difficulty can be overcome (26) by conversion of the alcohol, first to the dimethyl chlorophosphoramidate derivative using dimethylphosphoramidic dichloride followed by treatment of the resulting intermediate with dimethylamine to give the TMPDA derivative. Accordingly, alcohol **19** was converted to the corresponding alkoxy anion by treatment with *n*-butyllithium in 1,2-dimethoxyethane/tetramethylethylenediamine (80:20) at 0°C for 15 min. The anion was treated *in situ* with dimethylphosphoramidic dichloride (27) at room temperature for 23 h to give complete conversion to the intermediate **21**. This compound was not isolated but was rapidly converted, by the addition of excess liquid dimethylamine to the solution at 0°C, into the TMPDA derivative **22** in 84% overall yield from alcohol **19**.



17 R = $COOCH_3$
19 R = CH_2OH
20 R = CH_3
21 R = $CH_2OPO(Cl)N(CH_3)_2$
22 R = $CH_2OPO[N(CH_3)_2]_2$



18

Reduction of the TMPDA derivative **22** with lithium in ethylamine/tetrahydrofuran/*tert*-butyl alcohol gave three principal products. One product, obtained in 14% yield, was found to be identical with the alcohol **19** and clearly resulted from cleavage of the P—O bond rather than C—O cleavage. The minor product, obtained in 5% yield, was found to be identical with the *trans*-ketone **23** obtained previously (1). Possibly, this ketone could have been formed via a 1,3-glycol type cleavage in the radical, which would result from P—O bond fission in the TMPDA derivative **22**. The major product, obtained in 69% yield, was identified as the desired ketal **20**.

Transketalization of ketal **20** with acetone in the presence of *p*-toluenesulfonic acid rapidly (2.5 h) gave a product identifiable as *cis*-ketone **15** in 97% yield.

The synthesis of **5** could proceed from ketone **15** by two different routes: isomerization of the double bond (**15** → **24**) followed by homologation of the ketone ring, or homologation first (**15** → **25**) and then isomerization of the double bond. The isomerization of **25** to **5** has precedent in the acid catalyzed isomerization of **26** → **27** in which the equilibrium ratio of the two compounds was approximately 33:67 (1, 18, 28). On the other hand, examination of Dreiding models of **15** and **24** showed that in **15** the B ring could not achieve a stable quasi-chair conformation without exerting considerable torsional strain on the C-4a/C-8a bond. In ketone **24**, however, the quasi-chair conformation of the B ring could be attained without undue torsional strain. Ketone **24** therefore might be expected to predominate in an equilibrium mixture of **15** and **24**.

Treatment of **15** with *p*-toluenesulfonic acid in refluxing benzene for 2 h gave an 85:15 equilibrium mixture of two

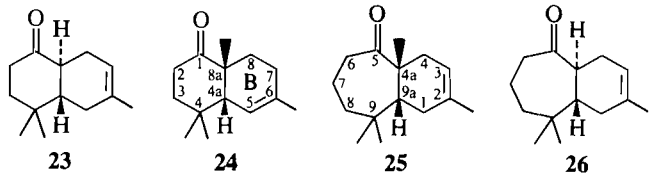
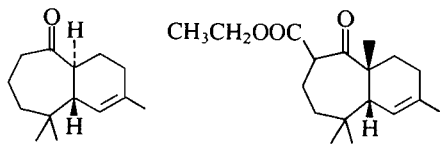
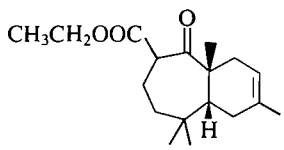
inseparable compounds in 89% yield. The minor component was identified as ketone **15** by its gc retention time and by comparison of the minor signals in the ^{1}Hmr spectrum of the mixture with the spectrum of pure **15**. The major component showed ^{1}Hmr signals at δ 5.40 (multiplet) due to a vinyl proton and at δ 1.71, 1.04, 0.97, and 0.94 (singlets) due to methyl groups. The structure **24** was tentatively assigned and this was confirmed by comparison of the ^{13}Cmr spectra (Table 1) of **15** and **24**. In both cases the signal due to C-4a appeared as the only high-field doublet in the off-resonance decoupled spectrum. In **15** the signal appeared at δ 48.9 whereas in **24** the signal appeared at δ 52.3 because of deshielding by the closer proximity of the double bond. As well, the olefinic carbon C-5 in **24** was deshielded (δ 120.5) relative to C-7 of **15** (δ 117.7) by the β-effect (29) caused by C-4.



23 **24** **25** **26**



27 **28**



29

As was stated for the synthesis of himachalenes (1), the ring expansion of ketones such as **24** with ethyl diazoacetate (30) was expected (31, 32) to proceed with predominant migration of the less substituted α-carbon to give β-keto esters such as **28**. Treatment of **24**[5] with ethyl diazoacetate and boron trifluoride etherate in ether for seven days gave two products (~1:1) in a combined yield of 41%, which were separated by column chromatography. The ^{1}Hmr spectrum of the faster-moving product showed a doublet at δ 5.32 due to a vinylic proton and a signal at δ 3.92 that was assigned to a proton on the α-carbon of a β-keto ester. This latter signal was a doublet of doublets with coupling constants of 12 and 4 Hz, indicating that two protons were adjacent. The spectroscopic data, especially the coupling patterns of the vinyl and keto ester protons, indicated that the structure of this product was **28**.

The other product of the ring expansion reaction was conclusively identified as **29** by comparison with an authentic sample obtained directly by ring expansion of pure ketone **15** (*vide infra*). The presence of **29** among the reaction products probably stemmed from the ring expansion of **15**, which was present as an impurity (~15%) in the starting material.

The decarboxylation of keto ester **28** with lithium iodide dihydrate (33) proceeded to give a ketone in 10% yield. The product showed a molecular ion at *m/e* 220.1823 in the mass spectrum and showed a band at 1699 cm^{-1} in the ir spectrum, indicating a ketone in a seven-membered ring. The ^{1}Hmr spectrum showed a vinyl proton as a doublet at δ 5.34 with a coupling constant of 4 Hz. Methyl groups appeared as singlets at δ 1.69, 1.01, 0.97, and 0.69. The appearance of the vinyl proton as a doublet strongly suggested that this product had structure **5**. The relatively poor yield obtained for conversion of **24** to **5** prompted investigation of the alternate route to **5** via ring expansion of ketone **15**.

Treatment of **15** with ethyl diazoacetate and boron trifluoride etherate in ether for 48 h gave a single product (18 lines in the ^{13}Cmr spectrum) in 82% yield. In the ^{1}Hmr spectrum, a signal at δ 3.86 was assigned to a proton at the α-carbon of a β-keto ester and appeared as a doublet of doublets with two coupling constants of 10 Hz each, indicating that there were two protons adjacent to it. The spectral data indicated that the structure of the ring expansion product was **29**.

Decarboxylation of **29** with lithium iodide dihydrate (33) gave a product identified as the corresponding ketone **25** in 86% yield.

The attempted acid catalyzed isomerization of **25** to **5** with oxalic acid in aqueous dioxane at reflux for 12 h gave only recovered starting material (89%). However, treatment of **25** with *p*-toluenesulfonic acid hydrate in refluxing benzene for 2 h produced two isomeric ketones, in addition to a 5% recovery of starting material. The major product, obtained in 53% yield, was identical in all respects with the ketone **5** produced by decarboxylation of keto ester **28**. The second product, obtained in 15% yield, gave a molecular ion at *m/e* 220.1831 in the mass spectrum. The ir spectrum showed a band at 1699 cm^{-1} due to a seven-membered ring ketone. The ^{1}Hmr spectrum showed a vinyl proton as a multiplet at δ 5.17 and methyl groups as singlets at δ 1.60, 1.26, 0.94, and 0.75. Although the spectral data indicated that this compound was very closely related to ketones **5** and **25**, the structure could not be assigned with certainty; however, mechanistic (Scheme 1), structural, and spectroscopic considerations give weight to our tentative assignment of structure **30**, the epimer of allohimachalone (5, 6, 12), to this product.[6]

Conclusive evidence in support of the assignment of the double bond position in ketones **5** and **25** was obtained from their ^{13}Cmr spectra (Table 2). In **5**, C-9a appeared as the only high-field doublet at δ 50.2, deshielded relative to C-9a of **25** (δ 45.0) by the adjacent double bond. Also the olefinic carbon C-1 of **5** (δ 121.8) was deshielded relative to C-3 of **25** (δ 119.7) due to a β-effect from the adjacent C-9.

With the placement of the double bond in **5** and **25** clearly

[5]The sample was contaminated with ~15 ± 5% of the isomeric ketone **15**.

[6]Continued heating of the acidic reaction mixture for 22 h gave this ketone as the major product.

0.97	0.98	0.90 (0.94)[a]	0.95	0.94
0.69	0.75	0.74	0.69	0.75

[a]Although the text of the paper refers to the chemical shift of this signal as δ 0.90, the spectrum, which is illustrated in the paper, shows a shift at ~δ 0.94.

defined by the spectroscopic evidence, and with the *cis* stereochemistry of the ring junction fixed by the structure of the key intermediate, Diels–Alder adduct **14**, the assignment of structures **5** and **25** to their respective compounds was assured.

It is essential to note at this point that the spectral data (Table 3) of neither ketone **5** nor **25**, nor indeed of the tentatively identified ketone **30** were identical with those reproted by Dev (4) for naturally occurring isohimachalone. Examination of the data in Table 3 further indicated that a very close similarity existed between the ^{1}Hmr spectra of Dev's (4) isohimachalone and Teisseire's (8) *trans*-ketone **4**. This, together with the non-identity of our synthetic **5** with the naturally occurring compound, strongly suggested that the naturally occurring isohimachalone isolated by Dev (4) might be identical with the *trans*-ketone **4** isolated by Teisseire (8). Unfortunately, authentic samples of both naturally occurring ketones were no longer available[7,8] and so direct comparison of the compounds with each other and with **5** was not possible.

Experimental

General

Melting points were determined on a Kofler hot stage apparatus and are uncorrected. Elemental analyses were performed by the microanalytical laboratory of this department. The ir spectra were recorded on a Perkin–Elmer model 457 or Nicolet 7-199 FT-IR spectrophotometer and, except where otherwise stated, were obtained on solutions in chloroform. The ^{1}Hmr spectra were recorded on a Varian HA-100, HA-100/Digilab, or Bruker WH-200 spectrometer and, except where otherwise stated, were obtained on solutions in carbon tetrachloride with tetramethylsilane as internal reference. The ^{13}Cmr spectra were recorded on a Bruker WP-60/Nicolet BNC-12 system or a Bruker HFX-90/Nicolet 1085 system and were obtained on solutions in deuteriochloroform using tetramethylsilane as internal reference. Mass spectra (ms) were recorded using A.E.I. model MS9, MS12, or MS50 mass spectrometers. All gas chromatography (gc) was performed on a Hewlett–Packard 5750 research chromatograph using stainless steel columns (8 ft × ⅛ in.) packed with 10% diethylene glycol succinate on 80–100 mesh Chromosorb-W, acid washed, and treated with dimethylchlorosilane. Unless stated otherwise, anhydrous magnesium sulfate was used for drying organic solutions.

Materials

Benzene was distilled over lithium aluminum hydride. Pyridine was distilled over barium oxide and stored over potassium hydroxide pellets. Boron trifluoride etherate was distilled over calcium hydride according to the procedure of Zweifel and Brown (34, 35). Nitrogen was passed through a purification train of Fieser's solution (35), saturated aqueous lead acetate, concentrated sulfuric acid, and potassium hydroxide pellets. Starting ketone **14** was prepared according to the procedure previously reported by this group (1). All products and raw materials used are racemic where applicable.

8aβ-Carbomethoxy-1,1-ethylenedioxo-4,4,6-trimethyl-1,2,3,4,4aβ,-5,8,8a-octahydronaphthalene (17)

Ketone **14** (1.01 g, 4.02 mmol) was dissolved in dry benzene (50 mL), and ethylene glycol (2.78 g, 45 mmol) and *p*-toluenesulfonic acid monohydrate (10 mg, 0.053 mmol) were added. The reaction flask was fitted with a Dean–Stark water separator with type 3 Å molecular sieve in the take-off arm. The reaction mixture was heated at reflux for 47 h, then cooled to room temperature. Saturated aqueous sodium bicarbonate (2 mL) was added and the resulting mixture was extracted with methylene chloride. The extracts were washed with water, dried,

filtered, and concentrated. Column chromatography of the residue on silica gel, eluting with 7–30% ether in petroleum ether, gave ketal **17** (1.09 g, 93% yield); ir: 1728 (C=O), 1386, 1368 (CH_3), and 794 (C=CH) cm^{-1}; ^{1}Hmr δ: 5.20 (dm, 1H, J = 5 Hz, =CH—), 3.73 (m, 4H, —O—CH_2—CH_2—O—), 3.54 (s, 3H, —O—CH_3), 2.81 (dd, 1H, J = 17, J' = 5 Hz, C-8 H_β), 1.56 (s, 3H, =C—CH_3), 0.96 (s, 3H, —CH_3), and 0.80 (s, 3H, —CH_3); ^{13}Cmr δ: 174.1, 133.3, 118.7, 111.5, 64.7, 64.5, 53.6, 52.0, 41.2, 37.6, 33.2, 32.9, 29.3, 28.9, 28.6, 23.5, and 21.3; ms M^+: 294.1833 (calcd. for $C_{17}H_{26}O_4$: 294.1830). *Anal.* calcd. for $C_{17}H_{26}O_4$: C 69.36, H 8.90; found: C 69.13, H 9.01.

Deketalization of ketal 17

Ketal **17** (28 mg, 0.095 mmol) was dissolved in acetone (2 mL) and *p*-toluenesulfonic acid hydrate (2.0 mg, 0.011 mol) was added. After stirring for 14 days the mixture was diluted with water and extracted with methylene chloride. The extracts were washed with water, dried, filtered, and concentrated. Column chromatography of the residue on silica gel, eluting with 1% ether in petroleum ether, gave keto ester **14** (14 mg, 59% yield, 100% based on consumption of 54% of starting ketal **17**). Further elution with 1–5% ether in petroleum ether gave recovered ketal **17** (13 mg, 46% recovery).

*1,1-Ethylenedioxo-8aβ-hydroxymethyl-4,4,6-trimethyl-1,2,3,4,4aβ,-5,8,8a-octahydronaphthalene (**19**)*

Ketal **17** (954 mg, 3.24 mmol) was dissolved in anhydrous ether (50 mL) and lithium aluminum hydride (369 mg, 9.71 mmol) was added. After 4.5 h the mixture was cooled to 0°C and water (5 mL) was added dropwise. The resulting mixture was extracted with methylene chloride and the extracts were washed with water, dried, filtered, and concentrated. Column chromatography of the residue on silica gel, eluting with 10–15% ether in petroleum ether, gave recovered ketal **17** (75 mg, 9% recovery). Further elution with 15–50% ether in petroleum ether gave alcohol **19** (721 mg, 84% yield, 92% based on consumption of 91% of the starting material), which crystallized on standing. Three recrystallizations from petroleum ether gave white crystals of pure alcohol **19**, the melting point of which did not change on further recrystallization; mp 109–112°C; ir 3546 (—OH), 1390, 1380, 1366 (CH_3), and 790 (C=CH) cm^{-1}; ^{1}Hmr δ: 5.14 (br s, 1H, —CH=), 3.95 (s, 4H, —O—CH_2—CH_2—O—), 3.51 (dd, 1H, J = 11, J' = 2 Hz, HO—C*H*), 3.10 (dd, 1H, J = J' = 11 Hz, HO—C*H*), 2.42 (dd, 1H, J = 11, J' = 2 Hz, —OH), 1.62 (br s, 3H, =C—CH_3), 0.97 (s, 3H, —CH_3), and 0.83 (s, 3H, —CH_3); ^{13}Cmr δ: 133.0, 118.2, 115.2, 64.9, 64.3, 63.8, 43.0, 39.1, 38.1, 33.5, 32.9, 29.1, 27.9, 26.7, 32.5, and 22.1; ms M^+: 266.1886 (calcd. for $C_{16}H_{26}O_3$: 266.1882). *Anal.* calcd. for $C_{16}H_{26}O_3$: C 72.14, H 9.84; found: C 71.85, H 9.85. After exchanging the ^{1}Hmr sample with D_2O, the following changes were observed in the ^{1}Hmr spectrum: δ 3.51 (d, 1H, J = 11 Hz, DO—C*H*), 3.10 (d, 1H, J = 11 Hz, DO—C*H*), and the disappearance of the signal at δ 2.42.

*1,1-Ethylenedioxo-8aβ-(N,N,N′,N′-tetramethylphosphorodiamidyl-oxymethyl)-4,4,6-trimethyl-1,2,3,4,4aβ,5,8,8a-octahydronaphthalene (**22**)*

Alcohol **19** (515 mg, 1.94 mmol) was dissolved in a 20% solution of *N,N,N′,N′*-tetramethylethylenediamine (distilled over sodium) in 1,2-dimethoxyethane (freshly distilled over lithium aluminum hydride) (19.4 mL of solution) under an atmosphere of nitrogen. The resulting solution was cooled to 0°C and a 1.99 *N* solution of *n*-butyllithium in hexane (1.47 mL, 2.92 mmol) was added dropwise with stirring over 5 min. The mixture was allowed to warm to room temperature over 10 min, then *N,N*-dimethylphosphoramidic dichloride (26) was added. After 23 h the mixture was cooled to 0°C and dimethylamine gas was passed through a potassium hydroxide drying tube and condensed (60 drops, ~3 mL) into the reaction mixture. After 30 min the resulting mixture was poured into ice-cold water and extracted with ether. The extracts were washed with water until the washings were neutral to pH paper, dried, filtered, and concentrated. Column chromatography of the residue on silica gel, eluting with 5–20% methanol in ether, gave TMPDA derivative **22** (652 mg, 84% yield), which crystallized on standing. One recrystallization from ether gave colourless rhombic crystals of pure TMPDA derivative **22** (330 mg); mp 100–102°C; ir 1383, 1372, 1359 (CH_3), 1296 (P=O) cm^{-1}; ^{1}Hmr δ: 5.20 (br s, 1H, =CH—), 4.18–3.73 (complex, total 5H, —O—CH_2—CH_2—O— and *H*—CH—O—), 3.39 (dd, 1H, J = 11, J' = 4 Hz, *H*—CH—O—), 2.57, 2.55 (both d, total 12H, each J = 10 Hz, 2× —$N(CH_3)_2$), 1.64 (br s, 3H, =C—CH_3), 0.93 (s, 3H, —CH_3), and 0.81 (s, 3H, —CH_3); ms M^+: 400.2487 (calcd. for $C_{20}H_{37}N_2O_4P$: 400.2491). *Anal.* calcd. for $C_{20}H_{37}N_2O_4P$: C 59.98, H 9.31, N 6.99; found: C 59.89, H 9.48, N 6.77.

*1,1-Ethylenedioxo-4,4,6-8aβ-tetramethyl-1,2,3,4,4aβ,5,8,8a-octahydronaphthalene (**20**)*

Ethylamine (400 mL) was distilled from lithium into a reaction vessel under an atmosphere of argon. Small pieces of lithium ribbon (2.74 g, 392 g-atom) were added and the mixture was stirred for 1 h to effect solution. Then a solution of TMPDA derivative **22** (15.7 g, 39.2 mmol) and *tert*-butyl alcohol (5.80 g, 78.4 mmol, dried over type 3 Å molecular sieves) in tetrahydrofuran (270 mL, freshly distilled over lithium aluminum hydride) was added dropwise over 1 h with stirring. After an additional 40 min water was added slowly to discharge the blue colour and the reaction mixture was poured into ice-cold water. The resulting mixture was extracted with ether and the extracts were washed with ice-cold water until the washings were neutral. The extracts were then dried, filtered, and concentrated. Column chromatography of the residue on silica gel, eluting with 2% ether in petroleum ether, gave ketal **20** (6.75 g, 69% yield), which crystallized on standing. One recrystallization from petroleum ether gave colourless rhombs of pure ketal **20**; mp 28–30°C; ir: 1388, 1371, 1363 (CH_3) and 780 (C=CH) cm^{-1}; ^{1}Hmr δ: 5.22 (br s, 1H, =CH—), 3.86 (s, 4H, —O—CH_2—CH_2—O—), 1.62 (br s, 3H, =C—CH_3), 0.88 (s, 3H, —CH_3), 0.83 (s, 3H, —CH_3), and 0.76 (s, 3H, —CH_3); ms M^+: 250.1930 (calcd. for $C_{16}H_{26}O_2$: 250.1933). *Anal.* calcd. for $C_{16}H_{26}O_2$: C 76.75, H 10.47; found: C 76.82, H 10.56. Further elution with 2–5% ether in petroleum ether gave *trans*-ketone **23** (354 mg, 5% yield) and further elution with 5–100% ether in petroleum ether gave alcohol **19** (1.42 g, 14% yield).

*4,4,6,8aβ-Tetramethyl-3,4,4aβ,5,8,8a-hexahydro-1(2H)-naphthalenone (**15**)*

Ketal **20** (265 mg, 1.06 mmol) was dissolved in acetone (20 mL) and *p*-toluenesulfonic acid monohydrate (110 mg, 0.58 mmol) was added. The resulting mixture was stirred for 2.5 h and then diluted with methylene chloride. The resulting solution was washed with saturated aqueous sodium bicarbonate and water, dried, filtered, and concentrated. Column chromatography on silica gel, eluting with 2–8% ether in petroleum ether, gave pure ketone **15** (211 mg, 97% yield); ir: 1706 (C=O), 1390, 1375 (CH_3), 820 and 790 (C=CH) cm^{-1}; ^{1}Hmr δ: 5.27 (m, 1H, =CH—), 2.68 (ddd, 1H, J = 15, J' = 12, J'' = 8 Hz, —CO—CH_α), 2.08 (ddd, 1H, J = 15, J' = J'' = 4 Hz, —CO—CH_β), 1.65 (s, 3H, =C—CH_3), 1.02 (s, 3H, —CH_3), and 0.95 (s, 6H, 2× —CH_3); ^{13}Cmr δ: 216.2, 132.1, 117.7, 48.9, 46.4, 40.7, 34.9, 33.7, 32.2, 28.0, 23.6, 23.2, and 21.0; ms M^+: 206.1671 (calcd. for $C_{14}H_{22}O$: 206.1671). *Anal.* calcd. for $C_{14}H_{22}O$: C 81.50, H 10.75; found: C 81.77, H 10.74.

*4,4,6,8aβ-Tetramethyl-3,4,4aβ,7,8,8a-hexahydro-1(2H)-naphthalenone (**24**)*

Ketone **15** (758 mg, 3.68 mmol) was dissolved in benzene (50 mL) under an atmosphere of nitrogen, and *p*-toluenesulfonic acid hydrate (350 mg, 1.84 mmol) was added. The mixture was heated to reflux with

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 190.90.36.8 on 09/07/12
For personal use only.

stirring for 2 h and then cooled to room temperature, diluted with water, and extracted with methylene chloride. The extracts were washed with saturated aqueous sodium bicarbonate and water, dried, filtered, and concentrated. Column chromatography of the residue on silica gel, eluting with 2–4% ether in petroleum ether, gave a mixture of ketones **24** and **15** (85:15 by gc analysis, 67.5 mg, 89% yield). The ^{1}Hmr and ^{13}Cmr spectra of this mixture showed the following signals, which were attributed to ketone **24**: ^{1}Hmr δ: 5.40 (m, 1H, =CH—), 1.71 (s, 3H, =C(CH$_3$)—), 1.04 (s, 3H, —CH$_3$), 0.97 (s, 3H, —CH$_3$), and 0.94 (s, 3H, —CH$_3$); ^{13}Cmr δ: 217.3, 133.7, 120.5, 52.3, 46.0, 38.5, 35.1, 34.0, 29.3, 26.2, 23.8, 23.1, and 22.8. The following spectra were also recorded: ir: 1703 (C=O), 1384, 1374, 1362 (CH$_3$) cm^{-1}; ms M$^+$: 206.1672 (calcd. for $C_{14}H_{22}O$: 206.1670). *Anal.* calcd. for $C_{14}H_{22}O$: C 81.50, H 10.75; found: C 81.48, H 10.95.

*6-Carboethoxy-2,4aβ,9,9-tetramethyl-3,4,4a,6,7,8,9,9aβ-octahydro(5*H*)-benzocyclohepten-5-one (28)*

Ketone **24**[9] (42 mg, 0.20 mmol) was dissolved in ether (4 mL) in a flask wrapped in aluminum foil to exclude light. Boron trifluoride etherate (145 mg, 1.02 mmol) was added, followed by ethyl diazoacetate (107 μL, 116 mg, 1.02 mmol). After stirring for 4 days, additional boron trifluoride etherate (145 mg, 1.02 mmol) and ethyl diazoacetate (116 mg, 1.02 mmol) were added. After further 3 days, saturated aqueous sodium bicarbonate (1 mL) was added and the resulting mixture was extracted with methylene chloride. The extracts were washed with water, dried, filtered, and concentrated. Column chromatography of the residue on silica gel, eluting with 2% ether in petroleum ether, gave ketone **24** (3 mg, 7% recovery). Continued elution gave keto ester **28** (12 mg, 20% yield, 21% based on recovered ketone **24**); ir: 1748 (ester C=O), 1706 (ketone C=O), 1389 and 1367 (CH$_3$) cm^{-1}; ^{1}H nmr δ: 5.32 (d, 1H, J = 5 Hz, =CH—), 4.09, 4.07 (both q, total 2H, both J = 7 Hz, —O—C*H*$_2$—CH$_3$), 3.92 (dd, 1H, J = 12, J' = 4 Hz, —CO—CH(—CO$_2$—)), 1.71 (br s, 3H, =C(CH$_3$)—), 1.21 (dd, 3H, $J = J'$ = 7 Hz, —O—CH$_2$—C*H*$_3$), 1.09 (s, 3H, —CH$_3$), 0.97 (s, 3H, —CH$_3$), and 0.67 (s, 3H, —CH$_3$); ms M$^+$: 292.2031 (calcd. for $C_{18}H_{28}O_3$: 292.2039). Continued elution gave keto ester **29** (11 mg, 19% yield, 20% based on recovered ketone **24**).

Lithium iodide dihydrate – collidine reagent

Finely divided anhydrous lithium iodide (514 mg, 3.84 mmol) was suspended in 2,4,6-collidine (3.05 mL) with vigorous stirring. Water (138 μL, 138 mg, 7.68 mmol) was added and the suspension rapidly dissolved. The resulting pale yellow solution had a calculated concentration of 1.28 *N* in lithium iodide dihydrate. The reagent was prepared fresh for each use.

*2,4aβ,9,9-Tetramethyl-3,4,4a,6,7,8,9,9aβ-octahydro-(5*H*)-benzocyclohepten-5-one (5) via keto ester 28*

Keto ester **28** (23 mg, 0.078 mmol) was dissolved in lithium iodide dihydrate – collidine reagent (244 μL, 0.312 mmol) and heated to reflux. After 45 min, the mixture was cooled to room temperature, poured into cold aqueous 5% hydrochloric acid, and extracted with ether. The extracts were washed with 5% hydrochloric acid and water, dried, filtered, and concentrated. Column chromatography of the residue on silica gel, eluting with 1% ether in petroleum ether, gave ketone **5** (1.4 mg, 10% yield based on recovered **28**). Further elution with 2–5% ether in petroleum ether gave keto ester **28** (5.4 mg, 23% recovery).

*6-Carboethoxy-2,4aβ,9,9-tetramethyl-1,4,4a,6,7,8,9,9aβ-octahydro-(5*H*)-benzocyclohepten-5-one (29)*

Ketone **15** (178 mg, 0.86 mmol) was dissolved in anhydrous ether (5 mL) in a flask wrapped in aluminum foil to exclude light. Boron trifluoride etherate (491 mg, 3.46 mmol) was added, followed by ethyl diazoacetate (394 mg, 3.46 mmol). After stirring for 48 h, the reaction mixture was cooled to 0°C and saturated aqueous sodium bicarbonate (2 mL) was added. The resulting mixture was extracted with methylene chloride and the extracts were washed with water, dried, filtered, and concentrated. Column chromatography of the residue on silica gel, eluting with 3–5% ether in petroleum ether, gave keto ester **29**[10] (205 mg, 82% yield), which crystallized on standing. One recrystallization from ether gave white crystals of pure keto ester **29**; mp 76–78°C; ir 1750 (ester C=O), 1700 (ketone C=O), 1392, 1364 (CH$_3$), 791 (C=CH) cm^{-1}; ^{1}Hmr δ: 5.34 (br s, 1H, =CH—), 4.11, 4.08 (both q, total 2H, both J = 7 Hz, —O—CH$_2$—), 3.86 (dd, 1H, $J = J'$ = 10 Hz, —CO—CH(—CO$_2$), 2.10 (br s, 4H, 2× =C—CH$_2$—), 1.66 (s, 3H, =C(CH$_3$)—), 1.22 (dd, 3H, $J = J'$ = 7 Hz, —O—CH$_2$—C*H*$_3$), 1.09 (s, 3H, —CH$_3$), 0.98 (s, 3H, —CH$_3$), and 0.71 (s, 3H, —CH$_3$); ^{1}Hmr ($CDCl_3$) δ: 5.35 (br s, 1H, =CH—), 4.20, 4.19 (both q, total 2H, both J = 7 Hz, —O—CH$_2$—), 4.14 (dd, 1H, $J = J'$ = 10 Hz, —CO—CH(—CO$_2$—)), 2.20 (br s, 4H, 2× =C—CH$_2$—), 1.68 (s, 3H, =C(CH$_3$)—), 1.24 (dd, 3H, J = 7 Hz, —O—CH$_2$—C*H*$_3$), 1.15 (s, 3H, —CH$_3$), 0.99 (s, 3H, —CH$_3$), and 0.72 (s, 3H, —CH$_3$); ^{13}Cmr δ: 212.1, 170.8, 132.0, 119.2, 61.0, 50.3, 49.5, 44.7, 37.3, 37.1, 29.6, 29.3 (two carbons), 26.0, 25.9, 23.1, 20.8, and 14.1; ms M$^+$: 292.2037 (calcd. for $C_{18}H_{28}O_3$: 292.2038). *Anal.* calcd. for $C_{18}H_{28}O_3$: C 73.93, H 9.65; found: C 73.75, H 9.61.

*2,4aβ,9,9-Tetramethyl-1,4,4a,6,7,8,9,9aβ-octahydro-(5*H*)-benzocyclohepten-5-one (25)*

Keto ester **29** (166 mg, 0.57 mmol) was dissolved in 2,4,6-collidine (1.8 mL) under an atmosphere of nitrogen. Lithium iodide (304 mg, 2.27 mmol) and water (82 μL, 4.54 mmol) were added and the mixture was heated to reflux with stirring for 2 h. The reaction mixture was then cooled to room temperature, poured into cold aqueous 5% hydrochloric acid, and extracted with ether. The extracts were washed with aqueous 5% hydrochloric acid and water, dried, filtered, and concentrated. Column chromatography of the residue on silica gel, eluting with 2–3% ether in petroleum ether, gave ketone **25** (108 mg, 86% yield), which crystallized on standing. One recrystallization from petroleum ether gave white clusters of pure ketone **25** (63 mg); mp 53–56°C; ir: 1701 (C=O), 1387, 1372, 1362 (CH$_3$), and 838 (C=CH) cm^{-1}; ^{1}Hmr δ: 5.30 (br s, 1H, =CH—), 2.84 (ddd, 1H, J = 11, J' = J'' = 9 Hz, —CO—CH*H*), 1.63 (br s, 3H, =C(CH$_3$)—), 0.97 (s, 3H, —CH$_3$), 0.95 (s, 3H, —CH$_3$), and 0.69 (s, 3H, —CH$_3$); ^{13}Cmr δ: 217.8, 132.1, 119.7, 49.1, 45.0, 38.2, 37.5, 35.04, 30.1, 29.6, 29.5, 26.6, 26.1, 23.1, and 18.1; ms M$^+$: 220.1829 (calcd. for $C_{15}H_{20}O$: 220.1827). *Anal.* calcd. for $C_{15}H_{20}O$: C 81.76, H 10.98; found: C 81.63, H 10.87.

*2,4aβ,9,9-Tetramethyl-3,4,4a,6,7,8,9,9aβ-octahydro-(5*H*)-benzocyclohepten-5-one (5) via ketone 25*

Ketone **25** (20 mg, 0.09 mmol) was dissolved in dry benzene (5 mL) under an atmosphere of nitrogen. *p*-Toluenesulfonic acid hydrate was added and the mixture was heated to reflux for 2 h. The reaction mixture was then cooled to room temperature, poured into water, and extracted with ether. The extracts were washed with water, dried, filtered, and concentrated. Column chromatography of the residue on silica gel, eluting with 0.5% ether in petroleum ether, gave a ketone (3 mg, 15% yield) to which structure **30** was tentatively assigned. The compound showed the following spectroscopic data: ir 1699 (C=O), 1384, 1377 and 1364 (CH$_3$) cm^{-1}; ^{1}Hmr δ: 5.17 (m, 1H, =CH—), 1.60 (s, 3H, =C(CH$_3$)—), 1.26 (s, 3H, —CH$_3$), 0.94 (s, 3H, —CH$_3$), and 0.75

[9]This material was contaminated with ~15% of the isomeric ketone **15**.

[10]This material required 24 h under vacuum (0.5 Torr) to remove an impurity which is thought to be ethyl glycolate on the basis of the ^{1}Hmr spectrum of the mixture.

A simple and efficient synthesis of 5′-($^2H_3$)olivetol

MICHEL GIRARD,[1a,2] DAVID B. MOIR,[1b] AND JOHN W. APSIMON[2]

Ottawa–Carleton Chemistry Institute, Department of Chemistry, Carleton University, Ottawa, Ont., Canada K1S 5B6

Received May 28, 1986

This paper is dedicated to Dr. O. E. (Ted) Edwards

MICHEL GIRARD, DAVID B. MOIR, and JOHN W. APSIMON. Can. J. Chem. **65**, 189 (1987).

The title compound **1** was prepared in 13% overall yield starting from the commercially available and inexpensive 3,5-dimethoxybenzoic acid (**4**). The *n*-pentyl side chain was elaborated from cross-coupling reactions between halides.

MICHEL GIRARD, DAVID B. MOIR et JOHN W. APSIMON. Can. J. Chem. **65**, 189 (1987).

On rapporte la synthèse du composé **1** à partir de l'acide diméthoxy-3,5-benzoïque (**4**) commercial. L'élaboration de la chaîne *n*-pentyle se fait par deux réactions de couplages croisés d'halogénures.

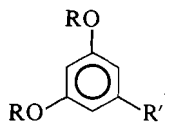
For personal use only.

In the course of studies directed towards the synthesis of isotopically substituted cannabinoid standards (for a recent review on cannabinoid synthesis, see ref. 1) we required the preparation of 5′-($^2H_3$)olivetol (**1**). The unlabelled parent compound olivetol (**2**) is generally best prepared by the method of Focella *et al.* (2) (Scheme 1). We reasoned, however, that the applicability of this method for the preparation of **1** suffers from two serious disadvantages: first, the lack of an easy access to the suitably labelled starting material (i.e., hexanal), and secondly, the high cost associated with the introduction of the label in the early stages of the synthetic scheme. Similarly, the only previous synthesis of **1**, reported by Pitt *et al.* (3), uses the relatively expensive 3,5-dimethoxybenzaldehyde (**3**) as starting

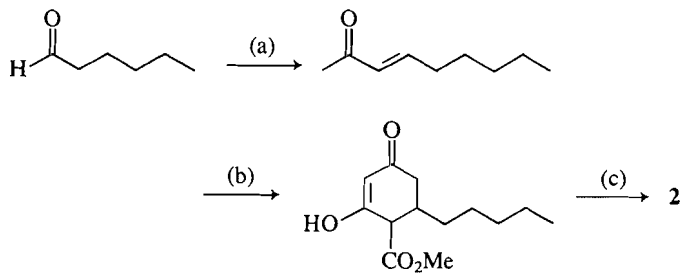


1 R = H, R′ = $(CH_2)_4C^2H_3$
2 R = H, R′ = $(CH_2)_4CH_3$
3 R = CH_3, R′ = CHO

compound. We have therefore devised an efficient synthesis of **1** that makes use of relatively inexpensive starting material and labelling agent and that allows for the introduction of the label in the penultimate step of the synthetic scheme.

We wish to report here the preparation of **1** by a stepwise elaboration of the labelled *n*-pentyl side chain starting from the commercially available 3,5-dimethoxybenzoic acid (**4**) (Scheme 2). Our approach relies on the use of two cross-coupling reactions between alkyl halides and Grignard reagents (for an overview, see ref. 4) to provide the side chain.

The starting acid **4** was first converted to bromide **5** by successive hydride reduction and nucleophilic displacement using phosphorus tribromide. A first cross-coupling reaction was then used to achieve a three-carbon unit chain extension by reacting bromide **5** with allyl magnesium bromide. The best yields of olefin **6** were obtained by using a 1:2 molar ratio of **4** to Grignard reagent. Hydroboration–oxidation at the terminal carbon of olefin **6**, followed by nucleophilic displacement according to the recently reported method of Olah *et al.* (5),



(a) NaOH, acetone; (b) NaOMe, $CH_2(CO_2Me)_2$; (c) Br_2, DMF

SCHEME 1

afforded bromide **7** in good yield. The label was then introduced by means of a second cross-coupling reaction between bromide **7** and deuterated methyl magnesium iodide in the presence of dilithium tetrachlorocuprate as catalyst (6). The labelled dimethoxyolivetol **8** thus obtained was demethylated using trimethylsilyliodide (7) to afford the title compound **1** in 13% overall yield.

Experimental

The ^1H and ^{13}C nmr spectra were recorded on a Varian XL-200 spectrometer. Deuterated chloroform ($CDCl_3$) was used as the standard solvent and tetramethylsilane (TMS) as an internal reference. All chemical shifts are expressed in ppm downfield from TMS. Infrared spectra were measured on a Perkin–Elmer 237-B grating infrared spectrophotometer. Mass spectra were obtained on a VG-7070E instrument.

All reactions were routinely monitored by analytical thin-layer chromatography (tlc) on precoated silica gel plates (Merck-60 PF-254). Silica gel (Davison Chemical Co., grade 923, 100–200 mesh) was used for column chromatography. High-performance liquid chromatography (hplc) was performed using a Waters Prep-500 high performance liquid chromatograph.

Dry solvents were obtained by distillation over lithium aluminum hydride (DME and THF) or sodium (ether and benzene).

3,5-Dimethoxybenzyl bromide (5)

To a suspension of lithium aluminum hydride (3.8 g, 0.10 mol) in 100 mL of anhydrous ether was added acid **3** (18.2 g, 0.10 mol) dissolved in 60 mL of ether at such a rate that a gentle reflux was maintained. The reaction was stirred for 16 h at room temperature, then worked up by the slow addition of 5 mL of water, 5 mL of 15% aqueous NaOH, and a further 15 mL of water. The suspension was filtered through a pad of Celite, which was washed with ether. The combined ether washings were concentrated under reduced pressure and the residual oil was immediately dissolved in 50 mL of anhydrous dichloromethane. After cooling the mixture to 0°C, phosphorus tribromide (27.1 g, 0.10 mol) was added dropwise and the reaction was allowed to warm to room temperature, then stirred for 1 h. The mixture

(a) LAH, ether; (b) PBr_3, CH_2Cl_2; (c) $H_2C{=}CHCH_2MgBr$, ether; (d) $BH_3{\cdot}Me_2S$, then $H_2O_2/NaOH$; (e) TMSCl, LiBr, MeCN; (f) $^2H_3CMgI$, Li_2CuCl_4, THF; (g) TMSI, $CHCl_3$

SCHEME 2

was poured into ice-water and the organic layer was collected. The aqueous phase was extracted with dichloromethane (75 mL) and the combined organic phases were washed with water (100 mL), saturated $NaHCO_3$ (100 mL), and saturated NaCl (100 mL), then dried over magnesium sulfate. Concentration gave 22 g (78%) of bromide **5** as a colorless solid; ^1H nmr: 3.8 (6H, s, OMe), 4.3 (2H, s, benzylic), 6.2–6.6 (3H, m, aromatic).

4-(3,5-Dimethoxyphenyl)-1-butene (6)

To a cooled solution of allyl magnesium bromide (286 mL of 1 *M* ether solution, 0.286 mol) was added dropwise bromide **5** (33.0 g, 0.14 mol) in ether (200 mL). The reaction was allowed to warm to room temperature and then stirred for 30 h. The reaction mixture was quenched by addition of a saturated ammonium chloride solution, followed by water (250 mL). The organic layer was separated and the aqueous layer was extracted with ether (200 mL). The resulting emulsion was passed through glass wool and the organic layers were combined and dried over magnesium sulfate. Solvent evaporation and purification by hplc (10% ethyl acetate in hexane) afforded olefin **6** (22.0 g, 80%); ir (neat): 1640 (C=C); 920 (C=CH_2) cm^{-1}; ^1H nmr: 2.2–2.8 (4H, m, CH_2's), 3.75 (6H, s, OMe), 4.8–5.3 and 5.5–6.1 (3H, m, CH=CH_2), 6.35 (3H, s, aromatics); ms *m/e* (relative intensity): 192 (M^+, 62), 177 (15), 151 (100). High resolution ms: M^+ calcd. for $C_{12}H_{16}O_2$: 192.1150; found: 192.1157.

4-(3,5-Dimethoxyphenyl)-1-bromobutane (7)

Olefin **6** (20.0 g, 0.104 mol) was dissolved in dichloromethane (35 mL) and cooled to 0°C. Borane–dimethyl sulfide complex (3.8 mL of 10.2 *M* BH_3, 38 mmol) was then added dropwise. The temperature was maintained at 0°C for 25 min, then allowed to rise to room temperature. The reaction was stirred for 3 h, then concentrated under reduced pressure. Dichloromethane (35 mL) and ethanol (35 mL) were added, followed by 12.8 mL of 3 *N* NaOH (38.5 mmol). The mixture was cooled to 0°C and an equivalent volume of 30% aqueous hydrogen peroxide was added. The reaction was refluxed for 1 h, cooled, and poured into 500 mL of ice-water. The mixture was extracted with ether (3 × 100 mL) and the combined organics were washed with water (200 mL) and brine (200 mL) and dried over magnesium sulfate. Concentration and purification by hplc afforded 14.2 g (65%) of 4-(3,5-dimethoxyphenyl)-1-butanol as an oil; ^1H nmr: 1.3–2.0 (4H, br m, CH_2's), 2.55 (2H, t, benzylic), 3.75 (6H, s, OMe), 3.5–3.7 (2H, m, CH_2OH), 6.3 (3H, br s, aromatics).

Lithium bromide (8.30 g, 0.095 mol) was suspended in 250 mL of acetonitrile. Trimethylsilyl chloride (12.93 g, 0.119 mol) was added, followed by the addition of a solution of the previously prepared alcohol (10.00 g, 0.048 mol) in acetonitrile (120 mL). The reaction was refluxed for 12 h. The solution was then poured into ice-water and extracted with ether (3 × 200 mL). The combined organic phases were washed with saturated sodium bicarbonate solution, then with brine, and dried over anhydrous magnesium sulfate. Purification by flash chromatography afforded 8.5 g of pure title compound (70% yield); ^1H nmr: 1.7–2.0 (4H, br m, CH_2's), 2.6 (2H, t, benzylics), 3.55 (2H, t, CH_2Br), 3.80 (6H, s, OMe), 6.4 (3H, br s, aromatics).

5'-($^2H_3$)-Olivetol dimethyl ether (8)

Bromide **7** (11.00 g, 0.040 mol) was dissolved in dry THF (30 mL) and cooled to 0°C. The Grignard reagent, prepared by the addition of ($^2H_3$)-iodomethane (7.60 g, 0.052 mol, MSD Isotopes >99.5%) in dry ether (15 mL) to magnesium (1.37 g, 0.056 mol) in ether (10 mL), was then added dropwise to the bromide **7** solution via stainless steel cannula. Li_2CuCl_4 (2.02 mL of a 0.1 *M* solution in THF, 0.2 mmol) (6) was added with a syringe. The reaction was allowed to warm to room temperature and stirred for 16 h. Sulfuric acid (1.8 *M*) was added slowly until all the precipitate had dissolved. The mixture was extracted with ether (3 × 150 mL). The combined organic layers were washed with saturated sodium bicarbonate solution, then with brine, and dried over $MgSO_4$. Concentration and purification by hplc (5% ethyl acetate in hexane) provided 6.55 g (60%) of the title compound as a viscous oil; bp 79–82°C (0.05 Torr; 1 Torr = 133.3 Pa); ^1H nmr: 2.3–2.6 (2H, t, benzylics), 3.8 (6H, s, OMe), 6.3 (3H, s, arom.); ^{13}C nmr: 14–15 ppm (septuplet, C^2H_3), 22.3, 31.05, 31.5, 36.3, 55.2 (OMe), 97.5, 106.5, 145.4, 160.7; ms *m/e* (relative intensity): 211 (M^+, 30), 192 (2.5), 169 (12), 165 (10), 152 (100). High resolution ms: M^+ calcd. for $C_{13}H_{17}{}^2H_3O_2$: 211.1665; found: 211.1671. The percentage of incorporation was determined by mass spectrometry and was found to be: $^2H_3$ = 98.7%; $^2H_2$ = 0.1%; $^2H_1$ = 0.1%; $^2H_0$ = 1.1%.

5'-($^2H_3$)-Olivetol (1)

The labelled dimethyl ether **8** (6.55 g, 0.031 mol) was dissolved in chloroform (30 mL) and treated with trimethylsilyl iodide (18.60 g, 0.093 mol). The mixture was heated to 40°C until no more starting material was detected by tlc (48 h). The reaction was cooled, poured into 150 mL of methanol, and evaporated *in vacuo*. Ether (100 mL) was added and the solution was washed with aqueous sodium bisulfite (100 mL), sodium bicarbonate, brine, and dried over magnesium sulfate. Concentration under reduced pressure and purification afforded the title compound (4.25 g, 75%); mp 38–39°C; ir ($CDCl_3$): 3400 (OH) cm^{-1}; ^1H nmr: 2.55 (2H, t, benzylics), 6.4 (3H, br s, arom.).

This paper is dedicated to Dr. O. E. (Ted) Edwards

MICHEL GIRARD, JOHN W. APSIMON, and CAROL P. HUBER. Can. J. Chem. **65**, 191 (1987).

Treatment of cyano-triketone **1** with bases such as ethoxide or methoxide ions affords the tetracyclic lactam **4** in high yield. Its formation can be rationalized by invoking a novel intramolecular rearrangement. Crystals of **4** are orthorhombic, $a = 10.351(3)$, $b = 11.503(2)$, $c = 11.935$ (2) Å, $Z = 4$, space group $P2_12_12_1$, $R = 0.043$ for 2037 observations. The structure analysis establishes the formation of a γ-lactam, with the lactam ring bridging a six-membered ring. The three six-membered rings are in chair conformations with some distortions, and the lactam ring is envelope shaped.

MICHEL GIRARD, JOHN W. APSIMON et CAROL P. HUBER. Can. J. Chem. **65**, 191 (1987).

La cyano-tricétone **1** conduit à la lactame tétracyclique **4** en présence d'un excès de bases comme l'éthylate ou le méthylate de sodium. On peut expliquer cette transformation par une transposition intramoléculaire inédite. Le composé **4** cristallise dans le système orthorhombique avec des dimensions de maille $a = 10{,}351(3)$, $b = 11{,}503(2)$, $c = 11{,}935(2)$ Å, $Z = 4$, et le groupe spatial $P2_12_12_1$. La valeur de R est 0,043 pour 2037 réflexions. L'analyse par diffraction de rayons-X confirme la présence d'une γ-lactame pontée. Chacun des trois cycles à six membres existe dans la conformation «chaise» avec une distortion variable et le cycle γ-lactame possède la forme d'une enveloppe.

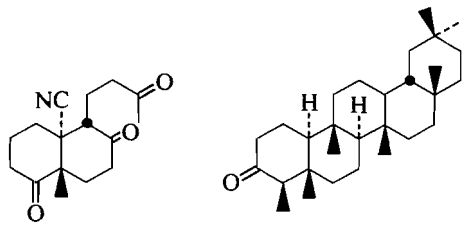
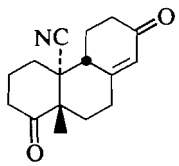
Since the pioneering work of Ireland *et al.* (1), the use of nitrile groups as precursors of angular methyl substituents has become common practice in the field of pentacyclic triterpene synthesis (for a recent review, see ref. 2). Our interest in that field led us to prepare the bicyclic cyano-triketone **1** as a key intermediate in a new approach to the naturally occurring friedelin **2**.[4] After several unsuccessful attempts at modifying (i.e., reducing, hydrolysing, ...) the nitrile functionality in suitably protected derivatives of **1**, we attempted a base-catalyzed aldol condensation on **1** to obtain the tricyclic enone **3**



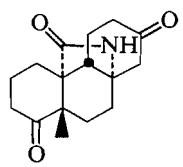
1

2



3

with the hope that the latter would prove a better substrate for reduction of the nitrile. Treatment of triketone **1** with an excess of sodium ethoxide in anhydrous ethanol afforded a single crystalline compound, which was tentatively identified as lactam **4** on the basis of spectroscopic properties, the most significant being the absence of the characteristic nitrile absorption band around 2200 cm^{-1} in the ir spectrum of the product. The presence of the lactam was revealed in the ^{13}C nmr spectrum by a resonance at 177.9 ppm. The structure was established by a single-crystal X-ray diffraction experiment.



4

X-ray structural studies

Figure 1 shows a view of the molecule with the numbering scheme. Final atomic coordinates are listed in Table 1, and bond lengths and angles are given in Fig. 2.

Compounds having a γ-lactam ring bridging a six-membered ring[5] have seldom been subjected to X-ray structure analysis. A search of the Cambridge Structural Database (3) (January 1986 release with 50 499 entries) found only three other compounds with such a feature (4–6), one of which (6) is *N*-substituted and therefore excluded from further discussion. The bond lengths and angles for the lactam moiety of the title compound agree well with the corresponding values in the two unsubstituted structures.

Nørskov-Lauritsen *et al.* (7) have compiled average bond lengths and angles for various lactams and lactones. Agreement of the pertinent values in the present structure with corresponding average values that they give for 41 γ-lactams is within 2.5 σ, but the e.s.d.'s associated with the averages are relatively large. The largest difference, perhaps due to the bridging

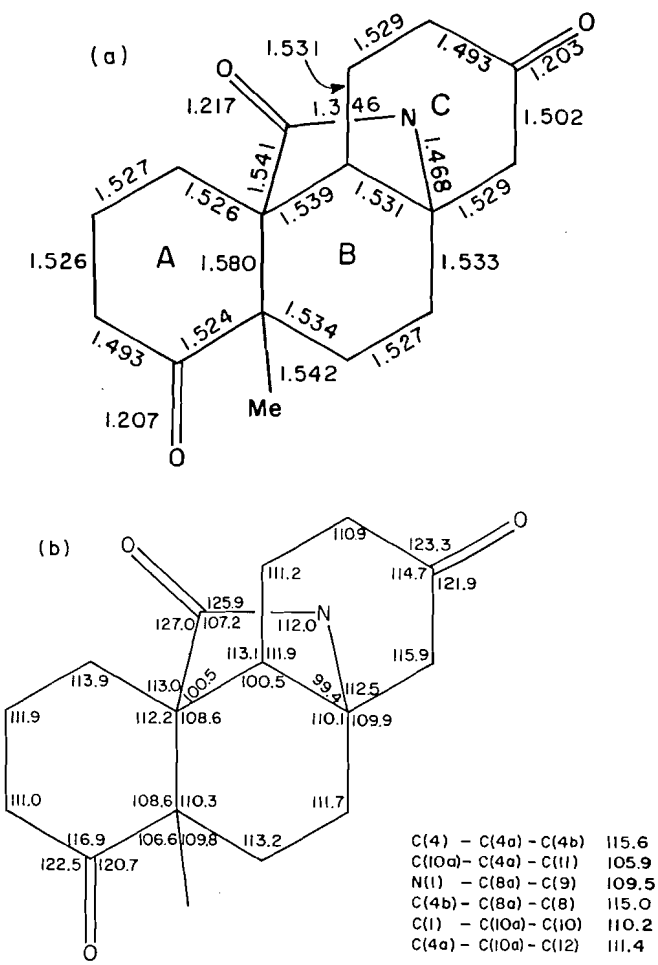

FIG. 2. (*a*) Bond lengths (Å) and (*b*) bond angles (°). Estimated standard deviations are 0.003–0.004 Å and 0.14–0.23°.

geometry, is in the C—N—C angles; the average value is 114.9(13)°, while the present value is 112.0(2)°. Corresponding values from refs. 4 and 5 are 111.8° and 112.4°, respectively.

In the present structure there is a small but significant (~3.9σ) difference between the C(4a)—C(11)—O(3) (127.0(2)°) and N—C(11)—O(3) (125.9(2)°) angles, whereas the average C—C=O and N—C=O angles are essentially equal (within the e.s.d.'s) for the 41 γ-lactams (7). It is not clear to us whether the slight enlargement of the C(4a)—C(11)—O(3) angle here, relative to N—C(11)—O(3), serves primarily to relieve intramolecular repulsion between O(3) and H(31), which are separated by only 2.44(3) Å, or whether a small anomeric effect is involved, or both. The latter effect should be smaller for lactams than for lactones (7).

Conformation

Ring A is in a relatively undistorted, although slightly flattened, chair conformation. Displacements of the ring carbon atoms from the mean plane vary in magnitude between 0.209(3) and 0.222(2) Å. The conformation of ring B is essentially a chair, with some distortion toward envelope form; C(4b) deviates most (0.377(2) Å) from the mean plane. This distortion is very probably due to the bridging lactam ring. Ring C is also in a distorted chair conformation, the distortion in this case being toward a half-chair form. The smallest torsional angle, C(4b)—C(8a)—C(8)—C(7), is −37.1(3)°, and the two largest displacements, for C(5) and C(6), are −0.274(2) and 0.259(3) Å. The lactam ring is close to envelope conformation with apex at C(4b); puckering parameters (8) for all four rings are given in Table 2. The amide group is significantly nonplanar; the C(8a)—N—C(11)—C(4a) torsional angle is 7.3(2)° and displacements from the mean plane through these four atoms plus O(3) vary from 0.018(2) (C(11)) up to 0.069(2) Å (N).

The molecules are linked into chains parallel to the *a* axis by intermolecular hydrogen bonds between the N—H and C=O(1) groups; the N···O distance is 2.892(3) Å, the N—H···O and H···O=C angles are 177(3) and 127.0(7)° respectively, and the H(1)···O(1) distance is 2.12(3) Å. The packing arrangement is shown in Fig. 3.

Formation of lactam **4** can be rationalized as shown in Scheme 1. Presumably the cyclic six-membered transition state of the intramolecular aldol condensation adopts the more stable chair conformation **5**, which leads to β-face attack by the side-chain enolate onto the ring ketone. The alkoxide thus generated can attack the nitrile group to give an intermediate cyclic imino-ether **6**. Such an intramolecular base-catalyzed

Pinner synthesis has recently been described (9). Finally, deprotonation at C(8) in **6** followed by ring opening of the imino-ether leads to enone-amide anion **7**, which then closes back via an intramolecular Michael-type addition to afford lactam **4**.

Lactam **4** is also obtained, although in slightly lower yield, when sodium methoxide is used as a base. We are now investigating the generality of the reaction as a tool for the formation of lactams.

Experimental

1,7-Dioxo-10a-methyl-perhydrophenanthrene-4a,8a-carbolactam (4)

To a solution of triketone **1** (0.23 mmol, 63 mg) in anhydrous ethanol (10 mL) was added a sodium ethoxide solution (7 mL of 0.44 *M*, 3 mmol) in anhydrous ethanol. The reaction mixture was stirred at room temperature for 20 h after which time no starting material could be detected by thin-layer chromatography. After evaporation of ethanol under reduced pressure, water was added and the mixture was extracted several times with chloroform. The combined organic phases were washed with dilute HCl solution, saturated $NaHCO_3$ solution, brine, and dried over anhydrous magnesium sulfate. Evaporation under reduced pressure afforded 57 mg (91%) of the title compound **4**, which crystallized in $CHCl_3$–MeOH mixtures; mp ($CHCl_3$–MeOH) 245–250°C (dec.); ir ($CDCl_3$) ν_{max}: 3210 (NH), 1700 and 1680 (C=O) cm^{-1}; ^1H nmr ($CDCl_3$) in ppm, δ: 1.3 (s, 3H, CH_3), 1.6–2.8 (br m, 17H), 7.65 (br s, 1H, NH); ^{13}C nmr ($CDCl_3$) in ppm, δ: 210.1 and 212.7 (q, C1 and C7), 177.9 (q, HN—C=O), 61.3 (C8a), 56.4 (C4a); ms (*m/e*, %): 275 (M^+, 100), 247 (44), 220 (78), 190 (25), 163 (31), 91 (28), 55 (36), 41 (49).

Compound **4** crystallized from a chloroform/methanol mixture as colourless transparent plates. A specimen 0.23 × 0.45 × 0.50 mm was cut for X-ray measurements, which were made with a CAD-4 diffractometer using Zr-filtered MoKα radiation.

Crystal data

$C_{16}H_{21}NO_3$ M. Wt. 275.33

Orthorhombic, space group $P2_12_12_1$, a = 10.351(3), b = 11.503(2), c = 11.935(2) Å, V = 1421.1 Å^3, Z = 4, ρ_c = 1.287 Mg m^{-3} (293 K, MoKα, λ = 0.7107 Å), μ(MoKα) = 0.095 mm^{-1}.

Cell dimensions were obtained by least-squares refinement on the θ angles of 24 reflections with $7 < \theta < 21°$. Relative intensities were measured with $\omega/2\theta$ scans of scan width $\Delta\omega(°) = 1.5(0.75 + 0.35 \tan\theta)$, and scan speed 0.59–1.68° min^{-1}. Three standards, monitored every hour of exposure time, showed only random fluctuations in intensity. A total of 2357 independent reflections with $\theta \leqq 30°$ were measured, of which 2037 with $I \geqq \sigma(I)$ were considered observed. Net intensities, after scaling, were corrected for Lorentz and polarization factors, but not for absorption. A correction for secondary extinction ($g/\mu = 0.285 \times 10^{-6}$) was made during refinement. The structure was solved by direct methods, using the MULTAN78 (10) program. Refinement was by block-diagonal least squares, minimizing $\Sigma w(\Delta F)^2$. Hydrogen atoms were located on difference maps and refined isotropically while non-hydrogen atoms were refined anisotropically. The weighting scheme used during the later cycles of refinement was $w = w_1 w_2$ where $w_1 = 20.0/|F_o|$ if $|F_o| > 20.0$, $w = 1.0$ otherwise; $w_2 = \sin^2\theta/0.05$ if $\sin^2\theta < 0.05$, $w_2 = 1.0$ otherwise. This scheme made $\langle w\Delta F^2\rangle$ essentially independent of $|F_o|$ and of $\sin^2\theta$. The final R value is 0.043 on all 2037 observed reflections, R_w = 0.046. At convergence the mean (shift/e.s.d.) was 0.045 and $(\Delta/\sigma)_{max}$ was 0.21, for a H parameter. Scattering factor values for O, N, C were taken from ref. 11 without any corrections for anomalous dispersion; those for H were from ref. 12. Calculations were made with the NRC set of crystallographic programs (13) unless otherwise specified. A difference map calculated from the final structure factors[6] shows density between 0.24 and −0.16 e/Å^3; the eight peaks over 0.19 e/Å^3 ($4\sigma(\rho)$) are essentially at the midpoints of C—C bonds, and presumably correspond to bonding electron density.

A synthetic strategy for tricholomic acid and acivicin

STEPHEN HANESSIAN AND BENOIT VANASSE
Department of Chemistry, Université de Montréal, Montréal (Qué.), Canada H3C 3J7

Received June 10, 1986

This paper is dedicated to Dr. O. E. (Ted) Edwards

STEPHEN HANESSIAN and BENOIT VANASSE. Can. J. Chem. **65**, 195 (1987).

A synthetic strategy towards tricholomic acid and acivicin has been established using the aldol condensation of *N*-pyruvilideneglycinatoaquocopper(II) and an optically active aldehyde derived from *S*-malic acid as the key bond-forming reaction. Although a viable strategy was developed, no asymmetric induction was observed.

STEPHEN HANESSIAN et BENOIT VANASSE. Can. J. Chem. **65**, 195 (1987).

La condensation aldolique entre le *N*-pyruvilidineglycinatoaquo cuivre(II) et un aldéhyde optiquement actif provenant de l'acide *S*-malique est utilisée comme réaction-clé dans une stratégie de synthèse de l'acide tricholomique et de l'acivicine. Bien que notre stratégie soit opérationnelle, nous n'avons pas observé d'induction asymétrique.

Tricholomic acid **1** isolated from *tricholoma muscarium* by Takemodo (1) in 1964 is an unusual amino acid (2) having flycidal properties (3). It bears stereochemical and structural resemblance to acivicin (AT-125) **2**, an antitumor antibiotic (4) isolated by Martin and co-workers (5), to its 4-hydroxy analog (6), and to ibotenic acid **3** (7).

The close relationship between tricholomic acid and acivicin makes the former an ideal target for the synthesis of this particular class of dihydroisoxazoleacetic acids. Indeed, several total syntheses of acivicin have been reported that utilize tricholomic acid as a precursor (8*a*).[1] Syntheses of tricholomic acid are also known (9).

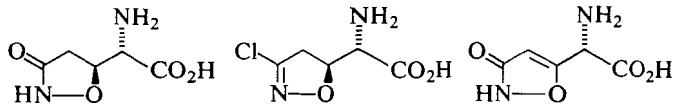
We envisaged a synthetic route to tricholomic acid based on a precursor related to a protected β-hydroxy glutamic acid,[2] since there was precedent (11) for displacing a leaving group in the β position of such a derivative with inversion of configuration.

Our strategy was to disconnect between C-2 and C-3, giving a malonaldehyde equivalent and a suitably activated glycine[3] unit as shown in Scheme 2.

It was reasoned that an aldol condensation of a glycine copper complex **4** and a suitable aldehyde derivative **8** would give the desired acyclic framework with the required functionality. *N*-Pyruvylideneglycinatoaquocopper(II) was used as a glycine anion equivalent (13), and the malonic amide hemialdehyde equivalent was derived from *S*-malic acid via a well-established route (14) (Scheme 3). Thus *S*-malic acid was expected to provide a chiral precursor to aldehyde **8**, which can be considered to be a latent malonic acid derivative.

Furthermore, it was hoped that some diastereofacial selectivity might be encountered in the aldol reaction[4] by virtue of the presence of an asymmetric center bearing an oxygen substituent in the aldehyde (16). Reaction of *N*-pyruvylideneglycinatoaquocopper(II) **4** with aldehyde **8** proceeded smoothly at room temperature at pH 9.8 (NaOH) to give a diastereomeric mixture of β-hydroxy α-amino acids **9** (Scheme 4). Although possible, isolation of **9** was not deemed necessary and the products were carried through without purification.

Protection of the α-amino group as its *N*-benzyloxycarbonyl (Z) derivative and esterification with benzyl bromide in the presence of triethylamine gave a good yield of a 3:2 mixture of diastereoisomers, which could be separated by chromatography. The major isomer **10***a* was then protected as the acetate derivative **11***a*, and the acetal function was hydrolyzed in excellent overall yield (90%). The resulting diol was subjected to oxidative cleavage with $KMnO_4/NaIO_4$ to give the monoacid **13***a* as an oil, in 81% yield. The identity of the diastereomeric monoacids **13***a* and **13***b* (*erythro* series not shown) was established by comparison with products obtained by a different route (11).



1 **2** **3**

SCHEME 1

The *threo* five-carbon monoacid **13***a* encompasses all the required functionality and oxidation state present in the target, except for an inversion of configuration at C-3. On the other hand, the *erythro* diastereomer **13***b* does have the correct relative stereochemistry of tricholomic acid and acivicin. However, access to the heterocycle from **13***b* would require cyclization mediated by the C-3 hydroxyl group in the formation of the dihydroisoxazole ring.

We opted to converge with the known synthetic route (11) in which intramolecular heterocycle formation utilizes the nucleophilic character of an *N*-substituted hydroxamate (17). Tricholomic acid thus obtained has been resolved (18) to give the optically pure natural product.

The *threo* isomer **13***a* was converted into the corresponding *O*-benzylhydroxamate derivative **14***a*, in the presence of 1-ethyl-3-(3-diethylaminopropyl) carbodiimide hydrochloride. Deacetylation of **14***a* gave a crystalline compound **15***a* whose physical constants were identical with the expected *threo* product (11). The *erythro* isomer **11***b* was subjected to the same protocol to give the *erythro* hydroxamate derivative **15***b*. Comparison of its physical constants with values reported in the literature (11) confirmed the *erythro* relative stereochemistry.

The carbon framework and functionality present in tricholomic acid (hence acivicin) was easily accessible by the methodology described in this work. There was a modest preference for the *threo* isomer, but the products were racemic in each diastereomeric series, which could be due to the unfavorable disposition of the oxygen-bearing asymmetric

[1]For other approaches to acivicin, see ref. 8*b*.

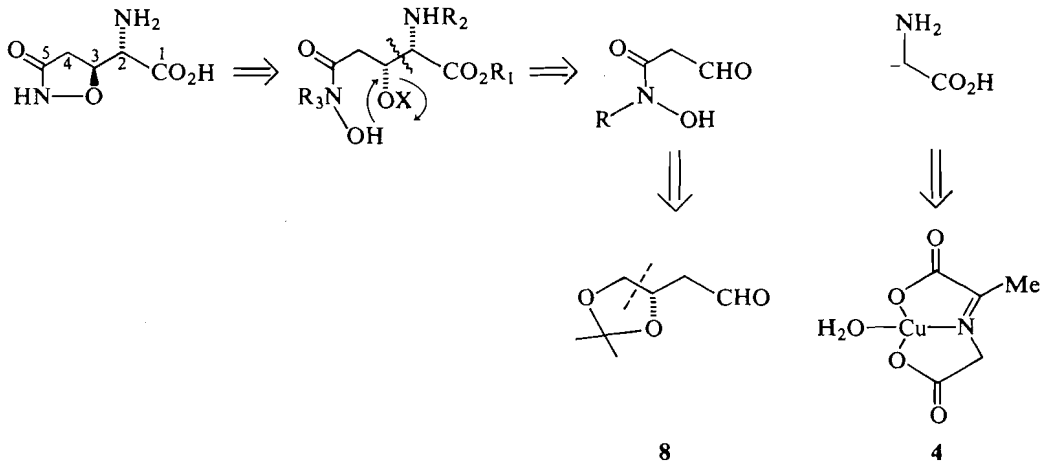
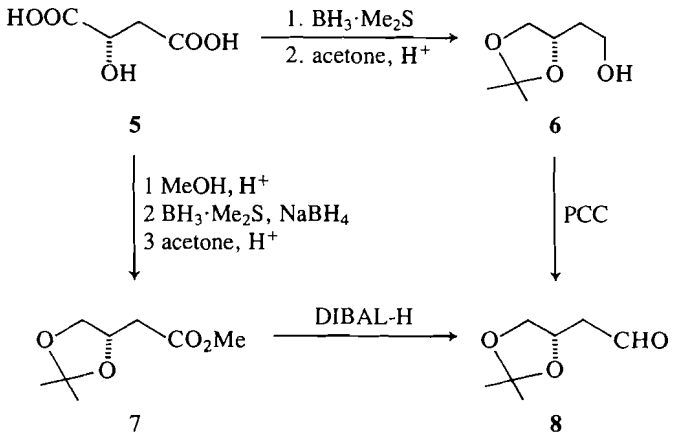


SCHEME 2



SCHEME 3

center in the aldehyde **8** (19).[5] Normally, a heteroatom assisted diastereoselection proceeds better in five-membered chelates (15) compared to the six-membered counterparts. In fact, Ishido and co-workers (13) had shown that reaction of 1,2-*O*-isopropylidene-D-glyceraldehyde with **4** gives 2-amino-2-deoxy-D-xylonic acid (31%) as the preponderant isomer. It is of interest, however, that there was a modest 3:2 preference in favor of the *syn* (*threo*) isomer in the condensation. Also noteworthy is the fact that the aldol condensation was carried out in *water*, hence the guidelines established for diastereofacial bias and stereoselection in nonaqueous systems (e.g. THF, etc.) may not be applicable here.

We are continuing to explore the synthetic utility of aldol and related C—C bond-forming reactions based on copper chelates of amino acids in aqueous and nonaqueous polar media.

Experimental

Melting points are uncorrected. Optical rotations were measured on a Perkin–Elmer automatic spectropolarimeter model 141. The ^{1}H nmr spectra were recorded on Varian 60 and Bruker 400 MHz instruments with tetramethylsilane as internal standard in deuteriochloroform as solvent. Mass spectra were recorded on a VG 1212 low resolution mass spectrometer by the direct chemical ionization technique (DCI). Column chromatography was done by the flash technique.

(S)-2,2-Dimethyl-1,3-dioxolane-4-ethanal

Method A

To a stirred suspension of pyridinium chlorochromate (20 g; 93 mmol) and molecular sieves (3Å, freshly activated; 20 g) in dichloromethane (125 mL) was added alcohol **6**[6] (3.8 g; 26 mmol) in dichloromethane (10 mL). After being stirred for an hour, the mixture was diluted with ether, then filtered on silica gel and evaporated to give aldehyde **8** (3.4 g; 23 mmol; 88%); ν_{max} (film): 1725 cm^{-1}; ^{1}H nmr (60 MHz) ppm: 1.37 (s, 3H), 1.42 (s, 3H), 2.70 (ddd, 2H, J = 2, 6, 17 Hz), 3.60 (dd, 1H, J = 6, 7.5 Hz), 4.20 (dd, 1H, J = 6, 7.5 Hz), 4.55 (9.1H, J = 6 Hz), 9.8 (t, 1H, J = 2 Hz).

Method B

To a stirred solution of ester **7** (14) (5.11 g; 29 mmol) in toluene (100 mL) at −78°C was added, dropwise over an hour, DIBAL-H (38.2 mL; 38.2 mmol) in toluene. The cold solution was then transferred through a cannula into a rapidly stirring solution of 50% aqueous acetic acid (130 mL). After being stirred for 30 min the mixture was extracted with toluene (3 × 100 mL), and the organic phases were combined, dried, and evaporated to dryness to give aldehyde **8** (3.4 g; 23 mmol; 80%).

(2R,3R,5S), (2R,3S,5S), (2S,3R,5S), and (2S,3S,5S)-2-amino-5,6-O-isopropylidine-3,5,6-trihydroxyhexanoic acids (9)

To a suspension of *N*-pyruvylideneglycinatoaquocopper(II) **4** (13) (5.2 g; 20 mmol) in water (200 mL) was added 2 *M* NaOH to pH 9.8, then a solution of **8** (3.4 g; 23 mmol) in ethanol (10 mL) was added dropwise. The resulting mixture was stirred for 4 h at room temperature while maintaining a constant pH. The solution was saturated with H_2S gas, then concentrated to approximately 30 mL, and ethanol (70 mL) was added. Filtration and washing gave **9** (2.19 g; 10 mmol; 50%), mp 215°C (dec.); ν_{max} (film): 1700 (br, COOH) cm^{-1}; ^{1}H nmr (D_2O) (60 MHz) ppm: 1.38 (s, 3H), 1.40 (s, 3H), 2.2–2.5 (m, 2H), 4.0–4.8 (m, 5H), 5.1 (HOD); ms: 220 (M + 1).

*Benzyl (2S,3R,5S) and (2R,3S,5S)-2-benzyloxycarbonylamino-5,6-O-isopropylidene-3,5,6-trihydroxyhexanoates **10**a, and benzyl (2R,3R,5S) and (2S,3S,5S)-2-benzyloxycarbonylamino-5,6-O-isopropylidene-3,5,6-trihydroxyhexanoates **10**b*

To a solution of **9** in water (100 mL) and DMF (200 mL) was added *N*-(benzyloxycarbonyloxy) succinimide (5.5 g; 22 mmol) in DMF (50 mL). After being stirred at room temperature overnight, the mixture was treated with 5% $NaHCO_3$ (200 mL), washed twice with ether (250 mL), acidified to pH ~2.0 with 10% HCl (slowly), and subsequently extracted with ether (4 × 100 mL) to give a syrup. To the crude syrup dissolved in dry DMF (50 mL), triethylamine (3.4 mL;

[5]See ref. 19*a* for usage of **8** in aldol condensation. For a related case in a Grignard reaction, see ref. 19*b*.

[6]This material is contaminated with 10% of the corresponding six-membered acetonide, see ref. 20.

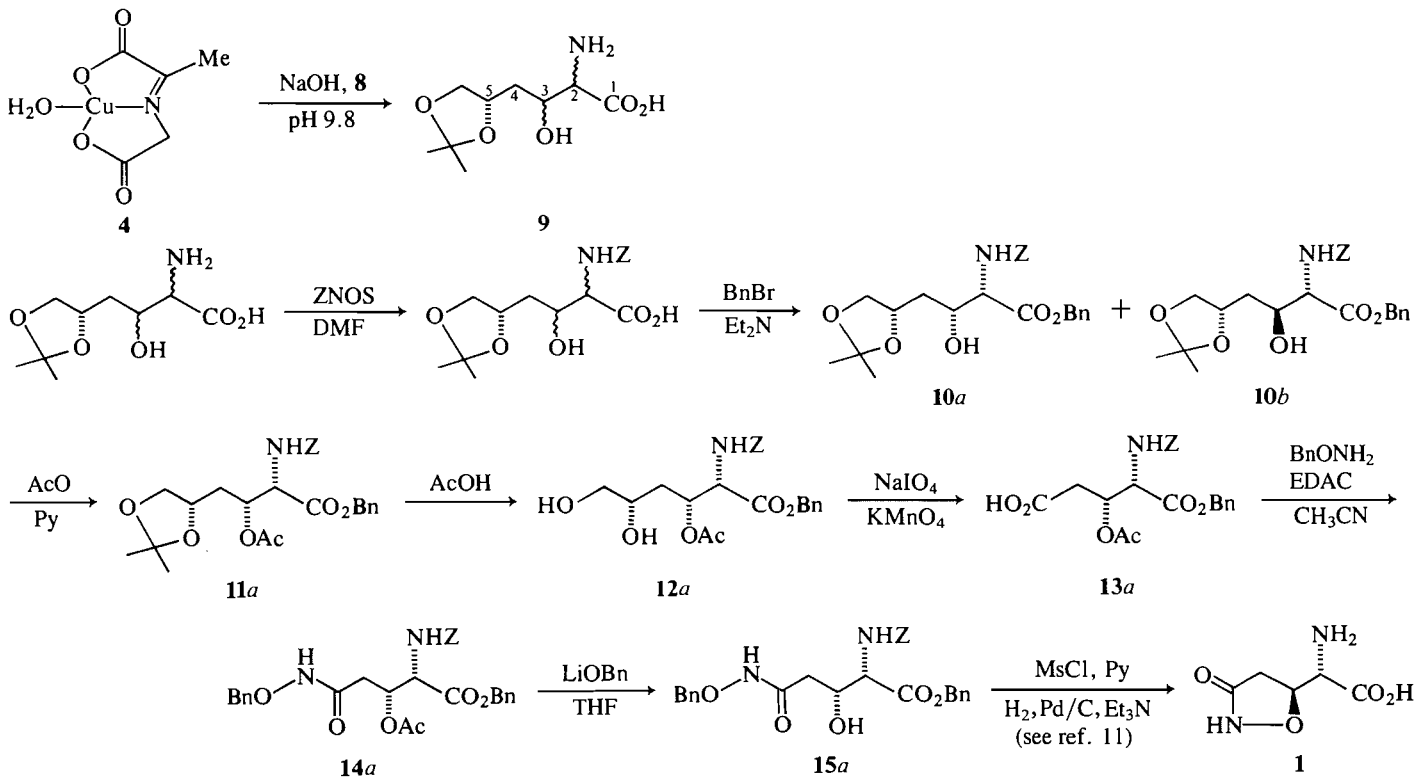

SCHEME 4

24 mmol) and benzylbromide (2.6 mL; 21.8 mmol) were added at room temperature. After stirring overnight, water (100 mL) was added and the mixture was extracted with ether (3 × 100 mL). The organic phase was washed with saturated $NaHCO_3$; then with brine, dried ($MgSO_4$), filtered, and evaporated to a syrup, which upon chromatography (ethyl acetate – chloroform–*n*-hexane 25:10:65) gave **10***a* (2.07 g; 4.68 mmol; 23% (3 steps)), **10***b* (1.38 g; 3.12 mmol; 16% (3 steps)), and benzyl *N*-benzyloxycarbonylamino glycinate (1.0 g; 3.34 mmol).

Compound **10***a*: mp 61.5–62.5°C; $[\alpha]_D$ +6.0° (*c* 1, $CHCl_3$); ν_{max} (film): 1740–1750 (ester, carbamate) cm^{-1}; ^1H nmr (400 MHz) ppm: 1.34–1.39 (2s, 6H, 2 × CH_3), 1.65–1.85 (m, 2H, H-4A, H-4B), 2.75 (d, 1H, OH, *J* = 4.9 Hz), 3.54 (dd, 1H, H-6A, *J* = 7.8, 7.9 Hz), 4.01 (dd, 1H, H-6B, *J* = 6.2, 7.9 Hz), 4.25–4.35 (m, 1H, H-5), 4.40–4.48 (m, 2H, H-3 + H-2), 5.19 (bs, 2H, CH_2Ph), 5.22 (bs, 2H, CH_2Ph), 5.89 (d, 1H, NH, *J* = 9.2 Hz), 7.35–7.40 (bs, 10H, arom); ms: 444 (*M* + 1).

Compound **10***b*: mp 72.5–73.5°C; $[\alpha]_D$ −2.8 (*c* 1, $CHCl_3$); ν_{max} (film): 1740 (ester, carbamate) cm^{-1}; ^1H nmr (400 MHz) ppm: 1.35, 1.41 (2s, 6H, 2 × CH_3), 1.73–1.76 (m, 2H, H-4A, H-4B), 3.52 (bs, 1H, OH), 3.54 (dd, 1H, H-6A, *J* = 7.1, 8.1 Hz), 4.07 (dd, 1H, H-6B, *J* = 6.1, 8.1 Hz), 4.25–4.32 (m, 1H, H-5), 4.40 (bd, 1H, H-2, *J* = 9.5 Hz), 4.45–4.50 (m, 1H, H-3), 5.13 (s, 2H, CH_2Ph), 5.22 (d, 2H, CH_2Ph, *J* = 3.4 Hz), 5.80 (d, 1H, NH, *J* = 9.5 Hz), 7.30–7.40 (bs, 10H, arom); ms: 444 (*M* + 1).

*Benzyl (2*R*,3*R*,5*S*) and (2*R*,3*S*,5*S*)-3-*O*-acetyl-2-benzyloxycarbonylamino-5,6-*O*-isopropylidene trihydroxyhexanoates **11***a*

To a solution of **10***a* (450 mg; 1.01 mmol) in pyridine (5 mL) was added acetic anhydride (2.5 mL) and 4-dimethylaminopyridine (catalytic). The mixture was stirred at room temperature for 3 h. Ethyl acetate was then added and the mixture was washed three times with $CuSO_4$ (saturated solution). The organic phase was then washed with water, dried ($MgSO_4$), filtered, and evaporated to an oil, which was chromatographed (ethyl acetate – *n*-hexane 15:85) to give **11***a* as an oil (460 mg; 94%); $[\alpha]_D$ +17.7° (*c* 1, $CHCl_3$); ν_{max} (film): 1740–1750 (carbamate, esters) cm^{-1}; ^1H nmr (400 MHz) ppm: 1.31, 1.41 (2s, 6H, 2 × CH_3), 1.80 (ddd, 1H, H-4A, *J* = 4.8, 6.0, 15.2 Hz), 1.86 (s, 3H, OAc), 1.96 (ddd, 1H, H-4B, *J* = 7.6, 9.2, 15.2 Hz), 3.55 (dd, 1H, H-6A, *J* = 6.7, 7.9 Hz), 4.03 (dd, 1H, H-6B, *J* = 6.0, 7.9 Hz), 4.15 (m, 1H, H-5), 4.67 (dd, 1H, H-2, *J* = 2.1, 9.8 Hz), 5.13, 5.14 (2s, 4H, 2 × CH_2Ph), 5.49 (d, 1H, NH, *J* = 9.8 Hz), 5.54 (m, 1H, H-3), 7.30–7.40 (s, 10H, arom, *J* = 9.8 Hz); ms: 486 (*M* + 1).

*Benzyl (2*R*,3*R*,5*S*) and (2*S*,3*S*,5*S*)-3-*O*-acetyl-2-benzyloxycarbonylamino-5,6-isopropylidene trihydroxyhexanoate **11** b*

Using the same procedure as for **11***a*, compound **11***b* was obtained as a solid (308 mg, 94%); mp 80–81°C; $[\alpha]_D$ −27.8° (*c* 1.2, $CHCl_3$); ν_{max} (film): 1740–1750 (br, esters, carbamate) cm^{-1}; ^1H nmr (400 MHz) ppm: 1.32, 1.37 (2s, 6H, 2 × CH_3), 1.84–1.90 (m, 2H, H-4A, H-4B), 1.92 (s, 3H, OAc), 350 (dd, 1H, H-6A, *J* = 7.4, 7.8 Hz), 4.00 (dd, 1H, H-6B, *J* = 6.1, 7.8 Hz), 4.05–4.15 (m, 1H, H-5), 4.65 (dd, 1H, H-2, *J* = 2.2, 9.7 Hz), 5.09–5.18 (m, 4H, 2 × CH_2Ph), 5.45 (d, 1H, NH, *J* = 9.7 Hz), 5.52 (m, 1H, H3), 7.30–7.40 (bs, 10H, arom); ms: 486 (*M* + 1).

*Benzyl (2*R*,3*S*,5*S*) and (2*S*,3*R*,5*S*)-3-*O*-acetyl-2-benzyloxycarbonylamino-5,6-dihydroxy trihydroxyhexanoates, **12***a*

A solution of **11***a* (460 mg; 0.95 mmol) in acetic acid – water (4:1, 10 mL) was stirred overnight at room temperature. Toluene was then added and the solution was evaporated twice under reduced pressure. The resulting oil was purified by chromatography (ethyl acetate – *n*-hexanes 7:3) to give **12***a* (400 mg; 95%) as a solid; mp 73–74°C, $[\alpha]_D$ +13.8° (*c* 1.0, HCl_3); ν_{max} (film): 1700–1760 (esters, carbamate) cm^{-1}; ^1H nmr (400 MHz) ppm: 1.74–1.78 (m, 2H, H-4A, H-4B), 1.81 (s, 3H, OAc), 2.9–3.2 (bs, 2H, 2 × OH), 3.31 (dd, 1H, H-6A, *J* = 6.7, 11.2 Hz), 3.46 (dd, 1H, H-6B, *J* = 2.8, 11.2 Hz), 3.65–3.75 (m, 1H, H-5), 4.63 (dd, 1H, H-2, *J* = 1.9, 9.8 Hz), 5.03 (bs, 4H, 2 × CH_2Ph), 5.41–5.50 (m, 1H, H-3), 5.54 (d, 1H, NH, *J* = 9.8 Hz), 7.30–7.40 (m, *J* = 10 Hz, arom); ms: 446 (*M* + 1).

*Benzyl (2*R*,3*R*,5*S*) and (2*S*,3*S*,5*S*)-3-*O*-acetyl-2-benzyloxycarbonylamino-5,6-dihydroxy trihydroxyhexanoates **12** b*

Using the same procedure as for **12***a*, compound **12***b* was obtained as an oil (267 mg, 95%); $[\alpha]_D$ −18.7° (*c* 1, $CHCl_3$); ν_{max} (film): 1700–1760 (esters, carbamate) cm^{-1}; ^1H nmr (400 MHz) ppm: 1.66–

1.69 (m, 2H, H-4A, H-4B), 1.84 (s, 3H, OAc), 2.2–2.8 (bs, 2H, 2 × OH), 3.47 (dd, 1H, H-6A, J = 7.1, 12.9 Hz), 3.53 (dd, 1H, H6-B, J = 2.8, 12.9 Hz), 4.68 (dd, 1H, H-2, J = 1.9, 9.6 Hz), 5.10–5.12 (m, 4H, 2 × CH_2Ph), 5.56–5.62 (m, 2H, H-3 + NH), 7.30–7.40 (m, 10H, arom); ms: 446 (M + 1).

(d,l)-threo-3-O-Acetyl-2-benzyloxycarbonylamino-3-hydroxyglutaric acid α-benzyl esters, ***13****a*

To a suspension of $NaIO_4$ (481 mg, 2.25 mmol), and potassium permanganate (18 mg, 0.11 mmol) in acetone–water (10:1, 11 mL) was added **12***a* (400 mg, 0.9 mmol) in acetone (1 mL) followed by $NaHCO_3$ (227 mg, 2.7 mmol). The resulting dark purple suspension was stirred overnight. The dark brown precipitate was filtered through Celite and the solids washed with ether. The organic phase was extracted with 5% $NaHCO_3$, the aqueous phase was washed twice with ether, acidified to pH ~2.0 with HCl 10%, then extracted twice with ether. The ether phase was dried ($MgSO_4$), filtered, and evaporated to give **13***a* as a yellow oil (350 mg, 81%); ν_{max} (film): 1735 (ester, carbamate, acid) cm^{-1}; ^1H nmr (400 MHz) ppm: 1.80 (s, 3H, OAc), 2.75 (bs, 1H, H-4A), 2.80 (bs, 1H, H-4B), 4.70–4.80 (m, 1H, H-2), 5.10 (bs, 4H, 2 × CH_2Ph), 5.50–5.65 (m, 2H, H-3, N-H), 7.35 (bs, 10H, arom), 9.50–9.70 (bs, 1H, COOH); ms: 430 (M + 1).

(d,l)-erythro-3-O-Acetyl-2-benzyloxycarbonylamino-3-hydroxyglutaric acid α-benzyl ester, ***13****b*

Using the same procedure as for **13***a*, compound **13***b* was obtained as an oil (200 mg, 80%); ν_{max} (film): 1735 (ester, carbamate, acid) cm^{-1}; ^1H nmr (400 MHz) ppm: 1.84 (s, 3H, OAc), 2.75 (bs, 1H, H-4A), 2.82 (bs, 1H, H-4B), 4.70–4.80 (m, 1H, H-2), 5.15 (bs, 4H, 2 × CH_2Ph), 5.50–5.65 (m, 2H, H-3, NH), 7.30–7.40 (bs, 10H, arom), 9.50–9.70 (bs, 1H, COOH); ms: 430 (M + 1).

(d,l)-threo-3-O-Acetyl-2-benzyloxycarbonylamino-3-hydroxyglutaric acid α-benzyl ester (δ-N-benzyloxyamide), ***14****a*

To a solution containing **13***a* (70 mg, 0.16 mmol) and *O*-benzylhydroxylamine (40 mg, 0.33 mmol) in acetonitrile (10 mL), was added successively 1-ethyl-3-(3-dimethylaminopropyl) carbodiimide hydrochloride (67.1 mg; 0.35 mmol) and 4-dimethylaminopyridine (catalytic quantity). The resulting solution was stirred for 15 h; the mixture was then poured into water (20 mL), extracted with CH_2Cl_2, dried ($MgSO_4$), and evaporated to an oil, which upon chromatography (ethyl acetate – *n*-hexanes 15:85) gave **14***a* (35 mg; 80%) as a solid, mp 104–105°C; ν_{max} (film): 1750 (br, ester, carbamate, hydroxamate) cm^{-1}; ^1H nmr (400 MHz) ppm: 1.80 (s, 3H, OAc), 2.70–2.81 (m, 2H, H-4A, H-4B), 4.70–4.80 (m, 1H, H-2), 4.90 (s, 2H, $PhCH_2ON$), 5.10 (bs, 4H, CH_2Ph), 5.5–5.65 (m, 3H, 2 × NH), 7.3–7.4 (bs, 15H, arom); ms: 535 (M + 1).

(d,l)-erythro-3-O-Acetyl-2-benzyloxycarbonylamino-3-hydroxyglutaric acid α-benzyl ester (δ-N-benzyloxyamide), ***14****b*

Using the same procedure as for **13***a*, compound **14***b* was obtained as an oil (80%); ν_{max} (film): 1740–1760 (ester, carbamate, hydroxamate) cm^{-1}; ^1H nmr (400 MHz) ppm: 1.81 (s, 3H, OAc), 2.71–2.83 (m, 2H, H-4A, H-4B), 4.72–4.80 (m, 1H, H-2), 4.90 (s, 2H, $PhCH_2ON$), 5.10 (bs, 4H, 2 × CH_2Ph), 5.5–5.65 (m, 3H, H-3, 2 × NH), 7.3–7.4 (bs, 15H, arom); ms: 535 (M + 1).

(d,l)-threo-2-Amino-3-hydroxyglutaric acid α-benzyl ester (δ-N-benzyloxyamide), ***15****a*

To a cooled solution of **14***a* (35 mg; 0.065 mmol) in THF (4 mL) was added dropwise a solution of lithium benzyloxide (LiOBn) in THF (0.65 mL of 0.1 M solution) at 0°C. After stirring at that temperature for an hour, Dowex H^+ resin was added, the suspension was filtered, and the filtrate was processed in the usual way to give a yellow oil, which was chromatographed (ethyl acetate – *n*-hexane 1:1) to give **15***a* (25 mg, 80%) as an oil that solidified on standing; recrystallization from ethyl acetate – *n*-hexane showed mp 131–132°C (lit. (11) mp 132–133.5°C); ν_{max} (film): 1750 (ester, carbamate, hydroxamate) cm^{-1}; ^1H nmr (400 MHz) ppm: 2.7–2.8 (m, 2H, H-4A, H-4B), 4.72–4.80 (m, 1H, H-2), 4.90 (s, 2H, $PhCH_2ON$), 5.10 (bs, 4H, 2 × CH_2Ph), 5.5–5.65 (m, 3H, H-3, NH (2×)), 7.3–7.4 (bs, 15H, arom); ms: 493 (M + 1).

(d,l)-erythro-2-Amino-3-hydroxyglutaric acid benzyl ester (δ-N-benzyloxyamide, ***15****b*

Using the same procedure as for **15***a*, compound **15***b* was obtained as a solid (81%); recrystallization in ethyl acetate – *n*-hexanes) gave crystals, mp 161–162°C (lit. (11) mp 166–167°C); ν_{max} (film): 1750 (ester, carbamate, hydroxamate) cm^{-1}; ^1H nmr (400 MHz) ppm: 2.7–2.8 (m, 2H, H-4A, H-4B), 4.70–4.82 (m, 1H, H-2), 4.92 (s, 2H, $PhCH_2ON$), 5.10 (bs, 4H, 2 × CH_2Ph), 5.52–5.65 (m, 3H, H-3, 2 × NH), 7.30–7.40 (bs, 15H, arom); ms: 493 (M + 1).

Received June 17, 1986

This paper is dedicated to Dr. O. E. (Ted) Edwards

STEWART MCLEAN, WILLIAM F. REYNOLDS, and XINGPEI ZHU. Can. J. Chem. **65**, 200 (1987).

The ^{13}C and ^1H spectra of aspidocarpine and the spectra, structure, and stereochemistry of the product of its von Braun reaction with cyanogen bromide have been totally assigned by a combination of homonuclear (COSY-45) and direct and indirect heteronuclear shift-correlated 2D nmr spectra.

STEWART MCLEAN, WILLIAM F. REYNOLDS et XINGPEI ZHU. Can. J. Chem. **65**, 200 (1987).

En se basant sur une combinaison de techniques impliquant des spectres rmn en 2D homonucléaires (COSY-45) et hétéronucléaires comportant une corrélation directe et indirecte avec les déplacements, on a pu faire des attributions pour toutes les bandes des spectres rmn ^1H et ^{13}C de l'aspidocarpine et de son produit de réaction avec le bromure de cyanogène (von Braun); de plus, ces techniques ont permis d'établir la structure et la stéréochimie de ce dernier composé.

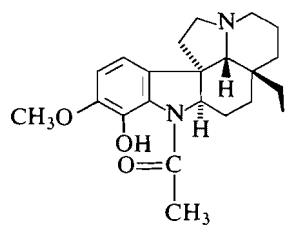
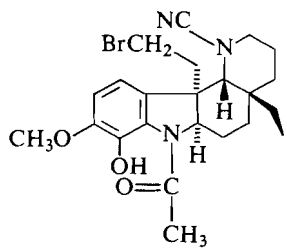
As part of our investigation (1) that led us to the elucidation of the structure of aspidocarpine (**1**), we subjected the alkaloid to a von Braun degradation by treatment with cyanogen bromide. The bromocyanamide formed without difficulty, but the normal solvolytic completion of the degradation failed and it was observed that merely heating the bromocyanamide in ethanol caused it to revert to aspidocarpine. Aspidospermine had been found to behave in a very similar manner (2) and Conroy *et al.* presented evidence that the bromocyanamide included a $-CH_2Br$ unit as part of a carbon chain with "few degrees of freedom" (2). Although the unprecedented reversal of the von Braun reaction was of considerable interest, the degradation provided little significant structural information and the question of the structure of the bromocyanamide has lain dormant since then. Once the structure of **1** was established, it was possible to conjecture that the bromocyanamide had structure **2** but alternative structures could also be suggested.



1



2

Aspidocarpine and aspidospermine were among the first alkaloids to which ^1H nmr spectroscopy was applied for purposes of structure elucidation (1, 2). However, the techniques available then were of limited power and the ^1H spectra were poorly resolved, providing limited and sometimes confusing information (2) regarding molecular structure. The importance of the aspidosperimidine alkaloids subsequently became apparent and a considerable range of nmr data for them is now available (3). However, only limited ^1H data (1) and no ^{13}C data are available for **1**. Consequently, we decided to apply modern nmr spectroscopic techniques to assign unambiguously the ^1H and ^{13}C spectra of **1** as well as to determine whether the structure of the von Braun reaction product was indeed **2**. We have succeeded not only in confirming **2** and totally assigning the spectra of **1** and **2**, but also have succeeded in deducing the conformations of rings C and D of **1** and **2**. These results are reported below.

[1]On leave of absence from the Department of Chemistry, Beijing Normal University, People's Republic of China.

Results and discussion

(a) Assignment of ^1H and ^{13}C spectra of 1

As a first step in assignment, normal and DEPT-edited (4) ^{13}C spectra of **1** were obtained. Then a two-dimensional (2D) heteronuclear (^1H–^{13}C) chemical shift correlation experiment (5) was carried out to determine the chemical shift(s) of the hydrogen(s) directly bonded to each protonated carbon. Next, a ^1H COSY-45 spectrum (6) (Fig. 1) was used to establish connectivities between coupled protons. There are four distinct sequences in the saturated carbon region that could be assigned from this experiment: C(2)H—C(3)H_2—C(4)H_2, C(6)H_2—C(7)H_2—C(8)H_2, C(10)H_2—C(11)H_2, and C(α)H_2—C(β)H_3. The COSY experiment did not allow distinction between C(6)H_2 and C(8)H_2 in the second sequence and C(10)H_2 and C(11)H_2 in the third sequence (due to the symmetry of each sequence). However, C(8)H_2 and C(10)H_2 were readily assigned due to their deshielding by the adjacent nitrogen. Assignments are summarized in Table 1.

Nonprotonated carbons were assigned by carrying out a heteronuclear shift-correlated experiment with delay times optimized for coupling between indirectly bonded carbons and hydrogens (e.g., $^2J_{CH}$ or $^3J_{CH}$). This experiment was performed using the recently proposed 2D pulse sequence XCORFE (7). This sequence detects cross peaks corresponding to ^{13}C–X–^1H and ^{13}C–X–C–^1H pairs (where X = C, N, O, etc.). Two-bond connectivities involving a pair of protonated carbons are distinguished from three-bond connectivities because the former are split by vicinal ^1H–^1H coupling, while the latter appear as singlets (7). Observed connectivities are summarized in Table 2. The remaining carbons are easily assigned using these connectivities (see Table 1). For example, it is trivial to distinguish C(5) from C(12) on the basis of their numerous cross peaks to adjacent protons. The aromatic carbons are assigned on the basis of cross peaks to OH, OCH_3, and to aromatic and saturated protons. Note that the aromatic protons show much stronger three-bond than two-bond peaks due to the relatively

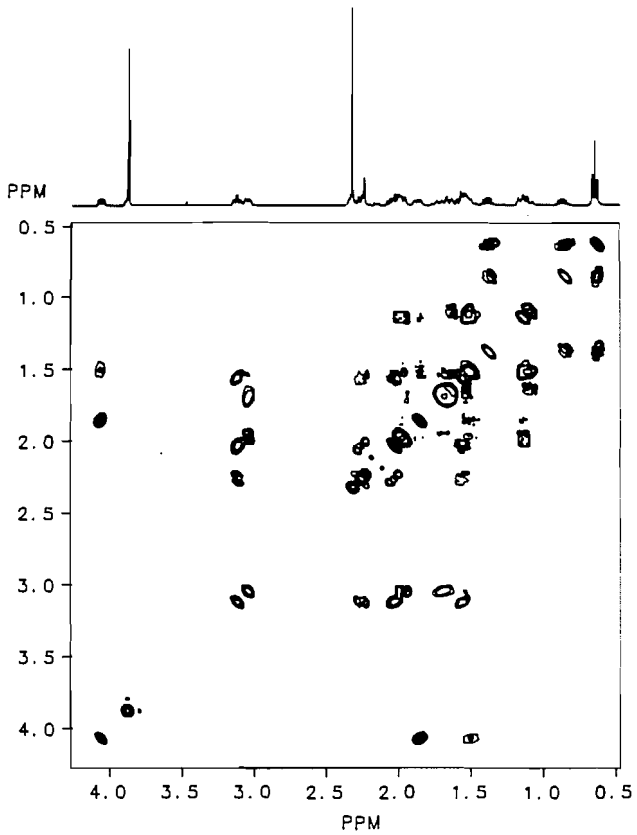

FIG. 1. COSY-45 spectrum for **1**. The normal spectrum lies along the diagonal with off-diagonal peaks indicating connectivities between coupled protons.

small magnitudes of $^2J_{CH}$ (12). The fact that the OH proton shows a three-bond cross peak with C(16) but not with C(18) may reflect stereospecific coupling arising from hydrogen bonding to the *N*-acetyl group (1).

The data in Table 2 also support the earlier assignments of C(8)H_2 and C(10)H_2 (made on chemical shift grounds), which are confirmed by the observation of three-bond connectivities between H(19) and C(8) and between H(8) and C(10). These connectivities, the cross peaks involving OH and OCH_3 protons, as well as several other connectivities in Table 2 illustrate the ability of this experiment to establish connectivities through heteroatoms.

(b) Assignment of the structure and ^1H and ^{13}C spectra of 2

Exactly the same combination of experiments as outlined in (*a*) was used to investigate **2** (e.g., see the COSY spectrum in Fig. 2) and spectral assignments were made in a similar manner. Results are summarized in Tables 3 and 4.

Several observations clearly indicate that **2** is the correct structure for the reaction product. First, the carbon assigned as C(10) is shifted from δ 52.4 in **1** to δ 27.0 in **2**, consistent with replacement of a bond to nitrogen by one to bromine (8). Second, the large nonequivalence of the methylene protons of C(10) in **1** has almost been eliminated in **2**, consistent with the fact that a bond has been broken between C(10) and the chiral nitrogen. Finally, the XCORFE experiment revealed two connectivities to the cyano group, one to H(19) and the other to the H(8) proton at δ 3.02, consistent with attachment of the cyano group to the nitrogen, as shown in **2**. The fact that no significant cross peak was observed involving the second H(8) proton at δ 3.63 provides useful conformational information. This is discussed below.

[a]Numbering shown below.

[b]Splitting pattern in parentheses (multiplicity, coupling constant (in Hz) where resolved).

[c]In cases of protons in rings C and D, the first listed proton of a methylene pair is the axial proton, while the second is equatorial. For C(10), C(11), and C(α), the protons are listed in chemical shift order.

(c) Deduction of the conformations of 1 and 2 from three-bond ^1H–^{13}C connectivities

The solution conformation of **1** is unknown. The *N*-methiodide of the closely related alkaloid aspidospermine has been shown by X-ray crystallography to have a chair conformation for ring C but a boat conformation for ring D (see **3**) (9). However, on the basis of infrared spectroscopy, it was concluded that ring D most probably is in a chair conformation in the free base (see **4**) (10). The nmr data strongly suggest that the conformation of **1** is very close to that shown in **4**. For example, the ^1H spectrum of **1** shows multiplets for the methylene protons of C(4), C(6), and C(8), all of which show the expected couplings for *axial* and *equatorial* proton pairs

[a]The number indicates the proton while the subscript indicates whether it is axial (a) or equatorial (e) in ring C or D, or high field (h) or low field (l) for other methylene pairs. Weak connectivities are indicated in parentheses. d = a doublet splitting, while b = a broadened line with unresolved splitting. Observation of coupling indicates a two-bond connectivity between a proton and an adjacent protonated carbon (see ref. 7). Couplings of less than 7 Hz are not detected due to limited data point resolution.

[a]Numbering is identical to that in Table 1.
[b]The C(10) protons appear as a complex multiplet centered at δ 3.27. The nonequivalence of these protons is approximately 0.03 ppm.

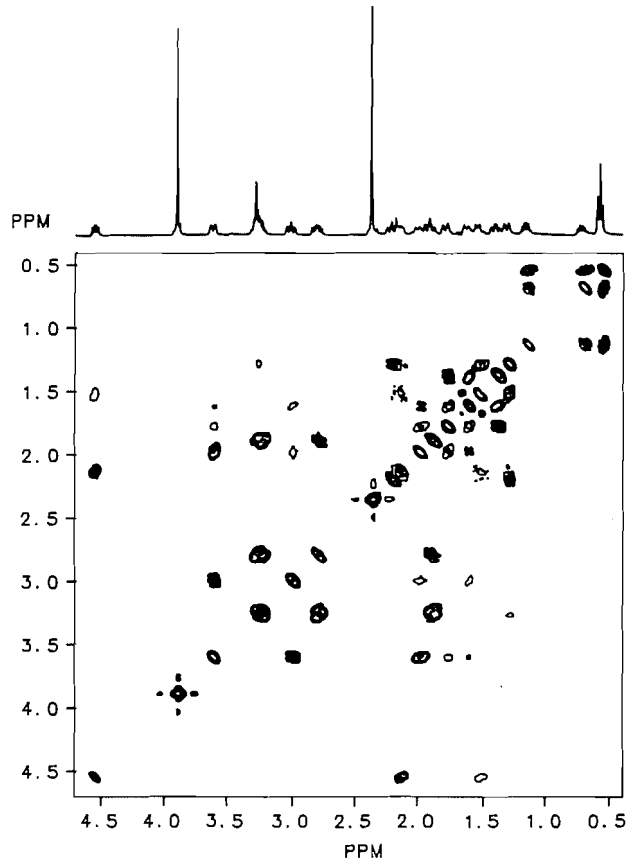

FIG. 2. COSY-45 spectrum for **2**.

in a chair form (11). i.e., the axial protons show two large (ca. 12 Hz) splittings corresponding to $^{2}J_{H(a)H(e)}$ and $^{3}J_{H(a)H(a)}$ plus a smaller splitting (ca. 4 Hz) corresponding to $^{3}J_{H(a)H(e)}$, while the equatorial protons show one large $^{2}J_{H(a)H(e)}$ splitting and two smaller splittings assignable as $^{3}J_{H(e)H(a)}$ and $^{3}J_{H(e)H(e)}$ (see Table 1). Similar splitting patterns are observed for the corresponding protons in **2** (see Table 2), suggesting that rings C and D in both **1** and **2** are in chair conformations.

Further evidence concerning the specific chair conformations in each case is provided by the indirect shift-correlated experiments. $^{3}J_{CH}$ couplings are conformationally dependent with typical values for *anti*, *syn*, and *gauche* couplings being, respectively, ca. 8, 5, and 2 Hz (12). Polarization transfer between ^{1}H and ^{13}C is maximum when the fixed delay, T, equals $(2J_{CH})^{-1}$ (7). Most spectra were run using $T = 0.06$ s (see Experimental), corresponding to an optimum $J_{CH} \cong 8$ Hz. Consequently, *gauche* $^{3}J_{CH}$ coupling vectors are still far removed from the antiphase orientation that leads to maximum polarization transfer (5). After polarization transfer, a second delay allows the $^{13}C-^{1}H$ coupling vectors to return to an in-phase orientation prior to ^{1}H decoupling and ^{13}C detection (5). Once again the delay is too short for *gauche* $^{3}J_{CH}$ coupling vectors to reach this optimum orientation. Consequently three-bond *gauche* C—H connectivities are effectively suppressed, while those corresponding to *anti* pathways are optimized.[2]

This allows one to probe conformations of rings C and D in terms of observed or missing three-bond peaks. Specifically, equatorial hydrogen should show three-bond $^{1}H-^{13}C$ cross peaks, while axial hydrogens do not. For example, the isolated

[2]A somewhat similar approach has recently been used to deduce conformational information for ryanodine (13).

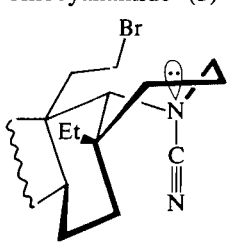
[a]See footnote *a* of Table 2.

proton, H(19), is in an axial orientation with respect to ring D and an equatorial orientation with respect to ring C. As expected, it shows strong three-bond cross peaks with C(2) and C(4) of ring C but no significant cross peaks with C(6) or C(8) in ring D. By contrast, in both **1** and **2** C(19) shows strong cross peaks with hydrogens $H(4)_e$ (δ 1.33), $H(6)_e$ (δ 1.82), and $H(8)_e$ but not from H(2), which is in a pseudo-axial orientation with respect to ring C. Similarly, there is a cross peak between C(2) and $H(4)_e$ but not between C(4) and H(2), while strong cross peaks are also observed between C(6) and $H(8)_e$ and C(8) and $H(6)_e$. All of these observations are entirely consistent with chair forms for rings C and D of **1** and **2**, similar to **4**.

The connectivity data also strongly imply an axial orientation for the cyano group bonded to nitrogen in **2** (see **5**). Three-bond connectivities are observed between the cyano group and both $H(8)_a$ and H(19) but not with $H(8)_e$. Since this indicates an *anti* orientation of the cyano group with respect to the two axial hydrogens, it follows that the former group is axial. This was further supported by selectively ^{1}H decoupled ^{13}C spectra for the cyano group, which indicated couplings of 9, 2, and 9 Hz to $H(8)_a$, $H(8)_e$, and H(19), respectively.

While the mechanism of the von Braun cyanogen bromide reaction received little earlier attention, it is now established that the reaction proceeds through the *N*-cyanoammonium salt (14). The reversal of the reaction, eliminating CNBr from the bromocyanamide, is rarely observed. The conformation deduced for the bromocyanamide (**5**) in the present case suggests an explanation for the reversal of the reaction: the equatorially disposed lone-pair electrons on nitrogen are well placed to effect an intramolecular displacement of the bromide. It is reasonable to suppose that this process corresponds to the microscopic reversal of the bond cleavage in the forward direction and leads to the conclusion that the configuration at the nitrogen of the cyanoammonium intermediate is opposite to that in the methiodide (see **3**). It follows then that the cyanogen bromide in the von Braun reaction undergoes a facile reaction with the free base in its dominant conformation (**4**), while methyl iodide fails to react with the nitrogen in this conformation and selectively quaternizes the nitrogen of the minor conformational isomer.



5

Experimental

The isolation of aspidocarpine has been described elsewhere (1). The von Braun reaction was carried out using previously described conditions (1).

All nmr data were obtained on a Varian XL-400 nmr spectrometer (^{13}C 90° pulse width = 13.5 μs, ^{1}H 90° pulse width **4** 13.6 μs, ^{1}H 90° pulse width through decoupler coil of multinuclear probe = 27.0 μs, probe temperature = 18°C). In each case, 70 mg of **1** or **2** was dissolved in ca. 0.5 mL of $CDCl_3$ in a 5-mm tube. Typical parameters for the COSY spectrum were $f_1 = f_2 = 2200$ Hz with 512 time increments (zero filled to 1024), 1024 data points, 16 transients per time interval, and 0.5 s relaxation delay. Pseudo-echo processing was used in both domains, followed by symmetrization by triangular folding. Typical parameters for direct heteronuclear shift-correlated spectra were $f_1 = 2200$ Hz, $f_2 = 7500$ Hz, 256 time increments (zero filled to 1024), 2048 data points, 64 transients per time interval, and 0.5 s relaxation delay. Separate spectra were obtained for the aromatic region.

Two sets of XCORFE spectra were obtained in each case with fixed times $T = 0.062$ s (272 time increments for 2200 Hz, f_1 spectral width) and $T = 0.08$ s (352 time increments for 2200 Hz, f_1 spectral width) and 256 transients per time interval. These are, respectively, optimized for $J_{CH} \cong 8$ Hz and $J_{CH} \cong 6$ Hz. Note that in XCORFE (7) and other similar 2D experiments (15, 16) one not only must choose $T \sim (^{2}J_{CH})^{-1}$ but also avoid the condition $T \sim (2J_{HH})^{-1}$ since polarization transfer is eliminated if $^{1}H-^{1}H$ coupling vectors are antiphase at the end of T (16). $T = 0.062$ is a good choice in most cases since J_{HH} is generally less than 5 Hz or greater than 10 Hz. However, in some cases (H(2), H(α), H(β), and the aromatic protons) $J_{HH} \sim 8$ Hz. The alternative time generally gave better cross peaks for these protons.

A systematic comparative study of the conformational dynamics of lupinine and epilupinine, two 1-hydroxymethyl quinolizidine epimers, as a function of phase transition and of their protonation is presented. Lupinine and epilupinine have a *trans*-quinolizidine configuration and they differ only in the position of the CH_2OH group. The axial position of this group allows the formation of an intramolecular hydrogen bond OH...N in lupinine, in contrast to epilupinine in which this group is in the equatorial position. Intrinsic conformational equilibria for both epimers have been defined. Despite the significant difference in the population of the preferred rotamers of lupinine and epilupinine, both epimers adopt very similar crystal structures, but in all other states and forms, e.g., pure liquids, solutions in inert and polar solvents, and protonated salts, they behave in drastically different ways.

K. KULIŃSKA et M. WIEWIÓROWSKI. Can. J. Chem. **65**, 205 (1987).

On présente une étude comparative systématique des dynamiques conformationnelles de la lupinine et de l'épilupinine (deux épimères de l'hydroxyméthyl-1 quinolizidine) en fonction de la transition de phase ainsi que de leur protonation. La lupinine et l'épilupinine possèdent une configuration *trans* au niveau de la quinolizidine et leur seule différence réside dans la position du groupement CH_2OH. Le fait que ce groupement soit en position axiale dans la lupinine lui fournit l'occasion de former des liaisons hydrogènes intramoléculaires OH...N qui ne se forment pas dans le cas de l'épilupinine dans laquelle le groupement se trouve en position équatoriale. On a défini les équilibres conformationnels intrinsèques des deux épimères. Malgré l'existence de différences importantes dans les populations des rotamères préférés dans la lupinine et dans l'épilupinine, chacun des épimères existe dans des structures cristallines assez semblables; toutefois, dans tous les autres états et formes (liquides purs, solutions dans des solvants inertes et polaires et sous formes de sels protonés), il se comportent très différemment.

[Traduit par la revue]

Introduction

Two 1-hydroxymethyl quinolizidine epimers, lupinine and epilupinine (Fig. 1), have a *trans*-quinolizidine configuration (*trans* Q) (1). Rotation of the exocyclic hydroxymethylene group makes three staggered conformers of lupinine and epilupinine (Fig. 2) possible. The axial position of the CH_2OH group creates good stereochemical conditions for the formation of an intramolecular hydrogen bond OH...N in the *syn*/−60° rotamer of lupinine. In contrast, the equatorial position of the CH_2OH group in epilupinine makes a similar intramolecular interaction impossible, because of the long nitrogen–oxygen atomic distance (in the most favourable rotamer it is >3 Å).

In previously published papers (2–4) it has been shown that the lupinine rotamer with an intramolecular hydrogen bond predominates in solution, in contrast to the solid state, where only a crystal structure with an *anti*/180° lupinine conformation was found (5).

This paper presents a systematic comparative study of the conformational dynamics of lupinine and epilupinine as a function of phase transition and of their protonation. Various self-association properties of both epimers, possessing analogous proton-donor and -acceptor centers, will be discussed in the light of different configuration and conformational dynamics in the next paper of this series.

Experimental

Infrared spectra were measured on a Perkin–Elmer ir spectrometer, type 180. The ir spectra of solids were obtained by the powder method of suspension in Fluorolub (4000–1400 cm^{-1}). The ir spectra of liquids were obtained using cells of various thickness with NaCl or CaF_2 windows, depending on the solvent and concentration of the solution.

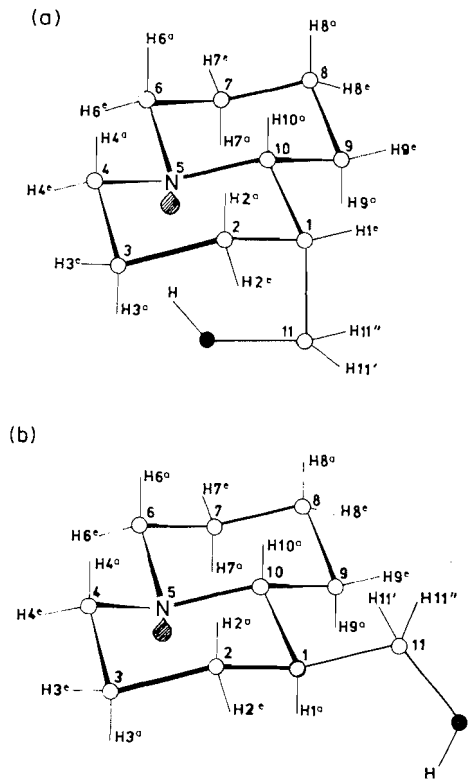

FIG. 1. Molecular structure of quinolizidine epimers: (*a*) lupinine and (*b*) epilupinine. Open circles denote carbon atoms; filled circles, oxygen atoms; "a" denotes axial, "e" equatorial, orientation of the hydrogen atoms.

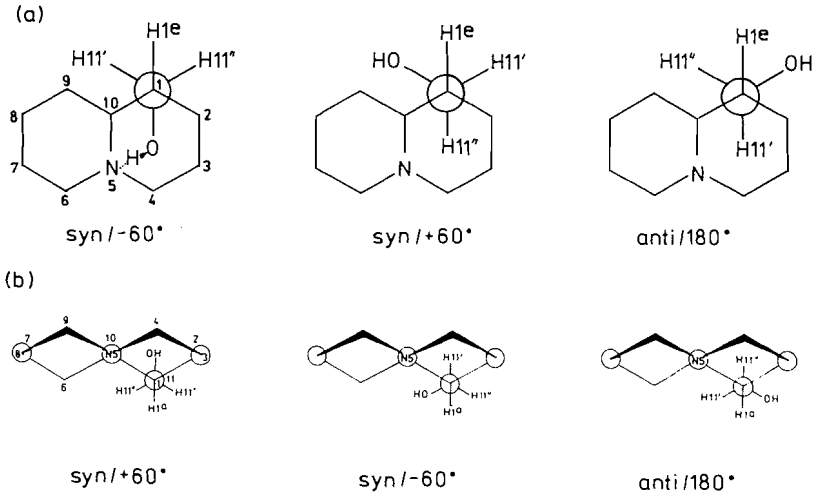

FIG. 2. Staggered (*a*) lupinine and (*b*) epilupinine conformers induced by rotations of the exocyclic CH_2OH group around the C1—C11 bond. The plane of projection of both epimers is perpendicular to C1—C11. Open rings indicate carbon atoms overlapped in projection. The terms "*syn*" and "*anti*" pertain to the relative position of the oxygen and C10 carbon atoms; the angular value describes the C10—C1—C11—O torsion angle.

All solvents were spectrally pure (Merck) and were dried prior to the experiment by passing through an aluminum oxide filled column and storing above 3 or 4 Å sieves.

The concentration of solutions was achieved by a precise weighing of each compound, which was then dissolved in an amount of solvent accurately measured with a micro pipette, or by the extinction of the C—H band at 2670 cm^{-1} (particularly in the series of concentration spectra). To avoid hydration of the solution, contact of the solvent with the environment was minimized, and the operation carried out partly in a dry box. Infrared spectra at higher temperatures were measured with the aid of a Specac temperature attachment, which enables stabilization of the temperature of the sample with a precision of ± 1°C.

The ^1H nmr and ^{13}C nmr spectra were recorded on JEOL FX-90Q Fourier transfer impulse equipment by the standard method and by double resonance, which facilitated the assignment of signals in the spectra. The ^{13}C nmr spectra were done by the noise band decoupling (NBD) and the single frequency of resonance decoupling (SFORD) techniques.

Results and discussion

Intrinsic conformational equilibrium

Conformational equilibrium can be defined by the free energy difference between conformations A and B

$$-RT \ln \frac{A}{B} = \Delta G^0(A) - \Delta G^0(B)$$

where ΔG^0 of each conformer is assumed to be equal to the algebraic sum of its 1,3 synaxial conformational interactions (6). The ΔG^0 values of 1,3 synaxial interactions were taken from the literature (4, 6).

Lupinine:

$$\Delta G^0(syn/-60°) = \Delta G^0(CH_2/OH) + \Delta G^0(CH_2/H) - \Delta G^0(OH\ldots N)$$
$$= 2.85 - \Delta G^0(OH\ldots N) \text{ kcal mol}^{-1}$$
$$\Delta G^0(anti/180°) = 2\Delta G^0(CH_2/H) + \Delta G^0(CH_2/N) + \Delta G^0(OH/H)$$
$$= 2.50 \text{ kcal mol}^{-1}$$
$$\Delta G^0(syn/+60°) = \Delta G^0(CH_2/OH) + \Delta G^0(CH_2/N) + \Delta G^0(CH_2/H)$$
$$= 3.30 \text{ kcal mol}^{-1}$$

TABLE 1. Lupinine and epilupinine free energy values and the population distribution of three staggered rotamers

	Rotamers	Free energies ΔG^0 (kcal mol^{-1})	Relative population of rotamers (%) 1[a]	2[b]
Lupinine	*syn*/−60°	2.85[c]	31	89
	anti/180°	2.50	55 }	11
	syn/+60°	3.30	14 }	
Epilupinine	*syn*/+60°	1.55	31	
	anti/180°	1.20	55	
	syn/−60°	2.00	14	

[a]Relative population of rotamers calculated according to the semi-empirical formula from refs. 4*a* and 6.

[b]Relative population of rotamers calculated from ir spectra of dilute lupinine and epilupinine solutions in inert solvent.

[c]Calculated without the contribution of the free energy, ΔG^0(OH...N), of the intramolecular OH...N hydrogen bond.

Epilupinine:

$$\Delta G^0(syn/+60°) = 2\Delta G^0(OH/H) + \Delta G^0(CH_2/H) = 1.55 \text{ kcal mol}^{-1}$$
$$\Delta G^0(anti/180°) = \Delta G^0(OH/H) + \Delta G^0(CH_2/H) = 1.20 \text{ kcal mol}^{-1}$$
$$\Delta G^0(syn/-60°) = \Delta G^0(OH/CH_2) = 2.00 \text{ kcal mol}^{-1}$$

The conformational equilibrium defined in this way is called an intrinsic conformational equilibrium, because it is determined exclusively by intramolecular steric tension. The free energy values obtained and the population of particular lupinine and epilupinine rotamers calculated on this basis are listed in Table 1.

Molecular structure in dilute solutions of inert solvent

The ir spectra of dilute lupinine and epilupinine solutions in CCl_4 in the region of stretching vibrations of the OH group are presented in Fig. 3. At low concentration, about 10^{-3} *M*, nearly all molecules of lupinine and epilupinine occur as monomers (4*a*). In the ir spectra of dilute epilupinine – carbon tetrachloride (CCl_4) solutions, where homoassociation processes take place

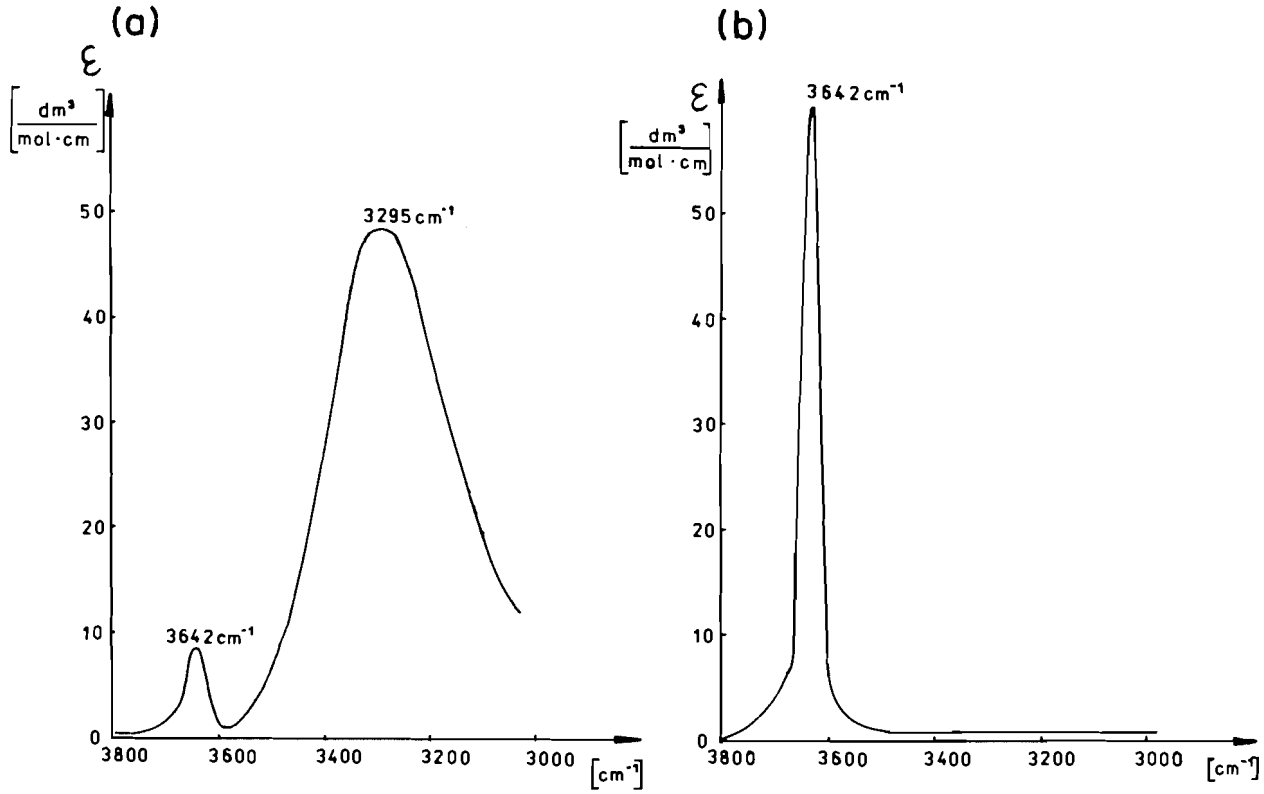

FIG. 3. The ir spectra of dilute (*a*) lupinine and (*b*) epilupinine solutions in CCl_4 in the region of stretching vibrations of the OH group (c = 0.003 M, 30°C).

only to a very small extent, only one ν(OH) band at 3642 cm^{-1} is present, indicating that "free" OH groups vibrate in the same manner in all rotamers of epilupinine. The ir spectrum of a dilute lupinine solution is in accordance with theoretical expectations and previous literature reports (4*b*), and exhibits two bands within this spectral range: (*i*) a low intensity band in the same position as in an epilupinine ir spectrum ν(OH) = 3642 cm^{-1}, corresponding to rotamers with a "free" OH group (*syn*/+60° and *anti*/180°); and (*ii*) a band ν(OH...N) = 3295 cm^{-1} corresponding to the *syn*/−60° rotamers in which the OH group is engaged in an intramolecular hydrogen bond. Integrative absorptions of the ν(OH) = 3642 cm^{-1} bands in the ir spectra of lupinine and epilupinine solutions in CCl_4 were compared, on the assumption that the molar extinction coefficient of free stretching vibrations of the OH group is identical for the epimeric compounds (4*b*). Approximately 11% of lupinine molecules occur in the *syn*/+60° and *anti*/180° conformations, from which it follows that 89% of the molecules take on the *syn*/−60° conformation.

Comparing the spectroscopically determined conformational equilibrium of lupinine with its intrinsic conformational equilibrium, one can calculate the unknown free energy value of the intramolecular hydrogen bond formation (4*a*), which equals ΔG^0 (OH...N) = −1.8 kcal mol^{-1}.

An increasing concentration of lupinine and epilupinine in such solutions as *n*-heptane, *n*-hexane, CCl_4, 1,2-dichloroethane, and benzene causes bands of homoassociated molecules to appear in the ir spectra beside those of solvated monomers.[1] Concentration does not influence the conformational equilibrium between intramolecular hydrogen bonded (*syn*/−60°) and other forms (*syn*/+60° and *anti*/180°) of lupinine monomers, as long as no crystallization takes place in the solution, since the ratio of integrative absorptions ν(OH) and ν(OH...N) is independent of concentration.

The ^{1}H nmr spectra of lupinine solutions in CCl_4 and deuterated chloroform ($CDCl_3$) add new information about the rotation of the exocyclic CH_2OH group. The ^{1}H nmr spectrum of a lupinine solution in $CDCl_3$, presented in Fig. 4*a*, shows four groups of signals originating from (*1*) the hydroxyl proton, δ 5.38 ppm, (*2*) protons H11′ and H11″ of the exocyclic CH_2OH group, δ 4.3–3.6 ppm, (*3*) equatorial protons from α carbons, δ 2.9–2.7 ppm, (*4*) the remaining protons of the quinolizidine ring, which give a broad band in the range δ 2.3–1.0 ppm. (The chemical shift assignments in the ^{1}H nmr and ^{13}C nmr spectra were made by comparison with previously reported values (7) and off-resonance decoupling. An extensive analysis of ^{1}H nmr spectra of lupinine and epilupinine solutions is presented in ref. 8.)

In solutions of lupinine in dilute CCl_4 and in 0.01–2.0 M $CDCl_3$ the signals of the H11′ and H11″ methylene protons of the CH_2OH group appear as doublets and quartets (Fig. 4*a*). The vicinal coupling constants of H11′ and H11″ protons with the H1^e proton, observed in the ^{1}H nmr spectrum, are the weighted average of vicinal coupling constants for all three lupinine rotamers. The fact that the value of the vicinal coupling constant for one of the methylene protons is reduced to 0 Hz can be attributed to the deformation of the ideal *syn*/−60° conformer, by an intramolecular hydrogen bond, into a *syn*/−30° form in which a dihedral angle of H1—C1—C11—H11″ equals nearly 90° (Fig. 5). Then, in accordance with the Karplus dependence, its vicinal coupling constant is a small negative number equilibrating the impact of the few (about 10%)

[1]A detailed discussion of homoassociation processes of lupinine and epilupinine will be presented in the following paper of this series (K. Kulińska and M. Wiewiórowski, in preparation).

anti/180° and *syn*/+60° rotamers. From model observations it follows that the *syn*/−30° conformation creates the most favourable geometrical conditions for the intramolecular hydrogen bond because the distance between the nitrogen and oxygen atoms becomes the shortest and the hydrogen bond is almost linear. The mean vicinal coupling constant of the H11′ methylene proton with $H1^e$ equals 6 Hz, as determined from the ^1H nmr spectrum (Fig. 4), which according to the Karplus correlation (9) should correspond to the values for dihedral angles of about 30° or 150°. The first value fits very well to the assumed 90° torsion angle for H1—C1—C11—H11″ bonds shown in Fig. 5*b*. In the ^1H nmr spectra of CCl_4–lupinine solutions of higher concentration, the methylene proton signals appear as two quartets, since as well as monomers among which the conformers with intramolecular hydrogen bonds dominate by 90%, there appear in increasing amounts associated molecules without intramolecular hydrogen bonds, i.e., without the deformed *syn*/−30° conformation in which the value of the vicinal coupling constant $J(H1^eH11'')$ is a small negative number.

Conformational dynamics of the hydrated and protonated quinolizidine ring system in aqueous solutions

A comparison of ^1H nmr spectra of aqueous solutions of lupinine and epilupinine measured under identical concentration and temperature conditions shows a lower resolution of the former (Fig. 6). This cannot be due to the high viscosity of lupinine solution in D_2O (9) because the spectra of epilupinine, which possesses a similar viscosity, show a much better resolution. Moreover, a decrease in the concentration of

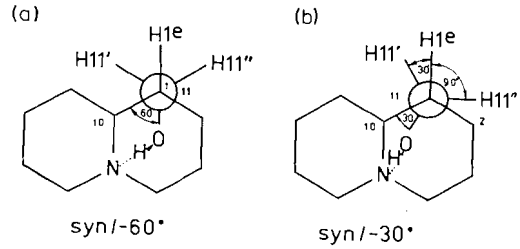

FIG. 5. Schematic presentation of lupinine rotamer with intramolecular hydrogen bond in its ideal *syn*/−60° and deformed *syn*/−30° form.

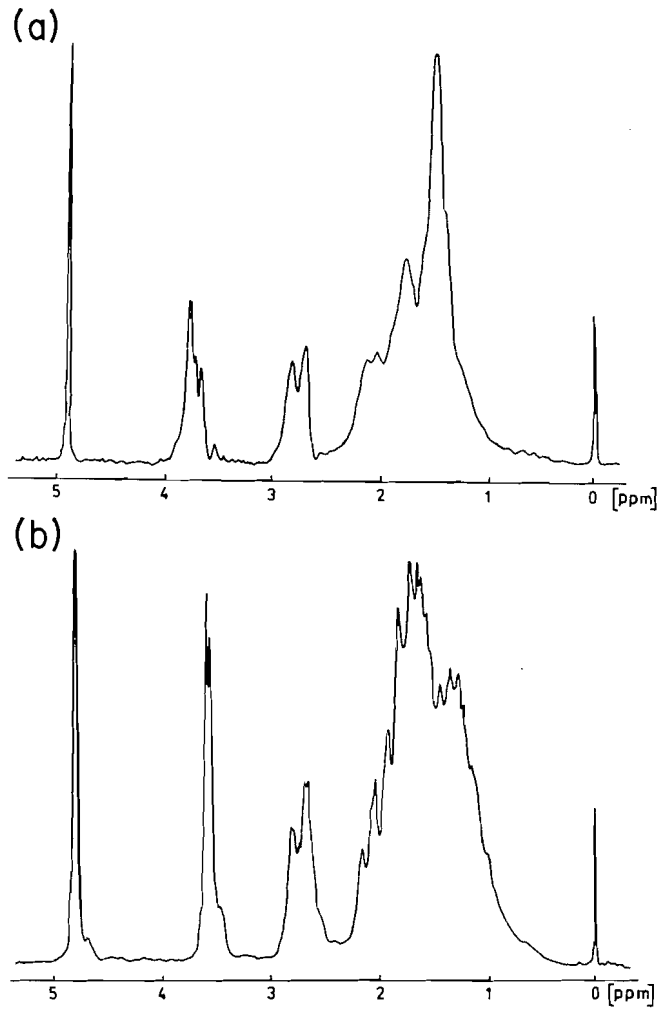

FIG. 6. The ^1H nmr spectra of (*a*) lupinine and (*b*) epilupinine aqueous solutions ($c = 0.4\,M$, 30°C).

lupinine solution decreases its viscosity but does not increase the resolution of the spectrum. On the other hand, an increase in temperature is accompanied by greater resolution of the ^1H nmr spectra of lupinine solution in D_2O, and by a shift of signals originating from the protons of the quinolizine rings within the range 1.0–2.3 ppm (Fig. 7).

In the second paper of this series[1] we will show that in aqueous solution intramolecular hydrogen bonds are not present within lupinine. Relatively small water molecules can interact specifically both with tertiary nitrogen and with the hydroxyl group. It is known from earlier papers that N-methylation and N-oxidation of lupinine cause inversion at the nitrogen atom

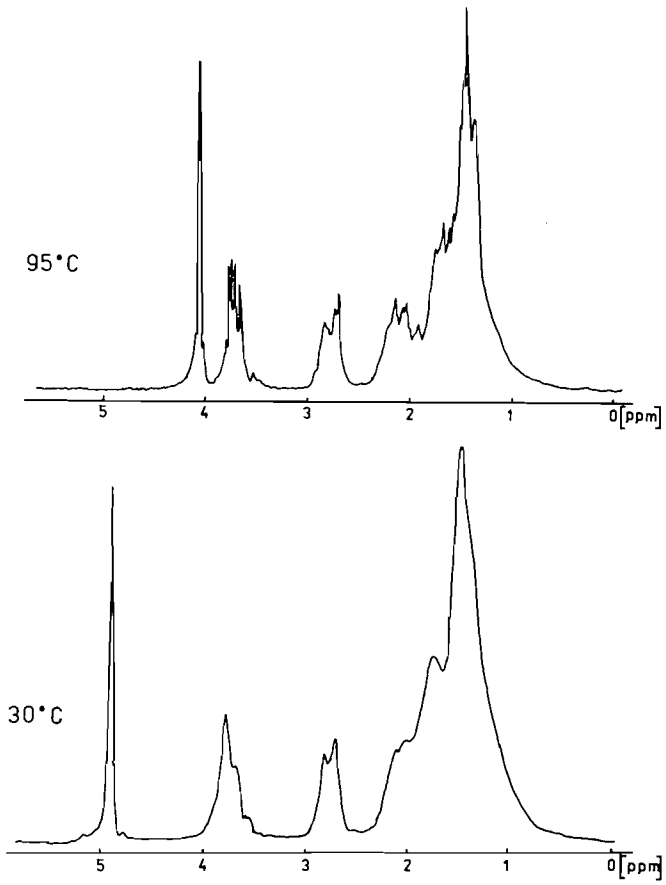

FIG. 7. The ^{1}H nmr spectra of aqueous solutions of lupinine at different temperatures (c = 0.8 M).

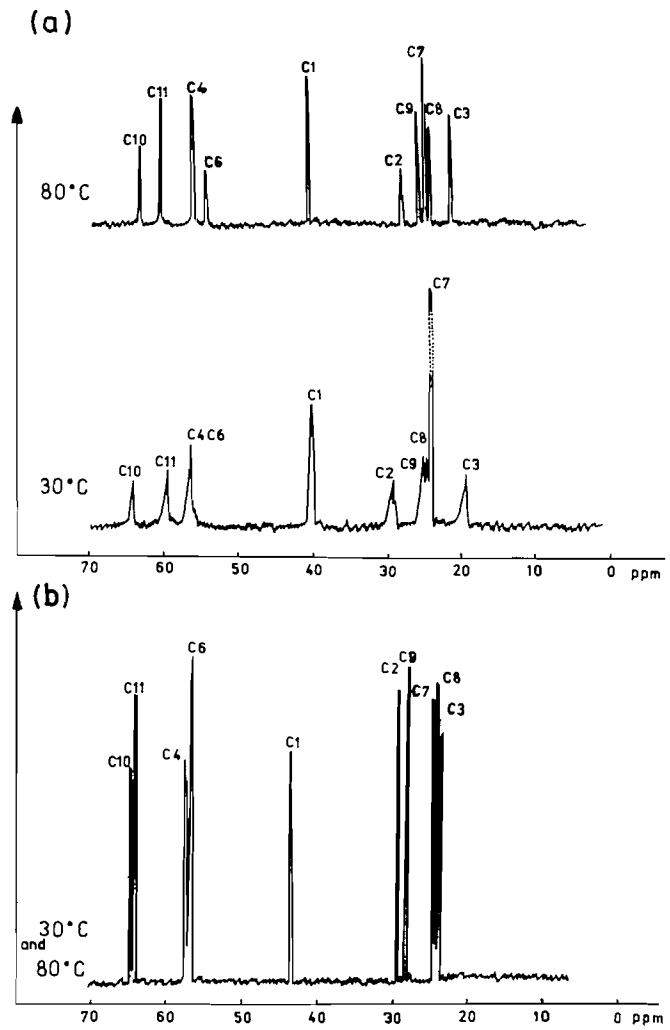

FIG. 8. The ^{13}C nmr spectra of aqueous solutions of (a) lupinine and (b) epilupinine (c = 0.4 M).

(10). We assume that the hydration of a lupinine molecule can also bring about a similar inversion and, in consequence, the occurrence of lupinine molecules in aqueous solution also in the "*cis*" configuration.

The above spectroscopic observations confirm the existence of this type of conformational and configurational dynamism in the quinolizidine system of lupinine.

At room temperature the *cis* ⇄ *trans* transformation is so slow that it only causes a broadening of the signals in the spectrum, but an increase in temperature accelerates the rate of configurational changes. In the ^{1}H nmr spectrum of an aqueous solution of epilupinine, increase in temperature does not bring about any changes, and the spectrum has a relatively good resolution over the whole temperature range. The presence of configurational *cis–trans* dynamism in a lupinine molecule, and the absence of this dynamism in a molecule of epilupinine in aqueous environment, is further confirmed by ^{13}C nmr spectra of aqueous solutions of these molecules.

The signals in a ^{13}C nmr spectrum of lupinine in D_2O vary in intensity and are broadened (Fig. 8*a*), contrary to the ^{13}C nmr spectra of aqueous solutions of epilupinine (Fig. 8*b*). By increasing the temperature the signals in a ^{13}C nmr lupinine spectrum become sharp, their intensities unified, and considerable shifts are also observed. In the ^{13}C nmr spectrum of the aqueous solution of lupinine the signal of carbon C7 exhibits an exceptionally high intensity. If one compares the Dreiding models of *trans* and *cis* lupinine conformers one notices that only the environment of carbon C7 does not undergo any changes as a consequence of a transition from the *trans* into the *cis* Q form. The high intensity of this signal in the ^{13}C nmr spectrum indicates long relaxation times T_1 and T_2. A broadening of the signals and their shift resulting from temperature changes indicate the presence of, and dynamic transition between, the *trans* and *cis* forms of lupinine.

Configurational changes within the quinolizidine system that were observed in aqueous solution of lupinine made us expect that the *cis* ⇄ *trans* equilibrium would also appear in solutions of protonated lupinine derivatives such as lupinine hydrochloride and perchlorate.

Crystalline lupinine hydrochloride preserves the *trans*-quinolizidine configuration (5) whereas the N-methylated derivative of lupinine occurs exclusively in the "*cis*" form (5). This indicates that, in the process of N-alkylation, inversion takes place at the nitrogen atom.

The ^{13}C nmr spectra of the aqueous lupinine hydrochloride solution contain a double number of signals (Fig. 9). This is evidence of the coexistence of comparable populations of the *trans* and *cis* forms of protonated lupinine molecules in aqueous solution. Either both these forms are stable and do not undergo mutual transformation, or the mutual transformation of both forms is very slow.

In the ^{13}C nmr spectra of aqueous epilupinine solutions no changes indicating the presence of a dynamic *cis* ⇄ *trans* equilibrium are observed, just as in the ^{1}H nmr spectra. As

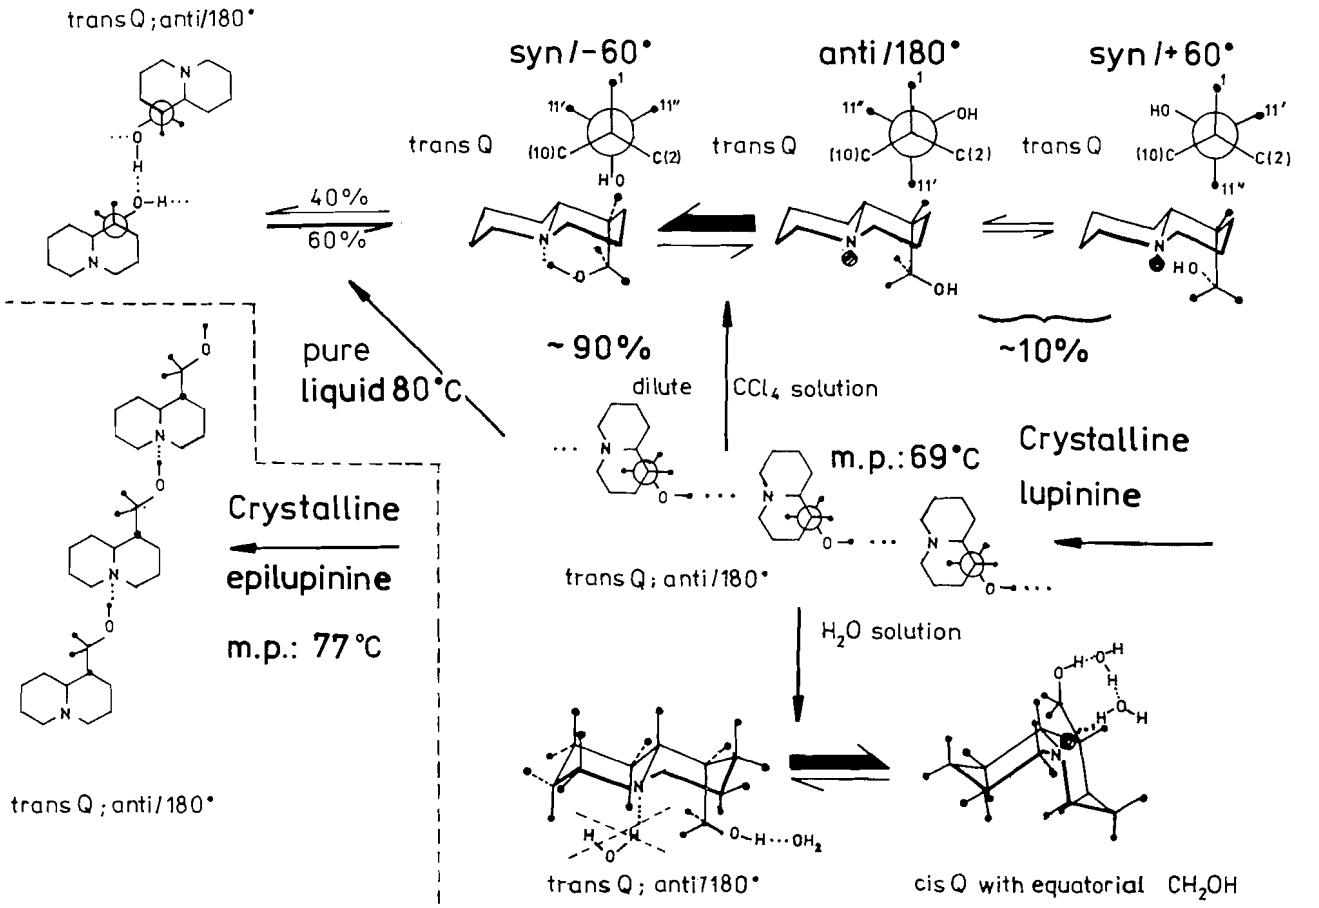

SCHEME 1. Schematic presentation of structural changes of lupinine molecule occurring on solid ⇄ liquid and solid ⇄ solute phase transitions.

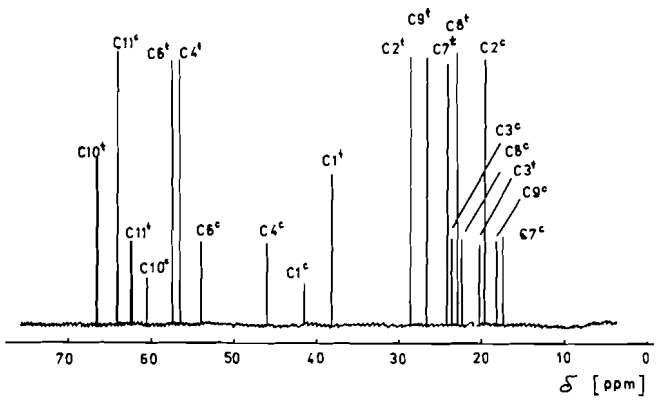

FIG. 9. The ^{13}C nmr spectra of aqueous solutions of lupinine hydrochloride (c = 0.4 M, 30°C).

expected, epilupinine exhibits no conformational dynamism other than the rotation of the exocyclic CH_2OH group around the C1—C11 bond.

Molecular structure in the solid and liquid states

In the crystalline structure, lupinine and epilupinine occur in the *anti*/180° conformation and form infinitely long linear polyassociates linked by intermolecular hydrogen bonds OH...N′ (Scheme 1). To compare the strengths of the OH...N′ intermolecular hydrogen bonds present in the monocrystals of lupinine and epilupinine, the ΔHB and $-\Delta H^0$ parameters were calculated (11*a*,*b*). The values of the ΔHB parameters, approximate values of enthalpy $-\Delta H^0$ corresponding to them,

TABLE 2. Selected parameters characterizing the geometry and strength of the intermolecular hydrogen bonds OH...N′ in the crystalline structure of lupinine and epilupinine

	ΔHB[a]	$-\Delta H^0$ (kcal mol^{-1})	d (Å)[b]	∢β[c]
Lupinine	132	2	2.868	10.2°
Epilupinine	98	1.5	2.902	15.1°

[a]The ΔHB parameter indicates the value by which the distance between the hydrogen bonded proton donor and acceptor groups is shorter than the sum of corresponding van der Waals radii. The following values of the van der Waals radii have been used: r_O = 1.45 Å; r_N = 1.55 Å; ΔHB = $(r_O + r_N - d) \times 10^3$ (Å).
[b]d = the distance between the oxygen atom and the nitrogen atom, from X-ray data.
[c]∢β = 180° − ∢(OH, ON′).

as well as some X-ray data describing the geometry of the O...N′ intermolecular hydrogen bonds are given in Table 2.

The values of the ΔHB parameters show that the OH...N′ intermolecular hydrogen bonds, which occur in the crystalline structure of both epimers, are of comparable strength and belong to the group of weak hydrogen bonds. The above observation is confirmed by the ir spectra of the solid state of lupinine and epilupinine (Fig. 10). The bands of the stretching vibrations of the OH group are shifted towards lower frequencies in respect to the band of the stretching vibrations of "free" OH, by 470 cm^{-1} in lupinine and by 480 cm^{-1} in epilupinine. The bigger shift in epilupinine suggests a stronger intermolecular hydrogen bonding OH...N′ in this compound, while X-ray data (namely, the distances between the hydrogen

TABLE 3. The stretching vibrations of the OH group (cm^{-1}) (free and involved in different types of hydrogen bonds)

Phase	Lupinine				Epilupinine		
	ν(OH)	ν(OH...O′)	ν(OH...N)	ν(OH...N′)	ν(OH)	ν(OH...O′)	ν(OH...N)

Liquid		3420 m	3310 m			3410 m	3200 m
Amorphic		3420 sh	3310 m	3170 s			
CCl_4 $c = 0.003\ M$	3640 w		3295 s		3640 s		
CCl_4 $c = 0.7\ M$	3640 w	3400 m	3295 m	3170 sh	3640 w	3380 m	3200 m

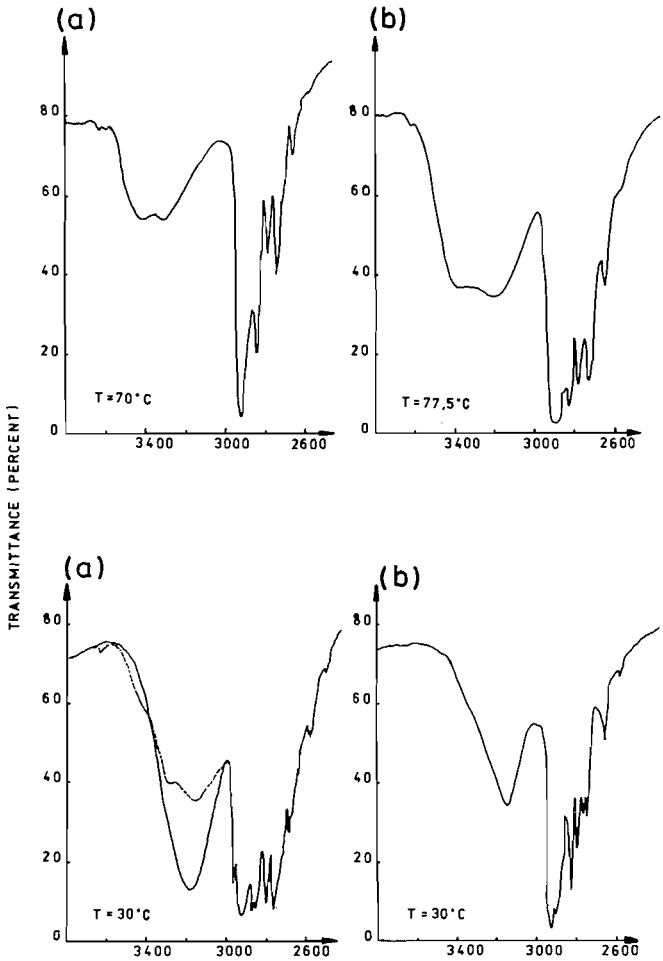

FIG. 10. The ir spectra of (*a*) lupinine and (*b*) epilupinine in the solid state at 30°C and at temperatures above the melting point. Dotted line denotes ir spectrum of lupinine in the amorphic phase ((*a*), 30°C).

bonded proton donor and acceptor groups and the ΔHB related parameters) suggest the opposite.

In spite of numerous attempts at the crystallization of lupinine under various conditions, we failed to obtain a different polymorphic crystalline form, in which lupinine would preserve the intramolecular hydrogen bond that is present in solution (see above). However, it has been observed that lupinine has a tendency to form an amorphic solid state. When the crystallization process of lupinine is fast, because of rapid cooling or the insertion of a crystalline germ into the supersaturated solution, the obtained ir spetrum of the solid state differs considerably from the ir spectrum of lupinine crystals obtained by way of slow crystallization (Fig. 10*a*, broken line).

The increase in temperature from 20°C to the melting point (69–70°C for lupinine, 77–78°C for epilupinine) does not cause any significant changes in the ir spectrum of the crystalline phase of either compound.

In the liquid state (temperature >70°C) nearly 50% of lupinine molecules adopt the form of a monomer with an intramolecular hydrogen bond (ν(OH...N) = 3310 cm^{-1}). A comparable number of molecules associate through the OH...O′ intermolecular hydrogen bond (ν(OH...O′) = 3420 cm^{-1}), and a small fraction of molecules (less than 10%) through the OH...N′ intermolecular hydrogen bond (the shoulder at 3170 cm^{-1}).

In liquid epilupinine, comparable fractions of the molecules associate through the OH...O′ (ν(OH...O′) = 3410 cm^{-1}) and OH...N′ (ν(OH...N′) = 3200 cm^{-1}) intermolecular hydrogen bonds.

The ir spectrum of the condensed amorphic phase of lupinine seems to be a superposition of the ir spectra of the crystalline and liquid phases (Fig. 10*a*, Table 3).

Summary and final remarks

Lupinine and epilupinine, two epimeric amino alcohols, differ in the position of the exocyclic hydroxymethyl group. This relatively small structural change has a drastic influence on the molecular and intermolecular dynamism of both epimers. The conformational and configurational dynamism of lupinine is much greater due to a sterically unfavourable axial location of the *exo* hydroxymethyl group. The exocyclic CH_2OH groups can rotate around the C1—C11 bonds and are the most dynamic fragments of both molecules.

Intrinsic conformational equilibria for lupinine and epilupinine have been defined in a semi-empirical way by calculation of conformational free energies assumed to depend only on intramolecular steric hindrances (6). Populations of the three staggered rotamers for lupinine and epilupinine are summarized in Table 1.

The *syn*/−60° rotamer in lupinine is additionally stabilized by an intramolecular OH...N hydrogen bond whose contribution to the conformational energy is ~1.8 kcal mol^{-1}. In consequence, the population of the *syn*/−60° rotamer of lupinine in dilute solution in inert solvents rises to ~90%, whereas that of the two remaining rotamers (*anti*/180° and *syn*/+60°) decreases to ~7 and ~3%, respectively.

Despite the significant difference in the populations of the preferred rotamers of lupinine (*syn*/−60°, 90%) and epilupinine (*anti*/180°, 55%), both epimeric amino alcohols adopt very similar crystal structures (5) containing infinite chains of hydrogen bonded *anti*/180° rotamers (Scheme 1). Close values of ν(OH) (3170 and 3160 cm^{-1}, Table 3) in the ir spectra of both crystalline samples indicate that also the strengths of the intermolecular hydrogen bonds in the above chains are almost identical.

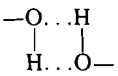
In all other states and forms, e.g. pure liquids, dilute solutions (in inert and polar solvents), and protonated salts, the two epimers behave in drastically different ways.

In the case of epilupinine, the melting and dissolution processes do not show any unusual features. In pure liquid at 80°C, in addition to the OH...N polyassociated chain present in the crystalline solid (ν(OH...N) at 3200 cm^{-1}), there appears another type of homoassociation with —O—H...O— hydrogen bonds (ν(OH) at 3410 cm^{-1}, Table 3). In dilute epilupinine solution in inert solvents there exist, mostly or exclusively, solvated monomeric epilupinine molecules characterized in ir spectra by a ν(OH) band at 3640 cm^{-1}. When the concentration of epilupinine increases, the two homoassociates begin to appear (Table 3).

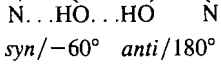
In the case of lupinine, phase transitions (i.e., melting and dissolution) are accompanied by disappearance of the polyassociated OH...N chains, present as exclusive forms in the single crystal of lupinine. Two forms dominate in pure liquid (temperature 70°C): monomeric *syn*/−60° rotamers with intramolecular hydrogen bonds, and OH...OH homoassociated *anti*/180° rotamers.

Scheme 1 presents in a very simplified manner the structural changes occurring in the solid ⇄ liquid and solid ⇄ solute phase transitions of lupinine.

In liquid lupinine, besides the association through intermolecular hydrogen bonds —OH...OH presented in Scheme 1, there certainly exist significant amounts of symmetric



and especially asymmetric dimers where *syn*/−60° rotamers with an intramolecular hydrogen bond are associated by intermolecular hydrogen bond with the *anti*/180° rotamers:



syn/−60° *anti*/180°

Lupinine molecules in dilute inert solvent solutions (e.g. CCl_4 or $C_2H_4Cl_2$) exist exclusively in two monomeric forms: homosolvated (rotamers, *syn*/−30° with intramolecular hydrogen bonds) and heterosolvated (rotamers, *anti*/180° and *syn*/+60°, solvated by solvent molecules).

The drastic change of conformational equilibrium in lupinine upon conversion to the crystalline phase seems to be brought about by competition between intermolecular OH...N′ and intramolecular OH...N hydrogen bonds. In solution and in the liquid state the formation of polymeric structures is hardly probable because of unfavourable entropy and limitations of the kinetics of the molecules. That is why the OH...N intramolecular hydrogen bond dominates, and the stronger OH...N′ intermolecular hydrogen bond is unstable. Only in the crystalline structure, when the molecular kinetics is blocked, is the *anti*/180° conformation of lupinine energetically more favourable. This facilitates the formation of the stronger OH...N′ intermolecular hydrogen bond. This is confirmed by recrystallization of the amorphic phase of condensed lupinine, in which process frozen structures containing intramolecular hydrogen bonds OH...N are gradually transformed into crystalline structures with OH...N′ intermolecular hydrogen bonds.

Both epimeric amino alcohols are very soluble in polar solvents, e.g. H_2O and DMSO. There is no doubt that these solvents are active enough to break the intermolecular hydrogen bonds existing in crystalline samples of lupinine and epilupinine. Water molecules, having both proton-donor and proton-acceptor centers, tend to interact with donor as well as acceptor centers of the epimeric amino alcohols. In epilupinine both the N and O atoms can be easily hydrated, especially in the *anti*/180° rotamer. However, in the case of lupinine, the axial CH_2OH group, even in the *anti*/180° form, creates significant steric hindrance around the nitrogen atoms and in consequence only the OH group can be easily hydrated when lupinine exists in the *trans* Q configuration. The ^{13}C nmr data of lupinine in D_2O suggest that, due to hydration, it is transformed in aqueous solution from the *trans* Q into the *cis* Q configuration by inversion at the nitrogen atoms. Thus the CH_2OH groups become equatorial and hence easily accessible by water molecules (Scheme 1). We assume that in an aqueous solution of lupinine the equilibrium between *trans* Q and *cis* Q is shifted almost completely to the *cis* side, but further evidence is needed. This statement is strongly supported by the previous chemical finding that the reactions of aqueous lupinine solution with H_2O_2 and CH_3I lead to the N-oxide and N-methyl derivatives of lupinine with the *cis* Q ring system (10).

Influence of solvent on the magnitude of the anomeric effect

J.-P. PRALY[1] AND R. U. LEMIEUX[2]
University of Alberta, Edmonton, Alta., Canada T6G 2G2

Received July 3, 1986

This paper is dedicated to Dr. O. E. (Ted) Edwards

J.-P. PRALY and R. U. LEMIEUX. Can. J. Chem. **65**, 213 (1987).

A novel application of ^{13}C nuclear magnetic resonance provided the effects of solvent polarity and hydrogen-bond formation on the conformational equilibria for a range of 2-substituted tetrahydropyrans and the results are interpreted in terms of how solvent affects the competition between the *endo*- and *exo*-anomeric effects in determining the magnitude of the anomeric effect. In accord with the generally accepted origin of the *endo*- and *exo*-anomeric effects (*anti*-periplanar n–σ^* interaction of the oxygen lone-pair orbital with the antibonding orbital of the adjacent C—O bond), the *exo*-anomeric effect for the α anomer is expected to be weaker because charge delocalization from the glycosidic oxygen to anomeric center is in competition with delocalization from the ring-oxygen atom. The effects of solvent on the relative magnitudes of the *endo*- and *exo*-anomeric effects are then considered to arise from the formation of specific complexes with the solvent, and the *exo*-anomeric effect of a β-glycoside is more strongly influenced. It is contended that hydrogen bonding of solvent to the ring oxygen increases the *exo*-anomeric effects. For this reason water is particularly effective for the strengthening of the *exo*-anomeric effect and, thereby, the conformational rigidity of glycosides. Experimental evidence is presented that indicates that the anomeric hydroxyl groups of free sugars dissolved in water tend to prefer the equatorial orientation because these provide stronger hydrogen bonds as proton donors to water.

J.-P. PRALY et R. U. LEMIEUX. Can. J. Chem. **65**, 213 (1987).

Une nouvelle application de la rmn du ^{13}C permet de déterminer les effets de la polarité du solvant et de la formation de liaisons hydrogènes sur l'équilibre conformationnel d'une série de tétrahydropyrannes portant un substituant en position 2; on interprète les résultats en fonction de comment les solvants affectent la compétition entre les effets anomères *endo* et *exo* dans la détermination de l'amplitude de l'effet anomère. En accord avec l'origine généralement acceptée des effets anomères *endo* et *exo* (interaction n–σ^* *anti*-périplanaire de l'orbitale de la paire libre de l'oxygène avec l'orbitale antiliante de la liaison C—O adjacente), il est prévu que l'effet anomère-*exo* de l'anomère-α sera plus faible parce que la délocalisation de la charge de l'oxygène glycosidique vers le centre anomère est en compétition avec la délocalisation de l'atome d'oxygène du cycle. On considère alors que les effets de solvant sur les amplitudes relatives des effets anomères *endo* et *exo* proviennent de la formation de complexes spécifiques avec le solvant et que l'effet anomère-*exo* d'un β-glycoside est plus fortement influencé. On prétend que la liaison hydrogène du solvant avec l'oxygène du cycle augmente les effets anomères-*exo*. Pour cette raison, l'eau est particulièrement efficace pour rehausser l'effet anomère-*exo* et, finalement, la rigidité conformationnelle des glycosides. On présente des données expérimentales qui indiquent que les groupements hydroxyles anomères de sucres libres dissous dans l'eau tendent à préférer l'orientation équatoriale parce que celle-ci donne lieu à des liaisons hydrogènes plus fortes comme donneurs de protons à l'eau.

Introduction

The term "anomeric effect" was introduced in 1959 (1) to indicate the existence of a stereoelectronic influence on chemical bonding that had been detected (2) in a study of the anomerization equilibria for acetylated glycopyranoses of known ring conformation (3). Since then, the subject has received major attention (4, 5). It was initially proposed (6) that the anomeric effect was the result of bond dipole – bond dipole interactions. Mainly on the basis of X-ray crystallographic data, Altona (7) suggested that the anomeric effect was a manifestation of charge delocalization (no-bond resonance) from the oxygen atom of the acetal group toward the anomeric carbon. Thus, the stabilization gained was greater for the anomer with the aglycon in axial orientation since this placed the polar glycosidic bond *anti*-periplanar to an unshared pair of electrons of the ring oxygen. The subject then drew very substantial attention from theoretical chemists. Wolfe *et al.* (8) have presented a fine review of these developments. The nature of the orbitals and how these are considered to interact for the stabilization of an acetal bond has been qualitatively presented in detail by Kirby (4).

The differences in conformational energy for the various conformers for dimethoxymethane as estimated by the *ab initio* molecular orbital calculations of Jeffrey, Pople, and co-workers (9) were used in this laboratory (10) to assign a value to what had been termed the *exo*-anomeric effect (11). Subsequently (12), this contribution to the energy of a glycosidic bond was expressed in terms of two torsion expressions, namely

$$[1]\quad exo\text{-}A_\beta = 2.61(1 - \cos\theta^\circ) - 1.21(1 - \cos 2\theta^\circ) - 1.18(1 - \cos 3\theta^\circ) + 2.86 \text{ kcal/mol}$$

$$[2]\quad exo\text{-}A_\alpha = 1.58(1 - \cos\theta^\circ) - 0.74(1 - \cos 2\theta^\circ) - 0.70(1 - \cos 3\theta^\circ) + 1.72 \text{ kcal/mol}$$

That the *exo*-anomeric effect appears some 1.66 times stronger for the anomers (**1**) that have the aglycon in equatorial orientation (normally the β anomers) is not surprising, even in the absence of theoretical calculation. As seen in formula **1**, both the unshared pairs of electrons of the ring oxygen are *syn*-clinal to the glycosidic bond and, therefore, unfavorably disposed for delocalization toward the anomeric carbon. Thus, there exists no important competition for delocalization of charge (back bonding) (13) from the glycosidic oxygen that, in the sterically most favorable orientation, has an unshared pair

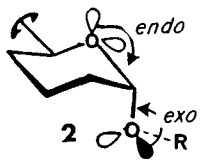
1



2

of electrons *anti*-periplanar to the C1—ring oxygen bond. In contrast to the β anomers, the α-glycosides have the aglycon in axial orientation and therefore, as displayed in **2**, are importantly stabilized by an *endo*-anomeric effect. However, for these α-anomers (**2**), competition exists between the *endo* and *exo*-anomeric effects for the electron deficiency at the anomeric carbon. Consequently, in accord with calculation (9, 14), the *exo*-anomeric effect for **2** should be weaker than that for the β anomer (**1**).

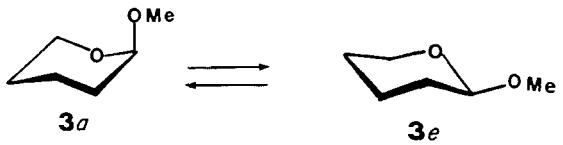
Fuchs *et al.* (15) examined the X-ray crystallographic data for 111 carbohydrate structures and found only orientations for the aglycon that are compatible with stabilization by way of an *exo*-anomeric effect.

The values for the *exo*-anomeric effects provided by expressions [1] and [2] are of course only a hopefully useful approximation. Certainly, the values for these stereoelectronic contributions to molecular stability will depend on the electronegativities of the substituents, both on the pyranose ring and on the aglycon (16). As will be discussed below, the solvent also appears to influence the values of *exo*-anomeric effects. Nevertheless, it was considered possible that the values for the α and β *exo*-anomeric effects, in conformers for dimethoxymethane as derived by *ab initio* molecular orbital calculation (9), would serve usefully for the molecular modelling of oligosaccharides. To date, this has proven to be the case. It was found, for example, that the conformational preference required by ^{1}H nmr data for the B human blood group trisaccharide determined in aqueous solution was not provided by hard-sphere calculation (12). However, addition of a contribution by the *exo*-anomeric effect to the hard-sphere calculations (12) provided a structure that was not only in accord with the nmr data but also present in the crystal structure (17).

Despite much such definitive evidence for the importance of the *exo*-anomeric effect (12, 13), this stereoelectronic feature continues to be disregarded in efforts to assess the conformational preferences of oligosaccharides. For example, Lipkind, Verovsky, and Kochetkov (18) recently published on the conformational states of cellulose, lactose, and maltose, and state, in the absence of acceptable experimental support, that the *exo*-anomeric effect does "not play a significant role under the conditions of an aqueous medium." In fact, as will be demonstrated below, the *exo*-anomeric effect appears to be not only of major importance but even of special importance in aqueous solution. The main purpose of this communication is to provide experimental support for this contention. Indeed, the neglect of a consideration of the *exo*-anomeric effect renders obsolete a large literature on the theoretical calculation of the conformational preferences of glycosidic structures. The fact that the *exo*-anomeric effect adds rigidity about the glycosidic bonds of oligosaccharides is a matter of major importance to an understanding of their interactions with the receptor sites of proteins to form specific carbohydrate–protein complexes. In this regard, it has become apparent that oligosaccharides present well-defined and substantially rigid surfaces about which the protein becomes organized (19).

The conformational analyses of compounds that contain polar bonds and atoms with unshared pairs of electrons require a consideration of specific solvent effects. For example, the conformational equilibrium for methyl 3-deoxy-β-L-*erythro*-pentopyranoside was more sensitive to the chemical nature of the solvent than to its polarity (20). Similarly, specific solvation effects were found to influence the conformational equilibrium for 2-methoxytetrahydropyran (2-MeO-THP) (**3**) (11).

The equilibrium data presented in Table 1 confirm the observation made in 1969 (11) that the polar solvent CD_3CN favors the more polar equatorial conformer **3e** to a greater extent



3a **3e**

than does the nonpolar CCl_4. In D_2O the two conformers have a near equal population (11). Thus, the anomeric effect for **3** is weak in water. Also, the mutarotation of many aldopyranoses in water favors the anomer with the anomeric hydroxyl in equatorial orientation (4). It is these kinds of observations that have led to the widespread notion that the anomeric effect is unimportant when the solvent is water. However, the stereoelectronic factors that are responsible for the anomeric effect cannot be expected to simply disappear in certain solvents. Instead, it must be considered that stereoelectronic effects on the strengths of the two C—O bonds of acetals remain but are exhibited differently in different environments because of changes in the interactions involving the unshared pairs of electrons. That this is the case clearly evident from the fact that, as seen in Table 1, weakly polar $CDCl_3$ is as effective as CD_3CN in favoring the more polar (11) conformer **3e**. In contrast, Tvaroska and Kozar (21) have presented a theoretical study of the hydration of the acetal segment in glycosides and concluded that hydration does not operate against the anomeric and *exo*-anomeric effects. Also, as already mentioned, Lipkind *et al.* (18) concluded, on the basis of a theoretical conformational analysis of disaccharide derivatives in aqueous solution, that the *exo*-anomeric effect and intramolecular hydrogen bonding are of no significance. We disagree. It is to be kept in mind, however, now that the origin of the anomeric effect has become established (8, 9), that an anomeric effect (ΔA) must be considered as the *difference* between the sum (A_{3e}) of the *endo*- and *exo*-anomeric effects in the equatorial conformer and the sum (A_{3a}) of these for the other conformer (22, 23). It is on this basis that the anomeric effect for **3** is defined as shown in expression [3]. As was mentioned above, the *endo*-A_e contributions are considered negligible and, therefore, A_{3e} is assumed to be equal to *exo*-A_{3e}.

$$[3]\quad \Delta A_3 = (exo\text{-}A_{3e} + endo\text{-}A_{3e}) - (exo\text{-}A_{3a} + endo\text{-}A_{3a}) = A_{3e} - A_{3a}$$

On the basis of eq. [3], anomeric effects will have a wide range of values, including negative and positive values, depending on the relative magnitudes of the various *exo*- and *endo*-anomeric effects. Indeed, for the equilibrium **3a** ⇄ **3e**, the axial conformer **3a** is strongly favored in CCl_4 and, therefore, A_{3e} must be less negative (less stabilizing) than A_{3a} in order that ΔA_3 be positive. In contrast, 2-methylaminotetrahydropyran (**4**) because of the basic nitrogen is expected to possess strong *exo*-anomeric effects. The *exo*-A_{4e} effect should be greater than the *exo*-A_{4a} contribution to the stability and, perhaps, sufficiently greater for the equilibrium to favor **4e** even though **4a** should be additionally stabilized by an *endo*-

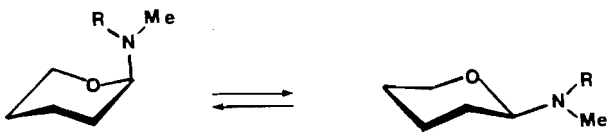
anomeric effect. In fact, Booth *et al.* (24) have recently shown that the process **4a** ⇄ **4e** favors the equatorial conformer. De Hoog (25) had earlier demonstrated a similar situation for 2-dimethylaminotetrahydropyran (**5**). On the other hand, the



4*a*, R=H
5*a*, R=Me

4*e*, R=H
5*e*, R=Me

substitution of the ring oxygen of a glycosidic structure by the stronger electron-donating NH group should increase the *endo*-anomeric effect of an α anomer but decrease the strengths of the *exo*-anomeric effects. Indeed, Pinto and Wolfe (26) have shown that the antibiotic Nojirimycin (5-amino-5-deoxy-D-glucopyranose) mutarotates in water to an equilibrium α/β = 1.7, in contrast to D-glucopyranose for which α/β = 0.56.

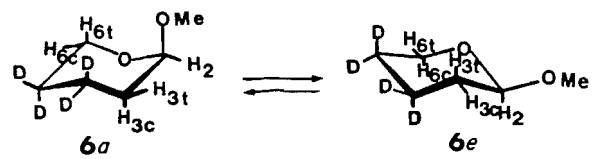
The conformational analysis of the equilibrium **3a** ⇄ **3e** can be expressed as

$$\Delta G^0 \simeq (\Delta A^0 + \Delta R^0) - T\Delta S^0$$

where ΔA^0 = anomeric effect, ΔR^0 = change in nonbonded interactions, and ΔS^0 = change in entropy. ΔG^0 is positive since **3a** is favored. For compound **3**, in nonpolar solvents, ΔS^0 should be negligible. The highest value to date for the anomeric effect (ΔA^0) is the 2.1 kcal/mol proposed by Franck (27) using CCl_4 as solvent. The change in nonbonded destabilizing interactions (ΔR^0) is not known but, because of the short C—O bond in the tetrahydropyranyl ring, should be greater than the *A* value (0.6 kcal/mol) (28) for a methoxy group. Assuming that **3a** is destabilized by 1.1 kcal/mol and that the change in entropy is negligible (27), the change in enthalpy ($\Delta H^0 = \Delta A^0 + \Delta R^0$) would appear to be about 1 kcal/mol in favor of **3a**. That this result has some validity is indicated by the fact that, with CCl_4 as solvent, ΔG^0 is near 1 kcal/mol (11) (see Table 5). However, Booth *et al.* (24) found ΔH for **3a** ⇄ **3e** with $CFCl_3$–$CDCl_3$ as solvent to be near zero. It was suggested that **3a** may be favored (K_e = 0.256) because of an unusually high difference in conformational entropy. On the other hand, Lemieux *et al.* (11) had provided evidence that **3** forms specific complexes with polar solvents and especially with solvents such as $CDCl_3$ and D_2O, which can provide a proton to hydrogen bond formation. Thus, it seemed possible that the near temperature independence of the change in free energy noted by Booth *et al.* (24) was due to stronger bonding of the solvent ($CFCl_3/CDCl_3$) with **3e** to form solvated species of nearly equal enthalpy contents. Since $CDCl_3$ solvent molecules are less prone to self-association than to bonding with the acetal (**3**), the decrease in entropy for the solvation of **3e** should be greater than that for **3a**. Thus, the net change in entropy should favor **3a**, as was observed. An examination of this possibility was a main purpose for this investigation. Deslongchamps (5*a*) has discussed the importance of stereoelectronic factors to the reactivity of acetals and, in this regard, pointed out (5*b*) that stereoelectronic effects should "influence the basicity of the oxygen atoms of the acetal function, thence their relative ease of protonation." The results to be presented below are in strong support of this contention.

Discussion of results

As already mentioned, this investigation was undertaken mainly because the conformational equilibrium for **3** in $CFCl_3$–$CDCl_3$ (85:15 v/v) was found to be essentially independent of temperature (23). The extension of temperature studies to other solvents appeared possible by the procedure used in 1969 (11), which involved measurement of the time-averaged values of $J_{2,3cis}$ and $J_{2,3trans}$ for 4,4,5,5-tetradeuterio-**3**; namely, the equilibrium **6a** ⇄ **6e**.



6*a* **6*e***

The conformational equilibria for the tetradeuterio compound **6** were estimated using the same procedure as previously described (11) except that the spacings in the ^1H nmr spectra were more precisely determined by operating at 400 MHz with deuterium decoupling. The results obtained using five different solvents and two different temperatures are presented in Table 2. As was previously done (11), the $J_{1,2a}$ and $J_{1,2e}$ coupling constants for the methyl 2-deoxy-α- and 2-deoxy-β-D-*arabino*-hexopyranosides were used to calculate the conformational equilibria from the observed values for $J_{2,3c}$ and $J_{2,3t}$. These equilibria are presented in Table 1, where it is seen that the results at 308 K agree well with those previously obtained (11) using a spectrometer operating at 100 MHz in the CW mode. The use of the coupling constants found for the 2-deoxyglucosides to calculate conformational equilibria for 2-MeO-THP (**3**) is, of course, arbitrary. That the procedure provides results useful for the present purposes was previously (11) supported by the optical rotations of an optically active sample of 2-MeO-THP in the various solvents. This conclusion is now supported, as described in the Experimental and involving structures **7**–**10**, by two other procedures: (*a*) the coupling of the H-6 atoms with deuterium atoms at C-5, and (*b*) the nuclear Overhauser enhancements (nOe) observed on saturation on H-2.

The above-described procedure for the determination of conformational equilibria of **6** by ^1H nmr was prohibitively

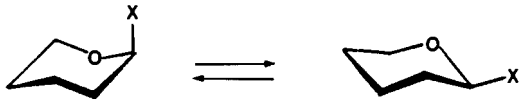
expensive, both in time and facilities, for broader application. However, it proved possible using the mole-fraction data presented in Table 2 to establish an efficient procedure based in ^{13}C nmr for the study of the conformational equilibria, not only under a variety of solvent conditions but also for a range of different 2-substituted tetrahydropyrans. The procedure, which is described in the Experimental, involves the assignment of "absolute" chemical shifts for C-4 in the conformations **3a** and **3e**. On this basis, time-averaged chemical shifts for C-4 could be interpreted to yield the mole fractions of **3a** and **3e** under the prevailing conditions. This procedure is made possible by the great stability of the magnetic fields produced by the superconducting solenoids of the modern high-frequency nmr spectrometers.

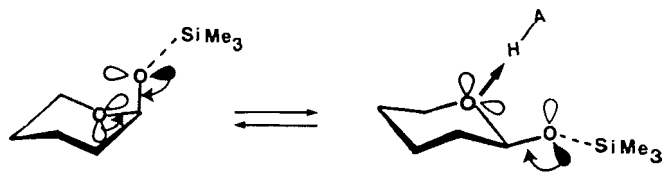
The equilibrium data at 308 K presented in Table 3, using CCl_4–C_6D_6 (10%) as solvent, are in accord with expectations based on the nature of the anomeric effect as it exists in the literature (4) and as discussed in the Introduction. The electronegativities of the aglycons CH_2FCH_2, CH_2OAcCH_2, and CH_3 are similar and, indeed, the conformational equilibria are all in the range 0.22 ± 0.02. As expected, the monofluoro compound (**12**) most favors the conformer with the aglycon in axial



11, X = CF_3CH_2O
12, X = CH_2FCH_2O
13, X = CH_2OAcCH_2O

orientation. Replacement of the CH_2F group of **12** by the much more electronegative CF_3 group to form **11** is seen to greatly enrich the population of the axial conformer. This consequence has long been appreciated (29), but is now considered to occur in part because the CF_3CH_2O group of **11** strengthens the *endo*-anomeric effect for conformer **11a** to a greater extent than does the less electronegative CH_2FCH_2O group of **12**. Also, however, the more electronegative CF_3CH_2 group of **11** weakens both the *exo*-anomeric effects to a greater extent than does the CH_2FCH_2 group.

As already discussed with reference to the amino compounds **4** and **5**, the equatorial orientation for the aglycon of a 2-substituted THP compound will be favored the stronger the *exo*-anomeric effect—an effect that increases with increasing ease for charge delocalization from the aglycon to the anomeric carbon. On this basis, the trimethylsilyl ether **14** was expected (30) to favor conformer **14e**, as compared to **3** favoring **3e**. In fact, the equilibrium for **14** in CCl_4–C_6D_6 is much more in favor of the equatorial conformer than is that for **3** and, for that matter, also those for **12** and **13**.



14a **14e**

As indicated in the conformational equilibrium for **14**, the ring oxygen of the **14e** conformer should serve best as proton acceptor for hydrogen bond formation with a protic solvent. Therefore, the population of **14e** at equilibrium should increase when the solvent is changed from carbon tetrachloride to chloroform (A = CCl_3). As seen in Table 3, the mole fraction of **14e** does increase from 0.28 to 0.47 on changing the solvent from CCl_4–C_6D_6 (10%) to $CDCl_3$. In D_2O, the mole fraction of **14e** was even greater at 0.70. This high abundance of **14e** can be

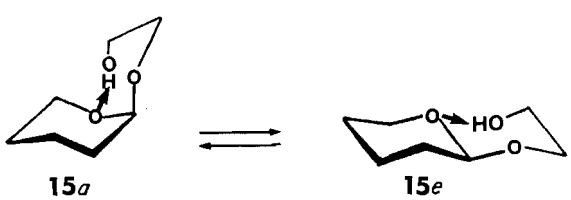
attributed to both the high polarity of D_2O as well as to its ability to behave as a "proton" donor for hydrogen bond formation. The polar CD_3CN provided an equilibrium with nearly the same population of **14e** as does the much less polar solvent $CDCl_3$ (11).

In CCl_4–C_6D_6, the abundance of conformer **15e** of the hydroxyethyl compound **15** is significantly greater (n_{15e} = 0.31) than that (0.19) of conformer **3e** for compound **3** although the CH_2ODCH_2 group of **15** is certainly more electronegative than the CH_3 group of **3**. This apparent anomaly can be attributed to involvement of the ring oxygen of **15** in hydrogen bonding with the hydroxyl of the aglycon as is displayed in the formulas for **15a** and **15e**. This driving force in favor of **15e** would be eliminated in solvents such as CD_3CN and D_2O, which can act as good proton acceptors. In fact, the mole fractions of **15e** in these solvents are greater and nearly the same as those for **12e**, **13e**, and **3e**. On the other hand, $CDCl_3$ is a very poor proton acceptor, and therefore **15e** should be favored to a greater extent in this solvent than would be either **12e**, **13e**, or **3e**. As seen in Table 3, this is the case and provides convincing evidence that engagement of the ring oxygen in hydrogen bond formation favors the equatorial orientation for the aglycon.



15a **15e**

Since the proposals made in the Introduction to rationalize the influences of solvent on the anomeric effect appear well supported, it was of interest to interpret the solvent effects on 2-hydroxy-THP (**16**) on the same basis. In fact, to do so not only provides an attractive rationalization of the effect of solvent on the conformational equilibrium of **16** but also on the anomerization equilibria for a number of sugars, such as glucose, which favor the equatorial orientation for the anomeric hydroxyl group.

As seen in Table 3, the conformational equilibria for **16** in both the solvents CCl_4–C_6D_6 (10%) and $CDCl_3$ are nearly the

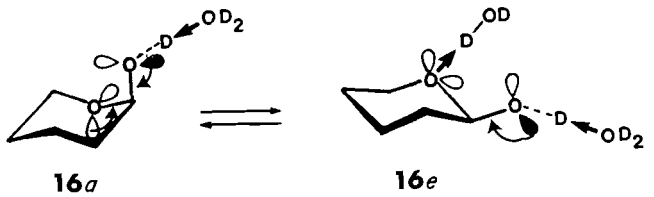
same as those for the hydroxyethyl compound (**15**). However, major differences in equilibria (0.58 versus 0.41 and 0.70 versus 0.50) occur when the solvent is CD_3CN or D_2O, respectively. These differences are attributed to the fact that when dissolved in these latter solvents, both **15** and **16** become extensively hydrogen bonded as hydrogen donors to solvent molecules. The changes in bond polarity that arise from the formation of these hydrogen bonds should not much influence the electronegativity of the CH_2OHCH_2 group of **15**. In fact, **15e** has nearly the same population (0.41) in CD_3CN as in $CDCl_3$ (0.44). On the other hand, the population of **16e** is significantly greater in CD_3CN than in $CDCl_3$ (0.58 versus 0.49). This is as expected, since hydrogen bonding of the hydroxyl group of **16** with a solvent molecule must enrich the electron density on the oxygen atom (20) and thereby increase the *exo*-anomeric effects, but more so that for the equatorial conformer (**16e**). Thus, the proton-accepting solvent should, as was observed, enrich the population of the equatorial conformer (**16e**). The situation is similar with water as solvent. As seen in Table 3, the 0.50 mole fraction for **15e** in D_2O is nearly the same as those for **12e**, **13e**, and **3e**, namely, 0.48, 0.48, and 0.47. On the other hand, the mole fraction for **16e** is 0.70 in D_2O. This result is attributed to a greater strengthening of the *exo*-anomeric effects, but more so for **16e** as the result of the



16a **16e**

hydrogen bonding with water as is indicated in the formula for **16e**. Experimental evidence exists for increased electron density on an oxygen atom of an hydroxyl group as the result of hydrogen bond formation (20), and Jeffrey and Mitra (31) have provided evidence, based in crystal structures, that anomeric hydroxyls are in fact strong proton donors but poor proton acceptors for hydrogen bond formation.

To better establish the influence of hydrogen bonding on the conformational equilibrium for **16**, a study was made of the effect of the addition of dimethylsulfoxide to solutions in CCl_4–C_6D_6 (10%). The results, presented in Fig. 1, show that the population of **16e** increases in a manner consistent with increasing hydrogen bonding of **16** with the DMSO, as displayed by the chemical shifts for both H-2 and OH-2. In contrast, the same addition of DMSO to solutions of 2-CH_3O-THP (**3**) had no effect on the chemical shift for H-2 and very little effect on the conformational equilibrium. We therefore abandon the earlier postulate that the influence of water on the conformational equilibria for 2-methoxytetrahydropyran (**3**) (11) and 2-hydroxytetrahydropyran (**16**) (32) is related to a more favorable water bridge between the two oxygen atoms when the conformer has the aglycon in equatorial orientation.

In view of the above observations on the effects of solvents on the conformational equilibria for **16**, we propose that certain sugars such as glucose, galactose, and xylose favor the β anomer when dissolved in water because of a strong β *exo*-anomeric effect. To further support this proposal, a brief study was made of the mutarotation of 2,3,4,6-tetra-*O*-methyl-D-glucopyranose (**17**) (33). The mole fraction of the β anomer, which has the anomeric hydroxyl in equatorial orientation, at

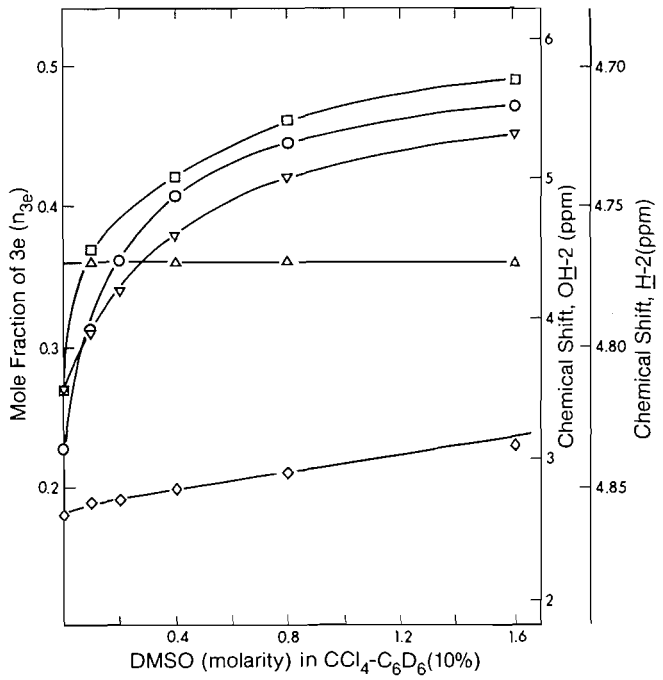


FIG. 1. The effects of additions of DMSO to 0.1 *M* solutions of 2-MeO-THP (△, $\delta_{H\text{-}2}$; ◇, n_e) and 2-HO-THP (○, $\delta_{OH\text{-}2}$; ▽, $\delta_{H\text{-}2}$; □, n_e) in CCl_4–C_6D_6 (10%), at 308 K, on chemical shifts and the conformational equilibria.

equilibrium in water and at 298 K was found to be 0.39. This result contrasts with that for the parent D-glucose for which the mole fraction at equilibrium is 0.64. Evidently the situation is not as straightforward for these complex structures as it is for **16**. Nevertheless, the mutarotation of the methylated glucose (**17**) (0.1 *M*) was examined in CCl_4–C_6D_6 (10%) and found to be well catalyzed at 298 K by the addition of 2-hydroxypyridone (34) (0.001 *M*). Under these conditions, at equilibrium, the mole fraction of the β anomer was 0.41. On rendering the solution 0.8 *M* in DMSO, the mole fraction of this anomer increased to 0.51, in accordance with the expectation that the hydrogen bonding with the DMSO more strongly strengthens the β *exo*-anomeric effect.

It was earlier suggested, with reference to the conformational equilibrium for 2-hydroxyethyloxy-THP (**15**), that the *exo*-anomeric effect is enhanced by hydrogen bonding involving the ring oxygen (O-5). It was further proposed that this enhancement is greater for the equatorial conformer since, for this conformer, O-5 is not importantly involved in an *endo*-anomeric effect. Intramolecular hydrogen bonding is supported by the presence of a bond between the hydroxyl and the ring oxygen of 2(*R*)-hydroxy-1(*R*)-cyclohexyl β-D-glucopyranoside tetraacetate in the crystalline form (35). To further test the hypothesis, the data reported in Table 4 were obtained. It is well known that phenol is a good proton donor to hydrogen bond formation. Therefore the addition of this substance to a solution of **3** in a nonpolar aprotic solvent such as CCl_4–C_6D_6 (10%) is expected to lead to hydrogen bonding between the phenol and the acetal group. As mentioned above, the ring oxygen of the equatorial conformer of **3** is expected to form the strongest hydrogen bond and, thereby, cause a shift of the conformational equilibrium toward a higher population of the equatorial conformer. As seen in Table 4, the addition of phenol at 308 K to a solution of **3** in CCl_4–C_6D_6 in fact led to an increase of n_{3e} from 0.18 to 0.29. In contrast, a similar addition of

[a]DMSO = dimethylsulfoxide; DTBPC = 2,6-di-*tert*-butyl-4-methylphenol; PhOH = phenol. All additions rendered the solution 0.8 *M* in the additive.

DMSO increased n_{3e} to only 0.21. The addition of both these compounds should increase n_{3e} to a lesser extent since the DMSO would compete with **3** for bonding with the phenol. This was the case (Table 4). Similar experiments were conducted using the highly hindered 2,6-di-*tert*-butyl-4-methylphenol, to strengthen the evidence that hydrogen bonding is responsible for the increase in the population of the equatorial conformer that occurred on adding phenol. As seen in Table 4, addition of this hindered phenol (DTBPC) had little influence on the conformational equilibrium whether or not DMSO was present. This is as expected, since the OH group of DTBPC is too hindered to form intermolecular hydrogen bonds.

As was discussed in the Introduction, the change in enthalpy for the conformational equilibrium **3a** ⇄ **3e** should be positive and about 1 kcal/mol. Table 5 reports the effects of changes in temperature and solvent on the equilibrium **3a** ⇄ **3e** as assessed by ^{13}C nmr. The effects of temperature change were then used to estimate the changes in enthalpy and entropy. As seen in Table 5, with the nonpolar and weakly associating solvent CCl_4–C_6D_6 (10%), the change in enthalpy (0.8 kcal/mol) is in fact nearly 1 kcal/mol and the conformational change involves a very small decrease in entropy. For reasons to be discussed below with reference to more polar solvents, it is apparent that C_6F_6 associates more strongly with **3** than does C_6D_6, and this is reasonable because of the presence of much more polar bonds in C_6F_6. The change in enthalpy with $CDCl_3$ as solvent was −0.2 kcal/mol, a value that is near the zero value observed by Booth *et al.* (24) using a mixture of $CDCl_3$ and $CFCl_3$ as solvent. Thus, in $CDCl_3$, the change in free energy (0.48 kcal/mol) is mainly determined by the decrease in entropy. This is not surprising, since $CDCl_3$ must form (through hydrogen bonding) much better defined (ordered) complexes with **3** by associating with the acetal oxygens than it can through self-association by way of extremely weak intermolecular hydrogen bonds. Furthermore, as was to be expected from the foregoing discussions, the interaction of $CDCl_3$ with **3e** should be stronger than with **3a**. Therefore $CDCl_3$ should decrease the enthalpy for **3e** to a greater extent than for **3a** and thereby, as was observed, lead to a smaller change in enthalpy in this solvent than in the non-hydrogen-binding solvent CCl_4–C_6D_6 (10%).

The results obtained with CD_3CN and D_2O as solvents are also in accord with the postulate that **3e** forms more stable and more ordered complexes with polar solvents than does **3a**. In other words, we contend that the changes in free energy with changes in solvent presented in Table 5 have their origins in the differences between the polar interactions of the solvent molecules with the two conformers. To reiterate, the polar interactions are considered to be stronger for an equatorial conformer because the absence of an *endo*-anomeric effect renders further charge delocalization energetically more facile. By affecting the charge delocalizations within the conformers, polar and hydrogen-bonding solvents must influence the magnitudes of the *endo*- and *exo*-anomeric effects, but these intramolecular effects cannot be separated from the forces of association.

These studies have shown that stereoelectronic influences on molecular structure are affected by interactions with polar molecules. Effects on the *exo*-anomeric effect present in β-glycopyranosides wherein the aglycon is in equatorial orientation can be expected to be especially large. In the case of the α anomers, the solvation influences the strengths of both the *endo*- and *exo*-anomeric effects. However, there can be no doubt that *hydration* of the ring oxygen will strengthen the *exo*-anomeric effect for both the anomers and thereby increase its contribution to the conformational rigidity of all glycosides. In this regard, the contributions used in HSEA calculations (12) that refer to an isolated molecule of dimethoxymethane are likely minimum values. It is of interest to note that simple rotation about a glycosidic bond must weaken the *exo*-anomeric effect and thereby activate the anomeric carbon toward nucleophilic attact. Likely, such rotations occur in the course of the formation of activated complexes with enzymes that catalyze transformations involving the replacement of the aglycons of glycosides.

Experimental

General procedures

Except for D_2O, all solvents were purified and stored over 3Å molecular sieves (BDH, Toronto).

The 2-alkoxytetrahydropyrans (**3**, **11**, **12**, **13**) were prepared, in the usual manner, by hydrogen chloride catalyzed addition of the alcohol to 2,3-dihydro-4*H*-pyran; **12**: bp 69°C, 17 Torr (1 Torr = 133.3 Pa); **13**: bp 126–127°C, 20 Torr. Deacetylation of **13** provided the 2-(2-hydroxyethoxy)tetrahydropyran (**15**) (bp 73–77°C, 3 Torr). Trimethylsilylation of the 2-hydroxytetrahydropyran (**16**) (36) readily afforded **14**.

The addition of either hexadeuteriobenzene or hexafluorobenzene (10%) to carbon tetrachloride was made for field frequency lock purposes.

Unless otherwise stated, the various solutions of the 2-substituted tetrahydropyrans were 0.1 *M*. These solutions were 0.05 *M* in tetrahydropyran, which served as the internal standard.

All the ^{13}C spectra recorded at 90.56 MHz in the FT mode used a Bruker WM 360 spectrometer interfaced with an Aspect-2000 computer for data accumulation and processing. The temperature was regulated with a VT-1000 temperature controller. Except for the studies involving **4**, the same spectrometer was used to measure the ^1H nmr spectra (360.13 MHz).

2-Methoxy-4,4,5,5-tetradeuterio-tetrahydropyran (6)

The compound was prepared as previously reported (11) except that pent-3-yne-5-ol-1-al dimethyl acetal was acetylated prior to the deuteration. The product was deacetylated (sodium methoxide – methanol) prior to treatment with a solution of methanol saturated with hydrogen chloride in dichloromethane for 15 min at 0°C. The product

[d]By subtracting the values for *J* with and without deuterium coupling.

(73% yield) was isolated by distillation and contained about 10% dichloromethane. The proton and deuterium decoupled ^{13}C spectrum was recorded at 100.61 MHz. The 5020 scans were accumulated at 308 K using a 0.5-mL sample containing 10 μL of 2-methoxytetrahydropyran (**3**) and 40 μL of the 4,4,5,5-tetradeuterated derivative (**6**) with 10% hexafluorobenzene in carbon tetrachloride as solvent. To assign the chemical shifts, a spectrum was recorded under the same conditions but in the absence of **3**.

The gc–ms using a 30-m capillary silicon-coated (DB-1) column (temperature increase: 8°C/min from 60 to 200°C) produced the following relative intensities for the various tetrahydropyranyl ions in the range $86 \leq m/e \leq 91$: 9, 25, 70, 100, 43, 9. Thus the product was a mixture of several deuterated derivatives of **3** with the main components being tri (27%), tetra (37%), and penta (18%) species. Nevertheless, the material proved useful for the planned application. In this regard, the ^1H nmr spectra in the various solvents (Table 2) all showed a major component that provided, on deuterium decoupling, a well-defined ABX pattern for H-3*c*, H-3*t*, and H-2 and an AB pattern for H-6*c*, H-6*t*. An examination of the ^{13}C nmr spectrum of the mixture under conditions of both hydrogen and deuterium decoupling showed that these signals arose from the 4,4,5-tri- and 4,4,5,5-tetradeuterio compounds (about 50% abundance). The ^{13}C nmr spectrum confirmed the presence of the 4,5,5- and 4,4,5-trideuterio and the 4,4,5,5-tetradeuterio compounds for the following reason. It is known (37) that the effect of deuteration on a ^{13}C atom in cyclohexane is an upfield shift of 0.418 ppm when the separation is by one bond, 0.104 ppm by two bonds, and 0.025 ppm by three bonds. Since the chemical shift for C-3 of MeO-THP (**3**) under the conditions used was 30.519 ppm, it could be expected that the mixture would produce signals for C-3 at 30.365, 30.286, and 30.261 ppm for the 4,5,5-, 4,4,5-, and 4,4,5,5-deuterated compounds, respectively. In fact, signals occurred at 30.366, 30.285, and 30.260 ppm. Low intensity signals at 30.013 and 29.900 ppm suggest that some exchange of H-3 atoms by deuterium had occurred. Since the deuteration was conducted prior to ring formation, the

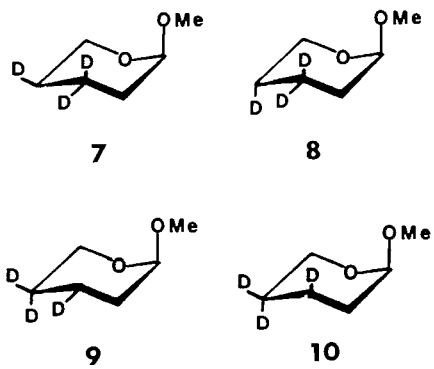
trideuterated compounds must be present in the mixture as equal amounts of their diastereoisomeric forms; namely, **7** and **8** for the 4,4,5- and **9** and **10** for the 4,5,5-deuterated compounds.



Conformational equilibria by ^1H nuclear magnetic resonance

The proton spectra of 2-methoxy-4,4,5,5-tetradeuteriotetrahydropyran, under deuterium decoupling (61.42 MHz, 30 db), were recorded at 400.13 MHz using a 2400-Hz spectral window and 32K data points (digital resolution after transformation: 0.15 Hz/pt). Since the deuterium signal was useless for lock purposes and in the absence of fluorine in the samples, one single scan was recorded after a 90° pulse. Prior to Fourier transformation, resolution enhancement was achieved through a Lorentz–Gauss transformation ($0.25 \leq$ Gaussian broadening ≤ 0.4, $-0.7 \leq$ line broadening ≤ -0.55), then the spin parameters were optimized through iterative calculations using the LAOCOON-III-like (38) PANIC program (39) for the above mentioned Aspect computer, resulting in a ± 0.02 Hz probable error for the coupling constants assigned to H-2, H-3*c*, H-3*t*, H-6*c*, and H-6*t*.

As was mentioned above, the ^1H nmr spectra of the mixture comprising mainly (37%) **6** but about equal amounts of **7**–**10** (each about 7% of the mixture) produced, on deuterium decoupling, readily distinguishable ABX patterns assignable to compounds **6**, **7**, and **8** and an A′B′ pattern assignable to H-6*c* and H-6*t* of compounds **6**, **9**, and **10**. The spectra of course displayed much weaker signals in close proximity to these main patterns, which are attributable to the other deuterated derivatives of **3** present in the mixture. Integration of the spectra and assuming that the methoxy group contained only natural abundance deuterium required very little, if any, deuteration of C-2 or C-6. As mentioned above, some deuteration of C-3 had occurred.

For an nOe study of **6** at 360.13 MHz, specially treated (40) 5-mm glass tubes were used. Argon was bubbled throughout the solutions for 5 min, then the tubes were immediately sealed. For these experiments, 99.96% enriched deuterium oxide with low paramagnetic impurity content was used. The data were obtained at 308 K in the difference mode from at least 950 accumulated scans.

The signals for the hydrogens at C-6 of **6** were readily assigned since saturation of H-2, while observing the signals for the hydrogens at C-6, showed that only one of these, the higher field signal, was enhanced and, therefore, the signal for the hydrogen (H-6*c*), which is in *cis*-relationship to H-2. The signal for the methyl group was also enhanced. For the two conformers, the distances between the average positions of the methyl group hydrogens and H-2 are very nearly the same. Therefore, the nOe's observed for the methyl group signals should be nearly equilibrium independent. Consequently, the ratio *R* for the nOe's observed for H-6*c* and the methyl group under a given set of experimental conditions should be proportional to the point of equilibrium and should increase as the population of **3e** increases. The *R* values in three different solvents are reported in the footnote to Table 1. That these values correspond to the mole fractions of **3e** is surely coincidental. This finding reinforces the contention that **6** exists essentially only in conformers **6a** and **6e**.

Further support for the equilibria reported in Table 1 was provided by the coupling of H-6*c* and H-6*t* with deuterium atoms at C-5 in the deuterated 2-MeO-THP preparation discussed above with reference to Table 1. As seen in Table 6, the decoupling of the deuterium atoms reduced the half-band widths observed for H-6*c* and H-6*t* and thereby provided a measure of the relative strengths of the deuterium couplings. It is expected that the coupling of the axial H-6*t* of the **6a** conformer with the deuteriums at C-5 will be the same as that for the axial H-6*c* of conformer **6e**, since their orientations relative to the deuteriums must be very similar, if not the same. Similarly, H-6*c* of **6a** is in an environment also present for H-6*t* of **6e**. Therefore the ratio of the change in the coupling with deuterium of one of the H-6's to the sum of the changes involving both H-6*t* and H-6*c* should provide a measure of the mole fraction of one of the two conformers. In fact, as seen in Table 6, the deuterium coupling with H-6*c* increased on increasing the polarity of the solvent in accord with an increasing abundance of **6e**. This follows, since in conformer **6e**, H-6*c* is *anti*-periplanar and *syn*-clinal to deuteriums at C-5 but is *syn*-clinal to both the deuteriums at C-5 in the case of **6a**. As seen in Table 1, the conformational equilibria estimated in this manner proved to be in fine agreement with those found by the other procedures.

Conformational equilibria by ^{13}C nuclear magnetic resonance

The frequency corresponding to tetramethylsilane (TMS) in CCl_4–C_6D_6 (10%) at 308 K was taken as the ultimate external reference chemical shift. To be sure that no appreciable drift in magnetic field had occurred, the position of this reference signal at the prevailing temperature was checked by repeating selected experiments at some later date. The chemical shift for C-4 of tetrahydropyran (THP) was then used as internal standard to adjust the observed chemical shifts for solvent and temperature effects. This was expected to be useful since the environments for C-4 in conformers **3a** and **3e** are very similar. The choice of the signal for C-4 in tetrahydropyran as a reference signal was also attractive because Booth *et al.* (24) had shown that there exists an important (4.59 ppm) chemical shift difference at 143 K for C-4 in these conformers. For these reasons, the chemical shifts for C-4 of THP, relative to the external TMS signal, are reported in Table 7. These shift differences ($\Delta C\text{-}4^{THP}$) are then used in Table 8 to adjust the observed values for C-4 of 2-MeO-THP (**3**) to the so-called "absolute" chemical shifts, i.e., chemical shifts that are expected to be indepen-

dent of solvent and temperature. On this basis, these chemical shifts were used in conjunction with the conformational equilibria reported in Table 3 to estimate "absolute" chemical shifts [δ] for C-4 in the conformers **3a** and **3e**. This was accomplished by solving the sets of simultaneous equations presented in Table 9. The data in Table 9 indicate that effects of changes in temperature on chemical shifts were not detected. Consequently, the simple expression

$$n_e = ([\delta]_{obs} - [\delta_a])/([\delta_e] - [\delta_a]) = ([\delta]_{obs} - 17.85)/5.11$$

was used to estimate the conformational equilibria, not only for compound **3**, but also for other 2-substituted tetrahydropyrans, since it was expected that changes at C-2 would not significantly affect the chemical shift of C-4. Following this procedure, the only requirement is that the observed chemical shift for C-4 be corrected for the general solvent and temperature effects using the Δ values for C-4 of tetrahydropyran as provided in Table 7. Application of the procedure is justified since it well reproduces the conformational equilibria measured by way of ^{1}H nmr. Although its accuracy cannot be predicted, the procedure is certainly not misleading.

Acknowledgement

The authors are particularly indebted to Dr. Ole Hindsgaul for his supervision of the work done on the 360-MHz ^{1}H nmr spectrometer, but also deeply thankful for the guidance by Dr. T. Nakashima and G. Bigam of the nmr-spectral service laboratory of the department. The research was supported by the Natural Sciences and Engineering Research Council of Canada (Grant A-172 to R.U.L.) and by the Alberta Heritage Foundation for Medical Research (grant to R.U.L.).

Attempted novel preparation of dihydrocoumarin and coumarin; obtention of aryl acrylates and 3-chloropropionates

JASWANT R. MAHAJAN AND HUGO C. ARAÚJO
Departamento de Química, Universidade de Brasília, 70910-Brasília, DF, Brasil

Received May 27, 1986

This paper is dedicated to Dr. O. E. (Ted) Edwards

JASWANT R. MAHAJAN and HUGO C. ARAÚJO. Can. J. Chem. **65**, 224 (1987).

It has been found that, contrary to the published report, there is no noticeable reaction between phenol and methyl acrylate in the presence of aluminum chloride to produce phenyl acrylate (**1**) and dihydrocoumarin (**2**). Although products having the reported spectral data can be obtained by the reaction of phenol with acrylyl chloride, these products are actually phenyl acrylate and phenyl 3-chloropropionate (**4**), there being detected no dihydrocoumarin. This reaction has now been extended to several substituted phenols and some naphthols. Attempts at cyclization of phenyl acrylate, phenyl 3-chloropropionate, or their mixtures have been unsuccessful.

JASWANT R. MAHAJAN et HUGO C. ARAÚJO. Can. J. Chem. **65**, 224 (1987).

Contrairement à ce qui a déjà été publié, on a trouvé que le phénol et l'acrylate de méthyle, en présence de chlorure d'aluminium, ne réagissent pratiquement pas pour donner de l'acrylate de phényle (**1**) et de la dihydrocoumarine (**2**). Même si la réaction du phénol avec le chlorure d'acrylyle conduit à des produits possédant les caractéristiques spectrales rapportées, on n'obtient que de l'acrylate de phényle et du chloro-3 propionate de phényle (**4**) et on ne détecte pas de formation de dihydrocoumarine. On a maintenant étendu cette réaction à plusieurs phénols substitués et à quelques naphtols. Des essais effectués en vue de cycliser l'acrylate de phényle, le chloro-3 propionate de phényle ou leurs mélanges se sont avérés inutiles.

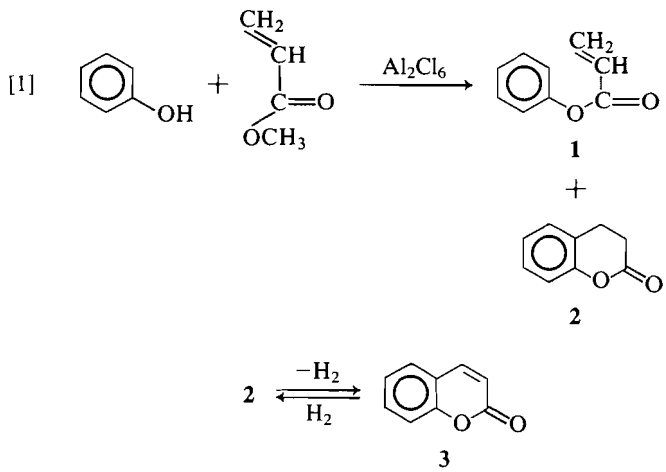
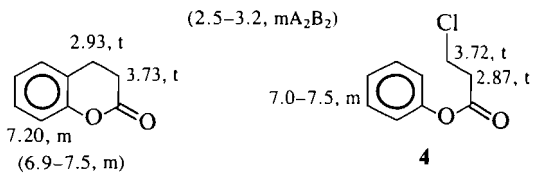
Dihydrocoumarin (**2**) and coumarin (**3**) are important flavor and fragrance substances and are accessible by several routes (1–8). Our interest in these compounds led us to repeat a simple preparation, by the reaction of phenol with methyl acrylate, as reported by Reddy (9) and illustrated by eq. [1].



However, we were unable to duplicate the reported results under a variety of experimental conditions. Eventually, we treated phenol with acrylyl chloride in the presence of aluminum chloride and obtained two products having spectral properties almost identical with the reported data. Subsequently, we found that the reaction could also be brought about by the reaction of phenol with acrylic acid, in the presence of $SOCl_2$, PCl_3, $POCl_3$, or PCl_5. However, due to the formation of some side products, prior conversion of the acid to its chloride was found to be advantageous. In view of the earlier reports on the preparation of acrylyl chloride (10) and based on our own experiments, we concluded that phosphorus pentachloride was best; 40–50 mol% of this reagent, with respect to acrylic acid, gave optimum results. The subsequent acylation of phenol could then be carried out either *in situ* or by using the distilled acid chloride. The optimized reaction conditions were applied to several substituted phenols and some naphthols, which also gave similar pairs of products (see Experimental).

However, when we undertook the dehydrogenation of the supposed dihydro compound, we again met with repeated failures, even when all such hypotheses as bad catalyst, impure sample or solvent, catalyst poison, etc., were discounted; the only doubt now resided in the identity of the alleged dihydrocoumarin. As an authentic sample of this compound was not at hand, we compared our spectra with those in the Aldrich spectra catalogs (11, 12) and proved beyond doubt that the compound under investigation was not dihydrocoumarin! Subsequent reasoning, and circumstantial as well as analytical evidence then revealed that we were dealing instead with phenyl 3-chloropropionate (**4**), the addition product of phenyl acrylate with hydrogen chloride, which are the initial products of the acylation reaction. The same was true for the rest of the supposed dihydrocoumarins obtained from other phenols and naphthols. The mistake was caused by the spectral data reported by Reddy being in an acceptable range for the alleged dihydrocoumarin; chemical shifts (δ ppm) from Reddy (9*a*), Aldrich (11, 12); values in parentheses), and those found for compound **4** are shown below.



ν_{max}(neat; C=O) cm^{-1}: 1760(1761); 1767

Finally, attempts at cyclization of phenyl acrylate, phenyl 3-chloropropionate, or their mixtures, using aluminum chloride, concentrated sulphuric acid, phosphorus pentoxide, boron trifluoride etherate *N,N*-dimethylaniline, etc., were unsuccessful, confirming earlier reports (13).

Experimental

Reagent grade chemicals were used as received from suppliers.

Infrared spectra were taken on a Perkin–Elmer 137 Infracord spectrophotometer. The ^{1}Hmr spectra were recorded on a Varian EM-390 (90 MHz) spectrometer. Mass spectra were obtained on a Hewlett–Packard spectrometer model 5987A, using direct inlet probe, 70 eV, and temperature program (40–250°C). Progress of reaction was followed by thin-layer chromatography (tlc; silica gel, toluene/EtOAc 95:5, I_2 vapours). An authentic sample of phenyl acrylate was prepared by exposing an aqueous solution of sodium phenolate to acrylyl chloride; ir ν_{max} (neat): 1750 cm^{-1}; ^{1}Hmr (CCl_4) δ: 5.8–6.7 (m, 3H, H_2C=CH—) and 7.0–7.4 (m, 5H, arom.).

Reaction of phenol with acrylyl chloride

Acrylyl chloride (Aldrich; 5 mL, 5.57 g, 61.5 mmol) was added dropwise to a mixture of phenol (4.8 g, 51 mmol) and anhydrous aluminum chloride (230 mg) contained in a flask cooled by tap water. The whole was stirred for 16 h, when the reaction mixture was put on a hot water bath (~80°C) for 4 h. The reaction mixture was decomposed with cold water (20 mL) and extracted with petroleum ether (bp 40–60°C), the organic phase being washed with water and brine. Drying over anhydrous Na_2SO_4 and evaporation of solvent gave a colorless liquid (6.31 g); ir ν_{max} (neat): 1770, 1748 cm^{-1}; ^{1}Hmr (CCl_4) δ: 2.90 (t, CH_2), 3.76 (t, CH_2), 5.8–6.7 (m, vinyl group), and 7.0–7.5 (m, aromatic H). Quantitative integral evaluation of the vinyl and methylene region indicated a 68:32 ratio for phenyl acrylate to phenyl 3-chloropropionate.

Fractional distillation afforded phenyl 3-chloroproprionate, virtually free from phenyl acrylate; bp 125–127°C/4 Torr (1 Torr = 133.3 Pa); ir and ^{1}Hmr as reported in the discussion section for structure **4**; ms *m/e*: 186 (*M* + 2, 1), 184 (M^+, 3), 94 (100).

General acylation procedure using acrylic acid and PCl_5

(*a*) Acrylic acid (13.7 mL, 14.4 g, 0.2 mol) containing hydroquinone (110 mg) was added dropwise, with care, onto phosphorus pentachloride powder (20.8 g, 0.1 mol) contained in a 3-necked flask, under magnetic stirring and anhydrous conditions. There was an immediate exothermic reaction with the evolution of HCl gas, which was led to a water trap. The reaction mixture soon turned fluid and the vigour of reaction was controlled by the slow addition of the acid. After complete addition, the reaction mixture was heated slowly to distill the crude acyl chloride (bp 70–88°C) directly onto phenol (18.8 g, 0.2 mol) containing hydroquinone (110 mg), and under magnetic stirring. Finally, anhydrous aluminum chloride (267 mg) was added and the whole heated with stirring in an air bath (80–90°C) for 3 h, followed by heating at 100°C for 1 h. After removing any low-boiling material on a rotary evaporator, the reaction mixture was distilled to afford a colorless liquid (28.8 g), bp 100–110°C/1.5 Torr. Redistillation furnished almost pure (^{1}Hmr, tlc) chloro ester **4** (19.4 g), bp 132–134°C/5 Torr, preceded by its mixture with phenyl acrylate (8.9 g).

(*b*) Acrylic acid (1.58 g, 22 mmol) was added slowly to PCl_5 (1.88 g, 9 mmol) and the whole gently refluxed in an air bath (110–120°C) for 1 h. After cooling, phenol (1.88 g, 20 mmol) was added and stirring continued at room temperature for 2.5 h, when the air bath was heated slowly to bring its temperature to 90°C during ~1 h, and maintained there for another 3 h. The cooled reaction mixture was taken up in ether (50 mL) and washed successively with water, 1 *N* NaOH, and brine. Drying (Na_2SO_4) and evaporation gave the crude product (3.5 g), which on short-path distillation furnished a colorless liquid (2.7 g) whose ^{1}Hmr analysis indicated a 7.5:92.5 ratio between phenyl acrylate and phenyl 3-chloropropionate.

2-Chlorophenol, *o*-, *m*-, and *p*-cresol, as well as 1- and 2-naphthol could be acylated similarly either by procedure (*a*) or (*b*), affording a 60–80% yield of the acylated mixture as indicated by their ^{1}Hmr spectra, which had a very close resemblance to those of phenyl acrylate and compound **4** in the vinyl and methylene region, respectively. In the case of 1-naphthol, the acylated product was predominantly (>90%) the corresponding acrylic ester, while in the case of 2-naphthol, the 3-chloropropionate ester was obtained as a colorless solid from ethanol (43% yield); mp 53–55°C; ir ν_{max} (KBr): 1761 cm^{-1}; ^{1}Hmr (CCl_4) δ: 2.85 (t, 2H, H_2CCO_2—), 3.70 (t, 2H, H_2C-Cl), and 7.0–7.8 (m, 7H arom.). *Anal.* calcd. for $C_{13}H_{11}O_2Cl$: C 66.52, H 4.69; found: C 66.76, H 4.66.

(2*S*,3*R*)- and (2*S*,3*S*)-[1-^{14}C,3-^{3}H]phenylalanine were fed in separate experiments to *Datura innoxia* plants. The distribution of isotopes in the resultant labeled hyoscyamine and scopolamine indicates that the biosynthesis of the acid moiety of these ester alkaloids, namely (*S*)-tropic acid, involves the migration of the carboxyl group of phenylalanine to its prochiral C-3 position with retention of configuration.

EDWARD LEETE. Can. J. Chem. **65**, 226 (1987).

Au cours d'expériences séparées, on a fait croître des plants de *Datura innoxia* en présence de [^{14}C-1,^{3}H-3]-phénylalanines soit (2*S*,3*R*) soit (2*S*,3*S*). En se basant sur la distribution des isotopes dans les hyoscyamine et scopolamine marquées qui en résultent, on peut en conclure que la biosynthèse de la portion acide de ces esters d'alcaloïdes, soit l'acide tropique-(*S*), implique la migration du groupement carboxyle de la phénylalanine vers sa position prochirale-3 et que cette migration se fait avec rétention de configuration.

Introduction

It has been established that the biosynthesis of (*S*)-tropic acid (**1**), the acid moiety of the tropane alkaloids hyoscyamine (**2**) and scopolamine (**3**), involves the intramolecular 1,2-migration of the carboxyl group of phenylalanine, from C-2 to C-3 (2). Recently, it has been shown that the biosynthesis of tropic acid also involves a 1,2-migration of hydrogen from C-3 of phenylalanine to C-2, which ultimately becomes the hydroxymethyl group of tropic acid (3). This preliminary result was obtained by feeding a mixture of all four possible stereoisomers of [1-^{14}C,3-^{3}H]phenylalanine (2*R*,3*R*; 2*R*,3*S*; 2*S*,3*R*; and 2*S*,3*S*) to *Datura innoxia* plants. The stereochemistry of the migration of the carboxyl group has now been probed by carrying out feeding experiments with (2*S*)-phenylalanine stereospecifically labeled with one tritium at its prochiral C-3 position. These substrates were obtained as previously described (4). The stereochemical purity at the C-3 position was determined by conversion to *trans*-cinnamic acid with the enzyme phenylalanine ammonia-lyase (PAL). This enzyme catalyses the *trans* elimination of ammonia. From the retention of tritium relative to carbon-14 (located at C-1), it was calculated that both the (3*R*)- and (3*S*)-[1-^{14}C,3-^{3}H]phenylalanine were 89% enantiomerically pure at their prochiral C-3 positions. The doubly labeled phenylalanines were fed to *Datura innoxia* plants by the wick method. The alkaloids were isolated and separated as previously described (5) from plants that were harvested 10 days after the initial feeding.

Results and discussion

Scheme 1 illustrates the fate of hydrogen at C-3 of phenylalanine when tropic acid is formed. If the migration of the carboxyl group occurs with retention of configuration, (2*S*,3*R*)-[1-^{14}C,3-^{3}H]phenylalanine (**5**) will afford (*S*)-tropic acid (**4**), retaining tritium at its chiral center. If the migration occurs with inversion, the tritium will be displaced and will be found on the hydroxymethyl group of (*S*)-tropic acid (**6**).

The results recorded in Table 1 are consistent with the first mechanism, that is, migration with retention of configuration. The interpretation of the results is complicated by the fact that the tropic acid moiety of hyoscyamine and scopolamine is readily racemized. Such racemization will result in loss of tritium from the chiral center of tropic acid. Thus the hyoscyamine isolated from the feeding of (2*S*,3*R*)-[1-^{14}C,3-^{3}H]phenylalanine (Expt. 1) had 50% enantiomeric excess of the (−)-isomer. However, it retained 65% of tritium relative to carbon-14. When this hyoscyamine was racemized (by addition of a trace of sodium hydroxide to a solution of the alkaloid in ethanol), the reisolated racemic hyoscyamine (atropine) retained only 10% of its tritium, indicating that most of the tritium was located at the chiral center of the tropic acid. Hydrolysis of the racemized hyoscyamine with aqueous barium hydroxide yielded racemic tropic acid with the same relative amount of tritium. The scopolamine, which is optically more stable than hyoscyamine, retained 83% of tritium relative to carbon-14. However, hydrolysis of this alkaloid with aqueous barium hydroxide yielded tropic acid that was almost racemic (18% enantiomeric excess), and retained only 13% of tritium relative to carbon-14. The residual tritium found in the racemic tropic acid presumably arises from the (2*S*,3*S*)-[1-^{14}C,3-^{3}H]phenylalanine (11%) present in the administered precursor.

Complementary results were obtained with (2*S*,3*S*)-[1-^{14}C,3-^{3}H]phenylalanine (Expt. 2). The alkaloids isolated from this feeding experiment retained most of the tritium relative to carbon-14. Racemization of the alkaloids caused little change in their ^{3}H/^{14}C ratios, indicating that the tritium was not located at the chiral center of tropic acid. Basic hydrolysis of the alkaloids yielded racemic tropic acid that retained 85% of the tritium, which was shown to be present on the hydroxymethyl group using the degradation previously described (3).

Independently, Haslam and co-workers (6) fed (2*S*,3*R*)- and (2*S*,3*S*)-[2-^{14}C,3-^{3}H]phenylalanine to *Datura stramonium* plants. They considered that their results were consistent with a stereospecific loss of the pro-*R* hydrogen at C-3 of phenylalanine, the carboxyl group migrating with inversion of configuration at this position. This conclusion is the direct opposite of the one reported in the present article. However, the authors apparently failed to realize that tritium located at the chiral center of tropic acid is very labile. The ^{3}H/^{14}C ratio of the isolated alkaloids was not reported. The mixture of alkaloids

TABLE 1. Feeding of labeled phenylalanines to *Datura innoxia*

Exp. No.	Experiment No. 1			Experiment No. 2		
Precursor fed:	(2*S*,3*R*)-[1-^{14}C,3-^{3}H]phenylalanine			(2*S*,3*S*)-[1-^{14}C,3-^{3}H]phenylalanine		
Time of feeding	April			June		
Fresh weight of plants (g)	220			350		
		^{14}C (dpm/mmol)	^{3}H/^{14}C		^{14}C (dpm/mmol)	^{3}H/^{14}C
Activity		1.83×10^7	10.6		4.89×10^6	3.60
Amount fed	0.5 mmol			0.5 mmol		
Alkaloids isolated						
Hyoscyamine·HCl						
Weight (mg)	119			142		
Enantiomeric excess[a]	50%			51%		
Activity		7.40×10^4	6.9		6.32×10^4	3.25
Absolute inc.[b] (^{14}C)	0.30%			1.13%		
Tropic acid		7.23×10^4	1.1		6.19×10^4	3.05
Scopolamine·HCl						
Weight (mg)	202			297		
Enantiomeric excess[a]	82%			95%		
Activity		5.21×10^4	8.8		5.74×10^4	3.48
Absolute inc.[b] (^{14}C)	0.34%			2.05%		
Tropic acid		5.06×10^4	1.35		5.70×10^4	3.10

[a]The optical purity was obtained by determination of the specific rotations of the alkaloid hydrochlorides. Optically pure hyoscyamine·HCl has $[\alpha]_D^{25}$ −24.2° (*c* 3.5, EtOH) and scopolamine·HCl has $[\alpha]_D^{25}$ −17.7° (*c* 4.5, EtOH).
[b]Absolute inc. = total activity (dpm) found in the isolated alkaloid divided by the total activity (dpm) fed to the plants.

was hydrolyzed by refluxing with aqueous 10% sodium hydroxide for 30 min, conditions which would cause racemization of tropic acid. The tropic acid was assayed for radioactivity after conversion to methyl-3-*O*-acetyltropate. It was reported that this tropic acid derived from (2*S*,3*R*)-[2-^{14}C,3-^{3}H]phenylalanine (88% enantiomeric excess at C-3) had lost 88–93% of its tritium relative to carbon-14. The tropic acid derived from (2*S*,3*S*)-[2-^{14}C,3-^{3}H]phenylalanine (83% enantiomeric excess at C-3) lost 30–35% of the tritium. These experimental results are thus entirely consistent with ours, the retention of tritium in the tropic acid derived from the [3*S*-^{3}H]phenylalanine being due to its migration to the hydroxymethyl group, and not because it remained at the chiral center of tropic acid.

The 1,2-migration of the carboxyl group of phenylalanine to ultimately yield (*S*)-tropic acid is analogous to the biochemical conversion of (2*R*)-methylmalonyl coenzyme A (**7**) to succinyl coenzyme A (**8**) (7), which is illustrated in Scheme 2. In this reaction, it is the thioester group that undergoes an intramole-

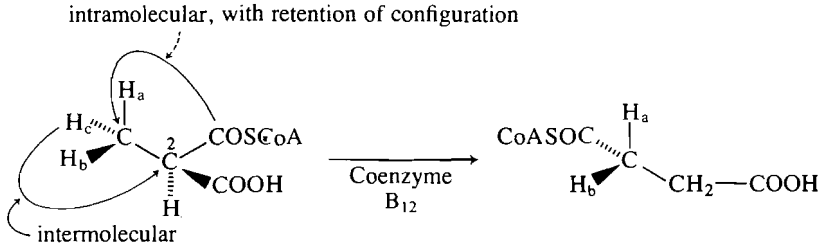
For personal use only.



7 8

SCHEME 2

cular migration with retention of configuration. The displaced hydrogen also migrates in the opposite direction; however, this migration is intermolecular. It has not yet been determined whether the 1,2-migration of the 3-pro-*S* hydrogen of phenylalanine that occurs during tropic acid biosynthesis is inter- or intra-molecular. Another point of interest is the fact that the conversion of **7** to **8** is catalyzed by coenzyme B_{12}. However, the presence of vitamin B_{12} or its derivatives in higher plants is tenuous and controversial (8–10). Twenty years ago I sent an extract of *Datura* plants to Professor R. H. Abeles (then at the University of Michigan), but he was unable to detect any vitamin B_{12} in this material.

Experimental

Radioactivity assay

Radioactivity measurements were carried out in a Tracor Analytic Mark III liquid scintillation counter. Samples (assayed in duplicate) were dissolved in water or EtOH (1 mL), which was then diluted with liquid scintillation solution (10 mL). The liquid scintillation solution was made by dissolving naphthalene (50 g), 2,5-diphenyloxazole (3.5 g), and 1,4-(5-phenyloxazol-2-yl)-benzene (0.25 g) in spectroscopic grade dioxane (500 mL). The backgrounds in the ^{14}C and ^{3}H channels were 8 and 14 dpm, respectively. In unquenched samples the efficiency of counting in the ^{14}C and ^{3}H channels was 60 and 45%, respectively, and spillover of ^{14}C into the ^{3}H channel was 10%.

(2S,3R)- and (2S,3S)-[1-^{14}C,3-^{3}H]phenylalanine

The (2*S*,3*R*)- and (2*S*,3*S*)-[1-^{14}C,3-^{3}H]phenylalanine were obtained from [*formyl*-^{3}H]benzaldehyde and [1-^{14}C]glycine as previously described (4). The enantiomeric excess at C-3 was determined by incubation with phenylalanine ammonia-lyase (EC 4.3.1.5) from *Rhodotorula glutinis* (Sigma Chem. Co.), as previously described (4).

Administration of the labeled phenylalanine to Datura innoxia *plants and isolation of the alkaloids*

The plants were 3 months old, growing in soil in a greenhouse at the time of feeding, which was done by means of cotton wicks inserted into the stems of the plants near to ground level. After 10 days the plants (both the roots and aerial parts) were harvested and the alkaloids, hyoscyamine and scopolamine, isolated and separated by thin-layer chromatography (tlc) as previously described (5).

Racemization of hyoscyamine and scopolamine

The following is a typical procedure, the optical rotations being determined in a Perkin–Elmer 242 polarimeter. The hyoscyamine hydrochloride (113.7 mg) from Expt. 1 was dissolved in absolute EtOH (10 mL) at 25°C. Aqueous 10% NaOH (0.05 mL) was added. Under these conditions the rotation was reduced by half in 12.5 min. After 2 h the solution was acidified with a drop of acetic acid and then evaporated to dryness. The residue was subjected to tlc on silica gel PF 254 (Merck), developing with a mixture of $CHCl_3$, EtOH, concentrated NH_3 (80:20:1). The zone (R_f 0.3) corresponding to atropine (detected by uv) was extracted with MeOH. This extract was neutralized with HCl, evaporated to dryness, and the residue crystallized from a mixture of EtOH and ethyl acetate to afford atropine hydrochloride. This salt had essentially the same ^{14}C specific activity as the initial hyoscyamine hydrochloride, but its $^{3}H/^{14}C$ ratio changed from 6.9 to 1.1. Scopolamine hydrochloride was similarly racemized; however, its half-life under the same conditions was longer (22 min).

Hydrolysis of the alkaloids

The alkaloid hydrochloride (200 mg) was dissolved in aqueous saturated $Ba(OH)_2$ solution (10 mL) and the mixture refluxed for 30 min. The cooled solution was acidified with HCl and extracted with Et_2O (3 × 30 mL). The residue obtained on evaporation of the dried (Na_2SO_4) Et_2O extract was crystallized from a mixture of benzene and hexane, affording tropic acid (50–60 mg), mp 118°C. Optically pure tropic acid has mp 129°C (11).

Spiro steroids via the Barbier–Grignard reaction of steroidal ketones with allyl bromide and magnesium

ZDZISŁAW PARYZEK AND KRZYSZTOF BŁASZCZYK
Faculty of Chemistry, Adam Mickiewicz University, 60-780 Poznań, Poland

Received June 3, 1986

This paper is dedicated to Dr. O. E. (Ted) Edwards

ZDZISŁAW PARYZEK and KRZYSZTOF BŁASZCZYK. Can. J. Chem. **65**, 229 (1987).

Barbier–Grignard reaction of 3- and 17-steroidal ketones gave excellent yields of the allyl steroids **1** + **2** and **15**. These were transformed into a mixture of 1,3- and 1,4-diols by hydroboration–oxidation. The diols **3**, **5**, and **18** were used for the preparation of spirolactones and spiroethers. Thus, the Barbier–Grignard allylation–hydroboration–cyclization sequence proved to be an effective method for the spiroannelation of steroidal ketones. It was also shown that an earlier assignment of the stereochemistry of the diols **3** and **5** was erroneous.

ZDZISŁAW PARYZEK et KRZYSZTOF BŁASZCZYK. Can. J. Chem. **65**, 229 (1987).

Par réaction de Barbier–Grignard sur des stéroïdes portant des groupements cétoniques en positions 3 ou 17, on peut obtenir les stéroïdes allyliques **1** + **2** et **15**. En soumettant ces composés à des réactions d'hydroboration/oxydation, on a pu les transformer en des mélanges de diols-1,3 ét-1,4. On a utilisé les diols **3**, **5** et **18** pour préparer des spirolactones et des spiroéthers. Ainsi, la séquence de réactions d'allylation selon Barbier–Grignard—d'hydroboration/oxydation et de cyclisation s'avère une méthode efficace pour effectuer la spiroannelation de cétones stéroïdales. On a aussi démontré qu'une attribution antérieure de stéréochimie des diols **3** et **5** était erronée.

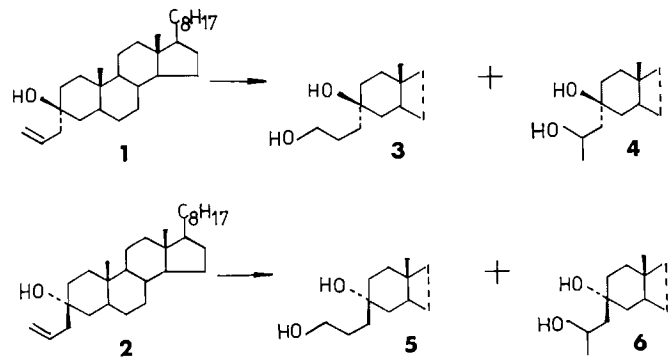
For personal use only.

The γ-butyrolactone and α-methylene-γ-butyrolactone structural units have been suggested to be responsible for the biological activity of many natural compounds and their synthetic analogues (1). In the steroidal series, some spirolactones were found to possess tumor-inhibiting activity (2). Other important steroids possess a spirolactone moiety in position 17 of the steroidal skeleton and exhibit aldosterone blocking activity (3). Since the first reports on the synthesis and antialdosterone activity of several steroid 17-spirolactones (e.g. 7α-acetylthio-3-oxo-17α-pregn-4-ene-21,17 carbolactone) (3*a*, 4), several synthetic methods leading to spirolactone steroids have been developed (5).

A simple and attractive possibility for synthesizing spirolactones is the introduction of the three-carbon unit in a Barbier–Grignard reaction of an alicyclic ketone with an allyl magnesium halide, followed by a two-step transformation leading to a spirolactone (eq. [1]). Since α-methylenation of lactones is a well-known process (6), the sequence shown in eq. [1] might be

[1] 
extended to the synthesis of steroidal spiro-α-methylene-γ-butyrolactones. The Barbier–Grignard reaction of aldehydes and ketones with allyl halides and magnesium has been extensively studied (7). However, reports on further chemical transformation of the allyl carbinols to spiro compounds are scarce (8). Surprisingly, this approach to spirolactones has not been attempted with steroidal ketones.

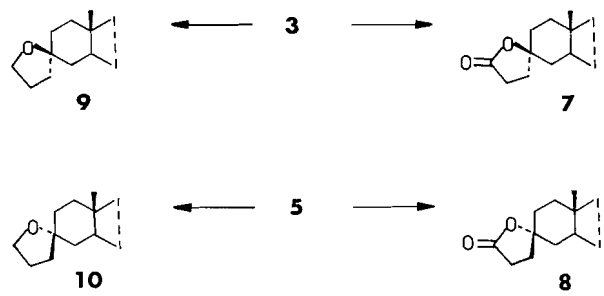
In our investigation 5α-cholestan-3-one and 3β-hydroxy-5α-androstan-17-one were chosen as model steroids. Barbier–Grignard (9) reaction of 5α-cholestan-3-one with allyl bromide and magnesium afforded two isomeric allyl derivatives **1** and **2** in 51 and 48% yield, respectively. The stereochemistry of the epimers was assigned on the basis of ^{1}H nmr and ir spectra and the expected polarity difference, since greater polarity of the isomer with an equatorial hydroxy group was reported for compounds bearing alkyl (10) and alkynyl (11) substituents in position 3 of the cholestane skeleton. According with the



suggestion (12) that steric compression due to typical 1,3 interactions with protons on the cyclohexyl ring would cause proton signals for axially situated methylene groups to be shifted to lower field, ^{1}H nmr analysis of both isomers showed distinctly that the allylic methylene group in **1** resonates at lower field (δ 2.31) than the analogous protons in **2** (δ 2.16). Compounds **1** and **2** were previously obtained in the reaction of allylzinc with 5α-cholestan-3-one (13).

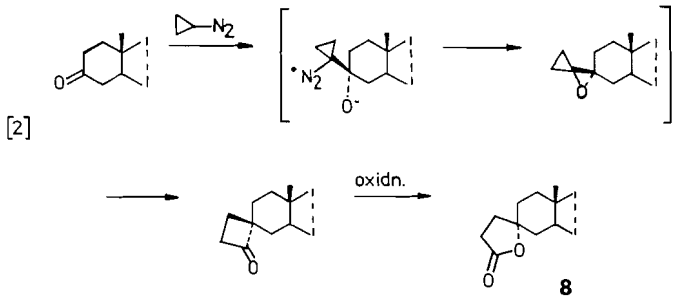
Hydroborations of allyl steroids, irrespective of the source of diborane, were less regioselective than was anticipated on the basis of the published data (8). Hydroboration–oxidation of the allyl compound **1** gave 1,4-diol **3** in 75% yield along with 1,3-diol **4** (21%). Similar regioselectivity was observed in hydroboration of the epimeric allyl compound **2**, the diols **5** and **6** being isolated in 74 and 23% yield, respectively. Fortunately, the regioisomers could be readily separated by chromatography on silica gel. The diols **3** and **5** were quantitatively oxidized with Jones reagent to the respective lactones **7** and **8**. The same diols on intramolecular etherification with *p*-toluenesulfonyl chloride in pyridine (15) gave spiroethers **9** and **10**.

Because the assigned configuration of the diols **3** and **5**, and consequently of the other C-3 stereoisomers, was opposite to that reported by Bladon and Rae (14), the 900–1150 cm^{-1} region in the infrared spectra of compounds belonging to the two epimeric series was carefully examined. The higher carbon–oxygen stretching frequencies were found in compounds with

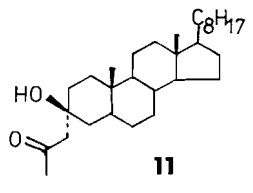


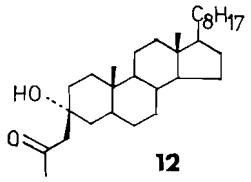
equatorial C(3)—O bonds when compared with the axial analogues (8, 11, 16) (see Table 1).

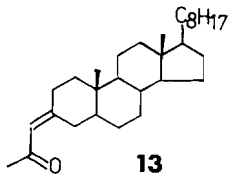
Spirolactones **7** and **8** have been synthesized previously from 5α-cholestan-3-one in two steps. Thus the ketone reacted with diazocyclopropane to give two isomeric spirocyclobutanone steroids, which could be oxidized to the appropriate lactones. In view of our stereochemical assignments, the stereochemistry of the nucleophilic addition of diazocyclopropane to 5α-cholestan-3-one (14) has to be revised. It is proposed that formation of the lactone **8** occurs by the route shown in eq. [2], assuming the predominantly equatorial approach (17) of diazocyclopropane to the carbonyl group.

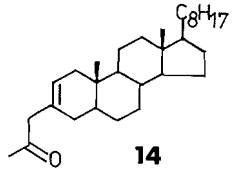


Jones oxidation of 1,3-diols **4** and **6** afforded two β-hydroxyketones **11** and **12**, which were dehydrated with *p*-toluenesulfonic acid in benzene to the mixture of conjugated and unconjugated ketones **13** and **14**. The ratio of these isomers, estimated by the integration of vinylic protons in the ^{1}H nmr spectra of the crude reaction products, was 9:1 when the substrate was compound **11** and 7:3 in the case of compound **12**. After prolonged treatment with methanolic potassium hydroxide the conjugated ketone **13** was entirely transformed to the unconjugated ketone **14**. The position of the olefinic double bond in **14** was assigned on the basis of the broad multiplet at δ 5.47 present in the ^{1}H nmr spectrum.









Next, the spiroannelation sequence was repeated on a 17-steroidal ketone. Accordingly, 17-oxo-5α-androstan-3β-yl-2-tetrahydropyranyl ether was treated with allyl bromide and magnesium in a Barbier–Grignard reaction to give a quantitative yield of the allyl carbinol **15**. The 17β orientation of the OH group in this compound was assigned on the basis of the known stereochemistry of addition of Grignard reagents to 17-oxosteroids (18). Acid hydrolysis of **15**, followed by acetylation, gave compound **17** (19). Hydroboration–oxidation of **17** gave a mixture from which the 1,4-diol **18** was isolated in 74% yield. The ^{1}H nmr spectrum of the second product (homogenous on tlc) suggested a mixture of C-2′ epimers of the 1,3-diol **19**. Thus the 10-methyl group of this compound resonates at δ 0.91 while the 13-methyl group gives two low intensity singlets at δ 0.84 and 0.82. Oxidation–lactonization of the diol **18** to compound **21** proceeded smoothly, as did the cyclization to the spiroether **20**. Each step leading from the 17-steroidal ketone to **20** and **21**, except the hydroboration step (74% of **18**), proceeded in over 95% isolated yield. Thus, the overall yield of compound **20** and **21** was considerably better than that reported earlier (3*a*, 19) and in more recent work (3*c*, 5).

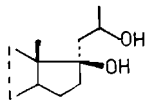
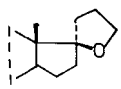
18 (3β-OAc)



19 (3β-OAc)



20 (3β-OAc)

The results obtained with the unhindered 3-steroidal ketone and the sterically hindered 17-ketone showed that the reaction sequence: Barbier–Grignard allylation–hydroboration–cyclization is a simple and effective method for the spiroannelation of steroidal ketones. Since Grignard-type reactions are known to proceed smoothly even with hindered steroidal ketones, it is assumed that the described spiroannelation can be extended to other positions in the steroidal skeleton.

Experimental

Melting points were determined on a Kofler hot-stage apparatus and are uncorrected. The ir spectra were determined with a Perkin–Elmer 580 spectrophotometer for solutions in chloroform. The ^{1}H nmr spectra

were recorded with a Varian EM-360 or JEOL FX 90 spectrometer for solutions in deuteriochloroform. The chemical shifts (δ) are expressed in ppm relative to tetramethylsilane. Mass spectra were recorded with a JEOL JMS-D spectrometer using electron impact.

Barbier–Grignard reaction of 5α-cholestan-3-one with allyl bromide

To a mixture of magnesium (0.72 g), allyl bromide (0.05 g), and a few crystals of iodine in benzene (5 mL) stirred under argon, a solution of 5α-cholestan-3-one (2.3 g) and allyl bromide (1.43 g) in diethyl ether (30 mL) was added dropwise in 30 min. The reaction mixture was stirred at room temperature for 2 h, diluted with benzene, and washed with water. The dried ($MgSO_4$) organic layer was evaporated and the crude reaction product was chromatographed on silica gel with benzene as eluent. The two products obtained are listed in the order of their emergence: 3β-allyl-5α-cholestan-3α-ol (**2**) (1.30 g, 51%), which had mp 89–91°C (methanol) (lit. (13) mp 90–92°C), and 3α-allyl-5α-cholestan-3β-ol (**1**) (1.22 g, 48%), which had mp 114–116°C (methanol) (lit. (13) mp 112–114°C); ^{1}H nmr and ir spectra of compounds **1** and **2** were in accordance with the reported data (13).

Hydroboration of compound 1

To a stirred solution of **1** (100 mg) and sodium borohydride (18 mg) in diglyme (7.5 mL) kept at room temperature under argon was added dropwise boron trifluoride diethyl ether complex (80 μL) over 5 min. After 40 min a mixture of potassium hydroxide (10%, 1.2 mL) and hydrogen peroxide (30%, 0.8 mL) was added dropwise over 5 min, and stirring was continued for 30 min. The reaction mixture was then poured into water and extracted with a 1:1 mixture of diethyl ether – benzene. The product was chromatographed on a silica gel column with benzene – ethyl acetate mixtures as eluent. Two compounds were obtained. 3α-(2′-Hydroxypropyl)-5α-cholestan-3β-ol (**4**) (22 mg, 21%) was a colorless oil; ir ν_{max}: 3610 and 3480 cm^{-1}; ^{1}H nmr δ: 4.10 (1H, m), 2.88 (2H, br s, $W_{1/2}$ = 18 Hz), 0.88, 0.79, 0.77, and 0.62; mass spectrum *m/z*: 446 (M^+), 387, 331, 330, 141, 128, 116, 109, 95, and 81. *Anal.* calcd. for $C_{30}H_{54}O_2$: C 80.65, H 12.18; found: C 80.51, H 12.44. 3α-(3′-Hydroxypropyl)-5α-cholestan-3β-ol (**3**) (78 mg, 75%) was recrystallized from methanol; mp 168–170°C; $[\alpha]_D$ +24.0° (*c* 1.7 pyridine) (lit. (14) mp 164–170°C; $[\alpha]_D$ +24.4° (*c* 0.41, pyridine)); ir ν_{max}: 3.600 and 3410 cm^{-1}; ^{1}H nmr δ: 3.64 (2H, m), 2.91 (2H, s), 0.88, 0.83, 0.77, and 0.62; mass spectrum *m/z*: 446 (M^+), 387, 141, 128, 115. *Anal.* calcd. for $C_{30}H_{54}O_2$: C 80.65, H 12.18; found: C 80.43, H 12.33.

Hydroboration of compound 2

The reaction of **2** (103 mg) was carried out in a similar manner to that described above. After chromatography on silica gel two compounds were obtained. 3β-(2′-Hydroxypropyl)-5α-cholestan-3α-ol (**6**) (25 mg, 23%) had mp 140–147°C (methanol); ir ν_{max}: 3610 and 3480 cm^{-1}; ^{1}H nmr δ: 4.27 (1H, m, $W_{1/2}$ = 22 Hz), 3.10 (2H, br s, $W_{1/2}$ = 16 Hz), 0.88, 0.79, 0.72, and 0.62; mass spectrum *m/z*: 446 (M^+), 387, 232, 128, 95. *Anal.* calcd. for $C_{30}H_{54}O_2$: C 80.65, H 12.18; found: C 80.44, H 12.30. 3β-(3′-Hydroxypropyl)-5α-cholestan-3α-ol (**5**) (80 mg, 74%) had mp 141–142°C (methanol); $[\alpha]_D$ +27.2° (*c* 0.6 pyridine) (lit. (14) mp 141–142°C; $[\alpha]_D$ +45.0° (*c* 0.6 pyridine)); ir ν_{max}: 3610 and 3410 cm^{-1}; ^{1}H nmr δ: 3.65 (2H, m), 2.17 (2H, s), 0.93, 0.89, 0.82, 0.74, and 0.65; mass spectrum *m/z*: 446 (M^+), 387, 95. *Anal.* calcd. for $C_{30}H_{54}O_2$: C 80.65, H 12.18; found: C 80.64, H 12.51.

(R)-Spiro[(5α-cholestane-3,5′-(2′-oxotetrahydrofuran)] (7)

Jones reagent was added dropwise to a stirred solution of compound **3** (75 mg) in acetone (20 mL) kept at 0°C until all the substrate had reacted (tlc control). Then a few drops of ethanol were added and the reaction mixture was poured into water. After extraction with a 1:1 mixture of benzene – diethyl ether, the crude product was purified on a column of silica gel to give lactone **7** (74 mg, 99%), which had mp 218–221°C (chloroform–methanol) and $[\alpha]_D$ +21.7° (*c* 0.91 chloroform) (lit. (14) mp 217–222°C; $[\alpha]_D$ +21.7° (chloroform); ir ν_{max}: 1760 cm^{-1}; ^{1}H nmr δ: 2.75–2.41 (2H, m), 0.87, 0.81, 0.78, and 0.63; mass spectrum *m/z*: 442 (M^+), 427, 287, and 180. *Anal.* calcd. for $C_{30}H_{50}O_2$: C 81.38, H 11.38; found: C 81.33, H 11.43.

(S)-Spiro[(5α-cholestane)-3,5′-(2′-oxotetrahydrofuran)] (8)

Oxidation of compound **5** (244 mg), carried out as described above, gave lactone **8** (229 mg, 94%), which had mp 199–201°C (methanol) and $[\alpha]_D$ +20.4° (*c* 6.13, chloroform) (lit. (14) mp 202–206°C; $[\alpha]_D$ +6.6° (*c* 0.91, chloroform)); ir ν_{max}: 1755 cm^{-1}; ^{1}H nmr δ: 2.60–2.33 (2H, m), 0.90, 0.87, 0.76, and 0.62; mass spectrum *m/z*: 442 (M^+), 427, 287, and 95. *Anal.* calcd. for $C_{30}H_{50}O_2$: C 81.38, H 11.38; found: C 81.45, H 11.46.

(R)-Spiro[(5α-cholestane)-3,2′-(tetrahydrofuran)] (9)

To a stirred solution of compound **3** (40 mg) in pyridine (0.5 mL) kept at 0°C under argon was added a solution of *p*-toluenesulfonyl chloride (34 mg) in pyridine (0.5 mL). After 1.5 h an additional portion of *p*-toluenesulfonyl chloride (34 mg) was added and stirring was continued for 18 h. The reaction mixture was poured into water. The usual work-up gave 38 mg (99%) of chromatographically pure **9**, which had mp 117–118°C (acetone); ir ν_{max}: 1045 cm^{-1}; ^{1}H nmr δ: 3.80 (2H, m), 0.88, 0.78, 0.70, and 0.62; mass spectrum *m/z*: 428 (M^+), 331, 123, 110, and 98. *Anal.* calcd. for $C_{30}H_{52}O$: C 84.04, H 12.23; found: C 83.77, H 12.12.

(S)-Spiro[(5α-cholestane)-3,2′-(tetrahydrofuran)] (10)

The reaction was carried out as above. Compound **5** (50 mg) and *p*-toluenesulfonyl chloride (42 mg) gave compound **10** (44 mg, 92%), which had mp 103–104°C (acetone); ir ν_{max}: 1035 cm^{-1}; ^{1}H nmr δ: 3.79 (2H, m), 0.87, 0.81, 0.77, 0.75, and 0.62; mass spectrum *m/z*: 428 (M^+), 123, 110, 98. *Anal.* calcd. for $C_{30}H_{52}O$: C 84.04, H 12.23; found: C 84.14, H 12.30.

3α-Acetonyl-5α-cholestan-3β-ol (11)

Compound **4** (40 mg) dissolved in acetone (10 mL) was oxidized with Jones reagent at 0°C. The usual work-up gave 38 mg (96%) of slightly impure (tlc) product. This was filtered through a column of silica gel to give **11** (28 mg, 71%), which had mp 109–111°C (pentane); ir ν_{max}: 3510 and 1700 cm^{-1}; ^{1}H nmr δ: 3.79 (1H, m, $W_{1/2}$ = 24 Hz, O*H*), 2.74 (2H, s, CH_2 α to CO), 2.17 (3H, s, CH_3CO), 0.91, 0.80, and 0.65; mass spectrum *m/z*: 444 (M^+), 426, 386, 368, 44. *Anal.* calcd. for $C_{30}H_{52}O_2$: C 81.02, H 11.79; found: C 80.63, H 11.70.

3β-Acetonyl-5α-cholestan-3α-ol (12)

Compound **6** (24 mg) was dissolved in acetone (5 mL) and oxidized with Jones reagent at 0°C. The usual work-up gave a crude product (20.5 mg, 86%), which was crystallized from pentane to give **12** (15 mg). It had mp 125–128°C; ir ν_{max}: 3520 and 1700 cm^{-1}; ^{1}H nmr δ: 3.45 (1H, br s, $W_{1/2}$ = 14 Hz, O*H*), 2.55 (2H, s, CH_2CO), 2.16 (3H, s, CH_3CO), 0.93, 0.89, 0.82, 0.74, and 0.64; mass spectrum *m/z*: 444 (M^+), 426, 368. *Anal.* calcd. for $C_{30}H_{52}O_2$: C 81.02, H 11.79; found: C 80.85, H 11.75.

Dehydration of 12

A solution of compound **12** (20 mg) and *p*-toluenesulfonic acid (2 mg) in benzene (0.6 mL) was stirred at room temperature for 22 h. The usual work-up and chromatography on a silica gel column gave a product (16 mg, 83%) consisting of **13** and **14** in the ratio 9:1 (estimated from ^{1}H nmr spectrum by the integration of olefinic proton signals at δ 5.98 and 5.47). This material, mostly 3-(2′-oxopropylidene)-5α-cholestane (**13**), was an oil; ir ν_{max}: 1680 and 1620 cm^{-1}; uv $\lambda_{max}(\varepsilon)$: 248 (12 800) (ethanol); ^{1}H nmr δ: 5.98 (1H, br s), 2.16 (3H, s), 0.93, 0.90, 0.82, and 0.65; mass spectrum *m/z*: 426 (M^+) and 368. *Accurate Mass* calcd. for $C_{30}H_{50}O$: 426.3862; found: 426.3845.

Dehydration of 11

A solution of compound **11** (14.5 mg) and *p*-toluenesulfonic acid (1.5 mg) in benzene (0.2 mL) was stirred at room temperature for 25 h. The usual work-up and filtration through a silica gel column gave a product (11 mg, 79%) consisting of **13** and **14** in the ratio 7:3, estimated from the ^{1}H nmr spectrum as in the preceding experiment.

3-Acetonyl-5α-cholest-2-ene (14)

To a solution of compound **13** (10.5 mg) in methanol (2 mL) stirred under argon was added a solution of potassium hydroxide in methanol (10%, 0.1 mL). The reaction mixture was stirred at room temperature

for 16 h. The usual work-up gave compound **14** (9 mg), which had mp 104–106°C (methanol); ir ν_{max}: 1705 cm^{-1}; ^1H nmr δ: 5.47 (1H, m), 3.00 (2H, s), 2.12 (3H, s), 0.96, 0.90, 0.83, 0.73, and 0.66; mass spectrum *m/z*: 426 (M^+), 368, 43. *Accurate Mass* calcd. for $C_{30}H_{50}O$: 426.3861; found: 426.3857.

17α-Allyl-3β-(tetrahydropyran-2-yloxy)-5α-androstan-17β-ol (15)

To a mixture of magnesium (60 mg), allyl bromide (0.014 g), and a few crystals of iodine in diethyl ether (1 mL) stirred under argon was added a solution of 3β-(tetrahydropyran-2-yloxy)-5α-androstan-17-one (300 mg) and allyl bromide (86 mg) in diethyl ether (9 mL). After completion of the addition (45 min) the reaction mixture was refluxed with stirring for 1.5 h, then poured into water and extracted with a 1:1 mixture of diethyl ether – benzene. The dried ($MgSO_4$) organic layer was evaporated to give chromatographically pure compound **15** (328 mg, 98%), which had mp 117–126°C (methanol); ir ν_{max}: 3620, 1630, and 1020 cm^{-1}; ^1H nmr δ: 5.94 (1H, m, $W_{1/2}$ = 34 Hz), 5.26–4.85 (2H, m), 4.67 (1H, m), 3.79 (1H, m), 3.51 (2H, m), 2.22 (2H, d, J = 6 Hz), 1.81 (1H, s), 0.86, and 0.82; mass spectrum *m/z*: 416 (M^+), 315, 297, 273, 255, 85. *Anal.* calcd. for $C_{27}H_{44}O_3$: C 77.83, H 10.64; found: C 77.42, H 10.69.

17α-Allyl-5α-androstan-3β,17β-diol (16)

A solution of **15** (252 mg) and concentrated hydrochloric acid (0.04 mL) in absolute ethanol was stirred at room temperature for 6 h. The usual work-up gave chromatographically pure compound **16** (190 mg, 95%), which had mp 173–174°C (methanol) (lit. (19*a*) mp 176–177°C); ir ν_{max}: 3605, 3450, 1635, and 1030 cm^{-1}; ^1H nmr δ: 5.97 (1H, m, $W_{1/2}$ = 32 Hz), 5.38–4.92 (2H, m), 3.53 (1H, m), 2.24 (2H, d, J = 7 Hz), 1.52 (2H, s), 0.87, and 0.82; mass spectrum *m/z*: 332 (M^+), 291, 273, 255, 161, 147, 107, 42. *Anal.* calcd. for $C_{22}H_{36}O_2$: C 75.38, H 10.92; found: C 75.57, H 10.95.

3β-Acetoxy-17α-allyl-5α-androstan-17β-ol (17)

Crude compound **16**, obtained from the Barbier–Grignard reaction of 3β-(tetrahydropyran-2-yloxy)-5α-androstan-17-one (300 mg) and subsequent hydrolysis of THP–ether, was acetylated in a mixture of pyridine (2 mL) and acetic anhydride (2 mL) at room temperature for 26 h. The usual work-up gave a crude product (284 mg, 95%). This was crystallized from hexane to give compound **17** (251 mg, total yield of the three-step sequence 84%), which had mp 124–128°C (lit. (19*a*) mp 132–133°C); ir ν_{max}: 3620, 3560, 1720, 1630, and 1250 cm^{-1}; ^1H nmr δ: 5.95 (1H, m, $W_{1/2}$ = 34 Hz), 5.33–4.90 (2H, m), 4.65 (1H, m), 2.22 (2H, d, J = 7 Hz), 1.97 (3H, s), 1.65 (1H, s), 0.83, and 0.80; mass spectrum *m/z*: 374 (M^+), 333, 273, 255, and 43. *Anal.* calcd. for $C_{24}H_{38}O_2$: C 76.95, H 10.22; found: C 76.30, H 10.56.

Hydroboration of compound 17

To a solution of compound **17** (1.072 g) in tetrahydrofuran (10 mL), stirred under argon at room temperature, three portions (1 mL each) of $BH_3 \cdot (CH_3)_2S$ complex (1 *M*) in methylene chloride were added at 0.5 h intervals. After the substrate had reacted (tlc control), a solution of sodium hydroxide (10%, 6 mL) was added, followed by dropwise addition of hydrogen peroxide (30%, 14 mL) during 4 h. The product was extracted with a 1:1 mixture of benzene – diethyl ether and purified chromatographically (silica gel, benzene – ethyl acetate 5:1). The major product was 3β-acetoxy-17α-(3′-hydroxypropyl)-5α-androstan-17β-ol (**18**) (830 mg, 74%), which had mp 219–221°C (methanol); ir ν_{max}: 3620, 3415, 1720, and 1255 cm^{-1}; ^1H nmr δ: 4.60 (1H, m, $W_{1/2}$ = 18 Hz), 3.62 (2H, m), 2.64 (2H, s), 1.97 (3H, s), 0.80; mass spectrum *m/z*: 374, 333, 115, 102, 97, and 43. *Anal.* calcd. for $C_{24}H_{40}O_4$: C 73.42, H 10.27; found: C 73.50, H 10.69. The minor product was a compound whose spectra were in agreement with structure **19**. It had mp 175–177°C (methanol); ir ν_{max}: 3620, 3480, 1720, and 1265 cm^{-1}; ^1H nmr δ: 4.66 (1H, m, $W_{1/2}$ = 16 Hz), 4.16 (1H, m, $W_{1/2}$ = 16 Hz), 2.56 (2H, s), 1.99 (3H, s), 0.91 (3H, s), 0.84, and 0.82 (two s integrating to 3H); mass spectrum *m/z*: 392 (M^+), 333, 115. This material did not give satisfactory analytical data.

(S)-Spiro[(3β-acetoxy-5α-androstane)-17,2′-tetrahydrofuran] (20)

A solution of **18** (50 mg) and *p*-toluenesulfonyl chloride (97 mg) in pyridine (1 mL) was stirred under argon at room temperature for 3.5 h. The usual work-up gave compound **20** (46 mg, 97%, homogenous on tlc), which had mp 113–114°C (methanol) (lit. (19*b*) mp 116–120°C and 124–125°C); ir ν_{max}: 1720 and 1255 cm^{-1}; ^1H nmr δ: 4.65 (1H, m, $W_{1/2}$ = 26 Hz), 3.74 (2H, m), 2.00 (3H, s), 0.85, and 0.82; mass spectrum *m/z*: 374 (M^+), 97, 84.

(R)-Spiro[(3β-acetoxy-5α-androstane)-17,5′-(2′-oxotetrahydrofuran)] (21)

Oxidation of compound **18** (650 mg) with Jones reagent gave a crude product (637 mg) that was crystallized from heptane to give lactone **21** (605 mg, 94%), which had mp 162–163°C (lit. (19*b*) mp 162–163°C); ir ν_{max}: 1760, 1720, and 1250 cm^{-1}; ^1H nmr δ: 4.65 (1H, m, $W_{1/2}$ = 20 Hz), 2.44 (2H, m), 1.97 (3H, s), 0.86, and 0.78; mass spectrum *m/z*: 388 (M^+), 328, 217, 147, 107, and 43.

(R)-Spiro[(3β-hydroxy-5α-androstane)-17,5′-(2′-oxotetrahydrofuran)] (22)

To a solution of lactone **21** (400 mg) in methanol (20 mL) was added potassium carbonate in methanol (1%, 20 mL), and the mixture was kept at room temperature for 17 h. The usual work-up gave a crude product, which was filtered through a column of silica gel. Compound **22** (343 mg, 96%) had mp 200–202°C (methanol) (lit. (3*a*) mp 199–201°C); ir ν_{max}: 3605, 3480, and 1760 cm^{-1}; ^1H nmr δ: 3.52 (1H, m), 2.45 (2H, m), 2.07 (1H, s), 0.88, and 0.79; mass spectrum *m/z*: 346 (M^+), 246, 217, 107, and 41.

Medium effects on activation parameters on alkaline hydrolysis of 2-carbomethoxypropionate ion in aqueous mixtures of ethylene glycol

PRASANTA KUMAR BISWAS, BIKAS CHANDRA BAG, AND MIHIR NATH DAS[1]

Department of Chemistry, Jadavpur University, Calcutta 700 032, India

Received May 27, 1986

PRASANTA KUMAR BISWAS, BIKAS CHANDRA BAG, and MIHIR NATH DAS. Can. J. Chem. **65**, 235 (1987).

The standard free energies of transfer (ΔG_{tr}^0) of the 2-carbomethoxypropionate ion (R^-) have been determined from the solubilities of the silver salt (AgR) in water and six aqueous mixtures of ethylene glycol (1–60%) at 25°C, using the literature values of ΔG_{tr}^0 of Ag^+. Utilizing these values of the R^- ion as well as the literature values of $\Delta G_{tr}^{\ddagger}$ of the OH^- ion, combined with the experimental values of $\Delta G^{\ddagger}$ for the alkaline hydrolysis of R^- ion, the corresponding transfer parameters of the transition states ($\Delta G_{tr}^{\ddagger}$) for the hydrolysis reaction in aquo-glycolic media at 25°C have been calculated. Attempts have been made to correlate the rates and activation parameters with the transfer quantities and solvent properties.

PRASANTA KUMAR BISWAS, BIKAS CHANDRA BAG et MIHIR NATH DAS. Can. J. Chem. **65**, 235 (1987).

En se basant sur les solubilités, mesurées à 25°C, du sel d'argent (AgR) dans l'eau et dans six mélanges aqueux d'éthylène glycol (10–60%) et utilisant les valeurs de la littérature pour le ΔG_{tr}^0 de l'ion Ag^+, on a déterminé les énergies libres standards de transfert (ΔG_{tr}^0) de l'ion carbométhoxy-2 propionate (R^-). Utilisant ces valeurs pour l'ion R^- et les valeurs de la littérature de ΔG_{tr}^0 pour l'ion OH^- en combinaison avec les valeurs expérimentales de $\Delta G^{\ddagger}$ pour l'hydrolyse alcaline de l'ion R^-, on a calculé les paramètres correspondants de transfert des états de transition ($\Delta G_{tr}^{\ddagger}$ pour la réaction d'hydrolyse, à 25°C, dans des milieux glycoliques aqueux. On a essayé d'établir une corrélation entre les vitesses de réaction et les paramètres d'activation d'une part avec les quantités de transfert et les propriétés de solvant d'autre part.

[Traduit par la revue]

Introduction

Rates and activation parameters for alkaline hydrolysis of the 2-carbomethoxypropionate ion (R^-), a negatively charged ester, in aqueous mixtures of ethylene glycol (EG) were reported earlier (1, 2). The reaction is

$$^-OCOCH_2CH_2COOCH_3 + OH^- \rightleftharpoons {}^-OCOCH_2CH_2COO^- + CH_3OH$$

Attempts were made to correlate the results by dissecting the parameters into electrostatic and non-electrostatic components. A meaningful analysis of the results, however, requires a knowledge of the relevant thermodynamic transfer parameters, and the present paper essentially deals with medium effects in the light of the transfer free energies of the reacting ions and the transition state in aquo-glycolic mixtures at 25°C.

Experimental

2-Carbomethoxypyropionic acid (the half ester of succinic acid) was prepared by a standard method (3). Ethylene glycol (E. Merck, India) was purified by the usual procedure (4). Aqueous mixtures of six different compositions (10–60% EG) were prepared by weight. The silver salt of the half ester (AgR) was prepared and its solubilities (S) in water and the aquo-glycolic mixtures at 25°C were measured by the same procedures as described earlier (5).

Results

From the rate constants at zero ionic strengths (k_0) at 20, 30, and 40°C, reported earlier (2), the k_0 values corresponding to 25°C were evaluated by interpolation for all the media, and are shown in Table 1, together with the ratios k_s/k_w, where k_w denotes the value of k_0 in water and k_s that in any mixed medium. The activation parameters on the molar scale were also evaluated for 25°C (Table 1).

The standard free energies of transfer of the silver salt, ΔG_{tr}^0(AgR), from water to the respective media were evaluated by eq. [1], assuming complete dissociation of AgR in all the media.

$$[1] \quad \Delta G_{tr}^0(\text{AgR}) = RT \ln \frac{K_{sp}(w)}{K_{sp}(s)}$$

where K_{sp} denotes the solubility product of AgR and w and s representing water and any other medium, respectively.

The standard free energies of transfer of the substrate ion, $\Delta G_{tr}^0(R^-)$, from water to the mixed media were calculated by subtracting from ΔG_{tr}^0(AgR) the corresponding values of transfer of Ag^+ ion, $\Delta G_{tr}^0(Ag^+)$, as obtained from literature (6). These latter values are based on the well-known extrathermodynamic TATB assumption that ΔG_{tr}^0 for the tetraphenyl arsonium (TA^+) ion is equal to that for the tetraphenyl boride (TB^-) ion for any particular medium at a given temperature.

The ΔG_{tr}^0 values for the other reactant, OH^- ion, were obtained from literature (7), these being based on the self-ionization constants of water and the mixed media (8), combined with the TATB assumption (9, 10). Wells (11) has used a different assumption for calculating $\Delta G_{tr}^0(OH^-)$, and his values are slightly different. The TATB assumption is, however, generally considered to be more sound (9, 12).

The medium effect on the free energy of activation, $m\delta\Delta G^{\ddagger}$,

is given by eq. [2].

$$[2] \quad m\delta\Delta G^{\ddagger} = \Delta G^{\ddagger}(s) - \Delta G/(w)$$

where s and w denote any mixed medium and water, respectively (Table 1). The standard free energy of transfer of the transition state, $\Delta G^{\ddagger}_{tr}$, for any medium is given by eq. [3].

$$[3] \quad \Delta G^{\ddagger}_{tr} = m\delta\Delta G^{\ddagger} + \Delta G^0_{tr}(OH^-) + \Delta G_{tr}{}^0(R^-)$$

The values of the standard free energies of transfer of the different species from water to the aquo-glycolic media of varying compositions are shown in Table 2.

Discussion

The rate constant monotonically decreases with increase in the proportion of glycol in the medium (Table 1). Only a small part of this decrease can, however, be ascribed to a decrease in the dielectric constant. In a series of isodielectric media (D = 50.38) comprising water and an organic solvent like acetone, dioxane, ethanol, and ethylene glycol, the rate constant for the same reaction at 30°C is the lowest in the aqueous mixture of glycol (1). A similar result was also found for the alkaline hydrolysis of another negatively charged ester, acetyl mandelate ion (13). It is true that amongst all these isodielectric media, the glycolic medium has the lowest mole fraction of water, and this may or may not be just a case of coincidence. But then, the rate of the title reaction in aqueous DMSO mixtures monotonically increases with decreasing mole fraction of water (5). Increase in rate with decrease in water content has also been found for the same reaction in some other aquo-organic mixtures (14).

In aquo-glycolic media, a disturbing factor to be considered (7, 15) is the possibility of formation of the glycoxide ion (OG^-) by reaction between the OH^- ion and the glycol molecule (GOH)

$$OH^- + GOH \rightleftharpoons OG^- + H_2O$$

If the glycoxide ion be present in an appreciable concentration, a parallel reaction between this ion and the ester ion is likely to occur. Hence, the rate constants and the activation parameters as well as the transfer free energies, $\Delta G^0_{tr}(OH^-)$ and $\Delta G^{\ddagger}_{tr}$, reported in the present work ought to be considered as composite quantities involving both OH^- and OG^- ions. This aspect of the problem, which has been discussed by Kundu and co-workers (7) in connection with the alkaline fading of crystal violet ion in aqueous mixtures of ethylene glycol, is an involved one and will remain so till the above equilibrium is studied quantitatively, and separate values for the two rate constants (for reactions with OH^- and OG^- ions) as well as the transfer free energies of the OH^- and OG^- ions for the different aquo-glycolic media are available. Certain plausible conclusions may, however, be profitably drawn from the observed overall values of the rate constants and the thermodynamic parameters, as presented below.

The observed decrease in rate, on changing the medium from water to aqueous glycol, may occur as a result of stabilization of the reacting ions and/or destabilization of the transition state. The observed $\Delta G^0_{tr}(OH^-)$ values (Table 2) are negative and rather small in magnitude, implying that the OH^- ion is slightly stabilized on adding glycol to water, but this becomes appreciable only beyond 40% glycol. The OH^- ion should thus be somewhat less reactive on adding glycol to water. The $\Delta G^0_{tr}(R^-)$ values (Table 2), however, are positive and of a higher magnitude, indicating that the substrate ion is appreciably destabilized and should become more reactive on adding glycol. It is significant that the ΔG^0_{tr} values for the anions, Cl^-, Br^-, and I^- are also reported to be positive on the basis of the TATB assumption (9, 10) as well as the other assumption used by Wells (11, 15). For the transition state, which is a doubly charged anion, the free energies of transfer ($\Delta G^{\ddagger}_{tr}$) are also positive and appreciably larger, indicating a relatively larger degree of destabilization. In fact, it is the destabilization of the transition state which essentially dictates the overall effect leading to decreased rates in aquo-glycolic media. In aqueous DMSO mixtures, on the other hand, it is the combined destabilization of the reacting ions, which predominates over even the very large destabilization effect on the transition state, leading to enhanced rates (5).

The greater destabilization of the transition state and also of the substrate ion to a smaller extent, on gradual replacement of water by glycol molecules, possibly arises from the reduced solvating capacity of glycol because of intramolecular hydrogen bond formation between the twin OH groups in the molecule (11). The $T\Delta S^{\ddagger}$ values (Table 1) become less negative with increasing proportion of glycol, thereby implying progressively less solvation of the transition state. The electrostatic effect arising from reduced dielectric constant also contributes to a smaller extent towards destabilization of the doubly charged transition state. For this reaction, the $\Delta H^{\ddagger}$ values (Table 1) in aquo-glycolic media are much higher than in any other medium studied so far (1, 2, 5, 14). The excess free energy function (G^E) for aqueous mixtures of ethylene glycol is negative (16, 17), but the observed results cannot be rationalized by the model of Caldin and Bennetto (18) according to which negative G^E for the solvent mixture should reduce the enthalpy of

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 80.58.250.72 on 09/07/12
For personal use only.

activation (19). Other unfavourable contributory factors, particularly desolvation, obviously preponderate over the effect of negative G^E.

On the basis of the classification of solvents into typically aqueous (TA) and typically nonaqueous with negative G^E (TNAN) (17, 20), the behaviour of ethylene glycol in aqueous mixtures is considered to form a borderline between TA and TNAN, but lying more towards TA (17). The present kinetic results also point towards a similar conclusion.

Fluorescence properties of polyene antibiotics in phospholipid bilayer membranes

N. O. PETERSEN, R. GRATTON, AND E. M. PISTERS
Department of Chemistry, The University of Western Ontario, London, Ont., Canada N6A 5B7

Received May 27, 1986

N. O. PETERSEN, R. GRATTON, and E. M. PISTERS. Can. J. Chem. **65**, 238 (1987).

The fluorescence characteristics of the polyene antibiotic Nystatin have been studied by measurements of quantum yields, lifetimes, and anisotropies in a model bilayer membrane. These measurements have been performed as a function of temperature and fluorophore-to-phospholipid molar ratio. Comparisons with data available for the parinaric acids demonstrate that the photophysics of the two polyene chromophores is similar. The quantum yield decreases at increasing Nystatin densities while the lifetimes are constant. These observations combined with quantitative comparisons with calculations of the density dependence of dynamic quenching in two-dimensional systems show that Nystatin fluorescence is quenched in bilayer membranes by a static process. This is likely due to the formation of complexes within the bilayer. The quenching is equally efficient in both the gel and liquid crystalline phases of the bilayer which suggests that the formation of the complexes occurs at all temperatures. At high Nystatin densities, there is also a quenching of the polarization, but the mechanism whereby this occurs is not clear. The limiting anisotropy at low concentrations is between 0.33 and 0.35 at all temperatures, suggesting that the Nystatin monomer is highly restricted in its reorientational motion in both gel and liquid crystalline phases.

N. O. PETERSEN, R. GRATTON et E. M. PISTERS. Can. J. Chem. **65**, 238 (1987).

En effectuant des mesures de rendements quantiques, de temps de vie et d'anisotropies dans une membrane modèle à double couche, on a étudié les caractéristiques de fluorescence de l'antibiotique polyénique Nystatine. On a effectué ces mesures en fonction de la température et du rapport molaire fluorophore/phospholipide. Des comparaisons avec les données disponibles pour les acides parinariques démontre que les photophysiques des deux chromophores polyéniques sont semblables. Le rendement quantique diminue avec une augmentation des densités des Nystatines; toutefois, les temps de vie sont constants. Ces observations, combinées avec des comparaisons quantitatives et avec des calculs de corrélation entre la densité et le piégeage dynamique dans des systèmes bidimensionnels, démontrent que la fluorescence de la Nystatine est piégée dans les membranes à doubles couches par un processus statique. Ceci est probablement dû à la formation de complexes à l'intérieur de la double couche. Le piégeage est également efficace tant des les phases en gel que dans les cristaux liquides de la double couche; ceci suggère que la formation des complexes se produit à toutes les températures. A des densités élevées de Nystatine, il se produit aussi un piégeage de la polarisation, mais le mécanisme par lequel ce piégeage se produit n'est pas clair. A des concentrations faibles et à toutes les températures, l'anisotropie limite se situe entre 0,33 et 0,35 et ceci suggère que le monomère de Nystatine est fortement restreint dans son mouvement de réorientation, tant dans la phase de gel que dans la phase cristalline liquide.

Introduction

Fluorescence properties of polyene antibiotics (1–4) have been used to characterize their interactions with sterols in solution and in some membrane preparations (5–7). Detailed interpretations have been hampered by a poor understanding of the photophysics of the polyene antibiotics, and in some cases by the presence of highly fluorescent impurities (8).

Recent lifetime and quantum yield measurements (9) suggest that in solution the fluorescence properties of Nystatin (a tetraene antibiotic) are virtually identical to those of the parinaric acids and similar to those of diphenyl hexatriene. These observations now make it possible to utilize the fluorescence of several polyene antibiotics in both solution and membrane preparations to investigate their intermolecular interactions, their incorporation into bilayers and their effect on bilayer structure (10). In this report we characterize the fluorescence properties of Nystatin in a simple bilayer membrane by measurements of quantum yields, lifetimes, and anisotropies as functions of temperature and Nystatin to phospholipid molar ratios. These experiments are compared to available data (11–14) for other polyenes, notably parinaric acid, and to calculations (15–17) of the concentration-dependent quenching of emission and polarization in two dimensions.

Experimental

Materials

Polyene antibiotic derivatives were prepared as described previously (8, 9). Nystatin and the lipids used were obtained from Sigma (St. Louis, MO). Solvents were spectroscopic grade and were obtained from Fisher.

Lipid dispersions of small vesicles were prepared by injection of concentrated ethanol solutions of the lipids and polyene antibiotics in the desired proportions into warm buffer solutions (Phosphate Buffered Saline at pH 7.4 (PBS)) which were stirred vigorously (15).

Fluorescence spectroscopy

(*A*) Quantum yield measurements: Fluorescence spectra were recorded on an MPF-4 (Perkin Elmer) fluorescence spectrophotometer. The quantum yields were calculated relative to micromolar concentrations of quinine sulphate (recrystallized from water) in 0.1 *N* H_2SO_4 using the quantum yield of 0.52 (18). The calculations were not corrected for refractive index differences between lipid suspensions and the sulfuric acid solutions, but were corrected for measurements in organic solvents (19). The quantum yields were calculated from the areas by cutting and weighing. The absorbance spectra were measured on a Cary 219 uv–visible spectrophotometer, in most cases on more concentrated solutions. We have not detected any concentration dependence of the absorbance spectra in these samples beyond that expected from the Beer–Lambert Law.

(*B*) Lifetime measurements: Fluorescence lifetimes were made using single photon counting equipment in Professor W. R. Ware's laboratory (Chemistry, University of Western Ontario). The Photochemical Research Associates Model 3000 ns lifetime system has been described elsewhere (20). The lifetimes were estimated from fitting by standard procedures to, in most cases, double exponential decays. In all cases the χ^2 values were close to unity.

(*C*) Anisotropy measurements: The fluorescence anisotropy was measured on a Photochemical Research Associates prototype fluorescence polarization spectrophotometer employing appropriate excitation and emission filters along with an excitation monochromator. The fluorescence intensity was always measured in all combinations of polarization: I_{vv}, I_{vh}, I_{hv}, and I_{hh} for both the solution of interest and for a membrane suspension at the same lipid concentration but without

the chromophore. The anisotropy, r, is corrected for the background light scattering by the calculation (21):

$$r = (I_{vv(corr)} - I_{vh(corr)} \times G)/(I_{vv(corr)} + 2 \times I_{vh(corr)} \times G)$$

where G corrects for the different detection efficiency for vertical and horizontal emission polarization ($G = I_{hv(corr)}/I_{hh(corr)}$; in all cases where the data were meaningful, the value for G was in the range 0.95–0.97). In these expressions $I_{(corr)}$ is calculated as the difference between the emission intensity of the sample and the blank membrane suspension (e.g. $I_{vv(corr)} = I_{vv(sample)} - I_{vv(blank)}$).

Results

The absorption, fluorescence emission, and fluorescence excitation spectra of the polyene antibiotic Nystatin and its nitrobenzoxadiazole derivative (NBD-Nys) have been reported for solutions in several solvents (9). These spectra are fairly insensitive to the solvent except that the quantum yield of fluorescence decreases as the polarity of the solvent increases. There are small changes in both the position and the relative amplitude of the four characteristic peaks. The absorption spectra of Nystatin in phospholipid membrane preparations is obscured by the substantial background scattering relative to the absorbance at the low concentrations employed in most of the experiments described in this report, but was measured for a few samples with larger amounts of Nystatin. The fluorescence spectra, in contrast, could be measured with good precision at concentrations as low as 10^{-7} M and in some cases lower than that. Examples of these spectra are shown in Fig. 1 at several temperatures along with the structure of Nystatin. The quantum yields and the peak positions are summarized in Table 1 for a particular Nystatin-to-lipid ratio, and are compared to the corresponding values in a few solvents. Clearly, the quantum yield is highly temperature dependent in the lipid system, ranging from 0.049 at low temperatures (comparable to that in THF) to 0.003 at high temperatures (comparable to that in water). This change is a result of a decrease in the lifetime of the emission (*vide infra*) rather than a transfer of the Nystatin from the membrane to the aqueous solution.

Figure 2 illustrates the temperature dependence of the fluorescence emission intensity at several concentrations of Nystatin in the lipid. The data are normalized to the intensities at 15°C for each composition and are compared to the temperature dependence in ethanol.

The fluorescence intensity is affected by the change in lipid matrix from the gel state to the more fluid liquid crystalline state. This is particularly evident at low Nystatin concentrations where the intensity drop occurs at the usual phase transition temperature of 23°C for dimyristoyl phosphatidyl choline. At higher concentrations of Nystatin the presence of the polyene antibiotic affects the phase transition temperature range, causing a broadening. At high (about 1%) Nystatin concentrations the relative intensity is almost insensitive to the phase transition. Thus small molar amounts of Nystatin cause perturbations in the bilayer structure, at least in the immediate vicinity of the emitting polyene chromophore.

The temperature variations in fluorescence intensity are reversible. On cooling the fluorescence intensity increase as rapidly as the temperature equilibration permits. This indicates that the polyene antibiotic remains in the membrane throughout the heating–cooling cycle. The vesicles with the Nystatin are also generated at high temperature, and cooled prior to any of the experiments. We, therefore, believe that the fluorescence changes reflect changes in equilibrium properties within the membrane rather than transient, nonequilibrium effects.

Fluorescence decay measurements of Nystatin emission in

THF are fit well by a single lifetime (9). In contrast, decays of Nystatin emission in bilayer membranes require at least two lifetimes for the fits to converge with χ^2 values close to unity (Table 2 (*A*)). In some preparations, light scattering provides a small, rapidly decaying component (<0.8 ns) in addition to the two major lifetimes shown in the tables.

At low temperatures (when the bilayer is in the gel phase) the lifetimes are long (33 and 17 ns) and approach the estimated radiative lifetime of 57 ns (9) as expected for a chromophore imbedded in a rigid medium. At higher temperatures (when the bilayer is in the less rigid liquid crystalline phase) the lifetimes are reduced about five-fold. This behaviour parallels that observed for the parinaric acids in membrane preparations (13). For comparison, the lifetimes measured for *trans*-parinaric acid (*t*PnA) in gel and liquid crystalline phases are listed in Table 2 (*B*). Although the numbers differ in details, there is a close correspondence: in solution the emission decays with a single, short lifetime while in bilayers it decays with two lifetimes which are long in the rigid gel phase and short (but not as short as in solution) in the liquid crystalline phase.

These data contrast with those for diphenylhexatriene (DPH) (Table 2 (*C*); 11, 14). This probe exhibits single exponential decays (or nearly so) in all systems with little variation in lifetime between solution, gel, and liquid crystalline phases.

The quantum yield of Nystatin fluorescence in the gel phase of the bilayer is comparable to that in THF even though the

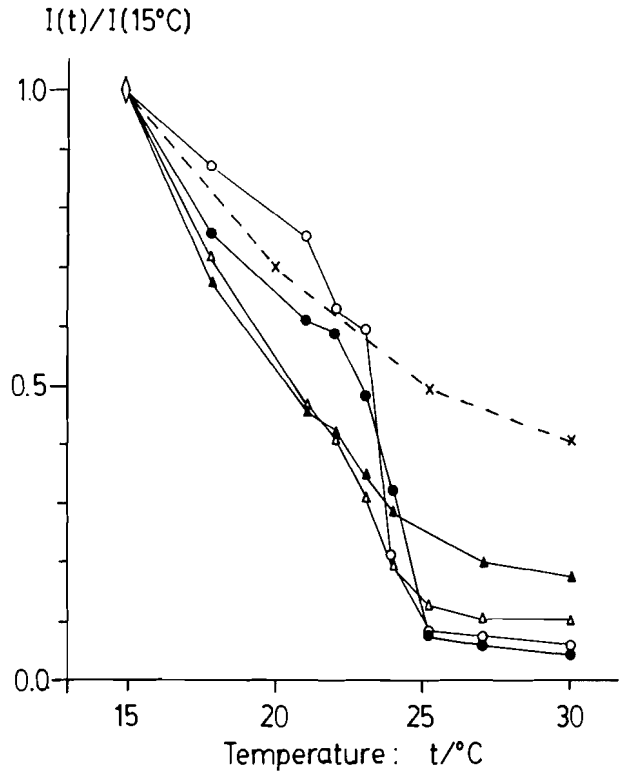

FIG. 2. Relative fluorescence intensity as a function of temperature for Nystatin in dimyristoyl phosphatidylcholine at selected mole ratios of Nystatin-to-lipid. In each case, the fluorescence is normalized to that at 14.8°C. For comparison the relative intensity is plotted for the same temperature range for Nystatin in an ethanol solution at a total concentration of 10^{-6} *M*. The Nystatin concentration in solution is 8×10^{-7} in all cases whereas the lipid concentrations were 2×10^{-3} (○); 8×10^{-4} (●); 2×10^{-4} (△), and 8×10^{-5} (▲).

lifetime is about ten-fold longer. Correspondingly, the lifetime in the liquid crystalline phase approaches that in THF while the quantum yield is at least ten-fold smaller (Table 2 (*A*)). These observations suggest strongly that the quantum yield of Nystatin fluorescence is reduced by a static quenching process in the bilayer environment. The quantum yields of the *t*PnA emission in bilayers were not reported (13) so it is unclear whether similar quenching occurs for the parinaric acids in bilayers.

The quantum yield of Nystatin fluorescence is sensitive to the Nystatin-to-lipid mole ratio (N/L), whereas the lifetimes are not. This appears to be true at both low and high temperatures, but it is difficult to get accurate or meaningful lifetime measurements at high temperatures and high N/L values since the quantum yield becomes less than 0.001. Table 3 lists the variation in quantum yields and lifetimes for samples in which the total concentration of Nystatin was kept constant and the phospholipid concentration was varied to achieve a 25-fold change in the mole fraction. While the quantum yield measured at 15°C changes from 0.055 to 0.006, the average lifetime (calculated as indicated in Table 3) remains unchanged. This indicates that the quenching process is a static quenching of Nystatin by itself.

Dynamic quenching in bilayer membrane systems have been calculated for several models and have been observed in a few systems (15–17). The results are typically presented as the relative intensity (I/I_0) as a function of the mole ratio of the acceptor to the lipid. Figure 3 shows the variation in relative intensity of Nystatin fluorescence as a function of the Nystatin-to-lipid ratio (N/L) at both 20 and 32°C. The graph also illustrates the expected variation for a dynamically quenched system for which the quenching cross-section radius (R_0) is either 4.5, 6.0, or 10.0 nm. It is evident that the quenching observed for Nystatin occurs with equal efficiency at both temperatures. It is also evident that the quenching occurs at a greater efficiency at lower N/L values than would be expected for a dynamic quenching process, unless the quenching cross-section radius is about 10.0 nm. For Nystatin this is an unreasonably large value, particularly because of the large Stoke shift (9) which reduces the spectral overlap of the absorption and emission bands. The data in Table 3 and Fig. 3 therefore both strongly suggest that the Nystatin is quenching itself in a static, density-dependent process. This may be understood if Nystatin forms complexes within the bilayer (3, 4, 10), in which the Nystatin chromophores interact to facilitate non-radiative decay processes, rather than internal conversion and emission.

The data in Fig. 3 also provide support for the assertion that

the Nystatin remains within the bilayer at all temperatures. Indeed, the close correspondence between the relative intensity drop at the two temperatures suggest that the complexes responsible for the static quenching exist to the same extent in both phases of the lipid bilayer.

In two-dimensional systems, processes which result in intensity quenching can also give rise to quenching of fluorescence polarization (17). Figure 4 illustrates this for the Nystatin–phospholipid system studied here. The anisotropy, measured in samples in which the concentration of lipid is constant and the Nystatin concentration is changed to provide a range of N/L values, drops systematically as the N/L value increases (Fig. 4*A*).

Snyder and Friere (17) have calculated, by numerical methods, the decrease in the anisotropy as a function of acceptor density for systems with either random or non-random distributions of fluorophores in a two-dimensional membrane. They fit their calculated changes in the relative polarization function ($g(p)/g(p_0)$) to a fourth-order polynomial function of the logarithm of a normalized fluorophore density (log γ) and express their results in terms of the five coefficients in the polynomial. The polarization function is $g(p) = 1/(1/p - 1/3) = 3r/2$, where p is the polarization and r is the anisotropy. Thus $g(p)/g(p_0) = r/r_0$. The normalized fluorophore density is $\gamma = NR_0^2/LA_L$, where R_0 is the quenching cross-section radius, A_L is the area per phospholipid (0.7 nm^2), and N/L is defined above. Thus $\log\gamma = \log(N/L) + \log(R_0^2/A_L)$.

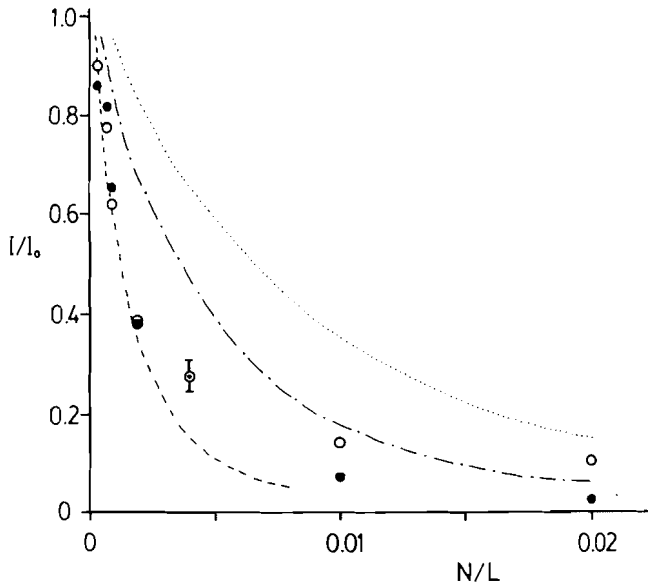

FIG. 3. Relative fluorescence intensity of Nystatin in dimyristoyl phosphatidylcholine as a function of the molar ratio of Nystatin-to-lipid at 20 (○) and 32°C (●). The smooth curve indicates the expected quenching if the fluorescence is dynamically quenched with a quenching cross section radius of 4.5 nm (···); 6.0 nm (-···-), and 10.0 nm (---). The intensity is normalized to that of infinite dilution, which is estimated from extrapolation of the actual fluorescence to zero Nystatin concentration. The uncertainty in the measurements are indicated by the error bar on one data point.

Figures 4 *A* and *B* compare the anisotropies measured for Nystatin to the anisotropies calculated by adjusting the anisotropy at infinite dilution (r_0) to a value of 0.33 and the

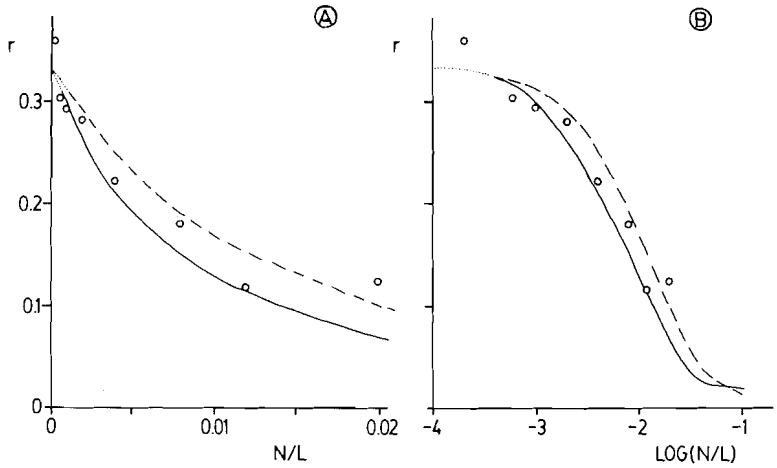

FIG. 4. The anisotropy of emission of Nystatin monomers in dimyristoyl phosphatidylcholine as a function the molar ratio (*A*) or the logarithm of the molar ratio (*B*) of Nystatin-to-lipid at 20°C. The smooth curves correspond to the expected curves using the numerical calculations in ref. 17 for a random (- - -) or a non-random (—) distribution of quenchers assuming a quenching cross section radius of 4.5 nm in both cases. Figures 4*A* and *B* contain the same data but in two representations to facilitate the comparison of the data with Fig. 3 and with ref. 17.

quenching radius (R_0) to a value of 4.5 nm for both a random (dashed lines) and the most non-random distribution (solid lines). These are not necessary the only or the best fit values. Qualitatively, the data correspond with the calculated values, but it is impossible to distinguish between random and non-random distributions without additional information. In either case, the infinite dilution value of the anisotropy is about 0.33 at 20°C. This compares with 0.36 measured for the limiting anisotropy of parinaric acids in the gel phase. It is possible that the difference corresponds to a slightly larger difference in the orientation of the absorption and emission transition moments for Nystatin than for parinaric acid. At the very least, the Nystatin monomer (whose emission is being measured) is reorienting only a little during the 20–30 ns lifetime. This is not surprising for a large polyene antibiotic molecule imbedded in a rigid phospholipid matrix. The corresponding quenching of polarization at 32°C is much harder to measure because the fluorescence intensities decrease rapidly. However, at low concentrations, the anisotropy is as large or larger than that at the corresponding concentration at lower temperature. This means that the Nystatin monomer undergoes less reorientation during the 5 ns lifetime at high temperatures than during its 23 ns lifetime at low temperatures. In either environment, the rotational motion of the Nystatin monomer is slow and as a consequence the anisotropy measurement is not likely to be a good measure of the membrane environment of polyene antibiotics.

Discussion

Characteristics of the fluorescence of tetraenes

In non-polar solvents (THF, dioxane) the fluorescence quantum yield of both Nystatin and parinaric acid is small and the emission decay is rapid (Table 2). These data yield intrinsic lifetimes of about 57 ns for Nystatin and 100 ns for parinaric acid. In isotropic solution non-radiative decay processes are therefore about 20-fold faster than the radiative process.

In aqueous suspensions of Nystatin better than 90% of the initial intensity decays within 100 ps (Turnbull and Petersen, unpublished results) and the quantum yield approaches the detection limit (Table 1). This rapid decay may arise from solvent relaxation and quenching.

In phospholipid membranes in their gel phase ($T < 23$°C) the lifetime for Nystatin and parinaric acid increases at least ten-fold and there is evidence for multiple radiative processes. Although the present data are fit to, and reported as, two exponential decays, more recent evidence with more precise data (200 000 counts in the peak channel) suggests that the decay is best described by a distribution of lifetimes whose mean and variance is sensitive to temperature (Turnbull, James, Petersen, and Ware, unpublished results). Accordingly, interpretation of τ_1 and τ_2, and changes in these, in terms of molecular processes is tenuous. Nevertheless, the lack of change in the lifetimes reported in Table 3 and discussed below is unambiguous.

The overall increase is decay time in the rigid membrane is compatible with a decrease in the rate of non-radiative decay. This is expected if the non-radiative relaxation requires conformational changes, i.e. twisting, in the conjugated polyene segment. These are hindered in the gel phase of the membrane but freely accessible in the isotropic liquid. The liquid crystalline membrane then provides an intermediate environment with intermediate lifetimes.

In our hands, the lifetimes of the parinaric acids in DMPC membranes are slightly shorter than those reported (Table 2) (e.g. 33 ns vs. 55 ns for the longer component in *trans*-parinaric acid). For these suspensions, the quantum yield is about 0.3–0.4. Hence the about ten-fold increase in lifetime is accompanied by a ten-fold increase in quantum yield as expected in systems where the rates of non-radiative processes are slowed down. In contrast, the quantum yield of Nystatin emission in DMPC is less than or about equal to that in solution even though the lifetimes increase about ten-fold. As discussed below, this provides strong evidence for static quenching of Nystatin even at the lowest concentrations measured.

Evidence for Nystatin incorporation into the bilayer

Several sets of data provide evidence that Nystatin is incorporated into the bilayer membrane at temperatures both above and below the phase transition temperature (23°C). The quantum yield drops dramatically at the phase transition temperature for low Nystatin density showing that it can monitor the change in phase. The decrease in quantum yield could be a result of Nystatin being transferred to the aqueous phase at higher temperatures. However, the lifetime of the

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 80.58.250.72 on 09/07/12

emission decreases in direct proportion to the decrease in quantum yield while it remains much higher than that expected in solution (~0.1 ns). The fluorescence decay is bi-exponential at both high and low temperatures, suggesting that the chromophore remains in an anisotropic environment. The lifetime changes are similar to those observed for the parinaric acids (13) in various membrane systems. The close correspondence between the photophysics of these chromophores was previously shown for solutions (9) and the extension seen here for the bilayers suggest that these polyenes are sensitive to the same environmental changes. Presuming that parinaric acid remains in the membrane at all temperatures, these lifetimes suggest that the polyene segment of Nystatin does as well.

The partition constant for partitioning of the polyene antibiotic Amphotericin B, which differs from Nystatin only by having an additional site of unsaturation (9), between water and the liquid crystalline phase of lecithin at room temperature has been estimated to be 5×10^5 (22). Assuming this number is applicable to Nystatin, the fraction of Nystatin in the bilayer at high temperatures ranges from 0.999 to 0.923 in the experiments presented here.

The anisotropy is between 0.33 and 0.35 for Nystatin in the bilayer at all temperatures. This compares with anisotropies measured in THF of 0.13 and in ethanol of 0.01. The environment of the Nystatin therefore permits much less, or much slower, reorientation of the chromophore during its much longer lifetime while in the membrane. This further suggests that the Nystatin remains within the bilayer.

The perhaps most convincing evidence for full incorporation at all temperatures comes from the virtually identical density dependence of the static quenching. This suggests that the complexes which are responsible for the static quenching form with equal ease at both 20 and 32°C (see next section).

Taken together, all these observations provide convincing evidence that Nystatin is predominantly within the bilayer structure at all temperatures and at all concentrations. The fluorescence lifetimes, quantum yields, and anisotropies are therefore characteristic of the emission from the monomeric species in a phospholipid matrix.

Evidence for static quenching in bilayer membranes

The lifetime of emission from the Nystatin fluorophore is longer in the more rigid, but still non-polar, environment of the phospholipid bilayer than in the non-polar solvent, THF. Yet, the quantum yield of emission is less. The quantum yield of emission can in general be expressed as

$$\phi_F = X_i \times \phi_i = X_i \times (k_F/(k_F + k_{NR} + k_Q \times [Q]))_i$$
$$= X_i \times (k_F \times t_F)_i$$

where the subscript denotes the ith species and the summation is over all species in the system each present at a mole fraction X_i. The measured lifetime of emission (t_F) equals the inverse of the sum of the rate constants in the denominator.

Dynamic quenching of a single species results in a decrease in the measured lifetime and a proportional decrease in the quantum yield as the quencher concentration is increased. This is not observed for Nystatin in the lipid bilayer (Table 3).

Dynamic quenching of only one of a pair of emitting species would result in a decrease in the lifetime of the quenched species along with an overall decrease in the quantum yield. The lifetime of the non-quenched species would remain unaltered. The small decrease in the shorter of the lifetimes observed for Nystatin (Table 3) is not enough to account for the ten-fold change in the total quantum yield, especially since this is the smaller component in the decay.

Static quenching is usually thought of as a highly efficient quenching process for those chromophores within a critical radius of the quencher, while ineffective for the remainder of the emitters. The static quenching will therefore divide the chromophores into two populations: "dark complexes" which are totally quenched and whose emission is not observed, and "normal" chromophores which are not affected in either quantum yield or lifetime. The total quantum yield is then solely a reflection of the mole fraction of the chromophores which are not complexed and hence not quenched. However, since only the normal chromophores are emitting, the measured fluorescence lifetime is unchanged. This general pattern fits the quantum yield and lifetime measurements listed in Table 3.

The static quenching observed for Nystatin in bilayers is sensitive to the Nystatin concentration relative to the lipid concentration. Since these measurements are for samples with a constant Nystatin concentration, and since the extent of quenching decreases as the amount of lipid in the sample increases it is highly unlikely that the quenching arises from addition of or changing concentrations of impurities. It follows that the Nystatin emission is quenched by the increasing density of Nystatin in the bilayer. This is compatible with the formation of Nystatin complexes within the lipid bilayer (3, 4, 10). The implication is that Nystatin aggregates cannot emit fluorescence, while the monomeric species in the bilayer can. The formation of Nystatin complexes is favoured at higher densities so the mole fraction of monomers decreases and the result is a lower quantum yield.

The density dependence of the fluorescence quenching is the same in both the gel and the liquid crystalline phases of the bilayer. Hence Nystatin complexes form with about equal ease in both rigid and fluid membranes. The thermodynamics controlling the monomer–complex equilibrium and stabilizing the complex must then be more important than any differences in solubility of the Nystatin between the two phases. The low density at which the complexes form (molar ratios < 0.001) also attest to their stability.

The fluorescence comes exclusively from the monomer. The lifetime and anisotropy measurements therefore reflect the properties of the monomer only. Correspondingly, the quantum yield is a direct measure of the mole fraction of Nystatin which exist as monomers. These points will be important for the interpretation of any fluorescence studies in the future. It should now be possible to measure whether sterols interact with Nystatin monomers and affect their emission lifetime, or whether they shift the equilibrium between monomers and complexes. In fact, careful quantum yield and lifetime measurements can in principle be used to measure the binding constant between various sterols and either the Nystatin complexes or the monomers within the bilayer. Analogous experiments have been used to measure lipid:protein binding affinities employing spin-labeled lipids as quenchers (23).

Concentration quenching of anisotropy

The anisotropy is quenched at high Nystatin densities (Fig. 4). Although the density dependence can be fitted to numerical predictions, the data cannot distinguish between random and non-random distributions of the emitting species. In this case, the anisotropy is always that of the monomer, so there should not be any correlation between the intensity quenching (which is static) and the anisotropy quenching

(which must be dynamic). It is important to recognize that the quenching of anisotropy cannot be through energy transfer to the Nystatin complexes, unless these can emit or transfer back. The concentration quenching of the monomer polarization must be a result of energy transfer among monomers. The fits of the data in Fig. 4 indicate that the Nystatin–Nystatin energy transfer can occur with a characteristic radius R_0 of about 4.5 mm.

The limiting anisotropy at low densities appears to approach 0.33. This value is close to the limiting anisotropy of the parinaric acids in rigid media. Consequently the Nystatin monomer does not reorient rapidly in the bilayer at low temperatures. This is not surprising because of the large cylindrical shape of the molecule. The slightly larger anisotropy measured at higher temperatures (0.33–0.35) shows that the Nystatin monomer is too bulky to reorient about its long axis even in the more fluid bilayer phase.

The anisotropy data have no bearing on the complexes, so their orientation (and location) is uncertain. It is nevertheless tempting to speculate that the traditional pore model (3, 4) is substantially correct.

Charge transfer fluorescence of some *N*-benzoylindoles[1]

BIMSARA W. DISANAYAKA AND ALAN C. WEEDON[2]

The Photochemistry Unit, Department of Chemistry, The University of Western Ontario, London, Ont., Canada N6A 5B7

Received July 28, 1986

BIMSARA W. DISANAYAKA and ALAN C. WEEDON. Can. J. Chem. **65**, 245 (1987).

The fluorescence properties of various *N*-carbonyl-substituted indoles (compounds **1**–**7**) are examined. The *N*-benzoyl-indole derivatives **1** and **3**–**5** are shown to fluoresce weakly and the effect of solvent polarity upon the energy of the emitting state and upon the quantum yield of fluorescence is described. It is concluded that the initially formed singlet excited state is non-emissive and can relax to an intramolecular charge transfer state which is weakly fluorescent. The solvent effects are consistent with a general type of solvent interaction, and the solvent-induced shifts in the wavelength of the fluorescence emission correlate well with the Lippert equation relating the stabilisation of the excited state to a function of solvent dielectric and refractive index. A poor correlation with the empirical $E_T(30)$ solvent polarity parameter is observed.

BIMSARA W. DISANAYAKA et ALAN C. WEEDON. Can. J. Chem. **65**, 245 (1987).

On a étudié les propriétés de fluorescence de divers indoles substitués portant un groupement *N*-carbonyle (composés **1** à **7**). On démontre que les dérivés *N*-benzoyle indoles **1** et **3**–**5** possèdent une légère fluorescence et on décrit aussi l'effet de la polarité du solvant sur l'énergie de l'état donnant naissance à l'émission ainsi que sur le rendement quantique de la fluorescence. On en conclut que l'état singulet qui se forme initialement ne donne pas lieu à de l'émission et qu'il peut subir une relaxation conduisant à un état de transfert de charge intramoléculaire qui est faiblement fluorescent. Les effets de solvant sont en accord avec un type général d'interaction de solvant; de plus, les déplacements de longueurs d'onde d'émission de fluorescence induits par le solvant sont en bon accord avec l'équation de Lippert qui établit une relation entre la stabilisation de l'état excité et une fonction de la constante diélectrique du solvant et l'indice de réfraction. On a observé une mauvaise corrélation avec le paramètre empirique $E_T(30)$ de la polarité du solvant.

[Traduit par la revue]

Introduction

Indole is relatively unreactive photochemically and the major route for decay of the excited state produced by ultraviolet light irradiation is fluorescence (1). However, if a carbonyl substituent is present upon the indole nitrogen then the excited state will readily undergo a reaction with alkenes to yield cyclobutane derivatives in which the alkene has become attached to the 2- and 3-positions of the indole nucleus. Thus *N*-benzoyl and *N*-acetyl indoles will form cyclobutane adducts when irradiated with simple alkenes (2), as will *N*-carboethoxy-substituted indoles.[3] As part of a study of the mechanism of this reaction we attempted to determine the multiplicity of the excited state involved. Sensitisation and quenching experiments indicated that the reaction proceeds via the triplet excited state of the indole derivative.[4] In order to demonstrate that the reaction did not also proceed through the singlet excited state we attempted to record the fluorescence spectra of some *N*-carbonyl-substituted indoles in the presence and absence of alkenes. No fluorescence quenching, which would have been indicative of a singlet excited state reaction, was observed. However, the fluorescence, which was much weaker than that of indole itself, occurred at anomalously long wavelength, and the position and intensity of this emission was exceedingly solvent dependent.

Given the common occurrence of indole rings in tryptophan-containing living tissue, and the potential utility of the solvent-dependent fluorescence of the *N*-carbonyl-substituted derivatives for studies of their environment in proteins, we digressed from our mechanistic examination in order to study the emission properties of some *N*-carbonyl-substituted indole derivatives. The results are described here.

Results

The absorption and emission spectra of compounds **1**–**7** were recorded at room temperature in various solvents. The absorption spectra were substantially different from that of indole itself and exhibited a strong band at ca. 250 nm (ϵ = ca. 5×10^5) along with a weaker band at ca. 300 nm (ϵ = ca. 1×10^5) which showed evidence of vibrational structure (see Fig. 1). The position of the absorption bands for each compound were not solvent dependent. At room temperature *N*-acetyl indole, **2**, and the cyclic analogue **6** did not emit detectably while compounds **1** and **3**–**5** fluoresced weakly and with very large Stokes' shifts. Compound **7** fluoresced strongly

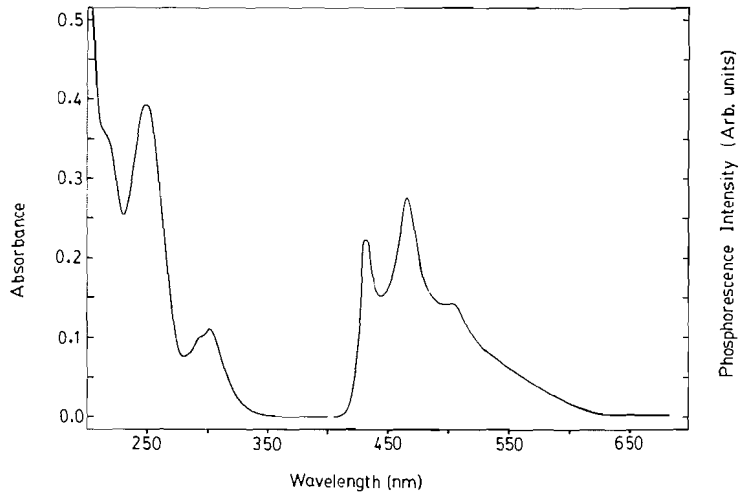

FIG. 1. Absorption spectrum at room temperature (23°C) in hexane (left hand curve) and phosphorescent emission spectrum in acetonitrile at 77 K (right hand curve) for compound **1** (10^{-5} *M*). The spectra were identical in all solvents.

but with a smaller Stokes' shift than compounds **1** and **3–5**. The wavelength and intensity of the emission was highly solvent dependent for those compounds which did emit, and this was most pronounced for compounds **1** and **3–5**. Generally, the more polar the solvent, the broader and weaker was the emission and the longer the wavelength of maximum intensity. The position of the emission maxima and some quantum yields of emission are given in Tables 1 and 2, and the appearance of the emission in some of the solvents examined is shown in Fig. 2 for compound **1**. The positions of the fluorescence maxima were not concentration dependent and the excitation spectra in all cases were in agreement with the emission being derived from the compound under study, and not from any strongly emitting impurity, of which indole was the most likely. The phosphorescence spectra were also measured at 77 K for compound **1** in three solvents (see Fig. 1); the position of the emission band was different from that of the fluorescence and did not shift with changing solvent. Its intensity was much greater than that of the room temperature fluorescence and completely masked it.

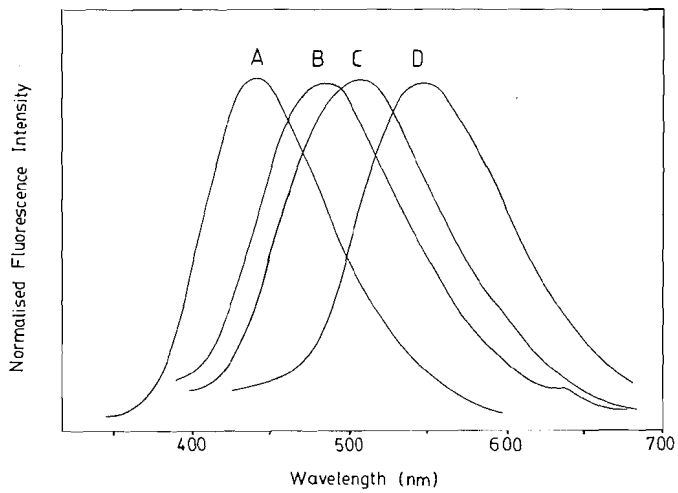

FIG. 2. Normalised fluorescence spectra of compound **1** (10^{-5} *M*). Curve *A*: hexane; curve *B*: diethyl ether; curve *C*: THF; curve *D*: MeCN.

Discussion

The appearance of the spectra in Fig. 1 indicates that the absorption and low temperature (phosphorescent) emission properties of compound **1** are unexceptional. However, the room temperature fluorescent emission (shown in Fig. 2) is at unexpectedly long wavelength, and the wavelength of the emission increases greatly with solvent polarity. The excitation spectra indicated that the emission at room temperature was indeed due to *N*-benzoyl indole and not some impurity. The possibility that the emission is due to an excimer species can be excluded since at the concentrations of the *N*-benzoyl indole used (10^{-5} *M*) the singlet excited state would have insufficient time to form an exciplex with a ground state molecule.

The fact that for compound **1** the positions of the absorption maxima do not change with solvent polarity suggests that the initially formed excited state possesses a similar degree of charge separation to the ground state molecule. In contrast, the large Stokes' shift of the fluorescent emission, along with the marked solvent dependence of the emission wavelength suggests that the emitting species is a singlet state possessing a large degree of charge transfer character, which is formed rapidly from the initially formed, non-emissive excited state. Thus as the solvent polarity increases the charge transfer state becomes more stabilised and therefore emits to longer wavelength. This type of long wavelength fluorescence has been observed previously in systems where potential electron donating systems are conjugated with chromophores capable of accepting charge. Examples of such systems are *p*-*N*,*N*-dimethylaminobenzonitrile and various aminononaphthalene sulphonates (3, 4).

The effect of structural changes in the fluorescing molecules suggests that the charge transfer is most probably from the indole ring to the benzoyl chromophore. Thus in hexane the energies of the charge transfer states for compounds **1**, **3**, **4**, and **5**, as determined from the positions of the emission maxima, is in the order **4** < **5** < **1** < **3**. This order is that which would be expected for charge transfer from the indole ring to the benzoyl group since an electron donor is present in the indole ring of **5** and an electron acceptor is present in the benzoyl ring of **4**, and these substituents would stabilise the charge transfer state. Similarly, the presence of an electron donor in the benzoyl group in **3** would be expected to destabilise the charge transfer state and result in a shorter wavelength emission, as is observed. This rationalisation is also consistent with the failure of *N*-acetyl

[a]Absorption and emission spectra were recorded on solutions of ca. 10^{-5} *M* concentration. λ_{abs} is the wavelength of the lowest absorption maximum. λ_{em} is the wavelength of maximum emission. $\bar{\nu}_{abs} - \bar{\nu}_{em}$ is $(1/\lambda_{abs} - 1/\lambda_{em}$ expressed in cm^{-1}. $E_T(30)$ is the Kosower solvent polarity parameter (see text). Δf_n is:

$$\frac{\epsilon - 1}{2\epsilon + 1} - \frac{n^2 - 1}{2n^2 + 1}$$

where ϵ is the solvent dielectric constant and n is the solvent refractive index.

indole **2** and its cyclic analogue **6** to fluoresce as no charge transfer would be expected if the delocalised π-system of the benzoyl group is necessary to accept the charge.

The cyclic analogue of *N*-benzoyl indole, compound **7**, was found to be highly fluorescent and the Stokes' shift was much smaller and less solvent sensitive than for *N*-benzoyl indole, and more reminiscent of indole (5). Whether this is due to the rigidity of the molecule which prevents rotation of the benzoyl group and enforces interaction with the indole ring through overlap with the nitrogen "non-bonding" pair, or whether it is due to the conjugation of the benzene ring with the indole ring is unclear.

The quantum yields of fluorescent emission for compounds **1** and **3–5** (Table 2) indicate that the efficiency of emission drops with increasing solvent polarity. This effect can be ascribed to a lowering of the energy gap between the polar, solvent-stabilised charge transfer excited state and the relatively non-polar ground state. The energy gap law which dominates transitions between electronic states predicts that this should accelerate the rate of internal conversion to the ground state so that emission from the

[a]No emission was observed.
[b]The emission was too weak to be quantified.

charge transfer state competes less effectively. An alternative explanation is that as the charge transfer state is stabilised by increasingly polar solvents the energy gap between it and the initially formed S_1 state will be increased. This will slow down the rate of formation of the charge transfer state and the charge transfer process will become less competitive with intersystem crossing to the triplet state. Thus less of the charge transfer state will be formed and the quantum yield of fluorescence from it will be reduced. It should be noted that the triplet state appears to be non-polar (since the position of the phosphorescent emission is not solvent dependent) and that it cannot be populated from the charge transfer state because in all the solvents examined the latter is lower in energy than the former (for *N*-benzoyl indole the triplet energy is 68 kcal/mol from phosphorescence measurements at 77 K; the energy of the charge transfer state is 65 kcal/mol at room temperature in hexane and lower in more polar solvents).

For the fluorescent charge transfer states which have been observed previously for molecules capable of intramolecular electron transfer between conjugated groups, the effect of solvent interactions upon the energy, and hence the wavelength of emission have been classified into specific solvent interactions (e.g. hydrogen bonding etc.) and general solvent effects (i.e. the way in which the solvent reorganises to stabilise the charge separated state electrostatically) (6). For non-hydrogen bonding solvents, the stabilisation of the charge transfer state arising from the general type of solvent interaction can be related to the polarisability of the solvent expressed in terms of a function of the solvent dielectric and refractive index. The relationship, derived by Lippert *et al.* (6, 7), takes the form:

$$\bar{\nu}_{abs} - \bar{\nu}_{em} \simeq \frac{2}{hc}\left\{\frac{\epsilon - 1}{2\epsilon + 1} - \frac{n^2 - 1}{2n^2 + 1}\right\}\frac{(\mu^* - \mu)^2}{r^3} + \text{constant}$$

or

$$\bar{\nu}_{abs} - \bar{\nu}_{em} \simeq \frac{2}{hc}\Delta f_n \frac{(\mu^* - \mu)^2}{r^3} + \text{constant}$$

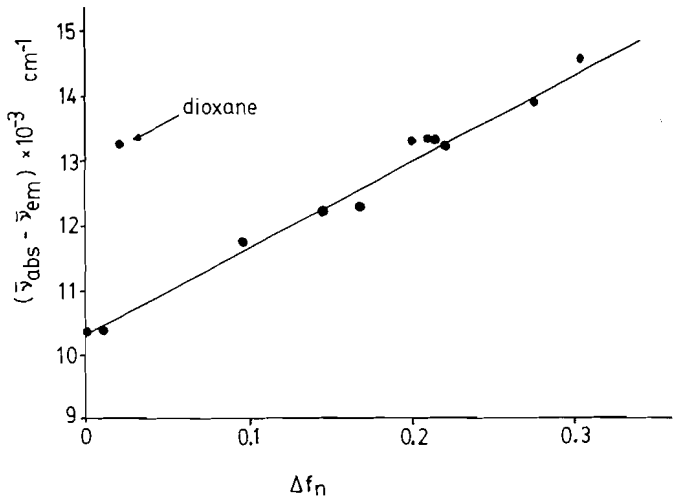

FIG. 3. Lippert plot for compound **1**.

where $\bar{\nu}_{abs}$ and $\bar{\nu}_{em}$ represent the absorption and emission energies in cm^{-1}, respectively, h is Plank's constant, c is the speed of light, ϵ is the solvent dielectric constant, n is the solvent refractive index, r is the Onsager radius (i.e. the radius of the sphere occupied by the molecule in the solvent), and μ and μ^* are the dipole moments of the ground state and emitting excited state, respectively.

By plotting the degree of solvent stabilisation of the excited state (i.e. $\bar{\nu}_{abs} - \bar{\nu}_{em}$) against the solvent polarisability function Δf_n it is possible to obtain a value of the change in dipole moment in going from the initially formed excited state to the charge transfer state if a value of the Onsager radius, r, can be estimated. Such a plot is shown for *N*-benzoyl indole in Fig. 3, and similar plots were obtained for the substituted derivatives **3** and **5**. The data point corresponding to dioxane is off the line; this has been observed (8) in other systems and it may arise because the conformation of the dioxane molecule may be altered when it is solvating the charge transfer excited state. From other solvent polarisability–fluorescence wavelength correlations it has been found (8) that the effective dielectric constant of dioxane is 6 or 7. Using a value of this order brings the dioxane point onto the line in Fig. 3. In addition, the chlorinated solvents examined did not fall on the line and are not included in Fig. 3. Presumably these solvents stabilise the charge transfer state by a specific solvent interaction. With the exception of dioxane, the data obtained in the 12 non-chlorinated, non-hydrogen bonding solvents examined give a good fit to the Lippert equation. This supports the assignment of a charge transfer state to the fluorescent emission of compounds **1** and **3–5**, and allows an estimate of the dipole moment change in going from the initially formed singlet excited state to the charge transfer state. The results are shown in Table 3; for reasonable values of r (i.e. 5.5 Å for **1** and 6.5 Å for **3** and **5**) the change in dipole moment is thus of the order of 15 D for **1** and 20 D for **3** and **5**. Since 4.8 D corresponds to the separation of a unit charge by one Å, these values of the change in dipole moment correspond to a movement of a unit charge across the molecules of 3 Å in **1** and 4 Å in **3** and **5**. These distances are of the order of the separation of the major chromophores in the *N*-benzoyl indoles and are consistent with the conclusion that the charge transfer occurs between the indole nucleus and the benzoyl ring.

For some systems exhibiting charge transfer fluorescence a correlation between the energy of the emitting state (as determined from the position of the fluorescence maximum)

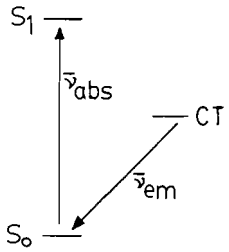

FIG. 4. Energy diagram showing relationship between the ground state (S_0), initially formed singlet excited state (S_1), and charge transfer state (CT) for *N*-benzoyl indoles **1**, **3**, **4**, and **5**. $\bar{\nu}_{abs}$ is the energy of the $S_0 \rightarrow S_1$ transition in cm^{-1}, and $\bar{\nu}_{em}$ is the energy of the CT $\rightarrow S_0$ transition in cm^{-1}.

and the empirical solvent polarity parameter $E_T(30)$ has been claimed (4). The $E_T(30)$ parameter for a solvent is obtained by measuring the position of the absorption maximum of the charge transfer transition of a pyridinium betaine dissolved in the solvent. In some cases the correlation is linear and in others the correlation takes the form of two intersecting lines, indicative of two emitting states, one charge transfer in nature and the other relatively non-polar (4). In principle, this situation could also apply to the *N*-benzoyl indole system described here. An energy-state diagram for compound **1** is shown in Fig. 4; in non-polar solvents the charge transfer state will be highly destabilised and it is possible that its energy could lie above that of the singlet state. As the solvent polarity is increased the charge transfer state will be lowered in energy and eventually will become much lower than that of the initially formed state. In this situation, the emission observed at low solvent polarity would be derived from the initially formed, non-polar singlet excited state and the wavelength of the emission maximum will be relatively insensitive to solvent polarity. At high polarity the emission will be derived from the charge transfer state and the wavelength of maximum intensity will change rapidly with solvent polarity. Thus a plot of the emission energy against solvent polarity should show two lines of different gradient. At low polarities the line would be near horizontal, while at high polarities a line of greater slope would be expected, corresponding to solvation of the charge transfer state. This has been observed for systems such as the *N*-phenylamino-naphthalene sulphonates (4).

A plot of the energy of the emitting state (derived from the wavelength of emission) for *N*-benzoyl indole against the solvent $E_T(30)$ value is shown in Fig. 5. It would appear that at low solvent polarities the position of the fluorescence is highly sensitive to the changing solvent polarity and that at higher polarity the position of the emission band is less dependent. This is the reverse of the trend which would be expected and would correspond to an unidentified non-polar low-lying electronic

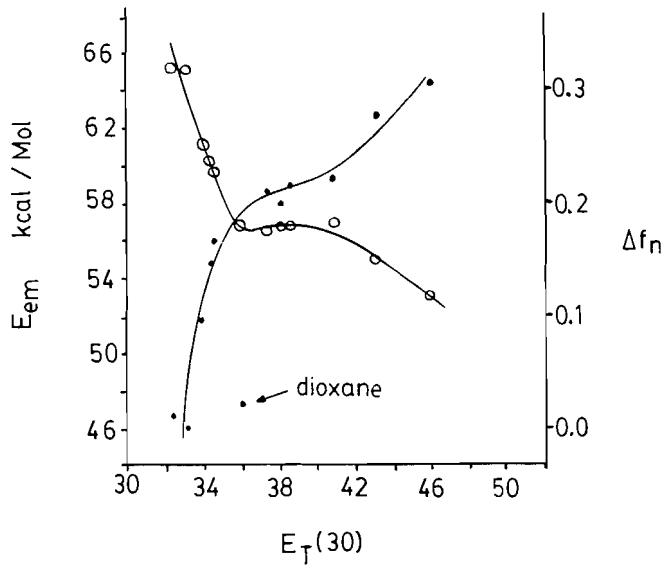

FIG. 5. Plots of energy of the $S_0 \rightarrow S_1$ transition in kcal/mol against the solvent $E_T(30)$ value (full circles), and solvent $E_T(30)$ value against the Lippert function Δf_n (open circles).

state of the *N*-benzoyl indole molecule. However, if the $E_T(30)$ parameter is plotted against the polarisability function Δf_n the curve obtained mirrors that for the $E_T(30)$ vs. emission energy plot for compound **1** (see Fig. 5). This would suggest that the curvature seen in the $E_T(30)$ vs. emission energy plot is an artifact of the $E_T(30)$ parameter and does not relate to a change in emitting state. These observations suggest that care should be exercised in correlating the $E_T(30)$ parameter with emission energy when large solvent polarity ranges and solvents of widely varying chemical structure are used.

Conclusions

The observations described are consistent with the existence of a fluorescent charge transfer state in *N*-benzoyl-substituted indoles. The pronounced solvent-induced shifts in the position of the fluorescence maximum suggest that *N*-benzoyl indole derivatives could be useful probes of environment.

Experimental

The *N*-benzoyl indoles **1**, **3–5** were prepared by treatment of indole or 5-methoxy indole with benzoyl chloride, or its *para*-methoxy or *para*-nitro derivatives using the two phase procedure described by Illi (9). *N*-Acetyl indole, **2**, was prepared similarly from indole and acetyl chloride. The cyclic analogues of *N*-acetyl indole and *N*-benzoyl indole, compounds **6** and **7**, were prepared by the literature procedure (10) which involves intramolecular Wittig cyclisation of the phosphonium salts of *ortho*-succinimidylbenzyl bromide and *ortho*-phthalimidobenzyl bromide, respectively.

Absorption spectra were recorded on a Hewlett Packard 8450 A diode array spectrophotometer. Fluorescence spectra were recorded on a Perkin-Elmer 650-40 fluorescence spectrometer and quantum yields of fluorescence were measured on this instrument relative to indole. Phosphorescence spectra were recorded on a Perkin-Elmer MPF-4 emission spectrometer.

Kinetics of the reaction of *p*-dinitrobenzene with basic hydrogen peroxide

RAYMOND A. HELLER AND RICHARD WEILER[1]
Department of Chemistry, Wilfrid Laurier University, Waterloo, Ont., Canada N2L 3C5

Received April 28, 1986

RAYMOND A. HELLER and RICHARD WEILER. Can. J. Chem. **65**, 251 (1987).

Kinetic studies of the reaction of *p*-dinitrobenzene with H_2O_2 and NaOH in 10%, 30%, and 50% aqueous dioxane have been carried out at 30.0°C. The reaction involves the formation of a reasonably stable intermediate which absorbs strongly in the visible region, with the rate of formation being about 18 times faster than the rate of conversion to final product which is *p*-nitrophenol. Proton and ^{13}C nmr spectra of the kinetic solution provide strong evidence that the intermediate is *p*-nitrophenyl hydroperoxide, apparently the first time that a true aryl peroxide species has been identified.

RAYMOND A. HELLER et RICHARD WEILER. Can. J. Chem. **65**, 251 (1987).

Opérant à 30,0°C et dans des solutions aqueuses de dioxanne à 10, 30 et 50%, on a mesuré la cinétique de la réaction du *p*-dinitrobenzène avec le H_2O_2 et le NaOH. La réaction implique la formation d'un intermédiaire relativement stable qui absorbe fortement dans la région du visible, avec une vitesse de formation qui est environ 18 fois plus rapide que sa vitesse de transformation en *p*-nitrophénol qui est le produit final. Les spectres rmn du ^1H et du ^{13}C des solutions fournissent de fortes indications que l'intermédiaire est l'hydroperoxyde de *p*-nitrophényle; apparemment, il s'agit de la première fois qu'une véritable espèce peroxyde d'aryle a pu être identifiée.

In comparison with other aromatic processes, nucleophilic displacements of aromatic nitro groups have not been investigated extensively, but the last few years have seen the publication of theoretical treatments of the reaction mechanism (1), a discussion of the synthetic utility of such reactions (2), and various related studies (3).

We recently published a paper (4) describing the results of our work on the reaction of *o*-dinitrobenzene (*o*DNB) with NaOH and H_2O_2 in 50% aqueous dioxane. In brief, we found that the presence of hydrogen peroxide results in accelerated, clean production of *o*-nitrophenol (*o*NP) and that absorbance changes corresponding to two distinct reaction steps can be discerned in the visible spectrum. Our kinetic analysis led to the conclusion that the rate constants for the two steps were of similar magnitude and that both were dependent on the concentration of hydrogen peroxide. We also suggested that the intermediate was the radical anion formed by the transfer of an electron from hydrogen peroxide anion to *o*DNB.

In this paper we report the results of our parallel investigations on the related compound, *p*-dinitrobenzene (*p*DNB), as well as our new conclusions concerning the nature of the intermediate in reactions of this kind.

Experimental

With minor modifications, the experimental methods used in this work were the same as those previously described (4). Commercial *p*DNB, mp 172–174°C uncorrected; lit. (5) mp 174°C) was used as supplied. The purity of the *p*DNB could be satisfactorily confirmed by diluting an accurately measured portion of *p*DNB stock solution to a specific volume with aqueous NaOH, heating the mixture overnight in a sealed tube, and then measuring the absorbance due to phenolate product (λ_{max} = 405 nm; ϵ = 20500 M^{-1} cm^{-1}).

For a typical kinetic run (50% v/v dioxane in water) 20 mL of redistilled 1,4-dioxane, 5 mL of aqueous H_2O_2 stock solution, and about 19 mL of NaOH stock solution were placed in a 50 mL volumetric flask. Both this flask and a separate container of *p*DNB–dioxane stock solution were brought to temperature equilibrium in a 30.0°C bath. To initiate the reaction, 5 mL of *p*DNB solution were added to the 50 mL volumetric flask which was quickly made up to volume by the dropwise addition of more NaOH solution. This sequence of addition minimizes the temperature increase (heat of mixing) which affected our *o*DNB experiments. Absorbance measurements and scans were done on a Beckman DU-7 spectrophotometer with the cell compartment thermostatted at 30.0°C.

The esr and nmr experiments were carried out at ambient temperature in the same (or appropriately deuterated) solvent system, but with reactant concentrations much higher than those used in the kinetic mixtures. The esr spectra were run on a Bruker ER100D epr spectrometer operating in the X/band mode. Proton and ^{13}C nmr spectra were recorded on Bruker WP-80, AM-250, and AM-500 spectrometers.

Results

In the absence of H_2O_2, both *o*DNB and *p*DNB slowly react with NaOH to form the corresponding phenol, the reaction likely occurring by straightforward nucleophilic displacement of nitrite ion. The kinetics of the *para* reaction in aqueous dioxane were examined some years ago by Tommila and Murto (6) who found that their experimental data did not conform to either first- or second-order rate behaviour.

In our kinetic study, we have determined that H_2O_2 triggers an accelerated *p*DNB-to-*p*NP reaction involving a reasonably stable intermediate which is spectrophotometrically detectable in the visible region. Thus, the *para* isomer behaves much like the *ortho* in the presence of hydrogen peroxide (reaction [1])

$$[1]\quad \mathrm{DNB} + \mathrm{HO_2^-} \xrightarrow{k_1} \text{intermediate} \xrightarrow{k_2} \mathrm{NP}$$

but noteworthy differences are apparent when a detailed comparison is made.

Figure 1 shows a set of spectra taken at various times during the reaction of *p*DNB with NaOH–H_2O_2 in 50% dioxane. The scans illustrate the key spectral characteristics common to the *ortho* and *para* reactions; (*a*) gradual shift of the λ_{max} from lower wavelength to the position of maximum nitrophenolate absorption; (*b*) early increase of absorbance in the 340 nm region followed by a decrease. These observations argue for the involvement of a long-lived intermediate in the reaction. The major difference between the *ortho* and *para* processes is the clear development of an isosbestic point (374 nm) in the *para* case. This feature, indicating that only two species are present during the latter stage of the reaction (7), allows the k_2 step to be analyzed independently. Although the isosbestic point could

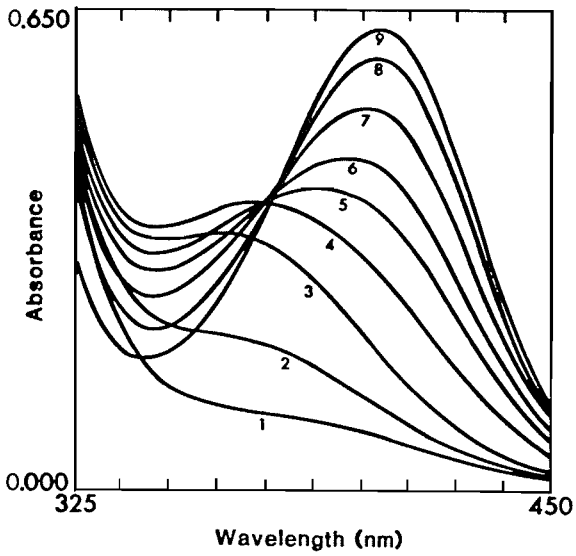

FIG. 1. Conversion of *p*-dinitrobenzene to *p*-nitrophenolate anion. Spectral changes during the course of the reaction (30.0°C; 50% v/v dioxane in water; $[p\text{DNB}]_0 = 3.0 \times 10^{-5}$ *M*; $[\text{NaOH}]_0 = 0.378$ *M*; $[H_2O_2]_0 = 0.230$ *M*). Scans started at: *1*, 2 min; *2*, 7 min; *3*, 22 min; *4*, 80 min; *5*, 123 min; *6*, 170 min; *7*, 260 min; *8*, 400 min; *9*, 1200 min.

reflect a reaction scheme as shown in [2] with the equilibrium shifted overwhelmingly toward the dead-end intermediate, we believe it is more reasonably interpreted in the context of sequence [1] which conforms to traditional models of aromatic

[2] $\text{DNB} + HO_2^- \longrightarrow \text{NP}$

$\downarrow \uparrow$

Intermediate

substitution. Working from this assumption, we anticipated that the kinetic elucidation of the *para* reaction would be more straightforward than the time-consuming computer matching which we were forced to adopt for the rationalization of our *ortho* data.

Instead, we discovered that the k_2 values (Table 1) were not cleanly reproducible and neither were they dependent on $[H_2O_2]$ contrary to the conclusion we reached in our *o*DNB studies. The supposed relationship between k_2 and $[H_2O_2]$ established in that earlier work can only be ascribed to unsuspected shortcomings of the computer-model methodology.

The rather high degree of uncertainty in the k_2 values prompted a brief examination of the secondary factors which might affect the reaction pathway. We found that although the reaction proceeded to >95% formation of *p*NP in quartz uv cells, the yield in Pyrex vessels was as much as 25% lower as measured by the infinity absorbance. Not only the yield, but also the apparent reaction rate was detectably different in Pyrex containers. We did not investigate this phenomenon in detail, but we have reason to suspect that both the composition and the relative wall area of the reaction vessel is important in this regard. For example, in Pyrex nmr tubes appreciable amounts of secondary product(s) are formed, giving rise to permanent peaks which are well upfield from the aromatic region. Some of them are partly obscured by the water signal.[2] It therefore

[2]Speculating that some fraction of the intermediate was undergoing additional nucleophilic displacement and ring opening as a result of surface catalysis, we subjected 1,4-benzoquinone and 1,4-hydroquinone to our reaction conditions, but these experiments did not reproduce the extraneous peaks obtained in the kinetic runs.

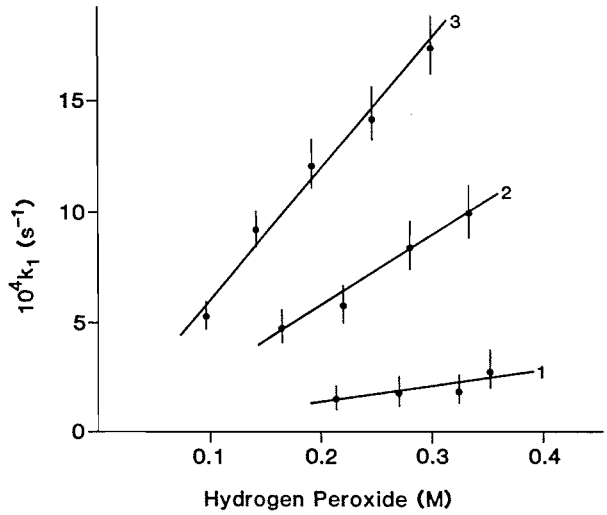

FIG. 2. Variation of k_1 with H_2O_2 concentration (30.0°C; [NaOH] = 0.35 *M*): *1*, 10% dioxane, $r = 0.857$; *2*, 30% dioxane, $r = 0.989$; *3*, 50% dioxane, $r = 0.993$.

TABLE 1. Values of k_2 ([NaOH] = 0.35 *M*, 30.0°C)

% Dioxane	$10^5 \times k_2$ (s^{-1})
10	11.75 ± 4.48
30	9.87 ± 2.47
50	6.78 ± 1.40

appears that our reaction is subject to surface effects for which peroxide decomposition reactions are well-known (8) and we ascribe our inconsistent results to such effects. It is likely that the *o*DNB reaction which we studied previously (4) behaves similarly although we were not aware of it at the time.

The absorbance changes in the 340 nm region allow us to determine t_{max}, the time at which the concentration of the intermediate reaches a maximum. In a well-behaved two-step kinetic system, t_{max} is directly related to the numerical values of k_1 and k_2 (9). Because of the uncertainty in our k_2 values, the evaluation of k_1 via t_{max} is subject to some error, but nevertheless the relationship between $[H_2O_2]$ and k_1 is apparently linear in aqueous solutions containing 10%, 30%, and 50% dioxane, as shown in Fig. 2. The larger k_1 values for the reactions in dioxane-rich media agree with the common observation that nucleophilic processes involving charge dispersal in the transition state are faster in solvents of lower polarity, presumably because of the greater, but relatively unsatisfied solvation requirements of the original ion in comparison with those of the transition state (10).

Our kinetic results therefore show that, within the framework of reaction [1], k_1 is considerably greater than k_2 for the *para* isomer whereas our earlier work (4) established that for the *ortho* compound, k_1 and k_2 are of comparable magnitude. Experimental values for the pseudo first-order rate constants under equivalent conditions are shown in Table 2.

Discussion

Kinetic results

A comparison of our k_1 values with those for similar aromatic substitutions is of some interest. Unfortunately, although there is an abundance of such data available for nucleophilic attack on 2,4-dinitro- and 2,4,6-trinitroaromatics, very little work has

[a]Approximate; from ref. 4.

been done on simpler systems such as ours. In particular, the vast majority of previous studies involve displacement (or Meisenheimer addition) at a position adjacent to a nitro group without a comparative examination of attack at a position free of *ortho* interference.

One directly analogous study is that of Tommila and Murto (6) who found that $k_{para}/k_{ortho} \sim 10$ for reaction [3]

[3] $DNB + RO^- \rightarrow (NO_2)C_6H_4OR + NO_2^-$

[4] $DNB + HO^- \rightarrow (NO_2)C_6H_4OH + NO_2^-$

(R = Me, Et) in aqueous alcohol while the ratios for [4] under the same solvent conditions were in the range 1.6–2.7. They also found that reaction [4] in pure water gave $k_{para}/k_{ortho} \sim 0.5$. Our k_1 ratio for attack by HO_2^- is 2.7, similar to their findings for HO^- attack in less polar solvent mixtures. This agreement is not surprising in light of the view that both HO^- and HO_2^- are "sterically unhindered" nucleophiles (11).

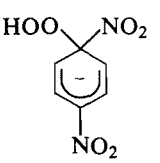
It is also interesting to compare our results with roughly equivalent electrophilic processes. Keeping in mind the "unhindered" nature of the HOO— moiety, one can argue that the σ complexes formed in our reactions have a reasonable *steric* resemblance to the *ortho* and *para* intermediates generated in the nitration of nitrobenzene and therefore their relative rates of formation might be similar. From the partial rate factors for nitrobenzene nitration (68–84% H_2SO_4; temperature 0–40°C) it is possible to calculate $k_{para}/k_{ortho} = 0.11$ (12*a*). A similar treatment of toluene nitration data (various solvents; temperature 0–40°C) gives $k_{para}/k_{ortho} = 1.4$ (12*b*) which is close to our result.

The "α-effect" phenomenon continues to arouse the curiosity of chemists even though its underlying origins remain obscure (13*a*) and its evaluation remains controversial (13*b*). Our data allow the α-effect, $(k_{HO_2^-}/k_{HO^-})$, to be estimated for attack on *p*DNB. Given the pK_a of H_2O_2 (14) and the pH of our reaction solutions, it is not unreasonable to assign $[HO_2^-]$ as being equal to the titrated H_2O_2 concentration. Then the slope (5.78×10^{-3}) of the 50% dioxane plot in Fig. 2 may be taken as $k_{HO_2^-}$, the second order rate constant for the reaction of HO_2^- with *p*DNB. From ref. 6, interpolation yields a value, $k_{HO^-} = 4.0 \times 10^{-5}\ M^{-1}\ s^{-1}$ for the same conditions, leading to an α-effect ratio of 145. In comparison, Behrman *et al.* report a ratio of 200 for displacement of chloride from 2,4-dinitrochlorobenzene (15) although $k_{HO_2^-}/k_{HO^-}$ ratios as large as 10 000 have been observed for attack on carbocation and carbonyl centers (13*a*) which are, like the benzene substrates, sp^2 hybridized.

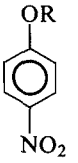
Structure of the intermediate

Our previous work (4) in this field led us to suggest that the intermediate in the *o*DNB–H_2O_2 reaction was a radical anion formed by electron transfer from HO_2^- to the aromatic electrophile. There is ample precedent for the formation of nitroaromatic radical anions in strong base (16), but an examination of our kinetic solutions by esr spectroscopy yields no evidence for the presence of long-lived organic radicals. In light of this, a radical anion must be ruled out as the intermediate which absorbs so noticeably in the 340–450 nm region during the first few hours of a kinetic run.

There is little published information dealing with the intermediates arising from reaction between peroxidic anions and nitroaromatic compounds. Some reports (11, 15, 17) touch on the empirically observed visible spectra of the intermediates formed when peroxide anions are reacted with 2,4-dinitrohalobenzenes; in one case (17) the intermediate is referred to as "2,4-dinitrophenyl peroxide anion" but no definitive structural evidence is put forward. Also on the basis of visible spectroscopy, Meisenheimer complexes are reported to result from the reaction of substituted 2,4,6-trinitroaromatics with alkyl peroxide anions (18). Parallel reasoning suggests that the Meisenheimer structure **1** and the aryl hydroperoxide **2** are sequentially involved in our reaction system, but which of these two is the long-lived intermediate?



1



2*a* R = OH
2*b* R = O$^-$

Over the years, many different Meisenheimer complexes (mostly di- and trinitro-) have been characterized in detail (19) and there can be no doubt as to their existence as a class. In contrast, aryl hydroperoxides are so notoriously unstable that no example of the class has ever been identified. Although there are many literature references to "aryl hydroperoxides" and "aryl peroxides", these invariably prove to be erroneously classified aralkyl compounds, usually derivatives of cumene, in which the peroxidic oxygens are bonded to an alkyl rather than an aryl carbon atom.

Mononitro–Meisenheimer complexes are not common but the proton nmr characteristics of a few such structures have been studied by Ohsawa (20). For *para*-nitro systems, Ohsawa reports that there is little shift of the ring proton signals when a mononitro–Meisenheimer complex is formed; for example, if methoxide is reacted with *p*-nitroaniline, the ring hydrogens appear at δ 6.56 and 7.97, a shift of less than 0.15 ppm, and the reaction of NH_2^- with the same substrate moves the signals only about 0.5 ppm to δ 6.02, 7.50. Such findings are in contrast to those observed for dinitro–Meisenheimer complexes which typically show a large upfield shift of about 2 or 3 ppm to δ 4–5 for protons *ortho* or *para* to the point of anion attack (19*a*, 21).

Our concentrated kinetic solutions yielded the proton nmr spectra shown as **2***a*–**2***d* in Fig. 3. The spectra taken early in the time sequence show considerable line broadening which may be associated with precipitation which occurs when the necessarily concentrated solutions are mixed to begin the runs for nmr studies. However, we have independently determined that a mixture of NaOD and *p*DNB displays some broadening of the *p*DNB peak even when no precipitate is present, suggesting chemical exchange involving a charge transfer complex. Another reasonable explanation[3] is the presence of very small quantities of dinitrobenzene radical anions and therefore, despite the

[3]We thank one of the referees for alerting us to this point.

negative esr results, we cannot totally eliminate the possibility that the radical anion is involved as an extremely short-lived intermediate in the first step of the reaction (16*b*). The line broadening develops as soon as the reactants are mixed together but, at the concentrations used in our regular kinetic runs, we detect no corresponding absorbance changes in the uv/visible regions. Therefore this phenomenon is not a direct factor in the analysis of our results.

Aside from the broadening, our spectra clearly show temporary peaks (AA′BB′ quartet; δ 7.06, 8.01) during the time period corresponding to uv/visible absorption by the intermediate in our kinetic runs. These temporary peaks are distinctly different

TABLE 4. Carbon-13 nmr data

Compound	Chemical shift (ppm) C-1	C-2	C-3	C-4
	161.2	116.7	125.1	141.2
p-Nitroanisole, calcd (23)	165.7	115.0	124.7	140.8
Intermediate, obsd (this work)	172.8	113.5	127.3	141.0

from the *p*-nitrophenolate product signals at δ 6.30 and 7.84. They are moved upfield by 1.30 and 0.35 ppm from the parent *p*DNB signal at δ 8.36, a difference which seems rather large compared to the small shifts observed by Ohsawa. In fact, as shown in Table 3, the positions of the intermediate's peaks agree rather better with those for simple aromatic systems having an oxygen or nitrogen substituent *para* to the nitro group. This observation seems to favour the aryl hydroperoxide **2**, as the structure of the intermediate, but the Meisenheimer complex **1** cannot be rigorously excluded on this basis.

The question is cleanly resolved by ^{13}C nmr spectroscopy. Structure **1** has an sp^3 carbon but as shown in Table 4, our intermediate displays only aromatic carbons, similar to, but not identical with the signals given by *p*-nitrophenolate anion. Furthermore, the peak positions observed for the intermediate correspond closely to those calculated (23) for *p*-nitroanisole and for unionized *p*-nitrophenol (which is totally converted to *p*-nitrophenolate under our reaction conditions). It is therefore logical to conclude that the intermediate has the aromatic structure *p*-NO_2—C_6H_4—OR, specifically, *p*-nitrophenyl hydroperoxide **2**. The high pH of the reaction medium coupled with the probable pK_a (14) of an aryl hydroperoxide suggest that the intermediate is actually in the form of the anion **2***b*.

In summary, the results presented here constitute the first firm evidence for the existence of an aryl hydroperoxide species and the overall reaction is best described by sequence [3]:

$$[3]\quad \mathrm{DNB} + \mathrm{HO_2^-} \xrightarrow{k_1} \mathbf{1} \xrightarrow[\text{fast}]{\text{very}} \mathbf{2a/2b} \xrightarrow{k_2} \mathrm{NP}$$

We are pursuing similar work on related aromatic systems.

The crystal and molecular structures of the dopaminergic ergoline derivative pergolide have been determined both as the free base and as the mesylate salt. Despite differences in protonation at the nitrogen atom, the two structures are extremely similar in all aspects. Stereochemical comparisons are made with bromocriptine, and possible dopaminergic pharmacophores in ergolines are discussed.

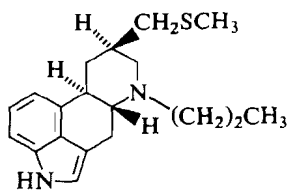
LILIAN Y. Y. MA, NORMAN CAMERMAN, JOHN K. SWARTZENDRUBER, NOEL D. JONES et ARTHUR CAMERMAN. Can. J. Chem. **65**, 256 (1987).

On a déterminé les structures cristallines et moléculaires, tant à l'état de base libre que sous la forme d'un sel mésylate, de la pergolide, un dérivé dopaminergique de l'ergoline. En dépit de différences dans la protonation de l'atome d'azote, les deux structures sont extrêmement semblables. Des comparaisons stéréochimiques ont été faites avec la bromocriptine et on discute des diverses possibilités de pharmacophores dopaminergiques dans les ergolines.

[Traduit par la revue]

Introduction

Physiological properties of ergots have been recognized since the Middle Ages when the fungus *Claviceps purpurea*, found on rye grain, was identified as the causative agent of St. Anthony's fire. More recently ergot alkaloids have been shown to exhibit dopaminergic, serotonergic, and α-adrenergic properties. As part of a program to separate these activities, the semisynthetic ergot, pergolide, (8β)-8-[(methylthio)methyl]-6-propylergoline (**1**), was prepared. Pergolide shows profound dopamine



1

agonist activity (1) and is currently being evaluated clinically for the treatment of Parkinson's Syndrome (2–4), as well as for a number of hyperprolactinemia characterized diseases (5–7). Its antiparkinson efficacy, like that of the other ergolines, can be attributed to the postsynaptic stimulation of central dopaminergic receptors (8, 9).

Attempts to delineate the dopaminergic pharmacophore of the ergot derivatives by stereochemical comparisons with dopamine and other dopamine receptor agonists, notably apomorphine, have resulted in postulations of imino-phenylethylamine (10, 11), pyrrolethylamine (12), and indolethylamine (13) as the dopaminomimetic entity. Among the criteria considered in some of the modelling attempts has been the direction of the amino nitrogen lone-pair electrons. Crystal structure determinations of protonated (10) and unprotonated[3] bromocriptine revealed opposite nitrogen lone-pair directions in the two cases, showing that inter- (and intra-) molecular attractions, rather than inherent stability, are determinants of this feature. Here we report the results of crystal structure determinations of pergolide as the free base and as the mesylate salt to further investigate the effects of molecular contacts on nitrogen lone-pair orientation and to provide more data for delineation of the stereochemical features of the ergoline type of dopamine agonists.

TABLE 1. Crystal data

Parameter	Pergolide	Pergolide mesylate
Formula	$C_{19}H_{26}N_2S$	$C_{19}H_{27}N_2S \cdot CH_3O_3S$

acetate, isolating the ethyl acetate layer, and allowing the solvent to evaporate slowly in a refrigerator. Crystal data are given in Table 1. A thin plate, 0.33 × 0.20 × 0.03 mm, was mounted along a and intensities of 1647 independent X-ray diffraction maxima were measured on an automated four circle diffractometer by using Ni-filtered CuKα (λ = 1.54178 Å) radiation with the θ–2θ scan technique ($2\theta_{max}$ = 125°, scan rate = 1°/min). Empirical absorption corrections were applied by measuring variation of intensities of 2 reflections (200 and 400 at 2θ = 25.33° and 52.02° respectively) with φ at χ = 90°. After data reduction 887 reflections were considered as observed ($I > 3\sigma(I)$) and were used in the structure refinement.

The structure was solved using the direct phasing methods program MULTAN80 (14), and was refined by full matrix least-squares techniques on F with weights = $1/(\sigma(F))^2$. Hydrogen atoms (located on difference Fourier plots) were assigned fixed positional and thermal parameters (B_{iso} = 6.0 Å^2) and were not refined. Non-hydrogen atoms were refined anisotropically. The absolute configuration was determined by Hamilton's test (15) using anomalous scattering from the S, N, and C atoms (16). Final values for R, Rw, and S for the presently determined enantiomer were 0.0737, 0.0778, and 1.8133 as compared to corresponding values of 0.0740, 0.0783, and 1.8251 for the other enantiomer.

B. Pergolide mesylate

Prismatic crystals were obtained from absolute methanol. Crystal data are given in Table 1. Intensities of 1547 unique reflections, to 2θ = 116°, were measured on an automated four-circle diffractometer by using monochromatic copper radiation (θ/2θ scan). After the usual Lorentz and polarization corrections, the data were put on an absolute scale with a calculated overall temperature factor, B = 3.71 Å^2. A total of 973 reflections had $I > 2.5\sigma(I)$ and were included in the refinement procedure. The structure was determined using the SOLV routine of the SHELXTL program (17) and was refined by least squares to an R value of 0.0497 (Rw = 0.0504). The final refinement included anisotropic temperature factors for all atoms except hydrogen, the latter being included with isotropic temperature factors at calculated positions. The weighting scheme was $w = 1/[\sigma^2(F) + G|F|^2]$ where G refined to 0.047. The absolute configuration of the molecule was determined by the anomalous dispersion technique, using the procedure of Rogers (18); the measure of fit parameter was 0.95 (σ = 0.06). The largest residual in the final difference electron density map was 0.4 ē/Å^3.

Table 2 lists the atomic fractional coordinates and equivalent isotropic thermal parameters for the heavy atoms for the two crystal structures. The anisotropic thermal parameters, hydrogen atomic positional parameters, and the observed and calculated structure factors have been deposited and are available.[4]

Results and discussion

Figure 1 shows the atomic numbering scheme and the bond lengths and angles; because the overall conformations and molecular parameters of pergolide and the mesylate salt are so similar (see below), the values shown are the averages of the two structures. Tables of bond lengths and angles for each compound have been deposited.[4] As expected, the bond lengths involving N6 are longer (by 0.02–0.04 Å) in the protonated form of pergolide but, because N6 is involved in intermolecular interactions in both structures, bond angles around N6 have (similar) tetrahedral values. The other bond lengths and angles exhibit normal values.

Figure 2 is a stereoscopic superposition of the two pergolide structures. The two structure determinations have each independently confirmed the absolute configurations at the three asymmetric centers, C5, C8, and C10. As can be seen from the figure, unprotonated pergolide and the pergolide cation of the

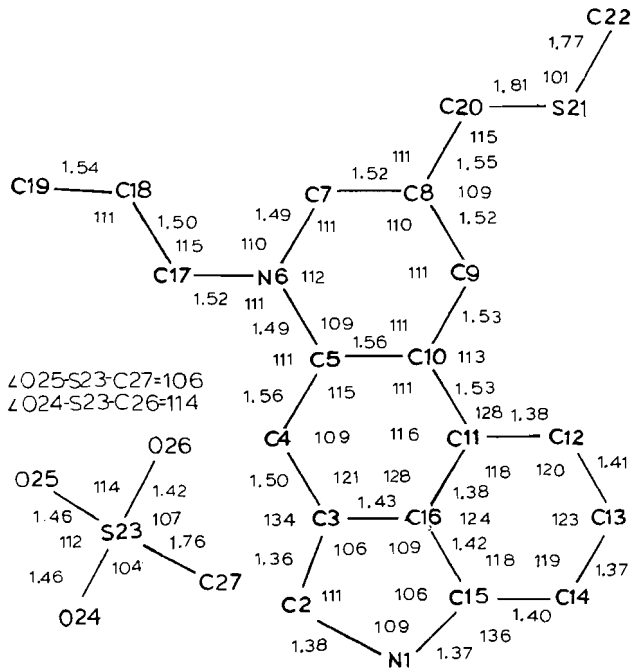

FIG. 1. Averaged bond lengths and angles in pergolide and pergolide mesylate. Standard deviations are less than 0.01 Å and 1°.

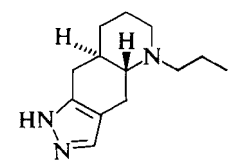
mesylate salt have virtually identical conformations, including the configuration at N6. This arises as a consequence of the molecular packing schemes: although N6 of the pergolide cation is an H-bond donor (to an oxygen of the mesylate ion) and N6 of unprotonated pergolide is an H-bond acceptor (from N1 of another molecule), both interactions occur on the same side of the pergolide moiety in the two crystal structures, thus giving rise to identical conformations. This is in contrast to the situation in the crystal structures of bromocriptine mesylate (10) and unprotonated bromocriptine: the hydrogen-bonding scheme in the former is similar to pergolide mesylate, resulting in a similar configuration at N6, but in the latter N6 is an H-bond acceptor in an intramolecular interaction from the opposite direction. This results in the opposite nitrogen lone-pair orientation at N6 (Fig. 3) in the unprotonated bromocriptine structure. Taken together, these results strongly suggest that the direction of the nitrogen atom lone pair of electrons in ergoline derivatives is variable and can be influenced by the side of approach of an interacting species, e.g. a hydrogen-bonding or charged side chain of a receptor.

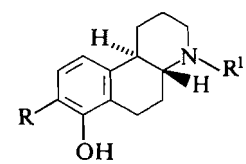
As in the bromocriptine structures, the indole nucleus in pergolide is planar, and the adjoining ring adopts a half-chair conformation with C5 lying out of the plane of the other atoms. In contrast to bromocriptine, in which the C9—C10 double bond causes the heterocyclic six-membered ring to be skewed, the saturated character of the ring in pergolide results in a chair conformation.

Details of the molecular packing are shown in Fig. 4. The hydrogen bonding in unprotonated pergolide has dimensions N1...N6 = 2.95 Å, H1...N6 = 2.03 Å, and the angle N1—H1...N6 = 163°. There are two intermolecular interactions with the mesylate ion in the pergolide salt structure, involving two different molecules; the parameters are N6...O24 = 2.72 Å, H6...O24 = 1.79 Å, and the N6—H6...O24 angle is 164°, and N1...O25 = 2.85 Å, H1...O25 = 1.90 Å, and the N1—H1...O25 angle is 170°.

The delineation of the dopamine pharmacophore in ergolines has been a subject of considerable interest. Syntheses of dopaminergic ergoline analogues (**2**) that lack the phenyl A-ring of the ergot compounds have resulted in the proposal (19, 20) that the pyrrolethylamine moiety (rather than the dopamine-like phenylethylamine) is the ergoline dopaminomimetic entity. However, as noted by Camerman and Camerman (21), if the hydrogen-bonding NH of the pyrrole (analogous to the *meta* OH of dopamine) rather than the phenyl or pyrrole ring per se is important for dopaminergic activity, then these syntheses do not differentiate between models. The primary function of the phenyl or pyrrole ring may be to position the NH properly, and neither ring may be necessary per se. If so, it would be



2



3

inaccurate to label either the phenylethylamine or the pyrrolethylamine as the ergoline dopamine pharmacophore. The structure determination of a dopaminergic ergoline analogue that lacks a pyrrole ring (22) (**3**) and subsequent stereochemical

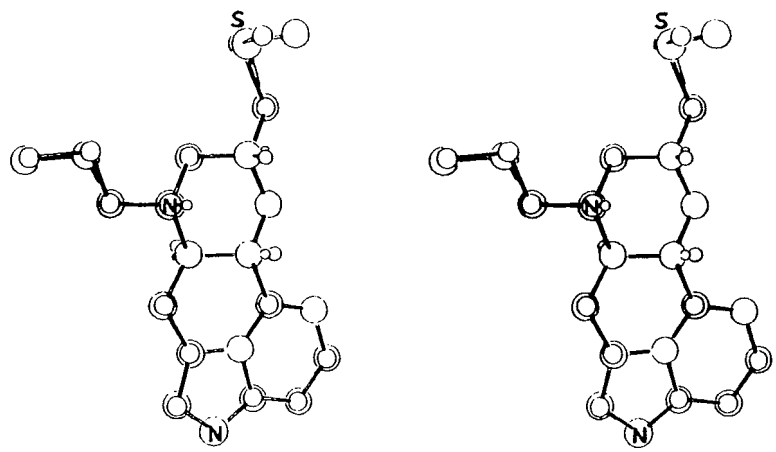


FIG. 2. Stereoscopic superposition of the structures of pergolide (large circles) and the pergolide ion of the mesylate (small circles).

comparisons would be of interest in addressing the pharmacophore question. Two such structures have recently been reported (23, 24); in the latter case, pharmacological structure–activity relationships of resolved enantiomers have indicated comparable activity at post-synaptic DA receptors for both enantiomers (but activity of unexplainably higher magnitude at DA autoreceptors for the absolute configuration opposite to that pictured in **3**).

Structural and vibrational studies of 1,1,3,3-tetracyanopropane and 2,2,4,4,6-pentacyanocyclohexenamine

R. A. BELL, B. E. BROWN, M. DUARTE, H. E. HOWARD-LOCK, AND C. J. L. LOCK[1]

Department of Chemistry and the Institute for Materials Research, McMaster University, Hamilton, Ont., Canada L8S 4M1

Received May 5, 1986

R. A. BELL, B. E. BROWN, M. DUARTE, H. E. HOWARD-LOCK, and C. J. L. LOCK. Can. J. Chem. **65**, 261 (1987).

1,1,3,3-Tetracyanopropane, **1**, was prepared in low yields by a literature method with 2,2,4,4,6-pentacyanocyclohexenamine, **2**, as a major by-product. The products were examined by X-ray crystallography. **1** has an orthorhombic space group, *Pbcn* (No. 60) with cell dimensions, $a = 7.158(2)$, $b = 10.510(3)$, $c = 9.733(2)$ Å and has four formula units in the unit cell. **2** has a monoclinic cell, $P2_1/c$ (No. 14) with cell dimensions $a = 14.368(3)$, $b = 6.626(1)$, $c = 12.300(2)$ Å, $\beta = 115.60(1)°$ and has 4 formula units in the unit cell. Data were collected with use of MoKα radiation and a Nicolet P3 diffractometer. The crystal structures were determined by standard methods and refined to $R_w = 0.037$ (**1**) and $R_w = 0.040$ (**2**) on the basis of 782 and 2108 unique reflections. Bond lengths and angles in the two compounds are normal. **2** has what has been considered to be the less likely tautomeric structure. Both compounds were examined by ^1H, ^{13}C nmr, vibrational spectroscopy, and mass spectroscopy. For **2** there was no evidence of the alternative tautomeric structure. New methods were developed for the preparation of both compounds and the mechanism of the original reaction rationalized.

R. A. BELL, B. E. BROWN, M. DUARTE, H. E. HOWARD-LOCK et C. J. L. LOCK. Can. J. Chem. **65**, 261 (1987).

Faisant appel à une méthode décrite dans la littérature, on a préparé le tétracyano-1,1,3,3 propane, **1**, avec un faible rendement; on a obtenu la pentacyano-2,2,4,4,6 cyclohexylamine, **2**, comme sous-produit principal. On a étudié les produits par diffraction des rayons-X. Le composé **1** cristallise dans le groupe d'espace orthorhombique *Pbcn* (No. 60) avec $a = 7,158(2)$, $b = 10,510(3)$ et $c = 9,733(2)$ Å et il compte quatre unités par cellule de base. Le composé **2** possède une cellule monoclinique $P2_1/c$ (No. 14) avec $a = 14,368(3)$, $b = 6,626(1)$ et $c = 12,300(2)$ Å et $\beta = 115,60(1)°$ et il comporte quatre unités dans la cellule de base. On a obtenu les données à l'aide d'une radiation MoKα et un diffractomètre Nicolet P3. On a déterminé les structures par des méthodes standards et on les a affiné jusqu'à des valeurs respectives de R_w de 0,037 (**1**) et 0,040 (**2**) sur la base de 782 et 2108 réflexions uniques. Les longueurs de liaisons observées dans les deux composés sont normales. Le composé **2** possède ce qui est considéré comme la structure tautomère la moins probable. On a étudié les deux composés par rmn du ^1H et du ^{13}C ainsi que par spectroscopies vibrationnelles et de masse. Dans le cas du composé **2**, il n'y a aucune indication qu'une autre structure tautomère puisse exister. On a développé de nouvelles méthodes pour préparer les deux composés et on a proposé un mécanisme qui rationalise la réaction originale.

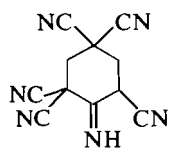
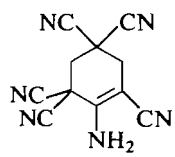
Introduction

Alkyl cyanides are good solvents for many transition metal complexes (1), often because they act as ligands (2). Recently, we have examined the complex $Pt(CH_3CN)_2Cl_2$ (3). Alkyl groups substituted by more than one cyanide group have the potential of binding more than one metal ion. To this end we have been interested in the preparation of 1,1,3,3-tetracyanopropane. The synthesis of 1,1,3,3-tetracyanopropane, **1**, was reported by Diels *et al.* in 1922 (4) who prepared it by the condensation of malononitrile with formaldehyde at 0°C. These authors noted the strong influence of reaction temperature and stoichiometry on the product yield and suggested a structure for a minor product formed in the reaction as 1,1,3,3,5,5-hexacyanopentane (5). The identity of this compound was subsequently questioned (6) and it was suggested a more likely formulation was either **3** or less likely **2**.



3



2

We have repeated the literature preparations and obtained **1** and established that the minor product is **2**. We could not, however, obtain the compounds from these reactions in a pure state. In addition, after long reaction times an orange insoluble material was obtained. The true natures of **1** and **2** were established by X-ray crystal structure determinations of selected single crystals. Subsequently, better methods of obtaining pure samples of **1** and **2** were developed and a study of the reactions of these compounds allowed an explanation of the course of the original preparation. We describe this work here.

Experimental methods

Reagents used in preparations

Malonitrile was purchased from Canlab and used without further purification. Formaldehyde (37% aqueous solution) was certified A.C.S. and purchased from Fisher Scientific Company. β-Alanine was purchased from Sigma Chemical Company and used without further purification.

Preparation of 1,1,3,3-tetracyanopropane, 1

A modified version of the preparation reported by Rybkina *et al.* (7) was followed. Malononitrile 1.500 g (0.0227 mol) was dissolved in 7.5 mL of absolute ethanol that contained 0.01% HCl. To this was added 0.860 mL (0.0144 mol) of a 37% aqueous solution of formaldehyde and 0.040 g of β-alanine. This mixture was stirred at room temperature for 4 to 5 h, and the resulting precipitate filtered off and washed with distilled water (5 × 20 mL) and ethanol (5 × 20 mL). The product was dried under vacuum for 1 h at room temperature. Recrystallizations were made from tetrahydrofuran or acetone. The product was obtained as 0.586 g of white microcrystals in 73% yield, mp 132–135°C. *Anal.* calcd. for $C_7H_4N_4$: C 58.3, H 2.8, N 38.9; found: C 58.3, H 3.0, N 38.8.

Preparation of 2,2,4,4,6-pentacyanocyclohexenamine, 2

1,1,3,3-Tetracyanopropane (0.3626 g, 0.00163 mol) prepared as above was dissolved in 50 mL distilled water by heating to 75–80°C. The reaction mixture was filtered hot and the filtrate allowed to cool and refrigerated for 3 h. White crystalline needles precipitated from the

solution and were filtered and washed with absolute ethanol. The product was then vacuum dried for 1 h at room temperature. The melting point of the product was 225°C and the yield 0.125 g (68%). *Anal.* calcd. for $C_{11}H_6N_6$: C 59.5, H 2.7, N 37.8; found: C 59.9, H 2.7, N 37.4.

Apparatus

Infrared spectra were recorded on a Perkin–Elmer 283 grating spectrometer in the range 4000–200 cm^{-1}. The samples were prepared as KBr pellets. The spectra were calibrated against polystyrene and indene. Spectra were also collected in the 500–100 cm^{-1} region on a Nicolet 7199 FT-IR Spectrometer with samples between polyethylene plates.

Raman spectra were obtained from powder samples at room temperature in the range 3000–50 cm^{-1} on a Spex spectrometer Model 14018 with a Coherent Radiation Argon Laser Model 52. The spectra were calibrated against $HgCl_2$.

The ^1H and ^{13}C nmr were recorded at room temperature on a Bruker WP80 instrument using tetramethylsilane as a reference. Samples were dissolved in dimethylsulphoxide-d_6. Carbon-13 data were acquired in 8K and over 6000 Hz with a pulse angle of approximately 15°.

Ultraviolet spectra were recorded on a Hewlett Packard 8451A Diode Array Spectrophotometer with samples in quartz cells. Samples were dissolved in tetrahydrofuran.

The mass spectra were recorded on a Micromass 70-70 mass spectrometer. The source temperature was varied from 100 to 250°C, and the ionization voltage was 70 eV.

Collection of diffraction data and solution of the structures

The plate-like crystals of compound **1** and the needle-like crystals of compound **2** were cut to acicular crystals of suitable size and each sealed in a Lindemann capillary. Systematic absences from the precession photographs were consistent with the space group $Pbcn$ for **1** and $P2_1/c$ for **2**. The cell parameters of both crystals were determined by a least-squares refinement based on 15 automatically centered independent reflections in the range 18° < 2θ < 27°, **1** and 20° < 2θ < 29°, **2**. Intensities were measured at 22°C on a Nicolet P3 diffractometer with the use of graphite monochromatized MoKα radiation (λ = 0.71069 Å). Crystal data and other numbers related to data collection are summarized in Table 1. Corrections were made for Lorentz-polarization effects but not for absorption. This will introduce a maximum error in F_o of 0.8% for **1** and 0.5% for **2**.[2]

For **1** and **2** the phases were determined by direct methods using 124 reflections with $|E| > 1.6$, and 50 reflections with $|E| > 1.6$ for **1** and **2**, respectively, and 12 sets of starting phases for each. All non-hydrogen atoms were found in the subsequent E map. Hydrogen atoms were found from subsequent difference maps and the coordinates of all atoms (C and N with anisotropic temperature factors) were then refined by minimizing the function $\Sigma w(|F_o| - |F_c|)^2$ until the final maximum shift/error was <0.001 for **1** and 0.009 for **2**. The large difference in R and R_w in both structures is because we have used an $I > 0$ cut-off. Refinement based on reflections with $I > 3\delta(I)$ cut-off gave R = 0.048 and R_w = 0.028 for **1** and R = 0.046, R_w = 0.033 for **2**. Nevertheless, the inclusion of the greater number of reflections gives a more accurate structure (13). No corrections for secondary extinction were necessary for either crystal. Scattering curves were taken from Cromer and Waber (12). The atom parameters are listed in Tables 2 and 3.

Discussion[3]

We were able to prepare 1,1,3,3-tetracyanopropane, **1**, in rather poor yields from the methods in the literature (4, 7),

[2]All calculations were carried out on a CYBER 170/730 computer. The programs DATCO5, ABSORB, and DATDRN from the XRAY 76 program (8) were used for preliminary data treatment. The structure was solved with SHELX (9). Plane and dihedral angles were made with NRC 22 (10). Diagrams were prepared with the program ORTEP II (11).

and also cyclic 2,4,4,6,6-pentacyanocyclohexenamine, **2**, in considerable yield. In addition, we also obtained, as the major product at long reaction times, an unidentified orange material which is probably polymeric. The natures of **1** and **2** were demonstrated by a number of physical methods, and subsequently much better methods of preparation were devised. The reactions of these pure materials allowed us to formulate mechanisms of reactions and explain the low yields obtained by the literature methods.

The structures of the compounds **1** and **2** were established by X-ray crystallography. The X-ray structure of **1** is shown in Fig. 1 and the bond lengths and angles are given in Table 4. The molecule has a two-fold axis through the CH_2 (C(1)) group and the C_2 arrangement of the cyanide groups minimizes intramolecular steric repulsion. Bond lengths and angles agree well with those found in similar compounds (14–19). The structure of **2** is shown in Fig. 2 and bond lengths and angles are

given in Table 5. It can be seen that the structure is that of the tautomer considered by Westfahl and Gresham to be least likely (6). Despite the unusual temperature factor on N(1) which might suggest a disorder between the two tautomers, there is no evidence in our work for the presence of the other tautomer. The olefinic bond causes the molecule to adopt a half-chair conformation with C(4) being the atom furthest out of the best plane. Bond lengths and angles are normal. There is considerable conjugation involving the amine and the olefin, but it is not as great as has been observed in similar structures (20–22). Thus, C(1)—N(1) (1.354(3) Å) is considerably shorter than 1.475 Å, which is typical for aliphatic C—N distances (23) but it is at the upper end of the range (1.30(1)–1.33(1) Å) observed in amine–olefin compounds (20–22). Conversely, C(1)—C(2), 1349(3) Å is marginally longer than a normal olefin distance, 1.337 Å (22) but not as long as similar distances (range 1.372(5)–1.390(5) Å) in other amine–olefin compounds (20–22). In addition, C(2)—C(3), 1.504(3) Å, and C(2)—C(7), 1.440(3) Å, are shorter than the other C—C ring (range 1.542(3)–1.554(3) Å) and C—C(cyanide) (range 1.484(3)–1.495(3) Å) distances. Surprisingly, considering this conjugation, the NH_2 group is twisted with respect to the N(1)C(1)C(2) framework (dihedral angle N(1)H(11)H(12)—N(1)—C(1)—C(2) 13(2)°). This is probably caused by intramolecular hydrogen bonding (see below).

The packing of **1** within the cell is unnoteworthy and all intermolecular distances are equal to or greater than van der Waals distances. Similarly, packing of **2** within the unit cell is primarily determined by van der Waals interactions, although there are two very weak intermolecular hydrogen bonds involving the amine group, (N(1)—H(11)...N(9), N(1)...N(9) 3.104(3) Å, H(11)...N(9) 2.28(3) Å, N(1)—H(11)...N(9) 145(1)°, N(1)—H(12)...N(11), N(1)...N(11) 3.207(3) Å, N(1)...H(12) 0.85 (3), H(12)...N(11) 2.37(3) Å, N(1)—H(12)...N(11) 168(1)°) (see Fig. 2).

The mass spectral data for **1** and **2** are given in Table 6. Since the mass spectra of **1** always showed a peak at $m/z = 222$, corresponding to the parent ion of **2**, the question arose as to whether this was caused by contamination of **1** with **2** or whether small amounts of **2** were formed by thermal decomposition on the inlet probe.

In early preparations of **1**, we knew from other experiments that there was contamination by **2**, but with improved preparative methods and examination of the samples by chromatography we are sure that in later samples there was no contamination. The $m/z = 222$ peak persisted, however, and thus we conclude that it is caused by thermal decomposition of **1** on the probe. We obtained evidence for this decomposition by obtaining spectra at different times after the sample was injected and the sample heated. At short times relatively reproducible spectra were obtained (see **1***a* and **1***b* in Table 6) but at longer times there are marked changes in the spectra. The decomposition is complex, since the extra peaks in addition to $m/z = 222$ clearly do not come from the decomposition of **2**; **2** had a reproducible mass spectrum.

Our principal evidence for the thermal decomposition formation of peak $m/z = 222$ in the mass spectrum of **1** is the low intensity of the peak $m/z = 62$ and the absence of peaks 58–61 in the spectrum of **1**. Peak $m/z = 62$ is a major peak in the decomposition of **2** and the other peaks also have considerable

intensity. If **1** were contaminated with **2** then peaks at the following values of *m/z* and intensity, in parentheses, should occur: 62 (22); 61 (3.7); 60 (4.0); 59 (2.1); 58 (1.3). None of these were observed, however.

The most important mass peaks are quite similar for the two compounds, differences being extra peaks at *m/z* = 119, 79, 66, and 52 for **1** and *m/z* = 168, 117, 104, 88, 62, and 60 for **2**. Masses 222 and 144 are the parent ions for **2** and **1** and the 168 peak is most likely formed by 4,6 cleavage of the hexenamine ring. Peaks at *m/z* = 131, 119, 117, and 92 are derived from **1** by the loss of CH, CN, with H transfer, HCN and 2CN, respectively. Peak *m/z* = 104 is derived from 131 by loss of HCN and 77 is similarly derived from 104. The fragment *m/z* = 66, $HC(CN)_2^+$ is derived from simple 1,2 cleavage of **1** giving the alternate fragment *m/z* = 79. Peaks *m/z* = 62, 60 corresponding to the fragments C_4N^+ and C_5^+ must be derived from the ring skeleton and *m/z* = 52 is either $(CN)_2^+$ or $(H_2C{=}CH{-}CN)^+$.

The infrared and Raman bands of malononitrile, 1,1,3,3-tetracyanopropane, and 2,4,4,6,6-pentacyanocyclohexenamine, are listed in Table 7. The assignments for the first two compounds are straightforward. The assignments for the last

*Infrared data, ν, I: 4000–450 cm^{-1}, intensity relative to strongest band = 100; 450 cm^{-1} and below, FTIR; intensity relative to 214 or 123 cm^{-1} band = 100. Abbreviations: s = strong, v = very, m = medium, w = weak, br = broad, shp = sharp, sh = shoulder, db = doublet, ρ is frequency ratio of normal to deuterated form.

†Raman data $\Delta\nu$, I: intensity relative to strongest band = 100.

‡Data from deuterated form (D_2O exchange).

§Assignments: ν = stretching frequency, a = antisymmetric, s = symmetric, δ = deformation, τ = twist, r = rock, ω = wag.

compound and its deuterated derivatives are discussed here. The NH_2 region was typical of most liquid aromatic amines, with two absorptions >3300 cm^{-1} and with a weaker band at 3250–3170 cm^{-1}. The relationship $\nu_s = 345.5 + 0.876\nu_a$ (24) holds exactly for the two observed NH_2 stretching bands, $\nu_a = 3440\,cm^{-1}$, $\nu_s = 3360\,cm^{-1}$. The slightly weaker band at 3240 cm^{-1} can be assigned as the overtone of the deformation which is intensified by Fermi resonance.

Primary amines with tertiary carbon atoms (C—NH_2) absorb weakly at 1038–1022 and more strongly at 1240–1170 cm^{-1} (24) (observed 1040 and 1242, 1218 cm^{-1}).

Nitriles are characterized by νC≡N at 2260–2240 cm^{-1} (24), which is lowered by conjugation to the ring system to 2235–2215 cm^{-1} (24). This vibration was observed at 2218 cm^{-1} for **2**. A nitrile group is reported to lower δCH_2 to 1425 cm^{-1} (24). The lowering is not so great in **2** where two bands are observed at 1452 and 1438 cm^{-1} and no lowering is observed in the deuterated compound. The CH_2 wag (a similar motion to $\delta_s CH_3$) occurs at 1328 cm^{-1}.

The calculated shifts on deuteration are 1.333 for ND_2/NH_2, 1.369 for ND/NH, and 1.372 for NHD/NH_2. It is apparent that the pentacyano compound subjected to D_2O exchange gave a mixture of —NHD and —ND_2, the former yielding new single bands νNH at 3392 cm^{-1}, νND at 2500 cm^{-1}, δNH at 1527 cm^{-1}, and δND at 1100 cm^{-1}.

The δNH_2 was observed at 1652 cm^{-1} (δND_2, 1245 cm^{-1}) and the νC=C observed at 1630 cm^{-1} was unshifted on deuteration. Our assignments are in the reverse order from those of Baldwin (δNH_2, 1631, 1650 cm^{-1}) (25). Our choices for these assignments, however, are in agreement with those for cyclohexenamine (26) and acrylonitrile (27) and are confirmed by the changes on deuteration. The lower frequency NH_2 bands (w, γ and τ) were less well-defined but followed the same general pattern of ND_2 shifts. In conclusion, the vibrational spectral results agree with the findings of the X-ray study, that compound **2** exists as the cyclohexenamine.

The results of the proton and carbon-13 nmr are given in Table 8. The ^1H nmr spectrum of a solution of 1,1,3,3-tetracyanopropane in DMSO-d_6 showed two triplets of equal intensities and a weak singlet. The minor peak at 4.44 ppm was ascribed to a small amount of the starting material, malononitrile, $CH_2(CN)_2$. The triplet centered at 2.96 ppm was assigned to the two H(1) hydrogens of the CH_2 group which were coupled to the two chemically equivalent H(2) hydrogen atoms. The triplet centered at 5.10 ppm was attributed to the two H(2) hydrogens.

The proton decoupled carbon 13-nmr of 1,1,3,3-tetracyanopropane exhibit singlets at 112.6 ppm, 28.2 ppm, and 20.5 ppm with relative intensities of 16:9:18 respectively. The peak at 112.6 ppm was assigned to the four CN carbons. The assignment of the remaining two peaks was confirmed with use of results of a "spin-sort" experiment (28).

The ^1H nmr spectrum of 2,2,4,4,6-pentacyanocyclohexenamine consisted of three singlets at 3.23 ppm, 3.66 ppm, and 7.68 ppm all of equal intensity. The peak at 7.68 ppm was assigned to the amine group, the peak at 3.66 ppm to the two hydrogen atoms on carbon 3, and that at 3.23 ppm to the two hydrogen atoms on carbon 5 (see Table 8).

The assignment of carbon-13 nmr spectrum is ambiguous with regard to some peaks. The singlet at 143.88 ppm was assigned to carbon C1 being adjacent to the electron-withdrawing nitrogen. The signal at 69.9 ppm was assigned to carbon C2. The high field position of this signal arises from the back donation of electron density from the nitrogen atom into the π-system of the alkene. From the intensities of the peaks at 117.3, 113.52, and 112.07 ppm these are assigned to the CN groups, with the first being assigned to the C-2 CN. It was not possible to distinguish between the remaining C-4 and C-6 groups. The assignments of C(3) and C(5) were confirmed by selective proton irradiation experiments.

The overall reaction and mechanism for the formation of the tetracyanopropane **1** are shown in Scheme 1. The initial process

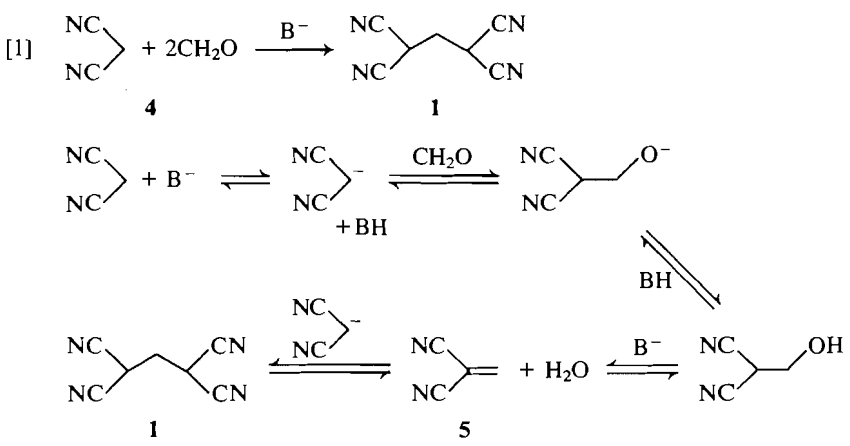

SCHEME 1

is a normal aldol condensation between the malononitrile anion and formaldehyde leading to the 1,1-dicyanoethylene, **5**. This intermediate then undergoes conjugate addition and protonation with another malononitrile anion. It should be noted that compound **1** is a kinetic product, its formation in good yield being governed by its rapid crystallization from the reaction medium. The continued exposure of **1** to base results in its transformation into either polymer or the mono-cyclic product **2** as the thermodynamic products (*vide infra*).

The overall reaction and suggested mechanism for the transformation of compound **1** into the pentacyanocyclohexenamine **2** are shown in Scheme 2. Traces of base in water (or other alcohol solvents) are sufficient to generate the anion of **1** and set up the reverse conjugate addition equilibrium between **1** and **5** and malononitrile anion as shown in Scheme 1. The anion of **1** can now add to 1,1-dicyanoethylene, **5**, to give an intermediate anion **6** which can either undergo further conjugate additions (giving polymer) or carry out an intramolecular aldol condensation which upon protonation and tautomerization leads to the vinylogous amino-nitrile **2**. The driving force which displaces the equilibria to **2** is the ease of formation of the six-membered ring and the stability of the vinylogous amino-nitrile system.

As noted above, the original preparation (7) will only give the desired product in good yields if the product crystallizes from solution and stops further reaction. If this does not occur then either the cyclic product or the polymer is formed.

The results of our ultraviolet–visible spectroscopic studies are assembled in Table 9. The malononitrile solution instability illustrated by the variations in peak intensities and peak positions was first documented by Mendelson *et al.* (29). We have also observed a similar dynamic nature in the uv spectra of the tetracyanopropane solutions. The instability was suspected given the ease of formation of the cyclic compound, **2** from the tetracyanide. As can be seen, the low ϵ values of the transitions for both malononitrile and tetracyanopropane represent $n \rightarrow \pi^*$ spin forbidden transitions. The spectra of the 2,4,4,6,6-pentacyanocyclohexenamine exhibited two intense transitions at 260 nm and 288 nm. The peak at 260 nm agrees well with a π–π^* transition reported for 2-cyanocyclohexenamine (26). Williams had previously reported a peak at 271 nm for this

Received June 18, 1986

GEORGE I. BIRNBAUM, MILOŠ BUDĚŠÍNSKÝ, and JIŘÍ BERÁNEK. Can. J. Chem. **65**, 271 (1987).

Crystals of 2′,5′-anhydroarabinosylcytosine hemihydrate belong to the monoclinic space group $P2_1$. The cell dimensions are a = 9.643(2), b = 10.328(1), c = 10.544(2) Å, β = 94.55(1)°. X-ray intensity data were measured on a diffractometer and the structure was determined by direct methods. Least-squares refinement, which included all nucleoside hydrogen atoms, converged at R = 0.041 for 2298 observed reflections. The asymmetric unit contains two molecules of the nucleoside and one molecule of water. In both nucleoside molecules, the conformation about the glycosyl bond is *anti*, with χ_{CN} values of 15.5(3) and 26.3(3)°, respectively. In the bicyclic sugar moiety, the arabinofuranose rings adopt a C(3′)*exo*/C(2′)*endo* conformation and are highly puckered (τ_m = 57°). The solution conformation was studied by ^{1}H and ^{13}C nmr spectroscopy. A difference nOe proton nmr spectrum and ^3J(C,H) coupling constants reveal an *anti* conformation in solution, with torsion angles very similar to those obtained from X-ray analysis. A comparison of observed ^3J(H,H) coupling constants with those calculated on the basis of a modified Karplus equation shows significant differences, probably due to the presence of the bicyclic system.

GEORGE I. BIRNBAUM, MILOŠ BUDĚŠÍNSKÝ et JIŘÍ BERÁNEK. Can. J. Chem. **65**, 271 (1987).

Les cristaux de l'hémihydrate de l'anhydro-2′,5′ arabinosylcytosine cristallisent dans le groupe d'espace monoclinique $P2_1$, avec a = 9,643(2), b = 10,328(1) et c = 10,544(2) Å et β = 94,55(1)°. On a mesuré les intensités de rayons-X à l'aide d'un diffractomètre et on a déterminé la structure par des méthodes directes. L'affinement par la méthode des moindres carrés, qui comporte tous les atomes d'hydrogène du nucléoside, converge à R = 0,041 pour 2298 réflexions observées. L'unité asymétrique contient deux molécules de nucleoside et une molécule d'eau. Dans chacune des molécules de nucléoside, la conformation autour de la liaison glycosyle est *anti* avec des valeurs de χ_{CN} qui sont respectivement de 15,5(3) et 26,3(3)°. Dans la portion du sucre, les cycles arabinofurannose adoptent une conformation C(3′)*exo*/C(2′)*endo* et ils sont fortement repliés (τ_m = 57°). On a étudié la conformation en solution à l'aide de la rmn du ^{1}H et du ^{13}C. En se basant sur un spectre rmn du proton en différentiel d'effet Overhauser nucléaire et sur les constantes de couplage ^3J(C,H), on peut en déduire que, en solution, la conformation est *anti* et que les angles de torsion sont très semblables à ceux observés par diffraction des rayons-X. Une comparaison des constantes de couplage ^3J(H,H) observées avec celles calculées en se basant sur une équation de Karplus modifiée présente des différences notables qui sont probablement dues à la présence du système bicyclique.

Introduction

In order to study structure–activity relationships (1–5), various derivatives of deoxynucleosides were recently synthesized, in particular those incorporating the cancerostatic agents 5-fluorouracil (1, 6) and arabinosylcytosine (2, 7). Attention was focussed on 5′-deoxy derivatives which are unable to form 5′-phosphate esters, the proposed active forms of both agents (8–10). In the 5-fluorouracil series, 5′-chloro-5-fluorouridine (6) and 5′-deoxy-5-fluorouridine (6) were later found to possess promising biological activities (11–13).

In the arabinosylcytosine series, 5′-chloroarabinosylcytosine (7) is a selective, very strong inhibitor of nucleic acid synthesis in L1210 cells (3). Both in alkaline medium and in a biological system, in a study with cytidine deaminase (14), the 5′-halogeno (chloro or bromo) derivatives of arabinosylcytosine as well as 5′-chloro-2,2′-cyclocytidine are converted to 2′,5′-anhydroarabinosylcytosine (15). The latter has an inhibitory effect against growth of L1210 cells which is comparable to that of 5′-bromoarabinosylcytosine, but lower than that of 5′-chloroarabinosylcytosine (2); however, it has a higher resistance to deaminase (14). One of the possible mechanisms of action of 5′-chloroarabinosylcytosine we envisage involves its conversion to 2′,5′-anhydroarabinosylcytosine. Consequently, it appeared worthwhile to determine the detailed conformation of the latter compound in the solid state and in solution.

[1]NRC No. 26555.

Experimental

Colorless prismatic crystals of 2′,5′-anhydroarabinosylcytosine hemihydrate were grown from water. X-ray precession photographs indicated space group $P2_1$. A crystal fragment measuring 0.45 × 0.55 × 0.65 mm was mounted on an Enraf-Nonius CAD-4 diffractometer; it provided the following data:

$C_9H_{11}N_3O_4.\frac{1}{2}H_2O$ fw = 234.21

Monoclinic, a = 9.643(2), b = 10.328(1), c = 10.544(2) Å, β = 94.55(1)°, V = 1046.80 Å^3, ρ_c = 1.49 g cm^{-3}, Z = 4 (20°C; CuKα$_1$, λ = 1.54056 Å); F(000) = 492, μ(CuKα) = 9.87 cm^{-1}.

The cell dimensions were determined from angular settings of 23 high-order (2θ > 107°) reflections. Intensities were measured with Ni-filtered CuKα radiation, using ω/2θ scans with variable scan ranges and speeds. Three standard reflections were monitored at frequent intervals; their intensities fluctuated by ± 1%. There were 2316 unique reflections accessible to the diffractometer (2θ ≤ 152°), of which two with $I \leq 3\sigma(I)$ were considered unobserved. The intensities were corrected for Lorentz and polarization factors; absorption corrections were considered unnecessary.

The structure was determined by direct methods with the aid of the computer program MULTAN78 (16). Of the 16 starting sets subjected to tangent refinement, the solution with the highest combined figure of merit yielded an E map on which all atoms of the two independent

[a]All values were multiplied by 10^4.

nucleoside molecules were located. The oxygen atom of the water molecule was found on a subsequent difference Fourier map. Other such maps, calculated at later stages, revealed the positions of all hydrogen atoms except one belonging to the water molecule. All atomic parameters were refined by block-diagonal least squares with anisotropic and isotropic temperature parameters for nonhydrogen and hydrogen atoms, respectively. The scattering factors were taken from the "International tables for X-ray crystallography" (17) and the oxygen curve was corrected for anomalous dispersion (17). Throughout the refinement the function $\Sigma w(|F_o| - |F_c|)^2$ was minimized and a factor of 0.8 applied to all shifts. The following weighting scheme was used during the final stages: $w = w_1 \cdot w_2$, where $w_1 = 1$ for $|F_o| \leq 4$, $w_1 = 4/|F_o|$ for $|F_o| > 4$; and $w_2 = \sin^2\theta/0.9$ for $\sin^2\theta < 0.9$, $w_2 = 1$ for $\sin^2\theta \geq 0.9$. This scheme made the average value of $w(\Delta F^2)$ independent of $|F_o|$ and $\sin^2\theta$. The refinement converged to a conventional residual index $R = 0.041$ and a weighted index $R' = 0.051$ for 2298 observed reflections (sixteen strong low-order reflections suffered from secondary extinction and were given zero weights). A final difference Fourier map showed no significant features. The coordinates of nonhydrogen atoms are listed in Table 1. Anisotropic temperature parameters, hydrogen atom parameters, and a list of observed and calculated structure factors are available.[2] A stereoscopic view of one of the molecules is shown in Fig. 1.

^{1}H and ^{13}C nmr spectra were measured at 30°C on a Varian XL-200 FT-NMR spectrometer at frequencies of 200 MHz and 50.3 MHz, respectively. For the ^{1}H nmr measurements, solutions were made up by dissolving ca. 5 mg in 0.4 mL of DMSO-d_6, CD_3OD, CD_3OD + pyridine-d_5 (2:1), and D_2O. Selective decoupling of H(1') was used for the determination of its coupling constants with other protons. The difference nOe spectrum in CD_3OD was obtained as difference of two spectra, with the irradiation frequency placed on the signal of H(5') and H(5") and the decoupler "on" or "off" during 5.3 s before data acquisition. The nOe enhancement values were determined by a comparison with the intensity of the signal for H(5') and H(5") (200%) in the difference spectrum. ^{13}C chemical shifts and the number of directly bonded protons were obtained from the "attached proton test" ^{13}C nmr spectrum (18) in DMSO-d_6. Signals were referenced to DMSO-d_6 and recalculated to the δ-scale using $\delta_{DMSO} = 39.7$. Coupling constants J(C,H) were extracted from the proton-coupled ^{13}C nmr spectrum with nOe enhancement.

Results and discussion

Pyrimidine moiety

Most bond lengths and bond angles in the cytosine residues (Tables 2 and 3) agree with previously observed values (19); only the N(1)—C(2)—N(3) angle in molecule A is slightly larger than normal. The difference between this angle and the corresponding one in molecule B is significant and so are the differences between the N(1)—C(2) and N(1)—C(1') bond lengths in the two molecules. These differences may reflect variations in electron delocalization. We note that the sums of the N(1)—C(2) and N(1)—C(1') bond lengths are equal in the two molecules, but the deviations of the six ring atoms from the mean plane are larger in molecule B than in molecule A.

Glycosyl linkage

In pyrimidine arabinonucleosides the glycosyl torsion angles have been found to have values of 30 ± 7° (20). In the present structure this torsion angle is restricted by intramolecular steric interactions to a narrow range of smaller values. On the one hand, it is desirable to avoid the total eclipsing of N(1)—C(6) and C(1')—O(4') bonds; on the other hand, the distance between H(6) and one of the hydrogen atoms attached to C(5') becomes unacceptably short with increasing χ_{CN}. In molecule A, with $\chi_{CN} = 15.5(3)°$, this nonbonded H···H distance is 2.22 Å (after normalizing the C—H distances to 1.09 Å), while in molecule B, with $\chi_{CN} = 26.3(3)°$, the H(6)···H(5') distance (2.00 Å) is extremely short.

Arabinosyl moiety

To the best of our knowledge, this is the first X-ray analysis of a 2',5'-anhydroarabinonucleoside. It is therefore of interest to compare the geometry of this moiety to that of normal nucleosides. The bridging of O(2') and C(5') imposes a C(3') *exo* pucker on the furanose ring. The phase angles of pseudorotation (P) are 193.9 and 195.0° for molecules A and B, respectively. These values are just outside the usual range. The [2,2,1]-bicyclic system makes the arabinofuranose ring much more puckered than normal: the maximum amplitudes of puckering (τ_m) are 57.5 and 57.1° in the two molecules rather than the usual value of ~39°. The similarities of P and τ_m in molecules A and B, as well as of the torsion angles shown in Figs. 2 and 3, reflect the rigidity of the bicyclic system.

The strain present in this portion of the molecule is made evident by the distortion of some bond angles. In particular, the C(2')—C(3')—C(4') and C(3')—C(4')—C(5') angles are at least 10° smaller than normal. The O(2')—C(5') bond is significantly longer (weaker) than O(2')—C(2'), particularly in molecule B. The apparent difference between the two molecules is very likely attributable to the significantly larger vibrational parameters of C(2'), O(2'), and C(5') in molecule A. An

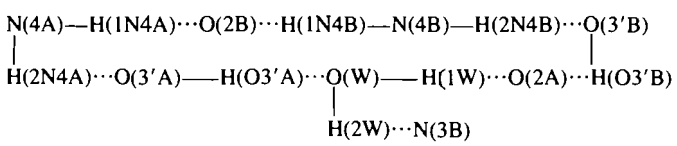
[a]The esd's are 0.2°.

additional indication of the strain is the C(2′)···C(4′) nonbonded distance (2.174(3) Å), shortened by ~0.2 Å from normal (20).

Hydrogen bonding and packing

Three protons in each nucleoside molecule and two in the water molecule are capable of participating in hydrogen bonding and all of them are involved in intermolecular hydrogen bonds. The network can be represented schematically as follows:



The geometrical details of these hydrogen bonds are given in Table 4. As commonly observed in X-ray analyses, the N—H and O—H bonds appear shorter than their real length. By extending these covalent bond lengths to their nominal values of 1.04 and 0.97 Å, respectively, one obtains corrected H···*A* distances which reflect more accurately the strengths of these hydrogen bonds. The strongest bonds are seen to be those in which the proton donor also acts as an acceptor, a phenomenon

[a]The esd's are 0.003–0.005 Å, 0.04–0.05 Å, and 3–5° for *D*···*A*, H···*A*, and *D*—H···*A*, respectively.

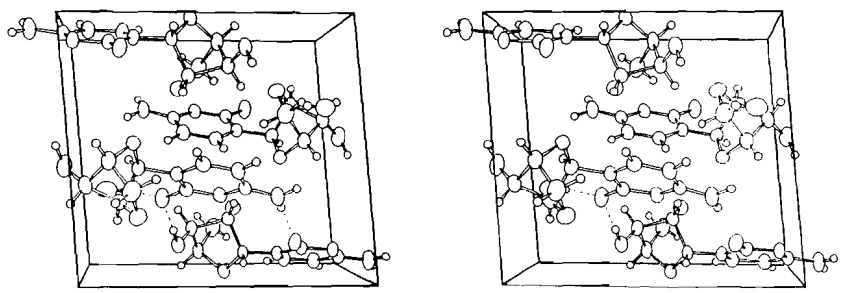

FIG. 4. Stereoscopic view, along the *y* axis, of molecular packing in the crystal.

known as the cooperativity effect (21). The ether oxygens do not participate in hydrogen bonding and only one N(3) atom acts as an acceptor. On the other hand, each carbonyl oxygen accepts two protons. One may therefore speculate that the carbonyl group, as well as the amino group, could play a significant role in binding to a receptor.

The packing of the molecules in the crystal is shown in Fig. 4. The A and B molecules form hydrogen-bonded dimers, involving both base and sugar moieties. There is neither base pairing nor base stacking.

Solution conformation

^1H and ^{13}C nmr spectra were studied in order to compare the conformation in solution with that determined by the X-ray analysis. In view of the rigidity of the bicyclic system in the sugar moiety, one would expect the differences, if any, to be due, primarily, to a different orientation about the glycosyl bond. On the other hand, the rigid system provides us with an opportunity to compare the experimentally obtained coupling constants with those calculated by the method of Haasnoot *et al.* (22).

The ^1H nmr spectra were recorded in four different solvents in order to find an optimal distribution of signals for H(2')—H(5"). As shown in Table 5, the best resolution was achieved in a mixture of CD_3OD and pyridine-d_5. While the proton chemical shifts are rather solvent dependent, the coupling constants remain unaffected. This fact, together with the long-range couplings of H(1'), indicates the rigidity of the

[a]The same J values were found in all solvents.
[b]Long-range J(C,H) values were determined only for cytosine carbons.
[c]These values may be interchanged.

sugar moiety of the molecule. The small values of all vicinal coupling constants (<3 Hz) are in agreement with the *gauche* orientations of interacting protons shown in Fig. 3. Using the generalized Karplus relations derived by Haasnoot *et al.* (22), we calculated the vicinal coupling constants corresponding to the torsion angles obtained from the X-ray analysis. As seen in Table 6, some values differ significantly from those obtained experimentally. We have shown recently that good agreement can be obtained for a pyranose (23) and for a diazepine ring (24). It is likely, therefore, that the differences can be attributed to the distortions and interactions occurring in bicyclic systems. In fact, Haasnoot *et al.* (22) specifically excluded derivatives of norbornane and norbornene from their dataset. The unusual conformation is also evidenced by the differences between the J values in Table 6 and those published by de Leeuw and Altona (25) for arabinonucleosides with a $_3T^2$ ring pucker. However, de Leeuw and Altona did not calculate J's for a highly puckered ring with $\tau_m = 57°$. Thus, the values presented in Table 6 should be useful in future studies of 2′,5′-anhydronucleosides.

The difference nOe proton nmr spectrum provided information about the orientation of the cytosine base with respect to the sugar moiety. Upon irradiation of H(5′) and H(5″) (it is not possible to irradiate selectively only one of them), we observed a 14% nOe enhancement of the H(6) signal. The proximity of H(6) to the C(5′) methylene group indicates the *anti* conformation about the glycosyl bond. We also observed smaller nOe enhancements on the H(3′) (6%) and H(4′) (10%) signals.

In DMSO-d_6 the hydroxyl proton H(O3′) gives a doublet at

TABLE 6. Proton torsion angles (in deg) and interproton coupling constants (in Hz)

Protons	Torsion angles[a] Mol. A	Mol. B	^3J(H,H) Mol. A[b]	Mol. B[b]	Exp.[c]

[c]From the nmr analysis.

δ 5.91 with J(3′,O3′) = 3.2 Hz, indicating a *gauche* orientation of these interacting hydrogens. In the crystal structure, where H(O3′) participates in hydrogen bonds, the H—C(3′)—O(3′)—H torsion angles are 92° and −49° in molecules A and B, respectively.

The proton decoupled "attached proton test" ^{13}C nmr spectrum (18) afforded nine signals. Structural assignment (Table 5) was done on the basis of numbers of directly bonded protons, chemical shift arguments, and a comparison with ^{13}C nmr data of cytosine nucleosides and arabinofuranoses. Very near signals of C(2′) and C(3′) at δ 75.99 and 75.11 were structurally distinguished by using ^1J(C,H) obtained from the

For personal use only.

proton-coupled ^{13}C nmr spectrum. Of the two values 168.5 and 155.0 Hz, only the former is very similar to the value 167.2 Hz for C(4′). Therefore, we assigned the signal at 75.99 to C(2′) which has the same substitution as C(4′) (ether oxygens) and the signal at 75.11 to C(3′) whose lower value of ^1J(C,H) is due to the hydroxyl substituent. All one-bond couplings J(C,H) and long-range couplings of cytosine carbons were determined from the proton-coupled ^{13}C nmr spectrum. Poorly resolved multiplets with many splittings make it very difficult to determine long-range couplings of the sugar carbons. The proof of individual interactions by heteronuclear selective decouplings is complicated by the close spacing of the signals for H(2′)—H(5″).

Two coupling constants are relevant to the orientation about the glycosyl bond, viz. ^3J(C(6),H(1′)) and ^3J(C(2),H(1′)). The significantly higher value of the former (4.8 Hz) provides additional evidence for a *trans* orientation of the fragment C(6)—N(1)—C(1′)—H(1′). Using a relation between J(C,H) and the torsion angle in the fragment C—N—C—H (26), we obtain values of 130° and 50° for the torsion angles C(6)—N(1)—C(1′)—H(1′) and C(2)—N(1)—C(1′)—H(1′), respectively. These values are in good agreement with the results of the X-ray analysis, viz. 137(3)° and 43(3)° in molecule A and 142(2)° and 38(2)° in molecule B. Thus, the results of the nmr analysis confirm the conclusion we mentioned above, i.e. the torsion angle about the glycosyl bond is restricted to a relatively narrow range.

Kinetics and mechanisms of oxidations by metal ions. Part VIII.[1] Oxidation of *n*-propanol by aquomanganese(III) ions

MAHENDRA MEHTA, RATAN R. NAGORI, AND RAJ N. MEHROTRA[2]
Department of Chemistry, University of Jodhpur, Jodhpur 342 001, India

Received January 24, 1986[3]

MAHENDRA MEHTA, RATAN R. NAGORI, and RAJ N. MEHROTRA. Can. J. Chem. **65**, 277 (1987).

The oxidation of *n*-propanol by aquomanganese(III) ions in perchlorate medium of constant ionic strength (4 mol dm^{-3}, $NaClO_4$) is described by the rate law [i] which is based on the consideration of the reactions [ii]–[ix].

$$[i] \quad \frac{-d[Mn^{III}]}{dt} = \frac{2(kK_a\beta[Mn^{II}]^{-1} + k_1\beta_1K_h[H^+]^{-1})[Mn^{III}][C_3H_7OH]}{(1 + K_c[H^+])(1 + K_h[H^+]^{-1}) + (\beta + \beta_1K_h[H^+]^{-1})[C_3H_7OH]}$$

[ii] $Mn^{3+}(aq) \overset{K_h}{\rightleftharpoons} MnOH^{2+}(aq) + H^+(aq)$

[iii] $C_3H_7OH + H^+(aq) \overset{K_c}{\rightleftharpoons} C_3H_7OH_2^+$

[iv] $C_3H_7OH + Mn^{3+}(aq) \overset{\beta}{\rightleftharpoons} C_3H_7OHMn^{3+}(aq)$

[v] $C_3H_7OH + MnOH^{2+}(aq) \overset{\beta_1}{\rightleftharpoons} C_3H_7OMn^{2+}(aq) + H_2O$

[vi] $C_3H_7OHMn^{3+}(aq) \overset{K_a}{\rightleftharpoons} C_2H_5CH_2\overset{+}{O}H + Mn^{2+}$

[vii] $C_2H_5CH_2\overset{+}{O}H \overset{k}{\rightarrow} C_2H_5\dot{C}HOH + H^+$

[viii] $C_2H_5CH_2OMn^{2+}(aq) \overset{k_1}{\longrightarrow} C_2H_5\dot{C}HOH + Mn^{2+}$

[ix] $C_2H_5\dot{C}HOH + Mn^{III} \rightarrow C_2H_5CHO + Mn^{II} + H^+$ (fast)

A further analysis of the rate law in terms of the results indicated that $MnOH^{2+}(aq)$ is the major oxidant. The values of the equilibrium constant (β_1) and rate determining constant (k_1) are reported together with the associated thermodynamic parameters. The values of the other constants, k, K_a, and β, could not be determined though an assumption was made that $\beta \approx \beta_1$.

MAHENDRA MEHTA, RATAN R. NAGORI et RAJ N. MEHROTRA. Can. J. Chem. **65**, 277 (1987).

La vitesse de la réaction du *n*-propanol avec les ions manganeux(III) aqueux, dans une solution perchlorique de force ionique constante (4 mol dm^{-3}, $NaClO_4$), est décrite par l'équation [i] qui est basée sur la considération des réactions [ii]–[ix] :

$$[i] \quad \frac{-d[Mn^{III}]}{dt} = \frac{2(kK_a\beta[Mn^{II}]^{-1} + k_1\beta_1K_h[H^+]^{-1})[Mn^{III}][C_3H_7OH]}{(1 + K_c[H^+])(1 + K_h[H^+]^{-1}) + (\beta + \beta_1K_h[H^+]^{-1})[C_3H_7OH]}$$

[ii] $Mn^{3+}(aq) \overset{K_h}{\rightleftharpoons} MnOH^{2+}(aq) + H^+(aq)$

[iii] $C_3H_7OH + H^+(aq) \overset{K_c}{\rightleftharpoons} C_3H_7OH_2^+$

[iv] $C_3H_7OH + Mn^{3+}(aq) \overset{\beta}{\rightleftharpoons} C_3H_7OHMn^{3+}(aq)$

[v] $C_3H_7OH + MnOH^{2+}(aq) \overset{\beta_1}{\rightleftharpoons} C_3H_7OMn^{2+}(aq) + H_2O$

[vi] $C_3H_7OHMn^{3+}(aq) \overset{K_a}{\rightleftharpoons} C_2H_5CH_2\overset{+}{O}H + Mn^{2+}$

[vii] $C_2H_5CH_2\overset{+}{O}H \overset{k}{\rightarrow} C_2H_5\dot{C}HOH + H^+$

[viii] $C_2H_5CH_2OMn^{2+}(aq) \overset{k_1}{\longrightarrow} C_2H_5\dot{C}HOH + Mn^{2+}$

[ix] $C_2H_5\dot{C}HOH + Mn^{III} \rightarrow C_2H_5CHO + Mn^{II} + H^+$ (vite)

Une analyse plus poussée de la loi de vitesse, en fonction des résultats, a indiqué que le $MnOH^{2+}(aq)$ est l'oxydant principal. On rapporte les valeurs de la constante d'équilibre (β_1) et de la constante de la réaction déterminant la vitesse (k_1) ainsi que les paramètres thermodynamiques qui leurs sont associés. On n'a pas pu déterminer les valeurs des autres constantes k, K_a et β bien qu'on suppose que $\beta \approx \beta_1$.

Introduction

Although the oxidation of secondary alcohols, isopropanol (2) and *s*-butanol and cyclohexanol (3), by aquomanganese(III) ions has been discussed in detail, the oxidation of primary alcohols has received scant attention. The only study reported so far is that of methanol (4). That the oxidation of methanol is different from those of *s*-alcohols is exemplified by the effect of Mn^{2+} ions on the rates of oxidation. The rate of oxidation of *s*-alcohols is independent of $[Mn^{2+}]$ whereas that of methanol is retarded by it. The retarding effect of Mn^{2+} ions was explained by the suggestion that the Mn^{2+} ion, the $\dot{C}H_2OH$ radical, and H^+ ion are formed in a solvent cage in the initial stage and that the backward reaction increased by additional Mn^{2+} ions present in the wall of the solvent cage. However, this explanation became untenable when it was found that Mn^{2+} ions did not retard the rate of oxidation of glycolic acid (5) which generates the $\dot{C}H_2OH$ radical during its oxidation.

It was therefore considered necessary to examine the oxidation of another primary alcohol with a view to understand its mechanism of oxidation with respect to the role of Mn^{2+} ions. The choice of *n*-propanol was influenced by the fact that there is spectrophotometric evidence (6) for its complexation by aquomanganese(III) ions.

Experimental

Solutions of aquomanganese(III) ions were freshly prepared by the electrolytic oxidation of stock manganese(II) perchlorate solution under nitrogen. The stock manganese(II) perchlorate (G. F. Smith) solution was standardized against a standard solution of sodium ethylenediaminetetraacetate (BDH) in the presence of ammonium hydroxide using 4-(2-pyridylazo)resorcinol as indicator.

The solution of aquomanganese(III) ions was standardized by allowing it to react with a known volume of standard iron(II) solution. The unreacted iron(II) solution was estimated titrimetrically using a standard vanadium(V) solution (barium diphenylamine sulphonate indicator used in presence of phosphoric acid). Other details are described elsewhere (7). Perchloric acid (E. Merck, GR) was standardized against standard sodium hydroxide using phenolphthalein as indicator. Anhydrous sodium perchlorate (G. F. Smith) was standardized gravimetrically and used with Mn(II) perchlorate to maintain the ionic strength at 4 mol dm^{-3}. *n*-Propanal (E. Merck) was refluxed with 2,4-dinitrophenylhydrazine to remove carbonyl impurities and distilled. The middle fraction, bp 97.8°C, was collected for use. Reductant solutions were made by direct weighing.

Stoichiometry

Reaction mixtures, aerobic or under nitrogen, with [alcohol] $\gg$ $[Mn^{III}]$ were prepared and left at 25°C until the reaction was complete. The reaction mixture was then treated with 2,4-dinitrophenylhydrazine and the precipitated phenylhydrazone was separated and purified. Its mp (156°C) did not change on mixing with the hydrazone prepared from an authentic sample of *n*-propanol (lit. (8), 155°C). The yield, 90–96% of the calculated amount, of the hydrazone was independent of acidity and atmospheric conditions. The $[Mn^{III}]/[\text{hydrazone}] = 2.15 \pm 0.1$ indicated that the oxidation of excess *n*-propanol is given by reaction [1]

$$[1] \quad 2Mn^{III} + C_2H_5CH_2OH \rightarrow C_2H_5CHO + 2Mn^{II} + 2H^+$$

Rate measurements

The kinetics were followed under pseudo-first order conditions, i.e. *n*-propanol was always present in large excess. Other details are described elsewhere (7). Temperature was maintained to ±0.1°C. In adopting the titrimetric method it was ensured that the presence of *n*-propanol in concentrations present in the reaction mixtures did not affect the titre value of Fe^{II} solution against vanadium(V) solution. The rates under nitrogen were similar to those in air. The rates reported are the mean of the values obtained from replicate runs which agreed to within ±2–3%.

The values of the pseudo first-order rate constant k_{obs} were calculated from the slopes of linear plots of log (titre change) vs. time. The slopes were obtained with a statistical calculator. The plots were linear for at least two half-lives and the correlation coefficients were always >0.99.

Test for free radicals

The formation of the free radical during the progress of the reaction was indicated by the observed polymerisation of acrylonitrile added to partially oxidised reaction mixtures which were previously saturated with nitrogen. The blank tests in which acrylonitrile was added separately to solutions of Mn^{III} and *n*-propanol did not show any polymerisation of acrylonitrile.

TABLE 1. The retarding effect of $[Mn^{II}]$ on the observed rate*

$[Mn^{II}]$ (mol dm^{-3})	$10^5 k_{obs}$ (s^{-1})	$[Mn^{II}]$ (mol dm^{-3})	$10^5 k_{obs}$ (s^{-1})
0.059	8.6	0.099	6.5
0.066	7.8	0.199	6.0
0.079	7.0	0.140	5.6

*$10^3[Mn^{III}]$ = 2.0 mol dm^{-3}, $[C_3H_7OH]$ = 0.2 mol dm^{-3}, T = 35°C, $[HClO_4]$ = 3.0 mol dm^{-3}, I = 4 mol dm^{-3}.

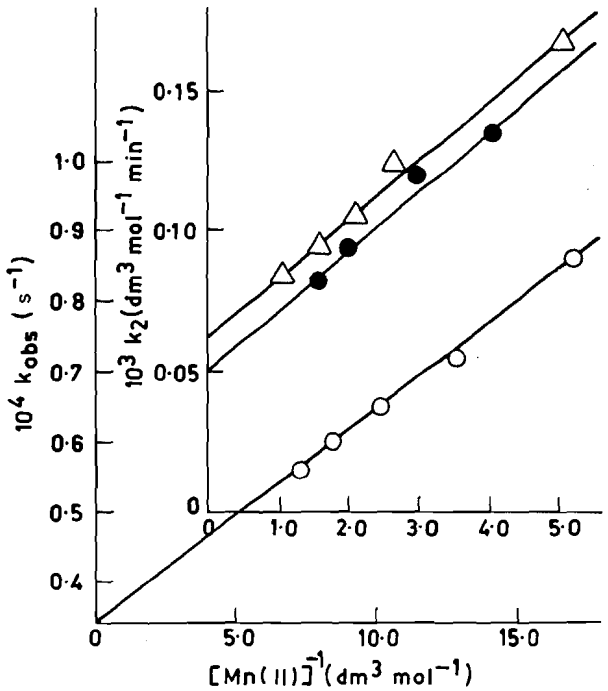

FIG. 1. Plots of k_{obs} against $[Mn^{II}]^{-1}$. The innermost plot between k_2 (dm^3 mol^{-1} min^{-1}) and $[Mn^{II}]^{-1}$ in the oxidation of methanol, at different acidities, is based on the rate data of ref. 4. The plots are (○) for *n*-propanol, and for methanol at $[HClO_4]$ = 1.0 (△) and (●) 2.0 mol dm^{-3} at 35°C.

Results

Dependence on $[Mn^{II}]$

The results in Table 1 at constant $[H^+]$ = 3 mol dm^{-3} and 35°C indicate that k_{obs} decreases with increasing $[Mn^{II}]$ at constant ionic strength (4 mol dm^{-3}). An analysis of the results indicated that the plot, Fig. 1, between k_{obs} and $[Mn^{II}]^{-1}$ was linear with an intercept on the rate axis. It is interesting to note

TABLE 2. Dependence of the observed rate constant k_{obs} on the initial [substrate]*

*10^3[Mn^{III}] = 2.0 mol dm^{-3}, [Mn^{II}] = 0.066 mol dm^{-3}, [$HClO_4$] = 3.0 mol dm^{-3}, I = 4 mol dm^{-3}.

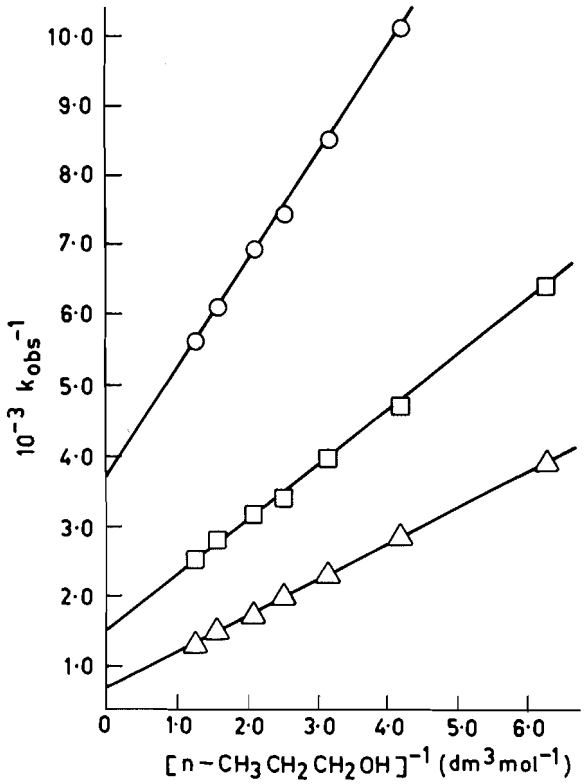

FIG. 2. Plots of k_{obs}^{-1} against [n-propanol]$^{-1}$ at (○) 35, (□) 40, and (△) 45°C. 10^3[Mn^{III}] = 2.0 mol dm^{-3}, [$HClO_4$] = 3.0 mol dm^{-3}, [Mn^{II}] = 0.066 mol dm^{-3}, and I = 4 mol dm^{-3}.

that the intercept/slope ratio is greater than 12. The significance of this ratio is discussed in a later section.

Dependence on [n-propanol]

The effect of the initial [n-propanol] on k_{obs} was investigated at different temperatures. The results in Table 2 indicated that the plot, Fig. 2, between k_{obs}^{-1} and [n-propanol]$^{-1}$ was linear with an intercept on the ordinate axis. These plots are consistent with complex formation between aquomanganese(III) ions and n-propanol (6).

Dependence on [H^+]

The results in Table 3 indicated that k_{obs} decreased with the increasing [H^+] at constant ionic strength. The actual relationship between k_{obs} and [H^+] is discussed later.

Discussion

Michaelis–Menten plots, Fig. 2, are consistent with the spectrophotometric evidence (6, 9) for the existence of Mn^{III}–Pr^{n}OH complexes. The retarding effect of [Mn^{2+}] on the observed rate could be explained by one of several possible alternatives discussed below:

(*a*) There is a possibility of the existence of equilibrium [2]. The equilibrium constant K for equilibrium [2] has an upper limit of 10^{-2} in 6 mol dm^{-3} perchloric acid (10) which is consistent with the value found in sulphuric acid (11) and the conclusions of Wells and Davies (12). The equilibrium [2] is attractive in the sense that alcohols are reported (13) to be oxidised by Mn^{IV}. However, consideration of this equilibrium implies that the reaction, at least partially, has a second order dependence in [Mn^{III}] which is contrary to the observed first-order dependence in [Mn^{III}].

[2] $Mn^{III} + Mn^{III} \rightleftarrows Mn^{IV} + Mn^{II}$

(*b*) The retardation in k_{obs} was also expected if Mn^{II} complexes the reductant which would cause a decrease in the reactive [n-propanol]. This possibility was not favoured because no spectral change in the uv–visible region was observed in the spectra of Mn^{II} in the presence of n-propanol. A similar conclusion is based on the absence of any effect of Mn^{II} on the spectra of Mn^{III} in aqueous methanol. Further a rate law deduced with this assumption predicted a linear correlation between k_{obs}^{-1} and [Mn^{II}]. However, a curved plot is obtained when k_{obs}^{-1} is plotted against [Mn^{II}], which eliminates this possibility.

(*c*) There could be a reversible rate determining reaction [3] where Ṡ is the free radical corresponding to the substrate SH. A variation of this idea in which an interaction between Mn^{II} and the free radical $\dot{C}H_2OH$ was assumed inside the solvent cage whose walls contained additional Mn^{II} ions at high [Mn^{II}] was considered in the oxidation of methanol (4).

[3] Mn^{III}–SH $\rightleftarrows Mn^{II} + \dot{S} + H^+$

This proposal is not favoured because Mn^{II} did not retard the rate of oxidation of glycolic acid (5) which gives the same free radical $\dot{C}H_2OH$ produced in the oxidation of methanol (4). There seems to be no reason to believe that, unlike the Mn^{III}–methanol complex, the Mn^{III}–glycolic acid complex cannot undergo intramolecular electron transfer inside the solvent cage. Moreover, the rate law deduced with this assumption is not consistent with the correlation between k_{obs} and [Mn^{II}]$^{-1}$ in Fig. 1.

Mechanism

The following mechanism, consisting of reactions [4]–[11], is suggested for the oxidation of n-propanol. It is consistent with the observed linearity of the plot between k_{obs} and [Mn^{II}]$^{-1}$ illustrated in Fig. 1. Reaction [4] is well established hydrolytic equilibrium between Mn^{3+}(aq) and $MnOH^{2+}$(aq) ions. The value of K_h at different temperatures was obtained from the known ΔH_h value (12). Reaction [5] is consistent with the known protonation of alcohols in aqueous solutions of strong mineral acids (14). The formation of $C_3H_7OHMn^{3+}$(aq) and $C_3H_7OMn^{2+}$(aq) complexes is consistent with the spectrophotometric studies reported earlier (6, 9).

[4] $Mn^{3+}(aq) \overset{K_h}{\rightleftharpoons} MnOH^{2+}(aq) + H^+$

[5] $C_3H_7OH + H^+(aq) \overset{K_c}{\rightleftharpoons} C_3H_7OH_2^+$

2.50	4.46	8.8	22.0	36.5					

*$10^3[Mn^{III}]$ = 2.0 mol dm^{-3}, $[Mn^{II}]$ = 0.066 mol dm^{-3}, $[Pr^nOH]$ = 0.2 mol dm^{-3}, I = 4 mol dm^{-3}.

[6] $C_3H_7OH + Mn^{3+}(aq) \overset{\beta}{\rightleftharpoons} C_3H_7OHMn^{3+}(aq)$

[7] $C_3H_7OH + MnOH^{2+}(aq) \overset{\beta_1}{\rightleftharpoons} C_3H_7OMn^{2+}(aq) + H_2O$

[8] $C_3H_7OHMn^{3+}(aq) \overset{K_a}{\rightleftharpoons} C_2H_5CH_2\overset{+}{O}H + Mn^{2+}$

[9] $C_2H_5CH_2\overset{+}{O}H \overset{k}{\rightarrow} C_2H_5\dot{C}HOH + H^+$

[10] $C_2H_5CH_2OMn^{2+}(aq) \xrightarrow{k_1} C_2H_5\dot{C}HOH + Mn^{2+}$

[11] $C_2H_5\dot{C}HOH + Mn^{III} \xrightarrow{fast} C_2H_5CHO + Mn^{II} + H^+$

Based on the above sequence of reactions, the rate of disappearance of $[Mn^{III}]$ is given by eq. [12].

$$[12]\quad \frac{-d[Mn^{III}]}{dt} = \frac{2(kK_a\beta[Mn^{II}]^{-1} + k_1\beta_1K_h[H^+]^{-1})[Mn^{III}][C_3H_7OH]}{(1 + K_c[H^+])(1 + K_h[H^+]^{-1}) + (\beta + \beta_1K_h[H^+]^{-1})[C_3H_7OH]}$$

where reaction [9] is considered as disproportionation of $C_2H_5CH_2\overset{+}{O}H$ ion and not as a deprotonation reaction. Further if reaction [9] is considered reversible, then there is a need to consider a rate-limiting reaction which is obviously the reaction of $C_2H_5\dot{C}HOH$ radical with Mn^{III} ion. The resultant rate law under this condition will thus have a second order term in Mn^{III} which is contrary to the first order dependence in $[Mn^{III}]$.

It might be noted that reactions [8] and [10] differ by protonation, yet reaction [8] is written as an equilibrium reaction because of the demand to explain the retardation of Mn(II) in such a way that the plot of k_{obs} and $[Mn^{II}]^{-1}$ has an intercept on the rate ordinate. If reaction [10] is also considered to be reversible, the retardation by Mn(II) could still be explained but the resultant rate law will no longer explain the intercept on the rate ordinate. The plot will be expected to pass through the origin.

Equation [12] is consistent with the observed linearity of the plot between k_{obs} and $[Mn^{II}]^{-1}$ in Fig. 1. Also illustrated are two other linear plots based on the rate data taken from the study of Wells and Barnes (4) for the oxidation of methanol at different acidities. The linearity of these two latter plots indicates that the mechanism proposed here is equally applicable to the oxidation of methanol (4) and there is no need for the assumption made (4) to explain the retarding effect of Mn^{2+} ions.

Now if we assume that $\beta \approx \beta_1$, eq. [12] is simplified to eq. [13] which can be rearranged to eq. [14]. The latter equation is consistent with the linearity of the plots between k_{obs}^{-1} and $[C_3H_7OH]^{-1}$ illustrated in Fig. 2. The slopes and intercepts of these plots are given by eqs. [15] and [16], respectively. The intercept/slope ratio, eq. [17], can be used to calculate the value of β_1. The value of β_1 obtained at different temperatures, Table 4, are essentially constant within the experimental limits. Hence the assumption of rapid equilibria [6] and [7] is justified.

$$[13]\quad k_{obs} = \frac{2\beta_1(kK_a[Mn^{II}]^{-1} + k_1K_h[H^+]^{-1})[C_2H_5CH_2OH]}{(1 + K_cH^+])(1 + K_h[H^+]^{-1}) + \beta_1(1 + K_h[H^+]^{-1})[C_2H_5CH_2OH]}$$

$$[14]\quad k_{obs}^{-1} = \frac{(1 + K_c[H^+])(1 + K_h[H^+]^{-1})}{2\beta_1(kK_a[Mn^{II}]^{-1} + k_1K_h[H^+]^{-1})[C_3H_7OH]} + \frac{(1 + K_h[H^+]^{-1})}{2(kK_a[Mn^{II}]^{-1} + k_1K_h[H^+]^{-1})}$$

$$[15]\quad \text{Slope} = \frac{(1 + K_c[H^+])(1 + K_h[H^+]^{-1})}{2\beta_1(kK_a[Mn^{II}]^{-1} + k_1K_h[H^+]^{-1})}$$

$$[16]\quad \text{Intercept} = \frac{(1 + K_h[H^+]^{-1})}{2(kK_a[Mn^{II}]^{-1} + k_1K_h[H^+]^{-1})}$$

$$[17]\quad \frac{\text{Intercept}}{\text{Slope}} = \frac{\beta_1}{1 + K_c[H^+]}$$

It should be noted that the value of K_c for *n*-propanol is available (14) only at 25°C. The temperature dependence of K_c for methanol (15) exhibits a slight maximum. Assuming similar behaviour for *n*-propanol, it is considered that the use of K_c(25°C) at other temperatures does not lead to serious error in the determination of β_1 from eq. [17].

Equation [18], obtained from [13], indicated that a plot of the left hand term against $[H^+]^{-1}$ should be linear with an intercept

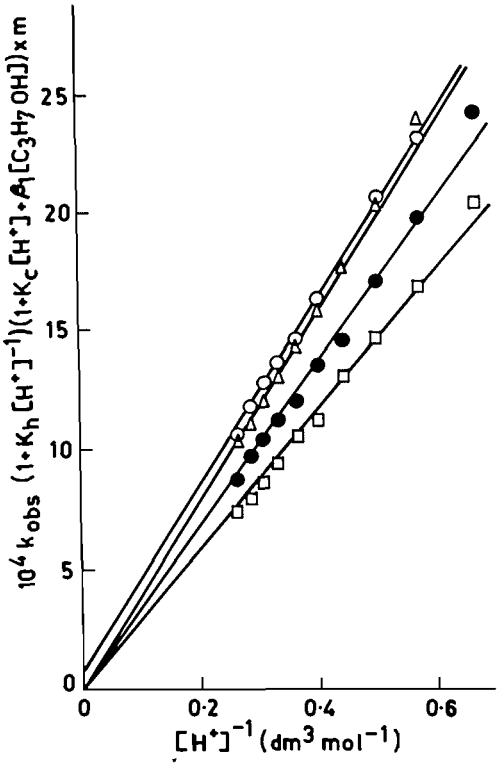

FIG. 3. Plots between k_{obs} $(1 + K_h[H^+]^{-1})(1 + K_c[H^+] + \beta_1[C_3H_7OH]) \times m$ and $[H^+]^{-1}$ at 30°C with $m = 0.1$ (○), 35°C with $m = 0.25$ (●), 40°C with $m = 0.8$ (□), and 45°C with $m = 1$ (△). $10^3[Mn^{III}] = 2.0$ mol dm^{-3}, $[Mn^{II}] = 0.066$ mol dm^{-3}, $[C_3H_7OH] = 0.2$ mol dm^{-3}, and $I = 4$ mol dm^{-3}.

on the rate ordinate. The plots at 35, 40, and 45°C, Fig. 3, have zero intercept indicating that $kK_a[Mn^{II}]^{-1} \ll k_1K_h$.

$$[18]\quad k_{obs}(1 + K_h[H^+]^{-1})(1 + K_c[H^+] + \beta_1[C_3H_7OH]) = 2\beta_1(kK_a[Mn^{II}]^{-1} + k_1K_h[H^+]^{-1})[C_3H_7OH]$$

However, the plot at 30°C does have an intercept on the rate ordinate confirming the validity of the eq. [18] at least at lower temperatures. The intercept $kK_a[Mn^{II}]^{-1}$, is 1×10^{-5} s^{-1}, and since $[Mn^{II}] = 0.066$ mol dm^{-3} the value of kK_a is 6.6×10^{-7} mol dm^{-3} s^{-1}. The corresponding slope value $K_1K_h = 2.28 \times 10^{-4}$ mol dm^{-3} s^{-1}, which explains the small retarding effect of Mn^{II}. The k_1 values at different temperatures, obtained from the slopes of Fig. 3 are given in Table 5 together with calculated activation parameters.

TABLE 5. Rate constant k_1 at different temperatures*

T (°C)	$10^4 k_1$ (s^{-1})
30	2.0
35	5.3
40	13
45	17

*Activation parameters are $\Delta H^{\ddagger} = 116 \pm 10$ kJ mol^{-1} and $\Delta S^{\ddagger} = 140 \pm 16$ kJ mol^{-1}.

The oxidation of *n*-propanol is faster than that of isopropanol (2) and the two oxidations appear to have different mechanisms. The formation of Pr^nOH–Mn^{III} complexes lowers the energy of activation. The $\Delta H^{\ddagger}$ value for *n*-propanol is about 12 kJ mol^{-1} less than that for isopropanol. Similarly the $\Delta S^{\ddagger}$ value for *n*-propanol is more positive because the formation of Pr^nOH–Mn^{III} complexes causes much more restructuring of the solvent molecules than caused by the approach of isopropanol and Mn^{III} molecules to a minimum distance before the electron is transferred. The formation of Pr^nOH–Mn^{III} in reaction [8] may explain the retarding effect of Mn^{II} ion: Mn^{II} retards the rate of oxidation of primary alcohols whereas it has no effect in the oxidation of *s*-alcohols.

Preparation of α-aminothioamides from aldehydes

MARTINO PAVENTI AND JOHN T. EDWARD
Department of Chemistry, McGill University, 801 Sherbrooke Street West, Montreal (Que.), Canada H3A 2K6

Received January 24, 1986[1]

MARTINO PAVENTI and JOHN T. EDWARD. Can. J. Chem. **65**, 282 (1987).

The conversion of aldehydes into α-aminonitriles and thence into imidazolidin-4-thiones has been studied. Hydrolysis of the appropriate imidazolidin-4-thiones gave thioamides of nine naturally occurring α-amino acids. The possible pre-biotic significance of these compounds is discussed.

MARTINO PAVENTI et JOHN T. EDWARD. Can. J. Chem. **65**, 282 (1987).

On a étudié la transformation des aldéhydes en α-amino-nitriles et éventuellement en imidazolidinethiones-4. L'hydrolyse des imidazolidinethiones-4 appropriées conduit aux thioamides de neuf acides α-aminés naturels. On discute de l'implication pré-biotique possible de ces composés.

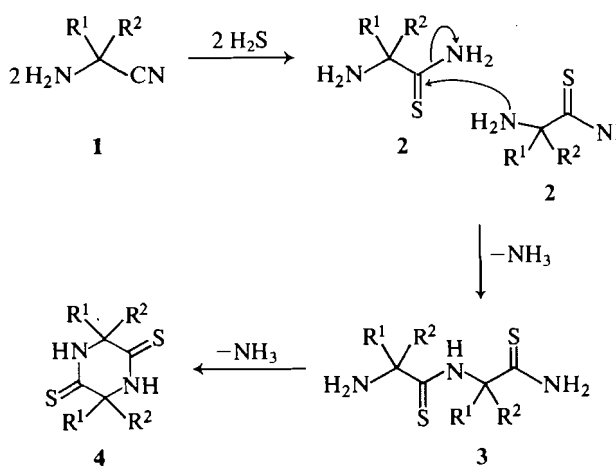
In 1953, Miller (1) showed that sparking a mixture of methane, ammonia, hydrogen, and water vapour furnished traces of glycine, alanine, and other common α-amino acids. This historic experiment awakened the interest of many organic chemists in possible pre-biotic routes to proteins, nucleic acids, and polysaccharides on the primitive earth.

It seems likely that under the conditions of Miller's experiment aldehydes and hydrogen cyanide are formed (2). These can react with ammonia to give α-aminonitriles **1**, which are hydrolysed to α-amino acids (2). However, the polymerization of α-amino acids to polypeptides and proteins requires an activation process. Various possible modes of activation that might operate under pre-biotic conditions (heat, cyanamide, adsorption on clays, etc.) have been suggested (2, 3) but are not very plausible.

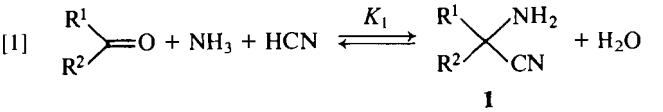
This activation step might have been avoided on the primitive earth if α-aminonitriles had been converted into reactive α-amino acid derivatives rather than into unreactive α-amino acid zwitterions. One such derivative might have been the thioamide. The reactivity of these compounds was demonstrated more than 70 years ago by Johnson and Burnham (4), in the course of their attempts to obtain the thioamide **2** ($R^1 = R^2 = H$) by treatment of the nitrile **1** ($R^1 = R^2 = H$) with hydrogen sulfide (a constituent of the earth's primitive atmosphere (3)) in ethanol saturated with ammonia. They obtained instead a small amount of the thiodipeptide derivative **3** ($R^1 = R^2 = H$), and possibly of the thiotripeptide and larger amounts of the cyclic product **4** ($R^1 = R^2 = H$), all presumably arising from further reaction of the sought-for thioamide **2** ($R^1 = R^2 = H$) (Scheme 1). Later attempts by Gatewood and Johnson (5, 6) to obtain other α-aminothioamides by this route gave either no product (6), or products from further reaction of initially formed α-aminothioamides (5, 6). However, Cook *et al.* (7) obtained **2** (R^1 = Ph, $R^2 = H$) in 12% yield by treating **1** (R^1 = Ph, $R^2 = H$) with H_2S for 24 h in ether containing a little pyridine.



SCHEME 1

This work indicates a possibility of producing thiopolypeptides and thence polypeptides by the general route of Scheme 1. Consequently, we have prepared α-aminothioamides **2** corresponding to several common α-amino acids as a preliminary to searching for conditions to convert them into linear thiopolypeptides.

We first required a convenient and general preparation of α-aminonitriles **1**. These compounds have long been obtained by the Strecker reaction:



[1]

1

but yields are often low and the products often decompose on standing. Commeyras *et al.*, in a masterly series of papers (reviewed in ref. 8), have explained the thermodynamic and kinetic factors underlying the formation of **1**. Because of the reversibility of the reaction, α-aminonitriles decompose completely in solutions sufficiently acidic to convert NH_3 to NH_4^+, and in solutions sufficiently alkaline to convert HCN into CN^-. Consequently the pH most favourable for the formation of **1** is ca. 9.2, given by the equation

$$[2] \quad pH = \frac{1}{2}(pK_{HCN} + pK_{NH_4^+})$$

However, while α-aminonitriles are thermodynamically unstable in weakly acid solution, complete protonation of $-NH_2$ to $-NH_3^+$ by strong acid renders them kinetically stable. Based on these considerations, we devised a simple two-phase (2P) procedure for the synthesis of these compounds. For safety and convenience, NH_4Cl and NaCN (≡ NaCl + NH_4CN ≡ NaCl + NH_3 + HCN) were used instead of liquid or gaseous NH_3 and HCN; enough aqueous ammonia was added to buffer the system to pH ≈ 9. The reaction was started in the two-phase system THF–H_2O (salts), but water was removed during the course of

[1]Revision received September 22, 1986.

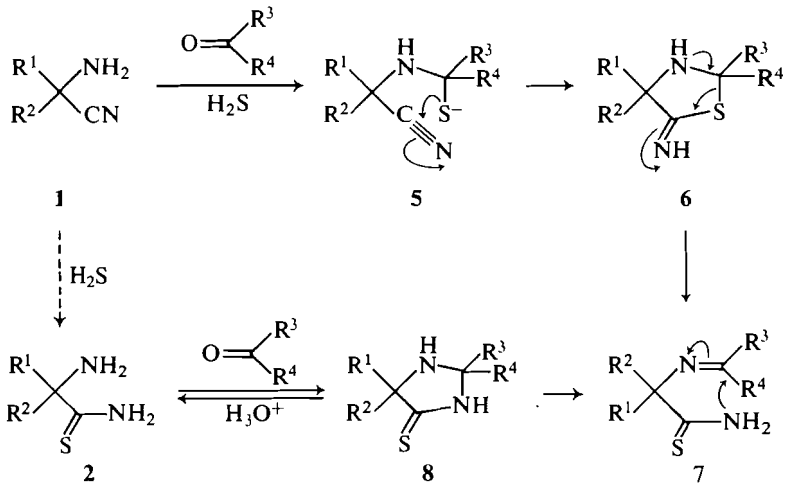

SCHEME 2

the reaction by addition of anhydrous sodium sulfate, to push reaction [1] to the right. The product was isolated as the stable and relatively insoluble hydrochloride or nitrate by treating the oily product in diethyl ether with HCl gas or 70% HNO_3. No systematic studies were made to optimize the yields shown in Table 1, but it is evident that the two-phase procedure usually gave better yields of α-aminonitriles from aldehydes (R^1 = H), if not from ketones, than the procedures described in the literature. This may be due in part to the isolation of the α-aminonitriles as salts rather than as the unstable free bases.

The identity of the α-aminonitrile salts was confirmed by their ir and nmr spectra, and by their conversion into the stable hydantoins when heated with ammonium carbonate (24). The ir spectra of the α-aminonitrile salts did not show a C≡N stretching band at 2200 cm^{-1}, but were otherwise unexceptional.

The formation of α-aminothioamides from the treatment of α-aminonitriles with hydrogen sulfide was mentioned above. This is a capricious reaction. Thus treatment of α-aminobenzyl cyanide (**1**; R^1 = Ph, R^2 = H) with hydrogen sulfide in 95% ethanol for 24 h gave the polymer $-(CH_2Ph\text{-}S)-_n$ (25), presumably because of the reversibility of [1] under these conditions. We have found the most convenient preparation of α-aminothioamides to be that of Cook, Heilbron, and Mahadevan (7), in which α-aminonitriles are treated with hydrogen sulfide and a ketone (a plausible pre-biotic reagent (26)) in basic solution to afford imidazolidin-4-thiones **8** in good yield[2] (Scheme 2). These in turn may be hydrolysed in dilute acids to yield α-aminothioamides **2** (7, 28).

Cook *et al.* (7) proposed that the imidazolidin-4-thiones **8** were formed by the route **1** → **2** → **8**. However, the rate of formation of **8** is much too great for this mechanism, when account is taken of the slowness of the proposed step **1** → **2**. Thus α-aminobenzyl cyanide (**1**; R^1 = pH, R^2 = H) reacted with hydrogen sulfide and cyclohexanone within ten minutes to give a 30% yield of the imidazolidin-4-thione **8** (R^1 = Ph, R^2 = H, R^3R^4 = $-(CH_2)_5-$); within an hour the reaction was essentially complete. In this time no detectable amount of the α-aminothioamide **2** (R^1 = Ph, R^2 = H) is formed by reaction of the α-aminonitrile with hydrogen sulfide.

A more plausible mechanism is the "assisted" thiohydrolysis of the nitrile group shown in Scheme 2. This mechanism parallels the assisted hydrolysis of the nitrile group of α-aminonitriles in the presence of aldehydes or ketones in basic

[2]The procedure described in the experimental section is a considerable improvement over those described in the literature (7, 27). In particular, some of the procedures of Asinger *et al.* (27) are unnecessarily complicated because of mistaken ideas of the mechanism of the reaction.

[g]Reported (27) yield 98%, mp 228.5°C.

solution to give the Schiff bases **7** (O in place of S), very thoroughly studied by Commeyras and others (29–32). The two reactions differ in that further cyclization of the Schiff bases **7** (O in place of S) requires strongly basic conditions or heating (32, 33), while cyclization of the corresponding thio compounds **7** → **8** takes place very easily, so that imidazolidin-4-thiones **8** are the ultimate products of this procedure.

The imidazolidin-4-thiones **8** from the reaction of α-aminobenzyl cyanide with H_2S and various ketones are listed in Table 2. None of the ketones gave significantly higher yields than cyclohexanone, as would be expected from the fact that cyclohexanone is one of the most reactive of the common ketones (34).[3] Consequently, the other α-aminonitriles were treated only with acetone and (or) cyclohexanone in the presence of hydrogen sulfide to give the imdazolidin-4-thiones listed in Table 3. Yields were good to excellent with all the α-aminonitriles (**1**; R^2 = H) derived from aldehydes, but poorer with the α-aminonitriles (**1**; R^1 and R^2 alkyl) derived from ketones, perhaps because of steric hindrance to the step **1** → **2** of the overall reaction sequence. Furthermore, in 95% ethanol the reaction with H_2S and ketones of α-aminonitriles having both R^1 and R^2 alkyl sometimes gave mixtures of products, because the slowness of the reaction sequence **1** → **5** → **8** gave time for appreciable decomposition of the α-aminonitrile to ketone, HCN, and NH_3 (8). Thus, the reaction of the α-aminonitrile **10** with acetone and H_2S would be expected to give only the imidazolidin-4-thione **9**. In fact, a mixture of the imidazolidin-4-thiones **9**, **11**, and **12** was obtained in the yields shown in Scheme 3.[4] These latter products require the decomposition of **10** to cyclohexanone, which can then react with more **10** and H_2S to form **11**, and to ammonia and hydrocyanic acid, which can then react with acetone to form the α-aminonitrile **13** and thence **12**.

The ease of acid hydrolysis of imidazolidin-4-thiones to α-aminothioamides and ketones depends upon their substitution pattern. When R^2 = H (i.e., the original α-aminonitrile was derived from an aldehyde) and $R^3 = R^4$ = Me (i.e., acetone was used in the assisted thiohydrolysis), the imidazolidin-4-thione was readily hydrolysed by one equivalent of hydrochloric acid in aqueous alcoholic solution to give the hydrochlorides of the α-aminothioamides. In this way the thioamides of the nine α-amino acids, glycine, phenylglycine, alanine, norvaline, valine, norleucine, isoleucine, leucine, and phenylalanine, were obtained as their hydrochlorides; these are listed in Table 4. However, when both R^1 and R^2 were alkyl, hydrolysis became very difficult, as already observed by Asinger *et al.*

[3]While aldehydes are more reactive than ketones in catalyzing the intramolecular assisted hydrolysis of α-aminonitriles (31), they were ineffective in promoting the conversion **1** → **8**, apparently because of their preferential reaction with H_2S to form linear or cyclic polythianes.

[4]Similar schemes can explain the formation of imidazolidin-4-thiones from the treatment of α-aminonitriles with hydrogen sulfide (6, 27) and of cyanohydrins with ammonium sulfide (27, 35).

(28). This may be explained by the mechanism[5] of Scheme 4, in which the rate-determining step is the breaking of the C—N bond of **14** to give **15** (the protonated form of **7**). Stereoelectronic theory would require the facility of this rupture to depend on the C—N bond being as closely as possible antiperiplanar to the free electron pair of nitrogen shown in **14** (36). Such an antiperiplanar arrangement requires the five-membered ring of **14** to be strongly puckered. The puckering will become difficult when R^1, R^2, R^3, and R^4 are all alkyl

[5]We are grateful to a referee for suggesting this mechanism.

groups, because then two alkyl groups are brought close together in an interaction similar to the 1,3-diaxial interaction of alkyl groups in cyclohexanes (see Scheme 4). The interconversion of **14** and **15** is a 5-*endo-trig* process (37), but is evidently not impossible here and elsewhere (29–32; see also ref. 38 and references therein).

α-Aminothioamides may be stored indefinitely as the stable hydrochlorides or other salts but, as the free bases, they decompose at differing rates into other products on standing. The nature of these products is being investigated.

Experimental

General

Melting points are uncorrected. Infrared spectra (KBr) were recorded with a Perkin–Elmer 297 spectrophotometer. Mass spectra were recorded on a Du Pont 21–492 B spectrometer. Proton magnetic resonance (^{1}H nmr) spectra in DMSO-d_6 were recorded with a Varian T-60 spectrometer using the hydrate of sodium 3-(trimethylsilyl)-1-propanesulfonate (TSPSA) as internal standard. Ultraviolet spectra were recorded using a Unicam SP800 spectrophotometer.

Two-phase procedure for preparing α-aminonitriles

The aldehyde (0.10 mol) was added to a stirred mixture of ammonium hydroxide (7.0 mL, 0.11 mol) and tetrahydrofuran (30 mL). After 10 min solid ammonium chloride or nitrate (0.10 mol) and potassium cyanide (6.51 g, 0.10 mol) were added, and the mixture was stirred for 1.5 h in a lightly stoppered flask. Then sodium sulfate (30 g) and diethyl ether (80 mL) were added, and the mixture was swirled frequently for 30 min. The solution was decanted from the solids, which were washed with ether. The combined solution and washings were concentrated under reduced pressure to a syrup, which was dissolved in ethyl ether

(300 mL). Hydrogen chloride gas was bubbled through the solution until precipitation was complete. (Alternatively, concentrated nitric acid (6 mL, ~0.10 mol) was added to the stirred ethereal solution). The solid precipitate was suction filtered, air-dried, and weighed. Yields are given in Table 1 and spectral data in Tables 5 and 6.

The two-phase mixture derived from ketones and from benzaldehyde was stirred for 7 h and dried over sodium sulfate overnight, but the procedure was otherwise identical to the one above. Recrystallization of **1** (R^1 = Ph, R^2 = H) was from ethanol/ether 1:10.

General procedure for preparing imidazolidin-4-thiones **8**

Hydrogen sulfide was bubbled for 1 h into an ethanolic solution (sometimes containing some water) (30 mL total) at 0°C containing the α-aminonitrile salt (0.020 mol), triethylamine (2.05 g, 0.020 mol), and the ketone (0.20 mol). The product started to separate after 10–45 min, depending on the ketone. After standing overnight in the stoppered reaction vessel, hydrogen sulfide was purged by a stream of N_2 that was passed into sodium hydroxide traps, the reaction vessel being kept in a water bath at 50–60°C. The suspension was then concentrated on a rotatory evaporator. The solid residue was treated with water (50 mL), removed by filtration, and washed with water (2 × 50 mL). Yields are shown in Tables 2 and 3, combustion analyses in Table 7, ir data in Table 8, and nmr data in Tables 9 and 10.

A modified procedure, in which the reaction was carried out in 30 mL of concentrated ammonium hydroxide with a little ethanol to obtain a homogenous solution, and with potassium hydroxide (1.12 g, 0.020 mol) instead of triethylamine, gave 96% and 91% yields of **8** ($R^1 = R^2 = R^3 = R^4$ = Me) and **8** ($R^1R^2 = R^3R^4 = -(CH_2)_5-$) respectively (cf. end of Table 3).

Hydrochlorides of the imidazolidin-4-thiones, prepared by bubbling hydrogen chloride into acetone solutions of the compounds, crystallized out as sharply melting, pure compounds.

*Reaction of 1-aminocyclohexane carbonitrile (**1**; $R^1R^2 = -(CH_2)_5-$) with acetone and hydrogen sulfide*

The hydrochloride (3.2 g) of the α-aminonitrile was neutralized with 2 *N* sodium hydroxide (10 mL), taken up in ether (3 × 30 mL), and dried (Na_2SO_4). The residue left by evaporation of the ether was dissolved in ethanol (10 mL) and acetone (4.5 mL), two drops of triethylamine were added, and then hydrogen sulfide was bubbled through the solution for 1.5 h. The solution was left for 24 h at room temperature, purged of H_2S by a stream of N_2, and concentrated to yield 1.2 g of white solid. Chromatography on Florisil with ethyl acetate – light petroleum yielded three compounds: cyclohexanespiro-2′-(imidazolidin-4′-thione)-5′-spirocyclohexane **11** (0.19 g), mp 227–228°C, identical (mp, ir, nmr) with authentic material (35); cyclohexanespiro-5′-(2′,2′-dimethylimidazolidin-4′-thione) **9** (0.50 g), mp 213–216°C (lit. (27) mp 215–216°C), identified by ir (Table 9) and nmr (Table 10) spectra; and 2,2,5,5-tetramethylimidazolidin-4-thione **12** (0.06 g), mp 152–156°C (lit. (6) mp 153–155°C), identified by ir (Table 9) and nmr (Table 10) spectra.

General procedure for preparing α-aminothioamide hydrochlorides

The hydrochloride of the requisite imidazolidin-4-thione **8** (R^2 = H) (0.010 mol) in 95% ethanol (15 mL) containing 3 drops of ethanolic hydrogen chloride (4.0 *M*) was refluxed for 2 h. The solution was evaporated under reduced pressure and the residual solids were recrystallized from acetonitrile. Yields are shown in Table 4. The hydrochloride of the thioamide of alanine turned out to be an oil, and so was treated in ethanol with excess bicarbonate and, isolated as

YANNICK VALLEE, JEAN-LOUIS RIPOLL, CHRISTOPHE LAFON, and GENEVIÈVE PFISTER-GUILLOUZO. Can. J. Chem. **65**, 290 (1987).

The flash vacuum pyrolysis of Diels–Alder adducts of anthracene constitutes a rapid and selective route to methanethial **1** and methanethial *S*-oxide **2**, as analyzed in the gas phase by photoelectron spectroscopy. Low temperature infrared and nuclear magnetic resonance (^1H, ^{13}C) spectra are also reported for sulfine **2**.

YANNICK VALLEE, JEAN-LOUIS RIPOLL, CHRISTOPHE LAFON et GENEVIÈVE PFISTER-GUILLOUZO. Can. J. Chem. **65**, 290 (1987).

La thermolyse éclair d'adduits de Diels–Alder dérivés de l'anthracène constitue une voie d'accès rapide et sélective au méthanethial **1** et au *S*-oxyde de méthanethial **2**, analysés en phase gazeuse par spectrométrie photoélectronique. Les spectres infrarouge et de résonance magnétique nucléaire (^1H et ^{13}C) à basse température sont également rapportés pour la sulfine **2**.

Introduction

The title compounds, methanethial **1** (thioformaldehyde) and methanethial *S*-oxide **2**, first members in the classes of thioaldehydes and sulfines, respectively, present a particular interest related to their simplicity (four and five atoms) and high reactivity. Methanethial **1** is also an interstellar molecule (1).

The Diels–Alder cyclo-addition and reversion has been employed several times as a protection–regeneration sequence for the purification of substituted thioaldehydes (2). Methanethial **1** and its *S*-oxide **2**, when generated by other thermal decompositions or eliminations, are easily contaminated with volatile co-formed reaction products and/or starting materials; these methods thus require careful optimization of the experimental conditions (3, 4).

The retro-Diels–Alder reaction under flash vacuum pyrolysis (fvp), hitherto not applied to the synthesis of **1** or **2**, was expected by us to constitute a simple, rapid alternative synthetic route. The anthracene adducts **3** and **4**, smoothly prepared from thiophosgene and anthracene (5), should lead more readily to clean thio-compounds **1** and **2**, owing to the low-volatility of both the precursors **3** or **4** and the formed anthracene (Fig. 1) (the formal Diels–Alder adduct between sulfene $H_2C{=}SO_2$ and anthracene, closely related to **3** and **4**, gives upon pyrolysis SO_2 elimination in place of the $(4\pi + 2\pi)$ cycloreversion (6)).

Experimental

Adducts **3** and **4** were sublimed under 10^{-6} Torr through a short path fvp oven (quartz tube 6 cm length × 1.6 cm i.d.). Anthracene, and eventually the unreacted starting material, crystallized immediately at the exit of the oven. Volatile products were condensed at 77 K, on frozen $CFCl_3$ for nmr analysis and attempts at chemical trapping, or on a NaCl pellet for ir spectroscopy (see ref. 7 for more experimental details). Gas phase analysis was performed, as previously described (8), by direct coupling of the fvp oven with a Helectros 0078 photoelectron spectrometer. The present impurities (CS_2, H_2S, SO_2) were identified by comparing their photoelectron spectra with those of authentic samples (9).

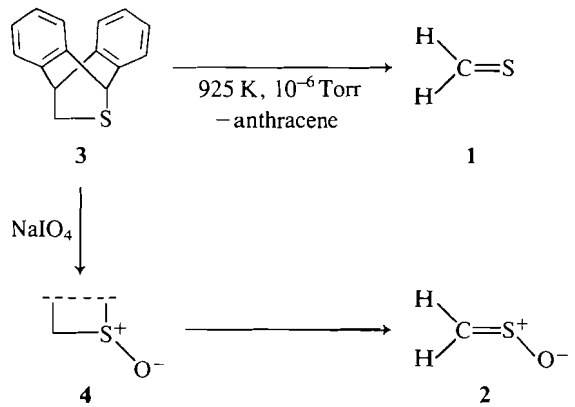

FIG. 1. Flash vacuum pyrolysis to synthesize **1** and **2**.

Results and discussion

A complete cycloreversion of sulfide **3** takes place at an oven temperature of 925 K, leading to anthracene in ~100% yield. Whereas only polymeric methanethial **1** was observed both in condensed phase and in solution (^1H nmr (CCl_4) 4.03 and 4.10 ppm; ir (film) 1368, 1173, 735, and 708 cm^{-1}, in agreement with ref. 10), the gas phase photoelectron analysis indicates the presence of monomeric **1** in a practically pure state (ionisations at 9.36, 11.87, 14.02, and 15.23 eV, in good agreement with ref. 11), the only impurities being traces of CS_2 and H_2S (Fig. 2).

On the other hand, the fvp of sulfoxide **4** at 925 K gives, besides anthracene (quantitatively obtained) and polymeric material, methanethial *S*-oxide **2** as evidenced by its nmr spectra recorded at 173 K (δ ^1H ($CFCl_3$): 7.73 and 7.84 ppm (2H AB, J 5.5 Hz); δ ^{13}C ($CFCl_3$ + CD_2Cl_2): 158.8 ppm; spectra in accordance with those of substituted sulfines (3, 12), no nmr data were hitherto reported for sulfine **2** itself). A rapid loss of the signals attributed to **2** takes place upon warming, and the concomitant formation of an insoluble white polymer is observed (attempts at trapping **2** by methyllithium, cyclopentadiene, or 1,3-diphenylisobenzofuran were unsuccessful).

The ir spectrum of the pyrolysis product of **4**, recorded

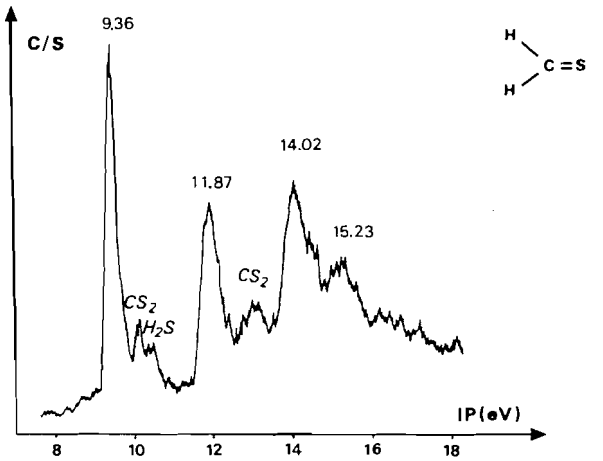

FIG. 2. Photoelectron spectrum of methanethial, **1**.

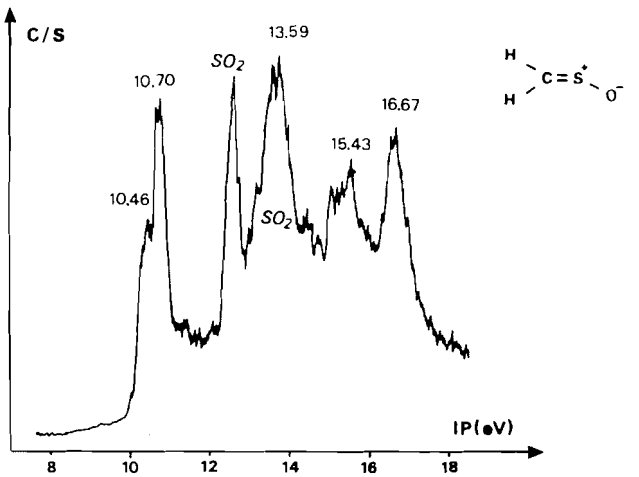

FIG. 3. Photoelectron spectrum of methanethial *S*-oxide, **2**.

under vacuum at 77 K, shows main transient absorptions at 1375, 1125, and 820 cm^{-1} and weaker bands at 3100 and 990 cm^{-1}. They are replaced at about 173 K by an intense band at 1048 cm^{-1}, assigned to polymers. Owing to the different conditions, these bands may be compatible with those reported in an argon matrix for sulfine **2** (13) (1357, 1165, 767 cm^{-1}). Also, fvp of the reported precursor of **2**, 1,3-dithietane-1-oxide (14), gave in our experimental conditions, in a less pure state, the above described ^1H nmr and ir spectra attributed to sulfine **2** in the pyrolysis of sulfoxide **4**.

The photoelectron spectrum of the pyrolysis product of **4** also agrees with that described for sulfine **2** (15) (Fig. 3); the characteristic ionisation pattern of SO_2, a known evolution product of **2** in the gas phase (14), is the only observed impurity.

Received September 27, 1985[3]

RONALD J. LAFRANCE, HARTFORD W. MANNING, and KEITH VAUGHAN. Can. J. Chem. **65**, 292 (1987).

A series of 4-hydroxy-3,4-dihydro-1,2,3-benzotriazines ("triazinols"), potential pro-drugs for the cytotoxic monoalkyltriazenes, have been investigated for anti-tumor activity and have been found to have marginal activity against the TLX5 tumor. The in vivo anti-tumor activity correlates with previously observed in vitro cytotoxicity of the compounds. The chemical behaviour of the triazinols is consistent with carbinolamine ⇌ triazene ring-chain tautomerism in solution. The triazinols undergo methanolysis to give a series of new 4-methoxytriazines; the rate of methanolysis is primarily dependent on the substituent at C-4 of the triazinol. Those triazinols that undergo methanolysis rapidly are also more active biologically, suggesting that cytotoxicity and anti-tumor activity derive from the *in situ* generation of the open chain triazene.

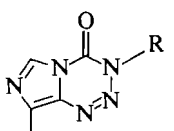
RONALD J. LAFRANCE, HARTFORD W. MANNING et KEITH VAUGHAN. Can. J. Chem. **65**, 292 (1987).

On a évalué l'activité contre les tumeurs d'une série d'hydroxy-4 dihydro-3,4 benzotriazines-1,2,3 («triazinols»), des pro-drogues potentielles pour les monoalkyltriazènes cytotoxiques; on a trouvé que ces composés n'ont qu'un effet marginal sur les tumeurs TLX5. Il existe une corrélation entre l'activité in vivo contre les tumeurs et la cytotoxicité in vitro observée antérieurement pour ces composés. Le comportement chimique des triazinols en solution est en accord avec une tautomérisation cycle/chaîne carbinolamine ⇌ triazène. Les triazinols subissent une méthanolyse qui conduit à une série de nouvelles méthoxy-4 triazines; les vitesses de méthanolyse dépendent principalement de la nature du substituant en position C-4 du triazinol. Les triazinols qui subissent la méthanolyse le plus rapidement sont aussi les composés qui sont les plus actifs d'un point de vue biologique; ces résultats suggèrent que la cytotoxicité ainsi que l'activité contre les tumeurs provient de la génération *in situ* du triazène en chaîne ouverte.

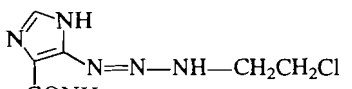
[Traduit par la revue]

Introduction

Imidazotetrazinones (**1**) have been shown to possess pronounced anti-tumor activity against mouse L1210 and P388 leukemias (1), and one of these agents, the N-chloroethyl derivative ("mitozolomide," CCRG 81010, M&B 39565, NSC 353451) has entered Phase II clinical trial (2). A mechanism of action study of this novel and potent anti-tumor agent has shown (3) that cytotoxicity is exerted by a metabonate of the drug and that the most likely species responsible for cytotoxicity is the monochloroethyltriazenoimidazole ("MCTIC") (**2**). Thus



1



2

mitozolomide acts as a "pro-drug," without the need for metabolic activation, for the cytotoxic monoalkyltriazene, in contrast to the anti-tumor dimethyltriazenes, which require metabolic N-demethylation to generate the cytotoxic monomethyltriazene (4).

The observation that mitozolomide is indeed a pro-drug for an acyclic triazene suggests that other nitrogen-containing heterocycles with NNN linkages might act as slow release forms of cytotoxic triazenes. In a previous report (5), it was shown that *o*-acylphenyltriazenes (**3**) undergo facile cyclization to the novel 4-hydroxy-3,4-dihydrobenzo-1,2,3-triazines ("triazinols", e.g. **4**). Nuclear magnetic resonance spectra of these novel cyclic carbinolamines suggest that they exist in equilibrium with the open-chain triazene tautomers in solution, and these triazinols have been shown to be cytotoxic towards M21 tumor cells in vitro *without* metabolic activation (6). These preliminary observations prompted us to investigate the anti-tumor activity of the triazinols and to determine the extent to which biological activity correlates with the tendency of the molecules towards ring-chain tautomerism with the open-chain triazenes.

The triazinols are important to us not only for their potential as anti-tumor agents. It has not escaped our attention that these 4-hydroxy-1,2,3-benzotriazines represent rare examples of stable α-carbinolamines (i.e., —N—C—OH). Although such species are widely reported in the literature as transient metabolites of N-alkyl xenobiotic molecules (7), very few examples of stable carbinolamines are available chemically for direct study. Thus molecules of type **4** represent excellent model compounds to test some widely accepted metabolic hypotheses. In this paper, we report (a) some chemistry of the cyclic triazinol – acyclic triazene system, (b) the anti-tumor evaluation of representative molecules of this series, and (c) some observations relevant to the metabolism of N-alkyl xenobiotic molecules.

Experimental

Synthesis

The 4-hydroxy-3,4-dihydro-1,2,3-benzotriazines (**4**, **5**, **7**, **8**, **10**, **13**) were prepared by the reported method (5).

*3-(2-Chloroethyl)-4-hydroxy-3,4-dihydro-1,2,3-benzotriazine (**6**)*

2-Aminobenzaldehyde (15 mmol) dissolved in chloroform (50 mL) was added to a solution of sodium nitrite (1.25 g) in water (50 mL) and the two-phase mixture cooled to 0°C. The cold mixture was stirred vigorously while 2 *N* hydrochloric acid (25 mL) was added dropwise. The chloroform layer was separated and washed once with water

(20 mL); the aqueous washing was combined with the aqueous diazonium salt layer. A solution of 2-chloroethylamine hydrochloride (16 mmol) in water (10 mL) was added slowly to the cold diazonium salt solution; the resulting solution was cooled below 0°C and rendered basic by the slow addition of saturated potassium carbonate solution (5 mL). The product was extracted into chloroform and evaporation of the dried chloroform extract gave the chloroethyltriazine (**6**) (10.3 mmol, 69%), mp 72–78°C; ir (Nujol): 3150 (br, OH) cm^{-1}; δ ($CDCl_3$): 3.85–4.00 and 4.21–4.38 (4H, m, $-CH_2CH_2-$), 5.87 (1H, s, CH at C-4), 7.16 (d, *J* 8.0 Hz), 7.34 (t, *J* 8.0 Hz), 7.35 (d, *J* 8.1 Hz), and 7.43 (t, *J* 7.3 Hz, aromatic) ppm; δ ($CDCl_3$): 42.8 (CH_2), 54.3 (CH_2), 73.3 (C4 of triazine), 119.4, 122.9, 126.8, 129.5, 130.0, 135.3 (arom), and 194.3 (*C*=O) ppm.

3-Alkyl-4-hydroxy-3,4-dihydro-1,2,3-benzotriazines

General procedure

The appropriate 2′-aminophenylketone (15 mmol) was dissolved in 1 *N* hydrochloric acid (50 mL), cooled to 0°C, and diazotized with sodium nitrite (15 mmol) in water (10 mL). A solution of the alkylamine hydrochloride (16 mmol) in water (10 mL) was added slowly to the diazonium salt solution; the resulting solution was cooled below 0°C and rendered basic with saturated potassium carbonate solution (5 mL). After stirring for 1 h, the precipitate was filtered, washed with water, and dried to afford the following 4-hydroxy-1,2,3-benzotriazines:

9, from 2′-aminopropiophenone and 2-chloroethylamine, 11 mmol (73%), mp 77–80°C; ir (Nujol): 3110 (br, OH) cm^{-1}; δ ($CDCl_3$): 1.20 (3H, t, *J* 8 Hz, $-CH_3$), 3.00 (2H, q, *J* 8 Hz, $-CH_2-$), 3.7–4.2 (4H, m, $-CH_2CH_2-$), and 6.9–8.0 (4H, m, arom) ppm; δ ($CDCl_3$): 8.4 (q, *J* 131 Hz, CH_3), 32.7 (t, *J* 126 Hz, N-CH_2), 42.0 (t, *J* 154 Hz, CH_2), 62.2 (t, *J* 140 Hz, CH_2), 114.3 (d, *J* 168 Hz, arom), 117.9 (s, arom), 120.2 (d, *J* 168 Hz, arom), 130.6 (d, *J* 157 Hz, arom), 134.3 (d, *J* 163 Hz, arom), 143.7 (s, arom), and 203.6 (s, C=O) ppm.

12, from 2′-aminobenzophenone and 2-chloroethylamine, 10.4 mmol (70%), mp 102–105°C; ir (Nujol): 2500–3300 (OH) cm^{-1}; δ ($CDCl_3$): 3.7–4.1 (4H, m, $-CH_2CH_2-$) and 7.2–7.9 (10H, m, arom + OH) ppm; δ ($CDCl_3$): 42.2 (CH_2), 44.3 (CH_2), 77.1 (C4 of triazine), 104.3, 111.0, 114.5, 116.8, 117.7, 127.9, 128.9, 130.8, 134.1, 134.4, 134.9, 135.5, 150.8 (arom), 199.2 (C=O) ppm.

11, from 2′-aminobenzophenone and ethylamine, 13 mmol (87%), mp 118–124°C; ir (Nujol): 3440 (br, OH) cm^{-1}; δ ($CDCl_3$): 1.3 (3H, t, *J* 8 Hz, CH_3), 3.7 (2H, br q, CH_2), 7.0–7.9 (10H, m, arom + OH) ppm.

*3-Alkyl-4-methoxy-3,4-dihydro-1,2,3-benzotriazines (**14–19**)*

General procedure

(a) The 4-hydroxy-1,2,3-benzotriazine (0.2 mmol) was dissolved in methanol (5.0 mL) and the solution stirred at room temperature until reaction was complete. Evaporation of the methanol under reduced pressure afforded the pure product as an oil.

(b) In those cases in which the 4-hydroxy-1,2,3-benzotriazine did not react readily at room temperature, the triazine was refluxed in methanol for 2 h and the product isolated as before.

Details of reaction times, reaction temperatures, and yields are given in Table 1. The 4-methoxytriazines were identified by analysis of infrared spectra and complete interpretation of ^1H nmr data (Table 1). Since the compounds were all prepared by the same sequence of reactions, and since the ^1H nmr spectra are consistent for the series, only representative compounds were analyzed (Table 2). The ^{13}C nmr data for representative compounds are as follows:

14: δ ($CDCl_3$): 40.3 (q, *J* 139 Hz, N-Me), 49.4 (dq, *J* 6, 143 Hz, O-Me), 78.9 (d, *J* 168 Hz, C4 of triazine ring), 115.3 (s, arom), 125.2 (dd, *J* 5, 163 Hz, arom), 126.9 (d, *J* 152 Hz, arom), 129.9 (dd, *J* 7, 163 Hz, arom), 130.2 (dd, *J* 8, 162 Hz), and 138.3 (t, *J* 8.3 Hz) ppm.

16: δ ($CDCl_3$): 8.5 (C-Me), 31.4 (CH_2), 35.8 (N-Me), 50.4 (O-Me), 87.2 (C4), 117.3, 124.3, 125.1, 129.6, and 139.5 (arom) ppm.

18: δ ($CDCl_3$): 42.3 (Cl-*C*H_2), 49.6 (O-*C*H_3), 54.3 (N-*C*H_2), 78.9 (*C*4), 115.6, 125.7, 126.7, 127.1, 130.4 and 136.3 (arom) ppm.

19: δ ($CDCl_3$): 41.6 (Cl-*C*H_2), 50.5 (O-*C*H_3), 50.9 (N-*C*H_2), 85.9 (*C*4), 119.8, 125.3, 127.4, 127.6, 128.2, 128.5, 129.8, 130.1, 137.9, and 143.1 (arom) ppm.

*Z-4-Ethylidene-3-methyl-3,4-dihydro-1,2,3-benzotriazine (**22**)*

(a) 4-Ethyl-4-hydroxy-3-methyl-3,4-dihydro-1,2,3-benzotriazine (**8**) (0.2 mmol) was refluxed in benzene (5 mL) containing a trace of *p*-toluenesulfonic acid for 2 h. Evaporation of the benzene under reduced pressure afforded the ethylidenebenzotriazine (**22**) (quantitative) as an oil; ^1H nmr, δ ($CDCl_3$): 1.98 (3H, d, *J* 8 Hz, *C*H_3—C=), 3.53 (3H, s, N-Me), 4.78 (1H, q, *J* 8 Hz, *H*—C=), and 7.17–7.88 (4H, m, arom) ppm; (Minor component: δ 1.94 (d), 3.52 (s), 3.60 (q), and 7.2–7.8 (m) ppm.) ^{13}C nmr δ ($CDCl_3$): 13.84 (ethylidene Me), 40.6 (N-Me), 94.6 (exocyclic sp^2 carbon of ethylidene group), 125.3, 126.0, 129.3, 129.6, 130.7/131.0, 134.0/134.4, 139.3 (arom) ppm.

(b) The 4-ethyl-4-hydroxytriazine (**8**) was dissolved in methanol and the solution stirred at room temperature for 1 h. Evaporation of the methanol afforded an oil; the nmr spectrum of the oil showed two components, the major product being the methyl ether (**16**) with a small

amount of the dehydration product (**22**). The mixture was redissolved in methanol and stirred at room temperature for 5 days. The methanol was evaporated under vacuum and the residue examined by nmr, showing the same two components as before but with the ethylidene-triazine (**22**) now the major component.

(c) 4-Ethyl-4-methoxy-3-methyl-3,4-dihydro-1,2,3-benzotriazine (**16**) was dissolved in 10% aqueous methanol and the solution left at room temperature for 24 h. Evaporation of the solution gave an oil residue; the nmr spectrum of the oil showed that the major component (77%) was the ethylidene triazine (**22**). The minor component was unchanged methyl ether (**16**).

Anti-tumor activity

In vivo anti-tumor activity against the P388 (6) and TLX5 (8) tumors was determined as described previously.

Discussion

Diazotization of the 2-acylaniline and coupling with the appropriate alkylamine affords the triazenes (**3**), which cyclize spontaneously to give the 4-hydroxytriazine, as described previously (5). A modified method for the diazotization of 2-aminobenzaldehyde is reported here, which gives improved yields of the triazinols **4** and **5**. This method was also extended to the 3-chloroethyl derivative (**6**); other chloroethyl derivatives **9** and **12** were prepared by the conventional diazotization method. The products were characterized by nmr spectroscopy, which showed some variation in the behaviour of the chloro-ethyl derivatives in deuteriochloroform solution. The 4-phenyl-(**12**) and 4-hydro-(**6**) 3-chloroethyltriazines exist in $CDCl_3$ in equilibrium with the openchain forms (**3***c* and **3***a* respectively); the ^{13}C nmr spectra of these compounds show signals from C-4 of the cyclic triazine (77.1 and 73.3 ppm respectively) and from the carbonyl carbon of the acyclic triazene (199.2 and 193.4 ppm). This behaviour is predictable, based on previous experience (5) with the N-methyl analogues. However, the 4-ethyl-3-chloroethyltriazine (**9**) is unusual in that it exists exclusively as the triazene form (**3***b*) in $CDCl_3$ solution. There is no doubt that these compounds exist in the cyclic form in the solid; the ir spectra in Nujol show an absorption band for the hydroxyl group but not for the carbonyl group.

Recrystallization of some of the triazinols from solvent mixtures containing methanol frequently resulted in failure to recover the 4-hydroxytriazine and it became apparent that the carbinolamines were undergoing methanolysis to give new products, the 4-methoxytriazines (**14–20**). When this methanolysis was studied in pure methanol, it was found that the reaction can give virtually quantitative yields of the methyl ethers and also that the rate of reaction is strongly dependent on the nature of the substituents R^1 and R^2. Table 1 summarizes the results of this study and also shows the ^{1}H nmr data of the 4-methoxytriazines.

Reaction of the 3-methyl-4-hydroxy-1,2,3-benzotriazine (**4**) with methanol takes place rapidly at room temperature and results in 100% conversion to the methoxytriazine (**14**). The analogous 3-chloroethyltriazine (**6**) also reacts rapidly at room temperature to give the analogous ether (**18**). In contrast, the 4-phenyl-4-hydroxy-3-methyltriazine (**10**) reacts much less readily in methanol and required 9 days at room temperature to achieve 82.5% conversion to the methoxymethyltriazine (**17**). When the N-Me group of **10** is replaced by N-chloroethyl, i.e., in **12**, the reactivity is restored and the rate of conversion

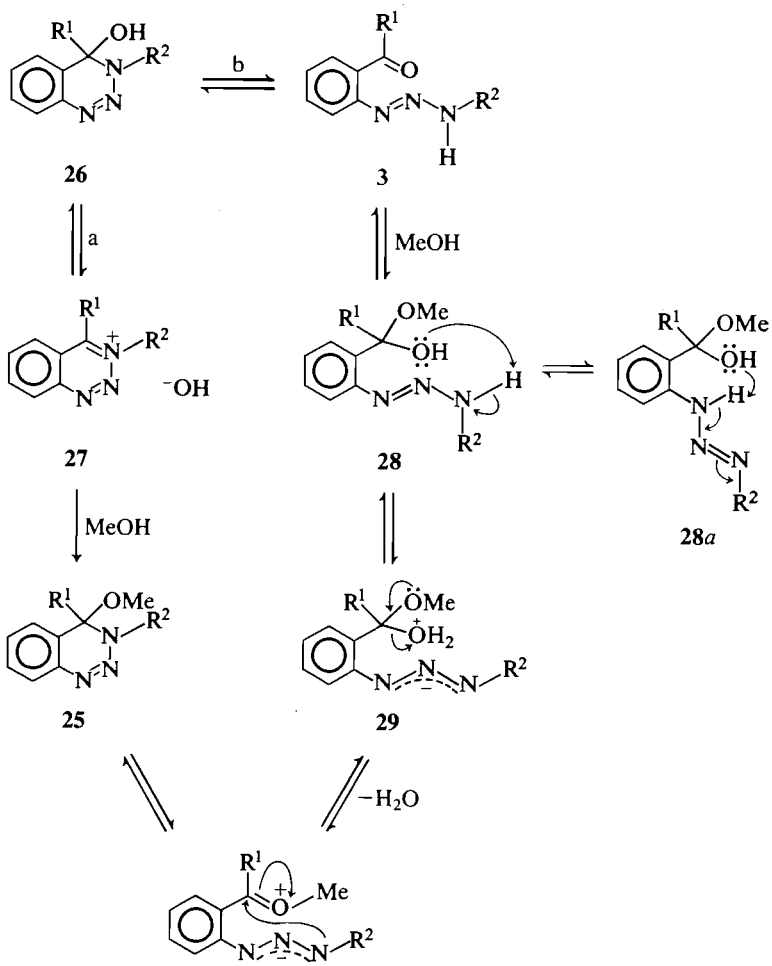
For personal use only.



SCHEME 1

of **12** to the ether (**19**) at room temperature is comparable to the conversion **4** → **14**.

The reactivity of the 4-methyl-(**7**) and 4-ethyl-(**8**) 4-hydroxytriazines is complicated by a competing reaction by dehydration to give 4-methylenetriazines (9), e.g., **21**. The 4-methyl-4-hydroxytriazine (**7**) does react rapidly in methanol at room temperature, giving 80% conversion to products after one hour. However, the major component of the product mixture is the 3-methyl-4-methylenetriazine (**21**) (58%), which was evident from the characteristic vinylic proton doublets in the nmr spectrum (9). The yield of the methyl ether (**15**) from this reaction was 23%. Refluxing the hydroxytriazine (**7**) in methanol did not appreciably change the course of the reaction; after 2 h, the product mixture contained unreacted **7** (13%), **15** (22%), and **21** (65%). An attempt to alkylate the hydroxytriazine (**7**) with diazomethane in methylene chloride surprisingly resulted in complete dehydration to the methylenetriazine (**21**) within 0.5 h. The methylenetriazine (**21**) was recovered unchanged after refluxing in ethanol for 1.5 h; thus it is unlikely that the dehydration product (**21**) is an intermediate in the conversion of **7** → **15**.

Refluxing the 3-methyl-4-ethyl-4-hydroxytriazine (**8**) in methanol was more successful and resulted in 100% conversion to the methyl ether (**16**) after 2 h, whereas reaction of **8** in methanol at room temperature was slow (120 h) and gave a mixture of the ether (**16**) (25%) and the analogous dehydration product, the 4-ethylidene triazine (**22**) (75%). Quantitative conversion of the hydroxytriazine (**8**) to the ethylidenetriazine (**22**), together with a trace of its geometric isomer **23**, was achieved by reaction in benzene with a trace of *p*-toluenesulfonic acid as catalyst. An interesting phenomenon was observed when the methyl ether (**16**) was left in aqueous methanol at room temperature for 24 h, which resulted in a 77% conversion to the ethylidenetriazine (**22**). This observation suggests that the methanolysis is reversible in the presence of water; the regenerated 4-hydroxytriazine (**8**) then undergoes irreversible dehydration to the observed product (**22**). The reversibility of the methanolysis is also evident in the reaction of the 3-chloroethyl-4-methoxytriazine (**18**), which reverts to the alcohol (**6**) when left in an aqueous medium for 12 h. Dehydration was also the major pathway of reaction of the 3-chloroethyl-4-ethyltriazin-4-ol (**9**) in methanol for 4 h at room temperature, which affords a 9:1 mixture of the *Z*-ethylidenetriazine (**24**) and the ether (**20**) respectively; refluxing **9** in methanol for 1 h gave a 4:1 mixture of the same products, with **24** in excess.

The ^{1}H nmr spectrum of the 4-ethylidenetriazine (**22**) confirms the assigned structure; the stereochemistry around the exocyclic C=C group is assigned as *Z* on the basis of comparisons of the chemical shift of the vinylic proton in **22** with the spectrum of the methylenetriazine (**21**). In **22**, the vinylic proton is in the R^1 position and is thus strongly deshielded, resulting in a chemical shift of 4.78 ppm for this proton; the analogous proton in **21** has a chemical shift of 4.4 ppm. The nmr spectrum of **22** shows a small but detectable amount of the *E* isomer (**23**), in which the vinylic proton (quartet), now situated at the more shielded position R^3, is

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 80.58.250.72 on 09/07/12
For personal use only.

found at 3.60 ppm; the analogous proton in **21** is found at 3.8 ppm.[4] The estimated composition, from nmr, of the mixture is 94% *Z*-(**22**) and 6% *E* isomer (**23**). The structure of **22** is corroborated by the ^{13}C nmr spectrum.

The structural assignment for the 4-methoxytriazines (**14**–**19**) is based on ^{1}H and ^{13}C nmr and ir data. The chemical shift of the OMe protons is in the range 2.7–2.9 ppm, which is an unusually high field for an O-Me group. The ^{13}C signal of the O-Me carbon, observed at ca. 50 ppm in **14** and **16**, is also an unusually high field for a methyl ether carbon (11). A possible explanation for this observation is that the O-Me carbon is shielded by the effect of the electron lone-pair at N-3, which could be held in close proximity to the O-Me group if the triazine ring is nonplanar (see structure **25**). Indeed, there is evidence that compounds of this type do have some deviation from planarity in the triazine ring, as shown by a crystal structure determination of a related compound 3-ethyl-4-hydroxy-3,4-dihydro-1,2,3-benzotriazine (**14**, Et for Me at R^2) (12).

The results of this study clearly show that the rate of methanolysis of the benzotriazinol is strongly dependent on the nature of the substituent R^1 at C-4 of the triazine. Thus, for triazinols in which R^2 is fixed as a methyl group, the reactivity order for various R^1 groups is: H ~ Me > Et > Ph. Scheme 1 shows two possible pathways for the mechanism of the methanolysis. Path (a), an addition/elimination mechanism, involves heterocyclic pseudo-base dissociation of **26** to give the benzotriazinium cation (**27**), which would be expected to undergo facile reaction with the solvent to give the methyl ether (**25**). However, the observed reactivity sequence does not accord with this hypothesis, since electron-donating groups at R^1 should stabilize the intermediate triazinium ion (**27**) and facilitate formation of the methyl ether. On the other hand, if the rate-determining step in path (a) is the addition of methanol to the triazinium ion, then the observed reactivity sequence would be consistent with the steric effect of R^1 rather than with its electron-releasing character.

The alternative mechanism for the methanolysis, path (b), involves the triazinol ⇆ triazene ring-chain tautomerism (**26** ⇆ **3**). The open-chain triazene (**3**) could react with methanol reversibly to afford the hemi-acetal or -ketal (**28**) and the reactivity sequence for variation of R^1 is consistent with the predicted reactivity of the carbonyl group towards nucleophilic addition by methanol in the steps **3** → **28**. Cyclization of **28**, or more likely from the tautomer **28***a*, then proceeds by an intramolecular proton transfer to give the zwitterionic-triazenido compound **29**, which is then set up for elimination of water and ring closure of the triazenido-methyloxonium zwitterion to give the observed product (**25**).

Although the evidence reported here does not clearly establish path (a) or (b) as the correct mechanism for the methanolysis, the authors favour path (b) since the triazinol ⇆ triazene tautomerism (**26** ⇆ **3**) has been clearly demonstrated (5) whereas the pseudo-base character of **26** has not.

It is worthwhile to compare the facility of methanolysis of these benzotriazinols with the apparent inactivity of their acyclic analogues, the hydroxymethyltriazenes (**30***a*). Analogous reaction of **30***a* with methanol would be expected to afford the methoxymethyltriazene (**30***b*); however, the only reaction we have observed with compounds of type **30***a* in methanol is loss of formaldehyde to afford the monomethyltriazene (Ar·N=N·NHMe). Furthermore, the hydroxymethyl group in **30***a* can be activated by derivatization to the acetoxymethyltriazene (**30***c*), which does react with methanol to give the methyl ether (**30***b*). This latter reaction has been shown by kinetic analysis to involve intermediate iminium ion (**31**) formation (13).

TABLE 3. In vivo antitumor activity of the 4-hydroxy-3,4-dihydro-1,2,3-benzotriazines

Compound no.	R^1	R^2	Tumor	Optimum dose (mg/kg)	%T/C[a]

31

The formation of α-carbinolamines by enzymatic oxidation is an ubiquitous pathway in the metabolism of N-alkyl xenobiotic molecules (7). A typical xenobiotic is the tobacco alkaloid nicotine, which undergoes enzymatic oxidation to a transient α-carbinolamine; it has been suggested (14) that the carbinolamine, and analogous metabolites from other xenobiotics (e.g., phencyclidine), might undergo ionization to give an electrophilic iminium ion analogous to **31**. The iminium ion could be an active metabolite capable of covalent interaction with biological nucleophiles, e.g. protein, DNA.

α-Carbinolamines of the type suggested as metabolites of nicotine and phencyclidine are not chemically isolable and consequently it has been difficult to provide a chemical model to test the iminium ion hypothesis. Clearly the 4-hydroxytriazines (e.g. **4**) and hydroxymethyltriazenes (**30***a*) are suitable model compounds to test these hypotheses. The mechanisms by which these compounds interact with nucleophiles have direct relevance to the biochemistry and pharmacology of many important xenobiotic molecules, and further studies of these

[4]A similar pair of geometric isomers in an ethylidene heterocyclic system has been observed in some isoquinoline enamides and characterized by the variation of nmr chemical shift (10).

mechanisms are being undertaken to assess the importance of the iminium ion hypothesis in their metabolism.

Anti-tumor activity

Table 3 shows the results of in vivo anti-tumor evaluation of the 4-hydroxytriazines. Only the triazines (**4**–**6**) without an alkyl or aryl substituent at C-4 are active against the TLX5 tumor, and the level of activity is only a little above marginal. None of the compounds tested had any activity against the P388 tumor; two of the compounds with TLX5 activity were found to be severely toxic during the P388 assay and one of the P388 inactive compounds (**8**) was similarly toxic during the TLX5 test. Substitution of the N-methyl group of the 4-hydroxytriazine by the chloroethyl group causes little change in the biological activity.

Although the degree of activity observed for these compounds is low and does not encourage consideration of further testing of analogues, there is an interesting correlation of these in vivo results with previous results of in vitro cytotoxicity (6). Compounds **4** and **5** are active on the TLX5 tumor *and* show significant in vitro cytotoxicity *without* metabolic activation, whereas two of the TLX5-inactive compounds, **10** and **13**, have a much lower degree of in vitro cytotoxicity. There appears to be a structure–activity correlation in this series: the biologically active compounds are those without an alkyl, or aryl, substituent at C-4 of the triazine. This activity correlates with the chemical reactivity of the triazinol in the methanolysis reaction.

Thus, there does appear to be a correlation between the biological activity of the triazinol and the facility of the triazinol to undergo chemical ring opening. For example, the 3-methyl-4-hydroxy-4-hydrotriazine (**4**) is cytotoxic to M21 tumor cells in culture (6), has measurable in vivo anti-tumor activity against the TLX5 tumor, and also undergoes facile methanolysis to give the methyl ether (**14**). In contrast, the 3-methyl-4-hydroxy-4-phenyltriazine (**10**) has only marginal cytotoxicity in vitro, is inactive against the TLX5 tumor, and undergoes methanolysis extremely slowly.

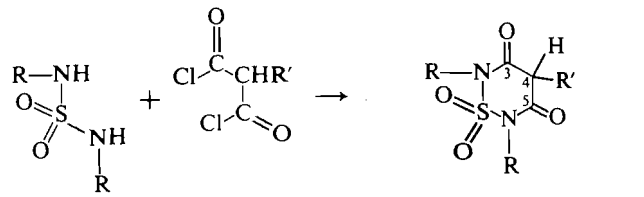
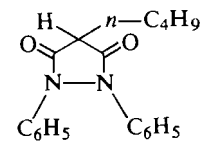
Introduction

In a previous paper (1) we carried out a comparative study between the physicochemical properties of 1,2,6-thiadiazine 1,1-dioxide derivatives and related pyrazoles. We have now extended the comparison to compounds of this series with antiinflammatory activity. Thus, we now wish to report the physico-chemical properties and preliminary biological screening of 1,2,6-thiadiazin-3,5(2*H*,6*H*)-dione 1,1-dioxides **1** (2), **2** and **3** (3), structurally related to phenylbutazone **4**. Compound **3** can be considered as pyrazolidindione **4** in which an SO_2 group has been introduced between the two nitrogen atoms. Thiadiazine derivatives **1** and **2** have been chosen because the cyclohexyl moiety seems to be useful for inducing antiinflammatory activity (4–6). Thus, whilst 1,2-dicyclohexyl pyrazole derivatives have shown some activity (7), the corresponding cyclopentyl compounds turned out to be inactive (8).



1 R = C_6H_{11}, R′ = H
2 R = C_6H_{11}, R′ = *n*-C_4H_9
3 R = C_6H_5, R′ = *n*-C_4H_9



SCHEME 1

Results and discussion

Synthesis, nmr data and pK_a values

Compound **2** was prepared from *N*,*N*′-dicyclohexylsulfamide and *n*-butylmalonyl chloride using the procedure used to prepare **1** (2).

The ^{1}H nmr data of compounds **1**, **2**, and **3** can be found in the experimental part. The assignments have been made by chemical correlation and signal multiplicity. The spectrum of compound **1** at 300 MHz shows the signals belonging to the protons of the cyclohexyl moieties separated in six multiplets. It was therefore possible to assign most of these signals on the basis of their multiplicity and coupling constants. The multiplet, a triplet of triplets, appearing at lower field ($J_{1'a,2'a}$ = 12.36 Hz, $J_{1'a,2'e}$ = 3.85 Hz) corresponds to H1′a indicating that the heterocyclic rest is, as expected, in the equatorial position. The following signal that corresponds to H2′a, appears as a double quartet indicating that J_{gem}, $J_{H2'a,H1'a}$, and $J_{H2'a,H3'a}$ have very close values ($J \sim |12|$ Hz). In this way, the signals corresponding to the other axial protons appear like a triplet of quartets and the signals corresponding to the equatorial protons as distorted doublets ($J_{gem} = \sim -12$ Hz, and $2.5 < J_{e,e}, J_{a,e} < 4$ Hz).

The ^{13}C nmr data of compounds **1**, **2**, **3**, and phenylbutazone (**4**) (9) are gathered in Table 1.

The effect of an SO_2 group on ^{13}C nmr chemical shift can be evaluated by comparing the data of thiadiazine derivatives **1**, **2**, **3**, and those of phenylbutazone (**4**). Thus, the signal belonging to the equivalent C3 and C5 is shifted to lower field (~5 ppm) in phenylbutazone, whilst the C4 signal is shifted to higher field (~6 ppm) as can be seen from the data of **3** and **4**. The signals corresponding to the *ortho*, *meta*, and *para* carbons of phenylbutazone are separated from each other about 3 ppm, whilst in compound **3** they appear with a difference of 0.3 ppm, the one corresponding to the *p*-carbon atom being that appearing at lower field.

The pK_a values (water) were measured using the spectrophotometric method and the data are shown in Table 2.

The substitution of a C—H (**1**) by a C-*n*-butyl group (**2**) slightly affects the acidity (+0.16 pK_a units), taking into account the statistical effect (10). On the other hand, the pK_a variation between compounds **3** and **4** can be explained by

TABLE 2. pK_a values of **1**, **2**, **3**, and phenylbutazone (**4**)

Compound	pK_{a_1}
1	6.04±0.11
2	6.18±0.06
3	3.92±0.04
4	4.42±0.10

the electron-withdrawing effect of the SO_2 group. The strong variation of the pK_a values between the two dicyclohexyl derivatives and the diphenyl derivative **3** is not easily explained. In related barbiturates, the presence of monooxo or dioxo tautomer forms in the salt formation accounts for changes in the pK_a values (11). However, in thiadiazine derivatives **1**, **2**, and **3** the variation in pK_a values cannot be due to the existence of different tautomers since their uv spectra are very similar and the ^1H nmr spectra of the three compounds show only the signal corresponding to the CH tautomers (dioxo form). Despite the fact that electronic and steric effects of substituents cause changes in pK_a values in barbituric acid derivatives (12), these effects do not seem to be enough to account for such strong variations in the pK_a values of the thiadiazines.

X-ray discussion

The crystal structures of **2** and **3** have been determined by single crystal X-ray diffraction techniques. Figures 1 and 2 are perspective drawings of their final X-ray models (13). A list of bond lengths and bond angles is given in Tables 3 and 4, which compare well with other thiadiazine compounds (1, 14–20), taking into account the different location of the double bonds within these molecules.

The thiadiazine rings of both compounds present boat conformations (21), $\phi 2$ = 179.8(3) and $\theta 2$ = 93.2(3) for **2**, $\phi 2$ = 0.0(2) and $\theta 2$ = 89.2(2) for **3**, with the C4 and S atoms at the flaps (see also Table 5). These structures, together with another one reported previously (22), are examples of thiadiazine rings showing boat conformations. The best planes of the cyclohexyl rings in **2** (C22, C23, C25, C26 and C62, C63, C65, C66) form similar angles, 88(1)°, with the best plane of the thiadiazine ring. The phenyl rings in **3** are also symmetrically oriented with respect to the best plane of the thiadiazine ring and make an angle of 95(1)° with it. This symmetrical orientation of the substituted rings does not occur in the analogue compound phenylbutazone (23), where the two phenyl rings make angles of ~60° and ~40°, respectively, with the main ring, this situation occurring in the two crystallographically independent molecules. The other structural difference of phenylbutazone is

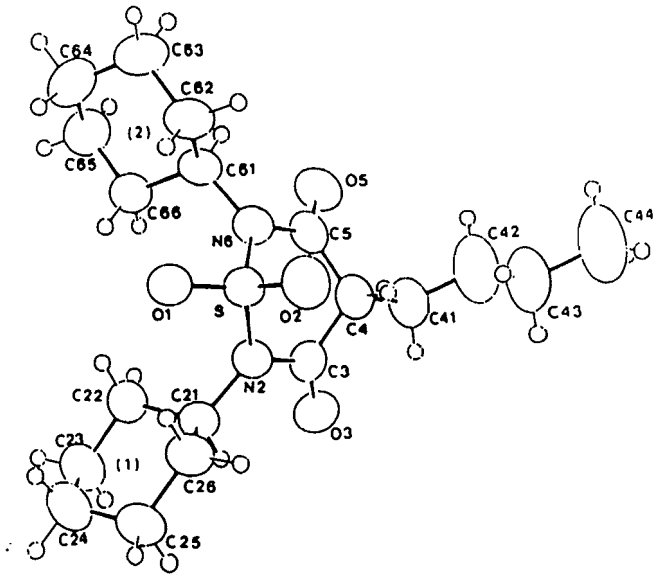

FIG. 1. A perspective view of molecule **2**.

the lack of planarity around its nitrogen atoms, which is not observed in **2** and **3**. Thus, the incorporation of the SO_2 group to phenylbutazone to produce the present thiadiazine derivatives plays an important role in determining the final molecular geometry.

The conformation of the thiadiazine rings in **2** and **3** described above causes the H-atom bonded to C4 to get near to one of the oxygen atoms of the SO_2 group (Fig. 3). In compound **2** (pK_a = 6.18) the distance H4...O2 = 2.48 Å is less than in compound **3** (2.70 Å, pK_a = 3.92). The contact H4...O2 cannot be considered as a typical hydrogen bond, but it indicates (24) a certain attractive interaction, that produces a major structural fixation of the H4 atom in **2**.

Biological results

The antipyretic, analgesic, and antiinflammatory activity of thiadiazines **1**, **2**, and **3** has been evaluated. The preliminary results are shown in Table 6.

Compound **3**, closely related with phenylbutazone, shows an antiinflammatory activity similar to this compound, whilst **1** and **2** present much lower activity. Compound **2** presents a remarkable analgesic activity and this result is the only one that is statistically significant.

There seems to be a correlation between the pK_a values and the antiinflammatory activity since the two more active compounds are also the more acidic.

In previous reports (25, 26) a relationship between the carbon

chemical shifts of the biological active center and hypnotic activity in barbituric acid derivatives and analgesic activity in antipyrine derivatives has been described. No relationship seems to exist between the chemical shifts of C4 and the biological activities of compounds **1**, **2**, **3**, and **4**, since the pairs of compounds with similar C4 chemical shifts (**1** and **4**, **2** and **3**) do not have similar activities. No more correlations have been made due to the few data available.

Although the antiinflammatory activity found in compound **3** seems to indicate that the parallelism between pyrazole and thiadiazine derivatives (1) exists also in what biological activities are concerned, the high toxicity of **3** and the not very significant activities of **1** and **2** do not encourage further development.

Experimental

Melting points were determined in a Kofler apparatus and are uncorrected. ^{1}H nmr spectra were recorded at 90 MHz on a Varian EM-390 or at 300 MHz on a Varian XL-300 spectrometers. ^{13}C nmr spectra were recorded at 20.15 MHz on a Bruker WP-80 spectrometer. Infrared spectra were recorded on a Perkin-Elmer 257 spectrophoto-

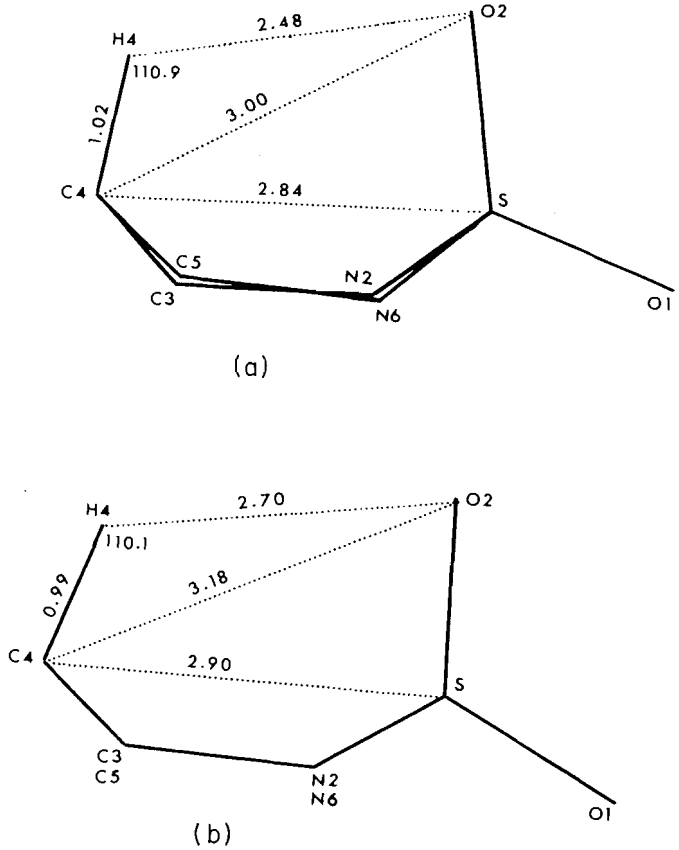

FIG. 3. Projection of a fragment of the molecule onto a plane normal to the best ring plane: (*a*) for **2**, (*b*) for **3**.

TABLE 6. Antipyretic (AP), analgesic (AN), antiinflammatory (AI) activities (in %) and LD_{50} of thiadiazines

Compound[a]	AP[b]	AN[c]	AI[d]	LD_{50} (mg/kg)
1	55	41	30	300–1000
2	28	67[e]	10	300–1000
3	—	—	100	100
4	—	—	100	500

[a]All compounds have been tested at the same dose as the standard.
[b]Aminopyrine as standard (100% activity, dose 50 mg/kg).
[c]Acetylsalicylic acid as standard (100% activity, dose 100 mg/kg).
[d]Phenylbutazone (**4**) as standard (100% activity, dose 50 mg/kg).
[e]Significant difference: $0.02 < p < 0.05$.

meter. Ultraviolet spectra were registered on a Perkin-Elmer 402 spectrophotometer.

Crystal data for **2** are as follows:

$C_{19}H_{32}N_2O_4S$ m.w. = 384.53
Triclinic, $P1$, a = 11.45(1), b = 15.678(2), c = 5.7669(2) Å, α = 90.22(1), β = 99.35(2), γ = 93.62(1), Z = 2, V = 1019.4(2) Å^3, D_x = 1.25 Mg m^{-3}, μ(CuKα) = 1.58 mm^{-1}, F(000) = 416.

Crystal data for **3** are as follows:

$C_{19}H_{20}N_2O_4S$ m.w. = 372.23
Orthorhombic, *Pnma*, a = 9.9891(3), b = 13.3077(4), c = 13.9982(2) Å, Z = 4, V = 1860.8(1) Å^3, D_x = 1.32 Mg m^{-3}, μ(CuKα) = 1.56 mm^{-1}, F(000) = 784.

Needle shaped colourless crystals, mounted on a PW1100 four circle diffractometer. Intensities were recorded in the $\omega/2\theta$ scan mode with θ between 2° and 65°. Graphite monochromatized CuKα radiation (λ = 1.54178 Å) was used. A total of 3710, for **2**, and 1659, for **3**, independent reflexions were measured, of which 2933 (for **2**) and 1200 (for **3**) were flagged as observed with $I > 2\sigma(I)$. Intensity data were corrected by Lorentz and polarization effects. No absorption correction was applied. Lattice parameters were determined by least-squares fit of the θ values for 45 and 32 reflexions respectively ($15° < \theta < 30°$) measured at 295 K for both positive and negative Bragg angles (gravity centres of the peaks), using only the most accurate circle (ω) of the diffractometer. Scattering factors for neutral atoms and anomalous dispersion corrections for S and O atoms were taken from International tables for X-ray crystallography (27). The structures were solved using MULTAN (28). Atoms C42, C43, and C44 of compound **3** are disordered as they do not lie on the mirror plane passing through O1, O2, S, C4, and C41, and so they have been assigned to a population parameter of 0.5. The structures were refined by full-matrix least-squares analysis using anisotropic temperature coefficients (H atoms as isotropic fixed contributors). All H atoms were located in a difference map, except those attached to C42, C43, and C44 in compound **3** which were calculated geometrically. A convenient weighting scheme of type $w = w_1 w_2$, with $w_1 = k/(a + b|F_o|)^2$ and $w_2 = 1/(c + d \sin\theta/\lambda)$, was used to obtain flat dependence in $\langle w\Delta^2 F\rangle$ vs. $\langle F_o\rangle$ and vs. $\langle \sin\theta/\lambda\rangle$ (29); the coefficients used for **2** are a = 0.9, b = −0.2 for $F_o < 11$, a = 0.3, b = 0 for $F_o > 11$, c = 1.85 and k = 0.6, d = −1.9 for all reflexions; the coefficients used for **3** are a = 1.4, b = −0.2 for $F_o < 12$, a = 0.5, b = 0 for $F_o > 12$, k = 0.4, c = 2.5, d = −5.0 for all reflexions. The unweighted and weighted final R values were 0.066 and 0.080 for **2** and 0.047 and 0.051 for **3**. Most calculations were performed with the XRAY76 System (30). Tables 7 and 8 show the final atomic parameters.[2]

The analgesic activity was tested following the Siegmund, Cadmus, and Lu method (31), using acetylsalicilic acid as standard. The antiinflammatory activity was measured by the Winter method (32)

[a] $U_{eq} = (1/3)\Sigma[U_{ij}a_i^*a_j^*a_ia_j \cos(a_i, a_j) \times 10^3]$.

with phenylbutazone as standard and the antipyretic activity by the Bianchi method (33) using aminopyrine as standard.

General synthetic method

To a stirred solution of the corresponding *N,N'*-disubstituted sulfamide (0.01 mol) in dry toluene (50 mL) a solution of malonyl or *n*-butylmalonyl chloride (0.01 mol) in dry toluene (10 mL) was added dropwise. The mixture was heated at 50°C for 30 min and then at 70°C for 4 h. On cooling, the resulting solution was evaporated to dryness *in vacuo* and the residue crystallized from ethanol. With this procedure, the following compounds were obtained.

*2,6-Dicyclohexyl-4*H*-1,2,6-thiadiazin-3,5(2*H*,6*H*)-dione 1,1-dioxide (1)*

Yield 70%, mp 152°C (lit. (2) 152°C); uv λ_{max} (MeOH): 213 (ε, 1400), 277 nm (ε, 850); ^{1}H nmr ($CDCl_3$) δ: 1.18 (m, 2H, H4′a, $J_{gem} \sim J_{a,a} = |12|$ Hz), 1.33 (m, 4H, H3′a, $J_{gem} \sim J_{a,a} = |12|$ Hz), 1.66 (m, 2H, H4′e, $J_{gem} = -12.4$ Hz), 1.80[3] (m, 4H, H3′e), 1.85[3] (m, 4H, H2′e), 2.16 (d.q, 4H, H2′a, $J_{gem} \sim J_{1'a,2'a} \sim J_{2'a,3'a} = |12|$ Hz, $J_{2'a,3'e} = 3.36$ Hz), 3.91 (s, 2H, H4), 4.48 (tt, 2H, H1′a, $J_{1'a,2'a} = 12.36$ Hz, $J_{1'a,2'e} = 3.85$ Hz), ir (Nujol) ν: 1760 cm^{-1} (C=O).

*4-*n*-Butyl-2,6-dicyclohexyl-1,2,6-thiadiazin-3,5-(2*H*,6*H*)-dione 1,1-dioxide (2)*

Yield 66%, mp 96°C; uv λ_{max} (MeOH): 225 (ε, 6650), 291 nm (ε, 3650); ^{1}H nmr ($CDCl_3$) δ: 0.9 (t, 3H, CH_3), 1.0–2.2 (m, 26H, H2′, H3′, H4′, $3CH_2$ butyl moiety), 3.9 (t, 1H, H4, $J = 4.5$ Hz), 4.3 (tt, 2H, H1′a, $J_{1'a,2'a} = 12$ Hz, $J_{1'a,2'e} = 4$ Hz); ir (Nujol) ν: 1700, 1740 cm^{-1} (C=O). *Anal.* calcd. for $C_{19}H_{32}N_2O_4S$: C 59.35, H 8.38, N 7.28; found: C 59.44, H 8.49, N 6.97.

*4-*n*-Butyl-2,6-diphenyl-1,2,6-thiadiazin-3,5-(2*H*,6*H*)-dione 1,1-dioxide (3)*

Yield 65%, mp 177–178°C (lit. (3) 177–178.5°C); uv λ_{max} (MeOH): 215 (ε, 1050), 289 nm (ε, 450); ^{1}H nmr ($CDCl_3$) δ: 1.0 (t, 3H, CH_3), 1.2–1.8 (m, 4H, CH_2-8, CH_2-9), 2.2 (m, 2H, CH_2-7), 4.5 (t, 1H, H4, $J = 6$ Hz), 7.4–7.7 (m, 10H, arom.); ir (Nujol) ν: 1720, 1760 cm^{-1} (C=O).

J. D. PANDEY, K. MISHRA, A. SHUKLA, and R. D. RAI. Can. J. Chem. **65**, 303 (1987).

The ultrasonic velocity, U, density, and viscosity of aqueous and non-aqueous (water + dioxan) solutions of tetracycline hydrochloride and chlorotetracycline have been measured at two different temperatures. Partial molal volumes, ϕ_v, partial molal compressibility, ϕ_k, Vand's interaction coefficients, Q and C, and thermodynamic activation parameters ΔG^*, ΔS^*, and ΔH^* of these solutions have been computed from the ultrasonic velocity, density, and viscosity data. The results are interpreted in terms of solute–solvent interaction.

J. D. PANDEY, K. MISHRA, A. SHUKLA et R. D. RAI. Can. J. Chem. **65**, 303 (1987).

Opérant à deux températures différentes, on a déterminé la vitesses ultrasoniques, U, et d'autres propriétés, comme la densité et la viscosité, de solutions aqueuses (eau + dioxanne) et non-aqueuses du chlorhydrate de tétracycline et de la chlorotétracycline. Utilisant les données de vitesse ultrasonique, de densité et de viscosité, on a calculé les volumes molals partiels, ϕ_v, la compressibilité molale partielle, ϕ_k, les coefficients d'interaction Q et C de Vand et les paramètres thermodynamiques d'activation ΔG^*, ΔS^* et ΔH^* de ces solutions. On interprète les résultats en fonction d'interactions soluté/solvant.

[Traduit par la revue]

Introduction

Tetracyclines are a group of broad spectrum antibiotics. These compounds are well known for their prophylatic and therapeutic values. Their contribution to the medical profession has been substantial since they act as antibiotics against a wide range of human and animal pathogens (1, 2). They are a group of structurally related complex compounds, the parent compound being tetracycline. Their mode of action (3), biogenesis (4–8), and chemical properties have been worked out extensively.

The different tetracyclines used as antibiotics have comparable activity (9). The exact mechanism of their drug action, so far, has not been proposed. However, they do form coordination complexes with metal ions *in vitro* (10–12).

The results of ultrasonic, volumetric, and viscometric studies of tetracycline hydrochloride and chlorotetracycline in water and water–dioxan system are presented in this work. They may throw some light on the intricate drug interaction mechanism.

Experimental

Analytical grade tetracycline (TC) and chlorotetracycline (CTC) were obtained from Cynamide India Limited (Ledereley Division) as hydrochlorides and used as such. These antibiotics were kept in a vacuum desiccator for 48 h before use. Melting points were checked.

Preparation of aqueous solutions

Stock solutions (10^{-3} M) of (TC) and (CTC) were prepared in double distilled water. Nine solutions of different concentrations ranging from 0.0001 to 0.0009 M were prepared.

Preparation of non-aqueous solutions

Stock solutions (10^{-3} M) of (TC) and (CTC) were prepared in double distilled water and in 1,4-dioxane. Nine different solutions were prepared having varying compositions (10–90% of water–dioxan mixture).

Density measurements

The density measurements were performed for different solutions at 25 and 35±0.01°C with the help of precalibrated bicapillary pyknometer. The estimated error in the density measurements were found to be ±0.005%, as reported in an earlier paper (13).

Ultrasonic measurements

Ultrasonic velocity (U) measurement has been performed by variable path ultrasonic interferometer having frequency of 2 MHz, as described earlier (13). The estimated error has been found to be ±0.02% which is an improvement over the previous estimated accuracy (±0.05%).

Viscosity measurements

Viscosity was measured with a calibrated modified Ostwald type viscometer 03 at 25 and 35 ± 0.01°C. Uncertainties in the measured viscosities were within ±0.03%. Viscosity data were analysed using Jones–Dole (14) and Vand's (15) equations.

Thermodynamic parameters have been evaluated from the experimental viscosity values.

Results and discussion

The apparent molal volumes, ϕ_v, and apparent molal compressibilities, ϕ_k, of tetracycline solutions were determined from density and adiabatic compressibility, using the following equations:

$$[1] \quad \phi_v = \frac{10^3(d_s - d_0)}{m d_s d_0} + \frac{M}{d_0}$$

$$[2] \quad \phi_k = \frac{10^3(\beta_s - \beta_0)}{m d_0} + \beta_s \phi_v$$

where d_0, d_s, β_0, and β_s are densities and compressibilities of solvent and solution, respectively, m is the molality, and M is the molecular weight of the true solute (Table 1).

The adiabatic compressibility, β_s, of the aqueous solutions were determined from the sound velocity using the relation,

$$\beta_s = \frac{1}{U^2 d}$$

Values of S_v and S_k at infinite dilution were obtained from the Masson's (16) equations [3] and [4] respectively.

$$[3] \quad \phi_v = \phi_v^0 + S_v\sqrt{C}$$

$$[4] \quad \phi_k = \phi_k^0 + S_k\sqrt{C}$$

where S_v and S_k are the experimental slope of ϕ_v vs. $\sqrt{C}$ and ϕ_k vs. $\sqrt{C}$ plots. ϕ_v^0 and ϕ_k^0 are the standard partial molal volume and partial molal compressibility, respectively. The

values of ϕ_v, ϕ_k, and S_v, S_k are listed in Table 2 and Table 3. The values of coefficients B and Q of viscosity data were obtained from Jones–Dole (14) and Vand's (15) equations

$$[5] \quad \eta/\eta_0 = 1 + A\sqrt{C} + BC$$

$$[6] \quad \frac{C}{\log \eta_r} = \frac{2.303}{2.5\,\bar{V}} - \frac{2.303\,QC}{2.5}$$

where η/η_0 is relative viscosity, A and B are empirical coefficients obtained from $(\eta/\eta_0 - 1/\sqrt{C}$ vs. $\sqrt{C}$ plots. Values of A and B are listed in Table 2. In eq. [6], C is the molar concentration and $\bar{V}$ is the molar volume of the solute which is the effective flowing volume. Q is a generalised particle interaction coefficient dealing with mutual interference between the spheres and with their Brownian motion. The values of Q and $\bar{V}$ were obtained from C (log $\eta_\gamma)^{-1}$ vs. C plots, and are presented in Table 3.

Calculated values of apparent molal volume, ϕ_v, have been found to be in good agreement with Masson's equation, as the plot of ϕ_v vs. $\sqrt{C}$ is linear. Calculated values of partial molal volumes, ϕ_v^0, are summarized in Tables 2 and 3. The values of ϕ_v^0 in the water–dioxan system are comparatively higher than those of pure water. This is attributed to the fact that dioxan does not penetrate the three dimensional structure of water. Positive values of ϕ_v^0 indicate that this does not restrict molecular motion within the solution.

Values of S_v obtained from the slope of ϕ_v vs. $\sqrt{C}$ are incorporated in Tables 2 and 3. Results of the experimental slope S_v reveal that solute–solute interaction decreases with the rise in the temperature. Values are comparatively low in water system compared to water–dioxan system, which indicates that solute–solute interaction is maximum at 25°C in the solute dioxan – water system (13, 17–26). Standard partial molal compressibilities, ϕ_k^0, obtained from the linear plot of ϕ_k vs. $\sqrt{C}$ are listed in Tables 2 and 3. Results show that the values are comparatively higher in tetracycline + dioxan – water system than chlorotetracycline + dioxan – water system in comparison to water alone. Negative values of ϕ_k are attributed to the loss of structural compressibility of the solvent molecules due to the increased population of four bonded water molecules in the water–dioxan mixtures (13, 17–26).

Viscosity data are analysed in the terms of Jones–Dole and Vand's equations. Values of B and Q interaction coefficients are displayed in Tables 2 and 3. Positive B and Q values indicate a strong alignment of solvent molecules with those of the solute (22–26). B and Q values increase with rise in temperature, showing that solute–solvent interaction are influenced by the temperature. The behaviour of tetracyclines in water–dioxan mixture can be analysed by observing the Q values. Tables 2 and 3 reveal that the tetracycline hydrochloride and chlorotetracycline have low positive B and Q values and are slightly influenced by variation in the temperature. Therefore, it can be stated that positive B and Q values for tetracycline hydrochloride and chlorotetracycline are exclusively due to solute–solvent interaction (22–26). Thus the tetracycline molecules can be labelled as "structure makers" in aqueous solution.

The analysis of solute activation parameters are presented in Tables 2 and 3. This has been done in light of Nightingale (27) and Feakins (28) formulations. It has been mentioned already that these tetracyclines have been used as therapeutic and prophylatic agents against bacterial activity. The data have been reported at 25 and 35°C, because at higher temperature these compounds may decompose. Besides, the main object of this work is to investigate the solute–solvent interaction

(tetracyclines in water and water–dioxan mixture) near body temperature. The observed appreciable changes in the viscosities enabled us to evaluate the thermodynamic activation parameters. The Gibbs–Helmholtz equation was used. The values of ΔH^* was deduced from the estimates of ΔS^* and ΔG^* (28). The values of ΔS^* were obtained from the slope of the plot of $\ln \eta_v/hN$ vs. T. The evaluation of ΔS^* values from such plots at only two temperature can not yield reliable results. The average values of the thermodynamic activation parameters are given in Tables 2 and 3.

The careful scrutiny of the thermodynamic parameters indicates that these values increase with increase in temperature. However, it is found that the ΔG^*, ΔS^*, and ΔH^* values are higher in the water–dioxan system than those in water alone. The positive value of the free energy of activation, ΔG^*, suggests that water has more affinity for tetracycline hydrochloride and chlorotetracycline than have water–dioxan mixtures (13, 17–25). Similarly, other activation parameters, such as ΔH^* and ΔS^*, have positive values at all solvent compositions of water–dioxan, thereby showing that entropies and enthalpies in water–dioxan mixtures are both enhanced relative to pure water and hence the net order created by the solutes in water–dioxan mixture is less than that in pure water. The hydrophilicities (lipophobicities) of tetracycline hydrochloride and chlorotetracycline are thus in accordance with their drug activity (Table 4). The conclusion drawn from the thermodynamic behaviour of these antibiotics in solution, viz., the lower entropies and enthalpies in pure water as compared to water–dioxan mixture are very much in keeping with their minimal requirement for drug action *in vivo*.

Chloration de l'acétanilide et de la benzanilide en présence des cyclodextrines et de l'amylose

ROBERT CHÊNEVERT [1] ET GUY AMPLEMAN

Département de chimie, Faculté des sciences et de génie, Université Laval, Québec (Qué.), Canada G1K 7P4

Reçu le 28 avril 1986

ROBERT CHÊNEVERT et GUY AMPLEMAN. Can. J. Chem. **65**, 307 (1987).

La présence des cyclodextrines ou de l'amylose lors de la chloration de l'acétanilide ou de la benzanilide favorise la formation de l'isomère *para* au détriment de l'isomère *ortho*. La constante de dissociation du complexe acétanilide–α-cyclodextrine ainsi que la disposition moléculaire de l'acétanilide dans la cavité de l'α-cyclodextrine ont été déterminées par spectroscopie de résonance magnétique nucléaire du proton et du carbone-13.

ROBERT CHÊNEVERT and GUY AMPLEMAN. Can. J. Chem. **65**, 307 (1987).

The ratio of *ortho* to *para* isomers in chlorination of acetanilide and benzanilide is changed in favour of the *para* isomer when the reactants are entrapped in cyclodextrins or amylose. The dissociation constant and the time-averaged position of acetanilide in the α-cyclodextrin cavity have been determined by proton and carbon-13 nuclear magnetic resonance spectroscopy.

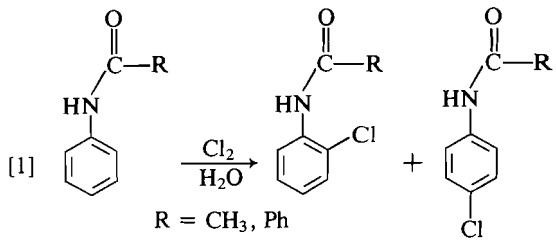
Introduction

Les cyclodextrines forment des composés d'inclusion en solution aqueuse avec une grande variété de substrats et elles sont des catalyseurs de certaines réactions organiques (1). Ces systèmes sont des modèles de la réaction enzymatique et leur cinétique a été fortement étudiée (2–4). Plus récemment, l'intérêt s'est porté vers l'étude de la sélectivité des réactions en présence de cyclodextrines. Les premiers travaux sont ceux de Breslow *et al.* sur la chloration de l'anisole par l'acide hypochloreux en présence de l'α-cyclodextrine (5, 6). Les cyclodextrines ont aussi une influence sur la réaction de Reimer–Tiemann (7), le réarrangement photochimique de Fries (8, 9), le réarrangement du tétrafluoroborate de benzylméthylsulfonium (10) et sur la réduction des énones par le borohydrure de sodium (11). D'autre part, l'amylose ou poly-(1→4)-α-D-glucose peut dans des conditions adéquates adopter la conformation d'une hélice α et inclure des substrats à l'intérieur de cette hélice. Malgré ce fait, l'amylose a rarement été employée comme catalyseur dans les réactions organiques. Hui *et al.* ont rapporté une cinétique de saturation de type enzymatique lors de l'étude de l'hydrolyse d'esters en présence de l'amylose ou de ses dérivés (12). Plus récemment nous avons décrit l'effet de l'amylose sur la réduction d'énones par le borohydrure de sodium (13) et sur un réarrangement photochimique de Fries (14). Nous décrivons dans cet article les effets des cyclodextrines et de l'amylose sur la chloration de l'acétanilide et de la benzanilide.

Résultats et discussion

La chloration de l'acétanilide et de la benzanilide par le chlore a d'abord été réalisée dans l'eau pure, puis les résultats ont été comparés à ceux obtenus en présence de l'α-cyclodextrine (α-CD), de la β-cyclodextrine (β-CD) ou de l'amylose. Un équivalent molaire de cyclodextrine (α-CD et β-CD) a été employé alors que la concentration relative d'amylose était de 1 g/mmol de substrat. Les résultats sont décrits par l'équation [1] et le tableau 1. Dans tous les cas, la cyclodextrine favorise l'introduction du chlore en position *para* et l'effet est plus prononcé avec l'α-CD. Nous avons donc étudié plus particulièrement le complexe α-CD–acétanilide. La constante de dissociation K_d du complexe a été mesurée par spectroscopie de résonance magnétique nucléaire du proton. Les déplacements



[1] R = CH_3, Ph

chimiques des protons aromatiques du substrat ont été mesurés en fonction de la concentration de l'α-CD (tableau 2). Les valeurs obtenues ont été traitées suivant la méthode décrite par Bergeron *et al.* (15, 16) (diagramme de Benesi–Hildebrand). La constante de dissociation trouvée est $5{,}0 \pm 0{,}3 \times 10^{-2}\ M$. Cette constante est comparable à celle de l'acétate de phényle ($2{,}2 \times 10^{-2}\ M$) (17) ou du *p*-nitrotrifluoroacétanilide ($6{,}1 \times 10^{-2}\ M$) (18) avec l'α-cyclodextrine.

La spectroscopie rmn à haute résolution (400 MHz) permet aussi de déterminer la position moyenne de l'acétanilide à l'intérieur de la cavité de la cyclodextrine. En effet, les protons méthine en position 3 et 5 de chaque unité de glucose pointent vers l'intérieur de la cavité de la cyclodextrine. L'observation de ces protons en rmn montre qu'ils sont blindés lorsqu'ils se trouvent dans le champ magnétique du nuage d'électrons π d'un noyau aromatique (15, 16, 19–23). Les déplacements chimiques des protons de l'α-cyclodextrine en fonction de la concentration de l'acétanilide sont rassemblés dans le tableau 3. Les constantes de couplage entre les différents protons de l'α-CD ($J_{1,2} = 3{,}3$ Hz, $J_{2,3} = 9{,}8$ Hz, $J_{3,4} = 8{,}8$ Hz, $J_{4,5} = 9{,}6$ Hz) varient très peu lors de l'addition d'acétanilide, ce qui signifie qu'il n'y a pas distorsion des cycles de glucose. À l'échelle des temps de la rmn ^{1}H, les six unités de glucose sont dans des conformations identiques. Les valeurs des constantes de couplage vicinaux sont en accord avec la conformation chaise *C*1. Il y a un déplacement vers les champs forts des protons H3 et H5, alors que les autres protons situés à l'extérieur de la cavité ne montrent pas de déplacements significatifs. Le déplacement de H3 est nettement plus prononcé que celui de H5. D'autre part, le déblindage des protons en position *ortho* du substrat est similaire à celui des protons *meta* et *para*. Ces résultats montrent que le noyau aromatique se trouve vis-à-vis le proton H3 de l'α-CD, c'est-à-dire du coté des hydroxyles secondaires (coté le plus large du tore). Le schéma 1 montre la position du noyau aromatique dans la cavité de la cyclodextrine. A priori, la molécule d'acétanilide peut prendre deux orienta-

tions différentes dans la cavité de α-CD : le groupement amide peut être orienté vers l'intérieur de la cavité ou encore émerger du coté des fonctions hydroxyles secondaires. L'orientation réelle pourrait être établie par une étude des déplacements chimiques (rmn ^1H) des protons sur le noyau aromatique du substrat : plus de déblindage est fort plus le proton est inclu profondement dans la cavité de la cyclodextrine (21). Toutefois, dans le cas de l'acétanilide, les déplacements des protons *ortho* sont presqu'identiques à ceux des protons *méta* et *para* et il est impossible d'établir l'orientation du substrat selon ce critère. L'orientation peut aussi être déterminée par une étude des déplacements chimiques en rmn ^{13}C des carbones du noyau aromatique. Les carbones 1 et 4 situés dans l'axe de l'α-CD seront blindés (déplacement vers les champs forts) s'ils sont profondement inclus dans la cavité et déblindés (déplacement vers les champs faibles s'ils sont dans la position inverse (24–26)). Il s'agit d'un effet de solvant, la cavité de la cyclodextrine fournissant un milieu moins polaire que son environnement. Les déplacements ont été prédits par des calculs de mécanique quantique et les orientations prédites sont conformes à celles déterminées en solution par la rmn ^1H et à l'état solide par des études de rayons-X (24). Ainsi, il a été démontré que l'acide benzoïque, l'acide *p*-hydroxybenzoïque et le *p*-nitrophénol ont respectivement leurs groupements acide et nitro orientés vers l'intérieur de la cavité de l'α-CD (24). Dans le cas de l'acétanilide le carbon 1 est déblindé de 0,29 ppm et le

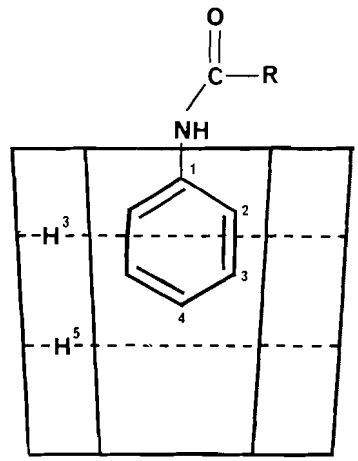

SCHÉMA 1

carbone 4 est blindé de 0,35 ppm (tableau 4). La fonction amide émerge donc de la cavité de la cyclodextrine par le coté des hydroxyles secondaires (schéma 1). Cette disposition du substrat permet d'expliquer la sélectivité de la réaction de chloration. Les positions *ortho* de l'acétanilide sont masquées par la cyclodextrine alors que la position *para* qui occupe l'axe de la cavité est relativement dégagée. Le chlore pénétre donc dans la cavité du coté des hydroxyles primaires pour réagir avec la position *para* de l'acétanilide. Un mécanisme similaire a été rapporté par Komiyama et Hirai (27, 28) lors d'une étude de la réaction de Reimer–Tiemann en présence de cyclodextrines. Ils ont démontré que l'addition de l'α-CD rend la réaction sélective en *para* et que le chloroforme pénétre dans la cavité de l'α-CD pour attaquer la position *para* du noyau aromatique. Lors de l'étude de la chloration de l'anisole par l'acide hypochloreux en présence de α-CD, Breslow a noté une augmentation de vitesse et une grande sélectivité en *para*. Cet effet avait deux origines : les positions en *ortho* sont masquées par la formation du complexe et la chloration en *para* est favorisée par la formation d'un ester hypochloreux avec un hydroxyle de la cyclodextrine permettant une réaction intra-complexe (5, 6, 29). Plus récemment, Tee et Bennett ont étudié la cinétique de la bromation de l'anisole par le brome en présence de α-CD et ont noté une réduction du taux de bromation en présence de α-CD; ils ont aussi démontré que la réaction n'implique pas l'acide hypobromeux ou son ester (30). Dans notre cas, la formation d'acide hypochloreux est possible par réaction entre le chlore et l'eau mais la constante d'équilibre est défavorable ($K = 4{,}2 \times 10^{-4}$) (31). Nos résultats doivent être expliqués principalement par un encombrement de position *ortho* car la formation d'un ester hypochloreux et une réaction intra-complexe devrait conduire à une plus grande sélectivité comparable à celle rapportée par Breslow.

Nous n'avons pas effectué d'études similaires de spectroscopie rmn pour le complexe α-CD–benzanilide car la solubilité de la benzanilide est infime dans l'eau et la présence de deux noyaux aromatiques sur le substrat rend l'interprétation des données complexes. La sélectivité plus faible de la benzanilide est due au moins en partie à la présence de deux noyaux aromatiques, le noyau benzoyle occupant la cavité de la cyclodextrine environ la moitié du temps. Il est à noter que la chloration d'un noyau aromatique par le chlore sans catalyseur n'est possible que sur un noyau activé; la chloration est impossible sur le noyau benzoyle car il est désactivé et nous

[a]Concentration : α-CD = 0,10 *M*; acétanilide = 0,04 *M*.
[b]Une valeur négative indique un déplacement vers les champs forts.

n'avons pas détecté d'autres produits que ceux décrits au tableau 1.

L'amylose est sans effet notable sur la chloration de l'acétanilide mais, tous comme les cyclodextrines, favorise l'introduction du chlore en *para* de la benzanilide. Nous avons déjà décrit des résultats similaires lors du réarrangement photochimique de Fries des acétate et benzoate de phényle (14). Le réarrangement du benzoate était modifié par la présence de l'amylose alors que celui de l'acétate ne l'était pas. Il semble que l'amylose requiert des substrats volumineux afin d'exercer son effet. Hui a rapporté lors de l'étude de l'hydrolyse d'esters de *p*-nitrophénol en présence d'amylose que l'effet catalytique est nul sur l'acétate et que l'effet augmente avec la longueur de la chaîne de l'ester (12). De même, Whitten et coll. ont étudié la photochimie de stilbènes porteurs de chaînes de diverses longueurs en présence d'amylose et ont aussi noté que l'effet de l'amylose augmente avec la longueur de chaîne (32). Nos résultats peuvent donc s'expliquer ainsi : l'amylose est sans effet sur la chloration de l'acétanilide car le complexe d'inclusion est instable; par contre, la benzanilide, plus volumineuse, est inclu dans l'hélice α de l'amylose, et la position *para* qui occupe l'axe de l'hélice est dégagée alors que les positions *ortho* sont masquées par les unités glucose formant cette hélice. L'amylose existe sous forme d'hélice α à un pH inférieur à 12 et une température inférieure à 60°C (32–34). Les hydrates de carbone de petite taille tel que le glucoside de méthyle sont sans effet sur la réaction.

L'amylose est un produit naturel abondant et moins dispendieux que les cyclodextrines. Il présente un site de complexation similaire à celui des cyclodextrines mais ce site est plus flexible et de dimensions variables dans le sens de l'axe de l'hélice. Enfin Hui (12) a souligné que le processus de complexation peut s'accomplir par de simples changements de conformation de la macromolécule mimant ainsi le processus enzymatique d'adaptation induite («Induced fit»).

Partie expérimentale

Réactifs

L'acétanilide et la benzanilide (Aldrich Chem. Co.) ont été recristallisés jusqu'à point de fusion constant et séchés sous vide. Des échantillons authentiques des chloro-2 et chloro-4 acétanilides ont été préparés par acétylation des chloroanilines correspondantes avec l'anhydride acétique. Les chloro-2 et chloro-4 benzanilides ont été préparés par benzoylation des chloroanilines correspondantes avec le chlorure de benzoyle. La masse moléculaire moyenne de l'amylose (Type III, Sigma Chem. Co.), mesurée par viscosimétrie, est de $4{,}38 \times 10^5$ g/mol (35).

Appareils

Les produits de chloration ont été analysés avec un chromatographe en phase gazeuse Varian 3740 couplé avec un intégrateur Varian 4270. Les spectres de rmn ont été enregistrés sur des spectromètres multinoyaux Varian XL-200 et Bruker WH-400. Le dioxane a été utilisé comme référence externe en rmn du carbone-13 et l'acétate de sodium 0,05 *M* comme référence externe en rmn du proton. Le solvant est l'eau deutériée.

Chloration des amides. Méthode générale

La cyclodextrine (1 mmol) et le substrat (1 mmol) sont dissous dans l'eau distillée (450 mL) et la solution est agitée durant 3 h. Dans le cas de l'amylose on utilise 1,0 g d'amylose/mmol de substrat. La solution est ensuite traversée par un filet de chlore (en excès) durant une heure. L'excès de chlore est chassé par de l'azote et la solution aqueuse est extraite à l'éther (3 × 100 mL). La phase organique est séchée sur du sulfate de magnésium puis évaporée sous vide. Le mélange brut est analysé par chromatographie en phase gazeuse à l'aide d'une colonne SE-30, 6 pi × 1/8 po. Le programme de température est le suivant : isotherme à 100°C durant 2 min, augmentation de 7°C/min jusqu'à 240°C, isotherme à 240°C.

Remerciements

Les auteurs remercient le Conseil de recherches en sciences naturelles et en génie du Canada et le Ministère de l'éducation du Québec qui ont financé ce travail. Les spectres de rmn 400 MHz proviennent du Centre régional de RMN à haut champ (Université de Montréal).

Rate constant for chlorine abstraction from CCl_4 by the 5-hexenyl radical

DEBORAH RAE JEWELL, LUKOSE MATHEW, AND JOHN WARKENTIN[1]
Department of Chemistry, McMaster University, Hamilton, Ont., Canada L8S 4M1

Received September 15, 1986

This paper is dedicated to Dr. O. E. (Ted) Edwards

DEBORAH RAE JEWELL, LUKOSE MATHEW, and JOHN WARKENTIN. Can. J. Chem. **65**, 311 (1987).

Cyclization of the 5-hexenyl free radical to the cyclopentylmethyl free radical was used to clock chlorine atom abstraction by 5-hexenyl from carbon tetrachloride in solution. The source of 5-hexenyl radicals was 5-hexenyl[1-hydroxy-1-methylethyl]diazene ($(CH_3)_2C(OH)N{=}N(CH_2)_4CH{=}CH_2$), which decomposes thermally in CCl_4 by a radical chain mechanism to afford chloroform, acetone, nitrogen, 6-chloro-1-hexene, cyclopentylchloromethane, 1-hexene, and methylcyclopentane as primary products. 6-Chloro-1-hexene is converted, in part, to a secondary product, 1,1,1,3,7-pentachloroheptane, by radical chain addition of CCl_4 to the double bond. The rate constant for chlorine atom abstraction, k_{Cl}, was calculated from the product composition and the known rate constant for cyclization of the 5-hexenyl radical. For the temperature range 274–353 K, k_{Cl} is given by $\log (k_{Cl}/M^{-1}\,s^{-1}) = (8.4 \pm 0.3) - (6.2 \pm 0.4)/\theta$ where $\theta = 2.3\,RT$ kcal mol^{-1}, which leads to $k_{Cl}^{25°C} = 7.2 \times 10^3\,M^{-1}\,s^{-1}$. This value is significantly smaller than recently reported estimates for other primary alkyl radicals.

DEBORAH RAE JEWELL, LUKOSE MATHEW et JOHN WARKENTIN. Can. J. Chem. **65**, 311 (1987).

On utilisé la cyclisation du radical libre hexène-5 yle en cyclopentylméthyle pour mesurer le temps qu'il faut au radical hexène-5 yle pour enlever un atome de chlore du tétrachlorure de carbone en solution. On a utilisé l'hexène-5 yl[hydroxy-1 méthyl-1 éthyl]diazène ($(CH_3)_2C(OH)N{=}N(CH_2)_4CH{=}CH_2$) comme source de radicaux hexène-5 yles qui se décomposent thermiquement en solution dans le CCl_4 par un mécanisme radicalaire en chaîne pour donner du chloroforme, de l'acétone, de l'azote, du chloro-6 hexène-1, du cyclopentylchlorométhane, de l'hexène-1 et du méthylcyclopentane comme produits primaires. Le chloro-6 hexène-1 se transforme, en partie, en un produit secondaire, le pentachloro-1,1,1,3,7 heptane, par une addition radicalaire en chaîne du CCl_4 à la double liaison. On a calculé la constante de vitesse pour la réaction d'abstraction de l'atome de chlore, k_{Cl}, en se basant sur la composition des produits et sur la constante de vitesse connue pour la cyclisation du radical hexène-5 yle. À des températures allant de 274 à 353 K, la valeur de k_{Cl} est exprimée par l'équation $\log (k_{Cl}/M^{-1}\,s^{-1}) = (8{,}4 \pm 0{,}3) - (6{,}2 \pm 0{,}4)/\theta$ dans laquelle $\theta = 2{,}3RT$ kcal mol^{-1}; ceci conduit à une valeur de $k_{Cl}^{25°C} = 7{,}2 \times 10^3\,M^{-1}\,s^{-1}$. Cette valeur est beaucoup plus faible que les évaluations qui ont été rapportées récemment pour d'autres radicaux alkyles primaires.
[Traduit par la revue]

Introduction

Rate constants for abstraction of a chlorine atom from CCl_4 by carbon centered free radicals are of considerable current interest. The reaction is a potential kinetic standard for determination of a variety of other free radical reaction rate constants by the competition method. Two groups (1, 2) have recently pointed to the need for reliable values of k_{Cl} for solution work with alkyl radicals. There are two problems with literature values for k_{Cl}. First, the numbers from solution work with similar or identical alkyl radicals in different laboratories are widely scattered and, second, the numbers from gas phase studies are considerably smaller than most of the lowest values of k_{Cl} for condensed systems.[2] Under the circumstances, it was necessary to redetermine values of k_{Cl}.

Ingold and co-workers (1) estimated k_{Cl} for the neophyl radical (N) by using values of $k_i^N/k_{HSnBu_3}^N$ (where i stands for isomerization) from the literature (3) and substituting for $k_{HSnBu_3}^N$ the average value $k_{HSnBu_3}^{Et\cdot,n\text{-}Bu\cdot}$ from laser flash photolysis work (4). That procedure gave $\log (k_{Cl}^N/M^{-1}\,s^{-1}) = (8.14 \pm 0.42) - (5.52 \pm 0.63)/\theta$ or $k_{Cl}^{N,25°C} = 1.2 \times 10^4\,M^{-1}\,s^{-1}$. Ethyl and *n*-butyl radicals were the best models then available. More recently, $k_{HSnBu_3}^{neopentyl}$ has been determined (5) by laser flash photolysis over a range of temperatures, and use of those values, which presumably represent $k_{HSnBu_3}^N$ more closely, leads to $\log (k_{Cl}^N/M^{-1}\,s^{-1}) = (7.6 \pm 0.4) - (4.5 \pm 0.5)/\theta$ and to $k_{Cl}^{N,25°C} = 2 \times 10^4\,M^{-1}\,s^{-1}$. Although the value of k_{Cl} is quite well defined, a question just as important regarding its magnitude is whether or not N is a good model for estimating the reactivities of unbranched 1°-alkyl radicals. Moreover, a recent estimate (2) of $k_{Cl}^{n\text{-}butyl}$ ($5.8 \times 10^4\,M^{-1}\,s^{-1}$ at 27°C) based on a kinetic epr (electron paramagnetic resonance) method (2), raised the possibility that k_{Cl}^N might indeed be 3- to 5-fold (or more, given the errors) smaller than k_{Cl}^N for a straight chain 1°-alkyl radical.

We now report the Arrhenius equation for attack of the 5-hexenyl radical (5-h) on CCl_4. The results represent an independent check of $k_{Cl}^{n\text{-}Bu}$ (epr) (2), because *n*-butyl and 5-hexenyl radicals are structurally similar. They also answer the question of whether or not the neophyl clock can be used with confidence to estimate reactivities of unbranched primary alkyl radicals toward CCl_4. Finally, a new source of 5-hexenyl radicals for clocking experiments is introduced.

Method, results, and discussion

Choice of radical source

An ideal source of free radicals for a competition study involving CCl_4 is one that undergoes facile induced decomposition, by trichloromethyl radicals, to generate the desired radical. Long kinetic chains are possible with such a source and the product mixture is potentially simple, being largely devoid of products from radical–radical reactions. Since the competition method requires the determination of product ratios, it is advantageous to have a relatively clean system, so that the chances of counting one or more coproducts accidentally with the products of interest are reduced.

Hydroxydiazene **1** was chosen for this study because of evidence that compounds with the combination of functional groups, $\rangle C(OH)N{=}N-$, decompose readily in CCl_4 at temperatures near room temperature to afford chloroform and

other products (6). We therefore expected **1** to decompose in CCl_4 according to Scheme 1. The facile decomposition of **1** at temperatures between 30 and 80°C, and the product composition, are in keeping with the postulate that those reactions are the major primary processes.[3] Secondary processes, including radical chain addition of CCl_4 to RCl, are discussed below.

Addition of CCl_4 to double bonds

A potential flaw in the use of a ring closure reaction of an unsaturated radical to clock Cl abstraction from CCl_4 is that radical chain addition of CCl_4 can occur prior to release of the radical from the source (Scheme 2(*a*)) or after the radical has abstracted from CCl_4, Scheme 2(*b*).

Any contribution from the steps under Scheme 2(*a*) would interfere with the competition method for determining k_{Cl} because there is no way to partition the R″Cl obtained overall between that from the pathway involving competition, Scheme 1, and that formed without competition from ring closure, Scheme 2(*a*). However, since k_{Cl} is obtained from eq. [1], it is clear that any R″Cl measured, over and above that which should

$$[1]\quad k_{Cl} = \frac{k_i^{5\text{-h}}([RCl] + [R''Cl])}{([R'Cl] + [R'H])[CCl_4]}$$

go into the equation, serves to increase the value of k_{Cl}. Thus, even if there are two pathways to R″Cl, the method will still serve to set an upper limit on the value of k_{Cl}.

There are several reasons for believing that the undesired pathway to R″Cl was not an important contributor. The fact that both RH and R′H (Scheme 1) were formed in competition with products from Cl abstraction (Table 1) indicates that H abstraction from **1**, and (or) from $HN{=}NR^2$, is a fast process. A preliminary estimate of $k_H^{R\cdot}$ ($k_H^{R\cdot}$ is the rate constant for H abstraction from **1** by the 5-hexenyl radical), obtained by thermolysis of **1** in C_6F_6 to ca. 10% conversion followed by analysis for RH and R′H, indicates a value near $1 \times 10^5\ M^{-1}\ s^{-1}$ at 25°C.[4] If a similar value is assumed for $k_H^{Cl_3C\cdot}$, and if the rate constant for addition of $Cl_3C\cdot$ to the C=C bond of **1** is taken to be $\leq 2 \times 10^3$ at 25°C,[5] then it follows that one out of 50 $Cl_3C\cdot$ would add to **1** rather than abstract from it. In spite of potential errors in the assumptions, the above analysis suggests that most of the R″Cl can be expected to come from the route of Scheme 2(*b*) and that R″Cl should therefore be included (as was done) in eq. [1]. Values of k_{Cl} in Table 1 would be reduced by small factors only, between 0.79 and 0.87 for the three highest temperatures, if none of the R″Cl were counted. For the 274 K experiments, the analogous factor would be 0.49, as those photo-initiated runs gave the highest relative yields of R″Cl. However, a control experiment, in which a solution of RCl in CCl_4 was photolyzed, indicated ca. 34% conversion to R″Cl in 2 h, suggesting that the photochemical conditions were simply more conducive than were the thermal conditions to the consumption of initially-formed RCl by radical chain addition of CCl_4. Finally, any radicals **4** that are formed from **1** cannot be expected to form **5** efficiently in any case, because **4** is set up for closure in the 6-*exo* sense.[6] That process, followed by H transfer and dehydration, could yield hydrazone **6**, eq. [2].

[2] **4** →  $\xrightarrow{\mathbf{1}}$ 
5 **6**

[3]A referee has pointed out that the equilibrium **1** ⇄ Me_2CO + $HN{=}N(CH_2)_4CH{=}CH_2$ could be involved. Such a contribution would not invalidate the conclusions from this study because it does not matter whether the 5-hexenyl radicals come directly or indirectly from **5**.

[4]L. Mathew and J. Warkentin. Unpublished observations.

[5]The rate constant for addition of $Cl_3C\cdot$ to vinyl acetate at 50°C is $2.16 \times 10^3\ M^{-1}\ s^{-1}$ (7).

[6]The rate constant for 6-*exo* cyclization of a primary alkyl radical onto a C=C bond is about $1.1 \times 10^4\ s^{-1}$ at 65°C (8). Corresponding cyclization involving the N=N bond is considerably faster (A. L. J. Beckwith, S. F. Wang, and J. Warkentin, unpublished observations).

		0.303	0.037	0.298	1.00	0.262			

[a]Initial concentations of **1** were between 0.26 and 0.32 *M* for all runs.
[b]Each set of numbers represents a separate run and the average results of at least three gc analyses of the products of that run. Actual average intergrator counts have been reduced to relative counts, to facilitate visualization of the ratio of products (unrearranged/rearranged or the inverse).
[c]Absolute yields estimated by gc: 274 K, RCl + R′Cl + R″Cl + R′H = 70%, azine ≤ 0.3%, $CHCl_3$ = 85%, 1-hexene = 2%; 323 K, RCl + R′Cl + R″Cl + R′H = 89%, azine ≤ 2%, $CHCl_3$ = 62%, 1-hexene = 7%.
[d]The ratios $CHCl_3/C_2Cl_6$ for the two runs in footnote *c* were 56 and 43, respectively.
[e]Neat CCl_4; concentrations corrected for **1** present and for thermal expansion of CCl_4.
[f](RCl + R″Cl)/(R′Cl + R′H); RCl = 6-chloro-1-hexene, R″Cl = 1,1,1,3,7-pentachloroheptane, R′Cl = cyclopentylmethyl chloride, R′H = methylcyclopentane.
[g]The error is expressed as the standard deviation.
[h]Calculated from the equation $\log (k_i^{5\text{-h}}/s^{-1}) = 10.4 - 6.9/\theta$, where $\theta = 2.3\,RT$ kcal mol^{-1}.
[i]Photolysis.

Examination of crude product mixtures by ^1H nmr spectroscopy showed, for all but the runs at 274 K, two singlets (δ 1.74 and 1.98, CCl_4, 250 MHz) suggestive of a hydrazone or an azine of acetone. The maximum yield of that product, estimated by gc analysis, was about 15% from one thermal run. Other thermal runs gave lower yields (ca. 2–8%). Analysis of products from the photo-induced (274 K) reactions by gc revealed a material with the same retention time (≤0.3%). Attempts to isolate the hydrazone or azine by-product were unsuccessful, but the possibility that it was acetone azine could be excluded by coinjection of authentic acetone azine.

Although the identity of the hydrazone or azine by-product is of interest, formation of **6** (eq. [2]) would not interfere with the operation of the 5-hexenyl clock. The fact that yields of the by-product varied, and that they were lowest from the low temperature, photo-initiated runs (complete in ≤3 h) suggests that the by-product actually came from a competing polar reaction, eq. [3], catalyzed by trace impurities or by wall surfaces.

[3] $\mathbf{1} \rightarrow H_2O + Me_2C{=}NN{=}CH(CH_2)_3CH{=}CH_2$

In summary, the inclusion of the total yield of R″Cl in eq. [1] is unlikely to have caused errors larger than the experimental errors involved in determining the product ratios (Table 1), and the formation of an unidentified by-product (azine or hydrazone), in significant quantity in some cases, is unlikely to invalidate the kinetic results. Numerous minor compounds formed in trace amounts (≤1% each) are probably the products expected from the many radical–radical reactions (coupling and disproportionation) that are not included in Scheme 1. Although some of those products should also be counted in eq. [1], the fact that they are very minor components and that their inclusion in eq. [1] would increase both the numerator and the denominator very slightly, and would therefore alter the ratio insignificantly, means that they can be ignored. Incidentally, the low yields of products expected from radical–radical reactions and the high ratio of chain transfer product ($CHCl_3$) to a chain termination product (C_2Cl_6), Table 1 (footnote *d*), point to the dominance of radical-chain decomposition of **1** in CCl_4.

Magnitude of k_{Cl}

The most reliable published (4) Arrhenius relationship for isomerization of 5-h is eq. [4]. That equation can now be modified slightly to eq. [5] by using the most recent data (5) for

[4] $\log (k_i^{5\text{-h}}/s^{-1}) = (10.37 \pm 0.32) - (6.85 \pm 0.42)/\theta$

[5] $\log (k_i^{5\text{-h}}/s^{-1}) = (10.4 \pm 0.3) - (6.9 \pm 0.4)/\theta$

H abstraction from $HSnBu_3$ by ethyl and *n*-butyl radicals. Equation [5] was used to calculate $k_i^{5\text{-h}}$ values for use in eq. [1].

The Arrhenius relationship for chlorine atom abstraction by 5-h, from the data in Table 1, is eq. [6], in which the errors are

[6] $\log (k_{Cl}^{5\text{-h}}/M^{-1}\,s^{-1}) = (8.4 \pm 0.3) - (6.2 \pm 0.4)/\theta$

estimated and in which $\theta = 2.3\,RT$ kcal mol^{-1}. Equation [6] gives $k_{Cl}^{5\text{-h},25°C} = 7.2 \times 10^3\ M^{-1}\ s^{-1}$, which is a factor of eight smaller than $k_{Cl}^{n\text{-butyl}}$ (esr) determined by Griller and co-workers (2) and a factor of 2.8 smaller than the best estimate of k_{Cl}^{N}, based on the $HSnBu_3$ method (1) and recalculated as outlined in the Introduction. The disagreement with the results from esr work (2) is not outside the considerable errors associated with that approach and the good agreement with k_{Cl}^{N} removes any serious qualms about the use of the neophyl radical as a model for unbranched 1°-alkyls in this case.

In summary, the present Arrhenius equation for $k_{Cl}^{5\text{-h}}$ should

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 80.58.250.72 on 09/07/12
For personal use only.

be used for studies of unhindered 1°-alkyl radicals in which abstraction from CCl_4 is the competitive clocking reaction. Reagent **1** is a promising source of 5-hexenyl radicals for studies such as this one because its radical chain decomposition eliminates the cage coupling that can complicate product analyses when non-chain sources are used.

Experimental

5-Hexenyl[1-hydroxy-1-methylethyl]diazene, 1

This compound was prepared by treatment of the corresponding hydroperoxide (**2**), described below, in ice-cooled petroleum ether with triphenylphosphine in petroleum ether, bp 30–60°C. When addition of the phosphine solution was complete, the reaction mixture was kept for several hours in a freezer to complete precipitation of triphenylphosphine oxide. Filtration, removal of most of the solvent with a rotary evaporator, and bulb-to-bulb distillation at room temperature (10^{-2} Torr) afforded **1**; uv (hexane, λ_{max}, log ε): 232 (1.97), 328 (1.33); ir (neat): 3412 (OH) cm^{-1}; ^1H nmr (CCl_4, 250 MHz) δ: 1.25 (s, 6H), 1.37 (quintet, 2H), 1.72 (quintet, 2H), 2.00 (m, 2H), 3.77 (m, 2H), 4.28 (s, br, 1H), 4.87 (m, 2H), 5.64 (m, 1H); ^{13}C nmr ($CDCl_3$, 250 MHz) δ: (5-hexenyl group) 26.50 (C-2 or C-3), 27.04 (C-3 or C-2), 33.36 (C-4), 66.57 (C-1), 114.80 (C-6), 138.30 (C-5); (1-hydroxy-1-methylethyl group) 26.94 (C-2), 93.61 (C-1); ms (high resolution) *m/z*: calcd. for $C_9H_{17}N_2$ ($M^+ - OH$): 153.1393; found: 153.1387.

5-Hexenyl[1-hydroperoxy-1-methylethyl]diazene, 2

Autoxidation of the 5-hexenyl hydrazone of acetone (**3**, described below, 1.02 g, 6.6 mmol), in light petroleum until the uptake of oxygen ceased, afforded **2** in solution for direct reduction to **1**. A small aliquot was freed from solvent by blowing N_2 onto the surface of the solution; uv (hexane, λ_{max}, log ε): 222 (1.98), 362 (1.35); ir (neat): 3317 (OH) cm^{-1}; iodometric titration: 97%, 98%; ^1H nmr (CCl_4, 90 MHz) δ: 1.32 (s, 6H), 1.32–2.25 (m, 6H), 3.81 (t, 2H), 4.97 (m, 2H), 5.73 (m, 1H), 9.33 (s, 1H); ^{13}C nmr ($CDCl_3$, 250 MHz) δ: (5-hexenyl group) 26.53 (C-3 or C-2), 26.96 (C-2 or C-3), 33.35 (C-4), 68.69 (C-1), 128.34 (C-6), 138.24 (C-5); 1-hydroperoxy-1-methylethyl group 21.63 (C-2), 102.73 (C-1).

5-Hexenylhydrazone of acetone, 3

To a cold solution of acetone (ca. 15 mL) in ether (50 mL) containing acetic acid was added, drop by drop, a solution of 5-hexenyl hydrazine (13.23 g, 0.116 mol) in 50 mL of ether. After it had been stirred for an hour the solution was washed with water (2 × 50 mL) and with brine (50 mL). The ether layer was dried over $MgSO_4$, the ether was then evaporated, and the residual liquid was distilled at 2.8 Torr. The fraction boiling at 71–72°C (15.6 g, 87% yield) was used in small scale autoxidations described above; uv (hexane, λ_{max}, log ε): 224 (1.93), 246 (1.96), 364 (0.88); ^1H nmr ($CDCl_3$, 250 MHz, ref. $CHCl_3$ at δ 7.21) δ: 1.32–1.42 (m, 4H), 1.57 (s, 3H), 1.77 (s, 3H), 1.47 (q, 2H), 2.94 (t, 2H), 4.05 (s, br, 1H), 4.84 (m, 2H), 5.65 (m, 1H); ^{13}C nmr ($CDCl_3$, 250 MHz) δ: (5-hexenyl group) 26.27 (C-3 or C-2), 28.97 (C-2 or C-3), 33.48 (C-4), 50.85 (C-1), 114.30 (C-6), 138.56 (C-5); remainder, 15.34 (*Z*-Me), 25.00 (*E*-Me), 145.15 (Me_2C); ms (high resolution) *m/z*: calcd. for $C_9H_{18}N_2$: 154.1471; found: 154.1478.

5-Hexenylhydrazine

5-Hexenyl tosylate (42.97 g, 0.169 mol) was added during 20 min, with stirring, to an ice-cooled solution of hydrazine hydrate (90 g, 1.8 mol) in absolute ethanol (100 mL). Stirring was continued for 2 h after addition was complete before most of the ethanol was removed with a rotary evaporator. Continuous extraction of the residue with ether (250 mL) for two days, drying of the ether layer with Na_2SO_4, and evaporation of the ether left a residue, which was distilled under N_2 at 3 Torr. The fraction boiling at 56–58°C was a clear, colourless liquid (13.23 g, 68% yield); ^1H nmr (CCl_4, 90 MHz) δ: 1.15 (m, 4H), 1.80 (m, 2H), 2.45 (m, 2H), 2.83 (s, 3H), 4.70 (m, 2H), 5.27–5.77 (m, 1H).

6-Chloro-1-hexene

A solution of 5-hexen-1-ol (1.8 g, 0.018 mol) in benzene (30 mL) containing *N,N*-dimethylaniline (2.18 g, 0.018 mol) was cooled to −5°C and thionyl chloride (2.22 g, 0.019 mol) in benzene (20 mL) was dropped in during 10 min, with stirring. The resulting yellow-brown mixture was stirred at ice-bath temperature for 1 h before it was heated to the reflux temperature for 1 h. The solution, now green, was washed twice with water, three times with 3 *M* HCl (25 mL), three times with saturated $NaHCO_3$ solution, and, finally, with water until the wash was neutral to litmus. Drying over $MgSO_4$ followed by evaporation of the solvent left a yellow liquid from which colourless 5-chloro-1-hexene was obtained by distillation, bp 130–132°C (760 Torr); ^1H nmr (CCl_4, 250 MHz) δ: 1.48–1.54 (m, 2H), 1.72 (m, 2H), 2.04 (m, 2H), 3.44 (t, 2H), 4.93 (m, 2H), 5.70 (m, 1H); ms (low resolution) *m/z*: 120, 118 (M^+), 55 ($C_4H_7^+$, 100%).

Cyclopentylmethyl chloride

A procedure similar to that described above afforded the title compound (9) from cyclopentyl methanol; ^1H nmr (CCl_4, 250 MHz, ref. $CHCl_3$ at δ 7.21) δ: 1.16–1.33 (m, 2H), 1.54–1.82 (2m, partly resolved, 6H), 2.21 (quint, 1H), 3.37 (d, 2H); ms (low resolution) *m/z*: 120, 118 (M^+), 55 ($C_4H_7^+$, 100%).

1,1,1,3,7-Pentachloroheptane

A solution of 6-chloro-1-hexene (0.10 g, 0.84 mmol) and benzoyl peroxide (0.010 g, 4.1×10^{-5} mol) in 2 mL of carbon tetrachloride was degassed and sealed at 10^{-2} Torr. It was then heated at 80°C for 48 h. The desired pentachloroheptane was obtained by preparative gc separation of the reaction mixture on OV-17 (10%); ^1H nmr (CCl_4, 250 MHz) δ: 1.7 (m, 6H), 2.9–3.3 (AB quartet, J_{AB} = 15.5 Hz, each line a doublet, J = 4.79 Hz for A, 5.21 Hz for B, 2H), 3.5 (m, 2H), 4.2 (m, 1H).

Purification of CCl_4

Reagent grade CCl_4 was washed thoroughly with dilute sodium bicarbonate solution. The CCl_4 layer was separated and dried over anhydrous K_2CO_3. A center cut from distillation in a grease-free glass system was stored in a brown bottle.

Thermolysis of 1

A small quantity of **1** (20–30 mg) was weighed in a small vial. Carbon tetrachloride (ca. 0.5 mL) was added to make a solution, near 0.3 *M* in **1**, which was transferred to an nmr tube fitted with a ground glass joint. The sample was degassed by means of freeze–pump–thaw cycles and the tube was sealed at 10^{-2}–10^{-3} Torr. A constant temperature oil bath was used for thermolysis of **1** in the sample and progress was monitored by nmr spectroscopy. When the *gem*-dimethyl signal of **1** had disappeared, the tube was opened and the contents were analyzed by gas chromatography, using authentic compounds to establish retention times and detector response factors. Identification of products was based also on the results of analysis by gc/ms and on comparison of ^1H nmr spectra of samples obtained by preparative gc with spectra of authentic materials.

Photolysis of 1

Diazene **1** (0.0430 g) was weighed in a calibrated, 1-mL volumetric flask and CCl_4 was added up to the calibration mark. The flask was shaken to mix the contents and 300 μL of the solution was transferred into each of three nmr tubes. The tubes were sealed after three freeze–pump–thaw cycles and they were transferred to a quartz Dewar flask, equipped with a stirrer and filled with ice and water, after acquisition of the ^1H nmr spectrum, which showed no evidence of either acetone or chloroform. After photolysis for 3 h with 300 nm light in a Rayonet apparatus, the ^1H nmr spectrum was free from the *gem*-dimethyl signal of **1** and the tubes were cut for analysis. During the photolysis, the temperature was monitored (1 ± 0.5°C) with a thermometer placed near to the sample tubes and portions of ice were added from time to time to maintain the temperature.

Chromatographic analysis

A Varian Vista 6000 gas chromatograph with a flame ionization detector at 300°C and an off-column flash injector at 220°C were used for analytical work. Two columns were used to check for signal overlap and (or) thermal decomposition during analysis. One was a 5 ft × 1/8 in. glass column packed with Carbowax 20 M (5%) on

Haloselenate(IV) formation and selenous acid dissociation equilibria in hydrochloric and hydrofluoric acids

JOHN MILNE

Ottawa–Carleton Institute for Research and Graduate Studies in Chemistry, University of Ottawa Campus, Ottawa, Ont., Canada KIN 9B4

Received June 4, 1986

JOHN MILNE. Can. J. Chem. **65**, 316 (1987).

Raman spectroscopy has shown that the initial stages of haloselenate(IV) formation equilibria are the same in HF and HCl solutions.

$$H_2SeO_3 + H^+ + X^- \overset{K_4}{=} HSeO_2X + H_2O \qquad (X = F, Cl)$$

$$HSeO_2X + H^+ + X^- \overset{K_5}{=} SeOX_2 + H_2O$$

The constants K_4 and K_5, evaluated by quantitative Raman measurements, for HCl solutions are 0.015 ($\pm$0.001) L^2 mol^{-2} and 0.9 ($\pm$0.1) $\times$ 10^{-5} L^2 mol^{-2}, respectively. These constants yield the minimum average deviation in normalized molar scattering intensity for the species formed in three regions of the spectra, 690 and 890 cm^{-1} (SeO stretching) and 100–450 cm^{-1} (deformation and SeCl stretching). Before the onset of haloselenate(IV) formation, changes in the SeO stretching band intensities with HX concentration occur due to repression of ionic dissociation of selenious acid

$$H_2SeO_3 \overset{K_1}{=} H^+ + HSeO_3^-$$

Quantitative Raman measurements yield K_1 = 9.8 ($\pm$0.3) $\times$ 10^{-3} mol L^{-1}. Reasons for the high value of this constant, compared to reported values, are discussed.

JOHN MILNE. Can. J. Chem. **65**, 316 (1987).

Il a été montré par la spectroscopie Raman que les équilibres initiaux de la formation des halosélénate(IV)s sont les mèmes dans les solutions de HF et HCl.

$$H_2SeO_3 + H^+ + X^- \overset{K_4}{=} HSeO_2X + H_2O \qquad (X = F, Cl)$$

$$HSeO_2X + H^+ + X^- \overset{K_5}{=} SeOX_2 + H_2O$$

Les constantes K_4 et K_5, evaluées à l'aide de mésures quantitatives Raman, pour les solutions d'HCl, sont respectivement 0.015 ($\pm$0.001) L^2 mol^{-2} et 0.9 ($\pm$0.1) $\times$ 10^{-5} L^2 mol^{-2}. Ces constantes donnent les écarts moyens minimums dans l'intensité molaire normalisée de la lumière diffusée à trois regions des spectres, 690 et 890 cm^{-1} (SeO allongements) et 100–450 cm^{-1} (déformations et SeCl allongements). Avant la formation de haloselenate(IV)s, les changements d'intensité des bandes de SeO allongement avec des changements de la concentration d'HCl ont lieu à cause de la repression de la dissociation ionique de l'acide sélénieux,

$$H_2SeO_3 \overset{K_1}{=} H^+ + HSeO_3^-$$

Les mésures quantitatives Raman donnent K_1 = 9.8 ($\pm$0.3) $\times$ 10^{-3} mol L^{-1}. Des causes de la haute valeur de cette constante en comparaison aux valeurs dans la literatures, sont discutées.

Introduction

While there is a considerable body of quantitative information concerning complexation equilibria involving metal ions in aqueous solution, little work has been done on semimetal complexation. The present work deals with Se(IV) complexation in hydrofluoric and hydrochloric acid and represents an extension of earlier studies on SeO_2 on HF (1), HCl (2), and HBr (3). The reasons for the extension of previous work are threefold. Firstly, it was reported without complete explanation in earlier work (2) that the relative intensities of the SeO double and single bond stretching bands in the Raman spectra of SeO_2 solutions changed with increasing HCl concentration (0.0 to 5.0 *M*), a range where only H_2SeO_3 was considered to be present, and it was felt that some rationalization of this change was necessary. Secondly, the activities of hydrochloric acid were applied erroneously in earlier work (2) and, while the equilibria occuring at high HCl concentrations (8.0–12.0 *M* HCl) were correctly identified, the formation constants calculated were incorrect. A reinterpretation of the quantitative Raman intensities with more detailed measurements over the entire HCl concentration range was called for. Finally, while the monohaloselenate(IV) anions, SeO_2X^- (X = F, Cl, Br) (4, 5) are familiar, only in the case of the SeO_2–HBr system (3) has one of the parent acids, $HSeO_2Br$, been observed. It seems likely that the analogous acids would be present in SeO_2–HF and SeO_2–HCl systems also.

Experimental section

Solutions were made up from SeO_2 (Alfa), which was found by permanganometric analysis (6) to be partially converted to H_2SeO_3. The SeO_2 used was found to be 95% pure. Hydrofluoric and hydrochloric acids (Baker) were analyzed by titration before use.

The methods for obtaining quantitative Raman spectra have been described elsewhere (2). The spectra of the hydrofluoric acid solutions were recorded at 488 nm using a sapphire cell and those of the hydrochloric acid solutions were recorded at 514.5 nm. The normalization assumption for calibration of band intensities was that the 925 cm^{-1} band in the spectrum of 1 *M* perchloric acid solution, used as an external standard, had an area intensity of 6.45 cm^2 (1 $in.^2$). This

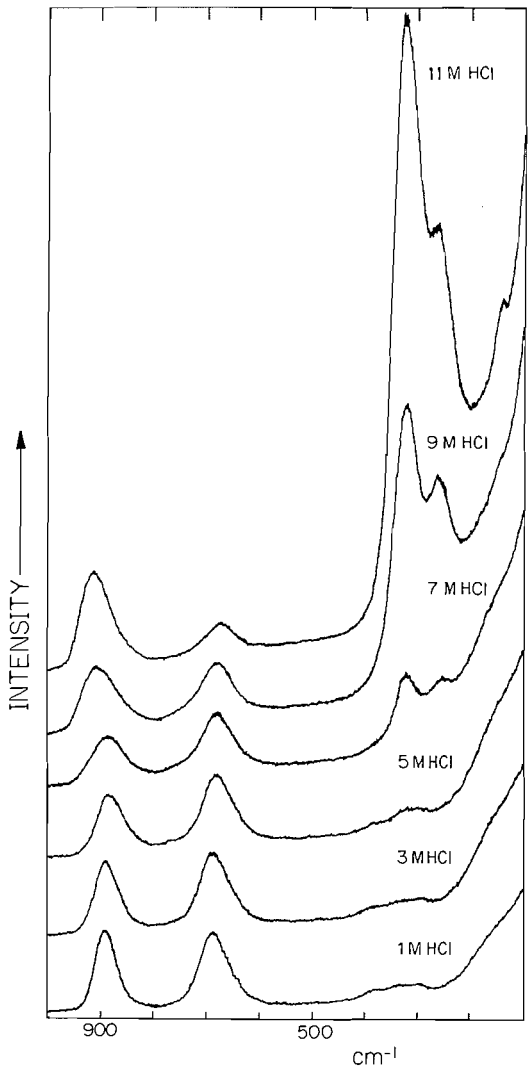

FIG. 1. Raman spectra of solutions of SeO_2 (0.95 *M*) in HCl (0.0–12.0 *M*).

standard was run before and after each SeO_2 solution spectrum with all spectrometer and laser conditions held constant.

Results and discussion

From consideration of the Raman spectra of 0.95 *M* SeO_2 in solutions with HCl concentration in the range 0.0 to 4.0 *M*, shown in Fig. 1, it is apparent that the SeO single bond stretching mode at 690 cm^{-1} increases in intensity relative to the SeO double bond mode at 890 cm^{-1}. Normalized intensities given in Table 1 for these bands show that there is an absolute increase in intensity of the 690 cm^{-1} band and a decrease in intensity of the 890 cm^{-1} band. These changes are not accompanied by the appearance of an Se—Cl stretching band near 300 cm^{-1} and must involve changes in selenous acid dissociation equilibria connected with changes in proton activity accompanying the increase in HCl concentration. An understanding of these changes requires first of all a consideration of the equilibria governing selenious acid and the various other non-chloro-coordinated Se(IV) species in solution. It should be noted that the changes in peak intensity and frequency for a single species due to changes in ionic strength as a result of differing solvation effects are normally small relative the effects discussed here. For instance, the position of the 925 cm^{-1} band of the perchlorate ion in solutions of perchloric acid over the

[a]Intensity of total band envelope (850 and 890 cm^{-1}).

concentration range 0.3 to 9 *M* increases by 5 cm^{-1} and the intensity varies directly as the concentration.

Cesium hydrogen selenate(IV) solutions

Plots of normalized intensity of peaks at 850 and 610 cm^{-1}, the double and single bond stretches for $HSeO_3^-$, for solutions of $CsHSeO_3$ (0.38, 0.57, 0.78, and 0.95 *M*) yield straight lines with molar intensities $I_{850}(HSeO_3^-) = 8.10\ (\pm 0.25)\ cm^2$ and $I_{610}(HSeO_3^-) = 2.40\ (\pm 0.30)\ cm^2$. These solutions apparently contain $HSeO_3^-$ ion as the only Se(IV) species. This is expected in view of the magnitude of the dissociation and hydrolysis constants for $HSeO_3^-$, $K_2 = 7.9 \times 10^{-9}$ mol L^{-1} and $K_h = 3.1 \times 10^{-12}$ mol L^{-1}, respectively (7). A single measurement of the bands in the deformation region (100–450 cm^{-1}) at $c(CsSeO_3) = 0.76\ M$ gave a molar intensity $I_{100-450}(HSeO_3^-) = 3.0\ cm^2$.

Selenous acid solutions

At low selenous acid concentrations and ambient temperatures the equlibria,

[1] $H_2SeO_3 = H^+ + HSeO_3^-$

[2] $HSeO_3^- \overset{K_2}{=} H^+ + SeO_3^{2-}$

governed by dissociation constants, $K_1 = 3.2 \times 10^{-3}$ mol L^{-1} and $K_2 = 7.9 \times 10^{-9}$ mol L^{-1}, occur (7). However, at higher concentrations more complex species such as $(H_2SeO_3)_2$, $H(HSeO_3)_2^-$, and $(HSeO_3)_2^{2-}$ may be formed (7–9). For concentrations in the range studied here the SeO double bond envelope at 890 cm^{-1} consists of two peaks, a main peak at 890 cm^{-1} due to H_2SeO_3 and a shoulder at 850 cm^{-1} due to $HSeO_3^-$ (8). This is shown in Fig. 2 where the relative intensity of the 850 cm^{-1} peak to the 890 cm^{-1} peak decreases with increasing concentration in accordance with equilibrium (1). It should also be noted at this time that the intensity of the 850 cm^{-1} peak in the 0.95 *M* SeO_2 in 1 *M* HCl solution spectrum is virtually eliminated compared to those in 0.95 *M* SeO_2 in water, confirming the origin of this peak. It is clear from the magnitude of K_2 that, in these solutions, the small concentration of SeO_3^{2-} ion would not be detected by Raman spectroscopy. However, an estimate of K_1 was made by resolving the SeO double bond envelope into contributions from H_2SeO_3 and $HSeO_3^-$ and determining $[HSeO_3^-]$ from the molar intensity at 850 cm^{-1}, $I_{850}(HSeO_3^-)$. $[H_2SeO_3]$ was

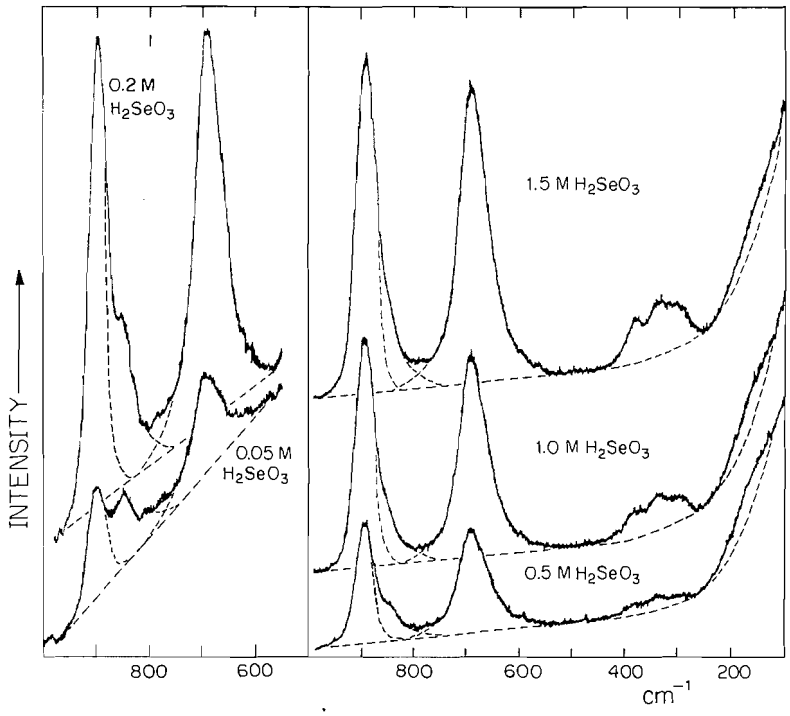

FIG. 2. Raman spectra of solutions of SeO_2 in water.

then calculated from stoichiometry. In the absence of measured ionic activity coefficients, those calculated from Debye–Hückel theory were used (10). In the range of ionic strength for these solutions (ca. 0.1 *M*), DH coefficients for strong acids with oxoanions are usually within 10% (lower) of measured values (ref. 10, p. 491) and this should apply for H^+ and $HSeO_3^-$ ions. The first dissociation constant,

$$[3] \quad K_1 = \frac{[H^+][HSeO_3^-]y_\pm^2}{[H_2SeO_3]}$$

where $y_\pm$ is the molar activity coefficient, was determined to be $9.3\,(\pm 0.7) \times 10^{-3}$ mol L^{-1}. The agreement between the values of K_1, as well as the reasonably constant value of the molar intensities calculated for H_2SeO_3 from the concentrations and molar intensities for the $HSeO_3^-$ ion given above, for the five solutions studied supports the interpretation and calculations. The data and calculated values are shown in Table 2. The value calculated for K_1 is higher than that reported in the literature (7). The large apparent concentration of hydrogen selenate(IV) ion may be due to the equilibrium,

$$[4] \quad H_2SeO_3 + HSeO_3^- \overset{K_3}{=} H(HSeO_3)_2^-$$

for which there is evidence from pH studies (7). However, calculations which include eq. [4] and which use as criteria of acceptability, the constancy of K_1 and K_3, lead to little change in K_1 (10% lower). Another possible reason for the relatively high value of K_1 is ion-pair formation. There exist instances of moderately strong acids where the dissociation constant, measured by infinite dilution methods or by methods which can be used in the millimolar range where $y_\pm = 1$ is a good approximation, is lower than that measured by high concentration methods such as nmr or Raman spectroscopy (11, 12). It has been proposed that the high dissociation constants at high concentration are due to the formation of the "hydronium ion – acid anion" ion pair, which would contribute to the high apparent anion concentration (12) and dissociation constant. Finally another possible reason for the difference may be the simplicity of the equilbria model chosen. Barcza and Sillen (7) have found evidence for the dimerization of H_2SeO_3 and $HSeO_3^-$ in solutions of moderately low selenous acid concentration (0.02–3.00 *M*). However, Raman studies show evidence for the formation of $(H_2SeO_3)_2$ only at much higher concentrations (8.07 *M*) (8) than those studied here and it is claimed in other potentiometric and spectrophotometric work (13) that anion dimerization does not occur under the acid conditions which exist in this work. At present the discrepancy between low and high concentration dissociation constants, K_1, is best accounted for in terms of ion-pair formation. The trend towards higher values of K_1 with increasing concentration shown in Table 2 might also be accounted for by ion-pair formation although $H(HSeO_3)_2^-$ formation would also cause the same change in the apparent K_1.

Solutions of selenium dioxide in hydrochloric acid

The changes in intensity of the 690 and 890 cm^{-1} bands in the spectra of 0.95 *M* SeO_2 in 0.0 to 4.0 *M* HCl solutions, which are in the opposite direction (Fig. 1), can be readily accounted for in terms of the repression of equilibrium (1). The 690 cm^{-1} band increases with increasing c_{HCl} because this band is more intense for H_2SeO_3 ($I_{690}(H_2SeO_3) = 7.4\ cm^2$) than for $HSeO_3^-$ ($I_{690}(HSeO_3^-) = 2.4\ cm^2$) while the 890 cm^{-1} band decreases since $I_{890}(H_2SeO_3)$ (5.45 cm^2) is lower than $I_{890}(HSeO_3^-)$ (8.1 cm^2). Quantitative treatment of this region of HCl concentration is difficult, since there is no clear way to deal with the ionic activities. Debye–Hückel activities are unrealistic in this range of ionic strength especially for acid electrolytes (except at $c_{HCl} = 0.0$). The measured molar ionic activities for HCl (H^+, Cl^-) probably represent a closer description of these activities for H^+ and $HSeO_3^-$ in these solutions than do Debye–Hückel activities. In view of these uncertainties as well as the relatively small changes in intensity of the 690 and

[b]$[Cl^-] = [H^+]$.
[c]Values calculated by choosing $I_{890}(HSeO_2Cl) = 4.92$ cm^2 M^{-1}, which gave the lowest average deviation from the mean of $I_{890}(SeOCl_2)$ $(= 13.0 \pm 1.1$ cm^2 $M^{-1})$.
[d]Values calculated by choosing $I_{100-450}(HSeO_2Cl) = 18$ cm^2 M^{-1}, which gave the lowest average deviation from the mean of $I_{100-450}(SeOCl_2)$ $(= 98 \pm 2$ cm^2 $M^{-1})$.

890 cm^{-1} bands (Table 1), it was not considered worthwhile to fit these data to K_1.

As HCl concentration is increased above 4.0 M, a band is seen to grow in intensity at 330 cm^{-1} in the SeCl stretching region of the spectrum. This peak is 50 cm^{-1} higher than that of the SeO_2Cl^- anion (5) in acetonitrile and is, therefore, unlikely to be due to this species. Moreover, the growth of this peak is accompanied by a growth in the intensity of the Se—OH stretching peak (690 cm^{-1}) over the range 4.0 to 6.0 M HCl where $[H_2SeO_3]$ is virtually constant if not decreasing. For these reasons it appears likely that $HSeO_2Cl$ is formed in these solutions. At even higher concentrations, $SeOCl_2$ is formed (2) and its spectrum is apparent in Fig. 1. In the range 4.0–12.0 M HCl the Se(IV) equilibria which occur are,

$$[5] \quad H_2SeO_3 + H^+ + Cl^- \overset{K_4}{=} HSeO_2Cl + H_2O$$

$$[6] \quad HSeO_2Cl + H^+ + Cl^- \overset{K_5}{=} SeOCl_2 + H_2O$$

Interpretation in terms of K_4 and K_5 is consistent with the observed peak intensities. If it is assumed that only $SeOCl_2$ is formed (2), the formation constants calculated vary by several orders of magnitude over the HCl concentration range 5.0–12.0 M.

The formation constants K_4 and K_5 may be evaluated from any one of the three peak intensity regions of the spectra, 100–450, 690, or 890 cm^{-1}. However, the 690 cm^{-1} region is simpler to deal with since only H_2SeO_3 and $HSeO_2Cl$ contribute to the peak intensity of this region. In addition, in the case of the deformation/SeCl stretching region, while greater peak intensity at high HCl concentrations yields greater accuracy, uncertainty in the background correction and of the H_2SeO_3 molar intensity remove this advantage except for the most concentrated solutions. The unknowns, K_4, K_5, and $I_{690}(HSeO_2Cl)$ may be evaluated by means of the following equations,

$$[7] \quad c_{IV} = [H_2SeO_3] + [HSeO_2Cl]$$

$$[8] \quad i_{690} = I_{690}(H_2SeO_3)[H_2SeO_3] + I_{690}(HSeO_2Cl)[HSeO_2Cl]$$

$$[9] \quad K_4 = \frac{[HSeO_2Cl]\,a_w}{[H_2SeO_3]\,a_{\pm HCl}{}^2}$$

$$[10] \quad K_5 = \frac{[SeOCl_2]\,a_w}{[HSeO_2Cl]\,a_{\pm HCl}{}^2}$$

$$[11] \quad [H^+] = [Cl^-] = c_{HCl} - [HSeO_2Cl] - 2[SeOCl_2]$$

where a_w is the activity of water, $a_{\pm HCl}$ is the molar activity of HCl (ref. 10, Appendix 8.10; refs. 14, 15) and c_{IV} and c_{HCl} are the stoichiometric concentrations of Se(IV) and HCl, respectively. Various values of K_4 and K_5 were chosen in increments of 10^{-3} and 10^{-6}, respectively, to yield a minimum in the average deviation in $I_{690}(HSeO_2Cl)$ for the eight highest

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 80.58.250.72 on 09/07/12
For personal use only.

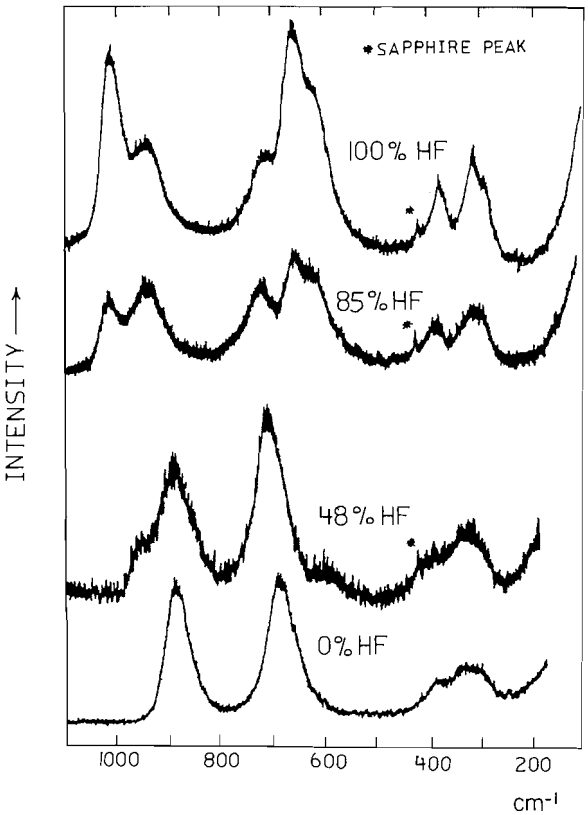

FIG. 3. Raman spectra of solutions of SeO_2 (3 M) in HF (0.0–100%).

HCl concentrations measured (5.0–12.0 M HCl). Smaller incremental changes in K_4 and K_5 were not felt to be useful since the minimum in the deviation on $I_{690}(HSeO_2Cl)$ then became very shallow. The best results were given by $K_4 = 1.5 \times 10^{-2}$ L^2 mol^{-2} and $K_5 = 9 \times 10^{-6}$ L^2 mol^{-2} which gave an average $I_{690}(HSeO_2Cl) = 7.25$ cm^2. The individual values of $I_{690}(HSeO_2Cl)$ at each c_{HCl} and mean value with average deviation as well as the concentrations of all species are given in Table 3. It is possible to calculate the molar intensities of $SeOCl_2$, $I_{890}(SeOCl_2)$ and $I_{100-450}(SeOCl_2)$, by choosing the analogous values for $HSeO_2Cl$, $I_{890}(HSeO_2Cl)$ and $I_{100-450}(HSeO_2Cl)$, which yield the minimum variation in the $I(SeOCl_2)$ values via the equations,

$$[12] \quad i_{890} = I_{890}(HSeO_2Cl)[HSeO_2Cl] + I_{890}(SeOCl_2)[SeOCl_2] + 5.45[H_2SeO_3]$$

$$[13] \quad i_{100-450} = I_{100-450}(HSeO_2Cl)[HSeO_2Cl] + I_{100-450}(SeOCl_2)[SeOCl_2] + 2.18[H_2SeO_3]$$

because of the low $[SeOCl_2]$, and thus the small influence on the intensity of the bands, at low c_{HCl}, these calculations were only carried out for solutions with $c_{HCl} > 7$ M. The molar intensities for H_2SeO_3 are taken from Table 2 and the concentrations from Table 3. The least variation, as judged by average deviation, in $SeOCl_2$ molar intensities was given by choosing $I_{890}(HSeO_2Cl) = 4.9$ cm^2 and $I_{100-450}(HSeO_2Cl) = 18$ cm^2. The individual $I(SeOCl_2)$ for each c_{HCl} and mean value with average deviation are given in Table 3. Because of the uncertainty in the background contribution to the 100–450 cm^{-1} envelope at low peak intensities and the uncertainty in $I_{100-450}(H_2SeO_3)$, the $I_{100-450}(SeOCl_2)$ calculated at $c_{HCl} < 9.0$ M are unreliable. The excellent agreement between $I_{100-450}(SeOCl_2)$ calculated for the range $c_{HCl} = 9.0$ to 12.0 M, when $i_{100-450}$ changes three-fold in intensity, is strong support for the interpretation in terms of equilibria [5] and [6] as well as the calculated values of K_4 and K_5.

Solutions of SeO_2 in hydrofluoric acid

The Raman spectra of solutions of SeO_2 in hydrofluoric acid shown in Fig. 3 exhibit the same changes at low HF concentrations as those of the corresponding solutions in hydrochloric acid. The changing intensities of the 690 and 890 cm^{-1} peaks reflect the repression of the dissociation equilibria of H_2SeO_3. When the HF concentration of the solvent used reaches 28.0 M the spectrum of a 3 M SeO_2 solution exhibits new peaks in addition to those of H_2SeO_3. A new peak appears at 930 cm^{-1} corresponding to an SeO double bond stretch, another peak appears at 600 cm^{-1} in the SeF stretching region and the SeO single bond peak at 690 cm^{-1} increases in intensity relative to that at 890 cm^{-1} indicating that the new species being formed has an SeO single bond. The spectral changes are consistent with the equilibrium

$$[14] \quad H_2SeO_3 + HF = HSeO_2F + H_2O$$

With 52.0 M HF as solvent the spectrum due to H_2SeO_3 has completely disappeared, the three principal peaks of $HSeO_2F$ are clearly evident but, in addition, peaks corresponding to those of $SeOF_2$ at 1008 and 650 cm^{-1} are apparent. The formation of $SeOF_2$ from SeO_2 and 100% HF has been demonstrated earlier (1). With 100% HF as solvent the spectrum of $SeOF_2$ is even more pronounced relative to that of $HSeO_2F$. In the absence of activity data for HF at the concentrations at which $HSeO_2F$ and $SeOF_2$ are formed, it is not possible to calculate formation constants.

Conclusions

In solutions of SeO_2 in HX (X = F, Cl, Br), as the concentration of HX is increased, there is first of all a repression of the ionic dissociation of H_2SeO_3 which then undergoes a stepwise substitution of OH groups by halogen X yielding first the monohaloselenous acid which is undissociated in HX solutions. Subsequently, the second OH group is substituted, giving seleninyl halide, which in HBr acts as a Br^- acceptor, forming the $SeOBr_3^-$ anion. Seleninyl fluoride is the most highly fluoride coordinated species in HF but in HCl and HBr, SeX_5^- and SeX_6^{2-} species are formed (2, 3).

Ultrasonic speeds and isentropic compressibilities of binary mixtures of *n*-octane with each of the hexane isomers at 298.15 K[1]

GEORGE C. BENSON[2] AND CARL J. HALPIN
Division of Chemistry, National Research Council of Canada, Ottawa, Ont., Canada K1A 0R6

Received June 9, 1986

GEORGE C. BENSON and CARL J. HALPIN. Can. J. Chem. **65**, 322 (1987).

Measurements of ultrasonic speed were carried out for *n*-octane + each of the five hexanes at 298.15 K. The results were combined with excess molar volumes reported previously to obtain excess isentropic compressibilities and isentropic pressure derivatives of the excess molar volumes. These are in good agreement with estimates from the Flory theory of mixtures.

GEORGE C. BENSON et CARL J. HALPIN. Can. J. Chem. **65**, 322 (1987).

Opérant à 298,15 K, on a effectué des mesures de vitesses ultrasoniques pour les mélanges de *n*-octane avec chacun des cinq hexanes. On a combiné les résultats obtenus avec les valeurs des volumes molaires en excès qui ont été déterminés antérieurement pour évaluer les compressibilités isentropiques en excès et les pressions isentropiques dérivées des volumes molaires en excès. Celles-ci sont en bon accord avec les évaluations faites à l'aide de la théorie de Flory pour les mélanges.

Previous papers from our laboratory have reported excess enthalpies (1), excess volumes (2), and excess isobaric heat capacities (3) of (*n*-octane + a hexane isomer) for the five hexanes: *n*-hexane (*n*-C_6), 2-methylpentane (2-MP), 3-methylpentane (3-MP), 2,2-dimethylbutane (2,2-DMB), and 2,3-dimethylbutane (2,3-DMB). As an extension of those studies, we have determined the speed of ultrasound in the same set of mixtures.

Experimental

Component liquids

The *n*-octane was Aldrich Chemical Co. Gold Label reagent with a specified purity of 99+ mol%. The isomeric hexanes were Phillips Research Grade reagents with purities of 99.88 mol% or greater. The component liquids were stored over molecular sieve pellets (BDH Type 4A) and partially degassed prior to their use. At 298.15 K, the densities (in kg m^{-3}) of the samples used for the ultrasonic studies were as follows: *n*-octane, 698.64; *n*-C_6, 654.92; 2-MP, 648.50; 3-MP, 659.81; 2,2-DMB, 644.44; 2,3-DMB, 657.02.

Ultrasonic measurements

A pulse-echo-overlap technique was used to determine the ultrasonic speed of 2 MHz waves in mixtures formed in a successive dilution cell. The apparatus and experimental procedure have been described in previous publications (4, 5). The speed of sound in pure water (1496.739 m s^{-1} at 298.15 K), reported by Kroebel and Mahrt (6), was used to determine the distance between the transducer and the reflector. The error of the ultrasonic speeds is estimated to be less than 0.2 m s^{-1}, and their reproducibility was about 0.02 m s^{-1}. The mole fractions of the mixtures are known with an accuracy better than $\pm 1 \times 10^{-4}$.

Results and discussion

The experimental results for the speed u of ultrasound in $\{xC_8H_{18} + (1 - x)C_6H_{14}\}$ mixtures at 298.15 K and ambient standard atmospheric pressure are summarized in Table 1 for the five hexanes. Also listed there are isentropic compressibilities κ_S, excess isentropic compressibilities κ_S^E, and values of the differential coefficient $(\partial V_m^E/\partial p)_S$ calculated from the relations:

$$[1] \quad \kappa_S = (\rho u^2)^{-1}$$

$$[2] \quad \kappa_S^E = \kappa_S - \kappa_S^{id}$$

and

$$[3] \quad (\partial V_m^E/\partial p)_S = [xV_1^0 + (1 - x)V_2^0]\kappa_S^{id} - V_m\kappa_S$$

where ρ is the density of the mixture and κ_S^{id} is the isentropic compressibility of the corresponding ideal mixture, V_1^0 and V_2^0 are the molar volumes of pure *n*-octane and hexane isomer, respectively, and V_m is the molar volume of the mixture. Values of ρ and V_m were estimated from the densities of the pure components and our previous results for the excess molar volumes V_m^E of the mixtures (2). The formula for evaluating κ_S^{id} has already been described (7). Values of the isobaric expansivities and molar isobaric heat capacities used in the present application were taken from our previous publications (2, 3).

For each system, an equation of the form

$$[4] \quad \Phi(x) = x(1 - x)\sum_{j=1}^{n} c_j(1 - 2x)^{j-1}$$

was fitted to the deviations Δu defined by the equation

$$[5] \quad \Delta u = u - xu_1^0 - (1 - x)u_2^0$$

where u_1^0 and u_2^0 are the ultrasonic speeds in pure *n*-octane and the hexane isomer, respectively. Values of the coefficients were determined by least-squares analyses in which all points were weighted equally. Equation [4] was also fitted to the results for κ_S^E and $(\partial V_m^E/\partial p)_S$. The coefficients c_j and standard deviations s for these representations are listed in Table 2.

The experimental results for Δu and their representations by eq. [4] are plotted in Fig. 1. The values of Δu at corresponding x decrease in the order:

$$2,2\text{-DMB} > 2,3\text{-DMB} > 2\text{-MP} > 3\text{-MP} > n\text{-}C_6$$

Similar plots for κ_S^E and $(\partial V_m^E/\partial p)_S$ are shown in Figs. 2 and 3, respectively. For both these functions, the order of the absolute values at corresponding x differs from the order for Δu by the interchange of the curves for 2,3-DMB and 2-MP. These features are qualitatively similar to our previous findings for (*n*-heptane + hexane isomer) mixtures (8) and (*n*-dodecane + hexane isomer) mixtures (9). Comparison of results for different *n*-alkanes with the same hexane isomer shows that the magnitudes of Δu, κ_S^E, and $(\partial V_m^E/\partial p)_S$ increase with increasing size of the *n*-alkane component, and that the curves for the longer *n*-alkanes tend to be more skewed toward $x = 0$.

Previously (2) we found that the Flory theory (10, 11) provided useful estimates of the excess molar volumes of (*n*-octane + hexane isomer) mixtures when the interchange energy parameter X_{12} was selected to give a least-squares fit between the experimental and theoretical excess molar enthalpy curves (1). A further investigation (3) showed that the excess molar isobaric heat capacities of these mixtures could also be reproduced fairly well by the theory when X_{12} was assumed to be a linear function of the temperature, and a suitable value was assigned to $(\partial X_{12}/\partial T)_p$. Table 3 summarizes the Flory characteristic pressures p^*, molar volumes V, and temperatures T^* for the component liquids; also listed there are values of X_{12} and $(\partial X_{12}/\partial T)_p$ for their mixtures. Details of the derivation of these values can be found in our earlier works (2, 3).

[a]Values of p^*, V^*, T^*, and X_{12} taken from ref. 2; $(\partial X_{12}/\partial T)_p$ from ref. 3.

Estimates of Δu, κ_S^E and $(\partial V_m^E/\partial p)_S$ were calculated from the Flory theory in the following way. According to the theory, the isothermal compressibility κ_T at zero pressure is given by the formula

$$[6] \quad \kappa_T = (3\tilde{v}^2/p^*)(\tilde{v}^{1/3} - 1)/(4 - 3\tilde{v}^{1/3})$$

where $\tilde{v}$ is the reduced volume of the mixture, obtained by solving the Flory equation of state. The isentropic compressibility is calculated from the thermodynamic relation

$$[7] \quad \kappa_S = \kappa_T - TV_m\alpha_p^2/C_{p,m}$$

using the theoretical expressions for the molar volume

$$[8] \quad V_m = \tilde{v}[xV_1^* + (1 - x)V_2^*] = \tilde{v}V_m^*$$

the isobaric expansivity

$$[9] \quad \alpha_p = (3\tilde{v}^{4/3}/T^*)/(4 - 3\tilde{v}^{1/3})$$

and the molar isobaric heat capacity

$$[10] \quad C_{p,m} = -xp_1^*V_1^*\alpha_{p,1}^0/\tilde{v}_1 - (1 - x)p_2^*V_2^*\alpha_{p,2}^0/\tilde{v}_2 + [xp_1^*V_1^* + (1 - x)p_2^*V_2^* - xV_1^*\theta_2X_{12}](\alpha_p/\tilde{v}) + (xV_1^*\theta_2/\tilde{v})(\partial X_{12}/\partial T)_p + xC_{p,1}^0 + (1 - x)C_{p,2}^0$$

where $\alpha_{p,1}^0$ and $\alpha_{p,2}^0$ are respectively the isobaric expansivities of the pure n-octane and hexane isomer, and $C_{p,1}^0$ and $C_{p,2}^0$ are their molar isobaric heat capacities. As in our previous work, it is assumed that the site fraction for the hexane isomer can be approximated by the expression

$$[11] \quad \theta_2 = (1 - x)/[1 + x\{(V_1^*/V_2^*)^{2/3} - 1\}]$$

Values of κ_S^{id} for the corresponding ideal mixture are obtained from eq. [7] where κ_T^{id} and α_p^{id} are volume fraction averages of the pure component values, and $C_{p,m}^{id}$ is a mole fraction average.

Values of u can be calculated from eq. [1] using the Flory estimates of ρ and κ_S. The corresponding Δu are shown as broken curves in Fig. 1. Theoretical estimates of κ_S^E and $(\partial V_m^E/\partial p)_S$, obtained from eqs. [3] and [4], are plotted in Figs. 2 and 3. It can be seen that the Flory model provides a fairly satisfactory representation of Δu, κ_S^E, and $(\partial V_m^E/\partial p)_S$ for the present mixtures. The order of the curves is reproduced correctly, however the differences between the curves for n-C_6 and 3-MP are underestimated.

Received July 3, 1986

LEO H. KOOLE, HENK M. BUCK, JAN A. KANTERS, and ARIE SCHOUTEN. Can. J. Chem. **65**, 326 (1987).

2′-Deoxy-3′,5′-di-*O*-acetyl adenosine crystallizes in the orthorhombic space group $P2_12_12_1$, and the cell dimensions are a = 7.768(1) Å, b = 12.890(1) Å, c = 15.495(1) Å; Z = 4 molecules per cell. Least-squares refinement converged at R = 0.054 for 1752 observed reflections. The adenine bases are linked via N_6—H...N_1 and N_6—H...N_7 hydrogen bonds, in such a way that infinite one-dimensional chains are formed. Comments are made on the fact that this structure is entirely different from the parallel dimer that was found for 3′,5′-di-*O*-acetyl thymidine. Furthermore, the conformational preferences of the title compound in aqueous solution have been determined with 300- and 500-MHz ^{1}H nmr. It is found that the X-ray structure and the solution conformation are essentially similar, except for the $C_{4'}$—$C_{5'}$ conformation, that is γ^- in the solid state, and predominantly γ^+ in solution.

LEO H. KOOLE, HENK M. BUCK, JAN A. KANTERS et ARIE SCHOUTEN. Can. J. Chem. **65**, 326 (1987).

La désoxy-2′ di-*O*-acétyl-3′,5′ adénosine cristallise dans le groupe d'espace orthorhombique $P2_12_12_1$, avec a = 7,768(1), b = 12,890(1) et c = 15,495(1) Å et Z = 4 molécules par maille. On a affiné la structure par la méthode des moindres carrés jusqu'à une valeur de R = 0,054 pour 1752 réflexions observées. Les bases adénines sont liées par le biais de liaisons hydrogènes N_6—H...N_1 et N_6—H...N_7 et elles forment ainsi des chaînes unidimentionnelles infinies. On fait des commentaires sur le fait que cette structure est entièrement différente de celle du dimère parallèle qui a été trouvé pour la di-*O*-acétyl-3′,5′ thymidine. De plus, faisant appel à la rmn du ^{1}H à 300 et à 500 MHz, on a déterminé les préférences conformationnelles du composé mentionné dans le titre, en solution aqueuse. On a trouvé que les structures observées par diffraction des rayons-X ainsi qu'en solution sont essentiellement semblables, excepté pour la conformation autour de la liaison $C_{4'}$—$C_{5'}$ qui est γ^- à l'état solide et en prédominance γ^+ en solution.

[Traduit par la revue]

Introduction[2]

The crystal structures of several acetylated nucleosides have been determined during the previous years (1–4). The interest in these compounds stems partly from their possible function as antitumor, antibacterial, and antiviral agents. For instance, the 1:1 complex of 2′,3′,5′-tri-*O*-acetyl uridine and *cis*-$Pt(H_2O)_2(NH_3)_2$ was shown to be particularly active (5). Moreover, this complex has the advantages of a high water solubility and a low renal toxicity. In addition, it is of interest that acetylated nucleosides generally show peculiar stacking interactions and hydrogen-bonded self-association of the nucleobases in the solid state. For example, the crystal structure of 3′,5′-di-*O*-acetyl thymidine shows a thymine–thymine dimer in which the bases are parallel and linked via two N_3—H...O_4 hydrogen bonds (2, 3). Using the hexanucleoside pentaphosphate $d(T_pT_pT_pT_pT_pT)$, it was shown that this type of base pairing results in the formation of a non-Watson and Crick parallel DNA duplex structure, provided that the phosphate groups are methylated (3). In the present work, we report the crystal structure of 2′-deoxy-3′,5′-di-*O*-acetyl adenosine (Fig. 1). The adenine bases are linked via two different hydrogen bonds (i.e. N_6—H...N_1 and N_6—H...N_7) to form infinite one-dimensional chains. The X-ray data of 2′-deoxy-3′,5′-di-*O*-acetyl adenosine are compared with the aqueous solution conformation, as determined with 300- and 500-MHz ^{1}H nmr spectroscopy.

[2]Nomenclature in this work follows the recent IUPAC-IUB recommendations on nucleotide conformational nomenclature. See ref. 27.

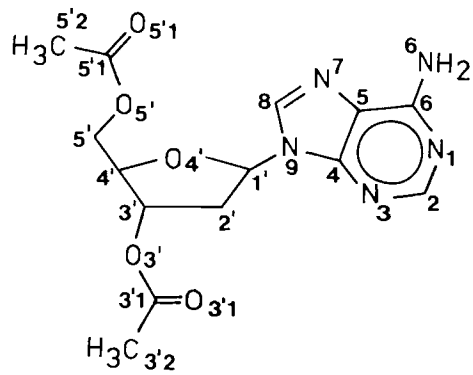

FIG. 1. Structural formula and atomic labelling of the 2′-deoxy-3′,5′-di-*O*-acetyl adenosine molecule.

Experimental section

Preparation

Acetic anhydride (1.06 g, 10.38 mmol) was added to a cooled (0°C) and stirred solution of 2′-deoxyadenosine (2.00 g, 8.00 mmol) in 30 mL of anhydrous pyridine. (2′-Deoxyadenosine was previously dissolved with heating and vigorous stirring.) The reaction mixture was stirred overnight at room temperature. After evaporation of the pyridine, thin layer chromatography using chloroform–ethanol (6:1 v/v) as eluent indicated the presence of four substances: 2′-deoxy-3′,5′-di-*O*-acetyladenosine (R_f = 0.41), 2′-deoxy-3′-*O*-acetyladenosine (R_f = 0.32), 2′-deoxy-5′-*O*-acetyladenosine (R_f = 0.16), and unreacted 2′-deoxyadenosine (R_f = 0). The isolation of 2′-deoxy-3′,5′-di-*O*-acetyladenosine was accomplished via chromatography on a Woelm silica gel column. The product was initially obtained as a white solid, yield 0.75 g, 28%. H_2O yielded rod-shaped colorless crystals, mp 148–150°C (6). *Anal.* calcd. for $C_{14}H_{17}N_5O_5$: C 50.15, H 5.11, N 20.89; found: C 50.08, H 5.11, N 20.38. ^{1}H nmr (solvent D_2O): δ 1.98 (3H, s, CH_3), 2.16 (3H, s, CH_3), 2.76 (1H, m, $H_{2''}$), 3.00 (1H, m, $H_{2'}$), 4.32 (2H, m, $H_{5'}/H_{5''}$), 4.50 (1H, m, $H_{4'}$), 5.50 (1H, m, $H_{3'}$), 6.44 (1H, dd, $H_{1'}$), 8.21 (1H, s, H_2), 8.30 (1H, s, H_8).

Crystallographic measurements and structure resolution

$C_{14}H_{17}N_5O_5$ fw = 335.32

Orthorhombic, a = 7.768(1) Å, b = 12.890(1) Å, c = 15.495(1) Å, V = 1551.5(3) Å^3, Z = 4, D_c = 1.435 g cm^{-3}, λ(CuKα) = 1.54184 Å, t = 20°C, μ(CuKα) = 9.53 cm^{-1}, F(000) = 704. Absent reflections: $h00$, h odd; $0k0$, k odd; and $00l$, l odd; space group $P2_12_12_1$ (D_2^4, No. 19).

A crystal of dimensions (mm) 0.75 × 0.25 × 0.25 was mounted on a Nonius CAD4 diffractometer. Unit cell dimensions were determined by least-squares refinement of the setting angles of 24 reflections in the θ range 11.4–45.8°. Intensities of 1842 reflections were measured within the sphere of reflection limited by 2θ = 150° and $0 \leqq h \leqq 9$, $0 \leqq k \leqq 16$, and $0 \leqq l \leqq 19$, using Ni-filtered Cu Kα radiation. The ω/2θ scan technique was applied with ω = (0.70 + 0.15 tan θ)°. The intensities of two reference reflections (024 and 210), measured every 60 reflections showed an average deviation less than 1% during the duration of the data collection. The intensities were corrected for Lorenz-polarization effects, but not for absorption. A total of 1752 reflections that satisfied the criterion $I \geqq 2.5\sigma(I)$ were retained for the structure determination and refinement. $\sigma(I)$ was derived from counting statistics. The structure was solved with the direct methods program of SHELXS84 (7), the coordinates of all non-hydrogen atoms being determined from an E-map. The hydrogen atoms, with the exception of one hydrogen atom of each methyl group, were located on subsequent difference maps. The hydrogen atoms of the methyl groups were placed at idealized positions (C—H 1.00 Å, H—C—H 109.5°) such that two hydrogen atoms of each methyl group were close to the maxima observed in the difference map. In the refinement the methyl groups were treated as rigid groups. The remaining hydrogen atoms were included in the refinement with constant isotropic thermal parameters, equal to those of their carrier atoms. Anisotropic blocked full-matrix refinement (5 blocks) on F of 260 parameters converged at R = 0.054 and R_w = 0.056 with $w = [\sigma^2(F_o) + 0.01697F_o^2]^{-1}$. The quantity minimized was $\Sigma w\Delta F^2$, the goodness of fit, $s = [\Sigma w\Delta F^2/(m - n)]^{-1/2}$, was 0.61 and the average shift to error ratio 0.048. A final ΔF map showed maximal fluctuations of +0.25 and −0.40 e Å^{-3}. Scattering factors were those of Cromer and Mann (8) and for hydrogen of Stewart, Davidson, and Simpson (9). Programs used include SHELX76 (10) (refinement) and EUCLID (11) (geometry and illustrations).

Nuclear magnetic resonance spectroscopy

One-dimensional spectra were recorded at different sample temperatures on a Bruker CXP-300 spectrometer[3] (^{1}H frequency: 300.13 MHz), operating in the Fourier transform mode. An internal D_2O field-frequency lock, and a spectral window of 3000 Hz (16 K data points) were used. Before Fourier transformation, the spectra were zero-filled to 32 K, and resolution enhanced by an appropriate Gaussian multiplication (12). A standard computer simulation–iteration procedure was employed to obtain accurate values for spin–spin coupling constants and chemical shifts. All nuclear Overhauser enhancement experiments reported in this work were performed at 300 MHz. In addition, a two-dimensional J-resolved spectrum (13, 14) was recorded at 500 MHz on a Bruker WM-500 spectrometer[4] (sample temperature 20°C). In this experiment, we used a spectral window of 4000 Hz on the chemical shift axis (16 K data points), and 15.6 Hz on the J axis (256 data points).

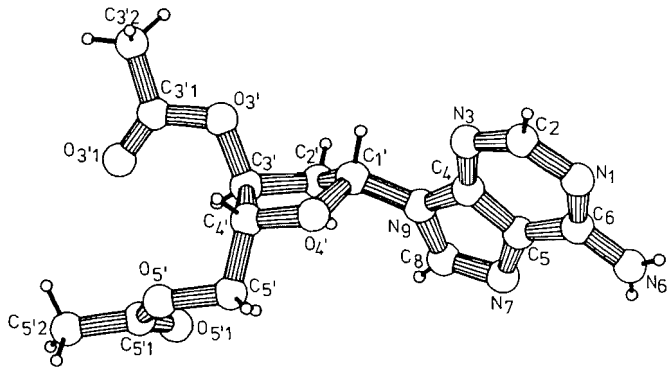

FIG. 2. Perspective drawing and atomic labelling of the 2'-deoxy-3',5'-di-*O*-acetyl adenosine molecule.

Results and discussion

Crystal structure[5]

The atomic labelling and a perspective drawing of the 2'-deoxy-3',5'-di-*O*-acetyl adenosine molecule are given in Fig. 2. The fractional coordinates are listed in Table 1. Table 2 summarizes bond angles between non-hydrogen atoms. Table 3 lists a selected set of torsion angles describing the geometry of the furanose ring, the acetylated backbone and the base, as well as the conformation around the glycosidic bond.

Furanose and backbone conformation

The 2'-deoxyribofuranose ring is found in the $C_{2'}$—endo envelope (^2E) conformation; the phase angle and amplitude of pseudorotation (15) are 156.0(6)° and 31.1(4)°, respectively. The furanose pucker deviates slightly from the standard South pucker. The bond lengths $O_{4'}$—$C_{1'}$ (1.419(2) Å) and $O_{4'}$—$C_{4'}$ (1.440(2) Å) exhibit the expected difference of approximately 0.02 Å, which is due to the anomeric effect (16). The conformation around the $C_{4'}$—$C_{5'}$ bond is γ^-, with $\gamma(O_{5'}—C_{5'}—C_{4'}—C_{3'})$ = −74.7(2)°. The acetyl geometries are as previously noted (1–4), showing short C=O bonds ($C_{3'1}$—$O_{3'1}$ = 1.186(3) Å, and $C_{5'1}$—$O_{5'1}$ = 1.204(3) Å). The glycosyl bond length N_9—$C_{1'}$ and bond angle N_9—$C_{1'}$—$O_{4'}$ are 1.451(2) Å and 108.5(1)°, respectively. The conformation around the glycosyl bond is *anti* with a value of 84.0(2)° for $\chi(O_{4'}—C_{1'}—N_9—C_8)$.

Base geometry

The values of the bond lengths and angles for the adenine base are similar to those reported for the "standard" adenine ring (17). Largest deviations were found for C_6—N_1 and C_8—N_7 (bond lengths smaller than the standard values by 0.036 and 0.051 Å, respectively), as well as for C_5—C_6 and C_5—N_7 (bond lengths greater than the standard values by 0.058 and 0.069 Å, respectively). The adenine ring is planar, the mean deviation of the nine atoms from the least-squares plane is 0.012(4) Å.

Hydrogen bonding and molecular stacking

In the structure each molecule is bonded to two molecules by intermolecular hydrogen bonds of the donor NH_2 group (Fig. 3). One hydrogen bond is between N_6 and N_7 at $(-\frac{1}{2} + x,$

[5]Bond distances, tables of structure factor amplitudes, anisotropic temperature factors of non-hydrogen atoms, hydrogen atom coordinates, as well as analyses of short intra- and intermolecular contacts and the hydrogen bond network, may be purchased from the Depository of Unpublished Data, CISTI, National Research Council of Canada, Ottawa, Ont., Canada K1A 0S2.

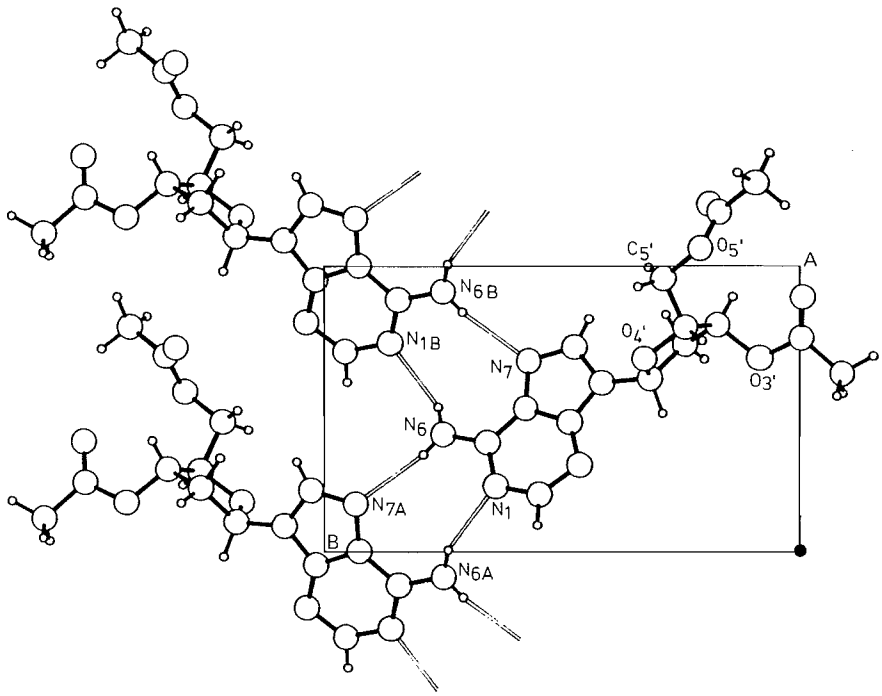

FIG. 3. Projection of a part of the structure down the *c* axis, showing the hydrogen-bonded chain in the *ab* plane. The cell origin is shown as a black dot. Some furanose and backbone atoms are labelled in the parent molecule. The others can be identified by comparison with Figs. 1 and 2. Molecule A is at $-\frac{1}{2} + x$, $1\frac{1}{2} - y$, $-z$; molecule B is at $\frac{1}{2} + x$, $1\frac{1}{2} - y$, $-z$.

$1\frac{1}{2} - y$, $-z$) with N...N 3.033(2), H...N 2.26(3) Å, and N—H...N 170(3)°, the other one involves N_6 and N_1 at ($\frac{1}{2} + x$, $1\frac{1}{2} - y$, $-z$) with N...N 3.014(3), H...N 2.23(3) Å, and N—H...N 149(2)°. The hydrogen-bond accepting molecules are one translation apart along the *a* axis and this results in a one-dimensional chain of hydrogen-bonded molecules, approximately parallel the *ab* plane, propagating along the *a* direction (Fig. 3). In addition there are three weak C—H...O contacts involving the polar carbonyl O atoms of the acetyl side chains. One contact is intramolecular, $C_{3'}$—H...$O_{3'1}$ with C...O 2.622(3), H...O 2.16(3) Å, and C—H...O 112(2)°. The other two are intermolecular, $C_{5'}$—H...$O_{3'1}$ at ($2 - x$, $\frac{1}{2} + y$, $\frac{1}{2} - z$) and $C_{1'}$—H...$O_{5'1}$ at ($1 - x$, y, z) with C...O, H...O, and C—H...O 3.236(4), 2.57(3) Å, 131(2)° and 3.521(3) Å, 2.57(2) Å, 157(1)°, respectively.

It has been reported (1, 2, 4) that acetyl groups play an important role in the stacking of acetyl-substituted nucleosides in that the polar carbonyl group takes up important stacking

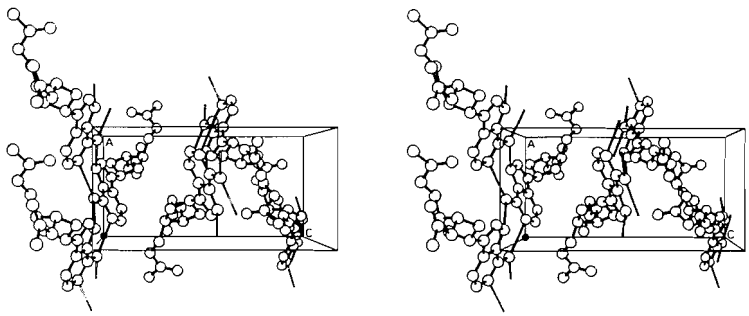

FIG. 4. Stereo view of the unit cell down the *b* axis. The cell origin is indicated by a black dot. The left of the cell also shows the hydrogen-bonded chain along *a*. Hydrogen atoms have been omitted for clarity.

positions in relation to neighbouring base rings. The stacking force involved in such an approach could be due to the polarization of the ring system by the polar carbonyl group (18). In the present structure there is a very close contact of 3.180(3) Å between the carbonyl $O_{5'1}$ and C_8 of a neighbouring base at $(\frac{1}{2} + x, \frac{1}{2} - y, -z)$, substantially to one side of the ring system. Though the $O_{3'1}$ acetyl group is one atom shorter and should therefore show less flexibility in bending toward a neighbouring ring (2) there are contacts of 3.419(3) and 3.612(3) Å with C_2 and N_3, respectively, of a base ring at $(1 - x, -\frac{1}{2} + y, \frac{1}{2} - z)$ and of 3.503(3) and 3.596(3) Å with C_5 and N_7 respectively of a base ring at $(\frac{1}{2} + x, \frac{1}{2} - y, -z)$. So, both $O_{3'1}$ and $O_{5'1}$ are bent toward the same base ring and $O_{3'1}$ is stacked between two different base rings. A stereo view of the contents of the unit cell is given in Fig. 4. Note that Fig. 4 also provides a stereoscopic view of the hydrogen-bonded chain that propagates in the *a* direction.

Conformation in solution

$C_{4'}$—$C_{5'}$ conformation

In solution, rapid interconversion between the three staggered rotamers γ^+, γ^t, and γ^- (Fig. 5) yields weighted time-averaged coupling constants $J_{4'5'}$ and $J_{4'5''}$ which are related to the individual rotamers and their populations $x(\gamma^+)$, $x(\gamma^t)$, and $x(\gamma^-)$:

$$^3J_{4'5'(5'')} = x(\gamma^+)J^{\gamma^+}_{4'5'(5'')} + x(\gamma^t)J^{\gamma^t}_{4'5'(5'')} + x(\gamma^-)J^{\gamma^-}_{4'5'(5'')}$$

with $x(\gamma^+) + x(\gamma^t) + x(\gamma^-) = 1$. The rotamer populations were obtained with the help of the empirically generalized Karplus equation developed by Altona *et al.* (19), from which $J_{4'5'}$ and $J_{4'5''}$ in the various rotamers can be calculated. Table 4 lists the proton–proton torsion angles in γ^+, γ^t, and γ^-,

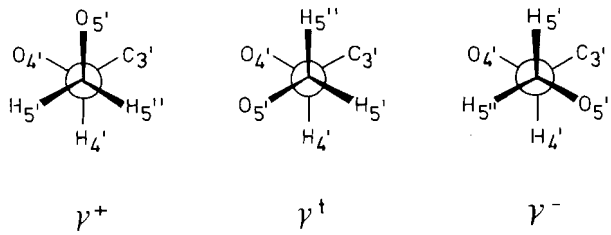

FIG. 5. Newman projection of the three staggered rotamers around the $C_{4'}$—$C_{5'}$ bond.

and the corresponding calculated coupling constants (20). The assignment of $H_{5'}$ and $H_{5''}$ was accomplished with variable temperature ^{1}H nmr at 300 MHz (21), and is found to agree with the Remin and Shugar rule (22). From the experimental data (Table 5), $J_{4'5'} = 3.8$ Hz and $J_{4'5''} = 4.3$ Hz, one calculates in this way: $x(\gamma^+) = 0.56$, $x(\gamma^t) = 0.28$, and $x(\gamma^-) = 0.16$. Thus, the γ^+ rotamer is clearly dominant in aqueous solution.

$C_{1'}$—N_9 conformation

The conformation around the $C_{1'}$—N_9 bond can be described in terms of a *syn* ⇄ *anti* equilibrium of the adenine base, on the basis of the relative Overhauser enhancements of the H_8 resonance, obtained by selective irradiation of $H_{1'}$, $H_{2'}$, and $H_{3'}$. Using the method of Guéron *et al.* (23, 24), it can be concluded from the experimental data $f_8\{1'\} = 0.10$, $f_8\{2'\} = 0.12$, and $f_8\{3'\} = 0.05$, that the contributions of the *syn* and *anti* conformations are roughly equal. This result is not surprising, since it is known that purine bases correspond with a marked rotational flexibility around the glycosidic bond. Pyrimidine bases, on the other hand, usually show a strong preference for the *anti* orientation of the base, since unfavorable

steric interactions between the C=O group at the 2-position of the base, and the furanose ring exist in the *syn* conformation (25).

Furanose conformation

The conformation of the furanose ring was determined with the PSEUROT method (26), which yields a quantitative picture of the solution conformation of the sugar ring in nucleosides and nucleotides. The procedure is based on the fact that the furanose ring is involved in a rapid conformational equilibrium between two states, which are denoted North (N) and South (S), see Fig. 6. The PSEUROT algorithm calculates the best fit of P_N, P_S (the phase angles of pseudorotation in the N and S forms), $\nu_{max,N}$, $\nu_{max,S}$ (the pucker amplitudes in the N and S forms), and the mole fraction of one of the participating conformers, to the experimental vicinal spin–spin couplings between the ring protons. The procedure was run in two ways, on the basis of the experimental data, listed in Table 5. First, $\nu_{max,N}$ and $\nu_{max,S}$ were assumed to be equal to 31°, i.e. the pucker amplitude for 2′-deoxy-3′,5′-di-*O*-acetyl adenosine in the crystalline state, yielding $P_N = 10°$, $P_S = 160°$, and 0.68 for the mole fraction of the S conformer. The rms error is 0.22. Secondly, the program was run under the assumption that one of the participating sugar conformations equals the crystal structure, i.e. $P_S = 156°$, and $\nu_{max,S} = 31°$. This results in $P_N = -40°$, $\nu_{max,N} = 40°$, and again a mole fraction of 0.68 for the S conformer. In this case, an rms error of 0.15 is achieved. Based on these results, it can be concluded that the furanose ring conformation in solution represents an equilibrium between an N conformer with $P \approx -40°$, and an S conformer as is found in the crystal structure. Presumably, the N conformer is slightly more puckered than its S counterpart.

Conclusion

The crystal structure of 2′-deoxy-3′,5′-di-*O*-acetyl adenosine consists of peculiar one-dimensional chains by virtue of intermolecular N_6—H...N_1 and N_6—H...N_7 hydrogen bonds. Obviously, the participation of the imidazole nitrogen N_7 in the hydrogen bonding scheme is essential in realizing this compact and complex structure, which differs markedly from the parallel base–base dimer that was encountered in the crystal structure of 3′,5′-di-*O*-acetyl thymidine. Comparison of the solution conformation of 2′-deoxy-3′,5′-di-*O*-acetyl adenosine with the X-ray structure reveals a close correspondence with respect to the structure of the 2′-deoxyribofuranose ring, and the glycosidic conformation. In the solid state, the sugar ring resides in an S-type conformation, which is also dominant in solution. The glycosidic conformation is *anti* in the solid state, which agrees well with experimental NOE data, obtained in solution. However, a remarkable anomaly is found for the $C_{4'}$—$C_{5'}$ conformation, which is in the very rare γ^- conformation in the solid state (20), and predominantly γ^+ in solution. The γ^+ conformation is commonly encountered for nucleosides and nucleotides, since a favorable *gauche* effect interaction exists between $O_{5'}$ and $O_{1'}$, as well as a stabilizing electrostatic attraction between $O_{5'}$ and the base proton H_8. Detailed examination of the crystal structure of 2′-deoxy-3′,5′-di-*O*-acetyl adenosine reveals that the γ^- conformation allows a favorable intermolecular stacking of $O_{5'1}$ and an adenine ring. Therefore, the present structural study adds another example to the growing number of compounds showing different conformations in the solid state and in solution.

The enantiomerically pure title compound ((4*R*,5*S*)-(5-methyl-2,2-dimethyl-1,3-dioxolane-4-ylmethyl)-phosphonium iodide) has been synthesized starting from (*R*,*R*)-(+)-tartaric acid. The synthesis of an olguine analog has been carried out. Attempts have been made to improve the stereoselectivity and yield of key steps.

SERAFIN VALVERDE, BERNARDO HERRADON, ROSA M. RABANAL et MANUEL MARTIN-LOMAS. Can. J. Chem. **65**, 332 (1987).

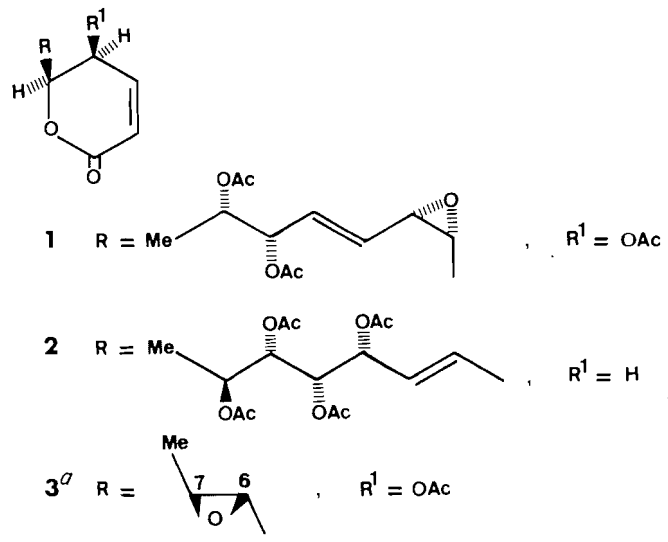
Utilisant l'acide (+)-tartrique-(*R*,*R*) comme produit de départ, on a réalisé la synthèse du composé mentionné dans le titre (l'iodure du (méthyl-5 diméthyl-2,2 dioxolane-1,3 yl-4 méthyl)-(4*R*,5*S*) phosphonium) sous une forme énantiomèrement pure. On a réalisé une synthèse d'un analogue olguine. On a fait des essais dans le but d'améliorer la stéréosélectivité et le rendement des étapes clés.

[Traduit par la revue]

Introduction

The synthesis of enantiomerically pure compounds has become one of the main concerns of organic chemists. In connection with our planned synthesis of olguine we were confronted with the need of preparing an enantiomerically pure phosphonium salt. Tartaric acid is one of the few compounds both enantiomers of which occur abundantly in nature in a readily isolable form. It has found wide application in this type of synthesis (1, 2). In the following, we describe our efforts to use (*R*,*R*)-(+)-tartaric acid for the synthesis of the required phosphonium salt.

There are numerous natural products containing an α,β-unsaturated lactone structure (3). Examples are the α,β-unsaturated δ-lactones olguine **1** and anamarine **2**, which have been isolated from an unclassified Hyptis species (4, 5), or asperlin **3**, an antibiotic isolated from *Aspergillus nidulans* (6).



[a]The stereochemistry indicated (6*S*,7*R*) for the oxirane ring has been assigned by synthesis (ref. 27)

The synthesis of these substances from carbohydrate precursors could be envisaged (7). We had previously made some synthetic efforts, directed towards the preparation of the side chain of these compounds (8), which have now been completed with the construction of the side chain of olguine **1**, using the same model compound.

Results and discussion

Compound **4** (see Scheme 1) was prepared from D-galactose using standard literature procedures (9). The oxidation step was carried out with PCC (pyridinium chlorochromate) in the presence of molecular sieves (10), and 82% of isolated product **4** was obtained. To achieve a two carbon atom chain extension, a Wittig olefination reaction appeared as most appropriate. In the case of compound **1** a *cis* stereoselectivity was desirable.

We have partly achieved this goal using the phosphorane derived from (1,3-dioxolan-2-ylmethyl)triphenylphosphonium bromide (8), which yielded a *Z*/*E* olefin mixture in a 7:3 ratio. Better results were obtained when compound **4** was reacted with methoxycarbonyltriphenylphosphorane (11) in methanol to give compound **5** in a 20:1 *Z*/*E* ratio. Both isomers were separated by flash chromatography. Compound **5** (*Z* isomer) was subjected to reduction with DIBAH (diisobutylaluminum hydride) at 0°C, affording alcohol **6** (8) in 87% yield. Almost the same yield (84%) was obtained when the reduction was carried out with $LiAlH_4$ in THF at −20°C.

The next step consisted in an epoxidation of compound **6**. It was important to achieve a good degree of stereoselectivity. With this aim in mind we essayed a variety of conditions, which have been collected in Table 1. The stereoselectivity obtained was only moderate, except in the case of asymmetric epoxidation (entry 7), which yielded a single isomer. It is also obvious that opposite results were obtained using *m*-CPBA (*m*-chloroperbenzoic acid) and TBHP (*tert*-butylhydroperoxide).

The oxidation of these epoxy-alcohols, **7** and **8**, was carried out separately using PCC/molecular sieves, with excellent yields, 92% in the case of **7** and 96% in the case of **8**.

At this point it was important to prepare a four carbon fragment and to establish adequate conditions to carry out the second extension of the side chain present in olguine **1**. The reaction of the dimethyl ester of L-(+)-tartaric acid **11** with benzaldehyde afforded (12) the corresponding benzylidene

acetal **12** with good yield (see Scheme 2). Next we carried out the $LiAlH_4$ reduction to the corresponding diol **13**, obtaining a disappointing low yield. Attempted monotosylation of **13**, under phase transfer conditions (13), was even more discouraging since, although the corresponding monotosylate could be detected in the reaction medium (^1H nmr and tlc), it reacted further during the chromatographic separation, leading to a complex mixture of compounds, none of which could be identified. It was decided then to modify our synthetic scheme to that represented in Scheme 3. In this new approach the unstability of the benzylidene group of **12** under reductive conditions was avoided, by preparing the acetonide derivative **14** instead. Compound **14** was prepared as previously described (14) (see Scheme 3) in good yield (90%). The $LiAlH_4$ reduction of **14** occurred as predicted (15, 16), with good yield (77%), leading to diol **15**. Tosylation of **15**, under phase transfer conditions, afforded the monotosylate derivative **17** (17) (89%) and a small amount of the corresponding ditosylate **16** (3.6%). Reductive displacement of the tosyl group was achieved using $NaBH_4$ in acetonitrile as solvent under reflux conditions. The alcohol **18** was obtained in good yield (69%).[3]

Using other solvents (HMPTA; HMPTA/DMF) led to zero or low yield of **18**. There was no formation of **18** when the reduction was attempted with $NaBH_4$ in toluene–water under phase transfer conditions (18).

The steps leading from **18** to the final product **21** are depicted in Scheme 4.

The monotosyl derivative was prepared from **18** using standard procedures but the substitution of this group by halogen appeared rather sluggish under a variety of conditions. To overcome this difficulty we decided to prepare the mesyl derivative instead. The reaction of **18** with mesyl chloride in THF and a slight excess of triethylamine gave compound **19** in excellent yield (96%). Refluxing an anhydrous acetone solution of **19** in the presence of NaI gave, after three days, compound

[3]The same reaction in DMF led to the formation of **18** in moderate yield only (40%).

20*a* in 45% yield. Compound **20***a* was relatively volatile and this fact may account, in part, for the moderate yield obtained since some of the product may be lost during the isolation procedure.

Compound **20***a* could be prepared directly from **18** by treatment with triiodoimidazol and triphenylphosphine in toluene solution (19). In this method the amount of toluene used was critical since an excess of solvent increases the coevaporation of **20***a* and causes fluctuation of the isolated **20***a*, 77% being the best yield we managed to obtain. Another more reproducible method of preparing **20***a* was by the reaction of **18** with triphenylphosphine, imidazole, and iodine in benzene solution, according to the method described by Ley and co-workers (20).

The corresponding bromide derivative **20***b* was also prepared

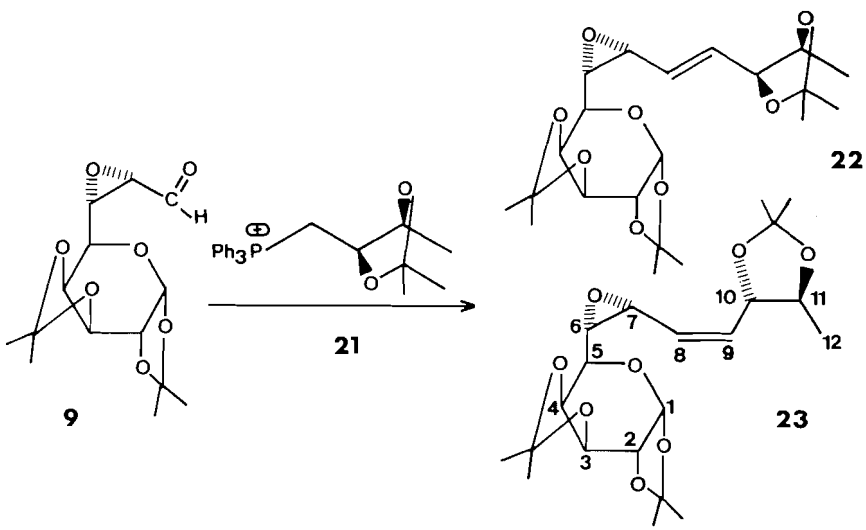
[a] The isolated yield of *Z*-olefin was 10%. The yield of *E*-olefin (40%) was estimated from a mixture with compounds **10** and **27**.



SCHEME 5

from **18** by treatment with zinc bromide and triphenylphosphine in THF solution and in the presence of DEAD (diethyl azodicarboxylate) (21).

Finally, reaction of **20***a* with triphenylphosphine in acetonitrile solution led to the formation of **21** in moderate yield (58%) with recovery of the remaining starting material (42%). When the same reaction was carried out in the absence of any solvent at 80°C (bath temperature) the yield of phosphonium salt **21** was 90%. Compound **21** is an amorphous solid, mp 71–73°C, rather hygroscopic, which was characterized by its ^{1}H nmr spectrum; $[\alpha]_D$ −35° (*c* 0.97).

Compound **21** could be used as one of the fragments required in a Wittig condensation leading to olguine (4). The reaction of the epoxy-aldehydes **9** and **10** with the phosphonium salt **21** gave a *Z* and *E* mixture of the olefins **22–25** in good yield (90% and 79% respectively) (see Tables 2 and 3, Schemes 5 and 6), when the reaction was carried out in THF/HMPTA (6:1). Unfortunately the use of these conditions (entries 2 and 6) led to mixtures of compounds of opposite stereoselectivity to the desired one.

In the case of aldehyde **9**, better *E*/*Z* ratios were achieved using the conditions specified in entries 1 and 3 (Table 2), but

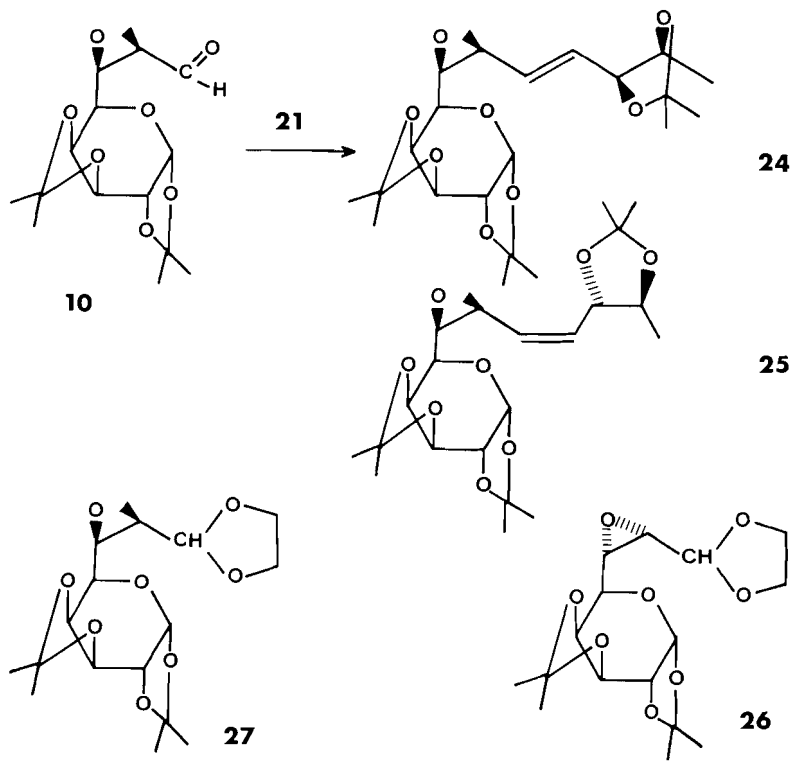

SCHEME 6

with low yield. For aldehyde **10**, the best *E*-stereoselectivity was achieved working in dichloromethane solution and with catalytic amounts of ethylene oxide (Table 3, entry 4).

Using large amounts of ethylene oxide (22) (1 equivalent or more) led to the formation of the acetals **26** and **27** as the main reaction products.

Experimental

Flash column chromatography (25) was done on silica gel 40–63 μm (Merck); tlc was carried out on plates on silica gel 60 F_{254} (Merck). The ^1H nmr spectra were measured either with a Varian 390 (90 MHz) or a Varian XL-300 (300 MHz) spectrometer and the ^{13}C nmr spectra were measured with a Bruker WP-80 (20.1 MHz) spectrometer in $CDCl_3$ solution with tetramethylsilane as internal reference. Assignments of ^{13}C nmr shifts were made with the aid of off-resonance and noise decoupled ^{13}C nmr spectra. Melting points were determined in a Kofler hot-stage apparatus. Optical rotations were measured in chloroform solution, unless otherwise stated, with a Perkin–Elmer 141 polarimeter. All the reactions with sensitive substrates were carried out under argon or nitrogen atmosphere.

Preparation of compounds 5

A solution of methoxycarbonyltriphenylphosphorane (3 mmol) in methanol (2 mL/mmol)[4] was added to aldehyde **4** (1 mmol) dissolved in the same solvent (2 mL/mmol). The mixture was stirred for 8 h at room temperature. The solvent was evaporated in the water pump and the residue subjected to flash chromatography with hexane – ethyl acetate (85:15) to yield **5** (*Z* isomer 77%; *E* isomer 3.6%), identified by its spectroscopic data (23).

Reduction of compound 5 (Z isomer)

Method A

To a cold solution (0°C) of **5** (*Z* isomer) (5.05 g, 16 mmol) in ether (90 mL) was added 56 mL of a 1.2 *M* solution of DIBAH in hexane (4.2 equiv.). The solution was stirred during 12 h and excess DIBAH was destroyed by the addition of MeOH (1 mL). The solvents were removed under vacuum and the residue purified by flash chromatography. Compound **6** (4.0 g, 87%) was isolated and identified (tlc, ^{13}C nmr, $[\alpha]_D$) with authentic material (8).

Method B

A solution of $LiAlH_4$ (505 mg, 2.2 equiv.) in THF (100 mL) was cooled at −20°C. To this solution, while stirring, was added **5** (*Z* isomer) (1.388 g, 5.93 mmol) in THF. The mixture was allowed to reach room temperature, cooled at −20°C, and then aqueous saturated Na_2SO_4 was added. The white precipitate was filtered and the solvents evaporated. Chromatography separation of the residue afforded **6** (1.42 g, 84%) and its dihydro derivative (102 mg, 6%).

Epoxidation of compound 6

A typical procedure for this transformation was the following.

With m*CPBA (see Table 1 for details)*

To a solution of the alcohol **6** in CH_2Cl_2, *m*CPBA was added. The solution was diluted and successively washed with aqueous $NaHSO_3$ and $NaHCO_3$ and, finally, with water. The residue obtained by evaporation of the solvents was purified by flash chromatography, affording compounds **7** and **8** in the yields stated in Table 1.

With TBHP

To a solution of **6** in CH_2Cl_2 the catalyst indicated in Table 1 was added, followed by a solution of TBHP in toluene (24). Excess of TBHP was destroyed by the addition of dimethyl sulphide. Evaporation of the solvents gave a residue, which was chromatographically separated to yield **7** and **8** (yields indicated in Table 1).

Preparation of compounds 8 and 10

The following procedure was applied to compounds **7** and **18** separately.

To a solution of PCC (3 equiv.) in CH_2Cl_2 (10 mL), 4 Å molecular sieves and anhydrous sodium acetate were added. After stirring for 1 h, a solution of the epoxy-alcohol (**7** or **8**) (1 equiv.) was added. Stirring was continued for 90 min, and finally the solution was diluted with ethyl ether and filtered through a short column of silica gel G. Epoxy-aldehydes **9** and **10**, identical (^1H nmr and ^{13}C nmr, $[\alpha]_D$) to

[4]Larger amounts of solvent or longer reaction times caused a lowering of the overall yield of isolated **5**, due to the formation of by-products through Michael type addition of methanol to the α,β-unsaturated ester.

For personal use only.

those previously described (8), were obtained in 92% and 96% yield respectively.

Reduction of compound ***12***

To a suspension of $LiAlH_4$ (408 mg, 11 mmol), in dry ethyl ether, was added compound **12** (12) (2.215 g, 8 mmol). The mixture was stirred for 2 h under reflux, excess $LiAlH_4$ destroyed by the cautious addition of water and 15% aqueous NaOH, and the solids separated by filtration. Evaporation of the solvent left a complex residue, which was purified by flash chromatography affording **13** (505 mg, 30%) (26).

Attempted preparation of the monotosyl derivative of compound ***13***

A CH_2Cl_2 solution of *p*-toluenesulphonyl chloride (718 mg, 2.9 mmol) was added to a flask containing diol **13** (647 mg, 3.1 mmol), tetrabutylammonium bisulfate (84 mg, 0.25 mmol), CH_2Cl_2 (10 mL), and 15% solution of aqueous NaOH (120 mg, 3 mmol). The mixture was strongly stirred during 90 min at room temperature. The two layers were separated and the organic layer was sequentially washed with water, aqueous saturated $NaHCO_3$, water, aqueous 5% HCl, and brine. Solvents were finally dried and evaporated, yielding a residue that showed spots on tlc attributable to a tosyl derivative. Flash chromatography of this residue failed to provide any of the possible monotosylate of **13**.

Reduction of the diester ***14***

A solution of $LiAlH_4$ (29 g, 0.76 mol) in anhydrous THF was mixed with compound **14** (14) (128.5 g, 0.59 mol) under nitrogen. The mixture was refluxed during 4 h, cooled at −20°C, and a saturated aqueous Na_2SO_4 solution was added to the THF solution. The white precipitate was filtered through a Celite layer and the solids washed with abundant CH_2Cl_2–MeOH mixture (3:1). Flash chromatography of the residue obtained by evaporation of the solvents provided diol **15** (73 g) (77%), identified by its physical and spectroscopic data (15).

Monotosylation of ***15***

A CH_2Cl_2 solution of tosyl chloride (25.7 g, 135 mmol) was added to a mixture of **15** (19.8 g, 122 mmol), tetrabutylammonium bisulfate (4.3 g), 15% aqueous NaOH (35 mL, 135 mmol), and CH_2Cl_2 (500 mL). This mixture was stirred at room temperature for 45 min and worked up as described previously (see above). The ditosylate **16** (3.6%) and the monotosylate **17** (89%) were isolated and identified by comparison with previously described products (17); ^{13}C nmr δ: 145.1 (s), 132.9 (s), 130.0 (d), 128.0 (d), 110.1 (s), 78.2 (d), 74.8 (d), 69.1 (t), 61.9 (t), 27.0 (q), 26.8 (q), 21.6 (q).

$NaBH_4$ reduction of ***17***

To a solution of **17** (7.8 g, 24.7 mmol) in acetonitrile (120 mL), $NaBH_4$ (4.7 g, 124.2 mmol) was added and the mixture heated under reflux for 20 h. Once cooled in an ice bath, the solution was diluted with ethyl ether and water, and enough 5% aqueous HCl added to reach pH 6.0. The two phases were separated and the aqueous layer washed with ethyl ether. All the organic solvents were washed with brine, dried, and evaporated. The residue was formed by pure compound **18**. An analytical sample could be obtained by bulb-to-bulb distillation (bp 35–40°C/0.1 Torr (1 Torr = 133.3 Pa)); $[\alpha]_D$ +1° (*c* 2.193); ^1H nmr δ: 4.10–3.40 (m, 4H), 2.0 (br s, exchangeable with D_2O), 1.33 (s, 3H), 1.30 (s, 3H), 1.20 (d, *J* = 6 Hz, 3H); ^{13}C nmr δ: 108.5 (d), 82.9 (d), 72.9 (d), 61.5 (t), 27.4 (q), 26.9 (q), 17.6 (q); ms *m/e*: 131 (M^+ − 15). *Anal.* calcd. for $C_7H_{14}O_3$: C 57.51, H 9.65; found: C 57.38, H 9.58.

Mesylation of compound ***18***

To a cold solution (10°C) of **18** (1.95 g, 13.4 mmol) in CH_2Cl_2 (20 mL) containing anhydrous triethylamine (4.4 mL, 31.6 mmol) was added, dropwise, mesyl chloride (1.2 mL, 16 mmol) dissolved in CH_2Cl_2 (25 mL). The mixture was allowed to reach room temperature and stirred during 2 h. It was then poured over saturated aqueous $NaHCO_3$, while cooling in an ice bath. The organic layer was separated and washed with saturated aqueous ammonium chloride. After drying and evaporating the organic solvents, a residue of **19** was obtained (2.35 g, 96%) that required no further purification; thick oil, $[\alpha]_D$ −3.6° (*c* 0.283); ^1H nmr δ: 4.25 (d, *J* = 4 Hz, 2H), 4.15–3.65 (m, 2H), 3.05 (s, 3H), 1.38 (s, 3H), 1.35 (s, 3H), 1.30 (d, *J* = 6 Hz, 3H); ^{13}C nmr δ: 109.3 (s), 79.9 (d), 73.5 (d), 68.5 (t), 37.7 (q), 27.3 (q), 26.8 (q), 17.7 (q); ms *m/e*: 209 (M^+ − 15).

Preparation of ***20***a

Method A

An anhydrous acetone solution (30 mL), containing **19** (1.211 g, 5.0 mmol) and NaI (3.5 g, 25.3 mmol), was heated under reflux during three days. After cooling, water and CH_2Cl_2 were added to the medium and the two phases separated. The organic layer was washed with 10% aqueous sodium thiosulfate and brine. The solvents were dried and evaporated, yielding a residue that was purified by flash chromatography (hexane – ethyl acetate, 95:5), affording **20***a* (600 mg, 45%).

Method B

A toluene solution (180 mL) of **18** (2.316 g, 15.9 mmol), triphenylphosphine (6.3 g, 24 mmol), and triiodomidazol (5.3 g, 11.9 mmol) was stirred under reflux at a bath temperature of 120°C for 3 h, following the procedure indicatd in ref. 19. Working up and chromatography of the crude product gave **20***a* (3.13 g, 77%).[5]

Method C

To a solution of **18** (369 mg, 2.53 mmol) in 70 mL of anhydrous benzene were successively added triphenylphosphine (1.5 g, 5.7 mmol, 2.2 equiv.), imidazole (500 mg, 11.6 mmol, 4.6 equiv.), and iodine (1.4 g, 5.5 mmol, 2.1 equiv.). The mixture was refluxed for 90 min. After this time the reaction was worked up as in ref. 20. Purification by flash chromatography yielded 648 mg (80%) of **20***a*, bp 30°C/1 Torr; $[\alpha]_D$ +6.2° (*c* 0.113); ^1H nmr δ: 3.85 (m, 1H), 3.60 (m, 1H), 3.30 (d, *J* = 6 Hz, 2H), 1.50 (s, 6H), 1.40 (d, *J* = 6 Hz, 3H); ^{13}C nmr δ: 108.1 (s), 81.2 (d), 77.3 (d), 27.2 (q), 22.5 (q), 18.6 (q), 4.9 (t). *Anal.* calcd. for $C_7H_{13}O_2I$: C 33.17, H 5.25; found: C 32.83, H 5.12.

Preparation of ***21***

Method A

Compound **20***a* (2.48 g, 9.7 mmol) and triphenylphosphine (2.75 g, 10.5 mmol) in acetonitrile (60 mL) were heated at a bath temperature of 80°C under argon. After nine days, elimination of the solvent left a residue, which was chromatographed. Compound **21** (2.88 g, 58%) and starting material **20***a* (1.04 g, 42%) were thus obtained.

Method B

Compound **20***a* (1.04 g, 4.1 mmol) and triphenylphosphine (1.18 g, 4.5 mmol) were mixed and heated in an oil bath at 80°C during 50 h. Flash chromatography of the residue gave **21** (1.9 g, 90%). Compound **21** is a rather hygroscopic solid, mp 71–73°C; $[\alpha]_D$ −35° (*c* 0.097); ^1H nmr δ: 7.95–7.65 (m, 15H), 4.45–4.25 (m, 2H), 4.05–3.95 (m, 1H), 1.25 (s, 3H), 1.15 (s, 3H). *Anal.* calcd. for $C_{25}H_{28}O_2P$: C 57.92, H 5.44; found: C 55.84, H 5.25.

Preparation of ***20***b

The alcohol **18** (552 mg, 3.8 mmol) and triphenylphosphine (3.0 g, 11.4 mmol) were dissolved in anhydrous THF (25 mL) under argon. Anhydrous zinc bromide (860 mg, 3.8 mmol) in THF (40 mL) and diethyl azidodicarboxylate (DEAD) (1.8 mL, 11.4 mmol) in THF (12 mL) were added consecutively. The mixture was stirred for 44 h, the solvents were removed, and the residue was chromatographed to yield 430 mg (55%) of **15***b*;[6] ^1H nmr δ: 4.1–3.6 (m, 2H), 3.45 (d, *J* = 5 Hz, 2H), 1.35 (s, 6H), 1.30 (d, *J* = 6 Hz, 3H).

Wittig condensation of the epoxyaldehyde ***9*** *and the phosphonium salt* ***21***

The following general procedure was used.

To a solution of the appropriate base in THF or THF/HMPTA (see Tables 2 and 3) was added compound **21** dissolved in the same solvent. After 2 min, a solution of compounds **9** or **10** in THF was added. The mixture was allowed to warm to 0°C and the reaction quenched by the addition of wet ethyl ether. Any solids formed were separated by filtration, and the residue dissolved in ethyl ether. This solution was washed with water, aqueous saturated $NaHSO_3$, and again with water. The organic layer was dried and evaporated, yielding a residue that was

[5]This compound appears to be relatively volatile and losses were detected at the water and oil pumps.

[6]Compound **20***b* was partially lost during the isolation process due to its appreciable volatility.

purified by flash chromatography, affording compounds **22**, **23**, **24**, and **25** (conditions and amounts collected shown in Tables 2 and 3).

22, ^{1}H nmr (300 MHz) δ: 5.58 (dd, J = 17.0 and 4.6 Hz, olefinic H), 5.50 (dd, J = 17.0 and 4.6 Hz, olefinic H), 4.92 (d, J = 5.8 Hz, anomeric H), 4.65 (m, 1H), 4.38 (m, 1H), 4.32 (m, 1H), 4.0 (m, 3H), 3.35 (m, epoxidic 2H), 1.50 (s, 6H), 1.49 (s, 3H), 1.43 (s, 3H), 1.37 (s, 3H), 1.36 (s, 3H), 1.32 (d, J = 3.8 Hz, 3H).

SERAFIN VALVERDE, BERNARDO HERRADON, ROSA M. RABANAL, and MANUEL MARTIN-LOMAS. Can. J. Chem. **65**, 339 (1987).

The synthesis of the D-enantiomer of asperlin has been carried out. The stereochemistry of the epoxide ring has been assigned as 6*R*,7*S* for this D-enantiomer.

SERAFIN VALVERDE, BERNARDO HERRADON, ROSA M. RABANAL et MANUEL MARTIN-LOMAS. Can. J. Chem. **65**, 339 (1987).

On a réalisé la synthèse de l'énantiomère D de l'asperline. On a attribué la stéréochimie 6*R*,7*S* au cycle époxyde de cet énantiomère D.

[Traduit par la revue]

Introduction

Asperlin is an antibiotic (U-13393) isolated from *Aspergillus nidulans* (1). It was assigned (1) the structure indicated in formula **1** (see Scheme 2). The D-enantiomer of asperlin was later synthesized (2), confirming the gross structural features of **1** and assigning a *trans* stereochemistry to the epoxide ring. A synthesis of racemic asperlin has recently appeared (3). Despite these synthetic efforts, the absolute stereochemistry of the epoxide ring remained to be established. Spin-lattice relaxation and nuclear Overhauser enhancement (nOe) measurements were used to tentatively propose the configuration of natural asperlin (4) as 6*R*,7*S*.

We have carried out an enantioespecific synthesis of the D-enantiomer of asperlin, which permits an unequivocal assignment of the stereochemistry of the oxirane ring, which turned out to be 6*R*,7*S*, **1***a*.

Results and discussion

The synthesis was initiated with tri-*O*-acetyl-D-glucal **2**, which was transformed into **3** by standard methods. Inversion of the configuration at C-4 (5) and manipulation of the C-4 and C-6 functions allowed for the preparation of aldehyde **4** (see Scheme 1). Reaction of **4** with the phosphorane derived from chloroacetaldehyde gave the *trans*-olefin **5** almost exclusively. $NaBH_4$ reduction of **5** at −20°C in methanol afforded **6** (95%) and the corresponding dihydro derivative (5%).

Epoxidation of **6** with *m*CPBA (*m*-chloroperbenzoic acid) in dichloromethane yielded a 5:4 ratio of the two possible epoxides (86% overall yield of isolated products). The major component (higher R_f) corresponds to the only product obtained by epoxidation of **6** using Sharpless conditions (6) (titanium isopropoxide, L-(+)-diethyl tartrate, and *tert*-butylhydroperoxide (TBHP)).

The mixture of epoxides **7***a* and **7***b* was separated by flash chromatography and the next sequence of reactions (see Scheme 2) was carried out separately with each isomer.

Epoxide **7***a* (6*R*,7*S*) was mesylated under standard conditions and this derivative treated (7) with $NaBH_4$ in acetonitrile under reflux. The 8-desoxy derivative **8***a* was obtained with good yield (90%). The same result was obtained (8) using "Red-Al", but the yield was significantly lower (50%).

Treatment of **8***a* (6*R*,7*S*) with Jones reagent (9) at 0–5°C during 30 min led to the formation of the lactone **9***a* (30%) and the recovery of starting material (60%). Accounting for this possible turnover, the overall yield of this oxidation approaches the 60%. Attempts to improve the lactone yield by carrying out a controlled hydrolysis of **8***a*, followed by oxidation of the corresponding hemiacetal, were not successful.

The attempted removal of the *tert*-butyldimethylsilyl (*t*-BDMSi) group of **9***a*, using conditions (10) (tetra-*n*-butylammonium fluoride in THF) ordinarily successful with this protecting group, also failed. Apparently, the basicity of the fluoride salt was sufficient to open the lactone ring, leading to a complex mixture of products. Hydrolysis (AcOH–H_2O, 7:3) (10) was rather sluggish at room temperature and led to undesirable side products when forcing these conditions.

The removal of the *t*-BDMSi group took place smoothly when compound **8***a* was treated with tetra-*n*-butylammonium fluoride in THF solution. Compound **10***a* (6*R*,7*S*), obtained in this way, was easily acetylated using standard conditions (Ac_2O/pyridine), and afforded the corresponding acetyl derivative **11***a* (100%).

Jones oxidation of **11***a* at 0–5°C, during 2 h, led to the isolation of the D-enantiomer of asperlin **1***a* (30%) and the recovery of starting material (60%). The identity with asperlin was established by comparison of the ^1H nmr spectra of **1***a* in $CDCl_3$ and C_6D_6 with published data (1, 4) (see Experimental).

The reaction sequence depicted in Scheme 2 was also applied to **7***b* (6*S*,7*R*). Compounds **8***b*, **9***b*, **10***b*, **11***b*, and **1***b* were thus obtained, and their data can be found in the Experimental.

We can then conclude that if the Sharpless rule for the asymmetric epoxidation of allylic alcohols is applicable to compound **6**, this synthesis establishes the absolute stereochemistry of natural asperlin as 6*S*,7*R*.

Experimental

For general experimental details see the preceding paper (16).

Preparation of compound ***3***

Compound **3** was prepared following literature procedures (12, 13).

Partial hydrolysis of ***3***

To a cold solution (−20°C) of **3** (120 mg, 0.32 mmol) in methanol (1.5 mL), a small amount (3 mg) of solid KOH was added and the solution stirred at −20°C for 12 h. Aqueous 5% HCl was added to reach pH 7.0. The solvent was removed and the residue separated by flash chromatography to yield 60 mg (67.5%) of ethyl 6-*O*-benzoyl-2,3-dideoxy-α-D-*threo*-hex-2-enopyranoside (14) and 6.0 mg each of starting material (4.9%) and ethyl 4-*O*-benzoyl-2,3-dideoxy-α-D-*threo*-hex-2-enopyranoside (6.7%).

Preparation of the tert-*butyldimethylsilyl derivative* ***4***

To a solution of **3***a*, ethyl 6-*O*-benzoyl-2,3-dideoxy-α-D-*threo*-hex-2-enopyranoside (4.0 g, 14.3 mmol), in CH_2Cl_2 (20 mL), under argon, were sequentially added DMAP (4-dimethylamino pyridine) (610 mg, 4.7 mmol), Et_3N (1.53 g, 18 mmol), and *t*-BDMSiCl (2.416 g, 16 mmol). The mixture was stirred at room temperature overnight. The organic layer was washed with water, brine, and again with water.

The residue obtained was dissolved in methanol (20 mL) and a catalytic amount of KOH was added to this solution. After 3 h the solution was diluted with water and extracted with CH_2Cl_2. Column chromatography of the crude product gave pure ethyl 4-*O*-*tert*-butyldimethylsilyl-2,3-dideoxy-α-D-*threo*-hex-2-enopyranoside (2.7 g, 81%).

PCC (pyridinium chlorochromate) (6.45 g, 3 equiv.) was dissolved in anhydrous CH_2Cl_2 (50 mL) and molecular sieves (3Å, 10 g) were added to this solution. After stirring for 2 h, a CH_2Cl_2 solution of the alcohol prepared above (2.5 g, 1 equiv.) was added to the reaction mixture. The oxidation was complete after 2 h. The solids were eliminated by filtering through a Celite layer. Evaporation afforded crude aldehyde **4**, which was purified by column chromatography yielding 1.8 g of pure **4** (67%, aldehyde proton at δ 9.70).

Preparation of the aldehyde ***5***

A solution of formylmethylenetriphenylphosphorane (11) (5.0 g, 16.4 mmol) in dry benzene (125 mL) was mixed with the aldehyde **4** (2.87 g, 10 mmol) dissolved in benzene (10 mL). The mixture was heated in an oil bath at 110°C for 2 h. Evaporation of the solvent and chromatographic separation yielded **5** (2.7 g, 86%), mp 69–71°C; $[\alpha]_D$ −170° (*c* 0.642); ^{1}H nmr δ: 7.0 (dd, *J* = 3 and 15 Hz, H-6), 6.68 (ddd, *J* = 1.5, 7.0, and 15.0 Hz, H-7), 9.65 (d, *J* = 7 Hz, H-8).

$NaBH_4$ reduction of ***5***

A solution of **5** (1.4 g, 4.8 mmol) in methanol (50 mL) was reduced with excess $NaBH_4$ at −20°C. The methanol was poured over water and the aqueous solution extracted with CH_2Cl_2. The residue obtained by evaporation of the CH_2Cl_2 solution was purified by flash chromatography, yielding **6** (1.3 g, 95%) and its dihydro derivative (63 mg, 5%); **6**, mp 70°C, $[\alpha]_D$ −124° (*c* 1.07); ^{1}H nmr δ: 6.07 (m, 4H, olefinic protons), 4.32 (d, *J* = 5 Hz, H-8).

Epoxidation of ***6***

(a) With m*CPBA*

To a solution of **6** (800 mg, 2.5 mmol) in anhydrous CH_2Cl_2 (40 mL) was added *m*CPBA (600 mg, 3.3 mmol). The epoxidation was complete after 2 h. The organic solvent was washed with aqueous $NaHSO_3$, aqueous $NaHCO_3$, and water. Evaporation of the solvent yielded a mixture of **7***a* and **7***b*. Careful flash chromatography of the crude product (hexane – ethyl acetate 9:1) afforded **7***a* (400 mg, 48%) and **7***b* (320 mg, 38%); **7***a*, thick oil, $[\alpha]_D$ −123° (*c* 0.75); ^{1}H nmr (300 MHz) δ: 5.04 (dd, *J* = 1.0 and 2.9 Hz, H-1), 5.88 (dd, *J* = 2.9 and 10.2 Hz, H-2), 6.01 (ddd, *J* = 1.0, 5.3, and 10.2 Hz, H-3), 3.98 (dd, *J* = 2.5 and 5.3 Hz, H-4), 3.78 (dd, *J* = 2.5 and 5.7 Hz, H-5), 3.28 (dd, *J* = 2.3 and 5.7 Hz, H-6), 3.23 (m, H-7), 3.60 (m, H-8), 4.00 (m, H-8′); ^{13}C nmr (δ): 93.7 (C-1), 127.8 (C-2),[2] 129.1 (C-3),[2] 62.3 (C-4), 70.6 (C-5), 54.1 (C-6), 57.2 (C-7), 61.7 (C-8). *Anal.* calcd. for $C_{16}H_{30}O_5Si$: C 58.19, H 9.08; found: C 58.41, H 9.27.

7*b* mp 51°C, $[\alpha]_D$ −69° (0.68); ^{1}H nmr (300 MHz) δ: 5.09 (dd, *J* = 1.0 and 2.9 Hz, H-1), 5.90 (dd, *J* = 2.9 and 10.2 Hz, H-2), 5.98 (ddd, *J* = 1.0, 5.1, and 10.2 Hz, H-3), 3.93 (dd, *J* = 2.6 and 5.1 Hz, H-4), 3.63 (dd, *J* = 2.6 and 6.8 Hz, H-5), 3.35 (dd, *J* = 2.3 and 6.8 Hz, H-6), 3.10 (m, H-7), 3.60 (m, H-8), 4.00 (m, H-8′); ^{13}C nmr (δ): 93.7 (C-1), 127.8 (C-2),[2] 129.1 (C-3),[2] 62.3 (C-4), 70.6 (C-5), 54.1 (C-6), 57.2 (C-7), 61.7 (C-8). *Anal.* calcd. for $C_{16}H_{30}O_5Si$: C 58.19, H 9.08; found: C 58.20, H 9.15.

(b) With TBHP

To a cold (−20°C), serum-capped flask, containing anhydrous CH_2Cl_2 (15 mL), under argon, the following compounds were sequentially added: titanium isopropoxide (42 mg, 1.4 mmol), L-(+)-diethyl tartrate (0.25 mL), **6** (400 mg, 1.25 mmol), and a solution (15) of TBHP in toluene (0.84 mL, 2.8 mmol). The mixture was kept at −20°C overnight. Aqueous 10% tartaric acid (5 mL) was added with stirring, and the organic layer was washed with water and aqueous $NaHCO_3$. Chromatography of the residue afforded **7***a* (300 mg, 72%) (see above).

Preparation of compound ***8***

The following procedure was applied separately to **7***a* and **7***b*.

To a cold solution (0°C) of the alcohol (**7***a* or **7***b*) (330 mg, 1 mmol) in pyridine (5 mL) was added, dropwise, 0.18 mL of mesyl chloride. After 2 h, the solution was poured over cold, aqueous saturated $NaHCO_3$ (30 mL). The aqueous solution was extracted with CH_2Cl_2 (3 × 20 mL) and the organic solvent dried and evaporated, yielding the mesyl derivative, which was used in the next step without further purification.

The whole crude product, obtained as above (~1 mmol), was dissolved in acetonitrile (15 mL) and powdered molecular sieves (3Å) were added to this solution, which was heated under reflux for 1 h. $NaBH_4$ (150 mg) was added and the heating continued for 24 h. A single product was formed, which was chromatographically purified to give **8***a* or **8***b* in 90 and 70% yields, respectively.

8*a*, thick oil, $[\alpha]_D^{20}$ −124° (*c* 0.98); ^{1}H nmr (300 MHz) δ: 5.02 (d, *J* = 3.3 Hz, H-1), 5.84 (dd, *J* = 3.3 and 11.3 Hz, H-2), 6.00 (ddd, *J* = 1.3, 6.0, and 11.3 Hz, H-3), 3.95 (dd, *J* = 3.0 and 6.0 Hz, H-4), 3.63 (dd, *J* = 3.0 and 7.0 Hz, H-5), 2.96 (dd, *J* = 2.3 and 7.0 Hz, H-6), 3.03 (m, H-7), 1.35 (d, *J* = 6.0 Hz, H-8). *Anal.* calcd. for $C_{16}H_{30}O_4Si$: C 61.15, H 9.55; found: C 61.43, H 9.44.

8*b*, mp 68–70°C; $[\alpha]_D^{20}$ −87.5° (*c* 0.665); ^{1}H nmr (300 MHz) δ: 3.03 (dd, *J* = 2.3 and 8.0 Hz, H-6), 2.89 (m, H-7). *Anal.* calcd. for $C_{16}H_{30}O_4Si$: C 61.15, H 9.55; found: C 60.92, H 9.85.

Preparation of the lactone ***9***

The following procedure (9) was applied separately to epoxides **8***a* and **8***b*.

To a cold (0–5°C) solution of **8***a* (157 mg, 0.5 mmol) in acetone (10 mL), a large excess (1.5 mL, 0.07 mL required) of Jones reagent was added, followed by solid $MgSO_4$. The mixture was stirred for 30 min. A few drops of isopropyl alcohol were added, the pH of the solution made neutral by the addition of solid $NaHCO_3$, and the solids filtered off. The solution was diluted with water and most of the acetone eliminated under vacuum. Finally, it was extracted with CH_2Cl_2 and this solvent dried and evaporated to give a mixture that was purified by tlc yielding **9***a* (42 mg, 30%) and **8***a* (86 mg, 60%).

9*a*, thick oil, $[\alpha]_D^{20}$ −167° (*c* 0.862); ^{1}H nmr (300 MHz) δ: 6.08 (d, *J* = 10.6 Hz, H-2), 6.86 (dd, *J* = 6.0 and 10.6 Hz, H-3), 4.29 (d, *J* = 3.0 and 6.0 Hz, H-4), 3.83 (dd, *J* = 3.0 and 7.6 Hz, H-5), 3.05 (m, H-6 and H-7), 1.35 (d, *J* = 5.3 Hz, H-8); ^{13}C nmr (δ): 162.2 (C-1), 122.5 (C-2), 144.2 (C-3), 61.3 (C-4), 81.3 (C-5), 55.4 (C-6),[2] 54.6 (C-7),[2] 17.2 (C-8).

9*b*, mp 93–95°C; $[\alpha]_D^{20}$ −78° (*c* 0.329); ^{1}H nmr (300 MHz) δ: 5.99 (d, *J* = 10.6 Hz, H-2), 6.69 (dd, *J* = 4.3 and 10.6 Hz, H-3), 4.5 (dd, *J* = 4.3 and 5.3 Hz, H-4), 4.09 (dd, *J* = 5.3 and 5.6 Hz, H-5), 3.14 (dd, *J* = 2.6 and 5.6 Hz, H-6), 2.93 (m, H-7), 1.31 (d, *J* = 6.0 Hz, H-8); ^{13}C nmr (δ): 165.8 (C-1), 122.1 (C-2), 144.5 (C-3), 63.4 (C-4), 80.2 (C-5), 56.5 (C-6), 50.4 (C-7), 17.0 (C-8).

Preparation of compound ***10***

The following procedure was applied separately to epoxides **8***a* and **8***b*.

To a solution of **8***a* (157 mg, 0.5 mmol) in freshly distilled THF (7 mL) was added tetra-*n*-butylammonium fluoride (260 mg, 1 mmol). The mixture was stirred for 30 min at room temperature. The solvent, once washed with water, was evaporated under vacuum and the residue, **10***a*, was acetylated with Ac_2O/pyridine at room temperature during 4 h. The usual work-up yielded compound **11***a* (120 mg, 100%) as a thick oil; ^{1}H nmr (300 MHz) δ: 5.06 (d, partially overlapping with H-4, H-1), 6.02 (dd, *J* = 2.6 and 11.0 Hz, H-2), 6.15 (ddd, *J* = 1.3, 6.0, and 11.0 Hz, H-3), 5.08 (ddd, *J* = 0.6, 3.0, and 6.0 Hz, H-4), 3.96 (dd, *J* = 3.0 and 6.0 Hz, H-5), 2.90 (dd, *J* = 6.0 and 2.3 Hz, H-6), 3.09 (m, H-7), 1.36 (d, *J* = 5.2 Hz, H-8).

[2]These assignments can be reversed.

Preparation of compound ***1***

The same procedure was applied to compounds **11***a* and **11***b* (this last one was not further characterized).

To a cold solution (0–5°C) of **11***a* (120 mg, 0.5 mmol) in acetone (10 mL), a large excess (1.5 mL, 0.07 mL required) of Jones reagent was added, followed by the addition of anhydrous $MgSO_4$ (140 mg). The mixture was stirred for 2 h. A few drops of isopropyl alcohol were then added and the solids filtered off. The solution was adjusted to pH 7.0 by the addition of solid $NaHCO_3$, diluted with water, and most of the acetone eliminated under vacuum. The solution was extracted with CH_2Cl_2 and this solvent dried and evaporated, affording a mixture of compounds that was separated by tlc. Compounds **1***a* (22 mg, 20%) and **11***a* (70 mg, 60%) were isolated; **1***a*, mp 69–71°C (lit. (1) mp 71–73°C), $[\alpha]_D^{30}$ −320° (*c* 0.951, $CHCl_3$); uv, λ_{max} (EtOH): 220 nm; ^{1}H nmr (300 MHz) ($CDCl_3$) δ: 6.22 (d, *J* = 9.6 Hz, H-2), 7.08 (dd, *J* = 5.7 and 9.6 Hz, H-3), 5.32 (dd, *J* = 3.0 and 5.7 Hz, H-4), 4.12 (dd, *J* = 3.0 and 7.2 Hz, H-5), 3.08 (m, H-6 and H-7), 1.39 (d, *J* = 5.1 Hz, H-8) (identical to published data, see ref. 1); (C_6D_6, 0.1 *M*) δ: 5.61 (d, *J* = 10.6 Hz, H-2), 6.19 (dd, *J* = 6.3 and 10.6 Hz, H-3), 4.76 (dd, *J* = 3.0 and 6.3 Hz, H-4), 3.23 (dd, *J* = 3.0 and 7.0 Hz, H-5), 2.69 (dd, *J* = 2.0 and 7.0 Hz, H-6), 2.48 (m, H-7), 0.82 (d, *J* = 5.6 Hz, H-8) (see ref. 4).

1*b* (prepared as above) (13 mg, 11%), mp 63–65°C; $[\alpha]_D^{30}$ −170° (*c* 0.355, $CHCl_3$); uv λ_{max} (EtOH): 220 nm; ^{1}H nmr (300 MHz) ($CDCl_3$) δ: 6.22 (d, *J* = 9.9 Hz, H-2), 6.87 (dd, *J* = 5.1 and 9.9 Hz, H-3), 5.51 (dd, *J* = 3.6 and 5.1 Hz, H-4), 4.36 (dd, *J* = 3.6 and 4.8 Hz, H-5), 3.02 (m, H-6 and H-7), 1.35 (d, *J* = 5.1 Hz, H-8); (C_6D_6) δ: 5.61 (d, *J* = 10.6 Hz, H-2), 5.81 (dd, *J* = 5.6 and 10.6 Hz, H-3), 4.73 (dd, *J* = 3.0 and 5.6 Hz, H-4), 3.41 (dd, *J* = 3.0 and 6.0 Hz, H-5), 2.53 (m, H-6), 2.46 (m, H-7), 0.80 (d, *J* = 5.6 Hz, H-8).

MARIE LAVAULT, JEAN BRUNETON, ADRIEN CAVÉ, KAI CHEONG CHAN, JEAN ROBERT DEVERRE, THIERRY SEVENET et HÉLÈNE GUINAUDEAU. Can. J. Chem. **65**, 343 (1987).

Quatre nouveaux alcaloïdes de structure bisbenzylisoquinoléique ont été isolés de *Albertisia* cf. *A. papuana* Becc. (Ménispermacées). Ce sont la (−)-bisnor-2,2′ phaeanthine (**5**), la (+)-pangkoramine (**7**), la (+)-pangkorimine (**9**) et la (+)-nor-2′ cocsuline (**14**). Ils sont accompagnés de la (+)-daphnoline (**2**), majoritaire, et de sept autres dimères déjà connus, mono-, di- ou tripontés.

MARIE LAVAULT, JEAN BRUNETON, ADRIEN CAVÉ, KAI CHEONG CHAN, JEAN ROBERT DEVERRE, THIERRY SEVENET, and HÉLÈNE GUINAUDEAU. Can. J. Chem. **65**, 343 (1987).

Four new bisbenzylisoquinoline alkaloids were obtained from *Albertisia* cf. *A. papuana* Becc. (Menispermaceae). These are (−)-2,2′-bisnorphaeanthine (**5**), (+)-pangkoramine (**7**), (+)-pangkorimine (**9**), and (+)-2′-norcocsuline (**14**). They are accompanied by the known (+)-daphnoline (**2**), which is the main alkaloid, and by seven known dimers with one, two, or three ether bridges.

Le genre *Albertisia* Becc. (1), longtemps demeuré monospécifique, comprend, depuis les travaux de Forman (2), 17 espèces dont la majorité, d'origine africaine, fût initialement classée dans le genre *Epinetrum* Hiern. Des cinq espèces spontanées dans le sud-est asiatique une seule, *A. papuana* Becc., a fait l'objet d'une étude chimique (3); l'échantillon étudié provenait du sud de Padang dans la partie occidentale de Sumatra (Indonésie). Ayant eu à notre disposition un lot de cette liane en provenance de l'Ile de Pangkor (Malaisie), il nous a semblé intéressant d'en étudier la composition alcaloïdique compte tenu de la très large dispersion de cette espèce (Sarawak, Moluques, Papouasie–Nouvelle-Guinée...(4)) et de l'hypothèse, un temps retenue, d'une subdivision de l'espèce en deux variétés (var. *bancana* et var. *buruensis*) (5).

La présente étude a permis l'isolement et l'identification de 12 alcaloïdes bisbenzylisoquinoléines. Huit sont connues : un dérivé monoponté 11–12′, la (+)-lindoldhamine **1**; trois dérivés dipontés 7–8′, 11–12′ de configuration 1*R*,1′*S*, la (+)-daphnoline **2**, la (+)-daphnandrine **3** et la (+)-bisnoraromoline **4**; quatre dérivés à enchaînement dibenzo-dioxine (6–7′, 7–8′, 11–12′) de configuration 1*S*,1′*S* : (+)-cocsuline **10**, (+)-cocsoline **11** et (+)-*O*-méthyl cocsoline **12**, ou de configuration 1*R*,1′*S* : c'est le cas de la (+)-apateline **13**. Tous ces alcaloïdes ont déjà été isolés à plusieurs reprises, en particulier à partir de diverses Ménispermacées (6–8), et ont été identifiés par comparaison de leurs constantes physiques et de leurs données spectrales avec celles publiées ainsi que par une comparaison directe avec des échantillons authentiques.

Les quatre autres alcaloïdes sont des bisbenzylisoquinoléines originales. La (−)-bisnor-2,2′ phaeanthine **5**, $C_{36}H_{38}N_2O_6$, présente, sur son spectre de masse, un pic moléculaire à *m/z* 594. Le pic de base à *m/z* 367 est caractéristique du fragment monovalent bisisoquinoléique formé par la rupture des liaisons benzyliques chez les dimères dipontés «tête à tête – queue à queue» (9). Le spectre de rmn du proton montre l'absence de singulets dûs à des N-CH_3 vers 2,5 ppm, ce qui indique le caractère bis-amine secondaire de **5**; cette absence de substituant sur les atomes d'azote est par ailleurs soulignée par le fort déblindage subi par les protons en 1 (4,06 ppm) et 1′ (4,35 ppm). La méthylation ($HCHO/NaBH_4$) conduit au composé **6** dont les groupements N-CH_3 apparaissent, sur le spectre de rmn protonique, sous la forme de deux singulets nettement séparés ($\Delta\delta$ = 0,29 ppm) comme cela est habituel chez les dérivés dipontés 8–7′, 11–12′ (10). La configuration de **5** et de **6** ne peut être que 1*R*,1*R*′ ou 1*S*,1*S*′ comme le montrent les positions du doublet dédoublé du proton en 10 (6,42 et 6,54 ppm) et du singulet du méthoxyle en 6′ (3,41 et 3,37 ppm) (cf. tableau 1); ces positions sont tout à fait comparables à celles observées dans le cas de la (−)-limacine ou de la (−)-gyroaméricine (11) : respectivement 6,56 et 6,53, 3,35 et 3,37 ppm pour ces deux signaux alors qu'ils apparaissent vers 6,25–6,40 et 3,60–3,90 pour la série 1*R*,1*S*′ (6, 7). Le pouvoir rotatoire négatif de **6** permet de l'identifier à la (−)-phaeanthine. Une comparaison directe avec un échantillon authentique confirme cette conclusion et démontre ainsi sans équivoque la structure de l'alcaloïde **5**.

L'alcaloïde **7** est également un dérivé «bis-nor» (absence de N-méthyle en rmn). Son spectre de masse est compatible avec une formule brute en $C_{34}N_{34}N_2O_6$ (M^+ 566) et, comme pour le composé **5** indique sa nature bipontée «tête à tête –

queue à queue» : pic de base à m/z 353 (cette valeur de 353 indique de plus que l'une des unités tétrahydroisoquinoléique est phénolique). La méthylation ($HCHO/NaBH_4$) conduit à un dérivé **8** qui est un dimère à deux ponts diphényl éther 7–8′, 11–12′ ($\Delta\delta$ des signaux des N-CH_3 = 0,1 ppm), de configuration 1*S*,1*S*′ ou 1*R*,1*R*′ (le signal du proton en 10 est à 6,56 ppm au lieu de 5,40–5,60 dans le cas des énantiomères 1*R*,1*S*′ : ((+)-daphnoline **2**, 5,59, (+)-daphnandrine **3**, 5,60) ou 1*S*,1*R*′ : ((−)-gyrolidine, 5,47, (−)-gyrocarpine, 5,48 (11)). La mesure du pouvoir rotatoire ainsi que l'enregistrement des courbes de dichroïsme circulaire permettent d'identifier le dérivé diméthylé **8** à la 1*R*,1*R*′(+)-candicusine isolée et décrite récemment chez une Ménispermacée sud-américaine : *Curarea candicans* Barneby et Krukoff (12). Cette corrélation prouve la structure proposée pour la (+)-pangkoramine **7** (ou (+)-bisnor-2,2′ candicusine) (tableau 2).

Le troisième alcaloïde nouveau, la (+)-pangkorimine **9** présente un spectre de masse décalé de deux unités et simplifié par rapport à celui du précédent. Le pic de masse à m/z 564 est le pic de base; il est accompagné d'un pic très intense à m/z 563 ce qui traduit une conjugaison supplémentaire de la molécule. Le spectre uv confirme cette observation : il montre en particulier un effet bathochrome en milieu acide caractéristique de la présence d'une fonction imine (13). Le spectre de rmn ne présente pas de singulet vers 2,5 ppm attribuable à un N-CH_3 et ne comporte qu'un seul signal (à 4,13 ppm) dû à un proton en 1 ou 1′. On remarque en outre un système AB (4,04 et 4,63 ppm, J = 13,6 Hz) attribuable aux protons du CH_2 benzylique situé du côté de l'imine. Le reste du spectre de rmn présente de fortes analogies avec ceux de **7** et de **8** comme le montre le tableau 1. La réduction de l'imine ($NaBH_4$–MeOH) conduit à une bis-amine secondaire identique en tous points à la (+)-pangkoramine **7**. La position exacte de la fonction imine est déduite des observations suivantes : le doublet du proton

Nor-2′ cocsuline	2,44	NH	3,32	4,35	6,60	6,31	6,12	6,50	6,90	6,79	7,13	6,96	7,17	7,63	3,86	OH

aromatique en 10 apparaît, dans le cas de **9**, à 5,02 ppm comme cela se produit dans le cas d'une autre imine en 1′,2′, la (−)-épistéphanine (14), qui appartient à la même série (liaisons 7–8′, 11–12′; configuration *R* du carbone 1) et dont le proton 10 apparaît à 4,98 ppm. Si la fonction imine était en 1,2 ce proton serait beaucoup moins affecté : ainsi, toujours dans la même série et avec une configuration 1′*R*, la (−)-déhydro-1,2 limacusine voit son proton en 10 résonner à 6,36 ppm (15). Ces indications, qui ne constituent que des présomptions, sont confirmées par mesure des nOe (effet Overhauser nucléaire) qui montre en particulier une augmentation de 8% et de 3% du signal des protons en α′ après irradiation du proton en 10′ ou en 14′ (réciproque : 14 et 4%); (les résultats des principales mesures figurent dans la partie expérimentale).

Le dernier alcaloïde nouveau est une bisbenzylisoquinoléine à trois ponts éther, monophénolique : la (+)-nor-2′cocsuline **14** : $C_{34}H_{32}N_2O_5$. La présence de l'enchaînement dibenzodioxine est reconnue par la classique réaction de ce type de composé en milieu nitro-sulfurique (16, 17) et par le spectre de masse qui montre des fragmentations superposables à celles observées dans le cas de la (+)-cocsoline **11** (9). Comme ce dernier composé, l'alcaloïde **14** conduit, par méthylation, à la (+)-cocsuline **10**; il s'agit donc bien d'un dérivé déméthylé à l'azote de la (+)-cocsuline. Le seul groupe *N*-methyle présent est en 2 comme le montre la valeur de son déplacement chimique à 2,44 ppm (cf. tableau 1 et la réf. 17; tableau 3).

Bien que tous les alcaloïdes minoritaires de cette espèce ne soient pas identifiés (des dimères ayant un cycle B ou B′ aromatique sont en cours d'étude), quelques remarques peuvent être formulées sur la composition alcaloïdique de cet échantillon qui montre des différences importantes par rapport à celle rapportée pour le matériel indonésien (3). Certes, comme dans le cas de l'étude citée, nous n'avons isolé que des alcaloïdes dimères mais les constituants majoritaires sont très différents : (+)-daphnoline (47%) et (+)-pangkoramine (16%) pour le lot malais, (+)-cocsoline (44%) et (+)-cocsuline (15%) pour le lot indonésien. Pour les autres alcaloïdes un seul, la (+)-lindoldhamine, est présent en quantité notable dans les deux cas : 12% dans notre échantillon, 5% dans celui étudié par Cavé et coll. (3). Enfin notons que six dimères décrits dans le spécimen indonésien n'ont pas été détectés dans celui récolté en Malaisie et que ce dernier fournit sept bisisoquinoléines absentes dans le premier.

Ces différences quantitatives et qualitatives semblent indiquer, si l'on exclut une division de l'espèce,[2] l'existence de chimiotypes : la saison de récolte étant la même dans les deux cas, de simples variations saisonnières sont à priori exclues. Comme dans le cas de l'échantillon récolté dans la partie occidentale de Sumatra, nous n'avons isolé que des dimères dipontés «queue à queue», ce qui démarque bien les *Albertisia* du sud-est asiatique des *Albertisia* africains initialement étudiés sous le nom générique d'*Epinetrum* et caractérisés par des dimères dipontés «tête à queue» (18, 19); cette observation est sans doute à mettre en relation avec un développement parallèle des Ménispermacées (originaires de l'Ouest du Pacifique) sur les deux continents.

Partie expérimentale

Appareillage

Les points de fusion sont mesurés en tube capillaire et ne sont pas corrigés. Les pouvoirs rotatoires sont mesurés à la température ambiante sur polarimètre Schmidt–Haensch, dans le chloroforme ou le méthanol. Les spectres sont enregistrés sur les appareils suivants : uv, Beckman 530, éthanol (λ_{max}, (log ε)); ir, Perkin–Elmer 580, KBr (ν cm^{-1}); rmn, Varian EM 360 (60 MHz) et Bruker WB 360 (360 MHz), $CDCl_3$, δ ppm, TMS = 0; spectres de masse, Varian MAT 311 (*m/z* (%)). Les chromatographies sur colonne sont réalisées sur Kieselgel 60 (Merck 7734) ou 60 H (Merck 7736) et les ccm analytiques sur DC Alufolien 60 F 254 (Merck 5554).

Matériel végétal

Les tiges de *A. papuana* ont été récoltées dans l'Ile de Pangkor le 7-12-1983. Un échantillon de référence est conservé sous le n° SD 42.

Extraction et isolement des alcaloïdes

La drogue pulvérisée (4,6 kg) et dégraissée par l'hexane est extraite par le chloroforme en milieu alcalin selon un procédé déjà décrit (15). Un premier fractionnement des alcaloïdes totaux (207 g) est obtenu par chromatographie sur colonne d'alumine désactivée par addition de 6% d'eau. La purification des différents constituants est obtenue par une suite de chromatographies sur colonnes de silice pour ccm avec pour éluant des mélanges $CHCl_3$–MeOH 95:5–90:10 + 0,3% NH_4OH; les chromatographies préparatives sur ccm sont développées avec des mélanges $CHCl_3$–MeOH 92:8, NH_4OH 0,2% ou $CHCl_3$–Me_2CO–MeOH 40:40:3 avec 5–10% de diéthylamine.

Description des produits isolés

Les constantes physiques et données spectrales des composés antérieurement décrits ne seront pas redonnées ici. Les composés **1**, **2**, **3** et **10** ont été formellement identifiés par comparaison avec des échantillons authentiques. Les constantes et données spectrales mesurées pour les autres alcaloïdes sont en bon accord avec celles de la bibliographie. L'identification des composés **5**, **7**, **9**, **11** et **14** est vérifiée par corrélation chimique.

Description des alcaloïdes nouveaux isolés

(−)-Bisnor-2,2′ phaeanthine **5**, amorphe, $[\alpha]_D$ −272° ($CHCl_3$, *c* 0,1); uv : 213 (4,29), 232 (4,58), 283 (3,86); rmn : cf. tableau 1; sm : 594 (6), 593 (8), 367 (100), 184 (28), 161 (10).

(+)-Pangkoramine **7**, amorphe, $[\alpha]_D$ +126° (MeOH, *c* 0,05); uv : 214 (4,72), 230 (4,39), 280 (4,58); OH^+ : 212, 290; sm *m/z* : 564, M^+ (24), 563 (36), 353 (100), 339 (9), 192 (22), 177 (35).

(+)-Pangkorimine **9**, $[\alpha]_D$ +65° (MeOH, *c* 0,05); uv : 213 (4,64), 228 (4,48), 283 (4,26), 314 (3,80); H^+ : 213 (4,63), 279 (4,13), 333 (4,09); sm *m/z* : 564, M^+ (100), 563 (94), 562 (46), 549 (8), 534 (20), 533 (53), 283 (16).

Principaux effets nOe observés : H-α'_1 sur H-10′ (14%), réciproque : 8%; H-α'_2 sur H-14′ (4%), réciproque : 3%; H-8 sur H-1 (7%), réciproque : 5%; H-5 sur OMe-6 (13%), réciproque : 18%; H-5′ sur OMe-6′ (14%), réciproque : 20%.

(+)-Nor-2′cocsuline **15**, $[\alpha]_D$ +238° ($CHCl_3$, *c* 0,15); uv : 212 (4,53), 225 (4,43), 287 (3,60); sm *m/z* : 548 (27), 547 (27), 335 (100), 321 (27), 319 (24), 168 (32), 167 (7)).

N-méthylation de **7**, **9** : 30 mg de l'alcaloïde sont dissous dans 20 mL de MeOH; on ajoute 2 mL de HCHO puis, sous agitation, du borohydrure de sodium en excès. Le produit réactionnel est purifié par ccm préparative.

Réduction de **9** en **7** : 20 mg de **11** sont dissous dans 10 mL de MeOH; on ajoute 50 mg de $NaBH_4$ et laisse sous agitation 2 h.

Remerciements

Ce travail a été effectué dans le cadre du programme de Recherche en Coopération CNRS Université de Malaisie. Les auteurs remercient MM. A. Cavé et M. Leboeuf (Université de Paris XI, centre de Châtenay–Malabry) pour la fourniture d'échantillons de référence, et M. A. J. Freyer (Pennsylvania State University) pour l'enregistrement de spectres de rmn à 360 MHz.

Solution and solid state studies of some ternary complexes of Cu(II) involving heteroaromatic *N*-bases and *o*-hydroxy aromatic carbonyls

NEELIMA D. KULKARNI AND P. K. BHATTACHARYA[1]

Department of Chemistry, Faculty of Science, M.S. University of Baroda, Baroda-390 002, India

Received May 26, 1986

NEELIMA D. KULKARNI and P. K. BHATTACHARYA. Can. J. Chem. **65**, 348 (1987).

Stability constants of some ternary complexes of *o*-hydroxy aldehydes (HL) with Cu(II) as central metal ion and bis(2-pyridyl)amine (dpa) and 5-nitro-1,10-phenanthroline (5-N-phen) as primary ligands (A) have been determined potentiometrically in 50% aqueous dioxane medium using a computer technique. The values of $\Delta \log K$ ($\log K^{MA}_{MAL} - \log K^{M}_{MA}$) have been compared within the series as well as with the corresponding bipyridyl complexes. The stability order has been explained on the basis of the electron repulsion concept. The complexes have been isolated in the solid state and characterized by elemental analysis, conductance and magnetic measurements, and ir and electronic spectral studies. Shifts in ligand field absorption wave numbers of the mixed ligand complex from the average value of the ligand field absorption wave numbers of $[MA_2]^{2+}$ and $[ML_2]$ have been correlated with the potentiometrically determined $\Delta \log K$ values.

NEELIMA D. KULKARNI et P. K. BHATTACHARYA. Can. J. Chem. **65**, 348 (1987).

Opérant dans un milieu formé de dioxanne/eau à 50%, faisant appel à la potentiométrie et à une technique d'ordinateur, on a déterminé les constantes de stabilité de quelques complexes ternaires des *o*-hydroxy aldéhydes (HL) avec le Cu(II) comme ion métallique central et avec la bis(pyridyl-2)amine (dpa) et la nitro-5 phénanthroline-1,10 (N-5-phen) comme ligands primaires (A). On procède à une comparaison des valeurs de $\Delta \log K$ ($\log K^{MA}_{MAL} - \log K^{M}_{MA}$) tant dans la série des composés examinés que dans celle des complexes bipyridyles correspondants. On explique l'ordre de stabilité en fonction du concept de repulsion électronique. On a isolé les complexes à l'état solide et on les a caractérisé par leurs analyses élémentaires, par des mesures magnétiques et de conductivité ainsi que par des études spectrales électroniques et infrarouges. On a établi une corrélation entre les valeurs de $\Delta \log K$ déterminées d'une façon potentiométrique et les déplacements des nombres d'onde d'absorbtion dans le champ de ligand du complexe avec un ligand mixte par rapport à la valeur moyenne des nombres d'onde d'absorbtion dans le champ de ligand de $[MA_2]^{2+}$ et $[ML_2]$.

[Traduit par la revue]

During the last two decades exhaustive studies have been made on ternary metal complexes with a variety of ligands to understand the factors governing the stability and behaviour of these complexes. Most of the work has been done on complexes containing bidentate heteroaromatic N bases (A) (1–3). A discriminating behaviour of $[MA]^{2+}$ has been shown towards the ligands containing N—N, O^-—N, and O^-—O^- coordinating sites (1, 4–6). Complexes $[MAL]^{n+}$ where L = O^-—O^- coordinating ligands were shown to be the most stable (ref. 1, Chapt. 2, p. 67; refs. 8–10).

Sigel *et al.* have studied pyrocatechol complexes (11) with dipyridyl analogues and explained the stability order of the complexes in terms of the electron-withdrawing or -releasing nature of the substituent on the primary ligand. To see the "cooperative effects" (6, 12, 13) which may occur between the π-systems of the amine and O^-—O^- containing ligand bound to the same Cu^{2+}, they made a comparative study of the complexes of $[Cudipy]^{2+}$ and $[Cu\text{-}o\text{-}phen]^{2+}$ with pyrocatechol and its derivatives (14). Their observation is similar to that made later by Bhattacharya and co-workers (15), who explained the stability order on the basis of an electron repulsion concept. The effect of dipyridyl analogues on the stability of the ternary complexes involving copper(II) and substituted *o*-hydroxy aldehyde has also been studied (16). Both groups conclude that the electron density over the ligand (L) with O^- as donor site has significant influence on the stability of the ternary $[CuAL]^+$ complexes. Electron-withdrawing substituents on L lower the stability of the complex and electron-donating substituents increase it (14, 16).

However, very few attempts have been made to isolate the ternary complexes in the solid state and to correlate their properties with solution characteristics. This would enable the study of various spectral and magnetic properties for the structural assignment of the complexes.

The present study involves the potentiometric determination of the stability constants of the ternary complexes $[CuAL]^+$ where A = bis(2pyridyl) amine (dpa = A^1) or 5-nitro-1,10-phenanthroline (5-N-phen, A^2) and HL = salicylaldehyde (SAL, HL^1), 5-bromosalicylaldehyde (5-B-SAL, HL^2), 5-nitrosalicylaldehyde (5-N-SAL, HL^3), 2-hydroxynaphthaldehyde (2-OH-naph, HL^4), and 2-hydroxyacetophenone (2-OH-acph, HL^5). These complexes have been isolated and characterised.

Experimental

Chemicals

The ligands dpa, 2-OH-acph, and 2-OH-naph were obtained from Fluka AG, 5-nitro-1,10-phenanthroline was from Sigma. Salycylaldehyde was reagent grade and was purified by distillation. 5-Nitrosalicylaldehyde was prepared by the known method (17), mp 127°C (126–127°C reported). 5-Bromosalicylaldehyde was prepared by low temperature (<5°C) bromination of salicylaldehyde by liquid bromine in acetic acid. The product, separated after addition of the reaction mixture to cold water, was recrystallised twice from ethanol; mp 107°C (lit. 18, 105–107°C).

Potentiometric determination of stability constants

An extended Irving–Rossotti titration technique (19) was used to determine preliminary values of formation constants of the complexes in aqueous dioxane (50% v/v) medium at $I = 0.2$ *M* ($NaClO_4$) and at temperature 30°C, using 0.2 *M* NaOH. pH values were corrected on the basis of experimental results,[2] to give the concentration of hydrogen

[1]To whom all correspondence should be addressed.

[2]pH values of standard perchloric acid solutions under the experimental conditions have been determined and compared with theoretical values. This difference takes into account liquid junction potential across the membrane and effect of the ionic strength of the medium (21). The constant difference has been considered as correction for other titration data.

[a]A^3 = 1,10-phenanthroline and A^4 = 2,2′-bipyridyl. Δ log K values are taken from ref. 16. Values in parentheses indicate standard deviation.

ion in the solution. Formation constant values were further refined by using the computer program SCOGS (22) wherein activity coefficient has been considered to be equal to 1 (23) and ionic product of water in 50% aqueous dioxane (1.419×10^{-16}) (23, 24) has been used. Both stepwise formation of the ternary complex, as well as simultaneous existence of all the species LH, L^-, AH^+, A, Cu^{2+}, $[CuA]^{2+}$, $[CuA_2]^{2+}$, $[CuL]^{1+}$, $[CuL_2]$, and $[CuAL]^+$ were considered.

General method for the preparation of complexes

To 2.5 mmol $Cu(Ac)_2.H_2O$ in 50% alcohol – water mixture was added a mixture of equimolar amounts of ligands A and L in alcohol–water mixture. The resulting solution was refluxed for 15–20 min[3] followed by the addition of concentrated $NaClO_4$ solution. The resulting crystalline solid was separated by filtration, washed with alcohol, and analyzed for Cu (by acid decomposition and iodometric titration with standard $Na_2S_2O_3$ solution) for C, H (on a Coleman analyzer model No. 33), and for N by Duma's method.

Room temperature magnetic susceptibility measurements were done using Gouy method. Electronic spectra of the complexes in 50% aqueous dioxane solutions and diffuse reflectance spectra (d.r.s.) of the powdered samples were recorded on a Shimadzu UV 240 spectrophotometer with $BaSO_4$ as reference. Infrared spectra were recorded in KBr phase (as discs) on a Perkin Elmer IR spectrophotometer model No. 567.

Results and discussion

The formation of the complex $[CuAL]^+$ can take place either in steps (reactions [1] and [2] or reactions [3] and [4]) or the two ligands may combine simultaneously with the metal ion leading to reaction [5]:

$$[1]\quad M + A \overset{K_{MA}^M}{\rightleftharpoons} MA$$

$$[2]\quad MA + L \overset{\beta_{MAL}^M}{\rightleftharpoons} MAL$$

$$[3]\quad M + L \overset{K_{ML}^M}{\rightleftharpoons} ML$$

$$[4]\quad ML + A \overset{K_{MLA}^{ML}}{\rightleftharpoons} MAL$$

$$[5]\quad M + A + L \overset{\beta_{MLA}^M}{\rightleftharpoons} MAL$$

[3]Cu(II) complexes are known to be formed at room temperature instantaneously. However, the solutions were refluxed just to ensure completion of the reaction and to avoid any possibility of $[CuA_2]$ or $[CuL_2]$ being left out.

The overall formation constant β_{MAL}^M can then be given by either of the following combinations:

$$[6]\quad \log \beta_{MAL}^M = \log K_{MA}^M + \log K_{MAL}^{MA} = \log K_{ML}^M + \log K_{MAL}^{ML}$$

and the relative stability of the ternary complex with respect to the binary complex can be given as

$$[7]\quad \Delta \log K = \log K_{MAL}^{MA} - \log K_{ML}^M = \log K_{MLA}^{ML} - \log K_{MA}^M$$

Close agreement between the values, log K_{MAL}^{MA}, determined by considering stepwise formation of the complex (reactions [1] and [2]) and the values $\log \beta_{MAL}^M - \log K_{MA}^M$ determined by considering simultaneous formation of all the species indicate that the complex formation takes place in steps.

Table 1 reveals that Δ log K values of the ternary complexes of dpa are less positive compared to their 5-N-phen analogues. However, both of them are less positive than their bipyridyl and 1,10-phenanthroline analogues (16). Δ log K values for the latter two have been incorporated in Table 1. Δ log$K$ values for 5-N-phen complexes clearly indicate that the electron-withdrawing —NO_2 group has a destabilizing effect. This is in keeping with the observation made earlier that 2-(2′-pyridyl) benzimidazol, 2-hydroxyaldehydatocopper(II) complexes are less stable than 2,2′-bipyridyl, 2-hydroxyaldehydato-copper(II) complexes. This has been explained to be due to the lowering of M → 2-OH-aldehyde π-interaction in the ternary complex, involving another stranger π-acid ligand.

The electron-withdrawing —NO_2 group makes 5-N-phen a stronger π-acceptor. Hence, the Cu-2-hydroxyaldehyde π-bond is weakened and a less stable [Cu-5-N-phen-L] complex is formed compared to [Cu-*o*-phen-L] (16). However, the electron-releasing >NH group in dpa does not exert a stabilizing effect. This may be because in [Cu-dpa-L] complexes, where L = aromatic *o*-hydroxy aldehydes, both the ligands form six-membered chelate rings which are observed to be less stable than a combination of 5–6 membered chelate rings (26) as formed in [Cu-dipy-L].

It is also interesting to observe the effect of the nature of substitution over salicylaldehyde on the formation constant of

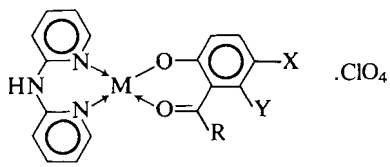
$[CuA^2L^2].ClO_4$	10.82 (10.81)	38.33 (38.78)	2.04 (2.04)	6.67 (7.14)	1.82	91
$[CuA^2L^3].ClO_4$	11.41 (11.46)	40.73 (41.15)	2.41 (1.98)	9.99 (10.11)	1.77	110
$[CuA^2L^4].ClO_4$	11.50 (11.36)	48.92 (49.35)	2.55 (2.50)	7.37 (7.51)	1.72	92
$[CuA^2L^5].ClO_4$	12.12 (12.15)	45.81 (45.88)	2.41 (2.87)	7.57 (8.03)	1.84	97

[a]Equivalent conductances measured for 10^{-3} M methanolic solutions are reported in Ω^{-1} cm^2 mol^{-1}. The values in parentheses are those calculated for the formula $[CuAL].ClO_4$.

the ternary complex. From Table 1 it can be seen that Δ log K is less positive for $[CuAL]^+$ complexes where HL = 5-bromo, or 5-nitro-salicylaldehyde than the respective [CuA salicylaldehydate]$^+$ complexes. This is also true for [CuA 2-hydroxynaphthaldehydate]$^+$ complexes where the phenyl ring is fused in the 5–6 position. This is because of the electron-withdrawing effect of the nitro, and bromo groups or the fused phenyl ring. Complexes of $[CuA]^{2+}$ with 2-hydroxy acetophenone, having an electron-releasing methyl group as a substituent at carbonyl carbon, are expected to be slightly more stable than their salicylaldehyde analogues due to the electron-releasing effect of the $—CH_3$ group. However, in the present study we found Δ log K for [CuA salicylaldehydate]$^+$ and [CuA-2-hydroxyacetophenonate]$^+$ to be very close, probably because of the small electron-releasing tendency of the $—CH_3$ group. These observations are in agreement with the earlier results (16). This can be explained on the basis of the electron repulsion concept. When a ligand coordinates with the metal ion through O^-, there is coulombic repulsion between the metal d_π electron and the extra lone pair of electrons on O^-. Coordination with a π-bonding ligand like tertiary diamine (A) decreases the π-electron density over the metal ion through metal-to-ligand π-bonding. When a secondary ligand with O^-—O coordinating sites binds with $[MA]^{n+}$, it realizes less repulsion from the metal d_π electrons than when it binds with the free metal ion. This results in greater stability of the ternary complex compared to the corresponding binary complex. Substitution over the secondary ligand will affect the electron density over the coordinating atom and hence stability of the complex. Observations made in the present study are in accordance with the expectation that the electron-withdrawing group lowers the negative charge density over O^-—O whereas an electron-releasing $—CH_3$ group increases the electron density, resulting in stabilization or destabilization, respectively, of ternary complexes.

Isolation of complexes

The elemental analyses of the complexes (Table 2) correspond to the empirical formula $[CuAL].ClO_4$. Molar conductivity values of methanolic solutions indicated that these are 1:1 electrolytes. On the basis of these results the general structure of dpa complexes can be given as follows:



1, 6 X = H, Y = H, R = H
2, 7 X = Br, Y = H, R = H
3, 8 X = NO_2, Y = H, R = H
4, 9 XY = $—(CH)_4—$, R = H
5, 10 X = H, Y = H, R = CH_3
6 to **10** dpa is replaced by 5-N-phen

Room temperature magnetic susceptibility measurements correspond to one unpaired electron except in some cases where a slight lowering in magnetic moment indicates a possibility of weak intermolecular spin–spin interaction between the Cu(II) centres in the dimers, possibly formed by the linking of Cu(II) of one molecule with O^- of the aldehyde of the adjacent molecule in the solid state. According to a very recent report (7) crystal

structure of (di-2-pyridylamine)salicylaldehydatocopper(II) perchlorate consists of a dimeric unit with two large apical Cu—O distances, one towards the O of the ClO_4 anion and the other one, linking two monomeric units, towards the O of the nearest salycylaldehyde molecule.

Electronic spectra

The complexes exhibit a broad band characteristic of paramagnetic Cu(II) centers in the region ~15 500 – 17 000 cm^{-1}. Diffuse reflectance spectra of these complexes in the solid state exhibit an unsymmetrical band which, in some cases, is split, giving two band maxima. This suggests a five coordinate structure due to dimerization. However, in solution there is only one band observed in all cases except in $[CuA^2L^5].ClO_4$. This indicates that the complex is four coordinated in solution. However, distortion from square planar geometry can not be ruled out.

Presuming D_{4h} geometry, the broad band in Cu(II) complexes (20) is due to the merger of three possible transitions, $A_{1g} \leftarrow B_{1g}$, $B_{2g} \leftarrow B_{1g}$, and $E_g \leftarrow B_{1g}$, which are close in energy. The central part of the broad band can be considered to correspond roughly to D_{qxy}. If we consider the $\bar{\nu}(d\text{–}d)$ in binary complexes $[CuA_2]$ and $[CuL_2]$ of primary and secondary ligands to be $\bar{\nu}_1$ and $\bar{\nu}_2$, respectively, and $\bar{\nu}_c$ for the ternary complex then the difference between observed $\bar{\nu}_c$ and the mean of $\bar{\nu}_1$ and $\bar{\nu}_2$ (eq. [8]) will be a measure of extra stabilization or destabilization of the ternary complex.

$$[8] \quad \Delta\bar{\nu} = \bar{\nu}_c - (\bar{\nu}_1 + \bar{\nu}_2)/2$$

It is observed that $\Delta\bar{\nu}$ has a positive value, indicating that the ternary complex is more stabilized than expected from average field created by the two ligands. The order of $\Delta\bar{\nu}$ can be correlated with $\Delta \log K$ value (eq. [7]) determined by potentiometric method. However, a linear relation between $\Delta\bar{\nu}$ and $\Delta \log K$ is not observed. This can not be expected because the stereochemistry of the binary and mixed complexes may not be perfect square planar and similar to each other.

Infrared spectra

All ten ternary complexes reported here exhibit carbonyl stretching frequencies between 1615–1640 cm^{-1}. They are shifted by about 50 cm^{-1} to the lower energy region in the complex compared to the corresponding bands in the free ligands, occurring at 1680–1700 cm^{-1} for aromatic $\diagdown$C=O and at 1695–1715 cm^{-1} for —CHO. The lowering in $\nu_{C=O}$ is due to its coordination with the metal ion. The complexes exhibit a strong absorption band at 1100 cm^{-1} corresponding to $\nu_{as\,Cl-O}$, supporting the presence of ionic perchlorate (25).

ROBERT A. MCCLELLAND and STEEN STEENKEN. Can. J. Chem. **65**, 353 (1987).

The photochromism of 2,4-dinitrotoluene in aqueous solution has been attributed to formation of the 2,4-dinitrobenzyl carbanion (J. Chem. Phys. **39**, 1218 (1963)). The spectrum of the colored transient is, however, significantly different from that of ground state carbanion when formed in aprotic solvents through thermal decarboxylation of potassium 2,4-dinitrophenylacetate (J. Org. Chem. **49**, 413 (1984)). In this paper absorption spectra obtained upon 248 nm laser photolysis are reported, for solutions in water, acetonitrile, and their mixtures. The spectrum in acetonitrile does closely resemble that of the carbanion formed by decarboxylation. It is suggested that the same ion is formed in water, and a solvent effect is responsible for the significantly different spectrum. Spectra in the mixed solvents suggest that there is an equilibrium between differently solvated forms of the anion, the extremes being an unspecifically solvated form with λ_{max} 400 and 640 nm as in acetonitrile and a form in water that is hydrogen bonded through the nitro group with λ_{max} 350 and 500 nm. Experiments with conductivity detection provide corroborative evidence for carbanion formation. In acetonitrile a non-conducting transient is produced as a precursor to the anion. This is suggested to be the conjugate acid of the aci-nitro anion, formed by intramolecular hydrogen abstraction in the excited nitrotoluene.

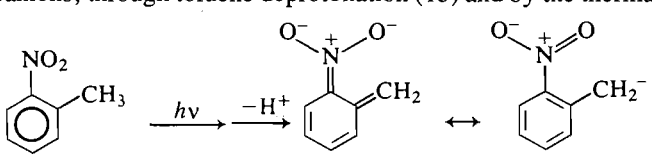
ROBERT A. MCCLELLAND et STEEN STEENKEN. Can. J. Chem. **65**, 353 (1987).

Le photochromisme du dinitro-2,4 toluène dans des solutions aqueuses a été attribué à la formation du carbanion dinitro-2,4 benzyle (J. Chem. Phys. **39**, 1218 (1963)). Toutefois, le spectre de l'espèce de transition colorée est très différent de celui du carbanion dans son état fondamental, formé dans des solvants atropiques par le biais d'une décarboxylation thermique du dinitro-2,4 phénylacétate de potassium (J. Org. Chem. **49**, 413 (1984)). Dans la présente publication, on rapporte le spectre d'absorption obtenu par photolyse laser à 248 nm pour des solutions dans l'eau, dans l'acétonitrile et dans leurs mélanges. Le spectre dans l'acétonitrile ressemble beaucoup à celui du carbanion qui se forme par décarboxylation. On suggère que le même ion se forme dans l'eau et qu'un effet de solvant est responsable pour le spectre qui est passablement différent. Les spectres dans des solvants mixtes suggèrent qu'il existe un équilibre entre les diverses formes solvatées de l'anion; les extrêmes sont, d'une part, une forme qui n'est pas solvatée d'une façon spécifique, avec λ_{max} 400 et 640 nm et que l'on retrouve dans l'acétonitrile, et, d'autre part, une forme observée dans l'eau qui est liée par une liaison hydrogène par le biais du groupement nitro et qui présente des λ_{max} à 350 et 500 nm. Des expériences impliquant une détection de conductivité fournissent une corraboration de la formation du carbanion. Dans l'acétonitrile, il se forme une entité transitoire non-conductrice comme précurseur de l'anion. On suggère que cette entité est l'acide conjugué de l'anion aci-nitro qui se forme par un enlèvement intramoléculaire d'hydrogène dans le nitrotoluène excité.

[Traduit par la revue]

The photochromism of aqueous solutions of derivatives of 2-nitrotoluene is a well studied phenomenon (1–4). Flash photolysis experiments have provided spectra of the colored species produced upon irradiation, and life-times of these relatively long-lived species have been measured (5–10). The structure of the intermediate has been assumed to be that of an aci-nitro anion or, in its other resonance contributor, a 2-nitrobenzyl carbanion. There is evidence (ref. 11, see also later) that this is not the initial photoproduct. Yip and co-workers (12) have shown recently that both singlet and triplet excited states can be involved as precursors of the carbanion. Intermediates with the same spectra as the carbanion have also been found in the photodecarboxylation of 2-nitrophenylacetate ions in aqueous solutions (13, 14).

Recently Buncel and co-workers working in aprotic media have generated relatively stable solutions of nitrobenzyl carbanions, through toluene deprotonation (15) and by the thermal decarboxylation of the potassium salt of the corresponding nitrophenylacetate (16). The absorption spectra recorded for these solutions, however, proved to be significantly different from those (13, 14) generated in the flash experiments. Two alternative explanations were offered to account for the difference (16) — (*a*) that there are significant solvent effects on the spectra and (*b*) that the photochemical intermediates are radical or radical anion in nature.



To resolve this question we have reinvestigated the photochemistry of the 2,4-dinitrotoluene system, employing laser flash photolysis with both optical and conductivity detection. Our results clearly establish that it is the 2,4-dinitrobenzyl carbanion which is formed upon irradiation, and that there are significant and interesting medium effects upon its absorption spectrum.

Results and discussion

Argon-bubbled solutions containing 1.6×10^{-4} molar 2,4-dinitrotoluene were irradiated with the 248.5 nm light of a Lambda Physik EMG 103 MSC excimer laser. As observed in previous flash experiments (9) transients of relatively long life-times are formed. Figure 1 shows spectra recorded in water and acetonitrile. In water, an intermediate is formed within the

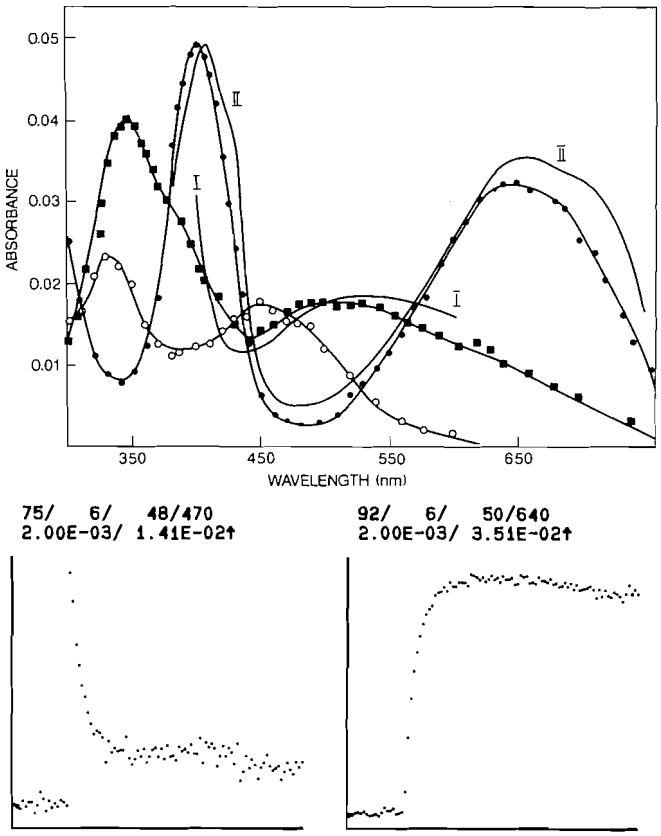

FIG. 1. Absorption spectra following 248.5 nm photolysis of 1.6×10^{-4} molar solutions of 2,4-dinitrotoluene in water (■) and in acetonitrile (○ and ●). (○) – intermediate **A**, spectrum recorded 3–5 $\times 10^{-6}$ s after flash and (●) – intermediate **B**, 3–5 $\times 10^{-4}$ s after flash. Spectrum I is the literature spectrum obtained upon flash photolysis in water (ref. 9). Spectrum II is the literature spectrum of the 2,4-dinitrobenzyl carbanion ion in dimethyl sulfoxide, obtained after ground state decarboxylation of potassium 2,4-dinitrophenylacetate (ref. 16). (Spectra I and II have been scaled such as to illustrate their correspondence to the laser spectra.) The bottom figures show time-resolved (2 ms entire trace) OD changes at 470 nm (left) and 640 nm (right) in acetonitrile.

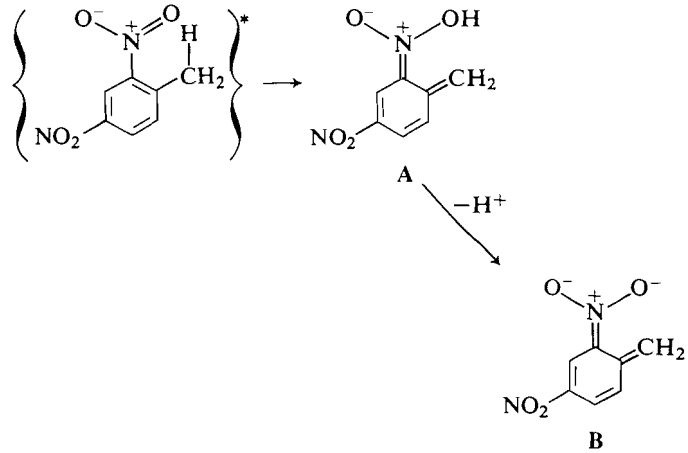
25 ns pulse of the laser, undergoing pH dependent first-order decay in the seconds time range. The spectrum in this solvent agrees with that obtained previously using flash photolysis by Wettermark and Ricci (9), although these workers covered a narrower wavelength range and did not see the absorption maximum at 349 nm.

In acetonitrile a transient (**A**) also forms within the laser flash, but, in contrast to water, this intermediate undergoes a first-order change (see Fig. 1, bottom section) over a period of about 100 μs resulting in a second transient (**B**). The spectrum of the latter closely resembles that of the thermally generated 2,4-dinitrobenzyl carbanion in dimethyl sulfoxide (16). We conclude therefore that it is this ion which is being produced photochemically, not radical products.[1] An extinction coefficient of 1.4×10^4 M^{-1} cm^{-1} at the λ_{max} of 408 nm was determined for this carbanion (16). The 0.05 absorbance

[1]This conclusion is supported by in-situ photolysis esr experiments which show that radicals are barely detectable, unless a good hydrogen donor such as propan-2-ol is present, in which case the radical anion of 2,4-dinitrotoluene is observed.



observed in the flash experiments therefore corresponds to 3.5×10^{-6} molar carbanion being produced (with the assumption that extinction coefficients are the same in the two solvents).

The presence in acetonitrile of a precursor to the anion suggests a mechanism with the excited state reaction involving hydrogen abstraction forming initially a neutral aci-nitro compound. Atherton and Craig (11) have recently reported similar observations with the same interpretation after laser photolysis of 2,6-dinitrotoluene in methanol and methanol:water mixtures. They have also carried out a detailed kinetic study of the deprotonation. We qualitatively observed that the transformation **A** → **B** is strongly accelerated by small amounts of water and amine bases. The possibility exists that even in the pure solvent, trace amounts of water are responsible for the ionization, not the weakly basic solvent. Wettermark and Ricci were able to observe a species assigned the structure of the acid form **A** in aqueous solutions by using strong acids (1 *M* $HClO_4$) to shift the **A** ⇄ **B** equilibrium (9). They observed also that the spectrum of the acid form is considerably shifted to lower wavelengths. A pK_a of 1 was determined by these workers from the spectroscopic change as a function of pH, and also from an analysis of the decay kinetics (9). We find that in water and in all water:acetonitrile mixtures investigated (Fig. 3) the neutral form is not observed as a precursor to the anion except in strongly acidic solutions (pH < 1). This is not unexpected. If **A** is a normal O—H acid, a pK_a of 1 means that deprotonation by the water solvent will occur with a rate constant of 10^8–10^9 s^{-1}, so that ionization will occur within the 25 ns flash.

Corroborating evidence comes from experiments carried out with conductivity detection. In dilute aqueous base irradiation results in a rapid conductivity decrease (Fig. 2*A*). This can be explained by the neutralization of hydroxide ion, that is, the replacement of hydroxide in the solution by the less mobile organic anion. In acid solution (Fig. 2*B*) a conductivity burst is observed. Here the photolysis is producing the anion and an equivalent amount of hydronium ion. In both acid and base solutions the conductivity returns to its original level in an exponential fashion. Rate constants for this change agree with those measured for the decay of the anion using optical detection. These also correspond with rate constants reported by Wettermark and Ricci (9). (Note the faster decay in acid as observed by these workers).

In aqueous solution the initial conductivity changes occur within the one μs resolution of the AC conductivity method, but as illustrated in Fig. 2*C* in acetonitrile irradiation results initially in a non-conducting solution. A conductivity increase then

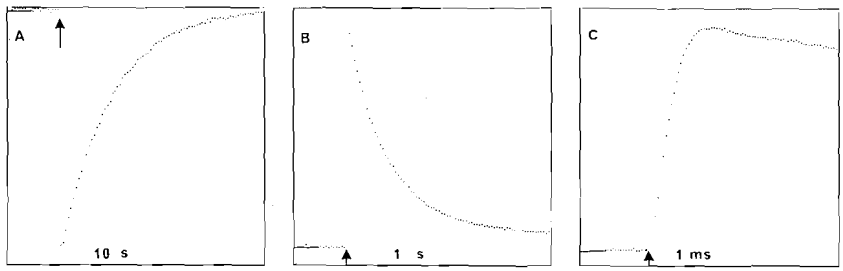


FIG. 2. Conductivity changes following 248.5 nm excitation of 1.6×10^{-4} *M* solutions of 2,4-dinitrotoluene. *A*, 10^{-4} *M* NaOH in water; *B*, 10^{-4} *M* HCl in water; *C*, acetonitrile. The arrow indicates the position of the laser flash. The time indicated is for the entire trace including the pre-flash.

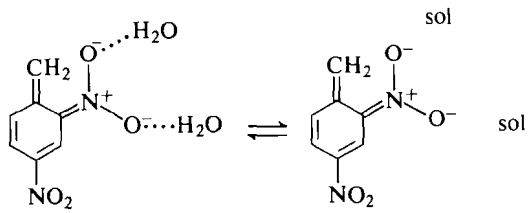
occurs, on the same time scale as the spectral transformation **A** → **B**. This observation is consistent with the formation in acetonitrile of the neutral aci-nitro form as the initial intermediate, followed by its slower deprotonation to produce charged species, the aci-nitro anion and H^+. A slower conductivity decrease follows, part of which can be seen in Fig. 2*C*.

As seen in Fig. 1 there is a very large solvent effect on the spectra of the carbanion. In order to probe this in more detail spectra were obtained in a series of water:acetonitrile mixtures (Fig. 3). These suggest that there are two quite different forms of the anion, and acetonitrile or aprotic solvent form absorbing at 400 nm and 640 nm, and a water form absorbing at 350 nm and 500 nm. In the mixed solvents both forms are present, although the water content must be relatively high to observe a large amount of water form. It is possible that even in pure water some of the 400 nm/640 nm form is present, since there appear shoulders at these wavelengths on the 350 nm/500 nm bands.

The phenomenon of two differently absorbing forms of a nitro anion has been encountered previously, for the anion derived from 4-nitrophenylacetonitrile (17, 18). The explanation which has been offered is that the anion exists in two differently solvated forms, one where a water molecule or molecules are tightly hydrogen bonded to the nitro group and a second unspecifically solvated form lacking this hydrogen bonding. This is indicated by the structures below, although



the actual number of water molecules involved in hydrogen bonding is unknown. The negative charge is obviously also delocalized to the 4-nitro group, and the relative contribution of this is also unknown. The exact nature of these solvations is unclear. As seen in Fig. 3 there are four reasonably isosbestic regions, indicating that there is an equilibrium between these two forms, with the concentration ratio depending upon the solvent composition.

Experimental section

2,4-Dinitrotoluene was a commercial sample and was used as received. Solvents were prepared with spectroscopic grade acetonitrile and water from a Millipore Milli-Q system. Solutions were prepared with 1.6×10^{-4} *M* nitro compound and had OD/cm = 0.6 at 248 nm. These were argon saturated and photolyzed with ≈20 ns pulses

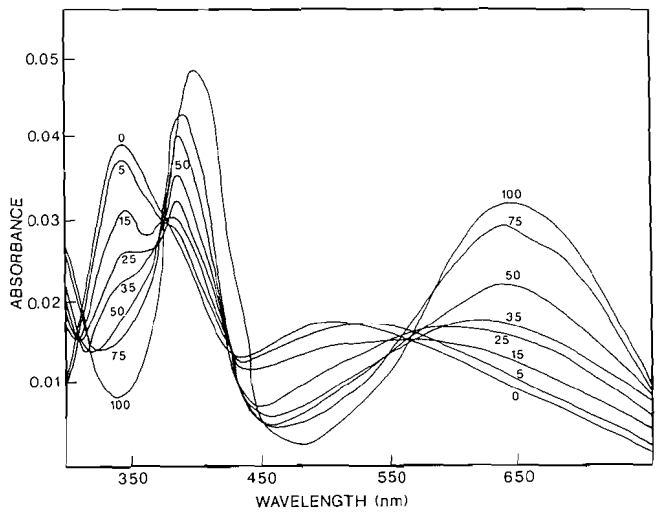


FIG. 3. Absorption spectra of the 2,4-dinitrobenzyl carbanion in water:acetonitrile mixtures (percent by volume acetonitrile shown). Curves have been drawn to provide the best fit to the experimental points.

(≈100 mJ) of 248 nm light (KrF) from a Lambda Physik EMG 103 MSC excimer laser. The optical and conductance signals were digitized by a Tektronix 7612 transient recorder interfaced with a DEC 11/73 computer which also ran the experiment and was used for the analysis and documentation of the data.

A carbon-13 nuclear magnetic resonance study of solid tetracyclines

SANDRA MOOIBROEK[1] AND RODERICK E. WASYLISHEN[2]
Department of Chemistry, Dalhousie University, Halifax, N.S., Canada B3H 4J3

Received June 2, 1986

SANDRA MOOIBROEK and RODERICK E. WASYLISHEN. Can. J. Chem. **65**, 357 (1987).

Magic angle sample spinning and proton/carbon-13 cross-polarization techniques have been used to obtain high resolution solid state ^{13}C nuclear magnetic resonance spectra of several tetracycline antibiotics. Carbon-13 resonances in the solid state are assigned by measuring the extent of dipolar broadening due to neighbouring quadrupolar nuclei and by using a pulse sequence that suppresses non-quaternary carbon resonances. The observed ^{13}C chemical shifts are discussed in light of the known solid state structures derived from X-ray diffraction, and are compared with those in solution. It is shown that the solid state nuclear magnetic reosnance technique is capable of clearly distinguishing between the neutral and zwitterionic forms of the tetracycline free bases.

SANDRA MOOIBROEK et RODERICK E. WASYLISHEN. Can. J. Chem. **65**, 357 (1987).

On a utilisé les techniques de l'angle magique de couplage de l'échantillon et de polarisation croisée proton/carbone-13 pour obtenir des spectres rmn ^{13}C à l'état solide de plusieurs antibiotiques de la famille des tétracyclines. On a attribué les résonances en ^{13}C du spectre à l'état solide en mesurant l'amplitude de l'élargissement dipôlaire provenant du noyau quadrupôlaire voisin et en utilisant une séquence pulsée qui supprime les résonances de carbones qui ne sont pas quaternaires. On discute des déplacements chimiques observés pour les ^{13}C en fonction des structures à l'état solide qui ont été obtenues par diffraction des rayons-X et on les compare avec ceux observés en solutions. On démontre que la technique rmn à l'état solide peut distinguer sans ambiguïtés entre les formes neutre et zwitterioniques des tétracyclines existant sous la forme de bases neutres.

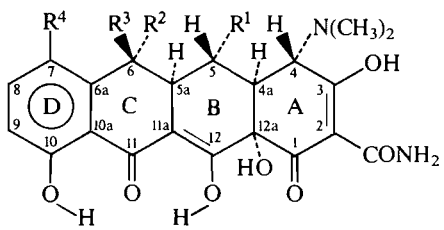
Introduction

Since the solid state nmr techniques of cross-polarization (CP) (1) and magic-angle spinning (MAS) (2) were first used in combination (3), high resolution ^{13}C nmr of many important biological and chemical compounds has become possible (4). The advantages of using CPMAS to obtain solid state ^{13}C nmr spectra are many. The solid state spectrum may contain unique structural features, which in solution are averaged and hence not observed in the corresponding solution spectrum. Problems with finding a solvent to dissolve the material, overlapping solvent peaks in the spectrum, or solvent effects on chemical shifts are obviously avoided. In addition, the chemical shifts of a ^{13}C spectrum obtained from a powdered sample are sensitive to the conformational and electronic properties of exactly the same structures reported by X-ray diffraction studies. The technique can thus provide a "bridge" between crystal structure information and ^{13}C nmr solution data. For this reason, we have obtained solid state ^{13}C CPMAS nmr spectra of tetracycline and some of its derivatives (**1**), to clarify subtle differences in the various forms.



Generic Name	R^1	R^2	R^3	R^4	Abbreviation
Tetracycline	H	CH_3	OH	H	TC
Oxytetracycline	OH	CH_3	OH	H	OTC
Chlortetracycline	H	CH_3	OH	Cl	CTC
Demeclocycline	H	H	OH	Cl	
Doxycycline	OH	CH_3	H	H

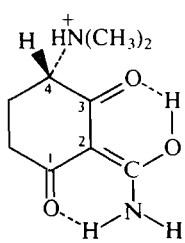
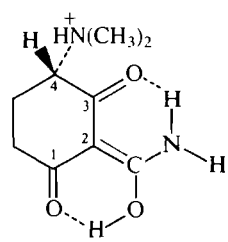
[1]Holder of an NSERC 1967 Science and Engineering Scholarship.
[2]Author to whom correspondence may be addressed.

The chemical properties of this broad class of antibiotics have been of considerable interest (5), particularly the conformation of the free (6–23) and the complexed (24–32) molecules, since the mechanism by which the drug enters the cell and blocks ribosomal protein production, and what role metal ions or other complexes play in the action, are still not clear (33).

Crystal structures have been reported for the chlortetracycline (CTC) (6), oxytetracycline (OTC) (7), tetracycline (TC) (10), doxycycline (6-deoxy-OTC) (18), and demeclocycline (6-demethyl-7-CTC) (23) hydrochloride salts, and for the TC and OTC free bases (15–17). The conformations of the hydrochloride salts are very similar, differing mainly in the tautomeric form of the amide substituent (**2**, **3**), and in localization of the hydroxy proton, depicted on the C3 hydroxy in **1** as is commonly found in the literature, but, more realistically, is associated with the amide carbonyl in **2** and **3** as is reported by X-ray crystallographers (6, 18, 23).



2



3

By contrast, oxytetracycline free base has been shown (15, 16) to crystallize in either a non-ionized anhydrous form (OTC^0, **4**), or as the zwitterionic dihydrate (OTC ±, **5**). The two differ markedly in intra- and intermolecular hydrogen bonding, and in the conformation of the A ring with respect to the plane of the BCD rings; OTC ± being very similar to the fully protonated salt, and OTC^0 displaying a conformation similar to that of an inactive derivative, 5,12a-diacetyloxytetracycline (8, 34). While Palenik *et al.* (23) argue that due to the relatively extreme methods used to obtain the anhydrous crystal (15), the OTC^0 modification is probably not biologically significant, Stezowski and co-workers (19) report that both forms of the free base

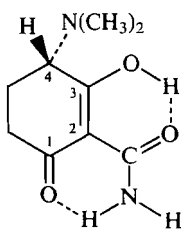
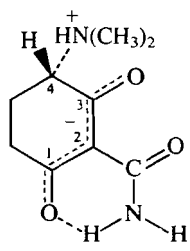
[a]Solution shifts are from ref. 14. Errors in peak positions are approximately ±0.2 ppm. Where appropriate, corrections have
[b]Errors in peak positions for TC (non-ionized) estimated to be ±1.0 ppm.

coexist in $EtOH/H_2O$ solutions, and that when the composition of the solvent is less than 20% H_2O, the non-ionized form (OTC^0) predominates. They propose that biological activity of the antibiotic involves both conformations, and that interconversion occurs in vivo in aqueous or lipid-rich phases.

Solvent induced changes in conformation have not been discussed in ^{13}C nmr solution studies (11, 13, 14), although differences in the ^{13}C chemical shifts of tetracycline derivatives in DMSO-d_6 and in H_2O are noted (14). These differences, though subtle for most of the resonance peaks, are nonetheless critical for the understanding of chemical shifts due to structural changes (e.g., **4** vs. **5**).



4



5

In this respect, we present the solid state ^{13}C nmr chemical shifts of the fully protonated, zwitterionic, and non-ionized forms of tetracycline and oxytetracycline, as well as the solid state ^{13}C shifts of several other tetracycline-derived salts. The results are discussed in terms of both corresponding solution values (14) and X-ray crystal data (6, 7, 10, 15–23), and should serve as the basis for further ^{13}C nmr studies of tetracycline derivatives and their metal complexes (26, 27).

Experimental

The hydrochloride salts of TC, OTC, CTC, demeclocycline, doxycycline, and minocycline and the free base hydrates of TC and OTC were purchased from the Sigma Chemical Company. All gave well-resolved, good signal-to-noise solid state nmr spectra except for tetracycline hexahydrate, which was purified by recrystallization from aqueous acetone solution. Anhydrous TC and OTC free base were prepared by the method of Stezowski (15); 4-epi-TC was prepared by the method of Doerschuk *et al.* (35). The purity of the samples was checked by the appearance of the solid state nmr spectrum, and, in the case of the salt, base, and epimer of TC, by ultraviolet absorbance ratio assay (36).

Powdered samples of the tetracyclines (≈0.5 g) were packed into cylindrical rotors made from alumina. Carbon-13 nmr spectra were obtained at 50.3 MHz on a Bruker MSL-200 while magic angle spinning at a rate of 4.5–5 kHz. Cross-polarization was acomplished using the Hartmann–Hahn match with 90° pulses of about 4 μs and contact times of 2–3 ms. Data tables of 8 K points were collected over a sweep width of 13.5 kHz. To improve signal-to-noise, spectra were signal averaged for at least 100 transients using recycle times of 2–3 s. Also, a sensitivity enhancement corresponding to 15 Hz of line broadening was applied before Fourier transformation. During non-quaternary suppression experiments (37), the high power decoupler was switched off for 40–50 μs.

All carbon-13 chemical shifts were referenced with respect to external adamantane, which has shifts of 29.50 ppm (*C*H) and 38.56 ppm (CH_2) with respect to TMS (38).

Results and discussion

Representative spectra are shown in Fig. 1 and chemical shifts are listed in Table 1. Assignment of the spectra was primarily based upon non-quaternary suppression experiments, comparison to solution state results (14), and the solid state ^{13}C shifts of other tetracycline derivatives.

The non-quaternary suppression sequence (37) suppresses resonance signals from strongly dipolar coupled nuclei, and thus only quaternary and methyl resonances are observed. In the case of the tetracycline family, use of the experiment can immediately distinguish signals C6a from C8, C10a from C7 and C9, C6 from C4, and the methyl resonances of C6-CH_3 and the C4-$N(CH_3)_2$ group. Important to note here is the inequivalence of the amino-methyls: the two resonance signals typically diverge by 3–7 ppm (see Table 1), except in TC^0 and OTC^0 where the amino group is not protonated (15, 16), and in the inactive 4-epimer of TC in which the configuration of the C4-H and C4-$N(CH_3)_2$ is opposite to that in TC and the other derivatives (39). The separation of the $N(CH_3)_2$ peaks in these cases is unresolved, ≤2 ppm, 10.6 ppm, and 1.7 ppm, for TC^0,

been made for C—N dipolar splitting.

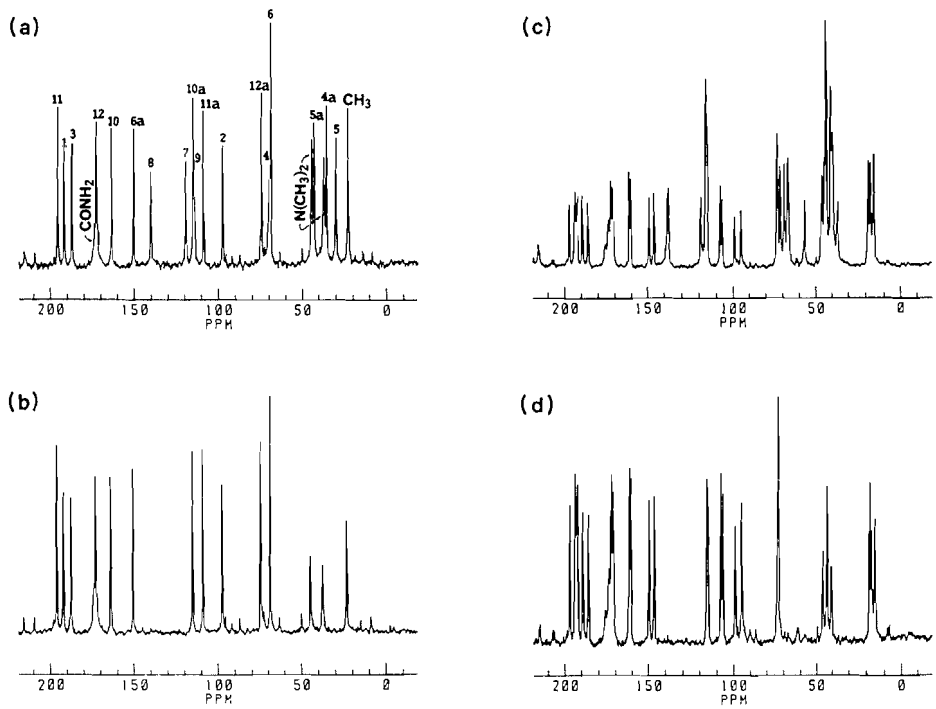

FIG. 1. ^{13}C CPMAS solid state nmr spectra of (*a*),(*b*) tetracycline·HCl and (*c*),(*d*) doxycycline·HCl. Spectra (*b*) and (*d*) were obtained using the non-quaternary suppression pulse sequence (37).

OTC^0, and epi-TC, respectively. In solution, the dimethylamino signals are averaged to a single peak, which in DMSO-d_6 is buried underneath the solvent septet centred at 39.5 ppm, along with the C5a signal (14a). At low pH the proton resonances of the two methyl groups are inequivalent (14*b*).

Also unique to the solid state spectra is the observation of broadening and (or) splitting of the resonance signals of carbons attached to quadrupolar nuclei having nonzero electric field gradients (EFG) (40, 41). The most obvious example is the C7 resonance of chlortetracycline and demeclocycline hydrochlorides (see Fig. 2). The chlorine substituent has such a large quadrupole coupling constant that the spin 3/2 nucleus (^{35}Cl, natural abundance 75.53%, or ^{37}Cl, natural abundance 24.47%) is not quantized along the magnetic field (B_0) direction. As a result, ^{13}C–chlorine dipolar coupling cannot be averaged by rapid spinning at the magic angle (54.7°) with respect to B_0 (40, 41).

The actual ^{13}C nmr lineshape for an aromatic carbon dipolar coupled to directly bonded ^{35}Cl can be estimated using the analysis of Zumbulyadis *et al.* (41). Assuming a quadrupolar coupling constant A of 71.09 MHz (42), the ratio of the chlorine Zeeman interaction, Z, to A is 0.276 at $B_0 = 4.7$ T. Carbon-13

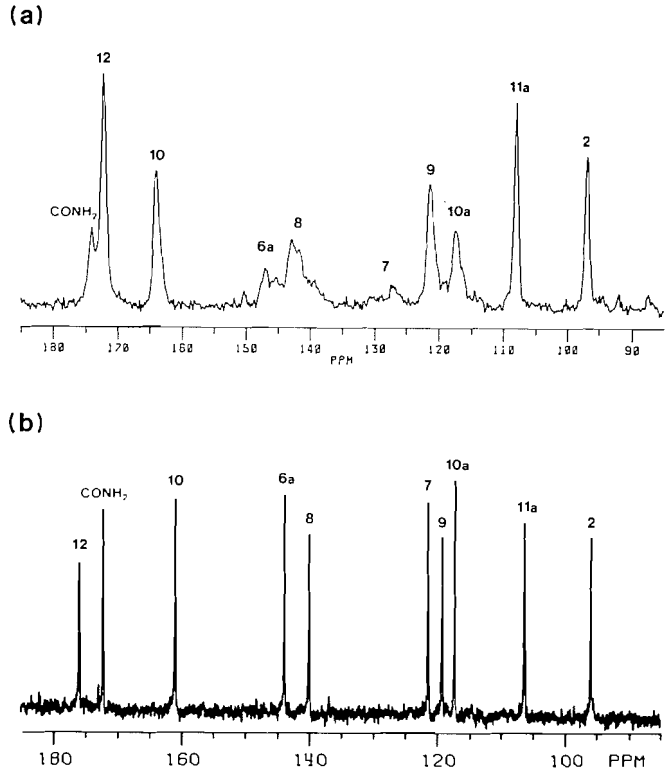

FIG. 2. Expanded region of (*a*) of the solid and (*b*) solution state ^{13}C nmr spectra of chlortetracycline·HCl, showing $^{13}C-^{35}Cl$ dipolar broadening of the substituted carbon 7 and neighbouring carbons 6a and 8. The solution spectrum was obtained with a 0.2 *M* DMSO-d_6 solution, using the central DMSO-d_6 transition (39.56 ppm (51)) as reference.

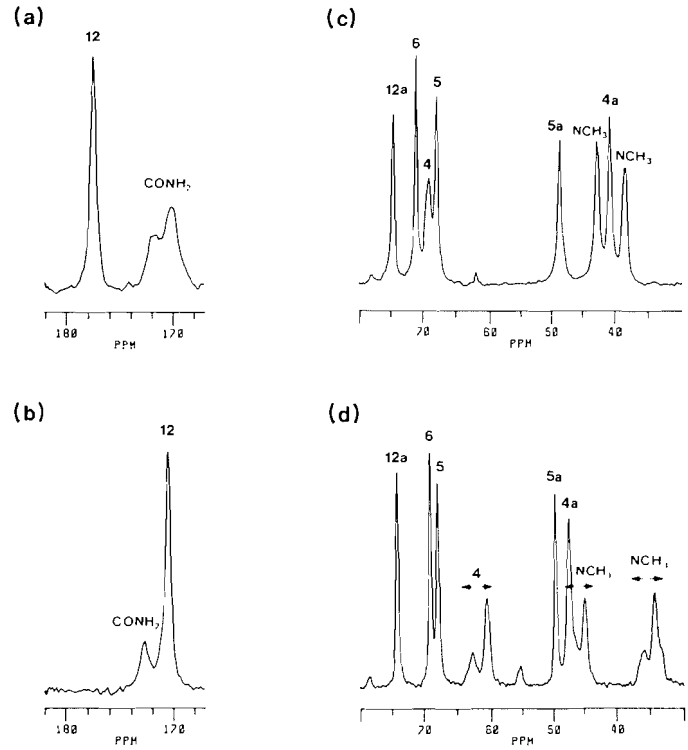

FIG. 3. Segments of the ^{13}C solid state nmr spectrum of (*a*),(*c*) OTC·$2H_2O$ and (*b*),(*d*) OTC^0 showing $^{13}C-^{14}N$ dipolar splitting in the C_{amide} carbonyl peak (*a*) and deprotonated $N(CH_3)_2$ methyl peaks (*d*).

nmr spectra calculated using Z/A ratios of 0.25 and 0.33 are illustrated in Fig. 2 of ref. 41. If the ^{35}Cl relaxation times are long enough to neglect $^{13}C-^{35}Cl$ self-decoupling (43), the calculated spectrum is expected to span a range of at least 2.0 D, where $D = (\gamma_C\gamma_{Cl}\hbar)/2\pi r^3 = 590$ Hz. In Fig. 2*a*, the expanded region of the ^{13}C solid state spectrum of CTC·HCl shows a broadening and splitting of at least 200 Hz of the C7 resonance signal, and neighbouring carbons C6a and C8 are also substantially broadened by the chlorine substituent. The signal-to-noise and overlap with other resonances make it difficult to rule out the possibility of partial self-decoupling. Similar effects were observed in demeclocycline hydrochloride.

Another example of dipolar broadening due to directly bonded quadrupolar nuclei is the amide carbonyl signal, which is affected by the amino ^{14}N. The breadth and low intensity of this signal serve to distinguish it from the nearby C12 peak. In solution, the amide shift is always reported to be upfield of the C12 signal (14), but in the solid this order is occasionally reversed. Typically, the amide resonance appeared as an asymmetric doublet (41, 44–46) with an apparent splitting of approximately 100 Hz (Fig. 3*a*). In some cases part of the doublet was obscured by the C12 resonance (e.g., Fig. 3*b*). The magnitude of the observed splitting is in good agreement with that calculated (47) using the method of Hexem *et al.* (45). Assuming a ^{14}N quadrupolar coupling constant of 2.274 MHz ($\eta = 0.378$) for the amide moiety (48) and a nitrogen–carbon bond length of 1.35 Å, calculations predict an apparent splitting of approximately 125 Hz, in good agreement with experiment.

The effect of ^{14}N on the C4 resonance signal is of particular interest. The peak is very sharp when the dimethylamino group is fully protonated (Fig. 3*c*) and the symmetry about the ^{14}N is approximately tetrahedral (i.e., the field gradient is small (49), and the ^{14}N nuclear spins are quantized along B_0). In the non-ionized form of OTC base, however, the $N(CH_3)_2$ group is not protonated (15) and the large EFG of the nitrogen (50) broadens and splits the C4 and $N(CH_3)_2$ resonance signals as shown in Fig. 3*d*. This feature of the C4 signal is useful not only for its sensitivity to the degree of $N(CH_3)_2$ protonation, but also as a means of differentiating the C4 and C5 signals in OTC and doxycycline (**1**). The two peaks are close together in the spectra of these compounds due to the 35–40 ppm downfield shift of the C5 signal by the hydroxy substituent.

Assignment of most of the other resonance peaks is straightforward since the chemical shifts differ little from solution values. Exceptions include: (*i*) C7 and C9 signals that are very close and may be interchanged (except in CTC, demeclocycline, and minocycline where C7 is shifted to higher frequency by substituents); (*ii*) C11a and C2, which are assigned by similarity to solution shifts (14), but are too close in epi-TC and non-ionized OTC^0 for the assignment to be reliable; and (*iii*) the group of low field carbonyls C11, C1, and C3. These last three have been tentatively assigned by consideration of the available X-ray data (6, 7, 15, 23), and by comparison to pH induced shifts obtained in solution (12).

Asleson and Frank (12) report that tetracycline carbon-13 signals that have an appreciable change in chemical shift (≥ 1.0 ppm) in the pH 1–6 range are the C1, C2, amide, C3, C4, $N(CH_3)_2$, C4a, C5, C12 and C12a carbons, and associate the observed pK_a (≈ 3.3) to the deprotonation of the A ring

tricarbonyl system. Their results indicate low frequency (high field) shifts in the positions of the C1, C3, and Cam peaks of −2.3, −2.7, and −1.9 ppm, respectively, upon increasing the pH from 1 to 6 for TC·HCl in 50% DMSO, 50% H_2O solution. The assigned solid shifts in TC·HCl as compared to TC·hexahydrate are −4.6, −1.5, and −2.6 ppm for the C1, C3 and Cam, while the corresponding shifts in OTC·HCl as compared to OTC/$2H_2O$ are +0.5, −4.8, and −4.2 ppm, respectively. The different behavior of C1, C3, and Cam in TC·HCl and OTC·HCl upon deprotonation of the A ring tricarbonyl system is consistent with the different known solid state structures of TC± (15, 17) and OTC± (15). X-ray diffraction studies indicate that the amide group of OTC± exists in a conformation depicted by **2** (15) while in TC± the conformation of the amide group is that shown in **3** (15, 17); the hydrochloride salts of both TC and OTC exist in form **2** (7, 10). The high frequency shifts of C12, C2, C4, and C12a, and the concurrent low frequency shifts of C4a, C11, and C11a confirm that the crystalline TC±·$6H_2O$ and OTC±·$2H_2O$ correspond to the solution zwitterionic free bases of TC and OTC respectively (10, 14).

The ^{13}C shifts of the anhydrous free base derivatives are consistent with the non-ionized (enol) conformation (**4**) reported by Stezowski and co-workers for both the anhydrous OTC^0 crystal (15) and for the free base in nonaqueous solution (19). The deprotonation of the C4-$N(CH_3)_2$ group and enolization of the A ring is particularly noticeable in (*i*) TC, by the high frequency shifts of C4a (+5.9 ppm) and C1 (+5.1 ppm), and the low frequency shift of C5 (−5.4 ppm); (*ii*) also in OTC, by the high frequency shifts of C4a (+6.5 ppm) and C3 (+8.3 ppm), and the low frequency shifts of C4 (−7.7 ppm) and C12 (−7.0 ppm). The magnitude and direction of these shifts is comparable to the results of Asleson and Frank upon deprotonation of the dimethylamino group in solution (12). Again, the observed shifts depend on the tautomeric form of the amide and conformation of the A ring, with TC shifts being more influenced in the adjacent B ring carbons (C5, C5a) than the OTC chemical shifts, which show a more pronounced effect on A ring carbon positions.

Shifts due to tautomeric form and slight changes in conformation are also clearly seen in the ^{13}C solid state spectrum of doxycycline hydrochloride, Fig. 1*c*,*d*. Unlike the salts of other TC derivatives, which have only one type of molecule per unit cell (6, 7, 10, 23), doxycycline·HCl crystallizes with one ethanol, one water, and two unique doxycycline molecules per unit cell (18). The two molecules differ mainly in the amide conformation, with DOXY(1) having the form indicated in **2** and DOXY(2) having the form shown in **3**. Each molecule has its own set of resonance peaks and hence many of the ^{13}C signals are split, some by as much as 4 ppm (e.g., C2). Signals due to ethanol in the crystal are also observed at 56.9 ppm and 18.6 ppm (see Fig. 1*d*).

In most cases, the assignment of a pair of signals to a particular carbon is quite obvious, but the high frequency carbonyl resonance peaks overlap and the choice of which two belong to C1, C3, or C11 is not clear. On the basis of the development of peak intensity with increasing contact time, these resonance signals were paired and tentatively assigned as shown in Table 1. The change in amide conformation appears to affect the C3 position much more than C1. Surprisingly, the shift difference between the C11 peaks is also quite large, as is the range of C11 shifts in the different forms of TC and OTC. Since the conformation of the BCD rings and the C11—O11 and $O_{11}\cdots H$ bond lengths show little variation among the crystal structures determined so far (15, 23), the range of C11 shifts is likely due to intermolecular effects such as packing or hydrogen bonding with water.

Conclusions

^{13}C CPMAS nmr has proven to be particularly useful in clarifying the chemical shift differences between various forms of tetracycline and oxytetracycline. These differences must be understood to interpret ^{13}C nmr data of the complexed antibiotics. In addition, the solid state spectra have displayed interesting phenomena that are not observed in the corresponding ^{13}C solution state spectra, namely, inequivalence of the amino methyl groups and quadrupole effects of adjacent ^{35}Cl and ^{14}N nuclei. The latter are particularly important in distinguishing the zwitterionic and neutral forms of the tetracycline.

The ion-pair mechanism and bimolecular displacement at saturated carbon. VI.[1] Racemization and *radio*-bromide exchange for substituted 1-phenylbromoethanes; solvent effects

ALLAN R. STEIN
Department of Chemistry, Memorial University of Newfoundland, St. John's, Nfld., Canada A1B 3X7

Received May 14, 1986

ALLAN R. STEIN. Can. J. Chem. **65**, 363 (1987).

Racemization and *radio*-bromide exchange kinetics for 1-phenylbromoethanes in acetonitrile and in nitromethane using tetrabutylammonium bromide are reported. The results, together with those previously reported for acetone solutions, provide direct empirical support for the ion-pair mechanism for nucleophilic substitution at saturated carbon. Changing the substituents on the phenyl from the 4-nitro through to the 3,4-dimethyl substrate and the solvent from acetone to the more polar acetonitrile and nitromethane shifts the transition state for bromide substitution from an early to a late stage of the equilibria series substrate ⇄ intimate ion pair ⇄ various solvated ion pairs ⇄ free or dissociated ions. For all the substrates in acetone and, for the species giving the less stable carbocations, in acetonitrile and nitromethane, both racemizations and exchanges are bimolecular. In the latter solvents, the substrates giving the more stable carbocations show mixed kinetics.

ALLAN R. STEIN. Can. J. Chem. **65**, 363 (1987).

On rapporte les cinétiques de la racémisation et de l'échange du *radio*-bromure de phényl-1 bromoéthanes, dans l'acétonitrile et dans le nitrométhane, sous l'influence du bromure de tétrabutylammonium. Les résultats obtenus, considérés avec ceux rapportés antérieurement pour des solutions dans l'acétone, fournissent un support empirique direct pour le mécanisme par paires d'ions pour les substitutions nucléophiles au niveau de carbones saturés. Lorsqu'on change les substituants portés par le groupement phényle de nitro-4 à diméthyl-3,4 et le solvant de l'acétone aux solvants plus polaires comme l'acétonitrile et le nitrométhane, l'état de transition se déplace, pour les substitutions de bromures, d'une étape du début vers une étape plus tardive de la série d'équilibres substrat ⇄ pair d'ions intimes ⇄ paires d'ions diversement solvatés ⇄ ions dissociés ou libres. Pour tous les substrats observés dans l'acétone et, pour les espèces donnant les carbocations les moins stables, dans l'acétonitrile et dans le nitrométhane, tant les racémisations que les échanges sont bimoléculaires. Dans ces derniers solvants, les substrats donnant lieu aux carbocations les plus stables présentent des cinétiques qui ne sont pas claires.

Over fifty years ago, Hughes and Ingold first published what must surely be the most broadly known and accepted reaction mechanisms in organic chemistry, the S_N1 (1) and the S_N2 (2) mechanisms for the uni- and bimolecular nucleophilic substitutions at saturated carbon. Their proposals brought order to, and, hence for organic chemists, understanding of, large amounts of empirical data that had already been and have continued to be accumulated. Despite their apparent generality and success, the two mechanistic schemes are not universally successful. An alternate mechanistic proposal, an elaboration of an earlier ion pair scheme due to Winstein (3), was made by Sneen and Larsen in 1969 (4). Their ion-pair mechanistic scheme, as summarized in Scheme 1, facilitates explanation and understanding of the "mixed" or "intermediate" behavior shown by many reactions. Such reactions, which most commonly show mixed stereochemistry — that is, bimolecular reactions which show considerable racemization or unimolecular ones which show considerable net inversion of stereochemistry (see, for example, ref. 5) — or, rarely, intermediate or mixed kinetics which are not cleanly uni- or bimolecular (see, for example, ref. 6), have long troubled organic chemists (see, for example, ref. 7).

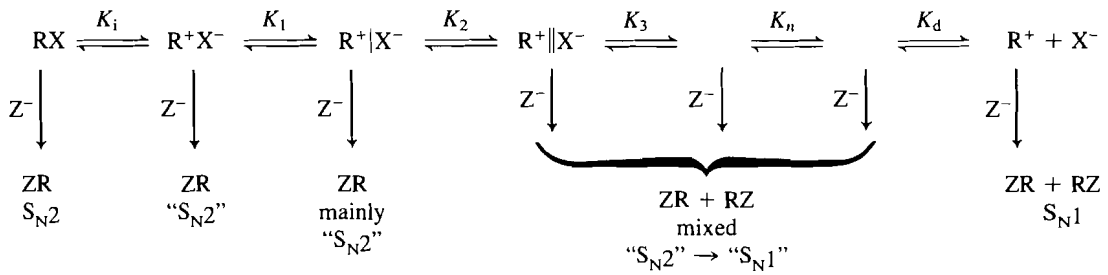
The ion-pair mechanism for nucleophilic substitution at saturated carbon was presented in some detail in the previous paper in this series (8). It was pointed out that while there was much direct empirical evidence for the involvement of ion pairs, especially for solvolysis in reactions at or near the unimolecular extreme (3, 9), perhaps the best direct empirical evidence for their involvement in bimolecular substitutions was provided in that paper.

Chiral 1-phenylbromoethanes were prepared (10) with the following substituents on the phenyl group: 4′-nitro, 4′-bromo, unsubstituted, 3′-methyl, 4′-methyl, and 3′,4′-dimethyl. The rates of racemization of chiral substrate and of *radio*-bromide–bromide exchange on racemic substrate were determined in acetone containing lithium bromide. If the Hughes–Ingold mechanisms apply, the rate constants of racemization and exchange should be equal for a unimolecular process whereas for a bimolecular one the ratio should be 2.00:1.00 since the inversion of one half of the substrate results in a racemic mixture. In fact Hughes and Ingold reported that, for the parent compound, 1-phenylbromoethane itself, the rate of racemization was, within experimental error, indeed twice the rate of bromide exchange (2), an observation we previously confirmed (11). With the 4-methyl compound, by contrast, the racemization to exchange rate constant ratio (k_{rac}/k_{exch}) was found to average 2.36:1.00. Both racemization and exchange were bimolecular, first order in each of alkyl bromide concentration and bromide activity.[2] These results are very difficult to accommodate with the Hughes–Ingold mechanisms but present no problem with the ion pair cheme (Scheme 1). Apparently a portion of the initially formed contact ion pair is being sufficiently solvent separated for some of the carbocations to turn over with respect to the bromide ion before collapsing to starting material with partial racemization. The observed rate ratio means that racemization via the internal pathway is more than one third as fast as substitution.

Substrates which would give a less stable carbocation, and hence less stable and shorter-lived ion-pair species, would be

[1]For Part V, see ref. 8.

[2]Lithium bromide associates to form ion pairs in acetone. Bromide ion activities were calculated using the data in ref. 25.



SCHEME 1

less likely to show such racemization with internal return. Indeed, in acetone, the nitro-, bromo-, and unsubstituted substrate had racemization to exchange rate constant ratios that deviated little from 2:1. The 1-(3′,4′-dimethylphenyl)bromoethane substrate, on the other hand, gave stereochemical behavior intermediate between S_N1 and S_N2 with an average racemization to exchange ratio of 1.52:1.00; the kinetics remained bimolecular, however. These results in acetone suggested that extending the study to both less polar and to more polar solvents was warranted. We report results for the more polar solvents acetonitrile and nitromethane in this paper.

Results

Racemization kinetics were done in acetonitrile and nitromethane containing the indicated concentrations of tetrabutylammonium bromide, Bu_4NBr, by starting with the corresponding chiral 1-phenylbromoethane (10) and following the loss of optical activity as previously described for the parent compound in acetone (11). Exchange kinetics were followed by the electrodeposition method of Beronius (12), again as previously described for acetone (11), except that Bu_4NBr rather than LiBr was used to make up the electrolyte solution. Irradiation of Bu_4NBr at the high neutron flux required to make ^{82}Br resulted in charring and decomposition so that LiBr was used. The solid, radioactive LiBr was dissolved in the appropriate solvent, acetonitrile or nitromethane, and a small aliquot added to the Bu_4NBr solution in the exchange cell. In all cases, the lithium ion concentration was less than 0.75%, generally less than 0.4%, of that of the tetrabutylammonium ion and was consequently ignored.

The results reported in this paper were obtained in three different laboratories; all racemization kinetics were done in one, exchanges in a second, and eliminations in a third. Each reaction type was followed by a different method with different equipment, solvents from different suppliers and with different thermometers calibrated only at 0°C where that temperature was within the thermometer's range. (The previously reported results for acetone (8), some of which are summarized in Table 1, with the exception of the exchanges with 1-(3′,4′-dimethylphenyl)bromoethane, were all done using the same thermometer and hence are more internally consistent.) Consequently, small systematic errors due to slight solvent property and temperature differences are to be expected; care must be exercised when considering small differences in rates, etc.

The ratio of the racemization to exchange rate constants (k_{rac}/k_{exch}) for acetonitrile and nitromethane, together with those for acetone, are reported in Table 1. Elimination, a competing process, would lead to isotopic dilution of *radio*-labelled ionic bromide and hence contribute to the rate assigned to bromide exchange. The elimination product, the appropriate styrene (or its readdition product) would be achiral (or racemic)

TABLE 1. Racemization to exchange rate ratios for 1-phenylbromoethanes in several solvents[a]

Substrate	Acetone[b]	Acetonitrile[c]	Nitromethane[c]
4′-Nitro	2.14	2.12	2.18
4′-Bromo	2.09	2.22	2.25
Unsubstituted	1.94	2.17	2.01
4′-Methyl	2.36	3.65	5.50
3′,4′-DiMe	1.52	4.26	2.82

[a]Rate ratios reported are average values for $[M^+Br^-] = 0.0002\ M$ at various temperatures.
[b]LiBr was used (ref. 8).
[c]Bu_4NBr was used.

so that elimination would also contribute to the observed racemization rate. Elimination rate determinations were done with added lutidine to prevent readdition of liberated HBr. Some results, along with the corresponding racemization rates, are reported in Table 2 for acetone, acetonitrile, and nitromethane. The relative and absolute rates of elimination increase progressively through those three solvents. Additional elimination results appear in Table 6.

Rate constants for racemization and bromide exchange are tabulated in Table 3 for acetonitrile and in Table 4 for nitromethane. The reported values are the average of two-to-four runs.

Discussion

In the previous paper of this series where the acetone results were reported (8), the racemization:exchange rate constant ratios were discussed in some detail. As perusal of the data in Table 1 shows, deviations in the ratio from the theoretical 2.00 are relatively small for the unsubstituted substrate and for those substrates with elecron-withdrawing *p*-Br and *p*-NO_2 substituents. Deviations are far greater for the substrates substituted with electron-donating substituents. The 4′-methyl-substituted material shows a rate ratio much greater than 2.00 for all three solvents while that for the 3′,4′-dimethyl substrate is much more erratic, falling below 2.00 in acetone, above in the other two solvents but lower than that for 4′-methyl in nitromethane; in acetonitrile it is perhaps lower than would have been anticipated considering the value for the 4′-methyl substrate. Before these rate constant ratios are further discussed, the more detailed kinetic results must be considered.

Average racemization rate constants are reported in Table 3 for acetonitrile. If the observed rate of racemization, that is $k_{rac}[Bu_4NBr]$ is plotted vs. $[Bu_4NBr]$, as has been done in Fig. 1, the first four substrates, 4′-NO_2, 4′-Br, unsubstituted, and 3′-Me behave as expected — the rate increases linearly with $[Bu_4NBr]$ and shows essentially a zero intercept, that is,

[a] k_{rac} with error limits are empirical values, others are recalculated from activation parameters.

there is no racemization without added Bu_4NBr. The last two substrates, 4′-methyl and 3′,4′-dimethylphenylbromoethane, behave quite differently. They have a large positive intercept while still showing a linear rate increase with concentration of ionic bromide. Such behavior is that expected for mixed kinetics with a uni- and a bimolecular component, that is:

$$\text{Rate} = k_1[RX] + k_2[RX][X^-]$$

Similar behavior was found in nitromethane but, as reported earlier, not in the less dipolar acetone where all compounds gave a near zero intercept (8).

Separated uni- and bimolecular components for racemizations in acetonitrile and nitromethane are reported in Table 5. The reported bimolecular component would include any salt effect due to the increasing ionic strength of the medium as the concentration of the Bu_4NBr was increased. The racemization and exchange rates were to be compared and earlier studies in acetone (11) had shown that all "inert electrolytes" added, lithium chlorate, perchlorate, nitrate, picrate, ..., either interfered with the electrodeposition of AgBr or were not sufficiently soluble. The tetrabutylammonium salts of most of the above anions should be sufficiently soluble in acetonitrile and nitromethane to permit racemization kinetics at constant ionic strength to access the salt effects. Such studies have not yet been done. Racemization studies with 1-phenylbromomethane in acetone using LiBr at constant lithium ion concentration ($LiNO_3$) have, however, been reported (13). The rate of racemization decreased progressively as the ionic strength increased, falling by 46% as the lithium ion concentration was increased ten fold, from 0.01 to 0.1 *M*, with [LiBr] = 0.01 *M* at 40.38°C. Of course there are a number of components in this "salt effect". While the ionic strength increased so did the degree of association of the lithium bromide, decreasing the activity of the bromide ion. Also, of course, there was no or at most a very small unimolecular contribution in that racemization. These results cannot be extrapolated to the present situation because, at the concentrations used, Bu_4NBr does not show significant association and the reactions of the

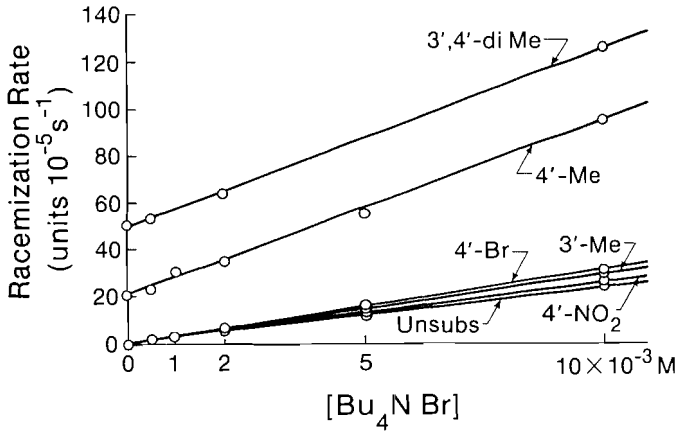

FIG. 1. Observed racemization rate versus the concentration of added Bu_4NBr in acetonitrile at 45°C.

4′-methyl and 3′,4′-dimethyl substrates do have large unimolecular components. While hundreds of papers report salt or ionic strength effects in solvolysis, such studies for "identity" or symmetrical substitution reactions are rare indeed. Fava *et al.* (6) have examined thiocyanate exchanges for various benzhydryl thiocyanates in acetone and in acetonitrile at constant ionic strength and separated uni- and bimolecular components. Unfortunately they did not undertake ionic strength effect studies, in part because of problems with association of NaSCN. We found LiBr association problems in acetone (8, 11, 13). Beronius and Gupta report such problems for various halides, including Et_4NI in the iodide exchange at methyl iodide (14).

There is an ionic strength effect contribution to all of our rate constants, including both the uni- and bimolecular components of those reactions showing mixed kinetics. How large that contribution is and indeed that it is an accelerating one, can not be stated with certainty at this time. For the cleanly bimolecular reactions, the salt effects must be small since the second order rate constant is apparently very nearly independent of the concentration of Bu_4NBr — a small rate retardation may in

[a]With no added Bu_4NBr, at 40 and 45°C, there was no change in rotation in the racemization studies for the first 90 min — racemization commenced over longer times.

[b]Initial slopes were used to calculate k_{rac} — racemization accelerated in later stages.

[c]With no added Bu_4NBr, at 45°C, the initial rate of racemization was $(0.344 \pm 0.012) \times 10^{-5}$ s^{-1}.

[d]With no added Bu_4NBr, at 30, 40, and 45°C, respectively, the initial rates of racemization were (4.392 ± 0.033), (10.77 ± 0.38), and $(20.78 \pm 0.26) \times 10^{-5}$ s^{-1}.

[e]With no added Bu_4NBr, at 40 and 45°C, respectively, the initial rates of racemization were (33.02 ± 0.44) and $(50.49 \pm 0.30) \times 10^{-5}$ s^{-1}.

fact be present. Certainly the bimolecular rate constants, k_2, reported in Table 5 are not unrealistic for the 4′-methyl and 3′,4′-dimethyl substrates even though there is most likely a positive salt effect on the unimolecular component which would increase the apparent k_2. In acetone at 30°C, for example, where any unimolecular component was very small, the second order rate constant for the 4′-methyl compound was slightly more than double that of the unsubstituted compound, in acetonitrile at 45°C it is triple. Still, as Bunton *et al.* have shown, there is most likely a positive salt effect on the unimolecular component, a contribution which probably increases linearly with Bu_4NBr concentration (15). Just how large a fraction of the k_2 value should be assigned to that salt effect remains to be established.

Table 5 also includes the elimination rate constants measured with added excess lutidine to prevent readdition. As pointed out previously (8), the elimination rate given should be considered an upper limit since there is evidence that in buffered solutions, even such weak bases as the trifluoroacetate ion in trifluoroacetic acid (16) or various chloro- and trifluoroacetate ions in 50:50 2,2,2-trifluoroethanol:water (17) promote elimination side reactions, for the solvolysis of butyl tosylate and 1-(4′-methylphenyl)chloroethane, respectively. Without added lutidine, eliminations were slower and the bromide ion concentration tended to reach a plateau value a bit above the initial concentration, a plateau value that varied considerably even in duplicate runs. With lutidine added, the elimination rate was quite insensitive to the concentration of Bu_4NBr, decreasing

TABLE 6. Elimination rate vs. [Bu_4NBr]: acetonitrile, 4′-methyl, 55°C [lutidine] = 34.3×10^{-3} *M*

$[Br_4NBr] \times 10^{-3}$ *M*	$k_{elim} \times 10^{-5}$ s^{-1}
5.000	8.012±0.0066
2.000	8.375±0.059
1.000	8.936±0.010
(rate vs. $\sqrt{\mu}$, slope = −0.4)	

only very slightly with increasing concentration (Table 6). This elimination contributes to the unimolecular component of the racemizations.

Thus the observed racemization rate is made up of the components:

$$\text{Rate observed} = [RBr](k_{1\,rac} + k_{1\,elim} + k_{2\,rac}[Bu_4NBr])$$

For the 4′-methyl substrate in acetonitrile at 40°C the values of the three rate constants are:

$$k_{1\,rac} = (17.43 \pm 0.70) \times 10^{-5}\ s^{-1}$$

$$k_{1\,elim} = (3.19 \pm 0.06) \times 10^{-5}\ s^{-2}$$

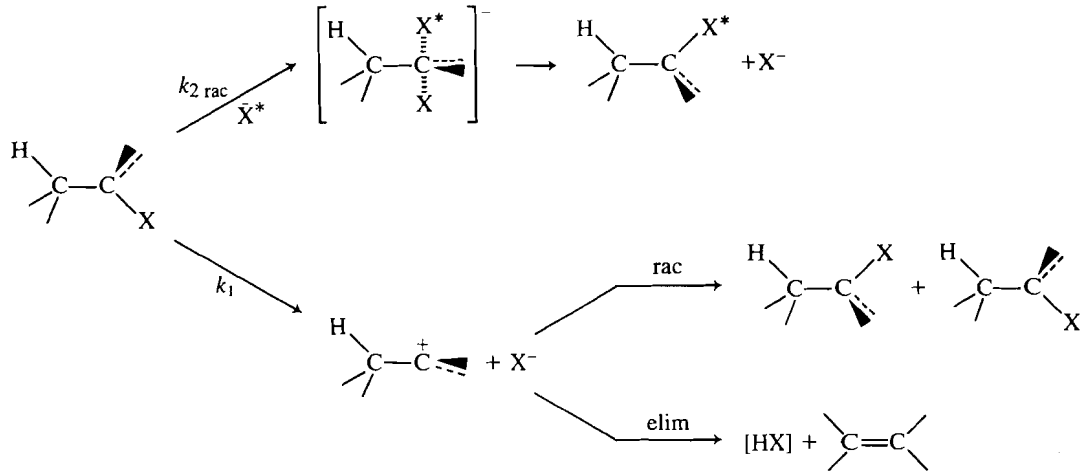
$$k_{2\,rac} = (69.5 \pm 1.4) \times 10^{-3}\ L/m\ s$$

or at $[Bu_4NBr] = 0.01$ *M*,

$$k_{2\,rac}[Bu_4NBr] = (69.5 \pm 1.4) \times 10^{-5}\ s^{-1}$$

Thus at the highest concentration of salt used, the elimination would account for only 3.5% of the observed rate, at the lowest concentration (0.0005 *M* Bu_4NBr) it would be 13.2%, whereas in nitromethane the corresponding percentages would be 13.1% and 25.0%. In all cases, elimination, even with added lutidine, accounts for only a fraction of the unimolecular component.

The simplest approach is to assume there are uni- and bimolecular processes with the carbocation formed in the former partitioning between elimination and nucleophile addition and the latter being simple bimolecular nucleophilic substitution as represented in Scheme 2. This is not, however, a complete picture.



SCHEME 2

For such a scheme the rate ratio for racemization:exchange should fall between the value of 2.00 for S_N2 and 1.00 for S_N1 mechanisms. Instead, in acetonitrile, it is 3.65, in nitromethane, 5.50 for the 4′-methyl substrate. This discrepancy is more easily accommodated in the ion-pair mechanistic scheme (Scheme 1). A considerable amount of internal return with racemization is occurring in a reaction where the average stage for nucleophilic attack is quite far over towards dissociation. This explanation is supported by the fact that the rac:exch rate ratios increase as the concentration of bromide ion decreases. Thus, for example, at 45°C, for the unsubstituted compound the ratios are 2.07, 2.25, 2.29 and 2.75 at 0.01, 0.002, 0.001 and 0.0005 *M* respectively, for 4′-methyl the ratios are 2.37 and 3.93 and for 3′,4′-dimethyl 2.38 and 3.98 at 0.01 and 0.002 *M*, respectively. This behavior is exactly what would be predicted since at the higher concentrations of nucleophile, the average stage of nucleophilic attack should be earlier in the ion pair solvation–dissociation sequence and the amount of internal return with racemization would be reduced both by faster, earlier nucleophilic attack and by reducing the total amount of internal return.

The drop in $k_{rac}:k_{exch}$ ratio for 1-(3′,4′-dimethylphenyl)bromoethane is consistent with an even more stable carbocation than that from the 4′-methyl substrate. Consequently, the average stage of nucleophilic attack is farther delayed, the reaction has a larger S_N1 component (i.e. dissociation of more of the ion pair before reaction) and shows a reduced amount of internal return.

The picture presented above is incomplete. As pointed out by Bentley *et al.* (18) chemists tend to treat the ion pair scheme of Winstein or as applied by Sneen and represented in Scheme 1 as though it was "exact" and "complete". Even unimolecular processes in relatively non-ionizing solvents are greatly accelerated by added "inert" electrolyte giving rise to the "special salt effects" first noted by Winstein *et al.* (for a summary, see ref. 3). That this is through some sort of one-on-one process is confirmed by the fact that, at higher electrolyte concentration, the rate acceleration reverts to a "normal salt effect". Clearly other ionic species present directly affect the ionization–dissociation process.

In recent years, nucleophilic substitutions in the gas phase have received extensive study (19–21). Studies of methyl

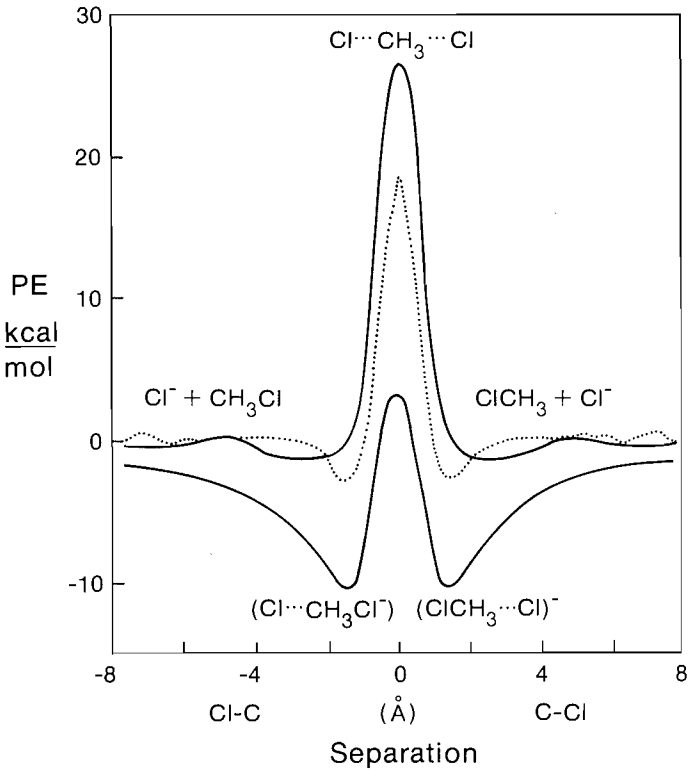

FIG. 2. Calculated energies as a function of reaction coordinate separation in Å for the reaction of Cl^- with CH_3Cl in aqueous solution (upper), in DMF (middle), and in the gas phase (lower curve) (from ref. 19*a*).

halide – halide ion exchange in the gas phase by Olmstead and Brauman (20) show an energy well with the transition state for substitution being a maximum within that well, a potential energy profile which is supported by the calculations of Jorgensen *et al.* (19*a*), Fig. 2, lowest curve. The minima preceding and following the transition state correspond to the exothermic "solvation" or ion–dipole interaction of $X^-\cdots H_3\overset{\delta+}{C}—\overset{\delta-}{X}$ and $\overset{\delta-}{X}—\overset{\delta+}{C}H_3\cdots X^-$, respectively. While the effect of progressive solvation of the nucleophile apparently has not been reported for such degenerate processes, empirical (19*b*, 21) and theoretical (22) results have been reported for gas phase substitutions on methyl halides by hydrated hydroxide ions. Thus for $OH^-(H_2O)_n$ as the nucleophile with methyl bromide, Bohme and MacKay (21) found that, as the degree of hydration, n, is progressively increased, n = 0, 1, 2, 3, ..., that is, as the nucleophile is stabilized by solvation, the depth of the pre-transition state energy well decreases and the net energy barrier to reaction increases from near zero towards the aqueous solution value of E_a = 23 kcal/mol. The observed reaction rate also decreases progressively, being 1×10^{-9}, 6×10^{-10}, 2×10^{-12}, $\lesssim 2 \times 10^{-13}$, and 2.3×10^{-25} cm^3/molecule s for the reactions with n = 0, 1, 2, 3, and in aqueous solution, respectively.

Solvent effects on the potential energy profile of a degenerate process have been considered by Chandrasekhar and Jorgensen (19*a*) and are summarized in Fig. 2. Notice that small energy minima corresponding to the ion–dipole association of Cl^- and CH_3Cl are still predicted for even such polar solvents as DMF (d.c. = 36.7). Presumably, solvents of similar polarity, such as acetonitrile (d.c. = 37.5) and nitromethane (d.c. = 35.9), would have similar minima to that calculated for DMF while a much less polar solvent like acetone (d.c. = 20.7) would show much more pronounced minima, falling somewhere between the gas phase and DMF pictures of Fig. 2. As Chandrasekhar and Jorgensen point out, such results "lead one to question the likelihood of concerted S_N2 reactions in nonaqueous media, i.e. (reactions) preceding without ... intermediates" (19*a*).

Our results, which show a large uni-molecular component for the species which would give the most stable carbocation in the relatively polar aprotic solvents, acetonitrile and nitromethane, prove that at least in such favourable cases nucleophilic assistance is not necessary to promote ion-pair formation–dissociation. The unassisted unimolecular process is in competition with the nucleophile-assisted, bimolecular one. Yamabe and Hirao (23) have done SCF computations which show the chloride ion in acetonitrile to be tetrahedrally solvated, through the carbon of the methyl group, by four acetonitrile molecules. Kebarle and co-workers (19*c*), on the other hand, find that in DMSO, the chloride ion is solvated through the sulfur of the S—O group and is located between and below the methyls, directly along the S—O bond. It is unlikely the bromide ion would differ greatly in those two solvents; as for the chloride, solvation would be considerably better in DMSO with the concomitant reduction in nucleophilicity. Apparently analogous calculations have not been done for nitromethane but our results suggest the bromide ion is less reactive, better solvated in that solvent since the uni-molecular components are proportionally much larger. Presumably, solvational exchange, that is, displacement of nitromethane from a solvation site by alkyl bromide ($—\overset{\delta\oplus}{C}—\overset{\delta\ominus}{Br}$), is less exothermic and the pre- and post-transition state energy wells are shallower than for acetonitrile. For acetone apparently those wells are considerably deeper. Unfortunately, preliminary exchange experiments in dimethylformamide and in dimethylsulfoxide indicated problems in the electrodeposition — unstable AgBr films formed and current efficiencies were less than 100% and irreproducible.

A parallel solvational effect would be acting on the leaving group — the better the solvation, the less the assistance of the nucleophile would be required for, first, ionization to ion pair and, then, dissociation to solvated carbocation and bromide ion.

We now have a fairly complete picture for the range of transition states. For the less dipolar, "poorer" solvents like acetone, ionization–dissociation does not proceed without involvement of the nucleophile. For the more dipolar, "better" solvents like acetonitrile and nitromethane, the same applies for those substrates giving the less stable carbocations and, hence, ion pairs. For these cases, nucleophilic assistance is required. Except for the most readily ionized substrates, once formed the ion pair either collapses to starting material or undergoes nucleophilic attack fairly early in the ionization–dissociation process since there is little or no internal return with racemization. The k_{rac}:k_{exch} ratio is 2:1, the value predicted for the S_N2 mechanism and racemization and exchange show "clean" second order kinetics.

Even in acetone, a more readily ionized substrate, one giving a more stable carbocation such as 1-(4′-methylphenyl)bromoethane, has the transition state for nucleophilic substitution shifted sufficiently towards dissociation to show considerable internal return with racemization. k_{rac}:k_{exch} becomes greater than 2:1. For the even more readily ionized substrate, 1-(3′,4′-dimethylphenyl)bromoethane, the rate ratio falls to less than 2:1 but both racemization and exchange remain bimolecular; the bromide ion is still necessary to promote ionization–

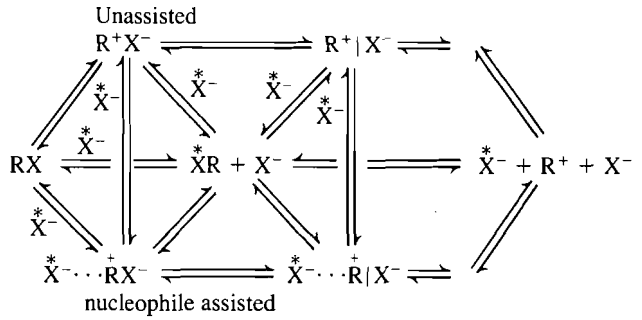
For personal use only.



SCHEME 3

dissociation. Here though either a significant fraction of the ion pairs "dissociate" before reaction with the nucleophile or the separation is sufficient for considerable leaving group — nucleophile exchange before collapse.

In more ionizing media, nucleophilic involvement is still essential for those substrates giving the less stable carbocations–ion pairs. Substrates giving somewhat more stable species, the 4′-methyl substrate in our case, show large amounts of internal return with racemization but here, and more markedly with the 3′,4′-dimethyl substrate, nucleophilic assistance is no longer crucial. A unimolecular component has appeared. These reactions show mixed kinetics as well as mixed stereochemistry.

The evolving picture is difficult to represent in two dimensions. Lowry and Richardson (24) have given one of the better representations which is presented, somewhat modified, in Scheme 3.

If such a scheme is operating here, the bulk of the reactions follow the nucleophile assisted pathway. Only the unimolecular component of those reactions showing mixed kinetics, that is those substrates giving the most stable carbocations/ion pairs in the more polar solvents acetonitrile and nitromethane, represent reaction via the unassisted pathway. (3′,4′-Dimethylphenyl)bromoethane in acetone, which reacts with bimolecular kinetics but gives a k_{rac}/k_{exch} ratio halfway between that expected for uni- and bimolecular processes, presumably undergoes "intersystem crossing"; it starts along the nucleophile assisted pathway but, because the carbocation/ion pair is sufficiently stable, nucleophile involvement is not essential for completion of ion pair separation. The reaction proceeds, at least in part, by crossing to the unassisted pathway.

Obviously even Scheme 3 is far from complete since it includes reactions of only one solvated ion pair and does not consider stereochemistry, the possibility of return with racemization, and elimination. As such, it is a much better representation of the bromide exchange than of the racemization process. The scheme does, however, contain most other components.

Experimental

All solvents were reagent or Analar grade and were stored over a generous quantity of Type 4A molecular sieves before being freshly distilled under dry tank nitrogen which had been further dried by bubbling through concentrated H_2SO_4 followed by a column of Type 3A molecular sieves. Analytical grade tetrabutylammonium bromide (Eastman) was pumped at 0.1 mm Hg and 60°C overnight and kept under vacuum or, for brief periods, tightly stoppered in a glove box. Stock solutions 0.0200 or 0.0500 *M* in Bu_4NBr were prepared, sealed in Hypo-vials and stored in a dry nitrogen flushed glove box (racemizations) or bag (exchanges and eliminations). Solutions of the appropriate concentration for kinetics were prepared using freshly distilled solvent as required. Normally the stock solutions were used within 1–2 weeks, the diluted solutions within 1–2 days. Racemization rates obtained using stock solutions that had been stored for several months were within a few percent of those obtained using freshly prepared stock solutions for acetonitrile and for nitromethane; the rate decreased somewhat more, about 8% for three month storage, for acetone. The dilute solutions which were kept in stoppered volumetric flasks went "off" much more quickly.

Except as indicated below, all experimental details and data handling were analogous or identical to those previously described (8, 11, 13).

Kinetics of exchange were followed as outlined for LiBr in acetone (8) except that Bu_4NBr was used. Since that salt was destroyed when irradiated at the high neutron fluxes required to prepare ^{82}Br, $Li^{82}Br$ was used instead. LiBr, 0.87 mg was sealed *in vacuo* in a thin-walled quartz vial — the appropriate volume of aqueous LiBr was added to the vial, the water evaporated and the vial heated at 225–250°C before sealing. After irradiation, the vial was broken below the surface of 5 mL of the solvent being used in a small erlenmeyer flask. Aliquots of this 0.002 *M* solution were then added to the kinetics cell containing 50 mL of the Bu_4NBr solution. The aliquot volume was 0.05–0.5 mL, chosen to give a reasonable count rate after electrodeposition of AgBr on the silver electrodes. The volume added was smallest for the lowest concentrations with the freshest radioactive material.

Substitution reactions of some pseudo-halides in *trans*-$[Ru(NH_3)P(OEt)_3(H_2O)]^{2+}$

SONIA MARIA NEIVA, LUCÍDIO SOUZA SANTOS, SEBASTIÃO BARROS ARAÚJO,
JOSÉ CARDOSO DO NASCIMENTO FILHO, AND DOUGLAS WAGNER FRANCO
Instituto de Física e Química de São Carlos, USP São Carlos, 13.560 – SP, CP. 369 – Brasil

Received October 1, 1984[1]

SONIA MARIA NEIVA, LUCÍDIO SOUZA SANTOS, SEBASTIÃO BARROS ARAÚJO, JOSÉ CARDOSO DO NASCIMENTO FILHO, and DOUGLAS WAGNER FRANCO. Can. J. Chem. **65**, 372 (1987).

The kinetics and mechanism of the formation of *trans*-$[Ru(NH_3)_4P(OEt)_3X]^{1+}$ (X = SCN^-, CN^-, and N_3^-) have been investigated. The second order specific rate constants k_1 for the substitution of the water molecule in *trans*-$[Ru(NH_3)_4P(OEt)_3(H_2O)]^{2+}$ for CN^-, N_3^-, and SCN^- are $(3.1 \pm 0.3) \times 10^2$, $(1.7 \pm 0.1) \times 10^2$, and $(1.4 \pm 0.1) \times 10^2\ M^{-1}\,s^{-1}$, respectively, at 25°C, μ = 1.0 ($NaCF_3COO$). Under the same experimental conditions the aquation of the pseudohalide derivatives, *trans*-$[Ru(NH_3)_4P(OEt)_3X]^+$, proceeds at specific rates of $(1.8 \pm 0.1) \times 10$ and $(2.8 \pm 0.1) \times 10\,s^{-1}$ for X = N_3^- and SCN^-, respectively, and the upper limit for the rate of CN^- loss from *trans*-$[Ru(NH_3)_4P(OEt)_3CN]^+$ was estimated as $1.2 \times 10^{-1}\,s^{-1}$. The order of affinities for the monophosphite complex in the series of ligands studied is:

$$SO^{2-} \sim P(OEt)_3 > CN^- > imN > isn > pyr > Mepyr^+ > N_3^- > SCN^-$$

where imN = imidazol, pyr = pyrazine, and $Mepyr^+$ = methylpyrazinium. From enthalpies of activation it is possible to estimate that net replacement of H_2O in *trans*-$[Ru(NH_3)_4P(OEt)_3(H_2O)]^{2+}$ by azide ions is exothermic by 2.8 ± 2 kcal/mol.

SONIA MARIA NEIVA, LUCÍDIO SOUZA SANTOS, SEBASTIÃO BARROS ARAÚJO, JOSÉ CARDOSO DO NASCIMENTO FILHO et DOUGLAS WAGNER FRANCO. Can. J. Chem. **65**, 372 (1987).

On a étudié la cinétique et le mécanisme de formation du complexe $[Ru(NH_3)_4P(OEt)_3X]^{1+}$-*trans* (X = SCN^-, CN^- et N_3^-). On a déterminé que, à 25°C et à une valeur de μ = 1,0 ($NaCF_3COO$), les constantes de vitesses spécifiques du deuxième ordre, k_1, pour la substitution de CN^-, N_3^- et SCN^- par la molécule d'eau dans le $[Ru(NH_3)_4P(OEt)_3(H_2O)]^{2+}$-*trans* sont respectivement de $(3{,}1 \pm 0{,}3) \times 10^2$, $(1{,}7 \pm 0{,}1) \times 10^2$ et $(1{,}4 \pm 0{,}1) \times 10^2\ M^{-1}\,s^{-1}$. Dans des conditions expérimentales semblables, les réactions d'aquation des dérivés pseudo halogénés, $[Ru(NH_3)_4P(OEt)_3X^-]^{1+}$-*trans* dans lesquels X = N_3^- et SCN^-, se produisent respectivement à des vitesses spécifiques de $(1{,}8 \pm 0{,}1) \times 10$ et $(2{,}8 \pm 0{,}1) \times 10\,s^{-1}$ et on a évalué que la limite supérieure pour la vitesse de la perte du CN^- du $[Ru(NH_3)_4P(OEt)_3CN]^{1+}$-*trans* est égale à $1{,}2 \times 10^{-1}\,s^{-1}$. L'ordre des affinités pour le complexe monophosphite dans la série des ligands étudiés est

$$SO^{2-} \sim P(OEt)_3 > CN^- > imN > isn > pyr > Mepyr^+ > N_3^- > SCN^-$$

dans lesquels imn = imidazole, pyr = pyrazine et $Mepyr^+$ = méthylpyrazinium. A partir des enthalpies d'activation, il est possible d'évaluer que le remplacement net de l'eau dans $[Ru(NH_3)_4P(OEt)_3(H_2O)]^{2+}$-*trans* par les ions azotures et exothermique par 2,8 ± 2 kcal/mol.

[Traduit par la revue]

Introduction

The substitution of one of the ammonia molecules in $[Ru(NH_3)_6]^{2+}$ by the $P(OEt)_3$ ligand provides a good model for the study of the substitutional reactivity of the ligand *trans* to the phosphite molecule.

The substitution of the water molecule in the monophosphite complex *trans*-$[Ru(NH_3)_4P(OEt)_3(H_2O)]^{2+}$ by some nucleophilic and electrophilic reagents was reported earlier (1).

In contrast to other ruthenium(II) ammines (2–4), it was observed for the monophosphite complex that the mechanism of the substitution reactions is sensitive to the properties of the substituent ligand. Proceeding with our investigations on this subject we report further studies on the substitution reactions of monophosphite complex by azide, thiocyanate, and cyanide ions.

Experimental section

Doubly distilled water was used throughout, and all chemicals of analytical grade were used as supplied. Sodium azide (Sigma), sodium thiocyanate (Merck), sodium cyanide (Merck), and triethyl phosphite (Aldrich) were purified as described previously (1).

The $[Ru(NH_3)_5Cl]Cl_2$ and *trans*-$[Ru(NH_3)_4SO_2(H_2O)](CF_3SO_3)_2$ were prepared from $[Ru(NH_3)_6]Cl_3$ (Matthey-Bishop) and $[Ru(NH_3)_5Cl]Cl_2$ according to the literature (5, 6). The *trans*-$[Ru(NH_3)_4(P(OEt)_3)_2](CF_3SO_3)_2$ was prepared by reaction of *trans*-$[Ru(NH_3)_4SO_2(H_2O)](CF_3SO_3)_2$ with $P(OEt)_3$ in acetone (1). The monophosphite complex *trans*-$[Ru(NH_3)_4P(OEt)_3(H_2O)]^{2+}$ was generated in solution by aquation (1, 7) of the biphosphite complex *trans*-$[Ru(NH_3)_4(P(OEt)_3)_2](CF_3SO_3)_2$. Due to air sensitivity of ruthenium(II) complexes all the manipulations were carried out in an inert atmosphere of argon or nitrogen. Electronic spectra of solutions were recorded on a Varian Techtron model 635 spectrophotometer. Reactions were run under pseudo-first-order conditions (excess of ligand), and kinetic determinations made by following changes in absorbance at a selected wavelength in an Aminco-Morrow stopped-flow spectrophotometer. The observed pseudo-first-order rate constant for the approach to equilibrium in reaction [2] is expressed by:

$$[1] \quad k_{obsd} = k_1[X^-] + k_{-1}$$

Values of k_1 and k_{-1} were calculated from the slope and intercept of plots of k_{obsd} versus $[X^-]$ and by employing an H.P. 97 calculator with a standard least squares program. The K_{eq} were calculated from the quotient k_1/k_{-1}. The thermodynamic parameters were evaluated from data at three different temperatures using the Eyring equations (8). The temperature of cell compartment of the spectrophotometer was kept within ±0.1°C by circulating water from a thermostat.

Zwickel flask (9), Teflon tubing, or syringe techniques were used to transfer air-sensitive materials.

Results

The pseudo-halides react with the monophosphite complex according to:
