The cycloaddition reaction of propargyl allenyl type 1,3-dipoles [R—A≡B—C] with π bonds has been extensively investigated and reviewed (4). There has, however, been only a limited number of studies on the theoretical aspects of nitrile sulphide cycloadditions (28). The frontier molecular orbitals (HOMO: Highest Occupied Molecular Orbital, LUMO: Lowest Unoccupied Molecular Orbital) of a number of nitrile sulphides and π bonds were calculated at the semi-empirical level (PM3) and the results are given in Table 9. The inter-atomic distances were set by the default values in the program and fully geometry optimised at the PM3 level prior to the single point calculation of the molecular orbitals. The substitution of the nitrile sulphide with alkyl groups slightly stabilises the π LUMO more than the π HOMO therefore decreasing the HOMO-gap with increasing substituent size. The composition and energies of the frontier π orbitals of a nitrile sulphide with DMAD and thiazyl chloride are shown in Fig. 6. The π frontier orbitals are of the appropriate orientation to allow a symmetry allowed cycloaddition reaction to occur with the π bonds. The difference in energy of the nitrile sulphide HOMO and the π bond LUMO is consistently and significantly smaller than the complementary HOMO–LUMO pair. This is consistent with calculations reported for both nitrile oxides and nitrile sulphides (4, 28). The incorporation of elements with high electronegativity into the π manifold acts to stabilise the π orbitals with respect to the frontier orbitals of the dipolarophile.

These data in Table 9 indicate that substitution of nitrile sulphides with alkyl groups minimizes the energy difference of the critical HOMO–LUMO pair. When the nitrile sulphide is substituted with an aryl group the π HOMO and π LUMO of the nitrile sulphide have substantial contributions from the 2p orbitals on the carbons of the aromatic ring. This delocalisation of the π orbitals may act to stabilise the nitrile sulphide but it does not enhance the interactions of the frontier orbitals. Our experimental results show that the reaction of the alkyl substituted nitrile sulphides gives the thiazyl chloride cycloadduct in higher yield (54 ± 2%) than the aryl substituted derivative (17%). This may be due to the ability of the alkyl nitrile sulphides to successfully undergo cycloaddition to the thermally

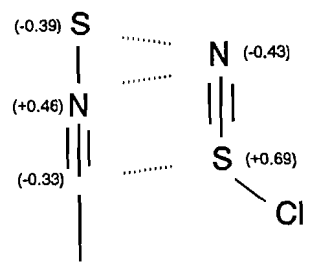
[d]The value quoted is for the carbon in the —C≡N—S moiety. Other carbon atoms in the phenyl substituent make significant contributions to this orbital (λ > 0.2).

unstable thiazyl chloride π bond faster than the aryl substituted derivative.

The calculated charges on the atoms in *t*-butyl nitrile sulphide and thiazyl chloride are shown in 13. The cycloaddition reaction to produce a sulphur-sulphur and a carbon-nitrogen bond is preferred electrostatically to the complementary cycloaddition which would produce carbon–sulphur and nitrogen–sulphur bonds. This is also supported thermodynamically in a bonds broken – bonds formed thermochemical analysis which indicates that generation of the 1,2,3,5-dithiadiazolium heterocycle is preferred by ~56 $kJmol^{-1}$ over the 1,3,2,5-dithiadiazolium alternative (if one assumes that the values for bond delocalisation and autoionisation are the same for both cations).

The π structure of the nitrile sulphides is very similar to that reported for the SNS^+ cation (3). The lower symmetry of the nitrile sulphides and the incorporation of carbon into the π manifold would appear to make the frontier orbitals of the nitrile sulphides asymmetric and of higher energy. Nevertheless, in both species the dominant frontier orbital interaction is the same and one would expect their cycloaddition chemistries to be very similar.

These calculations indicate that the cycloaddition of nitrile sulphides with thiazyl chloride are symmetry allowed processes



13

that are driven by the HOMO (NSCl) - LUMO (RCNS) frontier molecular orbital pair. The thermal instability of the thiazyl sulphide creates a situation where the best nitrile sulphide derivatives for cycloaddition will be substituted with saturated alkyl groups. Aryl substitution may stabilise the nitrile sulphide itself but the cycloaddition is dependant on highly reactive 1,3-dipoles to give significant yields. It may yet be possible to isolate a stable nitrile sulphide by substitution with sterically protective aromatic substituents such as mesityl or super mesityl but they may also be less reactive in similar cycloaddition reactions.

Received August 31, 1993

WOLFGANG KLIEGEL, GOTTFRIED LUBKOWITZ, STEVEN J. RETTIG, and JAMES TROTTER. Can. J. Chem. **72**, 1154 (1994).

Three 2-(hydroxyamino)alkanols have been reacted with sterically hindered arylboronic acids, $ArB(OH)_2$. When Ar = *o*-tolyl, 1:2 condensates having bicyclic structures are formed but when Ar = mesityl (2,4,6-$(CH_3)_3C_6H_2$), 1:1 condensates having six-membered cycloboronate structures result. These 1:1 condensates represent the first examples of *N*-unsubstituted 1,3-dioxa-4-aza-2-boracyclohexane derivatives. An X-ray analysis of one example provides unambiguous proof of the structure. Crystals of 2-mesityl-6,6-pentamethylene-1,3-dioxa-4-aza-2-boracyclohexane, **3***c*, are monoclinic, $a = 11.076(9)$, $b = 23.94(2)$, $c = 13.414(9)$ Å, $\beta = 109.40(5)°$, $Z = 8$, space group $P2_1/n$. The structure was solved by direct methods and refined by full-matrix least-squares procedures to $R = 0.051$ and $R_w = 0.058$ for 2037 reflections with $I \geq 3\sigma(F^2)$.

WOLFGANG KLIEGEL, GOTTFRIED LUBKOWITZ, STEVEN J. RETTIG et JAMES TROTTER. Can. J. Chem. **72**, 1154 (1994).

On a fait réagir trois 2-(hydroxyamino)alcanols avec des acides arylboroniques stériquement empêchés, $ArB(OH)_2$. Lorsque Ar = *o*-tolyle, il se forme de produits de condensation 1 : 2 de structures bicycliques; toutefois, lorsque Ar = mésityle (2,4,6-$(CH_3)_3C_6H_2$), les produits de condensation sont de nature 1 : 1 et il s'agit de cycloboronates à six chaînons. Ces produits de condensation 1 : 1 représentent les premiers exemples de dérivés 1,3-dioxa-4-aza-2-boracyclohexanes non *N*-substitués. Une analyse d'un exemple par diffraction des rayons X fournit une preuve non ambiguë de la structure. Les cristaux du 2-mésityl-6,6-pentaméthylène-1,3-dioxa-4-aza-2-boracyclohexane, **3***c*, sont monocliniques, groupe d'espace $P2_1/n$, avec $a = 11,076(9)$, $b = 23,94(2)$ et $c = 13,414(9)$ Å, $\beta = 109,40(5)°$ et $Z = 8$. On a résolu la structure par des méthodes directes et on l'a affinée par la méthode des moindres carrés jusqu'à des valeurs de $R = 0,051$ et $R_w = 0,058$ pour 2037 réflexions avec $I \geq 3\sigma(F^2)$.

[Traduit par la Rédaction]

Introduction

2-(Hydroxyamino)alkanols **1** react with phenylboronic acid to give eight-membered heterocyclic pyroboronates **2** (Ar = C_6H_5) that are stabilized by transannular N–B coordination (1–3). These bicyclic compounds are obtained even if only one molar equivalent of phenylboronic acid is applied. The six-membered cycloboronates **3** or their dimers **4** could not be isolated in these cases. Since the formation of cyclic arylboronates from 1,3-diol compounds is generally well known, and the structures of several six-membered cycloboronates have been established by X-ray crystallographic analyses (ref. 4, and references therein), we attempted to achieve the synthesis of **3** by impeding the formation of the bicyclic ring skeleton through steric hindrance via the introduction of one or two *ortho* methyl groups into the phenylboronic acid.

The application of *o*-tolylboronic acid, however, did not lead to the monoarylboronates **3** but gave instead compounds containing two molecules of the arylboronic acid each. Elemental analyses and infrared and nmr spectra suggest bicyclic structures for **2***a–c*, like those established for **2** ($R^1 = R^2 = H$, $R^3 = R^4 = CH_3$, Ar = C_6H_5) (1) and the *N*-benzyl derivative **5** (5) by X-ray structure analyses. The ^{11}B nmr spectrum of **2***b* shows two signals of nearly equal peak area at $\delta(Et_2OBF_3) = 11.7$ and 30.7 ppm, indicating tri- and tetravalent boron atoms, respectively (6). These values correspond to the shifts of 13.3 and 28.0 ppm observed in the spectrum of the *N*-substituted bicyclic pyroboronate **5**, which possesses two different states of boron hybridization (5). It can therefore be assumed that the *o*-tolylboronates **2***a–c* have a comparable bicyclic pyroboronate structure.

In contrast to the above results, elemental analyses and ^1H nmr spectra suggested that the reaction of **1** with mesitylboronic acid gave 1:1 condensation products having the monocyclic structure **3**. The N—H stretching vibration in the infrared spectra of **3***a–c* appears between 3160 and 3290 cm^{-1}, different from the N—H absorptions in the infrared spectra of **2***a–c* which appear between 3050 and 3100 cm^{-1}, as observed for the bicyclic phenylboronates **2** (Ar = C_6H_5) (1–3). The shift of the N—H absorption bands in **3***a–c* to higher frequencies (by 100–200 cm^{-1}) corresponds to a decreased positive charge at the hydroxylamine nitrogen atom in a type **3** compound lacking the transannular N–B coordination.

As expected, the ^{11}B nmr spectrum of **3***c* displays only one signal at $\delta(Et_2OBF_3) = 29.3$ ppm, indicating a trivalent (sp^2) boron moiety. In the solid state, however, a dimeric association product of the type **4** cannot be excluded. The phenylboronate of an *N*-methyl derivative of **1** (R^1 = Me, $R^2 = R^3 = R^4 = H$) exists as a type **4** BONBON dimer in the crystalline state and displays a main ^{11}B nmr signal at 27.2 ppm in solution (5). The spectroscopic data do not unambiguously exclude a five-membered arylboronate of the type **6**[3] nor its *N*-oxide tautomer **7**

that could dimerize to the BONBON compound **8** (at least in the solid state). To distinguish between the structural possibilities **3**, **4**, **6**, and **8** in the solid state, a structure analysis of compound **3***c*, which yielded the most suitable crystals, was undertaken.

Experimental

8,8-Dimethyl-3,5-di(o-tolyl)-2,4,6-trioxa-1-azonia-3-bora-5-boratabicyclo[3.3.0]octane, ***2a***

2-(Hydroxyamino)-2-methylpropanol, **1***a* (7) (0.21 g, 2 mmol) and *o*-tolylboronic acid (0.54 g, 4 mmol) are dissolved in 20 mL of benzene and refluxed for 1 h using a Dean–Stark trap for continuous removal of water. The solvent is distilled off in vacuo and the solid residue crystallized from toluene, yielding 0.60 g (93%) of colorless crystals, mp 144–146°C (dec.). Infrared (KBr): 3060 (N—H), 1600 (aryl C═C) cm^{-1}; ^1H nmr (90 MHz, $CDCl_3$/TMS), δ (ppm): 1.25 and 1.33 (s and s, $C(CH_3)_2$), 2.40 and 2.56 (s and s, 2 aryl-CH_3), 3.57 (q, O-CH_2), 6.98–7.35 (m, NH and 6 aromatic H), 7.54–7.88 (m, 2 aromatic H). Anal. calcd. for $C_{18}H_{23}B_2NO_3$: C 66.93, H 7.18, N 4.34; found: C 66.63, H 7.28, N 4.02.

7,8,8-Trimethyl-3,5-di(o-tolyl)-2,4,6-trioxa-1-azonia-3-bora-5-boratabicyclo[3.3.0]octane, ***2b***

3-(Hydroxyamino)-3-methyl-2-butanol, **1***b* (7) (0.24 g, 2 mmol), and *o*-tolylboronic acid (0.54 g, 4 mmol) are reacted as described for **2***a*, yielding 0.64 g (94%) of colorless crystals, mp 167–168°C (dec.). Infrared (KBr): 3100 (N—H), 1600 (aryl C═C) cm^{-1}; ^1H nmr (90 MHz, $CDCl_3$/TMS), δ (ppm): 1.07 and 1.36 (s and s, $C(CH_3)_2$), 1.26 (d, J = 6 Hz, O-C-CH_3), 2.42 and 2.57 (s and s, 2 aryl-CH_3), 3.95 (q, J = 6 Hz, CH-O), 6.58 (s, exchangeable, NH), 6.95–7.34 (m, 6 aromatic H), 7.61–7.86 (m, 2 aromatic H); ^{11}B nmr (64 MHz, $CDCl_3/Et_2OBF_3$), δ (ppm): 11.7 ($w_{1/2}$ = 214 Hz) and 30.7 ($w_{1/2}$ = 514 Hz); ratio of peak areas 1:1. Anal. calcd. for $C_{19}H_{25}B_2NO_3$: C 67.71, H 7.48, B 6.42, N 4.16; found: C 67.84, H 7.47, B 6.28, N 4.37.

7,7-Pentamethylene-3,5-di(o-tolyl)-2,4,6-trioxa-3-bora-5-boratabicyclo[3.3.0]octane, ***2c***

1-(Hydroxyaminomethyl)cyclohexanol, **1***c* (7) (0.30 g, 2 mmol), and *o*-tolylboronic acid (0.54 g, 4 mmol) are reacted as described for **2***a*, yielding 0.67 g (92%) of colorless crystals, mp 188–189°C. Infrared (KBr): 3050 (N—H), 1600 (aryl C═C) cm^{-1}; ^1H nmr (90 MHz, DMSO-d_6/TMS), δ (ppm): 1.1–1.9 (m, $(CH_2)_5$), 2.34 and 2.52 (s and s, 2 aryl-CH_3), 3.00 and 3.47 (q, AB-system, N-CH_2), 6.94–7.33 (m, 6 aromatic H), 7.51–7.70 (m, 2 aromatic H), 10.91 (d, J = 5 Hz, exchangeable, NH). Anal. calcd. for $C_{21}H_{27}B_2NO_3$: C 69.47, H 7.50, N 3.86; found: C 69.34, H 7.67, N 4.04.

2-Mesityl-5,5-dimethyl-1,3-dioxa-4-aza-2-boracyclohexane, ***3a***

2-(Hydroxyamino)-3-methyl-2-propanol, **1***a* (0.32 g, 3 mmol), and mesitylboronic acid (0.49 g, 3 mmol) are refluxed in 20 mL of benzene for 1 h using a Dean–Stark trap for continuous removal of water. After evaporation of the solvent in vacuo the oily residue is dissolved in a small quantity of petroleum ether and cooled down until crystallization yields 0.51 g (73%) of colorless crystals, mp 88°C. Infrared (KBr): 3160 (N—H), 1610 (aryl C═C) cm^{-1}; ^1H nmr (90 MHz, $CDCl_3$/TMS), δ (ppm): 1.29 (s, $C(CH_3)_2$), 2.24 (s, 2 aryl-*p*-CH_3), 2.39 (s, aryl-*o*-CH_3), 3.83 (s, O-CH_2), 5.43 (s, br, exchangeable, NH), 6.74 (s, 2 aromatic H). Anal. calcd. for $C_{13}H_{20}BNO_2$: C 66.98, H 8.65, B 4.64, N 6.01; found: C 67.05, H 8.80, B 4.54, N 6.15.

2-Mesityl-5,5,6-trimethyl-1,3-dioxa-4-aza-2-boracyclohexane, ***3b***

3-(Hydroxyamino)-3-methyl-2-butanol, **1***b* (0.36 g, 3 mmol), and mesitylboronic acid (0.49 g, 3 mmol) are reacted as described for **3***a*, yielding 0.51 g (69%) of colorless crystals, mp 54°C. Infrared (KBr): 3180 (N—H), 1610 (aryl C═C) cm^{-1}; ^1H nmr (90 MHz, $CDCl_3$/TMS), δ (ppm): 1.16 and 1.24 (s and s, $C(CH_3)_2$), 1.25 (d, J = 7 Hz, O-C-CH_3), 2.22 (s, aryl-*p*-CH_3), 2.38 (s, 2 aryl-*o*-CH_3), 4.10 (q, J = 7 Hz, O-CH), 5.40 (s, br, exchangeable, NH), 6.73 (s, 2 aromatic H). Anal. calcd. for $C_{14}H_{22}BNO_2$: C 68.04, H 8.97, N 5.67; found: C 68.08, H 8.97, N 5.72.

[a]Temperature 294 K, Rigaku AFC6S diffractometer, Mo-K_α (λ = 0.71069 Å) radiation, graphite monochromator, takeoff angle 6.0°, aperture 6.0 × 6.0 mm at a distance of 285 mm from the crystal, stationary background counts at each end of the scan (scan/background time ratio 2:1, up to 8 rescans), $\sigma^2(F^2) = [S^2(C + 4B) + (0.03F^2)^2]/Lp^2$ (S = scan rate, C = scan count, B = normalized background count), function minimized $\Sigma w(|F_o| - |F_c|)^2$ where $w = 4F_o^2/\sigma^2(F_o^2)$, $R = \Sigma||F_o| - |F_c||/\Sigma|F_o|$, $R_w = (\Sigma w(|F_o| - |F_c|)^2/\Sigma w|F_o^2|^2)^{1/2}$, and gof = $[\Sigma w(|F_o| - |F_c|)^2/(m - n)]^{1/2}$. Values given for R, R_w, and gof are based on those reflections with $I \geq 3\sigma(F^2)$.

2-Mesityl-6,6-pentamethylene-1,3-dioxa-4-aza-2-boracyclohexane, ***3c***

1-(Hydroxyaminomethyl)cyclohexanol, **1***c* (0.44 g, 3 mmol), and mesitylboronic acid (0.49 g, 3 mmol) are reacted as described for **3***a*, yielding 0.60 g (73%) of colorless crystals, mp 79–80°C. Infrared (KBr): 3290 (N—H), 1610 (aryl C═C) cm^{-1}; ^1H nmr (90 MHz, $CDCl_3$/TMS), δ (ppm): 1.23–1.97 (m, $(CH_2)_5$), 2.24 (s, aryl-*p*-CH_3), 2.36 (s, 2 aryl-*o*-CH_3), 3.16 (s, N-CH_2), 6.09 (s, br, exchangeable, NH), 6.47 (s, 2 aromatic H); ^{11}B nmr (64 MHz, $CDCl_3/Et_2OBF_3$), δ (ppm): 29.3 ($w_{1/2}$ = 280 Hz). Anal. calcd. for $C_{16}H_{24}BNO_2$: C 70.35, H 8.86, B 3.96, N 5.13; found: C 70.36, H 8.91, B 4.10, N 5.28. Crystals suitable for X-ray analysis were obtained by slow recrystallization from petroleum ether.

X-ray crystallographic analysis of ***3c***

Crystallographic data appear in Table 1. The final unit-cell parameters were obtained by least squares on the setting angles for 25 reflections with 2θ = 20.2–24.5°. The intensities of three standard reflections, measured every 200 reflections throughout the data collection, showed only small random fluctuations. The data were pro-

cessed,[4] and corrected for Lorentz and polarization effects and for absorption (empirical, based on azimuthal scans for three reflections).

The structure was solved by direct methods, the coordinates of the non-hydrogen atom being determined from an *E*-map or from subsequent difference Fourier syntheses. There are two crytallographically independent molecules in the asymmetric unit. The thermal parameters of the N-O moieties of the six-membered heterocyclic rings of both of the independent molecules suggested conformational disordering. Split-atom anisotropic models were employed for the atoms N(1), N(2), O(1), and O(3), the site occupancy factors being adjusted as the refinement progressed to result in approximately equal thermal parameters for the two components of each disordered atom. It is likely that the disorder extends beyond the modeled regions and therefore some of the derived geometrical parameters may be affected. The paucity of significant data along with probable separations of component atoms that are below the limits of resolution, however, preclude modeling of this probable extended disorder. Non-hydrogen atoms were refined with anisotropic thermal parameters. The hydrogen atoms were fixed in idealized positions (N—H/C—H distances normalized to 0.98 Å, $B_H = 1.2\ B_{\text{bonded atom}}$, least-squares fit to difference map positions for the methyl groups, N-H orientation based on difference map positions). A correction for secondary extinction was applied, the final value of the extinction coefficient being $8.1(3) \times 10^{-7}$. Neutral atom scattering factors for all atoms and anomalous dispersion corrections for the non-hydrogen atoms were taken from the *International Tables for X-Ray Crystallography* (8). Final atomic coordinates and equivalent isotropic thermal parameters, bond lengths, and bond angles appear in Tables 2–4, respectively. Stereoviews of the two independent **3***c* molecules are shown in Fig. 1, and the packing arrangement is shown in Fig. 2. Hydrogen atom parameters, anisotropic thermal

parameters, torsion angles, intermolecular contacts, least-squares planes, and measured and calculated structure factor amplitudes are included as supplementary material.[5]

Results and discussion

The structure analysis confirms the six-membered cycloboronate structure **3***c* for the product of the reaction of **1***a* with mesitylboronic acid. The spectroscopic data for compounds **3***a* and **3***b* indicate that these materials have structures analogous to that of **3***c*, and, to the best of our knowledge, represent the first *N*-unsubstituted 1,3-dioxa-4-aza-2-boracyclohexane derivatives to be reported. *N*-Substituted BONCCO ring systems of this type have been reported for the phenylboronates **9** (9), and, as a conformational variant, in the BONBON dimer of 4,6-dimethyl-2-phenyl-1,3-dioxa-4-aza-2-boracyclohexane (type **4**) (5). In the present case the formation of a dimeric associate **4** is probably impeded by steric effects associated with the *B*-mesityl group. The *o*-methyl groups would have substantial steric interactions with the cyclohexane moiety at C-6 (crystallographic numbering C(2) and C(18) for the two independent molecules, Fig. 1) as well as with the N-H hydrogen atom. A similar example of steric hindrance between mesityl *o*-methyl groups and the N-H hydrogen can be clearly seen in a model of a bicyclic pyroboronate with *B*-mesityl substituents (type **2**, Ar = 2,4,6-$(CH_3)_3C_6H_2$), and may be the reason that this type of compound is not formed. The steric hindrance is less restrictive with *B*-*o*-tolyl groups which do not prevent the formation of the generally favored pyroboronate **2**, as demonstrated by the examples **2***a–c*.

In the solid state structure of **3***c* (Fig. 2) the two independent molecules are connected in alternating linear chains extending along the *a* axis by intermolecular N—H···O hydrogen bonds (N(1)—H(1)···O(4)(1 + *x*, *y*, *z*), N(1A)—H(1A)···O(4)(1 + *x*, *y*, *z*), N(2)—H(25)···O(2), and N(2A)—H(25A)···O(2); H···O = 2.27, 2.09, 2.26, and 2.05 Å; N···O = 3.168(9), 3.021(11), 3.185(8), and 3.045(12) Å; N—H···O = 154, 171, 157, and 167°; respectively).

The six-membered BONCCO boronate rings in **3***c* have irregular, "semiplanar", C(1)/C(17) sofa conformations similar to the BONCCO ring systems in **9** (9), the BONCNO ring systems in **10** (4, 10), and to those in other six-membered cycloboronate rings (ref. 4, and references therein). In each of the two independent molecules, the disorder generates two different sofa conformations that have opposite chiralities at the asymmetric (presumably pyramidal) nitrogen atoms. This arrangement of the disordered portions of the rings allows for the formation of hydrogen bonds involving both disorder components, the hydrogen bonding parameters (above) actually being more favorable for the lower-occupancy moieties.

A partial double bond character of the O—B bonds resulting from O—B $pp(\pi)$ back-donation is in accord with the near planarity about the sp^2-hybridized boron atoms, as noted for many boronic acid esters. The bond angle sums at the trivalent boronate B atoms (357.8 and 357.6° (involving O(1) and O(3), respectively), 354.7 and 353.1° (involving O(1A) and O(3A), respectively)) suggest slight pyramidalization at B(1) and B(2), but it is highly probable that this is an artifact of the disorder. The differences between the two O—B bond lengths in each boronate moiety of **3***c*, 0.063(13) and 0.072(13) Å, are similar to those observed in the compounds of type **9** (9). The O—B bond from the alcoholate ligand is the shorter one in each case, probably as a consequence of a better $p(\pi)$ donor quality relative to that of the hydroxylamine ligand in **3***c* and the hydroxamate ligand in **9**.

The orientation of the mesityl rings with respect to the sp^2-boron coordination planes is roughly perpendicular, the angles between normals to the BO_2C and mesityl mean planes being 79.4 and 83.8° for the major, and 84.0 and 77.9° for the minor components at B(1) and B(2), respectively. The O-B-C-C torsion angles involving the ordered oxygen atoms O(2) and O(4) are all near 90° while those involving the disordered oxygen atoms (O(1), O(1A), O(3), and O(3A)) range from 57° to 75°. A similar, near perpendicular, orientation of the *B*-mesityl group has been found in the mesitylboronate **10***a* with a dihedral angle between normals to the aromatic ring and boron coordination mean planes of 87.2° (4). In a phosphorus analog of borazine with considerable aromatic character, $(MesBPC_6H_{11})_3$, the *B*-mesityl groups are also oriented perpendicular to the plane of the B_3P_3 ring (11). The steric hindrance that results from *ortho*-methyl groups presumably forces the aryl ring out of a resonance-favored coplanarity with the boronate ester group in these cases. The mean B—C(aryl) bond length in **3***c* (1.553 Å) does not differ significantly from that in the mesitylboronate **10***a* (1.560(2) Å) (4), and is slightly shorter than the mean B—C(aryl) bond length in $(MesBPC_6H_{11})_3$ (1.575(8) Å) (11).

The spiro-connected cyclohexane moieties at C(2) and C(18) in the two independent molecules of **3***c* have slightly distorted chair conformations with the boronate ester groups in equatorial

positions. This arrangement was noted for the related spiro compounds **9** (9).

The most obvious differences between the bond lengths of the *N*-unsubstituted and the *N*-acylated BONCCO rings of **3***c* and **9**, respectively, are those involving the nitrogen atoms. The N—O distance in **3***c* (mean 1.465 Å) is distinctly longer than those in **9***a* (1.401(1) Å) and **9***b* (1.402(3) Å). The intra-annular C—N bonds in **3***c* (mean 1.353 Å) appear to be considerably shorter than the corresponding bonds in **9***a* (1.448(2) Å) and **9***b* (1.440(4) Å) (9), but in this case imperfect modeling of the disorder (see Experimental) may be partially responsible even though some shortening is expected. The distances between the resolved, disordered, N and O atoms are almost certainly more realistic.

Unusual Weiss–Cook condensation of dimethyl 2,3-dioxobutanedioate and dimethyl 3-oxoglutarate[1]

GHISLAIN DESLONGCHAMPS,[2] DANIEL MINK, PAUL D. BOYLE, AND NINA SINGH
Department of Chemistry, University of New Brunswick, Fredericton, NB E3B 5A3, Canada

Received May 17, 1993

GHISLAIN DESLONGCHAMPS, DANIEL MINK, PAUL D. BOYLE, and NINA SINGH. Can. J. Chem. **72**, 1162 (1994).

The Weiss–Cook condensation of dimethyl 2,3-dioxobutanedioate with two equivalents of dimethyl 3-oxoglutarate in aqueous bicarbonate produces an "abnormal" product, pentamethyl *cis*-3-(carbomethoxymethyl)-3,7-dihydroxy-2-oxabicyclo-[3.3.0]oct-7-ene-1,4,5,6,8-pentacarboxylate **7**, whose structure has been determined by X-ray crystallography. Krapcho decarbomethoxylation (sodium chloride, aqueous dimethyl sulfoxide, 140°C) of this compound produces dimethyl *cis*-3,7-dioxobicyclo[3.3.0]octane-1,5-dicarboxylate **4** in quantitative yield. These results suggest that compound **7** may be the product of a kinetically controlled reaction pathway involving 4-hydroxypent-2-en-1-one intermediate **5**. Heating of **7** in dimethyl sulfoxide may have promoted thermodynamic equilibration to a Weiss–Cook product, which then decarbomethoxylated to produce **4**.

GHISLAIN DESLONGCHAMPS, DANIEL MINK, PAUL D. BOYLE et NINA SINGH. Can. J. Chem. **72**, 1162 (1994).

La condensation de Weiss–Cook du 2,3-dioxobutanedioate de diméthyle avec deux équivalents du 3-oxoglutarate de diméthyle effectuée dans une solution aqueuse de bicarbonate conduit à un produit «anormal», le *cis*-3-(carbométhoxyméthyl)-3,7-dihydroxy-2-oxabicyclo[3.3.0]oct-7-ène-1,4,5,6,8-pentacarboxylate de pentaméthyle, **7**, dont on a déterminé la structure par diffraction des rayons X. Soumis à une décarbométhoxylation de Krapcho (chlorure de sodium, diméthylsulfoxyde aqueux, 140°C), ce composé conduit au *cis*-3,7-dioxobicyclo[3.3.0]octane-1,5-dicarboxylate de diméthyle avec un rendement quantitatif. Ces résultats suggèrent que le composé **7** est probablement le produit d'une voie réactionnelle contrôlée d'une façon cinétique et impliquant la 4-hydroxypent-2-én-1-one **5** comme intermédiaire. Le chauffage du composé **7** dans le diméthylsulfoxyde a probablement provoqué un équilibre thermodynamique vers un produit de Weiss–Cook qui par une décarbométhoxylation conduit au produit **4**.

[Traduit par la Rédaction]

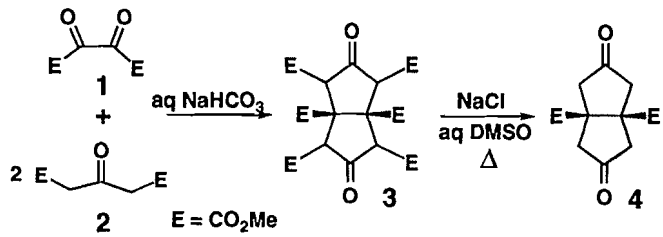
Introduction

The Weiss–Cook reaction, involving the condensation of two equivalents of 3-oxoglutarate with one equivalent of an α-dicarbonyl compound, has been widely used for the convergent synthesis of polyquinanes and polyquinenes (1). The general mechanism for this reaction is thought to involve a series of aldol condensations, dehydrations, and Michael reactions (2).

Our research group has been engaged in the design and synthesis of new abiotic receptors capable of selective binding of neutral organic targets via a tandem of complementary hydrogen-bonding and hydrophobic interactions. During preliminary work, a 1,5-difunctionalized 3,7-dioxobicyclo[3.3.0]-octane was sought that could be readily obtained via the Weiss–Cook reaction. In this paper, we wish to report an unusual Weiss–Cook condensation product between dimethyl 3-oxoglutarate **2** and dimethyl 2,3-dioxobutanedioate **1** and its conversion to the desired compound **4**.

Results and discussion

One of the starting materials for our receptor synthesis was dimethyl *cis*-3,7-dioxobicyclo[3.3.0]octane-1,5-dicarboxylate **4**. The synthesis of **4** has already been reported (3) and involves Weiss–Cook condensation (aqueous $NaHCO_3$) of one equivalent of α-dicarbonyl **1** with two equivalents of 3-oxoglutarate **2**, followed by Krapcho decarbomethoxylation (4) (NaCl, aqueous DMSO, 140°C) of the resulting hexaester **3** to produce bicyclic diester **4** (Scheme 1). Compound **1** was obtained by treating dihydroxytartrate with methanolic HCl.



SCHEME 1

In an attempt to optimize the procedure,[3] we sought to pinpoint which step gave the poorest yield.

Work-up of the Weiss–Cook reaction had produced a syrupy product containing a crystalline material and was assumed to contain condensation product **3**. Trituration of the crude product with ether, followed by filtration, enabled the isolation of a white crystalline material in 26.2% overall yield (from dihydroxytartrate), thought to be condensation product **3**. The mother liquor was shown to contain unreacted **2**. The other reaction products were presumably hydrophilic enough to be lost during the extractive work-up.

The UV spectrum of the crystals suggested the presence of an enolized β-ketoester (λ_{max} = 247, ϵ = 14 900). The ^1H nmr spectrum gave support for an enol proton (δ 10.66) but also showed six nonequivalent methyl ester singlets, an alcohol (δ 6.17), and an AB quartet centered at δ 3.12. The nmr spectrum could not be correlated to any of the possible tautomers of **3**. At this point it was believed that the crystals were simply a by-product of the Weiss–Cook reaction. In fact, X-ray crystallographic analysis showed that the crystalline condensation

[3]The reported yield for the overall conversion of dihydroxytartrate to **4** was only 18% and, in our hands, we could reproducibly increase this yield to only 26%.

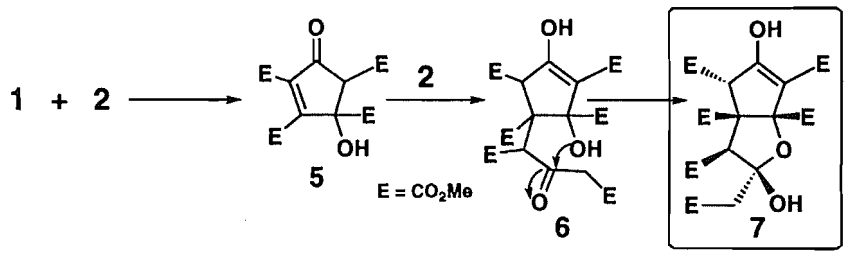
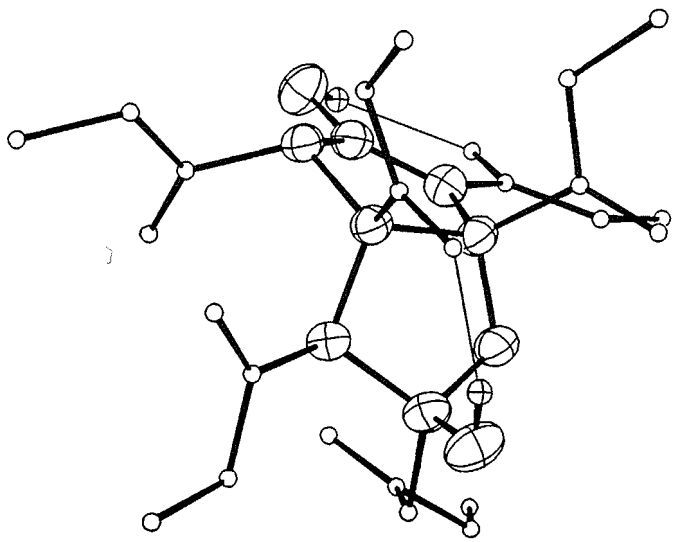


SCHEME 2



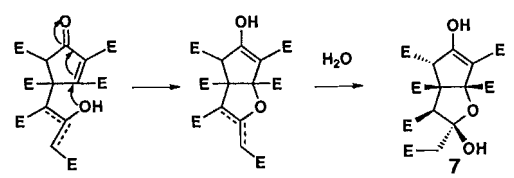
SCHEME 3. ORTEP diagram of compound **7**. Side-chain atoms are represented by spheres of arbitrarily small radii. Hydrogens attached to carbons were omitted for clarity.

product was not the anticipated compound **3** but, instead, compound **7** (Schemes 2 and 3).

This abnormal Weiss–Cook product would have most likely been produced via the intermediacy of the 4-hydroxycyclopent-2-en-1-one 1:1 adduct **5**. 4-Hydroxycyclopent-2-en-1-one derivatives have been suggested to be important intermediates in the Weiss–Cook condensation at both high and low pH (1*a*, 2*b*, 5). Michael addition of a second molecule of 3-oxoglutarate to intermediate **5** followed by intramolecular cyclization of the resulting 2:1 adduct **6** could have produced hemiketal **7**.

The isolation of compound **7** gives additional support to the reaction sequence proposed by Weiss and Cook (2*b*), which involved the formation of 4-hydroxycyclopent-2-en-1-ones as key intermediates. Interestingly, hemiketal **7** must arise from a different mechanism than that which generates the hemiketal in the 1:1 adduct of camphorquinone and 3-oxoglutarate (2*b*).[4,5]

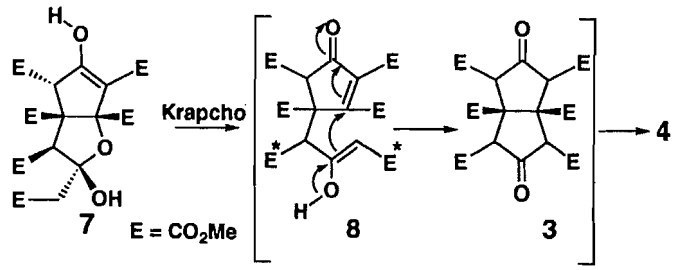
[4]An alternate mechanism can be proposed which involves O-alkylation by the enol during the final Michael addition (instead of C-alkylation). Although the O-alkylation can be rationalized based on stereoelectronic principles (6), this mechanism can be disregarded since it later necessitates hydration of the resulting enol ether, a step that is less likely to occur in bicarbonate solution.



Could "abnormal" Weiss–Cook product 7 be in fact the true precursor to diketone 4?

To test this hypothesis, compound **7** was subjected to Krapcho's decarbomethoxylation conditions (NaCl, aqueous DMSO, 140°C, 4 h), which resulted in diketone **4** being isolated in quantitative yield! Since the overall yield for the conversion of dihydroxytartrate to diketone **4** was 26%, this result indicated that virtually *all* of diketone **4** had been produced via the intermediacy of compound **7**.

One must then assume that, under the Krapcho decarbomethoxylation conditions, compound **7** somehow underwent ring opening and recyclization to generate a bicyclo[3.3.0]octane carbocycle (such as **3**), which would have subsequently decarbomethoxylated to produce **4** (Scheme 4). There are many plausible pathways to the formation of **4** from **7** and we are only illustrating the simplest one. We have been unable to isolate intermediates such as hexaesters **8** and **3** from the crude decarbomethoxylation mixture. It is worth noting that decarbomethoxylation of two of the methyl esters in an intermediate such as **8** (i.e., asterisks on **8**) could not have preceded the ring closure or else the cyclization would have involved Michael addition of an unactivated ketone, in bicarbonate solution.



SCHEME 4

Weiss–Cook condensations are generally carried out under equilibration conditions such that the thermodynamically favored C-alkylated adduct (as in **3**) is the product obtained. It is reasonable to assume that the cyclization of precursor **6** (Scheme 2) to form hemiketal **7** was kinetically preferred over the elimination of the tertiary hydroxyl that would have led to hexaester **3**. In our particular case, the tertiary hydroxyl in compound **6** presumably does not undergo elimination as readily as one might expect because of the presence of an electron-withdrawing ester at the ring junction[6] and because of developing steric repulsion between adjacent ester groups. Elimination of

[5]Although of a different type, another interesting case of abnormal Weiss–Cook condensation was recently reported (7).

[6]Varying the electron density on the β-carbon does not seem to hamper the Michael addition itself (8).

Can. J. Chem. Downloaded from www.nrcresearchpress.com by EESC ESCOLA DE ENGENHARIA on 09/08/12
For personal use only.

the tertiary hydroxyl group in **6** (instead of hemiketal formation) would have set up one final Michael addition to produce a "normal" Weiss–Cook carbocycle. Upon heating, hemiketal **7** could have readily undergone ring opening and elimination to revert to an acyclic precursor such as **8**, allowing proper channeling to a thermodynamically more stable compound (such as **3**) that cleanly produced diketone **4** upon decarbomethoxylation.

Our findings add strong support to the 4-hydroxycyclopent-2-en-1-one pathway of the Weiss–Cook condensation since compound **7** can be readily rationalized as the kinetic product obtained along this mechanistic route. The conversion of **7** into **4** can also be rationalized by a thermodynamic equilibration of **7** followed by decarbomethoxylation of the resulting bicyclo[3.3.0]octane carbocycle.

Experimental

The nmr spectra were recorded on a Varian Unity-400 spectrometer with $CDCl_3$ as solvent. High-resolution mass spectra (EI) were run on a Kratos MS50 mass spectrometer.

Abnormal Weiss–Cook adduct 6

The crude Weiss–Cook condensation mixture was prepared as described (3) using 100 g (0.44 mol) of disodium dihydroxytartrate. Trituration with ether and filtration afforded 56.5 g (26.2%) of compound **6** as white crystals: mp 175–177°C (from CH_3OH); uv (EtOH): λ_{max} = 247, ϵ = 14 900; ir ($CHCl_3$): 3600, 2960, 1755, 1690, 1455, 1350 cm^{-1}; ^1H nmr δ: 10.66 (br s, 1H), 6.17 (s, 1H), 5.09 (s, 1H), 4.69 (s, 1H), 3.85 (s, 3H), 3.731 (s, 3H), 3.726 (s, 3H), 3.71 (s, 3H), 3.70 (s, 3H), 3.53 (s, 3H), 3.18 (A of AB q, J = 15.4, 1H), 3.07 (B of AB q, J = 15.4, 1H), minor enolic form also visible at 10.5, 4.87, 3.65, 3.64, 3.61, and 3.59; ^{13}C nmr δ: 174.28, 171.07, 170.51, 169.22, 168.29, 167.95, 167.70, 106.09, 103.67, 94.06, 64.70, 55.65, 54.26, 53.32, 52.89, 52.66, 52.04, 51.92, 51.51, 41.67, minor enolic form also visible at 170.96, 168.17, 65.02, 54.64, 52.39, 51.73. Exact Mass calcd. for $C_{20}H_{24}O_{15}$ ($M^+ - H_2O$): 486.1009; found: 486.1084.

Dimethyl cis-3,7-dioxobicyclo[3.3.0]octane-1,5-dicarboxylate 4 from compound 7

A solution of **7** (56.5 g, 0.112 mol), NaCl (6.86 g, 0.118 mol), and water (25.2 mL) in DMSO (95 mL) was heated at 140°C for 4 h. After cooling to room temperature, water (150 mL) was added and the mixture was extracted with $CHCl_3$ (7 × 100 mL), washed with saturated $NaHCO_3$ solution (4 × 50 mL) and water (3 × 50 mL), and dried over Na_2SO_4. Evaporation of solvents afforded 30.0 g (quantitative) of diketone **4**, which crystallized upon standing.

X-ray crystallography of compound 7

The structural analysis of **7** was uneventful. Compound **7** shows interesting C-H···O hydrogen bonding. An in-depth analysis of this structure will be the subject of a forthcoming paper that will include a full complement of crystallographic details.[7]

Supplementary material available

400-MHz ^1H, ^{13}C, and HETCOR nmr spectra of compound **7** as well as crystallographic data have been deposited.[8]

Studies on the interaction of selenite and selenium with sulphur donors. Part 1. 2-Mercaptoethanol[1]

W. Amaratunga, O. Chaudry, and J. Milne[2]

Ottawa Carleton Chemistry Institute, Department of Chemistry, University of Ottawa, Ottawa, ON K1N 6N5, Canada

Received August 12, 1993

W. Amaratunga, O. Chaudry, and J. Milne. Can. J. Chem. **72**, 1165 (1994).

Raman spectroscopy and proton and ^{77}Se NMR have been used to show that selenous acid reacts with 2-mercaptoethanol (HOC_2H_4SH), according to Ganther's reaction (H.E. Ganther, Biochemistry, **7**, 2898 (1968)).

$$H_2SeO_3 + 4HOC_2H_4SH \rightarrow HOC_2H_4SSC_2H_4OH + HOC_2H_4SSeSC_2H_4OH + 3H_2O$$

The bis(hydroxyethylthio)selenide decomposes readily in strongly acidic and moderately basic solution to selenium and disulfide,

$$HOC_2H_4SSeSC_2H_4OH \rightarrow Se + HOC_2H_4SSC_2H_4OH$$

Selenium dissolves in excess hydroxyethylmercaptide to give the catenated anion, $HOC_2H_4SSe^-$

$$HOC_2H_4S^- + Se = HOC_2H_4SSe^-$$

Air oxidation of this equilibrium mixture yields disulfide and selenium. Formation of the hydroxyethylthioselenide is endothermic ($\Delta H = 0.66 \pm 0.02$ kJ mol^{-1}).

W. Amaratunga, O. Chaudry et J. Milne. Can. J. Chem. **72**, 1165 (1994).

On a utilisé la spectroscopie Raman el la rmn du proton et du ^{77}Se pour montrer que l'acide sélénieux réagit avec le 2-mercaptoéthanol ($HOCH_2.CH_2SH$) selon la réaction de Ganther (H.E. Ganther, Biochemistry, **7**, 2898 (1968)).

$$H_2SeO_3 + 4HOC_2H_4SH \rightarrow HOC_2H_4SSC_2H_4OH + HOC_2H_4SSeSC_2H_4OH + 3H_2O$$

Le bis(hydroxyéthylthio)séléniure se décompose facilement en milieu acide fort et en solution basique modérée pour donner du sélénium et du disulfure,

$$HOC_2H_4SSeSC_2H_4OH \rightarrow Se + HOC_2H_4SSC_2H_4OH$$

Le sélénium se dissout dans l'excès d'hydroxyéthylmercapture pour donner le caténo-anion, $HOC_2H_4SSe^-$

$$HOC_2H_4S^- + Se = HOC_2H_4SSe^-$$

Une oxydation à l'air de ce mélange à l'équilibre fournit le disulfure et du sélénium. La formation de l'hydroxyéthylthiosélénure est endothermique ($\Delta H = 0{,}66 \pm 0{,}02$ kJ mol^{-1}).

Introduction

Thiols react with selenous acid generally, according to reaction [1]

[1] $H_2SeO_3 + 4\ RSH \rightarrow RSSeSR + RSSR + 3H_2O$

Bis(alkythio)selenides exhibit variable stability depending upon pH and the concentration of any excess RSH present (2, 3). The decomposition reaction has been shown to yield elemental selenium and disulfide generally (1*b*),

[2] $RSSeSR \rightarrow RSSR + Se$

although exceptions have been reported (4, 5). Reactions [1] and [2] combined are the basis of a turbidimetric method of analysis for selenium, using 2-mercaptoethanol (3). Excess 2-mercaptoethanol was found to cause precipitated selenium to redissolve and this was attributed to the formation of a zero valent selenium complex with the ligand, having the formula $Se(HOC_2H_4SH)_6$.

Neither bis(hydroxyethylthio)selenide nor the zero valent selenium complex with 2-mercaptoethanol have been characterized and, as part of our continuing studies on Se(II) species (6), we initiated a study of the interaction of 2-mercaptoethanol and selenous acid.

Experimental

Selenium dioxide (Aldrich) was analyzed by potentiometric titration and found to be 91.3% SeO_2 (8.7% H_2O). The chemical was used directly, allowing for this analysis. 2-Mercaptoethanol (BDH) was analyzed iodometrically (7),

[3] $2HOC_2H_4SH + I_3^- \rightarrow HOC_2H_4SSC_2H_4OH + 2HI + I^-$

and found to be 98.8% pure in agreement with the proton NMR spectrum, which showed the presence of a trace of disulfide. Oxygen-free distilled water was used as a solvent for all reactions. Solutions of the disulphide for spectroscopic studies were prepared at ambient temper-

[1]This paper is dedicated to the memory of a valued colleague, Professor J.L. Roustan.

ature by reactions [3] as well as by using air oxidation of basic solutions of the thiol and hydrogen peroxide oxidation. Bis(hydroxyethylthio)selenide was prepared by multiple extraction of the insoluble yellow oil produced by reaction [1]. Disulfide is more soluble in water than bis(hydroxyethylthio)selenide and may be extracted using water adjusted to pH 5.0. In a typical preparation, 3.9 g of SeO_2 (0.036 mol) were dissolved in 10 mL distilled water and 10 mL of 2-mercaptoethanol (0.14 mol) were added dropwise with stirring and cooling. After a few minutes a yellow oil settled from the solution. The oil mixture of disulfide and bis(hydroxyethylthio)selenide of 9 mL volume, was extracted 15 times with 2.0 mL portions of dilute HCl (pH = 5.0) and then pumped free of water. Bis(hydroxyethylthio)selenide recovered (0.5 mL; 6% yield) was free of disulfide as shown by the absence of a proton signal at 2.5 ppm ($CDCl_3$). The product was found to be stable to laser light at 647.1 nm but subject to decomposition at basic pH, in the presence of excess thiol or in strongly acidic solutions. Similar findings regarding the stability of bis(thio)selenides have been reported previously (2, 3). Attempts to purify bis(hydroxyethylthio)-selenide by crystallization, distillation, and chromatographic methods failed.

Raman spectra were recorded, using a Jobin-Yvon Ramanor HG2 monochromator with a Princeton Applied Instruments photon counter. The spectra were excited with a Krypton ion laser operating at 647.1 nm. Slits were fixed at 1600 μ, giving a resolution of 6 cm^{-1} at 1000 cm^{-1}.

The ^{77}Se NMR spectra were recorded using a Bruker AMX 500 spectrometer, operating at 95.47 MHz, with a 90° tip angle and a 1 s pulse delay. Proton spectra were recorded on both Varian T60 and Gemini 200 machines. ^{13}C NMR spectra were recorded on the Gemini 200 machine. The chemical shifts for H_2O solutions were measured unlocked by sample replacement. Field drift was found to be within the accuracy of the quoted chemical shifts over the time span of the experiments. In the case of sample No. 10, Table 2, 10% D_2O by volume was added as lock and the H_2O signal at 4.8 ppm was suppressed. All sample concentrations were in the molar range. The proton chemical shifts are referred to TMS. The ^{77}Se chemical shifts are referenced to pure dimethyl selenium via an external secondary standard of saturated H_2SeO_3 in H_2O (8). The reference for ^{13}C NMR was internal tetramethylsilane. The mass spectrum was measured with VG 7070E spectrometer. Equilibrium constants were determined by gravimetry.

Results and discussion

Bis(hydroxyethylthio)selenide formation

Raman spectroscopy

The Raman spectra of 2-mercaptoethanol, the bis(hydroxyethylthio)selenide, the disulfide formed by oxidation of mercaptoethanol, and the products of the reaction of a 4:1 2-mercaptoethanol/selenous acid mixture are given in Fig. 1 and the observed frequencies up to 1000 cm^{-1} are given in Table 1. The strongest band observed for 2-mercaptoethanol is the CS stretching mode at 662 cm^{-1}. This band shifts to lower frequency by 20 cm^{-1} on oxidation to the disulphide (reaction [3]) and a stronger band appears at 512 cm^{-1}. The frequency and intensity of this peak supports its assignment to the SS stretching mode. The SS stretching frequency for S_2Cl_2 and S_2Br_2 appear at 540 and 529 cm^{-1}, respectively (9). The insoluble yellow oil produced from a 4:1 2-mercaptoethanol/selenous acid mixture in water gives a Raman spectrum consistent with the reaction.

$$[4]\quad H_2SeO_3 + 4HOC_2H_4SH \rightarrow HOC_2H_4SSC_2H_4OH + HOC_2H_4SSeSC_2H_4OH + 3H_2O$$

The spectrum has three characteristic bands at 512, 642, 820 cm^{-1} due to disulfide and seven bands due to bis(hydroxyethylthio)selenide, the most characteristic of which is the symmetric stretching mode of the —SSeS— moiety in the molecule, arising at 399 cm^{-1}. The spectrum of pure bis(hydroxyethylthio)selenide exhibits this strong band at 399 cm^{-1} and the sum of the spectra of the disulfide and the selenide accounts for all the bands in the 4:1 HOC_2H_4SH/H_2SeO_3 mixture. No evidence for the formation of thiosulfonate, as observed for some sterically hindered thiols (4), was found. The assignments of the observed peaks to the two species formed in the mixture is given in Table 1. The nearest analogous structural unit to that of the angular —SSeS— moiety for which Raman spectra are reported is the $SeCl_2$ molecule (10). In this case the symmetric and asymmetric stretching modes are found at 412 and 381 cm^{-1}, which supports the assignment of these modes at 399 and 373 cm^{-1} in the bis(hydroxyethylthio)selenide.

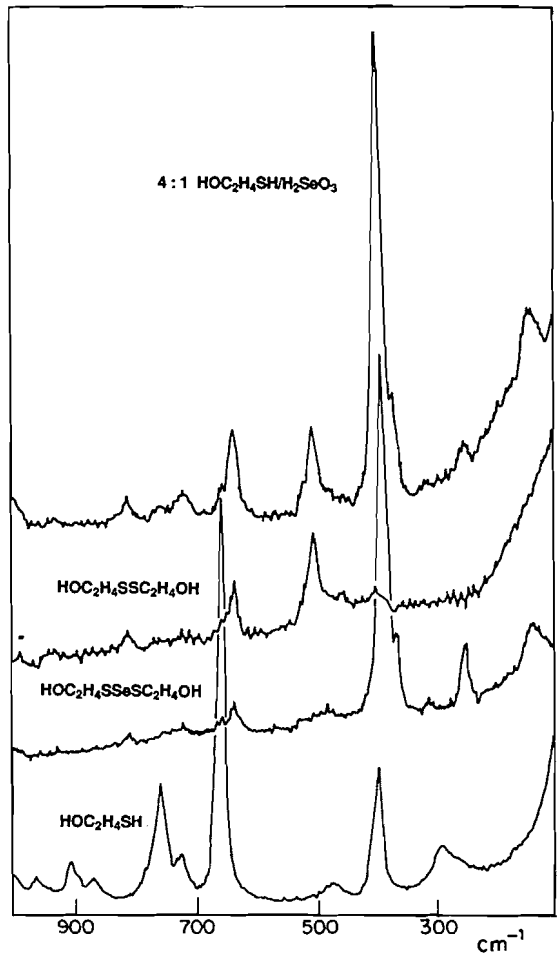

FIG. 1. Raman spectra of HOC_2H_4SH, $HOC_2H_4SSeSC_2H_4OH$, $HOC_2H_4SSC_2H_4OH$ and 4:1 molar ratio aqueous HOC_2H_4SH/H_2SeO_3.

The pale yellow aqueous supernatant in the 4:1 2-mercaptoethanol/selenous acid mixture also exhibited the 642, 512, and 399 cm^{-1} bands showing the presence of the —SS— and —SSeS— species. However, the SSeS band at 399 cm^{-1} was only three times the intensity of the SS stretching band, compared to six times, in the spectrum of the oil, indicating that the —SSeS— species was relatively more soluble in the oil than in the aqueous phase.

[f]Insoluble yellow oil layer from 4:1 HOC_2H_4SH/H_2SeO_3 mixture.

exhibits a five line group of peaks clustered around mass 234, which is the mass of the selenide with ^{80}Se, the most abundant isotope. The five lines are the highest mass lines in the spectrum and have, in increasing order of mass, the intensities 8.5(230), 6(231), 21(232), 42.5(234), and 10(236) (mass numbers in parentheses). This is the order of intensity expected for the masses of the selenides formed with the distribution of isotopes in natural abundance. In addition, strong peaks are observed for the fragments: C_2H_3 (27/35); CH_2OH (31/50); CHS (45/100); C_2H_3S (59/74); SC_2H_4OH (77/20); CSe (92/21); SeS (112/18); $(HOC_2H_4)_2S$ (154/13); $(CH_2S)_2Se$ (172/30).

NMR spectroscopy

The proton chemical shifts and coupling constants for HOC_2H_4SH, $HOC_2H_4S^-$, $HOC_2H_4SSC_2H_4OH$, $HOC_2H_4SSeSC_2H_4OH$, and $HOC_2H_4SSe^-$ are given in Table 2. The proton NMR spectrum of pure mercaptoethanol (Sample No. 1) consists of four signals, in order of increasing shielding, 4.90

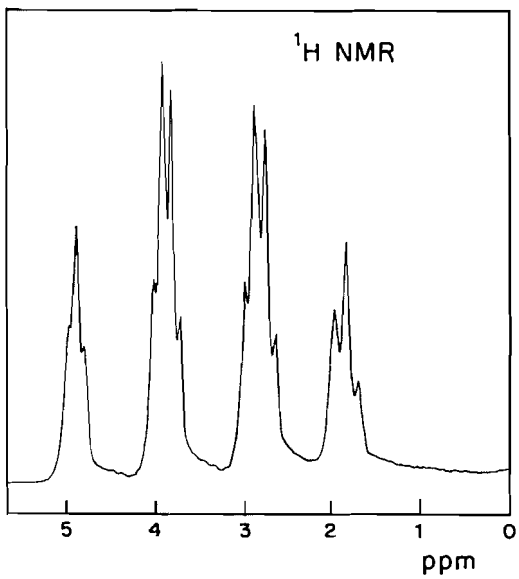

FIG. 2. Proton NMR spectrum of neat HOC_2H_4SH.

(H on O), 3.93 (H on C bound to O), 2.87 (H on C bound to S), and 1.89 (H on S) with relative intensities of 1:2:2:1 respectively, as shown in Fig. 2. Only three-bond couplings are apparent in the spectrum with the hydrogen on carbon signals, appearing as overlapped triplets, which resemble quartets. The chemical shifts for hydrogen on carbon and hydrogen on sulfur as well as the coupling constant for the two types of protons on carbon are similar for 2-mercaptoethanol in aqueous solution but coupling with protons on O and S is eliminated due to exchange of these protons with solvent. The spectrum of 2-mercaptoethanol dissolved in $CDCl_3$ shows hydrogen on carbon and hydrogen on sulfur resonances all slightly more shielded than for the aqueous solutions but the hydrogen on oxygen resonance moves 2 ppm upfield with the breakdown, in $CDCl_3$, of the relatively strong hydrogen bonding of H_2O and HOC_2H_4SH.

Deprotonation of 2-mercaptoethanol gives the mercaptide ion, $HOC_2H_4S^-$ ($pK_a(HOC_2H_4SH)$ = 9.61 (11)). The NMR spectrum exhibits no characteristic hydrogen on sulfur resonance and the hydrogen on carbon signals (1:1 relative intensities) are more shielded than in the parent acid, due to greater negative charge on these protons. The proton NMR spectrum of solutions of 2-mercaptoethanol oxidized with SeO_2 (weakly basic conditions), I_3^- and H_2O_2 with oxidant/HOC_2H_4SH stoichiometries of 1:4, 1:2, and 1:2 respectively, do not show a signal, corresponding to hydrogen bound to sulfur and oxidation to the disulfide is complete via reactions [3], [5], and [6].

[5] $H_2O_2 + 2HOC_2H_4SH \rightarrow HOC_2H_4SSC_2H_4OH = 2H_20$

[6] $H_2SeO_3 + 4HOC_2H_4SH \rightarrow 2HOC_2H_4SSC_2H_4OH + Se + 3H_2O$

Reaction [6] is the basis of a turbidimetric analysis for selenium(IV) (3). The hydrogen on carbon chemical shifts of the disulfide (1:1 relative intensities) are less shielded than those of HOC_2H_4SH and $HOC_2H_4S^-$, reflecting the greater degree of oxidation of the system.

Under weakly acid conditions (pH < 7), 4:1 mixtures of 2-mercaptoethanol and selenous acid do not yield elemental selenium (reaction [6]) but proceed according to reaction [4]. At the concentrations used in this work aqueous and oil layers were formed and the proton NMR spectra of both layers showed four triplets, two of which correspond, in chemical shifts and J_{23} coupling constant, to the spectrum of the disulfide and the remaining two of which must be due to the bis(hydroxyethylthio)selenide, as shown in Table 2. The relative intensities of the disulfide and selenide signals in the aqueous layer show that the disulfide is more soluble in water than the selenide and this is the basis of the method isolation of the selenide. The hydrogens on carbon next to sulfur bound to selenium are deshielded with respect to the comparable hydrogens of other species studied in the same solvent, by the presence of selenium bound to sulphur, which is the reverse of what might be expected, if Se is considered to be more metallic than S.

The ^{77}Se NMR spectrum of bis(hydroxyethylthio)selenide in acetone exhibits a chemical shift of 691.1 ppm. In the oil, which is a mixture of selenide and sulfide, containing a small amount of water, the shift is 690.5 ppm and in aqueous 4:1 HOC_2H_4SH/H_2SeO_3 solutions, 684.5 ppm. All signals are narrow ($w_{1/2} \sim$ 0.5 ppm.) These peaks lie at the high end of the chemical shift range for RSSeSR species (2). No coupling to the methylene protons was observed. The ^{13}C NMR spectrum of the bis(thio)selenide dissolved in chloroform exhibits only two peaks at δ = 41.2 ppm (carbon bound to sulfur) and 60.5 ppm (carbon bound to oxygen). No ^{77}Se–^{13}C coupling was observed probably because ^2J(SeC) is small compared to the baseline width of the 41.2 ppm line (30 Hz) and low relative intensity of the expected doublet. Two bond coupling in the CCSe chain of alkyl selenides is of the order of 12 Hz (12) and, if coupling over the CSSe chain were comparable, it would not be observed.

According to ^{77}Se NMR, the addition of base to solutions of the bis(hydroxyethylthio)selenide results in complete decomposition to selenium and disulfide.

[7] $HOC_2H_4SSeSC_2H_4OH \rightarrow HOC_2H_4SSC_2H_4OH + Se$

Excess base causes disproportionation of Se, according to

[8] $(2n + 1)Se + 6OH- = 2Se_n^{2-} + SeO_3^{2-} + 3H_2O$

The ^{77}Se NMR spectrum of a 4:1 $Na[HOC_2H_4S]/H_2SeO_3$ solution ($c(Na[HOC_2H_4S]$ = 2.83 M) shows signals at 1273 and –461 ppm due to the presence of SeO_3^{2-} ($\delta(Me_2Se)$ = 1272.6 ppm (8)) and Se^{2-} ($\delta(Me_2Se)$ = –435 ppm in ethylenediamine (13)). No signals due to polyselenides were observed in this solution and further work will be required to clarify the exact stoichiometry of this reaction.

Hydroxyethylthioselenide ion, $HOC_2H_4SSe^-$

The dissolution of elemental selenium in a solution of hydroxyethylmercaptide produces a deep brown coloured solution. The colour has been attributed to the formation of a zero valent selenium complex of the type $Se(HOC_2H_4SH)_6$ (3). It is also possible that disproportionation, according to reaction [8], could be the cause of the Se solubility and colour formation but reaction [8] only becomes extensive at hydroxide ion concentrations above 1 M (14). Hydroxide ion concentrations in these experiments and in previous work (3) did not exceed 0.01 M. In view of the tendency of chalcogen species to catenate, a likely cause of the selenium solubility in mercaptide solutions is the reaction,

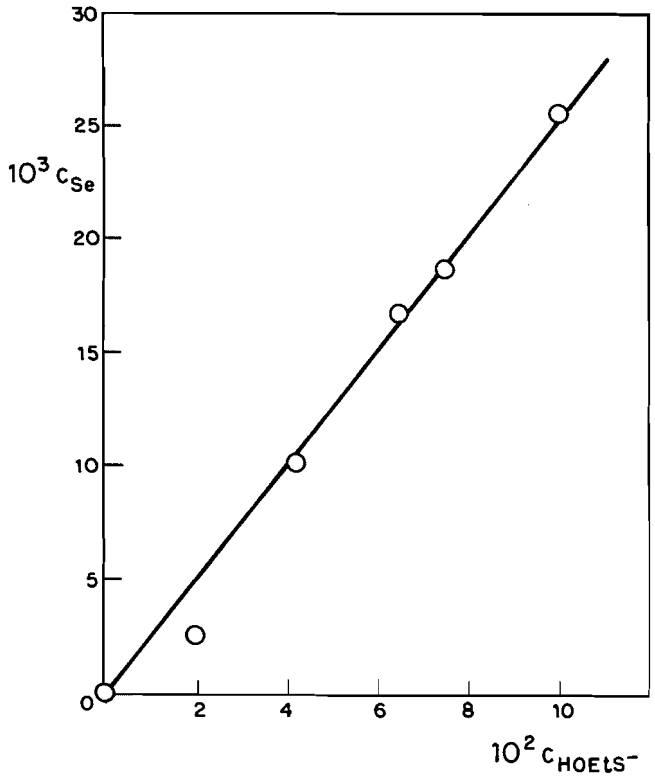

FIG. 3. Selenium solubility, c_{Se}, dependence on mercaptide concentration, $c(HOC_2H_4S^-)$, at 23°C.

[9] $Se + HOC_2H_4S^- = HOC_2H_4SSe^-$

A plot of mercaptide concentration, $c(HOC_2H_4S^-)$, against selenium solubility, c(Se), at 25°C, shown in Fig. 3, shows a linear dependance, which excludes $Se(HOEtSH)_6$ as a possibility and supports solubility due to equilibrium [9]. The lowest mercaptide concentration point shows a low value of c(Se) due to the susceptibility of the basic mercaptide solutions to air oxidation. The formation constant for equilibrium [9] is found to be 0.33 ± 0.06 at 23°C.

The Raman spectra of aqueous solutions of 1.0 M $Na[SC_2H_4OH]$ before and after saturation with selenium are listed in Table 3. After saturation with selenium the pH of the solution was 9.68. Calculation from the K_a for HOC_2H_4SH and K for equilibrium [9] shows that the concentrations of HOC_2H_4SH, $HOC_2H_4S^-$, and $HOC_2H_4SSe^-$ are respectively 0.39, 0.47, and 0.14 M. From these estimated concentrations, the Raman peaks have been assigned to the various species present, as given in Table 3. The SeS stretching mode for the $HOC_2H_4SSe^-$ anion, which is expected to be one of the most intense bands in the spectrum, in spite of the low relative concentration, appears at 382 cm^{-1}.

The proton NMR spectrum of a 2.0 M $Na[SC_2H_4OH]$ solution saturated with elemental selenium shows, in addition to the equal intensity triplets of the $HOC_2H_4S^-$ ion, two additional broad signals ($w_{1/2}$ = 18 Hz) of equal intensity, due to the selenium containing anion. No coupling between the different protons on carbon is observed for this species, which may be a result of restricted rotation about the C—C bond due to a steric effect of the attached Se. As in the case of bis(hydroxyethylthio)selenide, the hydrogens on carbon are deshielded, compared to the disulfide, by the attachment of Se to S. The ^{77}Se NMR spectrum of a 1.0 M $Na[SC_2H_4OH]$ solution saturated with selenium consists of a broad signal at 243 ppm ($w_{1/2}$ = 30 ppm), indicating that moderately fast Se exchange is occurring in these solutions, and a very weak peak at 1297 ppm ($w_{1/2}$ = 3 ppm) due to selenite (8). Relative concentrations of these species, estimated from peak intensities, are 300:1 $HOC_2H_4SSe^-$/Se(IV). The selenite arises from a small amount of selenium disproportionation, according to equilibrium [8]. No peaks for any Se_n^{2-} species (13) were observed in the spectrum and this is probably due to a combination of their weakness and breadth. The $HOC_2H_4SSe^-$ anion is probably undergoing exchange with these polyselenide species and this accounts for the breadth of the $HOC_2H_4SSe^-$ signal.

TABLE 3. Raman spectra of 1.0 M $Na[SC_2H_4OH]$ before and after saturation with elemental selenium

TABLE 4. Variation of K for equilibrium [9] with temperature

T (K)[a]	K
288.0	0.208
293.0	0.278
296.0	0.333
300.0	0.431
303.0	0.536

[a]Temperature control, ±0.2°C.

The solubility of selenium in $HOC_2H_4S^-$ solutions increases with temperature, as shown in Table 4. A plot of ln K vs. $1/T$ yields $\Delta H = 0.66 \pm 0.02$ kJ mol^{-1}, $\Delta S = -7 \pm 1$ J mol^{-1} deg^{-1}, $\Delta G = 2.8 \pm 0.4$ kJ mol^{-1}. The formation of the SeS bond in these solutions is endothermic and the negative entropy change is consistent with the loss in translational degrees of freedom with formation of the $HOC_2H_4SSe^-$ ion.

Mercaptide solutions are subject to slow oxidation (15). The addition of elemental selenium to the solutions accelerates the process. No signals due to the disulfide were detected in the proton NMR spectrum of a 0.10 M $Na[SC_2H_4OH]$ solution after bubbling oxygen for 15 min. However, such a solution saturated with elemental selenium gave a detectable amount of red selenium after bubbling oxygen for 15 min. The oxidation product was identified by NMR as the disulfide.

[10] $2H_2O + 4HOC_2H_4SSe^- + O_2 \rightarrow 2HOC_2H_4SSC_2H_4OH + 4Se + 4OH^-$

Selenium apparently catalyses the oxidation to disulfide. The selenite ion has also been shown to act as a catalyst in the oxidation of thiols to disulfides (16). In view of the ease of reduction of Se(IV) to elemental selenium in basic thiol solution, it is possible that Se is the actual catalyst in this process also.

Conclusion

Selenous acid or selenite are readily reduced by thiols. In moderately acid solution 2-mercaptoethanol reacts quantitatively with Se(IV) to give bis(hydroxyethylthio)selenide and the corresponding disulfide. Bis(hydroxyethylthio)selenide decomposes in strongly acidic and moderately basic solutions (pH > 7) to elemental selenium and disulfide (1*b*, 3). No evidence for disporportionation of the bis(hydroxyethylthio)-selenide to selenite and selenium (and mercaptide) as has been suggested for protein bis(thio)selenides (5) has been found. Excess mercaptide dissolves the selenium formed in the decomposition of the bis(thio)selenide to yield $HOC_2H_4SSe^-$ ion. Solutions of this ion are oxidized by oxygen to give selenium and disulfide. Selenium acts as a catalyst for the oxidation of $OC_2H_4S^-$ to the disulfide.

4-CF_3—C_6H_4—CN_3S_2, **1**, forms symmetrical sulfur-bound adducts with norbornene (NBE), norbornadiene (NBD), and 1-heptene (C_7H_{14}), which were studied by ^1H, ^{13}C, COSY-45, and HETCORR NMR. **1**·NBE exists in solution in a single isomeric form which corresponds to that found in the solid state for 4-CH_3O—C_6H_4—CN_3S_2·NBE by single-crystal X-ray diffraction: orthorhombic, $P2_12_12_1$ with $Z = 4$, $a = 10.224(3)$, $b = 10.369(5)$, $c = 14.075(5)$. $R = 0.0475$ and $R_w = 0.0492$ for 634 data. **1**·NBD exists in solution in two isomeric forms which are not interchangeable. One of these corresponds to that found in the NBE adduct, i.e. *exo* addition; the other is the first example of *endo* addition. Two *bis* adducts of stoichiometry NBD·**21** have been prepared and separated. They are isomers exhibiting *exo-exo* and *exo-endo* addition. The structure of the latter was confirmed by X-ray diffraction: orthorhombic, *Pcab* with $Z = 8$, $a = 7.816(2)$, $b = 17.264(3)$, $c = 36.842(5)$. $R = 0.068$ and $R_w = 0.106$ for 1506 data. **1**·C_7H_{14} exists as a mixture of *syn* and *anti* isomers. NMR structure parameters derived here have been applied to published data on over 15 thiazene NBE and NBD adducts.

Le 4-CF_3—C_6H_4—CN_3S_2 (**1**) réagit avec le norbornène (NBE), le norbornadiène (NBD) et le hept-1-ène (C_7H_{14}) pour donner des adduits symétriques liés par le soufre; on a étudié ces adduits par rmn ^1H, ^{13}C, COSY-45 et HETCORR. En solution, l'adduit **1**·NBE existe sous la forme d'un seul isomère qui correspond à celui trouvé pour l'état solide, par diffraction des rayons x sur un cristal unique du 4-CH_3O—C_6H_4—CN_3S_2·NBE: cristaux orthorhombiques, groupe d'espace $P2_12_12_1$, avec a = 10,224(3), b = 10,369(5) et c = 14,075(5), $Z = 4$ et R = 0,0474 et R_w = 0,0492 pour 634 réflexions. En solution, l'adduit **1**·NBD existe sous deux formes isomères qui ne sous pas interchangeables. L'une d'elles correspond à celle observée pour l'adduit avec le NBE, à savoir une addition *exo*; l'autre est le premier exemple d'une addition *endo*. On a préparé et séparé les deux bis-adduits de stoechiométrie NBD·**21**. Ce sont des isomères correspondant à des additions *exo-exo* et *exo-endo*. On a confirmé la structure du dernier par diffraction des rayons x: cristaux orthorhombiques, groupe d'espace *Pcab*, avec a = 7,816(2), b = 17,264(3) et c = 36,842(5), $Z = 8$ et R = 0,068 et R_w = 0,106 pour 1506 réflexions. L'adduit **1**·C_7H_{14} existe sous la forme d'un mélange des isomères *syn* et *anti*. On a appliqué les paramètres de structure rmn obtenus avec ces composés à quinze adduits thiazène–NBE ou –NBD.

Introduction

The study of inorganic heterocycles containing conjugated —S—N— units has been greatly assisted by their ability to form, sometimes reversibly, adducts with alkenes (1–13). These have commonly been olefins which are activated by reason of ring strain, of which the most used has been norbornadiene (NBD), although there are a few examples where norbornene (NBE) (12) or dicyclopentadiene (9, 13) have been employed. The resulting adducts facilitate the chemical analysis of unstable rings and ring fragments, are often highly crystalline and allow X-ray structure determination of the parent ring system, sometimes before the parent rings are structurally characterized (1). For certain rings, for example salts of $S_3N_3^+$ (12), only the adducts have been characterized. Mass spectra of alkene adducts usually only show molecular peaks for the components.

Compared to other thiazene compounds, 1,3,2,4,6-dithiatriazines form particularly strong adducts with alkenes, making them especially suitable for a study of alkene addition. These additions are probably similar to 1,3-dipolar cycloaddition reactions (14). The high affinity of dithiatriazines for alkenes can be attributed to the strongly anti-aromatic 8π electronic structure of the parent ring system (2, 15). In the case of the directly-bound trifluoromethyl dithiatriazine, $CF_3CN_3S_2$, even unactivated olefins such as ethene and butenes form stable cycloadducts (13) (Scheme 1).

NMR spectroscopy of the alkene adducts is usually possible, and over the years a large amount of NMR data on such systems has been published (see Table 4). However, the assignments of the published NMR spectra have often been in error. These errors are easily corrected by the use of 2-D NMR, in particular ^1H-^1H COSY and ^1H-^{13}C HETCORR methods.

In the course of our study of aryl dithiatriazines we noted indications of isomers in the NMR spectra of their NBD adducts, and therefore chose to use NBE to derivatize them (16). Only single solution species were observed for the NBE adducts by NMR. In this paper we report on a detailed investigation of the alkene adducts of aryl dithiatriazines, focusing on 4-$CF_3C_6H_4CN_3S_2$, **1** (Scheme 1), a choice determined by the

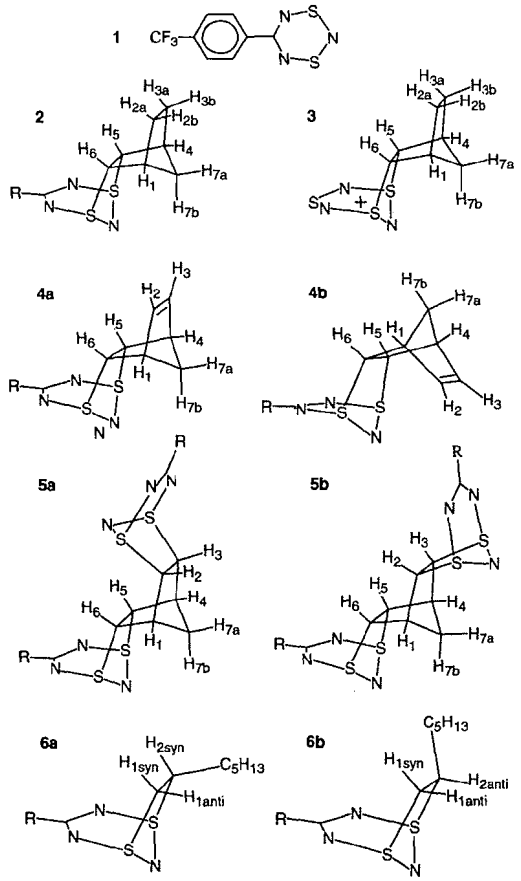
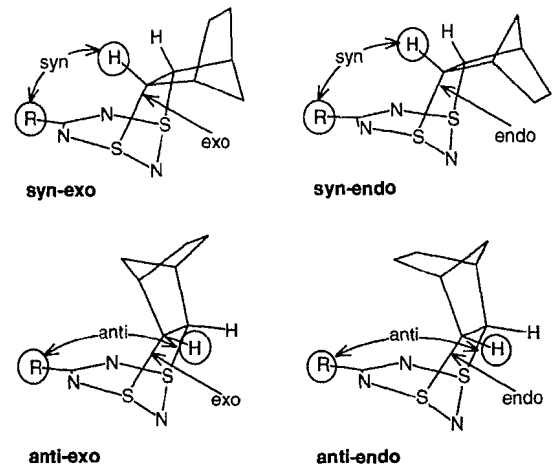


SCHEME 1. Structures of **1–6** as calculated on the model compounds with R = H by the MNDO method. The labeling of the H atoms is shown as they are used in the discussion of the NMR spectra and in Tables 4–6.

suitable solubility properties of its adducts. Using 2-D NMR we have made reliable assignments of the ^1H and ^{13}C spectra of their NBD and NBE adducts (**4** and **2**, respectively). We also provide an assignment of the previously unpublished ^1H NMR spectrum of the closely related $[S_3N_3{\cdot}NBE]^+$ adduct, **3** (12). Adducts **4** exist in two isomeric forms, which are not interchangeable in solution. There are four possible structures for such adducts which are consistent with the chemical shifts and symmetry of the NMR spectra, and with known crystallographic structures for related complexes. These possibilities are shown in Scheme 2. The NMR data we report here allow us to assign the two observed isomers conclusively to the *syn-exo* and *syn-endo* geometries. These assignments have been corroborated by MNDO calculations on model compounds.

In view of the relatively high thermal stability of NBD adducts of dithiatriazines, we speculated on the possibility of *bis* addition using both the double bonds in a single NBD molecule. We report here that such adducts can indeed be prepared, and that they also exist in two isomeric forms, which can be isolated and separated. The isomers have been shown to contain *exo-endo* (**5***a*) and *exo-exo* (**5***b*) addition modes by 2-D NMR methods. The identity of the *exo-endo* isomer has been confirmed by a single-crystal X-ray structure determination. We have also demonstrated that **1** forms stable adducts with the unactivated olefin 1-heptene in two isomeric forms **6***a* and **6***b*. The isomers have been conclusively identified from their NMR spectra.



SCHEME 2. The four possible geometries of norbornane–dithiatriazine attachment which are consistent with the observed plane of symmetry in the adducts. The nomenclature used to describe the isomers is defined here.

Experimental section

Starting materials and general procedures

1 and **2** were prepared as reported previously (16). The $AlCl_4^-$ salt of **3** was prepared by the literature method (12). 1,5-Norbornadiene, norbornene, and 1-heptene (Aldrich) were obtained commercially and used as received. $AlCl_3$ (Aldrich) was vacuum sublimed before use and handled in a glove box. CH_3CN was double-distilled from P_2O_5 and CaH_2. SO_2 (Matheson) was stored over molecular sieves (4 Å) in a glass bulb fitted with a Rotaflo stopcock. Unless otherwise indicated, all procedures were performed under an atmosphere of purified N_2 using a dry-box, Schlenk-ware, and vacuum-line techniques. Infrared spectra were recorded on a Bomem MB102 Fourier transform spectrometer as Nujol mulls between CsI plates and are reported in the 1600–200 cm^{-1} region only, unless otherwise indicated. NMR spectra were recorded on a Bruker AC-F 250 MHz FT spectrometer. Mass spectra were recorded by the Mass Spectrometry Centre, University of Alberta. Elemental analyses were performed by MHW Laboratories, Phoenix, Az.

Preparation of 4-$CF_3C_6H_4CN_3S_2{\cdot}C_7H_8$, 4

To a suspension of **1** (0.21 g, 0.80 mmol) in 3 mL CH_3CN was added 2.0 mL (excess) 1,5-norbornadiene. After several hours stirring, the brown colour faded to give a clear solution. Removal of solvent *in vacuo* followed by recrystallization from a minimum volume of hot CH_3CN and cooling to 0°C gave colourless plates, mp 179–181°C. Yield 0.15 g (0.42 mmol, 53%). Anal. calcd. for $C_{15}H_{12}F_3N_3S_2$: C 50.69, H 3.40, N 11.82, S 18.04; found: C 50.57, H 3.67, N 11.91, S 18.18. IR (1600–250 cm^{-1} region) 1514 (w), 1427 (s), 1319 (s), 1261 (w), 1161 (m), 1124 (m), 1099 (m), 1064 (m), 1016 (m), 983 (w), 923 (w), 868 (m), 856 (m), 787 (m), 763 (m), 702 (m), 678 (m), 657 (w), 592 (w), 551 (m), 536 (s), 480 (s), 462 (s), 426 (m), 384 (m), 368 (w), 282 (m). Mass spectrum, *m/z* 355 ($CF_3C_6H_4CN_3S_2{\cdot}C_7H_8^+$, 3%), 336 ($CF_2C_6H_4CN_3S_2{\cdot}C_7H_8^+$, 2%), 263 ($CF_3C_6H_4CN_3S_2^+$, 100%), 249 ($CF_3C_6H_4CN_2S_2^+$, 3%), 217 ($CF_3C_6H_4CN_2S^+$, 35%), 171 ($CF_3C_6H_4CN^+$, 6%), 152 ($CF_2C_6H_4CN^+$, 10%), 91 ($C_7H_7^+$, 25%).

Preparation of (4-$CF_3C_6H_4CN_3S_2)_2{\cdot}C_7H_8$, 5

In a typical reaction, 0.450 g (1.71) mmol of **1** was suspended in 15 mL of CH_3CN, and 92.3 μL (0.855 mmol) of 1,5-norbornadiene was added by micropipette. The reaction was heated to 63°C in an oil bath for 4 h, until all the brown starting material had been consumed. The resulting solution was yellow–brown in colour, and usually contained a small amount of colourless solids. The solution was filtered hot. The solid collected from the hot filtration was rinsed with cold CH_3CN and dried *in vacuo* to give 0.07 g (0.15 mmol, 13% yield) of **5***a*. On cooling

NMR studies

NMR samples were prepared in 5 mm tubes using $CDCl_3$ as the solvent (except for **3**). The $AlCl_4^-$ salt of **3**, which is quite insoluble in common NMR solvents, was dissolved in SO_2 in a tube insert constructed of 4 mm Pyrex tubing, which was sealed under vacuum. This 4 mm tube was fitted into a round-bottom 5 mm NMR tube, and the small remaining space was filled with C_6D_6 which acted as a lock for the NMR spectrometer. The top of the nmr tube was sealed against the walls of the insert with a small amount of Teflon plumbers tape. With this sample we were able to obtain standard COSY-45 and HETCORR spectra using the automated software included with the Bruker spectrometer.

Crystal structure determinations

The crystal structures of **2***b* (at Calgary) and **5***a* (at Arkansas) were determined using Enraf-Nonius CAD-4 diffractometers. At an intermediate stage in the refinement of the structure of **2***b*, a difference map revealed a few maxima consistent with the positions of the hydrogen atoms. H atoms were included in the subsequent cycles of refinement at geometrically idealized positions (C—H 0.95 Å) and with a fixed overall isotropic temperature factor. Calculated H atom positions were used for **5***a*. Crystals of **5***a* were extremely thin and tended to cleave parallel to the flat side. These were the best crystals we could obtain after much effort (see Results and discussion section).

Scattering factors used at Calgary were those of Cromer and Mann (17) and Stewart, Davidson, and Simpson (18), and allowance was made for anomalous dispersion (19); at Arkansas the values from the International tables for crystallography, Vol. 4, were used. Computer programs used at Calgary included SHELX'76 (20) and ORTEP II (21); at Arkansas NRC386, a PC version of NRCVAX (22). Experimental details for both structures are summarized in Table 1, fractional coordinates and U_{eq} in Table 2, and important interatomic distances in Table 3.[2] ORTEP diagrams showing the atom numbering scheme are found in Figs. 1 and 3.

Computational methods

The computational studies were performed on NBE, NBD, and 1-heptene adducts of the model dithiatriazine HCN_3S_2. The HyperChem suite of programs was employed (23) running under Windows on a 486/66 MHz Intel-based personal computer. In this method, the molecule is drawn on the computer screen, and a default three dimensional structure is calculated by the program. This crude geometry is refined by molecular mechanics using the MM+ force field (proprietary to HyperChem, but based on Alinger's MM2). Full geometry optimizations were then performed using HyperChem's implementation of MNDO (using RHF wavefunctions and Polak–Ribiere conjugate gradients, with convergence set at RMS of 0.1 kcal mol^{-1}).[3] HyperChem does not use symmetry constraints during geometry minimizations, relying instead on a close starting geometry from the molecular mechanics minimization. The energy of the model adducts are reported in Table 7 as enthalpies of formation. The absolute heats of formation have little meaning, but the relative energies for a series of isomers can be usefully compared. The reliability of these MNDO calculations was assessed by comparison of the bond lengths and angles with crystal structures of adducts containing these fragments (for example, those of **2***b*, **5***a*, and $PhCN_3S_2{\cdot}$NBD (24). In all cases excellent agreement was observed between the calculated (gas phase) structures and the crystallographically determined structures in solids.

Results and discussion

Structures of NBE adducts

The NBE adducts of the aryl dithiatriazines reported in our previous work (16), in contrast to their NBD derivatives, have NMR spectra consistent with a single species in solution. The NMR parameters of two such derivatives, $CF_3C_6H_4CN_3S_2{\cdot}C_7H_{10}$, **2***a*, and $CH_3OC_6H_4CN_3S_2{\cdot}C_7H_{10}$, **2***b*, are included in Table 4. The solution NMR spectra of these two, and all the other derivatives we have prepared, are virtually identical. However, **2***b* formed crystals suitable for an X-ray crystallographic structure determination. This structure is a necessary

[2]Tables of bond lengths and angles (S1, S5, and S6), anisotropic thermal parameters (S2 and S7), calculated H atom positions (S3 and S8) and observed and calculated structure factors (S4 and S9) for the crystal structure may be purchased from the Depository of Unpublished Data, Document Delivery, CISTI, National Research Council of Canada, Ottawa, ON K1A 0S2, Canada.

Tables of bond lengths and angles have also been deposited with the Cambridge Crystallographic Data Centre and can be obtained on request from: The Director, Cambridge Crystallographic Data Centre, University Chemical Laboratory, 12 Union Road, Cambridge, CB2 1EZ, U.K.

[3]HyperChem has implemented the MNDO method (along with several other semi-empirical methods), but has re-written the original FORTRAN code in C and C++. These calculations are therefore not directly comparable to those from other popular packages containing MNDO. In order to facilitate comparison of the methods, the authors are providing MOPAC-style **Z**-matrix files of the minimized adduct geometries. These may be obtained from the corresponding author by E-Mail as file "ALKTHIA.TXT".

starting point for our analysis, since there have previously been no X-ray structures of NBE adducts of dithiatriazines.

The structure of the adduct in the solid state, presented in Fig. 1, shows *syn-exo* geometry. The labels for the possible isomeric structures are depicted in Scheme 2, and are based on the standard organic nomenclature for fused rings (25). We consider the adducts to be comprised of three central fused rings: the 6-membered dithiatriazine portion, the five-membered C_2S_2N portion, and the 6-membered ring of the norbornene or norbornadiene. The protons attached to the fused C_2 fragment may then be located *syn* or *anti* to the substituent at the 5-position of the dithiatriazine ring. At the same time, the S atoms are located either in *endo* or *exo* positions on the bicyclic hydrocarbon.

The *syn-exo* geometry has been observed in numerous thiazene adducts of the related olefin NBD, for example (24), as well as in the NBE adduct of $S_3N_3^+$ (12). In this geometry, there is a close approach of H_{7b} to the unique nitrogen atom (N1 in Fig. 1), which is tipped out of the plane of CNSSN atoms. (This tipping is a consequence of re-hybridization at S, and has been noted previously (2); it does not seem to be *caused* by the proximity of H_{7b}.)

Table 4 presents the ^{1}H NMR assignments of the NBE and NBD adducts. These are based on a combination of well-known Karplus angle and W-coupling relationships in rigid hydrocarbon compounds (26). All the expected ^{1}H—^{1}H correlation peaks in the COSY-45, as well as the ^{1}H—^{13}C correlations in the HETCORR spectra were observed. On this basis, most of the signals could be unambiguously assigned; any exceptions to this generalization are noted in the table.

Table 4 also tabulates a chemical shift difference parameter, Δδ, for the bridge methylene protons H_{7a} and H_{7b}. In free NBE, this parameter is 0.25 ppm, reflecting the difference in environment of H_{7a} facing a C—C single bond and H_{7b} facing the double bond, while in the adducts **2** Δδ = 0.93 ppm. We believe that the large increase in this parameter, which is primarily caused by a downfield shift in the resonance frequency of H_{7b}, is due to through-space deshielding of H_{7b} caused by its proximity to the apical N atom of the dithiatriazine ring. The expected *reverse* effect on the ^{13}C resonance of C_7 is consistent with this interpretation. This observation gives us a great deal of confidence that the solution structure of **2** is similar to the solid-state structure in the crystal. We thus identify a value of Δδ ≈ 1 ppm with the

[a]Atomic numbering scheme as defined in Fig. 1.
[b]Atomic numbering scheme as defined in Fig. 3.

syn-exo geometry of norbornene derivatives of dithiatriazines, at least in $CDCl_3$ solution.

The results of MNDO calculations on the four possible geometries of addition of a model HCN_3S_2 to NBE are presented in Table 7. The *syn-exo* isomer has a significantly lower calculated energy than the other three possibilities. These data are consistent with the known fact that 1,3-dipolar cycloadditions to NBE *always go exo* (14).

Structure of NBD adducts

Tables 4 and 6 list the solution NMR spectral data for $CF_3C_6H_4CN_3S_2{\cdot}C_7H_8$, **4**. These are highly similar to those observed for a range of dithiatriazine NBD adducts, so that discussion of a single example is entirely sufficient. The presence of two distinct isomers is evident from both the ^{13}C and the ^1H NMR spectra. Intensity differences due to different isomer populations resulting from different preparations have been an aid

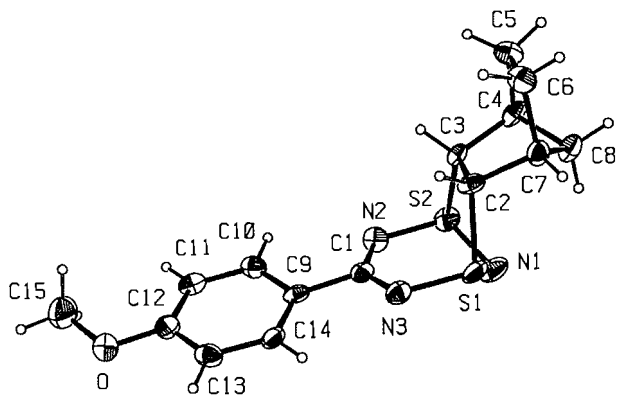

FIG. 1. ORTEP diagram of **2***b* showing the atom numbering scheme and the *syn-exo* orientation of the norbornene unit, as well as the way in which N_1 tips below the CNNSS plane.

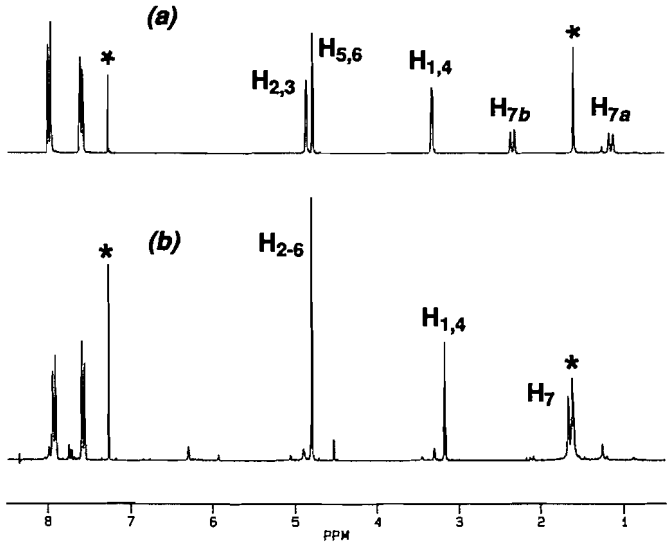

FIG. 2. ^{1}H NMR spectra of solutions of (*a*) **5***a* and (*b*) **5***b* in $CDCl_3$. Asterisks mark solvent impurities. Small peaks in (*b*) are due to the presence of a little **4***a* and **4***b*.

in assigning the peaks. In ^{1}H spectra (Table 4), the aromatic signals for the two isomers are not differentiated, while in the ^{13}C spectra (Table 6) only the signals of $C_{11,12,13}$ are not differentiated (i.e. those of the nuclei furthest from the point of attachment to NBD). In the ^{1}H spectrum, the total NBD region integrates to 8 H, and the aromatic region to 4 H. Since the NMR data for free dithiatriazines are known (16), and are quite different in the $CF_3C_6H_4$ region from those reported here, we are also not dealing with an association–dissociation equilibrium. Moreover, although we experienced a fair degree of variation in the relative abundances of the two isomers, it appears that these are established during synthesis, and we were not able to alter the ratio of any particular sample of adduct. The relative populations were not affected by heating the sample within the NMR tube, nor by the addition of excess NBD. We were also not able to effect a separation of these components, or even a noticeable enrichment of one component through frequent attempts at fractional crystallization.

There is a very strong similarity among the chemical shifts of comparable protons and carbons of **4***a* and **2** (Tables 4 and 6), as well as with the reported values of $PhCN_3S_2$·NBD which has the *syn-exo* geometry in the solid state (2, 24). We thus assign **4***a* to this *syn-exo* geometry in solution. It is characterized by the parameter $\Delta\delta = 0.92$ ppm. We further suggest that **4***b* has one of the other three possible geometries (listed in Scheme 2) which are consistent with S addition and a plane of symmetry in the molecule. Addition to any other atoms in the ring would either lead to a lower symmetry product, or alter the electronic environment sufficiently that the aromatic protons would no longer be shift-equivalent in the two isomers. The data in Table 7 show the MNDO calculated heats of formation for model derivatives of the four possible structures. In fact, the lowest energy belongs to the *syn-endo* geometry, although the difference with the *syn-exo* geometry is very small. On the other hand, the two *anti* structures are calculated to have considerably higher energy (23–26 kJ mol^{-1} more). The *syn-endo* geometry has H_{7b} far removed from the dithiatriazine ring, and in a similar environment to H_{7a}. Consistently, $\Delta\delta = 0.09$ ppm for this isomer in solution, very close to that of the free diene, for which of course $\Delta\delta = 0$.

The difference in ^{1}H chemical shifts are mirrored in the ^{13}C spectra of the two isomers (Table 6). Thus the resonance due to C_7 shifts from 50.76 ppm in **4***b* about 10 ppm upfield to 40.87 ppm in **4***a*. This supports the idea of a through-space deshielding of H_{7b}, since it is well known that under such conditions the attached carbon atom becomes more shielded as the substituent is deshielded.

These conclusions are further supported by the NMR param-

eters recently reported for *cis*- and *trans*-2-butene adducts of $CF_3CN_3S_2$ (13). These workers demonstrated by combined crystallographic and solution NMR studies that protons attached to the fused C—C bond have characteristic chemical shifts in $CDCl_3$ or CD_3CN solution depending on whether they are *syn* or *anti*. For a number of strained and unstrained olefin adducts H_{syn} are found in the range 4.4 to 5.2 ppm, while H_{anti} are 2.8 to 3.9 ppm. Presumably this is due to *antiaromatic* shielding from the dithiatriazine ring. These protons correspond to $H_{5,6}$ in NBD and NBE adducts of dithiatriazines, which in *all* cases fall within the range 4.16–5.06 ppm.

In conclusion the MNDO calculations as well as the chemical shifts of $H_{5,6}$ rule out the formation of *anti* adducts. This geometry has considerably higher energy attributable to strong steric interactions. Thus the NBD and NBE adducts have *syn* geometry, and so **4***b* must have *syn-endo* geometry as shown in Scheme 1. This mode of addition has never been demonstrated before for any thiazene or heterothiazene NBD adduct. Precedents for such isomerism exist, however, for 1,3-dipolar cycloadditions to NBD (14, 27). Taniguchi et al. conclude "1,3-dipoles cannot undergo cycloadditions from the *endo* side of norbornene. This is probably because of the steric hindrance of the *endo*-5,6-hydrogens. On the other hand, in the case of norbornadiene, it is possible that 1,3-dipoles attack the carbon–carbon double bond from the *endo* side because of the absence of such steric hindrance" (27). These workers suggest that homoconjugation on the *endo* side of NBD serves to balance the π-electron distribution on the two non-identical faces of the double bond.

Structures of bis adducts of dithiatriazines with NBD

Isomer formation in alkene adducts of cyclic thiazenes was not reported before ref. 13. Such isomerism may not be observed for weakly bound thiazene–alkene adducts, for which rapid equilibria are established leading to only the most thermodynamically stable species being formed (8). If, as we believe, the adducts with dithiatriazines are relatively stable,[4] we speculated that it may be possible to add a single NBD molecule to two dithiatriazine rings. Thus we have reacted **1** with exactly 0.5 equivalents of NBD in refluxing acetonitrile for several hours. The resulting brown solutions contained a small amount of colourless precipitate, which was removed in a hot filtration. This proved to be **5***a*. On cooling to room temperature, colour-

[4]One indication for this stability is the presence of small parent ion peaks in the mass spectra of all the dithiatriazine NBD adducts reported in this work.

less microcrystalline **5***b* precipitates, and more of this could be won from the mother liquor. Considerable care must be taken with solvent volumes and reaction conditions in order to avoid contamination of the products by both **1** and **4**. Taking the mother liquor to dryness always leads to some **4**. **5***a* and **5***b* correspond to two isomeric forms of the *bis* adducts.

The NMR parameters of these *bis* adducts are also presented in Table 4, as well as in Fig. 2. Their spectra are extremely simple; **5***a* is the less abundant species and is also the less symmetric; **5***b* is the more symmetrical isomer. The spectrum of **5***b* can only be interpreted in terms of identical addition geometry at both double bonds in NBD. We only consider the *syn* mode of addition; *anti* addition can be ruled out both on steric grounds and by the chemical shifts of $H_{5,6}$ (identical to $H_{2,3}$ in **5***a*). MNDO calculations on model compounds of these adducts with H atoms on the dithiatriazine ring in place of the $CF_3C_6H_4$ groups showed that only two structures are reasonable, one which we label *exo-exo*, the other *exo-endo*. The energy of these two isomers is calculated to be only 8 kJ mol^{-1} apart, and the *exo-endo* is the higher of these two, in full accord with the proportion of **5***a* and **5***b* obtained from our reactions. On the other hand, the *endo-endo* geometry lies a full 71 kJ mol^{-1} higher than the *exo-endo*, and is thus a much less likely structure. Our confidence in the assignment of the *exo-exo* geometry to **5***b* is increased by the dominance of *exo* addition in all known mono adducts of NBD and NBE. In fact the formation of **5***a* and **5***b* can be explained by a second *exo* addition occurring to a typical mixture of **4***a* and **4***b* in solution.

The only geometry for **5***a* consistent with the spectra is *exo-endo*, which establishes it as only the second species in which *endo* addition of a thiazene to NBD has been identified. This geometry has been confirmed by a single crystal X-ray structure (Fig. 3). Very thin, long plates of **5***a* were grown by slow diffusion of hexanes into CH_2Cl_2 solutions of the adduct at room temperature. Care had to be taken not to heat the adduct or leave its solutions exposed to sunlight for long periods, otherwise the crystal formed contained orange zones which appear to be intergrown crystals of dithiatriazine. The thinness of the crystals has limited the amount of X-ray data available, leading to structural parameters less accurate than normal. However, the structure is entirely conclusive regarding the geometry of addition.

Finally, we comment on the other ^1H NMR parameters of these species. As mentioned above, $H_{2,3}$ and $H_{5,6}$ fall within the expected range for *syn* addition. $H_{1,4}$ for all NBD adducts fall within the same narrow range. The chemical shifts of the bridge methylene protons are the most interesting. First of all, the $\Delta\delta$ parameter in **5***a* is the largest of any thiazene adduct reported at 1.20 ppm. Consistently, in the MNDO calculated structures of the model adducts, the through-space contact between the H_{7b} and the apical N atom is 2.579 Å in the *exo-endo bis* adduct (2.450 Å in the X-ray crystal structure using the *calculated* hydrogen atom position), whereas in the MNDO calculated *syn-exo mono* adduct this distance is larger at 2.680 Å. These distances are all less than the sum of the accepted van der Waals radii for H and N of 2.75 Å (28).

Structure of 1-heptene adducts

To demonstrate the utility of the combined data from our work and from that of ref. 13, we have prepared and characterized by NMR the 1-heptene adduct of **1**. An indication of the strength of the adduct bond is the observation of a small parent-ion peak in the mass spectrum of **6**. The NMR spectra of **6** also show the presence of isomers (Tables 5 and 6 and Fig. 4).

TABLE 5. ^1H NMR data of 1-heptene adducts

	6*a*	**6***b*
H_{1syn}	4.49 d.d. (12.4, 7.1)	3.83 d.d. (11.6, 5.7)

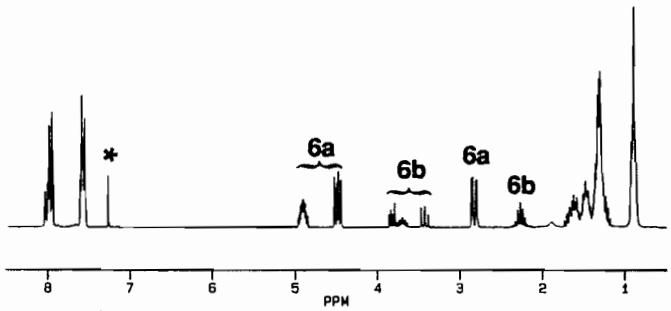

FIG. 4. ^1H NMR spectrum of a mixture of two isomers of **6***a* and **6***b* in $CDCl_3$ solution. An asterisk marks solvent impurity.

Different samples from different preparations of **6** show different amounts of these two isomers which we label as **6***a* and **6***b*. The main features of the spectrum are readily interpreted from the 2-D correlation spectra. We also see clear evidence that the *anti* protons are at much higher field than the *syn* protons (13). Deshielding of the latter by proximity to the antiaromatic dithiatriazine ring is invoked to explain these large differences ranging between 0.5 and 1.7 ppm. The deshielding of the CH_2 group of C_3 is also marked, at 2.3 ppm compared to the average of H_3 for the anti isomer of 1.4 ppm. The ^{13}C spectra have undifferentiated signals for C_6 and C_7 in the olefin, and the CF_3 carbon atom on the aryl ring. All other signals are differentiated in the two isomers.

We have not attempted to separate these isomers, although recrystallization from pentane significantly altered the isomer population. Our main interest in synthesizing this adduct was to demonstrate the ability to assign alkene adduct structures of dithiatriazines with confidence based on the NMR parameters alone, and to determine whether aryl dithiatriazines form stable adducts with unactivated alkenes. In this vein we have also attempted to prepare an ethene adduct. The reaction of dithiatriazine with ethene does lead to the formation of a fine white solid. However, this solid proved to be extremely insoluble and we therefore concentrated on longer-chain alkenes which greatly enhanced solubility of the adducts.

Solution structures of alkene adducts of thiazenes

Over the years numerous alkene adducts, mostly with norbornadiene, have been reported for a wide variety of cyclic and acyclic thiazenes (1–11). The data for NBD adducts are collected together in Table 4. Erroneous assignments in the literature have been corrected; corrected entries have been marked.

	Exo-endo	—	1096	—
	Endo-endo	—	1167	—

We focus discussion on our calculated parameter $\Delta\delta$ for $H_{7a,b}$ in these compounds. Very small values occur for the acyclic adducts of S_3N (10) and S_4N_2 (11), which lack an apical nitrogen atom. The largest values are found for the dithiatriazine derivatives (0.92–0.99 ppm) and the fused-ring analogue $C_6H_4S_2N_2$ (1.05 ppm) (8). Smaller values are found for adducts of phosphadithiatriazines, ranging from 0.3–0.6 ppm (4, 5). The smallest value for a cyclic system is the *bis* NBD adduct of S_4N_4 (9), which has been the subject of much controversy. Essentially the value of $\Delta\delta$ decreases with increasing ring size and ring floppiness. We believe that the trend emerging from all this data is that the smaller the thiazene ring that the olefin is attached to, the

more distinct the environments of $H_{7a,b}$ becomes in the dominant *syn-exo* mode of addition. Thus these NMR parameters are most reliable in the structure assignment of small ring systems.

^1H NMR spectrum of 3

Recently Chivers et al. reported the synthesis, crystal structure, and ^{13}C NMR spectra of $S_3N_3{\cdot}C_7H_{10}$, **3** (12). This adduct is isoelectronic to the dithiatriazine adducts **2**. However, the ^1H NMR spectrum was not reported. 2-D NMR techniques are readily extended to the assignment of this proton spectrum. The results are reported in Table 1. This compound is only soluble in SO_2. We found that acceptable spectra, including COSY-45 and HETCORR sequences, could be obtained in an automated **5** mm dual ^1H–^{13}C probe by using a 4 mm Pyrex tube insert which contained the SO_2 solution, sealed under vacuum, within a standard 5 mm NMR tube. The remaining coaxial space was filled with deuterated benzene for a lock signal.

We found very large solvent effects on the ^1H chemical shifts for both NBE and the adduct in liquid SO_2. However, the relative positions of the protons is unaltered from those in $CDCl_3$. Assignment is again straightforward using standard Karplus and W-coupling reasoning. The surprising fact is the small value of $\Delta\delta$ for the adduct, which by crystallography has the *syn-exo* geometry in the solid state (12). $\Delta\delta$ is hardly different from that in the free alkene in the same solvent. The spectra are consistent with only one solution species, and since this is an NBE adduct, isomerism is not expected; the solution species must be a *syn-exo* adduct. We feel that strong solvent interactions between SO_2 and $H_{7a,b}$ are overriding the through-space interaction with the apical nitrogen atom in this compound. Thus while 2-D NMR techniques can easily be applied in this exotic solvent using a modern FT-NMR spectrometer, the structural parameters developed above for standard NMR solvents such as $CDCl_3$ cannot be used.

Conclusions

The application of 2D-NMR techniques to the interpretation of the NMR spectra of alkene adducts of thiazenes is essential in order to reduce the risk of wrong spectral assignments. The parameters identified in this paper allow reliable structure determination using NMR for both chain- and cyclic-alkene thiazene adducts in conventional NMR solvents such as $CDCl_3$ or CD_3CN. The reliability of this method is greater for addition to small ring thiazenes for which more rigid adducts are expected in solution.

We have presented conclusive NMR evidence for the presence of a second, *endo*, mode of addition of thiazenes to NBD. The presence of such species may have been overlooked in the past as "impurity" signals in NMR spectra of the adducts. The strongly anti-aromatic electronic structure of dithiatriazines make this ring system an excellent candidate for observing potential isomerism. We have discovered the first example of *bis* addition of thiazenes to a single NBD molecule, and the first crystallographic confirmation of *endo* addition.

1993 R.U. Lemieux Award Lecture
Organometallic-type reactions in aqueous media — a new challenge in organic synthesis[1]

T.H. CHAN,[1] C.J. LI, M.C. LEE, AND Z.Y. WEI
Department of Chemistry, McGill University, Montreal, QC H3A 2K6, Canada

Received July 5, 1993

T.H. CHAN, C.J. LI, M.C. LEE, and Z.Y. WEI. Can. J. Chem. **72**, 1181 (1994).

The development of organometallic-type reactions in aqueous media is reviewed. Coupling reactions of allyl halides with carbonyl compounds mediated by zinc, or tin, or indium in aqueous media to give homoallylic alcohols are discussed. The stereochemical outcome is compared with similar reactions in organic solvents. A concise synthesis of (+)-muscarine is used to illustrate the usefulness of aqueous organometallic-type reactions in organic synthesis. The procedure to protect–deprotect hydroxy functional groups may not be necessary in these reactions. An application in the carbohydrate area is demonstrated with the synthesis of (+)-3-deoxy-D-*glycero*-D-*galacto*-nonulosonic acid (KDN). The mechanistic possibilities of organometallic-type reactions in aqueous media are outlined.

T.H. CHAN, C.J. LI, M.C. LEE et Z.Y. WEI. Can. J. Chem. **72**, 1181 (1994).

On passe en revue le développement de réactions de type organométalliques dans des milieux aqueux. On discute des réactions de couplage des halogénures allyliques et des composés carbonylés, catalysées par le zinc, l'étain ou l'indium en solutions aqueuses et conduisant à des alcools homoallyliques. On compare le résultat stéréochimique de ces réactions avec ceux de réactions semblables dans des solvants organiques. On a utilisé une synthèse concise de la (+)-muscarine pour illustrer l'utilité des réactions de type organométallique, en solutions aqueuses, en synthèse organique. Dans ces réactions, il n'est pas toujours nécessaire de protéger, puis déprotéger, les groupes hydroxyles fonctionnels. On a démontré son utilité dans le domaine des carbohydrates en procédant à la synthèse de l'acide (+)-3-désoxy-D-*glycéro*-D-*galacto*-nonulosonique. On décrit brièvement les possibilités mécanistiques des réactions du type organométallique en solutions aqueuses.

[Traduit par la Rédaction]

Introduction

The importance of organometallic reactions in organic synthesis is well recognized. Organometallic reactions using Grignard reagents or organolithium compounds are the cornerstone of organic synthesis. In their most general form, these reagents are used to construct new carbon–carbon bonds, leading to compounds of greater complexity. A cardinal restriction in the use of many organometallic reagents is the strict exclusion of moisture. Thus, we accept, without question, the limitations imposed by these restrictions, namely, that the reactions cannot be carried out in aqueous media, and that these reagents cannot coexist with a trace of water, or with reactive hydroxy or acidic hydrogens. These inherent limitations profoundly govern our thinking about organic synthesis. We accept, first of all, that anhydrous organic solvents are required for these reactions. Furthermore, reactive hydroxy or acidic groups must be protected, and indeed, extensive protection–deprotection chemistry has been developed for that purpose. As well, we accept that compounds such as carbohydrates, insoluble in organic solvents, will have to be derivatized so that they become soluble. This has evolved to become part of the accepted way of doing synthesis in the carbohydrate field. Finally, many stereochemical formulations, e.g., Cram's rule (1) and its modifications, are based generally on conclusions reached from reactions carried out in organic solvents.

If one can perform organometallic-type reactions in aqueous media just as generally and easily as in organic solvents, such reactions may offer considerable advantages: (*i*) There is the practical convenience of not having to handle inflammable and anhydrous organic solvents. (*ii*) The tedious task of protection–deprotection chemistry for certain functional groups often encountered in organic synthesis may not be required. (*iii*) Water-soluble compounds can be reacted directly without the need of derivatization. This is a point of particular interest in carbohydrate chemistry. (*iv*) The stereochemical outcomes of organometallic reactions may well change from organic to aqueous media and thus offer new opportunities in synthesis. Several years ago, we began a program to study organometallic-type reactions in aqueous media with a view to exploring the above-mentioned possibilities.

It may be useful to examine the factors that may lead to choosing appropriate organometallic reagents for aqueous media. It is generally known that the less reactive organometalloid reagents, such as organosilicon compounds, do not react with water (2). Can they be used for organometallic-type reactions in aqueous media? The answer is negative. Precisely because silicon is less reactive, the preparation of organosilanes directly from silicon and organic halides is not as easy as the Grignard reagents or organolithiums. Furthermore, formation of a C—C bond using organosilicon reagents requires strongly acidic conditions (3). Organosilanes are not likely to be candidates.

What about the somewhat more reactive organotin compounds? It was known as early as 1961 that tin reacts with benzyl chloride directly to form the corresponding organotin compounds **1** and **2** (Scheme 1) (4). What is interesting, and was little exploited at that time, is the fact that the reaction could be carried out in a number of solvents, including water. It was reported that the yield of tribenzyltin chloride (**2**) was quite respectable when the reaction was carried out in aqueous medium. Even though the tin–chlorine bond was partially hydrolysed, the tin–carbon bond survived in water to a large extent in spite of the fairly high temperature. It was in the 70s, and then increasingly so in the 80s, that the use of tin, and zinc as well, to mediate the allylation of aldehydes and ketones in water to give the corresponding homoallylic alcohols (**3**) (Scheme 2) was reported, first by Wolinsky and co-workers in

[1]This work was presented by Professor Chan as the Lemieux Award Lecture at the 76th Annual Conference of the Canadian Society for Chemistry, Sherbrooke, Québec, June 1, 1993.

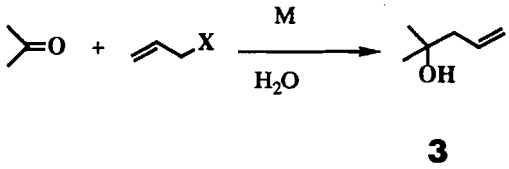
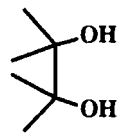


SCHEME 2

1977 (5), then by Nokami et al. in 1983 (6), later on more systematically by Luche and co-workers in France (7), and more recently by Wilson and Guazzaroni in the U.S. (8). The metal used can be either Sn or Zn, and the solvent used can be water, with or without organic cosolvents. The yields are in general good to excellent. But there is always an induction period of indefinite time, and the use of catalyst, ammonium chloride or hydrobromic acid, appears to promote the reaction. The use of heat or ultrasound radiation has also been found to facilitate the reaction. The side products most often reported are the reduced carbonyl compounds, the alcohols **4**, and (or) the pinacols **5**

4



5

from the reductive coupling of the precursor carbonyl compounds.

Results and discussion

When we began our work in this area, the first question we posed was a very simple one: can one extend the known reactions to synthesize compounds other than homoallylic alcohols? Indeed, we found (9) that aldehydes and ketones could be converted to 1,3-butadienes **6** or vinylepoxides **7** by reaction with 1-chloro-3-iodopropene (**8**). Powdered zinc metal was used (Scheme 3). The intermediate chlorohydrin **9** could be isolated, which on further reaction with zinc in water gave the diene **6** in good to excellent yields. Alternatively, treatment of the chlorohydrin with base gave the vinylepoxide **7**. The results of this reaction are summarized in Table 1. The following features of the reaction are noteworthy. The carbonyl compound can contain an unprotected hydroxy group, and the reaction proceeds equally well. While this is not surprising in view of the fact that the reaction is carried out in water, one can hardly expect an hydroxy group to prevent the reaction if water is present everywhere. This is nevertheless quite contrary to conventional organometallic reactions: namely, the hydroxy group would first have to be protected, and then deprotected after the reaction. Secondly, the reaction seems to proceed in a 1,2-addition fashion. With cinnamaldehyde, the corresponding triene is obtained. Thirdly, the butadienes **6** are formed stereoselectively and, in the case of aldehydes, exclusively as the *E* isomers. On the other hand, the vinylepoxides **7** are formed as a mixture of *cis/trans* diastereomers, and the ratio is in agreement with the diastereomeric ratio of the precursor chlorohydrins **9**. This suggests that the reduction of **9** to give **6** under the experimental conditions is non-stereospecific but selective in giving the thermodynamically more stable *E* isomer. This is contrary to the usual *trans* elimination under metal/dihalide reduction conditions (10).

Another simple modification is to use 2-chloromethyl-3-iodopropene (**10**) as the allylic halide. This provides a synthesis of methylenetetrahydrofurans **11** from the carbonyl precursors in good to excellent yields (Scheme 4) (11). The reaction can be looked upon as providing a trimethylenemethane equivalent **12**, the 1,3-dipolar species. The conventional trimethylenemethane

[a]Method: (A) A mixture of the carbonyl compound (1 mmol), 1,3-dichloropropene (1 mmol), and zinc powder (2 mmol) in 10 mL of water was heated to 35°C with vigorous stirring for 3–4 h. The reaction mixture was cooled and quenched with ether. The organic product was isolated from the ether phase and purified by flash column chromatography. (B) A mixture of the carbonyl compound (1 mmol), 1-chloro-3-iodopropene (1.5 mmol), and zinc powder (1.5 mmol) in 10 mL of water was stirred at room temperature until the zinc almost disappeared (in cases where the reaction did not start properly, 2–3 drops of hydrobromic acid or saturated ammonium hydrochloride solution could be added to initiate the reaction). To the reaction mixture was then added 2 mL of hydrobromic acid (48%) and zinc powder (10 mmol) over a period of 5 h. The reaction mixture was then extracted with ether to give, after purification by flash column chromatography, the diene. (C) The reaction was interrupted after the first stage of method (B) by extraction with ether. The intermediate chlorohydrin was isolated, and treated in ethanolic NaOH (0.4 g/10 mL) to give the vinylepoxide in quantitative yield.

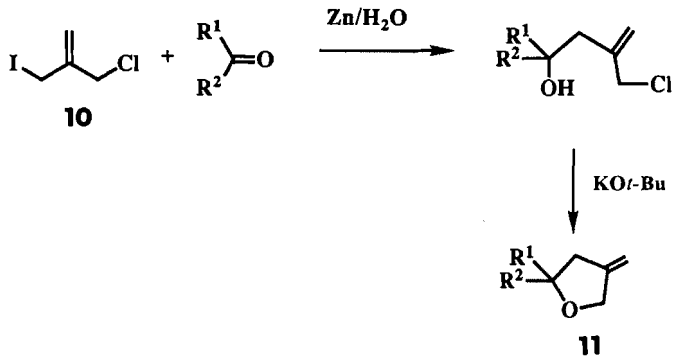
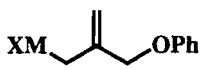


SCHEME 4

equivalents usually require balanced reactive ends, for example, compound **13** with a less reactive silyl or stannyl nucleophilic end, but a more reactive acetate electrophilic end (12), or compound **14** with a more reactive zinc or magnesium halide end

12

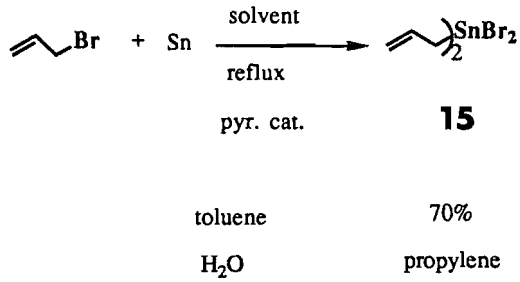
13 M=Si or Sn



14 MX=ZnBr or MgCl

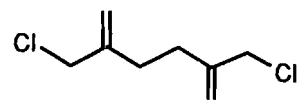
together with a less reactive phenoxy end (13). Such a balance in reactivity of the two polar centers is required to prevent self-cyclization, or di- and polymerization. In the case of the present reaction, what is the possible mechanism? Is a true organozinc intermediate actually formed, in the presence of water, with a reactive allylic halide as the other polar center?

At this point, it might be profitable to speculate on the possible mechanism of this kind of organometallic-type reaction in aqueous media. In the case where metallic zinc is used, the actual formation of the allylzinc intermediate is considered unlikely, because such organozincs are known to react instantaneously with water (14). The involvement of the less reactive allyltin intermediate may also be unlikely, while it has been known that allylic bromide does react with tin in organic solvents to give the corresponding diallyltin dibromide (**15**). In water, the same reaction gives propene, presumably because the allyltin intermediate reacts with water under the reaction conditions (Scheme 5) (15). One possible mechanism is that the metal reacts with the carbonyl compound by a single electron transfer (SET) process to give the radical anion intermediate **16**. The ketyl radical anion couples with the allylic halide to give the alkoxy radical, which on further reduction by the metal in another single electron transfer step gives the alkoxide anion, which is then protonated by water to the homoallylic alcohol product (Scheme 6). This mechanism can account not only for the product, but also for the side product of the reaction, namely, the pinacol **5**, because of the coupling of the ketyl radical anion.



SCHEME 5

Another equally likely mechanism is the following: it is the allylic halide that reacts with the metal in an SET step to give the radical anion **17**. The radical anion then couples with the carbonyl compound to give the alkoxy radical species, which on further reduction by the metal gives the product (Scheme 7). In support of this mechanism, the self-coupling product **18** of the allylic halide **10** can also be found in the reaction mixture as a side product.



18

Irrespective of the real mechanism (a question that may take a long time to resolve), if a single electron transfer step is indeed involved, one may ask: can other metals perform the same function equally well or even better? This led us to search for other possibilities. If one looks at what is required of this metal, one

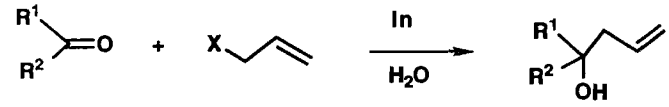
TABLE 2. First to fourth ionization potential of some metals

Metal	Ionization potential (eV)			
	I	II	III	IV
Indium	5.785	18.86	28.03	54.4
Aluminum	5.984	18.82	28.44	119.96
Magnesium	7.646	15.035	80.143	109.29
Zinc	9.39	17.96	39.7	
Tin	7.34	14.63	30.49	40.72

realizes that the metal itself must not react with water. This removes from consideration metals such as sodium, potassium, cesium, magnesium, etc., or similarly reactive metals. Furthermore, the metal must not react in air to form water-insoluble oxides. This eliminates metals such as titanium or aluminium whose oxides are water insoluble. Another consideration is that the metal must be somewhat more reactive than silicon and germanium, or perhaps even tin.

In this connection, indium metal offers some intriguing possibilities. Compared to other metals, indium has not been much explored in organometallic reactions (16). It is only recently that indium has been used in Reformatsky reactions (17), allylations (18), and cyclopropanations (19) of carbonyl compounds. While these results are interesting, the use of indium in organic solvents offers no obvious advantages over other conventional organometallic reactions. On the other hand, it is known that indium is unaffected by boiling water! It does not readily form oxide in air. Most interestingly, its first ionization potential is much lower than zinc. In Table 2, we compare the ionization potentials of five metallic elements. Indium has the lowest first ionization potential among them, but it has the highest second ionization potential. If the mechanism of the aqueous



SCHEME 8

organometallic reactions is indeed initiated by a single electron transfer step and not a two-electron transfer reaction, then indium should be a reasonable candidate.

Sure enough, when allylic halide and carbonyl compounds are stirred with indium in aqueous media, the reaction proceeds very well to give the corresponding homoallylic alcohols (Scheme 8) (20). The yields are usually good to excellent (Table 3). There are few side products of alcohols or pinacols. In contrast to the zinc- and tin-mediated reactions, where some acidic initiators are usually required, the indium reaction can be applied to carbonyl compounds with acid-labile groups. An example is found by comparing the three metals in the same reaction with the substrate **19** where there is a labile acetal group. With zinc as the metal, the reaction fails with destruction of the starting materials. Using tin, the yield is very poor, but with indium the reaction proceeds normally to give the desired product in 70% yield (Scheme 9).

A useful variation on the same theme is to use the allylic halide **20** with the ester functional group. The reaction can be mediated by indium in water to give the coupled product in very good yield. This can serve, of course, as a facile route to α-methylene-γ-lactones **21** (Scheme 10).

In 1990, we reported on crossed aldol-type condensation reactions in aqueous media. Aldehydes and α-halo-carbonyl compounds condense in water with zinc or tin to give the crossed aldol-type products **22** (Scheme 11) in reasonably good yields (21). The distinctive feature of this reaction is that there does not appear to be the normal complication of crossed aldol reaction in organic solvents in that there are few elimination products, poly-aldol condensations, or self-aldol products. The major side products appear to be owing to the reduction of the α-halo-carbonyl compounds, as well as the reductive coupled products, for example, the 1,4-diketone **23** from the bromoketone **24**. The diastereoselectivity of the reaction is between

24 **23**

1:1 and 2:1, not much different from the normal diastereoselectivity of this type of reaction performed in organic solvents.

When the same crossed aldol-type reaction is carried out

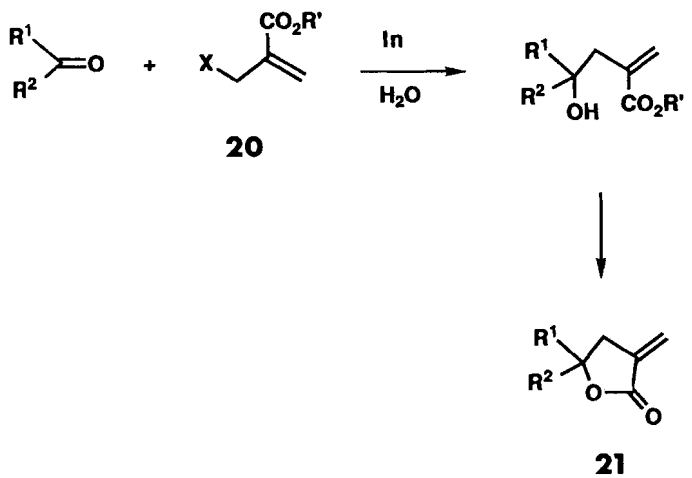
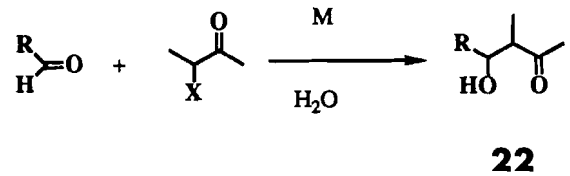


SCHEME 10



SCHEME 11

with indium instead of zinc or tin in aqueous media, the yield of the reaction is slightly improved (Table 4) (22). But the most interesting change is that the diastereoselectivity appears to have improved to between 2:1 and 12:1. Using the specific example of benzaldehyde reacting with α-bromopropiophenone (**25**), when the reaction is carried out in water with zinc as the metal, the yield is 82% with the ratio of the two diastereomeric products **26**, *erythro* to *threo*, being 2.5 to 1. Using tin as the metal for the same reaction, the yield is slightly poorer, and the ratio of the two diastereomers, *erythro* to *threo*, becomes 1 to 1.1. But when the same reaction is carried out with indium in water, the yield is good at 85% but, more dramatically, the ratio of the two diastereomers is now 12 to 1 in favour of the *erythro* compound (Scheme 12). While one cannot give a logical explanation at this time for the stereochemical differences, the improved diastereoselectivity renders the indium-mediated crossed aldol condensation reactions synthetically useful.

Not surprisingly, Reformatsky-type condensation reactions can also be carried out with indium in water. α-Haloesters (**27**)

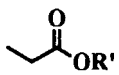
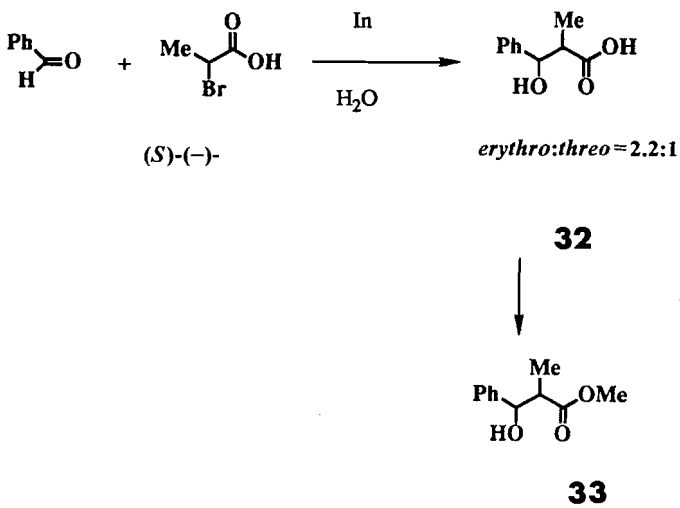
SCHEME 13

react with carbonyl compounds to give the corresponding β-hydroxyesters (**28**) in moderate yields (Scheme 13). The reaction appears to be chemoselective in that only aromatic aldehydes participate in this kind of reaction. Aliphatic aldehydes are recovered unchanged under identical reaction conditions (Table 5). The major products obtained in these situations are the reduced esters **29**. The diastereoselectivity observed is unexceptional, in the range of 2 to 1.



29
31 (R'=H)

Somewhat surprising is the observation that the free α-haloacids **30** can also undergo the same Reformatsky-type condensation reactions with aromatic aldehydes in water in more or less the same modest yields (Scheme 13). Again, the side product is the reduced acid **31** and the diastereoselectivity is uneventful (Table 5). An interesting aspect of the experimental result is that when optically active (*S*)-(−)-bromopropionic acid (88% ee) is reacted with benzaldehyde and



(*S*)-(−)-

erythro:*threo* = 2.2:1

32

33

SCHEME 14

indium in water, the condensation product **32** is obtained in about 50% yield. Two diastereomers are formed, in the ratio of 2.2 to 1 in favour of the *erythro* isomer. The two diastereomers have been separated as the methyl esters **33**, and both are found to be optically inactive (Scheme 14). This allows us to draw some limited conclusions about the possible mechanism of this reaction. If the reaction proceeds by first forming a radical anion with the carbonyl compound (path a), then the lack of optical activity in **33** would rule out a direct displacement of the halide by the radical anion in an S_N2-type process because this would have given an optically active **33**. On the other hand, if the reaction proceeds by first forming a radical anion with the α-haloacid (path b), the result of the

Can. J. Chem. Downloaded from www.nrcresearchpress.com by EESC ESCOLA DE ENGENHARIA on 09/08/12
For personal use only.

optical activity would imply that the carbon–halogen bond must have dissociated sufficiently, leading to racemization prior to reaction with the carbonyl compound (Scheme 15). A similar dissociation of the carbon–halogen bond on a magnesium metal surface, leading to racemization, was recently advanced to account for the stereochemical observations of Grignard reactions (23).

One can take advantage, in synthesis, of the change in stereoselectivity in organometallic-type reactions in aqueous media. We recently reported a concise synthesis of (+)-muscarine (**34**) by using the zinc-mediated allylation reaction (24). Normally, the stereoselectivity observed in the addition of C-nucleophiles such as organometallic reagents to chiral α-alkoxyaldehydes (and ketones) is opposite to Cram's rule. The anti-Cram stereoselectivity has been rationalized on the basis of chelation control. The carbonyl compound **35** forms the chelate **36** as shown in Scheme 16. The C-nucleophile (R–) attacks from the less hindered side as indicated by the arrow, giving the chelation-controlled product **37** in preference to the non-chelation product **38** (25). One would expect the formation of the chelate **36** in aqueous media to be much diminished or even disrupted. In Table 6, the allylation of a number of α-alkoxyaldehydes with allylmagnesium bromide in ether is compared with the reaction with allyl bromide/zinc in water. In all cases where the reaction is conducted in organic solvent, the *syn* isomer is obtained as the major isomer, in agreement with the chelation model. But in cases where the reaction is conducted in water, a reversal of stereoselectivity is observed, now with the *anti* isomer as the major product. While it is possible that the observed stereoselectivity in aqueous organometallic-type reactions may be due to factors associated with the metal surface in such heterogeneous reactions, it is interesting to note that in the case of

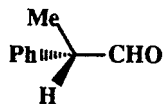
α-methylphenylacetaldehyde (**39**), where there is no possibility of chelation, there is no significant difference in the diastereoselectivity between allylations in organic or aqueous media.



39

(+)-Muscarine is synthesized from (*S*)-(−)-ethyl lactate in five steps with the application of the zinc-mediated allylation reaction in aqueous media (Scheme 17). In the critical step in which compound **40** is transformed into the two diastereomers **41***a* and **41***b*, the aqueous reaction gives the desired diastereomer **41***a* as the major product whereas the same reaction with allylmagnesium bromide in ether gives **41***b* as the major product.

Finally, organometallic-type reactions in aqueous media may offer a unique opportunity in carbohydrate chemistry. We have demonstrated this with the syntheses of the two carbohydrate molecules, KDO (**42**), an eight-carbon sugar, with a carboxylic acid end, and KDN (**43**), a nine-carbon compound of similar structure. They belong to a family of compounds called sialic acids, which are now known to play some critical role in many cell-surface glycoproteins (26). Chemical syntheses of these two compounds have been reported in the literature (27), very often involving the protective group chemistry that is standard in carbohydrate chemistry.

Using the indium-mediated reaction, D-mannose can be coupled in water with allyic halide **20** bearing a methyl ester group to give the two diastereomers **44** and **45** in a ratio of 6:1. The major isomer **44** can be conveniently crystallized out. Ozonolysis of the double bond (in methanol) gives the ketone **46**, which spontaneously cyclizes to the methyl ester **47** of KDN (28). Saponification with KOH in aqueous methanol according to literature procedure (29) gives KDN (Scheme 18). This synthesis is concise, and offers the distinct advantage that the mannose does not need to be derivatized, but is used directly in water.

The same approach can be carried out starting with D-arabinose (Scheme 19). Coupling with **20** by indium in water gives the two diastereomers **48** and **49**, in a ratio of 1 to 5 with the wrong isomer **49** predominating. The major epimer **49** can be acetylated and ozonolyzed to give the unsaturated keto-ester **50**, which was converted to KDO (**42**) (30).

It is perhaps instructive to compare these syntheses with the enzymic syntheses of both KDN and KDO recently reported by Wong and co-workers (31). With the sialic acid aldolase from *Escherichia coli* as the enzyme, D-mannose couples with pyruvate in water to give D-KDN (Scheme 20). However, when L-mannose is used as the substrate, L-KDN is obtained as the product. This represents a reversal of stereoselectivity at the new stereogenic center, a situation that is normally not the case for enzymic reactions. Similarly, when D-arabinose is used as a substrate (which is not a natural substrate of the enzyme), D-KDO and the 4-epimer (**51**) are obtained in a ratio of between 1:2.6 and 1:1.5, also with the wrong epimer predominating (Scheme 21). What is interesting is that in both the enzymic reactions, and in the chemical synthesis using indium in aqueous media, the same *syn* selectivity (anti-Cram) is observed in the critical C—C bond formation step. Normally, anti-Cram selectivity in the reaction of α-hydroxyaldehydes with nucleophiles in organic solvents is explained by chelation control. Since both the enzymic and the chemical coupling are carried out in aqueous solution, the chelation control explanation may be invalid, as we have demonstrated for the zinc-mediated allylation of α-alkoxyaldehydes in water. At present, we explain the *syn* selectivity for α-hydroxyaldehydes by the Felkin model (32), which predicts the *syn* stereochemical outcome if the hydroxy group is considered to be of medium size.

SCHEME 21

Conclusion

We have demonstrated that certain organometallic-type reactions can be carried out in aqueous media. The reactions offer the following advantages. Anhydrous organic solvents are no longer needed. We have shown that reactive hydroxy or acidic groups need not be protected, and therefore much of the protection–deprotection chemistry in synthesis may become unnecessary. In some cases there are different stereochemical outcomes from reactions in organic solvents. These can be exploited in organic synthesis. Finally, as demonstrated in the synthesis of KDN, water-soluble compounds can be used as such without the need to be derivatized. There remain many challenges. The types of reactions for forming the carbon–carbon bond are still quite limited, and one would like to extend the scope of aqueous organometallic-type reactions. The mechanism of the reactions is far from having been established. Nevertheless, there is no doubt that organometallic-type reactions in aqueous media can play a useful role in organic synthesis.

The stereofacially differentiated enone ester **5** has been used to study the effects of steric influence on the Diels–Alder reaction. In general, under Lewis acid catalysis, **5** adds to dienes at low to ambient temperatures in a reasonable rate. Yields of predictable chiral adducts are moderate with the unexpected exception of zinc chloride catalyzed reactions, which provide good to high yields. In all cases only products of addition to the *Si* face of general type **21** were observed. The regiochemistry of the adducts is exclusively that predicted by the *ortho* and *para* rules. The stereochemistry shows a high selectivity in favor of ester-*endo* transition state products. Rationales for the observed stereoselectivities are discussed. The fragmentation of adducts of **5**, in particular keto ester **9**, has been briefly examined. Olefins **30** and **46** derived from **9** have been converted to ring-opened cadinane skeletons **31** and **47**, respectively, by conditions we have previously reported. In an entirely new and unexpected reaction, simultaneous ketalization and fragmentation of the cyclobutane ring of ketones derived from **9** gave ring-opened ketals **34** + **35** (from **29**), **36** + **37** (from **9**), **39** (from **38**) and **42** + **43** (from **40**).

HSING-JANG LIU, SEW YEU CHEW, ERIC N.C. BROWNE et JEUNG BEA KIM. Can. J. Chem. **72**, 1193 (1994).

On a utilisé l'énone ester **5** stéréofacialement différencié pour étudier les effets stériques sur la réaction de Diels–Alder. En général, dans des conditions de catalyse acide de Lewis, le composé **5** s'additionne aux dièmes à des vitesses raisonnables, à des températures ne dépassant pas la température ambiante. Les rendements des adduits chiraux attendus sont modérés, à l'exception notable des réactions catalysées par le chlorure de zinc qui donnent des rendements allant de bons à excellents. Dans tous les cas, on n'observe que les produits d'addition sur la face *Si*, de type général **21**. La régiochimie des produits est exclusivement celle que l'on peut prédire sur la base des règles *ortho* et *para*. La stéréochimie présente une grande sélectivité pour les produits formés par le biais de l'état de transition *endo* de l'ester. On a examiné brièvement la fragmentation des adduits du produit **5**, en particulier le céto ester **9**. Utilisant des conditions rapportées antérieurement, on a transformé les oléfines **30** et **46**, provenant du produit **9**, en squelettes des cadinanes à cycle ouvert **31** et **47** respectivement. Par une réaction aussi nouvelle qu'inattendue, une cétalisation et une fragmentation simultanée du noyau cyclobutane des cétones dérivés du produit **9** ont fourni les cétals à cycles ouverts **34** + **35** (à partir de **29**), **36** + **37** (à partir de **9**), **39** (à partir de **38**) et **42** + **43** (à partir de **40**).

[Traduit par la Rédaction]

Introduction

Lewis acids such as aluminum chloride, boron trifluoride, and stannic chloride produce large increases in the rate of Diels–Alder reactions (1). Furthermore, catalysis by Lewis acids also influences the regio- and stereoselectivity of Diels–Alder reactions so that the *ortho* (2–4) and *para* selectivity (5–7) of the addition as well as the *endo* selectivity (8–11) are greatly increased. On the other hand, Valenta and co-workers (12) reported a reversal of regioselectivity of Diels–Alder reactions of quinones catalyzed by Lewis acids. Previously it was assumed that in a Diels–Alder reaction Lewis acids that increase the regioselectivity would promote formation of the major thermal regioisomer. It now appears that this is not the case and the orientation of the product may depend on the specific Lewis acid used (13, 14).

Recently, extensive efforts have been made to induce asymmetry in carbon–carbon bond-forming reactions (15, 16). Among these, the asymmetric Diels–Alder reaction pioneered by Walborsky et al. (17, 18) has been established as an important method. In this pericyclic reaction as many as four chiral centers can be created simultaneously. Hypothetically, 16 stereoisomers can be produced at four new chiral centers, but high stereoselection can be attained with the aid of the elements that govern the stereochemical course of the reaction such as *cis* addition, *endo* addition, and diastereofacial selectivities. The majority of the work on asymmetric Diels–Alder reactions deals with optically active dienophiles[3] or dienes[4] that carry a removable chiral auxiliary group. Such intermediates typically undergo Diels–Alder reactions in the presence of a Lewis acid catalyst with diastereoselection exceeding 90% (for example, see ref. 25). They are devised in such a way that the chiral auxiliary group effectively blocks the *Re* face of the dienophile or diene and this induces high diastereofacial selectivity. But compared to the use of a covalently attached chiral auxiliary group, the use of a chiral catalyst is a potentially more attractive method to achieve asymmetric Diels–Alder reactions of prochiral dienes and dienophiles because two synthetic steps, attachment and removal of the chiral auxiliary, are avoided. Unfortunately, the attempted use of chiral Lewis acids (26–31) has given variable results. Only chiral titanium reagents (30, 31) give greater than 90% asymmetric induction.

In principle, the addition of substituted cyclohexenones to a substituted 1,3-butadiene is a versatile approach to decalin systems. However, the thermal cycloaddition of dienes to cyclohexenones requires drastic conditions and produces low yields of the adduct (32). In recent years greater understanding of the steric and electronic effects governing this reaction and the use of Lewis acid catalysts has led to the use of specifically functionalized dienes and dienophiles to produce previously unat-

tainable substitution patterns regio- and stereoselectively.[5] Wenkert and co-workers[6] have made an extensive study of the Diels–Alder reaction of cyclohexenones using aluminum chloride as a catalyst. Our group (14, 35–38) has carried out an intensive study of the Diels–Alder reactions of the 4,4-dimethyl-2-cyclohexen-1-ones **1–4**. These studies have shown that structural features in the dienophile, such as the presence of a cross-conjugated carbalkoxy group or additional double bond, and the nature of the Lewis acid strongly influence the regio- and stereoselectivity of the reaction. The results have been rationalized on the basis of steric and electronic effects on the relative stabilities of keto–*endo* and ester–*endo* transition states.

After examining the steric and electronic effects influencing the regiochemistry of Diels–Alder reactions of enone esters **1–4** we were interested in further investigating the steric influence on the diastereofacial selectivity of Diels–Alder reactions of enones. The stereofacially differentiated chiral dienophile **5** was chosen for this study. A series of Diels–Alder reactions of **5** and various dienes using different Lewis acid catalysts under different reaction conditions is described in the first part of this report.[7] This study shows that dienophile **5** can be a useful chiral reagent for Diels–Alder based synthetic schemes. In the second part of this report we briefly describe our initial examination of the fragmentation chemistry of adducts of **5** with the goal of generating the cadinane skeleton. The synthetic potential of dienophile **5** has been demonstrated by strategic application to the synthesis of chiral cadinane sesquiterpenes.[8]

Results and discussion

1. Diels–Alder reactions of enone ester 5

As this study was beginning, a single example of a Diels–Alder addition of a symmetrical diene to the corresponding ethyl ester of **5** was reported (40). However, that report did not explore the use of Lewis acid catalysis nor the influence of stereochemical and electronic factors on the addition. Enone ester **5** could be prepared in high yield from (−)-β-pinene (**6**)[9] in three steps (eq. [1]). (−)-β-Pinene has been used as an inexpensive chiral starting material for a number of chiral syntheses and for the preparation of chiral reagents (41–46). The preparation of (+)-nopinone (**7**) by ozonolysis of (−)-β-pinene has been frequently reported.[10] In our hands ozonolysis of (−)-β-pinene in a 1:1 mixture of dichloromethane–methanol followed by reduction of the products of ozonolysis with dimethyl sulfide gave (+)-nopinone (**7**)[11] in 78% yield. The carbomethoxy group was introduced by treating (+)-nopinone (**7**) with sodium hydride and dimethyl carbonate. Keto ester **8** identical to that previously reported (45) was obtained in 94% yield. The dehydrogenation

[5]For a recent review of Diels–Alder reactions of cycloalkenones see ref. 33.

[6]For the most recent paper in the series see ref. 34.

[7]Some of this work has been reported in a preliminary communication (39).

[8]The full synthetic application of dienophile **5** to natural product targets will be reported in a separate publication.

[9]Commercial (−)-β-pinene, which was obtained from the Aldrich Chemical Co., had an optical purity of 92%.

[10]For examples of ozonolysis of (−)-β-pinene see refs. 40, 43, 47, and 48.

[11]Problems in the synthesis of (+)-nopinone have been reported. In one case the attempted purification of (+)-nopinone by vacuum distillation resulted in an explosion (49). Similarly, allowing the concentrated reduction mixture to warm up from 0°C to room temperature also resulted in a violent explosion (50). Because of the risk of explosion we recommend that researchers exercise appropriate caution when attempting this synthesis. The conversion of **6** to **7** by an alternate method would be advantageous. A recent report accomplishes the conversion in reasonable yield by osmate dihydroxylation followed by oxidative cleavage (51, 52).

$ZnCl_2$	−20	21	95

[a]The major identified products of this reaction were **10** and **11**.

of keto ester **8** was carried out by the routine selenenylation/oxidative elimination method first developed by Reich et al. (53). Keto ester **8** was treated with phenylselenenyl chloride pyridine complex (54) in dichloromethane. The resulting selenide was oxidized with aqueous hydrogen peroxide to give the required enone ester **5** in 88% yield (65% overall from β-pinene).

A variety of conditions and Lewis acids, particularly boron trifluoride etherate, stannic chloride, and ferric chloride, were examined for the Diels–Alder reactions of enone ester **5**. These particular Lewis acids were chosen because we had previously observed that they were suitable as catalysts for related dienophiles (14, 38, 55, 56). However, it was found that in the present case these Lewis acids gave poor to moderate yields of Diels–Alder adducts (Table 1). In addition, the reaction of enone ester **5** with *trans*-piperylene catalyzed by stannic chloride and boron trifluoride etherate gave no Diels–Alder adduct and no starting material was recovered. To examine the cause of these poor yields, the stability of **5** and the adduct **9** under the various reaction conditions was examined. The adduct **9** in ether was treated with stannic chloride at room temperature and was found to remain intact even after 26 h. On the other hand, a mixture of **5** and stannic chloride in ether at room temperature rapidly decomposed. At −20°C, however, decomposition of the enone ester was not observed. Because of the demonstrated sensitivity of the dienophile to stannic chloride, the Diels–Alder reaction of **5** with isoprene using zinc chloride, a weaker Lewis acid, was investigated. Although the reaction was slower, a very high yield (95%) of adduct **9** was obtained. Consequently, in further investigations of the scope of Diels–Alder reactions of **5**, zinc chloride was used as the Lewis acid catalyst and good to high yields of adducts were obtained.[12] The results of this study are summarized in Table 2. Although it has been successfully used in Diels–Alder reactions (57–64), the striking superiority of zinc chloride as a catalyst in this series was unexpected. The yields of Diels–Alder adduct **9** formed with various Lewis acids were in the order of $Et_2AlCl < BF_3{\cdot}OEt_2 < FeCl_3 < SnCl_4 < ZnCl_2$, which was almost exactly opposite to the general order of Lewis acidity: $BX_3 > AlX_3 > FeX_3 > SbX_5 > SnX_4 > ZnX_2$ (65). This could be the result of greater stability of the strained ring system in the reactant and products to the relatively mild acid condition of zinc chloride catalysis than to the stronger Lewis acids examined.

In principle, Diels–Alder addition to enone ester **5** could occur from either the sterically more hindered *Re* face or the less hindered *Si* face to give stereochemically distinct products. However, only products of addition to the *Si* face of general type **21** were obtained (eq. [2]), as indicated by the stereochemistry of the ring junction of all the adducts. As expected, the *gem*-dimethyl group in **5** served to direct the Diels–Alder addition exclusively to the less hindered *Si* face. The structures of the adducts were established by spectroscopic methods including ^1H nmr, ^1H decoupling, and NOE experiments. The results of the NOE experiments are summarized in Table 3.

A. Addition to isoprene

The reaction of enone ester **5** with isoprene in ether under zinc chloride catalysis proceeded smoothly to give a single adduct in 95% yield. The spectral data of the adduct suggested that structure **9** could be assigned. However, orientational reversal in violation of the *para* rule in the Diels–Alder addition of isoprene has been observed (14, 36, 37). To rule out the possibility that the addition of isoprene to enone ester **5** could produce the regioisomeric keto ester **22**, extensive proton decoupling experiments were carried out and all the protons of the adduct were assigned. The signal due to the peri-deshielded

[12]The experimental procedure for zinc chloride catalyzed reactions was slightly different from the typical method for stannic chloride, ferric chloride, and boron trifluoride etherate. Zinc chloride is only slightly soluble in ether and requires a comparatively large amount of ether to dissolve it completely. To keep the initial concentration of **5** in the reaction mixture the same for all catalysts studied, the zinc chloride solution was introduced before the diene whereas for stannic chloride, ferric chloride, and boron trifluoride etherate catalyzed reactions the Lewis acid was introduced after the diene. The zinc chloride used in the Diels–Alder reactions was dried either by a flame or under vacuum before dissolving it in ether to make a clear solution. This ethereal zinc chloride solution was added to a solution of enone ester **5** at the stated temperature followed by the diene. When the zinc chloride solution was added, a thick white precipitate formed and the progress of the reaction was monitored by the disappearance of this precipitate. The formation of this precipitate was probably due to the formation of a complex between zinc chloride and **5**. Attempts to recrystallize this white precipitate were unsuccessful as it decomposed at room temperature or when it was exposed to air.

TABLE 2. Zinc chloride catalyzed Diels–Alder addition of dienes to enone ester **5**[a]

Entry	Diene (equiv.)	Temp (°C)	Time (h)	Product(s)	(ratio)	Yield (%)
1		–20	1.5	 **12** + **13**	(88:12)	59
2	(10)	–40	24		(91:9)	100
3		–20	109	 **14** + **15**	(86:14)	77
4[b]	(10)	–20	55		(100:0)	58
5	(20)	–20	41	 **16**		93
6	(20)	–20	88	 **17** + **18**	(81:19)	84[d]
7	(20)	–20	61	 **19** + **20**	(89:11)	53

[a]Unless otherwise specified, reactions were carried out in ether using 1 equiv. of zinc chloride.
[b]Two equivalents of zinc chloride were used.
[c]A 3:7 mixture of *cis*- and *trans*-3-methyl-1,3-pentadiene was used.
[d]Based on 76% consumption of starting enone ester **5**.

allylic C-4 equatorial methine proton (δ 3.05) was coupled to the C-5 vinylic proton (δ 5.48) with a normal vicinal coupling pattern (6 Hz). The regioisomeric adduct **22** would be expected to show a much smaller allylic coupling of the C-4 equatorial proton to the vinylic C-6 proton. Clearly, the observed coupling was consistent only with structure **9**.

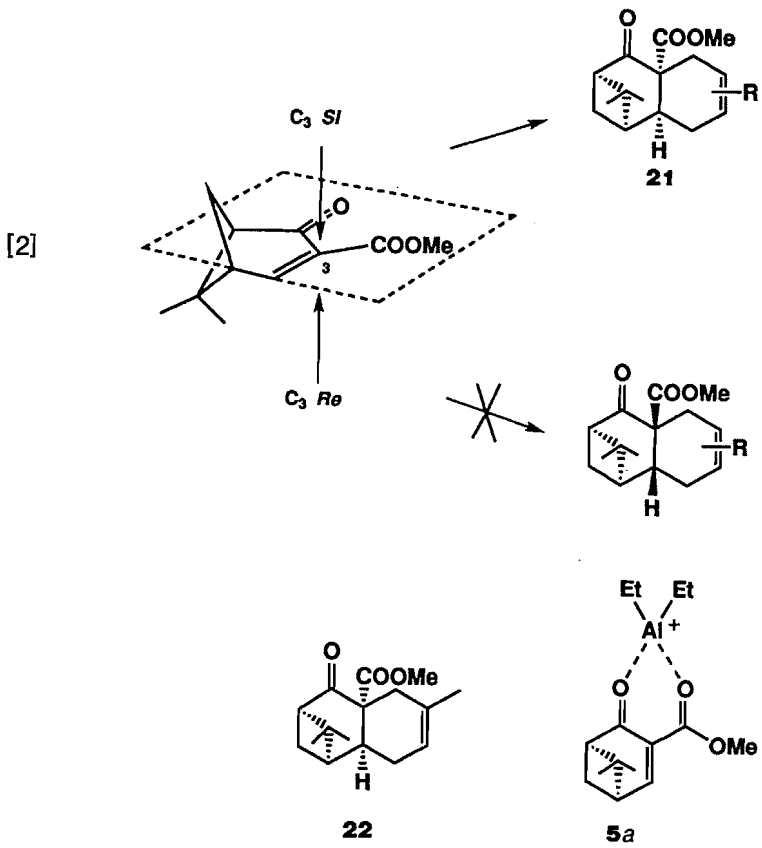
The stereochemistry of the ring junction was determined by NOE experiments. Irradiation of the methyl singlet at δ 0.97 resulted in enhancements of the ring junction C-8 proton (δ 3.20, 4.9%) and the methyl at δ 1.34 (3.1%), respectively. When the methyl at δ 1.34 was irradiated, NOE enhancements of the bridgehead C-1 proton (δ 2.66, 3.9%), bridge C-11$_{exo}$ proton (δ 2.47, 3.4%), bridgehead C-9 proton (δ 2.15, 3.2%), and the methyl at δ 0.97 (2.9%) were observed. This implied that the ring junction C-8 proton was on the same face as the *gem*-dimethyl group and therefore the addition of isoprene was to the *Si* face of **5**, giving adduct **9** with the C-8 proton in the α orientation. On the basis of the *cis* principle the adduct would be expected to have an α-carbomethoxy group. The regiochemistry and stereochemistry of adduct **9** has been further confirmed by its successful conversion to various cadinane sesquiterpenes.[8]

The Diels–Alder reaction of enone ester **5** with isoprene catalyzed by diethylaluminum chloride produced three identifiable compounds. The first two eluted were isolated as an inseparable 1:5 mixture. The minor component of this mixture was identical by ^{1}H nmr to **9**. The major component was readily identified as the 1,4-ethyl addition product **10**. The third product eluted was identified as chloro compound **11**. Compounds **10** and **11** were apparently formed by preferential 1,4-addition of an ethyl anion equivalent and isoprene, respectively, to the enone ester. Diethylaluminum chloride has been used as a catalyst in both Diels–Alder (22, 66, 67) and ene reactions (68, 69). In ene reactions the alkly group of diethylaluminum chloride can act as a nucleophile and add to aldehydes to give secondary alcohols (68). Thus the ethyl equivalent from the catalyst could add to enone ester **5** in a Michael fashion to give compound **10**. Evans et al. reported (22) that the influence exerted by diethylaluminum chloride is most likely attributed to the formation of a bidentate complex (such as **5***a*) with β-dicarbonyl groups. During the formation of this complex, free chloride would be liberated and the chloride could then trap the intermediate from the Friedel–Crafts type addition of isoprene to **5** to give **11**.

B. Addition to trans*-2-methyl-1,3-pentadiene*

The zinc chloride catalyzed Diels–Alder reaction of enone ester **5** with *trans*-2-methyl-1,3-pentadiene proceeded smoothly at −20°C to give a mixture of two separable adducts

Can. J. Chem. Downloaded from www.nrcresearchpress.com by EESC ESCOLA DE ENGENHARIA on 09/08/12
For personal use only.



(88:12) in 59% combined yield. If the Diels–Alder reaction obeyed the normal *ortho* and *para* rules, then structures **12** and **13** could be tentatively assigned to the two adducts on the basis of their spectral data. To conclusively determine the regiochemistry of the adducts, extensive proton decoupling experiments were carried out on the major isomer and a complete spectral assignment was made.

The ring junction C-8 proton (δ 2.94), which appeared as a dddd, was coupled to C-7_{ax} (7.5 Hz), C-7_{eq} (7.5 Hz), C-9 (2 Hz), and C-11_{exo} (W-coupling, 2 Hz) protons. This coupling pattern indicated that two hydrogens were attached to C-7, a feature which was also observed in adduct **9** in which there was no substituent at C-7. Consequently the methyl substituent could only be located at C-4. The regiochemistry of the minor isomer was assigned in the same manner on the basis of its ^{1}H nmr spectrum, which also showed a dddd (6, 6, 1.5, 1.5 Hz) for the C-8 proton (δ 3.25).

The relative stereochemistry of adducts **12** and **13** remained to be determined. The two adducts could be epimers as a result of diastereoselective addition to **5** by both the keto-*endo* and ester-*endo* routes. On the other hand, they could be diastereomers resulting from the nonspecific addition of the diene to the *Re* and *Si* face of the enone ester. The conclusive assignment of stereochemistry was determined by NOE experiments. Irradiation of the *endo* methyl (δ 0.89) of the minor isomer resulted in enhancement of the C-8 proton (δ 3.25, 5.6%). Similarly saturation of the *endo* methyl (δ 0.90) of the major isomer gave enhancement of the C-8 proton (6.8%). This indicated that both isomers had the same relative stereochemistry of the bridge and ring junction. The addition of *trans*-2-methyl-1,3-pentadiene must have occurred exclusively from the *Si* face, and adducts **12** and **13** were therefore epimeric at C-4. Irradiation of the C-4 methyl doublet (δ 1.26) of the major isomer resulted in enhancement of C-5 (δ 5.19, 4.6%) and C-4 (δ 2.46, 3.6%) protons while saturation of the C-4 methyl doublet (δ 1.04) of the minor isomer gave enhancement of C-4 (δ 3.16, 8.5%) and C-11_{endo} (δ 1.87, 4.6%) protons, respectively. This experiment showed that the C-4 methyl of the minor isomer was on the same face as the bridge methylene group and so the minor isomer must have structure **13**. As well, the stereochemistry of the major adduct must be that depicted by structure **12**.

When the zinc chloride catalyzed reaction of **5** and *trans*-2-methyl-1,3-pentadiene was carried out at −40°C a slight increase in stereoselectivity in favor of **13** was observed and the combined yield of isolated adducts improved dramatically from 59% to 100%.

C. Addition of trans-*piperylene*

When an ether solution of enone ester **5** was reacted with *trans*-piperylene at −20°C using zinc chloride catalysis two separable adducts in a ratio of 86:14 were obtained in 77% combined yield. If the Diels–Alder reaction obeyed the normal *ortho* rule then the structures of the adducts could tentatively be assigned as **14** and **15**. Previous examples in this series indicated that the multiplicity and coupling pattern of the ring junction C-8 proton could be used to determine the regiochemistry of the Diels–Alder adducts of the 1-substituted dienes. Detailed proton decoupling experiments on the major isomer showed that irradiation of the C-8 proton dddd (δ 2.90) led to simplification of the signals for protons at C-11_{exo} (δ 2.46), C-7_{eq} (2.40), C-9 (2.11), and C-7_{ax} (1.92). When the signal for the C-9 proton (δ 2.11) was irradiated the multiplicity of the signal for the C-8 proton (δ 2.90) changed from dddd to ddd. Also irradiation of the C-7_{ax} proton (δ 1.92) resulted in simplification of

the signal for the proton at C-8 (δ 2.90). Similarly, ^{1}H nmr of the minor isomer also showed the proton at C-8 (δ 3.25) as a dddd (6.5, 6.5, 1.5, 1.5 Hz). As with the previous examples, this coupling pattern indicated that two hydrogens were attached at C-7 and consequently the methyl substituent had to be at C-4. This confirmed the regiochemistry of the Diels–Alder adducts shown by structures **14** and **15**.

To determine the stereochemistry of the ring junction and the C-4 methyl, NOE experiments were carried out. When the *endo* methyl (δ 0.94) of the major isomer was irradiated, enhancement of the signal for the C-8 proton (δ 2.90, 5.7%) was observed. Similarly, irradiation of the *endo* methyl (δ 0.90) of the minor isomer resulted in enhancement of the C-8 proton (δ 3.25, 5.3%). This indicated that the C-8 proton of both isomers was on the same face as the *gem*-dimethyl group and therefore addition of diene occurred at the *Si* face of enone ester **5** and the two isomers were epimers. The carbomethoxy group was assigned in accordance with the *cis* principle. When the C-4 methyl signal (δ 1.06) of the minor isomer was irradiated, NOE enhancements on protons at C-4 (δ 3.22, 8.7%) and C-11_{endo} (δ 1.86, 4.0%) were observed. On the other hand, saturation of the C-4 methyl signal (δ 1.30) of the major isomer resulted in enhancements on protons at C-4 (δ 2.46, 4.7%) and C-5 (δ 5.56, 4.7%). This evidence unambiguously fixed the stereochemistry of the substituents of the major isomer as specified by structure **14** and of the minor isomer as **15**.

When two equivalents of zinc chloride were used in the Diels–Alder reaction of enone ester **5** and *trans*-piperylene, only adduct **14** was obtained in a shorter time but in lower yield of 58%.

D. Addition to 2,3-dimethylbutadiene

Enone ester **5** reacted with 2,3-dimethylbutadiene using zinc chloride as a catalyst to give a single adduct in 93% yield. The spectral data were consistent with the expected product **16**. As in the preceding cases the stereochemistry was determined on the basis of the *cis* principle and by an NOE experiment. Irradiation of the *endo* methyl (δ 0.96) resulted in NOE enhancement of the proton at C-8 (δ 3.18, 8.7%) and the *exo* methyl (δ 1.34, 3.7%). This confirmed the assignment of the stereochemistry of **16** as shown.

E. Addition to 3-methyl-1,3-pentadiene

The zinc chloride catalyzed addition of a commercial 7:3 mixture of isomers of 3-methyl-1,3-pentadiene[13] to enone ester **5** gave a mixture (81:19) of two separable isomeric adducts in 84% combined yield (based on 76% conversion). If the Diels–Alder reaction followed the normal *ortho* rule then the structures of the adducts could be tentatively assigned as keto esters **17** and **18**. The regiochemistry of both adducts was confirmed after examination of the ^{1}H nmr spectra and extensive proton decoupling experiments on the minor isomer. The signal at δ 3.28 due to the C-8 proton of the minor isomer appeared as a dddd (11, 7.5, 2, 2 Hz), which was coupled to protons at C-7_{ax} (11 Hz), C-7_{eq} (7 Hz), C-9 (2 Hz), and C-11_{exo} (W-coupling, 2 Hz). The C-8 proton (δ 3.06) of the major isomer also showed a dddd splitting (8, 6, 1.5, and 1.5 Hz). In addition the C-4 proton (δ 3.04) of the minor adduct appeared as a quartet (7.5 Hz) while the C-4 proton (δ 2.73) of the major adduct appeared as a broad quartet (7 Hz). In each case this indicated the presence of two protons at C-7. The methyl substituent must then be at C-4 and the vinylic methyl substituent must be at C-5.

[13]The diene used in this study was obtained from Aldrich Chemical Co. as a mixture of *trans* and *cis* isomers. The ratio of this mixture was determined by ^{1}H nmr to be 7:3. Comparison of the ^{1}H nmr spectrum of this mixture to those of *trans*-piperylene and *cis*-piperylene clearly showed that the major isomer was *trans*-3-methyl-1,3-pentadiene.

Evidence of the ring junction and C-4 stereochemistry of both adducts was obtained from NOE experiments. Irradiation of the *endo* methyl (δ 0.93) of the major adduct resulted in enhancement of the C-8 proton (δ 3.06, 5.9%) and saturation of the C-4 methyl (δ 1.23) gave enhancement of the C-4 proton (δ 2.73, 6%). When the *endo* methyl (δ 0.82) of the minor isomer was irradiated, enhancement was observed on the proton at C-8 (δ 3.23, 4.0%) and when the C-4 methyl (δ 1.00) was saturated, enhancements on proton at C-4 (δ 3.04, 8.4%) and C-11_{endo} (δ 2.43, 3.8%) were observed. On the basis of the *cis* principle and these NOE experiments, the stereochemistry of the major and minor adducts was established as that of structures **17** and **18**, respectively. Again this indicated that complete diastereofacial selectivity was achieved and the addition of diene was to the *Si* face of enone ester **5**.

F. Addition of cyclopentadiene

The zinc chloride catalyzed addition of cyclopentadiene to enone ester **5** produced an inseparable mixture of two adducts (89:11 ratio) in 53% yield. Preliminary analysis of the spectra indicated that the adducts obtained were **19** and **20**. Extensive proton decoupling experiments on the major isomer led to assignment of all its protons. Irradiation of the protons at C-7 (δ 2.76) and C-9 (δ 2.42) led to a small change in the multiplicity of the ring junction C-8 signal (δ 2.61). When the *endo* methyl (δ 0.92) of the major isomer was irradiated in an NOE experiment the C-8 proton signal (δ 2.61, 3.0%) was enhanced. On the basis of the *cis* principle and this observation, the major isomer was assigned with the C-8 proton and the carbomethoxy group in the α orientation. Previous observations indicated that the addition of dienes to enone ester **5** occurred exclusively from the *Si* face of **5** and it was expected that exclusive addition to the *Si* face of **5** would also occur for cyclopentadiene. If so, the minor isomer would also contain the same stereochemistry for the C-8 proton and the carbomethoxy group. The stereochemistry of the methylene bridge on the bicyclo[2.2.1]heptene ring system was determined by comparing the difference in chemical shift between the two vinylic protons with the known compounds **23** and **24**.[14] Since the major isomer exhibited a larger difference in chemical shift between the two vinylic protons (Δδ 0.48) than the minor isomer (Δδ 0.17), it was assigned structure **19** while the minor isomer was assigned structure **20**.

G. endo *Selectivities of the addition*

The results summarized in Table 2 show that the addition of dienes to enone ester **5** occurred in moderate to very high diastereomeric excess (62–100%). As we have described for other related dienophiles (14, 55, 56), there are in fact two dienophilic components in enone ester **5**: the unsaturated ketone (**5***b*) and the unsaturated ester (**5***c*) moieties. Normally it would not be necessary to distinguish between these two moieties except in certain cases where the diene substituents at C-1 or C-4 are not identical. In those cases *endo* addition to the enone or to the unsaturated ester moiety of **5** would give stereochemically distinguishable products. The factors determining which dienophilic moiety would dominate the reaction pathway are expected to be a function of the most effective secondary orbital overlap with the diene. We found that addition of 1-substituted dienes (Table 2, Entries 1–4, 6, and 7) to enone ester **5** occurs predominantly with secondary overlap of the ester group (ester-*endo* transition state **25**) rather than of the ketone carbonyl (keto-*endo* transition state **26**). This stereoselectivity in favor of the ester-*endo* transition state may be due to combined electronic and steric effects.

Comparison of the two transiton states indicates that addition via transition state **26** should encounter significant steric interaction between the diene and the methylene bridge of the dienophile. For example, keto ester **13** would be the result of addition via transition state **26***a* while keto ester **12** would result from addition via transition state **25***a*. The preferential formation of adduct **12** can be attributed at least in part to the destabilization of transition state **26***a* by a steric interaction of the diene with the methylene bridge of the dienophile. On the other hand, addition via transition state **25***a*, allowing preferential secondary orbital interaction with the ester carbonyl, would eliminate this steric interaction. Similarly, addition of the other C-1 substituted dienes in this study also must have occurred preferentially by transition states of type **25**.

H. Optical purity

The (−)-β-pinene used to prepare enone ester **5** was 92% optically pure. After having demonstrated the Diels–Alder reaction of enone ester **5**, the optical purity of the Diels–Alder adducts was examined. Optically active nmr shift reagents such as $Eu(hfc)_3$ have been used to evaluate the optical yield of reactions (70, 71). The direct application of $Eu(hfc)_3$ to adduct **9** showed separation of the signals for the methoxy group (δ 3.75) and the vinylic methyl (δ 1.72). The chemical shift difference (Δδ) increased with an increase in the amount of the shift reagent $Eu(hfc)_3$ added. In all experiments the integral of the split signals was consistently in the ratio of 96:4. Thus the optical purity of the starting material (92%) was retained in the Diels–Alder adducts. The enantiomeric set of adducts that would be obtained from the relatively unavailable enantiomeric (+)-β-pinene can nevertheless be prepared relatively easily using the conversion of (+)-α-pinene to (−)-nopinone reported by Lavallee and Bouthillier (72). The (−)-nopinone so obtained would provide the (−)-enantiomer of **5** by the method we have described.

2. Cyclobutane ring fragmentation reactions

Having successfully generated various Diels–Alder adducts of enone ester **5**, we wished to demonstrate its utility in the synthesis of natural products. The carbon skeleton of cadinane sesquiterpenes can be readily obtained from adduct **9** by cleavage of the cyclobutane ring system (eq. [3]). The first requirement of such a plan would be to selectively open the cyclobutane ring. The results of our preliminary investigation of these ring opening reactions are summarized in Scheme 1. A number of methods have been reported for fragmentation of the cyclobutane ring system of pinene derivatives (40, 44, 73, 74). Our group (75) has reported the fragmentation of pinenes to limonene derivatives using dimethyl sulfoxide activated by phenyl dichlorophosphate. To apply this method, the transformation of **9** to **27** by a Wittig reaction was attempted. Unfortunately the starting material was recovered unchanged. The failure of the Wittig reaction is probably due to steric hindrance at the ketone carbonyl by the neighbouring groups. Removal of the carbomethoxy group prior to the Wittig reaction could reduce any such hindrance.

Thus treatment of **9** with lithium iodide monohydrate in 2,4,6-collidine under reflux for 2.3 h gave two chromatographically separable products (1:9 ratio, 97% combined yield). The

isomers were easily identified by their spectral data as the epimeric pair of ketones **28** and **29**. Conclusive assignment of the ring junction stereochemistry in each isomer was determined from NOE and proton decoupling experiments. Extensive proton decoupling of the less polar minor isomer resulted in the assignment of all protons. The ring junction C-8 proton (δ 2.30) appeared as a multiplet that was simplified when the C-11_{exo} (δ 2.47), C-9 (δ 2.06), and C-7 (δ 1.99) protons were irradiated individually. Irradiation of the C-1 (δ 2.58) and C-4_{ax} (δ 1.82) protons led to changes of the C-3 proton signal (δ 2.36) indicating a long-range W-coupling between the C-1 and C-3 protons. In an NOE experiment, irradiation of the *endo* methyl (δ 0.91) resulted in enhancement of the C-3 (5.5%) and C-8 (5.5%) protons. The simultaneous NOE enhancement of those protons indicated that the minor isomer has *cis*-fused structure **28**. Thus the major isomer was assigned *trans*-fused structure **29**. In final confirmation of the stereochemistry at C-3, the minor isomer **28** was epimerized with sodium hydroxide in aqueous methanol. A 1:9 mixture of **28** and **29** was obtained in 92% yield.

Transformation of *trans*-fused ketone **29** to *exo*-methylene derivative **30** was accomplished by a modification of the Wittig reaction developed by Corey and co-workers (76). Treatment of **29** with methylenetriphenylphosphorane at room temperature for 20 h gave **30** in 99% yield. Compound **30** was added to a mixture of dimethyl sulfoxide and phenyl dichlorophosphate at −40°C and stirred for 1 h. The mixture was warmed to 10°C and, after distillation,[15] a pale yellow solid with a melting point of 40–41°C was obtained in 56% yield. The spectral data indicated structure **31** for the product. The stereochemistry was presumed to have remained unchanged as no epimer was isolated. We have rationalized the formation of **31** as outlined in eq. [4]. Complex **32** (77), which results from the interaction of dimethyl sulfoxide and phenyl dichlorophosphate, would serve as an electrophile. Selective electrophilic attack on the exocyclic double bond would induce cleavage of the cyclobutane ring and deprotonation. The resulting allylic sulfonium ion would then be readily displaced by chloride to give the product **31**.

The easy rearrangement of **30** to **31** provides a useful route to the cadinane sesquiterpenes. However, since **31** contains three double bonds, this might contribute to problems in selectively functionalizing a particular double bond in later stages of a planned synthetic sequence. Thus in an attempt to reduce the trisubstituted double bond **29** was reacted with excess borane in tetrahydrofuran followed by the addition of hydrogen peroxide. A mixture of two isomeric alcohols identified as **33** (1:2 ratio, quantitative yield) was obtained in which both the double bond and the ketone carbonyl were attacked.

To prevent the undesired over-reduction, the ketone clearly required protection prior to hydroboration. Routine ketalization of **29** with *p*-toluenesulfonic acid and ethylene glycol in refluxing benzene (Dean–Stark apparatus) surprisingly gave an inseparable mixture of two fragmentation products **34** and **35** (2:1 ratio) in 81% yield. The stereochemistry of the ring junction was presumed to be the usually thermodynamically more stable *trans* configuration. Epimerization at C-7 was not expected since migration of the double bond was not observed. Migration of the endocyclic double bond during ketalization of a decalin system is not unprecedented (78) and so the products were tentatively assigned structures **34** and **35**. It has been reported (79)

[15]Purification by distillation gave more product than the yield obtained using flash chromatography (36%).

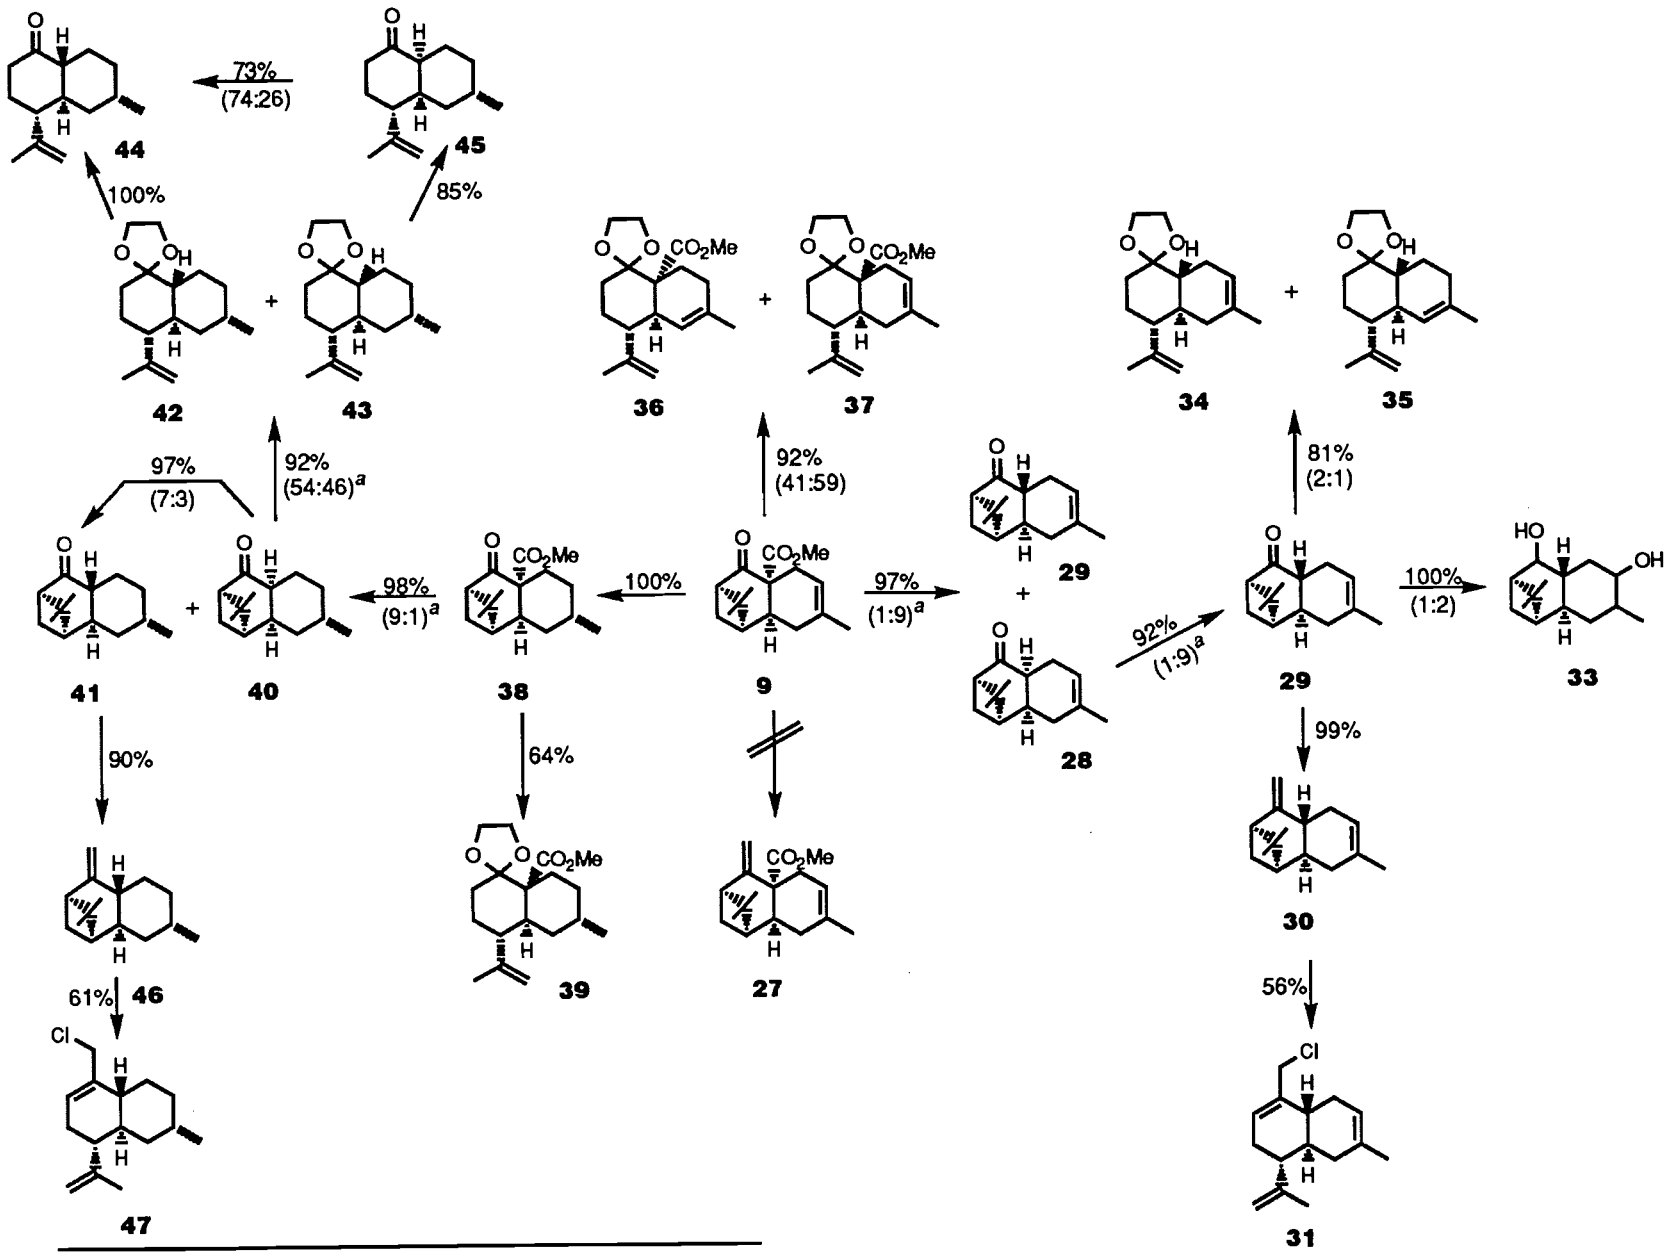
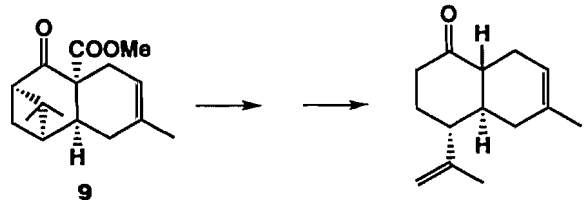
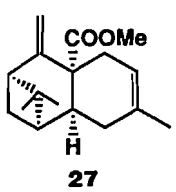
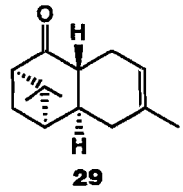


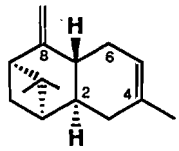
SCHEME 1. Cyclobutane ring fragmentation reactions.

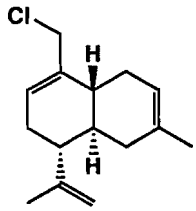
[3]

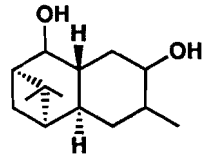




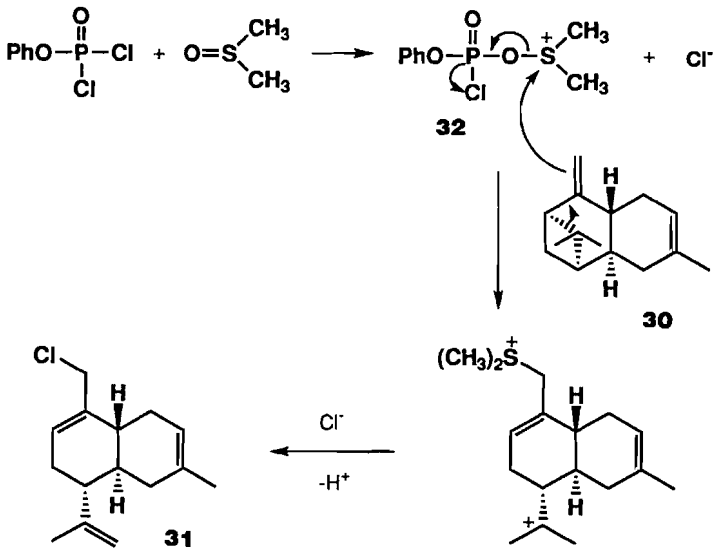








[4]



that ^{1}H nmr data can be used to differentiate between the *cis* and *trans*-fused pairs of $\Delta^{4,5}$-cadinenes. In the *cis*-fused compounds there is a significant coupling between the olefinic proton and the ring junction C-6 proton whereas in the *trans* isomers there is little or no coupling between these two protons. The only coupling constant of 1.5 Hz (q) observed for the C-5 proton of **35** is most likely due to long-range coupling with the vinylic methyl group since the dihedral angle between C-5 and C-6 protons is about 90°. This further supports our assignment of a *trans* ring junction to **35** and, by inference, to **34**.

Having discovered this somewhat unexpected ring-opening reaction we undertook an investigation of the reaction with various other substrates. Ketalization–fragmentation of **9** gave the inseparable double bond isomeric ring cleavage products **36** and **37** (41:59 ratio, 92% yield based on 46% consumed starting material). The reaction was slow due to the more sterically hindered ketone carbonyl.

To obtain a clean product of the ring cleavage reactin for unambiguous identification without the complication caused by isomeric mixtures of products from migration of the double bond, the trisubstituted double bond of **9** was hydrogenated on platinum oxide. After filtration and concentration a quantitative yield of **38** was obtained. Extensive ^{1}H decoupling on **38** allowed all the protons to be assigned. Most of the signals for protons in the cyclohexane ring were close together, which unfortunately obscured the results of NOE experiments. We

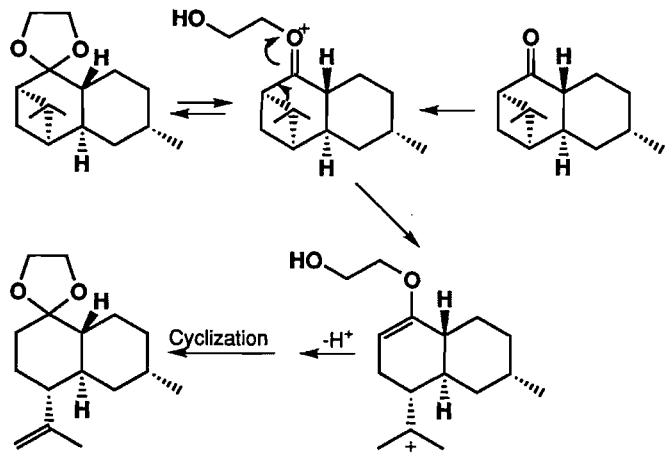
[5]



have presumed, after examination of a molecular model of **9**, that the addition of hydrogen would occur from the less hindered face opposite to the carbomethoxy group. In this case **38** would then have an α-methyl on C-6.

Using the same ring ketalization–fragmentation conditions used on **29** and **9**, keto ester **38** was converted to a single compound **39** (64% yield based on 30% consumed starting material). The ketalization–fragmentation of **38** proceeded very slowly (100 h) with only 30% conversion of starting material, probably due to steric hindrance at the ketone carbonyl by the carbomethoxy group. To facilitate the fragmentation, the hindering carbomethoxy group was removed. Treatment of **38** with lithium iodide monohydrate in refluxing 2,4,6-collidine gave two chromatographically separable ketones (1:9) in virtually quantitative yield. From the spectral data the two decarbomethoxylated compounds were assigned structures **40** and **41**. The ring junction stereochemistry was confirmed by epimerization. The minor isomer was treated with sodium hydroxide in aqueous methanol to give an equilibrium 3:7 mixture of the minor and major isomers in 97% yield. Thus the minor and major isomers could be assigned structures **40** and **41**, respectively.

Ketone **40** was then subjected to the ketalization–fragmentation reaction to give chromatographically separable ketals **42** and **43** (54:46) in 92% yield. The spectral data confirmed the assignment of structures **42** and **43** to the ketals. To prove the ring junction stereochemistry, both ketals were hydrolyzed. Treatment of **42** with *p*-toluenesulfonic acid in refluxing aqueous acetone gave ketone **44** in quantitative yield. When ketal **43** was similarly treated, ketone **45** was obtained in 85% yield. Extensive ^{1}H decoupling experiments on ketone **45** allowed assignment of all the cyclohexanone protons. The ring junction C-1 proton at δ 2.40 had a W-coupling of 1 Hz to the C-3 equatorial proton at δ 2.28. Examination of a molecular model shows that ketone **45** would have conformation **45***a* in which a long-range W-coupling between the C-1 and C-3$_{eq}$ protons would be expected in the ^{1}H nmr spectrum. On the other hand, such a W-coupling would not be expected in **44***a*. To fully confirm the ring junction stereochemistry, ketone **45** was epimerized with sodium hydroxide in aqueous methanol to give an equilibrium mixture (74:26) of **44** and **45** in 73% yield. Thus C-1 of ketal **42** was assigned with a β-oriented hydrogen and the C-1 hydrogen of **43** was α-oriented.

This new fragmentation reaction employing *p*-toluenesulfonic acid and ethylene glycol gave clean products in high yields. Significantly, under this mild reaction condition no epimerization of the C-5 stereogenic center was observed. We were interested in determining a possible mechanism for this reaction. An investigation was made to determine if fragmentation occurred without the presence of ethylene glycol. Treatment of **40** with *p*-toluenesulfonic acid in refluxing benzene for 41 h resulted in the formation of a complex mixture. Six spots, including the starting material, were observed by thin-layer chromatography. This indicated that ethylene glycol was essential for the fragmentation to occur cleanly. Based on this, a plausible mechanism for the fragmentation reaction is shown in eq. [5].

Since the fragmentation reaction of **30** with phenyl dichlorophosphate and dimethyl sulfoxide gave only a moderate (56%) yield of the fragmentation product **31**, this fragmentation was also applied to **46** to see if the yield would be improved. Wittig reaction of ketone **41** with methylenetriphenylphosphorane gave **46** in 90% yield. Compound **46** was then treated with phenyl dichlorophosphate and dimethyl sulfoxide. After purification, compound **47** was obtained in 61% yield. Since **30** and **46** gave almost the same yield of fragmentation products it seems likely that the trisubsituted double bond in **30** does not affect the yield of the fragmentation reaction.

Conclusion

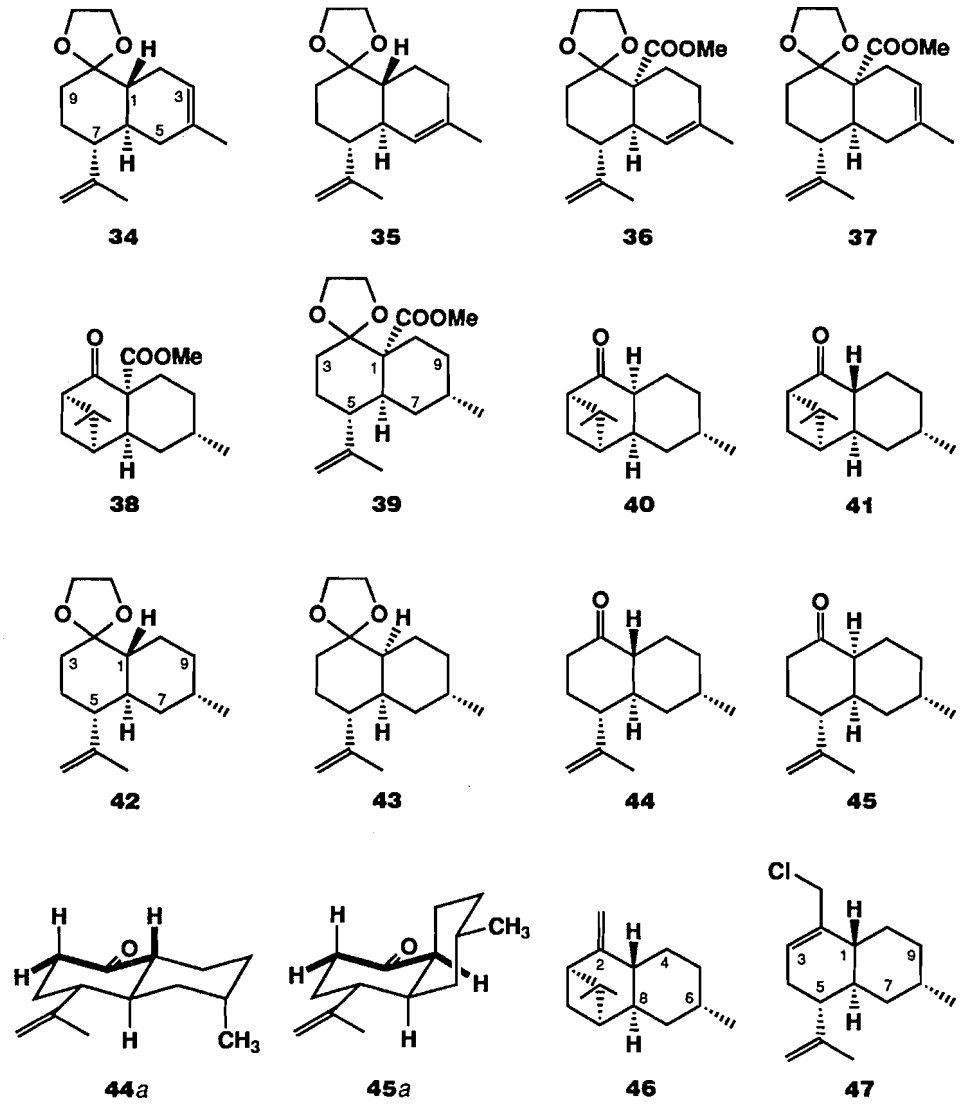
The Diels–Alder reactions of enone ester **5** with various dienes provided good to high yields of chiral adducts with complete diastereofacial selectivity in 62–100% diastereomeric excess. The observed regiochemistry was as predicted by the *ortho* and *para* rules. We have shown that enone ester **5** is a new versatile intermediate and, in addition, that it is a useful chiral synthon for synthetic chemists. The new and established fragmentation reactions described provide useful access to cadinane and related skeletons. We will report on wider use of these adducts and fragmentations and their application to the synthesis of natural products in a future publication.[8]

Experimental

General

All melting points were determined on a Kofler hot stage apparatus and are uncorrected. Elemental analyses were performed by the microanalytical laboratory of this department. Infrared spectra (ir) were recorded on a Perkin–Elmer model 457 or Nicolet 7-119 FT-IR spectrometer and were obtained in chloroform cast unless otherwise stated. High-resolution mass spectra (ms) were obtained using a Kra-

Can. J. Chem. Downloaded from www.nrcresearchpress.com by EESC ESCOLA DE ENGENHARIA on 09/08/12
For personal use only.



tos AEI MS-50 high-resolution mass spectrometer. Chemical ionization mass spectra (cims) were obtained using an AEI MS-12 mass spectrometer with ammonia as the reagent gas. Proton nuclear magnetic resonance spectra (^{1}H nmr) were recorded on Bruker AM-300 (300 MHz) or AM-400 (400 MHz) spectrometers and were obtained from solutions in deuteriochloroform using tetramethylsilane (TMS) as an internal reference. Coupling constants are reported to within ±0.5 Hz. Chemical shift measurements are reported in ppm downfield from TMS in delta (δ) units. The following abbreviations were used: s = singlet, d = doublet, t = triplet, q = quartet, m = multiplet, ax = axial, eq = equatorial. Carbon-13 nuclear magnetic resonance spectra (^{13}C nmr) were recorded on a Bruker AM-300 (75 MHz) spectrometer from solutions in deuteriochloroform. Carbon-13 multiplicities were derived from off-resonance or the APT (Attached Proton Test) experiment. Methyl and methine groups were shown as signals possessing opposite phase (a) with respect to the deuteriochloroform signal whereas methylene groups, quaternary carbon atoms, and carbonyl groups appeared in phase (p) with it. Nuclear Overhauser Enhancement (NOE) experiments were determined in the difference mode in which a control spectrum was computer-subtracted from the irradiated spectrum after Fourier transformation. Positive enhancements were defined as signals possessing antiphase with respect to the irradiated signal. Samples for NOE measurements were deoxygenated with argon gas for 5–10 min. Optical rotations were determined in a Perkin–Elmer 241 polarimeter. Specific rotation ($[\alpha]_D$) was reported in degrees at the specified temperature and concentration (*c*) was given in g/100 mL in the specified solvent.

All reactions were carried out under a slight positive pressure of argon gas. Argon was passed through a column of 4A molecular sieves and self-indicating silica gel. All reactions were monitored by analytical thin-layer chromatography (tlc) on silica gel. Visualization of the chromatograms was completed either by dipping in an ethanol solution of vanillin (5% w/v) or an aqueous solution of phosphomolybdic acid (3% w/v). Solvents were removed under reduced pressure on a rotary evaporator. Purification and separation of product mixtures were carried out using flash chromatography (80) on silica gel (230–400 mesh).

Materials

The anhydrous solvents used were distilled under an argon atmosphere. Diethyl ether, tetrahydrofuran (THF), and 1,2-dimethoxyethane (DME) were dried with sodium and benzophenone. Dichloromethane, pyridine, and dimethyl sulfoxide (DMSO) were distilled from calcium hydride. Benzene was distilled from lithium aluminium hydride. Anhydrous zinc chloride was fused or vacuum dried before use. Unless otherwise stated, anhydrous magnesium sulfate was used for drying organic solutions.

(1R,5S)-(+)-6,6-Dimethylbicyclo[3.1.1]heptan-2-one ((+)-nopinone) (7)

WARNING: *See footnote 11.* At −78°C ozone was passed through

a solution of (1*S*,5*S*)-(−)-β-pinene (**6**) (39.17 g, 0.288 mol) in methylene chloride – methanol (1:1, 386 mL). After 6 h a persistent blue color appeared and the reaction was stopped. Excess ozone was purged with oxygen for 10 min and dimethyl sulfide (25.3 mL) was added to the reaction mixture at −78°C. The mixture was stirred overnight at room temperature and the solvent was removed under reduced pressure on a rotary evaporator. Flash chromatography of the residue eluting with 0–10% ether in petroleum ether gave pure **7** (24.294 g) as a colorless oil and also impure **7** (ca. 10 g). The impure product was chromatographed again to give additional **7** (6.608 g, total yield 30.902 g, 0.244 mol, 78% yield): $[\alpha]_D^{23}$ +16.5 (neat);[16] ir: 1715 (C=O) cm^{-1}; ^1H nmr (300 MHz) δ: 2.48–2.66 (complex, 3H), 2.34 (ddd, 1H, *J* = 19, 9, 2.5 Hz, C-3 *H*α), 2.24 (m, 1H), 1.88–2.12 (complex, 2H), 1.59 (d, 1H, *J* = 10 Hz), 1.33 (s, 3H, *exo* CH_3), 0.85 (s, 3H, *endo* CH_3); ^{13}C nmr δ: 214.9 (C=O), 58.0 (*C*HC=O), 41.2 (*C*Me$_2$), 40.4 (*C*HCMe$_2$), 32.8 (*C*H$_2$C=O), 25.9 (*exo* CH_3), 25.2 (CH_2), 22.1 (*endo* CH_3), 21.4 (CH_2); ms M^+: 138.1046 (calcd. for $C_9H_{14}O$: 138.1045).

*(1R,5R)-3-Carbomethoxy-6,6-dimethylbicyclo[3.1.1]heptan-2-one (**8**)*

Sodium hydride (80% dispersion in oil, 4.038 g, 0.168 mol, washed with petroleum ether and DME) was suspended in DME (60 mL) under argon. Dimethyl carbonate (30.280 g, 0.336 mol) was added and the suspension was heated under reflux while stirring with a mechanical stirrer. A solution of (+)-nopinone (**7**) (9.293 g, 0.0673 mol) in DME (22 mL) was added dropwise. Heating was continued for 6 h and the mixture was then cooled to 0°C. An aqueous 10% solution of acetic acid was then added with stirring until the solution was acidic. The mixture was extracted with ether (3 × 70 mL). The extracts were washed with water, saturated aqueous sodium bicarbonate, water, and saturated aqueous sodium chloride, and then were dried, filtered, and concentrated. Flash chromatography of the residue eluting with 0–4% ether in petroleum ether gave keto ester **8** (12.410 g, 0.063 mol, 94% yield) as a light yellow liquid that crystallized on standing. This compound existed as a 1:1:2 mixture of enol and epimeric β-keto esters: ir: 1739 (ester, C=O), 1704 (ketone, C=O) cm^{-1}; ^1H nmr (300 MHz) δ: 11.94 (br s, C=CO*H*, enol), 3.77, 3.76, 3.61 (each s, OCH_3), 1.35, 1.33 (each s, *exo* CH_3), 0.95, 0.88, 0.87 (each s, *endo* CH_3); ms M^+: 196.1105 (calcd. for $C_{11}H_{16}O_3$: 196.1100). *(1R,5R)-(+)-3-Carbomethoxy-6,6-dimethylbicyclo[3.1.1]hept-3-en-2-one (**5**)*

Pyridine (1.39 mL, 0.0172 mol) was added to a solution of phenylselenenyl chloride (3.70 g, 0.0193 mol) in dichloromethane (99.7 mL) at 0°C under argon. After stirring for 10 min keto ester **8** (3.07 g, 0.0157 mol) in dichloromethane (15.5 mL) was added. After 4 h the reaction mixture was washed with aqueous 1 M hydrochloric acid (2 × 50 mL). The organic solution was cooled to 0°C and aqueous 30% hydrogen peroxide solution (1.7 mL) was added. After stirring for 10 min additional aqueous 30% hydrogen peroxide (1.7 mL) was added. After 1 h aqueous sodium bisulfite solution (50 mL) was added and the layers were separated. The organic layer was washed with saturated aqueous sodium bicarbonate, dried, filtered, and concentrated. Flash chromatography of the residue eluting with 2–30% ether in petroleum ether gave **5** (2.680 g, 0.0138 mol, 88% yield) as a colorless oil: $[\alpha]_D^{23}$ +229.83 (*c* 1.15, $CHCl_3$); ir: 1747, 1714, 1698 (C=O) cm^{-1}; ^1H nmr (300 MHz) δ: 8.40 (dd, *J* = 6, 1.5 Hz, 1H, =C*H*), 3.84 (s, 3H, OCH_3), 2.77–2.93 (complex, 3H), 2.14 (d, 1H, *J* = 9 Hz, O=CCHC*H*$_{endo}$), 1.54 (s, 3H, *exo* CH_3), 1.04 (s, 3H, *endo* CH_3); ^{13}C nmr δ: 197.8 (C=O), 165.6 (=CH), 164.1 (OC=O), 127.9 (=C), 58.8 (CH), 54.8 (C), 51.9 (OCH_3), 44.2 (CH), 40.2 (CH_2), 26.5 (CH_3), 22.3 (CH_3); ms M^+: 194.0946 (calcd. for $C_{11}H_{14}O_3$: 194.0943). Anal. calcd. for $C_{11}H_{14}O_3$: C 68.01, H 7.27; found: C 67.91, H 7.37.

[16]The specific rotation reported for the product as a neat liquid ranges from +17.4 to +18.9 (45, 47, 48). The specific rotation reported for solutions in methanol ranges from +35.3 to +38.8 (40, 43, 48).

General Diels–Alder reactions

The Diels–Alder reactions were carried out using the general procedures illustrated below with isoprene for boron trifluoride etherate, stannic chloride, ferric chloride, and diethylaluminum chloride catalyzed reactions and *trans*-2-methyl-1,3-pentadiene for zinc chloride catalyzed reactions. Temperatures and times of the reactions as well as the quantities of dienes and Lewis acids are shown in Tables 1 and 2.

$BF_3{\cdot}OEt_2$, $SnCl_4$, and $FeCl_3$ catalyzed reactions

*(1R,3R,8S,9R)-(+)-3-Carbomethoxy-6,10,10-trimethyltricyclo[7.1.1.0^{3,8}]undec-5-en-2-one (**9**).* To a solution of **5** (104.3 mg, 0.538 mmol) and isoprene (1.08 mL, 10.8 mmol) in ether (3.90 mL) at −20°C was added stannic chloride (63 μL) under argon. After stirring for 3 h a saturated aqueous sodium bicarbonate solution (3 mL) was added. The mixture was extracted with ether and the extracts were washed with water, dried, filtered, and concentrated. Flash chromatography eluting with 2–3% ether in petroleum ether gave **9** (77.6 mg, 0.296 mmol, 55% yield) as a colorless oil: $[\alpha]_D^{23}$ +54.20 (*c* 1.12, $CHCl_3$); ir: 1741, 1726 (C=O, ester), 1710 (C=O, ketone) cm^{-1}; ^1H nmr (300 MHz) δ: 5.48 (m, 1H, C=C*H*), 3.75 (s, 3H, OCH_3), 3.20 (dddd, 1H, *J* = 8, 8, 1.5, 1.5 Hz, C-8*H*), 3.05 (dd, 1H, *J* = 15.5, 6 Hz, =CHC*H*$_{eq}$H), 2.66 (dd, 1H, *J* = 5.5, 5.5 Hz, O=CC*H*), 2.47 (dddd, 1H, *J* = 11, 7, 5.5, 1.5 Hz, O=CCHCH*H*$_{exo}$), 2.15 (complex, 3H, C(CH$_3$)$_2$C*H*, =CHCH*H*$_{ax}$, C*H*$_{eq}$HC(CH$_3$)=), 1.95 (d, 1H, *J* = 11 Hz, O=CCHCH*H*$_{endo}$), 1.87 (m, 1H, CH*H*$_{ax}$C(CH$_3$)=), 1.72 (br s, 3H, =CC*H*$_3$), 1.34 (s, 3H, *exo* CH_3), 0.97 (s, 3H, *endo* CH_3); ^{13}C nmr δ: 209.8 (C=O), 172.5 (OC=O), 136.8 (C=), 118.8 (CH=), 58.8 (C), 57.9 (CH), 52.9 (OCH_3), 48.6 (CH), 42.4 (C), 34.4 (CH_2), 33.5 (CH), 32.7 (CH_2), 26.7 (CH_3), 25.1 (CH_2), 23.3 (CH_3), 21.7 (CH_3); ms M^+: 262.1561 (calcd. for $C_{16}H_{22}O_3$: 262.1570). *Epimerization of **28** to **29***

Ketone **28** (21 mg, 0.103 mmol) was dissolved in methanol (5 mL), and aqueous 3 M sodium hydroxide solution (1 mL) was added. After refluxing for 24 h water was added and the mixture was extracted with ether. The extracts were washed with saturated aqueous sodium chloride solution, dried, filtered, and concentrated. The crude product (19.4 mg, 92% yield) was a mixture of **28** and **29** (1:9 ratio by 300 MHz ^1H nmr integration).

*(1R,2S,7R,9R)-(−)-4,10,10-Trimethyl-8-methylenetricyclo-[7.1.1.0^{2,7}]undec-4-ene (**30**)*

Potassium hydride (1.44 g, 35% by weight) was washed three times with dry benzene under argon. DMSO (6 mL) was introduced by syringe and the mixture was stirred at room temperature until evolution of hydrogen stopped (ca. 25 min). Methyltriphenylphosphonium bromide (4.30 g, 12 mmol) in DMSO (11 mL) was then added to the light greenish yellow solution. The resulting bright yellowish green solution was stirred at room temperature for 10 min. Ketone **29** (1.176 g, 5.77 mmol) in benzene (4 mL) was added to the above solution of methylenetriphenylphosphorane. The resulting dark red solution was stirred at room temperature for 20 h. Water was added and the mixture was extracted with petroleum ether. The combined extracts were washed with water, dried, filtered, and concentrated. The crude product was passed through a layer of silica gel in a sintered glass funnel and the silica gel was washed with 1–2% ether in petroleum ether. The filtrate was concentrated to give **30** (1.1585 g, 5.74 mmol, 99% yield) as a colorless liquid: $[\alpha]_D^{23}$ −84.67 (*c* 2.10, $CHCl_3$); ir: 1643 (C=C) cm^{-1}; ^1H nmr (300 MHz) δ: 5.47 (br m, 1H, =C*H*), 4.66 (dd, 1H, J = 2, 2 Hz, =C*H*H), 4.60 (dd, 1H, J = 2, 2 Hz, =CH*H*), 2.53 (dd, 1H, J = 5.5, 5.5 Hz, C-9*H*), 2.18–2.40 (complex, 3H), 1.98 (complex, 2H), 1.79 (complex, 3H), 1.70 (complex, 4H, =CCH_3, CHCHH_{endo}), 1.29 (s, 3H, *exo* CH_3), 0.66 (s, 3H, *endo* CH_3); ^{13}C nmr δ: 153.7 (C=), 135.6 (=C), 121.5 (=CH), 103.85 (=CH_2), 52.9 (CH), 45.4 (CH), 42.8 (C), 38.2 (CH), 37.5 (CH), 37.3 (CH_2), 28.4 (CH_2), 26.8 (CH_3), 24.2 (CH_2), 23.8 (CH_3), 21.4 (CH_3); ms M^+: 202.1722 (calcd. for $C_{15}H_{22}$: 202.1723).

*(1R,5R,6S)-(−)-2-Chloromethyl-8-methyl-5-(1-methylethenyl)-bicyclo[4.4.0]deca-2,8-diene (**31**)*

Phenyl dichlorophosphate (73 μL, 0.491 mmol) and DMSO (63 μL, 0.892 mmol) were added to dry dichloromethane (0.5 mL) at −40°C. A colorless solution formed. Compound **30** (90.1 mg, 0.446 mmol) in dichloromethane (1 mL) was then added. After stirring at −40°C for 1 h and then at −20°C to 10°C for 45 min, water (50 μL) was added. The mixture was filtered through a layer of silica gel in a sintered glass funnel and washed with 40% ether in petroleum ether. The filtrate was concentrated and the residue was distilled (bulb-to-bulb at 66–68°C/1.5–2 Torr) to give **31** (58.8 mg, 0.248 mmol, 56% yield) as a solid: $[\alpha]_D^{26}$ −193.9 (*c* 2.33, $CHCl_3$); mp 40–41°C; ir: 1643 (C=C) cm^{-1}; ^1H nmr (300 MHz) δ: 5.86 (br d, 1H, J = 5 Hz, $ClCH_2C$=C*H*), 5.49 (br d, 1H, J = 5 Hz, CH_3C=C*H*), 4.78 (m, 2H, CH_3C=CH_2), 4.20 (dm, 1H, J = 11 Hz, C*H*HCl), 3.95 (d, 1H, J = 11 Hz, CH*H*Cl), 1.50–2.50 (complex, 9H), 1.67 (br s, 6H, CH_3C=CH_2, CH_3C=CH); ^{13}C nmr δ: 146.9 (C=), 136.4 (C=), 134.4 (=C), 127.8 (=CH), 120.2 (=CH), 112.2 (=CH_2), 47.9 (CH_2Cl), 47.5 (CH), 38.2 (CH), 37.3 (CH), 35.6 (CH_2), 31.0 (CH_2), 29.8 (CH_2), 23.5 (CH_3), 18.2 (CH_3); ms M^+: 238.1305, 236.1331 (calcd. for $C_{15}H_{21}Cl$: 238.1303, 236.1333).

*6,10,10-Trimethyltricyclo[7.1.1.0^{3,8}]undecane-2,5-diol (**33**)*

To a solution of **29** (119.7 mg, 0.587 mmol) in THF (0.60 mL) cooled to 0°C, 1 M borane–THF solution (1.50 mL) was added dropwise under argon. The reaction mixture was stirred at 0°C for 1 h and for a further 2 h at room temperature. Excess borane was decomposed by dropwise addition of water (0.6 mL). Aqueous 3 M sodium hydroxide solution (0.6 mL) was introduced followed by dropwise addition of aqueous 30% hydrogen peroxide solution (0.6 mL). The reaction mixture was stirred for 1 h at room temperature and potassium carbonate (1.25 g) was then added. The mixture was extracted with ether (3 × 5 mL) and the combined organic layers were washed with water, dried, filtered, and concentrated to give **33** (177.5 mg as a 1:2 mixture, 135% crude yield): ir: 3362 (OH) cm^{-1}; ^1H nmr (300 MHz) δ: 4.21 (m, 0.67H), 3.92 (m, 0.33H), 3.65 (t, 0.67H, J = 6.5 Hz), 3.31 (m, 0.33H), 0.9–2.26 (complex, 22H); ms $M^+ - H_2O$: 206.1669 (calcd. for $C_{14}H_{22}O$: 206.1672); $M^+ - 2H_2O$: 188.1562 (calcd. for $C_{14}H_{20}$: 188.1566).

(1S,5R,6S,8S)-(+)-8-Methyl-5-(1-methylethenyl)bicyclo[4.4.0]-decan-2-one (45)

A solution of acetal **43** (26.5 mg, 0.106 mmol) in acetone–water (10:1, 1.5 mL) containing *p*-toluenesulfonic acid (6.6 mg, 0.035 mmol) was refluxed for 3.5 h. Excess solvent was then removed by a rotary evaporator. The residue was diluted with ether and the ethereal solution was washed with aqueous 1 M sodium hydroxide solution and saturated sodium chloride solution and then was dried, filtered, and concentrated. Flash chromatography eluting with 2–3% ether in petroleum ether gave **45** (18.6 mg, 0.09 mmol, 85% yield) as an oil: $[\alpha]_D^{26}$ +106.75 (*c* 1.17, $CHCl_3$); ir: 1710 (C=O), 1640 (C=C) cm^{-1}; ^1H nmr (300 MHz) δ: 4.72 (m, 2H, C=CH_2), 2.72 (ddd, 1H, J = 12, 12, 3.5 Hz, CHC=), 2.56 (ddd, 1H, J = 15, 13.5, 6 Hz, O=CCHH_{ax}), 2.40 (dddd, 1H, J = 12, 4.5, 4, 1 Hz, CHC=O), 2.28 (dddd, 1H, J = 15, 4, 2, 1 Hz, O=CCH_{eq}H), 2.00 (m, 1H, C-6*H*), 1.90 (m, 1H, O=CCH_2CHH), 1.48–1.82 (complex, 6H), 1.64 (dd, 3H, J = 1, 1 Hz, CH_3C=), 0.91 (complex, 2H), 0.84 (d, 3H, J = 6 Hz, $CHCH_3$); ^{13}C nmr δ: 215.2 (C=O), 146.6 (=C), 112.4 (=CH_2), 52.6 (CH), 42.5 (CH), 39.0 (CH), 38.0 (CH_2), 36.2 (CH_2), 34.4 (CH_2), 31.6 (CH_2), 26.1 (CH), 26.1 (CH_2), 22.8 (CH_3), 18.2 (CH_3); ms M^+: 206.1659 (calcd. for $C_{14}H_{22}O$: 206.1672).

Epimerization of 45 to 44

Ketone **45** (11.0 mg, 0.053 mmol) was dissolved in methanol (2.0 mL) and aqueous 3 M sodium hydroxide solution (0.35 mL) was added to this solution. The mixture was refluxed for 22 h, cooled to room temperature, and extracted with ether. The ether extracts were washed with water, dried, filtered, and concentrated to give a mixture of **44** and **45** (8.0 mg, 73% yield, 74:26 ratio by ^1H nmr integration).

(1R,3R,6S,8S,9R)-(+)-6,10,10-Trimethyl-2-methylenetricyclo-[7.1.1.0^{3,8}]undecane (46)

Potassium hydride (291 mg, 35% by weight, 2.55 mmol) was washed three times with dry benzene under argon. DMSO (1.5 mL) was introduced by syringe and the mixture was stirred at room temperature until the evolution of hydrogen ceased. Methyltriphenylphosphonium bromide (903.9 mg, 2.53 mmol) in DMSO (1.5 mL) was added to the light greenish yellow solution. The resulting bright yellowish green solution was stirred at room temperature for 10 min. Ketone **41** (122.7 mg, 0.6 mmol) in benzene (2 mL) was added to the above solution of methylenetriphenylphosphorane. The resulting dark red solution was stirred at room temperature for 21 h. Water was then added and the mixture was extracted with petroleum ether. The extracts were washed with water, dried, filtered, and concentrated. The crude product was then passed through a layer of silica gel in a sintered glass funnel and the silica gel was washed with petroleum ether. The filtrate was concentrated to give **46** (109.1 mg, 0.535 mmol, 90% yield) as an oil: $[\alpha]_D^{26}$ +28.83 (*c* 0.822, $CHCl_3$); ir: 1640 (C=C) cm^{-1}; ^1H nmr (300 MHz) δ: 4.67 (dd, 1H, J = 2, 2 Hz, C=C*H*H), 4.55 (dd, 1H, J = 2, 2 Hz, C=CH*H*), 2.49 (dd, 1H, J = 5.5, 5.5 Hz, C-1*H*), 1.97–2.22 (complex, 3H), 1.48–1.86 (complex, 8H), 1.36 (m, 1H), 1.28 (s, 3H, *exo* CH_3), 1.02 (d, 3H, J = 7 Hz, $CHCH_3$), 0.68 (s, 3H, *endo* CH_3); ^{13}C nmr δ: 154.1 (=C), 103.0 (=CH_2), 52.9 (CH), 46.4 (CH), 43.4 (C), 43.0 (CH), 38.5 (CH_2), 34.3 (CH), 32.6 (CH_2), 28.5 (CH), 27.0 (CH_3), 24.5 (CH_2), 22.6 (CH_2), 21.4 (CH_3), 19.5 (CH_3); ms M^+: 204.1888 (calcd. for $C_{15}H_{24}$: 204.1879).

(1R,5R,6S,8S)-(−)-2-Chloromethyl-8-methyl-5-(1-methylethenyl)-bicyclo[4.4.0]dec-2-ene (47)

Dimethyl sulfoxide (33 μL, 0.46 mmol) was added to a solution of phenyl dichlorophosphate (41 μL, 0.276 mmol) in dichloromethane (0.5 mL) at −50°C under argon. Compound **46** (37.5 mg, 0.184 mmol) in dichloromethane (0.5 mL) was then added. The reaction mixture was stirred at −50°C to −45°C for 24 h. Then sodium bicarbonate (23.7 mg, 0.282 mmol) in water (0.5 mL) was added and the reaction mixture was stirred at 0°C for 3 h. The mixture was extracted with ether and the extracts were washed with water, dried, filtered, and concentrated. The crude product was filtered through a layer of silica gel in a sintered glass funnel and the silica gel was washed with petroleum ether. After concentration compound **47** (26.7 mg, 0.113 mmol, 61% yield) was obtained as a white solid: $[\alpha]_D^{26}$ −34.21 (*c* 0.95, $CHCl_3$); mp 73–75°C; ir: 1658, 1644 (C=C) cm^{-1}; ^1H nmr (300 MHz) δ: 5.81 (m, 1H, $ClCH_2C$=C*H*), 4.73 (m, 2H, C=CH_2), 4.22 (br d, 1H, J = 11 Hz, C*H*HCl), 3.93 (d, 1H, J = 11 Hz, CH*H*Cl), 1.62 (s, 3H, =CCCH_3), 0.98 (d, 3H, J = 7.5 Hz, $CHCH_3$); ^{13}C nmr δ: 147.3 (=C), 136.8 (=C), 127.9 (=CH), 112.2 (=CH_2), 48.0 (CH_2Cl), 47.6 (CH), 42.2 (CH), 36.3 (CH_2), 35.4 (CH), 32.0 (CH_2), 31.2 (CH_2), 27.5 (CH), 23.9 (CH_2), 18.4 (CH_3), 17.8 (CH_3); ms M^+: 240.1465, 238.1490 (calcd. for $C_{15}H_{23}Cl$: 240.1460, 238.1487). Anal. calcd. for $C_{15}H_{23}Cl$: C 75.43, H 9.71; found: C 75.40, H 9.82.

Polarized near-infrared spectra of single crystals of $CsMnCl_3 \cdot 2X_2O$ (X = H, D) were recorded at 10 K. Those bands which could be assigned to O—H or O—D stretch overtones were analyzed using local-mode theory specifically adapted for systems having less than C_{2v} symmetry. Both O—H oscillators form nearly linear hydrogen bonds to neighboring chloride ions at different distances. As a result, the local-mode harmonic frequency and anharmonicity parameters show characteristic shifts from their gas-phase values. The parameter values cover an unusually narrow range in this crystal, considering the spread in hydrogen-bond distances. Assignment of stretch overtone bands to specific oscillators in the crystal was made by using the polarization behavior expected of local modes in the oriented gas model. Several of the overtone bands show combinations with lattice modes or low-energy hydrogen-bond modes in unusual detail.

IAN M. WALKER et PAUL J. MCCARTHY. Can. J. Chem. **72**, 1211 (1994).

Opérant à 10 K, on a déterminé les spectres polarisés du proche infrarouge de cristaux uniques de $CsMnCl_3 \cdot 2X_2O$ (X = H, D). Utilisant la théorie du mode local adaptée spécifiquement pour les systèmes ayant une symétrie inférieure à C_{2v}, on a analysé les bandes qui peuvent être attribuées aux harmoniques des élongations O—H et O—D. Les deux oscillateurs O—H forment des liaisons hydrogènes pratiquement linéaires avec les ions chlorures voisins, à des distances diverses. Il en résulte que la fréquence harmonique du mode local et les paramètres d'inharmonicité présentent des déplacements caractéristiques par rapport à leurs valeurs en phase gazeuse. Considérant la plage des distances des liaisons hydrogènes dans ce cristal, les valeurs des paramètres ne couvrent qu'un champ inhabituellement restreint. On a fait l'attribution des harmoniques des bandes d'élongation à des oscillateurs spécifiques du cristal en se basant sur le comportement de polarisation attendu des modes locaux dans le modèle gazeux orienté. Plusieurs bandes harmoniques présentent, avec un détail inusité, des combinaisons avec les modes du réseau ou les modes des liaisons hydrogènes de basse énergie.

Introduction

In a series of recent articles we have applied local-mode theory to the analysis of the fundamental and overtone vibrational spectra of water (1–3) and $-NH_2$ (4) in crystals. Our purpose has been to correlate the local-mode parameters with the length and strength of the hydrogen bonds formed by O—H and N—H oscillators with adjacent electronegative atoms in the crystal. Here we are extending our study to $CsMnCl_3 \cdot 2H_2O$ and its deuterated analog.

$CsMnCl_3 \cdot 2H_2O$ belongs to the orthorhombic space group, *Pcca* (D_{2h}^8, no. 54) (5). The unit cell has the following dimensions: $a = 9.060$ Å, $b = 7.285$ Å, and $c = 11.455$ Å, with $Z = 4$. The basic structure consists of chains of *cis*[-Cl(MnO_2Cl_2)-] propagating along the *a* axis with the cesium ions lying between the chains in the *ab* plane. Because of this the material has a layered structure with [001] cleavage planes. The X-ray study (5) has reported the positions of all atoms except hydrogen (Table 1). The fractional coordinates of the hydrogen atoms have been estimated by El Saffar (6) using Baur's method (7), in which the electrostatic energy is minimized as a function of proton position. De Jonge et al. (8) determined the hydrogen coordinates using two methods based on nuclear quadrupole resonance spectroscopy. One of these used the principal axes of the electric field gradient tensor at the deuterium sites in $CsMnCl_3 \cdot 2D_2O$, and the other used the observed dipole–dipole splitting of the proton resonances of $CsMnCl_3 \cdot 2H_2O$ in a field of 1350 Oe. The latter authors also calculated the positions using Baur's method. The four parameter sets differ little from each other, and we have used the average in Table 1, since it is not clear which might be most accurate. Refinement of the hydrogen positions must await a full neutron diffraction study.

Atom[b]	*x/a*	*y/b*	*z/c*
Cs	0.250	0.000	0.146
Mn	0.000	0.467	0.250
Cl_I	0.250	0.500	0.146
Cl_{II}	0.085	0.228	0.391
O	0.080	0.669	0.361
H_A	0.028_5	0.693	0.434
H_B	0.184	0.695	0.373

[a]Non-hydrogen values from ref. 5; hydrogen values are averages from data in refs. 6 and 8 (see text).

[b]Atom designations follow refs. 5 and 10, Cl_I is bridging, Cl_{II} is non-bridging.

The water molecules lie largely in the *ac* plane (Fig. 1), and the Raman spectrum of the bending mode shows that all water molecules are equivalent (9). (In the following the atom designations are those of refs. 5 and 10.) Hydrogen bonding to non-bridging chlorines (Cl_{II}) is a significant feature of the structure. O—H_A forms a hydrogen bond to Cl_{II} on a chain lying adjacent in the *ac* plane (O···Cl = 3.297 Å), and O—H_B forms one to Cl_{II} in the same chain (O···Cl = 3.145 Å). Both O—H···Cl angles are

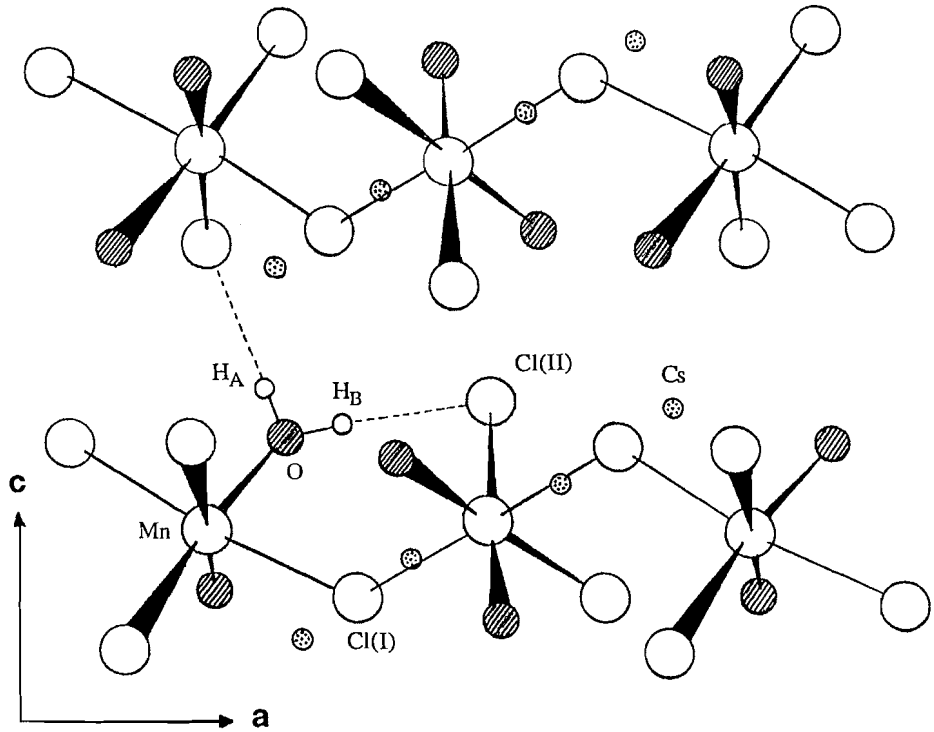

FIG. 1. Structure of $CsMnCl_3 \cdot 2H_2O$ in the *ac* projection. Only one set of hydrogens and hydrogen bonds are shown; adapted from refs. 5 and 10.

calculated to be 175°. Since the oxygen atom also lies 3.155 Å from a bridging chlorine (Cl_I), Jia et al. (9) have suggested that the O—H_B forms a bifurcated hydrogen bond. While the two O···Cl distances in this bifurcated hydrogen bond are quite similar, the interaction with Cl_I should be quite weak, since the $H_B \cdots Cl_I$ distance and O—$H_B \cdots Cl_I$ angle are calculated to be 3.023 Å and 89°. The fact that the two O···Cl_{II} distances are not equal suggests that the O—H bonds of water form hydrogen bonds of slightly different energy, and that the local-mode parameters of the two O—H bonds might be somewhat different. As will be seen below, this is *not* very clearly borne out by our results.

Since this crystal is orthorhombic, a rather strong correlation between known polarizations and relative intensities of the overtone–combination bands should be observed. This is indeed borne out by the experimental evidence.

The spectra are especially interesting in that the principal bands have considerable associated fine structure, which may be due to lattice modes or, more specifically, hydrogen-bond modes (see below).

Local-mode theory has proven itself to be especially well suited to the analysis of the overtone spectra of gas- and liquid-phase molecules containing C—H, N—H, and O—H bonds (11). The literature in the area has been reviewed (11*a*, 11*b*), and several treatments of the theory for HOH and other small molecules are available (11*c*, 11*d*, 11*e*). Our adaptation of the theory to water molecules on general sites in crystals has been presented in detail elsewhere (2, 3).

Briefly, following Mills and Robiette (11*d*), we write the vibrational basis functions as products of harmonic oscillator eigenfunctions along local coordinates, each being described by a local-mode quantum number v_i. So for a water molecule the basis ket could be written $|v_1 v_2\rangle$, or in the present case $|v_A v_B\rangle$. The diagonal elements of the secular determinant may be calculated from the relation:

$$[1] \quad \langle v_i, v_j|\mathrm{H}|v_i, v_j\rangle = \Sigma\omega_k(v_k + 1/2) + \Sigma X_k(v_k + 1/2)^2$$

where ω_k are the harmonic frequencies of the O—H bonds and X_k are the anharmonicity parameters, and index k runs over oscillators A and B. Allowance for coupling between stretching local modes that are close in energy is made by including off-diagonal elements of the form:

$$[2] \quad \langle v_i + 1, v_j - 1|\mathrm{H}|v_i v_j\rangle = \lambda[(v_i + 1)v_j]^{1/2}$$

The X terms are usually negative; thus, in first order, states such as $|1, 1\rangle$, which represents a stretch–stretch combination, occur at higher energy than the corresponding pure overtones, $|20\rangle$ and $|02\rangle$. In the case of the D_2O molecule, the eigenstates are roughly equal mixtures of the local-mode basis functions. We have adopted the literature convention (11) of designating the symmetric and antisymmetric combinations $|v0\rangle_+$ and $|v0\rangle_-$, respectively, even though such terminology does not rigorously apply in the present case. All other symbols have their conventional meanings (2, 3).

Experimental

Well-formed crystals of $CsMnCl_3 \cdot 2H_2O$ suitable for spectroscopy were grown from water by slow evaporation of a solution containing equimolar amounts of CsCl and $MnCl_2 \cdot 4H_2O$. Moderately deuterated crystals were obtained from the same starting materials by slow evaporation of a D_2O solution over concentrated H_2SO_4 in a desiccator. More highly deuterated crystals were obtained by using anhydrous $MnCl_2$; water of hydration is removed by heating at about 120°C for a few hours. $CsMnCl_3 \cdot 2H_2O$ grows as large rectangular plates showing the [001] face.

The crystals were mounted in a Displex cryogenic refrigerator and the near-infrared (near-ir) spectra were recorded at 10 K using a Varian-2300 spectrophotometer. Polarized light was obtained by a pair of Glan–Thompson prisms. Spectra were taken with the electric vector of the light parallel to each of the three orthogonal crystal axes of

TABLE 2. Squares of direction cosines of vibrations along the crystal axes in $CsMnCl_3 \cdot 2H_2O$

	Molecular frame			Local frame	
Polarization	A_1	B_1	B_2	O-H_A	O-H_B
E‖*a*	0.17	0.80	0.02	0.23	0.94

E‖*c*	0.73	0.20	0.08	0.74	0.02

$CsMnCl_3 \cdot 2H_2O$ and its deutero analog. The orientations were confirmed by comparison of the spectra in the visible region with those reported by Day and Dubicki (12).

The ir and Raman spectra of $CsMnCl_3 \cdot 2X_2O$ (X = H, D) below 350 cm^{-1} have been reported (13), as well as the complete Raman spectra to 3600 cm^{-1} (9). In addition, we recorded the ir spectra (4000–600 cm^{-1}) in Fluorolube and Nujol mulls at room temperature using a Nicolet 5DX FTIR spectrophotometer. The band energies we observed are for the most part the same as those reported by Jia et al. (9), but the various ν(OH) values they report are too close in energy to be resolved in our spectra. The fact that the ir and Raman values are identical or nearly so indicates that factor-group splitting is of relatively little importance in these spectra, a fact that has been previously noted (9, 13).

Results and discussion

Since the waters in $CsMnCl_3 \cdot 2H_2O$ lie on general sites, a fundamental problem in interpreting the intensities of the vibrational bands lies in relating the directions of the vibrational modes to the crystal axes. There are two situations that are likely to arise in the present instance. In the first situation some vibrations, including bends and librations, are expected to be polarized parallel or perpendicular to the HOH bisector of the water molecule (11*e*). In this situation it is useful to describe the orientation of the water molecule in the crystal by means of a molecular reference frame. It is convenient to label the axes of this frame with the symmetry species appropriate to gas-phase water (point group C_{2v}). Thus we place A_1, B_1, and B_2 axes along the HOH bisector, the H–H vector, and the normal to the plane of the water molecule, respectively. The values of the squares of the direction cosines of these vectors with respect to the crystal axes can be found in the first three columns of Table 2. Of the six fundamental vibrations for bound water, we expect the symmetric stretch (ν_s) and the bend (δ) to be A_1 polarized, while the antisymmetric stretch (ν_a) and the rock (ρ_r) would be B_1 polarized, and the wag (ρ_w) B_2. The twist (ρ_t) is inactive in high-symmetry environments, but may show up in crystals where the site symmetry is low (2, 3).

The symmetry of each combination will be the direct product of the symmetries of the fundamentals, and combination bands would be expected to behave as dipoles along the coordinates of the molecular frame. Coupled overtone states would also be expected to be polarized along the coordinates of the molecular frame (11*e*).

In the other situation where the upper states are localized primarily on one oscillator, the spectral bands are expected to be polarized along the individual OH (or OD) bond directions (14). Using the coordinates listed in Table 1, the squares of the direction cosines of the O—H bonds along the crystal axes can be calculated. They are listed in the last two columns of Table 2.

Spectra of $CsMnCl_3 \cdot 2H_2O$

For many parts of the near-ir spectra only general group assignments can be made. We will confine quantitative analysis to the O—H stretches, both fundamentals and first and second overtones.

Since the water molecules lie largely in the *ac* plane, electric dipole selection rules predict that the A_1 and B_1 bands will be found principally in the E‖*a* and E‖*c* spectra. The B_2 features, which represent out-of-plane vibrations of water, are expected to appear mainly in the E‖*b* spectrum. This latter spectrum in fact contains only two bands of notable intensity (3906 and 4074 cm^{-1}); these can reasonably be assigned to $\nu_a + \rho_t$ and $\nu_s + \rho_w$, although the order is not certain. The strong band at 4013 cm^{-1} in the other two polarizations could be $\nu_s + \rho_r$ and /or $\nu_a + \rho_r$, since both features can occur with some intensity in either the E‖*a* or E‖*c* spectrum. This analysis has the librations increase in energy in the order: $\rho_t < \rho_r < \rho_w$. This differs from the order, $\rho_w < \rho_t < \rho_r$, proposed by Jia et al. (9). Polarized near-ir spectra of combination bands have been of use in identifying in-plane and out-of-plane librations also in other systems (15).

Broad, rather weak, bands in the 4170–4830 cm^{-1} region most probably represent $\nu + 2\rho$ combinations, while a sharp spike at 4786 cm^{-1} may be assigned to 3δ.

The very strong band in E‖*a* and E‖*c* polarizations around 5000 cm^{-1} can be seen in a very thin crystal as a poorly resolved multiplet with principal components 4965, 4984, and 5015 cm^{-1}. These are readily assigned to $\nu + \delta$, and the polarization behavior is that expected for water lying mainly in the *ac* plane. Weaker features lying between 5350 and 5750 cm^{-1} are probably due to $\nu + \rho + \delta$. None of the bands mentioned thus far are shown in the figures.

The first overtone bands appear as an intense doublet at 6438 and 6454 cm^{-1} (Fig. 2). A study of the intensities of the C—H stretch overtones of the methyl groups of durene in several polarizations shows very good agreement with the predictions of the oriented gas model, and indicates that the dipole moment has components along the C—H local modes (14). We therefore feel justified in using the direction cosines of the local O—H oscillators as a guide in assigning the transitions. The band at 6438 cm^{-1} is strongly *a* polarized, which is expected for the O—H_B oscillator (Table 2). The band at 6454 cm^{-1} has a strong *c* and weaker *a* component, behaviour expected for the O—H_A oscillator. The bands are assigned accordingly in Table 3. As expected, neither band has a significant *b* component.

The $|11\rangle$ local mode is expected to be A_1 polarized (11*e*), and so to be strongest in E‖*c* and weakest in E‖*b* polarization. The band whose average position is 6746 cm^{-1} corresponds quite well to these expectations. The $|11\rangle$ band is broader than the $|20\rangle$ or $|02\rangle$ bands. Since the Raman spectra of $CsMnCl_3 \cdot 2H_2O$ show three intense and three very weak features in the ν(OH) region (9), the $|11\rangle$ band may be composed of various combinations of the fundamentals in which oscillators on adjacent waters of the same chain are excited. All these combinations are expected to be close in energy and so may appear as an unresolved, broad multiplet. Since a different combination may be predominant in each polarization, it is not surprising that this band shows somewhat different maxima in the three polarizations. The $\nu + 2\delta$ bands are expected to be in this same region, and the weak bands at 6576 and 6657 cm^{-1} may be these. These weak features are, however, more probably lattice modes, and their nature will be discussed below.

A group of bands between 7800 and 8500 cm^{-1} (not shown in the figures) is due to $2\nu + \delta$. The assignment is strengthened by a comparison with the spectra of the partially deuterated crystal discussed below.

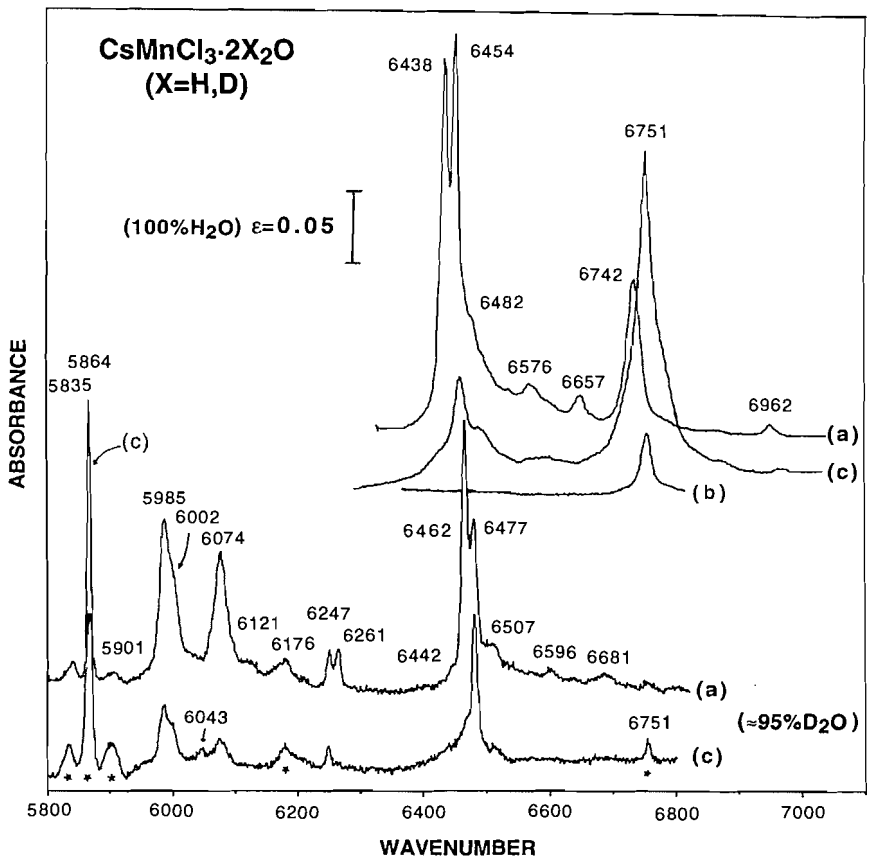

FIG. 2. Polarized crystal spectra (5800–7000 cm^{-1}) of $CsMnCl_3 \cdot 2X_2O$ (X = H, D) at 10 K. The spectra were recorded with the electric vector of the light parallel to the *a*, *b*, and *c* crystal axes. In the mixed crystal in *b* polarization only the bands marked with an asterisk appear weakly.

The second overtones are assigned to the doublet at 9189 and 9218 cm^{-1} (Fig. 3). The lower energy band is, like the $|02\rangle$ band, largely *a* polarized, so is assigned to the excitation of the O—H_B oscillator. The band at 9218 cm^{-1} is strongest in polarization *c*, but has a significant *a* component, like the corresponding $|20\rangle$ band.

The $|21\rangle$ and $|12\rangle$ bands should be very similar in energy, and they are seen as a rather broad, unresolved band at 9808 cm^{-1}.

Spectra of $CsMnCl_3 \cdot 2HOD$ and $CsMnCl_3 \cdot 2D_2O$

Since the deuterated crystals that we prepared contained residual H_2O, the spectra are quite complex. Bands due to H_2O, D_2O, and HOD are all present, and indeed are often found together in the same region of the spectrum. Crystals with two different degrees of deuteration were studied, and this allows us to make some rather firm band assignments. Because of uncertainty about the exact amout of H_2O present in the deuterated crystals, extinction coefficients for bands in these crystals could only be roughly estimated. The deuterated spectra appear to be more intense than the protiated spectra, but by less than a factor of two.

The region 3850–4760 cm^{-1} contains many rather weak features of varying intensity as well as two strong bands at 3909 and 4010 cm^{-1}. These two bands increase in intensity as the amount of H_2O increases and could be due to ν(OD) + δ(HOD) or to $\nu + \rho$ of residual H_2O. The remaining bands could be due to any of the three species of water present. Since the region contains no bands that pertain directly to this report, we have made no attempt to characterize them further.

In terms only of binary combinations, the region 4700–5100 cm^{-1} (Fig. 4) contains $\nu + \delta$ of H_2O, ν(OH) + δ of HOD, and 2ν(OD) of both HOD and D_2O. The strong bands at 4781 and 4799 cm^{-1} increase in intensity with addition of H_2O. They can be assigned to ν(OH) + δ(HOD), since they lie about 1427 cm^{-1} above ν(OH); δ(HOD) in the ir is found at 1431 cm^{-1}. The complex band centered around 4850 cm^{-1} contains a lower energy doublet (4830, 4842 cm^{-1}) that decreases in intensity as D_2O concentration decreases. These bands are accordingly assigned to $|20\rangle_+$ and $|02\rangle_-$ of D_2O. The 4830 cm^{-1} band is the weaker of the pair, and this mirrors the 2ν region of the protiated species. As expected, these bands are very weak in E$\|b$ polarization. The higher energy part (4857 cm^{-1}) of this complex band increases in intensity as D_2O concentration decreases. It is most probably one of the 2ν(OD) bands of HOD. (It can be noted in Fig. 2 that 2ν(OH) in HOD also lies higher in energy than the analogous band in H_2O.) The multiplet around 5000 cm^{-1}also has a complex dependence on H_2O concentration, and it is likely that the component centered around 5012 cm^{-1} is the $|11\rangle$ band of D_2O. The position of the band maximum varies with polarization, as was also found for the $|11\rangle$ band of the protiated species. The rest of this band seems to be principally $\nu + \delta$ of H_2O. The other features in this region cannot be assigned at present.

The region 5100–5700 cm^{-1} contains a few weak features that could be any of the ternary bands, $\nu + \delta + \rho(H_2O)$, ν(OH) + 2δ(HOD), or $2\nu + \rho(D_2O)$.

In the region 5800–6850 cm^{-1} (Fig. 2) the band at 5864 cm^{-1} is due to ν(OH) + ν(OD) of HOD. Since only a single band is seen, the two possible combinations must lie within 11 cm^{-1},

Parameters used in best fit[c]

O—H	O—D	Ratio (O—D/O—H)[d]
ω_A = 3677 (9)	2679 (10)	0.729
ω_B = 3666 (9)	2662 (10)	0.726
X_A = −151 (3)	−87 (3)	0.577
X_B = −151 (3)	−83 (3)	0.550
λ = 0	−24	

[a]The numbers in the kets refer to oscillators A and B, respectively. States $|v0\rangle_+$ and $|v0\rangle_-$ refer to symmetric and antisymmetric combinations of the $|v0\rangle$ and $|0v\rangle$ states, respectively. The mixtures are in general somewhat unequal.

[b]Data below 4000 cm^{-1} from ref. 9.

[c]Standard deviations in parentheses; all data in cm^{-1}.

[d]Theoretical ratios are 0.728 and 0.529.

which is the width of the band at half-height in E||*c*. This band is strongest in *c* polarization, just as is the $|11\rangle$ band of H_2O.

The band at 5985 cm^{-1} with shoulder at 6002 cm^{-1} as well as the band at 6074 cm^{-1} decrease in intensity as D_2O content decreases. The first pair lies ca. 1158 cm^{-1} above the 2ν(OD) bands and can be assigned to be $|20\rangle_+ + \delta$ and $|20\rangle_- + \delta$ of D_2O; $\delta(D_2O)$ is observed at 1196 cm^{-1} in the ir spectrum. The band at 6176 cm^{-1} gains some intensity as H_2O increases. Since it lies about 1385 cm^{-1} above the 4781, 4799 cm^{-1} multiplet, it may represent ν(OH) + 2δ(HOD).

The 6247, 6261 cm^{-1} pair is most probably $|02\rangle$(OD) + δ and $|20\rangle$(OD) + δ of HOD, since it increases in size as H_2O is added and lies ca. 1418 cm^{-1} above 2ν(OD). The higher energy band is almost absent from the *c* spectrum. This is reminiscent of the $|02\rangle$ and $|20\rangle$ bands of H_2O, but in this case it is the lower energy band which is absent.

The next set of bands can be assigned with more assurance. In polarization *a* the principal bands at 6462 and 6477 cm^{-1} are the $|02\rangle + |20\rangle$ of OH in HOD. These lie about 24 cm^{-1} higher in energy than the corresponding bands in the nondeuterated crystal. In polarization *c* only the higher energy band is seen, as was

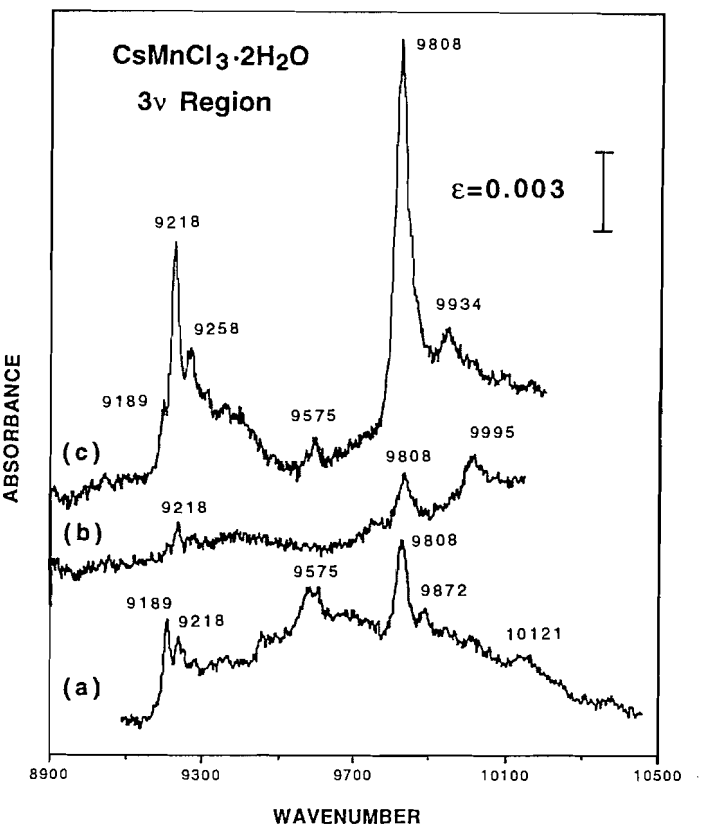

FIG. 3. Polarized crystal spectra (8900–10 500 cm^{-1}) of $CsMnCl_3 \cdot 2H_2O$ at 10 K.

found also in the nondeuterated crystal. The weak satellite at 6442 cm^{-1} is very sensitive to the amount of H_2O present and appears to be $|02\rangle$ of H_2O; the $|20\rangle$ band would lie under the strong band at 6462 cm^{-1}. The weak $|11\rangle$ band of H_2O is at 6751 cm^{-1}. It is strongest in *c* polarization, as it is in the nondeuterated crystal, and its intensity matches that expected for the amount of H_2O present. In the more highly deuterated crystal only the bands due to $|02\rangle$ and $|20\rangle$ of OH in HOD are observed, since there is too little H_2O present for its bands to be seen. It seems possible that the lower values in the protiated crystal are due to Fermi resonance between 2ν and ν + 2δ. This would be lacking in the highly deuterated crystals, since almost all OH would be in HOD and δ(HOD) lies about 200 cm^{-1} lower in energy than $\delta(H_2O)$. No assignments can be made at present for the other features shown in the spectra in Fig. 2.

In the region 6850–7350 cm^{-1} some very weak bands are probably due to 3ν of D_2O and HOD. Studies in this region are hindered by the presence of background absorption due to water vapour in the sample beam. A band at 6984 cm^{-1} found in both *a* and *c* polarizations is a reasonable choice for the second overtones of D_2O.

The region 7350–8330 cm^{-1} (not shown here) contains a band group with principal peak at 7884 cm^{-1}; the group lies about 1415 cm^{-1} above the 6462, 6477 cm^{-1} doublet. These peaks can therefore be assigned to 2ν(OH) + δ(HOD). The peak at 7884 cm^{-1} has a width of 26 cm^{-1} at half-height and so the expected two components are not seen. These bands increase in intensity as the H_2O/D_2O ratio increases. A similar band group was found in $CsMnCl_3 \cdot 2H_2O$ with principal peak at 8014 cm^{-1}, which lies about 1568 cm^{-1} (approximately $\delta(H_2O)$) above the

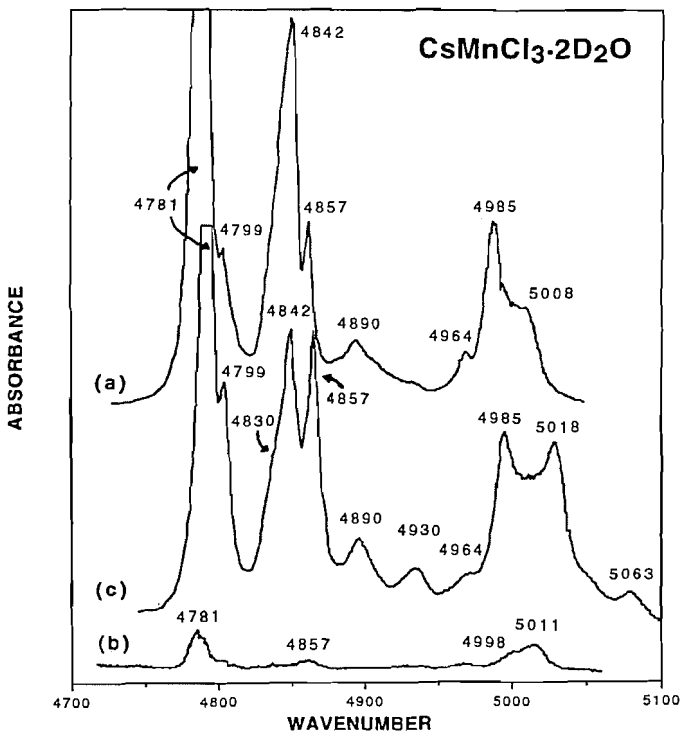

FIG. 4. Polarized crystal spectra (4700–5100 cm^{-1}) of $CsMnCl_3 \cdot 2D_2O$. The *a* spectrum is in reality 3 times as strong as shown here.

doublet at 6438, 6454 cm^{-1}. Since the peak has a width of 42 cm^{-1} at half-height, the expected two components are again not seen.

Fine structure

On the high-energy side of several bands are one or more weak shoulders or discrete bands. The best example we found is the E||*c* spectrum of a thick crystal of $CsMnCl_3 \cdot 2H_2O$. In this spectrum 11 bands lie 32–246 cm^{-1} above the $|20\rangle$ band at 6454 cm^{-1}, the bands at 137 and 220 cm^{-1} being especially prominent. These satellite bands are most probably lattice vibrations coupled to the principal mode. Their frequencies closely match those of the lattice modes found in the Raman spectra of this compound (9, 13). Similar, but less extensive, structure is found above the $|11\rangle$ band, especially notable being a band at 222 cm^{-1}. Likewise, five bands lie between 41 and 365 cm^{-1} above $|30\rangle$, and at least one weak band lies 127 cm^{-1} above $|12\rangle + |21\rangle$. There are also bands associated with the $\nu + \delta$ doublet, as well as with the principal $2\nu + \delta$ peak at 8014 cm^{-1}. Coupling of ν(OH) and ν(OD) with lattice modes has also been observed in the fundamental Raman spectrum (9).

A slightly different view would interpret some of these features as specific hydrogen-bond modes that are excited along with the stretch overtone or stretch plus bend combination band. It was pointed out by Sandorfy (16) that the coupling by hydrogen bonding of two nonlinear species results in the conversion of six rotational and translational degrees of freedom into six hydrogen-bond modes. For an O—H···O hydrogen bond these are: (1) the oxygen–oxygen stretch; (2) the O—H···O deformation; (3) the O—H···O wag; and (4) the torsional motion. (2) and (3) are doubly degenerate, but the degeneracy will be lifted if the symmetry is less than C_3. For weak or moderately strong hydrogen bonds (1) is often about 100–200 cm^{-1}, (2) about 500–700 cm^{-1}, and (3) less than 100 cm^{-1} (16). Similar values might be expected for O—H···Cl groups.

Local-mode results

The vibrational energies were calculated by diagonalization of the appropriate matrices (2). Because of the inequivalence of the O—H or O—D bonds in the compound, the matrices for each species contain five parameters: ω and X for each O—H or O—D oscillator, and λ, the coupling constant between the two oscillators. An initial set of 10 parameters was chosen and the vibrational energies were calculated. An iterative process adjusted all parameters to minimize the sum of the squares of the differences between calculated and observed energies. The parameters that gave the most reasonable fit are listed in Table 3 along with the observed and calculated energies. As we found in earlier studies (2, 3), numerous local minima in the RMS function can be obtained by quite small variations in the initial input parameters.

The standard deviations of the parameters were calculated by the method outlined by Cowan (17). This, however, seems to depend mainly on the steepness of the approach to the minimum and assumes no uncertainty in the band positions. We have calculated that, if the latter uncertainties are included, the standard deviations will be about 2–4% greater than those listed in Table 3.

The energies of the fundamentals used in the fitting were taken from the Raman spectra of Jia et al. (9). Of the eight ν(OD) features found near 2500 cm^{-1}, we have reassigned some of the more prominent ones (Table 3).

The ν(OH) fundamentals appear to have the same energies in H_2O and HOD (9), suggesting an initial choice of λ close to zero in H_2O. This choice is strengthened by noting that the splitting of the first O—H overtone states of H_2O and HOD are very nearly the same.

On the basis of the observed X-ray data and the calculated hydrogen positions, the two O—H···Cl hydrogen bonds in this compound are expected to be of quite different strengths. The overtone spectra in the 2ν and 3ν regions indicate that they are, however, not very different at all, and the local-mode parameters of the two O—H and O—D bonds are the same to within one standard deviation. On the other hand, similar data for $M_2MnCl_4 \cdot 2H_2O$ (M = Rb, Cs)[2] indicate that the two hydrogen bonds should be rather similar in strength. Yet the 2ν region shows a large splitting between the $|20\rangle$ and $|02\rangle$ bands and the local-mode parameters are quite different. One may conclude that the dependence of local-mode parameters on the details of hydrogen-bond interactions is more complex than the simple model would suggest, and (or) that the theoretical apparatus used to determine the proton positions in these compounds does not give very reliable results.

The λ coupling in the D_2O crystal is considerably reduced compared to the value found in gas-phase D_2O (−58.3 cm^{-1}). The reduction in λ that we found here is greater than was observed in $BaCl_2 \cdot 2D_2O$ (3). The diminution in λ seems to be especially pronounced for H_2O as well; the value of λ is considerably smaller than in $BaCl_2 \cdot 2H_2O$ and in gas-phase water (−49.5 cm^{-1}). These effects are undoubtedly a consequence of hydrogen bonding, but are imperfectly understood at present.

[2]I.M. Walker and P.J. McCarthy. Unpublished data.

Conclusions

Several salient points emerge from this study. First, this solid affords the best opportunity to date to apply the oriented gas model to the study of the overtones of a hydrogen-bonded system containing only one kind of water molecule. Modes that involve only stretch overtones obey the predictions of the first-order theory in that they are polarized almost exclusively in the plane of the water molecule. We have presented evidence that the dipole moment operator has components along the individual O—H bonds, and we have assigned the spectra with this in mind. Certain families of combination bands involving stretch and bend features have a pronounced out-of-plane component in addition to the normal in-plane component. This behaviour is not expected for the dipole moment of water in the gas phase, and it may be attributed to a breakdown in the selection rules that accompanies the loss of C_{2v} symmetry (18).

Second, it is of interest to compare the local-mode results in the present case with those obtained in our study of $BaCl_2 \cdot 2H_2O$. In both crystals the water molecules lie on general positions. Three of the O—H oscillators in $BaCl_2 \cdot 2H_2O$ form normal hydrogen bonds, having O···Cl distances and hydrogen-bond angles that are comparable to those found in $CsMnCl_3 \cdot 2H_2O$. The average value of the X parameter for these three oscillators is $-162.5\ cm^{-1}$, with a spread of $11\ cm^{-1}$ between the values. The corresponding variation in the O···Cl distance is 0.05 Å, the mean value being 3.16 Å. The mean of the anharmonicity constants in $CsMnCl_3 \cdot 2H_2O$ is slightly smaller than that in $BaCl_2 \cdot 2H_2O$; this may reflect the longer O···Cl distances found in the latter case. It is surprising, however, that the X values are virtually identical in $CsMnCl_3 \cdot 2H_2O$, while the range in O···Cl distances is three times as great as in $BaCl_2 \cdot 2H_2O$. It is worth noting then that the difference in energy between the $|02\rangle$ and $|20\rangle$ and between the $|03\rangle$ and $|30\rangle$ bands of $CsMnCl_3 \cdot 2H_2O$ should be attributed principally to differences in ω for the two oscillators. We may conclude that O—H anharmonicities in similar salts are sensitive to the whole of the crystalline environment. Therefore, attempts to correlate anharmonicities with hydrogen-bond strengths must be carried out with great caution. On the whole, the most reliable guide to assigning overtone bands to specific oscillators is the polarization of the bands in crystals of known structure.

Finally, $CsMnCl_3 \cdot 2H_2O$ is unusual in that it is possible to observe under high resolution numerous combinations of stretch overtones with low-frequency crystal and (or) hydrogen-bond modes. While there is some evidence for such bands in several of the other crystals we have studied, only in the present case is there sufficient resolution to allow us to observe and catalogue the individual bands.

G.W. BUCHANAN, A RODRIGUE, K. BOURQUE, A.C. CHIVERTON, I.R. CASTLEDEN, and S. FORTIER. Can. J. Chem. **72**, 1218 (1994).

Solid phase 45.3 MHz ^{13}C NMR spectra of *ortho*-dimethoxydiphenyl ether, **1**, dibenzo[*b*,*e*]-15-crown-5- ether, **2**, and tetrabenzo[*b*,*e*,*q*,*t*]-30-crown-10 ether, **3**, have been obtained. Chemical shift trends are discussed in terms of the asymmetric units and structural features available from X-ray crystallographic data. Comparison with solution ^{13}C spectra are made. The crystal structures of **1** and **3** were determined by X-ray diffraction at room temperature. **1** crystallizes in space group $P2_1/a$ with a = 13.366(1), b = 8.230(1), c = 12.303(1) Å, β = 116.63(1)°, Z = 4. **3** crystallizes in space group $P2_1/c$ with a = 7.903(1), b = 26.337(2), c = 7.852(1) Å, β = 97.28(1)°, Z = 2. The structures were solved by direct methods and refined by full-matrix least squares to residuals of 0.055 using 1727 reflections for **1** and of 0.042 using 2590 reflections for **3**.

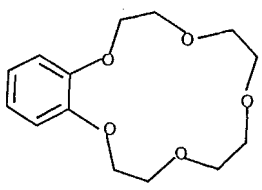
G.W. BUCHANAN, A RODRIGUE, K. BOURQUE, A.C. CHIVERTON, I.R. CASTLEDEN et S. FORTIER. Can. J. Chem. **72**, 1218 (1994).

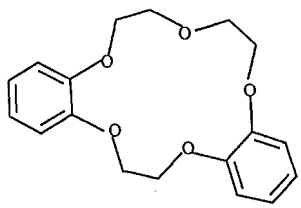
On a déterminé les spectres RMN du ^{13}C en phase solide, à 45,3 MHz, des éthers *ortho*-diméthoxydiphénylique, **1**, dibenzo[*b*,*e*]-15-couronne-5, **2**, et tétrabenzo[*b*,*e*,*q*,*t*]-30-couronne-10, **3**. On discute des tendances dans les déplacements chimiques en fonction des unités asymétriques et des caractéristiques structurales disponibles à partir de données de diffraction des rayons X. Une comparaison est faite avec les spectres RMN du ^{13}C obtenus en solution. On a déterminé les structures cristallines des composés **1** et **3** par diffraction des rayons X à la température ambiante. Le composé **1** cristallise dans le groupe d'espace $P2_1/a$, avec a = 13,366(1), b = 8,230(1) et c = 12,303(1) Å, β = 116,53(1)° et Z = 4. Le composé **3** cristallise dans le groupe d'espace $P2_1/c$, avec a = 7,903(1), b = 26,337(2) et c = 7,852(1) Å, β = 97,28(1)° et Z = 2. On a résolu les structures par des méthodes directes et on les a affinées par la méthode des moindres carrés jusqu'à des valeurs résiduelles de 0,055 pour 1727 réflexions pour le composé **1** et 0,042 pour 2590 réflexions pour le composé **3**.

[Traduit par la Rédaction]

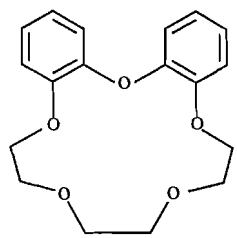
Introduction

Following the early work of Truter and co-workers (1), a number of recent publications (2–6) have dealt with correlations between solid state ^{13}C NMR behaviour and X-ray crystallographic structures of benz-annelated crown ethers with a variety of structures. This has included the benzo- and dibenzo-15-crown-5 systems depicted below (1, 5).





With the exception of some solution complexation studies (7), no work has yet been reported concerning crown ethers derived formally from diphenyl ether. Herein we present solid phase ^{13}C NMR results for the dibenzo-15-crown- 5 ether system (below) and its tetrabenzo-30-crown-10 dimer formally derived from such a precursor. As a simpler model, the *ortho*-dimethoxydiphenyl ether molecule has been studied in detail and correlations of sterically induced chemical shift trends with X-ray derived structural features are presented. Solution ^{13}C chemical shift assignments are made on the basis of NOESY and HETCOR results.



Results and discussion

Structures and numbering schemes for the three compounds examined are shown in Fig. 1. In Figs. 2 and 3, respectively, are the ORTEP diagrams resulting from the X-ray crystallographic studies of **1** and **3**. Solid phase ^{13}C spectra are illustrated in Fig. 4. Table 1 lists non-hydrogen atomic coordinates and equivalent isotropic displacement parameters. In Table 2 are presented the bond lengths and angles while selected torsional angles are listed in Table 3. Crystallographic data are in Table 4 and ^{13}C NMR chemical shifts are in Table 5.

Solution NMR assignments

For **1** the starting point for assignment of the ^{1}H spectrum is the NOESY correlation observed between the OCH_3 proton res-

onance and the *ortho* aromatic protons on C-6,9. Subsequent ^1H–^1H COSY and ^1H–^{13}C HETCOR (direct and long range) furnished the solution ^{13}C assignments shown in Table 4. These values are also consistent with predicted shieldings based on additivity employing the early published findings for anisole (8) and diphenyl ether (9). For the dibenzo-15-crown-5 system **2**, similar 2D experiments were used to obtain unambiguous ^{13}C chemical shifts in solution, with the key observation being the NOESY observed between the aromatic proton at 6.95 ppm and the CH_2O resonance at 4.15 ppm. This leads to clear assignment of the C6,9 and C13,18 sites. With these assignments as a starting point, the remainder followed via COSY and HETCOR. For the aromatic carbons, the results are all within 1 ppm of those found for corresponding sites of **1**, with the exception of C6, which is deshielded by ca. 3 ppm in **2**. This difference is most likely due to conformational effects involving the C6-C1-O-C18 unit. Unfortunately, X-ray crystallographic data for **2**

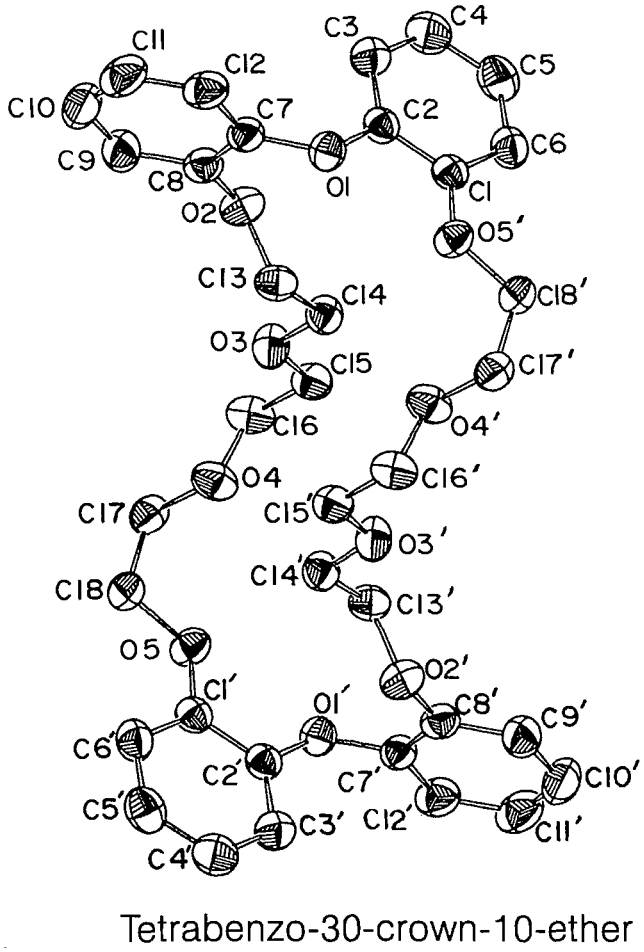

FIG. 3. ORTEP plot for **3**.

could not be obtained. The existence of nine ^{13}C resonances for **2** at temperatures between 300 and 173 K indicates rapid conformational interconversion on the NMR timescale over this range of temperatures, although substantial (up to 3 ppm) temperature-dependent chemical shifts were noted for some resonances. The solution ^{13}C spectrum for the tetrabenzo-30-crown-10 system **3** is remarkably similar to that of **2**, with the largest chemical shift difference between corresponding sites being 0.3 ppm. The spectrum of **3** is essentially temperature independent from ambient temperature to 173 K in CD_2Cl_2 solution, with the existence of nine lines indicating rapid conformational interconversion on the NMR timescale.

Solid phase ^{13}C spectra

As is clear from Fig. 4, the 45.3 MHz ^{13}C CPMAS spectrum of **1** suggests the existence of an asymmetric conformation in the solid, although crystal packing phenomena could also lead to additional resonances over those found in solution (1). In the event of an asymmetric conformation, a total of 14 lines should be observed. Experimentally, one finds a total of 12 lines with the aromatic CH at 111.9 ppm being of triple intensity. The X-ray crystallographic structure (Fig. 2) indeed shows the presence of such an asymmetric geometry. Unfortunately, 2D HETCOR NMR methods for unambiguous assignment of solid phase ^{13}C spectra are limited by the inherently low resolution of solid phase ^1H spectra even under the most optimal conditions. Hence one can make very few definite attributions of solid

phase ^{13}C resonances. In many cases, however, the solution spectral data serve as a valuable point of reference and many of the assignments in Table 4 have been made on this basis. It is of interest to speculate on the origin of the triple intensity aromatic CH at 111.9 ppm and also the relatively shielded quaternary carbon resonance at 142.0 ppm. Based on the solution spectrum, two of the carbons contributing to the triple intensity 111.9 resonance will be C6 and C9. For the other carbon, the expectation is that it must be either C3 or C12 (8, 9).

Examination of the torsional angles obtained from the X-ray crystal structure (Table 2) reveals one important difference in the environments of C3 vs. C12. Specifically, for the C2-O1-C7-C12 network, the torsional angle is −4.5°, while that for the corresponding C7-O1-C2-C3 network is 108.0°. Recent *ab initio* theoretical calculations of shieldings for

C-O-C-C networks as a function of dihedral angle (6, 10) as well as earlier experimental results (11) indicate that the terminal carbons of such four-atom networks will be substantially shielded (ca. 5 ppm) in the *cisoid* geometry relative to cases where the terminal atoms are nearly perpendicular. Hence we assign C12 as the third contributing carbon to the triple intensity resonance at 111.9 ppm. Via a similar argument, the highly shielded (δ_C = 142.0) quaternary carbon in the solid phase ^{13}C spectrum of **1** is attributed to C2, with its counterpart C7 being ca. 6 ppm deshielded.

The solid phase ^{13}C spectrum of **2** indicates that, in the crystalline state, the molecule lacks any symmetry elements. Unfortunately, the X-ray crystal structure is not available so that detailed discussion of shielding differences in terms of known structural features is not possible.

In the case of **3**, the X-ray crystal structure indicates that the molecule possesses a centre of symmetry and the ^{13}C CPMAS spectrum is consistent with this structural feature. Based on a consideration of torsional angles, one can make some predictions of relative shielding for many of the nonequivalent sites of **3** in the solid phase ^{13}C spectrum. For C3 vs. C12, for example, the torsional angles for the C3-C2-O1-C7 and C12-C7-O1-C2 networks are −32.2° and 121.9°, respectively. Based on a consideration of the calculated absolute ^{13}C isotropic shielding as a function of torsional angle for a *C-C-O-C network (10), one would predict that C3 should be ca. 2 ppm more shielded than C12. The experimental difference for **3** is 2.4 ppm.

In the case of the aliphatic carbons of **3**, solution nOe and HETCOR results (vide supra) show that the C13, C18 pair are most shielded. In the solid phase C13 and C18 are not averaged by conformational motion and thus give separate resonances in the ^{13}C CPMAS spectrum. In the crystal structure there is a large difference in the C18-O5-C1-C6 angle (9.8°), relative to that for the corresponding network containing C13, i.e., C13-O2-C8-C9, which is 116.0°. Based on our earlier calculations of shielding for a *C-O-C-C network as a function of dihedral angle (10), C18 is assigned as the most shielded aliphatic carbon, appearing at 67.9 ppm. The C13 position is deemed to be the next most shielded at 69.2 ppm. The geometry for the O3C15-C16-O4 network (70.1°) is close to that found for the O4-C17-C18-O5 unit (76.3°). Hence the triple intensity line at 70.4 ppm is attributed to C15, C16, and C17. The remaining solid phase ^{13}C resonance at 72.4 ppm is assigned to C14. The basis for this lies with the torsional angle of 78.1° found for the O2-C13-C14-O3 unit. Expansion of an O-C-C-O angle from 70 to ca. 78° is expected to lead to deshielding of ca. 1 ppm in the isotropic ^{13}C shift as calculated employing ethylene glycol as a model (10).

X-ray crystallographic structures

With respect to the torsional angles in the 30-membered ring of **3**, the O-C-C-O angles in the areas of the molecule not restricted by the geometry of the aromatic ring are *gauche*, in accord with that expected (12). There is, however, some expansion of the angles to 70°–78°, and noted previously. For the C-C-O-C units, the normal (11) crown ether geometry is *transoid*. In **3**, the C17-C18-O5-C1 angle is contracted to 163.3°, while the angles for the C13-C14-O3-C15 and C14-C13-O2-C8 moieties are 177.0° and 173.0°, respectively.

In the case of **1**, the molecule adopts a conformation that minimizes the steric interaction between the *ortho* methyl groups as well as between the two aromatic rings. The key torsional angles here are C2-O1-C7-C12, which is −4.5°, and C1-C2-O1-C7, which is −76.3°. The resulting angle between the planes of the two aromatic rings is ca. 72°. Previous studies of X-ray structures of *ortho*-substituted diphenyl ethers (13) have shown that a perpendicular conformation (interplanar angle of 90°) is adopted only in cases where at least three *ortho* substituents are present.

To conclude, these studies again show the complementarity between solid phase ^{13}C NMR and X-ray crystallography for solid state stereochemical studies. For systems such as **1**, it is hoped that the next step will be single crystal ^{13}C studies, so that details of the ^{13}C chemical shift anisotropies, as were recently published for 1,4-dimethoxybenzene (14), may be available.

Experimental

Materials

Compound **1** was prepared via condensation of the sodium salt of guaiacol (2-methoxyphenol) with *o*-bromoanisole according to the published method (15) using CuCl. Subsequently, didemethylation of **1** was carried out to give 2,2′-oxydiphenol using chlorotrimethylsilane and sodium iodide in dry acetonitrile as previously reported (16). A

mixture of **2** and **3** was obtained upon condensation of 2,2′- oxydiphenol with the ditosylate of triethylene glycol according to the following procedure.

To NaH (0.96 g, 0.04 mol), as a dispersion in dry THF (250 mL), was added 2,2′-oxydiphenol (3.13 g, 0.015 mol) and the mixture was stirred at room temperature for 2 h to allow complete salt formation. To this was added the ditosylate of triethylene glycol (9.20 g, 0.02 mol) in 100 mL of dry THF over a period of 30 min. This mixture was then heated at reflux and stirred for 2 days. After cooling the reaction vessel, the excess NaH was slowly destroyed with water (100 mL) and the organic compounds were extracted with CH_2Cl_2 and dried over anhydrous $MgSO_4$. After solvent removal, the crude oily product was purified by flash chromatography using silica gel and 1:1 ethyl acetate: 30–60 petroleum ether. The first material eluted was unreacted ditosylate and crude solid **2** (2.32 g). Later fractions contained a lower melting solid. Final purification was accomplished via recrystallization from ethyl acetate – petroleum ether to give **2** (yield 23%), mp 116–118°C (lit. (7) mp 114–115°C), and **3** (yield 20%), mp 93–94°C.

Spectra

Solid phase ^{13}C NMR spectra were recorded at 45.3 MHz on a Bruker CXP-180 spectrometer using techniques described previously (2). Solution ^{1}H and ^{13}C spectra were obtained using a Bruker AMX-400 system. In the NOESY experiments, the mixing times were selected to be consistent with the $1/T_1$ criterion (17), and for these molecules the time was set at 0.3 s. For the ^1J HETCOR experiments, delays were set to correspond to an average $^1J_{CH}$ value of 140 Hz.

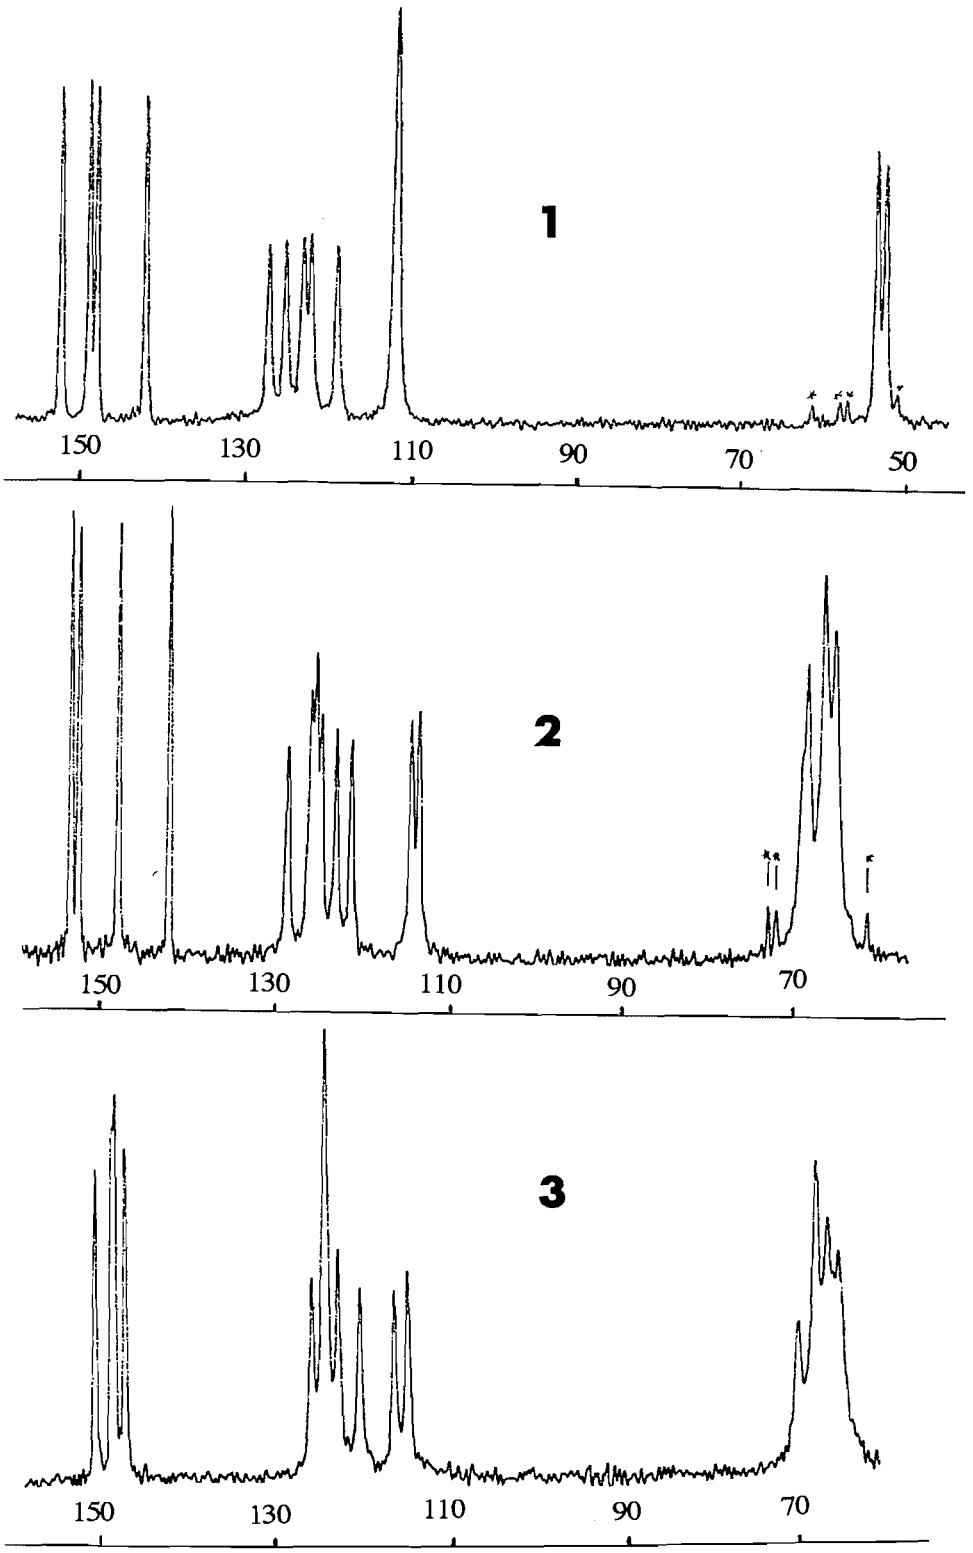

FIG. 4. 45.3 MHz ^{13}C CPMAS NMR spectra.

Cry*stallographic measurements and structure solution*

Pertinent data about the crytals use and the measurement of diffraction intensities are summarized in Table 4. The crystals of **1** and **3** were mounted at the end of glass fibres. The intensity data were collected on an Enraf–Nonius CAD-4 diffractometer using graphite-monochromated radiation, CuKα (λ = 1.5418 Å). The intensities were collected using the ω–2θ scanning procedure and three reflections were measured after every 7200 s of exposure time to check on the stability of the crystal. The maximum variation in the intensity of the standard reflections was 2.4% for **1** and 4.4% for **3**. The data were rescaled to take into account these variations, and were corrected for Lorentz and polarization effects. The two structures were solved by direct methods using the XTAL program package (18). For **1**, all of the hydrogen positions were found in the difference Fourier map. For **3**, all of the hydro-

gen atom positions, except the methyl hydrogens, were found in the difference Fourier map. The positions of the methyl hydrogens were calculated. The structures were refined by full-matrix least squares. The function minimized was $\Sigma w\|F_o - F_c\|^2$, where $w = 1/[\sigma_{Fo}{}^2 + eF_o{}^2]$, with $e = 0.0002$ for **1** and $e = 0.0004$ for **3**. All reflections with $I \geq 3\sigma I$ were used. Anisotropic temperature factors were used for the non-hydrogen atoms. Isotropic temperature factors equal in magnitude to the equivalent isotropic values of their parent atoms were assigned to the hydrogens. The hydrogen atoms were included in the calculations, but neither their positions nor their temperature factors were refined.[3] The scattering factors were taken from Cromer and Waber (19). Anomalous dispersion coefficients were taken from Cromer (20). All calculations were done on a Sparc station 1+ using the XTAL program package (18). The program ORTEP (21) was used for the preparation of the illustrations.

Synthesis of tridentate amine Pt(II) complexes and study of their reactions with purine and pyrimidine bases

FERNANDE D. ROCHON AND GUYLAINE LAPERRIÈRE

Département de chimie, Université du Québec à Montréal, C.P. 8888, Succ. A, Montréal, QC H3C 3P8, Canada

Received September 2, 1993

FERNANDE D. ROCHON and GUYLAINE LAPERRIÈRE. Can. J. Chem. **72**, 1225 (1994).

Complexes of the type [Pt(L)X] where L is a tridentate N ligand and X = Cl or I, were synthesized and characterized. Three of the ligands are N-derivatives of diethylenetriamine, (2-aminoethyl)(*N*-dimethyl-2-aminoethyl)amine, (2-aminoethyl)(*N*-diethyl-2-aminoethyl)amine, and (2-aminoethyl)(*N*-methyl-2-aminoethyl)*N*-methylamine. The other two ligands are di(3-aminopropyl)amine and (2-aminoethyl)(3-aminopropyl)amine. A new method for the synthesis of the chloro complexes from the direct reaction of the amine with $K_2[PtCl_4]$ was developed. The reactions of these five compounds with several purine and pyrimidine bases were studied by NMR techniques. The Pt(II) complexes containing two five-membered chelates were shown to be more reactive than the one containing two six-membered rings, while the complex containing one five- and one six-membered chelates showed intermediate reactivity. For the diethylenetriamine derivatives, the complexes containing ligands with two alkyl groups on the same terminal N atom were more reactive than the one containing one methyl group on a terminal N atom and one methyl group on a non-terminal N atom.

FERNANDE D. ROCHON et GUYLAINE LAPERRIÈRE. Can. J. Chem. **72**, 1225 (1994).

Des complexes de type [Pt(L)X]X où L est un ligand tridentate azoté et X = Cl or I, ont été synthétisés et caractérisés. Trois des ligands sont des dérivés du diéthylènetriamine, (2-aminoéthyl)(*N*-diméthyl-2-aminoéthyl)amine, (2-aminoéthyl)(*N*-diéthyl-2-aminoéthyl)amine et (2-aminoéthyl)(*N*-méthyl-2-aminoéthyl)*N*-méthylamine. Les deux autres ligands sont di(3-aminopropyl)amine et (2-aminoéthyl)(3-aminopropyl)amine. Une nouvelle méthode de synthèse des complexes chloro par une réaction directe de l'amine avec $K_2[PtCl_4]$ a été mise au point. Les réactions des cinq complexes avec quelques bases purines et pyrimidines ont été étudiées par rmn protonique. Les composés de platine contenant deux chélates à cinq membres sont plus réactifs que celui contenant deux chélates de six atomes, tandis que complexe contenant un cycle à cinq et un cycle à six atomes, a montré une réactivité intermédiaire. Pour les dérivés de l'éthylènediamine, les deux complexes contenant des ligands avec deux groupements alkyles sur le même atome N terminal ont montré une réactivité supérieure à celui contenant un groupement méthyl sur un N terminal et un autre méthyl sur le N non-terminal.

Introduction

[M(dien)Cl]Cl (dien = diethylenetriamine and M = Pt and Pd) has often been used to study substitution reactions of square-planar metal complexes (1). The reactions are usually simple since it contains only one leaving group. In particular, it has proved to be a very useful model for the first binding step of the antitumor compound *cisplatin* (*cis*-$Pt(NH_3)_2Cl_2$) to DNA (2–8).

Kinetic studies of the substitution reactions of [Pt(dien)X]X with pyridine have shown that these reactions are three times faster for X = Cl than for the iodo complex (9). This parallels the order of the increasing bond strength. With a more bulky ligand like *N,N,N,N*-tetraethyldiethylenetriamine (Et_4dien), the complex [Pt(Et_4dien)I]I is much less reactive than the *dien* complex. The greater stability of the latter was assumed to be due to the presence of two bulky ethyl groups on each side of the platinum plane, which severely blocks the access of the entering ligand towards the metal center (1). The crystal structure of [Pt(Et_4dien)I]I was reported in 1980 (10). The results have shown that the terminal methyl groups are oriented away from platinum, slightly reducing the steric hindrance around the metal center.

The synthetic procedure to prepare the complexes [Pt(dien)X]X, where X = Br and I, has been known since 1934 (11). The same method for X = Cl was later shown by Watt and Cude (12) to produce a dichloro-bridged dimer containing bidentate *dien* ligands. These authors suggested a new method to synthesize the iodo complex from the reaction of the ligand with $PtI_2 \cdot H_2O$. The chloro complex could then be obtained by adding HCl, after removing the iodide ligand with a silver salt. A different method was published more recently (13). The product of the reaction of $PtCl_2$ with HCl was treated with dien.3HCl, the pH adjusted to 3 with LiOH and the mixture refluxed for 3 days. [Pt(dien)Cl]Cl·HCl was then isolated and treated with LiOH at 80°C at pH 10. [Pt(dien)Cl]Cl was eventually obtained after adjusting the pH to 4. These authors have also synthesized [Pt(Me_4dien)Cl]PF_6 and [Pt(Et_4dien)Cl]PF_6·HCl by similar methods.

We have found that these published methods are not adequate to prepare [Pt(L)Cl]Cl for L other than *dien* derivatives. We have therefore decided to try to develop a new simple method which would be more general for tridentate N ligands. We have chosen three alkyl derivatives of *dien*, two of which have dialkyl groups of one of the terminal N atom, *N,N*-dimethyldiethylenetriamine (Me_2dien) and *N,N*-diethyldiethylenetriamine (Et_2dien), while the third ligand has one methyl group of a terminal N and a second methyl group on the non-terminal N (MeMedien). We have also chosen one tridentate ligand, containing three methylene groups between the N atoms (NH_2—$(CH_2)_3$—NH—$(CH_2)_3$—NH_2, dipn) and finally a fifth ligand containing two and three methylene groups between the N atoms (NH_2—$(CH_2)_2$—NH—$(CH_2)_3$—NH_2, enpn).

The reactions of the five synthesized complexes [Pt(L)Cl]Cl with several purine and pyrimidine derivatives were studied by ^{1}H NMR. The results of these studies are described below.

Experimental section

The decomposition points were measured on a Fisher-Johns instrument. The conductivity measurements were done on a Radiometer ohmmeter CDM2e with a Radiometer electrode CDC 114 RF. The IR spectra were recorded in the solid state (Nujol mull, CsI plates) on a Perkin-Elmer 783 spectrometer. The ^{1}H NMR spectra were measured on a Varian EM 360L instrument, equipped with a signal averager

Varian V2048 for accumulation purposes. Sodium-2,2-dimethyl-2-silapentane-5-sulfonate was used as an internal reference. The concentration of the solutions varied from 0.1 to 0.2 M. K_2PtCl_4 was bought from Johnson Matthey Inc. and was purified by crystallization from water before use.

$PtI_2 \cdot H_2O$

This was synthesized from K_2PtCl_4 as previously described (12).

[Pt(L)I]I

The three 5-membered chelates where L = Me_2dien, Et_2dien, and MeMedien were synthesized by the method described by Watt and Cude (12). The yields are 57, 45, and 35% respectively. The conductivities in water are Λ_{mol} = 127, 122, and 131 10^{-4} S m^2 mol^{-1}. Anal. calcd. for [Pt(Et_2dien)I]I: C 15.9, H 3.5; found: C 16.1, H 3.8.

[Pt(L)Cl]Cl

Method 1: The two complexes with L = Me_2dien and Et_2dien were synthesized by the method reported by Watt and Cude (12). Yields: 10 and 12% respectively; dec. pt: 200 and 190°C; Λ_{mol} = 125 and 121 10^{-4} S m^2 mol^{-1}.

Method 2a: [Pt(Me_2dien)Cl]Cl, [Pt(Et_2dien)Cl]Cl, and [Pt(MeMedien)Cl]Cl: Two mmoles of purified K_2PtCl_4 were dissolved in 10 mL of water. A 5 mL aqueous solution containing 2.5 mmol of ligand was added dropwise to the Pt solution. The mixture was stirred during 48 h and heated twice at 60°C for 8 h (not heated overnight). The mixture was then filtered and the yellow filtrate evaporated to dryness at room temperature. The residue was washed with cold acetone. The product was dissolved in 8 mL of ethanol to remove KCl. The filtrate was evaporated to dryness and the residue dissolved in 4 mL of ethanol. The mixture was filtered and the filtrate again evaporated to dryness. The residue was washed several times with acetone and then with ether and finally dried with a vacuum pump for at least 24 h. [Pt(Me_2dien)Cl]Cl: yield: 78%, dec. pt. 200°C, $\Lambda_{mol} = 123 \times 10^{-4}$ S m^{-2} mol^{-1}; anal. calcd.: C 18.1, H 4.3, Cl 17.8; found: C 18.8, H 4.9, Cl 17.0; IR (cm^{-1}): 3412s, 1600m, 1080s, 1042s, 785s, 726s, ν(Pt—Cl) 335s; ^{1}H NMR (ppm) in D_2O, ($\Delta\delta$ from ligand): CH_3, 2.91 (0.72) and CH_2, 3.04 (0.55). [Pt(Et_2dien)Cl]Cl: yield: 75%, dec. pt. 192°C, $\Lambda_{mol} = 120 \times 10^{-4}$ S m^2 mol^{-1}; anal. calcd.: C 22.6, H 5.0, Cl 16.7; C 23.2, H 5.6, Cl 16.0; IR (cm^{-1}): 3400s, 1600m, 1073s, 1028s, 755s, 725s, ν(Pt—Cl) 335s; ^{1}H NMR (ppm) in D_2O, ($\Delta\delta$ from ligand): CH_3, 1.57 (0.58) and CH_2, 3.06 (0.48). [Pt(MeMedien)Cl]Cl: yield: 68%, dec. pt. 195°C, $\Lambda_{mol} = 118 \times 10^{-4}$ S m^2 mol^{-1}; anal. calcd.: C 18.1, H 4.3, Cl 17.8; C 18.4, H 5.0, Cl 16.8; IR (cm^{-1}): 3405s, 1600m, 1042s, 1017m, 775m, 725s, ν(Pt—Cl) 333s; ^{1}H NMR (ppm) in D_2O, ($\Delta\delta$ from ligand): CH_3, 2.75 (ligand 2.20, 2.28) and CH_2, ~3.2 (~0.6).

Method 2b: [Pt(dipn)Cl]Cl and [Pt(enpn)Cl]Cl: Two mmoles of purified K_2PtCl_4 were dissolved in 10 mL of water. A 6 mL aqueous solution containing 3.0 mmol of ligand was added dropwise to the Pt solution. The mixture was stirred for 72 h and heated at 60°C for three periods of 8 h (not heated overnight). The mixture was then treated as described above. [Pt(dipn)Cl]Cl: yield: 65%, dec. pt. 198°C, $\Lambda_{mol} = 123 \times 10^{-4}$ S m^2 mol^{-1}; anal. calcd.: C 18.1, H 4.3, Cl 17.8; C 18.4, H 5.2, Cl 16.8; IR (cm^{-1}): 3395s, 1600s, 1080m, 1047s, 726s, ν(Pt—Cl) 332m; ^{1}H NMR (ppm) in D_2O, ($\Delta\delta$ from ligand): N—CH_2—C 3.13 (0.5) and C—CH_2—C, 2.07 (0.48). [Pt(enpn)Cl]Cl: yield: 62%, dec. pt. 189°C, $\Lambda_{mol} = 130 \times 10^{-4}$ S m^2 mol^{-1}; anal. calcd.: C 15.7, H 4.0, Cl 18.5; C 16.2, H 4.8, Cl 17.2; IR (cm^{-1}): 3392s, 1595s, 1061s, 1043m, 724s, ν(Pt—Cl) 335m ^{1}H NMR (ppm) in D_2O, ($\Delta\delta$ from ligand): N—CH_2—C ~2.95 (~0.35) and C—CH_2—C, 2.02 (0.43).

Reactions of [Pt(L)Cl]Cl with purine and pyrimidine bases

Two methods were used. The first procedure was used only with pyrimidine. [Pt(L)Cl]Cl (0.1 M) was dissolved in 0.5 mL of D_2O directly in the NMR tube. An equivalent amount of pyrimidine was added. The solution was then heated at 40°C (8 h per day) until equilibrium was reached (about 3–4 days). The second method was used for all the other reactions. The purine or pyrimidine bases were added in a 1:1 ratio to the 6 mL 0.1 M [Pt(L)Cl]Cl aqueous (H_2O) solution. The mixture was mixed and heated (~8 per day) to 70°C until equilibrium has been reached (for 2 to 6 days). The solution was then evaporated to dryness and the residue dissolved in D_2O for the NMR spectra.

Results and discussion

Complexes [Pt(L)Cl]Cl

Five complexes of the type [Pt(L)Cl]Cl where L is a tridentate N ligand, were synthesized and characterized mainly by elemental analysis, conductivity measurements, NMR and IR spectroscopy. Three of the complexes contain N-methyl derivatives of diethylenetriamine, (2-aminoethyl)(*N*-dimethyl-2-aminoethyl)amine (*Me_2dien*), (2-aminoethyl)(*N*-diethyl-2-aminoethyl)amine (*Et_2dien*) and (2-aminoethyl)(*N*-methyl-2-aminoethyl)*N*-methylamine (*MeMedien*). The fourth complex contains a ligand with three methylene groups between the N atoms, di(3-aminopropyl)amine (*dipn*) which allows the formation of two 6-membered rings chelates. The last compound will form one 6-membered and one 5-membered chelate (2-aminoethyl)(3-aminopropyl)amine (*enpn*).

Two different methods were used for the preparation of the Pt(II) complexes. The first method is based on the method reported by Watt and Cude (12). The iodo complex is synthesized from $PtI_2.H_2O$. This method has a few advantages over the use of K_2PtX_4 as starting material. The purification steps are greatly reduced since there are no by-products to remove (KX) and $PtI_2.H_2O$ is very insoluble in water which makes it easy to remove by filtration. A second step is necessary to obtain the chloro complexes. The iodo atoms are precipitated by a silver salt in the dark in the presence of HCl. This method gives a good yield for L = diethylenetriamine. We have attempted to prepare the iodo complexes with our five tridentate ligands using this method. The three N-derivatives of *dien* gave the complex [Pt(L)I]I but the yields were lower than the one reported for *dien*, 57% for L = *Me_2dien*, 45% for *Et_2dien*, and 35% for *MeMedien*. The other two ligands, *dipn* and *enpn* did not produce any significant amount of [Pt(L)I]I and a decomposition of the reacting mixtures was observed. From the three iodo complexes, attempts were made to prepare the corresponding chloro compounds following mainly the method described by Watt and Cude (12). Only two complexes were obtained and with very low yields, [Pt(Me_2dien)Cl]Cl 10% [Pt(Et_2dien)Cl]Cl 12%. The compound [Pt(MeMedien)Cl]Cl could not be isolated, even after prolonged periods of reaction time.

From these reactions, it can be seen that the substitution of the iodo ligand by the chloro ligand is more difficult for the N-substituted ligands than for *dien*. Furthermore, the iodo complex with the ligand *MeMedien* containing one methyl group on a terminal N atom and one on the non-terminal N atom, seems more stable than the iodo complexes containing the ligands with two methyl or two ethyl groups on a terminal N atom, which in turn are more stable than [Pt(dien)I]I. Molecular models have shown that steric reasons are an important factor for the difference between *dien* and the other ligands, but the different reactivities of the N-substituted complexes cannot be due only to steric factors. The two complexes with *Me_2dien* and *Et_2dien* have one alkyl group on each side of the platinum plane which severely limits access of the entering ligand towards the metal center. For the *MeMedien* complex, there are theoretically two isomers: the two methyl groups can be on the same side or on opposite sides of the platinum plane. The formation of the latter isomer should be predominant. Therefore the steric hindrance is not larger for *MeMedien* than for the *Me_2dien and Et_2dien* complexes. The rate of formation of the trigonal bypyramid in the

Can. J. Chem. Downloaded from www.nrcresearchpress.com by EESC ESCOLA DE ENGENHARIA on 09/08/12
For personal use only.

transition state might explain the lower reactivity of [Pt(MeMedien)I]I compared to the complexes with two alkyl groups on one terminal N atom. In the transition state, the two terminal N atoms are located in the apical positions, while the third N atom is located in the plane along with the entering and leaving ligands. For the terminal N-dialkyl complexes, the entering ligand might approach the complex almost in a position *trans* to the N-substituted atom. Therefore, the transition state might be of lower energy than the one of the complex containing *MeMedien*, with a methyl group on a terminal N atom and one methyl group on the non-terminal N atom.

Following these results (no formation of [Pt(dipn)I]I and [Pt(enpn)I]I and the low yields of [Pt(L)Cl]Cl), we decided to develop a new and more general method for the synthesis of the chloro complexes. We have tried several methods without success. The use of K_2PtCl_4 in water brings purification problems, since all the products are soluble in water. We have tried the reaction of K_2PtCl_4 in DMF, since KCl is not soluble in DMF. At room temperature no reaction was observed after three weeks. When the solution was heated to 60°C, insoluble brown compounds were observed. When the solution was heated over 60°C, decomposition occurred rapidly. We have tried using $PtCl_2$ as starting material in water or in a mixture of water–ethanol. Results similar to those with DMF were obtained. We therefore decided to come back to the use of K_2PtCl_4 in water and try the use of different organic solvents in the purification process.

Prolonged heating at ~60°C of K_2PtCl_4 in aqueous solution with the five ligands under study produced the complexes [Pt(L)Cl]Cl. An excess of ligand was required for the reaction to proceed. Acetone was used to remove the excess ligand while ethanol was used to remove KCl (solubility of KCl in ethanol is 0.03 g/100 mL at 20°C). The reaction is faster for the alkyl derivatives of *dien* (*Me_2dien*, *Et_2dien*, and *MeMedien*) and slower for the ligand containing more C atoms between the N atoms (*enpn* and *dipn*). The first syntheses indicated a high % of C and H and a low % of Cl. Further washings with acetone to remove the excess ligand, gave reasonably good elemental analyses (see Experimental section). The complexes must be thoroughly dried under vacuum for at least 24 h. Special care must be taken for handling some of the complexes, since they are quite hygroscopic.

The conductivities of the complexes were measured in water. The results on fresh solutions showed values ranging from 118 to 130×10^{-4} S m^2 mol^{-1}. The conductivities were again measured after 48 h. The results were identical suggesting that the complexes do not hydrolyze easily.

The IR spectra of the synthesized compounds [Pt(L)Cl]Cl were measured in the solid state in Nujol. The main bands are shown in the Experimental section. The stretching —NH_2 and N—H vibrations were observed around 3400 cm^{-1} while the bending modes were found at 1600 cm^{-1}. Two stretching C—N bands were observed between 1017 and 1080 cm^{-1}. Two bands for the complexes containing the dialkyl derivatives of *dien* were observed for $\rho(NH_2)$ at 725 and ~770 cm^{-1}, while only one band was observed at 725 cm^{-1} for the *dipn* and *enpn* complexes. One band around 334 cm^{-1} was observed for the stretching ν(Pt—Cl). These assignments are based on those reported for similar complexes (12–15).

The ^{1}H NMR spectra of the complexes were measured in D_2O. All the peaks were observed at lower fields than those of the free ligands measured in the same solvent. The results are shown in the Experimental section. As expected, the protons located closer to Pt were more deshielded than those located further away. Most of the peaks overlapped and it was not possible to detect ^{195}Pt couplings with certainty. No free ligands could be detected in the aqueous solutions of the complexes.

Reactions with purine and pyrimidine bases

The reaction of [Pt(L)Cl]Cl with several purine and pyrimidine bases were studied in aqueous solution by ^{1}H NMR spectroscopy. The binding site of the bases can be determined by the chemical shift of the protons of the ligand in the complex and by the coupling of the protons in the close environment of Pt with ^{195}Pt (~34% natural abundance).

Two types of reactions were performed. A few reactions were done directly in the NMR tube in D_2O solution at room temperature. The spectra were recorded several times until equilibrium had been obtained. The intensity of the peaks of the complexed ligands (purine or pyrimidine) was compared to those of the free ligands. The extent of reaction was very small. Furthermore, since the reactions are very slow, some deuteration was noted after a few days on some of the protons. Therefore, most of the reactions were studied according to the following method. The reactants were dissolved in H_2O and the solution heated to 70°C 8 h per day, for 3–6 days. The solution was then evaporated to dryness under reduced pressure and the residue dissolved in D_2O. This method has the advantage of increasing the extent of reaction and also eliminates the problems due to deuteration of some of the protons. The results reported below correspond to equilibrium concentrations. Only the study with pyrimidine was done by the first method, because it has a low boiling point and the second method would eliminate some of the ligand in the evaporating process.

The reactions of the five complexes [Pt(L)Cl]Cl with inosine (ino) in a 1:1 ratio produced the complexes [Pt(L)(ino)]Cl_2. The binding site of inosine is N(7) as expected. The ^{1}H NMR spectra showed that the proton H(8) is deshielded by 0.54–0.74 ppm upon coordination, compared to 0.10–0.14 ppm for H(2) and 0.07–0.11 ppm for H(1′). Furthermore, a coupling with ^{195}Pt was observed for H(8) with $^3J(^{195}\text{Pt}—^1\text{H}(8)) = 22$ –24 Hz. The amount of coordinated inosine was 50% for *Me_2dien* and *Et_2dien*, 30% for *MeMedien*, 10% for *enpn*, and <5% for *dipn*. It seems that for the *dien* derivatives, [Pt(MeMedien)Cl]Cl is less reactive towards inosine than [Pt(Me_2dien or Et_2dien)Cl]Cl. The complex containing two six-membered chelate (L = *dipn*) is very stable and hardly reacts with inosine, while [Pt(enpn)Cl]Cl is slightly more reactive.

Similar reactions with guanosine were slightly more difficult to study, since guanosine is not very soluble in water. The NMR solutions were more dilute. The binding site is again N(7). The proton H(8) was deshielded by 0.34 to 0.47 ppm and H(1′) by 0.04–0.10 ppm upon coordination. The amount of coordinated guanosine was 90% for the *Me_2dien* and *Et_2dien* complexes, ~40% for *MeMedien*, ~20% for *enpn*, and ~10% for *dipn*. For the three latter complexes, free solid guanosine was observed. It was removed by filtration and weighed in order to determine the extent of the reactions. The order of reactivity of the complexes towards guanosine is similar to the results obtained with inosine.

Since the complexes containing six-membered chelates were not very reactive towards purine bases, similar reactions were done with smaller molecules, cytosine and pyrimidine. The reactions with cytosine were done at 70°C for 3 days. The

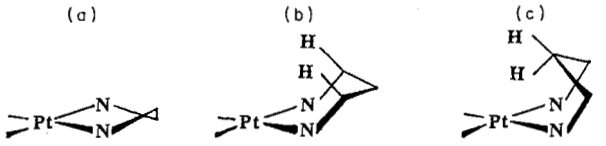

FIG. 1. Conformation of a Pt-chelate for (a) a five-membered ring, (*b*) a six-membered ring: chair (*c*) a six-membered ring: boat.

results have shown that the binding site of cytosine is N(3). The protons H(5) and H(6) are doublets with coupling constants of 7 Hz (free and bonded cytosine). The deshielding of H(5) in bonded cytosine is slightly larger (0.11–0.13 ppm) than of H(6) (0.07–0.09 ppm). No coupling $^4J(^1H(5)—^{195}Pt)$ could be measured. The amount of coordinated cytosine was 50% (*Me_2dien*), 40% (*Et_2dien*), 30% (*MeMedien*), 20% (*enpn*), and 15% (*dipn*). When the solutions were heated for another 6 days at 40°C, the amount of bonded cytosine was increased to 70% for *Me_2dien* and 65% for *Et_2dien*, but not for the other ligands. One side of the coupling $^4J(^1H(5)—^{195}Pt)$ could then be observed (~12 Hz for *Me_2dien* and ~15 Hz for *Et_2dien*).

Pyrimidine is a small simple molecule with two equivalent N atoms. By convention, N(1) is the binding site. These studies were done only in the NMR tubes. The reactions were first done in a mole-to-mole ratio. For the three ligands *MeMedien*, *enpn*, and *dipn* whose spectra indicated a great quantity of unreacted pyrimidine, the reactions were repeated in a Pt:pyrimidine ratio of 2:1 in order to reduce the intensity of the peaks caused by free pyrimidine. The spectra were measured 3 days after mixing the complexes with pyrimidine. The spectrum of free pyrimidine in D_2O solution, showed couplings ^3J(H(6 or 4)—H(5)) of 6 Hz, and ^5J(H(5)—H(2)) of 1.5 Hz. Binding of Pt at N(1) destroys the symmetry of pyrimidine and the number of peaks observed is increased. The deshielding of H(2) upon coordination varies from 0.40 to 0.52 ppm, H(6) 0.35 to 0.47 ppm, H(4) 0.16 to 0.20 ppm, and H(5) 0.15 to 0.21 ppm. ^{195}Pt couplings were observed with H(2) (^3J(Pt—H(2)) = 22–24 Hz) and with H(6) (^3J(Pt—H(2)) = 25–26 Hz). No such coupling was detected for H(4), indicating that pyrimidine does not bind as a bidentate ligand. H(6) is observed as a doublet of doublets of doublets with $^3J = 6$ Hz, $^4J = 2$ and 1 Hz. H(5) is observed as a doublet of triplets with $^3J = 5.4$ Hz and $^5J \sim 1.5$ Hz. H(2) is observed as a triplet (plus the satellites caused by coupling with ^{195}Pt) with $^4J = 2.1$ Hz. The amount of coordinated pyrimidine for the 1:1 ratio reactions were ~85% for *Me_2dien*, ~80% for *Et_2dien*, ~30% for *MeMedien*, and ~20% for *enpn* and *dipn*.

A few reactions with guanosine-5′ monophosphate were performed on three of the complexes. This ligand is interesting, since it is very soluble in water (in contrast to guanosine). The results have shown that for *Me_2dien* and *MeMedien*, the reactions were complete since no free guanosine-5′-monophosphate was observed. With [Pt(dipn)Cl]Cl, the amount of coordinated nucleoside at equilibrium was ~40%. The binding site is N(7). The proton H(8) was deshielded upon coordination by 0.44–0.55 ppm and coupled with ^{195}Pt with $^3J = 22$–24 Hz and H(1′) (doublet with $J \sim 5$ Hz) was deshielded by 0.12–0.15 Hz.

This study clearly shows that the complexes [Pt(L)Cl]Cl, where L is a diethylenetriamine derivative with two 5-membered chelate rings, are more reactive than the complex containing two 6-membered chelates (dipn). The complex [Pt(enpn)Cl]Cl containing one 5-membered chelate and one 6-membered chelate showed intermediate behavior. For the *dien* derivatives, the complexes containing two alkyl groups on a terminal N atom (*Me_2dien* and *Et_2dien*) are more reactive than [Pt(MeMedien)Cl]Cl which contains a ligand with one alkyl group on a terminal N and one alkyl group on a non-terminal N atom. The extent of reaction of the two complexes [Pt(Me_2dien)Cl]Cl and [Pt(Et_2dien)Cl]Cl are very similar. This is in agreement with the results obtained from the crystal structure of [Pt(Et_4dien)I]I (9). The authors have found that the terminal —CH_3 are located away from the Pt atom. Therefore the access to the metal center is not too different for the two ligands.

The addition of one more C atom in the chelate ring seems to play an important role in the kinetics of the reactions. The crystal structures of several [Pt(dien)X]X (10, 16–20) have shown that the C atoms of the *dien* ligand are close to the platinum coordination plane (Fig. 1*a*). For the 6-membered ring chelate, molecular models have shown that the three C atoms are considerably out of the plane (21). Two types of conformation (chair and boat) are possible for the 6-membered chelate with trimethylenediamine (Fig. 1).

In solution, the two forms probably exist, but the chair conformation should predominate. The approach of the entering ligand towards the metal will be much more difficult with the complex containing the 6-membered chelate compared to the 5-membered chelate. Furthermore, the presence of two 6-membered chelates where the three C atoms of each chelate could be located on different sides of the platinum plane, would severely block the access of the entering ligand towards the platinum center. In a different project, we have studied the reaction of [Pt(bis(aminopropyl)phenylphosphine)Cl]Cl (which contains two 6-membered chelates) with pyridine, inosine, guanosine, cytosine, and pyrimidine. No reaction was observed.

The results obtained with diethylenetriamine derivatives might seem surprising, but are similar to the substitution reactions of [Pt(L)I]I for chloride ligands, described earlier in this publication. The complex [Pt(MeMedien)Cl]Cl which contains one methyl group on a terminal N atom and one on a non-terminal N atom is much more stable than the two complexes containing two methyl or ethyl groups on a terminal N atom. If we examine the molecular models, the two substituents on the same terminal N atom are much closer to the leaving group than a methyl group on a non-terminal N atom. Therefore we must assume a S_N2 substitution reaction. The rate of formation of the trigonal bypyramid in the transition state might explain the lower reactivity of [Pt(MeMedien)Cl]Cl compared to the complexes with two alkyl groups on one terminal N atom. In the transition state, the two terminal N atoms are located in the apical positions, while the third N atom is located in the plane along with the entering and leaving ligands. For the terminal *N,N*-dialkyl complexes, the entering ligand might approach the complex almost in a position *trans* to the N-substituted atom. Therefore, the transition state might be of lower energy than the one of the complex containing *MeMedien*, with a methyl group on a terminal N atom and one methyl group on the non-terminal N atom.

The Generalized-Valence-Bond-Perfect-Pairing (GVB-PP) method has been used to investigate the structural behaviour, energy, and dipole moment along the reaction coordinates for propene ↔ H + *cis*- or *trans*-propen-1-yl. Geometry optimizations were carried out at the GVB(9)/STO-3G level (complete valence shell) for the minimum energy propene structure (complete optimization) and for numerous structures up to r(C—H) = 10 Å (only the elongated C—H distance kept fixed). The dissociation curves are smooth, without a maximum, and yield predicted dissociation energies of propene to H + *cis*-propen-1-yl and H + *trans*-propen-1-yl of 555.8 and 554.8 kJ mol^{-1}, respectively. These values are within several percent of those obtained for C—H bond rupture in ethylene using GVB and MCSCF methods with the same basis set. They are obviously too high but they confirm that removal of a hydrogen atom from the CH_2 moiety in propene requires about the same energy as removal of a hydrogen atom from ethylene. GVB(7)/6-31G//GVB(9)/STO-3G computations lower the predicted dissociation energies of propene → H + *cis*-propen-1-yl and H + *trans*-propen-1-yl to 448.2 and 448.6 kJ mol^{-1}, respectively.

The reduced energy concept ($E_R = (E_\infty - E_r)/D_e$) is applied to the reaction coordinates. Linear behaviour for ln E_R versus bond length is observed at long bond distances. At r(C—H) = 3 Å, the values of the slopes, d(ln E_R)/dr(C—H), which are related to the effective Morse constant B are –3.73 and –3.74 (GVB(9)/STO-3G) and –2.75 and –2.81 (GVB(7)/6-31G//GVB(9)/STO-3G) for the H + *cis*- and H + *trans*-propen-1-yl reaction coordinates, respectively.

GEORGE R. DE MARÉ, EARL M. EVLETH, RAYMOND A. POIRIER et GUY J. COLLIN. Can. J. Chem. **72**, 1230 (1994).

On a utilisé la méthode de l'appariement parfait de la liaison de valence généralisée (GVB-PP) pour étudier le comportement structurel, l'énergie et le moment dipolaire le long des coordonnées de la réaction propène ↔ H + *cis*- ou *trans*-propén-1-yle. On a effectué les optimisations de géométrie au niveau GVB(9)/STO-3G (couche de valence complète) pour la structure du propène à énergie minimale (optimisation complète) et pour de nombreuses structures jusqu'à r(C—H) = 10 Å (seule la distance C—H allongée est maintenue constante). Les courbes de dissociation sont lisses, sans un maximum, et elles conduisent à prédire des énergies de dissociation pour les réactions du propène en H + *cis*-propén-1-yle et en H + *trans*-propén-1-yle de 555,8 et 554,8 kJ/mol respectivement. Ces valeurs sont à l'intérieur des limites de quelques pour-cent de celles obtenues pour la rupture de la liaison C—H dans l'éthylène lorsque des calculs ont été effectuées par les méthodes GVB et MCSCF, avec le même ensemble de base. Ces valeurs sont évidemment trop élevées, mais elles confirment que l'enlèvement d'un atome d'hydrogène à partir de la portion CH_2 du propène nécessite approximativement la même énergie que l'enlèvement d'un atome d'hydrogène à partir de l'éthylène. Des calculs au niveau GVB(7)/6-31G//GVB(9)/STO-3G abaissent les valeurs des énergies de dissociation des réactions du propène en H + *cis*-propén-1-yle et en H + *trans*-propén-1-yle à 448,2 et 448,6 kJ/mol respectivement.

On a appliqué le concept de l'énergie réduite ($E_R = E_\infty - E_r)/D_e$) aux coordonnées de la réaction. Pour des longueurs de liaison élevées, on observe un comportement linéaire de ln E_R en fonction de la longueur de liaison. À r(C—H) = 3 Å, les valeurs des pentes d(ln E_R)/dr(C—H), qui sont reliées à la constante de Morse efficace, B, sont respectivement de –3,73 et –3,74 (GVB(9)/STO-3G) et de –2,75 et –2,81 (GVB(7)/6-31G//GVB(9)/STO-3G) pour les coordonnées des réactions H + *cis*- et H + *trans*-propén-1-yle.

[Traduit par la Rédaction]

1. Introduction

Propene (**1**) has been the object of many investigations of its thermal (1–8) and photochemical reactions (9–19), but the overall reaction mechanisms are still not fully elucidated. An important reason is the large number of products at lower pyrolysis temperatures: for instance Kallend et al. (8) identified 26 products, many of which are more reactive than **1**. Another reason is the low relative importance of the three α-CH bond cleavages compared to cleavage of the β-CH and α-CC bonds. The primary unimolecular processes involving cleavage of only one formal single bond in **1** are shown in Fig. 1. In this paper we examine the reaction coordinates for **1** ↔ H + C_3H_5 where C_3H_5 corresponds to either the *cis*-propen-1-yl or the *trans*-propen-1-yl radical (structures **2** and **3** in Fig. 1, respectively), using the Generalized-Valence-Bond-Perfect-Pairing (GVB-PP) method (20). Radicals **2** and **3** are formed in the direct photolysis of **1**.[1] They are also formed in the addition of methyl radicals to acetylene (21) and in the direct photolysis of both *trans*-

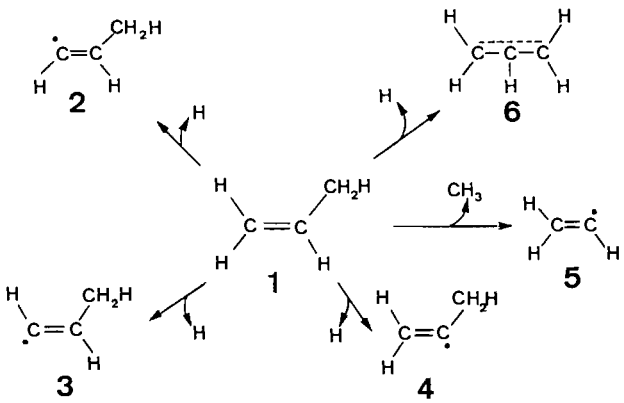

FIG. 1. Unimolecular dissociation processes in propene (**1**) involving the rupture of only one bond.

and *cis*-2-butene (9, 22, 23) and of larger olefins with the double bond in the 2-position (24). It is therefore of interest to obtain information on their structures, relative energies, etc.

Recently we reported an *ab initio* study of the reaction coordinate for ethylene ↔ H + vinyl(**5**), corresponding to C—H bond-breaking in ethylene or to hydrogen atom capture by **5** (25). As expected the single configuration Self-Consistent-Field (SCF) computations predicted an energy plateau at large C—H separations but this plateau is much too high energetically. The dipole moment increased with increasing C—H separation, indicating that the separated species constitute an ionic pair (25). This behaviour was expected: it is the result of the methodology employed in generating the wave function and is independent of the composition of the basis. However, if a correct methodology is employed, the computed bond energy will be dependent on the basis set composition. Both GVB-PP and Multi-Configuration-SCF (MCSCF) methods were used: the single configuration SCF method is inadequate except (*a*) at equilibrium geometries or (*b*) at long internuclear distances with an open-shell methodology. The minimal levels necessary for the GVB-PP and MCSCF calculations to obtain satisfactory results were determined, not only for the C—H reaction coordinate in ethylene, but also for H—X reaction coordinates where X = CH_3, OH, and F (25).

Thermal reactions of 1

At low temperatures and moderate to high pressures the thermal reactions of **1** are initiated mainly by the bimolecular disproportionation reaction [1] (6)

[1] $2\,\mathbf{1} \rightarrow$ allyl(**6**) + isopropyl

whereas at higher temperatures and low concentrations of **1** the decomposition processes [2]–[5] are necessary to explain the results (see ref. 1 and references therein).

[2] $\mathbf{1} \rightarrow H + \mathbf{6}$

[3] $\mathbf{1} \rightarrow \dot{C}H_3 + \mathbf{5}$

[4] $\mathbf{1} \rightarrow CH_4 + C_2H_2$

[5] $\mathbf{1} \rightarrow H_2 + C_3H_4$

The relative importance of the primary steps

[6] $\mathbf{1} \rightarrow H + \mathbf{2}$

and

[7] $\mathbf{1} \rightarrow H + \mathbf{3}$

in the thermal reactions of **1** have not yet been determined experimentally but the participation of $H\dot{C}{=}CH{-}CH_3$ radicals of undefined geometry in its shock tube pyrolysis has been proposed by Hidaka et al. (1).

Photochemical reactions of 1

Because processes [2] and [3] require less energy than the cleavage of any of the three vinylic α-CH bonds, the equivalent bond ruptures are quite important in the triplet mercury photosensitization of **1** at low pressures (13, 26) and also in its direct photolysis (17, footnote 1). Process [2] is very interesting because, on the time scale for photon absorption, the in-plane C—H bond of the methyl group differs from the two out-of-plane ones (27).

Avrahami and Kebarle (19) were the first to show that isomerization to cyclopropane occurs in the triplet mercury photosensitization, presumably via the trimethylene biradical

[8] $\mathbf{1} \rightarrow$ cyclopropane

formed by a 1,2-H atom migration in triplet **1**. Product analysis led them to conclude that processes [2], [3], and [8] occur in the ratio 89:11:0.2 at a total pressure of ca. 10 torr. Placzek and Rabinovitch (28) found that the relative cyclopropane yield increased to a maximum of about 1.4% at 70 torr pressure, its precursor(s) being deactivated by collisional quenching. It is interesting to note that the formation of the trimethylene biradical requires a 1,2 H-atom shift and that if it were followed by a second 1,2 shift in the biradical to yield **1**, H-atom scrambling in the "unreacted" parent compound should be observed. Thus starting with the 1,3,3,3,-**1**-d_4 isotopomer, one would expect the formation of the 1,1,3,3-**1**-d_4, 1,1,2,3-**1**-d_4 and 1,2,3,3-**1**-d_4 isotopomers. However, Hirokami and Sato (13) reported that the ratio of the *cis*- to *trans*-1,3,3,3-**1**-d_4 isomers after prolonged photosensitization with Hg $6(^3P_1)$, Cd $(^3P_1)$, or benzene was unity. No other isotopomers were reported. Furthermore they searched specifically for 2,3,3,3-**1**-d_4 and found no evidence for its formation. This is even more remarkable when one considers the facile H-atom scrambling observed in the triplet photosensitizations of ethylene-d_2 by mercury (29, 30), cadmium (31), and organic compounds (32). This underlines the remarkable effect of the CH_3 moiety on the processes following energy transfer to **1**. Note also that *trans*-cyclopropane-d_2 isomerizes to **1**-d_2 (33). A possible explanation, put forward by Bernardi et al. (34) is that "It is conceivable that the structural isomerization proceeds by a path not involving trimethylene, and hence may not be pertinent to the [1,2] shift transition state." Clearly more experimental work is needed on this problem which we are currently investigating by theoretical methods.

To our knowledge, the importance of the 1,3-H atom shift corresponding to the reaction ↔ no-reaction sequence $H{-}CH_2CH{=}CH_2 \leftrightarrow CH_2{=}CHCH_2{-}H$ (the products of which would be indistinguishable from those from two consecutive 1,2-H atoms shifts in the same direction) has not been determined experimentally. However, *ab initio* computations on the relative energy of the transition state (barrier) for this isomerization indicate that it may be in competition with process (2) (33–35) in the vibrationally excited ground state.

[e,f]The sum of the energies from a SCF/STO-3G computation on an isolation H atom (E = −0.466582 hartree) and for the ROHF-GVB(8)/STO-3G optimized structure of **2** (E = −115.119237 hartree) or for the ROHF-GVB(8)/STO-3G optimized structure of **3** (E = −115.119652 hartree) are equal to that of the GVB(9)/STO-3G optimized C_3H_6 structures with r(H1—C1) or r(H2—C1) ≥ 4 Å (E = −115.585819 and −115.586234 hartree, respectively).

In our previous work it was shown that inexpensive GVB and MCSCF computations could yield reasonable potential energy curves and total dissociation energies that are within 20% of the best experimental values (25). This paper is the first of several that will be devoted to the chemistry of **1**, including new experimental results on its direct photolysis[1] and theoretical studies on decomposition/isomerization processes in its ground and first triplet electronic states. Here we report surfaces for **1** ↔ H + **2** and **1** ↔ H + **3** which can be treated by GVB methods. Later work will deal with the methodologically difficult surface **1** ↔ H + **4**. The eventual goal is to use the information in theoretically modeling the photochemistry (and thermal reactions) of **1**.

2. Method

The computations were performed with the MONSTERGAUSS *ab initio* program package (37) with the STO-3G (38) and 6-31G (39) basis sets. The optimally conditioned (OC) variable-metric gradient minimization technique (40)[2] was used for all geometry optimizations. The molecular orbitals generated by a complete SCF (single configuration) geometry optimization of **1** were used to identify the valence-virtual orbital pairs for use in the GVB-PP computations. The computations designated by GVB(N) indicate that N correlated valence – virtual orbital pairs were used. Thus GVB(9)/STO-3G included all nine valence orbitals in the correlated valence – virtual pairs. Complete geometry optimization was performed at the minimum energy structure of **1**. Along the reaction coordinate only the C—H internuclear distance corresponding to the bond being broken was kept rigorously fixed. No symmetry restrictions were imposed during the optimizations. However, if one starts the optimization with a slightly deformed structure, the minimum energy structure was found to have C_s symmetry.

Single computations, with the extended 6-31G basis set and including seven correlated pairs were performed at the STO-3G optimized geometries. These are designated by GVB(7)/6-31G//GVB(9)/STO-3G throughout the text. The number of correlated pairs had to be reduced because of memory limitations in the program. The seven valence – virtual orbital pairs chosen for the correlations represent the three σ(C—H) bonds, the two σ(C—C) bonds, the π(C1—C2) bond, and the π-bond involving the methyl group and localized on the C3, H5, and H6 atoms. The two valence orbitals excluded in the excitations were essentially localized on the methyl group and this should not influence the relative energetics to any appreciable extent (25, 41, 42).

3. Results and discussion

3.1. GVB(9)/STO-3G optimizations on 1 ↔ H + cis-propen-1-yl

The results of the GVB(9)/STO-3G optimizations at four points (including the minimum energy structure) along the reaction coordinate for process (6) (or the inverse process, capture of an H atom by **2**) are presented in Table 1. The experimental r_s (substitution) structure, determined from the microwave spectra of seven isotopomers of **1** (43), is also given for comparison. As expected, the GVB(9)/STO-3G optimized bond lengths are all longer than those obtained in a complete RHF/STO-3G optimization of **1**. They are shown in Fig. 2 along with the atom numbering used throughout the text. The consistency of the GVB(9)/STO-3G results at long H1—C1

[2]The routine is described in ref. 40*a*.

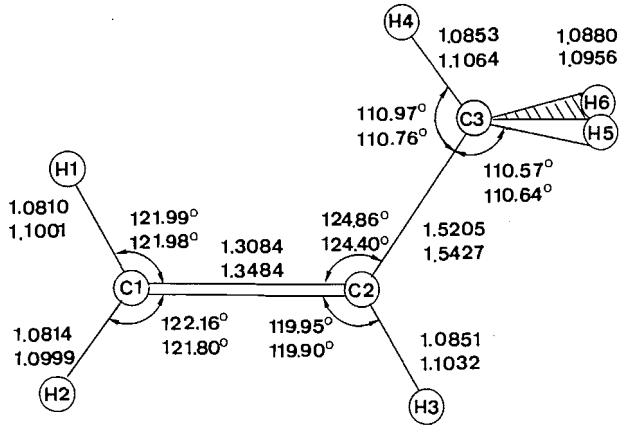

FIG. 2. Atom numbering used throughout the text. The top and bottom values of the geometrical parameters are those obtained by complete SCF/STO-3G and GVB(9)/STO-3G optimizations, respectively.

internuclear distances was tested by carrying out a ROHF-GVB(8)/STO-3G optimization on the radical **2**. The results are juxtaposed in Table 1 next to those for **1** with r(H1—C1) = 10 Å. Only minor differences are observed between the corresponding geometrical parameters for the radical and structures of **1** with r(H1—C1) ≥ 3 Å. (Indeed all parameters are predicted to be essentially independent of r(H1—C1) for internuclear distances greater than about 3.0 Å.) Especially, as noted in Table 1, the GVB(9)/STO-3G energy of **1** at large H1—C1 internuclear distances is equal to the sum of the STO-3G energy of an isolated H atom and the ROHF-GVB(8)/STO-3G energy of **2**. Also the computed dipole moments for the radical and the complex are the same.

The geometrical parameters which undergo the largest variations as the H1—C1 bond is elongated from the optimized equilibrium position (r(H1—C1) = 1.1001 Å) are the two C—C bonds and the angles H1C1C2 and H2C1C2. The behaviour of these four geometrical parameters along the reaction coordinate is shown in Fig. 3 for a large number of optimizations. It is interesting to note that H1 is predicted to move towards the space above the C—C bond. This may reflect the attraction of the π electrons or alternatively it may be due to the role of a lower energy singlet propylidene on the hypersurface of this reaction. H2, which is on the radical center, moves towards the free electron. Similar behaviour was observed for the corresponding H atoms along the ethylene ↔ H + **5** reaction coordinate (25). It is probably a common feature for α-CH bond cleavage in olefins.

For the optimized minimum energy structures, the H2—C1 bond length is predicted to be shorter in **2** than in **1** by about 0.001 Å while the remaining C—H bond lengths remain essentially unchanged (see Table 1). This is in contrast to the GVB(2)/STO-3G results on ethylene which predicted that the C—H bond lengths in **5** are longer than in the parent compound by 0.001 to 0.003 Å (25). The difference between these results for **2** and **5** appears to be an artifact of including all or only part of the valence shell orbitals in the correlated pairs. Indeed, including the full valence shell in the correlated pairs in a series of optimizations (GVB(6)/STO-3G) along the ethylene ↔ H + **5** reaction coordinate results in a shortening of the C—H bond on the radical center whereas those on the CH_2 moiety remain essentially unchanged.[3] Note also that Wu and Carter (42) performed a full valence GVB-PP optimization on **5**, using a VDZP (valence double-ζ with polarization) basis set, and found that the C—H bond on the radical center was predicted to be shorter than those on the CH_2 moiety.

The strange behaviour of ∠H1C1C2 for r(H1—C1) in the range 2.5–3.5 Å merits attention. Is it an artifact of the computations or is it real? Note that similar behaviour is observed for the corresponding angle in ethylene.[3] At first glance one might impute the behaviour to computational (integral-space) accuracy.

As the H1—C1 bond is elongated, the relative energy rises smoothly to a plateau lying 555.8 kJ mol^{-1} above the minimum (Fig. 4). Thus there is no predicted activation energy for the reverse step, capture of an H atom by **2**. This appears to be a general feature for the GVB-PP potential energy curves for these reactions, even if the correlated pairs include only part of the valence shell (25).

3.2. *GVB(9)/STO-3G optimizations on* **1** ↔ *H + trans-propen-1-yl*

Some results of the optimizations are given in Table 1 (at r(H2—H1) = 1.5, 3.0, and 10.0 Å) and in Figs. 5 and 6. As expected the two C—C bonds and the angles H1C1C2 and H2C1C2 undergo the largest variations as H2 is drawn away from the equilibrium position at r(H2—C1) = 1.0999 Å. The dissociation energy is predicted to be 554.8 kJ mol^{-1}, thus only 1 kJ mol^{-1} less than for the removal of H1 from **1**. It is not expected that zero-point energies will make a big difference in this result. It is therefore concluded that the important difference in the ratio for α-CC/β-CH bond cleavage observed in the photolysis of the 2-butenes (α-CC/β-CH = 0.95 and 1.34 for *cis*- and *trans*-2-butene, respectively (22)) does not originate in the energies of formation of the radicals **2** and **3**.

The terminal α-CH bond dissociation energies in **1** are expected to be near that for the C—H bond dissociation energy in ethylene, $D_e(CH_2CH—H)$. Using various geometries and GVB-PP and MCSCF treatments with the same basis set, we previously found $D_e(CH_2CH—H)$ values in the range 543–549 kJ mol^{-1} (25) or about 1 to 2% less than those found here for the terminal α-CH bond cleavages in **1**. These values are obviously too high but they confirm that removal of a hydrogen atom from the CH_2 moiety in **1** requires about the same energy as removal of a hydrogen atom from ethylene. Note that the scatter in the experimental data for the C—H dissociation in ethylene is important, as exemplified by recent literature values of $D_0(CH_2CH—H)$ = 459.0 ± 3.3 kJ mol^{-1} (45) and 488.3 ± 5.0 kJ mol^{-1} (46).

Using various GVB and CI methods, Wu and Carter (42) obtained theoretical $D_e(CH_2CH—H)$ from 436.0 to 490.3 kJ mol^{-1}, thus covering the experimental range of values. They used a much higher level of theory and computing enough points along the reaction coordinate would be expensive in computational time. It is suggested that as a first approximation the GVB(9)/STO-3G curves for **1** could be simply multiplied by a factor of 460/555 = 0.83 to obtain realistic reaction coordinates. Alternatively, considering that the highest value obtained by Wu and Carter (42) was obtained at the highest level of theory, a scaling factor of 490/555 = 0.88 may be more appropriate.

The effect on the reaction coordinates of using a split-valence basis-set in the computations has been investigated by carrying out complete series of GVB(7)/6-31G//GVB(9)/STO-3G computations (see below).

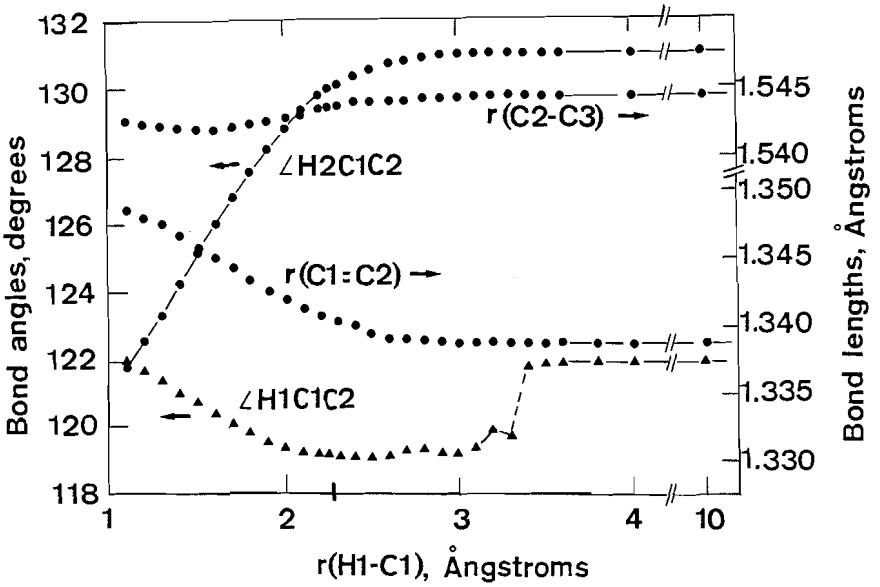

FIG. 3. The GVB(9)/STO-3G optimized values of r(C1—C2), r(C2—C3), ∠H1C1C2, and ∠H2C1C2 as a function of the H1—C1 internuclear distance in **1**. For r(H1—C1) greater than 3.2 Å, ∠H1C2C1 remains essentially equal to the input value.

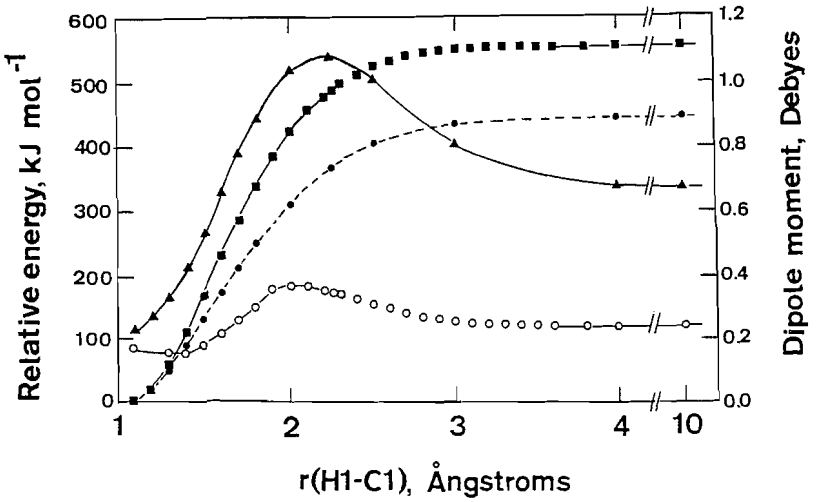

FIG. 4. The GVB(9)/STO-3G relative energies (■) and dipole moments (○) and the GVB(7)/6-31G//GVB(9)/STO-3G relative energies (●) and dipole moments (▲) as a function of the H1—C1 internuclear distance in **1**.

3.3. GVB(7)/6-31G//GVB(9)/STO-3G computations

The relative energies from the GVB(7)/6-31G//GVB(9)/STO-3G computations are represented in Figs. 4 and 6 for comparison with the GVB(9)/STO-3G results. Whereas the form of the curves for the GVB(7)/6-31G//GVB(9)/STO-3G relative energies are similar to those from the GVB(9)/STO-3G optimizations, the predicted dissociation energies are now much closer to the expected values (see above) being lowered by about 100 kJ mol^{-1} to 448.2 and 448.6 kJ mol^{-1} for the formation of **2** and **3**, respectively. The order of the relative energies of **2** and **3** is reversed but complete geometry optimizations of the radical structures at the GVB(7)/6-31G level could change this. Any effect on the total energy due to the methyl group being *cis* or *trans* to the free electron is predicted to be very small.

3.4. Reduced energy surfaces for propene

Plots of the reduced energy E_R (see below) and of ln E_R versus the H1—C1 and H2—C1 internuclear distances in **1** for the series of GVB(9)/STO-3G optimizations and GVB(7)/6-31G//GVB(9)/STO-3G computations are given in Fig. 7.

We have previously shown (25, 47) that computed surface forms obtained with various molecular orbital generating methodologies and different basis sets can be compared by using a reduced energy (E_R) expression, $E_R = 1 - E(r)/D_e$, where $E(r)$ is the computed relative energy at interatomic distance r and D_e is the total computed dissociation energy. ($E(r) = 0$ at r_e, the equilibrium bond distance.) It was also shown that ln E_R is linear with distance at long bond distances. This also occurs when one employs the Morse equation, $E_R = 2 \exp(-B(r - r_e)) - \exp(-2B(r - r_e))$. At long bond distances the slope, d(ln E_R)/dr, approaches a value of $-B$. Note that $B = (k/2D_e)^{1/2}$ where k is the force constant. The resulting linearity can be used as a criterion of whether the computational results are valid. It should be noted that various molecular dynamic modeling schemes have assumed exponential linearities in the long bond distance region (e.g. see refs. 48, 49). Such linearity is expected for sim-

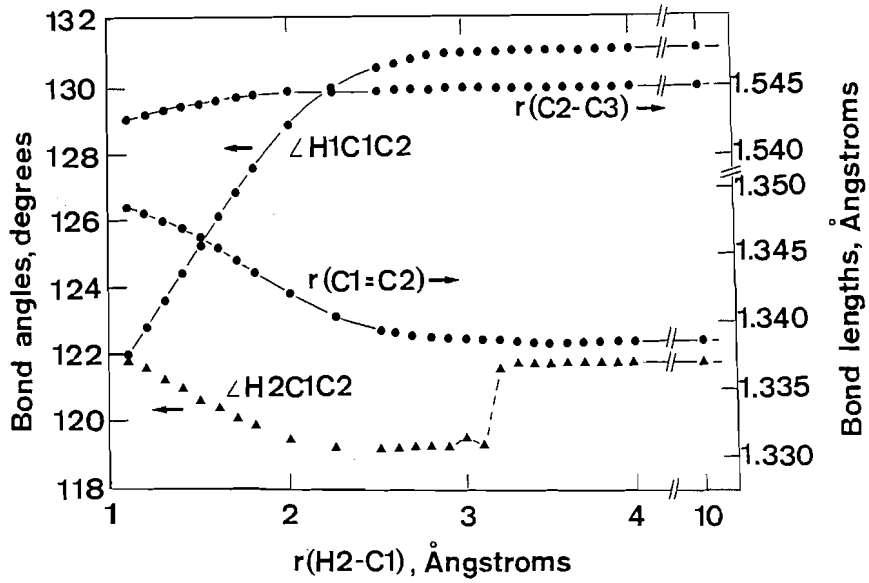

FIG. 5. The GVB(9)/STO-3G optimized values of r(C1—C2), r(C2—C3), ∠H1C1C2, and ∠H2C1C2 as a function of the H2—C1 internuclear distance in **1**. For r(H2—C1) greater than 3.2 Å, ∠H2C2C1 remains essentially equal to the input value.

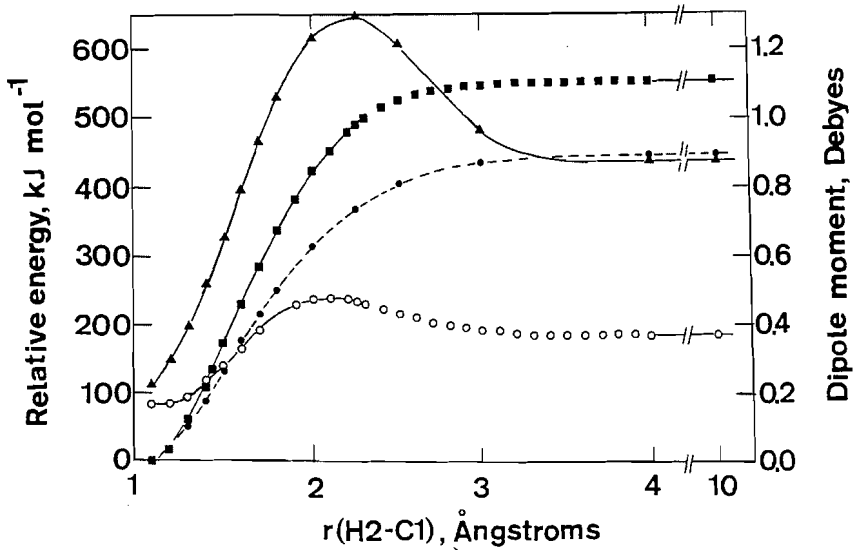

FIG. 6. The GVB(9)/STO-3G relative energies (■) and dipole moments (○) and the GVB(7)/6-31G//GVB(9)/STO-3G relative energies (●) and dipole moments (▲) as a function of the H2—C1 internuclear distance in **1**.

ple two electron bond ruptures because various integral forms that are involved in calculating the interaction energies at longer distances contain exponential terms.[4] Since linearity is expected, one of the goals of this paper is to verify if this situation exists along the computed primary α-CH bond rupture surfaces of **1**, as has been observed for its homolog, ethylene (25). Nevertheless we point out that in other work[5] one of us has found that both the large MCSCF treated OO rupture in HOOH and the H—O rupture in the HOO radical have non-linear ln E_R behaviour in the region where one finds linearity in the other systems discussed in ref. 25.

Although it may be fortuitous, the E_R and ln E_R curves from the GVB(9)/STO-3G optimizations for steps [6] and [7] are superimposable. Moreover, they can also be superimposed on the corresponding curves from the GVB(2)/STO-3G optimizations on ethylene ↔ H + **5**. The differences in the curves are less than the diameters of the points in Fig. 7. There are nearly linear regions in the plots of ln E_R versus the H1—C1 and the H2—C2 internuclear distances in the range r(C—H) = 2.5 to 3.5 Å. It is at these internuclear distances that the interaction energy becomes greater than kT and radical-H capture is becoming dynamically important. As noted above and in ref. 25, the optimized geometries of the radical moieties are essentially independent of the distance to the departing (or approaching) H atom for r(H—C) ≥ 3 Å.

As for the d(ln E_R)/dr(C—H) slopes, which are related to the effective Morse constant B discussed above, the corresponding values at 3 Å for the GVB(9)/STO-3G curves are both 3.7 Å^{-1}. These slopes are thus the same as those found for all the GVB and MCSCF calculations carried out in the study on ethylene (25). Although this value is much larger than normal Morse B

[4]Reference 50. For example, see formulae 11.29, 11.32, and 11.33. This rationalization is highly simplistic but it was the guiding one in first examining the possibility of this relationship.

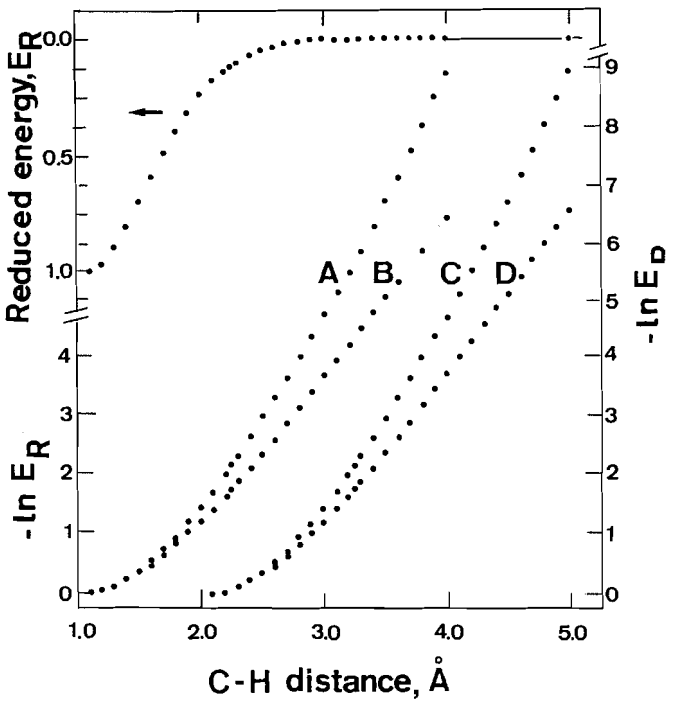

FIG. 7. Plots of the reduced energies (E_R) (upper curve) and of –ln E_R as a function of the internuclear distance along the reaction coordinates for **1** — H + **2** (plots A and B) and **1** — H + **3** (plots C and D). On the scale used the plots of E_R are superimposed. Plots A and C: GVB(9)/STO-3G; plots B and D: GVB(7)/6-31G//GVB(9)/STO-3G. Plots C and D have been displaced by 1 Å to the right.

constants (1.8–1.9 $Å^{-1}$ (48)), it is in the same range as those found for other STO-3G calculations (47). It was speculated that the slopes might be reduced by using a larger basis set (25). This is in fact the case for the GVB(7)/6-31G//GVB(9)/STO-3G results: the $d(\ln E_R)/dr$(C—H) slopes at 3 Å are lowered to 2.75 and 2.81 $Å^{-1}$ for the reaction coordinates of steps [6] and [7], respectively.

The essential fact is that for a given basis set, E_R is nearly insensitive to the GVB or MCSCF level of treatment within a range capable of providing gradient optimizations and frequency calculations of the interacting system.

3.5. Dipole moments

One of the salient conclusions made in ref. 25 for the GVB and MCSCF computations is that the dipole moment behaviour can be used as a criterion to predict whether the computations are valid and also to predict the distance at which effective interaction between dissimilar (or polar) species begins or ends. The same conclusion can be made for the present results (see Figs. 4 and 6).

4. Conclusions

The main result of the study presented here is that the behaviour of the potential energy surfaces for primary α-CH bond rupture in **1** are similar to hydrogen bond ruptures in ethylene, methane, water, and HF. The behaviour of the reduced energy curves, E_R is very similar to that found for ethylene, where it was found to be independent of geometry optimization. This behaviour will allow for a simple modeling of the dynamics of unimolecular decomposition via primary α-C—H bond dissociation in olefins. These channels are identical to those for H-atom capture by the corresponding radicals.

Another important conclusion is that the bond dissociation energies (and therefore the energies of formation of the radicals) are nearly equal for both the primary α-CH bonds in **1**. Thus the energies of formation of the radicals can not explain the difference in the ratios for α-CC/β-CH cleavage in the direct photolysis of the 2-butenes (α-CC/β-CH = 0.95 and 1.34 for *cis*- and *trans*-2-butene, respectively (22)).

Although the energy is still increasing, the remaining structural parameters become essentially independent of the *r*(C—H) distance somewhere between 2.75 Å and 3.0 Å. It is interesting to note that, as in the case of ethylene, the departing H atom is predicted to move towards the space above the formal C—C double bond, probably reflecting the attraction of the π electrons.

Contribution à l'étude du polymorphisme de quelques métallothionéines par chromatographie liquide de haute performance

GUY BORDIN,[1] FERNANDO CORDEIRO RAPOSO ET ADELA-ROSA RODRIGUEZ

Commission des Communautés Européennes, Centre Commun de Recherche, Institut des Matériaux et Mesures de Référence, Retieseweg, B-2440 Geel, Belgique

Reçu le 19 octobre 1992

GUY BORDIN, FERNANDO CORDEIRO RAPOSO et ADELA-ROSA RODRIGUEZ. Can. J. Chem. **72**, 1238 (1994).

Quatre métallothionéines commerciales extraites de foie de lapin (RL, RL I, RL II) et de rein de cheval (HK) ont été étudiées par chromatographie d'exclusion stérique et sur phase non-polaire, afin de caractériser leur polymorphisme. Les isoformes sont détectées en UV à 250 nm. Les séparations par exclusion stérique montrent que les métallothionéines sont partiellement dimérisées, avec des proportions molaires de dimères variant de 5% pour HK à 15% pour RL II. Par chromatographie sur phase non-polaire, on montre que RL est composée de quatre isoformes dominantes, RL I de deux, RL II de trois et HK de deux. Pour la série RL, RL I et RL II, une attribution des pics est proposée. Les résultats des deux méthodes convergent pour estimer que RL est constituée de 20 à 30% de RL I et de 70 à 80% de RL II.

GUY BORDIN, FERNANDO CORDEIRO RAPOSO, and ADELA-ROSA RODRIGUEZ. Can. J. Chem. **72**, 1238 (1994).

Four commercially available metallothioneins from rabbit liver (RL, RL I, RL II) and from horse kidney (HK) have been studied by size exclusion chromatography and by reverse-phase chromatography, to characterize their polymorphism. The isoforms are detected by UV at 250 nm. Separations by size exclusion show that the metallothioneins are partially dimerized, with molar rates of dimer ranging from 5% for HK to 15% for RL II. The four chromatograms obtained by reverse phase exhibit a different morphology: RL separates in four main isoforms, RL I into two, RL II into three, and HK into two. An attribution of the various peaks for the RL, RL I, and RL II series is proposed. The comparable results obtained by the two methods allow us to estimate that RL is composed of 20–30% RL I and 70–80% of RL II.

Introduction

Les métallothionéines (MT) constituent une famille de métalloprotéines originales. Un poids moléculaire relativement bas, une proportion élevée de cystéine (≈30%), l'absence d'acides aminés aromatiques et la présence permanente de cations métalliques complexés (essentiellement cadmium, zinc et (ou) cuivre selon l'origine des MT) dont la teneur totale varie peu sont les éléments structuraux qui caractérisent ces protéines atypiques (1). La distribution des 20 résidus cystéinyles sur les 61 acides aminés que compte une chaîne métallothionéinique est invariante quelle que soit l'origine des MT, au moins chez les mammifères (2), avec 7 séquences Cys-X-Cys, où X est un amino-acide autre que la cystéine. Les caractéristiques optiques traduisent parfaitement l'existence de liaisons entre les atomes de soufre des cystéines et les cations métalliques (de 6 à 7 atomes par gramme de métal par mole de MT). Les 20 thiolates participent ainsi à la chélation des cations dans un rapport global soufre/métal de 3/1 environ (3, 4). Découvertes en 1957 par Margoshes et Vallee (5) dans le cortex rénal du cheval, des MT ont été identifiées depuis cette époque chez de très nombreuses espèces animales dont l'homme (6) et la moule *Mytilus edulis* (7), chez divers microorganismes comme l'ascomycète *Neurospora crassa* (8) et même chez certaines plantes dont la tomate (9). Il est donc acceptable d'envisager une présence ubiquiste des métallothionéines dans le monde vivant.

Au cours des 15 dernières années, les connaissances sur la structure chimique et sur les fonctions biochimiques des MT ont fortement progressé. On a par exemple pu mettre en évidence le fait que certaines MT existent sous plusieurs isoformes (isométallothionéines, isoMT), ce polymorphisme provenant d'une variation de structure primaire par substitution de 1 à 15 acides aminés survenue au cours de l'évolution des espèces (10). Le nombre d'isoformes d'une MT pourra donc tout naturellement dépendre de l'espèce considérée. Kojima et al. (11) parlent d'au moins quatre isoMT chez le cheval (foie et rein), Klauser et al. (12) également d'au moins quatre chez le lapin (foie), alors que Hunziker et Kägi (13) identifient cinq isoformes humaines (foie) et Richards et Steele (14) en dénombrent trois chez le porc (foie et rein) et deux chez le rat (foie).

Cependant, au-delà de cette variabilité «naturelle» parfois importante du nombre d'isométallothionéines, des écarts d'ordre méthodologique divisent toujours les auteurs. Les méthodes classiquement employées pour séparer les isoMT sont celles basées sur les différences de charges électriques induites par les variations de structure primaire : électrophorèse, chromatographie d'échange d'ions (15). Mais une substitution de quelques amino-acides n'induira pas toujours une différence de charges électriques telle qu'elle puisse permettre une séparation efficace des isoformes (10). Cette limitation semble toutefois pouvoir être levée par l'utilisation d'une autre technique chromatographique, la chromatographie liquide sur phase non-polaire. Elle conduit généralement à de bien meilleures résolutions et permet de montrer la présence d'isoformes supplémentaires non détectées par les méthodes «classiques» (12, 16). Par exemple, Richards et Steele (14) identifient deux isoMT dans le cytosol de foie de porc par échange d'ions (DEAE-Séphadex A 25), mais en isolent trois sur une colonne de phase non-polaire (RP C_{18}). Enfin, l'emploi d'une même méthode de séparation ne constitue pas encore à ce jour une garantie de similitude de résultats. Bien qu'ils utilisent des méthodologies très voisines (même type de colonne, mêmes solvants d'élution) pour étudier la MT extraite du rein de cheval, Richards et Steele (14) et van Beek et Baars (17) n'aboutissent à des résultats que difficilement comparables. Au-delà du nombre de pics observés (respectivement sept et trois), les chromatogrammes présentent des morphologies fort différentes. Les conclusions ne peuvent donc qu'être partielles.

Les divergences sur l'existence voire sur la possibilité d'existence de formes dimères et (ou) polymères de MT sont également importantes. En réalité, fort peu de travaux font men-

TABLEAU 1. Concentrations en cadmium et en zinc de chaque métallothionéine

MT	Cd (10^{-2}) (mol g^{-1})	Zn (10^{-2}) (mol g^{-1})	Cd + Zn (10^{-2}) (mol g^{-1})
RL – M 7641 lot 20H9650	74,01	20,34	94,35
RL I – M 5267 lot 90H9600	62,72	17,44	80,16
RL II – M 5392 lot 79F9510	64,14	15,30	79,44
HK – M 4766 lot 41H9505	44,12	26,00	70,12

tion de MT dimérisées et encore moins de formes polymérisées. En 1977, Webb et Etienne (18) observent dans des MT extraites de foie de rat et de lapin qu'une petite proportion du cadmium apparaît associée à des composés protéiniques de poids moléculaires supérieurs — non déterminés — à ceux des MT. Ils pensent que ces composés sont des polymères de MT, formés par des liaisons S—S intermoléculaires. Suzuki et Yamamura (19) suggèrent également la présence dans le foie de lapin de dimères de MT dont les liaisons S—S peuvent être rompues sous l'action d'un agent réducteur. Cet important travail ne présente cependant aucun aspect quantitatif. Langston et Zhou (20) identifient chez le bivalve marin *Littorina littorea* deux métalloprotéines Cd-BP_I et Cd-BP_{II} aux caractéristiques semblables à celles des MT et dont les poids moléculaires (PM) sont d'un rapport 2. Ils envisagent ainsi la possibilité que l'un des composés (PM = 20 000 D) soit la forme dimère de l'autre (PM = 10 000 D), mais n'avancent aucun argument. On pourra encore citer Suzuki et al. (16) qui, en 1983, font mention, sans plus de précision, de la présence de MT dimérisées dans le foie de caille du Japon et de la grenouille *Xenopus laevis* mais de leur absence chez le rat (foie et rein).

Considérant tous ces résultats parfois contradictoires, il nous a paru nécessaire d'entreprendre une étude chromatographique systématique des seules MT actuellement disponibles, celles commercialisées par Sigma et que certains auteurs utilisent déjà comme «références» sans que toutes leurs caractéristiques soient encore bien connues. Pour ce travail, deux types de séparation ont été utilisés, la chromatographie d'exclusion stérique et celle sur phase non-polaire. De nouvelles caractéristiques de ces MT sont ainsi révélées : proportion de forme dimère, nombre d'isoformes dominantes.

Matériel et méthodes

Echantillons et réactifs

Les quatre MT étudiées proviennent de la firme Sigma (Saint Louis, EUA) et sont extraites soit de foie de lapin (RL lot 20H9650, RL I lot 90H9600 et RL II lot 79F9515) soit de rein de cheval (HK lot 41H9505). RL I et RL II sont les isoformes de RL obtenues par séparation «classique» (échange anionique). Leurs concentrations métalliques (Cd et Zn) figurent dans le tableau 1. Les solutions mères de MT (1000 mg L^{-1}) sont préparées dans des solutions tampon de phosphate de sodium (voir ci-dessous) et conservées à 4°C. Eau (Alltech) et acétonitrile (Merck) sont de qualité chromatographique, les sels minéraux étant «pro analisi».

Appareillage et mode opératoire

Le système chromatographique (Kontron, Zürich, Suisse) se compose d'une pompe HPLC 420, d'un mélangeur de solvants GF 425, d'un injecteur automatique HPLC 360 avec une boucle d'injection de 100 μL et d'un détecteur UV 430 à double longueur d'onde. L'ensemble des opérations, ainsi que le traitement des données (intégration des pics) sont contrôlés par le système informatique Data System 450-MT.

Exclusion stérique : élution isocratique sur une colonne Bio-Sil SEC 125 (300 × 7,8 mm, Bio-Rad) avec une solution tampon de phosphate (Na_2HPO_4 0,15 M, NaH_2PO_4 0,04 M, NaCl 0,15 M, pH = 7,15) à un débit de 0,5 mL min^{-1}.

Phase non-polaire : élution sur une colonne Bio-Sil C_{18} HL 90-5S (150 × 4,6 mm, silice à greffes octadécyle C_{18}, Bio-Rad) en mode binaire linéaire A–B (A : tampon phosphate Na_2HPO_4 0,01 M, pH = 7,0; B : acétonitrile), 3–20% B en 30 min à un débit de 1,3 mL min^{-1}.

Les phases mobiles sont filtrées sur des membranes Millipore de 0,22 μm et continuellement dégazées à l'hélium. Les pics sont détectés à 250 nm (absorbance due aux thiolates métalliques Cd-S et Zn-S) et à 280 nm (détection «négative» : absorbance faible due à l'absence d'acides aminés aromatiques). Sauf spécification, les résultats exposés ci-dessous se rapportent à la détection à 250 nm. Toutes les expériences décrites sont réalisées à température ambiente (≈20°C).

Les concentrations métalliques sont déterminées par spectrométrie d'absorption atomique sur un Perkin Elmer 5000, muni d'un four de graphite HGA-400 et d'un échantillonneur automatique AS-40.

Résultats et discussion

Chromatographie d'exclusion stérique

Afin de déterminer le poids moléculaire (PM) de chaque MT, la colonne a d'abord été calibrée au moyen d'un mélange standard (Bio-Rad) contenant les protéines suivantes : thyroglobuline (PM = 670 000 D, t_R = 11,28 min), IgG (PM = 158 000 D, t_R = 12,62 min), ovalbumine (PM = 44 000 D, t_R = 14,63 min), myoglobuline (PM = 17 000 D, t_R = 16,98 min) et cyanocobalamine (PM = 1350 D, t_R = 21,54 min). La répétabilité de la séparation a été vérifiée en injectant cinq fois de suite le mélange de protéines. Pour chacun des temps de rétention, le coéfficient de variation (c.v.) est inférieur à 1,5%. La résolution (R) de chaque pic est excellente ($1,2 < R < 3,3$). On a obtenu la droite de calibration suivante :

$$\ln PM = 19{,}48 - 0{,}58 t_R \quad (r = -0{,}991)$$

où t_R est le temps de rétention en minutes, pour un intervalle d'application en PM s'étendant de 1000 à 700 000 D. Chaque métallothionéine a ensuite été chromatographiée cinq fois. Les chromatogrammes obtenus sont montrés sur la figure 1. Leur morphologie est semblable avec un pic dominant élué vers 17,60 min précédé d'un pic d'absorbance beaucoup plus faible élué vers 16,40 min (c.v. < 1%). Le tableau 2 rassemble les temps de rétention des deux pics et les poids moléculaires correspondants pour chacune des MT. Les pics 1 et 2 (pic principal) correspondent respectivement à l'élution de molécules de PM de 21 000 à 22 000 D et 11 000 D (c.v. < 6%).

Ce poids moléculaire moyen de MT d'environ 11 000 D s'accorde parfaitement aux valeurs classiquement déterminées par cette technique chromatographique, l'écart avec la valeur obtenue à partir de la structure primaire (6000–7000 D) étant attribué à la forme non globulaire de cette métalloprotéine (21). Le petit pic, PM double de celui des MT, pourrait donc provenir de l'élution des dimères des MT formés par des liaisons S—S intermoléculaires. Ces produits étant purifiés, cette hypothèse seule paraît envisageable.

L'échange thiol–disulfure est un mécanisme chimique ayant une fonction fondamentale au niveau biologique (22) :

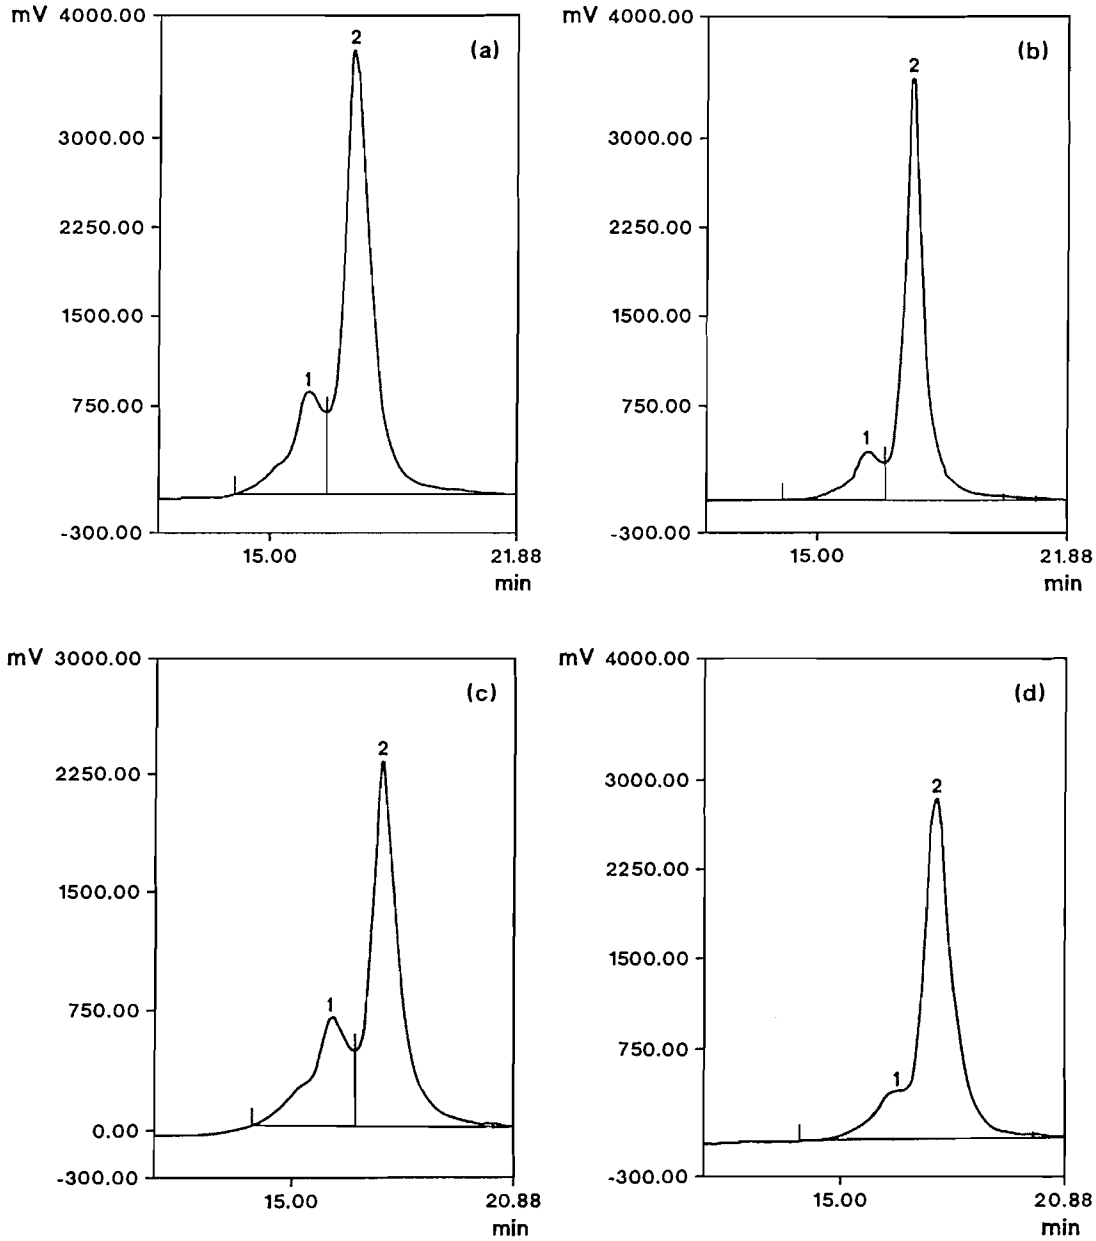

FIG. 1. Profils d'élution des métallothionéines en exclusion stérique. Détection UV à 250 nm (conditions expérimentales dans le texte). (*a*) RL $C_{MT} = 200$ mg L^{-1} ($1{,}83 \times 10^{-5}$ M); (*b*) RL I $C_{MT} = 150$ mg L^{-1} ($1{,}39 \times 10^{-5}$ M); (*c*) RL II $C_{MT} = 150$ mg L^{-1} ($1{,}33 \times 10^{-5}$ M); (*d*) HK $C_{MT} = 150$ mg L^{-1} ($1{,}40 \times 10^{-5}$ M). Unité en ordonnée : 1000 mV sur l'enregistreur correspondent à 0,005 unités d'absorbance pleine échelle.

$$RSH + XSSX \rightarrow RSSX + XSH$$

$$RSH + RSSX \rightarrow RSSR + XSH$$

Cette réaction est ainsi classiquement utilisée pour réduire les liaisons S—S protéiniques. Les dimères de MT devraient donc être réduits par un thiol tel que le 2-mercaptoéthanol. La figure 2 montre le chromatogramme de RL avant (2*a*) et après (2*b*) l'addition de mercaptoéthanol (0,5% v/v, 80°C pendant 10 min). On observe effectivement une quasi-disparition du premier pic parallèlement à une augmentation du pic principal. Un résultat identique est obtenu pour les trois autres MT. Le taux moyen de récupération (aire du pic après réduction/somme des aires des deux pics avant réduction) est de 102% (±4%, n = 13), pour l'ensemble des quatre MT. Il y a donc une réponse spectrophotométrique identique des deux espèces. L'excès de réducteur (PM = 78,13) est logiquement élué quelques minutes après la MT.

Chaque MT a été chromatographiée une dizaine de fois à des concentrations (C_{MT}) comprises entre 10 et 200 mg L^{-1} afin d'étudier d'une part, la linéarité entre le signal UV et la concentration et d'autre part, l'évolution du rapport entre les deux pics. Pour chaque MT, on a étudié la linéarité de l'aire du premier pic (S_1) et de celle du second pic (S_2) en fonction de C_{MT} en mg L^{-1}. Les droites ainsi obtenues ($r > 0{,}996$) sont caractérisées par les pentes rassemblées dans le tableau 3. Deux importantes conclusions peuvent déjà être tirées. Premièrement, pour chaque MT, l'excellence des corrélations de S_1 et $S_2 = f(C_{MT})$ montrent que le taux de dimères est indépendant de la concentration totale en MT. Deuxièmement, les différences qui existent entre

TABLEAU 2. Temps de rétention (t_R) et poids moléculaires (PM) des deux espèces correspondant aux deux pics obtenus par chromatographie d'exclusion stérique des MT

	Pic 1		Pic 2	
MT	t_R (min)	PM (D)	t_R (min)	PM (D)
RL	16,40 ± 0,05	21 380 ± 700	17,55 ± 0,02	10 940 ± 400
RL I	16,41 ± 0,02	21 160 ± 700	17,57 ± 0,02	10 830 ± 400
RL II	16,33 ± 0,50	22 250 ± 1100	17,50 ± 0,05	11 270 ± 700
HK	16,41 ± 0,02	21 160 ± 500	17,59 ± 0,04	10 700 ± 300

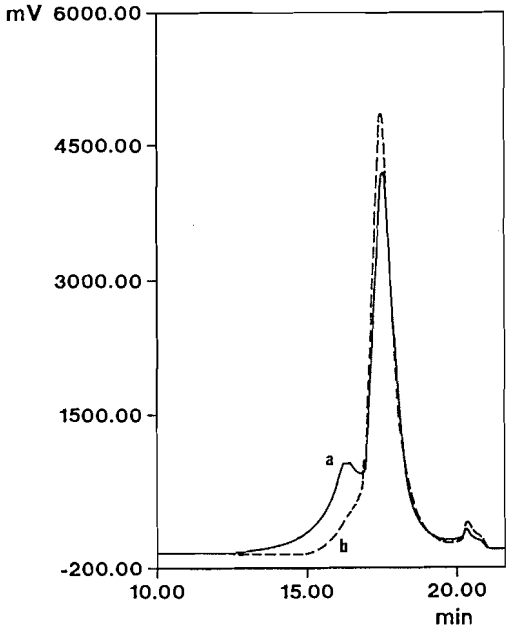

FIG. 2. Chromatogramme de RL en exclusion stérique avant (*a* : —) et après (*b* : ---) addition de 2-mercaptoéthanol. C_{MT} = 200 mg L^{-1} (1,83 × 10^{-5} M). Unité d'ordonnée : cf. figure 1.

les rapports de pentes ($S_2 = f(C_{MT})/S_1 = f(C_{MT})$) indiquent clairement que le taux de dimères varie d'une MT à l'autre : plus ce rapport sera élevé, plus le taux de dimérisation de la MT considérée sera faible. On peut donc déjà établir la séquence décroissante suivante pour les taux de dimères : RL II > RL > RL I > HK.

Estimation du pourcentage molaire de dimères : la formation du dimère (D) à partir du monomère (M) de chaque MT résulte de la réaction (simplifiée) 2M ⇌ D. Pour une concentration molaire totale en MT, nous avons $C_{MT} = C_M + 2C_D$, où C_M est la concentration molaire en monomères et C_D celle en dimères. Pour chaque chromatogramme, on peut exprimer l'aire des pics comme suit : $S_1 = a_D \cdot C_D$ et $S_2 = a_M \cdot C_M$, où a_D et a_M sont les adsorptivités molaires respectives du dimère et du monomère. Par ailleurs, on peut poser $a_D = 2a_M$, pour tenir compte du fait que la réponse du détecteur est la même pour le monomère et pour le dimère. De toutes ces équations, on tire $C_M = 2C_D(S_2/S_1)$. À titre d'exemple, le tableau 4 rassemble les détails de calcul de S_2/S_1, de C_D, de C_M et du pourcentage de dimères pour la métallothionéine RL. On constate une très bonne reproductibilité du rapport S_2/S_1 et de la proportion de dimères (c.v. = 3,5%).

Le tableau 5 regroupe les valeurs moyennes des pourcentages molaires de dimères de chaque MT. On constate bien que, d'une MT à l'autre, la proportion molaire de protéine dimérisée est variable, allant de 5% pour HK à environ 15% pour RL II. On

TABLEAU 3. Pentes des droites «aire du premier pic S_1» et «aire du second pic S_2» en fonction des concentrations totales en MT (en mg L^{-1})

	Pentes (mV min mg^{-1} L)		
MT	$S_1 = f(C_{MT})$	$S_2 = f(C_{MT})$	Rp[a]
RL	4,84 ± 0,52	16,88 ± 0,69	3,49
RL I	2,56 ± 0,18	14,78 ± 2,56	5,77
RL II	4,64 ± 0,50	13,50 ± 1,39	2,91
HK	2,44 ± 0,89	17,32 ± 1,65	7,10

[a]Rp est le rapport des pentes $S_2 = f(C_{MT})/S_1 = f(C_{MT})$.

notera également que RL II a un taux de dimères double de celui de RL I, RL étant dans une situation intermédiaire. La nature (structure primaire) d'une MT intervient donc dans son degré de dimérisation.

De ce modèle, il découle également que la pente de la droite $S_1 = f(C_D)$ devrait être double de celle de $S_2 = f(C_M)$. Les pentes de ces droites ($r > 0,997$) sont rassemblées dans le tableau 6. Pour chaque MT, le rapport des pentes évoqué est bien égal à 2, confirmant ainsi le modèle proposé.

L'examen des absorbances à 280 nm renforce ces conclusions. Dans cette zone, contrairement aux disulfures (22), les thiolates n'absorbent pratiquement plus. Dans notre cas, bien que faible, cette absorbance reste mesurable pour chaque pic. Le tableau 7 regroupe les rapports S_2/S_1 à 250 et à 280 nm des quatre MT. Celles ayant les plus faibles taux de dimères (RL I et HK) montrent la plus grande diminution de ce rapport. On en déduit que la réduction d'absorbance entre 250 et 280 nm affecte beaucoup plus le second pic (monomère) que le premier (dimère). La présence de liaison(s) S—S explique donc probablement cette absorbance relativement plus grande du premier pic à 280 nm.

Tous ces éléments militent donc pour la thèse de la dimérisation partielle des MT étudiées.

Étant donné que l'absorbance à 250 nm est due aux thiolates métalliques Cd-S et Zn-S, il nous a semblé intéressant de considérer également S_1 et S_2 en fonction de (Cd + Zn). Les pentes correspondantes sont rassemblées dans le tableau 8. Il existe un écart non négligeable entre les pentes de la série RL, RL I, RL II d'un côté et celle de HK de l'autre, ceci étant probablement explicable par les caractéristiques métalliques différentes de HK. Par rapport aux trois MT RL, elle a en effet une concentration totale en métal plus faible tout en ayant une proportion de Zn assez supérieure (tableau 1). Tout ceci s'accorde bien avec les résultats des études spectrophotométriques menées sur ces mêmes MT (23).

Nous avons déjà mentionné que la RL (13,1% de dimères) est en réalité un «mélange» des deux formes RL I (7,5% de dimères)

1,833	3,21	2,177	1,398	13,4
1,371	3,38	1,565	1,058	12,8
0,914	3,34	1,053	0,703	13,0
0,731	3,32	0,846	0,562	13,1
0,640	3,01	0,798	0,480	14,2
0,457	3,38	0,522	0,353	12,9
0,183	2,93	0,233	0,136	14,6
0,137	3,69	0,146	0,108	11,9
0,091	3,52	0,101	0,071	12,4
0,091	3,44	0,103	0,071	12,7
Moyenne	3,32 ± 0,17			13,1 ± 0,4

TABLEAU 5. Pourcentage molaire de dimères de chaque MT

MT	% de dimère	*n*
RL	13,1 ± 0,4	13
RL I	7,5 ± 0,5	8
RL II	15,3 ± 0,8	12
HK	5,1 ± 0,6	8

TABLEAU 6. Pentes des droites «aire du premier pic S_1» en fonction de la concentration en dimères, «aire du second pic S_2» en fonction de la concentration en monomères et rapports de pentes (dimères/monomères) correspondants

	Pentes de $S = f(C)$ ($\times 10^8$) (mV min M^{-1})		
MT	$S_1 = f(C_D)$	$S_2 = f(C_M)$	Rp[a]
RL	4,75 ± 0,33	2,37 ± 0,13	2,00
RL I	3,73 ± 0,38	1,87 ± 0,21	1,99
RL II	4,07 ± 0,42	2,02 ± 0,25	2,01
HK	4,26 ± 0,35	2,12 ± 0,22	2,01

[a]Rp est le rapport de pentes $S_1 = f(C_D)/S_2 = f(C_M)$.

TABLEAU 7. Variation (δ) de rapport des aires des deux pics (S_2/S_1) de 250 à 280 nm pour chaque MT

MT	S_2/S_1 (250 nm)	S_2/S_1 (280 nm)	δ (%)	*n*
RL	3,32 ± 0,17	1,90 ± 0,50	−43	13
RL I	6,24 ± 0,44	2,55 ± 3,35	−59	8
RL II	2,77 ± 0,20	1,39 ± 0,11	−50	12
HK	8,93 ± 1,35	2,76 ± 0,31	−69	8

et RL II (15,3% de dimères). Les taux moyens de dimères que nous venons de déterminer doivent donc permettre de calculer la proportion respective de chacune des deux isoformes (x% de RL I et y% de RL II) de RL à l'aide du système suivant :

$$x \cdot 7{,}5 + y \cdot 15{,}3 = 13{,}1$$

$$x + y = 1$$

TABLEAU 8. Pentes des droites «aire du premier pic S_1» et «aire du second pic S_2» en fonction de la somme des concentrations métalliques de chaque MT

	Pentes (mV min M^{-1}) ($\times 10^6$)	
MT	$S_1 = f(\text{Cd} + \text{Zn})$	$S_2 = f(\text{Cd} + \text{Zn})$
RL	5,11 ± 0,55	17,86 ± 0,72
RL I	3,19 ± 0,21	18,42 ± 2,28
RL II	5,83 ± 0,38	17,00 ± 1,14
HK	3,47 ± 1,33	24,64 ± 2,49

On obtient ainsi $x = 28\%$ (±4%) de RL I et $y = 72\%$ (±11%) de RL II.

En 1982, Geller et Winge (24), sur la base des travaux de Kägi et Vallee (3, 4) et de Tsunoo et al. (25) entre autres, écrivaient que les métallothionéines ne contenant pas de cuivre, c'est-à-dire celles induites par Cd^{2+} ou Zn^{2+}, ne contenaient que des cystéines réduites (sous forme de thiolates de cadmium et (ou) de zinc). Nos résultats semblent donc devoir infirmer cette assertion. Il a effectivement bien été montré que la présence de cuivre, in vivo ou in vitro, conduisait à la formation de liaisons S—S intramoléculaires (16, 26). Cependant, Webb et Etienne (18) expliquent la présence de MT (extraites de foie de lapin et de rat) polymérisées par la perte partielle de Zn^{2+}, moins fortement complexé que Cd^{2+} (3), suivie de la formation de liaisons S—S intermoléculaires. Des auteurs comme Minkel et al. (27) considèrent que la polymérisation des MT ne serait que le résultat de l'oxydation des MT survenue au cours de leur extraction. Or, plusieurs auteurs travaillant sur les MT extraites de mollusques marins comme l'huître *Crassostrea virginica* (28, 29) ont pu montrer que l'origine écologique (écosystème) avait une influence sur la présence ou non de forme dimère : les huîtres de Caroline du Nord (EUA) possèdent les deux formes MT 10 et MT 20 (nomenclature faisant référence aux poids moléculaires respectifs de 10 et 20 kD), celles provenant de la Baie de Chesapeake ou de zones plus nordiques d'Amérique du Nord, soumises au même procédé d'extraction, ne possédant que la forme monomère MT 10. La forme dimère n'est donc assurément pas le résultat du mode opératoire utilisé pour l'extraction des MT.

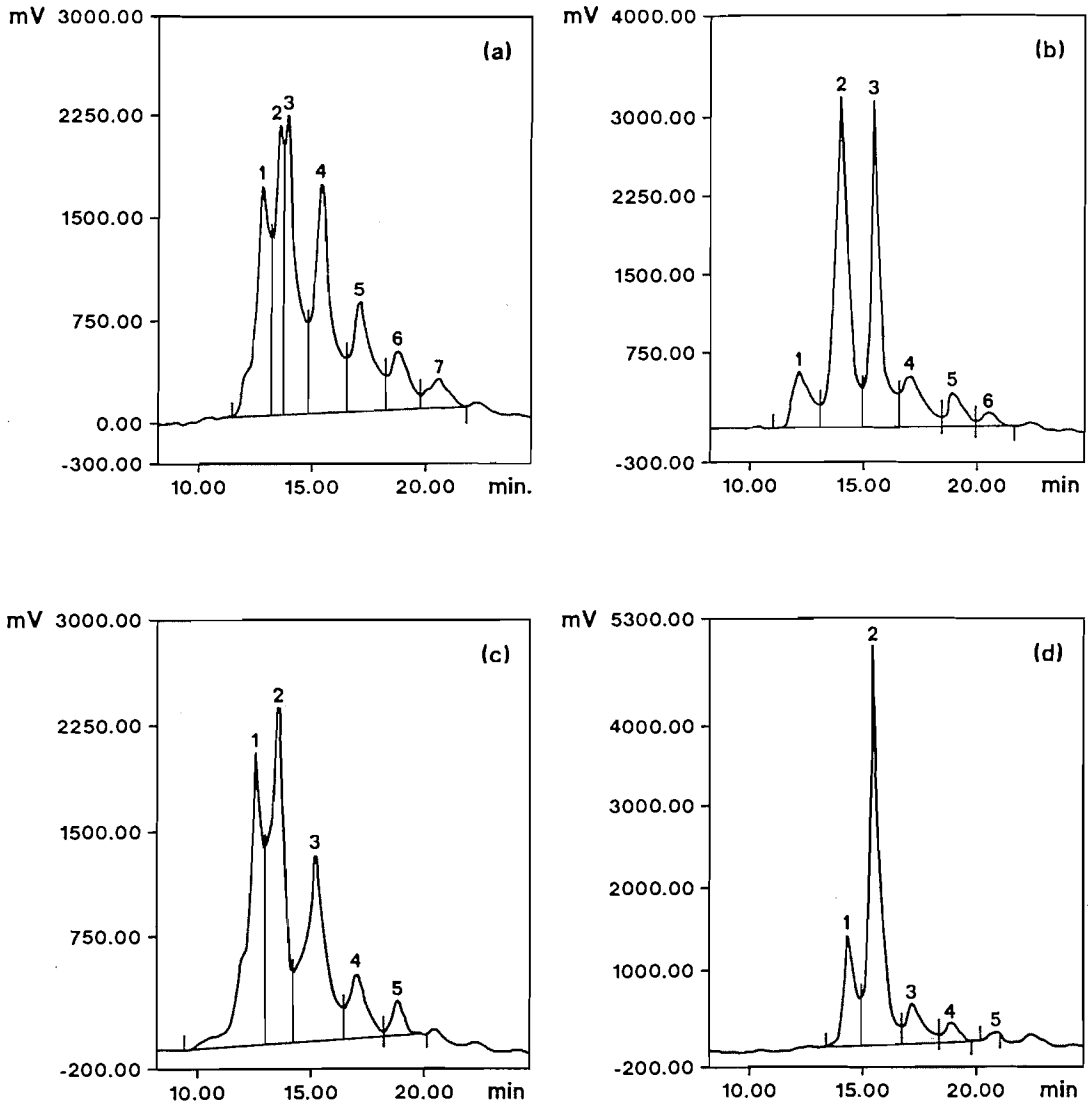

FIG. 3. Profils d'élution des métallothionéines en chromatographie sur phase non-polaire. Détection UV à 250 nm (conditions expérimentales dans le texte). (*a*) RL C_{MT} = 130 mg L^{-1} (1,19 × 10^{-5} M); (*b*) RL I C_{MT} = 100 mg L^{-1} (9,23 × 10^{-6} M); (*c*) RL II C_{MT} = 100 mg L^{-1} (8,87 × 10^{-6} M); (*d*) HK C_{MT} = 100 mg L^{-1} (9,35 × 10^{-6} M). Unité d'ordonnée : cf. figure 1.

Chromatographie sur phase non-polaire

Les chromatogrammes-types obtenus pour chaque MT sont représentés sur la figure 3. Bien que les morphologies soient différentes, on peut néanmoins dégager plusieurs caractéristiques communes : (*i*) tous les pics sont élués entre 12 et 21 min, soit par une phase mobile contenant entre 10 et 15% d'acétonitrile; (*ii*) les pics sont toujours très bien séparés ($R > 1$, sauf pour les pics 2 et 3 de RL où $R \approx 0,7$, figure 3*a*); (*iii*) la reproductibilité des temps de rétention de chaque pic est excellente (c.v. < 1% pour 10–15 séparations à différentes concentrations entre 50 et 180 mg L^{-1}), de même que celle du signal UV (somme des aires des pics ΣS) (c.v. compris entre 1 et 7%).

Considérons à présent chaque chromatogramme séparément. La RL se sépare en sept pics, dont quatre dominants et trois de moindre importance. La morphologie de RL I est très différente et relativement simple : deux pics largement dominants entourés de trois à quatre petits pics. RL II se compose de trois isoformes principales et de deux à trois autres formes de moindre importance quantitative. Enfin, la HK montre un pic prépondérant (pic n°2 de la figure 3*d*), un pic secondaire (pic n°1) et deux à trois pics mineurs.

Livrons-nous à une étude comparative des quatre chromatogrammes. Le tableau 9 rassemble les temps de rétention des principaux pics de chaque MT. On peut en tirer les conclusions suivantes : (*i*) un seul pic est «commun» aux quatre MT, celui élué à 15,30 minutes, soit par une phase mobile contenant 11,7% d'acétonitrile; (*ii*) le pic secondaire de HK (à 14,30 min) est propre à cette molécule : on ne le retrouve pas dans la série RL; (*iii*) la superposition des chromatogrammes de RL I et de RL II conduit, en termes de nombre de pics et de temps de rétention, à un nouveau chromatogramme qualitativement semblable à celui de RL (figure 4). Il semble donc probable que les deux premiers pics de RL soient attribuables à RL II, que le troisième le soit à RL I et que le quatrième provienne d'une double contribution.

L'ordre d'élution (valeurs des facteurs de capacité k') des différentes isoformes dépend de leur composition en acides aminés. Le caractère plus ou moins hydrophobe de chaque amino-acide détermine son facteur de capacité sur une colonne de phase non-polaire (30). Nos résultats montrent une élution plus rapide de RL II que de RL I, celle-ci devant donc être plus hydrophobe. En 1979, Kimura et al. (31) déterminaient la struc-

TABLEAU 9. Temps de rétention des principaux pics de chaque MT chromatographiée sur phase non-polaire. La structure du tableau schématise la position relative des différents pics de chaque MT

MT	t_R des principaux pics (min)				
RL	12,85	13,59	13,91		15,36
RL I			13,74		15,28
RL II	12,82	13,47			15,28
HK				14,30	15,30

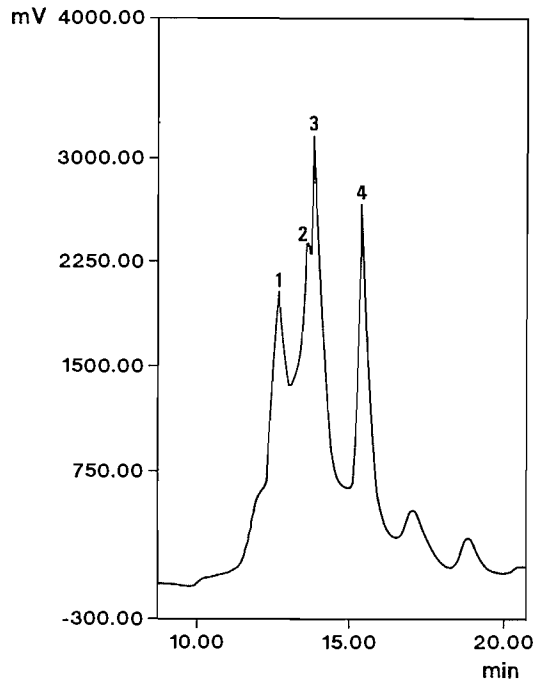

FIG. 4. Superposition des chromatogrammes en phase non-polaire de RL I et de RL II (C_{MT} = 100 mg L^{-1}). A comparer *qualitativement* à la figure 3*a*. Unité d'ordonnée : cf figure 1.

ture primaire des formes I et II de la RL. La principale différence réside en la présence dans RL I d'arginine et parfois de leucine, deux acides aminés plus hydrophobes que leurs substituts dans RL II comme la sérine. La RL I est séparée en deux pics principaux (figure 3*b*). Or, toujours selon les mêmes auteurs, il existerait une variante de cette MT dans laquelle une sérine serait substituée par une leucine, ce qui devrait induire une différence notable de comportement chromatographique. Il a déjà été montré (32, 33) que les facteurs de capacité de peptides contenant jusqu'à une vingtaine d'acides aminés, pouvaient se calculer en additionnant les facteurs de capacité des acides aminés constitutifs. Au-delà de 20 amino-acides, ce calcul devient plus spéculatif, le comportement chromatographique des longues chaînes peptidiques dépendant également de leurs structures secondaires et tertiaires. Il peut néanmoins fournir une bonne approximation. Pour tout ce qui suit, nous insistons sur le fait que nous ne procédons qu'à des estimations de l'hydrophobicité relative des différentes isoformes, sachant pertinemment que les échelles d'hydrophobicité d'acides aminés dont nous disposons ont été établies sur des phases non-polaires et avec des phases mobiles différentes des notres.

Par rapport à la structure primaire de RL II, celle de RL I varie de la manière suivante, +1 Glu, +1 Arg, −1 Ser et −1 Ala. Cette variation devrait provoquer, selon les k' d'acides aminés publiés par Grushka et al. (30), ou selon les paramètres d'hydrophobicité déterminés par Parker et al. (34), une augmentation du caractère hydrophobe de RL I, donc de son temps de rétention. C'est bien ce que l'on observe, avec $t_{R\,RL\,I} > t_{R\,RL\,II}$. Si on substitue dans RL I une sérine supplémentaire par une leucine ($t_{R\,Leu} \gg t_{R\,Ser}$), on devrait assister à une nouvelle augmentation du caractère hydrophobe et avoir $t_{R\,RL\,I(Leu)} > t_{R\,RL\,I(Ser)} > t_{R\,RL\,II}$. Sur le chromatogramme de RL I, le premier pic (t_R = 13,74 min) pourrait donc correspondre à la forme «sérine» et le second (t_R = 15,28 min) à la forme «leucine». Cette hypothèse reste naturellement à vérifier. Pour RL II, seule la structure primaire globale est connue. La séparation de RL conduit donc à l'ordre suivant (selon les t_R indiqués dans le tableau 9) : RL II (2 isoformes non identifiées) – RL I_{Ser} – RL I_{Leu}.

Kojima et al. (11) ont publié en 1976 la structure primaire de HK-A et de HK-B, les deux isoMT obtenues par séparation anionique classique de HK. Les compositions moyennes montrent que HK-A auraient deux variantes sérine/leucine. Par rapport à RL I_{Leu}, et en se basant sur les échelles d'hydrophobicité déjà citées (30, 32–34), l'isoforme HK-A_{Leu} (+1 Pro, +3 Gly, +1 Val, +1 Arg, −1 Asp, −2 Ala, −1 Ile, −2 Lys) ne devrait voir son caractère hydrophobe que fort peu varier, ce qui équivaudrait à des temps de rétention très proches. Nos chromatogrammes montrent que le pic principal de HK et celui de RL I_{Leu} ont le même t_R = 15,3 min. On estime également de la même manière que la variante sérine HK-A_{Ser} serait moins hydrophobe que RL I_{Leu} et aurait donc un temps de rétention plus faible que celui de RL I_{Leu} et de HK-A_{Leu}. Cette isoforme HK-A_{Ser} doit donc correspondre au premier pic de HK à 14,3 min. Enfin, on peut également estimer le caractère hydrophobe de HK-B (−1 Pro, +2 Val, +2 Thr, +2 Ala, −2 Gly, +1 Gln, −1 Arg, +1 Lys) comme étant plus faible que celui de HK-A_{Ser}. On devrait alors avoir $t_{R\,HK\text{-}B} < t_{R\,HK\text{-}ASer}$. Soit un pic qui devrait sortir à un t_R < 14,3 min, mais qui est absent de notre chromatogramme. Le lot de HK étudié dans ce travail semble donc correspondre à l'isoforme pure HK-A.

La linéarité de la réponse UV en fonction des concentrations en MT et en métal a été étudiée pour le signal total (ΣS) et pour celui du pic «commun», pic toujours le mieux résolu (S_c, aire du pic commun). Les pentes des droites obtenues (r > 0,991) sont rassemblées dans le tableau 10. Compte tenu des incertitudes et suite au traitement statistique classique effectué, on peut estimer que les pentes «totales» ne diffèrent pas significativement les unes des autres, à l'exception de celle de HK calculée par rapport à la concentration en MT, notablement plus faible. Cette dernière apparaît bien différente des trois RL. Les pentes du pic «commun» $S_c = f(C_{MT})$ et $S_c = f(Cd + Zn)$ varient assez fortement, reflétant la contribution relative de cette isoforme à chacune des MT. HK montre ainsi des pentes nettement plus élevées que celles de la série RL. Ces valeurs de pentes permettent alors de calculer, par rapport aux pentes totales, que les isoformes éluées à 15,30 minutes représentent 70,0% de la HK (c'est à dire 70% de variante «leucine»), 21,1% de la RL, 29,5% de la RL I et 18,8% de la RL II.

Concernant la série MT RL, on déduit de ces chiffres une participation inégale des formes RL I et RL II à la RL globale. Si x et y sont respectivement les proportions de RL I et de RL II dans RL, on peut alors écrire :

$$x \cdot 29{,}5 + y \cdot 18{,}8 = 21{,}1$$

$$x + y = 1$$

For personal use only.

TABLEAU 10. Pentes des droites «somme des aires des pics ΣS» et «aire du pic commun S_c» de chaque MT séparée sur phase non-polaire, en fonction des concentrations en MT et en métaux

	Pentes (mV min M^{-1}) ($\times 10^7$)			
MT	$\Sigma S = f(C_{MT})$	$S_c = f(C_{MT})$	$\Sigma S = f(Cd + Zn)$	$S_c = f(Cd + Zn)$
RL	38,57 ± 8,25	8,12 ± 1,30	6,28 ± 1,34	1,32 ± 0,21
RL I	40,45 ± 1,95	11,95 ± 0,65	7,78 ± 0,39	2,29 ± 0,13
RL II	43,96 ± 10,91	8,25 ± 1,04	8,52 ± 2,46	1,60 ± 0,21
HK	25,78 ± 6,04	18,31 ± 5,00	5,66 ± 1,33	4,02 ± 1,10

On aboutit ainsi à 21% (±5%) de RL I et à 79% (±14%) de RL II. Ces résultats confirment ceux obtenus précédemment à partir des pourcentages de dimères, À notre connaissance, aucun travail quantitatif de cet ordre n'avait encore, à ce jour, été publié. En 1987, Richards et Steele (14) ne faisaient que mentionner que l'isoforme la plus abondante de la RL était une sous-espèce de la RL II. Plus globalement, travaillant, entre autres, sur les MT-RL et MT-HK, ces mêmes auteurs obtenaient des chromatogrammes fort semblables pour ces deux molécules : deux pics dominants et quatre à cinq pics mineurs. Notre travail montre ainsi que le polymorphisme de la métallothionéine extraite de foie de lapin (RL) est en fait nettement plus complexe. Pour la HK, nos résultats s'apparentent davantage.

Conclusion

L'utilisation de la chromatographie d'exclusion stérique et de la chromatographie sur phase non-polaire avec détection UV nous a permis de mieux caractériser les quatre métallothionéines RL, RL I, RL II extraites du foie de lapin et HK, extraites du rein de cheval. On a ainsi pu montrer que : (*i*) les quatre MT sont partiellement dimérisées (pourcentage molaire de forme dimère : 5–15%); (*ii*) la RL, composée de RL I et RL II séparables par échange d'ions, apparaît constituée de quatre isoformes dominantes, alors que la HK ne se sépare qu'en deux isoformes; (*iii*) RL I et RL II se subdivisent également en deux et trois sous-espèces respectivement; les deux pics de RL I correspondent essentiellement à une substitution sérine/leucine; (*iv*) globalement, RL I et RL II contribuent respectivement pour 20–30% et 70–80% de RL; (*v*) le lot de HK ne semble contenir que la forme HK-A, dont environ 70% de sous-espèce contenant de la leucine.

Photoionophores derived from crown ether polycarboxylic acids: synthesis, ion binding, and spectroscopic characterization

THOMAS M. FYLES[1] AND VALIA VEETTIL SURESH

Department of Chemistry, University of Victoria, Box 3055, Victoria, BC V8W 3P6, Canada

Received November 1, 1993

THOMAS M. FYLES and VALIA VEETTIL SURESH. Can. J. Chem. **72**, 1246 (1994).

Three types of potential photoionophores based on polycarboxylic acid crown ethers were prepared, and their cation complexation behaviours and spectroscopic properties were surveyed. The first type were neutral macropolycyclic hosts prepared by capping across the faces of the crown ether with aromatic diamine chromophores. The second were bis-crown ether carboxylates bearing a bridging aromatic chromophore. The third type appended an additional chromophore-donor site on the crown ether carboxylic acid framework. Cation complexation was examined by potentiometric titration. The neutral ligands were rather poor hosts for alkali metal cations. The other two types of crown ether carboxylates showed a combination of size selectivity and electrostatic stabilization, leading to significant and selective ion binding in water. Ligands of the third type also exhibited cation-dependent absorption spectra in neutral and basic aqueous solution. No significant alkali metal or alkaline earth cation-induced perturbation of the emission spectra was uncovered, but a sodium- and cesium-dependent long wavelength emission enhancement was observed in one of the neutral ligand systems.

THOMAS M. FYLES et VALIA VEETTIL SURESH. Can. J. Chem. **72**, 1246 (1994).

On a préparé trois types de photoionophores potentiels basés sur des éthers couronnes portant des acides polycarboxyliques et on a étudié leurs comportements dans la complexation de cations ainsi que leurs propriétés spectroscopiques. Le premier type comprend des hôtes macropolycycliques neutres dont les faces de l'éther couronne sont recouvertes de chromophores diaminés aromatiques. Le second comporte des carboxylates de bis(éther couronne) portant un chromophore aromatique agissant comme pont. Dans le troisième type, l'éther couronne d'acide carboxylique porte un site additionnel de chromophore donneur. On a étudié la complexation des cations par titrage potentiométrique. Les coordinats neutres sont des hôtes relativement mauvais pour les cations des métaux alcalins. Les deux autres types de carboxylates d'éthers couronnes présentent une combinaison de sélectivité selon la grosseur et de stabilisation électrostatique qui conduit, dans l'eau, à des liaisons sélectives et importantes avec les ions. En solutions aqueuses neutres ou basiques, les coordinats du troisième type présentent aussi des spectres d'absorption qui varient avec la nature du cation. On n'a mis en évidence aucune autre perturbation importante des spectres d'émission qui aurait pu être induite par des métaux alcalins ou alcalinoterreux; toutefois, dans un des systèmes de coordinats neutres, on a observé que le sodium et le césium provoquent une augmentation d'une émission à une grande longueur d'onde.

[Traduit par la Rédaction]

Photoionophores are selective complexing agents for specific ionic species in which the complexed guest species induces a perturbation in the electronic state of the host molecule. Perturbations can be detected by absorption or emission spectroscopy to define chromoionophores (1, 2) or fluoroionophores (2), respectively. In principle, ion-selective complexing agents could be modified by addition of a suitable chromophore to yield a functional photoionophore with the selectivity of the unmodified ion-binding host. For alkali metal and alkaline earth cations several examples of this strategy are reported for crown ether (2–12), cryptand (13, 14), hemispherand (15), calixarene (16, 17), and cyclophane hosts (18). Phenols (1, 4, 12), polycyclic aromatic (3, 13, 18), and heteroaromatic chromophores (5, 8, 9, 11) have all been exploited. Despite the successes, there is still a need for photoionophores for alkali metal cations that could be used in aqueous solution over a range of pH values (10). The majority of the known photoionophores are either insoluble in water, insensitive to alkali metal cations, or pH sensitive.

This paper evaluates several potential photoionophores derived from crown ether polycarboxylic acids based on *R,R*-(+)-tartaric acid. The parent crown ether offers a conformationally controlled framework and an array of carboxylate donors that provide electrostatic stabilization of bound guests (19). These features could promote favourable ion–chromophore organization (20), together with favourable ion binding in water (21). Figure 1 summarizes the geometries of the photoionophores investigated. Each case builds on the tendency of the carboxylic acid groups to occupy axial positions on the macrocyclic periphery (22). In case of type A this would lead to capping across the face of the macrocycle; hence, this type is referred to as captand. The additional arms above and below the macrocyclic plane place the chromophore in proximity to a bound cation and define a three-dimensional cavity (23, 24). Type B is akin to other bis-crown ethers (25), with the additional feature that the chromophore lies between the rings. The crown ethers are expected to act as independent carboxylate crown ethers. Type C unites several themes in crown ether chemistry: lariat ether structure (26), phenol ionization to provide a cation-sensitive chromophore (1), and axial orientation to place the additional donor site above the crown ether plane.

The goals of this survey were to establish synthetic procedures with simple chromophores, to evaluate cation binding by potentiometric methods, and to examine the optical properties of the photoionophores produced. This would provide essential information for the design of more sensitive photoionophores incorporating more sophisticated chromophores.

Results and discussion

Synthesis

The synthesis of captands (24) (Fig. 1, type A) was achieved by coupling the known tetraacid chloride **1** with appropriate diamines (Scheme 1). Precedent literature discouraged the use of flexible diamines (23), so rigid aromatic spacers of approximately complementary span to the known transannular dimensions of the crown ether tetraacid were chosen. High dilution coupling of **1** with excess *m*-xylylene, *p*-xylylene, or 2,2′-

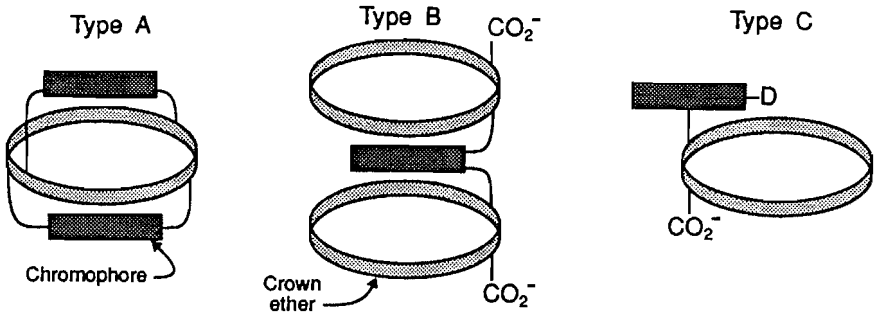

FIG. 1. Schematic diagrams of photoionophores prepared.

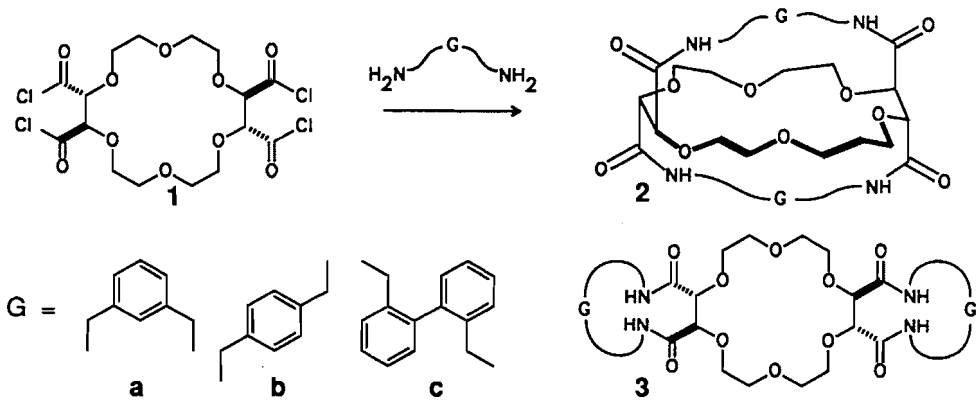

SCHEME 1

bis(aminomethyl)biphenyl gave the captands **2***a*, **2***b*, and **2***c* in yields of 95, 40, and 85%, respectively (Scheme 1). The characterization of **2***a* and **2***b* by NMR and crystal structure determination has been discussed previously.

Compound **2***c* offers an interesting candidate to explore the effect of rotational freedom of diamines on the capping reaction. Rotation around the central bond between the two benzene rings is partly hindered and the two amino groups have a constrained but variable span. This diamine could potentially cap across the faces of the crown ether ring (*syn*-capping, between the acid groups of two different tartaric acid units, **2**) or along the edges (*ortho*-capping, between the acid groups of the same tartaric acid unit, **3**). *Anti*-capping (between the two different tartaric acid units spanning the two faces of the crown ether) is very unlikely from the analysis of CPK models and simple molecular mechanics explorations.[2] The ^{13}C NMR spectrum of the compound showed four signals for each major subunit (carbonyl, crown ether methine, $ArCH_2$) and two equal groups of crown ether ring signals. The spectra suggested either a mixture (approximately 1:1) of *syn*- (**2***c*) and *ortho*-capped (**3**) isomers, each undergoing rapid motion about the Ar—Ar bond, or two slowly interconverting *syn*-capped isomers differing in the biphenyl chirality. The latter possibility was more likely, as no evidence for a mixture could be obtained from careful chromatographic examinations of the product (normal and reverse-phase TLC, high performance size exclusion chromatography). Variable temperature NMR showed apparently homogeneous broadening, suggesting a single conformational process of a single compound. The molecular ion observed in the mass spectrum and the elemental analysis indicate that if a mixture was present, it was a mixture of isomers.

The synthesis of bis-crown ethers (Fig. 1, type B) derived from tartaric acid crown ethers is a straightforward extension of previous synthetic work with the crown ether anhydride **4**, which reacts readily with amines to give crown ether amide–acids (27). Thus *m*-xylylene diamine cleanly quenched 2 equiv. of **4** in excess triethylamine to give the expected product **5***a* (Scheme 2) in 89% yield, full characterized by ^1H NMR, ^{13}C NMR, mass spectrometry, and elemental analysis.

A potentially more useful chromophore was incorporated via 9,10-bis(aminomethyl)anthracene. Unfortunately this diamine was only sparingly soluble in organic solvents, which precluded its use in the high dilution capping process of Scheme 1. It was sufficiently soluble in tetrahydrofuran (THF) containing triethylamine, so that the reaction of solid diamine with a solution of **4** eventually gave the bis-crown ether **5***d* in reasonable yield (76%). The product **5***d* was quite soluble and characterized by ^1H NMR, ^{13}C NMR, mass spectrometry, and elemental analysis. Over a period of 2 months, **5***d* decomposed in diffuse daylight, so subsequent samples were kept in brown vials covered with aluminium foil.

Lariat ethers (Fig. 1, type C) derived from tartaric acid crown ethers were simply prepared by quenching the known crown ether acid anhydrides **4** or **7** with 2-aminophenol (Scheme 3). This was expected to place an additional ionizable donor in an axial position, potentially adjacent to a cation bound in the crown ether ring. The monophenol adduct **6** was isolated in 84% yield and characterized by ^1H NMR, ^{13}C NMR, mass spectrometry, and elemental analysis.

The bisphenol crown ether **8** could be formed as either the *syn*- or *anti*-**8** isomer, or more likely as a mixture of the two. Excess triethylamine with stoichiometric aromatic amines is known to favour the formation of the *syn* isomers in many other cases (28). The product, isolated in 85% yield, was predominantly (75–85%) one isomer as judged by ^1H NMR and ^{13}C NMR. The isomeric nature of the product was confirmed by

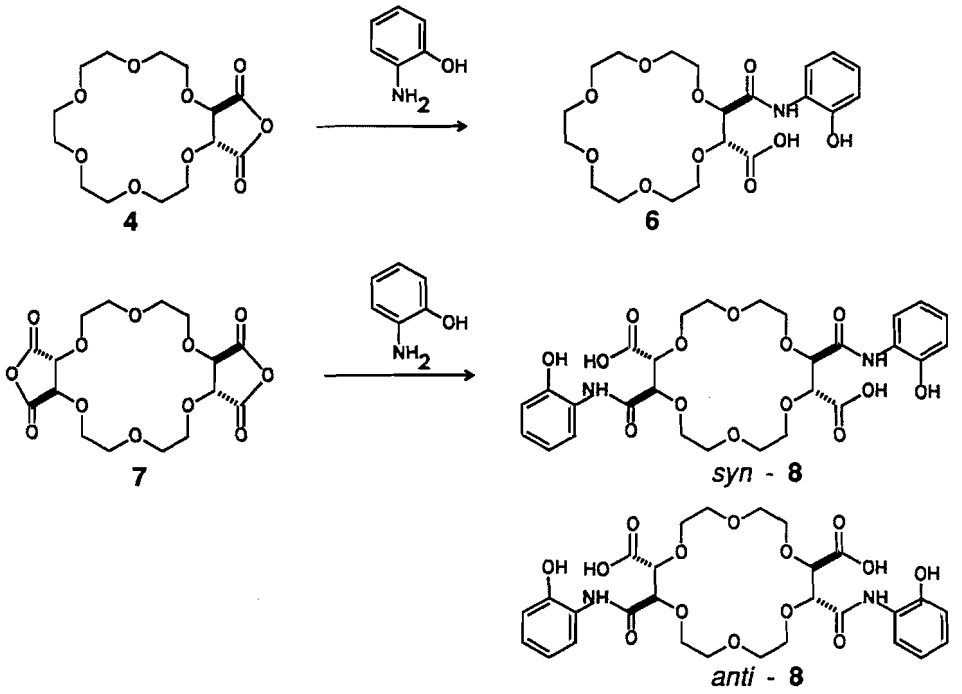

SCHEME 3

mass spectrometry (single molecular ion), elemental analysis, and equivalent weight determination by acid–base titration. That the major isomer was *syn* rests on similarity with excellent synthetic precedent (28). Like all acidic crown ethers, **8** was strongly bound to chromatographic media and separation by chromatography was fruitless. Fractional crystallization was not productive, the hydrodynamic radii of *syn*- and *anti*-**8** were too similar to permit separation by size-exclusion chromatography, and the chemoselectivity of the reaction could not be improved by variation in reaction time, solvent, or temperature. Consequently, all studies were done with a mixture of isomers, assumed to be predominantly *syn*-**8**. The composition of this mixture (78% *syn*) was established by integration of the carbonyl carbon signals of a ^{13}C NMR spectrum with an acquisition delay of 10 s to permit full relaxation between pulses.

Stability constants for complexation of cations

The stability constants for K^+ complex formation by the neutral captands **2***a*–**2***c* were determined in 50% aqueous methanol by potentiometric titration using a potassium-selective electrode. The values of log $K_s \pm 0.3$ (M^{-1}) were found to be 2.8 for **2***a*, 3.0 for **2***b*, and 3.6 for **2***c*. These stability constants are comparable to neutral crown ethers, but considerably smaller than cryptands in similar solvents (29). The values increased as the length and flexibility of the aromatic cap increased, suggesting that the captand cavity was too small or too rigid for optimal cation–donor interactions.

The stability constants for ion binding by ionizable crown ethers **5***a*, **5***d*, and **6** and the *syn*-**8**–*anti*-**8** mixture were determined by pH-metric titration (30). Table 1 summarizes the results in comparison with the parent di- and tetra-carboxylate crown ethers (Di and Tet). As previously, the reported values are cumulative association constants defined by equilibria between l ligands of charge z^-, m cations of charge y^+, and h protons:

$$[1]\quad lL + mM^{yx+} + hH^+ \rightleftharpoons l\mathrm{L}^{z-}m\mathrm{M}^{y+}h\mathrm{H}^+$$

$$[2]\quad \beta_{lmh} = \frac{[l\mathrm{L}^{z-}m\mathrm{M}^{y+}h\mathrm{H}^+]}{[\mathrm{L}^{z-}]^l[\mathrm{M}^{y+}]^m[\mathrm{H}^+]^h}$$

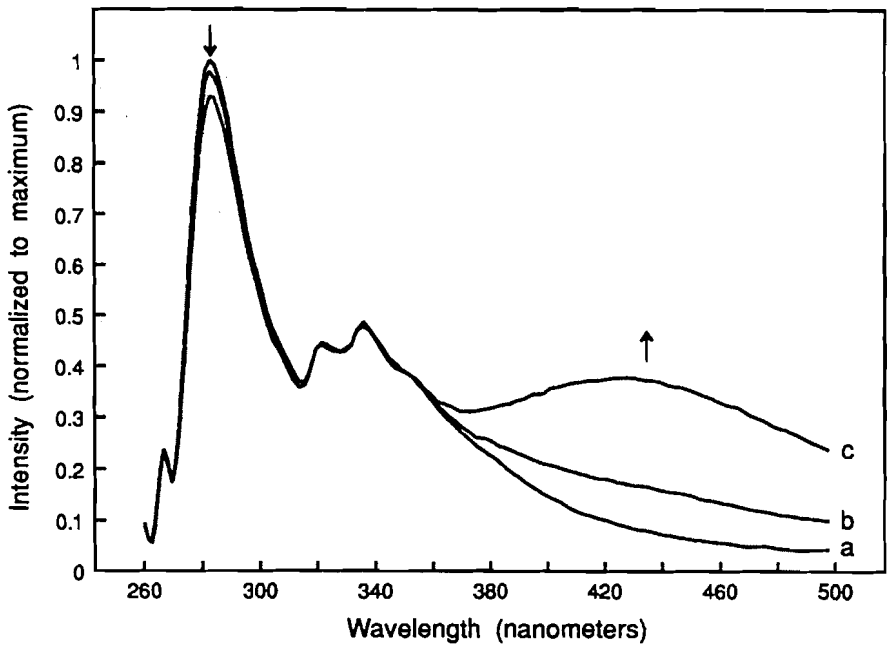

FIG. 3. Effect of Cs^+ on the emission spectrum of **2***c* [L] = 8×10^{-6} M in 0.03% methanol in water; excitation wavelength = 250 nm. (*a*) No cation added. (*b*) [Cs^+] = 4×10^{-3} M. (*c*) [Cs^+] = 2×10^{-2} M.

where β_{lmh} is the cumulative association constant and the integers *l*, *m*, and *h* represent the number of ligands, number of metal ions, and the number of protons. For comparison between complexes formed at different levels of ligand protonation, stepwise association constants could be calculated by correcting for the pK_a values imbedded in the cumulative constants.

The mixture of *syn*- and *anti*-**8** was treated as a mixture of two ligands in a 78:22 ratio. The differences between the phenolic pK_as could not be distinguished, but significant differences in the carboxylate pK_as were evident in the unprocessed titration curves. Nonlinear fitting of the titration curve gave values of 5.85 for pK_3 and 4.36 for pK_4 of *anti*-**8**. The metal ion complexes of the *syn* and *anti* isomers were insignificantly different at the ligand and cation concentrations used, so the data reported in Table 1 reflect a weighted average value for the mixture.

The complexation data are completely consistent with previous studies of the parent crown ethers Di and Tet (19, 21). Cation recognition is controlled by two factors: a crown ether recognition factor that reflects host–guest size complementarity effects and an electrostatic enhancement factor involving additional coordination in favourable instances. The cation size effect is evident in the optimal binding of potassium ion from among the alkali metal cations. The electrostatic factor is evident in the preferential association with divalent alkaline earth cations over alkali metal cations and in the general destabilization provoked by ligand protonation in all cases. Comparison of **6** and Di, or **8** and Tet, shows that a phenolic donor is inferior to a carboxylate donor at constant ligand charge. This is consistent with a proximity effect, suggesting that direct phenolate–cation chelate interaction is not a major stabilizing factor.

Chromoionophore survey

The UV–visible absorption spectra of compounds **5***a*, **5***d*, **6**, and **8** were examined in the presence of alkali metal and alkaline earth cation chlorides in water and basic buffer solution. Compounds **5***a* and **5***d* showed no significant changes of any type. Both compounds **6** and **8** showed bathochromic shifts on deprotonation (275–308 nm), but only **6** showed significant influence of cation type and concentration. Figure 2 shows the cation-dependent intensity changes provoked by addition of 0.01 M salt to a 10^{-4} M solution of **6**. The pH 10 phosphate buffer solution contained 0.01 M Li^+ in all cases, underscoring the cation selectivity of the changes. The changes were salt concentration dependent in the range $5 \times 10^{-4} - 5 \times 10^{-3}$ M; Fig. 2 illustrates the limiting spectra for all cations.

The ordering of the intensity changes ($Sr^{2+} > Ba^{2+} > Ca^{2+} > K^+$ etc.) paralleled the order of the stability constants reported in Table 1. The preferred cation was Sr^{2+}, as this guest had both good size complementarity with an 18-crown-6 cavity and a favourable charge density for electrostatic stabilization by phenolate and carboxylate groups. The destabilization on ligand protonation, represented by the difference in the stepwise association constants for the 110 and 111 complexes, also followed the same series. It is tempting to speculate that the absorption spectrum is reporting the extent of direct phenolate–cation chelation in the different complexes. This is likely to be modest, even in a favourable case such as Sr^{2+}, since the potential for chelation did not play a major role in complex stabilization based on the evidence discussed above.

Fluoroionophore survey

The quenching of fluorescence of the three captands and two bis-crown ethers with alkali metal cations (Li^+, Na^+, K^+, Rb^+, and Cs^+), alkaline earth metal cations (Ca^{2+}, Ba^{2+}, and Sr^{2+}), and heavy metal cations (Cu^{2+}, Hg^{2+}, and Cd^{2+}) was examined (Table 2). The emission spectra were recorded and the change in emission intensity at the emission maximum provoked by a change in the concentration of metal ion was considered as a quenching efficiency.

A cursory examination of Table 2 indicates no significant (higher than 20%) quenching of the fluorescence by alkali

[g]$[Hg^{2+}] = 1.6 \times 10^{-2}$ M.
[h]$[Hg^{2+}] = 2.4 \times 10^{-2}$ M.
[i]$[Cu^{2+}] = 6.0 \times 10^{-3}$ M.
[j]$[Hg^{2+}] = 1.4 \times 10^{-2}$ M.

metal ions in any case. Significant quenching by heavy metal cations was noted. A preliminary study of the Cu^{2+} and Hg^{2+} quenching suggested that the quenching involves both simple diffusional quenching and a complexation induced static quenching (31). Owing to the weak fluorescence exhibited by these fluorophores, a more detailed study appeared to be unwarranted at this stage.

One significant feature was noted in the emission spectrum of the biphenyl captand **2c**: the appearance of a new emission band at long wavelength region (455 nm) in the presence of increasing concentrations of Cs^+ or Na^+. Other alkali metal cations did not give a significant long wavelength enhancement. All the emission maxima in Fig. 3 originated from a single species, as established by comparison of the excitation spectra for different emission maxima. One possible explanation might be based on excimer formation of the biphenyl capped crown ether with the metal ion, provided that the excimer emitted much more intensely than the parent captand molecule. The slight decrease in intensity of the emission at 288 nm would be due to the depletion of the population of either the ground or excited state of the free ligand to form an excimer. Since the intensity of emission was proportional to the concentration of metal ion, the excimer, if present, was potentially an inclusion complex of metal ion and the captand molecule. This interesting observation warrants more detailed investigation, particularly as it relates to the development of a sodium-sensitive fluoroionophore.

Summary

This survey demonstrates that modification of known ion-binding ligands, particularly by appending additional donors, can result in a combination of satisfactory levels of ion complexation in water and significant spectroscopic changes. The survey data, combined with literature reports, suggest that useful photoionophores might be assembled as lariat ethers (type C) with betaine phenolate donors (ref. 12; chromoionophore) or coumarin donors (ref. 11; fluoroionophore).

Experimental

Melting points were taken on a Riechardt hot-stage microscope and are uncorrected. ^1H NMR spectra were recorded with a Perkin-Elmer R32 (90 MHz, CW) or Bruker AMX 360 (360.14 MHz, FT) spectrometer using $CDCl_3$, CD_2Cl_2, or CD_3OD as solvent. The 90-MHz spectra were referenced to Me_4Si as internal standard. The 360-MHz spectra were referenced with the central solvent line as standard (7.24 δ for $CDCl_3$, 5.32 δ for CD_2Cl_2 and 3.30 δ for CD_3OD, all relative to Me_4Si). ^{14}C NMR spectra were recorded with a Bruker WM250 (62.89 MHz) or Bruker AMX360 (90.57 MHz) spectrometer, with the central solvent line as standard (77.0 ppm for $CDCl_3$, 53.8 for CD_2Cl_2, and 49.0 for CD_3OD, all relative to Me_4Si). Mass spectra were recorded on a Finnegan 3300 GC–MS instrument, with methane chemical ionization (CH_4 CI), or a Kratos Concept IH32 operating in LSIMS mode (Cs^+ ion bombardment, cooled thiogycerol matrix). Elemental analyses were performed by Canadian Microanalytical Services, New Westminster, B.C., and are quoted as percentages. Absorption spectra were recorded using a Cary 14 UV–visible spectrometer. Fluorescence spectra were recorded using a Perkin-Elmer 3300 spectrofluorimeter.

The crown ether diacid (Di) and tetraacid (Tet) were synthesized as previously described (19, 27). The known diamine 2,2′-bis(aminomethyl)biphenyl (32) was prepared from the dibromide by a Gabriel synthesis. Thus 2,2′-bis(bromomethyl)biphenyl (2 g, 5.8 mmol; mp 88–90°C (lit. (32) mp 90°C)) was dissolved in dimethylacetamide (DMA; 250 mL), along with freshly prepared potassium phthalimide (3 g, 16 mmol) containing two drops of diethylamine catalyst. The mixture was stirred at 50°C for 5 h and the solvent was removed under reduced pressure. The resulting yellow paste was dissolved in water and extracted with dichloromethane; the organic layer was washed with water, dried with anhydrous sodium sulphate, and evaporated to dryness under reduced pressure to yield a white solid. The solid was dissolved in ethanol (200 mL) and hydrazine (10 mL, excess) was added. The mixture was stirred for 5 h at 50°C. The resulting white solid was filtered and washed twice with ethanol (50-mL portions). The ethanol filtrate was evaporated to dryness and dichloromethane (50 mL) was added. The resulting white precipitate was filtered and washed twice with small portions of dichloromethane. The filtrate was dried over anhydrous sulphate and evaporated to dryness to yield 1.5 g (85%) of a colourless oil. ^1H NMR ($CDCl_3$) δ: 7.54 (d, 2H), 7.25–7.48 (m, 4H), 7.11 (d, 2H), 3.55 (dd, 4H), 3.0 (br s, 4H); ^{13}C NMR ($CDCl_3$) δ: 141.2, 136.8, 128.8, 127.9, 127.8, 127.6, 48.8; MS *m/z*: 213 $(M + 1)^+$.

The known diamine 9,10-bis(aminomethyl)anthracene (33) was similarly prepared from 9,10-bis(chloromethyl)anthracene (34) in an initial yield of 84%, mp 221–229°C (lit (34) mp 222–228°C for the same initial product). MS (CH_3 CI) *m/z*: 237 $(M + 1)^+$. This crude diamine was used without further purification for subsequent reactions.

The known tetraacid chloride (**1**) (ref. 35) was prepared from the crown ether tetraacid (0.6 g, 1.4 mmol) dissolved in $POCl_3$ (25 mL) and freshly sublimed PCl_5 (1.14 g, 5.5 mmol) was added with continuous stirring. The mixture was stirred at 45°C for 12 h and the solvent was removed under reduced pressure. The excess PCl_5 was removed by sublimation under high vacuum. The crude white solid product was dissolved in dry toluene (10 mL) and used without further purification.

m-Xylylene capped crown ether (2a)

Dry toluene (500 mL) was placed in a 3-L four-neck flask equipped with two precision dropping funnels and a mechanical stirrer. A toluene solution of acid chloride **1** (0.63 g, 1.4 mmol, 100 mL) was placed in one of the funnels and a toluene solution of 1,3-bis(aminomethyl)benzene (0.59 g, 4 mmol, 100 mL) was placed in the other funnel.

For personal use only.

The solutions were added dropwise at equal rates to the reaction flask with continuous and vigorous stirring over 48 h at room temperature. After completion of the addition, the mixture was stirred for another 12 h and the solvent was removed under reduced pressure. The resulting pale yellow solid was dissolved in water (200 mL) and extracted twice with petroleum ether, diethyl ether, dichloromethane, and chloroform (100-mL portions) in that order. The chlorocarbon extracts were mixed and evaporated to dryness to give a 95% yield of **2***a* (mp > 275°C). The product was further purified by recrystallization from acetonitrile. ^{1}H NMR ($CDCl_3$) δ: 7.6 (d, 4H), 7.2 (s, 8H), 5.0 (dd, 2H), 4.3 (s, 4H), 3.6 (d, 2H), 3.6–3.3 (m, 16H); ^{13}C NMR ($CDCl_3$) δ: 169.3, 138.8, 128.5, 127.1, 125.0, 80.9, 70.4, 69.4, 42.4; MS (CH_4 CI) *m/z*: 641 $(M + 1)^+$. Anal. calcd. for $C_{32}H_{40}O_{10}N_4 + H_2O$: C 58.34, H 6.42, N 8.50; found: 58.34, H 6.31, N 8.31.

p-*Xylylene capped crown ether (***2**b*)*

As described above for **2***a*, 1,4-bis(aminomethyl)benzene (0.85 g, 6.2 mmol) and acid chloride **1** (0.63 g, 1.4 mmol) gave **2***b* as a white solid (0.35 g, 40%). ^{1}H NMR ($CDCl_3$) δ: 7.1 (s, 8H), 6.7 (d, 4H), 4.9 (t, 2H), 4.4 (s, 4H), 3.7 (d, 2H), 3.6–3.5 (m, 6H), 3.3–3.2 (m, 16H); ^{13}C NMR ($CDCl_3$) δ: 169.2, 139.2, 128.5, 78.1, 70.4, 70.3, 43.4; MS (CH_4 CI) *m/z*: 641 $(M + 1)^+$; mp > 275°C. Anal. calcd. for $C_{32}H_{40}O_{10}N_4 + H_2O$: C 58.34, H 6.42, N 8.50; found: C 58.07, H 6.25, N 8.23.

*Biphenyl capped crown ether (***2**d*)*

As described for **2***a* acid chloride **1** (0.6 g, 1.14 mmol) and 2,2′-bis(aminomethyl)biphenyl (0.65 g, 3.1 mmol) gave **2***d* as a pale yellow solid (0.76 g, 85%). ^{1}H NMR ($CDCl_3$) δ: 7.6–6.9 (m, 12H), 4.8 (m, 2H), 4.7–4.6 (m, 4H), 4.2–3.6 (m, 2H), 3.5–3.1 (m, 16H); ^{13}C NMR ($CDCl_3$) δ: 170.3, 170.1, 169.5, 169.4, 139.5, 139.2, 138.7, 138.4, 135.9, 135.5, 135.0, 134.7, 130.5, 130.0, 129.6, 129.5, 129.4, 129.0, 128.6, 128.5, 128.4, 128.0, 127.9, 127.6, 127.2, 126.7, 83.0, 82.4, 81.9, 81.3, 77.3, 71.6, 71.3, 71.2, 70.7, 68.5, 68.2, 67.9, 67.4, 42.5, 42.2, 41.6 (2 peaks); MS (CH_4 CI) *m/z*: 793 $(M + 1)^+$. Anal. calcd. for $C_{44}H_{48}O_{14}N_4 + 2.5\ H_2O$: C 63.07, H 6.37, N 6.68; found: C 63.25, H 6.18, N 6.46.

*1,3-Bis(*R,R-*1′,4′,7′,10′,13′,16′-hexaoxacyclooctadecan-2-carboxyl-3-carboxamidomethyl)benzene (***5**a*)*

A solution of anhydride **4** (ref. 27, 0.95 g, 2.8 mmol) in THF (150 mL) was mixed with 1,3-bis(aminomethyl)benzene (0.2 g, 1.4 mmol), followed by the addition of dry triethylamine (2 mL). The mixture was stirred for 7 h at room temperature under an inert atmosphere. The excess solvent was removed under reduced pressure to give a glassy solid. The product was dissolved in water and extracted twice with dichloromethane (20 mL) to remove neutral impurities. The water solution was passed through a cation-exchange resin to remove triethylammonium chloride. The acidic fractions (< pH 3) were collected and the water was removed under reduced pressure to give **5***a* as a colourless solid (1.02 g, 89%). ^{1}H NMR ($CDCl_3$) δ: 7.5 (t, 1H), 7.4–7.2 (m, 3H), 4.9 (m, 2H), 4.5 (dd, 4H), 3.9–3.8 (m, 2H), 3.6–3.4 (m, 40H); ^{13}C NMR ($CDCl_3$) δ: 171.7, 168.4, 138.7, 128.5, 127.0, 126.2, 81.3, 80.5, 71.2, 70.5, 70.2, 69.9, 69.8, 69.7, 69.6, 42.8; MS (CH_4 CI) *m/z*: 805 $(M + 1)^+$; MS (LSIMS) *m/z*: 805 $(M + H)^+$, 827 $(M + Na)^+$. Anal. calcd. for $C_{36}H_{56}O_{18}N_2 + 2\ H_2O$: C 51.42, H 7.19, N, 3.33; found: C 51.31, H 7.29, N 3.47.

*9,10-Bis(*R,R-*1′,4′,7′,10′,13′,16′-hexaoxacyclooctadecan-2-carboxyl-3-carboxamidomethyl)anthracene (***5**c*)*

A solution of anhydride **4** (ref. 27; 0.9 g, 2.6 mmol) in THF (300 mL) was stirred with solid 9,10-bis(aminomethyl)anthracene (0.5 g, 2 mmol) for 14 h in presence of triethylamine (2 mL) at room temperature. The solvent was removed under reduced pressure. The resulting yellow pasty solid was dissolved in water and extracted with dichloromethane. The chlorocarbon layer was washed with water and evaporated to dryness to yield 0.9 g (76%) of **5***c* as yellow powder. ^{1}H NMR ($CDCl_3$) δ: 8.4 and 7.5 (AA′XX′, 4H), 5.6 (dd, 2H), 5.4 (dd, 2H), 4.3 (dd, 4H), 3.6–2.9 (m, 40H); ^{13}C NMR ($CDCl_3$) δ: 171.5, 168.8, 130.3, 130.2, 130.1, 126.3, 126.2, 124.9, 124.6, 81.3, 80.7, 71.4, 71.2, 70.5, 70.0, 69.9, 69.8, 69.5, 69.3, 35.6; MS (LSIMS) *m/z*: 906 $(M + H)^+$. Anal. calcd. for $C_{44}H_{60}O_{18}N_2 + 2\ H_2O$: C 56.16, H 6.85, N 2.97; found: C 56.04, H 6.91, N 3.01.

R,R-N-*(2-Hydroxyphenyl)-1,4,7,10,13,16-hexaoxacylcooctadecan-2-carboamido-3-carboxylic acid (***6**)*

2-Aminophenol (0.3 g, 3.7 mmol) and the crown ether anhydride **4** (ref. 27; 0.93 g, 2.7 mmol) were dissolved in dry THF (150 mL), followed by triethylamine (1 mL). The mixture was stirred for 6 h at room temperature, the solvent was removed under reduced pressure, and the resulting brown solid was dissolved in water (150 mL) and extracted twice with dichloromethane (50-mL portions). The combined extracts were washed twice with water (100 mL) and evaporated. The brown residue was dissolved in water and passed through a cation-exchange column. Acidic fractions were combined and evaporated to dryness to give a pale yellow solid (1.0 g, 84%). ^{1}H NMR ($CDCl_3$) δ: 9.4 (b, 1H), 7.3 (d, 1H), 7.1 (t, 1H), 7.0 (d, 1H), 6.8 (t, 1H), 4.4 (d, 2H), 3.8–3.4 (m, 20H); ^{13}C NMR ($CDCl_3$) δ: 171.2, 169.1, 149.2, 127.3, 125.2, 123.4, 120.3, 119.3, 80.9, 80.7, 71.2, 71.0, 70.5, 70.4, 70.1, 69.9, 69.6, 69.4; MS (LSIMS) *m/z*: 466 $(M + Na)^+$, 445 $(M + H)^+$. Anal. calcd. for $C_{20}H_{29}O_{10}N + H_2O$: C 52.05, H 6.77, N 3.03; found: C 52.50, H 6.45, N 3.19.

syn- *and* anti-R,R-N,N′-*Bis(2-hydroxyphenyl)-1,4,7,10,13,16-hexaoxacyclooctadecan-2,11(12)-dicarboxamido-3,12(11)-dicarboxylic acid (***8**)*

Crown ether bisanhydride **7** (ref. 35; 0.92 g, 2.2 mmol) and triethylamine (1 mL) were dissolved in dry THF (150 mL) and a solution of 2-aminophenol (0.5 g, 4.5 mmol) in dry THF (50 mL) was added dropwise within 4 h with constant stirring at room temperature. The solvent was removed under reduced pressure, and the brown residue was dissolved in water and extracted with two portions of dichloromethane (100 mL). The organic extract was washed twice with water (50 mL), and the solvent was evaporated to give 1.41 g of tan solid. The solid was dissolved in water and passed through a cation-exchange column. Acidic fractions were combined and evaporated to a viscous oil which solidified on evacuation under high vacuum (1.3 g, 91%). ^{1}H NMR ($CDCl_3$) δ: 8.7 (b, 2H), 7.3 (d, 2H), 7.0 (d, 2H), 6.9 (t, 2H), 6.8 (t, 2H), 4.3 (d, 4H), 3.9–3.5 (m, 16H); ^{13}C NMR ($CDCl_3$) δ: 171.7, 169.2, 148.8, 127.4, 124.8, 123.6, 120.4, 118.7, 81.2, 79.9, 71.0, 70.5, 69.2, 68.8; MS (LSIMS) *m/z*: 623 $(M + H)^+$. Anal. calcd. for $C_{28}H_{34}O_{14}N_2 + 2\ H_2O$: C 51.06, H 5.81, N 4.25; found: C 51.14, H 5.65, N 4.17.

Stability constant determinations

Stability constants for ionizable ligands were determined by pH titration using procedures previously described (30). Stability constants for the neutral ligands (captands) were determined using an ion selective electrode. The cell assembly comprised calomel‖0.1 M tetramethylammonium nitrate (TMAN)‖sample solution|potassium selective glass electrode (Phillips G515K). The potassium electrode was preconditioned in 1:1 v/v methanol–water mixture and titrated with a 0.1 M KCl solution. The titrations were repeated to get a concordant values of slope and intercept. The titrant was taken in an automatic burette (Metrohm 655 Dosimat) and added to the cell in aliquots scaled to give concentration corresponding to increase of 0.2 pK^+. Ten millilitres of 1:1 v/v methanol–water solution was placed in a temperature controlled cell and the ionic strength was maintained constant using 0.1 M TMAN. In a typical titration, 20 μL of the ligand solution was introduced into the cell and titrated against the standard KCl solution. The added volume of the titrant was stored along with the response of the electrode. The collected data was then analyzed by using the slope and intercept from the electrode calibration titrations to derive $[M^+]_{free}$ values at each point in the titration. A 1:1 complexation stoichiometry was assumed, to give via the mass balance relationships the expression for

$$K_s = \frac{[M^+]_{tot} - [M^+]_{free}}{[M^+]_{free}([L]_{tot} - [M^+]_{tot} + [M^+]_{free}}$$

Values of K_s were calculated at each point and averaged over the range of $0.2 < [M^+]_{free}/([M^+]_{tot} - [M^+]_{free}) < 0.8$.

Fluorescence studies

In the case of neutral ligands, the ligands were dissolved in 50% methanol–water and 0.02 mL of the stock solution was diluted to 3 mL with water and the required amount of metal ion solution. All metal ion solutions (0.1 M) were prepared by dissolving the chloride salts in deionized water. The appropriate concentration of the metal ions for individual fluorescence spectrum was obtained by diluting the stock solution with water. The excitation wavelength was determined from the absorption spectrum, taking the absorption maximum as the excitation wavelength. The emission wavelength was scanned from 10 nm higher than the excitation wavelength. The purity and absorption of all metal ion solutions and the solvent were recorded separately and subtracted from the emission spectrum of the compound wherever necessary. Emission and Raman scattering were differentiated by changing the excitation wavelength. All fluorescence spectra were recorded with excitation slits and emission slits set to 5 nm and uncorrected spectra were recorded.

In the case of ionizable ligands, a lithium–phosphate buffer of pH 10 was used. A few microlitres of the stock solution of the ligand was added to the cell containing buffer solution. The emission of the buffer was recorded and subtracted from the emission of the ligands. The metal ion effect was monitored using different volumes of 0.1 M metal chloride stock solution added to the cell. The solutions were prepared individually with the ligand solution, metal chloride solution, and made up to 3 mL with a pH 10 buffer solution.

The photochemistry of 1-naphthylmethyl carbonates and carbamates

T. PARMAN, J.A. PINCOCK,[1] AND P.J. WEDGE
Department of Chemistry, Dalhousie University, Halifax, NS B3H 4J3, Canada

Received August 16, 1993

T. PARMAN, J.A. PINCOCK, and P.J. WEDGE. Can. J. Chem. **72**, 1254 (1994).

The photochemistry in methanol of 1-naphthylmethyl phenyl carbonate (**3**) and 1-naphthylmethyl benzyl carbonate (**4**) has been studied. Products resulting from both the 1-naphthylmethyl cation and the 1-naphthylmethyl radical are obtained for **3**, but only from the cation for **4**. Similar results were obtained for the corresponding 1-naphthylmethyl derivatives **5** and **6** of *N*-phenyl and *N*-benzyl carbamic acids. The product yields for all four compounds can be explained by a mechanism of initial homolytic cleavage of the 1-naphthylmethyl carbon–oxygen bond from the excited singlet state. The radical pair generated then partitions between the two pathways: electron transfer to form the ion pair or decarboxylation. For PhO-CO-O˙ and PhNH-CO-O˙, decarboxylation is rapid and competitive with electron transfer. For $PhCH_2O$-CO-O˙ and $PhCH_2NH$-CO-O˙, decarboxylation is slower, electron transfer dominates, and only products from the ion pair are obtained.

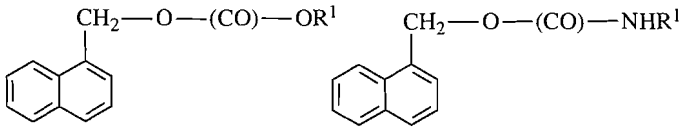
T. PARMAN, J.A. PINCOCK et P.J. WEDGE. Can. J. Chem. **72**, 1254 (1994).

On a étudié la photochimie du carbonate de 1-naphtylméthyle phényle (**3**) et du carbonate de 1-naphtylméthyle phényle (**4**) dans le méthanol. Avec le composé **3**, on obtient les deux produits provenant du cation et du radical 1-naphtylméthyle; toutefois, avec le composé **4**, on n'obtient que le composé provenant du cation. On a obtenu des résultats semblables avec les dérivés 1-naphtylméthyles correspondants **5** et **6** des acides *N*-phényl- et *N*-benzylcarbamiques. On peut expliquer les rendements obtenus pour les quatre produits en se basant sur un mécanisme impliquant un clivage initial homolytique de la liaison oxygène–carbone du 1-naphtylméthyle à partir de l'état singulet excité. La paire de radicaux qui est générée conduit à deux voies réactionnelles, une décarboxylation ou la formation d'une paire d'ions après un transfert d'électron. Pour les PhOCOO˙ et PhNHCOO˙, la décarboxylation est rapide et est en compétition avec le transfert d'électron. Pour le $PhCH_2OCOO$˙ et le $PhCH_2NHCOO$˙, la décarboxylation est plus lente, le transfert d'électron domine et on obtient seulement des produits provenant de la paire d'ions.

[Traduit par la Rédaction]

Introduction

The solution photochemistry of esters of carboxylic acids (R^1-CO-OR^2) has been extensively studied and the fundamental excited state processes are well understood (1, 2). Esters with saturated alkyl groups have only a weakly absorbing n,π^* transition around 215 nm, which is outside the range of the standard Hg arc light sources. Therefore, most results have been obtained for compounds that have chromophores such as aromatic rings (i.e., R^2 = Ar or $ArCH_2$) conjugated to the ester functional

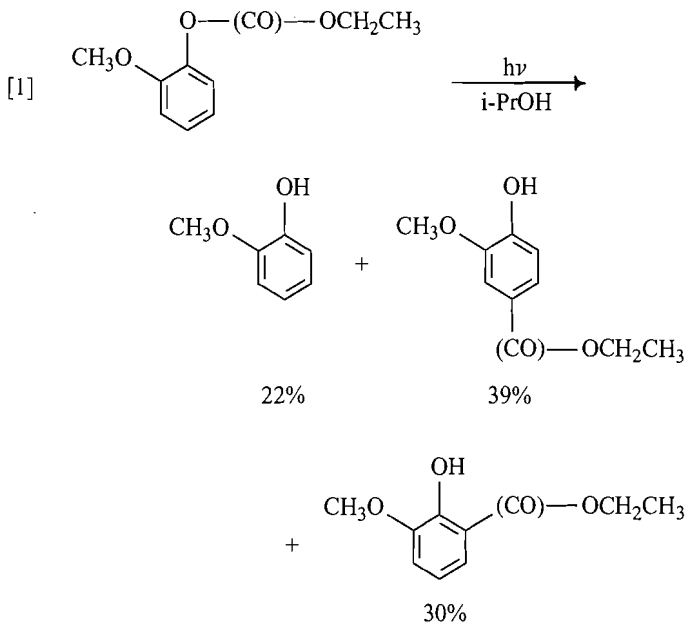


3 R^1 = Ph
4 R^1 = $PhCH_2$

5 R^1 = Ph
6 R^1 = $PhCH_2$

group. For the former (R^2 = Ar), carbonyl carbon–oxygen bond cleavage in the excited state is usually the dominant process often leading to photo-Fries products (3–5). For the latter (R^2 = $ArCH_2$), arylmethyl carbon–oxygen bond cleavage is facile and products characteristic of arylmethyl cations and radicals result (vide infra).

Much less is known about the photochemistry of carbonates (R^1O-CO-OR^2) and carbamates (R^1NH-CO-OR^2), and again, most of the information available deals with compounds having chromophores conjugated to the functional group. In agreement with the observations for esters, when R^1 is aryl in carbonates and carbamates and R^2 is methyl or ethyl, carbonyl carbon–oxygen (ArO-CO) or carbonyl carbon–nitrogen (ArNH-CO) bond



cleavage, respectively, dominate and photo-Fries products result. Two examples are given in eqs. [1] (6) and [2] (7).

More recently, there has been interest in the photochemistry of carbamates as a method for the generation of amines in solution. An efficient procedure has been developed using σ-nitrobenzyl carbamates (eq. [3], ref. 8), although the photochemistry involved is that of the nitrobenzyl functional group and not of the carbamate directly. The amine is released by ground state fragmentation of the α-hydroxy carbamate **1**. More relevant to carbamate photochemistry is the irradiation of the 3,5-dimethoxybenzyl derivatives (**2**) (eq. [4], ref. 9). This particular substitution pattern was chosen to enhance the efficiency

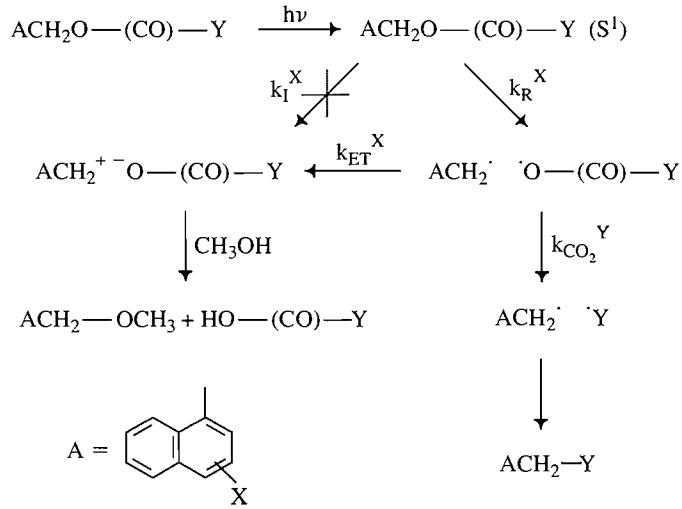
of heterolytic cleavage of the benzylic carbon–oxygen bond according to "*meta* effect" arguments (10).

According to the *meta* effect, substituents on the aromatic ring in photochemical cleavage reactions of arylmethyl substrates with leaving groups operate by controlling the competition between homolytic (k_R^X, R for radical) and heterolytic (k_I^X, I for ionic) cleavage of the arylmethyl carbon–oxygen bond in the excited singlet state (Scheme 1). The idea was founded on the observation (10), for substituted benzylic acetates, that the *meta*-methoxy isomer gave higher yields of the product derived from the intermediate cation than did the isomeric *para* compound. The effect was rationalized by electron density changes upon excitation giving enhanced rates of heterolytic cleavage for the *meta* isomer, electron donation favouring the pathway



SCHEME 1. General mechanism for the photolysis in methanol of 1-naphthylmethyl compounds of carboxylic acid derivatives. For esters, Y = R; for carbonates, Y = OR; and for carbamates, Y = NHR.

for the formation of the arylmethyl cation. This observation, which is contrary to ground state expectations, was called the photochemical *meta* effect (10).

Recently, we have reported (11–13) on the photochemistry of 1-naphthylmethyl esters of carboxylic acids in the solvent methanol. As expected (14), for an arylmethyl substrate with a leaving group, the products obtained resulted from both the intermediate arylmethyl radical and the arylmethyl cation. On the basis of the variation in product yields as a function of substituents (X) on the naphthalene ring (11, 12) and of the structure (Y = alkyl) of the carboxylic acid (13), a mechanism was formulated as outlined in Scheme 1.

After excitation, homolytic carbon–oxygen bond cleavage forming the radical pair (k_R^X) occurs from the excited singlet state. Although intersystem crossing is reasonably efficient for naphthalene derivatives, the triplet state is unreactive because the excitation energy (~250 kJ/mol) is lower than the bond dissociation energy (~270 kJ/mol). The two critical steps that control product distribution follow the formation of the radical pair: electron transfer that converts the radical pair to the ion pair (k_{ET}^X) and decarboxylation of the acyloxy radical ($k_{CO_2}^Y$) to give a new radical pair. The ether and carboxylic acid products result from reaction of the ion pair with the solvent methanol and the hydrocarbon product results from in-cage coupling of the radical pair. The competition between these two reaction pathways can be systematically varied by changing the structure of the ester. Thus, variation of the alkyl group Y from methyl to *t*-butyl in the acyloxy radical changes $k_{CO_2}^Y$ from 1×10^9 to 11×10^9 s^{-1}, in agreement with the expectation that this process should be faster for the more stable alkyl radical. Variation in substituents (X) on the naphthalene ring varies the oxidation potential of the 1-naphthylmethyl radical and, thus, the rate of electron transfer. These oxidation potentials were shown to correlate with σ^+ ($\rho^+ = -8.4$) (15). The rates of electron transfer agreed very well with Marcus theory in both the normal and inverted regions (11, 12). For electron-withdrawing groups, the rates were slow (6.9×10^8 s^{-1} for X = 4-CN), passed through a maximum (6.0×10^{10} s^{-1} for X = 4-CH_3), and then decreased for strong electron-donating groups (3.3×10^9 s^{-1} for X = 4,7-$(OCH_3)_2$). The calculated reorganization energy was 0.52 eV. The important feature of Scheme 1 is that only homolytic cleavage of the excited state is

TABLE 1. Photophysical data for the carbonates and carbamates

[a]NM, 1-naphthylmethyl.
[b]ϕ_f were determined by comparing the emission spectrum of the compound to the emission spectrum of naphthalene.

required to explain the product yields. No heterolytic cleavage to form ion pairs is included, i.e., $k_R^X \gg k_I^X$.

Based on these ideas, the photochemistry of 1-naphthylmethyl carbonates and carbamates is of obvious interest. The acyloxy radicals generated (R-O-CO-O· and R-NH-CO-O·, respectively) should have very different reactivity than those generated in ester photochemistry (R-CO-O·). If rates of electron transfer and decarboxylation are the dominant factors controlling product distribution, major changes in yield should be observed. Moreover, the study of the carbamates will provide the information necessary to design photolabile amine protecting groups.

In this paper, we report on the synthesis and photochemistry in methanol of the compounds **3–6**. The results are consistent with the mechanism outlined in Scheme 1.

Results and discussion

Synthesis of carbonates and carbamates

The carbonates were prepared by reaction in benzene with pyridine of 1-naphthylmethanol with phenyl chloroformate for **3** and benzyl chloroformate for **4**. The carbamates were prepared by reaction of 1-naphthylmethanol with phenyl isocyanate for **5** and benzyl isocyanate for **6**. Details and data for characterization are in the Experimental section.

*Excited state properties of carbonates **3** and **4** and carbamates **5** and **6***

To understand the excited state properties of the substrates, absorption and fluorescence measurements were taken. Values for the singlet energy, fluorescence quantum yield, and singlet lifetime are reported in Table 1, along with the corresponding values for 1-naphthylmethyl phenylacetate and naphthalene for comparison. The similarity in the values for the ester, carbonates, and carbamates indicates that inclusion of the oxygen or nitrogen into the functional group has little effect on the excited state behaviour. Therefore, the excitation energy is still localized on the naphthalene ring and the excited state should react by the normal arylmethyl carbon–oxygen bond cleavage. The decrease in fluorescence quantum yield and lifetime by going from naphthalene to the functionalized derivatives is a reflection of the efficiency of this bond cleavage process.

*Photolysis of carbonates **3** and **4***

A solution of the carbonate in methanol (nitrogen purged) was photolyzed in an immersion well with a 200-W, Pyrex-filtered medium-pressure Hanovia mercury lamp. Conversion of 1.3 g of starting material took 6 h. Progress of the reaction was monitored by HPLC. The products obtained and their yields (in parentheses) by calibrated HPLC are shown in eq. [5] for **3** and eq. [6] for **4** (A equals 1-naphthyl). The mass balance is

clearly excellent. Determining that the structure of **11** was *para* was simply based on the coupling pattern of the aromatic H's in the ^1H NMR and the carbon count in the ^{13}C NMR. The assignment of **10** as *ortho* was based on the observation that the hydrogen *para* to the OH at δ 6.80 (calcd. (16), 6.76) showed two *ortho* couplings. The *meta* isomer, which was not detected, would have had a hydrogen *para* to the OH at δ 6.68 (calcd.) with only one *ortho* coupling.

The first observation to discuss is that none of the products derived from the carbonates **3** and **4** contained CO_2. In Scheme 1, for esters, the carboxylic acids (Y = alkyl) are stable and isolable. For carbonates (Y = OR), this is not so. The ground state

decomposition by loss of carbon dioxide of alkyl monocarbonates in aqueous solution has been studied (17). Not surprisingly, the reaction is base catalyzed and the rate levels off at high pH where the carbonate is completely ionized (eq. [7]). Based on

[7] $RO—(CO)—OH \rightleftharpoons RO—(CO)—O^- + H^+ \longrightarrow RO^-$

the pK_a of the alcohol and a Bronsted plot, rate constants for decomposition in water of about 10^{-3} s^{-1} for $PhCH_2OCO_2^-$ and about 10^3 s^{-1} for $PhOCO_2^-$ can be estimated. The values in methanol should not be much different. Since these alkyl carbonates are also reasonably strong acids ($pK_a^R \leq 0$) (17), they will be greater than 50% ionized in neutral solvents, so that the rate of loss of CO_2 will be fast relative to the photolysis times. Thus, the phenolic products **8**, **10**, and **11** in [5] and the alcohol **12** in [6] could be formed by thermal decomposition of the corresponding monocarbonates. In fact for the benzyl carbonate **4**, the essentially equivalent and quantitative yields of the ether **7** and the alcohol **12** suggest that both products are derived from the ion pair in Scheme 1. If the general mechanism in the scheme is correct, this means $k_{ET}^X \gg k_{CO_2}^Y$ (Y = OCH_2Ph) for this substrate. A value for the rate constant of decarboxylation of acyloxy radicals of this type (RO-CO-O·) has been estimated by laser flash photolysis studies (18) to be less than 10^6 s^{-1}. Since electron transfer rates in these radical pairs can be expected to be greater than 10^9 s^{-1} (vide supra), the mechanism is reasonable.

The situation is not so clear for the phenyl carbonate **3** (eq. [5]). The phenolic products **10** and **11** could be derived from the ion pair by a Friedel–Crafts type reaction of the 1-naphthylmethyl cation with the monocarbonate anion $PhOCO_2^-$. The oxygen, of course, would be *ortho–para* directing. Thermal loss of carbon dioxide would then give **10** and **11**. This possibility was tested by studying the ground state solvolysis of **3**. Thus, reaction of **3** in CH_3OH at 50°C (40% conversion after 35 h) resulted in conversion to only the ether **7** and the phenol **8**. No **10** and **11** were observed. Thus, **10** and **11** are not derived from the ion pair; neither is **9**, which could have been formed from the ion pair by coupling of the 1-naphthylmethyl cation with the phenoxide anion. This possibility is unlikely anyway, since the estimated rate constant of $\sim 10^3$ s^{-1} for thermal decarboxylation of $PhOCO_2^-$ is too small to compete with the expected very rapid trapping ($>10^9$ s^{-1}) of the ion pair in methanol.

A referee has raised the point that the above conclusions are based on the assumption that the ground state solvolysis of **3** in methanol occurs by the S_N1 mechanism. This is a valid comment, since the solvolysis of benzyl systems represents one of the classic cases of curved Hammett plots, as the mechanism changes from an ion pair S_N1 mechanism for stable cations to a solvent-assisted S_N2 mechanism for less stable cations. A detailed study of substituent effects on solvolysis rates in 80% acetone – water for benzyl tosylates (19) indicates that the change occurs near $\sigma^+ = 0$ for the unsubstituted case with $\rho^+ = -5.8$, indicating an S_N1 mechanism, for better electron-donating groups. A similar conclusion was reached from results on the rates of solvolysis of benzyl tosylates as a function of both substituents and solvents (20), including methanol. Fitting solvolysis rates to the Grunwald–Winstein equation indicated that the sensitivity to solvent nucleophilicity (L) dropped and the sensitivity to solvent ionizing power (*m*) exceeded unity as the substituent changed from H to 4-CH_3. To our knowledge, there is no available literature on the solvolysis of arylmethyl carbonates. However, based on the similarity of the pK_a of carbonic (17) and sulfonic (21) acids, they should be comparable as leaving groups. As well, changing from phenyl to 1-naphthyl is known to increase the rate of solvolysis of arylmethyl derivatives by a factor of about 20 (22). This is similar to the rate increase observed for changing a substituent from H to 4-CH_3 in benzyl systems (19). By analogy then, the solvolysis of 1-naphthylmethyl carbonates in methanol probably proceeds by a rate-determining S_N1 ionization to the very short-lived ion pair.

The conclusion drawn from this section is that photolysis of these carbonates again follows the general mechanism shown in Scheme 1 for ester photochemistry. Compounds **3** and **4** have very similar excited state properties. Therefore, the logical expectation is that the partitioning between k_R^X and k_I^X should be the same for both. However, the ratio of the yields of products derived from the ion pair versus the radical pair is 43:57 for **3** and >20:1 for **4**. Again, processes occurring after the excited state step must be of major importance.

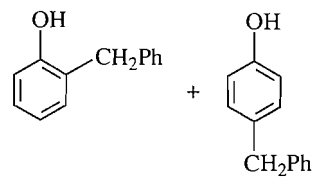
One question still left to discuss is at what stage does decarboxylation occur in the pathway for formation of the radical coupled products **9–11**. Product **9** would have to be formed by coupling of the radical pair after decarboxylation. Products **10** and **11** could be formed either before or after decarboxylation. The rate constant for this decarboxylation process (eq. [8]) is

[8] $ACH_2^{\cdot}\ {}^{\cdot}O—(CO)—OPh \xrightarrow{-CO_2} ACH_2^{\cdot}\ {}^{\cdot}OPh$

unknown but, because of the stability of the phenoxy radical, will certainly be much greater than the case of RO-CO-O· ($<10^6$ s^{-1}) (18) where R is alkyl. However, coupling of the radical pairs after decarboxylation to form the products cannot be the explanation because the product distribution between **9**, **10**, and **11** should reflect the spin density in the phenoxy radical. Estimates of these values, from ESR measurements (23), are approximately 20% at oxygen, 40% at the *para* carbon, and 20% at each of the two *ortho* carbons. The yield of **9** (2%), therefore, seems lower than expected.

A resolution of this problem was prompted by a literature observation (24) on the photoreactivity of benzyl phenyl ether, which gave phenolic products analogous to **10** and **11** (eq. [9]).

[9] $PhCH_2—OPh$ (**13**) $\xrightarrow[CH_3CH_2OH]{h\nu}$



18% 14%

In agreement with this report, photolysis of **9** in methanol resulted in rapid conversion (0.72 g in 3.5 h) to **10** and **11**. The product ratio of **10**:**11** was 47:53. Therefore, the conversion of **9** and **10** to **11** is more efficient than the formation of **9** from the carbonate **3**. Since the chromophores of **3** and **9** are the same, no buildup of **9** in the reaction mixtures would be expected and none was observed. Thus, although most of the phenols **10** and **11** probably result from coupling after decarboxylation of the acyloxy radical (eq. [8]), some probably result from secondary photolysis of **9**.

As mentioned above, another possibility is that coupling occurs before decarboxylation as shown in eq. [10] for the for-

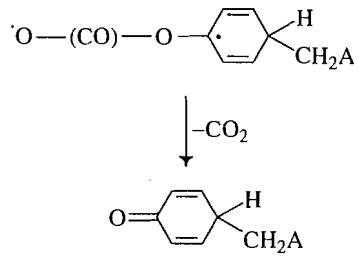
For personal use only.

[10] $ACH_2^{\cdot}$ $^{\cdot}O-(CO)-Ph \longrightarrow$



mation of **11**. The intermediate should rapidly lose CO_2 and the resulting ketone would then tautomerize to the phenol **11**. The choice between these various possibilities can only be made if a rate constant for decarboxylation of PhO-CO-O$^{\cdot}$ can be determined by laser flash photolysis.

No matter what the mechanism for decarboxylation, the conclusion reached is that for the photolysis of the phenyl carbonate **3**, the products **9–11** come from the initially formed radical pair. The general mechanism in Scheme 1 rationalizes all the results for both carbonates without including k_1^X. For the benzyl carbonate **4**, decarboxylation of the acyloxy radical is slow ($<10^6$ s^{-1}) and, therefore, electron transfer to form the ion pair dominates. For the phenyl carbonate **3**, decarboxylation is much faster and competes with electron transfer so that products from both the radical pair and the ion pair are observed.

*Photolysis of carbamates **5** and **6***

Products and their yields for these two photolyses are shown in eqs. [11] and [12]. These reactions were not as clean as the

$ACH_2OCH_3 + NH_2CH_2Ph$

7 (73%) **18**

carbonate cases and the solutions turned murky as the reaction proceeded. Moreover, the mass balances are clearly lower (~70%). However, the products obtained show the same general trend as for the carbonates. For the phenyl carbamate **5**, the ether **7** (from the ion pair intermediate) and the radical coupling products **15–17** are formed in competition with each other, whereas for the benzyl carbamate **6**, only the ion pair derived products, the ether and amine, were detected.

Once again there is information (25, 26) about the ground state stability of the potential carbamic acid products **19** (eq. [13]). Now at high pH, decarboxylation is slow because the

[13] $R-NH_2^+-(CO)-O^- \rightleftharpoons R-NH-(CO)-OH$ (**19**)

$R-NH_2 + CO_2$

$R-NH-(CO)-O^-$

$R-NH^- + CO_2$

instability of R-NH– makes it a poor leaving group. At lower pH, the rate constant for decarboxylation through the zwitterion has been estimated at 10^8–10^{10} s^{-1} depending on the amine. Therefore, these products will not survive the photolysis reaction times.

As far as the radicals are concerned, nothing is known about the rate constants for decarboxylation of RNH-CO-O$^{\cdot}$ species, although unsuccessful attempts to measure them have been reported (18).

Finally, the possibility that the coupling products **16** and **17** result from secondary photolysis of **15** was investigated. Surprisingly, in contrast to the ether **9**, irradiation of **15** in methanol gave no reaction. Therefore, the products shown in eq. [11] are all primary photoproducts. The fact that the ether **9** is photoreactive, but the structurally analogous amine **15** is not, may be a result of a stronger bond in the amine. Bond strengths of 277 kJ/mol for CH_3-OPh versus 298 kJ/mol for CH_3-HPh have been reported (27).

The conclusion to be reached from the carbamate photochemistry is essentially the same as that for the carbonates. Again the general mechanism shown in Scheme 1 rationalizes all the results without including heterolytic cleavage of the excited state. Homolytic cleavage gives the radical pair. For carbamate **5**, the decarboxylation of the radical PhNH-CO-O$^{\cdot}$ competes with electron tranfer and products derived from both the ion pair and the radical pair are observed. For **6**, on the other hand, decarboxylation of $PhCH_2NH$-CO-O$^{\cdot}$ is slower, electron transfer dominates, and only products from the ion pair are detected.

Experimental

General experimental

^1H and ^{13}C NMR spectra were obtained in $CDCl_3$ on a Bruker AC 250F NMR spectrometer in automation mode. Chemical shifts are reported in parts per million (δ) relative to tetramethylsilane (0.00) as an internal standard. Multiplicities are abbreviated as follows: s = singlet, d = doublet, t = triplet, q = quartet, m = multiplet. IR spectra were obtained on a Nicolet 205 FT-IR spectrometer and the frequencies are reported in wave numbers (cm^{-1}). C, H, and N analyses were done by Canadian Microanalytical Services Ltd, Delta, BC V4G 1G7, Canada. GC–MS analyses were done on a Hewlett Packard 5890A GC 5970 with a mass selective detector, using a Hewlett Packard 9816 microcomputer. The column used was a 25 m × 0.2 mm 5% phenyl methyl silcone on fused silica with a film thickness of 0.25 μm. Masses are reported in units of mass over charge (*m/z*). Intensities are reported as a percent of the base peak intensity. The molecular ion is indicated by $M^{+\cdot}$. GC–FID analyses were performed using a Hewlett Packard 5890A gas chromatograph and a Hewlett Packard 7673 automatic injector, with a Hewlett Packard 7673A controller and a Hewlett Packard 3396A integrator. A 1-m glass column was used with 10% Fluorad FC-431 and 1% H_3PO_4 on Chromosorb W HP 80/100 mesh. The detector used was a flame ionization detector. HPLC analyses were obtained with a Waters 6000 solvent delivery system and a Waters U6K injector under isocratic conditions with a flow rate of 2 mL/min, using a Brownlee Lab Spheri-10 10-μL reverse-phase column (25 × 0.46 cm) with a Waters model 450 variable wavelength detector. UV

*1-Naphthylmethyl N-benzyl carbamate (**6**)*

The crude carbamate was purified by column chromatography using silica gel and eluting with dichloromethane. The carbamate was further purified by recrystallization from hexane–dichloromethane to constant melting point. mp 118–119°C; IR (Nujol) ν_{max}: 3310 (NH), 2953, 2854, 1680 (C═O), 1545, 1456, 1264, 777, 700 cm^{-1}; ^1H NMR δ: 8.06 (d, 1H, J = 7.8 Hz), 7.86 (m, 2H), 7.47 (m, 4H), 7.29 (s, 5H), 5.61 (s, 2H), 5.05 (br s, 1H), 4.40 (d, 2H, J = 5.8 Hz); ^{13}C NMR δ: 156.4 (C═O), 138.4 (C), 133.6 (C), 131.9 (C), 131.6 (C), 129.1 (CH), 128.6 (CH), 128.5 (CH), 127.4 (CH), 127.3 (CH), 126.4 (CH), 125.8 (CH), 125.2 (CH), 123.6 (CH), 65.0 (CH_2), 45.0 (CH_2); GC–MS 291 ($M^{+\cdot}$, 29), 158 (76), 150 (19), 142 (14), 141 (100), 140 (18), 139 (18), 129 (37), 128 (14), 127 (13), 115 (37), 106 (11), 91 (19), 77 (14), 51 (14). Exact mass calcd. for $C_{19}H_{17}NO_2$: 291.1259; found: 291.1256.

Fluorescence measurements

A Perkin-Elmer MPF 66 fluorescence spectrometer was used for the fluorescence studies. The samples were degassed by three freeze–pump–thaw cycles. Fluorescence quantum yields were determined by comparison with a fluorescence quantum yield of 0.24 (28) for naphthalene in methanol. Singlet state energies were determined by the position of the 0,0 band using the overlap between the excitation and emission spectra. Fluorescence lifetimes were measured using a Photochemical Research Associates single photon counting apparatus, using a H_2 lamp with a pulse width of about 1 ns.

Preparative photolysis

A solution of ~1 g of the 1-naphthylmethyl carbonate or carbamate in 420 mL of distilled methanol was placed in an immersion well and degassed with nitrogen for 15 min before irradiation; degassing was continued during the irradiation. The light source was a Pyrex-filtered 200-W medium-pressure Hanovia mercury lamp. Irradiation was continued until the starting material was greater than 90% consumed. The photolysis solution was concentrated under vacuum to give an oil. The products were separated on a column packed with silica gel. The products isolated in this manner were further purified if necessary.

Characterization of the photoproducts

Phenol (**8**), benzyl alcohol (**12**), aniline (**14**), and benzyl amine (**15**) were purchased from the Aldrich Chemical Company and purified if necessary. Product **7**, 1-naphthylmethyl methyl ether, was available in the laboratory and has been previously characterized (13).

*1-Naphthylmethyl phenyl ether (**9**)*

An insufficient quantity of pure compound was isolated from the photolysis mixture of the carbonate for the study of its photochemistry. This compound was synthesized using the following procedure. Sodium phenoxide was prepared by adding 1.02 g (0.044 mol) of sodium to 30 mL of methanol, followed by the addition of 4.02 g (0.043 mol) of phenol. The sodium phenoxide solution was slowly added to 4.6 mL (0.031 mol) of 1-(chloromethyl)naphthalene in 20 mL of methanol. The reaction mixture was stirred overnight and then concentrated by rotary evaporation to 10 mL. Water (40 mL) was added and the water layer was washed with dichloromethane (3 × 20 mL). The organic layers were combined and dried over $MgSO_4$. The crude product was recrystallized from ethanol. mp 68–68.5°C (lit. (29) mp 66–67°C); ^1H NMR δ: 8.05 (m, 1H), 7.90 (d, 1H, J = 5.7 Hz), 7.85 (d, 1H, J = 9.3 Hz), 7.60 (1H, d, J = 5.9 Hz), 7.55–7.43 (m, 3H), 7.32 (t, 2H, J = 7.3 Hz), 7.07 (d, 2H, J = 7.8 Hz), 6.99 (t, 1H, J = 7.3 Hz), 5.49 (s, 2H); ^{13}C NMR δ: 158.9 (C),133.8 (C), 132.4 (C), 131.6 (C), 129.6 (CH), 129.0 (CH), 128.7 (CH), 126.6 (CH), 126.5 (CH), 125.9 (CH), 125.4 (CH), 123.7 (CH), 121.1 (CH), 114.9 (CH), 68.6 (CH_2); GC–MS *m/z*: 234 (5, $M^{+\cdot}$), 142 (12), 141 (100), 115 (37), 65 (11).

4-(1-Naphthylmethyl)phenol (11)

IR (neat) ν_{max}: 3380 (br), 3075, 2990, 2924, 1620, 1511, 1440, 1260, 792 cm^{-1}; ^1H NMR δ: 7.97 (m, 1H), 7.84 (m, 1H), 7.73 (d, 2H, J = 8.4 Hz), 7.48–7.30 (m, 4H), 7.03 (d, 2H, J = 8.2 Hz), 6.71 (d, 2H, J = 8.4 Hz), 4.36 (s, 2H); ^{13}C NMR δ: 153.2 (C), 140.6 (C), 133.9 (C), 131.3 (C), 129.8 (CH), 128.6 (CH), 127.1 (CH), 127.0 (CH), 125.9 (CH), 125.6 (CH), 125.5 (CH), 124.2 (CH), 115.2 (CH), 38.2 (CH_2); GC–MS *m/z*: 234 (100, $M^{+\cdot}$), 233 (44), 217 (16), 215 (32), 203 (11), 202 (20), 189 (9), 141 (16), 128 (32), 107 (14), 77 (11).

N-*(1-Naphthylmethyl)aniline (15)*

This compound was isolated from the photolysis mixture and also synthesized because more compound was needed for further analyses. Aniline (2.2 mL, 0.024 mol) was added to a solution of 3.75 g (0.024 mol) of 1-naphthaldehyde in 80 mL of methanol. The solution was refluxed overnight. After cooling, the solvent was removed to give the crude imine. The crude imine was purified by column chromatography using 250 g of silica gel and eluting with 90% hexane – 10% ethyl acetate. Fractions were collected every 20 mL and fractions 9–19 were found to contain the imine. The fractions were combined and the solvent was removed to give 3.9 g (0.017 mol) of the imine (yield 79%). The imine was dissolved in 200 mL of methanol and 0.63 g (0.017 mol) of sodium borohydride was added slowly. The solution was refluxed for 20 min and then cooled. Excess sodium borohydride was added to ensure that all of the imine had been reduced (as indicated by the disappearance of the yellow color). The amine was liberated by addition of an equal amount of water to the flask. The amine was precipitated and collected. It was purified by recrystallization from methanol–water to give 0.60 g of the amine (15% yield), which was identical by spectroscopy to that isolated from the photolysis mixture of carbamate **5**. mp 63.4–64°C (lit. (30) mp 64°C); ^1H NMR δ: 7.89–7.77 (m, 4H), 7.51–7.40 (m, 2H), 6.77–6.65 (m, 4H), 4.70 (s, 2H), 3.97 (br s, 1H); ^{13}C NMR δ: 148.2 (C), 134.3 (C), 133.8 (C), 131.5 (C), 129.3 (CH), 128.7 (CH), 128.2 (CH), 126.3 (CH), 126.0 (CH), 125.8 (CH), 125.5 (CH), 123.6 (CH), 117.5 (CH), 112.7 (CH), 47.2 (CH_2); GC–MS *m/z*: 233 ($M^{+\cdot}$, 31), 142 (40), 141 (100), 115 (29), 77 (12), 65 (19).

2-(1-Naphthylmethyl)aniline (16)

^1H NMR δ: 8.08 (m, 1H), 7.88 (m, 1H), 7.76 (d, 1H, J = 8.2 Hz), 7.52–7.48 (m, 2H), 7.37 (t, 1H, J = 8.2 Hz), 7.15–7.08 (m, 2H), 6.92 (d, 1H, J = 7.5 Hz), 6.76–6.70 (m, 2H), 4.31 (s, 2H), 3.57 (br s, 2H); ^{13}C NMR δ: 144.6 (C), 134.7 (C), 133.8 (C), 132.2 (C), 130.7 (CH), 128.8 (CH), 127.6 (CH), 127.2 (CH), 126.1 (CH), 125.9 (CH), 125.7 (CH), 125.68 (CH), 124.3 (C), 123.8 (CH), 118.9 (CH), 115.7 (CH), 34.5 (CH_2); GC–MS *m/z*: 233 ($M^{+\cdot}$, 100), 232 (57), 215 (28), 128 (13), 115 (14), 106 (11).

4-(1-Naphthylmethyl)aniline (17)

^1H NMR δ: 7.99 (m, 1H), 7.84 (m, 1H), 7.73 (d, 1H, J = 8.1 Hz), 7.46–7.37 (m, 3H), 7.26 (d, 1H, J = 6.6 Hz), 7.00 (d, 2H, J = 8.1 Hz), 6.66 (d, 2H, J = 8.1 Hz), 4.36 (s, 2H), 3.60 (br s, 2H); ^{13}C NMR δ: 143.0 (C), 137.2 (C), 133.9 (C), 132.1 (C), 129.6 (C), 128.6 (CH), 127.1 (CH), 127.0 (CH), 125.9 (CH), 125.53 (CH), 125.50 (CH), 124.3 (CH), 116.0 (CH), 38.2 (CH_2); GC–MS *m/z*: 233 ($M^{+\cdot}$, 100), 232 (59), 217 (13), 215 (17), 115 (11), 106 (25).

Quantitative photolysis

Compounds **3–6** were irradiated in the same manner as was described under the preparative photolysis section, but in this case only 100 mg of the substrate was used. Analyses were done with less than 50% of the starting material consumed. The product yields were calculated at various percent conversions and no change in product ratio as a function of time was indicated. Dark reactions were found to be negligibly slow. Standard solutions were prepared which contained a known amount of the photoproducts. These standards were used to determine the yields of photoproducts for the photolysis by HPLC. The peak heights of the products in the sample were measured and compared with the peak heights of a standard solution of the corresponding product.

Photolysis of 1-naphthylmethyl phenyl ether (9)

A solution of 173 mg of the ether in 300 mL of methanol was irradiated until >90% of the ether had reacted. There were two photoproducts formed from this reaction. They were separated on a 30 × 2.2 cm column packed with 25 g of silica gel. One 100-mL fraction was collected, followed by ten 10-mL fractions and then ten 30-mL fractions. The fractions were analyzed by HPLC. Fractions 9–13 were combined. The solvent was removed giving 47 mg of photoproduct. This product was identified as 2-(1-naphthylmethyl)phenol (**10**) by comparison with previously recorded spectra. Fractions 17–19 were combined and the solvent was removed to give 18 mg of photoproduct. By comparison with previously recorded spectra this photoproduct was identified as 4-(1-naphthylmethyl)phenol (**11**).

Photolysis of N-*(1-naphthylmethyl)aniline (15)*

This compound was photolysed in a manner analogous to that described above. After 48 h of irradiation, no product formation was detected.

The preparation of *C*-aryl glucals via palladium-catalyzed cross-coupling methods

RICHARD W. FRIESEN,[1] RICHARD W. LOO, AND CLAUDIO F. STURINO

Lash Miller Chemical Laboratories, Department of Chemistry, University of Toronto, Toronto, ON M5S 1A1, Canada

Received September 27, 1993

RICHARD W. FRIESEN, RICHARD W. LOO, and CLAUDIO F. STURINO. Can. J. Chem. **72**, 1262 (1994).

The *C*-aryl glucals **17–31** have been prepared by the palladium-catalyzed cross coupling of 1-tributylstannyl-3,4,6-tri-*O*-(*tert*-butyldimethylsilyl)-D-glucal (**11**) and aryl bromides. The major by-product in all of these reactions is the dimer **33**, the product of homocoupling of **11**. Alternatively, the *C*-aryl glucals **34–40** can be obtained from the palladium-catalyzed coupling of 1-iodo-3,4,6-tri-*O*-(triisopropylsilyl)-D-glucal (**16**) and a variety of metalated aromatics, including ArZnCl, $ArB(OH)_2$, and $ArB(OMe)_2$. The advantages of the latter procedure include superior coupling yields under milder reaction conditions and the high yielding preparation of **16** directly from 3,4,6-tri-*O*-(triisopropylsilyl)-D-glucal (**12**) by a metalation–iodination sequence.

RICHARD W. FRIESEN, RICHARD W. LOO et CLAUDIO F. STURINO. Can. J. Chem. **72**, 1262 (1994).

On a préparé les *C*-aryl glucals **17–31** par un couplage croisé catalysé par le palladium du 1-tributylstannyl-3,4,6-tri-*O*-(*tert*-butyldiméthylsilyl)-D-glucal (**11**) et des bromures d'aryle. Le sous-produit principal de toutes ces réactions est le dimère **33**, le produit d'homocouplage du produit **11**. On peut aussi obtenir les *C*-aryl glucals **34–40** par un couplage catalysé par le palladium du 1-iodo-3,4,6-tri-*O*-(triisopropylsilyl)-D-glucal (**16**) avec une variété de produits aromatiques métallés comportant le ArZnCl, le $ArB(OH)_2$ et $ArB(OMe)_2$. Les avantages de la dernière méthode incluent des rendements supérieurs de couplage dans des conditions plus douces et la préparation avec un rendement élevé du composé **16** directement à partir du 3,4,6-tri-*O*-(triisopropylsilyl)-D-glucal (**12**) par une séquence de métallation et d'iodation.

[Traduit par la Rédaction]

Introduction

The class of natural products known as the *C*-aryl glycosides (1, 2) has recently received a great deal of attention in the synthetic community since many of these compounds exhibit unique antibiotic and (or) antitumor activity. Although the key structural unit that identifies these compounds is the novel carbon–carbon bond that unites the carbohydrate and aromatic fragments, a further subclassification can be made based upon the type of substitution at C1 and C2 of the carbohydrate moiety. Three broad groupings of naturally occurring *C*-aryl glycosides made on this basis can be illustrated in general terms by **1–3** with representative examples including vineomycinone B2 methyl ester (3), chaetiacandin (4, 5), and papulacandin D (6, 7), respectively. Synthetic strategies directed toward the preparation of any of these classes must address not only the method of creating the key carbon–carbon bond with a large array of substituted aromatics, but also must be concerned with its stereoselective formation with respect to the various substituents at C1–C5 on the carbohydrate framework. Previously reported strategies directed toward the synthesis of *C*-aryl glycosides[2] address, for the most part, the preparation of only one of the three main *C*-aryl glycoside subclasses (8).

We became interested in developing a rapid, facile, and general route to *C*-aryl glycosides that would be relatively flexible with respect to aromatic substitution pattern and type and with respect to the availability of the range of *C*-aryl glycoside subclasses as described above (9–12). The fundamental difference between our anticipated route to *C*-aryl glycosides and previous results is that the functionalization of C1 and C2, and the determination of the anomeric carbon stereogenicity, would occur subsequent to the key C—C bond-forming reaction by the regio- and stereoselective functionalization of the enol ether double bond in a *C*-aryl glucal **8**. The general strategy that we

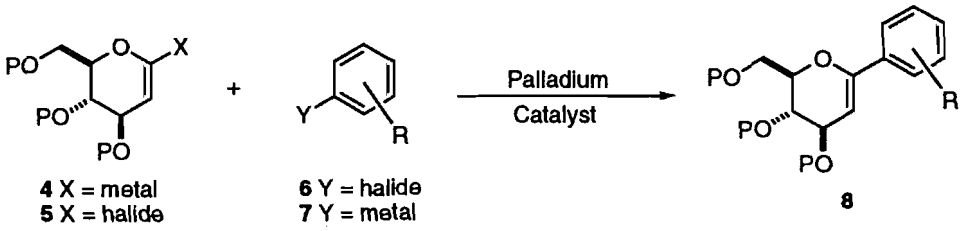
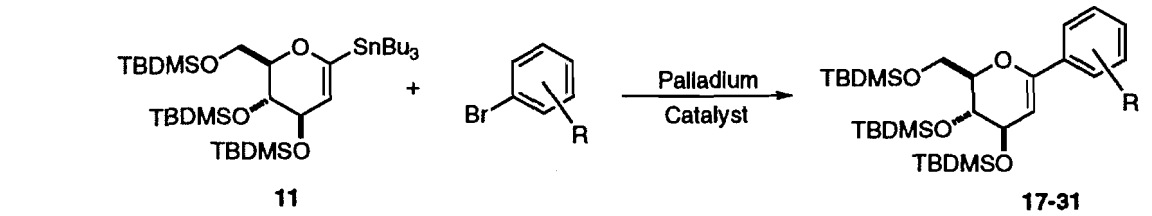


SCHEME 1



SCHEME 2

envisaged for the preparation of **8** was the palladium-catalyzed reaction (13, 14) of suitably derivatized organometallic and organic halide coupling partners (**4** + **6** → **8** or **5** + **7** → **8**) (see Scheme 1). Herein, we deail the results of our investigations that have led to the facile and efficient preparation of *C*-aryl glucals **8**, the key intermediates with respect to a general entry into the synthesis of *C*-aryl glycosides.[3]

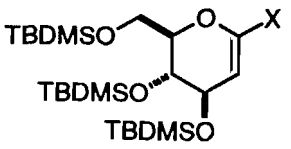
Results and discussion

*(a) Palladium-catalyzed coupling reactions of 1-tributylstannyl-3,4,6-tri-O-(tert-butyldimethylsilyl)-D-glucal (**11**) and 1-tributylstannyl-3,4,6-tri-O-(triisopropylsilyl)-D-glucal (**14**)*

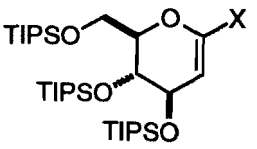
At the time we began this study, there was some indication in the literature that simple metalated enol ethers related to those illustrated by **4** (X = tin, zinc) would undergo palladium- catalyzed coupling reactions with aryl halides (22, 23). In addition, the preparation of stynnylated glucal **4** (X = *n*-Bu_3Sn) had been described by several groups (24–26). Therefore, it was the strategy illustrated by **4** + **6** → **8** (Scheme 1) that received our initial attention.

Previous reports from this laboratory have detailed the preparation of 1-tributylstannyl-3,4,6-tri-*O*-(*tert*-butyldimethylsilyl)-D-glucal (**11**) and 1-tributylstannyl-3,4,6-tri-*O*-(triisopropylsilyl)-D-glucal (**14**) (27). These compounds were prepared from the corresponding C1-unsubstituted silylated glucals **9** (TDMS = *tert*-butyldimethylsilyl) and **12** (TIPS = triisopropylsilyl), respectively, via metalation (*t*-BuLi, ether, 0°C) and trapping of the derived vinyl anions **10** and **13** with *n*-Bu_3SnCl. The problems that we have encountered in the preparation of **11**, due to competing metalation α to silicon on one or more of the *tert*-butyldimethylsilyl (TBDMS) protecting groups, have been documented (27).[4] As a result, the optimum yield in the preparation of **11** via this method is 30%. Conversely, the C1-metalation of **12** proceeds cleanly and **14** is readily obtained in 70–90% yield (27).

We now report the full details of a study involving the palladium-catalyzed coupling reactions of 1-tributylstannyl-



9 X = H
10 X = Li
11 X = *n*-Bu_3Sn



12 X = H
13 X = Li
14 X = *n*-Bu_3Sn
15 X = ZnCl
16 X = I

3,4,6-tri-*O*-(*tert*-butyldimethylsilyl)-D-glucal (**11**) with aryl bromides (Scheme 2, Table 1).[5] The initial investigation was concerned with the coupling of the simplest substrate, bromobenzene, and involved systematic variation of the typical palladium catalysts (14, 22, 23), solvent, and temperature. A representative sampling of the results is found in Table 1, entries 1–7. The optimum reaction conditions for the preparation of the *C*-phenyl glycal **17** (R = H) by the coupling of glucal **11** and bromobenzene were realized in refluxing THF (0.06 M in **11**), using $Pd(Ph_3P)_4$ as catalyst (Table 1, entry 3). Employing these conditions, **17** was produced very cleanly along with a small amount (ca. 10%) of a single by-product (vide infra).

While the coupling of bromobenzene proceeded readily under these "standard" conditions, similar reactions of glucal **11** with substituted bromobenzenes (1-bromo-4-nitrobenzene and 4-bromoanisole) were not reproducible and often failed completely under apparently identical reaction conditions. Similarly, attempts at using aryl iodides or aryl triflates (31, 32) in these coupling reactions gave poor and irreproducible results. After a great deal of experimentation, it was found that concentration, temperature, and catalyst all play an important role in the success or failure of the coupling reaction of **11** with substituted aryl bromides. The reaction conditions that appear to be

[3]Similar palladium-catalyzed coupling strategies (15–18) and alternative strategies (19–21) have been directed toward the preparation of *C*-aryl glycals.

[4]There have been other reports describing the problems associated with the vinylic deprotonation of a variety of highly substituted cyclic vinyl ethers containing silyl protecting groups (28–30). For example, Crich and Ritchie isolated a phenylthio derivative of **9** that had been formed upon metalation of **9** followed by trapping with $(PhS)_2$. They proposed that the phenylthio moiety had been introduced into the TBDMS group at C6 although no evidence in support of this proposal was given (30).

[a]See Scheme 2; 5 mol% catalyst. Approximate concentration **11** in refluxing solvent unless stated otherwise: 0.05 M for entries 1–7 and 0.2–1 M for entries 8–25.

[b]Yields of isolated, chromatographically pure products. Numbers in parentheses refer to the isolated yield of dimer **33**. Note that a 10% yield of dimer **33** involves the consumption of 20% of **11**.

[c]Dimer yield not measured.

[d]Reaction done at 100°C.

[e]The yield is based on an ^1H NMR integrated ratio of a chromatographically pure mixture of **20** and **33**. A small amount of pure **20** was isolated and characterized.

[f]Four equivalents of **11** used with respect to aryl bromide.

[g]Reaction carried out with glucal **14**.

universally successful involve refluxing toluene solutions of the stannyl glucal **11**, at concentrations of 0.2–1.0 M in **11**, in the presence of $Pd(Ph_3P)_2Cl_2$ (5 mol%) and the aryl bromide (1.1–2 equiv.).

Employing the revised "standard" reaction conditions, a wide variety of substituted aryl bromides were coupled successfully (Table 1, entries 8–24). Included in this list are aryl bromides containing electron-withdrawing and -donating substituents along with several highly substituted aromatics (see Table 1, entries 21–24). In all cases, the crude reaction mixtures were quite clean, providing the expected *C*-aryl glucals **17–31** in moderate to good yields. Several trends and additional points of interest regarding this coupling reaction are worth noting.

Firstly, the conditions of choice for the preparations of the unsubstituted *C*-phenyl glucal **17** are the original "standard" reaction conditions (compare Table 1, entries 3 and 16). For reasons that we cannot explain, bromobenzene is the sole example in which satisfactory coupling reactions take place under conditions of $Pd(Ph_3P)_4$ catalysis in THF. Secondly, the isolated yields of the *C*-aryl glucals reflect, at least qualitatively, an ordering based on the electronic properties of the aromatic substituent. In most cases, electron-poor aryl bromides (X = CN, NO_2, CO_2R) provide higher yields of coupled products than those aryl bromides with electron-donating substituents (X = alkyl, OR).[6] In addition, a general trend towards greater forma-

[6]A similar ordering, based on electron-withdrawing properties, has been observed in the palladium-catalyzed rate (not yield) of reaction of organostannanes with substituted aryl bromides (33) and terminal acetylenes (34, 35).

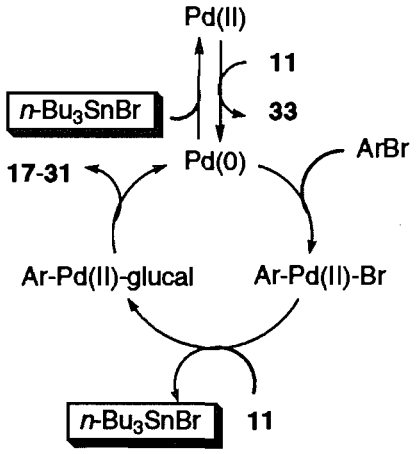
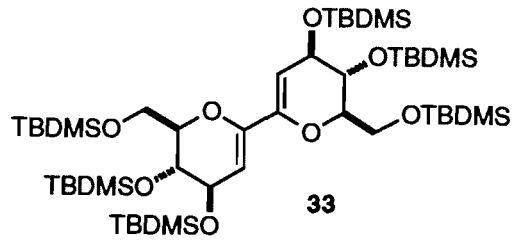


SCHEME 3

tion of the by-products (vide infra) is observed with electron-rich aryl bromides. Thirdly, more efficient coupling reactions could be effected in some cases by using an excess (with respect to the aryl bromide) of the stannyl glucal **11** and considering the aryl bromide as the limiting reagent (compare Table 1, entries 21 and 23).[7] However, due to the difficulties associated with obtaining significant quantities of **11** (vide supra), we have generally used **11** as the limiting reagent in our coupling reactions. The entries in Table 1 result from an optimization of the reaction conditions in light of this limitation. Finally, the major by-product that is produced in all of the reactions that we have performed results from the homocoupling of **11** (36). This dimer **33** accounts for the consumption of up to



36% of the starting material **11** (Table 1, entry 21) and in many cases proved to be extremely difficult to separate from the desired *C*-aryl glucal. A variety of reaction modifications were considered in order to decrease the production of this dimer. None of these attempts, including employing nickel catalysts or using the vinyl zinc glucal derived from **10**, met with success.

Several established synthetic procedures for the preparation of 1,3-dienes involve the Pd(II) mediated homocoupling of vinylsilanes (37) or vinylstannanes (38). The mechanism that has been postulated to account for the dimerization reaction in the presence of Pd(II) suggests that dimerization of the organometallic reagent should proceed to an extent equal to the amount of Pd(II) used (Scheme 3).[8] Indeed, when stannylated glucal **11** is treated solely with $Pd(Ph_3P)_2Cl_2$ in refluxing toluene, dimer formation is observed, while repeating the same reaction using $Pd(Ph_3P)_4$ as catalyst produces no dimer. Thus, it is the presence of Pd(II) that is responsible for dimer formation. In our work, this dimerization mechanism would limit the yield of dimer **33** to a maximum of 5%. However, from Table 1 we see that many of the cited reactions result in the production of more dimer than would be expected based on the use of 5 mol% of Pd(II) catalyst. A possible explanation for these results involves the oxidation of the catalytically active Pd(0) species back to Pd(II) by one of two processes. Either advantitious molecular oxygen is responsible or, alternatively, the oxidation of Pd(0) to a Pd(II) is being mediated by Bu_3SnBr, the by-product that is formed in the catalytic cross-coupling cycle.[9] Support for the latter hypothesis can be found by treating stannylated glucal **11** solely with $Pd(Ph_3P)_4$ and *n*-Bu_3SnCl in the absence of aryl bromide. The formation of dimer **33** takes place after several hours. Regardless of which mechanism is operative, the additional Pd(II) that is produced can lead to excessive dimer formation. Furthermore, the latter experiment suggests that dimerization of **11** is unavoidable under the conditions that we are using.

Although the preparation of *C*-aryl glucals **17–31** via this method is fairly efficient and broad in scope, there are several problems that are evident. The first is the limited availability of the stannylated glucal **11** via vinylic metalation/stannylation methods (27). This problem is especially evident if one is considering using **11** in excess with respect to the aryl bromide, a set of conditions that is desirable when the aryl bromide is the more difficult reaction partner to obtain.[7] In addition, we are faced with poor yields in the coupling reactions of **11** with electron-rich aromatic bromides as well as the consumption of the stannylated glucal **11** by an apparently unavoidable dimerization process.

The first of these problems has been overcome by the facile and high-yielding formation of 1-tributylstannyl-3,4,6-tri-*O*-(triisopropylsilyl)-D-glucal (**14**) (27). Therefore, it was imperative that we demonstrate that this stannylated glucal could be utilized in the key palladium-catalyzed cross-coupling reaction with aryl bromides.

It soon became evident that the apparently simple change from TBDMS to TIPS protecting groups on the stannylated glucal was in fact a major and detrimental modification. Whereas the *C*-aryl glucal **19** was efficiently prepared (81% yield) by the coupling of **11** and 4-bromobenzonitrile (Table 1, entry 9), the best yield that we could achieve in the coupling of **14** and 4-bromobenzonitrile was 67% (Table 1, entry 25). Results with other substituted aryl bromides including 4-bromo anisole and methyl 2-bromobenzoate were similarly discouraging, in many cases providing no coupled material.

The mechanism that has been proposed for the Stille reaction (see Scheme 3) (40) involves a rapid oxidative addition of Pd(0) to the organic halide (here ArBr), followed by a slow transmetalation step with the organometallic partner to provide a diorgano-Pd(II) species.[10] We attributed the disappointing results that were observed in the attempted coupling reactions of

[7]We have used this observation to our advantage in the synthesis of the tricyclic spiroketal core of the papulacandins, a synthesis that involves the intermediacy of glucal **30** (10).

[8]For those cases in which the diene was the desired product, an added oxidant such as Cu(II) or *t*-BuOOH was used to reoxidize the Pd(0) that was produced in the reaction back to Pd(II) to make the reactions catalytic in Pd(II). In our reactions, it is this dimerization process that produces Pd(0), the species that is catalytically active in the desired cross-coupling process.

[9]In a subsequent but related study, Tius et al. noted that the rigorous exclusion of oxygen minimized the dimerization of a zinc glucal during palladium-mediated coupling reactions with aryl bromides (17). In addition, the oxidative addition of Pd(0) to a Six—X bonds has been reported (39).

[10]Detailed mechanistic investigations into the related reactions with platinum have been described (41, 42).

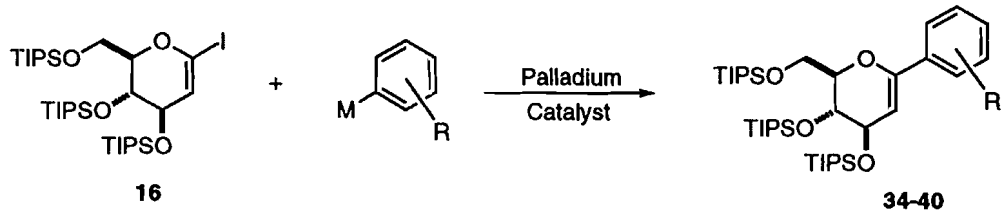

SCHEME 4

stannylated glucal **14** and aryl bromides to a decrease in the rate of an already slow transmetalation step. Although not initially obvious, but clearly seen from molecular models, the protecting group change from TBDMS to TIPS dramatically increases the steric bulk around the C1 position of the glucal. We believe that it is this protecting group change from TBDMS to TIPS that manifests itself in decreasing the rate of the slow transmetalation step, leading to inferior results in the cross-coupling reaction. Therefore, we reasoned that if we could reverse the sense of the coupling reaction by making the carbohydrate moiety the more reactive organic halide partner, we might be able to overcome this steric bias. The initial rapid oxidation addition of Pd(0) to a 1-haloglucal would be much less susceptible to steric factors (14) and the slow transmetalation step would then take place on the metal centre of a glucal-Pd(II)-halide, remote from the sterically encumbered C1 position of the glucal.

*(b) Preparation and palladium-catalyzed coupling of 3,4,6-tri-O-(triisopropylsilyl)-1-iodo-D-glucal (**16**) with metalated aromatics*

The readily available stannylated glucal **14** was converted into the iodo glucal **16**[11] (89–100% yield) by treatment of a CH_2Cl_2 solution of **14** with I_2 in CH_2Cl_2 (43–45). Based on the success of the coupling reaction of the iodo glucal **16** with metalated aromatics (vide infra), we sought a more direct pre-paration of **16** that would bypass the intermediacy of **14** and the use of toxic tributyltin chloride that is required in this method.

Reaction of the easily generated vinyl lithium intermediate **13** (27) with *N*-iodosuccinimide (NIS) met with limited success. The optimum conditions provided **16** in 30% yield along with 25% of recovered **12**. The preparation of other organometallic species from **13** (vinyl copper, vinyl silane, vinyl Grignard) followed by the attempted trapping of these intermediates with an iodonium source (I_2 or NIS) were similarly unsuccessful. However, metalation of **12** with *t*-BuLi (27) followed by transmetalation of the derived lithio derivative **13** with $ZnCl_2$ (approximately 4 equiv., ether solution) and subsequent quenching of the reaction mixture with either NIS (4.4 equiv.) or I_2 (3.7 equiv.), provided the iodo glucal **16** in yields of 67 and 81%, respectively, along with recoverable starting material (27 and 6%, respectively). It was imperative in this preparation of **16** that an excess of $ZnCl_2$ (with respect to the amount of *t*-BuLi that was used initially to metalate **12**) be used to generate **15** from **13**, presumably to convert the excess *t*-BuLi into the less reactive *t*-BuZnCl. In the event that less $ZnCl_2$ was used, the *t*-BuLi remaining in the reaction mixture would simply react (metal–halogen exchange) with the iodo glucal **16** that was produced.

Although a variety of metalated aromatics (such as zinc halides (46, 47) and boronic acids (48, 49)) have been demonstrated to undergo palladium-catalyzed cross-coupling reactions with organic halides, the use of 1-alkoxy-1-iodo alkenes as the organic halide partner in a Stille coupling reaction with organometallics had not been documented prior to our initial report (12). To test the utility of the iodo glucal **16** in the coupling reaction, **16** and a variety of metalated benzenes were treated with a palladium catalyst under appropriate reaction conditions (Scheme 4; Table 2, entries 1–13).[12] The optimum isolated yields of the *C*-phenyl glucal **34** (R = H) were obtained using phenylboronic acid (81%), dimethyl phenylboronate[13] (87–90%), and phenylzinc chloride (90%) as coupling partners. Inferior results were observed with PhLi, *n*-Bu_3SnPh, and PhMgBr (Table 2, entries 1–3). The coupling reactions in the former cases were extremely clean. The only by-product that was observed was biphenyl, arising from the now expected dimerization of the metalated benzene. The palladium catalyst is necessary in these reactions since, in its absence, no cross coupling is observed (Table 2, entry 10). A noteworthy exception is the reaction of **16** with the higher-order mixed cuprate reagent $Ph_2Cu(CN)Li_2$ (Table 2, entry 5) that produced **34** in low yield in the absence of palladium (51). While the reaction with phenylzinc chloride proceeds quickly and cleanly at room temperature in THF with $Pd(Ph_3P)_2Cl_2$ as catalyst, the reaction occurs much more slowly and in lower yield using $Pd(Ph_3P)_4$ (compare Table 2, entries 12 and 13). It appears that 4 equivalents of PhZnCl, with respect to the iodo glucal **16**, is the ratio required for an optimum coupling reaction. When 2 equivalents of PhZnCl were utilized, there was incomplete consumption of **16** after 24 h (compare Table 2, entries 11 and 13). Similarly, 2–4 equivalents of $PhB(OH)_2$ or $PhB(OMe)_2$ are required for high-yielding coupling reactions. The ability to use the boronate esters in the coupling reaction[13] under a variety of reaction conditions (see Table 2, entries 6–9) is noteworthy since the (sometimes) problematic isolation of the boronic acids (derived from the esters by hydrolysis) can now be avoided.

The coupling reaction using iodo glucal **16** can be extended to include substituted arylboronic acids, dimethyl arylboronates, and arylzinc chlorides as well (Table 2, entries 14–21). The isolated yields of the *C*-aryl glucals **35–40** obtained under these mild reaction conditions are superior to those that we had observed for every analogous example in the coupling of tin glucal **11** and aryl bromides (compare Table 1, entries 3, 9, 10, 14, and 19 with Table 2, entries 9, 14, 20, 21, and 15, respectively). For example, the poorest substrates in the coupling

[11]An iodo glucal analogous to **16** was obtained as an unexpected product (75%) in the attempted cross coupling of a C-1 stannylated glucal with 3-iodo-2-propyn-1-ol (16). The isolable vinyl iodide **16** is stable for several months when stored under vacuum in the dark. We have only stored the iodide **16** for this length of time although it may be stable for longer storage periods since no decomposition was noted under these conditions. However, if **16** is stored in the presence of light, or even under argon in the dark, decomposition to a dark red mixture of unidentified compounds is rapid.

[12]For a preliminary account of this work, see ref. 12.

[13]Boronate esters can be used in the coupling reaction without prior hydrolysis to, or isolation of, the boronic acids (50).

reaction with the tin glucal **11** are electron-rich aromatic bromides. Thus, the improved yield in the preparation of the anisole derivative **36** (Table 2, entries 15 and 16 (73–81%)) compared with the yield for the preparation of **28** (Table 1, entry 19 (30%)) was gratifying since many of the naturally occurring *C*-aryl glycosides are oxygen-substituted aromatics (1, 2). As expected, there was no evidence for the production of the glucal dimer that previously had been the major by-product (up to 18%) in all of our coupling reactions with stannyl glucal **11**. Furthermore, purification of the glucals **34–40** is more easily accomplished than in the original procedure since the presence of the dimer **33** had, in some cases, hampered chromatographic isolation (see Table 1, entry 10). Finally, the reaction is not limited to the coupling of metalated benzenes but can be extended to include metalated heteroaromatics such as furan (Table 2, entries 17 and 18) as well as metalated olefins such as tetravinyltin or dimethyl vinylboronate (Table 2, entries 19 and 20). Each of the resulting *C*-glucal products **37** and **41**, respectively, have the potential for further synthetic manipulation. For example, *C*-furyl glucals such as **37** have been demonstrated to be useful synthetic equivalents for the preparation of C1-carboxyl glycosides (52) while dienes related to **41** undergo stereoselective Diels–Alder reactions (53).

Summary

A wide range of novel *C*-aryl glucals have been prepared by two complementary and operationally simple two-step procedures. The first process involves the vinylic metalation/stannylation of a suitably protected glucal followed by a palladium-catalyzed coupling of the resulting stannylated glucal with an aryl bromide (Scheme 2), while the second process calls for the initial preparation of an iodo glucal followed by coupling with a metalated aromatic (Scheme 4). This latter procedure is noteworthy since it does not require the use of stannylated intermediates and provides *C*-aryl glucals in an efficient three-step procedure from D-glucal (protection, metalation/iodination, coupling). We feel that the wide range of substituted aromatic moieties that can be appended onto the carbohydrate nucleus, creating the unique carbon–carbon bond present in the *C*-aryl glycosides, makes this an attractive method for the preparation of this class of compounds. The preliminary investigations that have been reported from our laboratories (10, 11) and from other groups (15, 17, 19–21) addressing the synthetic capabilities of the remaining enol ether double bond in the *C*-aryl glucals are encouraging. Indeed, several stereoselective procedures have been developed, resulting in an important and general method for the preparation of *C*-aryl glycosides.

Experimental

General information

^1H NMR spectra were recorded at 200 MHz in $CDCl_3$ unless stated otherwise. Broad band proton-decoupled ^{13}C NMR spectra were recorded at 50 MHz in $CDCl_3$ unless stated otherwise. IR spectra were recorded on neat samples unless stated otherwise. Work-up procedures involving the drying of organics was done with $MgSO_4$. The prepara-

tion of 1-tributylstannyl-3,4,6-tri-*O*-(*tert*-butyldimethylsilyl)-D-glucal (**11**), 3,4,6-tri-*O*-(triisopropylsilyl)-D-glucal (**12**), 1-tributylstannyl-3,4,6-tri-*O*-(triisopropylsilyl)-D-glucal (**14**), and other general experimental procedures have been described elsewhere (27). **Note:** Compounds for which high-resolution mass measurements are given exhibited one spot by TLC analysis.

*General procedure A: coupling of 1-tributylstannyl-3,4,6-tri-*O-(tert-*butyldimethylsilyl)-D-glucal (**11**) and aryl bromides*

A flame-dried 5 mL round-bottom flask was charged with the stannylglucal **11**, the appropriate aryl bromide (1.1–2 equiv.) and the reaction solvent (0.2–1 M in **11**). The palladium catalyst (5 mol%) was added and the reaction mixture was heated at the temperature and for the times indicated in Table 1. When TLC analysis indicated the disappearance of **11**, the reaction mixture was cooled to room temperature and the solvent was removed in vacuo. The crude reaction mixture was subjected to flash column chromatography on silica gel to provide the corresponding aryl *C*-glucal and the dimer **33**.

*1-C-Phenyl-3,4,6-tri-*O-(tert-*butyldimethylsilyl)-D-glucal (**17**)*

Following general procedure A, **11** (84.2 mg, 0.108 mmol) was reacted with bromobenzene (0.054 mL). After chromatography (elution with 50:1 hexanes:Et_2O v/v), **17** (42.4 mg, 70%) was obtained as a colorless oil; $[\alpha]_D^{25}$ −20.5 (*c* 1.2); IR: 2956, 2856, 2803, 1652, 1483, 1153, 813, 669 cm^{-1}; ^1H NMR (400 MHz) δ: 0.00 (s, 3H), 0.03 (s, 3H), 0.10 (s, 6H), 0.11 (s, 6H), 0.868 (s, 9H), 0.873 (s, 9H), 0.89 (s, 9H), 3.84 (m, 2H), 3.96 (dd, 1H, J = 4.3, 6.9 Hz), 4.14 (m, 2H), 5.23 (dd, 1H, J = 0.9, 4.2 Hz), 7.30 (m, 3H), 7.60 (m, 2H); ^{13}C NMR δ: −5.6, −5.5, −4.9, −4.4, −4.3, −4.2, 18.0, 18.2, 25.7, 25.8, 25.9, 61.6, 69.0, 70.3, 80.4, 98.1, 125.4, 128.2, 128.5, 135.7, 150.8. Exact Mass calcd. for $C_{29}H_{53}O_4Si_3$ $(M - CH_3)^+$: 549.3251; found: 549.3245.

*1-C-(4-Nitrophenyl)-3,4,6-tri-*O-(tert-*butyldimethylsilyl)-D-glucal (**18**)*

Following general procedure A, **11** (93.2 mg, 0.12 mmol) was reacted with 1-bromo-4-nitrobenzene (24 mg). After chromatography (elution with 50:1 hexanes:Et_2O v/v), **18** (56.8 mg, 78%) was obtained as a yellow solid (mp 50–52°C); $[\alpha]_D^{25}$ −17.1 (*c* 0.40); IR ($CHCl_3$): 2956, 2930, 2893, 1651, 1344, 1257, 765, 750 cm^{-1}; ^1H NMR (400 MHz) δ: −0.01 (s, 3H), 0.01 (s, 3H), 0.10 (s, 6H), 0.12 (s, 6H), 0.86 (s, 18H), 0.90 (s, 9H), 3.79 (m, 1H), 3.87 (t, 1H, J = 3.2 Hz), 3.98 (dd, 1H, J = 7.6, 11.2 Hz), 4.11 (t, 1H, J = 3.2 Hz), 4.21 (m, 1H), 5.43 (d, 1H, J = 4.4 Hz), 7.75 (d, 2H, J = 8.8 Hz), 8.17 (d, 2H, J = 8.8 Hz). Exact Mass calcd. for $C_{26}H_{46}NO_6Si_3$ $(M - C_4H_9)^+$: 552.2633; found: 552.2630. Anal. calcd. for $C_{30}H_{55}NO_6Si_3$: C 59.07, H 9.09; found: C 59.24, H 9.06.

*1-C-(4-Cyanophenyl)-3,4,6-tri-*O-(tert-*butyldimethylsilyl)-D-glucal (**19**)*

Following general procedure A, **11** (148.5 mg, 0.19 mmol) was reacted with 4-bromobenzonitrile (35 mg). After chromatography (elution with 50:1 hexanes:Et_2O v/v), **19** (90.7 mg, 81%) was obtained as a yellow oil; $[\alpha]_D^{25}$ −20.2 (*c* 0.60); IR: 2954, 2929, 2886, 2228, 1650, 1471, 1250, 777, 672 cm^{-1}; ^1H NMR (400 MHz) δ: −0.02 (s, 3H), 0.00 (s, 3H), 0.10 (s, 6H), 0.11 (s, 6H), 0.86 (s, 18H), 0.89 (s, 9H), 3.78 (dd, 1H, J = 3.7, 11.4 Hz), 3.86 (m, 1H), 3.96 (dd, 1H, J = 7.4, 11.4 Hz), 4.09 (m, 1H), 4.19 (m, 1H), 5.37 (dd, 1H, J = 1.0, 4.6 Hz), 7.61 (m, 2H), 7.69 (m, 2H). Exact Mass calcd. for $C_{27}H_{46}NO_4Si_3$ $(M - C_4H_9)^+$: 532.2734; found: 532.2726.

*1-C-(1-Naphthyl)-3,4,6-tri-*O-(tert-*butyldimethylsilyl)-D-glucal (**20**)*

Following general procedure A, **11** (50.3 mg, 0.065 mmol) was reacted with 1-bromonaphthalene (20 mg). After chromatography (elution with 50:1 hexanes:Et_2O v/v), a mixture of **20** and **33** was obtained. Integration of the ^1H NMR spectrum of the mixture indicated a 59% yield of **20** and a 15% yield of **33**. A small amount of pure **20** was isolated by drip column chromatography (elution with 100:1 hexanes:Et_2O v/v) as a colorless oil; $[\alpha]_D^{25}$ −15.7 (*c* 0.80); IR: 2954, 2929, 2886, 1662, 1472, 1463, 1256, 775, 667 cm^{-1}; ^1H NMR (400 MHz) δ: 0.00 (s, 3H), 0.02 (s, 3H), 0.099 (s, 3H), 0.103 (s, 3H), 0.146 (s, 3H), 0.150 (s, 3H), 0.86 (s, 9H), 0.91 (s, 9H), 0.94 (s, 9H), 3.93 (dd, 1H, J = 2.4, 11.3 Hz), 3.97 (m, 1H), 4.08 (dd, 1H, J = 7.3, 11.2 Hz), 4.15 (m, 1H), 4.26 (m, 1H), 5.01 (dd, 1H, J = 1.1, 4.8 Hz), 7.43 (m, 4H), 7.80 (m, 2H), 8.30 (m, 1H). Exact Mass calcd. for $C_{33}H_{55}O_4Si_3$ $(M - CH_3)^+$: 599.3408; found: 599.3394.

*1-C-(4-Carbomethoxyphenyl)-3,4,6-tri-*O-(tert-*butyldimethylsilyl)-D-glucal (**21**)*

Following general procedure A, **11** (129.1 mg, 0.166 mmol) was reacted with methyl 4-bromobenzoate (39 mg). After chromatography (elution with 30:1 hexanes:Et_2O v/v), **21** (57.8 mg, 56%) was obtained as a colorless oil; $[\alpha]_D^{25}$ −17.5 (*c* 2.1); IR: 2954, 2930, 2857, 1728, 1651, 1472, 1463, 1277, 1256 cm^{-1}; ^1H NMR (400 MHz) δ: −0.02 (s, 3H), 0.01 (s, 3H), 0.10 (s, 6H), 0.11 (s, 3H), 0.12 (s, 3H), 0.86 (s, 18H), 0.89 (s, 9H), 3.81 (dd, 1H, J = 3.6, 11.4 Hz), 3.87 (m, 1H), 3.90 (s, 3H), 3.98 (dd, 1H, J = 7.2, 11.3 Hz), 4.12 (m, 1H), 4.17 (m, 1H), 5.36 (d, 1H, J = 4.4 Hz), 7.66 (m, 2H), 7.98 (m, 2H); ^{13}C NMR δ: −5.6, −5.5, −4.9, −4.5, −4.4, −4.3, 17.9, 18.2, 25.6, 25.7, 52.0, 61.4, 68.5, 70.1, 80.6, 100.0, 125.2, 129.5, 129.9, 140.0, 149.8, 167.2. Exact Mass calcd. for $C_{31}H_{55}O_6Si_3$ $(M - CH_3)^+$: 607.3306; found: 607.3293.

*1-C-(2-Carbomethoxyphenyl)-3,4,6-tri-*O-(tert-*butyldimethylsilyl)-D-glucal (**22**)*

Following general procedure A, **11** (124.0 mg, 0.159 mmol) was reacted with methyl 2-bromobenzoate (42 mg). After chromatography (elution with 30:1 hexanes: Et_2O v/v), **22** (47.3 mg, 48%) was obtained as a colorless oil; $[\alpha]_D^{25}$ −43.8 (*c* 0.021); IR: 2954, 2929, 2857, 1735, 1665 cm^{-1}; ^1H NMR (400 MHz) δ: −0.05 (s, 3H), −0.02 (s, 3H), 0.11 (s, 6H), 0.115 (s, 3H), 0.121 (s, 3H), 0.83, 0.89, 0.91 (s each, 9H each), 3.83 (s, 3H), 3.83–3.96 (m, 4H), 4.27 (m, 1H), 4.94 (d, 1H, J = 3.7 Hz), 7.34 (m, 1H), 7.41 (m, 2H), 7.62 (m, 1H). Exact Mass calcd. for $C_{31}H_{55}O_6Si_3$ $(M - CH_3)^+$: 607.3306; found: 607.3315.

*1-C-(4-Chlorophenyl)-3,4,6-tri-*O-(tert-*butyldimethylsilyl)-D-glucal (**23**)*

Following general procedure A, **11** (142.1 mg, 0.183 mmol) was reacted with 4-chlorobromobenzene (40.7 mg). After chromatography (elution with 150:1 hexanes: Et_2O v/v), **23** (52.6 mg, 49%) was obtained as a colorless oil; $[\alpha]_D^{25}$ −17.7 (*c* 1.3); IR ($CHCl_3$): 2955, 2929, 2857, 1654, 1472, 1463, 1255 cm^{-1}; ^1H NMR (400 MHz) δ: −0.01 (s, 3H), 0.02 (s, 3H), 0.10 (s, 6H), 0.11 (s, 6H), 0.869 (s, 9H), 0.873 (s, 9H), 0.89 (s, 9H), 3.79 (m, 2H), 3.97 (dd, 1H, J = 7.2, 11.4 Hz), 4.15 (m, 2H), 5.23 (dd, 1H, J = 1.0, 4.5 Hz), 7.27 (m, 2H), 7.53 (m, 2H). Exact Mass calcd. for $C_{29}H_{52}ClO_4Si_3$ $(M - CH_3)^+$: 583.2862; found: 583.2861.

*1-C-(2-Methylphenyl)-3,4,6-tri-*O-(tert-*butyldimethylsilyl)-D-glucal (**24**)*

Following general procedure A, **11** (113.0 mg, 0.145 mmol) was reacted with 2-bromotoluene (30 μL). After chromatography (elution with 50:1 hexanes: Et_2O v/v), **24** (40.3 mg, 48%) was obtained as a colorless oil; $[\alpha]_D^{25}$ −23.5 (*c* 0.80); IR: 2955, 2929, 2857, 1663, 1463, 1360, 1346, 777, 760 cm^{-1}; ^1H NMR (400 MHz) δ: 0.00 (s, 3H), 0.04 (s, 3H), 0.08 (s, 3H), 0.09 (s, 3H), 0.10 (s, 3H), 0.11 (s, 3H), 0.86 (s, 9H), 0.89 (s, 9H), 0.90 (s, 9H), 2.37 (s, 3H), 3.88 (m, 2H), 3.97 (dd, 1H, J = 7.2, 11.1 Hz), 4.08 (m, 1H), 4.79 (dd, 1H, J = 0.9, 4.6 Hz), 7.19 (m, 4H). Exact Mass calcd. for $C_{27}H_{49}O_4Si_3$ $(M - C_4H_9)^+$: 521.2938; found: 521.2940.

*1-C-(2-Acetyloxymethylphenyl)-3,4,6-tri-*O-(tert-*butyldimethylsilyl)-D-glucal (**25**)*

Following general procedure A, **11** (104.6 mg, 0.134 mmol) was reacted with 2-acetoxymethylbromobenzene (38 mg). After chromatography (elution with 50:1 hexanes: Et_2O v/v), **25** (38.7 mg, 46%) was obtained as a colorless oil; $[\alpha]_D^{25}$ −20.4 (*c* 0.50); IR: 3068, 3030, 2929, 1747, 1661, 1472, 1463, 1253 cm^{-1}; ^1H NMR (400 MHz) δ: 0.00 (s, 6H), 0.088 (s, 3H), 0.093 (s, 3H), 0.10 (s, 3H), 0.11 (s, 3H), 0.86 (s, 9H), 0.88 (s, 9H), 0.89 (s, 9H), 2.07 (s, 3H), 3.87 (m, 2H), 3.97 (dd, 1H,

J = 7.1, 11.2 Hz), 4.08 (m, 1H), 4.15 (m, 1H), 4.90 (dd, 1H, J = 1.0, 4.6 Hz), 5.24 (d, 1H, J = 12.9 Hz), 5.28 (d, 1H, J = 12.9 Hz), 7.31 (m, 4H); ^{13}C NMR δ: −5.7, −4.9, −4.5, −4.4, 17.8, 18.1, 20.9, 25.6, 25.8, 61.6, 64.1, 67.9, 69.5, 80.9, 101.6, 127.9, 128.7, 129.3, 134.6, 136.3, 151.7, 170.9. Exact Mass calcd. for $C_{29}H_{51}O_6Si_3$ $(M - C_4H_9)^+$: 579.2993; found: 579.2974.

*1-C-(2-Acetyloxyphenyl)-3,4,6-tri-O-(*tert*-butyldimethylsilyl)-D-glucal (**26**)*

Following general procedure A, **11** (92.5 mg, 0.119 mmol) was reacted with 2-bromophenyl acetate (31.4 mg). After chromatography (elution with 30:1 hexanes: Et_2O v/v), **26** (29.6 mg, 40%) was obtained as a colorless oil; $[\alpha]_D^{25}$ −21.3 (*c* 0.70); IR: 2954, 2923, 2857, 1772, 1660, 1488, 1212, 1190 cm^{-1}; ^{1}H NMR (400 MHz) δ: −0.01 (s, 3H), 0.01 (s, 3H), 0.08 (s, 3H), 0.09 (s, 3H), 0.10 (s, 6H), 0.86 (s, 9H), 0.88 (s, 9H), 0.89 (s, 9H), 2.25 (s, 3H), 3.89 (m, 3H), 4.05 (m, 1H), 4.11 (m, 1H), 5.02 (dd, 1H, J = 1.0, 4.5 Hz), 7.01 (dd, 1H, J = 1.2, 8.0 Hz), 7.25 (m, 2H), 7.49 (dd, 1H, J = 1.8, 7.7 Hz). Exact Mass calcd. for $C_{31}H_{55}O_6Si_3$ $(M - CH_3)^+$: 607.3306; found: 607.3296.

*1-C-(2-Benzyloxyphenyl)-3,4,6-tri-O-(*tert*-butyldimethylsilyl)-D-glucal (**27**)*

Following general procedure A, **11** (97.4 mg, 0.125 mmol) was reacted with 2-benzyloxybromobenzene (36 mg). After chromatography (elution with 30:1 hexanes: Et_2O v/v), **27** (36.9 mg, 44%) was obtained as a colorless oil; $[\alpha]_D^{25}$ −3.1 (*c* 1.1); IR: 2953, 2856, 1648, 1254, 1222, 1158 cm^{-1}; ^{1}H NMR (400 MHz) δ: −0.02 (s, 3H), −0.01 (s, 3H), 0.00 (s, 3H), 0.03 (s, 3H), 0.10 (s, 6H), 0.84 (s, 9H), 0.86 (s, 9H), 0.87 (s, 9H), 3.90 (m, 3H), 4.12 (m, 2H), 5.10 (s, 2H), 5.23 (dd, 1H, J = 0.8, 4.3 Hz), 6.91 (m, 2H), 7.18 (m, 1H), 7.31 (m, 3H), 7.40 (m, 2H), 7.63 (dd, 1H, J = 1.8, 7.8 Hz); ^{13}C NMR δ: −5.5, −4.9, −4.5, −4.5, 17.9, 18.2, 25.8, 61.5, 69.0, 70.2, 70.6, 80.3, 103.1, 113.4, 120.8, 125.6, 127.4, 127.8, 128.6, 129.2, 129.5, 137.4, 147.7, 156.4. Exact Mass calcd. for $C_{33}H_{53}O_5Si_3$ $(M - C_4H_9)^+$: 613.3200; found: 613.3205.

*1-C-(4-Methoxyphenyl)-3,4,6-tri-O-(*tert*-butyldimethylsilyl)-D-glucal (**28**)*

Following general procedure A, **11** (122.1 mg, 0.157 mmol) was reacted with 4-bromoanisole (32 mg). After chromatography (elution with 50:1 hexanes: Et_2O v/v), **28** (26.5 mg, 30%) was obtained as a colorless oil; $[\alpha]_D^{25}$ −19.9 (*c* 0.70); IR: 2954, 2929, 2885, 1653, 1252, 1175, 1104 cm^{-1}; ^{1}H NMR (400 MHz) δ: 0.00 (s, 3H), 0.03 (s, 3H), 0.09 (s, 3H), 0.10 (s, 3H), 0.11 (s, 6H), 0.87 (s, 9H), 0.88 (s, 9H), 0.89 (s, 9H), 3.79 (s, 3H), 3.85 (m, 2H), 3.96 (dd, 1H, J = 6.7, 11.3 Hz), 4.12 (m, 2H), 5.12 (d, 1H, J = 4.0 Hz), 6.84 (m, 2H), 7.53 (m, 2H). Exact Mass calcd. for $C_{30}H_{55}O_5Si_3$ $(M - CH_3)^+$: 579.3357; found: 579.3324.

*1-C-(2,5-Dimethoxyphenyl)-3,4,6-tri-O-(*tert*-butyldimethylsilyl)-D-glucal (**29**)*

Following general procedure A, **11** (101.8 mg, 0.131 mmol) was reacted with 2,5-dimethoxybromobenzene (33 mg). After chromatography (elution with 50:1 hexane:Et_2O v/v), **29** (52.4 mg, 65%) was obtained as a colorless oil; $[\alpha]_D^{25}$ −5.0 (*c* 0.70); IR ($CHCl_3$): 2993, 2953, 2886, 1650, 1500, 1471, 812, 778 cm^{-1}; ^{1}H NMR (400 MHz) δ: 0.02 (s, 3H), 0.04 (s, 3H), 0.106 (s, 3H), 0.111 (s, 3H), 0.12 (s, 6H), 0.87 (s, 9H), 0.90 (s, 9H), 0.91 (s, 9H), 3.75 (s, 3H), 3.77 (s, 3H), 3.87 (m, 1H), 3.92 (s, 1H), 3.93 (d, 1H, J = 0.8 Hz), 4.03 (m, 1H), 4.23 (m, 1H), 5.62 (d, 1H, J = 3.5 Hz), 6.79 (m, 2H), 7.20 (d, 1H, J = 3.0 Hz); ^{13}C NMR δ: −5.5, −4.9, −4.2, 17.9, 18.1, 18.2, 25.8, 25.9, 55.7, 56.3, 61.9, 70.2, 70.4, 80.4, 103.8, 113.3, 114.0, 114.7, 125.4, 147.6, 151.7, 153.6. Exact Mass calcd. for $C_{28}H_{51}O_6Si_3$ $(M - C_4H_9)^+$: 567.2993; found: 567.2973.

*1-C-(6-Acetyloxymethyl-2,4-dibenzyloxyphenyl)-3,4,6-tri-O-(*tert*-butyldimethylsilyl)-D-glucal (**30**)*

Following general procedure A, **11** (139.2 mg, 0.179 mmol) was reacted with 1-acetyloxymethyl-2-bromo-3,5-dibenzyloxybenzene (7) (86.8 mg) in mesitylene. After chromatography (elution with 9:1 hexanes: EtOAc v/v), **30** (72.2 mg, 51%) was obtained as a colorless oil; $[\alpha]_D^{25}$ −23.8 (*c* 1.45); IR: 2953, 2930, 2885, 1743, 1671 cm^{-1}; ^{1}H NMR (400 MHz) δ: −0.059, −0.056, 0.05, 0.08, 0.10, 0.11 (s each, 3H each), 0.83, 0.87, 0.89 (s each, 9H each), 2.07 (s, 3H), 3.73 (dd, 1H, J = 5.6, 10.3 Hz), 4.00–4.09 (m, 4H), 4.81 (dd, 1H, J = 1.1, 4.7 Hz), 4.99 (s, 2H), 5.00 (s, 2H), 5.13 (d, 1H, J = 12.9 Hz), 5.19 (d, 1H, J = 12.9 Hz), 6.48 (d, 1H, J = 2.3 Hz), 6.57 (d, 1H, J = 2.3 Hz), 7.34–7.37 (m, 10H); ^{13}C NMR δ: −5.63, −5.58, −5.0, −4.7, −4.5, 17.8, 17.9, 18.0, 20.8, 25.6, 25.7, 61.1, 63.6, 67.7, 69.3, 70.0, 80.4, 100.6, 103.0, 105.8, 119.2, 127.1, 127.6, 127.7, 128.1, 128.5, 128.7, 136.8, 137.1, 137.9, 146.8, 157.9, 170.7. Exact Mass calcd. for $C_{47}H_{72}O_8Si_3$ (M^+): 848.4534; found: 848.4573. Anal. calcd. for $C_{47}H_{72}NO_8Si_3$: C 66.46, H 8.54; found: C 66.31, H 8.53.

*1-C-(6-*tert*-Butyldimethylsiloxymethyl-2,4-dibenzyloxyphenyl)-3,4,6-tri-O-(*tert*-butyldimethylsilyl)-D-glucal (**31**)*

Following general procedure A, **11** (135.6 mg, 0.174 mmol) was reacted with 1-*tert*-butyldimethylsilyloxymethyl-2-bromo-3,5-dibenzyloxybenzene (107 mg). After chromatography (elution with 10:1 hexanes: EtOAc v/v), **31** (89.9 mg, 56%) was obtained as a colorless oil; $[\alpha]_D^{25}$ −17.1 (*c* 1.38); IR: 2959, 2931, 2854, 1680, 1602, 1469, 1258, 1159, 1061, 836 cm^{-1}; ^{1}H NMR (400 MHz) δ: −0.08, −0.07, 0.03, 0.04, 0.05, 0.06, 0.09 (s, each, 3H each), 0.82, 0.86, 0.89, 0.91 (s each, 9H each), 3.69 (m, 1H), 4.02–4.10 (m, 4H), 4.70–4.81 (m, 3H), 4.96–5.04 (m, 4H), 6.41 (d, 1H, J = 2.4 Hz), 6.82 (d, 1H, J = 2.4 Hz), 7.22–7.39 (m, 10H); ^{13}C NMR δ: −5.6, −5.5, −5.4, −4.9, −4.6, −4.5, −4.4, 17.90, 17.96, 18.02, 18.1, 25.7, 25.8, 61.1, 62.1, 68.1, 69.5, 69.9, 70.4, 80.1, 99.8, 102.6, 103.6, 117.0, 127.2, 127.6, 127.7, 128.0, 128.5, 128.7, 137.2, 137.5, 143.4, 147.1, 157.6, 160.0. Exact Mass calcd. for $C_{51}H_{85}O_7Si_4$ $(M + H)^+$: 920.5294; found: 920.5303.

*Dimer **33***

The isolated yields of **33** from each individual experiment can be found in Table 1. Colorless oil; $[\alpha]_D^{25}$ −35.4 (*c* 0.50); IR: 2954, 2936, 1623, 1251, 1105 cm^{-1}; ^{1}H NMR (400 MHz) δ: 0.01 (s, 6H), 0.03 (s, 6H), 0.06 (s, 18H), 0.07 (s, 6H), 0.84 (s, 18H), 0.86 (s, 18H), 0.87 (s, 18H), 3.71 (dd, 2H, J = 3.7, 11.3 Hz), 3.8 (m, 2H), 3.86 (dd, 2H, J = 7.0, 11.4 Hz), 3.98 (m, 2H), 4.03 (m, 2H), 5.80 (dd, 2H, J = 1.5, 4.8 Hz); ^{13}C NMR δ: −5.7, −5.4, −4.9, −4.6, −4.6, −4.4, 17.8, 18.2, 25.6, 25.7, 25.8, 61.5, 67.7, 70.2, 80.5, 98.6, 145.8. Exact Mass calcd. for $C_{48}H_{102}O_8Si_6$ (M^+): 974.6190; found: 974.6194.

*Preparation of 1-iodo-3,4,6-tri-O-(triisopropylsilyl)-D-glucal (**16**) from **14***

Tin glucal **14** (15) (2.0 g, 2.3 mmol) was dissolved in CH_2Cl_2 (10 mmol) under an argon atmosphere. To this colorless mixture was added a solution of iodine (0.5 g) in CH_2Cl_2 (10 mL) dropwise until a persistent red color, indicating an excess of iodine, remained. The complete consumption of **14** was confirmed by TLC and saturated aqueous $Na_2S_2O_3$ was then added. The mixture was subsequently extracted with CH_2Cl_2, and the combined organic phases were dried and concentrated. Column chromatography of the residual oil on silica gel (5% ether in hexanes or 10% CH_2Cl_2 in hexanes) yielded **16** (1.5 g, 89%) as a colorless oil; $[\alpha]_D^{25}$ −23.6 (*c* 0.30); IR: 1463, 1624, 2866-2958 cm^{-1}; ^{1}H NMR δ: 1.03–1.05 (m, 63H), 3.82–3.91 (m, 2H), 4.06–4.15 (m, 2H), 4.30–4.37 (m, 1H), 5.38 (dd, 1H, J = 1.5, 5.5 Hz); ^{13}C NMR δ: 12.2, 12.5, 12.6, 18.2, 61.9, 68.2, 69.7, 86.2, 107.8, 111.9. Exact Mass calcd. for $C_{30}H_{62}O_4Si_3I$ $(M - C_3H_7)^+$: 697.3001; found: 697.3013.

*Preparation of 1-iodo-3,4,6-tri-O-(triisopropylsilyl)-D-glucal (**16**) from **12***

To a solution of **12** (15) (1.8595 g, 3.0 mmol) in THF (9 mL, 0.35 M) at −78°C was added *t*-BuLi (7.2 mL of a 1.7 M solution in pentane, 12.0 mmol) dropwise. The mixture was stirred for 1.25 h at 0°C and then $ZnCl_2$ (15.1 mL of a 1.0 M solution in Et_2O, 15.0 mmol) was added and the mixture was stirred at room temperature for 40 min. I_2 (1.4 g, 11.1 mmol) was added as a solid and the resulting solution was stirred for 2 h at room temperature. Work-up and chromatography as above provided **16** (1.8238 g, 81%) and the starting material **12** (0.1085 g, 6%).

*General procedure B: preparation and coupling of arylzinc chlorides with 1-iodo-3,4,6-tri-*O*-(triisopropylsilyl)-*D*-glucal (**16**)*

A solution of 4-bromoanisole (0.41 mL, 3.3 mmol) in THF (1 mL) at −78°C was treated dropwise with *n*-BuLi (2.0 mL of a 1.6 M solution in hexane) and the resulting white mixture was stirred for 1 h at −78°C. $ZnCl_2$ (3.2 mL of a 1.0 M solution in ether) was then slowly added, and the mixture was warmed to room temperature and stirred for a further 30 min. The ensuing two-phase mixture was concentrated in vacuo and the viscous residue containing 4-methoxyphenylzinc chloride was then dissolved in 1 mL THF to yield a 1.4 M solution of the arylzinc chloride.

4-Methoxyphenylzinc chloride (0.67 mL of a 1.4 M solution in THF) was added dropwise to a solution of **16** (162.1 mg, 0.21 mmol) and $Pd(PPh_3)_2Cl_2$ (7.7 mg, 0.01 mmol) in THF (0.5 mL). The light yellow mixture was stirred at room temperature until the color of the solution changed to dark red (15 min). The consumption of **16** was then confirmed by TLC analysis and the solvent was removed on the rotovap. The crude reaction mixture was purified by column chromatography on silica gel (4:1 hexanes:benzene) to yield 1-*C*-(4-methoxy)phenyl-3,4,6-tri-*O*-(triisopropylsilyl)-*D*-glucal (**36**) (115.3 mg, 73%, Table 2, entry 16) as a colorless oil. This material exhibited: $[\alpha]_D^{25}$ −0.8 (*c* 0.99); IR: 1651, 2866-2945 cm^{-1}; ^1H NMR δ: 1.01–1.06 (m, 63H), 3.79–3.91 (m, 4H), 4.08–4.18 (m, 3H), 4.39–4.44 (m, 1H), 5.22 (dd, 1H, *J* = 1.4, 5.4 Hz) 6.81–6.87 (m, 2H), 7.52–7.59 (m, 2H); ^{13}C NMR δ: 12.2, 12.6, 12.7, 18.2, 18.3, 18.4, 55.6, 62.3, 67.2, 70.5, 81.6, 95.6, 113.7, 127.2, 129.6, 150.6, 160.3. Exact Mass calcd. for $C_{40}H_{76}O_5Si_3$ (M^+): 720.5001; found: 720.4988.

*1-C-Phenyl-3,4,6-tri-*O*-(triisopropylsilyl)-1-*D*-glucal (**34**)*

Following general procedure B, **16** (108.4 mg, 0.15 mmol) was reacted with phenylzinc chloride (Table 2, entry 13). After chromatography (elution with 0.5% EtOAc in hexanes), **34** (91.3 mg, 90%) was obtained as a colorless oil: $[\alpha]_D^{25}$ −8.2 (*c* 0.77); IR: 1463, 1495, 1650, 2866–2964 cm^{-1}; ^1H NMR δ: 1.02–1.08 (m, 63H), 3.90 (dd, 1H, *J* = 4.3, 11.1 Hz), 4.06–4.20 (m, 3H), 4.43–4.48 (m, 1H), 5.35 (dd, 1H, *J* = 1.5, 5.3 Hz); ^{13}C NMR δ: 12.2, 12.6, 12.7, 18.2, 18.3, 18.4, 62.3, 67.1, 70.4, 81.7, 97.1, 125.9, 128.4, 128.7, 136.9, 150.9. Exact Mass calcd. for $C_{39}H_{74}O_4Si_3$ (M^+): 690.4895; found: 690.4885. Anal. calcd. for $C_{39}H_{74}O_4Si_3$: C 67.76, H 10.79; found: C 67.43, H 11.00.

*1-O-(2-Furyl)3,4,6-tri-*O*-(triisopropylsilyl)-*D*-glucal (**37**)*

Following general procedure B, **16** (91.5 mg, 0.12 mmol) was reacted with 2-furylzinc chloride (Table 2, entry 17). After chromatography (elution with 20% benzene in hexanes), **37** (66.2 mg, 79%) was obtained as a colorless oil; $[\alpha]_D^{25}$ −8.3 (*c* 0.41); IR: 1463, 1492, 1667, 2868–2963 cm^{-1}; ^1H NMR δ: 1.02–1.06 (m, 63H), 3.88 (dd, 1H, *J* = 4.4, 11.2 Hz), 4.02–4.19 (m, 4H), 4.35–4.40 (m, 1H), 5.39 (dd, 1H, *J* = 1.5, 5.3 Hz), 6.37 (dd, 1H, *J* = 1.8, 3.4 Hz), 6.50 (d, 1H, *J* = 3.4 Hz), 7.33 (s, 1H); ^{13}C NMR δ: 12.2, 12.6, 12.7, 18.2, 18.3, 18.4, 62.3, 66.4, 70.6, 81.6, 95.9, 107.4, 111.4, 142.5, 143.6, 150.8. Exact Mass calcd. for $C_{37}H_{72}O_5Si_3$ (M^+): 680.4688; found: 680.4700. Anal. calcd. for $C_{37}H_{72}O_5Si_3$: C 65.24, H 10.65; found: C 64.79, H 10.55.

*1-C-(2-Methylphenyl)-3,4,6-tri-*O*-(triisopropylsilyl)-*D*-glucal (**40**)*

Following general procedure B, **16** (101.8 mg, 0.14 mmol) was reacted with 2-methylphenylzinc chloride (Table 2, entry 21). After chromatography (elution with 10% benzene in hexanes), **40** (66.2 mg, 68%) was obtained as a colorless oil; $[\alpha]_D^{25}$ −24.9 (*c* 0.33); IR: 681, 1463, 1658, 2866–2958 cm^{-1}; ^1H NMR δ: 1.00–1.06 (m, 63H), 2.39 (s, 3H), 3.97 (dd, 1H, *J* = 4.8, 11 Hz), 4.10–4.19 (m, 3H), 4.36–4.40 (m, 1H), 4.89 (dd, 1H, *J* = 2.2, 4.8 Hz), 7.11–7.27 (m, 4H); ^{13}C NMR δ: 12.2, 12.6, 18.2, 18.3, 20.1, 62.4, 66.7, 69.8, 82.0, 99.8, 125.8, 128.8, 129.6, 130.6, 137.4, 137.7, 153.4. Exact Mass calcd. for $C_{40}H_{76}O_4Si_3$ (M^+): 704.5051; found: 704.5048.

*General procedure C: preparation and coupling of arylboronate esters with 1-iodo-3,4,6-tri-*O*(triisopropylsilyl)-*D*-glucal (**16**)*

A solution of distilled bromobenzene (60 μL, 0.5 mmol) in THF (0.5 mL) at −78°C was treated with *n*-BuLi (0.2 mL of a 2.5 M solution in hexanes, 0.5 mmol) and the resulting solution was stirred for 1.25 h. Trimethylborate (60 μL, 0.5 mmol) was then added dropwise and the resulting milky white solution was warmed to room temperature and stirred a further 30 min. Iodo glucal **16** (185.1 mg, 0.25 mmol) dissolved in THF (2 mL), Na_2CO_3 (0.5 mL of a 2.0 M aqueous solution), and $PdCl_2(PPh_3)_2$ (7.8 mg, 0.0125 mmol) were added to the solution. The reaction temperature was then raised to 70°C and stirring was continued for another 4 h. The crude mixture was concentrated and the residual material was subjected to column chromatography (eluting with 5% benzene in hexanes) to afford 1-*C*-phenyl-3,4,6-tri-*O*-(triisopropylsilyl)-*D*-glucal (**34**) (145.6 mg, 84%, Table 2, entry 6) as a colorless oil.

*1-C-(4-Cyanophenyl)-3,4,6-tri-*O*-(triisopropylsilyl)-1-*D*-glucal (**35**)*

Following general procedure C, **16** (187.8 mg, 0.25 mmol) was reacted with the boronate ester generated from 4-bromobenzonitrile (Table 2, entry 14). After chromatography (elution with 20% benzene in hexanes), **35** (162.4 mg, 90%) was obtained as a colorless oil; $[\alpha]_D^{25}$ −8.2 (c 0.27); IR: 1646, 1650, 2229, 2866–2959 cm^{-1}; ^1H NMR δ: 1.03–1.05 (m, 63H), 3.84 (dd, 1H, *J* = 3.8, 11.4 Hz), 4.07–4.20 (m, 3H), 4.47–4.53 (m, 1H), 5.49 (dd, 1H, *J* = 1.4, 5.4 Hz), 7.68 (dd, 4H, *J* = 8.7, 25.6 Hz); ^{13}C NMR δ: 11.8, 12.2, 12.3, 17.8, 17.9, 18.0, 61.7, 66.3, 69.8, 81.7, 99.6, 111.7, 119.1, 125.9, 132.0, 140.6, 148.7. Exact Mass calcd. for $C_{40}H_{73}O_4Si_3N$ (M^+): 715.4847; found: 715.4808. Anal. calcd. for $C_{40}H_{73}O_4Si_3N$: C 67.07, H 10.27; found: C 67.12, H 10.19.

*1-C-(2-Furyl)-3,4,6-tri-*O*-(triisopropylsilyl)-*D*-glucal (**37**)*

Following general procedure C, **16** (134.9 mg, 0.18 mmol) was reacted with the boronate ester generated from furan (Table 2, entry 18). After chromatography (elution with 5% benzene in hexanes), **37** (96.1 mg, 78%) was obtained as a colorless oil.

*1-C-Ethenyl-3,4,6-tri-*O*-(triisopropylsilyl)-*D*-glucal (**41**)*

Following general procedure C, **16** (119.1 mg, 0.16 mmol) was reacted with the boronate ester generated from vinyl magnesium bromide (Table 2, entry 22). After chromatography (elution with 5% benzene in hexanes), **41** (61.1 mg, 60%) was obtained as a colorless oil; $[\alpha]_D^{25}$ −34.2 (*c* 0.64); IR: 1600, 1658, 2866–2958 cm^{-1}; ^1H NMR δ: 1.03 (s, 63H), 3.81 (dd, 1H, *J* = 3.7, 11.3 Hz), 3.95–4.04 (m, 3H), 4.30–4.34 (m, 1H), 4.81 (t, 1H, *J* = 3.2 Hz), 5.08 (d, 1H, *J* = 10.8 Hz), 5.62 (dd, 1H, *J* = 1.6, 17.2), 6.03 (dd, 1H, *J* = 10.7, 17.5); ^{13}C NMR δ: 12.2, 12.5, 12.7, 18.2, 18.3, 62.4, 66.9, 70.5, 81.2, 101.6, 115.2, 133.2, 149.6. Exact Mass calcd. for $C_{35}H_{72}O_4Si_3$ (M^+): 640.4738; found: 640.4747. Anal. calcd. for $C_{35}H_{72}O_4Si_3$: C 65.56, H 11.32; found: C 65.96, H 11.57.

*General procedure D: preparation and coupling of arylboronic acids with 1-iodo-3,4,6-tri-*O*-(triisopropylsilyl)-*D*-glucal (**16**)*

A solution of the Grignard reagent derived from the reaction of 1-bromonaphthalene (0.7 mL, 5 mmol) and magnesium turnings (136.4 mg, 5.5 mmol) in ether (5 mL) was added over 45 min to a solution of trimethylborate in ether (15 mL) at −78°C. The reaction mixture was stirred at this temperature overnight and then treated with 10% H_2SO_4 (10 mL). The mixture was extracted with ether and then the ether extract was acidified with concentrated H_2SO_4. The ether phase was washed with saturated brine and water and was then concentrated to provide 1-naphthylboronic acid, which was used as such.

To a solution of 1-naphthylboronic acid (25.8 mg, 0.15 mmol), **16** (54.3 mg, 0.073 mmol), and $Pd(PPh_3)_2Cl_2$ (5 mg, 0.007 mmol) in THF (0.5 mL) was added Na_2CO_3 (0.15 mL, 2 M aqueous solution) and the resulting two-phase mixture was stirred at 75°C for 90 min. The consumption of **16** was confirmed by TLC analysis, the mixture was cooled to room temperature, and water was added. The crude mixture was extracted with ether, and the combined organic phases were dried and concentrated. Column chromatography of the residual oil on silica gel (1% EtOAc in hexanes) yielded 1-*C*-(1-naphthyl)-3,4,6-tri-*O*-(triisopropylsilyl)-*D*-glucal (**39**) (40.7 mg, 75%, Table 2, entry 20) as a

colorless oil; $[\alpha]_D^{25}$ −8.8 (*c* 0.16); IR: 1666, 2867–2945 cm^{-1}; ^1H NMR δ: 1.02–1.11 (s, 63H), 4.06 (dd, 1H, *J* = 4.8, 11 Hz), 4.20–4.29 (m, 3H), 4.47–4.51 (m, 1H), 5.10 (t, 1H, *J* = 3.4 Hz), 7.36–7.47 (m, 4H), 7.77–7.82 (m, 2H), 8.34–8.39 (m, 1H); ^{13}C NMR δ: 12.2, 12.6, 12.7, 18.2, 18.4, 62.5, 66.8, 69.8, 82.2, 101.1, 125.5, 126.2, 126.3, 126.4, 126.9, 127.0, 128.3, 129.2, 132.1, 134.0, 152.8. Exact Mass calcd. for $C_{43}H_{76}O_4Si_3$ (M^+): 740.5051; found: 740.5007.

1-C-Phenyl-3,4,6-tri-O-(triisopropylsilyl)-1-D-glucal (34)

Following general procedure D, **16** (98.4 mg, 0.13 mmol) was reacted with phenylboronic acid (Table 2, entry 4). After chromatography (elution with 1% EtOAc in hexanes), **34** (72.8 mg, 81%) was obtained as a colorless oil.

1-C-(4-Methoxyphenyl)-3,4,6-tri-O-(triisopropylsilyl)-1-D-glucal (36)

Following general procedure D, **16** (29 mg, 0.04 mmol) was reacted with 4-methoxyphenylboronic acid (Table 2, entry 15). After chromatography (elution with 1% EtOAc in hexanes), **36** (22.9 mg, 81%) was obtained as a colorless oil.

1-C-(2,4-Dichlorophenyl)-3,4,6-tri-O-(triisopropylsilyl)-1-D-glucal (38)

Following general procedure D, **16** (58.9 mg, 0.08 mmol) was reacted with 2,5-dichlorophenylboronic acid (Table 2, entry 19). After chromatography (elution with 1% EtOAc in hexanes), **38** (49.8 mg, 79%) was obtained as a colorless oil; $[\alpha]_D^{25}$ −18.9 (*c* 0.35); IR: 1463, 1492, 1662, 1666, 2867–2945 cm^{-1}; ^1H NMR δ: 1.02–1.06 (m, 63H), 3.96 (dd, 1H, *J* = 4.7, 11.1 Hz), 4.10–4.19 (m, 3H), 4.37–4.41 (, 1H), 5.11 (dd, 1H, *J* = 2.5, 4.3 Hz), 7.18 (dd, 1H, *J* = 1.9, 8.3 Hz), 7.35 (d, 1H, *J* = 1.9 Hz) 7.36 (d, 1H, *J* = 8.3 Hz); ^{13}C NMR δ: 12.2, 12.5, 12.6, 18.2, 18.3, 62.1, 66.5, 69.8, 82.2, 102.2, 127.2, 130.2, 132.1, 134.0, 134.9, 135.0, 149.0. Exact Mass calcd. for $C_{36}H_{65}O_4Si_3Cl_2$ $(M-C_3H_7)^+$: 715.3568; found: 715.3560.

1-C-Phenyl-3,4,6-tri-O-(triisopropylsilyl)-1-D-glucal (34) from higher order mixed cuprate and 1-iodo-3,4,6-tri-O-(triisopropylsilyl)-D-glucal (16)

To a slurry of CuCN (90.2 mg, 1.0 mmol) in THF (2 mL) at −78°C was added phenyllithium (5.8 mL of a 0.35 M solution in ether) and the resulting mixture was warmed to −20°C for 5 min. After recooling to −78°C, a solution of **16** (241.5 mg, 0.33 mmol) in THF (2 mL) was added and the resulting mixture was stirred at −20°C for 15 h. Saturated NH_4Cl was added and the mixture extracted with ether. The ether phase was washed with water and saturated brine, dried, and concentrated. Flash chromatography as described above provided **34** (55.3 mg, 25%, Table 2, entry 5) as a colorless oil together with 109.7 mg of recovered **16**.

1-C-Ethenyl-3,4,6-tri-O-(triisopropylsilyl)-D-glucal (41) from tetravinyltin *and 1-iodo-3,4,6-tri-O-(triisopropylsilyl)-D-glucal (16)*

A mixture of tetravinyltin (0.024 mL, 0.13 mmol), **16** (45 mg, 0.061 mmol), and $Pd(PPh_3)_2Cl_2$ (4.3 mg, 0.006 mmol) in THF (0.5 mL) was refluxed for 8 h. The mixture was concentrated and column chromatography of the residual oil on silica gel (5% CH_2Cl_2 in hexanes) yielded **41** (26.1 mg, 67%, Table 2, entry 23) as a colorless oil.

Acknowledgements

We would like to thank Dr. Thomas Keller (University of Toronto) for a generous gift of the boronic acids found in Table 2, entries 15 and 19, and Professor Brian Keay (University of Calgary) for helpful discussions regarding the boronate ester coupling reactions. Financial support from the Natural Sciences and Engineering Research Council (NSERC) of Canada is gratefully acknowledged.

The aim of this investigation is to provide a classification and examples of N—H...π (and also O—H...π) bonds to the aromatic π systems in organic ammonium tetraphenylborates that would serve as reference for X—H...π(arene) bonds in general. To this end the crystal structures of the tetraphenylborates of the following cations have been determined: Me_3NH^+, Et_3NH^+, quinuclidinium, DabcoH$^+$, Et(*iso*-Pr)$_2$NH$^+$ (monohydrate), $(Ph_3B)NH[—(CH_2)_2—]_2NHMe^+$ (Me_2CO solvate), $Me_2NH_2^+$ (MeCN and Et_2CO solvates), $Et_2NH_2^+$, (*iso*-Pr)$_2NH_2^+$, azoniacycloheptane, guanidinium (monohydrate), $MeNH_3^+$, $EtNH_3^+$, and 1-adamantammonium (monohydrate). These structures contain a variety of normal, bifurcated, and trifurcated N—H...π bonds as well as normal O—H...π bonds to the phenyl groups of the anion. The X—H...π bonds will form whenever opportunity arises, even though the result may be unfavourable bonding geometry. Branched bonds and orientational disorder represent compromise solutions in situations where the H(X) hydrogens are presented with competing phenyl acceptors or where the general organization of the crystal structure offers unfavourable bonding conditions to these hydrogens. The distributions of the distances from X or H(X) to the centre of the phenyl-ring skeleton are analyzed in detail, as are also those of the mean X...C and H(X)...C distances to the ring carbons.

PRADIP K. BAKSHI, ANTONY LINDEN, BEVERLY R. VINCENT, STEPHEN P. ROE, D. ADHIKESAVALU, T. STANLEY CAMERON et OSVALD KNOP. Can. J. Chem. **72**, 1273 (1994).

Le but du présent travail est de fournir une classification et des exemples de liaisons N—H...π (ainsi qui O—H...π) impliquant des systèmes π aromatiques dans des tétraphénylborates d'ammonium organiques qui pourrait servir de référence pour des liaisons X—H...π(arène) en général. À cette fin, on a déterminé les structures cristallines des tétraphénylborates des cations suivants: Me_3NH^+, Et_3NH^+, quinuclidinium, DabcoH$^+$, Et(*iso*-Pr)$_2$NH$^+$ (monohydraté), $(PhB)_3NH[—(CH_2)_2—]_2NHMe^+$ (solvaté par du Me_2CO), $Me_2NH_2^+$ (solvaté par du MeCN ou par du Et_2CO), azoniacycloheptane, guanidinum (monohydraté), $MeNH_3^+$, $EtNH_3^+$ et 1-adamantammonium (monohydraté). Ces structures comportent diverses liaisons N—H...π normales, bifurquées et trifurquées ainsi que des liaisons O—H...π normales vers les groupes phényles de l'anion. Les liaisons X—H...π se forment chaque fois que la possibilité existe, même si la géométrie qui en résulte n'est pas toujours favorable. Les liaisons formant des branches et le désordre orientationnel représentent des solutions de compromis pour des situations dans lesquelles les hydrogènes H(X) se voient offrir des différents accepteurs phényles ou dans lesquelles l'organisation générale de la structure cristalline offre des conditions de liaison non favorables à ces hydrogènes. On a analysé en détail les répartitions des distances allant de X ou H(X) au centre du noyau phényle du squelette ainsi que les distances moyennes X...C et H(X)...C avec les atomes de carbone du cycle.

[Traduit par la Rédaction]

In this paper we present the results of what we believe is the first systematic, goal-oriented experimental investigation of hydrogen bonding to aromatic π systems is crystals, a subject of sustained and growing interest. The investigation was undertaken to lay a more secure foundation for a better understanding of this type of bonding interaction, in particular as regards its geometric aspects.

The possibility of formation of an X—H...acc hydrogen bond in which the acceptor is a delocalized π system was recognized as early as the 1940s. Since then numerous spectroscopic investigations (3–27) have furnished evidence for the existence of such bonding interactions, mostly in solution. There has also been some theoretical work (27–37). In contrast, crystallographic studies, which would provide direct rather than stereochemically circumstantial evidence of such interactions in solids, have been sporadic and often serendipitous, and those involving *aromatic* π systems have been even fewer (38–50). Moreover, at times a crystal-structure determination actually may have uncovered an X—H...π bond, but this feature went unnoticed by the authors because of lack of attention to hydrogen bonding, or was noticed but not reported because the authors may not have been comfortable with the idea of an X—H...π interaction (see below).

Historically, the first demonstration of the existence of an X—H...π bond *in a crystal* appears to come from a calorimetric-cum-crystallographic study of NH_4BPh_4 (38). This was also the first reported demonstration of such an interaction (later confirmed and elaborated in ref. 43) involving specifically an aromatic π system, albeit one between weakly charged[8] rather than neutral species. On ir evidence this interaction is very weak and is associated with an estimated activation energy for NH_4^+ reorientation of the order of only 0.5 kcal/mol (cf. also refs. 24 and 26); its effect on the spectral features is not easy to assess and interpret (16, 43).

[1]For Part 3, see ref. 1.

[2]Erratum for Part 2 (2): the *b* value of $Ph_4Br.H_2O$ in Table 1 (p. 3060) should read 10.659(2) Å, not 10.65(2) Å.

[h] 1-Azoniapropellane TB.

In the following we shall be concerned mostly with interionic N—H^+...π^- interactions in crystalline tetraphenylborates (TB) of organic ammonium cations (Table 1). The fifteen title compounds **1–15** plus the previously reported (1) iminium TBs **19–22**, ATB (**16**), and 3BnTBw (**18**) now provide a sufficient variety of H...π bonding interactions on which to base a classification of bond types and geometries.

Types of X—H...π bonds (X = N, O)

In the crystal structures of the TBs in Table 1 the N atom may be bonded to 1–4 atoms; some of the structures (**12**, **14**, **15**) contain more than one cation nitrogen; and in yet others (**5**, **12**, **15**, **18**, **22**) the H(N) atom is bonded to a phenyl ring indirectly, via a water molecule. These structures thus provide examples of normal N—H...π bonds (types **A–D**, Fig. 1), bifurcated N—H...2π bonds (**E**, **F**) as well as of trifurcated N—H...3π bonds (**H**, **J**). In addition to these homodesmic geometries there are also heterodesmic bifurcation (**G**) and normal N—H...O(—H...π)$_2$ bonds (**L**), the latter of course corresponding to O—H...π rather than N—H...π interactions.

In the **L** type situation the oxygen of the water molecule is 3-coordinate, i.e. the N—H(N) vector approximately bisects the H—O—H angle and thus also the angle between the two lone electron pairs on the O atom. An extension to tetrahedrally 4-coordinate oxygen, in which *two* N—H(N) vectors point at the O atom (each H(N) engages a lone pair on the oxygen; type **L'**, not shown in Fig. 1), has also been observed (see below under GTBw).

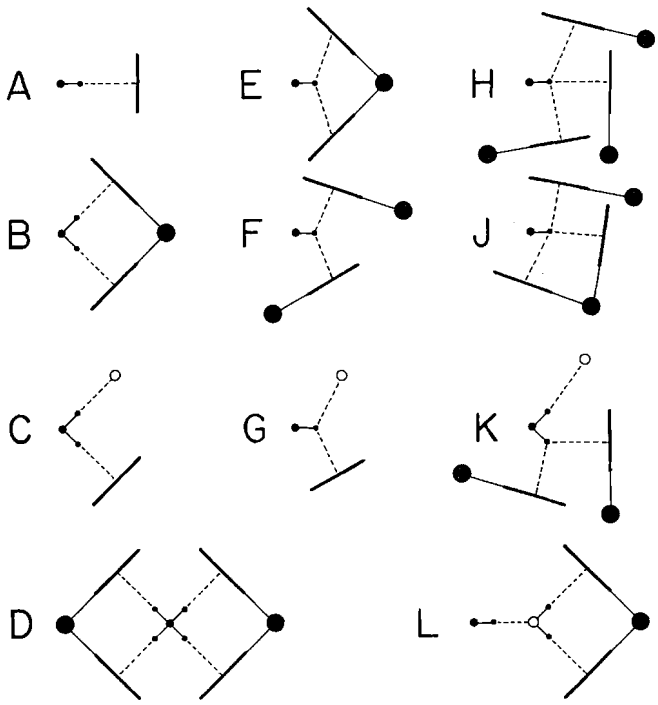

FIG. 1. Schematic synopsis of N—H(N)...π and N—H(N)...O—H-(O)...π bonding geometries in the tetraphenylborates **1–16**, **18–22**, and in **27** (Table 1). Full circles: large, B; medium, N; small, H. Open circles: X = N or O. Heavy lines represent phenyl rings projected on edge. For occurrence of types **A–L** see footnote 9.

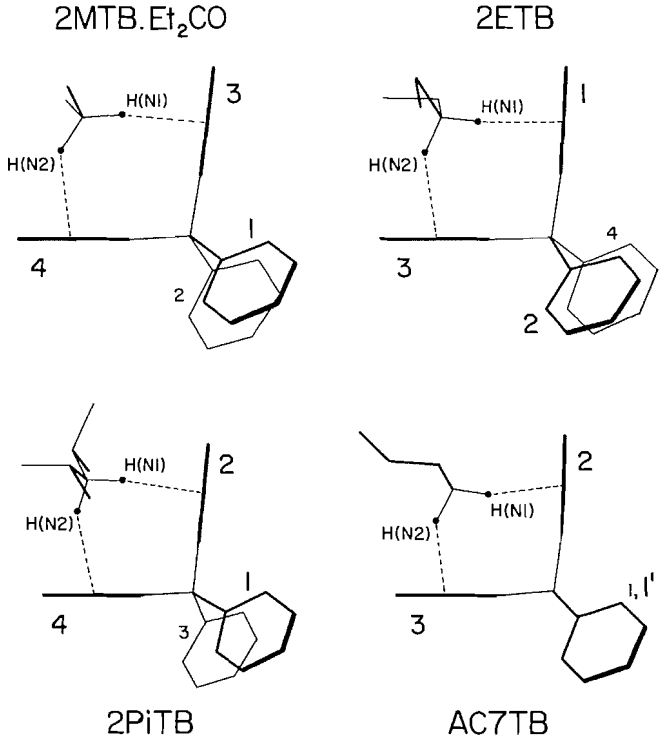

FIG. 3. Normal N—H...π bonds in tetraphenylborates in which the cation nitrogen carries two H(N) atoms, both engaged in H bonds. The projection plane is approximately the N,H(N),H(N)′ plane. Type **B**: 2MTB.Et_2CO, 2ETB, 2PiTB, AC7TB.

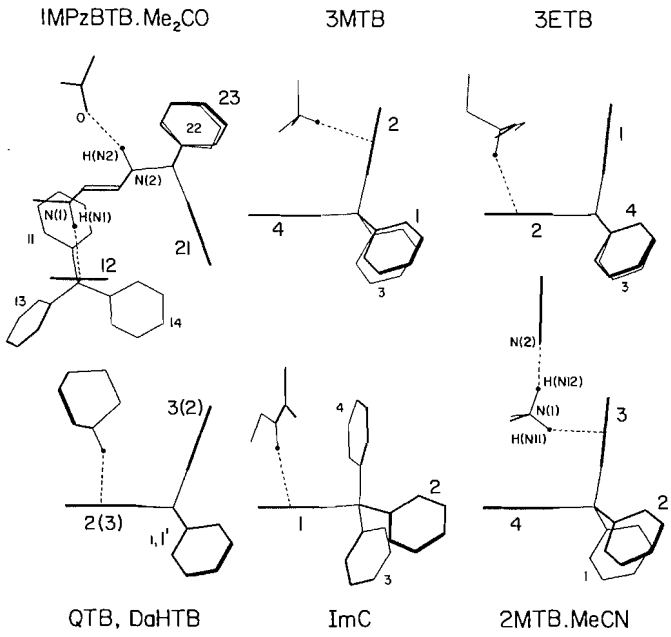

FIG. 2. Normal hydrogen bonds in tetraphenylborates in which the cation is engaged in one N—H(N)...π bond. The black dot represents H(N). Ring numbers in parentheses refer to DaHTB. Broken lines connect H(N) with the centre π_c of the associated ring. Type **A**: 3MTB, 3ETB, QTB, DaHTB, ImC, IMPzBTB.Me_2CO. Type **C**: 2MTB.MeCN.

Some of the structures contain more than one type of hydrogen bond.[9] The actual H-bonding situations are presented in Figs. 2–8.

Directionality and length of the X—H(X)...π bond: general considerations and 1:1 complexes

In a normal X—H...acc hydrogen bond where the acceptor is an atom or, more properly, an electron lone pair localized on an atom, description of the bond geometry presents no problem. The X...acc and H...acc distances ideally are distances between atomic nuclei, and their accuracy and that of the X—H—acc angle in the crystal will depend primarily on the confidence and accuracy with which the H atom has been located, but in principle there is no fundamental difficulty with characterizing the dimensional properties of the bond. This is not so with H bonds to delocalized π systems, especially where the delocalization extends over several atoms. Here the nature and position of the acceptor are ill defined: in general, one cannot single out the acceptor nucleus at which the X—H vector would preferentially point and which would constitute the terminal point of the H...acc segment, i.e. define the H...acc bond length.

For the purposes of the present, purely qualitative considerations we shall regard the H bonding as an essentially electrostatic interaction between the charge on the poorly shielded proton and the electron density in the phenyl

[9]The bond types are distributed among the structures of Table 1 as follows: **A**, **1–4**, **6**, **7**, **12–15**, **20**; **B**, **8–11**; **C**, **7**; **D**, **16**; **E** symmetric, **19**; **E** asymmetric, **13**, **14**, **21**; **F**, **12**, **14**; **G**, **12**; **H**, **12**; **J**, **13**, **14**; **K**, **27**; **L** symmetric, **5**; **L** asymmetric, **15**, **18**, **22**; **L′**, **12**.

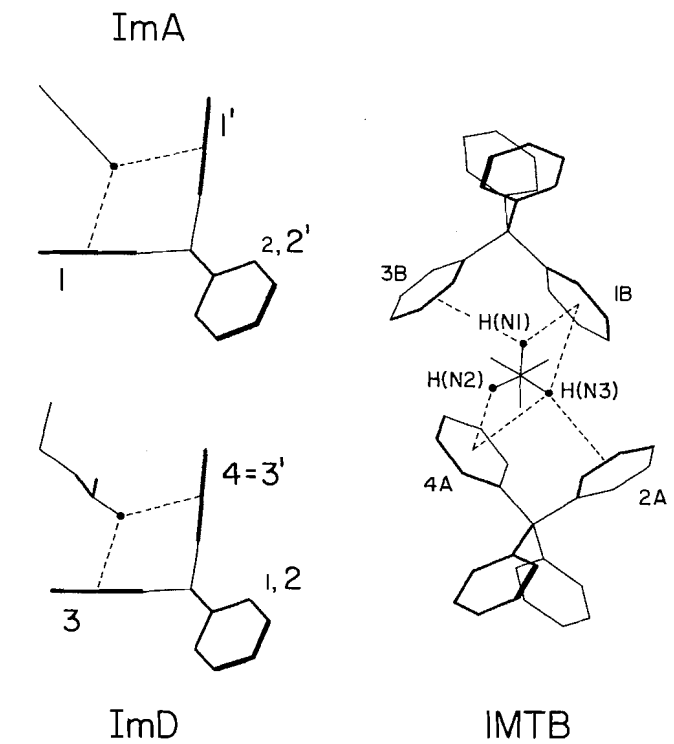

FIG. 4. Bifurcated and trifurcated N—H...π bonds in tetraphenylborates (see also Figs. 6 and 7). Type **E**: ImA, ImD, 1MTB. Type **J**: 1MTB. The projection plane for ImA and ImD is the N,π_c,π_c' plane, for 1MTB the H(N1),H(N2),H(N3) plane.

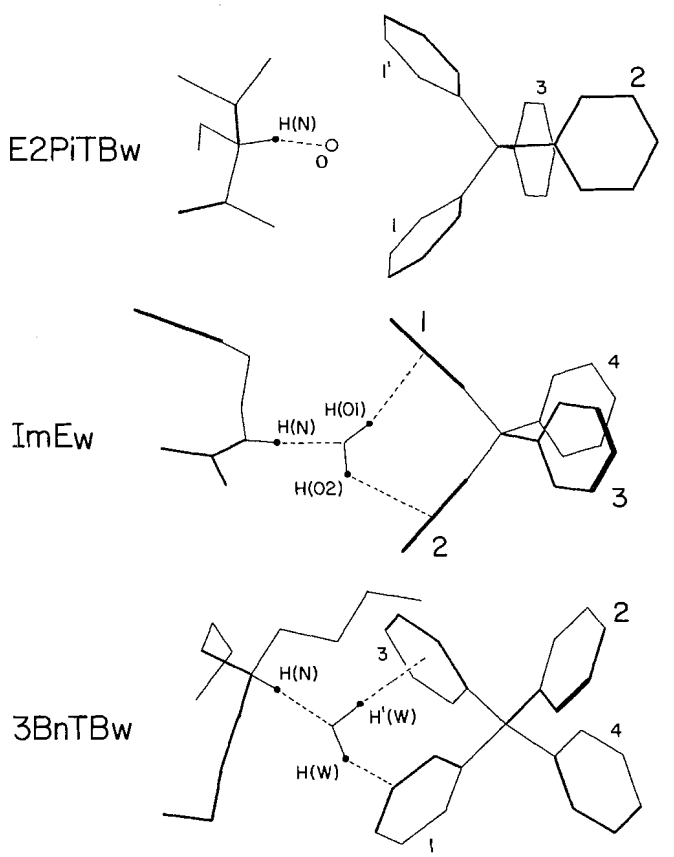

FIG. 5. N—H(N)...O[—H(O)...π]$_2$ bonds in tetraphenylborates. Projection on the N,H(N),O plane. Type **L**: symmetric, E2PiTBw; asymmetric, 3BnTBw, ImEw (see also Figs. 6 and 8).

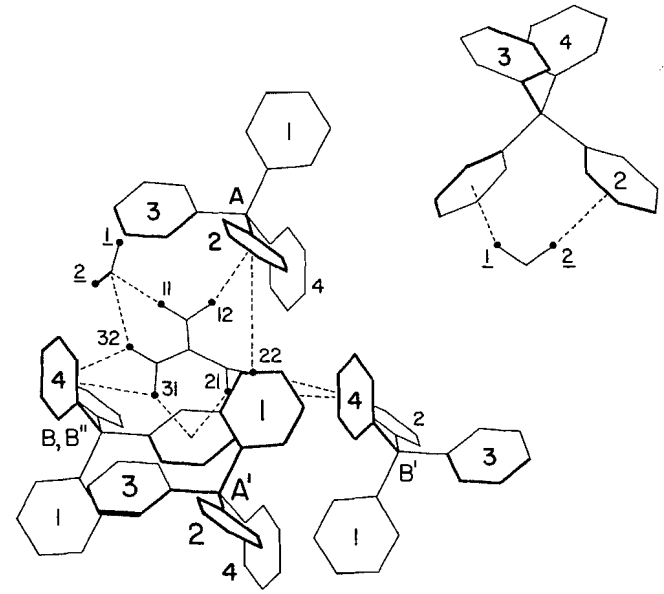

FIG. 6. Hydrogen bonding in GTBw (**12**). Projection on the cation-skeleton plane. Broken lines, H bonds drawn to the centres of the associated rings. Numbering: 32 = H(N32) etc.; 1, 2 = H(O1), H(O2). Upper right-hand corner: H bonding of the H_2O molecule.

ring.[10] The salient features of this simple model will not be obscured if we examine the electron-density distribution in the *benzene molecule* instead of the more specific (though more complicated and currently unavailable) distribution in the C_6H_5—B group itself.

Inspection of the calculated electron-density distribution in C_6H_6 (Figs. 9 and 10) shows that the outer contours above and below the C_6 ring skeleton (in planes *B–D* perpendicular to the molecular plane σ_h) are relatively flat. This is certainly true for *C*, the plane passing through neighbouring carbon nuclei, up to ~0.4 au = 2.7 e/Å^3 (about 0.5 Å above σ_h) for the total density, and up to ~0.04 au = 0.3 e/Å^3 (about 1 Å above σ_h) even for the π density. In planes *B* and *D*, which pass through the centre π_c of the molecule, significant indentation above π_c is observed for the >0.008 au contours (at ~1 Å above σ_h), but the shapes of these higher-density contours are such that the region of low electron density (i.e. unfavourable for electrostatic interaction) toward the centre is relatively narrow and thus not extensively exclusionary.

If it is assumed that the interaction between the H(X) atom and the electron cloud is strongest in regions of high electron density, then the features of the density distribution in Figs. 9 and 10 will not lead to expectation of high directional selectivity of the X—H(X)...π bond. This has also been concluded from *ab initio* model studies of isolated H_2O–C_6H_6 (25, 27, 30, 31, 34–37), NH_3–C_6H_6 (30, 31, 34, 36), HF–C_6H_6 (31, 33, 36) and other such pairs as well as from the limited number of experimental studies of such pairs (22, 23, 25, 27). While the results differ in the details, the consensus for the H_2O–C_6H_6 complex, which has received the most attention, appears to be that the

[10]The conclusion from an *ab initio* (MP2) study of the isolated HF–C_6H_6 complex (33) was that roughly half of the bonding is electrostatic (induced dipole – permanent dipole interaction) and the other half is due to charge-transfer H-bond formation. In the present case of *interionic* H-bond formation the Coulombic component may be expected to be at least half the total interaction and probably significantly higher.

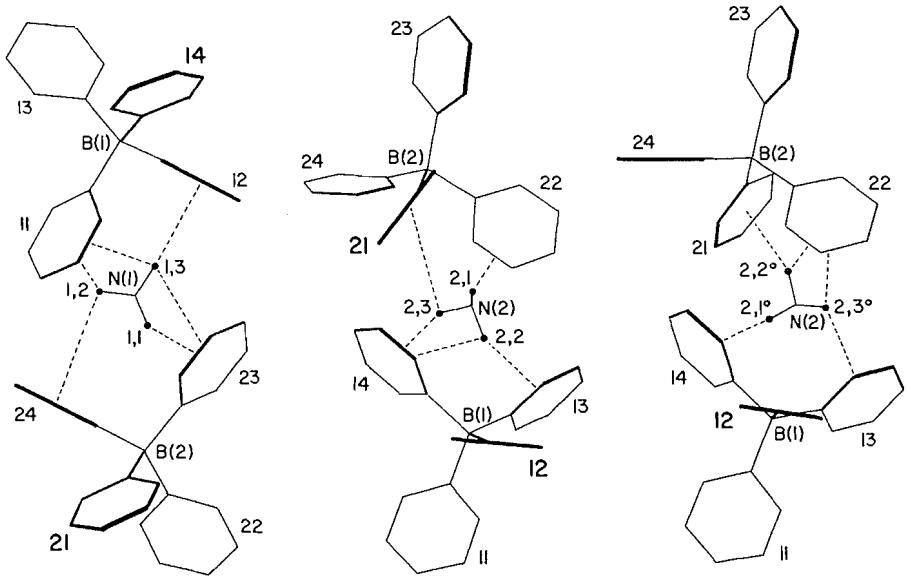

FIG. 7. Hydrogen bonding in 1ETB (**14**). For clarity the N(1) system and the two orientations of the N(2) system (resolved twofold disorder) are presented separately. Projections approximately on the plane of the respective H(N) atom triplets with avoidance of overlap. Broken lines, H bonds drawn to the centres of the associated rings. Numbering: 1,1 = H(N1,1) etc.; 2,3 = H(N2,3) etc.; 2,3° = H(N2,3*) etc.

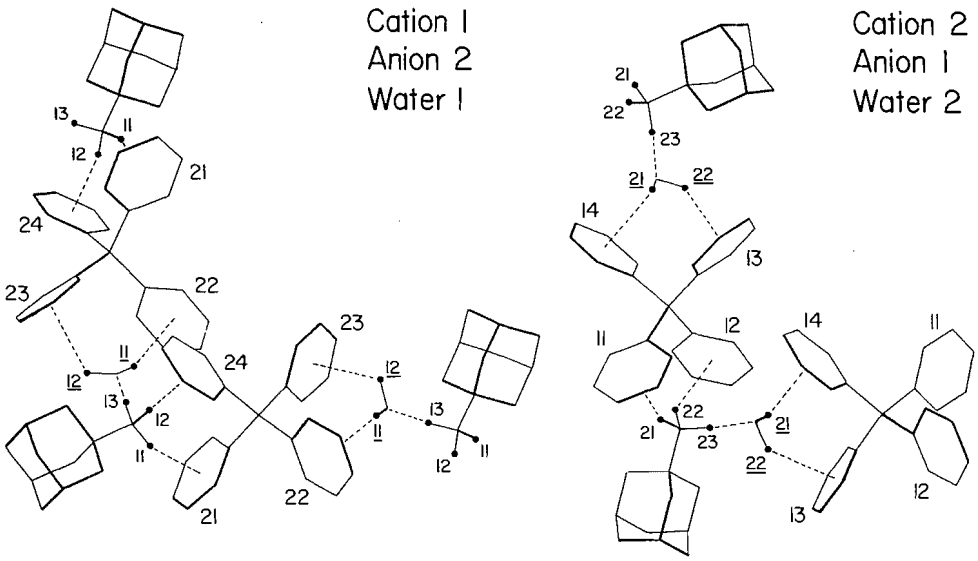

FIG. 8. Hydrogen bonding in AdTBw (**15**). For clarity the two H-bonding systems are presented separately. Broken lines, H bonds. Numbering: large type, rings; small type, 12 = H(N12) etc.; small type underlined, 22 = H(O22) etc.

H_2O molecule is situated above the C_6 ring skeleton, with the oxygen atom on or somewhat off (statically or dynamically) the C_6 axis and with the O—H vectors pointing simultaneously (?) and probably asymmetrically at the annular electron cloud above the ring skeleton. The potential surface for the movement of the H_2O molecule relative to the C_6H_6 molecule is very flat, permitting the H_2O molecule to rotate nearly freely with respect to the C_6 axis. These findings are consistent with the above expectation from the electron-density distribution in Figs. 9 and 10 concerning the lack of strong directional preference of the H bond. The estimates of the O...π_c distance in the complex range from 3.2 to 3.4 Å,[11] which is in good agreement with the corresponding distances observed in crystals (see below).

[11]In some of the studies the distance specified is that between the centres of mass of the two molecules, i.e. between π_c and a point ~0.07 Å from the oxygen atom on the C_2 axis of the H_2O molecule.

The conclusions for the NH_3–C_6H_6 complex are less compelling.

Directionality and length of the X—H(X)...π bond: crystals

In crystals the conditions for the formation of X—H(X)...π bonds are quite different. In the isolated donor–acceptor pairs of the preceding section there are no external constraints on the component molecules and the direction of the bond is the outcome of the two molecules being free to assume a relative orientation that corresponds to the minimum energy of the system. By contrast, in crystals the donor–acceptor pair is not isolated and constraints arise from packing and from multiple choices: the environment and relative orientation in a crystal are largely determined by packing efficiency (and Coulombic energy in ionic crystals), and there may be more than one π system available for bond formation. Thus an H_2O molecule in the TBs is

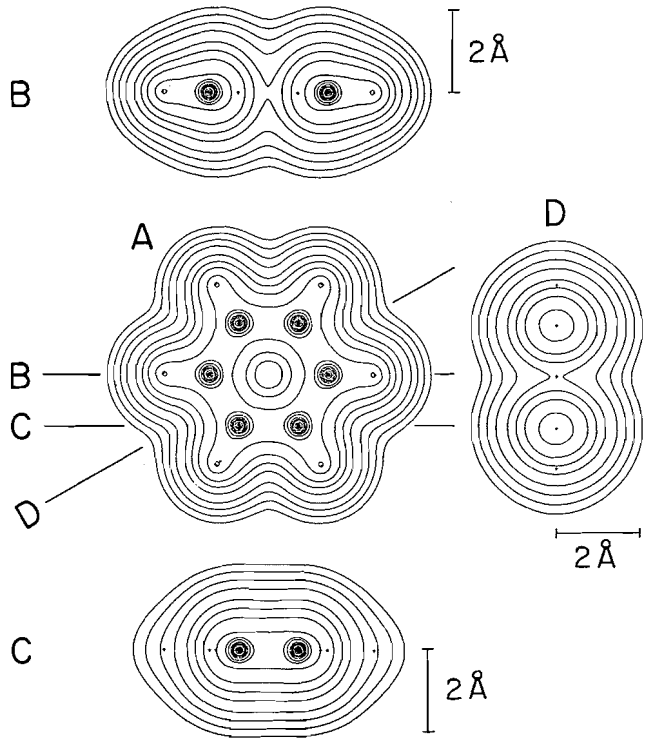

FIG. 9. Distribution of the calculated total electron density in the benzene molecule (6-31G**). *A*, distribution in the molecular plane; *B–D*, distributions in planes perpendicular to the molecular plane, as indicated. The outermost contour represents 0.002 au and is followed by the 0.004, 0.008, 0.02, 0.04, 0.08 au etc. contours (1 au = 6.749 e/Å^3).

found to be H-bonded simultaneously to *two* phenyl rings (types **L** and **L′**, Fig. 1); in **23** and **24** the direction of the —O—H vector is determined by the conformational limits of the molecule. The actual direction of the bond with respect to the ring cannot therefore be predicted with confidence and a reliable crystal-structure determination is required.

In the TBs that contain cations in which a nitrogen carries at most two N(H) atoms the positions of these hydrogens (and hence the orientations of the corresponding N—H vectors) are known with reasonable confidence, either from a difference map or from geometrical considerations (cf. Experimental).[12] In a normal bond the N—H vector is seen to be directed at some point in the general area of the electron cloud of the associated ring. The angle $\phi \leq 90°$ which this vector makes with the ring plane varies considerably from situation to situation and is undoubtedly strongly affected by accidents of packing. Furthermore, since the N—H vector can approach the ring from a variety of directions, the angle ψ formed by the projection of the N—H vector onto the ring plane and the (approximate) B—C(α)—C(δ) line (Fig. 11) should be examined in conjunction with ϕ. In a crystal, both ϕ and ψ are likely to be governed less by "chemical" forces than by the particulars of packing, and although the distribution of ϕ values and the possibility of a correlation between these two angles must not be left uninvestigated, it is not certain that ϕ is the quantity best suited to serve as a principal parameter in formulating general norms of N—H...π bonding from empirical data. It seems more profitable at this, the fact-finding stage to concentrate instead on examining interatomic *distances*. Similar considerations apply to the O—H vector in the water of hydration.

Since the length of the X—H(X)...π bond cannot be properly defined, a suitable device must be substituted if bonds are to be compared. Any such device must be capable of being uniquely specified from the parameters of the crystal structure. Two quantities that are known with considerable accuracy and that will be used in the following are the mean distance $\bar{d}$(X...C) of the X atom to the ring carbons and the distance d(X...π_c) from X to the centre π_c of the associated ring. The two companion distances $\bar{d}$[H(X)...C] and d[H(X)...π_c], in the absence of neutron-diffraction results, are not as reliable, but their lower accuracy does not render them less informative. Basing a discussion of the X—H(X)...π bonding on distances from the ring centre when the X—H vector in reality points elsewhere is of course artificial (see below). Yet this artifice provides us with a simple and generally applicable scheme which is useful for classification and statistics without obscuring the essential features of the bonding.

The $\bar{d}$(X...C), d(X...π_c), $\bar{d}$[H(X)...C], and d[H(X)...π_c] distances for the compounds of Table 1 are detailed in Table 5. The standard deviations of $\bar{d}$(X...C) and $\bar{d}$[H(X)...C] in fact give indirect information about ϕ, and the X—H(X)—π_c = ω "bond" angle is obtained directly from d[X—H(X)] ~ 1 Å, d(X...π_c), and d[H(X)...π_c].

Within the accuracy of a standard X-ray structure determination the uncorrected X—H bond length may be taken as constant. For collinear X,H(X), π_c triplets (ω = 180°) the difference d(X...π_c) − d[H(X)...π_c] would thus also be constant, and the corresponding points in a d[H(X)...π_c] vs. d(X...π_c) plot for normal (i.e. not branched) X—H(X)...π bonds would fall on a 45° line. This is seen to be the case for a number of X = N points in Fig. 12 which also shows the range and distribution of the H(N)...π_c and N...π_c distances in the compounds of Table 1. For bonds that can be identified visually and from distances to the ring as normal the ω angles for X = N fall between 180° and 120°, with a sample mean $\bar{\omega}$ = 156(16)°. However, a more detailed analysis (Table 6) reveals that $\bar{\omega}$ for cations with a single H atom on the nitrogen is 163(13)°, whereas where there are competing H(N) donors on the nitrogen, $\bar{\omega}$ for the normal bonds is 144(12)°.[13]

For type **B** bonds, with two H(N) on the cation nitrogen and two normal bonds to phenyl rings of the same anion, one bond angle is consistently and significantly larger than the other: $\bar{\omega}_1$ = 178(4)°, $\bar{\omega}_2$ = 149(5)°, i.e. one N—H vector points at the centre of the associated ring (ϕ ~ 90°), while the other points at the electron cloud in the general vicinity of C(δ) of *its* associated ring (Fig. 3). This appears to be the consequence of the constraint of the H(1)—N—H(2) angle at the nitrogen to approximately tetrahedral: one of the H(N) atoms makes a "better" bond than the other, although the H(1)—N—H(2) triplet probably undergoes a significant quasi-librational motion which would tend to compensate, dynamically, for the disparity. In the extreme case of ATB (**16**) the four N—H...π bonds are equivalent by symmetry and ω = 141° (43).

The means of the 26 N...π_c and H(N)...π_c distances in the normal-bonds sample are 3.25(18) and 2.34(19) Å, respectively. The corresponding means for particular subsets of the

[12]Where the nitrogen carries three H atoms, as in **13–15**, the positions of these hydrogens are known with less certainty, but they are still adequate for describing the geometry of the bonds (see below).

[13]One abnormally high value is not included in the mean.

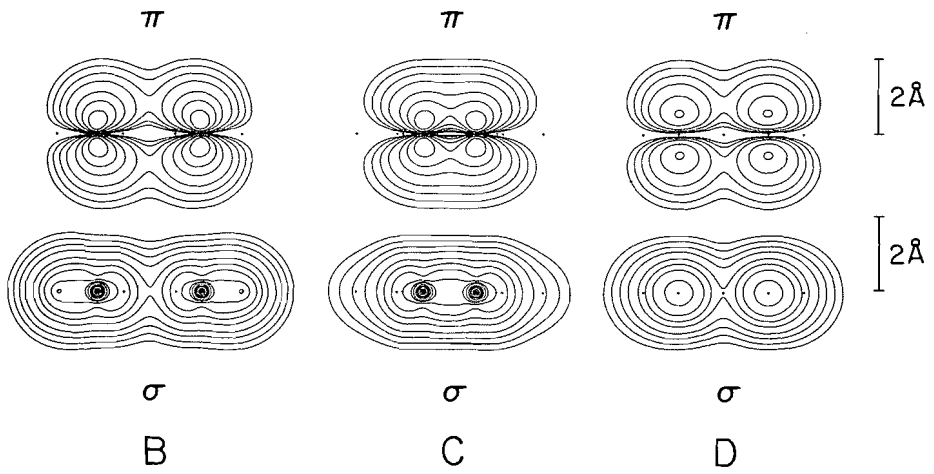

FIG. 10. Electron-density distribution in the σ and π systems of the benzene molecule (6-31G**) in planes *B–D* of Fig. 9.

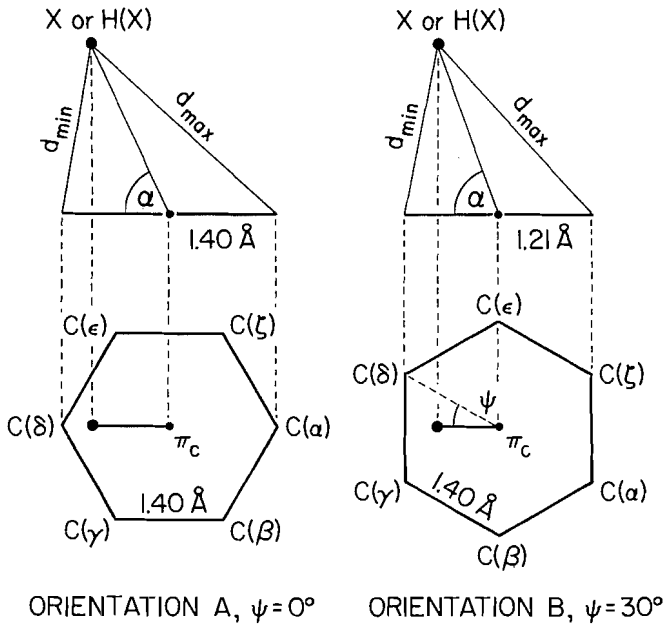

FIG. 11. Orientation of the X—π_c or H(X)—π_c vector relative to the benzene ring plane. Only orientations in planes perpendicular to the ring plane are considered; the ring is taken to contain C_6 symmetry; the C(α) may or may not be attached to the B atom of the TB anion, i.e. $0 < |\alpha| \leq 90°$.

normal-bonds sample (Table 6) are statistically indistinguishable from the overall means. The distributions of the distances are strongly skewed toward low values, $0.9 \leq \gamma_1 < 1.3$.[14]

The distribution of the points in the companion plot, $\bar{d}$[H(N)...C] vs. $\bar{d}$(N...C) (Fig. 12), resembles that of the d[H(N)...π_c] vs. d(N...π_c) plot, in that it too is skewed toward low values. The points cluster about the $\bar{d}$(N...C),$\bar{d}$[H(N)...C] means of 3.54(16),2.72(16) Å for the normal bonds and 3.59(20),2.73(18) Å for the type **A** bonds only. In comparing $\bar{d}$(X...C) with d(X...π_c) etc. the following should be realized: d(X...π_c) is a distance between an atom and π_c, which is a point not occupied by an atom but well defined by the C atoms of the phenyl ring, and ω represents the angle defined by X,H(X),π_c. By contrast, $\bar{d}$(X...C), although a length, does not represent the distance from X to any uniquely defined and physically significant point in the crystal structure; it should be regarded as exactly what it stands for, an arithmetic mean, i.e. a number. The angle ω calculated from $\bar{d}$(X...C) and $\bar{d}$[H(X)...C] is therefore a *fictitious* angle, the value of which should not be compared with the ω obtained from d(X...π_c) and d[H(X)...π_c]. Nevertheless, its *distribution* is qualitatively similar to that for the latter distances and thus corroborative.

Linear regressions of $\bar{d}$(X...C) on d(X...π_c) for X = N, X = O, and X = N + O show that, statistically, there is no difference between N and O in our sample. The combined regression yields $\bar{d}$(X...C) = 0.64(1) + 0.89(1)d(X...π_c) (n = 70, r^2 = 0.99, σ = 0.02 Å ~ 2% of range) and $\bar{d}$[H(X)...C] = 0.68(1) + 0.87(1)d[H(X)...π_c] (n = 67, r^2 = 1.00, σ = 0.03 Å ~ 2% of range). Converting regression equations to differences one obtains $\delta_X = \bar{d}$(X...C) − d(X...π_c) = 0.64(1) − 0.11(1)d(X...π_c) and $\delta_H = \bar{d}$[H(X)...C] − d[H(X)...π_c] = 0.68(1) − 0.13(1)d-[H(X)...π_c], i.e. the differences are not constant. Their mean values are 0.28(5) Å for δ_X and 0.36(6) Å for δ_H in the normal bonds, and 0.25(4) and 0.28(6) Å, respectively, in the branched bonds.

Reference to Fig. 11 will show that for X (or H(X)) situated on the C_6 axis of the C_6H_6 molecule, $\delta_{bz} = \{[d(X...\pi_c)]^2 + 1.96\}^{1/2} - d(X...\pi_c)$. This expression is nonlinear, but it turns out that $\delta_X - \delta_{bz} = -0.001$, −0.015, and −0.038 Å, respectively, for d(X...C) = 3.0, 3.5, and 4.0 Å; and $\delta_H - \delta_{bz} = -0.021$, −0.010, and −0.021 Å, respectively, for $\bar{d}$[H(X)...C] = 2.0, 2.5, and 3.0 Å. If one keeps in mind that $\bar{d}$ in addition responds to pivoting of the phenyl ring about π_c, the linear expressions for δ_X and δ_H obtained from the regressions will be seen to represent the differences between $\bar{d}$(X...C) and d(X...π_c), and between $\bar{d}$[H(X)...C] and d[H(X)...π_c], over the observed ranges reasonably well.

The ranges and distributions of the bond distances and ω for X = O are qualitatively very similar to those for X = N (Tables 5 and 6), especially when allowance is made for the greater uncertainty in the location of the H(O) atoms of the H_2O molecules. The means for $\bar{d}$(O...C) and d(O...π_c) are 3.64(14) and 3.34(17) Å, respectively, which is in agreement with the O...π_c distances of 3.2–3.4 Å estimated from investigations of the H_2O–C_6H_6 complex. The two H(O) hydrogens of a water molecule form asymmetric bonds, $\bar{\omega}_1$ = 145(10)°, $\bar{\omega}_2$ = 126(8)°,

[14] γ_1 and γ_2 are the moment coefficients of skewness and kurtosis, respectively.

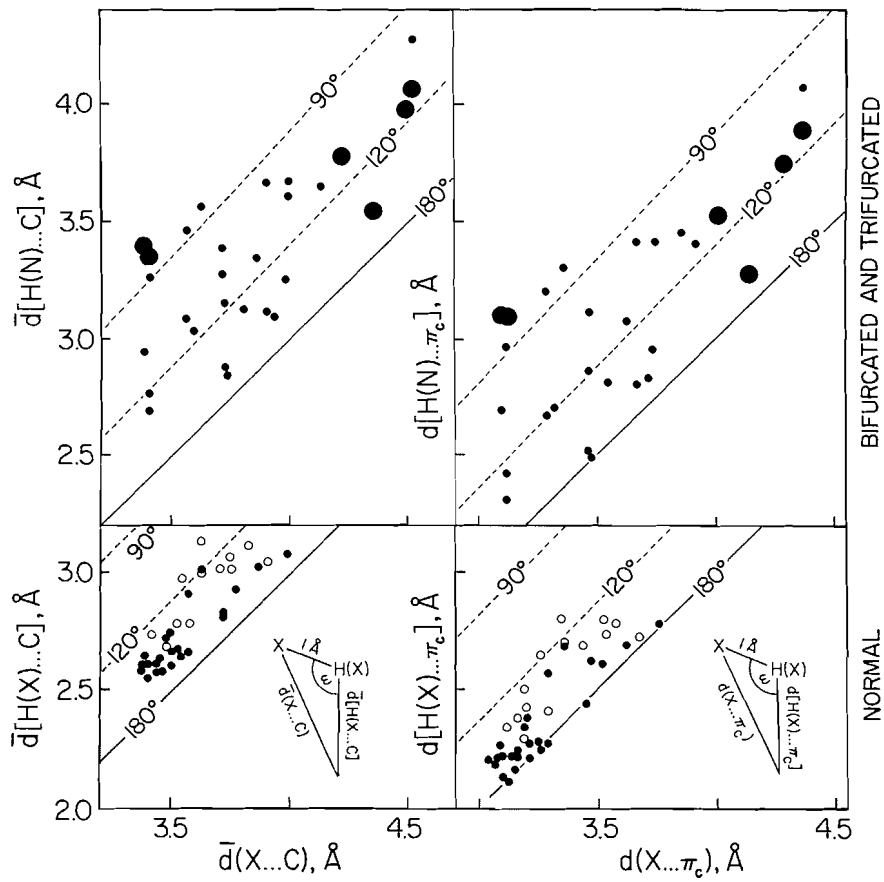

FIG. 12. The mean H(X)...C distances plotted against the mean X...C distances, and the H(X)...π_c distances against the X...π_c distances (Table 5). Full circles: small, X = N, normal or bifurcated bonds; large, X = N, trifurcated bonds. Open circles: X = O, normal bonds. The angle ω describes the angularity of the X—H...π_c bond as described in the figure.

but this is not reflected in the d(O...π_c) and d[H(O)...π_c] means.

Branched X—H(X)...π bonds

We now turn to the branched (bifurcated and trifurcated) N—H(N)...π bonds (no example of a branched O—H(O)...π bond appears to have been reported to date). All the branched bonds in Table 5 except that in **19** are asymmetric.

Bifurcation (and *a fortiori* trifurcation) is the result of compromise in the choice of acceptor. The N—H vector now cannot be said to point at the electron cloud of the phenyl ring in a particular direction, so the notion of bond angle becomes diffuse: in type **E** bonds the vector points more or less at the boron atom, and there appears to be no clear way of dealing with lateral H-bonding interaction. However, the angle ω = N—H(N)—π_c retains its validity and in fact is the only "bond" angle that in the circumstances can be uniquely defined. This angle in general is significantly smaller than for the normal bonds, and its distribution is considerably broader (Fig. 12). The overall mean $\bar{\omega}$ is 119(22)° (n = 24, γ_1 = 0.47, γ_2 = 2.65); the mean for the smaller of the two ω angles in the bifurcated bonds is 103(11)° (n = 12, γ_1 = 0.02, γ_2 = 2.02) and that for the larger angle is 136(16)° (n = 12, γ_1 = 0.66, γ_2 = 2.32), i.e. the skewness of the ω distribution comes from the larger angle.

The three means for d(N...π_c) in bifurcated bonds (Table 6) are numerically different, as are those for d[H(N)...π_c] and again for $\bar{\omega}$. However, the sample of Table 1 is too small for definite statistical inferences to be drawn, even though the means for the larger ω and for the smaller ω are probably genuinely different. The frequency of occurrence of significant asymmetry in bifurcated bonds will have to be investigated further.[15]

Only two examples of trifurcated bonds are available at present, those in **12** and **13**, so any discussion of such bonds would be of necessity incomplete. Of the two, the bond in **12** is the more symmetric, the three component N...π_c distances being quite similar, and likewise for the three H(N)...π_c distances and for the three ω angles.

Although the statistics leave something to be desired, there is a clear increase in the numerical value of the means for N...π_c and H(N)...π_c from the normal to the trifurcated bonds and a decrease for $\bar{\omega}$ (Table 6). This trend would be expected: if bifurcation represents a compromise, trifurcation represents an even greater compromise. The difficulty that sometimes arises with multibranched H bonds involves the ambiguity in recognizing which and how many acceptors should legitimately be included in the H-bonded environment of the donor hydrogen. Correlations like those of Fig. 12 may be helpful in verifying visual assignment of acceptors, but on occasion it may be difficult to

[15]This matter for ordinary H bonds (i.e. bonds not to delocalized π acceptors) and the question of whether bifurcated H bonds are stronger than normal H bonds in situations that warrant comparison have been discussed, on ir and crystallographic evidence, by Knop, Falk et al. in a series of papers on the ammonium and alkylammonium ions published between 1979 and 1985 in Can. J. Chem. and J. Chem. Soc. Faraday Trans. 2.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by EESC ESCOLA DE ENGENHARIA on 09/08/12
For personal use only.

know whether or not bifurcated bonds with one ω close to 180° or below 90°, and with large N...π_c and H(N)...π_c separations, should be reassigned as normal bonds (or vice versa), and trifurcated bonds with such characteristics as bifurcated bonds. These are problems for further empirical analysis as additional data accumulate.

Minimum and maximum X...C and H(X)...C distances

As mentioned above, information about ϕ can be obtained indirectly from the esd's of the $\bar{d}$(X...C) and $\bar{d}$[H(X)...C] values. For an X atom situated on the C_6 axis of the benzene molecule the X...C distances would be equal and the esd of $\bar{d}$(X...C) would be zero, while for an X atom in the molecular plane and 3.5 Å from π_c the esd of $\bar{d}$(X...C) would be approximately equal to 1 Å. The *observed* esd range for $\bar{d}$(N...C) is 0.03–0.39 Å for the normal bonds (mean, 0.14(6) Å; $\gamma_1 = 2.55$, $\gamma_2 = 13.4$), 0.13–0.91 Å for the bifurcated bonds (mean, 0.28(22) Å; $\gamma_1 = 1.46$, $\gamma_2 = 4.34$), and 0.13–0.67 Å for the trifurcated bonds (Table 5). The corresponding esd ranges for $\bar{d}$[H(N)...C] are 0.04–0.50 Å (mean, 0.18(12) Å; $\gamma_1 = 1.04$, $\gamma_2 = 3.40$), 0.14–0.96 Å, and 0.21–0.59 Å, respectively. For $\bar{d}$(O...C) and $\bar{d}$[H(O)...C] the esd ranges are 0.06–0.59 and 0.12–0.59 Å, respectively. Thus even when allowance is made for the distortion of the ring in the TBs, the range of ϕ is seen to be wide. However, the distributions of the esd's are strongly skewed toward low values, indicating preference for large ϕ.

Another way of assessing the inclination of the X—H vector to the ring skeleton plane is to examine the difference Δ(X...C) between the longest, d_{max}(X...C), and the shortest, d_{min}(X...C) distance from X to the ring carbons, and the corresponding differences Δ[H(X)...C] between d_{max}[H(X)...C] and d_{min}[H(X)...C] (Table 7). The lower bound of Δ is zero, which for an undistorted benzene ring would correspond to an X—H vector coincident with the C_6 axis. For the normal X—H(X)...π bonds in the TBs, Δ(N...C) ranges from 0.04 to 1.0 Å, Δ[H(N)...C] from 0.04 to ~1.3 Å, Δ(O...C) from 0.04 to 1.14 Å, and Δ[H(O)...C] from ~0.3 to ~1.0 Å. The difference $\Delta\Delta_N = \Delta$(N...C) − Δ[H(N)...C] for these bonds ranges from −0.32 to 0.44 Å (mean, 0.13(20) Å; $n = 20$, $\gamma_1 = -0.34$, $\gamma_2 = 2.53$), and $\Delta\Delta_O = \Delta$(O...C) − Δ[H(O)...C] from −0.46 to 0.49 Å (mean, 0.14(28); $n = 12$, $\gamma_1 = -0.65$, $\gamma_2 = 2.52$). The differences $\Delta\Delta_N$ and $\Delta\Delta_O$ reflect not only the inclination of the X—H(X) vector to the ring plane but also the proximity of the X and H(X) atoms to the quasi-C_6 axis of the phenyl ring.

The difference Δ, for the geometry referred to the undistorted benzene molecule (Fig. 11), is related to the angle α_X formed by the X—π_c vector with the ring plane (the plane X,H(X), $\pi_c \perp$ ring plane) by $\Delta = d_{max}(X...C) - d_{min}(X...C) = (K + k\cos\alpha_X)^{1/2} - (K - k\cos\alpha_X)^{1/2}$, where X = N, O, or H(X), $K = [d(X...\pi_c)]^2 + b^2$, $k = 2bd(X...\pi_c)$, $K \pm k = [d(X...\pi_c) \pm k]^2$, and $b = d$(C—C) = 1.40 Å for orientation A and d(C—C) cos 30° = 1.21 Å for orientation B in Fig. 11. Then for $\alpha_X = 90°$, Δ = 0; for $\alpha_X = 0°$, $\Delta = (K + k)^{1/2} - (K - k)^{1/2}$, with $0 < \Delta < 2.80$ Å for orientation A and $0 < \Delta < 2.42$ Å for orientation B. In Fig. 13 the loci of equal α_X calculated for this model are represented by solid contour lines for orientation A and by broken contour lines for orientation B. Further, $\phi = \omega + \alpha_H - 180°$, provided the X,H(X),$\pi_c$ plane remains perpendicular to the ring plane.

The distribution of the Δ values (Fig. 13), especially for X = O, is erratic, but this may merely reflect the relative smallness of the sample. For the normal bonds there appears to exist a weak correlation between Δ(X...C) and d(X...π_c), and between

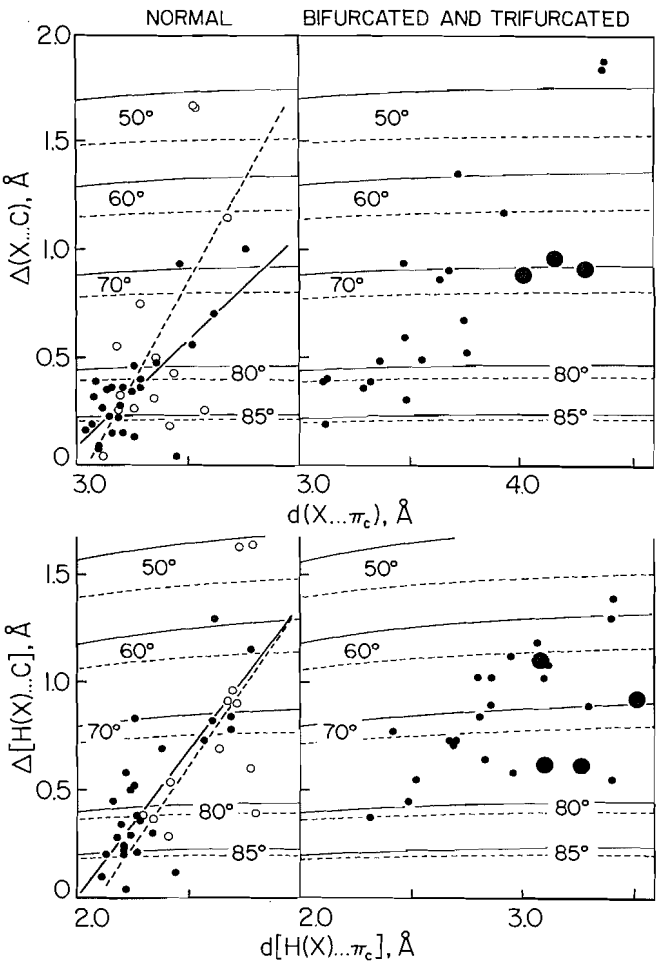

FIG. 13. The difference Δ(X...C) between the maximum and minimum X...C distances plotted against the X...π_c distances, and the differences Δ[H(X)...C] between the maximum and minimum H(X)...C distances plotted against the H(X)...π_c distances (Tables 5 and 7). For circle symbols see caption of Fig. 12. Regression lines Δ(X...C) on d(X...π_c): solid, X = N, $r^2 = 0.56$; broken, X = O, $r^2 = 0.36$. Regression lines Δ[H(X)...C] on d[H(X)...π_c]: solid, X = N, $r^2 = 0.64$; broken, X = O. $r^2 = 0.37$. Constant-α lines: solid, orientation A; broken, orientation B of Fig. 11.

Δ[H(X)...C] and d[H(X)...π_c]. For X = N, the approximate means of d(N...π_c), Δ(N...C), and α_N in the Δ(N...C) vs. d(N...π_c) plot of Fig. 13 are 3.27 Å, 0.35 Å, and 82°, respectively. Recognizable trends also exist for the branched bonds. The more distant X or H(X) is from the ring plane, the larger Δ and the smaller α; for H(X) specifically, the smaller α_H in straight X—H(X)—π_c bonds, the smaller ϕ.

Individual crystal structures

The crystal data of compounds **1–15** (Table 1; all new structure determinations) are listed in Tables 2–4. Tables of other crystallographic parameters and derived quantities have been deposited.[16] The contents of the deposited tables are as follows:

[16]This material may be purchased from the Depository of Unpublished Data, Document Delivery, CISTI, National Research Council of Canada, Ottawa ON, Canada K1A 0S2.

Tables A, B, C have also been deposited with the Cambridge Crystallographic Data Centre, and can be obtained on request from The Director, Cambridge Crystallographic Data Centre, University Chemical Laboratory, 12 Union Road, Cambridge, CB2 1EZ, U.K.

[a]For compound identification see Table 1. Numbers in parentheses: standard deviations of mean for the six X...C and H(X)...C distances to the ring carbons, respectively. R1, phenyl ring 1 etc., as in the original description (Tables A and C for **1–15**).
[b]Symmetrically bifurcated.
[c]Asymmetrically bifurcated.
[d]Asymmetrically trifurcated.
[e]Bifurcated to O_w.
[f]Hydrogen not located.
[g]Intermolecular contact; N—H(1)—$\pi_c(1)$ = 116°.
[h]Intramolecular contact; N—H(1)—$\pi_c(2)$ = 106°.

Tables A (Positional and anisotropic thermal parameters of nonhydrogen atoms), B (Positional parameters and isotropic temperature factors of hydrogen atoms), C (Interatomic distances and bond angles), and D (Deviations $\bar{d}$(C) and δ(B) from and angles between best planes through the phenyl-rings skeletons of the anions). Tables E–U (Observed and calculated structure factors for **1–15**) (150 pages) are available from the Editorial Office.

3MTB and 3ETB

The unit cells of these two structures ($P2_1$) are quite similar and the ion packing in both is of a distorted zincblende type. The N—H...π bonding is of type **A** (Fig. 2).

The reorientational behaviour of the cation in the 3MTB crystal between 185 and 348 K has been studied by ^{2}H nmr spectroscopy (26). The authors concluded that the cation undergoes a complicated composite motion: the complete ion jumps about its N—H axis (E_a = 20.1(20) kJ/mol), the CH_3 groups jump about their respective C_3 axes, and the N—H axis undergoes large-amplitude librations. A TLS analysis of our results for 3MTB indicates that while the anisotropic thermal parameters of the nonhydrogen atoms in the cation are relatively large

TABLE 6. Mean values of the X...π_c and H(X)...π_c distances (Å) and "bond" angles ω (deg) in compounds of Table 1

Sample[a]	⟨d(X...π_c)⟩	⟨d[H(X)...π_c]⟩	$\bar{\omega}$
Normal bonds, X = N			
All	3.25(18)	2.34(19)	156(16)
A	3.31(23)	2.35(23)	163(13)
B, large ω	3.28(11)	2.28(10)	178(4)
B, small ω	3.26(21)	2.36(20)	149(5)
Competing	3.22(12)	2.36(19)	144(12)[b]
16[c]	3.04	2.20	141
Normal bonds, X = O			
All	3.34(17)	2.58(18)	135(12)
H_2O, all	3.35(17)	2.58(18)	135(13)
H_2O, large ω	3.36(18)	2.50(17)	145(10)
H_2O, small ω	3.33(15)	2.65(17)	126(8)
Bifurcated bonds, X = N			
All	3.51(29)	2.92(40)	119(22)
Large ω[d]	3.47(21)	2.70(22)	136(16)
Small ω[d]	3.61(33)	3.21(37)	103(11)
Trifurcated bonds, X = N			
12 + **13**	3.84(53)	3.43(31)	109(23)
12 only	4.22(15)	3.71(15)	114(2)

[a]All = all appropriate values in Table 5; competing = bonds to a single acceptor ring under constraint in cations with multiple H-bond engagements (**12–15**); **A** = type **A** bonds in **1–4**, **6**, **7**, **20**; **B** = type **B** bonds in **8–11**. d(N—H) = 1.02 Å; d(O—H) = 1.00 Å.

[b]An ω value of 180° (**14**) excluded; if included, $\bar{\omega}$ = 148(16)°.

[c]Low-temperature structure determination.

[d]The corresponding means for the *shorter distances* (instead of large ω) are 3.33(20) and 2.69(12) Å, and for the longer distances (instead of small ω), 3.69(26) and 3.22(36) Å, respectively.

(0.06 Å^2 < U_{ii} < 1.14 Å^2, Table A), they are quite satisfactorily accounted for as arising from a rigid-body motion (RBM) of the cation: $R(U_{ij})$ = 5.1%, rms(U_{ij}) = 0.0037, rms[esd(U_{ij})] = 0.0020. The translation component of the RBM is practically isotropic, the mean principal displacements being ~0.25 Å. The mean amplitudes about the principal axes L_1, L_2, L_3 of libration are 6.2°, 10.1°, and 10.8°, respectively (Fig. 14). The component with the largest amplitude, about L_3, corresponds to a pivoting motion of the N—H vector about N between the C(α) and the C(δ) atoms of the associated ring; the librations about L_2 and L_1 pivot the N—H vector along a path approximately perpendicular to the N,C(α),C(δ) plane, also by significant amounts. In addition, the H(N) atom would ride on the N atom, which would extend the displacement range of the N—H vector even further. The conformity of the librational behaviour to the RBM model seems to indicate that the drag which the H bond would be expected to exert on the motion of the cation is either not appreciable or absorbed by the U_{ij} of the N atom or both. The combined effect of the three librational components thus confirms the one conclusion from the nmr study that can be verified by crystallography, viz. the N—H axis undergoes large-amplitude librations.

QTB and DaHTB

Stereochemically the two cations, HC(—CH_2CH_2—)$_3NH^+$ and N(—CH_2CH_2—)$_3NH^+$, differ only in minor respects, so it is not surprising to find that QTB and DaHTB are isostructural. The anions are of symmetry C_s, and the ion packing is of a distorted NaCl type. The H(N)...π bonding is of type **A** (Figs. 1 and 2).

The thermal motion of the cation is reasonably consistent with the RBM model (first number, QTB; second number, DaHTB): $R(U_{ij})$ = 10.1% (5.1%); rms (U_{ij}) = 0.0061 (0.0025); rms[esd(U_{ij})] = 0.0044 (0.0021); mean librational amplitude about L_1, 4.0° (5.0°); about L_2, 6.2° (6.2°); about L_3, 8.3° (8.0°)

[a] $\Delta = d_{max} - d_{min}$. Numbers in parentheses identify the carbon atoms in the original papers. For compound identification see Table 1.
[b] Symmetric bifurcation.
[c] Asymmetric bifurcation; also in **12–14**; asymmetric trifurcation in **12** and **13**.

(Fig. 15). The poorer fit for QTB probably stems from the lower-quality data for that crystal and not from a basic difference between the two cations.

It is noteworthy that DaHTB was obtained by recrystallization of a precipitate that had formed on adding a solution of $NaBPh_4$ to a solution of the amine neutralized by HCl to yield the *doubly protonated* $DabcoH_2^{2+}$ cation, in the expectation that the 1:2 tetraphenylborate might result (cf. Experimental). However, the final product was the TB of the *singly* protonated cation, $DabcoH^+$.

E2PiTBw

The $Et(iso\text{-}Pr)_2NH^+$ cation (Hünig's base) is of interest in that the packing of the alkyl groups round the N atom

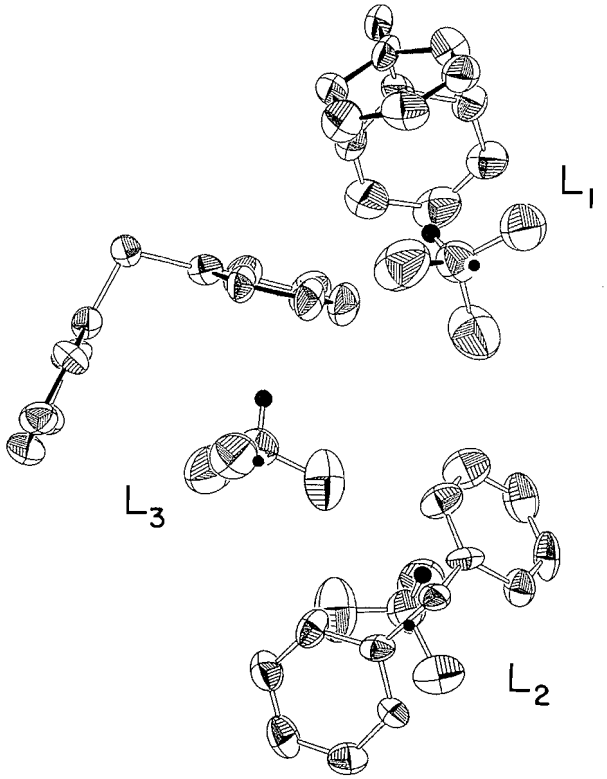

FIG. 14. Rigid-body libration of the cation in 3MTB. Projections down the principal axes of libration L_1, L_2, L_3. Large black circles, H(N); small black circles, points of intersection of the librational axes with the projection plane.

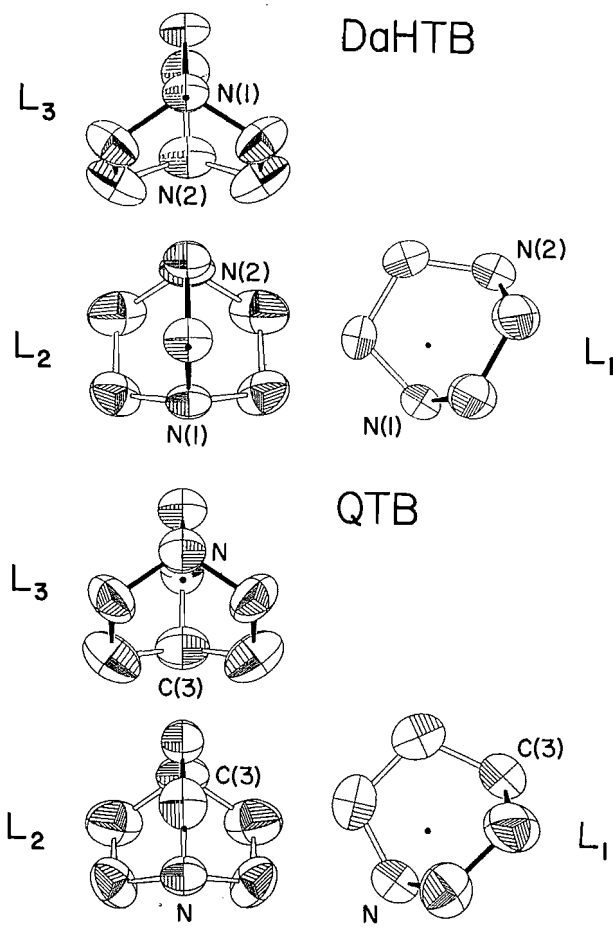

FIG. 15. Rigid-body libration of the cation in QTB and DaHTB (see caption of Fig. 14).

approaches the limit of sterical crowding in alkylammonium ions.

The arrangement of the B and N atoms in this orthorhombic structure can be related in a simple way to the NaCl-type packing. The unit-cell dimension a is, within $\frac{1}{2}$%, double the c dimension. Furthermore, the ratio $(\frac{1}{2}a\sqrt{2}):b:c\sqrt{2}$ is 0.999:0.998:1.003 when normalized to the mean, 14.193 Å. The positions of the B and N atoms are then found to be close to those that would be occupied by the ions in a fcc cells of a NaCl-type structure with $a \sim 14.19$ Å. This cell is bounded by planes parallel to (201), (20$\bar{1}$), and (010). The TB ions are bisected by 040 planes and approximately also by planes parallel to (201) or (20$\bar{1}$), i.e. the anion is of symmetry C_s but close to C_{2v}. Since the B and N atoms are the approximate centroids of the anions and of Et(*iso*-Pr)$_2$NH...OH$_2$ units, respectively, the ion packing may be formulated as an assembly of [cat...OH$_2$]$^+$[TB]$^-$ pairs with a NaCl arrangement.

The H bonding in E2PiTBw is of the symmetrically bifurcated **L** type (Fig. 5), with d(N...O) = 2.765(1) Å, $\bar{d}$(O...C) = 3.70(6) Å, and d(O...π_c) = 3.42 Å. The H(N) atom was placed geometrically; the hydrogens of the H$_2$O molecule could not be located.

The refinement of the cation required considerable care because of the disorder in the positions of some of the C atoms. This disorder is reminiscent of that encountered previously (1) in [Me$_2$C=NHMe]TB (**19**) and [Me$_2$C=NMe$_2$]TB (**28**) but is more complicated (Fig. 16). The N atom and three of the peripheral C atoms (C(2), C(6), C(6)′) are well fixed in the structure but the three C(α) atoms are disordered. The N atom and C(2), the C(β) atom of the ethyl group, are located on the mirror plane, but the C(α) of the ethyl group is clearly displaced well away (~0.7 Å) from the plane. Since C(6), a C(β) atom of the *iso*-propyl group, is well fixed in the structure and related to C(6)′ by the mirror, there must also be two alternative positions for the C(α) *iso*-propyl C atoms. This also requires two different positions for the second C(β) of the *iso*-propyl group attached to C(6).

1MPzBTB.Me$_2$CO

As explained in Experimental, the intended product was *N*-Me-piperazinium(2+) tetraphenylborate, [MeHN(—CH$_2$-CH$_2$—)$_2$NH$_2$]$^{2+}$[TB$^-$]$_2$. Unexpectedly, abstraction of a phenyl group from a TB cation resulted in a singly-charged cation containing a N—B bond, and ultimately in the above solvated salt (Fig. 2).

The length of the N—B bond, 1.683(8) Å, is in the general range of N—B bond lengths: the corresponding bond lengths in Ph$_3$B—NH$_2$Me and Ph$_3$B—NHMe$_2$ (both crystals $P2_1/c$; unpublished results) are 1.670(7) and 1.675(8) Å, respectively.

The simultaneous presence of the quasi-neutral Ph$_3$B—N group and of Ph$_4$B$^-$ in the structure affords us a comparison of their stereochemistries:

	Ph$_3$B—N (**6**)	Ph$_4$B$^-$ (**6**)	Ph$_4$B$^-$ (overall)
$\bar{d}$(B—C), Å	1.618(11)	1.653(9)	1.646(18)
⟨C—B—C⟩, $\bar{\alpha}$	112.3(33)°	111.7(1)°	104.4(17)°
⟨C—B—C⟩, $\bar{\alpha}'$	112.3(33)°	108.4(8)°	112.1(12)°
⟨C—B—N(2)⟩	106.5(8)°	—	—
⟨C(2)—C(1)—C(6)⟩	114.9(3)°	114.6(9)°	

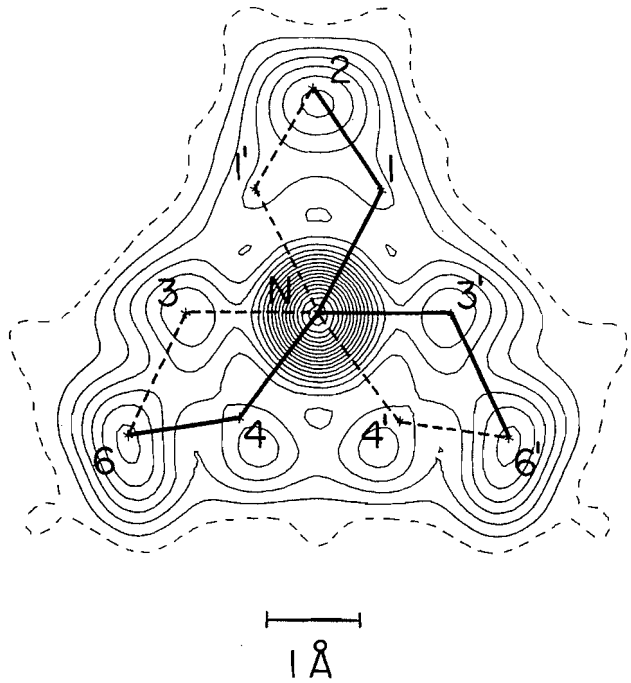

FIG. 16. Electron-density map of the cation in E2PiTBw (**5**) in the plane defined by the atoms 1 = C(1), 3 = C(3), and 3′ = C(3)′. The alternative orientations of the disordered cation are shown. Contour intervals, 0.25 e/Å^3.

(for the meaning of α and α′ and for the overall means in the anion see below). The shortening of the B—C bond in the cation is significant. It is curious that in the anion of **6** the mean C—B—C valence angle $\bar{\alpha}$ is larger than the mean conjugate angle $\bar{\alpha}'$. The opposite is observed in all the other quasi-D_{2d} TB anions discussed in the relevant section below.

The N(1)—H(N1)...π_c(12) bond is of type **A**. The second *N*-hydrogen of the cation is engaged in a weak normal H bond to the O atom of the acetone molecule, N(2)—H(N2)...O: *d*[N(2)...O] = 3.09 Å, *d*[H(N2)...O] = 2.11 Å.

2MTB.MeCN and 2MTB.Et$_2$CO

The TB precipitates that form on combining the requisite reagent solutions are microcrystalline and must be recrystallized to obtain crystals suitable for X-ray diffraction. In this 2MTB is no exception. The products of recrystallization from both MeCN and Et_2CO were solvated, which would suggest that the initial precipitate (from H_2O or EtOH/H_2O solution) also was solvated, and that unsolvated 2MTB, if it does form, does not do so readily. Attempts to prepare the unsolvated salt have therefore been abandoned, at least for the present.

The crystal packing in 2MTB.MeCN may be described, probably not very usefully, as of a highly distorted NaCl type. The hydrogen bonding of the cation is of type **C** (Fig. 1): one H(N) is involved in a bond to a phenyl ring, N(1)—H(N11)...π_c(3), while the other forms a bond to the N atom of the MeCN molecule (N(1)—H(N12)...N(2), *d*[N(1)...N(2)] = 2.89(1) Å, *d*[H(N12)...N(2)] = 1.90 Å, N(1)—H(N12)—N(2) ~ 161°, Fig. 2).

In contrast to 2MTB.MeCN, the solvent molecule in 2MTB.Et_2CO is not involved in H bonding. Each H(N) is bonded to a phenyl ring of the same anion (type **B**, Fig. 1), though not symmetrically (Fig. 3).

A recent ^{2}H nmr study (26) of the precipitate from aqueous (D_2O) solutions of Me_2ND_2Cl and $NaBPh_4$ indicated that between 215 and 245 K the Me groups undergo rapid C_3 jumps about their respective C—N axes. Between 250–300 K the detailed reorientational behaviour of the cation could not be clearly determined, but above 320 K the complete cation exerts also rapid C_2 jumps about its C_2 axis. The latter behaviour would be consistent with a type **B** situation, but in view of what is said above the exact composition of the precipitate and hence the nature of the cation environment cannot be regarded as known, so the structural interpretation of the C_2 cation reorientation in that material must await further clarification.

2ETB, 2PiTB, and AC7TB

The ion packing in AC7TB ($P2_1/m \subset Cmcm$) is of a distorted NaCl type; in 2ETB and 2PiTB the packing could be regarded as of a highly distorted zincblende type, although it is probably better described as a transition type between ZnS and NaCl.

The hydrogen bonding in all three crystals is of type **B** (Fig. 3): 2ETB, N—H(N1)...π_c(1), N—H(N2)...π_c(3); 2PiTB, N—H(N1)...π_c(2), N—H(N2)...π_c(4); AC7TB, N—H(N1)...π_c(2), N—H(N2)...π_c(3).

While the mean conformation of the 7-membered ring cation in AC7TB is of C_s symmetry, the large U_{ii} values of the C atoms more distant from the N atom indicated the presence of disorder. Treating the C(2) and C(3) atoms as if in twofold orientational disorder with respect to the crystallographic mirror plane significantly reduced the U_{ii} of these atoms, even though some of them still remain large (Table A).

GTBw

This is the most interesting structure of the fifteen in the context of this investigation. The presence of three pairs of H(N) hydrogens in the trigonal, essentially planar $C(NH_2)_3^+$ cation plus the water molecule of hydration (all atoms in general positions) would lead us to expect a variety of hydrogen-bond types, especially since the NH_2 groups are geometrically fixed relative to one another. Faced with the multiple bonding choices, the cation must thus find a compromise situation in which its tendency to formation of hydrogen bonds to the anions and to the water molecule is, on the average, only imperfectly satisfied. Thus while *all* the H(N) and H(O) atoms are found to be engaged in hydrogen bonding, with the exception of N—H(N11)...O, N—H(N12)...π_c(2), O—H(O1)...π_c(1), and O—H(O2)...π_c(2) all the H bonds are branched, with presumed trifurcation in N—H(N22)...3π (Fig. 6, Tables 5 and 7). Beside some of the types illustrated in Fig. 1 the structure contains an example of type **L′** bond, in which the water oxygen is approximately tetrahedrally coordinated by four hydrogens (H(O1), H(O2), H(N11), and H(N32); Fig. 17). The H(N32) atom is involved in a bifurcated bond to ring 4 (cf. Fig. 6). The H—O—H angles in this coordination range from ~92° to ~147°, with a mean of 111(2)°.

The skeleton planes of the disc-like guanidinium cations, the B atoms, and the O atoms are all arranged in planes ||(100) (at $z \sim \pm\frac{1}{4}$), which accounts for the length of the *c* dimension of the unit cell. These planar slabs also contain the H bonds, although some cross-linking occurs through branched components of a few of the bonds.

The cation skeletons are planar (mean deviation $\bar{d}$(C, N) from the best plane, 0.005 Å; Table D) and rigid. A TLS analysis of the thermal motion of the cation reveals a surprising degree of compliance with the RBM model and a considerable librational freedom in spite of the H bonding: $R(U_{ij})$ = 2.6%,

rms(U_{ij}) = 0.0025, rms[esd(U_{ij})] = 0.0039; mean amplitudes about the three principal axes of libration, 8.3° about L_1, 10.4° about L_2, and 12.2° about L_3 (Fig. 18). The translation motion is essentially isotropic, with mean principal displacements of ~0.25 Å.

1MTB and 1ETB

In these crystals the cation is situated between two pairs of phenyl rings, each pair from a different anion (Figs. 4 and 7). This arrangement is reminiscent of ImC (Fig. 5 of ref. 1).

The cation is H-bonded to all four rings by bonds of different types. In 1MTB the H(N2) atom is involved in a type **A** bond to ring 4A; H(N1) forms a bifurcated bond to rings 1B and 3B; and the bonding of H(N3) is probably best described as trifurcated, to rings 1B, 2A, and 4A (cf. Tables 5, 7, and C for interatomic distances). The boron atoms and the ethane-like cations are arranged in sheets ||(100) in such a way that strings of H-bonded ...an...cat...an...cat... sequences run parallel to (011) in the sheets at $z \sim \frac{1}{4}$ and parallel to (0$\bar{1}$1) in the sheets at $z \sim \frac{3}{4}$ (Fig. 19). These sheets are separated by the van der Waals surfaces of the phenyl rings, so that the whole arrangement can be regarded as a

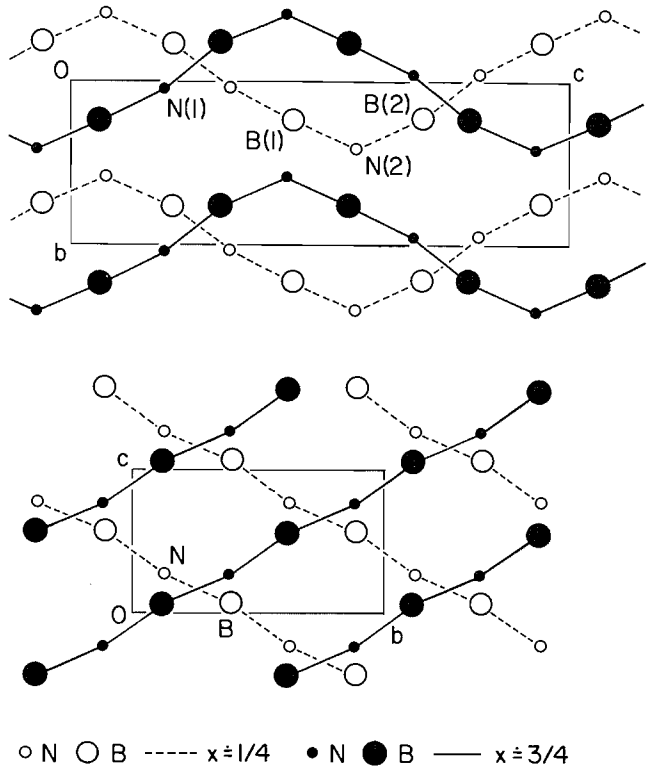

FIG. 19. Organization of H-bonded ...an...cat...an...cat... sequences in sheets ||(100) in 1MTB (bottom) and 1ETB (top). Drawing schematic but to scale. Labelled circles, atoms with coordinates as listed (Table A). Note the nonequivalent N and B atoms in 1ETB.

molecular crystal consisting of stacks of electroneutral infinite cation–anion sheets in the direction perpendicular to (100).

The organization of the H-bonded cations and anions in 1ETB is similar, but instead of essentially straight ...an...cat...an...cat... strings the ions in a sheet are arranged in zigzag chains with a period |cat(2)...an(1)...cat(1)...an(2)| (Fig. 19). As a consequence the cations now have two types of H-bond environment, at N(1) and N(2). Furthermore, cat(2), which is at the turning point in the zigzag chain, is subject to twofold orientational disorder, with the result that N(2) can engage in either of the two alternative sets of H bonds (Fig. 7). At N(1) there are three N—H(N)...π bonds, one each of types **A**, **F**, and **J**; at N(2) there are two alternative sets of such bonds, one each of types **A**, **E**, and **F**.

The relationship of the arrangements of the B and N atoms in 1MTB and 1ETB is seen when the upper half ($\frac{1}{2} \leq c \leq 1$) of the 1ETB cells is reflected in the (020) plane and the two halves are joined along (002) after the cation–anion strings have been brought into smooth continuation by suitable translation and scaling adjustments. The resulting arrangement corresponds to the 1MTB cell doubled along its *b* axis. This relationship is reflected in the dimensions of the two unit cells: *a*(1ETB) ~ *a*(1MTB), *b*(1ETB) ~ *c*(1MTB), *c*(1ETB) ~ 2*b*(1MTB). The difference V_1(1ETB) − V_1(1MTB) between the volumes per fomula unit of the two compounds is ~27 Å^3, consistent with the average volume increment per CH_2 (see below).

The conclusion from a variable-temperature ^{2}H nmr study of 1MTB (26) is that in the experimental temperature interval 158–298 K the ND_3 and CD_3 groups undergo rapid C_3 jumps about the C—N axis. At the upper end of this interval the correlation times τ are in the ps range, and the activation energy E_a

Can. J. Chem. Downloaded from www.nrcresearchpress.com by EESC ESCOLA DE ENGENHARIA on 09/08/12

for the C_3 reorientation of the ND_3 group is 4.1(5) kJ/mol, comparable to that in $MeNH_3ClO_4$. Motion of the C—N axis appears to be restricted to large-amplitude librations. This last conclusion is consistent with the large U_{ii} values of the N and C atoms in the cation (Table A). The low E_a value for the C_3 reorientation of the ND_3 group is somewhat surprising in view of the N and H(N2) to ring 4A distances, which are short compared to the total distribution of distances in our sample (Tables 5 and 7, Figs. 12 and 13), i.e. correspond to a H-bond energy at the high end of the N—H...π sample. In fact, points for the H(N2)...π_c(4A) and H(N1)...π_c(1B) appear to lie outside the main body of the sample distribution, so that the obliqueness of the N—H...π_c angle may play a role.

AdTBw

This compound, like 1ETB, contains two sets of cations and two sets of anions (Fig. 8). The structure ($P2_1/m \subset Cmcm$) may be viewed as having a very obliquely distorted zincblende-type packing. Each of the two N atoms is engaged in two normal (type **A**) bonds and a type **L** bond, so that an N atom is involved both in normal N—H(N)...π and normal N—H(N)...O bonding.

Although adamantane is a cage-like entity, the cations conform poorly to the RBM model, regardless of whether the N atom is excluded from or included in the TLS analysis:

	$R(U_{ij})$	rms(U_{ij})	L_1	L_2	L_3	T
cat(1) (ex N)	14.0%	0.0095	3.0°	5.3°	7.1°	0.2 Å
(in N)	13.8%	0.0092	3.5°	5.1°	7.1°	0.2 Å
cat(2) (ex N)	10.4%	0.0063	3.5°	3.7°	8.8°	0.25 Å
(in N)	10.7%	0.0063	3.4°	3.8°	8.8°	0.25 Å

(L_1 stands for the mean librational amplitude about the principal libration axis L_1 etc.; T, mean translational displacement).[17]

Comments and conclusions

Tetraphenylborate anion

The fifteen crystal structures of Tables 2–4 contain 17 distinct TB anions, of which four (**3–5**, **11**) are of symmetry C_s and 13 of symmetry C_1. However, most of these anions retain conformations close to D_{2d} or C_{2v} in spite of the chemical and geometric diversity of the counter cations. Notably, the two C—B—C valence angles α, which in the D_{2d} conformation are bisected by the S_4 axis (resulting in α_1 and α_2 in C_{2v}) and which are defined by two pairs of C(α) atoms with non-repeating labels (e.g. C(1)—B—C(3) for α_1 and C(2)—B—C(4) for α_2), persist as the two smallest C—B—C angles of the six in the anion. The mean of the difference between α_1 and α_2 is only 2.1°. The conjugate C—B—C valence angle α′ is significantly larger than α.

The means (uncorrected for thermal motion) for the B—C bond length, α, α′, and the endocyclic C—C—C angle at the C(α) carbon[18] in **1–15** *plus* the iminium TBs **19–22** and **28** *plus* 4MTB (**17**) are $\overline{d}$(B—C) = 1.646(18) Å (n = 88, γ_1 = 0.81, γ_2 = 4.49), $\overline{\alpha}$ = 104.4(17)° (n = 47, γ_1 = 1.05, γ_2 = 4.55), $\overline{\alpha'}$ = 112.1(12)° (n = 92, γ_1 = −0.47, γ_2 = 5.60), ⟨C(2)—C(1)—C(6)⟩ = 115.0(9)° (n = 83, γ_1 = −0.06, γ_2 = 5.87). These values compare with the respective means for **17**, **19–22**, and **28** (1), 1.640(20) Å, 104.0(10)°, 112.8(13)°, and 114.7(6)°, i.e. the two sets of data are statistically indistinguishable.

The planarity of the 60 phenyl ring skeletons in **1–14** is satisfactory. The mean deviation $\overline{d}$(C) of the C atoms from the best planes through the ring skeletons is 0.007(4) Å, i.e. comparable to that for the five iminium salts (1). The deviations δ(B) of the boron atoms from their respective ring planes are listed in Table D, which also contains the interplane angles.

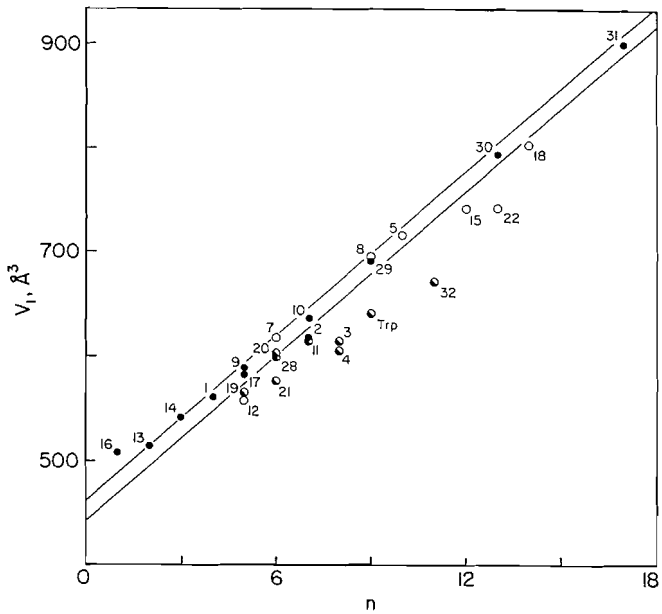

FIG. 20. Volume per formula unit V_1 plotted against the number n of nonhydrogen atoms (C, N, O, but excluding the anion atoms) per formula for compounds of Table 1 (for Trp see footnote 20). Full circles, alkyl cations, unsolvated compounds; half-full circles, cations deficient in hydrogen, unsolvated compounds; open circles, solvated compounds (see text). Only points **12** and **29–31** are included in the regression of V_1 on n. Vertical width of the regression band, 6σ of regression.

Volume relationships and solvation

When the volume V_1 per formula unit for the unsolvated tetra-*n*-alkylammonium TBs 4MTB (**17**), 4ETB (**29**), 4PnTB (**30**), and 4BnTB (**31**)[19] is regressed on the number n of C+N atoms in the cation, an excellent straight line results (Fig. 20): $V_1 = 452(4) + 26.4(3)n$, $r^2 = 1.000$, σ = 3 Å ~ 1% of V_1 range. The intercept of this line (n = 0) may be taken as an estimate of the effective volume of the TB^- anion in *n*-alkylammonium TB crystals. Points for most of the other unsolvated *n*-alkyl $R_nNH_{4-n}^+$ ($n \neq 4$) TBs of Table 1 fall within the ±3σ limits of the regression line. The exceptions are 3ETB (**2**), which is significantly outside these limits, and ATB (**16**), which for its n is overhydrogenated, as are 1MTB and 1ETB, though to a lesser extent. The number of H(N) atoms thus seems to be a factor, i.e. H bonding plays a role.

[17]Compare ref. 54 for a discussion of the analysis of segmented RBM.

[18]In **15** the rings were constrained to regular hexagons, see Experimental.

[19]The crystal data (unpublished) for compounds **29–32** are as follows: 4ETB, a = 9.930(3) Å, c = 24.308(8) Å, V = 2076(4) Å^3, Z = 3; 4PnTB, a = 20.199(4) Å, b = 16.391(2) Å, c = 11.810(3) Å, β = 125.77(2)°, V = 3173(2) Å^3, Z = 4; 4BnTB, a = 10.202(5) Å, b = 18.710(8) Å, c = 20.756(10) Å, α = 69.26(4)°, β = 86.21(4)°, γ = 76.45(4)°, V = 3601(6) Å^3, Z = 4; AzPpTB, a = 9.903(2) Å, b = 19.897(2) Å, c = 13.630(2) Å, β = 92.33(1)°, V = 2684(2) Å^3, Z = 4.

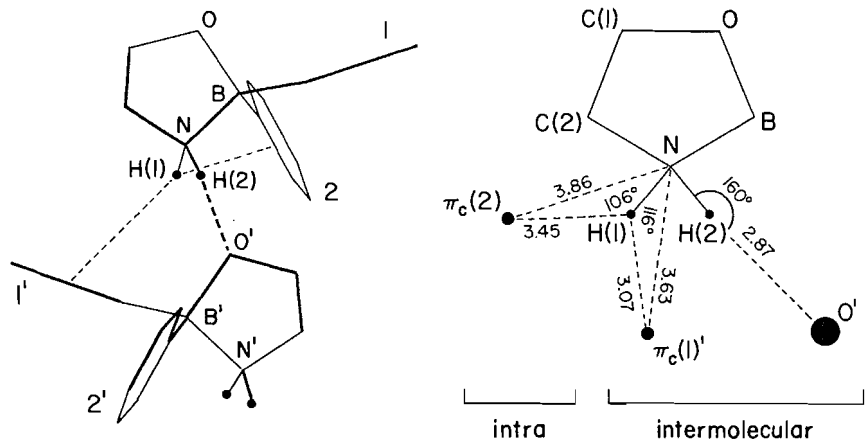

FIG. 21. Hydrogen bonding in *B,B*-Ph_2boroxazolidine (**27**). H(1) and H(2) are H(N) and H(N'), respectively, of ref. 52; rings 1 and 2 are defined, respectively, by carbon atoms C(3)—C(8) and C(9)—C(14) of that reference.

Points for the remaining unsolvated TBs all fall below the regression line, most of them considerably below the -3σ limit. The cations in these TBs contain either a double bond (**19–21**, **28**), a ring (**11**), or a cage (**3**, **4**, **32**; also tropanium TB),[20] i.e. they are all deficient in hydrogen relative to the *n*-alkyl compounds with the same *n* value. The deviations of these points from the regression line are roughly proportional to the H deficit. This leaves the monohydrates E2PiTBw (**5**), GTBw (**12**), AdTBw (**15**), 3BnTBw (**18**), ImEw (**22**), and the monosolvated **7** and **8**, as well as the question, can a criterion of the tendency to solvation of the TBs be formulated?

Of the cations in the five monohydrates only those in **5** and **18** are *n*-alkylammonium ions; the cation in **22** contains a double bond *and* a phenyl ring, that in **15** contains a cage, and the $C(NH_2)_3^+$ ion in **12** is H-deficient, disc-like and rigidly compact. If allowance is made for these features and *n* is increased to *n* + 1 to take account of the H_2O oxygen, the point for **5** in Fig. 20 falls on the regression line, the point for **18** is slightly below the -3σ limit, and the points for **12**, **15**, and **22** are now significantly below the -3σ limit, in accordance with the expectation for H-deficient cations. Furthermore, the points for the two nonaqueous solvates of 2MTB, **7** and **8**, fall within the $\pm 3\sigma$ regression band when their *n* are adjusted to include the nonhydrogen atoms of the two solvent molecules, MeCN and Et_2CO, respectively.

These observations suggest that whatever the specific reason for solvation (awkward cation shape, inefficient packing), the V_1/n(C+N+O) ratio in a particular solvate structure remains constant and equal to ~26 Å^3 per nonhydrogen atom outside the BPh_4^- anion, i.e. the same as the slope of the above regression line. However, in TBs with a reduced H-atom complement V_1 is decreased, on the average, by ~12 Å^3 per "missing" H atom in the cation (unsolvated structures) and by about 5 Å^3 per "missing" H atom in the cation *and* solvent units (solvated structures).

Unrecognized or unreported X—H...π bonds

As pointed out in the introductory section, the presence of a H bond to an aromatic π system may not always have been noticed, even though the published crystal-structure determination contains, implicitly, evidence of such a bond. This situation in fact appears to occur more frequently than might be supposed (cf. ref. 55). Since this paper is not intended to be an enchiridion of N—H...π bonds, we have not attempted (with the exception of TBs) a systematic literature search for such unrecognized or unreported bonds, especially since an exhaustive search of the Cambridge Structural Data Base for N—H...π and possibly other X—H...π bonds already is underway (55). However, we should like to draw attention to a particularly interesting but less than obvious example, that of a heterodesmic bifurcated N—H...2π bond in *B,B*-Ph_2-boroxazolidine (**27**). Determination of the crystal structure of this compound was undertaken for other chemical reasons, namely to demonstrate the existence of a 5-membered heteroatomic ring in this molecule (52). Besides succeeding in this demonstration, the authors noted that one of the two H(N) atoms is involved in an intermolecular N—H(N)...O bond of moderate strength. However, it appears that the second H(N) also is engaged in a H bond. The interesting feature of this bifurcated N—H(N)...2π bond is that it involves an intermolecular *and* an intramolecular interaction (Fig. 21), at N...π_c and H(N)...π_c distances that may seem marginal (Tables 5 and 7). Referring to this situation as H bonding would probably have appeared contentious at the time; even today one might hesitate to regard the N,H(N),Ph grouping as H-bonded if it were not for the suggestive geometry and for having the benefit of the general N—H(N)...π scheme such as is now available in Figs. 1, 12, and 13.

Conclusions

The crystal structures of the TBs **1–15** (Table 1) contain a variety of normal and branched N—H...π bonds as well as of normal O—H...π bonds. These bonds are classified in Figs. 1 and 17. Together with the bonds in the other structures of Table 1 they constitute a sample which is sufficiently large and homogeneous to permit a number of general observations on the characteristics of X—H...π(arene) bonds in crystals.

An N—H...π bond in the TBs is established whenever opportunity arises. Only strongly competing interactions (e.g. N—H...OH_2, N—H...N≡C—, N—H...Cl^-) or exceptionally unfavourable packing will engender other bonding engagements. Where the overall organization of the crystal structure offers to the H(N) atom more than one choice of phenyl accep-

[20]Tropanium TB = 8-Me-8-azoniabicyclo[3.2.1]octane TB, $C_8H_{16}N^+TB^-$, *C2/m*, *a* = 15.866(4) Å, *b* = 11.873(4) Å, *b* = 13.625(4) Å, β = 92.58(3)°, *V* = 2564(2) Å^3, *Z* = 4 (unpublished result).

tor, orientational disorder may occur between two equivalent or near-equivalent H-bonding situations. An alternative to disorder is the formation of a bifurcated (occasionally trifurcated) H bond, which provides a (partially dynamic) compromise between orientations that otherwise would constitute the components of a disorder. Temperature lowering may resolve the compromise solutions, bifurcation and dynamic disorder, into unambiguous normal bond arrangements, possibly with simultaneous occurrence of a crystallographic transition.[15]

The presence of a solvent molecule in a TB structure may result in the formation of a heterodesmic H bond, such as in types **C**, **G**, and **K** (Fig. 1), or in the formation of a type **L** or **L′** bond (Figs. 1 and 17), in which a H(N) hydrogen is bonded to a phenyl ring via an H_2O molecule. In the last-named situation the relation of the H_2O molecule to the ring is quite different from that considered in studies of the isolated H_2O–C_6H_6 complex: in a crystal the direction of the O—H(O) vector(s) is constrained by packing and the overall organization of the crystal structure, so that the geometry of the O—H(O)...ring grouping is determined not solely by the energy-minimization requirement of this grouping alone, as it would be in the isolated H_2O–C_6H_6 pair. However, the distances O...π_c to the centre of the phenyl ring in the crystal are in the same range as the O...π_c distances estimated for the H_O–C_6H_6 complex; in the present sample statistically meaningful distinction cannot be made between the distances implicit in the O—H(O)...π_c and N—H(N)...π_c bonds.

The means of the N...π_c and H(N)...π_c distances in the normal N—H(N)...π bonds of the TBs are 3.25(18) and 2.34(19) Å, respectively. The distributions of the distances in the normal and the branched bonds have been analyzed in detail.

The individual crystal structures exhibit many interesting features in their own right. The ion packing in the unsolvated TBs is either of a distorted NaCl or a distorted zincblende type. A structure of particular interest is that of the guanidinium TB hydrate: all six H(N) atoms of the cation participate in H bonding to the phenyl groups or to the water molecule (Fig. 6). The guanidinium skeleton in GTBw offers a textbook example of a unit conforming to the rigid-body-motion model, in spite of the extensive involvement of the cation in hydrogen bonding.

Experimental

Preparation

The title compounds were prepared by combining an aqueous solution of $NaBPh_4$ with an aqueous or ethanolic solution of the requisite organic ammonium halide at room temperature. The resulting precipitate of the tetraphenylborate was filtered, washed, and recrystallized from a suitable solvent (water/acetone, Et_2CO, MeCN, MeOH) by evaporation at room temperature. The recrystallized salt was unsolvated (**1–4**, **9–11**, **13**, **14**) or monosolvated (**5–8**, **12**, **15**).

The formation of DaHTB and 1MPzBTB.Me_2CO calls for special comment. Since the original intention was to see if it was possible to obtain crystalline $DabcoH_2^{2+}(TB^-)_2$, an aqueous solution of Dabco = $N(—CH_2CH_2—)_3N$ was neutralized with HCl to $HN(—CH_2CH_2—)_3NH^{2+}$ and aqueous $NaBPh_4$ was added to give a $DabcoH_2^{2+}$:TB^- ratio of 1:2. In spite of this solution stoichiometry the precipitate that formed was $DabcoH^+TB^-$, not $DaH_2^{2+}(TB^-)_2$. The circumstances of this process as a means of controlling stoichiometry are being investigated, with a view to practical application.

In the case of 1MPzBTB.Me_2CO, the intended product was $[MeHN(—CH_2CH_2—)_2NH_2]^{2+}(TB^-)_2$. Considering the reluctance of Dabco to form the diprotonated 1:2 salt, one would not have been surprised to obtain an analogous result with *N*-Me-piperazine, i.e. a 1:1 instead of the 1:2 salt. However, either in the initial precipitation or on recrystallizing by evaporation from water/acetone solution *at room temperature*, elimination of a phenyl ring from a TB^- anion as benzene must have taken place, resulting in the formation of the solvated 1MPzBTB.Me_2CO salt. While it is known that the TB^- anion in alkylammonium salts, when heated in solution or on pyrolysis, can lose a phenyl ring and form a B—N bond, it is unexpected to find that this process should occur under room-temperature conditions.

Structure determination

The general details of the structure determinations will be found in ref. 1; particulars are listed in Tables 2–4 and under the individual crystal structures, otherwise as below.

We wish to reiterate that in general organic ammonium tetraphenylborate crystals are weak and fickle scatterers. As pointed out previously (1), significant reflections were seldom observed above a $(\sin\theta)/\lambda$ limit of 0.48 $Å^{-1}$ ($\theta = 20°$ for Mo radiation). Since in this laboratory X-ray data collection routinely extends to a limit of 0.55 $Å^{-1}$ ($\theta = 23°$), the ratios of observed reflections to total measured unique reflections never exceeded 50%. When attempts were made to collect the data at lower temperatures they produced little if any improvement in these ratios. However, a worthwhile improvement in the volume and quality of usable reflections was obtained for QTB by substituting Cu for Mo radiation.[21] Low-angle reflections were examined for possible second-order intensity leakage from their respective *2h2k2l* homologues.

Tables of structure factors are available from the Editorial Office (Tables E–U).[16]

Systematic absences. Pnma (**3–5**): 0*kl*, *k+l* odd; *hk*0, *h* odd; *h*00, *h* odd; 0*k*0, *k* odd; 00*l*, *l* odd. $Pna2_1$ (**13**): 0*kl*, *k+l* odd; *h*0*l*, *h* odd; *h*00, *h* odd; 0*k*0, *k* odd; 00*l*, *l* odd. $P2_12_12_1$ (**9**): *h*00, *h* odd; 0*k*0, *k* odd; 00*l*, *l* odd. *P2/c* (**14**): *h*0*l*, *l* odd; 00*l*, *l* odd. $P2_1/m$ (**11**), $P2_1$ (**1**, **2**, **15**): 0*k*0, *k* odd. $P2_1/c$ (**12**): *h*0*l*, *l* odd; 0*k*0, *k* odd; 00*l*, *l* odd. $P2_1/a$ (**7**): *h*0*l*, *h* odd; 0*k*0, *k* odd; *h*00, *h* odd. $P2_1/n$ (**6**, **8**, **10**): *h*0*l*, *h+l* odd; 0*k*0, *k* odd; *h*00, *h* odd; 00*l*, *l* odd.

Weighting schemes. Unit weights: **1**, **2**, **4–9**, **12**, **13**. SHELX weights, $w = p/[\sigma^2(F) + qF^2]$: **11** ($p = 2.360$, $q = 0.000485$), **14** ($p = 1.506$, $q = 0.0100$), **15** ($p = 3.024$, $q = 0.00103$). Sigma weights (see under compound **C** of ref. 1): **3**, **10**.

Location of hydrogen atoms. The H(C) atoms were placed geometrically and refined isotropically or not refined (Tables 2–4). Similar procedure was followed for H(N) in cations containing one or two hydrogen atoms on the nitrogen; in some cases evidence of the H(N) atom was seen in the difference map. In 1MTB, 1ETB, and AdTBw, in which there are three H atoms on the nitrogen, at least one H(N) was located from a difference map and the others were generated geometrically. The N—H distances were then constrained to 1.02 Å and kept fixed during the refinement. The hydrogens of the water molecules were located from the difference map, the O—H distances were then constrained to 1.0 Å and kept fixed in the refinement.

Other comments. The problem of cation disorder in E2PiTBw has been dealt with above (cf. Fig. 16). In the refinement of the AdTBw structure the phenyl-ring skeletons were constrained to regular hexagons, hence all the endocyclic C—C—C angles were fixed at 120°.

Acknowledgments

We thank Mr. Pierre Losier and Professor Neil Burford for the crystal of 2PiTB; Dr. Witold Kwiatkowski for calculating the net charges; and Professor R.J. Boyd and Mr. Jian Wang for supplying us with the graphs of the electron-density distribution in the benzene molecule. This investigation was supported by grants from the Natural Sciences and Engineering Research Council of Canada to the two last-named authors.

Appendix

The Mulliken net charges in the 6-31G* optimized NH_4^+ ion are $\epsilon_M(N) = -0.951$ e and $\epsilon_M(H) = 0.488$ e, and in CH_4, $\epsilon_M(C) = -0.660$ e and $\epsilon_M(H) = 0.165$ e (56). The corresponding Löwdin net charges ϵ_L are -0.489 and 0.372 e in NH_4^+, and -0.630 and 0.158 e in CH_4. In H_2O the charges are $\epsilon_M(O) = -0.869$ e and $\epsilon_M(H) = 0.434$ e.

The MNDO net charges in BPh_4^- (in the S_4 conformation corresponding to the global energy minimum) are -0.233 e on B, 0.048 e on C(α), -0.085 e on the other C atoms (mean), and 0.037 e on the H atoms (mean); in CPh_4 they are 0.149 e on the central carbon, -0.066 e on C(α), -0.054 e on the other carbons (mean), and 0.060 e on the H atoms (mean). The corresponding AM1 net charges in BPh_4^- are 0.054, -0.040, -0.155, and 0.110 e, respectively; in CPh_4 they are 0.114, -0.064, -0.128, and 0.135 e, respectively.[22] Thus the difference in the net charges on the corresponding C and H atoms (other than C(α)) in the charged species BPh_4^- and the neutral species CPh_4 are relatively small and justify qualitative comparisons of hydrogen bonding to phenyl rings carrying an ionic charge (BPh_4^-) with that to phenyl rings in molecular crystals.

WILLIAM R. CULLEN, STEVEN J. RETTIG, and EUGENE B. WICKENHEISER. Can. J. Chem. **72**, 1294 (1994).

Bis(μ-*t*-butylacetato)bis(norbornadiene)dirhodium(I) **1** is prepared by a reaction between pivaloyl camphor and (norbornadiene)rhodium(I) chloride dimer. A molecular rearrangement takes place in which the pivaloyl groups of the pivaloyl camphor starting material are incorporated into the end product as bridging *t*-butylcarboxylate ligands. A variable temperature ^{1}H NMR study and corresponding dynamic computer fit of the NMR data, and crystal structure are reported for the structurally nonrigid dimer. Crystals of **1** are triclinic, $a = 10.454(1)$, $b = 10.817(1)$, $c = 12.424(1)$ Å, $\alpha = 64.904(7)$, $\beta = 100.320(7)$, $\gamma = 109.382(8)°$, $Z = 2$, space group $P\bar{1}$. The structure was solved by heavy atom methods and was refined by full-matrix least-squares procedures to $R = 0.070$ and $R_w = 0.081$ for 3093 reflections with $I \geq 3\sigma(I)$.

WILLIAM R. CULLEN, STEVEN J. RETTIG et EUGENE B. WICKENHEISER. Can. J. Chem. **72**, 1294 (1994).

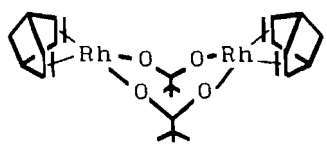
On a préparé le bis(μ-*tert*-butylacétato)bis(norbornadiène)dirhodium(I), **1**, par réaction du pivaloyl camphre avec le chlorure de (norbornadiène)rhodium(I) à l'état dimère. Il se produit un réarrangement moléculaire au cours duquel les groupes pivaloyles du pivaloyl camphre s'incorporent dans le produit final sous la forme de coordinats *tert*-butylcarboxylates agissant comme ponts. On rapporte les résultats d'une étude rmn du ^{1}H et de l'ajustement dynamique des données rmn correspondantes ainsi que la structure cristalline du dimère de structure non rigide. Les cristaux du composé **1** sont tricliniques, $a = 10{,}454(1)$, $b = 10{,}817(1)$, $c = 12{,}424(1)$ Å, $\alpha = 64{,}904(7)$, $\beta = 100{,}320(7)$, $\gamma = 109{,}382(8)°$, $Z = 2$ et groupe d'espace $P\bar{1}$. On a résolu la structure par la méthode aux atomes lourds et on l'a affinée par la méthode des moindres carrés jusqu'à des valeurs de $R = 0{,}070$ et $R_w = 0{,}081$ pour 3093 réflexions avec $I \geq 3\sigma(I)$.

[Traduit par la rédaction]

Introduction

There are several reasons for the ongoing interest in binuclear transition metal complexes, ranging from theoretical studies of metal–metal interactions, and spectroscopic, magnetic, and structural modelling of biological molecules, to their involvement in catalytic processes (1–14). Complexes in which two metal centres are closely situated may exhibit the cooperative catalytic effects of two metals in the activation and reaction of the substrate molecule (15–21). The catalytic activity can also reflect the reactivity of metal cluster compounds, a bimetallic complex being the smallest imaginable cluster. Complexes of carboxylate ligands are usually found as bridged dimers and as such lend themselves to the preparation of bimetallic compounds. The bridging mode is common for the transition metal carboxylates; the preferred conformation is the hinged form (22) in which the two metals are brought into close proximity, allowing metal–metal interactions in the case of $Rh_2(O_2CR)_4$ compounds (1–3, 23, 24). Transition metal dimers with carboxylate ligands are a reasonably stable class of molecules with potential for catalytic activity, and thus have been studied as catalyst precursors and as synthetic precursors for other classes of molecules (6, 25–31).

Of the bridged-carboxylate complexes that have been prepared, some have been observed to be sterically nonrigid, or evidence exists suggesting this property (4, 32, 33). Studying the associated molecular motion can yield insight into the nature of the species and the interactions between the atoms making up the molecule. The focus of this paper is the characterization and quantification of the nonrigid behaviour of a dirhodium complex, bis(μ-*t*-butylacetato)bis(norbornadiene)-dirhodium(I), **1**, manifest in its temperature-dependent ^{1}H NMR spectrum.



1

Experimental

The preparation of the dimer was carried out under a nitrogen atmosphere, using standard Schlenk and vacuum line techniques. Ether and hexane were distilled from calcium hydride prior to their use in the reactions. The (norbornadiene)rhodium(I) chloride dimer and pivaloyl-(+)-camphor were prepared by literature methods (34, 35).

Preparation of bis(μ-t-butylacetato)bis(norbornadiene)dirhodium, ***1***

A suspension of the (norbornadiene)rhodium(I) chloride dimer (100 mg, 217 μmol) and pivaloyl-(+)-camphor (110 mg, 493 μmol) in 20 mL of diethyl ether, was prepared, cooled to −78°C, and a solution of potassium hydroxide (120 mg, 2.1 mmol), in 2 mL of water, was added dropwise. The mixture was stirred at −78°C for 2 h, allowed to warm to room temperature, and was stirred for an additional 1 h. The product was extracted from the aqueous layer with several portions of ether, the extracts combined, and the solvent removed at reduced pressure. The red powder thus obtained was recrystallized from ether/hexane giving 167 mg of deep red crystals (65% yield) which were identified as **1**. Anal. calcd. for $C_{24}H_{34}O_4Rh_2$: C 48.66, H 5.78; found: C 48.24, H 5.79. ^{1}H NMR (toluene-d_8, ambient temperature): d 1.01 (s, 4H, C(14)H_2 and C(7)H_2), 1.09 (s, 18H, C(16)$(CH_3)_3$ and C(21)$(CH_3)_3$), 3.62 (broad unresolved peak, 4H, C(1)H, C(4)H, C(8)H, and C(12)H), 3.85 (broad s, 8H, C(2)H, C(3)H, C(5)H, C(6)H, C(9)H, C(10)H, C(12)H, and C(13)H). The electron ionization (70 eV) mass spectrum showed the presence of the parent molecular ion (592 *m/z*) and fragmentation peaks corresponding to the presence of the mono-

mer (296 *m/z*) and the NBDRh$^+$ ion (195 *m/z*). The base peak is due to the presence of the $CH(CH_3)_3^+$ ion (57 *m/z*).

The ^{1}H NMR spectrum was recorded on a Varian XL-300 spectrometer, and the mass spectrum on a Kratos AES M50 spectrometer.

X-ray crystallographic analysis of $[(CH_3)_3CCO_2]_2Rh_2(C_7H_8)_2$

A crystal ca. 0.12 × 0.25 × 0.45 mm in size was mounted on a glass fibre. Unit-cell parameters were refined by least-squares on setting angles for 25 reflections (2θ = 60.0–76.8°) measured on a diffractometer with Cu-K_α radiation ($\lambda_{K\alpha1}$ = 1.54056, $\lambda_{K\alpha2}$ = 1.54439 Å). Crystal data at 21°C are as follows:

$C_{24}H_{34}O_4Rh_2$ fw = 592.35

Triclinic, a = 10.454(1), b = 10.817(1), c = 12.424(1) Å, α = 64.904(7), β = 100.320(7), γ = 109.382(8)°, Z = 2, ρ_c = 1.641 Mg m^{-3}, $F(000)$ = 600, μ(Cu-K_α) = 116.03 cm^{-1}. Absent reflections: none, space group $P\bar{1}$ (No. 2, reduced cell) from structure analysis.

Intensities were measured with graphite-monochromated Cu-K_α radiation on an Enraf-Nonius CAD4-F diffractometer. An ω–2θ scan at 1.1–10.0° min^{-1} over a range of (1.00 + 0.14 tan θ)° in ω (scan extended by 25% on each side for background measurement) was employed. Data were measured to 2θ = 150°. The intensities of three check reflections, measured every hour of X-ray exposure time throughout the data collection, showed only small random variations. The data were processed[1] and corrected for Lorentz and polarization effects, and absorption (analytical, transmission factors 0.055–0.343). Of the 4903 independent reflections measured, 3093 (63.1%) had intensities greater than or equal to 3σ(I) above background where $\sigma^2(I) = [C + 2B + (0.040(C - B))^2]$ with C = scan count, B = normalized total background count.

The structure was solved by heavy atom methods, the coordinates of the rhodium atoms being determined from the Patterson function and those of the remaining non-hydrogen atoms from a subsequent difference Fourier synthesis. The non-hydrogen atoms were refined with anisotropic thermal parameters, the hydrogen atoms associated with the metal-bound carbon atoms of the norbornadiene ligands were refined with isotropic thermal parameters, and the remaining hydrogen atoms were fixed in idealized positions (C—H = 0.98 Å, U_H = 1.2 $U_{\text{bonded atom}}$). Scattering factors for all atoms and anomalous dispersion corrections for the non-hydrogen atoms were taken from ref. 36. An isotropic type I extinction correction was applied, the final value of g being 0.29(4) × 10^4. The weighting scheme $w = 1/\sigma^2(F)$ gave uniform average values of $w(|F_o| - |F_c|)^2$ over ranges of both $|F_o|$ and sin θ/λ and was employed in the final stages of full-matrix least-squares refinement of 304 variables. Reflections with $I < 3\sigma(I)$ were not included in the refinement. Convergence was reached at R = 0.070 and R_w = 0.081 for 3093 reflections with $I \geq 3\sigma(I)$. The function minimized was $\Sigma w(|F_o| - |F_c|)^2$, $R = \Sigma||F_o| - |F_c||/\Sigma|F_o|$, $R_w = (\Sigma w(|F_o| - |F_c|)^2/\Sigma w|F_o|^2)^{1/2}$. On the final cycle of refinement the maximum parameter shift corresponded to 0.22σ. The mean error in an observation of unit weight was 1.71. The final difference map showed maximum fluctuations of −3.1 and +2.1 e Å^{-3} (both near Rh atoms). The relatively high values of R and R_w are due to poor crystal quality. A data set collected earlier with molybdenum radiation was of even lower quality, with only about 25% of the reflections out to 2θ = 45° having significant intensity.

The final positional and (equivalent) isotropic thermal parameters for the non-hydrogen atoms appear in Table 1. Bond lengths and angles are given in Tables 2 and 3, respectively. Hydrogen atom parameters, anisotropic thermal parameters, torsion angles, and structure factors have been deposited.[2]

Dynamic NMR computer modelling

The computer modelling of the nonrigid behaviour of **1** was done using the dynamic computer fitting program DNMR4. The modified version used here works on an AT-compatible personal computer equipped with a math coprocessor. The low-temperature-limit spectrum was collected at a temperature of −44°C and T_2 values were calculated by half-height line widths ($w_{1/2}$) from this spectrum ($T_2 = 1/\pi w_{1/2}$ = 0.090 s). The coupling constants employed were as follows: $J_{\text{aliph H, adjacent olefin H}}$ = 3.3 Hz, $J_{\text{aliph H, distant olefin H}}$ = 0 Hz, $J_{\text{aliph H, bridgehead H}}$ = 1.7 Hz, $J_{\text{cis olefin H's}}$ = 3.3 Hz. Because of the size of the spin system, the aliphatic exchange and the olefinic exchange was modelled sepa-

[1]Computer programs used include locally written programs for data processing and locally modified versions of the following: MULTAN80, multisolution program by P. Main, S.J. Fiske, S.E. Hull, L. Lessinger, G. Germain, J.P. Declercq, and M.M. Woolfson; ORFLS, full-matrix least-squares, and ORFFE, function and errors, by W.R. Busing, K.O. Martin, and H.A. Levy; FORDAP, Patterson and Fourier syntheses, by A. Zalkin; ORTEP II, illustrations, by C.K. Johnson.

[2]Supplementary material mentioned in the text may be purchased from the Depository of Unpublished Data, Document Delivery, CISTI, National Research Council of Canada, Ottawa, ON K1A 0S2, Canada.

Tables of hydrogen atom coordinates, bond lengths and bond angles have also been deposited with the Cambridge Crystallographic Data Centre, and can be obtained on request from The Director, Cambridge Crystallographic Data Centre, University Chemical Laboratory, 12 Union Road, Cambridge, CB2 1EZ, U.K.

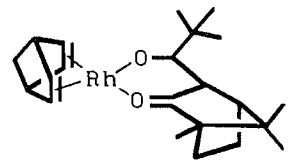
rately. The displayed plots were obtained by the addition of the two individual spectra obtained from the DNMR program.

^{1}H NMR data were collected on a Varian XL-300 (300 MHz) equipped with variable temperature apparatus. The toluene-d_8 employed as solvent for the variable temperature study was run through an alumina column and degassed by three freeze–pump–thaw cycles prior to its use.

Results and discussion

Compound **1** was obtained during the attempted synthesis of a (nbd)rhodium β-diketonate complex. The formation of **1** may have occurred by the initial formation of the target complex (**2**)



2

followed by a rearrangement. It is conceivable that the pivaloyl camphor underwent a base hydrolysis reaction, possibly catalyzed in the presence of rhodium, to give camphor and *t*-butyl acetic acid. The *t*-butyl acetic acid could then have reacted with the rhodium moiety to give the observed product. The high yield indicates that the operative reaction path is favourable. It is interesting to note that the preparation of several rhodium(I) β-diketonates with adjacent phenyl groups have been carried out successfully under the same conditions (37). Rhodium diketonates of this type are hydrogenation and hydrosilylation catalysts, and the phenyl analogue of the target complex, bis(ethene)(3-benzoyl-(+)-camphorato-*O*,*O*′)rhodium(I), **3**, is among this group of catalysts (37, 38). Compound **1** was tested for its ability to act as a hydrogenation catalyst using the same conditions as the rhodium diketonates (1 atm H_2; 25°C, methanol as solvent; 1-octene as substrate) and no reaction was observed.

The acetato analogue of **1**, bis(μ-acetato)bis(norbornadiene)dirhodium(I), **4**, has previously been prepared and stud-

ied by X-ray crystallography (39). The major structural differences between **1** and **4** arise from the steric constraints of the *t*-butyl group, thus a significant difference is present in the angle between the acetate ligand planes (97.7° for the *t*-butyl carboxylate and 82.49° for the acetate bridges) and in the Rh—O—C bonds. The rhodium atoms are displaced further from their coordination planes in **1** owing to the repulsion of the *t*-butyl ligands; the Rh(1) and Rh(2) atoms are displaced 0.165(1) and 0.138(1) Å, respectively, from the mean planes of their substituents (two O atoms, two midpoints of C=C bonds) corresponding to 0.1574(2) and 0.0985(2) Å in **4**.

The crowding effect of the *t*-butyl group is not otherwise apparent. The bond lengths between the rhodium atoms and the olefins, as well as those between the rhodium atoms and the oxygens of the carboxylate groups, do not show significant differences in **1** and **4**. The dihedral angle between the normals to the mean coordination planes of the two Rh atoms (calculated with the midpoints of the coordinated C=C bonds) is 50.5° in **1**, coinciding with an angle of 50.1° in **4**. Furthermore, the angles of the bonds surrounding the rhodium atoms show like deviations from the square planar model with M—Rh—M bond angles being 71.8(6)° for Rh(1) (corresponding to 72.7(1)° in **4**); for Rh(2): 72.0(6)° (72.7(1)° in **4**); the O—Rh—M angles being 97.9(5)° and 98.0(5)° in Rh(1) (96.6(1)° and 97.4(1)° in **4**); for Rh(2): 96.2(5)° and 100.3(5)° (95.8(1)° and 99.6(1)° in **4**); the O—Rh—O angles being 91.3(4)° for Rh(1) and 90.1(4)° for Rh(2) (91.9(1)° and 91.6(1)° in **4**).

The ^{1}H NMR at ambient temperature contains a sharp singlet (1.09 ppm), assigned to the methyl-group protons of the bridging carboxylate ligands, and two broad resonances (3.62 and 3.85 ppm), the shapes of which are temperature dependent, suggesting that **1** is structurally nonrigid. From chemical shift and integral intensity these resonances can be assigned to the protons of the norbornadiene ligands as follows: the resonance at 3.62 ppm is due to the aliphatic hydrogen atoms attached to C(1), C(4), C(8), and C(11), and the resonance at 3.85 ppm is due to the olefinic hydrogen atoms attached to C(2), C(3), C(5), C(6), C(9), C(10), C(12), and C(13) (Fig. 1). In the low-temperature-limit spectrum, where lowering the temperature no longer effects resonance resolution, the broad resonances resolve into two resonances for the aliphatic protons and two resonances for the olefinic protons. The areas of these peaks are consistent with the assignments.

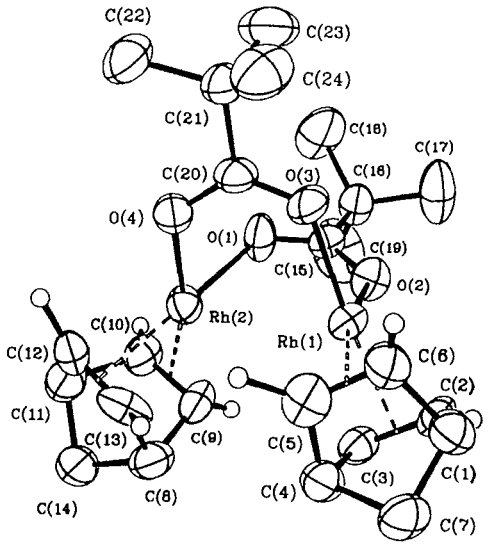

FIG. 1. Crystal structure of **1**.

The ^{1}H NMR spectrum can be understood by observing the crystal structure of **1** (Fig. 1; stereoview in Fig. 2). Two mirror planes exist in the symmetry of **1**, giving rise to, in the static (or solid state) structure, two sets of aliphatic protons (one set inside and one set outside the hinged form of **1**) and, similarly, two sets of olefinic protons. It does appear that the hinged form of **1** is the most stable conformation in solution as this form explains the low temperature limit. It is possible to envision another form of the molecule in solution in which one carboxylic unit is above the plane defined by the oxygen atoms and the other unit is below the plane. This chair form (with reference to the position of the carboxylate groups relative to the internal plane of the carboxylate oxygens) would make the aliphatic protons chemically equivalent and give rise to a single resonance. The olefinic protons in this form would be in two separate groups, depending on the protons' relative proximity to the

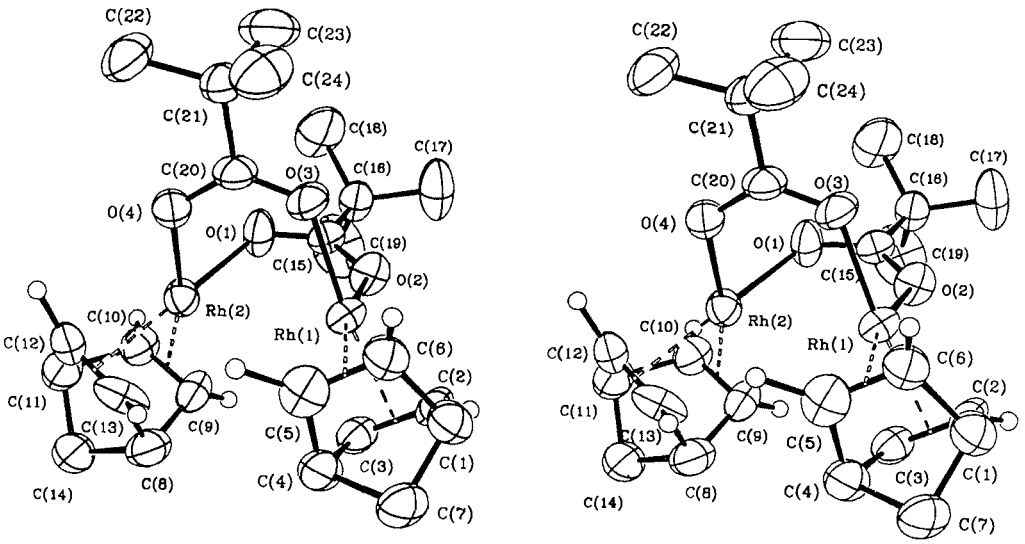

FIG. 2. Stereoview of the bis(μ-*t*-butylcarboxylato)-bis[(η^4-norbornadiene)rhodium(I)] molecule; 50% probability thermal ellipsoids are shown for the non-hydrogen atoms.

t-butyl groups on the bridging carboxylate ligands. Although the observed ^1H NMR spectra do not support the presence of this structure, it may play a part in the motion the complex undergoes.

Several mechanisms have been proposed to explain the observed nonrigid behaviour of related carboxylate-bridged transition metal complexes; these are discussed here. One possible explanation for the exchange process is the rotation of the nbd ligand about an axis through the bridgehead carbon and the rhodium on each side of the dimer. A motion of this type would explain the exchange of the olefinic and aliphatic protons in **1**, and has been used to explain the observed olefin ligand exchange in bis(olefin)(acac)Rh species (40–42), as well as the exchange of the protons of the nbd ligand observed in the $^{13}C^1H$ NMR spectrum of the acetate complex **4** (6). The activation energies associated with this type of exchange are significantly higher than those associated with the motion studied here, ranging from 58.2 to 63.6 kJ/mol in the bis(olefin)(acac)Rh complexes (42).

Another way to account for the exchange is by the dissociation of one rhodium–oxygen bond followed by rotation and reassociation to give the inverted dimer. This process has been shown to occur in the palladium carboxylate dimers of the type bis(μ-acetato)dihalobis(dimethylphosphine)dipalladium(II). In the presence of coordinating solvents the rate of exchange is increased; in the absence of a coordinating solvent, the rate of exchange is not significant and any motion is then attributable to other possible modes (33).

A third model employed to explain the behaviour in carboxylate-bridged palladium complexes involves an inversion of the eight-membered ring including the metals and the carboxylate bridges. This motion best fits the present observations and is further explored below.

To calculate the exchange rate for the observed process, the NMR data were fitted using the computer fitting program DNMR4. The exchange between the olefinic protons was calculated separately from the exchange of the aliphatic protons due to the size limitations of the program; each whole computer generated spectrum was obtained by the addition of the two independently generated spectra. A comparison between the experimental and calculated spectra is shown in Fig. 3. The rate constants obtained from the computer fits are listed in Table 4.

Having obtained the rate constants for the exchange (Table 4), the activation parameters were calculated from the slope and intercept of the plot of ln k versus $1/T$ (Fig. 4; Tables 5 and 6). The data in Table 5 represent the treatment of the data as though the two sets of protons are independent and the corresponding activation parameters are listed in Table 7. Assuming that the exchange of the olefinic and aliphatic protons are fixed to occur at the same rate, the combined data gives rise to the following activation parameters: $\Delta H^{\ddagger}$ = 73.68 kJ/mol; $\Delta S^{\ddagger}$ = 100.3 J/mol·K; $\Delta G^{\ddagger}$ = 44.43 kJ/mol. The standard deviations calculated for the activation parameters have been obtained statistically and are a reflection of the goodness of the fit of the plot to a straight line. The correspondingly lower standard deviation of $\Delta G^{\ddagger}$ is due to the covariance of $\Delta H^{\ddagger}$ and $\Delta S^{\ddagger}$ (43). The rigid nature of the nbd ligand ensures that the rate constants are the same for both groups of protons, therefore the calculation of the activation parameters can be done by treating the data as one group. In combining the rate constants, the associated error in the activation parameters decreases as there are more data points. This treatment of data is contained in Table 6; a summary of the activation parameters can be found in Table 7.

[a] $S^2_{Y|X} = 1/(n-2) \cdot \Sigma(Y - \hat{Y})^2$; $\sigma_a = S_{Y|X} \cdot \sqrt{[(1/n) + \bar{X}^2/((n-1) \cdot S_X^2)]}$; $\sigma_b = S_{Y|X}/(S_X \cdot \sqrt{(n-1)})$.

The magnitude of the activation parameters is indicative of a ring inversion process giving rise to the exchange. The spectra of **1** were collected in the non-coordinating solvent toluene-d_8, the dissociation–rotation–association mode of exchange is thus expected to be insignificant. Free carboxylate ligand is not detectable in the NMR spectrum at any of the temperatures employed in the DNMR study, neither is a broadening of the resonance of the *t*-butyl protons which is also expected in this type of exchange. If, on the other hand, the nbd rotation occurs as previously suggested for **4**, then the activation parameters for the motion should be very close for **1** and **4** since the crystal structures are very similar and suggest the same nbd–rhodium and carboxylate–rhodium interactions (bond distances and angles are within experimental error for the Rh–nbd data of **1** and **4**). An activation energy of ~30 kJ/mol ($CDCl_3$, $^{13}C^1H$ NMR, $T_{coal} = -12°C$) was reported for **4**. The effects of the *t*-butyl group can account for the difference in the activation parameters for a ring inversion mechanism but not for a nbd rotation mechanism. The above therefore demonstrates that, in the case of rhodium carboxylate dimers, the exchange is due to a ring inversion. Sufficient evidence has not yet been presented to indicate the presence of nondissociative rotational motion

occurring between a square-planar rhodium atom and a chelating ligand (44).

The fluxionality of the carboxylate-bridged rhodium dimer can be compared to that of six-membered rings; its eight- membered ring may imply that a cyclooctane-like molecule or one of its unsaturated derivatives would be comparable; however, present knowledge points towards the boat–chair conformation of cyclooctane as the dominant form, unlike the hinged form which explains the solution and solid phase of **1**. The use of the unsaturated hydrocarbon cyclooctatetraene as a model for the nonrigidity of **1** is inappropriate on two counts: the paths to ring inversion are not accessible to the dimer and the energy requirements for the paths are much higher than those observed here. One path is that of bond rehybridization (57.3 kJ/mol) (45), and the other proceeds by way of a planar intermediate (≈65.7 kJ/mol), requiring highly strained bond angles in the intermediate. Furthermore, it appears that any possible form of unsaturated cyclooctane would not contain a reasonable facsimile of the fixed carboxylate units present in **1**. It is the rigid nature of the carboxylate group and the stable boat conformation then that beg comparison with a six-membered ring.

Heterocyclic six-membered rings with varying degrees of saturation and substitution have energy barriers to inversion in the range of ~21–46 kJ/mol (46). The acetate complex **4** has an activation barrier in the middle of this range, and the free energy of activation for **1** lies at the high end of this region. Three major factors contribute to the moderate to relatively high inversion barriers. Firstly the carboxylate bridges are not the equivalent of a single bond between the two oxygen atoms in that rotation of the connection between the oxygen atoms is not possible. The rotation must then occur elsewhere in the ring, decreasing the number of different molecular motions that can lead to the inversion. Secondly, oxygen atoms may hinder the rotation of the O—Rh bond by an interaction of the oxygen's *p*-

TABLE 7. Calculated activation parameters with estimated standard deviations in parentheses[a]

	$\Delta H^{\ddagger}$ (kJ/mol)		$\Delta S^{\ddagger}$ (J/mol)		$\Delta G^{\ddagger}$ (kJ/mol)[b]

Combined plots	73.7(5.8)	73.7(5.8)	100.3(21.0)	100.3(21.0)	44.4(0.44)	44.4(0.44)

[a]Standard deviations are calculated as follows: (*a*) $\sigma_{\Delta H^{\ddagger}} = \sigma_b \cdot 1.987 \times 10^{-3}$ kJ/mol; (*b*) $\sigma_{\Delta S^{\ddagger}} = \sigma_a \cdot 1.987 \times 10^{-3}$ kJ/mol; (*c*) $\sigma_{\Delta G^{\ddagger}}$: $(\sigma_{\Delta G^{\ddagger}})^2 = (\sigma_{\Delta H^{\ddagger}})^2 + (T \cdot \sigma_{\Delta S^{\ddagger}})^2 - (2T \cdot \sigma_{\Delta H^{\ddagger}} \cdot \sigma_{\Delta S^{\ddagger}})$.
[b]Calculated at 291.8 K.

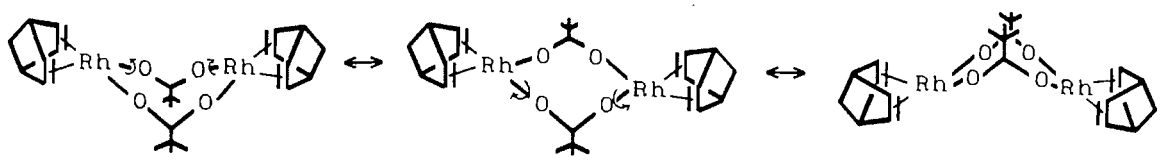

FIG. 5. Proposed mechanism for the exchange of aliphatic and olefinic nbd protons in **1**.

and unoccupied rhodium d_{xz} orbitals; motion through a conformation of this sort would require additional energy to disengage these interactions. Finally, the presence of the bulky *t*-butyl groups force the inversion to take place with the accompanying strain and bond angle deformation expected in the motion of a sterically crowded molecule. The presence of a rhodium–rhodium bond would further increase the barrier; however, the existence of such an interaction is not justifiable from the crystal-structure data.

The predicted transition state is similar to that of the twist-boat form of cyclohexane (47), since we expect the inversion to occur by a sequential progression of the rigid carboxylates from one side of the ring to the other. The transition state here is equivalent to the "chair" form of **1** described as a possible solution structure. If the inversion does not happen sequentially, the transition state would be planar and the energy barrier similar to that of cyclooctatetraene; the difference in activation energies between that of the motion observed here (44.4 kJ/mol) and the planar mechanism of cyclooctatetraene (65.7 kJ/mol) favours the postulated intermediate. It is difficult, if not impossible, to prove the structure of the transition state; however, the form described here does account for the difference in the energy barrier in **1** and **4** as being due to the steric restriction of the motion due to the presence of the *t*-butyl groups; on the other hand, a planar transition state should be relatively unaffected by the bulky groups. (The steric crowding caused by these groups is evidenced in the crystal structures mentioned earlier.) The implied, and most feasible, mechanism for the ring inversion of rhodium–carboxylate dimers can thus be represented by the sequence shown in Fig. 5.

Received August 24, 1993

MARK L.J. REIMER, JOHN B. WESTMORE, and MANORANJAN DAS. Can. J. Chem. **72**, 1302 (1994).

Positive ion electron ionization mass spectra are presented for palladium(II) β-diketonates and monothio-β-diketonates of the general form $Pd^{II}[RC(X)CHC(O)R']_2$, where R = phenyl, 4-methoxyphenyl, 2-thienyl, or 2-naphthyl; R′ = trifluoromethyl, pentafluoroethyl, or *n*-heptafluoropropyl; and X = O or S. The mass spectral behavior is in sharp contrast to that of metals of the first transition series. The spectra of the β-diketonates are dominated by metal-containing ions that arise by migration of the R group from the ligand (L) to palladium, but there is no evidence for fluorine-to-metal transfer. These findings are consistent with HSAB theory. The strong tendency of palladium to form bonds with unsaturated carbon also leads to remarkably abundant metal-containing ions that arise by losses of CO or aryloxy radicals from $[PdRL]^{+\cdot}$ ions. In contrast, in decompositions of ions in the spectra of the monothio-β-diketonates, migration of the R group is suppressed; competition for palladium $d\pi$ electrons by the sulfur donor makes palladium a poorer aryl group acceptor.

MARK L.J. REIMER, JOHN B. WESTMORE et MANORANJAN DAS. Can. J. Chem. **72**, 1302 (1994).

On rapporte les spectres de masse des ions positifs obtenus par ionisation électronique des β-dicétonates et des monothio-β-dicétonates de palladium(II) de formule générale $Pd^{II}[RC(X)CHC(O)R']_2$, dans laquelle R = phényle, 4-méthoxyphényle, 2-thiényle ou 2-naphtyle, R′ = trifluorométhyle, pentafluoroéthyle ou *n*-heptafluoropropyle et X = O ou S. Les spectres de masse font contraste avec ceux des dérivés de la première série de métaux de transition. Les spectres des β-dicétonates sont dominés par les ions contenant des métaux qui se forment par la migration du groupe R du ligand (L) vers le palladium; on n'a pas de données suggérant un transfert de fluor vers le métal. Ces observations sont en accord avec la théorie HSAB. La forte tendance du palladium à former des liaisons avec des carbones insaturés conduit aussi à une quantité importante d'ions contenant un métal qui provient d'une perte de CO ou des radicaux aryloxy par les ions $[PdRL]^{+\cdot}$. Par ailleurs, les spectres de décomposition des ions des monothio-β-dicétonates montrent que la migration du groupe R est supprimée; la compétition du soufre donneur pour les électrons $d\pi$ palladium fait de ce dernier un piètre accepteur du groupe aryle.

[Traduit par la Rédaction]

Introduction

Our recent efforts in characterizing the mass spectral behavior of volatile transition metal chelates under electron ionization (EI) conditions have included the examination of fluorinated β-diketonates and monothio-β-diketonates of cobalt(III) (1) and nickel(II) (2). The mass spectra of these complexes showed interesting differences, which could be attributed to the relative stabilities of the +3, +2, and +1 oxidation states of the metals, and also to the relative acid hardness of the metals in these oxidaion states, according to the Hard and Soft Acid and Base (HSAB) principle (3–6). As well, the HSAB concept can be used to rationalize ion decompositions involving metal–fluorine bond formation on the basis of the specific oxidation state of the metal, and whether it is bound to oxygen or sulfur. Other authors had earlier suggested the usefulness of these approaches (7). Thus, the mass spectra of metal complexes can often be used to draw conclusions about the condensed phase chemistry of the metals. In addition, an understanding of such spectra is useful for characterization of synthesized complexes, and for development of analytical methods.

The chemistry of palladium is significantly different from that of cobalt or nickel, or any other first transition series metal. A number of its features of importance to this paper, drawn from authoritative texts (8, 9), are now summarized. The +2 oxidation state is the most common, though the zero oxidation state is also well known. The +4 state is also well known but is less easily formed. The +1 and +3 states are both very rare. The reluctance of palladium to assume an odd-oxidation state is attributed to the instability associated with an unpaired electron in an outer orbital. This is typical for second and third transition series elements, where even-electron configurations are generally more stable than odd-electron ones (10). In the +2 oxidation state, or lower, palladium is classified as a class "b" metal (11), i.e., as a soft acid (HSAB), so that it forms stronger bonds to sulfur than to oxygen or fluorine. The strong binding preference of palladium(II) for sulfur (and other heavy-atom donors) is due in large part to metal–ligand π-bond overlap of filled metal *d* orbitals with empty *d* orbitals of the heavy atom (ref. 8, p. 165, and ref. 12). Palladium(II) also readily forms σ and π bonds to a wide variety of carbon compounds, especially to alkenes and alkynes (ref. 9, p. 871). We shall show that these characteristics account for some novel features in the mass spectra of the title compounds. Although the mass spectra of several of the palladium(II) β-diketonates have appeared in an earlier communication (13), this study provides the first opportunity for direct comparisons with those of the corresponding palladium(II) monothio-β-diketonates generated under comparable ionizing conditions. We correlate the features of the spectra to the rela-

tive stabilities of the metl oxidation states, to the HSAB concept, and to the electronic properties of the ligand donor atoms and of the R and R′ substituents.

The electron ionization (EI) positive ion mass spectra of organic compounds often show an abundant molecular ion ($M^{+\cdot}$), which initially eliminates an odd-electron ($OE^{\cdot}$) neutral species; generally, the resulting ion then loses one or more even-electron (EE^0) neutral species. (An explanation of the symbolism used has been given previously (1).) In the case of transition metal compounds the odd- ($OE^{+\cdot}$) or even-electron (EE^+) character of the metal-containing ion can be altered by a formal change of the oxidation state of the metal (14, 15). For example, we may depict the molecular ion, $[NiL_2]^+$, of a nickel complex either as $[Ni^{II}L_2]^{+\cdot}$ or $[Ni^{III}L_2]^+$ by formal movement of an electron between nickel and the ligand, L. This is a reasonable approach for nickel because, although its +2 state is the usual one, its +3 state is also known (ref. 9, p. 753). In view of the discussion above, in this paper we represent the molecular ion of the palladium complexes as $[PdL_2]^{+\cdot}$ without specifying whether the unpaired electron resides in a molecular orbital based mainly on the metal or on the ligand, even though all of the present ligands contain substituents capable of delocalizing the positive charge and unpaired electron so that it is not therefore necessary to propose a formal +3 state for palladium. Similarly, we represent fragment radical ions without specifying a particular formal oxidation state for palladium, leaving the radical nature of the ion to alert the reader to the considerations discussed here. In the case of even-electron ions that are reasonably d^8 it seems appropriate to represent palladium as Pd^{II}. In the tables we write ion formulae without specifying their odd- or even-electron character, or the oxidation state of the metal.

Table 1 lists the palladium complexes for which the positive ion EI mass spectra were obtained. These are fluorinated β-diketonates and monothio-β-diketonates having the general formula $Pd^{II}(RCXCHCOR')_2$, where R = phenyl, 4-methoxyphenyl, 2-thienyl, or 2-naphthyl; R′ = trifluoromethyl, pentafluoroethyl, or *n*-heptafluoropropyl; and X = O or S. Decompositions of selected collisionally activated ions were studied with the aid of product ion and constant neutral loss spectra acquired under linked scanning conditions.

Experimental

Mass spectrometry

For these studies a VG 7070E-HF double-focusing (EB geometry) mass spectrometer (VG Analytical Ltd., Manchester, England) equipped with a data system based on a DEC PDP-11/73 microcomputer (Digital Equipment Corp., Maynard, Mass.) was used. Samples were admitted to the ion source on a direct insertion probe. In many cases ambient heating from the ion source was sufficient to obtain steady evaporation and reproducible EI mass spectra; in other cases the probe temperature was raised but it never exceeded 100°C. The mass spectra were recorded under the following conditions: ion accelerating voltage, 6 kV; ionizing energy, 70 eV; trap current, 200 μA; source temperature 200°C; scan rate, 1.0 s/decade; resolving power, 1400 (10% valley definition). Ion decomposition mass spectra of selected ions in the spectra of **2***a* and **3***b* were recorded by linked scanning, at a scan rate of 5.0 s/decade, as follows: (*a*) product ion scans at a constant magnetic field/electric field ratio (i.e., *B*/*E* constant with accelerating voltage (*V*) fixed), and (*b*) constant neutral loss scans such that $B[1-(E/E_0)]^{1/2}/E$ was constant, with *V* fixed. Precursor ions were collisionally activated in the first field-free region of the instrument by adjusting the helium pressure in the collision cell to achieve approximately 50% attenuation of the parent ion signal.

Ligand syntheses

The fluorinated β-diketones used in the syntheses of complexes **1***a* and **2***a* were purchased from Aldrich Chemical Co. (Milwaukee, Wis.). The remaining β-diketones were synthesized by a Claisen condensation of the appropriate methyl ketone ($RCOCH_3$) with the fluorinated ethyl ester ($R'COOC_2H_5$), as previously described (16). The fluorinated monothio-β-diketones were synthesized from their corresponding β-diketones (17–20).

Syntheses of palladium chelates

(a) β-Diketonates

A filtered solution of potassium tetrachloropalladate(II) (4.9 mmol; Aldrich) in 50 mL of water was added to a solution of the ligand (9.8 mmol) in ethanol (50 mL). The mixture was digested on a steam bath for 15 min and then cooled in ice water for 1 h. The desired product, obtained as a yellow-green precipitate, was filtered off under suction, washed with water and then with ice-cold absolute alcohol, and air dried (21).

(b) Monothio-β-diketonates

Potassium tetrachloropalladate(II) (4.9 mmol) in water (50 mL) was added to a solution of the ligand (9.8 mmol) in acetone (50 mL). The resulting red/orange precipitate was filtered off under suction and recrystallized from acetone (20, 22, 23).

Results and discussion

Relative abundances of ions in the EI mass spectra (Tables 2 and 4) are quoted for specific *m/z* values; for palladium-containing ions the *m/z* value is listed for the biggest peak within a given group of isotopic peaks observed for a given ion type, and corresponds to those containing ^{106}Pd (natural abundance 27.1%). Thus, the listed abundances of palladium-free ions should be multiplied by 0.271 to find their abundances relative to palladium-containing ions.

Mass spectra of β-diketonates

Table 2 lists the EI mass spectra of the six palladium(II) β-diketonates, while, as representative plots, Figs. 1(*a*) and 1(*b*) show the spectra of **1***a* and **2***a*. All of the spectra show many palladium-containing ions, to which the discussion in this section will be largely confined. Although the base peak corre-

[c]Quoted because isotopic contribution from $C_6H_5CO^+$ ion interferes with abundance of ^{106}Pd.

ponds to a palladium-free ion, when isotopic abundances are taken into account the molecular ion, $[PdL_2]^{+\cdot}$, is actually the most abundant ion in each spectrum. Collisionally activated decompositions (CAD) of selected ions generated from **1***a* and **2***a* are summarized in Table 3.

Chart 1 shows proposed fragmentation pathways. Initially, we will limit our discussion to features of the spectra that appear to be peculiar to the present complexes. Many of the more prominent fragment ions are formed by reactions involving migration of the phenyl or 2-thienyl group (R) to Pd. The $[PdRL]^{+\cdot}$ ion, formed from $[PdL_2]^{+\cdot}$ by migration of the R group with elimination of the remainder of the ligand, is a confirmed precursor of the $[PdR(L - CO)]^{+\cdot}$, $[Pd^{II}(L - O)]^+$, $[Pd^{II}R(CHR)]^+$, $[PdR_2]^{+\cdot}$, and $[Pd^{II}R]^+$ ions, and a probable precursor of the $[Pd^{II}R(L - R')]^+$ ion. The formation of $[PdRL]^{+\cdot}$ from $[PdL_2]^{+\cdot}$ parallels the formation of $[Met^{III}RL]^+$ from $[Met^{III}L_2]^+$ (Met = Co or Ni, R = aryl, R′ = CF_3 (1, 2)). However, its subsequent decompositions exhibit a number of new features.

The $[PdRL]^{+\cdot}$ ion eliminates CO (confirmed for **1***a* and **2***a* by linked-scanning results) to give a fragment ion that is much more prominent in the spectra of phenyl-containing complexes (**1***a*, **4***a*, **7***a*) than of 2-thienyl-containing complexes (**2***a*, **5***a*, **8***a*), an observation to which we shall return. A similar elimination of CO is observed in the fragmentation $[Pd^{II}L]^+ \rightarrow [Pd^{II}(L - CO)]^+$. This unusually prominent decomposition, which is not a significant feature of the corresponding complexes of cobalt or nickel, is, presumably, a feature of the electronic properties of palladium(II). Bearing this in mind, a number of competing fragmentation mechanisms can be proposed. Three possibilities, shown in Scheme 1, are based on the following guidelines: (*a*) according to the HSAB principle,

migration of hard F to soft Pd^{II} is not expected, even though Pd—F bonds are known in the chemistry of palladium(II) (supporting this, the mass spectra show no evidence of fragment ions that *must* contain Pt—F bonds), and (*b*) the known tendency of palladium to form bonds to carbon, especially to unsaturated carbon (ref. 9, p. 871), as illustrated by the presence of ions such as $[PdR_2]^{+\cdot}$, $[Pd^{II}R]^+$, and $[Pd^{II}R(CHR)]^+$ in the mass spectra. Since the mass spectra contain no evidence regarding which CO group is eliminated, mechanisms in which either CO group can be lost are presented. In mechanism (a), the perfluoroalkyl substituent migrates to the central carbon atom, accompanied by extrusion of the included CO group. The resulting ion, by migration of the phenyl group to palladium, would readily eliminate a substituted ketene to give $[PdR_2]^{+\cdot}$, as shown. However, CAD/linked-scanning for **1***a* did not provide support for the latter step; the only confirmed precursor of $[PdR_2]^{+\cdot}$ is $[PdRL]^{+\cdot}$. Hence, while mechanism (a) cannot be excluded, its occurrence remains in doubt. Therefore, we make alternative proposals, in which the phenyl group migrates to the central carbon atom, accompanied by elimination of CO, either preceding (mechanism (b)) or following (mechanism (c)) formation of a bond between palladium and the central carbon atom. The resulting ion, by elimination of R'CO$^{\cdot}$, supported for **1***a* by CAD/linked-scanning, gives rise to $[Pd^{II}R(CHR)]^+$, a major ion species, especially for phenyl-substituted complexes. While the details of mechanisms (b) and (c) are uncertain, the formation of a tropylium ion structure for the product ion is attractive. The tropylium ion structure might also be present in $[Pd(CHR)]^{+\cdot}$, a further fragment ion observed for all complexes.

Table 2 shows that, among the phenyl-containing complexes, the relative abundances of the $[PdR(L - CO)]^{+\cdot}$ ions vary con-

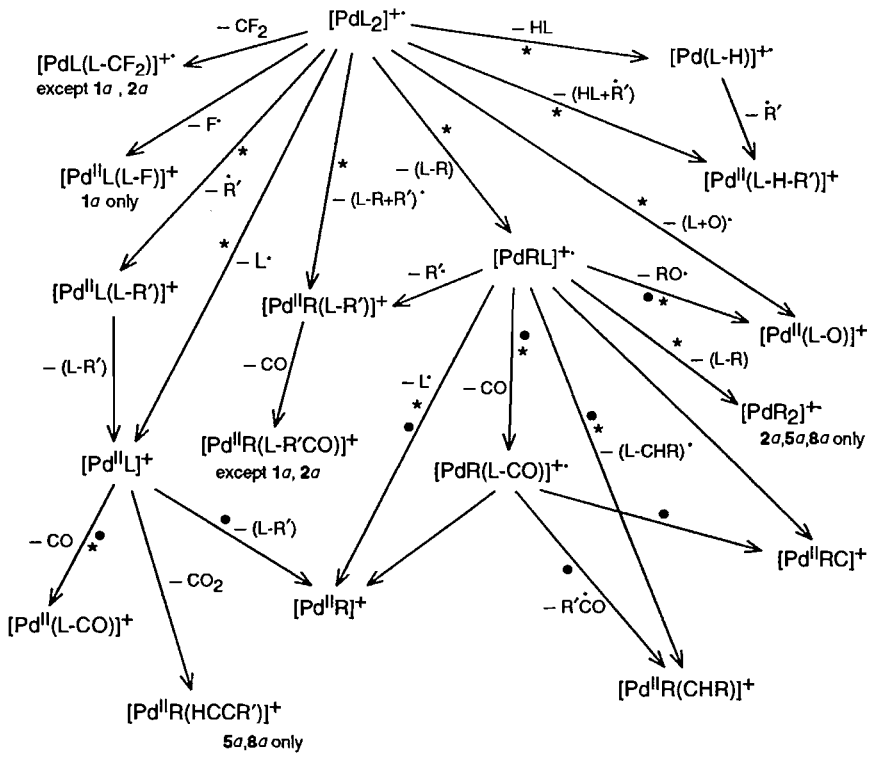

CHART 1. Fragmentation pathways proposed for β-diketonates. Fragment ions are common to all complexes, except where noted.

siderably, decreasing in the order **1***a* > **4***a* > **7***a*. This trend is consistent with the mechanisms of Scheme 1 since conformational/steric factors would become increasingly restrictive with increasing bulk of the perfluoroalkyl group.

The low abundances of the $[PdR(L - CO)]^{+\cdot}$ and $[Pd^{II}R(CHR)]^{+}$ ions for 2-thienyl-substituted complexes suggest that other decomposition channels are favored for these complexes; suitable candidates are those leading to formation of the $[PdR_2]^{+\cdot}$ and $[Pd^{II}(L - O)]^{+}$ ions, which are strongly favored for 2-thienyl-substituted over phenyl-substituted complexes. Rationales for these channels now follow.

The $[PdR_2]^{+\cdot}$ ion is observed only when R = 2-thienyl; recalling the introductory discussion, we can represent this ion by the canonical forms $[Pd^{II}R_2]^{+\cdot}$ and $[Pd^{III}R_2]^{+}$. The latter presumably makes a minor contribution because it is evident that the 2-thienyl group is better able to stabilize the $OE^{+\cdot}$ ion, perhaps as illustrated in Scheme 2. Of the many canonical forms that can be written when R is 2-thienyl, those involving Pd^{II} would be reponsible for the high stability of this species. On the other hand, the $[Pd^{II}R]^{+}$ ion is prominent in the mass spectra of all phenyl- and 2-thienyl-containing β-diketonates, to give an EE^{+} ion with palladium in its natural +2 oxidation state.

The EI mass spectra of all complexes exhibit ions that can only be assigned as $[Pd^{II}(L - O)]^{+}$. These ions are prominent for β-diketonates with a 2-thienyl substituent (**2***a*, **5***a*, and **8***a*) but are also observed, at lower abundance, when R = phenyl. The CAD/product ion spectra of ions generated from **2***a* (Table 3) indicate that both $[PdRL]^{+\cdot}$ and $[PdL_2]^{+\cdot}$ are precursors of this ion. Since the latter may be an indirect precursor, we propose a decomposition of $[PdRL]^{+\cdot}$ by a fragmentation mechanism involving elimination of RO· and leading to a stable product ion (shown in Scheme 3 for R = 2-thienyl). The extraordinary abundance of this species for the 2-thienyl-substituted complexes may be attributed to the resonance stabilization afforded by the lone pair of electrons on the sulfur of the 2-thienyl group. Similarly, the appearance of an abundant "$[PdL - 16]^{+\cdot}$" ion in the mass spectrum of bis(1,1,1-trifluoro-4-(2-furyl)-2,4-butanedionato)Pd(II) (13) reinforces the importance of a substituent-based, heteroatom lone pair in the formation of $Pd^{II}(L - O)]^{+}$.

The formation of $[Pd(L - H)]^{+\cdot}$ from $[PdL_2]^{+\cdot}$ involves the intramolecular transfer of hydrogen into the eliminated ligand, resulting in the expulsion of the neutral product HL. Earlier (2), we discussed mechanisms for this decomposition in which the transferred hydrogen originates either from the central carbon of the ligand or from the aryl substituent. In the present spectra, two pieces of evidence suggest that hydrogen is transferred from the central position: (*a*) by analogy with the earlier work, transfer from the aryl group would be favored by an increase in palladium oxidation state to +3; this does not readily occur, and (*b*) the observation of prominant $[Pd^{II}(L - H - R')]^{+}$ ions suggests that $[Pd(L - H)]^{+\cdot}$ readily eliminates the (OE˙) neutral species R′˙. These observations are consistent with the mechanisms shown in Scheme 4.

Low abundance, but mechanistically significant, ions are observed for loss of CF_2 from $[PdL_2]^{+\cdot}$ when R′ = C_2F_5 or *n*-C_3F_7. For fluorinated β-diketonate complexes of many metals this loss has been attributed to decompositions resembling mechanism (a) in Scheme 5. Support for migration of fluorine to the metal in such cases was given by the observation of fragment ions, and eliminated neutral species, that *had* to contain metal–fluorine bonds (1, 2, 24, 25). This mechanism probably

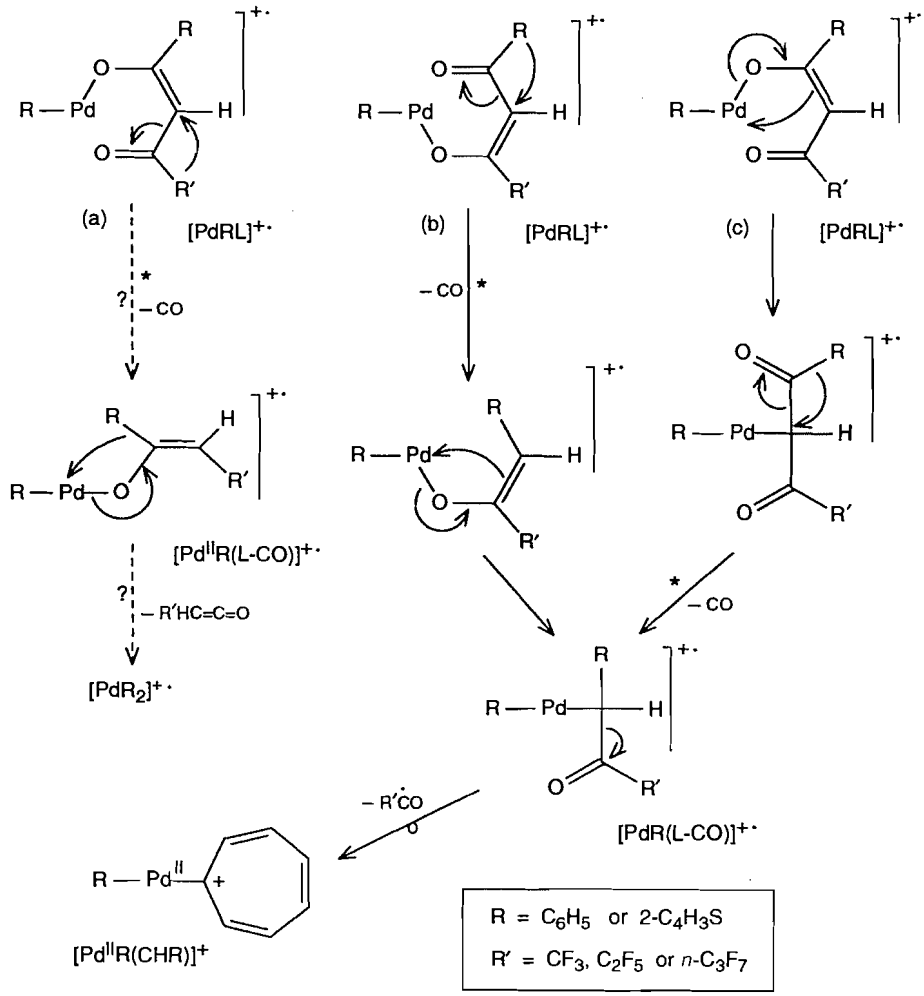
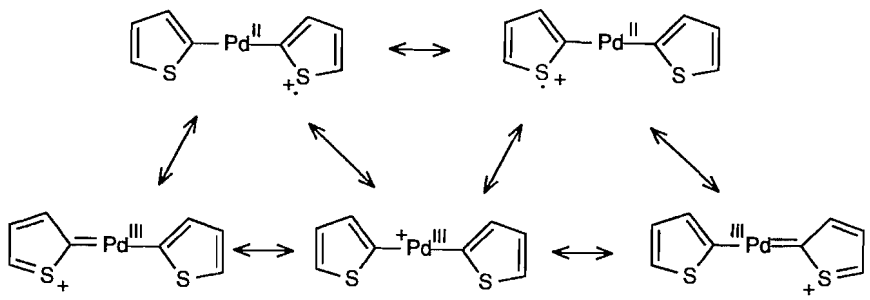


SCHEME 1



SCHEME 2

does not operate for the current complexes for we have noted above that palladium is reluctant to form bonds to fluorine, and to adopt the +3 oxidation state. Also, experimentally, we find no evidence for formation of Pd—F bonds. We therefore propose mechanism (b) in Scheme 5 as an alternative to mechanism (a), in which F (when R′ = C_2F_5) or CF_3 (when R′ = *n*-C_3F_7) migrates to the central carbon atom. (If CF_3 migration does not occur then more extensive fluorine rearrangement is required.)

The $[Pd^{II}R(HCCR')]^+$ ions formed when R = C_4H_3S (**5***a* and **8***a* only) could occur by elimination of CO_2 from $[Pd^{II}L]^+$, as shown in mechanism (a) of Scheme 6. After initial migration of the 2-thienyl substituent to palladium, to yield an acylium ion, the bond rearrangements shown lead to formation of a bond between palladium and unsaturated carbon, and elimination of CO_2. This mechanism is very similar to that proposed (26, 27) for elimination of CO_2 from the $[MetL(L - CF_3)]^+$ acylium ion in the mass spectra of aryl-substituted trifluoro-β-diketonates of iron and cobalt (mechanism (b)) but differs in the way by which the product ion is stabilized. For the iron and cobalt complexes it was suggested that stabilization of the vinyl cation by the aromatic group was necessary to explain the non-occurrence of such ions in the absence of the aromatic group. In the case of palladium we propose that migration of the 2-thienyl substituent to palladium (for which the spectra provide ample support) leads to the required acylium ion intermediate and that the driving force for the decomposition is formation of the bond between palladium and unsaturated carbon. The resulting ion would be stabilized by back-bonding from

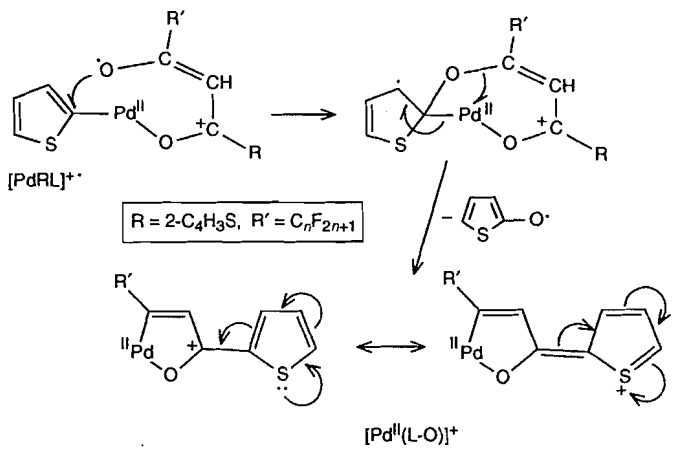
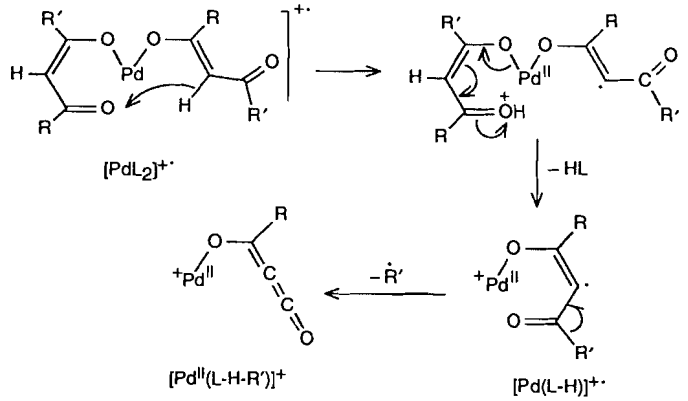


SCHEME 3



SCHEME 4

occupied palladium d/π orbitals into vacant π^* orbitals on the unsaturated group.

Many of the remaining fragment ions in the spectra can be accounted for by straightforward eliminations of the OE· species F·, R′·, and L· from $[PdL_2]^{+\cdot}$ to yield $[Pd^{II}L(L - F)]^+$, $[Pd^{II}L(L - R')]^+$, and $[Pd^{II}L]^+$, respectively, and by loss of R′CO· (or a two-step loss of R′· and CO) from $[PdRL]^{+\cdot}$ to give $[Pd^{II}R(L - R'CO)]^+$. There are also a number of lighter fragment ions, of uncertain origin, containing Pd—C bonds.

Finally, Table 2 shows data supporting formation of L^+ from

$[Pd^{II}L]^+$ and $[PdRL]^{+\cdot}$ precursors (not shown in Chart 1), indicating that thermal decomposition, while it cannot be ruled out to a minor extent, is probably not a significant feature of the spectra. Also not shown in Chart 1 are decompositions of $[PdRL]^{+\cdot}$ and $[PdR(L - CO)]^{+\cdot}$ to the prominent palladium-free ion $[R_2CH]^+$. While the formation mechanisms involved are obscure, the prominence of the latter ion suggests that it has a tropylium ion structure, [R—trop]$^+$.

Pd(II) monothio-β-diketonates

Table 4 lists EI mass spectra of the nine monothio-β-diketonates, while, as a representative plot, Fig. 1(*c*) shows the mass spectrum of **4***b*. Compared to the mass spectra of the corresponding β-diketonates, there are fewer palladium-containing ions and their relative abundances are lower. Notably absent are ions resulting by migration of the aryl substituent to palladium. Table 3 gives CAD/linked-scanning results for selected ions generated from **3***b*. Chart 3 shows proposed fragmentation pathways. In the following paragraphs, attention is drawn mainly to contrasts between the palladium-containing ion sin the spectra of the monothio-β-diketonates and β-diketonates, but we also discuss the formation of some unusual palladium-free ions.

Palladium-containing ions

The minor loss of elemental sulfur, observed in the cases of **7***b* and **8***b* (R′ = *n*-C_3F_7) in the decomposition $[PdL_2]^{+\cdot} \rightarrow [PdL(L - S)]^{+\cdot}$ and (possibly) $[Pd^{II}L]^+ \rightarrow [Pd^{II}(L - S)]^+$, is noteworthy. This shows that, although Pd—O bond scission would be expected to occur more readily, Pd—S scission does occur to a limited extent; subsequent elimination of a sulfur atom may be promoted by Pd—C bond formation.

The $[Pd^{II}R]^+$ ion appears as a minor species in the spectra of **1***b* and **3***b*, in marked contrast to its predominance in the β-diketonate spectra. In fact, this ion is the only evidence given by the spectra for aryl group migration to Pd. Thus, the sulfur atoms reduce the ability of palladium to act as an aryl group acceptor. Above, we have noted the tendency of palladium(II) to back-bond to sulfur. Consequently, the ability of palladium to back-bond to an aryl group would be decreased when it is already engaged in back-bonding to sulfur. Only when the Pd—S bonds are not longer present does bond formation between palladium and an aryl group occur.

The $[PdSC(R)CH]^{+\cdot}$ ion would be formed most readily from $[Pd^{II}L]^+$ by loss of R′CO$^{\cdot}$. Its analogue is also observed in the mass spectra of cobalt(III) and nickel(II) monothio-β-dike-

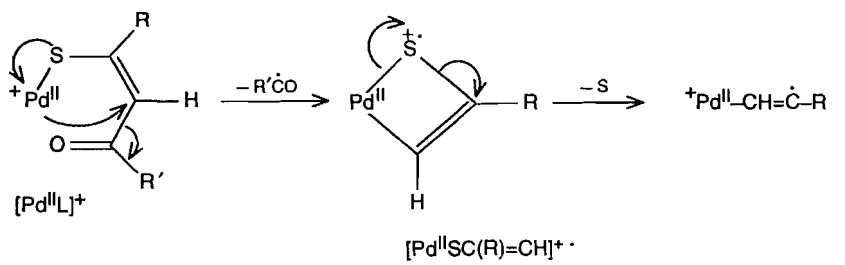
* decomposition supported by CAD/linked scanning for **3***b*

CHART 2. Fragmentation pathways proposed for monothio-β-diketonates. Fragment ions are common to all complexes, except where noted.



SCHEME 7

tonates (1, 2). For such complexes the decomposition would result in a formal reduction of the metal to its +1 oxidation state. Since this oxidation state is not favored in palladium complexes, we propose the alternative mechanism shown in Scheme 7 for this decomposition. Because elimination of the $OE^{+\cdot}$ fragment R′CO· from the EE^+ ion $[Pd^{II}L]^+$ should not be a favored process, the decomposition may be assisted by Pd—C bond formation, as shown. The sequence of bond reorganizations differs from a similar mechanism proposed earlier for decomposition of analogous platinum complexes (23). By loss of S the $[PdSC(R)CH]^{+\cdot}$ ion would yield $[PdCHCR]^{+\cdot}$.

The $[Pd^{II}(L - H - R')]^+$ ion, here observed for all monothio-β-diketonates, was also observed in the mass spectrum of bis(1,1,1-trifluoro-4-mercapto-4-(2-naphthyl)-but-3-en-2-onato)Pt(II) (28), but was not reported for the analogous palladium(II) complexes (23, 28). For its formation we propose the mechanism already shown in Scheme 4.

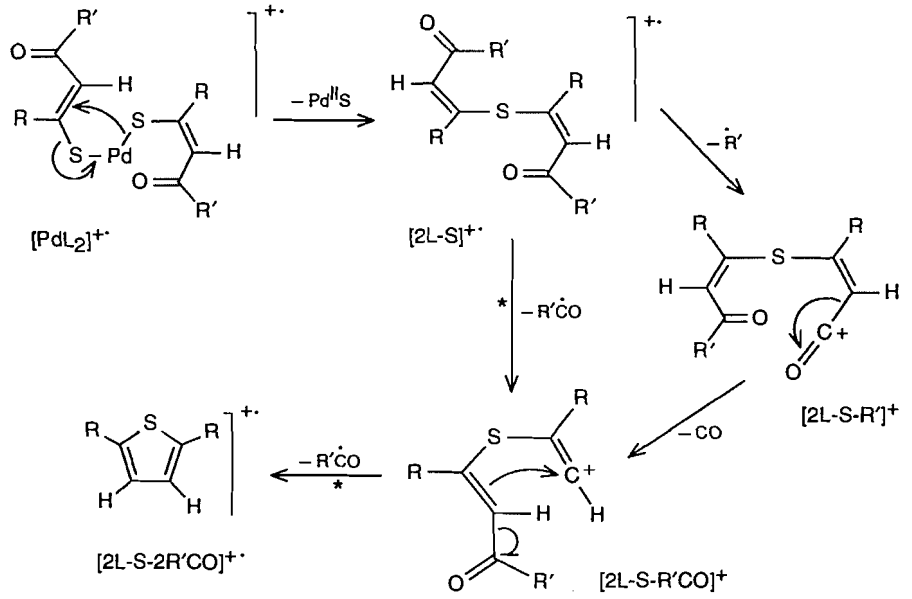
Palladium-free ions

With the exception of **1***b*, all of the monothio-β-diketonates exhibit metal-free ions at *m/z* values greater than $[L]^+$. Initially, loss of $Pd^{II}S$ from $[PdL_2]^{+\cdot}$ forms $[2L - S]^{+\cdot}$, which then loses R′·, CO, and R′CO· to form $[2L - S - R']^+$, $[2L - S - R'CO]^+$, and $[2L - S - 2R'CO]^{+\cdot}$. Except for minor details, the mechanisms shown in Scheme 8 are similar to those described for corresponding decompositions observed for chelates of 1,1,1-trifluoro-4-mercapto-4-(2-naphthyl)-but-3-en-2-one formed with Ni, Pd, Pt, Fe, Ru, Co, and Rh metal ions (28).

Conclusions

There are significant differences between the mass spectra of the β-diketonates and monothio-β-diketonates. The mass spectra of the former are dominated by ion decompositions in which the aryl or thienyl group migrates to palladium. In the mass spectra of the latter, migration of such groups is suppressed

Can. J. Chem. Downloaded from www.nrcresearchpress.com by EESC ESCOLA DE ENGENHARIA on 09/08/12
For personal use only.



SCHEME 8

because competition for $d\pi$ electrons by sulfur makes palladium a poorer aryl group acceptor. The reluctance of palladium(II) to undergo valency changes, together with the characteristic electronic properties, as discussed, gives rise to some remarkably prominent ions, thus leading to mass spectra that differ considerably from those of the corresponding complexes of first transition series metals.

Acknowledgements

We thank Mr. Wayne Buchannon for his assistance in the operation and maintenance of the mass spectrometer and the Natural Sciences and Engineering Research Council of Canada (NSERC) for financial support. We also thank NSERC and the University of Manitoba for grants to purchase the mass spectrometer.

Received July 19, 1993

ANNE GAUCHER, JEAN OLLIVIER, JACQUELINE MARGUERITE, RENÉE PAUGAM, and JACQUES SALAÜN. Can. J. Chem. **72**, 1312 (1994).

(3*R*)-2-(*N*-Benzylideneamino)-4-chloro-3-methylbutyronitrile **3**, prepared from the commercially available methyl (2*S*)-3-hydroxy-2-methyl propionate **5** (96% ee), readily underwent potassium carbonate induced cyclization to provide, after acid hydrolysis (6 N HCl) and chromatography, the (1*S*,2*S*)-norcoronamic acid **1***a* with 88% diastereoselectivity and >95% enantiomeric excess. From (2*R*)-2-(hydroxymethyl)butyl acetate **23** (>88% ee) obtained by enzymatic enantioselective hydrolysis with lipase PS, was prepared the (3*S*)-2-(*N*-benzylideneamino)-3-(chloromethyl)valeronitrile **29**, which after base-induced cyclization (K_2CO_3) and acid (6 N HCl) or basic (0.8 N NaOH) hydrolysis led to the non-natural (1*R*,2*R*)-coronamic acid **18** (>88% ee). Also from this same acetate (2*R*)-**23** was prepared the (3*R*)-3-(chloromethyl)-2-[(diphenylmethylene)amino]pentanenitrile **37**, which provided the (1*S*,2*S*)-coronamic acid **17** (>88% ee) after base-induced cyclization (K_2CO_3 or LDA) and acid hydrolysis (6 N HCl). It is noteworthy that these short synthetic sequences, which do not require any expensive chiral auxiliary or optically active precursors, do not alter the enantiomeric purity of the stereogenic centers of these 2,3-methanoamino acids. However, the *E* diastereoselectivity of these cyclizations was not improved by using bulky *N*-(diphenylmethylene)amino substituent, contrary to results of some molecular mechanic calculations (MAD).

ANNE GAUCHER, JEAN OLLIVIER, JACQUELINE MARGUERITE, RENÉE PAUGAM et JACQUES SALAÜN. Can. J. Chem. **72**, 1312 (1994).

Le (3*R*)-2-(*N*-benzylidèneamino)-4-chloro-3-méthylbutyronitrile **3**, préparé à partir du (2*S*)-3-hydroxy-2-méthylpropionate de méthyle **5** (96% ee) commercial, est facilement cyclisé par le carbonate de potassium, pour fournir après hydrolyse acide (HCl, 6 N) et chromatographie l'acide (1*S*,2*S*)-norcoronamique **1***a* avec 88% de diastéréosélectivité et >95% d'excès énantiomérique. À partir de l'acétate de 2-(hydroxyméthyl)butyle (2*R*)-**23** (>88% ee), obtenu par hydrolyse enzymatique énantiosélective avec la lipase PS, a été préparé le (3*S*)-2-(*N*-benzylidèneamino)-3-(chlorométhyl)pentanenitrile **29**, lequel après cyclisation en milieu basique (K_2CO_3) et hydrolyse acide (HCl, 6 N) ou basique (NaOH 0,8 N) conduit à l'acide (1*R*,2*R*)-coronamique-**18** non naturel (>88% ee). À partir du même acétate (2*R*)-**23**, a été préparé le (3*R*)-3-(chlorométhyl)-2-[diphénylméthylèneamino]pentanenitrile **37**, lequel après cyclisation en milieu basique (K_2CO_3 ou LDA) et hydrolyse acide (HCl, 6 N) fournit l'acide (1*S*,2*S*)-coronamique **17** (>88% ee). Il est remarquable que ces courtes séquences de synthèse, ne nécessitant pas d'auxiliaire chiral ou de précurseurs optiquement actifs coûteux, n'altèrent pas la pureté énantiomérique des centres asymétriques de ces 2,3-méthanoaminoacides. Cependant, la diastéréosélectivité *E* de la cyclisation n'est pas améliorée par l'utilisation de substituant *N*-(diphénylméthylène)amino stériquement encombrant, contrairement aux résultats indiqués par les calculs de la mécanique moléculaire (MAD).

1-Amino-1-cyclopropanecarboxylic acid (ACC) and its derivatives are currently attracting special attention because of their outstanding biological activities and potential use in conformationally restricted peptides providing biosynthetic and mechanistic probes (2–4). As a matter of fact, they constitute a unique form of constrained amino acids, naturally occurring either unbound or simply linked as dipeptides (5). However, the structure of BZR-cotoxin, the major component of BZR-toxin, which causes leaf spot disease in corn and induced high pathogenicity in rice plant, has been recently determined to be a cyclic nonadepsipeptide involving the ACC moiety (6).

Asymmetric syntheses of 1-aminocyclopropanecarboxylic acid derivatives have recently been reported from the cycloaddition of diazomethane to a dehydro amino acid derivative using (1*R*,2*R*,5*R*)-2-hydroxy-3-pinanone as chiral auxiliary (7), from the cyclopropanation of optically active 3-alkylidene-1,4-oxazin-2-ones with (diethylamino)phenyloxosulfonium methylide (8), or from the stepwise dialkylation of the bislactim ethers of cyclo(L-Val-Gly-) and (L-*tert*-Leu-Gly-) with a large excess of *trans*-1,4-dichloro-2-butene (9). (For other stereocontrolled approaches to differentially substituted ACC derivatives see ref. 10*a*–*g*).

We have recently reported a new preparation of ACC based on the quantitative base-induced cyclization of a 2-imino-4-chlorobutyronitrile readily available from acrolein; this synthesis is suitable for large-scale preparations (11). We report herein an adaptation of this route to the general construction of the *E* 2-alkyl ACC frameworks that permits us to prepare these 2,3-methanoamino acids, in either *d* or *l* enantiomeric forms, in high optical purity, and which do not require any chiral auxiliary or cyclopropanating reagents.

Synthesis of (1*S*,2*S*)-norcoronamic acid 1*a*

(1*S*,2*S*)-2-Methyl-1-aminocyclopropanecarboxylic acid **1***a* (norcoronamic acid) was isolated from norcoronatine, a component of the phytotoxic fraction of *Pseudomonas syringae* pv *glycinea* (12). *N*-Methyl (1*S*,2*S*)-norcoronamic acid **1***b*, isolated from streptomyces *braegensis* subsp. *japonicus*, has been found to be a constituent of the cyclic peptide portion of the recently discovered DNA-intercalating antibiotics of the quinomycin family (13).

Taking into account our synthesis of ACC from acrolein (11), a suitable precursor of the amino acid (1*S*,2*S*)-**1***a* could be a 1-(benzylideneamino)cyclopropylcarbonitrile such as (1*S*,2*S*)-**2**, arising from the diastereoselective base-induced cyclization of the (3*R*)-4-chloro-2-(benzylideneamino)-3-methylbutane-

[1]Parts of this work were presented orally by J.S. to the IUPAC 9th International Conference on Organic Synthesis (ICOS-92), see ref. 1.

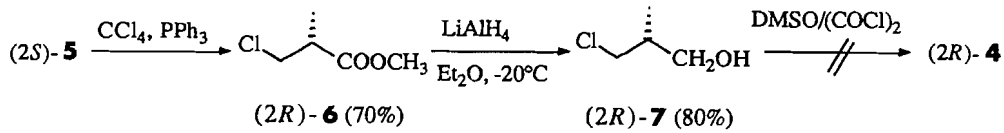

SCHEME 2

nitrile **3**. A convenient Strecker synthesis (14) would provide this Schiff base **3** from the 3-chloroisobutyraldehyde (2*R*)-**4** prepared by chlorination and controlled reduction of the commercially available methyl 3-hydroxy-2-methyl propionate (2*S*)- **5**,[3] as shown on the retrosynthetic scheme (Scheme 1).

Chlorination of the hydroxyester (2*S*)-**5** by triphenylphosphine in carbon tetrachloride (16) at 80°C for 11 h gave the expected methyl (2*R*)-3-chloro-2-methylpropionate **6** in 70% yield. Then, addition of a 1 M lithium aluminum hydride solution in diethyl ether (2 equiv.) at –20°C, to avoid any further reduction of the chlorine atom (17), provided the (2*R*)-3-chloro-2-methylpropan-1-ol (2*R*)-**7** in 80% yield. However, Swern oxidation (DMSO, $(COCl)_2$, NEt_3) (18) of (2*R*)-**7** did not provide the expected β-chloroisobutyraldehyde (2*R*)-**4**, but led exclusively to 2-methyl acrolein, likely arising from base-induced (NEt_3) dehydrochlorination (Scheme 2).

To overcome this problem, the leaving group, i.e., the chlorine atom, should be introduced at a further step of this sequence. Effectively silylation of (2*S*)-**5** by *tert*-butyldimethylsilyl chloride[4] in DMF in the presence of 2.5 equivalents of imidazole (20) gave the (2*S*)-methyl 3-*tert*-butyldimethylsiloxy-2-methylpropionate **8** in 93% yield. Controlled reduction of the ester **8** by 2 equivalents of diisobutylaluminum hydride (DIBAH) in dichloromethane at –78°C gave the (2*S*)-3-*tert*-butyldimethylsiloxy-2-methyl propanal **9** in 80% yield, as well as 20% of the corresponding alcohol. Alternatively, complete stepwise reduction of **8** by DIBAH (5 equiv.) followed by a Swern oxidation (DMSO, $(COCl)_2$, NEt_3) (18) led exclusively to the expected aldehyde (2*S*)-**9** in 86% yield (21). To avoid any racemization, the crude aldehyde (2*S*)-**9**[5] was treated directly by an excess of trimethylsilylcyanide (TMSCN) in the presence of a catalytic amount of zinc iodide at 0°C. When complete disappearance of the carbonyl stretching of **9** was observed by IR ($\nu_{C=O}$ 1730 cm^{-1}), addition of methanol and 1.1 equivalents of benzylamine led, after heating at 40°C for 2 h, to a 1:1 diastereomeric mixture of the (2*R*,3*R*)- and (2*S*,3*R*)-2-(*N*-benzylamino)-4-*tert*-butyldimethylsiloxy-3-methylbutyronitriles (3*R*)-**10**, in 60% overall yield from the siloxy ester (2*S*)-**8**. Although these diastereoisomers are easily separable by simple liquid chromatography, due to the formation of a planar carbanion at the C-2 carbon of the nitrile **10** in the further cyclization step (vide infra), such a separation appeared in fact not necessary.

Deprotection of **10** with tetra-*n*-butylammonium fluoride (20) in THF at room temperature for 30 min gave the (3*R*)-2-(*N*-benzylamino)-4-hydroxy-3-methylbutyronitrile **11***a* (X = OH) in 94% yield. Treatment of aminoalcohol **11***a* with tosyl chloride in pyridine at 0°C following the classical conditions of tosylation was ineffective, while reaction with tosyl chloride and pyridine in chloroform (23) provided a 32:42:26 mixture of O-tosyl, *N*-tosyl, and *N*,*O*-ditosyl derivatives; on the other hand, use of tosyl chloride in triethylamine containing a catalytic amount of *N*,*N*-dimethylaminopyridine (DMAP) (24) in dichloromethane led in 91% yield, exclusively, to the (3*R*)-2-(*N*-benzylamino)-3-methyl-4-*p*-tosyloxybutyronitrile **11***b* (X = OTs). Thus, as reported, the chemoselectivity of the O- or N-tosylation appeared highly dependent on the basicity of the amine used for the dehydrochlorination (25). Reaction of the *O*-tosylate **11***b* with lithium chloride in *N*-methyl pyrrolidine (NMP) at room temperature[6] for 2 h gave a 1:1 diastereomeric mixture of (3*R*)-2(*N*-benzylamino)-4-chloro-3-methyl butyronitriles **11***c* in 81% yield (Scheme 3).

ACC is biosynthesized from (*S*)-adenosylmethionine under the catalytic influence of a pyridoxal 5′-phosphate-linked enzyme (ACC synthase) (27) obtained, for instance, from ripe tomatoes (28). Base-induced cyclizations of *N*-protected

[3]The (*R*)- and (*S*)-methyl 3-hydroxy-2-methylpropionate, resulting from the enantioselective hydroxylation of methyl isobutyrate by microorganisms, are convenient bifunctional building blocks for the synthesis of a wide variety of optically active molecules, see ref. 15.

[4]This protecting group is stable to the Swern oxidation conditions, see T.T. Tidwell (19).

[5]Silica gel chromatography of aldehyde (2*S*)-**9** entailed partial isomerization, see ref. 22.

[6]Use of dimethylformamide (DMF) for the nucleophilic substitution of tosylate by lithium chloride generally required heating at 85°C, while use of *N*-methylpyrrolidone (NMP) activates and achieves the reaction at room temperature (26).

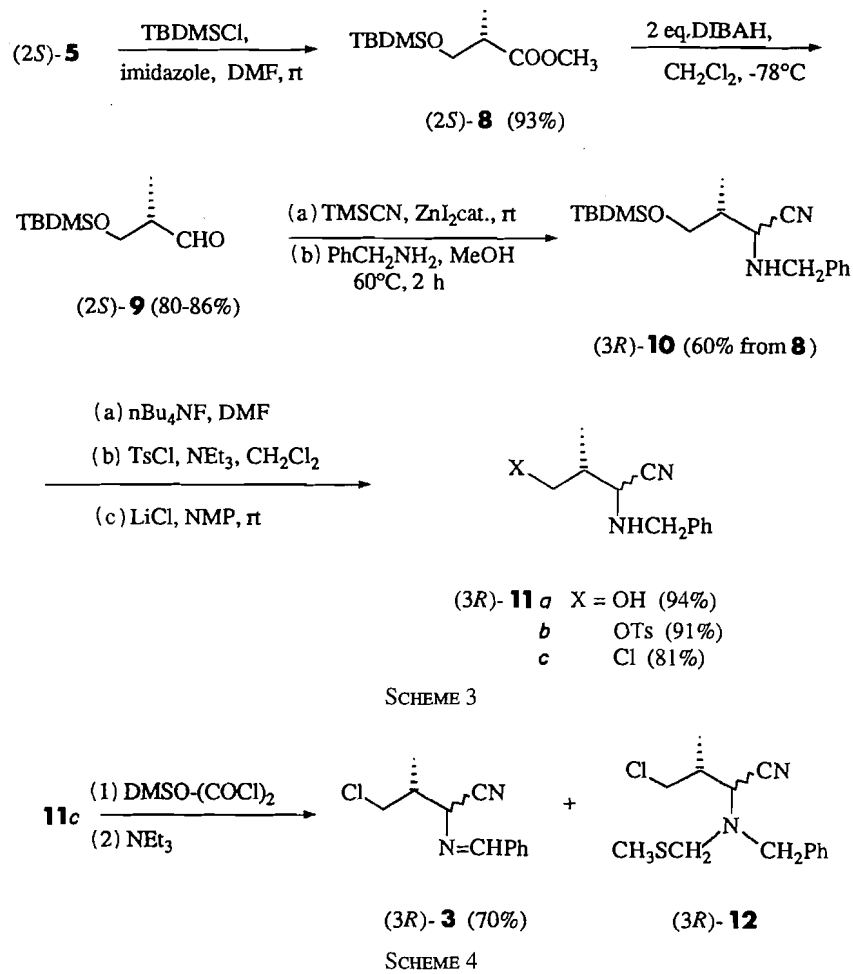

SCHEME 3

SCHEME 4

2-aminobutyrates substituted in γ by a leaving group (i.e., bromide (29–31) dimethylsulfonium (32), trimethylammonium (33), and 4-bromo-2-azidobutyrates (34)) have been reported to provide ACC in high yields. However, although the nitrile and carboxylate groups have comparable ability to stabilize an adjacent carbanion,[7] the cyclization of 2-*N*-benzyl-4-chlorobutyronitrile (36, 37) and of (3*R*)-**11***c* were unfortunately not achieved under a variety of basic conditions (i.e., K_2CO_3 and Cs_2CO_3 in DMF at 80°C, KOH in DMSO, K-*t*-BuO in THF, *n*-BuLi, NaH in THF, ...) (37). As we had previously reported the quantitative ready cyclization of a 4-chloro-2-iminobutyronitrile under smooth basic conditions (i.e., K_2CO_3 in DMF at room temperature, for instance (11, 36)), we undertook the transformation of the benzylamine **11***c* into the corresponding imine. First of all, we tried to cleave the *N*-benzyl protecting group; curiously, in spite of many attempts under various hydrogenolysis conditions (i.e., either with 5–10% Pd/C catalysis under 1–53 psi (1 psi = 6.9 kPa) hydrogen pressure (38), with a stoechiometric amount of Pd/C and ammonium formiate as hydrogen source (39), or with 20% of the Pearlman catalyst (40) ($Pd(OH)_2$) under 1–53 psi hydrogen pressure), the amine deprotection of **11***c* and of its chlorohydrate derivative, prepared by bubbling gaseous HCl through an etheral solution of **11***c*, failed. So, formation of the corresponding imine by transimination with benzophenone imine (41), which was successfully achieved from the parent 2-amino-4-chlorobutyronitrile (11), was not obtained from **11***c* by this way.

Swern oxidation is currently used to prepare carbonyl compounds from primary or secondary alcohols (18), but only a few reports concern the oxidation of amines into imines by the DMSO($(COCl)_2$/NEt_3 reagent (42); effectively, treatment of the *N*-benzylamine **11***c* under Swern oxidation conditions (18, 43) led to the expected imine, i.e., the (3*R*)-2-(phenylmethyleneamino)-4-chloro-3-methylbutyronitrile **3**, in 70% yield, as well as 5% of methylthiomethylamine **12** as by-product (44) (Scheme 4).

Indeed, formation of the imine moiety activates the proton in α of the nitrile function since the Schiff base (3*R*)-**3** underwent cyclization even upon simple treatment with potassium carbonate in DMF at room temperature for 30 min to provide, in 80% yield, a 84:16 diastereomeric mixture of (1*S*,2*S*)-**2** and (1*R*,2*S*)-1-(phenylmethyleneamino)-2-methylcyclopropanenitrile **13**. Simple chromatography on silica gel allowed us to obtain a mixture containing 94% of the diastereomer (1*S*,2*S*)-**2**. This ratio was determined by ^{1}H NMR spectroscopy, from the integration of the benzylic proton of the imines (1*S*,2*S*)-**2** and (1*R*,2*S*)-**13** recorded at δ 8.60 and 8.65 ppm, respectively.

The diastereoselectivity observed in the cyclization of (3*R*)-**3**, i.e., major formation of the *E* diastereomer (1*S*,2*S*)-**2**, likely arises from an *s-trans* conformation of the intermediate iminonitrile carbanion **15** (10*f*, 45) where the methyl and nitrile groups would have a *syn* relationship, to minimize the steric

[7]Effectively, the pK_a of phenylacetonitrile and ethylphenylacetate in DMSO (K as counterion) are 21.9 and 22.6, respectively; see F.G. Bordwell (35).

FIG. 1

interactions as confirmed by molecular mechanic calculations MAD (Molecular Advanced Design) (Fig. 1).[8]

Then, acid hydrolysis of (1*S*,2*S*)-**2** (ds 94:6) with 1 M HCl at room temperature for 15 h (11) gave the (1*S*,2*S*)-1-amino-2-methylcyclopropanecarbonitrile hydrochloride **14** containing 6% of its (1*R*,2*S*) stereoisomer, as evidenced from ^{1}H NMR spectroscopy by the occurrence of two doublets at δ 1.19 and 1.29 ppm (ratio 94:6, J = 6.7 and 6.27 Hz, respectively). Finally, 6 M HCl hydrolysis of (1*S*,2*S*)-**14** at reflux for 11 h (11) followed by ion-exchange chromatography (Dowex 50 × 8-100) furnished, quantitatively (97% overall yield from (1*S*,2*S*)-**2**), the (1*S*,2*S*)-norcoronamic acid **1***a*, as well as one-pot 6 M HCl hydrolysis of the iminonitrile (1*S*,2*S*)-**2**. Alternatively, basic hydrolysis of the iminonitrile (1*S*,2*S*)-**2** by 0.8 M sodium hydroxide at reflux for 24 h (11) also gave, after neutralization to pH 7 by concentrated HCl and reverse-phase liquid chromatography, (1*S*,2*S*)-**1***a*, quantitatively (Scheme 5).

It must be emphasized that the competitive formation of any products arising from three-membered ring opening has not been observed under these conditions, contrary to recent reports concerning the syntheses of 2,2-dialkyl-ACC derivatives (46).

The 94:6 diastereomeric excess of this norcoronamic acid **1***a* was easily determined from its ^{1}H NMR spectra: effectively, the (1*R*,2*S*) stereoisomer is characterized by a multiplet at δ 0.75 attributed to the proton at C-2 of the cyclopropane ring, while the methyl of (1*S*,2*S*)-**1***a* is clearly characterized by a doublet at δ 1.03 ppm (3H, J = 6 Hz) (47). To determine its enantiomeric excess, (1*S*,2*S*)-**1***a* was treated with 4 N sodium hydroxide and chloroacetic anhydride to provide the (1*S*,2*S*)-1-(*N*-chloroacetyl)-2-methylcyclopropanecarboxylic acid **16**. It had previously been reported that only the (1*S*,2*S*) diastereomer of this aminochloroacetamide is a substrate for the Porcine Kidney Acylase (48); effectively, (1*S*,2*S*)-**16** underwent total hydrolysis upon treatment with this enzyme to give back the free amino acid (1*S*,2*S*)-**1***a* as shown in ^{1}H NMR spectroscopy by the total disappearance of the chloroacetylmethylene signal at δ 3.88 ppm (Scheme 6).

In conclusion, in nine steps from commercially available (2*S*)-methyl 3-hydroxy-2-methylpropionate **5** we have prepared in 22% overall yield the (1*S*,2*S*)-norcoronamic acid **1***a* with 94:6 diastereoselectivity and >95% enantiomeric excess. This scheme did not alter the optical purity of the stereogenic center of the asymmetric precursor **5**, and the availability of both its enantiomers allows for the unambiguous preparation of either the *d* or *l* forms of this 2,3-methano amino acid.

Synthesis of non-natural (1*R*,2*R*)-coronamic acid 18

The coronamic acid, i.e, the (1*S*,2*S*)-2-ethyl-1-aminocyclopropanecarboxylic acid **17**, was isolated from the hydrolysis of coronatine, produced by *Pseudomonas caronafacience* var. *atropupurea* (49, 50). This plant toxin induces chlorosis in Italian ryegrass or soya (50, 51), hypertrophy of potato cells, and inhibition of corn root grown (52). Its (1*S*,2*R*) non-natural

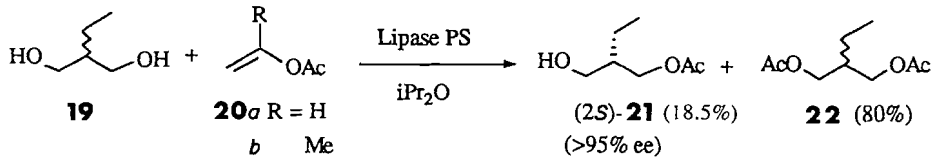
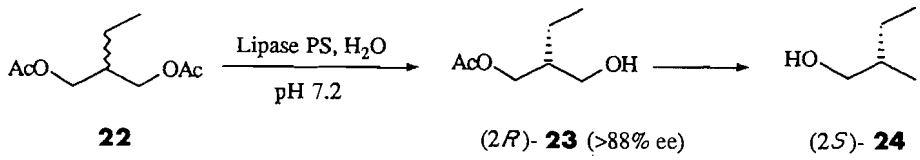


SCHEME 7



SCHEME 8

diastereoisomer known as *allo* coronamic acid is converted into 1-butene by plant tissues (53).

Synthesis of coronamic acid following the scheme used for the preparation of (1*S*,2*S*)-norcoronamic acid **1***a* (see Scheme 1) required (2*S*)-methyl 2-(hydroxymethyl)butyrate; unfortunately in contrast to (2*S*)-**5**, this chiral ester was not available. Condensation of 2-ethylmalonic acid with (–)-menthol in the presence of dicyclohexylcarbodiimide and 4-*N*,*N*-dimethylaminopyridine (DMAP) was reported to furnish the corresponding (2*R*)-monomenthyl acid ester with 99% diastereoselectivity (54); following this procedure, we in fact obtained, after recrystallization, a 1:1 diastereomeric mixture of these half-esters. To readily obtain a suitable precursor of the 2-methanoamino acid **17** we first investigated the enzymatic monoacetylation of 2-ethyl-1,3-propanediol **19**, by the lipase PS extracted from the microorganism *Pseudomonas cepacia* (55). After many attempts, it appeared that vinyl acetate **20***a* (R = H) (2 equiv.) was more effective than 2-propenyl acetate **20***b* (R = Me) as enantioselective acetylation agent and that diisopropyl ether must be preferred to chloroform or vinyl acetate as solvent. Higher enantiomeric excesses (>95%) were obtained when the reaction of the 1,3-diol **19** was complete (as monitored by TLC) but, under these conditions, the 1,3-diacetate **22** was formed in 80% yield and the expected (2*S*)-2-(hydroxymethyl)butyl acetate **21** ($[\alpha]_D^{20}$ –13.8, *c* = 1, $CDCl_3$) was isolated after silica gel chromatography in only 18.5% yield (Scheme 7).

Otherwise, hydrolysis of 2-(acetoxymethyl)butyl acetate **22**, readily available from the 1,3-diol **19** (acetic anhydride, DMAP in ether at 0°C) by lipase PS led in 65% yield, after silica gel chromatography, to the monoacetate (2*R*)-**23** ($[\alpha]_D^{20}$ + 12.1, *c* = 1, $CDCl_3$) with 88% enantiomeric excess, as determined from its ^{1}H NMR spectra recorded in the presence of 0.5 equivalent of a chiral shift reagent ($Eu(hfc)_3$), by relative integration of the methylene signals at δ 10.2 and 12.6 ppm, compared to the racemic monoacetate. It must be emphasized that the diacetate **22** underwent ready hydrolysis into racemic monoacetate in the lack of lipase PS; thus **22** must be added to an aqueous solution of lipase PS buffered at pH 7.2 by 0.1 M potassium phosphate. Higher enantiomeric excesses were obtained when the reaction was stopped after 69% hydrolysis. Enzymatic hydrolysis of homologous esters, i.e., 3-butyryloxy-2-ethylpropyl butyrate, did not improve the enantiomeric excess.

The (2*R*) absolute configuration of **23** was established by its transformation into the known (2*S*)-2-methylbutan-1-ol **24**,[9] by tosylation (TsCl, pyridine, DMAP) and reduction ($LiAlH_4$); therefore the (2*S*) absolute configuration of the monoacetate **21** was also confirmed (Scheme 8).

First of all, we performed the total synthesis of the non-natural (1*R*,2*R*)-coronamic acid **18** from the monoacetate (2*R*)-**23** (>88% ee). Silylation by *tert*-butyldimethylsilyl choride (DMF, 2.5 equiv. of imidazole, cat. DMAP) (19, 20) followed by deacetylation with potassium carbonate in methanol provided the (2*S*)-2-(*tert*-butyldimethylsiloxymethyl)-butanol **25** in 84% overall yield. Swern oxidation (DMSO, $(COCl)_2$, Et-iPr_2N) (18)[10] gave the corresponding aldehyde (2*R*)-**26**, which was directly treated with an excess of TMSCN in the presence of zinc iodide in diethyl ether at 0°C. After complete reaction of the aldehyde monitored by gas chromatography, addition of a solution of 1.1 equivalents of benzylamine in methanol led, upon heating at 60°C for 4 h, to a 1:1 diastereomeric mixture of (2*R*,3*S*)- and (2*S*,3*S*)-2-(*N*-benzylamino)-3-(*tert*-butyldimethylsiloxymethyl) pentanenitrile **27**, in 66% overall yield from the butanol (2*S*)-**25**.

Desilylation of (3*S*)-**27** (nBu_4NF, THF) (20), chemoselective tosylation (TsCl, 1 equiv. NEt_3, DMAP, CH_2Cl_2) (24), and chlorination (LiCl, NMP) (26), analogous to the transformation of (3*R*)-**10** into the 4-chlorobutyronitrile (3*R*)-**11***c* (vide supra, Scheme 3) gave a 1:1 diastereomeric mixture of (2*R*,3*S*)- and (2*S*,3*S*)-2-(*N*-benzylamino)-3-(chloromethyl)valeronitriles **28** in 76% overall yield from (2*S*)-**25** (Scheme 9).

Contrary to (3*R*)-**11***c*, the 2-(*N*-benzylamino)-3-(chloromethyl)valeronitrile **28** underwent Swern oxidation (42) into the imine **29** with only 30% yield; use of an excess of DMSO and $(COCl)_2$ reagents did not improve the yield but entailed mainly formation of methylthiomethylamine derivative (3*S*)-**30** (18, 19, 44). Use of *N*,*N*-diisopropylethylamine, known to limit, by steric hindrance, formation of methylthiomethyl ether (44) in the Swern oxidation of alcohol, totally inhibited the reaction of (3*S*)-**28**. Manganese dioxide in refluxing toluene was ineffective (58*a*),[11] as was also pyridinium dichromate (59) in dichloromethane (3% of oxidation). On the other hand, use of *tert*-butyl hydroperoxide (8 equiv., TBHP) (60) and a catalytic amount of ruthenium dichloride – triphenylphosphine (5% $RuCl_2$–$(PPh_3)_2$) (61) in the presence of molecular sieves (4 Å) to trap *tert*-butanol and water formed as by-products, at room temperature, gave the expected imine (3*S*)-**29** in 60% yield (Scheme 10).

[9](S)-2-Methyl-1-butanol ($[\alpha]_D^{20}$ –6.3 ± 0.3, c = 1, ethanol) is used as chiral building block: see ref. 56.

[10]Hindered amine, i.e., iPr_2EtN, and work-up with buffered water at pH 7 were used to avoid any racemization of the aldehyde. See ref. 57.

[11]For a review of manganese dioxide oxidation see ref. 58*b*.

SCHEME 10

Upon treatment with potassium carbonate in DMF at room temperature for 30 min the chloroimine (3*S*)-**29** underwent cyclization to provide, in 70% yield, a 80:20 mixture of (1*R*,2*R*)-**31** and (1*S*,2*R*)-1-(*N*-phenylmethyleneamino)-2-ethyl cyclopropanecarbonitrile **32**, as shown by ^{1}H NMR spectroscopy from the simple integration of the benzylic proton of these *N*-benzyl cyclopropylimines at δ 8.55 and 8.60 ppm, respectively. Acid hydrolysis of (1*R*,2*R*)-**31** (containing 20% of (1*S*,2*R*)-**32**)[12] with 1 M HCl at room temperature for 15 h gave the (1*R*,2*R*)-1-amino-2-ethylcyclopropanecarbonitrile hydrochloride (1*R*,2*R*)-**33** in 80% yield. Addition of 6 M hydrochloric acid to (1*R*,2*R*)-**33** led, on heating at reflux for 15 h, to a 80:20 mixture of (1*R*,2*R*)- and (1*S*,2*R*)-coronamic acid hydrochlorides, in 70% yield.

Otherwise, treatment of the aminonitrile hydrochloride (1*R*,2*R*)-**33** with an 0.8 M sodium hydroxide solution at reflux for 24 h led, quantitatively, after neutralization (conc. HCl) and reverse-phase liquid chromatography, to the (1*R*,2*R*)-coronamic acid **18** (Scheme 11).

The absolute stereochemistry was determined from ^{1}H NMR spectroscopy by the occurrence of two triplets at δ 0.72 and 0.84 ppm corresponding to the (1*R*,2*R*)-coronamic acid **18** and (1*S*,2*R*)-*allo* coronamic acid, respectively, with the diastereomeric ratio 80:20. As reported, the corresponding methyl esters, prepared upon treatment with an esterifying medium (MeOH–$SOCl_2$) (45), were readily separable by flash liquid chromatography on silica gel (9); then, acidic hydrolysis (HCl, propylene oxide) allowed us to isolate diastereomerically pure (1*R*,2*R*)-coronamic acid **18**. The enantiomeric excess of (1*R*,2*R*)-**18** determined by examination of the ^{19}F NMR of its Mosher amide derivative (8) (obtained upon treatment with the (*S*)-2-methoxy-2-trifluoromethylphenyl acetyl chloride) (62), was 88%; thus, this sequence also did not alter the optical purity of the stereogenic center of the asymmetric precursor, i.e., the monoacetate (2*R*)-**23**.

In nine steps from (2*R*)-2-(hydroxymethyl)but-1-yl acetate **23**, readily prepared by enantioselective hydrolysis of 2-(acetoxymethyl)but-1-yl acetate **22** catalysed by lipase PS, we have prepared in 18% overall yield the non-natural (1*R*,2*R*)-coronamic acid **18** with 88% enantiomeric excess.

Synthesis of (1*S*,2*S*)-coronamic acid 17

To improve the *E* diastereoselectivity of the cyclization of the 2-(*N*-benzylideneamino)-4-chlorobutyronitriles, and taking into account the results of some molecular mechanic calculations (MAD)[8] indicating that a bulky *N*-benzylideneamino substituent should favor formation of the *E* 1-amino-2-ethylcyclopropanecarboxylic acid, we prepared the suitable benzophenone imine (3*R*)-**37**.

Thus, treatment of the (2*S*)-2-(acetoxymethyl) butanal **34**, prepared by Swern oxidation (18) of the butanol (2*R*)-**23** by 1.25 equivalents of TMSCN and 5% of ZnI_2 at room temperature for 1 h, was followed by the addition of 1.1 equivalents of aminodiphenylmethane in methanol. The mixture was heated at reflux for 8 h. After cooling to room temperature, 2 equivalents

[12]In spite of many attempts, and in contrast to (1*S*,2*S*)-**18**, the iminonitrile **36** was not separated from its stereomer (1*S*,2*R*)-**37** by simple liquid chromatography on silica gel.

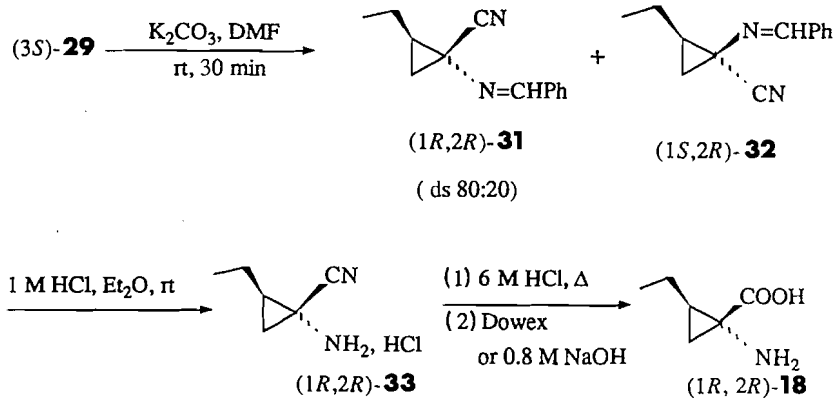
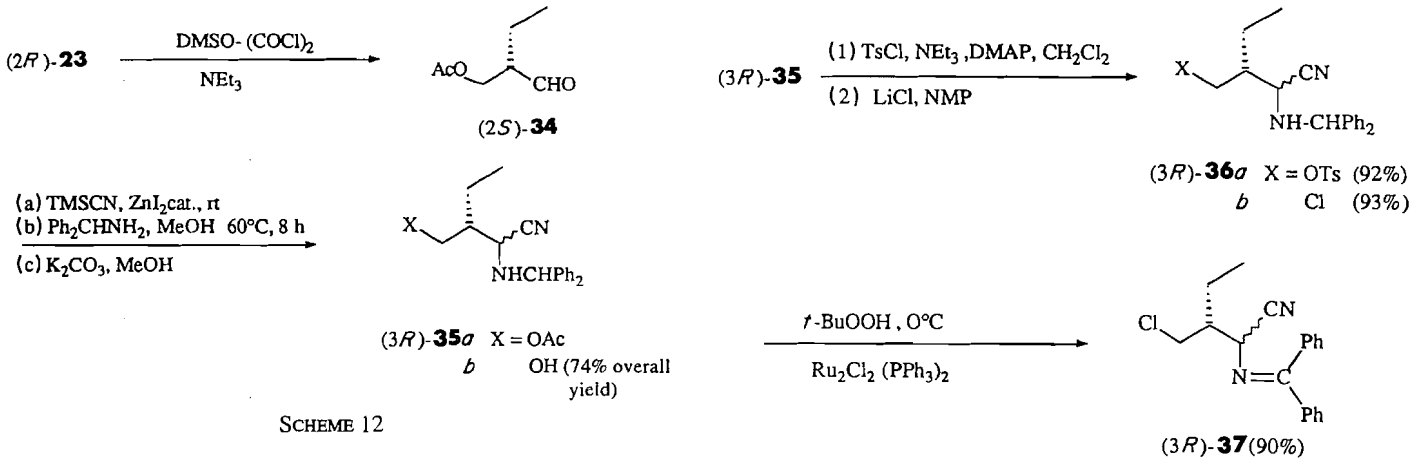


SCHEME 11



SCHEME 12

SCHEME 13

of potassium carbonate were added to the acetate **35***a* to give directly a 55:45 diastereomeric mixture of (2*R*,3*R*)- and (2*S*,3*R*)-2-[N-(diphenyl)methylamino]-3-(hydroxymethyl)-valeronitrile **35***b* in 74% overall yield from (2*R*)-**23** (Scheme 12).

Chemoselective tosylation (TsCl, NEt_3, DMAP, CH_2Cl_2) (24) gave the tosylate (3*R*)-**36***a* (92%), and chlorination (LiCl, NMP) (26) gave the (3*R*)-2-[*N*-(diphenyl)methylamino)-3-(chloromethyl)valeronitrile **36***b* in 93% yield. Oxidation of this chloroamine **36***b* with a 3 M solution of *tert*-butylperoxide in isooctane in the presence of $RuCl_2$–$(PPh_3)_2$ at 0°C for 15 h gave the expected (3*R*)-3-(chloromethyl)-2-[diphenylmethyleneamino)valeronitrile **37** in 90% yield (Scheme 13).

Upon treatment with 1.1 equivalents of potassium carbonate in DMF at room temperature for 3 h, the chloroimine (3*R*)-**37** underwent cyclization to provide, in 92% yield a 65:35 diastereomeric mixture of (1*S*,2*S*)-**38** and (1*R*,2*S*)-1-(*N*-diphenylmethyleneamino)-2-ethyl cyclopropanecarbonitrile **39** (Scheme 14). Unfortunately, contrary to the forecast of the molecular mechanic calculations (MAD),[8] the diastereoselectivity of the cyclization (3*R*)-**37** → (1*S*,2*S*)-**38** was only slightly improved by the presence of a diphenylmethyleneamino substituent. The cyclization was performed under various basic conditions, and the diastereoselectivity was improved to 76:24 by using lithium diisopropylamide at –90°C; however, addition of HMPA has no effect on the diastereoselectivity.

Flash chromatography eluted with dichloromethane allowed us to readily isolate the diastereomerically pure cyclopropylcarbonitrile (1*S*,2*S*)-**38** in 72% yield, and its diastereomer (1*R*,2*S*)-**39** in 23% yield (Scheme 14). Finally, addition of 1 N HCl in diethyl ether to (1*S*,2*S*)-**38** provided the (1*S*,2*S*)-1-amino-2-ethylcyclopropane carbonitrile hydrochloride **40**, while addition of 6 M hydrochloric acid provided, after heating at reflux for 15 h, the expected amino acid hydrochloride, which by chromatography through a Dowex 50 × 8-100 ion-exchange column led in 97% yield to the (1*S*,2*S*)-coronamic acid **17** with 88% enantiomeric excess, determined by ^{19}F NMR analysis of the corresponding Mosher amide (Scheme 15).

Analogously, the cyclopropylcarbonitrile (1*R*,2*S*)-**39** was hydrolyzed by 6 N HCl at reflux into the (1*R*,2*S*)-*allo*-coronamic **17′** (88% ee).

In seven steps from the butanol (2*R*)-**23** and in 30% overall yield we have performed the total synthesis of the (1*S*,2*S*)-coronamic acid **17**. Again, the enantiomeric purity of this 2,3-methano amino acid depends only on the optical purity of its precursor, i.e., the 2-(hydroxymethyl)but-1-yl acetate (2*R*)-**23**. It is noteworthy that these sequences did not alter at all the enantiomeric purity of the stereogenic centers.

Experimental section

Methyl (2R)-3-chloro-2-methylpropionate ***6***

To a solution of 16.7 g (63.3 mmol) of triphenylphosphine in 90 mL of carbon tetrachloride was added dropwise, under argon at room temperature, 4.7 mL (42.19 mmol) of (2*S*)-methyl- 3-hydroxy-2-methyl-propionate **5**. The mixture was stirred for 11 h at 80°C; then carbon

tetrachloride and chloroform (formed as by-product) were removed under reduced pressure. The residue was treated with 80 mL of pentane and the triphenylphosphine oxide was eliminated by filtration. The solvent was removed under reduced pressure and the residue was distilled to yield 4.6 g (80%) of pure methyl (2*R*)-3-chloro-2-methylpropionate **6**: bp 70°C/27 Torr (1 Torr = 133.3 Pa); $[\alpha]_D^{20}$ +10.4 (*c* = 1, CCl_4); IR (CCl_4): 2960–2660 (CH alkyl), 1750 ($\nu_{C=O}$), 1170 (ν_{C-O}) cm^{-1}; ^1H NMR (250 MHz, $CDCl_3$) δ: 1.29 (s, 3H, *J* = 7.06 Hz), 2.85 (m, 1H), 3.68 (dd, 1H, *J* = 18.58 and 5.96 Hz), 3.76 (dd, 1H, *J* = 18.56 and 8.49 Hz), 3.75 (s, 3H); ^{13}C NMR (250 MHz, $CDCl_3$) δ: 15.01 (CH_3), 42.10 (C-H), 45.87 (CH_2Cl), 51.97 (CH_3O), 173.5 (C=O); MS (70 eV) *m/z* (%): 136 (0.2) [M^+], 121 (2.3), 103 (47), 101 (2).

(2R)-3-Chloro-2-methylpropan-1-ol 7

To a solution of 400 mg (2.9 mmol) of (2*R*)-methyl 3-chloro-2-methylpropionate **6** in 4 mL of anhydrous diethyl ether, under argon at –20°C, was added dropwise 2.9 mL (2.9 mmol) of 1 M lithium aluminum hydride solution in ether. The mixture was stirred at –20°C for 30 min, then hydrolyzed by portionwise addition of wet sodium sulfate. After filtration on Celite, the ethereal solution was dried (Na_2SO_4); evaporation of the solvent afforded 231 mg (75%) of (2*R*)-3-chloro-2-methylpropan-1-ol **7**: IR (CCl_4): 3600, 3060, 2880, 1050 (C—O) cm^{-1}; ^1H NMR (250 MHz, $CDCl_3$) δ: 1.05 (d, 3H, *J* = 6.85 Hz), 1.65 (s, 1H, OH), 2.05 (m, 1H, CH), 3.63 (m, 4H, CH_2Cl and CH_2OH); ^{13}C NMR (250 MHz, $CDCl_3$) δ: 14.40 (CH_3), 37.74 (CH), 47.62 (CH_2Cl), 64.58 (CH_2OH); MS (70 eV) *m/z* (%): 110 (0.1) [M^+], 109 (0.4), 109 (0.1) [M^+], 107 (0.2), 93 (0.33), 92 (0.21), 90 (0.6), 57 (12.25), 42 (100).

Swern oxidation of 7

To a solution of 140 μL of oxalyl chloride in 4 mL of dichloromethane was added dropwise at –60°C a solution of 250 μL of dimethyl sulfoxide in 0.5 mL of dichloromethane. The solution was stirred for 5 min, then was added a solution of 158 mg (1.46 mmol) of (2*R*)-3-chloro-2-methylpropan-1-ol **7** in 2 mL of dichloromethane within 5 min, maintaining the temperature of the mixture below –55°C. The mixture was stirred at –50°C for 20 min, after which it was cooled to –70°C to add dropwise 1 mL of triethylamine. Then the mixture was allowed to reach room temperature. After addition of 3.5 mL of water, the mixture was stirred for 1 h and extracted twice with 10 mL of dichloromethane. The organic was washed with saturated NaCl and dried over Na_2SO_4. Evaporation of solvent left a volatile residue identified by ^1H NMR as 2-methyl acrolein.

*Methyl (2S)-3-(*tert*-butyldimethylsiloxy)-2-methylpropionate 8*

To a solution of 7.2 g (105.9 mmol) of imidazole and 7.6 g (5.8 mmol) of *tert*-butyldimethylsilyl chloride in 7.5 mL of dimethylformamide (DMF) was added dropwise, under argon, a solution of 5 g (42 mmol) of (2*S*)-methyl 3-hydroxy-2-methylpropionate **5** in 7.5 mL of DMF. The mixture was stirred for 12 h at room temperature and 120 mL of ether and 12 mL of water were added. The organic layer was then washed with water (3 × 12 mL), and dried over anhydrous sodium sulfate. Evaporation of the solvent afforded 9.3 g of an oil, which was purified by chromatography on silica gel (hexane:ether, 95:5) to give 9.1 g (93%) of methyl (2*S*)-3-(*tert*-butyldimethylsiloxy)-2-methylpropionate **8**: $[\alpha]_D^{20}$ +20.7 (*c* = 1, CCl_4); IR (neat): 2960, 2860, 1750 ($\nu_{C=O}$), 1255 (ν_{C-Si}) cm^{-1}; ^1H NMR (250 MHz, $CDCl_3$) δ: 0.03 (s, 6H, $Si(CH_3)_2$), 0.9 (s, 9H, Si-$C(CH_3)_3$), 1.14 (d, 3H, *J* = 7 Hz), CH_3), 2.67 (m, 1H, CH), 3.68 (s, 3H, CH_3O), 3.64 (dd, 1H, *J* = 14.56 and 5.97 Hz), 3.75 (dd, 1H, *J* = 14.56 and 7.06 Hz); ^{13}C NMR (50 MHz, $CDCl_3$) δ: –5.55 (CH_3-Si), 13.40 (CH_3), 18.15, 25.72, 42.47, 51.44 (CH_3-O), 65.19 (CH_3-O), 175.39 (C=O). Anal. calcd. for $C_{11}H_{24}O_3Si$ (232.4): C 56.85, H 10.41; found: C 56.61, H 10.62.

*(2S)-3-(*tert*-Butylidimethylsiloxy)-2-methylpropanal 9*

To a solution of 5 g (21.5 mmol) of (2*S*)-methyl-3-*tert*-butyldimethylsiloxy-2-methylpropionate in 125 mL of dichloromethane at –78°C, under argon, was added dropwise 45.5 mL (45.5 mmol) of a 1 M solution of diisobutylaluminum hydride in toluene. As shown by thin-layer chromatography, the reaction was instantaneous; then 6.3 mL of methanol was added, the mixture was allowed to reach room

temperature, and 55 mL of a saturated sodium and potassium tartrate solution was added followed by 350 mL of ethyl acetate. The organic phase was decanted, dried on anhydrous sodium sulfate, and the solvent removed under reduced pressure to give 4.36 g of an oil containing the (2*S*)-3-(*tert*)butyldimethylsiloxy)-2-methylpropanal (80%), as well as 20% of (2*R*)-3-(*tert*-butyldimethylsiloxy)-2-methyl propanol. To avoid any racemization, the crude aldehyde was not isolated for the further steps: however, 100 mg of this mixture was purified by chromatography on silica gel (ether:hexane, 25:75) to furnish the pure aldehyde (2*S*)-**9**: $[\alpha]_D^{20}$ +25.4 (*c* = 1, CCl_4); IR (neat): 2960, 2860, 2720, 1730 ($\nu_{C=O}$), 1255 (ν_{C-Si}) cm^{-1}; ^1H NMR (200 MHz, $CDCl_3$) δ: 0.03 (s, 6H, CH_3Si), 0.85 (s, 9H, $SiC(CH_3)_3$), 1.09 (d, 3H, *J* = 6.95 Hz, CH_3), 2.53 (m, 1H), 3.80 (dd, 1H, *J* = 10.1 and 6.2 Hz), 3.84 (dd, 1H, *J* = 10.1 and 5.3 Hz), 9.75 (d, 1H, *J* = 1.52 Hz, CHO); ^{13}C NMR (250 MHz, $CDCl_3$) δ: –5.57 (CH_3Si), 10.23 (CH_3), 18.17, 25.73, 48.75, 63.38 (CH_2O), 204.65 (C=O); MS (CI) *m/z* (%): 220 (M + 18, 8.7), 203 (M + 1, 100), 202 (M^+, 13.64), 147 (43.64).

(2R,3R)- and (2S,3R)-2-(N-Benzylamino)-4-(tert-butyldimethylsiloxy)-3-methylbutyronitrile ***10***

To a mixture of 4.36 g (21.5 mmol) of (2*S*)-3-*tert*-butyldimethylsiloxy-2-methylpropanal **9** (containing 20% of the corresponding alcohol) and 40 mg (0.11 mmol) of zinc iodide, kept under argon, was added 3.6 mL (26.8 mmol) of trimethylsilylcyanide ($CNSiMe_3$). The reaction was monitored by IR; after 1 h at room temperature the carbonyl stretching ($\nu_{C=O}$ = 1730 cm^{-1}) disappeared completely. A sample (~100 mg) was purified by chromatography on silica gel (ether:hexane, 5:95) to give a 1:1 diastereomeric mixture of (3*S*)-3-methyl-2-trimethylsiloxy-4-(*tert*-butyldimethylsiloxy)butyronitrile: IR (neat): 2960–2860, 1260 (C-Si), 1100 (CH_2OSi), 870 and 840 (C—Si) cm^{-1}; ^1H NMR (200 MHz, $CDCl_3$) δ: 0.08 (s, 12H), 0.22 (s, 18H, $SiCH_3)_3$), 0.9 (s, 18H, C-$(CH_3)_3$), 1.06 (d, 3H, *J* = 6.89 Hz), 1.09 (d, 3H, *J* = 6.89 Hz), 2.0 (m, 2H), 3.55 (m, 4H, CH_2O), 4.63 (d, 1H, *J* = 6.3 Hz), 4.67 (d, 1H, *J* = 4.86 Hz); ^{13}C NMR (50 MHz, $CDCl_3$) δ: –5.56 (CH_3Si), –5.15 (CH_3Si), 10.89, 11.63, 18.17, 25.80, 41.32, 61.50, 62.84, 63.08, 63.28, 119.24 (C≡N).

To this 2,4-disiloxybutyronitrile was added 34 mL of methanol and the mixture was stirred at room temperature for 5 min. Then 2.3 mL (19 mmol, 1.1 equiv.) of benzylamine was added dropwise, and the mixture was stirred at 40°C for 2 h. The solvent was removed under reduced pressure and the residue treated with 30 mL of ether. The precipitate was eliminated by filtration through Celite and the organic phase concentrated under reduced pressure. The residue was purified by chromatography on silica gel (ether:pentane, 20:80) to give 4.13 g (60% overall yield from (2*S*)-**8**) of a 1:1 diastereomeric mixture of (2*R*,3*R*)- and (2*S*,3*R*)-2-*N*(benzylamino)-4-(*tert*-butyldimethylsiloxy)-3-methylbutyronitrile **10**, which were separated, although not necessary for the following steps, by a second chromatography on silica gel (ether:hexane, 5:95).

*First diastereomer (2R,3R)- or (2S,3R)-**10***: R_f: 0.46 (ether:pentane, 25:75), colourless oil; $[\alpha]_D^{20}$ +84 (*c* = 1, CCl_4): IR (CCl_4): 3340 (NH), 3040, 2960–2860, 2210 ($\nu_{C=O}$), 1260 (C—Si) 1100 (CH_2OSi) cm^{-1}; ^1H NMR (200 MHz, $CDCl_3$) δ: 0.05 (s, 6H, CH_3Si), 0.85 (s, 9H, $C(CH_3)_3$), 1.15 (d, 3H, *J* = 7 Hz, CH_3), 2.15 (m, 2H), 3.50–3.70 (m, 3H), 3.85 (d, 1H, *J* = 12.78 Hz), 4.05 (d, 1H, *J* = 12.78 Hz), 7.45 (m, 5H); ^{13}C NMR (50 MHz, $CDCl_3$) δ: –5.64 (CH_3Si), 13.20, 18.08, 25.74, 38.39, 51.89, 53.30, 65.07, 119.45 (C≡N), 127.36, 128.38, 128.44, and 138.45 (arom. C). Anal. calcd. for $C_{18}H_{30}N_2OSi$ (318.54): C 67.88, H 9.49; found: C 67.63, H 9.46.

*Second diastereomer (2S,3R)- or (2R,3R)-**10***: R_f: 0.40 (ether:pentane, 25:75), colourless oil; $[\alpha]_D^{20}$ –59 (*c* = 1, CCl_4); IR (CCl_4): 2210 ($\nu_{C=O}$) cm^{-1}; ^1H NMR (250 MHz, $CDCl_3$) δ: 0.05 (s, 6H, $Si(CH_3)_2$), 0.85 (s, 9H, $C(CH_3)_3$), 1.07 (d, 3H, *J* = 6.9 Hz, CH_3), 1.88 (br s, 1H, NH), 2.05 (m, 1H, CH_3), 3.55–3.75 (m, 3H), 3.82 (d, 1H, *J* = 12.9 Hz), 4.14 (d, 1H, *J* = 12.9 Hz), 7.45 (m, 5H, arom. H); ^{13}C NMR (50 MHz, $CDCl_3$) δ: –5.61 (CH_3Si), 12.65, 18.08, 25.72, 38.83, 50.69, 51.96, 64.30, 119.25 (C≡N), 127.41, 128.31, 128.47, and 138.32 (arom. C). Anal. calcd. for $C_{18}H_{30}N_2OSi$ (318.54): C 67.88, H 949; found: C 67.92, H 9.52.

(3R)-2-(N-Benzylamino)-4-hydroxy-3-methylbutyronitrile ***11***a

To a solution of 330 mg (1.04 mmol) of the 1:1 stereoisomeric mixture of (3*R*)-2-(*N*-benzylamino)-4-*tert*-butyldimethylsiloxy-3-methylbutyronitrile **10** in 4 mL of anhydrous THF, under argon, was added at room temperature 2.7 mL (2.7 mmol) of a 1 M solution of *N*-tetrabutylammonium fluoride in THF. The mixture was stirred at room temperature for 30 min. The solvent was removed under reduced pressure and the residue treated with 20 mL of ether. The organic phase was washed with 2 mL of half-saturated sodium chloride, dried on sodium sulfate, filtered, and concentrated under reduced pressure, to produce a brown oil that was purified by chromatography on silica gel (ether:hexane, 90:10) to offer 200 mg (94%) of a 1:1 stereoisomeric mixture of (2*R*,3*R*)- and (2*S*,3*R*)-2-(*N*-benzylamino)-4-hydroxy-3-methylbutyronitrile **11***a*: IR (neat): 3700–3140 ($\nu_{OH,NH}$), 2210 (ν_{C-O}), cm^{-1}; ^1H NMR (200 MHz, $CDCl_3$) δ: 1.05 (d, 3H, *J* = 7.16 Hz, CH_3), 1.09 (d, 3H, *J* = 7.52 Hz, CH_3), 2.15 (m, 4H), 2.50 (nr s, 2H, OH), 3.52 (m, 2H), 3.70 (m, 4H), 3.80 (d, 1H, *J* = 12.9 Hz), 4.09 (d, 1H, *J* = 12.9 Hz), 3.84 (d, 1H, *J* = 12.7 Hz), 4.1 (d, 1H, *J* = 12.7 Hz), 7.30 (m, 10H, arom. H); ^{13}C NMR (50 MHz, $CDCl_3$) δ: 12.61, 13.82, 38.39, 37.79, 51.91, 53.37, 54.67, 65.44, 68.88, 118.74 (C≡N), 127.70, 127.84, 128.39, 128.68, 128.74, and 137.47 (arom. H). Anal. calcd. for $C_{12}H_{16}N_2O$ (204.27): C 70.56, H 7.89; found: C 70.50, H 8.08.

(3R)-2-(N-Benzylamino)-4-(p-tolylsulfonyloxy)-3-methylbutyronitrile ***11***b

(a) Tosylation by tosyl chloride in pyridine

To a solution of 347 mg (1.7 mmol) of (3*R*)-2-(*N*-benzylamino)-4-hydroxy-3-methylbutyronitrile **11***a* in 8.5 mL of freshly distilled pyridine was added portionwise at 0°C under argon 356 mg (1.9 mmol) of tosyl chloride. The mixture was kept at 0°C for 48 h. After addition of 10 mL of water, the aqueous phase was extracted by 2 × 20 mL of ether; then the gathered organic phases were washed twice with 5 mL of a 0.1 M hydrochloric acid solution and with 5 mL of a saturated solution of sodium bicarbonate, dried on anhydrous sodium sulfate, filtered, and concentrated under reduced pressure to give a residue identical with the alcohol **11***a*.

(b) Tosylation by tosyl chloride and pyridine in chloroform

To a solution of 300 mg (1.5 mmol) of (3*R*)-**11***a* and 243 μL (3 mmol, 2 equiv.) of pyridine in 2 mL of chloroform freshly purified by chromatography through basic alumina (to remove stabilizing ethanol) was added, at 0°C under argon, 430 mg (2.25 mmol, 1.5 equiv.) of tosyl chloride in 500 μL of chloroform. The mixture was kept at 0°C for 48 h. After work-up (see above), ^1H NMR of the crude residue showed the formation of a 2.6:4.2:3.2 mixture of *N,O*-ditosyloxy, *N*-tosyloxy, and *O*-tosyloxy derivatives of **11***a*.

(c) Tosylation by tosyl chloride, triethylamine, and 4-N,N-dimethylaminopyridine in dichloromethane

To a solution of 1 g (4.9 mmol) of benzylaminoalcohol **11***a* in 20 mL of dichloromethane were added 750 μL (5.39 mmol, 1.1 equiv.) of triethylamine and 30 mg (5%) of 4-*N,N*-dimethylaminopyridine (DMAP). The mixture was cooled to 0°C, then a solution of 1.03 g (5.39 mmol, 1.1 equiv.) of tosyl chloride in 10 mL of dichloromethane was added dropwise. The mixture was stirred at 0°C for 4 h and added to 100 mL of dichloromethane. After the usual work-up (see above) the residue was purified by chromatography on silica gel to offer 1.6 g (91%) of a 1:1 diastereomeric mixture of (3*R*)-2-(*N*-benzylamino)-3-methyl-4-(*para*-tolylsulfonyloxy)butyronitrile **11***b* as a colourless oil: IR (neat): 3340–3220 (ν_{NH}), 2220 ($\nu_{C\equiv N}$), 1600 ($\nu_{C=C}$) cm^{-1}; ^1H NMR (200 MHz, $CDCl_3$) δ: 1.07 (d, 3H, *J* = 7.2 Hz, CH_3), 1.09 (d, 3H, *J* = 7.2 Hz), 1.51 (br s, 2H, NH), 2.25 (m, 2H), 2.44 (s, 6H), 3.4–4.2 (m, 10H), and 7.29–7.80 (m, 18H, arom. H); ^{13}C NMR (50 MHz, $CDCl_3$) δ: 11.73, 12.86, 21.04, 35.69, 50.44, 50.97, 51.29, 70.06, 118.11 (C≡N), 118.40 (C≡N), 127, 127.33, 127.70, 128.01, 129.52, 132.09, 137.76, and 144.63 (arom. C).

(3R)-2-(N-Benzylamino)-4-chloro-3-methylbutyronitrile ***11***c

To 16 mL of *N*-methylpyrrolidone (NMP) under argon was added

Can. J. Chem. Downloaded from www.nrcresearchpress.com by EESC ESCOLA DE ENGENHARIA on 09/08/12
For personal use only.

528 mg (12.5 mmol, 3 equiv.) of lithium chloride. The mixture was stirred at room temperature until complete dissolution of LiCl. Then, a solution of 1.5 g (4.19 mmol) of (3*R*)-2-(*N*-benzylamino)-3-methyl-4-*p*-tolylsulfonyloxybutyronitrile **11***b* in 3 mL of NMP was added dropwise. The mixture was stirred at room temperature for 2 h, filtered through silica gel (ether:hexane, 25:75), and concentrated under reduced pressure to give 754 mg (81%) of a 1:1 diastereomeric mixture of (3*R*)-2-(*N*-benzylamino)-4-chloro-3-methylbutyronitrile **11***c* which was separated by chromatography on silica gel (ether:pentane, 25:75).

*First diastereomer (2*R*,3*R*) or (2*S*,3*R*)-**11**c*: R_f: 0.54 (ether:pentane, 50:50); colourless oil; $[\alpha]_D^{20}$ + 104.3 (*c* = 1, CCl_4); IR (CCl_4): 3380–3320 (ν_{NH}), 1600 (ν arom.$_{C=C}$) cm^{-1}; ^1H NMR (200 MHz, $CDCl_3$) δ: 1.20 (d, 3H, *J* = 6.78 Hz), 1.57 (br s, 1H, NH), 2.25 (m, 1H), 3.3–3.75 (m, 3H), 3.82 (d, 1H, *J* = 12.84 Hz), 4.08 (d, 1H, *J* = 12.84 Hz), 7.35 (m, 5H, arom. H); ^{13}C NMR (50 MHz, $CDCl_3$) δ: 13.83, 38.96, 46.18, 51.56, 51.86, 119.12 (C≡N), 127.54, 128.26, 128.47, and 138.05. Anal. calcd. for $C_{12}H_{15}ClN_2$ (222.77): C 64.71, H 7.02, Cl 15.94; found: C 64.49, H 6.78, Cl 15.92.

Anal. calcd. for $C_{12}H_{15}ClN_2$ (222.77): C 64.71, H 7.02, Cl 15.94; found: C 64.96, H 6.78, Cl 16.17.

*(3*R*)-2-(*N*-Benzylideneamino)-4-chloro-3-methylbutyronitrile 3*

To a solution of 35.74 mg (0.59 mmol, 1.1 equiv.) of oxalyl chloride in 1.3 mL of dichloromethane, under argon at –60°C, was added dropwise a solution of 76.30 mg (1.2 mmol, 2.2 equiv.) in 140 μL of dichloromethane. The mixture was stirred for 5 min at –60°C and a solution of 120 mg (0.54 mmol) of (3*R*)-2-(*N*-benzylamino)-4-chloro-3-methylamine in 675 μL of dichloromethane was added within 5 min. The mixture was stirred at –60°C for 20 min, then cooled to –78°C to add 450 μL (2.7 mmol, 5 equiv.) of triethylamine. The mixture was allowed to reach room temperature and 1.1 mL of water was added. After separation, the aqueous phase was extracted by 2 × 10 mL of dichloromethane. The gathered organic phases were washed by 2 mL of saturated NaCl, and concentrated under reduced pressure to eliminate dichloromethane. The residue was dissolved with 15 mL of ether, dried on anhydrous sodium sulfate, and after filtration the solvent was removed under reduced pressure to give a yellow oil that was purified by chromatography on silica gel (ether:hexane, 20:80, containing 1% of triethylamine) to give 84 mg (70%) of a 1:1 mixture of (2*R*,3*R*)- and (2*S*,3*R*)-2-(*N*-benzylideneamino)-4-chloro-3-methylbutyronitriles **3** as a pale yellow oil: IR (CCl_4): 2215 ($\nu_{C\equiv N}$), 1665 ($\nu_{C=C}$), 1600 ($\nu_{C=C}$) cm^{-1}; ^1H NMR (250 MHz, $CDCl_3$) δ (diastereomeric mixture): 1.18 (d, 3H, *J* = 6.78 Hz), 1.22 (d, 3H, *J* = 6.72 Hz), 2.50 (m, 2H), 3.67 (m, 4H), 4.88 (dd, 1H, *J* = 6.65 and 1.6 Hz), 4.97 (dd, 1H, *J* = 4.52 and 1.60 Hz), 7.50 (m, 6H), 7.8 (m, 4H), 8.57 (d, 2H, *J* = 1.6 Hz); ^{13}C NMR (50 MHz, $CDCl_3$) δ: 13.89, 14.17, 39.96, 40.29, 46.06, 46.51, 59.57, 60.79, 116.34 (C≡N), 128.78, 131.89 and 134.79 (arom. C), 163.86 (C=N), 164.09 (C≡N); MS (CI, NH_3) (*m/z*): 221 (100), 200 (M^+, 1.71), 199 (M – 1, 2.44).

*(1*S*,2*S*)-1-(*N*-Benzylideneamino)-2-methylcyclopropanecarbonitrile 2*

To a solution of 110 mg (0.5 mmol) of (3*R*)-2-(*N*-benzylideneamino)-4-chloro-3-methylbutyronitrile in 2 mL of dimethylformamide (DMF) was added, portionwise, 76 mg (0.55 mmol, 1.1 equiv.) of potassium carbonate. The mixture was stirred at room temperature for 30 min, then 40 mL of ether and 4 mL of water were added. After separation, the organic phase was washed by 2 × 4 mL of water, dried on anhydrous magnesium sulfate, filtered, and concentrated under reduced pressure to give a brown oil that, after chromatography on alumina (ether:pentane, 20:80), gave 75 mg (80%) of a 84:16 mixture of (1*S*,2*S*)- and (1*R*,2*S*)-cyclopropanecarbonitriles **2** and **13**. A second chromatography on silica gel (ether:hexane, 10:90 containing 1% of triethylamine) provided a 94:6 diastereomeric mixture containing as major product the (1*S*,2*S*)-1-(*N*-benzylideneamino)-2- methylcyclopropanecarbonitrile **2** as a pale yellow oil: IR (CCl_4): 2215 ($\nu_{C\equiv N}$) and 1650 ($\nu_{C=N}$) cm^{-1}; 1H NMR (200 MHz, $CDCl_3$) δ (94:6 diastereomeric mixture): 1.42 (d, 3H, *J* = 6.09 Hz, CH_3), 1.45–1.68 (m, 2H), 1.78 (m, 1H), 7.45 (m, 3H), 7.70 (m, 2H), 8.6 (s, 1H, CH=N, major diastereomer **2**), 8.65 (s, 1H, CH=N, minor diastereomer **13**); ^{13}C NMR (50 MHz, $CDCl_3$) δ (94:6 diastereomeric mixture): 12.29, 14.94, 25.14, 25.65, 26.26, 29.64, 42.70, 117.06 (C≡N), 128.05, 128.63, 130.99, 135.31, 158.99 (CH=N), 160.07 (CH=N); MS (70 ev) (*m/z*) ((1*S*,2*S*)-**2**): 184 (M^+, 60.58), 169 (87.89), 142 (99.60), 115 (69.29), 104 (79.70), 89 (100), 77 (50.02); ((1*R*,2*S*)-**13**): 184 (M^+, 58.20), 169 (72.60), 142 (100), 115 (75.61), 104 (71.04), 89 (98.57), 77 (43.79).

*(1*S*,2*S*)-1-Amino-2-methylcyclopropanecarbonitrile hydrochloride **14***

To a solution of 70 mg (0.38 mmol) of (1*S*,2S)-1-(*N*-benzylideneamino)-2-methylcyclopropanecarbonitrile **2** in 2.4 mL of ether was added dropwise 4.8 mL (4.8 mmol) of a 1 M hydrochloric acid solution. The mixture was stirred at room temperature for 15 h. After separation, the aqueous phase was extracted by 2 × 0.5 mL of ether, and concentrated under reduced pressure to give 50 mg (100%) of a 94:6 diastereomeric mixture of (1*S*,2*S*)-**14** and (1*R*,2*S*)-1-amino-2-methylcyclopropanecarbonitrile hydrochloride as a white solid: ^1H NMR (200 MHz, DMSO-d_6) δ (94:6 diastereomeric mixture) **14**: 1.19 (d, 3H, *J* = 6.7 Hz, CH_3, major diastereomer), 1.29 (d, 3H, *J* = 6.27 Hz, CH_3, minor diastereomer), 1.35 (dd, 2H, *J* = 7.40 and 6.40 Hz), 1.58–1.90 (m, 2H); ^{13}C NMR (50 MHz, DMSO-d_6) δ (94:6 diastereomeric mixture): 14.09, 19.02, 19.85, 26.57, 118.51 (C≡N).

*(1*S*,2*S*)-Norcoronamic acid **1**a*

(a) Acid hydrolysis

A solution of 16 mg (0.12 mmol) of (1*S*,2*S*)-1-amino-2-methylcyclopropanecarbonitrile hydrochloride **14** (containing 6% of its (1*R*,2*S*) diastereomer) in 2 mL (12 mmol) of 6 M hydrochloric acid was refluxed for 11 h. Removal of water and HCl under reduced pressure left 18 mg (100%) of a 94:6 mixture of (1*S*,2*S*)- and (1*R*,2*S*)-norcoronamic acid hydrochloride as a white solid: ^1H NMR (200 MHz, D_2O) δ (94:6 diastereomeric mixture): 0.93 (d, 3H, *J* = 7.45 Hz, CH_3, minor diastereomer), 1.04 (d, *J* = 6.10 Hz, CH_3, major diastereomer), 1.20–1.41 (m, 2H), 1.44–1.70 (m, 1H); ^{13}C NMR (50 MHz, D_2O, dioxane as internal reference) δ: 11.92, 20.78, 23.45, 47.81, 172.5 (COOH). Finally, ion exchange chromatography through Dowex resin (50 × 8-100) with water until the eluent was neutral gave 11 mg (97%) of (1*S*,2*S*)-norcoronamic acid **1***a*.

(b) Basic hydrolysis

To a solution of 12 mg (0.09 mmol) of 1-amino-2-methyl cyclopropanecarbonitrile hydrochloride **14** in 500 μL of water was added 16 mg (0.4 mmol, 4.5 equiv.) of sodium hydroxide and the mixture was refluxed for 24 h. After cooling to 0°C, concentrated hydrochloric acid was added until the solution was neutral. Reverse-phase liquid chromatography through octadecyl-functionalized silica gel gave 8 mg (100%) of a 94:6 mixture of (1*S*,2*S*)- and (1*R*,2*S*)-norcoronamic acid **1***a* as a white solid: ^1H NMR (250 MHz, D_2O) δ (94:6 diastereomeric mixture): 0.75 (m, 1H, minor diastereomer), 1.03 (d, 3H, *J* = 6 Hz, CH_3, major diastereomer), 1.08–1.22 (m, 2H), 1.30–1.48 (m, 1H) in accordance with the literature (47).

*Determination of the enantiomeric excess of (1*S*,2*S*)-norcoronamic acid **1**a*

To a solution of 38 mg (0.33 mmol) of norcoronamic acid in 83 μL of 4 N sodium hydroxide aqueous solution was added 113 mg of chloroacetic acid anhydride and 167 μL of 4 N sodium hydroxide aqueous solution. The mixture was stirred at room temperature for 4 h and the aqueous phase extracted by 12 × 5 mL of ethyl acetate. The gathered organic phases were dried on anhydrous sodium sulfate and, after filtration, concentrated under reduced pressure. The residue was dis-

For personal use only.

solved in methanol. Reverse-phase chromatography (octadecyl-functionalized silica gel) eluted by methanol:water (90:10) provided 10 mg (16%) of (1*S*,2*S*)-*N*-chloroacetyl norcoronamic acid **16** as a yellow oil: ^{1}H NMR (250 MHz, D_2O) δ (94:6 diastereomeric mixture): 1.01 (d, 3H, J = 6.16 Hz, CH_3, major diastereomer), 1.07 (dd, 1H, J = 9.67 and 5.20 Hz), 1.22–1.28 (m, 1H), 1.38–1.46 (m, 1H), 1.67 (br s, 1H), 3.88 (s, 2H, CH_2Cl, major diastereomer), 3.92 (s, 2H, CH_2Cl, minor diastereomer); ^{13}C NMR (250 MHz, D_2O, dioxane as internal reference) δ (94:6 diastereomeric mixture): 12.44, 24.88, 26.42, 39.19, 43.11, 171.90, and 175.69 (C=O).

To a solution of 6.30 mg (0.033 mmol) of (1*S*,2*S*)-*N*-chloroacetyl norcoronamic acid **16** in 2 mL of 0.1 M potassium phosphate in water was added 1.5 mg of porcine Kidney Acylase. The mixture was stirred at 37°C for 15 h. After filtration and removal of water under reduced pressure, the residue was dried under high vacuum (0.05 Torr) to give 4 mg of crude (1*S*,2*S*)-norcoronamic acid; ^{1}H NMR spectroscopy exhibited complete disappearance of the *N*-chloroacetyl signal at δ 3.88 ppm.

*2-(Hydroxymethyl)butanol **19***

To a solution of 6 g (159.6 mmol) of lithium aluminum hydride in 150 mL of anhydrous diethyl ether under argon was added dropwise a solution of 20 g (106.4 mmol) of ethyl 2-ethylmalonate in 150 mL of ether. The mixture was stirred at room temperature for 1.5 h, then cooled to 0°C and hydrolyzed by portionwise addition of wet sodium sulfate until a clear solution was obtained. After filtration through a sintered glass funnel, the organic phase was dried on anhydrous sodium sulfate and concentrated on a rotary evaporator to give an oil that was distilled to yield 8.86 g (80%) of pure 2-(hydroxymethyl)butanol **19**: bp 128°C/12 Torr; IR (neat): 3700–3020 (ν_{OH}), 2960–2860 cm^{-1}; ^{1}H NMR (250 MHz, $CDCl_3$) δ: 0.95 (3H, t, J = 7.4 Hz), 1.31 (2H, dq, J = 7.4 and 5.1 Hz), 1.70 (1H, m), 2.35 (2H, t, J = 4.2 Hz), 3.58–3.84 (4H); ^{13}C NMR (50 MHz, $CDCl_3$) δ: 11.4 (CH_3), 20.39 (CH_2), 43.62 (CH), 64.26 (CH_2O); MS (70 eV) (*m/z*) (%): 86 (M – 18, 2), 68 (7.2), 57 (30), 56 (100), 41 (27.50).

*(2S)-2-(Hydroxymethyl)butyl acetate **21***

To a solution of 3 g (29 mmol) of 2-(hydroxymethyl)butanol **19** in 58 mL of diisopropyl ether containing 1.6 g of lipase PS (*Pseudomonas cepacia* (55) was added dropwise 5.4 mL (58 mmol, 2 equiv.) of vinylacetate. The mixture was stirred at room temperature for 1 h, until complete disappearance of the 1,3-diol as monitored by TLC, then filtered through a sintered glass funnel, and concentrated by removal of the solvent on a rotary evaporator. The residue was purified by chromatography on silica gel (ether:pentane, 50:50) to yield 760 mg (18.5%) of (2*S*)-2-(hydroxymethyl)butyl acetate **21** as a colourless oil: $[\alpha]_D^{20}$ –13.8 (*c* 1, $CHCl_3$); IR (neat): 3700–3100 (ν_{OH}), 1745 ($\nu_{C=O}$) cm^{-1}; ^{1}H NMR (250 MHz, $CDCl_3$) δ: 0.97 (3H, t, J = 7.45 Hz), 1.37 (2H, m), 1.91 (1H, br s), 2.1 (3H, s), 3.47–3.68 (2H, m), 4.11 (1H, dd, J = 11.26 and 6.38 Hz), 4.24 (1H, dd, J_{AB} = 11.26 and 4.42 Hz); ^{13}C NMR (250 MHz, $CDCl_3$) δ: 11.27 (CH_3), 20.55 (CH_2), 20.77 (CH_3CO), 41.90 (CH), 62.12 (CH_2O), 64.30 (CH_2O), 171.64 (C=O); MS (CI/NH_3) (*m/z*) (%): 147 (M – H$^+$, 0.14), 129 (0.12), 103 (M$^+$ – CH_3CO, 2.45), 61 (29), 57 (23), 56 (70), 43 (100). Anal. calcd. for $C_7H_{14}O_3$ (146.19): C 57.51, H 9.65; found: C 56.37, H 9.63.

The >95% enantiomeric excess of (2*S*)-**21** was determined from its ^{1}H NMR spectra, recorded in the presence of Eu(hfc)$_3$, in comparison with the corresponding racemic monoacetate.

*2-(Acetoxymethyl)butyl acetate **22***

To a solution of 5 g (48 mmol) of 2-(hydroxymethyl)butan-1-ol **24** in 48 mL of diethyl ether containing 12.9 g (105.6 mmol) of 4-*N*,*N*-dimethylaminopyridine was added dropwise 10 mL (105.6 mmol) of acetic anhydride. The mixture was stirred for 1.5 h, then filtered through a sintered glass funnel. Removal of the solvent on a rotary evaporator left an oil that was purified by chromatography on silica gel (ether:pentane, 20:80) to give 8.7 g (98%) of diacetate **22**; bp 108°C/15 Torr; IR (neat): 1745 ($\nu_{C=O}$) cm^{-1}; ^{1}H NMR (200 MHz, $CDCl_3$) δ: 0.95 (3H, t, J = 7.43 Hz), 1.41 (2H, d, J = 7.3 Hz), 1.91 (1H, m), 2.05 (6H, s, CH_3-CO), 4.02 (2H, dd, J = 11.10 and 6.08 Hz), 4.09 (2H, dd, J = 11.10 and 5.38 Hz); ^{13}C NMR (50 MHz, $CDCl_3$) δ: 11.91 (CH_3), 20.85 (CH_2), 20.98 (CH_3-CO), 38.71 (CH), 64.30 (CH_2O), 171.09 (C=O); MS (CI/NH_3) (*m/z*) (%): 206 (M$^+$ + 18, 100), 189 (M$^+$ + 1, 6), 188 (M$^+$, 0.1).

*(2R)-2-(Hydroxymethyl)butyl acetate **23***

In a 200 mL Erlenmeyer fitted with an automatic burette and a pH-meter was stirred at room temperature a suspension of 2 g of lipase PS (*Pseudomonas cepacia*) in 100 mL of a buffered (pH 7.2) aqueous 0.1 M phosphate solution (KH_2PO_4). Then 2 g (10.6 mmol) of 1,3-diacetate **22** was added dropwise. The pH was maintained at 7.2 by the automatic addition of 2 M NaOH. When 3.62 mL of NaOH was consumed (69% of hydrolysis), the mixture was filtered through Celite and extracted by 5 × 200 mL of ether. The organic phase was dried over anhydrous sodium sulfate and concentrated on a rotary evaporator to leave an oil that was purified by chromatography on silica gel (ether:pentane, 50:50) yielding 1 g (65%) of (2*R*)-2- (hydroxymethyl)butyl acetate **23** as a colourless oil: $[\alpha]_D^{20}$ +12.1 (*c* 1, $CHCl_3$), ee >88% determined by ^{1}H NMR in the presence of Eu(hfc)$_3$, as compared to the racemic monoacetate **23**. IR (neat): 3700–3100 (ν_{OH}), 1745 ($\nu_{C=O}$) cm^{-1}; ^{1}H NMR (200 MHz, $CDCl_3$) δ: 0.89 (3H, t, J = 7.33 Hz), 1.28 (2H, m), 1.67 (1H, m), 2.01 (3H, s), 2.66 (1H, br s), 3.44 (1H, dd, J = 13.14 and 5.60 Hz), 3.54 (1H, dd, J = 13.14 and 4.29 Hz), 4.04 (1H, dd, J = 14.44 and 6.56 Hz), 4.24 (1H, dd, J = 14.44 and 4.48 Hz); ^{13}C NMR (62.5 MHz, $CDCl_3$) δ: 11.22 (CH_3), 20.55 (CH_2), 20.73 (CH_3CO), 41.83 (CH), 62.00 (CH_2O), 64.28 (CH_2O), 171.59 (C=O); MS (70 eV) (*m/z*) (%): 146 (M$^+$, 0.03), 128 (M – 18, 0.12), 117 (M – 29, 0.17), 103 (M – 43, 6.37), 61 (42), 57 (33), 56 (76), 43 (100). Anal. calcd. for $C_7H_{14}O_3$ (146.19): C 57.51, H 9.65; found: C 56.53, H 9.58.

*(2S)-2-Methylbutan-1-ol **24***

To a solution of 200 mg (1.4 mmol) of acetate (2*R*)-**23** in 7 mL of dichloromethane containing 250 mg (2.1 mmol) of 4-*N*,*N*-dimethylaminopyridine was added 530 mg (2.8 mmol) of tosyl chloride. The mixture was stirred at room temperature for 48 h, and then 35 mL of dichloromethane was added. The organic phase was washed by 5 mL of saturated sodium chloride solution, dried over anhydrous sodium sulfate, and concentrated on a rotary evaporator. The residue was purified by chromatography on silica gel to yield 252 mg (60%) of (2*S*)-3-(*p*-tolylsulfonyloxy)-2-ethylprop-1-yl acetate: IR (neat): 1750 ($\nu_{C=O}$) and 1600 ($\nu_{C=C}$) cm^{-1}; ^{1}H NMR (200 MHz, $CDCl_3$) δ: 0.85 (3H, t, J = 7.45 Hz), 1.23–1.41 (2H, m), 1.81–2.04 (1H, m), 1.92 (3H, s), 2.42 (3H, s), 3.85–4.08 (4H, m), 7.33 (2H, d, J = 8.1 Hz), 7.76 (2H, d, J = 8.1 Hz); ^{13}C NMR (50 MHz, $CDCl_3$) δ: 10.88 (CH_3), 20.31 (CH_2), 20.55, 21.49, 38.88 (CH), 62.93 and 69.25 (CH_2O), 127.79, 129.73, 132.57 and 144.75 (arom. C), 170.60 (C=O).

To a solution of 50 mg (1.33 mmol) of lithium aluminum hydride in 7 mL of ether was added dropwise a solution of 120 mg (0.4 mmol) of (2*S*)-2-(*p*-tolylsulfonyloxy-2-ethylprop-1-yl acetate in 3 mL of ether. The mixture was stirred at room temperature for 1 h and hydrolyzed by portionwise addition of wet sodium sulfate to get a clear solution. After filtration through a sintered glass funnel the organic phase was dried on anhydrous sodium sulfate and concentrated on a rotary evaporator. The residue was purified by chromatography on silica gel (ether:hexane, 50:50) to yield 31.7 mg (90%) of (2*S*)-2-methylbutanol **29** as a colourless oil:$[\alpha]_D^{20}$ –6.7, *c* 1, ethanol (56).

*(2S)-2-(*tert*-Butyldimethylsiloxymethyl)butanol **25***

To a solution of 1.75 g (25.7 mmol) of imidazole and 1.86 g (12.3 mmol) of *tert*-butyldimethylsilyl chloride in 12.5 mL of DMF containing 50 mg (0.4 mmol) of *N*,*N*-dimethylaminopyridine was added 1.5 g (10.3 mmol) of (2*R*)-2-(hydroxymethyl)butyl acetate **23**. The mixture was stirred for 2 h at room temperature, then 500 mL of ether and 50 mL of water were added. The organic phase was separated and washed by 3 × 50 mL of water, dried on anhydrous sodium sulfate, and concentrated on a rotary evaporator to give an oil that was purified by chromatography on silica gel (pentane:ether, 90:10) to yield 2.52 g (94%) of 2*S*)-2-(*tert*-butyldimethylsiloxymethyl)butanol **25**: ($[\alpha]_D^{20}$ –2.3, *c* 1,

$CDCl_3$); IR (neat): 1750 ($\nu_{C=O}$), 1250 (ν_{C-Si}) cm^{-1}; ^1H NMR (200 MHz, $CDCl_3$) δ: 0.04 (6H, s) 0.89 (9H, s), 0.93 (3H, t, J = 7.41 Hz), 1.36 (2H, m), 1.72 (1H, m), 2.06 (3H, s), 3.55 (1H, dd, J = 10.05 and 5.84 Hz), 3.61 (1H, dd, J = 10.05 and 4.97 Hz), 4.07 (2H, d, J = 5.8 Hz); ^{13}C NMR (250 MHz, $CDCl_3$) δ: –5.67, 11.31, 18.16, 20.61, 20.78, 25.76, 41.77, 62.15, 64.29, 170.94. Anal. calcd. for $C_{13}H_{28}O_3Si$ (260.45): C 59.96, H 10.85; found: C 60.25, H 10.72.

To a solution of 1.5 g (5.75 mmol) of this acetate in 45 mL of methanol was added 2.6 g (18.5 mmol) of potassium carbonate and the mixture was stirred for 2 h. Then, 250 mL of ether and 30 mL of saturated ammonium chloride solution were added. The mixture was stirred, the organic phase separated and dried on anhydrous sodium sulfate, and concentrated on a rotary evaporator. The residue was purified by chromatography on silica gel to yield 1.12 g (89%) of (2*S*)-2-(*tert*-butyldimethylsiloxymethyl)butanol **25** as a colourless oil: $[\alpha]_D^{20}$ –8.6, *c* 0.8, $CHCl_3$); IR (neat): 3700–3100 (ν_{OH}) cm^{-1}; ^1H NMR (250 MHz, $CDCl_3$) δ: 0.08 (6H, s), 0.9 (9H, s), 0.93 (3H, t, J = 7.39 Hz), 1.15–1.35 (2H, m), 1.55–1.75 (1H, m), 2.95 (1H, dd, J = 6.5 and 4.8 Hz), 3.47–3.86 (4H, m); ^{13}C NMR (50 MHz, $CDCl_3$) δ: –5.64 (CH_3-Si), 11.74 (CH_3), 18.12 (C), 20.55, 25.82, 43.57, 66.45 and 67.22 (CH_2-O); MS (EI) (*m/z*): 161 (M – 57, 5.64), 105 (29), 75 (100), 74 (47), 69 (39); MS (CI, NH_3) (*m/e*): 220 (M^+ + 2, 27), 219 (M^+ + 1, 100). Anal. calcd. for $C_{11}H_{26}O_2Si$ (218.41): C 60.49, H 11.20; found: C 60.54, H 11.78.

*(2*R*)-2-(*tert*-Butyldimethylsiloxymethyl)butanal **26***

To a solution of 0.87 mL (9.9 mmol) of oxalyl chloride in 23 mL of dichloromethane at –60°C was added dropwise within 5 min a solution of 0.82 mL (11.6 mmol) of DMSO in 1.8 mL of dichloromethane. The mixture was stirred for 5 min and a solution of 1.8 g (8.25 mmol) of (2*S*)-**25** in 16 mL of dichloromethane was added dropwise. The mixture was stirred at –60°C for 20 min, cooled to –78°C, and 8.34 mL (48 mmol) of *N,N*-diisopropylethylamine was added. The mixture was allowed to reach 0°C and poured into 50 mL of ice-water. The aqueous phase was extracted by 2 × 50 mL of dichloromethane. The collected organic phases were successively washed by 2 × 20 mL of 1 M HCl solution and 20 mL of a buffered 0.1 M phosphate solution (pH 7). Removal of dichloromethane on a rotary evaporator left a residue that was dissolved in 50 mL of ether. The ethereal solution was dried on anhydrous sodium sulfate, filtered, and concentrated on a rotary evaporator to give the crude aldehyde **26**, which was directly used for the next step.

However, a 50 mg sample was purified by chromatography on silica gel (ether:pentane, 25:75) to give the pure aldehyde. IR (neat): 1730 ($\nu_{C=O}$), 1250 (ν_{C-Si}) cm^{-1}; ^1H NMR (250 MHz, $CDCl_3$) δ: 0.05 (6H, s), 0.87 (9H, s), 0.96 (3H, t, J = 7.40 Hz), 1.49–1.75 (2H, m), 2.35 (1H, m), 3.86 (2H, d, J = 5.65 Hz), 9.7 (1H, d, J = 2.42 Hz); ^{13}C NMR (250 MHz, $CDCl_3$) δ: –5.57 (CH_3-Si), 11.42 (CH_3-CH_2-), 18.54 (CH_2-CH_3), 18.17 (C), 25.75 (C-CH_3), 55.75 (CH), 61.56 (CH_2-O), 204.97 (C=O); MS (CI, NH_3) (*m/z*): 234 (M^+ + 18, 16), 217 (M^+ + 1, 100), 216 (M^+, 17).

*(3*S*)-2-(*N*-Benzylamino)-3-(*tert*-butyldimethylsiloxymethyl)valeronitrile **27***

To a solution of 1.8 g (7 mmol) of aldehyde (2*R*)-**26** in 14 mL of anhydrous diethyl ether containing 12 mg (0.03 mmol) of zinc iodide was added dropwise 1.71 mL (8.8 mmol) of trimethysilyl cyanide. The mixture was stirred at room temperature; after 1 h the aldehyde was totally consumed, as monitored by gas chromatography. The crude (3*S*)-2-(*N*-benzylamino)-3-(*tert*-butyldimethylsiloxymethyl)valeronitrile **27** was directly used for the next step. However, 50 mg were purified by chromatography on silica gel (ether:hexane, 10:90). IR (neat): 2080, 2960, 1260, and 1100 cm^{-1}; ^1H NMR (200 MHz, $CDCl_3$) δ: 0.06 (6H, s), 0.07 (6H, s), 0.21 (18H), 0.90 (18H, s), 0.97 (3H, t, J = 7.44 Hz), 0.98 (3H, t, J = 7.32 Hz), 1.2–1.8 (6H, m), 3.48–3.75 (4H, m), 4.63 (1H, d, J = 6.17 Hz), 4.65 (1H, d, J = 4.56 Hz); ^{13}C NMR (6.25 MHz, $CDCl_3$) δ: –5.51 and –0.47 (CH_3-Si), 11.70 (CH_3), 11.81 (CH_3), 18.98 (CH_2), 20.96 (C), 25.80 (CH_3-C), 47.89, 48.04, 60.12, 60,41, 61.43, 62.66, 119.56, and 120.25 (C≡N); MS (EI) (*m/z*): 287 (M^+, 0.21), 258 (M – 29, 15), 230 (M – 57, 0.78), 159 (100).

To a solution of 7 mmol of this nitrile in 21 mL of methanol at 0°C was added dropwise 0.84 mL (7.7 mmol) of benzylamine. The mixture was stirred at 60°C for 4 h; then, methanol was removed on a rotary evaporator and the residue was dissolved in 25 mL of anhydrous diethyl ether. After filtration of Celite and removal of ether in vacuo, the residue was purified by chromatography on silica gel (ether:pentane, 40:60) to yield 1.8 g (66% overall yield from (2*S*)-**25**) of a 1:1 diastereomeric mixture of (2*S*,3*S*)- and (2*R*,3*S*)-2-(*N*-benzylamino)-3-(*tert*-butyldimethylsiloxymethyl)pentanenitrile **27** as a colourless oil. IR (CCl_4): 3340 (ν_{N-H}), 2220 ($\nu_{C\equiv N}$) cm^{-1}; ^1H NMR (250 MHz, $CDCl_3$) δ: 0.057 (6H, s), 0.068 (6H, s), 0.84 (9H, s), 0.85 (9H, s), 0.94 (3H, t, J = 7.27 Hz), 0.95 (3H, t, J = 7.39 Hz), 1.10–2.0 (8H, m), 3.56–3.94 (6H, m), 3.78 (1H, d, J = 12.74 Hz), 3.79 (1H, d, J = 12.91 Hz), 4.07 (1H, d, J = 12.74 Hz), 4.09 (1H, d, J = 12.91 Hz), 7.34 (10H, m); ^{13}C NMR (50 MHz, $CDCl_3$) δ: –5.66 (CH_3-Si), 11.60, 11.80, 18.1, 20.44, 20.99, 25.75, 45, 45.11, 51.40, 51.93, 52.75, 61.65 and 63.46 (CH_2-O), 119.35 and 119.84 (C≡N), 127.40, 128.40, 128.47, and 138.50 (arom. C); MS (EI) (*m/z*): 261 (2.12), 245 (1.82), 244 (1.42), 219 (26), 218 (33), 217 (100), 216 (21).

*(3*S*)-2-(*N*-Benzylamino)-3-(chloromethyl)pentanenitrile **28***

To a solution of 1.7 g (5 mmol) of siloxyvaleronitrile (3*S*)-**27** in 18 mL of anhydrous THF was added, at room temperature, 11.3 mL (11.3 mmol) of a 1 M solution of *N*-tetrabutylammonium fluoride in THF. The mixture was stirred at room temperature for 30 min; then, THF was removed on a rotary evaporator and the residue was dissolved in 100 mL of ether and washed with 10 mL of half-saturated sodium chloride. The organic phase was dried over anhydrous sodium sulfate, filtered, and concentrated in vacuo. The residue was purified by chromatography on silica gel (ether:hexane, 75:25) to yield 1 g (92%) of a 1:1 diastereomeric mixture of (2*R*,3*S*)- and (2*S*,3*S*)-2-(*N*- benzylamino)-3-(hydroxymethyl)valeronitrile as a white paste. IR (neat): 3680–3140 ($\nu_{OH\ and\ NH}$), 2220 ($\nu_{C\equiv N}$), 1610 (arom. C=C) cm^{-1}; ^1H NMR (250 MHz, $CDCl_3$) δ: 0.87 (3H, t, J = 7.47 Hz), 0.90 (3H, t, J = 7.47 Hz), 1.20–1.85 (6H, m), 2.20–2.80 (4H, m), 3.52–3.78 (6H, m), 3.73 (1H, d, J = 12.85 Hz), 3.75 (1H, d, J = 11.88 Hz), 4.01 (1H, d, J = 12.85 Hz), 4.03 (1H, d, J = 11.88 Hz), 7.31 (10H, m); ^{13}C NMR (50 MHz, $CDCl_3$) δ: 11.24, 11.71, 20.06, 21.36, 44.30, 44.51, 51.83, 51.97, 53.13, 53.44, 63.23, 63.88, 118.84 and 119.05 (C≡N), 127.64, 127.75, 128.33, 128.62, 128.68 (arom. CH), 137.56 and 137.78 (arom. C); MS (EI) (*m/z*): 174 (1.15), 173 (5.56), 172 (5.52), 92 (18.68), 91 (100), 77 (1.43); MS (CI, NH_3) (*m/e*): 175 (33), 174 (100). Anal. calcd. for $C_{13}H_{18}N_2O$ (218.3): C 71.53, H 8.31; found: C 71.38, H 8.27.

To a solution of 900 mg (4.1 mmol) of this hydroxyvaleronitrile in 15 mL of dichloromethane containing 50 mg (0.1 equiv.) of 4-*N,N*-dimethylaminopyridine and 0.75 mL (4.5 mmol) of triethylamine was added, dropwise at 0°C under argon, a solution of 0.86 g (4.5 mmol) of tosyl chloride in 8 mL of dichloromethane. The mixture was stirred at 0°C for 4 h and added to 100 mL of dichloromethane. The organic phase was washed with 10 mL of a saturated sodium chloride solution, dried on anhydrous sodium sulfate, and concentrated on a rotary evaporator. The residue was purified by chromatography on silica gel (ether:pentane, 50:50) to yield 1.5 g (98%) of a 1:1 diastereomeric mixture of (2*R*,3*S*)- and (2*S*,3*S*)-2-(*N*-benzylamino)-3-(*p*-tosylsulfonyloxymethyl)valeronitrile as a pale yellow oil. IR (neat): 3340–3220 (ν_{NH}), 2220 ($\nu_{C\equiv N}$), and 1600 (arom. C=C) cm^{-1}; ^1H NMR (200 MHz, $CDCl_3$) δ: 0.88 (3H, t, J = 7.41 Hz), 0.97 (3H, t, J = 7.38 Hz), 1.21–2.05 (8H, m), 2.44 (6H, s), 3.51–4.37 (10H, m), 7.29–7.80 (18H, m); ^{13}C NMR (50 MHz, $CDCl_3$) δ: 10.89, 11.40, 20.19, 20.45., 21.57, 42.85, 43, 50.64, 50.87, 51.68, 52, 67.45 and 68.49 (CH_2-O), 118.8 (C≡N), 127, 127.60, 127.90, 128.25, 128.54, 129.91, 132.70, 137.98, and 145.03 (arom. C).

To a solution of 255 mg (6 mmol) of lithium chloride in 8 mL of *N*-methylpyrrolidone was added dropwise a solution of 1.5 g (4 mmol) of this tosylate. The mixture was stirred at room temperature for 2 h; after evaporation of the solvent on a rotary evaporator the residue was purified by chromatography on silica gel (ether:hexane, 25:75) to yield 800 mg (84%) of a 1:1 diastereomeric mixture of (2*R*,3*S*)-

*(3S)-2-(N-Benzylideneamino)-3-(chloromethyl)valeronitrile **29***

To a mixture of 22 mg of ruthenium dichloride – bis(triphenylphosphine) ($RuCl_2$–$(PPh_3)_2$) and 345 mg of 4 Å molecular sieves was added dropwise at room temperature a solution of 470 mg (2 mmol) of (3*S*)-2-(*N*-benzylamino)-3-(chloromethyl)pentanenitrile **28** in 6.5 mL of freshly distilled benzene. The mixture was stirred at room temperature for 5 min; then, 10 mL of a 1.6 M solution of *tert*-butylperoxide in benzene (8 equiv.) was added dropwise. The mixture was stirred at room temperature for 30 h, and 20 mL of 10% sodium hydrogen sulfite was added to destroy the excess peroxide. After addition of 200 mL of ether, the organic phase was separated, washed by 2 × 20 mL of saturated sodium chloride solution, dried on anhydrous sodium sulfate, and concentrated on a rotary evaporator. The residue was purified by chromatography on silica gel previously treated by a solution of ether and pentane (15:85) containing 1% of NEt_3 to yield 281 mg (60%) of a 1:1 mixture of the imine (2*R*,3*S*)- and (2*S*,3*S*)-**29** as a pale yellow oil. IR (neat): 2220 ($\nu_{C\equiv N}$), 1660 ($\nu_{C=N}$), 1610 (arom. C=C) cm^{-1}; ^1H NMR (200 MHz, $CDCl_3$) δ: 0.99 (3H, t, J = 7.4 Hz), 1.01 (3H, t, J = 7.4 Hz), 1.48–1.94 (4H, m), 2.15–2.42 (2H, m), 3.80 (4H, m), 4.85 (1H, d, J = 7.26 and 1.2 Hz), 4.98 (1H, dd, J = 5.92 and 1.2 Hz), 7.40 (6H, m), 7.82 (4H, m), 8.53 (2H, d, J = 1.2 Hz); ^{13}C NMR (62.50 MHz, $CDCl_3$) δ: 11.12, 21.05, 43.74, 46.49, 58.92, 59.98, 116.87 (C≡N), 124, 128.05, 128.77, 129.5, 131.89, 132.36 and 134.72 (arom. C), 163.81 and 163.99 (CH=N); MS (CI, NH_3) (*m/z*): 237 (M^+ + 1, 38), 236 (M^+, 22), 235 (100), 234 (M^+, 4.20).

*(1R,2R)-1-(N-Benzylideneamino)-2-ethylcyclopropanecarbonitrile **31***

To a solution of 560 mg (2.4 mmol) of the imine (3*S*)-**29** in 9.6 mL of anhydrous DMF was added portionwise 360 mg (2.6 mmol) of potassium carbonate. The mixture was stirred at room temperature for 1.5 h; then, 200 mL of ether containing 20 mL of water was added. The organic phase was separated, washed by 2 × 20 mL of water, and dried on a rotary evaporator. The residue was purified by chromatography on silica gel (ether:pentane containing 1% of NEt_3, 5:95) to yield 332 mg (70%) of a 80:20 diastereomeric mixture of 1-(*N*-benzylideneamino)-2-ethylcyclopropanecarbonitrile (1*R*,2*R*)-**31** and (1*S*,2*R*)-**32**, as a colourless oil. IR (CCl_4): 2220 ($\nu_{C\equiv N}$), 1640 ($\nu_{C=N}$), 1600 (arom. C=C) cm^{-1}; ^1H NMR (200 MHz, $CDCl_3$) δ: 0.98 (3H, t, J = 7.37 Hz), 1.1 (3H, t, J = 7.37 Hz), 1.55–1.90 (10H, m), 7.45 (6H, m), 7.70 (4H, m), 8.55 (1H, s, CH=N), 8.60 (1H, s, CH=N). The 80:20 diastereomeric ratio was determined from the relative integration of these imine proton signals at δ 8.55 and 8.6, respectively.) ^{13}C NMR (6.25 MHz, $CDCl_3$) δ: 10.13, 12.85, 23.89, 25.35, 26.56, 32.44, 42.19, 117.29 (C≡N), 128.13, 127.7, 131.04 and 132.35 (arom. C), 158.95 (CH=N); MS (CI, NH_3) (*m/z*): 199 (M^+ + 1, 100), 198 (M^+, 14), 197 (M^+ – 1, 1).

*(1R,2R)-1-Amino-2-ethylcyclopropanecarbonitrile hydrochloride **33***

To a solution of 265 mg (1.35 mmol) of the 80:20 mixture of cyclopropanecarbonitrile (1*R*,2*R*)-**31** and (1*S*,2*R*)-**32** in 9.5 mL of ether was added dropwise 19 mL (19 mmol, 12.6 equiv.) of a 1 M solution of HCl. The mixture was stirred at room temperature for 15 h. The aqueous phase, separated, was washed by 2 × 1 mL of ether and concentrated on a rotary evaporator. The residue was dried in vacuo (0.05 Torr) to yield 158 mg (80%) of the 80:20 mixture of hydrochlorides (1*R*,2*R*)- and (1*S*,2*R*)-**33** as a white solid. ^1H NMR (250 MHz, D_2O) δ: 0.85 (3H, t, J = 7.3 Hz), 1.21–1.32 (2H, m), 1.37–1.49 (2H, m), 1.51–1.63 (1H, m); ^{13}C NMR (250 MHz, D_2O, dioxane as internal reference) δ: 12.86, 20.61, 24.04, 28.16, 35.62, 117.64 (C≡N).

*(1R,2R)-Coronamic acid **18***

(a) Acid hydrolysis

A solution of 20 mg (0.14 mmol) of 1-amino-2-ethyl cyclopropanecarbonitrile hydrochloride (1*R*,2*R*)-**33** (containing 20% of its (1*S*,2*R*) diastereomer) in 2 mL of 6 M HCl was heated at reflux for 11 h. Removal of water and HCl under vacuum, on a rotary evaporator, yielded 200 mg (70%) of (1*R*,2*R*)-1-amino-2-ethylcyclopropanecarboxylic acid hydrochloride (containing 20% of its (1*S*,2*R*) diastereomer) as a white solid. ^1H NMR (250 MHz, D_2O) δ: 0.70 (3H, 5, J = 7.1 Hz), 1.24 (2H, d, J = 8.15 Hz), 1.29–1.60 (3H, m); ^{13}C NMR (62.5 MHz, D_2O, dioxane as internal reference) δ: 14.97, 21.57, 22.06, 27.44, 32.34, 40.31, 174.29.

(b) Basic hydrolysis

To a solution of 110 mg (0.75 mmol) of hydrochloride (1*R*,2*R*)-**33** (containing 20% of its (1*S*,2*R*) diastereomer) in 5.1 mL of freshly distilled water was added 160 mg (4.13 mmol) of sodium hydroxide and the mixture was heated as reflux for 24 h.

After cooling to 0°C, concentrated HCl was added until the solution was neutral (pH 7). Reverse-phase liquid chromatography through octadecyl-functionalized silica gel provided 96 mg (100%) of a 80:20 mixture of (1*R*,2*R*)- and (1*S*,2*R*)-coronamic acid **18** as a white solid. ^1H NMR (250 MHz, D_2O) δ: 0.72 (3H, t, J = 7.04 Hz, major (1*R*,2*R*) diastereomer), 0.84 (3H, t, J = 7.04 Hz, minor (1*S*,2*R*) diasteromer), 1.08 (2H, d, J = 7.91 Hz), 1.18–1.48 (3H, m) (^1H NMR data according to the literature (47)); ^{13}C NMR (50 MHz, D_2O, dioxane as internal reference at 67.6 MHz) δ: 13.81, 13.94, 18.17, 18.86, 20.92, 21.66, 26.80, 28.69, 40.69, 44.18, 175.28, and 177.09 (C=O).

Following reported procedures, the methyl esters of (1*R*,2*R*)- and (1*S*,2*R*)-coronamic acid **18** (45) were readily isolated by flash liquid chromatography (9).

*Procedure for the preparation of the Mosher amide of (1R,2R)-coronamic acid **18***

To a mixture of 10 mg (0.077 mmol) of coronamic acid **23** in 2 mL of THF was added a solution of 22 mg (0.08 mmol) of (*R*)-2-methoxy-2-trifluoromethylphenyl acetic acid chloride (62) in 24 mL (0.33 mmol) of propylene oxide. The mixture was heated to reflux for 0.5 h, cooled to room temperature, and concentrated on a rotary evaporator. ^{19}F NMR spectroscopy of the resulting Mosher amide showed two singlets at δ –92.98 and –92.85 ppm, ratio 94.25:5.75, respectively; which compared to provided data,[13] allowed us to determine the 88% ee of (1*R*,2*R*)-**18**.

*(2S)-2-(Acetoxymethyl) butanal **34***

To a solution of 2.03 mL (23.35 mmol, 1.1 equiv.) of oxalyl chloride in 31 mL of dichloromethane at –60°C were added dropwise 3.3 mL (46.71 mmol, 2.2 equiv.) of DMSO. The mixture was stirred for 5 min; a solution of 3.1 g (21.23 mmol) of (2*R*)-2-(acetoxymethyl) butanol **23** in 16 mL of dichloromethane was added dropwise. The mixture was stirred at –60°C for 20 min and cooled to –78°C. Then 21.5 mL (123 mmol, 5.8 equiv.) of diisopropylethylamine was added. The mixture was allowed to reach 0°C and was poured into 50 mL of water containing 15 g of ice. The aqueous phase was extracted by 2 × 100 mL of dichloromethane. The organic phase were washed by 2 × 20 mL of 1 M HCl and by a 0.1 M buffered phosphate solution at pH 7. The dichloromethane was removed on a rotary evaporator and the residue added to 100 mL of diethyl ether. The organic phase was dried on anhydrous Na_2SO_4 and concentrated under vacuum. The crude aldehyde (2*S*)-**34** was used directly for the next step. However, 50 mg of the residue was purified by chromatography on silica gel (Et_2O:pentane, 25:75) to give the pure (2*S*)-2-(acetoxymethyl)butanal **34**. IR (neat): 2985, 2880,

[13]We are grateful for spectroscopic data on the Mosher amide of amino acid **23**, kindly provided by Professor R.M. Williams.

2730, 1745–1730 ($\nu_{C=O}$) cm^{-1}; ^1H NMR (250 MHz, $CDCl_3$) δ: 1.0 (3H, t, J = 7.45 Hz), 1.48–1.90 (2H, m, CH_2), 2.10 (3H, s), 2.58 (1H, m), 4.28 (1H, dd, J = 12.5 and 5 Hz), 4.36 (1H, dd, J = 12.5 and 6.25 Hz), 9.70 (1H, d, J = 1.5 Hz); ^{13}C NMR (50 MHz, $CDCl_3$) δ: 10.88, 18.59, 20.35, 52.08, 61.55, 170.49 (C=O), 202.07 (CHO); MS (CI, NH_3) (*m/z*): 162 (M + 18, 100), 145 (M + 1, 58), 144 (M^+, 25), 143 (M − 1, 0.26).

(3R)-3-(Acetoxymethyl)-2-[N-(diphenyl)methylamino]valeronitrile ***35****a*

To 900 mg (6.25 mmol) of the neat aldehyde (2*S*)-**34** was added, under argon, at room temperature 1.04 mL (7.8 mmol, 1.25 equiv.) of trimethylsilylcyanide. After stirring for 1 h, an NMR sample of the mixture confirmed the total disappearance of the aldehyde. To the crude mixture was then added a solution of 1.18 mL (6.87 mmol, 1.1 equiv.) of aminodiphenylmethane in MeOH (30 mL). After refluxing for 8 h, the reaction was allowed to warm to room temperature. A sample extracted for structural analysis provided, after the usual work-up, the expected nitrile: (3*R*)-3-(acetoxymethyl)-2-[*N*-(diphenyl)methylamino]valeronitrile **35***a*. IR (neat): 3340, 3080, 3040, 2980, 2950, 2890, 2230, 1745, 1610 cm^{-1}; ^1H NMR (250 MHz, $CDCl_3$) δ: 0.95 (3H, t, J = 7.45 Hz), 1.01 (3H, t, 7.44 Hz), 1.42–1.54 (2H, m), 1.62–1.77 (2H, m), 1.93 (3H, s), 1.98 (3H, s), 2.01–2.14 (2H, m), 3.45–3.53 (2H, m), 3.59 (1H, d, J = 4.2 Hz), 3.64 (1H, d, J = 4.2 Hz), 4.20–4.46 (4H, m), 5.14 (1H, s), 5.16 (1H, s), 7.23–7.49 (20H, m); ^{13}C NMR (50 MHz, $CDCl_3$) δ: 11.18, 11.62, 20.38, 20.79, 42.36, 42.59, 49.18, 49.31, 61.75, 62.66, 65.30, 119.18, 119.31, 126.74, 127.32, 127.48, 127.62, 128.60, 140.94, 142.94, 170.59; MS (CI, NH_3) (*m/z*) (%): 336 (M^+), 252 (7), 251 (19), 250 (100), 167 (16). (3R)-2-[N-(Diphenyl)methylamino]-3-(hydroxymethyl)valeronitrile ***35****b*

To this crude aminoacetate **35***a* was added at room temperature 860 mg (2 equiv.) of potassium carbonate. The mixture was stirred for 2 h, the solvent was removed on a rotary evaporator, and the residue was added to CH_2Cl_2; the organic phase was filtered on Celite, dried on Na_2SO_4, filtered, and concentrated on a rotary evaporator. Chromatography on silica gel (CH_2Cl_2:ether, 24:1) provided 992 mg (54%) of a 55:45 diastereomeric mixture of the aminoalcohol **35***b*. IR ($CDCl_3$): 3640, 3350, 3100, 3080, 3040, 2980, 2945, 2890, 2220, 1610 cm^{-1}; ^1H NMR (250 MHz, $CDCl_3$) δ: 0.96 (3H, t, J = 7.36 Hz), 0.98 (3H, t, 7.26 Hz), 1.23–1.91 (6H, m), 2.10–2.50 (2H, m), 2.90–3.10 (2H, m), 3.48–3.96 (6H, m), 5.08 (1H, s), 5.13 (1H, s), 7.22–7.56 (20H, m); ^{13}C NMR (50 MHz, $CDCl_3$) δ: 11.21, 11.52, 20.15, 20.87, 44.42, 44.70, 51.32, 62.62, 62.82, 65.33, 65.50, 118.95, 119.20, 126.72, 127.21, 127.36, 127.45, 127.58, 127.68, 128.56, 128.74, 140.67, 140.85, 142.68, 142.85; MS (CI, NH_3) (*m/z*): 294 (M^+, abs), 221 (6), 220 (30), 206 (17), 205 (100), 177 (10), 145 (12), 81 (12), 57 (22).

*(3R)-2-[N-(Diphenyl)methylamino]-3-(*p*-tosyloxymethyl)valeronitrile* ***36****a*

To a solution of 1 g (3.4 mmol) of the alcohol **35***b* in CH_2Cl_2 (12 ml) at 0°C were added NEt_3 (0.52 mL, 3.74 mmol, 1.1 equiv.) and 2,4-dimethylaminopyridine (DMAP, 0.1 equiv.). To the mixture was added dropwise a solution of tosylchloride (3.74 mmol, 1.1 equiv.) in CH_2Cl_2 (5 mL). After stirring for 4 h at 0°C, the mixture was poured into a mixture of CH_2Cl_2 (70 mL) and brine (10 mL). The organic fraction was separated, dried on $MgSO_4$, filtered, and concentrated. Purification by chromatography on silica gel (CH_2Cl_2:Et_2O, 98.5:1.5) provided 1.4 g (92%) of a white crystalline 55:45 diastereomeric mixture of the expected tosylate **36***a*. IR (CCl_4): 3340, 3220, 3090, 3030, 2980, 2880, 2220, 1600 cm^{-1}; ^1H NMR (200 MHz, $CDCl_3$) δ: 0.82 (3H, t, J = 7.4 Hz), 0.91 (3H, t, J = 7.4 Hz), 1.10–1.96 (8H, m), 2.44 (3H, s), 2.46 (3H, s), 3.38–3.58 (2H, m), 4.06–4.48 (4H, m), 5.04 (1H, s), 5.08 (1H, s), 7.20–7.77 (28H, m); ^{13}C NMR (50 MHz, $CDCl_3$) δ: 10.77, 11.35, 20.14, 29.39, 21.52, 42.79, 42.89, 49.26, 49.45, 67.02, 68.20, 118.69, 126.81, 127.22, 127.54, 127.74, 127.74, 128.60, 128.81, 129.80, 132.29 (a and b), 140.47, 142.84 (a and b), 145.00 (a and b); MS (CI, NH_3) (*m/z*) (%): 449 (M + 1) (76). Anal. calcd. for $C_{26}H_{28}N_2SO_3$ (448.58): C 69.62, H 6.29, N 6.24; found: C 69.45, H 6.33, N 5.95.

(3R)-3-(Chloromethyl)-2-[N-(diphenyl)methylamino]valeronitrile ***36****b*

To a solution of 1 g (2.23 mmol) of the tosylate **36***a* in *N*-methylpyrrolidone (2.5 mL) was added dropwise at room temperature 142 mg (3.34 mmol, 1.5 equiv.) of LiCl. After stirring for one night, ether (70 mL) and water (5 mL) were added. The organic phase was separated and washed with water (3 × 10 mL), dried on $MgSO_4$, filtered, and concentrated. Purification by silica gel chromatography (hexane:ether, 17:3) provided 650 mg (93%) of a white crystalline (55:45) diastereomeric mixture of the chloride **36***b*. IR (neat): 3330, 3100–2840, 2220, 1620 cm^{-1}; ^1H NMR (250 MHz, $CDCl_3$) δ: 0.99 (3H, t, J = 7.5 Hz), 1.02 (3H, t, J = 7.5 Hz), 1.4–2.1 (8H, m), 3.45–4.15 (6H, m), 5.17 (1H, s), 5.20 (1H, s), 7.10–7.60 (20H, m); ^{13}C NMR (50 MHz, $CDCl_3$) δ: 10.89, 11.52, 21.17, 43.28, 43.67, 44.90, 45.67, 49.75, 50.20, 65.47, 126.93, 127.42, 127.62, 127.79, 128.72, 140.50, 143.03; MS (CI, NH_3) (*m/z*) (%): 315 (M + 1) (6), 313 (M + 1) (13), 314 (71), 311 (8), 252 (16), 251 (26), 250 (40), 167 (100). Anal. calcd. for $C_{19}H_{21}ClN_2$ (312.84): C 72.95, H 6.77, N 8.95; found: C 72.95, H 6.74, N 8.65.

(3R)-3-(Chloromethyl)-2-[diphenylmethyleneamino]pentanenitrile ***37***

To a mixture of 30 mg (1%) of $RuCl_2(PPh_3)_2$ and 560 mg of 4 Å powdered molecular sieves in C_6H_6 (5 mL) was added, under argon, 1 g (3.2 mmol) of the chloroamine **36***b*. After stirring for 5 min, the solution was cooled to 0°C and 8.5 mL (8 equiv.) of a 3 M solution of *tert*- butylperoxide in isooctane was added. After additional stirring for 15 h at 0°C, dimethyl sulfide (1.8 mL) was added and the mixture was allowed to warm to room temperature. After concentration on a rotary evaporator, the crude product was dissolved in a minimum amount of CH_2Cl_2 and purified by flash chromatography on silica gel eluted with CH_2Cl_2 to provide 900 mg (90%) of the expected imine (3*R*)-**37**. IR (neat): 1678, 1638, 1610, 1588 cm^{-1}; ^1H NMR (250 MHz, $CDCl_3$) δ: 0.95 (3H, t, J = 7.5 Hz), 0.98 (3H, t, 7.5 Hz), 1.2–1.86 (2H, m), 2.08–2.18 (1H, m), 2.29–2.36 (1H, m), 3.66–3.80 (6H, m), 4.26 (1H, d, J = 8.25 Hz), 4.48 (1H, d, J = 5.25 Hz), 7.23–7.83 (20 H, m); ^{13}C NMR (50 MHz, $CDCl_3$) δ: 10.99, 11.14, 20.54, 21.25, 43.42, 43.90, 46.17, 46.60, 53.60, 54.09, 119.49, 126.81, 127.13, 127.23, 127.47, 127.65, 128.07, 128.69, 128.80, 129.25, 129.83, 131.19, 132.22, 134.80, 138.10, 174.55; MS (CI, NH_3) (*m/z*) (%): 312 (M + 1) (10), 310 (M + 1) (16), 313 (8), 311 (15), 263 (12), 262 (77), 220 (45), 219 (31), 117 (14), 116 (100), 115 (18), 104 (18), 55 (16), 51 (35). Anal. calcd. for $C_{19}H_{19}ClN_2$ (310.82): C 73.42, H 6.16; found: C 73.29, H 6.34.

(1S,2S)-1-(Diphenylmethyleneamino)-2-ethyl cyclopropanecarbonitrile ***38***

(a) Cyclization by potassium carbonate

To a solution of the chloroimine (3*R*)-**37** (200 mg, 0.64 mmol) in DMF (10 mL) was added K_2CO_3 (100 mg, 1.1 equiv.). After stirring for 3 h, ether (50 mL) and water (10 mL) were added. The organic fraction was washed with H_2O (2 × 10 mL), dried on $MgSO_4$, filtered, and concentrated on a rotary evaporator. Purification by flash silica gel chromatography eluted with CH_2Cl_2 gave 113 mg (65%) of the (1*S*,2*S*)-cyclopropylcarbonitrile **38** and 48 mg (27%) of the (1*R*,2*S*)-cyclopropylcarbonitrile **39**.

(b) Cyclization by lithium diisopropylamide

A solution of 200 mg (0.64 mmol) of the chloroimine (3*R*)-**37** in 10 mL of THF was added dropwise within 30 min to a solution of lithium diisopropylamide (prepared from 2.5 mL of 1.6 M *n*-BuLi and 0.54 mL of diisopropylamine) in 20 mL of THF at –90°C. After stirring for 3 h at –90°C the reaction mixture was quenched by 10 mL of saturated NH_4Cl solution. Addition of 100 mL of diethyl ether and the usual work-up gave, after flash chromatography on silica gel (CH_2Cl_2), 127 mg (72%) of (1*S*,2*S*)-**38** and 40 mg (23%) of (1*R*,2*S*)-**39**.

(1S,2S)-1-Amino-2-ethylcyclopropanecarbonitrile hydrochloride ***40***

To a solution of 144 mg (0.42 mmol) of the imine **38** in 8 mL of diethyl ether was added 8 mL (15 equiv.) of 1 N HCl. The solution was stirred for 15 h (monitored by TLC), then extracted with ether (2 × 5 mL). The aqueous phase was concentrated on a rotary evaporator to provide 75 mg (97%) of the hydrochloride (1*S*,2*S*)-**40**. $[\alpha]_D^{20}$ –14.5 (*c* 0.7, H_2O); 1H NMR (200 MHz, $CDCl_3$) δ: 0.85 (3H, t, *J* = 7.3 Hz), 1.23–1.64 (5H, m); ^{13}C NMR (50 MHz, $CDCl_3$) δ: 12.76, 20.54, 23.93, 27.32, 28.08, 117.53.

(1R,2S)-1-Amino-2-ethylcyclopropanecarbonitrile hydrochloride ***41***

To a solution of 120 mg (0.43 mmol) of the imine **39** in 7 mL of diethyl ether was added 7 mL (15 equiv.) of 1 N HCl. The mixture was stirred for 15 h (monitored by TLC). Work-up as for (1*S*,2*S*)-**40** led to 62 mg (98%) of the hydrochloride (1*S*,2*S*)-**41**. $[\alpha]_D^{20}$ +29.8 (*c* 1.2, H_2O). ^1H NMR (200 MHz, $CDCl_3$) δ: 0.85 (3H, t, *J* = 7.3 Hz), 1–1.8 (5H, m); ^{13}C NMR (50 MHz, $CDCl_3$) δ: 14.67, 21.12, 22.13, 27.44, 30.05, 120.62.

(1S,2S)-1-Amino-2-ethylcyclopropanecarboxylic acid: coronamic acid ***17***

A solution of 37 mg (0.25 mmol) of the nitrile hydrochloride (1*S*,2*S*)-**40** in 10 mL of 6 N HCl was heated at reflux for 15 h. After cooling, removal of HCl and H_2O under vacuum provided 39 mg (95%) of a white solid hydrochloride. ^1H NMR (250 MHz, D_2O) δ: 0.69 (3H, 5, *J* = 7.2 Hz), 1.24 (2H, d, *J* = 8 Hz), 1.27–1.52 (3H, m); ^{13}C NMR (50 MHz, $CDCl_3$) δ: 14.97, 21.57, 22.06, 27.44, 32.34, 40.31, 174.29.

The residue was dissolved in 2 mL of distilled H_2O and purified by chromatography through an ion exchange resin (Dowex 50 × 8-100) to give 14 mg (97%) of (1*S*,2*S*)-coronamic acid **17**. $[\alpha]_D^{20}$ +28 (*c* 0.5, H_2O) (lit. (9) $[\alpha]_D^{20}$ +30.8 (*c* 0.51, H_2O)), ^1H NMR (200 MHz, D_2O) δ: 0.66 (3H, t, *J* = 7.2 Hz), 1.03 (2H, d, *J* = 8.3 Hz), 1.15–1.45 (3H, m); ^{13}C NMR (50 MHz, D_2O, $CDCl_3$ as external reference) δ: 15.16 19.43, 22.36, 30.04, 42.12, 176.68.

Mosher amide synthesis of coronamic acid ***17***

To a suspension of 4 mg (0.03 mmol) of the coronamic acid (1*S*,2*S*)-**17** in 1 mL of THF was added 8 mg (0.031 mmol) of the (*S*) Mosher acid chloride (62) and 0.5 mL of propylene oxide. The mixture was heated at reflux for 30 min, cooled to room temperature, and evaporated to leave an oil. The enantiomeric excess was determined by ^{19}F NMR analysis of the resulting amide: ^{19}F NMR (δ CF_3CH_2OH as reference –80 ppm): –71.93 (94%) for (1*S*,2*S*)-coronamic acid, –71.81 (6%) for (1*R*,2*R*)-coronamic acid[13] compared to data kindly provided by Prof. R.M. Williams (ref. 8 and footnote 13).

JOHN E. DRAKE, LAYLA N. KHASROU, ANIL G. MISLANKAR, and RAJU RATNANI. Can. J. Chem. **72**, 1328 (1994).

Dimethyltellurium alkylene dithiophosphates of the type $Me_2Te[S_2POGO]_2$, where G = —CMe_2CMe_2—, —CHMeCHMe—, —$CH_2CMe_2CH_2$—, and —$CH_2CEt_2CH_2$—, have been synthesized in 80–90% yields by reaction of the corresponding sodium or ammonium salts of the appropriate dithiophosphoric acids with dimethyltellurium dichloride in toluene. $Me_2Te[S_2P(OPh)_2]_2$ was also prepared in a similar fashion. The compounds have been characterised by elemental analyses and ^1H, ^{13}C, ^{31}P, and ^{125}Te NMR, infrared and Raman spectroscopy. The crystal structures of $Me_2Te[S_2POCMe_2CMe_2O]_2$ and $Me_2Te[S_2POCH_2CEt_2CH_2O]_2$ were determined. $Me_2Te[S_2POCMe_2CMe_2O]_2$, **1**, crystallizes in space group $P2_1/c$ (No. 14) with the cell parameters a = 12.707(3) Å, b = 11.482(2) Å, c = 16.782(2) Å, β = 98.00(1)°, V = 2424(1) Å^3, Z = 4, R = 0.0399, R_w = 0.0343. $Me_2Te[S_2POCH_2CEt_2CH_2O]_2$, **4**, crystallizes in space group $P\bar{1}$ (No. 2) with the cell parameters a = 12.580(3) Å, b = 13.313(3) Å, c = 8.206(1) Å, α = 91.28(2)°, β = 104.94(2)°, γ = 78.52(2)°, V = 1301(1) Å^3, Z = 2, R = 0.0364, R_w = 0.0295. The immediate environment about tellurium in both molecules is that of the saw-horse structure typical of tellurium(IV) compounds with the two methyl groups equatorial and one sulfur atom from each dithiophosphate group occupying the axial positions. The consideration of the second sulfur atom as part of the coordinating sphere is discussed in terms of a modification of Pauling's approach to partial bond orders. The ^1H NMR spectra suggest that these dithiophosphates may be fluxional in solution and/or that there is rapid exchange of the sulfur atoms.

JOHN E. DRAKE, LAYLA N. KHASROU, ANIL G. MISLANKAR et RAJU RATNANI. Can. J. Chem. **72**, 1328 (1994).

On a synthétisé les dithiophosphates d'alkylidène du diméthyltellure, $Me_2Te[S_2POGO]_2$ dans lesquels G = —CMe_2CMe_2—, —CHMeCHMe—, —$CH_2CMe_2CH_2$— et —$CH_2CEt_2CH_2$—, avec des rendements allant de 80 à 90% par réaction des sels correspondants de sodium ou d'ammonium des acides dithiophosphoriques appropriés avec le dichlorure de diméthyltellure dans le toluène. On a aussi préparé le $Me_2Te[S_2P(OPh)_2]_2$ de la même manière. On a caractérisé les composés par des analyses élémentaires, par rmn du ^1H, du ^{13}C, du ^{31}P et du ^{125}Te et par spectroscopies infrarouge et Raman. On a déterminé les structures cristallines des composés $Me_2Te[S_2POCMe_2CMe_2O]_2$ et $Me_2Te[S_2POCH_2CEt_2O]_2$. Le produit $Me_2Te[S_2POCMe_2CMe_2O]_2$, **1**, cristallise dans le groupe d'espace $P2_1/c$ (No. 14) avec a = 12,707(3), b = 11,482(2) et c = 16,782(2) Å, β = 98,00(1)°, V = 2424(1) Å^3, Z = 4, R = 0,0399, R_w = 0,0343. Le produit $Me_2Te[S_2POCH_2CEt_2O]_2$, **4**, cristallise dans le groupe d'espace $P\bar{1}$ (No. 2) avec a = 12,580(3), b = 13,313(3) et c = 8,2061(1) Å, α = 91,28(2), β = 104,94(2) et γ = 78,52(2)°, V = 1301(1) Å^3, Z = 2, R = 0,0364, R_w = 0,0295. Dans chacune de ces molécules, l'environnement immédiat du tellure est une structure typique des composés du tellure(IV) avec deux groupes méthyles équatoriaux et une atome de soufre de chaque groupe dithiophosphate se trouvant dans les positions axiales. On discute de la considération due deuxième atome de soufre comme une partie de la sphère de coordination en fonction d'une modification de l'approche de Pauling auz ordres des liaisons partielles. Les spectres de RMN du ^1H suggèrent que ces dithiophosphates peuvent être en fluxion en solution et/ou qu'il existe un échange rapide des atomes de soufre.

[Traduit par la Rédaction]

Introduction

Tetrakis compounds of tellurium(IV) containing the dithiocarbamate entity such as $Te(S_2CNR_2)_4$ have been reported in the literature (1–4), whereas the analogous xanthates and dithiophosphates are unknown. This presumably reflects a greater tendency in the xanthates and dithiophosphates to undergo reductive-elimination to tellurium(II) and the corresponding disulfide. Related tellurium(IV) compounds can be stabilized by the introduction of organic substituents on tellurium. In general, the stability of compounds of the general type $R_2Te[S—S]_2$ increases in the order for changing R of Ph < MeOPh < Me and within each series in the order for changing the nature of the [S—S] group of xanthate < dithiophosphate < dithiocarbamate. Thus a variety of stable compounds of organotellurium(IV) with 1,1-dithio ligands such as *N*,*N*-dialkyl dithiocarbamates (5–14), *O*-alkyl dithiocarbonates (xanthates) (11, 12, 15–17) and *O*,*O*-dialkyl dithiophosphates (11–14, 17–22) have been described in the literature. However, related cyclic dithiophosphate derivatives of tellurium(IV) that contain glycolic units have received much less attention despite the fact that they may be less susceptible to reductive elimination to tellurium(II) than their alkyl counterparts. Thus only a few derivatives of the type $R_2Te[S_2POGO]_2$ (23) and $RTe[S_2POCH_2CMe_2CH_2O]_3$ (21) where (R = Ph, or MeOPh) have been reported in the literature.

We report on the synthesis and characterization of dimethyltellurium(IV) alkylene dithiophosphates of the type $Me_2Te[S_2POGO]_2$, where G = —CMe_2CMe_2—, —CHMe-CHMe—, —$CH_2CMe_2CH_2$—, and —$CH_2CEt_2CH_2$—, as well as $Me_2Te[S_2P(OPh)_2]_2$. X-Ray crystal structures are reported for $Me_2Te[S_2POCMe_2CMe_2O]_2$, **1**, which contains a five-membered ring

including phosphorus, and $Me_2Te[S_2POCH_2CEt_2CH_2O]_2$, **4**, which contains a six-membered ring.

Experimental

Materials

$TeCl_4$ and Me_4Sn were obtained from Aldrich. Me_2TeCl_2 was prepared by the reaction of $TeCl_4$ and Me_4Sn in toluene at 60°C under reflux for 4 h based on a procedure previously reported for the preparation of Ph_2TeCl_2 (24). Sodium/ammonium salts of alkylene (25) and diphenyl (26) dithiophosphates were prepared by literature methods. The reactions were carried out under anhydrous conditions.

*Synthesis of the dimethyltellurium(IV) alkylene dithiophosphate compounds, $Me_2Te[S_2POCMe_2CMe_2O]_2$, **1**, $Me_2Te[S_2POCHMeCHMeO]_2$, **2**, $Me_2Te[S_2POCH_2CMe_2CH_2O]_2$, **3**, and $Me_2Te[S_2POCH_2CEt_2CH_2O]_2$, **4***

Typically, the sodium salt of *O,O*-2,3-dimethylbutylene dithiophosphate (0.316 g, 1.35 mmol) was added to a solution of dimethyltellurium dichloride (0.154 g, 0.67 mmol) in dried toluene (15 mL). The mixture was stirred and refluxed at 30°C for 2 h. The reaction mixture was filtered to remove NaCl and any unreacted materials. The solvent was reduced to 5 mL under vacuum. Then *n*-hexane (approximately 5 mL) was added and the solution was left overnight in the refrigerator at –6°C. Crystals of $Me_2Te[S_2POCMe_2CMe_2O]_2$, **1**, were formed, washed with *n*-hexane, and dried under vacuum (white crystals; decomp. 153–155°C; 0.320 g; yield 82%; Anal. calcd. for $C_{14}H_{30}O_4P_2S_4Te$: C 29.98, H 5.21; found: C 30.42, H 5.42; IR 1137 (s), 954 (s), and 910 (vs) compared with 1138 (s), 955 (s), and 902 (s) in the starting salt). Similarly were formed crystals of the follow ing compounds. $Me_2Te[S_2POCHMeCHMeO]_2$, **2**, pale brown crystals; mp 109–110°C; yield 81%; IR 1065 (m), 1018 (m), and 931 (vs) compared with 1068 (m), 1020 (m), and 926(vs) in the starting salt. $Me_2Te[S_2POCH_2CMe_2CH_2O]_2$, **3**, pale brown crystals, decomp. 159–161°C; yield 88%; IR 1047 (s) and 994 (vs) compared with 1051 (s) and 1001 (s) in the starting salt. $Me_2Te[S_2POCH_2CEt_2CH_2O]_2$, **4**, white crystals; mp 136°C; yield 83%; IR 1067 (s), 1016 (s), 991 (vs), and 935 (s) compared with 1070 (s), 1019 (s), 993 (vs), and 933 (s) in the starting salt.

*Synthesis of dimethyltellurium(IV) diphenyl dithiophosphate, $Me_2Te[S_2P(OPh)_2]_2$, **5***

The ammonium salt of diphenyl dithiophosphate (0.348 g, 1.16 mmol) was added to a solution of dimethyltellurium dichloride (0.133 g, 0.58 mmol) in toluene (15 mL). The reaction solution was refluxed at 30°C with stirring for 2 h. The product solution was filtered to remove NH_4Cl and any unreacted materials and the solvent removed under reduced pressure. $Me_2Te[S_2P(OPh)_2]_2$, **5**, was obtained as a pale yellow viscous oil (0.385 g; 92% yield; IR 1186 (vs), 1024 (m), 867 (vs) compared with 1192 (vs), 1025 (m), and 867 (vs) in the starting salt). Attempts to bring about crystallization were not successful.

*Alternative synthesis of $Me_2Te[S_2POCH_2CMe_2CH_2O]_2$, **4***

A solution of neopentylene dithiophosphoric acid (0.252 g, 1.27 mmol) in toluene (10 mL) was added to a solution of dimethyltellurium dichloride (0.145 g, 0.63 mmol) in toluene (15 mL). The reaction mixture was refluxed at 60°C for 3 h. Then *n*-hexane (approximately 5 mL) was added and the solution was left in the refrigerator overnight at –6°C. Crystals of $Me_2Te[S_2POCH_2CMe_2CH_2O]_2$ were obtained, washed with *n*-hexane and dried under vacuum (pale brown crystals; decomp. 159–161°C; 0.28 g; yield 80%).

Physical measurements

All solvents were dried and distilled prior to use. The elemental analysis was performed at Guelph Laboratories. Density measurements were performed by the flotation method. The infrared spectra were recorded on a Nicolet 5DX FT spectrometer as CsI pellets and far infrared spectra on a Bomem IR Spectrometer between polyethylene films. The Raman spectra were recorded on a Spectra-Physics 164 spectrometer using the 5145-Å exciting line of an argon ion laser with samples sealed in capillary tubes. The ^1H and ^{13}C NMR spectra were recorded on a Bruker 300 FT/NMR spectrometer in $CDCl_3/C_6D_6$ using Me_4Si as internal standard. The ^{31}P and ^{125}Te NMR spectra were recorded on a Bruker 200 FT/NMR spectrometer in $CDCl_3/C_6D_6$ using H_3PO_4 and Me_2Te as external standards as appropriate. The melting points were determined on a Fisher-Johns apparatus.

X-ray crystallographic analysis

White block crystals of $Me_2Te[S_2POCMe_2CMe_2O]_2$ (**1**) and $Me_2Te[S_2POCH_2CEt_2CH_2O]_2$ (**4**) were sealed in thin-walled glass capillaries and mounted on a Rigaku AFC6S diffractometer, with graphite-monochromated Mo Kα radiation.

Cell constants and an orientation matrix for data collection, obtained from a least-squares refinement using the setting angles of 25 carefully centered reflections in the range $20.24° < 2\theta < 25.53°$ corresponded to monoclinic (for **1**) and triclinic (for **4**) cells whose dimensions are given in Table 1. For **1**, the systematic absences ($h0l$, $l = 2n + 1$; $0k0$, $k = 2n + 1$) are observed. Based on packing considerations, statistical analyses of intensity distributions, and the successful solution and refinement of the structures, the space groups were determined to be $P2_1/c$ (No. 14) for **1** and $P\bar{1}$ (No. 2) for **4**.

The data were collected at a temperature of 23 ± 1°C using the ω-2θ scan technique to a maximum 2θ value of 50.0°. The ω scans of several intense reflections, made prior to data collection, had an average width at half-height of 0.38° for **1** and 0.42° for **4** with a takeoff angle of 6.0°. Scans of $(1.31 + 0.30 \tan\theta)°$ for **1** and $(1.68 + 0.30 \tan\theta)°$ for **4** were made at a speed of 8.0°/min (in ω). The weak reflections ($I < 10.0\sigma(I)$) were rescanned (maximum of 2 rescans) and the counts were accumulated to assure good counting statistics. Stationary background counts were recorded on each side of the reflection. The ratio of peak counting time to background counting time was 2:1. The diameter of the incident beam collimator was 0.5 mm, and the crystal to detector distance was 285.0 mm.

Of the 4720 (for **1**) or 4840 (for **4**) reflections which were collected, 4507 (for **1**) or 4573 (for **4**) were unique (R_{int} = 0.072 and 0.055). The intensities of three representative reflections which were measured after every 150 reflections remained constant throughout data collection indicating crystal and electronic stability (no decay correction was applied).

The linear absorption coefficient for Mo Kα is 17.05 cm^{-1} (for **1**) and 15.93 cm^{-1} (for **4**). An empirical absorption correction, based on azimuthal scans of several reflections, was applied which resulted in transmission factors ranging from 0.76 to 1.00 (for **1**) and 0.85 to 1.00 (for **4**). The data were corrected for Lorentz and polarization effects.

The structures were solved by direct methods.[3] The non-hydrogen atoms were refined anisotropically and the hydrogen atoms were included in their idealised positions with C—H set at 0.95 Å and with isotropic thermal parameters set at 1.2 times that of the carbon atom to which they were attached. The final cycle of full-matrix least-squares refinement[4] was based on 2326 (for **1**) and 2283 (for **4**) observed reflections ($I > 3.00\sigma(I)$) and 226 (for **1**) and 244 (for **4**) variable parameters and converged (largest parameter shift was 0.001 times its esd) with unweighted and weighted agreement factors of $R = \Sigma||F_o| - |F_c||/\Sigma|F_o| = 0.0399$ (for **1**) and 0.0364 (for **4**) and $R_w = [(\Sigma w(|F_o| - |F_c|)^2/\Sigma wF_o^2)]^{1/2} = 0.0343$ (for **1**) and 0.0295 (for **4**).

[3]For structure solution methods, see ref. 27(*a*); for DIRDIF: direct methods for difference structures — an automatic procedure for phase extension and refinement of difference structure factors, see ref. 27(*b*).

[4]Least-squares: Function minimized: $\Sigma w(|F_o| - |F_c|)^2$, where $w = 4F_o^2(F_o^2)$, $\sigma^2(F_o^2) = [S^2(C + R^2B) + (pF_o^2)^2]/(Lp)^2$, S = scan rate, C = total integrated peak count, R = ratio of scan time to background counting time, Lp = Lorentz-polarization factor, and p = p factor.

TABLE 1. Summary of crystal data, intensity collection, and structural refinement for $Me_2Te[S_2\overline{POCMe_2CMe_2O}]_2$ and, $Me_2Te[S_2\overline{POCH_2CEt_2CH_2O}]_2$, **4**

The standard deviation of an observation of unit weight[5] was 1.50. The weighting scheme was based on counting statistics and included a factor (p = 0.03) to downweight the intense reflections. Plots of $\Sigma w(|F_o| - |F_c|)^2$ versus $|F_o|$, reflection order in data collection, sin θ/λ, and various classes of indices showed no unusual trends. The maximum and minimum peaks on the final difference Fourier map corresponded to 0.54 and –0.75 e/Å^3, respectively for **1** and 0.49 and –0.38 e/Å^3, respectively for **4**.

Neutral-atom scattering factors were taken from Cromer and Waber (28*a*). Anomalous dispersion effects were included in F_c (29); the values for $\Delta f'$ and $\Delta f''$ were those of Cromer and Waber (28*b*). All calculations were performed using the TEXSAN (30) crystallographic software package of Molecular Structure Corp.

The final atomic coordinates and equivalent isotropic thermal parameters (Tables 2 and 3) are given, respectively, for **1** and **4** for the non-hydrogen atoms and important distances and bond angles in Tables 4 and 5. The molecular structures of the two compounds are displayed as ORTEP diagrams in Figs. 1 and 2. Tables of final thermal parameters of non-hydrogen atoms, final fractional coordinates, and thermal parameters of hydrogen atoms as well as tables of observed and calculated structure factors have been deposited.[6]

Calculation of Pauling bond order

The formula proposed by Pauling (31) for calculating the bond orders of partial bonds is given by $d_n - d = -0.60 \log n$, where d_n is the bond length for bond number, n, and d is the length of the single bond of the same type. Based on the C—C single bond of 1.54 Å, Pauling's formula gives a bond length of 1.36 Å for n = 2; 1.72 Å for n = 0.5; and 1.90 Å for n = 0.25. These give percentage increases in bond length for the partial bonds of approximately 12 and 23% respectively for n = 0.5 and 0.25. It is reasonable to assume that similar relationships relating bond order to interatomic distances for the much longer secondary interactions or partial bonds involving Te and S should utilize percentage differences "normalized" to 1.54 as follows rather than absolute differences. Pauling's relationship, which can be written as $n = 10^X$, where $X = (d - d_n)/0.6$, can be modified to allow for percentage differences "normalized" to 1.54 to give $X = [1.54(d - d_n)/d]/0.6$ or $X = 2.5(d - d_n)/d$. Based on a Te—S single bond length of 2.63 Å, typical calculated values of the lengths of partial bonds for various values of n are as follows: 2.63 Å (n = 1.0), 2.76 (0.75), 2.95 (0.50), 3.26 (0.25) and 3.68 Å (n = 0.10). This scale appears to be compatible with the sum of the van der Waals radii of 3.86 Å for Te and S (32).

Results and discussion

A variety of dimethyltellurium(IV) alkylene and diphenyl dithiophosphate compounds are prepared in 80–90% yields by the reaction of dimethyltellurium dichloride with the ammonium or sodium salts of the appropriate dithiophosphoric acids in toluene at 30°C.

$$Me_2TeCl_2 + 2MS_2\overline{POGO} \rightarrow Me_2Te[S_2\overline{POGO}]_2 + 2MCl$$

M = NH_4 or Na; G = —CMe_2CMe_2—, —CHMeCHMe—, $CH_2CMe_2CH_2$—, —$CH_2CEt_2CH_2$—

$$Me_2TeCl_2 + 2NH_4S_2P(OPh)_2 \rightarrow Me_2Te[S_2P(OPh)_2]_2 + 2NH_4Cl$$

Alternatively, these compounds can be prepared in similar yields by the reaction of Me_2TeCl_2 and the corresponding

[5]Standard deviation of an observation of unit weight: $[\Sigma w(|F_o| - |F_c|)^2/(N_o - N_v)]^{1/2}$, where N_o = number of observations and N_v = number of variables.

[a]Symmetry equivalent position $(1 - x, 0.5 + y, 0.5 - z)$ is denoted by a prime, $(-x, 2 - y, 1 - z)$ by a double prime, and $(x, y, 1 + z)$ by a triple prime.
[b]Numbers in parentheses refer to estimated standard deviations in the least significant digits.

dithiophosphoric acids in toluene by refluxing at 60°C.

$$Me_2TeCl_2 + 2HS_2\overline{POGO} \rightarrow Me_2Te[S_2\overline{POGO}]_2 + 2HCl$$

In contrast with other organotellurium compounds of the type Ph_2TeL_2, where L = dithiocarbamate, dithiocarbonate, or *O,O*-dialkyl dithiophosphate, which were found to undergo complete reductive elimination in solution within a matter of days, these Me_2TeL_2 derivatives are stable in common organic solvents such as C_6H_6, CS_2, CCl_4, and $CHCl_3$ for several weeks. The cyclic derivatives, which are crystalline solids, are less soluble than the open chain $Me_2Te[S_2P(OPh)_2]_2$ derivative, which is a pale yellow viscous liquid.

The crystal structures of $Me_2Te[S_2\overline{POCMe_2CMe_2O}]_2$, ***1***, *and* $Me_2Te[S_2\overline{POCH_2CEt_2CH_2O}]_2$, ***4***

Dimethylbis(*O,O*-2,3-dimethylbutylene dithiophosphato)tellurium(IV), **1**, crystallizes in the space group $P2_1/c$ and dimethylbis (*O,O*-2,2-diethylpropylene dithiophosphato)tellurium(IV), **4**, in the space group $P\bar{1}$. The ORTEP diagrams (Figs. 1 and 2) illustrate that for both molecules the immediate environment about tellurium is that of the saw-horse structure typical of tellurium(IV) compounds in which the lone-pair is assumed to

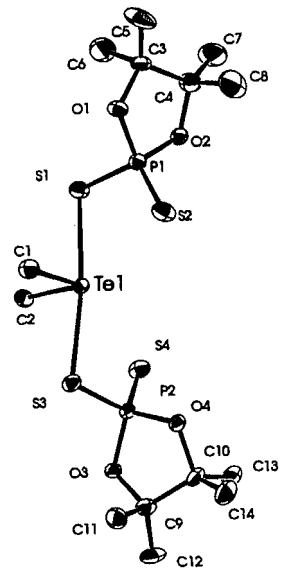

FIG. 1. ORTEP plot of the molecule $Me_2Te[S_2\overline{POCMe_2CMe_2O}]_2$ (**1**). The atoms are drawn with 25% probability ellipsoids. Hydrogen atoms are omitted for clarity.

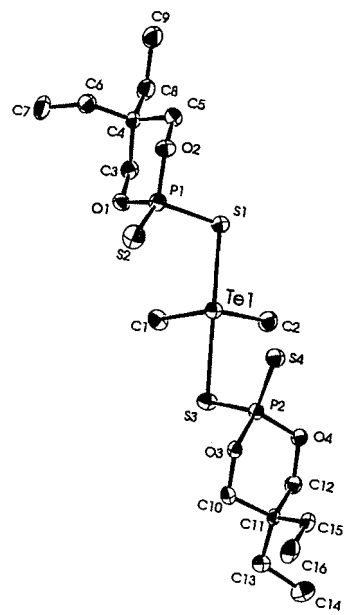

FIG. 2. ORTEP plot of the molecule $Me_2Te[S_2\overline{POCH_2CEt_2CH_2O}]_2$ (**4**). The atoms are drawn with 25% probability ellipsoids. Hydrogen atoms are omitted for clarity.

be stereochemically active and occupying an equatorial position in a distorted trigonal bipyramid. The two methyl groups occupy the other two equatorial positions with the axial positions being occupied by one sulfur atom from each of the dithiophosphate groups. The Te—C bond lengths, 2.127(8) and 2.117(8) Å in **1** and 2.128(7) and 2.113(7) Å in **4**, are similar to those reported for the related species $Me_2Te[S_2CNMe_2]_2$ (10) and $Me_2Te[S_2COMe]_2$ (15). In both **1** and **4**, one of the Te—S bonds is significantly longer than the other, 2.604(2) and 2.661(2) Å in **1** and 2.597(2) and 2.660(2) Å in **4**. These bond lengths bracket those reported for the non-cyclic dithiophosphate derivatives, $Ph_2Te[S_2P(OMe)_2]_2$ (18) and $Ph_2Te[S_2P(OEt)_2]_2$ (13) in which both Te—S bonds are of

similar length and average 2.622(3) and 2.615(6) Å, respectively. By contrast, in $Me_2Te[S_2COMe]_2$ the two Te—S bonds again differ in length, 2.566(1) and 2.280(1) Å, and the sulfur atom of the longer Te—S bond is 3.755(1) Å from the tellurium atom of an adjacent molecule. This is the only such contact less than the sum of the van der Waals radii of 3.86 Å (32) and it has been proposed that it constitutes a secondary intermolecular interaction (15). A similar phenomenon was noted for R_2TeCl_2 where one Te—Cl bond was much longer than the other and it too appeared to be the only one involved in any intermolecular association (33). However, neither of the longer Te—S bonds in **1** and **4** is associated with an intermolecular contact under 5.0 Å.

As was found for non-cyclic dithiophosphates (11, 13, 18), the terminal sulfur atoms are oriented toward the tellurium atom at distances, 3.341(2) and 3.349(3) Å in **1** and 3.490(3) and 3.516(2) Å in **4**, well within the sum of the van der Waals radii. The nature and importance of these secondary interactions is not clear so we introduce a more quantitative approach than hitherto attempted by estimating bond orders for these partial bonds based on proposals made recently in calculating a bond order for an unusually long Si—Si bond in a disilane derivative (34). The calculation was based on that devised by Pauling for partial bonds primarily involving hydrogen and first-row elements (31). We allow for the involvement of heavier elements and estimate that intramolecular Te--S interactions ranging from 3.345(4) to 3.50(1) Å, as in **1** and **4**, correspond to partial Pauling bond orders of 0.20 to 0.14. This suggests that the second sulfur atom of these anisobidentate ligands could be included in the coordination sphere around tellurium. This was the approach taken for $Me_2Te[S_2COMe]_2$ (15) and $Ph_2Te[S_2P(OEt)_2]_2$ (13) in which the two Te--S intramolecular secondary interactions, 3.303(1) and 3.352(1) Å in the former and 3.367(2) and 3.353(3) Å in the latter, were included and the structures were described as a pseudo-pentagonal bipyramid and a bi-capped trigonal bipyramid, respectively, rather than as the pseudo-trigonal bipyramid formed by the closest atoms. The same trigonal bipyramidal arrangement occurs in $C_8H_8Te[S_2P(OEt)_2]_2$ (10) but it was described as an eight coordinate linear polymer because in addition to the two Te--S intramolecular contacts at approximately 3.47 Å, there is an intermolecular contact at 3.729(4) Å. The immediate environments around tellurium are identical in $Ph_2Te[S_2P(OEt)_2]_2$ and $C_8H_8Te[S_2P(OEt)_2]_2$, but the relative orientations of the dithiophosphate ligands differ, presumably as a result of the additional intermolecular link in the latter (13).

The structures of **1** and **4** more closely resemble that of $C_8H_8Te[S_2P(OEt)_2]_2$ than that of $Ph_2Te[S_2P(OEt)_2]_2$ although neither have the intramolecular Te--S link observed in the former. If the dithiophosphates are considered to be mono-

dentate and only linked through the one sulfur atom then tellurium is at the centre of a distorted pseudo trigonal bipyramid with a stereochemically active lone pair occupying the third trigonal planar position. On the other hand, if the dithiophosphate groups are considered to be anisobidentate with the second sulfur atoms forming part of the coordination sphere, then the environment is a distorted octahedron with each of the anisobonding sulfur atoms taking up positions approximately *trans* to one of the methyl groups attached to tellurium. Thus, the methyl carbon atom C(2), Te(1), S(1), and S(2) are essentially coplanar (mean deviation from plane is 0.002 Å in **1** and .023 Å in **4**) with the second methyl carbon atom C(1) out of the plane by 2.11(1) Å in **1** and 2.10(1) Å in **4**. Similarly, C(1), Te(1), S(3), and S(4) are approximately coplanar (mean deviations of 0.07 and 0.13 Å, respectively, for **1** and **4**) with the C(2) methyl group out of the plane by 2.07(1) and 2.14(1) Å, respectively, for **1** and **4**. The dihedral angle between the plane Te(1), S(1), and S(2) and the plane Te(1), S(3), and S(4) in **4** is 94.0(2)°, indicating minimal distortion from the arrangement that would exist if the linkages were bidentate, with the anisobonded atoms *cis* to one another. The deviation from 90° is somewhat larger in **1**, where the corresponding dihedral angle is 77.0(2)°.

It has been proposed that dithiocarbamates have stronger chelating ability than xanthates because the secondary Te--S bonds in $C_8H_8Te[S_2CNEt_2]_2$ are slightly shorter than those of the corresponding xanthate, and conversely that dithiophosphates have lesser chelating ability because the corresponding distances in $C_8H_8Te[S_2P(OEt)_2]_2$ are longer. The average Te--S secondary interactions in $Ph_2Te[S_2P(OMe)_2]_2$ and $Ph_2Te[S_2P(OEt)_2]_2$, 3.37(1) and 3.360(7) Å, respectively, are shorter than those in **1** and **4** suggesting that the cyclic dithiophosphates are weaker chelating agents than non-cyclic dithiophosphates and both are weaker than dithiocarbamates and xanthates.

The S—Te—S angles in **1** and **4** are 173.26(7) and 169.52(7)°, respectively, so that deviation from 180° is slightly less than in the dimethyltellurium xanthate and dithiocarbamate derivatives $Me_2Te[S_2COMe]_2$ (15) and $Me_2Te[S_2CNMe_2]_2$ (10), where the angles are 165.90(3) and 166.5(1)°, respectively. The C—Te—C bond angles of 96.2(3) and 96.6(3)°, respectively, in **1** and **4** are the same as in $Me_2Te[S_2COMe]_2$, and larger than the values of 93.9(2) and 95.5(3)° for $Me_2Te[S_2CNMe_2]_2$. The bite angles of 66.31(6) and 66.86(7)° in **1** and 64.66(6) and 65.56(7)° in **4** are comparable to those reported for non-cyclic dithiophosphate derivatives such as $Ph_2Te[S_2P(OMe)_2]_2$ (18) and $Ph_2Te[S_2P(OEt)_2]_2$ (13) which range from 66.3(1) to 66.88(6)°.

The TeS—P bonds, which average 2.042(3) Å in **1** and 2.056(4) Å in **4**, are longer than the terminal or anisobonded P=S bonds, which average 1.942(3) Å in **1** and 1.919(2) Å in **4**. These distances are comparable to those reported for the related non-cyclic derivatives. The S—P—S bond angles average 113.7(1)° in **1** and 116.5(2)° in **4**. The comparable angles in $Ph_2Te[S_2P(OMe)_2]_2$ (18) and $Ph_2Te[S_2P(OEt)_2]_2$ (13) range from 114.4(1) to 116.3(1)° so the values in **1** and **4** bracket those reported for non-cyclic derivatives. The O—P—O bond angles average 97.05(5)° in **1** and 103.8(3)° in **4**. The comparable angles in the two derivatives containing the non-cyclic dimethoxy and diethoxy dithiophosphates (18, 13) range from 93.6(5) to 96.2(5)°, which indicates that the larger O—P—O angle is related to the constraints imposed by the ring systems and particularly by the six-membered ring in **4**. The bond lengths and angles within the ring systems are as expected.

In **1**, a view down a C—C bond, either C(3)—C(4) or C(9)—C(10), shows that the four methyl groups attached to the carbon atoms of the ring are in the staggered configuration expected for the more stable arrangement of the ring. As a result, two methyl groups are oriented above and below the approximate plane of the distorted five-membered ring at an average distance of 3.23(3) Å from P. The second pair of methyl groups, at an average distance of 3.80(1) Å, are oriented away from phosphorus. The twist in the ring is demonstrated by the fact that C(3) is 0.15 Å below and C(4) 0.31 Å above the plane formed by P(1), O(1), and O(2). The distortion is slightly greater in the second five-membered ring.

In **4**, the six-membered rings take up the chair conformation expected for an "inorganic hexane ring." Thus P(2) is 0.63 Å above the plane containing O(3), O(4), C(10), and C(12) and C(11) is 0.71 Å below it. The second ring is similar, with the corresponding distances for P(1) and C(4) being 0.62 and 0.72 Å. The orientation within the rings results in one of the ethyl groups being oriented away from phosphorus and the other towards it to give two very different distances; 3.661(8) and 3.691(8) Å for P(1)—C(6) and P(2)—C(15), respectively, and 4.460(9) and 4.448(8) Å for P(1)—C(8) and P(2)—C(13). The staggered configuration around the ring also gives non-equivalent hydrogen positions for the CH_2 groups of the two rings.

Infrared and Raman spectra

Characteristic features of the infrared and Raman spectra involving bonding to tellurium are summarized in Table 6 for compounds **1**–**5**. The infrared spectra, particularly in the region around 1000 cm^{-1}, provide useful fingerprint identifications because all of the compounds have distinctive strong bands which are similar, but not identical, to those of the starting salts. This is exemplified in the cyclic derivatives, **1**–**4**, by the bands of strong intensity in the region 994–908 cm^{-1}, which are attributable to ring vibrations that are probably coupled with C—C stretching vibrations (35, 36). The similarity of these outstanding features suggests that either the bonding within the dithiophosphate groups is essentially unchanged or that the vibrational spectra are unlikely to provide definitive evidence as to the mode of attachment of the dithiophosphate.

There are three dominant peaks in the Raman spectra of $Me_2Te[S_2POCMe_2CMe_2O]_2$, **1**, and $Me_2Te[S_2POCH_2CEt_2CH_2O]_2$, **4**, at 525 (70), 313 (100), and 270 (45) cm^{-1} for **1** and 525 (75), 344 (60), and 257 (100) cm^{-1} for **4**. None of these peaks are present in the starting salts and so, by analogy with the Me_2TeX_2 series, X = Cl, Br, I (37), these can be assigned to the symmetric Te—C and two Te—S stretching vibrations. The relative intensities of the bands differ in the two compounds as they do in the infrared spectra. This lack of consistency, which is also a common feature in the spectra of the Me_2TeX_2 derivatives, is not related to structural changes, because the crystal structures show similar Te—C and Te—S environments in **1** and **4**. As is the case in the infrared spectrum of Me_2TeI_2 (37), there is no strong feature in the 525 cm^{-1} region, but a weak peak at 526 cm^{-1} can be assigned to the asymmetric Te—C stretch. The observation of near accidental degeneracy of the two Te—C stretches is consistent with the observation of C—Te—C angles of 96.2(3) and 96.6(3)°, respectively for **1** and **4**, as found for the Me_2TeX_2 species (38), while the considerable separation between the two Te—S stretching vibrations in both molecules is to be expected for two bonds at nearly 180° to one another. Finally, the features in the spectra of compounds **2**, **3**, and **5** are sufficiently

similar to those of **1** and **4** to suggest that the dithiophosphate groups are bonded in similar fashion in all five derivatives.

Nuclear magnetic resonance spectra

The ^1H NMR spectra data for compounds **1–5** are presented in Table 7. The methyl group directly attached to tellurium experiences an upfield shift of approximately 0.35 ppm in all four cyclic derivatives, **1–4**, relative to the sharp singlet observed for Me_2TeCl_2 at 3.13 ppm, and close to the shift observed for monosubstituted dithiocarbamate derivatives, $Me_2TeCl[S_2CNR_2]$ (10). The shift for compound **5** is slightly larger with the result that its chemical shift is essentially the same as those of the analogous bis substituted dithiocarbamates, $Me_2Te[S_2CNR_2]_2$ (10). Changes in the chemical shifts of methyl groups have been related to changes in the electronegativity of the groups attached to the central atom so the effective electronegativity of the non-cyclic dithiophosphate is, not unexpectedly, of a similar order of magnitude to that of the dithiocarbamate group, which in $Me_2Te[S_2CNMe_2]_2$ is also bonded in an anisobidentate manner (10). The effective electronegativity of the cyclic dithiophosphates is slightly larger but still less than that of chlorine as expected. The similarity of the chemical shift is consistent with all of the compounds having identical links between tellurium and the sulfur atoms of the dithiophosphate groups.

The values of the chemical shifts within the dithiophosphate groups are found to be similar to those of the salts from which they were prepared so that, as with the vibrational spectra, there are no significant changes as a result of being linked to tellurium. Despite the fact that the solid state structure of **1**

shows non-equivalent methyl groups substituted on the five-membered ring, only a single peak is observed at 1.44 ppm. The corresponding peak in the salt is also a singlet at 1.46 ppm, so in neither case is the non-equivalence maintained in solution. The same is true for the hydrogen atoms of the CH_2 groups in the six-membered ring, which are also non-equivalent in the solid state structure of **4** but only show single peaks at 4.12 ppm, compared to 4.13 ppm in the ammonium salt. However, in both **4** and its starting salt, these hydrogen atoms attached to the α-carbon atoms of the glycoxy groups show coupling with phosphorus to give doublets, with very similar values for $J(PCCH)$ close to 15 Hz. This is equally true for **2** and **3** and their starting salts and, in general, the chemical shifts and coupling constants for **1–4** are very similar to those reported for other metal complexes in which the linkage of the dithiophosphate groups was assumed to be bidentate (39–45).

The $^{13}C\{H\}$ NMR spectra data for compounds **1–5** are presented in Table 8. The peaks attributable to CH_3—Te fall between 19.11 and 19.47 ppm for the cyclic dithiophosphates, **1–4**, and at 18.19 ppm for $Me_2Te[S_2P(OPh)_2]_2$, which are bracketed by those of the related mono- and bis-substituted dithiocarbamates $Me_2TeCl[S_2CNMe_2]$ and $Me_2Te[S_2CNMe_2]_2$ of 20.5 and 16.6 ppm, respectively (10); all of the values being shifted slightly when compared with the value for Me_2TeCl_2 of 26.9 ppm. However, the signals attributable to all of the carbon atoms of the cyclic dithiophosphate groups are hardly shifted at all relative to the positions of the corresponding salts. In general, the values of the coupling constants, $J(P^2C)$ and $J(P^3C)$, which are included in Table 8, are typical of such groups in a variety of environments, as is the fact that these couplings are not observed in a consistent manner (40, 41, 44, 46).

The ^{125}Te NMR chemical shifts for compounds **1–5**, which are displayed in Table 8 along with those of the ^1H and ^{31}P NMR spectra, fall in the range of 559–590 ppm; a shift towards Me_2TeCl_2, 727.7 ppm, relative to the related dithiocarbamate derivatives, $Me_2Te[S_2CNMe_2]_2$ and $Me_2Te[S_2CNEt_2]_2$, 475 and 463 ppm, respectively (10).

The $^{31}P\{H\}$ NMR spectral data, which are presented in Table 7 along with the ^1H NMR data, show the presence of a single peak in all compounds **1–5**. This indicates the presence of only one species and also that the two dithiophosphate groups are in identical environments. It has been proposed that the difference in the phosphorus chemical shift between that of the appropriate free acid and the derivative is a strong indicator of the mode of binding (47). Downfield shifts in the range 8–15 ppm were claimed to be consistent with the presence of bidentate ligands while negligible shifts or even upfields shifts were associated with monodentate linkages. In compounds **1–5** the downfield shifts range from 11 to 16 ppm, which is consistent with the presence of bidentate ligands in solution rather than anisobidentate as found in the solid state structures. This is indicative of rapid interchange between the two sulfur atoms in a similar process found in phosphorus compounds containing four-membered rings (48). It could also account for the fact that, as with other bidentate dithiophosphate complexes, there was no sign of the non-equivalence of substituents on the carbon atoms in the ring in either the ^1H or ^{13}C NMR spectra; a fact confirmed by recording spectra down to –90°C. In this connection it should be noted that in general tin dithiophosphates are bidentate and the ^1H and ^{13}C NMR spectra of $Me_2Sn[S_2POCH_2CMe_2CH_2O]_2$ and related species show no signs of non-equivalence even though the solid state structures show anisobidentate linkages (49, 50). In discussing the orientation of the groups about tellurium, we pointed out that if the anisobonded sulfur atoms were included in the coordination sphere, then the implications were for an inactive lone pair of electrons. This could be a contributing factor in allowing rapid exchange to take place.

Ab initio study on the thermal decarboxylation of but-3-enoic acid and its derivatives

YOULIANG WANG AND RAYMOND A. POIRIER[1]

Department of Chemistry, Memorial University of Newfoundland, St. John's, NF A1B 3X7, Canada

Received September 2, 1993

YOULIANG WANG and RAYMOND A. POIRIER. Can. J. Chem. **72**, 1338 (1994).

The mechanism for thermal decarboxylation of but-3-enoic acid and its derivatives HXC=CYCH$_2$COOH (X, Y = H, F, CH$_3$, C$_2$H$_5$, and Cl) leading to carbon dioxide and olefins has been studied from the theoretical point of view by *ab initio* MO calculations. The transition states obtained by our *ab initio* calculations are completely consistent with the experimental data, and support the "synchronous" mechanism for thermal decarboxylation of but-3-enoic acid and its derivatives via a "twisted chair" six-membered cyclic transition state. The effects of β- and γ-substituents on the activation energy (E_a) can be explained in terms of electronic charge distribution. β-Substitution decreases the activation energy, while γ-substitution increases it. Changes in the activation energy are related to changes in the charges at C_γ(C1) and C_β(C2) as the substituents are varied. The activation energy decreases with an increase of negative charge at C_γ, while it increases with an increase of negative charge at C_β. The best estimate of 156.8 kJ/mol for the activation energy with MP2/6-31G*//HF/3-21G$^{(*)}$ is in reasonable agreement with the available experimental values of 164 ± 7 kJ/mol and 160 kJ/mol for decarboxylation of but-3-enoic acid. The calculated primary k_H/k_D, 2.86, and k_{12C}/k_{14C}, 1.03, for the decarboxylation of but-3-enoic acid, are also in excellent agreement with the available experimental values of 2.7 and 1.035, respectively, supporting the transition state structure obtained.

YOULIANG WANG et RAYMOND A. POIRIER. Can. J. Chem. **72**, 1338 (1994).

Faisant appel à des calculs d'OM *ab initio*, on a étudié d'un point de vue théorique le mécanisme de la décarboxylation thermique de l'acide but-3-énoïque et de ses dérivés HXC=CYCH$_2$COOH (X, Y = H, F, CH$_3$, C$_2$H$_5$ et Cl) qui conduit au dioxyde de carbone et à des olléfines. Les états de transition obtenus par nos calculs *ab initio* sont en parfait accord avec les données expérimentales et ils supportent le mécanisme "synchrone" pour la décarboxylation de l'acide but-3-énoïque et de ses dérivés qui se produirait par le biais d'un état de transition cyclique à six chaînons possédant une conformation chaise déformée. On peut expliquer les effets des substituants en β et en γ sur l'énergie d'activation (E_a) en fonction d'une distribution de la charge électronique. Une substitution en β diminue l'énergie d'activation alors qu'une substitution en γ l'augmente. Les changements dans les énergie d'activation sont reliés aux changements dans les charges sur les C_γ(C1) et C_β(C2) qui accompagnent les variations de substituants. L'énergie d'activation diminue avec une augmentation de la charge négative sur C_γ alors qu'elle augmente avec une augmentation de charge négative sur le C_β. La meilleure évaluation de l'énergie d'activation (156,8 kJ/mol) déterminée avec l'ensemble MP2/6-31G*//HF/3-21G$^{(*)}$ est en bon accord avec les valeurs expérimentales disponibles (164 ± 7 et 160 kJ/mol) pour la décarboxylation de l'acide but-3-énoïque. Les valeurs calculées de k_H/k_D (2,86) et de k_{12C}/k_{14C} (1,03) pour la décarboxylation de l'acide but-3-énoïque sont aussi en bon accord avec les valeurs expérimentales disponibles (2,7 et 1,035 respectivement); ces résultats supportent la structure proposée pour l'état de transition.

[Traduit par la Rédaction]

I. Introduction

A great deal of effort has and is being made to further our understanding of the relationship between structure and reactivity (1–3). In the past the attention focused on the electronic properties of the reactants or on the electronic properties of an assumed transition state structure. With quantum mechanical calculations it is now possible to look at structure reactivity relationships in terms of what occurs in "the transition state," giving us better insight into what factors control reactivity (3). In this paper we investigate the factors which control the reactivity of the decarboxylation reaction in but-3-enoic acids. Decarboxylation is an important organic reaction in many fields, e.g., organic synthesis, molecular biochemistry in which many life processes in both plants and animals are related to decarboxylation (4), and mechanistic studies (1–3). Because of its importance, the mechanism for the decarboxylation of acids has been studied since the 60's (5) and is still of great interest both experimentally and theoretically (3*b*–3*d*, 6, 7). For instance, the thermal decarboxylation of formic acid has been the object of recent high level experimental and theoretical work (3*b*).

As a β,γ-unsaturated acid, but-3-enoic acid decomposes to propene and eliminates carbon dioxide (1, 2, 5, 6).

$$CH_2{=}CHCH_2COOH \rightarrow CH_3CH{=}CH_2 + CO_2$$

FIG. 1. Transition states considered for thermal decarboxylation of but-3-enoic acid.

The kinetics of this vapor-phase thermal decarboxylation process were first studied several years ago (5). Most of the mechanistic studies, owing largely to Bigley and co-workers (5, 6), were directed towards understanding the nature of the transition state. Several possible transition state structures were considered, which are illustrated in Fig. 1.

Experimental energies of activation and relative rates of decarboxylation for but-3-enoic acid and some substituted but-3-enoic acids are listed in Table 1. The experimental evidence indicates that substituents at C_α, C_β, and C_γ all affect the reaction rate (5), for example, methyl substitution at the partially positive C_β increases reaction rates but substitution at C_γ causes an appreciable decrease in the reaction rate. This gas-phase thermal decomposition reaction shows sizable primary kinetic isotope effects (5*c*), e.g., k_H/k_D = 2.81 ± 0.18 at 543 K and k_{12C}/k_{14C} = 1.035 ± 0.01 at 551 K for 2,2-dimethyl-4-phenyl but-3-enoic acid. The results of these studies are consistent with a synchronous reaction via a six-membered cyclic transition state (cf. structure **III** in Fig.

TABLE 1. The experimental activation energies and relative rates of reaction (5*d*) for the decarboxylation of several substituted but-3-enoic acids (at 500 K)

Reactants	E_a (kJ/mol)	Relative rate
$H_2C{=}CHCH_2COOH$	168	1
	164 ± 7 (ref. 5*a*)	
	160 (ref 6)	
$H_2C{=}CHC(CH_3)_2COOH$	153	5.6
$H_2C{=}C(CH_3)C(CH_3)_2COOH$	138	168
$H(CH_3)C{=}CHC(CH_3)_2COOH$	168	0.84
$H(CH_3)C{=}C(C_2H_5)C(CH_3)_2COOH$	150	54.1
$C_6H_5CH{=}CHC(CH_3)_2COOH$	162 (ref. 1)	—
$H_2C{=}C(C_6H_5)C(CH_3)_2COOH$	128 (ref 1)	—

1). The experimental results also suggest that the reaction is homogeneous, first order, has a negative entropy of activation, proceeds at the same rate in the gas as in the liquid phase.

To date, no *ab initio* calculations have been reported on the decarboxylation of but-3-enoic acid and no quantum mechanical calculations have been reported on the decarboxylation of substituted but-3-enoic acids. The only calculated results available for $H_2C{=}CHCH_2COOH$ are from MINDO/3 calculations carried out by Dewar and Ford (8). Dewar and Ford predicted a "flattened boat" six-membered cyclic transition state structure with an activation enthalpy (ΔH^*) of 194 kJ/mol and a primary kinetic isotope effect of $k_H/k_D = 2.1$. The MINDO/3 results are consistent with the known experimental data. In this paper the results of *ab initio* calculations on the decarboxylation of a series of substituted but-3-enoic acids have been reported in order to further our understanding of how different substituents stabilize or destabilize the transition state.

II. Computational details

Ab initio calculations were carried out for some selected β-, γ-substituted but-3-enoic acids $HXC{=}CYCH_2COOH$ (X, Y = H, F, CH_3, C_2H_5, and Cl). These are typical substituents (experimentally) that represent both electron donation and electron withdrawing types of groups. The compounds calculated are $CH_2{=}CHCH_2COOH$ (**1**), $HFC{=}CHCH_2COOH$ (**2**), $CH_2{=}CFCH_2COOH$ (**3**), $CH_3CH{=}CHCH_2COOH$ (**4**), $CH_2{=}C(CH_3)CH_2COOH$ (**5**), $CH_3CH_2CH{=}CHCH_2COOH$ (**6**), $CH_2{=}C(CH_2CH_3)CH_2COOH$ (**7**), $HClC{=}CHCH_2COOH$ (**8**), $HFC{=}CFCH_2COOH$ (**9**), and $CH_2{=}CClCH_2COOH$ (**10**). All minima were fully optimized with the OC method (9) and the transition states were fully optimized using the minimization of sum of squares gradient technique VA05AD (10). The transition structures were characterized to ensure that the symmetrized force constant matrix had only one negative eigenvalue, i.e., only one imaginary frequency.

All geometry optimizations and single-point SCF calculations were carried out with MUNGAUSS (11). The structures were optimized with the 3-21G(*) basis set and single-point calculations performed with the 6-31G* basis set (HF/6-31G*//HF/3-21G(*)). For but-3-enoic acid, the MP2/6-31G//HF/3-21G(*) calculations were performed with GAUSSIAN 86 (12). The additivity rule (13) was used to obtain MP2/6-31G*//HF/3-21G(*) estimates of the activation energy E_a, where, E_a(MP2/6-31G*) = E_a(MP2/6-31G) + E_a(HF/6-31G*) − E_a(HF/6-31G). The normal-mode vibrational frequencies for but-3-enoic acid were calculated at the HF/6-31G//HF/3-21G(*) level. These frequencies were used to compute the zero-point energy (ZPE) corrections and primary kinetic isotope effects (k_H/k_D and k_{12C}/k_{14C}) using a modified version of BEBOVIB (14).

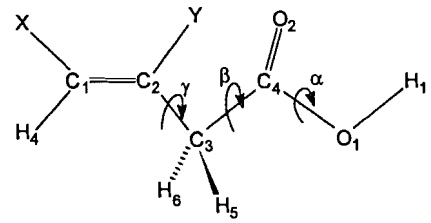

FIG. 2. The structural parameters of but-3-enoic acids. The different conformations calculated in Table 2 are defined by the torsion angles α, β, γ, and all have C_s symmetry. α = 0, β = 0, γ = 0 for conformer **a**.

III. Results and discussion

III.1. Electronic structure and properties of reactants

Conformational change and stability

The structural parameters for the equilibrium geometries of but-3-enoic acids are illustrated in Fig. 2. Because of the free rotation about the C—O and C—C single bonds, there are many possible conformations. The different conformations are defined by the three torsion angles, α, β, and γ (cf. Fig. 2), which correspond to rotation (clockwise) about the C4—O1, C3—C4, and C2—C3 single bonds respectively. Conformers **a** to **h** in Table 2, defined by α, β, and γ, are constrained to have C_s symmetry. Breaking of the C_s symmetry leads to other four structures (**i**, **j**, **k**, and **l**) of which three are transition states and one is a minimum (**l**). The relative energies of these eight conformers are given in Table 2, along with the corresponding HF/3-21G(*) total energies. Conformer **a** with α, β, γ = 0° is the lowest energy conformation, while conformer **h** with α, β, γ = 180° is the highest energy conformation. The conformational energy hypersurface illustrated in Fig. 3, indicates that the rotational barriers connecting these conformers (**a**, **b**, **d**) are relatively low and that their interconversion essentially involves free rotation about the C2—C3, C3—C4, or C4—O1 single bonds.

Equilibrium geometries

For all the substituted but-3-enoic acids conformer **a** (cf. Fig. 2) was assumed to be the lowest energy conformation. The HF/3-21G(*) optimized structural parameters for all of the reactants $HXC{=}CYCH_2COOH$ (X, Y = H, F, Cl, CH_3, C_2H_5), are listed in Table 3. These results indicate that β- and γ-substitution primarily affects the C1—C2 double-bond (1.304–1.320 Å) and C2—C3 single-bond (1.502–1.528 Å) lengths. The influence of

l	184	−133	164	−302.97111	35.5

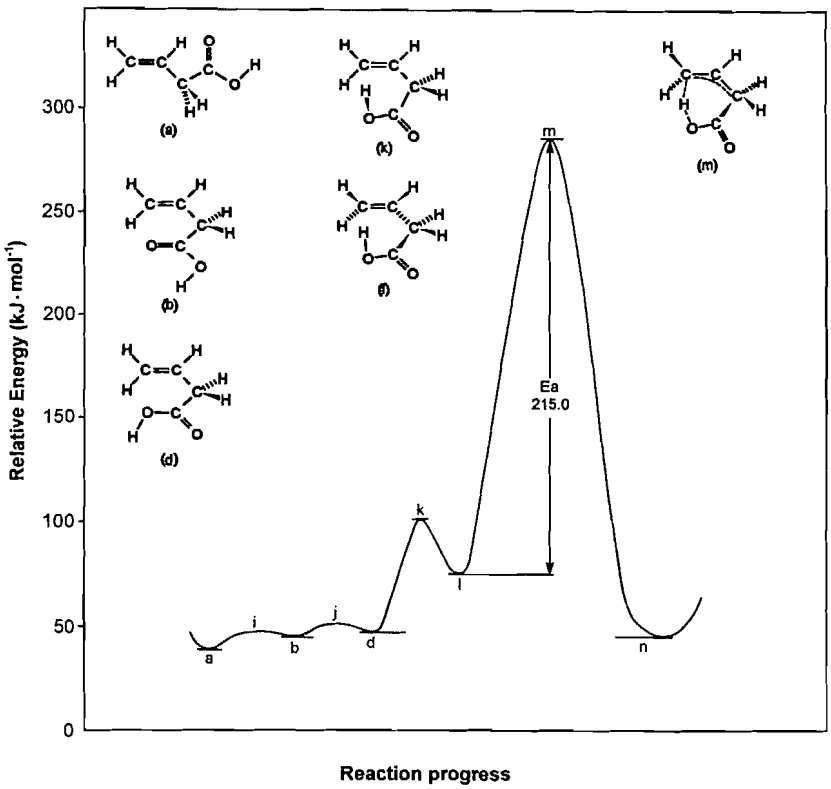

FIG. 3. HF/3-21G(*) relative energies (in kJ/mol) of the stationary points examined on the $H_2C{=}CHCH_2COOH$ potential energy surface.

substituents on the geometries is related to their electronic properties. CH_3 and C_2H_5 increase the C1—C2 and C2—C3 bond lengths, while F and Cl decrease the C1—C2 and C2—C3 bond lengths. For instance, both the C1—C2 and C2—C3 bond lengths are longer (by 0.005 and 0.019 Å, respectively) in the β-CH_3 and β-C_2H_5 cases, while in the β-F and β-Cl cases, these bond lengths are shorter (by −0.007 and −0.004 Å, respectively). For γ-CH_3 and γ-C_2H_5 the C1—C2 and C2—C3 bond lengths increase slightly, while for γ-F and γ-Cl, and C1—C2 and C2—C3 bond lengths decrease, significantly in the case of the C1—C2 bond (by −0.011 Å). Since in going from the reactant to the product, the C1—C2 double-bond becomes a single-bond and the C2—C3 single-bond becomes a double-bond, longer C1—C2 bond and shorter C2—C3 bond in the reactant are expected to facilitate the decarboxylation reaction.

III.2. Electronic structure and properties of the transition state

Barrier heights, relative energies and activation energies

The relative energies for the different stationary points on the $H_2C{=}CHCH_2COOH$ potential energy surface are illustrated in Fig. 3. It shows the energy change for the process of thermal decarboxylation of $H_2C{=}CHCH_2COOH$ starting with the most stable conformer (**a**), going through intermediates, the transition state (**m**) and finally to product (**n**) $H_3CCH{=}CH_2$ and CO_2. The geometries corresponding to stationary points **a**, **b**, **d**, and **l** are different conformers of but-3-enoic acid and **i**, **j**, **k** are characterized to be the saddle points, interconnecting these conformers, respectively. The **d** to **l** conformational change, which involves rotation about the C4—O1 single- bond, has the highest rotational barrier (40.6 kJ/mol) but much lower than the activation energy (215.0 kJ/mol). The geometry corresponding

[a]MP2/6-31G* results were estimated on those of MP2/6-31G for H$_2$C═CHCH$_2$COOH, and the same correlation energy was used to estimate for the substituted cases.
[b]Smith and Blau's experimental result (5*a*).
[c]Bigley and Clarke's experimental result (6).
[d]Dewar's MINDO/3 result (8).
[e]After ZPE correction.

to stationary point **l** is taken as the reacting conformer. The activation energy (E_a) is defined as the energy difference between stationary points **m** and **l** which should correspond to the rate-determining step of reaction.

For but-3-enoic acid, the *ab initio* activation energies (E_a) are compared with Dewar's MINDO/3 result (8) and the available experimental values (5, 6). The results are listed in Table 4. Dewar's MINDO/3 activation energy of 199 kJ/mol is close to our HF/3-21G(*) result (215.0 kJ/mol). The MP2/6.31G//HF/321G(*) single point calculation (E_a = 161.2 kJ/mol), compared with HF/6-31G//HF/3-21G(*) result (E_a = 237.4 kJ/mol), shows the importance of electron correlation (−76.2 kJ/mol) in this decarboxylation reaction. The MP2/6-31G*//HF/3-21G(*) E_a is 156.8 kJ/mol, which is in reasonable agreement with the experimental values of 164 ± 7 kJ/mol (5*a*) and 160 kJ/mol (6). This agreement supports the reliability of the transition state structure obtained from our *ab initio* calculations. The normal mode vibrational frequencies were also calculated (scaled by 0.9) to

correct for ZPE at HF/6-31G//HF/3-21G(*). The ZPE contribution to E_a is −16.1 kJ/mol and therefore the cyclic transition state has a smaller ZPE than the reacting conformer.

The HF/3-21G(*) optimized geometries for the reacting conformers (**I**) and transition states (**m**) are given in Tables 5 and 6, respectively. The HF/6-31*//HF/3-21G(*) single point calculations were carried out on these optimized geometries to obtain E_a. The HF/6-31G*//HF/3-21G(*) E_a for the cases studied are all within 210~260 kJ/mol and are higher than HF/3-21G(*) values. For the substituted but-3-enoic acids the activation energy is estimated as E_a (MP2/6-31G*) = E_a (HF/6-31G*) + ΔE_0, where ΔE_0 is the correlation contributions for but-3-enoic acid (−76.2 kJ/mol). Since all the HXC=CYCH$_2$COOH geometries for **l** and **m** are very similar (cf. Tables 5 and 6) the correlation energy contribution to E_a is expected to be approximately constant.

The results of activation energies for all the substituted but-3-enoic acids at HF/3-21G(*), HF/631G*//HF/3-21G(*), and MP2/6-31G*//HF/3-21G(*) levels, are listed in Table 4. Comparison of the activation energies of γ- and β-substitution at the three levels considered indicates that β-substitution leads to a decrease in E_a and that γ-substitution leads to an increase in E_a. These results (e.g., for CH_3, and C_2H_5-substituted cases) are consistent with the experimental observation (5*d*) (cf. Table 1).

It is interesting to note that for HFC=CFCH$_2$COOH, the substitution effect is almost balanced, resulting in an activation energy of 157.4 kJ/mol with MP2/6-31G*//HF/3-21G(*) essentially equal to that of but-3-enoic acid (156.8 kJ/mol). For β-substitution, E_a decreases in the order, H > Cl > F > CH_3 > C_2H_5. For γ-substitution, E_a increases in the order, H < CH_3 < Cl < C_2H_5 < F. The effect of these substituents on the activation energies can be explained in terms of their electronic properties. For instance, substitution at the γ position decreases the negative charge at C1, making the hydrogen (H1) transfer from O1 to C1 less favourable, and thus resulting in a higher activation energy. Substitution at the β-position increases the positive charge at C2 stabilizing the allyl-like anion (involving C1—C2—C3) in the transition state, resulting in a lower activation energy. The relationship between the activation energy and the charge distribution is presented in Fig. 5, and will be discussed in detail in the following section.

Transition state geometries

The structural parameters for optimized transition states at HF/3-21G(*) are listed in Table 6. All transition states have similar cyclic structures as illustrated in Fig. 4.

The transition states obtained by our *ab initio* calculations are consistent with the experimental data and resemble struc-

ture **III** proposed by Bigley (1) (shown in Fig. 1). Several features may be noted with respect to the "synchronicity" of thermal decarboxylation. In going from reactant to transition state the C1—C2 bond increases from ~1.31 Å (double bond) to ~1.40 Å. The C2—C3 bond decreases from 1.51~1.53 Å (single bond) to 1.40~1.43 Å. Therefore, in the transition state the C1—C2 and C2—C3 bonds are almost equal. Both C3—C4 and H1—O1 bonds which are breaking in the transition state have increased significantly. The C3—C4 bond increases from ~1.50 Å to ~1.80 Å and the H1—O1 bond increases from ~0.97 Å to ~1.35 Å. The hydrogen atom (H1) being transferred is approximately midway between C1 and O1 (C1—H1 ~1.25 Å), and the O1—C4—O2 bond angle (~139°) is intermediate between that in the reactant (~120°) and the CO_2 molecule. The *ab initio* transition state structure is not a "flattened boat" as obtained by Dewar's MINDO/3 calculations, but a "twisted chair" six-membered cyclic transition state (cf. Fig. 4). For both Dewar's and our *ab initio* transition states, C1—C2 and C2—C3 bonds are almost equal (exactly equal in Dewar's case, 1.420 Å). *Ab initio* H1—C1 bond is longer (1.306 vs. Dewar's 1.218 Å), and *ab initio* H1—O1 is shorter (1.374 vs. Dewar's 1.419 Å). The largest discrepancy between the *ab initio* and the MINDO/3 result occurs in the C3—C4 bond, 1.81 Å compared to Dewar's 1.68 Å respectively. These results show that *ab initio* transition state is looser than Dewar's.

All the *ab initio* transition state structures are quite similar (cf. Tables 6). β-, γ-Substituents only result in minor changes in bond angles and torsion angles. For all substituted transition states, only H1—O1, H1—C1, C2—C1, C3—C4, and C2—C3 bond lengths change slightly with the different substituents. The C3—C4 and H1—C1 bonds are longer in the case of γ-substituted than in the case of β-substituted acids, which have a tighter transition state. For example, H1—C1 in β-F and β-Cl cases (~1.305 Å) are shorter than the corresponding γ-substitution cases (1.315 ~ 1.320 Å) and the unsubstituted one (1.306 Å). H1—C1 in all $CH_3$and C_2H_5 substituted cases (1.28 ~ 1.29 Å) are shorter and close to that in the corresponding product.

The relative energies ($(E_\gamma - E_\beta)_{ts}$) between γ- and the corresponding β-substituted transition state (**m**) at HF/3-21G(*) and HF/6-31G*//HF/3-21G(*) are given in Table 7, along with the relative energies ($(E_\gamma - E_\beta)_{re}$) between γ- and the corresponding β-substituted reacting conformers (**l**). These results clearly show that the values of $(E_\gamma - E_\beta)_{re}$ are much smaller than the corresponding $(E_\gamma - E_\beta)_{ts}$, while all β-substituted transition states are more stable than the corresponding γ-substituted

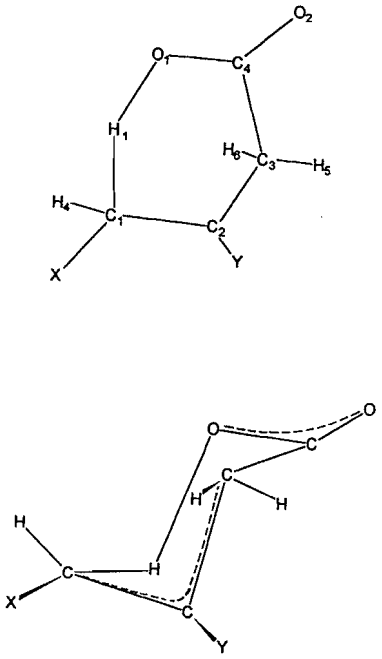

FIG. 4. Geometry of the decarboxylation transition state.

ones. Therefore it is the stability of β-substituted transition states that result in lower activation energies than the γ-substituted ones.

Electronic structure

The effect of substituents on the activation energies is consistent with the electronic structure. The net atomic charge (Q) calculated from Mulliken population analysis at HF/6-31G*//HF/3-21G$^{(*)}$ are tabulated in Table 8 for all the transition states considered. Since we are only interested in trends in atomic charges to obtain a "qualitative" understanding of the relationship between activation energy and electronic structure, simple Mulliken population analysis (MPA) is suitable for our purpose. All the results show that there is a high degree of delocalization in the transition state as predicted in structure **III** of Fig. 1. Mulliken charges are consistent with the expected charge distribution (cf. Fig. 1). There is a sizable positive charge at C2 and C4 (except for γ-F substituted case), and negative charge at C1 and C3. The charges at C1(Q_{C1}) and C2(Q_{C2}) play a dominant role in affecting the stability of the transition state. The activation energy is related to the trends in the charges at C1 and C2 as the substituents are varied. The relationship between E_a and Q_{C1}, and between E_a and Q_{C2} are presented in Fig. 5. The correlation coefficients (+0.555 for Q_{C1} and −0.596 for Q_{C2}, respectively) are obtained with the assumption that all data points are linearly related. The analysis of the data in Table 8 illustrates that the charge distribution for the three F-substituted cases is different from the others because of its high electronegativity. For instance, the β-F case has a large positive charge at C2 (0.65 vs. ~0.03 for theothers), and the γ-F case has a small negative charge at C1 (−0.03 vs. ~−0.60 for the others). In Fig. 5(*a*) (E_a vs. Q_{C1}), the two points involving γ-F do not correlate with the others and in Fig. 5(*b*) (E_a vs. Q_{C2}), the two points involving β-F do not correlate with the others. Excluding the three F-substituted cases, the correlation coefficients of E_a vs. Q_{C1} and E_a vs. Q_{C2} become +0.866 and −0.907, respectively. Such a good correlation indicates that the activation energy decreases

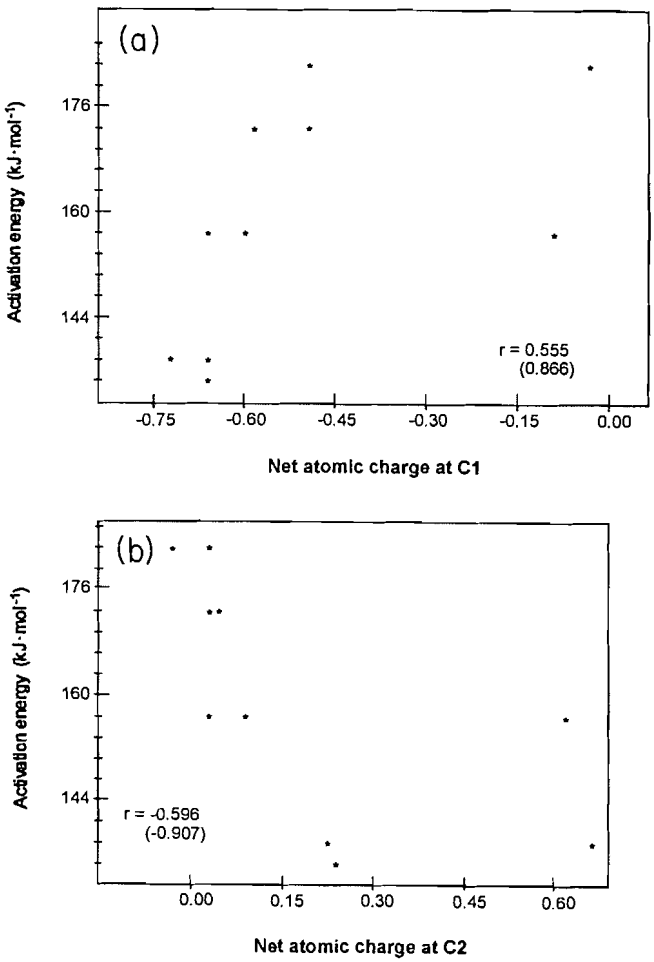

FIG. 5. Relationships between E_a and the atomic charges at C1 and C2, respectively. The values of r are the correlation coefficients, and in parentheses are the correlation coefficients excluding the three F-substituted cases. (*a*) E_a vs. Q_{C1}; (*b*) E_a vs. Q_{C2}.

with an increase of negative charge at C1, while it increases with an increase of negative charge at C2. Therefore, the atomic charges at C1 and C2 are important factors in controlling the activation energy. For example, in β-Cl substituted cases, the charge at C1 is −0.65 and the charge at C2 is 0.09, very close to the unsubstituted case for which Q_{C1} and Q_{C2} are −0.66 and 0.04, respectively, and thus leading to only a small change in activation energy. The MP2/6-31G*//HF/3-21G$^{(*)}$ E_a is 155.4 kJ/mol for β-Cl substituted case, compared with 156.8 kJ/mol for the unsubstituted case. In general, β-substitution affects the charge at the β-carbon, with only small variations at the γ-carbon, and similarly for γ-substitution. For the three F-substituted cases, both Q_{C1} and Q_{C2} change significantly and therefore the two factors combine. For example, in the γ-F substituted case, Q_{C1} is −0.03, demonstrating the most positive charge at C1, and Q_{C2} is −0.03, demonstrating the most negative charge at C2. Both of these factors increase the activation energy so that for this case, it is the highest among all cases considered (MP2/6-31G*//HF/321G$^{(*)}$ E_a, in this case, is 182.7 kJ/mol). Therefore, for highly electron-withdrawing substituents, such as F, the activation energy depends on both Q_{C1} and Q_{C2}.

In general, for all β-substituted cases, Q_{C1} is negative and Q_{C2} is positive, resulting in tighter or more reactant-like transi-

tion state structures. On the other hand, in the γ-substituted cases, Q_{C1} is less negative and Q_{C2} is only slightly positive (negative for γ-F substituted case), leading to looser or more product-like transition state structures. Therefore β-substitution decreases the activation energy, while γ-substitution increases the activation energy. The relation of charge distribution to the activation energy indicates that the "ideal" transition state is one which can be characterized as the interaction between an allyl-like anion (C1—C2—C3) and a protonated CO_2 molecule, both of which involve charge delocalization.

III.3. Kinetic isotope effects

The primary kinetic isotope effects (KIEs) k_H/k_D (at H1) and k_{12C}/k_{14C} (at C4) for thermal decarboxylation of $H_2O{=}CHCH_2COOH$ were calculated using a modified BEBOVIB program (14). The KIEs are calculated at the HF/3-21G(*) optimized geometry using HF/6-31G normal-mode vibrational frequencies scaled by a factor of 0.9. The calculated and available experimental KIE results are listed in Table 9. The sizable primary k_H/k_D (2.86) at H1 and k_{12C}/k_{14C} (1.03) at C4 are obtained for but-3-enoic acid at 650 K, which are in excellent agreement with the available experimental values of 2.7 (15) and 1.035 (5*b*), respectively, and with Dewar's MINDO/3 results of 2.1 and 1.031, respectively (8), supporting the "twisted chair" sixmembered cyclic transition state structure.

IV. Conclusions

In summarizing our results the following conclusions can be drawn:

(*a*) The transition states obtained by our *ab initio* calculations are consistent with the experimental data, and support the "synchronous" mechanism for thermal decarboxylation of but-3-enoic acid and its derivatives via a six-membered cyclic transition state.

(*b*) The calculated results are also similar to Dewar's MINDO/3 result, but there are some improvements. The geometry of transition state is a "twisted chair" rather than Dewar's "flattened boat."

(*c*) The effects of β- and γ-substituents on the activation energy can be explained in terms of the electronic charge distribution. The atomic charges at C1 and C2 are important factors in controlling the activation energy. The "ideal" transition state is characterized as the interaction between an allyl-like anion (C1—C2—C3) and a protonated CO_2 molecule, both of which involve charge delocalization. β-Substitution decreases E_a, while γ-substitution increases E_a. This conclusion is also consistent with experimental observations.

(*d*) The result of E_a (156.8 kJ/mol) for thermal decarboxylation of $H_2C{=}CHCH_2{-}COOH$ with MP2/6-31G*///HF/3-21G(*) is in good agreement with the available experimental values of 164 ± 7 kJ/mol and 160 kJ/mol.

(*e*) Our calculated results of primary k_H/k_D (2.86) and k_{12C}/k_{14C} (1.03) is also in excellent agreement with the available experimental values (2.7 and 1.035, respectively) for but-3-enoic acid, supporting the transition state structure obtained.

Synthesis of enantiomeric β-amino ketones via 1,3-dipolar cycloaddition and chromatographic resolution

CHANTAL LOUIS, SIBEL MILL, VINCENT MANCUSO, AND CLAUDE HOOTELÉ[1]

Organic Chemistry Department, Faculty of Sciences, University of Brussels, B-1050 Brussels, Belgium

Received August 19, 1993

CHANTAL LOUIS, SIBEL MILL, VINCENT MANCUSO, and CLAUDE HOOTELÉ. Can. J. Chem. **72**, 1347 (1994).

The cycloaddition reactions of 3,4,5,6-tetrahydropyridine 1-oxide **1** with the homochiral alkynyl sulfoxides **6***a–e* proceed in high yield to afford, with low asymmetric induction, mixtures of diastereomeric isoxazolines that are readily separated by column chromatography. The resolved isoxazolines can be subsequently converted, by hydrogenolysis, to enantiomeric β-amino ketones.

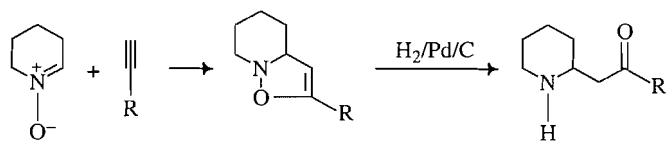
CHANTAL LOUIS, SIBEL MILL, VINCENT MANCUSO et CLAUDE HOOTELÉ. Can. J. Chem. **72**, 1347 (1994).

Les réactions de cycloaddition entre la 3,4,5,6-tétrahydropyridine 1-oxyde **1** et les sulfoxydes acétyléniques homochiraux **6***a–e* conduisent avec de bons rendements et une induction asymétrique faible à des mélanges d'isoxazolines diastéréoisomères facilement séparables par chromatographie sur colonne. Les isoxazolines résolues peuvent être converties, par hydrogénolyse, en β-aminocétones énantiomères.

[Traduit par la Rédaction]

Introduction

β-Amino ketones constitute an important class of compounds for which the synthesis deserves interest. In this regard, we previously reported a new efficient synthesis based on the observation that 4-isoxazolines **3** can be viewed as masked β-amino ketones, which could be released by hydrogenolysis of the N—O bond (1) (Scheme 1). Although 4-isoxazolines have proven to be thermally labile heterocycles and display an array of rearrangements (2, 3), we established that under carefully controlled conditions they can be prepared in good yield by nitrone–alkyne cycloaddition. Hydrogenolysis of the N—O bond can be performed by hydrogen in the presence of Pd/C. Application of this procedure to the synthesis of 2-phenacylpiperidine, for example (**4**, R = C_6H_5), proceeds from nitrone **1** and phenylacetylene with 70% overall yield. In the present study we report the extension of our method for the synthesis of the two enantiomers of β-amino ketones.



1 **2** **3** **4**

SCHEME 1

Asymmetric nitrone–alkene 1,3-dipolar cycloadditions involving either chiral nitrones or chiral alkenes have received attention: high asymmetric induction has been observed, for example, in the condensation of nitrones with alkenyl sulfoxides (4) or, very recently, with chiral allyl ethers (5). On the other hand, to the best of our knowledge, no attention has been paid to nitrone–alkyne cycloadditions in the chiral mode. Hence we undertook a study of the cycloaddition of the prochiral nitrone **1** onto several chiral alkynyl sulfoxides as dipolarophiles.

Results and discussion

(+)-1-Alkynyl *p*-tolyl sulfoxides **6***a–e* were prepared by the Andersen synthesis using the reaction of alkynylmagnesium bromides **5***a–e* with *l*-menthyl (−)-*S*-*p*-toluenesulfinate in toluene (6) (Scheme 2). Based on the fact that Grignard reactions with chiral sulfinate esters proceed stereospecifically with inversion of configuration at the sulfur atom (7), the acetylenic sulfoxides **6***a–e* are assigned the *S* configuration; the optical purity and the absolute configuration of **6***c–e* were previously confirmed by their conversion into the corresponding alkenyl derivatives (6).[2]

The reaction of nitrone **1** with the alkynyl sulfoxides **6***a–e* gave mixtures of the diastereomeric isoxazolines **7***a–e* and **8***a–e* (Scheme 3); the large differences in the R_fs allowed the complete separation of the individual diastereomers of each pair by flash chromatography on silica gel. Typical results are presented in Table 1 and deserve some comments.

All the cycloadditions proceed with excellent yields. It appears that the electron-poor alkynyl sulfoxides possess a higher reactivity than the corresponding terminal alkynes: whereas the condensation of **1** with pentyne or heptyne requires refluxing toluene or 1,1,1-trichloroethane (1), these new cycloadditions are performed in chloroform at room temperature (with a 1:1 alkyne: nitrone ratio). On the other hand, the cycloadditions are highly regioselective, the electron-withdrawing group occupying the 3-position of the isoxazolines (as demonstrated by their subsequent conversion). The enhanced reactivity and the observed regioselectivity are in agreement with previous observations and theoretical predictions (2, 8). According to Houk's perturbation treatment of 1,3-dipolar cycloadditions, the preferred regioisomer will arise from the transition state in which the atoms with the largest orbital coefficients interact, i.e., the transition state in which the carbon of the nitrone moiety becomes bonded to the carbon of the dipolarophile bearing the sulfoxide group. Furthermore, lowering of the LUMO level of the dipolarophile is responsible for the observed increased reactivity of the alkynyl sulfoxides.

The asymmetric induction is low in all the cycloadditions. In the case of **6***e*, experiments were also carried out in other solvents: 1,4-dioxane, benzene, acetonitrile, and chloroform:ethanol (4:1); apart from a substantial acceleration relative to chloroform in the first two solvents, the results were essentially identical. In the same way, replacement of the *p*-tolyl group of

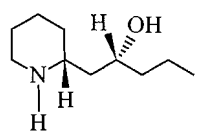
6*e* by a methyl, a *tert*-butyl, or an α-naphthyl group brought no new prospect.

The results described above indicate a very low level of asymmetric induction, but the quantitative chromatographic diastereomeric resolution of the isoxazolines **7** and **8** opened a new route to optically active β-amino ketones. Hydrogenolysis of the separated isoxazolines furnished, after filtration through alumina, the expected enantiomeric β-amino ketones in good yield. The best results were achieved when the hydrogenolysis (H_2/Pt) was carried out in methanol in the presence of citric acid; this acid was intially introduced to slower racemization of the β-amino ketones;[3] its presence was found to improve the yield. Typical results obtained from **7***b–e* and **8***b–e* are presented in Table 2.

Control experiments allowed us to establish that in the conditions described above, the ketones **4** suffered no loss of optical activity (9). It appears therefore that the β-amino ketones obtained by this method should be of high optical purity. Indeed a sample of resolved (−)-pelletierine **4***b*, liberated from pure (*R*)-pelletierine hydrogen (*R*)-6,6′ dinitrobiphenyl-2,2′-dicarboxylate[4] ($[\alpha]_D^{22}$ +156 (pyridine, *c* 3)) showed an optical rotation $[\alpha]_D^{22}$ −26 ($CHCl_3$, *c* 1.6) comparable with the value reported in Table 2. Moreover, (−)-**4***c* was transformed[5] into (−)-halosaline **9**, indentical with the natural compound (11, 12) of which the optical purity is known to be higher than 90%.[6]

The levorotatory ketones **4***b* and **4***c* were previously assigned



9

[3]We have observed that the optically active compounds **4** epimerize more slowly (in methanol at room temperature) than the corresponding N-Me derivatives. This difference was already pointed out in the case of pelletierine **4***b* and N-methylpelletierine: see ref. 9.

[4]Racemic pelletierine has been resolved with 6,6′-dinitrobiphenyl-2,2′-dicarboxylic acid, see refs. 9 and 14.

[5]S. Mill and C. Hootelé; to be published.

[6]In ref. 11, an optical purity of 90% was determined for a sample of **4***c* prepared from natural halosaline; the specific rotation value quoted ($[\alpha]_D^{22}$ −11.4 (chloroform, *c* 1)) is, however, clearly in error.

TABLE 2. Reduction of isoxazolines **7** and **8** to β-amino ketones

Entry	Isoxazoline	β-Amino ketone	Yield, %	$[\alpha]_D$[a] (*c*)
1	**7***b*	(+)-(*S*) **4***b*	82	+25 (1.4)
2	**8***b*	(−)-(*R*) **4***b*	74	−22 (0.9)
3	**7***c*	(+)-(*S*) **4***c*	95	+21 (2.5)
4	**8***c*	(−)-(*R*) **4***c*	94	−21 (1.8)
5	**7***d*	(+)-(*S*) **4***d*	85	+20 (1.9)
6	**8***d*	(−)-(*R*) **4***d*	89	−20 (2.1)
7	**7***e*	(+)-(*S*) **4***e*	88	+15 (1.8) +22 (2.3)[b]
8	**8***e*	(−)-(*R*) **4***e*	79	−15 (1.1) −23 (1.1)[b]

[a]Measured for solutions in $CHCl_3$ at 22°C unless otherwise stated.
[b]Measured for solutions in MeOH at 22°C.

R configurations, inter alia through correlation with pipecolic acid (10, 11, 13). We assign the homologous levorotatory ketones **4***d* and **4***e* the same *R* absolute configuration from the sign of the rotation and from the similar chromatographic behaviour of the diastereomer isoxazolines throughout the series.

The methodology described here represents an alternative to the classical resolution with a chiral acid (14); it gives access to both enantiomeric forms and should be applicable to a wide range of β-amino ketones.

Experimental

Mass spectra were obtained on a Micromass 7070 spectrometer with electron impact inonization. ^1H and ^{13}C NMR spectra were recorded on a Bruker WM 250 apparatus, in $CDCl_3$, with TMS as internal standard unless otherwise stated. Optical rotations were measured on a Perkin–Elmer 141 polarimeter. Analytical thin-layer chromatography was performed on Polygram Sil G/UV254 plates. Visualization was accomplished with UV light and ethanolic phosphomolybdic acid solution followed by heating.

General procedure for the synthesis of 1-alkynyl p*-tolyl sulfoxides*

(+)-1-Alkynyl *p*-tolyl sulfoxides were prepared according to the procedure described in the literature (6) for **6***c–e*. The following specific rotation values ($[\alpha]_D^{22}$, (*c*)) were measured in chloroform: **6***a*: +76 (2.5); **6***b*: +122 (2.8); **6***c*: +89 (1.4); **6***d*: +84 (2.2); **6***e*: +77 (2.5). For **6***a*: ^1H NMR (60 MHz), δ: 7.9–7 (9H, m), 2.3 (3H, s); for **6***b*: ^1H NMR, δ: 7.67 (2H, d, J = 8 Hz), 7.33 (2H, d, J = 8 Hz), 2.42 (3H, s), 2.06 (3H, s); ^{13}C NMR, δ: 142.5, 141.4, 130.4, 125.3, 102.0, 78.0, 21.6, 5.1.

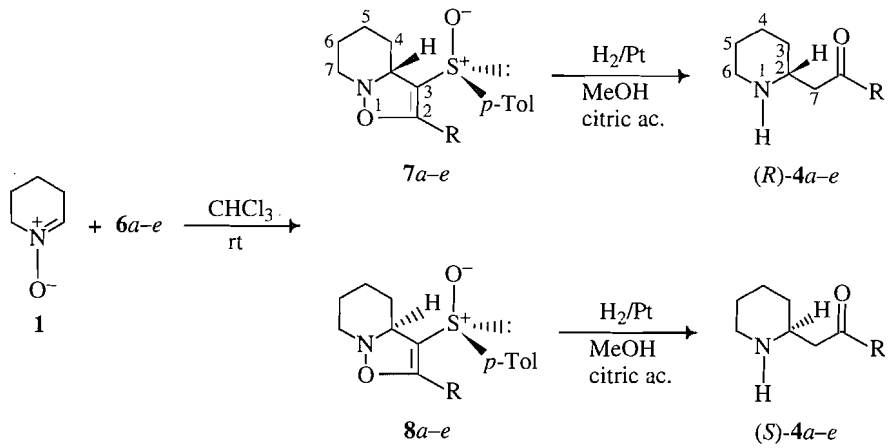

SCHEME 3

Sulfoxide **6***a* is somewhat unstable and proved difficult to obtain in a pure state.

General procedure for the cycloaddition reactions

To a well-stirred solution of *N*-hydroxypiperidine (3.06 mmol; 1 equiv.) in chloroform (free of ethanol and freshly distilled, 20 mL) at 0°C was added yellow mercury(II) oxide (6.14 mmol; 2 equiv.). The mixture was then allowed to come to room temperature and the reaction was checked by TLC (alumina, AcOEt). After 10 min, the slurry was filtered through Celite (chloroform, 10 mL). Half of the solvent was then removed under reduced pressure and the alkynyl sulfoxide (3.06 mmol; 1 equiv.) was added to the solution. The mixture was left at room temperature for 24 h and the reaction followed by TLC (silica, AcOEt). The solvent was removed under reduced pressure and the recovered oil was flash chromatographed over silica (AcOEt) to give the isoxazolines **7** and **8**.

Isoxazoline 7a. ^{1}H NMR, δ ppm: 7.83–7.79 (m, 2H, aromatic), 7.54–7.43 (m, 5H), 7.32 (d, 2H, aromatic, J = 8 Hz), 4.26 (m, 1H, H3a), 3.26 (m, 2H, H7), 2.41 (s, 3H, $ArCH_3$), 2.09–2.0 (m, 1H), 1.77–1.64 (m, 3H), 1.55–1.40 (m, 2H); ^{13}C NMR, δ ppm: 163.5 (C2), 140.5, 139.1, 131.4, 130.0, 129.6, 128.9, 128.7, 127.2, 124.6, 113.5 (C3), 65.3 (C3a), 51.7 (C7), 26.6, 22.5, 21.3 ($ArCH_3$), 19.9; MS *m/z*: 321 ($M^{+\cdot}$ − H_2O, 14%), 320 (13), 246 (69), 226 (1), 200 (13), 139 (10), 124 (20), 123 (68), 105 (100), 91 (31); R_f: 0.51 (AcOEt:hexane 9:1).

Isoxazoline 8a. ^{1}H NMR, δ ppm: 7.89–7.26 (m, 9H, aromatic), 4.77 (m, 1H, H3a), 3.36–2.89 (m, 2H, H7), 2.40 (s, 3H, $ArCH_3$), 2.0–1.49 (m, 5H), 1.06–0.97 (m, 1H); ^{13}C NMR, δ ppm: 161.8 (C2), 140.6, 140.4, 131.1, 130.0, 129.8, 128.8, 128.6, 124.6, 124.3, 113.0 (C3), 64.8 (C3a), 52.3 (C7), 25.6, 22.9, 21.3 ($ArCH_3$), 19.9; MS *m/z*: 339 ($M^{+\cdot}$, <1%), 278 (5), 258 (7), 246 (19), 226 (13), 200 (13), 139 (56), 123 (30), 105 (100), 91 (32); R_f: 0.38 (AcOEt:hexane 9:1).

Isoxazoline 7b. ^{1}H NMR, δ ppm: 7.43 (d, 2H, J = 8 Hz, aromatic), 7.30 (d, 2H, J = 8 Hz, aromatic), 4.06 (m, 1H, H3a), 3.17 (m, 1H, eq. H7), 3.06 (dt, 1H, J = 3 and 12 Hz, ax. General procedure for the hydrogenolysis of isoxazolines 7 and 8

The isoxazoline (7.7×10^{-4} mol; 1 equiv.) was dissolved in a methanolic solution (15 mL) of citric acid (566 mg; 2.68 mmol; 3.5 equiv.). The mixture was hydrogenated over PtO_2 (25 mg; 5 wt.%) at room temperature and atmospheric pressure. After 3 equivalents of H_2 were absorbed, the slurry was filtered through Celite. After removal of the solvent under reduced pressure, chloroform (30 mL) was added to the residue. The solution was extracted with 0.2 M aqueous HCl (3 × 30 mL). The aqueous solution was basified with 15 M aqueous ammonia and extracted with chloroform (3 × 30 mL). Removal of the solvent under reduced pressure followed by filtration through a short column of alumina gave the pure β-amino ketone **4**.

(−)4b. ^{1}H NMR, δ ppm: 3.03–2.90 (m, 2H), 2.65 (dt, 1H, J = 3 and 12 Hz), 2.49 (d, 2H, J = 6 Hz), 2.27 (br signal, 1H), 2.13 (s, 3H), 1.8–1.1 (m, 6H); MS *m/z*: 141 ($M^{+\cdot}$, 11%), 98 (18), 84 (100).

Received August 3, 1993

ADELE BOLOGNESE, MARINA BUONANNO, ANTONIO CANTILENA, GIOVANNI MUSCI, and ANGELO ALBERTI. Can. J. Chem. **72**, 1351 (1994).

Alkaline oxidation of *ortho*-anisidine by potassium ferricyanide in alkaline aqueous solution was examined. Azo compounds, a diamine, and *para*-iminoquinones were isolated from the highly coloured reaction mixture. The reaction was also carried out within the cavity of an EPR spectrometer and two radical species have been detected. Following these product results and EPR studies, a radical mechanism is proposed for the process.

ADELE BOLOGNESE, MARINA BUONANNO, ANTONIO CANTILENA, GIOVANNI MUSCI et ANGELO ALBERTI. Can. J. Chem. **72**, 1351 (1994).

On a examiné l'oxydation alcaline de l'*ortho*-anisidine par le ferricyanure de potassium, en solution aqueuse alcaline. On a isolé des composés azo, une diamine et des *para*-iminoquinones du milieu réactionnel très coloré. On a aussi réalisé la réaction à l'intérieur de la cavité d'un spectromètre de RPE et on a détecté deux espèces radicalaires. Sur la base de la nature des produits observés et des études de RPE, on propose un mécanisme radicalaire pour ce processus.

[Traduit par la Rédaction]

Introduction

The oxidations of phenols, catechols, and *o*-aminophenols have particular interest in relation to the biosynthesis of ommochromes, cinnabarines, actinomycins, and melanins (1, 2). Since, in striking contrast with the well-known behaviour of phenols and catechols, no carbon–carbon dimer formation has ever been reported in the oxidation of *o*-aminophenols, the possibility of the occurrence of a radical process has never been taken into account and an ionic mechanism has usually been credited (3–5).

On the other hand, some of us recently proposed that the first step in the formation of the phenoxazine-3-one system present in ommochrome pigments might be a radical–radical coupling of the *o*-aminophenol residue of the 3-hydroxykynurenine, this hypothesis being supported by EPR investigations carried out on the oxidation mixture of the latter compound and potassium ferricyanide (6, 7). It is actually possible that the reactivity of *o*-aminophenols is more akin to that of aromatic amines than to that of phenols, and as a consequence a radical pathway cannot be excluded on the basis of the absence of carbon–carbon dimeric products. To further check this point we have investigated the potassium ferricyanide oxidation of *o*-anisidine by combining conventional product studies with EPR spectroscopy.

Results

Product studies

When *o*-anisidine **1** (10 mmol in 20 mL of water–methanol 1:1 vv) was treated with an excess of alkaline potassium ferricyanide (40 mmol in 20 mL of water, pH 9) at room temperature for 1 h a deep red mixture was obtained from which five coloured products **2**, **2′**, **3**, **4**, and **5** were chromatographically isolated and then characterized. No trace of **1** was left in the reaction mixture.

The structures of compounds **2** and **2′**, whose colour shifted from yellow to pink by mineral acid treatment, were determined on the basis of the following mass and NMR spectroscopic data. Both compounds showed the molecular ion peak at *m/e* 242 along with a strong peak at *m/e* 107 due to the anisyl residue. The ^{1}H NMR of **2** exhibited two doublets (2H, δ 8.74 and 2H, δ 7.06) and two triplets (2H, δ 6.99 and 2H, δ 7.40) for the eight aromatic protons and a singlet (6H, δ 4.00) for the two equivalent methoxy groups. On the other hand **2′** exhibited two doublets (2H, δ 6.82 and 2H, δ 6.57) and two triplets (2H, δ 7.12 and 2H, δ 6.73) for the eight aromatic protons and a singlet (6H, δ 3.76) for the two methoxy groups. The actual assignment of the two isomers was based on the assumption that in the *syn* isomer the N=N double bond would shield the aromatic ring(s) more than in the *anti* isomer.

Similarly, the very polar brown compound **3**, with a molecular ion signal at *m/e* 244, was identified as 2-methoxy-4-(2-methoxyphenylamino)aniline. It exhibited signals from the four protons of the disubstituted ring (δ 7.10, 7.01, 7.16, 6.84), the three protons of the trisubstituted ring (δ 6.59, 6.81, and 5.80), and the signals from the two different methoxy groups (δ 3.83 and 3.81) along with signals from NH (δ 6.82, D_2O changeable) and NH_2 protons (δ 4.82, D_2O changeable). Treatment of a chloroform solution of **3** with aqueous ferricyanide afforded **4**. The mass spectrum of this latter compound, identified as the 2-methoxy-4-(2methoxyphenylimino)cyclohexa-2,5-dien-1-one, showed, along with the molecular ion peak at *m/e* 243, the characteristic peak at M + 2, i.e., *m*/2 245, typical of a

high-potential *p*-quinoneimine (8). The ^{1}H NMR signals at δ 6.11, 7.33, and 6.69 were assigned to the three protons of the quinonic ring, while the four protons of the aryliminic group were assigned the signals at δ 6.96, 7.21, 6.95, and 6.75, and the signals at δ 3.65 and 3.85 were attributed to the quinonic and aryliminic methoxy groups, respectively.

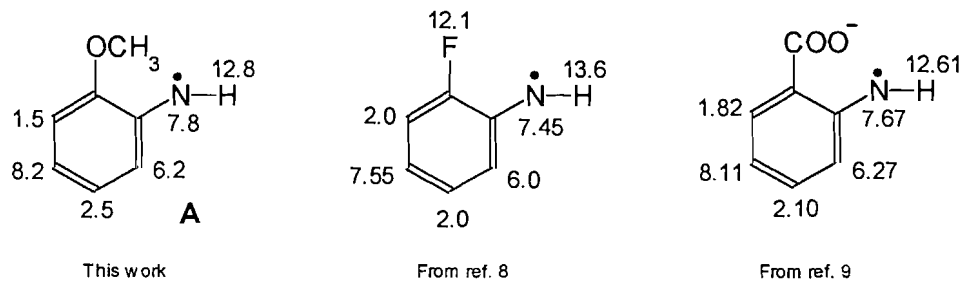
Also the mass spectrum of compound **5**, identified as the 2-methoxy-4-(2-methoxyphenylimino)-5-(2′-methoxyphenyl)-aminocyclohexa-2,5-dien-1-one, showed, beside the molecular ion peak at *m/e* 364, a peak at M + 2 (reduction peak), while the NMR spectrum exhibited signals for the two protons of the quinoneiminic ring (δ 6.23 and 5.76), the four protons of the arylimic ring (δ 7.46, 6.95, 7.89, and 7.00), the four protons of the arylaminic ring (δ 7.02, 7.20, 7.00, and 6.87), the three different methoxy groups (δ 3.62, 3.86, and 3.83), and a broad D_2O changeable singlet at δ 8.65 due to the NH group.

EPR studies

When the reaction between *o*-anisidine and potassium ferricyanide in alkaline water (pH 9) was carried out in a flat flow-cell inside the cavity of an EPR spectrometer and the spectra recorded within 500 ms of mixing, the broad signal shown in Fig. 1 was obtained. A well-fitting computer simulation of the signal, which was characterized by a *g*-factor of 2.0035, was obtained by assuming coupling of the unpaired electron with five different hydrogens and a nitrogen atom (a_H 1.5, a_H 2.5, a_H 6.2, a_H 8.2, a_H 12.8, a_N 7.8 gauss). On the basis of these spectral parameters, and by analogy with data available in the literature for the *ortho*-fluoro (9) and *ortho*-carbossiphenyl aminyl (10), the spectrum was attributed to the *o*-anisyl aminyl radical **A**.

When the flow of the reaction mixture through the flat cell inside the EPR cavity was interrupted, a rather persistent and very broad three-line spectrum (coupling with a single nitrogen, a_N 12.8 G, *g* 2.0059) appeared after ca. 5 min. This very simple signal must be due to a nitroxide originating in situ from oxidation of a reaction product (Fig. 2).

In an attempt to obtain aminyl **A** by a different method, a degassed benzene solution of amine **1** was continuously photolysed in the presence of di-*tert*-butyl peroxide. This resulted in the observation of a much better resolved spectrum than the one observed in aqueous alkaline solution, exhibiting a much



Hyperfine coupling constants for some arylaminyl radicals

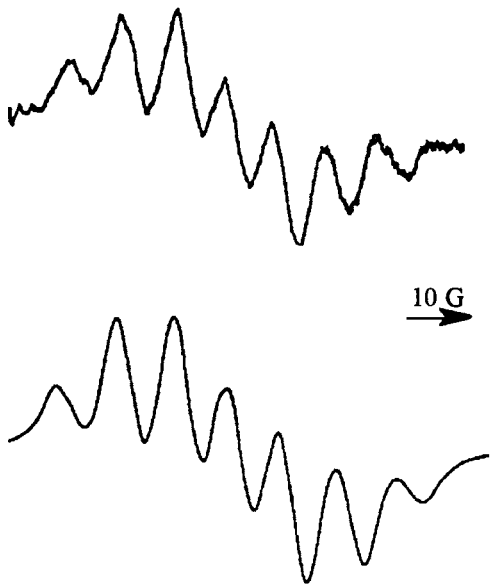

FIG. 1. Experimental and simulated EPR spectrum observed within 500 min from mixing of *o*-anisidine and ferricyanide in alkaline aqueous solution.

smaller overall splitting. Simulation of the spectrum indicated coupling of the unpaired electron with a set of two equivalent protons, in addition to two unequivalent protons and a nitrogen (a_{2H} 1.47, a_H 4.9, a_H 5.35, a_N 10.36 gauss). The spectrum cannot be due to the expected aminyl because the number of interacting nuclei, the values of the couplings, as well as the value of the measured *g*-factor (2.0043_9) are in agreement with an aryl(oxy)aminyl radical of type Ar(RO)N˙(11), and we therefore assign the observed spectrum to the *tert*-butoxy(2-methoxyphenyl)aminyl **B**.

The oxidation of *o*-anisidine also led to the observation of radical species, but again their spectra were not found indicative of an aminyl structure. Addition of a small amount of *meta*-chloroperbenzoic acid to a degassed benzene solution of compound **1** afforded a strong EPR signal due to a single radical species, which was identified as the *o*-anisyl nitroxide **C** on the basis of its spectral parameters, i.e., a_{2H} 0.95, a_{2H} 3.47, a_N 9.62, a_H 12.46, *g* 2.0060_0. A very similar spectrum still assigned to **C**, i.e., a_{2H} 1.01, a_H 3.6, a_H 3.7, a_N 10.32, a_H 13.03 G, *g* 2.0059_1, was obtained by reacting *o*-anisidine with hydrogen peroxide in acetic acid solution.

Treatment of compound **3** with *m*-chloroperbenzoic acid in benzene afforded a partially resolved EPR spectrum characterized by a *g*-factor of 2.0056 and by the following couplings: a_{3H} 0.22, a_{2H} 0.73, a_N 0.73, a_H 0.94, a_H 2.2, a_H 2.93, and a_H 10.78 G, which was attributed to radical **D**.

Discussion

In comprehensive studies of the oxidation of aromatic amines, Haynes and Hewgill (12, 13) reported that, contrary to the oxidation of phenols, no products arising from carbon–carbon coupling have ever been isolated. Indeeed, also in the present study on the oxidation of *o*-anisidine by ferricyanide, all the isolated products arise from nitrogen–nitrogen or nitrogen–carbon couplings whereas no occurrence of carbon–carbon coupling could be established.

Consistent with the formation of nitrogen-centred radicals in the oxidation of aniline with one-electron oxidizing agents in basic solutions (14), we propose the reaction sequence shown in Scheme 1 to account for the formation of the products isolated, **2–5**. Accordingly, oxidation of **1** would result in the initial formation of the aminyl radical **A**, which undergoes rapid nitrogen–nitrogen or nitrogen–carbon dimerization within the cage. The former process leads to the formation of hydrazo(2,2′-dimethoxy)benzene, which readily undergoes further oxidation to the isomeric *anti*, **2**, and *syn*, **2′**, 2,2′-dimethoxyazobenzenes representing the major reaction products. The *anti* isomer, by far the most abundant, could be partially converted to the *syn* by heating at 60°C in chloroform solution (*anti/syn* = 80/20 after 30 min, as determined by NMR); **2** ⇌ **2′** isomerization also took place under visible light irradiation either in chloroform solution or on silica gel plate. Nitrogen–carbon dimerization, on the other hand, takes place at the positions of higher spin density, resulting in the formation of 2-methoxy-4-(2-methoxyphenylamino)aniline **3**. While bielectronic oxidation of this compound, followed by hydrolysis of the resulting quinonediimine (not observed), may account for the formation of the quinoneimine **4**, monoelectronic oxidation would result in the diarylaminyl radical **D** whose coupling with aminyl **A** followed by bielectronic oxidation and hydrolysis would eventually afford compound **5**.

Although the mechanism outlined in the scheme accounts for the isolated products, it should be substantiated by additional evidence, such as the detection and identification of some of the intermediates. Indeed, the first, very short-lived radical observed in EPR experiments within 500 ms from the mixing of the reactant solutions can be assigned to the hypothesized aminyl on the basis of its spectral parameters. The observed spectrum was, however, characterized by a very large linewidth (see Fig. 2), and the values of the two *meta* couplings were obtained by computer simulation. As no EPR parameters are available for this radical in the literature, we tried to generate aminyl **A** through abstraction of an aminic hydrogen from *o*-anisidine by means of in situ photolytically generated *tert*-butoxyl radicals to gain further support for the assignment. The spectrum observed in this case was characterized by a higher *g* and by the absence of the α-hydrogen splitting and could be assigned to

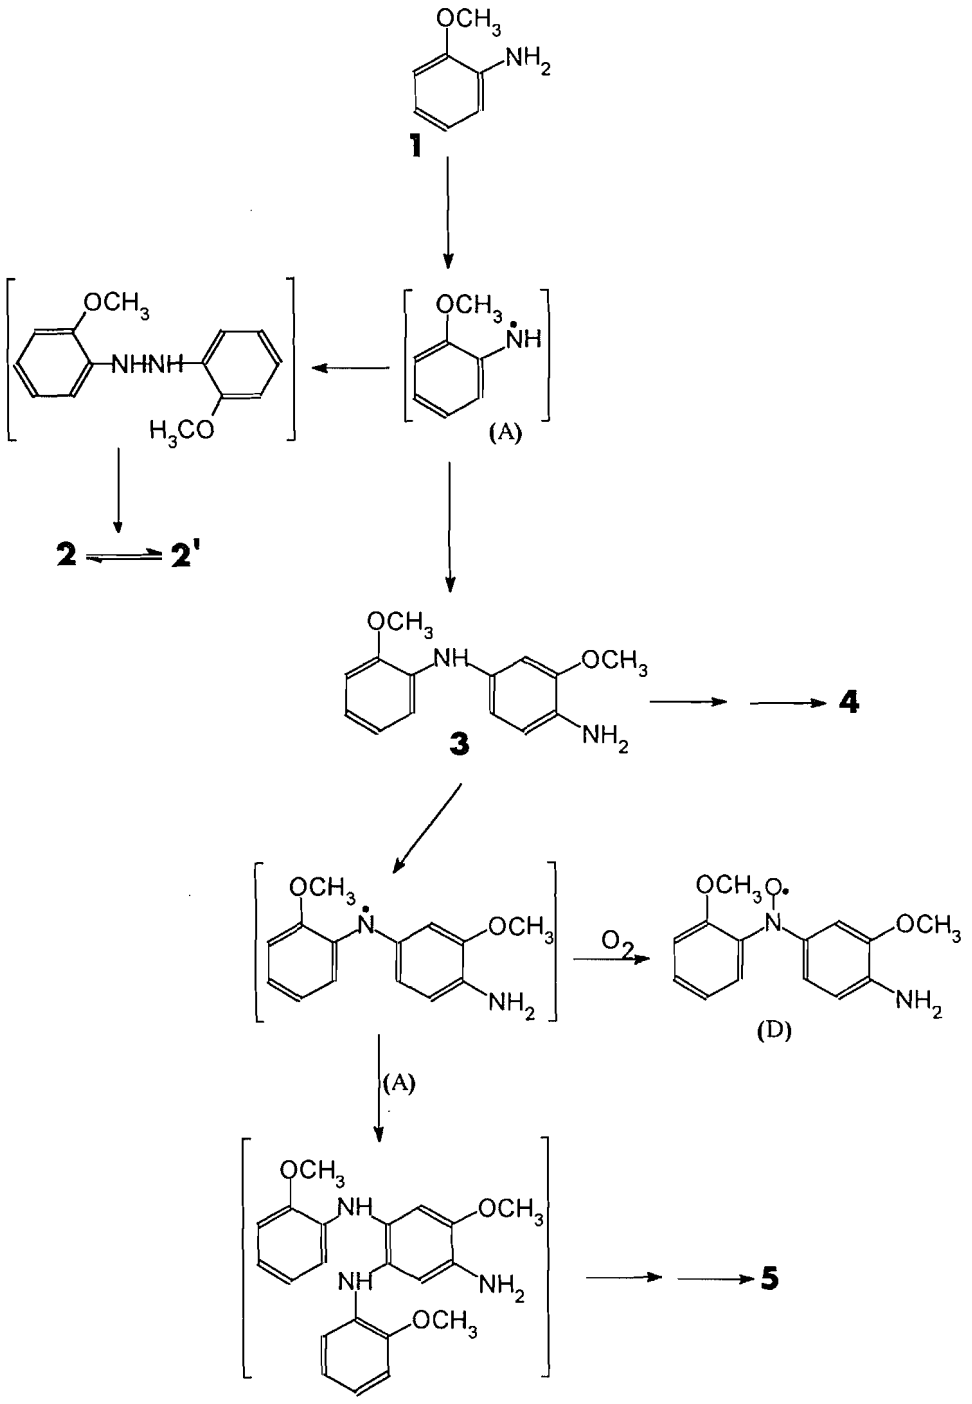

SCHEME 1

the *tert*-butoxyl aminyl **B**. The formation of this species can be explained by proposing hydrogen abstraction by $^tBuO^{\cdot}$ radicals with formation of the aminyl, which immediately couples with another *tert*-butoxy radical giving an intermediate compound that by further hydrogen abstraction produces **B**. Compound **1** did not react with PbO_2, while the anisylnitroxide **C** was formed with other oxidizing agents such as H_2O_2 or *m*-Cl-C_6H_4-CO_3H.

To find out whether the nitroxide reponsible for the broad three-line spectrum observed in the anisidine/ferricyanide system under static conditions could be originate from oxidation of **3**, we treated this compound with *meta*-chloroperbenzoic acid in benzene and obtained the spectrum shown in Fig. 3 together with its computer simulation.

The spectrum parameters indicate that the species responsible for this spectrum is a nitroxide; although it is also evident that the unpaired electron is delocalized onto just one aromatic ring, it is believed that the nitroxide can be identified as radical **D**: couplings with the two hydrogens and the nitrogen of an amino group and with the three hydrogens of a methoxy group are actually observed, whereas the lack of delocalization with the ring on the left might be explained in terms of steric hindrance that might force the anisyl moiety into a plane orthogo-

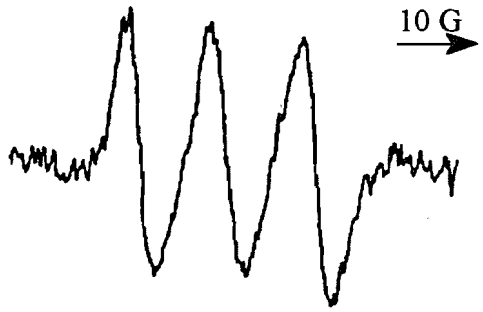

FIG. 2. EPR spectrum observed after 5 min from mixing *o*-anisidine and ferricyanide.

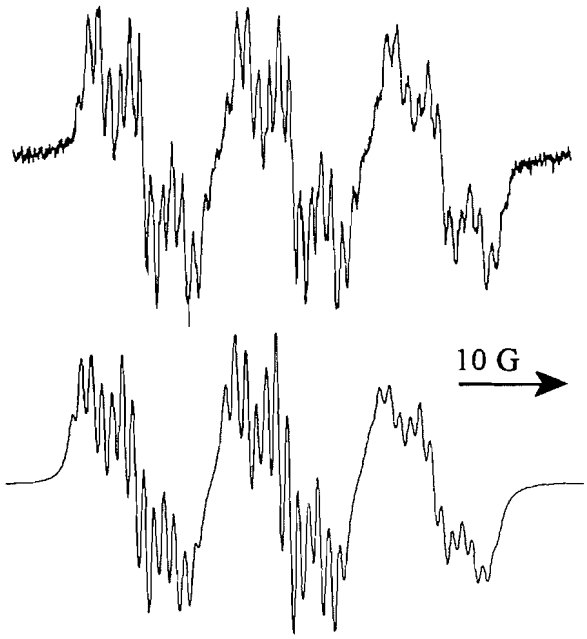

FIG. 3. Experimental and simulated spectra of nitroxide (D).

nal to that of the rest of the molecule, thus making spin delocalization impossible. It is hard to say whether nitroxide **D** is also responsible for the three-line spectrum mentioned above.

The *g*-values are the same in both cases, and the complex spectral pattern observed for **D** might explain the broad unresolved lines observed in the aqueous solution where dissolved oxygen is present. However, the nitroxyl nitrogen splitting is rather different in the two spectra, being markedly smaller in the "authentic" **D**. It should, however, be borne in mind that the nitrogen splitting in nitroxides is extremely sensitive to solvent (15), being larger in water, owing to hydrogen-bonding stabilization of structures characterized by large spin density on the nitrogen, than in apolar solvents such as benzene. Although it is not unambiguously proved that radical **D** is actually responsible for the broad spectrum observed in the oxidation of *o*-anisidine with ferricyanide in alkaline water under static conditions, we believe that our results do not contradict this possibility.

Conclusions

Oxidation of *ortho*-anisidine with potassium ferricyanide in alkaline water affords mainly *anti*-2,2′-dimethoxyazobenzene, together with a smaller amount of the *syn* isomer. No traces of carbon–carbon coupling compounds could be detected, other minor products being 2-methoxy-4-(2-methoxyphenylamino)aniline, 2-methoxy-4-(2-methoxyphenylimimo)-cyclohexan-2,5-dien-1-one, and 2-methoxy-4-(2-methoxyphenilimino)-5-(2′-methoxyphenyl)aminocyclohexa-2,5-dien-1-one. The nature of the observed products as well as EPR studies suggest a radical nature for the process. The *o*-anisyl aminyl is the first radical formed.

Experimental

Materials and product studies

ortho-Anisidine, potassium ferricyanide, di-*tert*-butyl peroxide, and *meta*-chloroperbenzoic acid were commercial chemicals.

The IR spectra were taken on a Perkin–Elmer IFT 1760-X spectrometer in chloroform. The ^{1}H NMR spectra, in deuterochloroform (reported in δ), were recorded on a Bruker 270 MHz spectrometer with Me_4Si as internal reference. Mass spectra were obtained with a VG ZAB 2F mass spectrometer (electron energy 70 eV, ion source temperature 250°C). UV spectra, in chloroform, were recorded with a Perkin–Elmer Lambda 7 spectrophotometer. Melting points were determined with a Kofler apparatus and are uncorrected. The purity of the compounds was checked by ascending TLC on Merck's precoated silica gel F-254 plates (0.25 mm) with fluorescent backing and the reported R_f are measured using chloroform as eluent.

Oxidation of o*-anisidine in alkaline medium*

To a solution of *o*-anisidine (**1**) 10 mmol in 20 mL of a water–methanol mixture (1:1, vv) an excess of a solution of potassium ferricyanide (40 mmol in 20 mL of water at pH 9) was added dropwise. After 2 h stirring, the mixture was extracted with chloroform. The organic layer was washed, dried, and analyzed chromatographically on silica gel plates (0.500 mm) using chloroform as eluent. Four fractions were isolated showing R_f 0.8, 0.7, 0.5, and 0.3, identified with compounds **2** (240 mg), **2′** (8 mg), **3** (9 mg), and **4** (162 mg), respectively.

anti *2,2′-Dimethoxyazobenzene (2)*

The compound was obtained as yellow crystals with mp 152–153°C; UV, λ_{max} (log ε): 312 (3.50), 368 (3.57), 460s; IR: 1615, 1250 cm^{-1}; ^{1}H NMR: 7.67 (2H, d, J_m = 1.6 Hz, J_o = 8.2 Hz), 7.40 (2H, t, J_m = 1.6 Hz, J_o = 8.2 Hz), 7.06 (2H, d, J_m = 1.6 Hz, J_o = 8.2 Hz), 6.99 (2H, t, J_m = 1.6 Hz, J_o = 8.2 Hz), 4.00 (6H, s); MS: 242 (M^+), 107. Anal. calcd. for $C_{14}H_{14}N_2O_2$: C 69.40, H 5.83, N 11.56; found: C 69.43, H 5.81, N 11.58.

syn *2,2′-Dimethoxyazobenzene (2′)*

The compound was obtained as pale-yellow crystals with mp 153–155°C; UV, λ_{max} (log ε): 312 (3.45), 360 (3.75); IR: 1615, 1250 cm^{-1}; ^{1}H NMR: 7.12 (2H, t, J_m = 1.5 Hz, J_o = 8.1 Hz), 6.83 (2H, d, J_m = 1.5 Hz, J_o = 8.1 Hz), 6.73 (2H, t, J_m = 1.5 Hz, J_o = 8.1 Hz), 6.57 (2H, d, J_m = 1.5 Hz, J_o = 8.1 Hz), 3.76 (6H, s); MS: 242 (M^+), 107. Anal. calcd. for $C_{14}H_{14}N_2O_2$: C 69.40, H 5.83, N 11.56; found: C 69.40, H 5.80, N 11.57.

2-Methoxy-4-(2-methoxyphenylimino)cyclohexa-2,5-dien-1-one (3)

The compound **3** was isolated as orange crystals with mp >250°C; UV, λ_{max} (log ε): 348 (3.47), 479 (3.45) nm; IR: 1680, 1245 cm^{-1}; ^{1}H NMR: 7.33 (1H, d, J_m = 2.3 Hz, J_o = 8.7 Hz), 7.21 (1H, t), 6.96 (1H, d), 6.95 (1H, t), 6.75 (1H, d), 6.69 (1H, d, J_o = 8.7), 6.11 (1H, s, J_m = 2.3 Hz); MS: 243 (M^+), 245 (M + 2). Anal. calcd. for $C_{14}H_{13}NO_3$: C 69.12, H 5.39, N 5.76; found: C 69.09, H 5.40, N 5.74.

2-Methoxy-4-(2-methoxyphenylimino)-5-(2′-methoxyphenyl)-aminocyclohexa-2,5-dien-1-one (4)

The compound was isolated as purple crystals with mp 101–102°C; UV, λ_{max} (log ε): 458 (3.81) nm; IR: 3300, 1680, 1245 cm^{-1}; ^{1}H NMR: 8.65 (1H, bs), 7.89 (1H, t), 7.46 (1H, d), 7.20 (1H, t), 7.02 (1H, d), 7.00 (2H, d + t), 6.95 (1H, t), 6.87 (1H, d), 6.23 (1H, s), 5.76 (1H, s), 3.86 (3H, s), 3.83 (3H, s), 3.62 (3H, s); MS: 364 (M^+), 366 (M + 2). Anal. calcd. for $C_{21}H_{20}N_2O_4$: C 69.22, H 5.53, N 7.68; found: C 69.29, H 5.51, N 5.70.

EPR studies

Can. J. Chem. Downloaded from www.nrcresearchpress.com by EESC ESCOLA DE ENGENHARIA on 09/08/12
For personal use only.

EPR studies

EPR spectra were recorded at room temperature either on a Varian E-9 spectrometer equipped with a Stelar Prometheus data system for acquisition and handling of the data, or on a Bruker ER 200 D spectrometer equipped with a Bruker 3220 data system, an NMR gaussmeter for field calibration, and a Systron Donner frequency counter for the determination of g-factors. The latter were calibrated with respect to that of the perylene radical cation in concentrated sulphuric acid. Where necessary, the EPR cavity was irradiated with the light from a high-pressure 1-kW mercury lamp.

Rapid flow experiments were carried out by allowing two pump-driven solutions to mix immediately before the flat section of the EPR cell. The mixture reached the central part of the cell in 50–500 ms.

Acknowledgment

We are grateful to Dr. C. Chatgilialoglu for the helpful discussions. We also thank the Centro di Metodologie Chimico Fisiche of the University of Naples for the NMR spectra and M.U.R.S.T. (Rome) for financial support.

Reçu le 3 juin 1993

MOHAMED AKSSIRA, FARID EL GUEMMOUT, PATRICK BAUCHAT et ANDRÉ FOUCAUD. Can. J. Chem. **72**, 1357 (1994).

Les réactions des 3-acétoxy-3-aryl-2-méthylène propionitriles **1** avec l'ammoniac donnent les diallylamines **3***ZZ* correspondantes. La réaction de **1** avec une allylamine primaire ou avec l'éthylène diamine donne la diallylamine **11** ou **13***ZZ*. Le traitement des 3-acétoxy-3-aryl-2-méthylène propionate de méthyle **2** avec l'isopropylamine ou l'éthylène diamine donne les allylamines **6***EE*, **14** ou **15**, mais la réaction de **2** avec l'ammoniac donne seulement les triallylamines **4***EEE* avec de bons rendements.

MOHAMED AKSSIRA, FARID EL GUEMMOUT, PATRICK BAUCHAT, and ANDRÉ FOUCAUD. Can. J. Chem. **72**, 1357 (1994).

The reactions of 3-acetoxy-3-aryl-2-methylene propionitriles **1** with ammonia yielded the corresponding diallylamines **3***ZZ*. The reaction of **1** with a primary allylamine or with ethylene diamine gave the diallylamine **11** or **13***ZZ*. The treatment of methyl 3-acetoxy-3-aryl-2-methylene propionates **2** with isopropylamine or ethylene diamine gave the allylamines **6***EE* or **14** and **15**, but the reaction of **2** with ammonia gave only the triallylamines **4***EEE* in good yields.

Introduction

Les groupements aminoallyliques existent dans de nombreux composés naturels (1) et les allylamines sont des composés biologiquement importants (2–4). Diverses méthodes de synthèses des allylamines ont été développées (5–7) mais les voies d'accès aux diallylamines restent limitées (8–10). Nous avons décrit la préparation de monoallylamines primaires ou secondaires à partir des 3-acyloxy 2-méthylène propionates de méthyle **2** (11). Nous rapportons dans ce mémoire la synthèse stéréosélective de diallylamines et triallylamines qui présentent, en β de l'atome d'azote, un groupement nitrile ou ester.

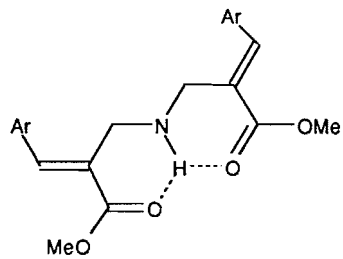
Résultats et discussion

Les matériaux de départ **1** et **2** sont aisément obtenus par la réaction, en présence de diazabicyclooctane, d'un aldéhyde avec l'acrylonitrile pour **1**, ou avec l'acrylate de méthyle pour **2** (réaction de Baylis–Hillman (12)) suivie de l'acétylation par le chlorure d'acétyle de l'alcool obtenu (11).

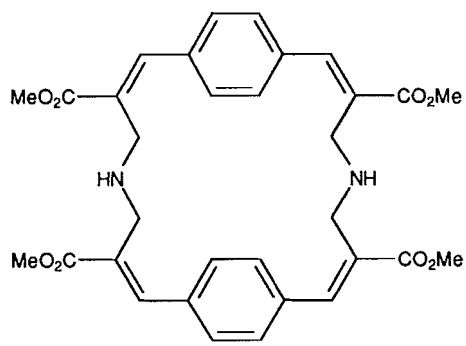
La réaction d'un excès d'ammoniaque, en solution aqueuse, avec les nitriles **1***a–c* dans le méthanol, à la température ambiante, donne les diallylamines **3***a–c* (schéma 1). Dans les mêmes conditions, les esters **2** donnent uniquement les amines tertiaires **4** (schéma 2). Les diallylamines intermédiaires **5** ne sont pas obtenues, même lorsque la température reste voisine de 0°C.

Ces résultats suggèrent que l'état de transition dans la réaction d'addition de l'amine **5** sur l'ester **2** est bien solvaté par chélation des carbonyles des groupements esters avec le groupement NH (liaison H à trois centres) (13). Il en résulte que la vitesse d'addition de **5** sur **2** pour donner **4** devient plus grande que la vitesse de formation de **5** (14). Cet intermédiaire **5** ne peut donc pas être isolé.

Les diallylamines tertiaires **6** sont obtenues en traitant 2 équivalents d'esters **2** avec 3 équivalents d'isopropylamine



5



8

dans le tetrahydrofurane (l'amine en excès neutralise l'acide acétique formé). La réaction des esters **2** avec un excès d'isopropylamine conduit aux allylamines **7** (11). La chélation entre le groupement NH et le carbonyle de l'ester est observée dans le spectre infrarouge des composés **7** (ν_{NH} = 3340 cm^{-1}, fréquence indépendante de la concentration de **7** dans le tétrachlorure de carbone) (schéma 2). Le paracyclophane **8**, qui a été isolé (15), comprend des motifs analogues à **5**, dont l'encombrement

SCHÈMA 1

SCHÈMA 2

stérique diminue la réactivité. Une liaison H forte est observée dans le spectre infrarouge de ce composé (ν_{NH} = 3300 cm^{-1} dans $CHCl_3$), ce qui est en faveur de l'existence de liaison H dans **5**.

Cette réactivité particulière des amines intermédiaires **5** peut être mise à profit pour préparer les triallylamines dissymétriques **9** et **10** par la réaction des amines primaires **12** (11) avec les esters **2** (schéma 3). Lorsque **12***d* est traité par **1***a*, la diallylamine **11** est effectivement obtenue. Contrairement à la diallylamine **5**, ce composé **11** ne réagit pas sur **2***a* dans les conditions utilisées. Ce résultat confirme l'importance de la présence de deux groupements esters pour accélérer la réaction de **5** avec les esters **2**.

La réaction d'un équivalent d'éthylènediamine dans le THF avec un équivalent de nitrile **1** ou d'ester **2** conduit aux allylamines **13** ou **14**. En utilisant deux équivalents d'ester **2**, le composé **15** est obtenu (schéma 4).

Les structures des composés sont établies à partir des données de RMN. En particulier les spectres de RMN ^{13}C montrent une constante de couplage à longue distance entre le carbone du groupement nitrile et le proton vinylique de ^3J = 14,5 Hz pour les composés **3**, **11** et **13**, ce qui est en accord avec une configuration *Z* de la double liaison (16).

Les spectres de RMN ^1H des composés **4**, **6**, **9**, **10**, **14** et **15** montrent un signal du proton vinylique, déblindé par le groupement ester voisin en position *cis*, vers δ = 7,40–8,05, en accord avec la littérature (17–20). Deux isomères *EE* et *EZ* du composé **6***a* sont obtenus dans le rapport *EE* : *EZ* = 68 : 32. Le proton vinylique en *trans* du groupement ester pour **6***a EZ* est à δ = 6,62 et les protons vinyliques en *cis* du groupement ester dans **6***a EE* et **6***a EZ* sont à δ = 7,67–7,74.

Ainsi les nitriles **1** conduisent, en général de façon exclusive ou très prépondérante, aux allylamines *Z*, alors que les esters **2**

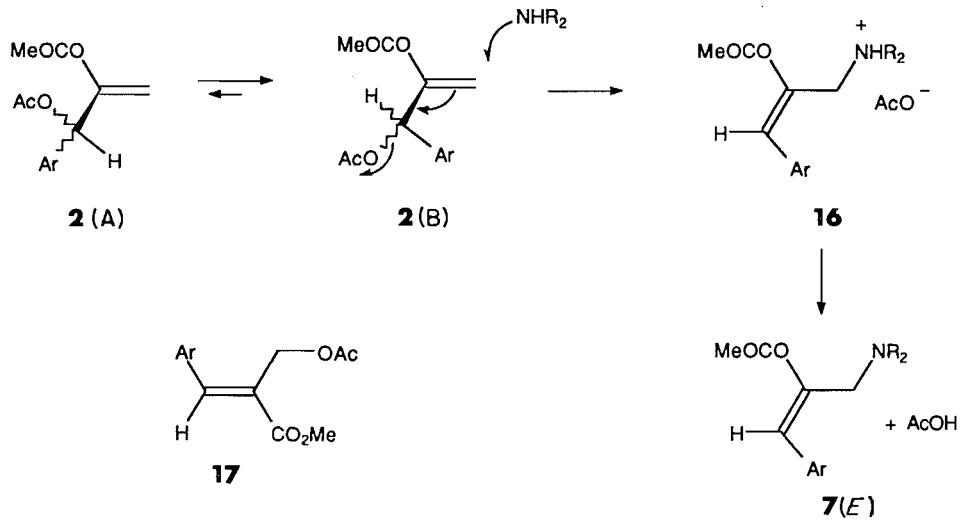
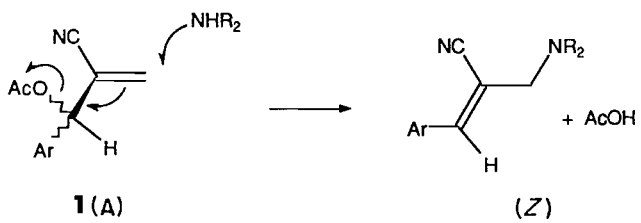
SCHÈMA 4



SCHÈMA 5



SCHÈMA 6

donnent les isomères *E* (sauf pour **6***a* où les isomères *EE* et *EZ* sont obtenus). Cette stéréochimie pourrait s'expliquer par les mécanismes présentés dans les schémas 5 et 6.

L'ester **2** possède une conformation privilégiée **2** (B) (schéma 5), qui conduira, par un état de transition où les intéractions stériques entre les groupements CO_2Me et Ar sont faibles, au sel **16** qui est déprotoné pour donner **7***E*. Un sel analogue à **16** a été proposé comme intermédiaire lors de l'isomérisation des esters **2** en acétate **17** catalysée par le diazabicyclo octane (11). La déprotonation de **16** est un processus plus rapide que la transformation de **16** en acétate **17**. L'acétate **17** n'est donc probablement pas un intermédiaire dans la formation de **7**. Les exigences stériques du groupement nitrile étant faibles, **1** (A) représente une conformation privilégiée qui conduira à l'isomère *Z* (schéma 6).

En conclusion, nous avons précisé les limites d'utilisation d'une méthode simple de synthèse de diallylamines qui comportent un groupement électroattracteur en β du groupement amino. À partir des nitriles **1**, on obtient les diallylamines secondaires *Z,Z*. À partir des esters **2**, il n'est pas possible d'isoler les diallylamines secondaires, leur réactivité vis à vis des esters **2** étant trop importante. On peut cependant préparer, à partir de **2**, les diallylamines tertiaires *E,E* ou les triallylamines, *E,E,E*.

Partie expérimentale

Les spectres RMN ont été enregistrés à 300 MHz (^{1}H) et 75,4 MHz (^{13}C) avec un spectromètre Bruker AC 300 (solvant $CDCl_3$). Les spectres de masse sont obtenus avec un spectromètre Varian MAT 311 à 70 eV et les spectres infrarouge sont enregistrés avec un spectromètre Perkin Elmer 1420. Les analyses élémentaires ont été effectuées au Laboratoire Central de Microanalyse du CNRS (Lyon). Les points de fusion sont pris à l'aide d'un banc chauffant Kofler.

Diallylamines 3 and triallylamines 4

À une solution de **1** ou **2** (5 mmol) dans le méthanol (10 mL) est ajouté goutte à goutte, sous agitation et à la température ambiante, un mélange d'une solution aqueuse de NH_3 à 28% (1 mL) et de méthanol (5 mL). Après agitation à la température ambiante pendant 10 h, le méthanol est évaporé. Le résidu est dissous dans le chloroforme (50 mL) et extrait à l'eau (2 × 20 mL). La phase organique est séchée (Na_2SO_4) et évaporée. Les produits **3** ou **4** cristallisent.

Di-(2-cyano-3-phényl-2-propényl) amine **3**a Z. *F* = 73°C ($CHCl_3$), 50%. IR (Nujol) ν : 2210, 3320 cm^{-1}. RMN ^{1}H, δ : 1,85 (s, 1H), 3,60 (s, 4H); 7,12 (s, 2H), 7,3–7,5 (m, 6H), 7,6 – 7,9 (m, 4H). RMN ^{13}C, δ : 52,02, 109,51 (C-2), 118,38 (dt, *J* = 14,6, 4,3 Hz, C≡N), 128,95,

In model studies designed to study the synthesis of potentially hexadentate chelates based on the linkage of three furan rings to a triamine via amide linkages, new 2- and 4-substituted 3-hydroxy-5-methylfurans have been prepared. Particularly, 3-hydroxy-5-methyl-(*N*-methylformamido)furan (Hahm) and its Al and Ga complexes ($M(ahm)_3$) have been prepared and thoroughly characterized by a variety of techniques, in the solid state and in solution. Solution equilibrium studies ($\mu = 0.6$ M NaCl, 25°C) uncovered a complicated set of equilibria in the Al^{3+}/Hahm system; the solution potentiometric data were best explained by the presence of mixed ligand (HL = Hahm, $L^- = ahm^-$) hydroxo species $[Al_3(OH)_4L_3]^{2+}$ and $[Al(OH)_2L_2]^-$, in addition to the expected $[AlL_n]^{(3-n)+}$ ($n = 1, 2, 3$) species. Further solution studies at HL:M ratios of 3:1 ($\mu = 0.15$ M NaCl, 25°C) showed that Hahm is a relatively weak complexing agent for both Al and Ga, forming tris-ligand species with overall formation constants of $10^{19.5}$ and $10^{20.6}$, respectively.

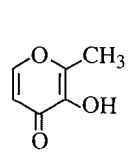
Dans le cadre de travaux orientés vers l'étude de la synthèse de chélates hexacoordinés potentiels basés sur la liaison de trois noyaux furaniques à une triamine par le biais de liaisons amides, on a synthétisé de nouveaux 3-hydroxy-5-méthylfuranes substitués en positions 2 et 4. On a préparé en particulier le 3-hydroxy-5-méthyl-2-(*N*-méthylformamido)furane (Hahm) ainsi que ses complexes avec de l'aluminium et du gallium ($M(ahm)_3$) et on les a caractérisés à fond par diverses techniques, tant à l'état solide qu'en solution. Les études d'équilibre en solution ($\mu = 0{,}6$ M NaCl, 25°C) ont permis de mettre en évidence l'existence d'un ensemble d'équilibres compliqués dans le système Al^{3+}/Hahm; pour bien expliquer les données potentiométriques en solution, on doit suggérer l'existence d'espèces hydroxo $[Al_3(OH)_4L_3]^{3+}$ et $[Al(OH)_2L_2]^-$ à coordinats mixtes (HL = Hahm, $L^- = ahm^-$), en plus des espèces $[AlL_n]^{(3-n)+}$ ($n = 1$, 2 et 3) attendues. Des études ultérieures en solution, à des rapports HL:M des 3:1 ($\mu = 0{,}15$ M NaCl, 25°C) montrent que le Hahm est un agent complexant relativement faible tant pour l'aluminium que pour le gallium, formant des espèces tricoordinées avec des constantes de formation globales respectives de $10^{19,5}$ et $10^{20,6}$.

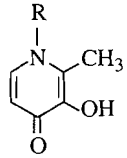
[Traduit par la Rédaction]

Introduction

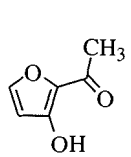
A number of low molecular weight complexes of aluminum, gallium, and indium have been prepared and investigated in these laboratories in recent years; their properties have recommended them for *in vivo* examination (2, 3). These complexes are tris(bidentate ligand)metal(III) species, and incorporate as ligands various pyrones (e.g. maltol, **1**) (4, 5), *N*-substituted-3-hydroxy-4-pyridinones (**2**) (6–8) and isomaltol (**3**) (9). The



1



2



3

properties of interest are hydrolytic stability, water solubility, neutral charge, and lipophilicity, all occurring simultaneously. Some of these ligands had very high affinities for the group IIIA (or 13) ions (8) and certain of the complexes formed unusual solid state hydrogen bonding arrays (6, 7).

In efforts to extend the coexistence of these four properties into hexadentate analogs of these binding moieties, we have undertaken model studies involving the preparation of some new ligands for the group 13 ions. The hydrolytic instability (10) of aluminum, gallium, and indium is an important factor in the aqueous chemistry of their trivalent ions and must be compensated for in the design of their chelates.

Initial model studies designed to study the synthesis of potentially hexadentate chelates were based on the functionalization of maltol (**1**) with triamines to form hexadentate tris(3-hydroxy-4-pyridinone) analogs of **2** similar to the bis(pyridinones) already reported (11); however, in both the bis and tris cases the 1 position of the maltol ring (where R—N is substituted for O) is far removed from the α-hydroxyketone chelating moiety and the resulting ligands form polymeric complexes by bridging metal ions. The ketone carbonyl of isomaltol (**3**) does not undergo Schiff base condensation with amines to form imines, rather isomaltol undergoes a ring opening, dehydration, and ring closing sequence of reactions to produce *N*-substituted-3-hydroxy-2-methyl-4-pyridinones (**2**) (12). The failure to form imines with isomaltol initiated a search for a ligand that had a

bulkier substituent at the 5 position to inhibit the ring opening reaction. An attractive candidate was found, 2-ethoxycarbonyl-3-hydroxy-5-methylfuran (Hehm, see Scheme 1), which not only had a methyl group at the 5 position, but also had an ester group at the 2 position, allowing for a route to modify the ligand by the formation of various amides. Little work has been done on such highly substituted furans, especially those containing a butanedionyl moiety, but a short communication by Takei et al. described the synthesis of furan derivatives (including the desired Hehm) by reacting diketene with various sulfur ylides in benzene (13).

The possibility of linking three isomaltol analogs together to a tripodal backbone such as tris(2-aminoethyl)amine (tren) via the replacement of the 2-acyl group with an amide linkage was envisaged. We report herein on model studies toward the objective of linking three furan rings to a triamine via amide linkages; new 2- and 4-substituted 3-hydroxy-5-methylfurans have been prepared, and their chemistry has been studied both in the presence and absence of the group 13 ions. 3-Hydroxy-5-methyl-2-(*N*-methylformamido)furan (Hahm) and its Al and Ga complexes ($M(ahm)_3$) have been prepared and thoroughly characterized by a variety of techniques in the solid state and in solution.

Experimental

Materials and methods

These were mostly as previously described (4, 6, 8, 9). Dimethylsulfide (Aldrich), ethyl bromoacetate (Aldrich), methylamine (40% in H_2O — Fisher), and $Al(NO_3)_3{\cdot}9H_2O$ (Mallinckrodt) were used as supplied. Ga ingots (Alfa) were dissolved in concentrated HCl; this solution was standarized and used as the starting material for the synthesis of Ga complexes. Diketene and benzene were freshly distilled before use. Carbethoxymethyldimethylsulfonium bromide was synthesized according to the method of Payne (14).

NMR spectra are reported δ downfield from TMS (^{13}C, ^1H, APT, SINEPT) and were recorded on Bruker AC-200E, Varian XL 300, and Varian XL 400 spectrometers. IR spectra were recorded as KBr disks with a PE 783 spectrophotometer and are referenced to polystyrene film. Mass spectra were obtained with either a Kratos MS 50 (electron-impact ionization, EI) or an AE MS-9 (fast-atom-bombardment ionization, FAB) instrument. Melting points were measured on a Mel-Temp apparatus and are uncorrected. Analyses for C, H, N were performed by Mr. Peter Borda in this department.

Ethyl (dimethylsulfuranylidene)acetate (EDSA)

This was prepared from dimethylsulfide and ethyl bromoacetate via carbethoxymethyldimethylsulfonium bromide according to Payne (14), with some modification. The carbethoxymethyldimethylsulfonium bromide solution was stirred vigorously using an overhead stirrer, and was cooled for 15 min in an ice bath. After the additions of the saturated K_2CO_3 and 12.5 M NaOH solutions, the ice bath was removed and the mixture was left to stir for an additional 25 min. The light yellow ylide was stored at 5°C under N_2.

2-Ethoxycarbonyl-3-hydroxy-5-methylfuran (Hehm) (13)

EDSA (12 g, 75 mmol) was stirred in 40 mL of benzene. To this, freshly distilled diketene (4.8 g, 57 mmol) was added, and the mixture was refluxed for 15 h. Most of the benzene was removed by rotary evaporation; the remaining solution was cooled and a precipitate formed. The precipitate was removed by filtration and recrystallized from methanol to give 6.9 g (75%) of an off-white crystalline product (mp 50–51°C). It was soluble in methanol, ethanol, chloroform, ether, ethyl acetate, benzene, and water. Anal. calcd. for $C_8H_{10}O_4$: C 56.47, H 5.92; found: C 56.40, H 5.80. ^1H NMR ($CDCl_3$): 7.6 (br, OH), 5.9 (q, J = 1 Hz, 1H, ring H), 4.3 (q, J = 6 Hz, 2H, CH_2), 2.25 (s, 3H, ring CH_3), 1.35 (t, J = 6 Hz, 3H, CH_3). ^{13}C NMR ($CDCl_3$): 160.4 (*C*=O), 156.2 (*C*C=O), 155.9 (*C*CH_3), 124.4 (*C*OH), 100.9 (*C*H), 59.7 (CH_2CH_3), 13.6 (C*C*H_3), 13.5 (CH_2CH_3). EIMS *m/z*: 170 (M^+), 142, 124. IR (cm^{-1}): 3240 (br); 1670, 1630, 1555 ($\nu_{C=O}$, $\nu_{C=C}$, mixed); 1260, 1180, 1080.

4-(1′,3′-Butanedionyl)-2-ethoxycarbonyl-3-hydroxy-5-methylfuran (Hehbm)

A preparation similar to that for Hehm using a 2:1 ratio of diketene to EDSA afforded a pale yellow solid. Anal. calcd. for $C_{12}H_{14}O_6$: C 56.69, H 5.55; found: C 56.59, H 5.80. ^1H NMR ($CDCl_3$): 8.45 (s, ~1H, OH), 6.23 (s, 1H, ring H), 4.41 (q, J = 6 Hz, 2H, ethyl CH_2), 2.67 (s, 3H, acetyl CH_3), 2.19 (s, 3H, ring methyl), 1.43 (t, J = 6 Hz, 3H, ethyl CH_3). ^{13}C NMR ($CDCl_3$): 191.4 (CH_3CO), 179.4 (exocyclic *C*OH), 160.8 (ring *C*C=O), 160.5 (ring *C*=O), 153.6 (*C*CH_3), 124.7 (ring *C*OH), 111.1 (ring *C*=CCH_3), 99.1 (methine C), 60.7 (CH_2CH_3), 24.7 (CO*C*H_3), 15.4 (C*C*H_3), 14.1 (CH_2CH_3). EIMS: *m/z*: 254 (M^+), 239, 197, 166, 151, 124. IR (cm^{-1}): 3320 (br); 1680, 1630 ($\nu_{C=O}$, $\nu_{C=C}$, mixed).

3-Hydroxy-5-methyl-2-(N-methylformamido)furan (Hahm)

Hehm (4.67 g, 27 mmol) was dissolved in 110 mL ethanol and methylamine (40% in H_2O) (2.12 g, 27 mmol) was added. The resulting solution was refluxed for 20 h. The volume was then reduced by rotary evaporation to give 3.3 g (77%) of an off-white powder which was recrystallized from ethanol. It was soluble in methanol, ethanol, chloroform, water, and benzene. Anal. calcd. for $C_7H_9NO_3$: C 54.20, H 5.85, N 9.03; found: C 53.94, H 5.82, N 8.79. ^1H NMR (CD_3OD): 5.94 (q, J = 1 Hz, 1H, ring H), 3.47 (s, 3H, amide CH_3), 2.27 (d, J = 1 Hz, 3H, ring methyl). EIMS: *m/z*: 155 (M^+), 140, 126. IR (cm^{-1}): 3390 (s, ν_{NH}); 3400–2800 (br, ν_{OH}); 1665, 1610, 1575, 1485, 1445 (amide bands, $\nu_{C=O}$, $\nu_{C=C}$, all mixed).

$Al(ahm)_3{\cdot}3H_2O$

Hahm (0.475 g, 3.1 mmol) was dissolved in 40 mL H_2O and the pH was raised to 9 (2 M NaOH). $AlCl_3{\cdot}6H_2O$ (0.246 g, 1.0 mmol) was then added and the pH was adjusted to 7.3. A white precipitate formed (0.36 g, 72%) which was recrystallized from methanol. $Al(ahm)_3$ was soluble in methanol, acetone, and water (3.1 mM). Anal. calcd. for $C_{21}H_{24}AlN_3O_9{\cdot}3H_2O$: C 46.16, H 5.53, N 7.72; found: C 45.94, H 5.27, N 7.66. ^1H NMR (CD_3OD): 6.11 (s, 1H, ring H), 3.56 (s, 3H, amide CH_3), 2.28 (s, 3H, ring methyl). FABMS *m/z*: 824 ($M_2L_5^+$); 490 (HML_3^+); 355 (ML_2^+). IR (cm^{-1}): 3700–2800 (br, ν_{NH}, ν_{OH}); 1645, 1590, 1530, 1475, 1450 (amide bands, $\nu_{C=O}$, $\nu_{C=C}$, all mixed).

$Ga(ahm)_3$

Hahm (0.528 g, 3.4 mmol) was dissolved in 60 mL H_2O and the pH was raised to 9. A solution of 0.445 M $GaCl_3$ in excess HCl (2.5 mL, 1.1 mmol) was added. Adjustment of the pH to 7.0 with 2 M NaOH resulted in an off-white powder (0.45 g, 75%) which was recrystallized from pyridine. It was soluble in pyridine, methanol, water (1.6 mM), and slightly soluble in acetone. Anal. calcd. for $C_{21}H_{24}GaN_3O_9$: C 47.39, H 4.55, N 7.93; found: C 47.15, H 4.70; N 7.99. ^1H NMR (pyridine-d_5): 6.38 (s, 1H, ring H), 3.03 (s, 3H, amide CH_3), 1.86 (s, 3H, ring methyl). FABMS *m/z*: 532 (HML_3^+); 377 (ML_2^+). IR (cm^{-1}): 3700–2500 (br, ν_{NH}, ν_{OH}); 1630, 1580, 1530, 1470, 1440 (amide bands, $\nu_{C=O}$, $\nu_{C=C}$, all mixed).

Potentiometric equilibrium measurements

Potentiometric measurements (at μ = 0.6 or 0.15 M NaCl for the Al/Hahm system; at μ = 0.15 M NaCl for the Ga/Hahm system) of the ligand in the absence, and presence, of metal ions were performed as described previously (9, 15). The temperature was maintained at 25.0 ± 0.1°C throughout. Stock solutions of Hahm were prepared by dissolving it in slightly acidified solutions ($-\log [H^+] \approx 2.5$, μ = 0.6 or 0.15 M NaCl). The total ligand concentration was determined potentiometrically using the Gran extrapolation method (16). The titrated amount was found to be within ± 0.2% of the value expected from weighing. Stock solutions of NaCl, $AlCl_3$, and dilute HCl were prepared and standarized as described previously (15). Metal containing

Can. J. Chem. Downloaded from www.nrcresearchpress.com by EESC ESCOLA DE ENGENHARIA on 09/08/12
For personal use only.

solutions were also prepared from appropriate dilution of atomic absorption standard solutions of Al or Ga (Sigma or Aldrich). The exact amount of excess acid present in the metal ion solutions was determined by a Gran's plot (17). The reproducibility and reversibility of Al/Hahm equilibria (μ = 0.6 M NaCl) were tested by performing both forward titrations (increasing – log [H^+] by coulometrically generated OH^-) and backward titrations (decreasing – log [H^+] by the addition of H^+).

The deprotonation of Hahm in 0.6 M NaCl was studied in separate experiments within the range $2.5 \leq -\log [H^+] \leq 9$. The three component titrations (μ = 0.6 M NaCl) were performed at constant ratios of the total concentrations of Hahm (B) and Al (C). The B/C ratios 1, 2, 3, 6, and 8 were studied with $0.001 \leq B \leq 0.008$ M and $0.001 \leq C \leq 0.007$ M. The upper – log [H^+] limits in these titrations were set by the appearance of sluggish equilibria, probably due to the formation of polynuclear hydrolysis products, viz. $[Al_{13}O_4(OH)_{24}]^{7+}$, at low B/C ratios; and $-\log [H^+] \geq 4$. At B/C high ratios with $-\log [H^+] \geq 7$ the formation of a precipitate was frequently observed.

A limited number of potentiometric titrations in μ = 0.15 M NaCl were then undertaken at 3:1 HL:M ratios to compare the overall formation constants of the 3:1 Hahm complexes with aluminum and gallium. For the determination of the formation constants, titrations were done with $B \sim 0.002$ M in the range $2 \leq -\log [H^+] \leq 4$ because the formation of mixed hydroxo species can be neglected in this range.

Data treatment

The equilibria can be divided into three groups:

(*i*) the binary Hahm equilibrium:

$$[1] \quad HL \rightleftharpoons H^+ + L^- \qquad \beta_{-110}$$

(*ii*) the hydrolytic equilibria for the metal ions:

$$[2] \quad pH^+ + rM^{3+} \rightleftharpoons [H_pM_r]^{(p+3r)+} \qquad \beta_{p0r}$$

incorporating the hydrolysis species for Al: $[Al(OH)_n]^{(3-n)+}$ (n = 1, 2, 3, 4), $[Al_3(OH)_4]^{5+}$, and $[Al_{13}O_4(OH)_{24}]^{7+}$ with appropriate formation constants (18–20)

(*iii*) three component equilibria of the general form:

$$[3] \quad pH^+ + q\text{Hahm} + rM^{3+} \rightleftharpoons [H_p(\text{Hahm})_qM_r]^{(p+3r)+} \qquad \beta_{pqr}$$

In the evaluation of the experimental μ = 0.6 M data, the least-squares computer program LETAGROPVRID (21) (version ETITR (22)) was used. Triplets of pqr, and corresponding equilibrium constants that best fit the experimental data were determined by minimizing the error squares sum $U = \Sigma(H_{calc} - H_{exp})^2$. The LETAGROP calculations also give standard deviations $\sigma(H)$ and $3\sigma(\log \beta_{pqr})$ defined according to Sillén (23, 24). Here H denotes the total proton concentration calculated over the zero level H_2O, HL, and Al^{3+}.

The analysis of the μ = 0.6 M experimental data was started by calculating Z values for each point in a titration using the relation

$$[4] \quad Z = ([H^+] - H - k_w[H^+]^{-1})/B$$

This is the average number of OH^- reacted per B. The experiments thus provide sets of data Z vs. – log [H^+] which are presented in Fig. 1; the Al complexation clearly starts at low $-\log [H^+] < 2$. Furthermore, at B/C ratios of 1, Z clearly exceeds 1. This is direct evidence that hydroxo and/or mixed ligand hydroxo-complexes of Al were formed. To discover whether specified ranges existed where the formation of binary Al^{3+}/L^- complexes prevail, $\bar{n}$ vs. – log [L^-] (L^- = ahm$^-$) curves were plotted (Fig. 2). The quantity $\bar{n}$ is the average number of L^- coordinated per Al^{3+} (25). Coincident $\bar{n}$ curves are obtained if predominantly mononuclear AlL_n complexes are formed. A limited curve with $\bar{n} \leq 2.5$ was found; however, deviations from this curve are clearly seen at C/B ratios 1 and 2, as well as at high ratios with $\bar{n} > 2.5$. Data from the "mononuclear wall" were used to evaluate the stability of the different

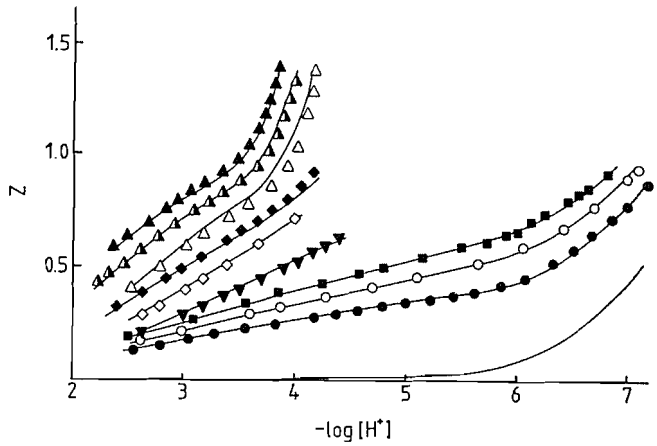

FIG. 1. A part of the experimental data (25°C, μ = 0.6 M NaCl) plotted as curves of Z vs. –log [H^+]. The full curves were calculated using the set of proposed constants in Table 1. The bottom curve represents the ligand in the absence of Al^{3+}. The different symbols denote starting concentrations B, C: ▲ 7.29, 7.00; Δ 3.79, 3.75; △ 1.89, 1.88; ◆ 4.67, 2.30; ◇ 2.35, 1.18; ▼ 5.04, 1.67; ■ 5.76, 1.15; ○ 6.32, 1.05; ● 7.28, 0.91.

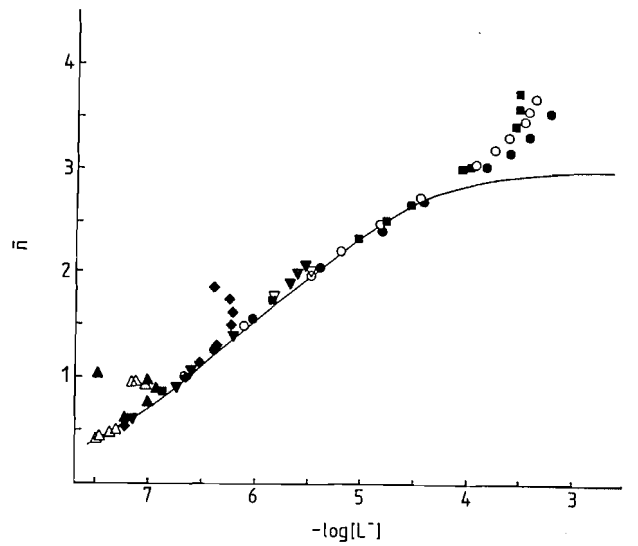

FIG. 2. Experimental data (25°C, μ = 0.6 M NaCl) plotted as curves of $\bar{n}$ vs. –log [L^-] (L^- = ahm$^-$). The symbols are the same as in Fig. 1. The full curve was calculated using log $\beta_{-n,n,1}$ values (n = 1, 2, 3) from Table 1.

$Al(ahm)_n$ species (n = 1, 2, 3). The results of this calculation are presented in Table 1.

In the search for composition (pqr) and stability (β_{pqr}) of any additional complexes (necessary to explain the deviations from the mononuclear $\bar{n}$ curve), pqr analysis using the LETAGROPVRID program was undertaken. The principle behind this method is that complexes of different pqr compositions are tested successively, one by one, and the complex that gives the lowest error square sum is considered to give the best fit. If there are still systematic deviations between calculated and experimental values of H, additional complexes must be included and combinations of two or more pqr sets must be tested. In this work, two data sets were defined; one with $B/C \geq 3$ (set 1) and one with B/C = 1 and 2 (set 2). The result of the analysis on set 1 is presented in Fig. 3, and shows that the lowest value in U was obtained for the complex $[H_{-4}(HL)_2Al]^-$; log β_{-421} = –12.08 (5) and $\sigma(H)$ = 0.05 mM indicate a good fit to experimental data, and no systematic deviations were

[a]The formation constants are defined according to the reaction: $pH^+ + qHL + rM^3 \rightleftharpoons [H_pM_r]^{(p+3r)+}$ where HL = Hahm. Numbers in parentheses represent errors corresponding to $3\sigma(\log \beta_{pqr})$.

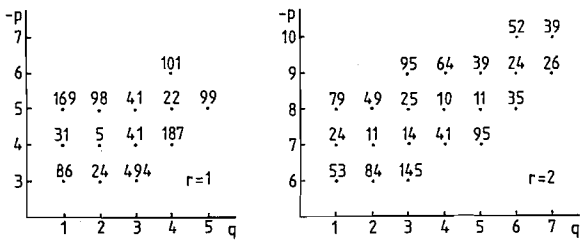

FIG. 3. Results of the *pqr* analysis on data with $B/C > 3$. The figure gives $U_H(p, r)_q$ assuming one ternary complex.

observed. Similar calculations were performed on set 2. The high Z values ($Z \leq 1.5$) that were observed with $-\log [H^+] \approx 4$, indicate the formation of ternary hydroxo species; furthermore, the high buffer capacity of the system in this range also implied that polynuclear Al complexes were likely. The *pqr* search clearly showed that polynuclear complexes were formed, the best fit being obtained with p,q,r −7,3,3. No attempts were made to include additional complexes as the remaining residuals were too small to justify this ($\sigma(H)$ = 0.07 mM). The results of the final calculation where the different formation constants were refined on the whole data set are given in Table 1. In order to visualize the amounts of different species, the program SOLGASWATER (26) was used and calculated distribution diagrams are presented in Fig. 4.

In the μ = 0.15 NaCl HL:M 3:1 studies, the computations allowed for the presence of hydrolytic species of Al and Ga with formation constants for these various metal species taken from ref. 10. The stability constants for the main species ML^{2+}, ML_2^+, and ML_3 were determined by using the Fortran computer program BEST (27). Because of the presence of mixed hydroxo/ligand/aluminum complexes noted from the μ = 0.6 M data, these 3:1 results are noted in the results and discussion section only for comparison between the two metal ions.

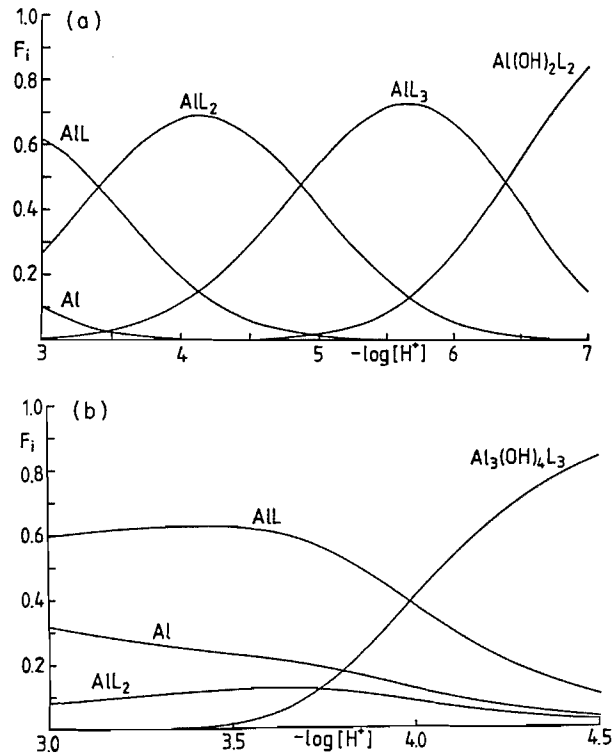

FIG. 4. Distribution diagrams F_i vs. $-\log [H^+]$, where F_i is defined as the ratio between Al^{3+} in a species and total Al^{3+}. The total ligand and Al^{3+} concentrations (mM): (*a*) 5 and 1, respectively, and (*b*) 5 and 5, respectively.

Results and discussion

Hehm

The yield of Hehm was improved significantly by increasing the ratio of EDSA to diketene to 1.3:1 from 1:1 (13) and by refluxing for 6 h (Scheme 1). Any impurities in the starting materials or benzene solvent resulted in a red oil, shown by thin layer chromatography to consist of at least eight products. Hexanes extraction of the oil gave rise to Hehm and another product (Hehbm) that was separable from Hehm by fractional crystallization. For this reason, both the benzene and the diketene were distilled before use, and the EDSA was checked for impurities by ^1H NMR. Using pure starting materials in the appropriate stoichiometry resulted in a 75% yield of Hehm, which was then recrystallized from ethanol.

A short communication characterized Hehm only by elemental analysis and mp (13). In our work, the IR spectrum of Hehm showed a broad OH stretch at 3240 cm^{-1} indicative of a hydrogen bonded, rather than a free, OH group. Hehm also has two strong bands occurring at 1670 and 1630 cm^{-1} corresponding to C=O and C=C stretches, respectively (28). The C=O stretch occurs at a lower energy than in saturated esters due to exten-

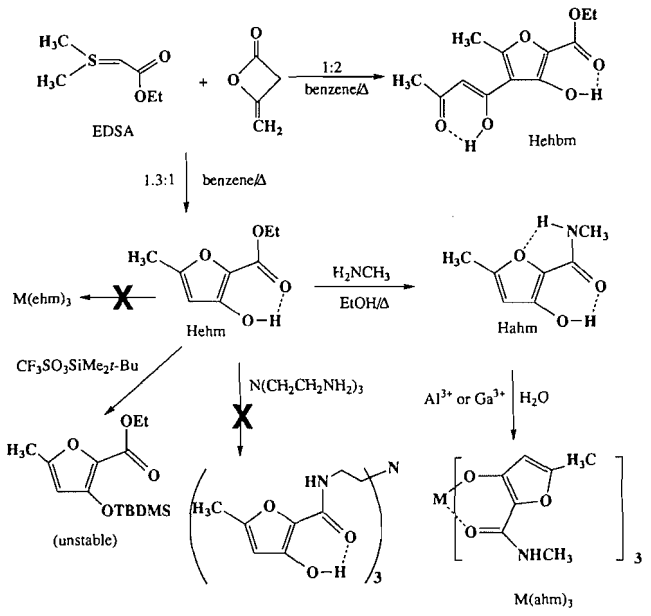

SCHEME 1

sive conjugation and hydrogen bonding with the hydroxyl hydrogen, analogous to that seen with isomaltol (9). There are three bands in the C—O stretch region at 1260, 1180, and 1080 cm^{-1}, but it is not possible to assign any one band due to ring vibrations and C—H bending modes occurring in the same region. The ^1H NMR spectrum showed the presence of an ethyl group with chemical shifts diagnostic of esters. The long range coupling between the ring methyl hydrogens and the adjacent ring hydrogen is also consistent with the Hehm structure. A broad OH peak was also seen further downfield at δ 8.45 in $CDCl_3$. The EI mass spectrum of Hehm showed a parent peak at *m/z* 170, a peak at *m/z* 142 from loss of ethanol, and a base peak at *m/z* 124 from fragmentation typical of β-hydroxy esters by means of the McLafferty rearrangement (29).

Functionalization of Hehm

Hehm did react with methylamine to form the amide Hahm, but did not react completely with triamines such as tren to form potentially hexadentate chelating ligands (Scheme 1). With tren (dioxane, 24 h, 65°C) there was evidence that two of the three amines had reacted to form a difunctionalized compound with the third arm unreacted. There was, however, ample evidence that Hehm would not lend itself to a variety of transformations. Its reaction with di(isobutyl)aluminumhydride gave starting material; even functionalization of the 3-OH was elusive as reactions with benzyl chloride, or KH/benzyl bromide, yielded no reaction. The only successful reaction, the protection of the 3-hydroxy group as a *t*-butyldimethylsilyl ether, worked satisfactorily (Scheme 1); however, the protected compound underwent basic hydrolysis (NaOH/THF) to yield the starting material. A considerable number of attempts were made to make Hehm analogs in which the ester functionality was more active in order to complete the target hexadentate molecule; these were all unsuccessful.

Metal complexes of Hehm

Metal complexes of Hehm were prepared by a 3:1 stoichiometric addition of ligand to metal in a 3:2 water:ethanol solution due to the low water solubility of Hehm. The pH was initially raised to 9, and upon slow addition of the metal salt, the pH dropped to ~ 2. The pH was then raised again to 6.5 with 2 M NaOH resulting in an off-white precipitate. ^1H NMR, IR and MS evidence was found for the Al and Ga complexes $M(ehm)_3$, but isolation of analytically pure samples was impossible, and the spectra always contained features attributable to Hehm. Hehm reversibly hydrolyzes under the acidic synthetic conditions, so that as the pH was increased from 2 to 7, only low yields of the complexes were found. The isolated products usually contained ~ 20% Hehm. Any attempts to purify the complexes resulted in decomposition to starting materials. The IR spectra showed the expected bathochromic shifts in $\nu_{C=O}$, but there was also a peak at 1670 cm^{-1} from Hehm. The DCI (negative ion detection) mass spectrum of the gallium complex of Hehm showed two parent ion peaks corresponding to $[ML_3 - H]^-$ at *m/z* 575 and 577 (^{69}Ga, ^{71}Ga). The base peaks were *m/z* 547 and 549 ($[M(ehm)_3 - CH_2CH_3]^-$) suggesting that a gallium complex incorporating one hydrolyzed Hehm ligand may be formed.

Hehbm

If the reaction of EDSA and diketene was carried out using an excess of diketene, rather than an excess of EDSA, the side product in the synthesis of Hehm became the predominant product (Scheme 1). This product (Hehbm-4-(1′,3′-butanedionyl)-2-ethoxycarbonyl-3-hydroxy-5-methylfuran) was characterized by IR, NMR, MS, and elemental analyses. If two equivalents of diketene react instead of one, the extra diketene unit is attached at the 4 position of the ring. Hehbm has potential as a ligand in its own right, and has not been reported in the literature. The mass spectrum of Hehbm showed a parent peak at *m/z* 254, loss of a methyl group (*m/z* 239), loss of CH_3CO and a methyl (*m/z* 197), and loss of ethanol from the 197 peak (*m/z* 151). The base peak at *m/z* 124 is from the loss of CO from the *m/z* 151 fragment peak. The ^1H NMR spectrum in deuterated chloroform confirmed the structure shown (Scheme 1) by comparison with the spectrum of Hehm. There was no long range coupling between the methine hydrogen and the furan ring methyl hydrogens (as seen in Hehm), thus providing evidence that the methine hydrogen is not directly attached to the C-4 ring carbon. Only one peak due to the OH hydrogen on the side chain at the 4-position is seen at 8.45 ppm, suggesting that strong hydrogen bonding is occurring in the enol form in solution. Further evidence to support this structure was found in the ^{13}C NMR spectrum ($CDCl_3$). An attached proton test (APT) showed twelve carbons present, three of which were methyl, one methylene, one methine, and six quaternary. The extra C_4 unit attached to the 4-position of the ring showed ^{13}C NMR chemical shifts of 179.4, 99.1, 191.4, and 24.7 ppm, analogous to a similar β-diketone compound (30).

The positions of the various ring substituents were confirmed by using the NMR technique SINEPT. Irradiation of the methine hydrogen on the side chain on the ring 4-position resulted in the enhancement of ^{13}C signals at 99.1 ppm (one bond coupling), 191.4 and 179.4 ppm (two bond coupling), and at 111.1 ppm (three bond coupling). No enhancement was seen at the methyl carbon on the C_4 side chain. The pulse sequence requires a known $^3J_{CH}$ value for three bond coupling (in this case 4 Hz), or an approximation if not known, such that enhancement of the ^{13}C signal will be selective to coupled carbons that are three bonds away. However, some enhancement breakthrough can occur at carbons that are coupled through

Can. J. Chem. Downloaded from www.nrcresearchpress.com by EESC ESCOLA DE ENGENHARIA on 09/08/12

For personal use only.

only one or two bonds if the coupling constants through one and/or two bonds are multiples of the chosen $^3J_{CH}$ value; the ^{13}C enhancements at 99.1, 191.4, and 179.4 ppm are all due to breakthrough. The lack of enhancement expected at the methyl carbon on the C_4 side chain and at the ring 4 carbon may be because the time involved in the refocussing sequence is longer than the hydrogen relaxation time, a factor commonly found when trying to enhance carbon signals through three bonds. This results in the hydrogens relaxing to their normal Boltzmann distribution of populations before the ^{13}C spectrum is acquired. However, the enhancement breakthroughs as well as the expected enhancement, confirm the presence of the predicted side chain, which is bonded to the 4-position of the ring. Irradiation of the methyl at the 5 position resulted in enhancement of the carbon signals at 160.8, 15.4 ppm, as well as 191.4, 99.1, and 24.7 ppm. The 15.4 and 160.8 ppm enhancements occur through two and three bond couplings, respectively. The other three enhancements are actually due to the irradiation of the methyl group on the C_4 side chain, also showing enhancements due to one (24.7 ppm), two (191.4 ppm), and three (99.1 ppm) bond coupling. Simultaneous irradiation of both methyl groups was seen because the irradiation was not selective enough to distinguish between the two methyl groups. This SINEPT experiment shows that the ring 5-methyl is bonded to a carbon having a chemical shift of 160.8 ppm, and therefore must be bonded to the carbon next to the ring oxygen. This experiment also reinforces the structure of the C_4 side chain. Due to the presence of two metal binding sites on Hehbm, its use as a ligand was not pursued in this work but should be of interest.

Hahm

Hahm (3-hydroxy-5-methyl-2-(*N*-methylformamido)furan) is a new potentially bidentate amide ligand which has not been previously reported, to our knowledge. Hahm was prepared in high yield by refluxing overnight equimolar quantities of Hehm and methylamine (40% in H_2O) in ethanol. Reactions of isomaltol (**3**) with methylamine, or other primary amines, resulted in 6-membered-ring pyridinone insertion products (**2**) obviating the formation of furan-based Schiff base chelating agents (31); however, the fact that Hehm contains a bulkier methyl group at the 5 position on Hehm rather than a hydrogen, favored the formation of an amide, and no pyridinones were detected. Two intramolecular hydrogen bonds probably provide a very stable structure for Hahm (Scheme 1). In the solid state, Hahm is a stable off-white powder; however, in water, it undergoes a slow decomposition which is time-, concentration-, and pH-dependent. Unusual aqueous solution behavior was first observed during the potentiometric titrations; as a result compound preparation (*vide infra*) and solution studies in water were undertaken with freshly prepared solutions.

The infrared spectrum of Hahm, in the solid form, showed an N—H stretch at 3390 cm^{-1}, suggesting that a conjugate structure predisposed to chelation may be formed (Scheme 1). The O—H stretching vibration results, due to hydrogen bonding, in a broad band centered around 3100 cm^{-1}. Due to solubility limitations in non-protic solvents, solution studies to investigate the hydrogen bonding in Hahm, although desirable, were not undertaken. A band characteristic of all amides is the strongly absorbing $\nu_{C=O}$ (amide I band) which occurs at 1665 cm^{-1} in Hahm. There is considerable mixing of the C=O and the C=C vibrations such that the bands at 1665 and 1610 cm^{-1} are most likely combination bands, being primarily due to $\nu_{C=O}$ and $\nu_{C=C}$, respectively. The broad band at 1575 cm^{-1} (amide II band) is a combination band primarily due to a δ_{NH} coupled to a ν_{CN}. The C—N stretch (amide III band) region occurs between 1305 and 1220 cm^{-1}, but because of the presence of many other bands in this region, a definite assignment was not possible.

The ^1H NMR spectra of Hahm were obtained in D_2O, CD_3OD, and DMSO-d_6. In all solvents, the spectra of the ring substituents were consistent with the proposed structure (three peaks in a 3:3:1 ratio). A small long range coupling (1 Hz) between the ring hydrogen at the 4-position and the methyl group at the 5-position was also observed. The EI mass spectrum of Hahm showed the parent peak at *m/z* 155; loss of a methyl group resulted in a peak at *m/z* 140 and loss of N—CH_3 gave rise to a peak at *m/z* 126.

Hahm complexes

Synthesis of the metal complexes of Hahm in high yield were carried out in water, but required that the pH be raised to 9 initially due to the lower water solubility of Hahm. The nitrate salt of the desired metal was then added to a freshly prepared Hahm solution, giving a 3:1 Hahm-to-metal ratio; the pH was readjusted to ~7. The aluminum and gallium complexes were obtained in 72 and 75% yields, respectively.

Upon coordination to the metal, the N—H and O—H stretches in the IR spectrum broadened to cover the ~3500 to 2800 cm^{-1} region, with maximum absorbance at 3400 cm^{-1}. Notably, the carbonyl stretch shifted 20 to 40 cm^{-1} lower in the complexes, consistent with complexation, and there was one very strong amide band at 1530 cm^{-1}, with weaker shoulder bands at higher wavenumbers. The two bands at 1610 and 1575 cm^{-1} in the spectrum of Hahm shifted into one overlapped band at 1530 cm^{-1}.

The ^1H NMR spectra of the Hahm complexes were consistent with the formulations; they showed that the environment at the 5-methyl was scarcely affected by chelation to the metal and the 1 Hz coupling constant between the ring 4-hydrogen and 5-methyl group, which was small for the ligand, was unresolvable for the metal complexes. The ring hydrogen and the amide methyl underwent significant shifts, since they are closer to the binding site. $Ga(ahm)_3$ decomposed in methanol, showing a broad shoulder or additional peaks from the free ligand. A spectrum consistent with the proposed structure was obtained in pyridine-d_5. In an effort to detect the amide hydrogen, DMSO-d_6 was used, but both the aluminum and gallium complexes decomposed becoming solvolyzed in this solvent.

The metal complexes decomposed under electron impact ionization conditions, so their mass spectra were obtained by fast atom bombardment ionization. Peaks from HML_3^+, ML_2^+, and ML^+ were present for both complexes. For the aluminum complex, the base peak was that from ML_2^+, while a weak $M_2L_5^+$ peak was observed at *m/z* 824, typical of neutral tris(bidentate) chelate complexes (4). The mass spectrum of the gallium complex showed many peaks due to the matrix (thioglycerol), but the most intense metal–ligand fragment was ML_2^+. Peaks due to HML_3^+ and $M_2L_5^+$ were observed with the appropriate isotopic ratios, the former being more intense.

Stability constants for $M(ahm)_3$

Solution potentiometry at $\mu = 0.6$ M demonstrated that Hahm is a weak acid ($K_a = 10^{-7.09}$) and that the ahm^- anion is not an outstanding binding group for aluminum (Table 1). The ahm^-

Can. J. Chem. Downloaded from www.nrcresearchpress.com by EESC ESCOLA DE ENGENHARIA on 09/08/12
For personal use only.

anion, however, may have potential as the metal binding component of higher dentate chelating agents. Table 1 lists the formation constants β_{pqr} at μ = 0.6 M as defined in the experimental section. The speciation was characterized by a series of $AlL_n^{(3-n)+}$ complexes (n = 1, 2, 3). These had the following stepwise constants: log K_1 = 7.28, log K_2 = 6.14, log K_3 = 4.83 as calculated from the data in Table 1 and defined by:

$$[5] \quad K_n = \frac{[ML_n^{\{3-n\}+}]}{[ML_{n-1}^{\{4-n\}+}][L^-]}$$

(for an overall stability constant for the $Al(ahm)_3$ complex of $10^{18.25}$). The formation constants are less than those for the group 13 M^{3+} complexes of the 2,4-pentanedionato (acac) anion where log K_1 is ~ 8.7, log K_2 ~ 7.8, and log K_3 ~ 6.5 (32).

In neutral solutions with excess ligand ($B/C > 3$), a deprotonation of the AlL_3 complex was observed with elimination of the ligand. Whether the resulting –4,2,1 complex was a mixed hydroxo complex, $[Al(OH)_2L_2]^-$, or a species where the amide N is deprotonated cannot be predicted from the pH measurements; however, it seems reasonable to assume this species to be a mixed hydroxo complex. Similar anions have been found in other Al^{3+} systems with ligands forming complexes of high and intermediate stability, such as polycarboxylates like oxalate (33) and citrate (20), polyphenols like gallate (15), catecholate (34), and 1,2-dihydroxynaphthalene-4-sulfonate (35), as well as aromatic *o*-carboxylic phenols like salicylate (36). All these complexes are formed in neutral or slightly alkaline solutions and can be regarded as precursors to the $[Al(OH)_4]^-$ ion. In acidic solutions (– log $[H^+] \approx 4$) with $B/C < 3$ a cationic trinuclear complex is formed (cf. Fig. 4*b*). A possible structure of this complex is $[Al_3(OH)_4L_3]^{2+}$, consistent with the connection between the binary hydrolysis (cf. $[Al_3(OH)_4]^{5+}$) and mixed ligand/hydroxo complexes formed. Mixed complexes of this type have been reported in several Al^{3+} systems and seem to be formed more as a rule than as an exception (37).

For purposes of rough comparison, the pK_a of Hahm and the logarithms of the overall formation constants for the 3:1 aluminum and gallium complexes were determined from the 0.15 M data to be 7.15, 19.5, and 20.5, respectively. Determination of the protonation constant of Hahm actually showed two inflection points, one corresponding to the deprotonation of the hydroxyl proton, and one that might be due to the deprotonation of the amide nitrogen (– log $K \approx 12.4$); however, the ionic strength was no longer constant at – log $[H^+] > 12$. Although the overall values are higher than those of isomaltol (9), at millimolar concentration, the predominant species was still due to undesirable hydrolysis, at pH greater than 7 for gallium and at pH greater than 8.5 for aluminum. The onset of hydrolysis was delayed until a higher pH compared to isomaltol, but still occurred to a significant extent. At higher ratios of Hahm:M, the ligand easily competes with hydrolysis, such that the ML_3 species predominate in the intermediate pH regime.

Concluding remarks

The synthesis of Hehm can be carried out cleanly and in high yield if the starting materials are pure and an excess of EDSA is used. A close analogue of Hehm, Hehbm, was formed as an impurity if the ratio was inappropriate and as a major product if a 1:1 ratio of EDSA:diketene was used. Attempts to prepare potentially hexadentate ligands based on the amidation of Hehm failed and Hehm did not undergo reactions typical of an ester; however, Hahm was produced in high yield from Hehm and methylamine. Aluminum and gallium complexes of Hahm have been prepared and thoroughly characterized; they have higher formation constants than their isomaltol analogs, likely as a result of the amide carbonyl being a harder donor by resonance than a ketone carbonyl. The Al system has been shown by extensive potentiometric study to contain mixed ahm⁻/hydroxo $[Al(OH)_2L_2]^-$ and $[Al_3(OH)_4L_3]^{2+}$ complexes, in addition to the simple $AlL_n^{(3-n)+}$ species (n = 1, 2, 3).

Solubility and solvation of pyronato and pyridinato complexes of aluminum, gallium, and indium in alcohol–water mixtures

EMMA BEATTY, JOHN BURGESS,[1] AND MARTTAND S. PATEL
Department of Chemistry, University of Leicester, Leicester LE1 7RH, U.K.

Received April 20, 1993[2]

EMMA BEATTY, JOHN BURGESS, and MARTTAND S. PATEL. Can. J. Chem. **72**, 1370 (1994).

Solubilities are reported for aluminum, gallium, and indium tris-ligand complexes of the pyrones maltol and ethylmaltol and of a number of 4-pyridinones in water–methanol and water – *tert*-butyl alcohol solvent mixtures, at 298.2 K. Trends and patterns in transfer chemical potentials derived from these solubilities are discussed in terms of the dependence of solvation on the nature of the ligand, the metal, and the cosolvent.

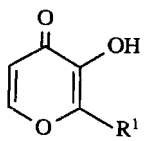
EMMA BEATTY, JOHN BURGESS et MARTTAND S. PATEL. Can. J. Chem. **72**, 1370 (1994).

Opérant à 298,2 K, dans des mélanges d'eau–méthanol et d'eau – alcool *tert*-butylique, on a mesuré les solubilités des complexes tricoordinés de l'aluminium, du gallium et de l'indium avec les pyrones maltol et éthylmaltol et un certain nombre de 4-pyridones. On discute des tendances et des patrons observés dans les potentiels chimiques de transfert dérivés de ces solubilités en fonction de la dépendance de la solvatation sur la nature du coordinat, du métal et du cosolvant.

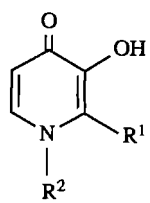
[Traduit par la Rédaction]

Introduction

Extensive series of ligands of the 4-pyrone (maltol), **1**, and 4-pyridinone, **2**, type have been developed for the control of



1



2

iron levels in the body, either for administering iron to anaemic patients or for the removal of excessive body burdens, as in haemochromatosis or thalassemia (1, 2). In view of the similarities between iron(III) and aluminum(III) complexes, it seems possible that ligands of this type might be useful in lowering aluminum levels in the body (3), perhaps thereby slowing the progress of at least some types of dementia. These ligands and their metal(III) complexes are able to penetrate various body membranes, hence the possibilities of the control of iron and aluminum levels. Complementarily, these species may afford a convenient way of administering elements, particular those with a stable 3+ oxidation state, of diagnostic or therapeutic value into the body (2). Such elements include, for example, gallium (^{67}Ga, ^{68}Ga) (4–7) and indium (^{111}In) (4, 5, 8) for diagnosis, yttrium (^{90}Y for radiotherapy of tumours (5, 9)), and gadolinium (for magnetic resonance imaging, MRI (10)). These tris-ligand–metal(III) complexes are moderately water-soluble, and also reasonably soluble in a number of organic solvents. Their favorable pharmacokinetic characteristics (11) may derive from the balance between hydrophilic and lipophilic regions. In the present paper we report the results of our measurements of solubilities of some aluminum(III), gallium(III), and indium(III) complexes of ligands of type **1** and **2** in methanol–water and in *tert*-butyl alcohol – water solvent mixtures. It is especially interesting that the pyrone complexes are more soluble in alcohol–water mixtures than in water or the alcohol alone. This suggests particularly favorable solvation when the water component can solvate the hydrophilic areas, the alcohol the lipophilic areas, of the complex. Such solvation characteristics may stabilize this type of complex at fat–water interfaces, e.g., at the surfaces of membranes. They may thus be important in connection with transport through membranes and barriers, for adsorption at the interface is a necessary prerequisite to passage through the membrane (12).

Experimental

Maltol was obtained from Aldrich, ethylmaltol from Pfizer; the pyridinones were prepared from these by published methods (13). Yields were between 45 and 70%; products were characterized by their melting points and ^{1}H NMR spectra. The aluminum, gallium, and indium complexes were also prepared by established methods (7) in yields of 80–90%. The complexes were characterized by melting points, ^{1}H NMR, and ultraviolet–visible spectra (where known).

Saturated solutions were obtained by equilibrating a generous excess of solid complex with the appropriate solvent medium for several days, with occasional agitation, in a thermostatted bath (298.2 K). Aliquots of supernatant saturated solution were removed and diluted as appropriate. Absorbances were measured at the wavelengths given in Table 1, and solubilities thence calculated from the dilutions used and the respective molar extinction coefficients (Table 1) (13).

Results

Absorbances and solubilities for all the complexes studied are collected in Table 1. This table also includes transfer chemical potentials calculated from these experimental results (cf. Discussion below). The absorbances in Table 1, and the solubilities calculated from them, are reported to a higher precision than warranted by the experimental procedure to avoid the introduction of any rounding-off uncertainties. The transfer chemical potentials are quoted to one decimal place; uncertainties in these values may be taken to be between 5 and 10%.

Discussion

The maltol and ethylmaltol complexes show solubility maxima in methanol–water mixtures. The solubility plot for tris-maltolato–indium(III), In(memal)$_3$, is shown in Fig. 1, which indicates particularly favorable solvation in 60–80% methanol. This is compatible with the greater solubility of this complex in methanol than in water. Presumably the higher sol-

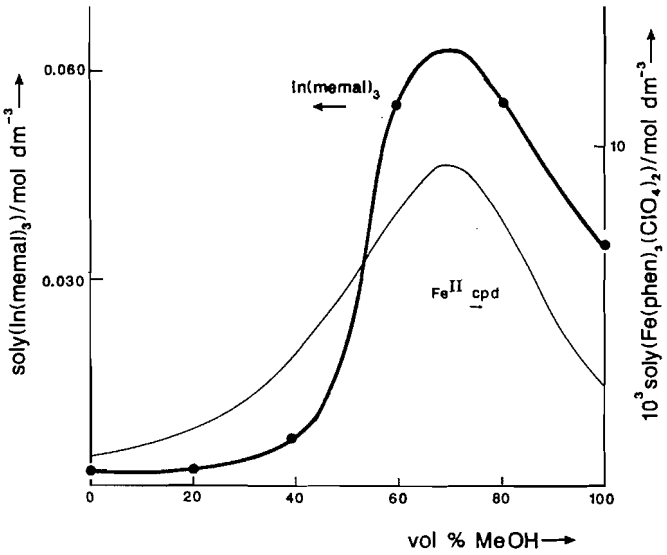

FIG. 1. Dependence of the solubilities of tris-maltolato–indium(III) and of tris-1,10-phenanthrolineiron(II) perchlorate on solvent composition in methanol–water mixtures, at 298.2 K.

ubility in the binary aqueous mixtures than in either water or methanol alone can be attributed to favorable interactions between ligand oxygens and water, and favorable interactions at lipophilic parts of the periphery of the complex with the methanol. It is interesting to compare this behavior for [In(memal)$_3$] with that of a salt, e.g., [Fe(phen)$_3$](ClO$_4$)$_2$, consisting of a hydrophobic cation well solvated by methanol and a hydrophilic anion well solvated by water. The solubility patterns of the indium complex and of the perchlorate of the [Fe(phen)$_3$]$^{2+}$ cation (14) are compared in Fig. 1, which shows a remarkably similar pattern for these two compounds.

The solubility results of Fig. 1 and in Table 1 can be converted into transfer chemical potentials using the formulae

$$\delta_m\mu^0 = -RT \ln\{(\text{soly in mixed solvent})/(\text{soly in water})\}$$

for an uncharged solute,

$$\delta_m\mu^0 = -nRT \ln\{(K_{sp} \text{ in mixed solvent})/(K_{sp} \text{ in water})\}$$

for an electrolyte with $z_+ + z_- = n$ (K_{sp} = solubility product). Relative solubilities can thence be discussed in energy-related terms. The consequent minima in transfer chemical potentials are shown in Fig. 2. This figure also shows analogous plots, derived from published solubilities (15), for a number of other compounds that have both hydrophilic and lipophilic areas on their surfaces. Thus eicosanoic acid (arachidic acid, Me(CH$_2$)$_{18}$CO$_2$H) has a long hydrocarbon chain balanced to a modest extent by the hydrophilic carboxylic acid group; the sulfa drug sulfathiazole, **3**, and the amino acid tryptophan, **4**, are other examples of compounds with similarly balanced peripheries. These compounds can be linked to the salt [Fe(phen)$_3$](ClO$_4$)$_2$ mentioned above through ternary complexes such as [Fe(CN)$_2$(bipy)$_2$], where hydrophilic cyanide and hydrophobic 2,2′-bipyridyl ligands are now both bonded to the iron(II) center. [Fe(CN)$_2$(bipy)$_2$] also exhibits solubility maxima, and thus transfer chemical potential minima, in alcohol–water mixtures (16).

Figure 3 compares our new results for the tris-maltolato com-

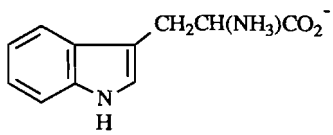
3



4

plexes of indium and of gallium with published data for analogous complexes of iron and of aluminum (17). In all cases there is a minimum at about 2:1 methanol:water. The indium complex shows a bigger minimum than the gallium, aluminum, and iron complexes. This comparison also applies to transfer chemical potentials from water to methanol. Thus complexes of the largest metal ion, viz., indium, show greatest sensitivity to solvation environment. This behavior is not unique to the present group of ligands, for similar behavior has been established for tris(8-hydroxyquinolinato)–aluminum(III) and –indium(III) (18), and in comparisons of the acetylacetonate (2,4-pentanedionate) complex UO$_2$(acac)$_2$ with VO(acac)$_2$ and with first-row transition metal(II) complexes M(acac)$_2$ (19), though in these latter comparisons the presence of different numbers of oxide ligands rather complicates the discussion. It seems likely that the

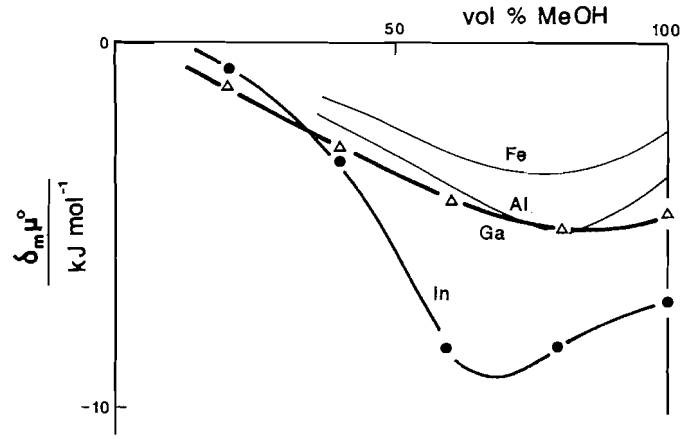

FIG. 3. Transfer chemical potentials for tris-maltolato complexes to methanol – water mixtures, at 298.2 K.

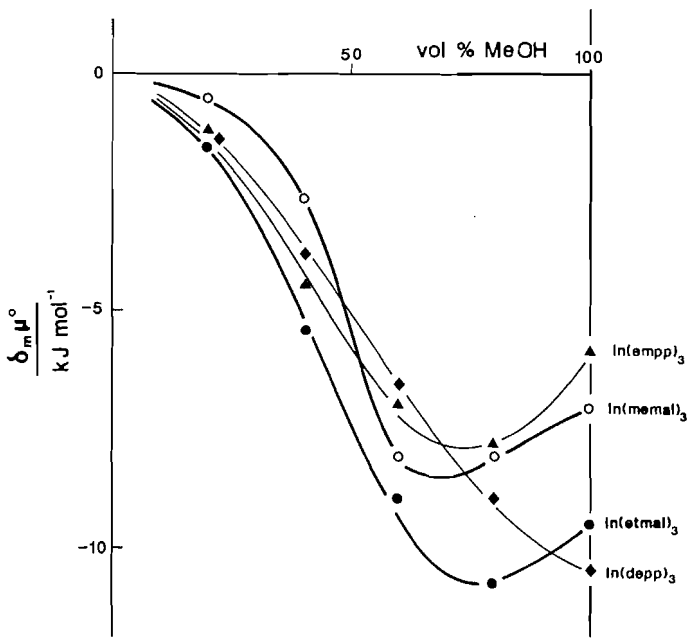

FIG. 4. Transfer chemical potentials for indium complexes to methanol–water mixtures, at 298.2 K.

observed size effects can be attributed to sterically controlled differences in hydrogen-bonding interactions between solvent components and coordinated oxygen atoms in the respective complexes. The importance of such hydrogen bonding in complexes of this type seems to have been first suggested to explain effects of dissolved β-diketonate complexes of a variety of metals on the infrared spectra of chloroform and of methanol (20). This evidence was later considerably strengthened by the results of water–alkane partition experiments on beryllium β-diketonates (21) and on tris-acetylacetonate and tris-monothioacetylacetonate complexes of cobalt(III) (22). X-ray diffraction studies have indicated significant hydrogen bonding between waters of crystallization in, for example, *fac*-[M(dmpp)$_3$], M = Al or Ga, and the coordinated oxygens of the dimethylpyridinone ligands (23).

Figure 4 shows transfer chemical potential trends for a range of indium complexes. Tris-ethylmaltolato–indium(III), In(etmal)$_3$ (ethylmaltol = **1** with R = Et), exhibits a solubility

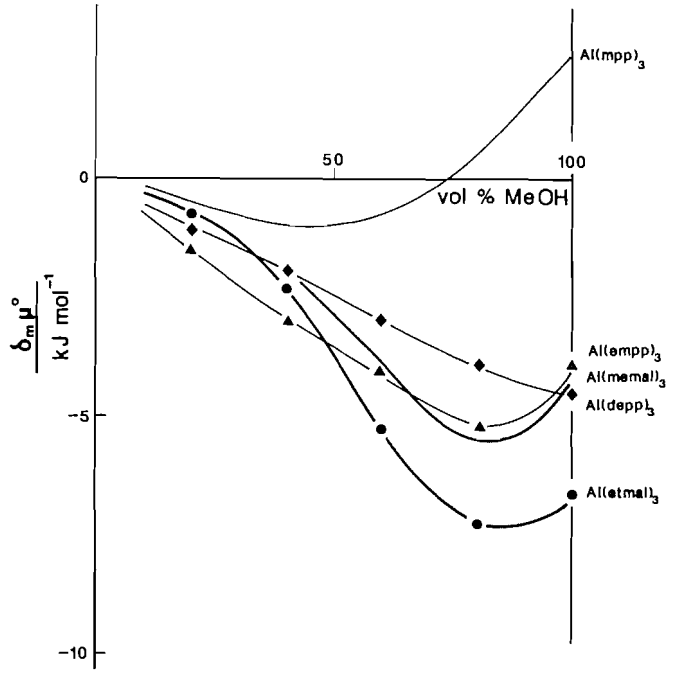

FIG. 5. Transfer chemical potentials for aluminum complexes to methanol–water mixtures, at 298.2 K.

maximum, and a transfer chemical potential minimum, at a mixed solvent composition similar to that of the parent complex tris-maltolato–indium(III). The less hydrophilic ethyl-substituted derivative is, as expected, markedly more soluble in methanol in comparison with water than is its parent. The ethyl methyl derivative In(empp)$_3$, empp = **2** with R^1 = Et, R^2 = Me, also shows a marked transfer chemical potential minimum. On going to significantly more hydrophobic species, such as the tris-diethylpyridinone (**2** with R^1 = R^2 = Et) complex of indium(III), In(depp)$_3$, the transfer chemical potential minimum disappears. Such complexes are continuously more favorably solvated by the methanol as its proportion increases.

Figures 5 and 6 show transfer chemical potential trends for a range of aluminum complexes, with methanol and *tert*-butyl alcohol as cosolvents, respectively. As expected, the pattern for transfer to methanol–water mixtures is similar to that for the analogous indium complexes (Fig. 4), though for aluminum the published (17) trend for Al(mpp)$_3$, mpp = **2** with R^1 = Me, R^2 = H, provides a comparison with a particularly hydrophilic pyridinone complex. Figure 5 has been drawn to the same scale as Fig. 4 to facilitate comparison, as indeed has Fig. 6. This last figure's main feature is that it shows all the complexes, except Al(mpp)$_3$, to have positive transfer quantities to *tert*-butyl alcohol-rich mixtures. Thus in general *tert*-butyl alcohol solvates not just less well than methanol but also less well even than water. All complexes, again with the exception of the particularly hydrophilic Al(mpp)$_3$, show a minimum. In other words, addition of up to 40–60% *tert*-butyl alcohol increases solvation, but then further decreasing the proportion of water leads to a fairly rapid rise in potential, with the pyridinone complexes having more positive transfer chemical potentials than the pyrone complexes. The tris-pyridinone complexes of aluminum thus become relatively less favorably solvated than the tris-pyrone complexes on transfer from water into 90% *tert*-butyl alcohol. This comparison, and the greater stabilization of aluminum tris-pyridinone complexes on addition of

Can. J. Chem. Downloaded from www.nrcresearchpress.com by EESC ESCOLA DE ENGENHARIA on 09/08/12
For personal use only.

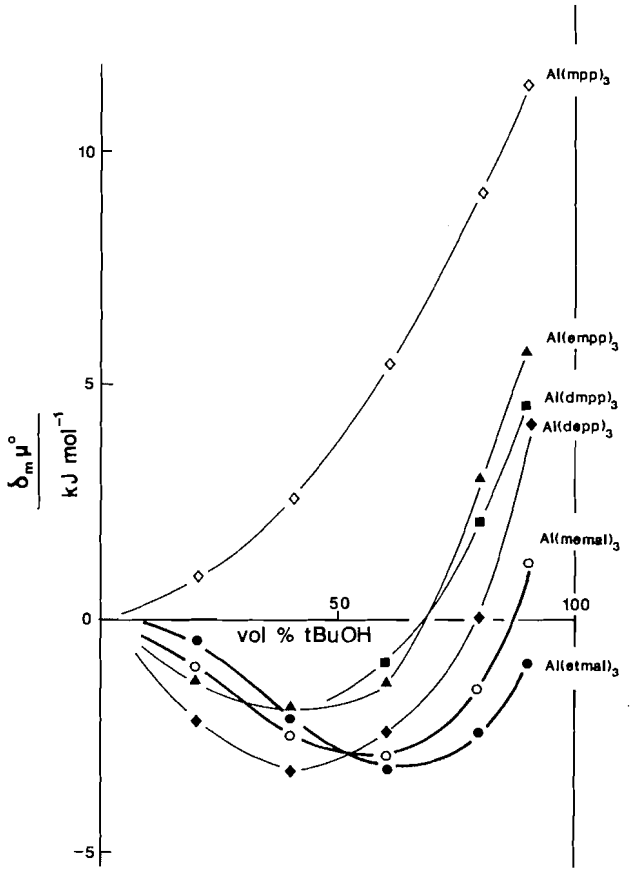

FIG. 6. Transfer chemical potentials for aluminum complexes to *tert*-butyl alcohol – water mixtures, at 298.2 K.

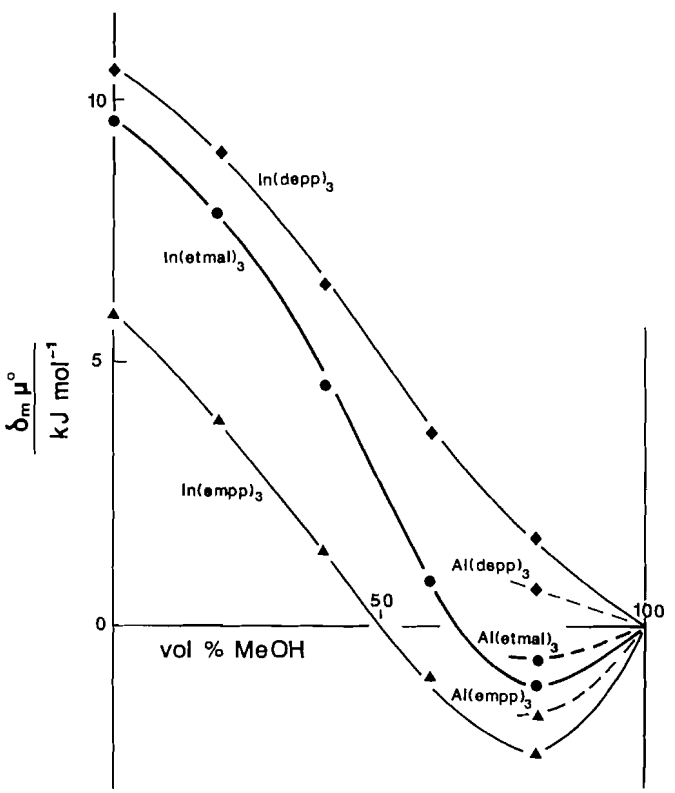

FIG. 7. Transfer chemical potentials for indium and aluminum complexes from methanol to methanol–water mixtures, at 298.2 K.

water to 90% *tert*-butyl alcohol, both suggest that the pyridinone complexes are the more hydrophilic. Greater hydration of pyridinone than of pyrone complexes is also supported by partial molar volumes, which are 264 cm^3 mol^{-1} for $Al(memal)_3$, 238 cm^3 mol^{-1} for the slightly larger complex $Al(dmpp)_3$ {memal = **1** with R^1 = Me; dmpp = **2** with $R^1 = R^2$ = Me}.[3] This comparison strongly suggests more electrostrictive hydration around the latter.

Most of the above discussion has been based on water as the reference solvent. The complementary point of view takes methanol or *tert*-butyl alcohol as the reference medium. The addition of water to the latter causes marked stabilization of *all* the aluminum complexes (Fig. 6), showing the importance of hydration at the  sites in the heterocyclic rings and at coordinating oxygens. The consideration of methanol as reference solvent leads to greater discrimination (Fig. 7). Now the addition of water destabilizes the most hydrophobic complexes, viz., the diethyl derivatives $Al(depp)_3$ and $In(depp)_3$, stabilizes the memal and etmal complexes moderately, and the empp complexes a little more.

The well-established intermolecular associations in alcohol–water mixtures (24) may have an influence on solubility trends through their effects on solvent–solute interactions. Thus the increased hydrogen-bonding structure of alcohol–water mixtures may make both components less available for solvating a solute. If solvent–solvent interactions play a dominant rôle, then extrema in the solubility and transfer chemical potential trends at solvent compositions corresponding to regions of maximum structuredness would be expected, i.e., at around mole fractions of 0.23 (40% by volume) methanol and of 0.04 (17% by volume) *tert*-butyl alcohol (24). This is not the case, as is apparent from several of the figures, and indeed the marked dependence of transfer chemical potential minima on the nature of the solute in *tert*-butyl alcohol – water mixtures (Fig. 6) shows that solute–solvent interactions dominate over solvent–solvent. The situation is analogous to that reported earlier for the tris(3-hydroxy-1,2-dimethylpyridin-4-ato)aluminum(III)–water–methanol system (25).

The success and potential value of these complexes in a pharmacological context is due in considerable measure to their solvation characteristics, which enable them to cross various biological barriers and membranes. Significant solubility both in water and in alcohols (e.g., Table 1) is important both in relation to significant solvation in aqueous and lipoid environments and in relation to distribution between these two types of environment. The synergic solvation reported for several systems in the present paper may prove advantageous in stabilizing the respective ligands or complexes at interfaces and thus positioning them favorably for trans-membrane transport, as mentioned in the Introduction. However, if the solute is particularly well stabilized at an interface, then it may be reluctant to move on. The ideal properties in the present context are probably a combination of appreciable and similar solubilities in water and in alcohols, and a small degree of synergic solvation in alcohol–water mixtures (26).

TODD L. ARSENAULT, DAVID B. MACLEAN, WEI ZOU, AND WALTER A. SZAREK. Can. J. Chem. **72**, 1376 (1994).

Hepta-*O*-acetyl-*O*-α-D-Rha*p*-(1→3)-*O*-α-D-Rha*p*-(1→2)-glycerol (**5**) was the major component derived by way of Smith degradation of A-band polysaccharide (a D-rhamnan isolated from a mutant, AK1401, of *Pseudomonas aeruginosa* strain PAO1). The structure has been verified by an unambiguous synthesis of **5**. Based on mass spectrometric evidence, hepta-*O*-acetyl-*O*-Rib*p*-(1→3)-*O*-α-D-Rha*p*-(1→2)-glycerol is considered to be one of the minor components. The Smith degradation of A-band polysaccharide and the synthesis of **5** are reported.

TODD L. ARSENAULT, DAVID B. MACLEAN, WEI ZOU ET WALTER A. SZAREK. Can. J. Chem. **72**, 1376 (1994).

L'hepta-*O*-acétyl-*O*-α-D-Rha*p*-(1→3)-*O*-α-D-Rha*p*-(1→2)-glycérol (**5**) est le produit majeur obtenu par une dégradation de Smith du polysaccharide de la bande A (un D-rhamnane isolé d'un mutant, le AK1401, de la lignée PAO1 de la *Pseudomonas aeruginosa*). On a vérifié la structure par un synthèse non ambiguë du composé **5**. Sur la base des données de la spectrométrie de masse, on considère que l'hepta-*O*-acétyl-*O*-Rib*p*-(1→3)-*O*-α-D-Rha*p*-(1→2)-glycérol est un des produits mineurs. On rapporte la dégradation de Smith du polysaccharide de la bande A ainsi que la synthèse du composé **5**.

[Traduit par la Rédaction]

Introduction

AK1401 is a mutant of *Pseudomonas aeruginosa* strain PAO1 (serotype O5) that does not express O-antigen, but does express A-band lipopolysaccharide (LPS) (1, 2). The polysaccharide portion of the A-band LPS (A-PS) from AK1401 was found (2) to consist mainly of D-rhamnose, with smaller amounts of 3-*O*-methylrhamnose, ribose, mannose, glucose, and a 3-*O*-methylhexose. ^{1}H NMR spectra of the intact A-PS indicated that the main structural feature was a repeating trisaccharide of α-D-rhamnose, namely [→2)-*O*-α-D-Rha*p*-(1→3)-*O*-α-D-Rha*p*-(1→3)-*O*-α-D-Rha*p*-(1→]$_n$ (see **1**, Scheme 1). Here we report a Smith degradation (3) of A-PS, which was undertaken to test the validity of the deductions, from NMR analysis, of the structural features. The degradation of A-PS was expected to follow the course outlined in Scheme 1. Thus the polymer **2**, resulting from periodate oxidation – sodium borohydride reduction, would afford, after hydrolysis, the disaccharide **3** and 1,2-propanediol (**4**). Compound **5** would be formed upon reduction of **3** followed by acetylation. Also, we report the synthesis of **5**.

Results and discussion

The A-PS was subjected to the degradation procedure outlined in Scheme 1 and the acetylated product was examined by TLC on silica ($CHCl_3$–MeOH, 19:1 v/v). The chromatogram showed a major component (oblong spot, $R_f = 0.5$) and at least two minor components (sharp spots, $R_f = 0.31$ and 0.26) contained within a streak from the origin to the top spot. The product mixture was resolved into two fractions by column chromatography, one containing the major component and the other containing both of the minor components. HPLC analysis was not helpful in resolving the mixture.

A GC examination of the fraction containing the major component isolated by column chromatography and of the whole

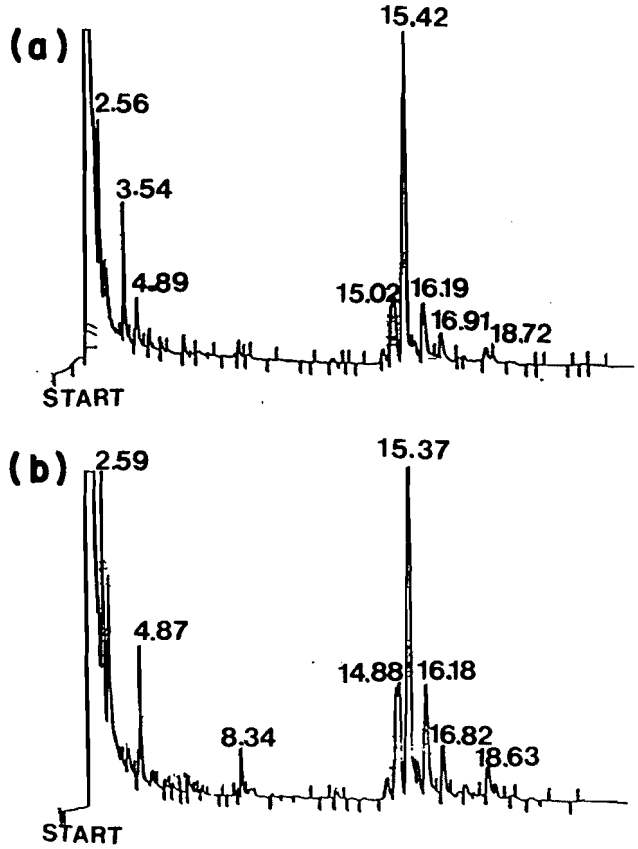

FIG. 1. Gas chromatography of oligosaccharide acetates resulting from Smith degradation of the AK1401 A-PS. (*a*) Total mixture. (*b*) Fraction isolated by column chromatography ($R_f = 0.5$ in TLC).

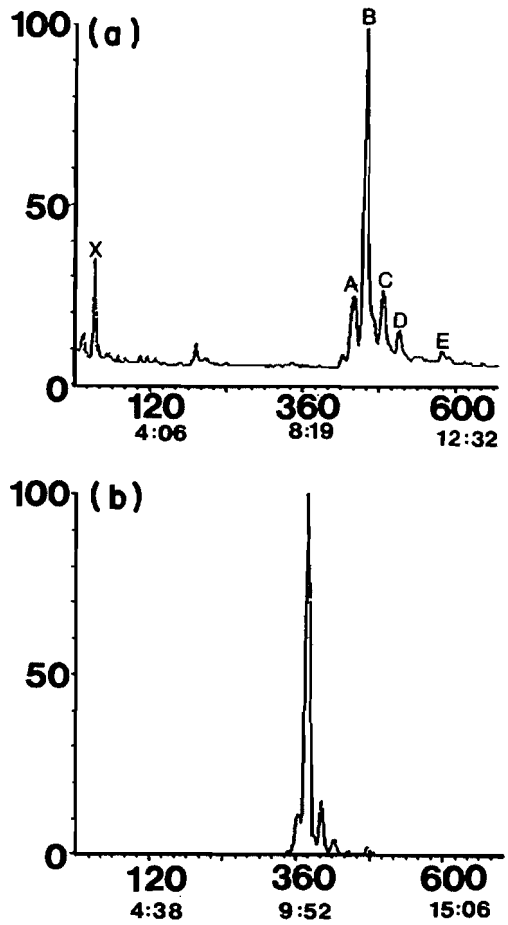

FIG. 2. Total ion-current chromatograms of oligosaccharide acetates from Smith-degraded AK1401 A-PS. (*a*) Electron impact. (*b*) Ammonia chemical ionization.

mixture gave the same chromatogram (Fig. 1), suggesting that the higher polarity components were involatile. (Mass spectrometric examination has shown that the involatile compounds are oligomers; their structures are under investigation.) Moreover, the chromatograms clearly show that the mixture was much more complex than TLC or column chromatography had indicated. GC–MS under EI conditions of the whole mixture gave the chromatogram shown in Fig. 2*a*; that obtained using GC–MS under NH_3-CI conditions is shown in Fig. 2*b*. In the latter case, the chromatographic resolution was not as good as it was in the EI experiment, because the column had to be overloaded to overcome the relative insensitivity of the CI experiment. The relative abundances of the volatile components of the mixture, namely X:A:B:C:D:E = 0.053:0.163:0.584:0.114:0.042:0.044, were derived from the integrated areas of the peaks in Fig. 1*b*.

Interpretation of the mass spectra of the components is not straightforward because literature spectra do not exist (based on a search of probable compositions in the Chemical Abstracts Formula index and the EPA/NIH mass spectral data base). However, the principal component seen in the GC (peak B in Fig. 2*a*) shows an intense ion at *m/z* 696 $(M + NH_4)^+$ in the NH_3-CIMS experiment, which corresponds in mass to the composition expected for the major degradation product derived from the rhamnan, namely *O*-α-D-Rha*p*-(1→3)-*O*-α-D-Rha*p*-(1→2)-Gly-ol$(OAc)_7$ (**5**) (see Scheme 1).

In the course of an investigation of a rhamnan isolated from *P. aeruginosa* IID 1008 (ATCC 27584), Yokota et al. (4) reported on its Smith degradation. They isolated a compound containing two D-rhamnose units and one glycerol, to which they assigned the structure of **5**; their structural assignment was based upon the structure of the rhamnan from which it was derived.

Interpretation of the spectrum of **5** was facilitated by the presence of a related compound of lower molecular weight (peak X, Fig. 2*a*). The NH_3-CI spectrum of peak X shows an ion at *m/z* 466 $(M + NH_4)^+$, suggesting that the formula weight is 448. The EI spectrum of peak X, shown in Fig. 3, is interpreted in Scheme 2. The structures assigned to the ions are based on analogous fragmentations proposed for monosaccharide peracetates (5). Therefore, peak X is attributed to *O*-α-D-Rha*p*-(1→2)-Gly-ol$(OAc)_5$ (**6**) (see Table 1), which can result from overhydrolysis of the Smith-degraded A-PS or be derived from the nonreducing terminus of the A-PS if the end sequence was *O*-α-D-Rha*p*-(1→3)-*O*-α-D-Rha*p*-(1→2)-*O*-α-D-Rha*p*-(1→. In this sequence the nonreducing, terminal unit would be oxidized and lost, the central unit would survive intact, and the third rhamnose unit would be converted into the glycerol portion.

The EI spectrum of peak B is shown in Fig. 4 and is interpreted in Scheme 3. The ion at *m/z* 273 is prominent in the case of this component, as are its daughter ions, thus indicating that rhamnose is the monosaccharide at the nonreducing terminus; the ion at *m/z* 159 is again indicative of the presence of the glycerol portion. The presence of an ion at *m/z* 503 shows that this compound contains a rhamnose–rhamnose disaccharide moiety coupled with the glycerol unit. The ion at *m/z* 259 is assigned by analogy to a corresponding fragment ion described by Peltier et

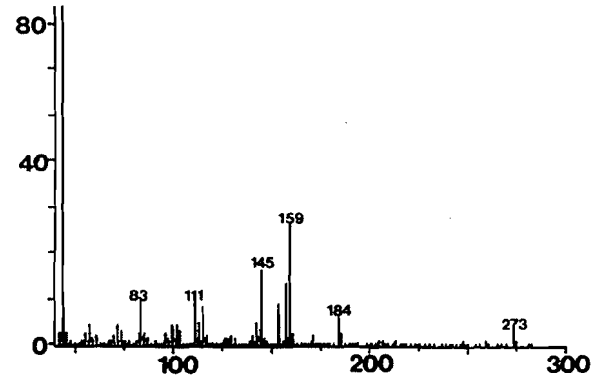

FIG. 3. EI mass spectrum of peak X (molecular weight = 448), i.e., *O*-α-D-Rha*p*-(1→2)-Gly-ol(OAc)$_5$.

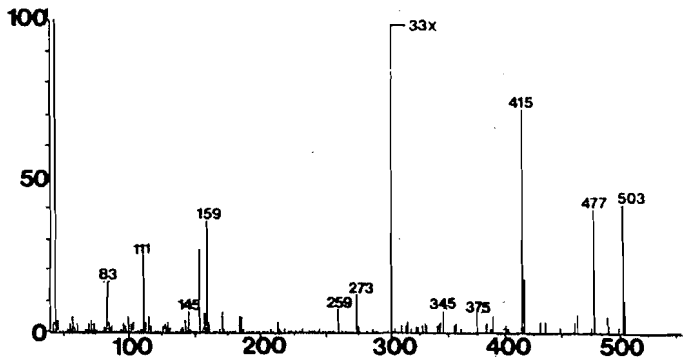

FIG. 4. EI mass spectrum of peak B (molecular weight = 678), i.e., *O*-α-D-Rha*p*-(1→3)-*O*-α-D-Rha*p*-(1→2)-Gly-ol(OAc)$_7$.

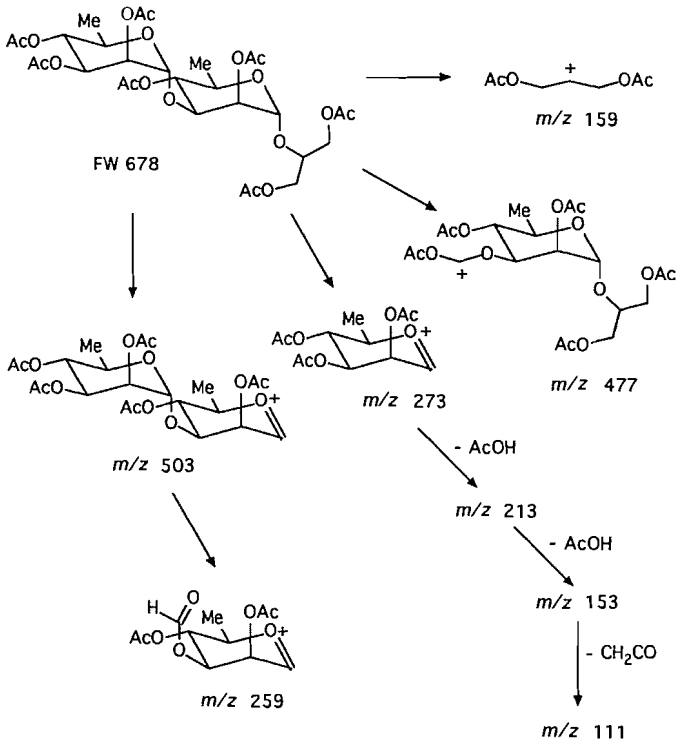

SCHEME 3

al. (6). The ion at *m/z* 477 is analogous to an ion in the spectrum of *N*-arylglycosylamine disaccharide peracetates (7), disaccharide peracetates (8, 9), and permethylated disaccharides (10, 11). The ion at *m/z* 415 could not be assigned with certainty. The ions at *m/z* 259 and 477 resulted from decomposition of the ring at the nonreducing terminus. The masses of the ions illustrated in Scheme 3 were measured by high-resolution mass spectrometry and agree with calculated values within ±0.005 Da.

Only the spectra of D and E of the remaining peaks of Fig. 2*a* were amenable to interpretation. The more straightforward was the spectrum of D (see Fig. 5), which has an ion at *m/z* 159 derived from a glycerol moiety and an intense ion at *m/z* 259, but none at *m/z* 273. These data suggest that the nonreducing terminal unit is not rhamnose and the ion at *m/z* 259 arises from a route different from, or additional to, that proposed for an ion of the same mass in the major component. A pentose in the nonreducing terminal position would be expected to form an ion at *m/z* 259; thus the terminal sugar in compound D may be ribose, a minor component of A-PS (2). Moreover, the disaccharide – oxonium ion is shifted from *m/z* 503 in the spectrum of B to *m/z* 489 in the spectrum of D. Also, the ion at *m/z* 415 in peak B is absent, but is replaced by an ion at *m/z* 401, a change that corresponds to replacement of a rhamnose unit by ribose and which indicates that the nonreducing terminal unit is a component of this ionic species. The mass of the disaccharide – oxonium ion (*m/z* 489) suggests that the other monosaccharide is rhamnose, an indication that is confirmed by the presence of ions at *m/z* 477 and 259. The former was observed in the spectrum of the major component and may be assigned the same structure in this spectrum; the latter ion signal is more intense than that in the spectrum of the major component and probably is derived from two ions, that shown in Scheme 3 and the oxonium ion

TABLE 1. Products of Smith degradation

Component	FW	Structure
X	448	 **6**
B	678	 **5**
D	664	 **7**
E	692	 **8**

arising from the ribose unit. The EI data suggest the composition of component D is Rib-Rha-Gly-ol$(OAc)_7$ (FW = 664), an assignment corroborated by the observation of the ion at *m/z* 682 $(M + 18)^+$ in the NH_3-CI spectrum.

A more specific structure can be assigned to component D if one considers the possibility of different ring sizes. If the ribose were present as the furanoside, one would expect fragmentation at C-4–C-5 of the molecular ion of the pentofuranoside to give *m/z* 591 $(M - CH_2OAc)^+$ and 73 $(CH_2OAc)^+$. Since neither of these fragments is present, component D probably contains a ribopyranose unit. From an analysis of possible linkages, a ribopyranoside would survive Smith degradation only if it were linked at C-3 or occupied a branching position in A-PS; similarly, the rhamnose residue in this component must be linked at C-3. Thus, the structure of component D can be defined as *O*-Rib*p*-(1→3)-*O*-α-D-Rha*p*-(1→2)-Gly-ol$(OAc)_7$ (**7**). Only the absolute configuration of the ribose unit and the stereochemistry of the ribose–rhamnose linkage are uncertain.[2] This proposed structure is consistent with the EI and CI mass spectra of this component; however, the structure could be verified only by an examination by GC and GC–MS of the corresponding synthetic standard.

Peak E, although the least abundant component of the mixture, is interesting; by NH_3-CI, its formula weight is 692 (14 amu more than for component B). The EI spectrum (Fig. 6) does not have an ion at *m/z* 159 (glycerol moiety) and contains ions indicative of a rhamnose–rhamnose disaccharide moiety (*m/z* 503, 415, 273, 259, 153, 111). Therefore, the aglycone would have the extra 14 amu; this deduction cannot beverified by the EI spectrum because the aglycone-containing ion (*m/z* 477 in component B) is absent (no *m/z* 477 nor 491).However, there is an abundant ion at *m/z* 87. An ion of this mass might be expected from a compound having the structure of **8**, a compound derived from that which might form intramolecularly in the course of the acid hydrolysis of **2**. A recent example of a similar intramolecular acetalation has been observed by Aspinall et al. (12).

Compound **5** has been synthesized by an unambiguous

[2]The D configuration for the ribose unit is shown arbitrarily in the structural formula given for **7**.

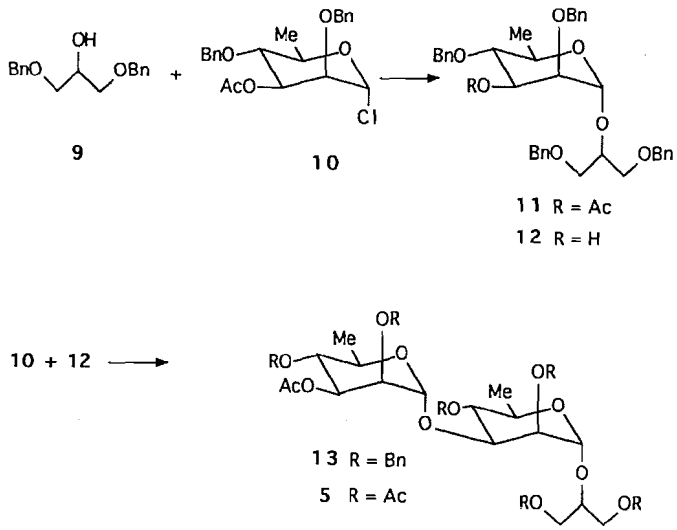

SCHEME 4

method (see below) and the properties of the synthetic and naturally derived materials have been compared. Their EI spectra are virtually identical and their GC retention times are identical. Thus, peak B of Fig. 2*a* may be attributed to the presence of compound **5** and one may conclude that the repeating unit of the rhamnan present in A-PS has the structure deduced from the NMR analysis (2). Unfortunately, the relationship of the minor sugars to the overall structure was not clarified in the present work.

*Synthesis of hepta-*O*-acetyl-*O*-α-D-Rha*p*-(1→3)-*O*-α-D-Rha*p*-(1→2)-glycerol (5)*

The synthesis of an authentic sample of compound **5** is shown in Scheme 4. The reaction of 1,3-di-*O*-benzylglycerol (**9**) (13) with 3-*O*-acetyl-2,4-di-*O*-benzyl-α-D-rhamnopyranosyl chloride (**10**) (14) was performed in the presence of silver triflate and powdered, 4 Å molecular sieves at −10°C to afford the rhamnopyranoside **11** in 50% yield. *O*-Deacetylation of **11** with 0.5% sodium methoxide in methanol at room temperature for 4 h gave *O*-(2′,4′-di-*O*-benzyl-α-D-rhamnopyranosyl)-(1′→2)-1,3-di-*O*-benzylglycerol (**12**), a glycosyl acceptor, that was in turn glycosylated with **10**, again by use of silver triflate and powdered, 4 Å molecular sieves, to give the disaccharide–glycerol conjugate **13**. *O*-Debenzylation of **13** by catalytic hydrogenolysis over 10% Pd–C in methanol, followed by treatment of the product with acetic anhydride–pyridine, afforded the title compound **5**.

Experimental

Methods and materials

Optical rotations were measured with a Perkin-Elmer model 241 polarimeter for solutions in a 0.1-dm cell at room temperature. NMR spectra were recorded on a Bruker AC-F200 spectrometer; $CDCl_3$ was the solvent and Me_4Si was used as the internal standard. Chemical shifts (δ) are given in ppm downfield from the signal of Me_4Si.

Gas chromatography was performed on a Hewlett-Packard 5890 instrument equipped with an on-column injector, a flame ionization detector, and an HP3990A integrator. The columns used were all wide-bore (0.32 mm inside diameter), bonded-phase (0.25 μm film thickness), fused-silica capillary columns (J&W Scientific). The carrier gas was helium, which was passed through an oxygen trap and a water trap (Chromatographic Specialities). Nitrogen at a pressure of 30 psig (1 psi = 6.895 kPa) was used as a makeup gas. GC–MS was performed on a VG MassLab TRIO-2 instrument using the same column and oven temperature. The helium pressure was 2 psig, the transfer line was maintained at 280°C, and the ion-source temperature was 200°C. The sample was analyzed by electron impact and chemical ionization (NH_3) in separate experiments.

The mixture of oligosaccharide acetates resulting from the Smith degradation of the AK1401 A-PS was analyzed by TLC on silica (developed in CH_2Cl_2–MeOH (19:1 v/v) and visualized by spraying with 1% orcinol in 50% sulfuric acid). Analytical HPLC was performed using a Supelco LC-Sil silica column, an eluting solvent of CH_2Cl_2–MeOH (99:1 v/v), and differential refractive-index detection. Preparative column chromatography was performed on a 20 × 2 cm diameter column packed with Merck Kieselgel 60 (230–400 mesh). Elution was performed initially with CH_2Cl_2–MeOH (99:1 v/v) and

then with CH_2Cl_2–MeOH (97:3 v/v). Fractions were monitored by TLC as described.

In the synthetic sequence TLC was performed using glass plates precoated with E. Merck Silica Gel 60 F-254. The developed plates were dried, sprayed with a solution of cerium(IV) sulfate (1%) and molybdic acid (1.5%) in 10% aqueous sulfuric acid, and heated at 150°C. Column chromatography was performed using E. Merck No. 9385-5 Silica Gel 60 (230–400 mesh).

The isolation of A-PS from *P. aeruginosa* has been described elsewhere (2).

Smith degradation

A solution of AK1401 A-PS (26 mg) in distilled water (25 mL) was cooled to 4°C and treated with sodium periodate (268 mg, 0.00125 mol). The mixture was kept in the dark at 4°C for 75 h, after which the excess of sodium periodate was destroyed with ethylene glycol. The resulting solution, at ambient temperature, was treated with sodium borohydride (40 mg, 0.001 mol) and stirred for 0.5 h. More sodium borohydride (40 mg) was then added and the mixture was stirred an additional 1.5 h. The reaction was quenched by the addition of 2 M HCl and the pH was adjusted to neutral with 5% sodium hydrogen carbonate. The sample was concentrated to ≈1 mL and transferred to dialysis bags (12 000 – 14 000 molecular weight cutoff). The bags were dialyzed against two 4-L portions of distilled water (first portion, 6 h; second portion, 10 h) and then their contents were freeze-dried to yield a white solid (21 mg).

The bulk of the polymer so obtained was hydrolyzed by dissolving it in aqueous HCl (10 mL, 0.5 M) and allowing the solution to stand at ambient temperature for 52 h with occasional shaking (these very mild conditions allow the selective hydrolysis of the glycosidic linkages of the oxidized residues). The reaction mixture was neutralized with 5% sodium hydrogen carbonate, sodium borohydride (50 mg) was added, and the mixture was stirred at ambient temperature for 18 h. The reaction was quenched by the addition of 5% acetic acid in methanol and the boric acid was removed by distillation. The residue was dried under vacuum (0.005 Torr, 1 Torr = 133.3 Pa) and treated with acetic anhydride (5 mL); the mixture was stirred in an oil bath at 115°C for 2 h. The reaction mixture was quenched by the addition of a saturated aqueous solution (20 mL) of sodium hydrogen carbonate and stirred for 1 h. The solution was extracted with $CHCl_3$ (3 × 20 mL), and the combined extracts were washed with a saturated aqueous solution of sodium hydrogen carbonate (2 × 50 mL) and then with water (2 × 25 mL). The extract was dried over anhydrous sodium sulfate, filtered, and evaporated to yield a yellow oil (20 mg).

*Synthesis of hepta-*O*-acetyl-*O*-α-D-Rha*p*-(1→3)-*O*-α-D-Rha*p*-(1→2)-glycerol (**5**)*

*1,3-Di-*O*-benzylglycerol (**9**)*

This compound was prepared by the method of Fairbourne et al. (13).

*3-*O*-Acetyl-2,4-di-*O*-benzyl-α-D-rhamnopyranosyl chloride (**10**)*

This compound was prepared in several steps from methyl α-D-mannopyranoside as described previously (14).

*O-(3′-*O*-Acetyl-2′,4′-di-*O*-benzyl-α-D-rhamnopyranosyl)-(1′→2)-1,3-di-*O*-benzylglycerol (**11**)*

To a solution of **9** (131 mg) and silver triflate (200 mg) in dichloromethane (3 mL) in the presence of powdered, 4 Å molecular sieves (200 mg) was added **10** (140 mg) in dichloromethane (2 mL) at −10°C under nitrogen. The mixture was stirred at that temperature for 1 h and then at room temperature for 12 h. The mixture was filtered, the filtrate was concentrated, and the residue was purified by chromatography on silica gel (hexane – ethyl acetate, 3:1 v/v) to give **11** as a syrup (111 mg, 50%). ^{13}C NMR (50.32 MHz, $CDCl_3$) δ: 18.00 (C-6′), 21.12 (*C*H_3CO), 67.85 (C-5′), 70.33, 70.82 (C-1, C-3), 73.67, 75.01, 76.56, 79.37 (C-2′, C-3′, C-4′, C-2), 72.89, 73.42, 74.80 (4 *C*H_2Ph), 97.44 (C-1′), 127.55, 127.65, 127.70, 127.74, 127.86, 128.06, 128.35, 128.40, 128.43, 128.52, 137.69, 138.23, 138.84 (4 Ph), 170.03 (C=O).

*O-(2′,4′-Di-*O*-benzyl-α-D-rhamnopyranosyl)-(1′→2)-1,3-di-*O*-benzylglycerol (**12**)*

Compound **11** (111 mg) was dissolved in a solution (4 mL) of 0.5% sodium methoxide in methanol, and the reaction mixture was kept at room temperature for 4 h when it was shown by TLC that the deacetylation was complete. The solution was passed through a column of Amberlite IR-120 (H^+ form) ion-exchange resin and the column was washed with methanol. Evaporation of the solvent gave **12** (100 mg, 96%). ^{13}C NMR (50.32 MHz, $CDCl_3$) δ: 18.00 (C-6′), 67.38 (C-5′), 70.26, 70.65 (C-1, C-3), 71.54, 74.73, 78.86, 82.45 (C-2′, C-3′, C-4′, C-2), 72.84, 73.49, 74.96 (4 *C*H_2Ph), 96.61 (C-1′), 127.61, 127.69, 127.96, 128.40, 128.53, 137.81, 137.92, 138.23, 138.56 (4 Ph); ^{1}H NMR (200 MHz, $CDCl_3$) δ: 1.24 (3H, d, $J_{5',6'}$ = 6.2 Hz, 6′-CH_3), 2.26 (1H, d, J = 9.2 Hz, 3-OH), 3.29 (1H, t, $J_{3',4'} = J_{4',5'}$ = 9.35 Hz, H-4′), 3.46–4.04 (8H, m, H-1(2), H-2, H-3(2), H-2′, H-3′, H-5′), 4.40–4.92 (8H, m, 4 *C*H_2Ph), 5.11 (1H, d, $J_{1',2'}$ = 1.35 Hz, H-1′), 7.23–7.45 (20H, m, 4 Ph).

*O-(3″-*O*-Acetyl-2″,4″-di-*O*-benzyl-α-D-rhamnopyranosyl)-(1″→3′)-*O*-(2′,4′-di-*O*-benzyl-α-D-rhamnopyranosyl)-(1′→2)-1,3-di-*O*-benzylglycerol (**13**)*

To a solution of **12** (100 mg) and silver triflate (120 mg) in dichloromethane (3 mL) in the presence of powdered, 4 Å molecular sieves (200 mg) was added **10** (150 mg) in dichloromethane (2 mL) at −10°C under nitrogen. The mixture was stirred at that temperature for 1 h and then at room temperature overnight. The mixture was filtered, the filtrate was concentrated, and the residue was subjected to chromatography on silica gel (hexane – ethyl acetate, 3:1 v/v) to give **13** (ca. 100 mg). ^{13}C NMR (50.32 MHz, $CDCl_3$) δ: 17.97, 18.19 (C-6″, C-6′), 21.13 (*C*H_3CO), 67.88, 68.35 (C-5″, C-5′), 70.40, 70.59 (C-1, C-3), 72.73, 72.93, 73.42, 74.72 (6 *C*H_2Ph), 73.69, 76.55, 77.19, 78.29, 78.41, 79.21, 80.94 (C-2″, C-3″, C-4″, C-2′, C-3′, C-4′, C-2), 97.32, 98.65 (C-1″, C-1′), 127.10, 127.53, 127.59, 127.65, 127.70, 127.90, 128.31, 128.39, 128.45, 128.60, 138.17, 138.88 (6 Ph), 170.16 (C=O).

*O-(2″,3″,4″-Tri-*O*-acetyl-α-D-rhamnopyranosyl)-(1″→3′)-O-(2′,4′-di-*O*-acetyl-α-D-rhamnopyranosyl)-(1′→2)-1,3-di-*O*-acetylglycerol (**5**) (hepta-*O*-acetyl-*O*-α-D-Rha*p*-(1→3)-*O*-α-D-Rha*p*-(1→2)-glycerol)*

To a solution of **13** (100 mg) in methanol (3 mL) was added 10% Pd–C (ca. 100 mg). The mixture was subjected to a hydrogen pressure (50 psig) at room temperature for 10 h and then filtered to remove the catalyst. The filtrate was concentrated to a residue which was treated with acetic anhydride – pyridine (2 mL, 1:1 v/v) at room temperature for 2 h. Toluene was added and the solution was evaporated. Chromatography of the residue on silica gel (ethyl acetate – hexane, 2:1 v/v) gave compound **5** (55 mg) as an amorphous, low-melting solid. $[\alpha]_D$ 36 (*c* 1.2, MeOH); ^{13}C NMR (50.32 MHz, $CDCl_3$) δ: 17.22, 17.31 (C-6″, C-6′), 20.59, 20.66, 20.89 (7 *C*H_3CO), 63.02, 63.54 (C-1, C-3), 67.08, 67.20 (C-5″, C-5′), 68.50, 70.13, 70.73, 76.16, 72.07, 73.46, 74.89 (C-2″, C-3″, C-4″, C-2′, C-3′, C-4′, C-2), 97.03, 98.73 (C-1″, C-1′), 169.57, 170.01, 170.26 (7 C=O); ^{1}H NMR (200 MHz, $CDCl_3$) δ: 1.17 (3H, d, $J_{5'',6''}$ = 6.3 Hz, 6″-CH_3), 1.19 (3H, d, $J_{5',6'}$ = 6.3 Hz, 6′-CH_3), 1.96–2.19 (21H, 7s's, 7 CH_3CO), 3.87 (1H, dq, $J_{5'',6''}$ = 6.3 Hz, $J_{4'',5''}$ = 9.4 Hz, H-5″), 3.91 (1H, dq, $J_{5',6'}$ = 6.3 Hz, $J_{4',5'}$ = 9.4 Hz, H-5′), 4.02–4.20 (6H, m, H-3′, H-1(2), H-2, H-3(2)), 4.89 (1H, d, $J_{1'',2''}$ = 1.60 Hz, H-1″), 4.93 (1H, d, $J_{1',2'}$ = 1.65 Hz, H-1′), 5.04–5.19 (5H, m, H-4″, H-3″, H-2″, H-4′, H-2′).

Received April 15, 1993

ARYA K. MUKERJEE, LAXMI RAO, SEYED SAIED HOMAMI, and KIRAN JOSEPH. Can. J. Chem. **72**, 1383 (1994).

Unsaturated azlactones undergo thiolysis with toluene-α-thiol, but 2-substituted (*Z*)-4-*o*-acetoxybenzylidene-4,5-dihydrooxazol-5-ones form 3-acylaminocoumarins in the presence of triethylamine. Sodium sulfide in ethanol brings about ethanolysis of the 1,5 bond and deacetylation of an acetoxy group. (*Z*)-4-Benzylidene-4,5-dihydrooxazol-5-one reacts with potassium thiocyanate to give (*E*)-4(5)-benzylidene-2-thiohydantoin.

ARYA K. MUKERJEE, LAXMI RAO, SEYED SAIED HOMAMI et KIRAN JOSEPH. Can. J. Chem. **72**, 1383 (1994).

Sous l'influence du toluène-α-thiol, les azlactones insaturées subissent une thiolyse; toutefois, les (*Z*)-4-*o*-acétoxybenzylidène-4,5-dihydrooxazol-5-ones substituées en position 2, mises en présences de triéthylamine, conduisent à des 3-acylaminocoumarines. Le sulfite de sodium dans l'éthanol provoque une éthanolyse de la liaison 1,5 et une désacylation du groupe acétoxyle. La (*Z*)-4-benzylidène-4,5-dihydrooxazol-5-one réagit avec le thiocyanate de potassium pour conduire à la (*E*)-4(5)-benzylidène-2-thiohydantoïne.

The reaction of thiols with unsaturated azlactones, for example, **1***a*, *d* (1, and, for the synthesis of penicillamine, ref. 2) and α,β-unsaturated acid derivatives (3), was reported to form adducts, but these additions do not seem to have been properly investigated. Compounds **1***a–g* can behave as bielectrophiles, undergoing cleavage of the 1,5 bond and (or) involvement of the olefinic centre. To probe regioselectivity of the reaction and stereochemistry of the products, the present work using sulfur nucleophiles was undertaken (see ref. 4 for a preliminary communication, and ref. 5).

The required substrates **1***a*, *c*, *d*, *e* were prepared by known methods (for a recent review on azlactones, see ref. 6). The condensation of hippuric acid with triethyl orthoformate and benzaldehyde by the Erlenmeyer procedure (1, 7) afforded 4-ethoxymethlene- and 4-benzylidene-2-phenyl-4,5-dihydrooxazol-5-ones (**1***a*) and (**1***d*), respectively, the (*Z*) isomer being the major product (6). The similar acetic anhydride-mediated condensation of hippuric acid with salicylaldehyde produced (8) 3-benzoylaminocoumarin (**2***a*) and (*Z*)-4-*o*-acetoxybenzylidene-2-phenyl-4,5-dihydrooxazol-5-one (**1***e*). The separation was not only tedious but gave low yields of contaminated compounds. Pure **1***e* was therefore prepared by the acetic anhydride-mediated cyclodehydration of (*Z*)-2-benzoylamino-*o*-hydroxycinnamic acid **4***a*. The condensation of aniline with **1***a* furnished 4-anilinomethylene-2- phenyl-4,5-dihydrooxazol-5-one (**1***c*) (1).

Toluene-α-thiol reacted with **1***a* in pyridine or benzene containing triethylamine to give a mixture from which *S*-benzylthio 2-benzoylamino-3-(*S*-benzylthio)-acrylate (**6**) was separated in pure form by preparative tlc (Scheme 1). The conversion of **1***a* to **6** could proceed by initial thiolysis of the 1,5 bond, followed by conjugate addition of toluene-α-thiol and subsequent elimination of ethanol. Alternatively, it could involve substitution of the ethoxy group by the thiol moiety to form **1***b*, which in turn would undergo thiolysis, affording **6**. The latter pathway would be favored because of the following reasons. Compound **1***a* reacted with aniline to give only the 4-anilinomethylene derivative **1***c*, the 1,5 bond remaining unaffected. This indicated the greater vulnerability of the 4-ethoxymethylene group towards nucleophiles. The ir absorption band near 1790 cm^{-1}, characteristic of the azlactone carbonyl, and the absence of signals due to the ethoxy group in the ^1H nmr spectrum of the crude mixture clearly indicated the presence of **1***b*. Also, two doublets due to the CH-CH group in the ^1H nmr spectrum of the crude mixture could be assigned to structure **7**. As already mentioned, only compound **6** could be separated in pure form. It is noteworthy that the condensation of toluene-α-thiol with **1***c* in boiling eth-

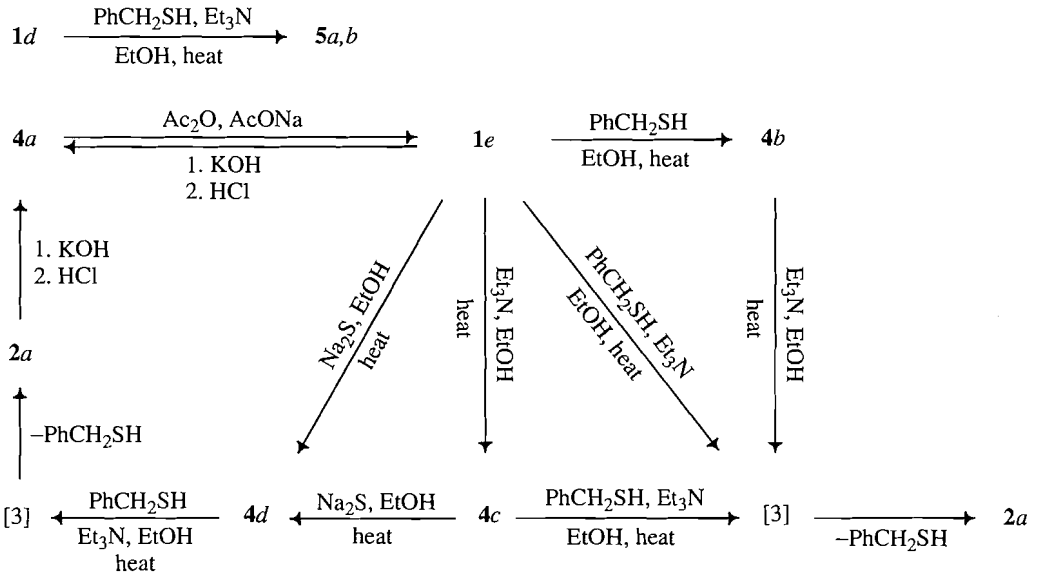

SCHEME 2

anol containing triethylamine led to the formation of *S*-benzylthio 2-benzoylamino-3-anilinoacrylate (**10**), which was also obtained by the triethylamine-mediated reaction of toluene-α-thiol with **1***a* in the presence of aniline. Unlike the ethoxy group of **1***a*, the 4-anilino moiety of **1***c* remained unaffected in this reaction. Dethionation of **10** led to the formation of **1***c*, which lent support to the proposed structure. It should be emphasized that the similar reaction of the alternative isomeric structure **9** would not form **1***c*.

Triethylamine-mediated reaction of toluene-α-thiol with **1***d* in boiling ethanol afforded a sulfur-free product that has been characterized as an (*E*)–(*Z*) mixture of ethyl 2-benzoylaminocinnamate (**5***a*, *b*). The same mixture **5***a*, *b* was also obtained when pure ethyl (*Z*)-2-benzoylaminocinnamate (**5***a*), known in the literature (9), was subjected to the described reaction conditions. These isomers, characterized on the basis of ^{1}H nmr data, could not be separated. The conversion of **1***d* to **5***a*, *b* would be possible by addition of thiol to the double bond of **5***a*, generated in situ, followed by β-elimination.

To probe the mechanism, the reaction of **1***e* with toluene-α-thiol was carried out under different reaction conditions. When the reactants were heated in ethanol alone, a sulfur-containing product was isolated that has been characterized as *S*-benzylthio (*Z*)-2-benzoylamino-*o*-acetoxycinnamate (**4***b*); it recyclized to **1***e* on passage through a silica gel column, but it was stable in neutral solutions. The use of triethylamine in this reaction furnished 3-benzoylaminocoumarin (**2***a*) in good yields. It is noteworthy that **1***e* underwent ethanolysis of the 1,5 bond, when heated in ethanol containing triethylamine, to give (*Z*)-2-benzoylamino-*o*-acetoxycinnamate (**4***c*), which afforded the coumarin **2***a* on reaction with toluene-α-thiol in ethanol in the presence of triethylamine. On the other hand, the thiolester **4***b* furnished **2***a* on heating in ethanol containing triethylamine.

The reaction of **1***e* with sodium sulfide gave ethyl (*Z*)-2-benzoylamino-*o*-hydroxycinnamate (**4***d*). Similarly, the acetyl derivative **4***c* when heated with sodium sulfide in ethanol gave **4***d*, which in the presence of triethylamine underwent thiol-aided cyclization to the coumarin **2***a* (Scheme 2).

These results indicate that the conversion of **1***e* into **2***a* involves, first, thiolysis of the 1,5 bond to give the thiolester **4***b*, which upon transesterification with ethanol under the basic conditions liberates the thiol moiety, which, in turn, leads to

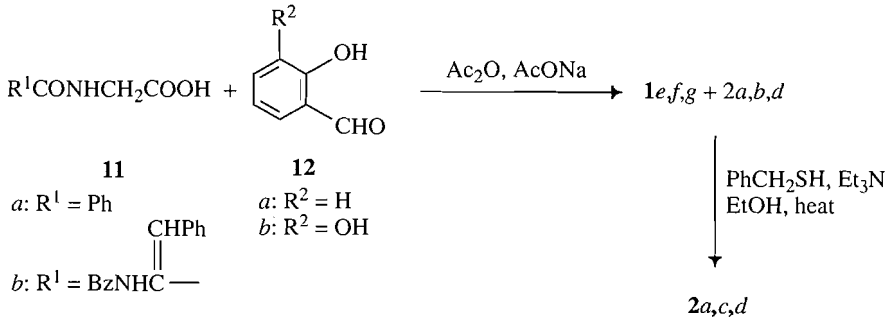
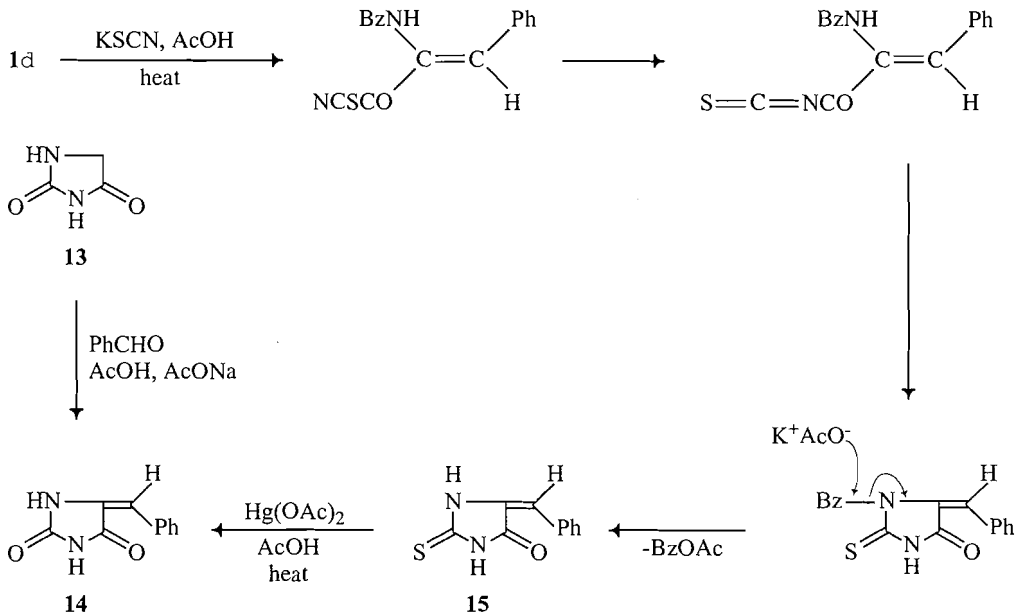


SCHEME 3



SCHEME 4

deacetylation of **4***c*. *S*-Benzylthio acetate, generated in the medium, subsequently undergoes ethanolysis to liberate the free thiol, which, once again, reacts with the ethyl ester **4***d*, acting as a Michael acceptor, to give 3-benzoylamino-4-benzylthio-3,4-dihydrocoumarin (**3**); this then undergoes β-elimination to afford **2***a*.

In the light of the observation that the thiol–triethylamine combination brings about a useful isomerization, the mixture of **1***e*, *f*, *g* and **2***a*, *b*, *d*, obtained by the Erlenmeyer procedure was subjected, without separation, to the reaction conditions described to give 3-acylaminocoumarins **2***a*, *c*, *d* exclusively (Scheme 3). It would be mentioned that **2***d* was isolated in somewhat lower yields, as it underwent partial deacylation.

Compounds **1***a*, *c*, *e* when heated with potassium thiocyanate failed to give any tangible results, but **1***d* furnished (*E*)-4(5)-benzylidene-2-thiohydantoin (**15**) on prolonged heating with potassium thiocyanate in glacial acetic acid (Scheme 4). The stereochemistry of **15** was assigned on the basis of its ^{1}H nmr spectrum in which the olefinic proton was shielded. Dethionation of **15** with mercury(II) acetate in boiling glacial acetic acid afforded (*E*)-4(5)-benzylidenehydantoin (**14**), which was characterized by comparison with an authentic sample and with its (*Z*) isomer, already known in the literature (9).

The role of sulfur nucleophiles in the isomerization process is quite apparent. Some of the present reactions resemble ordered biochemical transformations and are potentially important. In view of the speed and simple work-up, the reported findings may have synthetic utility.

The products reported were characterized on the basis of spectral data, elemental analyses, and (or) by comparison with authentic samples.

Experimental

Melting points were determined on a Toshniwal melting point apparatus and are uncorrected. The ir and ^{1}H nmr spectra using TMS as an internal reference were recorded on Perkin–Elmer 720 or 783 and Jeol FX-90Q spectrometers, respectively. The mass spectra were recorded on a VG micromass 70-70H and (or) Finnigan-Mat 1020 instrument, using the direct inlet system at 70 eV.

Compound ***1****e*

An equimolar mixture of the cinnamic acid derivative **4***a* (10) and freshly fused sodium acetate, in acetic anhydride (5.0 mol), was heated over a steam bath for 20 min, cooled, and poured into crushed ice to give a solid that was collected, washed with distilled water, and recrystallized from ethanol–benzene to afford yellow crystals; yield, 79%; mp 160°C (lit. (11) mp 162°C); ν_{max} (Nujol): 1790, 1770, 1640 cm^{-1}; δ ($CDCl_3$): 2.35 (s, 3H, $COCH_3$), 6.97–8.97 (m, 10H, =CH and ArH) ppm.

Compound **2**a

Method A

A mixture of **1***e*, toluene-α-thiol, and triethylamine, in the molar

Can. J. Chem. Downloaded from www.nrcresearchpress.com by EESC ESCOLA DE ENGENHARIA on 09/08/12

ratio of 1:1:2, was heated under reflux in ethanol (30 mL g^{-1} of **1***e*) for 2 h. The mixture was concentrated to dryness under reduced pressure, triturated with ethanol, filtered under suction, and the crude product recrystallized from ethanol–benzene to give colourless crystals; yield, 69%; mp 175°C (lit. (8) mp 173°C).

Method B

A mixture of the ethyl ester **4***c* or **4***d*, toluene-α-thiol, and triethylamine, in the molar ratio of 1:1:2, was heated under reflux in ethanol (30 mL g^{-1} of **4***c*) for 2–5 h and worked up as before; yield, 48%.

The similar heating of a mixture of the thiol ester **4***b* and triethylamine, in the molar ratio of 1:2, in ethanol (30 mL g^{-1} of **4***b*) for 2 h, followed by the usual work-up, afforded **2***a* in 79% yield; mp 175°C (lit. (8) mp 173°C); ν_{max} (Nujol): 3360, 1710, 1665, 1625 cm^{-1}; δ ($CDCl_3$): 7.39–8.13 (m, 9H, ArH), 9.04 (s, 2H, one exchangeable with D_2O, 4-CH and NH) ppm.

*3-Acylaminocoumarins (***2**a, c, d*); general procedure*

An equimolar mixture of 3-acylglycine (**11***a*), salicylaldehyde and freshly fused sodium acetate, and acetic anhydride (2.5 mol) in glacial acetic acid (10 mL g^{-1} of **11***a*) was heated over a steam bath for 3 h. On using **11***b*, the mixture was stirred for 8 h at room temperature. The mixture was poured into cold water to give yellowish crystals, which were filtered, washed, dried, and subjected to the reaction conditions described above under compound **2***a*. For the physical constants of **2***a*, see above.

Compound **2**c

Yield, 90%; mp 221°C (lit. (12) mp 224°C). ν_{max} (Nujol): 3350, 3260, 1710, 1650, 1620 cm^{-1}; δ (DMSO-d_6): 7.05–8.0 (m, 8H, ArH), 8.56 (s, 1H, 4-CH), 9.64 (s, 1H, exchangeable with D_2O, NH), 10.25 (s, 1H, exchangeable with D_2O, OH) ppm. Anal. calcd. for $C_{16}H_{11}NO_4 \cdot \frac{1}{2}H_2O$: C 66.20, H 4.14, N 4.82%; found: C 66.09, H 4.32, N 4.64%.

Compound **2**d

Yield, 40%; mp 207°C. ν_{max} (KBr): 3400, 3200, 1710, 1680, 1645 cm^{-1}; δ ($CDCl_3$): 7.17–7.92 (m, 16H, one exchangeable with D_2O, =CH, ArH, and NH), 8.70 (s, 1H, 4-CH), 8.79 (brs, 1H, exchangeable with D_2O, NH), ppm; M^+: 410; Anal. calcd. for $C_{25}H_{18}N_2O_4 \cdot \frac{1}{3}H_2O$: C 72.11, H 4.48, N 6.82%; found: C 71.95, H 4.30, N 6.54%.

Compound **4**b

A mixture of **1***e* and toluene-α-thiol, in the molar ratio of 1:2, was heated under reflux in ethanol (50 mL g^{-1} of **1***e*) for 22 h. The solvent was removed under reduced pressure, and the residue triturated with cold ethanol to give a colorless undefined solid that was collected and recrystallized from benzene; yield, 69%; mp 155°C. ν_{max} (Nujol): 3200, 1770, 1660, 1620 cm^{-1}; δ ($CDCl_3$): 2.35 (s, 3H, CH_3CO), 4.35 (s, 2H, PhCH_2S), 7.22 (d, 1H, J = 4.0 Hz, ArH), 7.30 (s, 1H, =CH), 7.39–8.04 (m, 14H, one exchangeable with D_2O, ArH and NH) ppm; *m/z* (%): 308(4) (M^+ − $PhCH_2S$), 307 (6) (M^+ − $PhCH_2SH$). Anal. calcd. for $C_{25}H_{21}NO_4S$: C 69.60, H 4.87, N 3.24%; found: C 69.96, H 4.81, N 3.23%.

Compound **4**c

An equimolar mixture of **1***e* and triethylamine was heated under reflux in ethanol (50 mL g^{-1} of **1***e*) for 1.5 h and worked up as before. The crude product was recrystallized from ethanol to give a colorless undefined solid; yield, 98%; mp 165°C. ν_{max} (Nujol): 3240, 1760, 1715, 1660, 1645 cm^{-1}; δ ($CDCl_3$): 1.26 (t, 3H, J = 7.0 Hz, CH_3CH_2), 2.13 (s, 3H, CH_3CO), 4.33 (q, 2H, J = 7.0 Hz, CH_3CH_2), 7.19 (s, 1H, =CH), 7.39–8.39 (m, 10H, one exchangeable with D_2O, ArH and NH) ppm; Anal. calcd. for $C_{20}H_{19}NO_5 \cdot \frac{1}{3}H_2O$: C 66.85, H 5.47, N 3.89%; found: C 66.98, H 5.47, N 4.07%.

Compound **4**d

An equimolar mixture of **1***e* or **4***c* and sodium sulfide was heated under reflux in ethanol (50 mL g^{-1} of **1***e*) for 2 h. The solvent was removed under reduced pressure to give a pasty mass, which was washed with cold benzene. The residue was treated with water and left at room temperature for 24 h in an open container. A solid separated out that was filtered and recrystallized from benzene; yield, 40%; mp 169°C. ν_{max} (KBr): 3400, 3240, 1730, 1690, 1645, 1635 cm^{-1}; δ ($CDCl_3$): 1.35 (t, 3H, J = 7.0 Hz, CH_3CH_2), 4.37 (q, 2H, J = 7.0 Hz, CH_3CH_2), 6.83–8.0 (m, 11H, one exchangeable with D_2O, =CH, ArH, and OH), 8.88 (s, 1H, exchangeable with D_2O, NH) ppm; M^+: 311.

It was characterized as its *O*-acetyl derivative **4***c*. Thus, acetylation of **4***d* with acetic anhydride and fused sodium acetate afforded **4***c* in quantitative yields. For the physical constants of **4***c*, see above.

Compound **6**

An equimolar mixture of **1***a* and toluene-α-thiol was heated under reflux in benzene containing triethylamine (2 mol mol^{-1} of **1***a*) for 3 h. It was concentrated to dryness under reduced pressure, treated with hexane, filtered, and washed with aqueous ethanol. The crude product was subjected to tlc (silica gel/benzene), when pure **6** was obtained. The same colorless product was also obtained on storing a mixture of **1***a* and toluene-α-thiol in dry pyridine for 24 h at room temperature, followed by work-up as before; yield, 27%; mp 152–154°C. ν_{max} (Nujol): 3220, 1640 cm^{-1}; δ ($CDCl_3$): 4.09 (s, 2H, PhCH_2S), 4.19 (s, 2H, PhCH_2S), 7.07–8.0 (m, 17H, one exchangeable with D_2O, =CH, ArH, and NH) ppm; *m/z* (%): 419 (1) (M^+), 328 (3) (M^+ − $PhCH_2$), 296 (23) (M^+ − $PhCH_2S$), 295 (10) (M^+ − $PhCH_2SH$). Anal. calcd. for $C_{24}H_{21}NO_2S_2 \cdot \frac{1}{3}H_2O$: C 67.76, H 5.09, N 3.29, S 15.05%; found: C 67.93, H 5.13, N 3.36, S 14.86%.

Compound ***10***

A mixture of **1***c*, toluene-α-thiol, and triethylamine, in the molar ratio of 1:1.1:1.2, was heated under reflux in ethanol (75 mL g^{-1} of **1***c*) for 30 min. It was concentrated and the curdy white solid was filtered. The crude product was recrystallized from ethanol or benzene. Compound **10** was also obtained when a mixture of **1***a*, aniline, and toluene-α-thiol was heated under reflux in triethylamine-containing ethanol and worked up as before; yield, 98%; mp 222–224°C. ν_{max} (Nujol): 3340, 3250, 1670, 1640 cm^{-1}; δ (DMSO-d_6): 4.07 (s, 2H, CH_2), 6.97–8.04 (m, 16H, =CH and ArH), 9.30 (d, 1H, J = 12.8 Hz, exchangeable with D_2O, =CH-N*H*), 9.38 (s, 1H, exchangeable with D_2O, CONH) ppm; *m/z* (%): 388 (19) (M^+), 310 (25) (M^+ − C_6H_6), 265 (9) (M^+ − $PhCH_2S$), 264 (100) (M^+ − $PhCH_2SH$). Anal. calcd. for $C_{23}H_{20}N_2O_2S$: C 71.13, H 5.15, N 7.21%; found: C 71.28, H 5.40, N 6.97%.

Compound ***15***

An equimolar mixture of **1***d* and potassium thiocyanate was heated under reflux in glacial acetic acid (12 mL g^{-1} of **1***d*) for 10 h. It was concentrated to dryness over a steam bath, washed with water, and dried. The pasty residue was triturated with benzene and filtered. The benzene-insoluble material was recrystallized from ethanol to give yellow crystals of **15**. This compound was identical to the product obtained by a known method; yield, 51%; mp 257–258°C (lit. (13*a*)[2] mp 257–258°C); ν_{max} (Nujol): 3220, 1720, 1640 cm^{-1}; δ[H_2] (Me_2CO): 6.44 (s, 1H, =CH), 7.20–7.60 (m, 6H, one exchangeable with D_2O, ArH and NH), 10.65 (s, 1H, exchangeable with D_2O, NH) ppm.

Dethionation (14) of ***10*** *and* ***15****; formation of* **1**c and ***14***

A mixture of **10/15** and mercury(II) acetate, in the molar ratio of 1:1.2, in glacial acetic acid (50 mL g^{-1} of **10**), was heated under reflux for 3 h. A blackish precipitate separated that was filtered off and the filtrate concentrated to dryness over a steam bath. The residue was treated with water, filtered, and recrystallized from ethanol to give yellow crystals of **1***c*/**14**.

Compound **1**c

Yield, 77%; mp 155–156°C (lit. (1) mp 156–157°C); ν_{max} (Nujol):

[2]This compound was reported to be formed on using ammonium thiocyanate, carrying out the condensation for several hours in a sealed tube. The stereochemistry, however, was not discussed. See: ref. 13*b*.

3270, 3210, 1780, 1740, 1720, 1660, 1630 cm^{-1}; δ ($CDCl_3$): 7.17–8.17 (m, 11H, =CH and ArH), 9.46 (d, 1H, J = 12.0 Hz, exchangeable with D_2O, =CHN*H*) ppm.

Compound ***14***

Yield, 42%; mp 219–222°C (lit. (15) mp 220°C); ν_{max} (Nujol): 3200, 3150, 1760, 1720, 1645 cm^{-1}; δ[H_2] (Me_2CO): 6.39 (s, 1H, =CH), 7.16–7.51 (m, 6H, one exchangeable with D_2O, NH and ArH), 9.48 (brs, 1H, exchangeable with D_2O, NH) ppm.

The search for efficacious drug molecules involves, amongst other considerations, identifying compounds that will have activity in the receptor microenvironment through some highly specific microscopic pathway that is governed by molecular interactions. Widespread in the search for compounds with biological activity is the use of quantum pharmacologic structure-activity calculations. In this study, we identify the topological features of *ab initio* charge densities for a series of carboxylated pyridines. As well, results from conformational and geometric analysis obtained with semi-empirical AM1 and *ab initio* level geometries are compared. Carboxylated pyridines such as quinolinic and dipicolinic acids, both known to be neuroactive compounds, are logical candidates for a systematic study investigating the suitability of relating topological properties calculated in this manner to biological activity. Future reports will detail the correlation of these properties to biological activity.

KENNETH E. EDGECOMBE, DONALD F. WEAVER et VEDENE H. SMITH, JR. Can. J. Chem. **72**, 1388 (1994).

La recherche de molécules efficaces comme drogues implique, entre autres considérations, l'identification de composés qui auront une activité dans le microenvironement du récepteur par le biais de voies microscopiques hautement spécifiques dirigées par des interactions moléculaires. Dans cette recherche de composés possédant une activité biologique, on fait grand usage de calculs quantiques de l'activité pharmacologique en fonction de la structure. Dans le présent travail, on a identifié les caractéristiques topologiques des densités de charge *ab initio* d'une série de d'acides pyridinecarboxyliques. De plus, on compare les résultats d'analyses conformationnelles et géométriques obtenues avec des géométries de niveau semi-empirique AM1 et *ab initio*. Les acides pyridinecarboxyliques comme les acides quinolinique et dipicolinique, qui sont tous les deux reconnus comme des composés neuroactifs, sont des candidats logiques pour une étude systématique visant à déterminer la possibilité d'établir une corrélation entre les propriétés topologiques calculées de cette manière et l'activité biologique. Des travaux ultérieurs donneront les détails de la corrélation entre ces propriétés et l'activité biologique.

[Traduit par la Rédaction]

1. Introduction

Drug discovery has traditionally relied on the time-honored methods of serendipity and massive screening programs which are inefficient, both in time and economics. Clearly, there is a need for rational drug design in which fundamental insights concerning the molecular properties of the disease are exploited to permit the intelligent design of new drugs. Recent advances in quantum chemistry are permitting computer-assisted rational drug design to emerge as a forceful new drug design strategy. In the past decade, advances in computer technology and the development of efficient computational packages have allowed quantum pharmacology to enjoy a leap forward not only in the size of the pharmacological problem to be investigated but also in the range of theoretical models and methods to be used.

Quantum pharmacology has been (and continues to be) dominated by empirical force field (molecular mechanics) calculations. Such calculations emphasize the importance of conformational, geometric, and other steric considerations in directing the drug-receptor interaction while inadequately treating electronic properties. However, as Birley et al. (1) have observed: "...the electron distribution in the ring is of importance for activity and the three-dimensional structure is not the only criterion." This statement emphasizes that the electron density is likewise of fundamental importance when modeling the interaction of a drug with its receptor. Molecular mechanics, employing a simple Coulomb potential within the force field energy function, fails to treat electrons explicitly and fails to provide an adequate evaluation of subtle electronic effects key to drug reactivity. The need for an improved theoretical treatment of electronic effects in bioactive molecules is thus a quantum pharmacologic priority. In this study we examine the topological properties of the electron density and its associated fields ($\nabla\rho$, the gradient, and $\nabla^2\rho$, the Laplacian) in a series of neuroactive molecules. Examining the electron density in this manner reveals elements of molecular structure within the theory of molecular structure proposed by Bader et al. (2).

This approach uses the topological properties of the charge density to define atoms in molecules. By using zero-flux surfaces which satisfy the condition

$$\nabla\rho(\boldsymbol{r})\cdot\boldsymbol{n} = 0$$

for every point on the surface of the subsystem, where $\boldsymbol{n}$ is a unit vector normal to the surface, a molecule may be partitioned into atoms. Points on these surfaces where $\nabla\rho(\boldsymbol{r}) = 0$ are critical points. Should a critical point fall on the path between bonded atoms along which the electron density is a maximum with respect to lateral displacement, it is known as a bond critical point. As well, critical points in the density may be characterized by the eigenvalues of the second derivatives of the electron density (the Hessian) at the critical point with its rank equal to the number of nonzero eigenvalues and its signature equal to the sum of the signs of the eigenvalues. There are four possible sig-

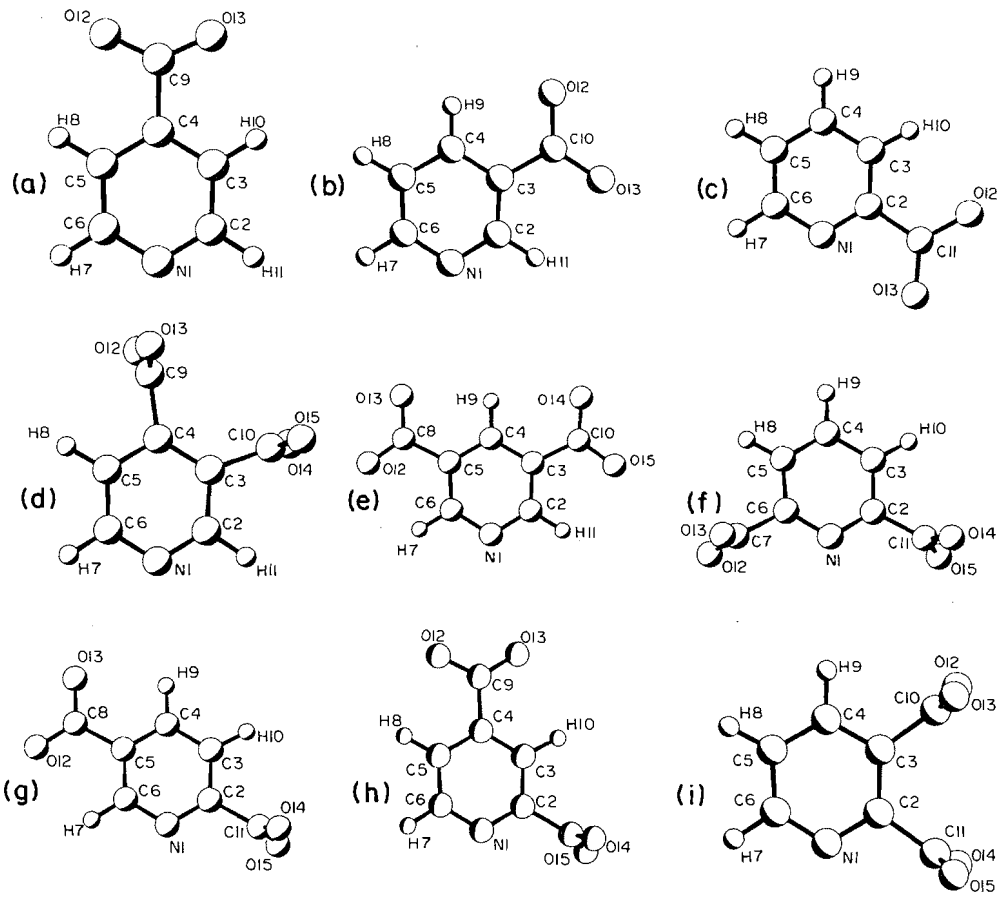

Fig. 1. Structures of the mono- and dicarboxylated pyridines: (*a*) isonicotinate, (*b*) nicotinate, (*c*) picolinate, (*d*) cinchomeronate, (*e*) dinicotinate, (*f*) dipicolinate, (*g*) isocinchomeronate, (*h*) lutidinate, (*i*) quinolinate.

natures of critical points of rank three and these are denoted as (rank,signature). These critical points correspond to a local maximum in $\rho(\boldsymbol{r})$, a peak, (3,–3); a saddle point in $\rho(\boldsymbol{r})$ which is a maximum in the surface it defines, a pass, (3,–1); a saddle point in $\rho(\boldsymbol{r})$ which is a minimum in the surface it defines, a pale, (3,+1); and a local minimum in $\rho(\boldsymbol{r})$, a pit, (3,+3).

Bader et al. (2) have shown that by examining the Laplacian of the charge density, the Lewis model of localized electron pairs and the VSEPR model of molecular geometry may be recovered. Where the Laplacian of the charge density is negative ($\nabla^2\rho(\boldsymbol{r}) < 0$) charge is locally concentrated and where it is positive ($\nabla^2\rho(\boldsymbol{r}) > 0$) it is locally depleted. Thus, by examining the field $\nabla(-\nabla^2\rho(\boldsymbol{r}))$ for critical points in the same manner as examining the field $\nabla\rho(\boldsymbol{r})$, it is possible to recover the VSEPR model of lone and bonding pairs of electrons. That is, if

$$\nabla(-\nabla^2\rho(\boldsymbol{r})) = 0$$

$\boldsymbol{r}$ is a critical point in that field and may be classified in much the same manner as the critical points in $\nabla\rho(\boldsymbol{r})$. A (3,–3) critical point is a local maximum in $-\nabla^2\rho(\boldsymbol{r})$ and this feature may be used to locate the electron pairs of the VSEPR model. It must be noted, however, that these regions of negative Laplacian values are not localized electron pairs.

This report, part of an extensive systematic study of possible neuroactive drug candidates, focuses on the mono- and dicarboxylated pyridines. Of these, quinolinic acid is an endogenous excitatory amino acid and is active at the *N*-methyl-*D*-aspartate (NMDA) receptor. As well, dipicolinic acid behaves as a partial agonist on NMDA receptors (1). This behavior makes the carboxylated pyridines an ideal series for investigations into drug design targeted at the NMDA receptor. The suitability of using the topological properties of the electron density to correlate with biological activity will be examined in a later report.

2. Method

The geometries of each of the pyridine mono- and dicarboxylates have been energy optimized at the semi-empirical AM1 (3) and *ab initio* molecular orbital levels of theory. AM1 calculations were performed using MOPAC 5.01 (4) utilizing the keywords PRECISE, PULAY, and SHIFT=10. *Ab initio* calculations used the HONDO 8 (5) and GAUSSIAN 92 (6) series of programs. The *ab initio* calculations utilized the STO-3G (7), 3-21G (8), and 3-21+G (9) basis sets. After AM1 optimizations, single point *ab initio* calculations at the STO-3G and 3-21G levels were performed to obtain the appropriate wavefunctions for the electron density analysis. The topological analysis of the electron density was facilitated by use of the AIMPAC series of programs (10). All calculations were carried out on an IBM RISC 6000 Model 520 computer.

The nine species examined in this report are displayed in Fig. 1 along with their common names. The geometries displayed are those calculated at the 3-31+G basis set level. Note that the basis set level and geometry used will be indicated by the nota-

tion "basis set"//"geometry", where "geometry" will be the level of calculation or basis set used in the optimization.

3. Results

3.1. Conformational analysis

The heats of formation and total energies for the mono- and dicarboxylated pyridines are listed in Table 1. Symmetry was not used in any of the optimizations. The carboxylate groups are co-planar to the ring in the monocarboxylated pyridines, however, the results vary in the dicarboxylates. At the AM1 level, although there may be several possible stationary points on the potential surface, only one geometry is found for each of the dicarboxylates. Using the HONDO 8 program, at the STO-3G and 3-21G levels, depending on the species, there may be up to four stationary points involving rotation of the carboxylate groups. In fact, at the STO-3G level, three points are essentially equivalent (to five places after the decimal) for cinchomeronate while a fourth is slightly higher in energy. Proceeding to the 3-21G level, however, leads to differentiation resulting in the conformation with both carboxylate groups perpendicular to the plane of the ring being the lower in energy, in agreement with the AM1 result. Similarly, with dinicotinate, the AM1 conformation is found to be the lowest energy at both the STO-3G and 3-21G levels. The AM1 conformation for quinolinate is not the lowest energy at the STO-3G or 3-21G levels. Improving the basis set by adding diffuse functions to the 3-21G basis sets for heavy atoms (3-21+G) yields conformations different from those obtained at the AM1 level except in two cases, cinchomeronate and dinicotinate. At the 3-21+G level, the pyridine ring in cinchomeronate is slightly distorted and no longer planar and the carboxylate groups are neither planar with the ring nor perpendicular to it either.

3.2. Topological analysis

3.2.1. Topological analysis on AM1 optimized geometries

At this point, the topological properties of wavefunctions found using AM1 optimized geometries are presented. This separates the effects of geometry and basis set from each other as here wavefunctions at the STO-3G//AM1 and 3-21G//AM1 levels are presented, whereas the results of STO-3G//STO-3G, 3-21G//3-21G, and 3-21+G//3-21+G level analysis will be discussed later.

(i) Positions of bond critical points

Tables 2 and 3 contain the distance from the bond critical point to each atom along the bond paths in the pyridine mono- and dicarboxylates, respectively. The distance from each atom involved in the bond is given for the STO-3G//AM1 and 3-21G//AM1 level densities. Only the distance from one atom involved in the bond is discussed as the other undergoes the reverse trend as the geometry is fixed.

There is a significant change in the distance from N to the

bond critical points with this distance decreasing in each species by about 0.12 au going from the STO-3G to 3-21G results. The distance from C2 to the bond critical point in the C2—C3 bond decreases unless a carboxylate group is directly attached to C2. The exception to this trend is quinolinate. The distance from C3 to the bond critical point in the C3—C4 bond increases except in lutidinate and isonicotinate. The distance from C4 to the bond critical point in the C4—C5 bond also increases but the exceptions are now picolinate, dipicolinate, and isocinchomeronate. In all cases, the distance from the ring carbon to the bond critical point in the C—H bond increases. However, the distance from the ring carbon to the bond critical point in the C—CO_2^- bond decreases.

(ii) Charge density at bond critical points

The value of the charge density at the bond critical points for the mono- and dicarboxylated pyridines are listed in Tables 4 and 5, respectively. The values found at the STO-3G//AM1 and

[a]Values in atomic units.
[b]The column numbers indicate the substitution position while STO-3G and 3-21G indicate the basis set used.

3-21G//AM1 levels are listed. The value of $\rho(\boldsymbol{r})$ at the critical point, $\rho(\boldsymbol{r}_c)$, is dependent on bond length as well as on the basis set used and the position of the substituents on the ring. However, some trends are apparent upon proceeding from the STO-3G to 3-21G basis set. The value of $\rho(\boldsymbol{r}_c)$ for the N—C bonds increases. The change is unevenly distributed but depends on the separation distance of the carboxylate substituents. The results for the C—C bonds also vary but the overall change is slight. Similarly, the change in $\rho(\boldsymbol{r}_c)$ for the C—H bonds is small and varies. Surprisingly, the value of $\rho(\boldsymbol{r}_c)$ in the C—CO_2^- bonds also changes very little but as the value of $\rho(\boldsymbol{r}_c)$ is the lowest here for each basis set, the lack of change and the low value of the density could be due to the long bond.

(iii) Laplacian of the charge density at $\mathbf{r}_c$

The value of the Laplacian of the charge density at the bond

[a]Values in atomic units.

critical points, $\nabla^2\rho(r_c)$, are listed in Tables 6 and 7 for the mono- and dicarboxylated pyridines. The values found with STO-3G//AM1 and 3-21G//AM1 level calculations are listed. Overall, there is a large decrease in the value of $\nabla^2\rho(r_c)$ to more negative values. Also, the value of the Laplacian at the bond critical point has been shown to indicate the type of bonding taking place between two atoms (2). That is, when $\nabla^2\rho(r_c) < 0$, charge is locally concentrated and the electronic charge in the bonding region is shared, indicating covalent or polar interactions. When $\nabla^2\rho(r_c)$ is positive, $\rho(r_c)$ is usually low in value and the bond is more closed-shell in nature or rather, ionic for the present circumstances. Thus, it is surprising to observe that $\nabla^2\rho(r_c)$ is positive (although small in value) or near zero at the STO-3G//AM1 level in several of the N—C bonds. Upon proceeding to the 3-21G//AM1 level, however, all $\nabla^2\rho(r_c)$ values are negative although slightly smaller in magnitude than in most other bonds in the ring of the species examined. No other bonds display this behavior and although they do become more negative, the change is substantially less than for the N—C bonds.

(iv) Maximum in $-\nabla^2\rho(\mathbf{r})$

Topological features of the Laplacian of the charge density, $\nabla^2\rho(r_c)$, recover the VSEPR model of lone and bonding pairs of electrons. Just as by examining the topological features of the charge density, locating and characterizing the critical points allows insight into the ebb and flow of bonding electrons around the ring, the lone pair of electrons on the nitrogen can be located and characterized using the Laplacian of the charge density. That is, the (3,–3) critical points in the field $\nabla(-\nabla^2\rho(r))$ can be located and properties at these points can be calculated.

Table 8 contains the distance of this (3,–3) critical point in $-\nabla^2\rho(r)$, associated with the lone pair on the pyridine nitrogen, r', from the nitrogen as a function of compound and basis set. As well, the charge and $\nabla^2\rho$ at that point are tabulated. Examining the values of r' going from the STO-3G to 3-21G basis set, there is a reorganization amongst the compounds in terms of the shortest to the longest r'. There is a definite increase in r' and a decrease in the range, from 0.6921 to 0.7016 au at the STO-3G level, to 0.7248 to 0.7286 au at the 3-21G level. Although there is reorganization of the ranking of the compounds with regards to the smallest to the largest in terms of $\rho(r)$ at this (3,–3) critical point in $-\nabla^2\rho(r)$, the variation in the value of $\rho(r)$ is now greater at the 3-21G level. Of interest is that this reorganization at the 3-21G level gives the inverse ordering to that of r' (smallest to largest), because the closer the critical point to N, the larger $\rho(r)$ is at the point. Similarly, examining the values listed for the Laplacian shows that there is again reorganization; now the trend at the 3-21G level is the same as that found for r', that is, from the smallest (most negative) to the largest (most positive). Also, although the value of $\nabla^2\rho$ is larger in magnitude at the STO-3G level, the range of this rapidly changing function is smaller, changing 0.08 au from the smallest to the largest as opposed to 0.13 au for the 3-21G basis set.

3.2.2. Topological analysis of ab initio *optimized geometries*

(i) Positions of bond critical points

The earlier discussion of results in Tables 2 and 3 focused on the change in the position of the bond critical point as a function of basis set with the geometries constant. Tables 9 and 10 contain the distance from the bond critical point to each atom along a bond path in the pyridine mono- and dicarboxylates, respectively, at the STO-3G//STO-3G, 3-21G//3-21G, and 3-21+G//3-21+G levels. With the geometries changing as well as the basis set, comparison of the distances of nuclei to bond critical points is made more difficult. For example, at the STO-3G level, the C—CO_2^- bond length in isonicotinate is 3.0972 au while at the 3-21+G level it is 2.9114 au. This bond shortening should be reflected in distances from the bond critical point to the nuclei if basis set effects on the density were minimal. However, at the STO-3G level the critical point is 1.3032 au from the carboxylate carbon and this distance increases to 1.3618 au at the 3-21+G level despite the decreased bond length. Since these bond critical points are points on the surface of the topologically defined atom in a molecule, the change in basis set may give rise to a change in the size of the atoms (or distortions), resulting in changes in the distances to the critical points and the bond lengths. Earlier, a change in basis set at fixed geometry would change the placement of the internuclear surface, thus distorting the "shape" of the atom. By allowing the geometry to change, the interatomic surfaces assume positions to lower the total energy. As observed by Boyd and Edgecombe (11), for a homonuclear diatomic molecule, by symmetry the bond critical point is required to be at the bond midpoint. Thus, lengthening the bond by amount x will result in a change of the distance between the bond critical point to a nucleus by $x/2$. There is no restriction in the present systems and so changes in bond lengths from the AM1 values may not give rise to symmetric or systematic changes in distances to the bond critical point.

Examination of Table 9 reveals that while the N—C bond length for isonicotinate decreases proceeding from the STO-3G to 3-21G levels, the distance from the bond critical point to the carbon increases and the distance to N decreases. The addition of diffuse functions leads to a slight increase in the N—C bond but now the distance to the N nucleus increases but that to C remains relatively unchanged. The underlying question is which basis set describes the species best.

The position of the carboxylate groups on the ring has a definite effect on the position of the bond critical points between the ring atoms. For example, examining the 3-21+G results in Table 9, the distance of the critical point from C2 in the N1—C2 bond changes from 0.9382 to 0.9350 to 0.9247 au as the position of substitution on the ring changes from 4 to 3 to 2. Similarly, the C6—N1 bond undergoes change but in the opposite direction with the C6 to critical point distance changing from 0.9382 to 0.9472 to 0.9489 au for the same process. As the distance from N1 to the critical point in the N1—C6 bond decreases, it appears that there is a distortion of the density around N1. In the N1—C2 bond this distance increases but then decreases slightly.

Examination of the 3-21+G results listed in Table 10 and specifically the series with 2,3, 2,4, 2,5, and 2,6 substitution, reveals that the distance from N1 to the bond critical point increases as the second carboxylate group is moved from 3 to 4 to 5 to 6. In the N1—C2 bond this distance decreases as the group is moved 3 to 4 to 5 but then increases slightly when the group is moved to 6. Similarly, examining this distance in the 2,3, 3,4, and 3,5 series, in the N1—C6 bond the distance increases while in the N1—C2 bond it decreases.

There are some trends found amongst the changes resulting from the changes in basis set level. The distance from N1 to bond critical points in all species decreases going from the STO-3G to 3-21G level and then increases slightly upon proceeding to the 3-21+G level. The distance from H to the bond critical point in the C—H bonds decreases for the same process with the exception of one bond in cinchomeronate which increases slightly upon proceeding to the 3-21+G//3-21+G level. The shortest distance from H to the bond critical point at the 3-21+G level is in lutidinate where the hydrogen is located between two carboxylate groups. In the other example of a hydrogen between two carboxylate groups, dinicotinate, the distance is also short.

The distance from the ring carbon to the critical point in the C—CO_2^- bond is decreased when the basis set is expanded.

3—10	0.2654	0.1901	0.2641
2—11	0.1875	0.2636	0.2608

[a]Values in atomic units.
[b]**2**, **3**, and **4** represent picolinate, nicotinate, and isonicotinate, respectively.

This shortening ranges from 0.2 to 0.11 au proceeding from the STO-3G to 3-21G results and from 0.06 to 0.05 au proceeding from the 3-21G to 3-21+G results.

Examining Tables 9 and 10 for trends in the distance from a ring carbon to a ring bond critical point it is apparent that the N—C bonds have the shortest values at all levels. Thereafter, the results are mixed, depending on the basis set level used and species examined. At the STO-3G level it is usually the carbon bonded to a carboxylate group that displays the shortest distance to the critical point. Proceeding to the 3-21G and then the 3-21+G levels does reveal a clear trend. At the 3-21+G level, disregarding the N—C bonds, the shortest critical point to ring carbon distance occurs at C3 and C5. While at the STO-3G level this distance may be very short at C4 in, for example, isonicotinate, with a value of 1.09 au, but upon proceeding to the 3-21+G level there is an increase of 0.21 au.

An intramolecular hydrogen bond was characterized in quinolinate between H9 and O12. The resulting distances from the H and O nuclei are listed in Table 10. This was the only intramolecular hydrogen bond that could be identified in this study.

(ii) Charge density at bond critical points $\rho(\mathbf{r}_c)$

The value of $\rho(\mathbf{r}_c)$ has been shown to vary monotonically with bond length in main group diatomic (11) and binary hydrides (12). Thus care must be taken when comparing charge densities at bond critical points of different length bonds. For example, in Tables 11 and 12, the charge density at bond critical points in the mono- and dicarboxylated pyridines calculated at

the STO-3G//STO-3G level are given. Examination reveals that the density is lowest at the C—CO_2^- bond critical point.However, at the STO-3G level, the C—CO_2^- bond is the longest at about 3.09 au as opposed to other heavy atom to heavy atom bonds which are 2.65 au or less. There have been attempts to link $\rho(\boldsymbol{r}_c)$ with bond order (13), however, there will be no attempt to do so in this report.

Tables 15 and 16 contain listings of $\rho(\boldsymbol{r}_c)$ for the mono- and dicarboxylated pyridines at the 3-21G//3-21G level. Tables 19 and 20 contain the corresponding values calculated at the 3-21+G//3-21+G level. As expected from the shortening of bonds, proceeding from the STO-3G to 3-21G level results in an increase in $\rho(\boldsymbol{r}_c)$. Proceeding further to the 3-21+G level gives rise to changes that appear to be related to the minor changes in bond length, increasing or decreasing slightly with the slight changes in bond length.

Examining the 3-21+G results, there is a trend of the N1—C6 bond $\rho(\boldsymbol{r}_c)$ being greater than or equal to that for N1—C2. There is one exception to this, isocinchomeronate. Here the N1—C2 value is greater, again reflecting differences in bond length. Note that this did not appear at the STO-3G level where these values could be considered equal.

The effect of the position of the substituents on the ring can be observed by comparing $\rho(\boldsymbol{r}_c)$ values of the C—C bonds from opposite sides of the ring. Although the differences at the STO-3G level are larger, they are still pronounced at the 3-21G and 3-21+G levels. For example, at the 3-21+G level, the series with substituents at the 2,3, 2,4, 2,5, and 2,6 positions, the value of $\rho(\boldsymbol{r}_c)$ in the C2—C3 bond increases as the second carboxylate group moves around the ring. On the opposite side of the ring in the C5—C6 bond, $\rho(\boldsymbol{r}_c)$ (which is larger) starts to increase but then decreases until it is the same with substituents at 2,6. At the STO-3G level, the same trend in $\rho(\boldsymbol{r}_c)$ for the C2—C3 bond is not followed when the carboxylate group moves from C5 to C6, i.e. 2,5 to 2,6. On the other hand, $\rho(\boldsymbol{r}_c)$ for the C5—C6 bond (larger than in the C2—C3 bond) decreases regularly until equal to that in the C2—C3 bond.

Although this analysis has emphasized that the change in the density at the bond critical points can be related to the change in bond length, from the previous analysis of changes in basis set at fixed geometries there are also changes arising from the selection of the basis set. However, the change in $\rho(\boldsymbol{r}_c)$ due to the change from the STO-3G to 3-21G basis set was small except in the N—C bonds. This trend was fairly constant. Also, the changes in geometries and $\rho(\boldsymbol{r}_c)$ are small between the 3-21G and 3-21+G results leading to the conclusion that the differences in $\rho(\boldsymbol{r}_c)$ are mainly due to geometric differences.

As indicated in the topological analysis of distances from the nuclei to the bond critical point, a hydrogen bond was characterized between H9 and O12 in quinolinate. The value of $\rho(\boldsymbol{r}_c)$ for that bond was found to be 0.0205 au. This may appear to be small, but it is a reasonable value given the bond length, 4.3256 au, and the weak nature of the interaction.

(iii) Laplacian of the charge density

Tables 13 and 14 contain values of $\nabla^2\rho(\boldsymbol{r}_c)$ for the mono- and

dicarboxylated pyridines, respectively, at the STO-3G//STO-3G level. As with the STO-3G//AM1 results, there are several values of $\nabla^2\rho(\boldsymbol{r}_c)$ in the N—C bonds that are positive or near zero. Tables 17 and 18 contain values of $\nabla^2\rho(\boldsymbol{r}_c)$ for the carboxylated pyridines calculated at the 3-21G//3-21G level. Again, as with the 3-21G//AM1 results, the $\nabla^2\rho(\boldsymbol{r}_c)$ values for the N—C bonds have become very negative. Tables 21 and 22 contain the $\nabla^2\rho(\boldsymbol{r}_c)$ values calculated at the 3-21+G//3-21+G level. The 3-21G and 3-21+G results are quite similar.

Examining the series with substitution in the 2,3, 2,5, 2,4, and 2,6 positions reveals a trend observed at all three levels in the N1—C2 bond. That is, $\nabla^2\rho(\boldsymbol{r}_c)$ in the N1—C2 bond becomes more negative as the second carboxylate group is moved around the ring.A similar trend but with $\nabla^2\rho(\boldsymbol{r}_c)$ becoming more positive is observed in the N1—C6 bond for the same movement. There is one exception to the latter trend at the 3-21G level at the last step (2,5 to 2,6) with $\nabla^2\rho(\boldsymbol{r}_c)$ becoming more negative. There is also a similar trend in the C2—C3 bond at the 3-21G and 3-21+G levels, that is, $\nabla^2\rho(\boldsymbol{r}_c)$ becomes more negative as the carboxylate group moves from C3 to C6. This trend is not evident at the STO-3G level. Table 22 contains an extra entry for quinolinate due to the characterization of a hydrogen bond between H9 and O12. As expected, $\nabla^2\rho(\boldsymbol{r}_c)$ is positive, although small in magnitude, indicating a closed shell interaction that is characteristic of hydrogen bonds.

(iv) Maximum in $-\nabla^2\rho(\mathbf{r})$

The distance of the (3,−3) critical point in the negative of the Laplacian to the nitrogen nucleus, r', the value of the charge density, $\rho(\boldsymbol{r}')$, and the value of the Laplacian at that point are listed in Table 23 for the carboxylated pyridines at the STO-3G//STO-3G, 3-21G//3-21G, and 3-21+G//3-21+G levels. At the STO-3G level, substitution at position 4 gives the largest r' value while substitution at 2 the smallest in the monocarboxylates. This holds for the dicarboxylates as well, so that 2,6 substitution gives the smallest value with those with 2,3 and 2,5 substitution following closely. 3,4 substitution gives the largest value of r'.

At the STO-3G level, substitution at position 2 gives the largest value of $\rho(\boldsymbol{r}')$ with that for substitution at 4 giving the lowest

value. In the dicarboxylated species this trend appears to hold with the 2,6-and 2,3-substituted species having the largest values while the lowest value is found with 3,4 substitution.

Substitution at the two position gives rise to the most negative value of the Laplacian at the critical point at the STO-3G level and the least negative is found with substitution at position 4. This trend appears to hold for the dicarboxylates with the most negative values found for the 2,3- and 2,6-substituted species. The least negative value was found for the 3,4-disubstituted species.

The results calculated at the 3-21G level can expect to be influenced by the change in geometric parameters, that is, the bond shortening found upon proceeding to the 3-21G level from the STO-3G level can be expected to influence the density around the position of the lone pair on nitrogen. Surprisingly, although r' increases slightly, $\rho(\boldsymbol{r}')$ decreases dramatically and $\nabla^2\rho(\boldsymbol{r}')$ becomes much less negative. At the STO-3G level, substitution at the 3 position resulted in values of $\boldsymbol{r}'$, r, and $\nabla^2\rho$ close to those found with substitution at position 2. At the 3-21G level these values are now closer to those found with substitution at position 4. Overall, in the mono- and dicarboxylated pyridines, those substituted in the 2 and 2,6 positions have the smallest r', largest ρ, and most negative $\nabla^2\rho$. As well, those substituted at the 3 and/or 4 positions have the largest r', smallest ρ, and least negative $\nabla^2\rho$. The difference between the smallest and largest value at each level has become larger. At the STO-3G level, r', ρ, and $\nabla^2\rho$ varied by 0.0029, 0.0073, and 0.1194 au, respectively. These differences become larger at the 3-21G level, having values of 0.0054, 0.0169, and 0.1631 au for differences in r', ρ, and $\nabla^2\rho$, respectively.

As with the 3-21G calculations, it should be expected that values calculated at the 3-21+G level would be affected by changes in geometries due to basis set level. The monocarboxylated series has the shortest r' value with picolinate and as with the 3-21G results, nicotinate and isonicotinate are almost equivalent. The effect of substitution in the 2 position can be seen in the dicarboxylates as well with dipicolinate having the lowest r' value of the species studied. The series of shortest to longest r' continues with 2,4, 2,5, 2,3, 3,5, and 3,4 substitution. The values of $\rho(\boldsymbol{r}')$ give rise to a series that follows the same trend going from highest to lowest $\rho(\boldsymbol{r}')$. Dipicolinate has the highest value of $\rho(\boldsymbol{r}')$ while cinchomeronate the lowest. The same pattern is followed when examining $\nabla^2\rho(\boldsymbol{r}')$ going from most negative to most positive. Note that the range of values has expanded again from those calculated at the 3-21G level. r', $\rho(\boldsymbol{r}')$, and $\nabla^2\rho(\boldsymbol{r}')$ now vary by 0.097, 0.0341, and 0.3608 au, respectively, roughly double the variation at the 3-21G level.

3.3. Geometric analysis: bond lengths

The calculated bond lengths at all levels of theory used in this study can be recovered using the critical point data listed in Tables 2 and 9 for the monocarboxylates, and in Tables 3 and 10 for the dicarboxylates. Using this technique trends are apparent when changes in bond lengths are considered in relation to the changes in method or basis set level.

[a]Values in atomic units.

(i) AM1 to STO-3G

With the exception of one N—C bond in cinchomeronate, all N—C bonds lengthen upon proceeding to the STO-3G level. In general, there is a decrease in the ring C—C and the C—H bond lengths but a significant increase in the C—CO_2^- bond lengths. The change in the C—O bond lengths vary but in a number of cases, considering the changes in the C—CO_2^- bonds, the variation is in the fourth place after the decimal.

(ii) STO-3G to 3-21G

For this process, all the N—C bonds shorten and, in general, all the C—C bonds shorten. The C—H and C—O bonds shorten, with the shortening in the area of about 0.02 au.The C—CO_2^- bonds decrease by as much as 0.15 to 0.17 au. The N—C2 bond in quinolinate does not shorten as much as in other compounds.

(iii) 3-21G to 3-21+G

The addition of diffuse functions to the heavy atoms should help in the description of the extra density in the anions. However, rather than having clear trends, the results are mixed. There is N—C bond lengthening in the monocarboxylates, but in the dicarboxylates there is a mixture of lengthening and shortening. In cinchomeronate and dinicotinate, the N—C bonds lengthen but in dipicolinate they shorten. The N—C bonds in the remaining dicarboxylates shorten if a carboxylate group is attached to C2 or lengthen if not. Thus, whether the N—C bond lengthens or shortens depends entirely, in the dicarboxylates, on the location of the carboxylate groups. The one compound that does not appear to follow this trend is quinolinate where the N—C2 bond shortening is minimal. All the ring C—C bonds lengthen. Interestingly, throughout the series, changes in the C—H bond lengths do not display systematic trends other than when *ortho* to the N position. Here the C—H bonds shorten slightly. There is definite shortening in all the C—CO_2^- bonds.

4. Discussion

4.1. Geometric, conformational, and topological analysis

The present results suggest that the AM1 method does not reproduce geometries and conformations correctly for the species studied. The method did not locate many of the stationary points on the energy surface and, in particular, gave the conformations that have been found to be the lowest in energy at the 3-21+G level in only two cases out of the nine examined. As well, in many cases the trends observed with the 3-21+G optimized bond lengths are not reproduced by the AM1 method; however, this may be a function of differing conformations. As would be expected (14), due to its small size, the STO-3G basis set is

For personal use only.

incapable of adequately describing the C—CO_2^- bond, resulting in extremely long C—CO_2^- bond lengths.

Comparisons of the results from the topological analysis of the charge density calculated at the AM1 and *ab initio* geometries is broken down into three sections: (*1*) comparison of distances of passes from atoms involved in the bond, (*2*) values of the charge density and its Laplacian at the critical points, and (*3*) values associated with the critical point in the Laplacian associated with the ring nitrogen lone pair.

Detailed direct comparison between the topological properties found using wavefunctions calculated at the STO-3G//AM1 and 3-21G//AM1 levels and those found using wavefunctions at the STO-3G//STO-3G, 3-21G//3-21G, and 3-21+G//3-21+G levels are difficult to undertake due to the changes in conformation and geometry. However, given the linear relationships found by Boyd and Edgecombe (11) between bond lengths and the position of bond critical points, passes, it is possible to correlate trends observed at these different geometries with the basis sets used. This permits the identification of the minimum level at which a certain degree of confidence can be placed in calculated trends. The approach used is to examine the ratio $r_A/(r_A + r_B)$, where r_A is the distance from atom A to the critical point in the bond to atom B which is a distance r_B from the critical point. The results found at the 3-21+G//3-21+G level will be used as the benchmark for comparison. The r_A and r_B values tabulated in Tables 4, 5, 11, and 12 are used to calculate this ratio.

Examining this ratio for the N1—C2 bond at the STO-3G//AM1 and STO-3G//STO-3G levels and comparing to the benchmark shows that the results at this level are approximately 0.04 too large. At the 3-21G//AM1 level the ratio is 0.01 or less too small while moving to the 3-21G//3-21G results gives differences that range from –0.006 to 0.002, that is, at this level the ratios are very close to the benchmark. Moving along the ring to the C2—C3 bond, the range of differences are ±0.06 and ±0.07, respectively, at the STO-3G//AM1 and STO-3G//STO-3G levels. With the 3-21G basis set these values fall with one fairly large difference, 0.02, at the AM1 geometry and a range of –0.009 to 0.004 at the 3-21G geometry. Similarly, in the C3—C4 bond the differences for this ratio have the ranges –0.08 to 0.06, ±0.08, ±0.008, and ±0.01, respectively, for the STO-3G//AM1, STO-3G//STO-3G, 3-21G//AM1, and 3-21G//3-21G calculations. Very similar results are found for the C4—C5 bond, that is, –0.05 to 0.08, –0.01 to 0.08, ±0.01, and ±0.01, respectively, for the ratio differences at the STO-3G//AM1, STO-3G//STO-3G, 3-21G//AM1, and 3-21G//3-21G levels. The corresponding ratio differences in the C5—C6 bond are in the ±0.04, ±0.04, ±0.009, and ±0.009 ranges, respectively. Lastly, the corresponding ratio differences for the N1—C6 bond are very much like those found for the N1—C2 bond, overestimated by approximately 0.04 at the STO-3G//AM1 and STO-3G//STO-3G levels, underestimated by approximately 0.01 at the 3-21G//AM1 level and having a range of –0.007 to 0.002 at the 3-21G//3-21G level.

Although none of the four levels compared with the 3-21+G//3-21+G ratio results reproduced those results completely, comparing the ratios with a view to overall changes from one species to another, the 3-21G//3-21G results are the best of the four. As well, the 3-21G//AM1 results appear to display the same trends with some minor exceptions. The ratio values found with the split-valence basis sets are also quite close to those found at the benchmark level.

The geometric changes that occur upon changing method or basis set preclude a direct comparison with $\rho(r_c)$ or $\nabla^2\rho(r_c)$. As pointed out by Boyd and Edgecombe (11), there is a linear correlation of $\rho(r_c)$ and $\nabla^2\rho(r_c)$ with bond length and examination of $\rho(r_c)$ for particular bonds throughout a series shows this to be true unless influenced by the ring substituents. Note that although the 3-21G//3-21G results are, on average, quite close to those found at the 3-21+G//3-21+G level, the 3-21G//AM1 results are not. This appears to be the result of geometric and conformational differences.

Values of r', ρ, and $\nabla^2\rho$ at the maximum in $-\nabla^2\rho$ associated with the lone pair of electrons on nitrogen in the pyridine ring found at the 3-21G//3-21G level appear to be quite well reproduced at the 3-21G//AM1 level. Both give values close to those found at the 3-21+G//3-21+G level. This indicates that the position and values associated with this maximum in $-\nabla^2\rho$ is not as sensitive to geometric change, but rather is very dependent on the basis set used. The STO-3G results are quite different.

4.2. Applicability of results to quantum pharmacology calculations

Quinolinic acid, an endogenous neurotoxin active at the NMDA receptor site, plays a role in epilepsy and neurodegenerative disease. Accordingly, quinolinic acid and its mono- and dicarboxylated pyridine analogues are important target molecules in the rational design of neuroactive drug molecules. Exploitation of these structures in drug design demands an exacting understanding of the geometric, conformational, and topological properties of this analogue series. These features are necessary for a comprehensive understanding of both drug molecule structure and drug–receptor interactions through such non-bonded interactions as ion–ion, ion–dipole, dipole–dipole, and hydrogen bonding.

Although molecular mechanics is the most widely cited methodology in quantum pharmacology, it fails to adequately consider electronic properties. These properties must be examined through molecular orbital calculations. Since there are a variety of molecular orbital methods ranging from semi-empirical to *ab initio*, it is also necessary to clarify the quality and interchangeability of results obtained using these methodologies.

As demonstrated in this study, AM1, STO-3G, and 3-21G calculations do not provide equivalent treatments of geometric, conformational, and topological properties. Split-valence basis sets yield answers significantly different from those obtained from semi-empirical parameterizations. Furthermore, the utility of the theory of molecular structure calculations in representing molecular topology and electron distribution properties (both essential in conceptualizing drug–receptor interactions) has been demonstrated.

Metal ion complexes of 1,4,7-triazacyclononane and their aminoalkyl derivatives. Analysis of chelate rings fusion and molecular mechanics study

IGOR V. PLETNEV

Department of Chemistry, Moscow State University, Moscow 119899 GSP-3, Russia

Received December 24, 1992[1]

IGOR V. PLETNEV. Can. J. Chem. **72**, 1404 (1994).

Stereochemistry of metal ion complexes of 1,4,7-triazacyclononane, their *N,N′,N″*-tris(aminoethyl), tris(aminopropyl), and their *N,N′*-(4,7-diazadecylene) derivatives is described in terms of the fusion of chelate rings at metal–nitrogen coordination bonds. Molecular mechanics calculations and analysis of the X-ray data confirm that the semi-quantitative analysis is valid and that fusion plays a critical role in the structure of the complexes. Molecular mechanics study of puckering of the ethylenediamine chelate ring, an essential part in this study, is also presented.

IGOR V. PLETNEV. Can. J. Chem. **72**, 1404 (1994).

On décrit la stéréochimie des complexes d'ions métalliques du 1,4,7-triazacyclononane et de ses dérivés *N,N′,N″*-tris(aminoéthyl)-, tris(aminopropyl)- et *N,N′*-(4,7-diazadécylène)- en fonctions de la fusion de noyaux chélates au niveau des liaisons de coordination métal–azote. Des calculs de mécanique moléculaire ainsi que des données de diffraction des rayons X confirment la validité d'une analyse semi-quantitative et prouvent le rôle critique que la fusion joue dans la structure des complexes. On présente aussi une étude de mécanique moléculaire du plissement du cycle chélaté de l'éthylènediamine qui est essentiel dans cette hypothèse.

[Traduit par la Rédaction]

Introduction

1,4,7-Triazacyclononane (tacn) and its derivatives are known as versatile ligands. They are useful in the selective complexation and sequestering of metal ions, the stabilization of unusual oxidation states, magnetic resonance imaging, biomimicricy, etc. (for a review, see ref. 1; for some representative examples, see refs. 2–6). Stereochemistry of complexation plays a key role in all applications. Much is known about the stereochemistry from both experimental (1) and theoretical studies (e.g., molecular mechanics, MM calculations (7)).

However, to understand the factors governing the stereochemical patterns, we believe one should focus on the fusion of the chelate rings in these complexes. Simple semi-quantitative analysis of how the conformation of one ring influence the conformation of the other and therefore the whole structure appears helpful in rationalizing the stereochemistry observed (8) and the molecular design (9).

In this paper we attempt to apply this approach to conceptualise the stereochemical configurations in tacn complexes and their aminoalkyl derivatives (Fig. 1). MM calculations are used to investigate the puckering of an ethylenediamine chelate ring, which is a key subject in the consideration, and to refine the conformations predicted in polychelate systems.

Computations

All MM calculations were performed on a PC AT clone equipped with 80286/287 processor using the program MMPC (Molecular Mechanics for Personal Computing; C language) written by the author (available upon request).

The program minimizes the energy of the molecule in the Cartesian atomic coordinates space, taking into account contributions to total energy, E, from: (*i*) bond lengths stretching, E_b; (*ii*) bond angles bending, E_a; (*iii*) torsional strain, E_t, and (*iv*) nonbonded interactions, E_{nb}. Fletcher–Reeves and Davidson–Fletcher–Powell gradient minimization algorithms (10) are implemented in conjunction with analytical first derivatives given by Boyd (11).

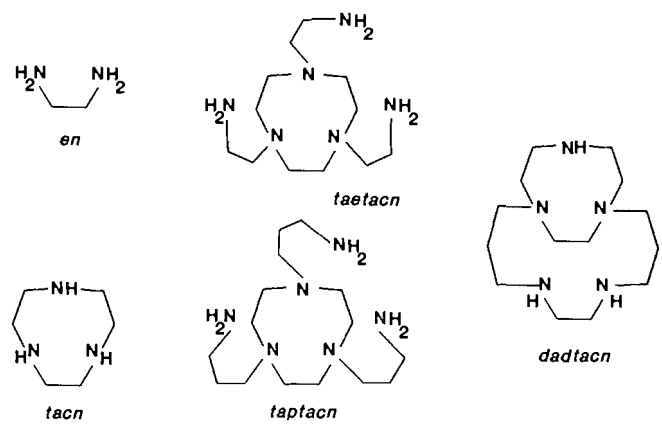

FIG. 1. Ligands discussed in this paper.

Test calculation of αα-[Co(tetraethylenepentaamine)Cl_2]$^+$, which has been subjected to an MM study earlier (12), is in excellent agreement with published data. The structures presented below are compatible with X-ray data; this proves that the software is reliable.

All calculations were performed using the force field developed by Hancock (13). This force field is one of the most extensively tested to date and the most reliable. Initially all nonbonded interactions in molecule(s) of interest were considered. However, it was found that the force field (13) demanded strongly that long-range interactions (i.e., those at distance greater than 1.20 times the sum of van der Waals atomic radii (14)) be excluded when computing the energy. Certain difficulties caused by the oscillations of the energy gradient were eliminated by multiplying all nonbonded energies by a smoothing function.

Typically, the initial geometry of the molecules under study (i.e., the starting point for MM optimization) was constructed using reasonable bond lengths, bond angles and torsional angles, the last set of parameters being derived from semi-quantitative fusion analysis. Minimization was considered complete when the root-mean-squared gradient decreased to 0.005 kcal mol^{-1} Å^{-1}. The puckering of the *en* ring was studied using the "torsional angle drive" method (15).

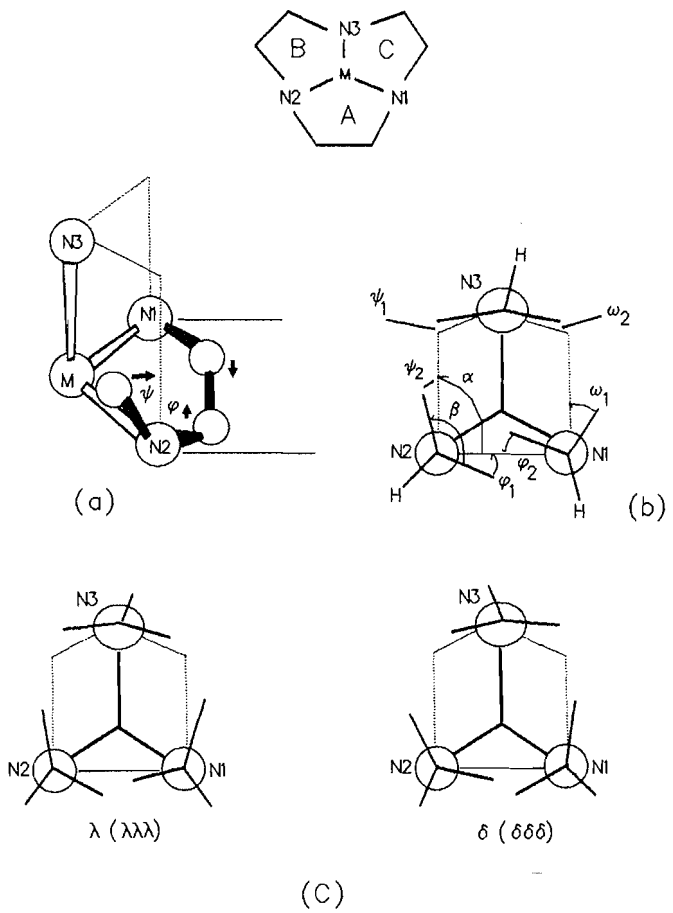

FIG. 2. Fusion of chelate rings in a complex of *fac*-coordinated tacn ligand.

Results and discussion

Theoretical basis

Stereochemistry of metal ion complexes can be most naturally described by the conformations of the chelate rings. Evidently, the conformations are not independent and they do influence each other. A very simple formalism is useful to describe such interrelations.

Let us consider a *fac*-coordinated tacn ligand in an octahedral complex (the usual mode of coordination). This moiety comprises three fused ethylenediamine (*en*) chelate rings, A–C in Fig. 2. Let us assume that the first ring, A, adopts some fixed conformation, e.g., the optimal (16) symmetrical *gauche*, *sym-gauche*. It means (see Fig. 2*a*) that one carbon atom, say, one adjacent to N_1, is above the coordination plane N_1MN_2, while another carbon lies below the plane (the placement could be inverted, resulting in an opposite chirality of puckered *en* ring). Fixing the conformation of ring A influences the conformation of ring B: the carbon adjacent to N_2, ring B, is forced — by the tetrahedral structure of the coordinated nitrogen — to appear in front of the plane N_2MN_3. This, in turn, induces positioning of another carbon in B to lie behind that plane (if *sym-gauche* form of the *en* ring is still to be maintained). Now, positions of *both* carbon atoms in ring C have been predefined by the structure of both rings A and B.

This qualitative consideration can easily turn semi-quantitative. The convenient way is to refer to the angles of rotation around the M—N coordination bond, needed to place carbon atoms into the respective coordination plane NMN of the *en* ring (see Newman projection, Fig. 2*b*). There are two such *principal* angles in each ring (Fig. 2*b*, angles φ_1, φ_2; ψ_1, ψ_2; ω_1, ω_2).

Clearly, the fusion of two chelate rings (say, A and B) means that the principal angles at the common coordination bond (φ_1 and ψ_2, rotation around M—N_2) are related to each other. The relationship is dictated by the directionality of bonds inherent to both ligating donor atom (N_2, sp^3-nitrogen; angle β of 120° on Fig. 2*b*) and the metal ion center (octahedral, angle α of 90°); that is, $\psi_2 = \varphi_1 + 30°$.[2] Apparently, such a relationship could be drawn for any pair of fused chelate rings; for example, $\omega_1 = \varphi_2 - 30°$.

For a *syn-gauche* conformation of the *en* ring, the principal angles, torsional angles NMNC, are near 15° (16).[3] Therefore, a value of −15° for φ_1, ring A, leads to $\psi_2 = 15°$, ring B; and a value of −15° for φ_2 leads to $\omega_1 = -45°$, ring C. Now $\omega_1 = -45°$ does not match the *sym-gauche* conformation. Therefore optimal conformations for neighboring *en* rings are untenable in a *fac*-coordinated tacn. To answer the question what ring conformations are possible and in what combination, we need a more detailed description of the way in which principal angles may vary in any ring, i.e., *en* ring puckering.

Puckering of the ethylenediamine chelate ring

It is well known that ethylenediamine chelate ring adopts various asymmetric conformations of the *gauche* type that have somewhat higher energy than the *sym* form (17). However, both the energy and the geometry of distorted conformations need further scrutiny (earlier works, e.g., (17–19), have used only rough computational models; a more recent paper (20) did not specifically consider the puckering of the ring). Therefore, a study of an isolated *en* ring with "state-of-the-art" MM parametrization (13) was carried out.

Calculations were made with different strain-free M—N bond lengths — 1.9, 2.10, and 2.30 Å, to include different-sized metals. Other force-field parameters were the same as those for high-spin nickel(II). Thus the results obtained at r^0(M—N) 2.10 Å are applicable directly to Ni complex, while results for r^0(M—N) = 1.9 Å and r^0(M—N) = 2.30 Å may serve as good approximations (an approach developed earlier (13)).

Full optimization of the *en* ring structure converged to the *sym-gauche* form despite variations in the starting conformation. The principal torsional angles (M—N rotation) are (φ_1, φ_2) = (−14.9°, −14.9°) (high-spin nickel; puckered *en* ring is chiral and the above values are only for the λ-enantiomer). The structural parameters are very close to those reported earlier, e.g., in ref. 16.

In order to obtain asymmetric conformations, one of two principal angles was fixed at some predefined value, allowing all other parameters to change. This technique was used earlier (19) and, evidently, simulates a situation in polychelate complexes, where the rings are fused. With such a constraint, a vari-

[2]Note, that for *quantitative* description one should consider all the rotation angles as having definite sign (from here on positive is clockwise) and fixed rotation axis (here MN_2). Thus (consult Fig. 2*b*), the angle φ_1, i.e., torsional angle N_1MN_2C, is < 0; ψ_2, angle N_3MN_2C is > 0; $\alpha > 0$; and $\beta > 0$. Note that one could change diastereotopic configuration of nitrogen center, i.e., exchange H and $C_{ring\ B}$ on Fig. 2*b*. In that case, β would be $< 0 = -120°$, resulting in $\psi_2 = \varphi_1 - 210° = \varphi_1 + 150°$.

[3]Accounting for the signs of rotation angles and enantiomeric duality, (15°, 15°) and (−15°, −15°).

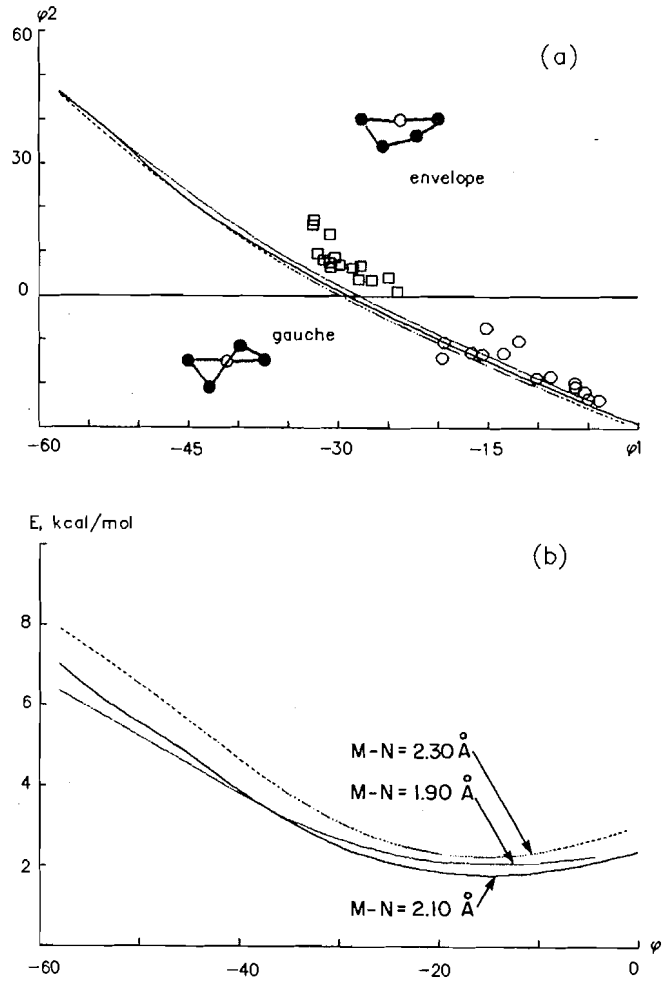

FIG. 3. (*a*) Interdependence between the two principal angles describing a puckering of *en* ring (λ-form). Experimental data: squares (*en* ring in tacn complexes) and circles. (*b*) Strain energy of puckered *en* ring vs. principal angle φ_1 (or φ_2). Calculated at ideal M—N bond lengths of 1.90 (···), 2.10 (--) and 2.30 Å (- -).

ety of asymmetric conformations were obtained. A pair of principal angles (φ_1, φ_2) uniquely described each of them. The curve that relates φ_1 with φ_2 (or vice versa) and, in a sense, represents the path of pseudorotation of the ring, is shown in Fig. 3*a*. The curve in Fig. 3*b* reflects the accompanying change of energy. (For simplicity, the curves are drawn for λ-enantiomer only.) Some experimental (X-ray (21–35)) points, also placed on Fig. 3*a*, confirm the validity of the calculated values.

The curves in Fig. 3 illustrate some features of *en* ring puckering. When starting from the *sym-gauche* point (−14.9°, −14.9°), one of the *en* ring carbon atoms progressively deviates below the coordination plane (φ_1 becomes more negative), the other carbon follows it, approaching the plane from the other-side (φ_2 becomes less negative). Finally, the second atom crosses over the plane ($\varphi_2 = 0°$) and appears on the same side as the first carbon (thus producing an *envelope* conformation). As Fig. 3*b* shows, this move costs energy, primarily because of an increase in torsional and bending strain. For example, moving from the *sym-gauche* point to the border-line point (−30°, 0°) requires ca. 0.7 kcal/mol, and further puckering to $\varphi_1 = -45°$ costs approximately 2.4 kcal/mol.

It should be mentioned that above values are only for "concerted" movement along the curve in Fig. 3*a*. Any deviation from this "least-energy" path requires additional energy. Indeed, any point on the curve is a local energy minimum obtained at fixed value of one principal angle, with the other principal angle being free to change. Thus, the puckering of *en* ring in polychelate "fused" systems must proceed along this path unless additional severe restrictions are present. Therefore, if two *en* rings are fused and one ring has a fixed conformation, e.g., (ψ_1, ψ_2), one principal angle in the neighboring ring, φ_1, is then fixed and one can deduce from Fig. 3*a* what should be the angle φ_2 and the conformation of the second ring (φ_1, φ_2). Moreover, with the curve in Fig. 3*b*, it is possible to conclude the energy of certain combinations of conformations. Consequently, it is also possible to find an optimal combination. (Naturally, chiral duality of puckered *en* ring must be taken into account. Thus, $\varphi_1 = -15°$ induces $\varphi_2 = -15°$ and *sym-gauche* conformation, if one assumes λ chirality; assuming δ chirality, $\varphi_2 = 40°$ and highly asymmetrical conformation will be obtained.)

Fusion of chelate rings in fac*-coordinated tacn*

The stereochemcial possibilities in tacn complexes may now be considered using an extremely simple mechanistic model. As it was stated above, principal angles of fused rings are related to each other: $\psi_2 = \varphi_1 + 30°$; $\omega_1 = \varphi_2 - 30°$; $\psi_1 = \omega_2 - 30°$.

Moreover, two principal angles in any ring are related, through the "least-energy" curve in Fig. 3 (least-squares approximation: $X_2 = (-33.3 \pm 2.6) + (-1.25 \pm 0.09)X_1$, $X = \varphi$, ψ, ω; λ-configuration; $X_2 = 33.3 - 1.25X_1$, δ-configuration). Thus, any of six principal angles in M(tacn) may be expressed as an explicit function of any other principal angles through a chain of relationships. Furthermore, owing to the cyclic nature of the ligand there are two such chains for any pair of principal angles. For examples, ψ_1 may be related to φ_1 through the chains φ_1–φ_2–ω_1–ω_2–ψ_1 and φ_1–ψ_2–ψ_1 (see Fig. 2). Apparently, the values produced either way must be equal. Solving this equality in conjunction with the above functions, one may estimate the values of the principal angles accounting for (*a*) macroring closure, (*b*) proper directionality of bonds around donor and metal centers, and (*c*) least steric strain in chelate rings.

Omitting computational details, two distinctly different sets of principal angles (φ_1, φ_2, ω_1, ω_2, ψ_1, ψ_2) were obtained this way: (*i*) (−30.8°, 5.2°, −24.8°, −2.3°, −32.3°, −0.8°) and (*ii*) (−54.5°, 34.8°, 4.8°, 27.3°, −2.7°, −24.5°). These values are dictated by geometric requirements. For energetic reasons, the first set seems to be preferable (first *en* ring in case (*ii*) is in a very strained conformation of a highly puckered *envelope*, cf. Fig. 3*b*). The values in selected set (*i*) should be averaged for all *en* rings due to the evident symmetry of the problem. This results in the following principal angles for the *en* rings in M(tacn): (−29.3°, 0.7°). They represent the *envelope* conformation which is practically on border-line *gauche/envelope* (see Fig. 3).[4]

As Table 1 shows, the values obtained with this simplest model are in surprisingly good agreement with the experimen-

[4]As for an isolated *en* ring, there are possible two enantiomers for *fac*-M(tacn), λ(λ, λ, λ) and δ(δ, δ, δ), as shown on Fig. 2*c*. For δ-form the values should be (−0.7, 29.3).

tal data. In all cases the three chelate rings of complex are in an *envelope* form with the same chirality.

However, calculations seem to have underestimated one of two principal angles, 0.7 vs. 5.7–7.5°, Table 1 (see also Fig. 3*a*). The main reason is likely in the assumption of ideal 90° interplanar angles α in the coordination octahedron. In practice, as X-ray data and molecular mechanics calculations show, each *en* ring tends to compress the angle at the metal ion, resulting in a decrease of the octahedral interplanar angles. Taking this effect into account, one could obtain more precise agreement. It should be noted that since we neglect inter-ring diatomic interactions in fusions, such omissions may lead to some discrepancies.

Nevertheless, the above simple analysis still provides a reasonable semi-quantitative description. This proves that the conformation of a coordinated tacn is rigidly dictated by the interior structure of the *en* rings and fusing them together "around an octahedral center" yields strained *envelope* conformations. MM calculations naturally produce better refined structural results (see Tables 1 and 2, where the data for $[Ni(tacn)_2]^{2+}$ complex are compared with the experimental values). But semi-quantitative analysis rationalizes the observed/calculated stereochemistry, and, more importantly, gives a good starting point for MM optimization of the complex structure. (A common choice of X-ray geometry as a starting one is, apparently, of little use if calculations were made *prior* to experiment, e.g., in a molecular design).

Complexes of tris (N-pendant) tacn

Attachment of complexing arms to tacn nitrogens means formation of extra chelate rings in complexes, and rigid structure of M(tacn) moiety strongly affects the conformation and orientation of the pendant arms.

Let us consider an octahedral complex of tris(N-functionalized) tacn. There are two *cis* positions available for coordination by pendant functionality at each tacn nitrogen (coordination in *trans* position is unlikely). Therefore, there are two enantiomeric ways to occupy these positions, relating to the Δ and Λ chirality of metal center (Fig. 4). Combining with the chirality of M(tacn) moiety, this gives rise to two clearly distinct isomers, A and B (diastereomeric configurations Δλ ≡ Λδ and Δδ ≡ Λδ, respectively). As it is seen from Fig. 4, where λ-M(tacn) is presented, the isomers differ greatly in the conformational possibilities of the "pendant chelate rings". Given the values of the principal angles in tacn rings ca. −30° and 0° and considering a fusion, the principal angle θ in pendant rings could be approximately 30° for isomer A and −60° for isomer B. Thus, isomer A favors ring conformations, which deviate much less from planarity.

The fusion requirements expressed through θ allow consideration for complexing arms of different types.

Aminoethyl pendant arms (taetacn)

The ligand taetacn is a best example since the pendant chelate rings are ethylenediamine. Isomer A is, undoubtedly, preferable because of the more reasonable principal angle θ of ca. 30°, just like *en* rings of M(tacn) itself. This should be combined with the counter-part angle θ′ of ca. 0°, resulting in a relatively stable *asym-gauche* (or close to *envelope*) conformation.

Note that the values correspond to δ chirality and the overall configuration of the complex cation should be described as Δλδ ≡ Λδλ (chiralities are given in the order metal – tacn rings – pendant rings). Inversion of pendant rings chirality, Δλλ ≡ Λδδ, forces them to adopt a highly strained *envelope* conformation (see Fig. 3, the region near (30°, −50°)). Therefore, the last configuration is unfavorable.

Isomer B of M(taetacn) is not favorable at all. An angle of θ ~ −60° requires too large a deviation of the carbon atom (adjacent to tacn nitrogen) from the pendant ring coordination plane NMN (cf. Fig. 3). Nevertheless, if a structure of B type existed, it should have pendant chelate rings in an envelope conforma-

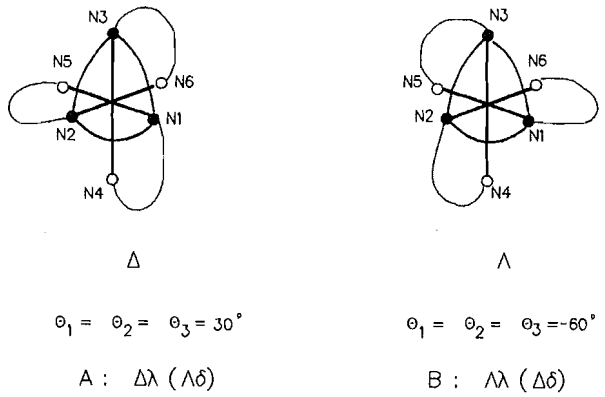

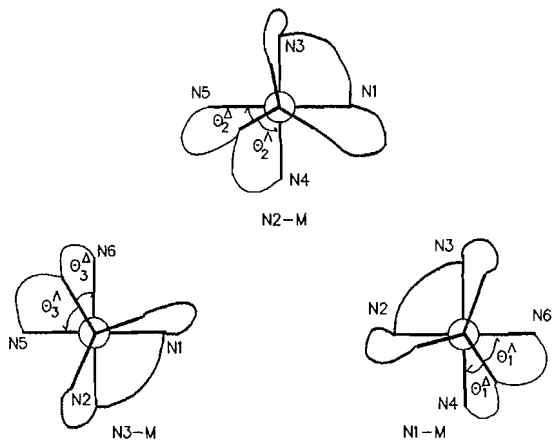

FIG. 4. Fusion of chelate rings in complexes of *N,N',N''*-tris(pendant arm) tacn. Tacn moiety is *fac*-coordinated and in λ-chirality.

tion, where both carbons are on the same side of NMN, and one primary nitrogen lies closer to the plane. It requires a λ chirality of rings and an overall configuration of ΛλΛ ≡ Δδδ. Configuration ΛλδΛ ≡ ΔδλΔ requires the latter carbon to deviate even further from NMN than the former, which seems to be a forbidden case.

Thus, isomer A, ΔλδΔ, should be the realistic choice for M(taetacn) octahedral complex. A corresponding trial structure (for Co(III) as central ion) was generated from the standard bond lengths, bond angles, and the above principal (torsional) angles, and was subjected to MM optimization. This results in the structure presented in Fig. 5*a* and Table 3. Table 3 shows that the calculated parameters are in agreement with those obtained in the X-ray study of $[Co(taetacn)]^{3+}$ (37). It should be emphasized that the starting point for MM minimization originated from semi-quantitative fusion analysis, and no X-ray data were used in the starting geometry.[5]

Molecular mechanics calculations provide further insight into the steric demands of the ligand. Figure 6 represents the strain energy of M(taetacn) as a function of "ideal" M—N bond

[5]The authors of ref. 37 have also performed MM analysis (Table 3). Extensive calculations were made for all four of possible diastereomers, and the result was exactly the same as ours. The ΔλδΔ form (isomer A), which is found in crystal structure, appeared to be the least-strained, while for the ΔδλΔ configuration, minimization proved impossible (i.e., the structure is not viable).

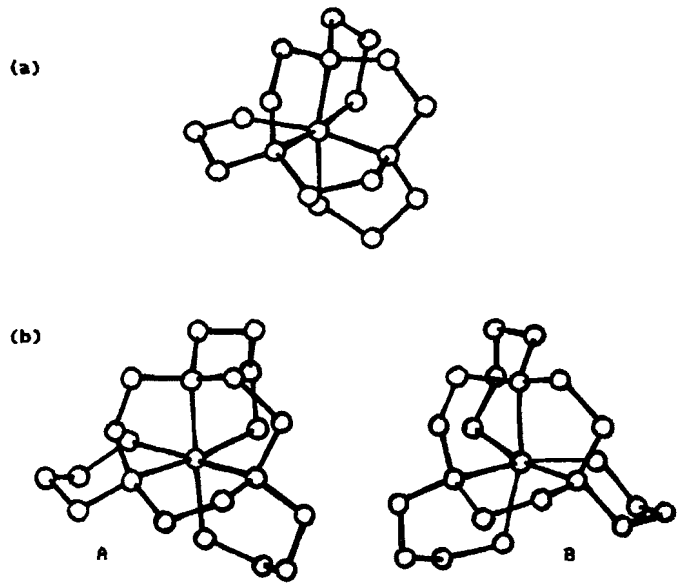

FIG. 5. Calculated structures of nickel(II) complexes of taetacn (*a*) and taptacn (*b*).

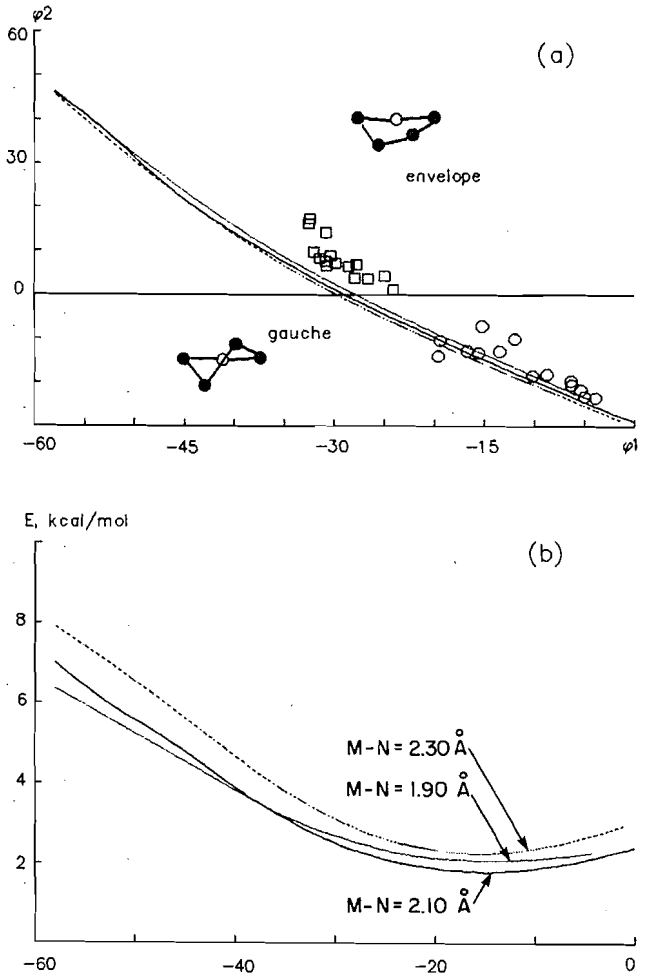

FIG. 6. Strain energy of metal ion complexes as a function of ideal strain-free M—N bond length.

length, that is, a function of the metal ion size. Ideal length was varied, while other metal-dependent force field parameters were kept constant and equal to those of high-spin Ni(II). For convenience, a curve for the bis(tacn) system is also presented in Fig. 6 (the curve is practically identical to that obtained earlier (36), best-fit M—N length 2.07 Å vs. 2.08 Å (36)).

It is clear that the size-selectivity profile of taetacn is essentially the same as that for bis(tacn); the best-fit M—N bond length, 2.08 Å, is only slightly shifted towards larger metal ions. Thus, the metal–nitrogen bond lengths in taetacn complexes should be identical or slightly longer than those in the bis(tacn) system (and the similarity should spread onto other size-dependent properties, e.g., redox potentials). This is in good agreement with crystal data for Co(III) complexes. The average Co—N bond length in $Co(taetacn)^{3+}$, 1.986 Å (37), is slightly longer than that in $Co(2\text{-methyl tacn})_2^{3+}$, 1.97 Å (38).

Interestingly, due to the analogous steric properties of sp^3 nitrogen and oxygen atoms, the above consideration of fusion (but not of size selectivity!) should be valid for tacn functionalized with hydroxyethyl arms as well. The data recently appeared (39) on Co and Mn complexes of tris(2-hydroxypropyl) tacn, thptacn, do confirm that conclusion. For example, complex cation $[Mn(thptacn)]^{2+}$ is of type A, configuration $\Delta\lambda\delta$, with the following principal angles (calculated from X-ray data (39)): $(\varphi_1, \varphi_2) = (-31.4°, 7.8°)$; $(\psi_1, \psi_2) = (-31.1°, 9.1°)$; $(\omega_1, \omega_2) = (-30.9°, 8.8°)$; $(\theta, \theta') = (24.9°, 1.3°)$ (averaged).

Aminopropyl pendant arms (taptacn)

The ligand taptacn forms trimethylenediamine (*tn*) pendant rings, and here a choice between A and B structural types is not evident. Indeed, though *tn* ring may adopt different conformations, the most widely occurred is the least strained *chair*, with principal angles of ±45° (16); this is exactly a mid-way position between 30° and −60° for isomers A and B.

Therefore, both A and B trial structures were constructed and subjected to MM optimization (metal = high-spin nickel). The following figures were obtained (kcal/mol):

	E_{total}	E_b	E_{nb}	E_a	E_t
Isomer A	28.02	1.92	7.46	9.45	9.20
Isomer B	32.87	2.24	9.54	13.88	7.22

Structure A (Fig. 5) is ca. 5 kcal/mol more stable, and this isomer was also found in the crystal form (34). Again, structural parameters, which were calculated through semi-quantitative analysis followed by MM refinement, are in very good agreement with those obtained in X-ray diffraction study (see Table 4). The work (34) provides an unusual possibility of comparison between two independent structures of the same complex cation. Though a "great similarity" (34) was present, the following figures come from crystallographic data: root-mean-squared difference in bond lengths 0.046 Å (27 bonds); in M—N bond lengths, 0.019 Å (six bonds); in bond angles, 2.5° (51 angles); in dihedral angles, 4.5° (87 torsions). When the MM-minimized structure is compared with one of those crystals, r.m.s. differences in the same order are as follows: 0.028 Å; 0.017 Å; 1.4°; 2.2°. Therefore the match "MM/crystal" is even more precise than the "crystal/crystal".

It should be mentioned that calculations, in agreement with X-ray data (34), predict considerable elongation of (average) coordination bond lengths in $Ni(taptacn)^{2+}$, 2.14 Å, comparing with the ideal value of 2.10 Å. This is indicative of a size-selectivity profile, which is completely different from those of taetacn and bis(tacn). Indeed, as Fig. 6 shows, the presence of aminopropyl pendant arms results in a ligand preference towards large metal ions, with a predicted best-fit M—N bond length of 2.18 Å. Interestingly, this value nicely fits the size of high-spin Co(II) also (ideal Co—N, 2.17 Å (13)). Therefore, taptacn ligand should stabilize this oxidation state much more than bis(tacn). In fact, the redox potential is −0.010 V (vs. NHE) for $Co(taptacn)^{3+/2+}$ and −0.41 V for $Co(tacn)_2^{3+/2+}$ (34, 40). Thus, the calculated size-selectivity curve confirms (34) that this may be attributable to sterical demands of taptacn.

N,N′-*Bridged tacn (dadtacn)*

The ligand dadtacn (Fig. 1) is a macrobicycle comprising "fused" tacn and cyclam moieties. Complexes of dadtacn itself, to our knowledge, have not yet been described, though some data on dadtacn synthetic precursors and analogues appeared recently (35). It is therefore possible to first study the topic theoretically and then verify the results with experiments.

The discussed ligand may be considered a tacn ring functionalized with two aminopropyl pendant arms that are linked together. Therefore, one could analyze the stereochemistry of its complexes, starting from that of taptacn and study the possibility of connecting the pendant nitrogens through the ethylene bridge.

Aminopropyl side arms may be oriented as in isomer A or

[c]This work.

isomer B. Since dadtacn only has two such arms, a third isomer with "inhomogeneous" orientation is possible. This isomer has type A conformation for one arm and type B conformation for the other.

Let us consider the fusion of chelate rings in the latter case, AB (Fig. 7, which illustrates the structure, may be easily compared with that in Fig. 4). Principal angles in pendant rings of taptacn were considered: they are $\theta_1 = -60°$ for B-type and $\theta_2 = 30°$ for A-type ring (see Fig. 4). If these *tn* rings are in symmetrical *chair* conformations, the counterpart principal angles will be $\theta_1' = 60°$ and $\theta_2' = -30°$. The values of θ_1', θ_2' may now be used to estimate the principal angles in *en* ring, which "bridges" pendant nitrogens, N_5 and N_6 in Fig. 7: $\gamma = 0°$, $\gamma' = 30°$. Thus, the AB orientation of the aminopropyl arms leads to quite reasonable principal angles, and, therefore, to relatively unstrained geometry of the bridging *en* ring. (Note that this consideration was made for λ-tacn, while the resulting values for bridging ring represents opposite chirality, δ.)

"Homogeneous" orientation of dadtacn aminopropyl arms, A

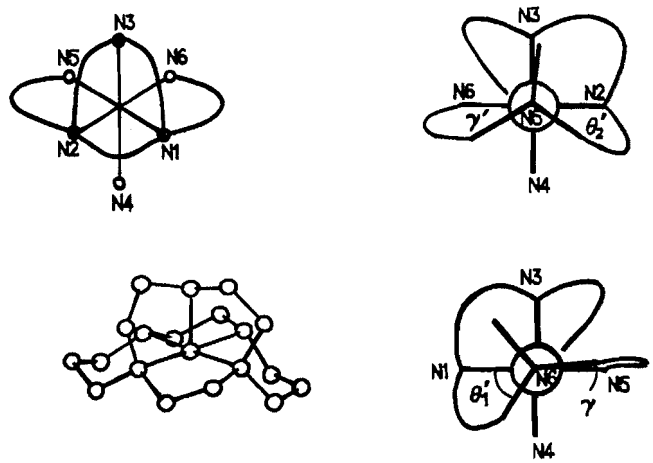

FIG. 7. Fusion of chelate rings (*a*) and calculated structure (*b*) of nickel(II) complex of dadtacn.

or B, leads to a very different picture. A simplified calculation yielded principal angles γ and γ′ to be (30°, −60°) and (0°, 90°), respectively. This gives rise to a very strained and practically impossible structure of the bridging *en* ring and makes these isomers unlikely.

Using the principal values above, a trial geometry for AB isomer of Ni(dadtacn)X was constructed and refined with MM (bare nitrogen atom was "introduced" to represent axial ligand X completing an octahedral environment). The following is a brief outline of the resulting structure.

All five coordination bonds formed by the ligand are shorter than the ideal Ni—N, average is 2.08 Å. This may be compared with an average Ni—N value of 2.07 Å, which was observed in crystal structure (35) of nickel complex of thia-substituted dadtacn (15-thia-1,5,8,12-tetraazabicyclo[10.5.2]nona decane). Average N—Ni—N bond angle in five-membered rings is 85.9°, and in six-membered ring the angle is 92.2°.

Ethylenediamine rings of tacn do have identical chirality, while cyclam's (or *N,N′*-bridging) *en* ring is in the opposite configuration. Average torsional angle around C—C bond in *en* rings is 48° (absolute value). One of the *tn* rings has a relatively flattened *chair* form, with principal angles (36°, −37°), and the other being much more puckered, (60°, −56°), thus giving rise to a nearly optimal conformation of the bridging *en* ring. This feature, predicted by fusion analysis, was also observed in Ni(thia-dadtacn), where the principal angles calculated from X-ray data (35) are (26°, −26°) and (54°, −48°).

Size selectivity profile of dadtacn as revealed from MM study is presented in Fig. 6. Best-fit M—N bond length is 2.07 Å, the same as that for bis(tacn) and taetacn, but much different from that for taptacn. It should be mentioned that cyclam itself (in *trans-I* conformation, which is identical to that of cyclam moiety in the dadtacn complex considered) has a best-fit value of 2.01 Å (41). Thus, the steric requirements of the more rigid tacn moiety override those of cyclam.

A series of methylenebisphenols, thiobisphenols, oxybisphenols, and iminobisphenols were evaluated as antioxidants for tetralin at 60°C by means of an oxygen-obsorption method. It was found that replacement of the bridged methylene group of methylenebisphenols by a nitrogen atom showed considerably better antioxidant effects. The antioxidant effects of these compounds were influenced by the positions of the phenolic hydroxyl groups in their molecules.

T. NISHIYAMA, T. KAGIMASA et F. YAMADA. Can. J. Chem. **72**, 1412 (1994).

Faisant appel à une méthode d'absorption d'oxygène, on a évalué une série de méthylènebisphénols, thiobisphénols, oxybisphénols et iminobisphénols comme antioxydants pour la tétraline, à 60°C. On a trouvé que le remplacement du groupe méthylène ponté des méthylènebisphénols par un atome d'azote générait des produits à effets antioxydants nettement supérieurs. Les effets antioxydants de ces composés sont influencés par les positions des groupes hydroxyles phénoliques présents dans ces molécules.

[Traduit par la Rédaction]

Introduction

In chemical industries, antioxidants have commonly been used to prevent deterioration due to the oxidation of organic substrates such as rubbers, plastics, and lubricating oils. The major pathway of the oxidation of organic materials involves a radical chain mechanism. It is well known that phenolic and amino compounds act as inhibitors for radical chain reactions of autoxidation of such organic substrates and sulfuric compounds act as decomposers for hydroperoxides (1). During the course of our studies of phenol derivatives as antioxidants, compounds containing a diarylmethyl group with a phenolic hydroxyl group showed high activities as antioxidants for paraffin wax (2), lard (3), mineral oils (4), and greases (4). In a recent study of benzylphenols (5, 6), we found that the introduction of a benzyl group to the *para* and (or) *ortho* positions on the phenols improved the antioxidant activities of phenols. The present study was initiated to compare the antioxidant activities of thiobisphenols, oxybisphenols, and iminobisphenols, in which the bridged methylene group of methylenebisphenols was replaced by a sulfur, oxygen, or nitrogen atom.

Experimental

Materials

The phenol derivatives studied in this work were as follows: 2,2′-methylenebisphenol (**1***a*), 4,4′–methylenebisphenol (**1***b*), 4,4′-methylenebis(2-methylphenol) (**1***c*), 2,2′-thiobisphenol (**2***a*), 4,4′-thiobisphenol (**2***b*), 4,4′-thiobis(2-methylphenol) (**2***c*), 2,2′-oxybisphenol (**3***a*), 4,4′-oxybisphenol (**3***b*), 2,2′-iminobisphenol (**4***a*), 4,4′-iminobisphenol (**4***b*), and 4,4′-iminobis(2-methylphenol) (**4***c*). Tetralin used for the test was washed with concentrated sulfuric acid, aqueous sodium bicarbonate, and water, dried over anhydrous sodium sulfate, and distilled under nitrogen before use. The oxidations were initiated with 2,2′-azobisisobutyronitrile (AIBN), which was recrystallized from methanol.

Determination of antioxidant activity

The volume of oxygen absorbed was determined as a function of time under 760 Torr (1 Torr = 133.3 Pa) of O_2 using 50 mL of tetralin containing an antioxidant (0.05 mmol) and AIBN as the initiator (0.5 mmol) (5). The oxidation temperature was kept at 60 ± 0.1°C. The induction period (IP) was determined graphically (7, 8) on the plot of oxygen consumption versus time as the point of intersection of a line of the rate of oxygen uptake after the inhibitor was consumed and a line tangent to the curve with a slope equal to half of the slope of the line after the inhibitor was consumed.

Results and discussion

Figure 1 shows the results of the oxidation of tetralin initiated by AIBN in the presence of bisphenols **1–4** and 2,6-di-*tert*-butyl-4-methylphenol (BHT) as antioxidants, along with a control test in the absence of an antioxidant. The oxidation proceeded smoothly in the absence of antioxidant without a noticeable IP, and a constant rate of oxygen uptake was observed, but in its presence the oxidation was found to be suppressed. Values of IP for compounds **1–4** along with BHT, are shown in Table 1. It was found that the compounds **1***c*, **2***b*, **2***c*, **3***b*, and **4** showed excellent antioxidant effects which were superior to BHT, whereas **1***a*, **1***b*, **2***a*, and **3***a* showed lower IP values compared with BHT.

In the case of methylenebis-, thiobis-, and iminobis-phenols, the compounds having two methyl substituents at *ortho* positions of the OH groups had longer IPs than that of the compounds having no methyl substituents at *ortho* positions. The effect of alkyl groups at *ortho* positions of the OH groups on its antioxidant activity has been studied by many authors. For example, Howard and Ingold (9) have reported the antioxidant activity of alkyl phenols depends on the position of substituents. They also reported that the steric effects due to *ortho* alkyl substituents are important.

Iminobisphenols **4** showed the highest antioxidant activity among **1–4**. Since diphenylamine has antioxidant ability, the increased activity of iminobisphenols (**4**) is ascribed to the synergistic effect of both bridged amino and phenolic hydroxyl groups.

When the IP values for 2,2′- and 4,4′-derivatives were compared, 4,4′-dihydroxy derivatives of **2–4** showed higher antioxidant effects than those of 2,2′-dihydroxy derivatives, whereas 2,2′-methylenebisphenol (**1***a*) exhibited higher antioxidant activities than **1***b*. From the fact that 2,2′-derivatives of **2–4** exhibited lower antioxidant activities, it can be assumed that an intramolecular hydrogen bonded *ortho*-hydroxyl groups to the

Diphenylamine	5.0	5.3	93
BHT	5.0	4.8	376
Control	—	5.6	22

[a]The rates of oxygen consumption: I, for an inhibited autoxidation during IP; II, for an uninhibited oxidation after IP.

bridged hetero atom and reduced its ability of the reaction with peroxyl radicals. Pospisil and co-workers (10) have reported the infrared spectra of the hydroxyl groups of 2,2′-thiobisphenols; the OH groups of 2,2′-thiobisphenols existed in the form of intramolecular OH···S hydrogen bond (10). Likewise, Binder and co-workers (11) proposed the same OH···S hydrogen-bonded hydroxyl groups.

Table 1 also shows the rate of oxygen consumption. When all ArO• radicals are consumed, the rate of autoxidation should be equal to that of the control test. In fact, the rate of oxygen consumption after IP of BHT was close to the control (see II in Table 1). On the other hand, its rates of compounds **3***b* and **4***b* showed a much lower value. This means that the retardation persists, even after IP is over, owing to transformation products of the antioxidant.

In conclusion, we have compared the antioxidant activity of heteroatom-bridged analogues of methylenebisphenols. Among these compounds, iminobisphenols (**4**) exhibited significant antioxidant effect.

TAHAR LAKHLIFI, AHMED SEDQUI, TOUFIK FATHI, BERNARD LAUDE et JEAN-FRANÇOIS ROBERT. Can. J. Chem. **72**, 1417 (1994).

La synthèse de sept 5-phényl-3,4-dihydro-2*H*-pyrrole-2-carboxylates de méthyle précurseurs d'ylures d'azométhine cycliques pentagonaux **1** est décrite. Ces produits à caractère dipolaire réagissent avec les *N*-méthyl et *N*-phénylmaléimides de façon diastéréospécifique. L'approche des réactants se fait sur la face la moins encombrée du dipôle-1,3 et en *endo* pour donner le cycloadduit thermodynamiquement le plus stable de structure *exo*. De plus, l'oxydation de ces composés **1** permet d'accéder aux pyrroles substitués correspondants.

TAHAR LAKHLIFI, AHMED SEDQUI, TOUFIK FATHI, BERNARD LAUDE, and JEAN-FRANÇOIS ROBERT. Can. J. Chem. **72**, 1417 (1994).

Seven derivatives of methyl 5-phenyl-3,4-dihydro-2*H*-pyrrole-2-carboxylates **1** were synthetized. These compounds are precursors of pentagonal cyclic azomethine ylids, the two sides of which are diastereotopic. The 1,3-dipolar species react with *N*-methyl and *N*-phenylmaleimides diastereospecifically. The approach of the reactant species occurs from the less hindered side of the 1,3-dipole and in *endo* to lead the thermodynamically stable *exo* cycloadduct. Moreover, oxidation of the compounds **1** gives the corresponding substituted pyrroles.

Introduction

L'étude de la diastéréochimie de l'approche dipôle–dipolarophile en cycloaddition dipolaire-1,3 a déjà fait l'objet de nombreux travaux dans notre laboratoire (1–10). Ces derniers ont consisté à examiner la diastéréosélectivité de l'approche d'un dipôle-1,3 sur un dipolarophile cyclique dont les deux faces sont diastéréotopiques par suite d'un encombrement dû à la présence d'un substituant. Selon la taille et la nature de celui-ci d'une part et sa position par rapport au site dipolarophilique d'autre part, on peut observer des approches totalement ou partiellement diastéréosélectives.

Dans le présent travail, nous nous sommes intéressés au cas où l'induction asymétrique est dû à la présence d'un substituant porté par un dipôle-1,3 totalement inséré dans un cycle.

La littérature décrit quelques dipôles-1,3 de ce type et les plus connus sont des dérivés cycliques mésoioniques du type «münchnones» ou «sydnones» (11). On peut aussi signaler des dipôles-1,3 dont deux sommets font partie d'un cycle, comme certaines nitrones étudiées par Tufariello (12) ou des ylures d'azométhine décrits par Harwood et coll. (13).

Récemment, Mkhairi et Hamelin (14) ont examiné la réactivité d'imines cycliques **1** et **2** qui, activées en α de l'azote, sont des précurseurs d'ylures d'azométhine dont la partie dipolaire est totalement insérée dans un cycle pentagonal ou hexagonal (figure 1). À leur suite, nous avons étudié les réactions de précurseurs d'ylures d'azométhine **3** dérivés de l'isoquinoléine (15).

Il nous a semblé intéressant de profiter de cette expérience pour envisager la synthèse d'imines cycliques **1** diversement substituées en position 3 et 4 en vue d'étudier leur activité en tant que précurseurs de dipôles-1,3 et la diastéréosélectivité que peuvent apporter les substituants R^3 et R^4 (figure 2).

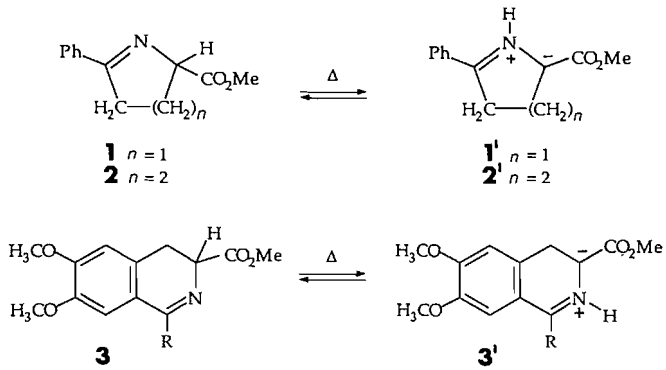

FIG. 1

Synthèse des précurseurs d'ylures d'azométhine cycliques 1 dérivés du 5-phényl-3,4-dihydro-2*H*-pyrrole-2-carboxylate de méthyle

Pour accéder à ces composés **1**, nous avions d'abord envisagé de nous inspirer de la stratégie mise en oeuvre par Mkhairi et Hamelin (14) dans le cas de **1***a* ($R^3 = R^4 = H$). Mais un examen de la littérature nous a conduit à choisir d'autres méthodes de synthèse comportant un nombre d'étapes plus réduit. En effet, les acides pyrrole-2-carboxyliques et leurs dérivés présentent un intérêt tant du point de vue de la chimie des substances naturelles que de celui de leur utilisation pharmacologique. Aussi n'est-il pas surprenant de trouver les travaux de nombreuses équipes ayant mis au point leurs propres méthodes de

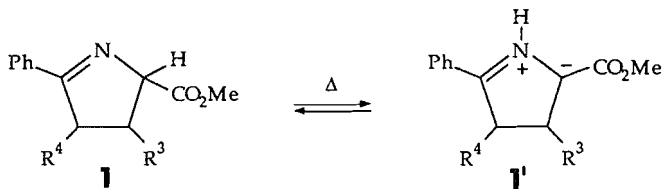

FIG. 2

synthèses en fonction de la structure particulière des dérivés recherchés. Les principales voies d'accès aux 2-carboxypyrrolines et pyrrolidines sont (*i*) les cycloadditions dipolaires [3+2] d'ylures d'azométhine sur des oléfines déficientes en électrons (16–18), (*ii*) la thermolyse de 2-azido-2,4-diénoates d'alkyle (19), (*iii*) et plus fréquemment les additions de Michaël de dérivés de la glycine et de l'acide aminomalonique aux alcènes activés (20–24).

C'est cette dernière voie que nous avons retenue en utilisant l'acétamidomalonate de diéthyle pour préparer les composés **1***a–e* et le chlorhydrate de l'aminomalonate de diéthyle pour obtenir les composés **1***f* et **1***g* (figure 3).

La synthèse des diesters acycliques **4** dérivés de l'acétamidomalonate de diéthyle a été menée à bien en adaptant un mode opératoire décrit par Leonard (22) et en améliorant certaines des réactions décrites par cet auteur. Ainsi le composé **4***a* ($R^3 = R^4 =$ H) est obtenu avec un rendement de 86% à partir de 3-bromopropiophénone au lieu de 68% à partir de la base de Mannich correspondante (22).

Pour obtenir les diesters cycliques **5***f* et **5***g*, nous avons utilisé la méthode de Koch et collaborateurs (21) qui consiste à chauffer le mélange des deux réactifs sans solvant (cf. partie expérimentale).

Les réactions successives d'hydrolyse acide par HCl 6 N puis d'estérification avaient déjà été décrites par Léonard (22) dans le cas du diester **4***a*. Nous les avons étendues aux cas de tous les composés **4** et **5** et obtenu les diverses pyrrolines **1***a–g* présentées sur la figure 3.

L'examen des valeurs de températures de fusion ou d'ébullition des composés **1** montre à l'évidence une grande disparité. Alors que le produit **1***f* fond à 220°C, on peut noter que le produit **1***c* fond à 60°C et que trois produits **1** sont restés huileux. Ceci n'est pas étonnant dans la mesure où la présence de deux et parfois trois centres de chiralité entraîne la possibilité d'existence de plusieurs diastéréoisomères pour ces composés (sauf **1***a*). Deux d'entre eux (**1***f* et **1***g*) ont été obtenus sous forme d'un seul diastéréoisomère (*trans* pour les groupes R^3 et R^4) et les autres (**1***b* à **1***e*) sous forme d'un mélange de deux diastéréoisomères.

Une étude configurationnelle et conformationnelle de ces diastéréoisomères est en cours.

En tout état de cause, l'existence des composés **1***b–e* sous forme d'un mélange de diastéréoisomères ne pose aucun

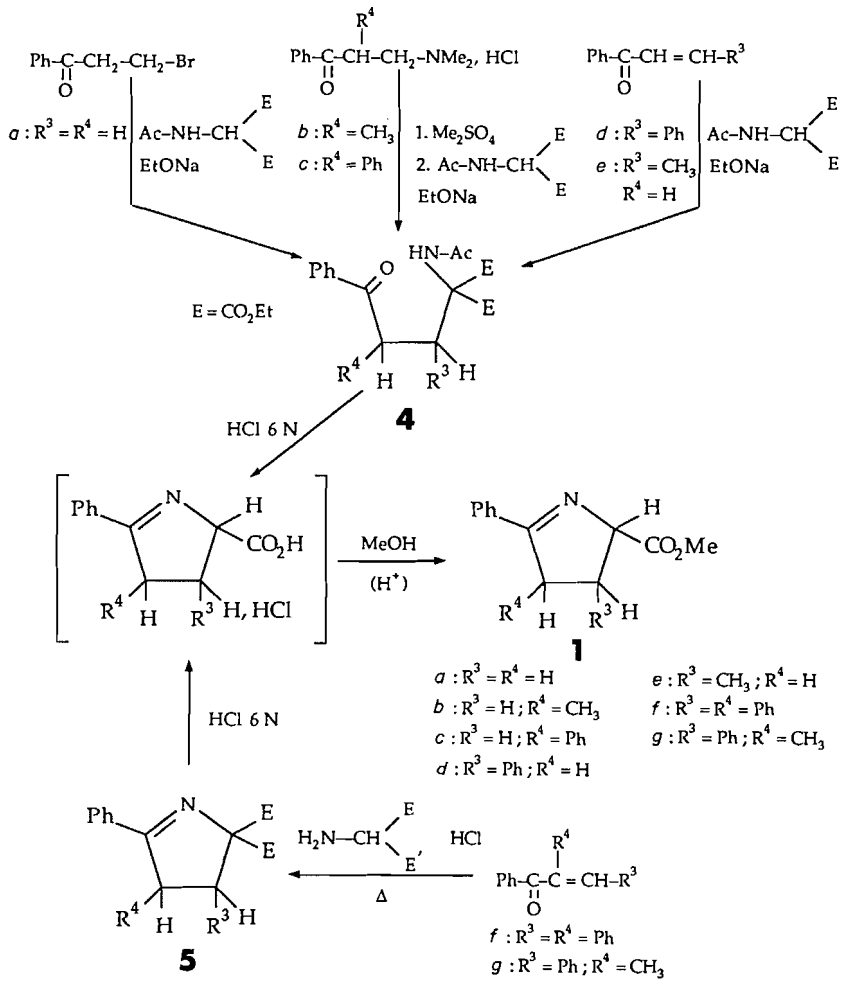

FIG. 3

6 R = CH_3
7 R = Ph

FIG. 4

problème pour l'étude diastéréochimique de la cycloaddition dipolaire puisqu'au cours de la réaction l'ylure d'azométhine **1′** ne présentera plus qu'un seul centre de chiralité.

Cycloaddition dipolaire-1,3 des ylures d'azométhine dérivés du 5-phényl-3,4-dihydro-2*H*-pyrrole-2-carboxylate de méthyle sur les *N*-méthyl et *N*-phénylmaléimides

Les imines dérivées d'α-aminoesters sont des précurseurs d'ylures d'azométhine dont la réactivité dipolaire-1,3 a été mise en évidence simultanément par Grigg et al. (25) et Joucla et Hamelin (26). Par la suite Mkhairi et Hamelin et Grigg et al. ont étudié ces motifs insérés dans une structure cyclique (14, 27).

Sur la base de ces travaux antérieurs, nous avons donc engagé les différentes imines **1** décrites ci-dessus avec divers dipolarophiles : acétylène dicarboxylate de diméthyle, fumarate et maléate de diéthyle, *N*-méthyl et *N*-phényl maléimide. Seuls ces deux derniers ont permis d'isoler un cycloadduit. La réaction est effectuée en tube scellé dans le toluène. Les rendements observés varient entre 55 et 79%. Nous avons ainsi obtenu 10 cycloadduits **6** et **7** dérivés du 1,4-imino-*exo*-2,3- dicarboximidocyclohexane.

Selon les cas, la numérotation du 7-aza-bicyclo[2,2,1]heptane débutera par le carbone tête de pont portant le reste phényle (R^4 = H, $R^3 \neq$ H) ou celui portant le groupe méthoxycarbonyl (R^3 = H, $R^4 \neq$ H) (figure 4).

Il faut noter que les ylures d'azométhine issus des imines **1***f* et **1***g* doublement substituées par les groupes R^3 et R^4 ne manifestent aucune réactivité en cycloaddition dipolaire-1,3. Dans ce cas les deux faces du dipôle portent un substituant et l'encombrement sur chacune des faces ne permet donc pas aux deux réactifs de s'approcher suffisamment près pour donner lieu à la réaction de cycloaddition. Cette observation constitue une preuve de la disposition *trans* des groupes R^3 et R^4 dans les imines **1***f* et **1***g*. Ceci laisse bien sûr augurer qu'avec les autres ylures d'azométhine **1** ne comportant qu'un seul substituant (R^3 ou R^4 = H) la réaction interviendra sur la face du dipôle la moins encombrée puisque dans chaque cas on n'obtient qu'un seul cycloadduit.

La réaction est donc doublement diastéréospécifique. La stéréochimie de la cycloaddition est élucidée par une étude radiocristallographique de la structure du composé **7***d* (28) représentée sur la figure 5. La stéréochimie est bien du type *exo* pour tous les substituants fixés sur les atomes de carbone 2, 3 et 5 de l'enchaînement 7-aza-bicyclo[2,2,1]heptane. L'approche du dipolarophile s'effectue à la fois dans le demi-espace le moins encombré du dipôle cyclique et de façon à conduire à une disposition *exo* pour le reste maléimido.

Ce dernier résultat est conforme à ce qui avait été observée par Mkhairi et Hamelin (14) d'une part et Grigg et al. (27) d'autre part dans le cas d'ylures d'azométhine cycliques non substitués. Il justifie en particulier les valuers des constantes de

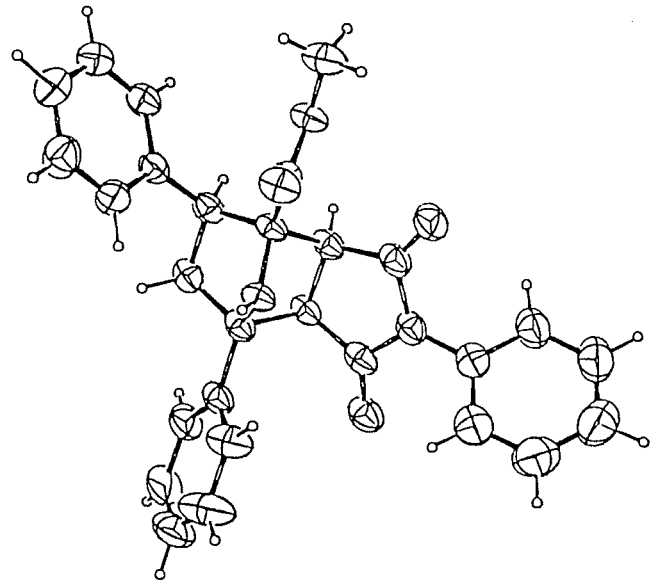

FIG. 5. Diagramne ORTEP du cycloadduit **7***d* (28).

couplage $^3J_{H2-H3}$ toutes comprises entre 6,9 et 7,1 Hz ce qui est en accord avec ce qui est généralement observé dans les systèmes du type norbornane (29) où $^3J_{Hexo-Hexo}$ = 9–10 Hz et $^3J_{Hendo-Hendo}$ = 6–9 Hz. De la même façon, on peut noter que pour tous les cycloadduits les constantes de couplages $J_{H5'-H6'}$ sont inférieures à 9 Hz ce qui implique que le substituant R^3 ou R^4 est en *exo*.

La disposition *exo* du reste maléimido est obtenue ici de façon spécifique alors que dans le cas d'autres ylures d'azométhine cycliques où l'ensemble dipolaire n'est pas complètement inséré dans le cycle on obtient un mélange résultant des deux approches *exo* et *endo*, cette dernière étant majoritaire (13, 30).

Cette apparente différence de comportement peut s'expliquer en examinant le mode d'approche des deux espèces réactantes, les dipolarophiles étant ici de configuration *Z* bloquée. On sait que les réactions de cycloaddition suivent la règle «*endo*» également appelée la règle de l'accumulation maximale de l'insaturation (31) de façon que les interactions entre les orbitales π du dipôle et du dipolarophile soient maximisées.

Lorsque l'entité dipolaire n'est pas complètement insérée dans le cycle comme c'est le cas dans l'étude présentée par Hamelin et coll. (30), l'approche des deux espèces s'effectue majoritairement de façon *endo* (figure 6) en conduisant au mélange des deux cycloadduits bien que le produit *exo* soit thermodynamiquement le plus stable.

Dans le cas de la présente étude, l'entité dipolaire est totalement insérée dans le cycle, et l'état de transition correspondant

For personal use only.

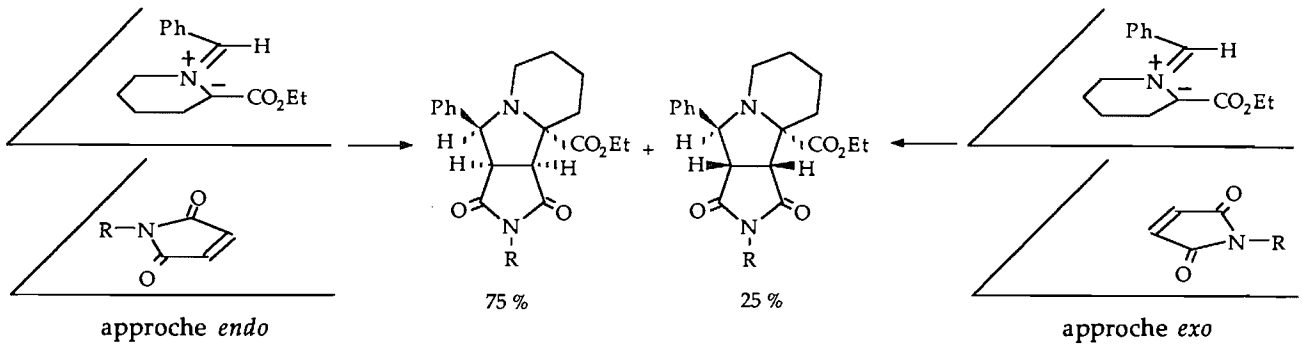

FIG. 6. Résultats décrits dans la référence 30.

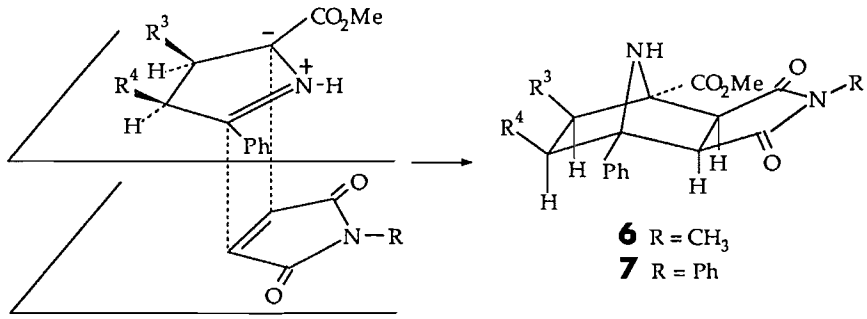

FIG. 7

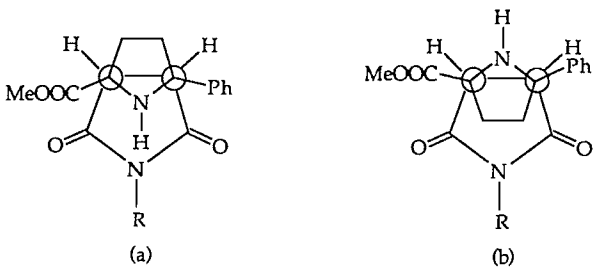

FIG. 8

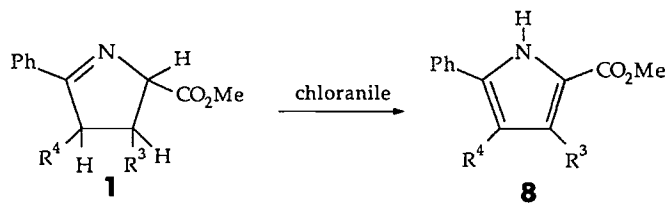

FIG. 9

à l'approche dite «*endo*» (figure 7) conduit au cycloadduit de stéréochimie *exo* puisque le reste maléimido se trouve du même côté que le pont 1,4-imino. C'est en même temps le produit thermodynamique.

Ce résultat peut aussi être expliqué en examinant les interactions stériques comme l'ont proposé Tsugé et al. (32). Les deux modes d'approche (a) et (b) dessinés sur la figure 8 représentent les deux états de transition possibles pour les réactions étudiées dans le présent travail (nous n'avons pas représenté les groupes R^3 ou R^4).

Dans le cas de (b) il existe quatre dispositions de type quasi-éclipsées autour des deux nouvelles liaisons qui se forment. Dans le cas de (a), par contre, la seule gêne stérique qui puisse intervenir est l'éventuelle répulsion entre le groupe N-H du dipôle et le groupe N-R du dipolarophile. Cette autre représentation met également en évidence, dans le cas de l'approche (a), la possibilité d'une stabilisation par interactions secondaires au niveau des orbitales frontières entre d'une part le phényle de l'ylure et l'un des groupes carbonyle du dipolarophile et d'autre part entre le groupe ester du dipôle et l'autre carbonyle du maléimide.

Il n'est donc pas étonnant d'obtenir diastéréospécifiquement le seul cycloadduit où le reste maléimido se trouve en position *exo*.

Synthèse de dérivés du 2-méthoxycarbonyl-5-phénylpyrrole

Disposant de sept composés dérivés du 5-phényl-3,4-dihydro-2*H*-pyrrole-2-carboxylate de méthyle nous avons complété cette étude en les transformant en dérivés du pyrrole par action du chloranile (figure 9).

Bien que les rendements restent très moyens, nous disposons donc d'une méthode permettant d'accéder à ces dérivés du 5-phénylpyrrole-2-carboxylate de méthyle diversement substitués sans qu'il soit nécessaire de séparer les divers diastéréoisomères des composés **1** lorsqu'on a affaire à un mélange.

Partie expérimentale

Les points de fusion déterminés sur banc Kofler ne sont pas corrigés. Les spectres d'absorption ir ont été obtenus avec un spectrophotomètre Beckman IR 33, les produits étant pastillés dans KBr. Les spectres de rmn ^1H ont été obtenus avec un spectromètre Bruker Spectrospin AC 200, les échantillons étant dissous dans $CDCl_3$ ou DMSO-d_6 avec le tétraméthylsilane comme référence interne. Les microanalyses ont été assurées par le Service d'Analyses du Centre national de la recherche scientifique à Vernaison.

1. Synthèse des diesters **4**

1.1. Synthèse de la 4-acétamido-4,4-diéthoxycarbonyl-1-phénybutan-1-one **4**a *($R^3 = R^4 = H$)*

Dans un Erlenmeyer de 100 mL, on dissout 1,36 g (0,02 mol) d'éthylate de sodium dans 25 mL d'éthanol anhydre. On ajoute alors 4,34 g

(0,02 mol) d'acétamidomalonate de diéthyle. Sous agitation magnétique, on additionne en 15 min 4,26 g (0,02 mol) de 3-bromopropiophénone. Le mélange est porté à reflux durant 18 h. Après refroidissement, la suspension obtenue est versée dans 100 mL d'eau glacée. Le solide est filtré et recristallisé dans l'isopropanol. Rdt. 86%, F = 119–120°C (litt. (22) F 119°C).

1.2. Synthèse de la 4-acétamido-4,4-diéthoxycarbonyl-2-méthyl-1-phénylbutan-1-one **4**b *(R^3 = H, R^4 = CH_3)*

Le chlorhydrate de 2-méthyl-3-diméthylaminopropiophénone est préparé selon un mode opératoire décrit dans la littérature (33, 34) avec un rendement de 81%. À une suspension de 0,05 mol de ce chlorhydrate dans 25 mL d'éthanol absolu, on additionne goutte à goutte, à température ambiante et en 30 min, 0,06 mol de sulfate de diméthyle. Une solution contenant 0.04 mol (8,68 g) d'acétamidomalonate de diéthyle et 0,08 mol (5,44 g) d'éthylate de sodium dans 30 mL d'éthanol absolu est rapidement ajoutée à la solution précédente. Le mélange est porté à reflux durant 5 h. Après retour à la température ambiante, la solution laiteuse obtenue est versée sur de la glace. On extrait à l'éther, lave la phase éthérée à l'eau, sèche sur sulfate de sodium et chasse l'éther. Le produit est purifié par distillation sous pression réduite. Rdt. 65%; Eb : 180–184°C (0,5 Torr; 1 Torr = 133,3 Pa); n_D^{20} = 1,5109; ir : ν(CO) = 1680 cm^{-1}, ν(NH) = 3360 cm^{-1}; rmn ^{1}H ($CDCl_3$) : 1,15 (d, 3H, J = 7,1), 1,20 (t, 3H, J = 7,0), 1,25 (t, 3H, J = 7,0), 1,80 (3H, s, CH_3-CO), 2,60 (dd, 1H, ^2J = 14,7, ^3J = 3,2), 3,00 (dd, 1H, ^2J = 14,7, ^3J = 9,7), 3,62 (ddq, 1H, ^3J = 9,7, ^3J = 3,2, ^3J = 7,1), 4,20 (m, 4H), 6,70 (sl, 1H, NH), 7,40–8,10 (m, 5H). Anal. calc. pour $C_{19}H_{25}NO_6$: C 62,79, H 6,93, N 3,85; tr. : C 63,01, H 6,78, N 3,73%.

1.3. Synthèse de la 4-acétamido-4,4-diéthoxycarbonyl-1,2-diphénylbutan-1-one **4**c *R^3 = H, R^4 = Ph)*

Le chlorhydrate de la 2-phényl-3-diméthylaminopropiophénone est préparé selon un mode opératoire adapté de ceux décrits dans la littérature (33, 34). Rdt. 55%; F = 204–206°C; ir : ν(CO) = 1675 cm^{-1}, ν(NH) = 3352 cm^{-1}; rmn ^{1}H ($CDCl_3$) : 2,70 (s, 3H), 2,80 (s, 3H), 3,10–4,45 (m, 3H), 5,80–6,10 (m, 1H), 7,20–8,30 (m, 10H).

Ce chlorhydrate est traité par l'acétamidomalonate de diéthyle selon le même protocole opératoire que celui décrit pour la préparation de **4***b*. Le traitement du brut réactionnel par de l'eau glacée permet d'obtenir un précipité qui est recristallisé dans l'isopropanol. Rdt. 68%; F = 104–106°C; ir : ν(CO) = 1678 cm^{-1}; rmn ^{1}H ($CDCl_3$) : 1,10 (t, 3H, J = 7,0); 1,25 (t, 3H, J = 7,0), 1,90 (s, 3H, CH_3-CO), 2,94 (dd, 1H, ^2J = 14,7, ^3J = 5), 3,27 (dd, 1H, ^2J = 14,7, ^3J = 8,2), 4,00–4,30 (m, 4H), 4,78 (dd, 1H, ^3J = 8,2, ^3J = 5), 6,70 (sl, 1H, NH), 7,15–7,95 (m, 10H). Anal. calc. pour $C_{23}H_{27}NO_6$: C 66,81, H 6,58, N 3,39; tr. : C 67,05, H 6,37, N 3,42%.

1.4. Synthèse de la 4-acétamido-4,4-diéthoxycarbonyl-1,3-diphénylbutan-1-one **4**d *(R^3 = Ph, R^4 = H)*

On dissout 0,002 mol (0,136 g) d'éthylate de sodium dans 50 mL d'éthanol absolu et ajoute 0,05 mol (10,85 g) d'acétamidomalonate de diéthyle. À la suspension obtenue, on additionne goutte à goutte à température ambiante et sous agitation magnétique une solution de 0,05 mol (10,5 g) de chalcone. Le mélange est agité à température ambiante durant 18 h puis neutralisé par 0,5 mL d'acide acétique glacial. Le solvant est éliminé, puis repris par du chloroforme, lavé à l'eau et séché sur sulfate de sodium. Après filtration et départ du solvant, le résidu est recristallisé dans l'isopropanol. Rdt. 78%; F = 102–104°C; ir : ν(CO) = 1675 cm^{-1}, ν(NH) = 3340 cm^{-1}; rmn ^{1}H ($CDCl_3$) : 1,20 (t, 3H, J = 7,0), 1,25 (t, 3H, J = 7,0), 2,10 (s, 3H, CH_3-CO), 3,40 (dd, 1H, ^2J = 17,4, ^3J = 11,5), 4,25 (dd, 1H, ^2J = 17,4, ^3J = 2,4), 4,00–4,30 (m, 4H), 4,53 (dd, 1H, ^3J = 11,5, ^3J = 2,4), 6,70 (sl, 1H, NH), 7,20–7,95 (m, 10H). Anal. calc. pour $C_{23}H_{27}NO_6$: C 66,81, H 6,58, N 3,39; tr. : C 66,98, H 6,45, N 3,47%.

1.5. Synthèse de la 4-acétamido-4,4-diéthoxycarbonyl-3-méthyl-1-phénylbutan-1-one **4**e *(R^3 = CH_3, R^4 = H)*

L'énone mise en oeuvre est la 1-phénylbut-2-èn-1-one obtenue selon le mode opératoire décrit par Fuson et al. (35). Celle-ci est mise en oeuvre selon le même protocole opératoire que celui décrit pour **4***d* et conduit à l'obtention de **4***e* avec un rendement de 74% après cristallisation de l'isopropanol. F = 118–120°C; ir : ν(CO) = 1670 cm^{-1}, ν(NH) = 3365 cm^{-1}; rmn ^{1}H ($CDCl_3$) : 0,90 (d, 3H, J = 6,7), 1,24 (t, 3H, J = 7,1), 1,28 (t, 3H, J = 7,1), 2,10 (s, 3H, CH_3-CO), 2,55 (dd, 1H, ^2J = 16,7, ^3J = 10,7), 3,30 (ddq, 1H, J = 6,7, ^3J = 10,7, ^3J = 2,2), 3,94 (dd, 1H, ^2J = 16,7, ^3J = 2,2), 4,15–4,36 (m, 4H), 6,75 (sl, 1H, NH), 7,40–8,10 (m, 5H). Anal. calc. pour $C_{19}H_{25}NO_6$: C 62,79, H 6,93, N 3,85; tr. : C 62,93, H 6,85, N 3,92%.

2. Synthèse des diesters **5**

Nous avons utilisé la méthode de Koch et coll. (21).

On mélange soigneusement 0,015 mol d'énone et 0,021 mol de chlorhydrate d'aminomalonate de diéthyle dans un Erlenmeyer de 100 mL. On porte à 170–180°C dans un bain d'huile paraffinique. On observe un dégagement de vapeurs de gaz chlorhydrique. Peu à peu le mélange se liquéfie, devient jaune soufre puis jaune clair. La réaction est terminée lorsque les vapeurs disparaissent. Après retour à la température ambiante, on ajoute 150 mL d'eau et 150 mL de benzène. La phase organique est séparée, lavée à l'eau salée, filtrée sur charbon actif et séchée sur sulfate de sodium. Après évaporation du solvant, le résidu est chromatographié sur gel de silice avec le benzène comme éluant.

*2.1. 3,4,5-Triphényl-3,4-dihydro-2*H*-pyrrole-2,2-dicarboxylate de diéthyle* **5**f *(R^3 = R^4 = Ph)*

L'énone de départ est l'α-phénylchalcone obtenue selon Dornow (36). Rdt. 39%; F = 132–134°C (méthanol); ir : ν(CO) = 1720 et 1740 cm^{-1}; rmn ^{1}H ($CDCl_3$) : 0,80 (d, 3H, J = 7,0), 1,35 (t, 3H, J = 7,0), 3,7 (AB d'un ABX_3, 2H, $^2J_{AB}$ = 10,6, J = 7,0), 4,40 (AB d'un ABX_3, 2H, $^2J_{AB}$ = 11,0, J = 7,0), 4,47 (d, 1H, J = 8,2), 5,00 (d, 1H, J = 8,2), 7,00–7,80 (m, 15H). Anal. calc. pour $C_{28}H_{27}NO_4$: C 76,16, H 6,16, N 3,17; tr. : C 76,29, H 6,05, N 3,22%.

*2.2. 3,5-Diphényl-4-méthyl-2*H*-pyrrole-2,2-dicarboxylate de diéthyle* **5**g *(R^3 = Ph, R^4 = CH_3)*

L'énone de départ est l'α-méthylchalcone obtenue selon Kohler (37). Rdt. 56%, F = 116–118°C (méthanol); ir : ν(CO) = 1730 et 1750 cm^{-1}; rmn ^{1}H ($CDCl_3$) : 0,80 (d, 3H, J = 7,0), 1,25 (t, 3H, J = 7,0), 1,30 (d, 3H, J = 7,0), 3,65 (AB d'un ABX_3, 2H, $^2J_{AB}$ = 10,6, J = 7,0), 3,80 (dq, 1H, J = 7,0, J = 5,6), 4,10 (d, 1H, J = 5,6), 4,32 (AB d'un ABX_3, 2H, $^2J_{AB}$ = 11,0, J = 7,0), 7,20–7,90 (m, 10H). Anal. calc. pour $C_{23}H_{25}NO_4$: C 72,80, H 6,64, N 3,69; tr. : C 72,95, H 6,53, N 3,57%.

3. Synthèse des dérivés du 5-phényl-3,4-dihydro-2H-pyrrole-2-carboxylate de méthyle **1**

La transformation des diesters **4** ou **5** en imines cycliques **1** a été effectuée selon un mode opératoire adapté de celui de Léonard (22).

Un mélange de 0,05 mol de diester **4** ou **5** et de 400 mL d'acide chlorhydrique 6 N est porté à reflux pendant 18 h. Après refroidissement, la solution est lavée à l'éther puis distillée sous pression réduite à l'évaporateur rotatif. L'huile résiduelle est reprise plusieurs fois par 50 mL de benzène qui est évaporé pour éliminer les traces d'eau. Le chlorhydrate de l'imino-acide brut est dissout dans 130 mL de méthanol absolu. On ajoute une quantité catalytique d'acide sulfurique concentré (3 mL) et porte à reflux pendant 3 h. Après retour à la température ambiante, on élimine le méthanol sous pression réduite. Le résidu est repris par l'eau puis porté à pH 8 par addition de carbonate de sodium solide. On extrait à l'éther ou au chloroforme. Les extraits organiques sont rassemblés, lavés et séchés sur sulfate de sodium. Après filtration et évaporation du solvant, on recristallise dans le cas des solides et distille sous pression réduite dans le cas des liquides.

*3.1. 5-Phényl-3,4-dihydro-2*H*-pyrrole-2-carboxylate de méthyle* **1**a *(R^3 = R^4 = H).* Rdt. 82%, F = 50°C (iPrOH) (litt. (22) F = 50°C); ir : ν(CO) = 1730 cm^{-1}; rmn ^{1}H ($CDCl_3$) : 2,20–2,40 (m, 2H), 3,00–3,20 (m, 2H), 3,80 (s, 3H, OCH_3), 4,95 (dddd, 1H, J = 8,0, J = 6,4, J = 1,9, J = 1,9, H^2), 7,35–7,95 (m, 5H).

5. Oxydation des dérivés **1** *en pyrroles* **8**

Mode opératoire général

À une solution de 5 mmol de composé **1** dans 20 mL de xylène (mélange des isomères) on ajoute 5,5 mmol de parachloranile. Le mélange est porté à reflux pendant 16 h. Après refroidissement, on dilue avec 50 mL d'éther et verse sous agitation magnétique dans 100 mL d'une solution aqueuse de carbonate de sodium à 5%. Les deux phases sont séparées et la phase organique est lavée à l'eau jusqu'à neutralité, filtrée sur charbon actif puis séchée sur sulfate de sodium. Après filtra-

6. Structure cristallographique du cycloadduit 7d *(résumé)*

Cette étude est décrite complètement dans la référence 28.

$C_{28}H_{24}N_2O_4$ M_r = 452,5

Groupe spatial $P2_1/c$ (monoclinique). a = 13,321(3) Å; b = 14,566(2) Å; c = 11,625(2) Å; β = 92,18(2)°; V = 2254(1) $Å^3$ Z = 4; D_x = 1,383 Mg m^{-3}; λ(MoKα) = 0,7107 Å; μ = 84 m^{-1}; F(000) = 952 électrons T = 290 K; R final = 0,037 pour 2420 réflexions indépendantes.

Des monocristaux du composé 7*d* ont été obtenus par cristallisation dans le toluène. Le cristal choisi avait la forme d'un parallelepipède dont les dimensions approximatives étaient 0,27 × 0,30 × 0,50 mm. Les mesures des intensités des taches de diffraction ont été réalisées sur un diffractomètre automatique 4 cercles Enraf–Nonius de l'Université de Paris-Sud. De l'ensemble des paramètres (28) on peut extraire les valeurs des angles de torsion significatifs :

H3-C3-C4-N7 = 159,8°; H2-C2-C1-N7 = 154,7°;

H5-C5-C4-N7 = 147,9°

Ces valeurs indiquent que le substituant R^3 = Ph et le reste maléimido sont en disposition *exo* (figure 5).

Comportement particulier d'arylidènebenzothiazinonedioxydes dans les cycloadditions [3+2]. Compétition entre sites dipolarophiliques. Évolution des cycloadduits

TOUFIK FATHI, KABULA CIAMALA, NGUYEN DINH AN[1] ET JOËL VEBREL

Laboratoire de chimie organique, Université de Franche-Comté, 16 Route de Gray, 25030 Besancon, France

Reçu le 21 juillet 1993

TOUFIK FATHI, KABULA CIAMALA, NGUYEN DINH AN et JOËL VEBREL. Can. J. Chem. **72**, 1424 (1994).

La réaction de la diphénylnitrilimine sur quelques arylidènebenzothiazinonedioxydes conduit à un mélange de deux produits séparables par chromatographie. Les données spectroscopiques (infrarouge, résonance magnétique nucléaire) et une étude radiocristallographique permet de démontrer une compétition des deux sites dipolarophiliques au cours des cycloadditions dipolaires.

TOUFIK FATHI, KABULA CIAMALA, NGUYEN DINH AN, and JOËL VEBREL. Can. J. Chem. **72**, 1424 (1994).

The reaction of diphenylnitrilimine with some arylidenebenzothiazinone dioxides leads to a mixture of two products that were isolated by chromatography. Spectroscopic data (infrared, nuclear magnetic resonance) and a radiocrystallographic study illustrate a competition between the two dipolarophilic sites in dipolar cycloaddition.

Introduction

La synthèse des (2*H*)-1,2-benzothiazine-4(3*H*)-1,1-dioxydes a été largement développée ces dernières années compte tenu des propriétés anti-inflammatoires potentielles (1, 2). Par ailleurs, certains de ces dérivés présentent des aptitudes dipolarophiliques au cours des réactions de cycloaddition dipolaire (3, 4).

La cycloaddition dipolaire-1,3 des diarylnitrilimines sur plusieurs 2-arylidènetétraline-1-ones, 3-arylidènechroman-4-ones, 3-arylidèneisochroman-4-ones, 3-arylidènethiochroman-4-ones et 3-arylidèneisothiochroman-4-ones a été réalisée récemment au sein de notre équipe de recherche. L'influence des facteurs conformationnels sur la diastéréochimie de la réaction a été mise en évidence grâce à la rmn ^1H et du ^{13}C (5). La structure des 3-arylidène-2*H*-1,2-benzothiazine- 4(3*H*)- one-1,1-dioxydes **1** (figure 1) étant proche des dipolarophiles antérieurement utilisés, nous nous sommes proposés d'étudier leurs comportements dipolarophiliques vis-à-vis de la diphénylnitrilimine afin de préciser la régiochimie de la réaction ainsi que le comportement des cycloadduits en milieu acide.

Réactions de cycloaddition de la diphénylnitrilimine sur les 3-arylidène-2*H*-1,2-benzothiazine-4(3*H*)-one-1,1 dioxydes 1

La réaction de cycloaddition dipolaire-1,3 conduit à des dérivés de la spiro(1,3,4-triaryl Δ-2pyrazoline-5;2′ benzothiazine-1′-one) **2** (cycloadduit attendu compte tenu de nos précédents résultats (5)) ainsi qu'aux produits **3** inattendus qui ne seraient ni régioisomère, ni diastéréoisomère de **2** au vu des résultats spectroscopiques (ir, rmn ^1H et ^{13}C, masse) (figure 1).

Pour tous les termes de la série, les spectres de rmn protonique des bruts réactionnels permettent d'observer les signaux correspondants aux produits **2** et **3** dont les proportions sont accessibles par examen des courbes d'intégration. Les composés **2** et **3** sont aisément séparés par chromatographie en phase liquide sur silice.

Mode d'approche dipole–dipolarophile au cours de la cycloaddition

Les paramètres de rmn protonique des dipolarophiles **1** (en solution soit dans $CDCl_3$, soit dans C_6D_6) ne permettent pas à priori de déterminer la stéréochimie de la double liaison éthylénique juxtacyclique. En effet, une première observation montre que dans tous les cas, on n'observe pas un effet de solvant ASIS marquant pour le proton éthylénique. Toutefois, le fait que ce proton soit fortement déblindé (8,2–8,3 ppm) indiquerait tout de même qu'il est en *cis* par rapport au groupe carbonyle et que les composés **1** seraient donc les isomères de structure *E* par rapport à la double liaison éthylénique juxtacyclique. Nous avons déjà observé cette isomérie géométrique *E* pour les dérivés des 2-arylidènetétraline-1-ones (5).

Les valeurs des fréquences d'absorption infrarouge de la vibration ν(C=O) de 1660–1670 cm^{-1} pour les dipolarophiles **1** indiquent que le groupe carbonyle et le noyau benzènique condensé sont conjugués et donc coplanaires. La conformation privilégiée du cycle cétonique serait donc la conformation diplanaire-1,3 dite «sofa» (figure 1) où les sommets 2, 1, 8a, 4a, 4 sont dans un même plan et l'atome d'azote 3 est au-dessus de ce plan; le groupe méthyle porté par l'azote adopterait une position axiale car il est suffisamment encombrant pour ne pas pouvoir adopter une position équatoriale. Une telle conformation du groupement-NCH_3 laisse prévoir une approche *anti* du dipôle (côté opposé du groupement -NCH_3).

Analyses spectroscopiques des cycloadduits 2

L'existence d'un singulet à 5,4 ppm en rmn ^1H pour le proton H4, et celle des protons aromatiques entre 6,7 et 8 ppm, la fréquence de la bande d'absorption ir à 1700 cm^{-1} de la fonction cétone conjuguée indiquent que les produits **2** sont bien des cycloadduits. Ce sont des spiropyrazolines dont le sommet commun est l'atome 5 de la pyrazoline et l'atome 2′ de la benzothiazinone. Cette régiochimie est prouvée par l'examen des paramètres de rmn ^{13}C puisque la forte valeur du déplacement chimique du carbone quaternaire de jonction spirannique C-5:2′ comprise entre 94,5 et 94,7 ppm est en accord avec un carbone lié d'une part à l'atome d'azote 3′ et d'autre part à l'extrémité azotée du dipôle. On observe aussi un pic à 190 ppm caractéristique d'une fonction cétone (C-1′ de **2**). La régiochimie ainsi définie est conforme à nos observations antérieures : au cours de la cycloaddition des diarylnitrilimines avec divers dipolarophiles, l'extrémité azotée du dipôle se fixe toujours sur l'atome de carbone du dipolarophile porteur d'un groupe électroattracteur (6–11).

En spectrométrie de masse, l'ion moléculaire $2^{+\cdot}$ se réarrange avec perte de 169 unités de masse pour conduire à l'ion radical **2′** (figure 2).

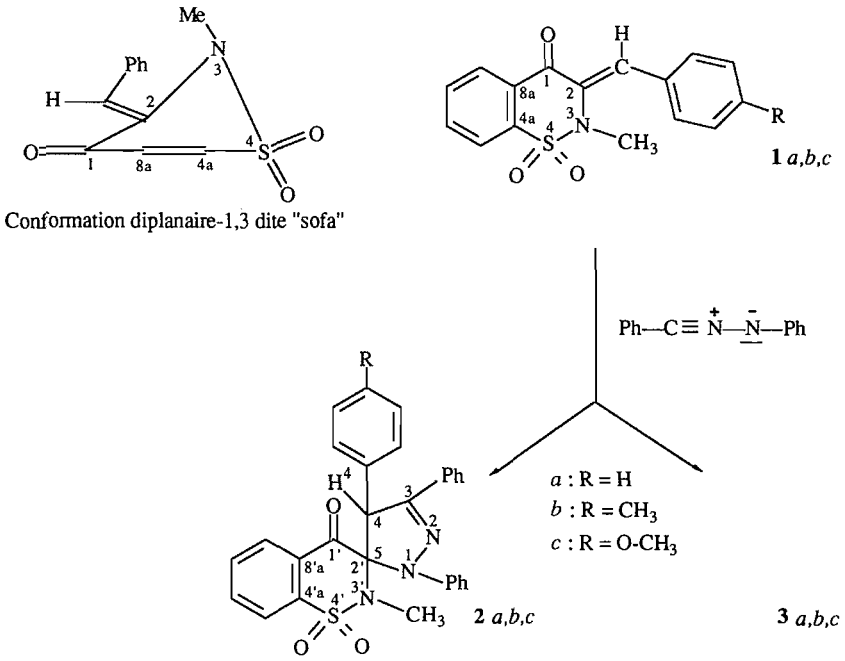

FIG. 1

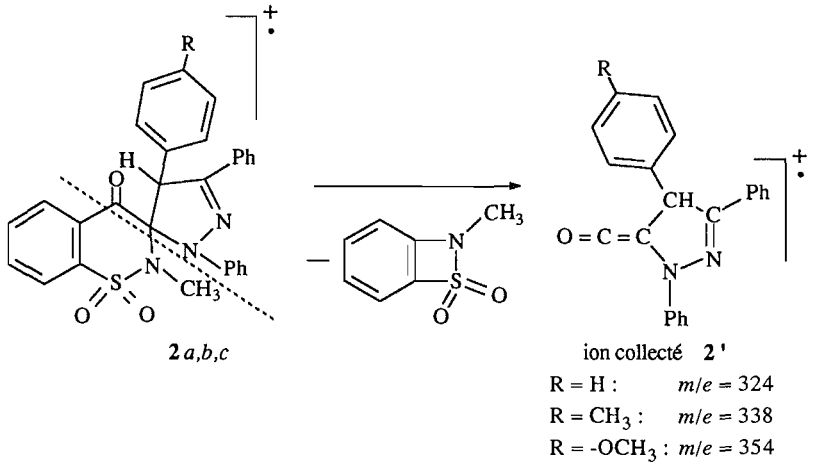

FIG. 2

Analyses spectroscopiques des produits 3

Compte tenu des observations faites pour des cycloadditions réalisées avec des produits comparables à **1** (6–11), il serait plausible de penser que les produits **3** pourraient être les régioisomères de **2** c'est-à-dire des dérivés de la spiro (1,3,5-triaryl-Δ-2-pyrazoline-4:2′-benzothiazine-1′-one).

Les données spectroscopiques ne permettent pas de retenir cette hypothèse. En effet, l'absence en rmn ^{13}C du signal vers 80 ppm pour le carbone de jonction spirannique tendrait à prouver que le produit **3** n'est pas le régioisomère de **2** mais peut être un produit d'évolution. On observe d'autre part en ir deux bandes d'absorption entre 1610 et 1660 cm^{-1} attribuables respectivement aux groupements C=C et C=O d'une fonction amide. On remarque par ailleurs pour les produits **3** un signal à 66 ppm pour un carbone tertiaire au lieu de 58 ppm dans le cas des composés **2**. Cette valeur de 66 ppm suggère une liaison entre l'atome de carbone tertiaire et un atome d'azote. L'existence d'un signal à 173 ppm est plutôt en faveur d'une fonction amide dans les composés **3** (au lieu de 190 ppm pour la fonction cétone des composés **2**). En spectrométrie de masse, on note une perte de 105 unités de masse caractéristique de l'ion benzoyle Ph-C≡O$^+$.

Une étude radiocristallographique (12) de **3***c* nous a permis d'accéder à la structure des composés **3** (figure 3). L'examen de cette structure démontre que la cycloaddition de la diphénylnitrilimine sur les dipolarophiles **1** s'effectue compétitivement sur la double liaison C=O et sur la double liaison C=C juxtacyclique. L'intermédiaire **A** obtenu lors de la réaction de la diphénylnitrilimine sur le site dipolarophilique C=O subit ensuite un réarrangement conduisant aux dérivés **3** (figure 4).

Pour confirmer cette hypothèse, nous avons effectué la cycloaddition d'une diarylnitrilimine sur un dipolarophile de même type que **1** mais ne comportant que le site dipolarophilique C=O (composé **4**) (figure 5). Nous avons pu ainsi observer une cycloaddition suivie d'un réarrangement conduisant au composé **5** (figure 5). Nous confirmons par la même

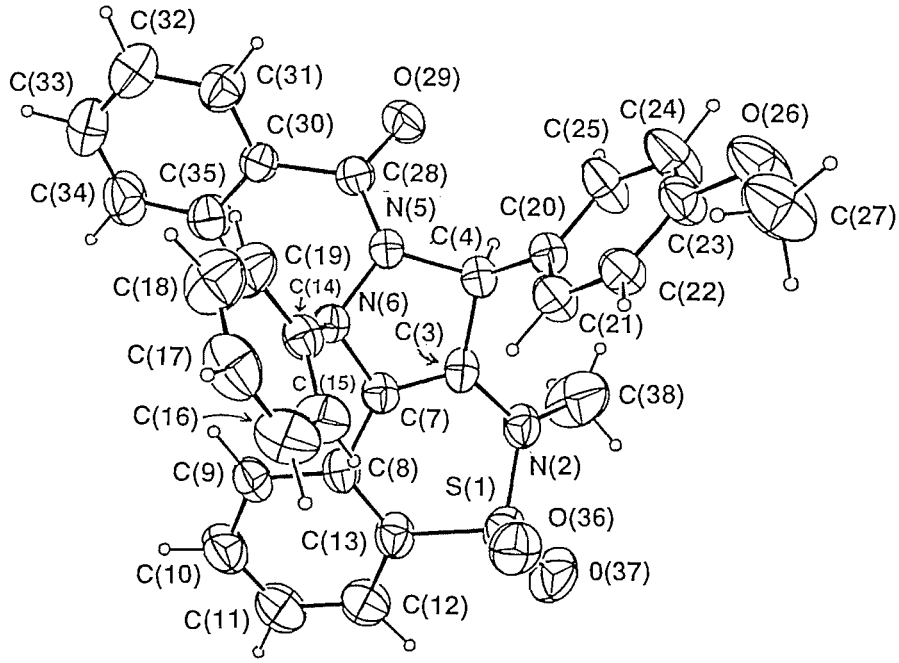

FIG. 3

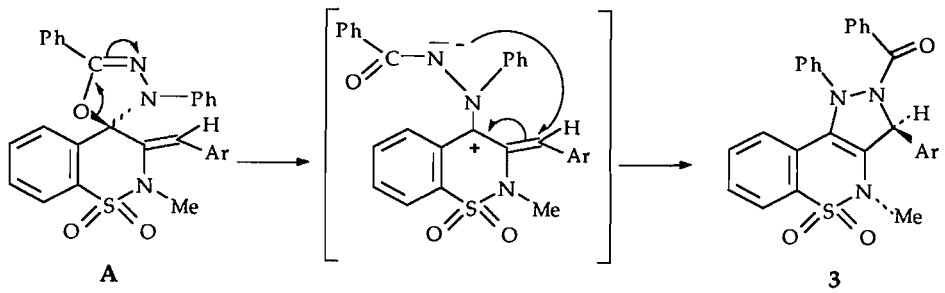

FIG. 4

occasion une compétition des deux sites dipolarophiliques des composés **1** au cours de la réaction de cycloaddition dipolaire.

La comparaison de l'aptitude réactionnelle des deux sites dipolarophiliques des composés **1** vis-à-vis des diarylnitrilimines avec celle conduisant à l'unique cycloadduit lors de la cycloaddition des mêmes dipôles sur les dérivés des arylidènetétraline-1-ones, chroman-4-ones, thiochroman-4-ones, isochroman-4-ones et isothiochroman-4-ones citées en introduction (5) nous permet de dire que le groupement SO_2 des dipolarophiles **1** active la fonction carbonyle. Par ailleurs, il n'y aurait pas d'activation par le groupement donneur $-NCH_3$ en position 3. Ceci est confirmé par les résultats obtenus avec les arylidèneisochroman-4-ones et isothiochroman-4-ones qui possèdent un groupement donneur en position 3 et qui ne présentent pas d'activité dipolarophilique au niveau du groupement carbonyle.

Étude du comportement des cycloadduits 2*a* et 2*b* en milieu acide

Les observations qui suivent se limitent au traitement acide des cycloadduits **2***a* et **2***b* car les transformations des autres produits **2***c* et **3***a*, *b*, *c* se sont révélées hasardeuses par suite de la formation de mélanges difficilement séparables.

Dans les deux cas, l'attaque par un acide fort (acide trifluoro-

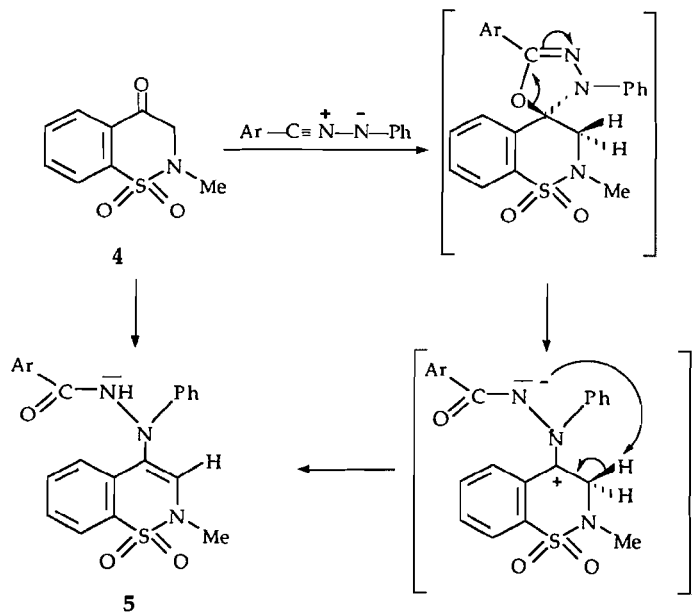

FIG. 5

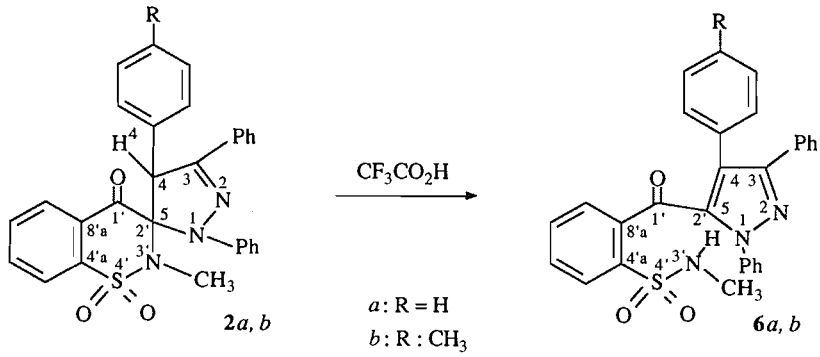

FIG. 6

acétique) aboutit à un sulfonamide **6** résultant de l'ouverture du cycle intermédiaire à la jonction spirannique entre l'atome de carbone C-5:2′ et l'atome d'azote en position 3′ (figure 6). En infrarouge, les composés **6** présentent une bande d'absorption à 1660 cm^{-1} caractéristique d'une fonction cétone fortement conjuguée. En rmn ^1H, on observe un signal fortement déblindé à 15,1 ppm attribuable au proton porté par l'atome d'azote du groupe sulfonamide. Le groupement méthyle porté par ce même atome d'azote apparaît sous la forme d'un doublet vers 3,1 ppm. La disparition du signal singulet à 15,1 ppm par addition de D_2O prouve qu'il s'agit d'un proton mobile. L'irradiation de ce proton simplifie le signal du -NCH_3 en singulet : ce proton et le groupe méthyle sont couplés entre eux et donc portés par l'atome d'azote en position 3′. En rmn ^{13}C, l'absence des signaux correspondant au carbone quaternaire de jonction spirannique et au carbone tertiaire C-4 confirme bien la structure **6**.

Conclusion

La cycloaddition de la diphénylnitrilimine sur des arylidènebenzothiazinonedioxydes a été étudiée. L'obtention de deux produits n'est pas à relier aux problèmes habituels de régio- ou de diastéréochimie. Elle résulte de la compétition entre les deux sites dipolarophiliques, la double liaison C=C arylidènique et le carbonyl cétonique. Dans le premier cas une pyrazoline est isolée et caractérisée. Dans le second cas, l'adduit subit un réarrangement inattendu conduisant à un produit d'évolution caractérisé sur la base des données spectroscopiques et d'une analyse radiocristallographique.

Partie expérimentale

Les points de fusion déterminés sur banc Kofler ne sont pas corrigés. Les spectres d'absorption ir ont été obtenus avec un spectrophotomètre Beckman IR 33, les produits étant pastillés dans KBr. Les spectres de rmn ont été obtenus avec un spectromètre Bruker Spectrospin AC 200 (200 MHz pour le proton et 50 MHz pour le ^{13}C), les échantillons étant dissous dans $CDCl_3$ (sauf indication contraire) avec le tétraméthylsilane comme référence interne. Les spectres de masse ont été enregistrés sur un spectromètre Hewlett-Packard MS Engine sous impact électronique (70 eV). Les ions moléculaires sont confirmés par l'observation de $(M + 1)^{+\cdot}$ en mode d'ionisation chimique avec le méthane comme gaz réactant. Les microanalyses ont été assurées par le Service d'Analyses du CNRS à Vernaison.

Les précurseurs de la diphénylnitrilimine et des diarylnitrilimines sont préparés selon la méthode de Huisgen et al. (13).

3-Arylidène-2H-1,2-benzothiazine-4(3H)-one-1,1-dioxydes ***1***

Ces produits ont été préparés suivant les modes opératoires décrits par Zinnes et al. (14). Les produits **1** sont cristallisés dans l'acétonitrile et chacun d'eux est décrit ci-après.

3-Benzylidène-2H-1,2-benzothiazine-4(3H)-one-1,1-dioxyde (***1***a). Rdt. 77%, *F* 163°C; ir, ν_{max} : 1670 (cétone); rmn ^1H, δ : 3,00 (s, 3H, N-CH_3), 7,50–8,20 (m, 10H).

3-p-Méthylbenzylidène-2H-1,2-benzothiazine-4(3H)-one-1,1-dioxyde (***1***b). Rdt. 76%, *F* 194°C; ir, ν_{max} : 1660 (cétone); rmn ^1H, δ : 2,40 (s, 3H, -CH_3), 3,00 (s, 3H, -N-CH_3), 7,30–8,20 (m, 9H).

3-p-Méthoxybenzylidène-2H-1,2-benzothiazine-4(3H)-one-1,1-dioxyde (***1***c). Rdt. 76%, F 171°C; ir, ν_{max} : 1665 (cétone); rmn ^1H, δ : 3,00 (s, 3H, -N-CH_3), 3,90 (s, 3H, -OCH_3), 7,00–8,20 (m, 9H).

Réactions de cycloadditions

Dans un Erlenmeyer bicol de 100 mL, on introduit 10 mmol du dipolarophile **1** et 10 mmol de l'α-chlorobenzylidènephénylhydrazone précurseur du dipôle dans 30 mL de benzène anhydre. On chauffe ce mélange à reflux sous agitation magnétique en additionnant en 15 min 2 mL de triéthylamine. Le reflux est maintenu durant 12 h. Après retour à la température ordinaire, on ajoute 20 mL de benzène, filtre le chlorhydrate de triéthylamine et élimine le solvant à l'évaporateur rotatif. Le résidu est séparé par chromatographie en phase liquide avec le chloroforme comme éluant sur la silice comme phase stationnaire. Les cycloadduits **2** et **3** ainsi séparés sont recristallisés dans l'éthanol.

*Traitement acide des cycloadduits **2**a, **2**b*

Dans un ballon de 50 mL, on introduit 1,5 mmol de cycloadduits **2** et 20 mL d'acide trifluoracétique. La solution obtenue est chauffée à 50°C pendant 1 h puis versée dans un mélange eau-glace. On extrait ensuite au chloroforme, lave avec une solution d'hydrogénocarbonate de sodium puis à l'eau. Le séchage sur sulfate de sodium suivi de l'évaporation du solvant conduit à un résidu qui sera cristallisé dans l'éthanol. On obtient ainsi les dérivés du 1,3-diphényl-4- aryl-5- (2-*N*-méthylsulfonylbenzoyl)-pyrazole (composés **6**).

*1,3,4-Triphényl-5-(2-*N*-méthylsulfonylbenzoyl)-pyrazole (**6**a).* Rdt. 38%, *F* > 250°C; ir, ν_{max} : 1665 (cétone); rmn ^{1}H, δ : 3,11 (d, 3H, -NCH_3, $^3J_{NH-CH_3}$ = 4,88 Hz), 7,10–8,20 (m, 19H), 15,20 (s élargi, 1H, NH); rmn ^{13}C, δ : 37,60 (-NCH_3), 123,70–151,20 (C arom.), 169,20 (C═O). Anal. calc. pour $C_{29}H_{23}N_3O_3S$: C 70,55, H 4,69, N 8,51, S 6,50; tr. : C 70,69, H 4,72, N 8,55, S 6,63.

*1,3-Diphényl-4-*p*-tolyl-5-(2-*N*-méthylsulfonylbenzoyl)-pyrazole (**6**b).* Rdt. 36%, *F* > 250°C; ir, ν_{max} : 1660 (cétone); rmn ^{1}H, δ : 2,38 (s, 3H, CH_3), 3,12 (d, 3H, -NCH_3, $^3J_{NH-CH_3}$ = 4,97 Hz), 7,00–8,25 (m, 18H), 15,10 (s élargi, 1H, NH); rmn ^{13}C, δ : 21,20 (CH_3), 37,60 (-NCH_3), 123,50–152,10 (C arom.), 169,51 (C═O). The isomeric purity of products from certain group-selective reactions can be significantly amplified when reactions can occur sequentially. The theoretical basis for a strategy that exploits reactions with modest enantiotopic group selectivity for asymmetric synthesis is described. The relationships between conversion, yield, and isomeric purity for such a process are calculated using a simple kinetic model. A simple method for selecting candidate group-selective reactions from known face-selective reactions is presented. Application of the strategy is illustrated with the reduction of D-glucose and D-galactose derived dialdehydes with *B*-isopinocampheyl-9-borabicyclo[3.3.1]nonane (Alpine-Borane®).

DALE E. WARD, YADONG LIU et CHUNG K. RHEE. Can. J. Chem. **72**, 1429 (1994).

On peut grandement améliorer la pureté isomérique des produits de certaines réactions sélectives pour des groupes si l'on effectue ces réactions d'une façon séquentielle. On décrit les bases théoriques d'une stratégie qui exploite des réactions possédant de modestes sélectivités énantiotopiques pour des groupes à des fins de synthèses asymétriques. Faisant appel à un modèle cinétique simple, on peut calculer facilement les relations entre la conversion, le rendement et la pureté isomérique de tels processus. On présente une méthode simple permettant de choisir les réactions plausibles pour leur sélectivité pour des groupes à partir de réactions connues pour leur sélectivité pour les faces. On illustre l'application de la stratégie à la réduction des dialdéhydes dérivés du D-glucose et du D-galactose par le *B*-isopinocamphéyl-9-borabicyclo[3.3.1]nonane (Alpine-Borane®).

[Traduit par la Rédaction]

Introduction

The development of methods for the synthesis of enantiomerically pure compounds has attracted considerable attention from synthetic organic chemists in recent years (1–3). In particular, significant advances have been achieved in the enantioselective conversion of achiral substrates into chiral products (1–3). Such transformations require a process where enantiotopic (4) faces or groups in the substrate are differentiated (5). This type of differentiation is possible since enantiotopic relationships become diastereotopic in the dissymmetric environment provided by a chiral reagent, auxiliary, solvent, additive, or catalyst (including enzymes (6) and abzymes (7)). While many methods that achieve high levels of enantiotopic face selectivity have been developed (1–3), nonenzymatic[2] examples of efficient enantiotopic group selectivity are less common (8).

An interesting feature of certain processes where enantiotopic groups can react sequentially is the coupling of an asymmetric synthesis with a kinetic resolution (9) to produce products with enhanced levels of enantiomeric purity.[3] Sih and co-workers (10*a*, *b*) explicitly demonstrated the viability of this approach in the enzyme-catalyzed hydrolysis of *meso* diacetates. Bosnich and co-workers (11) pointed out that enhanced enantiomeric purity by kinetic resolution with be general for this class of enantiotopic group-selective reactions. The synthetic potential of this type of process was brilliantly exploited by Schreiber et al. (12) who used the Sharpless epoxidation reaction to effect terminus differentiation after two-directional chain synthesis. While other nonenzymatic examples have appeared (13), no general synthetic methods that are designed to take advantage of the enhanced stereoselectivity from these reactions have been reported. We became interested in exploring the potential of this type of process to enhance the enantiomeric purity of products from reactions with innately poor enantioselectivity. In this paper we describe the theoretical basis for such a strategy and demonstrate a simple application involving the group-selective reduction of dialdehydes (14).[4]

Background and theory

Strategies for differentiating between enantiotopic faces or groups are readily illustrated by the use of two-dimensionally chiral (3, 15) objects (Fig. 1).[5] The objects **A** and **T** represent an achiral substrate with a pair of enantiotopic "reaction sites" and an achiral reagent with a single "reaction site," respectively. Interaction of **A** with **T** can occur in two different ways. Since these interactions (i.e., **p** and **q**) are enantiomorphic they should be isoenergetic and occur with equal probability. The interaction of **A** with **R**, representing a chiral reagent[6] with a

[2]For reference to recent examples of enzymatic enantiotopic group selective reactions, see ref. 6*c*.

[3]Although not generally appreciated, analogous enhancement of selectivity will also occur with chemoselective reactions (or diastereotopic group-selective reactions (41*a*)) where the groups can react sequentially. Thus it is possible to obtain much higher levels of selectivity (albeit with lower yields) than would be indicated by the relative reactivity of the groups. For example, in the chemoselective reduction of a dione (e.g., 4-androsten- 3, 17-dione) the isomeric purity of the hydroxyketone fraction will increase with increasing coversion (cf. ref. 48).

[4]Preliminary results have been reported (14).

[5]In two dimensions, an object is chiral if it cannot be superimposed onto its mirror image by any in-plane translation and (or) rotation; otherwise the object is achiral. Molecules are depicted by objects with the edges representing "reaction sites". Interactions (i.e., transition states) between molecules (i.e., substrates and reagents) are indicated by the juxtaposing of objects with the appropriate edge-to-edge contact. For convenience, the object depicting the "reagent" represents the reagent and the environment (i.e., solvent, catalyst, additive, etc.); thus, if the environment is chiral, then the object that depicts the reagent is also chiral.

[6]This can be an achiral reagent in a chiral environment or a chiral reagent in an achiral or chiral environment (see footnote 7).

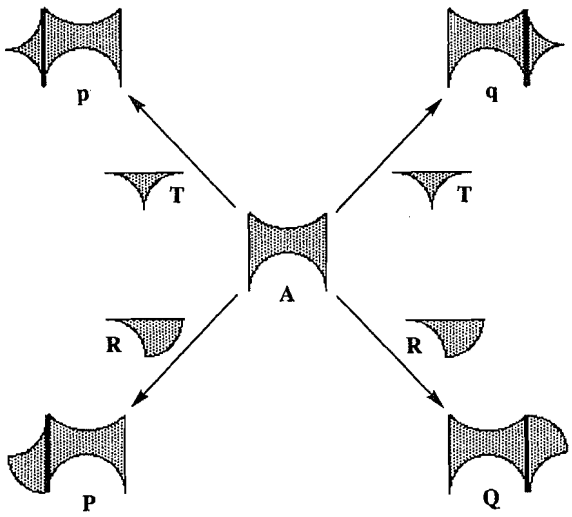

FIG. 1. Differentiation of enantiotopic faces or groups illustrated with two-dimensionally chiral objects.

single "reaction site," can also occur in two different ways. In this case, however, the interactions are heteromorphic (i.e., **P** and **Q**) and, in principle, will be of different energy and occur with unequal probability.[7]

A kinetically controlled reaction involving the differentiation of enantiotopic faces[8] or enantiotopic groups where sequential reaction is prevented[9] (e.g., eq. [1]) can be analyzed as a pair of mutually dependent parallel reactions (16). The ratio of products **P** and **Q** (i.e., the selectivity) is equal to the ratio of rate constants k_1 and k_2 at any point in the reaction.[10]

$$[1] \qquad \mathbf{P} \xleftarrow[\text{fast}]{k_1} \mathbf{A} + \mathbf{R} \xrightarrow[\text{slow}]{k_2} \mathbf{Q}$$

$$[2] \qquad \mathbf{P} + \mathbf{R} \xrightarrow[\text{slow}]{k_3} \mathbf{B} \xleftarrow[\text{fast}]{k_4} \mathbf{Q} + \mathbf{R}$$

The situation is fundamentally different when enantiotopic groups (or in certain cases[8] enantiotopic faces) can react sequentially (10–13). The initial products (**P** and **Q**) of the reaction of **A** with **R** still retain a "reaction site." Further reaction of **P** or **Q** with **R** produces **B**[11] in a pair of independent parallel reactions (16) (eq. [2]). In a process represented by eqs. [1] and [2], the ratio of **P** and **Q** (i.e., the selectivity) will be dependent on conversion and in favorable circumstances can become arbitrarily high. To determine the nature of the relationship between selectivity and conversion, expressions for the concentrations of **P** and **Q** as a function of the concentration of **A** are derived[12] (eqs. [3] and [4]).

Assuming: $[\mathbf{R}]_{\text{init}} \geq 2[\mathbf{A}]_{\text{init}}$; $[\mathbf{P}]_{\text{init}} = [\mathbf{Q}]_{\text{init}} = 0$

$$[3] \qquad [\mathbf{P}] = \frac{k_1[\mathbf{A}]_{\text{init}}}{k_1 + k_2 - k_3}\left[\left(\frac{[\mathbf{A}]}{[\mathbf{A}]_{\text{init}}}\right)^{\frac{k_3}{k_1+k_2}} - \frac{[\mathbf{A}]}{[\mathbf{A}]_{\text{init}}}\right]$$

$$[4] \qquad [\mathbf{Q}] = \frac{k_2[\mathbf{A}]_{\text{init}}}{k_1 + k_2 - k_4}\left[\left(\frac{[\mathbf{A}]}{[\mathbf{A}]_{\text{init}}}\right)^{\frac{k_4}{k_1+k_2}} - \frac{[\mathbf{A}]}{[\mathbf{A}]_{\text{init}}}\right]$$

The analysis is simplified by assuming that the reactivity of a particular group is independent of the state of the other group (i.e., $k_1 = k_4$ and $k_2 = k_3$).[13] Under this assumption, the ratio of **P** and **Q** as a function of the concentration of **A** is expressed by eq. [5]. Inspection of eq. [5] reveals that during the early part of the process (i.e., as $[\mathbf{A}]/[\mathbf{A}]_{\text{init}} \rightarrow 1$) the ratio of the initial products is approximately equal to the ratio of rate constants (i.e., $[\mathbf{P}]/[\mathbf{Q}] \rightarrow k_1/k_2$); however, at high conversion (i.e., as $[\mathbf{A}]/[\mathbf{A}]_{\text{init}} \rightarrow 0$) the ratio of these products becomes arbitrarily large (i.e., $[\mathbf{P}]/[\mathbf{Q}] \rightarrow \infty$) if k_1 is greater than k_2.

Assuming: $k_1 = k_4$ and $k_2 = k_3$

$$[5] \qquad \frac{[\mathbf{P}]}{[\mathbf{Q}]} = \frac{\left(\frac{[\mathbf{A}]}{[\mathbf{A}]_{\text{init}}}\right)^{\frac{-k_1}{k_1+k_2}} - 1}{\left(\frac{[\mathbf{A}]}{[\mathbf{A}]_{\text{init}}}\right)^{\frac{-k_2}{k_1+k_2}} - 1}$$

Figure 2 illustrates the calculated[14] results for a hypothetical process where the enantiotopic group selectivity ($E = k_1/k_2$) is 3. The yield of the initial products (**P** + **Q**) rises to a maximum, then decreases towards 0, while the stereoisomer excess (se)[15] and the yield of **B** continue to increase towards 1. In principle, any high level of se can be reached with an appropriate sacrifice in yield.

In considering how this type of process might be exploited

[7]In reactions involving the differentiation of enantiotopic groups or faces, it is useful to distinguish between those that produce unequal amounts of enantiomers and those that produce unequal amounts of diastereomers. In general (but not always), the first case involves differentiation by an achiral reagent in a chiral environment (i.e., in the presence of a chiral ligand, catalyst, additive, solvent, etc.) while the second case involves differentiation by a chiral reagent in an achiral or chiral environment. Differentiation requires the intervention of a chiral "entity." In reactions involving a chiral reagent, it is also useful to distinguish the reagents produced by the temporary attachment of a chiral "auxiliary" to an otherwise achiral substance from the others. In this way, the chiral auxiliary can be thought of as a special type of chiral environment that interacts with an achiral reagent via covalent bonding rather than some weaker form of association.

[8]Reaction at one face of a trigonal atom prevents reaction at the other face. Sequential reaction can occur (10*c*) at both faces of a diagonal atom (4*b*).

[9]The majority of examples of enantiotopic group selectivity in ref. 8 do not involve sequential reaction of the groups.

[10]Assuming that the kinetic order with respect to both substrate and reagent is the same for both reactions.

[11]The assumption that both **P** and **Q** react to give the same product (i.e., **B**) is convenient but not necessary for the analysis.

[12]See experimental for details. For an analogous derivation see refs. 10*a*, *b*.

[13]This is reasonable if the groups are relatively remote. For a similar analysis based on this assumption see ref. 12*a*. For a related analysis without this restriction see refs. 10*a*, *b* and 11. For an indication of the sensitivity of the analysis to this assumption see Table 1.

[14]Calculated according to eqs. [3] and [4] assuming that $k_1 = k_4$ and $k_2 = k_3$; see experimental section for details.

[15]Stereoisomer excess (se) is expressed in a way which is equivalent to ee if **P** and **Q** are enantiomers, or to de if **P** and **Q** are diastereomers.

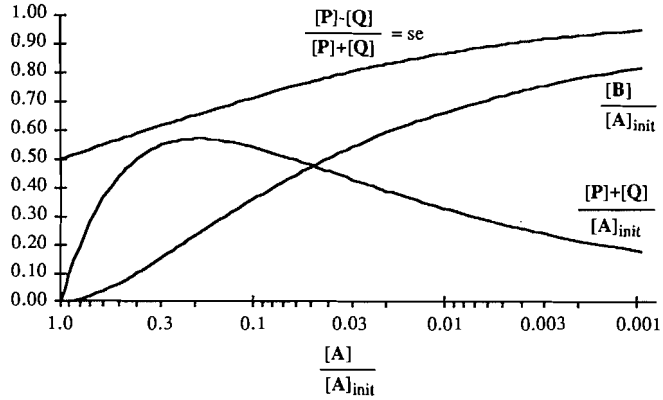

FIG. 2. Calculated evolution of stereoisomeric excess and mole fractions of products as a function of conversion for a group-selective process (i.e., eqs. [1] and [2]) assuming: $k_1 = k_4$; $k_2 = k_3$; $k_1/k_2 = 3$.

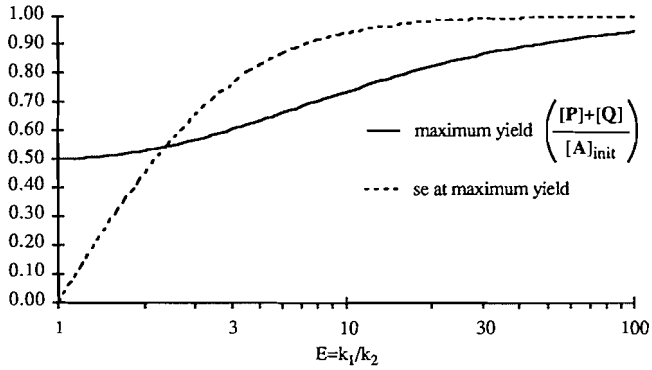

FIG. 3. Calculated maximum yield of initial products ($\mathbf{P} + \mathbf{Q}$) and stereoisomeric excess at the maximum yield as a function of the selectivity for a group-selective process (i.e., eqs. [1] and [2]) assuming: $k_1 = k_4$; $k_2 = k_3$.

in the preparation of enantiomerically pure compounds we were interested in the relationship between the group selectivity (E) of a reaction and the potential yield and stereoisomeric purity of the product. The maximum yield of the initial products ($\mathbf{P} + \mathbf{Q}$) and the se at the maximum yield as a function of the selectivity (E) were calculated.[14] The results are plotted in Fig. 3. Interestingly, the se rises much more sharply than does the maximum yield with increasing enantiotopic group selectivity. For example, it requires a calculated $E = 45$ to obtain a 90% yield of products (se = 99.6%); however, a process with $E = 7.1$ is predicted to give products with 90% se (yield = 69%).[14] Reactions (even enzyme-mediated ones (6)) with high enantiotopic group selectivity are extremely rare. However, processes with only modest selectivity can, in principle, be utilized to give modest yields of products with high se.

Figure 4 presents a plot of the maximum yield of initial products of a specific minimum se as a function of the selectivity.[14] Significantly, processes with selectivities of 3.2, 4.3, 5.3, and 6.6 are calculated to give a 50% yield of products with an se of 80%, 90%, 95%, and 98%, respectively.[16] The potential of this type of process to enhance the stereoisomeric purity of the products from reactions with innately poor selectivity is evident.[17]

[16]These cases approach the result from a hypothetical nonstereoselective reaction (100% yield) followed by separation of the stereoisomeric products. By contrast, these cases would require the separation of nonisomeric compounds (i.e., **P** and **B**).

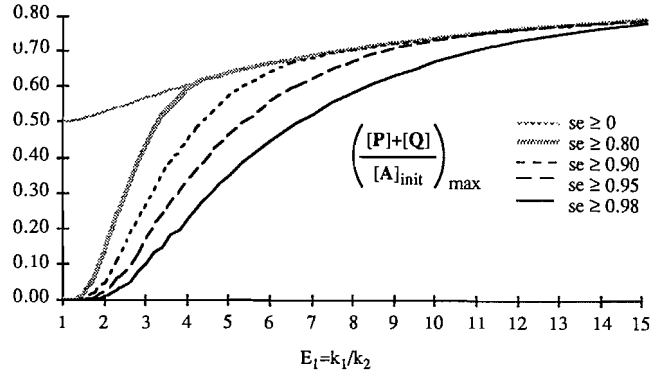

FIG. 4. Calculated maximum yield of initial products ($\mathbf{P} + \mathbf{Q}$) with a specified stereoisomeric excess as a function of the selectivity for a group-selective process (i.e., eqs. [1] and [2]) assuming: $k_1 = k_4$; $k_2 = k_3$.

To assess the sensitivity of the above conclusions to our simplifying assumptions (i.e., $k_1 = k_4$ and $k_2 = k_3$) we repeated the calculations according to eqs. [3] and [4] for various values of k_{1-4}. The enantiotopic group selectivity for the first reaction (k_1/k_2) was held constant while the selectivity (k_4/k_3) and the relative reactivity ($(k_1 + k_2)/(k_3 + k_4)$) for the "kinetic resolution" step were varied. The results are presented in Table 1. For a process with enantiotopic group selectivity of 5, variation in the relative reactivity ($(k_1 + k_2)/(k_3 + k_4)$) and (or) the relative selectivity ($(k_1/k_2)/(k_4/k_3)$) by a factor of 0.75–1.5 does not change the general prediction that obtention of a 50–60% yield of product with ≥90% se is possible. On the other hand, low selectivity ($k_4/k_3 < 2.5$) or high reactivity ($(k_1 + k_2)/(k_3 + k_4) < 0.25$) in the second (i.e., kinetic resolution) step reduces the potential yield of reasonably pure (se ≥90%) product to impractical levels (<40%).

Figure 5 shows the calculated[14] results for a hypothetical process ($E = 4.3$) indicating the possibility of obtaining a 50% yield of $\mathbf{P} + \mathbf{Q}$ with a se of 90%. This "optimal" result occurs when 2.5% of $[\mathbf{A}]_{init}$ remains. Importantly, at this point in the reaction, the yield of $\mathbf{P} + \mathbf{Q}$ is relatively insensitive to changes in the amount of remaining **A**. Thus, in practice, this point could be missed by as much as one half-life either way without seriously affecting the outcome.[18]

In principle, any reaction with an enantiotopic group selectivity of >4 might serve as the basis for a process that would provide a ≥50% yield of a product with ≥90% se. Candidate reactions can be evaluated if one knows or can estimate the relative reactivity of the two enantiomers of a chiral group with one enantiomer of a chiral reagent (or vice versa). There are numerous reports of diastereotopic face selectivity in reactions of chiral nonracemic (scalemic) (17) groups with

[17]If $k_3 = k_4 = 0$, reactions with $E = 6.6$, 5.3, 4.3, and 3.2 would produce products with se = 74%, 68%, 62%, and 54%, respectively. In general, this level of stereoselectivity is not synthetically useful.

[18]With 5% of $[\mathbf{A}]_{init}$ remaining, the calculated yield of $\mathbf{P} + \mathbf{Q}$ is 56% (se = 86%); with 1.25% of $[\mathbf{A}]_{init}$ remaining, the calculated yield is 44% (se = 93%). With initial conditions $[\mathbf{R}] = 3[\mathbf{A}]$ and $[\mathbf{P}] = [\mathbf{Q}] = 0$, if $[\mathbf{A}] = 0.025[\mathbf{A}]_{init}$ at $t = 10$ (arbitrary units) then $[\mathbf{A}] = 0.05[\mathbf{A}]_{init}$ at $t = 7.7$ and $[\mathbf{A}] = 0.0125[\mathbf{A}]_{init}$ at $t = 12.5$. Control of the reaction time to within one half-life ($t = 10 \pm 2.4$ in this case) should be straightforward.

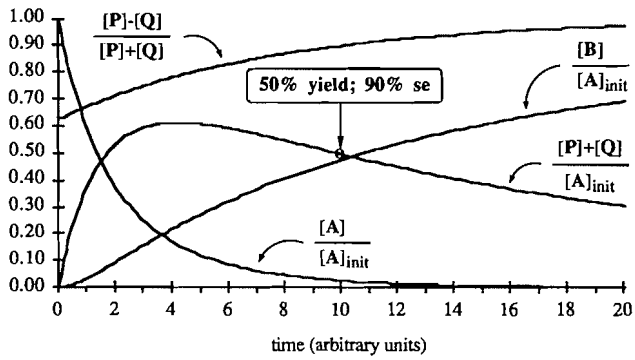

FIG. 5. Calculated evolution of stereoisomeric excess and mole fractions of components as a function of time for a group-selective process (i.e., eqs. [1] and [2]) assuming: $k_1 = k_4$; $k_2 = k_3$; $k_1/k_2 = 4.3$.

scalemic reagents (reagent and substrate selectivity or "double diastereoselectivity") (18). Unfortunately, although the diastereoselectivity for both the "matched" and "mismatched" cases is typically reported, the relative reactivity is usually not determined. The desired relative reactivity could be determined (19) from the diastereoselectivity observed in reactions of racemic groups with racemic reagents (mutual kinetic resolution) (9, 20); however, these data are rarely available (9).

Alternatively, the relative reactivity of enantiotopic groups containing diastereotopic faces towards addition of a chiral reagent can be crudely estimated from a knowledge of the individual substrate and reagent selectivities. There are numerous reports of enantiotopic face selectivity in reactions of achiral groups with chiral reagents (reagent selectivity, ***r***) and of diastereotopic face selectivity in reactions of chiral groups with achiral reagents (diastereoselectivity or substrate selectivity, ***s***) (1–3). The enantiotopic group selectivity (E) can be estimated from eq. [6] (20).[19]

$$[6] \qquad E = \frac{(r)(s) + 1}{r + s}$$

The value of E is limited by the lower of ***r*** and ***s***; high values of E require high values of both ***r*** and ***s***. Relatively few reactions[20] have been developed to date that might be predicted to have $E > 20$; however, several candidate reactions should be available with $E = 5$–10.[21,22]

The above analysis indicates how enantiotopic group-selective reactions can be identified and exploited in a strategy for asymmetric synthesis. Since processes with modest selectivity will produce only modest yields of products, we

[19]The face selectivity for one group will be (***r***)(***s***):1 (i.e., "matched"); total reactivity is (***r***):(***s***) + 1. The face selectivity for the enantiomeric group will be (***r***):(***s***) (i.e. "mismatched"); total reactivity is (***r***) + (***s***). The accuracy of this estimation depends on the suitability of the models used for the determination of ***r*** and ***s***. For a detailed discussion of the derivation, assumptions, and sources of error in the above multiplicitivity rule see ref. 18.

[20]For example, the Sharpless epoxidation reaction is the only generally used nonenzymatic method of kinetic resolution (9).

[21]Under ideal conditions, a reaction with $E = 20$ is calculated to give >80% yield of product with >98% se and according to eq. 6 would require $r,s \approx 40$. Similarly, a reaction with $E = 5$–10 would produce a 57–74% yield of product with >90% se and would require $r,s \approx 10$–20.

[22]For example, several examples of enantioselective addition of chiral nucleophiles (e.g., $LiAlH_4$ in the presence of a scalemic alcohol) to achiral carbonyl compounds together with corresponding examples of diastereoselective addition of related achiral nucleophiles (e.g., $LiAlH_4$) to related chiral carbonyl compounds with selectivities in the range of 10–20 are known (ref. 1, Vol. 2; ref. 3, Chap. 3).

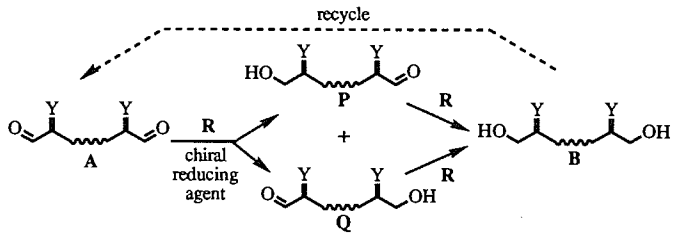

FIG. 6. Asymmetric synthesis by enantiotopic group selective reduction of *meso* dialdehydes.

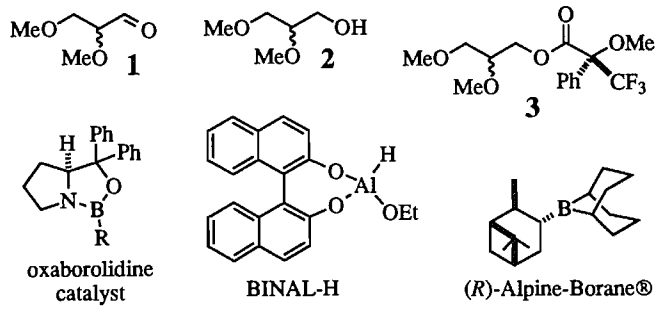
focussed on the use of reactions that would allow for efficient recycling of the undesired product (**B**). The process might be further simplified if the candidate reaction did not create any new elements of stereogenicity. Therefore, as an initial test of the feasibility of the strategy (14) we decided to examine the reduction of *meso* dialdehydes with chiral reducing agents (see Fig. 6).[4] Our objective was to demonstrate that, since only modest group selectivity is required, processes that provide useful yields of products with useful levels of stereoisomeric purity can be simply and rationally designed.

Results and discussion

Dialdehydes derived from hexoses were chosen for initial study since: (*i*) they should be readily available in stereochemically pure form; (*ii*) the product hydroxyaldehydes are known hexoses; (*iii*) a variety of hexoses are available that can provide dials both with enantiotopic -CHO groups (i.e., from galactose or allose) or with diastereotopic -CHO groups in which the local symmetry is enantiotopic (i.e., from glucose). It was of interest to determine if such "pseudo-enantiotopic" -CHO groups could be differentiated in the same manner as enantiotopic -CHO groups (vide infra).

The first task was to identify possible reagents and reaction conditions to effect enantiotopic group-selective reduction of a hexose-derived *meso* dialdehyde. Group selectivity should result from the matching and mismatching of substrate diastereotopic face selectivity with reagent enantiotopic face selectivity (eq. [6]). Although few studies on the stereoselectivity of reduction of α-alkoxy aldehydes have appeared (21), the addition of various nucleophiles to these aldehydes proceeds with modest to excellent diastereotopic face selectivity (22). Both the magnitude and the sense (i.e., chelation or Cram–Felkin) of the selectivity are highly dependent on the nucleophile and the reaction conditions (22). Several chiral reagents for enantiotopic face-selective reduction of carbonyl groups (23), including aldehydes (24), have been developed in recent years. Three of the best reagents on the basis of selectivity, availability, and (or) ease of preparation are Corey's oxazaborolidine catalysts (25) used with diborane or catechol borane as the reducing agent; binaphthol-modified lithium aluminum hydride (BINAL-H) (26); and *B*-isopinocampheyl-9-borabicyclo[3.3.1]nonane (Alpine-Borane®) (27). All of these reagents can reduce acetophenone to give 1-phenylethanol with an ee of >95%. The enantiotopic group selectivity of these reagents towards the model compound (±)-2,3-dimethoxypropanal (**1**) was examined. The intention was to reduce excess racemic **1** under a variety of conditions and measure the enantiomeric purity of the product **2**. If the conversion of **1** into **2** was kept to less than 25%, then the ratio of the enantiomers of **2** would be a reasonable approximation[23] of the ratio of the rate constants for the reaction of the individual enantiomers of **1** with the reagent (i.e., the enantiotopic group selectivity). The ratio of the enantiomers of **2** could be determined by ^{13}C NMR[24] of the derived Mosher's esters **3** (28).



The oxazaborolidine catalysts (R = Me and R = Bu) were prepared from (*S*)-proline according to the reported procedure (29). Reduction of **1** with 0.25 equivalent of catechol borane in THF at −78°C in the presence of either of these catalysts (0.1–0.25 equiv.) gave, in each case, the alcohol **2** with an ee of less than 10%.[25] Similar results were obtained in reductions of **1** with BINAL-H (0.25 equiv.; prepared (27) from (+)-1,1′-bi-2-naphthol) in THF at −78°C.[25] Reduction of **1** with commercially available (*R*)-Alpine-Borane® (Aldrich; 0.5 M in THF; 0.25 equiv.)[25] in THF at −78°C gave the alcohol **2** as a 2.3:1 mixture of enantiomers.[26] A similar experiment conducted at −100°C produced **2** as a 4:1 ratio of enantiomers.

The initial plan was to subject *galacto*-2,3,4,5-tetramethoxyhexan-1,6-dial (**4**) to reduction by (*S*)- or (*R*)-Alpine-Borane® to produce a mixture of D- and L-2,3,4,5-tetra-*O*-methylgalactose (D-**5** and L-**5**, respectively) and 2,3,4,5-tetra-*O*-methylgalactitol (**6**) (see Scheme 1). Reaction conditions would be refined to maximize both the yield and the ratio of D-**5** and L-**5**. A method for determining the relative amounts of **4**, **5**, and **6** as well as the ratio of D-**5** and L-**5** in the reaction mixture was required. As a prelude to the development an analytical

[23]An accurate determination requires knowledge of the conversion since the ratio of enantiomers of both **1** and **2** changes with time (9). We were unable to efficiently recover **1** or monitor its disappearance at low temperature. At 20% conversion, this "initial rate" method underestimates the ratio of rate constants by 10–20% if the observed ratio of enantiomers is 2–10.

[24]Resonances in both the ^{19}H NMR and the ^{1}H NMR spectra of the mixture of esters **3** were too congested to allow quantitative determination of the ratio of diastereomers; in the ^{13}C NMR spectrum the signals due to C-1 in the diastereomeric esters were well separated (δ 64.7 and δ 65.2) and the ratio of diastereomers was determined by the ratio of the intensity of these signals.

[25]The quality of our reagent was checked by reduction of acetophenone according to the literature procedure to give 1-phenylethanol with an ee of >90%

[26]Although not established unequivocally, the major enantiomer should have the (*S*) configuration. Since (*R*)-Alpine-Borane® reduces carbonyl groups with *re* face selectivity (24*b*) and, assuming Cram–Felkin diastereoselectivity, addition of nucleophiles to the carbonyl in (*S*)-**1** should be *re* face selective (23), the reaction of (*R*)-Alpine-Borane® with (*S*)-**1** should represent the matched pair and thus the faster reaction. This assumption is consistent with the observation that reaction of **4** with (*R*)-Alpine-Borane® gives predominantly the D-galactose derivative D-**5** (vide infra).

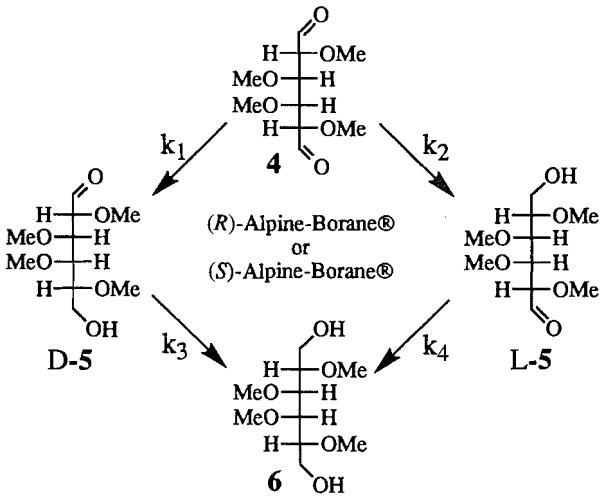
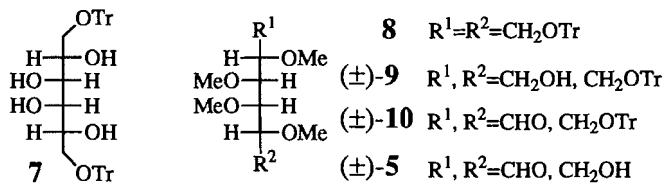


SCHEME 1

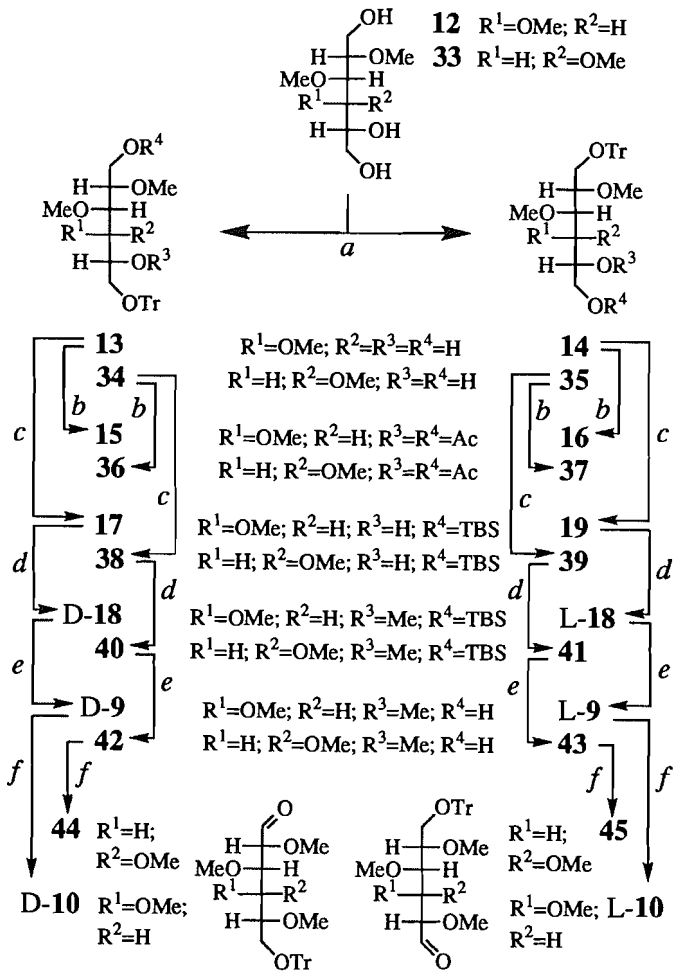
method, the independent synthesis of **4**, D-**5**, L-**5**, (±)-**5**, and **6**, was undertaken.

The diol **6** was readily prepared from galacitol in 67% yield via **7** and **8**. The diol **6** was oxidized under carefully controlled conditions using the Swern (30) protocol to give the crystalline dialdehyde **4**. The C_s symmetry of the structures of **4** and **6**–**8** was readily apparent from their ^1H and ^{13}C NMR spectra, which showed the expected simplicity. Partial hydrolysis of **8** gave (±)-**9**, which was oxidized (31) to the corresponding aldehyde (±)-**10** with tetrapropylammonium perruthenate (TPAP) and *N*-methylmorpholine *N*-oxide (NMO). Treatment of **10** with aqueous acid led to hydrolysis of the trityl group to give (±)-**5**. The ^1H NMR spectrum of **5** revealed it to be exclusively in the septanose (32) form as a 4:1 mixture of α and β anomers, as reported in the literature (33).



The preparation of D-**5** and L-**5** required a more circuitous route. The really available (34) 2,3,4-tri-*O*-methyl-D-galactose (**11**) was reduced (35) with sodium borohydride in ethanol to produce the known (36, 37) triol **12**. Treatment of a pyridine solution of **12** with trityl chloride (1.2 equiv.) in the presence of 4-(dimethylamino)pyridine (DMAP) gave a separable 2:1 mixture of trityldiols **13** and **14**, respectively, in 60% yield along with recovered **12** (20%). The structures of **13** and **14** were confirmed by conversion (Ac_2O, pyridine) to the corresponding diacetates **15** and **16**; the vicinal relationship between the C*H*-OAc and the CH_2-OAc protons in **16** was revealed by ^1H NMR through homonuclear decoupling experiments.

Reaction of **13** with TBDMSCl and imidazole selectively produced the primary silyl ether **17**, which was methylated (NaH, MeI) to give D-**18**. The silyl ether in D-**18** was selectively hydrolyzed by reaction with $HF_{(aq)}$ to give the alcohol D-**9** (64%) along with the diol **6** (33%). The preparation of D-**5** from D-**9** proceeded as described above for the racemic series. Alternatively, L-**18** was prepared by methylation of **19**, which was produced by reaction of **14** with TBDMSCl. Using the protocol established for the D series, L-**18** was converted into



SCHEME 2. (*a*) TrCl, pyridine, DMAP. (*b*) Ac_2O, pyridine, CH_2Cl_2. (*c*) TBDMSCl, imidazole, CH_2Cl_2. (*d*) NaH, MeI, THF. (*e*) $HF_{(aq)}$, CH_3CN *or* Bu_4NF, THF. (*f*) TPAP, NMO, CH_2Cl_2.

L-**5**. As expected for compounds **5**, **9**, **10**, and **18**, spectral data for D, L, and racemic samples were indistinguishable.

The measurement of the enantiomeric ratio of **5** was problematic due to the presence of an anomeric mixture of septanose forms (32). After considerable experimentation, we found that reaction of D-**5** with 2,4-dinitrophenylhydrazine (DNPH) led to a separable 4:1 mixture of hydrazones D-**20** and D-**21**, respectively (38).[27] Treatment of D-**20** with (*S*)-MTPACl (39)[28] gave the Mosher's ester D-**22**. Similar treatment of L-**5** with DNPH gave a mixture of hydrazones L-**20** and L-**21**, which had spectral properties indistinguishable from D-**20** and D-**21**, respectively. The major (*E*)-hydrazone D-**20** was converted into the Mosher's ester L-**22**. Significantly, the Mosher's esters D-**22** and L-**22** were distinguishable by ^1H NMR; the geminal protons at C-6 for D-**22** appeared at δ 4.66 (dd, J = 6, 11 Hz) and 4.46 (dd, J = 6, 11 Hz) while those for L-**22** were at δ 4.61

[27]The stereochemistry of the major isomer was assigned as *E* on the basis of: (*i*) expected greater stability; (*ii*) H-1 of the major isomer (δ 7.58, d, J = 6.5 Hz) is shifted downfield relative to the minor isomer (δ 7.00, d, J = 4 Hz) while H-2 of the major isomer is shifted upfield (δ 4.18, brd, J = 7 Hz) relative to the minor isomer (δ 4.29, dd, J = 3.5, 4 Hz). This is consistent with the deshielding effect of the dinitrophenyl group (38).

[28](*S*)-α-Methoxy-α-(trifluoromethyl)phenylacetic acid chloride ((*S*)-MTPACl) was prepared (39) from the corresponding (*R*)-acid ((*R*)-MTPA).

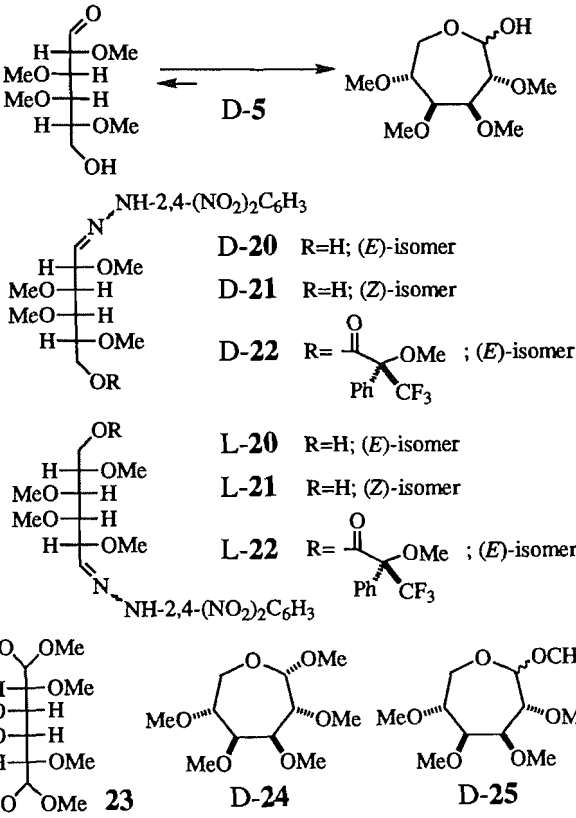
(dd, J = 6, 11 Hz) and 4.48 (dd, J = 6, 11 Hz). Integration of the signals for the C-6 protons in the ^{1}H NMR spectrum of the mixture of Mosher's esters produced by treatment of (±)-**5** as above indicated the presence of a 1:1 (±5%) mixture of D-**22** and L-**22**.

The next objective was to define reaction conditions for the reduction of **4** with Alpine-Borane® that would give high selectivity and facilitate control of the conversion. Initially, reduction under the conditions that proved successful for reduction of **1** was examined. (*R*)-Alpine-Borane® (0.5 M in THF; 3 equiv.) was added to a solution of **4** (0.05 M in THF) at −78°C. After stirring at −78°C for various times (0.1–4 h), acetaldehyde was added to quench the excess reagent and the reaction mixture was concentrated to dryness. The ^{1}H NMR spectrum of the crude product was complex and we could not determine the relative proportions of **4**, **5**, and **6**[29] present. Both **5** and **6** could be isolated by preparative thin-layer chromatography (PTLC); however, we were unable to recover **4** efficiently. Alternatively, treatment of the crude product with DNPH followed by chromatography (PTLC) gave **20** and **6**. The hydrazone **20** obtained after reduction of **4** with (*R*)-Alpine-Borane® was always enriched[30] with the D isomer (D:L = 3-20:1) while that obtained after reduction with (*S*)-Alpine-Borane® was enriched[30] with the L isomer (L:D = 3–20:1).

We required a method to determine the reaction conversion directly. Reaction of **4** with methyl orthoformate in methanolic HCl solution gave the bisacetal **23** in quantitative yield. Reaction of (±)-**10** (or (±)-**5**) under the same conditions gave (±)-**24**. In the ^{1}H NMR spectra of **23** and **24** the acetal protons appeared at distinct chemical shifts. Thus, the ratio of **4** and **5** in the crude reduction product could be conveniently determined by ^{1}H NMR after treatment with methyl orthoformate as above. The use of an internal standard allowed the amount of **4** and **5** in the reaction mixture to be estimated; the amount of **6** was determined by isolation.

We examined the ^{1}H NMR spectra of (±)-**24** in the presence of (+)-Eu(hfc)$_3$ with the hope of finding a more convenient method (cf. **22**) to determine the ratio of enantiomers of **5** (40). Although the signal due to the anomeric OCH_3 group was split, accurate integration was not possible due to spectral congestion in this region. On the basis of this observation, (±)-**10** was treated with trifluoroethanol in the presence of *p*-TsOH to obtain (±)-**25** as a 2:1 mixture of β and α anomers, respectively. The proton-decoupled ^{19}F NMR spectrum of (±)-**25** showed two signals, each of which was split in the presence of (+)-Eu(hfc)$_3$. The signals due to the α anomer could be accurately integrated, allowing for the determination of the enantiomeric ratio of **25** and thus of the precursor **10** (or **5**). Septanoside **25** could be readily isolated after treatment of the crude reduction product, obtained as described above, with trifluoroethanol and *p*-TsOH. The same result (±10%) was obtained when the enantiomeric ratio of **5** in the crude reduction product was determined both via **25** and via **20**.

With suitable analytical methods established, we examined the reduction of dialdehyde **4** under a variety of conditions (time, temperature, concentration, stoichiometry) with the aim of optimizing both the yield and the enantiomeric purity of the hydroxyaldehyde product **5**. After considerable



experimentation,[31] we found that addition of Alpine-Borane® (0.5 M in THF; 3 equiv.) to a solution of **4** in CH_2Cl_2 (0.12 M) at −78°C gave reproducible results and convenient reaction times (see Table 2). Analysis[31] of the crude product obtained after 2.0 h under these conditions consistently indicated the presence of **4**, **5**, and **6** in a ratio of <1:10:10; the ratio of D-**5** to L-**5** was found to be 7:1 (reduction with (*R*)-Alpine-Borane®). Reaction with (*R*)-Alpine-Borane® under the same conditions but on larger scale allowed the isolation of **5** (43%; 7:1, D:L) and **6** (46%). To demonstrate that the stereoselectivity was dependent on the conversion, the same reaction was repeated with reactions times of 1 h and 4 h. The results are presented in Table 2. As expected, reaction with (*S*)-Alpine-Borane® gave analogous results, with L-**5** being produced in excess. Reduction of **4** (0.12 M in CH_2Cl_2) with (*R*)-Alpine-Borane® at −95°C was investigated. At this temperature, a reaction time of 4 h was required to reach 95% conversion (**4**:**5**:**6** ca. <1:10:10). Again, the stereoselectivity was clearly shown to be dependent on the conversion.

To determine whether our results were consistent with the simple mathematical model represented in eqs. [3]–[5] we plotted the results against those calculated[14] assuming various values of k_1/k_2. As indicated in Figs. 7 and 8, the results observed for reduction of **4** at −78°C are reasonably predicted by the model assuming $k_1/k_2 \approx 2.9$ while reduction at −95°C can be modeled assuming $k_1/k_2 \approx 3.7$. The selectivity (i.e., k_1/k_2) for the reduction of **1** at −78°C was 2.3. It is possible to model (Fig. 7) the results observed for reduction for **4** at −78°C assuming $k_1/k_2 = 2.3$ by incorporating greater selectivity in the second step ($k_4/k_3 = 3.5$; $(k_1+k_2)/(k_3+k_4) = 0.9$). By contrast, the reduction at −95°C is not well modeled with the assumption of increased selectivity in the second step (i.e., eqs. [3] and [4]; $k_1/k_2 = 2.5$–4.0; $k_4/k_3 = (1.2–1.5) \times k_1/k_2$).

[29]Under these conditions, **5** and **6** would presumably be present as the corresponding 9-BBN borinate esters.

[30]Measured by ^{1}H NMR on the derived Mosher's esters **22**.

[31]See experimental section for details on procedures.

[a]Determined by ^{1}H NMR after treatment with acidic methanol. All reactions were performed at least twice; the relative error in determining the ratio of the components was typically ±10%.
[b]Isolated yield.
[c]Because **5** was difficult to purify, isolation was only attempted in larger scale reactions.
[d]%ee = |(D-**5**) − (L-**5**)| × 100/[(D-**5**) + (L-**5**)] and was measured by ^{19}F NMR in the presence (+)-Eu(hfc)$_3$ after conversion into **25**.

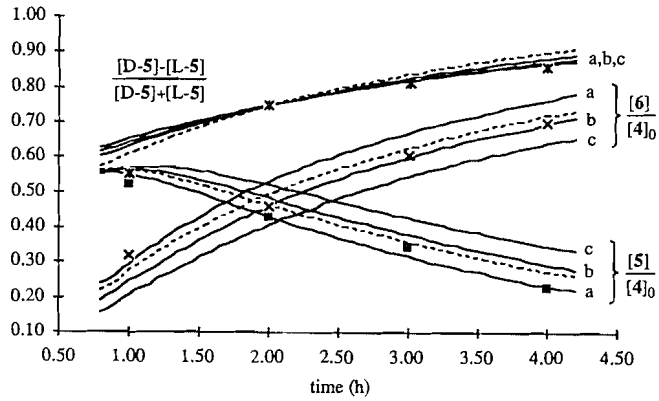

FIG. 7. Calculated and observed results for reduction of **4** with Alpine-Borane® at −78°C. Observed: ✕, ee of **5**; X, yield of **6**; ■, yield of **5**. Calculated: (a) $k_1/k_2 = k_4/k_3 = 2.7$; (b) $k_1/k_2 = k_4/k_3 = 2.9$; (c) $k_1/k_2 = k_4/k_3 = 3.1$; (- - -) $k_1/k_2 = 2.3$, $k_4/k_3 = 3.5$.

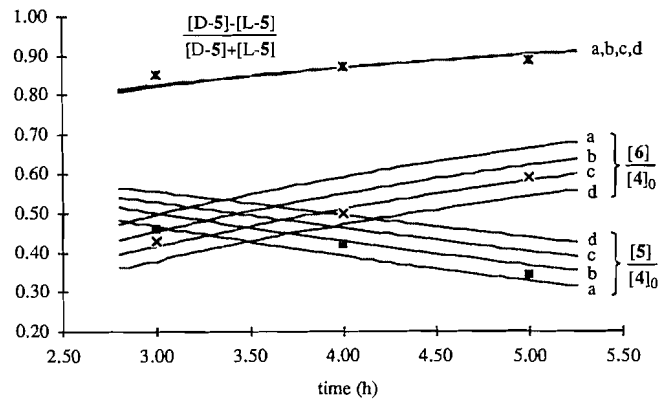

FIG. 8. Calculated and observed results for reduction of **4** with Alpine-Borane® at −95°C. Observed: ✕, ee of **5**; X, yield of **6**; ■, yield of **5**. Calculated: (a) $k_1/k_2 = k_4/k_3 = 3.3$; (b) $k_1/k_2 = k_4/k_3 = 3.5$; (c) $k_1/k_2 = k_4/k_3 = 3.7$; (d) $k_1/k_2 = k_4/k_3 = 3.9$.

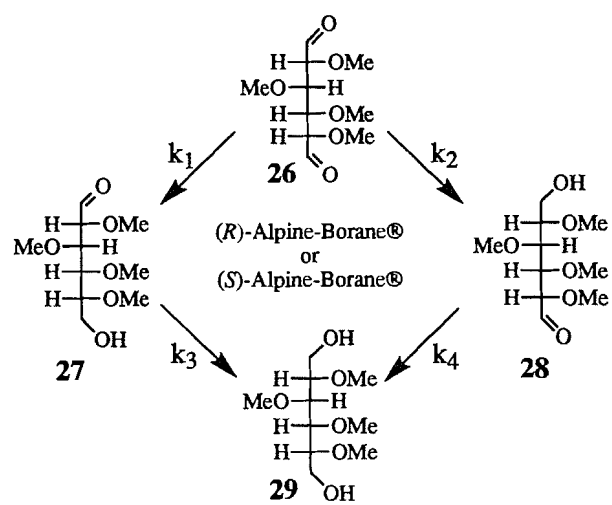
It was of interest to determine if the same strategy could also be applied to differentiate diastereotopic groups with a similar amplification of stereoselectivity. Examples of this type of stereoselective process are rare (41*a*).[32] We reasoned that if the diastereotopic groups had "enantiotopic" local symmetry, then predictable group selectivity might result from the matching and mismatching of substrate and reagent face selectivity as above. The configuration of the α-alkoxy group should govern the substrate diastereotopic face selectivity for addition to hexose-derived dials. Thus, a dial derived from glucose (or gulose) would have -CHO groups with the appropriate "pseudo-enantiotopic" relationship. We investigated the reduction of **26** with Alpine-Borane® (see Scheme 3).

Dial **26** was prepared by oxidation of diol **29**, which, in turn was readily available from D-glucitol (D-sorbitol) via **30** and **31**. Authentic samples of the D-glucose derivative **27** and the L-gulose derivative **28** were prepared from 2,3,4-tri-*O*-methyl-D-glucose (**32**) (42) in analogy with the chemistry developed in the galactose series. Thus, reduction of **32** with sodium borohydride (35) gave the known (37) triol **33**, which, in turn, gave a separable 1.7:1 mixture of **34** and **35** upon treatment with trityl chloride in pyridine. The structures of **34** and **35** were confirmed by ^{1}H NMR of the corresponding diacetates **36** and **37**. The synthesis of **27** from **34** and of **28** from **35** followed the sequence silylation (**38**, **39**), methylation (**40**, **41**), desilylation (**42**, **43**), oxidation (**44**, **45**), and hydrolysis as described



SCHEME 3

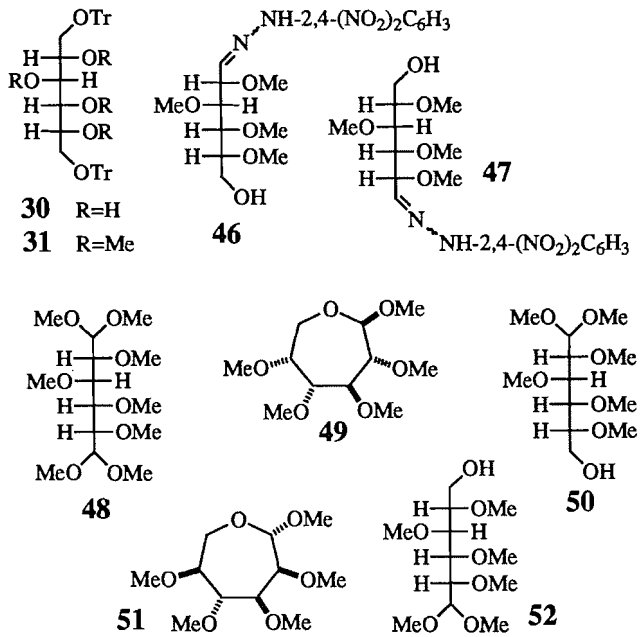
[a]Determined by ^{1}H NMR after treatment with acidic methanol. All reactions were performed at least twice; the relative error in determining the ratio of the components was typically ±10%.
[b]Isolated yield.
[c]Because the hydroxyaldehyde fraction (**27** + **28**) was difficult to purify, isolation was only attempted in larger scale reactions.
[d]%de = |(**27** − **28**)| × 100/(**27** + **28**) and was measured by ^{1}H NMR after treatment with acidic methanol and (or) after treatment with DNPH.
[e]The initial concentration of **26** was 0.012 M in CH_2Cl_2.
[f]The initial concentration of **26** was 0.025 M in CH_2Cl_2.

above. The ^{1}H NMR spectrum of **27** revealed it to be about a 1.5–2:1 mixture of the hydroxyaldehyde and β-septanose tautomers, respectively (43); similarly, **28** was shown to exist primarily in the β-septanose form. The diastereoisomeric relationship between **27** and **28** was confirmed by reduction with sodium borohydride to give, in each case, the diol **29**.

We anticipated that ring–chain tautomerism would make mixtures of **27** and **28** difficult to analyze directly by ^{1}H NMR. Individual reaction of **27** and **28** with DNPH gave the hydrazones **46** (4–6:1 mixture of *E* and *Z* isomers (38)) and **47** (3–4:1 mixture of *E* and *Z* isomers (38)), respectively. The hydrazones **46** and **47** were readily distinguishable by ^{1}H NMR. Methods for analysis of the products from reduction of **26** were developed in analogy to those in the galactose series. Treatment of **26** with methyl orthoformate in methanolic HCl solution gave the bisacetal **48** in near quantitative yield. Reaction of **44** under these conditions gave variable mixtures (depending on reaction time) of the septanoiside **49** and dimethyl acetal **50**; similar reaction of **45** gave **51** and **52**. The acetal protons in compounds **48–52** were readily distinguished by ^{1}H NMR.



We investigated the reduction of dialdehyde **26** with Alpine-Borane® under a variety of conditions. In each case, the relative amount of **26**, **27**, and **28** present in the crude reaction product was determined by ^{1}H NMR after treatment with methyl orthoformate. The amount of **29** present could be estimated from the above spectrum and was determined by isolation. Alternatively, treatment of the crude reaction product with DNPH gave **29** and a mixture of **46** and **47**. The ratios of **26** and **27** present in the crude reaction mixture when determined after treatment with methyl orthoformate and after treatment with DNPH agreed closely (±10%).

The results for reduction of **26** under the conditions previously described for reduction of **4** are summarized in Table 3. Qualitatively similar results were obtained under other reaction conditions (concentration, stoichiometry). The reaction of (*R*)-Alpine-Borane® with **26** was considerably faster than with **4**. Analysis[31] of the crude product (after treatment with methyl orthoformate) indicated that the ratio of **26**:**27**:**28**:**29** present was ca. 14:17:21:48 after reaction for 1 h. The selective formation of **28** was surprising as we expected that (*R*)-Alpine-Borane® would preferentially reduce the C-6 aldehyde group of **26** in analogy to reactions with **4**. The selectivity in favor of **28** was slightly higher at shorter reaction times; however, at longer reaction times the hydroxyaldehyde fraction was enriched in isomer **27**. These results indicated that **28** both is formed *and* reacts faster than **27** (i.e., Scheme 3; $k_1 < k_2$ and $k_3 < k_4$) and suggest the possibility of a "mismatched" pair (18) due to substrate diastereotopic group selectivity.

The substrate diastereotopic group selectivity for reduction of **26** was assessed by reaction with 9-BBN (1 equiv., 22°C). At low conversion (i.e., <15% of **29**) the hydroxyaldehyde product was a 1.6:1 mixture of **28** and **27**, respectively. The origin of this substrate selectivity in favor of reduction of the C-1 aldehyde group in **26** is uncertain. The results observed for reduction of **26** with (*R*)-Alpine-Borane® can be rationalized assuming that the substrate (*s*) and reagent (*r*) group selectivities are approximately equal in magnitude but mismatched, resulting in low selectivity for reduction of the C-1 aldehyde group and formation of **28** (i.e., $s > r$). In the second step, selectivities are again mismatched but with a slight selectivity in favor of reduction of a C-6 aldehyde group and reaction of **28** (i.e., $s < r$). As indicated in Fig. 9, the observed results can be crudely modelled by eqs. [3] and [4] by assuming that

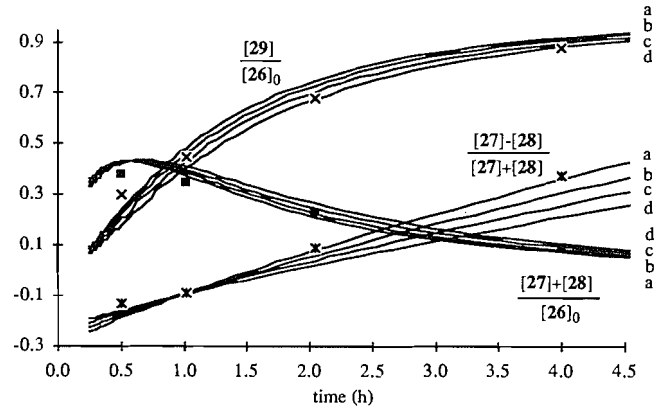

FIG. 9. Calculated and observed results for reduction of **26** with (*R*)-Alpine-Borane® at −78°C. Observed: ✕, de of (**27**, **28**); X, yield of **29**; ■, yield of (**27** + **28**). Calculated with $(k_1+k_2)/(k_3+k_4) = 0.75$: (a) $k_2/k_1 = k_4/k_3 = 1.85$; (b) $k_2/k_1 = k_4/k_3 = 1.75$; (c) $k_2/k_1 = k_4/k_3 = 1.67$; (d) $k_2/k_1 = k_4/k_3 = 1.6$.

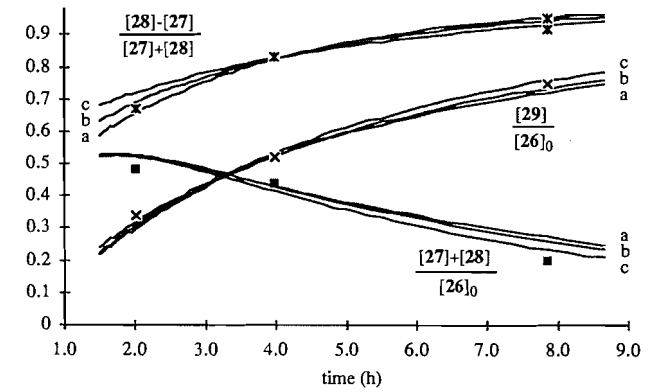

FIG. 10. Calculated and observed results for reduction of **26** with (*S*)-Alpine-Borane® at −78°C. Observed: ✕, de of (**27**, **28**); X, yield of **29**; ■, yield of (**27** + **28**). Calculated with $(k_1+k_2)/(k_3+k_4) = 0.75$: (a) $k_2/k_1 = 1.9$, $k_3/k_4 = 5.4$; (b) $k_2/k_1 = 2.4$, $k_3/k_4 = 4.3$; (c) $k_2/k_1 = k_3/k_4 = 3.2$.

the selectivities for the two steps are modest and mismatched (i.e., $k_2/k_1 \approx k_4/k_3 \approx 1.7$).

We examined the reduction of **26** with (*S*)-Alpine-Borane®, expecting the increase in selectivity associated with a matched pair. The results are presented in Table 3. Surprisingly, this reaction was considerably slower than the others and was conducted at higher concentration to achieve convenient reaction times. The selectivity observed was much higher than with (*R*)-Alpine-Borane® and is consistent with a reinforcing of reagent and substrate group selectivity. Initially, we attempted to model the results using eqs. [3] and [4] with the assumption that $k_2/k_1 = k_3/k_4$ (Scheme 3, Fig. 10). Although a reasonable approximation of the evolution of the yields with respect to time could be obtained under this assumption, the evolution of the se could be reasonably reproduced only by assuming that k_2/k_1 was considerably smaller than k_3/k_4.[33]

Considering the above, the results from reduction of **26** with Alpine-Borane® can be rationalized by assigning a small substrate diastereotopic group selectivity ($s \approx 1.8$) in favor of reduction of the C-1 carbonyl group and assuming that the reagent group selectivity is similar to that observed with **4** in the second step (i.e., $r_2 = k_4/k_3 \approx 3$) but highly attenuated in the first step (i.e., $r_1 = k_1/k_2 \approx 1.1$). Thus, in analogy to eq. [6], the selectivities for the matched case would be $k_1/k_2 = r_1 s \approx 2$ and $k_4/k_3 = r_2 s \approx 5.4$; and for the mismatched case $k_1/k_2 = r_1/s \approx 0.6$ and $k_4/k_3 = r_2/s \approx 1.7$ Possible origins for a reduced group selectivity in the first step are unclear.

Conclusion

In conclusion, theory suggests that enantiotopic group-selective reactions, even when the selectivity is modest, can be usefully exploited in asymmetric synthesis. The potential scope of such a strategy was revealed by a simple kinetic analysis. A method was presented for selecting candidate group-selective reactions that are likely to show appropriate selectivity in such processes. The strategy was illustrated by effecting the reduction of hexose-derived dialdehydes and showed that, despite low group selectivity (ca. 3–4:1), useful amounts of hydroxyaldehyde products (40–50% yield) with useful levels of stereoisomeric purity (7–15:1) could be obtained by this approach. The major by-product was the diol resulting from reduction of both aldehyde groups. The diol could be recycled by oxidation to the dialdehyde, increasing the efficiency of the overall process. The observed results were reasonably approximated by calculation using a simple mathematical model. We are actively investigating the application of this strategy to various synthetic problems. Results will be reported in due course.

Experimental

Calculations

Equations [3] and [4] are derived as follows (10*a*, *b*). Assuming that each of the reactions (eqs. [1] and [2]) is first order with respect to substrate and reagent leads to rate eqs. [7]–[9].

$$[7] \qquad \frac{d[\mathbf{A}]}{dt} = -(k_1 + k_2)[\mathbf{A}][\mathbf{R}]$$

$$[8] \qquad \frac{d[\mathbf{P}]}{dt} = k_1[\mathbf{A}][\mathbf{R}] - k_3[\mathbf{P}][\mathbf{R}]$$

$$[9] \qquad \frac{d[\mathbf{Q}]}{dt} = k_2[\mathbf{A}][\mathbf{R}] - k_4[\mathbf{Q}][\mathbf{R}]$$

Dividing eq. [8] by eq. [7] gives eq. [10] (first-order linear differential equation), which is readily solved (integrating factor method) to give eq. [3]. Equation [4] is obtained similarly. The stoichiometry of eqs. [1] and [2] dictates the relationships in eqs. [11] and [12]. Reaction time (t) is calculated by numerical integration of eq. [7] according to eq. [13] (Runge–Kutta, second order).

$$[10] \qquad \frac{d[\mathbf{P}]}{d[\mathbf{A}]} = \frac{k_3[\mathbf{P}]}{(k_1 + k_2)[\mathbf{A}]} - \frac{k_1}{(k_1 + k_2)}$$

$$[11] \qquad [\mathbf{R}]_n = [\mathbf{R}]_{\text{init}} - 2[\mathbf{A}]_{\text{init}} + 2[\mathbf{A}]_n + [\mathbf{P}]_n + [\mathbf{Q}]_n$$

$$[12] \qquad [\mathbf{B}]_n = [\mathbf{A}]_0 - [\mathbf{A}]_n - [\mathbf{P}]_n - [\mathbf{Q}]_n$$

$$[13] \qquad t_n = t_{n-1} + \frac{[\mathbf{A}]_{n-1} - [\mathbf{A}]_n}{2(k_1 + k_2)}\left[\frac{1}{[\mathbf{A}]_n[\mathbf{R}]_n} + \frac{1}{[\mathbf{A}]_{n-1}[\mathbf{R}]_{n-1}}\right]$$

All calculations were performed in a spreadsheet environment using Microsoft® Excel (v.2.2a) running on a Macintosh IIsi computer. In each case, specific values for k_1/k_2, k_4/k_3, and $(k_1+k_2)/(k_3+k_4)$ were assigned and k_{1-4} were calculated[34] with $k_1 = 1$ (arbi-

[33]Experimentally, the se is determined much more accurately than the yields (isolation). Note that keeping the product of the selectivities constant (i.e., $(k_2/k_1)(k_3/k_4) = (3.2)^2$) strongly attenuates the effect of different selectivities on the calculated evolution of the yields.

trary units). Values for $[P]_n/[A]_0$, $[Q]_n/[A]_0$, $([P]_n + [Q]_n)/[A]_0$, $([P]_n - [Q]_n)/([P]_n + [Q]_n)$, $[B]_n/[A]_0$, $[R]_n$, and reaction time (t_n) were determined for each of a series of 200 values of $[A]/[A]_0$ ranging from 1 to 0.0003. The series was set such that the nth value was equal to 96% of the $(n - 1)$th value. Initial conditions were $[A]_0 = 1$; $[R]_0 = 3$; $[P]_0 = [Q]_0 = [B]_0 = 0$ (arbitrary units). The values for $[P]_n$ and $[Q]_n$ were calculated according to eqs. [3] and [4] and $[R]_n$ was determined according to eq. [11]. Equations [12] and [13] were used to calculate values for $[B]_n$ and t_n, respectively. The maximum value of $([P]_n + [Q]_n)/[A]_0$ and the corresponding se [i.e., $([P]_n - [Q]_n)/([P]_n + [Q]_n)$] at that point were determined by inspection. Similarly, the maximum values of $([P]_n + [Q]_n)/[A]_0$ with corresponding se ≥ 0.80, 0.90, 0.95, and 0.98 were identified. Specific values of k_1/k_2 required to produce a given result were determined by calculations using successive approximations of k_1/k_2.

The data for Figs. 3 and 4 were obtained from calculations as above using a series of 100 values of k_1/k_2 ranging from 1 to 100. The series was set such that the nth value was equal to 105% of the $(n - 1)$th value. For cases where $k_1/k_2 < 3.4$, calculations using values of $[A]/[A]_0 < 0.0003$ were required to reach the desired se level. In these cases, additional $[A]/[A]_0$ data points were calculated until the desired se was reached or until $([P]_n + [Q]_n)/[A]_0 < 0.005$.

For Figures 7–10, the calculated data for each value of k_1/k_2 (and k_4/k_3) were "normalized" by adjusting the value of k_1 so that the observed se value was calculated to occur at the observed time (i.e., for Fig. 7, se = 0.75 when $t = 2$; for Fig. 8, se = 0.87 when $t = 4$; for Fig. 9, se = 0.09 when $t = 1$; for Fig. 10, se = 0.83 when $t = 4$).

Materials and methods

General experimental procedures have recently been described (44). Dimethyl sulfoxide (DMSO) was distilled from CaH_2 under reduced pressure (10 mbar; 1 bar = 100 kPa) and stored over 3Å molecular sieves. Acetaldehyde was freshly distilled. Racemine glyceraldehyde was obtained by oxidation of an equimolar mixture of D-fructose and L-sorbose with lead tetraacetate (45) and was, in turn, converted into **1** according to the known procedure (46). (*S*)-α-Methoxy-α-(trifluoromethyl)phenylacetic acid chloride ((*S*)-MTPACl) was prepared (39) from the corresponding (*R*) acid ((*R*)-MTPA). Galactitol was obtained by reduction (35) of D-galactose. 2,3,4-Tri-*O*-methyl-D-galactose (**11**) (34) and 2,3,4-tri-*O*-methyl-D-glucose (**32**) (42) were prepared from D-galactose and D-glucose, respectively. Unless otherwise noted, other reagents were commercially available and were used as received, and reactions were carried out under an atmosphere of argon and reaction temperatures refer to the bath. Low-temperature baths were $CO_{2(s)}$/acetone (−78°C), $N_{2(l)}/CH_2Cl_2$ (−95°C), and $N_{2(l)}$/EtOH (−100°C). Unless otherwise noted, all reported compounds were homogeneous by thin-layer chromatography (TLC) and by NMR. Flash column chromatography (FCC) was performed according to Still et al. (47).

*2,3-Dimethoxypropanol (**2**)*

Reduction with $NaBH_4$: $NaBH_4$ (27 mg, 0.71 mmol) was add to a solution of **1** (42 mg, 0.36 mmol) in MeOH (5 mL). After stirring for 5 min, acetaldehyde (0.1 mL) was added and the reaction mixture was concentrated under reduced pressure, and fractionated by FCC (EtOAc:hexane, 1:1) to give **2** as a colorless oil (36 mg, 84%); IR: 3409, 2970, 1378, 1101 cm^{-1}; ^1H NMR δ: 3.76 (1H, dd, $J = 4$, 11.5 Hz, H-1), 3.64 (1H, dd, $J = 5$, 11.5 Hz, H-1), 3.52 (2H, d, $J = 5$ Hz, H-3), 3.50–3.43 (1H, m, H-2), 3.46 (3H, s, OCH_3), 3.39 (3H, s, OCH_3); ^{13}C NMR δ: 80.0 (d, C-2), 72.3 (t, C-3), 62.3 (t, C-1), 59.4 (q, OCH_3), 57.7 (q, OCH_3).

Reduciton with Alpine-Borane®: A solution of the aldehyde **1** (ca. 50 mg, 0.4 mmol) in THF (4 mL) was cooled to the desired temperature and Alpine-Borane® (0.5 M in THF, 0.2 mL, 0.1 mmol) was added. After stirring for 1–3 h, acetaldehyde (ca. 0.05 mL, excess) was added. The reaction mixture was allowed to warm to room temperature and then concentrated under reduced pressure. The residual pinene was removed at 50°C under high vacuum. The residue was dissolved in ether (2 mL) and ethanolamine (7 mg, 0.11 mmol) was added to the ice-cold solution. After stirring for 15 min the cloudy mixture was filtered, concentrated, and fractionated by FCC (EtOAc:hexane, 1:1, and then MeOH:CH_2Cl_2, 1:9) to give the alcohol **2** as a colorless oil (10–12 mg, >80% based on Alpine-Borane®).

(2R)-2,3-Dimethoxypropyl (2R)-2-methoxy-2-(trifluoromethyl)phenylacetate (**3**)*

A solution of (*S*)-MTPACl (0.06 mmol) in CH_2Cl_2 (1 mL) was added to a solution of the alcohol **2** (5 mg, 0.04 mmol), Et_3N (0.02 mL), and DMAP (ca. 1 mg) in CH_2Cl_2 (1 mL). After stirring for 1 h, the reaction mixture was concentrated under reduced pressure. ^1H NMR of the crude product indicated complete conversion to the diastereomeric Mosher's esters **3**; the ratio of diastereomers could be determined by ^{13}C NMR.[24] Fractionation by preparative TLC (EtOAc:hexane, 1:1) gave a pure sample of **3**. The Mosher's esters prepared from "racemic" alcohol **2** (i.e., from $NaBH_4$ reduction of **1**) indicated a 5% de in favor of the 2*S*,2′*R* isomer[35] and showed the following spectral properties: ^1H NMR δ (2*S*,2*R* diastereomer): 7.55 (2H, m, Ph), 7.41 (3H, m, Ph), 4.51 (1H, dd, $J = 3.5$, 11.5 Hz, H-1), 4.35 (1H, dd, $J = 6.5$, 11.5 Hz, H-1), 3.58 (3H, m, C-2 OCH_3), 3.48–3.38 (3H, m, H-2, 3), 3.39 (3H, s, OCH_3), 3.34 (1.5H, s, OCH_3); (2*R*,2*R* disatereomer): 7.55 (2H, m, Ph), 7.41 (3H, m, Ph), 4.52 (1H, dd, $J = 4$, 11.5 Hz, H-1), 4.35 (1H, dd, $J = 5$, 11.5 Hz, H-1), 3.58 (3H, m, C-2 OCH_3), 3.48–3.38 (3H, m, H-2, 3) 3.39 (3H, s, OCH_3), 3.32 (3H, s, OCH_3); ^{13}C NMR (partial data; data for 2*R*,2*R* diastereomer in parentheses) δ: 77.6 (77.5) (d, C-2), 71.2 (71.2) (t, C-3), 65.2 (64.7) (t, C-1), 59.3 (59.3) (q, OCH_3), 57.9 (57.8) (q, OCH_3), 55.4 (55.4) (q, C-2′ OCH_3 (br, coupled to F)); ^{19}F NMR ([H]) δ (TFA): −72.17 (2*R*,2*R*), −72.15 (2*S*,2*R*).

galacto-*2,3,4,5-Tetramethoxyhexanedial (**4**)*

DMSO (2 M in CH_2Cl_2, 3.5 mL, 7 mmol) was added via syringe to a solution of $(COCl)_2$ (0.3 mL, 2 mmol) in CH_2Cl_2 (5 mL) at −78°C. The mixture was stirred at −78°C for 30 min. and a solution of **6** (200 mg, 0.84 mmol) in CH_2Cl_2 (3 mL) was added via syringe. The reaction mixture was allowed to warm to −50 to −55°C (internal) over 10 min and stirred at that temperature for a further 40 min. Et_3N (1.5 mL, excess) was added and, after stirring for 10 min, the reaction mixture was allowed to warm to room temperature and then was concentrated, and fractionated by FCC (MeOH:CH_2Cl_2, 1:19), yielding **4** as a white solid (mp 138–139°C; 152 mg, 76%); IR: 2938, 2842, 1728, 1106 cm^{-1}; ^1H NMR δ: 9.87 (2H, s, H-1, 6), 3.83 (4H, br s, H-2, 3, 4, 5), 3.54 (6H, s, OCH_3), 3.18 (6H, s, OCH_3); ^{13}C NMR δ: 202.7 (d, C-1, 6), 85.4 (d, C-2, 5), 79.4 (d, C-3, 4), 60.1 (q, OCH_3), 58.9 (q, OCH_3); MS (CI, NH_3), m/z (relative intensity): 252 ($[M + 18]^+$, 100), 235 ($[M + 1]^+$, 49), 146 (15), 101 (41).

*General procedure for reduction of **4** with Alpine-Borane®*

Alpine-Borane® (0.5 M in THF, 3 equiv.) was added via syringe to a cooled (−78 or −95°C) solution of **4** (10–50 mg, 0.04–0.2 mmol; 0.012 M in CH_2Cl_2). After stirring at the indicated temperature for the indicated time, acetaldehyde (excess, ca. 0.1–0.2 mL) was added and the mixture stirred for a further 0.5 h. The reaction mixture was allowed to warm to room temperature and concentrated. The resulting crude product (or aliquots) was processed in one (or more) of the following ways:

*For isolation of **5** and **6***: The crude product was dissolved in ether

[34] An absolute value for the rate constants is required for calculation of reaction time. All other variables can be determined by the ratio of the rate constants.

[35] Assignment is based on the fact that the major diastereomer present corresponds to the major diasteromer derived from **2** obtained by reduction of **1** with (*R*)-Alpine-Borane®. This indicates that the major enantiomer of our sample of **1** is also the most reactive with (*R*)-Alpine-Borane®. Since reduction of **4** with (*R*)-Alpine-Borane® gives predominantly D-**5**, it is concluded that the major enantiomer of **1** should be the (*S*) isomer (i.e., excess of L-glyceraldehyde).

For personal use only.

and silica gel was added. The suspension was stirred at ambient temperature for 40 min and filtered.[36] The combined filtrate and washings were concentrated and fractionated by FCC (EtOAc:hexane, 1:4, and then MeOH:CH_2Cl_2, 1:9) to give hydroxyaldehyde fraction and a diol fraction. The hydroxyaldehyde fraction was further purified by FCC (EtOAc:hexane, 1:1) to give **5**. The diol fraction was further purified by FCC (MeOH:CH_2Cl_2, 1:9) to give **6**.

For measurement of conversion: The crude product was dissolved in methanol (ca. 1 mL) and $(CH_3O)_3CH$ (0.1 mL) and HCl (5% in methanol, a few drops) were added. After stirring overnight at room temperature, the reaction mixture was quenched by addition of $NaHCO_{3(s)}$, filtered, and concentrated. The ratio of **23** to **24** was determined by ^1H NMR. Fractionation by preparative TLC (EtOAc:hexane, 1:1, and then MeOH:CH_2Cl_2, 1:9) gave a mixture of **23** and **24** and pure **6**.

For measurement of the ratio of D-**5** *and* L-**5**: The crude product was dissolved in CH_2Cl_2 (ca. 0.5 mL) and DNPH (ca. 5 mg) was added. After 24 h, the reaction mixture was concentrated, and fractionated by preparative TLC (EtOAc:hexane, 1:1) to give **20**. The hydrazone **20** was dissolved in CH_2Cl_2 and treated with (*S*)-MTPACl in the presence of Et_3N and DMAP (39). After ca. 1 h, the reaction mixture was concentrated and fractionated by preparative TLC (EtOAc:hexane, 1:1) to give **22**. The ratio of D-**22** and L-**22** was determined by ^1H NMR.

Alternatively, the crude product was dissolved in trifluoroethanol (0.5 mL) and *p*-TsOH (ca. 3 mg) was added. After stirring 24 h at room temperature, $NaHCO_{3(s)}$ was added and the reaction mixture was filtered, concentrated, and fractionated by FCC (EtOAc:hexane, 1:3) to give **25**. The ratio of D-**25** and L-**25** was determined by ^{19}F NMR [H] in the presence of (+)-Eu(hfc)$_3$.

*(±)-2,3,4,5-Tetra-*O*-methylgalactose ((±)-***5***)*

To a solution of (±)-**10** (26 mg, 0.054 mmol) in acetonitrile (2 mL) was added 5% $HF_{(aq)}$ (a few drops). After stirring for 6 h at room temperature, the reaction mixture was quenched by addition of $NaHCO_{3(s)}$, and filtered. The resulting filtrate was concentrated, and fractionated by FCC (EtOAc:hexane, 1:1) yielding (±)-**5** as a colorless oil (ca. a 4:1 mixture of α and β septanose anomers; 12.5 mg, 100%); IR: 3496, 2974, 2933, 2827, 1102 cm^{-1}; ^1H NMR δ (α anomer): 4.86 (1H, d, J = 3.5, Hz, H-1), 4.13 (1H, d, J = 14 Hz, H-6), 3.78–3.65 (3H, m), 3.59 (3H, s, CH_3O), 3.53–3.45 (1H, m), 3.49 (3H, s, CH_3O), 3.46 (3H, s, CH_3O), 3.40 (3H, s, CH_3O), 3.35 (1H, m); δ (α anomer): 4.96 (1H, d, J = 3.5, Hz, H-1), 4.05 (1H, dd, J = 2, 14 Hz, H-6), 3.53 (3H, s, CH_3O), 3.51 (3H, s, CH_3O), 3.50 (3H, s, CH_3O), 3.44 (3H, s, CH_3O); ^{13}C NMR δ (α anomer): 97.4 (d, C-1), 83.4 (d), 82.5 (d), 81.2 (d), 79.4 (d), 67.7 (t, C-6), 60.7 (q, CH_3O), 59.3 (q, CH_3O), 58.3 (q, CH_3O), 56.9 (q, CH_3O); MS (CI, NH_3), m/z (relative intensity): 254 ([M + 18]$^+$, 24), 236 (41), 219 (100).

*2,3,4,5-Tetra-*O*-methyl-*D*-galactose (*D*-***5***)*

Hydrolysis of D-**10** as described above for (±)-**10** gave D-**5** (spectral data indistinguishable from (±)-**5**).

*2,3,4,5-Tetra-*O*-methyl-*L*-galactose (*L*-***5***)*

Hydrolysis of L-**10** as described above for (±)-**10** gave L-**5** (spectral data indistinguishable from (±)-**5**).

*2,3,4,5-Tetra-*O*-methylgalacitol (***6***)*

To a solution of **8** (290 mg, 0.40 mmol) in CH_3CN (20 mL) was added 5% $HF_{(aq)}$ (1 mL) at room temperature. After stirring overnight at room temperature, $NaHCO_{3(s)}$ (ca. 1 g) was added. The mixture was filtered, concentrated, and fractionated by FCC (MeOH:CH_2Cl_2, 1:19, and then 1:9) yielding **6** as a light yellow oil (96 mg, quantitative); IR: 3435, 2929, 1119 cm^{-1}; ^1H NMR δ: 3.88 (2H, dd, J = 5, 12 Hz, H-1, 6), 3.80 (2H, dd, J = 4, 12 Hz, H-1, 6), 3.55–3.45 (4H, m, H-2, 3, 4, 5), 3.49 (6H, s, OCH_3), 3.48 (6H, s, OCH_3); ^{13}C NMR δ: 81.2 (d, C-2,5), 80.2 (d, C-3, 4), 60.9 (t, C-1, 6), 60.3 (q, OCH_3), 57.9 (q, OCH_3); MS (CI, NH_3), m/z (relative intensity): 239 ([M + 1]$^+$, 100), 207 (11).

*1,6-Di-*O*-tritylgalacitol (***7***)*

To a solution of Ph_3CCl (6.4 g, 23 mmol) and DMAP (0.75 g, 6.1 mmol) in pyridine (40 mL) was added galacitol (2.4 g, 13 mmol). After stirring 48 h at room temperature, the reaction mixture was quenched by addition of $NH_4Cl_{(aq)}$ (30 mL), and extracted with EtOAc (3 × 50 mL). The combined organic layers was washed sequentially with water and brine, and concentrated under reduced pressure. The resulting solid was fractionated by FCC (EtOAc:hexane, 1:1, and then MeOH:CH_2Cl_2, 1:4) yielding **7** as a colorless solid (6.1 g, 69%; mp 156–157°C (EtOH)); IR: 3377, 3031, 2936, 1606, 1075 cm^{-1}; ^1H NMR δ: 7.45–7.20 (30H, m, Ph), 4.02 (2H, m, H-2, 5), 3.58 (2H, br s, OH), 3.42 (2H, dd, J = 4, 10 Hz, H-1, 6), 3.26 (2H, dd, J = 5.5, 10 Hz, H-1, 6), 2.82 (2H, br s, OH), 2.67 (2H, d, J = 6 Hz, H-3, 4); ^{13}C NMR δ: 143.5 (s, Ph), 128.6 (d, Ph), 128.0 (d, Ph), 127.3 (d, Ph), 87.1 (s, CPh_3), 72.0 (d), 69.2 (d), 66.7 (t, C-1, 6); MS: molecular ion not detected.

*2,3,4,5-Tetra-*O*-methyl-1,6-Di-*O*-tritylgalacitol (***8***)*

To a suspension of NaH (60% in oil, 2.6 g, 65 mmol) in THF (60 mL) was added a solution of **7** (4.5 g, 6.8 mmol) in THF (5 mL). After stirring for 10 min, iodomethane (3.7 mL, 59 mmol) was added and the reaction mixture was stirred overnight at room temperature. The reaction was quenched by addition of $NH_4Cl_{(aq)}$ (**CAUTION**: H_2 evolution) and extracted with EtOAc (3 × 50 mL). The combined organic layers was washed sequentially with water and brine, dried over Na_2SO_4, and concentrated. The resulting oil was fractionated by FCC (EtOAc:hexane, 1:9) yielding **8** as a colorless solid (4.8 g, 98%; mp 163–164°C ($CHCl_3$)); IR: 3085, 3050, 2939, 2829, 1596, 1090 cm^{-1}; ^1H NMR δ: 7.45–7.20 (30H, m, Ph), 3.60–3.45 (6H, m), 3.41 (6H, s, CH_3O), 3.27–3.19 (2H, m), 3.22 (6H, s, CH_3O); ^{13}C NMR δ: 144.1 (s, Ph), 128.7 (d, Ph), 127.8 (d, Ph), 127.0, (d, Ph), 87.3 (s, CPh_3), 79.3 (d), 79.1 (d), 62.7 (t, C-1, 6), 60.7 (q, CH_3O), 58.5 (q, CH_3O); MS: molecular ion not detected.

*(±)-2,3,4,5-Tetra-*O*-methyl-6-*O*-tritylgalacitol ((±)-***9***)*

To a solution of **8** (105 mg, 0.15 mmol) in MeOH (5 mL) and $CHCl_3$ (25 mL) was added trifluoroacetic acid (TFA; 0.5 mL) at room temperature. After stirring overnight at room temperature $NaHCO_{3(s)}$ (ca. 1 g) was added. The mixture was filtered, concentrated, and fractionated by FCC (MeOH:CH_2Cl_2, 1:9) to give (±)-**9** as a light yellow oil (49 mg, 70%); IR: 3463, 3051, 2963, 1095 cm^{-1}; ^1H NMR δ: 7.55–7.20 (15H, m, Ph), 3.89 (1H, dd, J = 5, 11.5 Hz), 3.81 (1H, dd, J = 4, 11.5 Hz), 3.61 (1H, dd, J = 2, 8 Hz), 3.57–3.40 (5H, m), 3.46 (3H, s, OCH_3), 3.42 (3H, s, OCH_3), 3.39 (3H, s, OCH_3), 3.22 (3H, s, OCH_3), 3.22–3.18 (1H, m); ^{13}C NMR δ: 143.9 (s, Ph), 128.7 (d, Ph), 127.8 (d, Ph), 127.1 (d, Ph), 87.1 (s, CPh_3), 80.6 (d), 79.9 (d), 79.7 (d), 79.3 (d), 62.2 (t), 61.4 (t), 60.8 (q, OCH_3), 60.2 (q, OCH_3), 58.3 (q, OCH_3), 57.6 (q, OCH_3); MS (CI, NH_3), m/z (relative intensity): 498 ([M + 18]$^+$, 3), 243 (100); and recovered **8** (23 mg, 22%).

*2,3,4,5-Tetra-*O*-methyl-6-*O*-trityl-*D*-galacitol (*D*-***9***)*

5% $HF_{(aq)}$ (5 drops) was added to a solution of D-**18** (15 mg, 0.025 mmol) in CH_3CN (5 mL) and the resulting solution was stirred for 5 min. The reaction mixture was diluted with $NaHCO_{3(aq)}$ (5 mL), extracted with CH_2Cl_2 (2 × 20 mL), and the combined organic layers dried over $Na_2SO_{4(s)}$, filtered, and concentrated under reduced pressure. The residue was fractionated by preparative TLC (EtOAc:hexane, 1:1) yielding alcohol D-**9** as a colorless oil (7.8 mg, 64%; spectral data indistinguishable from (±)-**9**) and diol **4** as a colorless oil (2 mg, 33%).

*2,3,4,5-Tetra-*O*-methyl-6-*O*-trityl-*L*-galacitol (*L*-***9***)*

Hydrolysis of L-**18** (15 mg) as described above gave L-**9** (7 mg, 58%; spectral data indistinguishable from (±)-**9**) and diol **4** (2 mg, 33%).

*(±)-2,3,4,5-Tetra-*O*-methyl-6-*O*-tritylgalactose ((±)-***10***)*

NMO (7 mg, 0.06 mmol) was added to a suspension of alcohol (±)-**9** (14 mg, 0.03 mmol) and powdered 4 Å molecular sieves (30

[36]This treatment facilitated the hydrolysis of the presumed 9-BBN borinate esters.

For personal use only.

mg) in CH_2Cl_2 (4 mL). After stirring for 10 min, TPAP (ca. 1 mg) was added and, after stirring for a further 30 min, the reaction mixture was directly fractioned by FCC (EtOAc:hexane, 1:3) to give aldehyde (±)-**10** as a colorless oil (12 mg, 84%); IR: 3059, 2933, 1448, 1098 cm^{-1}; ^1H NMR δ: 9.85 (1H, d, J = 1 Hz, H-1), 7.50–7.20 (15H, m, Ph), 3.82–3.74 (2H, m), 3.60–3.37 (3H, m), 3.50 (3H, s, OCH_3), 3.38 (3H, s, OCH_3), 3.33 (3H, s, OCH_3), 3.25–3.20 (1H, m), 3.21 (3H, s, OCH_3); ^{13}C NMR δ: 202.6 (d, C-1), 143.9 (s, Ph), 128.7 (d, Ph), 127.8 (d, Ph), 127.1 (d, Ph), 87.1 (s, CPh_3), 86.0 (d, C-2), 79.7 (d), 79.3 (d), 78.8 (d), 62.0 (t, C-6), 60.6 (q, OCH_3), 60.6 (q, OCH_3), 58.6 (q(x2), OCH_3); MS (CI, NH_3), m/z (relative intensity): 496 ([M + 18]$^+$, 14), 428 (100), 411 (35), 366 (14).

*2,3,4,5-Tetra-*O*-methyl-6-*O*-trityl-*D*-galactose (*D*-**10**)*

Oxidation of D-**9** as described above for (±)-**9** gave D-**10** (spectral data indistinguishable from (±)-**10**).

*2,3,4,5-Tetra-*O*-methyl-6-*O*-trityl-*D*-galactose (*L*-**10**)*

Oxidation of L-**9** as described above for (±)-**9** gave L-**10** (spectral data indistinguishable from (±)-**10**).

*2,3,4-Tri-*O*-methyl-*D*-galacitol (**12**)*

$NaBH_4$ (150 mg, 3.9 mmol) was added to a solution of **11** (1.5 g, 6.8 mmol) in EtOH (10 mL) and the mixture was stirred overnight. TFA (2 mL) was slowly added (**CAUTION**: H_2 evolution) to the mixture and, after stirring for 10 min, the solution was diluted with toluene and concentrated under reduced pressure. Fractionation of the residue by FCC (EtOAc:hexane, 1:1, and then MeOH:CH_2Cl_2, 1:9) gave triol **12** (36, 37) as a colorless oil (1.2 g, 80%); IR: 3417, 2925, 1459, 1091 cm^{-1}; ^1H NMR (D_2O) δ: 3.65 (2H, m), 3.55 (2H, m), 3.40–3.20 (4H, m), 3.29 (3H, s, OCH_3), 3.16 (6H, s, OCH_3); MS (CI, NH_3), m/z (relative intensity): 242 ([M + 18]$^+$, 8), 225 ([M + 1]$^+$, 100), 111 (23), 101 (22), 87 (15).

*2,3,4-Tri-*O*-methyl-6-*O*-trityl-*D*-galacitol (**13**) and 2,3,4-tri-*O*-methyl-1-*O*-trityl-*D*-galacitol (**14**)*

Trityl chloride (61 mg, 0.21 mmol) was added to a solution of triol **5** (40.1 mg, 0.18 mmol) and DMAP (11 mg, 0.09 mmol) in pyridine (5 mL). After stirring for 24 h at room temperature, the mixture was diluted with toluene, concentrated under reduced pressure, and the residue fractionated by FCC (EtOAc:hexane, 1:1, and then MeOH:CH_2Cl_2, 1:9) yielding a 2:1 mixture (^1H NMR) of diols **13** and **14** as a yellow oil (50 mg, 60%) and recovered triol **5** as a yellow oil (8 mg, 20%). The mixture of diols was refractionated by preparative TLC (EtOAc:hexane, 1:1; multiple elution) to give diol **13** as a yellow oil (31 mg, 37%); IR: 3434, 3056, 2933, 1680, 1184, 1129 cm^{-1}; ^1H NMR δ: 7.50–7.15 (1.5H, m, Ph), 3.95 (1H, br t, J = 6 Hz, H-5), 3.87 (1H, dd, J = 5, 11.5 Hz, H-1), 3.78 (1H, dd, J = 4, 11.5 Hz, H-1), 3.60 (1H, dd, J = 1.5, 6.5 Hz, H-4), 3.52 (3H, s, OCH_3), 3.50 (1H, m, H-3), 3.47 (3H, s, OCH_3), 3.41 (1H, dt, J = 4, 4.5 Hz, H-2), 3.34 (1H, dd, J = 6, 9 Hz, H-6), 3.26 (3H, s, OCH_3), 3.13 (1H, dd, J = 7, 9 Hz, H-6); ^{13}C NMR δ: 143.9 (s, Ph), 128.7 (d, Ph), 127.9 (d, Ph), 127.1 (d, Ph), 86.8 (s, CPh_3), 81.5 (d), 80.2 (d), 79.1 (d), 69.8 (d, C-5), 64.5 (t, C-6), 60.9 (t, C-1), 60.5 (q, OCH_3), 60.1 (q, OCH_3), 58.0 (q, OCH_3); MS (CI, NH_3), m/z (relative intensity): 484 ([M + 18]$^+$, 1) 403 (2), 243 (100); and diol **14** as a yellow oil (15 mg, 18%); IR: 3456, 3054, 2935, 1093 cm^{-1}; ^1H NMR δ: 7.52–7.21 (15H, m, Ph), 3.76 (1H, m), 3.70–3.50 (3H, m), 3.48 (1H, m), 3.40 (6H, s, OCH_3), 3.37 (3H, s, OCH_3), 3.48–3.23 (5H, m); ^{13}C NMR δ: 143.8 (s, Ph), 128.7 (d, Ph), 127.9 (d, Ph), 127.2 (d, Ph), 87.1 (s, CPh_3), 80.5 (d), 79.9 (d), 79.3 (d), 71.4 (d, C-5), 64.7 (t, C-6), 61.9 (t, C-1), 61.2 (q, OCH_3), 59.7 (q, OCH_3), 58.4 (q, OCH_3); MS (Cl, NH_3), m/z (relative intensity): 484 ([M + 18]$^+$, 11), 403 (14), 263 (16), 262 (66), 260 (17), 243 (100).

*1,5-Di-*O*-acetyl-2,3,4-tri-*O*-methyl-6-*O*-trityl-*D*-galacitol (**15**)*

Acetic anhydride (4 drops) was added to a solution of diol **13** (5 mg) and pyridine (8 drops) in CH_2Cl_2 (1 mL) and the mixture was stirred overnight. The reaction mixture was diluted with toluene, concentrated under reduced pressure, and the residue fractionated by FCC (EtOAc:hexane, 1:1) yielding **15** as yellowish oil (5 mg); IR: 3058, 2929, 1741, 1234, 1093 cm^{-1}; ^1H NMR δ: 7.50–7.05 (15H, m, Ph), 5.34 (1H, dt, J = 2, 6.5 Hz, H-5), 4.41 (1H, dd, J = 6, 11.5 Hz, H-1), 4.21 (1H, dd, J = 6.5, 11.5 Hz, H-1), 3.73 (1H, dd, J = 2, 9 Hz, H-6), 3.59 (1H, dt, J = 2, 6.5 Hz, H-2), 3.50 (1H, m, H-4), 3.45 (3H, s, OCH_3), 3.38 (3H, s, OCH_3), 3.26 (3H, s, OCH_3), 3.22 (1H, dd, J = 2, 8.5 Hz, H-3), 3.15 (1H, dd, J = 7, 9 Hz, H-6), 2.09 (3H, s, CH_3CO), 2.07 (3H, s, CH_3CO); ^{13}C NMR δ: 170.7 (s, C=O), 170.2 (s, C=O, 143.7 (s, Ph), 128.6 (d, Ph), 127.9 (d, Ph), 127.1 (d, Ph), 87.1 (s, CPh_3), 79.8 (d), 78.1 (d), 77.8 (d), 72.1 (d, C-5), 62.9 (t), 61.6 (t), 60.8 (q, OCH_3), 60.8 (q, OCH_3), 58.3 (q, OCH_3), 21.1 (q, CH_3CO), 20.9 (q, CH_3CO); MS (Cl, NH_3), m/z (relative intensity): 568 ([M + 18]$^+$, 3), 244 (26), 243 (100).

*5,6-Di-*O*-acetyl-2,3,4-tri-*O*-methyl-1-*O*-trityle-*D*-galacitol (**16**)*

Acetylation of diol **14** (5 mg) as decribed above gave **16** as yellowish oil (5 mg); IR: 3054, 2933, 1743, 1221, 1093 cm^{-1}; ^1H NMR δ: 7.50–7.20 (15H, m, Ph), 5.30 (1H, dt, J = 1.5, 7.5 Hz, H-5), 4.27 (2H, m, H-6), 3.60–3.42 (4H, m), 3.47 (3H, s, OCH_3), 3.36 (3H, s, OCH_3), 3.22 (1H, m), 3.17 (3H, s, OCH_3), 2.14 (3H, s, CH_3CO), 2.05 (3H, s, CH_3CO); ^{13}C NMR δ: 170.6 (s, C=O), 170.2 (s, C=O), 143.9 (s, Ph), 128.6 (d, Ph), 127.9 (d, Ph), 127.2 (d, Ph), 87.2 (s, CPh_3), 79.3 (d), 78.7 (d), 78.2 (d), 70.9 (d, C-5), 62.7 (t, C-6), 61.6 (t, C-1), 61.0 (q, OCH_3), 60.8 (q, OCH_3), 58.2 (q, OCH_3), 21.0 (q, CH_3CO), 20.8 (q, CH_3CO); MS (CI, NH_3), m/z (relative intensity): 568 ([M + 18]$^+$, 2), 326 (19), 309 (14), 262 (13), 244 (31), 243 (100).

*1-*O*-(tert-Butyldimethylsilyl)-2,3,4-tri-*O*-methyl-6-*O*-trityl-*D*-galacitol (**17**)*

TBDMSCl (10 mg, 0.07 mmol) was added to a solution of diol **13** (27 mg, 0.06 mmol) and imidazole (7 mg, 0.11 mmol) in CH_2Cl_2 (4 mL), and the mixture was stirred overnight. The reaction mixture was diluted with $NH_4Cl_{(aq)}$ (4 mL), extracted with CH_2Cl_2 (3 × 10 mL), and the combined organic layers was dried over $Na_2SO_{4(s)}$, concentrated, and fractionated by preparative TLC (EtOAc:hexane, 1:1) to give **17** as a pale yellow oil (26 mg, 77%); IR: 3465, 3058, 2951, 1091 cm^{-1}; ^1H NMR δ: 7.50–7.20 (15H, m, Ph), 4.02 (1H, m), 3.88 (1H, dd, J = 5.5, 10 Hz), 3.76 (1H, dd, J = 6.5, 10 Hz), 3.53 (2H, br s), 3.51 (3H, s, OCH_3), 3.47 (3H, s, OCH_3), 3.47–3.30 (2H, m), 3.24 (3H, s, OCH_3), 3.13 (1H, dd, J = 7, 9 Hz), 0.91 (9H, s, $SiC(CH_3)_3$), 0.10 (6H, s, $SiCH_3$); ^{13}C NMR δ: 144.0 (s, Ph), 128.7 (d, Ph), 127.8 (d, Ph), 127.0 (d, Ph), 86.7 (s, CPh_3), 81.1 (d), 79.2 (d), 78.8 (d), 69.9 (d, C-5), 64.8 (t, C-6), 61.4 (t, C-1), 61.0 (q, OCH_3), 59.9 (q, OCH_3), 58.6 (q, OCH_3), 25.9 (q, $SiC(CH_3)_3$), 18.2 (s, $SiC(CH_3)_3$); MS (CI, NH_3), m/z (relative intensity): 598 ([M + 18]$^+$, 5), 395 (22), 354 (14), 340 (100); and the recovered diol **13** (2 mg, 11%).

*1-*O*-(tert-Butyldimethylsilyl)-2,3,4,5-tetra-*O*-methyl-6-*O*-trityl-*D*-galacitol (D-**18**)*

NaH (50% in oil, 10 mg, 0.21 mmol) was added to a solution of alcohol **17** (21 mg, 0.04 mmol) in THF (5 mL). After stirring for 10 min, CH_3I (0.014 mL, 0.23 mmol) was added to the suspension, and the mixture was stirred at room temperature overnight and then concentrated. The residue was triturated with $CHCl_3$ (3 × 5 mL) and the combined filtrates concentrated and fractionated by preparative TLC (EtOAc:hexane, 1:3) to give D-**18** as a colorless oil (20 mg, 93%); IR: 3054, 2923, 1447, 1097 cm^{-1}; ^1H NMR δ: 7.50–7.20 (15H, m, Ph), 3.92 (1H, dd, J = 6, 10 Hz), 3.73 (1H, dd, J = 7.5, 10 Hz), 3.60–3.40 (5H, m), 3.47 (3H, s, OCH_3), 3.46 (3H, s, OCH_3), 3.41 (3H, s, OCH_3), 3.30–3.20 (1H, m), 3.21 (3H, s, OCH_3), 0.89 (9H, s, $SiC(CH_3)_3$), 0.08 (6H, s, $SiCH_3$); ^{13}C NMR δ: 144.0 (s, Ph), 128.7 (d, Ph), 127.8 (d, Ph), 127.0 (d, Ph), 87.1 (s, CPh_3), 80.5 (d), 79.3 (d), 79.1 (d), 78.4 (d), 62.6 (t), 61.5 (t), 60.7 (q, OCH_3), 60.6 (q, OCH_3), 58.4 (q, OCH_3), 58.3 (q, OCH_3), 25.9 (q, $SiC(CH_3)_3$), 18.2 (s, $SiC(CH_3)_3$); MS (Cl, NH_3), m/z (relative intensity): 612 ([M + 18]$^+$, 23), 537 (100), 535 (17), 430 (20), 428 (43).

*1-*O*-(tert-Butyldimethylsilyl)-2,3,4,5-tetra-*O*-methyl-6-*O*-trityl-*L*-galacitol (L-**18**)*

NaH (50% oil, 7 mg, 0.15 mmol) was added to a solution of alcohol **19** (10 mg, 0.02 mmol) in THF (5 mL). After stirring for 10 min, CH_3I (0.01 mL, 0.16 mmol) was added to a suspension, and

Can. J. Chem. Downloaded from www.nrcresearchpress.com by EESC ESCOLA DE ENGENHARIA on 09/08/12
For personal use only.

the mixture was stirred at room temperature overnight and concentrated. The residue was triturated with $CHCl_3$ (3 × 5 mL) and the combined filtrates concentrated and fractionated by preparative TLC (EtOAc:hexane, 1:3) to give L-**18** as a colorless oil (9 mg, 88%; spectral data indistinguishable from D-**18**).

*1-O-(tert-Butyldimethylsilyl)-3,4,5-tri-O-methyl-6-O-trityl-L-galacitol (**19**)*

TBDMSCl (32 mg, 0.21 mmol) was added to a solution of diol **14** (81 mg, 0.17 mmol) and imidazole (29 mg, 0.42 mmol) in CH_2Cl_2 (4 mL), and the mixture was stirred overnight. The reaction mixture was diluted with $NH_4Cl_{(aq)}$ (4 mL), extracted with CH_2Cl_2 (3 × 10 mL), and the combined organic layers was dried over $Na_2SO_{4(s)}$, concentrated, and fractionated by preparative TLC (EtOAc:hexane, 1:1) to give alcohol **19** as a pale yellow oil (79 mg, 78%); IR: 3474, 3058, 2950, 1093 cm^{-1}; ^1H NMR δ: 7.50–7.20 (15H, m, Ph), 4.02 (1H, m), 3.82–3.70 (2H, m), 3.69–3.61 (1H, m), 3.50–3.45 (2H, m), 3.45–3.38 (2H, m), 3.44 (3H, s, OCH_3), 3.40 (3H, s, OCH_3), 3.30 (3H, s, OCH_3), 0.88 (9H, s, $SiC(CH_3)_3$), 0.08 (6H, s, $SiCH_3$); ^{13}C NMR δ: 144.0 (s, Ph), 128.7 (d, Ph), 127.8 (d, Ph), 127.1 (d, Ph), 87.2 (s, CPh_3), 79.6 (d), 79.2 (d), 78.4 (d), 71.1 (d, C-5), 64.4 (t, C-6), 62.3 (t, C-1), 60.8 (q, OCH_3), 60.2 (q, OCH_3), 58.5 (q, OCH_3), 25.9 (q, $SiC(CH_3)_3$), 18.2 (s, $SiC(CH_3)_3$); MS (Cl, NH_3), m/z (relative intensity): 598 ($[M + 18]^+$, 2), 353 (6), 339 (100), 330 (18); and the recovered diol **14** (5 mg, 6%).

*(E)-2,3,4,5-Tetra-O-methyl-D-galactose 2,4-dinitrophenylhydrazone (D-**20**) and (Z)-2,3,4,5-tetra-O-methyl-D-galactose 2,4-dinitro phenylhydrazone (D-**21**)*

DNPH (ca. 5 mg) was added to a stirred solution of D-**5** (3 mg) in CH_2Cl_2 (0.5 mL). After 24 h, the reaction mixture was diluted with $NaHCO_{3(aq)}$ (5 mL) and extracted with CH_2Cl_2 (10 mL). The CH_2Cl_2 layer was dried over $Na_2SO_{4(s)}$ and concentrated under reduced pressure. ^1H NMR of the crude product indicated the presence a 4:1 mixture of (*E*) and (*Z*) hydrazones.[27] Fractionation of the residue by preparative TLC (EtOAc:hexane, 1:1) gave D-**20** (4 mg, 75%); ^1H NMR δ: 9.15 (1H, d, J = 2.5 Hz, Ph), 8.35 (1H, dd, J = 2.5, 9.5 Hz, Ph), 8.00 (1H, d, J = 9.5 Hz, Ph), 7.58 (1H, d, J = 6.5 Hz, H-1), 4.18 (1H, br d, J = 7 Hz, H-2), 4.00–3.85 (2H, m), 3.61 (2H, br s), 3.58–3.50 (1H, m), 3.54 (3H, s, OCH_3), 3.51 (3H, s, OCH_3), 3.48 (3H, s, OCH_3), 3.45 (3H, s, OCH_3); and D-**21** (1 mg, 19%); ^1H NMR δ: 9.15 (1H, d, J = 2.5 Hz, Ph), 8.32 (1H, dd, J = 2.5, 9.5 Hz, Ph), 7.97 (1H, d, J = 9.5 Hz, Ph), 7.00 (1H, d, J = 4 Hz, H-1), 4.29 (1H, dd, J = 3.5, 4 Hz, H-2), 4.00–3.85 (2H, m), 3.72–3.62 (2H, m), 3.58–3.50 (1H, m), 3.54 (3H, s, OCH_3) 3.49 (3H, s, OCH_3), 3.46 (3H, s, OCH_3), 3.41 (3H, s, OCH_3).

*(E)-2,3,4,5-Tetra-O-methyl-L-galactose 2,4-dinitrophenylhydrazone (L-**20**) and (Z)-2,3,4,5-tetra-O-methyl-L-galactose 2,4-dinitro phenylhydrazone (L-**21**)*

Analogous treatment of L-**5** with DNPH as above provided L-**20** and L-**21** (^1H NMR indistinguishable from D-**20** and D-**21**, respectively).

*6-O-[(2R)-2-Methoxy-2-(trifluoromethyl)-2-phenylacetyl]-2,3,4,5-tetra-O-methyl-D-galactose 2,4-dinitrophenylhydrazone (D-**22**)*

A solution of (*S*)-MTPACl (2 mg, 0.007 mmol)[28] in CH_2Cl_2 (0.2 mL) was added to a solution of alcohol D-**20** (1.7 mg, 0.004 mmol), Et_3N (0.002 mL, 0.014 mmol), and DMAP (ca. 0.5 mg) in CH_2Cl_2 (0.3 mL). After stirring for 1 h, the reaction mixture was diluted with toluene and concentrated under reduced pressure. Fractionation of the residue by preparative TLC (EtOAc:hexane, 1:1) gave D-**22** as a yellow oil (2 mg); ^1H NMR δ: 9.14 (1H, d, J = 2.5 Hz, NPh), 8.35 (1H, dd, J = 2.5, 9.5 Hz, NPh), 7.98 (1H, d, J = 9.5 Hz, NPh), 7.60–7.50 (3H, m, Ph), 7.45–7.40 (3H, m, H-1, Ph), 4.66 (1H, dd, J = 6, 11 Hz, H-6), 4.46 (1H, dd, J = 6, 11 Hz, H-6), 4.13 (1H, dd, J = 2.5, 6 Hz, H-2), 3.73 (1H, dt, J = 2, 6 Hz, H-5), 3.58 (1H, dd, J = 2.5, 8.5 Hz, H-3), 3.56 (3H, br s, C-2′ OCH_3), 3.47 (1H, dd, J = 2, 8.5 Hz, H-4), 3.43 (3H, s, OCH_3), 3.42 (3H, s, OCH_3), 3.40 (3H, s, OCH_3), 3.39 (3H, s, OCH_3); MS (electron capture; negative ion: ECNI) (CI, NH_3), m/z (relative intensity): 632 ($[M]^-$, 5), 233 (6), 202 (8), 200 (10), 189 (10), 182 (100).

*6-O-[(2R)-2-Methoxy-2-(trifluoromethyl)-2-phenylacetyl]-2,3,4,5-tetra-O-methyl-L-galactose 2,4-dinitrophenylhydrazone (L-**22**)*

Treatment of L-**20** (1.8 mg) with (*S*)-MTPACl as above gave ester L-**22** as a yellow oil (2 mg); ^1H NMR δ: 9.14 (1H, d, J = 2.5 Hz, NPh), 8.35 (1H, dd, J = 2.5, 9.5 Hz, NPh), 7.98 (1H, d, J = 9.5 Hz, NPh), 7.60–7.50 (3H, m, Ph), 7.45–7.40 (3H, m, H-1, Ph), 4.61 (1H, dd, J = 6, 11 Hz, H-6), 4.48 (1H, dd, J = 6, 11 Hz, H-6), 4.13 (1H, dd, J = 2.5, 6.5 Hz, H-2), 3.80–3.70 (1H, m), 3.65–3.55 (1H, m), 3.57 (3H, s, OCH_3), 3.55–3.40 (2H, m), 3.48 (3H, s, OCH_3), 3.42 (6H, s, OCH_3), 3.36 (3H, s, OCH_3); MS (ECNI; CI, NH_3), m/z (relative intensity): 632 ($[M]^-$, 4), 182 (100).

*(galacto)-1,1,2,3,4,5,6,6-Octamethoxyhexane (**23**)*

To a solution of **4** (10 mg, 0.043 mmol) in methanol (1 mL) were added $(CH_3O)_3CH$ (0.1 mL) and HCl (5% in methanol, a few drops). After stirring overnight at room temperature, the reaction mixture was quenched by addition of $NaHCO_{3(s)}$, filtered, and concentrated. The resulting residue was fractionated by FCC (EtOAc:hexane, 1:1) yielded **23** as a colorless oil (14 mg, 100%); IR: 2937, 2832, 1100 cm^{-1}; ^1H NMR δ: 4.54 (2H, d, J = 7.5 Hz, H-1, 6), 3.57 (6H, s, CH_3O), 3.53–3.43 (4H, m, H-2, 3, 4, 5), 3.51 (6H, s, CH_3O), 3.45 (6H, s, CH_3O), 3.36 (6H, s, CH_3O); ^{13}C NMR δ: 105.2 (d, C-1, 6), 79.4 (d), 79.2 (d), 60.4 (q, CH_3O), 59.9 (q, CH_3O), 55.6 (q, CH_3O), 52.5 (q, CH_3O); MS (CI, NH_3), m/z (relative intensity): 295 ($[M - OCH_3]^+$, 100), 224 (23), 207 (43), 101 (73), 75 (100).

*Methyl (±)-2,3,4,5-tetramethoxy-α-galactoseptanoside ((±-**24**)*

To a solution of (±)-**10** (15 mg, 0.031 mmol) in methanol (1 mL) were added $(CH_3O)_3CH$ (0.1 mL) and HCl (5% in methanol, a few drops). After stirring overnight at room temperature, the reaction mixture was quenched by addition of $NaHCO_{3(s)}$, and filtered. The resulting filtrate was concentrated, and fractionated by FCC (EtOAc:hexane, 1:1) yielding (±)-**24** as a colorless oil (7 mg, 89%); IR: 2931, 2903, 2823, 1192 cm^{-1}; ^1H NMR δ: 4.50 (1H, d, J = 2.5 Hz, H-1), 4.11 (1H, dd, J = 2.5, 13.5 Hz, H-6), 3.80–3.75 (2H, m, H-3, 4), 3.69 (1H, dd, J = 3.5, 13.5 Hz, H-6), 3.57–3.50 (2H, m, H-2, 5), 3.54 (3H, s, CH_3O), 3.50 (3H, s, CH_3O), 3.48 (3H, s, CH_3O), 3.43 (3H, s, CH_3O), 3.40 (3H, s, CH_3O); ^{13}C NMR δ: 105.7 (d, C-1), 81.8 (d), 81.3 (d), 80.7 (d), 80.6 (d), 67.9 (t, C-6), 60.3 (q, CH_3O), 59.3 (q, CH_3O), 59.0 (q, CH_3O), 57.1 (q, CH_3O), 56.0 (q, CH_3O); MS (CI, NH_3), m/z (relative intensity): 268 ($[M + 18]^+$, 48), 236 (64), 219 (100).

Reaction of (±)-**5** under the same conditions produced (±)-**24** in analogous yield. Samples of D- and L-**24** (spectral data indistinguishable from (±)-**24**) were similarly available from D- and L-**10**, respectively.

*2,2,2-Trifluoroethyl (±)-2,3,4,5-tetra-O-methylgalactoseptanoside ((±)-**25**)*

To a solution of (±)-**10** (20 mg, 0.042 mmol) in trifluoroethanol (0.5 mL) was added TsOH (ca. 3 mg). After stirring 24 h at room temperature, the reaction mixture was quenched by addition of $NaHCO_{3(s)}$, and filtered. The resulting filtrate was concentrated, and fractionated by FCC (EtOAc:hexane, 1:3) yielding (±)-**25** as a colorless oil (ca. a 1:2 mixture of α and β amomers; 13.5 mg, 100%); IR: 2935, 2828, 1280, 1110 cm^{-1}; ^1H NMR δ (β anomer): 4.58 (1H, d, J = 6 Hz, H-1), 4.16–3.55 (5H, m), 3.54 (3H, s, CH_3O), 3.50 (6H, s, CH_3O), 3.46 (3H, s, CH_3O), 3.22 (1H, dd, J = 3.5, 3.5 Hz); δ (α anomer): 4.76 (1H, d, J = 2 Hz, H-1), 3.56 (3H, s, CH_3O), 3.50 (3H, s, CH_3O), 3.48 (3H, s, CH_3O), 3.40 (3H, s, CH_3O); ^{13}C NMR δ: 123.9 (s (q, $^1J_{CF}$ = 278 Hz), CF_3), 104.4 (d, C-1), 80.6 (d), 80.6 (d), 80.1 (d), 79.3 (d), 77.4 (d), 64.6 (t (q, $^2J_{CF}$ = 35 Hz), CH_2CF_3), 60.4 (q, CH_3O), 60.0 (q, (H_3O), 59.2 (q, CH_3O), 58.6 (t, C-6), 57.2 (q, CH_3O); δ (α anomer): 124.0 (s(q, $^1J_{CF}$ = 278 Hz), CF_3), 104.4 (d, C-1), 82.0 (d), 81.3 (d), 80.8 (d), 80.3 (d), 68.0 (t, C-6), 61.0 (q, CH_3O), 59.6 (q, CH_3O), 59.0 (q, CH_3O), 57.3 (q, CH_3O); ^{19}F NMR [H], δ (TFA): −74.63 (α anomer), −74.67 (β anomer); in the presence of (+)-Eu(hfc)$_3$ the signals for the enantiomers of the α anomer are cleanly separated. The high-field signal is due to the D-enantiomer; MS (CI, NH_3), m/z (relative intensity): 336 ($[M + 18]^+$, 51), 236 (59), 219 (100).

*(D-gluco-2,3,4,5-Tetramethoxyhexanedial (**26**)*

DMSO (1.0 M in CH_2Cl_2, 0.88 mL, 0.88 mmol) was added dropwise via syringe to a solution of $(COCl)_2$ (48 mg, 0.38 mmol) in CH_2Cl_2 (1 mL) at −78°C. The reaction mixture was stirred at −78°C for 30 min and a solution of diol **29** (30 mg, 0.12 mmol) in CH_2Cl_2 (1 mL) was added dropwise via syringe. The resulting mixture was allowed to warm to −55 to −50°C (internal) in 10 min and stirred at that temperature for a further 50 min. Et_3N (0.17 mL, 1.3 mmol) was added and, after stirring at −55°C for 10 min, the mixture was allowed to warm to room temperature, and then was concentrated and fractionated by FCC (EtOAc:hexane, 1:1) yielding **26** as a colorless oil (27 mg, 93%); IR: 2987, 2833, 1729, 1093 cm^{-1}; ^1H NMR δ: 9.72 (1H, s), 9.71 (1H, d, J = 2 Hz), 3.86 (1H, d, J = 5 Hz), 3.83 (1H, dd, J = 2, 5 Hz), 3.76 (1H, dd, J = 4, 5 Hz), 3.69 (1H, dd, J = 4, 5 Hz), 3.50 (3H, s, CH_3O), 3.48 (3H, s, CH_3O), 3.44 (3H, s, CH_3O), 3.31 (3H, s, CH_3O); ^{13}C NMR δ: 200.7 (d), 199.6 (d), 85.6 (d), 83.2 (d), 81.7 (d), 80.3 (d), 59.9 (q, CH_3O), 59.7 (q, CH_3O), 59.0 (q, CH_3O), 58.8 (q, CH_3O); MS (CI, NH_3), m/z (relative intensity): 252 ([M + 18]$^+$, 100), 235 ([M + 1]$^+$, 50), 101 (66).

*General procedure for reduction of **26** with Alpine-Borane®*

Alpine-Borane® (0.5 M in THF, 3 equiv.) was added via syringe to a solution of **26** in CH_2Cl_2 (10–50 mg, 0.04–0.2 mmol; 0.012 M for (*R*)-Alpine-Borane®; 0.025 M for (*S*)-Alpine-Borane®) at −78°C. After stirring for the indicated time, acetaldehyde (excess, ca. 0.1–0.2 mL) was added and the mixture stirred for a further 0.5 h. The reaction mixture was allowed to warm to room temperature and concentrated. The resulting crude product (or aliquots) was processed in one (or more) of the following ways:

*For isolation of **27**, **28**, and **29***: The crude product was dissolved in ether and silica gel was added. The suspension was stirred at ambient temperature for 40 min and filtered.[36] The combined filtrate and washings was concentrated and fractionated by FCC (EtOAc:hexane, 1:4, and then MeOH:CH_2Cl_2, 1:9) to give a hydroxyaldehyde fraction and a diol fraction. The hydroxyaldehyde fraction was further purified by FCC (EtOAc:hexane, 1:1) to give a mixture of **26** and **27**. The diol fraction was further purified by FCC (MeOH:CH_2Cl_2, 1:9) to give **29**.

*For measurement of conversion and ratio of **27** and **28***: The crude product was dissolved in methanol (ca. 1 mL) and $(CH_3O)_3CH$ (0.1 mL) and HCl (5% in methanol, a few drops) were added. After stirring for 1.5 h at room temperature, the reaction mixture was quenched by addition of $NaHCO_{3(s)}$, filtered, and concentrated. The relative amounts of **48–52** present were determined by ^1H NMR.[37] Fractionation by preparative TLC (EtOAc:hexane, 1:1, and then MeOH:CH_2Cl_2, 1:9) gave a mixture of **48–52** and pure **29**.

*For measurement of the ratio of **27** to **28***: The crude product was dissolved in CH_2Cl_2 (ca. 0.5 mL) and DNPH (ca. 5 mg) was added. After 24 h, the reaction mixture was concentrated, and fractionated by preparative TLC (EtOAc:hexane, 1:1) to give a mixture of **46** and **47**. The ratio of **46** and **47** was determined by ^1H NMR.

*2,3,4,5-Tetra-O-methyl-D-glucose (**27**)*

To a solution of **44** (30 mg, 0.063 mmol) in acetonitrile (3 mL) was added 5% $HF_{(aq)}$ (2 drops). After stirring for 3 h at room temperature, $NaHCO_{3(s)}$ was added and the reaction mixture was filtered, concentrated, and fractionated by FCC (EtOAc:hexane, 1:1) yielding **27** as colorless oil (13 mg, 87%); IR: 3420, 2930, 2827, 1727 (weak), 1096 cm^{-1}; ^1H NMR δ (hydroxyaldehyde tautomer; partial data): 9.74 (1H, s, H-1), 3.58 (3H, s, OCH_3), 3.53 (3H, s, OCH_3), 3.42 (3H, s, OCH_3), 3.30 (3H, s, OCH_3); δ (β-septanose tautomer; partial data): 4.64 (1H, d, J = 7.5 Hz, H-1), 3.55 (3H, s, OCH_3), 3.51 (3H, s, OCH_3), 3.50 (3H, s, OCH_3), 3.40 (3H, s, OCH_3); ^{13}C NMR δ: 81.3 (d), 81.2 (d), 81.1 (d), 79.0 (d), 61.6 (t), 60.5 (t), 60.3 (q, OCH_3), 59.6 (q, OCH_3), 58.7 (q, OCH_3), 57.3 (q, OCH_3); MS (CI, NH_3), m/z (relative intensity): 254 ([M + 18]$^+$, 6), 237 ([M + 1]$^+$, 5), 236 (6), 220 (100), 143 (37), 101 (53), 61 (62).

[37]Under these conditions, the major products from **27** and **28** were **50** and **52**, respectively.

*2,3,4,5-Tetra-O-methyl-L-gulose (**28**)*

To a solution of **45** (10 mg, 0.021 mmol) in acetonitrile (1 mL) was added 5% $HF_{(aq)}$ (1 drop). After stirring for 1 h at room temperature, $NaHCO_{3(s)}$ was added and then the reaction mixture was filtered, concentrated, and fractionated by preparative TLC (EtOAc:hexane, 1:1) yielding **27** as colorless oil (4 mg, 81%); IR: 3422, 2929, 2824, 1725 (weak), 1100 cm^{-1}; ^1H NMR δ: 5.09 (1H, d, J = 6 Hz, H-1), 3.85 (1H, dd, J = 2, 13.5 Hz), 3.77–3.50 (4H, m), 3.51 (3H, s, OCH_3), 3.50 (3H, s, OCH_3), 3.48 (3H, s, OCH_3), 3.43 (3H, s, OCH_3), 3.26 (1H, m); MS (CI, NH_3), m/z (relative intensity): 237 ([M + 1]$^+$, 62), 220 (100), 187 (53), 143 (26), 101 (88).

*2,3,4,5-Tetra-O-methyl-D-glucitol (**29**)*

To a solution of **31** (178 mg, 0.26 mmol) in $CHCl_3$ (5 mL) and MeOH (2 mL) was added TFA (0.1 mL). After stirring 14 h at room temperature $NaHCO_{3(s)}$ (ca. 1 g) was added and the resulting mixture was filtered, concentrated, and fractionated by FCC (MeOH:CH_2Cl_2, 1:9) to give **29** as a colorless oil (60 mg, quantitative); IR: 3434, 2930, 1111 cm^{-1}; ^1H NMR δ: 3.90 (1H, dd, J = 3.5, 12 Hz), 3.86 (1H, dd, J = 4, 11.5 Hz), 3.71 (1H, dd, J = 3.5, 12 Hz), 3.67 (1H, dd, J = 5, 11.5 Hz), 3.58–3.48 (3H, m), 3.54 (3H, s, OCH_3), 3.51 (3H, s, OCH_3), 3.50 (3H, s, OCH_3), 3.43 (3H, s, OCH_3), 3.42–3.37 (1H, m), 1.88 (2H, br s, OH); ^{13}C NMR δ: 81.3 (d), 81.2 (d), 81.1 (d), 79.0 (d), 61.6 (t), 60.5 (t), 60.3 (q, OCH_3), 59.6 (q, OCH_3), 58.7 (q, OCH_3), 57.3 (q, OCH_3); MS (CI, NH_3), m/z (relative intensity): 239 ([M + 1]$^+$, 100), 207 (25), 101 (26), 87 (15), 71 (19).

*1,6-Di-O-trityl-D-glucitol (**30**)*

To a solution of Ph_3CCl (3.1 g, 11.2 mmol) and DMAP (0.32 g, 2.6 mmol) in pyridine (25 mL) was added D-glucitol (1.0 g, 5.56 mmol). After stirring for 48 h at room temperature, the reaction mixture was diluted with EtOAc (70 mL) and $NH_4Cl_{(aq)}$ (30 mL). The organic layer was washed sequentially with water and brine, and concentrated under reduced pressure. The resulting solid was fractionated by FCC (EtOAc/hexane, 1:1, then MeOH/CH_2Cl_2, 1:4) yielding **30** as a colorless solid (3.7 g, 100%; mp 75.5–77°C [$EtOH_{(aq)}$]); IR: 3424, 3058, 1596, 1075 cm^{-1}; ^1H NMR δ: 7.45–7.20 (30H, m, Ph), 3.88 (2H, br s), 3.80 (1H, br s), 3.63 (1H, br t, J = 5.5 Hz), 3.37–3.30 (3H, m), 3.22 (1H, dd, J = 6, 10 Hz), 3.11 (1H, d, J = 5.5 Hz, OH), 3.01 (1H, br s, OH), 2.99 (1H, d, J = 5.5 Hz, OH), 2.78 (1H, d, J = 6 Hz, OH); ^{13}C NMR δ: 143.6 (s, Ph), 128.6 (d, Ph), 128.0 (d, Ph), 127.2 (d, Ph), 87.1 (s, CPh_3), 73.7 (d), 73.1 (d), 71.6 (d), 70.0 (d), 65.1 (t, C-1 or C-6), 64.9 (t, C-1 or C-6); MS: molecular ion not detected.

*2,3,4,5-Tetra-O-methyl-1,6-di-O-trityl-D-glucitol (**31**)*

To a suspension of NaH (60% in oil; 90 mg, 2.3 mmol) in THF (5 mL) was added a solution of **30** (210 mg, 0.31 mmol) in THF (1 mL) and then iodomethane (0.15 mL, 2.3 mmol). After stirring for 14 h, the reaction mixture was quenched by addition of $NH_4Cl_{(aq)}$ (**CAUTION**: H_2 evolution) and extracted with EtOAc (3 × 15 mL). The combined organic layers were washed sequentially with water and brine, dried over Na_2SO_4, and concentrated. The resulting liquid was fractionated by FCC (EtOAc:hexane, 1:3) yielding **31** as a colorless solid (mp 71–72°C; 310 mg, 72%); IR: 3085, 3051, 2925, 1598, 1093 cm^{-1}; ^1H NMR δ: 7.45–7.20 (30H, m, Ph), 3.67–3.56 (3H, m), 3.56 (3H, s, CH_3O), 3.54 (3H, s, CH_3O), 3.48 (3H, s, CH_3O), 3.43 (2H, m), 3.34 (1H, dd, J = 2.5, 7 Hz), 3.18–3.09 (2H, m), 2.90 (3H, s, CH_3O); ^{13}C NMR δ: 144.2 (s, Ph), 128.9 (d, Ph), 127.8 (d, Ph), 127.0 (d, Ph), 86.7 (s, CPh_3), 86.6 (s, CPh_3), 81.7 (d), 81.1 (d), 80.6 (d), 79.9 (d), 63.5 (t, C-1 or C-6), 62.7 (t, C-1 or C-6), 60.5 (q, CH_3O), 59.9 (q, CH_3O), 59.1 (q, CH_3O), 58.5 (q, CH_3O); MS: molecular ion not detected.

*2,3,4-Tri-O-methyl-D-glucitol (**33**)*

$NaBH_4$ (100 mg, 2.6 mmol) was added to a solution of **32** (1.3 g, 5.9 mmol) in EtOH (20 mL) and the mixture was stirred overnight. TFA (1 mL) was added slowly (**CAUTION**: H_2 evolution) to the mixture and, after stirring for 10 min, the solution was diluted with toluene and concentrated under reduced pressure. Fractionation of the residue by FCC (EtOAc:hexane, 1:1, and then MeOH:CH_2Cl_2, 1:9)

Can. J. Chem. Downloaded from www.nrcresearchpress.com by EESC ESCOLA DE ENGENHARIA on 09/08/12
For personal use only.

gave triol **33** (37) as a colorless oil (1.2 g, 87%); IR: 3394, 2934, 2831, 1085 cm^{-1}; ^1H NMR δ: 3.91–3.76 (2H, m), 3.75–3.68 (2H, m), 3.67–3.58 (1H, m), 3.58–3.40 (3H, m), 3.55 (3H, s, OCH_3), 3.48 (3H, s, OCH_3), 3.45 (3H, s, OCH_3); ^{13}C NMR δ: 81.2 (d), 80.9 (d), 78.8 (d), 71.5 (d), 63.6 (t, C-6), 61.2 (t, C-1), 60.0 (q, OCH_3), 59.3 (q, OCH_3), 58.4 (q, OCH_3); MS (CI, NH_3), m/z (relative intensity): 242 ($[M + 18]^+$, 17), 225 ($[M + 1]^+$, 100), 207 (13), 101 (27).

*2,3,4-Tri-*O*-methyl-6-*O*-trityl-*D*-glucitol* (**34**) *and 2,3,4-tri-*O*-methyl-1-*O*-trityl-*D*-glucitol* (**35**)

Trityl chloride (403 mg, 1.4 mmol) was added to a solution of triol **33** (270 mg, 1.2 mmol) in pyridine (20 mL), and the mixture was stirred at room temperature for 24 h. The mixture was diluted with toluene and concentrated, and fractionated by FCC (EtOAc:hexane, 1:1, and then MeOH:CH_2Cl_2, 1:9) yielding a 1.7:1 mixture (^1H NMR) of diols **34** and **35** as a yellow oil (314 mg, 56%) and recovered triol **33** as a yellowish oil (46 mg, 17%). The mixture of diols was refractionated by FCC (EtOAc:hexane, 1:1) to give diol **34** as a yellow oil (184 mg, 32%); IR: 3448, 2932, 1448, 1090 cm^{-1}; ^1H NMR δ: 7.60–7.20 (15H, m, Ph), 4.05 (1H, q, J = 5.5 Hz), 3.79 (1H, m), 3.60 (1H, m), 3.57–3.47 (3H, m), 3.44 (3H, s, OCH_3), 3.41 (3H, s, OCH_3), 3.35 (1H, dd, J = 6, 9.5 Hz), 3.33–3.27 (1H, m) 3.30 (3H, s, OCH_3); ^{13}C NMR δ: 143.8 (s, Ph), 128.7 (d, Ph), 127.9 (d, Ph), 127.2 (d, Ph), 86.8 (s, CPh_3), 81.4 (d), 81.0 (d), 79.1 (d), 70.2 (d, C-5), 64.7 (t, C-6), 61.5 (t, C-1), 59.9 (q, OCH_3), 58.7 (q, OCH_3), 58.7 (q, OCH_3); MS (CI, NH_3), m/z (relative intensity): 484 ($[M + 18]^+$, 1), 243 (100), 225 (13); and diol **35** as a yellow oil (102 mg, 18%); IR: 3437, 2935, 1448, 1092 cm^{-1}; ^1H NMR δ: 7.50–7.20 (15H, m, Ph), 3.78–3.62 (3H, m), 3.60–3.45 (3H, m), 3.43 (3H, s, OCH_3), 3.40 (3H, s, OCH_3), 3.37–3.32 (2H, m), 3.28 (3H, s, OCH_3), 3.24 (1H, dd, J = 5, 10 Hz); ^{13}C NMR δ: 143.9 (s, Ph), 128.6 (d, Ph), 127.9 (d, Ph), 127.1 (d, Ph), 86.9 (s, CPh_3), 80.4 (d), 79.8 (d), 78.5 (d), 71.6 (d, C-5), 63.9 (t, C-6), 61.7 (t, C-1), 59.9 (q, OCH_3), 58.7 (q, OCH_3), 58.3 (q, OCH_3); MS (CI, NH_3), m/z (relative intensity): 484 ($[M + 18]^+$, 3), 243 (100), 225 (12), 101 (14).

*1,5-Di-*O*-acetyl-2,3,4-tri-*O*-methyl-6-*O*-trityl-*D*-glucitol* (**36**)

Acetic anhydride (4 drops) was added to a solution of diol **34** (5 mg) and pyridine (8 drops) in CH_2Cl_2 (1 mL) and the mixture was stirred overnight. The reaction mixture was diluted with toluene, concentrated under reduced pressure, and the residue fractionated by FCC (EtOAc:hexane, 1:1) yielding **34** as yellowish oil (5 mg, 85%); IR: 3085, 3063, 3027, 2932, 2830, 1740, 1234, 1094 cm^{-1}; ^1H NMR δ: 7.50–7.15 (15H, m, Ph), 5.22 (1H, ddd, J = 3, 5.5, 5.5 Hz, H-5), 4.31 (1H, dd, J = 3.5, 12 Hz, H-1), 4.16 (1H, dd, J = 6.5, 12 Hz, H-1), 3.66 (1H, dd, J = 3.5, 5.5 Hz, H-4), 3.58 (1H, ddd, J = 3.5, 5.5, 6.5 Hz, H-2), 3.55–3.35 (3H, m, H-3, 6), 3.46 (3H, s, OCH_3), 3.38 (3H, s, OCH_3), 3.31 (3H, s, OCH_3), 2.17 (3H, s, CH_3CO), 2.08 (3H, s, CH_3CO); ^{13}C NMR δ: 170.8 (s, C=O), 170.0 (s, C=O), 143.8 (s, Ph), 128.7 (d, Ph), 127.8 (d, Ph), 127.1 (d, Ph), 86.6 (s, CPh_3), 80.4 (d), 79.3 (d), 79.3 (d), 73.1 (d), 64.1 (t), 62.0 (t), 60.6 (q, OCH_3), 60.2 (q, OCH_3), 59.0 (q, OCH_3), 21.2 (q, CH_3CO), 20.9 (q, CH_3CO); MS: molecular ion not detected.

*5,6-Di-*O*-acetyl-2,3,4-tri-*O*-methyl-1-*O*-trityl-*D*-glucitol* (**37**)

Acetylation of diol **35** (5 mg) as above gave **37** as yellowish oil (5 mg, 85%); IR: 2923, 1745, 1242, 1093, 706 cm^{-1}; ^1H NMR δ: 7.50–7.20 (15H, m, Ph), 5.20 (1H, m, H-5), 4.53 (1H, dd, J = 2.5, 12 Hz, H-6), 4.08 (1H, dd, J = 6.5, 12 Hz, H-6), 3.63–3.46 (3H, m), 3.47 (6H, s, OCH_3), 3.38 (1H, m), 3.13 (3H, s, OCH_3), 3.07 (1H, dd, J = 4.5, 10 Hz, H-1), 2.07 (3H, s, CH_3CO), 2.00 (3H, s, CH_3CO); ^{13}C NMR δ: 170.7 (s, C=O), 169.9 (s, C=O), 143.9 (s, Ph), 128.7 (d, Ph), 127.8 (d, Ph), 127.1 (d, Ph), 86.7 (s, CPh_3), 81.3 (d), 81.0 (d), 80.1 (d), 71.8 (d), 62.6 (t), 62.3 (t), 61.0 (q, OCH_3), 60.2 (q, OCH_3), 58.7 (q, OCH_3), 21.1 (q, CH_3CO), 20.8 (q, CH_3CO); MS: molecular ion not detected.

*1-*O*-(*tert*-Butyldimethylsilyl)-2,3,4-tri-*O*-methyl-6-*O*-trityl-*D*-glucitol* (**38**)

TBDMSCl (33 mg, 0.22 mmol) was added to a solution of diol **34** (85 mg, 0.18 mmol) and imidazole (30 mg, 0.44 mmol) in CH_2Cl_2 (5 mL). After stirring for 24 h, the reaction mixture was diluted with $NH_4Cl_{(aq)}$ (5 mL) and extracted with CH_2Cl_2 (2 × 10 mL). The combined organic layers were dried over $Na_2SO_{4(s)}$, concentrated, and fractionated by FCC (EtOAc:hexane, 1:1) to give alcohol **38** as a pale yellow oil (91 mg, 85%); IR: 3500, 2930, 1090 cm^{-1}; ^1H NMR δ: 7.60–7.20 (15H, m, Ph), 3.96 (1H, m) 3.78 (1H, dd, J = 5, 10.5 Hz), 3.69 (1H, dd, J = 5, 10.5 Hz), 3.55 (1H, dd, J = 3, 6.5 Hz), 3.50–3.40 (2H, m), 3.44 (3H, s, OCH_3), 3.43 (3H, s, OCH_3), 3.35–3.25 (2H, m), 3.28 (3H, s, OCH_3), 3.16 (1H, d, J = 5 Hz, OH); ^{13}C NMR δ: 143.9 (s, Ph), 128.8 (d, Ph), 127.6 (d, Ph), 127.1 (d, Ph), 86.7 (s, CPh_3), 81.6 (d), 80.1 (d), 78.6 (d), 70.9 (d, C-5), 64.7 (t, C-6), 62.3 (t, C-1), 59.6 (q, OCH_3), 58.9 (q, OCH_3), 58.8 (q, OCH_3), 25.9 (q, $SiC(CH_3)_3$), 18.5 (s, $SiC(CH_3)_3$); MS (CI, NH_3), m/z (relative intensity): 598 ($[M + 18]^+$, 1), 563 (10), 339 (8), 243 (100).

*6-*O*-(*tert*-Butyldimethylsilyl)-2,3,4-tri-*O*-methyl-1-*O*-trityl-*D*-glucitol* (**39**)

Silylation of diol **35** (30 mg, 0.06 mmol) as above gave **39** as a pale yellow oil (27 mg, 71%); IR: 3428, 2933, 1092 cm^{-1}; ^1H NMR δ: 7.60–7.20 (15H, m, Ph), 3.98 (1H, dd, J = 2, 11.5 Hz), 3.95 (1H, m), 3.71 (1H, dd, J = 4, 11.5 Hz), 3.57 (1H, dd, J = 1.5, 8 Hz), 3.50 (1H, dd, J = 1.5, 8 Hz), 3.47–3.42 (1H, m), 3.42 (3H, s, OCH_3), 3.40 (3H, s, OCH_3), 3.33–3.26 (2H, m), 3.24 (3H, s, OCH_3), 2.67 (1H, d, J = 6 Hz, OH), 0.91 (9H, s, $SiC(CH_3)_3$), 0.11 (6H, s, $SiCH_3$); ^{13}C NMR δ: 144.1 (s, Ph), 128.7 (d, Ph), 127.8 (d, Ph), 127.0 (d, Ph), 86.7 (s, CPh_3), 81.3 (d), 81.0 (d), 79.3 (d), 71.6 (d, C-5), 64.0 (t, C-6), 63.0 (t, C-1), 60.4 (q, OCH_3), 59.1 (q, OCH_3), 58.8 (q, OCH_3), 25.9 (q, $SiC(CH_3)_3$), 18.5 (s, $SiC(CH_3)_3$); MS (CI, NH_3), m/z (relative intensity): 598 ($[M + 18]^+$, 1), 243 (100); and recovered diol **35** (3 mg, 10%).

*1-*O*-(*tert*-Butyldimethylsilyl)-2,3,4,5-tetra-*O*-methyl-6-*O*-trityl-*D*-glucitol* (**40**)

NaH (50% oil, 20 mg, 0.42 mmol) was added to a solution of alcohol **38** (35 mg, 0.06 mmol) in THF (5 mL). After stirring for 10 min, CH_3I (0.025 mL, 0.42 mmol) was added to the suspension, and the mixture was stirred at room temperature overnight and concentrated. The residue was triturated with $CHCl_3$ (3 × 5 mL) and the combined filtrates concentrated and fractionated by preparative TLC (EtOAc:hexane, 1:3) to give **40** as a colorless oil (30 mg, 83%); IR: 2928, 1448, 1095 cm^{-1}; ^1H NMR δ: 7.50–7.20 (15H, m, Ph), 3.86 (1H, m), 3.70 (1H, m), 3.56 (1H, m), 3.48 (3H, s, OCH_3), 3.47 (6H, s, OCH_3), 3.47–3.40 (4H, m), 3.24 (3H, s, OCH_3), 3.15 (1H, m), 0.91 (9H, s, $SiC(CH_3)_3$), 0.09 (6H, s, $SiCH_3$); ^{13}C NMR δ: 145.1 (s, Ph), 129.6 (d, Ph), 128.6 (d, Ph), 127.7 (d, Ph), 87.2 (s, CPh_3), 83.1 (d), 81.6 (d), 80.9 (d), 80.5 (d), 63.6 (t), 62.9 (t), 60.9 (q, OCH_3), 60.5 (q, OCH_3), 59.6 (q, OCH_3), 58.8 (q, OCH_3), 26.2 (q, $SiC(CH_3)_3$), 18.4 (s, $SiC(CH_3)_3$); MS (CI, NH_3), m/z (relative intensity): 612 ($[M + 18]^+$, 6), 537 (55), 353 (100), 321 (20); and recovered **38** as a colorless oil (3.4 mg, 9%).

*6-*O*-(*tert*-Butyldimethylsilyl)-2,3,4,5-tetra-*O*-methyl-1-*O*-trityl-*D*-glucitol* (**41**)

Methylation of alcohol **39** (47 mg, 0.08 mmol) as above gave **41** as a colorless oil (47 mg, 96%); IR: 2928, 1448, 1098 cm^{-1}; ^1H NMR δ: 7.50–7.20 (15H, m, Ph), 3.87 (1H, dd, J = 2.5, 11 Hz), 3.70–3.60 (2H, m), 3.54 (3H, s, OCH_3), 3.52 (1H, dd, J = 3, 11 Hz), 3.47 (3H, s, OCH_3), 3.38 (1H, dd, J = 3, 10 Hz), 3.40 (3H, s, OCH_3), 3.33–3.23 (2H, m), 3.16 (1H, dd, J = 6, 10 Hz), 3.14 (3H, s, OCH_3), 0.89 (9H, s, $SiC(CH_3)_3$), 0.09 (6H, s, $SiCH_3$); ^{13}C NMR δ: 144.1 (s, Ph), 128.8 (d, Ph), 127.8 (d, Ph), 127.0 (d, Ph), 87.2 (s, CPh_3), 82.3 (d), 81.6 (d), 81.1 (d), 79.7 (d), 63.6 (t), 61.6 (t), 60.6 (q, OCH_3), 60.0 (q, OCH_3), 59.2 (q, OCH_3), 57.9 (q, OCH_3), 26.0 (q, $SiC(CH_3)_3$), 18.3 (s, $SiC(CH_3)_3$): MS (CI, NH_3), m/z (relative intensity): 598 ($[M + 18]^+$, 2), 563 (9), 243 (100).

*2,3,4,5-Tetra-*O*-methyl-6-*O*-trityl-*D*-glucitol* (**42**)

To a solution of **40** (40 mg, 0.067 mmol) in THF (3 mL) was added Bu_4NF (50 mg, 0.19 mmol). After stirring at room temperature overnight, the reaction mixture was concentrated, and fractionated by FCC (EtOAc:hexane, gradient elution from 1:4 to 1:1) yielding **42** as a colorless oil (30 mg, 93%); IR: 3460, 2930, 1093 cm^{-1}; ^1H NMR δ: 7.50–7.20 (15H, m, Ph), 3.82 (1H, dd, J = 3.5, 12 Hz), 3.63 (1H,

Can. J. Chem. Downloaded from www.nrcresearchpress.com by EESC ESCOLA DE ENGENHARIA on 09/08/12
For personal use only.

dd, J = 5.5, 12 Hz), 3.58–3.43 (5H, m), 3.50 (3H, s, OCH_3), 3.49 (3H, s, OCH_3), 3.48 (3H, s, OCH_3), 3.24 (3H, s, OCH_3), 3.14 (1H, dd, J = 4.5, 10 Hz); ^{13}C NMR δ: 144.0 (s, Ph), 128.8 (d, Ph), 127.8 (d, Ph), 127.0 (d, Ph), 86.7 (s, CPh_3), 81.3 (d), 81.0 (d), 80.5 (d), 79.5 (d), 62.2 (t), 62.0 (t), 60.4 (q, OCH_3), 60.0 (q, OCH_3), 58.8 (q, OCH_3), 58.3 (q, OCH_3); MS (CI, NH_3), m/z (relative intensity): 498 ($[M + 18]^+$, 1), 463 (10), 243 (100).

2,3,4,5-Tetra-O-methyl-1-O-trityl-D-glucitol (**43**)

Hydrolysis of **41** (56 mg, 0.094 mmol) as above gave **43** as a colorless oil (40 mg, 89%); IR: 3462, 2931, 1448, 1092 cm^{-1}; ^1H NMR δ: 7.50–7.20 (15H, m, Ph), 3.81 (1H, dd, J = 4, 12 Hz), 3.64 (1H, dd, J = 4, 12 Hz), 3.58–3.42 (3H, m), 3.51 (3H, s, OCH_3), 3.47 (3H, s, OCH_3), 3.39 (3H, s, OCH_3), 3.30–3.22 (2H, m), 3.18 (3H, s, OCH_3), 3.17–3.10 (1H, m); ^{13}C NMR δ: 143.9 (s, Ph), 128.7 (d, Ph), 127.8 (d, Ph), 127.0 (d, Ph), 86.7 (s, CPh_3), 81.5 (d), 81.3 (d), 81.2 (d), 79.6 (d), 62.7 (t), 60.7 (t), 60.2 (q, OCH_3), 60.0 (q, OCH_3), 58.8 (q, OCH_3), 57.3 (q, OCH_3); MS: molecular ion could not be detected; and diol **29** as a colorless oil (2.6 mg, 40%).

2,3,4,5-Tetra-O-methyl-6-O-trityl-D-glucitol (**44**)

To a suspension of **42** (44 mg, 0.092 mmol), 4 Å molecular sieves (200 mg), and NMO (40 mg, 0.34 mmol) in CH_2Cl_2 (5 mL) was added TPAP (8 mg). After stirring at room temperature for 40 min, the reaction mixture was directly fractionated by FCC (EtOAc:hexane, 1:2) yielding **44** as a colorless oil (41 mg, 94%); IR: 2931, 2829, 1727, 1448, 1093 cm^{-1}; ^1H NMR δ: 9.69 (1H, s, H-1), 7.50–7.20 (15H, m, Ph), 3.93 (1H, dd, J = 2, 5.5 Hz, H-3), 3.84 (1H, d, J = 5.5 Hz, H-2), 3.58 (1H, dd, J = 2, 8.5 Hz, H-4), 3.54 (1H, dd, J = 2.5, 10.5 Hz H-6), 3.54 (3H, s, OCH_3), 3.53 (3H, s, OCH_3), 3.50–3.42 (1H, m, H-5), 3.47 (3H, s, OCH_3), 3.05 (1H, dd, J = 4, 10.5 Hz, H-6), 2.97 (3H, s, OCH_3); ^{13}C NMR δ: 199.6 (d, C-1), 143.9 (s, Ph), 128.8 (d, Ph), 127.8 (d, Ph), 127.0 (d, Ph), 86.6 (s, CPh_3), 82.5 (d), 81.6 (d), 79.7 (d), 78.1 (d), 61.6 (t, C-6), 59.6 (q, OCH_3), 59.5 (q, OCH_3), 59.3 (q, OCH_3), 58.3 (q, OCH_3); MS (CI, NH_3), m/z (relative intensity): 496 ($[M + 18]^+$, 100), 372 (21), 262 (53).

2,3,4,5-Tetra-O-methyl-6-O-trityl-L-gulose (**45**)

Oxidation of alcohol **43** (40 mg, 0.083 mmol) as above gave **45** as a colorless oil (38 mg, 95%); IR: 2912, 2829, 1731, 1448, 1091 cm^{-1}; ^1H NMR δ: 9.65 (1H, s, H-1), 7.50–7.20 (15H, m, Ph), 3.74 (1H, dd, J = 2, 3.5 Hz, H-2), 3.58–3.35 (4H, m), 3.46 (3H, s, OCH_3), 3.41 (3H, s, OCH_3), 3.40 (3H, s, OCH_3), 3.18 (3H, s, OCH_3), 3.18–3.04 (2H, m); ^{13}C NMR δ: 200.7 (d, C-1), 143.9 (s, Ph), 128.7 (d, Ph), 127.9 (d, Ph), 127.1 (d, Ph), 86.8 (s, CPh_3), 86.6 (d), 81.8 (d), 81.2 (d), 80.7 (d), 62.1 (t, C-6), 60.8 (q, OCH_3), 59.9 (q, OCH_3), 58.6 (q, OCH_3) 58.3 (q, OCH_3); MS (CI, NH_3), m/z (relative intensity): 496 ($[M + 18]^+$, 3), 243 (100), 165 (10).

2,3,4,5-Tetra-O-methyl-D-glucose 2,4-dinitrophenylhydrazone (**46**)

DNPH (ca. 10 mg) was added to a solution of **27** (3 mg) in CH_2Cl_2 (1 mL). After stirring overnight, the reaction mixture was concentrated, and fractionated by preparative TLC (EtOAc:hexane, 1:1) to give the hydrazone **46** as a yellow oil (7:1 mixture of E:Z isomers; 5 mg); ^1H NMR δ: for (E) isomer (partial data): 9.14 (1H, d, J = 2.5 Hz, Ph), 8.33 (1H, dd, J = 2.5, 9.5 Hz, Ph), 7.97 (1H, d, J = 9.5 Hz, Ph), 7.54 (1H, d, J = 7 Hz, H-1), 4.27 (1H, dd, J = 6.5, 7 Hz, H-2), 3.96 (1H, dd, J = 3.5, 12 Hz, H-6), 3.75–3.65 (2H, m), 3.55 (3H, s, OCH_3), 3.49 (6H, s, OCH_3), 3.44 (3H, s, OCH_3); δ for (Z) isomer (partial data): 7.07 (1H, d, J = 3.5 Hz, H-1), 4.43 (dd, dd, J = 3.5, 6.5 Hz, H-2).

2,3,4,5-Tetra-O-methyl-L-gulose 2,4-dinitrophenylhydrazone (**47**)

Treatment of **28** (3 mg) with DNPH as above gave the hydrazone **47** as a yellow oil (ca. 4:1 mixture of E:Z isomers; 5 mg); ^1H NMR δ for E isomer (partial data): 9.14 (1H, d, J = 2.5 Hz, Ph), 8.34 (1H, dd, J = 2.5, 9.5 Hz, Ph), 7.99 (1H, d, J = 9.5 Hz, Ph), 7.54 (1H, d, J = 7 Hz, H-1), 4.04 (1H, dd, J = 7, 4 Hz, H-2) 3.87 (1H, dd, J = 3.5, 11.5 Hz, H-6), 3.72–3.58 (2H, m), 353 (3H, s, OCH_3), 351 (3H, s, OCH_3), 347 (3H, s, OCH_3), 340 (3H, s, OCH_3); δ for Z isomer (partial data): 7.97 (1H, d, J = 9.5 Hz, Ph), 6.97 (1H, d, J = 2 Hz, H-1), 4.36 (1H, dd, J = 5.5, 4 Hz, H-2).

(D-gluco)-1,1,2,3,4,5,6,6-Octamethoxyhexane (**48**)

To a solution of **26** (24 mg, 0.1 mmol) in MeOH (1 mL) was added $(CH_3O)_3CH$ (0.1 mL) and HCl (5% in methanol, few drops). After stirring overnight, the reaction mixture was quenched by addition of $NaHCO_{3(s)}$, and then filtered, concentrated, and fractionated by FCC (EtOAc:hexane, 1:1) yielding **48** as a colorless oil (32 mg, 94%); IR: 2932, 2829, 1095 cm^{-1}; ^1H NMR δ: 4.49 (1H, d, J = 5 Hz), 4.47 (1H, d, J = 3 Hz), 3.66 (1H, dd, J = 3.5, 7 Hz), 3.53 (3H, s, CH_3O), 3.53 (3H, s, CH_3O), 3.52 (3H, s, CH_3O), 3.49 (3H, s, CH_3O), 3.49–3.42 (1H, m), 3.47 (3H, s, CH_3O), 3.45 (3H, s, CH_3O), 3.42 (3H, s, CH_3O), 3.37 (3H, s, CH_3O), 3.34 (1H, dd, J = 3.0, 7.0 Hz), 3.21 (1H, dd, J = 3.5, 6 Hz); ^{13}C NMR δ: 105.4 (d), 104.6 (d), 82.2 (d), 82.0 (d), 81.7 (d), 80.4 (d), 61.0 (q, CH_3O), 60.9 (q, CH_3O), 60.1 (q, CH_3O), 59.0 (q, CH_3O), 55.9 (q, CH_3O), 55.8 (q, CH_3O), 54.7 (q, CH_3O), 53.2 (q, CH_3O); MS (CI, NH_3), m/z (relative intensity): 295 ($[M - OCH_3]^+$, 15), 224 (13), 207 (42), 101 (75), 75 (100).

Methyl 2,3,4,5-tetra-O-methyl-β-D-glucoseptanoside (**49**)

Reaction of **44** (30 mg, 0.063 mmol) with $(CH_3O)_3CH$ (0.1 mL) and HCl for 48 h as described above gave **49** as a colorless oil (13 mg, 81%); IR: 2931, 2825, 1464, 1097 cm^{-1}; ^1H NMR δ: 4.55 (1H, d, J = 7.5 Hz, H-1), 3.97 (1H, dd, J = 4, 10.5 Hz, H-6), 3.75–3.60 (4H, m), 3.51 (6H, s, CH_3O), 3.49 (3H, s, CH_3O), 3.42 (3H, s, CH_3O), 3.41 (3H, s, CH_3O), 3.15 (1H, dd, J = 3.5, 7.5 Hz, H-2); ^{13}C NMR δ: 106.4 (d, C-1), 86.0 (d), 81.4 (d), 81.2 (d), 78.2 (d), 65.6 (t, C-6), 59.5 (q, CH_3O), 59.4 (q, CH_3O), 58.8 (q, CH_3O), 58.0 (q, CH_3O), 55.5 (q, CH_3O); MS (CI, NH_3), m/z (relative intensity): 268 ($[M + 18]^+$, 10), 251 ($[M + 1]^+$, 7), 236 (11), 219 (100).

2,3,4,5-Tetra-O-methyl-D-glucose dimethyl acetal (**50**)

Reaction of **44** (40 mg, 0.084 mmol) with $(CH_3O)_3CH$ and HCl as above for 1.5 h gave, after fractionation by FCC (EtOAc:hexane, 1:1), **50** as a colorless oil (20 mg, 83%); IR: 3481, 2934, 2829, 1447, 1095 cm^{-1}; ^1H NMR δ: 4.43 (1H, d, J = 6 Hz, H-1), 3.76 (1H, dd, J = 4.5, 6.5 Hz), 3.64 (1H, dd, J = 5, 6.5 Hz), 3.54 (3H, s, CH_3O), 3.53 (3H, c, CH_3O), 3.53 (3H, s, CH_3O), 3.50 (3H, s, CH_3O), 3.46–3.38 (2H, m), 3.42 (6H, s, CH_3O), 3.29–3.24 (2H, m); ^{13}C NMR δ: 105.8 (d, C-1), 81.8 (d), 81.6 (d), 81.3 (d), 81.1 (d), 61.2 (q, CH_3O), 60.9 (q, CH_3O), 60.5 (t, C-6), 60.3 (q, CH_3O), 57.2 (q, CH_3O), 56.2 (q, CH_3O), 54.9 (q, CH_3O); MS (CI, NH_3), m/z (relative intensity): 300 ($[M + 18]^+$, 2), 265 (13), 219 (100).

Methyl 2,3,4,5-tetra-O-methyl-β-L-guloseptanoside (**51**) *and 2,3,4,5-tetra-O-methyl-L-gulose dimethyl acetal* (**52**)

Aldehyde **45** (35 mg, 0.074 mmol) was treated with $(CH_3O)_3CH$ and HCl as above for 1.5 h. Fraction of the crude product by FCC (EtOAc:hexane, 1:1) gave **52** as a colorless oil (15 mg, 72%); IR: 3474, 2933, 2829, 1096 cm^{-1}; ^1H NMR δ: 4.40 (1H, d, J = 4.5 Hz, H-1), 3.85 (1H, dd, J = 4, 12 Hz, H-6), 3.67 (1H, m, J = 5, 12 Hz, H-6), 3.55 (3H, s, CH_3O), 3.53 (3H, s, CH_3O), 3.55–3.35 (4H, m), 3.48 (3H, s, CH_3O), 3.47 (3H, s, CH_3O), 3.46 (3H, s, CH_3O), 3.45 (3H, s, CH_3O); ^{13}C NMR δ: 105.1 (d, C-6), 81.8 (d), 80.6 (d), 80.5 (d × 2), 61.8 (t, C-1), 60.3 (q, CH_3O), 59.8 (q × 2, CH_3O), 58.2 (q, CH_3O), 56.3 (q, CH_3O), 55.1 (q, CH_3O); MS (CI, NH_3), m/z (relative intensity): 300 ($[M + 18]^+$, 2), 265 (15), 236 (40), 219 (67), 101 (100); and **51** as a colorless oil (3 mg, 16%); IR: 2931, 2826, 1464, 1098 cm^{-1}; ^1H NMR δ: 4.63 (1H, d, J = 6 Hz, H-1), 3.82 (1H, dd, J = 2, 13.5 Hz, H-6), 3.76–3.68 (2H, m, H-3, 6), 3.64–3.61 (1H, dd, J = 2.5, 4 Hz, H-4), 3.51 (3H, s, CH_3O), 3.51–3.47 (1H, m, H-2), 3.47 (3H, s, CH_3O), 3.45 (6H, s, CH_3O), 3.42 (3H, s, CH_3O), 3.27–3.24 (1H, m, H-4); ^{13}C NMR δ: 102.5 (d, C-1), 81.6 (d × 2), 80.5 (d), 78.7 (d), 59.6 (q, CH_3O), 58.9 (q, CH_3O), 58.8 (t, C-6), 58.5 (q, CH_3O), 57.6 (q, CH_3O), 55.3 (q, CH_3O); MS (CI, NH_3), m/z (relative intensity): 268 ($[M + 18]^+$, 30), 251 ($[M + 1]^+$, 16), 236 (76), 219 (49), 101 (100).

The proportion of **51** in the reaction mixture increased with increasing reaction time.

The synthesis of β-mannopyranosides by intramolecular aglycon delivery: scope and limitations of the existing methodology

FRANK BARRESI AND OLE HINDSGAUL[1]

Department of Chemistry, University of Alberta, Edmonton, Alberta T6G 2G2, Canada

Received August 3, 1993

FRANK BARRESI and OLE HINDSGAUL. Can. J. Chem. **72**, 1447 (1994).

The synthesis of β-mannopyranosides by intramolecular aglycon delivery is shown to proceed with complete stereoselectivity in six separate cases. This strategy has been successfully applied to the synthesis of several disaccharides, including octyl 3,6-di-*O*-benzyl-4-*O*-(3,4,6-tri-*O*-benzyl-β-D-mannopyranosyl)-2-deoxy-2-phthalimido-β-D-glucopyranoside, a precursor of the naturally occurring β-D-Man-(1→4)-β-D-GlcNAc linkage, present in all N-linked glycoproteins. Exclusive formation of the β-mannosidic linkage has been confirmed in all six cases, since independently synthesized α-linked mannopyranoside standards were shown to be absent from the reaction products. The intramolecular stereocontrolled reaction proceeds even in the presence of competing methanol. The extension of this strategy to the synthesis of the core pentasaccharide of N-linked glycoproteins has revealed limitations to the methodology, especially when a block synthesis approach is investigated.

FRANK BARRESI et OLE HINDSGAUL. Can. J. Chem. **72**, 1447 (1994).

On montre que la synthèse des β-mannopyranosides par transfert intramoléculaire d'un aglycone se produit avec une stéréosélectivité complète dans six cas séparés. On a appliqué cette stratégie avec succès à la synthèse de plusieurs disaccharides, dont le 3,6-di-*O*-benzyl-4-*O*-(3,4,6-tri-*O*-benzyl-β-D-mannopyranosyl)-2-désoxy-2-phtalimido-β-D-glucopyranoside d'octyle, un précurseur du lien β-D-Man-(1→4)-β-D-GlcNAc que l'on retrouve naturellement présent dans toutes les glycoprotéines liées par l'azote. On a confirmé la formation exclusive de la liaison β-mannosidique dans les six cas puisque les mannopyranosides de référence avec liaisons α qui ont été synthétisés d'une façon indépendante sont tous absents des produits de réactions. La réaction intramoléculaire avec contrôle stéréochimique se produit même en présence de méthanol qui peut agir comme compétiteur. L'extension de cette stratégie à la synthèse du pentasaccharide central des glycoprotéines liées par l'azote a révélé les limitations de la méthodologie, spécialement lorsqu'on examine une approche à la synthèse d'un bloc.

[Traduit par la Rédaction]

Introduction

The field of glycobiology is enjoying an explosion in growth as the biological significance of oligosaccharides are becoming increasingly evident (1). The role of these structures are diverse, ranging from structural or stabilization molecules (2) to fertilization (3), viral and bacterial adhesion (4), protein trafficking (5), and intercellular recognition (i.e., P-selectins (6), L-selectins (7), E-selectins (8). To explore the functions of oligosaccharides, reliable methods of synthesizing sufficient amounts of high purity carbohydrates is necessary. Despite the great ingenuity applied in recent years to the development of new synthetic methods for stereospecific glycoside formation (9), problems in obtaining consistent high-yielding steps remain.

One of the most difficult glycosidic linkages to synthesize is found in 1,2-*cis*-β-D-mannopyranosides. This linkage is present in all N-linked oligosaccharides as part of the core pentasaccharide (Fig. 1).

Great effort has been expended in developing new methods for β-mannoside synthesis (10), with the most direct method being the insoluble silver silicate (10*a*) or silver zeolite (10*b*) procedures. The existing problems with these type of syntheses are the lack of reproducibility and the formation of the α-mannoside as a side product (often in significant quantity) which makes for difficult separation of anomers.

The ability to construct a completely stereocontrolled glycosidic linkage is of great importance in carbohydrate chemistry. More importantly, if available, such methods might permit the development of solid-phase synthesis of oligosaccharides. Experiments from this laboratory have shown that a stereocontrolled method for the synthesis of β-mannopyranosides can be accomplished (11) and was termed intramolecular aglycon

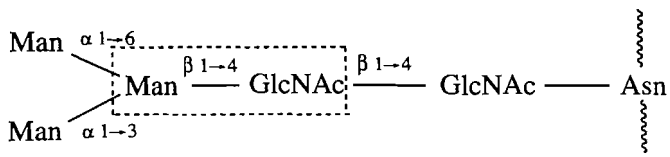

FIG. 1. Core pentasaccharide of N-linked glycoproteins.

delivery (IAD). The general strategy (Scheme 1, X = C, Y = SEt) involves covalent attachment of the aglycon alcohol **A** to a group on O-2 of a latent glycosyl donor **B**. Activation of the anomeric group in the adduct **C** leads to stereocontrolled intramolecular delivery of the aglycon to give the intermediate **D**. Quenching of **D** with water gives the β-mannoside **E**. Stork and Kim (12) have investigated a similar strategy using a temporary silicon connection (X = Si, Y = SOPh) that has been efficient for the transfer of primary carbohydrate alcohols, but not secondary carbohydrate alcohols (footnote 2) in the formation of β-mannosides. In addition, Bols has recently employed a similar approach where a silicon connection was used for the stereocontrolled synthesis of α-glucosides (13) which has been applicable to secondary carbohydrate alcohols.

The application of IAD using a carbon linker has so far produced the best results with the highly hindered and unreactive secondary carbohydrate alcohols. In this paper, the development of this strategy for the synthesis of disaccharides is described. In addition, this procedure is extended toward the synthesis of the core pentasaccharide. In applying IAD with an acetonide linker to the complex natural system, the scope and limitations of intramolecular aglycon delivery have become apparent.

Results and discussion

Our specific protocol for IAD, using an acetonide linker,

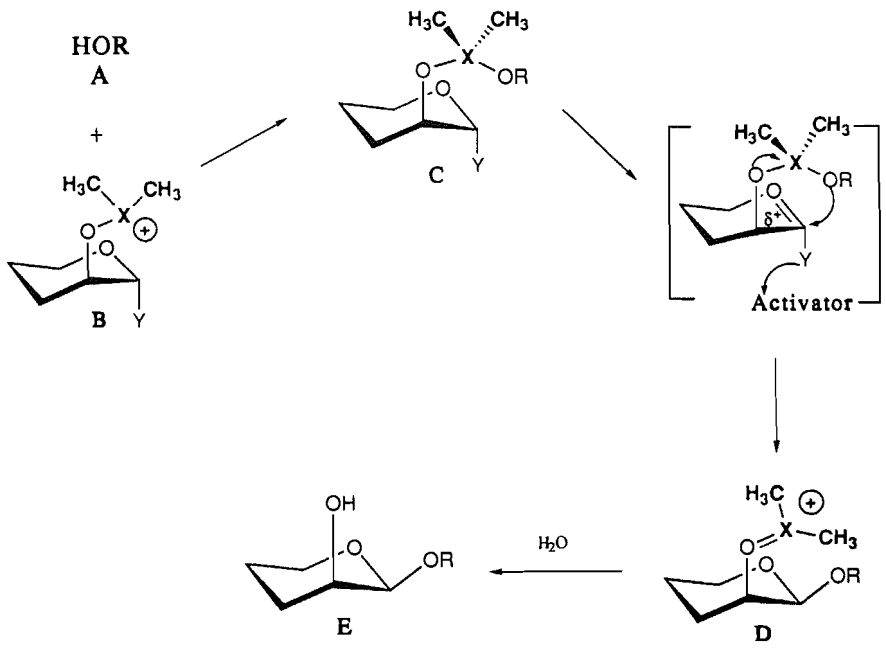
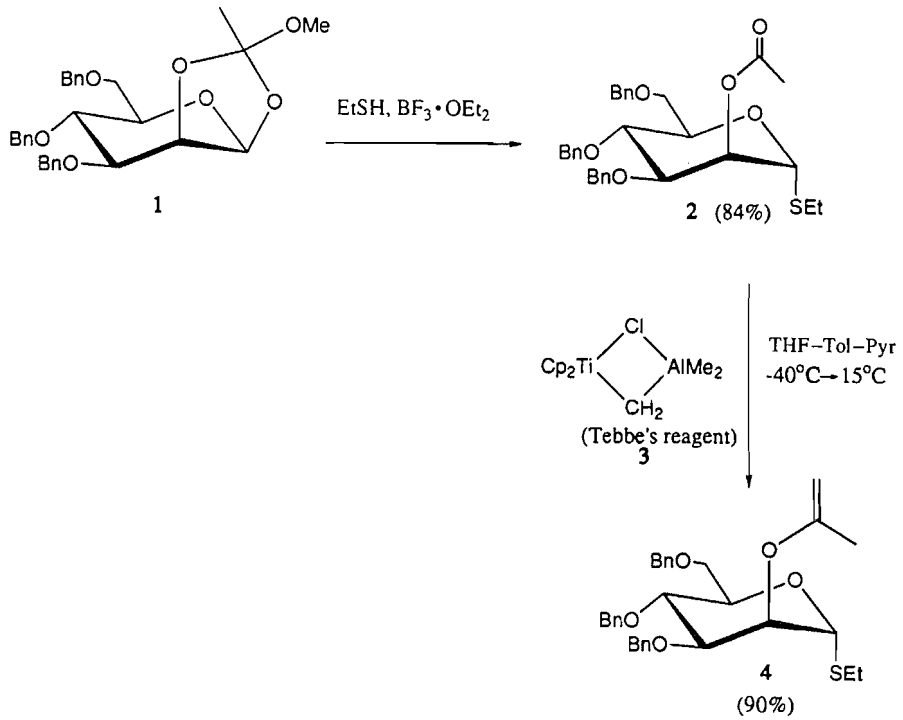


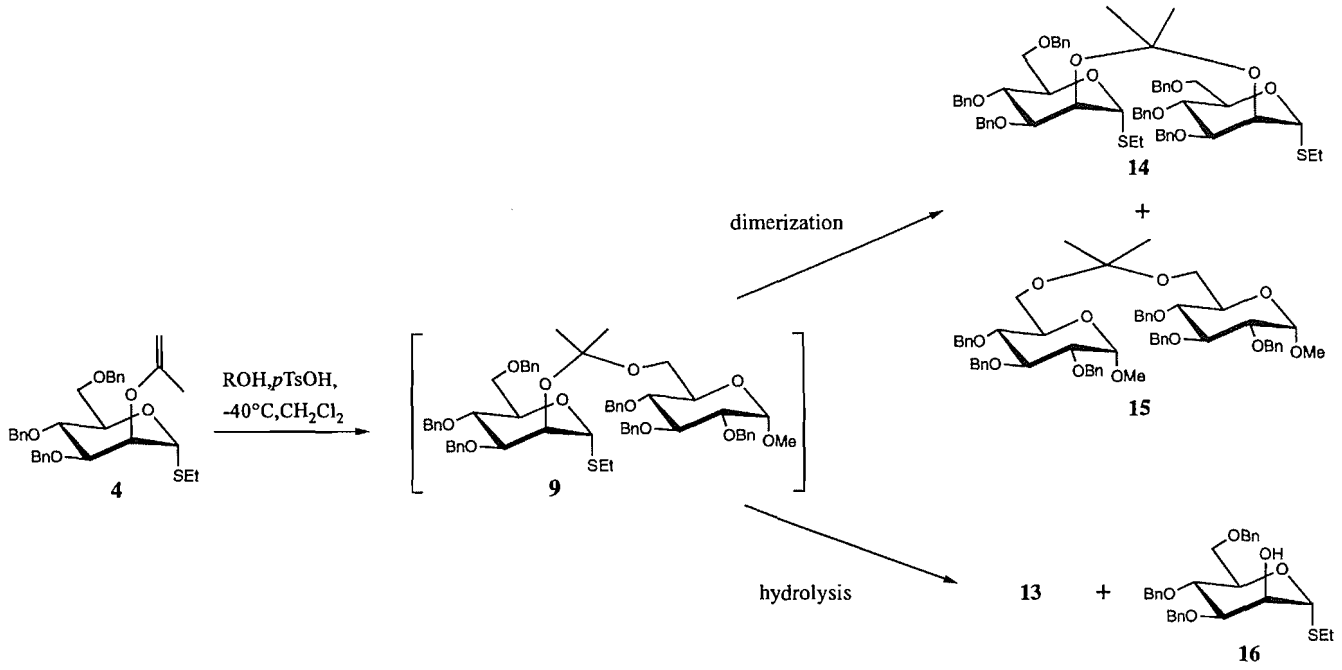
SCHEME 1



SCHEME 2

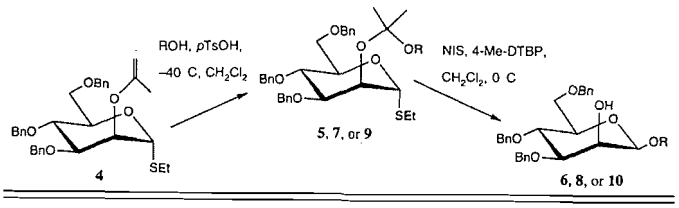
involves the synthesis of the 2-propenyl ether **4** (Scheme 2), which can be prepared from the 2-*O*-acetate **2** in good yield using a methylene transfer reagent such as Tebbe's reagent (**3**) (14). By choosing a thioglycoside, the freedom to manipulate the 2-position of the molecule was possible without affecting the anomeric centre. Furthermore, a wide variety of methods were available to activate the anomeric sulfur once the 2-position has been appropriately derivatized. The acetate **2** was prepared in 84% yield by treatment of the known ortho ester **1** (15) with boron trifluoride etherate in ethanethiol. The conversion to the vinyl ether **4** proceeds well when a solution of Tebbe's reagent is used and gave yields as high as 90%, but more consistently near 70%.

With the vinyl ether in hand, the key step was to link the alcohols **11** (16), **12**, and **13** (17) to the vinyl ether (Table 1). A variety of electrophilic agents were tried including *N*-iodosuccinimide (NIS), iodine, iodonium dicollidine perchlorate (IDCP), *N*-bromosuccinimide (NBS), mercuric acetate, mercuric sulfate, and mercuric triflate. NIS gave the best results of these reagents; however, this reagent could only couple primary carbohydrate alcohols. NIS-promoted coupling of secondary carbohydrate alcohols gave very poor yields (data not shown).



SCHEME 3. Side reactions observed during mixed acetal formation.

TABLE 1. Optimized results (11) for the synthesis of disaccharide β-mannoside



R	Mixed acetal (% yield)	β-Glycoside (% yield)
 **11**	**5** (57)	**6** (77)
 **12**	**7** (55)	**8** (51)
 **13**	**9** (74)	**10** (61)

A variety of acid catalysts were also tried such as hydrochloric acid, hydrobromic acid, triflic acid, pyridinium *p*-toluenesulfonate, amberlite IRC-120 (H^+) resin, *p*-toluenesulfonic acid, and camphorsulfonic acid, of which the last two acids gave satisfactory results. For example, for the formation of **9**, the coupling reaction was initiated by adding catalytic toluenesulfonic acid (0.02 equiv.) to a cooled (–40°C) solution of equimolar amounts of the vinyl ether **4** and the alcohol **13** in dry dichloromethane. The resulting reaction must be quenched by addition of a base (e.g., triethylamine) after about 10 min as the mixed isopropylidene acetal **5** can form symmetrical dimerization products such as **14** and **15**, and simultaneously alcohols **13** and **16** (Scheme 3). Optimum couplings are, therefore, very sensitive to structure and require great care to reproduce. However, consistent yields of mixed acetals ranged from 55% for **7** to 74% for **9**. The secondary alcohols **11** and **12** were more difficult to couple to the vinyl ether as indicated by their lower yields (Table 1). Furthermore, acetals **5** and **7** were less stable than **9** and could only be stored under basic conditions.

A satisfactory method was thus developed that permitted the synthesis of mixed acetals in quantities sufficient to examine the second key step involving transfer of the aglycon to the anomeric centre. Initial reaction conditions were optimized for the conversion of **5** to **6**. A variety of anomeric activators were examined including dimethyl(methylthio)sulfonium triflate (DMTST), IDCP, phenyl selenyl triflate, methyl triflate, NBS, and NIS. With the exception of methyl triflate, all the activators gave varying yields of β-mannosides; however, the best results were again obtained with NIS. Other parameters such as temperature, solvent, and equivalents of activator were examined, with the best results obtained using 5 equiv. of NIS in dichloromethane, starting the reaction at 0°C, and allowing the reaction to warm to room temperature overnight. The addition of a hindered base such as 4-methyl-di-*t*-butyl pyridine (4-Me-DTBP) (5 equiv.) importantly enhanced reaction yields, presumably by preventing any mixed acetal decomposition prior to transfer to the anomeric centre. For instance, the yield of **6** from **5** increased from 42 to 77% with added 4-Me-DTBP and for the conversion of **7** to **8** yields increased from 27 to 51% with added base (Table 1). Other bases such as collidine, diisopropylethyl amine (Hunigs base), or bis(dimethylamino)napthalene (proton sponge) were not stable to the reaction conditions.

To demonstrate the stereocontrolled nature of the reaction,

several approaches were taken. First of all, the stereochemistry of the anomeric linkage was confirmed by the gated ^{13}C NMR spectra of the β-mannosides **6**, **8**, and **10** where the $J_{C\text{-}1,H\text{-}1}$ couplings of the β-linkage were found to be less than 160 Hz, typical for this type of linkage (18). In addition, the α-mannosides **19**, **21**, and **23** were synthesized separately via Helferich (19) coupling of the acceptors **11**, **12**, and **13** with the bromide **17** (20), followed by de-*O*-acetylation of the 2-position (Scheme 4). ^{13}C NMR spectra of the α-anomers showed the typical α-mannoside coupling constants of >170Hz (Table 2).

With the α-mannosides synthesized, IAD reactions were monitored by TLC where the α-anomers could not be detected. Furthermore, all fractions that showed charring by TLC were isolated and NMR analysis of these fractions did not show any α-glycoside. It is important to note that in all cases, the major product was the β-mannosides and impurities isolated consisted

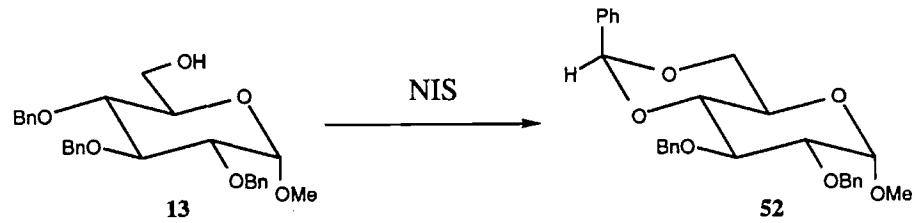

FIG. 2. Benzylidene acetal side product formed under IAD reaction conditions.

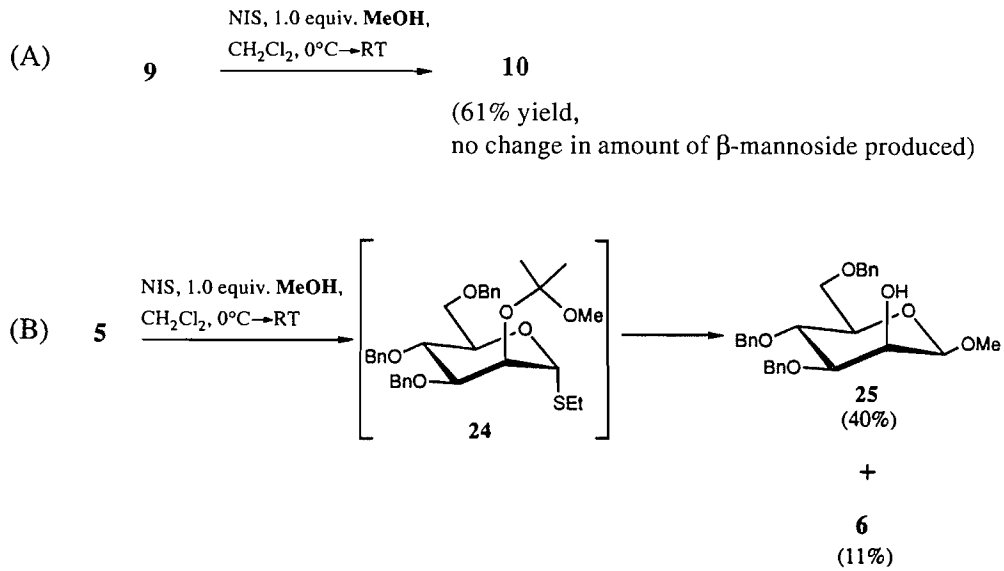

SCHEME 5. Intramolecular aglycon delivery in the presence of methanol.

of several minor compounds. In many cases small amounts of the aglycon alcohols, such as **11**, as well as the benzylidene acetal **52** (Fig. 2) could be identified. The formation of this acetal indicates that competing free radical side reactions of the benzyl groups are occurring.

A convincing experiment showing the intramolecular nature of this reaction was carried out by activation of the mixed acetals **5** and **9** in the presence of methanol. When the acetal **9** was activated with NIS in the presence of 1.0 equiv. of methanol, the yield of the β-mannoside **10** was not affected (Scheme 5*a*). This indicated that the intramolecular process was occurring faster than the competing intermolecular reaction, even with the very reactive methanol. If there were any acetal decomposition prior to activation of the anomeric group, the more reactive methanol would certainly have formed a mixture of methyl α,β-mannosides. This observation therefore supports a concerted reaction mechanism as outlined in Scheme 1. When the same reaction was carried out for the conversion of **5** to **6**, the yield of disaccharide **6** decreased to 11%, reflecting the well-known lower reactivity of secondary carbohydrate alcohols (Scheme 5B). In addition, 40% of the methyl β-mannoside **25** was obtained, presumably by *trans*-acetalization to form **24**, followed by intramolecular transfer of methoxide to give **25**. The fact that no corresponding methyl α-mannoside was observed in this reaction again supports that a free anomeric carbocation is not formed during IAD.

Further evidence for the trapping of the postulated carbocation intermediate (Scheme 1, **D**, X = C) was obtained from initial experiments using *N*-bromosuccinimide as the activator. When the mixed acetal **24** was reacted in the presence of NBS, 17% of the β-methyl glycoside **25** was isolated along with 43% of **26** (Scheme 6). The trapping of the carbocation with succinimide was observed during the formation of the disaccharide **10** as well (data not shown).

With sufficient evidence of the stereocontrolled nature of the reaction, and similar reported strategies (Refs. 12 and 13, footnote 2) supporting this concept, application of this procedure to more complex systems, namely the core pentasaccharide, was attempted. The trisaccharide **27**, containing the required 2-propenyl ether, was synthesized in 13 steps (5% overall yield) from D-mannose (21). When this vinyl ether was treated under acid-catalyzed conditions with the alcohols **11** or **13**, the mixed acetal could not be obtained. Only slow hydrolysis to alcohol **28** was observed (Scheme 7). An attempt to identify the reason for the failure of the coupling reaction was then made by synthesizing the α(1 → 6)-linked disaccharide **33** and examining its behaviour in the formation of mixed acetals.

Known disaccharide **29** (22) was converted to the ortho ester **30** (Scheme 8) via the glycosyl bromide. Zemplen deacetylation, followed by benzylation, gave the ortho ester **31** in 41% overall yield from **29**. Treatment of the ortho ester with boron trifluoride etherate in ethanethiol at 0°C gave the thioglycoside **32** (81%), which was converted to the vinyl ether with Tebbe's reagent in 69% yield.

When the disaccharide vinyl ether **33** was treated under acid-catalyzed conditions (camphorsulfonic acid, –40°C) in the presence of **12**, the mixed acetal **34** was isolated in 25% yield (61% based on recovered **12**, Scheme 8). This compound showed high instability unless stabilized by a base such as triethylamine or pyridine. Activation of its thioglycoside using

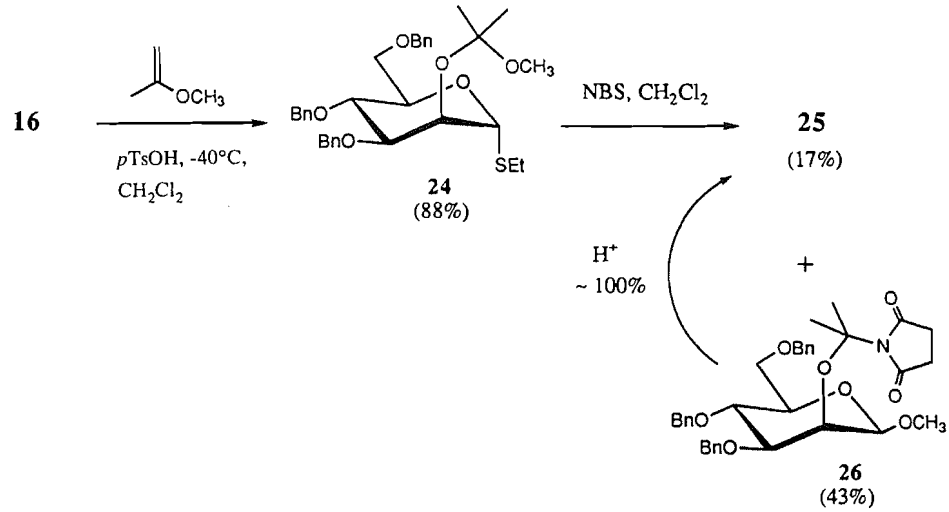
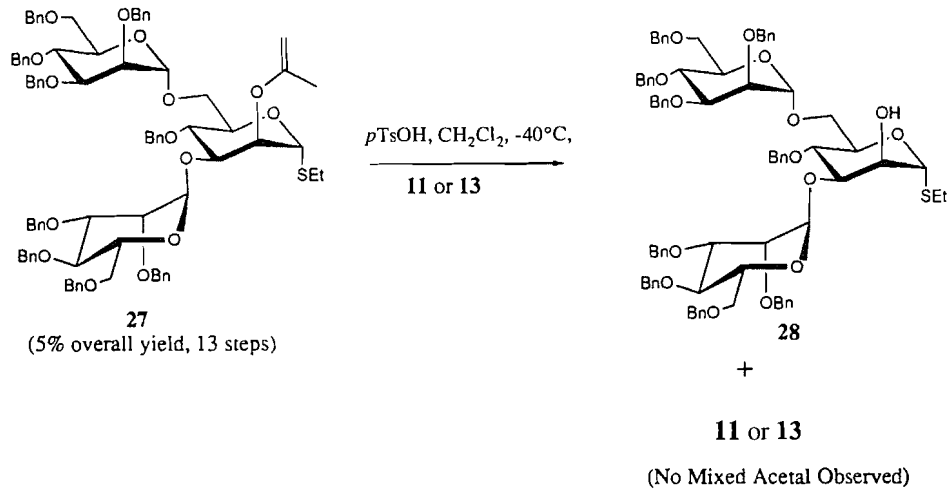


SCHEME 6



SCHEME 7. Unsuccessful attempt at mixed acetal formation using a trimannoside 2-propenyl ether.

the NIS–4-Me-DTBP procedure was sluggish, requiring extra NIS (10 equiv. total) and a reaction time of 70 h at room temperature for **34** to disappear. The reaction mixture was very complex by TLC with the β-mannoside **35** isolated as the major product in 28% yield. The corresponding α-anomer **36** was independently synthesized via a different procedure (Scheme 9) and confirmed to be absent from the reaction products (Table 3). Despite the sluggish reaction and low yield of β-mannoside **35**, glycosidic bond formation nevertheless proceeded in a completely stereocontrolled manner.

Coupling of the vinyl ether **33** with the chitobiose precursor **47** was attempted to see if the procedure could make the tetrasaccharide portion of the core pentasaccharide. Compound **47** was synthesized according to Scheme 10, by reaction of 1,3,4,6-tetra-*O*-acetyl-2-deoxy-2-phthalimido-β-D-glucopyranoside **37** (23) with octanol in a stannic chloride catalyzed reaction. De-*O*-acetylation gave the octyl glycoside **39** in 81% yield from **37**. Benzylidenation (78%) followed by benzylation of the 3-position gave **41** in 73% yield. Sodium cyanoborohydride ring opening (24) gave the alcohol **12** in 83% yield. The phthalimido chloride **45** was prepared from allyl glycoside **42** (25) by acetylation (90%), followed by isomerization and hydrolysis of the allyl group. Reducing sugar **44** was thus obtained in 75% yield from **43**. Treatment of the reducing sugar with dimethylformamide and oxalyl chloride (26) gave the glycosyl chloride **45** as a bright yellow solid, which was used directly in a silver triflate catalyzed glycosylation with the acceptor **12** (67%). The disaccharide **46** was de-*O*-acetylated to give the chitobiose precursor **47**.

Coupling of **33** and **47** was attempted, but proved to be extremely difficult. The only condition which yielded detectable product was a camphorsulfonic acid catalyzed reaction in the presence of calcium sulfate (–40°C), yielding the desired mixed acetal product **48** in only 8% yield (Scheme 11). The balance of the reaction products consisted of unreacted vinyl ether **33** and alcohol **47** as well as hydrolyzed vinyl ether. Insufficient material was obtained to attempt the activation of this mixed acetal.

With the chitobiose precursor **47** in hand, the effect of increasing the complexity of the alcohol, compared with **12**, was investigated by reacting **47** with the monosaccharide vinyl ether **4**. Acid-catalyzed conditions (camphorsulfonic acid, –40°C) yielded the trisaccharide acetal **49** in 38% isolated yield (Scheme 12); however, the reaction was virtually quantitative

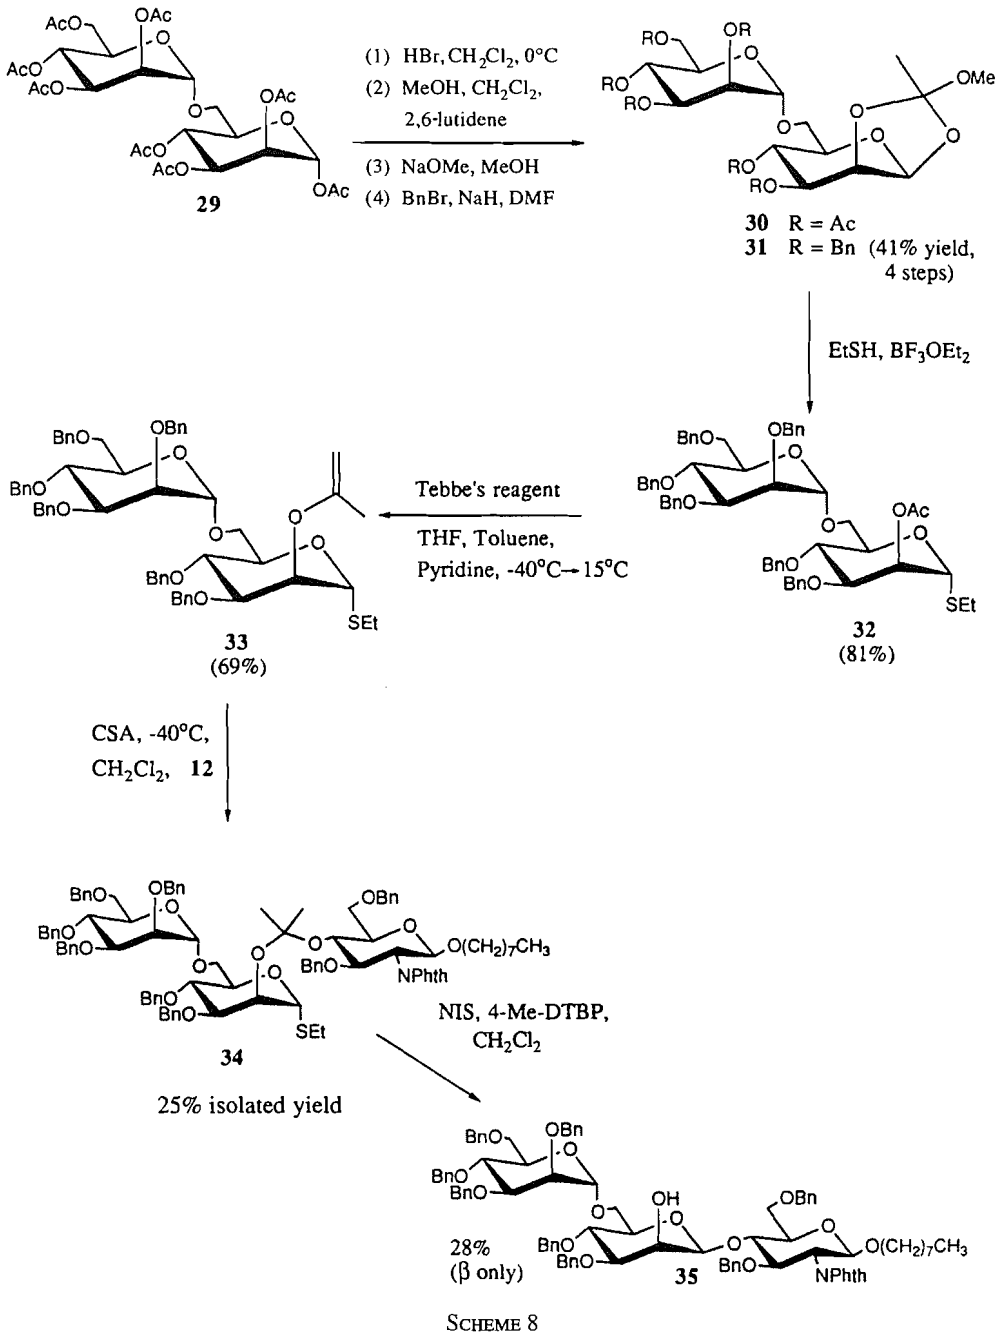
For personal use only.



SCHEME 8

based on recovered starting materials. Activation of the acetal required 42 h and a modest yield (27%) of β-mannoside **50** was isolated as the major product along with a number of minor impurities, one of them being a benzylidene acetal, formed as in the synthesis of **6** by free radical side reactions. Again comparison with authentic α-mannoside standard **51** (Scheme 13) showed no α-linked products formed from this transfer reaction (Table 3).

The dramatic drop in coupling yields as the complexity of the carbohydrate structures increase reveal severe limitations to the existing methodology. It is clear that when comparing the vinyl ethers **4**, **27**, and **33**, acid-catalyzed coupling to form the isopropylidene acetals is extremely sensitive to the size of the vinyl ether (Table 4). The size of the alcohol is also important, although the effect is not as dramatic as with the vinyl ethers. One reason to explain these observations is that the acetal acid sensitivity increases with increased complexity of the structure, as is supported by the stabilities on storage of these particular structures when not stabilized by base. Mixed acetals such as **9** or **24** were stable and did not need to be stored in basic solutions, as was the case with the acetals such as **5** or **7** which would decompose if left at room temperature overnight. Structures such as **34**, **48**, and **49** showed extreme instability, decomposing in several hours if stored without added base. This indicates that during the acid-catalyzed reaction conditions, some of the less stable acetals may be decomposing prior to isolation or do not form in appreciable amounts in the reaction vessel before decomposition occurs.

The transfer yields for the formation of the β-mannosides also decreases with increased molecular complexity (Table 5,

with the exception of compound **6**, in which extensive optimization was performed). Analysis of the reaction times involved for the formation of the β-mannosides may explain the reduced yields. Less hindered mixed acetals such as **9** and **24** gave good yields of β-mannosides (>60% for **10** and **25**) with short reaction times (2 h). With the mixed acetals of more hindered secondary carbohydrate alcohols such as **5** and **7**, the activation of the thioglycoside is slower (18 h), which may reflect increased steric repulsion impeding the transfer step. Extremely hindered structures such as **34** and **48** have even longer thioglycoside activation times (70 and 42 h respectively). Longer reaction times allow for competing side reactions to occur, such as the free radical formation of the benzylidene structure (**52**, Fig. 2), which causes a decrease in yield.

Conclusions

In summary, the synthesis of β-mannopyranosides has been shown to occur in a completely stereocontrolled fashion by IAD. The stereochemical nature of the β-mannopyranosidic linkage has been confirmed by comparison with independently synthesized α-mannopyranoside standards and the stereocontrolled reaction was shown to proceed even in the presence of added methanol. The extension of this strategy to the core pentasaccharide of *N*-linked glycoproteins has revealed severe limitations to the methodology as currently implemented. Application of this strategy to the formation of β-mannosides in structures as complex as disaccharides occurs in acceptable yields; however, extending this process to trisaccharides causes a dramatic decrease in yield. Different linkers and activation procedures are currently being examined in an attempt to overcome these limitations.

SCHEME 13

eter at 22 ± 2°C. Analytical TLC was performed on silica gel 60-F_{254} (Merck) with detection by quenching of fluorescence and (or) by charring with sulfuric acid. All commercial reagents were used as supplied and chromatography solvents were distilled prior to use. Column chromatography was performed on silica gel 60 (Merck, 40–60 μM). Iatrobead refers to a beaded silica gel 6RS-8060 manufactured by Iatron Laboratories (Tokyo). ^{1}H NMR spectra were recorded at 360 MHz (Bruker WM-360), 300 MHz (Bruker AM-300), or 500 MHz (Varian Unity-500) with internal $(CH_3)_4Si$ (δ 0, $CDCl_3$, CD_3OD, or D-5 pyridine). COSY spectra were obtained at 360 MHz (Bruker WM-360). ^{13}C NMR spectra were recorded at 75.5 MHz (Bruker Am-300) or 125.7 MHz (Varian Unity-500) with internal $(CH_3)_4Si$ (δ 0, $CDCl_3$ CD_3OD, or D-5 pyridine). Only partial NMR data are reported; the other data were in accord with the proposed structures. The chemical shifts and coupling constants (as observed splittings) for ^{1}H resonances are reported as though they were first order. The assignments of ^{13}C resonances, when applicable, are tentative. Organic solutions were concentrated under vacuum at ≤40°C (bath) and 12 Torr (1 Torr = 133.3 Pa). All anhydrous reactions were carried out under argon using dry solvents and phosphorous pentoxide (P_2O_5) dried starting materials (high vacuum ≅ 50 μm). Anhydrous transfers were done with standard syringe techniques; all glassware was predried overnight at 160°C. Microanalyses were carried out by the analytical services at this department and all samples submitted for elemental analysis were dried overnight under high vacuum over P_2O_5 at 56°C (refluxing acetone).

General procedure for the preparation of Tebbe's reagent (14c)

Titanocene dichloride (0.50 g, 2 mmol, 1.0 equiv.) was charged to a round-bottom flask and argon purged. Trimethylaluminum, (2.01 mL, 4 mmol, 2 equiv., 2.0 M solution in toluene) was carefully syringed into the flask. The mixture was stirred under argon atmosphere for 60 prior to use. The solution colour is a deep red, which blackens as it decomposes. When used, any exposure to air gives off white fumes.

Ethyl 2-O-acetyl-3,4,6-tri-O-benzyl-1-thia-α-D-mannopyranoside (2)

The ortho ester **1** (ref. 15; 5.0 g, 9.9 mmol) was charged to a round-bottom flask and argon purged. Ethanethiol (30 mL) was added and the solution was cooled to 0°C. Boron trifluoride etherate (1.22 mL, 9.9 mmol) was syringed into the stirred mixture and the reaction was quenched after 15 min by adding 5 mL of distilled water (dH_2O). The ethanethiol was removed in the fumehood by blowing air over the mixture for 3 h. Dichloromethane (200 mL) was added and the solution was washed with 2 × 200 mL of dH_2O. The organic layer was dried ($MgSO_4$), filtered, and concentrated to give a pale yellow syrup. Column chromatography using 18% ethyl acetate in hexane as eluent yielded 4.46 g (84%) of a colourless syrup (**2**). $[\alpha]_D$ + 86.8 (*c* 0.95, Ch_2Cl_2); R_f 0.53 in ethyl acetate – hexane (1:3); ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.30, 7.15 (m, 15H, Ph), 5.43 (dd, 1H, $J_{1,2}$ = 1.5 Hz, $J_{2,3}$ = 3.0 Hz, H-2), 5.32 (d, 1H, $J_{1,2}$ = 1.5 Hz, H-1, 4.85, 4.47 (2 × d, 2H, J_{gem} = 10.8 Hz, (CH_2Ph), 4.69, 4.48 (2 × d, 2H, J_{gem} = 12.2 Hz, OCH_2Ph), 4.68, 4.52 (2 × d, 2H, J_{gem} = 11.1 Hz, OCH_2Ph), 4.16 (m, 1H, H-5), 3.94 (dd, 1H, $J_{3,4}$ = 9.5 Hz, $J_{4,5}$ = 9.5 Hz, H-4), 3.90 (dd, 1H, $J_{2,3}$ = 3.0 Hz, $J_{3,4}$ = 9.5 Hz, H-3), 3.84 (dd, 1H, $J_{5,6}$ = 4.04 Hz, $J_{6,6'}$ = 11.0 Hz, H-6), 3.68 (dd, 1H, $J_{5,6'}$ = 1.8 Hz, $J_{6,6'}$ = 11.0 Hz, H-6′), 2.62 (m, 2H, S$CH_2$$CH_3$), 2.15 (s, 3H, CH_3, acetate), 1.28 (t, 3H, J_{vic} = 7.5 Hz, SCH_2CH_3); ^{13}C NMR (75.5 MHz, $CDCl_3$) δ: 170.4 (*C*OCH_3), 138.4, 138.2, 137.8, 129.1–127.6 (aromatic), 82.5 (C-1), 78.6 (C-2), 76.4, 71.9, 70.6 (C-3, C-4, and C-5), 75.2, 73.4, 71.9 (3 × OCH_2Ph), 68.9 (C-6) 25.5 (SCH_2CH_3), 21.2 (COCH_3), 14.9 (SCH$_2$*C*H$_3$). Ethyl 3,4,6-tri-O-benzyl-2-O-(2-propenyl)-1-thia-α-D-mannopyranoside (4)

The 2-*O*-acetylated thioglycoside **2** (1.3 g, 2.42 mmol) was dissolved in 12 mL toluene, 4 mL tetrahydrofuran, and 0.2 mL pyridine (all solvents anhydrous) under argon atmosphere. The solution was cooled to –40°C and Tebbe's reagent (**3**) (4.8 mL, 1 mM in toluene, 4.8 mmol, 2 equiv.) was slowly added, turning the solution deep red. After 1 h, another 4.8 mL of Tebbe's reagent was added (2 equiv.) and the reaction was gradually warmed to –10°C. After 3 h, the reaction was quenched by adding 0.2 mL of 1 N NaOH at –10°C and waiting for the vigorous bubbling to cease (≅5 min) before warming the mixture to room temperature and adding a further 0.8 mL of 1 N NaOH. The solution was then filtered through a celite pad, washed with ether until the filtrate was colourless, and concentrated. Column chromatography of the deep red oil using 8% ethyl acetate in hexane as eluent yielded 1.16 g (90%) of a pale yellow syrup (**4**). $[\alpha]_D$ + 95.6 (*c* 0.98, CH_2Cl_2); R_f 0.71 in ethyl acetate – hexane, (1:3); ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.32, 7.20 (m, 15H, aromatic), 5.53 (d, 1H, $J_{1,2}$ < 1.0 Hz, H-1), 4.89, 4.50 (2 × d, J_{gem} = 10.8 Hz, OCH_2Ph), 4.67, 4.49 (2 × d, 2H, J_{gem} = 12.1 Hz, OCH_2Ph), 4.64, 4.59 (2 × d, 2H, J_{gem} = 11.5 Hz, OCH_2Ph), 4.40 (dd, 1H, $J_{1,2}$ < 1 Hz, $J_{2,3}$ = 3,4 Hz, H-2), 4.13 (ddd, 1H $J_{4,5}$ = 9.2 Hz, $J_{5,6}$ = 4.4 Hz, $J_{5,6'}$ = 1.7 Hz, H-5), 4.02 (dd, 1H, $J_{3,4}$ = 9.2 Hz, $J_{4,5}$ = 9.2 Hz, H-4), 3.98, 3.75 (2 × d, 2H, J_{gem} = 2.0 Hz, C=CH_2), 3.88 (dd, 1H, $J_{2,3}$ = 3.4 Hz, $J_{3,4}$ = 9.2 Hz, H-3), 3.83 (dd, 1H, $J_{5,6}$ = 4.4 Hz, $J_{6,6'}$ = 10.7 Hz, H-6), 3.70 (dd, 1H, $J_{5,6'}$ = 1.7 Hz, $J_{6,6'}$ = 10.7 Hz, H-6′), 2.60 (m, 2H, SCH_2CH_3), 1.59 (s, 3H, CH_2=CCH_3, vinyl ether), 1.26 (t, 3H, J_{vic} = 7.6 Hz, SCH$_2$*C*H$_3$); ^{13}C NMR δ: 158.6 (*C*=CH_2), 138.7, 138.5, 138.2, 128.5–127.5 (aromatic), 82.7 (C=*C*H$_2$), 80.4, 79.2 (C-1 and C-2), 74.8, 73.8, 71.8 (C-3, C-4, and C-5), 75.2, 73.4, 71.8 (3 × OCH_2Ph), 69.2 (C-6), 25.4 (SCH_2CH_3), 21.3 (CH_2=CCH_3), 15.1 (s, SCH_2CH_3). Methyl 2,3,6-tri-O-benzyl-α-D-glucopyranoside-ethyl 3′,4′,6′-tri-O-benzyl-1′-thio-α-D-mannopyranoside-2′,4-isopropylidene acetal (5)

The vinyl ether **4** (374 mg, 0.699 mmol) and the alcohol **11** (ref. 16; 325 mg, 0.699 mmol) were argon purged and dissolved in 15 mL of dry dichloromethane. The mixture was cooled to –40°C and *p*-toluenesulfonic acid monohydrate (5 mg, 0.04 equiv.) was added to the mixture. The reaction was carefully monitored by TLC for the formation of the mixed acetal product **5** and quenched when the product spot was major (10 min) by adding 0.1 mL of triethylamine. Prolonged reaction times (>20 min) caused a drastic reduction in reaction yields. The mixture was concentrated and chromatographed using 18% ethyl acetate in hexane with 0.1% added triethylamine as eluent. The product **5** (397 mg, 57%) was obtained as a colourless syrup. The product was unstable after prolonged periods (>24 h) unless stabilized in an organic solution (dichloromethane or ethyl acetate – hexane) with 0.5% triethylamine (shelf life >2 months). R_f 0.46 in ethyl acetate – hexane (1:3); ^{1}H NMR (360 MHz, $CDCl_3$) δ: 5.44 (d, 1H, $J_{1,2}$ = 1 Hz, H-1′), 4.61 (d, 1H, $J_{1,2}$ = 2.5 Hz, H-1), 4.16 (dd, 1H, $J_{1,2}$ = 1 Hz, $J_{2,3}$ = 3.5 Hz, $J_{3,4}$ = 9.2 Hz, H-3′), 3.38 (s, 3H, OCH_3), 2.60 (m, 2H, SCH_2CH_3), 1.41 (s, 3H, CH_3CCH_3′), 1.37 (s, 3H, 1.37, CH_3CCH_3′), 1.28 (t, 3H,

SCH_2CH_3); ^{13}C NMR (75.5 MHz, D-5 pyridine) δ: 105.09 (CH_3CCH_3), 97.71 (C-1), 85.07 (C-1′), 81.64, 81.57, 80.59, 75.82, 72.68, 72.42, 71.95, 71.89 (C-2, C-3, C-4, C-5, C-2′, C-3′, C-4′, and C-5′), 75.29, 75.12, 73.46, 73.40, 72.70, 72.49 (6 × OCH_2Ph), 70.40, 70.27 (C-6 and C-6′), 54.93 (OCH_3), 26.57, 25.39 (CH_3CCH_3′), 25.39 (SCH_2CH_3), 15.35 (SCH_2CH_3).

*Methyl 2,3,6-tri-*O*-benzyl-4-*O*-(3,4,6-tri-*O*-benzyl-*β*-D-manno-pyranosyl)-*α*-D-glucopyranoside (6)*

The mixed acetal **5** (55 mg, 0.055 mmol) was charged to a round-bottom flask and argon purged. Dry dichloromethane (5 mL), as well as 56 mg (0.0275 mmol, 5 equiv.) of 2,6-di-*tert*-butyl-4-methylpyridine, was added and the mixture was cooled to 0°C. *N*-Iodosuccinimide (62 mg, 5 equiv.) was added to the mixture all at once and stirred overnight, allowing to warm to room temperature. After 18 h, the red solution was quenched by adding 3 mL of 0.5 M sodium thiosulphate solution, which caused the solution to go colourless. Dichloromethane (10 mL) was added and the mixture was washed with 2 × 10 mL of dH_2O. The organic layer was dried ($MgSO_4$), filtered, and concentrated to give a cloudy viscous syrup that was purified on silica gel using 40% ethyl acetate in hexane as eluent. The product **6** (38 mg, 77%), was isolated a clear syrup. In some instances, the kinetic benzylidene acetal **52** could be isolated from the reaction products in small (<20%) quantities.

Product **6**: $[\alpha]_D$ + 26.3 (*c* 0.80, CH_2Cl_2); R_f 0.14 in ethyl acetate – hexane (1:2); ^1H NMR (360 MHz, $CDCl_3$) δ: 7.40–7.16 (m, 30H, aromatic), 4.58 (d, 1H, $J_{1,2}$ = 3.7 Hz, H-1), 4.44 (d, 1H, $J_{1,2}$ < 1 Hz, H-1′), 4.00 (dd, 1H, $J_{2,3}$ = 9.2 Hz, $J_{3,4}$ = 9.2 Hz, H-3), 3.94 (dd, 1H, $J_{3,4}$ = 9.2 Hz, $J_{4,5}$ = 9.2 Hz, H-4), 3.94 (dd, 1H, $J_{2,3}$ = 3.0 Hz, $J_{1,2}$ < 1 Hz, H-2′), 3.83 (dd, 1H, $J_{3,4}$ = 9.5 Hz, $J_{4,5}$ = 9.5 Hz, H-4′), 3.76 (ddd, 1H, $J_{4,5}$ = 9.2 Hz, $J_{5,6}$ = 3.1 Hz, $J_{5,6'}$ = 2 Hz, H-5), 3.73 (dd, 1H, $J_{5,6}$ = 3.1 Hz, $J_{6,6'}$ = 10.8 Hz, H-6a), 3.66 (dd, 1H, $J_{5,6'}$ = 2 Hz, $J_{6,6'}$ = 10.8 Hz, H-6b), 3.64 (dd, 1H, $J_{5,6}$ = 1.8 Hz, $J_{6,6'}$ = 10.7 Hz, H-6′a), 3.58 (dd, 1H, $J_{5,6'}$ = 4.6 Hz, $J_{6,6'}$ = 10.7 Hz, H-6′b), 3.51 (dd, 1H, $J_{2,3}$ = 3.7 Hz, $J_{3,4}$ = 9.2 Hz, H-2), 3.37 (s, 3H, OCH_3), 3.32 (dd, 1H, $J_{2,3}$ = 3.0 Hz, *J3,4* = 9.5 Hz, H-3′), 3.24 (ddd, 1H, $J_{5,6}$ = 1.8 Hz, $J_{5,6}$ = 4.6 Hz, $J_{4,5}$ = 9.5 Hz, H-5′), 2.53 (d, 1H, J = 3.0 Hz, OH); ^{13}C NMR (75.5 MHz, $CDCl_3$) δ: 139.1–137.9, 128.5–127.4 (aromatic), 99.97 (d, $J_{C\text{-}1,H\text{-}1}$ = 157 Hz, C-1′), 98.26 (C-1), 81.64, 80.75, 79.66, 75.85, 75.73, 74.04, 69.63, 67.92 (C-2, C-3, C-4, C-5, C-2′, C-3′, C-4′, and C-5′), 75.58, 75.16, 73.54, 73.47, 73.47, 71.15 (6 × OCH_2Ph), 69.11, 68.84 (C-6 and C-6′), 55.27 (OCH_3). Anal. calcd. for $C_{55}H_{60}O_{11}$: C 73.64, H 6.74; found: C 74.06, H 6.81.

Product **52**: R_f 0.59 in ethyl acetate – hexane (1:2); ^1H NMR (360 MHz, $CDCl_3$) δ: 6.06 (s, 1H, PhC*H*), 5.81 (d, $J_{1,2}$ = 3.8 Hz, H-1), 4.13 (dd, 1H, $J_{3,4}$ = 9.0 Hz, $J_{2,3}$ = 9.0 Hz, H-3), 4.03 (m, 1H, H-5), 3.83 (dd, 1H, $J_{2,3}$ = 3.8 Hz, $J_{3,4}$ = 9.0 Hz, H-2), 3.77 (dd, 1H, $J_{5,6}$ = 2.5 Hz, $J_{6,6'}$ = 11.0 Hz, H-6), 3.62 (dd, 1H, $J_{5,6'}$ = 5.7 Hz, $J_{5,6'}$ = 11.0 Hz, H-6′), 3.42 (s, 3H, OCH_3), 3.41 (dd, 1H, $J_{3,4}$ = 9.0 Hz, $J_{4,5}$ = 9.0 Hz, H-4). The structure of this compound was confirmed by treating it with catalytic *p*-toluenesulfonic acid in dichloromethane at room temperature for 1 h, converting the kinetic benzylidene to the known thermodynamic benzylidene (27).

Activation of mixed acetal (5) in the presence of methanol

The acetal **5** (75 mg, 0.075 mmol) was added to a round-bottom flask and argon purged. Dry dichloromethane (5 mL), followed by 0.12 mL of a freshly prepared 0.62 M solution of dry methanol in dichloromethane (0.075 mmol), was added to the reaction vessel. The mixture was cooled to 0°C and NIS (84 mg, 5 equiv.) was added and the reaction was stirred overnight. The reaction was quenched at 17 h and worked up as above. Chromatographic isolation yielded 7.5 mg (11%) of **6** as well as 14 mg (40%) of the methyl glycoside **25** (see characterization under heading for the preparation of **25**).

*Octyl 3,6-di-*O*-benzyl-2-deoxy-2-phthalimido-β-D-glucopyranoside-ethyl 3′,4′,6′-tri-*O*-benzyl-1′-thio-α-D-mannopyranoside-2′,4-isopropylidene acetal (7)*

The vinyl ether **4** (150 mg, 0.28 mmol) and the alcohol **12** (169 mg, 0.28 mmol) were charged to a round-bottom flask and argon purged. Dry dichloromethane (7 mL) was syringed into the flask and the mixture was cooled to –40°C. Toluenesulfonic acid monohydrate (3 mg, 0.06 equiv.) was added and the reaction was treated as for the formation of **5**. Column chromatography using 14% ethyl acetate in hexane (0.1% added triethylamine) yielded the product **7** (175 mg, 55%). The product was unstable (<12 h) unless stored in an organic solution (dichloromethane or ethyl acetate – hexane) in 0.5% triethylamine. R_f 0.47 in ethyl acetate – hexane (1:3); ^1H NMR (300 MHz, D-5 pyridine) δ: 5.82 (d, 1H, $J_{1,2}$ = 1.0 Hz, H-1′), 5.62 (d, 1H, $J_{1,2}$ = 8.0 Hz, H-1), 3.93, 3.50 (2 × m, 2H, OCH_2, octyl), 2.72 (m, 2H, SCH_2CH_3), 1.64 (s, 3H, CH_3CCH_3′), 1.62 (s, 3H, CH_3CCH_3′), 1.33 (t, 3H SCH_2CH_3); ^{13}C NMR (75.5 MHz, D-5 pyridine) δ: 105.07 (CH_3CCH_3′), 98.74 (C-1), 85.01 (C-1′), 81.08, 80.38, 77.01, 75.84, 73.97, 72.88, 72.47 (C-2′, C-3′, C-4′, C-5′, C-3, C-4, and C-5), 75.84, 75.14, 73.42, 73.42, 72.63 (5 × OCH_2Ph), 70.30, 69.58 (C-6 and C-6′), 31.82, 29.70, 29.34, 26.15, 25.56, 22.79 (6 × CH_2, octyl, SCH_2CH_3), 27.19, 25.86 (CH_3CCH_3), 15.41 (SCH_2CH_3), 14.18 (CH_3, octyl).

*Octyl 3,6-di-*O*-benzyl-4-*O*-(3,4,6-tri-*O*-benzyl-*β*-D-manno-pyranosyl)-2-deoxy-2-phthalimido-β-D-glucopyranoside (8)*

The mixed acetal **7** (58 mg, 0.051 mmol) was dissolved, under argon atmosphere, in 5 mL of dry dichloromethane. Di-*tert*-butyl-4-methylpyridine (52 mg, 0.255 mmol, 5 equiv.) was added to the solution and cooled to 0°C. *N*-Iodosuccinimide (57 mg, 0.255 mmol, 5 equiv.) was added to the mixture and allowed to warm to room temperature overnight. The reaction was quenched after 16 h by adding 3 mL of NaS_2O_3 solution (0.5 M) and worked up as in the synthesis of **6**. Purification using 40% ethyl acetate in hexane as eluent gave 27 mg (51%) of the desired product **8** $[\alpha]_D$ + 27.6 (*c* 1.60, CH_2Cl_2); R_f 0.36 in ethyl acetate – hexane (1:2); ^1H NMR (360 MHz, $CDCl_3$) δ: 7.8–7.55 (m, 4H, phthalimido), 7.4–6.7 (m, 25H, benzyl aromatic), 5.09 (d, 1H, $J_{1,2}$ = 8.4 Hz, H-1), 4.67 (d, 1H, $J_{1,2}$ < Hz, H-1′), 4.38 (dd, 1H, $J_{2,3}$ = 10.6 Hz, $J_{3,4}$ = 8,7 Hz, H-3), 4.16 (dd, 1H, $J_{1,2}$ = 8.4 Hz, $J_{2,3}$ = 10.6 Hz, H-2), 4.07 (dd, 1H, $J_{3,4}$ = 8.7 Hz, $J_{4,5}$ = 8.7 Hz, H4), 4.02 (m, 1H, H-2′), 3.85 (dd, 1H, $J_{3,4}$ = 9.0 Hz, $J_{4,5}$ = 9.0 Hz, H-4′), 3.40 (dd, 1H, $J_{3,4}$ = 9.0 Hz, $J_{2,3}$ = 3.0 Hz, H-3′), 2.49 (d, 1H, $J_{H,OH}$ = 2.7 Hz, OH), 1.4–0.7 (m, 15H, octyl); ^{13}C NMR (75.5 MHz, $CDCl_3$) δ: 167.8 (*C*=O, phthalimido), 100.48 (d, $J_{C\text{-}1,H\text{-}1}$ = 158 Hz, C-1′), 98.48 (C-1), 81.76, 78.48, 78.21, 75.53, 74.58, 74.05, 68.06 (C-2′, C-3′, C-4′, C-5′, C-3, C-4, and C-5), 75.11, 74.80, 73.59, 73.39, 71.35 (5 × OCH_2Ph), 69.65, 69.05 (C-6 and C-6′), 68.87 (OCH_2, octyl), 55.90 (C-2), 31.67, 29.31, 29.12, 25.84, 22.60 (6 × CH_2, octyl), 14.06 (CH_3, octyl). Anal. calcd. for $C_{63}H_{71}O_{12}N$: C 73.16, H 6.92, N 1.35; found: C 72.92, H 6.99, N 1.43.

*Methyl 2,3,4,-tri-*O*-benzyl-α-D-glucopyranoside-ethyl 3′,4′,6′-tri-*O*-benzyl-1′-thio-α-D-mannopyranoside-2′,6-isopropylidene acetal (9)*

The vinyl ether **4** (100 mg, 0.187 mmol) and the alcohol **13** (ref. 17; 87 mg, 0.187 mmol) were charged to a flask and argon purged. Dry dichloromethane (5 mL) was added and the mixture was cooled to –40°C. Toluenesulfonic acid monohydrate (2 mg, ≅0.06 equiv.) was added to the flask and the reaction was treated as in the formation of **5**. Concentration of the reaction mixture, followed by column chromatography (14% ethyl acetate in hexane plus 0.1% triethylamine as eluent) yielded the mixture acetal **9** (138 mg, 74%) as a colourless syrup. The product was sufficiently stable (>24 h); however, storage for long periods (>2 months) was in an organic solution (dichloromethane or ethyl acetate – hexane) with 0.5% triethylamine. Prolonged reaction times increased the yields of vinyl ether hydrolysis products **13** and **16** (28), as well as symmetrical acetals **14** and **15**. Product **9**: R_f 0.50 in ethyl acetate – hexane (1:3); ^1H NMR (360 MHz, $CDCl_3$) δ: 7.4–7.1 (m, 30H, aromatic), 5.48 (d, 1H, $J_{1,2}$ = 1.2 Hz, H-1′), 4.63 (d, 1H, $J_{1,2}$ = 3 Hz, H-1), 4.21 (dd, 1H, $J_{1,2}$ = 1.2 Hz, $J_{2,3}$ = 3.5 Hz, H-2′), 4.11 (m, 1H, H-5′), 4.00 (dd, 1H, $J_{3,4}$ = 9.2 Hz, $J_{4,5}$ = 9.2 Hz, H-4), 3.92 (dd, 1H, $J_{3,4}$ = 9.5 Hz, $J_{4,5}$ = 9.5 Hz, H-4′), 3.86 (dd, 1H, $J_{2,3}$ = 3 Hz, $J_{3,4}$ = 9.2 Hz, H02), 3.48 (dd, 1H, $J_{2,3}$ = 3.5 Hz, $J_{3,4}$ = 9.5 Hz, H-3′), 3.32 (s, 3H, OCH_3), 2.47 (q, 2H, J_{vic} = 7.2 Hz, SCH_2CH_3), 1.38 (s, 3H, CH_3CCH_3′), 1.36 (s, 3H, CH_3CCH_3′), 1.16 (t, 3H, J_{vic} = 7.2 Hz, SCH_2CH_3); ^{13}C

For personal use only.

NMR (75.5 MHz, $CDCl_3$) δ: 104.08 (CH_3CCH_3), 97.92 (C-1), 84.92 (C-1′), 82.64, 80.56, 80.00, 78.92, 75.48, 72.40, 70.56 (C-2, C-3, C-4, C-5, C-2′, C-3′, C-4′, and C-5′), 76.00, 75.12, 75.10, 73.60, 73.36, 72.56 (6 × OCH_2Ph), 69.64, 61.68 (C-6 and C-6′), 55.24 (OCH_3), 26.16, 25.80 (CH_3CCH_3), 25.56 (SCH_2CH_3), 15.00 (SCH_2CH_3). Anal. calcd. for $C_{60}H_{70}O_{11}S$: C 72.12, H 7.06, S 3.21; found: C 71.80, H 7.33, S 3.53.

Product **14**: R_f 0.57 in ethyl acetate – hexane (1:3); ^1H NMR (360 MHz, $CDCl_3$) δ: 5.50 (d, 2H, $J_{1,2}$ = 1 Hz, H-1 × 2), 4.20 (dd, 2H, $J_{1,2}$ = 1 Hz, $J_{2,3}$ = 3 Hz, H-2 × 2), 4.14 (m, 2H, H-5 × 2), 3.90 (dd, 2H, $J_{3,4}$ = 9.4 Hz, $J_{4,5}$ = 9.4 Hz, H-4 × 2), 3.82 (dd, 2H, $J_{5,6}$ = 5.0 Hz, $J_{6,6'}$ = 10.8 Hz, H-6 × 2), 3.78 (dd, 2H, $J_{3,4}$ = 9.4 Hz, $J_{2,3}$ = 3.0 Hz, H-3 × 2), 3.72 (dd, 2H, $J_{5,6'}$ = 1.0 Hz, $J_{6,6'}$ = 10.8 Hz, H-6′ × 2), 2.60 (m, 4H, SCH_2CH_3 × 2), 1.38 (s, 6H, CH_3, acetal), 1.22 (t, 6H, SCH_2CH_3 × 2).

Product **15**: R_f 0.33 in ethyl acetate – hexane (1:3); ^1H NMR (360 MHz, $CDCl_3$) δ: 4.56 (d, 2H, $J_{1,2}$ = 3.5 Hz, H-1 × 2), 3.95 (dd, 2H, $J_{3,4}$ = 9.0 Hz, $J_{4,5}$ = 9.0 Hz, H-4 × 2), 3.72 (m, 4H, H-6, H-5 × 2), 3.46 (m, 6H, H-2, H-3, and H-6′ × 2), 3.32 (s, 6H, OCH_3 × 2), 1.30 (s, 6H, CH_3, acetal × 2); ^{13}C NMR (75.5 MHz, $CDCl_3$) δ: 100.01 (CH_3CCH_3), 97.74 (C-1 × 2), 82.30, 80.17, 78.08, 69.79 (C-2, C-3, C-4, and C-5 × 2), 59.92 (C-6 × 2), 54.81 (OCH_3 × 2), 24.89 (CH_3 acetal × 2). The structures of **14** and **15** were further confirmed by treatment of these acetals with *p*-toluenesulfonic acid for 60 min at room temperature in dichloromethane. The structures were converted to their respective alcohols **13** and **16** upon this treatment.

Product **16**: R_f 0.45 in ethyl acetate – hexane, (1:2); ^1H NMR (300 MHz, $CDCl_3$) δ: 5.42 (d, 1H, $J_{1,2}$ = 1.2 Hz, H-1), 4.19 (m, 1H, H-5), 4.11 (dd, 1H, $J_{1,2}$ = 1.2 Hz, $J_{2,3}$ = 3.2 Hz, H-2), 3.90 (dd, 1H, $J_{3,4}$ = 9.0 Hz, $J_{4,5}$ = 9.0 Hz, H-4), 3.86 (dd, 1H, $J_{2,3}$ = 3.2 Hz, $J_{3,4}$ = 9.0 Hz, H-3), 3.82 (dd, 1H, $J_{5,6}$ = 4.5 Hz, $J_{6,6'}$ = 10.8 Hz, H-6), 3.70 (dd, 1H, $J_{5,6'}$ = 2.0 Hz, $J_{6,6'}$ = 10.8 Hz, H-6′), 2.64 (m, 2H, SCH_2CH_3), 1.30 (t, 3H, SCH_2CH_3); ^{13}C NMR (75.5 MHz, $CDCl_3$) δ: 83.43 (C-1), 80.50, 74.62, 71.52, 69.94 (C-2, C-3, C-4, and C-5), 69.96 (C-6), 24.90 (SCH_2CH_3), 14.85 (SCH_2CH_3).

*Methyl 2,3,4,-tri-*O*-benzyl-6-*O*-(3,4,6-tri-*O*-benzyl-*β*-D-manno-pyranosyl)-*α*-D-glucopyranoside (**10**)*

The mixed acetal **9** (63 mg, 0.0631 mmol) was charged to a round-bottom flask and argon purged. Dry dichloromethane (4 mL) was syringed into the flask and the mixture was cooled to 0°C before 70.9 mg (0.315 mmol, 5 equiv.) of *N*-iodosuccinimide was added all at once. The reaction was stirred for 2 h and 45 min, quenched by adding 3 mL of sodium thiosulfate (0.5 M), and worked up as in the synthesis of **6**. Silica gel chromatography using ethyl acetate in hexane (1:2) as eluent gave 34 mg (60%) of a white solid **10**. When this reaction was carried out in the presence of 1.0 equiv of methanol as described for the activation of **5**, the yield of **10** was unchanged. $[\alpha]_D$ +35.2 (*c* 0.40, CH_2Cl_2), R_f 0.20 in ethyl acetate –hexane. (1:2); ^1H NMR (360 MHz, $CDCl_3$) δ: 7.35–7.15 (m, 30H, aromatic), 4.51 (d, 1H, $J_{1,2}$ = 3.5 Hz, H-1), 4.10 (d, 1H, $J_{1,2}$ < 0.5 Hz, H-1′), 4.09 (dd, 1H, $J_{5,6}$ = 1.5 Hz, $J_{6,6'}$ = 10.8 Hz, H-6a′), 4.00 (dd, 1H, $J_{3,4}$ = 9.5 Hz, $J_{4,5}$ = 9.5 Hz, H-4′), 3.91 (br s, 1H, H-2′), 3.82 (dd, 1H, $J_{3,4}$ = 9.5 Hz, $J_{4,5}$ = 9.5 Hz, H-4), 3.76 (ddd, 1H, $J_{4,5}$ = 9.5 Hz, $J_{5,6}$ = 1.5 Hz, $J_{5,6'}$ = 5.5 Hz, H-5′), 3.73 (dd, 1H, $J_{5,6}$ = 2.0 Hz, $J_{6,6'}$ = 10.2 Hz, H-6a), 3.66 (dd, 1H, $J_{5,6'}$ = 5.0 Hz, $J_{6,6'}$ = 10.2 Hz, H-6b), 3.56 (dd, 1H, $J_{5,6'}$ = 5.5 Hz, $J_{6,6'}$ = 10.8 Hz, H-6b′), 3.50 (dd, 1H, $J_{3,4}$ = 9.5 Hz, $J_{2,3}$ = 3.5 Hz, H-3′), 3.32 (m, 1H, H-5), 3.32 (s, 3H, OCH_3), 2.37 (br s, 1H, OH); ^{13}C NMR (75.5 MHz, $CDCl_3$) δ: 138.8–138.0, 128.5–127.6 (aromatic), 100.00 (d, $J_{C\text{-}1,H\text{-}1}$ = 155 Hz, C-1′), 97.94 (C-1), 82.22, 81.37, 79.95, 77.65, 75.45, 74.34, 69.87, 68.33 (C-2, C-3, C-4, C-5, C-2′, C-3′, C-4′, and C-5′), 75.76, 75.22, 74.78, 73.54, 73.41, 71.42 (6 × OCH_2Ph), 69.35, 68.18 (C-6, and C-6′), 55.20 (OCH_3). Anal. calcd. for $C_{55}H_{60}O_{11}$: C 73.64, H 6.74; found: C 73.40, H 6.79.

*Octyl 4-*O*-(2-*O*-acetyl-3,4,6-tri-*O*-benzyl-*α*-D-mannopyranosyl)-3,6-di-*O*-benzyl-2-deoxy-2-phthalimido-*β*-D-glucopyranoside (**18**)*

The acceptor **12** (91 mg, 0.166 mmol), crushed 4 Å molecular sieves, mercuric cyanide (50 mg, 0.20 mmol, 1.2 equiv.), and mercuric bromide (72 mg, 0.20 mmol, 1.2 equiv.) were charged to a flask and argon purged. Dry acetonitrile (5 mL) was syringed into the mixture and stirred for 30 min. Freshly prepared bromide **17** (ref. 20, 138 mg, 0.25 mmol, 1.5 equiv.), was dissolved in 2 × 1 mL acetonitrile and dropwise added to the reaction mixture. The mixture was stirred for 2 h, filtered through a celite pad, washed with dichloromethane (30 mL), and concentrated. Fresh dichloromethane (25 mL), was added and washed with 2 × 25 mL of saturated potassium iodide and 1 × 25 mL of distilled water. The organic layer was dried ($MgSO_4$), filtered, and concentrated. The concentrate was purified using 15% ethyl acetate in hexane as eluent to give the product **18** (71 mg, 40%), with 37 mg (40%) of recovered acceptor. R_f 0.62 in ethyl acetate – hexane, (1:3); ^1H NMR (360 MHz, $CDCl_3$) δ: 5.54 (m, 1H, H-2′), 5.42 (d, 1H, $J_{1,2}$ = 1.6 Hz, H-1′), 5.10 (d, 1H, $J_{1,2}$ = 8.4 Hz, H-1), 4.22 (dd, 1H, $J_{1,2}$ = 8.4 Hz, $J_{2,3}$ = 10.6 Hz, H-2), 3.66, 3.38 (2 × m, 2H, OCH_2, octyl), 2.04 (s, 3H, $COCH_3$).

*Octyl 3-6-di-*O*-benzyl-4-0-(3,4,6-tri-*O*-benzyl-*α*-D-mannopyranosyl)-2-deoxy-2-phthalimido-*β*-D-glucopyranoside (**19**)*

The 2-*O*-acetate **18** (65 mg, 0.0604 mmol) was dissolved in 5 mL of dry methanol and 3 mg of sodium methoxide was added. The reaction was stirred for 14 h and then neutralized by adding amberlite IRC-120 (H^+) resin until neutral, filtered, and concentrated. The syrup was purified using 20% ethyl acetate in hexane as eluent to give 55 mg (88%) of the desired product **19**. $[\alpha]_D$ + 44.6 (*c* 105, CH_2Cl_2); R_f 0.38 in ethyl acetate – hexane (1:2); ^1H NMR (360 MHz, $CDCl_3$) δ: 7.8–7.6 (m, 4H, phthalimido), 7.4–7.1, 7.05–6.67 (m, 25H, benzyl aromatics), 5.34 (d, 1H, $J_{1,2}$ = 1.8 Hz, H-1′), 5.08 (d, 1H, $J_{1,2}$ = 8.5 Hz, H-1), 4.19 (dd, 1H, $J_{1,2}$ = 8.5 Hz, $J_{2,3}$ = 10.7 Hz, H-2), 3.96 (m, 1H, H-2′), 3.7 3.35 (2 × m, 2H, OCH_2, octyl), 2.20 (d, 1H, $J_{H,OH}$ = 2.8 Hz, OH), 1.4–0.7 (m, 15H, octyl); ^{13}C (75.5 MHz, $CDCl_3$) δ: 101.23 (d, $J_{C\text{-}1,H\text{-}1}$ = 172 Hz, C-1′), 98.10 (C-1), 80.94, 79.89, 78.11, 74.90, 74.21, 72.35, 69.02 (C-2′, C-3′, C-4′, C-5′, C-3, C-4, and C-5), 75.07, 74.62, 73.50, 73.38, 72.11 (5 × OCH_2Ph), 69.60, 69.60 (C-6 and C-6′), 68.90 (OCH_2, octyl), 55.81 (C-2), 31.66, 29.29, 29.13, 25.84, 22.60 (6 × CH_2, octyl), 14.06 (CH_3, octyl). Anal. calcd. for $C_{63}H_{71}O_{12}N$: C 73.16, H 6.92, N 1.35; found: C 72.80, H 6.92, N 1.40.

*Methyl 4-*O*-(2-*O*-acetyl-3,4,6-tri-*O*-benzyl-*α*-D-mannopyranosyl)-2,3,6-tri-*O*-benzyl-*α*-D-glucopyranoside (**20**)*

The alcohol **11** (76 mg, 0.164 mmol), crushed 4 Å molecular sieves, mercuric cyanide (50 mg, 0.197 mmol, 1.2 equiv.), and mercuric bromide (71 mg, 0.197 mmol, 1.2 equiv.) were added to a reaction flask and argon purged. Dry acetonitrile (5 mL), was syringed into the mixture, which was stirred for 30 min. In a separate flask, freshly prepared bromide **17** (20) was argon purged, dissolved in 2 × 1.5 mL of dry acetonitrile, and dropwise added to the acceptor. After 3 h, the reaction was treated as in the preparation of **18**. Chromatography (15% ethyl acetate in hexane as eluent) yielded the desired product **20** (63 mg, 41%) with 35 mg (46%) of recovered acceptor. R_f 0.59 in ethyl acetate – hexane (1:2); ^1H NMR (360 MHz, $CDCl_3$) δ: 5.43 (dd, 1H, $J_{1,2}$ = 1 Hz, $J_{2,3}$ = 3.6 Hz, H-2′), 5.41 (d, 1H, $J_{1,2}$ = 1.5 Hz, H-1′), 4.58 (d, 1H, H-2), 3.54 (dd, 1H, $J_{2,3}$ = 3.6 Hz, $J_{3,4}$ = 9.8 Hz, H-3′), 3.38 (s, 3H, OCH_3), 1.99 (s, 3H, $COCH_3$).

*Methyl 2,3,6-tri-*O*-benzyl-4-*O*-(3,4,6-tri-*O*-benzyl-*α*-D-manno-pyranosyl)-*α*-D-glucopyranoside (**21**)*

The 2-*O*-acetate **20** (60 mg, 0.0639 mmol) was de-*O*-acetylated using the same procedure as for the preparation of **19**. Purification was performed using 18% ethyl acetate in hexane solvent system to give the product **21** (51 mg, 89%) as a colourless syrup. $[\alpha]_D$ + 61.7 (*c* 1.10, CH_2Cl_2); R_f 0.40 in ethyl acetate – hexane (1:2); ^1H NMR (360 MHz, $CDCl_3$) δ: 7.45–7.15 (m, 30H, aromatic), 5.31 (d, 1H, $J_{1,2}$ = 1.8 Hz, H-1′), 4.60 (d, 1H, $J_{1,2}$ = 3.8 Hz, H-1), 3.88–3.66 (m, 12H), 3.60 (dd, 1H, $J_{5,6}$ = 3.8 Hz, $J_{6,6'}$ = 10.5 Hz, H-6a′), 3.53 (dd, 1H, $J_{1,2}$ = 3.8 Hz, $J_{2,3}$ = 9.5 Hz, H-2), 3.49 (dd, 1H, $J_{5,6'}$ = 1.5 Hz, $J_{6,6'}$ = 10.5 Hz, H-6b′), 3.38 (s, 3H, OCH_3), 2.08 (br s, 1H, OH); ^{13}C NMR (75.5 MHz, $CDCl_3$) δ: 138.6–138.0, 128.5–127.5 (aromatic), 101.6 (d, $J_{C\text{-}1,H\text{-}1}$ = 171 Hz,

C-1′), 97.8 (C-1), 81.8, 80.02, 79.9, 77.4, 74.2, 72.3, 69.8, 68.8 (C-2, C-3, C-4, C-5, C-2′, C-3′, C-4′, and C-5′), 75.5, 75.0, 73.5, 73.3, 71.9 (6 × OCH_2Ph), 69.4, 69.0 (C-6 and C-6′), 55.3 (OCH_3). Anal. calcd. for $C_{55}H_{60}O_{11}$: C 73.64, H 6.74; found: C 72.97, H 6.76.

Methyl 6-O-(2-O-acetyl-3,4,6-tri-O-benzyl-α-D-mannopyranosyl)-2,3,4,-tri-O-benzyl-α-D-glucopyranoside (22)

The alcohol **13** (76 mg, 0.164 mmol), crushed 4 Å molecular sieves, mercuric cyanide (50 mg, 0.197 mmol, 1.2 equiv.), and mercuric bromide (71 mg, 0.197 mmol, 1.2 equiv.) were added to a reaction flask and argon purged. Dry acetonitrile (5 mL) was syringed into the mixture, which was stirred for 30 min. In a separate flask, freshly prepared bromide **17** (ref. 20; 137 mg, 0.25 mmol, 1.5 equiv.) was dissolved in 2 × 1.5 mL of acetonitrile and dropwise added to the acceptor. After 45 min, the reaction was worked up as in the synthesis of **18**. Column chromatography using 12% ethyl acetate in hexane as eluent yielded the desired product **22** (120 mg, 78%). R_f 0.65 in ethyl acetate – toluene (1:2); ^{1}H NMR (360 MHz, $CDCl_3$) δ: 5.38 (dd, 1H, $J_{1,2}$ = 1.8 Hz, $J_{2,3}$ = 3.0 Hz, H-2′), 4.89 (d, 1H, $J_{1,2}$ = 1.8 Hz, H-1′), 4.58 (d, 1H, $J_{1,2}$ = 3.2 Hz, H-1), 3.98 (dd, 1H, $J_{2,3}$ = 9.0 Hz, $J_{3,4}$ = 9.0 Hz, H-3), 3.91 (dd, 1H, $J_{2,3}$ = 3.0 Hz, $J_{3,4}$ = 9.2 Hz, H-3′), 3.86 (dd, 1H, $J_{3,4}$ = 9.2 Hz, $J_{4,5}$ = 9.2 Hz, H-4′), 3.44 (dd, 1H, $J_{1,2}$ = 3.2 Hz, $J_{2,3}$ = 9.0 Hz, H-2), 3.42 (dd, 1H, $J_{3,4}$ = 9.0 Hz, $J_{4,5}$ = 9.0 Hz, H-4), 3.32 (s, 3H, OCH_3), 2.15 (s, 3H, $COCH_3$).

Methyl 2,3,4,-tri-O-benzyl-6-O-(3,4,6-tri-O-benzyl-α-D-mannopyranosyl)-α-D-glucopyranoside (23)

The 2-O-acetate **22** (115 mg, 0.12 mmol) was de-*O*-acetylated as in the synthesis of **19**. Purification using 30% ethyl acetate in hexane as eluent yielded the product **23** (83 mg, 76%), along with 2 mg (2%) of the accompanying β-isomer. $[\alpha]_D$ + 74.4 (*c* 2.55, CH_2Cl_2); R_f 0.17 in ethyl acetate – hexane (1:2); ^{1}H NMR (360 MHz, $CDCl_3$) δ: 7.40 – 7.10 (m, 30H, aromatic), 5.02–4.40 (m, 12H, 6 × OCH_2Ph), 4.96 (d, 1H, $J_{1,2}$ = 1.5 Hz, H-1′), 4.60 (d, 1H, $J_{1,2}$ = 3.7 Hz, H-1), 4.03 (dd, 1H, $J_{1,2}$ = 15 Hz, $J_{2,3}$ = 3 Hz, H-2′), 3.99 (dd, 1H, $J_{3,4}$ = 9.4 Hz, $J_{4,5}$ = 9.4 Hz, H-3), 3.85 (dd, 1H, $J_{5,6}$ = 4.5 Hz, $J_{6,6'}$ = 10 Hz, H-6a), 3.83 (m, 1H, H-3′), 3.82 (dd, 1H, $J_{5,6'}$ = 3.5 Hz, $J_{6,6'}$ = 10 Hz, H-6b), 3.70 (m, 3H, H-5, H-4′, and H-5′), 3.62 (dd, 1H, $J_{5,6}$ = 4.0 Hz, $J_{6,6'}$ = 11.0 Hz, H-6a′), 3.55 (dd, 1H, $J_{5,6'}$ = 2.0 Hz, $J_{6,6'}$ = 11.0 Hz, H-6b′), 3.50 (dd, 1H, $J_{2,3}$ = 3.7 Hz, $J_{3,4}$ = 9.8 Hz, H-2), 3.45 (dd, 1H, $J_{4,5}$ = 9.4 Hz, $J_{3,4}$ = 9.4 Hz, H-4), 3.33 (s, 3H, OCH_3), 2.40 (br s, 1H, OH); ^{13}C NMR (75.5 MHz, $CDCl_3$) δ: 138.85–137.85, 128.55–127.58 (aromatic), 99.57 (d, $J_{C\text{-}1,H\text{-}1}$ = 175 Hz, C-1′), 97.88 (C-1), 82.17, 80.09, 79.74, 77.74, 74.22, 71.21, 69.84, 68.26 (C-2, C-3, C-4, C-5, C-2′, C-3′, C-4′, and C-5′), 75.82, 75.05, 74.96, 73.41, 73.29, 71.92 (6 × OCH_2Ph), 69.84, 65.92 (C-6 and C-6′), 55.14 (OCH_3). Anal. calcd. for $C_{55}H_{60}O_{11}$: C 73.64, H 6.74; found: C 73.57, H 6.82.

Ethyl 3,4,6-tri-O-benzyl-2-O-(methoxy isopropylidene)-1-thio-α-D-mannopyranoside (24)

The alcohol **16** (200 mg, 0.405 mmol) was charged to a round-bottom flask and argon purged. Dichloromethane (10 mL) was added followed by 0.047 mL (1.2 equiv.) of dimethoxy propene. The reaction was cooled to –40°C and catalytic *p*-toluenesulfonic acid was added. After 7 min, the reaction was quenched by adding triethylamine, concentrated and purified using a 10% ethyl acetate in hexane solvent system containing 0.1% triethylamine. The product **24** (201 mg, 88%) was isolated as a sticky whole solid. R_f 0.57 in ethyl acetate – hexane (1:3); ^{1}H NMR (360 MHz, $CDCl_3$) δ: 5.35 (d, 1H, $J_{1,2}$ = 1.5 Hz, H-1), 4.22 (dd, 1H, $J_{1,2}$ = 1.5 Hz, $J_{2,3}$ = 3.0 Hz, H-2), 4.11 (m, 1H, H-5), 3.98 (dd, 1H, $J_{3,4}$ = 9.4 Hz, $J_{4,5}$ = 9.4 Hz, H-4), 3.84 (dd, 1H, $J_{5,6}$ = 4.8 Hz, $J_{6,6'}$ = 11.0 Hz, H-6), 3.80 (dd, 1H, $J_{3,4}$ = 9.4 Hz, $J_{2,3}$ = 3.0 Hz, H-3), 3.71 (dd, 1H, $J_{5,6'}$ = 1.9 Hz, $J_{6,6'}$ = 11.0 Hz, H-6′), 3.28 (s, 3H, OCH_3), 2.60 (m, 2H, SCH_2CH_3), 1.41, 1.38 (2 × s, 6H, CH_3CCH_3), 1.26 (t, 3H, SCH_2CH_3); ^{13}C NMR (75.5 MHz, $CDCl_3$) δ: 101.46 (CH_3CCH_3), 84.39 (C-1), 80.05, 75.00, 72.18, 70.24 (C-2, C-3, C-4, and C-5), 69.42 (C-6), 49.62 (OCH_3), 25.0 (SCH_2CH_3), 24.94 (CH_3CCH_3), 15.17 (SCH_2CH_3). Anal. calcd. for $C_{33}H_{42}O_6S$: C 69.93, H 7.47, S 5.66; found: C 70.04, H 7.45, S 5.94.

Methyl 3,4,6-tri-O-benzyl-β-D-mannopyranoside (25)

The acetal **24** (50 mg, 0.0883 mmol) was charged to a round-bottom flask and argon purged. Dichloromethane (3 mL) was added and the reaction was cooled to –40°C. *N*-Bromosuccinimide (47.2 mg, 3 equiv.) was added and the reaction was stirred for 1 h. The reaction was quenched by adding 1 mL of 0.5 M NaS_2O_3 solution and worked up as in the synthesis of **6**. Chromatographic purification using 35% ethyl acetate in hexane yielded 6 mg (15%) of the β-mannopyranoside **25**, as well as 20 mg of the succinimide adduct **26** (37%). Treatment of **26** with catalytic *p*-toluenesulfonic acid converted **26** to **25** in quantitative yield.

Product **25**: R_f 0.38 in ethyl acetate – hexane (1:1); ^{1}H NMR (360 MHz, $CDCl_3$) δ: 4.34 (d, 1H, $J_{1,2}$ < 1Hz, H-1), 4.20 (dd, 1H, $J_{1,2}$ < 1Hz, $J_{2,3}$ = 3.2 Hz, H-2), 3.88 (dd, 1H, $J_{3,4}$ = 9.0 Hz, $J_{4,5}$ = 9.0 Hz, H-4), 3.81 (dd, 1H, $J_{5,6}$ = 2.1 Hz, $J_{6,6'}$ = 11.0 Hz, H-6′), 3.58 (dd, 1H, $J_{2,3}$ = 3.2 Hz, $J_{3,4}$ = 9.0 Hz, H-3), 3.57 (s, 3H, OCH_3), 2.39 (d, 1H, $J_{H,OH}$ = 2.4 Hz, OH).

Product **26**: R_f 0.26 in ethyl acetate – hexane (1:2); ^{1}H NMR (360 MHz, $CDCl_3$) δ: 4.36 (dd, 1H, $J_{1,2}$ < 1Hz, $J_{2,3}$ = 2.5 Hz, H-2), 4.22 (d, 1H, $J_{1,2}$ < 1 Hz, H-1), 3.94 (dd, 1H, $J_{3,4}$ = 9.2 Hz, $J_{4,5}$ = 9.2 Hz, H-4), 3.78 (d, 2H, $J_{5,6}$ = 3.8 Hz, H-6′s), 3.47 (s, 3H, OCH_3), 3.45 (m, 2H, H-3 and H-5), 3.31 (m, 4H, CH_2CH_2, succinimide), 1.94, 1.92 (2 × s, 6H, CH_3CCH_3); ^{13}C NMR (75.5 MHz, $CDCl_3$) δ: 178.29 (CO), 101.43 (C-1), 89.90 (OCN), 82.17, 76.42, 75.05, 71.22 (C-2, C-3, C-4, and C-5), 69.59 (C-6), 57.09 (OCH_3), 28.56 (CH_2CH_2, succinimide), 27.49, 27.33 (CH_3CCH_3).

Attempted acetalization of the trisaccharide **27**

The vinyl ether **27** ref 21; 182 mg (0.13 mmol), and the alcohol **11** (72.5 mg, 1.2 equiv.) were charged to a round-bottom flask and argon purged. Calcium sulfate (1 g) was added and the flask was argon purged. Dichloromethane was added and the reaction was stirred and cooled to –40°C. After stirring for 30 min, camphorsulfonic acid (0.08 equiv.) was added. The reaction was stirred at –40°C for 4 h and quenched by adding triethylamine. The vinyl ether **27** (84 mg) was recovered (46%), as well as 62 mg of recovered **11** and 78 mg of recovered hydrolyzed vinyl ether **28**.

Product **27**: The synthesis of **27** will be published elsewhere. For characterization purposes: R_f 0.72 in ethyl acetate – hexane (1:2); ^{1}H NMR (360 MHz, $CDCl_3$) δ: 5.46 (d, $J_{1,2}$ = 1Hz, H-1), 5.13 (d, $J_{1,2}$ = 1.8 Hz, H-1′), 5.01 (d, 1H, $J_{1,2}$ = 1.6 Hz, H-1″), 2.50 (m, 2H, SCH_2CH_3), 1.76 (s, 3H, $CH_2{=}CCH_3$), 1.18 (t, 3H, SCH_2CH_3); ^{13}C NMR (75.5 MHz, $CDCl_3$ + 10% D-5 pyridine) δ: 157.23 ($C{=}CH_2$), 100.28, 97.82 (C-1′ and C-1″), 83.28 ($C{=}CH_2$), 80.55 (C-1), 79.76, 79.37, 79.37, 75.79, 75.04, 74.50, 74.30, 73.91, 72.60, 71.00 (C-2, C-3, C-4, C-5, C-2′, C-3′, C-4′, C-5′, C-2″, C-3″, C-4″, and C-5″), 68.88, 68.61, 65.72 (C-6, C-6′, and C-6″), 24.91 (SCH_2CH_3), 20.97 ($CH_3C{=}CH_2$), 14.72 (SCH_2CH_3).

Product **28**: R_f 0.59 in ethyl acetate – hexane (1:2); ^{1}H NMR (360 MHz, $CDCl_3$) δ: 5.05, 5.00, 4.96 (H-1, H-1′, and H-1″), 3.36 (s, 1H, OH), 2.50 (m, 2H, SCH_2CH_3); ^{13}C NMR (75.5 MHz, $CDCl_3$) δ: 99.50, 98.13 (C-1′ and C-1″), 84.67 (C-1), 83.31, 79.94, 79.68, 75.51, 75.41, 74.65, 73.82, 72.21, 71.78, 71.44, 70.75 (C-2, C-3, C-4, C-5, C-2′, C-3′, C-4′, C-5′, C-2″, C-3″, C-4″, and C-5″), 69.93, 69.24, 66.23 (C-6, C-6′, and C-6″), 25.05 (SCH_2CH_3), 14.99 (SCH_2CH_3).

3,4-di-O-acetyl-6-O-(2,3,4,6-tetra-O-acetyl-α-D-mannopyranosyl)-1,2-methoxyethylidene)-β-D-mannopyranoside (30)

The peracetate **29** (ref. 22; 4.0 g, 5.9 mmol) was dissolved in dichloromethane and cooled to 0°C. Hydrobromic acid gas was passed through a $CaSO_4$ drying tube and bubbled through the dichloromethane solution for 30 min. The solution was then concentrated in vacuo, coevaporated twice with toluene, and dried under high vacuum for 2 h to give a golden foam. The foam was dissolved in dichloromethane (150 mL) and 2,6-lutidene (1.8 mL 14.7 mmol, 2.5 equiv.) was syringed into the mixture. Methanol (0.6 mL, 14.7 mmol, 2.5 equiv.) was added and the reaction was stirred for 60 h. Another 100 mL of CH_2Cl_2 was added and the mixture was washed with 250 mL of saturated sodium bicarbonate solution and 3 × 250 mL of dH_2O. The organic layer was dried ($MgSO_4$), filtered, and concentrated to

For personal use only.

give 4.0 g of a crude foam (≅100%). A portion of this foam was purified for characterization using ethyl acetate in hexane (1:1) as eluent, giving a white solid product **30** $[\alpha]_D$ + 47.8 (*c* 0.80, CH_2Cl_2); R_f 0.52 in ethyl acetate – hexane (7:3); ^1H NMR (360 MHz, $CDCl_3$) δ: 5.52 (d, 1H, $J_{1,2}$ = 2.8 Hz, H-1), 5.30 (m, 2H, H-2′, and H-4′), 5.24 (m, 1H, H-3′), 5.23 (dd, 1H, $J_{4,5}$ = 9 Hz, $J_{3,4}$ = 9.8 Hz, H-4), 5.15 (dd, 1H, $J_{3,4}$ = 9.8 Hz, $J_{2,3}$ = 3.8 Hz, H-3), 4.80 (d, 1H, $J_{1,2}$ = 1.7 Hz, H-1′), 4.62 (dd, 1H, $J_{1,2}$ = 2.8 Hz, $J_{2,3}$ = 3.8 Hz, H-2), 4.33 (dd, 1H, $J_{5,6}$ = 5.0 Hz, $J_{6,6'}$ = 12.6 Hz, H-6b), 4.06 (m, 2H, H-5′ and H-6b′), 3.79 (dd, 1H, $J_{5,6}$ = 5.8 Hz, $J_{6,6'}$ = 10.2 Hz, H-6a), 3.69 (ddd, 1H, $J_{5,6}$ = 5.8 Hz, $J_{5,6'}$ = 3.0 Hz, $J_{4,5}$ = 9 Hz, H-5), 3.60 (dd, 1H, $J_{5,6'}$ = 3.0 Hz, $J_{6,6'}$ = 10.2 Hz, H-6b), 3.28 (s, 3H, OCH_3), 2.15, 2.13, 2.10, 2.08, 2.06, 1.99 (6 × s, 18H, $COCH_3$), 1.72 (s, 3H, CH_3COCH_3, ortho ester); ^{13}C NMR (75.5 MHz, $CDCl_3$) δ: 170.66, 170.37, 169.98, 169.76, 169.69 (6 × $COCH_3$), 124.34 (CH_3COCH_3, ortho ester), 97.78 (C-1), 97.46 (C-1′), 76.32, 72.22, 70.51, 69.35, 69.09, 68.63, 66.41, 65.94 (C-2, C-3, C-4, C-5, C-2′, C3′, C-4′, and C-5′), 67.60 (C-6′), 62.30 (C-6), 50.05 (OCH_3), 24.17 (CH_3COCH_3, ortho ester), 20.88–20.68 ($COCH_3$). Anal. calcd. for $C_{27}H_{38}O_{18}$: C 49.85, H 5.89; found: C 49.58, H 5.85.

*3,4-Di-*O*-benzyl-6-*O*-(2,3,4,6-tetra-*O*-benzyl-α-D-mannopyranosyl)-1,2-(methoxyethylidene)-α-D-mannopyranoside (**31**)*

The crude peracetylated ortho ester **30** (4.0 g, 5.9 mmol) was dissolved in 150 mL of dry methanol, 30 mg of sodium methoxide was added, and the reaction was stirred overnight. The mixture was concentrated in vacuo and dried under high vacuum to give 2.6 g (≅100) of a white foam. A portion of this foam (2.0 g, 4.5 mmol) was dissolved in 80 mL of dry dimethyl formamide (DMF) and charged to a dropping funnel. In a separate flask, 3.0 g (75 mmol) of sodium hydride, 60% dispersion in oil was mixed with 120 mL DMF and stirred for 30 min, cooling to 0°C. The ortho ester was dropwise added to the DMF–NaH solution over a 15min period and stirred at 0°C for 30 min forming a thick gelatinous mixture. Benzyl bromide (8.9 mL, 75 mmol) was diluted in 20 mL of DMF and dropwise added to the mixture over a 10-min period. The solution became less viscous and allowed to warm to room temperature overnight. The reaction was quenched by adding 50 mL methanol and concentrating under reduced pressure to a total volume of 150 mL, and then 150 mL dichloromethane was added. This solution was washed with 2 × 300 mL of dH_2O and then 300 mL of a saturated solution of sodium chloride. The organic layer was dried ($MgSO_4$), filtered, concentrated, and purified (28% ethyl acetate in hexane with 0.1% added triethylamine as eluent) to give 2.26 g (41% from **29**) of a colourless syrup **31**. $[\alpha]_D$ + 24.4 (*c* 0.95, CH_2Cl_2); R_f 0.30 in ethyl acetate – hexane (2:3); ^1H NMR (360 MHz, $CDCl_3$) δ: 7.45–7.12 (m, 30H, aromatic), 5.33 (d, 1H, $J_{1,2}$ = 2.4 Hz, H-1), 5.00 (d, 1H, $J_{1,2}$ = 1.8 Hz, H-1′), 4.92, 4.49 (2 × d, 2H, J_{gem} = 11.0 Hz, OCH_2Ph), 4.89, 4.55 (2 × d, 2H, J_{gem} = 11.2 Hz, OCH_2Ph), 4.79 (s, 2H, OCH_2Ph), 4.72 (s, 2H, OCH_2Ph), 4.62, 4.43 (2 × d, 2H, J_{gem} = 12.2 Hz, OCH_2Ph), 4.62, 4.61 (2 × d, 2H, J_{gem} = 11.5 Hz, OCH_2Ph), 4.40 (dd, 1H, $J_{1,2}$ = 2.4 Hz, $J_{2,3}$ = 3.8 Hz, H-2), 4.02 (dd, 1H, $J_{3,4}$ = 9.2 Hz, $J_{4,5}$ = 9.2 Hz, H-4′), 3.95 (dd, 1H, $J_{5,6}$ = 4.0 Hz, $J_{6,6'}$ = 11.4 Hz, H-6a′), 3.89 (dd, 1H, $J_{2,3}$ = 3.0 Hz, $J_{3,4}$ = 9.4 Hz, H-3′), 3.83 (dd, 1H, $J_{3,4}$ = 9.2 Hz, $J_{4,5}$ = 9.2 Hz, H-4), 3.82 (dd, 1H, $J_{1,2}$ = 1.8 Hz, $J_{2,3}$ = 3.0 Hz, H-2′), 3.73 (dd, 1H, $J_{2,3}$ = 3.8 Hz, $J_{3,4}$ = 9.2 Hz, H-3), 3.73 (m, 1H, H-5), 3.68 (m, 2H, H-6a, and H-6′b), 3.61 (dd, 1H, $J_{5,6}$ = 1.6 Hz, $J_{6,6'}$ = 10.8 Hz, H-6a′), 3.35 (m, 1H, H-5′), 3.28 (s, 3H, OCH_3), 1.69 (s, 3H, CH_3COCH_3); ^{13}C NMR (75.5 MHz, $CDCl_3$) δ: 138.7–137.8, 128.9–127.4 (aromatics), 123.95 (CH_3COCH_3, ortho ester), 98.61 (C-1), 97.53 (C-1′), 79.88, 79.37, 77.14, 74.81, 74.68, 73.90, 73.35, 72.21 (6 × OCH_2Ph, C-6, and C-6′), 75.19, 74.98, 73.31, 72.62, 72.28, 71.95, 69.19, 66.34 (C-2, C-3, C-4, C-5, C-2′, C-3′, C-4′, and C-5′), 49.73 (OCH_3), 24.71 (CH_3COCH_3, ortho ester). Anal. calcd. for $C_{57}H_{62}O_{12}$: C 79.90, H 6.65; found: C 73.17, H 6.79.

*Ethyl 2-*O*-acetyl-3,4-di-*O*-benzyl-6-*O*-(2,3,4,6-tetra-*O*-benzyl-α-D-mannopyranosyl)-1-thio-α-Dmannopyranoside (**32**)*

The ortho ester **31** (1.26 g, 1.34 mmol) was charged to a round-bottom flask and argon purged. Ethanethiol (15 mL) was added and the solution was cooled to 0°C. Boron trifluoride etherate (0.17 mL, 1.34 mmol) was syringed into the mixture and the reaction was quenched after 10 min by adding 10 mL of dH_2O. The reaction was then worked up as in the preparation of **2**. Chromatography using 15% ethyl acetate in hexane yielded 1.06 g (81%) of a colourless syrup **32**. $[\alpha]_D$ + 64.9 (*c* 1.50, CH_2Cl_2); R_f 0.59 in ethyl acetate – hexane (1:2); ^1H NMR (300 MHz, $CDCl_3$) δ: 7.40–7.10 (m, 30H, aromatics), 5.42 (dd, 1H, $J_{1,2}$ = 1.5 Hz, $J_{2,3}$ = 3.2 Hz, H-2), 5.22 (d, 1H, $J_{1,2}$ = 1.3 Hz, H-1′), 5.03 (d, 1H, $J_{1,2}$ = 1.5 Hz, H-1), 4.86, 4.45 (2 × d, 2H, J_{gem} = 12 Hz, OCH_2Ph), 4.86, 4.47 (2 × d, 2H, J_{gem} = 11.0 Hz, OCH_2Ph), 4.76, 4.71 (2 × d, 2H, J_{gem} = 12 Hz, OCH_2Ph), 4.66, 4.49 (2 × d, 2H, J_{gem} = 10.8 Hz, OCH_2Ph), 4.63, 4.56 (2 × d, 2H, J_{gem} = 12.2 Hz, OCH_2Ph), 4.63, 4.44 (2 × d, 2H, J_{gem} = 10.4 Hz, OCH_2Ph), 4.13 (m, 1H, H-5), 4.01 (dd, 1H, $J_{3,4}$ = 9.5 Hz, $J_{4,5}$ = 9.5 Hz, H-4), 3.91 (dd, 1H, $J_{5,6}$ = 4.8 Hz, $J_{6,6'}$ = 11.0 Hz, H-6a′), 3.89 (m, 4H, H-2, H-3, H-2′, and H-3′), 3.75 (dd, 1H, $J_{4,5}$ = 9.2 Hz, $J_{3,4}$ = 9.2 Hz, H-4′), 3.74 (m, 1H, H-5′), 3.68 (dd, 1H, $J_{5,6}$ = 4.8 Hz, $J_{6,6'}$ = 10.8 Hz, H-6a), 3.66 (dd, 1H, $J_{5,6'}$ = 1.7 Hz, $J_{6,6'}$ = 11.0 Hz, H-6b′), 3.60 (dd, 1H, $J_{5,6'}$ = 1.7 Hz, $J_{6,6'}$ = 10.8 Hz, H-6b), 2.55 (m, 2H, J_{vic} = 7.8 Hz, SCH_2CH_3), 2.06 (s, 3H, $COCH_3$), 1.21 (t, 3H, J_{vic} = 7.5 Hz, SCH_2CH_3); ^{13}C NMR (75.5 MHz, $CDCl_3$) δ: 138.73–137.66, 128.44–127.45 (aromatic), 98.09 (C-1′), 82.28 (C-1), 79.85, 78.74, 74.89, 74.89, 74.55, 71.98, 71.46, 70.48 (C-2, C-3, C-4, C-5, C-2′, C-3′, C-4′, and C-5′), 75.06, 75.06, 73.30, 72.55, 71.88, 71.88 (6 × OCH_2Ph), 69.20, 66.13 (C-6 and C-6′), 25.41 (SCH_2CH_3), 21.10 ($COCH_3$), 14.94 (SCH_2CH_3). Anal. calcd. for $C_{58}H_{64}O_{11}S$: C 71.88, H 6.66, S 3.31; found: C 71.90, H 6.69, S. 3.23.

*Ethyl 3,4-di-*O*-benzyl-6-*O*-(2,3,4,6-tetra-*O*-benzyl-α-D-mannopyranosyl)-2-*O*-(2-propenyl)-1-thio-α-D-mannopyranoside (**33**)*

The thioglycoside **32** (583 mg, 0.60 mmol) was charged to a round-bottom flask and argon purged. Dry toluene (9 mL), tetrahydrofuran (3 mL), and pyridine (0.1 mL) were consecutively syringed into the flask and the mixture was cooled to –40°C. Tebbe's reagent (1.20 mL, 1.2 mmol, 2.0 equiv.) was slowly syringed into the mixture with some fuming. The reaction colour became a deep red. The solution was allowed to slowly warm to –10°C, and after 2.5 h, was quenched by carefully adding 0.1 mL of 1 M NaOH (vigorous methane evolution) at –10°C. After the gas evolution subsided, the mixture was warmed to room temperature and a further 0.5 mL of 1 M NaOH was added. The deep red mixture was filtered as for the preparation of **4** and then concentrated under reduced pressure and purified using column chromatography with 15% ethyl acetate in hexane with 0.1% added triethylamine as eluent. A clear syrup (402 mg, 69%) was obtained **33**. R_f 0.57 in ethyl acetate – hexane (1:3); ^1H NMR (300 MHz, $CDCl_3$) + 2% D-5 pyridine) δ: 7.40–7.10 (m, 30H, aromatic), 5.46 (d, 1H, $J_{1,2}$ = 1 Hz, H-1′), 5.05 (d, 1H, $J_{1,2}$ = 1 Hz, H-1), 4.89, 4.47 (2 × d, 2H, J_{gem} = 10.8 Hz, OCH_2Ph), 4.87 4.45 (2 × d, 2H, J_{gem} = 11.0 Hz, OCH_2Ph), 4.75, 4.70 (2 × d, 2H, J_{gem} = 12.0 Hz, OCH_2Ph), 4.63, 4.56 (2 × d, 2H, J_{gem} = 12 Hz, OCH_2Ph), 4.63, 4.44 (2 × d, 2H, J_{gem} = 11.5 Hz, OCH_2Ph), 4.40 (d, 1H, J_{gem} = 2.0 Hz, C=C*H*H′), 4.09 (m, 1H, H-5), 4.01 (d, $J_{4,5}$ = 9.0 Hz, $J_{3,4}$ = 9.0 Hz, H-4), 3.76 (d, 1H, J_{gem} = 2.0 Hz, C=CH*H*′), 3.74 (m, 1H, H-5′), 2.53 (m, 2H, SCH_2CH_3), 2.31 (s, 3H, $CH_3C{=}CH_2$), 1.20 (t, 3H, SCH_2CH_3); ^{13}C NMR (75.5 MHz, D-5 pyridine) δ: 158.73 ($C{=}CH_2$), 1.39.58–138.84, 129.27–127.69 (aromatics), 98.44 (C-1′), 83.37 ($C{=}CH_2$), 80.84 (C-1), 80.26, 75.93, 75.45, 75.31, 74.34, 72.62, 72.01 (C-2, C-3, C-4, C-5, C-2′, C-3′, C-4′, and C-5′), 75.31, 75.18, 73.38, 73.02, 71.69, 71.58 (6 × OCH_2Ph), 69.94, 66.75 (C-6 and C-6′), 25.39 (SCH_2CH_3), 21.31 ($CH_3C{=}CH_2$), 15.18 (SCH_2CH_3).

*Octyl 3,6-di-*O*-benzyl-2-deoxy-2-phthalimido-β-D-glucopyranoside-ethyl 3′,4′-di-*O*-benzyl-6′-*O*-(2″,3″,4″,6″-tetra-*O*-benzyl-α-D-mannopyranosyl)-1′-thio-α-D-mannopyranoside-2′,4-isopropylidene acetal (**34**)*

The vinyl ether **33** (88 mg, 0.091 mmol) was charged to a round-bottom flask and the alcohol **12** (66 mg, 0.109 mmol, 1.2 equiv.) was added under argon atmosphere. Dry dichloromethane (7 mL), was added to the mixture and cooled to –40°C. A 0.05 mM solution of camphorsulfonic acid was prepared by dissolving 23.3 mg of acid in 2 mL

Can. J. Chem. Downloaded from www.nrcresearchpress.com by EESC ESCOLA DE ENGENHARIA on 09/08/12
For personal use only.

of dry dichloromethane over molecular sieves under argon atmosphere. A 0.18-mL aliquot of the acid mixture (0.009 mmol, 0.1 equiv.) was syringed into the solution. The reaction was carefully monitored by TLC for product formation (60 min) and quenched by adding 0.05 mL of triethylamine. The mixture was concentrated and purified on silica gel using 17% ethyl acetate in hexane as eluent with added 0.1% triethylamine. The mixed acetal **34** (35 mg, 25%) was obtained as a colourless viscous syrup, as well as 28 mg recovered as vinyl ether **33** and 44 mg recovered as alcohol **12**. The product was unstable (<12 h at room temperature) unless stored in an organic solution with 0.5% added triethylamine. R_f 0.72 in ethyl acetate – hexane (1:2); ^{1}H NMR (360 MHz, $CDCl_3$ + 2% D-5 pyridine) δ: 5.35 (d, 1H, $J_{1,2}$ = 1 Hz, H-1_M), 5.10 (d, 1H, $J_{1,2}$ = 7.4 Hz, H-1_{Gn}), 5.03 (d, 1H $J_{1,2}$ = 1 Hz, H-$1'_M$), 2.56 (m, 2H, SCH_2CH$_3$), 1.42 (s, 3H, CH_3CCH$_{3'}$), 1.37 (s, 3H, CH$_3$CC$H_{3'}$), 1.30 (t, 3H, J_{vic} = 7.0 Hz, SCH$_2$CH_3), 1.3–0.75 (m, 15H, octyl); ^{13}C NMR (75.5 MHz, $CDCl_3$ + 2% D-5 pyridine) δ: 104.79 (OCO, acetal), 98.08, 97.76 (C-1_{Gn}, C-$1'_M$), 84.67 (C-1_M), 79.84, 79.83, 76.20, 75.06, 75.04, 74.92, 74.64, 73.14, 71.91, 71.61, 71.41 (C-2_M, C-3_M, C-4_M, C-5_M, C-$2'_M$, C-$3'_M$, C-$4'_M$, C-5_M, C-3_{Gn}, C-4_{Gn}, and C-5_{Gn}), 75.15, 74.85, 74.76, 74.72, 73.17, 73.01, 72.62, 72.49, 72.62, 72.49, 71.61, 69.43, 69.01 (8 × OCH_2Ph, C-6_M, C-$6'_M$, C-6_{Gn}, and OCH$_2$ octyl), 56.49 (C-2_{Gn}), 31.55, 29.23, 29.04, 29.00, 25.74, 25.22, 22.48 (6 × CH$_2$, octyl, SCH_2CH$_3$), 26.36, 25.81 (2 × CH$_3$, acetal), 15.21 (SCH$_2$CH_3), 13.94 (CH$_3$, octyl).

Octyl 3,6-di-O-benzyl-4-O-[3,4-di-O-benzyl-6-O-(2,3,4,6-tetra-O-benzyl-α-D-mannopyranosyl)-β-D-mannopyranosyl]-2-deoxy-2-phthalimido-β-D-glucopyranoside (35)

The mixed acetal **34** (35 mg, 0.0223 mmol) was argon purged in a round-bottom flask. Dry dichloromethane (6 mL) was syringed into the flask followed by 1.1 mL of a 0.10 mM solution of 4-Me-DTBP (0.112 mmol, 5.0 equiv.), prepared as for compound **49**. *N*-Iodosuccinimide (25 mg, 0.112 mmol, 5.0 equiv.) was added to the reaction and stirred overnight. After 18 h, the reaction was not completed, so another 25 mg (10 equiv. total) of NIS was added and the reaction was stirred an additional 52 h (70 h total) before quenching the reaction by adding 2 mL of 0.5 M sodium thiosulfate. Dichloromethane (10 mL) was then added and the solution was washed with 2 × 10 mL of dH_2O, dried ($MgSO_4$), filtered, and concentrated. Purification using 25% ethyl acetate in hexane yielded the trisaccharide **35** (9 mg, 28%) as a viscous syrup. R_f 0.37 in ethyl acetate – hexane (1:2); ^{1}H NMR (360 MHz, $CDCl_3$) δ: 7.7–7.5 (m, 4H, phthalimido), 6.95, 6.70 (m, 40H, benzyl aromatics), 5.07 (d, $J_{1,2}$ = 8.3 Hz, H-1), 4.96 (d, 1H, $J_{1,2}$ = 1.5 Hz, H-1″), 4.68 (d, 1H, $J_{1,2}$ < 1Hz, H-1′), 4.30 (m, 2H, H-3, H-3′), 4.12 (dd, $J_{1,2}$ = 8.5 Hz, $J_{2,3}$ = 10.5 Hz, H-2), 4.05 (m, 1H, H-2′), 3.70 (m, 1H, H-2″), 3.39 (dd, 1H, $J_{2,3}$ = 3.2 Hz, $J_{3,4}$ = 9.0 Hz, H-3′), 3.36 (m, 1H, OC*H*H′, octyl), 2.48 (d, 1H, $J_{H,OH}$ = 2.5 Hz, OH), 1.4–0.75 (m, 15H, octyl); ^{13}C NMR (125.7 MHz, $CDCl_3$) δ: 100.99 (d, $J_{C\text{-}1,H\text{-}1}$ = 159 Hz, C-1′), 98.44, 98.42 (C-1, C-1″), 81.82, 79.68, 78.69, 78.27, 74.88, 74.85, 74.71, 74.48, 73.54, 72.15, 67.64 (C-3, C-4, C-5, C-2′, C-3′, C-4′, C-5′, C-2″, C-3″, C-4″ and C-5″), 76.19, 75.03, 74.78, 74.73, 73.62, 73.28, 72.46, 71.59, 71.25, 69.69, 69.20, 68.87 (8 × OCH_2Ph, C-6, C-6′, C-6″, and OCH$_2$, octyl), 55.90 (C-2), 31.68, 29.31, 29.16, 29.13, 25.85, 22.62 (6 × CH$_2$, octyl), 14.08 (CH$_3$, octyl).

Octyl 3,6-di-O-benzyl-4-O-[3,4-di-O-benzyl-6-O-(2,3,4,6-tetra-O-benzyl-α-D-mannopyranosyl)-α-D-mannopyranosyl]-2-deoxy-2-phthalimido-β-D-glucopyranoside (36)

The thioglycoside **32** (58 mg, 0.0599 mmol) and the acceptor **12** (54 mg, 0.0898 mmol, 1.5 equiv.) were charged to a round-bottom flask, followed by crushed 4 Å molecular sieves (400 mg) under argon atmosphere. Dry dichloromethane (8 mL) was added and stirred for 30 min, cooling to 0°C. *N*-Iodosuccinimide (15 mg, 0.0659 mmol, 1.1 equiv.) was added to the cooled solution, followed by a catalytic amount of silver triflate (2 mg, 0.1 equiv.). After about 2 min, a deep red colour was observed in the solution and the reaction was complete by t = 4 min. The mixture was filtered and 10 mL of dichloromethane was added. The solution was washed with 10 mL of 0.5 M NaS_2O_3 solution and 10 mL of saturated sodium bicarbonate. The organic layer was dried ($MgSO_4$), filtered, concentrated, and redissolved in 10 mL of dry methanol. Sodium methoxide (3 mg) was added to the solution and stirred overnight. The reaction was neutralized with amberlite IRC-120 (H^+) resin, filtered, concentrated, and purified on Iatrobeads using 8% ethyl acetate in toluene as a solvent system. The desired trisaccharide (61 mg, 69%) was obtained as a colourless syrup. $[\alpha]_D$ + 39.9 (*c* 1.55, CH_2Cl_2); R_f 0.50 in ethyl acetate – hexane (1:2); ^{1}H NMR (500 MHz, $CDCl_3$) δ: 5.26 (d, 1H, $J_{1,2}$ = 1.5 Hz, H-1′), 5.07 (d, 1H, $J_{1,2}$ = 8.7 Hz, H-1), 5.02 (d, 1H, $J_{1,2}$ = 1Hz, H-1″), 4.36 (dd, 1H, $J_{2,3}$ = 10.7 Hz, $J_{3,4}$ = 8.9 Hz, H-3), 4.20 (dd, 1H, $J_{1,2}$ = 8.7 Hz, $J_{2,3}$ = 10.7 Hz, H-2), 3.96 (m, 1H, H-2′), 3.75 (m, 1H, H-2″), 3.34 (dt, 1H, J_{vic} = 7.0 Hz, J_{gem} = 9.8 Hz, OCHH′, octyl), 2.08 (s, 1H, OH), 1.4–0.8 (m, 15H, octyl); ^{13}C NMR (125.7 MHz, $CDCl_3$) δ: 101.08 (d, $J_{C\text{-}1,H\text{-}1}$ = 173 Hz, C-1′), 98.95 (C-1″), 98.07 (C-1), 80.82, 79.89, 79.46, 78.01, 74.86, 74.77, 74.70, 73.66, 72.12, 72.01, 68.81 (C-3, C-4, C-5, C-2′, C-3′, C-4′, C-5′, C-2″, C-3″, C-4″, and C-5″), 74.99, 74.99, 74.62, 73.39, 73.29, 72.35, 72.05, 71.72 (8 × OCH$_2$Ph), 69.55, 69.38, 69.22 (C-6, C-6′, and C-6″), 66.11 (OCH$_2$, octyl), 55.76 (C-2), 31.61, 29.24, 29.08, 25.78, 22.61, 22.55 (6 × CH$_2$, octyl), 14.03 (CH$_3$, octyl).

Octyl 3,4,6-tri-O-acetyl-2-deoxy-2-phthalimido-β-D-glucopyranoside (38)

Under argon atmosphere the anomeric acetate **37** (ref. 23; 5.0 g, 10.5 mmol) was dissolved in 50 mL of dry dichloromethane and cooled to 0°C. 1-Octanol (5.0 mL, 31.5 mmol, 3.0 equiv.) was syringed into the mixture, followed by 2.45 mL of tin tetrachloride (21 mmol, 2.0 equiv.). The mixture was allowed to warm to room temperature and quenched after 5 h by adding 100 mL of dH_2O and 50 mL of CH_2Cl_2. The organic layer was washed by another portion (100 mL) of water, dried ($MgSO_4$), filtered, and concentrated to give a tan-coloured syrup. A portion of this syrup was purified on silica gel (25% ethyl acetate in hexane as eluent) for characterization and the balance was used as crude material. $[\alpha]_D$ + 21.2 (*c 1.85, CH_2Cl_2*); R_f 0.69 in ethyl acetate – hexane (1:1); ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.90–7.70 (m, 4H, aromatic), 5.80 (dd, 1H, $J_{2,3}$ = 10.8 Hz, $J_{3,4}$ = 8.8 Hz, H-3), 5.36 (d, 1H, $J_{1,2}$ = 8.5 Hz, H-1), 5.18 (dd, 1H, $J_{3,4}$ = 8.8 Hz, $J_{4,5}$ = 10.0 Hz, H-4), 4.34 (dd, 1H, $J_{6,6'}$ = 12.2 Hz, $J_{5,6}$ = 4.6 Hz, H-6), 4.31 (dd, 1H, $J_{2,3}$ = 10.8 Hz, $J_{1,2}$ = 8.5 Hz, H-2), 4.17 (dd, 1H, $J_{6,6'}$ = 12.2 Hz, $J_{5,6'}$ = 2.3 Hz, H-6′), 3.85 (m, 2H, H-5, and OC*H*H′, octyl), 3.43 (m, 1H, OCH*H*′, octyl); ^{13}C NMR (75.5 MHz, $CDCl_3$) δ: 170.8, 170.2, 169.5 (3 × *C*OCH$_3$, acetates), 134.3, 131.5, 123.6 (aromatic), 98.3 (C-1), 71.9, 70.9, 69.2 (C-3, C-4, and C-5), 70.3 (C-6), 62.2 (O*C*H$_2$, octyl), 54.8 (C-2), 31.7, 29.3, 29.1, 25.8, 22.6 (6 × *C*H$_2$, octyl), 20.8, 20.7, 20.5 (3 × CH$_3$, acetates), 14.1 (*C*H$_3$, octyl). Anal. calcd. for $C_{38}H_{37}O_{10}N$: C 61.41, H 6.81, N 2.56; found: C 61.51, H 6.69, N 2.58.

Octyl 2-deoxy-2-phthalimido-β-D-glucopyranoside (39)

Crude **38** (10.5 mmol) was de-O-acetylated using the same procedure as in the formation of **19**. The white solid was purified by column chromatography using 7% methanol in dichloromethane as eluent. The product **39** was obtained as a white solid (3.6 g, 81% from **37**) $[\alpha]_D$ – 55.0 (*c* 0.20, CH_3OH); R_f 0.52 in methanol–dichloromethane (1:9); ^{1}H NMR (300 MHz, CD_3OD) δ: 7.92–7.75 (m, 4H, aromatic), 5.14 (d, 1H, $J_{1,2}$ = 8.5 Hz, H-1), 4.25 (dd, 1H, $J_{1,2}$ = 8.5 Hz, $J_{2,3}$ = 10.7 Hz, H-2), 3.96 (dd, 1H, $J_{2,3}$ = 10.7 Hz, $J_{3,4}$ = 8.4 Hz, H-3), 3.95–3.70, 3.60–3.46 (m, 6H, H-4, H-5, H-6, H-6′, OCH$_2$, octyl), 1.42–0.78 (m, 15H, octyl); ^{13}C NMR (75.5 MHz, CD_3OD) δ: 169.7 (CO, phthalimido), 135.5, 133.1, 124.1 (aromatic), 99.7 (C-1), 78.2, 72.6 (C-3, C-4, and C-5), 70.4 (C-6), 62.7 (O*C*H$_2$, octyl), 58.6 (C-2), 32.8, 30.3, 30.3, 30.2, 27.1, 23.6 (6 × *C*H$_2$, octyl), 14.4 (*C*H$_3$, octyl). *Octyl 4,6-di-*O*-benzyl-2-deoxy-2-phthalimido-*β*-*D*-glucopyranoside (**12**)*

In a three-neck, round-bottom flask, the benzylidene acetal **41** (285 mg, 4.75 mmol) was added and dissolved in 75 mL of tetrahydrofuran. Molecular sieves (3 Å), trace methyl orange (2 mg), and sodium cyanoborohydride (2.98 g, 47.5 mmol, 10 equiv.) were added and the mixture was cooled to 0°C. In a separate flask, 15 mL of ethyl ether was saturated with hydrochloric acid by bubbling HCl gas through the ethyl ether at 0°C for 20 min. The HCl–Et_2O solution was then transferred to a dropping funnel and dropwise added to the benzylidene acetal mixture until a strong pink colour persisted. The reaction was complete after 55 min and the mixture was filtered and poured into 250 mL of cold water (5°C). The solution was extracted with 2 × 200 mL of dichloromethane, and the organic layers were combined and washed with 250 mL of saturated sodium bicarbonate solution. The organic layer was then dried ($MgSO_4$), filtered, and concentrated. Purification on silica gel using 22% ethyl acetate in hexane as eluent gave the product **12** (2.37 g, 83%) as a colourless syrup. $[\alpha]_D$ + 14.4 (*c* 0.95, CH_2Cl_2); R_f 0.27 in ethyl acetate – hexane (1:3); ^{1}H NMR (360 MHz, $CDCl_3$) δ: 7.70, 7.35, 7.10, 6.95 (m, 14H, aromatics), 5.13 (d, 1H, $J_{1,2}$ = 8.3 Hz, H-1), 4.75, 4.54 (2 × d, 2H, J_{gem} = 12.1 Hz, OCH_2Ph), 4.66, 4.58 (2 × d, 2H, J_{gem} = 11.9 Hz, OCH_2Ph), 4.23 (dd, 1H, $J_{5,6}$ = 8.0 Hz, $J_{6,6'}$ = 10.5 Hz, H-6), 4.14 (dd, 1H, $J_{5,6'}$ = 8.0 Hz, $J_{6,6'}$ = 10.5 Hz, H-6′), 3.9–3.7 (m, 4H, H-2, H-3, H-4, H-5), 3.65, 3.35 (2 × m, 2H, OCHH′, octyl), 2.93 (d, 1H, $J_{4,OH}$ = 2.3 Hz, OH), 1.4–0.8 (m, 15H, octyl); ^{13}C NMR (75.5 MHz, $CDCl_3$) δ: 138.3, 137.7, 133.8, 131.8, 128.6, 128.2, 127.9, 127.9, 127.4, 123.3 (aromatics), 98.4 (C-1), 78.8, 74.7, 73.5 (C-3, C-4, and C-5), 74.3, 73.9, 71.0, 69.7 (2 × OCH_2Ph, C-6, OCH_2, octyl), 55.5 (C-2), 31.7, 29.3, 29.2, 29.1, 25.6, 22.6 (6 × CH_2, octyl), 14.1 (CH_3, octyl). Anal. calcd. for $C_{36}H_{43}O_7N$: C 71.86, H 7.20, N 2.33; found C 71.78, H 7.12, N 2.38.

*Allyl 4-*O*-acetyl-3,6-di-*O*-benzyl-2-deoxy-2-phthalimido-*β*-*D*-glucopyranoside (**43**)*

The alcohol **42** (ref. 25; 1.65 g, 3.12 mmol) was dissolved in 50 mL of pyridine. Acetic anhydride (10 mL) was added and the reaction was stirred overnight at ambient temperature. Dichloromethane (200 mL) was added, and the organic layer was washed with 2 × 200 mL of saturated sodium bicarbonate solution and 1 × 200 mL saturated sodium chloride solution. The organic layer was then dried ($MgSO_4$) filtered, and concentrated to give 1.61 g (90%) of the product **43** as a white solid after chromatography using 25% ethyl acetate in hexane as eluent $[\alpha]_D$ + 66.3 (*c* 0.80, CH_2Cl_2); R_f 0.46 in ethyl acetate – hexane (1:2); ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.80–7.60 (m, 4H, phthalimido), 7.40–7.25, 7.05–6.85 (m, 10H, benzyl), 5.68 (dddd, 1H, J_{trans} = 17.3 Hz, J_{cis} = 10.6 Hz, J_{vic} = 6.4 Hz, $J_{vic'}$ = 5.2 Hz, OCH$_2$C*H*=CH$_2$), 5.19 (d, 1H, $J_{1,2}$ = 8.5 Hz, H-1), 5.12 (dd, 1H, $J_{3,4}$ = 9.0 Hz, $J_{4,5}$ = 9.2 Hz, H-4), 5.10, 5.01 (2 × dddd, 2H, OCH$_2$CH=C*HH*′), 4.60, 4.32 (2 × d, 2H, J_{gem} = 12.0 Hz, OCH_2Ph), 4.56 (s, 2H, OCH_2Ph), 4.44 (dd, 1H, $J_{2,3}$ = 10.6 Hz, $J_{3,4}$ = 9.0 Hz, H-3), 4.31 (dd, 1H, $J_{2,3}$ = 10.6 Hz, $J_{1,2}$ = 8.5 Hz, H-2), 4.25, 4.01 (dddd, 2H, OCH_2CH=CH$_2$), 3.75 (dt, 1H, $J_{4,5}$ = 9.2 Hz, $J_{5,6}$ = 4.6 Hz, H-5), 3.62 (d, 2H, $J_{5,6}$ = 4.6 Hz, H-6), 1.96 (s, 3H, COCH_3); ^{13}C NMR (75.5 MHz, $CDCl_3$) δ: 169.68 (*C*OCH$_3$), 138.01, 137.76, 128.4–127.5 (benzyl aromatic), 133.7, 131.68, 123.37 (phthalimido), 133.58 (OCH$_2$*C*H=CH$_2$), 117.49 (OCH$_2$CH=*C*H$_2$), 97.32 (C-1), 77.06, 73.56, 72.63 (C-3, C-4, and C-5), 55.50 (C-2), 73.82, 73.67 (2 × OCH_2Ph), 69.84 (C-6, and OCH_2, octyl), 20.93 (COCH_3). Anal. calcd. for $C_{33}H_{33}O_8N$: C 69.34, H 5.82, H 2.45; found: C 68.88, H 5.95, N 2.49.

*4-*O*-Acetyl-3,6-di-*O*-benzyl-2-deoxy-2-phthalimido-α,β-*D*-glucopyranose (**44**)*

The allyl glycoside **43** (1.61 g, 2.82 mmol) was dissolved in 110 mL of a 7:3:1 mixture of ethanol–toluene–water. 1,4-Diazabicyclo[2.2.2]-octane (DABCO) (142 mg, 1.27 mmol, 0.45 equiv.) was added, followed by 391 mg of tris(triphenylphosphine)rhodium(I) chloride (Wilkinson's catalyst; 0.42 mmol, 0.15 equiv.). The mixture was refluxed for 44 h, cooled, and concentrated to a blackish solution, which was then dissolved in 50 mL of acetone. Mercuric oxide (15 mg, 0.005 equiv.) was added, followed by 50 mL of a 9:1 mixture of acetone–water containing 3.8 g (14.1 mmol, 5 equiv.) of dissolved mercuric chloride. The mixture was stirred for 12 h and then 200 mL of dichloromethane was added. The organic layer was washed with 3 × 200 mL of a saturated potassium iodide solution and 2 × 200 mL dH_2O. The organic layer was then dried ($MgSO_4$), filtered, and concentrated. Purification on silica gel using ethyl acetate – hexane (1:2) as eluent yielded 1.12 g (75%) of the product **44** as a 85:15 mixture of β:α-anomers. R_f 0.14 in ethyl acetate – hexane (1:2); ^{1}H NMR, β-anomer only (360 MHz, $CDCl_3$) δ: 7.80 – 7.60 (m, 4H, phthalimido), 7.40–7.25, 7.05–6.90 (m, 10H, benzyl aromatic), 5.38 (dd, 1H, $J_{1,2}$ = 8.2 Hz, $J_{1,OH}$ = 6 Hz, H-1β), 5.17 (dd, 1H, $J_{3,4}$ = 9.0 Hz, $J_{4,5}$ = 9.8 Hz, H-4), 4.63, 4.36 (2 × d, 2H, J_{gem} = 12.3 Hz, OCH_2Ph), 4.58 (s, 2H, OCH_2Ph), 4.52 (dd, 1H, $J_{1,2}$ = 8.2 Hz, $J_{2,3}$ = 10.6 Hz, H-2), 4.20 (dd, 1H, $J_{2,3}$ = 10.6 Hz, $J_{3,4}$ = 9.0 Hz, H-3), 3.82 (m, 1H, H-5), 3.60 (m, 2H, H-6), 2.92 (d, 1H, $J_{H,OH}$ = 6 Hz, OH), 1.93 (s, 3H, CH_3, acetate); ^{13}C NMR, β anomer only (75.5 MHz, $CDCl_3$) δ: 169.65 (CO, acetate), 133.95, 131.62, 123.42 (phthalimido), 137.72, 128.4–127.3 (benzyl aromatics), 92.94 (C-1), 76.78, 73.57, 72.28 (C-3, C-4, and C-5), 57.18 (C-2), 73.90, 73.69 (2 × OCH_2Ph), 69.38 (C-6). Anal. calcd. for $C_{30}H_{29}O_8N$: C 67.79, H 5.50, N 2.64; found: C 67.54, H 5.64, N 2.51.

4-O-Acetyl-3,6-di-O-benzyl-2-deoxy-2-phthalimido-α,β-D-gluco-pyranosyl chloride (45)

The reducing sugar **44** (600 mg, 1.13 mmol) was dissolved in dry dichloromethane (10 mL) under argon atmosphere. In a separate flask, Vilsmeier reagent was prepared by adding 0.84 mL (10.8 mmol) of dimethyl formamide (DMF) to 8.2 mL of chloroform. Oxalyl chloride (0.94 mL, 10.8 mmol) was syringed into the DMF–chloroform solution forming a deep yellow colour. The Vilsmeier reagent concentration was 1.08 mmol/mL. After stirring for 15 min, 5.2 mL (5.6 mmol, 5 equiv.) of the Vilsmeier solution was added to the reducing sugar and stirred for 20 min. The reaction was quenched by pouring the reaction mixture into 100 mL of cold water (5°C). Another 100 mL of dichloromethane was added and the organic layer was washed with 2 × 100 mL of dH_2O. The organic layer was dried ($MgSO_4$), filtered, and concentrated to give 620 mg of a bright yellow solid **45**. R_{fs} 0.55 (α) and 0.45 (β) in ethyl acetate – hexane (1:2); ^{1}H NMR (360 MHz, $CDCl_3$) δ: 6.22 (d, 0.45H, $J_{1,2}$ = 3.8 Hz, H-1α), 5.99 (m, 0.55H, $J_{1,2}$ = 9.2 Hz, H-1β), 5.43 (dd, 0.45H, $J_{2,3}$ = 11.0 Hz, $J_{3,4}$ = 9.0 Hz, H-3α), 5.31 (dd, 0.45H, $J_{3,4}$ = 9.0 Hz, $J_{4,5}$ = 9.0 Hz, H-4α), 5.21 (m, 0.55H, H4β), 4.64 (dd, 0.45H, $J_{1,2}$ = 3.8 Hz, $J_{2,3}$ = 11.0 Hz, H-2α), 4.43 (m, 1.1H, H-3β), 4.33 (m, 0.45H, H-5α), 3.85 (m, 0.55H, H-5β), 3.62 (m, 2H, H-6α, H-6β, H-6′α, and H-6′β), 1.94 (s, 1.65H, $COCH_3$, β), 1.90 (s, 1.35H, $COCH_3$, α); ^{13}C NMR, α only (75.5 MHz, $CDCl_3$) δ: 169.74 ($COCH_3$), 92.76 (C-1), 74.20, 73.90 (2 × OCH_2Ph), 73.86, 72.67, 72.16 (C-3, C-4, and C-5), 57.54 (C-2), 68.49 (C-6), 21.06 ($COCH_3$).

Octyl 4-O-(4-O-acetyl-3,6-di-O-benzyl-2-deoxy-2-phthalimido-β-D-glucopyranosyl)-3,6-di-O-benzyl-2-deoxy-2-phthalimido-β-D-glucopyranoside (46)

The octyl glucoside acceptor **12** (340 mg, 0.565 mmol), 4 Å molecular sieves, and 363 mg of silver triflate (1.41 mmol, 2.5 equiv.) were charged to a round-bottom flask and argon purged. Dry dichloromethane (6 mL) and *sym*-collidine (0.1 mL, 0.85 mmol, 1.5 equiv.) were added and the reaction was stirred for 30 min, cooling to –15°C. The chloride **45** (620 mg, 1.13 mmol, 2 equiv.) was dissolved in 2 × 2 mL of dichloromethane and dropwise added to the acceptor. A white colour was observed during the chloride addition (AgCl). The reaction was stirred at room temperature for 60 h and then diluted with 75 mL of dichloromethane. The organic layer was filtered and washed with 75 mL of dH_2O, 75 mL of 1 *N* HCl, 75 mL of saturated sodium bicarbonate, and then 75 mL of brine. The organic layer was then dried ($MgSO_4$), filtered, and concentrated. Purification using 17% ethyl acetate in toluene as eluent gave 423 mg (67%) of the disaccharide **46** and 70 mg (21%) of recovered acceptor **12**. R_f 0.63 in ethyl acetate – toluene (1:3); ^{1}H NMR (500 MHz, $CDCl_3$) δ: 5.33 (d, 1H, $J_{1,2}$ = 8.4 Hz, H-1′), 5.15 (dd, 1H, $J_{3,4}$ = 9.0 Hz, $J_{4,5}$ = 9.0 Hz, H-4′), 4.93 (d, 1H, $J_{1,2}$ = 8.1 Hz, H-1), 1.91 (s, 3H, $COCH_3$); ^{13}C NMR (75.5 MHz, $CDCl_3$) δ: 169.67 ($COCH_3$,), 98.18, 97.21 (C-1, and C-1′), 76.93, 76.93, 76.40, 74.61, 73.45, 72.74 (C-3, C-4, C-5, C-3′, C-4′, and C-5′), 74.43, 73.92, 73.60, 72.74 (4 × OCH_2Ph), 69.49, 69.40 (C-6 and C-6′), 68.23 (OCH_2, octyl), 56.32, 55.79 (C-2 and C-2′), 31.64, 29.24, 29.12, 25.80, 22.58 (6 × CH_2, octyl), 20.93 ($COCH_3$), 14.04 (CH_3, octyl).

Octyl 3,6-di-O-benzyl-4-O-(3,6-di-O-benzyl-2-deoxy-2-phthalimido-β-D-glucopyranosyl)-2-deoxy-2-phthalimido-β-D-glucopyranoside (47)

The disaccharide **46** (423 mg, 0.38 mmol) was dissolved in 10 mL of dry methanol and 5 mg of sodium methoxide was added. The reaction was stirred overnight, quenched by neutralizing with amberlite IRC-120 (H^+) resin, filtered, concentrated, and chromatographed using 15% ethyl acetate in toluene as eluent. The desired product **47** (282 mg) was obtained as a colourless syrup (69%). $[\alpha]_D$ –12.6 (*c* 0.70, CH_2Cl_2); R_f 0.50 in ethyl acetate – toluene (1:3); ^{1}H NMR (360 MHz, $CDCl_3$) δ: 7.9–7.5 (m, 8H, 2 × phthalimido), 7.4–6.8 (m, 20H, benzyl aromatics), 5.30 (d, 1H, $J_{1,2}$ = 8.1 Hz, H-1′), 4.92 (d, 1H, $J_{1,2}$ = 7.8 Hz, H-1), 4.25 (dd, 1H, $J_{2,3}$ = 10.5 Hz, $J_{3,4}$ = 8.5 Hz, H-3′), 4.2 (m, 4H, H-2, H-3, H-4, and H-2′), 3.82 (ddd, IH, $J_{3,4}$ = 8.5 Hz, $J_{4,5}$ = 8.5 Hz, $J_{H,OH}$ = 1.9 Hz, H-4′), 3.65, 3.23 (2 × m, 2H, OCHH′, octyl), 3.09 (d, 1H, $J_{H,OH}$ = 1.9 Hz, OH), 2.3–0.7 (m, 15H, octyl); ^{13}C NMR (75.5 MHz, $CDCl_3$) δ: 167.72 (C=O, phthalimido), 98.18, 97.08 (C-1 and C-1′), 78.41, 76.88, 75.94, 75.52, 74.65, 72.85 (C-3, C-4, C-5, C-3′, C-4′, and C-5′), 74.37, 74.22, 73.76, 72.73 (4 × OCH_2Ph), 71.06, 69.42 (C-6 and C-6′), 68.31 (OCH_2, octyl), 56.18, 55.78 (C-2 and C-2′), 31.65, 29.24, 29.11, 25.81, 22.59 (6 × CH_2, octyl), 14.05 (CH_3, octyl). Anal. calcd. for $C_{64}H_{68}O_{13}N_2$: C 71.61, H 6.39, N 2.62; found: C 71.68, H 6.32, N 2.56.

Octyl 3,6-di-O-benzyl-4-O-(3′,6′-di-O-benzyl-2′-deoxy-2′-phthalimido-β-D-glucopyranosyl)-2-deoxy-2-phthalimido-β-D-glucopyranoside-ethyl 3″,4″-di-O-benzyl-6″-O-(2‴,3‴,4‴6‴-tetra-O-benzyl-α-D-mannopyranosyl)-α-D-mannopyranoside-2″,4′-isopropylidene acetal (48)

The vinyl ether **33** (100 mg, 0.103 mmol, 1.2 equiv.), the alcohol **47** (90 mg, 0.0842 mmol, 1.0 equiv.), and 500 mg of crushed $CaSO_4$ were added to a round-bottom flask and argon purged. Dry dichloromethane (7 mL) was added and the mixture was stirred for 30 min before cooling to –40°C. A 0.05 mM solution of camphorsulfonic acid was prepared by adding 2 mL of dry dichloromethane to 23.3 mg of acid under argon. A 0.2-mL aliquot of this acidic solution (0.01 mmol, 0.11 equiv.) was syringed into the cooled solution containing vinyl ether and alcohol. A further 2 × 0.2 mL (total equiv. of acid added = 0.33) of acid was added to the reaction mixture to maximize the amount of mixed acetal as observed by TLC. The reaction was quenched after 2 h by adding 0.1 mL of triethylamine, warmed to room temperature, and filtered. The solution was then concentrated and chromatographed using 17% ethyl acetate in hexane with 0.1% added triethylamine as eluent. The mixed acetal product **48** (18 mg, 8%) was obtained, as well as 32 mg of recovered vinyl ether **13** and 53 mg of recovered alcohol **47**. The product **48** was unstable stored in a solution with 0.5% added triethylamine. R_f 0.50 in ethyl acetate – hexane (1:2); ^{1}H NMR (360 MHz, $CDCl_3$ + 2% D-5 pyridine) δ: 5.40 (d, 1H, $J_{1,2}$ = 1 Hz, H-1_M), 5.32 (d, 1H, $J_{1,2}$ = 7.5 Hz, H-1_{Gn}), 5.08 (d, 1H, $J_{1,2}$ = 1 Hz, H-$1_{M'}$, 4.92 (d, 1H, $J_{1,2}$ = 7.8 Hz, H-$1_{Gn'}$), 2.58 (m, 2H, SCH_2CH3), 1.43 (s, 3H, $CH_3CCH_{3'}$, acetal), 1.40 (s, 3H, $CH_3CCH_{3'}$, acetal), 1.26 (t, 3H, SCH_3CH_3), 1.1–0.7 (m, 15H, octyl); ^{13}C NMR (125.7 MHz, $CDCl_3$ + 2% D-5 pyridine) δ: 105.16 (OCO, acetal), 98.11, 97.72, 96.94 (C-$1'_M$, C-1_{Gn},), 84.85 (C-1_M), 80.55, 79.94, 79.87, 76.98, 76.29, 76.25, 75.15, 75.06, 74.78, 74.67, 73.03, 71.99, 71.58, 71.45 (C-2_M, C-3_M, C-4_M, C-5_M, C-$2'_M$, C-$3'_n$, C-$4'_M$, C-$5'_M$, C-3_{Gn}, C-4_{Gn}, C-5_{Gn}, C-$3'_{Gn}$, C-$4'_{Gn}$, and C-$5'_{Gn}$), 75.21, 75.00, 74.82, 74.45, 73.32, 73.30, 73.07, 72.71, 72.56, 71.76 (10 × OCH_2Ph), 69.37, 69.13, 68.51, 68.32 (C-6_{Gn}, C-$6'_{Gn}$, C-6_M, and C-$6'_M$), 66.41, (OCH_2, octyl), 57.27, 55.78 (C-2_{Gn} and C-$2'_{Gn}$), 31.66, 29.25, 29.10, 25.81, 22.60 (6 × CH_2, octyl), 25.33 (SCH_2CH_3), 26.44, 25.9 (2 × CH_3, acetal), 15.38 (SCH_2CH_3), 14.06 (CH_3 octyl).

Octyl 3,6-di-O-benzyl-4-(3′,6′-di-O-benzyl-2′-deoxy-2′-phthalimido-β-D-glucopyranosyl)-2-deoxy-2-phthalimido-β-D-glucopyranoside-ethyl 3″,4″,6″-tri-O-benzyl-1″-thio-α-D-mannopyranoside-2″,4′-isopropylidene acetal (49)

The vinyl ether **4** (137 mg, 0.256 mmol, 2.0 equiv.) and the alcohol **47** (138 mg, 0.129 mmol, 1.0 equiv.) were charged to a round-bottom flask and argon purged. Dry dichloromethane (8 mL) was syringed into the mixture and cooled to –40°C. A 0.05 mmol solution of camphorsulfonic acid in dichloromethane was prepared and 0.25 mL of this solution (0.1 equiv.) was syringed into the cooled mixture containing the vinyl ether and the alcohol. The reaction was carefully monitored by TLC for product formation and quenched after 60 min by adding several drops of triethylamine. Prolonged reaction times caused a reduction in product yield. The mixture was concentrated, and purified on silica gel using 17% ethyl acetate in hexane as eluent with 0.1% added triethylamine. The desired product **49** (78 mg, 38% was obtained, as well as 93 mg of recovered vinyl ether **4** and 82 mg of recovered alcohol **47**. The mixed acetal was unstable unless stored under basic conditions such as in a dichloromethane solution with 0.5% added triethylamine. R_f 0.53 in ethyl acetate–hexane (1:2); ^{1}H NMR (500 MHz, $CDCl_3$ + 2% D-5 pyridine) δ: 5.43 (s, 1H, $J_{1,2}$ = 1.0 Hz, H-1M), 5.32 (d, 1H, $J_{1,2}$ = 7.8 Hz, H-$1_{Gn'}$), 4.90 (d, 1H, $J_{1,2}$ = 7.8 Hz, H-1_{Gn}), 3.63, 3.21 (2 × dt, 2H, J_{vic} = 9.8 Hz, J_{gem} = 6.8 Hz, OCHH′,

octyl), 2.66 (m, 2H, SCH_2CH_3), 1.46 (s, 3H, $CH_3CCH_{3'}$), 1.42 (s, 3H, $CH_3CCH_{3'}$), 1.29 (t, 3H, SCH_2CH_3), 1.15–0.84 (m, 15H, octyl); ^{13}C NMR (125.7 MHz, $CDCl_3$ + 2% D-5 pyridine) δ: 104.76 (OCO, acetal), 98.05, 96.94 (C-1_{Gn}, and C-$1'_{Gn}$), 84.54 (C-1_M), 80.34, 79.73, 76.34, 76.31, 75.28, 74.65, 73.30, 72.12, 71.72 (C-3_{Gn}, C-4_{Gn}, C-5_{Gn}, C-$3'_{Gn}$, C-$4'_{Gn}$, C-$5'_{Gn}$, C-2_M, C-3_M, C-4_M, and C-5_M), 75.31, 74.89, 74.39, 73.20, 73.01, 72.66, 72.43 (7 × OCH_2Ph), 69.50, 69.26, 68.82, 68.29 (C-6_{Gn}, C-$6'_{Gn}$, C-6_M, and OCH_2, octyl), 57.15, 55.73 (C-2_{Gn}, C-$2'_{Gn}$).

*Octyl 3,6-di-*O*-benzyl-4-*O*-[3,6-di-O-benzyl-4-*O*-(3,4,6-tri-*O*-benzyl-β-D-mannopyranosyl)-2-deoxy-2-phthalimido-β-D-glucopyranosyl]-2-deoxy-2-phthalimido-β-D-glucopyranoside (50)*

The mixed acetal **49** (24 mg, 0.015 mmol) was charged to a flask and argon purged. Dry dichloromethane (3 mL) was syringed into the flask, followed by 1.5 mL of a 0.05 mM solution of 2,6-di-*tert*-butyl-4-methyl-pyridine (4-Me-DTBP, 0.075 mmol, 5 equiv.) prepared by dissolving 51 mg of 4-MeDTBP in 5 mL of dry dichloromethane under argon atmosphere over 4 Å molecular sieves). *N*- Iodosuccinimide (17 mg, 0.075 mmol, 5 equiv.) was added to the reaction and stirred overnight (42 h). The reaction was quenched by adding 2 mL of 0.5 M sodium thiosulfate solution, which caused the deep red reaction colour to become colourless. Dichloromethane, (10 mL) was added and the organic layer was washed with 2 × 10 mL of dH_2O, dried ($MgSO_4$), filtered, and concentrated. Purification using silica gel with 25% ethyl acetate in hexane as eluent gave the trisaccharide **50** (6 mg) as a viscous syrup. R_f 0.27 in ethyl acetate – hexane (1:2); ^1H NMR (500 MHz, $CDCl_3$) δ: 7.9–7.5 (m, 8H, phthalimido), 7.35–7.1, 7.0–6.9, 6.85–6.70 (m, 35H, benzyl aromatics), 5.27 (d, 1H, $J_{1,2}$ = 8.4 Hz, H-1′), 4.92 (d, 1H, $J_{1,2}$ = 8.6 Hz, H-1), 4.65 (d, 1H, $J_{1,2}$ < 0.5 Hz, H-1′), 4.40 (dd, 1H, $J_{2,3}$ = 10.8 Hz, $J_{3,4}$ = 8.6 Hz, H-3′), 4.22 (dd, 1H, $J_{1,2}$ = 8.4 Hz, $J_{2,3}$ = 10.8 Hz, H-2′), 4.10 (m, 2H, H-2, and H-4′), 4.00 (dd, 1H, $J_{1,2}$ < 0.5 Hz, $J_{2,3}$ = 3.0 Hz, H-2″), 3.84 (dd, 1H, $J_{3,4}$ = 9.4 Hz, $J_{4,5}$ = 9.4 Hz, H-4), 3.60 (dd, 1H, $J_{3,4}$ = 9.0 Hz, $J_{4,5}$ = 9.0 Hz, H-4″), 3.39 (dd, 1H, $J_{2,3}$ = 3.0 Hz, $J_{3,4}$ = 9.0 Hz, H-3″), 3.36 (dt, 1H, J_{gem} = 9.9 Hz, J_{vic} = 6.3 Hz, OC*H*H′, octyl), 3.22 (dt, 1H, J_{gem} = 9.9 Hz, J_{vic} = 6.3 Hz, OCH*H*′, octyl), 2.43 (br s, 1H, OH), 1.35–0.75 (m, 15H, octyl); ^{13}C NMR (125.7 MHz, $CDCl_3$) δ: 100.35 (d, $J_{C-1,H-1}$ = 157 Hz, C-1″), 98.12, 97.00 (C-1 and C-1′), 81.75, 78.51, 77.91, 75.72, 75.41, 74.52, 74.48, 74.01, 68.10 (C-3, C-4, C-5, C-3′, C-4′, C-5′, C-2″, C-3″, C-4″, and C-5″), 75.06, 74.83, 74.29, 73.33, 73.24, 72.59, 71.35 (7 × OCH_2Ph), 69.34, 68.90, 68.10, 68.01 (C-6, C-6′, C-6″, and OCH_2, octyl), 56.47, 55.75 (C-2 and C-2′), 31.59, 29.15, 29.12, 29.06, 25.74, 22.53 (6 × CH_2, octyl), 14.05 (CH_3, octyl).

Octyl 3,6-di-O-benzyl-4-O-[3,6-di-O-benzyl-4-O-(3,4,6-tri-O-benzyl-α-D-mannopyranosyl)-2-deoxy-2-phthalimido-β-D-glucopyranosyl]-2-deoxy-2-phthalimido-β-D-glucopyranoside (51)

The thioglycoside **2** (58 mg, 0.108 mmol, 2.0 equiv.) acceptor **47** (58 mg, 0.054 mmol), and crushed 4 Å molecular sieves were charged to a round-bottom flask and argon purged. Dry dichloromethane (7 mL) was added and stirred for 30 min, cooling the mixture to 0°C. *N*-Iodosuccinimide (24 mg, 0.108 mmol, 2.0 equiv.) and then catalytic silver triflate (0.011 mmol, 02. equiv.) were added and a characteristic burst of red colour was observed within 2 min of the addition of the silver triflate. The reaction was then worked up and de-*O*-acetylated according to the protocol for the preparation of **36**. Purification with Iatrobeads using 20% ethyl acetate in hexane as eluent gave the product **51** (40 mg, 49%), as well as some unreacted acetylated compound (13 mg, 16%). $[\alpha]_D$ + 24.8 (*c* 1.20, CH_2Cl_2); R_f 0.49 in ethyl acetate – toluene (1:3); ^1H NMR (500 MHz, $CDCl_3$) δ: 7.8–7.5 (m, 8H, phthalimido), 7.35–7.05, 7.0–6.7 (m, 35H, benzyl aromatics), 5.35 (d, 1H, $J_{1,2}$ = 1.3 Hz, H-1″), 5.26 (d, 1H, $J_{1,2}$ = 8.4 Hz, H-1′), 4.91 (d, 1H, $J_{1,2}$ = 8.2 Hz, H-1), 4.38 (dd, 1H, $J_{2,3}$ = 10.6 Hz, $J_{3,4}$ = 8.5 Hz, H-3′), 4.23 (dd, 1H, $J_{2,3}$ = 10.6 Hz, $J_{1,2}$ = 8.4 Hz, H-2′), 4.20–4.08 (m, 3H, H-2, H-3, H-4), 3.98 (dd, 1H, $J_{1,2}$ = 1.3 Hz, $J_{2,3}$ = 3.0 Hz, H-2″), 3.96 (dd, $J_{3,4}$ = 8.5 Hz, $J_{4,5}$ = 9 Hz, H-4′), 3.90 (d, 1H, $J_{3,4}$ = 9.0 Hz, $J_{4,5}$ = 9.0 Hz, H-4″), 3.81 (dd, $J_{3,4}$ = 9.0 Hz, $J_{2,3}$ = 3.0 Hz, H-3″), 3.81 (m, 1H, H-5″), 3.74 (dd, 1H, $J_{5,6}$ = 1.5 Hz, $J_{6,6'}$ = 11.0 Hz, H-6′a), 3.69 (dd, 1H, $J_{5,6}$ = 3.6 Hz, $J_{6,6'}$ = 10.8 Hz, H-6″a), 3.64 (dd, 1H, $J_{5,6'}$ = 3.5 Hz, $J_{6,6'}$ = 11.0 Hz, H-6′b), 3.64 (dt, 1H, J_{vic} = 6.6 Hz, J_{gem} = 9.8 Hz, OC*H*H′, octyl), 3.56 (dd, 1H, $J_{5,6}$ = 1.2 Hz, $J_{6,6'}$ = 10.8 Hz, H-6″b), 3.52 (dd, $J_{5,6}$ = 1.0 Hz, $J_{6,6'}$ = 11.0 Hz, H-6a), 3.41 (dd, 1H, $J_{5,6'}$ = 3.8 Hz, $J_{6,6'}$ = 11.0 Hz, H-6b), 3.32 (m, 1H, H-5′), 3.28 (m, 1H, H-5), 3.22 (dt, 1H, J_{vic} = 9.8 Hz, J_{gem} = 6.6 Hz, OCH*H*′, octyl), 2.21 (br s, 1H, OH), 1.4–0.7 (m, 15H, octyl); ^{13}C NMR (125.7 MHz, $CDCl_3$) δ: 100.01 (d, $J_{C-1,H-1}$ = 170 Hz, C-1″), 98.16, 96.81 (C-1, C-1′), 80.76, 79.91, 77.36, 75.92, 74.94, 74.60, 74.19, 72.20, 69.03 (C-3, C-4, C-5, C-3′, C-4′, C-5′, C-2″, C-3″, C-4″, and C-5″), 56.50, 55.76 (C-2 and C-2′), 75.10, 74.65, 74.35, 73.51, 73.17, 72.72, 72.07 (7 × OCH_2Ph), 69.36, 68.80, 68.29 (C-6, C-6′, and C-6″), 68.54 (OCH_2, octyl), 31.63, 29.21, 29.11, 29.08, 25.78, 22.57 (6 × CH_2, octyl), 14.04 (CH_3, octyl). Anal. calcd. for $C_{91}H_{96}O_{18}N_2$: C 72.58, H 6.43, N 1.87; found: C 72.28, H 6.45, N 1.84.

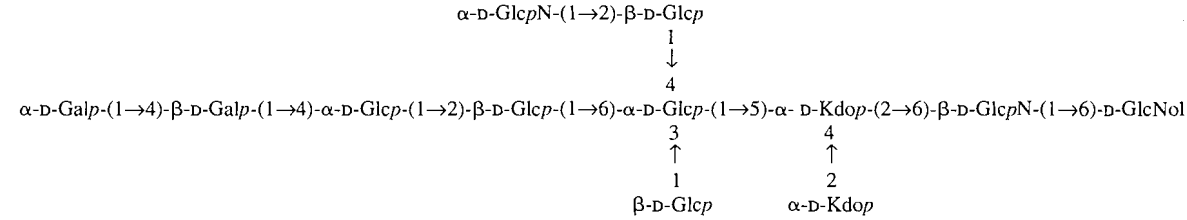
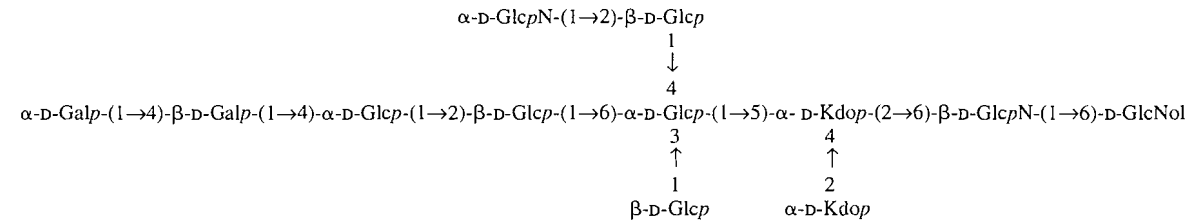
The cell-surface lipopolysaccharide produced by *Moraxella catarrhalis* serotype A is composed of a hydrophobic lipid A moiety and an oligosaccharide, but lacks high-molecular-weight O-polysaccharide chains. The oligosaccharide component is composed of D-glucose, D-galactose, D-glucosamine, and 3-deoxy-D-*manno*-octulosonic acid. The carbohydrate backbone was obtained from the lipopolysaccharide by employing a reaction sequence involving deacylation, dephosphorylation, and reduction of the reducing D-glucosamine terminus of the lipid A moiety. Structural analysis of the backbone oligosaccharide employed a combination of microanalytical methods and nuclear magnetic resonance spectroscopy. Homo- and hetero-nuclear chemical shift correlation techniques and nuclear Overhauser enhancement (NOE) experiments led to the unambiguous assignment of the ^{1}H and ^{13}C resonances associated with each of the component glycosyl residues and established their sequence within the backbone oligosaccharide as shown,



This lipopolysaccharide was found to consist of a highly branched, D-glucose-containing inner-core region which possesses a unique and unusual solution conformation. This was established by measurement of transglycosidic NOEs and three-bond ^{1}H–^{13}C coupling constants, in conjunction with molecular modeling. A D-galactose-containing disaccharide identified as a terminal group of the lipopolysaccharide was structurally identical to antigenic epitopes expressed by certain mammalian epithelial cells and may be related to the virulence potential of this human pathogen.

HUSSEIN MASOUD, MALCOLM B. PERRY, JEAN-ROBERT BRISSON, DUŠAN UHRÍN et JAMES C. RICHARDS. Can. J. Chem. **72**, 1466 (1994).

Le lipopolysaccharide de le surface cellulaire produit par le sérotype A du *Moraxella catarrhalis* est formé d'un lipide hydrophobe A et d'un oligosaccharide, mais il ne comporte pas de chaînes O-polysaccharides de poids moléculaire élevé. L'oligosaccharide comprend du D-glucose, du D-galactose, de la D-glucosamine et de l'acide 3-désoxy-D-*manno*-octulosonique. On a obtenu le squelette de l'hydrate de carbone à partir du lipopolysaccharide en faisant appel à une série de réactions impliquant une désacylation, une déphosphorylation et la réduction de la D-glucosamine réductrice terminale de la portion du lipide A. Une analyse structurale du squelette du oligosaccharide a fait appel à une combinaison de méthodes microanalytiques et de résonance magnétique nucléaire. Les techniques de corrélation des déplacements chimiques homo- et hétéronucléaires et se expériences d'effet Overhauser nucléaire ont conduit à une attribution non ambiguë des résonances du ^{1}H et ^{13}C associées à chacun des résidus glycosyles et ont permis d'établir que leur séquence dans le squelette de l'oligosaccharides est la suivante;



On a trouvé que ce lipopolysaccharide est formé d'une région intérieure fortement ramifiéé contenant un D-glucose, laquelle posséde une conformation unique et inhabituelle en solution. On a déterminé cette propriété par des mesures d'eOn transglycosidiques et de constantes de couplages ^{1}H–^{13}C à travers trois liaisons faites de concert avec un modelage moléculaire. Un un disaccharide contenant D-galactose identifié comme un groupe terminal du lipopolysaccharide est identique d'un point de vue structrual avec les épitipoes antigéniques fournis par des cellules épithéliales de mammaires et on peut le relier au potentiel de virulence de ce pathogène humain.

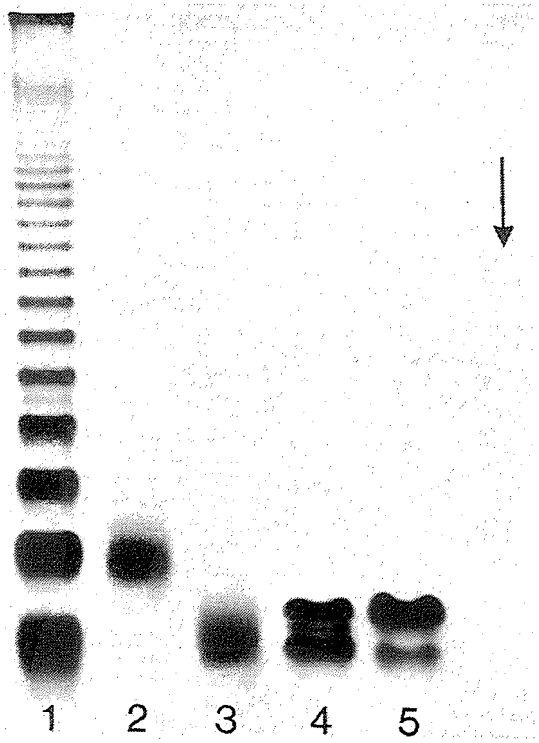

FIG. 1. DOC–PAGE patterns of LPS from *Salmonella* strains and *Moraxella catarrhalis*. Lane 1, *S. milwaukee* (S-type LPS, 10 μg); lane 2, *S. typhimurium* (SR-mutant, 5 μg); lane 3, *S. minnesota* R 60 (Ra-mutant, 2 μg); lane 4, *M. catarrhalis* serotype A (clinical isolate 0798, 3 μg); lane 5, *M. catarrhalis* serotype A (ATCC 25238, 3 μg). The vertical arrow indicates the direction of migration.

Introduction

Moraxella catarrhalis is a gram-negative diplococcus which has been reported with increasing frequency to be a significant human pathogen (1). It is currently the third most common cause of acute and chronic otitis media and it has been implicated in upper and lower respiratory tract infections, and in sporadic cases of meningitis and septicemia.

Lipopolysaccharides (LPSs, endotoxins) are biologically active components of gram-negative bacteria; they are virulence factors involved in pathogenesis of bacterial infections (2). The O-polysaccharide and core oligosaccharide moieties of LPS are immunogenic, giving rise to antibodies having specific serological properties that are involved in protective mechanisms and that also can be of diagnostic importance. The analysis of the LPS produced by strains of *M. catarrhalis* was undertaken to provide a molecular level understanding of its structural relationship with biological properties.

Very little structural information exists on the LPS of *M. catarrhalis*. Serological typing (3) and comparative immunochemical studies (4, 5) suggest that the LPS components are of the rough type (R-type) being composed of a core oligosaccharide glycosidically linked to lipid A and they lack an O-polysaccharide characteristic of smooth (S-type) LPS. A previous study of cellular and free LPS of *M. catarrhalis* ATCC 8176 and 25238 strains showed that they were identical and of the R-type in which the core oligosaccharide moieties were composed of D-glucose, D-galactose, 2-acetamido-2-deoxy-D-glucose, and 3-deoxy-D-*manno*-octulosonic acid. L-glycero-D-*manno*-Heptose and phosphate, common LPS core constituents, were noticeably absent. Our laboratory has recently reported the structure of the lipid A region of *M. catarrhalis* LPS by employing a combination of NMR- and MS-based techniques (6). In the present investigation, we describe the application of NMR techniques for the structural elucidation of the LPS core oligosaccharide of the *M. catarrhalis* serotype A reference strain (ATCC 25238) and relate the structure of the LPS to other clinical strains, suggesting the possible basis for the development of a common vaccine and a specific diagnostic antibody reagent.

Results and discussion

Extraction of fermentor-grown cells of *M. catarrhalis* serotype A by using the hot phenol – water extraction method (7), followed by ultracentrifugation of the dialyzed and concentrated separated aqueous phase, afforded a precipitated LPS gel in 2% yield based on dry cell weight. Deoxycholate–PAGE analysis of the LPS revealed two distinct bands that exhibited electrophoretic mobilities similar to that of reference Ra-type *Salmonella* LPS (Fig. 1, lanes 3–5) and showed that the preparations did not contain S-type LPS in which O-polysaccharide components would have been present. The R-type nature of the LPS is consistent with results of earlier investigations (4, 5).

Partial hydrolysis of the LPS with hot 1% (v/v) acetic acid (100°C, 2.5 h) afforded an insoluble lipid A (26%) and Bio-Gel P-2 gel filtration chromatography of the concentrated water-soluble products gave core oligosaccharide (OS) (K_{av} 0.2–0.3, 36%), and a fraction containing 3-deoxy-D-*manno*-octulosonic acid (Kdo) (K_{av} 0.98). The OS had $[\alpha]_D$ +85° (*c* 0.80, H_2O) and, on total acid hydrolysis followed by GLC–MS analyses, was found to be composed of D-glucose (D-Glc), D-galactose (D-Gal), and 2-amino-2-deoxy-D-glucose (D-GlcN) in the approximate molar ratios 5:2:1, in agreement with previous studies (4). The presence of Kdo in the core OS was confirmed by colorimetric assay (8).

Structural studies were made on *N*- and *O*-deacylated, dephosphorylated and terminal reduced LPS (Scheme 1, backbone OS). Methylation analysis of the backbone OS by the GLC–MS alditol acetate method (9) led to the identification of the *O*-acetyl derivatives from 2,3,4,6-tetra-*O*-methyl-D-glucitol-1-*d* (T_{GM} 1.0), 2,3,4,6-tetra-*O*-methyl-D-galactitol-1-*d* (T_{GM} 1.07), 3,4,6-tri-*O*-methyl-D-glucitol-1-*d* (T_{GM} 1.26), 2,3,6-tri-*O*-methyl-D-galactitol-1-*d* (T_{GM} 1.31), 2,3,6-tri-*O*-methyl-D-glucitol-1-*d* (T_{GM} 1.33), 2-*O*-methyl-D-glucitol-1-*d* (T_{GM} 1.88), 2-deoxy-3,4,6-tri-*O*-methyl-2-(*N*-methylacetamido)-D-glucitol-1-*d* (T_{GM} 2.00), 2-deoxy-1,3,4,5-tetra-*O*-methyl-2-(*N*-methylacetamido)-D-glucitol (T_{GM} 2.01), and 2-deoxy-3,4-di-*O*-methyl-2-(*N*-methylacetamido)-D-glucitol-1-*d* (T_{GM} 2.37), the latter two aminodeoxyglycitol derivatives arising from the disaccharide residue of the lipid A component. The methylation results indicated that the OS has a highly branched structure containing a D-Glc*p* residue glycosidically substituted at *O*-3, *O*-4, and *O*-6; D-Glc*p* residues monosubstituted at *O*-2 and *O*-4; a D-Gal*p* residue substituted at *O*-4; and nonreducing D-Glc*p*, D-Gal*p*, and D-Glc*p*N endgroups.

The linkages of the Kdo residues were determined from analysis of the hydrolysis products of the carboxyl-reduced methyl ester (superdeuteride) of a methylated sample of *O*-deacylated LPS (Scheme 1, LPS-OH). The *O*-methyl-reduced Kdo derivatives and accompanying *O*-methyl aldoses were sequentially hydrolyzed, reduced ($NaBD_4$), acetylated, and subjected to GLC–MS analysis. In addition to the abovementioned *O*-methyl aldose derivatives, the *O*-acetyl derivatives of 1,1,2-d_3-substituted 3-deoxy-1,4,5,7,8-penta-*O*-methyl- (T_{GM} 1.66 and 1.69) and 3-deoxy-1,7,8-tri-*O*-methyl-octitols (T_{GM}

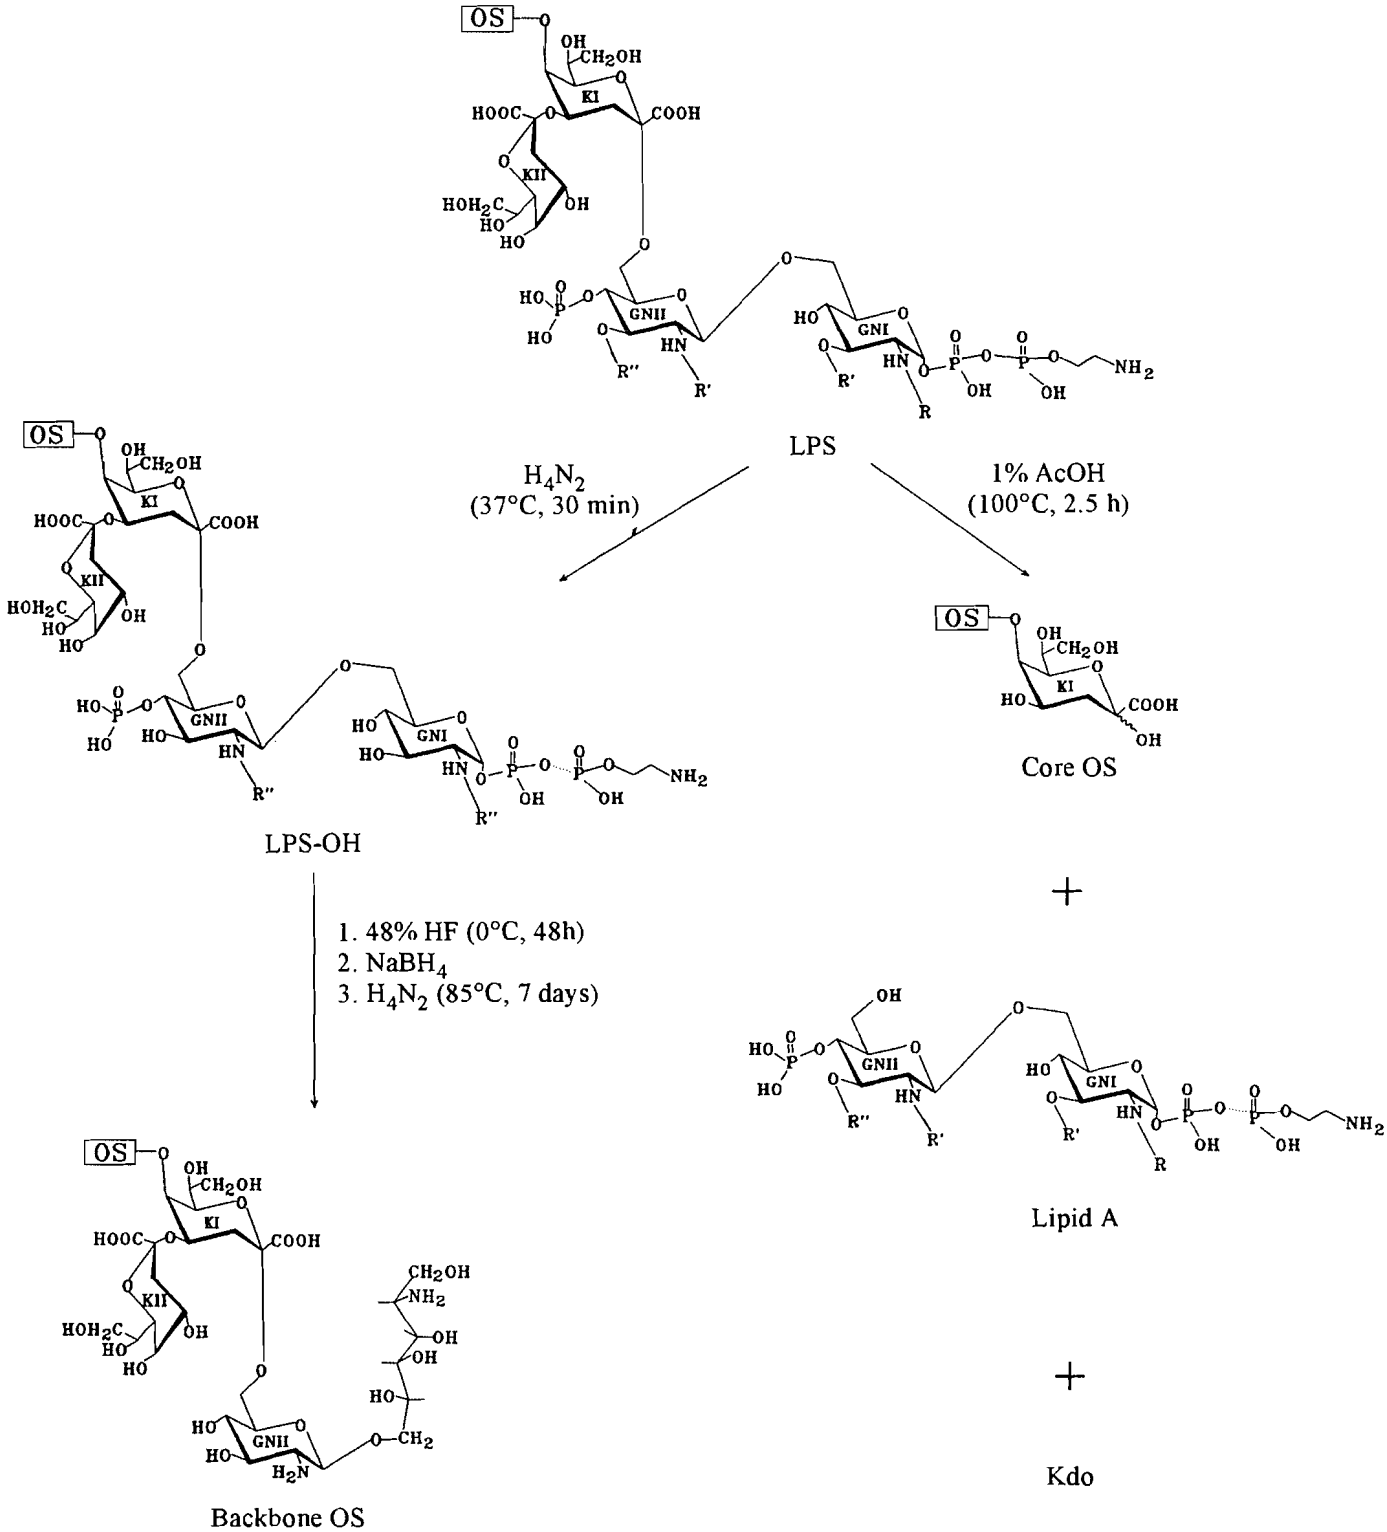

SCHEME 1. General procedure for preparation of oligosaccharides components from LPS.

~2.15) were detected. This indicated that the LPS contained one nonreducing Kdo end group and a second branched Kdo residue glycosidically substituted at positions *O*-4 and *O*-5 (Scheme 2).

The ^{1}H NMR spectrum of the backbone OS (Fig. 2) showed resonances of approximately equal signal area in the low-field region (5.5–4.5 ppm), corresponding to the anomeric protons from nine aldose residues. Correspondingly, nine major anomeric ^{13}C resonances were identified in the low-field region (90–110 ppm) of the 2D heteronuclear ^{13}C–^{1}H correlation (HMQC) spectrum (Fig. 3). In addition to these major resonances, minor anomeric resonances were observed at 4.46 (*d*, $J_{1,2}$ = 7.6 Hz, ca. 0.15 H) and 102.8 ppm (GAI′) in the ^{1}H and ^{13}C spectra, respectively (Figs. 2 and 3), which were subse-

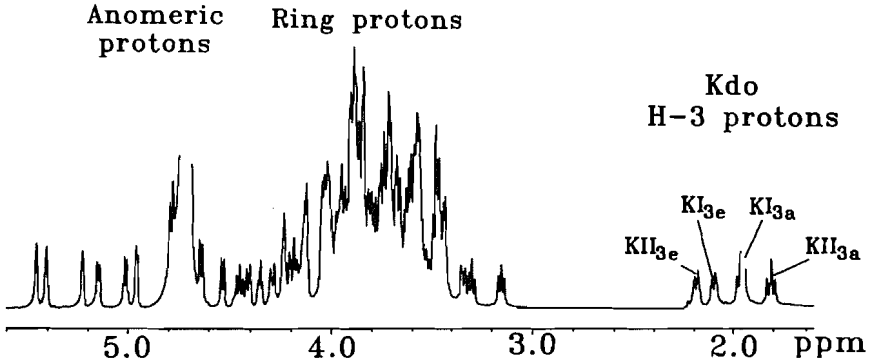

FIG. 2. ^{1}H spectrum of the LPS backbone OS from *M. catarrhalis* serotype A recorded at 600 MHz in D_2O at 32°C. The equatorial and axial protons from H-3 of the Kdo residues are indicated. The H-3a triplet of KI is partially overlapping with the methyl resonance from an acetate-containing impurity, but is fully resolved in the COSY.

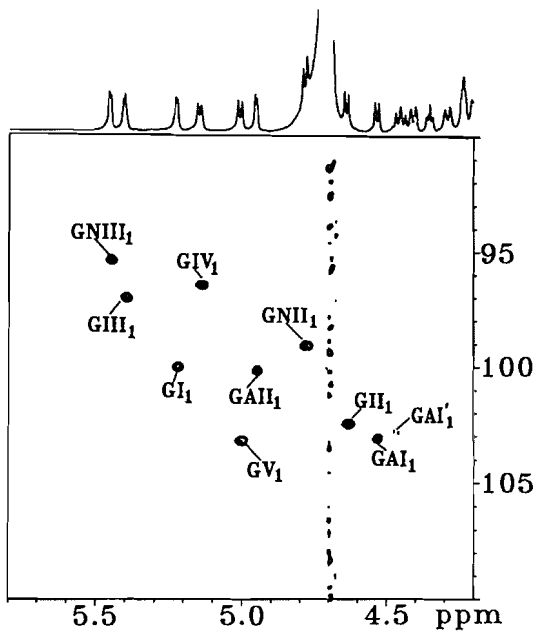

FIG. 3. Heteronuclear 2D ^{13}C–^{1}H chemical shift correlation map of the anomeric region for the backbone OS.

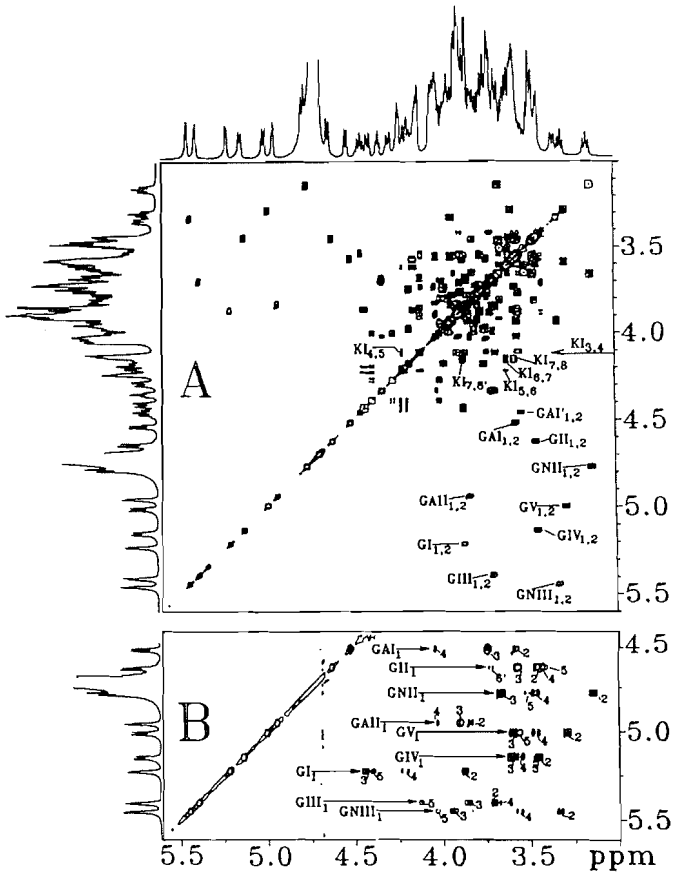

FIG. 4. Partial 2D COSY (A) and TOCSY (B) spectra of the LPS backbone OS. Cross-peaks relating anomeric and ring protons are indicated.

quently attributed to the presence of a minor OS component (ca. 15%) containing one less glycose residue. Four resonances in the high-field region (1.5–2.5 ppm) of the 1D ^{1}H NMR spectrum (Fig. 2) could be attributed to the equatorial and axial methylene protons (H-3e and H-3a, respectively) of two Kdo residues; the doublet of doublet patterns at 2.071 (J = 4.0, 12.3 Hz) and 2.161 ppm (J = 4.8, 13.0 Hz) were characteristic of equatorial H-3 protons, while the triplets at 1.937 (J = 12.0, 12.3 Hz) and 1.785 ppm (J = 12.1, 13.0 Hz) were indicative of the axial H-3 protons. The chemical shifts of the methylene proton resonances from the two Kdo residues indicated that both are in the pyranose ring form and have the α-D-configuration (10–12). As expected, cross-peaks having ^{13}C coordinates of 34.1 and 34.6 ppm in the 2D HMQC experiment could be attributed to the methylene carbons from the two Kdo residues.

^{1}H NMR resonances of the backbone OS were fully assigned from homonuclear proton correlation spectroscopy (COSY) and total correlated spectroscopy (TOCSY) (Fig. 4). From the ^{1}H chemical shifts and vicinal proton coupling constants, subspectra corresponding to all of the glycosyl residues (Fig. 5) were identified (Table 1) (13). Assignment of the ^{13}C resonances was made by direct correlation with the ^{1}H resonances by using the HMQC experiment, and by comparison with recorded ^{13}C-resonance chemical shift data (Table 2) (14, 15).

Seven ^{1}H subspectra were attributed to hexopyranosyl residues having the *gluco* configuration (labelled GI–GV; GNII and GNIII) on the basis of the observed large $J_{2,3}$ and $J_{3,4}$ couplings (~10 Hz). From the magnitude of the $J_{1,2}$ couplings, three of these residues were identified as having the α-D-configuration ($J_{1,2}$ ~4 Hz), while the other four residues were assigned the β-D-configuration ($J_{1,2}$ ~8 Hz) (Table 1). The residues labelled GNII and GNIII were identified as Glc*p*N residues on the basis of their C-2 ^{13}C chemical shifts. The H-2 resonances from these

residues (3.126 and 3.319 ppm) were correlated in the HMQC experiment to ^{13}C resonances at 55.7 and 54.1 ppm, respectively, the chemical shifts of which were diagnostic of amino-substituted carbons (14). A third ^{13}C resonance in this region of the spectrum (55.3 ppm) showed a correlation to H-2 of the glucosamintol end group (GNI[r]). Two subspectra having ^1H spin systems typical of α- and β-D-*galacto*-pyranosyl residues were also identified (labelled GAI and GAII) from their vicinal ring proton coupling constant values: $J_{1,2}$ (3.8 and 8.0 Hz, respectively), $J_{2,3}$ (~10 Hz), $J_{3,4}$ (~4 Hz), and $J_{4,5}$ (1 Hz). Subspectra corresponding to the two Kdo residues were identified from connectivity pathways that were accessed through the high-field H-3 resonances (Fig. 2, Table 1). Cross-peaks relating H-3e, H-3a, and H-4 in a full-scale COSY spectrum indicated that the resonances at 2.071 (H-3e) and 1.937 (H-3a) ppm belong to the same Kdo unit (KI), while the two resonances at 2.161 (H-3e) and 1.785 (H-3a) ppm belong to the second Kdo unit (KII). The ^{13}C resonances of C-4 and C-5 of KI showed significant downfield shifts of 4.5 and 9.6 ppm, respectively, compared with that of KII (Table 2), indicative of KI being substituted at the *O*-4 and *O*-5 positions (14, 15), a conclusion consistent with the methylation analysis.

A nuclear Overhauser effect spectroscopy (NOESY) experiment confirmed the anomeric configuration of the glycopyranosyl residues through the observed NOEs relating the anomeric proton resonances to protons within the same pyranose ring systems (Fig. 6). The observed intraresidue NOE effect between the H-1 and H-2 resonances provided evidence of α-D-glycopyranose linkages (GI, GIII, GAII, and GNIII), while the NOE effects between the H-1, H-3, and H-5 resonances indicated the β-D-glycopyranose linkages (GII, GIV, GV, GAI, and GNII).

The sequence of the glycosyl residues within the carbohydrate backbone of the LPS was mainly determined from interresidue ^1H–^1H NOE measurements between anomeric and aglyconic protons on adjacent glycosyl residues (Fig. 6). Thus, the occurrence of an interresidue NOE between H-1 of GAII and H-4 of GAI established the partial sequence α-D-Gal*p*-(1→4)-β-D-Gal*p*-(1→. In addition, interresidue NOE effects were observed between H-1 of GAI and H-4 of GIII, H-1 of GIII and H-2 of GII, H-1 of GII and H-6/H-6′ of GI, and H-1 of GI and H-5 of KI. Hence, the linear partial sequence of the backbone portion of the OS was established as α-D-Gal*p*-(1→4)-β-D-Gal*p*-(1→4)-α-D-Glc*p*-(1→2)-β-D-Glc*p*-(1→6)-α-D-Glc*p*-(1→5)-α-D-Kdo*p*-(2→.

An interresidue NOE effect between H-1 of GNIII and H-2 of GIV points to the disaccharide sequence α-D-Glc*p*N-(1→2)-β-D-Glc*p*, which forms part of a side chain. However, the anomeric protons of both GIV and GV showed strong interresidue NOEs to H-3 of GI (Fig. 6), precluding assignment of the substitution pattern at GI. Results from methylation analyses suggested that the branching glycosyl residue (i.e., GI) is substituted at *O*-3, *O*-4, and *O*-6 positions. Since NOE evidence clearly indicated that GII is linked to the *O*-6 position of GI, then GIV and GV must be linked at the *O*-3 and *O*-4 positions. The precise linkage positions at GIV and GV were determined from a heteronuclear multiple bond connectivity (HMBC) experiment. Since three-bond connectivities were observed between C-1 of GIV and H-4 of GI and between C-1 of GV and H-3 of GI, this unambiguously established that the branching D-Glc*p* residue (GI) is substituted at the *O*-4 and *O*-3 positions by the respective glycose units (Fig. 7).

In the inner-core region, the branching 4,5-di-*O*-substituted Kdo residue (KI) provides the bridge between the core OS and the lipid A backbone (cf. Scheme 1). The NOE evidence indicates that the branching D-Glc*p* (GI) is attached to the *O*-5 position of KI, while the methylation analysis data is consistent with substitution at the *O*-4 position of KI by the terminal nonreducing Kdo residue (KII). This latter assignment was confirmed from the HMBC experiment in which a *trans*-glycosidic con-

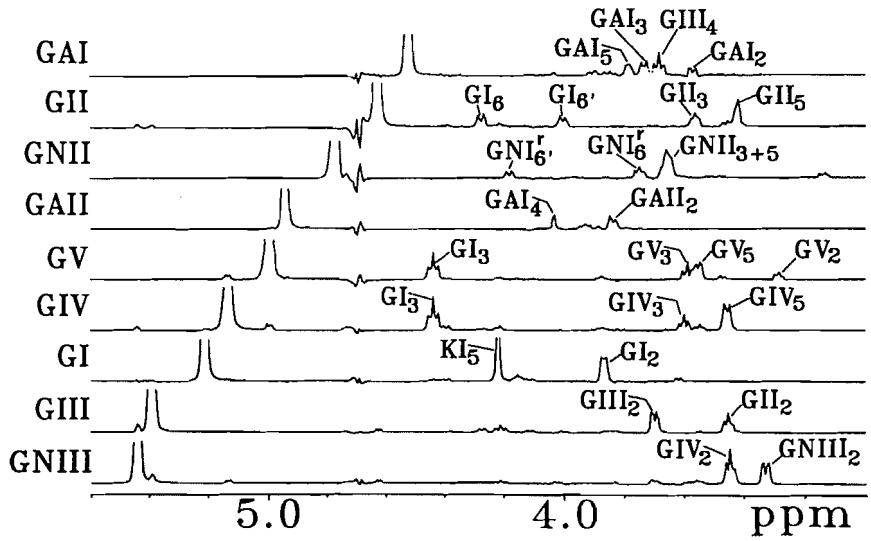

FIG. 6. Cross-sections through the anomeric resonances observed in the 2D NOESY spectrum of the backbone OS showing NOE connectivities from anomeric protons of nine glycosyl residues.

nectivity between C-2 of KII and H-4 of KI was observed. An interresidue NOE was observed between H-1 of GNII and the H-6/H-6′ pair of GNI, establishing the connectivity of the →6)-β-D-Glc*p*N-(1→6)-D-GlcNol unit derived from the lipid A region of the molecule (6). The observed rapid liberation of the lipid A from the LPS on treatment with dilute acid (Scheme 1) is in accord with the core OS being attached via a Kdo unit to the →6)-β-D-Glc*p*N-(1→ residue (GNII) and this was confirmed by tandem electrospray mass spectrometry (16). The connectivities and the linkage positions of the glycosyl residues of the backbone OS deduced from the NOE effects and $^3J_{C,H}$ couplings are illustrated in Fig. 7.

The relative deshielding of the carbon resonances observed for the ring carbons C-3 and C-4 of GI, C-2 of GII, C-4 of GIII, C-2 of GIV, C-4 of GAI, and C-4 and C-5 of KI and the resonances of the methylene carbons (C-6) of GI and GNI^r, when compared with resonances in unsubstituted residues (15), is in line with the established glycosylation at the respective linkage sites (Table 2). It is interesting to note that a similar deshielding effect was not see for ^{13}C resonance of the methylene carbon C-6 of the GNII residue, which is substituted by a Kdo unit. A similar observation has been previously reported (17). The ^{13}C chemical shifts are consistent with GAII, GNIII, and GV being the terminal nonreducing end groups, as also identified by methylation analysis.

Based on the combined NMR spectroscopic and methylation data, the structure of the major backbone OS from *M. catarrhalis* serotype A LPS can be assigned as follows:

α-D-Glc*p*N-(1→2)-β-D-Glc*p*
1
↓
4
α-D-Gal*p*-(1→4)-β-D-Gal*p*-(1→4)-α-D-Glc*p*-(1→2)-β-D-Glc*p*-(1→6)-α-D-Glc*p*-(1→5)-α-D-Kdo*p*-(2→6)-β-D-Glc*p*N-(1→6)-D-GlcNol
3 4
↑ ↑
1 2
β-D-Glc*p* α-D-Kdo*p*

The minor oligosaccharide component detected by NMR analysis (ca. 15% of backbone OS sample) was found to be a truncated form of the backbone OS that lacks the α-D-Gal*p* end group (GAII). The ^{1}H spin system (cf. Table 1) corresponding to a terminal β-D-Gal*p*-residue (labelled GAI′) was identified in the COSY spectrum from the connectivity pathway associated with the minor anomeric proton resonance at 4.46 ppm. An interresidue NOE was observed between H-1 of this residue and H-4 of GIII. In addition, the C-4 chemical shift of GAI′ (68.4 ppm) was typical of that from an unsubstituted β-D-Gal*p* residue, suggesting that the main chain of this minor OS terminates in β-D-Gal*p* and lacks the terminal α-D-Gal*p* present in the major backbone OS. As expected, treatment of the backbone OS with α-D-galactosidase afforded the truncated OS.[5]

The conformation about the glycosidic bond is to a large extent governed by the *exo*-anomeric effect (18), leading to the positioning of anomeric and aglyconic protons on contiguous residues within the expected range for the occurrence of an

[5]The backbone OS was treated with a commercial β-D-glucosidase preparation (Sigma) in an attempt to remove the terminal β-D-Glc*p* residue (GV) in the branched region of the molecule. Instead, the terminal α-D-Gal*p* residue (GAII) was quantitatively removed. The commercial preparation of β-D-glucosidase was known to contain minor amounts of α-D-galactosidase activity and this was confirmed by assaying the enzyme preparation with *p*-nitrophenyl-α-D-galactopyranoside.

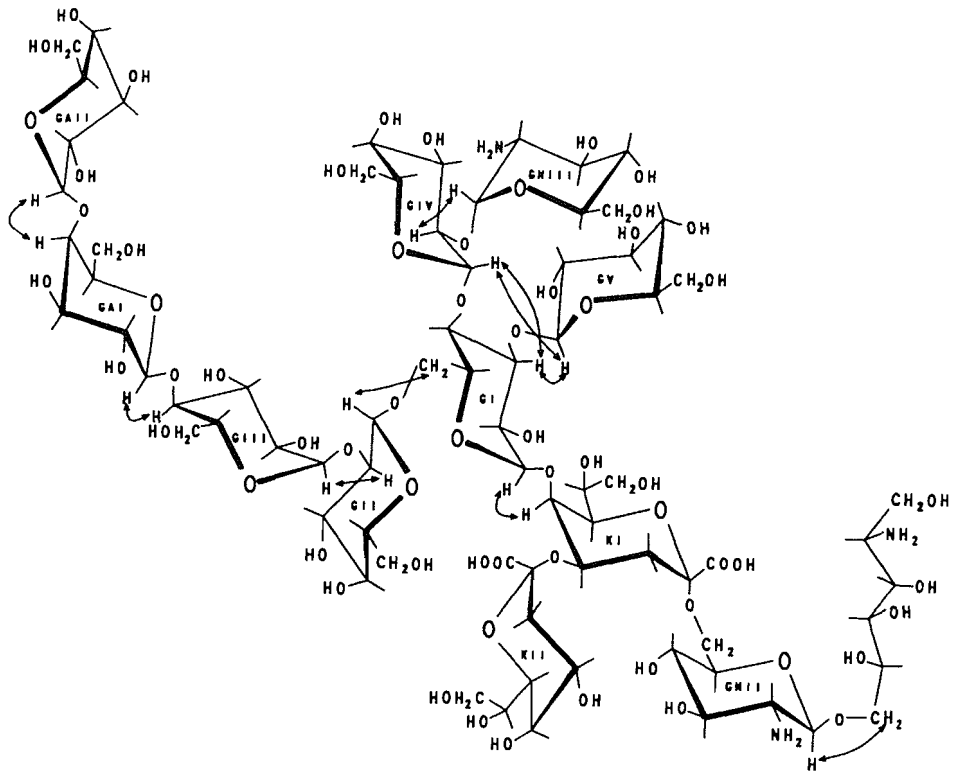

FIG. 7. Structure of the backbone OS from *M. catarrhalis* serotype A illustrating the network of observed interresidue NOE connectivities used to establish the sequence of the glycosyl residues.

interresidue NOE (i.e., interproton distance of less than ca. 3 Å) (19). This provides the basis for the successful application of NOE measurements in determining the sequence of an oligosaccharide. Thus, the observation of a strong transglycosidic NOE between H-1 of GIV and H-3 of GI, but not at H-4 of GI (Fig. 6), within the β-1,4-linked D-Glc*p*-containing disaccharide fragment (Fig. 7) suggested an unusual solution conformation in the highly branched inner core region of the molecule. The chemical shifts of H-1 (5.124 ppm) and C-1 (96.5 ppm) of GIV, which are significantly shifted from those expected for β-linked glycoses (20), also point to an unusual conformation in the →1)-β-D-Glc*p*-(1→4)-α-D-Glc*p*-(1→ disaccharide. To probe the conformation about this linkage, the $^3J_{C,H}$ value between C-1 of GIV and H-4 of GI was measured in a ^{1}H-detected 1D experiment (21). The interglycosidic proton–carbon coupling constant determined[6] from an antiphase multiplet was found to be 7.4 Hz (Fig. 8). Using a Karplus curve optimized for the COCH fragment in saccharides (22), the observed large $^3J_{C,H}$ value indicates that a C-1–O-1–C-4–H-4 conformation in which C-1 of GIV and H-4 of GI have a *trans* orientation is heavily populated. Such a conformation would position H-1 of GIV and H-3 of GI within the range expected for the occurrence of a NOE (Fig. 9). To the best of our knowledge, this is the first example of a D-Glc-containing disaccharide fragment hav-

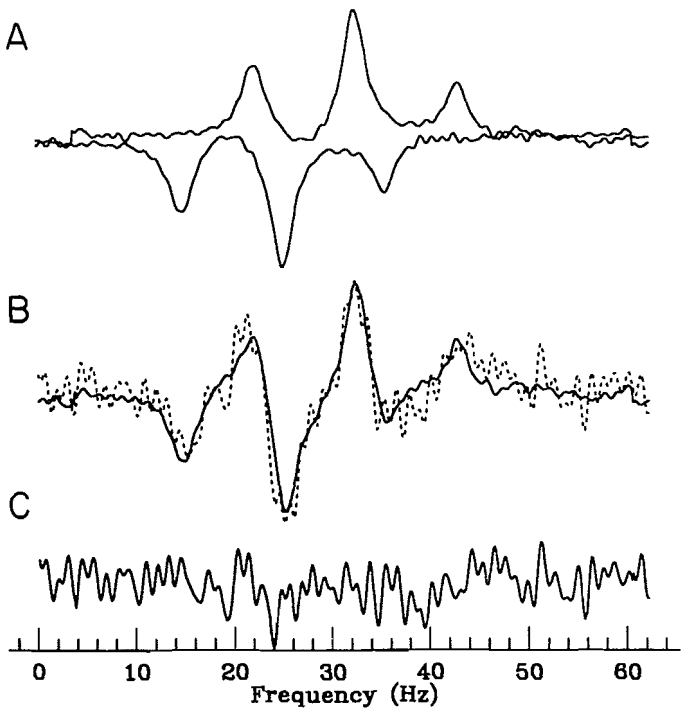

FIG. 8. Reconstruction of the antiphase proton multiplet H-4 of GI (dotted line, B) obtained in a ^{1}H-detected long-range proton–carbon correlated experiment (21). The inphase GI H-4 multiplet (A) was acquired in a z-filtered 1D TOCSY experiment (40, 41) and used to generate the theoretical antiphase multiplet (solid line, B). The difference of the two multiplets in B is shown in C.

[6]Two inphase multiplets of H-4 (GI) were shifted with respect to their chemical shifts and subtracted from each other to yield a theoretical antiphase multiplet. Their displacement and the intensity was varied and the sum of the square of the differences between the constructed and the experimental antiphase multiplets was minimized where the heteronuclear coupling constant is equal to twice the value of the displacement.

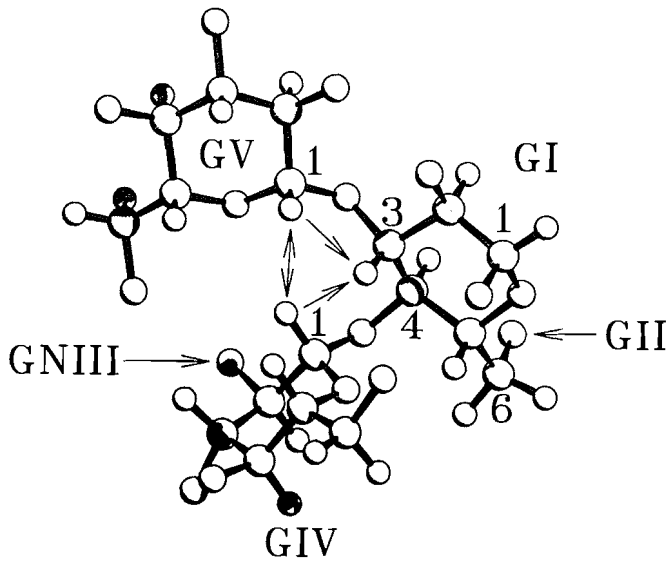

FIG. 9. Minimum energy structure of the branched region of the backbone OS showing the proximity of H-1 of GV, H-3 of GI, and H-1 of GIV to each other, and the *trans* orientation of C-1–O-1–C-4–H-4 for the GIV–GI glycosidic linkage ($\Psi_H = 208°$). This conformation is in accord with the interresidue NOEs observed between GIV H-1/GI H-3, GV H-1/GI H-3, and GIV H-1/GV H-1; and the large J (GIV C-1, GI H-4) coupling constant.

ing this conformation. Moreover, potential energy calculations predict a minor local energy minimum representative of this conformation in the highly branched core.

The structure of *M. catarrhalis* lipid A has been determined in detail (6), which permits the complete structure of the R-type LPS to be proposed as shown in Fig. 10.[7] The α-D-Gal*p*-(1→4)-β-D-Gal*p*-(→ terminal structure present in the *M. catarrhalis* LPS is also found as a component of the globo series of glycolipids associated with human epithilial cells (23). This form of molecular mimicry exhibited by *M. catarrhalis* may provide the pathogen with an advantage for evading host defence mechanisms. This structural feature also occurs in LPS of pathogenic strains of *Haemophilus influenzae* (24, 25) and *Neisseria* spp. (25) and it has been implicated in virulence potential (26). Concurrent studies on the LPS produced by clinical isolates of *M. catarrhalis* indicate that the OS structure deduced in the present investigation is common to LPS produced by these strains. A preliminary observation that mouse and rabbit antibody raised to the apparent common OS antigen shows strong cross-serological reactivity among the *M. catarrhalis* strains is being explored as the basis for a diagnostic reagent and a protective conjugate vaccine.

Experimental

Bacterial growth and LPS preparation

Moraxella catarrhalis serotype A (ATCC 25238) was grown and harvested as previously described (6). The cell pellets obtained by centrifugation were washed successively, once with ethanol, twice with acetone, and twice with petroleum ether (35–60°C), and the LPS was extracted by the hot phenol – water extraction procedure (7).

[7]The ^{1}H NMR spectrum of the *O*-deacylated LPS (Scheme 1, LPS-OH) was recently assigned (H. Masoud, M.B. Perry, and J.C. Richards, unpublished results) in which a singlet at 2.25 ppm (relative area, 3H) was attributed to the methyl protons of the acetamido substituent associated with the terminal nonreducing GlcN residue (GNIII).

Isolation and purification of core OS

Core OS was obtained by heating the LPS with 1% aqueous acetic acid (100°C, 2.5 h), followed by centrifugation (5000 rpm, 30 min) to remove insoluble lipid A. The OS was purified on a Bio-Gel P-2 (Bio-Rad) gel filtration system (2.6 × 140 cm), eluted with pyridinium acetate (0.05 M, pH 4.5). The column eluant was continuously monitored for changes in refractive index by using a Waters R403 differential refractometer. Collected fractions (4.5 mL) were assayed colourimetrically for neutral glycoses using the phenol – sulfuric acid method (27). Glycose-containing fractions were collected and lyophilized.

Preparation of LPS backbone OS

Deacylated, dephosphorylated, and reduced LPS (backbone OS) was prepared according to a modified method of that reported by Holst et al. (17). LPS samples (400 mg) were treated with anhydrous hydrazine (20 mL) with stirring at 37°C for 30 min. The reaction mixture was cooled (0°C), cold acetone (–70°C, 60 mL) was added gradually to destroy excess hydrazine, and precipitated *O*-deacylated LPS was obtained by centrifugation. The pellet was washed three times with acetone, dissolved in water, reprecipitated by addition of acetone, and lyophilized. *O*-Deacylated LPS was dephosphorylated by treatment with 48% aqueous hydrogen fluoride (20 mL) at 0°C for 48 h. The product was dried under a stream of nitrogen, dissolved in water, and dialyzed against water. The lyophilized *O*-deacylated and dephosphorylated LPS sample was treated with $NaBH_4$ (100 mg) in water (10 mL) at 22°C for 1 h, excess $NaBH_4$ was consumed by addition of acetic acid, and the solution was taken to dryness under a stream of nitrogen. The residue was successively evaporated from 10% acetic acid in methanol and then methanol, dialyzed, and lyophilized. *O*-Deacylated, dephosphorylated, and reduced LPS was dried over phosphorus pentoxide and treated with anhydrous hydrazine (15 mL, 85°C, 7 days) to remove amide-linked fatty acids. After removal of hydrazine in vacuo over sulfuric acid, the backbone OS was passed through a column (2 × 8 cm) of polyethylenimine cellulose anion-exchange resin (medium mesh, 1.06 mequiv./g, Sigma) and eluted with water (75 mL). The lyophilized product was purified on the Bio-Gel P-2 column as described above (yield, ~50 mg).

For NMR analysis the backbone OS was further purified by high-performance anion-exchange chromatography (HPAEC) on a Dionex Bio-LC system fitted with a CarboPac PA 1 pellicular anion-exchange column (9 × 250 mm) and a CarboPac PA 1 guard column (10 × 32 mm), using a flow rate of 2 mL/min. Prior to injection, the column was equilibrated with 95% of eluant A (150 mM NaOH) and 5% of eluant B (1 M sodium acetate in eluant A). Oligosaccharide samples (3 mg) in 50 μL of distilled water were eluted with the equilibration mixture of eluents A and B (0.95:0.05) for 5 min, followed by an increase in eluant B at a rate of 0.42%/min over 60 min. The column eluants were monitored with pulsed-amperometric detection (PAD) and fractions were collected, neutralized directly using aqueous acetic acid (10%), and lyophilized. Salt was removed by eluting the material on the Bio-Gel P-2 column as described above.

Analytical methods

Glycoses were determined by GLC as their alditol acetate derivatives. Samples (0.2–0.5 mg) containing *myo*-inositol (30 μg) as an internal standard were hydrolyzed with 2 M trifluoroacetic acid for 90 min at 125°C and evaporated to dryness under a stream of nitrogen. The liberated glycoses were reduced ($NaBH_4$) and acetylated (Ac_2O) as previously described (28). GLC analysis was performed with a Hewlett-Packard model 5710A gas chromatograph fitted with a hydrogen-flame ionization detector, using a fused-silica capillary column (0.3 mm × 25 m) containing 3% OV 17; an initial column temperature of 180°C was held for 2 min, followed by an increase to 240°C at 4°C/min.

Methylation analysis

Backbone OS (5 mg) was methylated with iodomethane (2 mL) in dimethyl sulfoxide (1 mL) containing an excess of potassium methylsulfinylmethanide (9). Excess iodomethane was evaporated under a

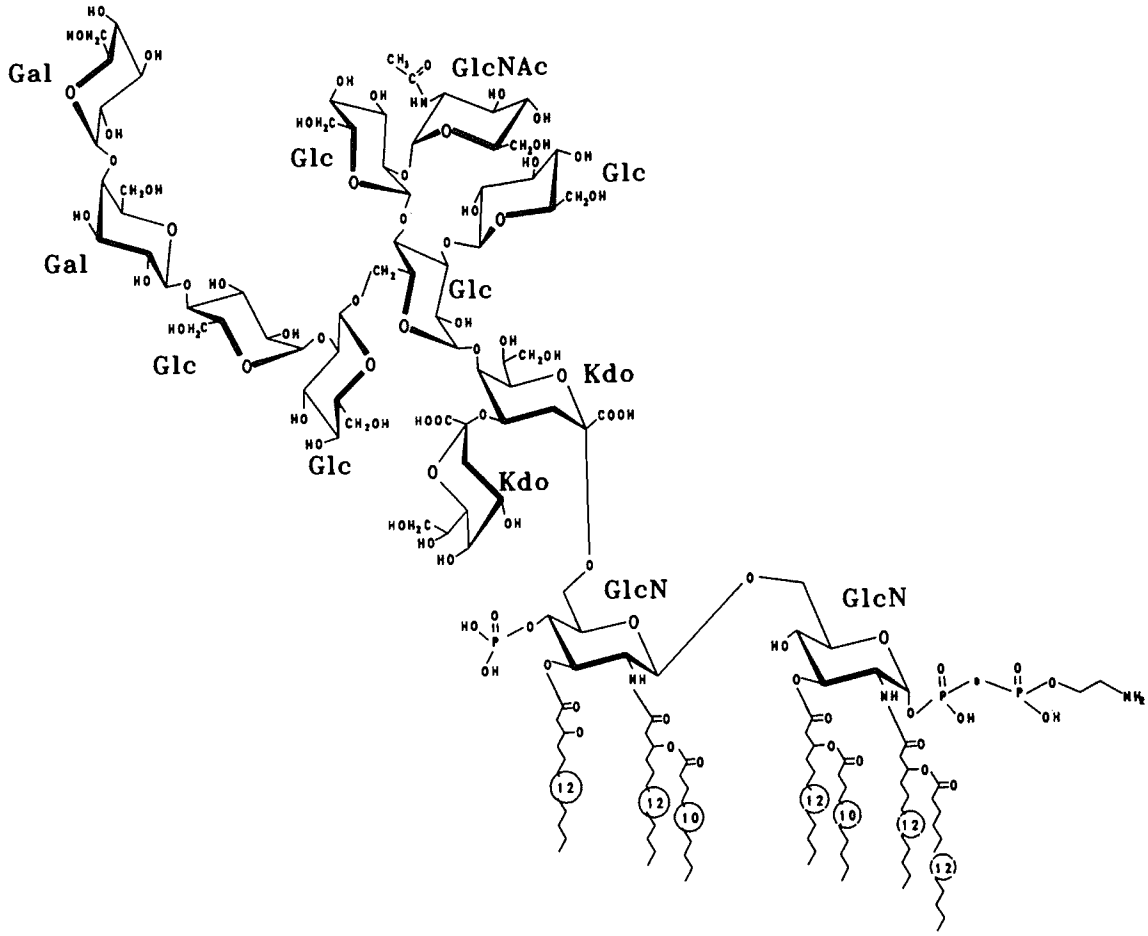

FIG. 10. Proposed chemical structure of the LPS from *M. catarrhalis* serotype A.

stream of nitrogen, water (3 mL) was added, and the methylated oligosaccharide was extracted into chloroform (2 × 5 mL) and purified on a Sep-Pak C-18 cartridge as previously described (29).

To identify 3-deoxyoctulosonic acid residues, *O*-deacetylated LPS (10 mg) was methylated and purified as described above, followed by reduction of the methylated octulosonate carboxy methyl ester groups with 1 M lithium triethylborodeuteride (0.5 mL) in tetrahydrofuran for 2 h at 22°C. The reaction mixture was acidified with glacial acetic acid, dried under a stream of nitrogen, and then evaporated from 10% acetic acid in methanol and then methanol. The residue was desalted using Dowex 50 (H^+ form) ion-exchange resin eluated with water–methanol (1:1). The methylated-reduced material was remethylated (Scheme 2) and purified as described above. Purified methylated oligosaccharides were hydrolyzed (either with 2 M trifluoroacetic acid, 100°C, 1 h, or with 0.25 M sulfuric acid in 95% acetic acid at 85°C, overnight), reduced ($NaBD_4$), acetylated according to the procedure of Stellner et al. (30), and finally analyzed using GLC–MS. Partially methylated alditol acetates were identified by EI–MS on a Hewlett-Packard 595B GLC–MS system fitted with a DB-17 fused silica capillary column (0.25 mm × 25 m), utilizing an ionization potential of 70 eV and a temperature program of 180°C for 2 min, followed by an increase to 320°C at 5°C/min.

Deoxycholate – polyacrylamide gel electrophoresis (DOC–PAGE)

PAGE was performed using the buffer system of Laemmli and Favre (31) as modified by Komuro and Galanos (32) with DOC as the detergent. LPS bands were stained and visualized by silver staining as described by Tsai and Frasch (33).

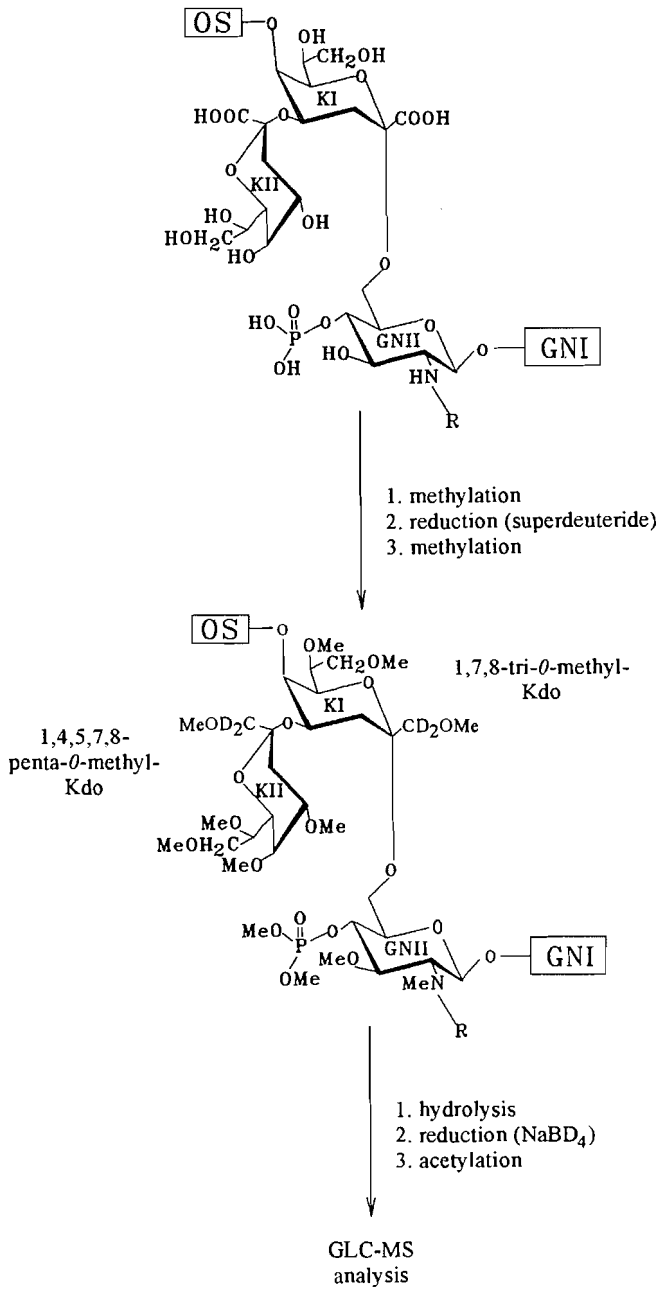
NMR spectroscopy

NMR spectra were obtained with a Bruker AMX 600 spectrometer using standard Bruker software. Measurements were made at 32°C on 2 mg of material dissolved in 0.5 mL D_2O subsequent to several lyophilizations with D_2O.

^1H NMR spectra (600 MHz) were measured using a spectral width of 4.8 kHz and a 90° pulse. Acetone was used as an internal standard. Chemical shifts were referenced to the methyl resonance (δ_H, 2.225 ppm; δ_C, 31.07 ppm). Two-dimensional COSY experiments (34) were measured over a spectral width of 2.0 kHz, using data sets (t_1, t_2) of 512 × 2048 points, and 64 scans were acquired. Spectra were processed in the magnitude mode and symmetrized about the diagonal. Two-dimensional TOCSY (35) and NOESY (36) experiments were performed in a phase-sensitive manner for a spectral width of 3.6 kHz using data sets of 512 × 2048 points and 64 scans for each t_1 value. Mixing times of 400 and 78.3 ms were employed for the NOESY and TOCSY experiments, respectively. ^1H chemical shifts and coupling constants were refined by spectral simulation using LACOONS 5 with the FT–NMR program. A full-scale COSY was carried out on a Bruker AMX 500 spectrometer for a spectral width of 2.0 kHz, by using a data set of 256 × 2048 points and 32 scans for each t_1 value.

Heteronuclear 2D ^{13}C–^1H chemical shift correlations were measured in the ^1H-detected mode via multiple quantum coherence (HMQC) with proton decoupling in the ^{13}C domain (37), using data sets of 1024 × 2048 points and spectral widths of 18.9 and 4.8 kHz for ^{13}C and ^1H domains, respectively. Thirty-two scans were acquired for each t_1 value.

The 2D heteronuclear multiple bond correlated experiment (HMBC) was carried out in the ^1H-detected mode using the pulse sequence described by Bax and Summers (38). The three-bond heteronuclear coupling constant ^3J (GIV C-1, GI H-4) was determined using a basic ^1H-detected, constant time, ^{13}C chemical shift selective filter experiment (21). The ^{13}C carrier frequency was set to the frequency of C-1 of



SCHEME 2. Reaction sequence for methylation analyses of Kdo residues present in LPS-OH.

GIV and the long-range evolution interval was 51.81 ms. An increment of 1.5 ms was used and 27 520 scans were acquired for each of eight experiments. The acquisition time was 1 s and the BIRD pulse (39) was applied 0.4 s before the start of the pulse sequence to suppress the ^{1}H resonances attached to ^{12}C. Total experimental time was 90 h. The inphase multiplet of H-4 of GI was acquired in a 1D TOCSY experiment (40) with a z-filter (41). A half-Gaussian pulse (42) of 53 ms was used to excite the GI H-1 proton and a mixing time of 150 ms was employed. The filter was incremented 24 times in 0.5-ms steps and 64 scans were acquired per spectrum.

Calculations

The conformational analysis was evaluated using the PFOS approach (43). The low-energy conformer which had a *trans* orientation for C-1–O-1–C-4–H-4 of the GIV–GI glycosidic linkage was further minimized by using the MM3 software (QCPE) (44).

T. NISHIYAMA, H. SHIOI, K. KORENAGA, R. TUJI, and F. YAMADA. Can. J. Chem. **72**, 1478 (1994).

A series of tetrakis(4-hydroxyphenyl)pentanes and tetrakis(4-hydroxyphenyl)-*p*-xylenes having relatively high molecular weights (550–810) were prepared and evaluated as antioxidants for tetralin at 60°C by means of an oxygen-absorption method. Introduction of alkyl groups to the *ortho* positions of the phenolic hydroxyl group was shown to improve antioxidant activities for both series of compounds.

T. NISHIYAMA, H. SHIOI, K. KORENAGA, R. TUJI et F. YAMADA. Can. J. Chem. **72**, 1478 (1994).

On a préparé une série de tétrakis(4-hydroxyphényl)pentanes et de tétrakis(4-hydroxyphényl)-*p*-xylènes de poids moléculaires relativement élevés (550–810) et on les a évalués comme antioxydants pour le tétraline, à 60°C, par une méthode d'absorption de l'oxygène. On a démontré que l'introduction de groupes alkyles en positions *ortho* du groupe hydroxyle du phénol améliore les activités antioxydantes dans les deux séries de composés.

[Traduit par la Rédaction]

Introduction

In chemical industries, antioxidants have commonly been used to prevent deterioration due to the oxidation of organic materials, for example, petroleum hydrocarbons, lubricating oils, rubbers, polymers, and foodstuffs (1). The oxidation upon storage at room temperature or during various processes at high temperature have been well recognized as radical chain reactions. Antioxidants such as 2,6-di-*tert*-butyl-4-methylphenol (BHT) and *tert*-butylated hydroxyanisole (BHA) react as chain-breaking inhibitors of the peroxyl radical. BHT and BHA are, however, relatively volatile and, consequently, of somewhat limited use at higher temperatures owing to their loss through vaporization. The development of antioxidants having high molecular weights (2) and the fixation of antioxidants to polymer chains (3, 4) are well-established methods to reduce the volatility of antioxidants.

During the course of our studies on phenol derivatives as antioxidants (5, 6), we have found that the introduction of the benzyl group at *ortho*- and (or) *para*-positions of the phenolic hydroxyl group improved the antioxidant activities. Furthermore, benzylphenols containing alkyl groups at both *ortho* positions for the phenolic hydroxyl group showed high activities as antioxidants.

On this basis, we expected that 1,1,5,5,-tetrakis(4-hydroxyphenyl)pentanes (**1–5**) and α,α,α′,α′-tetrakis(4-hydroxyphenyl)-*p*-xylenes (**6–11**) would act as better antioxidants compared with BHT or BHA, since they have four active phenolic moieties and alkyl or benzyl groups at the *ortho*- and or *para*-positions of the phenol skeleton. Herein, we wish to report the preparation of compounds **1–11** (Fig. 1) and their antioxidant activities evaluated by means of an oxygen-absorption method.

Results and discussion

Figure 2 shows the results of the autoxidation of tetralin initiated by 2,2′-azo-bis(isobutyronitrile) AIBN), in the presence of tetrakisphenols **1–11** and BHT as antioxidants, along with a control test in the absence of an antioxidant. The control curve was observed without any appreciable induction period (IP). On the contrary, the rates of oxygen uptake in the presence of tetrakisphenols were remarkably suppressed.

[1]Author to whom correspondence may be addressed.

First, the antioxidant activities of the tetrakis(4-hydroxyphenyl)pentanes and tetrakis(4-hydroxyphenyl)-*p*-xylenes were compared. In comparison with **1** and **6** having 2,5-dimethyl substituents on phenol rings, the IP value of **1** showed a slightly higher value (see IP values in Table 1). However, the IP values of **2** and **7**, **3** and **8**, and **5** and **10** showed almost the same values.

Next, the positions of the alkyl substituents on the phenol rings on their antioxidant effect were compared. The relative antioxidant potency of the tetrakis(4-hydroxyphenyl)pentanes was observed in the order **3** > **2** > **4**,**5** > **1**. Similarly, the IP values of the tetrakis(4-hydroxyphenyl)-*p*-xylenes decreased in the order **8**,**11** > **7** > **10** > **9** > **6**. In particular, for compounds **2**, **3**, **7**, **8**, and **11** having two alkyl substituents at *ortho* positions of OH groups, the IP values were 2.5–3.0 times larger than that for BHT. These results indicated that the factors which enhance the peroxyl radical trapping ability of tetrakisphenols are greatly dependent on the position of the ring substituents of the phenol nuclei. These factors are, first, alkyl substitution at both *ortho* positions and, second, a bulky substitution at the *ortho* position.

The stoichiometric factors (n) for all the antioxidants examined are listed in Table 1. Compounds **2**, **3**, **7**, **8**, and **11** exhibited much higher stoichiometric factors (5.2–6.0) in comparison with those of other compounds. This means that these four compounds react with five to six pieces of peroxyl radicals, respectively.

Table 1 also shows the rates of oxygen consumption after IP. As can be seen from Table 1, relatively lower rates were observed for all classes of tetrakisphenols in comparison with BHT. When all ArO· radicals are consumed, the rate of autoxidation should be equal to that of the control test. In fact, the rate of oxygen consumption after IP of BHT was close to the control value. On the other hand, the rates of oxygen consumption of compounds **1–11** were not close to the control value, but much lower. This means that the retardation ability persists, even after IP is over, owing to some transformation products of the antioxidant.

In conclusion, we have synthesized a series of tetrakisphenols. Among these compounds, the compounds having two alkyl substituents at *ortho* positions of OH groups, such as **2**, **3**, **7**, **8**, and **11**, exhibited significant antioxidant effect. However, no influence of the structure between tetrakis(4-hydroxyphenyl)pentanes and tetrakis(4-hydroxyphenyl)-*p*-xylenes on their antioxidant effect was observed.

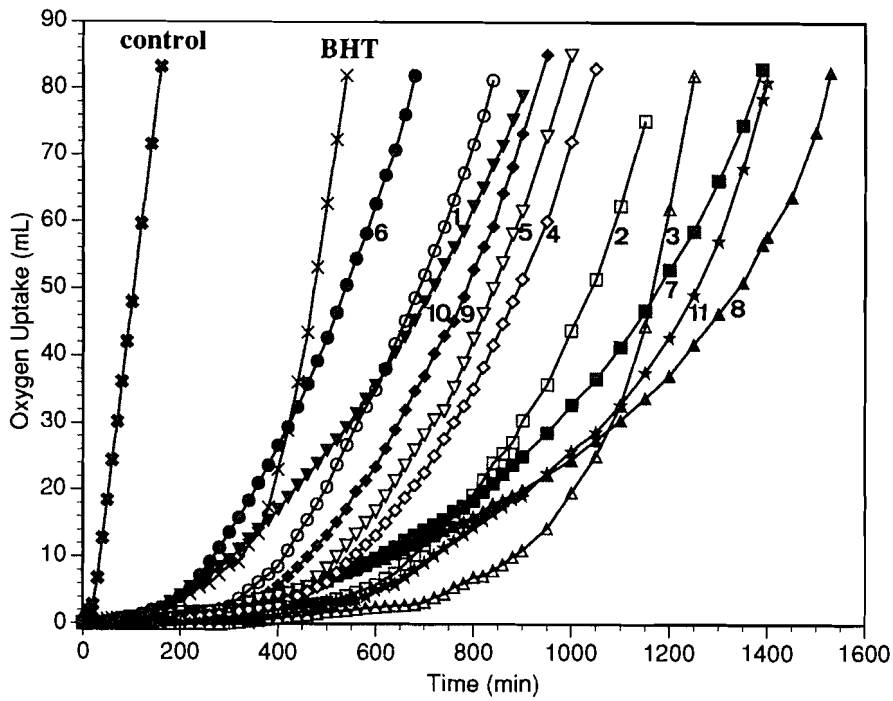

FIG. 2. Rate of oxygen uptake in the oxidation of tetralin in the absence and presence of antioxidant.

We are planning to test the toxicity of **1–11** and the antioxidant activities for other substrates.

Experimental

General

Melting points were measured on a Yanaco MP-J3 micro melting apparatus and uncorrected. Infrared spectra were determined with a Perkin-Elmer model 1600 grating infrared spectrophotometer using a potassium bromide pellet. Nuclear magnetic resonance spectra were recorded with a Jeol GSX-400 spectrometer operating at 400 MHz for ^1H and 100.6 MHz for ^{13}C. Unless otherwise noted, the solvent was $(CD_3)_2CO$ and chemical shifts are given with respect to TMS.

Determination of antioxidant activities

The volume of oxygen consumption was determined as a function of time under 760 Torr (1 Torr = 133.3 Pa) of O_2 (5). The oxidation temperature was kept at 60 ± 0.1°C. The IP was determined graphically (7, 8) on the plot of oxygen consumption versus time as the point of intersection of a line of the rate of oxygen uptake after the inhibitor was consumed and a line tangent to the curve with a slope equal to half of the slope of the line after the inhibitor was consumed. Stoichiometric factors (n) were determined at 60°C by the IP method (9, 10).

Materials

Tetralin was washed with concentrated sulfuric acid, aqueous sodium bicarbonate, and water, dried over anhydrous sodium sulfate, and distilled under nitrogen before use. AIBN was recrystallized from methanol.

The tetrakis(4-hydroxyphenyl)pentanes **1–5** and tetrakis(4-hydroxyphenyl)-*p*-xylenes **6–11** were prepared by the condensation reaction of glutaraldehyde or terephthalaldehyde with the corresponding phenols in the molecular ratio of one to four in the presence of an acidic catalyst (11, 12). A typical experimental procedure is described for the synthesis of **1**. To the solution of 2,5-dimethylphenol (12.2 g, 0.1 mmol) and glutaraldehyde (2.5 g, 25 mmol) in nitromethane (30 mL), concentrated HCl (1.5 mL) was added dropwise at room temperature.

After being stirred for 24 h, the mixture was poured into water and extracted with ethyl acetate. The organic layer was washed with water, dried over anhydrous Na_2SO_4, and concentrated. The residue was chromatographed on silica gel with 10% ethyl acetate in hexane as eluants. The first fraction contained 2,5-dimethylphenol. The second fraction was evaporated in vacuo to leave a solid. Recrystallization of the solid from acetone gave 2.8 g (20%) of **1**. The yield, spectral, and analytical data are as follows.

1,1,5,5-Tetrakis(2,5-dimethyl-4-hydroxyphenyl)pentane (1)
^{1}H nmr δ: 1.81–1.88 (m, 6H), 2.04 (s, 12H), 2.06 (s, 12H), 2.89 (br s, 4H), 3.95 (t, J = 7.3 Hz, 2H), 6.52 (s, 4H), 6.77 (s, 4H); ^{13}C nmr δ: 16.1, 19.3, 32.3, 37.0, 42.0, 117.3, 121.7, 130.2, 134.9, 153.7; ir: 3484 cm^{-1} (s, br). ROBERT R. FRASER, CORINNE BENSIMON, NEIL C. FAIBISH, and FANZUO KONG. Can. J. Chem. **72**, 1481 (1994).

The crystal structures for four α-chloro derivatives **2–5** of the titled ketone **1** have been determined, confirming their earlier assignments of stereochemistry. Variations in the conformations of **2–5** suggested some flexibility in the central seven-membered ring. Molecular mechanics calculations of the changes in energy as a function of the internal torsional angles at the carbonyl of these chloro derivatives indicated the ring flexibility to be comparable to that of cyclohexanone. In the three compounds containing an axial chlorine the distance between the chlorine atom and two of the carbon atoms of the more remote benzene ring was 3.2 ± 0.1 Å, suggesting the value for the thickness of a benzene ring may be significantly smaller than the accepted value when it is interacting with a single atom.

ROBERT R. FRASER, CORINNE BENSIMON, NEIL C. FAIBISH et FANZUO KONG. Can. J. Chem. **72**, 1481 (1994).

On a déterminé les structures cristallines des quatre dérivés α-chlorés **2–5** de la cétone **1** mentionnée dans le titre et on a ainsi confirmé les attributions de stéréochimie faites antérieurement. Les variations dans les structures des composés **2–5** suggèrent l'existence d'une certaine flexibilité dans le cycle central à sept chaînons. Des calculs de mécanique moléculaire des changements d'énergie en fonctions des angles de torsion internes au niveau du carbonyle de ces dérivés chlorés indiquent que la flexibilité du cycle est comparable à celle de la cyclohexanone. Dans les trois composés contenant un atome de chlore axial, la distance entre l'atome de chlore et deux des atomes de carbone du noyau benzénique le plus éloigné est de 3,2 ± 0,1 Å; ceci suggère que la valeur pour l'épaisseur d'un noyau benzénique interagissant avec un seul atome est peut-être beaucoup plus faible que la valeur généralement acceptée.

[Traduit par la Rédaction]

The bridged biaryl ketone, 5.7-dihydro-1, 11-dimethyl-6*H*-dibenzo[*a*,*c*]cycloheptene-6-one,[4] **1**, first reported by Mislow et al. (1), is a chiral derivative of biphenyl. A C_2 axis passes through its central ring giving rise to two possible orientations α to the carbonyl, either "axial" or "equatorial" on the basis of their similarity to the geometry at the α positions of cyclohexanone (see Fig. 1). The ring was considered by Mislow to possess a single rigid conformation as indicated by molecular models and supported by its proton nmr spectra (2). We have used this ketone in a variety of studies involving the effects of stereochemistry on reactivity since it offered certain advantages over cyclohexanone as a model. One example involves a study of the hydrogen–deuterium exchange reaction for the axial and equatorial protons α to the carbonyl (3). In another, measurement of the variation in rates of addition of nucleophiles to **1** as a function of the stereochemistry of its α methyl and chloro derivatives provided evidence for the primary importance of torsional interactions as contributors to the antiperiplanar effect (4). The validity of the assumption of rigidity of **1**, and thus its ability as a model to provide derivatives of known fixed stereochemistry, was examined for **1** and its methyl derivatives using X-ray crystallography complemented by molecular mechanics calculations (5). In the solid state, these compounds showed a C_2 symmetric structure except for the axial monomethyl derivative in which the torsional angles changed by 23° at the C—C bonds α to the carbonyl. Molecular mechanics calculations using the MMX program[5] provided conformations whose dihedral angles matched each of those observed to within 2° and energies matched to within 0.5 kcal/mol. Calculated energy differences between diastereoisomers similarly agreed with data obtained by equilibration experiments. The X-ray data for hydrocarbon derivatives of **1** not only verified their stereochemistry but provided a sucessful test of the performance of MMX as well as quantitative information on their rigidity. In this paper we describe the same combination of X-ray crystallographic analysis with information from MMX calculations in elucidating the conformational properties of the α chloro derivatives **2–5**.

X-ray crystallographic analysis

Table 1 presents a summary of the crystal data for the following derivatives of **1**: equatorial monochloroketone **2**, diaxial dichloroketone **3**, diequatorial dichloroketone **4**, and the geminal dichloroketone **5**. The X-ray data confirm the structural and stereochemical assignments made earlier (4) for compounds **2–5**. Each of the equatorial chlorines are oriented in eclipsed or nearly eclipsed conformations, the dihedral angles between the C—Cl and the adjacent C—O bond being 6° and 5° (or 14°) in **2** and **4**, respectively. The axial chlorines in **3** are found to be antiperiplanar (to the more remote π lobe of the carbonyl) as proposed (4*b*), having dihedral angles of 90° ± 10°.

The most descriptive information with respect to the conformation of these compounds is provided by the torsional or dihedral angles given in Table 2. For comparison, that previously reported for **1** appears in the first column. For the equatorial monochloroketone **2** two symmetry-independent molecules **2***a* and **2***b*, having very similar conformations, were found in one unit cell. The ORTEP plots for **2***a* and **2***b* along with those for **3***a*, **3***b*, **4**, and **5** appear in Fig. 2. In contrast to **1**, the seven-membered ring in this structure differs from the symmetric from primarily through a 15° rotation about C1—C2 and C1—C15, which is accompanied by much smaller changes at the C2—C3 and C15—C14 bonds. Again, for the diaxial α,α′-dichloroketone **3** two symmetry-independent molecules were found in

one unit cell. Both molecules possess conformations that deviate by less than 3° from C_2 symmetry. The diequatorial α,α′-dichloroketone **4** shows the presence of an asymmetrically distorted central ring that places the two equatorial chlorines in very different conformations with respect to the carbonyl group. An unusually low value for the C1-C15-C14-C13 torsional angle of **4** is also seen. These distortions likely arise from the intermolecular forces between the proximate pairs of C—Cl bonds in the unit cell. Geminal dichloro derivative **5** deviates only slightly more from C_2 symmetry than does **3**. The above variations in conformation, like those found previously for the methyl derivatives of **1**, indicate some flexibility in the central ring.

Bond lengths and nonbonded distances

Table 3 describes some bond lengths and nonbonded distances, selected for their representation of unusual spatial effects. The most notable variations in bond lengths are the longer C—Cl bonds for the axial chlorines of **3** and **5** compared with those equatorially oriented in **2**, **4**, and **5**, whose averages were 1.805 and 1.785 Å, respectively. This type of correlation was recently noted by Laube and Ha (6) in a survey of X-ray data for several types of α-substituted ketones. From the observation of a maximum length for conformations in which the X-C-C-O dihedral angle is 90° and ab initio calculations in support thereof, they attributed the stereochemical correlation to a hyperconjugative interaction. The constancy in length of the C1—C2 bond (see Table 3) in the α haloketones **2**, **3**, and **5** provides no evidence for or against this interpretation. Alternatively, the longer C—Cl bond length for the axial C—Cl bonds may be attributed to the same factors responsible for the longer axial bonds in cyclohexanes and six-membered

heterocycles (7) (as revealed by their smaller onebond ^{13}C–H coupling constants). The origin of this correlation remains uncertain (7).

The last entry in Table 3 shows the distance between the two carbon atoms of the *ortho* methyl groups of the biphenyl moiety, which is consistently at 3.26 Å, a value considerably less than the distance normally seen between neighboring methyls. At this separation considerable strain is clearly created, resulting in distortions elsewhere in the hydrocarbon framework. Notably, the dihedral angle between the two aromatic rings has a value of 58°–62°, about 10° higher than in the biaryl ketone lacking these methyls (5). In addition, each of the two aromatic rings is forced to be nonplanar by the prevention of further increase in dihedral angle by the three-carbon bridge at the other *ortho* positions. This can be seen in Table 2 where the dihedral angles C7-C8-C9-C10 are consistently larger than the C3-C8-C9-C14 angles.

The van der Waals thickness of a benzene ring

In those compounds possessing an axial chlorine, the distance between the chlorine and the carbon atoms of the distal benzene is provded by the crystal data. In Table 4, it is seen that the chlorine is found as close as 3.05 Å from C-8 or C-9. For the axial chlorines the average observed distance of closest approach[6] of 3.14 Å is significantly less than the sum (3.65 Å) of the van der Waals' distances for a chlorine atom (1.8 Å) and an aromatic ring (half thickness 1.85 Å) (8). In this instance, in which a chlorine atom is compressed against the benzene ring, its estimated thickness seems too large.[7] This appears to be true in situations involving other single atoms. There is recent theoretical (9) and experimental (footnote 5 and ref. 10) evidence that a hydrogen atom also attains a very close approach.

Molecular mechanics calculations using MMX

MMX is a new program recently made available[5] for performing molecular mechanics calculations on an IBM 386 or equivalent, and a detailed description of its method of operation has appeared (12). This program, based on the MM2 force field of

[6]This distance is normally considered to be the most reliable estimate for the sum of the van der Waals' radii for two contiguous atoms. Any example of distance less than the accepted minimum is then considered as evidence for the presence of a bonding interaction (8). Allinger and Burkert have pointed out that, in certain situations, this distance may require adjustments that include contributions from attractive intramolecular interactions (11).

[7]A referee has suggested the alternative view that this be referred to as a case of spatial overcrowding.

Allinger, has already gained considerable acceptance (13). As pointed out by Lipkowitz (14), any modifications of established programs such as MM2 should be adopted with some caution. Previously, we found that the conformational properties of **1** and its methyl derivatives as observed in the solid state could be reproduced satisfactorily using MMX. To further probe the reliability of MMX, we have used it to calculate the most stable conformations for the chloroketones **2–6**. The axial isomer **6**, though not attainable in crystalline form, was included for comparison. The resultant energies and torsional angles for the central ring are listed in Table 5. For **3** the torsional angles agree

well with those observed for its crystal structure. For **2**, **4**, and **5** we also calculated that conformation most closely corresponding to an observed crystal form. Table 5 gives their energies and torsional angles with the differences from the solid state values appearing in parentheses. The differences are generally small, less than 2°, except for several angles involving a C—H bond. The value for the energy of each structure calculated to match the X-ray structure differs by less than 0.5 kcal/mol from the calculated global minimum although the dihedral angle at C1—C2 changed by up to 12° in order to do so.

In addition to providing conformations compatible with those observed in the solid state, these calculations revealed considerable flexibility in the central ring. To compare the conformational mobility of the chloroketones **2–5** with the parent ketone **1**, we calculated their variation in energy over an 80° change in

the C3-C2-C1-C15 dihedral angle from the most stable conformation. In contrast to the parent 1,3-cycloheptadiene (15), only one conformation could be found for **1** or any of its derivatives, undoubtedly due to the aforementioned effect of the *ortho* methyl groups in maintaining the 60° dihedral angle between the rings of the biphenyl moiety. The flexibility of **1** is shown in Fig. 3(*a*), which depicts its variation in energy with change in dihedral angle, as previously reported (5). This curve shows the presence of a shallow energy well, allowing deviation from the minimum energy conformation by about 15° for a 1 kcal/mol change in energy. The energy dependence of equatorial monochloroketone **2** versus dihedral angle is plotted in Fig. 3(*b*). This curve shows a slightly less energetic dependence on dihedral angle (i.e., greater flexibility than **1**) as does that for the axial isomer **6** shown in Fig. 3(*c*). Curves calculated for the disubstituted derivatives **3** and **4** showed comparable shapes. Thus all chloro derivatives exhibit greater flexibility than **1**, just as we had found previously for its α methyl derivatives. One other comparison is noteworthy. The axial and diaxial isomers have greater calculated stabilities than the mono and diequatorial derivatives of **1**. The calculated difference between axial **6** and equatorial **2** is 1.7 kcal/mol, which agrees well with that recently calculated for the two rotamers of 2-chloropropionaldehyde, which have almost identical stereochemistry (16). The difference in stability was attributed mainly to a difference in the dipolar interactions as previously seen for 2-chlorocyclohexanone (17). The close correspondence of these results obtained for **6** and **2** with those for 2-chloropropionaldehyde (by ab initio methods) provides support for the MMX method as applied by us.

For comparison with **1** we also calculated the energy profiles versus dihedral angle at C1—C2 for cyclohexanone and its axial and equatorial conformational isomers. Figure 4 shows the results for **1** (curve *a*), cyclohexanone (curve *b*), and axial 2-chlorocyclohexanone (curve *c*). The curve for the equatorial conformer is not shown as it is very similar to that in (*c*). In fact all the curves have comparable profiles. In the MMX calculations, a value of 1.5 was used for the dielectric constant, *D*, of the medium. Selection of the appropriate value for this constant in any calculation of polar interactions has been a longstanding problem.[8] As a simple[9] check on the importance of the choice of dielectric constant on the plot of energy versus dihedral angle, we repeated the calculations on axial 2-chlorocyclohexanone us-ing a value of 6 for *D*. The resultant curve in Fig. 4(*d*) shows that the position of the minimum in energy is unaltered while the rigidity is diminished slightly with the increase in dielectric constant.

Summary

X-ray crystallography has confirmed the conformational and configurational properties in the α chloroketones **2–5**. The degree of rigidity in **1–5** has been estimated by calculation of the variation in the strain energy as a function of the dihedral angle at C1—C2. The parent ketone has the advantage[10] over cyclohexanone as a model system possessing slighter greater rigidity. Its chloro derivatives, like those of cyclohexanone, exhibit slightly reduced rigidity. At the same time it is important to bear in mind that none of these carbonyl compounds merits the description "rigid" in the strict sense of the word.

Experimental

The synthesis of compounds **2–5** has been reported previously (4*b*). Recrystallization of each of these from methylene chloride – hexanes gave suitable single crystals for X-ray determination.

A summary of the crystal data for compounds **2–5** is given in Table 1. The diffraction intensities were collected on a Nonius diffractometer at 295 K (except for **4** collected on a Rigaku diffractometer at 143 K) with MoKα radiation (λ = 0.7093 Å) using the θ/2θ scan technique with profile analysis (20). A graphite monochromator was used to achieve the monochromatic radiation. All the data were collected at a speed of 4° in ω/min. The standards were measured after every 150 reflections, no crystal decay was noticed. The space group is determined by systematic absence. Cell dimensions were obtained from 24

[8]The Kirkwood–Westheimer approach to the solution of this problem is reviewed by Hine (18).

[9]The work of Wiberg and Wong (19) illustrates the approximate nature of quantitative evaluation of solvent effect even in using ab initio calculations with the reaction field model.

[10]A major advantage for **1** is its single energy minimum. In contrast, cyclohexanone is in equilibrium with a boat conformation only 3–4 kcal/mol higher in energy.

reflections with 2θ in the range 30°–40° for **2**, and in the range 40°–45° for **3**; and from 25 reflections in the range 40°–50° for **4**, and from 21 reflections in the range 40°–45° for **5**. Lorentz and polarization factors were applied but no corrections were made for absorption.

The structures were solved by the direct method. All the atoms were refined anisotropically except for the hydrogen atoms, which were found by Fourier map for compounds **2** and **3**. For compounds **4** and **5**, the positions of the hydrogens were calculated. All the calculations were performed with the NRCVAX Crystal Structure Package (21). The refined atomic parameters are listed in Table 6.[11]

The calculation of steric energies for the compounds in this paper was carried out using PCMODEL, V4.0, and the MMX program contained therein.[5] In deriving the conformation of lowest energy we used the C_2 symmetric form as starting point. To obtain the variation in energy as a function of dihedral angle at the C1—C2 bond, this bond was fixed at each new value (using 4° intervals) and the energy for this specifically constrained conformation minimized. Energy values for changes in dihedral angle over twice the range plotted in Fig. 3 revealed no other conformational minimum. Each calculated total energy included stretching, bending, stretching–bending, torsional, van der Waals, and electostatic contributions. Except where noted, a value of 1.5 was used for the dielectric constant.

Received September 22, 1993

MICHELLE M. DUKE, ANDREW W. HAKIN, ROBERT M. MCKAY, and KATHRYN E. PREUSS. Can. J. Chem. **72**, 1489 (1994).

Densities and volumetric heat capacities have been measured for aqueous solutions of L-valine, L-leucine, and L-isoleucine at 288.15, 298.15, 313.15, and 328.15 K. These data have been used to calculate apparent molar volumes, $V_{2,\phi}$, and apparent molar heat capacities, $C_{p,2,\phi}$, which in turn have been used to obtain standard state volumes, $\bar{V}_2^0$, and standard state heat capacities, $\bar{C}_{p,2}^0$, for each aqueous amino acid system. Helgeson, Kirkham, and Flowers equations, for neutral organics in water, have been used to model the calculated standard state volumes and heat capacities of the amino acids as a function of temperature at constant pressure. The results of our fitting procedures may be used to predict the behaviour of $\bar{V}_2^0$ and $\bar{C}_{p,2}^0$ for the selected amino acid systems outside of the temperature range utilised in this investigation.

MICHELLE M. DUKE, ANDREW W. HAKIN, ROBERT M. MCKAY, et KATHRYN E. PREUSS. Can. J. Chem. **72**, 1489 (1994).

On a mesuré les densités et la capacités calorifiques volumétriques de solutions aqueuses de L-valine, de L-leucine, et de L-isoleucine, à 288,15, 298,15, 313,15, et 328,15 K. On a utilisé ces données pour calculer les volumes molaires apparents, $V_{2,\phi}$, ainsi que les capacités calorifiques molaires apparentes, $C_{p,2,\phi}$, qui ont été utilisées à leur tour pour déterminer les volumes de l'état de référence, $\bar{V}_2^0$, ainsi que les capacités calorifiques de l'état de référence, $\bar{V}_{p,2}^0$, de chaque système aquence d'acide aminé. On a utilisé les équations de Helgeson, Kirkham et Flowers, développées pour les composés organiques neutres dans l'eau, comme modèle des volumes et des capacités calorifiques calculés de l'état de référence des acides aminés en fonction de la température, à pression constante. On peut utiliser les résultats de nos procédures d'ajustement pour prédire le comportement des valeurs de $V_{2,\phi}^0$ et $C_{p,2,\phi}$ de systèmes d'acides aminés choisis à des températures à l'extérieur de la plage utilisée dans notre étude.

[Traduit par la Rédaction]

Introduction

The thermodynamic properties of aqueous amino acid systems have been investigated by several authors (1–7). Many previous investigators restricted their attention to ambient temperature and pressure conditions, 298.15 K and 1 atm. However, currently there is considerable interest in extending the temperature and pressure range of thermodynamic data for amino acid systems (7–10). Shock has recently applied semi-empirical modelling procedures to aqueous amino acid systems to yield estimates of thermodynamic properties up to 1000°C and 5 kbar (1 bar = 1000 000 Pa). These data are some of the essential building blocks that must be used in order to comprehend the documented existence of high temperature and pressure life forms (8).

Many of the Helgeson, Kirkham, and Flowers (HKF) equations for estimating standard state volumes and heat capacities of neutral organic species in aqueous solution are constructed using thermodynamic data collected at 298.15 K and 1 atm. To increase the accuracy and utility of these models we have collected density and volumetric heat capacity data for L-valine, L-leucine, and L-isoleucine in water at 288.15, 298.15, 313.15, and 328.15 K. These data have been used to calculate apparent molar volumes and heat capacities, which in turn have been used to calculate standard state volumes and heat capacities for each aqueous amino acid system as a function of temperature. The temperature dependencies of the standard state properties have been modelled using constant pressure variants of revised HKF equations for neutral organic species in water.

Experimental

L-Valine (99 + %), and L-leucine (99 + %), and L-isoleucine (99 + %), were obtained from Sigma Chemicals Limited. The acids were purified by repeated recrystallisation from water and were dried and stored over phosphorus pentoxide in a vacuum oven set at 50°C. The NMR spectra of the amino acids were obtained on a Brüker 250 MHz instrument using D_2O as an internal standard. The recorded spectra were in excellent agreement with the reference spectra (11).

All solutions were prepared by weight on the molality concentration scale using bi-distilled, degassed water. Solutions were stored in sealable 125 mL Nalgene bottles.

Densities were measured relative to water with a Sodev O2D vibrating tube, flow densitometer (12). This experimental apparatus routinely measures densities with part per million precision. Volumetric heat capacities were measured relative to water using a Picker flow microcalorimeter (13).

Details of the densitometer, the flow microcalorimeter, and the procedures used in their calibrations have been described previously (7, 14).

Results and discussion

Densities at 288.15, 298.15, 313.15, and 328.15 K for solutions of L-valine, L-leucine, and L-isoleucine in water are reported in Tables 1, 2, and 3, respectively. Apparent molar volumes, $V_{2,\phi}$, were calculated from these data using the equation:

$$[1] \qquad V_{2,\phi} = \left[\frac{M}{\rho}\right] - \left[\frac{\rho - \rho_1^0}{m\rho\rho_1^0}\right]$$

were m is the molality of the solution, M is the molecular weight of the solute, ρ_1^0 is the density of pure water at the temperature of interest (15), and ρ is the density of the solution under study. Calculated apparent molar volumes are reported for L-valine, L-leucine, and L-isoleucine in Tables 1, 2, and 3, respectively.

Specific heat capacity data for L-valine, L-leucine, and L-isoleucine in water were calculated from volumetric heat ca-

[a]Estimated uncertainties for $V_{2,\phi}$ and $C_{p,2,\phi}$ in parentheses.

pacity data at each temperature investigated. Apparent molar heat capacities, $C_{p,2,\phi}$, were calculated from specific heat data using eq. [2]:

$$[2] \qquad C_{p,2,\phi} = Mc_p + \frac{(c_p - c^0_{p,1})}{m}$$

were c_p is the specific heat capacity of the solution, and $c^0_{p,1}$ is the specific heat capacity of pure water at the temperature of interest (16). Apparent molar heat capacity data as a function of temperature are also contained in Tables 1, 2, and 3.

Procedures for estimating the uncertainties in apparent molar volumes, $\delta V_{2,\phi}$, and apparent molar heat capacities, $\delta C_{p,2,\phi}$, have been described previously (7, 17).

The apparent molar properties of the aqueous amino acid systems were found to be well represented by the linear equation:

$$[3] \qquad Y_{2,\phi} = \bar{Y}^0_2 + S_Y m$$

where Y represents the extensive thermodynamic property of interest, Y^0_2 is the value of $Y_{2,\phi}$ at infinite dilution, m is the molality of the solution, and S_Y is the experimental slope. The appropriate form of eq. [3] was fitted to our calculated $V_{2,\phi}$, and $C_{p,2,\phi}$ data using weighted linear least-squares regression analyses. Weights used in these analyses were calculated as the reciprocals of the square in the uncertainties in the apparent molar volumes and heat capacities.

Calculated standard state (infinite dilution) volumes, $\bar{V}^0_2$, and heat capacities, $\bar{C}^0_{p,2}$, are reported and compared to available literature data in Table 4. A review of this table indicates that our calculated standard state volume and heat capacity data are in very good agreement with those available in the literature. Unfortunately, we were unable to locate literature standard state data for the investigated amino acid systems at temperatures removed from 298.15 K.

Side chain contributions of amino acids to standard state volumes and heat capacities (1) can be calculated using the relationship:

$$[4] \qquad \bar{Y}^0_2(\text{R}) = \bar{Y}^0_2(\text{amino acid}) - \bar{Y}^0_2(\text{glycine})$$

[a]Estimated uncertainties for $V_{2,\phi}$ and $C_{p,2,\phi}$ in parentheses.

where $\bar{Y}_2^0$ (R) defines the side chain contribution of the amino acid relative to the C—H group of glycine. Combining standard state data from this investigation with those we have published previously (7) allows us to look at the temperature dependence of side chain contributions for L-alanine, L-serine, L-threonine, L-valine, L-leucine, and L-isoleucine. Standard state volume and heat capacity side chain contributions are shown as functions of temperature in Figs. 1 and 2, respectively.

Looking first at Fig. 2, it is clear that at any given temperature the magnitude of $\bar{C}_{p,2}^0$ (R) increases with increasing alkyl chain length (1). The interaction of alkyl groups with water is hydrophobic in nature i.e., the alkyl side chains have a structure promoting effect on the solvent, water. With increasing temperature, we observe decreasing $\bar{C}_{p,2}^0$ (R) values for L-alanine, L-valine, L-leucine, and L-isoleucine. This observation is expected, for as the temperature increases the extent of hydrogen bonding within the solvent decreases. In other words, the degree of ordering within the solvent decreases which has the effect of reducing the capacity of the structuring effect caused by the hydrophobic hydration of the alkyl groups of the amino acid side chains. L-Serine and L-threonine are distinct from the other aliphatic amino acids. An increase in $\bar{C}_{p,2}^0$ (R) as a function of temperature for these compounds appears

to indicate that hydrophilic hydration may play a role in their overall solution behaviour. For L-serine the increase in $\bar{C}_{p,2}^0$ (R) up to approximately 313.15 K indicates that hydrophilic hydration may be dominant for this particular side chain in water. For L-threonine, although the polar —OH group is expected to affect neighbouring water molecules, it is envisaged that the overall solution behaviour of the species will be determined predominantly by the interaction of the alkyl groups within the side chain with water.

Turning to Fig. 1, we observe increasing values for $\bar{V}_2^0$ (R) with increasing temperature. This observation reinforces our interpretation of the trends shown in Fig. 2, i.e., as the temperature increases the hydrophobic character of the alkyl groups on the amino acid side chains decreases. A more detailed look at $\bar{V}_2^0$ (R) values for L-alanine reveals that they are approximately independent of temperature. We are unable to explain this trend. However, we note the comments of previous authors (1) who have stated that the interpretation of standard state volumes in terms of solution structure is a more difficult proposition that the interpretation of standard state heat capac-

ity data. This is because a strict interpretation of standard state volume data demands that one considers the contributions of several components (21–23).

To obtain information on the stability of aqueous amino acid systems at elevated temperatures and pressures, one requires values of apparent standard molar Gibbs free energies. These data can be calculated for a given amino acid system, at the temperature and pressure of interest, provided one has suitable equations of state for the temperature and pressure dependencies of the standard state volume and heat capacity of the system. These equations of state are well represented by the revised HKF equations for neutral organics in water reported by Shock and Helgeson (10). The equations are defined by:

$$[5] \qquad \bar{V}_2^0 = a_1 + \frac{a_2}{\Psi + P} + \left(a_3 + \frac{a_4}{\Psi + P}\right)\left(\frac{1}{T - \theta}\right) - \omega_e Q$$

$$[6] \qquad \bar{C}_{p,2}^0 = c_1 + \frac{c_2}{(T-\theta)^2} - \left(\frac{2T}{(T-\theta)^3}\right)\left[a_3(P - P_r) + a_4 \ln\left(\frac{\Psi + P}{\Psi + P_r}\right)\right] + \omega_e T X$$

where a_1, a_2, a_3, a_4, c_1, and c_2 are species-dependent parameters; θ and Ψ represent solvent-dependent parameters. T, P, and P_r represent the temperature and pressure of interest and the reference pressure (1 bar), respectively. ω_e defines the effective Born coefficient for the neutral organic aqueous species of interest. This coefficient is assumed to be independent of temperature and pressure.

The revised HKF equations are comprised of two components; the solvation contributions defined by $-\omega_e Q$ and $\omega_e TX$, respectively, and the structural contributions represented by the remainder of the base equations. The Q and X parameters of the solvation contributions are defined using the temperature and pressure dependencies of the dielectric constant of water (8, 20).

At constant pressure, eq. [5] may be reduced to:

$$[7] \qquad \bar{V}_2^0 = \sigma + \frac{\xi}{T - \theta} - \omega_e Q$$

were σ and ξ are fitting parameters.

In a similar manner eq. [6] is simplified, under the constant pressure condition of $P = P_r$, to the form:

$$[8] \qquad \bar{C}_{p,2}^0 = c_1 + \frac{c_2}{(T-\theta)^2} + \omega_e T X$$

Regression analyses have been used to fit eqs. [7] and [8] to calculated standard state volumes and heat capacities for each amino acid system. Values for Q and X at the reference pressure, P_r, were calculated from a BASIC computer program that was constructed using the procedures outlined by Helgeson and Kirkham (18, 19). Values for the effective Born coefficients of the amino acids were obtained from the compilations reported in ref. 10. To remain consistent with the Shock and Helgeson analyses, the solvent parameter θ was given a value of 228 K in all of our fitting procedures. Calculated values for σ, ξ, c_1, and c_2 are reported in Table 5.

Figures 3 and 4 compare the temperature dependencies of calculated structural contributions to standard state volumes

TABLE 5. Calculated parameters to eqs. [7] and [8] for aqueous solutions of L-valine, L-leucine, and L-isoleucine

Amino acid	σ (cm^3 mol^{-1})	ξ (cm^3 K mol^{-1})	$\omega_e \times 10^{-5}$ [a] (J mol^{-1})
L-Valine	94.89	−343.02	−1.27653
L-Leucine	113.27	−466.46	−1.84054
L-Isoleucine	110.90	−442.07	−1.92297

Amino acid	c_1 (J K^{-1} mol^{-1})	c_2 (J K mol^{-1})	$\omega_e \times 10^{-5}$ [a] (J mol^{-1})
L-Valine	327.17	-1.6216×10^5	−1.27653
L-Leucine	405.30	-1.2270×10^5	−1.84054
L-Isoleucine	392.93	-1.3525×10^5	−1.92297

[a]Data obtained from ref. 10.

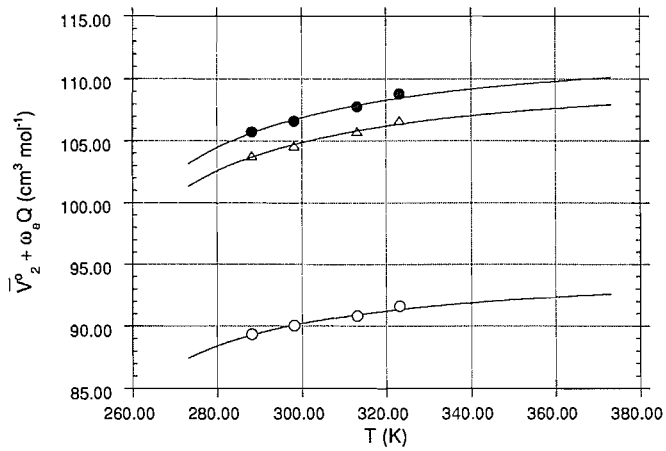

FIG. 3. Structural contributions to standard state volumes versus temperature for ○ L-valine, ● L-leucine, △ L-isoleucine in water. The solid curves represent fits of the revised HKF constant pressure equation, eq. [7], to the calculated structural contributions of the standard state volumes.

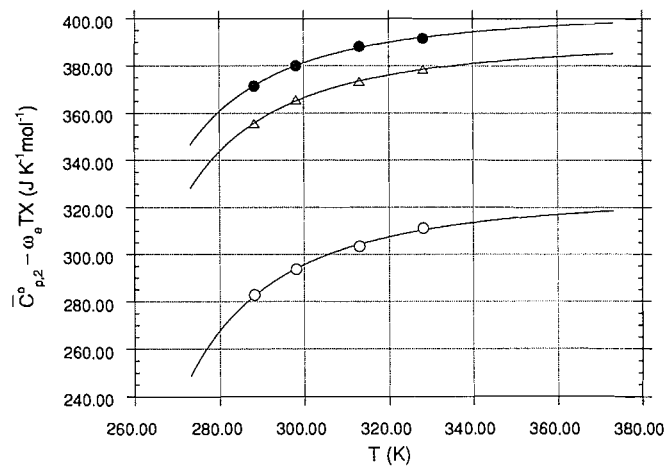

FIG. 4. Structural contributions to standard state heat capacities versus temperature for ○ L-valine, ● L-leucine, △ L-isoleucine in water. The solid curves represent fits of the revised HKF constant pressure equation, eq. [8], to the calculated structural contributions of the standard state heat capacities.

and heat capacities to those which can be estimated using the revised HKF constant pressure equations. The data calculated using the HKF equations are denoted using solid curves. Inspection of Figs. 3 and 4 indicates that the standard state volume and heat capacity data for the amino acids have characteristic profiles. Because these profiles define the structural contributions to the standard state properties one should be able to analyse these data using a group additivity type analysis. The limited information which one can obtain from side chain group analyses, of the type presented in this paper, clearly indicates the requirement for a detailed group additivity scheme.

Our aim is to use group contributions to standard state volumes and heat capacities of amino acids as a function of temperature to predict the temperature dependencies of standard state volumes and heat capacities of various aqueous peptide systems. Only very limited data are available in the literature for such systems. At present we have not analysed sufficient amino acid systems to amass the volumetric and thermochemical data sets required to perform such analyses, however this work is in progress.

FT-IR spectroscopy was used to study the conformation of the porcine neuropeptide galanin, fragments 1–16 of the porcine and human peptides and the antagonists M15 and M35. All peptides were shown to be structureless in aqueous solution. Upon addition to SDS micelles, only porcine galanin and the fragment consisting of amino acids 1–16 showed any evidence of interaction, adopting a helical structure. No interaction could be demonstrated with zwitterionic lipids for any peptide except M15 which formed a thermally unstable helical conformation which unfolded promoting aggregation at around 45°C.

Additional studies on rat galanin in various solvent systems were made by using circular dichroism spectroscopy. The results obtained support the observations made by FT-IR spectroscopy.

ANDERS B.A. WENNERBERG, MICHAEL JACKSON, ANDERS ÖHMAN, ASTRID GRÄSLUND, ÜLO LANGEL, TAMAS BARTFAI, RUDOLF RIGLER et HENRY H. MANTSCH. Can. J. Chem. **72**, 1495 (1994).

On a utilisé la spectroscopie IR par FT pour étudier la conformation du neuropeptide de porc, galanine, des fragments 1–16 des peptides humain et de proc et les antagonistes M15 et M35. On a montré que, en solutions aqueuses, tous les peptides sont sans structure. Par addition de micelles SDS, seule la galanine de porc et le fragment comportant les acides aminés 1–16 ont présenté des signes d'interaction en adoptant une structure hélicoïdale. Aucun des lipides zwitterioniques, à l'exception du M15 que donne une conformation hélicoïdale thermiquement instable et qui se défait avec une promotion de l'agrégation autour de 45°C, ne démontre d'interaction.

Faisant appel au dichroïsme circulaire, on a fait des études supplémentaires sur la galanine de rat dans divers systèmes. Les résultats obtenus confirment les observations faible à l'aide de l'IR par FT.

[Traduit par la rédaction]

Introduction

Galanin is a 29 amino acid neuropeptide initially isolated from the small intestine of the pig (1) and since located in various parts of the central and peripheral nervous system (2), including neurons in the respiratory, gastrointestinal and urogenital tracts, adrenal medulla and pancreas. The amino acid sequences of rat, pig, and human galanin (1) have been determined (Table 1). The first 15 residues are absolutely conserved in all species and receptor affinity has been correlated with this sequence. In particular, tryptophan in position 2 is crucial for receptor binding (3). All galanins, with the exception of the human isoform, are secreted as C-terminal amides. As the sequences bear no homology to any other family of neuropeptides, it appears that galanin is the first member of a new family of neuropeptides.

The physiological effects of galanin are diverse and vary with species. Depending upon species, galanin may modulate the physiological effects of growth hormone, insulin, glucagon, prolactin, somatostatin, and dopamine (4). Evidence exists that galanin functions as a neurotransmitter in the pancreas in some animals, with a possible role in the neural regulation of islet function as part of the metabolic response to stress (5). There are indications that the inhibitory effect of galanin on insulin secretion results from an action of the peptide on K^+ channels and indirectly, on Ca^{2+} channels within the β-cells (6). In addition, galanin is an effective inhibitor of substance P. Biochemical characterization of the galanin receptor shows that it is a glycoprotein of 54 kDa belonging to the G-protein coupled class of receptors (7). The involvement of a G-protein in galanin-mediated insulin suppression has been suggested (8).

The widespread physiological effects of galanin have stimulated interest in the preparation of pharmacologically useful derivatives, particularly given its possible use in pain modulation due to its antagonism of substance P (3). Such an undertaking will be greatly facilitated by an understanding of the relationship between galanin structure and function. Infrared and circular dichroism spectroscopy are valuable tools for obtaining semi-quantitative information concerning the secondary structure of proteins and peptides in solution. We have used these techniques to assess the conformation of rat and porcine galanin, the first 16 amino acids of porcine and human galanin as C-terminal acids as well as that of analogues composed of the first 13 amino acids of galanin and either the final 7 amino acids from the substance P sequence (M15) or the final 8 amino acids from the bradykinin sequence (M35) as C-terminal amides in aqueous solution. The amphipathic nature of galanin suggests the possibility of interaction with membranes. In addition, we have therefore studied the interaction of galanin with model membrane systems to assess the nature of any conformational changes induced upon interaction with membranes.

Experimental

Materials

Galanin and its analogues (see Table 1) were synthesized by solid phase synthesis or purchased from Sigma (St. Louis, MO). The purity of synthetic peptides was determined by HPLC chromatography and the amino acid sequence confirmed. Sodium dodecyl sulfate (SDS) was purchased from BDH Ltd (Poole, England), 2,2,2-Trifluoroethanol (TFE) from E. Merck (Darmstadt, Germany), and 1,1,1,3,3,3-hexafluoro-2-propanol (HFP) from Sigma. The lipids 1,2-dioleoyl-sn-glycero-3-phosphocholine (DOPC) and 1,2-dioleoyl-sn-glycero-3-phosphoglycerol (DOPG) were obtained either from Sigma or Avanti Polar Lipids (Pelham, AL).

Methods

FT-IR studies. Peptide samples in aqueous solution were prepared by dissolution of the peptide in TRIS buffered saline (50 mM TRIS, 150 mM NaCl, pD 7.6: TBS) to a final concentration of 10 mg/mL. Liposomes were prepared by sonication of lipids in the appropriate buffer and liposome suspensions added to the required amount of peptide to yield a lipid-to-protein ratio of 50:1 and a final peptide concentration of 10 mg/mL. Spectra were recorded on a Digilab FTS-60 Fourier transform infrared spectrometer equipped with a liquid-nitrogen cooled mercury–cadmium–telluride detector and continuously purged with dry nitrogen. Approximately 3 μL of sample was placed between a pair of CaF_2 windows separated by a 50 μm Mylar spacer and mounted in a Harrick demountable cell. Temperature was maintained by a circulating water bath. For each sample 100 interferograms were recorded, co-added, and Fourier transformed to generate a spectrum of resolution 2 cm^{-1}. Buffer spectra were recorded under identical conditions and interactively subtracted from sample spectra. Residual water vapour was interactively subtracted. All spectra were subjected to Fourier self-deconvolution performed as described previously (9) using a half width of 13.5 cm^{-1} and a resolution enhancement factor $k = 1.7$.

CD-studies. Rat galanin solutions with a concentration of approximately 25 μM were titrated with SDS and phospholipid vesicle solutions prepared from DOPC and DOPG. In the titration with SDS a 10 mM phosphate buffer (pH = 7.0) was used, in all other cases water was used. CD-spectra of the peptide were recorded in solvents with 0, 1, 2, 5, 10, and 20 mM SDS and with 0, 0.025, 0.05, 0.1, 0.2, 0.5, 1.0, and 2.0 mg/mL of vesicle solution. CD-spectra of the peptide in 100% TFE and 100% HFP were also recorded. CD-spectra were recorded using a Jasco-720 spectropolarimeter with 2 mm Hellma quartz cuvettes at a temperature of 25°C. A resolution of 0.5 nm and a scan speed of 10 nm per min were used. The acquired spectra were the average of three continuous scans, usually measured between 185 and 250 nm, and corrected with respect to baseline and for dilution. Quantitative evaluation of CD spectra is dependent upon a knowledge of the extinction coefficient of the peptide. This parameter was determined for galanin, dissolved in water, by quantitation of the peptide using amino acid analysis and light absorption spectroscopy and yielded a value of $\epsilon_{278} = 6620\ M^{-1}\ cm^{-1}$.

Results and discussion

The FT-IR spectrum of porcine galanin in TBS buffer (pD 7.6) is shown in Fig. 1. The amide I mode, predominantly (80%) a C=O stretching vibration, gives rise to a broad band centered at 1646 cm^{-1}. Such a position is characteristic of proteins and peptides which have little or no repetitive secondary structure, generally referred to as a "random" conformation (assignments

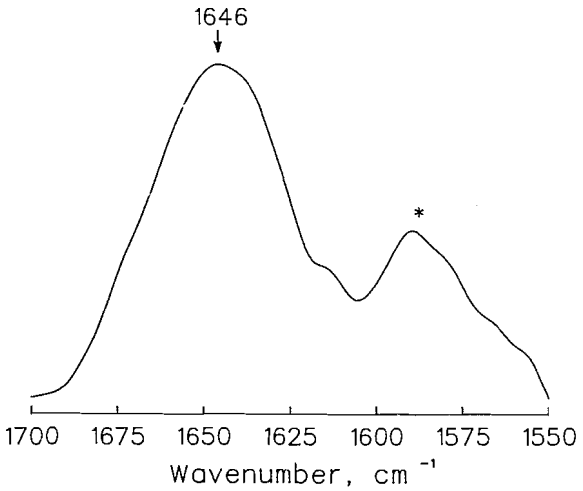

FIG. 1. Infrared spectrum of porcine galanin in TBS buffer, pD 7.6 in the spectral region 1550–1700 cm^{-1}.

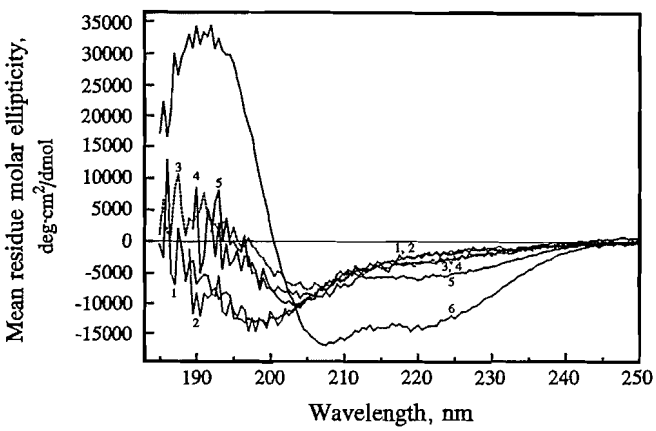

FIG. 2. Circular dichroism spectra of rat galanin at 25°C in pure water (*1*), in water containing 0.1 mg/mL DOPC (*2*), 10 mM SDS and 10 mM phosphate (*3*), 0.1 mg/mL DOPG (*4*), and in 100% HFP (*5*), or 100% TFE (*6*).

in this work are based on refs. 10–12). Useful structural information can also be obtained from the amide II mode, predominantly attributed to N—H bending vibrations, which gives rise to absorptions in the frequency range 1520 to 1560 cm^{-1}. The amide II mode is highly sensitive to the strength of hydrogen bonds involving the amide N—H groups, strong hydrogen bonds restricting the bending vibration and increasing the amide II frequency. In addition, upon dissolution in ^2H_2O, exchange of amide protons for solvent deuterons shifts the amide II band lower in frequency by approximately 100 cm^{-1}. The disappearance rate of the amide II band can therefore be a useful indicator of the degree of solvent exposure and the strength of any hydrogen bonds present, a high degree of solvent exposure and weak hydrogen bonds facilitating exchange. When galanin is dissolved in deuterated buffer the amide II band completely disappears, suggesting little if any hydrogen bonding involving the amide groups and a high degree of solvent exposure. Thus, analysis of both the amide I and the amide II bands suggests that galanin is unordered in aqueous solution. Circular dichroism spectra (Fig. 2) of rat galanin in aqueous solution are also indicative of a peptide with little or no long range order. The apparent lack of long range order in galanin is not surprising considering the high number of positive charges

TABLE 2. Percentages of α-helical structure of rat galanin as evaluated from CD spectra in pure water, in water containing 0.1 mg/mL DOPC, 0.1 mg/mL DOPG or 10 mM SDS as well as in pure hexafuropropanol and pure trifluoroethanol

carried by the peptide, charge repulsion preventing folding into a more compact and energetically favorable conformation.

The spectral features in the frequency range 1560–1620 cm^{-1} arise from amino acid side chain vibrations (tyrosine, tryptophan, arginine, and aspartate). The absorption at 1590 cm^{-1} from arginine (marked with an asterisk) is particularly prominent.

Similar results were obtained from fragments 1–16 of human and porcine galanin as well as from the two analogues M15 and M35 (spectra not shown).

While the structure of a biological peptide in solution is important, it does not necessarily reflect the active conformation of the peptide. It is possible that unstructured peptides must in fact be induced to adopt an active, folded conformation. This may be achieved by structural rearrangements upon interaction with a recognition site. This recognition site may be part of an integral membrane protein (receptor) or the lipid bilayer of the cell membrane. To assess any conformational changes which may occur in the presence of membranes we recorded CD and IR spectra in a range of membrane mimetic environments.

Organic solvents are often used as membrane mimetic agents, usually to avoid the problems inherent in studying membrane suspensions with such techniques as NMR spectroscopy. The most commonly used organic solvent for such purposes is trifluoroethanol. It has been suggested that TFE provides a "helix-stabilizing" medium, stabilizing helical structures in polypeptide strands which have helix-forming propensity (13).

It has been shown by NMR spectroscopy (14) that rat galanin adopts a helical structure in TFE solution but not in aqueous solution. In agreement with this finding CD spectra (Fig. 2) of rat galanin in TFE are indicative of the presence of significant proportions of α-helical secondary structure. If we assume that the peptide chain contains only unordered and α-helical secondary structures (there is no evidence from CD or NMR spectra to suggest the presence of β-sheet structures) the amplitude at 222 nm can be used to determine the relative fraction of either (15, 16). From the spectra in Fig. 2 the percentages of α-helical structure in a variety of environments could be calculated (see Table 2). The highest proportion of helical secondary structure was found in TFE, followed by hexafluoropropanol. Only minor differences in ellipticity at 222 nm are seen between spectra in pure H_2O and those measured in the presence of SDS, DOPG, and DOPC.

The FT-IR spectrum of porcine galanin in TFE is shown in Fig. 3. Following deconvolution the amide I maximum is observed at 1658 cm^{-1}, a position indicative of the adoption of helical structure. The other analogues of galanin studied here

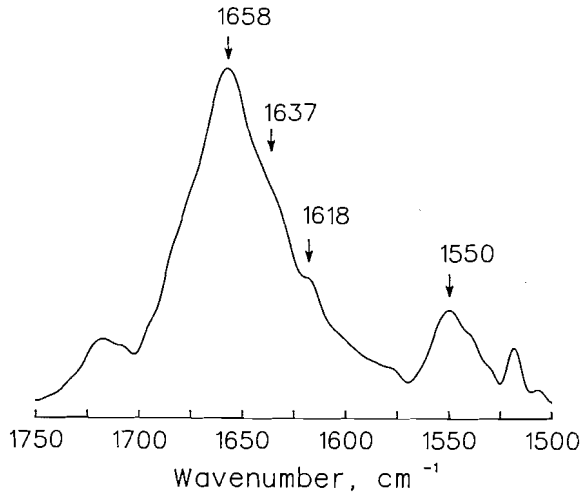

FIG. 3. Infrared spectrum of porcine galanin dissolved in TFE in the 1500–1750 cm^{-1} region.

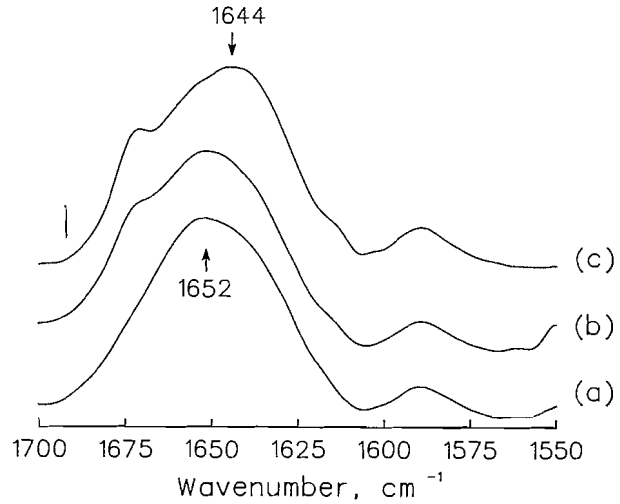

FIG. 4. Comparison of the infrared spectrum of porcine galanin (*a*) with porcine galanin fragment 1-16 (*b*) and human galanin fragment 1-16 (*c*), all in TBS buffer, pD 7.6 containing 5% SDS.

also adopted helical structures in TFE solution (spectra not shown). The frequency and small halfwidth of the amide I band suggest that helical structures are present in significant proportions (>75%). In addition, the position of the amide II band at 1550 cm^{-1} is also suggestive of significant helical structure. This result conflicts with the quantitative determination of the percentage of helices in galanin in TFE obtained from the CD data. This discrepancy may be related to the fact that in the CD calculations extinction coefficients obtained for helical and unordered polypeptide chains in aqueous solution were used for data obtained in organic solvents.

The presence of significant proportions of helical structures in peptides in TFE is often taken to indicate that the peptide is capable of adopting a helical secondary structure within the hydrophobic core of lipid membranes, i.e., is a reliable measure of its propensity to form helical secondary structures. However, we recently undertook a FT-IR spectroscopic examination of the effects of halogenated alcohols on the secondary structure of a variety of proteins and polypeptides (17). Each protein studied, whether it be predominantly helical, β-sheet or structureless in aqueous solution exhibited an amide I maximum at 1657 cm^{-1}. The adoption of helical secondary structures by peptide chains in TFE solution appears therefore to be the result of properties of TFE rather than any intrinsic properties of the polypeptide chain. Results obtained from studies of peptide conformation in halogenated alcohols should be treated with caution.

The weak absorption at 1618 cm^{-1} arises from tyrosine side chain vibrations. The additional feature in Fig. 3, at 1637 cm^{-1}, may have four possible origins. Firstly, it may be attributed to β-sheet structures. This is, however, unlikely, as preliminary NMR spectroscopic data show no resonances attributable to β-sheet in TFE solution (18). Secondly, a weak feature at 1637 cm^{-1} may be attributed to bound water present in the hygroscopic TFE (unpublished observations, M.J. H.M.). Thirdly, this feature may reflect hydrogen bonding of TFE to amide C=O groups. Finally, it may reflect the presence of β-turns. At present it is not possible to distinguish between the last three possibilities.

Another feature is apparent in spectra of galanin at around 1720 cm^{-1} in TFE solution (Fig. 3). This may be attributed to absorptions arising from the protonated COOH groups of aspartic acid residues present in galanin. The appearance of infrared bands arising from the protonated form of carboxylic acid side chains is a feature which we have consistently noted in spectra of proteins in TFE solution, which can be related to the acidic nature of this solvent. The relatively low frequency of the carbonyl absorption suggests that they are involved in hydrogen bonds, presumably with TFE. Protonation of and hydrogen bonding to side chains by TFE may be expected to have important structural consequences. Again, this illustrates the care with which data obtained for peptides in TFE solution should be treated.

More realistic attempts to study the interactions of peptides with membranes require the use of liposome or micellar systems. As galanin carries a net positive charge, any interaction would be expected to be specific for negatively charged liposomes or micelles. The spectrum of porcine galanin in the presence of 5% SDS is shown in Fig. 4*a*. The amide I maximum under these conditions is seen at 1652 cm^{-1}. Such an absorption in deuterated buffers is characteristic of peptides which have a helical structure. However, significant disorder in peptide chains is still present as evidenced by the large halfwidth of the amide I band (indicating a high degree of motional freedom of amide C=O groups) and the occurrence of a shoulder on the amide I band at 1644 cm^{-1}. This small increase in helical content agrees well with our CD results. The adoption of a partial α-helical structure is presumably the result of the neutralization of the positive charge on the peptide chain by the negatively charged sulphate headgroups. Porcine fragment 1–16 could also be shown to interact with SDS in a similar manner, resulting in the formation of a similar proportion of helical secondary structures (Fig. 4*b*). Rather surprisingly, the human galanin fragment 1–16 showed no interaction with SDS. This difference between the human and porcine fragments is difficult to rationalise considering the minor differences in sequence between the two peptides (porcine Ile16 to human Val16). The additional feature at 1672 cm^{-1} arises from the trifluoroacetate counterion commonly bound to synthetic peptides. In the presence of SDS, M35 and M15 exhibited spectra similar to those seen in aqueous solution.

Addition of porcine galanin, human or porcine fragments 1–16 and M35 to suspensions of the zwitterionic lipid DHPC

Can. J. Chem. Downloaded from www.nrcresearchpress.com by EESC ESCOLA DE ENGENHARIA on 09/08/12
For personal use only.

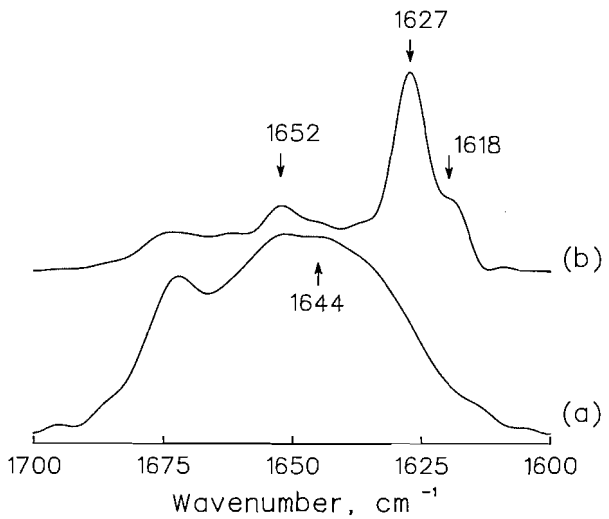

FIG. 5. FT-IR spectra in the amide I region of M15 in the presence at DHPC at 20°C (*a*) and 45°C (*b*).

resulted in spectra identical to those seen in aqueous solution, in agreement with our CD results obtained for rat galanin in the presence of DOPC. An amide I maximum centered at 1646 cm^{-1} (similar to that seen in Fig. 1) indicated that no interaction had occurred between the peptide and the lipid bilayer. On the other hand, the galanin antagonist M15 exhibited a weak band at 1652 cm^{-1} (in addition to the major band at 1644 cm^{-1}) in the presence of DHPC, indicative of the appearance of some helical structure (Fig. 5*a*). This may be attributed to the high content of hydrophobic amino acids in the sequence, which will favour penetration of the peptide into the hydrophobic bilayer core. Again, the band at 1672 cm^{-1} arises from trifluoroacetate contamination. Elevation of the temperature to 45°C (Fig. 5*b*) resulted in the appearance of a new band at 1627 cm^{-1}. This strong feature, typical of proteins which are aggregated following thermal or solvent denaturation (18), arises from the formation of intermolecular hydrogen bonds between amide C═O and N—H groups of peptide chains. Thermal denaturation of the peptide at the relatively low temperature of 45°C suggests that the membrane induced α-helix is unstable. In addition to the intense amide I band at 1627 cm^{-1} a weaker feature at 1618 cm^{-1} is apparent, a position similar to that seen for the side chain vibrations of tyrosine. However, the intensity of this absorption is greater than would be expected for a peptide of this size containing a single tyrosine residue. The additional intensity may be attributed to absorptions arising from a second class of intermolecular hydrogen bonds formed between peptide chains. The much lower frequency associated with this class of intermolecular hydrogen bonds indicates that it is extremely strong, suggesting close alignment of aggregated chains. The presence of two amide I bands indicative of aggregation is not unusual, and has been demonstrated for other biologically active peptides including magainins (19) and substance P (20).

In conclusion, studies such as that presented here highlight the utility of spectroscopic techniques in comparing the structural properties of biological peptides and their analogues, possibly as a first step in general screening for the design of novel therapeutic agents.

Acknowledgments

Design and synthesis of analogues of ionomycin

THOMAS Q. HU AND LARRY WEILER[1]

Department of Chemistry, University of British Columbia, 2036 Main Mall, Vancouver, BC V6T 1Z1 Canada

Received June 30, 1993[2]

THOMAS Q. HU and LARRY WEILER. Can. J. Chem. **72**, 1500 (1994).

Based on the analysis of the crystal structure of the Ca^{2+} salt of ionomycin and the chemical and physical data on ionomycin, a number of ionomycin analogues have been synthesized to study the structural features affecting the Ca^{2+} binding and transport. Compounds **2**, **3**, and **4** were synthesized to study the effect of additional intramolecular oxygen coordination sites on Ca^{2+} transport. Compounds ***5a–5d*** were prepared to study the effect of lipid solubility on Ca^{2+} binding and transport. Compounds ***6a–6c*** were prepared to study the effect of the distance between the β-diketone and the carboxyl group on Ca^{2+} transport. A general synthetic route to these compounds has been developed. The key reactions in this route are the consecutive regioselective alkylations of the dianion of 2,4-pentanedione with the appropriate bromides.

THOMAS Q. HU et LARRY WEILER. Can. J. Chem. **72**, 1500 (1994).

En se basant sur une analyse de la structure cristalline du sel de Ca^{2+} de l'ionomycine et sur les données chimiques et physiques de l'ionomycine, on a synthétisé une série d'analogues de l'ionomycine dans le but d'étudier leurs caractéristiques structurales affectant leur liaison au Ca^{2+} et son transport. On a synthétisé les composés **2**, **3** et **4** pour étudier l'effet d'une augmentation des sites intramoléculaires de coordination de l'oxygène sur le transport du Ca^{2+}. On a préparé les composés ***5a–5d*** pour étudier l'effet de la solubilité lipidique sur la liaison avec le Ca^{2+} et sur son transport. On a préparé les composés ***6a–6c*** pour étudier l'effet de la distance entre la β-dicétone et le groupe carboxyle sur le transport du Ca^{2+}. On a mis au point une méthode générale de synthèse de ces composés. Les réactions clés de cette voie sont les alcoylations régiosélectives consécutives du dianion de la pentane-2,4-dione avec les bromures appropriés.

Introduction

Ionomycin (**1**) is a polyether calcium ionophore isolated from a strain of *Streptomyces conglobatus* (1). Its molecular structure was determined by Toeplitz et al. using ^1H NMR spectroscopy, mass spectrometry, and X-ray crystallographic analysis of three crystalline forms of its cadmium and calcium salts (2).

Like other polyether Ca^{2+} ionophores, ionomycin has been found to be a potent antimicrobial agent. It is active against Gram-positive bacteria with no demonstrable effect against Gram-negative bacteria. However, ionomycin was found to have unusual physical, chemical and biological properties. It possesses a β-diketo group that, together with the carboxyl group, confers dibasic character to the ionophore. It has a very high affinity for Ca^{2+} and other divalent cations. In fact, the calcium salt of ionomycin was extracted from an aqueous solution of pH 12 that had been made alkaline with sodium hydroxide (3).

Ionomycin is unique among the polyether ionophores in that it forms a neutral 1:1 Ca^{2+} salt (2). As shown in the crystal structure of this Ca^{2+} salt of ionomycin (Fig. 1), the carboxylate group, the enolate of the β-diketone, two hydroxyl groups, and a tetrahydrofuranyl oxygen form an octahedral complex around the Ca^{2+}. The ligand wraps around the Ca^{2+} ion with the oxygen atoms directed towards the inside of the sphere. The alkyl groups, on the other hand, protrude from the shell, providing the Ca^{2+} salt with its lipophilic properties.

Liu and Hermann investigated the extraction of Ca^{2+} ions

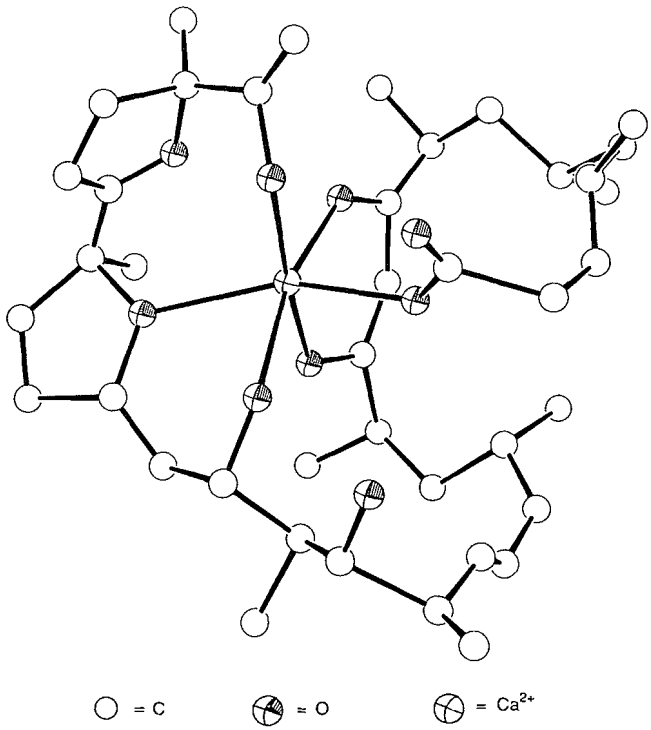

FIG. 1. Crystal structure of the calcium salt of ionomycin (2).

from an aqueous phase into an organic phase and the transport of Ca^{2+} across an organic barrier by ionomycin (4). The selectivity of ionomycin for divalent cations was shown to be $Ca^{2+} > Mg^{2+} \gg Sr^{2+} = Ba^{2+}$. No complexation or transport of monovalent cations by ionomycin could be detected.

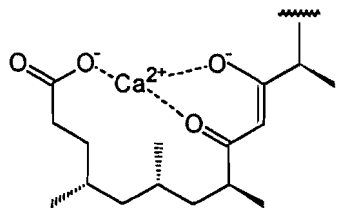
Owing to its ability to selectively bind and transport Ca^{2+} across an organic barrier, ionomycin has been widely used as a tool to investigate the role of calcium ion as a second messenger in biological systems. In studies of rat liver mitochondria, it was shown that ionomycin efficiently catalyzed the exchange of two protons for one Ca^{2+} across the cell membrane (5, 6). Ionomycin has been found to stimulate the release of histamine from mast cells and catecholamine from pheochromocytoma cells by transporting Ca^{2+} across the cell membranes (7). It has also been linked to the activation of human blood platelets by facilitating the transport of Ca^{2+} across the membrane and mobilizing Ca^{2+} stored in organelles (8).

Although the ability of ionomycin to mimic the effects of many physiological cell stimuli has been demonstrated, little is known about the structural features controlling Ca^{2+} binding and transport by ionomycin. This prompted us to design and synthesize a series of simple ionomycin analogues to study the role of the functional groups of ionomycin in Ca^{2+} binding and transport and to study the effect of other structural features, such as lipophilicity and oxygen coordination sites, on Ca^{2+} transport.

Results and discussion

The design of ionomycin analogues was based on the literature data on the mode of action of ionomycin itself. The functional groups thought to be vital to the function of ionomycin would be retained in the synthetic analogues while the numerous stereochemical centers found along the carbon backbone of ionomycin would be omitted to simplify the synthesis of these model compounds. The chemical and physical data on ionomycin suggest that the β-diketone and carboxyl groups are crucial to its ionophoric properties. The crystal structure of the Ca^{2+} salt of ionomycin (Fig. 1) shows that both these groups are ionized and coordinated to the metal cation in the formation of the 1:1 Ca^{2+} salt. It was considered important to retain these two functional groups in the model compounds.

In the natural product, there is a seven-carbon chain separating the β-diketone and the carboxyl groups. The presence of this seven-carbon chain could certainly contribute to the high lipid solubility of the ionophore–Ca^{2+} complex. The distance between these two functional groups is such that a 12-membered ring is formed on chelation of a calcium ion by the carboxylate oxygen and the first oxygen of the β-diketone enolate as shown in **A**. Thus a seven-methylene unit was chosen as the linker for these two functional groups in the initial model compounds.



A

High lipophilicity of the model compounds may be needed for suitable membrane solubility. One of the simplest analogues fulfilling these requirements would be a 9,11-dioxocarboxylic acid such as 9,11-dioxopentadecanoic acid (**2**), which was chosen as one of the first target molecules.

Since one tetrahydrofuranyl and two hydroxyl oxygens of ionomycin are involved in coordination to the Ca^{2+} (Fig. 1), we speculated that it might be necessary to incorporate a side chain that contained appropriately placed oxygen atoms to retain the six Ca^{2+} binding sites found in ionomycin. A side chain that contains an ethylene glycol and an ether function five methylene units away was chosen to mimic the Ca^{2+} coordination sites in ionomycin. An ether function, such as a benzyl ether, could compensate for the decrease of lipophilicity created by the introduction of three oxygen atoms in such a molecule. Therefore, a benzyloxypentyloxyethoxyl unit was incorporated into analogue **2** to give another target analogue, 15-[2-(5-benzyloxy)-pentyloxy]-ethoxy-9,11-dioxopentadecanoic acid (**3**).

The presence of six oxygen coordination sites may not be necessary for binding and transport of Ca^{2+}. A molecule of water from the aqueous medium could occupy a Ca^{2+} coordina-

tion site as is often observed in the binding of Ca^{2+} with proteins and other ionophores such as lasalocid A (9, 10). Thus, it may be sufficient to incorporate a side chain that contains only one or two oxygen atoms as potential Ca^{2+} coordination sites. With this in mind we added a methoxymethoxyl unit to analogue **2** to give the target molecule, 15-methoxymethoxy-9,11-dioxopentadecanoic acid (**4**).

In addition to these three analogues, compounds **5***a*–**5***d* were synthesized as models to study the effect of lipid solubility on Ca^{2+} binding and transport. On the other hand, compounds **6***a*–**6***c*, which should have the same lipid solubility as **5***b* but have a different number of methylene units separating the β-diketone and the carboxyl group, were synthesized to study the effect of the distance between the β-diketone and carboxyl groups on Ca^{2+} binding and transport. Compound **7** possesses only the β-diketo group and was chosen as the final target.

Retrosynthetically, the carboxyl function of each proposed analogue could be made by oxidation of a hydroxyl group. The ether units in analogues **3** and **4** could be prepared using known chemistry (11). Thus the crucial part in the synthesis of the analogues was the introduction of the β-diketone and the construction of the carbon framework. A β-diketone could be prepared by oxidation of a β-hydroxyl ketone, which in turn could be generated by an aldol condensation between a methyl ketone and an aldehyde (eq. [1]). This route was used for the synthesis of the β-diketone in ionomycin (12).

Alternatively, the β-diketone could be generated by alkylation of the anion of a dithiane with an epoxide, followed by oxidation of the hydroxyl group and hydrolysis of the dithiane (eq. [2]). This method was employed in the synthesis of an ionomycin fragment (13).

Either of these two methods could be applied to the synthesis

11

of the proposed analogues of ionomycin. However, neither route appeared to be very efficient for the synthesis of simple, unsubstituted compounds. A logical precursor of a β-diketone appeared to be the simplest β-diketone, the commercially available 2,4-pentanedione. Consecutive alkylation of 2,4-pentanedione at the methyl carbons could be achieved using the dianion chemistry (eq. [3]) (14). Thus we require bromides **8–12** for the synthesis of analogues **2–5**.

The synthesis of bromide **8**, a common intermediate in the preparation of many of the analogues, is illustrated in eq. [4]. Monobromination of 1,7-heptanediol (**13**) was achieved in 72% yield by continuously extracting a mixture of diol **13** and aqueous hydrobromic acid with heptane (15). The hydroxyl group of bromide **14** was protected as its *tert*-butyldimethylsilyl ether (16) to give bromide **8** in 82% yield. Bromide **11** was prepared in good yield by treatment of 3-bromo-1-propanol with phosphorus pentoxide and dimethoxymethane (17).

The synthesis of bromide **10** is outlined in Scheme 1. It started with the monobenzylation of 1,5-pentanediol (**15**) (18). The resulting mono alcohol **16** was subjected to the modified Williamson ether synthesis (19), which involved the vigorous mixing of a two-phase system containing **16**, 1-bromo-2-tetrahydropyranyloxylethane, and aqueous sodium hydroxide in the presence of a phase transfer catalyst, tetrabutylammonium hydrogen sulfate. The reaction gave the desired ether **17** in 83% yield. In contrast, only a small amount of alcohol **16** could be converted to ether **17** when the reaction was carried out using sodium hydride as a base in polar aprotic solvents such as dimethylformamide. The tetrahydropyranyl ether protecting group in **17** was cleaved to give alcohol **18** (20). The alcohol **18** was subjected to a second modified Williamson ether synthesis using 1-bromo-3-*tert*-butyldimethylsilyloxylpropane to give the ether **19**. Deprotection of the TBDMS ether (21) gave alcohol **20**, which was converted to bromide **10** (22) in good yield.

Next we proceeded to carry out the dianion alkylation reactions on 2,4-pentanedione as shown in Scheme 2 for the synthesis of analogue **2**. The dianion of 2,4-pentanedione was reacted with bromide **8** to give the monoalkylated β-diketone **21** in 81% yield.

The structure of the monoalkylated β-diketone **21** was confirmed by ^{1}H NMR spectroscopy, which exhibited a triplet at δ 2.51 that integrated to 0.4 proton and a triplet at δ 2.27 that integrated to 1.6 protons ascribable to the methylene protons at C-8 of the keto and enol forms of the β-diketone, respectively. A 0.6-proton singlet at δ 2.24 and a 2.4-proton singlet at δ 2.06 were assigned to the methyl protons at C-12 of the keto and enol forms, respectively. A 0.8-proton singlet at δ 15.50, a 0.8-proton singlet at δ 5.49, and a 0.4-proton singlet at δ 3.58 were assigned to the enol hydroxyl proton, the vinyl proton, and the methylene proton at C-10, respectively (Fig. 2).

The second dianion alkylation reaction was achieved by treat-

ing the β-diketone **21** with two equivalents of lithium diisopropylamide to regioselectively generate the primary dianion that subsequently was reacted with one equivalent of 1-bromopropane (**9**) to produce the β-diketone **22** in 81% yield. The regioselectivity in this alkylation was confirmed by ^{1}H NMR and mass spectroscopy. The ^{1}H NMR spectrum of compound **22** showed four triplets at δ 2.50, 2.48, 2.28, and 2.26 integrating to a total of four protons ascribable to the methylene protons at C-8 and C-12 of the keto and enol forms of **22**. In addition, three singlets at δ 15.51, 5.48, and 3.54 integrating to a total of two protons were assigned to the enol hydroxyl proton, the vinyl proton, and the methylene proton at C-10. The mass spectrum of compound **22** showed peaks at *m/z* 313 and 127 corresponding to fragmentation α to the β-diketone group of **22**.

To complete the synthesis of analogue **2**, the silyl ether protecting group of compound **22** was cleaved to give alcohol **23**, which was oxidized to aldehyde **24** under Moffatt conditions (23). Treatment of **24** with silver oxide (24) produced the acid **2** in 69% yield for the two steps.

The synthesis of analogues **3**, **4**, and **5***a*–**5***d* started with the β-diketone **21** and followed a similar path with comparable yields as for **2** (Scheme 3). The syntheses of analogues **6***a*–**6***c* were accomplished in similar yields to those of analogue **5***b* (Scheme 4) and the synthesis of compound **7** was achieved by two consecutive dianion alkylations.

In conclusion, a series of analogues of ionomycin were designed to study the structural features affecting the ability of Ca^{2+} binding and transport by ionomycin. The syntheses of these analogues were achieved by consecutive regioselective alkylation of the dianion of 2,4-pentanedione with the appropriate bromides and subsequent oxidation of the β-diketone ω-alcohols. The results of the studies on the Ca^{2+} binding and transport properties of these ionomycin analogues and their potential as Ca^{2+} ionophores are reported in the following paper in this series (25).

Experimental section

General procedures

Melting points were determined on a Mel-Temp II melting point apparatus and were not corrected. Infrared spectra were recorded on a Bomem Michelson 100 FT-IR spectrophotometer using internal calibration. Liquid samples were applied directly between two 3-mm NaCl plates, and solid samples were dissolved in chloroform. Proton nuclear magnetic resonance spectra were recorded at 400 MHz on a Bruker WH-400 spectrometer or at 300 MHz on a Varian XL-300 spectrometer. Chemical shifts are reported on the δ scale, with deuterochloroform as solvent and tetramethylsilane as an internal standard. The multiplicity, coupling constants (if observable), and integrated peak area are indicated in parentheses after each signal. High-resolution mass spectra were determined on a Kratos-AEI model MS 50 spectrometer at 70 eV. Elemental analyses were performed by Mr. Peter Borda, Microanalysis Laboratory, University of British Columbia, Vancouver, B.C.

All reactions were monitored by thin-layer chromatography (TLC). Analytical TLC was performed on aluminum backed, precoated silica (SiO_2) gel plates (E. Merck, type 5554). The plates were visualized by ultraviolet fluorescence or by heating the plates after spraying them with a mixture of methanol, acetic acid, sulfuric acid, and anisaldehyde (90:10:5:1 by volume). Silica gel $PF_{254+366}$ supplied by E. Merck was used for both analytical and preparative thin-layer chromatography.

Flash chromatography (26) was performed using Silica Gel 60, 230–400 mesh ASTM, supplied by E. Merck. All solvent systems are expressed in ratios by volume (v/v).

Materials

The petroleum ether used was of boiling range 30–60°C. Dry solvents and reagents were prepared as follows: diethyl ether and tetrahydrofuran by distillation from sodium benzophenone; dichloromethane by distillation from calcium hydride and methanol by distillation from magnesium methoxide. *n*-Butyllithium (in hexane) was obtained from the Aldrich Chemical Company and was standardized by titration against 2,2-diphenylacetic acid in THF at room temperature to the appearance of a faint yellow colour (27). All other reagents and solvents were either of reagent grade and used directly, or purified according to literature procedures (28). All reactions were run under a dry nitrogen atmosphere. Organic extracts were dried over anhydrous magnesium sulfate.

A. General procedure for the preparation of (1, n) bromo alcohols from (1, n)-diols

A suspension of the diol in 48% HBr was prepared in a 1-L liquid–liquid continuous extractor. The suspension was heated in an oil bath while being continuously extracted with 300 mL of heptane at 90°C for 72 h. The extract was cooled and the organic layer separated, washed

with saturated $NaHCO_3$, brine, and dried over $MgSO_4$. Removal of the solvent under reduced pressure gave the crude bromo alcohol, which was further purified by column chromatography.

*7-Bromo-1-heptanol (**14**)*

This compound was prepared according to procedure A using 1,7-heptanediol (**13**) (5.8 g, 44 mmol) and 48% HBr (7.5 mL, 66 mmol). The crude oil was purified by column chromatography using petroleum ether:ethyl acetate (6:1) as eluent to give 6.2 g (72%) of **14** as a colourless liquid: R_f 0.54 (1:1 petroleum ether:ethyl acetate eluent); IR ν_{max}: 3347, 2930, 2858, 1452, 1254, 1054, and 726 cm^{-1}; ^1H NMR (300 MHz) δ: 3.66 (t, J = 6 Hz, 2H), 3.42 (t, J = 6 Hz, 2H), 1.87 (qn, J = 6 Hz, 2H), 1.57 (m, 2H), and 1.52–1.25 (m, 7H). Exact Mass calcd. for $C_7H_{15}BrO$–H: 195.0204, 193.0224; found: 195.0213, 193.0228.

B. General procedure for the preparation of tert-*butyldimethylsilyl ethers from alcohols*

Freshly distilled triethylamine (2.0 equiv.) was added into a solution of the alcohol (1.0 equiv.) in 100 mL of CH_2Cl_2 at room temperature. A catalytic amount of 4-dimethylaminopyridine and *tert*-butyldimethylsilyl chloride (1.5 equiv.) was added. The reaction was stirred at room temperature for 24 h. The mixture was then quenched with 1 N HCl and extracted with ether three times. The combined organic layers were washed twice with saturated $NaHCO_3$ and once with brine. The organic phase was dried over $MgSO_4$ and concentrated under reduced pressure. The crude product was purified by column chromatography.

*1-Bromo-7-(*tert-*butyldimethylsilyloxy)-heptane (**8**)*

This compound was prepared according to procedure B, using the alcohol **13** (1.17 g, 6.0 mmol). Purification of the crude product by column chromatography using petroleum ether:ethyl acetate (15:1) as eluent gave 1.50 g (82%) of **8** as a colourless oil: R_f 0.83 (6:1 petroleum ether:ethyl acetate eluent); IR ν_{max}: 2937, 2858, 1466, 1388, 1361, 1254, 1101, 938, 838, and 776 cm^{-1}; ^1H NMR (400 MHz) δ: 3.64 (t, J = 6 Hz, 2H), 3.44 (t, J = 6 Hz, 2H), 1.86 (qn, J = 6 Hz, 2H), 1.53–1.31 (m, 8H), 0.89 (s, 9H), and 0.05 (s, 6H). Exact Mass calcd. for $C_{13}H_{29}SiBrO - C_4H_9$: 253.0438, 251.0458; found: 253.0450, 251.0460.

*1-Bromo-3-methoxymethoxypropane (**11**)*

To a solution of 3-bromo-1-propanol (3.08 g, 22.1 mmol) in 35 mL of CH_2Cl_2 was added dimethoxymethane (30.3 g, 399 mmol). The solution was cooled to 0°C and phosphorus pentoxide (approximately 1.0 g at a time) was added every 10 min until the reaction was completed as shown by TLC. The mixture was poured into 200 mL of an ice-cooled saturated $NaHCO_3$ and the gummy residue remaining in the reaction flask carefully quenched with saturated $NaHCO_3$. The aqueous layer from the combined work-up solutions was extracted with ether. The combined organic layers were washed with brine, dried over $MgSO_4$, and concentrated under reduced pressure. Vacuum distillation of the crude product gave 3.67 g (91%) of **11** as a colourless liquid: bp 85°C/32 Torr (1 Torr = 133.3 Pa); IR ν_{max}: 2931, 2886, 1476, 1449, 1383, 1284, 1258, 1216, 1144, 1045, 919, 880, and 766 cm^{-1}; ^1H NMR (400 MHz) δ: 4.63 (s, 2H), 3.67 (t, J = 6 Hz, 2H), 3.54 (t, J = 6 Hz, 2h), 3.38 (s, 3H), and 2.14 (qn, J = 6 Hz, 2H). Exact Mass calcd. for $C_5H_{11}BrO_2$–H: 182.9841; found: 182.9847.

*5-Benzyloxy-1-pentanol (**16**)*

Sodium hydride (4.58 g, 80% in oil, 153 mmol) was added to a 500-mL, two-neck, round-bottom flask and washed twice with 20 mL of THF. A solution of 1,5-pentanediol (**15**) (7.95 g, 76.4 mmol) in 20 mL of THF and 200 mL of THF was then added. The mixture was stirred at room temperature for 30 min. Benzyl bromide (9.1 mL, 77 mmol) was slowly added and the mixture was refluxed overnight. The reaction mixture was quenched with H_2O. The organic layer was washed once with 1 N HCl and twice with brine, dried over $MgSO_4$, and concentrated under reduced pressure. The crude product was chromatographed on a silica gel column using petroleum ether:ethyl acetate (3:1) as eluent to give 7.98 g (54%) of **16** as a colourless oil: R_f 0.38 (1:1 petroleum ether:ethyl acetate eluent); IR ν_{max}: 3372, 3090, 3063, 3030, 2897, 2850, 1496, 1454, 1363, 1206, and 1077 cm^{-1}; ^1H NMR (400 MHz) δ: 7.40–7.24 (m, 5H), 4.52 (s, 2H), 3.65 (t, J = 6 Hz, 2H), 3.52 (t, J = 6 Hz, 2H), and 1.70–1.40 (m, 7H). Exact Mass calcd. for $C_{12}H_{18}O_2$: 194.1302; found: 194.1304.

*5-Benzyloxy-1-(2-tetrahydropyranyloxy)-ethoxypentane (**17**)*

A 25-mL, three-neck round-bottom flask was charged with 50% sodium hydroxide (4.0 mL, 50 mmol), 1-bromo-2-tetrahydropyranyloxyethane (4.18 g, 20.0 mmol), and the alcohol **16** (0.97 g, 5.0 mmol). Tetrabutylammonium hydrogen sulfate (0.15 g, 0.44 mmol) was added. The two-phase mixture was stirred vigorously and heated to 65°C for 72 h. The reaction mixture was cooled to room temperature and taken up into 100 mL of ether. The organic layer was washed with H_2O, brine, dried over $MgSO_4$, and concentrated under reduced pressure. Purification of the crude product by column chromatography using petroleum ether:ethyl acetate (6:1) as eluent gave 1.34 g (83%) of **17** as a light yellow oil: R_f 0.16 (6:1 petroleum ether:ethyl acetate eluent); IR ν_{max}: 3086, 3060, 3029, 2935, 2861, 1495, 1453, 1359, 1269, 1201, 1184, 1106, 1032, 988, 929, 906, 872, 814, and 739 cm^{-1}; ^1H NMR (300 MHz) δ: 7.40–7.24 (m, 5H), 4.64 (t, J = 4 Hz, 1H), 4.50 (s, 2H), 3.94–3.80 (m, 2H), 3.62–3.55 (m, 2H), 3.50–3.46 (m, 6H), and 1.90–1.40 (m, 12H). Exact Mass calcd. for $C_{19}H_{30}O_4$: 322.2136; found: 322.2152.

*2-(5-Benzyloxy)-pentyloxy-1-ethanol (**18**)*

Pyridinium *p*-toluenesulfonate (42 mg, 0.16 mmol) was added to a solution of the tetrahydropyranyl ether **17** (550 mg, 1.60 mmol) in 15 mL of MeOH. The mixture was stirred at room temperature for 12 h. The solvent was removed under reduced pressure and the residue was taken up in ether, washed with saturated $NaHCO_3$ and brine, dried over $MgSO_4$, and concentrated under reduced pressure. The crude oil was chromatographed on a silica gel column using petroleum ether:ethyl acetate (6:1) as eluent to give 368 mg (91%) of **18** as a light yellow oil: R_f 0.30 (1:1 petroleum ether:ethyl acetate eluent); IR ν_{max}: 3414, 3082, 3063, 3030, 2932, 2862, 1495, 1454, 1362, 1207, 1086, 893, and 740 cm^{-1}; ^1H NMR (300 MHz) δ: 7.40–7.24 (m, 5H), 4.52 (s, 2H), 3.72 (m, 2H), 3.56–3.44 (m, 2H), 3.44 (t, J = 5 Hz, 4H), 2.04 (t, J = 5 Hz, 1H), and 1.69–1.53 (m, 4H), 1.50–1.40 (m, 2H). Exact Mass calcd. for $C_{14}H_{22}O_3$: 238.1563; found: 238.1559.

*5-Benzyloxy-1-[2-(3-*tert-*butyldimethylsilyloxy)propyloxy]-ethoxypentane (**19**)*

Following the procedure for the preparation of 5-benzyloxy-1-(2-tetrahydropyranyloxy)-ethoxypentane (**17**), the alcohol **18** (300 mg, 1.26 mmol) was reacted with 1-bromo-3-*tert*-butyldimethylsilyloxypropane (1.28 g, 5.04 mmol) to give the ether **19**. The crude product was purified by column chromatography using petroleum ether:ethyl acetate (6:1) as eluent to give 1.34 g (83%) of **19** as a light yellow oil: R_f 0.20 (6:1 petroleum ether:ethyl acetate eluent); IR ν_{max}: 3087, 3064, 3030, 2934, 2862, 1463, 1360, 1253, 1108, 1015, 841, 777, and 737 cm^{-1}; ^1H NMR (300 MHz) δ: 7.36–7.24 (m, 5H), 4.50 (s, 2H), 3.70 (t, J = 6 Hz, 2H), 3.58–3.51 (m, 6H), 3.50–3.42 (m, 4H), 1.79 (qn, J = 6 Hz, 2H), 1.69–1.58 (m, 4H), 1.49–1.40 (m, 2H), 0.89 (s, 9H), and 0.04 (6H, s). Exact Mass calcd. for $C_{23}H_{42}SiO_4$: 410.2841; found: 410.2861.

C. General procedure for the cleavage of tert-*butyldimethylsilyl ethers*

To a solution of the silyl ether (1.0 equiv.) in 40 mL of THF was added a solution of tetrabutylammonium fluoride in THF (2.0 equiv.). The solution was stirred at room temperature for 12 h. The solvent was removed under reduced pressure and the residue was taken up in ether. The organic layer was washed twice with brine, dried over $MgSO_4$, and concentrated under reduced pressure. The crude product was purified by column chromatography.

*3-[2-(5-Benzyloxy)-pentyloxy]-ethoxy-1-propanol (**20**)*

This compound was prepared according to procedure C using the silyl ether **19** (430 mg, 1.05 mmol) and a solution of tetrabutylammo-

For personal use only.

nium fluoride in THF (1.0 M, 2.10 mL, 2.1 mmol). Purification of the crude product by column chromatography using petroleum ether:ethyl acetate (3:1) as eluent gave 275 mg (89%) of **20** as a colourless oil: R_f 0.20 (1:1 petroleum ether:ethyl acetate eluent); IR ν_{max}: 3426, 3085, 3063, 3030, 2932, 2863, 1495, 1454, 1361, 1296, 1204, 1091, and 740 cm^{-1}; ^1H NMR (400 MHz) δ: 7.38–7.26 (m, 5H), 4.50 (s, 2H), 3.78 (bt, J = 6 Hz, 2H), 3.69 (t, J = 6 Hz, 2H), 3.62–3.58 (m, 2H), 3.57–3.55 (m, 2H), 3.47 (t, J = Hz, 2H), 3.45 (t, J = 6 Hz, 2H), 2.48 (bs, 1H), 1.83 (qn, J = Hz, 2H), 1.69–1.56 (m, 4H), and 1.49–1.40 (m, 2H). Exact Mass calcd. for $C_{17}H_{28}O_4 - C_3H_8O$: 236.1407; found: 236.1400.

*5-Benzyloxy-1-[2-(3-bromo)-propyloxy]-ethoxyheptane (**10**)*

A 25-mL round-bottom flask was charged with the alcohol **21** (296 mg, 1.00 mmol) in 12 mL of CH_2Cl_2. The solution was cooled to 0°C. Freshly recrystallized triphenylphosphine (340 mg, 1.30 mmol) and carbon tetrabromide (415 mg, 1.25 mmol) were added. The mixture was stirred at 0°C for 30 min, allowed to warm up to room temperature, and then diluted with ether. The organic layer was washed with H_2O, brine, dried over $MgSO_4$, and concentrated under reduced pressure. The crude product was purified by column chromatography using petroleum ether:ethyl acetate (9:1) as eluent to give 315 mg (88%) of **10** as a colourless oil: R_f 0.14 (9:1 petroleum ether:ethyl acetate eluent); IR ν_{max}: 3080, 3063, 3030, 2930, 2862, 1495, 1454, 1360, 1256, 1209, and 1110 cm^{-1}; ^1H NMR (400 MHz) δ: 7.38–7.25 (m, 5H), 4.50 (s, 2H), 3.66–3.36 (m, 6H), 3.54–3.44 (m, 6H), 2.12 (qn, J = 6 Hz, 2H), 1.69–1.56 (m, 4H), and 1.49–1.40 (m, 2H). Exact Mass calcd. for $C_{17}H_{27}BrO_3$: 360.1116, 358.1136; found: 360.1109, 358.1139.

D. General procedure for the alkylation of the dianion from 2,4-pentanedione

Sodium hydride (1.2 equiv.) was added to a 100-mL, two-neck round-bottom flask and washed twice with 20 mL of THF. Then 20 mL of THF was added and the resulting suspension was cooled to 0°C. A solution of 2,4-pentanedione (1.2 equiv.) in 15 mL of THF was added through an addition funnel. The resulting white suspension was stirred for 30 min and treated with *n*-BuLi (1.2 equiv.). The orange solution was stirred for 20 min. A solution of the bromide (1.0 equiv.) in 10 mL of THF was slowly added through the addition funnel and the mixture was stirred at 0°C for 1 h and at room temperature for 20 min. The mixture was quenched with saturated NH_4Cl, acidified with 1 N HCl, and extracted with ether three times. The combined organic layers were washed twice with saturated $NaHCO_3$ and once with brine, dried over $MgSO_4$, and concentrated under reduced pressure. The crude product was purified by column chromatography.

*12-(tert-Butyldimethylsilyloxy)-2,4-dodecanedione (**21**)*

This compound was prepared according to procedure D using sodium hydride (610 mg, 50% in oil, 12.7 mmol), 2,4-pentanedione (1.36 mL, 12.7 mmol), *n*-BuLi (7.84 mL, 1.62 M, 12.7 mmol), and the bromide **8** (3.26 g, 10.6 mmol). Purification of the crude product by column chromatography using a mixture of petroleum ether and ethyl acetate (15:1) as eluent gave 2.20 g of **21** and 700 mg of **8**. The yield, based on the recovered bromide, was 81%: R_f 0.61 (6:1 petroleum ether:ethyl acetate eluent); IR ν_{max}: 2934, 2857, 1709, 1614, 1465, 1253, 1100, 1006, 939, 838, and 776 cm^{-1}; ^1H NMR (400 MHz) δ: 15.50 (bs, 0.8 H), 5.49 (s, 0.8 H), 3.61 (t, J = 7 Hz, 2H), 3.58 (s, 0.4 H), 2.51 (t, J = 8 Hz, 0.4 H), 2.27 (t, J = 8 Hz, 1.6 H), 2.24 (s, 0.6 H), 2.06 (s, 2.4 H), 1.65–1.46 (m, 6H), 1.36–1.26 (m, 6H), 0.89 (s, 9H), and 0.04 (s, 6H). Exact Mass calcd. for $C_{18}H_{36}SiO_3 - CH_3$: 313.2190; found: 313.2208.

E. General procedure for the regioselective alkylation of β-diketone dianions

Lithium diisopropylamide (2.0 equiv.) was prepared at –78°C by addition of *n*-BuLi (2.0 equiv.) to a solution of diisopropylamine (2.0 equiv.) in 20 mL of THF and stirring of the mixture for 30 min. It was then cannulated into an addition funnel and added to a solution of the β-diketone (1.0 equiv.) in 20 mL of THF at –78°C over a period of 1 h. The mixture was stirred at –78°C for 24 h and allowed to warm up to 0°C. The bromide (1.0 equiv.) in 10 mL of THF was slowly added and the mixture was stirred at 0°C for 12 h. The mixture was then quenched with saturated NH_4Cl, acidified with 1 N HCl, and extracted with ether three times. The combined organic phases were washed with saturated $NaHCO_3$, brine, dried over $MgSO_4$, and concentrated under reduced pressure. The crude product was purified by column chromatography.

*15-(tert-Butyldimethylsilyloxy)-5,7-pentadecanedione (**22**)*

This compound was prepared according to procedure E using *n*-Buli (1.70 mL, 1.53 M, 2.60 mmol), diisopropylamine (0.36 mL, 2.6 mmol), the β-diketone **21** (426 mg, 1.30 mmol), and 1-bromopropane (**9**) (160 mg, 1.30 mmol). Purification of the crude product by column chromatography using petroleum ether:ethyl acetate (20:1) gave 294 mg of **22** and 294 mg of the starting β-diketone **21**. The yield, based on the recovered β-diketone **21**, was 81%: R_f 0.74 (6:1 petroleum ether:ethyl acetate eluent); IR ν_{max}: 2936, 2858, 1707, 1611, 1463, 1253, 1100, 949, 838, 776, and 704 cm^{-1}; ^1H NMR (400 MHz) δ: 15.50 (bs, 0.8H), 5.48 (s, 0.8H), 3.61 (t, J = 7 Hz, 2H), 3.54 (s, 0.4H), 2.50 (t, J = 8 Hz, 0.4H), 2.48 (t, J = 8 Hz, 0.4H), 2.28 (t, J = 8 Hz, 1.6H), 2.26 (t, J = 8 Hz, 1.6H), 1.66–1.48 (m, 6H), 1.40–1.24 (m, 10H), 0.93 (t, J = 7 Hz, 3H), 0.90 (s, 9H), 0.06 (s, 6H). Exact Mass calcd. for $C_{21}H_{42}SiO_3 - CH_3$: 355.2658; found: 355.2662.

*15-Hydroxy-5,7-pentadecanedione (**23**)*

This compound was prepared according to procedure C using the silyl ether **22** (444 mg, 1.20 mmol) and tetrabutylammonium fluoride in THF (2.40 mL, 1.0 M, 2.4 mmol). Purification of the crude product by column chromatography using petroleum ether:ethyl acetate (6:1) as eluent gave 277 mg of **23** as a colourless solid: R_f 0.58 (1:1 petroleum ether:ethyl acetate eluent); mp 41.5°C; IR ν_{max}: 3621, 3462, 2934, 2859, 1723, 1700, 1605, 1460, 1355, 1307, 1149, 1098, 1005, 957, and 916 cm^{-1}; ^1H NMR (400 MHz) δ: 15.50 (bs, 0.7H), 5.48 (s, 0.7H), 3.65 (t, J = 7 Hz, 2H), 3.53 (s, 0.6H), 2.51 (t, J = 8 Hz, 0.6H), 2.50 (t, J = 8 Hz, 0.6 H), 2.28 (5, J = 8 Hz, 1.4 H), 2.27 (t, J = 8 Hz, 1.4H), 1.67–1.50 (m, 8H), 1.40–1.12 (m, 9H), and 0.93 (5, J = 7 Hz, 3H). Exact Mass calcd. for $C_{15}H_{28}O_3$: 256.2031, found: 256.2031.

F. General procedure for the oxidation of alcohols to acids

To the alcohol (1.0 equiv.) in 15 mL of CH_2Cl_2 and 15 mL of dimethyl sulfoxide was added 1,3-dicyclohexylcarbodiimide (6.0 equiv.) and dichloroacetic acid (0.5 equiv.). This mixture was stirred for 2 h, diluted with ethyl acetate, and treated with oxalic acid (6.0 equiv.). The mixture was poured into brine, filtered to remove the urea precipitate, and extracted with ethyl acetate. The organic layer was concentrated under reduced pressure. The resulting oil was dissolved in 24 mL 50% THF–H_2O. Silver nitrate (8.0 equiv.) and NaOH (16 equiv.) were added and the mixture was stirred for 4 h. The precipitate was filtered and washed with ethyl acetate and water. The aqueous layer was acidified with 1 N HCl and was then extracted with ethyl acetate. The organic extract was washed with brine, dried over $MgSO_4$, and concentrated under reduced pressure. The crude product was purified by recrystallization from hexanes or by column chromatography.

*9,11-Dioxopentadecanoic acid (**2**)*

This compound was prepared according to F using the alcohol **23** (384 mg, 1.34 mmol), 1,3-dicyclohexylcarbodiimide (1.67 g, 7.95 mmol), and dichloroacetic acid (53 mL, 0.69 mmol). The crude aldehyde **24** was subsequently treated with silver nitrate (1.85 g, 10.8 mmol) and NaOH (0.86 g, 22 mmol). The crude product was purified by recrystallization from hexanes to give 270 mg (69%) of **2** as colourless crystals: R_f 0.54 (5% HOAc in 3:1 petroleum ether:ethyl acetate eluent); mp 43.0°C; IR ν_{max}: 3346-2480, 2937, 2861, 1713, 1601, 1459, 1286, 1116, 968, and 903 cm^{-1}; ^1H NMR (300 MHz) δ: 15.50 (bs, 0.7H), 5.48 (s, 0.7H), 3.53 (s, 0.6H), 2.51 (t, J = 8 Hz, 0.6H), 2.50 (t, J = 8Hz, 0.6H), 2.33 (t, J = 7 Hz, 2H), 2.28 (t, J = 8 Hz, 1.4H), 2.27 (t, J = 8 Hz, 1.4H), 1.70–1.56 (m, 7H), 1.40–1.27 (m, 8H), and 0.93 (t, J = 7 Hz, 3H). Exact Mass calcd. for $C_{15}H_{26}O_4$: 270.1824; found: 270.1828. Anal. calcd. for $C_{15}H_{26}O_4$: C 66.67, H 9.63; found: C 66.60, H 9.65.

*1-[2-(5-Benzyloxy)pentyloxy]-ethoxy-15-(*tert*-butyldimethylsilyloxy)-5,7-pentadecanedione (**25**)*

This compound was prepared according to E using the β-diketone **21** (426 mg, 1.30 mmol) and the bromide **10** (359 mg, 1.00 mmol). The crude product was purified by column chromatography using silica gel and petroleum ether:ethyl acetate (9:1) to give 270 mg of **25** and 104 mg of **10**. The yield, based on the recovered bromide, was 85%: R_f 0.12 (9:1 petroleum ether:ethyl acetate eluent); IR ν_{max}: 3080, 3060, 3026, 1710, 1703, 1609, 1460, 1360, 1252, 1110, and 840 cm^{-1}; ^1H NMR (400 MHz) δ: 15.48 (bs, 0.8H), 7.38–7.26 (m, 5H), 5.47 (s, 0.8H), 4.51 (s, 2H), 3.65–3.53 (m, 6.4H), 3.50–3.44 (m, 6H), 2.53 (t, J = 8 Hz, 0.4H), 2.48 (t, J = 8 Hz, 0.4H), 2.30 (t, J = 8 Hz, 1.6H), 2.26 (t, J = 8 Hz, 1.6H), 1.72–1.38 (m, 14H), 1.36–1.25 (m, 8H), 0.90 (s, 9H), and 0.50 (s, 6H). Exact Mass calcd. for $C_{35}H_{62}SiO_6$: 606.4299; found: 606.4313.

1-[2-(5-Benzyloxy)pentyloxy]-ethoxy-15-hydroxy-5,7-pentadecanedione

This compound was prepared according to procedure C using the silyl ether **25** (1.40 g, 2.58 mmol). The crude product was purified by column chromatography using petroleum ether:ethyl (6:1) as eluent to give 993 mg (87%) of the desired alcohol from **25** as a colourless oil: R_f 0.30 (1:1 petroleum ether:ethyl acetate eluent); IR ν_{max}: 3437, 3080, 3060, 3030, 2930, 2863, 1710, 1702, 1606, 1453, 1361, 1096, and 739 cm^{-1}; ^1H NMR (400 MHz) δ: 15.50 (bs, 0.8H), 7.38–7.24 (m, 5H), 5.48 (s, 0.8H), 4.50 (s, 2H), 3.64 (t, J = 7 Hz, 2H), 3.57 (s, 2H), 3.56 (s, 2H), 3.53 (s, 0.4H), 3.50–3.43 (m, 6H), 2.53 (t, J = 8Hz, 0.4H), 2.49 (t, J = 8 Hz, 0.4H), 2.30 (t, J = 8 Hz, 1.6H), 2.26 (t, J = 8Hz, 1.6H), 1.72–1.50 (m, 13H), 1.46–1.38 (m, 2H), and 1.38–1.25 (m, 8H). Exact Mass calcd. for $C_{29}H_{48}O_6$: 492.3438; found: 492.3445.

*15-[2-(5-Benzyloxy)-pentyloxy)-ethoxy-9,11-dioxopentadecanoic acid (**3**)*

This compound was prepared according to procedure F using the above alcohol (2.11 g, 4.29 mmol). The crude product was purified by column chromatography using petroleum ether:ethyl acetate (6:1) that also contained 5% acetic acid as eluent to give 1.58 g (74%) of **3** as a colourless oil: R_f 0.30 (5% HOAc in 3:1 petroleum ether:ethyl acetate eluent); IR ν_{max}: 3120, 3080, 3060, 3028, 2933, 2859, 1726, 1604, 1455, 1360, 1246, 1105, 928, and 738 cm^{-1}; ^1H NMR (400 MHz) δ: 15.50 (bs, 0.8H), 7.38–7.24 (m, 5H), 5.47 (s, 0.8H), 4.50 (s, 2H), 3.60–3.55 (m, 4H), 3.53 (s, 0.4H), 3.50–3.42 (m, 6H), 2.53 (t, J = 8 Hz, 0.4H), 2.48 (t, J = 8 Hz, 0.4H), 2.34 (t, J = 8 Hz, 2H), 2.30 (t, J = 8 Hz, 1.6H), 2.26 (t, J = 8 Hz, 1.6H), 1.72–1.52 (m, 13H), 1.46–1.38 (m, 2H), and 1.38–1.25 (m, 8H). Exact Mass calcd. for $C_{29}H_{46}O_7$: 506.3231; found: 506.3237.

*1-Methoxymethoxy-15-(*tert*-butyldimethylsilyloxy)-5,7-pentadecanedione (**26**)*

This compound was prepared according to procedure E using the β-diketone **21** (2.16 g, 6.59 mmol) and the bromide **11** (1.08 g, 5.93 mmol). The crude product was purified by column chromatography using petroleum ether:ethyl acetate (15:1) as eluent to give 1.56 g (73%) of **26** as a colourless oil: R_f 0.24 (6:1 petroleum ether:ethyl acetate eluent); IR ν_{max}: 2936, 2858, 1708, 1611, 1463, 1387, 1253, 1148, 1103, 1044, and 924 cm^{-1}; ^1H NMR (400 MHz) δ: 15.50 (bs, 0.8H), 5.48 (s, 0.8H), 4.62 (s, 1.6H), 4.61 (s, 0.4H), 3.61 (t, J = 7 Hz, 2H), 3.57 (s, 0.4H), 3.56 (t, J = 7 Hz, 2H), 3.38 (s, 3H), 2.56 (t, J = 8 Hz, 0.4H), 2.51 (t, J = 8 Hz, 0.4H), 2.32 (t, J = 8 Hz, 1.6H), 2.26 (t, J = 8 Hz, 1.6H), 1.78–1.45 (m, 8H), 1.38–1.25 (m, 8H), 0.90 (s, 9H), and 0.50 (s, 6H). Exact Mass calcd. for $C_{23}H_{46}SiO_5 - CH_3$: 415.2868; found: 415.2875.

1-Methoxymethoxy-15-hydroxy-5,7-pentadecanedione

This compound was prepared according to procedure C using the silyl ether **26** (215 mg, 0.50 mmol). The crude product was purified by column chromatography using petroleum ether:ethyl acetate (6:1) as eluent to give 136 mg (86%) of the desired alcohol from **26** as a white solid: R_f 0.36 (1:1 petroleum ether:ethyl acetate eluent); mp 42.0°C; IR ν_{max}: 3635, 3458, 2932, 2860, 1704, 1610, 1452, 1217, 1148, 1112, 1039, and 923 cm^{-1}; ^1H NMR (400 MHz) δ: 15.50 (bs, 0.8H), 5.48 (s, 0.8H), 4.62 (s, 1.6H), 4.61 (s, 0.4H), 3.65 (t, J = 7 Hz, 2H), 3.56 (s, 0.4H), 3.55 (t, J = 7 Hz, 2H), 3.37 (s, 3H), 2.57 (t, J = 8 Hz, 0.4H), 2.50 (t, J = 8 Hz, 0.4H), 2.32 (t, J = 8 Hz, 1.6H), 2.27 (t, J = 8 Hz, 1.6H), 1.77–1.50 (m, 9H), and 1.42–1.25 (m, 8H). Exact Mass calcd. for $C_{17}H_{32}O_5$: 316.2241; found: 316.2247.

*15-Methoxymethoxy-9,11-dioxopentadecanoic acid (**4**)*

This compound was prepared according to procedure F using the above alcohol (128 mg, 0.40 mmol). The crude product was purified by recrystallization from hexanes to give 94 mg (73%) of **4** as a white solid R_f 0.34 (5% HOAc in 3:1 petroleum ether:ethyl acetate eluent); mp 43.0°C; IR ν_{max}: 3116, 2932, 2860, 1717, 1611, 1461, 1416, 1221, 1148, 1111, 1039, and 923 cm^{-1}; ^1H NMR (300 MHz) δ: 15.50 (bs, 0.8H), 5.49 (s, 0.8H), 4.63 (s, 1.6H), 4.62 (s, 0.4H), 3.57–3.52 (m, 2.4H), 3.38 (s, 2.4H), 3.37 (s, 0.6H), 2.56 (t, J = 8 Hz, 0.4H), 2.50 (t, J = 8 Hz, 0.4H), 2.35 (t, J = 8 Hz, 2H), 2.32 (t, J = 8 Hz, 1.6H), 2.27 (t, J = 8 Hz, 1.6H), 1.77–1.52 (m, 8H), and 1.42–1.25 (m, 6H). Exact Mass calcd. for $C_{17}H_{30}O_6$: 330.2034; found: 330.2036. Anal. calcd. for $C_{17}H_{30}O_6$: C 61.78, H 9.09; found: C 61.72, H 9.08.

12-Hydroxy-2,4-dodecanedione

This compound was prepared according to procedure C using the silyl ether **21** (2.01 g, 6.13 mmol). The crude product was purified by column chromatography using petroleum ether:ethyl acetate (6:1) as eluent to give 1.23 g (94%) of the desired alcohol from **21** as a white solid: R_f 0.50 (1:1 petroleum ether:ethyl acetate eluent); mp 40.5°C; IR ν_{max}: 3621, 3460, 2932, 2858, 1720, 1702, 1610, 1440, 1362, 1304, 1157, 1074, 1011, 956, and 915 cm^{-1}; ^1H NMR (400 MHz) δ: 15.48 (bs, 0.8H), 5.48 (s, 0.8H), 3.65 (t, J = 7 Hz, 2H), 3.57 (s, 0.4H), 2.50 (t, J = 8 Hz, 0.4H), 2.27 (t, J = 8 Hz, 1.6H), 2.22 (s, 0.6H), 2.05 (s, 2.4H), 1.66–1.52 (m, 5H), and 1.42–1.28 (m, 8H). Exact Mass calcd. for $C_{12}H_{22}O_3$: 214.1563; found: 214.1569.

*9,11-Dioxododecanoic acid (**5a**)*

This compound was prepared according to procedure F using the above alcohol (750 mg, 3.50 mmol). The crude product was purified by recrystallization from hexanes to give 480 mg (60%) of **5a** as a white solid: R_f 0.48 (5% HOAc in 3:1 petroleum ether:ethyl acetate eluent); mp 41.5°C; IR ν_{max}: 3340–2500, 2935, 2860, 1712, 1607, 1460, 1410, 1364, 1290, 1135, 1097, 954, and 915 cm^{-1}; ^1H NMR (400 MHz) δ: 15.48 (bs, 0.8H), 5.48 (s, 0.8H), 3.57 (s, 0.4H), 2.48 (t, J = 8 Hz, 0.4H), 2.39 (t, J = 7 Hz, 0.8H), 2.32 (t, J = 8 Hz, 2H), 2.23 (t, J = 8 Hz, 0.8H), 2.21 (s, 0.6H), 2.11 (s, 1.2H), 2.03 (s, 1.2H), 1.66–1.50 (m, 4H), and 1.40–1.22 (m, 6H). Exact Mass calcd. for $C_{12}H_{20}O_4$: 228.1356; found: 228.1362.

*18-(*tert*-Butyldimethylsilyloxy)-8,10-octadecanedione (**27**b)*

This compound was prepared according to procedure E using the β-diketone **21** (4.00 g, 12.2 mmol) and 1-bromohexane (1.81 g, 11.0 mmol). The crude product was purified by column chromatography using petroleum ether: ethyl acetate (20:1) as eluent to give 3.50 g (85%) of **27***b* as a colourless oil: R_f 0.76 (6:1 petroleum ether:ethyl acetate eluent); IR ν_{max}: 2931, 2857, 1711, 1612, 1463, 1392, 1365, 1252, 1101, 837, and 776 cm^{-1}; ^1H NMR (400 MHz) δ: 15.50 (bs, 0.8H) 5.48 (s, 0.8H), 3.61 (t, J = 7 Hz, 2H), 3.53 (s, 0.4H), 2.50 (t, J = 8 Hz, 0.8H), 2.27 (t, J = 8 Hz, 3.2H), 1.66–1.46 (m, 8H), 1.38–1.22 (m, 14H), 0.90 (s, 9H), 0.88 (t, J = 7 Hz, 3H), and 0.06 (s, 6H). Exact Mass calcd. for $C_{24}H_{48}SiO_3 - CH_3$: 397.3126; found: 397.3137.

18-Hydroxy-8,10-octadecanedione

This compound was prepared according to procedure C using the silyl ether **27***b* (2.66 g, 6.46 mmol). The crude product was purified by recrystallization from hexanes to give 1.68 g (87%) of the desired alcohol from **27***b* as a white solid: R_f 0.62 (1:1 petroleum ether:ethyl acetate eluent); mp 56.0°C; IR ν_{max}: 3623, 3460, 2932, 2857, 1724, 1708, 1604, 1460, 1372, 1294, 1146, 1112, and 917 cm^{-1}; ^1H NMR (400 MHz) δ: 15.50 (bs, 0.8H), 5.48 (s, 0.8H), 3.66 (t, J = 7 Hz, 2H), 3.53 (s, 0.4H), 2.51 (t, J = 8 Hz, 0.8H), 2.27 (t, J = 8 Hz, 3.2H), 1.66–1.50 (m, 9H), 1.42–1.20 (m, 14H), and 0.88 (t, J = 7 Hz, 3H). Exact Mass calcd. for $C_{18}H_{34}O_3$: 298.2499; found: 298.2499.

For personal use only.

9,11-Dioxooctadecanoic acid (5b)

This compound was prepared according to procedure F using the above alcohol (850 mg, 2.85 mmol). The crude product was purified by recrystallization from hexanes to give 500 mg (56%) of **5*b*** as a white solid: R_f 0.55 (5% HOAc in 3:1 petroleum ether:ethyl acetate eluent); mp 57.0°C; IR ν_{max}: 3310–2480, 2932, 2859, 1707, 1609, 14,66, 1407, 1290, 1132, 951, and 916 cm^{-1}; IR (KBr) ν_{max}: 3543, 3483, 2931, 2849, 1719, 1688, 1642, 1461, 1440, 1421, 1310, 1237, 1188, 1138, and 903 cm^{-1}; ^1H NMR (300 MHz) δ: 15.50 (bs, 0.8H), 5.48 (s, 0.8H), 3.53 (s, 0.4H), 2.50 (t, J = 8 Hz, 0.8H), 2.36 (t, J = 7 Hz, 2H), 2.28 (t, J = 8 Hz, 3.2 H), 1.70–1.50 (m, 8H), 1.40–1.24 (m, 12H), and 0.90 (t, J = 7 Hz, 3H). Exact Mass calcd. for $C_{18}H_{32}O_4$: 312.2292; found: 312.2293. Anal. calcd. for $C_{18}H_{32}O_4$: C 69.23, H 10.33; found: C 69.22, H 10.33.

*1-(*tert*-Butyldimethylsilyloxy)-9,11-eicosanedione (27c)*

This compound was prepared according to procedure E using the β-diketone **21** (1.97 g, 6.0 mmol) and 1-bromooctane (1.04 g, 5.4 mmol). The crude product was purified by column chromatography using petroleum ether:ethyl acetate (20:1) as eluent to give 1.52 g (73%) of **27*c*** as a colourless oil: R_f 0.78 (6:1 petroleum ether:ethyl acetate eluent); IR ν_{max}: 2930, 2856, 1707, 1611, 1463, 1366, 1253, 1100, 1044, 943, 837, and 776 cm^{-1}; ^1H NMR (400 MHz) δ: 15.50 (bs, 0.8H), 5.48 (s, 0.8H), 3.61 (t, J = 7 Hz, 2H), 3.54 (s, 0.4H), 2.50 (t, J = 8 Hz, 0.8H), 2.27 (t, J = 8 Hz, 3.2H), 1.66–1.48 (m, 8H), 1.36–1.24 (m, 18H), 0.90 (s, 9H), 0.88 (t, J = 7 Hz, 3H), and 0.07 (s, 6H). Exact Mass calcd. for $C_{26}H_{52}SiO_3$: 440.3672; found: 440.3654.

1-Hydroxy-9,11-eicosanedione

This compound was prepared according to procedure C using the silyl ether **27*c*** (1.40 g, 3.2 mmol). The crude product was purified by recrystallization from hexanes to give 940 mg (91%) of the desired alcohol from **27*c*** as a white solid: R_f 0.65 (1:1 petroleum ether:ethyl acetate eluent); mp 65.5°C; IR ν_{max}: 3622, 2930, 2857, 1724, 1700, 1608, 1460, 1364, 1308, 1047, and 905 cm^{-1}; ^1H NMR (400 MHz) δ: 15.50 (bs, 0.8H), 5.48 (s, 0.8H), 3.66 (t, J = 7 Hz, 2H), 3.54 (s, 0.4H), 2.50 (t, J = 8 Hz, 0.8H), 2.27 (t, J = 8 Hz, 3.2H), 1.64–1.50 (m, 11H), 1.49–1.22 (m, 16H), and 0.88 (t, J = 7 Hz, 3H). Exact Mass calcd. for $C_{20}H_{38}O_3$: 326.2811; found: 326.2814.

9,11-Dioxoeicosanoic acid (5c)

This compound was prepared according to procedure F using the above alcohol (630 mg, 2.11 mmol). The crude product was purified by recrystallization from hexanes to give 520 mg (79%) of **5*c*** as a white solid: R_f 0.56 (5% HOAc in 3:1 petroleum ether:ethyl acetate eluent); mp 64.0°C; IR ν_{max}: 3355–2490, 2931, 2858, 1708, 1606, 1459, 1413, 1292, 1134, 1104, and 953 cm^{-1}; ^1H NMR (300 MHz) δ: 15.50 (bs, 0.8H), 5.48 (s, 0.8H), 3.53 (s, 0.4H), 2.49 (t, J = 8 Hz, 0.8H), 2.36 (t, J = 7 Hz, 2H), 2.28 (t, J = 8 Hz, 3.2H), 1.70–1.50 (m, 8H), 1.40–1.22 (m, 16H), and 0.90 (t, J = 7 Hz, 3H). Exact Mass calcd. for $C_{20}H_{36}O_4$: 340.2604; found: 340.2620. Anal. calcd. for $C_{20}H_{36}O_4$: C 70.59, H 10.58; found: C 70.32, H 10.66.

*1-(*tert*-Butyldimethylsilyloxy)-9,11-doeicosanedione (27d)*

This compound was prepared according to procedure E using the β-diketone **21** (1.67 g, 5.1 mmol) and 1-bromodecane (1.12 g, 5.1 mmol). The crude product was purified by column chromatography using petroleum ether:ethyl acetate (20:1) as eluent to give 0.95 g (70%) of **27*d*** as a colourless oil: R_f 0.80 (6:1 petroleum ether:ethyl acetate eluent); IR ν_{max}: 2928, 2856, 1711, 1611, 1463, 1390, 1365, 1252, 1101, 1011, 944, and 837 cm^{-1}; ^1H NMR (400 MHz) δ: 15.50 (bs, 0.8H), 5.48 (s, 0.8H), 3.60 (t, J = 7 Hz, 2H), 3.54 (s, 0.4H), 2.50 (t, J = 8 Hz, 0.8H), 2.27 (t, J = 8 Hz, 3.2H), 1.66–1.46 (m, 8H), 1.36–1.22 (m, 22H), 0.90 (s, 9H), 0.89 (t, J = 7 Hz, 3H), and 0.07 (s, 6H). Exact Mass calcd. for $C_{28}H_{56}SiO_3$: 467.3906; found: 467.3960.

1-Hydroxy-9,11-doeicosanedione

This compound was prepared according to procedure C using the silyl ether **27*d*** (870 mg, 1.86 mmol). The crude product was purified by recrystallization from hexanes to give 560 mg (85%) of the desired alcohol from **27*d*** as a white solid: R_f 0.68 (1:1 petroleum ether:ethyl acetate eluent); mp 70.5°C; IR ν_{max}: 3623, 3458, 2929, 2857, 1607, 1459, 1380, 1285, 1148, 1053, 947, and 898 cm^{-1}; ^1H NMR (400 MHz) δ: 15.50 (bs, 0.8H), 5.47 (s, 0.8H), 3.64 (t, J = 7 Hz, 2H), 3.54 (s, 0.4H), 2.50 (t, J = 8 Hz, 0.8H), 2.24 (t, J = 8 Hz, 3.2H), 1.64–1.50 (m, 11H), 1.42–1.22 (m, 20H), and 0.89 (t, J = 7 Hz, 3H). Exact Mass calcd. for $C_{22}H_{42}O_3$: 354.3123; found: 354.3132.

9,11-Dioxodoeicosanoic acid (5d)

This compound was prepared according to procedure F using the above alcohol (450 mg, 1.27 mmol). The crude product was purified by recrystallization from hexanes to give 140 mg (34%) of **5*d*** as a white solid: R_f 0.57 (5% HOAc in 3:1 petroleum ether:ethyl acetate eluent); mp 69.5°C; IR ν_{max}: 3370–2510, 2929, 2857, 1718, 1607, 1460, 1408, 1292, 1135, 1090, and 952 cm^{-1}; ^1H NMR (300 MHz) δ: 15.50 (bs, 0.8H), 5.48 (s, 0.8H), 3.54 (s, 0.4H), 2.50 (t, J = 8 Hz, 0.8H), 2.36 (t, J = 7 Hz, 2H), 2.26 (t, J = 8 Hz, 3.2 H), 1.72–1.52 (m, 8H), 1.42–1.22 (m, 20H), and 0.89 (t, J = 7 Hz, 3H). Exact Mass calcd. for $C_{22}H_{40}O_4$: 368.2916; found: 368.2935. Anal. calcd. for $C_{22}H_{40}O_4$: C 71.74, H 10.87; found: C 71.20, H 10.94.

5-Bromo-1-pentanol (28a)

This compound was prepared according to procedure A using 1,5-pentanediol (15.0 g, 140 mmol) and 48% HBr (24 mL, 211 mmol). The crude product was purified by column chromatography using petroleum ether:ethyl acetate (6:1) as eluent to give 12.4 g (52%) of **28*a*** as a colourless liquid: R_f 0.46 (1:1 petroleum ether:ethyl acetate); IR ν_{max}: 3346, 2936, 2865, 1456, 1434, 1274, 1238, 1137, 1061, 1014, 984, 950, and 734 cm^{-1}; ^1H NMR (400 MHz) δ: 3.70 (t, J = 8 Hz, 2H), 3.42 (t, J = 8 Hz, 2H), 1.92 (qn, J = 8 Hz, 2H), 1.72 (s, 1H), and 1.64–1.48 (m, 4H). Exact Mass calcd. for $C_5H_{11}BrO$ – H: 166.9892, 164.9912; found: 166.9902, 164.9911.

*1-Bromo-5-(*tert*-butyldimethylsilyloxy)-pentane (29a)*

This compound was prepared according to procedure B using the alcohol **28*a*** (2.90 g, 17.4 mmol). The crude product was purified by column chromatography using petroleum ether:ethyl acetate (15:1) as eluent to give 3.81 g (81%) of **29*a*** as a colourless oil: R_f 0.80 (6:1 petroleum ether:ethyl acetate); IR ν_{max}: 2950, 2940, 2890, 2858, 1467, 1388, 1361, 1254, 1102, 1006, 835, and 775 cm^{-1}; ^1H NMR (400 MHz) δ: 3.61 (t, J = 8 Hz, 2H), 3.41 (t, J = 8 Hz, 2H), 1.88 (qn, J = 8 Hz, 2H), 1.58–1.45 (m, 4H), 0.90 (s, 9H), and 0.07 (s, 6H). Exact Mass calcd. for $C_{11}H_{25}SiBrO$ – H: 281.0753, 279.0771; found: 281.0527, 2879.0772.

*10-(*tert*-Butyldimethylsilyloxy)-2,4-decanedione (30a)*

Following procedure D, the β-diketone **30*a*** was prepared using 2,4-pentanedione (1.72 g, 17.2 mmol) and bromide **29*a*** (4.83 g, 17.2 mmol). The crude product was purified by column chromatography using petroleum ether:ethyl acetate (15:1) as eluent to give 2.12 g (60%) of **30*a*** as a colourless oil: R_f 0.56 (6:1 petroleum ether:ethyl acetate); IR ν_{max}: 2936, 2858, 1716, 1614, 1465, 1361, 1252, 1100, 1005, 936, 837, and 775 cm^{-1}; ^1H NMR (400 MHz) δ: 15.50 (bs, 0.8 H), 5.49 (s, 0.8 H), 3.60 (t, J = 8 Hz, 2H), 3.59 (s, 0.4 H), 2.52 (t, J = 8 Hz, 0.4 H), 2.26 (t, J = 8 Hz, 1.6 H), 2.24 (s, 0.6 H), 2.07 (s, 2.4 H), 1.68–1.56 (m, 2H), 1.55–1.46 (m, 2H), 1.38–1.25 (m, 4H), 0.90 (s, 9H), and 0.06 (s, 6H). Exact Mass calcd. for $C_{16}H_{32}SiO_3$ – CH_3: 285.1879; found: 285.1884.

*1-(*tert*-Butyldimethylsilyloxy)-7,9-octadecanedione (31a)*

This compound was prepared according to procedure E using the β-diketone **30**a (1.2 g, 4.2 mmol) and 1-bromooctane (**12*b***) (0.77 g, 4.0 mmol). The crude product was purified by column chromatography using petroleum ether:ethyl acetate (20:1) as eluent to give 0.77 g (75%) of **31*a*** as a colourless oil: R_f 0.74 (6:1 petroleum ether:ethyl acetate); IR ν_{max}: 2930, 2856, 1722, 1707, 1611, 1463, 1387, 1360, 1252, 1101, 1006, 937, 836, 812, and 775 cm^{-1}; ^1H NMR (400 MHz) δ: 15.50 (bs, 0.8H), 5.48 (s, 0.8H), 3.61 (t, J = 8 Hz, 2H), 3.53 (s, 0.4H), 2.51 (t, J = 8 Hz, 0.4H), 2.50 (t, J = 8 Hz, 0.4H), 2.28 (t, J = 8 Hz, 1.6H), 2.27

Can. J. Chem. Downloaded from www.nrcresearchpress.com by EESC ESCOLA DE ENGENHARIA on 09/08/12
For personal use only.

(t, J = 8 Hz, 1.6H), 1.66–1.48 (m, 8H), 1.38–1.22 (m, 14H), 0.90 (s, 9H), 0.89 (t, J = 8 Hz, 3H), and 0.06 (s, 6H). Exact Mass calcd. for $C_{24}H_{48}SiO_3$: 412.3360; found: 412.3367.

*1-Hydroxy-7,9-octadecanedione (**32**a)*

This compound was prepared according to procedure C using the silyl ether **31***a* (640 mg, 1.55 mmol). The crude product was purified by recrystallization from hexanes to give 410 mg (89%) of **32***a* as a white solid: R_f 0.56 (1:1 petroleum ether:ethyl acetate); mp 57.5°C; IR ν_{max}: 3623, 2930, 2858, 1607, 1459, 1329, 1141, 1052, 965, and 904 cm^{-1}; ^1H NMR (400 MHz) δ: 15.50 (bs, 0.8H), 5.48 (s, 0.8H), 3.64 (t, J = 8 Hz, 2H), 3.55 (s, 0.4H), 2.52 (t, J = 8 Hz, 0.4H), 2.50 (t, J = 8 Hz, 0.4H), 2.29 (t, J = 8 Hz, 1.6H), 2.27 (t, J = 8 Hz, 1.6H), 1.70–1.50 (m, 9H), 1.42–1.18 (m, 14H), and 0.89 (t, J = 7 Hz, 3H). Exact Mass calcd. for $C_{18}H_{34}O_3$: 298.2499; found: 298.2505.

*7,9-Dioxooctadecanoic acid (**6**a)*

This compound was prepared according to procedure F using the alcohol 32*a* (298 mg, 1.00 mmol). The crude product was purified by recrystallization from hexanes to give 210 mg (67%) of **6***a* as a solid: R_f 0.52 (5% HOAc in 3:1 petroleum ether:ethyl acetate); mp 58.0°C; IR ν_{max}: 3340–2490, 2930, 2858, 1709, 1607, 1460, 1409, 1291, 1131, 950, and 907 cm^{-1}; ^1H NMR (300 MHz) δ: 15.50 (bs, 0.8H), 5.49 (s, 0.8H), 3.53 (s, 0.4H), 2.53 (t, J = 8 Hz, 0.4H), 2.49 (t, J = 8 Hz, 0.4H), 2.36 (t, J = 7 Hz, 2H), 2.30 (t, J = 8 Hz, 1.6H), 2.27 (t, J = 8 Hz, 1.6H), 1.72–1.52 (m, 6H), 1.46–1.22 (m, 14H), and 0.90 (t, J = 7 Hz, 3H). Exact Mass calcd. for $C_{18}H_{32}O_4$: 312.2292; found: 312.2291. Anal. calcd. for $C_{18}H_{32}O_4$: C 69.23, H 10.33; found: C 69.24, H 10.33.

*6-Bromo-1-hexanol (**28**b)*

This compound was prepared according to procedure A using 1,6-hexanediol (5.9 g, 50 mmol) and 48% HBr (8.2 mL, 73 mmol). The crude product was purified by column chromatography using petroleum ether:ethyl acetate (6:1) as eluent to give 4.2 g (46%) of **28***b* as a colourless liquid: R_f 0.48 (1:1 petroleum ether:ethyl acetate); IR ν_{max}: 3335, 2932, 2860, 1447, 1260, and 1055 cm^{-1}; ^1H NMR (400 MHz) δ: 3.68 (t, J = 8 Hz, 2H), 3.43 (t, J = 8 Hz, 2H), 1.88 (qn, J = 8 Hz, 2H), 1.62 (m, 2H), and 1.52–1.34 (m, 5H). Exact Mass calcd. for $C_6H_{13}BrO$ – H: 181.0048, 179.0068; found: 181.0043, 179.0063.

*1-Bromo-6-(*tert*-butyldimethylsilyloxy)-hexane (**29**b)*

This compound was prepared according to procedure B using the alcohol **28***b* (2.86 g, 15.8 mmol). The crude product was purified by column chromatography using petroleum ether:ethyl acetate (15:1) as eluent to give 4.12 g (88%) of **29***b* as a colourless oil: R_f 0.82 (6:1 petroleum ether:ethyl acetate); IR ν_{max}: 2936, 2858, 1466, 1253, 1101, 837, and 775 cm^{-1}; ^1H NMR (400 MHz) δ: 3.61 (t, J = 8 Hz, 2H), 3.41 (t, J = 8 Hz, 2H), 1.87 (qn, J = 8 Hz, 2H), 1.58–1.50 (m, 2H), 1.48–1.41 (m, 2H), 1.40–1.33 (m, 2H), 0.90 (s, 9H), and 0.06 (s, 6H). Exact Mass calcd. for $C_{12}H_{27}SiBrO$ – H: 295.2000, 293.2020; found: 295.0917, 293.0928.

2,4-Dodecanedione

Following procedure D, this β-diketone was prepared from 2,4-pentanedione (3.00 g, 30.0 mmol) and 1-bromoheptane (5.37 g, 30.0 mmol). The crude product was purified by column chromatography using petroleum ether:ethyl acetate (15:1) as eluent to give 2.70 g (63%) of 2,4-dodecanedione as a colourless oil: R_f 0.64 (6:1 petroleum ether:ethyl acetate); IR ν_{max}: 2931, 2856, 1713, 1614, 1449, 1363, 1241, 946, and 777 cm^{-1}; ^1H NMR (400 MHz) δ: 15.50 (bs, 0.8H), 5.49 (s, 0.8H), 3.58 (s, 0.4H), 2.50 (t, J = 8 Hz, 0.4H), 2.27 (t, J = 8 Hz, 1.6H), 2.24 (s, 0.6H), 2.07 (s, 2.4H), 1.68–1.52 (m, 2H), 1.40–1.20 (m, 10H), and 0.89 (t, J = 7 Hz, 3H). Exact Mass calcd. for $C_{12}H_{22}O_2$: 198.1614; found: 198.1626.

*1-(*tert*-Butyldimethylsilyloxy)-8,10-octadecanedione (**31**b)*

This compound was prepared according to procedure E using 2,4-dodecanedione (2.50 g, 12.6 mmol) and the bromide **29***b* (3.10 g, 10.5 mmol). The crude product was purified by column chromatography using petroleum ether:ethyl acetate (20:1) as eluent to give 2.30 g (75%) of **31***b* as a colourless oil: R_f 0.76 (6:1 petroleum ether:ethyl acetate); IR ν_{max}: 2909, 2856, 1704, 1615, 1459, 1360, 1251, 1100, 945, 838, and 775 cm^{-1}; ^1H NMR (400 MHz) δ: 15.50 (bs, 0.8H), 5.48 (s, 0.8H), 3.61 (t, J = 8 Hz, 2H), 3.53 (s, 0.4H), 2.50 (t, J = 8 Hz, 0.8H), 2.27 (t, J = 8 Hz, 3.2H), 1.66–1.42 (m, 8H), 1.40–1.22 (m, 14H), 0.90 (s, 9H), 0.89 (t, J = 7 Hz, 3H), and 0.06 (s, 6H). Exact Mass calcd. for $C_{24}H_{48}SiO_3$: 412.3360; found: 412.3377.

*1-Hydroxy-8,10-octadecanedione (**32**b)*

This compound was prepared according to procedure C using the silyl ether **31***b* (2.00 g, 4.85 mmol). The crude product was purified by recrystallization from hexanes to give 1.26 g (87%) of **32***b* as a white solid: R_f 0.64 (1:1 petroleum ether:ethyl acetate); mp 57.0°C; IR ν_{max}: 3622, 3460, 2931, 2857, 1703, 1607, 1458, 1335, 1051, and 902 cm^{-1}; ^1H NMR (400 MHz) δ: 15.50 (bs, 0.8H), 5.48 (s, 0.8H), 3.64 (t, J = 8 Hz, 2H), 3.54 (s, 0.4H), 2.51 (t, J = 8 Hz, 0.4H), 250 (t, J = 8 Hz, 0.4H), 2.26 (t, J = 8 Hz, 1.6H), 2.25 (t, J = 8 Hz, 1.6H), 1.70–1.20 (m, 23H), and 0.89 (t, J = 7 Hz, 3H). Exact Mass calcd. for $C_{18}H_{34}O_3$: 298.2499; found: 298.2514.

*8,10-Dioxooctadecanoic acid (**6**b)*

This compound was prepared according to procedure F using the alcohol **32***b* (596 mg, 2.00 mmol). The crude product was purified by recrystallization from hexanes to give 306 mg (50%) of **6***b* as a white solid: R_f 0.53 (5% HOAc in 3:1 petroleum ether:ethyl acetate); mp 58.5°C; IR ν_{max}: 3340–2480, 2931, 2858, 1708, 1608, 1459, 1300, and 1127 cm^{-1}; ^1H NMR (400 MHz) δ: 15.50 (bs, 0.8H), 5.49 (s, 0.8H), 3.54 (s, 0.4H), 2.51 (t, J = 8 Hz, 0.4H), 2.50 (t, J = 8 Hz, 0.4H), 2.36 (t, J = 8 Hz, 2H), 2.27 (t, J = 8 Hz, 1.6H), 2.26 (t, J = 8 Hz, 1.6H), 1.72–1.50 (m, 6H), 1.48–1.20 (m, 14H), and 0.90 (t, J = 7 Hz, 3H). Exact Mass calcd. for $C_{18}H_{32}O_4$: 312.2292; found: 312.2307. Anal. calcd. for $C_{18}H_{32}O_4$: C 69.23, H 10.33; found: C 68.94, H 10.38.

*9-Bromo-1-nonanol (**28**c)*

This compound was prepared according to procedure A using 1,9-nonanediol (10.0 g, 62.5 mmol) and 48% HBr (10.5 mL, 93.8 mmol). The crude product was purified by column chromatography using petroleum ether:ethyl acetate (6:1) as eluent to give 9.78 g (70%) of **28***c* as a white solid: R_f 0.58 (1:1 petroleum ether:ethyl acetate); mp 34.0°C; IR ν_{max}: 3622, 3460, 2929, 2857, 1459, 1386, 1352, 1274, 1111, 1044, and 889 cm^{-1}; ^1H NMR (400 MHz) δ: 3.64 (t, J = 7 Hz, 2H), 3.42 (t, J = 7 Hz, 2H), 1.83 (qn, J = 8 Hz, 2H), 1.58 (m, 2H), and 1.48–1.30 (m, 11H). Exact Mass calcd. for $C_9H_{19}BrO$ – H_2O: 206.0489, 204.0514; found: 206.0494, 204.0509.

*1-Bromo-9-(*tert*-butyldimethylsilyloxy)-nonane (**29**c)*

This compound was prepared according to procedure B using the alcohol **28***c* (2.66 g, 11.9 mmol). The crude product was purified by column chromatography using petroleum ether:ethyl acetate (15:1) as eluent to give 3.60 g (90%) of **29***c* (3.60 g, 90%) as a colourless oil: R_f 0.84 (6:1 petroleum ether:ethyl); IR ν_{max}: 2933, 2856, 1466, 1387, 1360, 1252, 1101, 1006, 839, 775, and 717 cm^{-1}; ^1H NMR (400 MHz) δ: 3.60 (t, J = 7 Hz, 2H), 3.41 (t, J = 7 Hz, 2H), 1.86 (qn, J = 7 Hz, 2H), 1.54–1.48 (m, 2H), 1.46–1.37 (m, 2H), 1.35–1.26 (m, 8H), 0.89 (s, 9H), and 0.05 (s, 6H). Exact Mass calcd. for $C_{15}H_{33}SiBrO$ – C_4H_9: 281.0173, 279.0193; found: 281.0748, 279.0786.

*14-(*tert*-Butyldimethylsilyloxy)-2,4-tetradecanedione (**30**c)*

Following procedure D, the β-diketone **30***c* was prepared from 2,4-pentanedione (0.98 g, 9.4 mmol) and bromide **29***c*. The crude product was purified by column chromatography using petroleum ether:ethyl acetate (15:1) as eluent to give 2.12 g (79%) of **30***c* as a colourless oil: R_f 0.66 (6:1 petroleum ether:ethyl acetate); IR ν_{max}: 2932, 2856, 1709, 1616, 1465, 1387, 1361, 1251, 1100, 1006, 940, 838, 813, and 776 cm^{-1}; ^1H NMR (400 MHz) δ: 15.50 (bs, 0.8H), 5.49 (s, 0.8H), 3.59 (t, J = 7 Hz, 2H), 3.57 (s, 0.4H), 2.49 (t, J = 8 Hz, 0.4H), 2.27 (t, J = 8 Hz, 1.6H), 2.24 (s, 0.6H), 2.06 (s, 2.4H), 1.65–1.46 (m, 6H), 1.40–1.24 (m, 10H), 0.89 (s, 9H), and 0.06 (s, 6H). Exact Mass calcd. for $C_{20}H_{40}SiO_3$ – H: 355.2658; found: 355.2676.

*18-(*tert*-Butyldimethylsilyloxy)-6,8-octadecanedione (**31**c)*

This compound was prepared according to procedure E using the β-diketone **30***c* (1.2 g, 3.2 mmol) and 1-bromobutane (0.60 g, 3.2 mmol). The crude product was purified by column chromatography using petroleum ether:ethyl acetate (20:1) as eluent to give 0.65 g (77%) of **31***c* as a colourless oil: R_f 0.77 (6:1 petroleum ether:ethyl acetate); IR ν_{max}: 2934, 2856, 1730, 1707, 1612, 1463, 1386, 1361, 1252, 1100, 1006, 940, and 838 cm^{-1}; ^1H NMR (400 MHz) δ: 15.66 (bs, 0.1H), 15.54 (bs, 0.7H), 5.48 (s, 0.7H), 5.47 (s, 0.1H), 3.61 (t, J = 7 Hz, 2H), 3.54 (s, 0.4H), 2.49 (t, J = 8 Hz, 0.8H), 2.27 (m, 3.2H), 1.66–1.46 (m, 8H), 1.38–1.22 (m, 14H), 0.90 (s, 12H), and 0.06 (s, 6H). Exact Mass calcd. for $C_{24}H_{48}SiO_3$ – H: 411.3282; found: 411.3287.

*18-Hydroxy-6,8-octadecanedione (**32**c)*

This compound was prepared according to procedure C using the silyl ether **31***c* (360 mg, 0.87 mmol). The crude product was purified by recrystallization from hexanes to give 250 mg (96%) of **32***c* as a white solid: R_f 0.66 (1:1 petroleum ether:ethyl acetate); mp 56.0°C; IR ν_{max}: 3621, 3456, 2974, 2931, 1700, 1608, 1455, 1390, and 1047 cm^{-1}; ^1H NMR (400 MHz) δ: 15.50 (bs, 0.8H), 5.48 (s, 0.8H), 3.64 (t, J = 7 Hz, 2H), 3.53 (s, 0.4H), 2.51 (t, J = 8 Hz, 0.8H), 2.27 (t, J = 8 Hz, 3.2H), 1.64–1.50 (m, 9H), 1.42–1.22 (m, 14H), and 0.92–0.86 (m, 3H). Exact Mass calcd. for $C_{18}H_{34}O_3$: 298.2499; found: 298.2504.

*11,13-Dioxooctadecanoic acid (**6**c)*

This compound was prepared according to procedure F using the alcohol **32***c* (200 mg, 0.67 mmol). The crude product was purified by recrystallization from hexanes to give 130 mg (64%) of **6***c* as a white solid: R_f 0.56 (5% HOAc in 3:1 petroleum ether:ethyl acetate); mp 56.5°C; IR ν_{max}: 3350–2500, 2933, 2859, 1710, 1605, 1458, 1395, 1281, 1138, 1047, 951, and 879 cm^{-1}; ^1H NMR (300 MHz) δ: 15.50 (bs, 0.8H), 5.48 (s, 0.8H), 3.55 (s, 0.4H), 2.50 (t, J = 8 Hz, 0.8H), 2.35 (t, J = 7 Hz, 2H), 2.27 (t, J = 8 Hz, 3.2H), 1.70–1.52 (m, 6H), 1.40–1.22 (m, 14H), and 0.94–0.86 (m, 3H). Exact Mass calcd. for $C_{18}H_{32}O_4$: 312.2292; found: 312.2294. Anal. calcd. for $C_{18}H_{32}O_4$: C 69.23, H 10.33; found: C68.94, H 10.25.

*2,4-Undecanedione (**33**)*

This compound was prepared according to procedure D using 1-bromohexane (**12***a*) (4.50 mL, 32.0 mmol) and 2,4-pentanedione (4.10 mL, 40.0 mmol). Distillation of the crude product under reduced pressure (155°C/50 Torr) gave 3.70 g (63%) of **33** as a colourless oil: R_f 0.60 (6:1 petroleum ether:ethyl acetate eluent); IR ν_{max}: 2930, 2858, 1711, 1613, 1446, 1364, 1254, and 947 cm^{-1}; ^1H NMR (400 MHz) δ: 15.50 (bs, 0.8H), 5.49 (s, 0.8H), 3.58 (s, 0.4H), 2.51 (t, J = 8 Hz, 0.4H), 2.27 (t, J = 8 Hz, 1.6H), 2.25 (s, 0.6H), 2.06 (s, 2.4H), 1.65–1.52 (m, 2H), 1.38–1.22 (m, 8H), and 0.89 (t, J = 7 Hz, 3H). Exact Mass calcd. for $C_{11}H_{20}O_2$: 184.1458; found: 184.1459.

*8,10-Octadecanedione (**7**)*

This compound was prepared according to procedure E using the β-diketone **33** (756 mg, 4.11 mmol) and 1-bromoheptane (660 mg, 3.69 mmol). Purification of the crude product by column chromatography using petroleum ether:ethyl acetate (20:1) gave 803 mg (77%) of **7** as a colourless oil: R_f 0.78 (6:1 petroleum ether:ethyl acetate eluent); IR ν_{max}: 2934, 2857, 1704, 1613, 1455, 1276, 1142, 1102, and 942 cm^{-1}; ^1H NMR (400 MHz) δ: 15.50 (bs, 0.8H), 5.48 (s, 0.8H), 3.53 (s, 0.4H), 2.50 (t, J = 8 Hz, 0.8H), 2.26 (t, J = 8 Hz, 3.2H), 1.64–1.50 (m, 4H), 1.48–1.22 (m, 18H), and 0.89 (t, J = 7 Hz, 6H). Exact Mass calcd. for $C_{18}H_{34}O_2$: 282.2550; found: 282.2565. Anal. calcd. for $C_{18}H_{34}O_2$: C 76.52, H 12.14; found: C 76.80, H 12.16.

Binding and transport of calcium ions by synthetic analogues of ionomycin

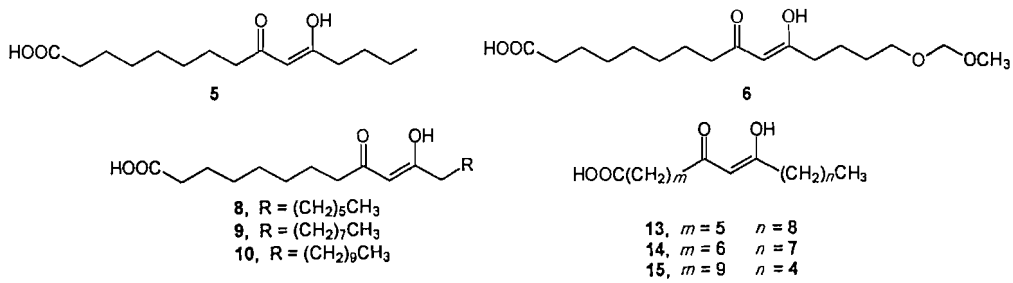
THOMAS Q. HU AND LARRY WEILER[1]

Department of Chemistry, University of British Columbia, 2036 Main Mall, Vancouver, BC V6T 1Z1, Canada

Received June 30, 1993[2]

THOMAS Q. HU and LARRY WEILER. Can. J. Chem. **72**, 1512 (1994).

The transport of calcium ions across an organic barrier by a series of synthetic analogues of ionomycin was measured in a cylindrical glass cell using chloroform as the artificial membrane. The presence of a β-diketone and carboxyl group in the same molecule and a sufficient lipid solubility of the compounds were shown to be necessary and sufficient conditions for Ca^{2+} transport. Small and no transport of Ca^{2+} were found for analogues **5** and **6**, respectively, due to the low lipid solubility of these compounds. The Ca^{2+} transport rate for analogues **8** and **13–15** followed the order of **8** > **13** > **14** > **15**, which demonstrated that optimal Ca^{2+} transport was achieved when the β-diketone was separated from the carboxyl group by seven methylene units, identical to that found in ionomycin. Analogues **8–10** were comparable to ionomycin and calcimycin in terms of Ca^{2+} transport. Ca^{2+} transport by the analogues was found to be a saturable process that obeyed Michaelis-Menten kinetics. It was dependent on the pH in the aqueous source phase and independent of the pH in the receiving phase. Both the carboxyl and the β-diketo groups were ionized in the transport of Ca^{2+}, indicating that the stoichiometry of Ca^{2+} complex in transport was 1:1. The pK_a of the β-diketone of the analogues was determined to be in the range of 10.90–11.16 in 80% MeOH–H_2O. The pK_a values were related to the lipid solubility of the compounds and the hydrocarbon chain length between the β-diketone and the carboxyl group. The binding constants of the analogues with Ca^{2+} and Mg^{2+} in 80% MeOH–H_2O were determined to be in the order of 10^2 M^{-1} and 10^3 M^{-1}, respectively, using the pK_a method. The stoichiometry of Mg^{2+} binding was found to be 1:1 by the mole ratio method. The selectivity in binding and in transport followed the same order, being $Mg^{2+} > Ca^{2+} \gg Na^+, K^+$.



THOMAS Q. HU et LARRY WEILER. Can. J. Chem. **72**, 1512 (1994).

Opérant dans une cellule de verre cylindrique et utilisant du chloroforme comme membrane artificielle, on a mesuré le transport d'ions calcium à travers une barrière organique par une série d'analogues de l'ionomycine. On a montré que la présence d'une β-dicétone et d'un groupe carboxyle dans la même molécule et une solubilité lipidique suffisante des composés sont des conditions nécessaires et suffisantes pour le transport du Ca^{2+}. À cause de faible solubilité lipidique de ces composés, on n'a observé aucun ou que de faibles transports avec les analogues **5** et **6** respectivement. Les vitesses de transport du Ca^{2+} des composés **8** et **13–15** sont dans l'ordre décroissant suivant : **8**, **13**, **14** et **15** qui démontre que le transport optimal du Ca^{2+} se fait lorsque la β-dicétone est séparée du groupe carboxyle par sept groupes méthylènes, comme dans l'ionomycine. En terme de transport du Ca^{2+}, les analogues **8–10** se comparent à l'ionomycine et à la calcimycine. On a trouvé que le transport du Ca^{2+} par les analogues est un processus qui peut être saturé et qui obéit à la cinétique de Michaelis–Menten. Il est dépendant du pH de la phase aqueuse agissant comme source et il est indépendant du pH de la phase qui les reçoit. Les groupes carboxyle et β-dicétonique sont tous les deux ionisés au cours du transport du Ca^{2+}; ceci indique que la stoechiométrie du complexe de transport du Ca^{2+} est 1 : 1. On a déterminé que, dans un mélange 80% de MeOH–H_2O, les pK_a des β-dicétones des analogues sont de l'ordre de 10,90–11,16. On a relié les valeurs de pK_a avec la solubilité lipidique des composés et la longueur de la chaîne carbonée entre la β-dicétone et le groupe carboxyle. Utilisant la méthode des pK_a, on a déterminé que, dans un mélange 80% de MeOH–H_2O, les constantes de liaison des analogues avec le Ca^{2+} et le Mg^{2+} sont respectivement de l'ordre de 10^2 et 10^3 M^{-1}. Utilisant la méthode des rapports molaires, on a déterminé que la stoechiométrie de liaison du Mg^{2+} est 1 : 1. On a observé que la sélectivité de liaison et de transport suit toujours l'ordre décroissant suivant : Mg^{2+}, Ca^{2+}, Na^+ et K^+.

Introduction

Although the importance of calcium ions in the skeletal structures of living organisms has been recognized for more than a century, only recently have other biological roles for Ca^{2+}, particularly its function as an intracellular messenger, been demonstrated (1). A minute flow of calcium ions across cell membranes has been found to trigger such diverse processes as the regulation of muscle contraction, the secretion of hormones, the transport of salt and water across the intestinal lining, and the control of glycogen metabolism in the liver (2). For a substance to serve as an intracellular messenger, a target protein must be able to bind it tightly and with high specificity. The size and charge of calcium ions are such that the negatively charged oxygens found on the side chains of aspartate and glutamate residues as well as uncharged oxygens from the carbonyls of a protein backbone can bind calcium ions more strongly and specifically than other common biological ions such as potassium, sodium, and magnesium ions (3).

The ability of the cell membrane to effect a large increase in Ca^{2+} concentration inside the cell is a key in the role of Ca^{2+} as an intracellular messenger (4). The intracellular concentration of free Ca^{2+} is very low, on the order of 10^{-7} M in virtually all animal cells (5). On the other hand, the concentration of free Ca^{2+} in the extracellular medium is high, on the order of 10^{-3} M in vertebrates and higher in marine invertebrates (4). This Ca^{2+} concentration gradient, together with a membrane potential of −40 to −90 mV, allows for a rapid entry of Ca^{2+} into the cell upon the activation of calcium-selective channels by appropriate electrical or chemical signals (4).

Because of the important role of Ca^{2+} in the cell, it is essential to regulate intracellular Ca^{2+} levels to be able to effectively control many cellular processes. Two typical ways of altering intracellular Ca^{2+} concentrations are to inject a calcium salt or a Ca^{2+} chelating agent such as ethylenediaminetetraacetic acid (EDTA) into the cell, or to add a substance to the extracellular fluid that will alter the concentration of intracellular Ca^{2+}.

The first approach was adopted by Heilbrunn and Wiercinski who injected calcium salts into frog muscle to stimulate contraction (6). This approach is simple, but it has several difficulties. First, the micropipette can cause irreversible damage to the cell. Second, the quantity of calcium salts that must be injected to significantly raise the concentration of Ca^{2+} in the cytoplasm, and yet be low enough to avoid irreparable damage, is often unknown. Finally, since calcium ion buffering systems exist within cells, an elevated free Ca^{2+} concentration in the cytoplasm is difficult to maintain for more than a few seconds by the injection method.

An alternative approach is to introduce a substance that affects either the Ca^{2+} permeability of the cell membrane or the intracellular Ca^{2+} reservoirs. Since the extracellular Ca^{2+} concentration is 10^3–10^6 higher than the intracellular Ca^{2+} concentration, Ca^{2+} may be transported across the cell membrane down its concentration gradient by lipophilic compounds known as Ca^{2+} ionophores (7). Such ionophores have proven useful in altering intracellular Ca^{2+} levels. Three such ionophores are lasalocid A (**1**) (formerly known as X-537A), calcimycin (**2**) (formerly known as A23187), and ionomycin (**3**) (8–12). The transport of Ca^{2+} from one aqueous phase to another by these ionophores is due to their ability to form lipid soluble ionophore–Ca^{2+} complexes (13) and to the favorable Ca^{2+} complexation and decomplexation kinetics involved in the transport cycle (14).

Efforts to develop synthetic Ca^{2+} ionophores based on the analysis of the structures of lasalocid A and calcimycin have met with certain success (15–17). Two diglycolamic acids prepared by Umen and Scarpa were shown to transport Ca^{2+} across an artificial membrane comparable to lasalocid A and calcimycin (15). The use of lipophilic acyclic polyether dicarboxylic acids as mobile carriers to transport Ca^{2+}, Mg^{2+}, and Ba^{2+} across an artificial membrane was reported by Hiratani et al. (16). Fyles and co-workers have shown that crown ether dicarboxylic acids selectively transported alkaline earth cations across an organic barrier as a 1:1 complex (17).

An artificial membrane such as bulk liquid membrane was used by the above authors and others as a simple method to study ionophore-catalyzed cation transport (18, 19). Chloroform is usually employed in these transport studies because its dielectric constant ($\epsilon = 4.8$) is similar to the dielectric constant of the interior of a phospholipid membrane ($\epsilon = 2$–4) (20).

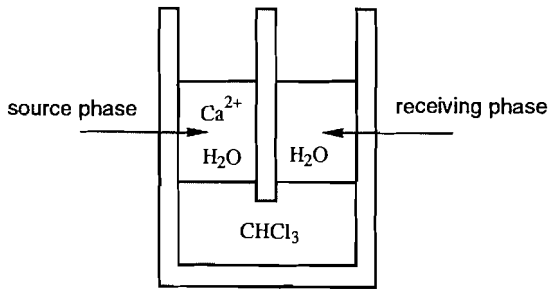

FIG. 1. Cylindrical glass cell for the studies of Ca^{2+} transport.

Among the known naturally occurring polyether Ca^{2+} ionophores, ionomycin is unique in that it forms a 1:1 Ca^{2+} salt and it has a high selectivity for Ca^{2+} in binding and transport (11, 12). Ionomycin has been widely used as a tool to investigate the role of Ca^{2+} as a second messenger in biological system (21, 22). However, no attempt has been made to understand the structural features controlling the Ca^{2+} binding and transport by ionomycin or to develop simple compounds that will mimic the action of ionomycin. We recently reported the design and synthesis of some simple analogues of ionomycin (23). Herein we describe the results of our studies on the Ca^{2+} binding and transport properties of these ionomycin analogues and their potential as Ca^{2+} ionophores.

Results and discussion

Transport experiments were carried out using a cylindrical glass cell system (Fig. 1) containing a source phase (10 mL), a chloroform phase (40 mL), and a receiving phase (10 mL). The volume of the chloroform solution was such that two separate compartments were created above the organic solution (Fig. 1). The chloroform solution was stirred continuously and samples (0.2 mL) were withdrawn from the receiving phase at different times and analyzed by calcium atomic absorption spectrophotometry.

Table 1 lists the amount of Ca^{2+} in the receiving phase at different times using analogue **4** as the carrier. Each value in the table is the average of three independent experiments with a standard error of less than 10%. The data in Table 1 illustrates that the amount of Ca^{2+} in the receiving phase increases linearly up to 24 h. At this time approximately 0.5% of the Ca^{2+} of the source phase has been transported into the receiving phase. A plot of Ca^{2+} transported versus time within this linear range (Fig. 2) gives a slope 0.50. The initial transport rate, J, expressed as the moles of Ca^{2+} transported per square centimeter of the chloroform per hour was $(7.3 \pm 0.7) \times 10^{-8}$ mol cm^{-2} h^{-1}. We observed this linear relationship between the initial Ca^{2+} transport and time in all our transport experiments and consequently we have used the initial transport rate J to compare the Ca^{2+} transport efficiency of the various analogues.

To insure that the above Ca^{2+} transport was not due to the leakage of Ca^{2+} across the chloroform layer (blank transport of Ca^{2+}), we carried out the transport experiment in the absence of analogue **4** in the chloroform phase. Analysis of the samples withdrawn from the receiving phase showed no detectable Ca^{2+}. This established the carrier role of analogue **4** in the transport of Ca^{2+} across an organic barrier. We next carried out the transport experiments on analogues **5** and **6** to examine the effect of oxygen donor sites on Ca^{2+} transport.

[a]No detectable Ca^{2+} transport.

Table 2 summarizes the transport results on analogues **4**, **5**, and **6**.

Compound **4** was the most efficient carrier for the transport of Ca^{2+} of these three analogues. This could be due to the effect of the three oxygen atoms on the side chain of **4** on coordination of Ca^{2+}. However, no detectable transport of Ca^{2+} was observed for analogue **6**, which has two additional oxygen atoms compared to analogue **5**. We anticipated that the additional oxygen atoms should facilitate Ca^{2+} transport (24). However, it appeared that the additional oxygen atoms on the side chain of **6** actually were detrimental to Ca^{2+} transport.

Besides providing potential Ca^{2+} coordination sites, additional oxygen atoms on the side chain of analogues **4** and **6** could change the lipophilicity of these molecules, which may affect the Ca^{2+} transport of the compounds. To investigate the effect of carrier lipophilicity on Ca^{2+} transport we car-

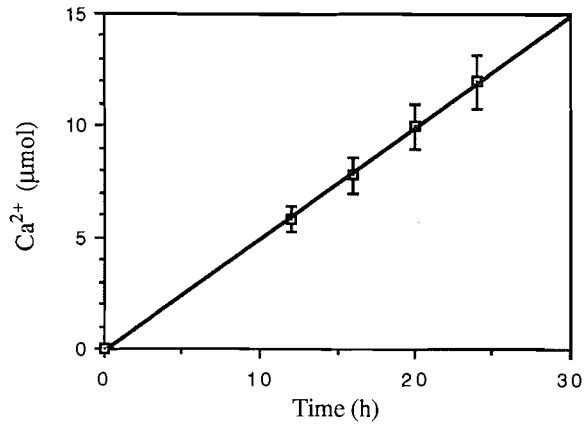

FIG. 2. Transport of Ca^{2+} by **4**.

ried out the transport experiments on analogues **7–10**, which have different hydrocarbon side chains (Table 2). These results demonstrate that the lipophilicity of the carrier does play an important role in the transport of Ca^{2+}. Analogue **7** with no methylene units on the hydrocarbon side chain did not transport Ca^{2+} across the chloroform phase. Analogue **5** with three methylene units on the side chain was able to transport Ca^{2+}. The addition of more methylene units in compounds **8**, **9**, and **10** resulted in a significant increase of Ca^{2+} transport. In fact, analogues **8–10** are more efficient Ca^{2+} carriers than analogue **4**.

Additional evidence pointing to the importance of lipid solubility of the carrier in Ca^{2+} transport was obtained when the concentration of the analogues **7–10** in the chloroform phase was monitored during the transport experiments. A small volume (1 mL) of the chloroform solution was withdrawn at different times, the solvent was evaporated, and the residue was dissolved in methanol. The magnitude of the UV absorption of the methanol solution at 276 nm was used to determine the carrier concentration in the organic phase. The concentration of analogues **8**, **9**, and **10** in the chloroform phase was found to remain constant throughout the transport experiments. In contrast, the concentration of analogue **7** in the chloroform phase steadily decreased. Using UV spectroscopy the lost carrier was found to be in the aqueous source phase. Thus, analogues **8**, **9**, and **10** are efficient Ca^{2+} carriers because they and their Ca^{2+} complexes had sufficient lipid solubility to remain in the chloroform phase. Analogue **7** did not transport Ca^{2+} across the chloroform layer because it was extracted into the aqueous source phase due to its higher hydrophilicity.

Interestingly, the transport rate of analogue **10** was only comparable to analogues **8** and **9** even though it had more methylene units on the side chain. This may be due to the low solubility of **10** in the high dielectric constant interface of the chloroform and aqueous source phase where Ca^{2+} transport is initiated (18*a*). If this rationale is correct, the transport of Ca^{2+} will depend upon the concentration of interfacial carrier. A good carrier must be neither too hydrophobic nor too hydrophilic. Analogues **8** and **9** appear to have the optimal lipid solubility for Ca^{2+} transport.

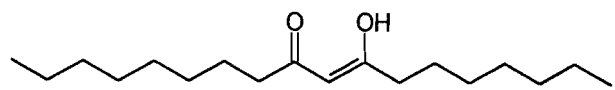
The above results not only illustrate the importance of lipophilicity of the carrier in Ca^{2+} transport, but also suggest that other compounds possessing the β-diketone and carboxyl group with different carbon skeletons may also be efficient Ca^{2+} carriers if their lipophilicity is similar to analogues **8–10**. The structural simplicity of analogues **5** and **7–10** allowed us to use Rekker's hydrophobic fragmental constant method (*f* method) (25) to calculate their logarithms of the partition coefficient (log *P*) between chloroform and water. Table 3 lists the calculated log *P* values and Ca^{2+} transport rates for analogues **5** and **7–10**. The *f* values are not available for the fragments of analogues **4** and **6**. The data in Table 3 suggest that the minimum value of log *P* for Ca^{2+} transport is about 4 and the optimal value of log *P* is in the range of 6–8. The future design of Ca^{2+} ionophores based on ionomycin should have a calculated or experimentally determined value of log *P* in this range.

TABLE 3. Ca^{2+} transport rates (*J*) and calculated log *P* values for analogues **5** and **7–10**

Analogue	*J* (10^{-8} mol cm^{-2} h^{-1})	log *P*
7	<0.1[a]	2.18
5	0.3 ± 0.1	4.06
8	15 ± 2	5.95
9	15 ± 2	7.20
10	13 ± 1	8.45

[a]No detectable Ca^{2+} transport.

To further understand the ability of analogues **8–10** to transport Ca^{2+} we studied the role of the β-diketone and carboxyl group in Ca^{2+} transport. Transport experiments were carried out using compounds **11** (log *P* = 9.40) and **12** (log *P* = 8.53), respectively. No detectable transport of Ca^{2+} was observed even though the lipid solubility of these two compounds was sufficiently high compared to compounds **8–10**. This indicates that both the β-diketone and carboxyl group are required for the transport of Ca^{2+}. The stronger binding of compounds containing two β-diketo groups relative to those with a single β-diketo binding site is known (26).



11

12

To determine if the presence of the two functional groups *within* the same molecule was required for Ca^{2+} transport, we performed a transport experiment with both **11** and **12** in the chloroform phase and again found no detectable presence of Ca^{2+} in the receiving phase. This demonstrates that both functional groups must be present in the same molecule for Ca^{2+} transport, and that the distance between the two functional groups may be important. The effect of the distance between these two functional groups on Ca^{2+} transport was then investigated using analogues **13–15**. These three compounds have the same lipid solubility (log *P* = 5.95) as analogue **8** but have the β-diketone and the carboxyl group closer together or further apart than in **8**. The number of methylene units (*n*) between the two functional groups and the Ca^{2+} transport rate (*J*) of these compounds is given in Table 2.

The results show that moving the β-diketone closer to or further away from the carboxyl group produces a significant decrease in the Ca^{2+} transport rate. The low Ca^{2+} transport rate of analogue **15** is likely due to the large unfavorable entropy

change associated with the formation of its Ca^{2+} complex. The first step in the ionophore-catalyzed Ca^{2+} transport is believed to be the binding of the ionophore with Ca^{2+} to form the Ca^{2+} complex (17, 18*a*, 27). As the number of methylene units between the β-diketone and the carboxyl group is increased, additional loss of entropy would be required to bind and transport Ca^{2+}, resulting in a less effective Ca^{2+} complexation and transport. This trend can be expected to continue until the β-diketone is so far removed from the carboxyl group that the two functional groups act independently, in which case no transport of Ca^{2+} would be observed.

On the other hand, as the number of methylene units between the β-diketone and the carboxyl group is reduced, the enthalpy of the Ca^{2+} complex would increase due to the increasing steric strain (bond angle strain, torsional angle strain, and transannular interactions) in the chelate rings of the complex. This unfavorable enthalpy may outweigh the more favorable entropy. It appears that the competing role of enthalpy and entropy may be minimized when seven methylene units separate the two functional groups such as in analogue **8**. It would also appear that ionomycin was biosynthesized with the optimal distance between the two functional groups for Ca^{2+} transport.

The high efficiency of analogues **8–10** as Ca^{2+} carriers was illustrated by comparison of these analogues with calcimycin and ionomycin (Table 2). As seen from these data, Ca^{2+} transport by ionomycin is about twice as fast as calcimycin at the same molar concentration. This is in agreement with the transport results obtained for these two ionophores in other transport systems (28) and is due to the difference in the molar ratio of the ionophore–Ca^{2+} complex. Ionomycin transports Ca^{2+} as a 1:1 complex while calcimycin transports Ca^{2+} as a 2:1 complex (12, 13).

Ca^{2+} transport by analogues **8–10** is faster than by calcimycin, but slower than by ionomycin. The higher Ca^{2+} transport rate of ionomycin relative to analogues **8–10** may be attributed to the smaller entropy change associated with the formation of ionomycin–Ca^{2+} complex. Although the β-diketone and carboxyl group in both ionomycin and analogues **8–10** are separated by a seven-carbon chain, there are three methyl substituents on this chain in ionomycin. These three methyl substituents, with their particular stereochemistry, may destabilize undesired rotomers of the acyclic bonds and reduce the number of conformations to those suitable for Ca^{2+} complexation (29). This would reduce the entropy loss in the formation of Ca^{2+} complex and thus could increase the Ca^{2+} transport rate for ionomycin.

Analogues **8–10** are interesting Ca^{2+} carriers because of their simple structures and high efficiency of Ca^{2+} transport. However, a useful Ca^{2+} ionophore should transport Ca^{2+} both efficiently and selectively. In particular, it should have selectivity for Ca^{2+} over Na^+ and K^+ because of the ubiquitous presence of Na^{2+} and K^+ in biological systems. Calcimycin and ionomycin both have selectivity for Ca^{2+} over Na^+ and K^+ (9, 20). Ionomycin is also selective for Ca^{2+} over Mg^{2+} (20).

To study the cation selectivity of our compounds, three transport experiments were carried out on analogue **8**. For each experiment, a solution of equimolar concentration of calcium chloride (250 mM) and the chloride of the competing cation was placed in the source phase. Samples were withdrawn from the receiving phase and analyzed for Ca^{2+} and the competing cation. No detectable transport of Na^+ or K^+ was observed in these experiments. Thus, the requirement of cation selectivity for Ca^{2+} over Na^+ and K^+ was met in analogue **8**. Unlike ionomycin, analogue **8** transported Mg^{2+} at a faster rate than Ca^{2+}.

The cation transport selectivity of **8** is likely due to the selectivity in binding (see later) which is expected to follow the order of ionic potentials of the cations $Mg^{2+} > Ca^{2+} > Na^+ > K^+$. Magnesium and calcium ions are both doubly charged and will bind to the enolate of β-diketone and the carboxylate more strongly than singly charged cations such as Na^+ and K^+. On the other hand, the smaller magnesium ion (0.65 Å) will bind to the enolate of β-diketone and the carboxylate more strongly than calcium ion (0.99 Å) (3).

The cation selectivity of ionomycin for Ca^{2+} over Mg^{2+} in transport may be due to the size-match selectivity (30). Ionomycin has a limited number of low-energy conformations in which the size of the chelating portion of the molecule matches the size of Ca^{2+}, but not the size of Mg^{2+}. The coordination of cations by the additional oxygen atoms of ionomycin could also be the source of its selectivity for Ca^{2+} over Mg^{2+}. The magnesium ion is small and its coordination with additional oxygen atoms of the ionophore would increase steric crowding of the molecule more than the coordination of a larger calcium ion. As a result, the less favourable enthalpy in the Mg^{2+} complex could lead to the reversed cation selectivity in transport by ionomycin.

Analogues **9** and **13** were found to induce Ca^{2+} transport across cultured human leukemic cells (THP-1 cells) at or greater than 1 mM.[3] Cellular Ca^{2+} transport by analogues **9** and **13** was transient and significantly smaller than that by calcimycin bromide or ionomycin. In vivo testing also showed that analogues **6** and **7** did not transport Ca^{2+} across the membrane of THP-1 cells.[3] This result is in agreement with those of the transport experiments using chloroform as the artificial membrane and is likely due to the low lipophilicity of the compounds in the cell membrane.

To gain insight into the transport mechanism of the analogues, we investigated the effect of substrate concentration and pH on Ca^{2+} transport. The first step in the transport of Ca^{2+} across the chloroform phase is the binding of the ionophore to Ca^{2+} at the interface of the chloroform and the aqueous source phase (18*a*, 27). This is followed by the diffusion of the Ca^{2+} complex across the chloroform phase and Ca^{2+} release into the aqueous receiving phase (18*a*, 27). If the binding of Ca^{2+} is reversible, the ionophore-catalyzed Ca^{2+} transport would show saturation kinetics (18*a*, 31). Equation [1] describes the process involved in an ionophore-catalyzed Ca^{2+} transport. The ionophore (L^{2-}) binds reversibly to Ca^{2+} to form an ionophore–Ca^{2+} complex (CaL) that then diffuses across the membrane and releases Ca^{2+} with the regeneration of the ionophore on protonation. If the binding of Ca^{2+} is reversible, the transport rate (J) can be related to the maximal rate (J_{max}) through the Michealis–Menten equation (eq. [2]) in which K_s and k_{-s} refer to the rate of association and dissociation at the interface of the organic phase and the source phase, and K_r refers to the dissociation at the interface of the organic phase and the receiving phase. K_M is approximately equal to the equilibrium dissociation constant of the ionophore–Ca^{2+} complex if $k_r \ll k_{-s}$ (31, 32).

$$[1] \qquad L^{2-} + Ca^{2+} \underset{k_{-s}}{\overset{k_s}{\rightleftharpoons}} CaL \xrightarrow{k_r} L^{2-} + Ca^{2+}$$

TABLE 4. Variation of Ca^{2+} transport rates (J) for analogue **8** with Ca^{2+} concentration in the source phase

$[Ca^{2+}]$(mM)	J (10^{-8} mol cm^{-2} h^{-1})
10	0.6 ± 0.1
50	4.4 ± 0.4
100	5.9 ± 0.6
250	13 ± 1
500	15 ± 2
1000	16 ± 2

TABLE 5. Ca^{2+} transport rates (J) for analogue **8** at various pH in the receiving phase

pH	J (10^{-8} mol cm^{-2} h^{-1})
8.0	15 ± 2
7.0	16 ± 2
6.0	16 ± 2
5.0	15 ± 2

$$[2] \qquad J = \frac{J_{max}[Ca^{2+}]}{K_M + [Ca^{2+}]} \qquad K_M = \frac{k_r + k_s}{k_s}$$

Table 4 lists the results of the transport experiments using analogue **8** and various concentrations of calcium chloride in the source phase. The data could be fitted into the Michaelis–Menten equation (eq. [2]) by nonlinear regression to give a hyperbolic curve with a standard error of less than 10% (33). Therefore, Ca^{2+} transport across the chloroform layer by analogue **8** is a saturable process that obeys the Michaelis–Menten kinetics. The values of the Michaelis–Menten constant K_M and the maximal transport rate J_{max} were determined to be K_M = 170 mM and $J_{max} = 20 \times 10^{-8}$ mol cm^{-2} h^{-1}, respectively, by the above nonlinear regression analysis. The large K_M indicates that the binding of Ca^{2+} by analogue **8** is weak ($k_{-s} \gg k_s$) and (or) the diffusion of the analogue-Ca^{2+} complex and the release of Ca^{2+} is very fast compared to the binding of Ca^{2+} ($k_r \gg k_s$). Our studies on the binding of **8** with Ca^{2+} in aqueous methanol (see later) also suggested that $k_{-s} \gg k_s$.

The exchange of Ca^{2+} from the ionophore–Ca^{2+} complex (CaL) in the chloroform layer for protons from the aqueous receiving phase is the final step of the ionophore-catalyzed transport cycle. If this process is irreversible as suggested by the Michaelis–Menten kinetics, a small change in the concentration of hydrogen ions in the receiving phase should not significantly affect the transport rate. This was found to be the case when the pH of the receiving phase was varied and the Ca^{2+} transport rate was determined (Table 5).

The presence of the carboxyl and β-diketo groups in the same molecule was shown above to be necessary for Ca^{2+} transport. However, it was not clear if ionization of the β-diketone is required for transport. The role of the enolate of the β-diketone in the transport of Ca^{2+} was investigated by varying the pH in the aqueous source phase above pH 7. No detectable transport of Ca^{2+} was found when the source phase was buffered at pH ≤ 7.0. Table 6 shows the results of the transport experiments using analogue **5** while varying the pH in the source phase.

The logarithm of Ca^{2+} transport rate (log J) was found to be linear with the pH in the source phase. Thus, transport of Ca^{2+} by analogue **5** is directly dependent on the hydroxide concentration in the source phase. The dependence of Ca^{2+} transport on the hydroxide concentration in the source phase suggests that the formation of the carboxylate and (or) the enolate of the β-diketone of analogue **5** is required for the transport of Ca^{2+}. Nonlinear regression analysis of the transport rate data versus pH using eq. [3] derived from the Henderson–Hasselbalch equation gave a typical plot (Fig. 3) for the ionization of a monoprotic acid with a pK_a of 9.6 ± 0.1.

TABLE 6. Effect of pH of the source phase on Ca^{2+} transport rates (J) for analogue **5**

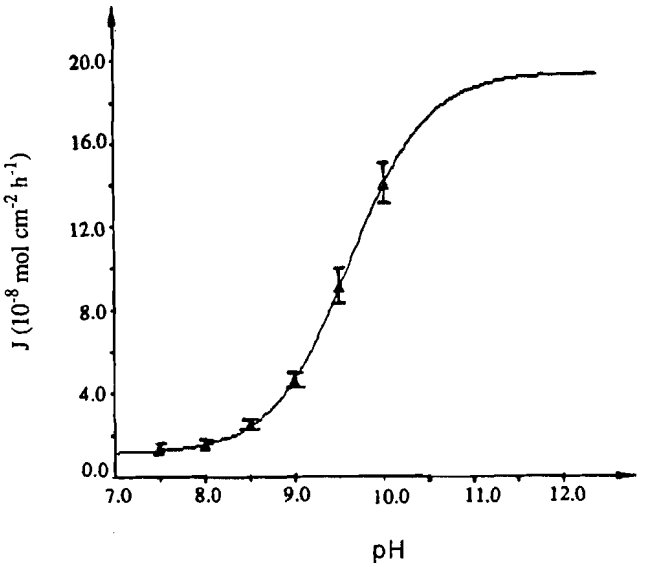

FIG. 3. Plot of the dependence of transport rates on pH of the source phase. The points represent the experimental values and the solid line is determined by nonlinear regression according to eq. [3].

$$[3] \qquad J = \frac{J_{min} + J_{max} \times 10^{pH-pK_a}}{10^{pH-pK_a} + 1}$$

In their studies of competitive alkaline-earth cations extraction from aqueous solution into chloroform by polyether dicarboxylic acids, Kang et al. demonstrated that the carboxyl groups of the alkanoic acids were completely deprotonated at the interface of the aqueous solution and chloroform at pH (pH in the aqueous phase) 6 or above and that the resulting dicarboxylates extracted divalent cations as neutral complexes into the chloroform phase (34). On the other hand, β-dicarbonyl compounds were shown to have pK_a values in the range of 8.5–10.5 (26*a*, 35). Thus we conclude that the carboxyl group in our analogues is completely ionized at the aqueous interface in all of our experiments and we assign the pK_a value of 9.6 to the ionization of the β-diketone of **5**. Such a dependence of transport rate on pH of the source phase indicates that ioniza-

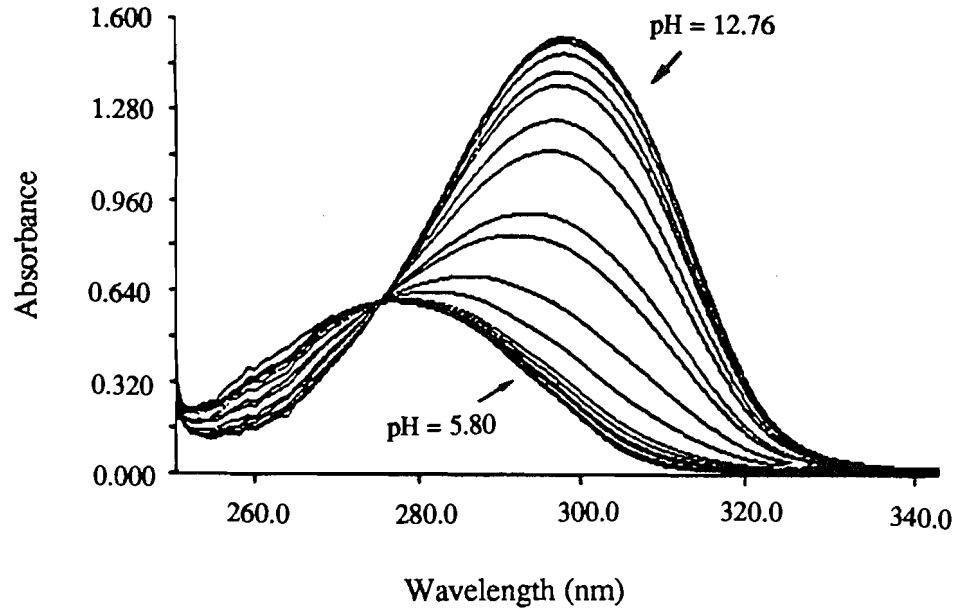

FIG. 4. UV absorption spectra of analogue **13** as a function of pH.

tion of the β-diketone at the interface of the aqueous source phase and chloroform is required for Ca^{2+} transport.

The formation of the carboxylate and the enolate of the β-diketone at the interface of the aqueous source phase and chloroform in the transport of Ca^{2+}, the requirement of both the carboxyl and β-diketone groups within the same molecule for Ca^{2+} transport, and the requirement of electrical neutrality of the Ca^{2+} complex in chloroform (34) indicate that the stoichiometry of the Ca^{2+} complex involved in transport is 1:1.

To understand the structural features controlling the Ca^{2+} specificity of ionomycin and the transport behavior of the analogues, we investigated the cation binding of analogues **5**, **8–11**, **13**, and **15** by UV spectrophotometric titrations (36). The inability of analogue **8** to transport Na^+ and K^+ suggests that the binding of the analogues with these cations may be very small. Thus neither the mole ratio method (37) nor the continuous variation method (38) appears to be applicable to the studies of Na^+ or K^+ binding. However, the binding constants of the analogues with various cations could be determined by measuring the pK_a difference of the β-diketone of an analogue in the absence and in the presence of a large excess of metal ions. For example, if HL^- represents a β-diketo ω-carboxylate, its acid dissociation constant K_a is then defined by eq. [5] and the binding constant (β) of the enolate L^{2-} with Ca^{2+} by eq. [7].

$$[4] \qquad HL^- \rightleftharpoons H^+ + L^{2-}$$

$$[5] \qquad K_a = \frac{[H^+][L^{2-}]}{[HL^-]}$$

$$[6] \qquad L^{2-} + Ca^{2+} \rightleftharpoons CaL$$

$$[7] \qquad \beta = \frac{[CaL]}{[Ca^{2+}][L^{2-}]}$$

In the presence of a large excess of Ca^{2+}, the acid dissociation constant $K_{a'}$ will be defined by eq. [9], which can be used to determine the binding constant β.

$$[8] \qquad HL^- + Ca^{2+} \rightleftharpoons H^+ + CaL$$

$$[9] \qquad K_{a'} = \frac{[H^+][CaL]}{[HL^-][Ca^{2+}]} = \frac{[CaL]}{[Ca^{2+}][L^{2-}]} \frac{[H^+][L^{2-}]}{[HL^-]}$$

$$= \beta K_a$$

Measurement of the pK_a of the β-diketone of the analogues by UV spectrophotometric titration is based on the different absorptions of the enol form of the β-diketone and its conjugated base, the enolate of the β-diketone (39, 40). For example, the UV absorbance maximum of analogue **13** in 80% MeOH–H_2O shifts to longer wavelength and increases in magnitude as the pH of the solution is raised (Fig. 4). The absorbance at 298 nm (ascribable to the enolate of the β-diketone) versus pH was fitted to a modified Henderson–Hasselbalch equation by nonlinear regression to give a pK_a value of 11.16 ± 0.02 for analogue **13** (Fig. 5) (33).

Table 7 summarizes the pK_a of the β-diketone of a number of analogues. The pK_a value of the β-diketone of ionomycin is significantly higher than that of the β-diketone of the analogues. This is likely due to the lower stability of the dianion of ionomycin in polar solvent such as 80% MeOH–H_2O. The alkyl groups on ionomycin may destabilize its dianion relative to its monoanion to a greater extent than in the case of the simple analogues. A similar hydrophobic effect is found in the series **5** and **8–10**. Namely the lipid solubilities and the pK_a values of these analogues follow the same order of **10** > **9** > **8** > **5**. The pK_a of the β-diketone also depends on the position of the β-diketone relative to the carboxylate group. The closer the β-diketone is to the carboxylate (as in analogue **13**), the higher the pK_a value, presumably due to stronger charge repulsion between the enolate anion and the carboxylate anion as they are brought closer together.

The binding constants of the analogues with Ca^{2+}, Mg^{2+}, K^+, and Na^+ were determined by measuring the pK_a values of the β-diketone in the presence of a large excess of the cation (molar ratio of cation to analogue > 200) and using eq. [9]

(Tables 8 and 9). The data shows that the selectivity in binding for the analogues is $Mg^{2+} > Ca^{2+} \gg Na^+ > K^+$. This follows the same order as the cation transport selectivity. Thus we suggest that the cation transport selectivity results from the cation binding selectivity for our analogues. The binding constants also correlate with the pK_a of the β-diketone. For example, moving the β-diketone closer to the carboxyl group in the series **15**, **8**, and **13** increases the pK_a of the β-diketone and its binding constants with cations. The binding constants of ionomycin with Ca^{2+} and Mg^{2+} are 3 to 4 orders of magnitude stronger than those of the analogues reported here. This may be due to the fact that ionomycin has a limited number of conformations available compared to the analogues and consequently the loss of entropy in binding of ionomycin is significantly less than the loss of entropy in binding of the analogues (41).

Because of the strong binding of these analogues with Mg^{2+}, the mole ratio method could be used to determine the binding constant of these analogues with Mg^{2+} and also to determine the stoichiometry of the complex on binding. At pH = 9.10 there was no significant ionization of the β-diketone of **13**, but in the presence of Mg^{2+} ionization of the β-diketone occurred at this pH (Fig. 6). From the absorbance at 298 nm in the absence of magnesium ion (A_0), the absorbance at complete complexation (A_{max}) and the absorbance at each titration point (A), the concentration of the Mg^{2+} complex at equilibrium $[Mg_xL_y]$ was calculated using eq. [10]. The concentrations of

free analogues $[L^{2-}]$ and free magnesium ion $[Mg^{2+}]$ were calculated respectively based on mass balance. Assuming a binding stoichiometry of 1:1, the binding constant calculated using eq. [11] (Table 10) was found to be β (Mg^{2+}) = (7.9 ± 0.5) × 10^3 M^{-1}. The consistency of the calculated binding constants at each titration point is additional evidence of the 1:1 stoichiometry (42). The binding constant determined using this method is in a good agreement with the binding constant of β (Mg^{2+}) = (7.6 ± 0.4) × 10^3 M^{-1} obtained using the pK_a method.

$$[10] \qquad [Mg_xL_y] = \frac{(A - A_0)[L]_t}{A_{max} - A_0}$$

$$[11] \qquad \beta(Mg^{2+}) = \frac{[MgL]}{[Mg^{2+}][L^{2-}]}$$

Alternatively, the data for the number of moles of magnesium ions $[Mg_xL_y]$ bound per mole of the analogue $[L]_t$ versus the concentration of free Mg^{2+} could be fitted to the Scatchard equation by nonlinear regression (Fig. 7) (33, 43) to give the binding constant of β (Mg^{2+}) = (7.1 ± 0.1) × 10^3 M^{-1}. The stoichiometry of binding again was found to be 1:1.

Table 11 summarizes the calculated binding constants of a number of analogues with Mg^{2+} using the pK_a method and the mole ratio method. The stoichiometry in binding for all the analogues was found to be 1:1 by the latter method. The binding constants of the analogues with Mg^{2+} determined by these two methods are consistent. Therefore, the binding constants of the analogues with Ca^{2+} determined by the pK_a method can confidently be compared with the binding constants of ionomycin and other Ca^{2+} ionophores with Ca^{2+} determined by the mole ratio method. The 1:1 stoichiometry of Mg^{2+} binding, together with the requirement of the presence of the carboxyl and β-diketone groups in the same molecule for Ca^{2+} transport, and the formation of both the carboxylate and enolate of the β-diketone in transport, suggested that the Ca^{2+} complex had a 1:1 stoichiometry in binding and transport.

In conclusion, the basic structural requirements for efficient Ca^{2+} transport are the presence of the β-diketone and the carboxyl group in the same molecule, and a simple alkyl side chain with sufficient lipid solubility. The distance between the β-diketone and the carboxyl group is important in controlling the efficiency of Ca^{2+} transport. Optimal Ca^{2+} transport is achieved when the β-diketone is separated from the carboxyl

[a]Values determined using the pK_a method.
[b]Values determined using the mole ratio method.

group by seven methylene units, identical to that found in ionomycin. It appears that additional oxygen binding sites on the side chain of the analogues do not enhance the transport of Ca^{2+}. Analogues with sufficient lipid solubility are comparable to calcimycin and ionomycin in terms of Ca^{2+} transport. Ca^{2+} transport by synthetic analogues of ionomycin is a saturable process that obeys Michaelis–Menten kinetics. Ca^{2+} transport is dependent of the pH in the aqueous source phase and independent of the pH in the receiving phase. Both the carboxyl and the β-diketone groups are ionized in the transport of Ca^{2+}, indicating that the stoichiometry of Ca^{2+} complex in transport is 1:1.

The pK_a of the β-diketone of the analogues was measured by UV spectrophotometric titration and found to be lower than that of the β-diketone in ionomycin. The pK_a values of the analogues were related to the lipid solubility of the compounds and the length of the hydrocarbon chain between the β-diketone and the carboxyl group. The binding constants of the analogues with Ca^{2+}, Mg^{2+}, K^+, and Na^+ were determined by measuring the pK_a and the β-diketone in the presence and absence of the cation. The selectivity in binding by the analogues were the same as the selectivity in transport, which was $Mg^{2+} > Ca^{2+} \gg Na^+$, K^+. The binding constants of the analogues with Ca^{2+} and Mg^{2+} were 3 to 4 orders of magnitude lower than those of ionomycin. The mole ratio method was used to determine the binding constants of the analogues with Mg^{2+} and the stoichiometry in binding. The consistency of the Mg^{2+} binding constants determined by both the pK_a and the mole ratio methods verified the utility of the pK_a method for the measurement of binding constants of the analogues with Ca^{2+}, K^+, and Na^+.

Experimental section

Determination of metal ion transport

The transport of metal ions across a chloroform liquid membrane by synthetic analogues of ionomycin was determined in a cylindrical glass cell shown in Fig. 1. To determine the Ca^{2+} transport of the various analogues, a 200 mM solution of analogue in 40 mL of glass-distilled chloroform (OmniSolv BDH Inc.) was placed at the bottom of the transport vessel. A solution of 500 mM calcium chloride and 40 mM CHES/Me_4NOH buffer in 10 mL of distilled deionized water at pH = 9.50 was placed on one side of the transport vessel as the source phase. A solution of 40 mM MOPS/Me_4NOH buffer in 10 mL of distilled deionized water at pH = 7.00 was placed on the other side of the transport vessel as the receiving phase. The chloroform solution was stirred continuously with a 10 × 3 mm microstirring bar at a constant speed of 400 ± 20 rpm as determined by a chronometric speedcounter.

An aliquot of 200 mL of the receiving phase was withdrawn at regular intervals, diluted with 4.80 mL of distilled deionized water and analyzed for Ca^{2+} by calcium atomic absorption spectrophotometry. In all the transport experiments the concentration of Ca^{2+} in the receiving phase increased linearly with time when the quantity of Ca^{2+} transported was small. Results from separate runs were reproducible within ±10%. The initial transport rate (J) is expressed as the moles of Ca^{2+} transported per square centimeter of the organic phase per hour.

Cation selectivity in transport was determined using a source phase of 10 mL of distilled deionized water containing equimolar concentration (250 mM) of calcium chloride and the chloride of the competing cation (Mg^{2+}, Na^+, and K^+ respectively), and 40 mM CHES/Me_4NOH buffer at pH = 9.50. The samples taken from the receiving phase were analyzed for the concentrations of both cations by atomic absorption spectrometry on a Perkin–Elmer model 560 atomic absorption spectrophotometer.

Buffers that had negligible affinity for Mg^{2+}, Ca^{2+}, Na^+, and K^+ were used to control the pH in the source phase and the receiving phase (44). They were prepared by mixing an aqueous solution of 10% tetramethylammonium hydroxide with an acid having a pK_a close to the desired working pH and diluting the solution with distilled deionized water to a final concentration of 40 mM.

Cation selectivity in transport

The transport experiments were carried out according to the general procedure for the determination of metal ion transport with 250 mM calcium chloride, 250 mM of the chloride of the competing cation, and 40 mM CHES/Me_4NOH buffer in 10 mL of distilled deionized water at pH = 9.5 for the source phase.

Effect of calcium concentration in the source phase on calcium transport

The transport experiments were carried out according to the general procedure for the determination of metal ion transport using a given concentration of calcium chloride and 40 mM CHES/Me_4NOH buffer in 10 mL of distilled deionized water at pH = 9.5 for the source phase.

Effect of pH in the receiving phase on calcium transport

The transport experiments were carried out according to the general procedure for the determination of metal ion transport using 40 mM of a given buffer in 10 mL of distilled deionized water at a given pH for the receiving phase.

positions of the three layers in the transport vessel were 300 mM of analogue **4** in 40 mL of chloroform for the organic phase, 40 mM MOPS/Me_4NOH buffer in 10 mL of distilled deionized water at pH = 6.5 for the receiving phase, and 500 mM calcium chloride and 40 mM of a given buffer in 10 mL of distilled deionized water at a given pH for the source phase.

Determination of the pK_a of the β-diketone of the synthetic analogues of ionomycin

The pK_a of the β-diketone of the synthetic analogues was determined in 80% MeOH–H_2O by UV spectrophotometric titration at 25°C on a Perkin–Elmer UV–visible Lambda 2 spectrometer with a thermostated sample cell. An aliquot of 1.0 mL 80% MeOH–H_2O was placed in a disposable cuvette (1.0 cm pathlength) in the sample cell and the baseline was recorded from 260 to 350 nm and stored. The solvent was then replaced by a solution of 80 mM analogue and 50 mM Et_4NClO_4 in 1.0 mL of 80% MeOH–H_2O. Small aliquots (4–20 μL) of 0.1, 0.25, 0.5, and 5.0% Me_4NOH (the titrant) in 80% MeOH–H_2O were added and the spectra were recorded. The addition of the titrant was terminated when the maximum absorption of the spectrum remained constant.

The values of pH at each titration point were determined with the same solutions on a 5-fold greater scale on a PHM82 Standard pH meter (Bach–Simpson Limited). The pH meter was standardized with pH = 7.0 and pH = 10.0 aqueous buffer solutions. No correction was made for differences in the pH readings between pure aqueous solutions and 80% MeOH–H_2O solutions.

The absorbance at 298 nm versus pH was computer-fitted to a modified Henderson–Hasselbalch equation by nonlinear regression (33) to calculate the pK_a values.

Determination of the binding constants of the analogues with various metal cations

The binding constant of the analogues with various metal cations was determined in 80% MeOH–H_2O by UV spectrophotometric titration at 25°C. The UV spectrophotometric titration of the analogues was carried out in the presence of 50 mM NaCl, 50 mM KBr, 16.7 mM $CaCl_2$, and 16.7 mM $MgCl_2$, respectively (in place of Et_4NClO_4). The absorbance at 298 nm versus pH was computer-fitted to a modified Henderson–Hasselbalch equation by nonlinear regression to calculate the pK_a of a β-diketone in the presence of the metal ion. The difference between p$K_{a'}$ and pK_a gave the logarithm of the dissociation constant of the analogue–cation complex.

The binding constant of the analogues with Mg^{2+} was also determined using the mole ratio method. A solution of 80 mM analogue and 50 mM CHES/Me_4NOH buffer in 80% MeOH–H_2O was titrated with a solution of 5, 10, 25, 50, 100, and 250 mM $MgCl_2$ in 80% MeOH–H_2O. Calculations of the number of moles of Mg^{2+} bound per mole of the analogue versus the concentration of free Mg^{2+} at each titration point were computer-fitted to the Scatchard equation by nonlinear regression to determine the binding constant (33, 43). This method also allowed the determination of the stoichiometry of the complex.

Crystal and solution structure of a pendant-armed macrocyclic complex of palladium(II)

B. CHAK, A. MCAULEY, AND T.W. WHITCOMBE
Department of Chemistry, University of Victoria, Victoria, BC V8W 3P6, Canada

Received August 17, 1993

B. CHAK, A. MCAULEY, and T.W. WHITCOMBE. Can. J. Chem. **72**, 1525 (1994).

The synthesis and X-ray crystal structure of [Pd)py_2[9]aneN_2S)]$(BF_4)_2$ (py_2[9]aneN_2S = 1-thia-4,7-bis(pyridylmethyl)diazacyclononane) ($P2_1/n$, a = 10.233(4) Å, b = 11.484(5) Å, c = 19.913(6) Å, β = 94.03(4)°, V = 2334(2) Å^3, R = 0.0705, R_w = 0.0759) are presented. The crystal structure indicates a long range interaction (2.92 Å) between the planar palladium and the apical sulphur atom. Although this distance is longer than the value for a Pd—S bond observed normally there is evidence for a net positive interaction provided by the solution structure as determined by NMR spectroscopy. Comparative analysis of the structural features exhibited by this complex with similar nine-membered chelating ligands emphasizes the presence of an axial Pd—S bond.

B. CHAK, A. MCAULEY et T.W. WHITCOMBE. Can. J. Chem. **72**, 1525 (1994).

On a réalisé la synthèse du [Pd(py_2[9]aneN_2S)]$(BF_4)_2$ (py_2[9]aneN_2S = 1-thia-4,7-bis(pyridylméthyl)-diazacyclononane) et on en a déterminé la structure par diffraction des rayons X ($P2_1/n$, a = 10,233(4), b = 11,484(5) et c = 19,913(6) Å, β = 94,03(4)°, R = 0,0705 et R_w = 0,0759). La structure cristalline indique la présence d'une interaction à longue distance (2,92 Å) entre le palladium plan et l'atome de soufre apical. Même si cette distance est plus longue que la valeur d'une liaison Pd—S observée normalement, la structure en solution, telle que déterminée par spectroscopie rmn, fournit une preuve de l'existence d'une nette interaction positive. Une analyse comparative des caractéristiques de structure de ce complexe avec ceux de coordinats chélatants à neuf chaînons semblables fait ressortir la présence d'une liaison Pd—S axiale.

[Traduit par la Rédaction]

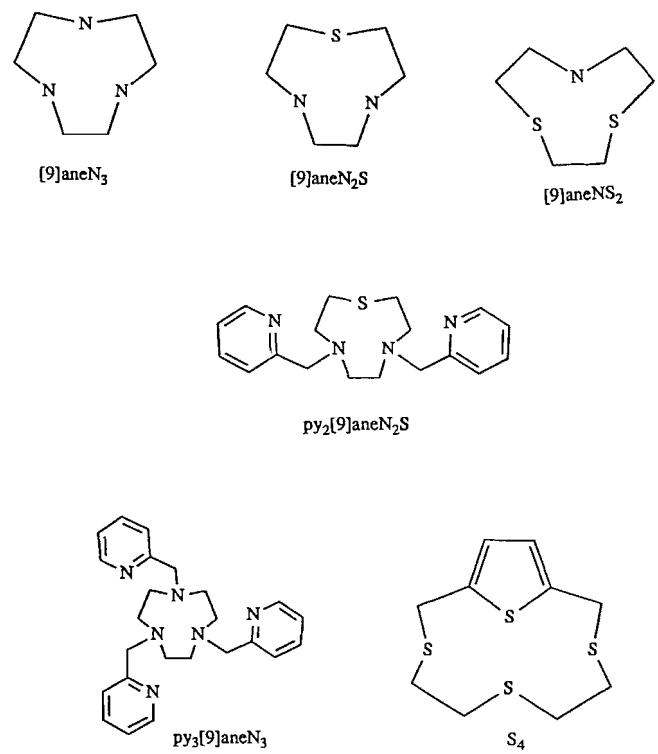
Introduction

There has been considerable recent interest in the chemistry of metal complexes involving macrocyclic ligands with pendant arms (1). In some instances this derives from biological studies where it has been demonstrated that the complexation of functional groups that are integral parts of the structure but not fixed rigidly in place, provides a mechanism for activation of the metal site (2, 3). Examples of novel chemistry have emerged from these studies, including the demonstrated electrochemical reduction of CO_2 to CO through the use of a pendant-arm macrocyclic complex of nickel (4).

In addition, less common coordination geometries have been detected. The tris(pyridylmethyl)-1,4,7-triazacyclonane (py_3[9]aneN_3) complex of Pd(II) has been shown to contain a square pyramidal PdN_5 core, in which the metal-coordinated and -uncoordinated pyridine nitrogens interconvert within the NMR time scale (5). There are also several recent examples of fluxionality at Pd(II) detected by NMR spectroscopy involving both pendant armed and simple macrocyclic ligands (6, 7). In particular, several complexes with thia-macrocyclic ligands have been examined (8, 9).

In the present paper, the synthesis of the ligand 1-thia-4,7-bis(pyridylmethyl)diazacyclononane (py_2[9]aneN_2S) (Scheme 1) is reported together with the crystal structure of its palladium(II) complex. The metal complex provides an interesting contrast to [Pd(py_3[9]aneN_3)]$^{2+}$ in that the presence of only two arms prohibits a complete scrambling of the coordination environment but does not preclude the possibility of fluxional NMR spectroscopy.

The coordination of the [9]aneN_2S ring in a facial geometry results in the sulfur atom being positioned axially[1] such that the inter-atomic distance is borderline between a "bonding" and "non-bonding" interaction. One method of investigating such potential bonding is to compare the torsional angles within the 9-membered ring of the present complex with those for well-characterized metal-ion – N_2S ring systems in which data for axial bonds have been structurally characterized. The structural rigidity of the complex in solution may also be monitored by NMR techniques in which fluxional processes involving the axial donor of the ligand are not observed.



SCHEME 1

Experimental

The nine-membered macrocyclic ligand, [9]aneN_2S, was prepared by literature procedures (10, 11). All chemicals used were of reagent grade unless otherwise specified.

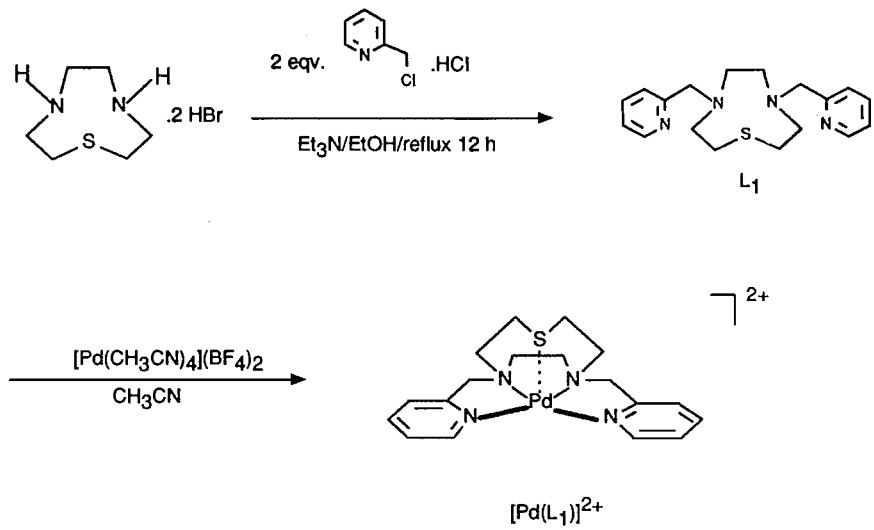

SCHEME 2

1-Thia-4,7-bis(pyridylmethyl)diazacyclononane ($py_2[9]aneN_2S$)

To a 100 mL round bottom flask equipped with a magnetic stirrer, reflux condensor, and nitrogen inlet was added a solution containing the dihydrobromide salt of [9]aneN$_2$S (0.465 g, 1.51 mmol), 2-(chloromethyl)pyridine.HCl (0.50 g, 3.05 mmol), and 9.5 equiv. of triethylamine (14.3 mmol) in absolute ethanol. The reaction mixture was refluxed for 12 h under a N_2 atmosphere and subsequently extracted with chloroform (3 × 100 mL). The chloroform extract was washed with water (5 × 100 mL) and dried over anhydrous Na_2SO_4. The solvent was removed using a rotary evaporator. The pale yellow oil obtained consisted of mainly the desired product but traces of unreacted 2-(chloromethyl)pyridine.HCl were detected. Yield: 0.3 g (≈ 60%). MS(CI): M + 1 329, M + 29 357. ^{1}H NMR ($CDCl_3$): δ 2.65 (s, 4H, NCH_2CH_2N), δ 2.95 (m, 4H, CH_2N), δ 3.05 (m, 4H, CH_2S), δ 3.82 (s, 4H, CH_2—py), δ 7.12, δ 7.51, δ 7.63, δ 8.48 (m, 8H, pyridine—H). ^{13}C NMR ($CDCl_3$): δ 32.0 (CH_2S), δ 56.0 (NCH_2CH_2N), δ 59.0 (CH_2N), δ 64.2 (CH_2—pyridine), δ 121.8, δ 123.2, δ 136.2, δ 148.9. δ 160.0 (pyridine—C). The oil was used directly in reaction with the metal ion to give the palladium(II) complex.

$[Pd(py_2[9]aneN_2S)](BF_4)_2$

To an acetonitrile solution of the ligand (0.11 g, 0.34 mmol) was added solid $[Pd(CH_3CN)_4](BF_4)_2$ (0.13 g, 0.29 mmol). The solution immediately turned orange/brown and was heated to a gentle reflux for an hour, under an atmosphere of nitrogen, to ensure complete complexation. After cooling to room temperature, the solution was taken to dryness to give an orange/brown solid. Redissolving this solid in a minimum of acetonitrile and slow diffusion of diethyl ether yielded orange/brown crystals of $[Pd(py_2[9]aneN_2S)](BF_4)_2$ of X-ray quality. Yield of crystals: 120 mg. Anal. calcd. for $C_{18}H_{24}N_4SPdB_2F_8$: C 35.53, H 3.98, N 9.21; found: C 35.74, H 3.91, N 9.29.

Crystallography

An orange/brown crystal was mounted inside a Lindemann tube using epoxy resin. An initial unit cell and space group were obtained by Weissenberg and precession photography. The crystal was transferred to a Picker Four-circle Diffractometer and the unit cell refined using 10 reflections in the 2θ range, 37° to 52°, while the choice of space group was confirmed. The data were collected using 200 steps of 0.01° in 2θ at 0.25 s per step. Background counting for 25 s was carried out before and after each reflection measurement. Three standard reflections were measured at the beginning of every 50 reflections, with no significant decay being observed.

A total of 5356 reflections were obtained of which 3790 were within the limits $I > 2\sigma(I)$. Refinement was achieved through location of the palladium atom by the direct methods package of SHELX76 (12) and subsequent structural refinement using the least-squares difference maps. The atomic scattering factors and Pd *f*-curve were taken from the usual source (13). Absorption correction was performed using a locally modified version of an existing program (14). Final values of R = 0.0705 and R_w = 0.0759 were obtained with all non-hydrogen atoms anisotropic. The hydrogen atoms were not included in the structure refinement. A final difference map gave a maximum residual electron density of 0.2 e/Å^3 and a maximum shift/e.s.d. of 0.005 for final convergence.

Spectroscopy

^{1}H and ^{13}C NMR spectra were recorded on either a Bruker WM 250 MHz or a Bruker AMX 360 MHz spectrometer, operating at the appropriate frequencies. The UVspectra were obtained with a Varian Cary 5 spectrometer. Electrochemical measurements were performed with a PAR 273 Galvanostat/Potentiostat connected to an IBM PC with the HEADSTART software package. The electrochemical cell consisted of the usual three electrode arrangement with a platinum working and counter electrode. The choice of reference electrode was solvent dependent, being Ag/AgCl in aqueous media (0.1 M $LiClO_4$) and Ag/AgNO3 in non-aqueous media (0.1 M Bu_4NPF_6). In the non-aqueous environment, the reference electrode was calibrated against the $Fc^{+/0}$ couple.

Results and discussion

Synthesis and spectroscopy

The synthesis of the ligand, $py_2[9]aneN_2S$, is outlined in Scheme 2, together with the formation of the palladium(II) complex. The formation of the dihydrobromide salt of 1,4-diaza-7-thiacyclononane (**II**) was achieved by literature procedures (10, 11) and proceeds with reasonable yields. Care must be taken during the detosylation of the amines to avoid cleavage of the C—S bonds with the ring.

The methyl pyridine moiety was added to the ring by the reaction of **II** with 2-(chloromethyl)pyridine.HCl in the presence of triethylamine in absolute ethanol. The ligand, which was isolated as a pale yellow oil in 60% yield, was found not to be stable upon exposure to air and light for periods of time, gradually darkening to a brown colored oil. Therefore, the freshly made ligand was complexed immediately with the metal ion upon isolation.

The palladium(II) complex was prepared by the reaction of equimolar quantities of the ligand and $[Pd(CH_3CN)_4](BF_4)_2$ in freshly distilled, dry acetonitrile under an atmosphere of nitrogen. The initial yellow color, arising from the palladium salt, disappeared rapidly giving an orange/brown solution. X-ray

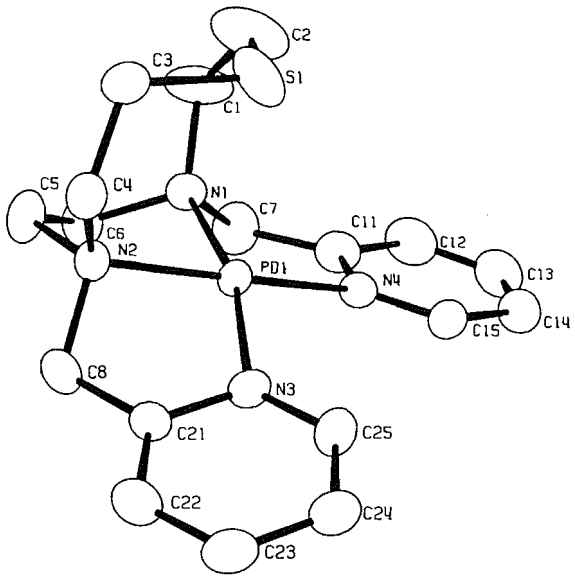

FIG. 1. ORTEP diagram of the cation $[Pd(py_2[9]aneN_2S)]^{2+}$. Bond distances, Pd...N(1) 2.044(6) Å, Pd...N(2) 2.028(6) Å, Pd...N(3) 2.041(6) Å, Pd...N(4) 2.041(6) Å, Pd...S(1) 2.915(3) Å.

quality crystals of $[Pd(py_2[9]aneN_2S)](BF_4)_2$ were obtained by slow diffusion of diethyl ether into an acetonitrile solution of the impure reaction product.

The UV/visible spectrum of the palladium complex in CH_3CN exhibits two bands at 264 and 301 nm with extinction coefficients of 6.2×10^3 and 3.5×10^3 M^{-1} cm^{-1}, respectively. No distinct absorptions were observed in the visible portion of the spectrum, even at high concentrations (≈0.01 M), suggesting that the *d–d* transitions have been shifted to higher energy and are masked by the charge transfer bands.

Electrochemical data for the palladium complex provides evidence for a single, irreversible reduction at −1.25 V in CH_3CN and no observable reactivity in aqueous media. The absence of reversible electrochemistry is suggestive of decomposition of the Pd(I) complex formed, although the observed shape and size of the reduction peak were invariant with scan speed. The lack of any observable oxidation peak is consistent with the "open-chain" structure of this macrocyclic complex and the presence of a sulphur donor atom which are known to result in an increase in the electrochemical potential for such complexes (15).

Crystallography

The ORTEP diagram of $[Pd(py_2[9]aneN_2S)](BF_4)_2$, together with the atomic labelling scheme, is provided in Fig. 1. The crystallographic parameters, fractional atomic coordinates, selected bond lengths, and bond angles are provided in Tables 1–4, respectively. All other crystallographic tables have been deposited as supplementary material (Table S1 contains experimental crystallographic data, Tables S2–S6 contain fractional coordinates, bond lengths, bond angles, interatomic distances, and anisotropic temperature parameters for the complex (11 pages), Tables S7 lists calculated and observed structure factors (16 pages), and full details of NMR simulations (9 pages)).[2]

TABLE 1. Crystallographic parameters for $[Pd(py_2[9]aneN_2S)](BF_4)_2$[a]

Formula	$C_{18}H_{24}N_4SB_2F_8Pd$
Molecular weight	608.5 g/mol
Space group	Monoclinic, $P2_1/n$ (no. 14)
Unit cell	
a	10.233(4) Å
b	11.484(5) Å
c	19.913(6) Å
β	94.03(4)°
Volume	2334(2) Å^3
Z	4
r_{calc}	1.731 g/cm^3
r_{meas}	1.721 g/cm^3
Radiation	Mo K_α, 0.71069 Å
2θ	0.1–55.0°
No. of reflections	5356
$I > 2\sigma(I)$	3790
No. of parameters	307
Residual electron density	0.68 e/Å^3
Maximum final shift/e.s.d.	0.005
R, R_w	0.0705, 0.0759

[a] $R = \Sigma(|F_o| - |F_c|)/\Sigma|F_o|$, $R_w = [\Sigma(|F_o| - |F_c|)^2/-\Sigma w(|F_o|^2]^{1/2}$.

The asymmetric unit for the compound contains the whole cation defining a static structure for the complex which does not express the time-averaged symmetry observed in the ^{13}C or ^1H NMR spectra (*vide infra*). The palladium atom is coordinated by the two tertiary nitrogens of the macrocyclic ring and the nitrogen atoms of the pyridine pendant arms, forming an approximate PdN_4 plane. The sulfur atom is disposed apically relative to this coordination plane.

The Pd—N bond distances are in the range 2.028(6) and 2.044(6) Å, with no significant structural variation. The chelating angles are, respectively, N(1)—Pd—N(2): 87.1(3)°, N—Pd—py: 82.5(3)° and 83.6(3)°, and py—Pd—py: 105.8(3)°, which are consistent with the structural constraints imposed by the five-membered chelating rings and the presence of a double bond within the pyridine ring. The angle obtained for the N(1)—Pd—N(2) chelate is close to the value of 86° obtained for the analogous $Pd(trien)^{2+}$ complex ion (trien: triethylenetetraamine) (16).

The distance to the apical sulfur atom is 2.915(3) Å, which is consistent with, but shorter than, the value of 2.952(4) Å reported (17) for $[Pd([9]aneS_3)_2](PF_6)_2$. Typically, palladium–sulfur bonds are in the range 2.2 to 2.4 Å, as observed in the equatorial plane for the $[Pd([9]aneS_3)_2](PF_6)_2$ complex (Table 5). Hence, the present distance is certainly longer than might be considered bonding. However, the coordination geometry of the palladium atom and the disposition of the macrocyclic ligand indicate some form of interaction is present. This is confirmed by the calculation of the mean plane for the four nitrogen atoms (Table 6). Although these atoms do not form a perfectly planar donor set, the calculations show that the palladium atom is distended 0.148 Å out of the mean plane described by the nitrogen atoms towards the apical sulfur atom. The basal angles, N(3)—Pd—N(1) and N(4)—Pd—N(2), are 165.3(3)° and 169.3(3)°, respectively, which are consistent with the theoretical value for a square pyramidal d^8 ion given by Hoffman et

[a]The equation for the mean plane described by the four coordinated nitrogen atoms is: $0.3821X - 0.9207Y - 0.0792Z + 2.9751 = 0$ and P is the perpendicular distance between the atom and the mean plane, given in Å.

al. (18). These angles are also consistent with the basal angles of 168.8(1)° and 163.3(2)° found (5) in $[Pd(py_3[9]aneN_3)]^{2+}$. Such results indicate that the ligand geometry around the palladium atom is consistent with a five-coordinate, square pyramidal geometry.

A further analysis of the disposition of the nine-membered N_2S ring is provided by the technique of dihedral mapping (19).

The torsion angles within the macrocyclic ligand provide a method for determining the consistency and similarity of the structure with respect to analogous compounds. This is illustrated in Fig. 2, where the complexes $[Pd(py_2[9]aneN_2S)]^{2+}$, $[Pd(py_3[9]aneN_3)]^{2+}$ (5), $[Ni([9]aneN_2S)_2]^{2+}$ (11), $[Ni(N_4S)(ClO_4)]^{2+}$ (20), $[Cu(N_4S)]^{2+}$ (20), $[Pd([9]aneN_3)_2]^{2+}$ (6), and $[Pt([9]aneN_3)_2]^{2+}$ (21) are mapped in this manner. The latter two complexes provide a distinct comparison with the other ions

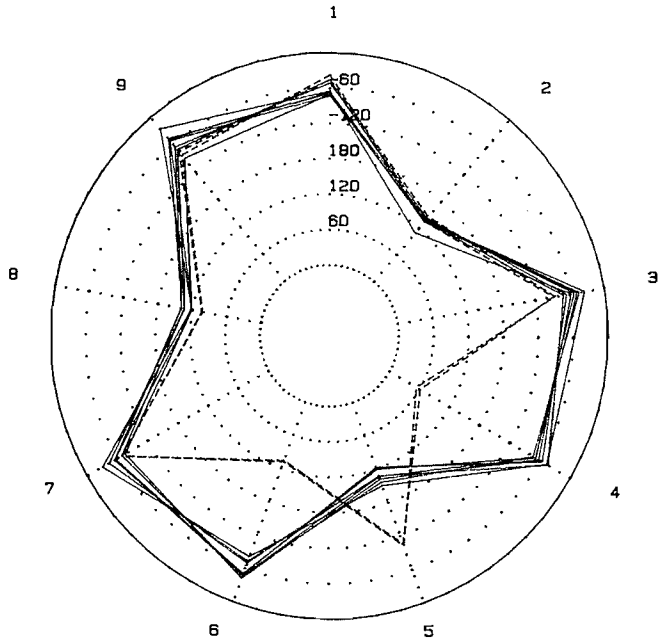

FIG. 2. Polar coordinate map of the torsion angles within the nine-membered rings of $[Pd(py_2[9]aneN_2S)]^{2+}$, $[Pd(py_3[9]aneN_3)]^{2+}$ (5), $[Ni([9]aneN_2S)_2]^{2+}$ (11*b*), $[Ni(N_4S)(ClO_4)]^{2+}$ (20), and $[Cu(N_4S)]^{2+}$ (20) (solid lines) and $[Pd([9]aneN_3)_2]^{2+}$ (6) and $[Pt([9]aneN_3)_2]^{2+}$ (21) (dotted lines).

since the apical nitrogens are not coordinated to the metal center and, as the map indicates, the [9]ane ring does not have the symmetrical shape exhibited by the octahedral and five-coordinate species. The similarity of the maps for $[Pd(py_2[9]aneN_2S)]^{2+}$, $[Pd(py_3[9]aneN_3)]^{2+}$, $[Ni([9]aneN_2S)_2]^{2+}$, $[Ni(N_4S)(ClO_4)]^{2+}$, and $[Cu(N_4S)]^{2+}$ is a result of the similar disposition of the apical atom. Also, since the latter complexes exhibit bonding to this apical donor, the observation provides confirmation for the interpretation of the apical Pd—S interaction as bonding.

Nuclear Magnetic Resonance Spectroscopy

The free ligand, $py_2[9]aneN_2S$, was characterized by ^1H and ^{13}C NMR spectroscopy. The ^{13}C NMR spectrum exhibits nine lines which is consistent with a time-averaging of the nine magnetically inequivalent carbon atom pairs in the ligand (Fig. 3). The ^1H NMR spectrum (Fig. 3) exhibits a singlet at δ2.65 which has been assigned to the methylene protons of the ethylene bridge between the two ring amines. The appearance of these protons as a singlet indicates that the molecule is undergoing rapid inversion of the nitrogen atoms at ambient temperature. If this were not the case, the chirality of the amine would impose an anisochronicity on these nuclei resulting in the appearance of an A_2B_2 or AA′BB′ sub-spectrum in the ^1H NMR spectra.

The ^1H NMR of the palladium complex contains such sub-spectra resulting from the coordination of the macrocyclic ligand. The coordination of the ligand around the metal center inhibits inversion of the nitrogens and produces a spectrum in which the magnetic equivalence of the protons has been removed. The resulting ^1H and ^{13}C spectra are consistent with the time-averaged spectrum obtained for the free ligand (Fig. 4). This is a result of vibrational motion in solution which is not observed in the solid state wherein time averaging of the structure is not possible.

The coordination of the macrocycle results in the divison of the protons into three distinct groups. The first group of protons

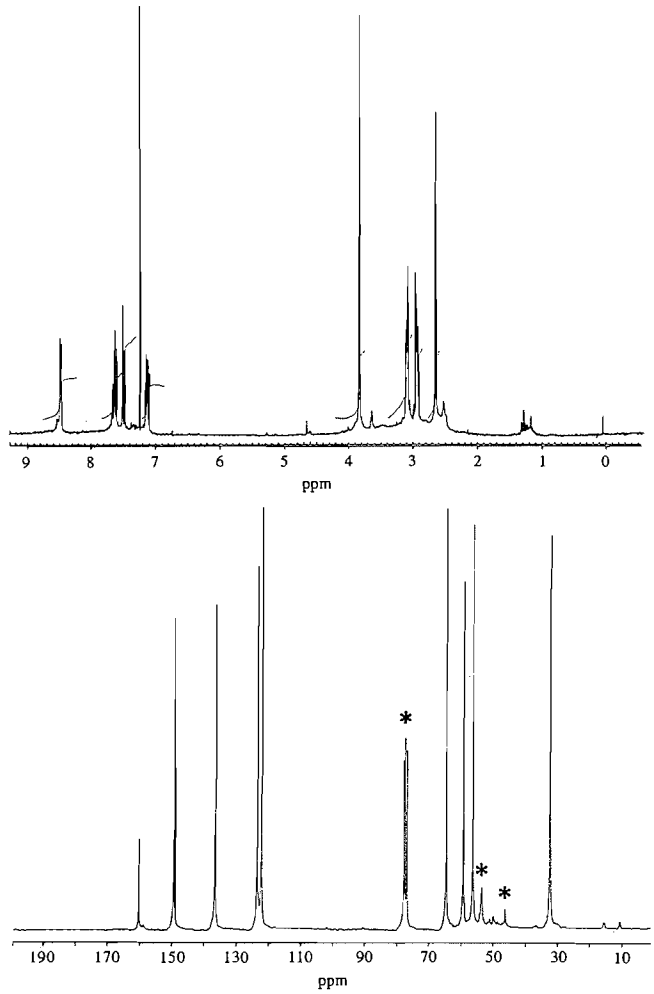

FIG. 3. ^{13}C and ^1H NMR spectra for the free ligand $py_2[9]aneN_2S$. Solvent ($CDCl_3$) and impurities are labelled with *.

are the ones on C5 and C6, the diamino chelate, which may be simulated using an AA′BB′ pattern (Table 7). The results are consistent with a time averaging of the envelope geometry observed in the solid state. In this case though, the time averaging only renders the H_a and H_a' protons equivalent and does not provide for the interconversion with the H_b and H_b' protons, as observed in the free ligand.

The thio-amino chelate results in a pattern that may be described as ABCC′. This portion of the molecule is difficult to simulate due to the overlapping resonances arising from the B and C protons and the equivalence of H_c and H_c'. The latter protons are assigned to the C2 and C3 carbon atoms, next to the apical sulphur. The remaining signals in the ^1H nmr spectrum may be assigned to the pyridylmethyl chelate which appears as an ABCDMX sub-spectrum, wherein the two protons of the methylene group are designated H_m and H_x. The H_m proton is equatorial and is coplanar with the pyridine ring resulting in coupling between this proton and the aromatic protons.

Further verification of the assigned resonances is provided by an analysis of the ^1H-^{13}C HETCORR (Fig. 4), where it is readily observed that the ^{13}C resonances at δ126.3 and δ142.5 are associated with the middle carbon positions of the pyridyl ring since they correlate with the proton triplets. However, designating an unambiguous choice for these resonances is dependent upon simulation of the proton spectrum.

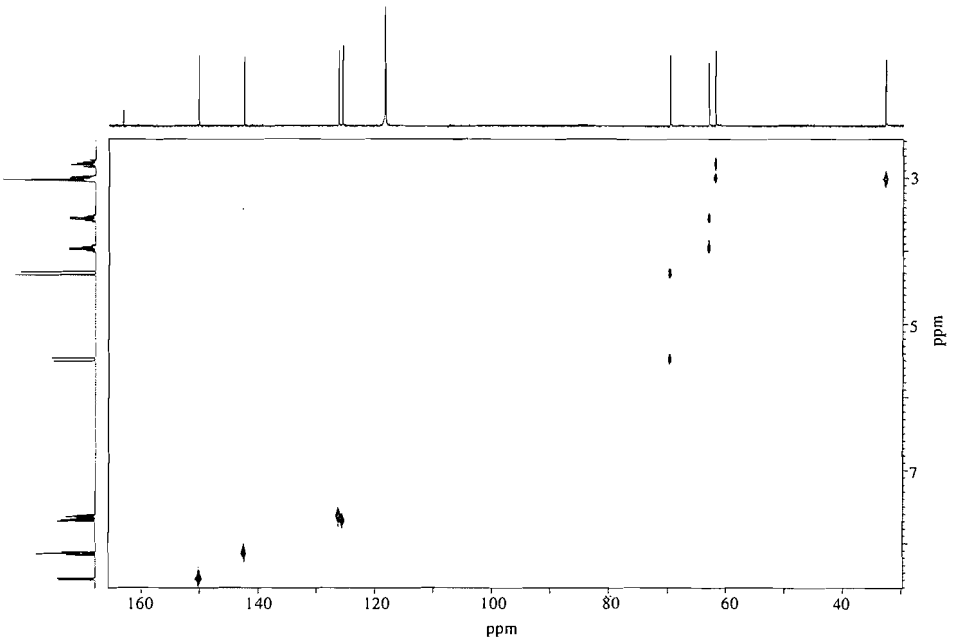

FIG. 4. HETCORR for $[Pd(py_2[9]aneN_2S)]^{2+}$ in CD_3CN. The ^1H and ^{13}C NMR spectra are displayed on the vertical and horizontal axes, respectively. The peak at 117 ppm is due to CD_3CN.

TABLE 7. Simulated ^1H NMR parameters for $[Pd(py_2[9]aneN_2S)]^{2+}$

(*a*) Diamino chelate: AA′BB′ sub-spectrum

$\delta_a = \delta_{a'} = 3.97$ ppm	$\delta_b = \delta_{b'} = 3.55$ ppm
$J_{ab} = J_{a'b'} = -14.64$ Hz	$J_{ab'} = J_{a'b} = 7.19$ Hz
$J_{aa'} = 6.55$ Hz	$J_{bb'} = 5.35$ Hz

(*b*) Thio-amino chelate: ABCC′ sub-spectrum

$\delta_a = 2.81$ ppm	$\delta_b = 3.00$ ppm	$\delta_c = \delta_{c'} = 3.03$ ppm
$J_{ab} = -10.34$ Hz	$J_{ac} = 0.73$ Hz	$J_{ac'} = 8.365$ Hz
$J_{bc'} = 6.56$ Hz	$J_{cc'} = -15.17$ Hz	$J_{bc} = 5.64$ Hz

(*c*) Pyridylmethyl chelate: ABCDMX sub-spectrum

$\delta_a = 8.49$ ppm	$\delta_b = 7.63$ ppm	$\delta_c = 8.14$ ppm	$\delta_d = 7.69$ ppm
$\delta_m = 5.48$ ppm	$\delta_x = 4.30$ ppm		
$J_{ab} = 5.67$ Hz $J_{ac} = -1.42$ Hz	$J_{ad} = 0.0$ Hz	$J_{am} = -0.70$ Hz	
$J_{bc} = 7.80$ Hz $J_{bd} = -1.219$ Hz	$J_{bm} = -0.302$ Hz		
$J_{cd} = 8.02$ Hz $J_{cm} = 0.001$ Hz	$J_{dm} = 0.002$ Hz		

Of particular interest is the AB sub-spectrum from the benzylic-like protons of the methylene group in the pendant arms. These two protons are rendered inequivalent by the chelation of the pyridine and tertiary nitrogens, resulting in an "axial" and "equatorial" disposition. Intuitively it would be expected that these two resonances display the same intensity since they integrate to the same area. However, the peak at δ5.48 is only one half of the height of the peak at δ4.30, which indicates that it is coupled to another proton. This coupling constant must be smaller than the intrinsic linewidth since the peak appears as a doublet. This is consistent with a long-range coupling of this peak with the protons of the pyridine ring.

Such a feature is accommodated structurally by considering the disposition of the equatorial proton which would be essentially co-planar with the ring, based upon "normal" bonding angles and distances for a methylene moiety. Furthermore, the presence of this coupling provides confirmatory evidence for the absence of fluxional processes within this molecule since disruption of the co-planarity of the equatorial proton with the ring would result in its elimination. Hence, the nitrogen atoms are not pivotting and it is difficult to envisage a mechanism for the displacement of the apical sulphur which does not involve a distortion of the coordinated amines. By itself, this does not necessitate that the apical sulphur is bonded to the palladium but provides evidence that the ligand is not changing its coordination environment in solution through a fluxional process.

This aspect facilitates the simulation of the resonances associated with the pyridine protons. The simulated parameters for the complete spectrum are provided in Table 7, while a comparison of simulated and experimental features is presented in Fig. 5. Such simulated parameters permit the assignment of the chemical shifts in the ^{13}C NMR spectra, with the resonance at δ142.5 arising from the carbon attached to H_c.

The remaining spectroscopic features observed in the proton spectrum have been simulated using standard iterative com-

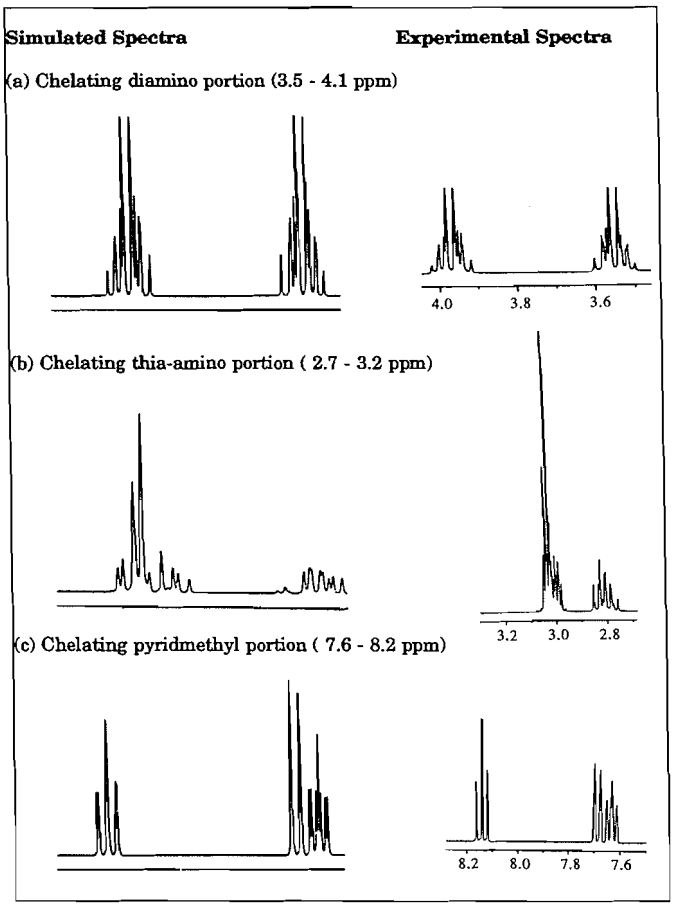

FIG. 5. Comparison of simulated and experimental ^{1}H NMR spectra for $[Pd(py_2[9]aneN_2S)]^{2+}$. Selected regions are shown.

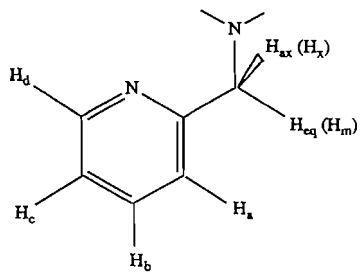
puter techniques (22*a*, 22*b*, footnote 3). The values obtained for the chemical shifts and coupling constants are consistent with a structural model in which the molecule adopts a "static" structure. That is, the sulphur atom maintains a constant position and does not undergo any fluxional displacement. Such a fluxional process has been observed (6, 21) for the platinum and palladium complexes of 1,4,7-triazacyclononane in which the apical donor is not bound to the metal center in the solid state. This results in ^{1}H NMR spectra that may be interpreted only in terms of a "dynamic" structure in which the metal is undergoing a series of inner-sphere substitutions reactions, rotating between several equivalent configurations.



Variable temperature spectra provide further evidence for the absence of a fluxional process in this molecule, since no coalescence of any of the peaks was observed between −45°C and +80°C, in contrast to $[Pd([9]aneN_3)_2]^{2+}$ (6). It is possible, but viewed as unlikely, that the inversion of the apical sulphur is more rapid than the temperature range accessed. However, the spectroscopic implications are that in solution, the molecule is constrained to a single configuration similar to that observed in the solid state. The coupling constants and chemical shifts observed for the ^{1}H NMR are consistent with an apical disposition of the sulphur atom providing further evidence for a distal palladium–sulphur interaction. Hence, in both the solid state and solution structures, the sulphur atom appears to be bonded to the palladium atom.

Reçu le 17 décembre 1993

SEVSER SAHPAZ, ALAIN LAURENS, REYNALD HOCQUEMILLER, ANDRÉ CAVÉ et DIEGO CORTES. Can. J. Chem. **72**, 1533 (1994).

Cinq acétogénines cytotoxiques ont été isolées de l'extrait méthanolique de graines d'*Annona senegalensis*. La première est nouvelle et a été dénommée sénégalène **1**. Sa structure, déterminée par étude spectroscopique (2D-NMR, SMIC, SMFAB-Li) est caractérisée par la présence d'un système diol et l'insaturation de la chaîne alkyle. Les quatre autres ont été identifiées à la molvizarine **2**, l'asimicine **3**, la rolliniastatine-2 **4** et la squamocine **5**. Une étude des relations structure–activité du sénégalène et de ses dérivés a été réalisée.

SEVSER SAHPAZ, ALAIN LAURENS, REYNALD HOCQUEMILLER, ANDRÉ CAVÉ, and DIEGO CORTES. Can. J. Chem. **72**, 1533 (1994).

Using activity-directed fractionation, the chromatography of the bioactive methanol extract of *Annona senegalensis* seeds led to isolation of a new mono-tetrahydrofuranic γ-lactone acetogenin characterized by the presence of a double bond on the alkyl chain, senegalene **1**. Its structure was elucidated on the basis of spectroscopic (2D-NMR and MS) and chemical methods. Four known acetogenins have been also isolated: molvizarin **2**, asimicin **3**, rolliniastatin-2 **4**, and squamocin **5**. Comparative structure–activity relationships were studied using senegalene **1** and its derivatives in KB and VERO cell lines in *in vitro* tests.

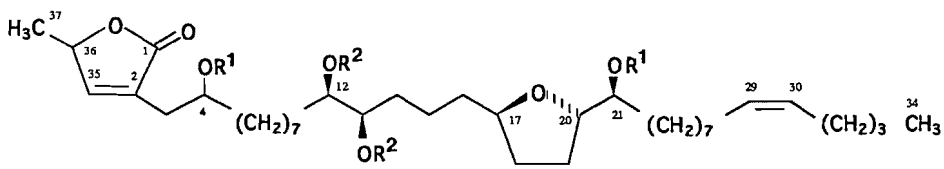
Introduction

Le genre *Annona* (Annonaceae) est caractérisé par la présence d'acétogénines à forte activité cytotoxique (1). Les acétogénines de sept espèces, *A. bullata*, *A. cherimolia*, *A. densicoma*, *A. montana*, *A. muricata*, *A. reticulata* et *A. squamosa* (2) ont fait pour le moment l'objet d'études approfondies. *Annona senegalensis* n'a jusqu'à présent fait l'objet d'aucune recherche dans ce domaine. Seule a été signalée, dans les feuilles et les fruits, la présence d'huile essentielle composée de mono et de sesquiterpènes (3), dans les racines, de diterpènes de type kaurane (4) et dans les écorces de tiges, d'acides aminés (5).

Dans le présent travail, nous décrivons l'isolement à partir des graines d'une nouvelle acétogénine oléfinique mono-tétrahydrofuranique (mono-THF), le sénégalène **1**, la détermination de sa structure ainsi que l'étude de son activité cytotoxique.

Résultats et discussion

L'extrait méthanolique (A) des graines d'*A. senegalensis* présente une importante cytotoxicité sur le test sur larves d'*Artemia salina* (1), CL_{50} : $2{,}5 \times 10^{-2}$ µg/mL. Le fractionnement de cet extrait a été guidé par ce test. (A), mis en solution dans du méthanol aqueux (95 : 5), est soumis successivement à une extraction liquide–liquide par l'hexane et le dichlorométhane. L'extrait chlorométhylénique (B) conserve l'activité cytotoxique de l'extrait initial (A), CL_{50} : $1{,}7 \times 10^{-2}$ µg/mL. Par chromatographie sur colonne de (B), cinq acétogénines sont isolées, une nouvelle, le sénégalène **1**, et quatre connues, caractérisées par la présence de trois hydroxyles alcooliques et par différentes configurations au niveau du système bis-THF α,α′-dihydroxylé, identifiées par comparaison à des échantillons authentiques : la molvizarine **2** (6), l'asimicine **3** (7), la rolliniastatine-2 **4** (8), et la squamocine **5** (9).



Sénégalène **1** :	$R^1 = R^2 = H$
Tétraacétyl-sénégalène **1***a* :	$R^1 = R^2 = Ac$
2-(35),29-(30)-Tétrahydro-sénégalène **1***b* :	$R^1 = R^2 = H$
2-(35),29-(30)-Tétrahydro-tétraacétyl-sénégalène **1***c* :	$R^1 = R^2 = Ac$
12,13-Acétonide-sénégalène **1***d* :	$R^1 = H$; R^2 = acétonide
29,30-Époxy-tétraacétyl-sénégalène **1***e* :	$R^1 = R^2 = Ac$

Le sénégalène **1** est un solide amorphe, $[\alpha]_D$ +16 (c = 0,21, $CHCl_3$). Il présente, sur le spectre de masse en ionisation chimique, un pic moléculaire à m/z 623 $[MH]^+$ et à m/z 640 [M +

Molvizarine **2** : R^1 = OH; R^2 = H; n = 8; * (*érythro*)
Asimicine **3** : R^1 = OH; R^2 = H; n = 10; * (*thréo*)
Rolliniastatine-2 **4** : R^1 = OH; R^2 = H; n = 10; * (*érythro*)
Squamocine **5** : R^1 = H; R^2 = OH; n = 10; * (*érythro*)

$NH_4]^+$ correspondant à une masse moléculaire de 622. Sa formule brute $C_{37}H_{66}O_7$, est déduite du HRSMIC, $[MH]^+$ = 623,4908 (calculé pour $C_{37}H_{67}O_7$ = 623,4887).

L'existence de quatre hydroxyles est mise en évidence par l'observation d'une bande large à 3350 cm^{-1} en IR, par les pertes successives de quatre molécules d'eau à partir de $[MH]^+$, et par la préparation du dérivé tétraacétylé **1***a*.

Le spectre IR de **1** présente une bande à 1750 cm^{-1}, caractéristique d'un carbonyle de γ-lactone α,β-insaturée. Ceci est confirmé par l'analyse des spectres 1D-RMN (^1H et ^{13}C spin echo) et 2D-RMN (^1H–^1H Cosy 45 et ^1H–^{13}C XH Corr). Le spectre RMN ^1H présente un système de trois signaux à δ 7,18 (d, 1H), δ 5,04 (dq, 1H) et δ 1,42 (d, 3H), corrélés en RMN ^{13}C avec trois carbones à δ 151,89 (C-35), δ 77,88 (C-36) et δ 18,84 (C-37), et deux autres signaux de carbones quaternaires à δ 174,57 (C-1) et δ 130,75 (C-2) caractéristiques d'une γ-lactone α,β-insaturée (voir tableau 1). De plus, la présence d'un système ABX en RMN ^1H à δ 2,50 (ddd, 1H), δ 2,36 (dd, 1H) et δ 3,81 (m, 1H), corrélé avec les résonances respectivement à δ 32,97 et δ 69,48 en RMN ^{13}C, prouve l'existence d'un OH en position 4, en β de la γ-lactone (10).

Le spectre de RMN ^{13}C montre deux autres signaux à δ 81,70 et δ 79,20 attribués aux carbones oxygénés d'un noyau mono-THF α-monohydroxylé (11). La corrélation de ceux-ci avec les multiplets à δ 3,81 et δ 3,90 en RMN ^1H confirme cette hypothèse (tableau 1).

La position du système mono-THF α-hydroxylé et celle des deux autres hydroxyles restant sur la chaîne hydrocarbonée sont déterminées par l'analyse des fragments de masse de **1**, **1***a*, **1***b* et **1***c*. Les fragmentations sur le SMIC de **1** à *m/z* 341 et 281, à *m/z* 411 et à *m/z* 441, permettent de placer le cycle THF entre les carbones 17 et 20 et le groupe OH adjacent sur le carbone 21 (voir figure 1), ce qui est confirmé par l'examen des spectres de masse des dérivés **1***a*, **1***b* et **1***c*.

L'emplacement du système diol sur les carbones 12 et 13 est mis en évidence par les fragments obtenus sur le SMIC (NH_3) de **1** (*m/z* 269 et *m/z* 353) et de **1***a* (*m/z* 353 et *m/z* 437). La préparation du dérivé acétonide **1***d* (12) et l'obtention sur le SM de **1***d* des fragments à *m/z* 339 (C-13/C-14), *m/z* 381 (C-16/C-17), *m/z* 451 (C-20/C-21) et *m/z* 481 (C-21/C-22), confirment la position du groupe diol sur la chaîne hydrocarbonée. Un système mono-THF α-hydroxylé accompagné d'un groupement α-diol a déjà été observé chez la gigantetrocine et la gigantriocine, acétogénines isolées de *Goniothalamus giganteus* (11) et la 10,13-*trans*-13,14-*érythro*-densicomacine et la 10,13-*trans*-13,14-*thréo*-densicomacine isolées d'*Annona densicoma* (13). Il semble que la 10,13-*trans*-13,14-*thréo*-densicomacine soit identique à la gigantetrocine. Mais par rapport à ces acétogénines, le sénégalène présente une grande originalité liée à la position du système diol entre le THF et la lactone.

Deux signaux en RMN ^{13}C à δ 130,36 et δ 128,91 corrélés avec un multiplet vers δ 5,35 (2H) en RMN ^1H correspondant à deux méthines sp^2, sont en faveur de la présence d'une double liaison de configuration *cis* sur la chaîne du sénégalène, ce qui est en accord avec les trois constantes de couplage mesurées lors de l'irradiation sélective des protons à δ 2,19 et δ 2,01 : J = 10,6 Hz, J' = 4,5 Hz et J'' = 6 Hz.

TABLEAU 1. Corrélation ^1H–^{13}C du sénégalène **1**

H	δ[a]	Couplage en RMN ^1H–^{13}C (multiplicités spin echo)
3a	2,36 dd	32,97 (CH_2)
3b	2,50 ddd	32,97 (CH_2)
4	3,81 m	69,48 (CH)
5	1,48 m	37,0 (CH_2)
6–10	1,25–1,45 m	29,15–29,57 (CH_2)
11	1,55 m	33,21 (CH_2)
12	3,41 m	74,06 (CH)[b]
13	3,41 m	74,20 (CH)[b]
14	1,33 m	35,27 (CH_2)
15,16	1,25–1,45 m	25,87–29,57 (CH_2)
17	3,90 m	79,20 (CH)
18,19	1,62, 1,95 m	25,87–29,57 (CH_2)
20	3,81 m	81,70 (CH)
21	3,41 m	73,54 (CH)[b]
22–26	1,25–1,45 m	29,15–29,57 (CH_2)
27	1,55 m	25,87 (CH_2)
28	2,19 m	29,57 (CH_2)
29, 30	5,35 m	130,36, 128,91 (CH)
31	2,01 m	27,06 (CH_2)
32	1,25–1,45 m	22,48 (CH_2)
33	1,25–1,45 m	31,69 (CH_2)
