The photophysical properties of quinones and derivatives, in particular those of triplet states, have been sufficiently investigated. Triplet lifetimes and triplet quantum yields depend on the π–π^* or n–π^* nature of the excited state involved (2, 6). Gollnick and Held (6) established that, in general, S_Δ seems to be large when Φ_T is large (see eq. [6]). Moore et al. (2) proposed that quinones with substituents in position 1, possibly due to interaction with the adjacent carbonyl group, possess T_1 states that are π–π^* in nature. This implies a consequent decrease in triplet quantum yields. Quinones substituted in position 2, on the contrary, mainly populate n–π^* triplet states, which are accompanied by longer lifetimes and higher triplet quantum yields. These observations are in agreement with our experimental results. No signal for $O_2(^1\Delta_g)$ generation could be observed for 1,5-dihydroxyanthraquinone (possessing two substituents in positions of potential interaction with the carbonyl groups). The same was true for 1,5-DSAAQ in both D_2O and MeCN, whereas for 2SAAQ a Φ_Δ value of 0.69 was obtained in MeCN. For this compound no signal for $O_2(^1\Delta_g)$ generation could be detected in heavy water, possibly due to two concurrent factors: an intrinsic low value for Φ_Δ accompanied by the extremely low quantum yield for the radiative transition $O_2(^1\Delta_g) \rightarrow O_2(^3\Sigma_g^-)$ in D_2O, which certainly precludes the neat observation of the emissive signal (22). The first assumption could be in agreement with previous results from Oliveros et al. (24) for carbonyl-containing sensitizers. For cases in which solvent-induced state inversion occurs, as commented upon above for the anthraquinones, the Φ_Δ values drop to near zero in protic solvents (19).

Concluding remarks

Quinones and hydroxy derivatives (excluding those derivatives with substituents in positions adjacent to the carbonyl groups) are excellent sensitizers for $O_2(^1\Delta_g)$ generation in aprotic solvents. In parallel, they are moderate quenchers of $O_2(^1\Delta_g)$. This fact should be carefully considered when the possible extent of the Type II sensitizing effect of quinones, in a given environment, is evaluated. The quenching process, exclusively physical in nature, deactivates the oxygen-excited species generated, without further destruction of the quinone. In substituted quinones, the main $O_2(^1\Delta_g)$–quinone interaction is driven by the quinone moiety, in spite of the potentially active nuclear substituents. Even when the ability of quinones to act as electron acceptors is a recognized fact, experimental evidence indicates that the quenching mechanism could involve a reversible charge transfer intermediate, the quinonic compound acting as an electron donor. In this context, the mechanistic way mentioned agrees with the poor k_t values exhibited by the quinones as compared to those observed (one to two orders of magnitude higher) for electron donor $O_2(^1\Delta_g)$ quenchers (19, 25).

Abstract: ^{51}V nuclear magnetic resonance spectroscopy has been utilized in the investigation of the reactions of vanadate with *N,N*-dimethylhydroxylamine in aqueous medium. The major components of the reaction products were mono- and bisliganded mononuclear vanadate compounds with ^{51}V chemical shifts near −630 and −740 ppm, respectively. Variation of the concentration of the reactants enabled the determination of stoichiometry and formation constants of the products. The two major signals near −740 ppm were assigned to two stereoisomers of a bisligand product. The proton stoichiometries and pK_a values of the major products were determined from pH variation studies. A crystalline product of the type $[V(O)(ONMe_2)_2]_2O$ was isolated from the reaction of vanadate with dimethylhydroxylamine and its structure determined from X-ray diffraction studies. The compound possesses a dimeric oxo-bridge structure with a six-coordinate vanadium core. The arrangement about each vanadium may be described as approximately tetrahedral considering the center of the N—O bond in each dimethylhydroxamide ligand as one vertex. Hydrolysis of the crystalline solid in D_2O provided two isomers that corresponded to the two bisligand products. A variable temperature ^1H NMR study in D_2O and 50% $D_2O/(CD_3)_2CO$ mixture revealed the existence of reasonably fast chemical exchange between the two predominant isomers. The nature of coordination of these and related compounds is discussed. Crystal structure of $[V(O)(ONMe_2)_2]_2O$: orthorhombic, space group $P22_12_1$; $Z = 2$; $a = 7.0955(9)$ Å; $b = 10.2313(12)$ Å; $c = 11.5942(11)$ Å; $V = 841.69$ Å^3; $T = 213$ K; $R_F = 0.021$ for 1141 data ($I_0 \geq 2.5\sigma(I_0)$) and 137 variables.

Key words: bis(*N,N*-dimethylhydroxamido)hydroxooxovanadate, vanadate, dimethylhydroxylamine, vanadium NMR, aqueous equilibria, peroxovanadate.

Résumé : On a fait appel à la RMN du ^{51}V pour étudier les réactions du vanadate avec la *N,N*-diméthylhydroxylamine, en solution aqueuse. Les produits principaux de la réaction sont des vanadates mononucléaires mono- et bicoordinés dont les déplacements chimiques du ^{51}V sont respectivement de −630 et −740 ppm. La variation de la concentration des réactifs a permis de déterminer la stoechiométrie et les constantes de formation des produits. Les deux signaux importants près de −740 ppm ont été attribués à deux stéréoisomères d'un produit bicoordiné. On a déterminé les stoechiométries et les valeurs de pK_a des produits principaux en se basant sur des études de variation de pH. À partir des produits de la réaction du vanadate avec la diméthylhydroxylamine, on a isolé un produit cristallin du type $[V(O)(ONMe_2)_2]_2O$ dont on a déterminé la structure par diffraction des rayons X. Le composé possède une structure dimère à pont oxo comportant un vanadium hexacoordiné central. L'arrangement autour de chaque vanadium peut être décrit comme pratiquement tétraédrique si l'on considère le centre de la liaison N—O de chaque coordinat diméthylhydroxamide comme un sommet. L'hydrolyse du solide cristallin dans du D_2O fournit deux isomères qui correspondent aux deux produits bicoordinés. Une étude par RMN du ^1H à température variable, dans du D_2O et dans un mélange 50/50 de $D_2O/(CD_3)_2CO$ a permis d'établir l'existence d'un échange chimique relativement rapide entre les deux isomères prédominants. On discute de la nature de la coordination de ces composés et de composés apparentés. Structure cristalline du $[V(O)(ONMe_2)_2]_2O$: orthorhombique, groupe d'espace $P22_12_1$; $Z = 2$; $a = 7,0955(9)$, $b = 10,2313(12)$ et $c = 11,5942(11)$ Å; $V = 841,69$ Å^3; $T = 213$ K; $R_F = 0,021$ for 1141 données ($I_0 \geq 2,5\sigma(I_0)$) et 137 variables.

Mots clés : bis(*N,N*-diméthylhydroxamido)hydroxooxovanadate, vanadate, diméthylhydroxylamine, RMN du vanadium, équilibre aqueux, peroxovanadate.

Introduction

Vanadium-dependent enzymes are found in haloperoxidases of some marine algae (1), in lichens and fungi (2, 3), and also in certain nitrogenases of a variety of nitrogen-fixing bacteria (4–6). The occurrence of these enzymes has generated interest in vanadium chemistry and this interest has been greatly stimulated by the findings that oxovanadium(IV), oxovanadium(V), and peroxovanadium(V) complexes give rise to a number of biological responses, the insulin-mimetic effects of vanadates and peroxovanadates being of predominant interest. For comprehensive reviews of these and other topics concerning vanadium biochemistry, the readers are referred to two recent compendiums (7, 8).

Because of the biochemical influences of peroxovanadates, a considerable amount of effort has gone into expanding our understanding of the aqueous chemistry of these materials. Complex formation with heteroligands (9–14), oxidative mechanisms (14–16), and oxygen transfer reactions (14, 17, 18) have been the topics of numerous studies. Our interest in the biochemistry of peroxovanadates, and also because they are interesting systems in their own right, has led us to extend our studies to include hydroxylamines. The reactions of aqueous vanadate with hydroxylamines provided a convenient point of departure from the studies with hydrogen peroxide. Also, the hydroxylamine ligand is found in the naturally occurring V(IV) product, amavadin (19, 20), models of which have been prepared and characterized by X-ray structure studies. It has also been shown that, electrochemically, the vanadium in amavadin is readily oxidized to the V(V) state with no apparent changes in coordination (21). Hydroxylamine and hydrogen peroxide are isoelectronic with each other and they undergo similar reactions with vanadate. However, the replacement of OH by NH_2 or $N(CH_3)_2$ provides sufficient differences from the peroxide chemistry to allow development of our insight into the reactions characteristic of these systems. Investigations into the H_2NOH–V reactions proved to be complicated somewhat by the slow decomposition of hydroxylamine. Because of this, it proved rewarding to turn to the dimethyllated hydroxylamine for initial studies into the aqueous chemistry of these systems. The results gathered from these studies allowed for a detailed interpretation of the hydroxylamine and methylhydroxylamine reactions (22). In addition, we have obtained a crystalline dimethylhydroxylamine–vanadate derivative that provided detailed structural information. Dissolution studies of the crystalline material using water and acetone–water solutions, in conjunction with known properties of the solution products from equilibrium studies, allowed structural assignments of many of the solution products to be made.

Experimental section

Materials

All chemicals used in this work are of reagent grade. Vanadium(V) oxide, 99.99% (Aldrich Chemical Co.), *N,N*-dimethylhydroxylamine (DMHA) hydrochloride (Aldrich Chemical Co.), *N*-(2-hydroxyethyl)-piperazine-*N'*-ethanesulfonic acid (HEPES) buffer (Boehringer Mannheim Gmbh), and tetraethylammonium hydroxide 20% aqueous solution (Sigma Chemical Co.) were used without further purification.

Solutions

A stock solution of sodium vanadate was prepared by adding 0.500 molar equivalents of V_2O_5 to a 1.00 M solution of NaOH in distilled water. The mixture was then stirred until all vanadium pentoxide went into solution and the solution became colourless (generally overnight). This solution was diluted with distilled water to a concentration of 0.100 M.

An *N,N*-dimethylhydroxylamine (DMHA) solution of concentration 0.100 M was prepared by dissolving the required amount of amine in distilled water. The 1.0 M HEPES buffer and 2.0 M KCl stock solutions were both prepared in distilled water. The ionic strength of all the final solutions, before recording the spectra, was brought to 1.0 M with KCl. The initial pH of the KCl stock solution was adjusted downward by the addition of HCl, then upward with NaOH, if required, so that when the HEPES buffer, DMHA, and vanadate solutions were added in a sequential fashion, the resultant pH was in the range 6.3–6.5. The various vanadate–ligand solutions of different concentrations were prepared by adding appropriate amounts of vanadate stock (0.100 M), ligand stock (0.100 M), and HEPES buffer stock (1.0 M) solutions to the pH-adjusted KCl solution (2.0 M). This solution was then diluted to near the desired final volume using distilled water. This process avoids the formation of decavanadate. The final upward adjustment of the pH of the final solution was done by using small aliquots of NaOH and the final volume was obtained with added distilled water. For the pH studies (6.5–8.0), the composition of the solution was maintained as: 3.00 mM total vanadate; 3.00 mM DMHA hydrochloride ; 20 mM HEPES buffer, and 1.0 M KCl, unless stated otherwise. Studies in the acidic pH range, i.e, at pH below 6, were carried out by keeping the ligand concentration in excess; a concentration of 3.00 mM vanadate, 20.0 mM DMHA hydrochloride, 20 mM HEPES, and 1.0 M KCl was used. Ligand and vanadate concentration studies at pH >9 were done with the composition, 2–4.5 mM total vanadate; 8–15 mM ligand; 20 mM HEPES, and 1.0 M KCl. A three- to fivefold excess ligand concentration was required in order to identify products of low formation constants in highly alkaline medium.

Synthesis of $V_2O_3(C_2H_6NO)_4$

Solid V_2O_5 (0.10 g; 0.55 mmol) was added to a solution of 20% tetraethylammonium hydroxide (0.75 mL) and water (~2 mL). The resultant slurry was warmed to 60°C with continuous stirring, to obtain a clear solution of tetraethylammonium vanadate. The pH of the vanadate solution was about 10. A solution of *N,N*-dimethylhydroxylamine hydrochloride (0.213 g; 2.19 mmol) dissolved in water (~2 mL) at pH 6 (adjusted by tetraethylammonium hydroxide) was added to the above vanadate solution with continuous stirring to give a yellow solution with the pH maintained between 7 and 8. The pH of the yellow solution was finally adjusted to 8.0. The reaction solution was then stirred for ~10 min, whereupon a yellow crystalline solid began to crystallize from solution. After crystallization was complete, the yellow solid was filtered, washed with cold water, and dried in vacuo. This material was stored at room temperature for several months without observable deterioration. Yield 0.15 g (70%).

^1H NMR spectra of $V_2O_3(C_2H_6NO)_4$ in D_2O, $(CD_3)_2CO$, and $CDCl_3$ solvents were recorded in order to check the stability of the compound in the respective solvents. Variable tem-

perature studies were carried out in D_2O and 50% $(CD_3)_2CO$–D_2O solutions.

Spectroscopy

^{51}V NMR spectra were obtained using a Bruker AMX-400 NMR spectrometer operating at 105.2 MHz at ambient temperature. Vanadium chemical shifts are quoted relative to the external reference $VOCl_3$ assigned to 0 ppm. Baseline corrections were applied to all spectra prior to their integration. NMR spectral parameters were the following: pulse widths, 60°; spectral widths, 60 kHz; acquisition times, 0.05 s; line broadening , 40 Hz; frequency domain size, 16K data points.

The acquisition parameters for the ^1H spectra were as follows: spectral window, 5000 Hz; pulse width, 60° (4 μs); time domain data points, 32 K; transform data points, 32 K; line broadening, 0.5 Hz. For the variable temperature studies a recycle delay of 2 s was also utilized during the acquisition of the spectra.

^{51}V spectra of freshly prepared solutions of V_2O_3-$(C_2H_6NO)_4$ in D_2O and $CDCl_3$ were recorded. The spectrum in $CDCl_3$ exhibited one signal at −728 ppm, while in D_2O two signals, found at −726 and −740 ppm, were observed. A separate experiment was also done in order to examine the change in the ^{51}V spectral pattern of $V_2O_3(Me_2NO)_4$ as the solvent was changed from pure acetone to a 50% acetone–water mixture. Approximately 5 mg of the powdered crystalline compound was dissolved in 3 mL of pure acetone in a 10 mm NMR tube and the spectrum was recorded. To this solution 3 mL of water was added in steps of 0.5 mL each to a total of 3 mL and spectra recorded for each addition.

For the variable temperature studies, approximately 1.5 mg of the powdered crystalline compound, $V_2O_3(Me_2NO)_4$, was dissolved in 0.5 mL D_2O in a 5 mm NMR tube and the proton NMR spectrum recorded as a function of temperature in the range 275–298 K. A similar study was carried out for the temperature range 248–73 K using a 1:1 $(CD_3)_2CO$—D_2O solvent.

X-ray diffraction

A yellow-colored needle-shaped crystal was mounted on a glass fiber. Data were recorded with an Enraf Nonius CAD4F diffractometer equipped with an in-house modified low-temperature attachment and using graphite monochromatized Mo K_α radiation. Absorption corrections were made using the Gaussian integration method. Data reduction included corrections for Lorentz and polarization effects.

Appropriate coordinates and anisotropic thermal parameters for all non-hydrogen atoms were refined. Hydrogen atoms were readily located in an electron density difference map and their coordinates were refined. A single parameter was refined for the isotropic thermal motion of the hydrogen atoms of each methyl group. Refinement of a chirality parameter unambiguously confirmed the correct hand for the crystal selected. An extinction parameter was also refined. A weighting scheme based on counting statistics was applied such that $\langle w(|F_o|-|F_c|)^2\rangle$ was near constant as a function of both $|F_o|$ and $\sin\theta/\lambda$. Final full-matrix least-squares refinement of 137 parameters for 1141 data ($I_0 \geq 2.5\sigma(I_0)$) converged at $R = 0.021$. Crystallographic details are summarized in Table 1. Final fractional atomic coordinates are listed in Table 2.

The computer programs used were: DIFRAC (23) for data collection; NRCVAX (24) for absorption correction, data reduction, structure solution, and graphical output; and CRYSTALS (25) for structure refinement and rigid body thermal motion analysis. Complex scattering factors for neutral atoms (26) were used in the calculation of structure factors. Computations were carried out on a Pentium-based computer.

Analysis of the anisotropic thermal parameters, using a rigid-body (27) model for one $OVO(ONMe_2)_2$ unit, yielded $R = 0.089$ for the agreement between observed and calculated U_{ij} and an r.m.s. discrepancy of 0.0020 Å^2. The resultant, corrected bond lengths are included in Table 3.

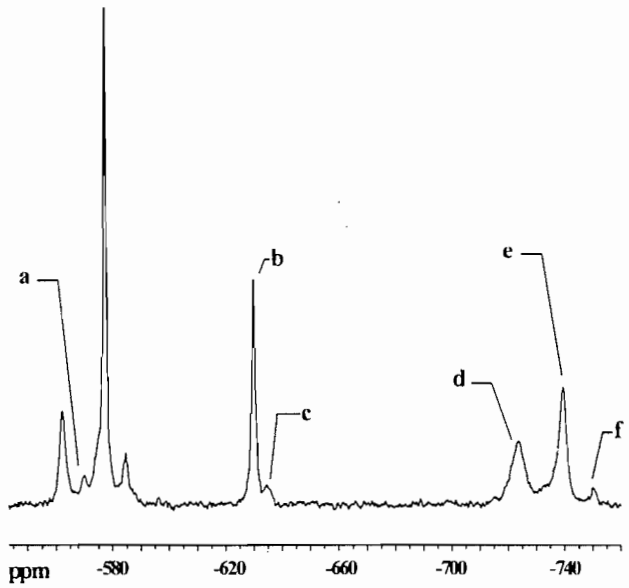

Fig. 1. ^{51}V NMR spectra showing the formation of the various vanadium complexes of *N,N*-dimethylhydroxylamine. Signal **a** may correspond to a product arising from complexation at the hydroxyl group of *N,N*-dimethylhydroxylamine ligand, signals **b**, **c**, and **d**, **e** and **f** correspond to the mono- and bisliganded bidentate products, respectively. The unassigned signals near −570 ppm, in order from low to high field, correspond to V_1, V_2 (partially superimposed on V_4), V_4, and V_5. Conditions of the experiments: 1.0 M KCl; 20 mM HEPES buffer; pH 7.2; 3.0 mM total vanadate; 3.0 mM *N,N*-dimethylhydroxylamine.

Results and discussion

N,N-Dimethylhydroxylamine (DMHA) reacts with vanadate to give a yellow solution consisting of a number of product complexes as evidenced by ^{51}V NMR spectroscopy. Figure 1 shows the results of mixing dimethylhydroxylamine with vanadate. The ^{51}V NMR spectrum shows two sets of product signals, one located near −630 ppm and the second near −740 ppm. These signals lie in the chemical shift region typical for peroxovanadium complexes (11, 12, 28–30). Within the −740 ppm set of signals, two types were observed (Fig. 1). Two broad (Fig. 1; **d**, **e**) and one comparatively sharp signal (Fig. 1; **f**) were found. A minor component was also observed in the −630 ppm region of the spectrum. This component (Fig. 1; **c**) gave rise to a rather broad signal compared to the major product (Fig. 1; **b**) in this region of the spectrum.

[a]U_{eq} is the cube root of the product of the principal axes of the thermal ellipsoid.

An additional product signal was observed at −571 ppm (Fig. 1; **a**). This latter signal is thought to originate from an ester type of product formed between vanadate and the hydroxyl group of the ligand as is typically observed for alcohols (31–33). The stoichiometry of the products formed can easily be ascertained by vanadate and ligand concentration studies. The initial concentration study indicates that the ratios of vanadium to DMHA are 1:1 and 1:2 for the −630 and −740 ppm products, respectively. The equilibrium equation for the formation of two kinds of products can be written as eqs. [1] through [3], where V_1 refers to vanadate, ℓ to ligand (DMHA) and $V\ell_1$ and $V\ell_2$ represent, overall, the mono- and bisligand products, respectively. The formation constants for the individual components of each set are then readily obtained from the relative concentrations within each set.

$$[1] \quad [V_1] + [\ell] \overset{K_{01}}{\rightleftharpoons} [V\ell_1], \qquad [V_1]\,[\ell]\,K_{01} = [V\ell_1]$$

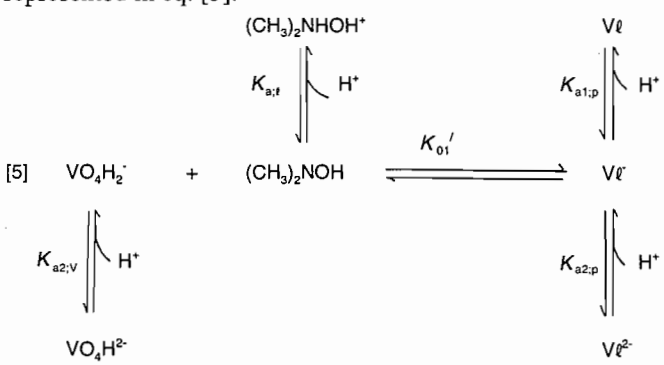
[2] $[V_1] + 2[\ell] \overset{K_{02}}{\rightleftharpoons} [V\ell_2], \qquad [V_1]\,[\ell]^2\,K_{02} = [V\ell_2]$

[3] $[V\ell_1] + [\ell] \overset{K_{12}}{\rightleftharpoons} [V\ell_2], \qquad [V\ell_1]\,[\ell]\,K_{12} = [V\ell_2]$

Initial studies revealed that the overall formation constants are large for both the Vℓ and Vℓ_2 products. As a consequence it was necessary to use the conservation equation, eq. [4], in order to properly specify the free ligand concentration as a



[4] $c\ell_t = [\ell] + [V\ell] + 2[V\ell_2]$

function of total ligand concentration ($c\ell_t$) and concentration of mono- and bisligand products.

The results of the ligand concentration study for both mono- and bisligand products at constant pH are summarized in Fig. 2. The total concentration of the products centered around −630 ppm (**b** + **c**, Fig. 2*A*) and those around −740 ppm (**e** + **f**, Fig. 2*B*) were utilized to obtain the pH-dependent formation constants K_{01}, K_{02}, and K_{12} ($K_{02} = K_{01}\,K_{12}$). These formation constants have the values $(7.5 \pm 0.2) \times 10^3\ M^{-1}$, $(8.1 \pm 0.7) \times 10^6\ M^{-2}$, and $(1.1 \pm 0.1) \times 10^3\ M^{-1}$, respectively, at pH 6.7. See Table 4 for a more detailed breakdown of these values.

The study of the vanadium and DMHA systems with varying pH showed that the signals originating from bisligand products are sensitive towards hydrogen ion concentration, while the signals at −630 ppm are pH insensitive. A gradual increase in pH led to a change in relative signal intensities of the broad and sharp components of the bisligand products. With a stepwise increase in pH from pH 6.5 to pH 8.0, there was a corresponding decrease and increase in intensities of the broad and sharp components, respectively. Figure 3 shows the change in spectral pattern as a function of hydrogen ion concentration within the pH range 6.5–8.0. Above pH 8.0 the intensity of the sharper signal starts decreasing and ultimately, at about pH 9.1, it no longer appears in the spectrum. At higher ligand concentrations, the pH range over which this signal is observed would doubtless be extended. Interestingly, an additional product signal is observed in the pH range above pH 9.2, but it is only easily observed when the ligand concentration is significantly in excess. The intensity of this signal attains its maximum at about pH 9.5 and the chemical shift at this pH value is −698 ppm. Ligand and vanadate concentration studies of the product at pH 9.5 show that it also is a monovanadium bisligand compound with a comparatively low formation constant, $K_{12} = 46 \pm 2\ M^{-1}$ (Fig. 4). The chemical shift of this signal was found to vary with pH, suggesting the product has a pK_a. However, because of its rather limited range of occurrence under the conditions of our studies, no quantitative analysis of the pH variation studies of this compound was made.

Detailed analysis of a pH-variation study requires consideration of the pK_a's of both the reactants and products. The pH-dependent equilibrium equation for the monoligand product is represented in eq. [5].

Fig. 2. A graphical representation of the results from ligand concentration studies carried out at constant pH. The linear relationships of these graphs are consistent with *A*, $V\ell$ (eq. [1]), and *B*, $V\ell_2$ (eq. [2]), stoichiometry, respectively, for the −630 ppm and −740 ppm products of Fig. 1. Conditions of the experiments: 1.0 M KCl; 20 mM HEPES buffer; pH 6.7; 3.0 mM total vanadate; variable *N,N*-dimethylhydroxylamine total concentration, 1–3.8 mM.

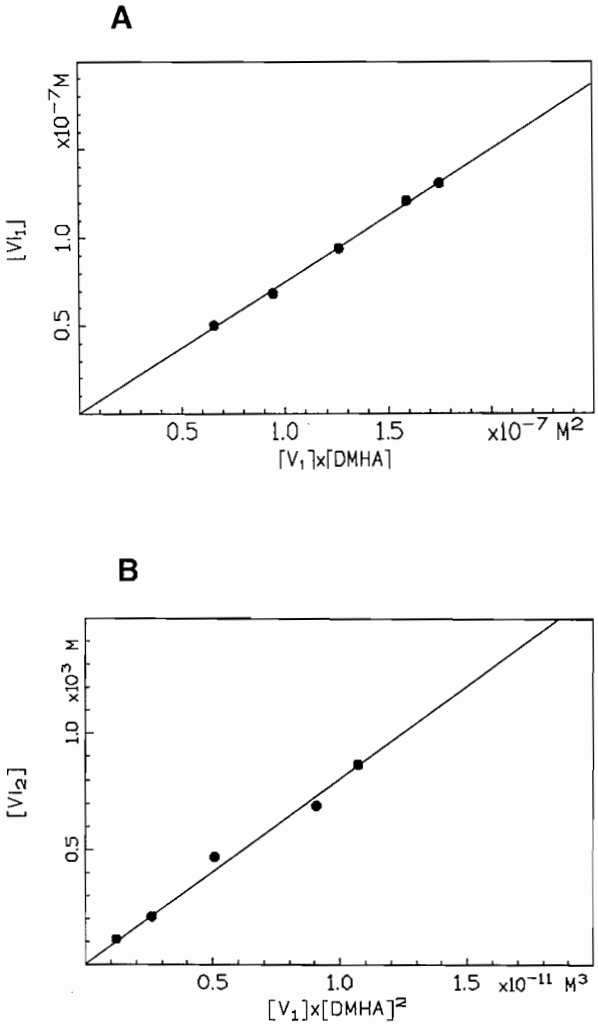

Fig. 3. ^{51}V spectra showing the influence of pH on the products of the reaction of vanadate with *N,N*-dimethylhydroxylamine. Conditions of the experiments: 1.0 M KCl; 20 mM HEPES buffer; 3 mM total vanadate; 5 mM total *N,N*-dimethylhydroxylamine; variable pH, pH 6.5–8.0, top to bottom spectra.

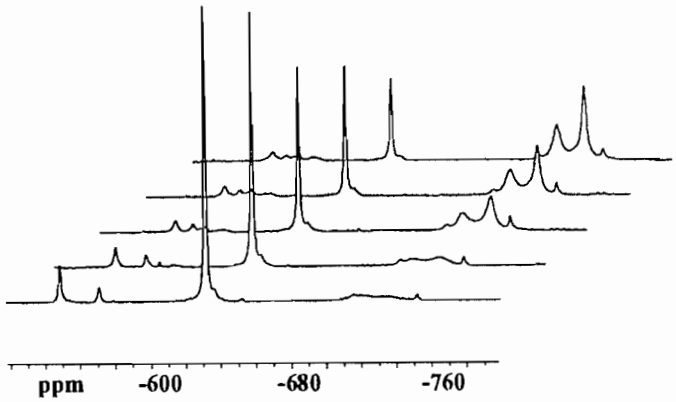

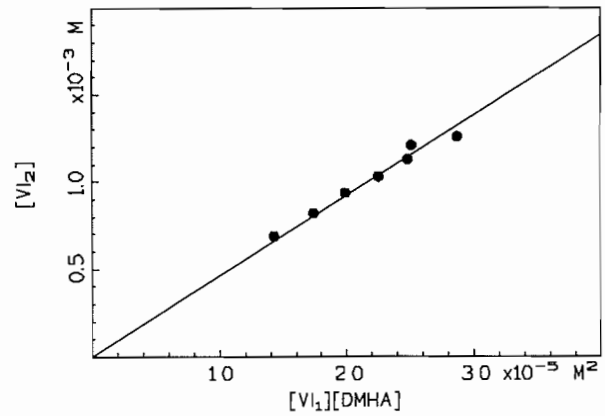

Fig. 4. A graphical representation of the formation of the −698 ppm product as a function of added vanadate at pH 9.5. The linear relationship is consistent with the occurrence of a single vanadium in this product. Conditions of the experiments: 1.0 M KCl; 20 mM HEPES buffer; 15 mM *N,N*-dimethylhydroxylamine; variable total vanadate concentration, 2.0–5.0 mM.

Since the values for $pK_{a2;V}$ (8.2), $pK_{a;\ell}$ (5.28)(34), and pH are known, all other quantites required for analysis of the pH-independent results can be obtained from eq. [5]. Initial studies revealed that the chemical shift of the monoligand product is pH independent. This suggested that the monoligand product does not have a pK_a within the pH range of this study, and was supported by plotting the total concentration of the monoligand products, $[V\ell]$, against the left-hand-side quantitities, $[VO_4H_2^-][(CH_3)_2NOH]$, of eq. [5] as a function of the hydrogen ion concentration. A linear relationship was obtained. This means that, for this pH range, there is no significant change in charge state of the product. If there were, curvature would be observed in this graph. The value $K'_{01} = (6.5 \pm 0.2) \times 10^3$ M^{-1} was obtained from the slope of the plot. To confirm that the product had no pK_a within the range of pH variation of this study, ligand concentration studies were carried out at various pH values and the results analysed according to eq. [1]. These pH-dependent, K_{01}, formation constants can then be written in terms of the pH-independent constant, K'_{01}, of eq. [5], and the hydrogen ion concentration. The relationship between K_{01} and K'_{01} is given by eq. [6], where it is assumed that the product can lose a proton as the pH is raised. A similar equation can be written if a proton were gained in the reaction.

$$[6] \quad (1 + K_{a2;V}/[H^+])\,(1 + [H^+]/K_{a;\ell})\,K_{01} = K'_{01}\,(1 + K_{a1;p}/[H^+])$$

A plot of the term on the left of eq. [6] versus $1/[H^+]$ gave a straight line with no observable slope. Since the line had no slope, it is evident that a proton is neither being gained nor released within the pH range (6.5–8.0) of this study. From the intercept of this line a value for K'_{01} of $(6.4 \pm 0.5) \times 10^3$ was obtained. With this value for K'_{01} and, because it cannot be observed, by neglecting the term in $K_{a1;p}$, eq. [6] can be used to calculate the pH-dependent formation constant, K_{01}, for any

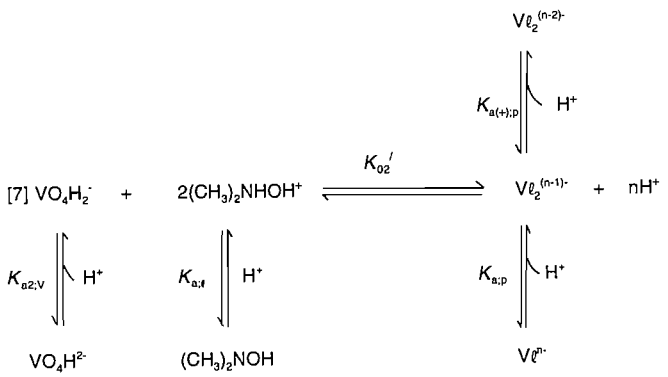
$V_1^- + \ell \rightleftharpoons V\ell^-$	−630 (**b**)	$(6.5 \pm 0.2) \times 10^3$ M^{-1}	6.5–8.0
$V_1^- + 2\ell^+ \rightleftharpoons V\ell_2 + H^+$[c]	−724 (**d**), −740 (**e**)	$(1.3 \pm 0.1) \times 10^3$ M^{-1}	6.5–8.0
$V\ell_2H^+ \rightleftharpoons V\ell_2 + H^+$	−724 (**d**, var)	$(2.2 \pm 0.8) \times 10^3$	1.5–7.0
$V\ell_2H^+ \rightleftharpoons V\ell_2 + H^+$	−740 (**e**, var)	$(6.3 \pm 0.8) \times 10^3$	1.5–7.0



[a]All chemical shifts are for pH 7.2 except that for the pH 9.4 value of the −698 ppm product. The assignments **a**, **b**, **c**, **d**, **e**, **f** correspond to the products so labelled in Fig. 1, var means the chemical shift varies from the pH 7.2 value with change in pH.

[b]The pH-independent formation constants and any corresponding pK_a values can be used to calculate formation constants for any pH that falls within the range of the pH study (see text).

[c]The formation constants are for the total of the two products that, above pH 5, are formed in an approximate 1:1 ratio for the −724 and −740 ppm products, respectively. Below pH 5, the pK_a values influence the ratio of products.

pH. The possibility of the existence of a pK_a for the monoligand product outside the pH range of this study can not be ruled out.

A pH variation study, for the range 6.5–8.0, was also carried out at higher ligand concentration in order to gather information concerning the bisligand product. The equilibrium reaction for these products can be written in a manner analogous to eq. [5]. The chemical shift of the signals originating from the

bisligand products remained the same over the pH range 6.5–8. This observation suggested, but certainly did not prove, that none of the bisligand products had a pK_a within the pH range of our study. Other studies had suggested that the products giving rise to the broader NMR signals had pK_a's below 6.5. To test this, ^{51}V NMR spectra were recorded for the acidic pH range of 1.5–7.0. For this study, an excess of ligand (V:ligand molar ratio of ~3 mM:20 mM) was used. Under these conditions, the vast majority of vanadate is converted into complexes so that no observable amounts of decavanadate were formed.

The decrease in pH led to a sharpening of the broad signals and an accompanying change in chemical shift. The behavior of the sharp component, Fig. 1: **f**, of the bisligand product signals was quite different from the other components. The intensity of the sharper component decreased with the increase in hydrogen ion concentration and the signal was not observed below pH 5.5. These observations are in keeping with the higher pH study and support the suggestion that the vanadium is coordinated in two different geometries. The pH dependence of the chemical shift values was utilized to determine the pK_a of the products giving rise to the broad NMR signals. In Fig. 5, chemical shift values for signals **d** and **e** of Fig. 1 are plotted against pH and the plots show an inflection point in both the cases. This pH-dependent chemical shift derives from protonation/deprotonation of the products and can be related to their pK_a's by eq. [8],

$$[8] \quad pH = pK_a + \log [(\delta_L - \delta_O) / (\delta_O - \delta_H)]$$

where δ_O is the observed chemical shift, δ_L is the limiting chemical shift at low pH, and δ_H is the corresponding value at high pH. A plot of pH versus the logarithm term provided a line of intercept pK_a and unit slope. The pK_a's were 3.35 ± 0.15 and 3.80 ± 0.15, for the bisligand products **d** and **e** (Fig. 1), respectively.

The pK_a values obtained for the major bisligand products fall within the acidic pH range and suggest that the quantitative analysis of the results of the pH variation study from pH 6.5 to 8.0 does not require consideration of a protonation/deprotonation state of the products. The total vanadate and ligand concentration was maintained constant throughout the pH-variation study. On plotting the data appropriately for eq. [7], (Fig. 6) a linear relationship was obtained only for a value of $n = 1$ for the major product and no evidence of curvature was obtained. This result showed that the product does not carry a charge and the absence of curvature in the graph was consistent with the above proposal that these products do not

Fig. 5. The influence of variation in pH on the chemical shifts of the major bisligand products. Conditions of the experiments: variable pH, 1.2–7.0; 3.0 mM total vanadate; 20 mM total *N,N*-dimethylhydroxylamine; 1.0 M KCl; 20 mM HEPES buffer.

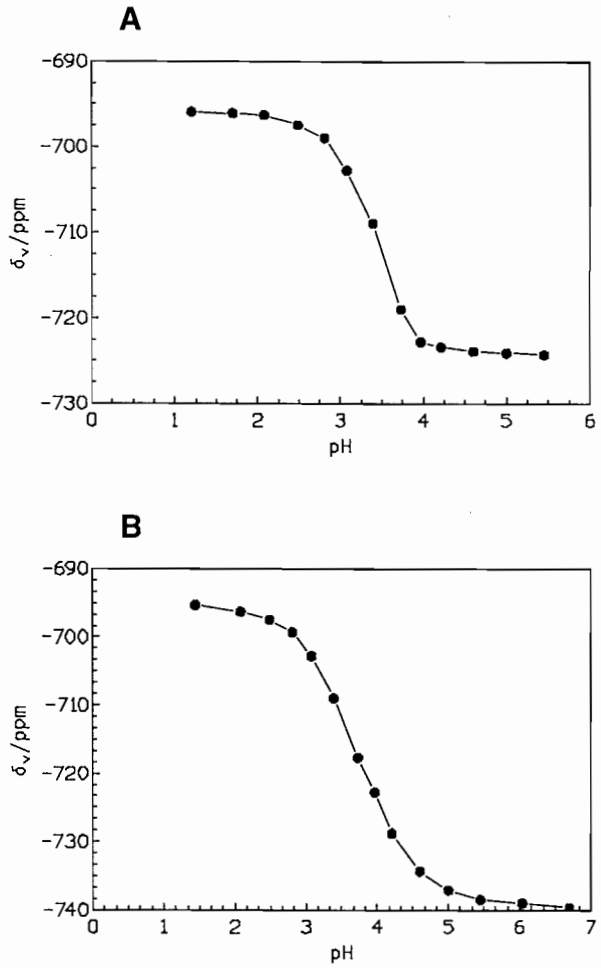

Fig. 6. Graphical representation of the formation of the bisligand products as a function of pH. The graph is plotted in accordance with eq. [7]. Conditions of the experiments: variable pH, pH 6.8–8.0; 3.0 mM total vanadate; 3.0 mM total *N,N*-dimethylhydroxylamine; 1.0 M KCl; 20 mM HEPES buffer.

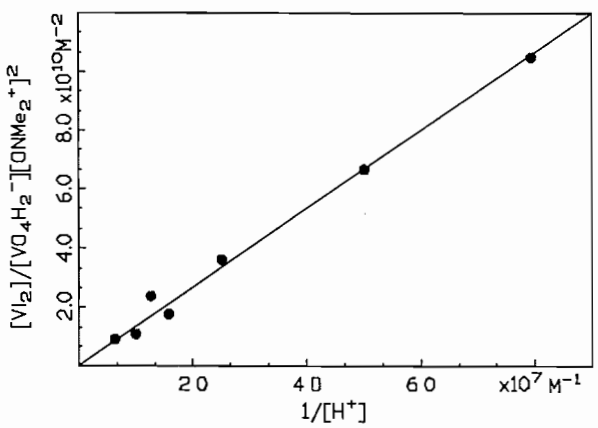

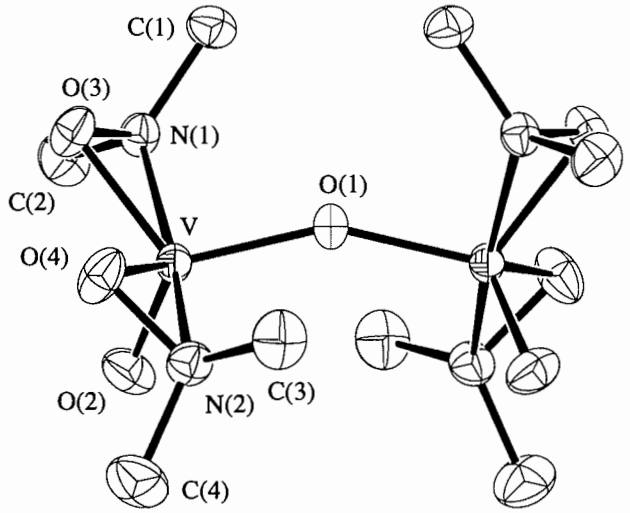

Fig. 7. The molecular structure of $[V(O)(ONMe_2)_2]_2O$ at 213 K. 50% Probability thermal ellipsoids are shown for all non-hydrogen atoms.

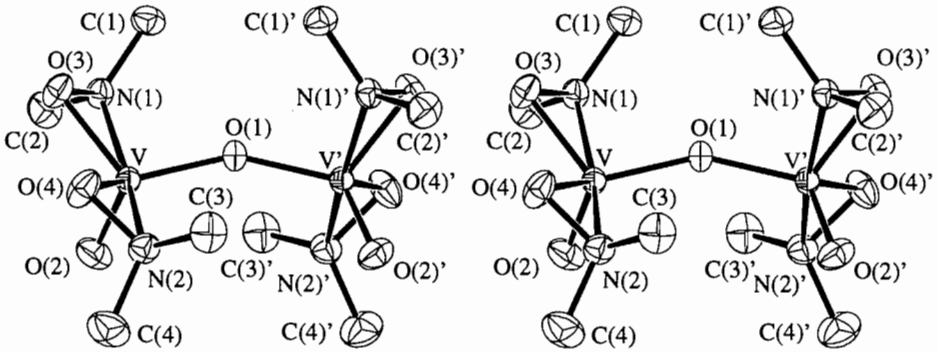
have a pK_a near this pH range. This is in keeping with the rapid loss of this product with increase in pH. The overall pH-independent formation constant K'_{02} for the major bisligand products (**d** + **e**, Fig. 1) was determined to be $(1.3 \pm 0.1) \times 10^3$ M^{-1}. The minor bisligand product persists with increase in pH and this suggests this product does have a pK_a and possibly a different charge state from the major products. Studies of methylhydroxylamine–vanadate have, however, shown that, for that system, the corresponding compound does not carry a charge. Although the major products do not carry a charge at neutral pH, they are protonated at lower pH. Taken together, this evidence clearly shows that there are two types of bisligand compound that probably vary in their coordination geometry. The two broad signals, corresponding to the major bisligand products, are assigned to one type of complex and are ascribed to stereoisomers. From the studies here, it is not possible to know whether there is a change in coordination when the neutral products are protonated. Table 4 summarizes the formation constants measured for the various products.



To obtain more information about these materials, an attempt was made to obtain a product in solid form. This proved successful and reaction of tetraethylammonium vanadate with DMHA at pH 8 (see Experimental) afforded a yellow crystalline solid in good yield (70%). The yellow, needle-shaped crystals were stable at room temperature for extended periods of time and suitable for X-ray structural studies.

The molecular structure is shown in Fig. 7. Bond distances and angles are given in Table 3.[3] In the structure of this com-

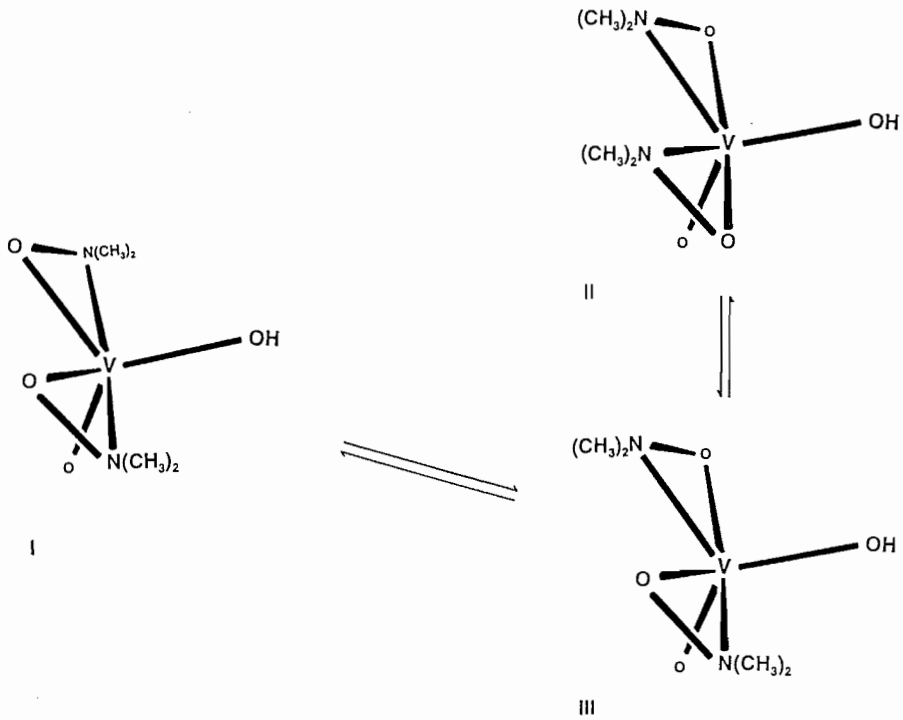
Fig. 8. A molecular stereodiagram of $[V(O)(ONMe_2)_2]_2O$ at 213 K. 50% Probability thermal ellipsoids are shown for all non-hydrogen atoms.

pound, no intermolecular separations significantly less than the sums of the appropriate van der Waals radii (35) were found. A structurally similar diethylhydroxamidovanadium(V) complex was previously prepared in a nonaqueous solvent system (36). This correspondence in structure, perhaps, is not surprising since neither complex is ionic.

The molecule has crystallographic twofold symmetry, the *2* axis passing through O(1). The vanadium atom is six-coordinate. As can be judged from the stereodiagram, Fig. 8, the arrangement about vanadium might be described as approximately tetrahedral, considering the center of the N—O bond in each dimethylhydroxamide as one vertex. The N and O atoms of the two dimethylhydroxamido ligands on each vanadium are very nearly coplanar. Similar coplanarity is ubiquitous in bisperoxovanadium complexes and this suggests the operation of a fundamental physical process leading to this characteristic behaviour. The deviations from the best least-squares plane through the four atoms are: O(3) −0.011(3) Å, O(4) 0.012(3) Å, N(1) 0.009(3), and N(2) −0.011(3) Å. The fact that both the bridging and terminal oxo groups lie well out of this plane on either side (O(1) −1.317(4) Å, O(2) 1.569(3) Å), while the vanadium atom is only slightly displaced towards the terminal oxo (0.087(2) Å), precludes describing this geometry as a pentagonal pyramid as is often found for oxoperoxovanadate(V) complexes. For example, in $[V(O)(O_2)_2(NH_3)][NH_4]$ (37), where the complex anion lies on a mirror plane and thus the atoms of the two mirror-related peroxo groups are precisely coplanar, the deviations of the other atoms from this plane are N(ammine) 0.29 Å, O(vanadyl) 2.12 Å, and V 0.52 Å. The pentagonal pyramidal or bipyramidal arrangements in such complexes (37–43) appear to be a consequence of coordination by a seventh ligand, such as the long (2.926(3) Å) intermolecular secondary bond to an adjacent vanadyl oxygen atom in $[V(O)(O_2)_2(NH_3)][NH_4]$.

The structure can also be compared to that exhibited by the $[(V(O)(O_2)_2)_2O]^{4-}$ anion as displayed in its tetraammonium salt (44). A major difference is the absence, in the dimethylhydroxylamine complex, of the seventh coordination site *trans* to the terminal oxo group. In $[(V(O)(O_2)_2)_2O][NH_4]_4$, this seventh site is occupied by a peroxo-oxygen atom that is primarily bound to the other vanadium atom within the molecule. The methyl groups in the present structure apparently preclude the formation of an analogous N—V secondary coordinate bond as well as obstructing further vanadium contacts to adjacent molecules and dictating the stereochemistry of the complex. The absence of intramolecular bridging by the dimethylhydroxylamine group allows the V-O(1)-V′ angle to open out to 153.87(14)° as compared to 98.9(1)° in $[(V(O)(O_2)_2)_2O][NH_4]_4$ (44). A further consequence is that the V—O(1) bond is much shorter (1.806(1) Å) than the analogous V—O bonds in $[(V(O)(O_2)_2)_2O][NH_4]_4$ (2.013(2), 1.994(2) Å). The implication of bond order greater than 1 for the V—O(1) bond and possible π-orbital conjugation through O(1) is supported by the approximately orthogonal torsional juxtaposition of the two $V(O)(ONMe_2)_2$ groups when projected along the V--V′ vector (e.g., N(1)-V--V′-N(1)′ 90.1(1)°; N(2)-V--V′-N(2)′ 113.4(1)°; O(2)-V--V′-O(2)′ −73.3(1)°; where (′) indicates the symmetry equivalent position (x, $-y$, $-z$)). Furthermore, the 153.87(14)° V-O(1)-V′ bond angle does not appear to be sterically imposed as there are no contacts between the ligands on the opposing vanadium atoms less than the sums of the appropriate atomic van der Waals radii.



The other V—O bond lengths are in good agreement with their counterparts in the array of known structures of oxobisperoxovanadate(V) complexes (37–43), while the V—N distances (V—N(1) 2.069(2) Å, V—N(2) 2.066(2) Å) are, quite reasonably, longer than the analogous V—O distances (typically about 1.9 Å). Consistent with this are the somewhat shorter O—N bonds (O(3)—N(1) 1.403(3) Å, O(4)—N(2) 1.398(3)) compared to the range of corresponding O—O bond lengths (1.451(6) – 1.474(4) Å).

The crystals dissolved readily in many organic solvents but were less soluble in water. When $CDCl_3$ was used as the solvent, a single signal at −728 ppm was observed in the ^{51}V NMR spectrum. This chemical shift is close to that reported for vanadate complexes with *N,N*-diethylhydroxylamine (−711 ppm) and *N,N*-dibenzylhydroxylamine (−696 ppm). When dissolved in D_2O, two signals, −726 ppm and −740 ppm, were found. Since these signals were of different intensities, the presence of two different complexes was evident. ^1H NMR spectra of the complex also were recorded for $CDCl_3$ and D_2O solvents and the results obtained were in keeping with the vanadium NMR spectra. The important feature of the proton spectrum in $CDCl_3$ was the presence of two sharp signals at 3.3 and 3.0 ppm that are assignable to the two types of ligand methyl groups in the dimeric complex. In D_2O, the spectrum exhibited two very broad signals in the range 2.5–3.5 ppm. This spectrum was indicative of a reasonably fast equilibration between the two different forms of the complex.

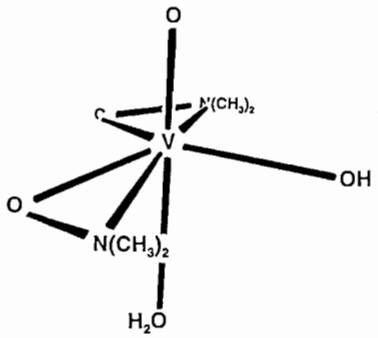
Scheme 1.

The ^{51}V NMR spectrum of the $[V(O)(ONMe_2)_2]_2O$ complex in acetone (3 mL) exhibited a sharp signal at −726 ppm. Gradual addition of water (total of 3 mL in 0.5 mL portions) to the above solution led to decrease in intensity of this peak. Simultaneously with the decrease in intensity of this peak, two other peaks, −722 to −738 ppm, appeared in the spectrum. The intensity of these two peaks increased with each addition of water. These three species, in each acetone–water solution, rapidly attained equilibrium, after which no appreciable change in intensities was observed. The signal at −726 ppm is attributed to a dimeric $[V(O)(ONMe_2)_2]_2O$ with a structure corresponding to the crystalline solid.

An ^1H NMR variable temperature study of the crystalline compound dissolved in D_2O (298–275 K) and in $(CD_3)_2CO/D_2O$ (273–248 K) revealed that the broad signal observed at room temperature sharpened with decrease in temperature, to give a well-resolved spectrum of several signals at the lowest temperature. This suggested that the broadening derived from a chemical exchange process that interconverted the two isomers. The low-temperature spectrum was somewhat complicated by the presence of more than two sets of signals, probably because of the presence of binuclear isomers. Since the vanadium signals, in frequency units, were much farther apart than the proton signals (~1600 Hz compared to ~300 Hz) the exchange broadening was not clearly observed in the vanadium spectrum. It is evident from these studies that, in an aqueous environment, hydrolysis of the dimer occurs to provide at least two product complexes that correspond to the broad signals of the equilibrium studies. In principle, a third product is possible. Its vanadium NMR signal may lie under either of those from the other products or its formation may be disfavoured because of steric interations or possibly electronic effects. Steric interactions could arise from the presence of the ligand methyl groups while electronic influences would result from the relative orientations of the oxygens and nitrogens of the two hydroxamido ligands.

[9] $V\ell_2(1) \rightleftharpoons V_2\ell_4 \rightleftharpoons V\ell_2(2)$

As found from the variable temperature proton spectra, these two products are undergoing quite rapid equilibration. This is in keeping with our previous suggesion that they are stereoisomers. This proposal is supported by a longer term study that showed that hydrolysis to free vanadate or the monoligand compound is, comparatively, very slow, requiring in the order of hours for hydrolysis to occur. This strongly suggests that the isomerization does not involve bond breaking but rather corresponds to a simple, in-plane, end-for-end rotation of the hydroxamido group. Any bond breakage in the kinetic pathway would be expected to promote dissociation.



In agreement with the results of the equilibium pH variation study that shows these two products do not carry a charge, it is proposed that the coordination about vanadium in the two major bisligand products is similar to that found in the crystalline material, that is, the tetrahedral-like coordination depicted in Scheme 1. In Scheme 1, compound III is thought to correspond to the stereoisomer for which no vanadium NMR signal has been observed in this study. This isomer, of the three possible, has been selected on the basis that no X-ray study has yet reported a bishydroxamidovanadium complex for which the hydroxamido groups are in a *trans* arrangement to each other. Such an arrangement, however, could possibly occur and the corresponding complex be present in solution. Several X-ray

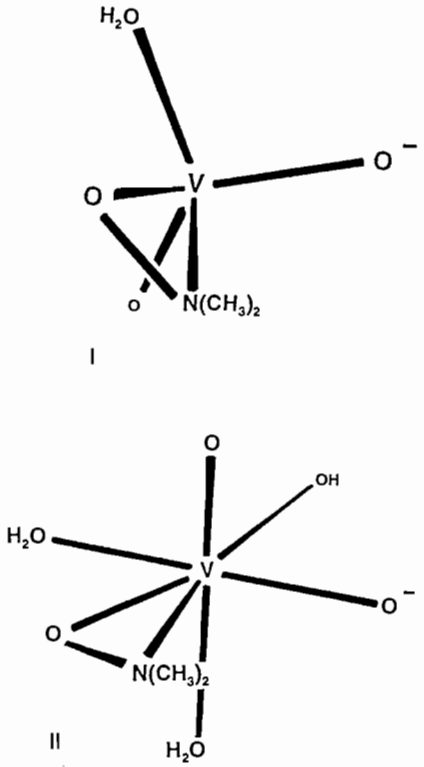
Scheme 2.



studies have reported structures where the oxygens of the two ligands are in close proximity as in Scheme 1, I (this work and refs. 36 and 45), and one report has shown the two nitrogens to be in close proximity, similar to Scheme 1, II (46). A very different arrangement in which the two hydroxamido moieties are oriented perpendicular to each other is found in a certain structural analogue of amavadin but, in this case, the multidentate ligand is constraining the system (47). The perpendicular orientation will, presumably, correspond to the intermediate in the isomerization observed here in the variable temperature ^{1}H NMR studies.

The minor bisligand complex (corresponding to signal **f**, Fig. 1) has different proton requirements than the major bisproducts. On this basis, it must have a different coordination geometry. It seems likely that it is heptacoordinate (Scheme 2), after the fashion proposed for bisperoxovanadates (12, 48). It should, however, be recognized that both pentagonal pyramidal (13, 49) and eight-coordinate structures (30) have been proposed for bisperoxovanadates. Formation of this product seems to be disfavoured by the presence of the two methyl groups on the nitrogen since a similar product is relatively much more readily formed from hydroxylamine and methylhydroxylamine (22). The influence may principally be a consequence of electronic influences since the pK_a values for *N,N*-dimethylhydroxylamine (pK_a = 5.28) is significantly lower than for *N*-methylhydroxylamine (pK_a = 6.00) and hydroxylamine (pK_a = 6.01) (34). On the other hand, the relative change in populations is not large enough to rule out small steric influences.

An additional bisligand compound is observed above pH 9. It is not highly favoured under the conditions of this study, having a formation constant a factor of 20 smaller than the major products (see Table 4). Its coordination geometry is unknown.

The coordination about vanadium in the monoligand products also is not known. The observation of two products suggests two different coordination schemes. Unless forced otherwise by the ligand, the tendency of vanadate coordination is to favour tetrahedral geometry so it seems likely that, if the predominant bisligand product has a tetrahedral-like coordination, the major monoligand product also does. In this case, a hydroxyl group would replace one of the DMHA ligands to give $(CH_3)_2NOVO(OH)_2$, which deprotonates to form the monoanionic product observed (Scheme 3, I). The second monoligand product, which is formed to an extent of about 12% of the total monoligand product, would then correspond to a higher coordination number complex (Scheme 3, II), most

Scheme 3.

probably a coordination similar to that proposed above for the minor bisligand product and for monoperoxovanadate (11,12).

A few other complexes are formed, all in very low proportions. Of these, only the product giving rise to the NMR signal at −571 ppm can be assigned a structure. It is highly likely that this signal corresponds to a vanadate ester formed between the hydroxylamine hydroxyl group and monovanadate. Its formation (Table 4) is relatively unfavoured when compared to the major products of this study but is highly favoured when compared to aromatic (32, 50) and aliphatic (33, 51, 52) alcohols.

The formation of these complexes with *N,N*-dimethylhydroxylamine compares very favourably with those from hydrogen peroxide (10, 28). In fact, the monoanionic monoligand product ($K_{01}' = (6.5 \pm 0.2) \times 10^3$ M^{-1}), Vℓ, is actually favoured by about a factor of 10 over that of the corresponding hydrogen peroxide complex ($K_{01}' = (6 \pm 2) \times 10^2$ M^{-1} (28)). The incorportion of the second ligand cannot be so easily compared because of the different proton requirements. However, at pH 6.7 the value for the reaction $V\ell + \ell \rightleftharpoons V\ell_2$ is K_{12} = $(1.7 \pm 0.6) \times 10^5$ M^{-1} for the formation of the bisperoxo derivative compared to $K_{12} = (1.1 \pm 0.1) \times 10^3$ M^{-1} for the corresponding reaction with *N,N*-dimethylhydroxylamine. The formation of the bisperoxo derivative from the monoligand precursor is therefore favoured by a factor of 100 compared to the corresponding reaction with dimethylhydroxylamine.

The observation of a reasonably fast rotational isomerization of the dimethylhydroxamide ligand suggests that a similar isomerization occurs with peroxo ligands. In this case, such an isomerization might be observed by partially ^{17}O enriching the hydrogen peroxide and observing the ^{17}O NMR spectrum.

© 1997 NRC Canada

The observation of a product that can be assigned to an end-on coordination to give a vanadate ester has potential implications for the function of haloperoxidases since it is very likely that similar complexes are formed with hydrogen peroxide and could have a role in the function of these enzymes.

Perhaps one of the most interesting findings of this study is that the dimethylhydroxamide ligand favours the formation of tetrahedral-like complexes rather than the trigonal bipyramidal-like structures of the hydrogen peroxide ligand. The more efficient electron donation by O-N compared to O-O could account for this. With increased electron density at the vanadium nucleus, there will be less propensity towards accepting ligands and thus expanding the coordination sphere. As discussed elsewhere for other ligands (29, 33, 53), similar subtle electronic influences have a significant impact on vanadate coordination and chemistry.

Reexamination of the Kirkwood–Westheimer theory of electrostatic effects. V. Effect of charged substituents on the rates of alkaline hydrolysis of substituted strychnines

Khamis A. Abbas, Phillip Hurst, and John T. Edward

Abstract: The rates of hydrolysis in aqueous sodium hydroxide of the alkaloid strychnine and seven of its derivatives have been determined at 50 and 75°C. The kinetic data indicate that all the compounds, except strychninesulfoni acid-I, hydrolyze by competing second- and third-order mechanisms, involving one and two hydroxide ions, respectively; strychninesulfonic acid-I hydrolyzes by the second-order mechanism only. The quantitative effect of positively charged groups in enhancing, and negatively charged groups in depressing, the rates of hydrolysis is in rough agreement with calculations using Kirkwood–Westheimer theory.

Key words: Kirkwood–Westheimer theory; strychnine derivatives, hydrolysis of; lactams, hydrolysis of; electrostatic effects on rates of alkaline hydrolysis; alkaloids, reactions of.

Résumé : On a déterminé, à des températures de 50 et de 75°C et dans l'hydroxyde de sodium aqueux, les vitesses d'hydrolyse de strychnine et de sept dérivés. Les données cinétiques indiquent que tous les composés, à l'exception de l'acide strychninesulfonique-I, subissent l'hydrolyse selon un mécanisme compétitif d'ordre 2 et 3, impliquant un et deux ions hydroxydes respectivement; l'acide strychninesulfonique-I s'hydrolyse uniquement selon un mécanisme d'ordre 2. L'effet quantitatif des groupes chargés positivement et des groupes chargés négativement sur l'augmentation et la diminution respectives des vitesses d'hydrolyses est grossièrement en accord avec les calculs utilisant la théorie de Kirkwood–Westheimer.

Mots clés : théorie de Kirkwood–Westheimer, hydrolyse des dérivés de la strychnine, hydrolyse des lactames, effets électrostatiques sur la vitesse de l'hydrolyse alcaline, réactions des alcaloïdes.

[Traduit par la rédaction]

Following earlier ideas of Bjerrum (1), Ingold (2), Eucken (3) and others, Kirkwood and Westheimer (KW) (4) elaborated a theory of electrostatic effects on reaction rates and equilibria that is still being investigated (5–11). Tests of the theory are best carried out with cage molecules of rigidly defined geometry, but the synthesis of such molecules is usually very time-consuming. However, many readily available alkaloids have cage structures, and in this paper we describe studies of the rates of alkaline hydrolysis of the alkaloid strychnine and of seven of its derivatives shown in Scheme 1. The derivatives (except brucine) carry charged or dipolar groups, which can be expected to affect their rates of hydrolysis, and each can be prepared in a few days, as compared with the months required by Roberts and Moreland (16) to synthesize the 1,4-disubstituted bicyclo[2.2.2]octanes used in their classic study of KW theory. We have already used the three isomeric strychninesulfonic acids shown in Scheme 1 to study the effect of the negatively charged sulfonate group on rates of detritiation from the methylene adjacent to the amide carbonyl in alkaline solution (17).

The opening of the lactam ring of strychnine **1** by alkaline hydrolysis to give the anion of the amino acid **2** has been known for almost a century (18–20), but its rate has never been measured. Since the lactam is a cyclic anilide, its alkaline hydrolysis would be expected to take place by competing second- and third-order paths, involving the singly and doubly charged intermediates Int^{1-} and Int^{2-} shown in Scheme 2 (21–26). However, the lactam rings of the compounds of Scheme 1 are all considerably more stable than most anilides, which hydrolyze at convenient rates at 25°C, and we have had to work at 50 and 75°C. Rates have been measured over a range of concentrations of sodium hydroxide, and results have been extrapolated back to zero concentration in order to apply KW theory (7, 27). The need to do this has sometimes been overlooked (28).

Experimental

Materials

Strychnine and brucine were commercial products, and were recrystallized to have melting points reported in the literature.

II (Y=SO_3^-, X=Z=H) (15)
III (Z=SO_3^-, X=Y=H) (15)

Scheme 2.

Other compounds were prepared and purified by the methods given in the references of Scheme 1. Sodium hydroxide solutions (0.100 N, 0.500 N, 1.00 N, 5.00 N) were Fisher carbonate-free products. Other concentrations were prepared by dilution of these solutions with carbon dioxide-free water.

Kinetic measurements

Sodium hydroxide (10 mL in a volumetric flask) of known concentration was brought to a temperature of 50 or 75°C by immersion in a thermostatted bath for 30 min. A 5.0 μL aliquot of a stock solution in trifluoroacetic acid of the compound being investigated was injected into the sodium hydroxide solution, and after rapid mixing the solution was poured into a cuvette, which was stoppered and put into the compartment of a Unicam SP 800 spectrophotometer. The latter was thermostatted by water circulating from a Haake model F5/FE circulator. Hydrolysis was followed by the decrease in peak absorbance A (at 265 nm for brucine, 250–256 nm for strychnine and its derivatives). Good isosbestic points (at 316 nm for brucine, 287.5–292 nm for strychnine and its derivatives) were obtained. Pseudo-first-order rate constants k_ψ were determined by least-squares plots of log $(A_t - A_\infty)$ against t, where A_t and A_∞ are the absorbances at time t and at infinite time. For slow (s) reactions A_0^s was calculated by $A_\infty^s = A_\infty^f A_0^s/A_0^f$, where A_∞^f is the experimentally determined absorbance for a fast reaction after a sufficient time for change in absorbance to be complete, and A_0^f and A_0^s are the absorbances of the fast and slow reaction at zero time. A_∞^s was tested by taking a slightly lower and slightly higher value, and comparing the regression coefficients (R) for the slopes of log $(A_t - A_\infty)$ against t, using the new values of A_∞^s, with R for the slope using the original A_∞^s.

Results and discussion

In the large excess of sodium hydroxide used, the rates of hydrolysis of the compounds of Scheme 1 all followed pseudo-first-order kinetics.[4] We now consider the kinetics of hydrolysis of the different types of molecules, starting with those lacking a charged group.

Hydrolysis of uncharged molecules (strychnine, brucine, and strychnine *N*-oxide)

The change in the pseudo-first-order rate constant k_ψ with change in hydroxide ion concentration [OH^-] shows that hydrolysis of the uncharged molecules S involves competing second- and third-order routes via Int^{1-} and Int^{2-} of Scheme 2. Assuming transition states ‡(1) and ‡(2) close to Int^{1-} and Int^{2-} in structure, application of the Bronsted–Bjerrum treatment gives

$$[1] \quad k_\psi = k_\psi^{(1)} + k_\psi^{(2)} = k_0^{(1)}[OH^-] f_S f_{OH^-}/f_{\ddagger(1)} + k_0^{(2)}[OH^-]^2 f_S f_{OH^-}^2/f_{\ddagger(2)}$$

k_0 representing a rate constant at ionic strength $\mu = 0$, and f representing molar activity coefficients, referred to infinitely dilute solution in water as the standard state.

Biechler and Taft (29) found that the rates of alkaline hydrolysis of *N*-methylanilides in aqueous sodium hydroxide were unaffected by changes in ionic strength over the range 0–0.577 M, the activity coefficient terms cancelling out, so that for these compounds eq. [1] becomes

[4] Tables 1S and 2S of experimental pseudo-first-order rate constants at 50 and 75°C are available as supplementary material and can be purchased from: The Depository of Unpublished Data, CISTI, National Research Council Canada, Ottawa, Canada K1A 0R6. Also available from this source are figures and details of computations mentioned later in the paper.

Table 1. Second-order rate constants $k_0^{(1)}$ (in mol^{-1} s^{-1}), third-order rate constants $k_0^{(2)}$ (in mol^{-2} s^{-1}), and β coefficients at 50 and 75°C.

Compound	50°C				75°C			
	$10^5k_0^{(1)}$	β	$10^5k_0^{(2)}$	β	$10^5k_0^{(1)}$	β	$10^5k_0^{(2)}$	β
Strychnine	0.85	—	2.95	—	5.84	—	10.2	—
Brucine	2.10	—	2.51	—	—	—	—	—
Strychnine *N*-oxide	2.18	—	36.6	—	30.2	—	66.6	—
N-Methylstrychninium chloride	10.5	−0.077	15.1	0.13	58.9	0.40	661	−0.004
N-Benzylstrychninium bromide	11.2	−0.86	17.4	0.079	74.1	−1.94	832	−0.13
Strychninesulfonic acid-I	0.10	0.37	—	—	0.46	0.39	—	—
Strychninesulfonic acid-II	0.29	0.82	0.19	0.19	2.69	0.099	0.81	0.068
Strychninesulfonic acid-III	0.89	0.23	0.16	0.16	3.16	0.27	0.93	0.027

[2] $$k_\psi + k_0^{(1)}[OH^-] + k_0^{(2)}[OH^-]^2$$

which can be rearranged to

[3] $$k_\psi/[OH^-] = k_0^{(1)} + k_0^{(2)}[OH^-]$$

Hence plots of $k_\psi/[OH^-]$ against $[OH^-]$ gave straight lines of slope $k_0^{(2)}$ and intercept $k_0^{(1)}$. We find the same behaviour for the uncharged compounds strychnine, brucine, and strychnine *N*-oxide. This is shown in Fig. 1 for strychnine and strychnine *N*-oxide at 50°C. Over the range 0–2 M sodium hydroxide for strychnine and 0–0.5 M for strychnine *N*-oxide, rates of hydrolysis followed eq. [3], with linear plots of log $k_\psi/[OH^-]$ against $[OH^-]$ (correlation coefficients *r* better than 0.980). The values of $k_0^{(1)}$ and $k_0^{(2)}$ obtained from these plots are given in Table 1. Similar plots[4] gave values of $k_0^{(1)}$ and $k_0^{(2)}$ at 75°C (Table 1).

At higher concentrations of sodium hydroxide the second-order pathway becomes progressively less important, accounting for less than 26% of the product from the hydrolysis of strychnine and for less than 8% of the product from the hydrolysis of strychnine *N*-oxide in concentrations above 1 M. The difference between the two compounds would be expected from simple electrostatic theory: the *N*-oxide dipole will stabilize Int^{2-} more than Int^{1-}, and hence favour the third- over the second-order route.

Hydrolysis of positively charged ions: the rate becomes almost exclusively third order in concentrations of sodium hydroxide above about 0.5 M

Even more than the *N*-oxide dipole, the positively-charged nitrogen atom of the methyl- and benzylstrychninum ions S^+ should stabilize Int^{2-} more than Int^{1-}, and favour the third-order route. We show below that, in fact, in concentrations of sodium hydroxide above about 0.5 M the contribution of the second-order route becomes negligible.

Consequently, in these concentrations,

[4] $$k_\psi = k_0^{(2)}[OH^-]^2 f_{S^+} f_{OH^-}^2 / f_{\ddagger(2)}$$

[4*a*] $$\log k_\psi = \log k_0^{(2)} + 2\log[OH^-] + \log(f_{S^+} f_{OH^-}^2 / f_{\ddagger(2)})$$

In reactions between ions, unlike reactions between an ion and a neutral molecule (30), the last term does not cancel out even in dilute solution, but must be calculated by Debye–Huckel theory (30–33). This theory (34) indicates that for a second-order reaction between ions 1 and 2 having unit charges z_1 and z_2, the rate constant *k* will vary with $\mu^{1/2}$ according to the equation:

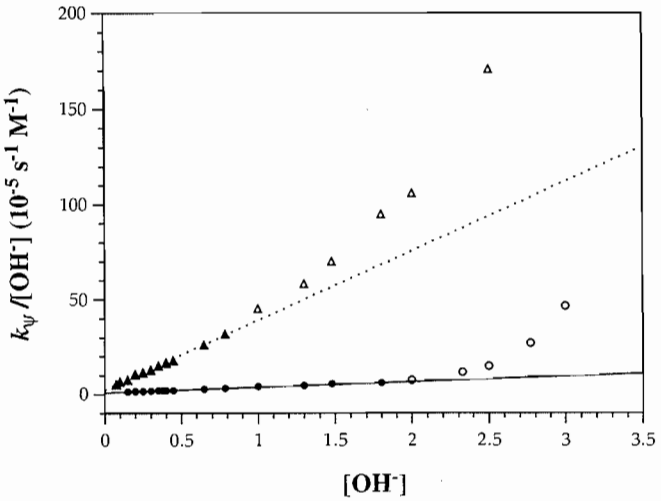

Fig. 1. Plots of $k_\psi/[OH^-]$ for strychnine (○) and strychnine *N*-oxide (△) against concentrations of sodium hydroxide at 50°C. Straight-line plots are based on solid points (●, ▲). (▲ ·····) $y = 2.1817 + 36.615x$; $R = 0.99767$. (● ——) $y = 0.85388 + 2.9473x$; $R = 0.99666$.

[5] $$\log k = \log k_0 + \frac{2z_1zA\mu^{1/2}}{1 + B\mathring{a}\mu^{1/2}}$$

where $\mathring{a}$ is the mean diameter of the ions and *A* and *B* are quantities varying with temperature, and calculable by Debye–Hückel theory (30–32). In higher concentrations of electrolyte it is necessary to add a term βμ (30–32):

[6] $$\log k = \log k_0 + \frac{2z_1zA\mu^{1/2}}{1 + B\mathring{a}\mu^{1/2}} + \beta\mu$$

where β is an empirically determined constant. For a third-order reaction involving ions 1, 2, and 3 having charges z_1, z_2, and z_3 the equation becomes (30)

[7] $$\log k = \log k_0 + 2(z_1z_2 + z_1z_3 + z_2z_3)\frac{A\mu^{1/2}}{1 + B\mathring{a}\mu^{1/2}} + \beta\mu$$

For the third-order reaction of methyl- or benzylstrychninium ions with two hydroxide ions, $(z_1z_2 + z_1z_3 + z_2z_3) = -1$. Accepting Weller's values (33) for A and $B\mathring{a}$, for hydrolyses at 50°C (31, 32, 35) eq. [4*a*] becomes

$$[8] \quad \log k_\psi^{(2)} = \log k_0^{(2)} + 2 \log [OH^-] - \frac{1.08\mu^{1/2}}{1 + 2.03\mu^{1/2}} + \beta\mu$$

This equation requires that (as long as the second-order reaction can be neglected) a plot of $y = \log k_\psi - 2 \log [OH^-] + 1.08\mu^{1/2}/(1 + 2.03\mu^{1/2})$ against μ should give a straight line of slope β and intercept $\log k_0^{(2)}$.

In fact, it can be seen that in concentrations of sodium hydroxide above about 0.8 M (Fig. 2) plots for the methyl- and benzylstrychninium ion are reasonably linear, so that in these concentrations the second-order pathway can be ignored. The slopes and intercepts of these plots give the values of β and $k_0^{(2)}$ recorded in Table 1. The values of β and $k_0^{(2)}$ at 75°C were obtained in similar fashion.[4]

Hydrolysis of methyl- and benzylstrychninium ions by competing second- and third-order mechanisms in dilute sodium hydroxide

In concentrations of sodium hydroxide below 0.5 M the experimental points in Fig. 2 diverge increasingly from the straight-line plots, showing that $k_\psi^{(1)}$ is making an increasingly important contribution to k_ψ and can no longer be ignored.

We can calculate $k_\psi^{(1)} = k_\psi - k_\psi^{(2)}$ by calculating $k_\psi^{(2)}$ at 50°C in 0–0.5 M sodium hydroxide from eq. [8] using the values of $k_0^{(2)}$ and β recorded in Table 1. The values of $k_\psi^{(1)}$ thus calculated should agree with those given by the equation

$$[9] \quad \log k_\psi^{(1)} = \log k_0^{(1)} + \log [OH^-] - \frac{1.08\mu^{1/2}}{1 + 2.03\mu^{1/2}} + \beta\mu$$

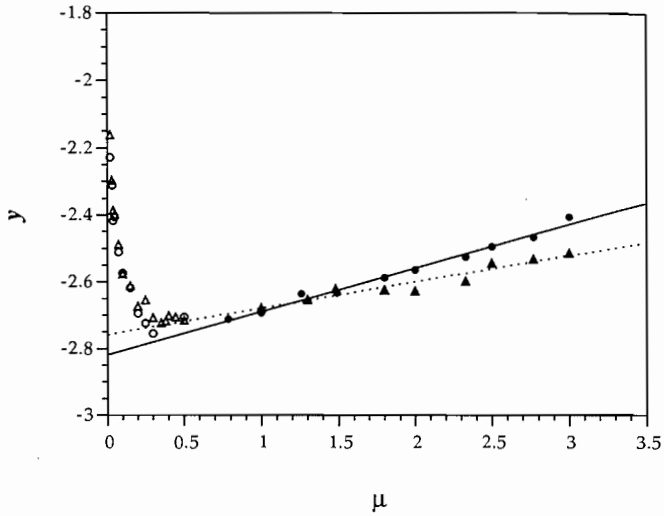
for data at 50°C. (The sign and magnitude of the term in $\mu^{1/2}$ comes from $z_1z_2 = -1$: see eq. [5].) This equation requires that plots of $y = \log k_\psi^{(1)} - \log [OH^-] + 1.08\mu^{1/2}/(1 + 2.03\mu^{1/2})$ against μ should give straight lines. We can see in Fig. 3 that scatter of points about the straight lines is appreciable. However, errors in $k_\psi^{(1)} = k_\psi - k_\psi^{(2)}$ would be expected to be large, not only because of experimental errors in k_ψ but also because of substantial errors in $k_\psi^{(2)}$, whose calculation depends upon a value of $k_0^{(2)}$ obtained by a lengthy extrapolation. We can accordingly expect much larger errors in $k_0^{(1)}$ and β, given by the slopes and intercepts of the straight-line plots in Fig. 3, than in $k_0^{(2)}$ and β for the termolecular reactions. These values are all given in Table 1. Similar computations and plots[4] give the corresponding values for 75°C recorded in the table.

Qualitatively, these values are those expected by simple electrostatic theory. The positive nitrogen atom of the strychninium ions causes $k_0^{(1)}$ to be 10–12 times greater than $k_0^{(1)}$ of strychnine, in which the nitrogen has no formal charge, and causes $k_0^{(2)}$ of the ions to be 51–82 times greater than $k_0^{(2)}$ of strychnine.

Hydrolysis of anions of the strychninesulfonic acids-I, -II, and -III

The sulfonic acids-I, -II, and -III exist as zwitterions in neutral solution (15), but as the anions depicted in Scheme 1 in alkaline solution.

Fig. 2. Plots of $y = \log k_\psi - 2 \log [OH^-] + 1.08\ \mu^{1/2}/(1 + 2.03\ \mu^{1/2})$ for hydrolysis at 50°C of methylstrychninium chloride (○) and benzylstrychninium bromide (Δ) in aqueous sodium hydroxide against ionic strength μ of the hydroxide solution. Straight-line plots are based on solid points (●, ▲). (● ——) $y = -2.8187 + 0.13024x$; $R = 0.99353$. (▲ ·····) $y = -2.7592 + 0.07908x$; $R = 0.95659$.



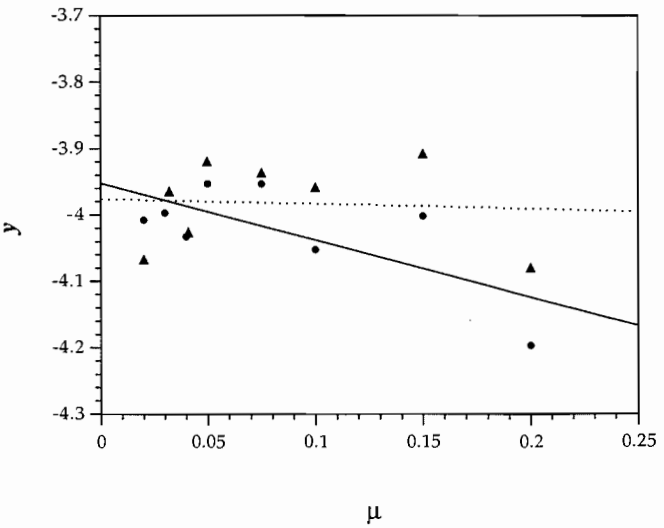


Fig. 3. Plots of $y = \log k_\psi^{(1)} - \log [OH^-] + 1.08\mu^{1/2}/(1 + 2.03\mu^{1/2})$ for hydrolysis of methyl (●) and benzylstrychninium ions (▲) at 50°C against ionic strength μ of the aqueous sodium hydroxide. Calculated straight line plots: methyl —; benzyl ---. (● ——) $y = -3.9528 + -0.85917x$; $R = 0.70145$. (▲ ·····) $y = -3.9767 + -0.076721x$; $R = 0.072815$.

On the basis of simple electrostatic theory, it would be expected that these anions would be hydrolyzed more slowly than strychnine, and furthermore that the rate for the third-order pathway via Int^{2-} would be more depressed than the rate for the second-order pathway via Int^{1-}. Both expectations were realized (Table 1). The kinetic data were analysed in the same fashion as the data for methyl- and benzylstrychninium ions, the equation for the third-order pathway being identical

with eq. [8], except for change in sign and magnitude of the coefficient for the term in $\mu^{1/2}$ determined by the fact that now $(z_1z_2 + z_1z_3 + z_2z_3) = +3$. The equation for the second-order pathway was identical with eq. [9], except for the sign of the term in $\mu^{1/2}$ ($z_1z_2 = +1$). The details of the computations and the plots are given elsewhere;[4] the results are given in Table 1.

Calculation of the increases in rates of hydrolysis caused by positive charges: *N*-methyl- and *N*-benzylstrychninium ions

The positively charged nitrogen atom in *N*-methyl- and *N*-benzylstrychninium ions causes their rate constants for hydrolysis by the second-order ($k_0^{(1)}$) and third-order ($k_0^{(2)}$) routes to be greater than the corresponding rates $k_0^{(1)}$(S), $k_0^{(2)}$(S) of the parent strychnine molecule, and for the effect to be greater on $k_0^{(2)}$ than on $k_0^{(1)}$ (see Table 1). Consequently the logarithms of the ratios $\log k_0^{(1)}/k_0^{(1)}$ (S) = $\Delta \log k_0^{(1)}$ and $\log k_0^{(2)}/k_0^{(2)}$ (S) = $\Delta \log k_0^{(2)}$ are positive and (based on the experimental data in Table 1) are gathered in Tables 2 and 3.

Also in these tables are the ratios calculated by KW theory. For this calculation we assume that the transition state for the second-order route (Scheme 1) is close to Int^{1-}, and hence has a charge close to unit electronic charge, distributed equally between the two geminal oxygen atoms and effectively localized midway between them. Similarly, for the third-order route it is assumed that a charge close to $2e$ is effectively localized at the same point. The distance R between this point and the centre of N^+ of the methyl and benzyl ion can be calculated from atomic coordinates given by an X-ray study of a strychnine derivative (36), and is given in Table 2. KW theory (4, 27) states that $\Delta \log k_0^{(1)}$ depends on R:

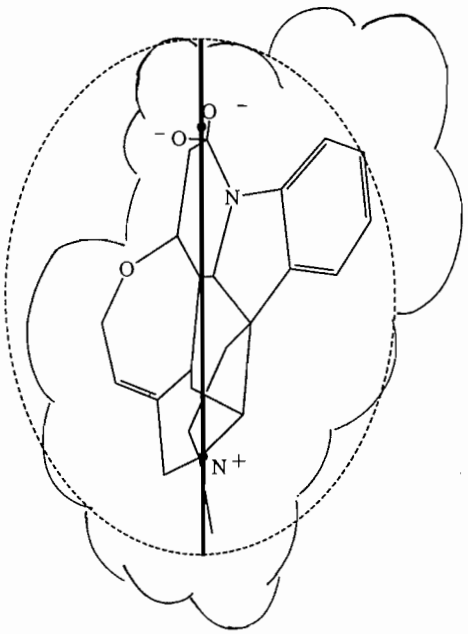
$$[10] \quad \Delta \log k_0^{(1)} = e^2/2.3\ \kappa T R D_{\text{eff}}$$

where κ is Boltzmann's constant, T the absolute temperature, and D_{eff} the effective dielectric constant, having a value intermediate between the dielectric constant D_e of the solvent (water at 50 and 75°C) and the dielectric constant D_i of the hydrocarbon framework of the solute molecule (assumed to be $D_i = 2$ (4, 37)). The third-order $\Delta \log k_0^{(2)}$ will be twice as great, if the charge on Int^{2-} is twice as great as on Int^{1-}.

For the particular case of molecules having the shape of a prolate ellipsoid with charges located at the foci, Kirkwood and Westheimer (4) calculated D_{eff} as a function of D_e and λ_0, the ratio of the major axis to the interfocal distance in the ellipsoid. The shapes of the strychnine molecule and its various derivatives approximate prolate ellipsoids, as shown in Fig. 4 for Int^{2-} for the *N*-methylstrychninium ion.

The most convenient method for obtaining λ_0 is that of Tanford (38, 39), in which each charged focus is located at a distance d beneath the end surface of the ellipsoid. Then

$$[11] \quad \lambda_0 = (R + 2d)/R$$



For the particular case of charged groups such as NH_3^+ and CO_2^- Tanford showed that the experimental data were accommodated with d = 1.0 Å, 0.9 Å less than the van der Waals radius of about 1.9 Å for NH_3^+ (cf. 2.0 Å for CH_3 (40)). In the *N*-methylstrychninium ion the distance from N^+ to the surface of the methyl group can be calculated (40) to be about 3.5 Å. Following Tanford, we reduce this by 0.9 Å to d = 2.6 Å for N^+ in methyl and benzyl ions. Retaining Tanford's d = 1.0 Å for the depth of the negative charges on oxygen[5] in Int^{1-} and Int^{2-}, we obtain an average d of 1.8 Å, which is used in drawing the ellipsoid in Fig. 4. The volume V_{Tan} calculated from d and R (315 Å^3: refs. 4 and 39) turns out to be only slightly less

[5] We (39) and Reynolds (41) differ from Eucken (3), Kirkwood and Westheimer (4), and workers following them in the precise nature and location of interacting charges, for reasons set out elsewhere (39, 41).

Fig. 4. Molecular model of Int^{2-} (Scheme 2) for *N*-methylstrychninium ion, drawn by Personal CAChe Software (version for Macintosh), from CAChe Scientific. Tanford ellipse, drawn to scale, is superimposed with N^+ at one focus and midpoint between two O^- at the other; interfocal instance *R*, 6.56 Å; major axis *R* + 2d, 10.16 Å.

than the van der Waals volume V_w of 325 Å^3 for Int^{2-} calculated by addition of van der Waals increments (42). (Only very rarely does V_{Tan} approach V_w (39).)

From eq. [11] we calculate λ_o = 1.55, which requires D_{eff} = 28.0 at 50°C and 26.5 at 75°C (4). With these values in eq. [12] we calculate $\Delta \log k_0^{(1)}$ (Table 2) and $\Delta \log k_0^{(2)}$ (Table 3). If we assume that the additional benzene ring of the *N*-benzylstrychninium ion has a negligible effect on D_{eff}, we obtain the same $\Delta \log k_0^{(1)}$ and $\Delta \log k_0^{(2)}$ for this ion. In fact, the agreement with experimental $\Delta \log k_0^{(1)}$ (Table 2) and $\Delta \log k_0^{(2)}$ (Table 3) is good. The experimental $\Delta \log k_0^{(1)}$ values are about 10% lower than the calculated values, which would be expected if the transition states have charges of about 0.9*e*, distributed between the two oxygen atoms, rather than the charge of 1.0*e* of Int^{1-}. The experimental $\Delta \log k_0^{(2)}$ values are about 30% lower than calculated values, expected if the two oxygen atoms of the transition state share a charge of 1.4*e*, rather than the charge of 2.0*e* of Int^{2-}.

Calculation of the decreases in rates of hydrolysis caused by negative charges: strychninesulfonic acids-I, -II, and -III

X-ray studies (36) show the sulfur atom of the SO_3^- group in strychninesulfonic acid – I to be roughly tetrahedral. We have located the negative charges of the SO_3^- groups in these zwitterionic acid anions at the midpoint between the three oxygen atoms, and obtained intercharge distances *R* (Table 2) by calculation from atomic coordinates given by X-ray measurements (36).

Models of the intermediates Int^{1-} and Int^{2-} involved in the hydrolysis of the strychninesulfonic acids-II and -III[6] show them to approximate Tanford ellipsoids with charges at the foci as required by KW theory. No value has been reported for the depth *d* of the negative charge of the SO_3^- group, although it might be expected to be greater than *d* = 1.0 Å for the CO_2^- group. We have adopted *d* = 1.4 Å, which gives, along with the *R* values reported in Table 2, volumes V_{Tan} of the Tanford ellipsoids (323 Å^3 for acid-II, 354 Å^3 for acid-III) in reasonable agreement with the van der Waals volume V_w (341 Å^3) calculated for Int^{2-} for all three sulfonic acids (42).

Using λ_0 and thence D_{eff} values obtained with these values of *R* and *d* (eq. [11]), we calculate (eq. [10]) $\Delta \log k_0^{(1)}$ (Table 2) and $\Delta \log k_0^{(2)}$ (Table 3). These turn out to be in reasonable agreement with experiment. In the case of $\Delta \log k_0^{(2)}$, experimental values were about 70% of calculated values, possibly again because the geminal oxygen atoms in the transition state share a total charge of about 1.4*e* and not 2.0*e* as used in the calculation. The experimental $\Delta \log k_0^{(1)}$ values probably have greater errors, which would account for the anomalous positive value of $\Delta \log k_0^{(1)}$ for strychninesulfonic acid-III at 50°C.

KW calculations for strychninesulfonic acid-I were expected to be very much in error. Examination of a model (see Fig. 1 in ref. 36) shows that while the midpoint between the geminal oxygens of Int^{1-} and Int^{2-} will again be close to the focus of any ellipsoid enclosing the molecule, the SO_3^- will not; i.e., that the Tanford ellipsoid will not enclose the bulk of the molecule. This is confirmed by the wide discrepancy between the volume of the Tanford ellipsoid for Int^{2-} (V_{Tan} = 200 Å^3) and the van der Waals volume (341 Å^3). In spite of this failure to fit the molecule into the ideal KW ellipsoid, the agreement between calculated and experimental values of $\Delta \log k_0^{(1)}$ is surprisingly good (Table 2).

Calculation of the increase in rate of hydrolysis of strychnine *N*-oxide

For a transition state having the shape of a prolate ellipsoid with a charge *ze* (*z* = number of electronic charges) at one focus and a point dipole of moment *M* at the other focus, Kirkwood and Westheimer (4, 27) showed that the effect of the dipole of moment *M* should be given by

$$[12] \quad \Delta \log k_0^{(z)} = \log k_0^{(z)}/k_0^{(z)}(S) = zeM \cos\theta/2.3\,\kappa TR^2 D_{eff}$$

where *R* is the distance from the charge to the centre of the dipole and θ is the angle between the line *R* joining the foci and the dipole vector. The effective dielectric constant D_{eff} is related to D_e of the solvent and λ_0 of the ellipsoid (but the relationship is not the same as that for two charges interacting from opposite foci of the ellipsoid).

Tanford (38) found eq. [12] valid for a large number of prolate ellipsoidal compounds having interacting charges and dipoles if he assumed *d* = 1.5 Å for both the charged group (e.g., NH_3^+, CO_2^-) and the dipole. (The contradiction that CO_2^- has *d* = 1.0 Å when interacting with another charged group and *d* = 1.5 Å when interacting with a dipole is not explained.) We have adopted *d* = 1.5 Å for strychnine

[6] The model took account of the stereochemistry (43).

N-oxide; *R* (Table 2) and θ (24.4°) were calculated from atomic coordinates given by X-ray diffraction results (36) and from the known bond length of N^+—O^- (44). With this *R* value and d = 1.5 Å, eq. [11] yielded λ_0 and thence D_{eff}. Then, with the dipole moment M (5.24 *D*) given in the literature (45), eq. [14] gave values of $\Delta \log k_0^{(1)}$ (z = 1.0: Table 2) and $\Delta \log k_0^{(2)}$ (z = 2.0: Table 3) in rough agreement with experiment.

Conclusions

Using the Tanford approximation, the KW equations have proved adequate in calculating the increase in rate of alkaline hydrolysis of the lactam ring of strychnine brought about by the presence of a positive charge (*N*-methyl- and *N*-benzylstrychninium ions), the decrease brought about by negative charges (strychninesulfonic acids- I, -II, and -III), and the increase brought about by a suitably oriented dipole (strychnine *N*-oxide). Furthermore, the results serve to confirm the mechanism of Scheme 2: the effects of charged substituents are greater on the rates of the third-order reactions than on the rates of the second-order reactions, as expected from the greater electrostatic interactions.

The behaviour of the strychninesulfonic acids is interesting. Rumpf (46) showed that in the ω-aminosulfonic acid zwitterions H_3N^+-$(CH_2)_n$-SO_3^- the negative sulfonate group, which should stabilize the ammonium group (i.e., should increase pK_{BH^+}), in fact does this only when $n > 5$; for n = 1–3 the ammonium ions are stronger rather than weaker acids, as expected. Hoefnagel et al. (7) have given further examples, and the same anomaly is observed in the pK_{BH^+} values of the strychninesulfonic acid-I, -II, and -III zwitterions (15). This behaviour has been explained by Bell (47), who assumes that the sulfur atom of the negative sulfonate group has a charge of +2 and the three oxygen atoms each a charge of −1. When n = 1–3 in the ω-aminosulfonic acid zwitterions, the effect of the positive sulfur atoms is more important than that of the more distant oxygen atoms. When $n \geq 5$, the difference in distance of sulfur and oxygen atoms becomes less important, and the sulfonate group can be regarded as a point negative charge. The latter is true for the reactions involving Int^{1-} and Int^{2-} in this paper and for the detritiation reactions described in a previous paper (17), reactions in which the distances of the sulfonate group from the reaction centres are sufficiently great.

More generally, the results in this paper point to the usefulness of the rigid cage structure of the strychnine and other alkaloid molecules for physical organic studies. Strychnine is cheap, has a rich chemistry (48), and has a variety of groups whose reaction rates would be expected to be affected by variously disposed charged centres, such as those of the compounds of Scheme 1. Thus the benzene ring undergoes various substitution reactions; the basic nitrogen atom undergoes the Menschutkin reaction; the double bond can be oxidized; the methylene adjacent to the amide carbonyl forms benzylidene derivatives; and so forth. Results from such reactions would serve to test the newer methods of Ehrenson (49–53) and Orttung (54) for deriving the effective dielectric constant of bodies more irregular than the ideal prolate ellipsoids of Kirkwood and Westheimer, and to discover the useful limits of eqs. [10] and [12].

Second harmonic generation study of the reconstruction of an Au(110) electrode in $HClO_4$

C. Dale Keefe, Erika Revesz, Michel Dionne, and Mario Morin

Abstract: Second harmonic generation (SHG) was used to carry out an in situ study of the potential-induced reconstruction of an Au(110) single crystal electrode in an aqueous solution of 0.01 M $HClO_4$. In this study, we found that the symmetries of the surface susceptibility of the reconstructed and the unreconstructed Au(110) surfaces have a large component of threefold symmetry. A detailed analysis shows that both surfaces have an overall C_s symmetry giving one-, two-, and threefold symmetries for the surface susceptibility. However, another, different, source of threefold symmetry, perpendicular to the first, is needed to fit the data. We suggest that this extra source of threefold symmetry is due to the (111) microfacets that are present on the open (110) surface.

Key words: electrochemistry, single crystal, reconstruction, second harmonic generation spectroscopy.

Résumé : On a utilisé la génération harmonique secondaire (SHG) pour effectuer, in situ, une étude de la reconstruction d'une électrode Au(110) monocristalline induite par le potentiel dans une solution aqueuse de $HClO_4$ 0,01 M. Dans cette étude, nous avons trouvé que les symétries de la susceptibilité de surface des surfaces de Au(110) reconstruites et non reconstruites sont surtout ternaires. Une analyse détaillée révèle que les deux surfaces ont une symétrie globale de type C_s donnant des symétries simple, binaire et ternaire pour la susceptibilité de surface. Cependant, on doit avoir recours à une autre source différente de symétrie ternaire perpendiculaire à la première pour confirmer les données. Nous suggérons que cette source supplémentaire de symétrie ternaire est due aux microfacettes(111) qui sont présentes sur la surface libre(110).

Mots clés : electrochimie, crystal unique, reconstruction, spectroscopie de génération harmonique de secondaire.

Introduction

The electrocatalytic properties of an electrode depend on its surface structure (1, 2). Recent in situ studies (3) with structural probes such as scanning tunneling microscopy (STM), surface X-ray scattering (SXS), and second harmonic generation (SHG) spectroscopy have shown that single crystal electrode surfaces can undergo reconstructions that are induced by the adsorption of molecules or by an applied potential. The surface reconstruction of gold single crystal electrodes has been studied extensively. In situ structural studies (4–14) reveal that when the low-index gold surfaces (100), (110), and (111) reconstruct when they are immersed in a solution containing a weakly adsorbed electrolyte at potentials more negative than the potential of zero charge (pzc). In perchlorate solutions the type of reconstruction depends on the crystallographicaphic orientation. The reconstruction of the densely packed Au(100) and Au(111) surfaces involves long-range order and small atomic displacements and is reversible and slow. In contrast, the more open Au(110) surface undergoes a more local reconstruction in which the atomic displacements are large. Although the Au(110) surface reconstruction is reversible, it leaves a significant amount of defects and islands on the surface because of the large mass transport involved in the reconstruction process.

In situ STM studies (4–6) of the reconstructed and unreconstructed surface of an Au(110) electrode in $HClO_4$ solution showed that the reconstructed surface consists of a mixture of (1×2) and (1×3) local structures at potentials negative to the pzc (−0.050 V (vs. a saturated calomel electrode (SCE)). In the (1×2) structure, half of the rows in the ⟨100⟩ direction have been removed by a missing row process whereas the (1×3) structure has two missing rows. The steps that are parallel to the rows are found to be well ordered and consist of (111) planes or microfacets. The steps across these rows display a lot of kinks. SXS measurements (7) indicate that the reconstructed Au(110) surface in $HClO_4$ forms an incommensurate first layer relative to the bulk. It was suggested that this is due to a random sequence of (1×2) and (1×3) structures. When the potential is more positive than the pzc the reconstruction is lifted. However, the (1×1) unreconstructed surface contains a significant amount of islands and adatoms (4–7).

In this paper, we present an SHG study of the Au(110) sur-

face reconstruction in an aqueous 0.01 M $HClO_4$ solution. Second harmonic generation is a surface-specific technique that has been used to study electrode surface reconstructions (15). The structural sensitivity of SHG spectroscopy arises from the fact that the nonlinear optical response of the surface depends on its symmetry (16). SHG has been shown to be sensitive to a variety of surface reconstructions as well as to the presence of steps and adsorption (11–20). When SHG is used as a structural probe there is, in general, a good correlation of the SHG results with the in situ STM and SXS results (12–20). However, in our in situ study of the Au(110) surface reconstruction in $HClO_4$ we find that the SHG rotational anisotropy curves, from which we obtain information about the surface symmetry, are more complex than predicted from the surface symmetry of the reconstructed and the unreconstructed surfaces. Similar results were observed in a previous SHG study (10) of the Au(110) surface in a 0.1 M $NaClO_4$ solution. Thus, we have done a further analysis to determine the origin of the complex SHG rotational anisotropy using a phenomenological theory (16) in addition to a model suggested earlier (10).

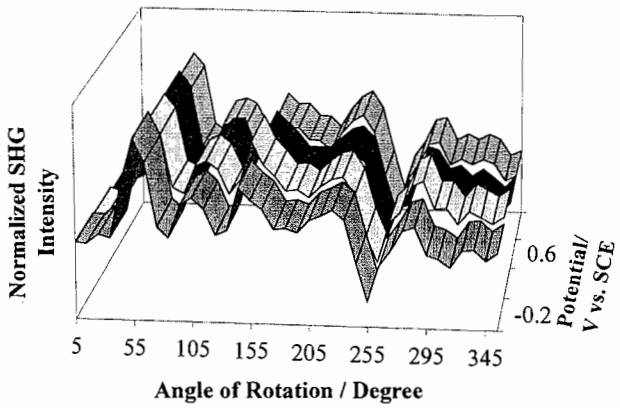
Experimental

The Au(110) sample was aligned to ±0.1° using Laue X-ray back scattering. It was then mechanically polished down to 0.1 μm with a diamond paste and electropolished in $HClO_4$. Before each set of measurements, the sample was annealed in a natural gas flame and then quenched with deionized water (21). The perchloric acid was from Seastar Chemicals (Vancouver, Canada) and the solutions were made with ultrapure deionized water (Milli-Q, Millipore). A three-electrode potentiostat was used for cyclic voltammetry and to control the electrode potential. The Au(111) electrode was mounted in a Teflon holder and used as the working electrode. The counter electrode was a gold foil. The reference electrode was a SCE housed in a separate compartment and linked to the electrochemical cell via a Luggin capillary. All the potential values used in this paper are relative to a SCE. The cyclic voltammogram of the Au(110) in 0.01 M $HClO_4$, obtained by forming a hanging meniscus in order to expose only the Au(110) surface, is presented in Fig. 1. The voltammogram is identical to that obtained in a previous study (22).

We used the fundamental wavelength (1.064 μm) of a picosecond (~35 ps FWHM), active–passive, mode-locked, pulsed Nd:YAG laser as the exciting source. In all the results presented in this paper, the polarization of the fundamental beam is in the plane of incidence (i.e., *p*-polarized). The fundamental light is slightly focused on the surface of the electrode at an angle of incidence of 45° by a 20 cm focal length lens. The energy density at the surface is on the order of 3 mJ/cm^2. In this geometry, the SHG signal generated at the surface is emitted in the same direction as the reflected fundamental (23). The reflected fundamental light and the generated second harmonic signal are collimated by a 15 cm focal length lens. The reflected fundamental is removed by passing it through a dichroic mirror and a low-pass filter. The second harmonic beam then goes through a polarizer so only the *s*-polarized 532 nm light is transmitted. Finally, the second harmonic is focused at the entrance slit of the photomultiplier tube, by a 10 cm focal length lens. The SHG signal is measured using a gated photon counter

Fig. 1. Cyclic voltammogram of Au(110) in 0.01 M $HClO_4$ at 10 mV s^{-1}.

and normalized against the laser power, which is obtained by splitting ~10% of the incident beam. The data presented in this paper are averages of 300 laser shots. The standard deviation of the SHG signal for an average of 300 laser shots is 5% or lower.



Before the SHG measurements we checked for the presence of contaminants (e.g., organic impurities, Cl^-, etc. ...) by recording a cyclic voltammogram. When the Au(110) surface was clean the potential was held at −0.2, +0.4, +0.6, and +0.8 V (SCE) and the SHG signal was collected. A scan rate of 10 mV/s was used to scan from one potential to the next. The crystal was rotated by 10° and the above procedure was repeated until a full rotation of 360° was achieved. The data shown are the average of four rotational anisotropy curves. Preliminary SHG rotational anisotropy curves obtained on a different Au(110) displayed the same number of peaks located at the same angles and with the same relative intensities. The normalized rotational anisotropy curves had a linear baseline removed before averaging. The angle of rotation is defined as the angle between the plane of incidence of the fundamental light and the ⟨100⟩ direction on the surface. The data were analyzed by a Gauss–Newton method that uses the first partial derivatives of the fitting function (24), i.e., the Levenberg–Marquardt algorithm. We checked the stability of the results by taking a randomly generated starting coefficient and obtaining the same fitted coefficients. The quality of the fit of the different models is based on the standard deviation (24) between the fitted function and the experimental data.

Fig. 2. Rotational anisotropy of an Au(110) electrode in 0.01 M $HClO_4$ vs. electrode potential for *p*-polarized fundamental and an *s*-polarized second harmonic. The rotational anisotropy was measured at −0.2, 0.4, 0.6, and 0.8 V (vs. SCE).

Results and discussion

The SHG rotational anisotropy curves at different electrode potentials are shown in Fig. 2. There are six maxima of different intensities on all the curves. No large change in the rotational anisotropy curves occurs over the potential range studied. STM measurements (4) show that the Au(110) surface is unreconstructed at potential more positive than ~0.1 V. Thus a change in the rotational anisotropy curves with the electrode potential is expected since the surface symmetry of the unreconstructed surface is C_{2v} and that of the reconstructed surface is C_s. A surface of C_{2v} symmetry would give either two or four maxima in the rotational anisotropy curves (16). Our results indicate that the nonlinear susceptibility of the Au(110) surface has a symmetry that differs from C_{2v} at all potentials.

A more more detailed analysis was done to find the origin of the complex shape of SHG anisotropy curves of the Au(110) electrode using a phenomenological theory (16). Our models are based on the results of previous STM (4–6) and, SXS (7). We also used a model suggested earlier (10).

The intensity of the SHG signal (23) can be expressed by

$$[1] \quad I^{(2\omega)} \propto |\chi^{(2)}:E^{(\omega)}E^{(\omega)}|^2$$

The SHG intensity is proportional to the square of the magnitude of the product of the third-order susceptibility tensor, $\chi^{(2)}$, and the incident electric field, $E^{(\omega)}$. The structural sensitivity of the SHG spectroscopy arises from the form of the susceptibility matrix, which depends on the surface symmetry (16). In the dipolar approximation, for centrosymmetric solids such as gold, the SHG anisotropy arises only from the surface. Experimental results have shown that the dipolar approximation is adequate for the gold surfaces (20).

Models for the rotational anisotropy of the SH signal

We have used a phenomenological theory developed by Sipe et al. (16) to analyze our data. We applied three different models to fit the experimental data. The first model was developed by Pettinger et al. (10) to take account of the (111) microfacets that appear on the reconstructed (110) surface. The second model was derived using the procedure described in ref. 16 for a reconstructed Au(110) surface that has C_s symmetry. The last model is a modified C_s model, that has two threefold components.

(111) Microfacetting model

Pettinger et al. (10) give the following equation for the second harmonic intensity from Au(110) for a *p*-polarized fundamental and *s*-polarized second harmonic.

$$[2] \quad I^{ps} \propto |b \sin(\phi + \alpha_1) + c \sin 2\phi + d \sin(3\phi + \alpha_3)|^2$$

In eq. [2], b and c are complex parameters while d is a real parameter. We define ϕ as the angle between the plane of the incident beam and the ⟨100⟩ axis on the (110) surface. α_1, and α_3 are angles added to take into account the fact that the (111) microfacets have a crystallographic orientation that is different than the $\langle 1\bar{1}0 \rangle$ axis. α_1 and α_3 are adjustable parameters. In this model, the onefold and threefold sine terms are associated with the pseudo-C_{3v} symmetry of the (111) microfacets.

Equation [2] can be rearranged to

$$[3] \quad I^{ps} \propto |a' \sin\phi + b' \cos\phi + c \sin 2\phi + d' \sin 3\phi + e' \cos 3\phi|^2$$

where $a' = a \cos\alpha_1$, $b' = \sin\alpha_1$, $d' = d \cos\alpha_3$, and $e' = e \sin\alpha_3$. The addition of α_1 and α_3 introduces cos ϕ and cos 3ϕ terms.

C_s model

The C_s model is based on the in situ STM studies (4–6), which showed that the reconstructed surface is formed from long chains of atoms in the $\langle 1\bar{1}0 \rangle$ direction and is highly corrugated in the ⟨100⟩ direction. The large corrugation across the rows (i.e., in the ⟨100⟩ direction) is due to a mixture of (1 × 2) and (1 × 3) local structures. The in situ SXS results (7) also show that there is a random sequence of (1 × 2) and (1 × 3) structures in the ⟨100⟩ direction giving rise to an incommensurate overlayer for the reconstructed Au(110) surface. These results indicate that the reconstructed Au(110) surface has a C_s symmetry with a mirror plane in the ⟨100⟩ direction. Thus the C_s surface in our model has a mirror plane along the ⟨100⟩ direction and perpendicular to the surface plane. The system of coordinates is defined as follow: the $\langle 1\bar{1}0 \rangle$ axis is the x direction, the y direction is along the ⟨100⟩ direction, and z is the direction perpendicular to the surface. In this case, the third-order susceptibility tensor is

$$[4] \quad \chi^{(2)} = \begin{pmatrix} 0 & 0 & 0 & 0 & \chi_{xxz} & \chi_{xxy} \\ \chi_{yxx} & \chi_{yyy} & \chi_{yzz} & \chi_{yyz} & 0 & 0 \\ \chi_{zxx} & \chi_{zyy} & \chi_{zzz} & \chi_{zyz} & 0 & 0 \end{pmatrix}$$

In eq. [4], $\chi^{(2)}$ is expressed in terms of the surface coordinates $(\hat{x}', \hat{y}', \hat{z}')$. These are transformed to the beam coordinates $(\hat{s}, \hat{k}, \hat{z})$ and, the tensor Δ' is obtained (16). The elements of Δ' are given in Table 1. From the elements of the third-order susceptibility tensor, Δ', the intensity of the second harmonic for a C_s surface is calculated to be

$$[5] \quad I^{ps} \propto |e \sin 2\phi + f \cos\phi + g \cos 3\phi|^2$$

where ϕ has the same definition as for the (111) microfacetting model and

$$e = f_c f_s(\chi_{xxz} - \chi_{yyz})$$

$$f = \frac{1}{2} f_c^2\left(\chi_{xxy} - \frac{3\chi_{yxx} + \chi_{yyy}}{2}\right) - f_s^2\chi_{yzz}$$

and

$$g = -\frac{1}{2} f_c^2\left(\chi_{xxy} - \frac{\chi_{yxx} - \chi_{yyy}}{2}\right)$$

f_c and f_s are the complex Fresnel factors (16). e, f, and g are complex quantities. For fitting purposes we take e and f as complex quantities and g as a real quantity.

Modified C_s *model*

In the modified C_s model, we account for the possibility of a second source of threefold symmetry for the surface nonlinear susceptibility. This modification is based on the fact that the (110) surface is very open. In the TLK (Terrace, Ledge, Kink) notation the (110) surface of a face-centered cubic metal is a combination of a one-atom (111) ledge and a two-atoms wide (111) terrace. The atoms in the (111) planes are in the grooves between the rows and can be excited by the fundamental light and generate a second harmonic signal. The symmetry of the second harmonic signal originating from these (111) planes is C_{3v}. However, there is a surface relaxation that accompanies the surface reconstruction and modifies the (111) microfacets so they do not have a perfect C_{3v} symmetry (4–6). When taking into account this relaxation, the (111) facets have two mirror planes. One of the mirror planes is coincident with the mirror plane in the C_s model and the other is at 90° to it. The modified C_s model thus consists of eq. [5] to which we added an extra threefold sine component perpendicular to the threefold cosine component. The extra threefold sine component is associated with the (111) microfacets as in the microfacetting model but the angle between the threefold components is fixed. The intensity of the SHG signal, for this model, is given by

$$[6] \quad I^{ps} \propto |h \sin 2\phi + i \cos \phi + j \sin 3\phi + k \cos 3\phi|^2$$

where h, i, j, and k are complex quantities. ϕ has the same definition as for the (111) microfacetting model. For fitting purposes we take h, i, and j as complex quantities and k as a real quantity.

Fitting of the experimental results

The SHG rotational anisotropy data at −0.2 V for the Au(110) electrode and the nonlinear least-squares fits (24) of eqs. [3], [5], and [6] are shown in Fig. 3. The parameters of the fitted equations are given in Table 2. From Fig. 3*B* it is clear that the C_s models cannot reproduce the SHG data. The number of peaks and their positions differ from the observed rotational anisotropy curve in Fig. 3*A*. It is not possible with the C_s model to have only one peak more intense than the others, as we and

Fig. 4. Magnitudes of the fitted components of the modified C_s model (eq. [6]) at different electrode potentials. Solid line: sin 2ϕ; long broken line: cos 3ϕ; short broken line: sin 3ϕ; long/short broken line: cos ϕ. The error bars represent the confidence limit of 75% (*t* test).

others (10) observed for a Au(110) electrode in weakly interacting electrolyte solutions. The microfacetting model suggested previously (10) provides an adequate fit of the rotational anisotropy curve at −0.2 V. The position and the relative intensity of the peaks are reproduced. The extra one- and threefold anisotropy sources provide enough flexibility to the fitting functions to have peaks of different intensities. The meaning of the angles α_1 and α_3 as the extra sources of anisotropy is not clear since they are adjustable parameters.

Our modified C_s model in Fig. 3*D* also reproduces the data adequately. In Fig. 4 we have the magnitude of the components of eq. [6] for the modified C_s model for all the potentials. We see that at −0.2 V the symmetry of the SHG rotational anisotropy is mainly threefold. The two perpendicular sources of threefold symmetry have similar magnitudes. The twofold component is also important; its magnitude is about 2/3 of one of the threefold components. In the modified C_s model the twofold component is assigned to domains of pseudo-C_{2v} symmetry. The onefold contribution to the rotational anisotropy is significantly smaller than the two- and threefold components due to the asymmetry of the SHG rotational anisotropy curve. The magnitude of the parameters of the fitted modified C_s model indicates that the surface nonlinear response of the reconstructed Au(110) could originate from two types of structures having a pseudo-C_{2v} and a pseudo-C_{3v} symmetry. However, our model shows that the presence of two- and threefold symmetry components can arise from a surface with C_s symmetry. This conclusion was also reached in a previous SHG study of the reconstruction of a Au(111) electrode (14). The magnitude of the threefold component cannot be clearly related to the (111) microfacetting. Nevertheless, it is likely that the (111) microfacets are the main source of the threefold anisotropy.

There is no large change in the magnitudes of the parameters over the potential range studied as shown in Fig. 4. This is similar to the reconstructed Au(110) electrode in a 0.1 M $NaClO_4$ solution (10) where the rotational anisotropy curves did not change significantly over a large potential range from −0.2 V to the beginning of the formation of the surface oxide. We see that the magnitudes of the threefold components are almost the same at −0.2 and 0.4 V. If the threefold components originate mainly from the atoms in the (111) microfacets or planes, this result indicates that the number of atoms in the (111) planes does not vary significantly between −0.2 and 0.4 V where the reconstruction is lifted according to STM (4, 5). There is a small decrease in the magnitude of the two threefold symmetry components from 0.4 to 0.8 V. This decrease is not significant at a degree of confidence of 75% (*t* test) represented by the error bars on Fig. 4. The magnitude of the twofold component that is related to the unreconstructed (110) surface or well-ordered (1 × 2) and (1 × 3) domains increases slightly from 0.4 to 0.8 V. This increase is significant at a degree of confidence of 75% (*t* test). We relate the increase of the twofold component to a small increase in the fraction of the surface forming (1 × 1) domains.

Capacitance measurements (5, 22) support the suggestion of a gradual reconstruction. The capacitance measurements show that in the double layer region the capacitance curve has a complex sigmoidal shape. A large hysteresis in the capacitance curve of the positive and negative direction potential sweeps between the pzc (−0.050 V) to 0.6 V is observed (4). If the hysteresis in the capacitance data is related to the surface reconstruction process then the reconstruction occurs gradually. This interpretation of the capacitance data and our observation of a small change of surface symmetry from 0.4 to 0.8 V do not agree with STM measurements (4), which indicate that at 0.1 V the surface has mainly a (1 × 1) (i.e., unreconstructed) structure. Based on the STM measurements, the hysteresis in the capacitance data must then be related to the presence of steps, defects, islands, and microfacetting (22). However, a gradual reconstruction of the Au(110) surface in aqueous 0.1 M H_2SO_4 and 0.1 M $HClO_4$ solutions was observed in another in situ STM (5) study. The reconstruction from a (1 × 2)/(1 × 3) to a (1 × 1) surface occurs between −0.1 and 0.25 V. In this potential range the three different structures are observed simultaneously on the surface. These STM measurements (5) and the capacitance data in 0.1 M H_2SO_4 show a good correlation in contrast to the STM results obtained in perchloric acid solutions (4).

The discrepancy between our, and other, results (5, 10, 22) and an STM study (4) reflects the complexity of the reconstruction of Au(110) in background electrolyte. The differences between the studies could arise from the different surface properties that are measured and from the dimension of the probed surface. SHG spectroscopy must be sensitive to the steps, defects, islands, and (111) microfacets that are present on the unreconstructed (1 × 1) surface. The amount of such defects is of the order of a few percent according to STM (5). Thus we do not expect that the surface defects are the only source of SHG rotational anisotropy. Larger (111) microfacetting can be observed depending on the quality of the flame-annealing process as well as on the purity of the perchloric acid solution used (22). Our analysis shows that SHG spectroscopy is sensitive to the presence of (111) microfacets that have a threefold symmetry (4, 5). Thus, part of the measured

rotational anisotropy signal could be due to the slow removal of the defects on the poorly ordered (1 × 1) surface. For strongly adsorbed halogen anions, the SHG rotational anisotropy and STM measurements are in close agreement for the surface symmetry. In the presence of adsorbed bromine anions in a neutral solution, the SHG rotational anisotropy curve (10) shows a clear transition to a C_{2v} symmetry over the range of potential measured in the STM studies (5) for a solution containing chlorine anions. Based on these results, we believe that SHG is monitoring the slow transition from a reconstructed to an unreconstructed Au(110) surface in aqueous perchloric acid solution. The comparison between the SHG and the STM results illustrates the limitations of SHG for studying the reconstruction of open, corrugated surfaces that undergo a local reconstruction. The complex SHG rotational anisotropy curve does not give a straightforward interpretation of the surface reconstruction as is the case for the STM results. Nevertheless, SHG spectroscopy is a useful tool to probe surface reconstructions that are potential induced because it is less invasive than STM, which requires the application of bias potential and a tunneling current.

The slow transition from a reconstructed to an unreconstructed surface suggested by the SHG and capacitance measurements could be due to the low mobility of the surface gold atom in a solution of weakly adsorbed electrolyte. The reason for the gradual transition between reconstructed (1 × 2) or (1 × 3) and unreconstructed (1 × 1) Au(110) surface in weakly adsorbed electrolyte solutions is not well understood. It seems that in a weakly interacting electrolyte the (1 × 1) surface cannot be stabilized by removal of electronic charge from the surface to the extent that the (1 × 1) structure becomes significantly more stable than the (1 × 2) and (1 × 3) structures. The relative stability of these structures is supported by recent first principles calculations (25) of the total energy of the equilibrium geometry of the (1 × 1), (1 × 2), and (1 × 3) structures. This theoretical study suggests that the (1 × 2) and (1 × 3) surfaces have similar energies and that they are more stable than the (1 × 1) surface in the absence of an electric field. This calculation supports our results as well as those of previous studies (5, 10, 22) that indicate that the potential-induced lifting of the Au(110) reconstruction in $HClO_4$ is gradual.

In summary, our results show that the SHG rotational anisotropy of an Au(110) electrode in perchloric acid varies very weakly with the applied potential. The analysis of the rotational anisotropy curves reveals important threefold symmetry components. We assign these components to the presence of (111) microfacets. The small variation of the rotational anisotropy with electrode potential is suggested to be due to the gradual removal of the reconstruction of the Au(110) as the potential is made more positive.

Acknowledgments

The financial support of the Natural Sciences and Engineering Research Council of Canada (NSERC) and the Centre of Excellence in Molecular and Interfacial Dynamics (CEMAID) is acknowledged, as are a postdoctoral (C.D.K.) and a summer (M.D.) fellowship from NSERC. Dr. D.-F. Yang is thanked for the preparation of the Au(110) crystals and for useful discussions. Prof. J. Lipkowski is thanked for the use of his equipment for making the single crystals used in this study.

Modeling of transfer properties using revised HKF theory: thermodynamics of transfer of an amino acid and small peptides from water to urea–water solutions at 298.15 K

Andrew W. Hakin, Lori L. Groft, Jocelyn L. Marty, and Matthew L. Rushfeldt

Abstract: Relative densities, $(\rho - \rho_1^0)$, and heat capacity ratios, $(c_p\rho/(c_{p1}^0\rho_1^0) - 1)$, have been measured for aqueous solutions of glycine, glycylglycine, and glycylglycylglycine in aqueous urea solutions containing 1–13 mol kg^{-1} urea. These data have been used to calculate apparent molar volumes, $V_{2,\phi}$, and apparent molar heat capacities, $C_{p2,\phi}$, which in turn have been used to obtain standard state volumes, $\overline{V}_2^0$, and standard state heat capacities, $\overline{C}_{p2}^0$. Volumes and heat capacities of transfer from water to urea have been calculated from our reported standard state data. Heat capacities of transfer of the investigated systems have been modeled using a procedure developed from the semiempirical calculation procedures proposed by Helgeson, Kirkham, and Flowers.

Key words: amino acids, peptides, calorimetry, transfer thermodynamics, HKF theory.

Résumé : On a mesuré les densités relatives $(\rho - \rho_1^0)$ et les rapports des capacités calorifiques $(c_p\rho/(c_{p1}^0\rho_1^0) - 1)$ pour des solutions aqueuses de glycine, de glycylglycine et de glycylglycylglycine dans des solutions aqueuses d'urée contenant 1–13 mol kg^{-1} d'urée. On a utilisé ces données pour calculer les volumes molaires apparents $V_{2,\phi}$, et les capacités calorifiques molaires apparentes, $C_{p2,\phi}$, à partir desquels on a obtenu les volumes à l'état standard, $\overline{V}_2^0$, et les capacités calorifiques de l'état standard $\overline{C}_{p2}^0$. On a calculé les volumes et les capacités calorifiques de transfert à partir de l'eau vers l'urée, à partir de nos données rapportées pour l'état standard. On a modélisé les capacités calorifiques de transfert des systèmes étudiés en utilisant une méthode développée à partir des méthodes de calcul semi-empiriques proposées par Helgeson, Kirkham et Flowers.

Mots clés : acides aminés, peptides, calorimétrie, transfert thermodynamique, théorie HKF.

Introduction

The precise role of urea in the denaturation of protein systems appears to remain unclear in spite of extensive investigation (1–3). However, a common thread in many discussions identifies urea's structure-breaking tendencies in water as being of prime importance. Two processes by which urea can interact with proteins have been described. In the first, the presence of urea is thought to diminish the hydrophobic hydration of protein apolar groups. In this way the apolar groups become more repulsive to each other, thus opening up the protein structure. In the second description, which may or may not work in cooperation with the first, urea is thought to preferentially solvate the peptide groups of proteins. This preferential solvation, sometimes referred to as binding, is thought to disrupt intramolecular hydrogen bonding, thus disrupting the native conformation of the protein. Although it appears clear that peptide groups in proteins play a central role in the urea-induced denaturation process, their exact role remains the subject of debate. In their investigation of the interactions of urea and guanidine hydrochloride with lysozyme, ribonuclease, and cyctochrome C, Makhatadze and Privalov (4) found a good correlation between the number of denaturant binding sites and the number of H-bonding groups exposed in the folded or unfolded protein. This finding is supported by the more recent work of Zolkiewski, Nosworthy, and Ginsburg who looked at the urea-induced dissociation and unfolding of dodecameric glutamine synthetase (5). Common to these two investigations is the contention that urea molecules H-bond to available peptide sites in the protein. Unfortunately, the preferential solvation model, which is based on calorimetric data that yield enthalpic pair interaction coefficients, does not support an H-bonding explanation.

Many denaturation protocols recommend the use of urea at a concentration of 8 mol L^{-1} (approximately 13 mol kg^{-1} at 25°C) to ensure complete protein denaturation. Urea at this concentration is thought to destroy the majority of structural organization within the protein molecule. Though disruption is most certainly significant at this concentration, whether the forces contributing to secondary and tertiary structure of a protein have been completely eliminated at this stage cannot be certain. In many cases, a protein's thoroughly denatured conformation, as judged by its hydrodynamic properties, may

be unattainable due to the limited solubility of urea in water. An example of such behaviour was found by Kawahara et al. (6) in the case of co-hemoglobin. Therefore, to better predict the actions of urea on secondary and tertiary protein conformation, one must first develop an understanding of the interactions of urea with less complicated molecules that model protein side chains, e.g., amino acids or simple oligopeptides.

To further probe this ongoing puzzle of urea-based protein denaturation, we have investigated the thermochemical and volumetric properties of glycine (gly), glycylglycine (digly), and glycylglycylglycine (trigly) in aqueous urea solutions (in the range 1–13 mol kg^{-1}). Apparent molar volumes and heat capacities for the investigated systems have been used to calculate standard state volumes and heat capacities, which in turn have been used to calculate the relevant extensive thermodynamic properties of transfer.

In addition, the semiempirical modeling procedures of Helgeson, Kirkham, and Flowers (7) have been applied to the calculated heat capacities of transfer from water to urea of gly, digly, and trigly. The methodology presented in this paper shows how calculated heat capacities of transfer may be subdivided into structural and solvation components. Trends in these contributions as a function of urea concentration are examined and discussed.

Experimental

Glycine (99+%), glycylglycine (99.5+%), and glycylglycylglycine (99.5+%), were obtained from Sigma Chemicals Ltd. (catalog numbers G-7126, G-7278, and G-1377, respectively).

All glycyl compounds were purified by repeated recrystallization from water + ethanol mixtures. The purified chemicals were dried and stored over phosphorus pentoxide in a vacuum oven at 50°C. An indication of the purity of the samples was obtained using NMR spectroscopy. The recorded spectra were in excellent agreement with those reported in the literature (8).

Samples of urea (reagent grade) were obtained from Fisher Scientific and BDH Inc. and were used without further purification.

All solutions used in our investigations were prepared by weight on the molality concentration scale using bidistilled, degassed water. Amino acid and peptide solutions in urea + water mixtures were stored in sealable 125 mL Nalgene bottles. All urea solutions were used within 24 hours of their preparation.

The densities of the prepared solutions were measured relative to the solvent (either water or the relevant aqueous urea solution) with a Sodev O2D vibrating tube, flow densitometer (9). This instrument has a thermal stability of ±0.001°C and routinely measures densities with part per million precision. The volumetric heat capacities of the investigated systems in aqueous urea solutions were measured relative to their respective solvent using a Picker flow microcalorimeter (10). Small residual heat leaks in our calorimeter were accounted for by using a calorimetric heat loss correction factor, or *f* factor (11). This factor was evaluated prior to the start of our investigations as $f = 0.9967$ using standard solutions of sodium chloride in water.

Details of the densitometer, the flow microcalorimeter, and procedures used in their calibration have been described previously (12–14).

Results and analysis

Experimentally determined data, namely, relative densities, $(\rho - \rho_1^0)$, and heat capacity ratios $(c_p\rho/(c_{p_1}{}^0\rho_1^0) - 1)$, for gly, digly, and trigly in various urea–water mixtures are reported in Tables 1, 2, and 3, respectively. These tables also contain apparent molar volume, $V_{2,\phi}$, and heat capacity, $C_{p2,\phi}$, data that were calculated from the experimental data using eqs. [1] and [2],

$$[1] \quad V_{2,\phi} = \left(\frac{M}{\rho}\right) - \left(\frac{\rho - \rho_1^0}{m\rho\rho_1^0}\right)$$

$$[2] \quad C_{p2,\phi} = Mc_p + \left(\frac{c_p - c_{p1}{}^0}{m}\right)$$

In these equations M defines the molar mass of the solute, m is the molality of the solution, ρ and ρ_1^0 are the densities of the sample and of pure water, and c_p and $c_{p1}{}^0$ are the specific heat capacities of the sample and pure water. The densities and heat capacities of pure water, used in our calculations, are those reported by Kell (15, 16). The densities and heat capacities of individual urea solvents were calculated using previously published data from this laboratory (17). Calculated uncertainties (13) in the apparent molar properties have been included in parentheses in Tables 1–3.

Standard state volumes and heat capacities for the three systems investigated were calculated at each experimental concentration of urea by fitting equations of the general form described by eq. [3] to our calculated apparent molar volume and apparent molar heat capacity data. A weighted regression analysis procedure was utilized (13).

$$[3] \quad Y_{2,\phi} = Y_{2,\phi}^0 + S_Y m$$

In eq. [3] Y represents the extensive thermodynamic property of interest, $Y_{2,\phi}^0$ is the value of $Y_{2,\phi}$ at infinite dilution (i.e., the standard state property $\overline{Y}_2^0$), and S_Y is the experimental slope. Calculated standard state volumes and heat capacities for each solvent system are reported in Table 4.

Values for standard state volumes and heat capacities for gly and digly in water have been taken from two of our previous investigations (13, 14). Our value of $\overline{V}_2^0 = 112.06 \pm 0.01$ cm^3 mol^{-1} for trigly in water at 298.15 K is in excellent agreement with the value of Chalikian et al. of 112.1 ± 0.3 cm^3 mol^{-1} (18) and in good agreement with Hedwig's value of 111.92 ± 0.03 cm^3 mol^{-1} (19). Similarly, our reported standard state heat capacity for trigly in water at 298.15 K, $\overline{C}_{p2}^0 = 186.3 \pm 0.9$ J K^{-1} mol^{-1} is in good agreement with Hedwig's value (19) of 188.3 ± 0.7 J K^{-1} mol^{-1} and Jolicoeur and Boileau's value (20) of 189.5 ± 0.9 J K^{-1} mol^{-1}. Compared to these values, Makhatadze and Privalov's (21) value of $\overline{C}_{p2}^0 = 175.3$ J K^{-1} mol^{-1} appears too low.

With respect to standard state volumes and heat capacities for gly, digly, and trigly in aqueous urea solutions, only limited literature data are available for comparison purposes. Enea and Jolicoeur (3) previously measured heat capacities and volumes of several oligopeptides in urea + water mixtures at 25°C; however, the only standard state data they report for gly, digly, and trigly refer to an aqueous urea

the standard state data reported in this paper they appear to slightly overestimate the standard state values.

An extensive thermodynamic function of transfer, $\Delta\overline{Y}_{2,t}^0\{X:(1) \rightarrow (2)\}$, for the transfer of an organic molecule, X, from water (1) to an aqueous solution of urea (2) may be defined in terms of thermodynamic standard state data using the equation:

$$[4] \quad \Delta\overline{Y}_{2,t}^0\{X:(1) \rightarrow (2)\} = \overline{Y}_2^0\{X:(2)\} - \overline{Y}_2^0\{X:(1)\}$$

One may estimate the uncertainties assigned to the calculated transfer properties of the bulk salts, $\delta\overline{Y}_{2,t}^0$, using the relationship:

$$[5] \quad \delta\overline{Y}_{2,t}^0(1\rightarrow 2) = \sqrt{\delta\overline{Y}_{2,t}^0(2)^2 + \delta\overline{Y}_{2,t}^0(1)^2}$$

where $\delta\overline{Y}_{2,t}^0(2)$ and $\delta\overline{Y}_{2,t}^0(1)$ are the calculated standard errors associated with our reported standard state data in urea + water and water, respectively. Calculated volumes and heat capacities of transfer for gly, digly, and trigly are reported with their estimated uncertainties in Table 5.

Modeling heat capacities of transfer of amino acids and small peptides using revised HKF theory

The semiempirical modeling procedures of Helgeson, Kirkham, and Flowers permit one to subdivide a standard state extensive thermodynamic property into two contributions: a structural contribution and an electrostatic contribution. These contributions are identified in eq. [6] by the subscripts s and e respectively.

$$[6] \quad \overline{Y}_2^0 = \overline{Y}_s^0 + \overline{Y}_e^0$$

The structural contribution in this equation is, in turn, the sum of two contributions: an intrinsic term and a term that reflects

[c]Reference 14.

the disruption of the solvent structure caused by the presence of the solute in the solution.

With respect to standard state heat capacities for neutral organic species in water, eq. [6] may be rewritten in the form:

$$[7]\quad \overline{C}_{p2}^0 = c_1 + \frac{c_2}{(T-\theta)^2} - \frac{2T}{(T-\theta)^3} \times \left(a_3(P-P_r) + a_4 \ln\left(\frac{\Psi+P}{\Psi+P_r}\right)\right) + \omega_e TX$$

where c_1 and c_2 are species-dependent parameters and θ and Ψ represent solvent-dependent parameters that are assigned values of 228 K and 2600 bar, respectively (22). T, P, and P_r represent the temperature and pressure of interest and the reference pressure (1 bar, or 100 kPa) and ω_e defines the effective Born coefficient for the neutral aqueous organic species of interest. Values of this constant for gly and digly may be estimated from Born Transfer Theory, but in the current calculations they were taken from the compilations reported by Shock (22). With respect to trigly, it was necessary to estimate the effective Born coefficient using the standard entropy relationship described by Shock and Helgeson (23). In turn, a value for the standard state entropy of trigly was estimated using the molecular connectivity index model described by Kim et al. (24).

Under the constant pressure condition of $P = P_r$ eq. [7] may be reduced to the form:

$$[8]\quad \overline{C}_{p2}^0 = c_1 + \frac{c_2}{(T-\theta)^2} + \omega_e TX$$

in which the electrostatic contribution to the standard state heat capacity, $\overline{C}_{ps}^0$, is represented by the term $\omega_e TX$. The Born function X is defined in terms of the temperature dependence of the dielectric constant of the solvent (23).

$$[9]\quad X = \frac{1}{\varepsilon}\left\{\left(\frac{\partial^2 \ln \varepsilon}{\partial T^2}\right)_p - \left(\frac{\partial \ln \varepsilon}{\partial T}\right)_p^2\right\}$$

In utilizing the HKF equations to model transfer properties, we begin by dividing calculated heat capacities of transfer into structural and solvation components.

$$[10]\quad \Delta\overline{C}_{pt}^0\{X:(1)\rightarrow(2)\} = \Delta\overline{C}_{ps}^0\{X:(1)\rightarrow(2)\} + \Delta\overline{C}_{pe}^0\{X:(1)\rightarrow(2)\}$$

Alternatively, as shown by eq. [11], these heat capacities of transfer can be expressed as the sum of the structural and electrostatic contributions to standard state heat capacities.

$$[11]\quad \Delta\overline{C}_{pt}^0\{X:(1)\rightarrow(2)\} = \overline{C}_{ps}^0(2) + \overline{C}_{pe}^0(2) - \overline{C}_{ps}^0(1) - \overline{C}_{pe}^0(1)$$

Introducing eq. [8] into the analysis yields:

$$[12]\quad \Delta\overline{C}^0_{pt}\{X:(1)\rightarrow(2)\} = c_1^* + \frac{c_2^*}{(T-\theta)^2} - c_1 - \frac{c_2}{(T-\theta)^2} + (\omega_e^* TX^* - \omega_e TX)$$

where the asterisk (*) has been used to identify a parameter associated with an aqueous urea solution. At this stage we are forced, by a lack of published thermodynamic data, to adopt the assumption that $\omega_e = \omega_e^*$. This step permits the calculation of both structural and electrostatic contributions to calculated heat capacities of transfer; eqs. [13] and [14].

$$[13]\quad \Delta\overline{C}^0_{ps}\{X:(1)\rightarrow(2)\} = c_1^* + \frac{c_2^*}{(T-\theta)^2} - c_1 - \frac{c_2}{(T-\theta)^2}$$

$$[14]\quad \Delta\overline{C}^0_{pe}\{X:(1)\rightarrow(2)\} = \omega_e T(X^* - X)$$

Wyman's dielectric constant data for urea + water systems (25) at 298.15 K were used to derive values for the Born parameters X^* for the investigated urea + water solutions. Values for c_1 and c_2 were obtained for each system by fitting eq. [8] to standard state heat capacity data for the relevant solute in water obtained as a function of temperature.

Calculated structural and electrostatic contributions to heat capacities of transfer are reported in Table 6.

In a similar fashion, the methodology described above may be applied to the analysis of volumes of transfer to yield:

$$[15]\quad \Delta\overline{V}^0_s\{X:(1)\rightarrow(2)\} = \sigma^* + \frac{\xi^*}{(T-\theta)} - \sigma - \frac{\xi}{(T-\theta)}$$

$$[16]\quad \Delta\overline{V}^0_e\{X:(1)\rightarrow(2)\} = \omega_e(Q - Q^*)$$

Table 6. Calculated structural, $\Delta\overline{C}^0_{ps}\{X:(1)\rightarrow(2)\}$, and electrostatic, $\Delta\overline{C}^0_{pe}\{X:(1)\rightarrow(2)\}$, contributions to heat capacities of transfer, for the transfer of gly, digly, and trigly from water to aqueous urea solutions at 298.15 K.

Urea concentration (mol kg^{-1})	$\Delta\overline{C}^0_{ps}\{X:(1)\rightarrow(2)\}$ (J K^{-1} mol^{-1})	$\Delta\overline{C}^0_{ps}\{X:(1)\rightarrow(2)\}$ (J K^{-1} mol^{-1})
	gly	
2	35.3	−1.3
4	45.6	−2.3
6	63.3	−3.2
11	82.7	−4.5
13	93.1	−4.7
	digly	
2	41.9	−2.7
3.8	78.0	−4.6
6	90.0	−6.6
8	109.8	−8.0
11	130.5	−9.3
13	134.1	−9.7
	trigly	
2	65.6	−2.8
5	118.8	−6.1
9	149.0	−9.0
13	152.3	−10.2

Coefficients required in the calculation of $\Delta\overline{C}^0_{pe}\{X:(1)\rightarrow(2)\}$: gly; $\omega_e = -97\,487$ J mol^{-1}, digly; $\omega_e = -201\,167$ J mol^{-1}, trigly; $\omega_e = -213\,170$ J mol^{-1}. X^* (K^{-2}) = -2.70×10^{-7}, -2.37×10^{-7}, -2.34×10^{-7}, -2.18×10^{-7}, -2.04×10^{-7}, -1.81×10^{-7}, -1.73×10^{-7}, -1.59×10^{-7}, and -1.53×10^{-7} at urea concentrations of m (mol kg^{-1}) = 2, 3.8, 4, 5, 6, 8, 9, 11, and 13, respectively.

Unfortunately, this avenue of exploration cannot be pursued further because we are unable to locate dielectric constants for urea + water solutions as a function of pressure at 298.15 K in the literature. These data are required to calculate the Born Q parameter, eq. [17].

$$[17]\quad Q = \frac{1}{\varepsilon}\left(\frac{\partial \ln \varepsilon}{\partial P}\right)_T$$

Discussion

Calculated volumes and heat capacities of transfer for gly, digly, and trigly are found to be positive at all investigated urea concentrations and are seen to increase in a smooth manner with increasing urea concentration. Such trends are indicative of specific urea–solute interactions. At increased urea concentrations transfer values appear to flatten out.

The reported positive volumes and heat capacities of transfer are consistent with the negative enthalpies of transfer for gly, digly, and trigly reported by Prasad and Ahluwalia (26). Heat capacities of transfer reported by these authors refer to 30°C and are therefore not directly comparable to those reported in this study.

In an attempt to interpret the trends observed in our transfer data we turn to several previous investigations of the thermodynamic properties of structurally similar compounds in aqueous urea solutions.

In their investigation of nucleic acid bases, nucleosides, and

nucleotides in water and aqueous urea solutions, Kishore and Ahluwalia (27) used the Gurney cosphere model (28) to account for observed trends in volumes and heat capacities of transfer. In brief, negative transfer properties were attributed to interactions of urea molecules with hydrophobic components of solute molecules, whilst positive contributions to transfer properties were attributed to interactions of urea molecules with hydrophilic or polar constituents of solute molecules. In the latter case this interaction was thought to take the form of hydrogen bond formation. In an earlier study of the thermodynamics of transfer of oligopeptides from water to aqueous urea solutions Enea and Jolicoeur (3) were able to successfully explain their results in terms of urea – peptide group interactions. However, they concluded that changes in the solvation of apolar and ionic groups in the presence of urea are key in the process of urea-induced protein unfolding.

Privalov et al. (29), in a study of heat capacities and conformations of proteins in the denatured state, advised caution in the interpretation of thermodynamic properties associated with the denaturation of proteins by guanidine hydrochloride or urea. Previous to their investigation it had been implied that heat capacities associated with thermally induced denaturation differed in value from those associated with guanidine hydrochloride induced denaturation. However, these authors were able to show that for the denaturation of lysozyme the heat capacities were in fact "indistinguishable" if the interactions of the denaturant with the protein were correctly accounted for (30). In another series of papers Makhatadze and Privalov (21, 31) supply data for the calculation of partial heat capacities of unfolded polypeptides. Applying their analysis to trigly results in a standard heat capacity of 276.2 J K^{-1} mol^{-1} for the completely unfolded species, an increase of approximately 90 J K^{-1} mol^{-1} over the standard state heat capacity of trigly in its natural state in water. The heat capacity of transfer of trigly for water to 13 mol kg^{-1} urea (a concentration at which complete "unfolding" may be expected) is 142.1 J K^{-1} mol^{-1}, some 52 J K^{-1} mol^{-1} greater than the Makhatadze and Privalov value. However, if one accepts Makhatadze and Privalov's proposal of H-bonding interactions between urea and peptide groups in trigly, then the two values will be brought closer together because such interactions have been shown to provide positive contributions to heat capacities of transfer.

Turning to our reported heat capacity of transfer data, the observed positive values would appear, from the evidence presented above, to be indicative of hydrophilic group – urea interactions and (or) of ionic group – urea interactions. Alternatively, one could argue that urea – apolar group interactions are small compared to urea – hydrophilic and urea – ionic group interactions.

With respect to our HKF analyses of the transfer data (see Table 6) we note that the electrostatic solvation contributions to reported heat capacities are small and negative. The sign of the contributions indicates that electrostatic solvation contributions to heat capacities are less in aqueous urea solutions than in water. Given that water is more polar than aqueous urea solutions, this result is not surprising.

At this stage it is perhaps prudent to reexamine the effect of our assumption, $\omega_e = \omega_e^*$, on the results of the analyses. Let us consider two possibilities for the behaviour of ω_e^*: (*i*) its value becomes more positive with increasing urea concentration; (*ii*) its value becomes more negative with increasing urea concentration. With respect to case (*i*), using $\omega_e/2$ as estimates for ω_e^* values in solutions containing 13 mol kg^{-1} urea yields electrostatic contributions to heat capacities of transfer of −6.9, −14.3, and −15.1 J K^{-1} mol^{-1} for gly, digly, and trigly, respectively. With respect to case (*ii*) using $2\omega_e$ as estimates for ω_e^* in 13 mol kg^{-1} urea produces electrostatic contributions to heat capacities of transfer of −0.2, −0.5, and −0.5 J K^{-1} mol^{-1} for gly, digly, and trigly. Comparing these results with those reported in Table 6 indicates that the term $T(\omega_e^* X^* - \omega_e X)$ is somewhat insensitive to the magnitude of the effective Born coefficient selected for a given solute in an aqueous solution of urea. Indeed, for reasonable differences between ω_e^* and ω_e values, the dominant factor in determining the electrostatic contribution to the transfer property appears to be linked to the change in the dielectric constant of the medium or, more precisely, the difference $X^* - X$. On this basis, our assumption of $\omega_e = \omega_e^*$ appears justifiable, although we acknowledge the magnitude of the uncertainty introduced into our analysis by the use of such an assumption.

Our analysis indicates that structural contributions appear to dominate reported heat capacities of transfer. Structural contributions increase with increasing urea concentration and also as one goes through the series gly to trigly at a fixed urea concentration. These observations appear to chime with the idea of an increase in the disruption of solvent structure; in other words, specific urea – solute molecule interactions appear to play a major role in determining the magnitude of the transfer property.

In conclusion, the results presented above appear to offer little support for the argument of urea denaturation driven by diminishing hydrophobic hydration of apolar groups. Rather our results appear to identify urea – hydrophilic group and (or) urea – ionic group interactions as being dominant. Unfortunately, our analysis is unable to distinguish between H-bonding interactions and the preferential solvation situation described by Lilley and co-workers (32, 33); however, pair enthalpic interaction coefficients appear to offer compelling evidence in support of the latter description.

Conversion of methane to ethylene

B.K. Miremadi, K. Colbow, and S. Roy Morrison

Abstract: A lithium aluminate – MgO catalyst has been found to convert methane to ethylene with a high selectivity. The rate of conversion increased when a MoO_3 co-catalyst was used to remove the poisoning products. It is shown that for optimum conversion and selectivity to ethylene, the oxygen pressure should be at an intermediate value, high enough to provide active sites but low enough to avoid ethylene oxidation. Thus the oxygen should be "bled-in" along the catalyst bed. In demonstration of these concepts we have shown a 28.6% CH_4 conversion with 63.2% ethylene selectivity and 9.8% ethane, producing a C_2 yield of about 21.4%.

Key words: methane oxidation, methane conversion, ethylene production, oxidation catalyst, aluminate catalyst.

Résumé : On a trouvé qu'un catalyseur d'aluminate de lithium – MgO permet de transformer le méthane en éthylène avec une grande sélectivité. La vitesse de conversion augmente lorsqu'on utilise un cocatalyseur de MoO_3, pour éliminer les produits provoquant un empoisonnement. On a démontré que, pour obtenir une conversion et une sélectivité optimales en éthylène, on doit utiliser une pression d'oxygène intermédiaire, suffisamment élevée pour fournir des sites actifs, mais suffisamment basse pour éviter l'oxydation de l'éthylène. On doit donc laisser l'oxygène s'écouler le long du lit du catalyseur. Une conversion à 28,6% du méthane, avec une sélectivité à 63,2% d'éthylène et 9,8% d'éthane correspondant à un rendement en produits en C_2 de 21,4%, permet de démontrer l'applicabilité de ces concepts.

Mots clés : oxydation du méthane, conversion du méthane, production d'éthylène, catalyseur d'oxydation, catalyseur d'aluminate.

[Traduit par la rédaction]

1. Introduction

There has been increasing interest in the possible use of oxidative coupling to convert methane to higher hydrocarbons, preferably ethylene. The concept is based on the fact that an oxidative reaction

[1] $2CH_4 + O_2 \rightarrow C_2H_4 + 2H_2O$

is exothermic and has been found to occur on many basic oxide catalysts (1–4). The interest in such a reaction is of course that methane is a relatively low-cost gas compared to ethylene, which is more valuable as a petrochemical or as a raw material for oligomerization to higher hydrocarbons.

Part of the problem has been that high C_2H_4 selectivity is usually accompanied by low CH_4 conversion (5). It has been found that the catalyst must be basic (6–8), that the reaction can proceed at temperatures between 700 and 850°C, and that one can best obtain a high selectivity if the CH_4 conversion rate is slow (6). It has been shown (9–12) that the rate-limiting step is the removal of one hydrogen from the methane, producing CH_3, which has been observed in the gas phase. The gas input can be alternated between air and methane (1, 6), but the reaction goes well with a mixture of the gases, and there seems no advantage in switching back and forth between gases. It has been concluded that the dehydrogenation to produce CH_3 occurs on the catalyst, but the remainder of the reaction occurs in the gas phase (2, 13, 14). The most promising catalysts have been based on manganese oxide, samarium oxide, and bismuth oxide (15), with lead oxide (16) or alkali additives as promoters (6, 13, 14).

We observed originally that a lithium aluminate catalyst we were studying for the Fischer–Tropsch reaction at 300–400°C produced a distribution of hydrocarbons in which the ethylene content was relatively high. We found the same kinetic preference to ethylene at the high temperatures for the methane coupling reaction. This was surprising because alumina has been considered a poor support because of its acidity (2, 6, 7), but presumably the high lithium content suppresses this acidity. Studies were initiated to further improve the catalyst. The catalyst was based on an MoS_2–Fe–Al_2O_3 material, featuring alumina platelets (17) obtained by reacting Li at room temperature, or LiOH at high temperature, with porous alumina. We found this lithium aluminate catalyst caused the preference for ethylene. Because of the higher cost of the platelets, we chose to study the catalyst prepared from LiOH.

2. Experimental

The porous alumina was Alcan AA-101 alumina, an activated porous Chi-alumina of 240 m^2/g in area; MoO_3 (98.5%) and LiOH (99%) were from BDH, and $MgCl_2 \cdot 6H_2O$ (98.5%) from Anachem. A model ISI-DS130 scanning electron microscope (SEM) with EG&G ORTEC energy-dispersive X-ray attach-

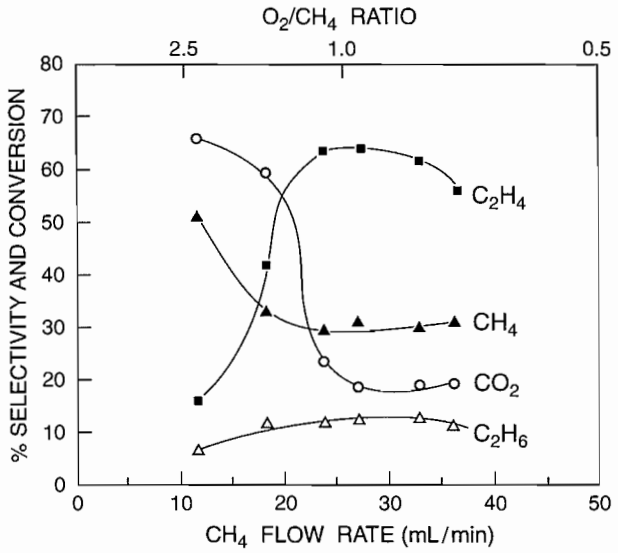
ment (EDX) was used to analyze the elemental compositions of the sample. For the analysis of elemental Li, laser ablation was employed.

The lithium aluminate was prepared by slurrying LiOH and the porous alumina with the Li and Al in the approximate atomic ratio 1/7. The slurry was dried, other additives (such as Mg and particularly powdered MoO_3) were mixed in if desired, and the powder was calcined for more than 5 h at 880°C. In most of the work to be reported, we have included $MgCl_2$ in the slurry at a Mg atomic ratio of 15–20%, calcining the alumina with the additives at 880°C for 10 h. This high-temperature treatment ensured that no trace of Cl^- ions remained in the catalyst. Calcination of the catalysts, for example, at 650°C resulted in poor catalytic activity and residual Cl^- ions of less than 0.4 atomic percent as measured by the Kα Auger line. The catalyst composition was in the approximate atomic ratio of Li:Al:Mg = 1:7:2. The as-received alumina had originally a BET area of 237.6 m^2/g. After the heat treatment the surface area was reduced to 156.8 m^2/g. Addition of Li and Mg produced a further reduction in area to 56.3 m^2/g.

The reactor was a single-pass quartz reactor, generally held at an optimum operating temperature of 785°C (±0.7%). The heating system used was limited to a maximum temperature of 825°C. The temperature was measured with a thermocouple placed in a narrow quartz tube inserted into the catalyst bed. At about 800°C most CH_4 was oxidized to CO_2, with poor selectivity for other products. About 0.1 g of catalyst was dispersed as a powder in quartz wool, held between quartz wool plugs, with the catalyst bed about 0.2 cm in length and 0.8 cm^2 in area. For some of our investigations two such identical catalyst beds were mounted in series 50 cm apart with the option of introducing more gas to the mixture before the second bed. Only one reactor was used except where indicated. The air–methane mixture was not preheated before entering the reactor except where so indicated, although the length of the heating zone was about 6 cm, compared to a length of 0.2 cm for the catalyst bed.

At a pressure of 1 atmosphere (101.3 kPa) the gas mixtures used were air and methane. When the methane flow was reduced, He gas flow was added to keep the total flow rate constant. A Varian gas chromatograph (model 6000), featuring a thermal conductivity and a flame ionization (1) detector, using a 13 X molecular sieve in series with a Porapak-N column was used to sample the gas mixture. The gas flow (air, methane, and helium) was monitored with mass flow meters calibrated against a bubble flow meter installed at the exit of the reactor. Good carbon balance was obtained, as will be noted later in discussion of Table 1. Nitrogen lost in mass balance, $(1 - N_{out}/N_{in})$, was obtained to within 2×10^{-2}. The calibrating gas used to convert the GC data to percent products was from Lil Squirt Ideal Gas Products provided by Varian Corp. It contained a mixture of all possible gases used and produced in our experiments.

3. Results



3.1 Lithium aluminate

Table 1 shows a comparison of selectivities and CH_4 conversion. In this experiment we had two identical quartz reactors r_1 and r_2 in series 50 cm apart. As far as was possible the reactors were held at the same temperature. From the results for a single reactor there was ample partial pressure of methane and air reaching the second reactor. However, we observed that the second reactor did not contribute appreciably to the ethylene production, except for an increase in CH_4 conversion (16.5%), which in turn increased the CO_2 production (34.2%). As will be discussed in the next section, a substantial increase in the conversion was observed by addition of 100 mg MoO_3 co-cat-

Fig. 1. Percent of products as a function of optimized CH_4 flow rate for catalyst and promoter (MoO_3) at 785°C in a double bed reactor with an air flow of 120 mL/min and an injected 20 mL/min of air at the input of the second reactor. At peak conversion methane flow is 27.2 mL/min and $O_2/CH_4 \approx 1$.

alyst powder mixed with the aluminate catalyst in both reactors. MoO_3 oxidizes hydrogen produced in the first reactor (r_1) that was poisoning the second reactor (r_2), thus leading to a further conversion of methane and higher selectivity for ethylene. With addition of MoO3 promoter, at an optimized methane flow rate of 27.2 mL/min and 20 mL/min air injection at the input of the second reactor, the conversion was 28.6%, selectivity was 63.6%, and CO_2 produced reduced to 17.3%. Without addition of MoO_3, the air injection at the input of the second reactor resulted in an increase in both CO_2 and H_2O products.

Figure 1 shows the percent of the products (ethylene and ethane selectivities, methane conversion, and CO_2 produced) of a MoO_3 promoted catalyst against the methane flow rate at a constant air flow of 120 mL/min and with an extra 20 mL/min of air bled-in at the input of the second reactor. The selectivity and conversion peak at a methane flow of 27.2 mL/min, where the oxygen/methane ratio is about 1 and CO_2 produced is a minimum. With high oxygen to methane ratio, conversion is high but most of methane is converted to CO_2. There is evidence of a peak in C_2H_4 conversion at intermediate oxygen-to-methane ratio and low conversion of methane with low oxygen-to-methane ratio.

4. Discussion

4.1 Lithium aluminate catalyst

It was observed that for good conversion of CH_4 and good selectivity to C_2H_4 a high oxygen partial pressure is required, much higher than the stoichiometric ratio (0.5) for

[2] $2CH_4 + O_2 \rightarrow C_2H_4 + 2H_2O$

This is consistent with the currently accepted model with adsorbed O^- as active sites (12); presumably a significant oxygen pressure is required to maintain a high state density. With ample reactive gases still present in the gas stream, no (or negligible) reaction occurred in the second reactor. This observation suggests strongly that the second reactor is poisoned by the products formed in the first reactor, mainly the hydrogen produced. Possible poisons, such as ethylene, carbon dioxide, water, and hydrogen, are all produced during the reaction. These were tested under our "standard" conditions. Addition of C_2H_4 to the input had no effect on the reaction; the ethylene in the output was simply increased by the extra amount added in the input. H_2O added to the input actually increased the yield and selectivity slightly. Added CO_2 at about 5 mL/min also showed no effect. Hydrogen was awkward to introduce in large quantities because of potential explosion, but a small addition of 5 mL/min Forming gas (5% H_2, 95% N_2) was found to lower the selectivity by 10–15%. Since the hydrogen flow from the Forming gas (0.25 mL/min) was lower than hydrogen produced in the reactors, we concluded H_2 was poisoning the active sites and (or) inducing the back reaction:

[3] $2H_2 + C_2H_4 \rightarrow 2CH_4$

With the consideration that such a back reaction is rather unlikely, our suggested model is based on poisoning the active sites.

4.2 MoO_3 and lithium aluminate – Mg as co-catalysts

A search was made for catalysts to remove the H_2, viz. catalysts that would catalyze the oxidation of 5% H_2 in He but not 5% C_2H_4 in He under our normal reaction conditions at 785°C. Of eight oxides tested (Fe_2O_3, Cr_2O_3, Mn_2O, ZnO, SnO_2, TiO_2, ZrO_2, MoO_3), MoO_3 and ZrO_2 were found to be most effective. With 100 mg commercial MoO_3 powder, 95% of the hydrogen but only 18% of the ethylene was oxidized in one pass through the reactor in a ratio of O_2 to reducing agent of 1:6. For this test the lithium aluminate catalyst was not present.

The activity of MoO_3 alone was also tested as a catalyst under our experimental conditions, which indicated a poor selectivity for ethylene production. In comparison to MgO aluminate catalysts, MoO_3 is a poor oxidation catalyst (18, 19), but together with aluminate catalyst (without additional air injection at the input of reactor r_2) it resulted in a 13% increase in selectivity, while the increase with optimized air injection was close to 23%. There is a good possibility that high-temperature calcination of MoO_3 used in this experiment has converted the oxide to some other phases that have become a part of the catalyst itself. Without addition of MoO_3, the air injection at the input of the second reactor resulted in an increase in both CO_2 and H_2O products. A similar test with ZrO_2 showed an overall increase of only 8%. Thus, both MoO_3 and air injection are equally contributing factors in improving ethylene production.

If hydrogen is the poison, the presence of an oxidation catalyst that selectively removes H_2 should (*a*) increase the conversion, either if the back reaction in eq. [3] occurs, or if hydrogen blocks active sites, and (*b*) permit continuing conversion if, as with the second reactor described above, the H_2

© 1997 NRC Canada

produced at the input to the catalyst bed poisons the rest of the catalyst bed and the second reactor.

4.3 Air injection

The conclusion from the above results is that addition of MoO_3 leads to lower hydrogen concentration and higher methane conversion. For such high conversion of methane it appears one must prevent the back reaction of eq. [1] and (or) the blocking of active sites of hydrogen. It also suggests that one must keep the oxygen pressure up, both to provide active sites and to oxidize the hydrogen. However, if the oxygen pressure is too high, there will be a greater tendency to oxidize the ethylene and the selectivity will drop, in addition to an increase in CO_2 product. This effect was also noticed when 20 mL/min air injection was replaced with 10 mL/min pure oxygen to avoid a substantial increase in the total flow. All this leads to the conclusion that oxygen should be admitted in a controlled manner along the catalyst bed, maintaining the oxygen partial pressure at the optimum value as it is consumed, in agreement with the suggestion by Smith and Galuszka (20). To permit somewhat better adjustment of the oxygen partial pressure in the experiments of Fig. 1, we introduced air not only at the input with CH_4, but also between the two reactors r_1 and r_2.

5. Conclusions

We have presented observations regarding the methane oxidative coupling reaction and a possible explanation of the process for the catalyst used. The observations are that lithium aluminate is an excellent catalyst for the reaction, providing a high yield of ethylene and a high conversion per pass of methane. An oxidation catalyst chosen to oxidize hydrogen but not ethylene under the reaction conditions improves the conversion rate substantially. Introducing oxygen along the length of the catalyst bed to replace that used in the reaction leads to a high conversion of methane with a high selectivity to ethylene.

The model suggested for ethylene generation differs from the standard model where the CH_3·radical first dimerizes to C_2H_6 and subsequently the ethane oxidizes to form C_2H_4 + H_2O. A dominant experimental feature suggesting a different role for our catalyst is the low concentration of C_2H_6 as shown in Table 1 and Fig. 1. The poisoning of active sites by hydrogen is the novel result of the analysis. Because the conversion of methane is so strongly limited, it is clear that sites for it must be poisoned, as is observed clearly where the added reactor in series does not affect the product yield, suggesting the sites are poisoned by a product generated in the first reactor.

Considering the confusion in the general behavior of the oxidative methane coupling, it is possible that unnoticed hydrogen poisoned other catalysts as well as ours. The strong effect of MoO_3, which is a comparatively poor catalyst for oxidation of methane (18, 19) as discussed in Sect. 4.2, could be difficult to explain by another model.

It may be possible, by carefully controlled oxygen admission, to further increase CH_4 conversion and the corresponding C_2 products.

Observation of a single-pot aromatic reductive denitration

Angelo G. Giumanini and Giancarlo Verardo

Abstract: 4,*N*,*N*-Trimethyl-3-nitrobenzenamine gave reductive denitration products (ca. 28%) upon treatment with *n*-butyl nitrite in the presence of catalytic amounts of ammonium chloride and water in an unprecedented one-reagent single-pot process. The three isomeric *N*,*N*-dimethylnitrobenzenamines showed the same behaviour to a much lesser extent; the *ortho* isomer was partially (7%) transformed into 1-methylbenzotriazole.

Key words: aromatic protolytic denitration, nitroaromatics, *n*-butyl nitrite, *E*- and *Z*-nitrosamine.

Résumé : Au cours d'un processus unipot sans précédent, la 4,*N*,*N*-triméthyl-3-benzèneamine fournit des produits de dénitration réductrice (environ 28%) lorsqu'on la soumet à l'action du nitrite de butyle, en présence de quantités catalytiques de chlorure d'ammonium et d'eau. Le trois *N*,*N*-diméthylnitrobenzènamines isomères ont le même comportement, même si le degré est moindre; l'isomère *ortho* se transforme partiellement (7%) en 1-méthylbenzotriazole.

Mots clés : dénitration aromatique protolytique, nitroaromatiques, nitrite de butyle, *E*- et *Z*-nitrosamine.

[Traduit par la rédaction]

One-batch-one reagent aromatic reductive denitration, which could in principle be the reversal of classical nitration by the nitronium ion, is such a rare event that there is no such entry for it in Chemical Abstracts. As a matter of fact, the only way to perform this process appears that of reducing the nitro group to amino, which is subsequently diazotized and reduced by a suitable reagent.

Indeed, a few coherent observations of this one-batch process have been reported (1) as a side reaction in the treatment of a number of tertiary aromatic amines bearing a nitro group in the *ortho* position, with strong acid or photochemically, to yield benzimidazoles and benzimidazole oxides. The envisaged mechanism in the ground state experiment assumed the migration of the nitro group to the amino nitrogen to yield an oximonium nitroso ester, eventually bound for the formation of a Wheland-type intermediate by amino group assisted protonation of the carbon bearing the nitro group, as a final step (route A, Scheme 1), or a more straightforward variation that we would rather like to advance (route B, Scheme 1): both pathways would amount to the reversal of the *ortho*-nitration of an aromatic amine.

Interestingly, this behaviour attributed to the *ortho*-effect (1*a*) was reported only for tertiary amines, inferring that enough steric hindrance is there to cause the phenomenology observed. We now wish to report the observation that stirring 4,*N*,*N*-trimethyl-3-nitrobenzenamine (**1**) at room temperature with *n*-butyl nitrite (BN, 3 mol-equiv.), water (10 mol-equiv.), and ammonium chloride (AC, 0.1 mol-equiv.) during 2 days caused the complete disappearance of **1** and produced two reductive denitration compounds, namely, *N*,4-dimethylbenzenamine (**2**, identified on the basis of its retention properties and mass spectrum) and *N*,4-dimethyl-*N*-nitrosobenzenamine (**3**, in the ratio ca. 5:1), the latter being the GC precursor of the former by pyrolysis in the injector port. The material balance of the volatile fraction was completed by *N*,4-dimethyl-3-nitrobenzenamine (**4**), analogously derived by the thermal decomposition in the GC injector of the corresponding *N*-nitrosamine **5**, as shown in an independent experiment, and two distinct dinitro derivatives of *N*,*N*,4-trimethylbenzenamine (Scheme 2). A suitable work-up of the reaction mixture led to the isolation of **3** and its full identification. In the absence of BN no reaction was observed. The same reaction under the conditions described (2) for the oxidative *N*-demethylation-*N*-nitrosation reaction gave some 81% **5** and 5% **3**.

All of the three isomeric *N*,*N*-dimethylnitrobenzenamines (**6***a–c*), which were found unreactive at room temperature, gave some, but smaller, amounts of reduced denitrated product (**7**) under similar conditions at reflux temperatures and short contact times. The *meta* isomer **6***b* underwent mainly *N*-nitrosation-*N*-demethylation (78%) to *N*-methyl-*N*-nitroso-3-nitrobenzenamine (**8***b*), but some 9% *N*-methyl-*N*-nitrosobenzenamine (**7**) was also present. A similar yield of **6***b* was obtained from the *ortho* isomer **6***a*, which gave only 7% 1-methylbenzotriazole (**9**) but some 58% *N*-methyl-*N*-nitroso-2-nitrobenzenamine (**8***a*). The latter product represented the main course of the process also with the *para* isomer **6***c*, which produced only traces of the reduction product **7**.

The identification of **8***a* was arrived at by elemental analysis, mass spectrometry (the parent ion at *m/z* 181 lost NO to

yield the base peak at *m/z* 151, this daughter ion subsequently lost OH, as expected from the location of the nitro group with respect to the methyl group), and infrared (2*a*, 3) ($\nu_{N=O}$ at 1459 cm^{-1}, ν_{N-N} at 961 cm^{-1}, and ν_{C-N} at 1198 cm^{-1}) spectroscopy. The ^1H NMR spectrum of **8***a* was in excellent agreement with what can be expected from a mixture of geometric isomers of a single nitrosamine, showing two sharp singlets for the methyl group. But, curiously, this is at variance with

Scheme 3.

the spectra of the strictly related nitrosamines **5** (vide infra) and *N*,4-dimethyl-*N*-nitroso-2-nitrobenzenamine **10** ($\delta_{N\text{-}Me}$ at 3.38, singlet, in $CDCl_3$) (*2a*), which exhibited under the same conditions a single peak for the *N*-methyl group, like all of the other *N*-nitroso aromatic nitrosamines investigated by us (*2a*), which are assumed to be in the *E* configuration. Like *N*-methyl-*N*-nitroso-2,6-diisopropylbenzenamine **11** ($\delta_{N\text{-}Me}$ at 3.36 ppm) (*2a*), the phenyl ring is expected to be almost perpendicular to the C-N-N=O plane also in **8***a*, but the ring in the latter case may be prone to some electron charge transfer from the oxygen of the nitro function, thus increasing the stability of the *Z* configuration, which would nonetheless be the lesser represented, showing the methyl resonance at δ 4.50 ppm. When a methyl group is in the *para* position, as is the case for **10**, its electron-releasing effect is allowed to restore a better planarity of the ring (not necessary of the NO_2 group!) and excludes the *Z* form from the equilibrium.

Nitronaphthalene, water, and AC did not yield any naphthalene after long reflux. The addition of BN to the mixture did not change matters. We have repeated the reported (*1b*) reaction between **6***a* and refluxing aqueous hydrochloric acid, but no substantial *N*-methylbenzimidazole-*N*-oxide was detected: denitration proceeded only to a very small extent. Moreover, 2-nitrobenzenamine did not undergo denitration at all under these conditions.

The mechanisms invoked for the reductive denitration of the *ortho*-nitrated tertiary amines cannot be valid here. By and large, the reaction conditions are far from being those for a necessary strong acid catalysis, although at the present time we have no well-grounded rationale for the behaviour of the system described. The formation of **9** indicated the involvement of ammonia (from AC) in the process. Speculations about mechanism are condensed in Scheme 3.

Experimental section

Materials

4,*N*,*N*-Trimethyl-3-nitrobenzenamine (**1**) (4) and 2-, 3-, and 4-nitro-*N*,*N*-dimethylbenzenamine (**6***a*, **6***b*, and **6***c*) (5) as well as *n*-butyl nitrite (BN) (6) were prepared according to described procedures. Compounds for which no references are given were available from previous work (*2a*). Alumina (active neutral Brockmann Grade I) was purchased from BDH (Milan, Italy). Solvents were used as received.

Equipment

GC–MS analyses were performed with a Fisons TRIO 2000 gas – chromatograph-mass spectrometer, working in the positive ion 70 eV electron impact mode. Injector temperature was kept at 250°C and column (Supelco® SE-54, 30 m long, 0.32 mm i.d., coated with a 0.25 μm phenyl methyl silicone rubber film) temperature was programmed from 80 to 300°C with a gradient of 10°C/min. Direct inlet mass spectra (DI-MS) were obtained on the same instrument: temperatures between 30 and 70°C were found suitable to volatilize all the compounds into the ion source. IR spectra were obtained with a Nicolet FT-IR Magna 550 spectrophotometer using the KBr technique for solids. ^{1}H NMR spectra were recorded in $CDCl_3$ at room temperature on a Bruker AC-F 200 spectrometer at 200 MHz. NMR peak locations are reported as δ-values from TMS. Some ^{1}H multiplets are characterized by the term *app* (apparent): this refers only to their appearance and may be an oversimplification. Elemental analyses were performed with a Carlo Erba model 1106 elemental analyzer and were in satisfactory agreement with calculated values. Melting points were determined with an automatic Mettler (model FP61) apparatus and are not corrected. Boiling points refer to the center cut of small distillations and are uncorrected.

Physical and spectroscopic properties of materials of common occurrence and (or) commercial origin are not reported.

4,*N*,*N*-Trimethyl-3-nitrobenzenamine (1), BN, AC, and water

Procedure A

The amine **1** (8.1 mmol), BN (24.5 mmol), AC (0.81 mmol), and water (81 mmol) were stirred during 2 days at room temperature. TLC analysis (alumina, hexane–CH_2Cl_2, 70:30 vol/vol) showed the total disappearance of starting material with the formation of two products. GC–MS analysis of the intact mixture from which volatile material was evaporated under vacuum showed the following: *N*,4-dimethylbenzenamine (**2**, 36%); *N*,4-dimethyl-*N*-nitrosobenzenamine (**3**, 8%), showing up as a peak tail of the former, of which it is a thermal decomposition product; *N*,4-dimethyl-3-nitrobenzenamine (**4**, 51%), analogously derived by thermal decomposition of the corresponding *N*-nitrosamine **5** in the injector; and two distinct dinitro derivatives (**12***a*, 1% and **12***b* 4%) of *N*,*N*,4-trimethylbenzenamines, identified on the basis of their mass spectra (**12***a*; MS *m/z*: 225(M^+, 46), 208(36), 180(24), 178(25), 162(48), 161(21), 150(100), 133(46), 132(57), 118(48), 117(28), 91(30), 77(24), 65(25), 51(17), and 42(24); **12***b*, MS *m/z*: 225(M^+, 70), 208(30), 180(5), 178(11), 162(17), 161(27), 150(64), 133(53), 132(100), 118(93), 117(43), 91(32), 77(19), 65(25), 51(10), and 42(24)]. Absorption chromatography, performed on alumina using hexane with increasing concentration of CH_2Cl_2 as eluant, of the total reaction mixture, after evaporation under vacuum of volatile material, yielded only *N*,4-dimethyl-*N*-nitrosobenzenamine (**3**, 28%; mp 56°C (lit. (7) mp 52°C); IR (KBr): 3020w, 2905w, 1510s, 1430vs, 1386vs, 1311s, 1287m, 1218vs, 1205vs, 1098vs, 1017s, 970s, 958s, 818vs, and 533s cm^{-1}; ^{1}H NMR ($CDCl_3$) δ: 2.39 (3H, s, ar-CH_3), 3.43 (3H, s, N-CH_3), 7.15–7.55 (4H, *app* m, ar-H); DI-MS *m/z*: 150(M^+, 34), 120(100), 92(51), 91(76), 77(54), 65(53), and 51(25). Anal. calcd. for $C_8H_{10}N_2O$: C 49.23, H 4.65, N 21.53; found: C 49.20, H 4.61, N 21.56) and *N*,4-dimethyl-*N*-nitroso-3-nitrobenzenamine (**5**, 75%; mp 58°C; IR (KBr): 3060w, 3020w, 1525vs, 1500s, 1460vs, 1400s, 1343vs, 1188vs, 1110s, 975s, 881m, 834s, 790m, 760m, and 708m cm^{-1}; ^{1}H NMR ($CDCl_3$) δ: 2.65 (3H, s, ar-CH_3), 3.46 (3H, s, N-CH_3), 7.22–8.19 (3H, m, ar-H); DI-MS *m/z*: 195(M^+, 19), 165(100), 148(13), 119(49), 118(29), 117(17), and 91(43). Anal. calcd. for $C_8H_9N_3O_3$: C 63.98, H 6.71, N 18.65; found: C 63.91, H 6.71, N 18.63).

Procedure B

A mixture of **1** (18.0 mmol), AC (2.0 mmol), and water (90.0 mmol) was refluxed during 60 min. Absorption chromatography, performed on alumina using hexane with increasing concentration of CH_2Cl_2 as eluant, of the total reaction mixture, after evaporation under vacuum of volatile material, yielded only **3** (5%) and **5** (81%).

N,*N*-Dimethyl-2-nitrobenzenamine (6*a*), BN, AC, and water

A mixture of **6***a* (18.0 mmol), BN (72.3 mmol), AC (2.0 mmol), and water (90.0 mmol) was refluxed during 120 min. Absorption chromatography, performed on alumina using hexane with increasing concentration of CH_2Cl_2 as eluant, of the total reaction mixture, after evaporation under vacuum of volatile material, yielded nitrobenzene (**13**, 1%), unreacted **6***a* (1%), *N*-methyl-2-nitrobenzenamine (**14***a*, 5%), *N*-methyl-*N*-nitrosobenzenamine (**7**, 9%; bp 83°C at 17 Torr (lit. (7) bp 86–87°C at 17 Torr; 1 Torr = 133.3 Pa) IR (neat): 3030w, 2910w, 1618m, 1595m, 1492m, 1467s, 1438vs, 1390m, 1350m, 1330m, 1312m, 1291m, 1263m, 1200s, 1090s, 1028m, 952m, 756s, and 690m cm^{-1}; ^{1}H NMR ($CDCl_3$) δ: 3.44 (3H, s, N-CH_3) and 7.29–7.66 (5H, m, ar-H); DI-MS *m/z*: 136(M^+, 40), 106(100), 105(38), 104(31), 79(73), and 77(92). Anal. calcd. for $C_7H_8N_2O$: C 61.75, H 5.92, N 20.57; found: C 61.72, H 5.92, N 20.58), *N*-methyl-*N*-nitroso-2-nitrobenzenamine (**8***a*, 58%; mp 39°C (lit. (8) mp 36°C); IR (KBr): 3100w, 3077w, 3049w, 1607m, 1528vs, 1459vs, 1441vs, 1358vs, 1277s, 1198s, 1070s, 1016s, 961s, 855m, 820m, 780vs, 748s, 704s, and 647m cm^{-1}; ^{1}H NMR ($CDCl_3$) δ: 3.42 and 4.23 (3H, two s, N-CH_3 in different conformations, % ratio 6.5/1) and 7.17–8.15 (4H, m, ar-H); DI-MS *m/z*: 181(M^+, 29), 151(100), 134(61), 120(8), 106(14), 105(28), 104(32), 93(34), 92(19), 91(22), 79(22), 78(47), 77(61), 76(23), 66(26), 65(31), 63(26), and 51(27). Anal. calcd. for $C_7H_7N_2O_2$: C 55.63, H 4.67, N 18.53; found: C 55.61, H 4.69, N 18.50), and 1–methylbenzotriazole (**9**, 7%; mp 66°C (lit. (9) mp 64–65°C); IR (KBr): 3050w, 2950w, 1498m, 1452m, 1299m, 1268m, 1198s, 1161m, 1024s, 780m, 739vs, and 662m cm^{-1}; ^{1}H NMR ($CDCl_3$) δ: 4.30 (3H, s, N-CH_3), 7.33–7.43 (1H, m, ar-H), 7.48–7.55 (2H, m, ar-H), and 8.06 (1H, *app* dt, J_o = 8.3 Hz, J_m = J_p = 1.1 Hz, ar-H); DI-MS *m/z*: 133(M^+, 100), 105(78), 104(42), 90(55), 78(27), 77(44), 64(27), 63(39), 51(21), and 50(16). Anal. calcd. for $C_7H_7N_3$: C 63.10, H 5.30, N 31.56; found: C 63.13, H 5.28, N 31.59).

N,*N*-Dimethyl-3-nitrobenzenamine (6*b*), BN, AC, and water

A mixture of **6***b* (18.0 mmol), BN (72.3 mmol), AC (2.0 mmol), and water (90.0 mmol) was refluxed during 120 min. Absorption chromatography, performed on alumina using hexane with increasing concentration of CH_2Cl_2 as eluant, of

Weak M—H···H—C interactions observed in ruthenium and iridium complexes containing hydride, amine, and bulky phosphine ligands

Wei Xu, Alan J. Lough, and Robert H. Morris

Abstract: New amineruthenium and amineiridium hydride derivatives have been synthesized and characterized with the objective of observing intramolecular MH···HN or MH···HO interactions. These include $RuHCl(CO)(L)(PPr^i_3)_2$ (**1***a*, L = NH_2NH_2; **1***b*, L = NH_3) and $IrCl_2(L)(H)(PCy_3)_2$ (**2***a*, L = $SC(NH_2)_2$; **2***b*, L = NH_3; **2***c*, L = NH_2NH_2; **2***d*, L = $NH_2(CH_2)_3NH_2$; **2***e*, L = NH_2OH). Instead, weak M—H···H—C van der Waals contacts have been detected in the solid state by X-ray analysis and in solution by NMR T_1 measurements and nOe techniques. Both X-ray crystal structure analysis and minimum T_1 measurements indicate that the H···H distances in the M—H···H—C interactions are ca. 2.0–2.2 Å. The weak interactions might influence the course of deuteration of these complexes under D_2 gas. The crystal and molecular structure of $IrCl_2(NH_3)(H)(PCy_3)_2$ **2***a* has been determined by X-ray diffraction at 173 K: monoclinic, space group $P2_1/n$, a = 14.859(2) Å, b = 18.579(3) Å, c = 18.548(3) Å, β = 97.29(1)°, V = 5079.1(13) Å^3, Z = 4, full-matrix least-squares refinement on F^2 for 10 953 independent reflections; $R[F^2 > 4\sigma(F^2)]$ = 0.0283, $wR(F^2)$ = 0.0704.

Key words: ruthenium, iridium, hydride, dihydrogen, complexes, hydrogen bond, NMR, X-ray.

Résumé : On a synthétisé et caractérisé de nouveaux hydrures dérivés de l'amineruthénium et de l'amineiridium pour observer des interactions intramoléculaires MH···HN ou MH···HO. Ils comprennent le $RuHCl(CO)(L)(PiPr_3)_2$ (**1***a*, L = NH_2NH_2; **1***b*, L = NH_3) et $IrCl_2(L)(H)(PCy_3)_2$ (**2***a*, L = $SC(NH_2)_2$; **2***b*, L = NH_3; **2***c*, L = NH_2NH_2; **2***d*, L = $NH_2(CH_2)_3NH_2$; **2***e*, L = NH_2OH). À la place des interactions recherchées, on a observé de faibles contacts de van der Waals MH···HC tant à l'état solide (par diffraction des rayons X) qu'en solution (par des mesures de T_1 et par les techniques d'eOn en RMN). L'analyse des structures cristallines et les minima dans les mesures de T_1 indique que les distances H···H dans les interactions M—H···H—C sont de l'ordre de 2,0–2,2 Å. Ces faibles interactions peuvent influencer le cours de la deutération de ces complexes par le D_2 à l'état gazeux. On a déterminé les structures cristalline et moléculaire du $IrCl_2(NH_3)(H)(PCy_3)_2$ (**2***a*) par diffraction des rayons X à 173 K; les cristaux sont monocliniques, groupe d'espace $P2_1/n$, avec a = 14,859(2), b = 18,579(3) et c = 18,548(3) Å, β = 97,29(1)°, V = 5079,1(13) Å^3, Z = 4, $R[F^2 > 4\sigma(F^2)]$ = 0,0283 et $wR(F^2)$ = 0,0704 pour un affinement par la méthode des moindres carrés sur F^2 pour 10 953 réflexions indépendantes.

Mots clés : ruthénium, iridium, hydrure, dihydrogène, complexes, liaison hydrogène, RMN, rayons X.

[Traduit par la rédaction]

Introduction

Weak hydrogen bonds involving carbon–hydrogen bonds, C—H···X (X = O, N, or Cl), have been found to play a significant role in molecular conformation, molecular assemblies, and crystal engineering (1–3). They sometimes are crucial in structural stabilization of biological systems (4). Such weak interactions are difficult to observe in solution. In our study on intramolecular interactions between iridium hydrides and protons on nitrogen (see Fig. 1(a)), we found that, in addition to the NH proton at about 1.8 Å, some hydrogens of cyclohexyl groups on phosphine ligands contribute to the rate of dipole–dipole relaxation of hydride ligands in iridium complexes containing pyridiniumthiolato and tricyclohexylphosphine ligands (5–7). Desrosiers et al. (8) have already discussed the importance of ligand-hydrogen to metal-hydride dipole–dipole interactions in the analysis of T_1 values of metal hydride and dihydrogen complexes. We find that intramolecular CH···HM interactions also appear to influence the chemistry of the complexes described here.

These observations were made while trying to observe new intramolecular interactions between a metal hydride and an HN or HO hydrogen bond donor as shown in Fig. 1. Amino groups and iminol groups acting as H-bond donors to hydrides have been reported by Crabtree and co-workers (9–12). In all cases but one, a six-membered ring similar to that of (a) in Fig. 1 is involved; the exception is the first intermolecular Re—H···HN interaction (12). Strong evidence for the existence of intermolecular W—H···HO (13) and B—H···HN (14)

Fig. 1. Observed (a) and hypothetical ((b)–(d)) intramolecular proton–hydride interactions between hydrogen bond donors and a metal hydride. The hydrogens in (e) are probably too far apart to interact.

interactions has also been provided recently. We wondered whether five-membered rings (Fig. 1 (c) with NH_2NH_2 ligand or (d) with NH_2OH ligand) would form. The corresponding ammine complexes (e) were prepared for comparison since they were not expected to show such an interaction in a four-membered ring; however, Milstein et al. postulated that there might be a weak attractive interaction between a *cis* hydride and hydroxide hydrogen in such a ring at an H—H distance of 2.4(1) Å in $[Ir(H)(OH)(PMe_3)_4]^+$ (15, 16).

Experimental

General procedures and materials

All operations were conducted in an argon atmosphere by use of Schlenk line techniques, or in a purified nitrogen atmosphere using a Vacuum Atmospheres glove box. Deuterated solvents were dried over Linde type 4 Å molecular sieves and degassed with argon using several evacuate–refill cycles. Reagent-grade chemicals were used as purchased from Aldrich Chemical Company, Inc. unless otherwise stated. Tricyclohexylphosphine (PCy_3) and triisopropylphosphine (PPr^i_3) were purchased from Strem Chemical Co. $IrCl_3{\cdot}3H_2O$ and $RuCl_3{\cdot}3H_2O$ were received as a loan from Johnson–Matthey Co. $IrHCl_2(PCy_3)_2$ was prepared from $IrCl_3{\cdot}3H_2O$–HCl–EtOH and PCy_3 as described elsewhere (17). Methods of preparation starting from other iridium complexes have been described (18). $RuHCl(CO)(PPr^i_3)_2$ was prepared by previously reported methods (19).

NMR spectra were recorded on Varian Unity-400 and Varian Gemini-300 spectrometers. Reported chemical shifts refer to room temperature conditions (20°C) unless specified otherwise. ^{31}P chemical shifts were measured in the proton decoupled mode and referenced externally to 85% H_3PO_4. ^1H chemical shifts were measured relative to partially deuterated solvent peaks, but are reported relative to tetramethylsilane. Fast atom bombardment mass spectrometry (FAB MS) spectra were obtained with a VG 70-250S mass spectrometer using a nitrobenzyl alcohol (NBA) or nitrophenyl octyl ether (NPOE) matrix. Microanalyses were performed by Guelph Chemical Laboratories Ltd.

Preparation of $RuHCl(CO)(L)(PPr^i_3)_2$ (1*a*, L = NH_2NH_2; 1*b*, L = NH_3)

$RuHCl(CO)(PPr^i_3)_2$ (0.5 g, 1 mmol) in toluene (20 mL) and L (L = 90% NH_2NH_2 aq. for **1***a*; L = 30% NH_3 aq. for **1***b*) were vigorously stirred for 20 min. The red toluene suspension of $RuHCl(CO)(PPr^i_3)_2$ turned to a light yellow solution very quickly. When methanol (50 mL) was added to the mixture, a light yellow crystalline compound $RuHCl(CO)(L)(PPr^i_3)_2$ **1** was formed. It was obtained in almost quantitative yield after washing the solid with methanol (2 × 5 mL) and drying under vacuum. $RuHCl(CO)(NH_2NH_2)(PPr^i_3)_2$ **1***a* (light yellow solid, yield 90%): ^1H NMR (CD_2Cl_2, 20°C) δ: −14.5 (br), −15.7 (t, J_{P-H} = 21 Hz). ^1H NMR (CD_2Cl_2, −60°C) δ: −13.6 (t, J_{P-H} = 21 Hz), −13.9 (t, J_{P-H} = 21 Hz), −15.9 (t, J_{P-H} = 21 Hz), 0.9–1.4 (m, 36H, CH_3), 2.56 (m, 6H, $CHMe_2$), 2.09 (br, $RuNH_2NH_2$), 2.36 (br, $RuNH_2NH_2$), 3.46 (br, $RuNH_2NH_2$), 3.60 (br, $RuNH_2NH_2$), 4.8 (s, CH_3OH, 3H). ^{31}P NMR δ: 45.6 (s), 43.0 (s). FAB MS: calcd. for $C_{19}H_{47}{}^{35}ClN_2OP_2{}^{101}Ru$: 517; observed: 517 ($M^+$). Anal. calcd. for $C_{19}H_{47}ClN_2OP_2Ru{\cdot}CH_3OH$: C 43.7, H 9.3, N 5.1; found: C 43.5, H 8.9, N 5.1. $RuHCl(CO)(NH_3)(PPr^i_3)_2$ **1***b* (light yellow solid, yield 88%): ^1H NMR (CD_2Cl_2, 20°C) δ: −14.1 (t, J_{P-H} = 21 Hz, relative int. 10), −14.4 (t, J_{P-H} = 20.5 Hz, relative int. 1), −15.9 (t, J_{P-H} = 20.6 Hz, relative int. 1), 0.9–1.4 (m, 36H, CH_3), 2.56 (m, 6H, $CHMe_2$), 2.3 (br, $RuNH_3$). ^{31}P NMR δ: 49.3 (s, relative int. 1), 49.1 (s, relative int. 10), 48.3 (d, J_{HP} = 20 Hz, relative int. 1). FAB MS: calcd. for $C_{19}H_{46}{}^{35}ClNOP_2{}^{101}Ru$: 502; observed: 502 ($M^+$). Anal. calcd. for $C_{19}H_{46}ClNOP_2Ru$: C 45.4, H 9.2, N 2.8; found: C 45.1, H 9.2, N 2.6.

Preparation of $IrCl_2(L)(H)(PCy_3)_2$ (2*a*, L = $SC(NH_2)_2$; 2*b*, L = NH_3; 2*c*, L = NH_2NH_2; 2*d*, L = $NH_2(CH_2)_3NH_2$; 2*e*, L = NH_2OH)

$Ir(H)Cl_2(PCy_3)_2$ (0.5 g, 0.6 mmol) in toluene (20 mL) and L (L = $SC(NH_2)_2$, 0.1 g, 0.6 mmol for **2***a*; L = NH_3, 5 mL of 30% aq., for **2***b*; L = NH_2NH_2, 5 mL of 90% aq. for **2***c*; L = $NH_2(CH_2)_3NH_2$, 5 mL for **2***d*, L = NH_2OH, 0.1 g of $NH_2OH{\cdot}HCl$ and 1 g KOH dissolved in 1 mL water for **2***e*) were vigorously stirred for 24 h. The red toluene solutions turned slowly into light yellow solutions and then pale yellow solids precipitated from the solutions. The products were filtered off, washed with methanol several times, and dried under vacuum. **2***a* (light yellow solid, 88% yield): ^1H NMR (CD_2Cl_2, 20°C) δ: −24.04 (t, $^2J_{HP}$ = 15.9 Hz, Ir-H), −24.07 (t, $^2J_{HP}$ = 18 Hz, Ir-H), 1.0–3.0 (m, C_6H_{11}), 4.8 (s, CH_3OH, 3H). ^{31}P NMR δ: −4.0 (s), −6.0 (s). FAB MS: calcd. for $C_{37}H_{71}{}^{35}Cl_2{}^{193}IrN_2SP_2$: 900; observed: 863 ($M^+$ − HCl − H), 823 (M^+ − $SC(NH_2)_2$ − H). Anal. calcd. for $C_{37}H_{71}Cl_2IrN_2SP_2{\cdot}CH_3OH$: C 48.9, H 8.1, N 3.0; found: C 48.6, H 8.2, N 3.1. **2***b* (light yellow solid, 100% yield): ^1H NMR (CD_2Cl_2, 20°C) δ: −24.4 (br, 1H), 1.0–3.0 (m, C_6H_{11}). ^1H NMR (CD_2Cl_2, −40°C) δ: −24.4 (t, $^2J_{HP}$ = 25.9 Hz, 1H). ^{31}P NMR δ: −6.2 (s). Anal. calcd. for $C_{36}H_{70}Cl_2IrNP_2$: C 51.4, H 8.4, N 1.7; found: C 51.2, H 8.6, N 1.6. **2***c* (light yellow solid, 100% yield): ^1H NMR (CD_2Cl_2, 20°C) δ: 3.83 (br, $IrNH_2NH_2$, 2H), 5.01 (br, $IrNH_2NH_2$, 2H), −24.1 (br, Ir-H, 1H). ^1H NMR (CD_2Cl_2, −40°C) δ: −24.1 (t, $^2J_{HP}$ = 25.9 Hz, 1H). ^{31}P NMR δ: −6.5 (s). FAB MS: calcd. for $C_{36}H_{71}{}^{35}Cl_2{}^{193}IrN_2P_2$: 856; observed: 819 ($M^+$ − HCl − H). Anal. calcd. for $C_{36}H_{71}Cl_2IrN_2P_2$: C 50.5, H 8.4, N 3.3; found:

X-ray crystal structure determination of 2*b*

A summary of selected crystallographic data for **2*b*** is given in Table 1. Crystals were prepared by slow diffusion of methanol into a THF (2 mL) solution of complex **2*b*** (50 mg) under 1 atm (101.3 kPa) Ar. A suitable pale yellow crystal was mounted on a glass fiber. Data were collected on an Siemens P4 diffractometer using graphite-monochromated MoKα radiation (λ = 0.71073 Å). The intensities of three standard reflections measured every 97 reflections showed no decay. The data were corrected for Lorentz and polarization effects and for absorption (20).

The structure was solved using the SHELXTL PC V5.0 (21) package and refined by full-matrix least squares on F^2 using all data (negative intensities included). The weighting scheme was $w = 1/[\sigma^2(F_o^2) + (aP)^2 + bP]$ where $P = (F_o^2 + 2F_c^2)/3$. Hydrogen atoms were included in calculated positions and

Fig. 2. The molecular structure of **2*b*** as determined by single crystal X-ray diffraction at 173 K.

treated as riding atoms. The hydride atom was refined with an isotropic thermal parameter. The hydrogen atoms of the -NH_3 group were visible from a difference Fourier map as a torus of electron density and these atoms were included in the refinement as six half-occupancy H atoms riding on N. The structure contains three THF molecules of solvation and in one of these molecules the oxygen is disordered over two sites (0.76/0.24). The structure of **2*b***, including the crystallographic labelling scheme, is shown in Fig. 2. Selected bond lengths and angles are listed in Table 2. A complete set of crystallographic tables have been deposited as supplementary material.[3]

Results and discussion

Synthesis

The yellow, air-sensitive complexes $RuCl(CO)H(L)(PPr^i_3)_2$ (**1*a***, L = NH_2NH_2; **1*b***, L = NH_3) can be obtained by reaction of $RuH(Cl)(CO)(PPr^i_3)_2$ with an excess of hydrazine (90% aq.) or amine (30% aq.) in toluene. There are a total of three possible isomers of the complexes **1** when the two bulky phosphine ligands stay in *trans* positions (Fig. 3). The ^{1}H and ^{31}P NMR spectra of $RuH(Cl)(CO)(NH_3)(PPr^i3)_2$ **1*b*** show three different hydride and ^{31}P resonances in a 10:1:1 ratio by integration corresponding to three isomers. The exact assignments are not certain. The ^{1}H and ^{31}P NMR spectra of the complex **1*a*** have only two hydride resonances at −14.5 and −15.7 ppm and ^{31}P

[3] Copies of material on deposit may be purchased from: The Depository of Unpublished Data, Document Delivery, CISTI, National Research Council Canada, Ottawa, Canada K1A 0S2. With the exception of thermal parameters, these data have also been deposited with the Cambridge Crystallographic Data Centre, and can be obtained on request from the Director, Cambridge Crystallographic Data Centre, University Chemical Laboratory, 12 Union Road, Cambridge, CB2 1EZ, U.K. Structure factor amplitudes are no longer being deposited and may be obtained directly from the author.

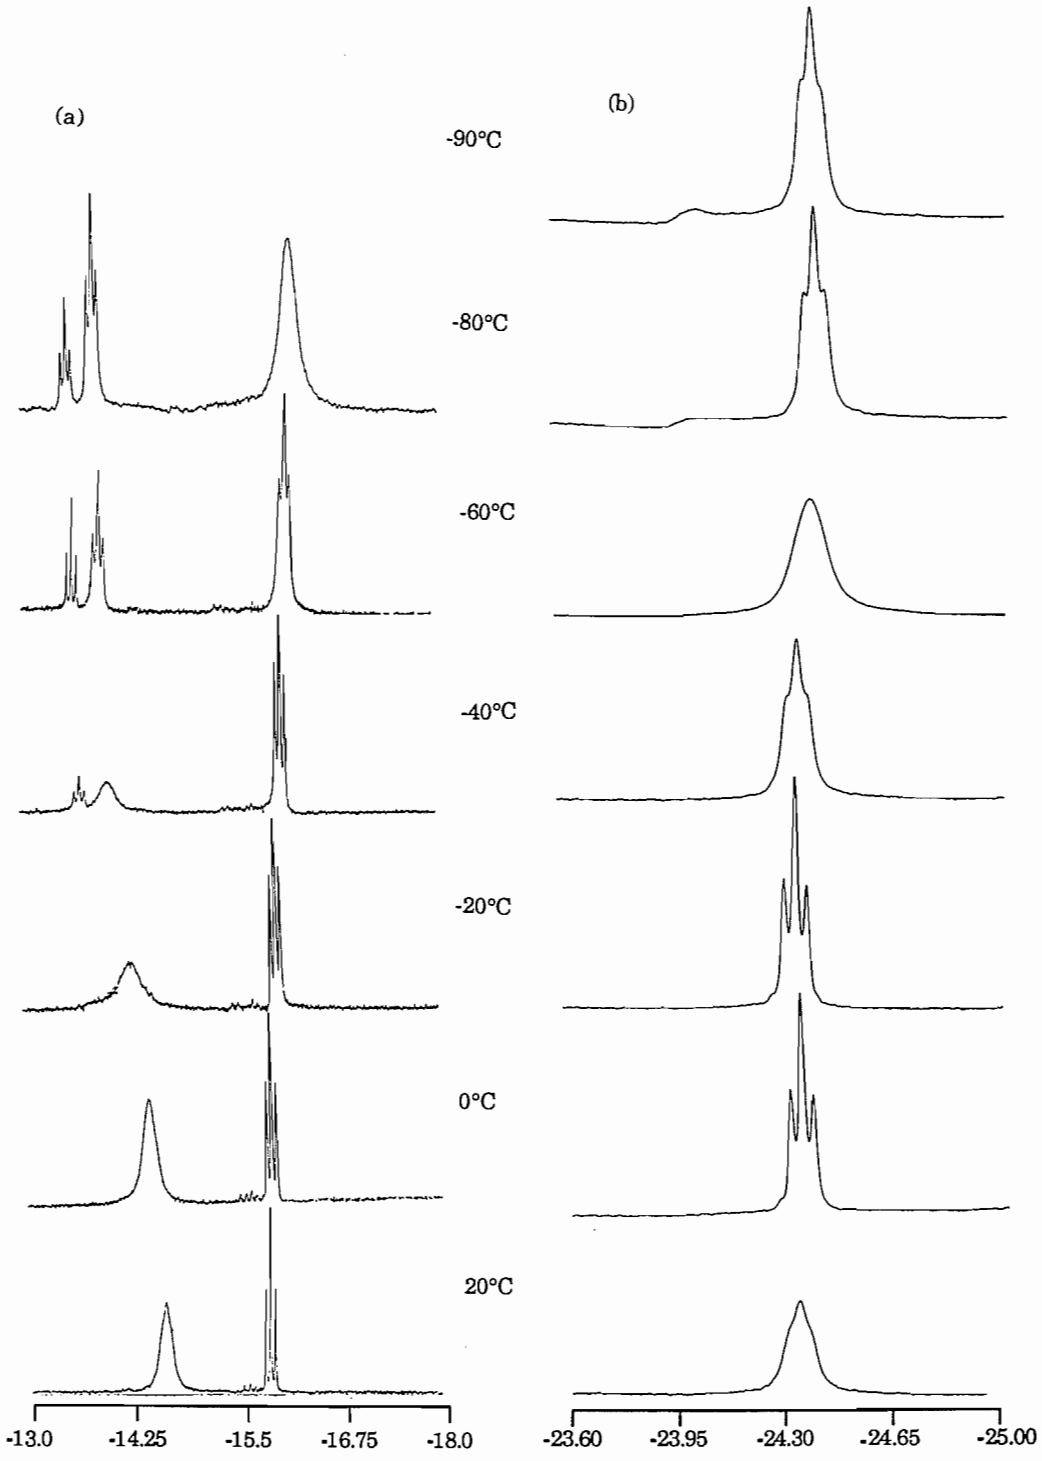
resonances at 45.6 and 43.0 ppm in a 2:1 ratio at room temperature. The broad peak at −14.5 ppm in the ^{1}H NMR spectrum splits into two triplets at −80°C (see Fig. 4(*a*)). Therefore there appear to be three isomers of this complex as well. However, we do not have a definitive explanation for the spectral changes that occur with the change in temperature.

The air-stable iridium derivatives $IrH(Cl)_2(L)(PCy_3)_2$ (**2***a*, L = $(NH_2)_2CS$; **2***b*, L = NH_3; **2***c*, L = NH_2NH_2; **2***d*, L = $NH_2(CH_2)_3NH_2$; **2***e*, L = NH_2OH) were prepared by the addition of excess L to a toluene suspension of $IrH(Cl)_2(PCy_3)_2$. There are two possible isomers for the complexes **2** (see Fig. 3). The ^{1}H and ^{31}P NMR spectra of complex **2***a* do show two different hydride and ^{31}P resonances in approximately equal amounts at room temperature. Complexes **2***b–d* have one broad hydride resonance in the ^{1}H NMR spectrum and one singlet in the ^{31}P NMR spectrum. The broad hydride resonance becomes a sharp triplet at temperatures of less than 0°C. The broadening is apparently caused by the dissociation and reassociation of the ligand L, which is labilized by a high *trans*-influence ligand, probably the hydride. The structure determination of crystalline **2***b* (see below) confirms that the ammine is *trans* to hydride. A broad triplet is observed for the hydride resonance of **2***e* at 20°C.

The hydride resonance of **2***b* in CD_2Cl_2 as a function of temperature is shown in Fig. 4(*b*). At least two exchange processes are apparent. The sharpening of the peak with cooling to around 0°C is probably due to the slowing of dissociation of the NH_3 ligand. The resonance for the five-coordinate product of this reaction is not visible in the ^{1}H NMR spectrum at low temperature and this indicates that the equilibrium greatly favors the six-coordinate complex **2***b*. There is no evidence for an isomer with ammine *cis* to hydride. In contrast, the complex $Ir(H_2)H(Cl)_2(P^iPr_3)_2$ is thermodynamically more stable with the π-acid dihydrogen ligand located *cis* to the hydride (22). A second broadening and then decoalescence occurs as the temperature is lowered below −60°C. The triplet at −24.4 ppm reappears along with an incompletely decoalesced, small, broad signal at −24.0 ppm. This might be due to the cyclohexyl groups taking up preferred positions in the complex, with the major species at −24.4 ppm having the conformation observed in the solid state (see the crystal structure presented below). No other isomers of **2***c–e* have been observed at low temperatures.



The complexes $IrH(Cl)_2(PCy_3)_2(OCMeNMe_2)$ and $IrH(Cl)_2(PCy_3)_2(CO)$ with structures related to those of **2** have been reported (18). The first complex, which was only characterized as a solid, appears to exist as one isomer since only one IR absorption due to CO stretching is observed. The second complex formed as the isomer with *trans* PCy_3 groups and CO *trans* to hydride in the reaction of $IrH(Cl)_2(PCy_3)_2$ with CO. This compound, with a structure similar to **2***b*, isomerized to a second isomer and also eliminated HCl to give *trans*-$IrCl(CO)(PCy_3)_2$. Complexes **2** in solution do not readily eliminate HCl considering that they are prepared in the presence of excess amine base. Complexes **2***a* and **2***c* do appear to eliminate HCl in the gas phase under the conditions of FAB mass spectroscopy.

X-ray analysis of complex 2*b*

The X-ray diffraction study at 173 K reveals that the iridium atom of **2***b* is in a distorted octahedral environment surrounded by two *trans* PCy_3 ligands, two *trans* chlorine atoms, and one ammine *trans* to the hydride. Selected bond lengths and angles are listed in Table 2. The two tricyclohexylphosphine ligands are bent toward the hydride (P-Ir-P, 164.28(3)°). The Ir-H hydride and hydrogens on cyclohexyl groups are well defined in electron difference maps. The iridium–hydride distance of 1.49(4) Å is reasonable on the basis of distances determined by neutron diffraction studies (23). Interestingly, two cyclohexyl groups tilt toward the hydride and their four H-C protons embrace the Ir-H hydride with close CH···H(Ir) distances that fall between 2.21(1) and 2.35(1) Å (Fig. 5). Similarly the CH···HN distances from six hydrogens on two half-occupancy ammine ligands to cyclohexyl hydrogens in the structure have short contacts of 2.0–2.4 Å. Considering that the van der Waals radius of hydrogen is about 1.2 Å (24), these contacts, at less than twice this radius, might be weakly attractive. Such MH···HC interactions might be energetically favorable considering that CH···O (H···O at 2.1–2.4 Å) hydrogen bonds have been confirmed by neutron diffraction

studies, and that NH···HIr (H···H at 1.7 Å) interactions have also been shown to be surprisingly strong (11). However, a more likely interpretation is that these short contacts are enforced by the steric bulk of the tricyclohexylphosphine ligands.

NMR studies

Complexes **1** and **2** were tested for the presence of intramolecular NH···HM or OH···HM interactions by use of ^{1}H NMR nOe difference experiments. Irradiation of the hydride resonance did not produce an enhancement in the NH resonance of

Complexes	$T_{1\,min}$ s, IrH (Temp. K)	Calcd. $d_{CH\cdots HM}$ (Å)	nOe enhancement (%) of hydride
1*a*	0.17 ± 0.01 (183)[a]	2.0	12.5
2*b*	0.23 ± 0.01 (213)	2.1	13.5
2*c*	0.22 ± 0.01 (223)	2.1	11.5

[a]δ(H) −15.6.

Fig. 5. Part of the molecular structure of **2***b* showing the CH···HIr interactions. The non-interacting cyclohexyl groups are omitted for clarity.

any of the complexes. However, weak CH···HM interactions, as observed in the complex **2***b* by X-ray analysis, are detectable in ^{1}H NMR nOe difference experiments.

Selective irradiation of the hydride resonance of **2***b* leads to an nOe enhancement of C-H proton resonances at 1.8 and 1.9 ppm, but the magnitude of specific interactions could not be calculated due to the large number of non-interacting protons of the cyclohexyl groups that appear in the same region of the ^{1}H NMR spectrum. When the whole region of cyclohexyl resonances is saturated, an nOe enhancement of the hydride signal of over 10% is observed. The hydride of **2***b* has an unusually short minimum T_1 value of 0.23 s at 400 MHz and 213 K that is caused by the presence of CH···HIr interactions. An average H···H distance from the hydride to the closest H-C groups is calculated to be 2.1 ± 0.1 Å when the rate of dipole–dipole relaxation of the hydride is assumed to be made up of contributions from four cyclohexyl protons. The distance estimated by the T_1 method is slightly less than the average H···H distance revealed by the X-ray structure analysis.

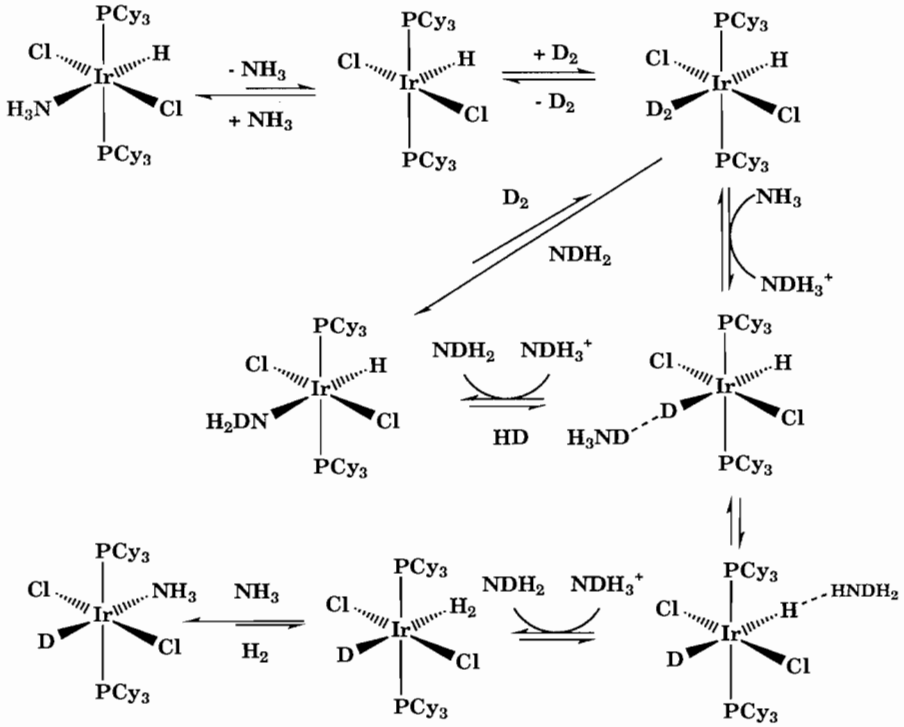
The same CH···HM interactions have been observed for the other complexes **1** and **2** in solution. The T_1 and nOe data for selected complexes are listed in Table 3. In each case the minimum T_1 value can be interpreted in terms of a structure containing four CH···HM at 2.0–2.1 Å.

H/D exchange study

When a solution of complex **2***b* in CD_2Cl_2 is exposed to D_2 (1 atm), slow H–D exchange at the ammine and hydride sites is observed by use of ^{2}H NMR. The NH protons exchange with D_2 faster than does the hydride. After 24 h ca. 90% of both (N)H and (Ir)H positions have been deuterated. Since the dihydrogen complexes *trans*- and *cis*-$Ir(H)(H_2)Cl_2(PPr^i_3)_2$ (23, 25, 26) have been reported, it is quite possible that the deuteration is initiated by a short-lived, dideuterium intermediate *trans*-$Ir(H)(D_2)Cl_2(PCy_3)_2$, in spite of the fact that no trace of this complex or the H_2 analogue in solution is detected by NMR spectroscopy. The fast exchange between the acidic dideuterium ligand and the active protons of amines could result in the deuteration as suggested in Scheme 1 (5). The slower H–D exchange of the hydride might involve an initial intermolecular interaction between *trans*-$[Ir(H)_2(Cl)_2(PCy_3)_2]^-$ and NH_3D^+ as indicated. The CH···HIr interactions might make this exchange a slower process than expected because of steric interactions.

^{2}H NMR experiments indicate that the deuteration not only occurs at the hydride and ammine sites, but also at the cyclohexyl groups. When the amine ligand dissociates from complex **2***b* to generate a 16-electron intermediate, certain CH bonds could coordinate to the metal (27). Coordination of the CH bond makes it acidic and susceptible to proton exchange with the deuterated ammine as proposed in Scheme 2. An intramolecular example of H–D exchange between ammine and C—H bonds has also been reported (28) but the stereochemistry of the complexes involved is different than that of **2***b*. Another possible mechanism could involve the oxidative addition of carbon–hydrogen bonds of cyclohexyl groups to the complex $IrCl(PCy_3)_2$ (29). The latter complex might be produced from **2***b* by reductive elimination of NH_4Cl but we do not have evidence to support this idea.

Conclusions



X-ray structural analysis and minimum T_1 and nOe techniques have revealed the presence of short CH···HM van der Waals contacts in complexes **1** and **2**. The H···H distances of 2.1–2.3 Å are less than the sum of the van der Waals radii of two hydrogens (2.4 Å), which might suggest that these interactions are favorable and might be similar to other hydrogen bonds formed by C-H hydrogen bond donors. However even in the absence of attractive interactions, the bulky cyclohexyl groups will probably occupy positions close to the small and polarizable hydride ligand for steric reasons alone. Therefore caution

Scheme 1.

Scheme 2.

is needed in claiming that CH···HM bonding is present because the size of van der Waals contact distances might vary depending on the steric pressures around the complex. Certainly the contributions of ligand hydrogens to hydride relaxation can be quite important, as suggested previously (8). Tricyclohexylphosphine ligands, when *cis* to a hydride, are likely to make a significant contribution to the relaxation. Such CH···H(Ir) interactions may also play an important role in H–D exchange and CH bond activation reactions. After the submission of this work, Crabtree's group reported that, on the basis of a survey of the Cambridge Crystallographic Database, CH...HM contacts (1.6–2.1 Å) commonly occur between arene CH bonds of phosphine ligands and hydride ligands and that such weak hydrogen bonds might influence the mechanism of cyclometallation of arenes (30).

No intramolecular NH···HIr interactions were observed for complexes **1** and **2**. Such interactions have been observed for ligands that can form six-membered HMXYZH rings. Only the thiourea ligand has the correct geometry to form such a ring; all the other amines would have to form four- (NH_3), five- (NH_2NH_2), or eight- ($NH_2CH_2CH_2CH_2NH_2$) membered rings. Thiourea and the other ligands might form stronger hydrogen bonds to the chloride ligand than to the hydride in these complexes.

Spectroscopic and thermochemical investigation of alkaline earth metal salts of 2-oximinopropionate

A.W. Apblett, G.D. Georgieva, and J.T. Mague

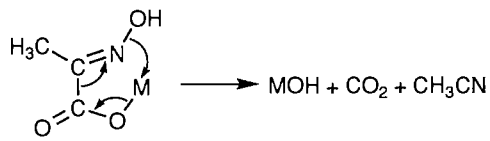
Abstract: Alkaline earth metal 2-oximinopropionates were prepared by the reaction of sodium 2-oximinopropionate with the respective metal nitrates or chlorides in water at room temperature. These compounds were characterized by infrared and multinuclear NMR spectroscopy and thermogravimetric analysis. The thermal decomposition of the salts occurs in the range 144–188°C and exhibits a trend towards lower temperature with increasing size of the cation. In all cases, the decomposition yields a metal carbonate. The molecular structure of calcium 2-oximinopropionate hydrate was determined by single-crystal X-ray crystallography. Crystal data: $C_6H_{10}N_2O_7Ca$, MW = 262.24 g/mol, triclinic, space group $P\bar{1}$ (No.2), a = 8.954(1) Å, b = 9.3851(7) Å, c = 6.2445(7) Å, α = 97.209(8)°, β = 104.917(9)°, γ = 87.250(8)°, V = 503.0(2) Å^3, Z = 2, D_{calc} = 1.73 g cm^{-3}, R = 0.03 and R_w = 0.04.

Key words: crystal structure, alkaline earth, 2-oximinopropionate, thermal decomposition.

Résumé : On a préparé les 2-oximinopropionates de métaux alcalino-terreux par réaction du 2-oximinopropionate de sodium avec les nitrates (ou les chlorures) métalliques appropriés, en solution aqueuse, à la température ambiante. On a caractérisé ces composés par spectroscopies infrarouge et RMN multinucléaire et par analyse thermogravimétrique. La décomposition thermale de ces sels se produit entre 144 et 188°C; cette température diminue avec une augmentation de la grosseur du cation. Dans tous les cas, la décomposition conduit à un carbonate métallique. La structure moléculaire de l'hydrate du 2-oximinopropionate de calcium a été déterminée par diffraction des rayons X sur un cristal unique. Les cristaux de $C_6H_{10}N_2O_7Ca$, PM = 262,24 g/mol, sont tricliniques, groupe d'espace $P\bar{1}$ (No.2), avec a = 8,954(1), b = 9,3851(7) et c = 6,2445(7) Å, α = 97,209(8)°, β = 104,917(9)° et γ = 87,250(8)°, V = 503.0(2) Å^3, Z = 2, D_{calc} = 1,73 g cm^{-3}, R = 0,03 et R_w = 0,04.

Mots clés : structure cristalline, alcalino-terreux, 2-oximinopropionate, décomposition thermique.

[Traduit par la rédaction]



Introduction

Salts of 2-oximinopropionate or pyruvic acid oxime (PAO) are promising candidates for use as low-temperature precursors for metal oxide ceramics (1, 2). These compounds undergo a low-temperature decomposition to yield acetonitrile, carbon dioxide, water, and a metal carbonate, oxide, or hydroxide depending on the nature of the metal (Scheme 1). Typically, these salts are readily prepared via ligand exchange reactions of a metal chloride or nitrate with sodium pyruvic acid oxime (NaPAO). Since most PAO salts of multivalent elements are sparingly soluble in water, this approach generally leads to the ready isolation of the PAO complexes as a precipitate or well-formed crystals.

Very few structural studies of metal PAO complexes have been reported. Previous reports have described the complexation of Cu(II), Ni(II), Co(II), Mn(II), Cr(III), Co(III), Zn(II), and alkali metals with PAO (3–5). However, the only crystal structures reported were for the complexes NaPAO (5) and [BH][M(HL)L] (M = Cu, B = pyridine and M = Co, B = imidazole) where HL is the PAO anion while L is the dianion of PAO in which both the carboxylate and the oxime are deprotonated (6, 7).

The thermal instability of 2-oximinocarboxylate complexes has been remarked upon in previous studies and they have been used for quantitative determination of Cu(II) ions via their precipitation from solution and subsequent pyrolysis to CuO (8). Similar reactions have also been used to prepare metal oxide ceramics (1, 2) and catalysts (9). As well, the thermal decomposition of 2-oximinocarboxylic acids is a useful synthetic route for the preparation of functionalized nitriles (10).

In this investigation, the thermal behavior of the alkaline earth metal salts of pyruvic acid oxime has been determined. The results of this study as well as the spectroscopic characterization of the complexes and the crystal structure of $Ca(PAO)_2\cdot(H_2O)$ are reported herein.

Experimental

Sodium pyruvic acid oxime was prepared by treatment of sodium pyruvate with hydroxylamine using a procedure described in a related paper concerning Group 1 2-oximinopropionates (5). $MgCl_2\cdot 6(H_2O)$, $CaCl_2\cdot 2(H_2O)$, $Sr(NO_3)_2$, and $BaCl_2\cdot 2(H_2O)$ were commercial reagents and were used without further purification. Water was distilled and deionized before use. Infrared spectra were obtained as KBr pellets on a Mattson Cygnus 100 FT-IR spectrometer. ^1H and $^{13}C\{^1H\}$ NMR spectra were recorded on either a GE 400 NMR spectrometer or Bruker AC 200 spectrometer and were referenced to TMS. Solid state ^{13}C CPMAS spectra were recorded on a Bruker DSX 300 spectrometer and are referenced to TMS using a hexamethylbenzene secondary standard. Thermogravimetric studies were performed using 20–30 mg samples in a Seiko TG/DTA 220 instrument under a 100 mL/min flow of dry air. The temperature was ramped from 25°C to 625°C at a rate of 2°C per min while the off-gases were analyzed on a Fisons Thermolab mass spectrometer. Bulk pyrolyses at various temperatures were performed in ambient air in a temperature-programmable muffle furnace using ca. 2 g samples, a temperature ramp of 5°C/min, and a hold time of 12 h. X-ray powder diffraction patterns were obtained on a Scintag XDS 2000 diffractometer using copper K_α radiation. Microanalysis for C, H, and N content was performed by Oneida Research Services or Tulane's Coordinated Instrument Facility.

Preparation of $Mg(PAO)_2\cdot 2(H_2O)$

A solution of $MgCl_2\cdot 6(H_2O)$ (2.03 g, 10.0 mmol) in 25 mL of water was added to a solution of $NaPAO\cdot(H_2O)$ (3.30 g, 23.0 mmol) in 25 mL of H_2O. The resulting solution gradually precipitated a white solid. After 48 h, the solid was filtered off, washed with water (2 × 10 mL) and acetone (3 × 10 mL), and then air dried to provide a yield of 1.89 g (72%) of $Mg(PAO)_2\cdot 2(H_2O)$, mp (dec.) 188°C. IR (cm^{-1})(KBr): 3448(s, br), 3399(s, br), 3041(s, br), 2906(s), 2812(s, br), 2283(m), 1750(m, sh), 1674(m, sh), 1674(s), 1647(s), 1483(s), 1394(s), 1367(s), 1219(s), 1045(s), 925(w), 858(s), 769(s, sh), 752(s), 744(m), 686(m), 553(m). ^1H NMR (d_6-DMSO) δ(ppm): 1.87(s, 3H, CH_3), 12.79(br s, ^1H, NOH). $^{13}C\{^1H\}$ NMR (d_6-DMSO) δ(ppm): 11.1 (CH_3), 152.8 (C═N), 167.2 (COO). Anal. calcd. for $C_6H_{12}N_2O_8Mg$ (%): C 27.25, H 4.57, N 10.59; found: C 27.42, H 4.45, N 10.42.

Preparation of $Ca(PAO)_2\cdot(H_2O)$

$Ca(PAO)_2\cdot(H_2O)$ was obtained as large white cubic crystals from the reaction of a solution of $CaCl_2\cdot 2(H_2O)$ (7.35 g, 50.0 mmol) in 50 mL of water with a solution of $NaPAO\cdot(H_2O)$ (14.30 g, 100.0 mmol) in 50 mL of H_2O. Filtration followed by washing with water (2 × 25 mL) and acetone (3 × 25 mL) and then drying in vacuo yielded 11.07 g (81%) of $Ca(PAO)_2\cdot(H_2O)$, mp (dec.) 165.6°C. CHN IR (cm^{-1})(KBr): 3422(s), 3249(s, sh), 3069(s, sh), 2992(m, sh), 2858(m, sh), 1675(s), 1640(s, sh), 1617(s), 1596(s, sh), 1465(s), 1418(m), 1389(m), 1364(m), 1256(m), 1216(s), 1109(m), 1038(s, sh), 1021(s), 980(w), 873(m), 846(m), 814(w), 780(m), 737(s), 617(s), 552(w), 470(w), 424(w). ^1H NMR (d_2O) δ(ppm): 1.83(s, 3H, CH_3), $^{13}C\{^1H\}$ NMR (d_6-DMSO) δ(ppm): 11.0 (CH_3), 153.0 (C═N), 166.1 (COO). Anal. calcd. for $C_6H_{10}N_2O_7Ca$ (%): C 27.48, H 3.84, N 10.66; found: C 27.40, H 3.84, N 10.75.

Preparation of $Sr(PAO)_2$

A solution of $Sr(NO_3)_2$ (6.33 g, 30.0 mmol) in 25 mL H_2O was added to a solution of $NaPAO\cdot(H_2O)$ (8.58 g, 60.0 mmol) in 50 mL of water. Immediate precipitation of a white solid occurred. After 12 h, the precipitate was isolated by filtration and was washed with water (2 × 25 mL) and acetone (3 × 25 mL). Drying in vacuo yielded 7.02 g (80%) of $Sr(PAO)_2$, mp (dec.) 156°C. IR (cm^{-1})(KBr): 3261(s, br), 3131(s, sh), 2945(s, sh), 2696(w), 1658(m, sh), 1674(s), 1594(s), 1479(s), 1393(s), 1358(s), 1203(s), 1023(s), 973(m), 945(m), 843(s), 727(s), 689(m, sh), 549(w). ^1H NMR (D_2O) δ(ppm): 1.85(s, 3H, CH_3). $^{13}C\{^1H\}$ NMR (D_2O) δ(ppm): 11.9 (CH_3), 156.8 (C═N), 171.8 (COO). Anal. calcd. for $C_6H_8N_2O_6Sr$ (%): C 24.70, H 2.76, N 9.60; found: C 24.76, H 2.83, N 9.75.

Preparation of $Ba(PAO)_2$

$Ba(PAO)_2$ was obtained as a white precipitate from the reaction of $BaCl_2\cdot 2(H_2O)$ (7.32 g, 30.0 mmol) in 50 mL of water with a 50 mL aqueous solution of $NaPAO\cdot(H_2O)$ (8.58 g, 60.0 mmol). After 12 h, the solid was isolated by filtration and was washed with water (2 × 25 mL) and acetone (3 × 25 mL). Drying in vacuo yielded 7.84 g (77%) of $Ba(PAO)_2$, mp (dec.) 144°C. IR (cm^{-1})(KBr): 3553(m, sh), 3474(s, sh), 3415(s), 3257(m, sh), 2929(m, br), 1684(s, sh), 1617(s), 1576(s), 1541(s), 1457(s), 1385(s), 1232(m), 1013(s), 842(m), 784(m), 748(m), 729(w), 689(m), 627(w), 518(w). ^1H NMR (D_2O) δ(ppm): 1.83(s, 3H, CH_3). $^{13}C\{1H\}$ NMRn (d_6- DMSO) δ(ppm): 11.7 (CH_3), 154.6 (C═N), 167.7 (COO). Anal. calcd. for $C_6H_8N_2O_6Ba$ (%): C 21.10, H 2.36, N 8.20; found: C 21.03, H 2.41, N 8.33.

X-ray structure determination of $Ca(PAO)_2\cdot(H_2O)$

Crystals of $Ca(PAO)_2\cdot(H_2O)$ suitable for X-ray analysis were obtained by slow evaporation of a saturated aqueous solution. A colorless crystal measuring 0.2 × 0.2 × 0.33 mm was mounted on a thin glass fiber and coated with a thin film of epoxy cement. General procedures for crystal alignment, unit cell determination, and data collection on the CAD4 diffractometer have been published (11) and details of the present study appear in Table 1. No higher symmetry than triclinic was indicated by the CAD4 software or by a check of the Laue symmetry of several reflections of medium to strong intensity. The consequent choice of $P\bar{1}$ as the space group was confirmed by the successful refinement. The data were corrected for Lorentz and polarization effects, for a 2.3% linear decay in intensity monitors, and for absorption using ψ scans on several reflections with χ near 90°. The calcium atom was readily located from an origin-removed Patterson map and the remainder of the structure developed by successive cycles of full-matrix, least-squares refinement followed by difference Fourier synthesis (12). Neutral atom scattering factors include correction for the real and imaginary effects of anomalous

[d]GOF $= [\Sigma w(||F_o| - |F_c||)^2/(N_o - N_v)]^{1/2}$ where N_o and N_v are, respectively, the number of observations and variables.

dispersion.[2] Towards the end of the refinement, all hydrogen atoms could be located in a difference map. Those of the methyl groups were placed in idealized positions with isotropic thermal parameters 20% larger than the attached carbon atoms and updated periodically while those attached to oxygen were refined with fixed, isotropic thermal parameters 20% larger than the respective oxygen atoms. The final difference map was essentially featureless (residual peaks 0.29 to −0.32 e/Å^3). Bond distances are given in Table 2, and bond angles are provided in Table 3.[3]

Results and discussion

Synthesis of alkaline earth metal PAO salts

The alkaline earth metal salts of pyruvic acid oxime may be readily prepared by reaction of aqueous solutions of the metal ions with an aqueous solution of sodium pyruvic acid oxime (NaPAO) (eq. [1]). Since the Group 2 salts are sparingly soluble, they are readily isolated as precipitates from this reaction. However, since these salts do have a finite solubility in water, the yields are less than quantitative (ca. 71–80%). The yields may be improved by concentrating the filtrate from the precipitation reaction but separation from the sodium nitrate or sodium chloride by-product becomes problematic.

Numbers in parentheses are estimated standard deviations in the least significant digits.

If the reaction is performed with less than a stoichiometric amount of NaPAO (e.g., one molar equivalent of NaPAO per metal ion), precipitation does not occur. Instead, slow growth of moderate-sized crystals happens over the course of several days. This may suggest that, under these conditions, complexes of the type $[M(PAO)]^+X^-$ form initially and these subsequently undergo ligand exchange with each other to yield the crystalline bis-PAO complexes (eq. [2]). Unfortunately, ^{13}C and ^1H NMR spectra of the reaction mixtures display only one set of resonances due to a single PAO environment that are not significantly different from those of the isolated bis-PAO salts. Thus, the presence of mono-PAO complexes has not been conclusively demonstrated.

[a]From ref. 5.
[b]From ref. 3.

sharp contrast with the high solubility of the Group 1 salts. This suggests that the alkaline earth salts are more polymeric than the alkali metal salts. The structure of $NaPAO \cdot (H_2O)$ was previously (5) found to be composed of chains of NaPAO five-membered metallocycles that are bridged by the carboxylate ions. The PAO ligand is bidentate and coordinates the sodium ions through the oxime nitrogen as well as one of the carboxylate oxygens. The crystal structure of the calcium bis(2-oximinopropionate) hydrate, $Ca(PAO)_2 \cdot (H_2O)$ (Fig. 1) reveals that much more extensive bridging in the solid state does occur for the calcium complex. The structure may be generally described as a three-dimensional polymer based on zigzag $Ca(PAO)_2$ units connected via the sharing of the carboxylate oxygen atoms between neighboring calcium atoms. The calcium ion is eight-coordinate (Fig. 2) with two of its coordination sites occupied by the oxime nitrogen and one of the carboxylate oxygen atoms from one of the PAO ligands. The so-formed N,O-chelate five-membered ring is similar to that observed in the NaPAO structure (5). The Ca—N(1) and Ca—O(1) bond distances are 2.503(2) and 2.513(1) Å, respectively, and are longer than those of the sodium derivative (2.440(2) and 2.490(2) Å, respectively (5)). The second PAO ligand coordinates as an O,O bidentate ligand through both oxygens of the carboxylate group to form a four-membered metallocycle. The Ca—O(4) and Ca—O(5) bond distances within the so-formed chelate are 2.451(1) and 2.557(1) Å, respectively. The inequivalency of these two bond lengths (approximately 0.1 Å) may be attributed to the fact that the O(5) oxygen atom also bridges to an adjacent calcium atom and is, therefore, three-coordinate. The bond distance for this oxygen atom to the second calcium atom, Ca—O(5)′, is 2.371(1) Å and is, therefore, even shorter than the Ca—O(5) bond length. The calcium–oxygen bond distances for the O, O-coordinated PAO ligand, Ca—O(4), Ca—O(5), and Ca—O(5)′, are similar to those found in calcium acetate monohydrate (2.450(2), 2.460(3), and 2.321(3) Å for the analogous bond distances) in which the carboxylate ligand is also coordinated as an O,O chelate through the carboxylate group (14). Two other coordination sites of the calcium ions in $Ca(PAO)_2 \cdot (H_2O)$ are occupied by bridging carboxylate oxygen atoms from PAO ligands coordinated as N,O chelates on two adjacent calcium centers, with the Ca—O(2) and Ca—O(1)′ bond distances being 2.465(1) and 2.387(1) Å. Each of the PAO ligands that form the N,O chelates in $Ca(PAO)_2 \cdot (H_2O)$ is linked to two other calcium centers via the oxygen atoms of its carboxylate group. One of these, the O(1)-type oxygen, bridges two calcium atoms in a similar fashion to O(5).

The coordination sphere of the calcium atom is completed by a solvent water molecule with the Ca—O(7) bond distance of 2.477(2) Å. This water molecule appears to be hydrogen-bonded to the nonbridging carboxylate oxygen atom and to the uncoordinated nitrogen atom of O,O-chelated ligands on adjacent formula units. Thus, the separation O(4)—H(7A)″ of the water molecule bound to Ca″ (Fig. 1) is 1.87(3) Å with an O(4)-H(7A)″-O(7) angle of 164(2)° while the separation N(2)—H(7B)′ of the water molecule bound to Ca′ (Fig. 1) is 1.94(3) Å with an N(2)-H(7B)′-O(7) angle of 172(3)°. In addition, the water molecule is hydrogen-bonded to the hydroxyl group O(6)—H(6) of an adjacent formula unit. Here the O(7)—H(6)′ separation is 1.90(3)Å with an O(7)-H(6)′-O(6)′ angle of 169(3)°.

Presumably, the other alkaline earth salts of PAO also display structures that are highly bridged. However, their X-ray powder diffraction patterns differ from that of $Ca(PAO)_2 \cdot (H_2O)$ and it may be concluded that they are not isomorphous although they may be isostructural.

Spectroscopic characterization of alkaline earth metal PAO salts

Several characteristic infrared vibrational frequencies of the PAO salts are summarized in Table 4. The assignment of these

[a]These chemical shifts were observed in dry d_6-DMSO and are attributable to the oxime protons and those of the waters of crystallization, which undergo rapid exchange.

frequencies is based on literature data for previously reported PAO complexes (3, 4) that utilized ^{15}N isotopic labelling to identify these bands. It may be noted that the IR bands of the alkaline earth PAO complexes more closely resemble those reported for the transition metal complexes than do those of NaPAO. One feature of the IR spectra of the PAO complexes is the significant lowering of the vibrational frequencies of the asymmetric carboxylate stretch by 49–102 cm^{-1} compared to that of the parent acid. These changes in this stretching frequency may be attributed to the deprotonation and delocalization of the negative charge in the carboxylate as well the coordination of the carboxylate to the metal centers and is typical for metal carboxylates (15). The $Ca(PAO)_2 \cdot (H_2O)$ salt displays two bands attributable to each of the asymmetric stretch and symmetric stretch of the carboxylate, reflecting the fact that there are two types of PAO ligand in the solid state. One set, ν_{as} = 1617 cm^{-1} and ν_s = 1386 cm^{-1}, may be assigned to the N,O-chelated PAO ligand due to their similarity to the frequencies of the nickel and sodium salts that contain the same type of chelate. The other set of vibrational frequencies, ν_{as} = 1640 cm^{-1} and ν_s = 1418 cm^{-1}, may then be assigned to the O,O-chelated PAO ligand. Remarkably, the split between ν_{as} and ν_s is approximately the same for the bridging carboxylate (231 cm^{-1}) and the chelating carboxylate (222 cm^{-1}). Usually, this difference is markedly larger for a bridging carboxylate versus a chelating one (16). In this case, the fact that a clear-cut difference is not observed may be due to the fact that the carboxylates are multiply-bridging. Indeed, the observed differences between ν_{as} and ν_s are comparable to those observed for bridging acetates (16).

The coordination of the nitrogen atom of the oximino

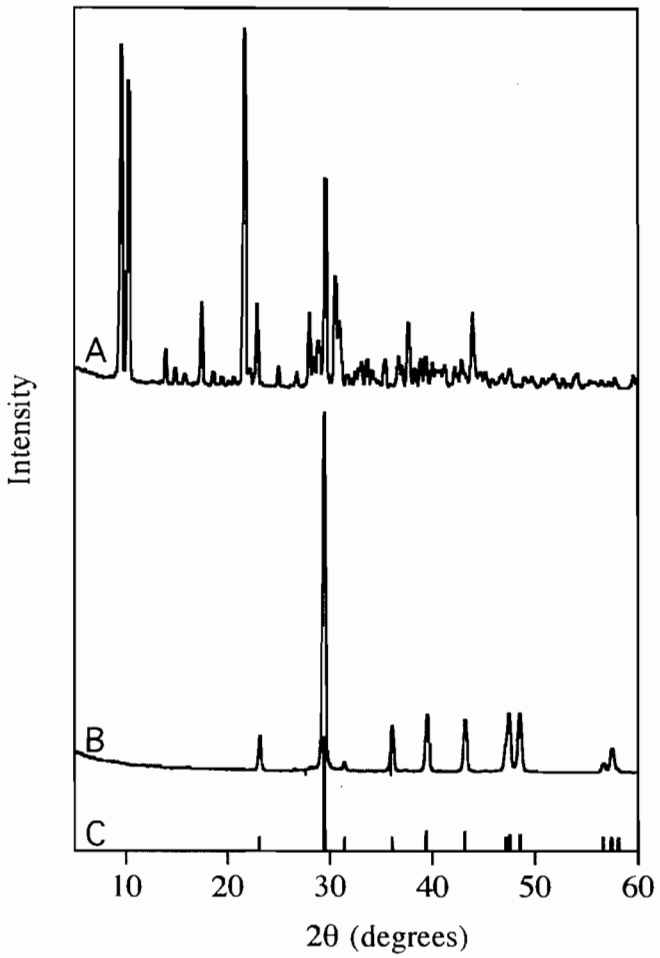
moiety in the PAO complexes of alkaline earth metals does not significantly affect the vibrational frequency corresponding to the C═N stretch, and is consistent with the data obtained in previous studies (3, 4). The vibrational frequencies attributable to the N-O stretch are lowered by 3–35 cm^{-1} in the Group 2 metal salts of PAO from that observed for the parent acid. This trend is opposite to that observed for transition metal derivatives of PAO, in which an increase in these frequencies was observed (3, 4) but is in the same direction as that observed for the alkali metal PAO salts (5). This difference may be a result of the weak coordination of the nitrogen atom of the oximino group in the alkali and alkaline earth metal salts, as indicated by the elongated Na—N and Ca—N bond distances in $NaPAO{\cdot}H_2O$ (5) and $CaPAO_2{\cdot}H_2O$. It is interesting to note that the frequency of the N-O stretch decreases almost linearly down the group. This phenomenon may be due to either the increase in size of the metal cations or the decrease in electronegativity as the group is descended.

The ^1H and ^{13}C NMR spectral data for these compounds are summarized in Table 6. The ^1H NMR spectra of the PAO salts in D_2O display a single resonance that may be attributed to methyl protons. The chemical shift for these protons is within the range of 1.83 to 1.87 ppm and are similar to those of the alkali metal salts (5). These chemical shifts are not significantly different from the corresponding one for the parent acid since the methyl protons are remote from the carboxylic acid moiety of the PAO ligand and are relatively unaffected by deprotonation. The ^{13}C NMR spectra of the PAO ligands are more indicative in terms of the changes in the local electron density in the ligand as a result of its deprotonation. As expected, the methyl carbon, with a chemical shift in the range 11.0–11.9 ppm, is less affected by the deprotonation and its signal is shifted only about 0.4–1.0 ppm downfield from the corresponding signal of the parent acid (10.7 ppm). The signals of the carbon atoms of the oximino and carboxylate groups undergo more significant downfield shifts from the parent acid upon removal of the proton (3.9–7.9 ppm for C═N and 0.1–11.8 ppm for COO). Since only one set of resonances is observed for $CaPAO_2{\cdot}(H_2O)$, it may be concluded that, as might be expected, the solid state structure is completely degraded upon dissolution in water. The degree of dissociation of individual $M(PAO)_2$ units in solution is difficult to assess but the significant variation of the chemical shifts of the various salts and their deviation from those of NaPAO (which is completely dissociated in water) suggest that complexation does occur to some degree.

The solid state ^{13}C NMR CPMAS spectrum of $CaPAO_2{\cdot}(H_2O)$, on the other hand, shows resolved peaks due to the two different carboxylates: 171.6 and 168.6 ppm for the carboxylate carbon, 153.5 ppm for the oxime carbon, and 12.1 and 11.4 ppm for the methyl protons. The corresponding resonances in NaPAO are 171.7, 153.5, and 12.2 (5). Due to the strong similarity to the NaPAO spectrum, the signals at 171.6 and 12.2 ppm may be assigned to the N,O-chelated PAO ligand while those at 168.6 and 11.4 may be attributed to the O,O-chelated ligand. Unfortunately, due to their high electronic asymmetry, the oxime carbons are broad and are unresolved.

Fig. 3. Thermogravimetric analysis (TGA) trace for $Ca(PAO)_2{\cdot}H_2O$ in dry air with a heating rate of 2°C/min.



Thermal behaviour of alkaline earth metal PAO salts

The thermogravimetric analysis of $Ca(PAO)_2{\cdot}(H_2O)$ (Fig. 3) exhibits two weight-loss steps. The lower temperature weight change with an onset at 63°C is endothermic and corresponds to the dehydration of the sodium salt. The second weight loss occurs at 166°C and is exothermic. Simultaneous analysis of the off-gases at this temperature by mass spectroscopy indicates that decomposition of the anion is occurring to yield the expected products: water, acetonitrile, and carbon dioxide. The metal-containing residue from this decomposition has a mass that corresponds to formation of calcium carbonate. The

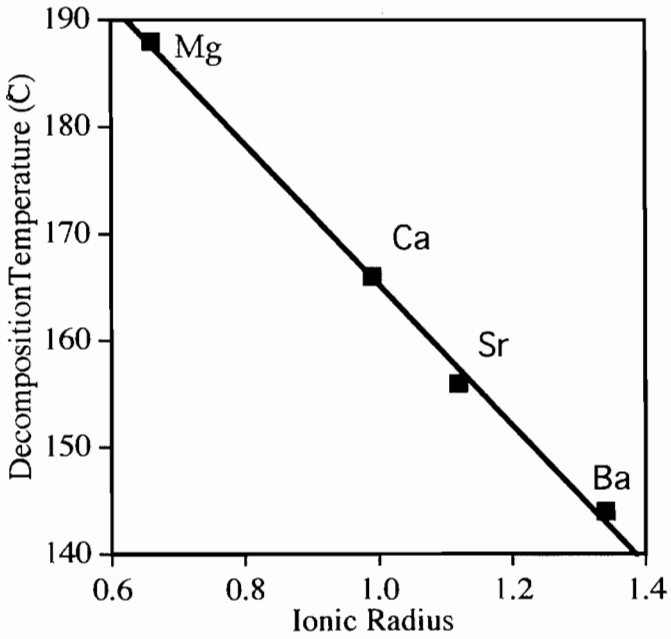
Fig. 4. X-ray powder diffraction patterns for: (*A*) $Ca(PAO)_2 \cdot H_2O$, (*B*) $Ca(PAO)_2 \cdot H_2O$ pyrolyzed at 200°C for 12 h, and (*C*) calcite.[4]



X-ray diffraction pattern of a bulk sample of $Ca(PAO)_2 \cdot (H_2O)$ pyrolyzed at 200°C (Fig. 4) confirms this identification since it matches that reported for calcite.[4]

The results of the thermal analysis of the other PAO salts were similar to that of the calcium salt with the exception of the barium and strontium salts, which do not exhibit a dehydration step since they do not contain waters of crystallization. Like the alkali metal salts, the thermal decomposition temperatures of the alkaline earth metal salts show a surprising decrease with increasing ionic radii of the metal ions (Fig. 5). This is contrary to the predictions of the ionic model based on lattice enthalpies for small cation/large anion lattice enthalpies (17). Indeed, the stabilities of the PAO salts follow a trend opposite to that observed for the alkaline earth metal carbonates. Typically, a failure of the ionic model is attributed to effects of covalent bonding. In the case of the PAO salts the ring strain in the five-membered metallocycles may account for the observed trend in decomposition points. Since the chelated ligand has a small bite angle, the ring strain should increase with increasing ionic radii of the cations and thus lead to destabilization of the complexes in accord with the observed

[4] Powder Diffraction File No. 05-0586. JCPDS (1995).

Fig. 5. Decomposition temperatures versus the ionic radius of alkaline earth metal PAO salts.

experimental data. However, a comparison of the decomposition temperatures of the Group 2 salts to those of the Group 1 salts with similar atomic radii shows that the alkaline earth salts are more stable and have decomposition temperatures 33–57°C higher than their alkali metal counterparts (Table 6). Again, this is contrary to the ionic model, which predicts that the decomposition of the salt with the more highly charged cation will occur at the lower temperature (17). Finally, it should be noted that the XRD patterns indicate that the salts are not isomorphous, so that the decomposition temperatures may also be affected to some degree by differences in the crystalline lattices.

Synthesis and characterization of the mixed valence Cu(I)/Cu(II) 3,5-bis(trifluoromethyl)-pyrazolate complex, $[Cu(II)_2Cu(I)(F_6dmpz)_5]$

Martin K. Ehlert, Alan Storr, David A. Summers, and Robert C. Thompson

Abstract: The reaction of molten 3,5-bis(trifluoromethyl)pyrazole (F_6dmpzH) with copper metal shot under an atmosphere of dioxygen yields the green trimetallic mixed valence $[Cu(II)_2Cu(I)(F_6dmpz)_5]$. Crystals of $[Cu(II)_2Cu(I)(F_6dmpz)_5]$ are triclinic, a = 9.0557(2), b = 9.6164(2), c = 11.8874(3) Å, α = 105.406(1)°, β = 112.317(1)°, γ = 90.662(1)°, Z = 1, space group $P\bar{1}$. The crystal structure was solved by direct methods and was refined by full-matrix least-squares procedures to a final R value of 0.0538 for 2591 reflections with $I \geq 2\sigma(I)$. Magnetic susceptibility studies over the range 2–300 K reveal strong antiferromagnetic exchange coupling between the two copper(II) centers. Fits of the magnetic data to the Bleaney–Bowers equation for two interacting S = ½ centers gives the exchange coupling constant $J = -235$ cm^{-1}.

Key words: trimetallic, copper, 3,5-bis(trifluoromethyl)pyrazolates, X-ray structure, antiferromagnetism.

Résumé : La réaction du 3,5-bis(trifluorométhyl)pyrazole (F_6dmpzH) avec du cuivre métallique projeté sous une atmosphère de dioxygène conduit à un complexe trimétallique vert de valence mixte, $[Cu(II)_2Cu(I)(F_6dmpzH)_5]$. Les cristaux du $[Cu(II)_2Cu(I)(F_6dmpzH)_5]$ sont tricliniques, groupe d'espace $P\bar{1}$, a = 9,0557(2), b = 9,6164(2), c = 11,8874(3) Å, α = 105,406(1)°, β = 112,317(1)°, et γ = 90,662(1)°, Z = 1. On a résolu la structure par des méthodes directes et on l'a affinée par la méthode des moindres carrés jusqu'à une valeur finale de R de 0,0538 pour 2591 réflexions avec $I \geq 2\sigma(I)$. Des études de susceptibilité magnétique à des températures allant de 2 à 300 K ont permis de mettre en évidence un important couplage d'échange antiferromagnétique entre les deux centres de cuivre(II). Un ajustement des données magnétiques à l'aide de l'équation de Bleaney–Bowers pour deux centres interagissant avec S = ½ permet de déterminer la constante de couplage d'échange, $J = -235$ cm^{-1}.

Mots clés : trimétallique, cuivre, 3,5-bis(trifluorométhyl)pyrazolates, structures, diffraction des rayons X, antiferromagnétisme.

[Traduit par la rédaction]

Introduction

Pyrazolate ligands have been used extensively in building polynuclear transition metal systems and this burgeoning field has recently been reviewed (1). Binary copper(II) pyrazolates and substituted pyrazolates have been shown to adopt structures in which the copper ions are doubly bridged by pyrazolate ligands to form extended linear chain polymers (2–5). The compounds show relatively strong antiferromagnetic coupling with values of J, the exchange coupling constant, in the range -58 to -105 cm^{-1}. These values vary with the substitution on the pyrazolate bridging ligands and attempts have been made to correlate structural variations with these numbers. An extension of these earlier studies to include the 3,5-bis(trifluoromethyl)pyrazolate, F_6dmpz^-, bridging ligand, with highly electron-withdrawing trifluoromethyl groups on the heterocyclic rings, is now reported. Interestingly the anticipated polymeric species, $[Cu(F_6dmpz)_2]_x$, was not obtained but instead the dark-green mixed Cu(I)/Cu(II) compound, $[Cu(II)_2Cu(I)(F_6dmpz)_5]$, was isolated. An X-ray structure determination of this complex shows the molecular unit to consist of a triangular arrangement of three copper ions held together by bridging pyrazolate ligands. The magnetic behaviour of the complex over the 2–300 K temperature range is discussed.

Experimental

3,5-Bis(trifluoromethyl)pyrazole, F_6dmpzH, was prepared by the method described by Trofimenko (6).

Synthesis of $Cu_3(F_6dmpz)_5$

Clean copper shot (1.954 g, 30.75 mmol) was mixed with F_6dmpzH (1.00 g, 4.90 mmol) and heated, without stirring, under an atmosphere of dioxygen at 95–105°C for 4 days (melting point of F_6dmpzH, 79–81°C). At the cessation of the reaction a dark-green material had formed. Excess F_6dmpzH

was sublimed from the product by heating at 60°C under vacuum and finally the dark-green compound was isolated by physical separation from the copper shot. Approximately 0.2 g of $Cu_3(F_6dmpz)_5$ was collected (71% yield based on amount of copper reacted). Anal. calcd. for $C_{25}H_5Cu_3F_{30}N_{10}$: C 24.91, H 0.42, N 11.62; found: C 25.01 H 0.42, N 11.68%.

$Cu_3(F_6dmpz)_5$ melts at 236°C without decomposition and is appreciably volatile at this temperature even at 1 atmosphere (101.3 kPa). It is soluble in dry solvents with a wide range of polarities but is very reactive towards water in solution, the initial green-coloured solution turning blue with the deposition of a purple solid. Upon prolonged exposure to moist air, the compound slowly changes to a purple material. All attempts to identify the purple decomposition product of $Cu_3(F_6dmpz)_5$ have been unsuccessful.

Spectroscopic studies

The electronic spectrum of a Nujol mull of $Cu_3(F_6dmpz)_5$ contained between quartz plates was obtained using a Varian Instruments Cary 5 UV / visible / NIR spectrophotometer. The spectrum consists of an asymmetric absorption band with a maximum at ~14 000 cm^{-1} with a shoulder to higher wave numbers.

An IR spectrum of a KBr pellet of the $Cu_3(F_6dmpz)_5$ was obtained using a Bomem MB-100 spectrometer. The broad band at ~3000 cm^{-1} attributed to the N-H function of the F_6dmpzH starting material was notably absent from the spectrum.

The low-resolution electron impact ionization spectrum of $Cu_3(F_6dmpz)_5$ was obtained using a Kratos MS50 mass spectrometer. The spectrum exhibits a parent ion peak, P^+, at *m/e* ~1206 along with strong signals due to ions arising from consecutive loss of two F_6dmpz ligands, L, from the parent species at *m/e* ~1003 ($P - L^+$) and *m/e* ~800, ($P - 2L^+$). The intensities of the individual lines in these multi-line signals are those expected from the presence of three Cu atoms and the naturally occurring isotopic abundance for the element.

Single crystal X-ray diffraction

Macroscopic well-formed crystals of $Cu_3(F_6dmpz)_5$ were prepared by sublimation of the bulk product under vacuum. Crystal data, data collection, and solution and refinement details are summarized in Table 1.

A single crystal of the compound was attached to a glass fiber and mounted on the Siemens SMART system for a data collection at 173 (2) K. Final cell constants were calculated from a set of 4018 strong reflections from the actual data collection.

The space group $P\bar{1}$ was determined based on systematic absences and intensity statistics.[2] A successful direct-methods solution was calculated that provided most non-hydrogen atoms from the *E*-map. Several full-matrix least-squares / difference Fourier cycles, which located the remainder of the non-hydrogen atoms, were performed. All non-hydrogen atoms were refined with anisotropic displacement parameters unless stated otherwise. All hydrogen atoms were placed in ideal positions and refined as riding atoms with relative ($1.2(U_{iso}$ host carbon)) isotropic displacement parameters.

The complex is disordered by fitting in two possible ways in the lattice. Two half-occupied complexes are related to each other by an inversion center. It is unusual for this to occur, but the criterion for this type of disorder exists with this complex. The equatorial plane contains three Cu atoms in the shape of an isosceles triangle. The two differing Cu···Cu nonbonded distances are due to the presence of one Cu(I) and two Cu(II) ions in the complex. Three F_6dmpz^- groups are equatorially bonded to the Cu atoms. The two Cu atoms in the +2 oxidation state are bridged by two additional F_6dmpz^- groups above and below the equatorial plane. A careful inspection shows that an inversion operation can place the CF_3 groups in the equatorial plane on top of the original ones. The backbones of the two axial F_6dmpz^- groups are superimposed when both images are overlayed. Therefore, regardless of which way the complex fits in the space it looks roughly the same to its environment. To make a more sensible result, 740 restraints were applied to the model. Ten pairs of atoms are close enough to each other to constrain the pairs to a single anisotropic displacement parameter. All F_6dmpz^- groups were restrained to similar bond lengths with the SHELXTL SAME restraint.[2]

Data collection and structure solution were conducted at the X-Ray Crystallographic Laboratory, 160 Kolthoff Hall, Chemistry Department, The University of Minnesota. All calculations were performed using SGI INDY R4400-SC or Pentium computers using the SHELXTL v5.0 suite of programs.

Final atomic coordinates and equivalent isotropic displacement parameters are given in Table 2 and selected bond lengths and angles appear in Tables 3 and 4, respectively. Anisotropic thermal parameters, torsion angles, hydrogen coordinates and isotropic displacement parameters, and least-square planes, together with tables of all bond distances and bond angles and a fully labeled molecular diagram are included as supplementary material.[3]

Magnetic susceptibility studies

Magnetic susceptibilities were measured using a Quantum Design (MPMS) SQUID magnetometer. The sample holder and procedures involving the use of the equipment were described previously (7). Magnetic susceptibilities were corrected for the background signal of the sample holder and for diamagnetic susceptibilities of all atoms (Cu^+, −14; Cu^{2+}, −11; F_6dmpz^-, −82). All corrections are in units of 10^{-6} cm^3mol^{-1}.

Susceptibility versus temperature behaviour (2 to 300 K) was measured at 1.0 and 2.0 T. Magnetization measurements at applied fields ranging from 0 to 5.5 T were made at 2, 50, 100 and 300 K.

Results and discussion

Attempts to prepare the binary copper(II) 3,5-bis(trifluoromethyl)pyrazolate polymer, $[Cu(F_6dmpz)_2]_x$, by the reaction of copper metal shot with 3,5-bis(trifluoromethyl)pyrazole under an atmosphere of dioxygen at ~100°C led to the formation of a dark-green material of composition $Cu_3(F_6dmpz)_5$. As this synthetic approach had led to the formation of polymeric materials with other pyrazolate ligands (2–5) it was somewhat surprising that no evidence of polymer formation was observed here. Infrared studies established that the green product was devoid of any residual N-H functionalities and mass spectral analysis showed the parent ion, P^+, cluster as the highest *m/e* signals in the spectrum, with strong signals arising from the ions resulting from the consecutive loss of two F_6dmpz ligands $P - L^+$ and $P - 2L^+$.

An X-ray crystal structure determination of well-formed crystals of $Cu_3(F_6dmpz)_5$ shows the three copper ions (two Cu(II) and one Cu(I)) to be arranged in an isosceles triangle with each side of the triangle being occupied by an exobidentate F_6dmpz^- ligand. The two Cu(II) ions, which form the short base of the triangle, are bridged by two additional F_6dmpz^- ligands, one above and one below the trigonal planar array. The molecular arrangement with a selected atom numbering scheme is shown in Fig. 1. The structural array adopted is similar to those arrangements found in the all Cu(I) trimers of formulas $[Cu(tmpz)]_3$ and $[Cu(dmpz)]_3$ (7, 8) with the significant difference arising from the two types of Cu ions found in the present structure. These differences are exemplified by comparing the nonbonded Cu···Cu distances in the trigonal structures. In the title compound the unique Cu(II)···Cu(II) distance is 2.975 Å (sum of van der Waals radii for Cu is 2.86 Å (9)) with the Cu(II)···Cu(I) distances being much longer at 3.236 and 3.250 Å. In the all-Cu(I) trimer species, $[Cu(tmpz)]_3$ (8), the Cu···Cu distance is 3.212 Å and in $[Cu(dmpz)]_3$ (7) the distance is 3.218 Å. Two other structures having the basic central trigonal planar array of Cu ions bridged by pyrazolate ions have been reported. Both are all-Cu(II) systems. In

$[Cu_3(OH)pz_3py_2Cl_2]py$ (10) there is one unique Cu···Cu distance at 3.112 Å and two Cu···Cu distances at 3.321 Å. In this structure there is significant deviation from planarity displayed by the Cu_3pz_3 trigonal core. On the other hand, the central Cu_3pz_3 feature of the complex $[Cu_3(OH)pz_3(Hpz)_2(NO_3)_2]H_2O$ (11) is essentially planar with Cu···Cu distances at 3.324, 3.364, and 3.365 Å. The present structure is completed by two additional bridging 3,5-

Fig. 1. The structure of $Cu_3(F_6dmpz)_5$ with selected atom numbering scheme.

bis(trifluoromethyl)pyrazolate, F_6dmpz^-, ligands above and below the trigonal planar array and bridging the two Cu(II) ions. These ligands are tilted towards the Cu(I) ion, thereby relieving steric interactions with the pyrazolate ion already bridging the two Cu(II) ions in the trigonal plane. The angle between the least-squares planes of these two bridging groups is ~154°. The coordination about the Cu(I) ion is almost linear (N(52)-Cu(3)-N(41)) at 176.2° whereas the Cu(II) ions display a very distorted square planar environment, (N(42)-Cu(2)-N(31), 171.2°, N(11)-Cu(2)-N(21), 121.7°, N(31)-Cu(2)-N(11), 89.1°, N(31)-Cu(2)-N(21), 89.3°, N(42)-Cu(2)-N(11), 94.7°, N(42)-Cu(2)-N(21), 94.3°).

The nonbonded Cu···Cu distances of the present structure may be compared also with those found in the Cu(II) pyrazolate polymer, $[Cu(pz)_2]_x$. In the latter structure (2) the Cu(II) ions are in a distorted tetrahedral environment created by the two bridging pyrazolate ligands between the Cu centers but the overall linear chain structure allows a much longer Cu···Cu nonbonded distance of 3.889 Å. The two Cu(II) ions of the present structure are in a constrained trigonal environment with the Cu(I) ion and are essentially triply bridged by F_6dmpz^- ligands. The coordination sphere of each of these Cu(II) ions is completed by the F_6dmpz^- ligands being shared with the Cu(I) ion.

The presence of two copper(II) ions triply-bridged by pyrazolate ligands leads to the possibility of strong antiferromagnetic coupling between the two paramagnetic centers. Magnetic susceptibility measurements on powdered samples of $Cu_3(F_6dmpz)_5$ revealed some field dependence over the entire temperature range studied. This observation prompted us to conduct magnetization versus field studies at four different temperatures. These studies revealed linear magnetization versus field behaviour above ~3000 G at all temperatures. Extrapolation of the linear region to zero field gave a non-zero intercept indicative of ferromagnetic impurity, the presence of which made a temperature-independent and field-dependent contribution to the susceptibility data. Subtracting the intercept magnetization from the data corrected for the impurity and gave field-independent susceptibilities. The source of the ferromagnetic impurity is not certain; however, as described above, $Cu_3(F_6dmpz)_5$ is very susceptible to moisture and traces of impurities should not be unexpected.

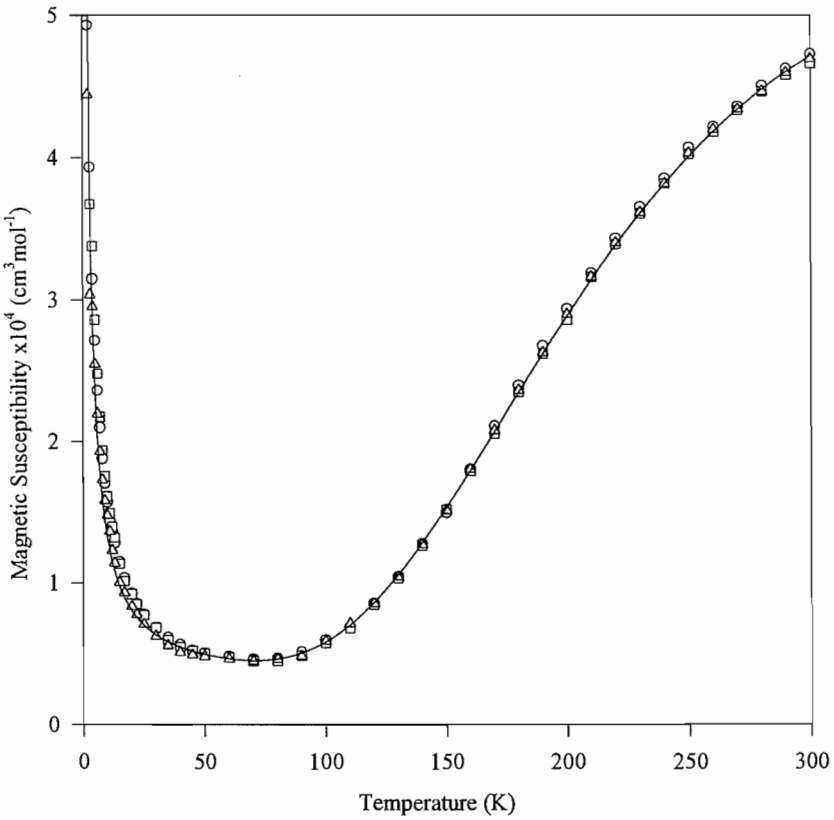
The magnetic susceptibilities (per mole of copper(II)) are plotted versus temperature for three runs in Fig. 2. The susceptibility decreases from 300 K to about 80 K, then at lower temperatures shows an increase as the temperature is decreased further. This is consistent with strong antiferromagnetic coupling between the copper(II) centers with the upturn in susceptibility at the lowest temperatures arising from trace paramagnetic impurity. To obtain a measure of the strength of the magnetic coupling we fitted the susceptibility data (per mole of Cu(II) for run no. 2 at 1 T) obtained over the entire temperature range to the equation for antiferromagnetic dimeric copper(II) systems developed by Bleaney and Bowers (12), with allowance for a paramagnetic component and for temperature-independent paramagnetism, TIP. The equation used is:

$$[1] \quad \chi = \frac{Ng^2\beta}{kT}\left[[1-P]\left[\frac{e^{2J/kT}}{1+3e^{2J/kT}}\right]+P/4\right]+\text{TIP}$$

where J is the exchange coupling constant and P is the fraction of copper present as paramagnetic impurity. In modelling, the J, g, P, and TIP were allowed to vary. This gave best fit values of $-J$, g, P, and TIP of 235 cm^{-1}, 2.11, 0.0025, and 29×10^{-6} cm^3mol^{-1}, respectively, with the fitting function $F = 0.063$. The function F:

$$[2] \quad F = \left[\frac{1}{n}\sum_{i=1}^{n}\left[\frac{\chi^i_{calc}-\chi^i_{obs}}{\chi^i_{obs}}\right]^2\right]^{1/2}$$

is minimized in the fitting procedure and provides a measure of the agreement between the experimental data and the model. Uncertainties in J and g are estimated to be between ±5% and ±2%, respectively.



The value of TIP is somewhat low for copper(II); however, it must be realized that the strong coupling in this compound renders the paramagnetism very weak. As a consequence, diamagnetism and TIP contribute a significant amount to the overall susceptibilities, each making a temperature-independent contribution. Diamagnetic corrections were estimated in the usual way (13) and an estimate only 10% greater than the values used here would, for example, not affect the quality of the fit or the other parameters but would lead to a 75% increase in TIP to a value of 51×10^{-6} cm^3mol^{-1}.

$Cu_3(F_6dmpz)_5$ appears to be the first copper compound structurally and magnetically characterized, to have three bridging pyrazolate groups linking two copper(II) centers (tri-μ-pz bridging). The antiferromagnetic exchange in this compound is likely mediated by the ligands as they provide significantly shorter pathways than that involving the copper(I) ion. The unique character of the bridging motif in this compound prevents any detailed discussion of magnetostructural correlations; however, to put the magnitude of the observed exchange coupling ($-J = 235$ cm^{-1}) in perspective, comparisons with related systems are in order.

The binary pyrazolates of copper(II) have polymeric chain structures involving di-μ-pz bridging and compressed tetrahedral MN_4 chromophore geometries (2–5). By virtue of their

Fig. 2. Magnetic susceptibilities (per mole of copper(II)) versus temperature plot. □, Δ, and ○ are data points for run no. 1 at 1 T, run no. 2 at 1 T, and one run at 2 T, respectively. The solid line is calculated from theory as described in the text.

chain structures, the antiferromagnetic exchange in these polymers arises from each metal center interacting with two nearest neighbours rather than one as in the title compound. In view of these differences it is perhaps not surprising that the magnitude of the exchange coupling in the polymers, as determined by $-J$ values in the range 58–105 cm^{-1}, differs significantly from that in the title compound.

More relevant, perhaps, are comparisons with dimetallic copper(II) systems. Structural and magnetic studies have been reported on copper(II) complexes containing binucleating ligands and incorporating singly bridging pyrazolate (1, 14). These compounds, however, also contain other bridging groups that are involved in the exchange, making comparisons with the present system inappropriate. Finally, we refer to a class of compounds that contain dinucleating pyrazolate ligands, which incorporate chelating arms in the 3,5-positions on the pyrazolate ring (15–17). In these compounds two copper(II) centers are bridged by two ligands; each ligand provides one pyrazolate bridge (di-μ-pz bridging) and chelates to each metal via the substituents in the 3,5-positions. The metal–ligand geometry in these systems is square pyramidal and the values of the exchange integral, J, vary from -159 to -214 cm^{-1}. Hence, for these systems the coupling approaches values of the same order of magnitude as that observed for the title compound in spite of the structural differences, including the number of bridging pyrazolate ligands.

The direct electrochemical synthesis of some metal derivatives of lapachol

E.H. de Oliveira, G.E.A. Medeiros, C. Peppe, Martyn A. Brown, and Dennis G. Tuck

Abstract: The electrochemical oxidation of a sacrificial metal anode (M = Zn, Cd, Cu) in an acetonitrile solution of 2-hydroxy-3-(3-methyl-2-butenyl)-1,4-naphthoquinone, lapachol, $C_{15}H_{14}O_3$ (= HL) gives ML_2. The results are in keeping with earlier work on direct electrochemical synthesis in related systems. Adducts with 2,2′-bipyridine (bpy) and *N,N,N′,N′*-tetramethylethanediamine (tmen) have also been prepared. The structure of the 2,2′-bipyridine adduct of Cu(lapacholate)$_2$ has been established by X-ray crystallography. The parameters are triclinic, space group $P\bar{1}$, a = 12.748(59) Å, b = 13.859(49) Å, c = 11.770(59) Å, α = 108.30(4)°, β = 108.08(3)°, γ = 68.94(3)°, Z = 2, R = 0.059 for 2256 unique reflections. The copper atom is in a distorted $CuN_2O_2O_2'$ environment. The mechanism of the formation of this Cu(lapacholate)$_2$ is discussed.

Key words: electrochemical synthesis, lapachol, X-ray crystallography, copper(II) complex.

Résumé : L'oxydation électrochimique de la 2-hydroxy-3-(3-méthylbut-2-ényl)-1,4-naphtoquinone, le lapachol ($C_{15}H_{14}O_3$) (= HL), en solution dans l'acétonitrile, à une anode métallique sacrifiée (M = Zn, Cd, Cu), conduit aux composés ML_2. Ces résultats sont en accord avec ceux obtenus antérieurement à l'occasion de la synthèse électrochimique directe dans des systèmes apparentés. On a aussi préparé les adduits avec la 2,2′-bipyridine (bpy) et avec la *N,N,N′,N′*-tétraméthyléthanediamine (tmen). Faisant appel à la diffraction des rayons-X, on a déterminé la structure de l'adduit Cu(lapacholate)$_2$ avec la 2,2′-bipyridine. Les cristaux sont tricliniques, groupe d'espace $P\bar{1}$, a = 12,748(59), b = 13,859(49) et c = 11,770(59) Å, α = 108,30(4)°, β = 108,08(3)°, γ = 68,94(3)°, Z = 2 et R = 0,059 pour 2256 réflexions uniques. L'atome de cuivre se trouve dans un environnement $CuN_2O_2O_2'$ déformé. On discute du mécanisme de formation de ce Cu(lapacholate)$_2$.

Mots clés : synthèse électrochimique, lapachol, diffraction des rayons-X, complexe du cuivre(II).

Introduction

The method of direct electrochemical synthesis consists in oxidizing a sacrificial metal anode in a cell containing a non-aqueous solution of an appropriate ligand, or ligand precursor, and the applications and advantages of this simple and rugged synthetic technique have been reviewed elsewhere (1). It is especially useful for the one-step preparation of derivatives of weak acids, such as metal thiolates (2–5), acetylides (6), dialkylthiocarbamates (7), and substituted catecholates (8). Of special relevance to the present work are recent reports of the synthesis of complexes of bidentate anionic oxygen donors in which a carbonyl group is *ortho* to a phenolate, as in aceto-naphthonate (9), flavonate (9), and pyronate (9, 10), and complexes of several metals have been obtained in this way.

We now report the use of the electrochemical method to prepare some metal derivatives of the naturally occurring compound lapachol, 2-hydroxy-3-(3-methyl-2-butenyl)-1,4-naphtho-quinone (Scheme 1). This interesting substance shows promise as an antibiotic and anti-tumor reagent (11). Its interest as a ligand lies in the unusual combination of a 1,4-quinone structure with the ketoenol function noted above. The results show that coordination to a metal centre may involve each of these functionalities, depending on the metal involved, and upon the oxidation state of that metal.

Scheme 1.

Experimental section

General techniques

Lapachol was obtained from the Institute of Antibiotics of the Universidade Federal da Pernanbuco, Brazil, and recrystallized from ethanol to a constant melting point of 141–143°C. Metals in the form of rods, and 2,2′-bipyridine (bpy) and *N,N,N′*,N′-tetramethylethanediamine (tmen) were used as

supplied (Aldrich). Tetraethylammonium perchlorate was prepared by mixing aqueous solutions of $NaClO_4$ and Et_4NBr; the product was recrystallized from aqueous ethanol (9:1, v:v). Acetonitrile was refluxed over calcium hydride and distilled before use.

Metal analysis was by complexometric titration with EDTA. Zinc and cadmium complexes (ca. 100 mg) were destroyed in aqueous HCl; the resulting solution was neutralized with NaOH and the pH adjusted to 10 by addition of ammonium hydroxide (1 mL). The resulting solution was titrated with a standard solution of EDTA (10^{-2} M) using Eriochrome Black T as indicator. Copper complexes were destroyed in HCl, and the solution was neutralized and mixed with HCl (0.5 mL) and ammonium acetate (2 g); the resulting solution was titrated with EDTA using 4-(2-pyridylazo)resorcinol, monosodium salt, as indicator.

^1H and ^{13}C nuclear magnetic resonance spectra were recorded on a Bruker AC-300L instrument, and ESR spectra on a Bruker ESP-300 instrument. Elemental analysis was by Canadian Microanalytical Services Ltd., and by the Departamento de Quimica Universidade Federal da Pernanbuco.

Electrochemical procedures

The electrochemical procedures were essentially those described in earlier papers. The electrochemical cell was a 100 mL round-bottomed flask containing the solution phase (~30 mL); the sacrificial metal electrode suspended by a platinum wire through the rubber septum formed the anode of the cell, and a second platinum wire similarly supported was the cathode. All operations were carried out under dry nitrogen, via a Schlenk arm on the flask, using standard vacuum line techniques up to the isolation of the solid products, which are air stable. The details of cell composition, electrical conditions, and electrochemical efficiency are given in Table 1.

The solution phase was degassed by pumping on a vacuum line for 3 min with continuous stirring and the cell was purged with dry nitrogen throughout the electrolysis. As soon as current flowed in the cell, bubbles of H_2 gas were visible at the cathode, and the yellow solution began to turn dark red. The electrolysis was conducted until more than 90% of the lapachol was consumed. Any decrease in the current was corrected by increasing the applied voltage. At the end of the electrolysis the anode was removed, washed, dried, and weighed to obtain the quantity dissolved, and hence the electrochemical efficiency. The dark red solids that precipitated in the cell were collected by filtration, dried under vacuum, and weighed. Analytical results are given in Table 2, and the details for each element are discussed below.

Preparation of adducts

(i) $Zn(Lap)_2$tmen

A suspension of $Zn(Lap)_2$ (118.0 mg, 0.22 mmol) in CH_3CN (8 mL) was treated with excess of tmen (1 mL, 770 mg, 6.64 mmol). The reaction was brought to the boiling point of CH_3CN (82°C) for 10 min and the resultant solution quickly filtered; all the volatiles were removed from the filtrate and the resulting solid washed with diethyl ether (2 mL). This solid was dried under vacuum to yield $Zn(Lap)_2$tmen (140.0 mg, 0.21 mmol, 96%).

Z	2
F(000)	738
D_c (g cm^{-3})	1.30
Crystal dimensions (mm)	0.1 × 0.1 × 0.1
μ (cm^{-1})	6.57
2θ (deg (max))	50
Total reflections measured	6624
Unique data used ($I \geq 3\sigma(I)$)	2256
T (°C)	23
No. of parameters	238
R	0.059
R_w	0.049
Maximum shift/error in final cycle	0.01
Maximum, minimum peaks in final difference map (e Å^{-3})	0.46, −0.33

(ii) $Cd(Lap)_2tmen$

A suspension of $Cd(Lap)_2$ (232.2 mg, 0.39 mmol) in CH_3CN (8 mL) was treated with excess of tmen (1 mL, 770 mg, 6.64 mmol). The reaction was brought to the boiling point of CH_3CN for 10 min and the resultant solution quickly filtered; the filtrate was concentrated under vacuum to 50% of its initial volume, and diethyl ether added to the resulting solution. When this was kept at −18°C, $Cd(Lap)_2tmen$ (155.8 mg, 0.22 mmol, 56%) precipitated.

(iii) $M(Lap)_2bpy$ (M= Zn, Cd)

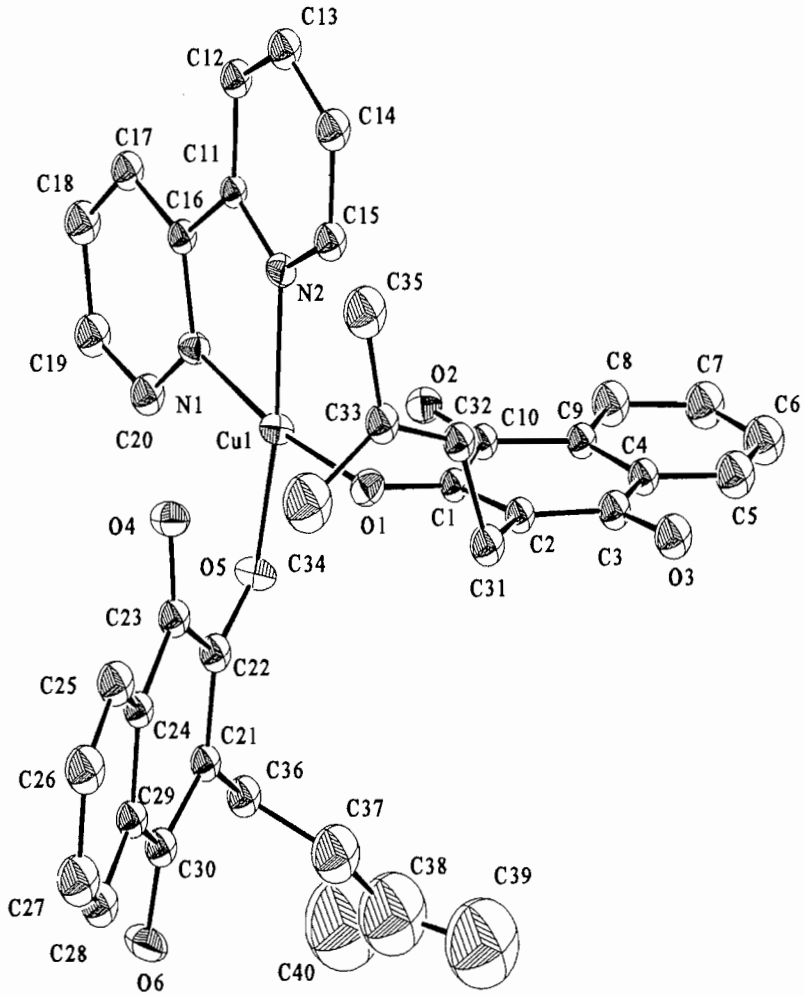
Equimolar amounts of bpy and $M(Lap)_2$ (Cd: 300 mg, 0.5 mmol; Zn: 250 mg, 0.46 mmol) were mixed in acetonitrile (8 mL). The reaction was brought to the boiling point of CH_3CN for 10 min and the resultant solution quickly filtered; the filtrate was concentrated under vacuum to 50% of its initial volume. Diethyl ether was added to the resulting solution, which was kept at −18°C until $M(Lap)_2bpy$ precipitated (Cd: 315 mg, 0.42 mmol, 84%; Zn: 263.0 mg, 37.4 mmol, 81%).

(iv) $Cu(Lap)_2bpy$

$Cu(Lap)_2$ (197 mg, 0.36 mmol) and bpy (60 mg,, 0.38 mmol) were stirred in 10 mL acetonitrile for 24 h; $Cu(Lap)_2bpy$ (116 mg, 0.17 mmol, 47%) was collected by filtration and dried in vacuo. Crystals for X-ray analysis were grown from hot acetonitrile.

(v) $Cu(Lap)_2tmen$

$Cu(Lap)_2$ (301 mg, 0.55 mmol) and excess tmen (0.5 mL, 3.3 mmol) were stirred in 10 mL acetonitrile for 24 h; $Cu(Lap)_2tmen$ (292 mg, 0.44 mmol, 80%) was collected by filtration and dried in vacuo.



Crystallographic analysis

In the study of $Cu(Lap)_2bpy$, $C_{40}H_{34}O_6N_2Cu$, **1**, a dark-red block crystal on a glass fibre was mounted in a Rigaku AFC6S diffractometer, equipped with graphite monochromated Mo-Kα radiation (λ = 0.71069 Å) and a rotating anode generator. Cell constants and orientation matrices for data collection were obtained from least-squares refinements, using 20 carefully centred reflections in the range $12.61° < 2\theta < 19.62°$. The space group was uniquely identified as $P\bar{1}$ (No. 2) by the lack of systematic absences, and this was confirmed by subsequent solution and refinement of the structure. Details of the intensity collection are given in Table 3.

The intensities of three representative reflections were measured after every 150 reflections. Over the course of data collection, the standards decreased by 0.24%, and a linear correction factor was applied to the results. Absorption corrections were made using Ψ scan (transmission factors 0.9281–1.000), and the values were corrected for Lorentz and polarization effects. The structure was solved by direct methods, and expanded using Fourier techniques. The non-hydrogen atoms were refined isotropically; hydrogen atoms on carbon were included in ideal positions (r = 0.95 Å), but were not refined. The final cycle of full-matrix least-squares refinement was based on 2256 observed reflections ($I > 3\sigma(I)$) and 238 variable parameters, refining the parameters $R = \Sigma||F_o| - |F_c||/\Sigma|F_o|$, $R_w = [\Sigma w(|F_o| - |F_c|)^2/\Sigma wF_o^2]^{1/2}$, $\sigma(F) = \Sigma w\ (|F_o| - |F_c|)^2$, and $p = 0.003$; the solution converged at $R = 0.059$, $R_w = 0.049$. A final Fourier difference map calculation showed no peaks of chemical significance; the maximum and minimum peaks corresponded to 0.46 and −0.33 e Å^{-3}, respectively. The large thermal parameters found for C38–C40 suggest

some degree of disorder around the C37—C38 double bond; no correction was applied for this.

Neutral-atom scattering factors were taken from Cromer and Waber (12). Anomalous dispersion effects were included in the calculations (13); the values for $-f'$ and $\Delta f''$ were those published by Cromer (14). All calculations were performed using the TEXSAN (15) crystallographic software package. The structure of the molecule is shown in Fig. 1, the positional parameters are in Table 4, and the important bond distances and angles in Table 5.

Tables of hydrogen-atom coordinates and thermal parameters, anisotropic thermal parameters for other atoms, and least-squares planes are available as supplementary data.[2]

[2] These supplementary data can be purchased from: The Depository of Unpublished Data, Document Delivery, CISTI, National Research Council Canada, Ottawa, Canada K1A 0S2. Tables of hydrogen atom coordinates have also been deposited with the Cambridge Crystallographic Data Centre, and can be obtained on request from The Director, Cambridge Crystallographic Data Centre, University Chemical Laboratory, 12 Union Road, Cambridge, CB2 1EZ, U.K.

Results and discussion

Preparative electrochemistry

The electrochemical synthesis of lapacholate derivatives shows that the chemistry of these systems is more complicated than those studied previously, and this is clearly the result of the presence within the parent molecule of both *para*-quinone and keto-enolate functions. The three metals studied in fact demonstrate two different types of behaviour. For zinc and cadmium, the products are the $M(Lap)_2$ derivatives (Lap = lapacholate anion), which are presumably four-coordinate and accordingly accept bidentate donors to give $M(Lap)_2bpy$ and $M(Lap)_2tmen$, and for these metals the parallels with earlier work are clear. For copper, the primary product is identified as $Cu^{I}(Lap)$, which isomerizes to $Cu^{II}(LapSQ)$ (LapSQ = lapacholate-semiquinone radical dianion), which subsequently reacts in situ to give $Cu^{II}(Lap)_2$ (see below). This in its turn will also form six-coordinate species, and the crystal structure study has confirmed this in the case of $Cu^{II}(Lap)_2bpy$.

The cathodic reduction of lapachol is accompanied by the evolution of hydrogen,

[1] $HLap + e \rightarrow Lap^{-} + 1/2\ H_2$

Studies of the redox chemistry of lapachol by Bodini and Arancibia (16), using cyclic voltammetry, have established that the anion undergoes no rearrangement at this stage, and is therefore as shown in Scheme 2:

Scheme 2.

With zinc or cadmium, discharge of this anion at the anode will yield the $M(Lap)_2$ species

[2] $2Lap^- + M \rightarrow M(Lap)_2 + 2e$

These compounds are diamagnetic, as shown by the clean NMR spectra obtained for these products and their adducts (see below). This overall mechanism (eqs. [1] + [2]), which is entirely in keeping with earlier results, predicts an electrochemical efficiency of 0.5 mol F^{-1}, as found experimentally (Table 1). The subsequent and separate adduct formation is a common feature of such zinc and cadmium compounds.

The copper system is noticeably different. The electrochemical efficiency is now 1.08 mol F^{-1}, indicating that the primary product is $Cu^I(Lap)$. The significant deviation from the theoretical value of unity is believed to be due to a slow chemical attack on copper by lapachol itself; a piece of clean copper placed in contact with a solution of lapachol in acetonitrile (152 mg, 0.62 mmol) in 5 mL for 48 h lost 34 mg (0.53 mmol) of element. The formation of copper(I) derivatives has been observed in a number of previous direct electrochemical syntheses (17–22), but the most striking feature here is that the final product is paramagnetic; no NMR spectra could be recorded, and the ESR spectrum shows that the anion is in fact the semiquinone, resulting from the sequence of electrochemical oxidation

[3] $Cu + Lap \rightarrow Cu^I(Lap) + e$

followed by an intramolecular electron transfer reaction

[4] $Cu^I(Lap) \rightarrow Cu^{II}(LapSQ)$

The elemental analysis (calcd. for $C_{15}H_{13}O_3Cu$: C 59.1, H 4.30; found: C 58.6, H 4.97) confirms that this is indeed the primary product. The ESR spectrum of this, and other paramagnetic copper derivatives of lapachol, will be discussed elsewhere, but we note here that these results are compatible with the structure of the dianion proposed by Bodini and Arancibia (16) (Scheme 3).

The reaction(s) by which $Cu^{II}(LapSQ)$ is converted to $Cu(Lap)_2$ are difficult to observe, since the reaction mixtures are intensely coloured (dark red) to the point of being virtually opaque. An apparently significant point is that the rate of precipitation of $Cu(Lap)_2$ is dependent on the quantity of excess lapachol in the solution. In the normal procedure 90% of the lapachol was consumed electrolytically, and in such cases the formation of $Cu(Lap)_2$ was slow, and the yield poor (~30%). When a solution of Cu(Lap) was stirred for 24 h with lapachol, the quantity of $Cu(Lap)_2$ that precipitated increased by 50%. We therefore suggest the sequence

Scheme 3.

[5] $Cu^{II}(LapSQ) + HLap \rightarrow Cu(Lap)_2 + H$

[6] $2\,H \rightarrow H_2$

As with zinc and cadmium, adducts of $Cu(Lap)_2$ are readily obtained with bidentate donors, and the structure of $Cu(Lap)_2bpy$ is clearly that of a tetragonal copper (II) complex of a keto-enolate form of the ligand.

The structure of $Cu(Lap)_2bpy$

Figure 1 shows that the bpy adduct of $Cu(Lap)_2$ is a six-coordinate copper(II) complex. The interaction of 2,2′- bipyridine with copper(II) centres has been the subject of a number of previous studies (see ref. 23 for a summary), and the average Cu—N bond lengths in a series of salts of $[Cu(bpy)_2X]^+$ (X = Cl, Br, I) are 1.99 Å (apical) and 2.08 Å (equatorial), in good agreement with the present values of 1.999(7) and 2.026(7) Å. The bite angle of 79.8(3)° is also very close to the previously reported values.

The Cu—O interactions give rise to two distinct sets of bond distances. Those in the CuN_2O_2 plane, which is planar to within +0.054 Å, are 1.950(6) and 1.923(6) Å, and are associated with C—O bonds in the ligand of 1.29(1) and 1.30(1) Å, respectively. These C—O bonds are shorter than those found in catecholate complexes, for which the average r(C—O) = 1.35 Å. The Cu—O bonds orthogonal to the CuN_2O_2 plane are substantially longer (2.40(1), 2.44(1) Å), and here the interaction is clearly with the oxygen atoms of carbonyl groups, for which the r(C═O) values of 1.22(1) and 1.23(1) Å are in fact almost identical with those in the *para*-position of the same rings (1.23(1), 1.24(1) Å. The bond lengths in the quinonoid ring, averaged over both ligands, are shown in Scheme 4 and establish that we are dealing with an *ortho*-enol of a 1,4-quinone, so that the complex is indeed $Cu(Lap)_2bpy$. The distortion from octahedral to tetragonal stereochemistry at copper(II) may be seen as the result of two synergistic factors. One is Jahn–Teller distortion, which has been invoked in many such situations, and the other is the significant electron localization in the appropriate C—O and C—C bonds in the *para*-quinonoid ring.

Zinc and cadmium complexes

As noted bove, the electrochemical oxidation of zinc or cadmium in the presence of lapachol gives the appropriate $M(Lap)_2$ complexes in good yield. These diamagnetic com-

pounds are clearly derivatives of the lapacholate monoanion (Scheme 2), and are Lewis acids, readily forming adducts with bidentate nitrogen donors. These are presumably six-coordinate, and isostructural with Cu(Lap)$_2$bpy.

The ^1H NMR spectra of these compounds (in d_6-DMSO) show that little change occurs between lapachol and the derivatives, other than the loss of the enol hydrogen, identified at 5.2 ppm (Me_4Si = 0). The ^{13}C spectra are more instructive, and Table 6 compares the results for lapachol and its zinc and cadmium derivatives. The largest changes in the ^{13}C chemical shift are at C2 and C1, corresponding to the transfer of charge to the metal centre and concomitant polarity changes in the C—O bonds. The effects are significantly greater for zinc, suggesting stronger binding of the ligand to this element than to cadmium, in keeping with the known behaviour of these metals with bidentate oxygen donors. Carbon-4, which carries the nonbonding carbonyl oxygen, becomes less shielded on complexation, with changes of ca. −5 ppm. The remaining differences are in the order of 0.5–1.0 ppm. Carbon atoms 5–8 are less shielded, while 4a and 8a show effects in the opposite sense. In general, complexation to zinc or cadmium causes a slight increase in negative charge on the fused aromatic ring, significantly stronger shielding at C1 and C2, and an interesting deshielding at C4. The chemical shifts of the carbon atoms of the side chain at C2 change by less than 0.5 ppm.

Quantitative description of analyte migration behavior based on the dynamic complexation model in capillary electrophoresis

Xuejun Peng, Gwendolyn M. Bebault, Stephen L. Sacks, and David D.Y. Chen

Abstract: A theory based on dynamic complexation is used to describe analyte migration behavior in capillary electrophoresis (CE). This theory is based on a one-phase system, instead of the commonly accepted two-phase system. The migration behavior of an analyte is described by three parameters (the electrophoretic mobility of the free analyte, the electrophoretic mobility of the analyte–additive complex, and the equilibrium constant (formation constant) that determines the fractions of the free analyte and the complex at a certain additive concentration). Varying the additive concentration shifts the equilibrium and changes the viscosity of the background electrolyte. Viscosity correction is crucial in interpreting the observed migration behavior of analytes. While electroosmotic flow in a capillary often varies from one capillary to another, the viscosity of a buffer is characteristic of the buffer composition and is constant for each buffer. The electrophoretic mobility of a certain species and the equilibrium constant are intrinsic properties and are less sensitive to changes in the environment. Understanding these relationships is indispensable in CE method development and method validation. A universal resolution equation is proposed, with a separation factor that has taken both the electrophoretic mobilities and equilibria into consideration. This resolution equation gives clear guidance for the optimization of CE separations. A group of nucleosides and their phosphates are used as analytes, and β-cyclodextrin is used as the additive in the model system studied in this paper. Both the observed analyte migration behavior and the resolution of analytes agree well with this theory.

Key words: dynamic complexation capillary electrophoresis, nucleoside and nucleotide separation, capacity factor, resolution equation, viscosity correction.

Résumé : On a utilisé une théorie basée sur la complexation dynamique pour décrire le comportement d'un analyte lors de la migration en électrophorèse capillaire (EC). Cette théorie repose sur un système à une phase, au lieu du système à deux phases communément accepté. Le comportement de l'analyte, lors de la migration, est décrit par trois paramètres (la mobilité électrophorétique de l'analyte libre, la mobilité électrophorétique du complexe analyte–additif, et la constante d'équilibre (constante de formation) qui détermine les fractions de l'analyte libre et du complexe pour certaines concentrations de l'additif). La variation de la concentration de l'additif déplace l'équilibre et change la viscosité de l'électrolyte de support. La correction de la viscosité est vitale pour interpréter le comportement des analytes en migration. Alors que le débit électroosmotique dans un capillaire varie souvent d'un capillaire à l'autre, la viscosité d'un tampon est caractéristique de la composition du tampon et elle est constante pour chaque tampon. La mobilité électrophorétique d'une certaine espèce et la constante d'équilibre sont des propriétés intrinsèques et sont moins sensibles aux changements dans l'environnement. La compréhension de ces relations est indispensable pour le développement de la méthode de l'électrophorèse capillaire et pour la validation de cette méthode. On propose une équation de résolution universelle, avec un facteur de séparation qui tient compte à la fois des mobilités électrophorétiques et des équilibres. Cette équation de résolution donne une orientation claire en vue de l'optimisation des séparations par électrophorèse capillaire. On a utilisé un groupe de nucléosides et leurs phosphates comme analytes et on a utilisé la β-cyclodextrine comme additif dans le système modèle étudié dans cette publication. Le comportement de l'analyte lors de la migration et la résolution de l'analyte sont tous deux en parfait accord avec cette théorie.

Mots clés : électrophorèse capillaire par complexation dynamique; séparation de nucléoside, et de nucléotide; facteur de capacité; équation de résolution; correction de viscosité.

Introduction

Carrier-free zone electrophoresis was first demonstrated by Hjertén in 1967 (1). Although capillary electrophoresis (CE) for the zone separation of substances was described by Everaerts and Hoving in 1970 (2), this technology was mainly developed after Jorgenson and Lukacs demonstrated the feasibility of achieving high-efficiency zone separations in a simple carrier-free open tube capillary in 1981 (3). The equilibrium process was introduced, through the use of additives in the buffer system, by Terabe et al. in 1984 (4). Terabe's contribution has made CE the most powerful separation technique by combining both field and equilibria in the separation process.

Because the amount of additive used in CE systems is always described by the additive concentration, and that concentration determines the probabilities of collision and reaction between different molecules in a homogeneous solution, it should be considered as a one-phase system. Viscosity is one of the fundamental parameters that determines analyte mobility. Both the electroosmotic mobility and the electrophoretic mobility of an analyte are influenced by the viscosity change when additives are used. However, the additives affect the two mobilities rather differently. Except in a few papers published recently (5–9), most theoretical studies have not included the viscosity change in their fundamental equations.

This paper describes the separation of 20 analytes based on the dynamic complexation equilibria between the analytes and the additive in a CE system. In a one-phase system, the net analyte electrophoretic mobility is determined by three factors: the electrophoretic mobility of the free analyte, the electrophoretic mobility of the analyte–additive complex, and the equilibrium constant that determines the fraction of the analyte in the free or complexed form. The mobility of the free additive does not contribute to the analyte electrophoretic mobility. The relationship between the equilibrium constant and the electrophoretic mobilities can be quantified only when the viscosity change is corrected to the ideal state. This dynamic complexation capillary electrophoresis (DCCE) theory should be applicable to all open tubular CE including micellar electrokinetic capillary chromatography (MECC) (8, 10), affinity CE (11), chiral CE (12, 13), and other types of complexation, e.g., with charged cyclodextrins (10). The migration behavior of all types of analytes and additives, charged or neutral, can be described by this theory.

Theory

Analyte mobilities and the equilibrium constant

The electrophoretic mobility of a charged spherical molecule, μ_{ep}, is described by Debye–Hückel–Henry theory:

$$[1] \quad \mu_{ep} = \frac{Q_{eff}}{6\pi\eta R}$$

where Q_{eff} is the effective charge of the molecule, η is the viscosity of the background electrolyte, and R is the effective radius. It should be noted that μ_{ep} is mostly an intrinsic property determined by the charge-to-size ratio of a molecule, and the viscosity of the background electrolyte.

The electroosmotic mobility, μ_{eo}, was described by Hjertén, also based on the Debye–Hückel–Henry theory (1):

$$[2] \quad \mu_{eo} = \frac{\varepsilon\zeta}{4\pi\eta}$$

where ε is the dielectric constant of the background electrolyte, ζ (zeta potential) is the potential across the diffuse layer at the capillary wall, and η is the viscosity. To an analyte, the electroosmotic flow (EOF) is an external force originating from the capillary wall, and applied equally to all species in the capillary when an electric field is applied. The electroosmotic mobility is affected by many factors. The condition of the capillary wall is never the same from one capillary to another. Any additive used in the buffer system will alter at least one of the parameters that determines the EOF, i.e., the ionic strength, the properties of the diffuse layer and the zeta potential, and the dielectric constant of the background electrolyte. It is apparent that a neutral EOF marker may not accurately reflect the viscosity change in a CE system. In contrast to μ_{ep}, which is a constant in most situations, μ_{eo} changes even when the same capillary and buffer are used.

The prerequisite to separate species A from B in an additive-free CE system is that the charge-to-size ratios, or the electrophoretic mobilities ($\mu_{ep,A}$ and $\mu_{ep,B}$), of the two free analytes are different. If the two free mobilities are the same, an additive can be used to form complexes with the two analytes. The differential complexation and the different complex mobilities can change the net electrophoretic mobility of the analytes (μ_{ep}^{A} and μ_{ep}^{B}).

For analyte A, when an additive C is used in the buffer of a CE system, the equilibrium in a homogenous system can be represented as

$$[3] \quad A + C \rightleftharpoons AC$$

where A is the analyte, C is the additive or complexing agent (such as surfactant, host molecule, polyether, protein, etc.), and AC is the complex. Equation [3] has been used to describe chiral separations (14), affinity CE (11), and analyte–additive pairs with hydrogen-bonding capabilities (15).

The equilibrium constant, K, for eq. [3] is

$$[4] \quad K = \frac{[AC]}{[A][C]}$$

where [AC] is the complex concentration, [A] is the analyte concentration, and [C] is the concentration of the additive.

The capacity factor, k', also called the mass distribution coefficient, is defined in chromatography as the ratio of the amount of the analyte in the stationary phase compared with the amount of analyte in the mobile phase. A similar concept can be used in CE, where we define the capacity factor as the ratio of the amount of complex to the amount of free analyte. Because the additive and the analyte are in the same solution, the capacity factor is

$$[5] \quad k' = \frac{AC}{A} = \frac{[AC]}{[A]} = K[C]$$

In CE, the capacity factor is proportional to the additive concentration. Although [AC] and [A] at the edges of the migration zone may change during the CE separation because

For personal use only.

of band broadening caused by diffusion, it is reasonable to assume that the concentrations are diluted to a similar extent and that this effect is canceled out in eq. [5]. Therefore, the capacity factor will not be affected. The fraction of the free analyte, f, is defined as $[A]/[A]_0$ ($[A]_0$ is the original analyte concentration). When $[C]_0$, the initial additive concentration, is much greater than $[A]_0$, [C] is equal to $[C]_0$. Substituting $[A]_0$ by [A] + [AC] gives:

$$[6] \quad f = \frac{1}{1 + k'}$$

The form of eq. [6] is identical to the fraction of time an analyte spends in the mobile phase as described in chromatographic theories. However, in chromatographic theories,[2] k' is defined as $K(V_S/V_M^0)$, where K is the concentration ratio of the analyte in the stationary phase and the mobile phase, V_S is the volume of the stationary phase, and V_M^0 is the corrected volume of the mobile phase, whereas in CE, k' is equal to K[C].

The net electrophoretic mobility of an analyte A (charged or neutral), μ_{ep}^A, is

$$[7] \quad \mu_{ep}^A = f\mu_{ep,A} + (1-f)\mu_{ep,AC} = \frac{1}{1+k'}\mu_{ep,A} + \frac{k'}{1+k'}\mu_{ep,AC}$$

where $\mu_{ep,AC}$ is the electrophoretic mobility of the complex.

Equation [7] is only valid for the ideal situation when changes in additive concentration do not affect the viscosity. In reality, the viscosity is often changed.

A viscosity correction factor, ν, is therefore introduced to convert the observed net electrophoretic mobility to an ideal state where the additive concentration approaches zero:

$$[8] \quad \nu\mu_{ep}^A = \frac{1}{1+k'}\mu_{ep,A} + \frac{k'}{1+k'}\mu_{ep,AC}$$

The correction factor, ν, is defined as η/η^0, where η is the viscosity of the running buffer at each [C], and η^0 is the viscosity of the solution when [C] is equal to 0. Because of the increase in viscosity, the value of ν is always greater than or equal to one, and the absolute value of the measured electrophoretic mobility is always smaller than or equal to the ideal state mobility. The effect of the correction factor is to convert the apparent electrophoretic mobility to an ideal state where the correction factor approaches one.

The apparent mobility of an analyte μ^A is equal to $\mu_{eo} + \mu_{ep}^A$. Rearranging eq. [8] and substituting μ_{ep}^A by $\mu^A - \mu_{eo}$ gives:

$$[9] \quad \frac{1}{\nu(\mu^A - \mu_{eo}) - \mu_{ep,A}} = \frac{1}{(\mu_{ep,AC} - \mu_{ep,A})K}\frac{1}{[C]} + \frac{1}{(\mu_{ep,AC} - \mu_{ep,A})}$$

Plotting $1/[\nu(\mu^A - \mu_{eo}) - \mu_{ep,A}]$ vs. $1/[C]$ should give a straight line. A similar equation without the correction factor has been proposed (16), however, the equation is only valid when the term $(\mu^A - \mu_{eo})$ is corrected if the viscosity varies with any change in additive concentration.

Note in eq. [9] that the term $\nu(\mu^A - \mu_{eo})$ is equal to net electrophoretic mobility of the analyte in the ideal state. Equations [7]–[9] describe the relationship between the equilibrium constant and the ideal state electrophoretic mobilities, because the analyte–additive interaction has nothing to do with electroosmotic flow.

The capacity factor can be expressed in terms of mobility by rearranging eq. [8]:

$$[10] \quad k' = \frac{\nu\mu_{ep}^A - \mu_{eo,A}}{\mu_{ep,AC} - \nu\mu_{ep}^A}$$

If the additives are large micelles, following the assumption made by Terabe et al. (4), the complex mobility is approximately the same as the mobility of the micelle. Assuming that the electrophoretic mobilities of free neutral analytes ($\mu_{ep,A}$) are zero, eq. [10] can be written as

$$[11] \quad k' = \frac{\nu(\mu^A - \mu_{eo}) - \mu_{ep,A}}{\nu(\mu^{MC} - \mu_{eo}) - \nu(\mu^A - \mu_{eo})} = \frac{\mu^A - \mu_{eo}}{\mu^{MC} - \mu^A}$$

where μ^A is the net mobility of the analyte, μ^{MC} is the mobility of the micelle, and μ_{eo} is the electroosmotic mobility. Equation [11] is identical to the original equation in MECC that was used to derive the k' expressed in terms of migration times. The fundamental difference between MECC theory and DCCE theory is that MECC theory uses the μ^{MC} to describe the analyte mobility, while DCCE theory uses $\mu_{ep,AC}$. It should be noted that, rigorously, μ^{MC} has nothing to do with the analyte mobility. The micelles should be treated as a second additive, and its concentration is related to the first one, the monomers, through the equilibrium of micelle formation. In addition, the MECC equation applies only to neutral analytes and charged micelles, while the theory based on dynamic complexation has no restriction on whether the analytes or additives are charged or not and thus should be applicable to all types of open tubular CE.

A universal resolution equation for open tubular CE

Many attempts have been made to formulate a resolution equation that can be used to describe the differential migration of two analytes. These attempts have been unsuccessful because the separation factor, α, has not been properly defined. In chromatographic theories, α has been known as the ratio of the two capacity factors (k'_B/k'_A).

However, the primary definition of α is $(c_A^M/c_A^S)/(c_B^M/c_B^S)$, where c_A^M, c_A^S, c_B^M, and c_B^S are the concentrations of analyte A and B in the two phases (mobile and stationary), respectively. This definition can not accurately describe the separation process for several reasons. First, the amount of analyte in moles, instead of the concentrations, should be used to describe the difference in the phase distribution of the analytes (even though the volumes will be canceled out in this definition). Secondly, the ratio does not correctly describe the differential migration between A and B, because (c_A^M/c_A^S) and (c_B^M/c_B^S) are not directly related to the migration rates of the analytes.

For personal use only.

Thirdly, if more than one stationary phase is used in a column, the separation factor will no longer have a clear physical meaning, and can not be used to predict the outcome of a separation. On the other hand, if α is defined as $[n_A^M/(n_A^S + n_A^M)]/[n_B^M/(n_B^S + n_B^M)]$, where $n_A^M/(n_A^S + n_A^M)$ and $n_B^M/(n_B^S + n_B^M)$ are the fractions of the analytes in the mobile phase, then the separation factor will reflect the difference in the migration rates of the two analytes. This is because the migration rate of an analyte is equal to the fraction of the analyte in the mobile phase times the velocity of the mobile phase. This definition can also be used to describe situations when more than one stationary phase is used. It should be noted that the previously defined α implies that the resolution is defined by k'_B/k'_A. In reality, the difference between the migration rates of the two analytes should be described by $(1 + k'_B)/(1 + k'_A)$, which is equal to α when defined as the ratio of the fractions of the analytes in the mobile phase.

In CE without complexation additives, the difference in migration rates is described by the difference in the electrophoretic mobilities of the analytes. Therefore, the separation factor should be defined as the ratio of the two electrophoretic mobilities ($\mu_{ep,A}/\mu_{ep,B}$).

Because both electric field and equilibrium are used in the separation process in DCCE, the separation is governed by both the electrophoretic mobilities and the equilibria involved. The separation factor should be defined as the ratio of the net electrophoretic mobilities (μ_{ep}^A/μ_{ep}^B) when the directions of the two mobilities are the same. This definition takes both mobility and equilibrium into account. When the additive concentration is zero, the separation factor is equal to $\mu_{ep,A}/\mu_{ep,B}$, which is the separation factor for carrier-free CE. A similar definition was suggested for chiral separations by Rawjee et al. (17). This definition should apply to all types of CE.

For two analytes in a one-additive CE system, the separation factor is

$$[12] \quad \alpha = \frac{\mu_{ep}^A}{\mu_{ep}^B} = \frac{\frac{1}{1 + k'_A}\mu_{ep,A} + \frac{k'_A}{1 + k'_A}\mu_{ep,AC}}{\frac{1}{1 + k'_B}\mu_{ep,B} + \frac{k'_B}{1 + k'_B}\mu_{ep,BC}}$$

Some authors have assumed that $K[C] \gg 1$ (i.e., $k' \gg 1$) without knowing the values of the equilibrium constants. This led to the conclusion that $\alpha = K_B/K_A$ (14). Actually, shifting the equilibrium is the most effective way of changing the net analyte mobility when k' is around 1. Others have defined $\alpha = k'_B/k'_A$, which again is equal to K_B/K_A (18). By assuming that α is a constant, it is also assumed that the resolution of two analytes can not be affected by a change in additive concentration. It should be emphasized that equilibrium is not the only factor that governs the separation process in CE. Electric field, which also leads to the differential migration of analytes, should also be included in the separation factor.

Assuming that the peak widths of the closely migrating analytes A and B are similar, the resolution, R_s, of two analytes is defined as

$$[13] \quad R_s = \frac{t_R^B - t_R^A}{\frac{1}{2}(W_A + W_B)} \approx \frac{\sqrt{N}}{4}\left(\frac{t_R^B - t_R^A}{t_R^A}\right)$$

where t_R^B and t_R^A are the migration times of the analytes, W is the average peak width, and N is the number of theoretical plates. Note that for two closely migrating analytes, either t_R^A or t_R^B can be used to calculate the separation efficiency.

Substituting $L_d/(\mu_{eo}^B + \mu_{eo})E$ and $L_d/(\mu_{eo}^A + \mu_{eo})E$ for t_R^B and t_R^A in eq. [13] gives:

$$[14] \quad R_s = \frac{\sqrt{N}}{4}(\mu_{ep}^A + \mu_{eo})\left(\frac{1}{\mu_{ep}^B + \mu_{eo}} - \frac{1}{\mu_{ep}^A + \mu_{eo}}\right)$$

$$= \frac{\sqrt{N}}{4}\left(\frac{1}{\mu_{ep}^B + \mu_{eo}}\right)(\mu_{ep}^A - \mu_{ep}^B)$$

where L_d is the length of the capillary from the inlet to the detector, and E is the electric field applied during the separation (applied voltage divided by the total length of the capillary).

Substituting μ_{ep}^A in eq. [14] by $\alpha\mu_{ep}^B$ (from eq. [12]) gives:

$$[15] \quad R_s = \frac{\sqrt{N}}{4}\frac{\mu_{ep}^B}{(\mu_{ep}^B + \mu_{eo})}(\alpha - 1)$$

Equation [14] is in agreement with the resolution equation proposed by Giddings in 1969 based on the assumption that $\Delta X \ll X$, where X is the migration distance and ΔX is the difference between the migration distances (19). However, there are two major differences between eq. [14] and the equation proposed by Giddings. First, equilibrium was not included in that equation, but is included in the μ_{ep}^A and μ_{ep}^B terms in eq. [14]. Second, there is a retention term in eq. [14] that is not apparent in Giddings' equation because μ_{eo} was not considered then.

Equation [14] can be divided into three distinct sections: the first part describes the column efficiency (N), the second part can be seen as the retention factor (longer migration time gives better resolution), and the third deals with selectivity. These three components give clear guidance for the optimization of CE separations. First, the column efficiency should be optimized. As demonstrated by Hjertén (20), we should not presume that band-broadening in CE is diffusion limited. Injection volume, the aggregation of analytes, wall effects, and electroosmotic flow can also cause significant band-broadening in CE. Second, analyte migration time has a direct impact on resolution because of the retention factor. When the column efficiency is the same, longer migration times give better resolution because the difference in the electrophoretic mobilities of the analytes can contribute longer to the differential migration. This has been demonstrated by Culbertson and Jorgenson (21), using hydrodynamic counter flow, and by Lucy and McDonald (22), and Bowser et al. (23), using EOF to counterbalance the electrophoretic mobility of the analytes, to increase the analyte migration time and achieve better resolution, and by many publications using gel or entangled polymer-filled capillaries. Third, the resolution can be improved by increasing the difference of the net electrophoretic mobilities of the analytes. This can be achieved by selecting an appropriate additive, adjusting the additive concentration, or even using more than one additive in the CE system.

Experimental section

Apparatus

A Beckman P/ACE 5000 Automated Capillary Electrophoresis System (Beckman Instruments (Canada) Inc., Misssissauga, Ont.) was used for the experiment. The capillary had a 75 μm inner diameter, 375 μm outer diameter, and was 57 cm in length (50 cm to the detector). Uncoated fused silica capillary columns were purchased from Polymicro Technologies (Phoenix, Ariz.). The capillary was cleaned with 1.0 M NaOH for 30 min followed by a 10 min rinse with deionized distilled water, and was equilibrated with electrophoresis running buffer overnight before being used for separation. Absorption was monitored at 254 nm except for benzene. A 0.1% v/v benzene in the buffer solution was used to measure the electroosmotic mobility and was monitored at 214 nm. Samples were introduced by pressure injection for 2 s, and a voltage of 25 kV was used to run the separations. Data were collected using the System Gold software package (Beckman) and a 486 PC computer.

Procedure

The instrument was programmed to rinse the capillary with the electrophoresis buffer at high pressure for 2 min. The buffer (pH 9.1) was prepared with 50 mM $Na_2B_4O_7{\cdot}10H_2O$ (Borax) and 200 mM boric acid. The 200 mM borate buffer was then diluted to 160 mM, which was the buffer used in this experiment. Different concentrations of β-cyclodextrin (β-CD) were added as described in the Results and discussion. The temperature of the capillary was held at 20°C. It should be noted that there will be some temperature gradient between the center of the capillary and the wall, but the average temperature is 20°C. However, because the viscosity is measured as a bulk property, the difference between a liquid of 20°C and a liquid with an average temperature of 20°C is not too great. The viscosity of the running buffer was measured by injecting a plug of thymidine into the capillary, and monitoring the time required for the plug to reach the detector window when a 20 psi (1 psi = 6.9 kPa) pressure was applied to the inlet of the capillary.

Chemicals

The nucleosides, adenosine (A), guanosine(G), uridine(U), thymidine (T), and cytidine (C), were in the form of free bases. Adenosine 5′-mono-, di-, and tri-phosphate (AMP, ADP, ATP); uridine 5′-mono-, di-, and tri-phosphate (UMP, UDP, UTP); cytidine 5′-mono-, di-, and tri-phosphate (CMP, CDP, CTP); guanosine 5′-mono-, di-, and tri-phosphate (GMP, GDP, GTP); thymidine 5′-mono, di-phosphate (TMP, TDP), and deoxythymidine 5′-triphosphate (dTTP) were sodium salts. All the nucleosides and nucleotides were purchased from Sigma (St. Louis, Mo.) and dissolved in water as stock solutions with concentrations ranging from 5.0×10^{-2} M to 1.0×10^{-3} M. Penciclovir (PCV), an acyclic guanosine analog (9-(4-hydroxy-3-hydroxymethylbut-1-yl)guanine), was provided by SmithKline Beecham Pharmaceuticals (Brentford, U.K.). A mixture of nucleosides (2.0×10^{-4} M each) and nucleotides (2.5×10^{-4} M each) was prepared by combining each component from stock solutions. Samples were prepared by adding 20 μL of the mixture to 200 μL of electrophoresis buffer, or by diluting the individual stock solutions to the appropriate concentration with buffer when used as standards for peak identification. β-CD, Borax, and boric acid were purchased from Sigma.

Results and discussion

Viscosity

Accurately measuring the viscosity of the solution in the capillary is necessary to obtain the viscosity correction factor and thus the equilibrium constant. The relationship between the viscosity of a Newtonic liquid and the average linear velocity of the liquid flowing through a capillary under a certain pressure can be described by Poiseuille's equation:

$$[16] \quad U^* = \frac{\Delta P r^2}{8\eta L_c}$$

where U^* is the average linear velocity of the liquid, ΔP is the pressure applied to the capillary, r and L_c are the radius and length of the capillary, respectively, and η is the viscosity of the liquid. Rearranging eq. [16] and replacing U^* with L_d/t gives:

$$[17] \quad \eta = \frac{\Delta P r^2 t}{8 L_c L_d}$$

where L_d is the effective length of the capillary (from the inlet to the detector), and t is the time required for the sample plug to travel from the inlet to the detector when a pressure of ΔP is applied.

Viscosity was measured by injecting a plug of 2×10^{-4} M thymidine into the inlet of a capillary and applying a constant pressure to push the sample plug through the capillary. The Beckman CE system used in this study has a lag period of 0.045 min between when the instruction is given by the computer and when the pressure of 20 psi is fully applied. This time lag must be subtracted from the measured sample migration time.

The viscosity of pure water was measured to be 1.1 cP (1P = 0.1 Pa s) at 20°C. This viscosity value is about 10% higher than the value listed in the CRC Handbook of Chemistry and Physics (1.002 cP) (24). This discrepancy may arise from variations in the capillary diameter, the time required for the pressure to rise to 20 psi, and the uncertainty in the length of the capillary. The accuracy of the pressure and the temperature may also affect the results of the absolute viscosity. The relative viscosity, however, should be unaffected. With a known value for the viscosity of pure water, the viscosity of other solutions can be obtained by:

$$[18] \quad \eta = \frac{\eta_{H_2O} \times t}{t_{H_2O}}$$

where η_{H_2O} and t_{H_2O} are the viscosity and time values for water, and η and t are the viscosity and time values of the solution to be measured. Table 1 is a list of the viscosity values for buffer solutions at different β-CD concentrations. The results were obtained from five measurements with two different capillaries. Using these viscosity values, the correction factor ν in eq. [8] can be calculated.

Table 1. Viscosity values for the 160 mM borate buffer solutions with different β-CD concentrations.[a]

β-CD Concentration (mM)	Viscosity (cP)
0	1.05 ± 0.01
5.0	1.06 ± 0.01
7.5	1.07 ± 0.01
10.0	1.08 ± 0.01
12.5	1.08 ± 0.01
15.0	1.09 ± 0.01
20.0	1.11 ± 0.01

[a]The Viscosity was measured in a 160 mM borate buffer (pH 9.1).

Although the electric current changes when the buffer viscosity is varied, the viscosity change is not the only factor that produces a change in the current. For example, addition of sodium dodecyl sulfate (SDS) increases the viscosity of a solution as well as the current. In other cases when nonionic species such as β-CD are added, the current decreases. Some interactions between species in the solution may also affect the current. Current ratio can be used as a correction factor only when it is proven experimentally that it changes at the same rate as the viscosity (7), thus eventually the viscosity ratio has to be obtained from direct viscosity measurements.

Calculating the equilibrium constants

Substituting the mobility μ with L_d/tE, where E is the electric field, and t is the migration time, eq. [9] can be rearranged to:

$$[19]\quad \frac{1}{\nu\left(\frac{1}{t}-\frac{1}{t_{eo}}\right)-\frac{1}{t_{ep,A}}} = \frac{1}{\left(\frac{1}{t_{ep,AC}}-\frac{1}{t_{ep,A}}\right)K}\frac{1}{[C]}+\frac{1}{\frac{1}{t_{ep,AC}}-\frac{1}{t_{ep,A}}}$$

The equilibrium constant was calculated by plotting $1\Big/\left[\nu\left(\frac{1}{t}-\frac{1}{t_e}\right)-\frac{1}{t_{ep,A}}\right]$ vs. 1/[C]. Electroosmotic flow rates were obtained by measuring the migration time of a benzene plug through the capillary at different additive concentrations. The neutral molecules, benzene, acetone, and dimethyl formamide, were tested and any of them can be used as the EOF marker in this case because the additive is neutral. The migration times of the analytes were measured from each electropherogram, and the electroosmotic flow rate was measured separately at each β-CD concentration using benzene as a marker. The $1/t_{ep,A}$ value was calculated from $[(1/t_A^0) - (1/t_{eo}^0)]$, where t_A^0 and t_{eo}^0 are the migration time of analyte A and the migration time of the EOF marker, respectively, when there is no additive added to the buffer solution. The migration times of the analytes and the EOF marker were then measured at different β-CD concentrations.

The K for each nucleoside and nucleotide with β-CD was obtained by dividing the intercept by the slope of the linear fitted line. When experiments were repeated with a different capillary and a different batch of buffer solution (same borate concentration), the migration times of the marker and the analytes changed by about 15% because of the change in the EOF. The K values, however, are nearly identical from the two experiments. The average K values, the standard deviations of the two sets of data, and the R^2 values for the curve fittings of both experiments are listed in Table 2. The standard deviations were calculated from the differences in the values obtained from independent measurements. When the change in viscosity is not significant, the K values will be affected less; when there is a significant change in viscosity because of the change in additive concentration, the effect of the correction factor may be very large. For example, when the β-CD concentrations range from 0 to 20 mM, and when the viscosity change is corrected for, the equilibrium constants (K) obtained for ADP and CMP are 50.7 ± 2.8 and 79.5 ± 4.2, respectively. Under the same conditions without the viscosity correction, the values are 21.6 ± 1.8 and 34.2 ± 3.3, respectively.

Table 2. Complexation equilibrium constants for five nucleosides and their phosphates with β-CD.[a]

[a]The formation constants are measured in 160 mM borate buffer at pH 9.1.

It should be emphasized that the purpose of obtaining the K value is to describe the analyte migration behavior. When the difference in the free and complex mobilities is small, a slight change in viscosity (even if it is less than 1%) will cause significant change in the K values. The error range obtained from regression analysis alone can be underestimated. However, in this situation, the effect of K values on the change in analyte mobility is also reduced because the equilibrium does not play as important a role as when there is a large difference in the free and complex mobilities. Another possibility for the error in the reported K values being underestimated is the influence of temperature. The temperature at the center of the capillary can be quite different from

Fig. 1. The electropherograms of nucleosides and their phosphates in 160 mM borate buffer at pH 9.1 with different amounts of β-CD added to the solution. The concentrations (mM) of β-CD are (a) 0, (b) 5, (c) 7.5, (d) 10, (e) 12.5, (f) 15, and (g) 20. The analytes are: 8. AMP, 9. GMP, 10. ATP, 11. TTP, 12. GTP, 13. TDP, 14. CMP, 15. UMP, 16. ADP, 17. GDP, 18. CTP, 19. UTP, 20. CDP, 21. UDP.

that of the region close to the capillary wall. However, for the purpose of predicting the migration behavior of the analytes, as our results show, the temperature difference does not introduce a significant amount of error. This is because it is the trend of the viscosity change that determines the accuracy of the K value, and it is the averaged macroscopic K value throughout the capillary that determines the analyte migration behavior, not the microscopic K value at a particular spot in the capillary.

It was suggested by Hoffman and Bock in 1970 that β-CD specifically complexes with adenosine nucleotides, and the formation constants were measured by UV spectroscopy (25). Formoso further investigated nucleotide–cyclodextrin complexation by circular dichroism, and indicated that β-CD also forms complexes with other nucleotides (26, 27). The formation constants obtained by DCCE are reasonably close to the values listed in these papers but exhibit much better precision. Because borate buffer was used in the separation media, the K values also reflect the effect of possible complexation between borate and the ribose hydroxyls. One should expect slight differences in the K values when a different buffer system is used. Equations [3]–[9] only describe the migration behavior of the analytes when the interaction between the additive and the analyte is (or can be considered) a simple 1:1 complex. Those equations can be modified to describe other types of interactions.

Changes in analyte mobilities

Borate buffer (160 mM, pH 9.1) with 0, 5, 7.5, 10, 12.5, 15, and 20 mM β-CD added to the solution was used in this study. The mobility of an analyte can be changed by changing the β-CD concentration. Figure 1 shows sections of electropherograms from separations of a mixture of nucleosides and their mono-, di-, and tri-phosphates at different β-CD concentrations. The differential migration of this group of analytes arises from their differences in size and charge, as well as the differences in their equilibrium constants with the additive. Similar phenomena have been discussed for chiral compounds (13).

Usually when an additive with a larger molecular weight is added to the buffer, the solution becomes more viscous. One would expect the analytes to migrate more slowly in the more viscous solution, especially in the presence of complexation equilibria. However, as shown in Fig. 1, there is no significant trend of increased migration times as the concentration of β-CD is increased from 0 to 20 mM. This phenomena is explained by eq. [8]. In the 160 mM borate buffer (pH = 9.1), all of the nucleosides and nucleotides have negative electrophoretic mobilities. When an analyte forms a complex with a neutral additive (β-CD), the electrophoretic mobility of the complex will be smaller than that of a free ion because of the smaller charge-to-size ratio. The complex should actually move faster with a reduced negative electrophoretic mobility. There was no significant reduction in the migration time either, except for a few analytes (e.g., AMP and CMP), because the increased viscosity impeded the movement of the analytes. AMP, CMP, and all other analytes would have moved faster if there were no viscosity changes. Without considering the viscosity correction factor, a smaller K would be obtained for this group of analyte–additive interactions because the apparent mobilities did not increase as much as they would have increased if there were no change in viscosity.

There are two factors that affect the electrophoretic mobility of an analyte: the difference between the mobilities of the free analyte and the complex ($\mu_{ep,AC} - \mu_{ep,A}$), and k'. Peak 8 (AMP) has a relatively large change in mobility when different concentrations of β-CD are added to the buffer because of the large difference between the $\mu_{ep,A}$ and the $\mu_{ep,AC}$ of AMP. Peaks 14 and 16 (CMP and ADP) demonstrate large mobility changes mainly because they have relatively large K values. Peaks 17 and 18 (GDP and CTP) have relatively smaller changes in mobilities because their K values are small. An analyte (e.g., peak 14, CMP) could overlap with or be separated from the other analytes by changing the additive concentration.

Optimizing separation conditions

As discussed in the theory section, the net electrophoretic mobility in the ideal state is described by $\mu_{ep,A}$, $\mu_{ep,AC}$, and the equilibrium constant, K. The effect of viscosity has to be included in order to interpret the real experimental results.

From electropherograms obtained without using β-CD, the electrophoretic mobilities of the free analytes can be obtained. The complex electrophoretic mobility can be calculated from the intercept of eq. [9]. These values are listed in Table 3. Based on the values in Tables 2 and 3, the net electrophoretic mobility of each analyte can be described by eq. [8]. Figure 2*a* shows the plots of the ideal state net electrophoretic mobilities for some of the harder-to-separate nucleotides in this buffer system. The curves in Fig. 2*b* are the net electrophoretic mobilities of the same group of nucleotides with the viscosity change taken into consideration (the ideal state mobility divided by the viscosity correction factor as a function of additive concentration). The symbols (e.g., +, x, etc.) are the μ_{ep}^{A} values measured experimentally. The experimental data agree well with the values predicted by DCCE theory. The experimental values are systematically higher than predicted at 12.5 mM β-CD, and lower at 20 mM. This may be due to the error introduced from measuring the EOF in separate runs.

Table 3. List of ideal state ([C] → 0) electrophoretic mobilities of the free analytes and the electrophoretic mobilities of the analyte–β-CD complexes.

Analyte	$\mu_{ep,A}$ ($\times 10^{-4}$ cm^2 V^{-1} s^{-1})	$\mu_{ep,AC}$ ($\times 10^{-4}$ cm^2 V^{-1} s^{-1})

The y intercepts of the curves in Fig. 2 are the electrophoretic mobilities of the free analytes in additive-free solutions. Depending on the K value, the electrophoretic mobility of each analyte changes differently. An optimum additive concentration can be found based on the electrophoretic mobility vs. concentration plot. The optimum condition is at the additive concentration where the overlap of the corrected electrophoretic mobility curves is minimal. The effect of mobility difference on peak resolution can be observed by comparing the μ_{ep} vs. [C] plot in Fig. 2 with the electropherograms in Fig. 1.

The resolution equation

When the separation factor is defined as the ratio of the electrophoretic mobilities of two analytes, the resolution of two peaks can be calculated from eq. [15] based on the analyte electrophoretic mobility, the migration time, and the separation factor. Figure 3 demonstrates the separation of nucleosides A and C at different β-CD concentrations. The measured resolution is obtained from eq. [13] using the average peak width and the difference in migration time measured from the

Fig. 2. The electrophoretic mobilities of analytes as a function of additive concentration. Figure 2*a* shows the changes in the net electrophoretic mobilities of different analytes in the ideal state. All curves are simulated using eq. [8] with the $\mu_{ep,A}$, the $\mu_{ep,AC}$, and the K values from Tables 2 and 3. The curves in Fig. 2*a* are numbered according to the numbers assigned to the compounds in Fig. 1. Figure 2*b* shows the changes in the measured net electrophoretic mobilities (μ_{ep}^{A}) of different analytes at different additive concentrations. The smooth curves (solid lines) are the calculated results with the viscosity change taken into consideration. The number beside each symbol represents the same analyte as in Fig. 1 and Fig. 2*a*. The symbols (e.g., +, x, etc.) are the μ_{ep}^{A} values measured experimentally.

electropherogram. Because it is not possible to accurately measure the peak widths of the overlapped A and C peaks when the concentration of β-CD is 0, 5.0, or 7.5 mM, the average peak width of PCV and G is used as the average peak width of A and C. At other concentrations, the average peak width of A and C is used to obtain the measured resolution. When eq. [15] is used to calculate the resolution, the theoretical plate number N is calculated from $5.54(t_r/W_{1/2})^2$, where the peak width at half maximum (PWHM, $W_{1/2}$) is obtained from a Gaussian fit of the analyte peak. For 0 and 5 mM β-CD, the number of theoretical plates is taken from the average of the PCV and the G peaks, while for other concentrations the C peaks are used. Both the measured and the calculated resolution values are listed in Table 4. The proposed resolution equation (eq. [15]) can accurately predict the resolution of two closely migrating analytes.

Conclusion

CE theory based on dynamic complexation describes the migration behavior of analytes at the molecular level. It is applied to the separation of 20 nucleosides and nucleotides when β-CD is used as an additive. Three parameters (K, $\mu_{ep,A}$, and $\mu_{ep,AC}$) and viscosity determine the net electrophoretic mobility of an analyte at any given additive concentration. Clarification of these fundamental relationships has tremendous impact on method development, separation optimization, and method validation. While the EOF is difficult to control, the electrophoretic mobility of an analyte, which is the real reflection of the intrinsic properties of a species, is reproducible. The μ_{ep} values, not the migration times, should be used as the comparison parameters in method validation. The equilibrium constant of an analyte–additive interaction and the viscosity of a solution with certain composition are also constants. More $\mu_{ep,A}$, $\mu_{ep,AC}$, K, and ν values should be collected to make CE a predictable systematic science.

A universal resolution equation is derived from DCCE theory. This resolution equation is verified by its ability to accurately predict separation results. The separation factor takes both analyte electrophoretic mobilities (free and complexed) and the analyte–additive interaction into account. The resolution equation gives clear guidance for method development.

Photodecarbonylation of chiral cyclobutanones

Jailall Ramnauth and Edward Lee-Ruff

Abstract: Triplet photosensitized irradiation of 2(*S*),3(*R*)-bis[(benzoyloxy)methyl]cyclobutanone gave optically pure (−) *E*-1(*S*),2(*S*)-bis(benzoyloxymethyl)cyclopropane as a major product in the nonpolar fraction along with its stereoisomer and cycloelimination products. The absolute stereochemistry of the chiral cyclopropane was established by independent synthesis and X-ray crystal structure determination of a synthetic precursor. The distribution of decarbonylation and cycloelimination products was inversely dependent on the concentration of the substrate. Irradiation of the same ketone in tetrahydrofuran or benzene gave mostly cycloelimination products. Addition of Michler's ketone increased the ratio of photodecarbonylation, suggesting a triplet state pathway for this process. This was corroborated by the addition of dicyanoethylene, which showed significant quenching of photodecarbonylation. Irradiation of 2(*S*)-[(benzoyloxy)methyl]cyclobutane in acetone gave the corresponding cyclopropane as the principal product.

Key words: photodecarbonylation, chiral cyclopropanes, cyclobutanones, triplet sensitization.

Résumé : L'irradiation triplet photosensibilisée de la 2(*S*),3(*R*)-bis[(benzoyloxy)méthyl]cyclobutanone conduit au (−)-*E*-1(*S*),2(*S*)-bis(benzoyloxyméthyl)cyclopropane comme produit majeur de la fraction non polaire avec son stéréoisomère et des produits de cycloélimination. La stéréochimie absolue du cyclopropane chiral a été déterminée par une synthèse indépendante et par diffraction des rayons X d'un précurseur de synthèse. La distribution des produits de décarbonylation et de cycloélimination varie d'une façon inverse de la concentration du substrat. L'irradiation de la même cétone dans du tétrahydrofurane ou le benzène conduit principalement à des produits de cycloélimination. L'addition de la cétone de Michler augmente le rapport de photodécarbonylation; ceci suggère que le processus se produit par le biais d'un état triplet. Cette conclusion est corroborée par l'addition de dicyanoéthylène qui provoque une désactivation importante de la photodécarbonylation. L'irradiation du 2(*S*)-[(benzoyloxy)méthyl]cyclobutane dans l'acétone conduit au cyclopropane correspondant comme produit principal.

Mots clés : photodécarbonylation, cyclopropanes chiraux, cyclobutanones, sensibilisation triplet.

[Traduit par la rédaction]

Introduction

The photochemistry of cyclobutanones has been thoroughly investigated during the last three decades (1, 2). The primary process involves α-cleavage to a short-lived 1,4-acylalkyl diradical that can undergo one of three independent transformations: cycloelimination to ketene and olefin; ring expansion to a cyclic oxacarbene (2-tetrahydrofuranylidene); and decarbonylation, the latter normally representing a minor process unless structural features permit stabilization of a 1,3-diradical (e.g., presence of a 3-alkylidene group). Furthermore, sensitization experiments with simple cyclobutanones suggest that cyclopropane formation is a dominant pathway from the triplet state (3). Of the three photodecomposition pathways, the solution photodecarbonylation of cyclobutanones has received scant attention. This is largely due to the inefficiency of this process from direct irradiation, with singlet excited states giving rise to efficient cycloelimination and ring expansion as the result of strain effects. Triplet sensitized photochemistry of cyclobutanones appears to take a completely different course of events and is an area that has been relatively unexplored. The triplet sensitized photochemistry of a series of α-vinylcyclobutanones using either acetone or Michler's ketone (4,4′-bis(dimethylamino)benzophenone) as triplet sensitizers gave products derived from a 1,4-acyl alkyl diradical but different from the direct irradiation, in which case the usual cycloelimination and ring expansion pathways are observed (4). Chiral cyclobutanones are now readily accessible by a number of routes (5). The decarbonylation of these derivatives would involve a 1,4-acyl alkyl diradical whose lifetime would influence the extent of epimerization of the resultant cyclopropanes formed. It was of interest to investigate conditions under which chiral cyclopropanes could be produced from photodecarbonylation of chiral cyclobutanones. Chiral cyclopropanes are important intermediates in natural product synthesis and a variety of methods are available for their synthesis (6); however, only a few of these have been reported from ring contraction of chiral cyclobutane derivatives. With the availability of 2(*S*),3(*R*)-bis[(benzoyloxy)methyl] cyclobutanone **1**(*a*) and 2(*S*)-[(benzoyloxy)methyl]cyclobutanone **1**(*b*) in optically pure form (7, 8), we were interested in carrying out exploratory studies on the conditions under which cyclopropanes are efficiently produced by sensitized photodecarbonylation. We

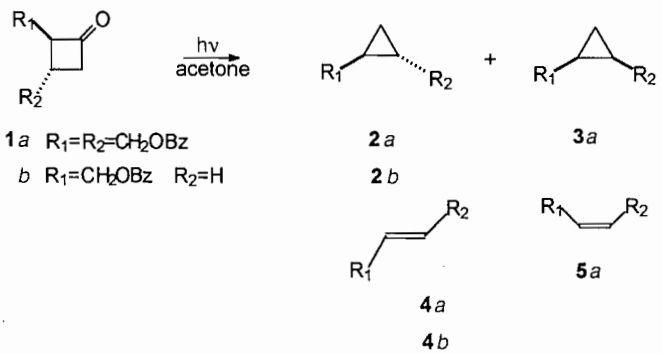
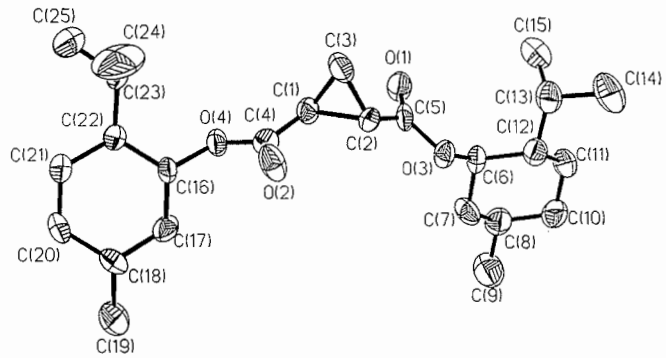
Scheme 1.



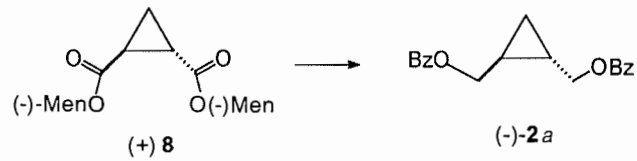
Scheme 2.

have reported the photochemistry of these derivatives under direct irradiation in the presence of purine bases as a novel method for producing ribonucleosides (8, 9). Decarbonylation of **1**(*a*) would produce two diastereomeric cyclopropanes **2**(*a*) and **3**(*a*), the latter derived from epimerization. The *E* isomer **2**(*a*) would be expected to be optically pure. Decarbonylation of **1**(*b*) would give achiral cyclopropane **2**(*b*).

Results and discussion



Cyclobutanone derivatives **1**(*a*) and **1**(*b*) were prepared according to literature methods (7, 8). The key step for the asymmetric synthesis of **1**(*a*) was the cycloaddition of dimen-



thyl fumarate with 1,1-dimethoxyethylene in the presence of a Lewis acid catalyst (7) giving greater than 98% diastereomeric enrichment. The preparation of optically pure **1**(*b*) was based on the enantioselective synthesis of a cyclobutane precursor from cycloaddition of 3-acryloyl-1,3-oxazolidin-2-one with 1,1-bis(methylthio) ethylene using a chiral titanium catalyst (10). This step occurred with an enantiomeric excess of greater than 98% (10).

Irradiation of a 6×10^{-3} M solution of **1**(*a*) in acetone for 4 h using a medium-pressure mercury lamp with unfiltered light gave a 25% conversion to a mixture of nonpolar compounds consisting of cyclopropanes **2**(*a*) (53%), **3**(*a*) (17%) and olefins **4**(*a*) (19%) and **5**(*a*) (11%). The structures of all photoproducts were assigned based on spectral data, elemental analysis, and independent synthesis. Olefin **5**(*a*) was prepared from benzoylation of *Z*-2-butene-1,4-diol. Its isomer **4**(*a*) was prepared by double nucleophilic substitution of *E*-1,4-dibromo-2-butene with potassium benzoate. Preparation of *Z*-1,2-bis(benzoyloxymethyl) cyclopropane (**3**(*a*))was based on

Fig. 1. X-ray crystal structure of (−) dimenthyl 1(*S*),2(*S*)-cyclopropanedicarboxylate (**+8**).

reduction of 1,2-cyclopropanedicarboxylic acid anhydride (**6**) followed by benzoylation (Scheme 1), whereas the racemic *E* isomer **2**(*a*) was prepared from commercially available diethyl *E*-cyclopropane-1,2-dicarboxylate (**7**) according to Scheme 2. That optically pure cyclopropane **2**(*a*) was produced in the photolysis of **1**(*a*) was established by the observed optical rotation of the nonpolar fraction. The measured specific rotation of **2**(*a*) was −7.5. To confirm the absolute configuration, cyclopropane (−)-**2**(*a*) was prepared from the known (−)-dimenthyl 1(*S*),2(*S*)-cyclopropane-1,2-dicarboxylate (**8**) (11).

We were not able to reproduce the literature procedure for the preparation of (+)-**8** from the methylenation of dimenthyl succinate with bromochloromethane under basic conditions (11). Our method for preparing (+)-**8** was based on the esterification of (±)-cyclopropane-1,2-dicarboxylic acid via the diacid chloride and separation of the diastereomeric diester by recrystallization from methanol. The optical purity of (+)-**8** was verified by matching the specific rotation ($[\alpha]_D$ = +17.5) with that reported in the literature ($[\alpha]_D$ = +17.8). Furthermore, the absolute configuration of (+)-**8** was confirmed by X-ray crystallographic analysis (Fig. 1). Reduction of (+)-**8** with lithium aluminum hydride followed by benzoylation gave

Table 1. Concentration dependence on the distribution (%) of products in acetone[a]

Conc. (10^{-3} M)	**2**(*a*)	**3**(*a*)	**4**(*a*)	**5**(*a*)	Cycl./olefin
5.6	12.4	3.9	4.4	2.8	2.3
3.0	16.5	5.1	3.4	3.4	3.2
1.5	20.3	5.1	3.3	1.6	5.2

[a]Yields were determined by HPLC analysis and calibration with standard solutions.

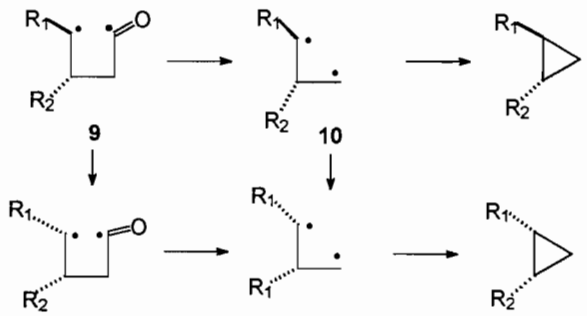
(±)-**2**(*a*) having identical spectral features with racemic (α)-**2**(*a*) and a specific rotation $[\alpha]_D = -7.5$ that was identical with the specific rotation for the sample obtained from photolysis.

A photostability study of each of the nonpolar photoproducts **2**(*a*)–**5**(*a*) under the irradiation conditions for **1**(*a*) indicated that cyclopropanes **2**(*a*) and **3**(*a*) were inert whereas olefins **4**(*a*) and **5**(*a*) underwent photoisomerization to give a 60:40 photoequilibrium mixture of **4**(*a*) and **5**(*a*). Thus olefin **5**(*a*) is a likely secondary photoproduct from the initially formed *E* isomer **4**(*a*). This photoequilibrium distribution of **4**(*a*) and **5**(*a*) was observed for all photolysis of **1**(*a*), indicating that photoequilibration competes with the primary photodecomposition.

The extent of photodecarbonylation as affected by substrate concentrations and nature of solvent was investigated. Decreasing concentrations led to increasing yields of cyclopropanes as seen in Table 1. This trend is what would be expected for solvent photosensitized processes. Direct excitation of ketone **1**(*a*) would be minimized under dilute conditions favouring triplet sensitized processes. Photolysis of **1**(*a*) in either tetrahydrofuran or benzene gave predominantly cycloelimination products **4**(*a*) and **5**(*a*) in the nonpolar fraction (Table 2). This latter observation further supports the speculation that decarbonylation of cyclobutanone is the consequence of triplet state decomposition. The formation of *cis*-olefin **5**(*a*) was somewhat surprising in view of the stereoselectivity of photocycloeliminations observed in other cyclobutanone derivatives (1). Further evidence for the intervention of the triplet state in the decarbonylation was obtained from irradiation of **1**(*a*) in THF in the presence of Michler's ketone (4,4′-dimethylamino)benzophenone) a known triplet photosensitizer for cyclobutanones (4). A significant increase in cyclopropane formation was observed under the photosensitized conditions (Table 2).[3] Quenching studies using dicyanoethylene (DCE) (13) showed significant reduction of photodecarbonylation dependent on the DCE concentration in the acetone photolysis (see Table 2). However, addition of DCE under the nonsensitized photolysis in THF did not supress the small amounts of cyclopropanes, indicating a minor singlet state route for photodecarbonylation.

Irradiation of ketone **1**(*b*) in acetone (6×10^{-3} M) gave efficient conversion to cyclopropane **2**(*b*) (86%) and olefin **4**(*b*) (10%). The identity of cyclopropane **2**(*b*) was established from its spectral data and independent synthesis from cyclopropane carboxylic acid as outlined in Scheme 3. The predominance for photodecarbonylation in ketone **1**(*b*) is probably associated with inefficient cycloelimination from β-cleavage of a secondary C—C bond as compared to a tertiary C—C bond in **1**(*a*).

Table 2. Solvent dependence on distribution (%) of products[a]



Solvent	**2**(*a*)	**3**(*a*)	**4**(*a*)	**5**(*a*)	Cycl./olefin
Acetone	12.4	3.9	4.4	2.8	2.3

[b]MK = Michler's ketone.

Scheme 3.

Scheme 4.

It has been shown that chiral cyclopropanes can be prepared from chiral cyclobutanones using acetone as a triplet sensitizer and solvent. The extent of epimerization at the α-carbon in the decarbonylation of cyclobutanones will depend on the lifetimes of the intermediate acyl-alkyl diradical **9** and the 1,3-diradical **10** (Scheme 4). Thermodynamic equilibration of these intermediates would give an epimeric mixture of cyclopropanes. However, 1,3-diradicals (trimethylene) generated from other precursors such as optically active pyrazolines retain their optical activity in the products (14, 15). These observations are rationalized in terms of the stereoselective ring-closure of these triplet trimethylenes. It would be expected that diradical **10** would be formed in the triplet state by spin conservation. Our results show that some epimerization takes place at the stereogenic radical site. Further studies on the triplet sensitized photochemistry of other chiral 2,4-disubstituted cyclobutanones are in progress.

[3] Although triplet-type photoreactions have been reported for cyclobutanones in the presence of Michler's ketone, energy transfer is endothermic. Evidence suggests an electron transfer process operating under these conditions (12).

Experimental

Melting points (mp) were determined on a Reichert melting point apparatus and are uncorrected. ^{1}H NMR spectra were recorded on a Bruker ARX 400 (400 MHz) spectrometer in $CDCl_3$ solutions containing 1% TMS. Optical rotations were measured using a Perkin–Elmer 241 polarimeter. HPLC analysis was performed on a Waters M-6000A instrument with a Lambda-Max model 481 LC detector using UV detection (254 mm), a Hewlett–Packard integrator, and a Spherisorb Silica analytical column from Sigma–Aldrich. Photolyses were carried out using a Hanovia 450 W medium-pressure mercury arc lamp in a water-cooled immersion well. Quartz tubes containing the samples were strapped around this well and the assembly immersed in an ice–water bath. The samples were degassed with argon for 30 min prior to irradiation. The X-ray crystal structure was performed on a Siemens R 3 m/v diffractometer using 1591 observed reflections. All solvents used in these reactions were dried and distilled. Analytical thin-layer chromatography (TLC) was done on commercially prepared silica gel 60F 254 plastic sheets (E. Merck & Co.). Preparative TLC was conducted on Aldrich silica gel 60F 254 precoated glass plates. Elemental analyses were performed by Guelph Chemical Laboratories Limited. The starting cyclobutanones **1**(*a*) and **1**(*b*) were synthesized according to literature methods (7, 8).

General photolysis procedures

A solution of ketone **1**(*a*) or **1**(*b*) in 70 mL of solvent ($\sim 10^{-3}$ M) was irradiated for 4 h (13 h for **1**(*b*)). The solvent was removed by rotoevaporation under reduced pressure. The residue was chromatographed on TLC plates (hexane:ethyl acetate, 95:5) to give a nonpolar fraction. The polar fraction was not analyzed but consisted of unreacted ketone and products containing an alcohol function. The nonpolar fraction was analyzed by analytical HPLC and comparison with synthesized samples as detailed below. Quenching studies with DCE were carried out under the same conditions using 6×10^{-3} M and 1.2×10^{-2} M solutions of DCE.

(±) E-1,2-Bis(benzoyloxymethyl)cyclopropane ((±) 2(a))

To a stirred suspension of $LiAlH_4$ (0.25 g, 6.44 mmol) in anhydrous ether (15 mL) at 0°C under argon was added diethyl *E*-1,2-cyclopropanedicarboxylate ((±)-**7**) (0.5 g, 2.7 mmol) in 20 mL ether. After 1 h, 3 mL of water was added and the solution filtered. To the filtrate was added anhydrous $MgSO_4$ and the solution was concentrated. ^{1}H NMR analysis of the residue showed the presence of the diol. Most of the diol remained in the filter cake. To the dry filter cake was added pyridine (10 mL), and benzoyl chloride (0.9 g, 6.0 mmol) was added dropwise with constant stirring. After 2 h, water (10 mL) was added to the reaction mixture and the organic layer was extracted with 50 mL ether, dried over anhydrous $MgSO_4$, and concentrated under reduced pressure. The residue was subjected to preparative TLC (benzene) to yield 70 mg (8.4%) of a white solid; mp 48–50°C; IR (KBr): 1715, 1600 cm^{-1}; ^{1}H NMR δ: 8.01–7.34 (m, 10H), 4.40–4.36 (dd, 2H, J = 5.8, 5.5 Hz), 4.48–4.04 (dd, 2H, J = 7.8, 4.0 Hz), 1.42–1.37 (m, 2H), 0.77–0.73 (t, 2H, J = 6.9 Hz). Anal. calcd. for $C_{19}H_{18}O_4$: C 73.55, H 5.81; found: C 73.42, H 5.71.

(−) Dimenthyl E-1(S), 2(S)-cyclopropanedicarboxylate ((+)8)

The title compound was prepared from (±)-cyclopropanedicarbonyl chloride which was prepared using the following procedures. A solution of diethyl *E*-1,2-cyclopropanedicarboxylate (±)-**7** (10 g, 53.7 mmol) in 100 mL of an aqueous methanol solution (9:1 methanol: H_2O) of 10% KOH was heated to reflux for 4 h. After cooling to room temperature, the mixture was diluted with 20 mL of H_2O and acidified with 50 mL of cold 6 M HCl. The solution was saturated with NaCl and extracted with 5 × 40 mL ether. The ether extract was dried over Na_2SO_4 and evaporated to yield 5.7 g of a white crystalline solid, mp 175–177°C (lit. (16) mp for *E*-1,2-cyclopropanedicarboxylic acid 175–177°C). To 4.6 g (38.4 mmol) of the dicarboxylic acid in 15 mL benzene was added 17 g (143 mmol) of $SOCl_2$. The mixture was heated to reflux for 4 h. The mixture was evaporated under reduced pressure. The residue was distilled (88°C, 10 Torr (1 Torr = 133.3 Pa) to give a colourless liquid of the acid chloride. ^{1}H NMR δ: 2.93–2.89 (t, 2H, J = 7.0 Hz), 1.91–1.88 (t, 2H, J = 7.2 Hz).

A solution of (−)-menthol (4.0 g, 25 mmol) in 3 g pyridine and 20 mL benzene was cooled in an ice–water bath. To this solution was added *E*-1,2-cyclopropanedicarbonyl chloride (2.0 g, 12.0 mmol) over a period of 20 min. The mixture was stirred for an additional 20 min at this temperature and for another 2 h at room temperature. After this time 50 mL of H_2O was added. The organic layer was extracted with 50 mL of ether and washed with 100 mL H_2O, dried over Na_2SO_4, and evaporated to yield 3 g (61%) of a white solid. This solid was dissolved in 50 mL of warm methanol. Colourless needles were obtained (1.2 g). An additional three recrystallizations gave optically pure (+)-**8** in 0.82 g (16.7%) yield; mp 94–95°C; $[\alpha]_D$ = +17.5 ($CHCl_3$, *c* 0.1), (lit. (11) $[\alpha]_D$ = +17.8 ($CHCl_3$, *c* 1.0)); IR (KBr): 1724 cm^{-1}. The absolute structure was confirmed by X-ray crystallography (Fig. 1).

(−) E-1(S),2(S)-Bis(benzoyloxymethyl)cyclopropane ((−)-2(a))

To a stirred suspension of $LiAlH_4$ (0.27 g, 1.1 mmol) in 20 mL of dry THF at 0°C under argon was added (−) dimenthyl *E*-1(*S*),2(*S*)-cyclopropanedicarboxylate ((+)-**8**) (0.7 g, 1.7 mmol) in 20 mL THF, dropwise over a period of 20 min. The reaction mixture was then heated to reflux for 4 h. After cooling in an ice–water bath the following were added sequentially:(1) 0.7 mL H_2O, (2) 0.7 mL of 15% aqueous NaOH, and (3) 2.1 mL of H_2O. The mixture was filtered and the precipitate washed with 200 mL of ether. The precipitate was subjected overnight to Soxhlet extraction with ether. The ether extracts were combined and evaporated and to the residue was added 20 mL H_2O, 1 mL methanol, and 20 mL hexane. The organic layer was separated and the aqueous layer was extracted with additional hexane (4 × 20 mL). The combined organic fractions were then washed with 10 mL H_2O. The combined aqueous layers were saturated with NaCl and extracted with ether (5 × 20 mL). The organic extract was dried over Na_2SO_4 and concentrated to give 50 mg (28.4%) of a colourless oil. To this material was added 1 mL of pyridine and the solution cooled to 0°C. Benzoyl chloride (0.25 mL) was added with constant stirring. The reaction mixture was allowed to warm to room temperature and stirred for an additional 2 h. After this time, 20 mL of H_2O was added. The mix-

For personal use only.

ture was extracted with 50 mL ether, and the ether extract was washed with 2 × 40 mL of H_2O, 2 × 40 mL of a 5% aqueous HCl solution, 2 × 40 mL of a saturated $NaHCO_3$ solution, 2 × 100 mL H_2O, and dried over Na_2SO_4. The ether was evaporated to give 70 mg (13.1%) of a white solid identical in all respects (except for specific rotation) with racemic **2**(*a*) prepared above; mp 49–50°C; $[\alpha]_D = -7.5$ ($CHCl_3$, *c* 0.042).

*Z-1,2-Bis(benzoyloxymethyl)cyclopropane (**3**(a))*

To a stirred suspension of $LiAlH_4$ (0.16 g, 4.2 mmol) in 20 mL of THF at 0°C under argon, was added *Z*-1,2-cyclopropanedicarboxylic acid anhydride (**6**) (0.14 g, 1.25 mmol) in 10 mL THF, dropwise over a period of 20 min. The reaction mixture was stirred for an additional 20 min at this temperature and then heated to reflux for 3 h. After cooling to 0°C, the following were added sequentially: (1) 0.17 mL H_2O, (2) 0.17 mL of 15% aqueous NaOH, (3) 0.51 mL H_2O. The mixture was stirred for 20 min. To this mixture was added dropwise 10 mL of pyridine and 1.0 g of benzoyl chloride over a period of 10 min. The mixture was stirred at room temperature for 24 h. After this time, 20 mL of H_2O was added to quench the excess benzoyl chloride. The reaction mixture was then filtered and the filter cake was washed with 50 mL of ethyl acetate. The filtrate was washed with 200 mL of H_2O, 200 mL of saturated $NaHCO_3$, 200 mL of a 5% aqueous HCl solution, and 200 mL of H_2O. The organic layer was dried over Na_2SO_4 and evaporated to give 0.2 g (52%) of a yellow oil. The residue was chromatographed on two preparative TLC plates to give 0.1 g of an oil (benzene); IR: 1717, 1602 cm^{-1}; ^1H NMR δ: 8.10–7.41 (m, 10H), 4.66–4.62 (dd, 2H, *J* = 6.1, 6.8 Hz), 4.23–4.18 (dd, 2H *J* = 8.6, 3.0 Hz), 1.57–1.51 (m, 2H). Anal. calcd. for $C_{19}H_{18}O_4$: C 73.55, H 5.81; found: C 73.21, H 5.77.

E-*1,4-Bis(benzoyloxy)-2-butene (**4**(a))*

Potassium benzoate (8.0 g, 50 mmol) was dissolved in 25 mL of 0.1 M NaOH and 200 mL acetonitrile. The solution was heated to reflux. To this solution was added *E*-1,4-diromo-2-butene (5.0 g, 23 mmol) in one portion. The mixture was heated under reflux with constant stirring for 4 h. After this time, the mixture was poured into 25 mL of a 0.1 M HCl solution with constant stirring. The diester was filtered off and washed several times with a 5% $NaHCO_3$ aqueous solution. The solid was recrystallized from methanol to afford 3.4 g (50%) of a white crystalline solid; mp 102–103°C (lit. (17) mp 100–101°C); ^1H NMR δ: 8.08–7.43 (m, 10H), 6.08–6.07 (t, 2H), 4.88–4.87 (d, 4H).

*Z-1,4-Bis(benzoyloxy)-2-butene (**5**(a))*

A solution containing *Z*-2-butene-1,4-diol (3 g, 34 mmol) in pyridine (6 g, 76 mmol) was cooled to 0°C. Benzoyl chloride (10.5 g, 75 mmol) was added dropwise over a period of 30 min. The mixture was allowed to warm to room temperature and stirring continued for an additional 2 h. After this time, 50 mL of water was added. The diester was filtered and recrystallized from 95% ethanol giving 7.0 g (70%) of a white crystalline solid; mp 66–67°C (lit. (17) mp 66–67°C); ^1H NMR δ: 8.06–7.41 (m, 10H), 5.96–5.95 (t, 2H), 5.04–5.00 (d, 4H).

*Benzoyloxymethylcyclopropane (**2**(b))*

A suspension of $LiAlH_4$ (0.57 g, 15.0 mmol) in 50 mL of anhydrous ether was cooled to 5°C. To this suspension was added dropwise a solution of cyclopropanecarboxylic acid (1 g, 11.6 mmol) in 20 mL ether over a period of 30 min. The reaction mixture was stirred at this temperature for an additional 30 min, then heated to reflux for 2 h. After cooling to 5°C the following were added sequentially: (1) 0.6 mL H_2O, (2) 0.6 mL of 15% aqueous NaOH, (3) 1.8 mL of water. The mixture was stirred for an additional 30 min and filtered. The precipitate was washed with 200 mL ether. The combined ether solution was concentrated to give 0.78 g of cyclopropane-methanol, which was used for the next step without purification. The crude alcohol was dissolved in 15 mL pyridine and cooled to 5°C. To this solution was added dropwise 2.3 g (16.4 mmol) of benzoyl chloride over a period of 15 min. This mixture was allowed to warm to room temperature and stirred overnight. After this time, 2 mL of H_2O was added. The solution was concentrated under reduced pressure and partitioned using 100 mL ethyl acetate and 200 mL H_2O. The organic layer was washed with 2 × 100 mL H_2O, 4 × 100 mL saturated $NaHCO_3$, and 2 × 100 mL of water. After drying over Na_2SO_4 the organic layer was concentrated under reduced pressure to give 1.4 g (68%) of the title compound as an oil; IR: 1718, 1602 cm^{-1}; ^1H NMR δ: 8.08–7.41 (m, 5H), 4.16 (d, 2H, *J* = 7.4 Hz), 1.28–1.24 (m, 1H), 0.63–0.59 (m, 2H), 0.38–0.35 (m, 2H). Anal. calcd. for $C_{11}H_{12}O_2$: C 74.97, H 6.86; found: C 75.00, H 6.97.

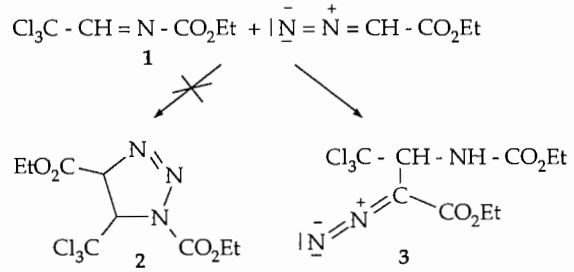
Réactivité dipolaire-1,3 du 4,4,4-trichloro-3-éthoxycarbonylamino-2-diazobutyrate d'éthyle issu de l'action du diazoacétate d'éthyle sur la *N*-éthoxycarbonyl-*N*-(2,2,2-trichloroéthylidène)amine

Abdelhak Belaissaoui, Sandrine Jacquot, Claude Morpain, Gérard Schmitt, Joël Vebrel et Bernard Laude

Résumé : La réaction du diazoacétate d'éthyle avec la *N*-éthoxycarbonyl-*N*-(2,2,2-trichloroéthylidène)amine conduit, via une réaction d'addition nucléophile, à un nouveau diazocomposé qui a manifesté ensuite une réactivité dipolaire-1,3 vis-à-vis des esters acétylèniques et des maléimides. Dans le cas des esters acétyléniques, la réaction de cycloaddition s'accompagne d'une évolution qui conduit à des pyrazoles très substitués par suite de transpositions sigmatropiques [1,5]. Avec les maléimides, on observe une réaction de cycloaddition diastéréospécifique suivie d'une élimination d'azote conduisant à un maléimidocyclopropane. La diastéréospécificité observée a été rationalisée en faisant appel à un mode d'approche des réactants du type *endo-anti*.

Mots clés : *N*-éthoxycarbonyl-*N*-(2,2,2-trichloroéthylidène)amine, diazoacétate d'éthyle, addition nucléophile, cycloaddition dipolaire-1,3, transposition sigmatropique, diastéréosélectivité.

Abstract: The reaction of ethyl diazoacetate with the *N*-ethoxycarbonyl-*N*-(2,2,2-trichloroethylidene)amine yields, by a nucleophilic addition, a new diazo compound that gives 1,3-dipolar cycloaddition reactions with acetylenic esters and maleimides. With acetylenic esters, the cycloadduct leads to substituted pyrazoles by [1,5] sigmatropic rearrangements. With maleimides, we observe a diastereospecific cycloaddition reaction. The intermediary cycloadduct evolves by nitrogen elimination to give a maleimidocyclopropane. The diastereospecificity was explained by an *endo-anti* approach of the reactants.



Key words: *N*-ethoxycarbonyl-*N*-(2,2,2-trichloroethylidene)amine, ethyl diazoacetate, nucleophilic addition, 1,3-dipolar cycloaddition, sigmatropic rearrangement, diastereoselectivity.

Introduction

La synthèse des anhydrochloraluréthanes a été rapportée pour la première fois par Moscheles en 1891 (1). Mais Feist a montré ultérieurement qu'il s'agissait de produits de structure $(ROOC\text{-}NH\text{-}CH(CCl_3))_2O$ (2) et c'est en 1968 que la première préparation de la *N*-éthoxycarbonyl-*N*-(2,2,2-trichloroéthylidène)amine **1** a été menée à bien en trois étapes par Ulrich et coll. (3). Les auteurs indiquent un rendement global de 45% que nous avons réussi à porter à 83% (cf. partie expérimentale).

Cette imine est un substrat fortement électrophile et de nombreuses réactions d'addition nucléophile ont été décrites (3). L'imine **1** est aussi un diénophile qui a été engagé dans des réactions de type Diels–Alder avec le cyclohexène (4). La seule réaction de cycloaddition dipolaire-1,3 concerne les nitrones et a été récemment décrite par Consonni et coll. (5) Pour notre part et après avoir étudié le comportement de la *N*-éthoxycarbonyl-*N*-(2,2,2-trichloroéthylidène)amine **1** avec quelques diarylnitrilimines et arylnitriloxydes (6), nous présentons ici les résultats obtenus en engageant le diazoacétate d'éthyle avec l'imine **1**. Dans la littérature (7–16), c'est essentiellement avec le diazométhane que diverses imines ont été mises en réaction, et les travaux décrits font tous état d'une réaction régiospécifique conduisant à une

Schéma 2.

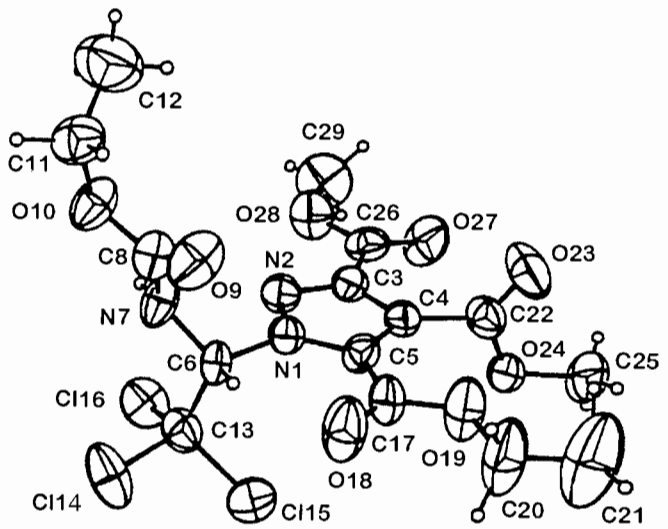
a : R = CO_2Me, R' = Me
b : R = H, R' = Me
c : R = CO_2Et, R' = Et
d : R = H, R' = Et

Δ^2-1,2,3-triazoline **2** qui dans le cas présent pourrait éventuellement s'isomériser en une Δ^3-1,2,3-triazoline (schéma 1).

Mais l'examen en spectrométrie IR du produit **3** obtenu ici permet d'observer la présence d'une bande intense à 2104 cm^{-1} caractéristique de la présence du groupe diazo. On obtient donc le 4,4,4-trichloro-3-éthoxycarbonylamino-2-diazobutyrate d'éthyle **3**. Cette structure est en bon accord avec les résultats de l'analyse élémentaire et les paramètres de RMN ^1H et ^{13}C. Ainsi on n'observe pas de signaux correspondant à la présence de deux chainons -CH- vicinaux mais à celle d'un seul groupe -CH- voisin d'un reste -NH- (J_{CH-NH} = 9,8 Hz). Il n'est pas étonnant que la réaction observée soit une addition nucléophile du diazoacétate d'éthyle puisque l'hydrogène fixé sur le carbone porteur du groupe diazo est rendu très mobile par la présence des deux groupes accepteurs liés à cet atome de carbone. On obtient donc un nouveau diazocomposé dont nous avons voulu tester l'activité dipolaire-1,3.

Compte-tenu des observations décrites ultérieurement, nous avons aussi examiné quelle pouvait être sa structure spatiale. À cet effet, nous avons effectué une étude en spectrométrie IR de solutions dans CCl_4 du produit d'addition **3** à différentes concentrations. La variation de la concentration de la solution dans CCl_4 n'entraîne aucune variation de la position et de l'intensité relative des bandes d'absorption $\nu_{(N-H)}$ situées à 3401 et 3436 cm^{-1}. Ce phénomène est caractéristique de l'existence d'une liaison hydrogène intramoléculaire lorsque la concentration est inférieure à 10^{-2} mol L^{-1} (17). On peut donc envisager l'existence de ce composé sous forme quasi-cyclique (Schéma 2).

Réaction du nouveau diazocomposé avec des dipolarophiles acétyléniques



Le diazocomposé **3** n'est pas stable dans le toluène à ébullition où il se dégrade peu à peu, aussi les réactions ont-elles été effectuées à une température de 60°C et suivies par CCM et IR (disparition de la bande $\nu_{(N_2)}$). Dans ces conditions les réactions sont lentes (60–100 h).

1. Cas de l'acétylènedicarboxylate de diméthyle et du propiolate de méthyle

Ce sont les premiers dipolarophiles acétyléniques que nous avons testés. Après départ du solvant, on obtient un résidu qui est purifié par chromatographie sur plaques préparatives.

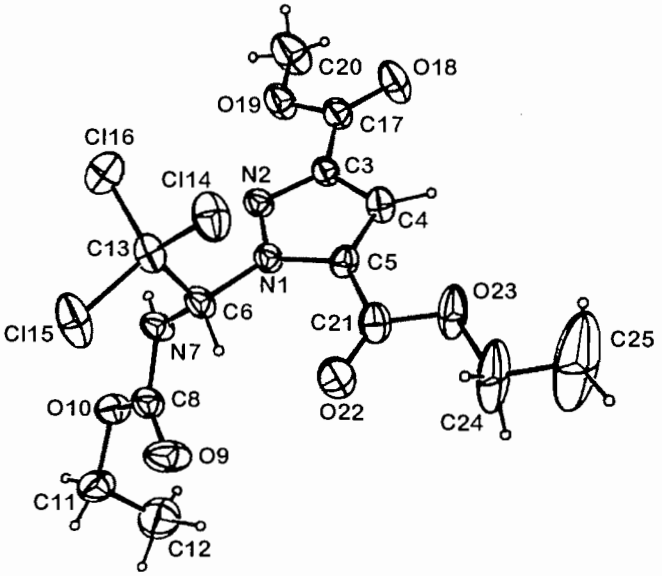
L'examen en RMN ^1H de chacun des produits ainsi purifiés (une seule tache en CCM) nous a permis d'observer le

Fig. 1. Structure du produit **5***a* (18*a*).

dédoublement de certains signaux. Ainsi dans le cas de l'acétylènedicarboxylate de diméthyle où un seul régioisomère peut être obtenu, on attendait le produit de structure **4***a* (schéma 2).

Nous avons envisagé l'existence de deux diastéréoisomères résultant de la présence de deux centres chiraux dans la structure **4**. Mais nous avons abandonné cette hypothèse parce que le spectre de RMN ^{13}C ne présentait aucun signal attribuable au carbone sp^3 quaternaire C(5) de la structure **4**. Nous avons donc fait appel à une détermination de structure par radiocristallographie X de chaque produit isolé à partir de l'acétylènedicarboxylate de diméthyle (18*a*) (figure 1) d'une part et du propiolate de méthyle (18*b*) (figure 2) d'autre part. Les monocristaux utilisés pour cette étude ont été prélevés au sein du dépôt solide obtenu après évaporation lente d'une solution éthanolique de chaque produit purifié par chromatographie sur plaques préparatives.

Ces structures montrent à l'évidence qu'il ne s'agit pas des cycloadduits **4** attendus mais que chaque produit **5** provient de l'isomérisation du cycloadduit initial (schéma 2).



Cette isomérisation peut s'expliquer par une transposition sigmatropique [1,5] dont la force motrice est l'aromaticité du dérivé pyrazolique **5**. De plus, dans le cas du produit **5***b*, la détermination radiocristallographique de sa structure permet

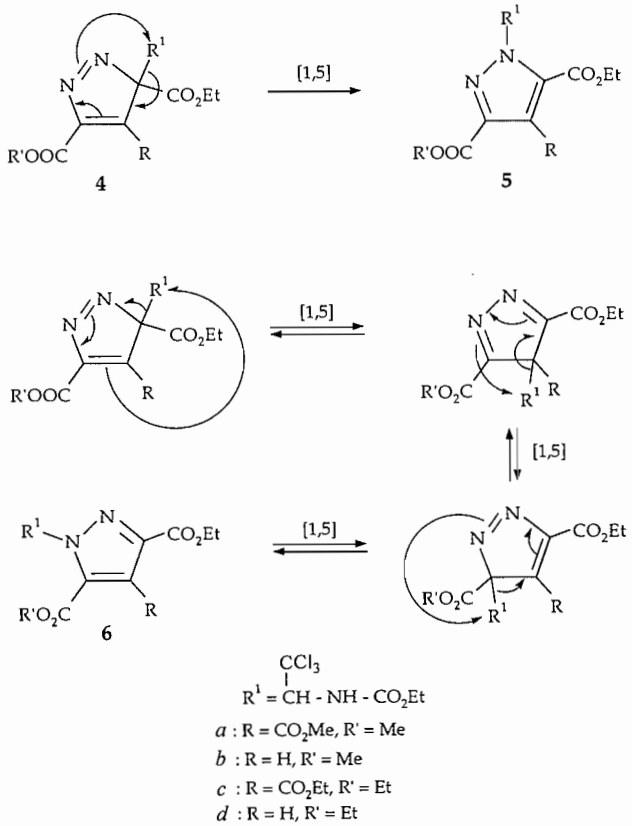
Fig. 2. Structure du produit **5***b* (18*b*).

de fixer la régiochimie unique de la réaction de cycloaddition initiale.



Pour tenter d'expliquer l'origine du dédoublement de certains signaux sur les spectres de RMN ^{1}H et ^{13}C des produits purifiés par chromatographie sur plaques préparatives, nous avons tracé les spectres de RMN ^{1}H et ^{13}C à partir d'une solution dans $CDCl_3$ des monocristaux séparés pour l'étude radiocristallographique. Ces derniers spectres ne présentent plus de dédoublement des signaux. Cette différence est illustrée par les spectres de RMN ^{1}H (figures 3 et 4) dans le cas du produit **5***b*.

Par ailleurs, dans le cas des spectres dédoublés, une étude en RMN à température variable (jusqu'à 213 K dans $CDCl_3$ et 383 K dans DMSO-d_6) ne nous a pas permis d'observer de phénomène de coalescence des signaux dédoublés. À basse température, les signaux sont légèrement élargis par suite d'une augmentation de la viscosité du solvant. Ce résultat nous permet de ne pas retenir l'existence éventuelle de rotamères résultant de la proximité du groupement 2,2,2-trichloro-1-éthoxycarbonylaminoéthyle sur l'azote-1 et du reste ester sur le carbone C-5 du cycle pyrazolique. La construction d'un modèle Dreiding confirme l'inexistence d'une rotation restreinte.

L'analyse élémentaire quantitative des produits isolés par chromatographie étant en excellent accord avec la structure **5** proposée, nous avons alors envisagé l'existence de deux isomères de constitution **5** et **6** non séparés par chromatographie sur plaques préparatives. Une étude en chromatographie HPLC analytique ne nous a encore pas permis de les séparer quelle que soit la polarité de l'éluant (mélange hexane–chloroforme en proportions variables). Néanmoins, l'hypothèse de l'existence de deux isomères de constitution **5** et **6** très difficiles à séparer peut être retenue et sur la suggestion d'un rapporteur[3] nous avons effectué les mêmes réactions entre le diazocomposé **3** et les esters éthyliques des acides butynedioïque et propiolique.

[3] Nous remercions vivement le rapporteur pour cette féconde suggestion.

Schéma 3.

2. Cas de l'acétylènedicarboxylate de diéthyle et du propiolate d'éthyle

Après départ du solvant, l'examen en RMN ^{1}H du brut réactionnel ne fait apparaître qu'un seul produit d'évolution **5** du cycloadduit initial **4** (schéma 2).

Dans le cas présent tous les groupes esters des réactants sont des esters éthyliques et il faut donc admettre que la différence entre ces deux résultats est due au fait que dans le cas précédent, les groupes esters des dipolarophiles étaient des esters méthyliques.

On peut donc proposer que l'évolution du cycloadduit **4** initial peut se faire de deux façons concurrentes (schéma 3). Une première voie consiste dans la transposition sigmatropique [1,5] — déjà explicitée sur le schéma 2 — qui conduit au produit **5**. La seconde voie peut être représentée par trois transpositions sigmatropiques [1,5] successives qui permettent d'aboutir au produit **6**.

Si R′ = Et, les produits **5** et **6** sont identiques et c'est ce que nous observons dans le cas des esters dipolarophiliques éthyliques (**5***c* ≡ **6***c*, **5***d* ≡ **6***d*).

Si R′ = Me, les produits **5** et **6** sont des isomères de constitution (**5***a* ≠ **6***a*, **5***b* ≠ **6***b*) dont les comportements chromatographiques et les paramètres spectroscopiques seront évidemment très voisins ce qui rend compte des dédoublements observés sur les spectres de RMN ^{1}H et ^{13}C du mélange des composés **5***a,b* et **6***a,b*.

On peut de plus noter que dans le cas des composés *a* et *b* les proportions relatives de ces isomères de constitution sont de l'ordre : 65% de composé **5** pour 35% de composé **6**.

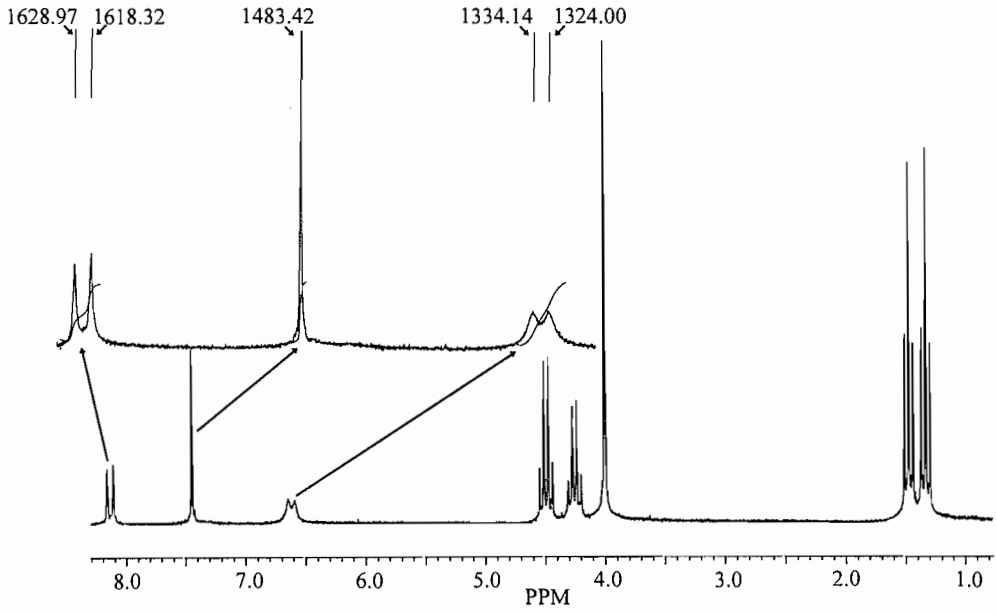
Fig. 3. Spectre tracé à partir d'une solution dans $CDCl_3$ des monocristaux de **5***b*.



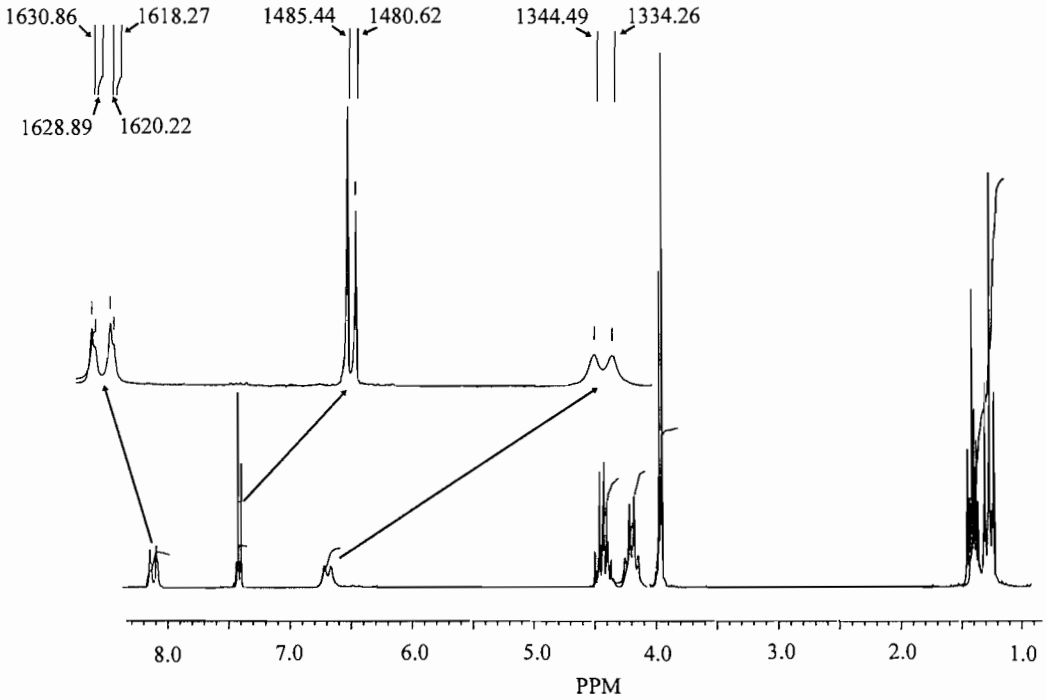


Fig. 4. Spectre tracé à partir d'une solution dans $CDCl_3$ du produit issu du propiolate de méthyle et chromatographié sur plaques préparatives.

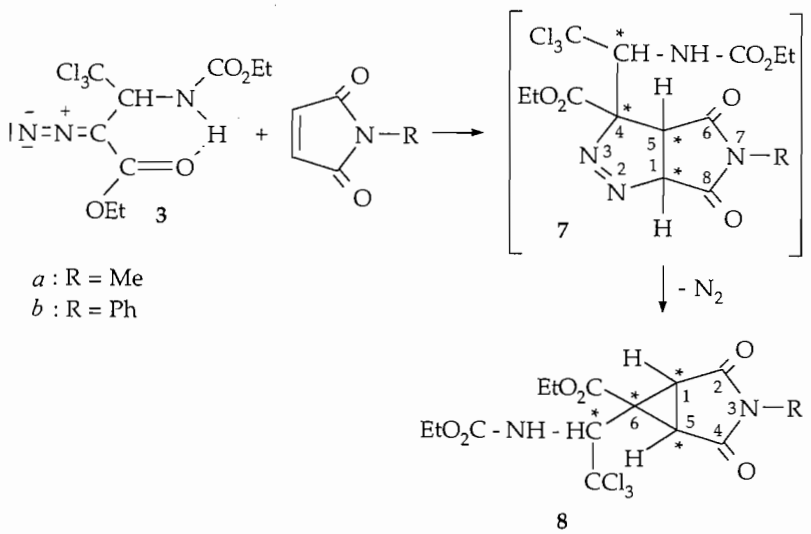
D'autres tentatives d'obtention d'un cycloadduit avec d'autres dipolarophiles acétyléniques tels que le phénylacétylène ou le phénylpropiolate de méthyle n'ont donné aucune réaction.



Réaction du nouveau diazocomposé avec les *N*-méthyl et *N*-phénylmaléimides

Nous avons testé divers dipolarophiles éthyléniques et notamment les esters acrylique, maléique et fumarique sans observer une réaction. Seuls les *N*-méthyl et *N*-phénylmaléimides ont permis d'obtenir un cycloadduit avec des rendements modestes (30 et 40%) vraisemblablement dûs au fait que la réaction étant effectuée au reflux du toluène, il y a compétition entre la dégradation du dipôle **3** et sa réaction de cycloaddition. Après retour à la température ambiante, le cycloadduit cristallise dans le toluène. L'analyse élémentaire et les paramètres spectroscopiques (IR, RMN et masse) permettent de retenir la structure de dérivés du maléimidocyclopropane ou 3-méthyl (ou phényl)-3-aza-6-éthoxycarbonyl-6-(2,2,2-

Schéma 4.

a : R = Me
b : R = Ph

trichloro-1-éthoxycarbonylaminoéthyl)bicyclo[3.1.0]hexane-2,4-dione **8** résultant de la perte d'azote du cycloadduit initial **7** qui est un dérivé d'une maléimido-1-pyrazoline (schéma 4).

Dans les deux cas, nous n'avons obtenu qu'un seul produit alors que la structure du cycloadduit intermédiaire **7** présente quatre centres de chiralité ce qui permettrait d'envisager a priori l'existence de quatre diastéréoisomères puisque les deux atomes d'hydrogène en positions 1 et 5 seront nécessairement dans une disposition *cis* par suite de la stéréochimie *cis* des réactions de cycloaddition. Pour expliquer cette remarquable diastéréospécificité nous pouvons invoquer successivement deux phénomènes :

1. La structure quasi-cyclique du dipôle-1,3 par suite de l'existence de la liaison hydrogène intramoléculaire caractérisée en spectrométrie IR permet de distinguer deux faces diastéréotopiques pour ce dipôle. L'un des « hémisphères » comporte le groupement trichlorométhyle beaucoup plus encombrant que l'atome d'hydrogène situé dans l'autre hémisphère et il est raisonnable d'envisager que l'approche dipôle–dipolarophile s'effectue sur la face la moins encombrée du dipôle-1,3.

2. Il subsiste alors deux approches possibles qui conduiront à des cycloadduits de stéréochimie relative différente entre les atomes C(1)–C(5) et l'atome C(4) dans le cycloadduit **7** qui devient C(6) dans **8** après perte d'azote. Ces deux approches A et B sont représentées sur la figure 5.

On peut désigner l'approche A comme étant une approche « *endo* » du maléimide par rapport au groupement ester du dipôle **3**, groupe ester qu'on retrouve fixé sur le carbone C(4) du cycloadduit **7** et C(6) du produit d'évolution **8**. Elle conduit à un produit où le groupe le plus encombrant (2,2,2-trichloro-1-ethoxycarbonylaminoéthyl) est en « *exo* » par rapport au reste maléimido, donc thermodynamiquement favorisé au contraire de celui qui résulterait de l'approche B.

Pour élucider cette structure nous avons d'abord vérifié que le produit obtenu présentait encore une liaison hydrogène intramoléculaire par une étude spectrométrique IR en dilution : alors que le produit dispersé dans KBr présente deux bandes $\nu_{(NH)}$ à 3345 et 3430 cm^{-1}, une solution dans CCl_4 de plus en plus diluée montre une diminution de l'intensité relative de la bande située à 3345 cm^{-1} jusqu'à sa disparition à la concentration de 10^{-2} mol L^{-1} et le maintien de la bande à 3430 cm^{-1}. Cette observation conforte l'existence d'une liaison hydrogène intramoléculaire.

Chacun des produits obtenus **8** (R = Me, Ph) a été soumis à une étude de NOE-différence en RMN ^1H. L'irradiation du proton H(1′) se traduit par une augmentation de l'intensité des signaux des protons H(1) et H(5) de 10 et 16% ce qui est un argument en faveur de la structure résultant de l'approche A. Il nous semble raisonnable de penser que cette approche « *endo* » pour le groupe ester fixé sur le carbone C(4) du cycloadduit intermédiaire puisse être dûe à des interactions orbitalaires secondaires entre l'un des groupes carbonyle du maléimide et ce groupe ester, ce qui contrôlerait alors la stéréochimie de l'approche pour donner lieu à une très grande diastéréosélectivité de la réaction.

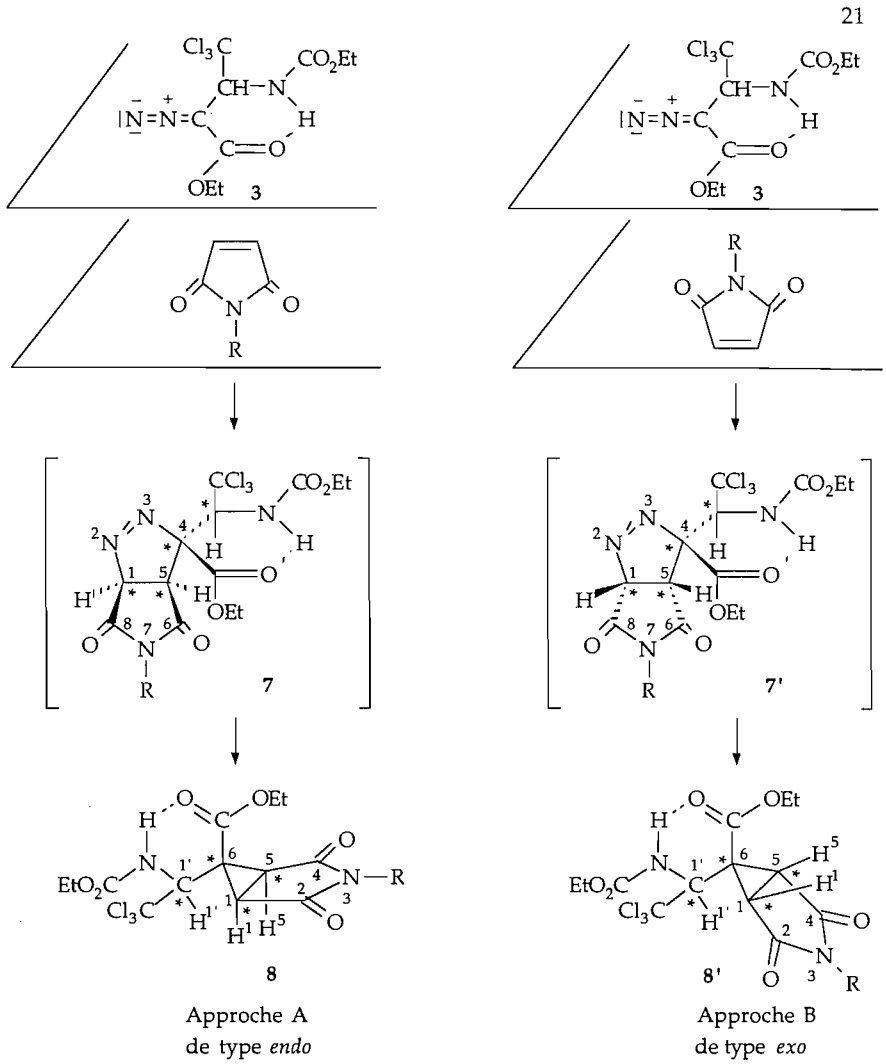
Il faut noter que cette approche préférentielle via l'état de transition cinétiquement favorisé conduit alors au produit thermodynamique et il n'est pas étonnant d'observer la formation unique du produit **8**.

Conclusion

La réaction du diazoacétate d'éthyle sur la *N*-éthoxycarbonyl-*N*-(2,2,2-trichloroéthylidène)amine conduit à un nouveau diazocomposé qui manifeste une réactivité dipolaire-1,3 vis-à-vis des esters acétyléniques et des maléimides.

Dans le cas des esters acétyléniques, la réaction de cycloaddition s'accompagne d'une évolution qui conduit à des pyrazoles par suite de transpositions sigmatropiques [1,5].

Avec les maléimides, on observe une réaction de cycloaddition dipolaire-1,3 diastéréospécifique suivie d'une élimination d'azote qui conduit à un maléimidocyclopropane. La diastéréospécificité observée a été rationnalisée en faisant appel à un mode d'approche des réactants de type *endo-anti*.



Partie experimentale

Toutes les matières premières sont préparées selon des méthodes déjà décrites dans la littérature et que nous avons

Fig. 5.

optimisées. Les points de fusion sont mesurés par projection sur banc Kofler et non corrigés. Les spectres d'absorption IR ont été tracés sur un spectrophotomètre Bio-Rad FTS-7, les produits étant dispersés en phase solide dans KBr à 5‰ ou examinés entre deux fenêtres de NaCl dans le cas des liquides. Les études en solution dans CCl_4 sont effectuées dans une cuve. Les spectres de RMN ^1H et ^{13}C ont été obtenus avec un spectromètre Bruker-Spectrospin AC200 (200 MHz pour ^1H et 50 MHz pour ^{13}C), les produits étant dissous dans $CDCl_3$ ou DMSO-d_6 (référence interne TMS). La chromatographie préparative sur plaques a été effectuée à partir de plaques préparées au laboratoire. Elles sont en verre Pyrex (20 × 20 ou 20 × 40) et recouvertes de gel de silice Merck 7747 (60 PF_{254}) (épaisseur 3 mm). Les microanalyses élémentaires ont été effectuées par le Service Central de Microanalyse du CNRS à Vernaison.

Synthèse de la *N*-éthoxycarbonyl-*N*-(2,2,2-trichloroéthylidène)amine 1

Cette imine est préparée selon Ulrich et coll. (3) mais ayant réussi à en améliorer le rendement, nous décrivons ici nos résultats expérimentaux.

1.1 Préparation de la 1-hydroxy-2,2,2-trichloroéthylcarbamate d'éthyle (19)

Dans un erlen rodé de 500 mL, 49,9 g (0,56 mol) d'uréthane sont mélangés à 82,7 g (0,5 mol) de chloral hydraté. Progressivement, une phase liquide se forme. La réaction endothermique est activée par un léger chauffage. On obtient une seule phase homogène qui est diluée avec 40 mL d'acide chlorhydrique concentré. Après 20 min, un bloc cristallin se forme avec un léger échauffement. Il est essoré, lavé à l'eau glacée jusqu'à pH 7. La poudre blanche est séchée à l'étuve à 50°C. Rdt = 94% ; P.F. = 106°C. IR : ν(OH) = 3400 cm^{-1}, ν(NH) = 3260 cm^{-1}, ν(C=O) = 1710 cm^{-1}. RMN ^1H ($CDCl_3$) : 1,20 (t, 3H, J = 7,15 Hz), 4,10 (q, 2H, J = 7,15 Hz), 5,70 (dd, 1H, J = 5,90 Hz et J = 9,70 Hz, CH), 6,60 (d, J = 5,90 Hz, OH), 7,10 (d, J = 9,70 Hz, NH). RMN ^{13}C ($CDCl_3$) : 14,2 (CH_3), 61,0 (OCH_2), 84,0 (CHOH), 102,3 (CCl_3), 155,7 (C=O ester).

1.2 Préparation du 1,2,2,2-tétrachloroéthylcarbamate d'éthyle

Dans un erlen tricol de 2 L équipé d'un réfrigérant et d'un tube à $CaCl_2$, une solution de 119 g de chlorure de thionyle (1 mol) et 2,2 g de pyridine, est additionnée à une suspension de 222,5

g (1 mol) de 1-hydroxy-2,2,2-trichloroéthylcarbamate d'éthyle dans 1200 mL de chlorure de méthylène. Après un reflux de 60 min, une solution claire est obtenue. Après évaporation du solvant, le résidu est distillé sous vide. Rdt = 99% (litt. (3) 97%), $Eb_{0,05\ Torr}$ (1 Torr = 133,3 Pa) = 90°C, P.F. = 67°C (litt. (3) 63°C). IR : ν(NH) = 3320 cm^{-1}, ν(C=O) = 1730 cm^{-1}. RMN ^1H (DMSO-d_6) : 1,20 (t, 3H, J = 7,15 Hz), 4,20 (q, 2H, J = 7,15 Hz), 6,50 (s, 1H). RMN ^{13}C (DMSO-d_6) : 14,0 (CH_3), 63,3 (OCH_2), 79,5 (CHCl), 101,2 (CCl_3), 154,8 (C=O ester).

1.3 Préparation du N-éthoxycarbonyl-N-(,2,2,2-trichloroéthylidène)amine ***1***

Dans un erlen tricol de 500 mL muni d'un réfrigérant, d'un tube à $CaCl_2$ et d'une ampoule à brome, on ajoute lentement une solution de 48,2 g (0,2 mol) de 1,2,2,2-tétrachloroéthylcarbamate d'éthyle dans 200 mL de benzène anhydre à une solution de 20,2 g (0,2 mol) de triéthylamine anhydre et fraichement distillée dans 200 mL de benzène anhydre. À la fin de l'addition, le chlorhydrate de triéthylamine est filtré. Après évaporation du solvant à l'évaporateur rotatif, le résidu est distillé sous vide. Rdt = 89% (litt. (3) 47,7%), $Eb_{0,3\ Torr}$ = 65°C (litt. (3) 70°C sous 1,1 Torr). IR : ν(C=O) = 1710 cm^{-1}, ν(C=N) = 1650 cm^{-1}. RMN ^1H ($CDCl_3$) : 1,30 (t, 3H, J = 7,15 Hz), 4,30 (q, 2H, J = 7,15 Hz), 8,20 (s, 1H). RMN ^{13}C ($CDCl_3$) : 13,8 (q, CH_3, J = 127,5 Hz), 63,9 (t, OCH_2, J = 149,0 Hz), 92,4 (s, CCl_3), 160,0 (s, C=O ester), 161,7 (d, CH=N, J = 186,5 Hz).

Réaction du diazoacétate d'éthyle avec la *N*-éthoxycarbonyl-*N*-(2,2,2-trichloroéthylidène)amine : obtention du 3-éthoxycarbonylamino-4,4,4-trichloro-2-diazobutyrate d'éthyle 3

Mode opératoire

Dans un ballon de 100 mL, muni d'un réfrigérant et d'un tube à $CaCl_2$, on introduit 4,37 g (2×10^{-2} mol) de *N*-éthoxycarbonyl-*N*-(2,2,2-trichloroéthylidène) amine **1**, 50 mL de toluène anhydre et 2,28 g (2×10^{-2} mol) de diazoacétate d'éthyle. Le mélange est chauffé à 60°C pendant 44 h. La réaction est suivie par CCM (éluant : chloroforme). Le solvant est éliminé à l'évaporateur rotatif. Le solide jaune obtenu est recristallisé dans l'hexane. Rdt = 83% ; P.F. = 70°C. IR : $\nu_{(NH)}$ = 3401 et 3436 cm^{-1}, $\nu_{(N_2)}$ = 2105 cm^{-1}, $\nu_{(C=O)}$ = 1695 et 1740 cm^{-1}. RMN ^1H ($CDCl_3$) : 1,29 (t, 3H, J = 7,25 Hz, CH_3), 1,31 (t, 3H, J = 7,10 Hz, CH_3), 4,20 (q, 2H, J = 7,10 Hz, CH_2), 4,24 (q, 2H, J = 7,25 Hz, CH_2), 5,50 (d, 1H, J = 9,8 Hz, CH), 6,50 (sl, NH). RMN ^{13}C ($CDCl_3$) : 14,3 (q, CH_3, J = 126,0 Hz), 14,4 (q, CH_3, J = 126,0 Hz), 61,5 (t, CH_2, J = 146,5 Hz), 62,2 (t, CH_2, J = 148,0 Hz), 63,0 (d, CH, J = 146,0 Hz), 102,9 (s, CCl_3), 164,8 (s, C=O ester), 164,9 (s, C=O ester). Analyse pour $C_9H_{12}Cl_3N_3O_4$ calculé : C 32,5%, H 3,64%, N 12,63%, Cl 31,58%, trouvé : C 32,5%, H 3,68%, N 12,38%, Cl 32,25%.

Réactions du 3-éthoxycarbonylamino-4,4,4-trichloro-2-diazobutyrate d'éthyle avec les dipolarophiles acétyléniques

Mode opératoire général

Dans un ballon rodé de 100 mL équipé d'un réfrigérant et d'un tube à $CaCl_2$, on introduit 1,66 g (5 mmol) de 3-éthoxycarbonylamino-4,4,4-trichloro-2-diazobutyrate d'éthyle **3**, 15 mL de toluène anhydre et 5 mmol d'ester acétylénique. Sous agitation magnétique, le mélange réactionnel est chauffé entre 60 et 70°C pendant 60–100 h. La réaction est suivie par CCM et IR (l'avancement de la réaction va dans le même sens que la disparition de la bande $\nu_{(N2)}$ à 2104 cm^{-1}). Le solvant est éliminé à l'évaporateur rotatif. On obtient une huile qui est purifiée par chromatographie préparative sur plaques de gel de silice (éluant : chloroforme) dans le cas des esters méthyliques ou par cristallisation dans l'éthanol dans le cas des esters éthyliques.

Cas des esters méthyliques

La chromatographie permet d'isoler les mélanges des composés **5** et **6**.

(*a*) Produits **5***a* et **6***a* issus de l'acétylènedicarboxylate de diméthyle. Rendement global : 80%. IR : $\nu_{(NH)}$ = 3367 et 3334 cm^{-1}, $\nu_{(C=O)}$ = 1732 cm^{-1}. RMN ^{13}C (DMSO-d_6) : tracé à partir du mélange **5***a* + **6***a*, l'existence des deux isomères de constitution entraîne le dédoublement de certains signaux indiqués par un astérisque. 13,9 et 14,0 (CH_3)*, 14,8 (CH_3), 52,9 et 53,9 (OCH_3)*, 53,1 (OCH_3), 61,7 (OCH_2), 61,9 et 63, (OCH_2)*, 73,5 (CH), 97,2 (CCl_3), 121,7 et 121,8 (Cq)*, 135,4 et 133,5 (Cq)*, 140,4 (Cq), 156,0 (Cq), 158,0 et 158,4 (Cq)*, 159,8 et 160,3 (Cq)*, 162,9 (Cq). Analyse pour $C_{15}H_{18}Cl_3N_3O_8$ calculé : C 37,94%, H 3,82%, N 8,86%, Cl 22,43%, trouvé : C 38,12%, H 3,67%, N 8,95%, Cl 22,37%.

3,4-Diméthoxycarbonyl-5-éthoxycarbonyl-1-(2,2,2-trichloro-1-*N*-éthoxycarbonylaminoéthyl)pyrazole **5***a* séparé par cristallisation fractionnée de l'éthanol. Rdt = 52% ; P.F. = 137°C (monocristaux de l'éthanol). IR : $\nu_{(NH)}$ = 3367 et 3334 cm^{-1}, $\nu_{(C=O)}$ = 1732 cm^{-1}. RMN ^1H (DMSO-d_6) : 1,20 (t, 3H, J = 7,10 Hz), 1,30 (t, 3H, J = 7,10 Hz), 3,90 (s, 3H), 3,99 (s, 3H), 4,20 (q, 2H, J = 7,10 Hz), 4,35 (partie AB d'un système ABX_3, J_{AB} = 11,7 Hz, $J_{AX_3} = J_{BX_3}$ = 7,10 Hz), 7,97 (d, 1H, J = 9,90 Hz), 9,34 (dl, NH, J = 9,90 Hz). Structure radiocristallographique (18*a*).

4,5-Diméthoxycarbonyl-3-éthoxycarbonyl-1-(2,2,2-trichloro-1-*N*-éthoxycarbonylaminoéthyl)pyrazole **6***a* non isolé. Rdt = 28%. RMN ^1H (DMSO-d_6) : 1,20 (t, 3H, J = 7,10 Hz), 1,28 (t, 3H, J = 7,10 Hz), 3,90 (s, 3H), 3,99 (s, 3H), 4,20 (q, 2H, J = 7,10 Hz), 4,35 (q, 2H, J = 7,10 Hz), 7,95 (d, 1H, J = 9,90 Hz), 9,34 (dl, NH, J = 9,90 Hz).

(*b*) Produits **5***b* et **6***b* issus du propiolate de méthyle. Rendement global : 63%; IR : $\nu_{(NH)}$ = 3320 et 3420 cm^{-1}, $\nu_{(C=O)}$ = 1730 cm^{-1}. RMN ^{13}C ($CDCl_3$) : tracé à partir du mélange **5***b* + **6***b*; l'existence des deux isomères de constitution entraîne le dédoublement de certains signaux indiqués par un astérisque. 14,0 (CH_3), 14,3 (CH_3), 52,4 et 52,7 (OCH_3)*, 61,5 (OCH_2), 62,2 et 62,4 (OCH_2)*, 73,5 (CH), 98,3 (CCl_3), 113,9 et 114,1 (CH)*, 135,9 (Cq), 143,6 (Cq), 154,8 (Cq), 158,7 (Cq), 160,9 et 161,5 (Cq)*. Analyse pour $C_{13}H_{16}Cl_3N_3O_6$ calculé : C 37,46%, H 3,97%, N 10,08%, Cl 25,55%, trouvé : C 37,58%, H 4,12%, N 9,87%, Cl 25,68%.

3-Méthoxycarbonyl-5-éthoxycarbonyl-1-(2,2,2-trichloro-1-*N*-éthoxycarbonylaminoéthyl)pyrazole **5***b* séparé par cristallisation fractionnée de l'éthanol. Rdt = 41% ; P.F. = 142°C (monocristaux de l'éthanol). RMN ^1H : 1,35 (t, 3H, J = 7,10 Hz), 1,45 (t, 3H, J = 7,15 Hz), 3,92 (s, 3H, OCH_3), 4,25 (q, 2H, J = 7,15 Hz), 4,50 (q, 2H, J = 7,10 Hz), 6,60 (dl, 1H, J = 10,6 Hz, NH), 7,39 (s, 1H, H-4), 8,10 (d, 1H, J = 10,6 Hz, CH). Structure radiocristallographique (18*b*).

5-Méthoxycarbonyl-3-éthoxycarbonyl-1-(2,2,2-trichloro-

Réactions du 3-éthoxycarbonylamino-4,4,4-trichloro-2-diazobutyrate d'éthyle avec les *N*-méthyl et *N*-phénylmaléimides

Mode opératoire

Dans un erlen rodé de 100 mL, surmonté d'un réfrigérant et d'un tube à $CaCl_2$, on introduit 5×10^{-3} mol de 3-éthoxycarbonylamino-4,4,4-trichloro-2-diazobutyrate d'éthyle **3**, 15 mL de toluène anhydre, et 5×10^{-3} mol de *N*-phényl ou *N*-méthylmaléimide. Sous agitation magnétique, le mélange est porté à reflux pendant 4 jours. La réaction a été contrôlée par IR en suivant la disparition de la bande du groupement diazo à 2104 cm^{-1}. On laisse revenir la solution à température ambiante. Après 1 nuit, un solide cristallise dans le toluène.

3-Méthyl-6-éthoxycarbonyl-6-(2,2,2-trichloro-1-éthoxycarbonylaminoéthyl)-3-azabicyclo[3.1.0]hexane-2,4-dione **8**a : Rdt = 30% ; P.F. = 188°C. IR : $\nu_{(NH)}$ = 3345 cm^{-1}, $\nu_{(C=O)}$ = 1722 et 1781 cm^{-1}. Arene–manganese and arene–rhenium compounds of formula (arene)$M(CO)_2(SiCl_3)$

Valerie M. Hansen, Jonathan L. Male, and Roland K. Pomeroy

Abstract: Derivatives of formula (arene)$M(CO)_2(SiCl_3)$ (M = Mn, Re) have been prepared in moderate to good yield by the reaction of $M(CO)_5(SiCl_3)$ and the appropriate arene (with heptane in those cases where the arene was a solid) in an evacuated sealed tube at 230–260°C for 12–24 h, depending on the arene and the metal. Carefully purified reagents were necessary to obtain satisfactory yields. The (η^6-1,4-$C_6H_4Bu^t_2$)$M(CO)_2(SiCl_3)$ complexes in solution exhibit free rotation of the arene ring about the metal atom to −120°C as ascertained by ^{1}H NMR spectroscopy. The manganese compound did show the onset of decoalescence of two of the signals due to the arene ligand in the $^{13}C\{^1H\}$ NMR spectrum in CD_2Cl_2 solution below −90°C. This, however, is interpreted in terms of restricted rotation of the *tert*-butyl substituent rather than restricted rotation of the arene ring.

Key words: arene, manganese, rhenium, restricted rotation.

Résumé : On a préparé les dérivés de formule (arène)$M(CO)_2(SiCl_3)$ (M = Mn, Re) avec des rendements allant de modérés à bons en faisant réagir du $M(CO)_5(SiCl_3)$ avec l'arène approprié (en présence d'heptane lorsque l'arène est solide), sous vide, dans un tube scellé, à des températures allant de 230 à 260°C pendant 12–24 h suivant la nature de l'arène et du métal. L'utilisation de réactifs purifiés avec soin est nécessaire pour obtenir des rendements satisfaisants. En se basant sur les résultats de la spectroscopie RMN du ^{1}H, les complexes (η^6-1,4-$C_6H_4tBu_2$)$M(CO)_2(SiCl_3)$ en solution présentent de la rotation libre du noyau arène autour de l'atome métallique, jusqu'à −120°C. Dans le cas du spectre RMN $^{13}C\{^1H\}$ du dérivé du manganèse en solution dans le CD_2Cl_2, une décoalescence des deux signaux dus au coordinat arène commence à se produire en dessous de −90°C. Toutefois, on interprète ce résultat en fonction d'une rotation restreinte du substituant *tert*-butyle plutôt que d'une rotation restreinte du noyau arène.

Mots clés : arène, manganèse, rhénium, rotation restreinte.

[Traduit par la rédaction]

Introduction

In 1980, work from this laboratory reported the restricted rotation of the arene ring about the metal atom of (η^6-1,4-$C_6H_4Bu^t_2$)$Ru(CO)(SiCl_3)_2$ in solution as detected by NMR line-broadening techniques (1). This was one of the first cases where this type of restricted rotation had been observed. At the time we were unable to synthesize iron complexes of the type (η^6-$C_6H_{6-x}R_x$)$Fe(CO)(SiCl_3)_2$ in order to compare the barriers to arene–metal rotation with those in the ruthenium analogues. More recently, however, we have found that with carefully purified reagents the iron complexes can indeed be prepared. Not surprisingly, the iron derivatives have large barriers to arene–metal rotation that are the highest so far observed (2).

In this study we report the application of the procedure used for the preparation of the Fe compounds to the synthesis of complexes of formula (arene)$M(CO)_2(SiCl_3)$ (M = Mn, Re) and an attempt to measure the barrier to arene–M rotation in the 1,4-$C_6H_4Bu^t_2$ derivatives. (A brief report of the ^{1}H NMR study of (η^6-1,4-$C_6H_4Bu^t_2$)$Re(CO)_2(SiCl_3)$ has appeared in a communication (3).) Arene–Mn and arene–Re complexes are also of interest since they are far less common than arene derivatives of the group 6 metals (4). Arene derivatives of transition metals, especially those of chromium, have found considerable use in organic synthesis particularly in the area of aromatic nucleophilic substitution (5). Furthermore, a recent review has illustrated the interesting and useful chemistry exhibited by the air-stable [(η^6-arene)$Mn(CO)_3$]$^+$ cations (6).

Experimental section

Unless otherwise stated, manipulations of starting materials and products were carried out under a nitrogen atmosphere with the use of standard Schlenk techniques. Heptane and the liquid arenes were refluxed over potassium, distilled, and stored over molecular sieves before use; olefins had been previously removed from the heptane by the accepted procedure (7). Dichloromethane and $CFCl_3$ were dried in a similar manner to the hydrocarbons except that P_2O_5 was employed as the drying agent. The $CDFCl_2$ was prepared by a literature method (8). Solid arene reagents were recrystallized from hexane and sublimed before use. The precursory complexes, $M(CO)_5(SiCl_3)$ (M = Mn, Re) were prepared by a literature procedure (9); they were also freshly sublimed before use. The

[a]In hexane for the Mn complexes; in CH_2Cl_2 for the Re complexes.
[b]Parent ion in each case.

reactions were carried out in thick-walled Carius tubes of approximate volume of 100 mL and fitted with a Teflon valve: the tubes were immersed in the temperature baths to a point only just above that of the reaction solution. Although no problems were experienced with this procedure, precautions against explosion were taken since the reaction temperatures were far above the boiling points of the solvent and most of the arene reagents employed.

Infrared spectra were recorded on a Perkin Elmer 983 spectrometer; electron-impact (70 eV) mass spectra were obtained with a Hewlett–Packard 5985 GC–MS instrument; NMR spectra were recorded on a Bruker WM400 or Bruker SY-100 spectrometer; microanalyses were determined by M. K. Yang of the Microanalytical Laboratory of Simon Fraser University. Infrared and mass spectroscopic data, and elemental analyses for the new compounds are given in Table 1; ^1H and $^{13}C\{^1H\}$ NMR data are given in Table 2.

Preparation of (η^6-arene)$Mn(CO)_2(SiCl_3)$ compounds

A Carius tube was charged with $Mn(CO)_5(SiCl_3)$ (100 mg, 0.304 mmol) and either the liquid arene (10 mL) or olefin-free heptane (1 mL) and the solid arene (1.0 g). The vessel and contents were cooled to −196 °C and evacuated; the solution was rigorously degassed with three freeze–pump–thaw cycles. The vessel was warmed to room temperature and placed in an oil-bath at 230 °C (located behind a protective shield) for 12 h (24 h for the preparation that involved benzene). For the reactions that involved liquid arenes, the vessel was cooled and volatiles removed on the vacuum line (with heating for reactions that involved arenes with high boiling points). The remaining solid was extracted with CH_2Cl_2 (3 × 10 mL); the extracts were filtered through Celite and the solvent was removed on the vacuum line. The crude product remaining after this procedure was recrystallized from the minimum amount of hot hexane to give the desired product. For reactions that involved solid arenes, the reaction mixtures (after cooling) were extracted with CH_2Cl_2 (3 × 10 mL); the extracts were filtered through Celite and all volatiles removed on the vacuum line. The arene was removed by sublimation at elevated temperatures (<0.02 Torr; 1 Torr = 133.3 Pa). The remaining crude product was recrystallized from hexane as described above. The yields in both procedures were 20–70%; the compounds are air-sensitive, pale-yellow crystals. The analytical samples were obtained from a second crystallization from hexane. The compounds may also be sublimed at >80°C (<0.02 Torr) to a probe cooled with cold water.

Preparation of (η^6-arene)$Re(CO)_2(SiCl_3)$ compounds

The methods employed were essentially those used to prepare the Mn complexes, but with the following differences: A reaction temperature of 240°C was employed except in the case of the benzene derivative where a temperature of 230°C and a reaction time of 24 h was used, and the C_6Me_6 derivative where a temperature of 260°C and a reaction time of 24 h was required. After the extraction step, the CH_2Cl_2 extracts were concentrated to ~10 mL, an equal volume of hexane was added, and the resulting solution was stored overnight at −20°C. The resulting crystals were separated from the mother solution, washed with hexane, and dried on the vacuum line. The analytical samples were obtained by heating in hot CH_2Cl_2 with decolorizing charcoal, followed by recrystallization from CH_2Cl_2–hexane. Yields ranged from 20 to 80%. The compounds are colorless, air-sensitive solids that, unlike the

Mn compounds, are insoluble in hexane; they are, however, soluble in CH_2Cl_2.

Preparation of (η^6-C_6Me_6)$Re(CO)_2(SiCl_3)$ from (η^6-C_6H_5Me)$Re(CO)_2(SiCl_3)$

A Carius tube was charged with (η^6-C_6H_5Me)$Re(CO)_2(SiCl_3)$ (20 mg), hexamethylbenzene (0.2 g), and olefin-free heptane (1 mL). The reaction mixture was cooled to −196°C and degassed with three freeze–pump–thaw cycles. The vessel and its contents were heated at 240°C for 12 h. The solution was cooled and extracted with hexane (3 × 5 mL) and the remaining solid dissolved in CH_2Cl_2. An infrared spectrum in the carbonyl stretching region indicated only the presence of product, (η^6-C_6Me_6)$Re(CO)_2(SiCl_3)$.

Results and discussion

Preparation of the (η^6-arene)$M(CO)_2(SiCl_3)$ (M = Mn, Re) compounds

The compounds were prepared in moderate to good yield by heating the appropriate arene with $M(CO)_5(SiCl_3)$ (M = Mn, Re) in an evacuated sealed tube at temperatures in the range 230–260°C, depending on the arene and the metal (eq. [1]). Analytical and spectroscopic data for the new compounds are

$$[1]\quad \text{arene} + M(CO)_5(SiCl_3) \xrightarrow{230\text{–}260^\circ C} (\eta^6\text{-arene})M(CO)_2(SiCl_3)$$

(M = Mn, Re; arene = $C_6H_{6-x}Me_x$ (x = 1–6), 1,4-$C_6H_4Bu^t_2$, etc.)

given in Tables 1 and 2. It was also found that under the same conditions C_6Me_6 displaced toluene from (η^6-C_6H_5Me)$Re(CO)_2(SiCl_3)$ to give (η^6-C_6Me_6)$Re(CO)_2(SiCl_3)$. In all preparations the reagents had to be meticulously purified and all traces of oxygen removed from the reaction. Failure to do this resulted in drastically reduced yields, which for some of the manganese compounds were essentially zero. Furthermore , in those syntheses that involved $Re(CO)_5(SiCl_3)$, when trace oxygen was not removed from the reaction a second product was formed that exhibited four carbonyl stretches in the solution infrared spectrum. Only two of these bands

For personal use only.

changed in frequency with a change of the arene reagent. For example, the product from the reaction that involved benzene exhibited CO-stretches at 2085, ~2024, 2024, and 1915.5 cm^{-1} in CH_2Cl_2 whereas the corresponding hexamethylbenzene product had bands at 2063.5, 2024, 1993.5, and 1916 cm^{-1}. The second product is tentatively identified as $[(arene)Re(CO)_3]^+[Re_2(\mu\text{-}Cl)_3(CO)_6]^-$ by comparison of the carbonyl stretches with those reported in the literature for the individual cation (10) and anion (11). The ionic product could not be readily separated from the $(\eta^6\text{-arene})Re(CO)_2(SiCl_3)$ derivatives and therefore they were not characterized further. It was found, however, for the reaction of C_6Me_6 and $Re(CO)_5(SiCl_3)$ in heptane, that when trace oxygen was deliberately not removed from the reaction (the solution was not degassed) the only detectable product was "$[(\eta^6\text{-}C_6Me_6)Re(CO)_3][Re_2(\mu\text{-}Cl)_3(CO)_6]$."

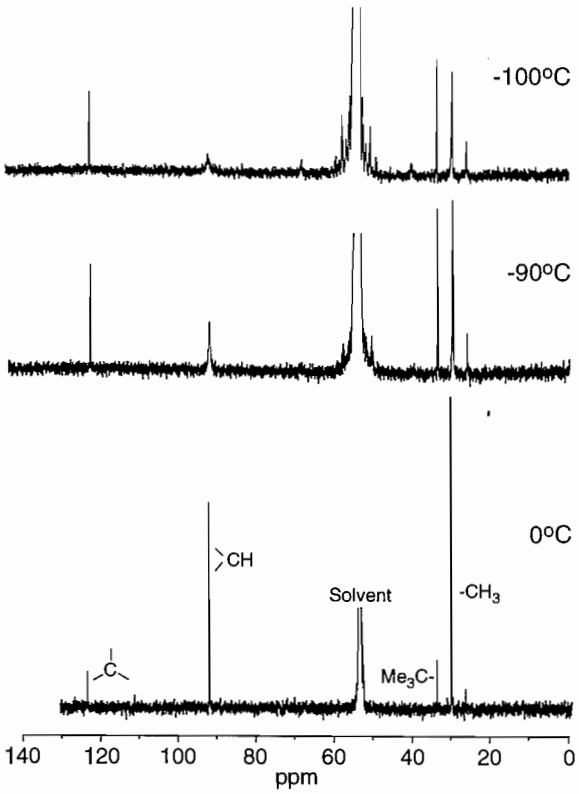
The crystal structures of two derivatives related to the current arene derivatives have been reported, namely, the structure of $(\eta^6\text{-}1,4\text{-}C_6H_4Bu^t_2)Ru(CO)(SiCl_3)_2$ (12) and that of $(\eta^6\text{-}1,4\text{-}C_6H_4Pr^i_2)Fe(CO)(SiCl_3)_2$ (2). In these complexes, the arene ligand is coordinated to the metal atom, in an η^6-mode with the carbonyl and silyl ligands occupying three sites about the metal atom, which is presumed to have approximate octahedral coordination. The arene compounds reported here are thought to have a similar piano-stool geometry. The $(\eta^6\text{-arene})Mn(CO)_2(SiCl_3)$ compounds are pale-yellow, air-sensitive solids that are soluble in hexane. The Re derivatives, although air-sensitive, are more robust than the Mn analogues; they are colorless solids that are insoluble in hexane (but soluble in dichloromethane). These physical properties may indicate stronger bonding of the arene ring to the metal atom in the Re complexes than that in the Mn complexes. A stronger bonding interaction in the Re complexes might be expected to lead to a larger HOMO–LUMO gap, giving rise to electronic transitions outside the visible region. A stronger bonding interaction could also lead to a greater charge separation between the arene and the rest of the molecule that in turn could give rise to lower solubility in nonpolar solvents of the Re derivatives.

Spectroscopic properties of the $(\eta^6\text{-arene})M(CO)_2(SiCl_3)$ compounds

The carbonyl stretching frequencies in the solution infrared spectra of the $(\eta^6\text{-arene})M(CO)_2(SiCl_3)$ compounds are given in Table 1. The stretches show the typical shift to lower frequencies with increasing methyl (or alkyl) substitution of the arene ring. The more electron-donating methyl groups increase the electron density at the metal atom, which in turn increases the backbonding to the π^* orbitals on the carbonyl ligands. The compound $(\eta\text{-}C_5H_5)Fe(CO)_2(SiMeCl_2)$ exhibits four, rather than two, IR-active carbonyl stretches in hexane solution which is attributed to the presence of two conformers arising from different orientations of the $SiMeCl_2$ group with respect to the Fe—Si bond (9). There was, however, no evidence for more than one conformer for $(\eta^6\text{-arene})Mn(CO)_2(SiCl_3)$ complexes in hexane solution where the arene (rather than the silyl ligand) was asymmetrically substituted: all the Mn complexes exhibited just two sharp CO stretches in hexane consistent with the presence of only one conformer in solution (Table 1).

As mentioned in the Introduction, the $(\eta^6\text{-}1,4\text{-}C_6H_4Bu^t_2)M'(CO)(SiCl_3)_2$ (M′ = Ru, Os) complexes are rare examples of molecules that exhibit restricted rotation of the arene ring about the metal atom as ascertained by NMR line-broadening techniques (1, 3). The slightly broadened singlet observed in the ^1H NMR spectrum (400 MHz) for the arene protons of these complexes in CD_2Cl_2 at ambient temperature decoalesces at lower temperatures such that at −60°C two sharp resonances (with H–H coupling) are observed (1, 3). In view of this behavior, the ^1H NMR spectra of $(\eta^6\text{-}1,4\text{-}C_6H_4Bu^t_2)Mn(CO)_2(SiCl_3)$ (**1**) in $CDFCl_2$–CD_2Cl_2, and its Re analogue (**2**) in $CFCl_3$–CD_2Cl_2, were recorded at low temperatures. In both cases, only a singlet, which did not appear significantly broadened even at −120°C, was obtained for the aromatic protons. As we have previously pointed out for $(\eta^6\text{-}1,4\text{-}C_6H_4Pr^i_2)Ru(CO)(SiCl_3)_2$ (2), from the observation that a sharp singlet is observed for the aromatic protons in the solution ^1H NMR spectrum to −120°C, an upper limit of approximately 5.3 kcal mol^{-1} for the barrier may be estimated for arene–metal rotation in the $(\eta^6\text{-}1,4\text{-}C_6H_4Bu^t_2)M(CO)_2(SiCl_3)$ complexes.

The iron compound, $(\eta^6\text{-}1,4\text{-}C_6H_4Bu^t_2)Fe(CO)(SiCl_3)_2$, could not be prepared, but the corresponding barriers (at 25°C) in the Ru (**3**) and Os analogues are 12.8 and 13.6 kcal mol^{-1}, respectively (1, 3).[2] This is therefore some 7.5–8.3 kcal mol^{-1} higher than the barrier in **1** and **2**. We initially attributed the lower barrier in **2** (compared to that in **3**) to the presence of only one bulky silyl ligand, which allowed the arene ring to tilt as the bulky *tert*-butyl substituents passed over the silyl ligand during the rotation of the arene ring about the metal atom. This tilting was thought to be severely restricted in **3** because of the presence of two bulky substituents on the arene ring and two bulky ligands attached to the metal atom (3). Subsequent studies on the $(\eta^6\text{-arene})Fe(CO)(SiCl_3)_2$ complexes have clearly shown that ground-state effects are also important in determining the barrier to arene rotation in these compounds (2). It is difficult to visualize, however, how the destabilization of the ground state of **2** could be sufficiently large to account for the much lower barrier to arene rotation in **2** compared to that in **3** and its Os congener. We therefore believe that the origin of the decrease in the barrier in **1** and **2** lies predominantly in transition-state stabilization arising from ring tilting that may be combined with more facile compression of the $M(CO)_2(SiCl_3)$ moiety compared to that of the $M'(CO)(SiCl_3)_2$ grouping. Detailed molecular mechanics calculations might resolve which factors are most important in determining the magnitude of barriers to arene–metal rotation in these complexes.



The onset of decoalescence of signals due to the slowing of a fluxional process is more likely to be detected by ^{13}C NMR spectroscopy than by ^1H NMR spectroscopy since the chemical shift separation between the signals due to each site undergoing exchange is invariably much larger in the ^{13}C NMR spectrum. For this reason and because of its favorable solubility, the ^{13}C NMR spectrum of **1** in CD_2Cl_2 was studied to low temperatures. At −90°C and below there were unmistakable signs of decoalescence of the resonance due to the methyl sub-

Fig. 1. Variable temperature $^{13}C\{^1H\}$ NMR spectra (100.6 MHz operating frequency) of (η^6-1,4-$C_6H_4Bu'_2$)$Mn(CO)_2(SiCl)_3$) (**1**) in CD_2Cl_2–CH_2Cl_2.

stituents and that due to the CH carbons of the arene ligand, but the other two signals attributed to the arene ligand remained sharp (Fig. 1). This behavior is consistent with restricted rotation of the *tert*-butyl substituent on the NMR time scale, rather than restricted rotation about the arene–Mn bond. As depicted in **A**, restricted rotation about the C—CMe_3

A

bond causes only the carbon atoms labeled 1 and 4 in **A** to become inequivalent, as is observed for **1**. Restricted rotation about the arene–Mn bond, on the other hand, would cause all four ^{13}C NMR resonances of the arene ligand to split into doublets; this is observed in complexes such as (η^6-1,4-$C_6H_4Bu^t2$)$Ru(CO)(SiCl_3)_2$ (1). The fluxional process in **1** is not detected by ^1H NMR spectroscopy, presumably because the chemical shift difference between the protons at the 1 and 1′ (1″), or between the protons at the 4 and 4′, sites are too small to cause significant line broadening.

In conclusion, a general route to molecules of formula (η^6-arene)$M(CO)_2(SiCl_3)$ (M = Mn, Re) has been established. (Because of the reactivity of the $SiCl_3$ ligands these derivatives are probably of little value for use in organic synthesis without further modification.) The barriers to arene–metal rotation in the manganese complexes are surprisingly low. For example, whereas the barrier to arene–Fe rotation in (η^6-1,4-$C_6H_4Me_2$)$Fe(CO)(SiCl_3)_2$ is 9.6 ± 0.1 kcal mol^{-1} ($\Delta G^{\ddagger}_{298}$) determined from an NMR line-shape analysis (2), in (η^6-1,4-$C_6H_4Bu'_2$)$Mn(CO)_2(SiCl_3)$ there is no evidence in the ^1H NMR spectrum of the compound in solution to −120°C for slowing of the rotation of the arene ring about the Mn atom. The latter observation indicates a barrier to arene–Mn rotation in the complex of no more than 5.3 kcal mol^{-1}.

Metal hydride mediated reduction of 3-(alkylthio)oxindoles containing other potentially reducible groups

Abstract: The reduction of several 3-(methylthio)oxindoles bearing ester groups on the benzene ring has been studied. The reaction is very dependent on the substitution of the oxindole, and the position of the ester group. Deprotonation of the C3 center by the metal hydride is the major initial pathway. This deprotonation plays a role in the reduction of the pendant ester group. Ester groups *ortho*, and presumably *para*, to C3 are very difficult to reduce, reaction only occurring with excess $LiAlH_4$ at elevated temperatures. Once reduction starts, it is very difficult to stop, with reduction of the ester to a methyl group being observed. When deprotonation at this center is blocked, ester reduction becomes straightforward and can be accomplished at room temperature with $LiEt_3BH$.

Key words: oxindole, reduction, anion.

Résumé : On a étudié la réduction de plusieurs 3-(méthylthio)oxindoles portant des groupes esters sur le noyau benzénique. La réaction varie grandement suivant la nature et la position du substituant présent sur l'oxindole. La déprotonation du centre C3 par l'hydrure métallique est le principal chemin réactionnel initial. Cette déprotonation joue un rôle important dans la réduction du groupe ester. Il est très difficile de réduire les groupes esters *ortho*, et probablement *para*, par rapport au centre C3; la réaction ne se produit qu'avec du $LiAlH_4$, à températures élevées. Lorsque la réduction est induite, il est difficile de l'arrêter; on observe alors la réduction de l'ester en groupe méthyle. Lorsqu'on bloque la déprotonation de ce centre, la réduction de l'ester redevient normale et on peut la réaliser à la température ambiante avec du $LiEt_3BH$.

Mots clés : oxindole, réduction, anion.

Introduction

The chemistry of oxindoles continues to attract considerable attention, possibly due to the biological activity of substituted oxindoles (1). Given the importance of these molecules, studies of fundamental reactions will lead to a greater understanding of their reactivity, and will be of general interest to those planning multistep syntheses.

Although the reaction of oxindole with $LiAlH_4$ has been known for quite some time, there is little mention in the literature of metal hydride reductions of oxindoles bearing other potentially reducible groups. Julian and Printy reported the reduction of 1-methyloxindoles to form 1-methylindoles and indolines with $LiAlH_4$ (2). This group also noted that oxindoles that were not substituted on nitrogen were not reactive towards $LiAlH_4$. Other studies supported these findings or showed that very little reduction occurs (3, 4). Based on numerous other studies, the conclusion was reached that oxindoles having a single 3-substituent undergo $LiAlH_4$ reduction to afford indoles whereas 3,3-disubstituted oxindoles are reduced to indolines when the reductions are carried out in refluxing dioxane (5–8). Nishio et al. have recently reexamined some of this chemistry, and the use of Dibal-H as a reducing agent (9). Their findings suggest that N-unsubstituted oxindoles, regardless of further substitution, are not reduced with Dibal-H. In addition, when reduction with Dibal-H occurred, indoles rather than indolines were obtained as the major products. Although a comprehensive study was conducted, very little speculation was made regarding the mechanism.

Even less is known regarding the mechanism of metal hydride mediated reductions of oxindoles carrying other potentially reducible groups. Brossi and co-workers, in a series of publications, showed that the nitrile group of 1,3,3-trisubstituted oxindoles with cyanomethyl groups at the 3 position could be reduced without reaction at the oxindole carbonyl (10–12). Pierce et al. studied in detail the reduction of 3-(methylene)oxindoles with $NaBH_4$ (13). Plieninger and Allen examined the reductions of oxindoles with borane (14, 15). To the best of our knowledge, there have not been any studies on the reduction of oxindoles that have pendant ester groups on the benzene ring. In the course of research in our laboratory, we recently had the opportunity to study this reaction in detail. An explanation of these results, and an extension to generalize such reductions by employing several isomers and various reduction conditions, is the subject of this paper.

Scheme 1.

Results

Recent synthetic studies in our laboratory required an efficient synthesis of oxindole **1**. Due to the literature precedent arguing that reduction of the oxindole carbonyl with metal hydrides is difficult when the oxindole has a free N-H, we believed that reduction of the pendant ester group of **2a** would afford the desired 4-hydroxymethyl group. Due to the pioneering work of Gassman and van Bergen (16, 17), oxindoles with the desired framework as shown in **2a** are available in a one-pot synthesis from substituted anilines via a rearrangement of the intermediate aza-sulfonium salts. Oxindole **2a** was prepared from ethyl (3-amino)benzoate in a yield consistently above 75%. However, reduction of **2a** with up to five equivalents of Dibal-H in THF returned starting material in a quantitative yield. Likewise, use of other reducing agents like $LiBH_4$, $LiEt_3BH$, Red-Al, and even $LiAlH_4$ in THF at room temperature resulted in the recovery of starting material. When more forcing reduction conditions were used (10 equivalents $LiAlH_4$, refluxing THF, 18 h), a 1:1.2 mixture of starting material and the completely reduced product **3a** was obtained.

In an attempt to gain more mechanistic insight into these results, a systematic study of various related isomers and analogs of **2** was undertaken. All of the desired starting oxindoles were prepared via Gassman's method (16, 17), or via the modified Gassman method reported by Wierenga et al. (18). All of the substrates in this paper were screened under two different reduction conditions: the reaction with $LiEt_3BH$ was done in THF at room temperature whereas reduction with $LiAlH_4$ was done in refluxing THF. Shown in Table 1 are the results from a series of reductions.

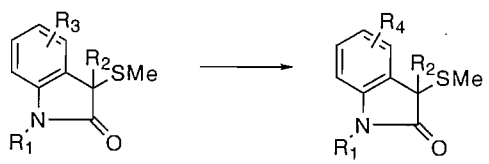

Table 1. Summary of reduction results for oxindoles **2a–2d**.

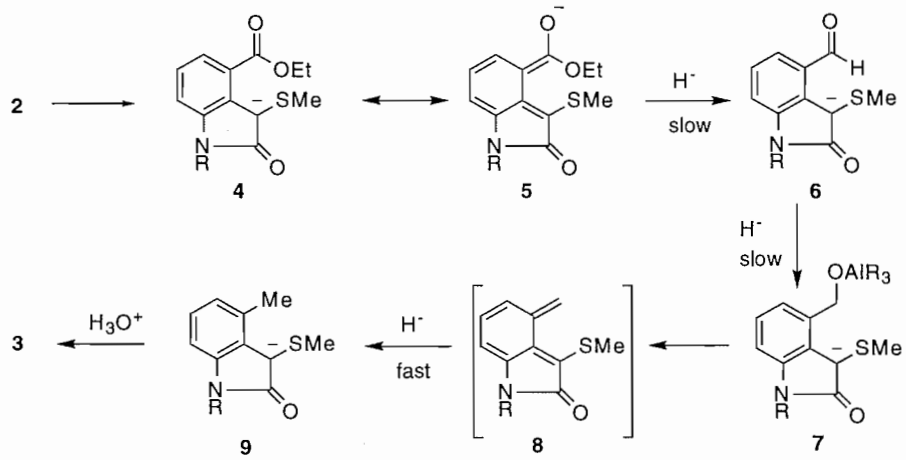
Entry	R_1	R_2	R_3	R_4	Yield	Conditions[a]
a	H	H	4-CO_2Et	4-CO_2Et	>95%	A
a	H	H	4-CO_2Et	4-CH_3	90%[b]	B
b	Me	H	4-CO_2Et	4-CH_3	90%	B
c	H	Me	6-CO_2Et	6-CH_2OH	88%	A[c]
d	H	H	7-CO_2Et	7-CH_2OH	~84%	A,B[c]

[a]A: $LiEt_3BH$, THF, RT; B: $LiAlH_4$, THF, Δ.
[b]Based on recovered starting material.
[c]Could not be reduced further on exposure to conditions B.

Examination of the table shows a number of trends. Under both $LiEt_3BH$ and $LiAlH_4$ reduction conditions, the oxindole carbonyl group was quite inert to reduction (typically, less than 5% of the product mass was composed of indole and indoline products). It is also evident from substrates **2a** and **2b** that, for oxindoles having a proton on C3 and the ester group *ortho* to this position, initial reduction of the ester group is quite difficult. However, in both cases, once reduction is initiated, it is difficult to stop at the benzylic alcohol stage. For both substrates, which differed only in the N-methyl group, reduction did not occur until excess $LiAlH_4$ was used and the reaction mixture was exposed to harsh conditions, i.e., refluxing THF for prolonged periods of time.

In the case of substrate **2c**, the oxindole was methylated at C3 and had the ester group *para* to C3. Reduction proceeded smoothly with both $LiEt_3BH$ and $LiAlH_4$ to afford the benzylic alcohols. Isolation of the alcohol and its exposure to the forcing conditions ($LiAlH_4$, THF, Δ) resulted in the recovery of starting material. Similarly oxindole **2d**, which was not methylated at C3 and had the ester group *meta* to C3, was also smoothly reduced to the benzylic alcohol with both $LiEt_3BH$ at room temperature and $LiAlH_4$ in refluxing THF. Again, isolation of the benzylic alcohol **3d** and attempted further reduction with $LiAlH_4$ in refluxing THF did not lead to further reduction of the alcohol. Instead, reduction of the oxindole carbonyl group occurred, although this was only about 5% of the mass balance even after 12 h.



Discussion

It is clear from the results discussed that both the position of the ester group and the substitution pattern at C3 play an important role in the results of the reduction. It seems reasonable that the problem of over-reduction observed for **2a** and **2b** may be ascribed to the presumably high acidity of the proton on C3. Although p*K*a data for these compounds are not available, Gassman has commented on the high acidity of the C3 methine proton, and taken advantage of it in his isatin syntheses (19, 20). Taylor has also commented on problems encountered during ester hydroysis of related structures due to the C3 proton (21). In the case of both **2a** and **2b**, initial deprotonation of the C3 proton would lead to an anion adjacent to the oxindole carbonyl. This increased electron density and enolate character militates against reduction of the oxindole carbonyl group, similar to that reported by Marshall et al. for malonic enolates (22). This C3 anion may also increase the electron density of the ester groups *ortho* or *para* to it by delocalization through the benzene ring, as shown by **4** and **5**. The vinylogous enolate **5** is also quite resistant to addition of hydride. However, once one hydride has added, the aldehyde product **6** is more susceptible to further hydride attack. The next hydride addition results in the benzyloxyaluminate **7**, and the C3 anion, which initially made hydride addition slow, now facil-

Scheme 2.

Scheme 3.

itates over-reduction, perhaps via the *ortho*-quinodimethane **8**. The end result is the 4-methyl oxindole, **3a** or **3b**.

To test the proposed mechanism shown in Scheme 2, **10** was an appealing target. This substrate had the ester at the 4 position and an additional methyl group at C3. Attempted monoalkylation of **2** always resulted in a mixture of products that included starting material, N-alkyl and N,C-dialkylated products.[2] An alternative synthesis relied on the Gassman technique. However, when ethyl (3-amino)benzoate was reacted with methyl (2-thiomethyl)propionate under standard Gassman conditions, the isomeric oxindole **2c** was formed. Although both 4- and 6-substituted oxindoles are possible products from *meta*-substituted anilines, only 4-substituted oxindoles were formed up to this point. As suggested in Scheme **3**, the increased steric demand of the branched sulfide-ester may be responsible for this switch in regiochemistry.

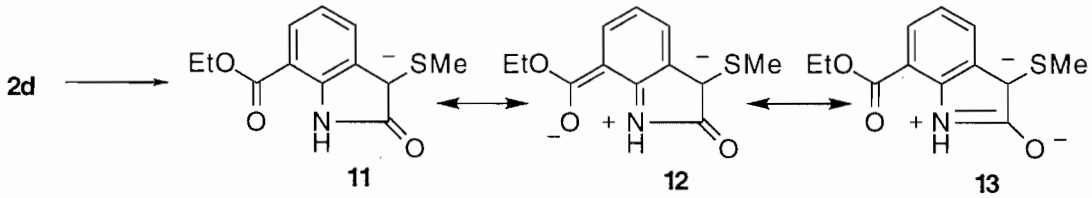
The ester groups of **2c** and **10**, which are *ortho* and *para*, respectively, to the C3 position, are electronically quite similar. Results of the reduction of oxindole **2c** also support the proposed mechanism. The additional methyl group at C3 does not allow enolate formation so the electron density of the ester group *para* to C3 is normal. The free NH still protects the oxindole carbonyl group from reduction. With both $LiEt_3BH$ and $LiAlH_4$, reduction of the ester **2c** to benzylic alcohol **3c** proceeded smoothly.

To finish our study on this series, we examined the reduction of oxindole **2d**. This substrate has a proton on C3, but to which the ester is *meta* (**11**). Although not expecting any interference from the C3 anion, we were interested in seeing what effect the nitrogen would have when placed *ortho* to the ester group. Reduction with $LiAlH_4$ in refluxing THF smoothly afforded the benzylic alcohol, which was inert to further reduction by $LiAlH_4$; no evidence was found to support over-reduction of the C7-benzylic alcohol. Reduction also occurred with $LiEt_3BH$ as the reducing agent. From these results, it seems that delocalization of the nitrogen electron density into the benzene (**12**) ring is probably not favored, since it would result in the loss of any resonance energy associated with the amide resonance (**13**).

Conclusion

In this paper, we have examined the reduction of a series of 3-(methylthio)oxindoles that had ester groups on the benzene ring. It was found that having a free proton α to the oxindole carbonyl group protects this group from any significant reduction by metal hydrides like $LiEt_3BH$ and $LiAlH_4$. This protection presumably occurs through deprotonation of the amide NH or the methine proton of the oxindole. This resistance to reduction is reminiscent of the situation reported by Marshall, who showed that malonic enolates are not reduced by $LiAlH_4$ (22). Deprotonation of the methine hydrogen also results in donation of significant electron density into the benzene ring. If the ester group is in a position to accept some of this electron density (*ortho* or *para* to C3) then initial reduction is difficult, resulting in the recovery of starting material when mild conditions are used, and in over-reduction of the ester to a methyl group when more vigorous conditions are used.

Experimental



General

All reactions were conducted under an inert atmosphere in flame-dried glassware that had been cooled under a stream of

[2] Reduction of the N-methyl analogue of **10** with $LiAlH_4$ and $LiEt_3BH$ leads to four different products. See accompanying paper.

dry nitrogen. Melting points were determined on a Fisher–Johns Unimelt melting point apparatus and are uncorrected. Infrared spectra were recorded with a Bomem MB 101 FT-IR spectrometer with solution cells using the highest grade of methylene chloride available unless otherwise stated. Proton and carbon nuclear magnetic resonance were recorded on either a Bruker AMX-500, Varian XL-300, or Varian Gemini 200 operating at frequencies of 500, 300, and 200 MHz for proton and 125, 75, and 50 MHz for carbon, using the specified solvent, and are reported relative to TMS = 0.00 ppm. Low- and high-resolution mass spectra were recorded on a VG 7070 mass spectrometer or a Concept II instrument. Peak intensities are reported as a percentage of the base peak.

The phrase "usual work-up" refers to drying the solvent over anhydrous magnesium sulfate, filtering, and removing the solvent under reduced pressure using a Buchi Rotovapor. The term chromatography refers to flash chromatography performed using 230–400 mesh silica gel supplied by Terochem Laboratories in the solvent specified. All solvents were routinely distilled prior to use. All starting materials were used as received from commercial sources except for the following: triethylamine was distilled from CaH_2 and THF was dried and distilled from sodium with benzophenone as an indicator; methylene chloride was distilled from P_2O_5 prior to use. *tert*-Butyl hypochlorite was prepared according to the literature immediately before use (23). All manipulations involving *t*-BuOCl, including the preparation, were conducted in the dark. The synthesis of all oxindole starting materials was conducted following the general procedure of Gassman or the modified Gassman approach of Wierenga (16–18). No attempt was made to optimize the syntheses of starting oxindoles.

3-(Methylthio)-4-(carboethoxy)oxindole 2a

Oxindole **2a** was prepared according to the general procedure of Gassman (17). A solution of freshly prepared *t*BuOCl (3.30 g, 30.4 mmol) in CH_2Cl_2 (15 mL) was added dropwise to a cooled (−78°C) solution of ethyl 3-aminobenzoate (5.00 g, 30.3 mmol) in CH_2Cl_2 (100 mL). The resulting bright yellow mixture was stirred at this temperature for 10 min, at which point a solution of methyl (methylthio)acetate (3.65 g, 30.4 mmol) in CH_2Cl_2 (15 mL) was added and stirring continued for 2.5 h. A solution of triethylamine (3.10 g, 30.7 mmol) in CH_2Cl_2 (15 mL) was then added, and the initially yellow solution was allowed to warm to room temperature (RT) over 12 h. The reddish solution that resulted was poured into a solution of H_2O (200 mL); the organic phase separated and was worked up in the usual manner to provide an orange solid. Recrystallization from CH_2Cl_2–hexanes afforded the title compound as colorless plates (5.70 g, 75%); mp 150–151°C; IR (CH_2Cl_2): 1613, 1723, 3424 cm^{-1}; ^1H NMR (200 MHz, $CDCl_3$) δ: 1.40 (t, 3H, J = 8.0 Hz), 2.51 (s, 3H), 4.38 (q, 2H, J = 8.0 Hz), 4.68 (s, 1H), 7.02 (d, 1H, J = 8.0 Hz), 7.31 (t, 1H, J = 8.0 Hz), 7.62 (d, 1H, J = 8.0 Hz), 8.05 (br, 1H); ^{13}C NMR (125 MHz, $CDCl_3$) δ: 12.15, 14.05, 46.74, 61.33, 113.39, 124.26, 127.89, 128.19, 129.00, 142.04, 165.52, 177.46; EI-MS *m/z* (%): 251 (2.2, M^+), 205 (100), 176 (13.2), 160 (36.6); HRMS calcd. for $C_{12}H_{13}NO_3S$: 251.06162; found: 251.06118.

Reduction of oxindole 2a with $LiAlH_4$: 3-(methylthio)-4-methyloxindole 3a

A solution of oxindole **2a** (100 mg, 0.40 mmol) in THF (10 mL) was added dropwise to a suspension of $LiAlH_4$ (150 mg, 3.95 mmol) in THF (10 mL). The resulting gray, cloudy solution was refluxed for 18 h, poured into a saturated solution of potassium sodium tartrate (50 mL) and EtOAc (50 mL), and stirred for 4 h. The organic phase was separated and subjected to normal work-up followed by column chromatography (2:1 hex:EtOAc), providing two compounds: recovered starting material (35 mg, 35%) and a less polar compound, **3a**, isolated as an off-white solid (30 mg, 43%); mp 154–155°C; IR (CH_2Cl_2): 1724 cm^{-1}; ^1H NMR (200 MHz, $CDCl_3$) δ: 2.10 (s, 3H), 2.50 (s, 3H), 4.25 (s, 1H), 6.70 (d, 1H, J = 8.0 Hz), 6.80 (d, 1H, J = 8.0 Hz), 7.20 (t, 1H, J = 8.0 Hz); ^{13}C NMR (75 MHz, $CDCl_3$) δ: 11.45, 17.85, 45.52, 107.17, 123.27, 124.31, 128.69, 135.96, 140.98, 177.17; EI-MS *m/z* (%): 193 (26.5, M^+), 146 (100), 118 (4.2); HRMS calcd. for $C_{10}H_{11}NOS$: 193.05614; found: 193.05684.

Ethyl 3-(methylamino)benzoate

Adapted from the procedure of Krishnamurthy (24). A round-bottom flask containing a toluene (50 mL) solution of ethyl (3-amino)benzoate (5 g, 30.30 mmol) and formic acid (5 mL, 98%) was equipped with a Dean–Stark trap and heated to reflux for 12 h. The solvent was removed and the resulting purple residue was suspended in CH_2Cl_2 (50 mL), and washed sequentially with H_2O (2 × 20 mL), HCl (10%, 2 × 20 mL), and $NaHCO_3$ (5%, 2 × 20 mL). The organic phase was worked up in the usual manner, affording a dark solid that was triturated with Et_2O, and filtered. The purplish solid was recrystallized from CH_2Cl_2–hexanes and filtered, affording 3.12 g of ethyl 3-(formyl amino)benzoate (53%) as white cubes.

The resulting N-formyl derivative (3.0 g, 15.54 mmol) was dissolved in THF (50 mL), and heated to reflux, at which point a solution of borane – methyl sulfide complex was added (3.0 mL, 10 M, 30.00 mmol) dropwise via syringe. After 12 h at reflux, the solution was cooled to RT, and MeOH (20 mL) was added slowly (**Caution**: H_2 evolution!). Stirring was continued until hydrogen evolution stopped, and then for 15 min longer, after which time the solution was concentrated to dryness, and the residue purified by column chromatography (2:1 hex:EtOAc), affording the title compound as a clear oil (2.5 g, 90%); IR (CH_2Cl_2): 3435, 1713 cm^{-1}; ^1H NMR (500 MHz, $CDCl_3$) δ: 1.35 (t, 3H, J = 6.8 Hz), 2.82 (s, 3H), 3.80 (br, 1H), 4.32 (q, 2H, J = 6.8 Hz), 6.74 (d, 1H, J = 6.5 Hz), 7.20 (t, 1H,

J = 6.5 Hz), 7.25 (d, 1H, J = 6.5 Hz), 7.35 (d, 1H, J = 6.5 Hz); ^{13}C NMR (125 MHz, $CDCl_3$) δ: 14.32, 30.62, 60.79, 112.84, 116.77, 118.23, 129.04, 131.35, 149.34, 167.13; EI-MS *m/z* (%): 179 (100, M^+), 150 (76.0), 134 (40.3), 106 (58.5), 77 (23.2); HRMS calcd. for $C_{10}H_{13}NO_2$: 179.09463; found: 179.09484.

1-Methyl-3-methylthio-4-(carboethoxy)oxindole 2b

Prepared from ethyl (3-*N*-methylamino)benzoate (0.98 g, 5.47 mmol) using the standard Gassman methodology. The orange solid obtained after usual work-up was recrystallized from CH_2Cl_2–hexanes and afforded the title compound as a white solid (175 mg, 12%); mp 82–83°C; IR (CH_2Cl_2): 1717 cm^{-1}; ^{1}H NMR (200 MHz, $CDCl_3$) δ: 1.40 (t, 3H, J = 7.1 Hz), 1.97 (s, 3H), 3.22 (s, 3H), 4.36 (m, 2H), 4.66 (s, 1H), 6.96 (d, 1H, J = 7.1 Hz), 7.41 (t, 1H, J = 7.1 Hz), 7.65 (d, 1H, J = 7.1 Hz); ^{13}C NMR (75 MHz, $CDCl_3$) δ: 12.32, 14.04, 26.33, 46.01, 61.30, 111.40, 124.02, 127.33, 127.86, 128.99, 144.72, 165.55, 174.86; EI-MS *m/z* (%): 265 (5.2, M^+), 219 (100), 190 (18.6), 174 (33.8); HRMS calcd. for $C_{13}H_{15}NO_3S$: 265.07727; found: 265.08194.

Reduction of oxindole 2b with $LiAlH_4$; 1-methyl-3-methylthio-4-methyl oxindole 3b

The general procedure outlined above from **2a** was followed. Oxindole **2b** (40 mg, 0.15 mmol) provided, after usual work-up and column chromatography (1:1 hex:EtOAc), compound **3b** as off-white needles (28 mg, 90%); mp 100–101°C; IR (CH_2Cl_2): 1712 cm^{-1}; ^{1}H NMR (200 MHz, $CDCl_3$) δ: 2.01 (s, 3H), 2.43 (s, 3H), 3.21 (s, 3H), 4.18 (s, 1H), 6.66 (d, 1H, J = 7.5 Hz), 6.88 (d, 1H, J = 7.5 Hz), 7.21 (t, 1H, J = 7.5 Hz); ^{13}C NMR (75 MHz, $CDCl_3$) δ: 11.66, 17.78, 26.01, 44.79, 105.27, 122.54, 124.31, 128.58, 135.53, 143.77, 174.81; EI-MS *m/z* (%): 207 (14.2, M^+), 160 (100), 130 (9.4), 117 (10.4), 77 (7.9); HRMS calcd. for $C_{11}H_{13}NOS$: 207.07179; found: 207.07322.

3-Methyl-3-methylthio-6-(carboethoxy)oxindole 2c

Standard Gassman methodology as reported for the synthesis of **2a** using ethyl (3-amino)benzoate and methyl (2-thiomethyl)propionate afforded, after purification via column chromatography (4:1 hex:EtOAc) and recrystallization from CH_2Cl_2–hexanes, the title compound **2c** as a white solid (24%); mp 135–136°C; IR (CH_2Cl_2): 3421, 1722, 1730 cm^{-1}; ^{1}H NMR (200 MHz, $CDCl_3$) δ: 1.30 (t, 3H, J = 7.2 Hz), 1.59 (s, 3H), 1.80 (s, 3H), 4.28 (q, 2H, J = 7.2 Hz), 7.29 (d, 1H, J = 7.9 Hz), 7.50 (d, 1H, J = 1.4 Hz), 7.73 (dd, 1H, J = 7.9, 1.4 Hz), 8.38 (br, 1H); ^{13}C NMR (75 MHz, $CDCl_3$) δ: 11.82, 14.01, 21.16, 50.19, 60.98, 110.29, 123.53, 124.53, 130.91, 136.38, 139.61, 165.63, 178.90; EI-MS *m/z* (%): 265 (2.9, M^+), 218 (100), 190 (34.5); HRMS calcd. for $C_{13}H_{15}NO_3S$: 265.07727; found: 265.07661.

Reduction of oxindole 2c with $LiEt_3BH$: 3-methyl-3-methylthio-6-(hydroxymethyl)oxindole 3c

A solution of $LiEt_3BH$ (0.45 mL, 1.0 M in THF, 0.45 mmol) was added dropwise to a cooled (0°C) solution of oxindole **2c** (45 mg, 0.17 mmol) in THF (5 mL). Stirring was continued at 0°C for 1 h, after which time the pale yellow solution was poured into a solution of H_2O (10 mL) and made acidic by the dropwise addition of HCl (10%). Extraction with EtOAc (4 × 20 mL), followed by normal work-up and chromatography (2:3 hex:EtOAc) afforded, in addition to returned starting material (7.8 mg), the title compound **3c**, which was recrystallized from CH_2Cl_2–hexanes as white prisms (27.4 mg, 88%); mp 167–168°C; IR (CH_2Cl_2): 3604, 1729 cm^{-1}; ^{1}H NMR (200 MHz, $CDCl_3$) δ: 1.54 (s, 3H), 1.80 (s, 3H), 4.60 (s, 2H), 6.85 (s, 1H), 6.95 (d, 1H, J = 7.5 Hz), 7.19 (d, 1H, J = 7.5 Hz), 8.10 (br, 1H); ^{13}C NMR (75 MHz, $CDCl_3$) δ: 11.79, 21.29, 49.98, 64.77, 108.11, 121.13, 123.71, 130.72, 139.78, 141.78, 179.22; EI-MS *m/z* (%): 223 (6.7, M^+), 176 (100), 148 (2.8); HRMS calcd. for $C_{11}H_{13}NO_2S$: 223.06670; found: 223.06858.

3-Methylthio-7-(carboethoxy)oxindole 2d

The modified Gassman conditions of Wierenga et al. were followed (18). A solution of sulfuryl chloride (2.26 g, 16.7 mmol) in CH_2Cl_2 (5 mL) was added dropwise to a cooled solution (−78°C) of methyl (methylthio)acetate (1.83 g, 15.3 mmol) in CH_2Cl_2 (50 mL), resulting in the slow formation of a white precipitate. After stirring for 1 h, a solution of ethyl (2-amino)benzoate (2.50 g, 15.1 mmol) in CH_2Cl_2 (50 mL) was added dropwise, resulting in slow dissolution of the white precipitate with the solution slowly turning pale yellow. After stirring for 2 h, triethylamine (1.59 g, 15.8 mmol) was added, and the solution was allowed to warm to RT overnight. Water (50 mL) was added, and the aqueous layer was separated and subjected to normal work-up conditions, resulting in a yellow semi-solid, which was dissolved in Et_2O (50 mL) and HCl (10%, 10 mL). The two-phase mixture was refluxed for 12 h, cooled, and the organic phase was separated and worked up in the usual manner. Column chromatography (5:1 hex:EtOAc) afforded a yellow solid, which was recrystallized from CH_2Cl_2–hexanes, affording the title compound **2d** as white flakes (383.8 mg, 10.1%); mp 87–88°C; IR (CH_2Cl_2): 3403, 1721, 1697 cm^{-1}; ^{1}H NMR (500 MHz, $CDCl_3$) δ: 1.39 (t, 3H, J = 7.0 Hz), 2.02 (s, 3H), 4.23 (s, 1H), 4.38 (q, 2H, J = 7.0 Hz), 7.08 (t, 1H, J = 7.5 Hz), 7.50 (d, 1H, J = 7.5 Hz), 7.81 (d, 1H, J = 7.5 Hz), 9.20 (br, 1H); ^{13}C NMR (125 MHz, $CDCl_3$) δ: 12.23, 14.32, 45.32, 61.39, 111.73, 122.14, 127.57, 129.58, 129.66, 143.79, 165.85, 175.92; EI-MS *m/z* (%): 251 (3.4, M^+), 205 (100), 158 (40.9), 130 (14.1); HRMS calcd. for $C_{12}H_{13}NO_3S$: 251.06162; found: 251.06239.

Reduction of oxindole 2d with $LiAlH_4$: 3-methylthio-7-(hydroxymethyl) oxindole 3d

Following the procedure described for **3a**, oxindole **2d** (50 mg, 19.9 mg) afforded, after usual work-up and column chromatography (1:1 hex:EtOAc), **3d** as a white crystalline solid (35 mg, 84%); mp 148–149°C; IR (CH_2Cl_2): 3620, 1721 cm^{-1}; ^{1}H NMR (500 MHz, $CDCl_3$) δ: 2.00 (s, 3H), 4.30 (s, 1H), 4.80 (s, 2H), 7.02 (m, 2H), 7.28 (d, 1H, J = 7.5 Hz), 8.50 (br, 1H); ^{13}C NMR (125 MHz, $CDCl_3$) δ: 12.33, 45.79, 63.43, 120.20, 122.56, 124.54, 127.24, 138.76, 142.36, 168.20; EI-MS *m/z* (%): 209 (7.6, M^+), 163 (100), 144 (42.0), 116 (48.6); HRMS calcd. for $C_{10}H_{11}NO_2S$: 209.05105; found: 209.04985.

Metal hydride mediated reduction of 1,3-dimethyl-3(methylthio)oxindole

Terrence J. Connolly and Tony Durst

Abstract: The metal hydride mediated reduction of 4-carboethoxy-1,3-dimethyl-3-(methylthio)oxindole with lithium aluminum hydride and lithium triethylborohydride was studied. The results show that reduction of the oxindole carbonyl group is competitive with reduction of the pendant ester. The hemi-aminal that results from initial addition of hydride to the oxindole carbonyl may follow a number of reaction pathways, one of which is an unprecedented rearrangement. A mechanism is proposed that accounts for all observed products.

Key words: oxindole, reduction, rearrangement.

Résumé : On a étudié la réduction du 4-carboéthoxy-1,3-diméthyl-3-(méthylthio)oxindole par $LiAlH_4$ et par le triéthylborohydrure de lithium. Les résultats montrent que la réduction du groupe carbonyle de l'oxindole est en compétition avec la réduction du groupe ester exocyclique. L'hémi-aminal qui résulte de l'addition initiale d'hydrure sur le groupe carbonyle de l'oxindole peut donner lieu à un certain nombre de réactions subséquentes; l'une d'elle est une transposition sans précédent. On propose un mécanisme pour expliquer la formation de tous les produits observés.

Mots clés : oxindole, réduction, transposition.

Introduction

The biological activity of some compounds possessing the oxindole nucleus and their structural relationship to indoles continue to make these compounds attractive targets in synthetic organic chemistry (1). In particular, the chemistry of 3-(alkylthio)oxindoles is of great interest. Much of this interest may be traced to the reliable yields and ease of preparation of this class of compounds, primarily due to the pioneering works of Gassman and van Bergen (2, 3). A number of notable variations of the original Gassman methodology have been published recently (4, 5). The fact that these advances and improvements have come primarily from industrial pharmaceutical laboratories lends credence to the importance of these compounds. In addition to the improvements in preparative methods, Karp has recently described conditions that allow for the selective alkylation of this nucleus, thus providing a method for the preparation of 1-, 3-, and 1,3-substituted oxindoles (6), a notable achievement given the difficulty associated with oxindole alkylation. Our contribution to this field has focused on a new, mild, and general nonreductive desulfenylation protocol allowing for the selective removal of the 3-alkylthio group always present if the Gassman approach is utilized (7). In the preceding paper, we described the results of a study dealing with the metal hydride mediated reduction of 3-(alkylthio)oxindoles bearing pendant ester groups on the aromatic ring (8). This study concluded that in this series of compounds the presence of a proton α to the oxindole carbonyl group protects it from reduction, presumably via deprotonation by the metal hydride. We also noted the complications involved in the reduction of ester groups attached at various positions on the benzene ring and ascribed these to the formation of a C3 anion. In continuing our studies in this area, we were interested in seeing what effect blocking both of the positions α to the oxindole carbonyl would have on the course of the reaction. The results of this chemistry, and a postulated mechanism regarding the unusual rearrangement we observed, are the focus of this publication.

Scheme 1.

Results

The required 1,3-(dimethylated)oxindole **1** was prepared by treating 4-carboethoxy-3-(methylthio)oxindole (8) with 2 equivalents of LDA at −78°C followed by the addition of excess MeI and allowing the reaction mixture to warm to room temperature. The product oxindole **1**, prepared in a yield of >95%, was readily identified based on the appearance of three equally intense singlets in the ^1H NMR spectrum, accounting for the three methyl groups. Reduction of oxindole **1** with excess $LiAlH_4$ in refluxing THF led to the formation of oxindole **2** as the major polar material in a yield of 35% after column chromatography (Scheme 1).

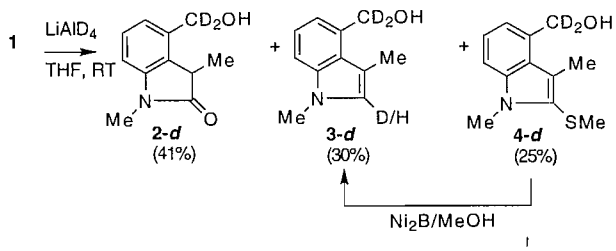
To gain insight into the reaction mechanism, the reaction was repeated with a controlled amount of $LiAlD_4$ at room temperature. Quenching the reaction mixture with a saturated solution of potassium sodium tartrate followed by careful chromatography led to the isolation of three products (Scheme 2). The most polar compound (**2-*d***), isolated as a pale yellow solid (mp 100–101°C) in 41% yield, was identical to **2** except that two atoms of deuterium had been incorporated at the benzylic alcohol position. The second compound, also obtained as a pale yellow solid (mp 81–82°C) in 30% yield, proved to be indole **3-*d***. Key spectral evidence included the absence of carbonyl and presence of alcohol functional groups (3391 cm^{-1}) and an aromatic region in the ^1H NMR spectrum that failed to show the fine structure associated with an oxindole. Additionally, ^2H NMR showed that two deuterium atoms had been incorporated into the molecule at chemical shifts of 4.68 and 6.78 ppm in a ratio of 2:1. These chemical shifts correspond to deuterium incorporation at the C4 benzylic and the C2 position of the indole, respectively. The third compound, isolated as a yellow solid (mp 106–107°C) in 25% yield, was confirmed as being **4-*d*** by converting it to **3** via desulfurization with Ni_2B (9–11).



Reduction with $LiEt_3BH$ in THF at room temperature followed by careful chromatography afforded *four* products (Scheme 3). The isolation of **4** and **5** indicates that reduction of the oxindole carbonyl is competitive with reduction of the C4 ester group.

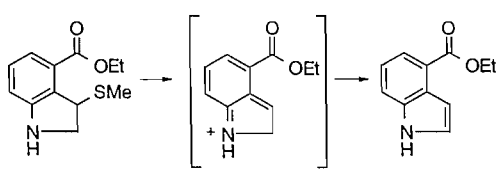
Discussion

The ease of reduction of the oxindole carbonyl group in **1** as compared to oxindoles lacking the 1,3-dimethyl groups (8) proves that an adjacent proton indeed protects it from reduction. In the case of **1**, reduction of the oxindole carbonyl group occurs and leads to either dethiomethylation or an interesting rearrangement. A proposed mechanism to account for all of the isolated products is shown in Scheme 4.

Although it was not possible to determine which carbonyl group was reduced first, it is apparent that reduction of the oxindole carbonyl is facile. Addition of one equivalent of hydride to the oxindole carbonyl results in the formation of hemi-aminal **7**. Further addition of hydride to **7** in a manner reminiscent of amide to amine reduction may occur through **8** to give indoline **9**. We have found that these 3-methylthioindolines are extremely susceptible to dethiomethylation, and readily afford indoles.[2] An analogous transformation on substrate **9** would account for **10**. Reduction of the ester group of **1** prior to or following oxindole reduction accounts for **3**.

Scheme 2.

To account for indole **4**, C3 to C2 migration of the methylthio group of **8** via an episulfonium salt **11** has been invoked. Migrations of alkylthio groups from the 3 to 2 position are known to occur for indoles. Ottenheijm and co-workers first proposed the intermediacy of episulfonium salts to account for this transformation (12). Hamel, Girard, and Atkinson (13, 14) have since shown that a complex intermolecular process can occur, although a concomitant intramolecular rearrangement via an episulfonium species remains a distinct possibility (15). The similarities between intermediate **8** and the intermediates formed in the acid catalyzed rearrangement of 3-alkylthioindoles is striking.

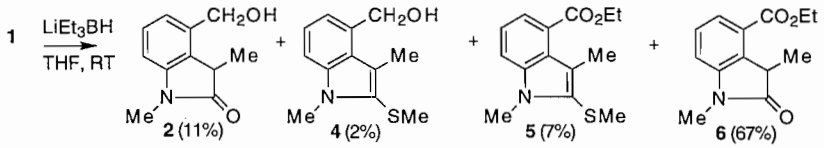


Finally, hemi-aminal **7** may lose MeS, possibly via a nitrogen-assisted 1,4-elimination giving **12**, which may re-aromatize to give enol **13**, which could then re-enolize, accounting for **7**. In this case, ester reduction *must* precede reduction of the oxindole. We have previously shown that C4 esters are difficult to reduce when a C3 anion is formed (8), which is the case for **13a**, and could be the case for **7**, which has a highly acidic C3 proton. We have also shown that reduction of **7** does not lead to the formation of **2**.

Alternatively, **12** may undergo a 1,2-hydride shift that would afford **7** or **2** directly. This latter 1,2-shift is not favored, since we could not detect any deuterium incorporation at this center when conducting the reductions with $LiAlD_4$. However, the high acidity of this C3 proton may cause exchange on work-up, thereby causing scrambling and facilitating against deuterium incorporation in the product.

In an extension of this work, oxygen analogs of the thioethers were prepared. Reduction of oxindole **15**, prepared in three steps from isatin, did not lead to **17**. This, indirectly, lends support to the intermediacy of the episulfonium salt **11** since the longer C—S bond may allow the formation of compounds like **11**, whereas oxonium salt **16** is not accessible due to the shorter C—O bond (Scheme 5).

In related work, the reactive carbonyl group of isatin was transformed into a dithiane and a dithiolane as in **18**. Reaction of **18** with $LiEt_3BH$ or $LiAlH_4$ did not result in the formation of **20** (Scheme 6). The failure to form **20** is probably the result of the rather unlikely nature of forming intermediate **19**, an idea which again supports the intermediary of an episulfonium salt in the migration of SMe from the 3 to 2 position reported earlier. It is also worth noting that this also supports the intermediacy of episulfonium salts in the acid-catalyzed isomerization of indole-3-sulfides to indole-2-sulfides.



[2] We found that 3-methylthio-4-carboethoxyindolines readily dethioalkylate to afford 4-carboethoxyindole. Although this transformation readily occurs by treatment with reducing agents, including $NaBH_4$, a sample of the pure indoline is slowly converted to the indole, in the absence of other reagents. This observation has led us to propose a nitrogen-assisted 1,4-elimination, followed by re-aromatization as shown below.

Conclusion

We have shown that the reduction of substituted 3-(methylthio)oxindoles with metal hydrides is a complicated reaction. In the case of 1,3-dialkyl derivatives, oxindole carbonyl reduction is facile, and competitive with the reduction of remote ester groups. The hemi-aminal that results from the first addition of hydride to the oxindole carbonyl affords a number of products. Two dethiomethylation routes compete for oxindole and indole formation. The other observed products, 1,3-dimethyl-2-(methylthio)indoles, seem to be the result of an unusual rearrangement. To the best of our knowledge, this is the first example of such a rearrangement from oxindoles under reductive conditions.

Experimental

General experimental procedures have been described previously (8). In addition to this, ^2H NMR spectra were recorded in CH_2Cl_2 solutions on a Varian XL-300 spectrometer, operating at a frequency of 46.06 MHz, and are referenced to the natural abundance of CD_2Cl_2 at 5.20 ppm.

1,3-Dimethyl-3-(methylthio)oxindole (1)

A solution of freshly prepared LDA (2.1 equiv.) in THF was added dropwise to a cooled (0°C) solution of oxindole 7 (500 mg, 1.99 mmol) in THF (20 mL). Stirring was continued for 1 h, after which time a solution of MeI (631 mg, 4.38 mmol) in THF (5 mL) was added dropwise. The ice bath was removed and the temperature of the resulting solution was allowed to slowly rise to room temperature (RT) over 12 h; the solution was then poured into H_2O (50 mL) and extracted with Et_2O (4 × 20 mL). The combined organic extracts were worked up in the usual manner, affording, after chromatography (2:1

hex:EtOAc), the title compound **14** as a pale yellow oil (540 mg, <95%); ^{1}H NMR (200 MHz, $CDCl_3$) δ: 1.40 (t, 3H, J = 7.5 Hz), 1.80 (s, 3H), 2.02 (s, 3H), 3.21 (s, 3H), 4.40 (q, 2H, J = 7.5 Hz), 6.98 (dd, 1H, J = 7.0, 1.0 Hz), 7.38 (t, 1H, J = 7.0 Hz), 7.59 (dd, 1H, J = 7.0, 1.0 Hz) ppm; ^{13}C NMR (75 MHz, $CDCl_3$) δ: 12.29, 14.20, 21.32, 26.55, 51.59, 61.40, 111.28, 124.61, 128.70, 129.09, 130.93, 143.62, 165.99, 177.25 ppm; EI-MS *m/z* (%): 279 (12.2, M^+), 233 (100); HRMS calcd. for $C_{14}H_{17}NO_3S$: 279.09292; found: 279.09141.

Reduction of oxindole 1 with $LiAlD_4$ (2-*d*, 3-*d*, 4-*d*)

A solution of oxindole **1** (200 mg, 0.72 mmol) was added dropwise to a suspension of $LiAlD_4$ (50 mg, 1.19 mmol) in THF (10 mL) at RT. After stirring at RT for 7 h, the resulting gray cloudy solution was poured into a solution (50 mL) of saturated potassium sodium tartrate and EtOAc (20 mL). After stirring for 4 h, the organic phase was separated and subjected to normal work-up, affording 180 mg of a pale yellow oil. Chromatography with a gradient of 2:1 to 1:1 hex:EtOAc provided three compounds.

Indole ***4*-d**: 40.3 mg (25.0%), R_f = 0.5 (1:1 hex:EtOAc), pale yellow solid; mp 106–107°C; IR (CH_2Cl_2): 3392 cm^{-1}; ^{1}H NMR (200 MHz, $CDCl_3$) δ: 2.12 (s, 3H), 2.58 (s, 3H), 3.75 (s, 3H), 6.95 (d, 1H, J = 7.5 Hz), 7.10 (m, 2H) ppm; ^{2}H NMR (46 MHz, CH_2Cl_2) δ: 4.87 (s) ppm; ^{13}C NMR (75 MHz, $CDCl_3$) δ: 12.03, 19.61, 29.89, 63.80 (quintet), 109.45, 116.38, 119.24, 122.11, 124.65, 130.10, 132.91, 137.88 ppm; EI-MS *m/z* (%): 223 (100) (M^+), 205 (15.0), 190 (48.5), 175 (28.5); HRMS calcd. for $C_{12}H_{13}NOSD_2$: 223.10309; found: 223.09989.

Indole ***3*-d**: 38.4 mg (30.1%), R_f = 0.40 (1:1 hex:EtOAc), pale yellow solid; mp 80–81°C; IR (CH_2Cl_2): 3391 cm^{-1}; ^{1}H NMR (500 MHz, $CDCl_3$) δ: 2.41 (s, 3H), 3.62 (s, 3H), 6.90 (d, 1H, J = 7.5 Hz), 7.15 (t, 1H, J = 7.5 Hz), 7.23 (d, 1H, J = 7.5 Hz); ^{2}H NMR (46 MHz, CH_2Cl_2) δ: 4.86 (s, 2D), 6.78 (s, 1D); ^{13}C NMR (125 MHz, $CDCl_3$) δ: 12.14, 32.54, 63.80 (quintet), 109.42, 109.75, 119.42, 121.36, 122.86, 128.72, 132.48, 138.62 (doublet); EI-MS *m/z* (%): 178 (96.3) (M^+), 160 (100).

Oxindole ***2*-d**: 56.0 mg (40.5%), R_f = 0.1 (1:1 hex:EtOAc), pale yellow solid; mp 99–101.3°C; IR (CH_2Cl_2): 3603, 1710 cm^{-1}; ^{1}H NMR (200 MHz, $CDCl_3$) δ: 1.38 (d, 3H, J = 7.5 Hz), 3.08 (s, 3H), 3.42 (q, 1H, J = 7.5 Hz), 6.65 (d, 1H, J = 7.5 Hz), 6.98 (d, 1H, J = 7.5 Hz), 7.18 (t, 1H, J = 7.5 Hz); ^{2}H NMR (46 MHz CH_2Cl_2) δ: 4.56 (s, 1D), 4.63 (s, 1D); EI-MS m/z (%): 193 (45.6, M^+), 175 (32.9), 160 (23.9), 43 (100); HRMS calcd. for $C_{11}H_{11}NO_2D_2$: 193.11028; found: 193.10784.

Reduction of oxindole 1 with $LiEt_3BH$ (2, 4, 5, 6)

A solution of $LiEt_3BH$ (2.80 mL, 2.80 mmol, 1.0 M in THF) was added dropwise via syringe to a solution of oxindole **3** (156.3 mg, 0.56 mmol) in THF (15 mL) at RT. The resulting bright yellow solution was stirred at RT for 3 h, after which time the yellow solution was poured into H_2O (20 mL), adjusted to pH 3 by the dropwise addition of HCl (10%), and extracted with EtOAc (4 × 20 mL). The combined organic extracts were worked up as usual, affording a pale yellow oil (120 mg) that was chromatographed with a gradient of 2:1 to 1:1 hex:EtOAc and afforded four compounds.

Indole ***5***: yellow oil, 9.8 mg (6.6%), R_f = 0.9 (1:1 hex:EtOAc); ^{1}H NMR (200 MHz, $CDCl_3$) δ: 1.40 (t, 3H, J = 7.5 Hz), 2.25 (s, 3H), 2.51 (s, 3H), 3.88 (s, 3H), 4.42 (q, 2H, J = 7.5 Hz), 7.20 (t, 1H, J = 7.5 Hz), 7.41 (d, 1H, J = 7.5 Hz), 7.52 (d, 1H, J = 7.5 Hz); EI-MS *m/z* (%): 263 (57.3, M^+), 248 (12.6), 234 (14.0), 219 (24.3), 205 (53.3), 57.0 (100); HRMS calcd. for $C_{14}H_{17}NO_2S$: 263.09800; found: 263.09847.

chromatography (2:1 hex:EtOAc), providing the title compound as a yellow solid (346.2 mg, 65%); ^{1}H NMR (200 MHz, $CDCl_3$) δ: 1.63 (s, 3H), 4.80 (d, 1H, J = 15.0 Hz), 4.95 (d, 1H, J = 15.0 Hz), 6.70 (d, 1H, J = 8.0 Hz), 7.05 (t, 1H, J = 8.0 Hz), 7.18 (dd, 1H, J = 8.0, 1.0 Hz), 7.30 (s, 5H), 7.42 (dd, 1H, J = 8.0, 1.0 Hz) ppm; ^{13}C NMR (50 MHz, $CDCl_3$) δ: 24.78, 43.44, 73.41, 109.28, 122.96, 123.21, 126.90, 127.43, 128.56, 129.26, 131.01, 135.16, 141.63, 178.30 ppm; EI-MS *m/z* (%): 253 (24.7, M^+), 235 (20.5), 149 (38.3), 91 (100); HRMS calcd. for $C_{16}H_{15}NO_2$: 253.11078; found: 253.11042.

1-Benzyl-3-methyl-3-(methoxy)oxindole (15)

A THF solution (10 mL) of *N*-benzyl-3-methyl-3-(hydroxy)oxindole (150 mg, 0.59 mmol) was added dropwise to a suspension of NaH (20 mg, 0.83 mmol) in THF (5 mL). The pale yellow solution was stirred at RT for 1 h, excess MeI was added, and the still pale yellow solution was stirred at RT for 18 h, after which time it was evaporated to dryness, leaving a pale yellow solid that was recrystallized from CH_2Cl_2–hexanes, affording the title compound as a bright yellow solid (81.2 mg, 51%); ^{1}H NMR (200 MHz, $CDCl_3$) δ: 1.60 (s, 3H), 3.06 (s, 3H), 4.91 (d, 1H, J = 16.0 Hz), 4.92 (d, 1H, J = 16.0 Hz), 6.70 (d, 1H, J = 8.0 Hz), 7.05 (t, 1H, J = 8.0 Hz), 7.20–7.40 (m, 7H) ppm; ^{13}C NMR (50 MHz, $CDCl_3$) δ: 23.83, 43.44, 52.87, 79.33, 109.21, 122.82, 123.51, 126.93, 127.44, 128.29, 128.55, 129.31, 135.37, 142.23, 176.31 ppm; EI-MS *m/z* (%): 267 (23.4, M^+), 237 (25.3), 176 (14.5), 144 (28.6), 91 (100); HRMS calcd. for $C_{17}H_{17}NO_2$: 267.12593; found: 267.12731.

1-Benzyl-3,3-(ethylenedithio)oxindole (18a)

A solution of *N*-benzylisatin (250 mg, 1.05 mmol) in CH_2Cl_2 (15 mL) containing ethane-1,2-dithiol (119 mg, 1.27 mmol) was stirred at RT while $BF_3{\cdot}OEt_2$ (1 mL) was added dropwise. The resulting solution was stirred at RT for 2 h, then quenched by the addition of H_2O (20 mL), washed with sodium carbonate (10%, 3 × 20 mL), and worked up in the usual manner. Chromatography (5:1 hex:EtOAc) afforded the title compound as a pale yellow solid (222 mg, 67%); mp 107–108°C; IR (CH_2Cl_2): 1717 cm^{-1}; ^{1}H NMR (200 MHz, $CDCl_3$) δ: 3.65 (m, 2H), 3.95 (m, 2H), 4.90 (s, 2H), 6.65 (d, 1H, J = 8.0 Hz), 7.10 (t, 1H, J = 8.0 Hz), 7.15 (t, 1H, J = 8.0 Hz), 7.30 (s, 5H), 7.55 (d, 1H, J = 8.0 Hz) ppm; ^{13}C NMR (50 MHz, $CDCl_3$) δ: 40.34, 43.82, 109.22, 123.13, 125.34, 125.94, 126.99, 127.54, 128.54, 128.69, 129.73, 135.31, 142.22, 177.96 ppm; EI-MS *m/z* (%): 313 (33.1, M^+), 254 (54.2), 222 (53.2), 162 (51.0), 91 (100); HRMS calcd. for $C_{17}H_{15}NOS_2$: 313.05951; found: 313.06144.

1-Benzyl-3,3-(propylenedithio)oxindole (18b)

The title compound was prepared as above, except that propane-1,3–dithiol was used in the place of ethane-1,2-dithiol. Chromatography (6:1 hex:EtOAc) afforded the title compound as a pale yellow solid (241.8 mg, 70.1%); mp 148–149°C; IR (CH_2Cl_2): 1708 cm^{-1}; ^{1}H NMR (200 MHz, $CDCl_3$) δ: 2.0–2.3 (m, 2H), 2.65 (dt, 2H, J = 14.0, 2.0 Hz), 4.09 (td, 2H, J = 14.0, 2.0 Hz), 4.85 (s, 2H), 6.63 (d, 1H, J = 7.6 Hz), 7.00 (t, 1H, J = 7.6 Hz), 7.15 (t, 1H, J = 7.6 Hz), 7.30 (s, 5H), 7.45 (d, 1H, J = 7.6 Hz) ppm; ^{13}C NMR (50 MHz, $CDCl_3$) δ: 24.18, 25.88, 43.16, 109.17, 122.94, 124.99, 126.80, 127.48, 128.71, 129.90, 135.39, 141.43, 175.67 ppm; EI-MS *m/z* (%): 327 (M^+, 23.2), 294 (22.0), 254 (39.5), 162 (61.5), 91 (100); HRMS calcd. for $C_{18}H_{17}NOS_2$: 327.07516; found: 327.07519.

Influence of working electrodes in Belousov–Zhabotinsky oscillatory system

V. Jayalakshmi and R. Ramaswamy

Abstract: The potential oscillatory profiles recorded simultaneously in the same B–Z system using platinum, glassy carbon, and graphite electrodes are different in their characteristics. The variance in the amplitude and potential range is a result of the difference in the potential response of the electrode to the different redox couples. The results obtained by employing cyanoacetic acid, syringic acid, malonic acid, citric acid, methylacetoacetate, or vanillin as the substrate and Ce(III), Mn(II), or Ferroin as the catalyst are presented. The response of the working electrode to the various redox couples is correlated to the value of the exchange current density.

Key words: potential oscillatory profile, redox couple, working electrode, potential response, exchange current density.

Résumé : Les profils de potentiel oscillatoire enregistrés simultanément dans le même système B–Z, en utilisant des électrodes de platine, de carbone vitreux et de graphite présentent des caractéristiques différentes. La variation dans l'amplitude et la plage de potentiel résultent de différences dans la réponse du potential de l'électrode aux différents couples rédox. On présente les résultats obtenus lors de l'utilisation des acides cyanoacétique, syringique, malonique et citrique ou de l'acétoacétate de méthyle ou de la vanilline comme substrats et du Ce(III), du Mn(II) ou de la ferroïne comme catalyseurs. On a établi une corrélation entre la réponse de l'électrode de travail à divers couples rédox et la valeur de l'échange de la densité de courant.

Mots clés : profile de potentiel oscillatoire, couple rédox, électrode de travail, réponse au potentiel, échange de la densité de courant.

[Traduit par la rédaction]

Introduction

The most extensively investigated oscillatory Belousov–Zhabotinsky (B–Z) reactions (1–9) fall into two major classes, namely, catalyzed and uncatalyzed systems. Catalyzed systems contain a metal ion catalyst and an organic substrate and the oscillations are usually registered by potentiometry, spectrophotometry (10), and EPR techniques (11, 12). The oscillations in redox potential measurements are mainly due to the metal ion catalyst and bromine. Uncatalyzed systems contain a highly reactive organic substrate and there is no metal ion catalyst. Oscillations observed in redox potential measurements are mainly due to bromine. The technique most widely used for investigating B–Z reactions is redox potential measurement employing a platinum working electrode. The issue regarding the species monitored in a complex oscillating reaction mixture containing several redox couples has not so far been satisfactorily resolved. The Ce(III) system with malonic acid as the substrate has been studied, employing working electrodes other than platinum (13). In the present paper we focus on the correlation among the potential oscillatory profiles recorded employing different working electrodes, namely, graphite, platinum, glassy carbon, and the Br^- selective electrode. Experiments were carried out by employing cyanoacetic acid, syringic acid, malonic acid, citric acid, vanillin or methylacetoacetate as the substrate and Mn(II), Ce(III), or Ferroin as the catalyst. The sensitivities of different working electrodes to the different redox couples present in the same mixture may vary with the chemical system. A critical examination of the oscillatory profiles with different electrodes represents a qualitative measure of such sensitivity. The conclusions resulting from such studies have been discussed in terms of the value of exchange current density of the redox couples involved.

Experimental

The batch reactor employed in the present investigation contained sulphuric acid, metal ion catalyst, and an organic substrate. Requisite volumes of the constituents were drawn from the stock solution. This was kept well stirred and thermostated at 30 ± 0.1°C in a polythene beaker. The system commences to oscillate after the addition of the last constituent, namely,

Results and discussion

(A) Oscillatory potential profile

The potential range of the oscillatory profile recorded using different working electrodes has a bearing on the E° value of the redox couple to which that particular electrode is responding. The values of the exchange current density for various electrode processes cover a wide range, from 10^{-18} to 10^{-2} A/cm^2. If the value of the exchange current density is lower than 10^{-7} A/cm^2, the potential of the electrode process cannot be attained and an alternative process capable of sustaining a greater current density assumes control of the electrode potential (14). The E° values of the different redox couples involved in the study are presented in Table 1.

The potential range of the oscillations is an index of the redox couple mainly controlling the oscillatory potential profile. The E° values of the redox couples (Table 1) of the ions of manganese and cerium are relatively large and comparable to that involving HOBr. It should therefore be expected that the peak potential values of the oscillations of the uncatalyzed bromate system should reach those observed in the catalyzed system if the redox couple involving HOBr contributed to the observed potential. However, the highest peak potential recorded in the uncatalyzed system is less than 1 V (vs. SCE) (15) whereas the peak potential in the catalyzed system reaches values larger than 1 V (vs. SCE). The peak potential value of the catalyzed system is higher than that of the uncatalyzed bromate system by at least 200 mV. It would therefore

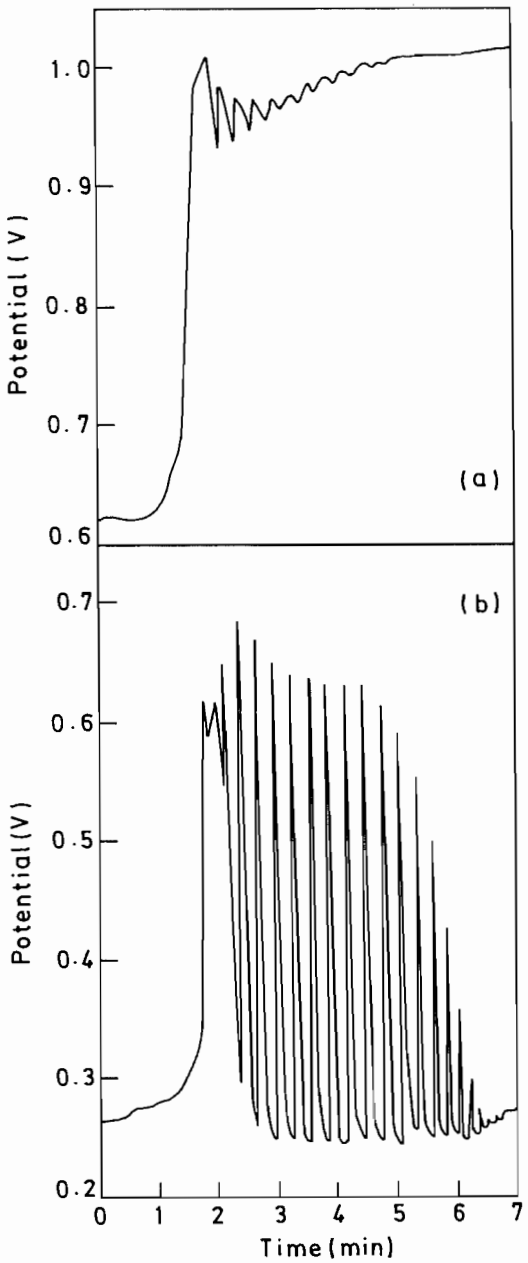
Fig. 4. Potential oscillatory profile of Mn(II) – syringic acid system with (*a*) graphite and (*b*) platinum electrodes. The concentrations of the various constituents are [S] = 0.02 M; [H_2SO_4] = 0.34 M; [$KBrO_3$] = 0.085 M; [Mn(II)] = 0.017 M.



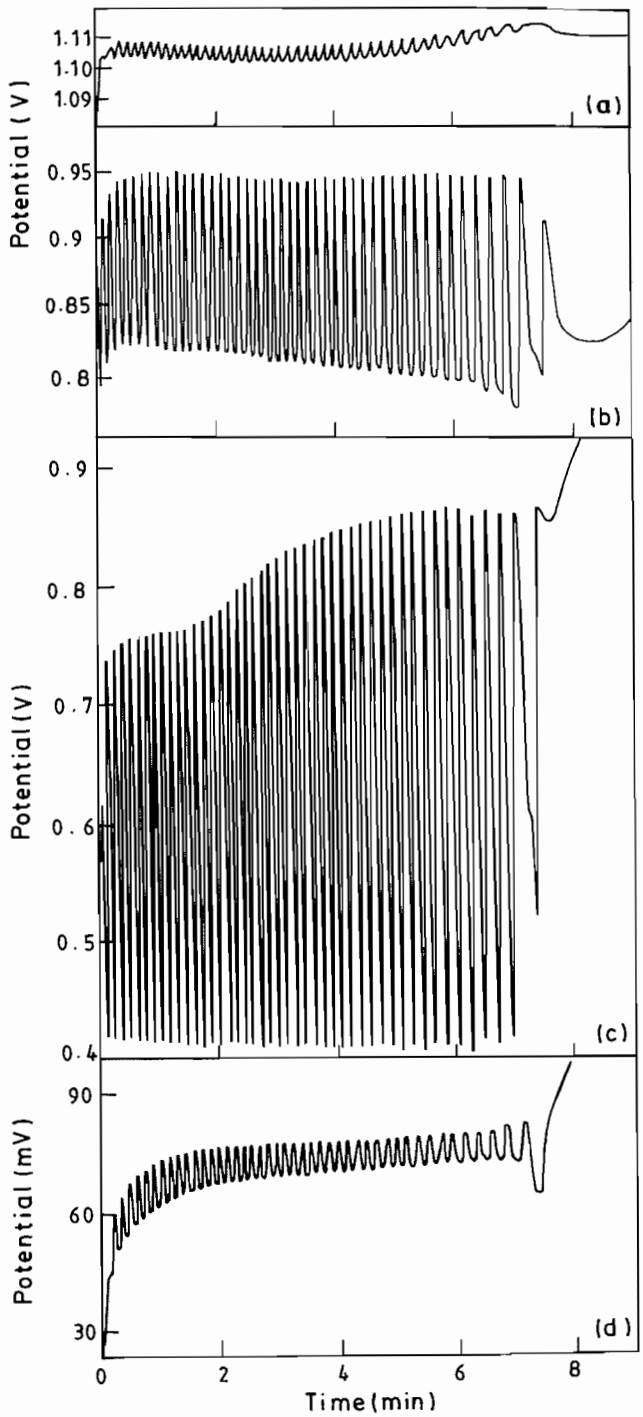


Fig. 5. Potential oscillatory profile of Mn(II) – methylacetoacetate system with (*a*) graphite, (*b*) platinum, (*c*) glassy carbon, and (*d*) Br^- selective electrodes. The concentrations of the various constituents are [S] = 0.06 M; [H_2SO_4] = 1.0 M; [$KBrO_3$] = 0.15 M; [Mn(II)] = 0.01 M.

be logical not to consider contributions to the potential from a redox reaction involving HOBr. It is also well known (16) that the concentration of HOBr in a medium containing 1 M H_2SO_4 would be smaller than 10^{-7} M. The equilibrium constant for the reaction $Br_2 + H_2O \rightleftharpoons H^+ + Br^- + HOBr$ is 7.2×10^{-9} at 298 K. A species existing in solution in such low concentration can hardly contribute to the potential of the electrode system. Likewise, the concentration of $HBrO_2$ in solution would be too insignificant to contribute to the potential. Thus the contribution from the Br_2/Br^- redox couple with its relatively lower value of $E°$ has to be considered as most significant in the uncatalyzed system. However, the catalyzed oscillatory system should be discussed by taking into account the role of the metal ion redox couple in addition to Br_2/Br^-.

The results obtained with Ferroin, Mn(II), and Ce(III) with different organic substrates employing graphite, platinum,

glassy carbon, and bromide selective electrodes are presented in Tables 2–4.

Ferroin system

It is observed from the oscillatory profile of cyanoacetic acid (Fig. 1) that the potential range with a graphite electrode is the highest (0.95–1.09 V vs. SCE), indicative of oscillations in [Ferrin]/[Ferroin] exclusively. However, the potential range with platinum (0.79–0.95 V) and glassy carbon is lower, indicative of predominant control of potential by [Ferrin]/[Ferroin] and some contribution to the potential by $[Br_2]/[Br^-]$.

The oscillatory profile of syringic acid (Fig. 2) under the concentration conditions indicated in Table 2 is characterized by a dual behaviour. The potential range of the oscillatory profile recorded employing a platinum electrode indicates that the high-amplitude oscillations in Phase 1 are under mixed control of potential by both redox couples, namely, Ferrin/Ferroin and Br_2/Br^-. The small-amplitude oscillations in Phase 2 are mainly due to the Ferrin/Ferroin redox couple. The oscillations recorded with the graphite electrode are controlled by the Ferrin/Ferroin redox couple, predominantly in Phase 1 and exclusively in Phase 2. It is also interesting to note that the oscillations of both profiles in Phase 2 are of almost the same amplitude.

The potential range of oscillations in the vanillin system with the platinum working electrode is 0.610–0.780 V. This is indicative of oscillations predominantly in Br_2/Br^- even though it is a Ferroin-catalyzed system. The potential range with the graphite electrode is 0.75–0.81 V. Such behaviour establishes the fact that under the concentration conditions employed the system behaves as an uncatalyzed bromate oscillator, presumably because of considerable buildup of bromine due to the high reactivity of the substrate. Under these conditions the graphite electrode registers oscillations in $[Br_2]$. This is further supported by the fact that in the catalyzed (Fig. 3*f* and 3*g*) and uncatalyzed bromate systems (Fig. 3*a*, *b* and *c*), with vanillin as the substrate, the potential ranges of the oscillations are almost the same individually for the platinum and graphite electrodes.

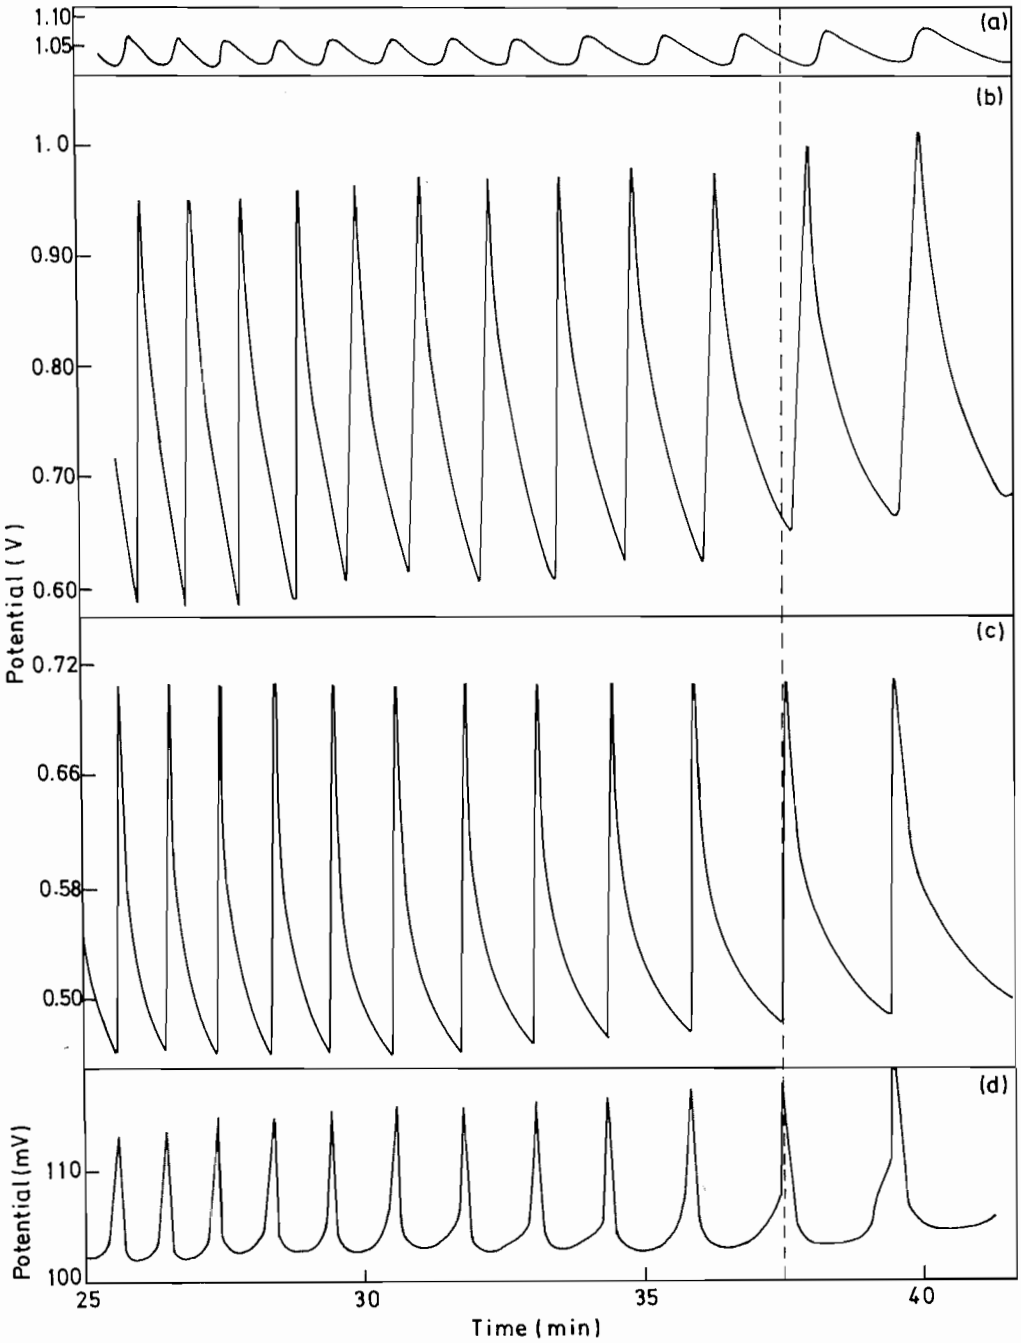
Mn(II) system

The concentration conditions employed for the Mn(II) system with syringic acid as the substrate are presented in Table 3. The oscillatory profile with the platinum working electrode is characterized by 11 large-amplitude oscillations (400 mV) in the potential range 0.25–0.65 V followed by 5 damped oscillations for the subsequent 1.2 min (Fig. 4). This indicates that the platinum working electrode is mainly responsive towards Br_2/Br^-. On the other hand the small-amplitude oscillations (11 oscillations in 5 min) with the graphite electrode in the range 0.93–1.0 V are indicative of exclusive control by the metal ion redox couple. It is noteworthy that the graphite electrode does not sense beyond the 11th oscillation at the 5th minute.

The concentration condition with methylacetoacetate is given in Table 3. The oscillatory profile (Fig. 5) indicates that the small-amplitude oscillations in the range 1.105–1.110 V are characteristic of oscillations in [Mn(III)]/[Mn(II)]. The potential range of oscillations with the platinum electrode is 0.8–0.95 V, indicative of mixed control of potential by both redox couples, namely, Mn(III)/Mn(II) and Br_2/Br^-. On the other hand the potential profile with the glassy carbon electrode is characterized by large-amplitude oscillations in the range 0.41–0.86 V. Such behaviour indicates that the glassy carbon electrode is more sensitive to oscillations in $[Br_2]$ than is the platinum electrode, and the buildup of bromine is to an optimum level.

The concentration conditions employed with malonic acid as the substrate are presented in Table 3 and Fig. 6. The response of the graphite electrode in the malonic acid system is similar to that with methylacetoacetate as the substrate. The potential range of oscillations with the platinum electrode (0.65–0.98 V) is indicative of mixed control by both redox couples. However, glassy carbon is responsive mainly to $[Br_2]$, as indicated by the potential range (0.48–0.75 V).

The potential oscillatory profile (Fig. 3*d*, *e*) recorded with the graphite electrode in the Mn(II)–vanillin system is characterized by oscillations in Phase 1 and Phase 2 separated by about 300 mV. The potential range of oscillations in Phase 1 (0.780–0.800 V) matches with the oscillatory phase in the Ferroin – vanillin system and is characteristic of $[Br_2]$ oscillation. The profile in Phase 2 (1.130–1.160 V) represents oscillations in [Mn(III)]/[Mn(II)]. The oscillatory profile recorded simultaneously with the platinum electrode is also characterized by Phase 1 and Phase 2. However, the oscillations in Phase 1 and Phase 2 are of larger amplitude. It is interesting to note that, with the glassy carbon electrode, although the amplitude of the oscillation in Phase 1 is almost of the same magnitude as that recorded with the graphite electrode, the amplitude of the oscillations in Phase 2 are much larger, indicating better sensitivity of the glassy carbon electrode towards bromine.



Ce(III) system

The malonic acid system has been studied under two different concentration conditions. The oscillatory profile (Fig. 7) obtained under the concentration condition 3.1 (Table 4) shows that with a platinum electrode the system oscillates in the potential range 1.02–1.10 V indicative of predominant control of metal ion at the initial stage. The potential profile with the graphite electrode indicates exclusive control of

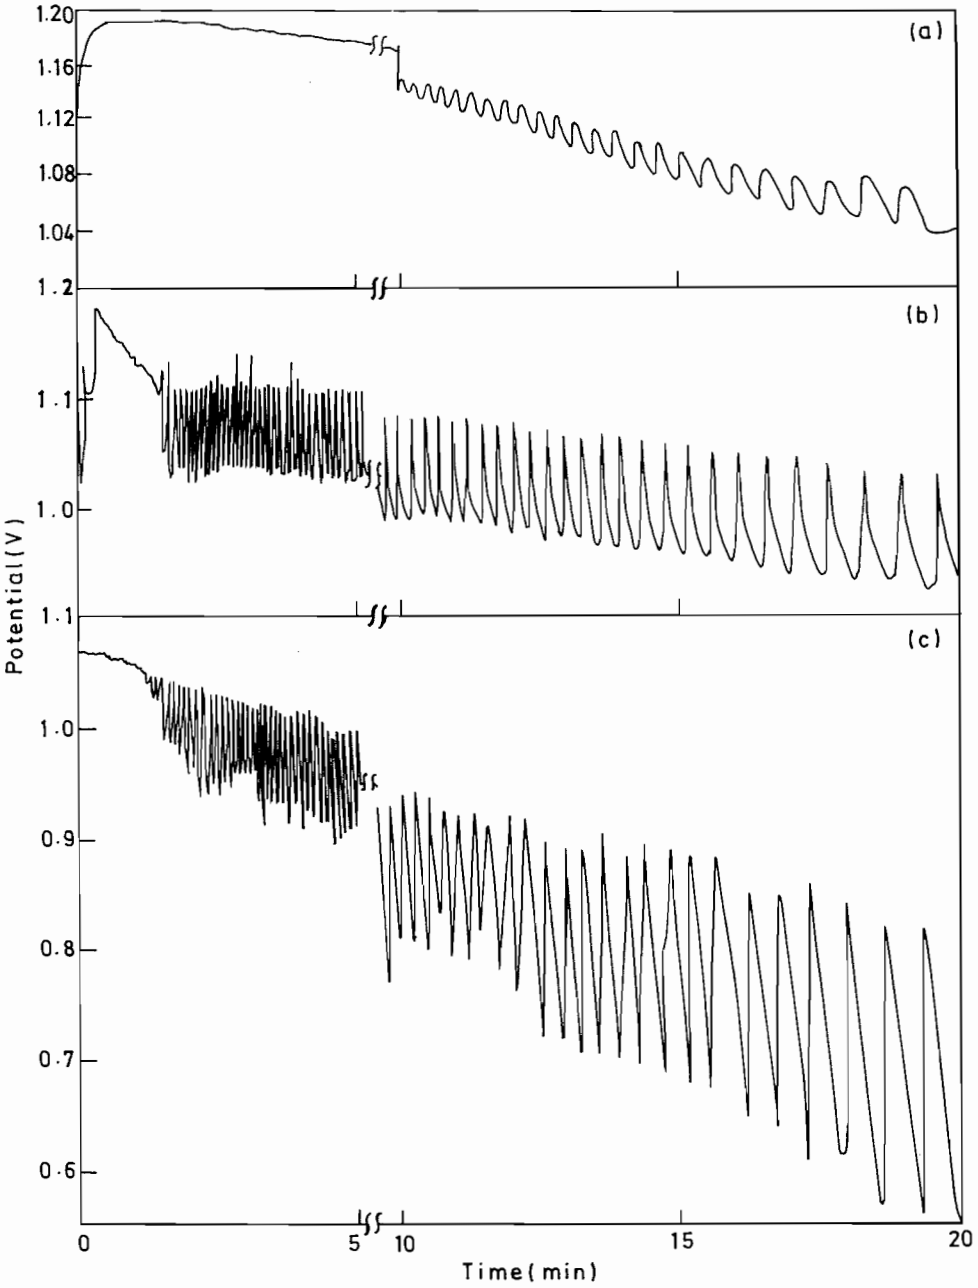
Fig. 6. Potential oscillatory profile of Mn(II) – malonic acid system with (*a*) graphite, (*b*) platinum, (*c*) glassy carbon, and (*d*) Br^- selective electrodes. The concentrations of the various constituents are [S] = 0.05 M; [H_2SO_4] = 1.0 M; [$KBrO_3$] = 0.05 M; [Mn(II)] = 0.01 M.

potential by the metal ion redox couple. It is interesting to note that initially the amplitude is very small and it increases gradually with the progress of the reaction. The amplitude of oscillation with the glassy carbon electrode is of considerable magnitude even in the beginning and there is a further increase in the amplitude simultaneously with a lowering of the potential range, indicating that the prevailing concentration of bromine gradually increases with the progress of the reaction.



The oscillatory parameters corresponding to the concentration conditions (3.2) given in Table 4 establish that with all three electrodes the oscillatory profile corresponds to change in [Ce(IV)]/[Ce(III)]. This is presumably due to a relatively large concentration of Ce(IV) (5×10^{-3} M) and the high ratio of bromate to substrate (1:1).

The concentration conditions with citric acid as the substrate are also given in Table 4. The potential range is indicative of an exclusive metal ion control with the graphite as well as the platinum electrode. However, an amplitude of 90 mV in the potential range 0.875–0.965 V in the case of the glassy carbon electrode indicates oscillations in the [Br_2]/[Br^-] redox couple as well, especially towards the end of the reaction.

(B) Potential response of the different electrodes

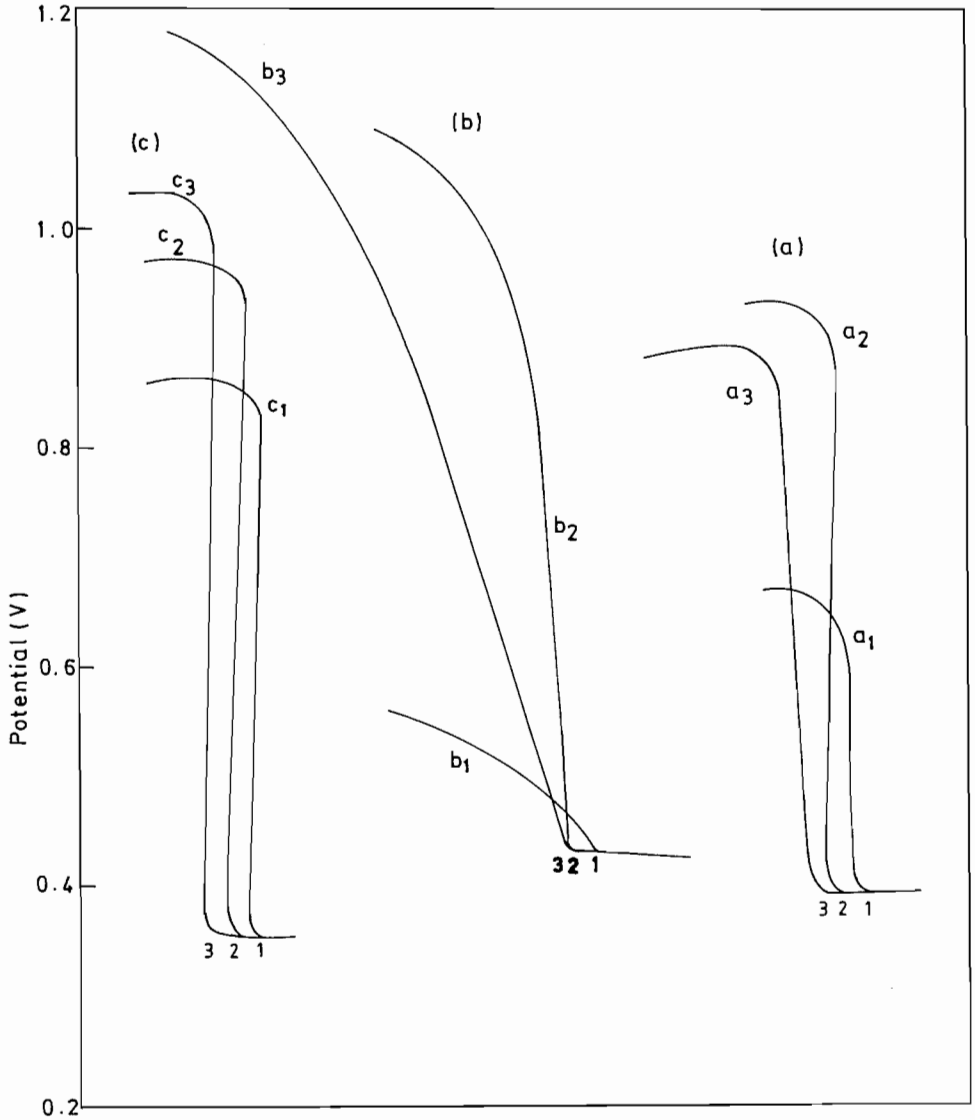
These oscillatory systems are characterized by periodic change in the concentration ratio of the metal ion redox couple as well as that of Br_2/Br^-. The formation and consumption of Br_2,Br^- as well as the oxidized and reduced form of the metal ion redox couple can be represented by the following individual steps involved in the overall reaction (17).

Sequence 1

[1.1] $HBrO_2 + Br^- + H^+ \rightleftharpoons 2\,HOBr$
[1.2] $HOBr + Br^- + H^+ \rightleftharpoons Br_2 + H_2O$

Sequence 2

[2.1] $HBrO_2 + BrO_3^- + H^+ \rightleftharpoons 2BrO_2^{\cdot} + H_2O$
[2.2] $BrO_2^{\cdot} + M^{n+} + H^+ \rightleftharpoons M^{(n+1)+} + HBrO_2$



Sequence 3

[3.1] $S + Br_2 \rightleftharpoons Br.S + Br^- + H^+$
[3.2] $S + M^{(n+1)+} \rightleftharpoons M^{n+} + Product$
[3.3] $Br.S + M^{(n+1)+} \rightleftharpoons M^{n+} + Br^- + Product$

Any difference in the response of the working electrode

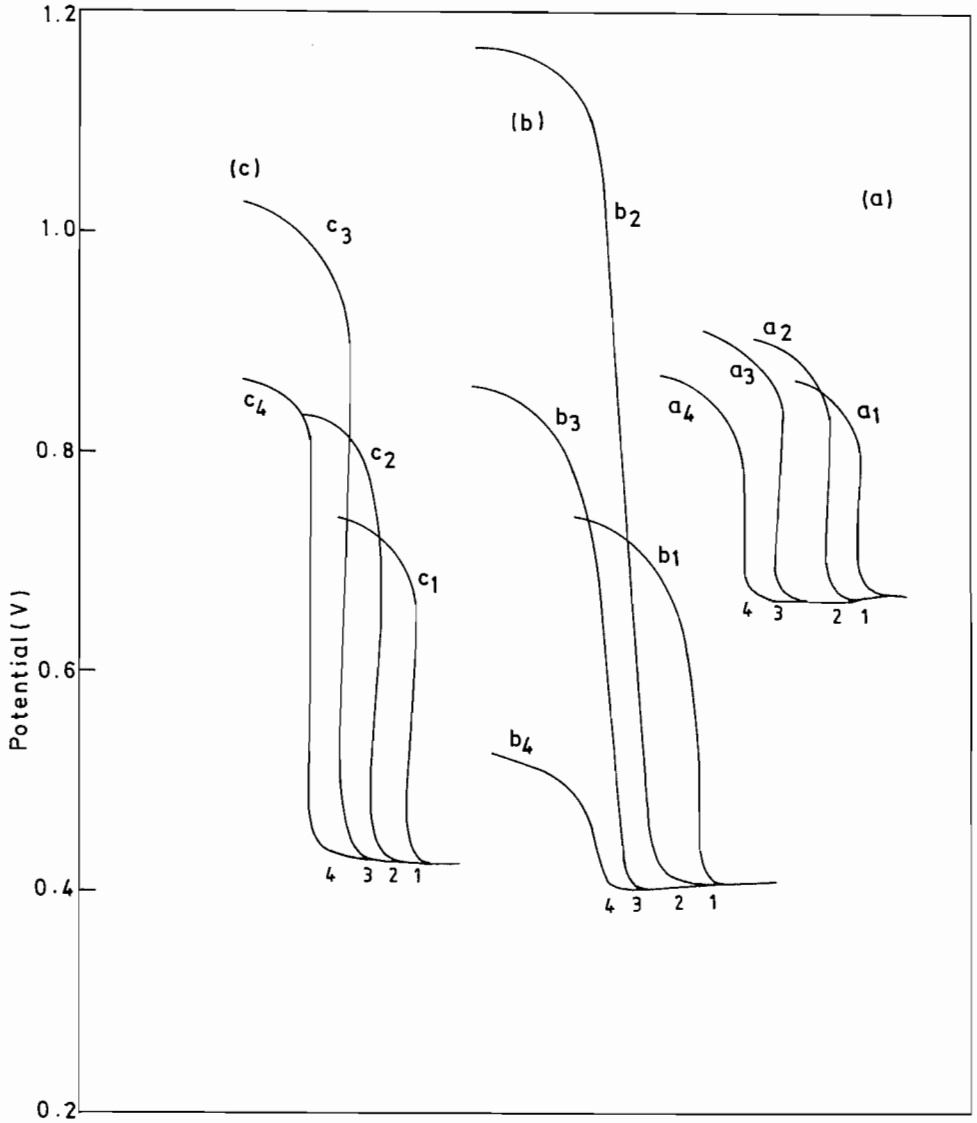
Fig. 8. The potential response of the working electrode immersed in 0.1 M sulphuric acid with (*a*) platinum, (*b*) graphite, and (*c*) glassy carbon electrodes. The concentration, of the redox couples included are (1) $[Br_2] = [Br^-] = 1 \times 10^{-4}$ M; (2) [Ce(III)] = [Ce(IV)] = 0.001 M; and (3) [Mn(II)] = [Mn(III)] = 0.01 M.

employed to the two redox systems would be manifested as a shift in the position of the peak value of the potential oscillatory profile.



The oscillatory profiles recorded simultaneously in the Mn(II) – malonic acid system employing graphite, platinum, glassy carbon, and Br^- selective electrodes are presented in Fig. 6. It is observed that the peak of the oscillatory profile with the glassy carbon electrode corresponding to maximum $[Br_2]$ almost coincides with the peak of the Br^- profile corresponding to low $[Br^-]$. There is a time lag before the oscillatory potential profile with the platinum electrode reaches the peak value. Such a time lag is a consequence of the fact that the platinum electrode responds to both redox couples, namely, Mn(III), Mn(II) and Br_2, Br^-. Further, the peak value with the graphite electrode is reached with an additional time lag and the response of the graphite electrode is exclusively towards [Mn(III)]/[Mn(II)] under these conditions. Such behaviour is also observed in the Ferroin system with cyanoacetic acid as the substrate (Fig. 1).

The experimental results obtained in oscillatory systems employing different metal ions and substrates establish that the oscillatory profiles recorded simultaneously differ from each other in many of their oscillatory characteristics, including a phase shift. Such behaviour is a direct consequence of the response of the working electrodes to the different redox couples involved. The response of a working electrode towards any redox couple depends upon the value of the exchange current densities and concentration. For this purpose the exchange current densities of Br_2/Br^-, Mn(III)/Mn(II), Ce(IV)/Ce(III), and Ferrin/Ferroin have been determined for each working electrode (platinum, graphite, and glassy carbon) in 1 M sulphuric acid and 0.015 M of the oxidized as well as the reduced species (using BAS 100, USA). The values of the exchange current density are given in Table 5. Thus the

Fig. 9. The potential response of the working electrode immersed in 0.05 M potassium bromate with (*a*) platinum, (*b*) graphite, and (*c*) glassy carbon electrodes. The concentrations of the various species included are (1) $[H^+]$ = 0.1 M; (2) $[H^+]$ = 0.1 M and Ce(III) = 0.002 M; (3) $[H^+]$ = 0.1 M and Mn(II) = 0.01 M; and (4) $[H^+]$ = 0.1 M and [ferroin] = 0.001 M.

better response of the glassy carbon electrode towards the Br_2/Br^- redox couple with its high value of exchange current density (2×10^{-4} A/cm^2) and the poor response of the graphite electrode with its low value of exchange current density (5×10^{-6} A/cm^2) are reflected in the oscillatory profiles obtained with these electrodes.

The response of the electrodes to the different individual redox systems was determined by the following procedure. In one set of experiments the platinum electrode was dipped in a solution of potassium bromate (0.05 M). The variation of the potential of each working electrode (vs. SCE) was recorded after including different species of known concentration in the experimental solution. In another set of experiments the solution initially contained sulphuric acid (0.1 M) and the variation in potential was followed by including different redox couples. The potential profiles are presented in Figs. 8 and 9.

The following general conclusions can be drawn from these experimental results. The response of the platinum electrode is good towards Br_2/Br^-, Mn(III)/Mn(II), and Ce(IV)/Ce(III). However, the final potential value reached with Br_2/Br^- is of lower magnitude. The response of the glassy carbon electrode is also good. Further, the response of the glassy carbon electrode extends over a larger range of potential than that of platinum. On the contrary, the response of the graphite electrode towards $[Br_2]/[Br^-]$ is poor and it shows a better response towards metal ion redox couples, especially Ce(IV)/Ce(III).

Conclusion

The oscillatory profiles recorded simultaneously with different electrodes differ in their oscillatory characteristics especially with respect to amplitude and potential range. Such a

difference is caused by the fact that the electrodes respond differently to Br_2/Br^- and metal ion redox couples. The difference in response is obvious from the potential developed at each electrode in the presence of the individual redox couples. The potential response of the electrode depends upon the relative magnitude of the exchange current density of the redox system.

Solvent structure effects on electrical conductivities of small-ion salts compared to large-ion salts in C_1–C_4 alcohols and water

Abstract: The electrical conductances of the small-ion salts LiI and $LiNO_3$ in water and C_1–C_4 alcohols were measured at different temperatures. At the concentrations used, ion association was negligible except when $\varepsilon T < 4200$ K, where ε is the relative permittivity of the solvent at temperature T. Consistent with Walden's rule, the values of $\eta\Lambda_0$ in each solvent are nearly constant as the temperature is increased; the value for LiI in each solvent is slightly higher than that for $LiNO_3$. Ion association occurs in *tert*-butanol and is more extensive for $LiNO_3$ than that for LiI; the planar NO_3^- ions fit less well than the spherical I^- ions into the packing of the rigid, spherical *tert*-butanol molecules. The effective radius of solvated ions in C_N primary alcohols increases approximately as the length of the randomly folded chain, $(N+1)^{1/2}$. For secondary alcohols this factor is somewhat too small for small-ions and too large for large tetraphenyl ions. The values of $E_{\Lambda 0}$ are close to the values of E_η in the corresponding alcohols.

Key words: electrical conductivity, large ions, small-ions, alcohols, solvent effects.

Résumé : Opérant à diverses températures, on a mesuré les conductivités électriques des sels de LiI et $LiNO_3$, à petits ions, dans l'eau ainsi que dans des alcools contenant de un à quatre carbones. Aux concentrations utilisées, l'association ionique est négligeable, excepté lorsque $\varepsilon T < 4200$ K, dans laquelle ε est la permittivité relative du solvant à la température T. En accord avec la règle de Walden, les valeurs de $\eta\Lambda_0$ dans chaque solvant sont pratiquement constantes lorsqu'on augmente la température; la valeur pour LiI dans chacun des solvants est légèrement supérieure à celle pour $LiNO_3$. Il se produit une association d'ions dans le *tert*-butanol qui est plus importante pour le $LiNO_3$ que pour le LiI; dans l'arrangement rigide des molécules de *tert*-butanol sphériques, les ions NO_3^- plans s'insèrent moins bien que les ions I^- sphériques. Les rayons effectifs des ions dans les alcools primaires en C_N augmentent, en première approximation, en fonction de la longueur de la chaîne repliée au hasard, $(N+1)^{1/2}$. Dans le cas des alcools secondaires, ce facteur est légèrement trop petit pour les petits ions et légèrement trop grand pour les gros ions du type tétraphényle. Dans les alcools correspondants, les valeurs de $E_{\Lambda 0}$ se rapprochent des valeurs de E_η.

Mots clés : conductivité électrique, ions volumineux, petits ions, alcools, effets de solvant.

[Traduit par la rédaction]

Introduction

The study of electrical conductivities of electrolytes in different solvents elucidates properties of ions and solvents (1, 2), and provides reference data for solvent effects on the mobilities of solvated electrons (3–6). For the molar conductivity Λ_0 of $LiNO_3$ in C_1–C_8 primary alcohols (4), and of the large-ion salts tetraphenylphosphonium chloride (TPPC), tetraphenylphosphonium bromide (TPPB), and sodium tetraphenylboride (STPB), in C_1–C_4 alcohols (7), it has been found that the value of $(N+1)^{1/2}\eta\Lambda_0$ is nearly constant, with about 15% decrease toward large N, where N is the number of carbon atoms in the alcohol and η is the solvent viscosity. For the separate ionic molar conductivities of the large ions (TPP^+ and TPB^-) in C_1–C_4 primary alcohols, $(N+1)^{1/2}\eta\Lambda_0$ = constant (7). The activation energies of shear viscosities of the butanols (8–10) increase from 1-butanol (19 kJ mol^{-1}) to *tert*-butanol (31 kJ mol^{-1}), whereas the activation energies of mobility of the large tetraphenyl ion salts through the butanols (mostly 20–23 kJ mol^{-1}) are relatively insensitive to the structure and packing of the molecules in the liquid butanols (7).

The value of $(N+1)^{1/2}$ represents the randomly folded chain length of an alcohol molecule, which increases the effective radius of an ion to which it adheres. Lithium nitrate contains small-ions whose sizes are smaller than those of C_1–C_4 alcohol molecules. It is expected that the solvent structure effect on the solvation and mobility of smaller-than-solvent ions will be greater than that on larger-than-solvent tetraphenyl ion salts such as TPPC, TPPB, and STPB. Therefore, it is interesting to compare the solvent structure effect on the electrical conductivities of small-ion salts with those of the large-ion salts in C_1–C_4 alcohols.

In the present work, the electrical conductance of lithium iodide was measured in water and C_1–C_4 alcohols at different temperatures. The electrical conductance of lithium nitrate was also remeasured in C_1–C_4 alcohols at lower salt concentrations than previously used, to minimize the ion atmosphere effect and ion association (2, 11, 12). Iodide ion has a spherical shape, and nitrate ion has a planar shape. Solvent -O-H hydrogen-bonding to the spherical I^- would not have a favored orientation, but the -O-Hs would tend to be directed toward the oxygen atoms at the corners of the triangular NO_3^-, which might strain the packing of the solvent molecules. Therefore, smaller amounts of ion pairing or clustering might be expected for iodide than for nitrate ions in alcohols, because the planar nitrate ions more easily form ion clusters or ion-pair aggregates (2).

Although there have been many studies of the conductivities of alkali halides (13) and hydrogen halides (14) in nonaqueous solvents, there are few conductivity data for LiI in C_1–C_4 alcohols except in methanol and ethanol (15).

Experimental

Lithium iodide (Aldrich, anhydrous, 99%) and lithium nitrate (Aldrich, 99.99%) were used as received. The iodide was kept under argon atmosphere in the dark to avoid oxidation of I^-.

The purification of the alcohols and the experimental techniques were described previously (7).

Results and discussion

Specific conductances of LiI and $LiNO_3$

Both salts dissolve easily in water. In alcohols, on going from methanol to butanols, both LiI and $LiNO_3$ are progressively slower to dissolve. In *tert*-butanol, LiI dissolved overnight with stirring, whereas $LiNO_3$ dissolved in about 2 h. The electrical conductances of each salt were measured at least twice in each solvent at different temperatures. The reproducibility of all the measurements at 298 K was better than ±1%.

To avoid or minimize curvature of plots of specific conductance against solute concentration, caused by the ion atmosphere effect (11) or ion association (12), low concentrations were used in the measurements. For LiI, the concentration range 0.025–0.125 mol m^{-3} was used in most measurements, except for those in water and 2-butanol, 0.1–0.5 mol m^{-3}; isobutanol, 0.0125–0.0625 mol m^{-3}. For $LiNO_3$, the concentration range used in the remeasurements in C_1–C_4 alcohols was 0.01–0.05 mol m^{-3}. For the few curved lines obtained with LiI and $LiNO_3$ in some alcohols, the measurement was repeated by using freshly prepared solutions at each temperature.

Figures 1 and 2 show the plots of the measured specific conductance (κ) against the salt concentration (C) of LiI in C_1–C_4 alcohols. On going from methanol to 1-butanol, the lines are straight; in isobutanol, the κ–C plot was slightly curved only at the highest temperature, 343 K, and in 2-butanol the line at 343 is more curved (Fig. 2). In *tert*-butanol, the lines at 318 and 328 K (Fig. 2) were so bent that the conductance values at higher concentrations actually overlapped or were lower than those at lower temperatures (299 K and 308 K).

Figure 3 shows the plots for $LiNO_3$ in propanols and iso and 2-butanols. The lines for $LiNO_3$ in 1-propanol, 2-propanol, and isobutanol are straight, except at the highest temperature (343 K) in 2-propanol and isobutanol; in 2-butanol the line is already curved at 308 K.

The ionic atmosphere effect and ion association vary inversely as the product of the relative permittivity and temperature (εT) (2, 11, 16). The value of εT at a given temperature decreases on going from methanol to butanols (Fig. 4). In methanol, ethanol, and 1-propanol εT is relatively high and the ionic atmosphere effect and ion association are negligible. However, in 2-propanol and butanols, the values of εT are lower, and the effects become significant.

In Fig. 4 the log scale is used to show the relative changes of εT with temperature in C_1–C_4 alcohols. As temperature is increased the values of εT decrease. Plots of κ against C start to bend at values of $\varepsilon T < 4200$ K, because the Coulombic attraction of the ions increases faster than the thermal agitation energy. The values of εT in *tert*-butanol are lower than those in the other alcohols, and decrease relatively rapidly with increasing temperature. Therefore, as temperature increases there is a larger increase of ion association in *tert*-butanol than in other alcohols (Fig. 2).

Another reason that ion association is more extensive in *tert*-butanol is that *tert*-butanol has rigid, globular molecules, and has the poorest ability to solvate small-ions, as we know from the optical spectra of solvated electrons in alcohols (17, 18); the energy of optical absorption of solvated electrons in *tert*-butanol is the lowest among the C_1–C_4 alcohols.

Comparing LiI and $LiNO_3$ in *tert*-butanol, the κ–C plot for LiI (Fig. 2) starts to bend at 318 K, whereas the κ–C plot for $LiNO_3$ (2) starts to bend at 299 K. This indicates that in *tert*-butanol, ion clustering of LiI is not as severe as that of $LiNO_3$. The planar NO_3^- ions fit less well than the spherical I^- ions into the packing of the rigid, spherical *tert*-butanol molecules, and more easily form ion clusters in that liquid (2).

Molar conductivities of LiI and $LiNO_3$

Table 1 lists the low concentration limits of the molar conductivities (Λ_0) of LiI and $LiNO_3$ in C_1–C_4 alcohols and water at different temperatures, along with the solvent viscosities and the relative permittivities. The measured values of molar conductivity limits of LiI and $LiNO_3$ in water, methanol, and ethanol at 298 K are close to those reported earlier (15). Λ_0 values of both LiI and $LiNO_3$ at 298 K decrease on going from water to butanols, and the values for LiI are slightly higher than those for $LiNO_3$.

The molar conductivity Λ(LiI) in *tert*-butanol at 298 K is only $0.23\Lambda_0$(LiI) in isobutanol, whereas the viscosity of *tert*-butanol is only 1.3η (isobutanol), so $\eta\Lambda$ in *tert*-butanol is $0.30\eta\Lambda_0$ in isobutanol (Table 1). Thus the value of Λ(LiI) in *tert*-butanol is not Λ_o(LiI) despite the linear κ–C plots at 299 and 308 K (Fig. 2). The values of εT in *tert*-butanol are below 4200 K (Fig. 4), so complex multiple-ion association causes the low Λ values (2).

The values of Λ(LiI) in 2- and isobutanol, and $\Lambda(LiNO_3)$ in 2-propanol and in 2- and isobutanol at the highest temperatures, were obtained from the initial slopes of the curved lines in the κ–C plots (Figs. 2 and 3); εT is <4200 K at these temperatures, so the ionic atmosphere effect and ion association are significant and these Λ values may not be the low concentration limits of molar conductivity Λ_0 (Table 1).

In water and C_1–C_4 alcohols, except *tert*-butanol, the values of $\eta\Lambda$ for LiI or $LiNO_3$ in each solvent are nearly constant as

the temperature is increased. This is consistent with Walden's rule (11). The value of ηΛ for LiI in *tert*-butanol decreases with increasing temperature due to increasing ion association. In isobutanol, ηΛ of $LiNO_3$ at 328 K is lower than the average ηΛ at other temperatures (Table 1). This indicates that the value of 20.4×10^{-4} S m^2 mol^{-1} is not $\Lambda_0(LiNO_3)$ in isobutanol at 328 K, despite the linear κ–C plot (Fig. 3).

Solvent structure effects on molar conductivities of different salts

In our previous studies of the molar conductivities of $LiNO_3$ in C_1–C_8 *n*-alcohols (4) and of large-ion salts in C_1–C_4 alcohols (7), the values $(N + 1)^{1/2}\eta\Lambda_0$ were approximately constant, where *N* is the number of carbon atoms in an alcohol molecule and $(N + 1)^{1/2}$ represents the randomly folded chain length of the alcohol. Figure 5 displays the correlations of $(N + 1)^{1/2}\eta\Lambda_0$, and $(N + 1)^{1/2}\eta\Lambda$ in *tert*-butanol, against $1/\eta$ at 298 K for the small-ion salts LiI and $LiNO_3$ (*A*), compared with those for the large-ion salts tetraphenylphosphonium bromide (TPPB) and sodium tetraphenylboride (STPB) (*B*), in C_1–C_4 alcohols. Diffusion behavior of a salt in a solvent depends on (*i*) the solvent molecular structure (4, 7), and (*ii*) the molecular shape and size of each ion (2, 7). These two factors are reflected in Figs. 5 *A* and *B*.

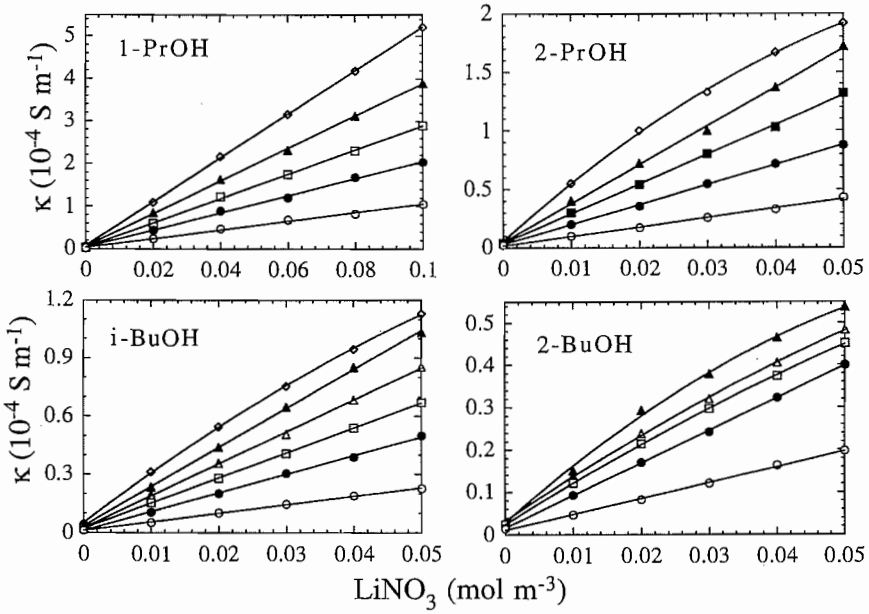
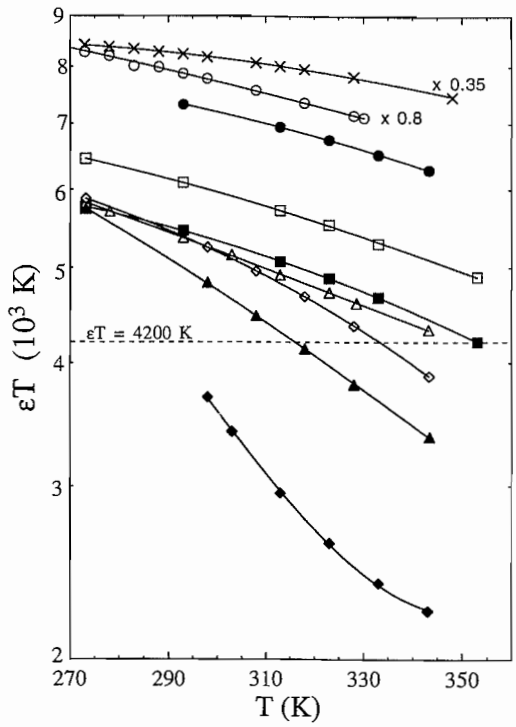
Fig. 3. Measured specific conductances κ of $LiNO_3$ against concentrations C at different temperatures in 1-, and 2-propanol, iso- and 2-butanol, respectively. The symbols are the same as in Fig. 1.





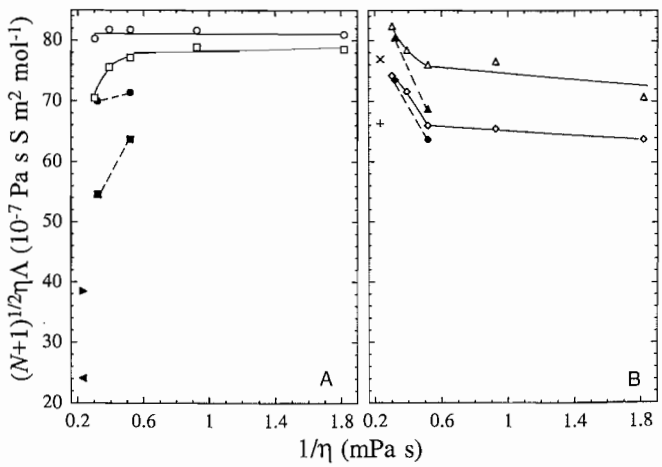


Fig. 4. The change of the product of the relative permittivity and the temperature, εT, with temperature in C_1–C_4 alcohols and water. ×, water; ○, methanol; ●, ethanol; □, 1-propanol; ■, 2-propanol; △, 1-butanol; ◇, isobutanol; ▲, 2-butanol; ◆, *tert*-butanol.

Firstly, for each salt the values of $(N + 1)^{1/2}\eta\Lambda$ in C_1–C_4 alcohols depend on the type of alcohol: primary, secondary, or tertiary. In primary *n*-alcohols, the value of $(N + 1)^{1/2}\eta\Lambda_0$ for LiI is constant at 81 ± 1 (10^{-7} Pa s S m^2 mol^{-1}) and in

Fig. 5. Correlations of $(N + 1)^{1/2}\eta\Lambda$ of salts with fluidity ($1/\eta$) of C_1–C_4 alcohols at 298 K. *A*: *Small-ion salts* LiI: ○, in 1-alcohols, ●, in 2-alcohols, and ◀, in *tert*-butanol; $LiNO_3$ □, in 1-alcohols, ■, in 2-alcohols, and ▶, in *tert*-butanol. *B*: *Large-ion salts* TPPB △, in 1-alcohols, ▲, in 2-alcohols, and ×, in *tert*-butanol; STPB ◇, in 1-alcohols, ◆, in 2-alcohols, and +, in *tert*-butanol. Decreasing $1/\eta$: primary alcohols (solid lines) methanol, ethanol, 1-propanol, 1-butanol, isobutanol; secondary alcohols (broken lines) 2-propanol, 2-butanol.

isobutanol the value is 80, and for $LiNO_3$ in *n*-C_1–C_4 alcohols the value is also constant at 78 ± 1 (Fig. 5*A*).

In the secondary alcohols, for LiI the average value of $(N + 1)^{1/2}\eta\Lambda_0$ in the two secondary alcohols is 12% lower than that in primary alcohols, because the secondary alcohol contains a nonrandom permanent fold and the factor $(N + 1)^{1/2}$ underestimates the effective chain length of the molecules ligated to the ion. The value difference between secondary and primary alcohols for $LiNO_3$ is even larger than that for LiI.

Furthermore, the decrease on going from 2-propanol to 2-butanol is greater for the nitrate than for the iodide (Fig. 5). Thus the normalization factor $(N + 1)^{1/2}$ is too small for secondary alcohols.

The value of $(N + 1)^{1/2}\eta\Lambda$ for LiI in *tert*-butanol is only 35% of that in 2-butanol, probably due to multiple-ion association in *tert*-butanol, despite the fact that the κ–C plots were straight at 299 and 308 K (Fig. 2). The value of $(N + 1)^{1/2}\eta\Lambda$ for $LiNO_3$ in *tert*-butanol is very low due to the low value of Λ caused by ion clustering (2). In *tert*-butanol the three methyl groups on the α-carbon atom increase the steric hindrance for the alcohol molecules to pack around an ion, and decrease the solvation energy of the ions, thereby leaving it easier for them to agglomerate in clusters.

Secondly, on going from NO_3^-, I^- to large tetraphenyl ions, NO_3^- has a planar shape, the I^- ion is spherical, and the large tetraphenyl ions have low surface charge densities. Thus the solvation of an ion is progressively less sensitive to the solvent molecular structure change on going from NO_3^-, I^- to large tetraphenyl ions.

For the large-ion salts TPPB and STPB, both in primary and secondary alcohols, the value of $(N + 1)^{1/2}\eta\Lambda_0$ increases with increase of chain length of the alcohol molecule (Fig. 5*B*). This indicates that the normalization factor $(N + 1)^{1/2}$ is too high, especially for 1-, 2-, and isobutanols. A tetraphenyl ion is much larger than a molecule of C_1–C_4 alcohols, so the mobility of a large ion is less sensitive to the solvent molecule chain length and structure change.

In *tert*-butanol the value of $(N + 1)^{1/2}\eta\Lambda_0$ for a large-ion salt is about the same as in 1-propanol (Fig. 5*B*). The value is much higher than that for LiI or $LiNO_3$ in *tert*-butanol. This indicates that ion association of the large-ion salt is negligible; the charge density on the surface of a large-ion is low and the electrical attraction between the ions is weak.

Activation energies $E_{\Lambda 0}$ and E_η

Values of the activation energies $E_{\Lambda 0}$ for the small-ion salts LiI (Fig. 6) and $LiNO_3$ (Fig. 7), and for the large-ion salts TPPB and STPB (7), are listed in Table 2, along with the activation energies of shear viscosity (E_η) for comparison. Ion conductance and shear viscosity are both driven by external forces, electrical and gravitational or applied pressure, respectively. Activation energies of diffusion of the ions, driven by thermal energy, are larger than $E_{\Lambda 0}$ by $RT \approx 2$–3 kJ mol^{-1}.

In the calculation of $E_{\Lambda 0}$ of LiI and $LiNO_3$ in 2- and isobutanol, the values of Λ at the highest measured temperatures (labelled * in Figs. 6 and 7) are not taken into account, since the values of Λ are estimates of the initial slopes of the corresponding curved lines in κ–C plots (Figs. 2 and 3) and they may not be the limiting molar conductivities Λ_0.

In *tert*-butanol, values of Λ_0, and hence of $E_{\Lambda 0}$, were not obtained. At temperatures above 318 K for LiI or 308 K for $LiNO_3$ (2), Λ decreases with the increase of temperature, because εT decreases so rapidly that multi-ion clustering or ion-pair aggregation (2) increases more rapidly than does the mobility of Li^+ and NO_3^- ions.

The values of $E_{\Lambda 0}$ (Table 2) for both small-ion salts and large-ion salts are close to the values of E_η in water and the corresponding alcohols, except that in *tert*-butanol. In *tert*-butanol $E_{\Lambda 0}$ of large-ion salts is about 10 kJ mol^{-1} lower than E_η; the latter is unusually high because the rigid, globular *tert*-

butanol molecules cannot efficiently move past each other in the liquid. Space-filling molecular models indicate that the large tetraphenyl ions would break the local structure of liquid *tert*-butanol, which would perhaps lower the activation energies of mobility and diffusion of the ions.

Electrochemical investigation of some potential antibacterials, II

Rajeev Jain, P. Padmaja, and Seema Gupta

Abstract: The electrochemical behaviour of 2-(4′-sulphonamoyl)hydrazonobutyrate-1,3-diones and sulphonamoylazoaminobenzenes has been studied over a wide range of pH at dropping mercury as well as glassy carbon electrodes. Both types of compounds exhibited a $4e^-$ reduction reaction at both electrodes. At pH > 4.5, 2-(4′-sulphonamoyl)hydrazonobutyrate-1,3-diones exhibited a $2e^-$ reduction wave at higher potentials. Both compounds undergo a $2e^-$ oxidation reaction. On the basis of polarography, linear and cyclic voltammetry, controlled potential electrolysis, coulometry, and spectral analysis, a detailed mechanism has been postulated for the reduction as well as the oxidation.

Key words: electrochemistry, sulphonamides, polarography, cyclic voltammetry, coulometry.

Résumé : Opérant sur une très large plage de pH et utilisant une électrode tombante de mercure ainsi qu'une électrode de carbone vitreux, on a étudié le comportement électrochimique de 2-(4′-sulfonamoyl)hydrazonobutyrate-1,3-diones et de sulfonamoylazoaminobenzènes. Les deux types de composés présentent une réaction de réduction à $4e^-$ avec les deux électrodes. À des pH supérieurs à 4,5, les 2-(4′-sulfonamoyl)hydrazonobutyrate-1,3-diones présentent une réduction à $2e^-$ à des potentiels plus élevés. Les deux types de composés subissent une réaction d'oxydation à $2e^-$. Sur la base des résultats obtenus par polarographie, voltammétrie linéaire et cyclique, électrolyse à potentiel contrôlé, coulométrie et analyse spectrale, on propose un mécanisme détaillé tant pour la réduction que pour l'oxydation.

Mots clés : électrochimie, sulfonamides, polarographie, voltammétrie cyclique, coulométrie.

[Traduit par la rédaction]

Sulphonamides were the first effective chemotherapeutic agents to be employed systematically for the prevention and cure of bacterial infections. Sulphonamides are widely used in the treatment of urinary tract infection, burn therapy, conjunctivitis, and chloroquine-resistant malaria and are also drugs of choice for the treatment of nocardiosis, toxoplasmosis, severe travellers diarrhoea, and meningococcal infections (1, 2).

Keeping in view the medicinal importance of sulphonamides (3), some new derivatives of sulphonamides have been synthesized. The redox behaviour (4, 5) of hydrazones has attracted considerable attention due to their importance as precursors (6) of various antineoplastic and antidiabetic compounds. However, no reference has been found dealing with those compounds bearing a -NH-N=N- group. This group of compounds having a -NH-N- as well as a -N=N- grouping in a single molecule deserve an extensive electrochemical study. In view of the importance of redox phenomena in reactions of physiological importance, it is considered worthwhile to study the mechanism and nature of the end products resulting from the reduction/oxidation of compounds of potential medicinal importance.

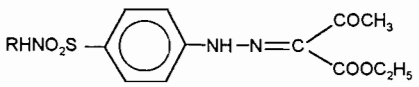
In continuation of our work (7–9) in exploring the redox behaviour of potential antibacterials, we have selected some hydrazono derivatives of sulphonamides, viz., 2-(4′-sulphonamoyl)hydrazonobutyrate-1,3-diones (A) and sulphonamoylazoaminobenzenes (B) for a comprehensive and comparative study taking into consideration such pertinent aspects of redox phenomena as the nature of the waves, characterization of the end products, and mechanism of the electrode process. These studies have been augmented, wherever possible, by results of controlled potential electrolysis, coulometry, and product analysis.

Experimental



Some representatives of both classes of compounds, viz., 2-(4′-sulphonamoyl)hydrazonobutyrate-1,3-diones (A) and sulphonamoylphenyl azoaminobenzenes (B), as represented in Scheme 1, were selected.

Compounds A and derivatives were synthesized by the literature method (10). Compounds B were synthesized and characterized in the following manner. Sulphanilamide (0.01 mol, 1.72 g) was dissolved in a mixture of concentrated hydrochloric acid (5 mL) and water (5 mL) and cooled to 0°C in an ice bath. To this, a cold aqueous solution of sodium nitrite (0.01 mol, 0.69 g) was added. The diazonium salt so obtained was filtered into an already cooled solution mixture of sodium acetate (8.0 g) and sulphanilamide in alcohol. A yellow precipitate of sulphonamoylphenylazoaminobenzene appeared immediately. The precipitate was filtered, washed with water, and recrystallized from light petroleum, mp 91°C, yield 68%. IR ν_{max}^{KBR}: 3370 ($NH\text{-}C_6H_5$), 3220, 3180 (NH_2SO_2), 1520

(-N=N-), 1340 (SO_2) cm^{-1}; ^1H NMR δ ($CDCl_3$): 2.2 (2H, -NH_2), 7.4 (5H, pH), 9.3 (H, NH). Anal. calcd. for $C_{12}H_{13}N_5S_2O_4$: C 40.56%, H 3.66%, N 19.70%; found: C 40.20%, H 3.5%, N 19.40%.

Similarly, other substituted sulphonamoylphenylazoaminobenzenes were synthesized and duly characterized.

Apparatus and technique

Polarographic measurements were carried out on an ELICO DC CL-25 polarograph. Potentiometric studies were carried out on an expanded-scale pH meter with a glass electrode that was previously standardized with buffer of known pH. All potentials reported are with reference to the SCE. Triply distilled mercury was used for the dropping mercury electrode (DME).

Cyclic voltammetric studies were carried out on a BAS CV-27 cyclic voltammograph in connection with a digital electronic 2000 Omnigraph X-Y/t recorder. A three-electrode cell was used for the purpose. The cell consists of a glass cylinder with a cap having holes for introducing electrodes and tubing for nitrogen gas. Oxygen was removed from the solution by passing nitrogen gas through the solution for about 10 min and then a blanket of nitrogen was maintained throughout the experiment. In the present study, glassy carbon (GC) was used as the working electrode, 1.0 M Ag/AgCl as the reference electrode, and platinum wire was used as the auxillary electrode. The working electrode was polished with fine-grade emery paper, followed by polishing with alumina (0.5 μm), then was washed and activated by triangular voltage sweeps from +1.0 V to −1.6 V at a rate of 5–200 mV/s for 15 min. The activity of the electrode was tested (11) using a ferricyanide–ferrocyanide redox couple in 0.01 M KCl.

For the purpose of cyclic voltammetric and polarographic measurements, solutions were prepared by mixing a 2.0 mL solution of the compound, 2.0 mL of DMF (which is necessary to keep the compound in solution), 1.0 mL of 1.0 M KCl, and 5.0 mL of appropriate Britton–Robinson buffers (12). Britton–Robinson buffers in the pH range 2.0–11.8 were prepared by adding suitable amounts of 0.2 M NaOH solution to a stock B.R. buffer solution (pH 1.8). B.R. buffer stock was prepared by mixing boric acid, phosphoric acid, and glacial acetic acid (mixture contains 2.472 g of boric acid, 2.14 mL of phosphoric acid, 2.30 mL of glacial acetic acid made up to 1000 mL).

For the coulometric determination (13) of the number of electrons transferred in the electrode process, 2.0 mL of the solution of the compound containing buffer, solvent, and supporting electrolyte in the same ratio as used for CV studies was electrolyzed at a slightly more negative potential than the peak potential for the respective peaks. From the decrease in current with time, the number of electrons transferred was calculated. The progress of electrolysis was monitored by recording voltammograms at regular intervals of time. The products of electrolysis were identified by comparison of their properties with authentic products using TLC.

Results and discussion

DC polarography

All the 2-(4′-sulphonamoyl)hydrazonobutyrate-1,3-diones (A) reduced in a single, $4e^-$, well-defined wave in the pH range 2.0–12.0. However, an additional $2e^-$ wave was observed at pH > 4.5 (Table 1). The first wave over the entire pH range was found to be the diffusion-controlled, irreversible reduction of hydrazono group. The diffusion-controlled nature of the limiting current was established on the basis of linear plots of i_d vs. concentration and i_d vs. $h^{1/2}$ (where h is the height of the mercury column). Sulphonamoylphenylazoaminobenzenes (B) exhibited one four-electron, diffusion-controlled irreversible reduction wave over the entire pH range 2.0–12.0 (Table 2). In these compounds, no additional wave was observed at pH > 4.5. The number of electrons involved in the polarographic wave was found, by coulometry, to be four. The value of n was also determined by controlled potential electrolysis using the following formula (14).

$$n = \frac{i_0}{2.30\, C_0 F u(\Delta \log i/\Delta t)}$$

where i_0 is the current at $t = 0$ when $C = C_0$, u is the volume of the solution and $\Delta\log i/\Delta t$ is the slope of the plot of log i against log t. This estimate provided support for the value obtained by the millicoulometric method. The controlled potential electrolysis was carried out at a potential corresponding to the plateau of the wave.

The half-wave potentials of both compounds A and B are a linear function of pH. The plot of $E_{1/2}$ vs. pH was linear up to 7.5 for A and to 9.2 for B and thereafter there is little change in $E_{1/2}$ with pH (Fig. 1). This suggests that protons are involved in the reduction process. However, in alkaline solution, the half-wave potential did not change with pH. Irreversibility of

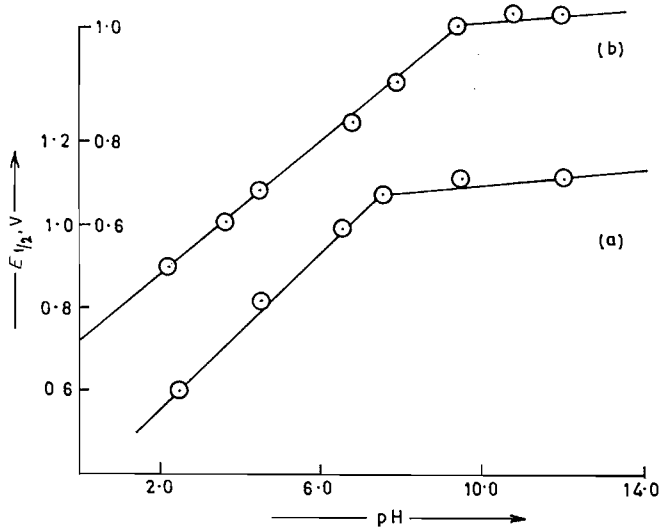
4.		107	0.81	±0.016	2.41	±0.012

the electrode process was confirmed by plotting $E_{d.e.}$ against $(i/i_d - i)$. It was found that the value of slope exceeded $59.2/n$ mV. The values of αn_a (product of transfer coefficient and number of electrons transferred in the rate-determining step) and p (number of protons involved in rate-determining step) were determined by using the following expressions (15, 16). The values of αn_a determined by logarithmic analysis of the polarographic wave are comparable with those values determined from the expressions given below. The value of p obtained from the expressions was nearly equal to 1.0.

$$E_{3/4} - E_{1/4} = \frac{0.0517}{\alpha n_a}$$

$$\frac{dE_{1/2}}{dpH} = \frac{0.0591}{\alpha n_a} p$$



Linear sweep and cyclic voltammetry

Cyclic voltammograms of 2-(4-sulphonamoyl)hydrazonobutyrate-1,3-diones (A) and sulphonamoylazoaminobenzenes (B) were recorded at different scan rates and concentrations using the glassy carbon electrode. Typical cyclic voltammograms are incorporated in Fig. 2. The cyclic voltammogram of compound A exhibited one well-defined cathodic peak in the pH range 2.5–12.0 (Table 1). One more peak, II_c, at higher negative potentials was observed at pH > 4.5. In sulphonamoylazoaminobenzene (B) two well-defined two-electron

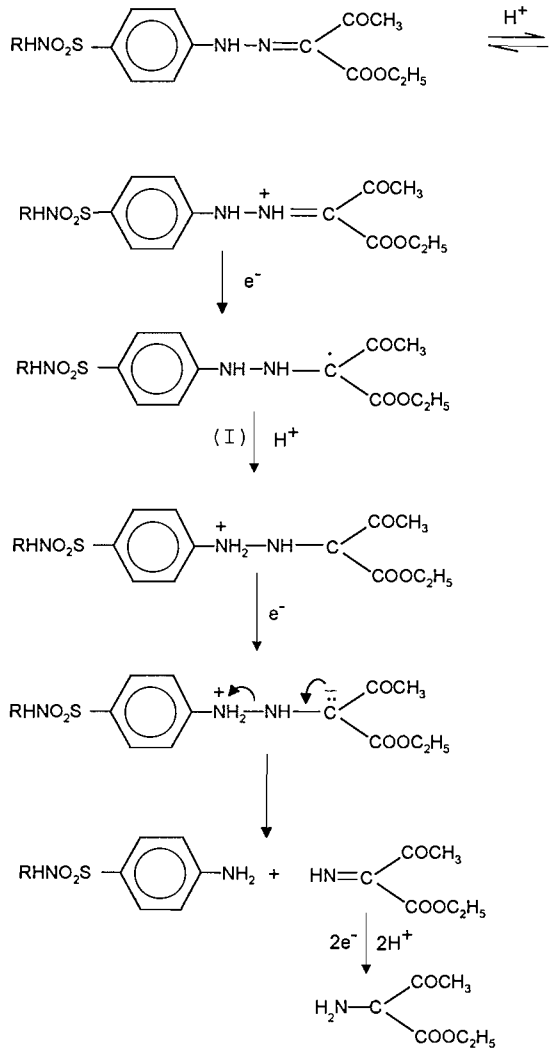
Fig. 1. Plot of $-E_{1/2}$ vs. pH for (*a*) 2-(4′-sulphonamoyl)-hydrazonobutyrate-1,3-diones; (*b*) sulphonamoylphenyl-azoaminobenzene.



reduction peaks were observed over the entire pH range (Table 3). The peak currents were measured from the direct reading shown on the digital display of the potentiostat. A cyclic voltammogram of the solvent and the supporting electrolyte was recorded after flushing with nitrogen gas for about 10 min. The current of the blank was considered as the base line (c) as indicated in Fig. 2. The peak currents (i_p) of the compound A were comparable to those of the compound B. The linear plots of peak current i_p vs. the square root of the scan rate (Fig. 3) and i_p vs. concentration of the depolarizer show a slight deviation from the origin, indicating adsorption (17) of the depolarizer in both waves, in acidic as well as in alkaline media. The peak potential was found to shift cathodically with scan rate. The peak potentials also shifted to negative values with the concentration of the compound.

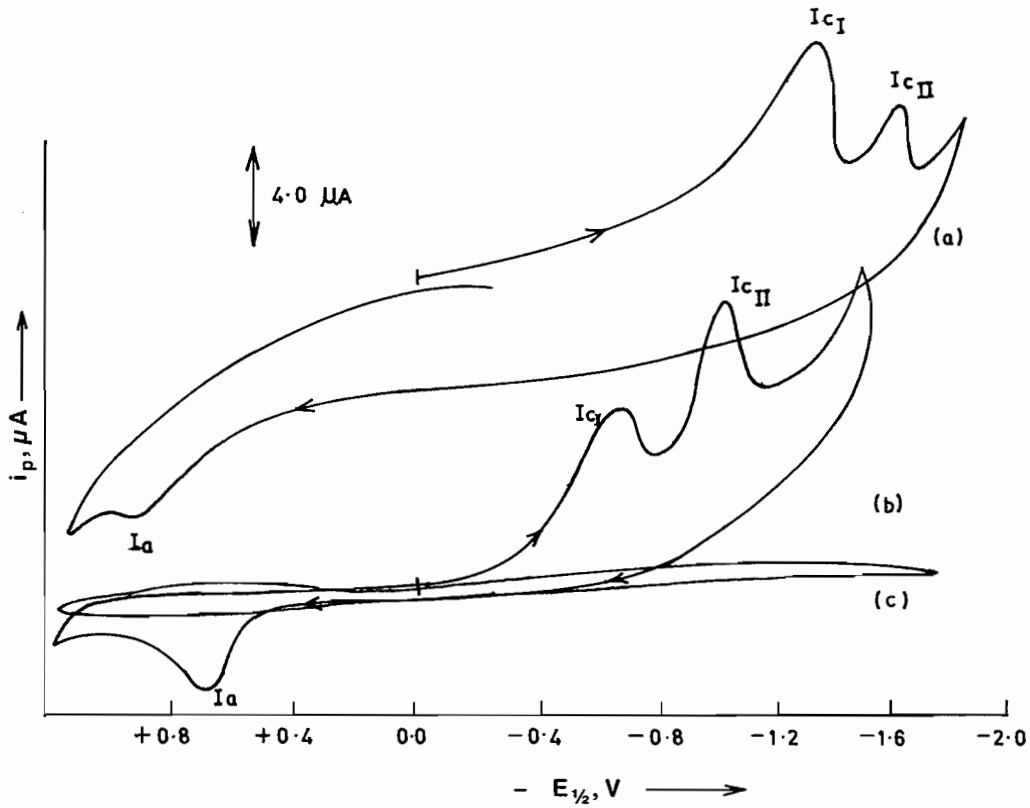
The peak potential was dependent on pH and shifted towards more negative potentials with an increase in pH up to 7.5 for compound A and 9.2 for compound B. On reversing the scan, only a small peak was observed at very high positive potentials, indicating that the processes corresponding to both peaks are irreversible. However, this small hump (I_a) in Fig. 2 at positive potentials indicates that these hydrazones and azoaminobenzenes also undergo oxidation at the glassy carbon electrode. To ascertain whether the peak is due to oxidation of hydrazones, voltammograms were initiated in the positive direction. It was found that the oxidation peak appeared at the same potential. Thus it can be safely concluded that the oxidation peak is due to the independent oxidation of hydrazones and azoaminobenzenes. No corresponding peak was observed in the reverse scan, indicating that the oxidation process in both cases is irreversible. The number of electrons involved in the oxidation process was calculated from coulometric measurements and found to be 2.0.

Coulometry and controlled potential electrolysis

At pH 2.5–4.0 at −1.0 V, 2-(4′-sulphonamoyl)hydrazonobutyrate-1,3-diones (A) undergo a four-electron reduction reac-

Scheme 2.

tion. The TLC of the electrolyzed solution on a silica-gel G-plate resulted in two spots. One of the separated compounds exhibited bands corresponding to primary amino stretching bands at 3210 cm^{-1}, C—H linkage at 2650 cm^{-1}, and a peak for the C=O group at 1695 cm^{-1}. The other compound was identified as sulphanilamide by comparison with standard sulphanilamide. It was also verified using different solvent mixtures.



Controlled potential electrolysis at pH 6.2 and 10.5 at −1.5 V and subsequent product analysis confirms the presence of sulphanilamide, ethyl acetoacetate, and ammonia. The presence of ethyl acetoacetate was proved by comparing with authentic ethyl acetoacetate using GLC, and ammonia was detected by Nessler's reagent. The number of electrons involved in the entire overall process was found to be 6.0 + 0.25. A detailed mechanism is given in Scheme 2 in the pH range 2.0–12.0 and at pH > 4.0 in Scheme 3, while azoaminobenzenes over the entire pH range studied consumed four electrons. Each peak required a two-electron process. Controlled potential electrolysis resulted in two products, as separated by TLC on silica gel G plates of 0.25 cm thickness

(chloroform and carbon tetrachloride in the ratio 1:1), $R_f = 0.8$ and 0.2. One of the spots is matched with an authentic sample of sulphanilamide (Anal. calcd. for $C_6H_8N_2SO_2$: C 41.86, H 4.65, N 16.27%; found: C 42.52, H 4.92, N 16.5%. IR ν_{max}^{KBr}: 1260 (C-N), 1340 (SO_2); 3180, 3210 (NH_2SO_2) cm^{-1}). The IR spectra could be superimposed on the IR spectra of an authentic sample, confirming that one of the products formed after electrolysis is sulphanilamide. The other product is identified as sulphonamoylphenylhydrazine by comparison of its R_f values with those of related compounds. Keeping these facts in view, the reduction may be proposed to be as given in Scheme 4 for compounds B.

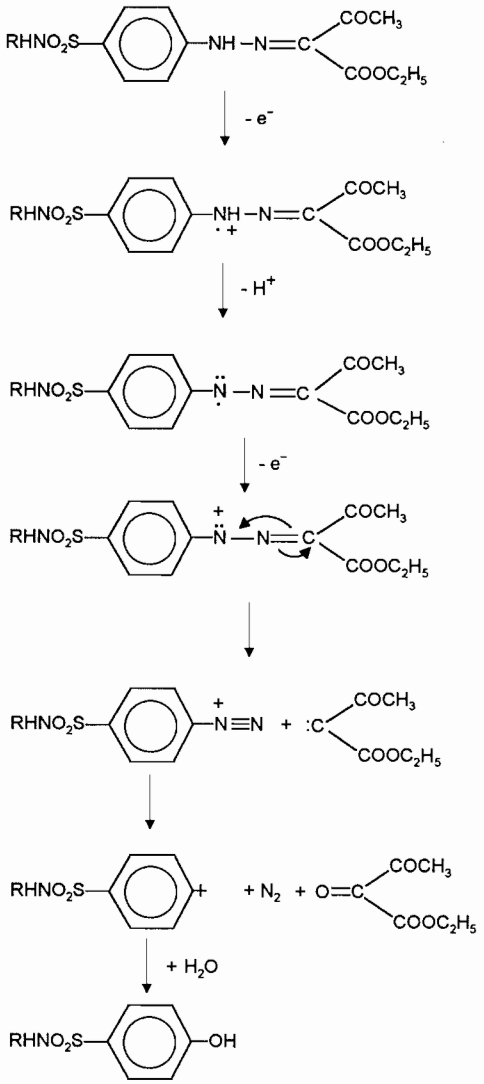
Scheme 4.

The above mechanism is supported by the shift of $E_{1/2}$ towards more negative values with pH as protons are consumed in the reduction. As the equilibrium shifts towards the unprotonated forms, $E_{1/2}$ becomes constant. In this mechanism (Schemes 2 and 4), the radical (I) could also combine with an electron instead of a proton, but this possibility is ruled out because such a mechanism involves only two electrons, whereas coulometric data clearly indicate a four-electron reduction process.

However, in compounds A, further reduction of the product formed at the four-electron stage takes place in a second 2e reduction wave at pH > 4.5. The peak/wave has been assigned to the reduction of the activated C—N bond, as shown in Scheme 3. Other workers have also reported a similar mechanism for the activated C—N bond (18, 19). Coulometric data for compounds A and B at the oxidation peak potential resulted in two electrons for each compound. Controlled potential electrolysis of these compounds resulted in two spots, indicating the formation of the different compounds.

Controlled potential electrolysis (CPE) of hydrazono compounds A was carried out to determine the number of products. For CPE, hydrazone was electrochemically oxidized at the GC electrode using 1.0 M tetraethylammonium bromide at 1.2 V. A cyclic voltammogram was recorded using the solvent and supporting electrolyte without depolarizer to determine whether or not oxidation is due to depolarizer. No peak was observed in the range of the hydrazone group. This observation ruled out the possibility of oxidation of any other component than the hydrazono group.



UV–visible spectra of the solution were recorded at different time intervals during electrolysis. λ_{max} at 390 nm due to the -NH-N=C- grouping showed a systematic decrease in the absorption maxima after each time interval and finally disappeared. Disappearance of the peak indicated cleavage of the NH-N=C- group during oxidation. After complete CPE, the analyte was subjected to product analysis. The electrolyzed solution, on separation by TLC using hexane + methanol (70:30 V/V), gave two products. One of the products was identified by TLC as *p*-hydroxy benzenesulphonamide by comparison with an authentic sample. The second product was characterized by spectral analysis, i.e., IR ν_{max}^{KBr} : 1720 cm^{-1}, characteristic of the >C=O group, and ^{1}H NMR δ ($CDCl_3$): 1.39 (t, 3H, -CH_3), 4.24 (q, 2H, -CH_2), clearly indicating that the second product is an α,β-diketoester. The α,β-diketoester was obtained in fairly good yield (20–45%).

The product was confirmed by its reaction with 2,4-dinitrophenylhydrazine. When the product of the electrooxidation was treated with an excess of 2,4-dinitrophenylhydrazine, it readily formed hydrazone, which was isolated and identified by elemental and spectral analysis. Keeping these products in view, a probable mechanism may be proposed, as depicted in Scheme 5. This mechanism is also supported by the work of others (20, 21), whereas in sulphonamoylazoaminobenzene (B), controlled potential electrolysis of the compound resulted in two spots on separation by TLC on alumina using benzene + chloroform (60:40 V/V). The products were identified by comparing with authentic compounds. The probable mechanism for the oxidation of this compound is given in Scheme 6. The products are expected to result from the cleavage of the diazonium cation and by the rearrangement of nitrene formed during the oxidation. The radical cation obtained after

Scheme 5.

Scheme 6.

abstraction of an electron undergoes two main reactions, viz., loss of a proton from the α-position to the azo group and cleavage of the arylazo group, forming a diazonium cation. The diazonium cation disproportionates into nitrogen and an aryl cation, which loses a proton when a water molecule is added. This compound is matched with an authentic sample. The nitrene formed undergoes tautomerism. This type of mechanism has been proposed by Fasani et al. (22) for the oxidation of azo benzenes.

Finally, it was observed that both reduction and oxidation proceed through the same pathways, although the products are different. In the case of hydrazones at higher pH, i.e., pH > 4.5, the product obtained at the $4e^-$ stage undergoes further reduction due to the activated C—N bond. Lack of electron-withdrawing groups in azoaminobenzene may be the reason why further reduction of hydrazine is hindered, whereas oxidation of hydrazones, as well as azominobenzenes, follows the same path. In hydrazones, carbene formed is flanked by electron-withdrawing groups and hence readily adds a water molecule and is converted into a ketone, while in azoaminobenzene the nitrene obtained readily undergoes tautomerism.

Étude expérimentale et modélisation des réactions d'oxydation du *n*-pentane et du cyclopentane

V. Simon, Y. Simon, G. Scacchi et F. Baronnet

Résumé : La réduction des émissions et la reformulation des carburants nécessitent une meilleure compréhension du mécanisme de combustion, en particulier afin de déterminer les processus importants responsables du phénomène de cliquetis dans les moteurs à allumage commandé. Nous avons donc étudié les mécanismes d'oxydation de deux hydrocarbures d'indices d'octane différents : le *n*-pentane (62) et le cyclopentane (100). Cette étude fait suite aux travaux déjà effectués sur l'oxydation du *n*-heptane et de l'isooctane. L'étude expérimentale a été effectuée, à 873 K, en utilisant un réacteur continu autoagité par jets gazeux. Les mécanismes réactionnels du *n*-pentane et du cyclopentane ont alors été analysés en utilisant des considérations purement cinétiques, basées sur les résultats expérimentaux, puis modélisés grâce à un logiciel de simulation de mécanismes réactionnels. La différence de comportement entre ces deux hydrocarbures, vis à vis des phénomènes d'autoinflammation, a été essentiellement attribuée à la concentration relative, dans le milieu réactionnel, de radicaux stabilisés par résonance.

Mots clés : réaction d'oxydation, *n*-pentane, cyclopentane, modélisation, autoinflammation.

Abstract: The reduction of automotive emissions and the reformulation of gasoline composition require a better understanding of the combustion mechanism, in particular aiming at the determination of the influential reactions which are responsible for the onset of knock in spark ignition engines. We have studied the oxidation mechanism of two hydrocarbons of different research octane number: *n*-pentane (62) and cyclopentane (100). This work follows a previous study on the oxidation of *n*-heptane and isooctane. The experimental study was performed at 873 K in a jet-stirred flow reaction vessel. The reaction mechanisms of *n*-pentane and cyclopentane were analysed on a purely kinetic basis, derived from our experimental results, and were finally modelled by using a programme of simulation of reaction mechanisms. The different behaviour of these two hydrocarbons with respect to autoignition phenomena is mainly dependent on the relative concentration of resonance-stabilized radicals in the reaction medium.

Key words: oxidation reaction, *n*-pentane, cyclopentane, modelling, autoignition.

Introduction

L'existence des phénomènes d'autoinflammation dans les moteurs à allumage commandé est connue depuis plus de 50 ans; à cet égard les travaux de P. Dumanois (1) sont particulièrement intéressants et peuvent être considérés comme les précurseurs des travaux et interprétations modernes. Plusieurs expériences, réalisées dans les années trente, ont en effet mis en évidence l'augmentation brutale de pression accompagnant ces phénomènes de cliquetis. Cependant, la découverte de substances antidétonantes, en particulier le plomb tétraéthyle, a résolu ce problème de façon empirique pendant de longues années.

Reçu le 13 novembre 1996.

Pourtant, l'étude du mécanisme de la réaction d'oxydation des hydrocarbures (alcanes en premier lieu) a pris ces dernières années une importance croissante dans le but de déterminer les processus importants responsables du phénomène de cliquetis dans les moteurs à allumage commandé (2) et d'établir des corrélations entre structure des hydrocarbures et indice d'octane (3, 4). En effet, le développement de l'essence sans plomb implique l'utilisation de nouvelles substances à indice d'octane élevé (substances oxygénées par exemple) et la recherche de ces nouveaux composés nécessite une meilleure compréhension du mécanisme de combustion.

C'est pourquoi nous avons étudié les mécanismes d'oxydation d'hydrocarbures d'indice d'octane différent : le *n*-heptane et de l'isooctane (5) puis le *n*-pentane (indice recherche : 62) et le cyclopentane (indice recherche : 100). Cette étude, qui se poursuit actuellement sur l'oxydation de l'isopentane et du néopentane, couplée aux résultats précédents doit permettre l'approfondissement de l'effet de deux paramètres : (*i*) la longueur de la chaîne carbonée et (*ii*) la ramification de celle-ci.

La détermination des mécanismes d'oxydation du *n*-pentane et du cyclopentane est présentée en utilisant deux approches différentes. La première approche est une étude cinétique classique basée sur les résultats expérimentaux bruts

et plus particulièrement sur l'analyse des caractères primaire[2] ou secondaire des produits de réaction. La deuxième approche consiste en une simulation des résultats expérimentaux et une analyse de sensibilité qui permet de détecter les processus négligeables et donc de simplifier un mécanisme réactionnel écrit a priori.

Conditions expérimentales

L'étude de l'oxydation du *n*-pentane et du cyclopentane a été réalisée en utilisant un réacteur continu autoagité par jets gazeux en silice. L'injection de l'hydrocarbure liquide dans le réacteur est assurée par un pousse-seringue. Les caractéristiques de l'appareillage expérimental ont déjà été exposées précédemment (5).

Les expériences ont été réalisées à une température de 873 K. Afin d'éviter des problèmes de vaporisation de l'hydrocarbure au niveau du système d'injection, la pression totale au sein du réacteur a été fixée à 540 Torr (1 Torr = 133,3 Pa) dans le cas du *n*-pentane et à 400 Torr dans celui du cyclopentane, valeurs supérieures aux pressions de vapeur saturante (à température ambiante) des composés étudiés. Les pressions partielles d'oxygène et d'hydrocarbure ont été choisies de façon à obtenir un rapport HC/O_2 de 1/4, ce qui correspond à une richesse 2, les conditions stoechiométriques de la réaction d'oxydation totale étant :

$$C_5H_{12} + 8\ O_2 \longrightarrow 5\ CO_2 + 6\ H_2O$$

$$cy\text{-}C_5H_{10} + 15/2\ O_2 \longrightarrow 5\ CO_2 + 5\ H_2O$$

Les produits de réaction formés ont été analysés par chromatographie en phase gazeuse.

Résultats expérimentaux

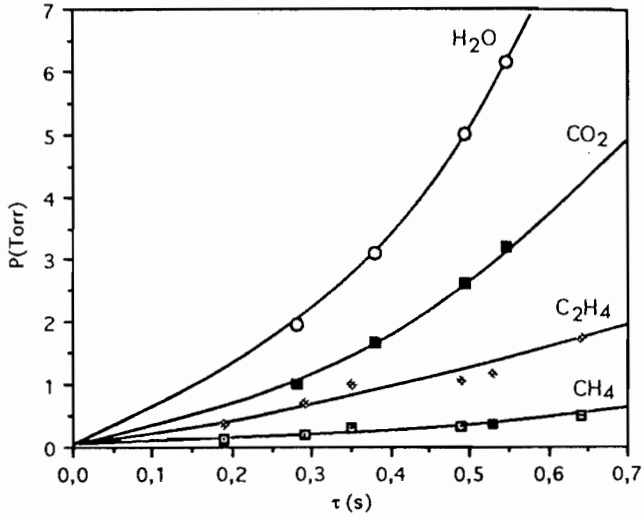
Cas de l'oxydation du *n*-pentane

La réaction d'oxydation du *n*-pentane a été étudiée pour des temps de passage dans le réacteur variant de 0,2 à 0,6 s, ce qui correspond à un avancement de réaction, par rapport au *n*-pentane, compris entre 4% et 15% (1% correspond à 0,27 Torr). La consommation en oxygène varie de 1% à 10% (1% représente 1 Torr).

L'analyse chromatographique a permis d'identifier 10 produits de réaction différents : H_2, CH_4, C_2H_4, C_3H_6, 1-C_4H_8, 1-C_5H_{10}, H_2O, CO_2, CH_3CHO et C_2H_5CHO. On peut remarquer l'absence de CO, ou tout au moins une présence inférieure à la limite de détection du chromatographe utilisé (environ 0,1 Torr). De même, il faut noter que les aldéhydes identifiés ici sont présents en quantité insuffisante pour pouvoir être dosés. L'hydrogène a été dosé, mais sa courbe de formation n'a pu être tracée pour des raisons d'irreproductibilité. Les courbes de formation des produits de réaction sont représentées sur les figures 1 et 2.

2. Un produit de réaction est dit «primaire» lorsqu'il est formé à partir des réactifs ou radicaux libres uniquement. Il est dit «secondaire» lorsqu'il est formé à partir des produits primaires. Un produit primaire se caractérise par une vitesse de formation initiale non nulle, alors qu'un produit secondaire possède une vitesse de formation initiale nulle.

Fig. 1. Oxydation du *n*-pentane à 873 K. Courbes de formation de C_2H_4, CH_4, CO_2 et H_2O.



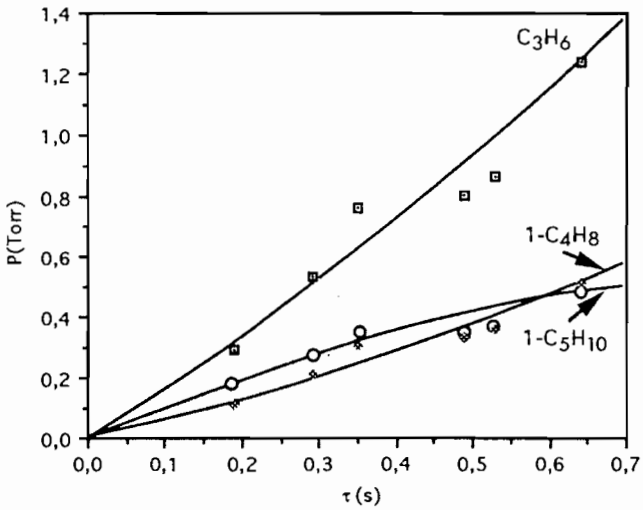


Fig. 2. Oxydation du *n*-pentane à 873 K. Courbes de formation de C_3H_6, 1-C_4H_8 et 1-C_5H_{10}.

Les «diagrammes horizontaux» correspondants à ces produits de réaction sont représentés sur les figures 3 et 4. Ces diagrammes sont tracés en portant le pourcentage molaire du produit considéré par rapport à l'ensemble des produits dosés (réactifs et H_2 non compris) en fonction du temps de passage. Le caractère primaire de la formation d'un composé est alors caractérisé par une courbe ne passant pas par l'origine. On observe donc que tous les produits représentés sont de caractère primaire.

Cas de l'oxydation du cyclopentane

La réaction d'oxydation du cyclopentane a été étudiée pour des temps de passage dans le réacteur variant entre 0,1 et 0,5 s, ce qui correspond à des avancements de réaction, par rapport au cyclopentane, compris entre 2% et 24% (1% représente 0,2 Torr). La consommation en oxygène, par contre, ne dépasse pas 1% (0,8 Torr) pour le temps de passage le plus élevé.

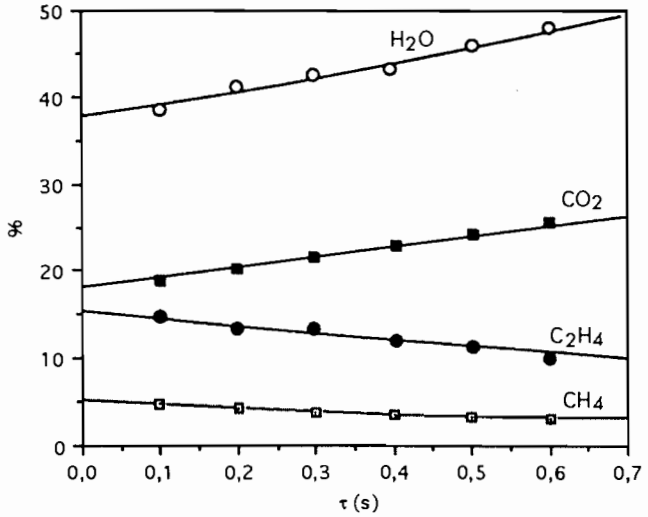
Fig. 3. Oxydation du *n*-pentane à 873 K. Répartition des produits majoritaires de la réaction en fonction du temps de passage.



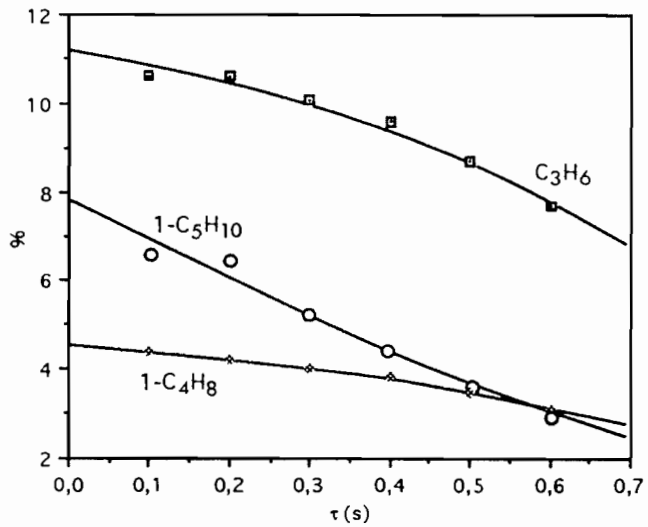


Fig. 4. Oxydation du *n*-pentane à 873 K. Répartition des produits minoritaires de la réaction en fonction du temps de passage.

Cette étude a permis d'identifier les produits de réaction suivants : H_2, CH_4, C_2H_4, C_3H_6, 1,3-C_4H_6, cy-C_5H_6, cy-C_5H_8, CO_2 et H_2O. Le monoxyde de carbone ainsi que les aldéhydes n'ont pu être détectés. Les courbes de formation de ces produits sont représentées sur les figures 5 et 6 et les «diagrammes horizontaux» correspondants sur les figures 7 et 8. Comme dans le cas du *n*-pentane, la courbe de formation de H_2 n'est pas représentée en raison des irreproductibilités. On notera que seul cy-C_5H_6 présente un caractère non primaire.

Interprétation des résultats expérimentaux

L'amorçage des réactions d'oxydation d'hydrocarbures se fait par arrachement d'un atome H· de la molécule d'alcane RH par une molécule d'oxygène :

$$RH + O_2 \longrightarrow R^{\cdot} + HO_2^{\cdot}$$

Fig. 5. Oxydation du cyclopentane à 873 K. Courbes de formation de H_2O, CO_2, cy-C_5H_8, C_2H_4 et cy-C_5H_6.

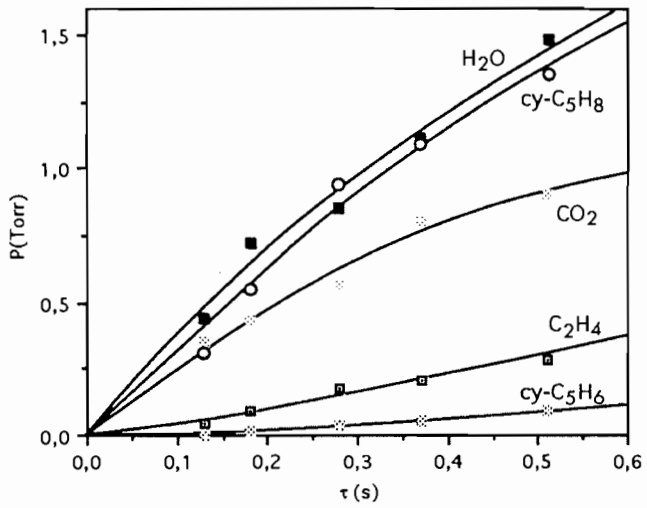

Fig. 6. Oxydation du cyclopentane à 873 K. Courbes de formation de C_3H_6, CH_4 et 1,3-C_4H_6.

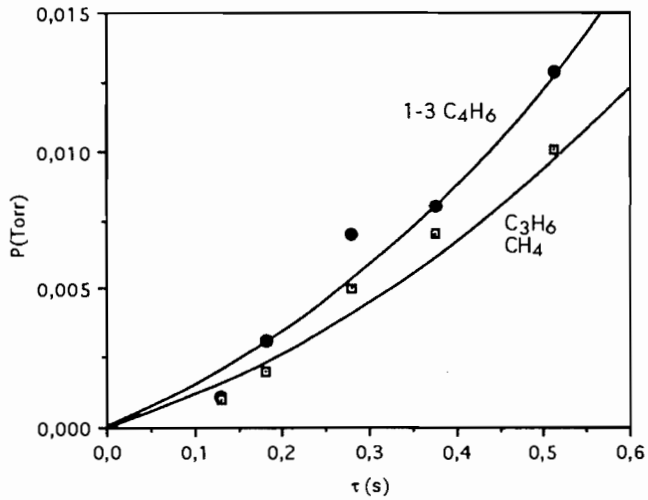

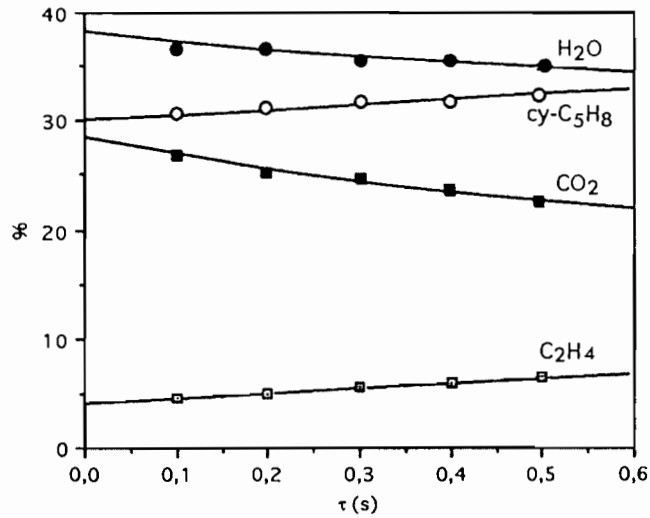

Fig. 7. Oxydation du cyclopentane à 873 K. Répartition des produits majoritaires de la réaction en fonction du temps de passage.

© 1997 NRC Canada

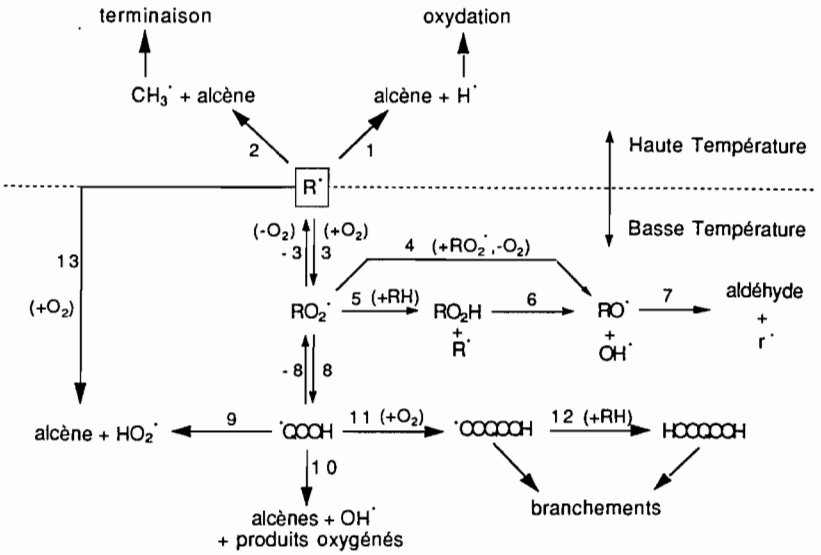
Le radical alcoyle R· peut alors réagir suivant deux mécanismes différents en fonction du domaine de température exploré.

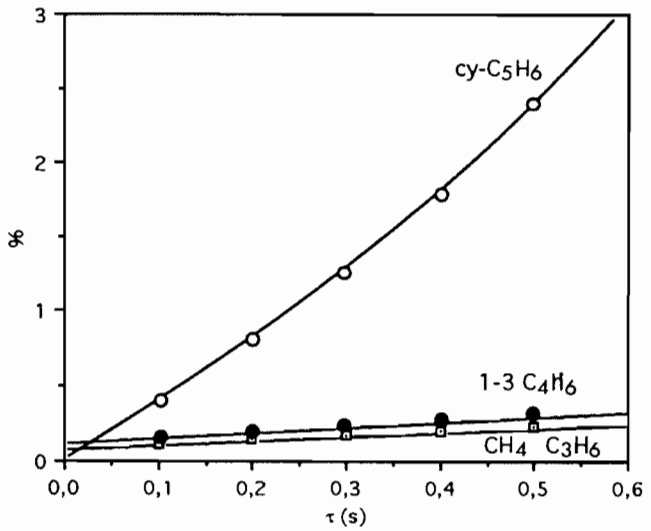
Le radical R· peut se décomposer par rupture de liaisons C—C jusqu'à l'obtention de petits radicaux, qui seuls s'oxydent. Ce mécanisme, dit de *«haute température»*, valable au-dessus de 1000 K, a été proposé par Westbrook, Pitz et al. (6–15) ainsi que par Warnatz (16–19).

Ce radical R· peut aussi réagir avec une molécule d'oxygène pour former le radical peroxyalcoyle RO_2· qui est susceptible de s'isomériser par transfert interne d'atomes H· et conduire aux produits d'oxydation correspondants. Ce mécanisme, dit de *«basse température»*, est valable au-dessous de 800 K et constitue l'aboutissement des travaux de Fish (20–23) dans les années 60, puis de Quinn et Halstead (24) dans les années 70 et enfin de Cox et Cole (25) en 1985.

L'étude de l'oxydation du *n*-pentane et du cyclopentane ayant été réalisée à 873 K, les deux mécanismes précédents doivent être pris en compte. Le mécanisme général de l'oxydation de ces deux alcanes peut donc être schématisé de la façon suivante (Schéma 1) :

Schéma 1. Mécanisme général de l'oxydation des alcanes.





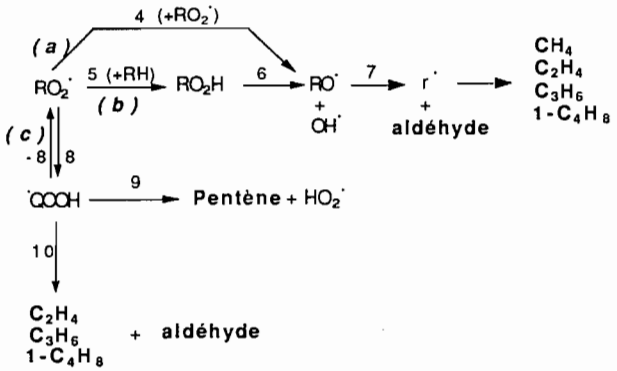


Fig. 8. Oxydation du cyclopentane à 873 K. Répartition des produits minoritaires de la réaction en fonction du temps de passage.

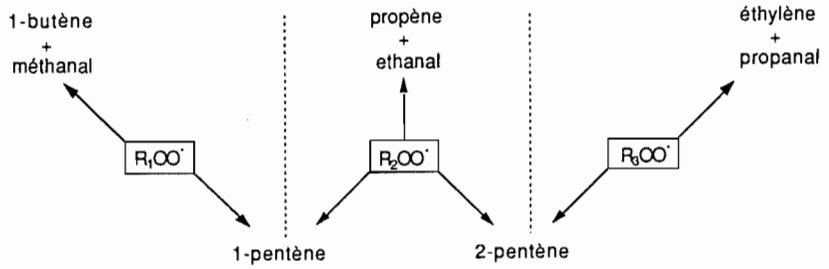
Ce mécanisme général est en fait une synthèse des deux mécanismes de *«haute et basse températures»*. Les différentes parties de ce mécanisme seront analysées en détail dans ce qui suit.

Schéma 2. Oxydation du *n*-pentane : mécanisme de *«basse température»*.

Cas de l'oxydation du *n*-pentane



L'amorçage de la réaction d'oxydation du *n*-pentane (noté : RH) conduit à la formation de trois radicaux alcoyles R· différents ; ce sont les radicaux : pentyl-1, pentyl-2 et pentyl-3. Ces radicaux peuvent alors réagir suivant le mécanisme représenté sur le schéma 1. Nous allons tenter de simplifier ce mécanisme en utilisant les résultats expérimentaux et plus particulièrement le caractère primaire ou secondaire des produits formés.

Suivant le mécanisme de *«basse température»*, le radical R· s'oxyde en radical peroxyalcoyle ROO· qui peut réagir de trois manières différentes (Schéma 2).

Schéma 3. Oxydation du *n*-pentane : isomérisation des radicaux ROO·

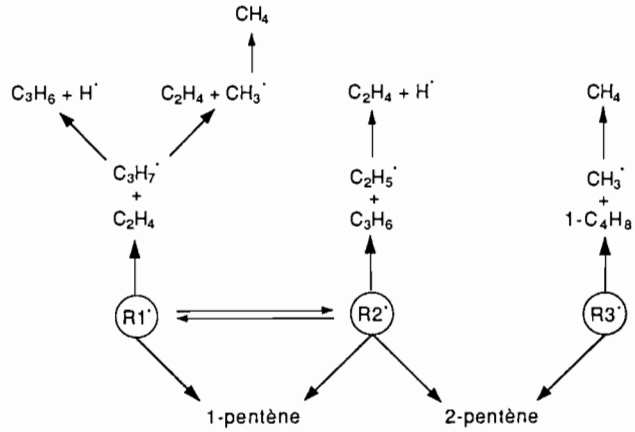
Séquence réactionnelle (a)
Dans ce cas, le mécanisme prévoit la formation primaire de CH_4, C_2H_4, C_3H_6 et 1-C_4H_8, ce qui est compatible avec l'expérience (Figs. 3 et 4). Cependant, les aldéhydes sont formés expérimentalement à l'état de traces, alors que la formation des alcènes et même du méthane est beaucoup plus importante. Ces composés ne sont donc manifestement pas formés par la voie (*a*) qui pourra être considérée comme minoritaire, mais qui peut cependant rendre compte de la formation des aldéhydes.

Séquence réactionnelle (b)
Tous les produits de réaction formés par cette voie sont secondaires, puisqu'ils proviennent de la décomposition d'un produit primaire ROOH. Or l'examen des diagrammes horizontaux (Figs. 3 et 4) montre très clairement que CH_4, C_2H_4, C_3H_6 et 1-C_4H_8 sont primaires. La voie (*b*) peut donc être considérée comme négligeable.

Séquence réactionnelle (c)
Soient R_1·, R_2· et R_3· respectivement les radicaux pentyl-1, 2 et 3. La formation d'alcènes à partir du radical ROO· peut être schématisée de la façon suivante (Schéma 3).

D'après les séquences réactionnelles développées ci-dessus, on peut établir un certain nombre de relations entre les concentrations des divers produits formés :

[1] $(C_2H_4) = (C_2H_5CHO)$



[2] $(C_3H_6) = (CH_3CHO)$

[3] $(1\text{-}C_4H_8) = (CH_2O)$

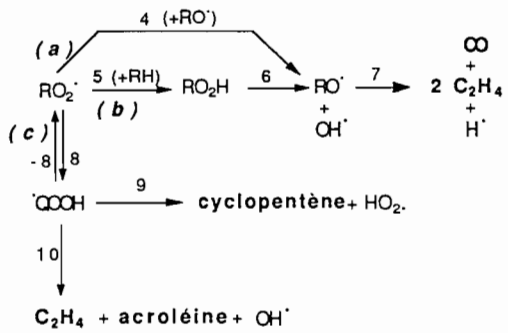
Or, les pourcentages initiaux (Fig. 4) des alcènes sont respectivement : 11,2; 4,5 et 7,8 pour C_3H_6; 1-C_4H_8 et 1-C_5H_{10} alors que ceux des aldéhydes (présents à l'état de traces) sont proches de 0. Manifestement, cette voie réactionnelle (*c*) ne rend pas compte des résultats expérimentaux. Le mécanisme d'oxydation de «*basse température*» semblerait donc être d'importance minoritaire en ce qui concerne la formation du butène-1, du propène et de l'éthylène. On ne peut, cependant, rien conclure sur l'importance des processus de formation des pentènes.

Si on considère maintenant le mécanisme de «*haute température*», le radical pentyle R· se décompose par cassure de liaisons C—C ou éventuellement C—H pour conduire au schéma réactionnel suivant (Schéma 4) :

Schéma 4. Oxydation du *n*-pentane : mécanisme de «*haute température*».

Si ce mécanisme est effectivement majoritaire, la répartition des produits d'oxydation doit vérifier la relation :

[4] $(C_3H_6) + 2[(CH_4) - (1\text{-}C_4H_8)] = (C_2H_4)$



Or, aux premiers instants de la réaction (Figs. 4 et 5) : (C_2H_4) = 15% et $(C_3H_6) + 2[(CH_4) - (1\text{-}C_4H_8)]$ = 13,2%.

En tenant compte des erreurs expérimentales, l'égalité précédente peut-être considérée comme assez bien vérifiée. Il semblerait donc que la réaction d'oxydation du *n*-pentane s'effectue de façon préférentielle suivant le mécanisme de «*haute température*».

Cas de l'oxydation du cyclopentane

L'amorçage de la réaction d'oxydation du cyclopentane conduit à la formation d'un seul type de radical R·, le radical cyclopentyle. L'oxydation de ce radical suivant le mécanisme de «*basse température*» conduit au schéma réactionnel suivant (Schéma 5) :

Schéma 5. Oxydation du cyclopentane : mécanisme de «*basse température*».

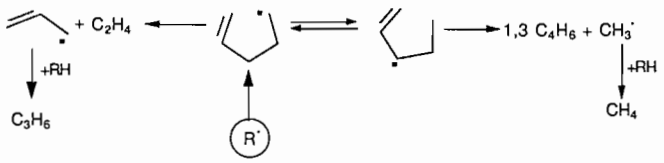
Séquence réactionnelle (a)
Les produits de réaction formés par cette voie sont de nature primaire, ce qui est le cas, expérimentalement, pour l'éthylène (Fig. 7). Cependant, l'éthylène est formé en grande quantité, alors que le monoxyde de carbone est présent à l'état de traces dans le milieu réactionnel. Cette séquence de processus (*a*) n'a probablement que très peu d'effet sur la production de l'éthylène et pourra donc être considérée comme minoritaire.

Séquence réactionnelle (b)
Cette voie conduit à la formation de composés de caractère secondaire. Or expérimentalement, l'éthylène est de nature primaire, comme le montrent les diagrammes horizontaux de la figure 7. Cette séquence réactionnelle semble donc être minoritaire dans l'oxydation du cyclopentane.

Séquence réactionnelle (c)
Cette voie conduit à la formation d'éthylène, d'acroléine et de cyclopentène primaires (Fig. 8). Expérimentalement, l'éthylène et le cyclopentène sont effectivement de nature primaire, alors que l'acroléine n'a pu être détectée. Les résultats expérimentaux ne permettent donc pas de conclure sur l'importance relative de cette séquence de processus.



Cependant, l'application de l'AEQS au radical ·QOOH (à 873 K) conduit aux relations suivantes :

$$[5] \quad V_9 = 7 \times 10^5 \, V_{10}$$

Les constantes de vitesse utilisées dans ce calcul étant estimées selon les méthodes de la cinétique thermochimique (26), ce résultat quantitatif ne peut être considéré que comme une approximation. Qualitativement, on peut considérer que la vitesse du processus 9 est beaucoup plus grande que celle du processus 10 et donc que le radical ·QOOH se décompose préférentiellement en formant du cyclopentène.

Si on considère, maintenant, le mécanisme de *«haute température»*, le radical cyclopentyle réagit suivant le schéma 6 :

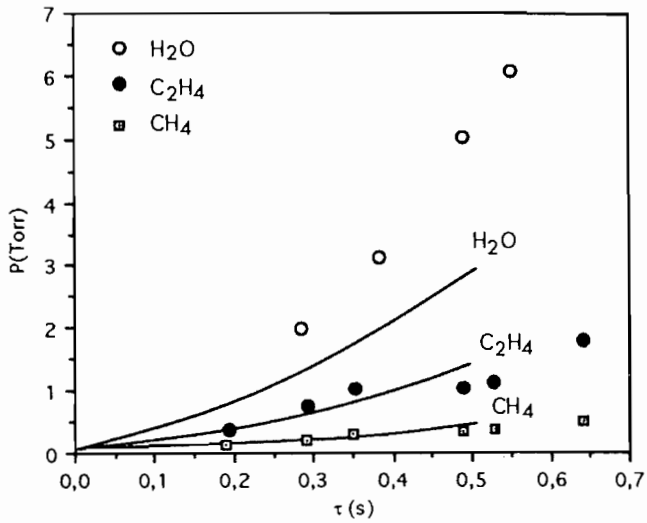
Schéma 6. Oxydation du cyclopentane : mécanisme de *«haute température»*.

D'après ce mécanisme les concentrations en éthylène et propène ainsi que celles en méthane et butadiène doivent être égales. Or, si le méthane est bien formé en quantité voisine de celle du butadiène, la concentration en éthylène est, quant à elle, cinq fois plus importante que celle du propène. Ce mécanisme ne rend pas compte à lui seul de la formation de l'éthylène qui est probablement formé en quantité non négligeable par le mécanisme de *«basse température»* à partir de l'oxydation des radicaux pentyles.

Modélisation des réactions d'oxydation du *n*-pentane et du cyclopentane

Les mécanismes d'oxydation du *n*-pentane et du cyclopentane ont été simulés grâce au logiciel de simulation de mécanismes réactionnels Morse (27). Cette simulation permet de simplifier les mécanismes d'oxydation des deux hydrocarbures étudiés en identifiant les processus négligeables et ainsi de vérifier la validité des suppositions faites au paragraphe précédent.

Fig. 9. Oxydation du *n*-pentane à 873 K. Courbes de formation simulées de H_2O, C_2H_4 et CH_4.



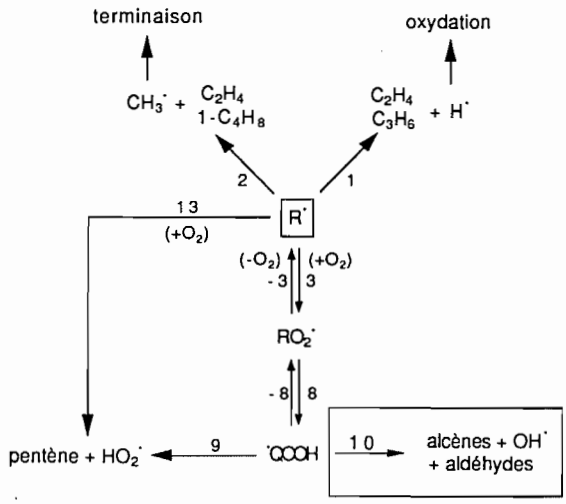


Schéma 7. Mécanisme final de l'oxydation du *n*-pentane (R· représente les radicaux R1·, R2· et R3·).

Cas de l'oxydation du *n*-pentane

Le mécanisme utilisé pour modéliser la réaction d'oxydation du *n*-pentane comporte 168 processus élémentaires représentant les mécanismes primaires de *«haute et basse température»*. De façon à ne pas travailler avec des mécanisme de tailles démesurées, seuls les processus conduisant à la formation de composés identifiés expérimentalement ont été conservés.

Les constantes de vitesse ont été ajustées, dans des limites raisonnables compte tenu de la précision existant sur les paramètres cinétiques, de manière à obtenir, pour les produits d'oxydation dosés, des courbes de formation théoriques aussi proches que possible des courbes expérimentales. La figure 9 montre cet ajustement dans le cas de CH_4, C_2H_4 et H_2O.

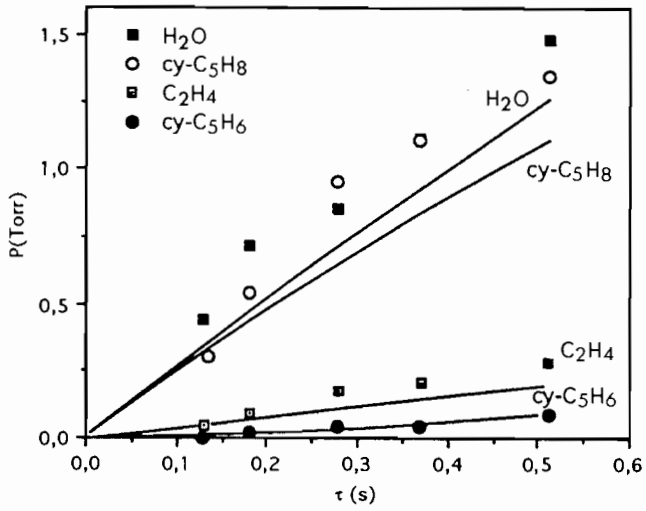
NOTA : RH représente la molécule de *n*-pentane. R1$^{\cdot}$, R2$^{\cdot}$ et R3$^{\cdot}$ sont respectivement les radicaux pentyles 1, 2 et 3. Q*p*OOH($^{\cdot}n$) représente le radical hydroperoxyalcoyle issu du radical R*p*$^{\cdot}$ et dont l'électron célibataire se positionne sur le $n^{ème}$ carbone de la chaîne.

L'analyse de sensibilité, effectuée sur les constantes de vitesse, a permis de simplifier considérablement ce mécanisme, en détectant les processus négligeables. Le mécanisme ne comprend plus, après cette simplification, que 82 processus élémentaires (Tableau 1).

Cette simulation a effectivement permis de vérifier les simplifications faites par des considérations d'ordre expérimental.

La réaction d'oxydation du *n*-pentane relève donc des mécanismes de *«haute et basse températures»*. Le processus 10 n'a été conservé que pour rendre compte de la formation des aldéhydes, présents, rappelons-le, à l'état de traces dans le milieu réactionnel. Ce mécanisme, représenté sur le Schéma 7, regroupe les Schémas 2 et 4 après simplification.

Cas de l'oxydation du cyclopentane



Le mécanisme de départ utilisé pour simuler la réaction d'oxydation du cyclopentane comporte 94 processus élémentaires. Comme pour l'oxydation du *n*-pentane, seuls ont été pris en compte les processus donnant lieu à la formation de composés identifiés expérimentalement.

L'ajustement des constantes de vitesse a permis d'obtenir des courbes de formation théoriques très proches des courbes expérimentales comme le montre la figure 10 dans le cas de l'eau, du cyclopentène, du cyclopentadiène et de l'éthylène. L'éloignement croissant, avec l'augmentation du temps de

passage, entre les courbes théoriques et expérimentales peut être interprété par l'intervention de processus secondaires.

Après analyse de sensibilité, le mécanisme d'oxydation du cyclopentane ne comporte plus que 47 processus élémentaires (Tableau 2). La réaction semble partagée entre une évolution suivant le mécanisme de *«haute température»* et une évolution suivant le mécanisme de *«basse température»*, ce qui avait déjà été pressenti dans le paragraphe précédent. Ce mécanisme, qui est une synthèse des Schémas 5 et 6, peut être schématisé de la façon suivante (Schéma 8) :

Schéma 8. Mécanisme final de l'oxydation du cyclopentane (C5H9. représente les deux formes isomères du radical pentènyle)

Interprétation et discussion

La comparaison des mécanismes d'oxydation du *n*-pentane et du cyclopentane montre que ces deux réactions évoluent de manière similaire. En effet, l'oxydation du *n*-pentane, comme celle du cyclopentane, fait intervenir les mécanismes de *«haute et de basse température»*, la part du mécanisme de *«haute température»* semblant cependant être un peu plus importante dans le cas du *n*-pentane.

La différence de comportement de ces deux hydrocarbures vis à vis des phénomènes d'autoinflammation ne peut être interprétée par la seule étude des mécanismes primaires d'oxydation.

NOTA : RH représente la molécule de cyclopentane et R· le radical cyclopentyle. 1-C_5H_8(OOH-*p*)(·*q*) représente le radical hydroperoxyalcoyle portant le groupement OOH sur le carbone n° *p* et l'électron célibataire sur le carbone n° *q*.

Ces résultats sont, par ailleurs, identiques à ceux obtenus lors de l'étude des réactions d'oxydation du *n*-heptane et de l'isooctane pour lesquels les mécanismes d'oxydation, déterminés dans des conditions expérimentales identiques, étaient également tout à fait similaires (5, 28).

© 1997 NRC Canada

Tableau 3. Indices d'octane recherche de mélange et % initiaux des principaux produits d'oxydation.

	BRON (réf. 29)	*n*-Heptane (RON : 0)	*n*-Pentane (RON : 61,7)	Isooctane (RON : 100)	cy-Pentane (RON : 100)
		0	62	100	141
Éthylène	—	20	15	—	5
Propène	—	8	12	7	—
Isobutène	170	—	—	31	—
cy-Pentène	171	—	—	—	30

Comme dans le cas du *n*-heptane et de l'isooctane, la seule différence existant entre les réactions d'oxydation du *n*-pentane et du cyclopentane réside dans la nature des produits formés et plus particulièrement des alcènes.

En effet, les alcènes formés par les réactions d'oxydation pourraient, par l'intermédiaire de processus secondaires, former, dans certains cas, des radicaux stabilisés par résonance qui inhiberaient la réaction. Ces alcènes se comporteraient, en fait, comme des substances antidétonantes.

L'analyse des produits de réaction formés lors de l'oxydation du *n*-pentane et celle du cyclopentane montre effectivement que le cyclopentane conduit essentiellement à la formation de cyclopentène, précurseur du radical cyclopentényle, stabilisé par résonance.

Le tableau 3 résume les résultats obtenus pour les réactions d'oxydation du *n*-pentane, du cyclopentane, du *n*-heptane et de l'isooctane .

Parmi les produits principaux d'oxydation de ces quatre hydrocarbures, seul l'éthylène ne conduit pas à la formation de radicaux stabilisés. On remarque que plus l'indice d'octane de recherche de l'hydrocarbure (RON) augmente, plus la production d'alcènes précurseurs de radicaux stabilisés par résonance est importante; ceci est également vérifié pour l'indice d'octane recherche de mélange (BRON). L'étude des réactions d'oxydation du *n*-pentane et du cyclopentane confirme donc bien l'hypothèse émise pour expliquer la différence d'indice d'octane entre le *n*-heptane et l'isooctane.

La différence d'indice d'octane entre le *n*-pentane (RON : 62) et le cyclopentane (RON : 100) s'expliquerait donc par la formation, suivant un mécanisme secondaire, de radicaux stabilisés par résonance qui inhiberaient la réaction d'oxydation du cyclopentane.

Cette explication est en concordance avec les études faites sur le caractère antidétonant de certains éthers : le méthyl *tert*-butyléther (MTBE), l'éthyl *tert*-butyléther (ETBE) et le tertio-amylméthyléther (TAME). En effet, les réactions d'oxydation du MTBE et de l'ETBE génèrent de l'isobutène et celle du TAME forme du méthyl-2 butène-1 (BRON : 146) et du méthyl-2 butène-2 (BRON : 176) précurseurs de radicaux stabilisés par résonance (30–32).

Il faut toutefois noter que cette tentative d'explication de la différence d'indice d'octane des hydrocarbures ne peut encore être considérée que comme une hypothèse basée sur l'étude de seulement quatre hydrocarbures différents.

An examination of sodium alginate from *Sargassum* by NMR spectroscopy

Francisco Llanes, Françoise Sauriol, Frederick G. Morin, and Arthur S. Perlin

Abstract: Alginic acid, obtained from *Sargassum* brown algae that drift from the Sargasso Sea to beaches in Cuba, has been examined as an aqueous solution by ^{1}H and ^{13}C NMR spectroscopy, and also in the solid state by MAS ^{13}C NMR spectroscopy. Its composition is distinctive, relative to that for alginic acid from most other brown algae, in having a lower content of β-D-mannopyranosyluronic acid residues (M) than of α-L-gulopyranosyluronic acid residues (G). That is, M/G is ~0.6, whereas ratios of >1 have been reported for many other species, including *Macrocystis pyrifera*, which was examined here as well. In acquiring the high-resolution spectra, partial depolymerization was used to give solutions of reduced viscosity; as is well known, this procedure may cause separation into fractions and the formation of sediments, examples of which are cited. Proton resonances of the reducing end units of chain-shortened segments of the polymers exhibited unusual, marked, line broadening at elevated temperature, which may reflect thermal dehydration. MAS ^{13}C experiments offered the advantage of information about the intact alginate samples. Although the spectra consisted of broad, heavily overlapping peaks, curve-fitting analysis afforded qualitative and quantitative data that supplement those obtained with solutions of the polymers.

Key words: *Sargassum* alginate, ^{1}H NMR of fractions, M/G constituent ratios, MAS ^{13}C NMR, curve-fitting analysis.

Résumé : On a fait appel à la RMN du ^{1}H et du ^{13}C en solutions aqueuses et de la RMN « MAS » du ^{13}C à l'état solide pour étudier l'acide alginique obtenu d'algues brunes du type *Sargassum* qui vont à la dérive de la mer des Sargasses jusqu'aux plages de Cuba. Sa composition se distingue de celle de l'acide alginique obtenu à partir de la plupart des autres algues brunes. Il contient moins de résidus d'acide β-D-mannopyranosyluronique (M) que de résidus d'acide α-L-gulopyranosyluronique (G); le rapport M/G ≈ 0,6 alors que l'on observe généralement des rapports >1 avec la plupart des autres espèces, y compris *Macrocystis pyrifera* que nous avons étudié antérieurement. Alors de l'obtention des spectres à haute résolution, on a provoqué une dépolymérisation partielle afin de réduire la viscosité; il est bien connu que cette procédure peut provoquer une séparation en fractions et la formation de sédiments et plusieurs exemples sont cités. À température élevée, les résonances du proton des unités réductrices en bout de chaîne des segments de polymères raccourcis présentent un important élargissement de bande inhabituel qui est peut-être le reflet d'une déshydratation thermique. Les expériences de RMN « MAS » du ^{13}C fournissent plus d'information concernant les échantillons intacts d'alginate. Même si les spectres sont composés de pics larges qui se recouvrent fortement, une analyse par ajustement de courbe a permis d'obtenir des données tant qualitatives que quantitatives qui servent de supplément à celles obtenues avec les solutions de polymère.

Mots clés : alginate de *Sargassum*, RMN du ^{1}H, RMN « MAS » du ^{13}C, rapport M/G des constituants, analyse par ajustement de courbe.

[Traduit par la rédaction]

Introduction

Alginic acid is the major structural polysaccharide of marine brown algae (*Phaeophyceae*). Although brown algae are its most important source (1), similar types of polysaccharide are found in bacteria (2–5). Alginic acid is a (1 → 4)-linked copolymer of β-D-mannopyranuronosyl (M) and α-L-gulopyranuronosyl (G) residues. Individual seaweed species characteristically differ from each other in their relative proportions (M/G ratios) of these two constituent sugar acids, as well as in their sequencing within the polymer chain (6–9) structural elements that have a bearing on physical properties. Also, for a given species, the polysaccharide composition and yield vary considerably depending upon the season, age, and the part of the plant used for extraction (10–14). Consequently, the term "alginic acid" covers a range of chemically distinct compounds.

Currently, most of the alginic acid used commercially is obtained from Lessoniaceae (*Macrocystis pyrifera*, *Laminaria digitata*, *Laminaria hyperborea*, *Laminaria japonica*), and *Fucaceae* (*Ascophyllum nodosum*, *Fucus serratus*), whereas *Sargassaceae* (*Sargassum* and *Turbinaria* species)(15–17) are of lesser importance. A unique source of *Sargassum* seaweed is material originating from the Sargasso Sea of the south-west Atlantic Ocean, and carried by tides to the shores of Cuba, where it accumulates in large quantities along beaches.

Results and discussion

Estimation of M/G ratios by ^{1}H NMR spectroscopy

NMR spectroscopy has proven (8, 9, 18–21) to be highly effective in the characterization of alginates. Although solutions of these polymers are usually too viscous to give well-resolved spectra, early workers showed (18) that the viscosity can be lowered to satisfactory levels by careful partial acid hydrolysis. Pretreatment in that way was adopted here, i.e., in 0.5 N hydrochloric acid at ~100°C for 1 h, to obtain ^{1}H spectra of the *Sargassum* alginate, as represented in Fig. 1*a*. Signals due to the anomeric protons of the D-mannuronosyl (M) and L-guluronosyl (G) residues, well separated at δ 4.70 and 5.08, respectively, have relative intensities corresponding to an M/G ratio of 0.4. However, this appeared unlikely to be the composition of the unmodified alginate, because there was material in suspension during the pretreatment, and more sedimented out following neutralization. Also, reproducibility was unsatisfactory, as the M/G ratios obtained from several, seemingly comparable, runs ranged from 0.25 to 0.52. Nevertheless, the data suggested that L-guluronic acid is the major constituent. A more valid indication of this feature was obtained by subjecting the alginate to longer prehydrolysis periods. At 4 h, for example, there was less sediment and, hence, a higher percentage of solubilized material in the NMR sample. (As discoloration also occurred, longer reaction times were deemed unsuitable.) The spectrum recorded in this instance (see Fig. 2) afforded an M/G value of 0.5. However, allowance had to be made for the presence of minor H-1 resonances due to reducing end units (which receive further attention below). As the most prominent of these were attributable to species of α,β-mannuronic acid, we estimated that the M/G ratio for the *Sargassum* alginate is close to 0.6.

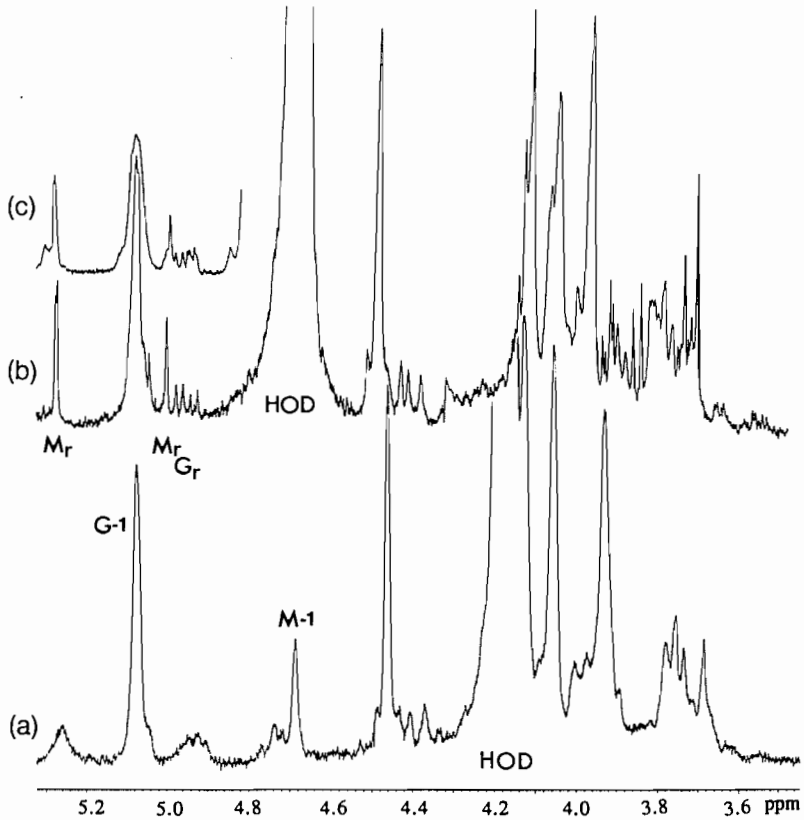
For comparative purposes, we also examined sodium alginate from *Macrocystis pyrifera*, which has been well characterized by other workers and, in contrast to *Sargassum*, has a higher content of D-mannuronic acid than of L-guluronic acid. Through numerous studies (13, 17–19), M/G ratios ranging from 1.2 to >2.0 have been found, depending on such variables as location, age, season, and the part of the plant analysed. Following prehydrolysis of the *Macrocystis* sample for 1 h and the removal of insoluble material, the ^{1}H NMR spectrum recorded

Fig. 1. ^{1}H NMR spectra (500 MHz) for solutions in D_2O at 90°C of sodium alginate from (*a*) *Sargassum* sp. and (*b*) *Macrocystis pyrifera*. Each alginate had been subjected to prehydrolysis with 0.5 N HCl at ~100°C for 1 h. (Signal assignments are given in Table 1.)

(see Fig. 1*b*) was found to contain a strong cluster of anomeric resonances centered at δ 5.07, their relative intensities corresponding to an M/G ratio of 2.5. Although this is consistent with the mannuronic acid-rich nature of *Macrocystis*, the solution that it represents probably (9, 18, 19) constitutes a fraction of the alginate having relatively fewer residues of guluronic acid than did the intact sample. Evidence supporting this assumption is presented below.

Many alginates possess relatively high M/G ratios, such as those obtained (9, 18, 20, 22–25) from *A. nodosum* (~1.2), *L. japonica* (~2.2), as well as from (12) some other *Sargassum* species (0.8–1.4). Hence, the monosaccharide composition of the polymer extracted from the *Sargassum* seaweed collected on beaches in Cuba is relatively unusual among alginates. Whether or not this composition is also characteristic of the plant in the Sargasso Sea from which the Cuban harvest originates remains to be determined, as are possible variations with age and season.

^{1}H and ^{13}C NMR parameters



Partial depolymerization of alginates by acid allows, not only for better solubility, but also for fractionation into materials having widely different compositions. This fact has been utilized in several studies (9, 18–20) to provide impressively detailed information about a variety of mixed sequences of the monomeric residues, both by ^{1}H and ^{13}C NMR spectroscopy. For example (20), an alginate from *A. nodosum*, in which the M and G components are close to equimolar, exhibited eight anomeric ^{13}C signals (δ 103.0 ± 0.8) each of which was attributed to a unique triad sequence (MMG, GMG, etc.). By con-

Fig. 2. ^{1}H NMR spectra (500 MHz) for solutions in D_2O of sodium alginate from *Sargassum* sp. (*a*) subjected to prehydrolysis for 4 h, recorded at 90°C, and (*b*) the same sample at 25°C. Inset, (*c*) downfield region for the *Macrocystis* sample (1 h prehydrolysis) recorded at 25°C; the corresponding region at 90°C is displayed in Fig. 1*b* (*r* = reducing end).

trast, the anomeric (as well as the other) ^{13}C signals in spectra of the *Sargassum* preparations were not resolved into distinctly separate component lines. This indicated, therefore, that little of the solubilized material contained M and G residues in close proximity to each other, and that the polymeric segments comprised primarily *either* M or G residues.

Assignments for the ^{1}H signals of α-L-guluronic acid residues in Fig. 1*a* were readily obtained from an ^{1}H 2-D COSY spectrum. In turn, the identity of the resonances detected in the corresponding ^{13}C NMR spectrum was determined by ^{13}C–^{1}H 2D correlation spectroscopy. Both sets of data, listed in Table 1, were fully in agreement with earlier ^{1}H and ^{13}C assignments (9, 18–20) for polymeric α-L-guluronic acid residues. Additional information contained in Fig. 1*a*, derived from the COSY spectrum, concerns protons-2, -3, and -4 of D-mannuronic acid residues, which resonate within a narrow region centered at δ 3.7. An ^{1}H-coupled ^{13}C spectrum afforded a value of 169 (±2) Hz for $^1J_{CH}$ of the C-1—H-1 bond of the α-L-guluronosyl residues. As this magnitude of coupling is characteristic (26) of an equatorial anomeric C—H bond (axial C—O glycosidic linkage), it supports earlier proposals (18, 20, 27) that these residues possess the $^1C_4$ (L) conformation.

An unusual effect of temperature change on some ^{1}H resonances

The absence from Fig. 1*a* of signals in the regions of δ 5.2–5.3 and δ 4.8–4.9, expected (9) for the anomeric protons, respectively, of α and β reducing end units liberated, shows that only limited hydrolysis of the *Sargassum* alginate could have occurred. By contrast, according to the readily detectable signals in those regions in Fig. 1*b*, the *Macrocystis* alginate had undergone substantial depolymerization under analogous conditions. That those minor signals are, indeed, due to reducing end units was confirmed by introducing sodium borodeuteride to the solution, whereupon the signals were rapidly eliminated. Although it is not evident from Fig. 1*b* that anomeric protons of both D-mannuronic and L-guluronic acid end units are represented, because they have comparable chemical shifts, this point is clarified later.

By extending the period of acid hydrolysis of the *Sargassum* alginate from 1 to 4 h, as already mentioned, minor resonances attributable to low molecular weight species were generated (see Fig. 2*a*). Polyguluronic acid segments were still in preponderance, as the main signals of the spectrum were not markedly altered from those in Fig. 1*a*; i.e., the patterns of the H-1 to H-5 resonances are closely similar in the two spectra. In addition, however, this more extensively depolymerized alginate produced a group of broad, minor signals centered at δ 5.26 and 4.95. By analogy with the minor peaks for *Macrocystis* at the same positions (in Fig. 1*b*), these signals may also be attributed to the anomeric protons of reducing end units. The fact that they are exceptionally broad is related to the elevated experimental temperature (90°C), because it was found that when the spectrum was recorded at 25°C (see Fig. 2*b*), they were replaced by well-resolved sig-

nals. Considering literature values of δ, *J*, and anomeric equilibria, the signals at δ 5.28 and 5.02 are compatible (9) with those of α- and β-*manno* anomers ($J_{1,2}$ < 2 Hz; α:β ≃ 2:1), respectively, whereas the doublets at δ 4.98 and 4.92 ($J_{1,2}$ 8.3 Hz) are taken to be those of β-*gulo* reducing end units (probably (9) in MG and GG diads). Not only these anomeric protons, but some secondary protons as well, are highly sensitive to the temperature change, which is seen in the marked line broadening of the group of peaks centered at δ 3.9 in Fig. 2*b* (a COSY spectrum shows that H-2, e.g., of the α-*manno* anomer, resonates there).

Similarly striking temperature effects on lineshape also occurred with the *Macrocystis* alginate. That is, the broad reducing-end ^{1}H signals observed at 90°C, at δ 5.26 and δ 4.92 in Fig. 1*b*, were replaced at 25°C by a group of far better resolved peaks (see Fig. 2*c*, inset), which closely resemble those in Fig. 2*b* for α,β-mannuronic and β-guluronic acid anomeric protons.

As these changes in peak width are observed only with the reducing end units, one possibility is that they originate from tautomeric exchange during equilibration of the α and β anomeric forms of the units. Nevertheless, the well-resolved anomeric ^{1}H signals observed at 25°C are characteristic of aqueous solutions of reducing sugars at equilibrium under conditions of slow exchange. Normally, their appearance should not be altered materially at such a temperature as 90°C because there would be an accompanying increase in the rate of proton exchange. It appears more likely that the thermally induced line broadening is caused by a qualitative effect on molecular motion. This would apply only to relatively short chains, because the major resonances, attributable to "intact" polymer molecules, exhibit little change in lineshape. Perhaps the oligomeric fragments are relatively easily dehydrated as the temperature is raised, which specifically permits them to aggregate, or to become rigid rods, and thereby induces broadening of their ^{1}H resonances.

Solid state ^{13}C NMR spectra

As already mentioned, it was difficult to obtain alginate solutions free of sediment for use in the NMR experiments, a complication also encountered by earlier workers. In such circumstances, an NMR spectrum of the solubilized portion of a given alginate specimen need not have been representative of the total sample. This kind of limitation would be less likely to arise if the intact sodium alginate powder were to be examined directly by MAS ^{13}C spectroscopy, and hence it appeared worthwhile to compare data obtained by this technique with the data reported above for solutions of alginate.

In the spectrum of the *Sargassum* polymer (Fig. 3*a*) there are (at least) two overlapping anomeric ^{13}C signals, centered at δ 103. This corresponds closely to the location of signals of the anomeric carbons of the β-D-mannuronic and α-L-guluronic residues of alginates in solution, i.e., at δ 102.6 and 103.7, respectively (Table 1). As to their assignments in Fig. 3*a*, we assume that the stronger, downfield peak is due to the main constituent, i.e., α-L-guluronic acid. A curve-fitting analysis suggests, however, that these two peaks, which together correspond to an M/G ratio of 0.78, overlay a far broader peak comprising 20% of the total signal intensity (see Fig. 4*a* (inset)), and hence may not give a close estimate of composition.

Fig. 3. Solid state ^{13}C NMR spectra of sodium alginate from (*a*) *Sargassum* sp., and (*b*) *Macrocystis pyrifera*.

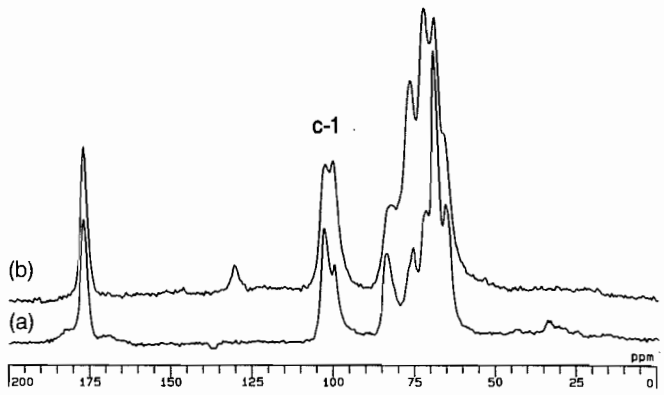

Table 1. ^{13}C and ^{1}H chemical shifts (δ) for residues of α-L-gulopyranosyluronic acid (G) and β-D-mannopyranosyluronic acid (M) in *Sargassum* sodium alginate.

	Carbon Atom

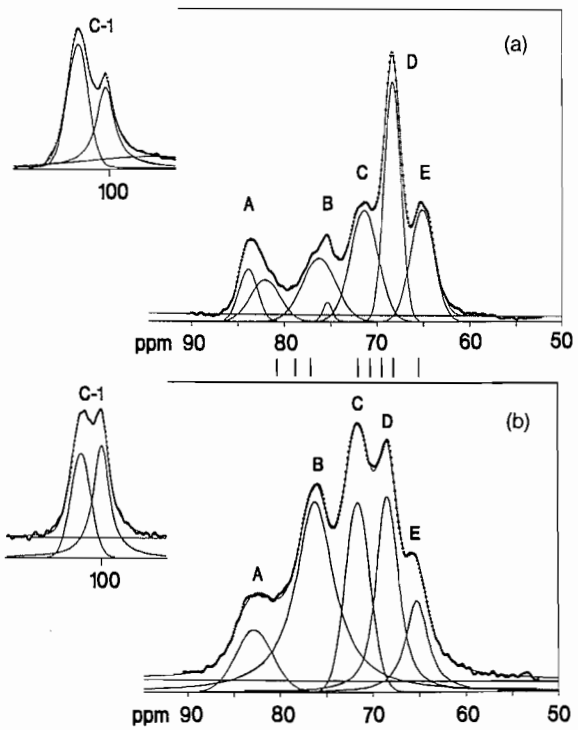
G	103.7[a]	67.5	71.6	83.0	69.8	178.3
M	102.8	73.0[b]	74.0[b]	80.7	78.9	177.1
	Proton					
G	5.07	3.89	4.02	4.12	4.45	
M	4.68		3.70–3.74[c]			

[a] $^1J_{CH}$ from ^{13}C–^{1}H coupled spectrum, 169 ± 2 Hz.
[b]May be interchanged.
[c]H-2, -3, -4 unresolved.

Another concern, which arises from observations (20) of ^{13}C spectra of alginates in solution, is the identification of the ^{13}C-1 signals of M and G residues in mixed sequences. As the anomeric carbons of β-mannuronic and α-guluronic acid resonate at close to the same frequency, small inequalities in the effects of neighbouring residues on their chemical shifts in diads, triads, etc., of mixed composition become important (20) in determining the actual chemical shifts found. Hence, a given peak could consist of contributions from both types of uronic acid residues. If signals were to converge similarly in the solid state spectra, then the origins of the overlapping peaks in Fig. 4*a* (inset) are uncertain.



Curve-fitting analysis of the two ^{13}C-1 peaks of the *Macrocystis* alginate (see Fig. 4*b*, inset) afforded an M/G ratio of 1.2 The fact that this value differs widely from the results (M/G = 2.5) obtained from the ^{1}H spectrum is of little consequence, however, because the same uncertainty about the origins of the ^{13}C-1 signals applies here as well.

By contrast, resonances of the secondary ^{13}C nuclei may offer a less equivocal basis for comparison. In solution, according to the data in Table 1 and complementary information (20) about diad and triad mixed sequences of residues, all of these nuclei differ appreciably in chemical shift. A contributing factor (28) is the presence of more axial C—O

Fig. 4. Curve-fitting analysis (inner lines) of peaks (outer lines) in the solid state ^{13}C NMR spectra (Fig. 3) of sodium alginate from (*a*) *Sargassum* sp. and (*b*) *Macrocystis pyrifera*. Peaks designated A–E are attributed, respectively, to resonances due to guluronic acid C-4 (A), C-3 and C-5 (overlapping, D), and C-2 (E); and due to mannuronic acid C-4 and C-5 (overlapping, B), and C-3 and C-2 (overlapping, C). Inset, anomeric ^{13}C peaks. The corresponding ^{13}C chemical shifts in solution are represented by the row of eight vertical bars (positioned upfield by 2 ppm; see text), attributed (left to right) to carbons G-2, G-5,G-3, M-2 and M-3, M-5, M-4, G-4 (see Table 1).

bonds in the α-*gulo* than in the β-*manno* residues (i.e., at C-1, -3, and -4, vs. C-2, respectively) that specifically induce upfield shifts for C-2, -3, and -5 of the guluronide (C-4 resonates downfield owing to its involvement in the glycosidic bond). To compare the solution ^{13}C data with those of the solid state spectrum, the chemical shifts in Table 1 for individual carbons have been represented by eight vertical lines in Figs. 4*a* and 4*b* (which are expanded portions of Figs. 3*a* and 3*b*). In fact, these lines have been positioned upfield by 2 ppm, which, we assumed, is an allowable adjustment for the "solvent" effect on chemical shift. It then appears that the lines coincide with the MAS peaks (or shoulders) in such a manner that guluronic acid accounts for peaks A (C-4), D (overlapping C-3 and C-5), and E (C-2), whereas mannuronic acid produces peaks B (overlapping C-4 and C-5) and C (overlapping C-3 and C-2). That is, the two sets of five peaks in Figs. 4*a* and 4*b* are both accounted for equitably. As well, it is particularly noteworthy that the peak intensities vary in accord with this analysis of the signals. For example, the far greater prominence of peaks B and C in Fig. 4*b* than in 4*a* is consistent with the known enrichment of *Macrocystes* alginate in mannuronic acid. In principle, then, one may account for the difference in composition between the two types of alginate examined here by comparing the total area of A + D + E (*gulo*) with that for B + C (*manno*).

Analysis conducted on the basis of these considerations afforded the M/G ratios listed in Table 2. As the curve-fitting procedure involved the testing of different types of lineshapes, it afforded a set of different values for each alginate, ranging from 0.57 to 0.61 for *Sargassum* and from 1.3 to 1.4 for *Macrocystis*. The latter values suggest a far different composition than does the ratio (M/G = 2.5) obtained for the *Macrocystis* alginate by ^{1}H NMR spectroscopy. As noted earlier, however, there is precedence (9, 18–20), for the probability that the solution spectrum had not represented the entire sample, but rather, a fraction enriched in mannuronic acid.

As to the *Sargassum* alginate, these MAS ^{13}C ratios are in good agreement with the value (M/G ≈ 0.6) estimated from integrals of the anomeric ^{1}H signals recorded with the 4 h pre-hydrolysis preparation. It appears reasonable to conclude, then, that this alginate contains substantially more guluronic than mannuronic acid, which makes it relatively unique among this class of polymers.

Experimental

Materials

Samples of sodium alginate from *Sargassum* sp. were supplied by the Biomaterials Center of the University of Havana, Cuba. Sodium alginate of *Macrocystis pyrifera* was obtained from commercial sources.

High-resolution NMR spectroscopy

Solutions of sodium alginate examined by NMR spectroscopy were prepared as follows: the alginate (100 mg) was subjected to mild hydrolysis in 0.5 N hydrochloric acid (10 mL) at ~ 100°C for 1 h. After cooling, neutralization, and filtration of the solution, an aliquot was concentrated and exchanged with deuterium oxide, followed, when required, by a second filtration. Ethylene dinitrilotetraacetic acid, disodium salt (EDTA) (Anachemia) was included to avoid signal broadening by divalent cations, and sodium 3-trimethylsilylpropionate-2,2,3,3-d_4 (TSP) (Anachemia) was used as internal reference. The ^{1}H spectra were recorded with a Varian Unity 500 spectrometer, using a temperature of 90°C (or 25°C), a sweep width (SW) of 8000 Hz, a 45° pulse, and an acquisition time of 1.892 s. For COSY spectra, the spectral window was 2333.6 Hz, number of points 1024, number of increments 256, with zero-filling along the evolution domain to provide a 1K × 1K matrix. For HMQC spectra, the SW (^{1}H) was 3237.6 Hz, acquisition time 0.158 s, no. of points 1024, and no. of transients 16; and the SW (^{13}C) was 10 055.8 Hz, number of increments 125; processing was Gaussian in both domains, and the ^{13}C-evolution domain was zero-filled to provide a 1K × 1K matrix. The ^{13}C NMR spectra were recorded with a Varian XL-300 spectrometer operating at 75.42 MHZ, using a temperature of 90°C (or 25°C), a SW of 16 501.7 Hz, a 60° pulse, and an acquisition time of 0.909 s.

trometer at 75.3 MHz. The spectral width was 30 kHz, the acquisition time was 17 ms, and 512 points were acquired in the FID and zero-filled to 4096 before Fourier transformation. An ^1H decoupling field of 60 kHz was used. Samples were held in 7.5 mm Zirconia Pencil rotors and spun at 3–4 kHz. The contact time and pulse delay were 1.5 ms and 3s, respectively. No differences in the spectra were noticed when the contact time was varied between 1 and 3 ms or when the recycle delay was varied between 2 and 10 s, except for changes in the overall signal intensity. Nor were changes observed when the spinning rate was changed, even when the spectra were obtained with the TOSS (*To*tal *S*uppression of *S*idebands) pulse sequence. Deconvolutions of the spectra were performed using the program PEAKFIT from Jandel Scientific. A number of fits were performed, each employing such different lineshape types as Lorentzian or Gaussian (or combinations thereof). It was found that although different results may have been obtained for the area of a given peak, depending on the choice of lineshape, the ratios of M/G calculated from the fitted areas were quite consistent (see Table 2).

Abstract: Examination of the stability constants of Fe(II) and Fe(III) chelates of a wide variety of ligands that contain only acetate and amino groups shows a linear correlation. A separate linear correlation displaced toward the ferric ion was obtained for those ligands that contain more basic phenolate donor groups. The ligands of the latter group generally are unsuited to the oxidation of H_2S to sulfur, while ligands in the first correlation are suitable for that purpose. Ligands that do not contain α-methylene groups are relatively resistant to oxidative degradation. Molecular mechanics is employed to compare the Fe(III) complexes of three such ligands, dipicolinic acid (DIPIC), pyridine-2-phosphonic-6-carboxylic acid (2PP6C), and 2-carboxy-8-hydroxyquinoline (CHOX). The calculations show that there is considerable strain in the formation of the Fe(II) and Fe(III) complexes of these ligands, both with respect to the O–O distance and the O-Fe-O angle. The relatively high stability of the CHOX complex compared to that of DIPIC, therefore, is due mainly to the higher basicity of the phenolate oxygen compared to the carboxylate groups of DIPIC. The higher stability of the Fe(III) complex of 2PP6C relative to that of DIPIC is due to the higher basicity and charge of the phosphonate group compared to a carboxylate group of DIPIC that it replaces. In spite of the lack of α-methylene groups in CHOX, the ligand undergoes rapid oxidative degradation when its iron chelate is used as a catalyst for the oxidation of H_2S to sulfur by air. However, the oxidation products were found to also be effective catalysts for this process.

Key words: hydrogen sulfide, oxidation catalysis, dipicolinic acid, pyridine-2-phosphonic-6-carboyxlic acid, 2-carboxy-8-hydroxyquinoline.

Résumé : L'examen des constantes de stabilité de chélates du Fe(II) et du Fe(III) avec une grande variété de coordinats ne contenant que des groupes acétate et amino présente une corrélation linéaire. Avec des coordinats contenant des groupes donneurs plus basiques, des phénolates, on a obtenu une autre corrélation linéaire, déplacée vers l'ion ferrique. Les coordinats de ce dernier groupe ne sont généralement pas appropriés pour l'oxydation du H_2S en soufre alors que les coordinats de la première corrélation peuvent être utilisés à cette fin. Les coordinats qui ne contiennent pas de groupe α-méthylène sont relativement résistants à la dégradation oxydante. On a fait appel à la mécanique moléculaire pour comparer les complexes du Fe(III) de trois de ces ligands, l'acide dipicolinique (DIPIC), l'acide pyridine-2-phosphonique-6-carboxylique (2PP6C) et la 2-carboxy-8-hydroxyquinoléine (CHOX). Les calculs montrent que la formation des complexes de Fe(II) et de Fe(III) de ces coordinats impliquent une grande tension, tant par rapport à la longueur de la liaison O–O que par rapport à l'angle O-Fe-O. La stabilité relativement grande du complexe avec la CHOX par rapport à celle du complexe avec le DIPIC découle donc principalement de la plus grande basicité de l'oxygène du phénolate par rapport aux groupes carboxylates du DIPIC. La plus grande stabilité du complexe du Fe(III) du 2PP6C par rapport à celui du DIPIC découle de la plus grande basicité et de la charge du groupe phosphonate par rapport au groupe carboxylate du DIPIC qu'il remplace. Même si la CHOX ne comporte pas de groupe α-méthylène, ce coordinat subit une rapide dégradation oxydante lorsqu'on utilise son chélate de fer comme catalyseur pour l'oxydation du H_2S en soufre par l'air. Toutefois, on a trouvé que les produits d'oxydation sont aussi des catalyseurs efficaces pour ce processus.

Mots clés : sulfure d'hydrogène, catalyseur d'oxydation, acide dipicolinique, acide pyridine-2-phosphonique-6-carboxylique, 2-carboxy-8-hydroxyquinoléine.

Introduction

There are several features necessary in a ligand for the complexation of Fe(II)/Fe(III) in the catalytic oxidation of H_2S to sulfur: (*i*) H_2S is best absorbed at higher pH values where HS^- ion is formed, and so the pH should be at least 8.5 (p*K*a of H_2S = 7.02 (1). (*ii*) The stability of the Fe(II) complex should be high enough to prevent precipitation of FeS(s) (log K_{sp} = −18.1 (1) at the pH employed. (*iii*) The stability of the Fe(III) complex should be high enough to prevent precipitation of $Fe(OH)_3$(s) (log K_{sp} = −38.8 (1) at the operating pH of 8.5. (*iv*) The relative stabilities of the Fe(II) and Fe(III) complexes with the ligand should produce a reduction potential ($E°$) that is of the right range of values. ($E°$ for: $Fe^{III}L_n + e = Fe^{II}L_n$.) If the relative stability of the Fe(III) complex is too high, then the reduction potential will be too low, and H_2S will not be oxidized to S(s). (*v*) The ligand should be resistant to attack by oxidizing species such as the hydroxyl radical ($OH^•$), which is generated in the Fe(III)/Fe(II) systems used for oxidation of H_2S (2). This is the most serious deficiency in the currently used NTA (nitrilotriacetate) ligand for the oxidation of H_2S (3). NTA degrades rapidly in the system, ultimately forming CO_2 and NH_3. The rate of degradation can be slowed considerably by the addition of $Na_2S_2O_3$, which is an effective scavenger for the hydroxyl radical. However, the rate of degradation of NTA has been an obstacle to the use of this system in large installations for the removal of H_2S by catalytic oxidation, and a major aim of this study has been to find a ligand that is considerably more resistant to degradation. It has been found empirically that ligands such as dipicolinic acid (DIPIC) that contain no methylenic carbons (-CH_2-) survive in the presence of the hydroxyl radical much longer than those currently used, such as NTA, that do contain methylenic carbons (2).

Recently two pyridine phosphonic acids, pyridine-2-phosphonic-6-carboxylic acid (2PP6C) and 2,6-pyridinediphosphonic acid (2,6PDPA), which do not have α-methylene groups, were reported to undergo negligibly slow degradation when their iron chelates were used as catalysts in the oxidation of H_2S to S_8 by air (4, 5). To better understand the requirements of iron chelates to be used in this process, the structures of the Fe(II) and Fe(III) chelates of DIPIC and 2PP6C were simulated by molecular mechanics, and compared with the structure of the iron(II,III) chelates of a new ligand, 2-carboxy-8-hydroxyquinoline (CHOX).

Experimental

The molecular mechanics procedure employed

In the MM approach, the structure of molecules and complexes of metal ions can be reproduced using a simple model where the total strain energy of the complex (ΣU) is considered to be the sum of various contributions, typically bond length deformation (U_B), bond angle deformation (U_θ), torsional strain (U_ϕ), and nonbonded (van der Waals) interactions (U_{NB}).

$$[1] \quad \Sigma U = U_B + U_\theta + U_\phi + U_{NB}$$

The energy of deformation of bond lengths is reproduced with a simple Hooke's law expression.

$$[2] \quad U_B = \tfrac{1}{2}K_B(r - r°)^2$$

In eq. [2] U_B is the energy of bond length deformation, K_B is the bond length deformation force constant, r is the observed bond length, and $r°$ is the ideal bond length. The value of $r°$ is determined by fitting calculated to observed structures, which are usually those determined by X-ray crystallography. For a study of Fe(III) and Fe(II) it is necessary here to examine crystal structures of complexes of these ions to obtain values of $r°$ for the Fe—N and Fe—O bonds applicable to Fe(II) and Fe(III).

The energy of deformation of bond angles is reproduced using a similar expression:

$$[3] \quad U_\theta = \tfrac{1}{2}K_\theta(\theta - \theta°)^2$$

Here U_θ is the energy of bond angle deformation, K_θ is the bond angle force constant, θ is the observed bond angle, and θ° is the ideal bond angle. The value of θ° for angles around the metal ion is set to be those appropriate for the geometry found for the metal ion, i.e., O-Fe-O angles would be 90° for octahedral Fe(II) or Fe(III).

Torsional strain energy (U) is given by the expression:

$$[4] \quad U\phi = V/n(1 - 3\cos\phi)$$

where φ is the torsion angle about the particular bond in consideration, and V is the torsional constant for the particular type of torsional interaction being considered, e.g., for H-C-C-H torsion around the C—C bond in a hydrocarbon, for which n = 3. The torsional interactions around M—L bonds such as the Fe—N bond are likely to be small, and so are usually omitted in modeling complexes of metal ions.

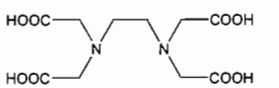
The nonbonded interactions (U_{NB}) between atoms that are not bonded to each other are very important, and are usually modeled with the expression:

$$[5] \quad U_{NB} = A\exp(-Br) - C/r^6$$

where A, B, and C are constants typical of the type of nonbonded interaction being modeled, and r is the internuclear separation between the two-bonded atoms.

MM calculations are a powerful tool for modeling the structures of complexes. Computer programs locate the minimum energy structure by perturbing the atomic coordinates for the molecule, and using a minimization routine such as the Newton–Raphson approach to minimize the strain energy of the molecule. The strain energy is an unfavorable contribution to complex formation and, in a series of ligands with the same donor set, where one may consider the energy of formation of the M—L bonds to be the same, differences in energies of complex formation should relate to the changes in strain energy on complex formation, ΔU.

$$[6] \quad \Delta U = U_{ML_n} - nU_L - U_M$$



where U_{ML_n}, U_L, and U_M are the strain energies, respectively, of the complex ML_n, the free ligand L, and the metal ion M. For a series of ligands with the same M, U_M will be constant, and can therefore be ignored.

To evaluate steric aspects of the complexation of ligands

DIPIC, 2PP6C, and CHOX with Fe(III) and Fe(II), we need to develop parameters for the Fe—N and Fe-O bonds involved. The calculations were carried out using the program SYBYL (6). To the TAFF force field (6), which has all the parameters necessary for modeling organic molecules, were added parameters to describe the Fe(II) and Fe(III) complexes of linear NO_2 donor set ligands DIPIC, 2PP6C, and CHOX. The Fe(III) Fe—N and Fe—O ideal bond lengths were taken to be 2.08 and 2.01 Å, respectively, while Fe—N and Fe—O for Fe(II) were taken to be 2.24 and 2.20 Å, respectively, with force constants of 100 kcal mol^{-1} $Å^{-1}$. The L-Fe-L and Fe-L-C angle (where L represents O or N donor atoms of the ligand) bending force constants were set to 0.005 kcal mol^{-1} deg^{-1} with ideal angles of 90° and 120°, respectively.

Oxidative degradation of ligands

The rate of oxidative degradation of CHOX when used as the Fe(III) chelate in the oxidation of H_2S by air was determined under simulated industrial conditions in the continuous glass apparatus described previously for degradation studies of NTA (3). The pH was maintained at 8.5 with a 2.0 molar ratio of ligand to metal and the temperature was 25.0°C. The H_2S flow rate was 2.0 mL/min. The Fe(III) solution was 0.018 M and the CHOX concentration was 0.036 M, and the volume of the test solution was 1.00 L.

HPLC Analysis of CHOX

Preparation of iron-free sample

To 5.0 mL of solution taken from the continuous reactor, 125 mg of NaOH in 30 mL water was added dropwise with stirring. The mixture was heated to 80–90°C for 40 min. The $Fe(OH)_3$ that precipitated was carefully filtered off and was washed several times with water. The filtrate was combined with the washing and was transferred to a 50 mL volumetric flask. To this was added 10.0 mL 1 M KCl solution and the solution was then diluted with distilled water to 50 mL. (The HPLC peak seemed to be improved by the addition of KCl.)

Operating conditions

IB-SIL 5 C8 reverse phase HPLC columns 4.5 × 150 mm; column temperature, ambient; mobile phase, 18% methanol, 77.9 water, 4.1% acetic acid; flow rate 1.5 mL/min; detector UV 250 nm, sample 20 μL; recorder 100 mV full scale, chart speed 0l5 cm/min. The height of the chromatographic peak was taken as a measure of the molar concentration of CHOX. The analytical method was calibrated with known samples of ligand and a linear calibration was obtained for ligand concentrations of 5–0.5 M.

Results and discussion

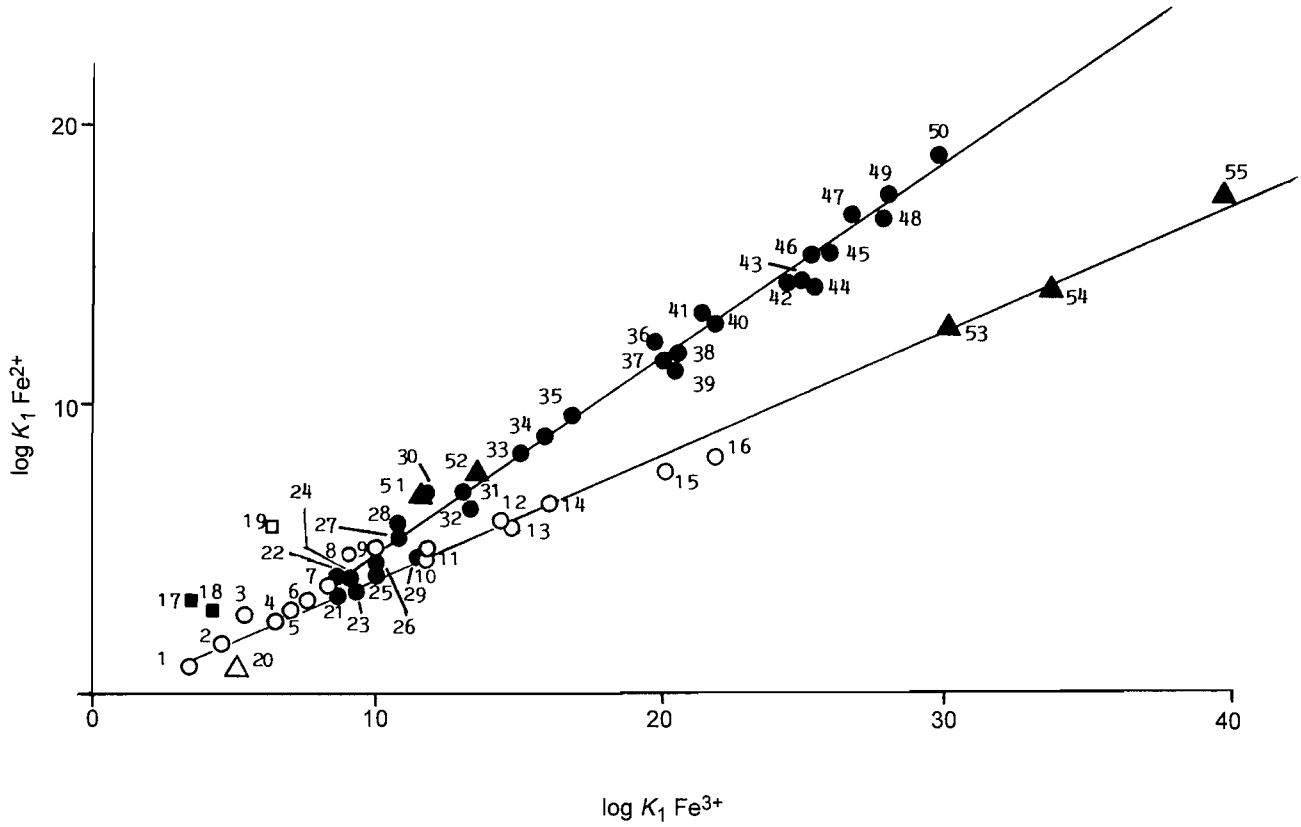
Types of ligands that meet specified requirements

We may gain an idea of what types of ligands will be suitable for this purpose by examining the relationship between log K_1 for Fe(II) and Fe(III) in Fig. 1. Figure 1 shows a typical relationship found (7) for pairs of metal ions. Fe(III) is considerably harder than Fe(II) in the hard and soft acids and bases (HSAB) classification of Pearson (8). The effect that this has on diagrams such as Fig. 1 is that ligands are separated into different correlations by their hardness in the HSAB sense. Thus, Fig. 1 shows that a single correlation occurs which contains all of the ligands that contain only acetate and amino groups. This group of ligands includes NTA and DIPIC, which have, respectively, saturated nitrogens and pyridine nitrogens as donors, in addition to acetate groups. A separate correlation exists for those ligands that contain the more basic phenolate oxygen groups. The correlation for the phenolate donors is displaced in the direction of the Fe(III) ion, showing a much greater preference for Fe(III) relative to Fe(II). This is illustrated by the log K_1 values (1) for EDTA and HBED.

	Fe(II)	Fe(III)	Δ log K_1 (Fe(III) – VFe(II))
log K_1 EDTA	14.27	25.0	10.7
log K_1 HBED	17.3	39.68	22.4

The large difference between Fe(III) and Fe(II) for HBED above would produce much too unfavorable an oxidation potential for the Fe(II)/Fe(III) couple, and so HBED would not be active as a catalyst for the oxidation of H_2S (9).

Ligands that have proved useful in complexing Fe(II) and Fe(III) to give satisfactory catalysts for oxidation of H_2S to sulfur are EDTA, NTA, and dipicolinic acid. The use of these ligands has been described in several patents, only a few of which are cited here (10–13).



New ligand systems

It has recently been shown that pyridine-2-phosphonic-6-carboxylic acid (2PP6C) and 2,6-pyridinediphosphonic acid (2,6-PDPA) are effective ligands for use in Fe(II)/Fe(III) systems for catalyzing the oxidation of H_2S to sulfur (4, 5). The logic here is that DIPIC has been shown to be resistant to attack by the hydroxyl radical. It appears that ligands with no saturated carbons, especially α-methylene carbons such as DIPIC, may be more resistant to attack by hydroxyl radicals because the aromatic ring is less affected by attack by hydroxyl radical. DIPIC suffers from formation constants with Fe(II) and Fe(III) that are too low, so that the system can operate only at pH 6.5 if precipitation of $Fe(OH)_3$(s) and FeS(s) is to be avoided. The ligands 2PP6C and 2,6-PDPA resemble DIPIC in having no methylene carbon atoms, but the phosphonate donor group (p*K*a about 8.0 rather than 4.8 for a carboxylic acid) is a much stronger base, so that 2PP6C and 2,6-PDPA should be much stronger ligands than DIPIC, but share the important feature of DIPIC in having no methylene carbons. As discussed, both 2PP6C and 2,6-PDPA are successful ligands for the catalytic oxidation of H_2S.

In a search for further ligand systems, it seemed possible that the ligand 2-carboxy-8-hydroxyquinoline (CHOX) described below would resemble DIPIC very closely in its bonding properties with Fe(II) and Fe(III). The hydroxy group of 8-hydroxyquinoline has a protonation constant (1) of 9.81, which means that it will resemble DIPIC in having no methylenic protons, but is a stronger ligand because of the much more basic oxygen donor group. A problem that might arise with ligands such as CHOX is that they are fairly rigid, and there might be problems in relation to the steric fit of such a ligand when coordinating Fe(II) and Fe(III). To gain some insight into the metal ion coordinating properties of the ligands containing pyridyl groups, a Molecular Mechanics

(MM) analysis of the Fe(II) and Fe(III) complexes of DIPIC, 2PP6C, and CHOX was undertaken.

The role of p_π–d_π π-bonding in complexes of Fe(III)

The mechanical model of molecules and complexes employed in MM accounts very well for many types of effects. In the first instance, it accounts, for example, for changes in M—L bond lengths that are caused by steric forces within the molecule. This is seen (14) for complexes of Co(III) with N6 donor groups where the Co—N bond lengths cover a considerable range:

This change of bond length over a wide range is reproduced by MM calculations with no reference to any electronic effects. In contrast, in carrying out MM calculations on organic molecules, it is found that the C—C bond length may vary in a way that is caused by electronic effects due to the electronegativity of the atoms attached to the carbons. Thus, the C—C bond in $HOCH_2CH_2OH$ is only 1.51 Å, in contrast to the C—C bond in ethane, which is 1.54 Å. This is not reproduced in calculations of $HOCH_2CH_2OH$ where $r°$for the C—C bond of 1.54 Å is used, and an extra term to correct for the change in $r°$as a

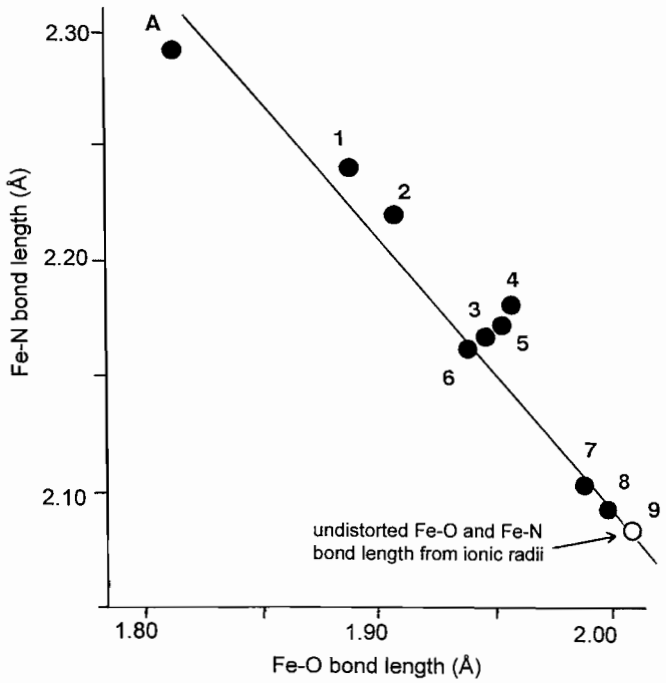
function of the electronegativity of the groups attached to the carbon atom has to be introduced. This is usually done only in MM programs such as MM3, where the interest is modeling the structures and energies of organic molecules with maximum accuracy. In approaches such as that adopted here, where the interest lies in the geometry around the metal ion, such extra terms are not included. However, one must be alert for structural and energetic effects that might arise in the bonds involving the metal ions that are due to electronic rather than steric effects. For the Fe(III) ion, it is clear that dramatic electron effects are present in complexes containing mixtures of neutral nitrogen and charged oxygen donors. This can be illustrated by considering complexes of Fe(III) with N_3O_3 sets of donor atoms, as an example, but appears to be a general phenomenon for all complexes of Fe(III) containing both N and O donors.



The ligands with N_3O_3 sets of donor atoms considered are as follows:

R = CH_2COOH = TACN-TA
R = Me = Me_3-[9]aneN_3
R = CH_2CH_2OH = THETACN
R = 2-hydroxybenzyl = TACN-HB
R = (3-hydroxy-6-methyl-2-pyridylmethylene) = TACN-HP

The structures (15–22) of the Fe(III) complexes with these ligands reveal an inverse relationship between Fe—N and Fe—O bond lengths, which is shown in Fig. 2. The interpretation of the shortening of the Fe—O bonds (14,18) is that p_π–d_π π-bonding involving the *p*-oribtals on the oxygen, and the half-filled t_{2g} level of the Fe(III), leads to the shortening observed. The longer Fe—N bonds are caused by a *trans* effect, which is demonstrated by the inverse relationship between the Fe—N and Fe—O bonds observed in Fig. 2. The question posed by Fig. 2 is the importance of this π-bonding in the present study. Figure 2 shows that the two complexes that demonstrate almost normal Fe—O and Fe—N bond lengths are those involving the tris-pyrazolylborate ligand (TPB). One sees here that where the nitrogen donors are sp^2 hybridized and capable of competing with the oxygen donors as π-bonders, in the tris-pyrazolylborate ligands, the nearly normal Fe—O and Fe—N bond lengths are observed (points 7 and 8 in Fig. 2). This result indicates therefore, that in modeling complexes of Fe(III) with negative oxygen donor atoms, such as the carboxylate and phenolate present on CHOX, one must be aware that π-bonding could lead to a distortion of the Fe—N and Fe—O bond lengths. However, since (*a*) the nitrogens in such a ligand can only coordinate to each other in a *trans* fashion, and cannot be *trans* to any oxygen donors, and (*b*) the nitrogen of a pyridine should, like those in TPB, be capable of p_π–d_π π-bonding, and therefore minimize shortening of the Fe—N bond due to a *trans* effect from negative oxygen donors, it is concluded that π-bonding distortions do not take place in the Fe(III) complexes of the present ligands.

Fig. 2. The relationship between Fe—N and Fe—O bond lengths in complexes of Fe(III) with N_3O_3 donor sets. The complexes are (1) [Fe(TACN-TB)], (2) [Fe(TACN-HP)], (3) [$(Fe(TPB))_2$-μ-O-μ-$(CH_3COO)_2$], (4) [Fe(TACN-TA)], (5) [$Fe(taci)_2$], (6) [Fe(THETACN)H_{-3}], (7) [(Fe(TPB))2-μ-OH-μ-$(CH_3COO)_2]^+$, (8) [Fe(TPB(TMP)]. Point 9 is for the hypothetical undistorted Fe(III) complex with N_3O_3 donor set, where the Fe—O and Fe—N bonds are as expected from the sum of the ionic radii (14). The point at A is for the very long Fe—N bond found *trans* to the bridging oxide in [(Fe(Me_3-[9]-aneN_3))2-μ-O-μ-$(CH_3COO)_2$], where a very short Fe—O bond is present.

The distortion of complexes of Fe(III) towards trigonal prismatic coordination

Most six-coordinate complexes of trivalent metal ions of the first row of transition metals (Sc^{3+} through Ga^{3+}) show a preference for maintaining a regular octahedral (O_h) coordination geometry, and in metal ions such as Cr(III) and Co(III), where a loss in ligand field stabilization energy (LFSE) results in distortion of the geometry away from O_h, this preference can be very strong. The high-spin Fe(III) ion has the d^5 electronic configuration, which means that LFSE is zero, and preference for O_h geometry should be much weaker. One thus finds, for example, that in the complexes of TACN-TA, where the pendant acetate donor arms of the ligand are too short to wrap effectively around the Fe(III) and achieve regular octahedral coordination geometry, distortion towards trigonal prismatic coordination occurs (Fig. 3). In contrast, the ligand TACN-HP has longer donor groups, and forms six-membered chelate rings on complex formation, and so (Fig. 3) has nearly regular coordination geometry. The extent of distortion toward trigonal prismatic coordination in the TACN-TA complex can be modeled only if the L-Fe-L angle bending force constants around the Fe(III) are set to zero. The available evidence suggests, however, that this loss of maintenance of the ability to maintain O_h geometry is coupled with the distortion of the

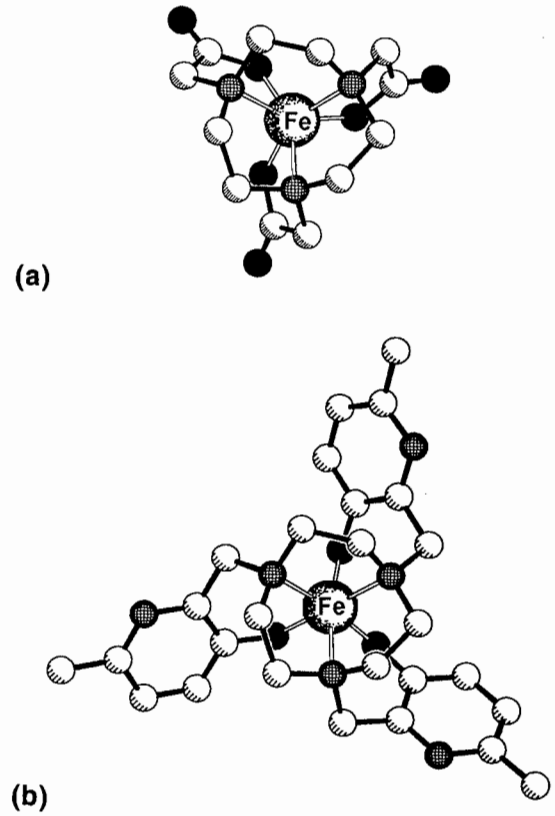
Fig. 3. The structures of (*a*) the complex [Fe(TACN-TA)], showing the distortion of the coordination geometry toward trigonal prismatic, and (*b*) the more nearly regular octahedral coordination geometry found with the complex [Fe(TACN-HP)]. The twist angle, which is defined as the projection of the Fe—L bond angles onto a plane at right angles to the C_3 axis of the complex, is 60° for a regular octahedron, and 0° for the trigonal prism. In (*a*) the twist angle is 25°, while in (*b*) it is 54°.



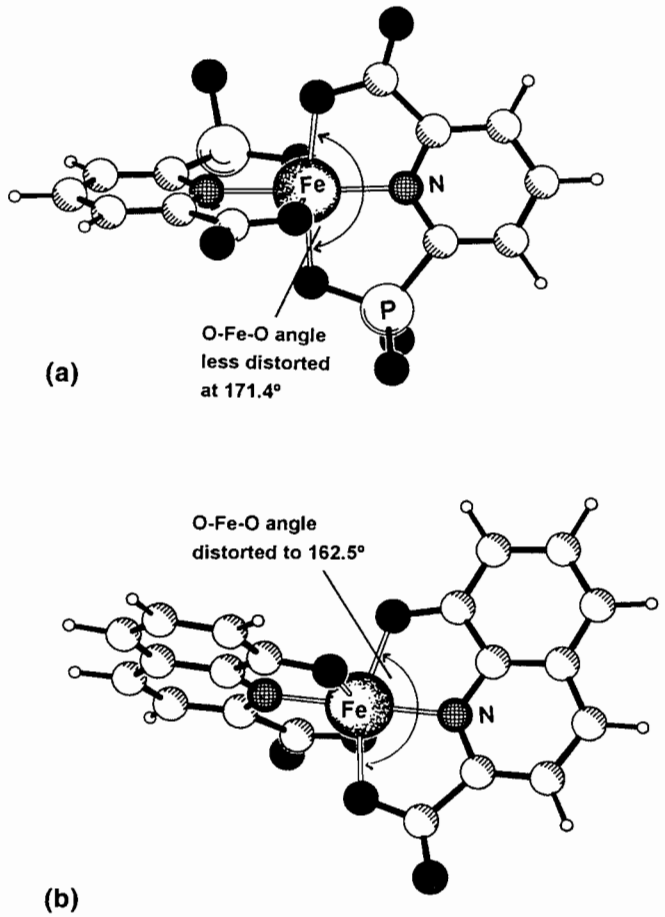


Fig. 4. The structure generated by MM calculation for [Fe(CHOX)]. The structure illustrates the steric difficulty for coordination of this ligand to metal ions in an octahedral fashion, since the O-Fe-O angles are distorted away from the ideal value of 180°.

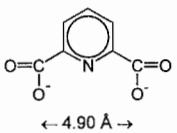
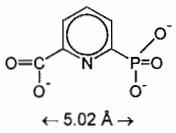
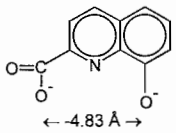
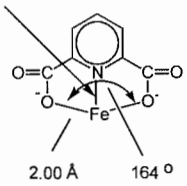
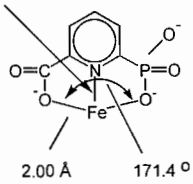
Fe—N and Fe—O bond lengths, and so where such distortion is not present, it should be assumed that octahedral geometry will be maintained.

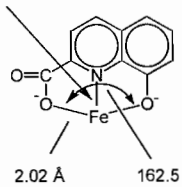












MM analysis of Fe(III) and Fe(II) complexes of CHOX, 2PP6C, and DIPIC

The ligand DIPIC complexes Fe(II) and Fe(III) too weakly, with resulting precipitation of FeS and $Fe(OH)_3$. A solution to this problem, which retains the resistance of DIPIC to attack by hydroxyl radicals, is the ligand CHOX, discussed above. The latter ligand is stronger since it contains a more basic phenolate donor in place of one of the weakly basic carboxylates of DIPIC. A problem with CHOX is its rigidity, which might lead to complexes of Fe(III) and Fe(II) that are not sufficiently stable because of the steric difficulty of coordination to the metal ion. We therefore report here the strain energies of the free ligands DIPIC and CHOX, and of the complexes of these ligands with Fe(III) and Fe(II).

In Fig. 4 are shown the energy minimized structures of $[Fe(2PP6C)_2]^-$ and $[Fe(CHOX)_2]^-$. Figure 4 shows the distortion of the O-Fe-O angle produced by the steric difficulty of coordinating in an octahedral fashion to these ligands. The MM calculations show that all three ligands, CHOX, 2PP6C, and DIPIC, have steric difficulty in coordinating to metal ions. In Table 1 are shown the free ligands CHOX, 2PP6C, and DIPIC. In all three ligands, the O–O distance is shown by MM calculation to be close to 5.0 Å, which is more than double the ideal Fe—O distance for either Fe(II) (2.20 Å) or Fe(III) (2.01 Å). Thus metal ions should experience steric difficulty because the O--O distance is too great. A second problem is that, if the O-Fe-O angles are 180°, then the Fe—N distance in these complexes will be very short, of the order of 1.8 Å. The MM calculations show that the strain energy of $[Fe(CHOX)_2]^-$ is somewhat higher than that of $[Fe(2PP6C)_2]^-$, and $[Fe(DIPIC)_2]^-$. This arises from the greater rigidity of CHOX, which means that stronger distortion of the O-Fe-O angle, as seen in Fig. 4, occurs in $[Fe(CHOX)_2]^-$; the higher strain energy is caused by the greater rigidity, which worsens the problems of coordinating a metal ion to the two oxygens and nitrogen of the ligand, with the Fe—O distances required by the ligand being too long, and the Fe—N distances required being too short. The problem is less serious for the 2PP6C complexes. The long bonds involving the phosphorus (P—C and P—O) of the phosphonate groups mean that the ligand

requires a somewhat longer M—N bond than does DIPIC and CHOX, and so, sterically, 2PP6C is better suited to complexing the Fe(III) ion. The strain energies calculated for the Fe(II) complexes show that the increase in strain energies that occurs for the complexes of both ligands on passing from the Fe(III) to the Fe(II) complex is fairly similar, so that we should expect the steric contributions to the oxidizing power of these complexes to be similar.

Degradation of the Fe(III)–CHOX complex at pH 8.5

CHOX forms sufficiently stable complexes with Fe(III) so that $Fe(OH)_3$ does not precipitate until the pH is above 10.0 when a 2:1 molar ratio of ligand to Fe(III) ion is used (Fe(III) 0.018 M; CHOX 0.030 M). A precipitate is formed above pH 9.0 when a 1.5:1 molar ratio of ligand to Fe(III) is employed (Fe(III) 0.018 M, CHOX 0.027 M, Fe(III):CHOX = 1:1.5).

The degradation of Fe(III)-CHOX at pH 8.5, with a 2:1 ratio of ligand to Fe(III) ion, is shown in Table 2 and Fig. 5. The results show that the ligand degrades very rapidly during the redox reaction in the continuous reaction apparatus. After the redox reaction was carried out for 52.5 h, about 96% of CHOX

Fig. 5. Comparison of degradation of CHOX and of NTA at pH 8.5: ○, CHOX; ▽, CHOX + 5% $Na_2S_2O_3$; ▲, NTA; ●, NTA + 5% $Na_2S_2O_3$; Fe(III) = 0.018 M; ligand = 0.036 M. % is percent of 0.036 M ligand left in reaction mixture.

was lost. The redox reaction was continued for 160 h and no precipitate of $Fe(OH)_3$ was observed during this period of time. This observation, together with the evidence in Fig. 5 for the rapid degradation of CHOX, indicates that the degradation product of CHOX is also a strong ligand for Fe(III).

The degradation of Fe(III)-CHOX with 5% $Na_2S_2O_3$, when used as a redox catalyst in the continuous flow apparatus, is shown in Table 3 and Fig. 5. The results show that CHOX degrades so rapidly that in 54 h about 94% of the ligand was lost, presumably by hydroxylation. The presence of 5% $Na_2S_2O_3$ does not stabilize this ligand from oxidation by the hydroxyl radical. The relative concentrations of CHOX and thiosulfate in Table 3 and Fig. 5 lead one to believe that the ligand has a much greater affinity for $^{\cdot}OH$ than does $S_2O_3^{2-}$.

Sodium thiosulfate is a free-radical scavenger that is used industrially as an additive to slow down the oxidative degradation of chelating agents such as NTA and EDTA when used in this redox process. Its properties and use in this process have been described (2).

The rate of degradation of NTA, with and without thiosulfate, under the same conditions (2), is also shown in Fig. 5 for comparison. It is seen that NTA degrades much less rapidly than CHOX, and is greatly stabilized against oxidative degradation by thiosulfate. The oxidative degradation of CHOX, on the other hand, is much more rapid, and is not stabilized very much by thiosulfate. However, the most remarkable characteristic of this system, and of the degradation tests that have been carried out, is that the degradation product, the nature of which is still to be determined, is also a good catalyst for the redox reaction, because the production of sulfur from H_2S continues at about the initial rate, even after the ligand, CHOX, has been completely degraded. Therefore the product of oxidative attack of the initial ligand is probably a polyhydroxy compound, produced by hydroxylation of CHOX. Such a polyhydroxy compound would probably be a catechol, which would have high affinity for Fe(III), and its iron chelate would be expected to be a good redox catalyst for the oxidation of H_2S to sulfur.

Research is now in progress on the isolation, identification, and purification of the oxidation product of CHOX that seems to be effective (in the form of its Fe(III)/Fe(II) complexes) as a redox catalyst for the oxidation of H_2S. It is hoped to describe this catalyst in a subsequent report.

Conclusions

Therefore the absence of easily oxidized α-methylene groups does not guarantee against oxidative degradation. Also in some cases, as in CHOX, the initially formed chelating agent derivatives may also be effective ligands for Fe(II)/Fe(III) and may form effective catalysts for the oxidation of H_2S to elemental sulfur. Additional work on the tridentate phosphates 2PP6C and 2,6PDPA is now in progress, and will be reported later.

Abstract: Treatment of 3-[2-(4,4-dimethyl-4,5-dihydrooxazolin-2-yl)]-4-phenyl-1,4-dihydropyridine (**13**) with NaH–DMSO, and then reaction with 1,1-bis(2-methylphenyl)-4-bromobutane (**12***c*) afforded 1-[4,4-bis(2-methylphenyl)butyl]-3-[2-(4,4-dimethyl-4,5-dihydrooxazolin-2-yl)]-4-phenyl-1,4-dihydropyridine (**14**). Reaction of methyl nicotinate with 2.1 equivalents **12***c* or 1,1-bis(2-methylphenyl)-4-bromo-1-butene (**11***b*) afforded 4,4-bis(2-methylphenyl)butyl 1-[4,4-bis(2-methylphenyl)butyl]pyridinium-3-carboxylate bromide (**17**) or 4,4-bis(2-methylphenyl)-3-butenyl 1-[4,4-bis(2-methylphenyl)-3-butenyl]pyridinium-3-carboxylate bromide (**18**), respectively. The nonregioselective reaction of the pyridinium salts (**17/18**) with PhMgCl in THF at −23°C using a catalytic amount of CuI afforded a mixture of isomeric 4-phenyl-1,4-dihydropyridyl (**21** or **22**) and 6-phenyl-1,6-dihydropyridyl (**27** or **28**) products in a ratio of approximately 1:1. All attempts to hydrolyze the 4,4-bis(2-methylphenyl)butyl or 3-butenyl ester moiety of **21/22** or **27/28** to a carboxyl group resulted in decomposition products. In contrast, the corresponding 3-(2-cyanoethyl) esters (**23**, **24**, **29**, **30**) were readily converted to the corresponding carboxyl analogs (**25**, **26**, **31**, **32**) via a β-elimination reaction of acrylonitrile using the non-nucleophilic base DBU. The 4-phenyl-1,4-dihydropyridyl (**14**, **25**, **26**) and 6-phenyl-1,6-dihydropyridyl (**27/28** or **31/32**) compounds inhibited the in vitro uptake of [^{3}H]GABA into striatal prisms in the 21–44% range at a 10^{-4} M test compound concentration, relative to the reference drug nipecotic acid (87% inhibition). Structure–activity correlations showed the dihydropyridyl C-3 substituent was a determinant of [^{3}H]GABA uptake where the potency order was CO_2H > 2-(4,4-dimethyl-4,5-dihydrooxazolin-2-yl) > $CO_2(CH_2)_3CH$-(*o*-tolyl)$_2$ and $CO_2(CH_2)_2CH{=}C$-(*o*-tolyl)$_2$. Compounds possessing C-3 and (or) N-1 $CO_2(CH_2)_3CH$-(*o*-tolyl)$_2$ substituents were generally more potent than analogs having $CO_2(CH_2)_2CH{=}C$-(*o*-tolyl)$_2$ substituents. In general, 1,6-dihydropyridyl compounds were more potent than the corresponding 1,4-dihydropyridyl isomers.

Key words: 1,4- and 1,6-dihydropyridines, GABA-uptake inhibitors.

Résumé : Le traitement de la 3-[2-(4,4-diméthyl-4,5-dihydrooxazolin-2-yl)]-4-phényl-1,4-dihydropyridine (**13**) par du NaH–DMSO, suivi d'une réaction avec du 1,1-bis(2-méthylphényl)-4-bromobutane (**12***c*) conduit à la 1-[4,4-bis(2-méthylphényl)butyl]-3-[2-(4,4-diméthyl-4,5-dihydrooxazolin-2-yl)]-4-phényl-1,4-dihydropyridine (**14**). La réaction du nicotinate de méthyle avec 2,1 équivalents de **12***c* ou du 1,1-bis(2-méthylphényl)-4-bromobut-1-ène (**11***b*) fournit le bromure du 1-[4,4-bis(2-méthylphényl)butyl]pyridinium-3-carboxylate de 4,4-bis(2)-méthylphényl)butyle (**17**) ou le bromure du 1-[4-4-bis(2-méthylphényl)but-3-énYl]pyridinium-3-carboxylate de 4,4-bis(2-méthylphényl)but-3-ényle, respectivement. La réaction non régiosélective des sels de pyridinium (**17/18**) avec le PhMgCl dans le THF, à 23°C, en présence d'une quantité catalytique de CuI conduit à un mélange de produits isomères 4-phényl-1,4-dihydropyridylés (**21** ou **22**) et 6-phényl-1,6-dihydropyridylés (**27** ou **28**) dans un rapport approximativement 1 : 1. Tous les essais d'hydrolyser les portions 4,4-bis(2-méthylphényl)butyles ou but-3-énYles des esters **21/22** ou **27/28** en groupe carboxylique n'ont conduit qu'à des produits de décomposition. Par opposition, l'utilisation de la base non nucléophilique DBU permet de transformer facilement les esters 3-(2-cyanoéthylés) (**23**, **24**, **29**, **30**) en analogues carboxylés correspondants (**25**, **26**, **31**, **32**) par une réaction d'élimination-β d'acrylonitrile. Lors d'essais à des concentrations de 10^{-4} M des composés 4-phényl-1,4-dihydropyridylés (**14**, **25**, **26**) et 6-phényl-1,6-dihydropyridylés (**27/28** ou

31/32), ceux-ci inhibent l'assimilation in vitro du [^{3}H]-«GABA» dans des prismes striataux par des facteurs de 21–44% alors que le médicament de référence, l'acide nopécotique, provoque une inhibition de 87%. Des corrélations structure–activité ont permis de démontrer que le substituant en C-3 du dihydropyridyle est déterminant dans l'assimilation du [^{3}H]-«GABA» et que l'importance de l'activité de ces substituants varie dans l'ordre CO_2H > 2-(4,4-diméthyl-4,5-dihydrooxazon-2-yl) > $CO_2(CH_2)_3CH$-(*o*-tolyl)$_2$ et $CO_2(CH_2)_2CH{=}C$-(*o*-tolyl)$_2$. Les composés comportant des substituants $CO_2(CH_2)_3CH$-(*o*-tolyl)$_2$ en C-3 ou en N-1 sont généralement plus actifs que les analogues possédant des substituants $CO_2(CH_2)_2CH{=}C$-(*o*-tolyl)$_2$. En général, les composés 1,6-dihydropyridylés sont plus actifs que les isomères correspondants 1,4-dihydropyridylés.

Mots clés : 1,4- et 1,6-dihydropyridines, inhibiteurs de l'assimilation de «GABA».

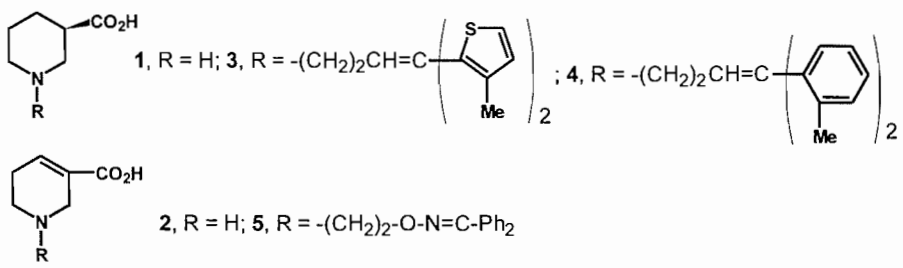
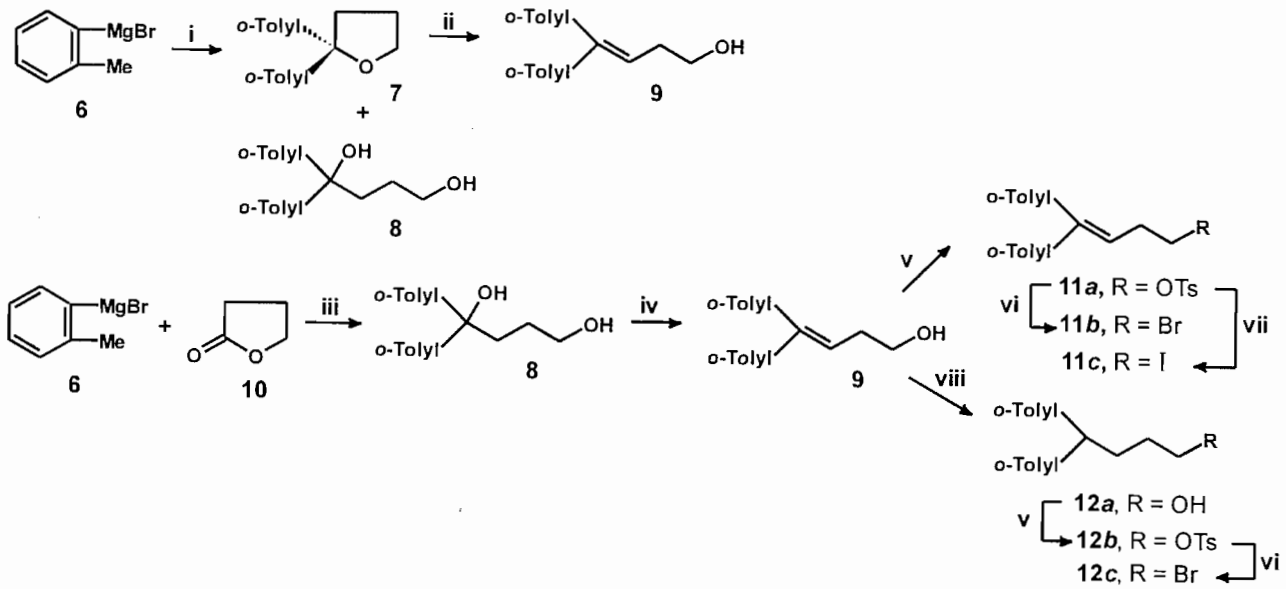
Introduction



γ-Aminobutyric acid (GABA), the major inhibitory neurotransmitter in the central nervous system (CNS) (1), has been estimated to be present in 60–70% of all synapses within the CNS (2). GABA-mediated neurotransmission is terminated by its rapid uptake via specific, high-affinity transporters located in the presynaptic terminal and (or) surrounding glial cells (3). A reduction in GABA neurotransmission has been implicated in the etiology of a variety of neurological disorders including epilepsy, anxiety, and pain (1). One mechanistic approach to elevate GABA neurotransmission in the CNS involves the inhibition of GABA uptake into neurons and glia. Conventional GABA-uptake inhibitors such as the cyclic amino acids nipecotic acid (**1**) and guvacine (**2**), which can be viewed as conformationally restricted analogs, display in vitro activity as GABA-uptake inhibitors. However, **1** and **2** do not readily cross the blood–brain barrier (BBB), presumably due to their hydrophilic nature (4–6), which precludes their therapeutic usefulness. To overcome this problem, lipophilic side chains were attached to the nitrogen atom of nipecotic acid (**1**) and guvacine (**2**). Thus, tiagabine (**3**), the 4,4-bis(2-methylphenyl)-3-butenyl compound (**4**), and NNC-711 (**5**) were found to be potent GABA-uptake inhibitors that possessed in vivo efficacy as anticonvulsant agents (1, 7, 8). Compounds **3** and **4** having a substituent in an "*ortho*" position in one or both aromatic/heteroaromatic groups exhibited the most potent in vitro GABA-uptake inhibition (7). It was anticipated that coupling a lipophilic 4,4-bis(2-methylphenyl)-3-butenyl or 4,4-bis(2-methylphenyl)butyl moiety to the N-1 position of a 3-carboxy-4-phenyl-1,4-dihydropyridyl moiety would provide agents that inhibit GABA uptake into neurons. This postulate was based on the fact that (*i*) 1-alkyl-1,4-dihydronicotinate esters and related nicotinic acid derivatives exhibit potent anticonvulsant activity in the maximal electroshock screen (9, 10), and (*ii*) that a substituent at the C-4 position of nipecotic acid (**1**) possessing a 1-(4-CF_3-C_6H_4)$_2$-$CHOCH_2CH_2$- substituent is tolerated with respect to GABA-uptake inhibition (11). We now report the synthesis of 4,4-bis(2-methylphenyl)-3-butenyl- and 4,4-bis(2-methylphenyl)butyl analogs of 4-phenyl-1,4- and 6-phenyl-1,6-dihydropyridine-3-carboxylates and their evaluation as neuronal GABA-uptake inhibitors.

Chemistry

Our intitial attempt to prepare 1,1-bis(2-methylphenyl)-4-bromo-1-butene (**11***b*) by reaction of *ortho*-tolylmagnesium bromide with ethyl 4-bromobutyrate afforded a mixture of 2,2-bis(2-methylphenyl)tetrahydrofuran (**7**, 14%) and 1,1-bis(2-methylphenyl)-1,4-butanediol (**8**, 10%), which are likely produced by the respective cyclization and hydrolysis of the intermediate product (*ortho*-tolyl)$_2$-$C(OH)(CH_2)_3Br$ as illustrated in Scheme 1. Since the 1,4-butanediol product **8** was readily converted to 1,1-bis(2-methylphenyl)-1-buten-4-ol (**9**, 94%) using HCl, an alternate preparation of 1,1-bis(2-methylphenyl)-1,4-butanediol (**8**) was investigated. Accordingly, reaction of *ortho*-tolylmagnesium bromide with γ-butyrolactone (**10**) afforded **8** (90%), which was readily converted to 1,1-bis(2-methylphenyl)-1-buten-4-ol (**9**, 90%) by acid-catalyzed dehydration using HCl. Elaboration of **9** to the tosylate analog (**11***a*) and subsequent reaction with either LiBr or NaI in acetone afforded the respective 1,1-bis(2-methylphenyl)-4-bromo-1-butene (**11***b*, 88%) or iodide (**11***c*, 85%). Hydrogenation of 1,1-bis(2-methylphenyl)-1-buten-4-ol (**9**) using 10% Pd/C and H_2 gas at 60 psi (1 psi = 6.9 kPa) gave 1,1-bis(2-methylphenyl)-4-hydroxybutane (**12***a*, 94%), which was elaborated to the tosylate analog (**12***b*, 83%) and then to 1,1-bis(2-methylphenyl)-4-bromobutane (**12***c*, 83%).



The reaction of 3-[2-(4,4-dimethyl-4,5-dihydrooxazolin-2-yl)]-4-phenyl-1,4-dihydropyridine (**13**) (12) with NaH in DMSO, followed by reaction with 1,1-bis(2-methylphenyl)-4-bromobutane (**12***c*), afforded the *N*-alkylated product **14** (19%) as illustrated in Scheme 2.

Reaction of methyl nicotinate with 2.1 equivalents of 1,1-

Scheme 1.

Reagents: i, $EtO_2C(CH_2)_3Br$, THF, 0°C → 25°C, 4 h and then aqueous NH_4Cl hydrolysis; ii, 6 N HCl, EtOH, THF, reflux, 4 h; iii, THF, 25°C, 2 h and then aqueous NH_4Cl hydrolysis; iv, 4 N HCl, EtOH, reflux, 6 h; v, 4-Me-C_6H_4-SO_2Cl, pyridine, CH_2Cl_2, 25°C, 12 h and then aqueous NH_4Cl hydrolysis; vi, LiBr, acetone, reflux, 12 h; vii, NaI, acetone, reflux, 12 h; viii, 10% Pd/C, EtOH, H_2 gas, 60 psi, 4 h, 25°C.

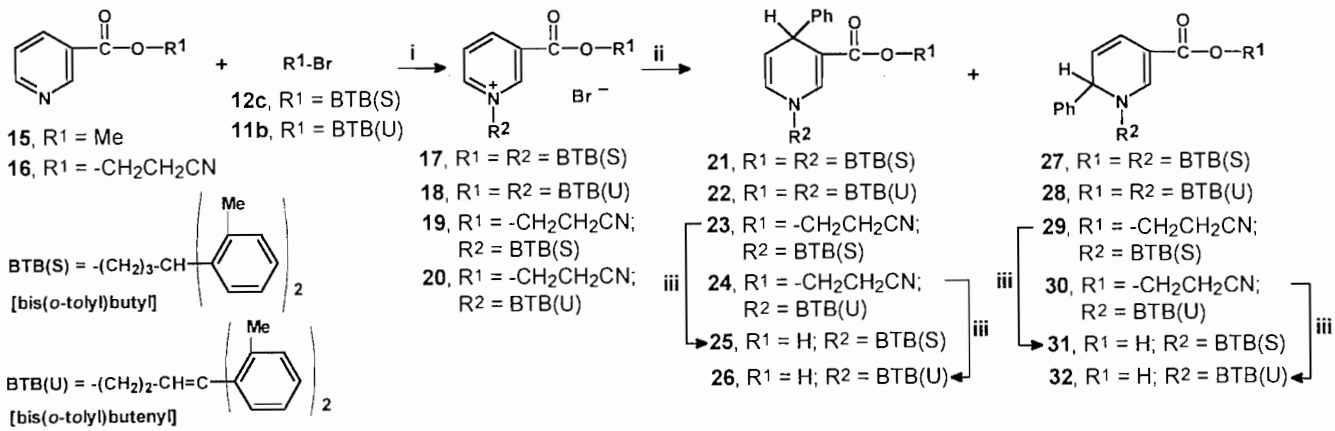
Scheme 2.

Reagents: i, NaH/DMSO, 25°C, 12 h.

bis(2-methylphenyl)-4-bromobutane (**12***c*) afforded the pyridinium salt (**17**, 74%) (see Scheme 3). When 1.1 equivalents of **12***c* were employed, **12***c* was all consumed but a considerable amount of methyl nicotinate remained. Similar results were observed in the synthesis of **18** (67%) using a similar reaction with 1,1-bis(2-methylphenyl)-4-bromo-1-butene (**11***b*). A plausible explanation for the replacement of the methyl R^1 substituent by a 4,4-bis(2-methylphenyl)butyl (**17**) or a 4,4-bis(2-methylphenyl)-3-butenyl (**18**) substituent is shown in Scheme 4. This replacement of the Me R^1 substituent proceeds to completion since the volatile by-product MeBr (bp 4°C) would escape from the reaction mixture (reflux in MeCN for 48 h). No product resulting from replacement of the cyanoethyl moiety of **16** was isolated for similar reactions of **16** with either **11***b* or **12***c*.

The nonregioselective reaction of the pyridinium salts (**17**–**20**) with PhMgCl in THF at −23°C using a catalytic amount of CuI afforded a mixture of isomeric 4-phenyl-1,4-dihydropyridyl and 6-phenyl-1,6-dihydropyridyl products in a ratio of approximately 1:1 (**17** → **21** (22%) + **27** (18%); **18** → **22** (24%) + **28** (19%); **19** → **23** (22%) + **29** (20%); **20** → **24** (20%) + **30** (21%)). No product resulting from reaction of the Grignard reagent with the methyl ester moiety was detected. Comins et al. (13) observed that the CuI-catalyzed reaction of methyl nicotinate with phenyl chloroformate in THF – methyl sulfide (3 equiv.) at −20°C resulted in regioselective attack at C-4 (1,4-dihydropyridine : 1,6-dihydropyridine = 95:5).

All attempts to hydrolyze the 4,4-bis(2-methylphenyl)butyl (**21**, **27**), or 4,4-bis(2-methylphenyl)-3-butenyl (**22**, **28**), ester moiety to the corresponding acid using ethanolic NaOH or LiOH were unsuccessful since only decomposition products were produced. In contrast, the cyanoethyl esters were readily converted to the carboxyl analog using the non-nucleophilic base 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU), which proceeds via a β-elimination reaction of acrylonitrile (14) (**23** → **25** (70%); **24** → **26** (56%); **29** → **31** (62%); **30** → **32** (50%)). 2-Cyanoethyl nicotinate (**16**), required for the preparation of the pyridinium salts (**19**, **20**), was prepared by the condensation of nicotinoyl chloride with 2-cyanoethanol in the presence of Et_3N (85%).



Biological evaluation as GABA-uptake inhibitors

The 1,4-dihydropyridyl (DHP) (**21**–**26**) and 1,6-dihydropyridyl (**27**–**32**) ring systems possess conformational and steric features that are distinctly different from those present in nipecotic acid (**1**), which exists in a chair conformation. Hoffman

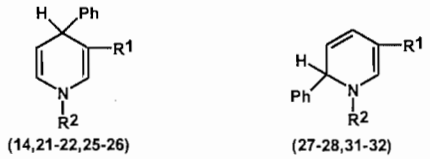
Scheme 3.

Reagents: i, dry MeCN, reflux, 48 h; ii, dry THF, CuI, PhMgCl, −23°C, 30 min; iii, 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU), MeOH, 25°C, 14 h.

Scheme 4.

and Cimeraglia (15) reported, based on ab initio STO-3G calculations for 4-phenyl-3,5-dicarboxy-1,4-dihydropyridine, that the boat conformation of the 1,4-dihydropyridine ring is favored over a planar ring arrangement, that ring distortion was greater at C-4 than at N-1, and that the C-4 phenyl substituent on the 1,4-DHP ring having a pseudoaxial orientation relative to the plane of the olefinic bonds was unequivocally favored (16). Related theoretical calculations indicated that 1,4-dihydronicotinamide (17) and 1,4-DHP calcium channel antagonists (18) also exist in a boat conformation. The 1,6-DHP ring system is less puckered that the boat-shaped 1,4-DHP ring system, or the chair-shaped piperidine ring system. While the diene (C=C-C=C) moiety of the 1,6-DHP ring system is quasi-planar, there is distortion at the C-6 and N-1 positions. These differences, together with the steric effects due to the ester, N-1, and the 1,4-DHP C-4 and 1,6-DHP C-6, substituents (**21–32**) are expected to alter the overall volume of the molecule, the in vivo biodistribution of the drug between hydrophobic and hydrophilic tissues, and their affinity for a brain GABA transporter(s) (19).

All of the compounds evaluated in the in vitro [^{3}H]GABA-uptake inhibition striatal tissue assay, except for **21** and **22**, which were inactive, inhibited uptake in the 21–44% range, relative to the reference drug nipecotic acid (87% inhibition), at a test compound concentration of 10^{-4} M (see Table 1). All compounds (**14**, **21/22**, **25/28**, and **31/32**) were inactive inhibitors at a test compound concentration of 10^{-5} M relative to nipecotic acid (48% inhibition). Although the differences in percent inhibition of [^{3}H]GABA uptake were sometimes small, some structure–activity correlations are evident. In the 1,4-DHP series of compounds the C-3 R^1 substituent was a determinant of activity where the relative potency order was CO_2H (**25**) > 4,4-dimethyl-4,5-dihydrooxazolin-2-yl) (**14**) > CO_2BTB(S) (**21**, inactive), and CO_2H (**26**) > CO_2BTB(U) (**22**, inactive). These results indicate the 2-(4,4-dimethyl-4,5-dihydrooxazolin-2-yl) ring system (**14**) is a bioisostere of a carboxyl group (**25**) with respect to [^{3}H]GABA-uptake inhibition. A similar activity profile was observed in the 1,6-DHP series of compounds where CO_2H (**31**) ≥ CO_2BTB(S) (**27**) and CO_2H (**32**) > CO_2BTB(U) (**28**). A comparison of compounds having C-3 and (or) N-1 CO_2BTB(S) and CO_2BTB(U) substituents indicated that the relative activity order was generally CO_2BTB(S) > CO_2BTB(U) (**26** > **25** and **27** > **28**), although **31** and **32** were equipotent. In general, the relative potency order was 1,6-DHP > 1,4-DHP (**27** > **21** (inactive), **28** > **22** (inactive), **32** > **26** and **31** ≈ **25**). Although this class of 1,4- and 1,6-DHP compounds are less effective in vitro inhibitors of [^{3}H]GABA uptake than the hydrophilic cyclic amino acid nipecotic acid, which does not readily cross the blood–brain barrier, their enhanced lipohilicity, and potentially more favorable brain uptake, could result in a greater inhibition of neuronal GABA uptake in vivo, and hence therapeutic efficacy.



The stability of the 1,4- (**14**, **21/22**, **25/26**) and 1,6- (**27/28**, **31/32**) dihydropyridine analogs during the in vitro [^{3}H]GABA-uptake inhibition assay in striatal tissue was not determined. These 1,4- and 1,6-dihydropyridine analogs could undergo partial oxidation to an inactive pyridinium species (20, 21), whereas the 1,4-dihydropyridine analogs could undergo hydration to yield the corresponding 6-hydroxy-1,4,5,6-tetrahydropyridine analog (20, 22), which may also conceivably act as a GABA-uptake inhibitor. The 4- or 6-

Table 1. In vitro inhibition of [^{3}H]GABA uptake in striatal tissue by 1,4- (**14**, **21/22**, **25/26**) and 1,6- (**27/28**, **31/32**) dihydropyridine analogs.

Compound	R^1	R^2	% Inhibition, 10^{-4} M[a]
14	-Ox	BTB(S)	34.6 ± 6.7 (4)
21	-CO_2BTB(S)	BTB(S)	Inactive (4)
22	-CO_2BTB(U)	BTB(U)	Inactive (4)
25	-CO_2H	BTB(S)	44.1 ± 3.3 (5)
26	-CO_2H	BTB(U)	27.2 ± 7.0 (5)
27	-CO_2BTB(S)	BTB(S)	31.4 ± 1.8 (4)
28	-CO_2BTB(U)	BTB(U)	21.1 ± 10.6 (4)
31	-CO_2H	BTB(S)	38.8 ± 7.8 (5)
32	-CO_2H	BTB(U)	40.4 ± 3.0 (5)
Nipecotic acid[b]			87.1 ± 1.6 (11)

[a]The result is presented as the mean ± S.E.M. with the number of experiments shown in parentheses.

[b]At a concentration of 10^{-5} M, nipecotic acid inhibited [^{3}H]GABA uptake by 48.5 ± 6.1% (n = 5).

phenyl substituent is expected to alter the redox potential of these dihydropyridine compounds. The longer N substituents (BTB(S), BTB(U)) are expected to decrease the oxidation rate, which is potentially attributed to steric crowding and a lower degree of solvation for lipophilic derivatives (21). On the basis of previous in vitro and in vivo studies for 3-[2-[[(1-methyl-1,4-dihydropyrid-3-yl)carbonyl]oxy]-ethyl] 5-methyl 1,4-dihydro-2,6-dimethyl-4-(2,3-dichlorophenyl)-3,5-pyridinedicarboxylate (23), it is not expected that oxidative and (or) hydration transformations had a significant effect under the incubation conditions employed in the in vitro [^{3}H]GABA-uptake inhibition assay.

Experimental

Melting points were determined using a Buchi capilliary apparatus and are uncorrected. Nuclear magnetic resonance spectra (^{1}H NMR, ^{13}C NMR) were determined on a Bruker AM-300 spectrometer. The assignment of exchangeable protons (O*H*, N*H*) was confirmed by the addition of D_2O. ^{13}C NMR spectra were acquired using the *J* modulated spin echo technique where methyl and methine carbon resonances appear as positive peaks, and methylene and quaternary carbon resonances appear as negative peaks. High-resolution electron impact (EI) mass spectra were determined using an AEI-MS-50 mass spectrometer. Infrared (IR) spectra were acquired using a Nicolet 550 Series II Magna FT-IR spectrometer. Silica gel column chromatography was carried out using Merck 7734 silica gel (60–200 mesh). 3-[2-(4,4-Dimethyl-4,5-dihydrooxazolin-2-yl)]-4-phenyl-1,4-dihydropyridine (**13**) was prepared using a literature procedure (12). γ-Butyrolactone was purchased from the Aldrich Co. [^{3}H]GABA (specific activity 36.8 Ci/mmol) was purchased from New England Nuclear.

2,2-Bis(2-methylphenyl)tetrahydrofuran (7) and 1,1-bis(2-methylphenyl)-1,4-butanediol (8, Method A)

A solution of *o*-tolylmagnesium chloride in THF (0.1 mol, 100 mL of 1 M) was added dropwise to a solution of ethyl 4-bromobutyrate (9.75 g, 50 mmol) in THF (150 mL) at 0°C with stirring. The reaction was allowed to proceed at 25°C for 4 h, the reaction mixture was cooled to 0°C, and a saturated aqueous solution of NH_4Cl (100 mL) was added. The aqueous fraction was extracted with EtOAc (3 × 100 mL), the combined organic solutions were washed with brine (100 mL), and the organic solution was dried ($MgSO_4$). Removal of the solvent in vacuo gave a residue that was purified by silica gel flash chromatography. Elution with EtOAc–hexane (1:49, v/v) afforded **7** (1.76 g, 14%). Continued elution with EtOAc–hexane (2:3, v/v) gave **8** (1.35 g, 10%).

Fraction 1 (7): mp 120–121°C (recrystallized from hexane); ^{1}H NMR ($CDCl_3$) δ: 1.97 (s, 6H, tolyl *Me*'s), 2.04 (m, 2H, tetrahydrofuranyl H-4), 2.60 (t, J = 7.2 Hz, 2H, tetrahydrofuranyl H-3), 4.04 (t, J = 7.2 Hz, 2H, tetrahydrofuranyl H-5), 7.03 (dd,

J = 6.8, J = 1.7 Hz, 2H, tolyl H-3), 7.17 (m, 4H, tolyl H-4, H-5), 7.63 (dd, J = 7.2, J = 1.8 Hz, 2H, tolyl H-6); ^{13}C NMR ($CDCl_3$) δ: 21.5, 25.7, 36.3, 67.4, 88.7, 124.9, 126.7, 127.0, 132.1, 136.2, 143.1. Anal. calcd. for $C_{18}H_{20}O$: C 85.67, H 7.99; found: C 85.30, H 7.90.

*Fraction 2 (**8**)*: mp 161–163°C (recrystallized from EtOAc); ^{1}H NMR (CD_3COCD_3) δ: 1.47 (m, 2H, CH_2CH_2OH), 1.86 (s, 6H, tolyl *Me*'s), 2.44 (m, 2H, C(OH)CH_2), 2.86 and 2.89 (two s, 1H each, O*H*'s), 3.52 (m, 2H, CH_2OH), 6.98 (d, J = 7.2 Hz, 2H, tolyl H-3), 7.14 (m, 4H, tolyl H-4, H-5), 7.73 (dd, J = 7.6, J = 1.0 Hz, 2H, tolyl H-6); ^{13}C NMR (CD_3COCD_3) δ: 21.6, 28.2, 37.9, 62.9, 78.0, 125.6, 127.4, 128.0, 132.6, 136.9, 145.7. Anal. calcd. for $C_{18}H_{22}O_2$: C 79.96, H 8.20; found: C 79.73, H 8.28.

1,1-Bis(2-methylphenyl)-1-buten-4-ol (9, Method A)
A solution of **7** (1.25 g, 5 mmol) in THF (5 mL), EtOH (5 mL), and 6 N HCl (5 mL) was refluxed for 4 h; the reaction mixture was cooled to 25°C, and extracted with EtOAc (3 × 50 mL). The combined organic fractions were washed with brine (40 mL) and dried ($MgSO_4$). Removal of the solvent in vacuo gave a residue that was purified by silica gel flash chromatography using EtOAc–hexane (1:4, v/v) as eluant to yield **9** as an oil (1.18 g, 94%); ^{1}H NMR ($CDCl_3$) δ: 2.07 (m, 1H, O*H*), 2.14 and 2.31 (two s, 3H each, tolyl *Me*'s), 2.35 (m, 2H, CH_2CH_2OH), 3.70 (t, J = 6.7 Hz, 2H, CH_2OH), 5.83 (t, J = 7.2 Hz, 1H, C═C*H*), 7.10–7.25 (m, 8H, tolyl H-3, H-4, H-5, H-6).

1,1-Bis(2-methylphenyl)-1,4-butanediol (8, Method B)
A solution of **6** in THF (110 mL of a 1 M solution, 0.11 mol) was added to a solution of γ-butyrolactone (4.3 g, 50 mmol) in THF (150 mL) at 0°C with stirring, and the reaction was allowed to proceed at 25°C for 2 h. The reaction mixture was cooled to 0°C, saturated aqueous NH_4Cl (100 mL) was added, and the aqueous fraction was extracted with EtOAc (3 × 100 mL). The combined organic fractions were washed with brine (50 mL), the organic solution was dried ($MgSO_4$), and the solvent was removed in vacuo. Purification of the residue obtained by silica gel flash column chromatography using EtOAc–hexane (2:3, v/v) as eluant afforded **8** (12.15 g, 90%), which was identical (mp, ^{1}H NMR) to **8** prepared according to Method A. Product **8**, required for all subsequent reactions, was prepared according to Method B.

1,1-Bis(2-methylphenyl)-1-buten-4-ol (9, Method B)
A solution of **8** (8.1 g, 30 mmol, from Method B) in EtOH (30 mL) and 4 N HCl (30 mL) was heated at reflux for 6 h; the reaction mixture was cooled to 25°C, and extracted with EtOAc (3 × 100 mL). The combined organic extracts were washed with brine (60 mL), the organic fraction was dried ($MgSO_4$), and the solvent was removed in vacuo. Purification of the residue by silica gel flash column chromatography using EtOAc–hexane (1:4, v/v) as eluant yielded **9** as an oil (6.8 g, 90%), which was identical to **9** prepared according to Method A).

1,1-Bis(2-methylphenyl)-4-(4-methylbenzenesulfonyloxy)-1-butene (11*a*)
p-Toluensulfonyl chloride (9.5 g, 50 mmol) was added to a solution of **9** (6.3 g, 25 mmol) in pyridine (4.75 g, 60 mmol) and CH_2Cl_2 (100 mL) at 0°C with stirring, and the reaction was allowed to proceed at 25°C for 12 h. Saturated aqueous NH_4Cl (100 mL) was added, the mixture was extracted with EtOAc (3 × 100 mL), the combined organic extracts were washed with brine (2 × 50 mL), and the organic fraction was dried ($MgSO_4$). Removal of the solvent in vacuo gave a residue that was purified by silica gel column chromatography using EtOAc–hexane (1:9, v/v) as eluant to give **11*a*** (9.2 g, 92%); ^{1}H NMR ($CDCl_3$) δ: 2.03 (s, 3H, tosyl *Me*), 2.10 and 2.28 (two s, 3H each, tolyl *Me*'s), 2.39 (m, 2H, butenyl H-3), 4.12 (t, J = 6.7 Hz, 2H, CH_2OTs), 5.76 (t, J = 7.2 Hz, 1H, C═C*H*), 7.05–7.20 (m, 12H, phenyl hydrogens). Product **11*a*** was used immediately in subsequent reactions for the preparation of **11*b*** and **11*c***.

1,1-Bis(2-methylphenyl)-4-bromo-1-butene (11*b*)
A mixture of **11*a*** (4.1 g, 10 mmol) and LiBr (3.48 g, 40 mmol) in acetone (80 mL) was refluxed for 12 h; the reaction mixture was cooled to 25°C, and then poured onto saturated aqueous NH_4Cl (50 mL). Extraction with EtOAc (3 × 50 mL), washing the combined EtOAc extracts with brine (50 mL), drying the EtOAc fraction ($MgSO_4$), and removal of the solvent in vacuo gave a residue. Purification by silica gel column chromatography using EtOAc–hexane (1:99, v/v) as eluant yielded **11*b*** (2.77 g, 88%); ^{1}H NMR ($CDCl_3$) δ: 2.19 and 2.40 (two s, 3H each, tolyl *Me*'s), 2.70 (m, 2H, butenyl H-3), 3.49 (t, J = 6.7 Hz, 2H, CH_2Br), 5.87 (t, J = 7.1 Hz, 1H, C═C*H*), 7.15–7.30 (m, 8H, phenyl hydrogens); ^{13}C NMR ($CDCl_3$) δ: 19.9, 21.1, 32.5, 32.7, 125.3, 125.5, 126.8, 127.2, 129.8, 130.3, 130.8, 135.4, 136.1, 139.5, 141.8, 143.0. Product **11*b*** was used immediately in subsequent reactions.

1,1-Bis(2-methylphenyl)-4-iodo-1-butene (11*c*)
A mixture of **11*a*** (4.1 g, 10 mmol) and NaI (3.0 g, 20 mmol) in acetone (80 mL) was refluxed for 12 h, the reaction was completed, and the product purified according to the procedure described for the preparation of **11*b*** above, to yield **11*c*** (3.08 g, 85%); ^{1}H NMR ($CDCl_3$) δ: 2.12 and 2.32 (two s, 3H each, tolyl *Me*'s), 2.65 (m, 2H, butenyl H-3), 3.20 (t, J = 6.9 Hz, 2H, CH_2I), 5.75 (t, J = 7.1 Hz, 1H, C═C*H*), 7.10–7.25 (m, 8H, phenyl hydrogens).

1,1-Bis(2-methylphenyl)-4-hydroxybutane (12*a*)
10% Palladium-on-charcoal (800 mg) was added to a solution of **9** (8.0 g, 31.7 mmol) in ethanol (40 mL) and the mixture was agitated at 25°C for 4 h under hydrogen gas at 60 psi. The reaction mixture was filtered, the solvent was removed in vacuo, and the residue was purified by silica gel column chromatography using EtOAc–hexane (1:4, v/v) as eluant to yield **12*a*** as an oil (7.6 g, 95%); IR (film): 3360 (OH) cm^{-1}; ^{1}H NMR ($CDCl_3$) δ: 1.60–1.70 (m, 2H, $CH_2CH_2CH_2$), 2.0–2.08 (m, 2H, $CH_2CH_2CH_2OH$), 2.31 (s, 6H, tolyl *Me*'s), 3.67 (t, J = 7.0 Hz, 2H, OCH_2), 4.29 (t, J = 7.0 Hz, 1H, $CHCH_2$), 7.08–7.20 (m, 8H, phenyl hydrogens). Product **12*a*** was used immediately in the subsequent reaction.

1,1-Bis(2-methylphenyl)-4-(4-methylbenzensulfonyloxy)-butane (12*b*)
p-Toluenesulfonyl chloride (9.5 g, 50 mmol) was added to a solution of **12*a*** (6.35 g, 25 mmol) in pyridine (4.75 g, 60 mmol) and CH_2Cl_2 (100 mL) at 0°C with stirring. The reaction

For personal use only.

was allowed to proceed at 25°C for 12 h and the reaction mixture was poured onto a solution of saturated aqueous NH_4Cl (100 mL). Extraction with EtOAc (3 × 100 mL), washing the combined extracts with brine (50 mL), drying the organic fraction ($MgSO_4$), and removal of the solvent in vacuo gave a residue. Purification by silica gel column chromatography using EtOAc–hexane as eluant (1:9, v/v) gave **12***b* (9.0 g, 83%) as a solid; mp 103°C (recrystallized from EtOAc–hexane); ^{1}H NMR ($CDCl_3$) δ: 1.66–1.76 (m, 2H, CH_2CH_2OH), 1.92–2.0 (m, 2H, $CHCH_2CH_2$), 2.26 (s, 6H, tolyl *Me*'s), 2.46 (s, 3H, *p*-tosyl *Me*), 4.05 (t, *J* = 7.0 Hz, 2H, OCH_2), 4.21 (t, *J* = 7.0 Hz, 1H, $CHCH_2$), 7.06–7.16 (m, 8H, *o*-tolyl ring hydrogens), 7.34 and 7.79 (two d, *J* = 8.0 Hz, 2H each, tosyl ring hydrogens). Product **12***b* was used immediately in the subsequent reaction.

1,1-Bis(2-methylphenyl)-4-bromobutane (12*c*)

A mixture of **12***b* (4.08 g, 10 mmol) and LiBr (3.41 g, 40 mmol) in acetone (80 mL) was refluxed for 12h. The reaction mixture was cooled to 25°C, and the mixture was poured onto an aqueous solution of saturated NH_4Cl (50 mL). Extraction with EtOAc (3 × 50 mL), drying the EtOAc extract ($MgSO_4$), and removal of the solvent in vacuo gave a residue. Purification by silica gel column chromatography using EtOAc–hexane (1:99, v/v) as eluant afforded **12***c* as an oil (2.8 g, 83%); ^{1}H NMR ($CDCl_3$) δ: 1.90–2.01 (m, 2H, CH_2CH_2Br), 2.08–2.16 (m, 2H, $CHCH_2$), 2.30 (s, 6H, *o*-tolyl *Me*'s), 3.44 (t, *J* = 7.0 Hz, 2H, CH_2Br), 4.29 (t, *J* = 7.0 Hz, 1H, $CHCH_2$), 7.10–7.22 (m, 8H, phenyl hydrogens).

1-[4,4-Bis(2-methylphenyl)butyl]-3-[2-(4,4-dimethyl-4,5-dihydrooxazolin-2-yl)]-4-phenyl-1,4-dihydropyridine (14)

Sodium hydride (100 mg, 3.26 mmol, 80% suspension in mineral oil) was washed with dry hexane and dried under a nitrogen atmosphere prior to addition of DMSO (5 mL). A solution of **13** (1.37 g, 2.8 mmol) in DMSO (30 mL) was added dropwise at 25°C during 30 min under a nitrogen atmosphere with stirring. The reaction mixture was maintained at 50°C for 30 min, and then at 25°C for 1.5 h at which time no further evolution of hydrogen gas was observed. A solution of **12***c* (0.88 g, 2.8 mmol) in DMSO (2 mL) was added during a 10 min period, and the reaction was allowed to proceed at 25°C for 12 h. Excess DMSO was partially removed in vacuo, the reaction mixture was poured onto ice-water (5 mL), extracted with ether (3 × 100 mL), the ether extract was dried (Na_2SO_4), and the solvent was removed in vacuo to give a residue. Purification by silica gel column chromatography using EtOAc–hexane (1:1, v/v) as eluant gave **14** as an oil (0.5 g, 19%); IR (film): 1589, 1491, 1458 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ: 1.12 and 1.26 (two s, 3H each, oxazolinyl *Me*'s), 1.60–1.80 (m, 2H, $CHCH_2CH_2$), 1.90–2.10 (m, 2H, $CHCH_2$), 2.30 and 2.32 (two s, 3H each, tolyl *Me*'s), 3.24 (t, *J* = 7.0 Hz, 2H, NCH_2), 3.82 (m, 2H, OCH_2), 4.27 (t, *J* = 7.0 Hz, 1H, $CHCH_2$), 4.68 (d, $J_{4,5}$ = 5.0 Hz, 1H, H-4), 4.88 (dd, $J_{5,6}$ = 8.0, $J_{4,5}$ = 5.0 Hz, 1H, H-5), 5.92 (d, $J_{5,6}$ = 8.0 Hz, 1H, H-6), 6.98 (s, 1H, H-2), 7.10–7.40 (m, 13H, phenyl hydrogens). Anal. calcd. for $C_{34}H_{38}N_2O\cdot 1H_2O$: C 80.27, H 7.92, N 5.50; found: C 79.92, H 8.10, N 5.13.

4,4-Bis(2-methylphenyl)butyl 1-[4,4-bis(2-methylphenyl)-butyl]pyridinium-3-carboxylate bromide (17)

A mixture of methyl nicotinate (137 mg, 1.0 mmol) and **12***c* (350 mg, 1.1 mmol) in dry MeCN (20 mL) was refluxed for 24 h. TLC analysis indicated that **12***c* was all consumed, but a considerable amount of methyl nicotinate was still present. Additional **12***c* (317 mg, 1 mmol) was added and the reaction was continued at reflux for 24 h at which time TLC showed the reaction was nearly complete. After cooling to 25°C, the solid product was filtered, washed with ether, and dried (Na_2SO_4) to afford **17** (0.5 g, 74%); mp 80°C; IR (KBr): 1737, 1638 cm^{-1}; ^{1}H NMR (DMSO-d_6) δ: 1.72–2.10 (m, 8H, $-CH_2CH_2CH-$), 2.21 and 2.23 (two s, 6H each, tolyl *Me*'s), 4.20–4.30 (m, 2H, CH_2CH), 4.41 (t, *J* = 7.0 Hz, 2H, OCH_2), 4.66–4.78 (m, 2H, NCH_2), 7.04–7.24 (m, 16H, phenyl hydrogens), 8.26 (dd, $J_{4,5}$ = 8.0 Hz, $J_{5,6}$ = 6.0 Hz, 1H, H-5), 8.96 (d, $J_{4,5}$ = 8.0 Hz, 1H, H-4), 9.30 (d, $J_{5,6}$ = 6.0 Hz, 1H, H-6), 9.58 (s, 1H, H-2). The pyridinium salts **18** (from reaction of **15** with 2.1 equivalents of **11***b*), **19** (from reaction of **16** with 1.1 equivalents of **12***c*) and **20** (from reaction of **16** with 1.1 equivalents of **11***b*) were prepared using a similar procedure.

4,4-Bis(2-methylphenyl)-3-butenyl 1-[4,4-bis(2-methylphenyl)-3-butenyl]pyridinium-3-carboxylate bromide (18)

Yield: 67%; mp 75°C; IR (KBr): 1738, 1639, 1490 cm^{-1}; ^{1}H NMR (DMSO-d_6) δ: 1.86, 2.0, 2.06, and 2.22 (four s, 3H each, tolyl *Me*'s), 2.42–2.58 and 2.60–2.78 (two m, 2H each, OCH_2CH_2, NCH_2CH_2), 4.48 (t, *J* = 7.0 Hz, 2H, OCH_2), 4.82–4.90 (m, 2H, NCH_2), 5.92–5.94 (m, 1H, $CH{=}C$), 6.54 (t, *J* = 7.0 Hz, 1H, $CH{=}C$), 6.92–7.30 (m, 16H, phenyl hydrogens), 8.30 (dd, $J_{4,5}$ = 8.0, $J_{5,6}$ = 6.0 Hz, 1H, H-5), 8.98 (d, $J_{4,5}$ = 8.0 Hz, 1H, H-4), 9.29 (d, $J_{5,6}$ = 6.0 Hz, 1H, H-6), 9.56 (s, 1H, H-2).

2-Cyanoethyl 1-[4,4-bis(2-methylphenyl)butyl]pyridinium-3-carboxylate bromide (19)

Yield: 72%; mp 180–183°C; IR (KBr): 2253 (CN), 1737, 1638 cm^{-1}; ^{1}H NMR (DMSO-d_6) δ: 1.90–2.04 (m, 4H, $CH_2CH_2CH_2CH$), 2.24 (s, 6H, tolyl *Me*'s), 3.11 (t, *J* = 6.0 Hz, 2H, CH_2CN), 4.25 (t, *J* = 7.0 Hz, 1H, CH_2CH), 4.60 (t, *J* = 6.0 Hz, 2H, OCH_2), 4.72–4.82 (m, 2H, NCH_2), 7.06–7.20 (m, 8H, phenyl hydrogens), 8.32 (dd, $J_{4,5}$ = 8.0, $J_{5,6}$ = 6.0 Hz, 1H, H-5), 8.98 (d, $J_{4,5}$ = 8.0 Hz, 1H, H-4), 9.34 (d, $J_{5,6}$ = 6.0 Hz, 1H, H-6), 9.66 (s, 1H, H-2).

2-Cyanoethyl 1-[4,4-bis(2-methylphenyl)-3-butenyl]pyridinium-3-carboxylate bromide (20)

Yield: 60%; mp 75–79°C; IR (KBr): 2250 (CN), 1740 (CO_2); ^{1}H NMR (DMSO-d_6) δ: 1.90 and 2.04 (two s, 3H each, tolyl *Me*'s), 2.64–2.76 (m, 2H, CH_2CH_2CH), 3.10 (t, *J* = 6.0 Hz, 2H, CH_2CN), 4.60 (t, *J* = 6.0 Hz, 2H, OCH_2), 4.88 (t, *J* = 7.0 Hz, 2H, NCH_2), 5.86 (t, *J* = 7.0 Hz, 1H, $CH_2{=}CH$), 6.92–7.20 (m, 8H, phenyl hydrogens), 8.32 (dd, $J_{4,5}$ = 8.0, $J_{5,6}$ = 6.0 Hz, 1H, H-5), 9.0 (d, $J_{4,5}$ = 8.0 Hz, 1H, H-4), 9.32 (d, $J_{5,6}$ = 6.0 Hz, 1H, H-6), 9.61 (s, 1H, H-2).

2-Cyanoethyl nicotinate (16)

A solution of 2-cyanoethanol (0.71 g, 10 mmol) in dry CH_2Cl_2 (5 mL) was added, during 10 min with stirring, to a solution of nicotinoyl chloride (1.78 g, 10 mmol) in dry CH_2Cl_2 (20 mL) at 0°C under a nitrogen atmosphere. The reaction was allowed to proceed at 0°C for 30 min and then at 25°C for 14 h. Water (20 mL) was added, the mixture was extracted with EtOAc (3 × 50 mL), the EtOAc extracts were washed with brine (2 × 50

For personal use only.

mL), and the EtOAc solution was dried (Na_2SO_4). Removal of the solvent in vacuo gave a residue that was purified by silica gel column chromatography using EtOAc–hexane (1:4, v/v) as eluant to yield **16** (1.5 g, 85%) as an oil; IR (film): 2253 (CN), 1728 (CO_2) cm^{-1}; ^1H NMR ($CDCl_3$) δ: 2.88 (t, J = 6.0 Hz, 2H, CH_2CN), 4.58 (t, J = 6.0 Hz, 2H, OCH_2), 7.44 (dd, $J_{4,5}$ = 8.0, $J_{5,6}$ = 6.0 Hz, 1H, H-5), 8.32 (dt, $J_{4,5}$ = 8.0, $J_{4,6}$ = $J_{2,4}$ = 2.0 Hz, 1H, H-4), 8.85 (dd, $J_{5,6}$ = 6.0, $J_{4,6}$ = 2.0 Hz, 1H, H-6), 9.26 (d, $J_{2,4}$ = 2.0 Hz, 1H, H-2).

4,4-Bis(2-methylphenyl)butyl 1-[4,4-bis(2-methylphenyl)-butyl]-4-phenyl-1,4-dihydropyridine-3-carboxylate (21) and 4,4-bis(2-methylphenyl)butyl 1-[4,4-bis(2-methylphenyl)butyl]-6-phenyl-1,6-dihydropyridine-3-carboxylate (27). General method for the synthesis of 1,2- and 1,6-dihydropyridines

A solution of the pyridinium salt **17** (0.675 g, 1 mmol) in dry THF (20 mL) and CuI (35 mg) was stirred under a nitrogen atmosphere until a homogeneous solution was obtained. This solution was cooled to −23°C (Dry Ice – CCl_4 bath), PhMgCl (0.6 mL of a 2 M solution in THF, 1.2 mmol) was added dropwise with stirring, and the reaction mixture was maintained at −23°C for 30 min prior to warming to 25°C. Quenching the reaction with saturated aqueous NH_4Cl (5 mL), extraction with EtOAc (3 × 30 mL), washing the combined EtOAc extracts with brine (2 × 30 mL), drying the EtOAc solution ($MgSO_4$), and removal of the solvent in vacuo afforded a residue. Purification of the residue by silica gel column chromatography using EtOAc–hexane (3:7, v/v) as eluant gave **21** as an amorphous solid. Continued elution afforded **27** as an oil. Attempts to recrystallize **21** and **27** resulted in partial decomposition. Compounds **22** (amorphous solid) and **28** (oil), **23** (oil) and **29** (oil), **24** (oil) and **30** (oil) were also prepared using this general procedure (same molar quantities of reactants).

*Product **21***: (150 mg, 22%); mp 48°C; IR (KBr): 1687, 1589 cm^{-1}; ^1H NMR ($CDCl_3$) δ: 1.52–1.64, 1.66–1.72, 1.80–1.90, and 1.96–2.06 (four m, 2H each, $OCH_2CH_2CH_2CH$, $NCH_2CH_2CH_2CH$), 2.25, 2.26, 2.30, and 2.32 (four s, 3H each, tolyl *Me*'s), 3.26 (t, J = 7.0 Hz, 2H, NCH_2), 3.93–4.09 (m, 2H, OCH_2), 4.18 and 4.27 (two t, J = 7.0 Hz, 1H each, CH_2CH), 4.52 (d, $J_{4,5}$ = 4.5 Hz, 1H, H-4), 4.90 (dd, $J_{5,6}$ = 8.0, $J_{4,5}$ = 4.5 Hz, 1H, H-5), 5.85 (d, $J_{5,6}$ = 8.0 Hz, 1H, H-6), 7.05–7.15 (m, 22H, H-2, phenyl hydrogens). Exact Mass calcd. for $C_{48}H_{51}NO_2$: 673.3919; found: 673.3904.

*Product **27***: (120 mg, 18%); IR (film): 1687, 1589 cm^{-1}; ^1H NMR (DMSO-d_6) δ: 1.42–1.64 and 1.96–2.0 (two m, 4H each, $OCH_2CH_2CH_2CH$, $NCH_2CH_2CH_2CH$), 2.18 and 2.20 (two s, 3H each, tolyl *Me*'s), 2.22 (s, 6H, tolyl *Me*'s), 3.3–3.4 (m, 2H, NCH_2), 4.04 (t, J = 7.0 Hz, 2H, OCH_2), 4.18 and 4.25 (two t, J = 7.0 Hz, 1H each, CH_2CH), 5.08 (dd, $J_{4,5}$ = 9.5, $J_{5,6}$ = 5.0 Hz, 1H, H-5), 5.18 (d, $J_{5,6}$ = 5.0 Hz, 1H, H-6), 6.24 (d, $J_{4,5}$ = 9.5 Hz, 1H, H-4), 7.07–7.40 (m, 21H, phenyl hydrogens), 7.48 (s, 1H, H-2). Exact Mass calcd. for $C_{48}H_{51}NO_2$: 673.3919; found: 673.3907.

4,4-Bis(2-methylphenyl)-3-butenyl 1-[4,4-bis(2-methylphenyl)-3-butenyl]-4-phenyl-1,4-dihydropyridine-3-carboxylate (22)

Yield: 165 mg, 24%; mp 35°C; IR (KBr): 1687, 1589 cm^{-1}; ^1H NMR ($CDCl_3$) δ: 2.09, 2.10, 2.21, and 2.24 (four s, 3H each, tolyl *Me*'s), 2.22–2.40 (m, 4H, $CH_2CH{=}C$), 3.31 (t, J = 7.0 Hz, 2H, NCH_2), 4.04 (t, J = 7.0 Hz, 2H, OCH_2), 4.50 (d, $J_{4,5}$ = 4.5 Hz, 1H, H-4), 4.86 (dd, $J_{5,6}$ = 8.0, $J_{4,5}$ = 4.5 Hz, 1H, H-5), 5.64 (t, J = 7.0 Hz, 1H, $CH_2CH{=}C$), 5.72–5.80 (m, 2H, $CH_2CH{=}C$, H-6), 7.02–7.30 (m, 22H, H-2, phenyl hydrogens). Exact Mass calcd. for $C_{48}H_{47}NO_2$: 669.3607; found: 669.3606.

4,4-Bis(2-methylphenyl)-3-butenyl 1-[4,4-bis(2-methylphenyl)-3-butenyl]-6-phenyl-1,6-dihydropyridine-3-carboxylate (28)

Yield: 125 mg, 19%; IR (film): 1687, 1638, 1573 cm^{-1}; ^1H NMR ($CDCl_3$) δ: 2.10, 2.16, 2.24, and 2.30 (four s, 3H each, tolyl *Me*'s), 2.40–2.50 (m, 4H, $CH_2CH{=}C$), 3.02–3.20 (m, 2H, NCH_2), 4.20–4.30 (m, 2H, OCH_2), 4.95 (dd, $J_{4,5}$ = 9.5, $J_{5,6}$ = 5.0 Hz, 1H, H-5), 5.01 (d, $J_{5,6}$ = 5.0 H, 1H, H-6), 5.70 and 5.88 (two t, J = 7.0 Hz, 1H each, $CH_2CH{=}C$), 6.43 (d, $J_{4,5}$ = 9.5 Hz, 1H, H-4), 7.08–7.37 (m, 21H, phenyl hydrogens), 7.39 (s 1H, H-2). Exact Mass calcd. for $C_{48}H_{47}NO_2$: 669.3607; found: 669.3580.

*2-Cyanoethyl 1-[4,4-bis(2-methylphenyl)butyl]-4-phenyl-1,4-dihydropyridine-3-carboxylate (**23**)*

Yield: 110 mg, 22%; IR (film): 2395 (CN), 1687, 1589 cm^{-1}; ^1H NMR (DMSO-d_6) δ: 1.50–1.62 (m, 2H, $CH_2CH_2CH_2$), 1.80–1.98 (m, 2H, $NCH_2CH_2CH_2CH$), 2.24 and 2.26 (two s, 3H each, tolyl *Me*'s), 2.70–2.80 (m, 2H, CH_2CN), 3.30–3.46 (m, 2H, NCH_2), 4.09–4.14 (m, 2H, OCH_2), 4.24 (t, J = 7.0 Hz, 1H, CH_2CH), 4.38 (d, $J_{4,5}$ = 4.5 Hz, 1H, H-4), 4.88 (dd, $J_{5,6}$ = 8.0, $J_{4,5}$ = 4.5 Hz, 1H, H-5), 6.12 (d, $J_{5,6}$ = 8.0 Hz, 1H, H-6), 7.04–7.28 (m, 13H, phenyl hydrogens), 7.38 (s, 1H, H-2). Product **23** was used immediately for the preparation of **25**.

*2-Cyanoethyl 1-[4,4-bis(2-methylphenyl)butyl]-6-phenyl-1,6-dihydropyridine-3-carboxylate (**29**)*

Yield: 100 mg, 20%; IR (film): 2385 (CN), 1679, 1638 cm^{-1}; ^1H NMR (DMSO-d_6) δ: 1.42–1.60 (m, 2H, CH_2CH_2CH), 1.70–1.80 (m, 2H, CH_2CH_2CH), 2.18 and 2.20 (two s, 3H each, tolyl *Me*'s), 2.86 (t, J = 6.0 Hz, 2H, CH_2CN), 3.30–3.40 (m, 2H, NCH_2), 4.26 (t, J = 7.0 Hz, 3H total, OCH_2, CH_2CH), 5.09 (dd, $J_{4,5}$ = 9.5, $J_{5,6}$ = 5.0 Hz, 1H, H-5), 5.20 (d, $J_{5,6}$ = 5.0 Hz, 1H, H-6), 6.26 (d, $J_{5,6}$ = 9.5 Hz, 1H, H-4), 7.07–7.40 (m, 13H, phenyl hydrogens), 7.54 (s, 1H, H-2). Product **29** was used immediately for the synthesis of **31**.

*2-Cyanoethyl 1-[4,4-bis(2-methylphenyl)-3-butenyl]-4-phenyl-1,4-dihydropyridine-3-carboxylate (**24**)*

Yield: 100 mg, 20%; IR (film): 2196 (CN), 1671, 1638 cm^{-1}; ^1H NMR (DMSO-d_6) δ: 2.02 and 2.06 (two s, 3H each, tolyl *Me*'s), 2.18–2.28 (m, 2H, $CH_2CH{=}$), 2.68–2.76 (m, 2H, CH_2CN), 3.43 (t, J = 7.0 Hz, 2H, NCH_2), 4.08 (t, J = 6.0 Hz, 2H, OCH_2), 4.33 (d, $J_{4,5}$ = 4.5 Hz, 1H, H-4), 4.74 (dd, $J_{5,6}$ = 8.0, $J_{4,5}$ = 4.5 Hz, 1H, H-5), 5.77 (t, J = 7.0 Hz, 1H, $CH_2CH{=}$), 5.96 (d, $J_{5,6}$ = 8.0 Hz, 1H, H-6), 7.0–7.24 (m, 13H, phenyl hydrogens), 7.29 (s, 1H, H-2). Product **24** was used immediately for the synthesis of **26**.

*2-Cyanoethyl 1-[4,4-bis(2-methylphenyl)-3-butenyl]-6-phenyl-1,6-dihydropyridine-3-carboxylate (**30**)*

Yield: 105 mg, 21%; IR (film): 2368 (CN), 1687, 1581 cm^{-1};

^{1}H NMR ($CDCl_3$) δ: 2.10 and 2.24 (two s, 3H each, tolyl *Me*'s), 2.30–2.40 (m, 2H, CH_2CH), 2.74 (t, J = 6.0 Hz, 2H, CH_2CN), 3.02–3.20 (m, 2H, NCH_2), 4.26–4.40 (m, 2H, OCH_2), 4.96 (dd, $J_{4,5}$ = 9.5, $J_{5,6}$ = 5.0 Hz, 1H, H-5), 5.02 (d, $J_{5,6}$ = 5.0 Hz, 1H, H-6), 5.69 (t, J = 7.0 Hz, 1H, CH_2CH=), 6.69 (d, $J_{4,5}$ = 9.5 Hz, 1H, H-4), 7.04–7.36 (m, 13H, phenyl hydrogens), 7.43 (s, 1H, H-2). Product **30** was used immediately for the synthesis of **32**.

1-[4,4-Bis(2-methylphenyl)butyl]-4-phenyl-1,4-dihydropyridine-3-carboxylic acid (25). General procedure

A solution of **23** (100 mg, 0.2 mmol) and DBU (91 mg, 0.6 mmol) in MeOH (10 mL) was stirred at 25°C for 14 h, and the solvent was removed in vacuo to give an oil residue. Addition of 0.5 N HCl to the oil (pH 1–2) precipitated **25** as a solid, which was filtered and recrystallized from Et_2O–hexane (62 mg, 70%); mp 101–102°C; IR (KBr): 2551–2942 (CO_2H), 1638, 1564 cm^{-1}; ^{1}H NMR (DMSO-d_6) δ: 1.46–1.62 (m, 2H, CH_2CH_2CH), 1.82–1.98 (m, 2H, CH_2CH_2CH), 2.23 and 2.26 (two s, 3H each, tolyl *Me*'s), 3.30–3.42 (m, 2H, NCH_2), 4.24 (t, J = 7.0 Hz, 1H, CH_2CH), 4.34 (d, $J_{4,5}$ = 4.5 Hz, 1H, H-4), 4.80 (dd, $J_{5,6}$ = 8.0, $J_{4,5}$ = 4.5 Hz, 1H, H-5), 6.06 (d, $J_{5,6}$ = 8.0 Hz, 1H, H-6), 7.04–7.24 (m, 13H, phenyl hydrogens), 7.30 (s, 1H, H-2), 11.14 (s, 1H, CO_2H). Anal. calcd. for $C_{30}H_{31}NO_2 \cdot 3/4H_2O$: C 79.88, H 7.26, N 3.10; found: C 79.80, H 7.41, N 3.00. A similar procedure was used for the reactions **29** → **31**, **24** → **26**, and **30** → **32** using the same molar quantities of reactants.

*1-[4,4-Bis(2-methylphenyl)butyl]-6-phenyl-1,6-dihydropyridine-3-carboxylic acid (**31**)*

Yield: 55 mg, 62%; mp 85°C; IR (KBr): 3543–2951 (CO_2H), 1630, 1573 cm^{-1}; ^{1}H NMR (DMSO-d_6) δ: 1.42–1.56 (m, 2H, CH_2CH_2CH), 1.74–1.88 (m, 2H, CH_2CH_2CH), 2.18 and 2.20 (two s, 3H each, tolyl *Me*'s), 3.32–3.50 (m, 2H, NCH_2), 4.16 (t, J = 7.0 Hz, 1H, CH_2CH), 5.04 (dd, $J_{4,5}$ = 9.5, $J_{5,6}$ = 5.0 Hz, 1H, H-5), 5.15 (d, $J_{5,6}$ = 5.0 Hz, 1H, H-6), 6.24 (d, $J_{4,5}$ = 9.5 Hz, 1H, H-4), 7.07–7.34 (m, 13H, phenyl hydrogens), 7.44 (s, 1H, H-2), 11.0 (s, 1H, CO_2H). Anal. calcd. for $C_{30}H_{31}NO_2$: C 82.35, H 7.14, N 3.20; found: C 81.97, H 7.23, N 3.17.

*1-[4,4-Bis(2-methylphenyl)-3-butenyl]-4-phenyl-1,4-dihydropyridine-3-carboxylic acid (**26**)*

Yield: 50 mg, 56%; mp 130–131°C; IR (KBr): 3518–2992 (CO_2H), 1671, 1646, 1589 cm^{-1}; ^{1}H NMR (DMSO-d_6): δ: 2.04 and 2.16 (two s, 3H each, tolyl *Me*'s), 2.17–2.28 (m, 2H, CH_2CH=), 3.43 (t, J = 7.0 Hz, 2H, NCH_2), 4.32 (d, $J_{4,5}$ = 4.5 Hz, 1H, H-4), 474 (d, $J_{5,6}$ = 8.0, $J_{4,5}$ = 4.5 Hz, 1H, H-5), 5.77 (t, J = 7.0 Hz, 1H, CH_2CH=), 5.96 (d, $J_{5,6}$ = 8.0 Hz, 1H, H-6), 7.04–7.22 (m, 13H, phenyl hydrogens), 7.28 (s, 1H, H-2), 11.1 (s, 1H, CO_{2H}). Anal. calcd. for $C_{30}H_{29}NO_2$: C 82.73, H 6.71, N 3.22; found: C 82.48, H 6.83, N 3.32.

*1-[4,4-Bis(2-methylphenyl)-3-butenyl]-6-phenyl-1,6-dihydropyridine-3-carboxylic acid (**32**)*

Yield: (45 mg, 50%); mp 80–82°C; IR (KBr): 3567–2959 (CO_2H), 1630, 1564 cm^{-1}; ^{1}H NMR (DMSO-d_6) δ: 2.01 and 2.17 (two s, 3H each, tolyl *Me*'s), 2.20–2.30 (m, 2H, CH_2CH=), 3.34–3.50 (m, 2H, NCH_2), 4.90–5.0 (m, 2H, H-5, H-6), 5.72 (t, J = 7.0 Hz, 1H, CH_2CH=), 6.20 (d, $J_{4,5}$ = 9.5 Hz, 1H, H-4), 7.0–7.34 (m, 13H, phenyl hydrogens), 7.45 (s, 1H, H-2), 11.0 (s, 1H, CO_2H). Anal. calcd. for $C_{30}H_{29}NO_2$: C 82.73, H 6.71, N 3.22; found: C 82.50, H 6.79, N 3.41.

[^{3}H]GABA-uptake inhibition assay

Male Sprague–Dawley rats were sacrificed by decapitation and the brains were immediately removed and cooled in ice-cold incubation medium. The brains were then transferred to Petri dishs on ice, and the striata were dissected out and chopped into prisms (0.1 mm × 0.1 mm × approximately 2 mm) using a McIlwain tissue chopper. These prisms were suspended in incubation medium that was used for the [^{3}H]GABA-uptake experiments, essentially using the procedure of Iversen and Neal (24). Aminooxyacetic acid (100 mM) was added to the incubation medium to inhibit GABA-transaminase. [^{3}H]GABA (specific activity 36.8 Ci/mmol, which was mixed with unlabeled GABA to give a final concentration of 1.0 mM) was added to the flasks, after a 15 min preincubation of the the prisms at 37°C, in the presence or absence (control) of the test compound. Incubation was continued at 37°C for 5 min, and the contents of the flasks were transferred to a Millipore filter apparatus containing 12 wells with paper filters, and connected to a vacuum line. The samples were rapidly washed twice with incubation medium at 37°C, and the filters added to scintillation vials containing Ready-Safe® scintillation fluid. The amount of radioactivity in the test sample was measured using a liquid scintillation counter, and the % inhibition of [^{3}H]GABA uptake by the test compound (relative to the control) was calculated.

An annulene TCNQ derivative with rather weak acceptor properties

Reginald H. Mitchell, Xin Jin, Tetsuo Otsubo, and Kazuo Takimiya

Abstract: Reaction of the bridged [14]annulenequinone, *trans*-10b,10c-dimethyl-10b,10c-dihydropyrene-2,7-quinone (**12**), with malononitrile in the presence of pyridine and $TiCl_4$ gave 68% of the deep-purple extended TCNQ derivative, α,α,α′,α′-tetracyano-*trans*–10b,10c-dimethyl-10b,10c-dihydropyrene-2,7-quinodimethide (**13**). In solution, quinodimethide **13** appears to form a complex with diethylamine, but is too weak an electron acceptor to form complexes with tetrathiafulvalene, TTF, and related donors. The reduction potential of **13** was substantially lower than that found for TCNQ itself, and in properties **13** behaves more like a benzannelated TCNQ derivative, e.g., α,α,α′,α′-tetracyanopentacene-7,14-quinodimethide (**11**), than a pyrene derivative, e.g., α,α,α′,α′-tetracyanopyrene-2,7-quinodimethide (**6**). This is in agreement with molecular orbital calculations, which indicate that the LUMOs of **13** and **11** are approximately 0.6 eV higher in energy than those for **6** and TCNQ.

Key words: TCNQ — extended, TCNQ-pyrene derivative, reduction potential, annulene-quinodimethide, electron acceptor — weak.

Résumé : La réaction de la [14]annulènequinone pontée, *trans*-10b,10c-diméthyl-10b,10c-dihydropyrène-2,7-quinone (**12**), avec le malononitrile, en présence de pyridine et de $TiCl_4$, conduit à un rendement de 68% du dérivé TCNQ étendu violet foncé α,α,α′,α′-tétracyano-*trans*-10b,10c-diméthyl-10b,10c-dihydropyrène-2,7-quinodiméthane (**13**). En solution, il semble que le composé **13** forme un complexe avec la diéthylamine; c'est toutefois un accepteur d'électron trop faible pour former des complexes avec le tétrathiafulvalène, TTF, et les donneurs apparentés. Le potentiel de réduction du composé **13** est beaucoup plus faible que celui observé pour le TCNQ lui-même et ses propriétés s'apparentent plus à celles d'un dérivé TCNQ ayant subit une annelation avec le benzène, comme l'α,α,α′,α′-tétracyanopentacène-7,14-quinodiméthane (**11**), qu'à celles d'un dérivé pyrène, comme l'α,α,α′,α′-tétracyanopyrène-2,7-quinodiméthane (**6**). Cette constatation est en accord avec les calculs d'orbitales moléculaires qui suggèrent que les énergies des BV des composés **11** et **13** sont approximativement 0,6 eV plus élevées que celles du composé **6** et du TCNQ.

Mots clés : TCNQ étendue, dérivé TCNQ-pyrène, potentiel de réduction, annulène-quinodiméthane, faible accepteur d'électron.

[Traduit par la rédaction]

Introduction

Tetracyano-*p*-quinodimethane (TCNQ) (**1**) has become a very well-known molecule because its charge transfer (CT) salts exhibit a wide array of electrical properties ranging from insulating to "organic metal" (1, 2). Soon after the initial reports (3) on TCNQ itself in the early 1960s, extended π-systems were investigated, for example, the naphthalene derivative TNAP (**2**) (4). Then following the 1973 report (5) of metallic conductivity in TTF–TCNQ (TTF = tetrathiafulvalene), extension of the π-system again became of interest since theoretical studies (6) suggested that extending the π-system of TCNQ would result in a lowering of the intramolecular Coulomb repulsion and lead to highly conducting CT complexes. Weiler and co-workers (7) investigated the biphenyl compound TCNDQ (**3**) and Wudl et al. (8) the tetra-azapyrene TCQQ (**4**). The tetrahydropyrene TCNTP (**5**) and the pyrene TCNP (**6**) were finally made in 1979 and 1980, respectively (9–11), and the anthracene compound TANT (**7**) in 1993 (12). At the same time considerable effort went into studying the benzo-annelated derivatives, e.g., (**8**) (13), (**9**) (14, 15), (**10**) (15, 16), and (**11**) (17). However, quinomethide derivatives in which the quinoid partial structure is *not* derived from a benzenoid aromatic, or equivalent 5-ring heterocycle (18), seem to be rather rare (19), perhaps in part due to the sparsity of annulene quinones (19–21) from which they would be derived. Our recent route (22) to the [14]annulene quinone **12** provided an opportunity to explore the synthesis and properties of the novel π-extended TCNQ derivative **13**. This paper reports the results of this investigation.

Received September 10, 1996.

This paper is dedicated to Professor William A. Ayer on the occasion of his 65th birthday.

(malononitrile, $TiCl_4$, and pyridine in refluxing chloroform) in 68% yield. It was obtained as dark-purple metallic-looking crystals, which decompose above 350°C, and gave a correct mass spectrum and elemental analysis for **13**. In its IR spectrum, the intense carbonyl absorption of **12** at 1640 cm^{-1} was replaced by the -CN absorption at 2215 cm^{-1} in **13**. In their ^1H NMR spectra, the vinyl protons of **13** at δ 6.84 and 6.56 are more deshielded than those of **12**, δ 6.30 and 6.07, while the internal methyl protons at δ 1.40 are more shielded than those of **12**, δ 1.87. The UV absorption maximum of quinone **12** at 333 nm is red shifted to 460 nm in **13**.

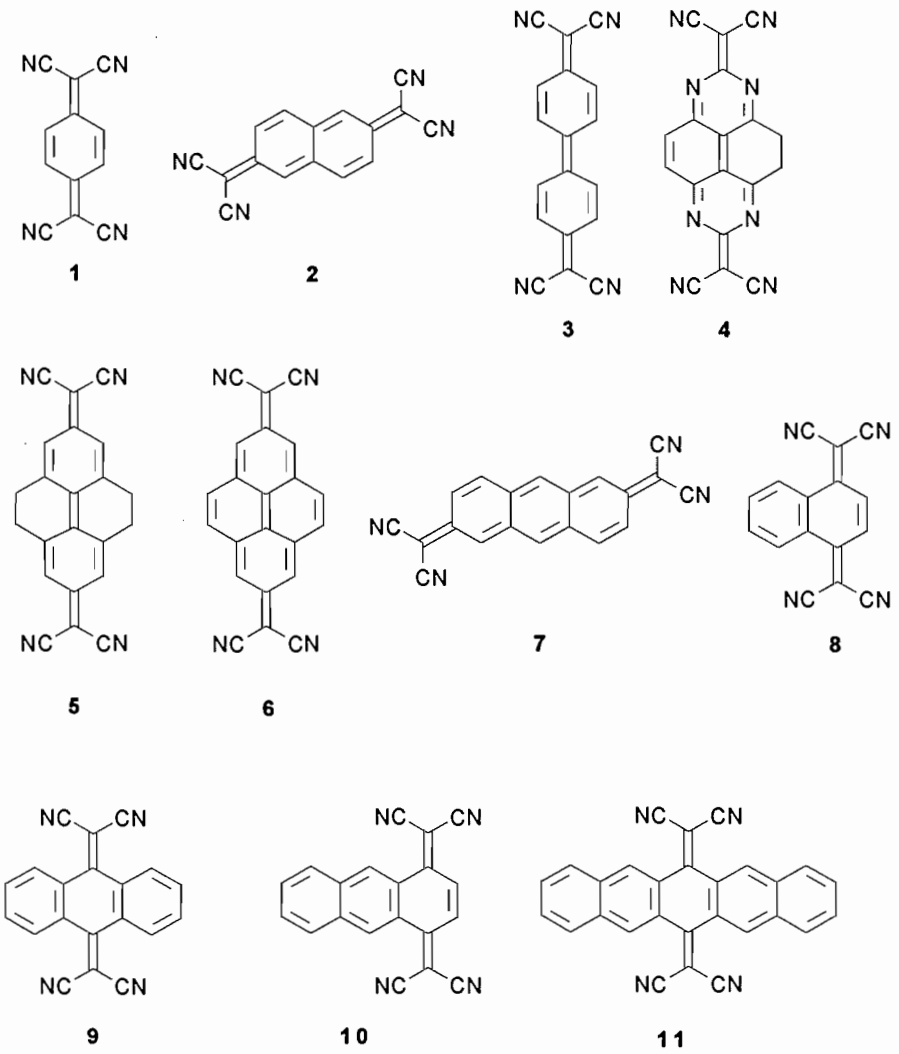
Complexation

Stirring a mixture of the TCNQ **13** and diethylamine in dichloromethane or acetonitrile causes a color change from purple to dark green, with a resultant change in the absorption spectrum, in which the absorption at 460 nm is replaced by a maximum at 770 nm, presumably due to formation of a charge transfer complex. Isolation of the complex was, however, not successful.

Because of the interest in TTF–TCNQ complexes mentioned above, we also attempted formation of complexes of our TCNQ derivative **13** with TTF (**14**) (24), and four stronger donors: tetrathiotetracene, TTT (**15**) (25), tetraselenotetracene, TST (**16**) (26), tetraphenylbipyranylidene, TPBP (**17**) (27), and tetraphenylbithiopyranylidene, TPTP (**18**) (27), by mixing hot solutions of donor and acceptor in chlorobenzene. Collection of the solid material after cooling, and IR analysis indicated only a physical mixture of compounds to be present.

Reduction potential

To understand these rather disappointing results, we measured the reduction potential of **13** in benzonitrile (better solubility than acetonitrile) and found reversible redox waves with half-wave reduction potentials of −0.34 V and −0.60 V, substantially lower than those found for TCNQ itself, and comparable derivatives, see Table 1.



Evidentially, compound **13** is a rather weak acceptor with ΔE much lower than that found for TCNQ itself, and even with the stronger donors (**15–18**) with first oxidation potentials of 0.19, 0.21, 0.12, and 0.19 V, respectively, the accepting ability of **13** is not enough to form a CT complex. When the difference between the donor's oxidation potential and acceptor's reduction potential is beyond the range −0.05 to 0.32 V, conducting CT complexes are not obtained (28).

To better understand the low reduction potential of **13**, we

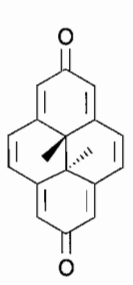
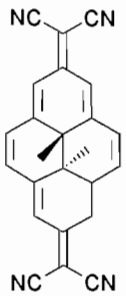
carried out some molecular orbital calculations on **13** and several π-extended TCNQs. These are arranged in decreasing reduction potential order (increasing LUMO energies) and are reported in Table 2. It is well known (29) that the electrode reduction potentials of many aromatic hydrocarbons correlate well with the Hückel LUMO energies. This appears to be approximately true for the TCNQ derivatives studied in Table 2. The AM1 values reported in Table 2 could be obtained for the larger systems, e.g., **11**, in a few hours on a 486 PC, while the PCMODEL calculations only take a few minutes. In either case the trend is remarkably evident, the reduction potential decreases with increasing LUMO energy, and the compound becomes a worse electron acceptor as the table is descended. In terms of electron-accepting ability, annulene derivative **13** is more like the benzannelated TCNQs **21** and **11** than like the pyrene **6**. This is not because of a lack of planarity. The π-systems of **12** and **13** are calculated to be planar (MM2-SCF, AM1, PM3), like that found for the parent bridged [14]annulene (30). The internal bridge atoms are above and below the plane of the 14-π periphery, and serve to keep the latter rigid and planar. Addition of one and then two electrons, to give the radical anion and then the dianion, also leads to planar calculated structures. We believe the main difference between **13** and **6** is that the latter system on reduction gives two distinct 6π circuits, with the top and bottom ring bond lengths becoming more equal on addition of one and then two electrons, i.e., more aromatic (the pyrene 4–5 and 9–10 bonds remain distinctly olefinic). The annulene **13** can also form a more delocalized π-system on reduction, but this time it has to involve the whole 14-π periphery (no 6-π circuits are possible), and this is energetically less favourable. It thus accepts electrons much less willingly than pyrene **6** or TCNQ itself. The benzannelated annulenes, e.g., **11**, become aromatic in the central ring, but the annelating rings remain relatively alternating, i.e., only one 6π circuit is formed.



In properties then, extended TCNQ **13** behaves rather like the benzannelated TCNQs **9**–**11**, which also have high negative first reduction potentials and do not form TTF complexes (17), and unlike compounds **2**, **6**, and **7**, which are stronger acceptors than TCNQ (4, 11, 12).

Conclusions



The unusual annulene TCNQ **13** was synthesized in 68% yield from quinone **12**. Even though it has conjugation considerably extended from that of TCNQ itself, it shows (to us) unexpect-

edly weak acceptor properties and does not form a TTF complex. In these properties **13** behaves more like the benzannelated derivatives of TCNQ, e.g., **11**, than the π-extended pyrene derivative **6**.

Experimental

Melting points were determined on a Reichert 7905 melting point apparatus integrated to a chrome–alumel thermocouple. Infrared spectra, major peaks only, calibrated with polystyrene, were recorded on a Bruker IFS25 FT-IR spectrometer as KBr disks. Ultraviolet–visible spectra were recorded on a Cary 5 or a Perkin–Elmer Lambda-4B spectrometer in dichloromethane. Proton NMR spectra were recorded at 360 MHz on a Bruker AMX 360 using $CDCl_3$ as solvent and either TMS as internal standard or the $CHCl_3$ peak at 7.24 ppm. Carbon NMR spectra were recorded at 90.6 MHz in $CDCl_3$, using the solvent peak at 77.0 ppm for calibration. Exact Mass measurements used a Kratos Concept-H instrument with perfluorokerosene as calibrant. Elemental analyses were carried out by Canadian Microanalytical Services Ltd, Vancouver, B.C. All evaporations were carried out under reduced pressure on a rotary evaporator, and all organic extracts were washed with water and dried over anhydrous $MgSO_4$. SiGel refers to Merck Silica Gel, 70–230 mesh. PE refers to distilled petroleum ether, bp 30–60°C.

trans-*10b,10c-Dimethyl-10b,10c-dihydropyrene-2,7-quinone (12)*

Dimethyldihydropyrene (31) (531 mg, 2.3 mmol) in dry DMF (40 mL) was added over 5 h to pyridinium dichromate (32) (4.30 g, 11.4 mmol) in dry DMF (50 mL) at −5°C. After a further 3 h at 0°C, ice-water and CH_2Cl_2 were added and were stirred well to extract the brown precipitate. The organic layer was washed, dried, and evaporated and the residue was dissolved in CH_2Cl_2 and chromatographed over SiGel using CH_2Cl_2–ether (7:3) to yield 455 mg (75%) of quinone **12**. Recrystallization from benzene returned 90% as yellow needles with mp 267–269°C (lit. (33) mp 252°C (dec.)). IR: 1636, 1605, 1555, 1442, 1367, 1291, 930, 915, 905 cm^{-1}; UV λ_{max} nm (ϵ_{max}): 273 (57 900), 317 sh (20 400), 333 (24 600), 348 sh (17 800), 399 (9000). ^1H NMR δ: 6.30 (4H, s, H-4,5,9,10), 6.07 (4H, s, H-1,3,6,8), 1.87 (6H, s, int-CH_3); ^{13}C NMR δ: 186.2, 157.1, 131.6, 128.4, 47.4, 28.5.

α,α,α′,α′-*Tetracyano*-trans-*10b,10c-dimethyl-10b,10c-dihydropyrene-2,7-quinodimethide (13)*

$TiCl_4$ (0.2 mL, 2 mmol) was added dropwise to a well-stirred solution of quinone **12** (131 mg, 0.5 mmol) in dry $CHCl_3$ (20 mL) at 0°C. The resultant brown suspension was stirred for 10 min without further cooling. A solution of malononitrile (0.6 mL, 5 mmol) and pyridine (0.8 mL, 10 mmol) in dry $CHCl_3$ (5 mL) was then added, and the mixture was heated under reflux for 12 h and then cooled. The reddish precipitate was filtered, washed well with water, and was dried under vacuum to give 103 mg (68%) of **13**. This sample was purified further by Soxhlet extraction using CH_2Cl_2, and concentrated to give purple crystals, mp > 350°C (dec.). IR: 2215, 1626, 1509, 1400, 1358, 981, 915 cm^{-1}; UV λ_{max} nm (ϵ_{max}): 296 (47 700), 460 (41 000), 485 sh (32 900); ^1H NMR (CD_2Cl_2) δ: 6.84 (4H, s, H-4,5,9,10), 6.56 (4H, s, H-1,3,6,8), 1.40 (6H, s, int-CH_3); ^{13}C NMR: too insoluble, but CH peaks at 132.1 and 123.6 ppm were just visible; HRMS calcd. for $C_{24}H_{14}N_4$: 358.122; found: 358.124. Anal. calcd: C 80.43, H 3.94; found: C 80.51, H 3.96.

*Complexation of **13** with* N,N-*diethylamine*

Quinodimethide **13** (3.5 mg, 0.01 mmol) was dissolved in dry CH_2Cl_2 (30 mL), freshly distilled Et_2NH (0.7 mg, 0.01 mmol) was added, and the mixture was stirred under N_2 for 8 h, during which time the colour changed from orange to dark green. Evaporation caused disappearance of the green colour. The UV spectrum of the green solution showed broad absorption between 350 and 450 nm and then a strong absorption at 770 nm (ε about 50 000).

*Measurement of reduction potential of **13***

The reduction potential of **13** was measured using a 10^{-3} M solution of **13** in benzonitrile in the presence of 0.1 M tetra-*n*-butylammonium perchlorate as supporting electrolyte, using Pt rods as both working and counter electrode, and Ag/AgCl as reference. The sample showed reversible redox waves with half-wave reduction potentials of −0.34 and −0.60 V. Cyclic voltammetry was carried out on a Hokuto Denko HA-301 using a scan rate of 100 mV s^{-1}. TCNQ was measured under identical conditions (see Table 1).

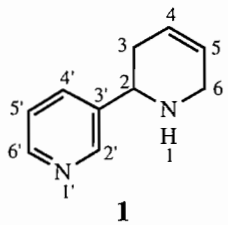
A simple synthesis of (±)-1,2,3,6-tetrahydro-2,3′-bipyridine (anatabine) and (±)-3-(2-piperidinyl)pyridine (anabasine) from lithium aluminum hydride and pyridine

Chi-Ming Yang and Dennis D. Tanner

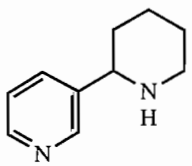
Abstract: The hydrolysis of a pyridine solution of lithium tetrakis(*N*-dihydropyridyl)aluminate (LDPA), which was prepared at 0°C, yields a mixture of 1,4-, 1,2-, and 2,5-dihydropyridines (DHPs) in a ratio of 26:37:38. The subsequent reversible base-catalyzed condensation of a 1:1 mixture of 1,2- and 2,5-DHPs carried out in the presence of oxygen affords an 89% yield of (±)-anatabine. When the reaction mixture is allowed to stand in the presence of oxygen, anabasine is slowly formed from anatabine by the reaction of the residual DHPs. Anatabine can also be converted into (±)-anabasine by catalytic hydrogenation.

Key words: lithium aluminum hydride, pyridine, anatabine, anabasine.



Résumé : L'hydrolyse d'une solution dans la pyridine du tétrakis(*N*-dihydropyridyl)aluminate de lithium («LDPA»), préparée à 0°C, conduit à un mélange de 1,4-, 1,2- et 2,5-dihydropyridines (DHP) dans un rapport de 26 : 37 : 38. Opérant en présence d'oxygène, on a effectué par la suite une condensation réversible, catalysée par les bases, d'un mélange 1 : 1 de 1,2- et 2,5-DHP qui conduit à un rendement de 89% de (±)-anatabine. Quand on laisse le mélange réactionnel en présence d'oxygène, l'anatabine conduit lentement à de l'anabasine par le biais de la réaction des DHP résiduelles. On peut aussi transformer l'anatabine en (±)-anabasine par hydrogénation catalytique.

Mots clés : hydrure de lithium et d'aluminium, pyridine, anatabine, anabasine.



[Traduit par la rédaction]

Introduction

Anatabine (**1**) is the most abundant of the minor alkaloids of tobacco plants (1). In fresh *Nicotiana tabacum L.*, the plant from which it was first isolated (2), the alkaloid mixture consisted of 93% nicotine, 3.9% anatabine, 2.4% nornicotine, and 0.5% anabasine (**2**) (1).

1

2

The total synthesis of anatabine has been reported by three groups of workers (3–5). These syntheses yielded racemic anatabine, which is also isolated from tobacco (2). Two of the synthetic routes (3, 5) proposed, as transient intermediates, 2,5-dihydropyridine like structures.

Four syntheses of anabasine, **2**, have been reported (2, 6–8). The first report was the conversion of (−)-anatabine to (−)-anabasine by catalytic hydrogenation (2).

Recently we observed that the hydrolysis, in the absence of oxygen, of lithium tetrakis(*N*-dihydropyridyl)aluminate (LDPA), **3**, yields a mixture of three dihydropyridines, **4–6** (9). The ratio of 1,4-/1,2-dihydropyridyl ligands in **3** was dependent on the temperature and time of "aging" at which **3** was synthesized (9). When LDPA is formed by mixing lithium aluminum hydride and pyridine at 0°C and "aged" for 2 days the average ratio of 1,4-/1,2-dihydropyridyl ligands, *n*/*m*, in the isomeric mixture of LDPAs, **3a–e** (**3a** $m = 4$, $n = 0$; **3b** $m = 3$, $n = 1$; **3c** $m = 2$, $n = 2$; **3d** $m = 1$, $n = 3$; and **3e** $m = 0$, $n = 4$) was 0.35. The hydrolysis of LDPA formed at 0°C yields a mixture of three isomeric dihydropyridines: **4**, **5**, and **6** in a ratio of 26:37:38. The ratio of $n'/(m' + m'')$ was equal to the original 1,4-/1,2-ratio of ligands in the LDPA before hydrolysis (9).[2]

The biosynthetic pathway established for the synthesis of anatabine (1) suggested that two molecules of nicotinic acid, **7**, undergo 2,5-reduction to form **8**, which then decarboxylates to form the anion, **i**. The same anion, **i**, was derived in this work from the heretofore uncharacterized dihydropyridine, **5**.

Received September 13, 1996.

This paper is dedicated to Professor William A. Ayer on the occasion of his 65th birthday.

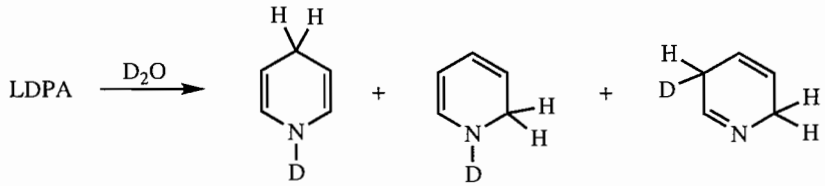
3 4 5 6

Scheme 1. The suggested biosynthetic pathway for the synthesis of anatabine from [6-^{14}C], ●, and [2-^{14}C], ○, nicotinic acid (refs. 1, 3).



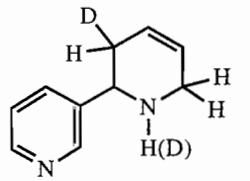
7 8 i 1

In the proposed biosynthetic path, a condensation of **i** and one mole of **6** presumably yields anatabine, **1**, see Scheme 1. The biosynthetic pathway proposed for the synthesis of **1** was suggested on the basis of incorporation studies using [6-^{14}C] and [2-^{14}C] nicotinic acid and upon the expectation that the intermediate, 3,6-dihydronicotinic acid (**8**), a β-imino acid, would readily decarboxylate to form **i** (Scheme 1). Both the decarboxylation of **8** and its subsequent condensation with **6** are reasonable pathways for the formation of anatabine from [6-^{14}C]- or [2-^{14}C]nicotinic acid.

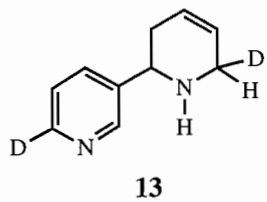
Protonation of **i** yields both tautomers, **6** and **5**, and the condensation of **i** with **5** also yields **1**. Since the hydrolysate of LDPA (formed at low temperature) yields an almost equimolar mixture of **5** and **6**, it was reasonable to suspect that a basic solution (pyridine, $Al(OH)_4$) of the hydrolysate would yield, after oxidation, anatabine. The mixture of dihydropyridines, **4–6**, was stable in the presence of base (>14 days) in the absence of oxygen (9). However, in the presence of oxygen, **1** was slowly formed.

A consistent mechanism for the formation of **1** from a basic solution of **4**, **5**, and **6** (26:37:38) must accommodate the experimental observations that: (*a*) the mixture after hydrolysis is stable for extended periods of time; (*b*) only in the presence of oxygen is **1** slowly formed; (*c*) **2** is slowly formed at the expense of **1**; and (*d*) when LDPA is synthesized using $LiAlD_4$ the deuterated DHPs yield 6,6′-dideuteroanatabene. A mechanistic pathway can be suggested that accommodates these experimental observations: a reversible base-catalyzed condensation followed by a subsequent radical chain autoxidation, followed by a base-catalyzed elimination (Scheme 2). A chain autoxidation is a likely pathway which accounts for the high yield and its chemical specificity although the chain nature of oxidation is only speculative.

The proposed condensation pathway was investigated. When LDPA was hydrolyzed in D_2O, the 1,4-dihydropyridyl ligands yielded **9** while the 1,2-ligands yielded **10** and **11**.



9 10 11



The formation of **1** from **10** and **11** by Scheme 2 yields **12**. Since only **12** is formed, Scheme 2 appears to be the most reasonable pathway that describes the synthesis of **1**.

When **3** is synthesized using $LiAlD_4$ (LAD), the LDPAs formed have ligands with 4-deuterated 1,4-dihydropyridyl ligands and 2-deuterated 1,2-dihydropyridyl ligands. Upon hydrolysis, the dihydropyridines formed are deuterated in the 2- and 4-positions (9). When anatabine is formed from the deuterated DHPs, only 6,6′-dideuteroanatabine (**13**) is found.

The absence of either 6,4′- or 4,4′-dideuterated **1** clearly rules out the involvement of **4** in the formation of **1**. The high yield of **1** from the condensation of **5** (0.68 M) and **6** (0.7 M) attests to the high efficiency of the reaction and confirms that **1** is formed from both **5** and **6**. If **5** is used as the limiting

Scheme 2.

reagent, when LDPA is hydrolyzed, then the 59% isolated yield accounts for an 89% yield of **1**, i.e., for a 1:1 condensation of **5** and **6**.[3]

After the mixture of hydrolysates stood at room temperature for more than 3 days during the formation of **1**, a minor amount (~10%) of anabasine, **2**, was formed. Since the LAH and LDPA had been hydrolyzed, the only active reducing agents present in the reaction mixture are the three dihydropyridines, **4**–**6**. Presumably these hydride reagents are responsible for the reduction of **1** and formation of **2.** Unlike the biosynthetic pathway to anabasine, which is formed from nicotinic acid and lysine (10), the precursor of **2** under our reaction conditions must be anatabine.

Experimental

Materials

Pyridine (certified reagent grade, ACS or Caledon Laboratories Ltd.) was freshly distilled over barium oxide and potassium hydroxide pellets prior to use. Lithium aluminum hydride (General Intermediates of Canada) was purified by recovering from ether after filtration (11). D_2O (99.8%, General Intermediates of Canada), and lithium aluminum deuteride (Aldrich, 98% atom D) were used as supplied.

Instrumentation

The ^1H, ^2H, and ^{13}C NMR spectra were obtained using either a Bruker AM-400 (400 MHz) or Bruker AM-300 (300 MHz)

[3] The calculation of the concentration of **5** and **6** was based on the assumption that LAH was converted quantitatively to LDPA (^{27}Al NMR) (9), and that LDPA was hydrolyzed quantitatively to the three dihydropyridines (^1H NMR) (9).

NMR spectrometer. Unless otherwise noted, the ^{1}H NMR spectra are referenced to tetramethylsilane as an internal standard at 0.00 ppm or to $CHCl_3$ as an internal standard at 7.26 ppm. The ^{13}C NMR chemical shifts were reported in δ (ppm) relative to chloroform (δ $CDCl_3$ = 77.0). The ^{13}C spectra were studied by APT (attached proton test) to determine the number of protons attached to each carbon.

High-resolution mass spectra were obtained with a Kratos MS50 high-resolution EI$^+$ spectrometer connected to a DS 55 data system. GC analysis was performed with a HP 5840A gas chromatograph equipped with a hydrogen flame ionization detector using a stainless steel column 15 ft. × 1/4 in. packed with 10% SE-30 on Chromosorb W (100–200 mesh) and interfaced with a HP5840A integrator.

GC–IR analysis was performed using an HP-5965 GC/FTIR analytical system; GC–MS were run using a VG 70E mass spectrometer interfaced to a 11–250 data system.

Synthesis of (±)-anatabine, 1

A pyridine solution of LDPA or tetra deutero-LDPA (0.5 or 0.45 M) was treated with H_2O or D_2O (9). While the solution was stirred (3 days) at room temperature, and while it was exposed to atmospheric oxygen the solution was analyzed periodically by GC (10% SE-30 on Chromosorb W). After 3 days, chloroform was added to dilute the slurry and the solution was filtered through sintered glass. After filtration the solvent was evaporated under reduced pressure and the residue was dissolved in a mixture of chloroform/methanol/concentrated ammonium hydroxide (90:10:1)[3] and subjected to silica gel chromatography. The eluate was subjected to vacuum distillation and an isolated yield, 59%, was achieved (3).

(±)-Anatabine: bp 116–117°C/1 Torr (lit. (2) bp 145–156°C/10 Torr; 1 Torr = 133.3 Pa), IR (gas phase) ν: 3043(vs), 2924(s), 2800(s), 1901(w), 1657(w), 1579(m), 1429(s), 1315(m), 1190(m), 1108(s), 1019(m), 946(w), 783(m), 714(s) cm^{-1} (ref. 12). ^{1}H NMR ($CDCl_3$, 400 MHz) δ: 8.54 (d, 1H, $J_{2'4'}$ = 2.0 Hz, H-2′), 8.42 (dd, 1H, $J_{6'5'}$ = 5.0, $J_{6'4'}$ = 1.8 Hz, H-6′), 7.67 (dt, 1H, $J_{4'5'}$ = 8.0, $J_{4'6'}$ = 1.8, $J_{4'2'}$ = 2.0 Hz, H-4′), 7.20 (ddd, 1H, $J_{4'5'}$ = 8.0, $J_{5'6'}$ = 5.0, $J_{5'2'}$ = 0.8 Hz, H-5′), 5.78 (A of AB type, 1H, J_{AB} = 10.0 Hz, H-4), 5.72 (B of AB type, 1H, J_{AB} = 10.0 Hz, J_{56ax} = 4.0 Hz, J_{56eq} = 2.0 Hz, H-5), 3.80 (t, 1H, J_{23} = 7.0 Hz, H-2), 3.53 (dm, 1H, J_{ae} = 17.0 Hz, J_{56eq} = 2.0 Hz, H-′6eq), 3.40 (dm, 1H, J_{ae} = 17.0 Hz, J_{56ax} = 4.0 Hz, H-6 ax), 2.22 (m, N-H), 2.18 (m, 2H, H-3) (refs. 3, 4, 13). ^{13}C NMR ($CDCl_3$, 100.6 MHz) δ: 148.35(C-2′), 148.25(C-6′), 139.79(C-3′), 134.17(C-4′), 126.09(C-5′), 124.89(C-4), 123.49(C-5), 55.04(C-2), 45.71(C-6), 33.58(C-3) (refs. 3, 11); EI$^+$ mass spectrum, m/z^+ (relative intensity): 160 (M$^+$, 100), 159(29), 156(25), 155(16), 149(196), 131(18), 118(12), 107(23), 106(35), 105(42), 95(33), 54(42); high-resolution mass spectrum, m/z obsd.: 160.0996 (M$^+$, calcd. for $C_{10}H_{12}N_2$: 160.1000). A synthesis of α-cuparenone based on symmetry considerations

Tse-Lok Ho and May-Hua Chang

Abstract: A ring expansion approach to α-cuparenone was accomplished in 5 or 6 steps. The key intermediate is 3-methyl-3-(4-methylphenyl)cyclobutanone, which was derived from a [2+2]cycloaddition of dichloroketene on a styrene derivative, followed by dechlorination.

Key words: symmetry, α-cuparenone, ring expansion, sesquiterpene.

Résumé : On a réalisé une synthèse de l'α-cuparénone en 5 ou 6 étapes par le biais d'une extension de cycle. L'intermédiaire clé est la 3-méthyl-3-(4-méthylphényl)cyclobutanone obtenue par une cycloaddition [2+2] du dichlorocétène sur un dérivé du styrène, suivie d'une déchloration.

Mots clés : symétrie, α-cuparénone, extension de cycle, sesquiterpène.

Cuparene (**1**) is one of the simplest sesquiterpenes. Its synthetic challenge lies in the presence of two contiguous quaternary carbon centers on a cyclopentane unit. Our interest in the pursuit of a cuparene synthesis stemmed from symmetry considerations (1).

The ring expansion theme formed the basis of several previous approaches (for details, see ref. 2). However, we thought that routes traversing a symmetrical cyclobutanone intermediate would offer distinct advantages by avoiding any regiochemical problems due to indiscriminate C—C bond migration in the ring expansion step. In other words, extra caution of design is not needed to avoid production of regioisomeric cyclopentane derivatives. Accordingly, we started our work by a [2+2]cycloaddition of α,*p*-dimethylstyrene with dichloroketene under ultrasonic irradiation. The adduct **2**, obtained in 76% yield, was dechlorinated with zinc dust and sodium iodide in glacial acetic acid at 80–90°C to afford 3-methyl-3-(4-methylphenyl)cyclobutanone (**3**) in 84% yield. Originally we failed to achieve this transformation using zinc dust alone, zinc–copper couple, or aluminum amalgam as reducing agent; therefore sodium iodide appears to have played a critical role in the reduction. Interesting also is an adventitious observation of ring cleavage to provide dehydrocurcumone on heating **3** to temperatures above 190°C. We can attribute this transformation either to a bond reorganization reminiscent of a McLafferty rearrangement, the driving force being relief of ring strain, or to an electrocyclic reversion via the enol species (eq. [1]). With the symmetrical ketone **3** at hand, the stage was set for ring expansion (3). Reaction of **3**

[1]

with [tris(methylthio)methyl]lithium afforded a mixture of *cis* and *trans* hydroxythioorthoesters **4A/4B**, in a combined yield of 94%. The more polar isomer was considered to have the tolyl and the tris(methylthio)methyl groups disposed in a *trans* relationship because 2D-NMR indicated a nuclear Overhauser effect of the *S*-methyl substituents with the benzylic methyl. Both **4A** and **4B** were elaborated with equal efficiency to the same product **5** on treatment of the corresponding lithium alkoxide with copper(I) perchlorate – acetonitrile complex; therefore in the preparative routine we could perform this step using the stereoisomeric mixture.

At the outset, it was our intention to exploit the blocking of the appropriate α-methylene group by the bis(methythio) unit in **5** to achieve the desired *gem*-dimethylation in a regioselective fashion. Several attempts were made to perform the transformation with various bases (NaH, *t*-BuOK, LDA) and methylating agents (MeI, Me_2SO_4) but, unfortunately, the desired product could not be obtained in acceptable yield. The reaction was complicated by elimination of one methanethiol molecule, presumably after *S*-methylation, and also by enol methylation. In hindsight it may be reasonable to attribute this behavior to steric hindrance by a methylthio group to the approach of the electrophile. Both faces of the cyclic enolate intermediate were shielded by substituents of two quaternary centers. The pathway involving methanethiol elimination apparently did not fare any better, the enolate species being a *cisoid* 2,3-disubstituted diene in which the bulky groups are

forced to adopt a coplanar conformation. Formation of such an enolate must be quite unfavorable.

Reports (4) that 3-methyl-3-arylcyclopentanones undergo methylation at C-2 with good selectivity ensured us an escape, although the yield was low (26%) and we were still disappointed at the failure of our original design. Desulfurization of **5** with Raney nickel in refluxing ethanol furnished ketone **6** in 85% yield, and the methylation proceeded to give α-cuparenone (**7**). α-Cuparenone is a well-known synthetic precursor of cuparene; therefore our work also represents a formal synthesis of the hydrocarbon.

An alternative and more direct method for the conversion of **3** to **6** is by Wittig reaction followed by treatment of the methylenecyclobutane derivative **8** with thallium(III) nitrate trihydrate (5). We also considered a route in which **3** was subjected to reaction with methylmagnesium iodide, dehydration, ozonolysis, and aldolization (eq. [2]) to reach another known precursor **9** of α-cuparenone. On preliminary investigations we found this last reaction sequence to be much inferior, the cyclobutene intermediate being rather prone to ring opening by electrocyclic reversion.

In conclusion, we have evaluated the concept of symmetry by an expedient route to α-cuparenone.

[2]

Experimental

General

Infrared spectra (IR) were obtained from neat film on KBr disks using a Jasco FT/IR-200 spectrometer. Mass spectra were measured with a TRIO-2000 or JEOL JMS-HX110 instrument. Proton and carbon nuclear magnetic resonance spectra in deuterochloroform solutions were determined by a Varian Unity-300 spectrometer. The following abbreviations were indicated: s = singlet, d = doublet, t = triplet, q = quartet, m = multiplet.

Materials

Anhydrous sodium sulfate was used for drying organic solutions during work-up of reactions. Thin-layer chromatography was performed on aluminum-backed silica gel plates with fluorescent coating. Separation by column chromatography was performed on silica gel 60 as supplied by E. Merck.

2,2-Dichloro-3-methyl-3-(4-methylphenyl)cyclobutanone (2)

A two-necked round-bottom flask was charged with α,*p*-dimethylstyrene (2.26 g, 17.1 mmol) and zinc dust (2.4 g, 36.7 mg-atm) in anhydrous ether (50 mL). The flask, equipped with a rubber septum and a condenser topped with a drying

For personal use only.

tube, was placed in an ultrasonic cleaning bath. While maintaining the temperature of the bath water below 20°C by occasional addition of ice during irradiation, trichloroacetyl chloride (3.0 mL, 26.9 mmol) was introduced slowly into the flask via a syringe. At the end of 3 h, the reaction mixture was diluted with more ether, filtered through Celite, and washed with sodium carbonate solution. Removal of the ether from the dried solution and evaporative distillation gave **2** (3.16 g, 76% yield). IR: 1811 cm^{-1}. ^1H NMR (300 MHz, $CDCl_3$ δ: 1.63 (s, 3H), 2.37 (s, 3H), 3.05 (d, 1H, J = 16 Hz), 3.96 (d, 1H, J = 16 Hz), 7.16 (d, 1H, J = 8 Hz), 7.22 (d, 2H, J = 8 Hz). HRMS, *m/z*: 242.0271, 244.0236, 246.0203 (calcd. for $C_{12}H_{12}OCl_2$: 242.0257, 244.0227, 246.0197).

3-Methyl-3-(4-methylphenyl)cyclobutanone (3)

A mixture of dichloroketone **2** (0.50 g, 2.06 mmol), sodium iodide (0.77 g, 5.14 mmol), and zinc dust (0.34 g, 5.2 mg-atm) in glacial acetic acid (6 mL) was magnetically stirred and maintained between 80 and 90°C for 11 h. On cooling to room temperature, water and dichloromethane were added to the reaction mixture. The organic layer was washed with sodium carbonate solution, dried, and evaporated to give a residue that was filtered through a short column of silica gel, affording **3** (0.30 g, 84% yield). IR: 1795 cm^{-1}. ^1H NMR (300 MHz, $CDCl_3$) δ: 1.58 (s, 3H), 2.36 (s, 3H), 3.07 (d, 2H, J = 16 Hz), 3.42 (d, 2H, J = 16 Hz), 7.16 (d, 2H, J = 8.4 Hz), 7.18 (d, 2H, J = 8.4 Hz). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 20.9 (q), 31.0 (q), 33.5 (s), 59.15 (t), 125.4 (d), 129.1 (d), 135.5 (s), 145.2 (s), 205.4 (s). HRMS, *m/z*: 174.1027 (calcd. for $C_{12}H_{14}O$: 174.1045).

3-Methyl-3-(4-methylphenyl)-1-[tris(methylthio)]-methylcyclobutanols (4A/4B)

A magnetically stirred solution of tris(methylthio)methane (1.40 g, 9.1 mmol) in dry THF (15 mL) at −78°C was treated with *n*-butyllithium (2.5 M in hexane, 3.6 mL, 9.0 mmol). After 0.5 h, ketone **3** (1.06 g, 6.1 mmol) was introduced via a syringe. The reaction was allowed to proceed for 1.5 h, quenched with a mixture of glacial acetic acid (0.6 mL) and ethanol (6 mL), and the cooling bath was removed. When room temperature was reached, the reaction mixture was distributed between CH_2Cl_2 and water; the organic solution was washed with aqueous sodium bicarbonate, dried, and concentrated in vacuo to provide a 1:1 mixture of products **4A** and **4B** (1.87 g, 94% yield), which were separated by silica gel chromatography.

The less polar isomer: IR: 3481 cm^{-1}. ^1H NMR (300 MHz, $CDCl_3$) δ: 1.56 (s, 3H), 2.23 (s, 9H), 2.34 (s, 3H), 2.35 (d, 2H, J = 18.6 Hz), 2.93 (d, 2H, J = 18.6 Hz), 3.64 (s, 1H, OH), 7.25 (s, 4H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 14.0 (q), 20.8 (q), 27.1 (q), 41.7 (t), 42.4. (s), 75.7 (s), 81.1 (s), 124.1 (d), 128.8 (d), 135.1 (s), 146.0) (s). HRMS, *m/z*: 328.0946, 281.1066 (calcd. for $C_{16}H_{24}OS_3$: 328.0991, for $C_{15}H_{21}OS_2$: 281.1035).

The more polar isomer: IR: 3480 cm^{-1}. ^1H NMR (300 MHz, $CDCl_3$) δ: 1.36 (s, 3H), 2.17 (s, 9H), 2.25 (s, 3H), 2.46 (dd, 2H, J = 13.2, 2.7 Hz), 2.77 (dd, 2H, J = 13.2, 2.7 Hz), 3.02 (s, 1H, OH), 7.07 (d, 2H, J = 8.1 Hz), 7.19 (d, 2H, J = 8.1 Hz). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 14.9 (q), 20.9 (q), 32.7 (q), 35.9 (s), 47.1 (t), 76.6 (s), 79.1 (s), 125.5 (d), 128.9 (d), 134.7 (s), 147.3 (s). EIMS, *m/z*: 328 ($M^{+\cdot}$).

2,2-Bis(methylthio)-3-methyl-3-(4-methylphenyl)-cyclopentanone (5)

To a solution of **4A/4B** (0.25 g, 0.76 mmol) in toluene (40 mL) cooled to −78°C was added by syringe *n*-butyllithium (1.6 M in hexane, 0.6 mL, 0.94 mmol). After 0.5 h, tetrakis(acetonitrile)copper(I) perchlorate (0.55 g, 1.68 mmol) was added in one portion, and the cooling bath was then removed to allow the reaction to proceed at room temperature for 1.5 h, after which it was heated to 78°C for 2 h. The reaction mixture was quenched with a mixture of aqueous NH_4Cl–NH_4OH (pH 8), cooled to room temperature, filtered, and extracted with ether. After washing with water, drying, concentration, and chromatography, **5** was obtained (0.14 g, 64% yield). IR: 1730 cm^{-1}. ^1H NMR (300 MHz, $CDCl_3$) δ: 1.44 (s, 3H), 1.99 (s, 3H), 2.10 (s, 3H), 2.26 (s, 3H), 2.45 (d, 2H, J = 16.8 Hz), 2.59 (d, 2H, J = 7.5 Hz), 2.60 (d, 2H, J = 7.5 Hz), 3.21 (d, 2H, J = 16.8 Hz), 7.08 (s, 4H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 12.4 (q), 13.0 (q), 20.9 (q), 31.5 (q), 40.5 (s), 49.1 (t), 51.5 (t), 62.5 (s), 125.0 (d), 129.2 (d), 135.9 (s), 145.8 (s), 207.4 (s). HRMS, *m/z*: 280.0949 (calcd. for $C_{15}H_{20}OS_2$: 280.0957).

3-Methyl-3-(4-methylphenyl)-1-methylenecyclobutane (8)

A solution of ketone **3** (0.94 g, 5.4 mmol) in ether (2 mL) was added to the Wittig reagent prepared from methyltriphenylphosphonium bromide (1.785 g, 5 mmol) in anhydrous ether (10 mL) by treatment with *n*-butyllithium (1.43 M, 3.5 mL, 5 mmol) for 5 min at room temperature. The mixture was stirred overnight, filtered, and the residue was triturated with ether. The organic solution was evaporated, and the product was purified by silica gel chromatography to afford **8** (0.865 g, 93% yield). IR: 1687, 876, 816 cm^{-1}. ^1H NMR (300 MHz, $CDCl_3$) δ: 1.53 (s, 3H), 2.37 (s, 3H), 2.73 (d, 2H, J = 13.5 Hz), 3.08 (d, 2H, J = 13.5 Hz), 4.90 (s, 2H), 7.12 (s, 4H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 21.1 (q), 30.5 (q), 38.3 (s), 44.9 (t), 107.3 (t), 125.8 (d), 128.7 (d), 134.7 (s), 144.6 (s), 147.7 (s). EIMS; *m/z*: 172 ($M^{+\cdot}$).

3-Methyl-3-(4-methylphenyl)cyclopentanone (6)

From 5

A suspension of Raney nickel (ca. 2 mL) was washed three times with ethanol. A solution of **5** (114 mg, 0.41 mmol) in ethanol (6 mL) was added and the mixture was refluxed under nitrogen overnight. The metal was filtered, the filtrate was evaporated, and the residue was chromatographed to provide ketone **6** (65 mg, 85% yield). IR: 1741 cm^{-1}. ^1H NMR (300 MHz, $CDCl_3$ δ: 1.33 (s, 3H), 2.18–2.33 (m, 4H), 2.30 (s, 3H), 2.40 (d, 1H, J = 18 Hz), 2.58 (d, 1H, J = 18 Hz), 7.11 (d, 2H, J = 6 Hz) 7.14 (d, 2H, J = 6 Hz). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 20.7 (q), 29.2 (q), 35.7 (t), 36.5 (t), 43.2 (s), 52.1 (t), 125.1 (d), 129.0 (d), 135.5 (s), 145.2 (s), 218.5 (s). HRMS, *m/z*: 188.1185 (calcd. for $C_{13}H_{16}O$: 188.1202).

From 8

A mixture of the methylenecyclobutane **8** (0.10 g, 0.58 mmol) and thallium(III) nitrate trihydrate (0.26 g, 0.58 mmol) in methanol (6 mL) was stirred at room temperature for 12 h. At this point solid NaCl (0.17 g) was added, the solid was filtered after 10 min, and the filtrate was evaporated in vacuo, redissolved in CH_2Cl_2, washed with brine, then water, dried, and concentrated. The product was purified by silica gel chromatography to give **6** (0.074 g, 68% yield).

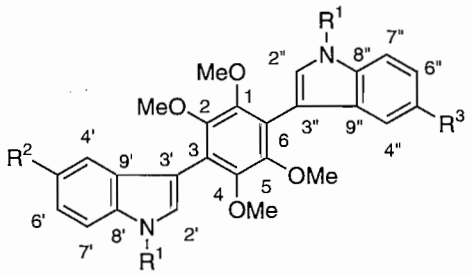
Bisindolylbenzenoids from ascostromata of *Petromyces muricatus*

Mikiko Ooike, Koohei Nozawa, Shun-ichi Udagawa, and Ken-ichi Kawai

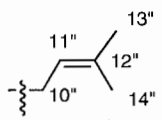
Abstract: New bisindolylbenzenoids designated petromurins A (**1**), B (**2**), C (**3**), and D (**4**) were isolated from the ascostromata of *Petromyces muricatus*. These structures were determined by chemical and spectroscopic methods.

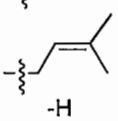
Key words: *Petromyces muricatus*; bisindolylbenzenoids; petromurin A, B, C, and D; ascostromata; *Aspergillus muricatus*.

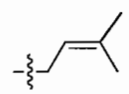
Résumé : On a isolé de nouveaux bisindolylbenzénoïdes, appelés pétromurines A (**1**), B (**2**), C (**3**) et D (**4**), à partir des ascostromates du *Petromyces muricatus*. On a déterminé les structures par des méthodes chimiques et spectroscopiques.



Mots clés : *Petromyces muricatus*; bisindolybenzénoïdes; pétromurines A, B, C et D; ascostromates; *Aspergillus muricatus*.







[Traduit par la rédaction]

Introduction

Petromyces muricatus Udagawa et al., the teleomorph of *Aspergillus muricatus* Udagawa et al. in the section *Circumdati*, subgenus *Circumdati* (= *A. ochraceus* group sensu Raper and Fennell), is characterized by producing pale yellow sclerotiodal bodies that may be converted slowly into an ascostroma. This fungus is the third *Petromyces* isolated from grassland soil of the Philippines in 1993 (1).

In the course of chemical studies on the indoloditerpenic metabolites of sclerotium-producing fungi, we previously reported the isolation of nominine, an anti-insectan indoloditerpene originally isolated from sclerotia of *Aspergillus nomius* Kurtzman et al. by Gloer et al. (2), and from ascostromata of *Petromyces alliaceus* Malloch et Cain, along with bicoumarins (3). This is the first case of isolation of sclerotial metabolites from the genus *Petromyces*. It is, therefore, of great interest to compare a profile of sclerotial metabolites of *P. muricatus* with that of taxonomically related species such as sclerotium-forming members of the sect. *Circumdati* of *Aspergillus*, e.g., *A. ochraceus* Wilhelm, *A. sclerotiorum* Huber, and *A. sulphureus* (Fres.) Thom et Church. As a result of an investigation of metabolites that showed positive colorations with Ehrlich's reagent (4), four indole derivatives designated as petromurins A (**1**), B (**2**), C (**3**), and D (**4**) were isolated from ascostromata of *P. muricatus*. The structures of **1**, **2**, **3**, and **4** are now reported in this paper.

Results and discussion

The molecular formulae of petromurins A (**1**), B (**2**), C (**3**), and D (**4**) were determined by high-resolution mass spectrometry as $C_{31}H_{32}N_2O_5$, $C_{31}H_{32}N_2O_4$, $C_{26}H_{24}N_2O_5$, and $C_{27}H_{26}N_2O_6$, respectively. All of these compounds showed positive coloration (purple) with Ehrlich's reagent. Compounds **1**, **3**, and **4** were also positive with iron(III) chloride reagent. These results suggested the presence of an indole group in **1**–**4** and a phenolic OH in **1**, **3**, and **4**. The ^{1}H NMR spectrum of **1** revealed the presence of two isolated 1,2,4-trisubstituted benzene rings (δ_H 6.99, 6.75, and 7.29, and 7.36, 6.98, and 7.37), four OMe groups (δ_H 3.49, 6H and 3.50, 6H),

Received September 12, 1996.

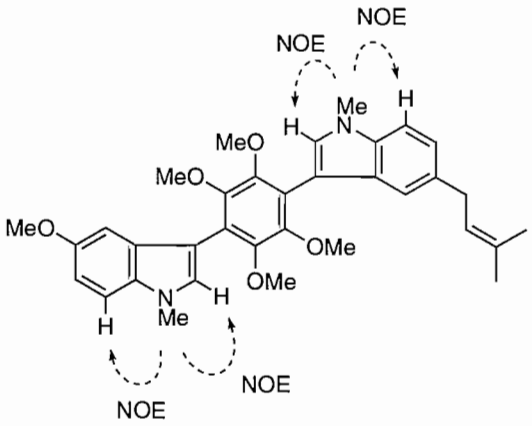

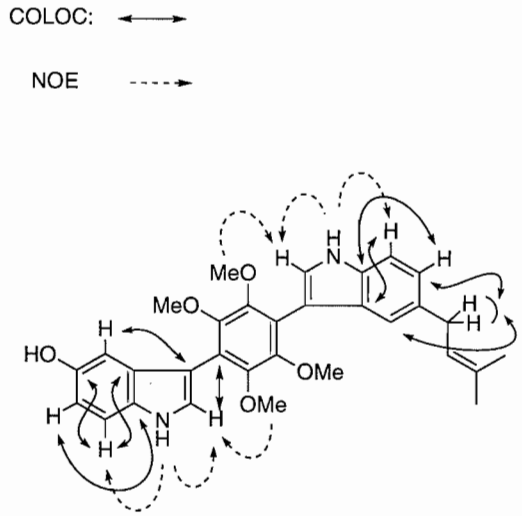

Fig. 2. ^{13}C–^{1}H correlation in COLOC and difference NOE for petromurin A (**1**).

and a 3-methyl-2-butenyl side chain. Each doublet signal at δ_H 7.44 and 7.45 in **1** changed into a singlet when D_2O was added, along with the disappearance of three signals at δ_H 7.55 (phenolic OH), 10.17 (NH), and 10.28 (NH). Petromurin A (**1**) thus contains two 3,5- or 3,6-disubstituted indole units. From these results and the consideration of the molecular formula, the remaining atoms in **1** were assigned to a hexasubstituted benzene ring. To confirm the substitution pattern of the two indole units in petromurin A (**1**), trimethylpetromurin A (**5**) was prepared from **1**. Irradiation of the signal at δ_H3.91 in **5**, attributed to the overlap of two NMe groups, brought about strong enhancements of signals at δ_H 7.38 (1H, br s, H-2″), 7.36 (1H, br s, H-2′), 7.34 (1H, d, J = 8.3 Hz, H-7″), and 7.33 (1H, d, J = 8.8 Hz, H-7′) (Fig. 1). These data coupled with other NMR data (see below) established that **1** had two 3,5-disubstituted indole groups.

The ^{1}H and ^{13}C NMR assignments of **1** and the substitution pattern of the benzene ring in **1** were established on the basis of long-range ^{13}C–^{1}H COSY (COLOC) spectra and difference NOE experiments on petromurin A (**1**) (Fig. 2). The signals at δ_C 121.2 (C-4″) and 123.4 (C-6″) showed COLOC correlations with the methylene proton signals of the 3-methyl-2-butenyl group at δ_H 3.42. The carbon signal at δ_C 136.1 (C-8″) showed a COLOC correlation with a proton at δ_H 6.98 (H-6″), along with correlations to protons at H-2″ and H-4″. The carbon signals at δ_C 129.1 (C-9″) and 133.2 (C-5″) were correlated with a proton at δ_H 7.37 (H-7″). On the other hand, the carbon at δ_C 108.6 (C-3′) in the other indole showed COLOC correlations with a proton at δ_H 6.99 (H-4′). The carbon signal at δ_C 132.3 (C-8′) was correlated with protons at δ_H 6.75 (H-6′) and 6.99 (H-4′). The carbon signals at δ_C 129.7 (C-9′) and 152.0 (C-5′), which were not correlated to any OMe proton signal, showed COLOC correlation with a proton at δ_H 7.29 (H-7′). These results indicated that the 3-methyl-2-butenyl group was situated at C-5 of one indole unit and the phenolic OH at C-5 of the other indole unit of **1**. The six carbons of the hexasubstituted benzene ring in **1** appeared as four signals comprised of signals at δ_C 149.4 (2C) and 149.5 (2C), which were correlated with OMe proton signals at δ_H 3.49 and 3.50, respectively, and signals at 123.9 (C-3) and 123.6 (C-6). Irradiation of the OMe protons at δ_H 3.49 and 3.50 in **1** caused weak enhancements of the signals at δ_H 7.44 (H-2′) and 7.45 (H-2″), respectively. We therefore concluded that the petromurin A (**1**) had a 1,2,4,5-tetramethoxylbenzene ring. Furthermore, a COLOC peak was observed between the carbon at δ_C 123.9 (C-3) and the proton at δ_H 7.44 (H-2′) when the COLOC spectrum of **1** was optimized for J_{CH} = 4 Hz. The structure of petromurin A (**1**), consequently, was assigned as depicted in structure **1** and the ^{13}C NMR assignments of **1** are provided in Table 1.

The ultraviolet (UV) spectra of petromurins B (**2**), C (**3**), and D (**4**) were essentially superimposable on those of petromurin A (**1**). The ^{1}H NMR spectrum of petromurin B (**2**) was similar to that of **1**, except for the presence in **2** of a 1,2-disubstituted benzene ring (δ_H 7.00 (H-5′), 7.09 (H-6′), 7.43 (H-7′), and 7.51 (H-4′)) instead of the 1,2,4-trisubstituted benzene ring of **1** that carried the hydroxyl group. Petromurin C (**3**) also has a 1,2-disubstituted benzene ring (δ_H 7.04 (H-5″), 7.14 (H-6″), 7.47 (H-7″), and 7.55 (H-4″)) lacking the 3-methyl-2-butenyl group present in **1**. The ^{1}H and ^{13}C NMR assignments of **2** and **3** were established by NOE difference experiments and analyses of the ^{13}C–^{1}H COSY and the COLOC spectra. The signals at δ_C121.2 (C-4″) and 123.5 (C-6″) assigned to one of the indole units in **2** showed COLOC correlations with the methylene proton signals (δ_H 3.37) of the 3-methyl-2-butenyl side-chain. The carbons at C-3″ (δ_C 109.2) in **2** and C-3′ (δ_C 108.7) in **3** were correlated with the protons at H-4″ (δ_H 7.31) and H-4′ (δ_H 6.99) in COLOC spectra, respectively. Irradiation of the NH protons (δ_H 10.25, 1″-NH) in **2** and the NH (δ_H 10.17, 1′-NH) in **3** caused strong enhancements of the signals at δ_H 7.32 (H-7″) and 7.41 (H-2″), and 7.29 (H-7′) and δ_H 7.44 (H-2′), respectively. The protons of the four methoxyl groups in **2** and **3** were correlated with the carbons in the central benzene ring. Thus, it is clear that petromurins B and C possess a substituent at C-5 in one indole ring, leading to assignments of the structures as **2** and **3**, respectively.

The ^{1}H NMR spectrum of petromurin D (**4**) was also similar to that of **1**, except for the absence of the 3-methyl-2-butenyl side chain and the appearance of an additional methoxyl group at δ_H 3.77. The ^{1}H and ^{13}C NMR assignments of **4** were established on the basis of the ^{1}H–^{1}H and ^{13}C–^{1}H COSY, and ^{1}H-detected heteronuclear multiple bond connectivity (HMBC) spectra. The substitution pattern of two indoles in **4** was

[a,b,c]Assignments may be reversed.

assigned from the HMBC spectrum. The HMBC spectrum of **4** indicated a cross peak between the carbon at C-5″ and the methoxyl protons at δ_H3.77. On the basis of these results, the structure of petromurin D was proposed as shown in **4**.

Members of this general structural class (5) have been previously reported as fungal metabolites, e.g., cochliodinol from *Chaetomium* spp. (6) and asterriquinones from *Aspergillus terreus* (7). The known compounds commonly contain prenyl groups at various positions on the indole moieties, except for the ochrindoles A–D from sclerotia of *A. ochraceus* Thom, in which the prenyl side chain was located on the central benzenoid ring (8). Petromurins A, C, and D (**1**, **3**, and **4**) are the first examples where O functional group(s) have been observed on the indole moiety in the bisindolylbenzenoids.

Experimental

General procedure

Melting points were determined on a Yanagimoto micro-melting point apparatus and are uncorrected. Mass spectra were taken with a Jeol JMS-D-300 spectrometer. UV and IR spectra were recorded on a Hitachi U-3210 spectrophotometer and a Jasco IR-810 spectrophotometer, respectively. ^1H NMR and ^{13}C NMR spectra were recorded on a Jeol JNM-GX-400 spectrometer at 399.78 and 100.43 MHz, respectively, using tetramethylsilane as internal standard. The HMBC experiment of petromurin D was taken with a Jeol Lambda-500 spectrometer at 500.00 MHz. The coupling patterns are indicated as follows: singlet = s, doublet = d, triplet = t, multiplet = m, and broad = br. Column chromatography was performed using Kieselgel 60 (Art. 7734; Merck). Low-pressure liquid chromatography (LPLC) was performed on a Chemco Low-Prep 81-M-2 pump and glass column (10 mm i.d. × 300 mm) packed with silica gel CQ-3 (30–50 μm; Wako). TLC was conducted on precoated Kieselgel 60 F_{254} plates (Art. 5715; Merck). Spots on TLC plates were detected on the basis of their absorption of UV light, and (or) by spraying Ehrlich's reagent (4) and then heating.

Isolation of metabolites

Petromyces muricatus, strain IMI 368521, was cultivated at 35°C for 3 weeks in 480 Petri dish plates (i.d. 90 mm) containing 25 mL of melted Czapek yeast extract agar (CYA) per dish. The fresh ascostromata were collected and extracted with chloroform at room temperature. The evaporated residue (1.8 g) was separated by silica gel column chromatography into five fractions: cyclohexane – ethyl acetate (10:1), cyclohexane – ethyl acetate (5:1), cyclohexane – ethyl acetate (2:1), acetone, and EtOH. The second fraction was subjected to LPLC using cyclohexane–acetone (5:1) to give petromurin B (**2**) (80 mg). The third fraction was separated by LPLC using cyclohexane–acetone (2:1) to give petromurin A (**1**) (315 mg), petromurin C (**3**) (227 mg), petromurin D (**4**) (113 mg) in that order.

C_3 Symmetric oxazolinyl ligand as catalyst in the enantioselective addition of diethylzinc to aldehydes

T.H. Chan and G.Z. Zheng

Abstract: The C_3 symmetric oxazolinyl ligand **1** has been synthesized. Compound **1** catalyzed the addition of diethylzinc to aromatic aldehydes to give secondary alcohols with high enantiomeric excesses (up to 90%).

Key words: diethylzinc, enantioselective synthesis, C_3 symmetric ligands, enantioselective addition reactions, oxazolinyl ligands.

Résumé : On a synthétisé le coordinat oxazolinyle **1**, de symétrie C_3. Le composé **1** catalyse l'addition du diéthylzinc sur les aldéhydes aromatiques qui conduit à des alcools secondaires avec des excès énantiomériques élevés (jusqu'à 90%).

Mots clés : diéthylzinc, synthèse énantiosélective, coordinats de symétrie C_3, réactions d'addition énantiosélective, coordinats oxazolinyles.

Introduction

The success of many C_2 symmetric ligands as catalyst in a number of highly enantioselective chemical transformations (1) has underscored the important role that symmetry could play in the stereocontrol of these reactions. It has been suggested that the C_2 ligand enhances the optical yield of the reaction by reducing the number of competing diastereomeric pathways due to the homotopic nature of the remaining coordination sites of the complexes formed by the ligand (1). As a consequence, considerable efforts have been directed to prepare higher order symmetrical compounds (2), such as C_3 symmetric ligands, to see if they can be useful reagents to induce high enantioselectivity in chemical reactions. Although C_3 symmetric phosphine ligands (2*a*), pyrazolyl compounds (2*c*,*d*,*e*), pyridinyl compounds (2*f*), and tris-alkoxides (2*b*) have been made previously, there have been few reports on the use of these ligands in asymmetric synthesis. One example (2*a*) is the asymmetric hydrogenation of dimethyl itaconate using a C_3 phospine ligand giving high ee (95%). On the other hand, for carbon–carbon bond formation, the single report on the use of a chiral C_3 copper complex that catalyzed the cyclopropanation of styrene with diazoacetates gave maximum ee's of only 60% (2*d*). We report here the synthesis of a C_3 symmetric tris(oxazolinyl) compound **1** and its application in asymmetric synthesis.

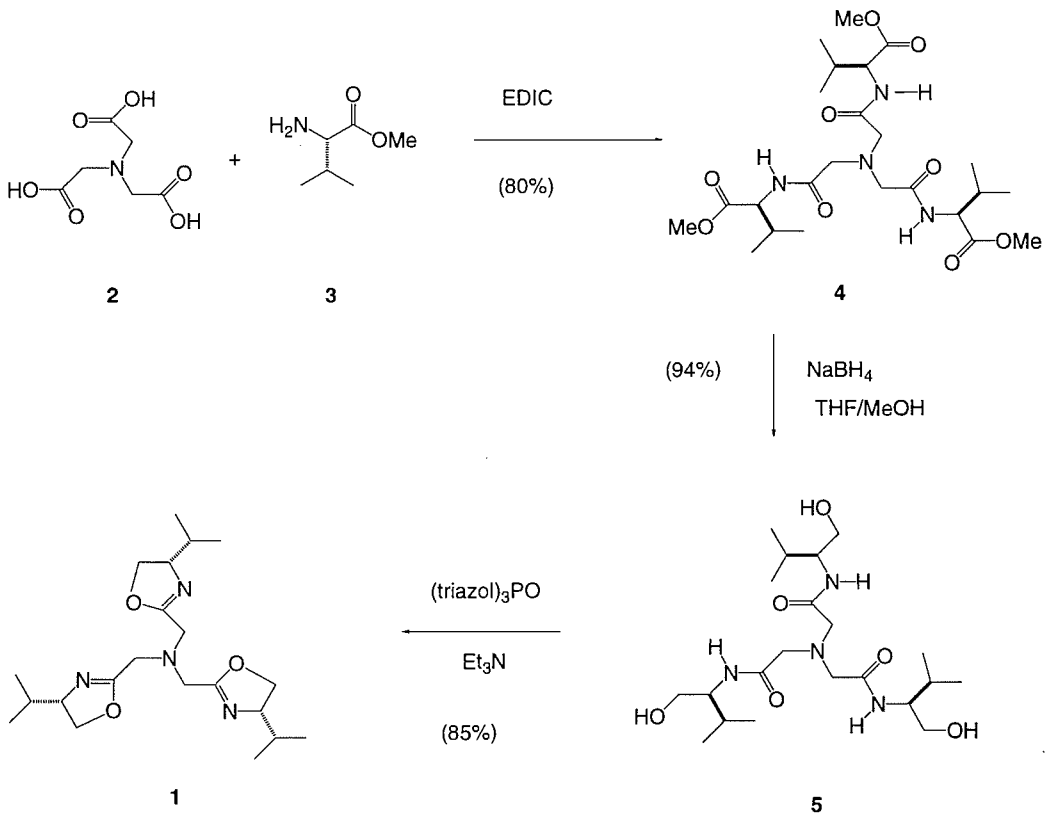
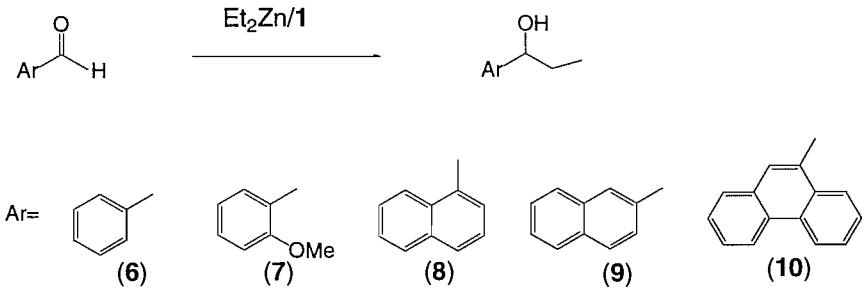
Synthesis



Compound **1** was prepared via the coupling of the triacid **2** with (*S*)-valine methyl ester (**3**) mediated by the coupling agent *N*-(3-dimethylaminopropyl)-*N'*-ethylcarbodiimide hydrochloride (EDCI) (3) (80% yield, Scheme 1). As three chiral centers have been implanted into compound **4**, any racemization during the coupling step should be easily detected by ^{1}H NMR spectroscopy of **4**. The results showed that there was no significant racemization at any of the chiral centres, with or without the presence of 1-hydroxybenzotriazole (HOBT), a reagent reported to prevent racemization during such coupling reactions (4). Selective reduction of the ester functions of **4** to the alcohol **5** was achieved using sodium borohydride (5). The reaction had to be carried out in a mixed solvent system (MeOH:THF = 50:50), and a large excess (5–10 equiv.) of sodium borohydride was used to drive the reduction to completion (94%). The alcohol **5** was subsequently cyclized with the assistance of tris(triazole)phosphine oxide (6) to give the final C_3 product **1** with high yield (85%; Scheme 1). Other cyclization reagents, such as thionyl chloride (7), $(CF_3CO)_2O$–Et_3N (8), *N,N*-dimethylchloromethyleneammonium chloride (9), and $(CF_3SO_2)_2O$–Ph_3PO (10) gave a mixture of products with no significant amount of **1**. Compound **1** could be obtained pure using gel (Sephadex LH-20) filtration (11). It was reasonably stable when stored as a solution of benzene at low temperature. Since the completion of our work, another synthesis of **1** has been reported in the literature (12), using a somewhat different synthetic scheme with lower overall yield.

Enantioselective addition of diethylzinc to aldehydes



The C_3 symmetric ligand **1** was used as catalyst in the addition of diethylzinc to aromatic aldehydes **6**–**10** (Scheme 2). The results were encouraging in that the enantiomeric excesses of the alcohols obtained were quite high (up to 90% ee), even

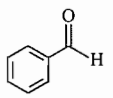
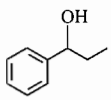
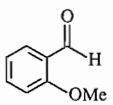
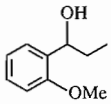
Scheme 1.

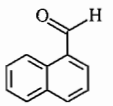
Scheme 2.

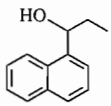


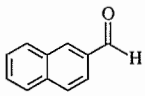


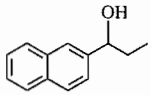


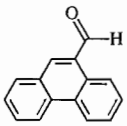


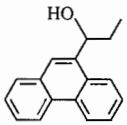












though slightly lower than the best results reported for the same reaction using other types of chiral ligands (13). The results are summarized in Table 1. The optical purity and the absolute configuration of the product were determined by conversion to the corresponding Mosher ester and analysed by NMR. The reaction was carried out in toluene as solvent and gave excellent chemical yield in general, with good to high optical yield (72–90% ee). Similar chemical yields were obtained in hexane as solvent, but with somewhat lower enantiomeric excesses for the products. Even in toluene, the amounts of compound **1** in the reaction mixture were crucial for good stereochemical outcome. Relatively large amounts of **1** (>2% mol) were required to produce high ee. However, over 20% mol concentration of catalyst **1** in the reaction mixture did not enhance the enantiomeric excess significantly. When using 26% mol of the catalyst in the reaction, similar enantiomeric excess was obtained (82% ee (*R*); 90% yield) when the substrate was benzaldehyde (**6**). Reducing the amounts of diethylzinc from 6 equivalents (substrate/Et_2Zn = 1 mmol: 3 mmol) to 4 equivalents (substrate/Et_2Zn = 1 mmol:2 mmol) reduced the enantiomeric excess of the product (to 68% ee (*R*) (82% yield) for **6**). Upon further reduction of the relative amount of diethylzinc to 2 equivalents, the enantiomeric excess decreased even further (to 54% (*R*) (70% yield) for **6**). Such concentration dependence is in agreement with the proposed mechanism in which a dinuclear zinc species involving a second molecule of diethylzinc has been postulated as the reactive intermediate in the critical alkyl transfer step (13).

It is interesting to note that under identical reaction conditions, the use of a similar C_2 symmetric ligand **11**, prepared according to literature procedures (14), as the catalyst gave much lower ee's (<20%) for the reaction of diethylzinc with benzaldehyde. We conclude therefore that the C_3 symmetric ligand **1** is an effective catalyst in promoting high enantioselective addition of diethylzinc to aromatic aldehydes. The results justify the search for other C_3 symmetric ligands, as

well as further exploration of these ligands in asymmetric synthesis.

Experimental section

General

THF was distilled over sodium – benzophenone ketyl radical prior to use. Hexanes, ethyl acetate, dichloromethane, triethylamine, pyridine, DMF, and acetonitrile were distilled over calcium hydride. 1,2,4-Triazole was recrystallized from CH_2Cl_2–*n*-pentane. Thionyl chloride, phosphoryl chloride, and oxalyl chloride were distilled prior to use. Nuclear magnetic resonance spectra were recorded on Varian Gemini 200 (^{1}H 200 MHz, ^{13}C 50 MHz), XL-200 (^{1}H 200 MHz, ^{13}C 50 MHz), XL-300 (^{1}H 300 MHz, ^{13}C 75 MHz), and Unity 500 (^{1}H 500 MHz, ^{13}C 125 MHz) spectrometers. Chemical shifts are expressed in parts per million (ppm) and the references are the residual proton signals of $CDCl_3$ (δ = 7.24 ppm for ^{1}H, δ = 77.00 ppm for ^{13}C NMR). The following abbreviations were used for NMR spectra: s = singlet; d = doublet; t = triplet; q = quartet; m = multiplet; br = broad. IR spectra were recorded on an Analet FT A25-18 spectrometer between NaCl plates (neat liquids), a film on a NaCl plate, or as a KBr disk. Mass spectra were recorded on a Kratos MS25RFA mass spectrometer.

All the solvents, liquid reagents, and substrates used in asymmetric hydrosilation were degassed via a freeze–thaw cycle under argon prior to use. All asymmetric addition reactions were carried out under an inert atmosphere (argon). The glassware, syringes, needles, and magnetic stirring bars (Teflon coated) were dried at 120°C overnight or longer and were then allowed to cool over Drierite in a glass desiccator. Enantiomeric excess was determined via the (*S*) Mosher's esters of the products using ^{1}H NMR. The corresponding (*R*)-α-methoxy-α-trifluoromethylphenylacetyl chloride was prepared from (*S*)-α-methoxy-α-trifluoromethylphenylacetic acid and thionyl chloride.

Flash column chromatographic separations were performed with Merck Kieselgel 60 (230–400 mesh ASTM) under air pressure. All thin-layer chromatography (TLC) was carried out using precoated cellular plates with Silica Gel 60 F254. The spots were detected by using UV light, or phosphomolybdic acid – Ce_2SO_4 solution followed by charring with a hot-air gun. Gel filtration was performed using Sephadex LH-20.

Low-temperature reactions were carried out in a Dry Ice – acetone bath (−78°C), and in methanol baths cooled by Neslab Cryocool CC-100 II (−20°C to −100°C) and Cryocool PBC-75 II (20°C to −20°C).

N,N,N-Tris[1-((*S*)-1-methoxycarbonyl-2-methylpropyl)]-nitrilotriacetamide (4)

L-Valine methyl ester hydrochloride (7.50 g, 44.7 mmol), nitrilotriacetic acid (2.48 g, 13.0 mmol), 1-(3′-dimethylaminopropyl)-3-ethylcarbodiimide hydrochloride (7.5 g, 39.1 mmol), and DMAP (0.12 g, 0.1 mmol) were dissolved in CH_2Cl_2 (250 mL) in a 500 mL flask under argon. 4-Methylmorpholine (6 mL, 5.52 g, 55 mmol) was added dropwise at room temperature. The reaction mixture was stirred at room temperature for 2 days. To the clear, light-yellow solution, saturated aqueous ammonium chloride solution was added. The organic layer was washed with water (2 × 30 mL) and dried over Na_2SO_4. Removal of solvent gave a reasonably pure product (5.51 g, 80%). IR (film): 1116, 1154, 1210, 1530, 1535, 1543, 1649, 1656, 1742, 2938, 2964, 3263 cm^{-1}; ^{1}H NMR (200 MHz, $CDCl_3$) δ: 7.63 (d, J = 8.9 Hz, 3H), 4.53 (dd, J = 8.9, 5.2 Hz, 3H), 3.72 (s, 9H), 3.44 (d, J = 15.2 Hz, 3H), 3.28 (d, J = 15.2 Hz, 3H), 2.20 (m, 3H), 0.96 (d, J = 6.3 Hz, 9H), 0.92 (d, J = 6.6 Hz, 9H); ^{13}C NMR (50 MHz, $CDCl_3$) δ: 172.1, 169.4, 58.3, 57.6, 52.4, 30.6, 19.7, 18.5; MS *m/z* calcd. for $C_{24}H_{42}O_9N_4$: 530.2952; found: 530.2959; $[\alpha]_D^{20}$ +9.1 (c = 0.0527 g/mL, MeOH).

N,N,N-Tris[2-((*S*)-1-hydroxy-3-methylbutyl)]-nitrilotriacetamide (5)

In a 500 mL, three-neck flask equipped with a condenser, *N,N,N*-tris[1-((*S*)-1-methoxycarbonyl-2-methylpropyl)]nitrilotriacetamide (**4**, 5.40 g, 10.2 mmol) was dissolved in methanol

(50 mL) and THF (50 mL) under argon. $NaBH_4$ (3.0 g, 78.9 mmol) was added in small portions to the solution at room temperature. Another portion of $NaBH_4$ (3.0 g, 78.9 mmol) was added to the reaction mixture 2 h later at room temperature. The reaction mixture was stirred at room temperature for 3 h before being quenched with saturated aqueous ammonium chloride solution at 0°C. A clear solution was obtained after HCl (2 N, 30 mL) was added at 0°C. The latter was then neutralized by saturated aqueous K_2CO_3 solution. The organic solvents were removed via rotary evaporator, and the aqueous residue was extracted with ethyl acetate (10 × 40 mL). The combined organic layers were washed with saturated aqueous K_2CO_3 solution (2 mL), water (3 × 10 mL), and then dried over Na_2SO_4. Removal of solvent gave a reasonably pure product (4.33 g, 96%). The product can be purified by flash chromatography on silica gel (ethyl acetate:methanol = 10:1). IR (film): 1076, 1371, 1389, 1466, 1558, 1657, 2934, 2963, 3280, 3294, 3318 cm^{-1}; ^1H NMR (200 MHz, $CDCl_3$) δ: 7.69 (d, 3H), 4.21 (br, 3H), 3.73 (m, 6H), 3.52 (dd, J = 10.1, 8.3 Hz, 3H), 3.39 (d, J = 5.9 Hz, 6H), 1.77 (m, 3H), 0.91 (d, J = 5.1 Hz, 9H), 0.88 (d, J = 5.1 Hz, 9H); ^{13}C NMR (50 MHz, $CDCl_3$) δ: 170.5, 62.9, 59.9, 57.3, 29.9, 20.1, 19.6; MS *m/z* calcd. for $C_{21}H_{40}O_5N_4-(M-H_2O)$: 428.2999; found: 428.3003; $[\alpha]_D^{20}$ −13.7 (c = 0.0648 g/mL, MeOH).

N,N,N-Tris[((4*S*)-isopropyl-2-oxazolin-2-yl)methyl]-amine (1)

1,2,4-Triazole (21.9 g, 317 mmol) was dissolved in acetonitrile (425 mL) in an 1 L flask furnished with a Drierite drying tube. Phosphorus oxychloride (9.7 mL, 15.96 g, 104 mmol) was added at 0°C, followed by triethylamine (50 mL, 36.3 g, 359 mmol) dropwise. The reaction mixture was then stirred at 0°C for 2 h. The mixture was siphonated through a cannula to a sealed sintered glass filter, which was placed in the neck of a 2 L flask, so that the clear filtrate could be added directly to the solution of *N,N,N*-tris[2-((*S*)-1-hydroxy-3-methylbutyl)]nitrilotriacetamide (**5**, 4.07 g, 9.1 mmol) in triethylamine (900 mL) and acetonitrile (100 mL). After the addition was finished, the reaction mixture was stirred another 20 min before saturated aqueous $NaHCO_3$ solution (100 mL) was introduced to the reaction flask. The organic solvents were removed via a rotary evaporator, and the remaining mixture was extracted with CH_2Cl_2 (10 × 50 mL). The combined organic layers were washed with water (3 × 40 mL) and then dried over Na_2SO_4. Removal of solvent gave a reasonably pure product (3.04 g, 85%). The product could be further purified using a gel filtration method (Sephadex LH-20, ethyl acetate). IR (film): 983, 1145, 1194, 1386, 1468, 1672, 2873, 2963, 33.52 cm^{-1}; ^1H NMR (200 MHz, $CDCl_3$) δ: 4.21 (m, 3H), 3.89 (m, 6H), 3.59 (s, 6H), 1.69 (m, 3H), 0.91 (d, J = 6.7 Hz, 9H), 0.83 (d, J = 6.8 Hz, 9H); ^{13}C NMR (125 MHz, $CDCl_3$) δ: 163.9, 72.0, 67.0, 50.3, 32.4, 18.7, 18.1; MS *m/z* calcd. for $C_{21}H_{36}N_4O_3$: 392.2787; found: 392.2785; $[\alpha]_D^{20}$ −73.7 (c = 0.1191 g/mL, CH_2Cl_2).

General procedure for addition of diethylzinc to aldehydes

Benzaldehyde (106 mg, 1.0 mmol) was placed in a 25 mL round-bottom flask furnished with a magnetic stir bar and sealed with a rubber septum under argon. Diethylzinc (2.7 mL, 1.1 M in toluene, 3.0 mmol) was added to this flask at 0°C followed by compound **1** (80 mg, 0.20 mmol) in toluene (1 mL). The reaction mixture was maintained at 0°C for 2 days before quenching with saturated ammonium chloride in aqueous solution.

The reaction mixture was then acidified with HCl (2 N), followed by sodium carbonate (saturated aqueous solution). The mixture was extracted with dichloromethane (3 × 5 mL), and the combined organic layers were dried over Na_2SO_4. After removal of solvent, the crude product was purified via a Kugelröhr apparatus (80°C/5 Torr (1 Torr = 133.3 Pa); 125 mg, 92%). IR (neat): 3400, 3000, 2950, 1500, 1100, 1000, 800 cm^{-1}; ^1H NMR (500 MHz) δ: 7.34 (m, 3H), 7.26 (m, 2H), 4.58 (t, J = 7.0 Hz, 1H), 1.84 (br, 1H), 1.75–1.80 (m, 2H), 0.90 (t, J = 7.0 Hz, 3H); ^{13}C (125 MHz) δ: 144.6, 128.4, 127.5, 126.0, 76.0, 31.9, 10.1; MS (*m/z*): 77 (16.5), 79 (35.2), 92 (13.1), 107 (100.0), 108 (9.1), 136 (14.5, M), 137 (3.0).

1-(2′-Methoxyphenyl)-1-propanol: IR (neat): 753, 1029, 1046, 1089, 1237, 1458, 1464, 1491, 1494, 1588, 1601, 2838, 2936, 2968, 3386 cm^{-1}; ^1H NMR (500 MHz) δ: 7.27 (dd, J = 8.0, 2.0 Hz, 1H), 7.22 (td, J = 7.5, 2.0 Hz, 1H), 6.94 (t, J = 7.5 Hz, 1H), 6.86 (d, J = 8.0 Hz, 1H), 4.76 (t, J = 6.5 Hz, 1H), 3.83 (s, 3H), 1.80 (m, 2H), 0.94 (t, J = 7.5 Hz, 3H); ^{13}C (125 MHz): 156.6, 132.3, 128.2, 127.1, 120.7, 110.5, 72.5, 55.2, 30.1, 10.5; MS (*m/z*): 77 (19.5), 94 (10.0), 107 (58.7), 109 (14.0), 121 (14.0), 137 (100.0), 138 (13.6), 166 (8.9, M).

1-(1′-Naphthyl)-1-propanol: IR (neat): 777, 800, 1029, 1168, 1259, 1458, 1511, 1598, 2875, 2965, 2280 cm^{-1}; ^1H (500 MHz) δ: 7.81 (m, 3H), 7.77 (s, 1H), 7.45 (m, 3H), 4.76 (t, J = 5.0 Hz, 1H), 1.87 (m, 2H), 0.93 (t, J = 8.0 Hz, 3H); ^{13}C (125 MHz) δ: 141.9, 133.2, 132.9, 128.2, 127.9, 127.6, 126.1, 125.7, 124.7, 124.1, 76.1, 31.7, 10.1; MS (*m/z*): 127 (25.6), 128 (39.5), 129 (76.3), 157 (100.0), 158 (15.2), 186 (37.8, M), 187 (5.4).

1-(2′-Naphthyl)-1-propanol: IR (neat): 748, 819, 856, 1018, 1126, 1455, 1463, 2875, 2931, 2965, 3378 cm^{-1}; ^1H (500 MHz) δ: 8.11 (d, J = 8.0 Hz, 1H), 7.86 (d, J = 9.0 Hz, 1H), 7.77 (d, J = 8.0 Hz, 1H), 7.63 (d, J = 7.0 Hz, 1H), 7.48 (m, 3H), 5.39 (dd, J = 7.5, 5.0 Hz, 1H), 2.02 (m, 1H), 1.92 (m, 1H), 1.02 (t, J = 7.5 Hz, 3H); ^{13}C (125 MHz) δ: 140.1, 133.7, 130.3, 128.7, 127.7, 125.8, 125.3, 125.2, 123.1, 122.7, 72.5, 30.9, 10.4; MS (*m/z*): 127 (36.2), 128 (49.2), 129 (100.0), 130 (12.8), 157 (97.5), 158 (14.2), 186 (32.2, M), 187 (4.7).

1-(9′-Phenanthrenyl)-1-propanol: IR (neat): 763, 807, 970, 1046, 1450, 1496, 1654, 2875, 2963, 3301 cm^{-1}; ^1H (500 MHz) δ: 8.74 (dd, J = 8.0, 1.5 Hz, 1H), 8.65 (d, J = 8.0 Hz, 1H), 8.15 (dd, J = 7.5, 1.5 Hz, 1H), 7.89 (s, 1H), 7.88, dd, J = 8.5, 1.5 Hz, 1H), 7.62 (m, 4H), 5.42 (dd, J = 8.0, 5.0 Hz, 1H), 1.96–2.11 (m, 2H), 1.08 (t, J = 7.0 Hz, 3H); ^{13}C (125 MHz): 138.3, 131.4, 130.8, 130.0, 129.7, 128.8, 126.7, 126.6, 126.5, 126.3, 123.9, 123.7, 123.4, 122.4, 72.8, 30.8, 10.5; MS (*m/z*): 177 (21.9), 178 (59.5), 179 (94.2), 180 (13.9), 207 (100.0), 208 (16.7), 236 (32.1, M), 237 (6.1).

Isolation, structure, and synthesis of chenopodanol and the absolute configuration of chenopodene and chenopodanol

Motoo Tori, Tomonobu Hamaguchi, Mamiko Aoki, Masakazu Sono, and Yoshinori Asakawa

Abstract: (−)-Chenopodanol (**2**) has been isolated from the liverwort *Marchantia chenopoda* and its structure determined by spectroscopic techniques as well as by total synthesis. Chenopodene (**1**) has also been synthesized in an optically active form, resulting in revision of the originally assigned absolute configuration.

Key words: chenopodanol, chenopodene, liverwort, *Marchantia chenopoda*, sesquiterpene.

Résumé : On a isolé du (−)-chénopodanol (**2**) de l'hépatique trilobée *Marchantia chenopoda*; on en a déterminé la structure par des techniques spectroscopiques ainsi que par une synthèse totale. On a aussi synthétisé le chénopodène (**1**) sous forme optiquement active; il en résulte que l'on doit réviser la configuration absolue qui lui avait été originalement attribuée.

Mots clés : chénopodanol, chénopodène, hépatique trilobée, *Marchantia chenopoda*, sesquiterpène.

[Traduit par la rédaction]

Introduction

The absolute configuration of terpenoids isolated from liverworts is very interesting and important (1). In connection with our synthetic studies on liverwort terpenoids in optically active form, we undertook the synthesis of chenopodene (**1**), whose structure, including the absolute configuration, has already been reported (2). At the same time, we further searched for new compounds in the extract of *Marchantia chenopoda* collected in Venezuela and found (−)-chenopodanol (**2**) as a minor constituent. Because **2** is not chemically related to **1**, we decided to prepare both **1** and **2** in optically active forms. We are currently engaged in synthetic studies using the chiral Michael reaction product (+)-**3** to prepare several liverwort sesquiterpenoids (3). This kind of substance could be prepared through the intermediate **4** by introduction of a cyclopropane ring *cis* to the methyl group as shown in Scheme 1. We now describe the details of structure elucidation and the synthesis of **1** and **2**.

Results and discussion

Isolation and structure of chenopodanol

A slightly more polar fraction than (+)-chenopodene (**1**) was further separated by HPLC to afford (−)-chenopodanol (**2**) (see Experimental). The molecular formula of **2** was determined by HRMS to be $C_{15}H_{26}O$, and its IR spectrum indicated the presence of a hydroxyl group (3400 cm^{-1}), which was supported by the ^{13}C NMR (δ 68.5). The presence of a cyclopropane ring and a trisubstituted double bond was indicated by the ^1H NMR spectrum (δ: 5.12 (1H, t, J = 6.8 Hz), 0.44 (1H, ddd, J = 7.4, 7.4, 4.4 Hz), 0.34 (1H, ddd, J = 4.4, 4.4, 4.4 Hz)). The chenopodane skeleton was deduced by HMBC along with the HSQC spectra as shown in Fig. 1. The stereochemistry was inferred by the NOESY spectrum as shown in Fig. 2. Thus the structure of chenopodanol was determined as depicted in formula **2**. The isolation of a compound having the chenopodane skeleton is the second example from nature (2). However, the absolute configuration could not be verified due to the minute quantity of the compound. Because the absolute configuration of (+)-chenopodene (**1**) was deduced by the CD spectrum as reported (2), **2** was temporarily assigned to have the same configuration.

Synthesis of chenopodanol and chenopodene

Chiral keto ester (+)-**3** was easily prepared by the Michael reaction between the imine, prepared from 2-methylcyclohexanone and (*S*)-(−)-1-phenylethylamine and methyl acrylate (96% ee) (4). The absolute configuration was already determined by the original workers by conversion into the known substance (4) and also by our independent work (3). Ketone (+)-**3** was reduced and the primary alcohol **5** was selectively protected by TBDMS to afford a monoprotected alcohol **6**. The alcohol was dehydrated to give olefin **7**, which was oxidized by PDC and *t*BuOOH to afford enone **4**. Attempted cyclopropanation using trimethylsulfoxonium iodide and dimsyl anion (5) failed due to deprotection of the TBDMS group, followed by etherification to the α,β-unsaturated double bond. Methylation (MeLi) and Simmons–Smith cyclopropanation (6) resulted mainly in dehydration of the tertiary hydroxyl group. Therefore, enone **4** was first reduced and the isomeric

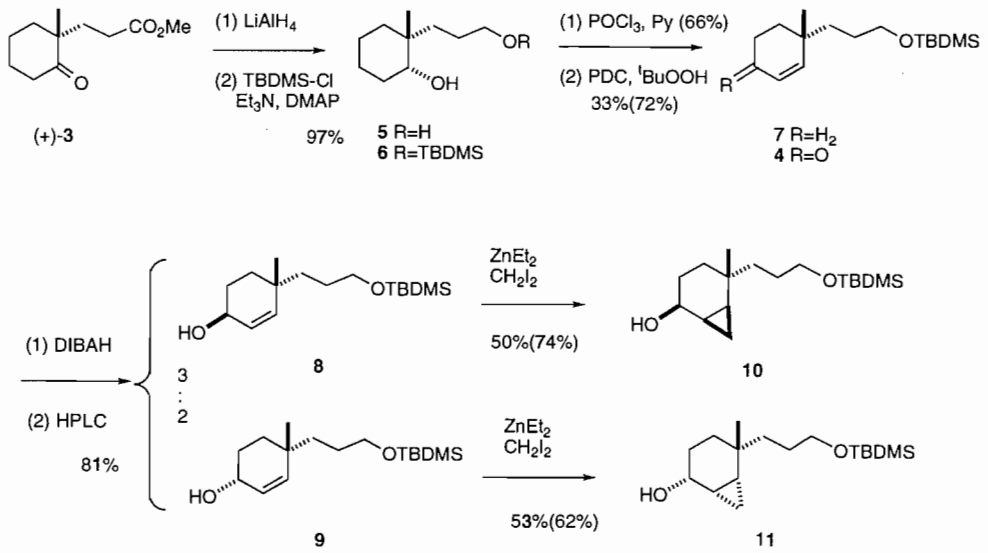
alcohols were separated to give **8** and **9**, although the stereochemistry was not clear at this stage. Simmons–Smith cyclopropanation (6) of alcohols **8** and **9** occurred smoothly to give a sole product, **10** and **11**, respectively, each of which must be a *cis* product, considering the cyclopropane and hydroxyl groups from the mechanistic standpoint (Scheme 2) (7). They were further oxidized by PDC to give the ketones **12** and **15**, respectively. The side chain was formed by a three-step conversion ((*i*) TBAF, (*ii*) PDC, (*iii*) Wittig) to afford **14** and **17**. The stereochemical assignment of the resulting ketones **14** and **17** was determined by the CD spectra as well as NOESY experiments (Fig. 3.). In the case of the α,β-cyclopropyl ketones, the expected Cotton effect is opposite to those for normal ketones as discussed by Djerassi et al. (8). Ketone **14**

Fig. 3. NOEs for ketones **14** and **17**.

14 **17**

showed a positive Cotton effect, while ketone **17** showed a negative effect. Therefore, the stereochemistries were assigned as depicted in Scheme 3.

When ketone **14** was methylated with MeLi, the major product was (+)-**18**, while the desired chenopodanol (**2**) was the minor one. The stereochemistry for the alkylation of the cycloalkanone having a cyclopropane ring in its α,β-position has been discussed by Mash et al. (9). Thus there was poor selectivity for the alkylation of **14** or **17**. The spectral data for product **2** were completely identical with those of the natural product. However, the specific rotation of the synthetic **2** was $[\alpha]_D$ +56.0, while that of the natural product was $[\alpha]_D$ −59.1. Thus the synthetic **2** was the enantiomer and the absolute configuration of the natural chenopodanol ((−)-**2**) must be as depicted in Scheme 1.



Ketone **17** was similarly methylated to afford **19** and **20**, neither of which was identical to chenopodanol. The stereochemistry of these products was determined by the NOESY spectra.

Compound (+)-**18** was dehydrated by $SOCl_2$ to afford chenopodene (−)-(**1**), which showed the specific rotation $[\alpha]_D$

Scheme 2.

Scheme 3.

-31.0 (lit. $[\alpha]_D(2)$ +32.0). These results established the absolute configuration for both chenopodanol and chenopodene (Scheme 1). The absolute configuration of chenopodene ((+)-**1**) was originally deduced by the CD spectrum to be the enantiomer (2). This was based on the empirical rule proposed by Itô et al. (10). However, this rule was highly dependent upon the molecular conformation and, as pointed out in the literature (10), there is an exception. This must be one of the ambiguous cases for this rule. In such a case, the synthesis is really necessary.

Experimental

General

IR spectra were measured on a Jasco FTIR 500 spectrophotometer. ^1H and ^{13}C NMR spectra were recorded on a Varian Unity 600, a JEOL JNM GX-400, a Varian Unity 200, or a Gemini 200 spectrometer. The solvent used for NMR spectra was $CDCl_3$ unless otherwise stated. Mass spectra were measured on a JEOL JMS HX-100 or a JEOL AX-500 spectrometer. The specific rotation and the CD spectra were taken on a JASCO DIP-140 polarimeter and a JASCO J- 500 spectrometer, respectively. Chemcopak Nucleosil 50-5 (10 × 250 mm), (4.6 × 250 mm), and Develosil 60-10 (20 × 250 mm) columns were used for HPLC (JASCO pump system). Silica gel 60 for column chromatography was purchased from Merck.

Isolation of chenopodanol

The crude ether extract of *M. chenopoda*, collected in Venezuela, was separated by Sephadex LH-20 ($CHCl_3$–MeOH) followed by silica gel column chromatography (hexane–EtOAc) to afford chenopodene (**1**) as described in ref. 2. A slightly more polar fraction (101 mg) than **1** was further purified by silica gel column chromatography (hexane-EtOAc) to give a mixture of several compounds (43 mg). This fraction was then separated by HPLC (Nucleosil 50-5, 10 × 250 mm, hexane–EtOAc 9:1, 3.5 mL/min) to give marchantin P (2) and impure chenopodanol (9.6 mg), which was again purified by HPLC (Nucleosil 50-5, 4.6 × 250 mm, hexane–EtOAc 95/5, 3.5 mL/min) to isolate pure (−)-chenopodanol (**2**) (1.0 mg).

(−)-Chenopodanol (2): oil; $[\alpha]_D^{20}$ −59.1 (*c* 0.1, $CHCl_3$); IR: 3400 cm^{-1}; ^1H NMR (600 MHz) δ: 0.34 (1H, ddd, *J* = 4.4, 4.4, 4.4 Hz, H-5), 0.44 (1H, ddd, *J* = 7.4, 7.4, 4.4 Hz, H-5), 0.92 (1H, m, H-6), 0.94 (3H, s, H-14), 1.05 (1H, ddd, *J* = 11, 8, 2.3 Hz, H-1 or H-2), 1.10 (1H, ddd, *J* = 7.4, 7.4, 4.4 Hz, H-4), 1.20 (1H, m, H-1 or H-2), 1.27 (1H, m, H-1 or H-2), 1.33 (1H, m, H-8b), 1.35 (1H, m, H-1 or H-2), 1.41 (3H, s, H-15), 1.43 (1H, m, H-8a), 1.62 (3H, s, H-12), 1.69 (3H, s, H-13), 1.98 (2H, m, H-9), 5.12 (1H, t, *J* = 6.8 Hz, H-10); ^{13}C NMR (150 MHz) δ: 5.1 (C-5), 17.6 (C-12), 22.7 (C-9), 24.4 (C-4), 25.1 (C-6), 25.7 (C-13), 26.7 (C-14), 30.0 (C-7), 30.1 (C-2 or C-1), 31.6 (C-15), 33.2 (C-1 or C-2), 42.9 (C-8), 68.5 (C-3), 125.0 (C-10), 131.2 (C-11); MS *m/z*: 222 $(M)^+$, 207, 204, 189, 179, 161, 151, 135, 121, 107, 93 (base), 81, 69, 55; HRMS *m/z* calcd. for $C_{15}H_{26}O$ 222.1944; found: 222.1955.

Preparation of diol 5

A solution of keto ester **3** (9.0 g, 37.5 mmol) in dry ether (100 mL) was added slowly to a stirred suspension of $LiAlH_4$ (4.1 g, 0.107 mol) in dry ether (300 mL), and the mixture was stirred at room temperature for 3 h. Ethyl acetate (40 mL), H_2O (4 mL), 15% NaOH solution (4 mL), and H_2O (12.0 mL) were added successively, and filtration followed by evaporation afforded diol **5** (7.8 g, quant.); oil; FTIR: 3350 cm^{-1}; ^1H NMR (200 MHz, $CDCl_3$) δ: 0.77 (s), 0.83 (s), 1.0–1.8 (m), 2.80 (br s), 3.3–3.4 (m), 3.5–3.6 (m); MS (CI) *m/z*: 173 $(M + H)^+$, 155, 137, 129, 109, 95 (base), 81, 69, 55; CI-HRMS *m/z* calcd. for $C_{10}H_{21}O_2$: 173.1542; found: 173.1538.

Preparation of monosilyl ether 6

A mixture of diol **5** (4.54 g, 27.48 mmol), triethylamine (5.9 mL, 42.3 mmol), 4-DMAP (0.43 g), and TBDMSCl (6.3 g, 41.8 mmol) in CH_2Cl_2 (180 mL) was stirred at 0°C for 10 min and was kept at room temperature overnight. Water was added and the mixture was extracted with CH_2Cl_2. The organic phase was washed with water, HCl (1.0 M), saturated $NaHCO_3$ solution and brine, dried ($MgSO_4$), and evaporated to give a residue. The residue was purified by silica gel column chromatography (hexane–EtOAc, 0-20%) to afford monosilyl ether **6** (7.33 g, two steps, 97%); oil; FTIR: 3460 cm^{-1}; ^1H NMR (200 MHz) δ: 0.09 (6H, s), 0.90 (12H, s), 1.2–1.8 (12H, m), 1.65 (1H, br s), 3.4 (1H, m), 3.5–3.7 (2H, m); MS (CI) *m/z*: 287 $(M + H)^+$, 269, 253, 153, 137 (base), 109, 95, 81; CI-HRMS *m/z* calcd. for $C_{16}H_{35}O_2Si$: 287.2406; found: 287.2408.

Preparation of olefin 7

A solution of mono silyl ether **6** (18.7 g, 65.38 mmol) in pyridine (150 mL) was treated with $POCl_3$ (20.0 mL, 0.22 mol) at 0°C in the presence of 4A molecular sieves (900 mg). The mixture was stirred at room temperature overnight. Saturated $NaHCO_3$ solution was added and the mixture was extracted with ether. The organic phase was washed with water, dried ($MgSO_4$), and evaporated to give a residue, which was purified by silica gel column chromatography (hexane–EtOAc, 0–20%) to afford olefin **7** (11.5 g, 66%); oil; $[\alpha]_D^{21}$ −9.7 (*c* 0.94, $CHCl_3$); FTIR: 1650, 1460, 780 cm^{-1}; ^1H NMR (200 MHz) δ: 0.05 (6H, s), 0.89 (9H, s), 0.92 (3H, s), 1.2–2.0 (10H, m), 3.57 (2H, t, *J* = 6.6 Hz), 5.39 (1H, br dt, *J* = 10.0, 1.8 Hz), 5.58 (1H, dt, *J* = 10.0, 3.6 Hz); ^{13}C NMR (50 MHz) δ: −5.22 (q × 2), 19.3 (t), 25.2 (t), 26.0 (q × 3), 27.3 (q), 27.6 (t), 29.7 (s), 33.9 (s), 34.8 (t), 38.7 (t), 64.1 (t), 125.3 (d), 136.8 (d); MS (CI) *m/z*: 269 $(M + H)^+$, 267, 253, 211 (base), 137, 135, 109, 95, 81; CI-HRMS *m/z* calcd. for $C_{16}H_{33}OSi$: 269.2301; found: 269.2272.

A solution of the olefin **7** (11.4 g, 42.5 mmol) in PhH (800 mL) was treated with PDC (23.2 g, 63.2 mmol), Celite (89.0 g), and 70% *t*BuOOH (27 mL) at 0°C. The mixture was stirred at room temperature overnight. The mixture was filtered under reduced pressure and the solvent was almost evaporated. The residue was extracted with ether, and the ethereal solution was washed with 10% KOH solution. The residue was purified by silica gel column chromatography (hexane–EtOAc, 0–20%) to afford enone **4** (4.0 g, 33%, 72% based on consumed **7**) and the recovered olefin **7** (6.1 g).

4: oil; $[\alpha]_D^{22}$ −22.2 (*c* 0.90, $CHCl_3$); CD (EtOH) [θ]: −290 (311 nm), −3940 (245 nm); FTIR: 1690, 1620 cm^{-1}; ^1H NMR (200 MHz) δ: 0.03 (6H, s), 0.88 (9H, s), 1.13 (3H, s), 1.4–1.6 (4H, m), 1.7–1.8 (1H, m), 1.95 (1H, m), 2.35–2.45 (2H, m), 3.60 (2H, dd, *J* = 5.8, 4.8 Hz), 5.86 (1H, d, *J* = 10.2 Hz), 6.63 (1H, d, *J* = 10.2 Hz); ^{13}C NMR (50 MHz) δ: −5.4 (q × 2), 18.2 (s), 24.8 (q), 25.9 (q × 3), 27.5 (t), 33.4 (t), 34.1 (t), 35.2 (s), 37.0 (t), 63.2 (t), 127.3 (d), 159.2 (d), 199.5 (s); MS (CI) *m/z*: 283 $(M + H)^+$, 267, 225 (base), 165, 151, 133, 123, 105; CI-HRMS *m/z* calcd. for $C_{16}H_{31}O_2Si$: 283.2093; found: 283.2086.

Reduction of ketone 4

A solution of ketone **4** (1.5 g, 5.32 mmol) in THF (120 mL) was treated with DIBAH (1.0 M in toluene, 16.5 mL, 16.5 mmol) at room temperature for 4 h. Water was added and THF

was evaporated. The residue was extracted with ether and the ethereal solution was washed with water, dried ($MgSO_4$), and evaporated. The residue was purified by silica gel column chromatography (hexane–EtOAc, 0–50%) and HPLC (hexane–EtOAc 85:15, Nucleosil 50-5, 10 × 250 mm) to afford alcohols **8** (723 mg, 48%) and **9** (494 mg, 33%).

8: oil; $[\alpha]_D^{21}$ −42.3 (*c*, 1.0, $CHCl_3$); FTIR: 3350 cm^{-1}; ^1H NMR (200 MHz) δ: 0.04 (6H, s), 0.88 (9H, s), 0.99 (3H, s), 1.2–2.0 (8H, m), 3.56 (2H, t, *J* = 6.5 Hz), 4.15 (1H, m), 5.48 (1H, d, *J* = 10.6 Hz), 5.61 (1H, dd, *J* = 10.6, 2.1 Hz); ^{13}C NMR (50 MHz) δ: −5.2 (q × 2), 18.4 (s), 26.0 (q × 3), 26.7 (q), 27.5 (t), 29.3 (t), 31.5 (t), 34.4 (s), 38.2 (t), 63.8 (t), 66.6 (d), 128.6 (d), 139.2 (d); MS (CI) *m/z*: 285 $(M + H)^+$, 283, 267, 251, 227, 211, 171, 151, 135 (base); CI-HRMS *m/z* calcd. for $C_{16}H_{33}O_2Si$: 285.2250; found: 285.2245.

9: oil; $[\alpha]_D^{21}$ +18.9 (*c* 1.0, $CHCl_3$); FTIR: 3350 cm^{-1}; ^1H NMR (200 MHz) δ: 0.04 (6H, s), 0.89 (9H, s), 0.93 (3H, s), 1.2–2.0 (8H, m), 3.57 (2H, t, *J* = 6.1 Hz), 4.15 (1H, m), 5.53 (1H, d, *J* = 10.0 Hz), 5.66 (1H, dd, *J* = 10.0, 3.4 Hz); ^{13}C NMR (50 MHz) δ: −5.2 (q × 2), 18.4 (s), 26.0 (q × 3), 26.2 (q), 27.7 (t), 28.7 (t), 30.6 (t), 34.3 (s), 38.0 (t), 63.9 (t), 65.3 (d), 127.5 (d), 140.0 (d); MS (CI) *m/z*: 285 $(M+H)^+$, 283, 267, 251, 227, 209, 171, 151, 135 (base); CI-HRMS *m/z* calcd. for $C_{16}H_{33}O_2Si$ $(M + H)^+$: 285.2250; found: 285.2223; *m/z* calcd. for $C_{16}H_{31}O_2Si$ $(M - H)^+$: 283.2094; found: 283.2101.

Cyclopropanation of alcohol 8

Diethylzinc (1.0 M in hexane, 6.5 mL, 6.5 mmol) was added to a solution of the alcohol **8** (723 mg, 2.55 mmol) in CH_2Cl_2 (68 mL) at 0°C under Ar atmosphere. Diiodomethane (0.4 mL, 4.97 mmol) was slowly added, and the mixture was stirred for 30 min at this temperature and at room temperature for 5 h. Water was added and the mixture was extracted with CH_2Cl_2. The organic phase was washed with water, 10% H_2SO_4, and brine, dried ($MgSO_4$), and evaporated. The residue was purified by silica gel column chromatography (hexane–EtOAc, 0–30%) to afford **10** (382 mg, 50%, 74% based on consumed **8**) and the recovered **8** (230 mg).

10: oil; $[\alpha]_D^{21}$ −1.30 (*c* 1.3, $CHCl_3$); FTIR: 3400 cm^{-1}; ^1H NMR (200 MHz) δ: 0.05 (6H, s), 0.3–0.5 (2H, m), 0.90 (12H, s), 0.8–1.7 (10H, m), 3.58 (2H, t, *J* = 6.5 Hz), 4.15 (1H, m); ^{13}C NMR (50 MHz) δ: −5.3 (q × 2), 3.5 (t), 18.4 (s), 18.6 (d), 24.5 (d), 26.0 (q × 3), 26.1 (q), 26.4 (t), 27.6 (t), 29.5 (s), 32.1 (t), 39.8 (t), 63.9 (t), 66.8 (d); MS (CI) *m/z*: 299 $(M + H)^+$, 297, 281, 265, 241, 223, 167, 149 (base); CI-HRMS *m/z* calcd. for $C_{17}H_{35}O_2Si$ $(M + H)^+$: 299.2407; found: 299.2374; *m/z* calcd. for $C_{17}H_{33}O_2Si$ $(M - H)^+$: 297.2250; found: 297.2268.

Cyclopropanation of alcohol 9

Alcohol **9** (889 mg, 3.13 mmol) was similarly treated with Et_2Zn (8 mL, 8 mmol) and CH_2I_2 (0.55 mL, 1.09 mmol) in CH_2Cl_2 (85 mL). Work-up and chromatography (hexane–EtOAc, 0–30%) afforded **11** (495 mg, 53%, 62% based on consumed **9**) and the recovered **9** (131 mg).

11: oil; $[\alpha]_D^{21}$ +26.1 (*c* 0.88, $CHCl_3$); FTIR: 3400 cm^{-1}; ^1H NMR (200 MHz, $CDCl_3$) δ: 0.05 (6H, s), 0.3–0.6 (2H, m), 0.89 (9H, s), 0.8–1.7 (8H, m), 1.02 (3H, s), 3.60 (2H, t, *J* = 6.6 Hz), 4.23 (1H, ddd, *J* = 6.0, 5.5, 5.8 Hz); ^{13}C NMR (50 MHz) δ: −5.2 (q × 2), 3.5 (t), 18.4 (s), 18.5 (d), 23.8 (d), 26.0 (q × 3), 26.7 (t), 27.6 (t), 27.8 (q), 29.6 (s), 32.4 (t), 38.0 (t), 64.1 (t), 66.2 (d); MS (CI) *m/z*: 299 $(M + H)^+$, 297, 281, 265, 241, 223, 167, 149 (base); CI-HRMS *m/z* calcd. for $C_{17}H_{35}O_2Si$ $(M + H)^+$: 299.2407; found: 299.2377; *m/z* calcd. for $C_{17}H_{33}O_2Si$ $(M - H)^+$: 297.2250; found: 297.2254.

Oxidation of alcohol 10

A solution of alcohol **10** (382 mg, 1.28 mmol) in CH_2Cl_2 (40 mL) was treated with PDC (975.0 mg, 2.66 mmol) and 4A molecular sieves (318.0 mg) for 12 h at room temperature. The mixture was filtered through Celite and passed through a short column of silica gel (elution with ether). Evaporation of the solvents afforded a ketone **12** (363 mg, 96%); oil; $[\alpha]_D^{21}$ −1.85 (*c* 1.0, $CHCl_3$); CD ($CHCl_3$) [θ]: +2020 (298 nm); FTIR: 1700 cm^{-1}; ^1H NMR (200 MHz) δ: 0.04 (6H, s), 0.7–1.6 (9H, m), 0.90 (9H, s), 1.06 (3H, s), 1.85 (1H, m), 2.1–2.2 (2H, m), 3.59 (2H, t, *J* = 5.9 Hz); ^{13}C NMR (50 MHz) δ: −5.2 (q × 2), 10.0 (t), 18.3 (s), 26.0 (q × 3), 26.5 (q), 26.6 (d), 27.3 (t), 28.1 (t), 29.8 (d), 31.0 (s), 32.7 (t), 35.3 (t), 63.6 (t), 209.4 (s); MS (CI) *m/z*: 297 $(M + H)^+$, 281, 239 (base), 193, 165, 147; CI-HRMS *m/z* calcd. for $C_{17}H_{33}O_2Si$: 297.2250; found: 297.2245.

Oxidation of alcohol 11

Alcohol **11** (195 mg, 0.65 mmol) was treated with PDC (517.0 mg, 1.41 mmol) and molecular sieves (168 mg) in CH_2Cl_2 (20 mL) for 12 h at room temperature. Work-up as above afforded a ketone **15** (178 mg, 92%); oil; $[\alpha]_D^{21}$ −18.0 (*c* 1.3, $CHCl_3$); CD ($CHCl_3$) [θ]: −2340 (297 nm); FTIR: 1700 cm^{-1}; ^1H NMR (200 MHz) δ: 0.04 (6H, s), 0.88 (9H, s), 1.06 (3H, s), 1.0–1.8 (10H, m), 2.19 (2H, q, *J* = 5.1 Hz), 3.60 (2H, t, *J* = 6.3 Hz); ^{13}C NMR (50 MHz) δ: −5.3 (q × 2), 10.5 (t), 18.3 (s), 24.6 (q), 25.9 (q × 3), 26.1 (d), 27.3 (t), 28.7 (t), 29.0 (d), 30.9 (s), 32.9 (t), 39.1 (t), 63.7 (t), 209.6 (s); MS (CI) *m/z*: 297 $(M + H)^+$, 281, 239 (base), 193, 165, 147; CI-HRMS *m/z* calcd. for $C_{17}H_{33}O_2Si$: 297.2250; found: 297.2242.

Deprotection of silyl ether 12

A solution of silyl ether **12** (363 mg, 0.99 mmol) in THF (5 mL) was treated with TBAF (1.0 mol/L, 1.5 mL, 1.5 mmol) at 0°C for 4 h. Water was added and the mixture was extracted with ether. The organic phase was washed with water and brine, dried ($MgSO_4$), and evaporated. The residue was purified by silica gel column chromatography (hexane–EtOAc, 0–100%) to afford alcohol **13** (181 mg, 81%); oil; $[\alpha]_D^{21}$ +9.4 (*c* 1.2, $CHCl_3$); CD ($CHCl_3$) [θ]: +1820 (297 nm); FTIR: 3440, 1690 cm^{-1}; ^1H NMR (200 MHz) δ: 1.06 (3H, s), 1.2–2.2 (12H, m), 3.63 (2H, t, *J* = 6.0 Hz); ^{13}C NMR (50 MHz) δ: 10.1 (t), 26.5 (q), 26.6 (d), 27.1 (t), 28.1 (t), 29.8 (d), 31.0 (s), 32.7 (t), 35.4 (t), 63.3 (t), 209.6 (s); MS (CI) *m/z*: 183 $((M + H)^+$ (base), 165, 147, 137, 123, 111, 95; CI-HRMS *m/z* calcd. for $C_{11}H_{19}O_2$: 183.1385; found: 183.1373.

Deprotection of silyl ether 15

Silyl ether **15** (178 mg, 0.60 mmol) in THF (2 mL) was similarly treated with TBAF (1.0 M, 0.71 mL, 0.71 mmol) and work-up afforded alcohol **16** (108 mg, 99%); oil; $[\alpha]_D^{21}$ −23.9 (*c* 1.0, $CHCl_3$); CD ($CHCl_3$) [θ]: −2040 (296 nm); FTIR: 3450, 1690 cm^{-1}; ^1H NMR (200 MHz) δ: 1.10 (3H, s), 1.0–1.8 (10H, m), 2.22 (2H, m), 3.65 (2H, t, *J* = 6.4 Hz); ^{13}C NMR

(50 MHz) δ: 10.5 (t), 24.5 (q), 26.0 (d), 27.0 (t), 28.4 (t), 29.0 (d), 30.8 (s), 32.7 (t), 39.0 (t), 63.0 (t), 210.0 (s); MS (CI) *m/z*: 183 ((M + H)$^+$ (base), 165, 147, 123, 111, 95, 81; CI-HRMS *m/z* calcd. for $C_{11}H_{19}O_2$: 183.1385; found: 183.1385.

Preparation of ketone 14

A solution of alcohol **13** (181 mg, 0.99 mmol) in CH_2Cl_2 (20 mL) was treated with PDC (703.0 mg, 1.91 mmol) and 4A molecular sieves (120 mg) at room temperature for 2 h. The mixture was filtered through Celite and passed through a short column of silica gel (elution with ether) to afford the aldehyde (101 mg, 56%); oil; $[\alpha]_D^{21}$ +7.0 (*c* 1.0, $CHCl_3$); CD ($CHCl_3$) [θ]: +1870 (297 nm); FTIR: 1720, 1690 cm^{-1}; ^{1}H NMR (200 MHz) δ: 1.08 (3H, s), 1.1 (1H, m), 1.29 (1H, td, *J* = 5.5, 4.6 Hz), 1.4–1.6 (3H, m), 1.7–1.9 (3H, m), 2.1–2.2 (2H, m), 2.45–2.60 (2H, m), 9.81 (1H, t, *J* = 1.6 Hz); ^{13}C NMR (50 MHz) δ: 9.7 (t), 26.1 (q), 26.4 (d), 28.0 (t), 29.0 (d), 30.6 (s), 30.7 (t), 32.3 (t), 38.6 (t), 201.7 (d), 208.5 (s); MS (EI) *m/z*: 180 (M$^+$), 165, 137, 123 (base), 107, 95, 81; CI-HRMS *m/z* calcd. for $C_{11}H_{16}O_2$: 180.1150; found: 180.1148.

Butyllithium (1.69 M, 1.0 mL, 1.69 mmol) was added to a suspension of isopropyltriphenylphosphonium iodide (730 mg, 1.69 mmol) in ether (25 mL) at room temperature, and the mixture was stirred for 1 h. A solution of the aldehyde (101 mg, 0.56 mmol) in ether (3 mL) was added, and the mixture was stirred for 50 min. Water was added and the mixture was extracted with ether. The organic phase was washed with brine, dried ($MgSO_4$), and evaporated. The residue was purified by silica gel column chromatography (hexane–EtOAc, 0-100%) to afford olefin **14** (23.2 mg, 20.1%) and the recovered aldehyde (39.7 mg).

14: oil; $[\alpha]_D^{22}$ −5.0 (*c* 1.0, $CHCl_3$); CD ($CHCl_3$) [θ]: +1550 (304 nm); FTIR: 1700 cm^{-1}; ^{1}H NMR (200 MHz) δ: 1.09 (3H, s), 1.09 (1H, m), 1.28 (1H, m), 1.4–1.6 (5H, m), 1.61 (3H, s), 1.68 (3H, s), 1.80 (1H, m), 1.96–2.05 (2H, m), 2.14–2.19 (2H, m), 5.11 (1H, tsept., *J* = 7.0, 1.4 Hz); ^{13}C NMR (50 MHz) δ: 10.0 (t), 17.6 (q), 22.4 (t), 25.7 (q), 26.4 (q), 26.6 (d), 28.1 (t), 29.8 (d), 31.2 (s), 32.7 (t), 39.4 (t), 124.3 (d), 131.6 (s), 209.6 (s); MS (EI) *m/z*: 206 (M$^+$), 191, 163, 149, 137, 123 (base), 109, 95, 81; EI-HRMS *m/z* calcd. for $C_{14}H_{22}O$: 206.1671; found: 206.1653.

Preparation of ketone 17

Alcohol **16** (108 mg, 0.59 mmol) was similarly treated with PDC (426 mg, 1.16 mmol) and 4A molecular sieves (86 mg) in CH_2Cl_2. Work-up as above afforded aldehyde (78.8 mg, 74%); oil; $[\alpha]_D^{21}$ −32.0 (*c* 0.72, $CHCl_3$); CD ($CHCl_3$) [θ]: −3020 (296 nm); FTIR: 1720, 1690 cm^{-1}; ^{1}H NMR (200 MHz) δ: 1.04 (3H, s), 1.0−1.8 (8H, m), 2.1−2.2 (2H, m), 2.4−2.6 (2H, m), 9.77 (1H, t, *J* = 1.6 Hz); ^{13}C NMR (50 MHz) δ: 10.3 (t), 24.5 (q), 25.9 (d), 28.3 (d), 28.4 (t), 30.7 (s), 32.6 (t), 34.4 (t), 38.9 (t), 202.1 (d), 208.7 (s); MS (CI) *m/z*: 181 (M + H)$^+$ (base), 163, 145, 135, 121, 107, 93, 81. CI-HRMS *m/z* calcd. for $C_{11}H_{17}O_2$: 181.1229; found: 181.1209.

The aldehyde (78.8 mg, 0.44 mmol) was similarly treated with Wittig reagent and work-up afforded olefin **17** (18.0 mg, 20%) and the recovered aldehyde (4.1 mg).

17: oil; $[\alpha]_D^{22}$ −22.1 (*c* 0.8, $CHCl_3$); CD ($CHCl_3$) [θ]: −2240 (304 nm); FTIR: 1700 cm^{-1}; ^{1}H NMR (200 MHz) δ: 1.10 (3H, s), 1.08–1.23 (2H, m), 1.34–1.56 (5H, m), 1.62 (3H, s), 1.70 (3H, s), 1.79 (1H, m), 2.03–2.07 (2H, m), 2.20–2.22 (2H, m), 5.13 (1H, tsept., *J* = 7.0, 1.4 Hz); ^{13}C NMR (50 MHz) δ: 10.5 (t), 17.6 (q), 22.5 (t), 24.5 (q), 25.7 (q), 26.1 (d), 28.6 (t), 29.0 (d), 31.2 (s), 32.9 (t), 43.2 (t), 124.6 (d), 131.5 (s), 209.6 (s); MS (EI) *m/z*: 206 (M$^+$), 191, 173, 163, 149, 135, 123 (base), 110, 95, 81; EI-HRMS *m/z* calcd. for $C_{14}H_{22}O$: 206.1671; found: 206.1677.

Methylation of ketone 14

MeLi (1.10 M, 0.6 mL, 0.66 mmol) was added to a solution of the ketone **14** (20.4 mg, 0.1 mmol) in ether (3 mL) at 0°C, and the mixture was stirred for 2 h. Water was added and the mixture was extracted with ether. The organic phase was washed with brine, dried ($MgSO_4$), and evaporated. The residue was purified by HPLC (hexane–EtOAc 95:5, Nucleosil 50-5, 4.5 × 250 mm) to afford alcohol **2** (2.2 mg, 10.0%), **18** (5.3 mg, 24.1%), and the recovered **14** (3.1 mg).

2: oil; $[\alpha]_D^{20}$ +56.0 (*c* 0.3, $CHCl_3$); FTIR: 3400 cm^{-1}; ^{1}H NMR (400 MHz) δ: 0.34 (1H, q, *J* = 4.4 Hz), 0.44 (1H, td, *J* = 8.0, 4.4 Hz), 0.92 (1H, m), 0.94 (3H, s), 1.00–1.15 (2H, m), 1.20–1.45 (5H, m), 1.41 (3H, s), 1.62 (3H, s), 1.70 (3H, s), 1.96–1.98 (2H, m), 5.12 (1H, t, *J* = 7.0 Hz); ^{13}C NMR (100 MHz) δ: 5.1 (t), 17.6 (q), 22.8 (t), 24.4 (d), 25.1 (d), 25.7 (q), 26.8 (q), 30.0 (s), 30.1 (t), 31.6 (q), 33.3 (t), 42.9 (t), 68.6 (s), 125.0 (d), 131.2 (s); MS (EI) *m/z*: 222 (M$^+$), 204, 189, 175, 161, 147, 135, 133, 122, 107, 105, 93 (base); EI-HRMS *m/z* calcd. for $C_{15}H_{26}O$: 222.1984; found: 222.2013.

18: oil; $[\alpha]_D^{21}$ +20.6 (*c* 0.2, $CHCl_3$); FTIR: 3400 cm^{-1}; ^{1}H NMR (600 MHz) δ: −0.07 (1H, q, *J* = 5.4 Hz), 0.49 (1H, td, *J* = 9.3, 5.4 Hz), 0.84 (1H, td, *J* = 9.3, 5.4 Hz), 0.88 (3H, s), 0.93 (1H, ddd, *J* = 13.9, 5.1, 2.9 Hz), 1.01 (1H, m), 1.21 (1H, ddd, *J* = 14.2, 13.2, 2.9 Hz), 1.15 (1H, m), 1.29 (3H, s), 1.30 (1H, m), 1.38–1.50 (3H, m), 1.62 (3H, s), 1.69 (3H, s), 2.05 (2H, m), 5.12 (1H, tsept., *J* = 7.2, 1.3 Hz); ^{13}C NMR (100 MHz) δ: 6.8 (t), 17.6 (q), 22.4 (d), 24.8 (t), 24.1 (d), 25.7 (q), 26.3 (q), 29.2 (s), 29.9 (q), 30.6 (t), 31.6 (t), 45.7 (t), 69.2 (s), 125.1 (d), 131.1 (s); MS (EI) *m/z*: 222 (M)$^+$, 204, 189, 176, 161, 147, 135, 133, 122, 107, 105, 93 (base); CI-HRMS *m/z* calcd. for $C_{15}H_{25}$: 205.1956; found: 205.1941 (M − H_2O + H)$^+$.

Methylation of ketone 17

Ketone **17** (15.0 mg, 0.07 mmol) was similarly methylated with MeLi (1.10 M, 0.4 mL, 0.44 mmol) to afford a mixture of alcohol **19** (1.0 mg, 9.6%, a small amount of the recovered **17** was included) and the alcohol **20** (3.0 mg, 21.9%).

19: oil; ^{1}H NMR (200 MHz) δ: 0.34 (1H, q, *J* = 5.4 Hz), 0.47 (1H, td, *J* = 8.3, 4.8 Hz), 0.8–1.8 (8H, m), 1.04 (3H, s), 1.42 (3H, s), 1.61 (3H, s), 1.69 (3H, s), 1.9–2.1 (2H, m), 5.12 (1H, m); MS (CI) *m/z*: 205 (M − H_2O + H)$^+$ (base), 189, 161, 147, 135, 123, 121, 107, 95, 81; CI-HRMS *m/z* calcd. for $C_{15}H_{25}$: 205.1956; found 205.1961 (M − H_2O + H)$^+$.

20: oil; $[\alpha]_D^{21}$ +51.5 (*c* 0.3, $CHCl_3$); FTIR: 3400 cm^{-1}; ^{1}H NMR (600 MHz) δ: −0.07 (1H, q, *J* = 5.4 Hz), 0.54 (1H, td, *J* = 9.3, 5.4 Hz), 0.76 (1H, td, *J* = 9.3, 5.4 Hz), 1.0–1.1 (3H, m), 1.13 (3H, s), 1.2–1.4 (4H, m), 1.28 (3H, s), 1.62 (3H, s), 1.69

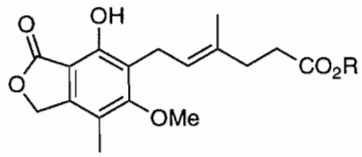
Total synthesis of mycophenolic acid

Ricardo A. de la Cruz, Francisco X. Talamás, Alfredo Vázquez, and Joseph M. Muchowski

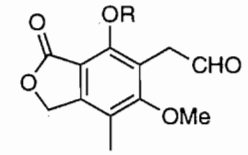
Abstract: A total synthesis of mycophenolic acid is reported. Diels–Alder reaction of [5-methoxy-3-(1-methoxypropenyl)-4,5-dihydrofuran-2-yloxy]-trimethylsilane with 3-benzenesulfinyl-5*H*-furan-2-one afforded the hexasubstituted nucleus. The side chain was constructed from the unveiled aldehyde.

Key words: mycophenolic acid, Diels–Alder reaction, pentasubstituted diene.



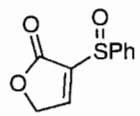
Résumé : On a effectué une synthèse totale de l'acide mycophénolique. Une réaction de Diels–Alder du [5-méthoxy-3-(1-méthoxypropényl)-4,5-dihydrofuran-2-yloxy]-triméthylsilane avec la 3-benzènesulfinyl-5*H*-furan-2-one a permis d'obtenir le noyau hexasubstitué. On a créé la chaîne latérale à partir de l'aldéhyde déprotégé.

Mots clés : acide mycophénoliquie, réaction de Diels–Alder, diène pentasubstitué.

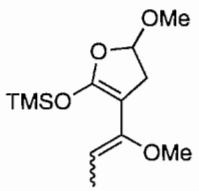


[Traduit par la rédaction]

Introduction



Mycophenolic acid (**1***a*), a metabolite of several Penicillium species (1), has been known as a potent inhibitor of inosine monophosphate dehydrogenase (IMPDH; EC 1.1.1.205) for over 25 years (2). It has recently become of importance in organ transplant rejection due to its immunosuppressive activity and low degree of toxicity (3). As a consequence of the pharmacological activity of **1***a*, much effort has been devoted to the preparation of congeners thereof (4) as well as to its total synthesis (5). The known (5b) phthalide **2***b* was chosen as a synthetic target because it is a useful precursor of mycophenolic acid itself and of several highly active side-chain-modified derivatives (4). This article describes a new synthesis of the phthalides **2***a*-**2***c* and the conversion of **2***c* into mycophenolic acid using the process of Patterson and Huang (5*b*, 6). Like others (5) who have utilized phthalides as precursors of **1***a*, we chose to use a Diels–Alder strategy, as did Watanabe et al. (5*d*), as the first step en route to **2***b*. Of several processes studied, the most successful involved the use of the dienophile **3** and the pentasubstituted diene **4**.



1*a* R = H
1*b* R = Et

2*a* R = H
2*b* R = $SiMe_2t$-Bu
2*c* R = $CH_2O(CH_2)_2OCH_3$

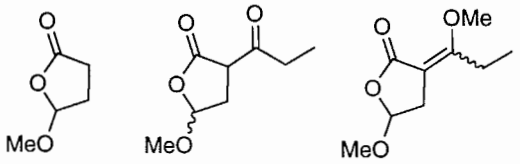
4

Results and discussion

Compound **3** was prepared (98% yield) by *m*-chloroperbenzoic acid oxidation from the corresponding (7) sulfide. The starting material for the diene **4** was 5-methoxy-2(3H)-dihydrofuranone **5** (8), which was deprotonated with lithium bis(trimethylsilyl)amide (2.1 equiv.) in anhydrous THF (−78°C) and treated with propionyl chloride (1.1 equiv., −78°C) to give the β-ketolactone **6** (68%). The extra equivalent of base used was required to drive the reaction to completion. When lithium diisopropylamide (LDA) was used as the base in this reaction, the yield decreased considerably. Attempts to transform **6** into the enol ether **7** under different basic conditions (e.g., KH, MeI, HMPA) resulted in complex mixtures. Better results were obtained when acid catalysis was used for this transformation. Reaction of **6** with trimethyl orthoformate (2.0 equiv.), containing a catalytic quantity of concentrated H_2SO_4 (r.t.) (9) gave the enol ether **7** (63% yield after flash chromatography, SiO_2) contaminated by a minor amount (ca 10%) of its geometric isomer (10). This compound was converted into the diene **4** (60% yield after distillation) by lithiation with LDA (THF, −78°C) followed by reaction with chlorotrimethylsilane (TMSCl) (−78°C to r.t.) (11).

The optimum conditions for the [4π + 2π] cycloaddition

Received November 1, 1996.



This paper is dedicated to Professor William A. Ayer on the occasion of his 65th birthday.

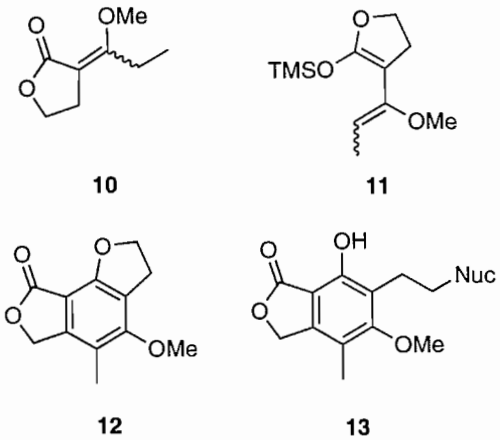
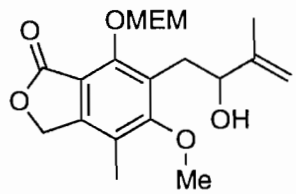
5 6 7

and subsequent aromatization involved reaction of **3** with 2.0 equivalents of the diene **4** in toluene solution under mild conditions (0°C, 1 h; r.t., 1 h) followed by thermolysis of the putative adduct **8** at reflux temperature (30 min). Column chromatography separation (SiO_2) of the reaction mixture provided the expected phthalide derivative **9***a* as well as the phenol **9***b* in 33 and 14% yields, respectively. Since **9***b* is readily and efficiently (89%) methylated (MeI, NaH, DMF), **9***a* is thus obtained in 45% combined yield. When the reaction was carried out under the same reaction conditions but with the sulfoxide **3** as the excess reagent (2.0 equiv.), compound **9***a* was obtained in only 13% yield. To convert **9***a* into the desired phthalide, deprotection with 89% formic acid (r.t., 20 min, quant.) to the phenolic aldehyde **2***a* was carried out. The most notable feature of this process is that a hexasubstituted benzenoid derivative containing all the functionality required for conversion into mycophenolic acid, or side-chain congeners thereof, is produced with a considerable economy in steps and reasonable efficiency.



8 **9***a* R = Me
9*b* R = H

Protection of the latent aldehyde protected as an acetal through the synthesis up to this point solved the problem encountered in an early attempt as described in Scheme 1. Thus, 3-propionyldihydrofuran-2-one was converted into the enol ether **10** (10) under acid conditions (H_2SO_4, trimethyl orthoformate). Compound **10** was converted to the diene **11** in 75% yield, using the conditions employed for the transformation of **7** to **4**. Reaction of sulfoxide **3** and diene **11** (2.0 equiv.) in toluene solution (0°C–reflux, 2.5 h) afforded, after column chromatography, the phthalide **12** in 46% yield. Attempts to obtain the phenol **13** by opening of the dihydrofuran moiety on **12** with nucleophiles were unsuccessful. Although transient formation of **13** presumably occurred, closure back to the starting material or loss of the methoxy group was observed. Extensive studies were carried out before it was decided to start with the desired oxidation state on an early intermediate as described above.



The synthesis was completed as follows. Treatment of compound **2***a* with *tert*-butyldimethylsilyl chloride (TBDMSCl) (imidazole, DMF) (12) afforded the desired aldehyde **2***b* in only 18% yield along with other by-products. Although the aldehyde **2***b* could not be generated with acceptable efficiency under a wide variety of conditions (13), the ether **2***c* was easily

Scheme 1.

10 11 12 13

prepared (86%) from **2***a* and 2-methoxyethoxymethyl chloride (MEMCl) by the procedure of Corey et al. (*i*-Pr_2NEt–CH_2Cl_2) (14). This compound was reacted with prop-2-enyl magnesium bromide (THF, −40°C) and the allylic alcohol **14** so obtained (67%) was subjected to the *ortho*-ester Claisen conditions of Patterson (5*b*, 6). Removal of the MEM group from the product (PPTS, *t*-BuOH, 80°C, 6 h) gave ethyl mycophenolate **1***b* (60% from **14**), which on saponification provided mycophenolic acid (**1***a*) in near quantitative yield.

14

The process described herein could without doubt be applied to the synthesis of a wide variety of nucleus- and side-chain-modified analogs of mycophenolic acid.

Experimental

General methods

Unless otherwise noted, materials were obtained from commercial suppliers and were used without further purification. Tetrahydrofuran (THF) was distilled under argon atmosphere from sodium–benzophenone directly before use. Hexamethyldisilazane and diisopropylamine were distilled from CaH_2 before use. Toluene was degassed by bubbling argon and applying ultrasound for 5 min. Reactions and chromatography fractions were monitored by thin-layer chromatography. Chromatography was carried out using Merck 60 (230–400 mesh) silica gel. Melting points are uncorrected. IR spectra were recorded as $CHCl_3$ solution using a Perkin–Elmer 1720-X instrument. ^1H NMR measurements were recorded at 200.0 MHz and ^{13}C NMR measurements were recorded at 50.0 MHz using a Varian Gemini-200 instrument. Spectra are reported in ppm downfield from tetramethylsilane as the internal standard. Unless otherwise noted, NMR spectra were measured in $CDCl_3$ solution. Low-resolution mass spectra (LRMS) were

recorded on a Finnigan MAT-INCOS XL instrument. Elemental analyses were performed using a Fison EA-1108 instrument or were done at Midwest-Microlab, 7212N Shadeland Ave. Indianapolis, IN 46250, U.S.A.

3-Benzenesulfinyl-5*H*-furan-2-one (3)

Sulfoxide **3** was prepared as reported (*7a*) to obtain an oil, which was crystallized to obtain yellow needles; mp 87–88.5°C (EtOH); IR: 3014, 1766, 1216, 1052 cm^{-1}; ^1H NMR δ: 8.05 (t, J = 1.6 Hz, 1H), 7.89–7.76 (m, 2H), 7.59–7.48 (m, 3H), 5.05 (dd, J = 19.0, 1.7 Hz, 1H), 4.89 (dd, J = 19.0, 1.6 Hz, 1H); ^{13}C NMR δ: 167.2, 151.6, 141.6, 141.3, 132.2, 129.6, 124.9, 71.3; LRMS (EI), *m/z* (relative intensity): 208 (M^+, 14), 51 (100). Anal. calcd. for $C_{10}H_8O_3S$: C 57.67, H 3.87, S 15.39; found: C 57.52, H 3.81, S 15.19.

5-Methoxy-3-propionyl-dihydrofuran-2-one (6)

A 1.38 M solution of *n*-BuLi–hexanes (145.0 ml, 0.2 mol) was added to hexamethyldisilazane (42.3 mL, 0.2 mol) in THF (195.0 ml) at 0°C under argon. The reaction was stirred for 20 min, cooled to −78°C, and **5** (11.1 g, 0.095 mol) was added in THF (27.0 ml). After 30 min, propionyl chloride (9.14 mL, 0.105 mol) was added and the mixture was stirred for 15 min at −78°C and then allowed to reach room temperature. The reaction was quenched with 10% NH_4Cl (50.0 mL), diluted with EtOAc, and the organic phase was washed with 10% NH_4Cl (2 × 50.0 mL) and dried over anhydrous Na_2SO_4. The solvent was removed under vacuum and the residue (14.5 g) purified by flash chromatography (SiO_2, hex–EtOAc 85:15) to obtain **6** as an oil (11.1 g, 68%). The NMR spectra show **6** as a 1:1 mixture of two diastereoisomers: IR: 3025, 1774, 1724, 1355, 1110, 932 cm^{-1}; ^1H NMR δ: 5.45 (dd, J = 5.8, 1.7 Hz, 1H), 3.88 (t, J = 8.8 Hz, 0.5H), 3.50 (s, 3H), 3.25–2.82 (m, 2H), 2.81–2.38 (m, 2H), 2.14 (ddd, J = 13.8, 9.0, 1.9 Hz, 0.5 H), 1.10 (t, J = 7.1 Hz, 3H); LRMS (EI), *m/z* (relative intensity): 173 (M^+, 11), 57 (100). Anal. calcd. for $C_8H_{12}O_4$: C 55.80, H 7.03; found: C 55.72, H 7.10.

5-Methoxy-3-(1-methoxypropylidene)-dihydrofuran-2-one (7)

To a solution of the β-keto lactone **6** (11.2 g, 0.065 mol) in trimethyl orthoformate (14.2 mL, 0.13 mol) at 0°C under argon was slowly added concentrated H_2SO_4 (0.18 mL, 3.24 mmol); the mixture was stirred for 15 min at the same temperature and then for 3.5 h at room temperature. The reaction was diluted with CH_2Cl_2, washed with 10% $NaHCO_3$ (2 × 50.0 mL) and brine, and dried over anhydrous Na_2SO_4. After removal of the solvent, the residue (12.2 g) was purified by flash chromatography (SiO_2, hex–EtOAc 85:15) to obtain the enol ether **7** as an oil (7.69 g, 63%). IR: 3020, 1738, 1654, 1229, 1074, 1014, 915 cm^{-1}; ^1H NMR δ: 5.32 (dd, J = 6.5, 2.2 Hz, 1H), 3.81 (s, 3H), 3.49 (s, 3H), 3.05–2.80 (m, 3H), 2.71 (dd, J = 16.7, 2.1 Hz, 1H), 1.15 (t, J = 7.5 Hz, 3H); ^{13}C NMR δ: 171.4, 170.3, 101.0, 98.7, 56.1, 54.6, 32.8, 19.0, 12.2; LRMS (EI), *m/z* (relative intensity): 186 (M^+, 28), 57 (100). Anal. calcd. for $C_9H_{14}O_4$: C 58.05, H 7.58; found: C 57.66, H 7.74.

[5-Methoxy-3-(1-methoxypropenyl)-4,5-dihydrofuran-2-yloxy]-trimethylsilane (4)

A 1.38 M solution of *n*-BuLi–hexanes (18.0 mL, 24.9 mmol) was added to diisopropylamine (3.8 mL, 27.1 mmol) in THF (44.0 mL) at 0°C under argon. The reaction was stirred for 20 min, cooled to −78°C, and **7** (4.1 g, 21.9 mmol) was added in THF (22.0 mL). After 30 min, chlorotrimethylsilane (3.4 mL, 27.1 mmol) was added; the mixture was stirred for 15 min at −78°C and then allowed to reach room temperature. The reaction mixture was concentrated until a precipitate formed, then diluted with hexane, filtered through Celite®, and concentrated to dryness to obtain an oil. The crude product was distilled to obtain the diene **4** (3.39 g, 60%) as a colorless liquid; bp 74–76°C (0.37 Torr; 1 Torr = 133.3 Pa); IR: 3014, 2938, 1694, 1255, 855 cm^{-1}; ^1H NMR δ: 5.29 (dd, J = 7.2, 2.4 Hz, 1H), 4.53 (q, J = 7.0 Hz, 1H), 3.46 (s, 3H), 3.45 (s, 3H), 2.99 (dd, J = 15.0, 7.2 Hz, 1H), 2.56 (dd, J = 15.0, 2.2 Hz, 1H), 1.56 (d, J = 6.8 Hz, 3H), 0.26 (s, 9H); ^{13}C NMR δ: 152.3, 150.1, 103.8, 103.1, 93.7, 55.3, 54.5, 37.0, 12.7, 0.24; LRMS (EI), *m/z* (relative intensity): 258 (M^+, 4), 73 (100).

2,4-Dimethoxy-5-methyl-3,6-dihydro-2*H*-1,7-dioxa-*as*-indacen-8-one (9*a*) and 4-hydroxy-2-methoxy-5-methyl-3,6-dihydro-2*H*-1,7-dioxa-*as*-indacen-8-one (9*b*)

To a solution of the sulfoxide **3** (1.24 g, 6.0 mmol) in degassed toluene (10.0 mL) at 0°C under argon was added dropwise the diene **4** (3.27 g, 12.65 mmol). The reaction was stirred for 1 h at 0°C, 1 h at room temperature, and for 30 min at reflux. The solvent was removed and the crude product purified by flash chromatography (SiO_2, CH_2Cl_2–acetone 98:2) to obtain **9*a*** (489 mg, 33%) and **9*b*** (199 mg, 14%). Compound **9*a***, mp 135–137°C (hex–EtOAc), presents the following spectroscopic data: IR: 3023, 1759, 1639, 1615, 951 cm^{-1}; ^1H NMR δ: 5.83 (dd, J = 6.4, 2.1 Hz, 1H), 5.14 (s, 2H), 3.97 (s, 3H), 3.59 (s, 3H), 3.49 (dd, J = 16.3, 6.5 Hz, 1H), 3.25 (dd, J = 16.1, 2.0 Hz 1H), 2.06 (s, 3H); ^{13}C NMR δ: 168.8, 159.7, 155.8, 146.8, 115.1, 114.1, 109.0, 102.8, 69.0, 59.0, 56.3, 35.3, 10.9; LRMS (EI), *m/z* (relative intensity): 250 (M^+, 100). Anal. calcd. for $C_{13}H_{14}O_5$: C 62.39, H 5.64; found: C 62.01, H 5.70. Compound **9*b***, mp 168–170°C (hex–EtOAc), presents the following spectroscopic data: IR: 3588, 3250, 3019, 1757, 1625, 950 cm^{-1}; ^1H NMR ($CDCl_3$ + DMSO-d_6) δ: 9.08 (s, 1H, D_2O exchange), 5.82 (dd, J = 6.4, 2.3 Hz, 1H), 5.13 (s, 2H), 3.57 (s, 3H), 3.26 (dd, J = 16.5, 6.5 Hz, 1H), 3.07 (dd, J = 16.6, 2.1 Hz, 1H), 2.06 (s, 3H); ^{13}C NMR (DMSO-d_6) δ: 168.2, 157.2, 154.5, 147.4, 111.8, 110.9, 109.4, 99.3, 68.7, 55.6, 33.4, 10.5; LRMS (EI), *m/z* (relative intensity): 236 (M^+, 57), 43 (100). Anal. calcd. for $C_{12}H_{12}O_5$: C 61.01, H 5.12; found: C 60.83, H 5.14.

Conversion of 9*b* to 9*a*

To a solution of **9*b*** (100 mg, 0.42 mmol) in DMF (5.0 mL) at 0°C under argon was added 60% NaH–oil (20 mg, 0.5 mmol) The reaction was stirred for 15 min and then CH_3I (0.06 mL, 1.05 mmol) was added. The reaction was stirred for 30 min at 0°C and 30 min at room temperature, then poured on water and the product extracted with EtOAc (3×). The organic phase was washed with water, brine, and dried over anhydrous Na_2SO_4. The solvent was removed and the residue purified by flash chromatography (SiO_2, hex–EtOAc 6:4) to obtain **9*a*** (94 mg, 89%).

(4-Hydroxy-6-methoxy-7-methyl-3-oxo-1,3-dihydroisobenzofuran-5-yl)-acetaldehyde (2*a*)

A solution of **9*a*** (73 mg, 0.29 mmol) in 89% formic acid (2.0 mL) was stirred at room temperature for 20 min and con-

For personal use only.

centrated to dryness. The residue was azeotroped with toluene (3×) to remove traces of acid. The aldehyde **2***a* (66 mg, quantitative) was obtained as a white solid in pure form. The NMR spectra shows the phenol-aldehyde **2***a* to be in equilibrium with the corresponding cyclic hemiacetal in solution; mp 144–145°C (hex–CH_2Cl_2); IR: 3417, 1755, 1640, 1612 cm^{-1}; ^1H NMR δ: 9.75 (t, J = 1.5 Hz, 0.18H, aldehyde), 7.70 (s, 1H, D_2O exchange), 6.29 (dd, J = 6.5, 2.6 Hz, 0.82H, hemiacetal), 5.24 (s, 0.36H), 5.14 (s, 1.64H), 3.98 (s, 2.46H), 3.80 (d, J = 1.4 Hz, 0.36 H), 3.73 (s, 0.54H), 3.49 (dd, J = 16.0, 6.5 Hz, 0.82H), 3.22 (dd, J = 16.1, 2.5 Hz, 0.82H), 2.17(s, 0.54H), 2.05 (s, 2.46H); LRMS (EI), *m/z* (relative intensity): 236 (M^+, 2), 208 (55), 159 (100). Anal. calcd. for $C_{12}H_{12}O_5$: C 61.01, H 5.12; found: C 61.29, H 5.03.

3-(1-Methoxypropylidene)-dihydrofuran-2-one (10)

To a solution of 3-propionyl-dihydrofuran-2-one (16.8 g, 0.12 mol) in trimethyl orthoformate (19.4 mL, 0.17 mol) at 0°C was added concentrated H_2SO_4 (0.3 mL). The reaction was allowed to reach room temperature and was stirred for 15 h. The solution was concentrated and quinoline (0.8 mL) added. The crude product was distilled to give **10** as the *E* isomer (10) (2.76 g) and *Z* isomer (10.9 g) as colorless liquids in 74% yield. The *E* isomer, bp 68–70°C (3.0 Torr), presents the following spectroscopic data: IR: 1689, 1640 cm^{-1}; ^1H NMR δ: 4.41 (t, J = 9.7 Hz, 2H), 3.71 (s, 3H), 2.89 (tt, J = 9.6, 1.0 Hz, 2H), 2.66 (qt, J = 7.6, 1.0 Hz, 2H), 1.12 (t, J = 7.5 Hz, 3H); LRMS (EI), *m/z* (relative intensity): 155 ($M^+ - 1$). The *Z* isomer, bp 120–122°C (3.0 Torr), presents the following spectroscopic data: IR: 1728, 1653 cm^{-1}; ^1H NMR δ: 4.25 (t, J = 7.7 Hz, 2H), 3.82 (s, 3H), 3.03–2.80 (m, 4H), 1.15 (t, J = 7.5 Hz, 3H); LRMS (EI), *m/z* (relative intensity): 156 (M^+).

[3-(1-Methoxypropenyl)-4,5-dihydrofuran-2-yloxy]-trimethylsilane (11)

Enol ether **10** (3.0 g, 19.2 mmol) was converted to the diene **11** (3.28 g) in 75% yield as described for **4**; bp 75–81°C (0.35 Torr); IR: 1691, 860 cm^{-1}; ^1H NMR δ: 4.51 (q, J = 6.7 Hz, 1H), 4.27 (dd, J = 9.1, 8.6 Hz, 2H), 3.46 (s, 3H), 2.75 (t, J = 0.9 Hz, 2H), 1.55 (d, J = 6.9 Hz, 3H), 0.21 (s, 9H); LRMS (EI), *m/z* (relative intensity): 228 (M^+).

4-Methoxy-5-methyl-3,6-dihydro-2*H*-1,7-dioxa-*as*-indacen-8-one (12)

Diels–Alder reaction of **11** (1.21 g, 5.0 mmol) and **3** (0.54 g, 2.6 mmol) as described for **9** afforded compound **12** (0.26 g) in 46% yield; mp 141–142°C (hex–CH_2Cl_2); IR: 1749 cm^{-1}; ^1H NMR δ: 5.13 (s, 2H), 4.78 (t, J = 8.8 Hz, 2H), 3.98 (s, 3H), 3.41 (t, J = 8.8 Hz, 2H), 2.06 (s, 3H); LRMS (EI), *m/z* (relative intensity): 220 (M^+).

[4-(*tert*-Butyldimethylsilanyloxy)-6-methoxy-7-methyl-3-oxo-1,3-dihydroisobenzofuran-5-yl]-acetaldehyde (2*b*)

To a solution of **2***a* (200 mg, 0.85 mmol) and imidazole (116 mg, 1.7 mmol) in DMF (10.0 mL) was added TBDMSCl (153 mg, 1.02 mmol). The reaction was stirred at room temperature overnight, then diluted with water and EtOAc. The organic phase was separated and washed with 10% HCl, 10% $NaHCO_3$, and brine, and dried over anhydrous Na_2SO_4. After removal of the solvent the residue was purified by flash chromatography (SiO_2, hex–EtOAc 4:1) to give **2***b* (53 mg, 18%) as a white solid (4*a*). 1H NMR δ: 9.62 (m, 1H), 5.10 (s, 2H), 3.72 (s, 5H), 2.18 (s, 3H), 1.01 (s, 9H), 0.21 (s, 6H); LRMS (EI), *m/z* (relative intensity): 350 (M^+).

[6-Methoxy-4-(2-methoxyethoxymethoxy)-7-methyl-3-oxo-1,3-dihydroisobenzofuran-5-yl]-acetaldehyde (2*c*)

A solution of the phenol **2***a* (1.76 g, 7.45 mmol), *N,N*-diisopropylethylamine (3.24 mL, 18.6 mmol), and 2-methoxyethoxymethyl chloride (1.1 g, 8.9 mmol) in CH_2Cl_2 (50.0 mL) was stirred for 2 h at room temperature. The reaction was diluted with CH_2Cl_2 and washed with 10% $NaHCO_3$, water, and brine, and dried over anhydrous Na_2SO_4. The solvent was removed and the residue purified by flash chromatography (SiO_2, hex–acetone 7:3) to obtain the MEM ether **2***c* (1.98 g, 86%) as a solid; mp 45–50°C; IR: 3021, 1760, 1724, 1130, 1069, 961 cm^{-1}; ^1H NMR δ: 9.72 (t, J = 1.5 Hz, 1H), 5.44 (s, 2H), 5.17 (s, 2H), 3.92–3.84 (m, 4H), 3.74 (s, 3H), 3.60–3.52 (m, 2H), 3.37 (s, 3H), 2.21 (s, 3H); ^{13}C NMR δ: 199.0, 168.7, 162.9, 154.0, 148.3, 121.1, 120.4, 112.2, 100.2, 71.5, 69.4, 68.3, 60.8, 59.0, 39.7, 11.6; LRMS (EI), *m/z* (relative intensity): 324 (M^+, 1), 59 (100). Anal. calcd. for $C_{16}H_{20}O_7$: C 59.25, H 6.21; found: C 59.42; H, 6.35.

6-(2-Hydroxy-3-methylbut-3-enyl)-5-methoxy-7-(2-methoxyethoxymethoxy)-4-methyl-3*H*-isobenzofuran-2-one (14)

To a solution of the aldehyde **2***c* (1.4 g, 4.3 mmol) in THF (40.0 mL) at −40°C under argon was added freshly prepared prop-2-enyl magnesium bromide (0.58 M in THF, 15 mL) and stirred for 40 min. The reaction was diluted with EtOAc and 50% NH_4Cl and allowed to reach room temperature. The organic phase was washed with 10% NH_4Cl and brine, and dried over anhydrous Na_2SO_4. The solvent was evaporated and the residue purified by flash chromatography (SiO_2, hex–EtOAc 7:3) to obtain the MEM alcohol **14** (949 mg, 67%) as an oil. IR: 1758, 1604, 1129, 1068 cm^{-1}; ^1H NMR δ: 5.45 (q, J = 6.7 Hz, 2H), 5.14 (s, 2H), 4.99 (br t, J = 0.82 Hz, 1H), 4.84 (br t, J = 1.2 Hz, 1H), 4.32 (dd, J = 8.2, 5.0 Hz, 1H), 4.06–3.86 (m, 2H), 3.82 (s, 3H), 3.59 (t, J = 4.7 Hz, 2H), 3.37 (s, 3H), 3.12–2.92 (m, 2H), 2.20 (s, 3H), 1.86 (s, 3H); ^{13}C NMR δ: 169.0, 163.1, 154.3, 147.7, 147.2, 126.8, 120.5, 112.3, 110.4, 100.4, 75.5, 71.5, 69.4, 68.2, 60.9, 59.0, 31.3, 18.0, 11.7; LRMS (EI), *m/z* (relative intensity): 366 (M^+, 1), 220 (25), 59 (100). Anal. calcd. for $C_{19}H_{26}O_7$: C 62.27, H 7.53; found: C 61.95, H 7.49.

6(4-Hydroxy-6-methoxy-7-methyl-3-oxo-1,3-dihydroisobenzofuran-5-yl)-4-methyl-hex-4-enoic acid ethyl ester (1*b*)

A solution of the allylic alcohol **14** (930 mg, 2.56 mmol), freshly distilled triethyl orthoformate (8.0 mL, 43.6 mmol), and pivalic acid (6 mg, 0.05 mmol) in xylene (45.0 mL) was heated in an oil bath at 135–140°C for 6 h. The solvent was removed, the residue dissolved in *t*-BuOH (70.0 mL), PPTS (700 mg, 2.8 mmol) was added, and the solution stirred at 80°C for 6 h. The reaction was diluted with EtOAc, washed with 10% $NaHCO_3$, and water, and dried over anhydrous Na_2SO_4. The solvent was removed and the residue (1.34 g) was purified by flash chromatography (SiO_2, hex–acetone 85:15) to give the ester **1***b* (516 mg, 60% from **14**); mp 95–96°C (hex–CH_2Cl_2); IR: 3454, 1735, 1628, 1138 cm^{-1};

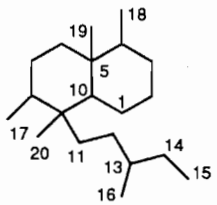
Synthetic studies on clerodane diterpenoids. The total synthesis of (±)-2-oxo-5α,8α-13,14,15,16-tetranorclerod-3-en-12-oic acid

Hsing-Jang Liu, Kak-Shan Shia, Yongxin Han, Daqing Sun, and Yu Wang

Abstract: A general synthetic approach to diterpenoids of the *cis*-clerodane family has been developed, leading to the first total synthesis, in racemic form, of 2-oxo-5α,8α-13,14,15,16-tetranorclerod-3-en-12-oic acid (**2**). The key operation involved is the face-selective Diels–Alder reaction of dienone ester **10** with *trans*-piperylene, giving rise to adduct **11** containing the decalin nucleus and correct stereogenic centers common to many *cis*-clerodane diterpenoids.

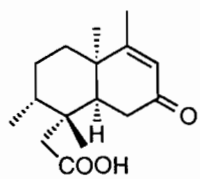
Key words: *cis*-clerodanes, general synthetic approach, total synthesis, face-selective Diels–Alder reaction.



Résumé : On a développé une méthode générale de synthèse des diterpénoïdes de la famille du *cis*-clérodane qui a conduit à la première synthèse totale de l'acide 2-oxo-5α,8α-13,14,15,16-tétranorclérod-3-én-12-oïque (**2**) sous forme racémique. L'opération clé implique une réaction de Diels–Alder face spécifique de la diénone-ester **10** avec le *trans*-pipérylène qui conduit à l'adduit **11** contenant le noyau décaline et les centres stéréogéniques corrects pour plusieurs diterpénoïdes du *cis*-clérodane.

Mots clés : *cis*-clérodanes, méthode générale de synthèse totale, réaction de Diels–Alder face sélective.

[Traduit par la rédaction]



Introduction

Diterpenoids possessing the clerodane (**1**) carbon skeleton are widely distributed in nature and constitute one of the largest and, yet, still rapidly growing family of secondary metabolites. To date, more than 800 compounds have been isolated and structurally characterized from various natural sources, about one quarter in the last four years (1). Clerodanes are best

1

known for their antifeedant properties. Of the relatively few tested for biological activity, many were also found to possess interesting medicinal properties and are potentially useful as antiviral, antitumor, antifungal, antibiotic, anti-peptic ulcer, and psychotropic agents (1, 2). The structural complexity and biological activity associated with this class of natural products have attracted extensive effort towards their total syntheses. More than 15 successful syntheses have been reported for the sub-series of *trans*-clerodanes (Fig. 1) (3). Relatively few syntheses, however, are known for the *cis* sub-series of compounds (Fig. 1) (4). In virtually all of the reported syntheses, a linear approach to the specific target molecule is involved. Since naturally occurring clerodanes are vast in number and their structural differences are mainly due to stereochemistry, oxidation level, and oxygen contents of various centers, it is highly desirable to develop a general nonlinear synthetic approach, whereby a large number of target molecules can be synthesized by a common strategy with minor adjustments. We wish to demonstrate herein such an approach highlighted by the first total synthesis, in racemic form, of the title carboxylic acid **2**, which was recently isolated from *vellozia bicolor* L.B. Smith by Garcez and co-workers (5).

2

Results and discussion

In recent years, an extensive study of the Diels–Alder chemistry of 4,4-dimethyl-2-cyclohexenones and several closely related cross-conjugated cyclic unsaturated β-dicarbonyl compounds has been carried out in our laboratories (6–12). On the basis of these studies, a general synthetic scheme

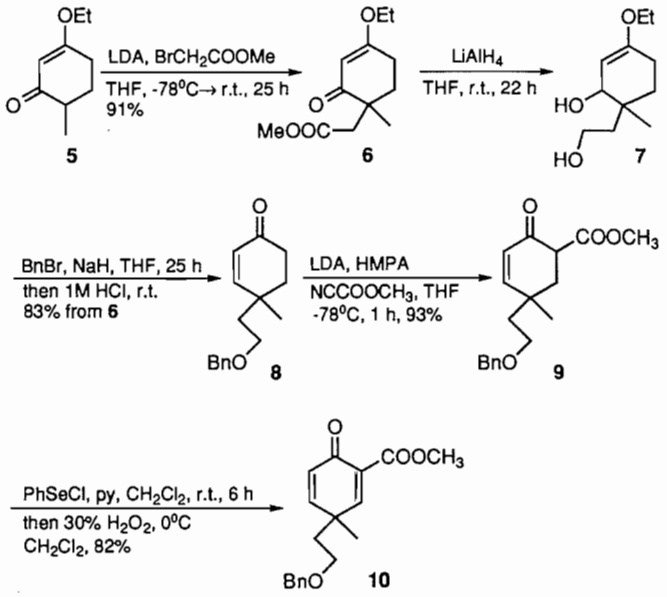
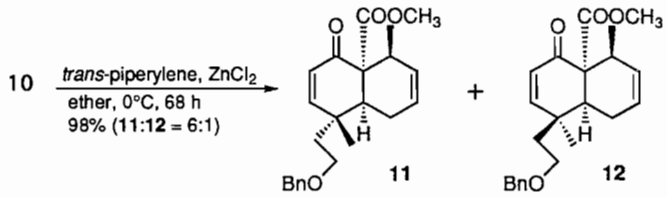
Fig. 1. Major structural types of clerodane diterpenoids.

Scheme 1.



(Scheme 1) that would facilitate the rapid assembly of a variety of *cis*-clerodane diterpenes, especially the highly oxygenated ones, via a general intermediate **4** has been conceived. By this Diels–Alder approach, the relative stereochemistry of the three contiguous chiral centers C_5, C_9, and C_{10} (clerodane numbering) of **4** is expected to be arranged in the same manner as those of the natural *cis*-clerodanes based mainly on the following steric consideration. It is highly conceivable that, if R^2 is bulkier than R^1, addition of the diene to dienophile **3** will occur preferentially from the sterically less hindered R^1 face. This approach has now been experimentally realized, culminating in the total synthesis of 2-oxo-5α,8α-13,14,15,16-tetranorclerod-3-en-12-oic acid (**2**) in racemic form and the formation of several advanced intermediates potentially useful for the preparation of a variety of *cis*-clerodanes.



During the preliminary investigation, several dienophiles of formula **3** have been synthesized and explored. The outcome revealed that Diels–Alder adducts obtained with an angular aldehyde moiety α to the ketone carbonyl were not stable enough for further elaboration. A more practical dienophile **10**, a dienone with an α-ester group, was finally adopted.

Compound **10** was readily prepared from 3-ethoxy-6-methyl-2-cyclohexenone (**5**) (13) according to the synthetic sequence shown in Scheme 2. Stork–Danheiser alkylation (14) of **5** with methyl bromoacetate gave enone ester **6** in 91% yield. This compound was reduced with lithium aluminum hydride to give a mixture of two diastereomeric diols **7** in nearly equal amounts. Without further purification, the mixture of the unstable diols **7** was immediately subjected to selective benzylation with a slight excess of sodium hydride and benzyl bromide. Treatment of the crude product with dilute hydrochloric acid afforded enone **8** in 83% yield from **6**. Later,

Scheme 2.

Scheme 3.

it was found that, even if benzylation occurred at both hydroxyls when excess benzyl bromide and base were applied, the *bis*-benzylated product could also be easily converted into **8** under the same hydrolysis conditions. Enone **8** was subjected to carbomethoxylation using lithium diisopropylamide and methyl cyanoformate (15) to give keto ester **9** as a mixture of three isomers (a pair of epimers and an enol ester) in a ratio of 2:1.4:1 as indicated by the ^{1}H nmr spectrum. Keto ester **9** was then treated with phenylselenenyl chloride in the presence of pyridine (16). Oxidative elimination of the resulting selenide with hydrogen peroxide gave the required dienone ester **10** in 82% yield.

Dienone ester **10** proved to be an excellent dienophile. Under zinc chloride catalysis, it underwent cycloaddition with *trans*-piperylene to furnish adducts **11** (from the sterically less hindered methyl face) and **12** in 84% and 14% yield, respectively (Scheme 3). Slightly inferior results (95% yield; **11**:**12** = 5.3:1) were obtained when ferric chloride was used as a catalyst (CH_2Cl_2, −55°C, 21 h). The Diels–Alder adducts were readily separated by flash chromatography, and their regiochemistries were deduced by the following evidences. For the less polar major isomer **11**, the splitting pattern (ddd, J = 10, 7, 2 Hz) of the ring junction C_6 proton at δ 2.75 in the ^{1}H nmr spectrum clearly demonstrated that it was an *ortho* adduct. In a similar fashion, the minor isomer **12** showed a doublet of doublet of doublets (J = 10, 7, 2 Hz) for the C_6 proton at δ 2.68 suggesting that it was also an *ortho*-addition product. To determine the relative stereochemistry of each, extensive NOE

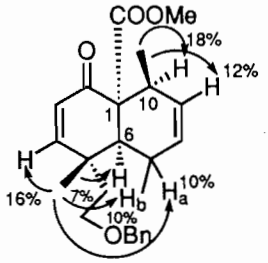
For personal use only.

Fig. 2. NOE effects for **11**.



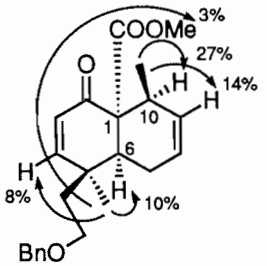


Fig. 3. NOE effects for **12**.

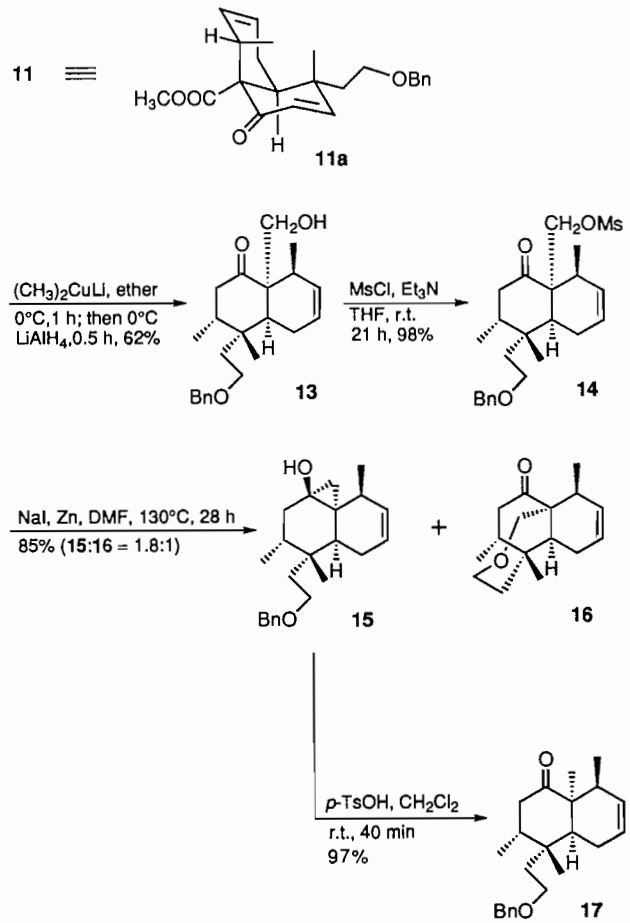
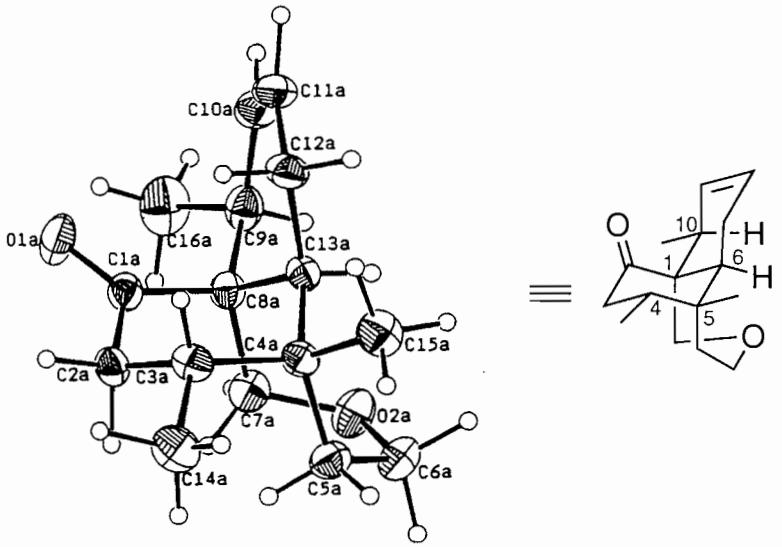


experiments were carried out for both compounds. For the major isomer, irradiation of the C_5 methyl at δ 1.10 resulted in enhancements for H_4 (16%), H_6 (6.9%), H_{7a} (10.2%), and H_{7b} (10.2%) (Fig. 2). On the other hand, irradiation of the C_5 methyl (δ 1.15) of the minor isomer gave enhancements for the methoxy methyl (2.8%), the C_4 vinylic proton (8.4%), and the C_6 proton (10%) (Fig. 3). No enhancements were observed for H_{7a} and H_{7b}. Therefore, structures **11** and **12** were assigned to the major and minor products, respectively.

Although, at this stage, the relative stereochemistry at each C_{10} position of **11** and **12** could not be confirmed based on the NOE studies, the configuration of this center in each case was tentatively assigned based on the previously observed preferential *endo*-to-ketone addition of *trans*-piperylene to several dienophiles resembling compound **10** (6). These structural assignments were later substantiated by the X-ray crystallographic analysis of a more advanced intermediate **16** (*vide* infra).

Adduct **11** possesses four contiguous stereogenic centers incorporated simultaneously in a correct sense for many naturally occurring *cis*-clerodanes. The remaining crucial stereogenic center was introduced via a conjugate addition process (Scheme 4). Treatment of adduct **11** with lithium dimethylcuprate followed by reduction of the resulting enolate with lithium aluminum hydride afforded keto alcohol **13** in 62% yield by a single operation. In this transformation, the enolate resulting from the conjugate addition served as an effective protecting group for the more reactive ketone carbonyl; thereby the desired reduction of the less reactive ester carbonyl could be achieved without further elaboration. Compound **13** was formed as the only stereoisomer, presumably via preferential axial addition of the cuprate to the sterically less hindered side of the conformer **11a**. To remove its hydroxy group, keto alcohol **13** was converted to the corresponding mesylate in quantitative yield using methanesulfonyl chloride and triethylamine. Reduction of mesylate **14** with sodium iodide and zinc dust (17) in DMF at 130°C gave rise to a 55% yield of cyclopropanol **15** and a 30% yield of the crystalline tricyclic ketone **16**, mp 74.5–76.0°C. The former product was likely formed via the addition of the intermediate carbanion resulting from the reductive removal of the methanesulfonyloxy group to the ketone carbonyl, and the latter via the displacement of the mesylate with the benzyl ether followed by debenzylation. Ketone **16** was subjected to X-ray crystallographic analysis. The crystal structure of **16** as shown in Fig. 4 made unambiguous the assignment of the five contiguous stereogenic centers along C_1, C_4, C_5, C_6, and C_{10} present in **16** and its precursors. Cyclopropanol **15** was found to be a suitable intermediate for the formation of the desired ketone **17** (Scheme 4). Upon exposure to a catalytic amount of *p*-toluenesulfonic acid in methylene chloride, it underwent rapid ring cleavage to give ketone **17** in 97% yield.

Scheme 4.



Several other methods were explored in attempts to produce the desired ketone **17** more efficiently. These efforts, however, were not fruitful. Reduction of mesylate **14** with an excess of lithium triethylborohydride in tetrahydrofuran gave rise to alcohol **18** as a result of the reduction of the ketone carbonyl followed by a Grob fragmentation and further reduction of the ensuing aldehyde. In another approach, keto alcohol **13** was transformed to thiocarbonate **19** in 72% yield by treatment with phenyl chlorothionoformate and pyridine in dichloromethane at room temperature. Unfortunately, other functionalities present in **19** were shown to be incompatible with

the reaction conditions required to remove the thiocarbonate moiety using tri-*n*-butyltin hydride.

18 **19**

Ketone **17** can, in principle, serve as a key intermediate for two groups of *cis*-clerodane diterpenes, one with an oxygen atom at C_6 (clerodane numbering), such as solidagolactones II–VIII (18–21), 6β-acetoxy-2-oxokolavenool (22), etc., and the other without an oxygen atom at C_6, such as solidagoic acid A (23, 24), tinotufolin B (25), 2-oxo-5α,8α-13,14,15,16-tetranorclerod-3-en-12-oic acid (**2**), etc. The total synthesis of **2** has been accomplished as follows (Scheme 5). The ketone carbonyl of **17** was removed by a Wolff–Kishner reduction using hydrazine, and potassium hydroxide in diethylene glycol at ~210°C. Two isomeric products **20** and **21** were formed in 3:1 ratio (^{1}H nmr analysis) and in a total yield of 60%. Subsequent irradiation (tungsten lamps) of this inseparable mixture in carbon tetrachloride in the presence of oxygen, 5,10,15,20-tetraphenyl-21*H*,23*H*-porphine, acetic anhydride, pyridine, and 4-dimethylaminopyridine (26) gave rise to enone **22** (56% yield based on **20**) along with an unidentified product. The regioselectivity observed for the photooxygenation reaction was somewhat unusual. Instead of forming an enone system with a less substituted double bond following the "normal" regiochemical course of photooxygenation, the double bond moved towards the carbon center possessing a greater number of substituents. The unusual regiochemistry in the present case was nevertheless quite predictable based on the studies on several structurally closely related compounds in this series (27–29). However, exactly what controls the regiochemistry is

Scheme 5.

not fully understood. Enone **22** was subjected to treatment with ferric chloride (30) to effect the removal of the benzyl protecting group. Finally, alcohol **23** thus obtained in 82% yield was oxidized using Jones reagent (31) to afford the target clerodenoic acid **2** (63% yield) in racemic form, m.p. 226–227°C (236°C for the optically active natural **2** (5)). The spectral data (^{1}H nmr, ^{13}C nmr, and mass) of the synthetic material are in good agreement with those reported for the natural product.

Conclusion

The foregoing describes a simple nonlinear, general synthetic approach to diterpenoids of the clerodane family. Several advanced synthetic molecules, e.g., **13**, **17**, and **23**, are potentially useful for the preparation of a variety of naturally occurring compounds. Furthermore, by careful selection of the starting diene involved in the early Diels–Alder cycloaddition, oxygen functionalities can, in principle, also be directly incorporated to C_1, C_2, C_3, and C_{18}. Thus, by a small adjustment, the

demonstrated scheme should also facilitate the synthesis of those clerodanes oxygenated at one or more of these positions. The validity of this synthetic approach is illustrated with the total synthesis of (±)-2-oxo-5α,8α-13,14,15,16-tetranorclerod-3-en-12-oic acid (**2**).

Experimental

General

Melting points were recorded on a Kofler hot stage apparatus and are not corrected. Combustion elemental analyses were performed by the microanalytical laboratory of this department. Fourier transform infrared spectra (ir) were recorded on a Nicolet 7199 or Nicolet MX-1 FTIR spectrophotometer. Proton nuclear magnetic resonance (^{1}H nmr) spectra were recorded on a Bruker WH-80, Bruker WH-200, Bruker WH-300, Bruker WH-400, or Bruker AM-400 spectrometer using deuteriochloroform ($CDCl_3$) as solvent unless otherwise stated. Tetramethylsilane (TMS) was used as an internal reference. Coupling constants are reported to ±0.5 Hz. Chemical shift measurements are reported in ppm downfield from TMS in delta (δ) units. The following abbreviations are used: s = singlet, d = doublet, t = triplet, q = quartet, m = multiplet, and br = broad. Carbon-13 nuclear magnetic resonance (^{13}C nmr) spectra were recorded on a Varian Unity-500 (125 MHz) spectrometer or a Bruker WH-300 (75 MHz) NMR spectrometer, and were obtained as solutions in deuteriochloroform as the internal standard setting the central peak at 77.00 ppm. Carbon-13 multiplicities were derived from Carr–Purcell–Meiboom–Gill spin echo *J*-modulated experiments (APT or Attached Proton Test) (32, 33). Methyl and methine groups are shown as signals possessing an antiphase (a) with respect to the deuteriochloroform signal, whereas methylene groups, quaternary carbons, and carbonyl groups appear in phase (p) with it. Nuclear Overhauser enhancement (nOe) experiments were determined in the difference mode in which a control (undecoupled) spectrum was computer subtracted from the irradiated spectrum after Fourier transformation. Positive enhancements are defined as signals possessing an antiphase with respect to the irradiated signal. Samples for nOe measurements were deoxygenated with argon for 10 min prior to use. High-resolution electron impact mass spectra (hrms) were recorded using an A.E.I. model MS-50 mass spectrometer. Chemical ionization mass spectra (cims) were recorded on an A.E.I. model MS-12 mass spectrometer, using ammonia as the reagent gas. Spectral data are reported as *m/z* values.

All reactions were carried out under slight positive pressure of argon. Bulb-to-bulb distillation was performed using a Kugelrohr distillation apparatus. Flash chromatography developed by Still et al. (34) was used routinely for purification and separation of product mixtures, using silica gel (Merck) of 230–400 mesh. All solvents for chromatography were distilled prior to use. Concentrations of solvent systems used in column chromatography are given by volume, e.g., 20% ethyl acetate in petroleum ether means 20 parts of ethyl acetate by volume to 80 parts of petroleum ether by volume. Analytical thin-layer chromatography (tlc) was carried out on aluminum sheets precoated (0.2 mm layer thickness) with silica gel 60 F_{254} (E. Merck, Darmstadt). Ultraviolet-active materials were detected by visualization under a uv lamp (254 or 350 nm). For tlc, the visualization of the chromatograms was completed by dipping in an ethanol solution of vanillin (5%, w/v) and sulfuric acid (5%, v/v), followed by careful charring on a hot plate. Alternatively, an aqueous solution of phosphomolybdic acid (3%, w/v) containing ceric sulfate (0.5%,w/v) and sulfuric acid (3%, v/v) was used as the dipping solution, followed by charring on a hot plate.

Materials

Unless otherwise stated, all materials used are commercially available. All compounds made are racemic. Solvents used were distilled under an argon atmosphere from appropriate drying agents. Tetrahydrofuran (THF), diethyl ether, toluene, and 1,2-dimethoxyethane (DME) were dried with sodium and benzophenone. Acetone was predried with potassium carbonate, and then distilled from potassium permanganate. Diisopropylamine was obtained by distillation from sodium hydroxide or potassium hydroxide. Pyridine, benzene, dichloromethane, carbon tetrachloride, and triethylamine (TEA) were distilled from calcium hydride. Reactions requiring anhydrous conditions were performed in oven- or flame-dried glassware that was assembled and allowed to cool while being purged with argon. Argon was passed through a column of 4 Å molecular sieves and self-indicating silica gel.

6-(Carbomethoxymethyl)-3-ethoxy-6-methyl-2-cyclohexenone (6)

To a solution of diisopropylamine (8.3 mL, 59 mmol) in THF (17 mL) at 0°C under an argon atmosphere, was added *n*-BuLi (34 mL, 1.6 M in hexane) slowly. The mixture was stirred at 0°C for 15 min and then cooled down to −78°C. A solution of 3-ethoxy-6-methyl-2-cyclohexenone (**5**) (7.65 g, 49 mmol) in THF (20 mL) was added dropwise over a period of 15 min. The resulting mixture was stirred at −78°C for 1 h, and methyl bromoacetate (9.6 mL, 98 mmol) was added in one portion. The mixture was allowed to warm up slowly to room temperature and stirred overnight. Saturated ammonium chloride was added and the mixture was extracted with ether (3 × 40 mL). The extracts were combined, washed with water, brine, and dried over magnesium sulfate. Filtration and concentration followed by bulb-to-bulb distillation at 128–130°C/0.7 Torr (1 Torr = 133.3 Pa) gave rise to the alkylation product **6** (10.2 g, 91% yield) as a light yellow oil: ir (CH_2Cl_2 cast): 1737 (C=O, ester) and 1654 (C=O, enone) cm^{-1}; ^{1}H nmr (200 MHz) δ: 5.29 (d, *J* = 1 Hz, 1 H, -C=C**H**-C=O), 3.91 (q, *J* = 7 Hz, 1 H, CH_3C**H**HO-), 3.90 (q, *J* = 7 Hz, 1 H, CH_3CH**H**O-), 3.62 (s, 3 H, -COOC**H**$_3$), 2.79 (d, *J* = 15.5 Hz, 1 H, -C**H**HCOOCH$_3$), 2.35 (d, *J* = 15.5 Hz, 1 H, -CH**H**COOCH$_3$), 2.60–2.19 (m, 3 H), 1.81–1.67 (m, 1 H), 1.35 (t, *J* = 7 Hz, 3 H, C**H**$_3$CH$_2$O-), and 1.16 (s, 3 H, -C**H**$_3$); ^{13}C nmr (75 MHz) δ: 200.18 (p), 174.54 (p), 171.64 (p), 101.31 (a), 63.87 (p), 50.84 (a), 42.33 (p), 41.76 (p), 31.56 (p), 26.08 (p), 22.33 (a), and 13.98 (a); hrms M$^+$: 226.1200 (calcd. for $C_{12}H_{18}O_4$: 226.1205). Anal. calcd. for $C_{12}H_{18}O_4$: C 63.70, H 8.02; found: C 63.70, H 8.39.

4-(2-Benzyloxyethyl)-4-methyl-2-cyclohexenone (8)

To a suspension of lithium aluminium hydride (0.81 g, 21.3 mmol) in THF (20 mL) at 0°C under an argon atmosphere, was added dropwise a solution of enone ester **6** (2.1 g, 9.3 mmol) in THF (20 mL). The resulting mixture was stirred at 0°C for 1 h and then at room temperature for 21 h. To the mixture cooled to 0°C and diluted with ether (30 mL), were added alternately

For personal use only.

portions of water (0.12 mL) and 3 N NaOH (0.12 mL) over a period of 1 h. The resulting grey suspension was stirred for another hour and filtered. The residue was washed thoroughly with ether. The filtrate was concentrated to give the crude product (1.9 g), which, without purification, was dissolved in THF (18 mL) and added to a suspension of sodium hydride (0.48 g, 11.4 mmol) in THF (20 mL) at 0°C under argon. The mixture was stirred for 1 h (0°C→room temperature), and then benzyl bromide (3.25 g, 19 mmol) was introduced at 0°C. After stirring at room temperature for 25 h, the solution was acidified to pH = 1-1.5 with 1 N HCl, and the resulting solution stirred for 2 h. After the hydrolysis was complete, the mixture was extracted with ether (3 × 40 mL). The extracts were combined and washed with saturated sodium bicarbonate, water, and brine. After being dried over magnesium sulfate, the solution was filtered and concentrated to give the crude product. Flash chromatography using ethyl acetate and hexane (20:80) gave compound **8** (1.88 g, 83% yield from **6**) as a light yellow oil. Alternatively, it could be distilled at 175°C/1 torr to give the product as a colorless oil: ir ($CHCl_3$ cast): 1680 (C═O, enone), 738 and 698 (C-H bending, aromatic) cm^{-1}; ^1H nmr (300 MHz) δ: 7.32 (m, 5 H, aromatic **H**), 6.75 (d, J = 10 Hz, 1 H, -C**H**═CH-C═O), 5.86 (d, J = 10 Hz, 1 H, -CH═C**H**-C═O), 4.49 (s, 2 H, -OC**H**$_2$Ph), 3.51–3.64 (m, 2 H, -C**H**$_2$OBn), 2.47 (m, 2 H), 2.02 (ddd, J = 15, 7, 7 Hz , 1 H, -C**H**HC═O), 1.73–1.90 (complex, 3 H), and 1.18 (s, 3 H, -C**H**$_3$); ^{13}C nmr (75 MHz) δ: 199.27 (p), 158.75 (a), 138.11 (p), 128.31 (a, 2 × aromatic **C**), 127.54 (a), 127.49 (a, 2 × aromatic **C**), 127.12 (a), 73.04 (p), 66.59 (p), 40.20 (p), 34.92 (p), 34.05 (p, 2 × -**C**H$_2$-), and 25.19 (a); hrms M^+: 244.1459 (calcd. for $C_{16}H_{20}O_2$: 244.1463). Anal. calcd. for $C_{16}H_{20}O_2$: C 78.65, H 8.25; found: C 78.93, H 8.52.

4-(2-Benzyloxyethyl)-6-carbomethoxy-4-methyl-2-cyclohexenone (9)

To a suspension of sodium hydride (60% dispersion in mineral oil, 4.21 g, 105 mmol) in THF (20 mL) under an argon atmosphere, was added dimethyl carbonate (17 mL, 180 mmol). The mixture was brought to boiling, and then a solution of enone **8** (11.3 g, 46 mmol) in THF (20 mL) was added dropwise over a period of 30 min. The resulting mixture was heated under reflux for 24 h and then cooled to 0°C. Ice-cold 1 N HCl (35 mL) was added cautiously to the mixture, and the resulting solution extracted with ether (3 × 50 mL). The extracts were combined and washed with water and brine. After being dried over magnesium sulfate, the solution was filtered and concentrated to give the crude product. Flash chromatography using ethyl acetate and hexane (10:90) gave keto ester **9** (7.56 g, 54% yield) as a yellowish oil: ir ($CHCl_3$ cast): 1744 (C═O, ester), 1681 (C═O, enone), 1626 and 1592 (C═C, enol ester), 738 and 698 (C-H bending, aromatic) cm^{-1}; ^1H nmr (300 MHz), three isomers in a ratio of 2:1.4:1; isomer 1: δ: 7.32 (m, 5 H, aromatic **H**), 6.81 (dd, J = 10, 2 Hz, 1 H, -C**H**═CHCO), 5.90 (d, J = 10 Hz, 1 H, -CH═C**H**CO), 4.48 (s, 2 H, -OC**H**$_2$Ph), 3.78 (s, 3 H, -COOC**H**$_3$), 3.50–3.65 (m, 2 H, -C**H**$_2$OBn), 1.64–2.50 (m), and 1.21 (s, 3 H, -C**H**$_3$); isomer 2: δ: 6.72 (dd, J = 10, 1.5 Hz, 1 H, -C**H**═CHCO), 5.92 (d, J = 10 Hz, 1 H, -CH═C**H**CO), 4.49 (s, 2 H, -OC**H**$_2$Ph), 3.74 (s, 3 H, -COOC**H**$_3$), and 1.18 (s, 3 H, -C**H**$_3$); isomer 3: δ: 11.87 (s, 1 H, -C═C-O**H**), 6.11 (d, J = 10 Hz, 1 H, -C**H**═CHCO), 5.88 (d, J = 10 Hz, 1 H, -CH═C**H**CO), 4.47 (s, 2 H, -OC**H**$_2$Ph), 3.73 (s, 3 H, -COOC**H**$_3$), and 1.07 (s, 3 H, -C**H**$_3$); hrms M^+: 302.1515 (calcd. for $C_{18}H_{22}O_4$: 302.1518). Anal. calcd. for $C_{18}H_{22}O_4$: C 71.49, H 7.34; found: C 71.41, H 7.39.

Alternatively, the above carbomethoxylation could be achieved by the following method in higher yield. *n*-Butyllithium (6.06 mL, 2.5 M in hexane) was added to a stirred solution of anhydrous diisopropylamine (2.25 mL, 15.9 mmol) in THF (20 mL) at 0°C under an atmosphere of argon. After 30 min, the temperature was lowered to −78°C, a solution of enone **8** (1.85 g, 7.58 mmol) in THF (10 mL) was added dropwise to the mixture over a period of 15 min, and stirring continued at 0°C for 1 h. The temperature was lowered again to −78°C, and then HMPA (1.45 mL, 8.34 mmol) was added, followed by the addition of methyl cyanoformate (0.91 mL, 11.4 mmol) in one portion. After stirring for 1 h at −78°C, the mixture was warmed up to room temperature and quenched with cold water (10 mL). The product was extracted into ether (3 × 20 mL), dried ($MgSO_4$), filtered, concentrated, and chromatographed on silica gel (10% ethyl acetate in hexane) to afford compound **9** (2.1 g, 93% yield) as a yellowish oil.

4-(2-Benzyloxyethyl)-2-carbomethoxy-4-methyl-2,5-cyclohexadienone (10)

Pyridine (0.51 mL, 5.9 mmol) was added slowly to a solution of phenylselenenyl chloride (1.10 g, 5.7 mmol) in dichloromethane (25 mL) at 0°C. After 20 min, keto ester **9** (1.4 g, 4.6 mmol) in dichloromethane (10 mL) was added. The mixture was stirred at 0°C for 1 h and then at room temperature for 6 h. The organic layer was separated, washed with 10% HCl (2 × 10 mL), and cooled again to 0°C. A solution of 30% H_2O_2 was added successively (0.2 mL every 5 min) until the white precipitate was formed. After an additional 20 min, H_2O (5 mL) was added. The organic layer was separated, and the aqueous solution extracted with dichloromethane (2 × 20 mL). The combined extracts were washed with water, saturated aqueous sodium bicarbonate, and brine. After being dried over $MgSO_4$, the solution was filtered and concentrated. The residue was subjected to flash chromatography using ethyl acetate and hexane (30:70) as the eluant to give dienone ester **10** (1.14 g, 82% yield) as a light yellow oil: ir (CH_2Cl_2 cast): 1741 (C═O, ester), 1664 (C═O, enone), 739 and 699 (C-H bending, aromatic) cm^{-1}; ^1H nmr (300 MHz) δ: 7.59 (d, J = 3 Hz, 1 H, -C**H**═C-COOCH$_3$), 7.21–7.36 (m, 5 H, aromatic **H**), 6.78 (dd, J = 10, 3 Hz, 1 H, -C**H**═CHC═O), 6.29 (d, J = 10 Hz, 1 H, -CH═C**H**C═O), 4.35 (s, 2 H, -OC**H**$_2$Ph), 3.80 (s, 3 H, -COOC**H**$_3$), 3.26–3.41 (m, 2 H, -C**H**$_2$OBn), 1.97–2.13 (m, 2 H, -C**H**$_2$CH$_2$OBn), and 1.32 (s, 3 H, -C**H**$_3$); ^{13}C nmr (75 MHz) δ: 181.59 (p), 165.03 (p), 160.88 (a), 153.52 (a), 137.77 (p), 130.53 (p), 129.19 (a), 128.34 (a, 2 × aromatic **C**), 127.62 (a, 2 × aromatic **C**), 73.15 (p), 66.66 (p), 52.18 (a), 41.05 (p), 40.54 (p), and 25.98 (a); hrms M^+: 300.1353 (calcd. for $C_{18}H_{20}O_4$: 300.1361). Anal. calcd. for $C_{18}H_{20}O_4$: C 71.98, H 6.71; found: C 71.81, H 6.76.

(1*R**,5*R**,6*S**,10*S**)-5-(2-Benzyloxyethyl)-1-carbomethoxy-5,10-dimethylbicyclo[4.4.0]deca-3,8-dien-2-one (11) and (1*R**,5*S**,6*S**,10*S**)-5-(2-benzyloxyethyl)-1-carbomethoxy-5,10-dimethylbicyclo[4.4.0]deca-3,8-dien-2-one (12)

$ZnCl_2$ (1.0 g, 7.5 mmol) in a three-neck round bottom flask was fused under argon and then cooled to room temperature.

Dry ether (25 mL) was added and the $ZnCl_2$ was crushed to small pieces using a spatula. The mixture was stirred for 15 min until a fine suspension was formed. It was then cooled to 0°C and a solution of dienone ester **10** (0.75 g, 2.5 mmol) in ether (20 mL) was added dropwise. After the addition, the cloudy suspension turned clear, presumably due to the complexation of the dienophile and $ZnCl_2$. *trans*-Piperylene (3.75 mL, 7.52 mmol) was added and the resulting mixture was stirred under argon at 0°C for 68 h. The solution was quenched by addition of water and made basic with saturated aqueous sodium bicarbonate. The aqueous solution was extracted with ether (2 × 15 mL) and the combined extracts were washed with water, saturated sodium bicarbonate, and brine. Drying ($MgSO_4$), filtration, concentration, and flash chromatography using ethyl acetate and petroleum ether (5:95) gave adduct **11** (0.77 g, 84% yield) as a colorless oil: ir ($CHCl_3$ cast): 1725 (C=O, ester), 1690 (C=O, enone), 734 and 699 (C-H bending, aromatic) cm^{-1}; ^1H nmr (300 MHz) δ: 7.32 (m, 5 H, aromatic **H**), 6.29 (dd, *J* = 10, 2 Hz, 1 H, -C**H**=CHC=O), 5.92 (d, *J* = 10 Hz, 1 H, -CH=C**H**C=O), 5.57 (ddd, *J* = 10, 4, 2 Hz, 1 H, C-9 **H**), 5.50 (ddd, *J* = 10, 7, 3 Hz, 1 H, C-8 **H**), 4.52 (d, *J* = 14 Hz, 1 H, -OC**H**HPh), 4.48 (d, *J* = 14 Hz, 1 H, -OCH**H**Ph), 3.69 (s, 3 H, -COOC$\mathbf{H}_3$), 3.58–3.66 (m, 2 H, -C$\mathbf{H}_2$OBn), 2.83 (m, 1 H, C-10 **H**), 2.75 (ddd, *J* = 10, 7, 2 Hz, 1 H, C-6 **H**), 2.16 (dm, *J* = 18 Hz, 1 H, C-7 $\mathbf{H}_a$), 1.95 (dm, *J* = 18 Hz, 1 H, C-7 $\mathbf{H}_b$), 1.78 (dd, *J* = 14, 7 Hz, 1 H, -C**H**HCH$_2$OBn), 1.72 (dd, *J* = 14, 7 Hz, 1 H, -CH**H**CH$_2$OBn), 1.22 (d, *J* = 7 Hz, 3 H, C-10 C$\mathbf{H}_3$), and 1.10 (s, 3 H, C-5 C$\mathbf{H}_3$); ^{13}C nmr (75 MHz) δ: 196.33 (p), 174.54 (p), 152.27 (a), 138.37 (p), 130.62 (a), 128.42 (a, 2 × aromatic **C**), 127.57 (a, 2 × aromatic **C**), 127.32 (a), 123.36 (a), 73.12 (p), 66.64 (p), 59.29 (p), 52.37 (a), 43.07 (a), 39.61 (p), 39.10 (p), 37.66 (a), 26.62 (p), 24.22 (a), and 16.87 (a); hrms M^+: 368.1980 (calcd. for $C_{23}H_{28}O_4$: 368.1987). Anal. calcd. for $C_{23}H_{28}O_4$: C 74.97, H 7.66; found: C 75.03, H 7.81.

Further elution gave adduct **12** (0.13 g, 14% yield) as a colorless oil: ir ($CHCl_3$ cast): 1726 (C=O, ester), 1689 (C=O, enone), 735 and 699 (C-H bending, aromatic) cm^{-1}; ^1H nmr (300 MHz) δ: 7.33 (m, 5 H, aromatic **H**), 6.29 (dd, *J* = 10, 2 Hz, 1 H, -C**H**=CHC=O), 5.85 (d, *J* = 10 Hz, 1 H, -CH=C**H**C=O), 5.56 (ddd, *J* = 10, 4, 2 Hz, 1 H, C-9 **H**), 5.47 (ddd, *J* = 10, 7, 3 Hz, 1 H, C-8 **H**), 4.51 (d, *J* = 14 Hz, 1 H, -OC**H**HPh), 4.49 (d, *J* = 14 Hz, 1 H, -OCH**H**Ph), 3.71 (s, 3 H, -COOC$\mathbf{H}_3$), 3.54–3.66 (m, 2 H, -C$\mathbf{H}_2$OBn), 2.75 (m, 1 H, C-10 **H**), 2.68 (ddd, *J* = 10, 7, 2 Hz, 1 H, C-6 **H**), 2.30 (dddd, *J* = 19, 7, 4, 3 Hz, 1 H, C-7 $\mathbf{H}_a$), 2.02 (dm, *J* = 19 Hz, 1 H, C-7 $\mathbf{H}_b$), 1.93 (ddd, *J* = 14, 8, 6 Hz, 1 H, -C**H**HCH$_2$OBn), 1.64 (ddd, *J* = 14, 8, 6 Hz, 1 H, -CH**H**CH$_2$OBn), 1.26 (d, *J* = 7 Hz, 3 H, C-10 C$\mathbf{H}_3$), and 1.15 (s, 3 H, C-5 C$\mathbf{H}_3$); ^{13}C nmr (75 MHz) δ: 196.23 (p), 174.65 (p), 152.03 (a), 138.16 (p), 130.55 (a), 128.46 (a, 2 × aromatic **C**), 127.71 (a), 127.58 (a, 2 × aromatic **C**), 127.04 (a), 123.37 (a), 73.26 (p), 65.67 (p), 59.22 (p), 52.20 (a), 46.27 (a), 39.81 (p), 38.75 (a), 38.69 (p), 27.04 (p), 24.78 (a), and 16.69 (a); hrms M^+: 368.1984 (calcd. for $C_{23}H_{28}O_4$: 368.1987).

(1*S**,4*R**,5*R**,6*S**,10*S**)-5-(2-Benzyloxyethyl)-1-(1-hydroxymethyl)-4,5,10-trimethylbicyclo[4.4.0]dec-8-en-2-one (13)

A suspension of CuI (1.4 g, 7.3 mmol) in ether (20 mL) in a flame-dried round bottom flask was cooled to 0°C under argon. Methyllithium (10.5 mL, 1.4 M in ether) was added dropwise over a period of 5 min, and the resulting solution was stirred at 0°C for 1 h. Enone ester **11** (900 mg, 2.44 mmol) in ether (5 mL) was then introduced slowly over a period of 25 min. After the resulting yellow mixture was stirred for 1 h, lithium aluminium hydride (0.28 g, 7.3 mmol) was added. The reaction mixture turned into a dark suspension immediately after the addition of lithium aluminium hydride. This dark suspension was stirred for 30 min. Saturated aqueous ammonium chloride (10 mL) was added carefully until gas evolution ceased, followed by the addition of 3 N HCl (18 mL). The mixture was extracted with ether (4 × 20 mL). The combined extracts were washed with water (2 × 10 mL), saturated aqueous sodium bicarbonate, and brine. Drying (magnesium sulfate), filtration, and concentration gave the crude product, which was subjected to chromatography. Elution with ethyl acetate and hexane (20:80) gave alcohol **13** (501 mg, 61% yield) as a colorless oil: ir (CH_2Cl_2 cast): 3448 (br, OH), 1692 (C=O, ketone), 736 and 698 (C-H bending, aromatic) cm^{-1}; ^1H nmr (500 MHz) δ: 7.31 (m, 5 H, aromatic **H**), 5.85 (dt, *J* = 10, 4.5 Hz, 1 H, C-8 **H**), 5.75 (dd, *J* = 10, 5 Hz, 1 H, C-9 **H**), 4.49 (s, 2 H, -OC$\mathbf{H}_2$Ph), 3.58 (d, *J* = 11 Hz, 1 H, -C**H**HOH), 3.55 (t, *J* = 7 Hz, 2 H, -C$\mathbf{H}_2$OBn), 3.45 (d, *J* = 11 Hz, 1 H, -CH**H**OH), 3.26 (br s, 1 H, -O**H**), 2.50 (m, 1 H, C-10 **H**), 2.36 (dd, *J* = 10.5, 10.5 Hz, 1 H, C-3 **H**), 2.00–2.19 (complex, 5 H), 1.60 (m, 2 H), 1.10 (d, *J* = 7 Hz, 3 H, C-10 C$\mathbf{H}_3$), 0.97 (s, 3 H, C-5 C$\mathbf{H}_3$), and 0.89 (d, *J* = 6.5 Hz, 3 H, C-4 C$\mathbf{H}_3$); ^{13}C nmr (125 MHz) δ: 219.94 (p), 138.30 (p), 132.36 (a), 132.20 (a), 128.21 (a, 2 × aromatic **C**), 127.65 (a, 2 × aromatic **C**), 126.60 (a), 73.25 (p), 69.36 (p), 67.01 (p), 55.24 (p), 45.95 (p), 41.63 (a), 37.32 (p), 35.07 (a), 34.84 (p), 33.03 (a), 22.67 (p), 22.53 (a), 17.31 (a), and 15.53 (a); cims $[M+NH_4]^+$: 374. Anal. calcd. for $C_{23}H_{32}O_3$: C 77.49, H 9.05; found: C 77.29, H 9.26.

(1*S**,4*R**,5*R**,6*S**,10*S**)-5-(2-Benzyloxyethyl)-1-(1-mesyloxymethyl)-4,5,10-trimethylbicyclo[4.4.0]dec-8-en-2-one (14)

To a solution of alcohol **13** (110 mg, 0.31 mmol) and triethylamine (0.22 mL, 1.5 mmol) in THF (8 mL) at 0°C under an argon atmosphere, mesyl chloride (0.12 mL, 1.5 mmol) was added slowly. The reaction mixture was stirred at room temperature for 21 h, at which time 1 N HCl (3 mL) was added. The mixture was extracted with ether (3 × 15 mL), and the extracts were combined and washed with saturated aqueous sodium bicarbonate, water, and brine. The solution was dried over magnesium sulfate, filtered, and concentrated to afford the crude product, which was purified by flash chromatography on silica gel. Elution with ethyl acetate and hexane (5:95) gave mesylate **14** (131 mg, 98% yield) as a colorless oil: ir (CH_2Cl_2 cast): 1701 (C=O, ketone), 1357 and 1176 (S=O), 737 and 699 (C-H bending, aromatic) cm^{-1}; ^1H nmr (300 MHz) δ: 7.35 (m, 5 H, aromatic **H**), 5.91 (m, 1 H, -C**H**=CH-), 5.67 (m, 1 H, -CH=C**H**-), 4.54 (d, *J* = 12 Hz, 1 H, -OC**H**HPh), 4.51 (d, *J* = 9.5 Hz, 1 H, -C**H**HOMs), 4.44 (d, *J* = 12 Hz, 1 H, -OCH**H**Ph), 4.04 (d, *J* = 9.5 Hz, 1 H, -CH**H**OMs), 3.57 (m, 2 H, -C$\mathbf{H}_2$OBn), 2.96 (s, 3 H, -OSO$_2$C$\mathbf{H}_3$), 2.43 (dd, *J* = 7.5, 4.5 Hz, 1 H), 2.31 (dd, *J* = 16, 6 Hz, 1 H), 1.96–2.03 (complex, 5 H), 1.50–1.72 (complex, 2 H), 1.03 (d, *J* = 7 Hz, 3 H, C-10 C$\mathbf{H}_3$), 1.00 (s, 3 H, C-5 C$\mathbf{H}_3$), and 0.91 (d, *J* = 6.5 Hz, 3 H, C-4 C$\mathbf{H}_3$); ^{13}C nmr (75 MHz) δ: 213.39 (p), 138.45 (p), 130.93 (a), 128.43 (a, 2 × aromatic **C**), 127.80 (a, 2 × aromatic

C), 127.61 (a), 127.40 (a), 74.05 (p), 73.25 (p), 67.04 (p), 54.20 (p), 45.24, (p), 39.60 (a), 37.28 (p), 37.09 (a), 35.60 (a), 35.23 (p), 34.36 (a), 22.88 (p), 22.76 (a), 17.13 (a), and 15.70 (a); hrms M^+: 434.2127 (calcd. for $C_{24}H_{34}O_5S$: 434.2127).

(1*S,3*S**,5*R**,6*R**,7*S**,11*S**)-6-(2-Benzyloxyethyl)-5,6,11-trimethyltricyclo[5.4.0.0^{1,3}]undec-9-en-3-ol (15) and (1*S**,2*S**,6*S**,7*R**,14*R**)-2,7,14-trimethyl-10-oxatricyclo[5.4.3.0^{1,6}]tetradec-3-en-12-one (16)**

To a stirred solution of mesylate **14** (0.11 g, 0.25 mmol) in DMF (10 mL with 0.15% H_2O), were added sodium iodide (0.36 g, 2.5 mmol) and zinc powder (0.33 g, 5.0 mmol). The reaction mixture was immersed in a preheated oil bath at 130°C and maintained at that temperature for 28 h. The mixture was then filtered to remove excess sodium iodide and zinc powder. The filtrate was poured into water (6 mL) and extracted with 15% ethyl acetate in hexane (3 × 15 mL). The combined organic layers were then washed with water and brine, dried over $MgSO_4$, and concentrated under reduced pressure. The residual oil was purified by flash chromatography using ethyl acetate and hexane (6:94) to give tricyclic ketone **16** (19 mg, 30% yield) as a white solid, which was recrystallized from ethyl acetate and *n*-hexane to form a crystalline compound: mp 74.5–76.0°C; ir ($CHCl_3$ cast): 1704 (C=O, ketone) cm^{-1}; ^1H nmr (300 MHz) δ: 5.53 (m, 2 H, -C**H**=C**H**-), 4.21 (d, *J* = 13.5 Hz, 1 H, -C**H**HO-), 4.00 (m, 2 H, -CH_2C$\mathbf{H}_2$O-), 3.61 (d, *J* = 13.5 Hz, 1 H, -CH**H**O-), 2.63 (dd, *J* = 16.5, 8.5 Hz, 1 H, -C**H**HC=O), 2.10–2.36 (complex, 5 H), 1.92 (m, 1 H), 1.57 (dd, *J* = 5.5, 4.5 Hz, 1 H), 1.51 (dd, *J* = 5.5, 4.5 Hz, 1 H), 1.26 (d, *J* = 7.5 Hz, 3 H, C-2 C$\mathbf{H}_3$), 1.05 (s, 3 H, C-7 C$\mathbf{H}_3$), and 0.98 (d, *J* = 6.5 Hz, 3 H, C-14 C$\mathbf{H}_3$); ^{13}C nmr (APT) δ: 211.87 (p), 131.85 (a), 123.00 (a), 69.54 (p), 65.68 (p), 58.11 (p), 49.81 (a), 46.78 (p), 38.79 (p), 38.75 (a), 36.59 (a), 35.52 (p), 27.23 (a), 25.22 (p), 16.72 (a), and 15.92 (a); hrms M^+: 248.1788 (calcd. for $C_{16}H_{24}O_2$: 248.1778). Anal. calcd. for $C_{16}H_{24}O_2$: C 77.38, H 9.74; found: C 77.34, H 9.63.

Further elution gave compound **15** (47 mg, 55% yield) as a colorless oil: ir (CH_2Cl_2 cast): 3436 (br, OH), 735 and 696 (C-H bending, aromatic) cm^{-1}; ^1H nmr (300 MHz) δ: 7.32 (m, 5 H, aromatic **H**), 6.22 (m, 1 H, -C**H**=CH-), 5.96 (m, 1 H, -CH=C**H**-), 4.50 (s, 2 H, -OC$\mathbf{H}_2$Ph), 3.49 (t, *J* = 8 Hz, 2 H, -C$\mathbf{H}_2$OBn), 1.92–2.23 (complex, 6 H), 1.56–1.72 (complex, 3 H), 1.46 (m, 1 H), 1.08 (s, 3 H, C-7 C$\mathbf{H}_3$), 1.06 (d, *J* = 7 Hz, 3 H, C-2 C$\mathbf{H}_3$), 0.83 (d, *J* = 7 Hz, 3 H, C-8 C$\mathbf{H}_3$), 0.58 (dd, *J* = 5, 1.5 Hz, 1 H, cyclopropyl **H**), 0.52 (d, *J* = 5 Hz, 1 H, cyclopropyl **H**); hrms M^+: 340.2393 (calcd. for $C_{23}H_{32}O_2$: 340.2402).

(1*S,4*R**,5*R**,6*S**,10*S**)-5-(2-Benzyloxyethyl)-1,4,5,10-tetramethylbicyclo[4.4.0]dec-8-en-2-one (17)**

To a solution of compound **15** (60 mg, 0.18 mmol) in dichloromethane (5 mL) at room temperature, was added a crystal of *p*-toluenesulfonic acid. After stirring for 40 min, the reaction mixture was diluted with dichloromethane (6 mL) and then washed with saturated aqueous sodium bicarbonate, water, and brine. The organic solution was dried over $MgSO_4$, filtered, and concentrated. Flash chromatography of the residue with 10% ethyl acetate in hexane gave **17** (58 mg, 97% yield) as a colorless oil: ir ($CHCl_3$ cast): 1695 (C=O, ketone), 735 and 698 (C-H bending, aromatic) cm^{-1}; ^1H nmr (300 MHz) δ: 7.31 (m, 5 H, aromatic **H**), 5.85 (m, 1 H, -C**H**=CH-), 5.72 (m, 1 H, -CH=C**H**-), 4.52 (d, *J* = 12 Hz, 1 H, -OC**H**HPh), 4.48 (d, *J* = 12 Hz, 1 H, -OCH**H**Ph), 3.57 (m, 2 H, -C$\mathbf{H}_2$OBn), 2.23 (dd, *J* = 13, 9 Hz, 1 H, -C**H**HC=O), 2.21 (dd, *J* = 8, 4 Hz, 1 H), 2.04–2.18 (complex, 3 H), 1.96 (t, *J* = 7 Hz, 1 H), 1.58–1.71 (complex, 3 H), 1.27 (s, 3 H, C-1 C$\mathbf{H}_3$), 1.00 (d, *J* = 7 Hz, 3 H, C-10 C$\mathbf{H}_3$), 0.98 (s, 3 H, C-5 C$\mathbf{H}_3$), and 0.91 (d, *J* = 6.5 Hz, 3 H, C-4 C$\mathbf{H}_3$); ^{13}C nmr (75 MHz) δ: 217.10 (p), 138.44 (p), 132.67 (a), 129.61 (a, 2 × aromatic **C**), 128.44 (a, 2 × aromatic **C**), 127.62 (a), 126.70 (a), 73.19 (p), 67.13 (p), 51.05 (p), 47.53 (a), 45.07 (p), 39.43 (a), 37.70 (p), 35.87 (a), 35.18 (p), 29.50 (a), 23.70 (p), 23.14 (a), 17.08 (a), and 16.05 (a); hrms M^+: 340.2395 (calcd. for $C_{23}H_{32}O_2$: 340.2402).

(3*R,4*R**)-6-Benzyloxy-3,4-dimethyl-4-((1*S**,5*S**)-5-methyl-6-methylene-3-cyclohexenyl)-1-hexanol (18)**

To a solution of compound **14** (0.15 g, 0.35 mmol) in dry THF (8 mL) at 0°C under an argon atmosphere, was added lithium triethylborohydride (1.38 mL, 1.0 M in THF). After the mixture was stirred at 0°C for 30 min and then at room temperature for 3 h, the reaction was quenched with water (3 mL), and the aqueous phase was extracted with ether (2 × 10 mL). The combined organic layers were washed with brine, dried over magnesium sulfate, filtered, and concentrated under reduced pressure to give an oil, which was purified by flash chromatography using 10% ethyl acetate in hexane as eluant to yield **18** (0.1 g, 82% yield) as a colorless oil: ir (CH_2Cl_2 cast): 3342 (OH, broad) cm^{-1}; ^1H nmr (300 MHz) δ: 7.35 (m, 5 H, aromatic **H**), 5.62 (m, 1 H, -C**H**=CH-), 5.41 (m, 1 H, -CH=C**H**-), 4.97 (br s, 1 H, **H**HC=C), 4.88 (d, *J* = 1.5 Hz, 1 H, H**H**C=C), 4.42 (s, 2H, -OC$\mathbf{H}_2$Ph), 3.65 (m, 1H), 3.45–3.56 (complex, 3 H), 2.88 (m, 1 H), 2.45 (dd, *J* = 10, 5 Hz, 1H), 2.05–2.31 (complex, 2 H), 1.95 (m, 1 H), 1.85 (dd, *J* = 10, 7 Hz, 1 H), 1.62–1.75 (complex, 2 H), 1.35 (br s, 1 H, -O**H**), 1.18 (m, 1 H), 1.09 (d, J = 7 Hz, 3 H, -C$\mathbf{H}_3$), 1.0 (s, 3 H, -C$\mathbf{H}_3$), 0.89 (d, *J* = 7 Hz, 3 H, -C$\mathbf{H}_3$); hrms [M − C_5H_8]$^+$: 274.1934 (calcd. for $C_{18}H_{26}O_2$: 274.1933); cims [M+H]$^+$: 343, [M+NH_4]$^+$: 360.

(1*S,4*R**,5*R**,6*S**,10*S**)-5-(2-Benzyloxyethyl)-1-(1-phenoxythiocarbonyloxymethyl)-4,5,10-trimethylbicyclo[4.4.0]dec-8-en-2-one (19)**

Keto alcohol **13** (0.12 g, 0.34 mmol) was dissolved in dichloromethane (10 mL) and cooled to 0°C under an atmosphere of argon. 4-Dimethylaminopyridine (5 mg), pyridine (0.05 mL, 0.68 mmol), and phenyl chlorothionoformate (0.08 mL, 0.64 mmol) were introduced sequentially to the stirred solution. After stirring at room temperature for 20 h, the reaction mixture was poured into ice-cold 1 M hydrochloric acid and extracted with ether (3 × 10 mL). The extracts were washed with ice-cold 1 M hydrochloric acid, water, dried ($MgSO_4$), filtered, and concentrated. The residue was subjected to flash chromatography on silica gel, eluting with 10% ethyl acetate in hexane to give **19** (0.1 g, 70% yield) as a light yellow oil: ir (CH_2Cl_2 cast): 1703 (C=O, ketone), 1590 (C=C stretching, aromatic),1290 and 1200 (C=S) cm^{-1}; ^1H nmr (300 MHz) δ: 7.16–7.39 (complex, 8 H, aromatic **H**), 7.00 (m, 2 H, aromatic **H**), 5.82 (m, 1 H, -C**H**=CH-), 5.61 (m, 1 H, -CH=C**H**-), 4.67 (d, *J* = 10.5 Hz, 1 H, -C**H**HOCSOPh), 4.43 (s, 2 H, -OC$\mathbf{H}_2$Ph), 4.41 (d, *J* = 10.5 Hz, 1 H, -CH**H**OCSOPh), 3.53 (m, 2 H, -C$\mathbf{H}_2$OBn), 2.34 (dd, *J* = 8, 3.5 Hz, 1 H), 2.24 (dd, *J* = 17, 6 Hz, 1 H, -C**H**HCO-), 1.93–2.19 (complex, 6 H), 1.61 (ddd, *J* =

8, 8, 2 Hz, 1 H), 1.00 (d, J = 7 Hz, 3 H, C-10 C**H**$_3$), 0.98 (s, 3 H, C-5 C**H**$_3$), and 0.86 (d, J = 7 Hz, 3 H, C-4 C**H**$_3$); cims [M+NH$_4$]$^+$: 494.

(1*S,2*S**,6*R**,7*R**,8*R**)-7-(2-Benzyloxyethyl)-1,2,7.8-tetramethylbicyclo[4.4.0]dec-3-ene (20) and (1*R**,6*S**,7*R**,8*R**)-7-(2-Benzyloxyethyl)-1,2,7,8-tetramethylbicyclo[4.4.0]dec-2-ene (21)**

To a solution of ketone **17** (28 mg, 0.08 mmol) in diethylene glycol (7 mL) at room temperature, were added potassium hydroxide (32 mg, 0.56 mmol) and anhydrous hydrazine (0.2 mL, 4.0 mmol). The mixture was heated at 130–140°C for 12 h under argon. The temperature was then raised to 220°C to remove water and excess hydrazine using a Dean–Stark apparatus, and maintained at 210-220°C for 10 h. The reaction mixture was then cooled, diluted with water (6 mL), acidified with aqueous NH_4Cl, and extracted with ethyl acetate (3 × 10 mL). The combined extracts were dried ($MgSO_4$), filtered, and concentrated to give a yellow oil, which was chromatographed using 5% ethyl acetate in hexane to furnish an inseparable 3:1 mixture of compounds **20** and **21** (16 mg, 60% yield) as a colorless oil: ir (CH_2Cl_2 cast): 736 and 697 (C-H bending, aromatic) cm^{-1}; ^{1}H nmr (300 MHz) δ: **20**: 5.57 (m, 1 H, -C**H**=CH-), 5.29 (m, 1 H, -CH=C**H**-), 4.57 (d, J = 12 Hz, 1 H, -OC**H**HPh), 4.50 (d, J = 12 Hz, 1 H, -OCH**H**Ph), 3.54 (m, 2 H, -C**H**$_2$OBn), 1.14 (s, 3 H, -C**H**$_3$), 0.93 (s, 3 H, -C**H**$_3$), 0.87 (d, J = 7 Hz, 3 H, -C**H**$_3$), and 0.85 (d, J = 7 Hz, 3 H, -C**H**$_3$); **21**: 5.32 (m, 1 H, -C=C**H**-), 4.52 (s, 2 H, -OC**H**$_2$Ph), 3.70 (m, 2 H, -C**H**$_2$OBn), 1.61 (s, 3 H, -CH=CC**H**$_3$), 1.17 (s, 3 H, -C**H**$_3$), 0.93 (d, J = 7 Hz, 3 H, C-8 C**H**$_3$), and 0.81 (s, 3 H, -C**H**$_3$); hrms [M-C$_5$H$_8$]$^+$: 258.1984 (calcd. for $C_{18}H_{26}O$: 258.1983); cims [M + NH$_4$]$^+$: 344.

(1*S,6*R**,9*R**,10*R**)-10-(2-Benzyloxyethyl)-5,6,9,10-tetramethylbicyclo[4.4.0]dec-4-en-3-one (22)**

A solution of the 3:1 mixture of **20** and **21** (25 mg, 0.07 mmol), acetic anhydride (0.06 mL, 0.5 mmol), pyridine (0.05 mL, 0.5 mmol), a catalytic amount of 4-dimethylaminopyridine, and 5,10,15,20-tetraphenyl-21*H*,23*H*-porphine (2 mg) in dry carbon tetrachloride (40 mL) was saturated with oxygen for 10 min and then irradiated with two 200 W tungsten lamps for 58 h. During this period a gentle stream of oxygen was bubbled through the reaction mixture. After 58 h, irradiation was stopped and oxygen was bubbled through the solution for another 10 h. The reaction mixture was washed sequentially with saturated aqueous sodium bicarbonate (2 × 5 mL), 1 M hydrochloric acid (2 × 5 mL), saturated aqueous copper sulfate (1 × 5 mL), and saturated aqueous sodium chloride. After being dried over $MgSO_4$, the organic solution was filtered and concentrated. The resulting residue was subjected to flash chromatography using 5–15% ethyl acetate in hexane as the eluant to give **22** (11 mg, 56% yield based on **20**) as a colorless oil as well as an unidentified uv-active product (6.2 mg). For compound **22**: ir (CH_2Cl_2 cast): 1661 (C=O, enone), 736 and 697 (C-H bending, aromatic) cm^{-1}; ^{1}H nmr (300 MHz) δ: 7.32 (m, 5 H, aromatic, **H**), 5.88 (br s, 1 H, -C=C**H**C=O), 4.48 (s, 2 H, -OC**H**$_2$Ph), 3.50 (m, 2 H, -C**H**$_2$OBn), 2.73 (dd, J = 18, 6 Hz, 1 H, -C**H**HC=O), 2.60 (dd, J = 18, 3 Hz, 1 H, -C**H**HC=O), 1.95 (d, J = 1.5 Hz, 3 H, C-5 C**H**$_3$), 1.91 (dd, J = 6, 3 Hz, 1 H, C-1 **H**), 1.78–1.86 (complex, 2 H), 1.40–1.65 (complex, 5 H), 1.25 (s, 3 H, C-6 C**H**$_3$), 0.97 (d, J = 7 Hz, 3 H, C-9 C**H**$_3$), and 0.86 (s, 3 H, C-10 C**H**$_3$); hrms M$^+$: 340.2400 (calcd. for $C_{23}H_{32}O_2$: 340.2402).

(1*S,6*R**,9*R**,10*R**)-10-(2-Hydroxyethyl)-5,6,9,10-tetramethylbicyclo[4.4.0]dec-4-en-3-one (23)**

To a solution of compound **22** (4.0 mg, 0.012 mmol) in dry dichloromethane (6 mL) under an atmosphere of argon, was added anhydrous $FeCl_3$ (7 mg, 0.04 mmol) in one portion. After stirring for 50 min at room temperature, the reaction was quenched by addition of water (1 mL). The aqueous solution was separated and extracted with dichloromethane (2 × 6 mL). The combined organic layers were washed with brine, dried ($MgSO_4$), filtered, and concentrated to give the crude product, which was purified by flash chromatography with ethyl acetate and hexane (50:50) to afford **23** (2.4 mg, 82% yield) as a colorless oil: ir (CH_2Cl_2 cast): 3439 (OH, broad) and 1651 (C=O, enone) cm^{-1}; ^{1}H nmr (300 MHz) δ: 5.89 (br s, 1 H, -C=C**H**C=O), 3.69 (t, J = 7.5 Hz, 2 H, -C**H**$_2$OH), 2.75 (dd, J = 18, 6 Hz, 1 H, -C**H**HC=O), 2.59 (dd, J = 18, 3 Hz, 1 H, -CH**H**C=O), 1.96 (br s, 3 H, C-5 C**H**$_3$), 1.92 (dd, J = 6, 3 Hz, 1 H, C-1 **H**), 1.79–1.88 (complex, 2 H), 1.40–1.68 (complex, 6 H), 1.27 (s, 3 H, C-6 C**H**$_3$), 1.11 (d, J = 7 Hz, 3 H, C-9 C**H**$_3$) and 0.89 (s, 3 H, C-10 C**H**$_3$); hrms M$^+$: 250.1931 (calcd. for $C_{16}H_{26}O_2$: 250.1932), [M − H$_2$O]$^+$: 232.1825 (calcd. for $C_{16}H_{24}O$ 232.1827).

(±)-2-Oxo-5α,8α-13,14,15,16-tetranorclerod-3-en-12-oic acid (2)

Enone **23** (1.6 mg, 0.006 mmol) was dissolved in acetone (4 mL, distilled over $KMnO_4$) and the solution was cooled to 10°C. Freshly prepared Jones reagent (0.02 mL) was added dropwise, and the resulting solution stirred for 30 min at room temperature. Water was added to dissolve all green precipitates and the aqueous layer was extracted with dichloromethane (3 × 5 mL). The combined extracts were washed with brine, dried over $MgSO_4$, filtered, and concentrated to give the crude product, which was subjected to flash chromatography using ethyl acetate and hexane (50:50) as the eluant to afford pure acid (1.1 mg, 63% yield) as a white powder: mp 226–227°C; ir (CH_2Cl_2 cast): 3300–2450 (OH, carboxylic acid), 1725 (C=O, carboxylic acid), and 1628 (C=O, enone) cm^{-1}; ^{1}H nmr (300 MHz, $CDCl_3$) δ: 8.7 (br s, 1 H, -COO**H**), 5.90 (br s, 1 H, -C=C**H**C=O), 2.79 (dd, J = 18, 6.5 Hz, 1 H, -C**H**HC=O), 2.56 (d, J = 15 Hz, 1 H, -C**H**HCOOH), 2.48 (dd, J = 18, 2.5 Hz, 1 H, -CH**H**C=O), 2.21 (d, J = 15 Hz, 1 H, -CH**H**COOH), 2.07 (dd, J = 6.5, 2.5 Hz, 1 H, C-10 **H**), 2.00 (m, 1 H), 1.97 (d, J = 1 Hz, 3 H, C-4 C**H**$_3$), 1.85 (dm, J = 14 Hz, 1 H), 1.45–1.70 (m, 2 H), 1.30–1.36 (m, 1 H), 1.28 (s, 3 H, C-5 C**H**$_3$), 1.06 (s, 3 H, C-9 C**H**$_3$), and 1.05 (d, J = 7.5 Hz, 3 H, C-8 C**H**$_3$); ^{1}H nmr (200 MHz, $CDCl_3$–C_5D_5N) δ: 5.90 (br s, 1 H,-C=C**H**C=O), 3.06 (br s, 1 H, -COO$^-$C$_5$D$_5$N$^+$H), 2.79 (dd, J = 18, 6.5 Hz, 1 H, -C**H**HC=O), 2.59 (d, J = 15 Hz, 1 H, -C**H**HCOOH), 2.54 (dd, J = 18, 2.5 Hz, 1 H, -CH**H**C=O), 2.24 (d, J = 15 Hz, 1 H, -CH**H**COOH), 2.13 (dd, J = 6.5, 2.5 Hz, 1 H, C-10 **H**), 2.11 (m, 1 H), 1.97 (d, J = 1 Hz, 3 H, C-4 C**H**$_3$), 1.85 (dm, J = 14 Hz, 1 H), 1.50–1.75 (m, 3 H), 1.29 (s, 3 H, C-5 C**H**$_3$), 1.13 (s, 3 H, C-9 C**H**$_3$), and 1.09 (d, J = 7.5 Hz, 3 H, C-8 C**H**$_3$); ^{13}C nmr (125 MHz, $CDCl_3$) δ: 198.5, 176.1, 168.6, 128.6, 45.9, 42.2, 39.8, 39.6, 35.7, 35.5, 31.0, 29.6, 26.6, 23.5, 20.9, and 15.0; hrms M$^+$: 264.1721 (calcd. for

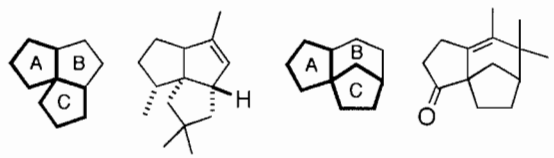
Assembly of tricyclic compounds that include the spiro[4.4]nonane subunit

Pei-Ying Liu, Yong-Jin Wu, and D. Jean Burnell

Abstract: Spiroannulation of ketals derived from unsaturated cyclohexenone derivatives by the Lewis acid-catalyzed reaction of 1,2-bis((trimethylsilyl)oxy)cyclobutene **5** led to spiro[4.5]decene-diones **9** and **30**. These were transformed into spiro[4.4]nonene derivatives **25** and **35/36** via similar sequences involving ozonolysis and aldol ring reclosure. Reduction of an annular double bond allowed facile closure of a third ring, also by an aldol reaction. This work led to a single oxygenated angular triquinane **28** from **9**, and to the tricyclo[6.2.1.$0^{1,5}$]undecane derivative **41** from **30**. An oxatricyclo[5.3.1.$0^{1,5}$]undecane derivative **19** was also obtained from **9**.

Key words: spiroannulation, geminal acylation, sesquiterpene synthesis.



Résumé : La spiroannelation de cétals a été réalisée à partir de dérivés insaturés de la cyclohexénone en effectuant une réaction catalysée par les acides de Lewis avec du 1,2-bis((triméthylsilyl)oxy)cyclobutène (**5**); elle conduit aux spiro[4.5]décènediones **9** et **30**. Ces cétones ont été transformées en dérivés spiro[4.4]nonène **25** et **35/36** par le biais d'une séquence de réactions impliquant une ozonolyse et une refermeture aldolique de cycle. La réduction d'une des doubles liaisons annulaires permet de former facilement un troisième cycle par une autre réaction aldolique. Ce travail a permis de transformer le produit **9** en un seul triquinane angulaire oxygéné, **28**, alors que le produit **30** conduit au dérivé tricyclo[6.2.1.$0^{1,5}$]undécane **41**. On a aussi obtenu un dérivé oxatricyclo[5.3.1.$0^{1,5}$]undécane, **19**, à partir du produit **9**.

Mots clés : spiroannelation, acylation géminée, synthèse de sesquiterpène.

[Traduit par la rédaction]

Introduction

In a large number of tricyclic natural products, two cyclopentane rings (rings A and C) are joined in a spirocyclic manner, with the third ring (ring B) being a two-carbon bridge joining rings A and C. The angular triquinane system **1** is the result of bridging between carbons on rings A and C that are α to the spirocyclic center, and **1** is found in sesquiterpenes such as pentalenene (**2**), silphinene, silphiperfolene, isocomene, β-isocomene, and subergorgic acid. On the other hand, bridging between carbons that are α and β to the spirocyclic center gives the tricyclo[6.2.1.$0^{1,5}$]undecane system **3**, which is the ring system of sesquiterpenes such as isokhusimone (**4**), zizanoic acid, and prezizanol. Natural products with ring systems **1** and **3** have been the targets of a large number of synthetic studies (1), but very few of these have employed spiroannulation to establish rings A and C.[2]

1 **2** **3** **4**

The Lewis acid-catalyzed geminal acylation of acetals with 1,2-bis((trimethylsilyl)oxy)cyclobutene (**5**) (2), shown in its simplest form in Scheme 1, can be a method of considerable utility for the synthesis of spirocyclic compounds. Kuwajima's original procedure involved the isolation of the cyclobutanone **6**, followed by a separate rearrangement step with trifluoroacetic acid to the cyclopentanedione **7** (3). We improved the process such that the cyclopentanedione derivative can be obtained from the acetal in a single operation in higher overall yield (4–6). More recently, we showed that geminal acylation can also be carried out directly on a ketone (7). The geminal acylation on acetals has been exploited successfully in a number of synthetic applications (8, 9) but, to our knowledge, only our own syntheses of pentalenene (**2**) (10) and isokhusimone (**4**) (6) have targeted molecules with ring systems **1** and **3**.

Retention of an oxygen function in ring A would be a significant improvement in our spiroannualtion approach to **1** because this oxygen would be well positioned for elaboration or extension of the tricyclic system. This characteristic would not be available by a simple modification of the previously reported synthesis of pentalenene (10) because functionality in ring A is lost fairly early in that reaction sequence. Also, an extension of this strategy for the assembly of the ring system **3**

has been examined. Progress in both of these directions is described in this paper.

Results and discussion

Synthesis of the angular triquinane skeleton

During the development of the geminal acylation methodology it was shown that a substituent α to the acetal or ketone markedly reduces the yield of the reaction (4, 7). Therefore, the present strategy involved spiroannulation with an unencumbered cyclohexenone derivative and subsequent ring cleavage followed by recyclization to the required spiro[4.4]nonanedione system. Isophorone was the starting compound for the approach to **1** because its *gem*-dimethyl groups could serve as the *gem*-dimethyl groups of a number of natural products including the more highly oxygenated congeners of **2**. The strategy necessitated isomerization of the double bond of isophorone. This was accomplished concomitantly with its acetalization to **8**, and **8** underwent geminal acylation with **5** under catalysis by $BF_3 \cdot Et_2O$ to provide **9**, as we described previously (4, 10).

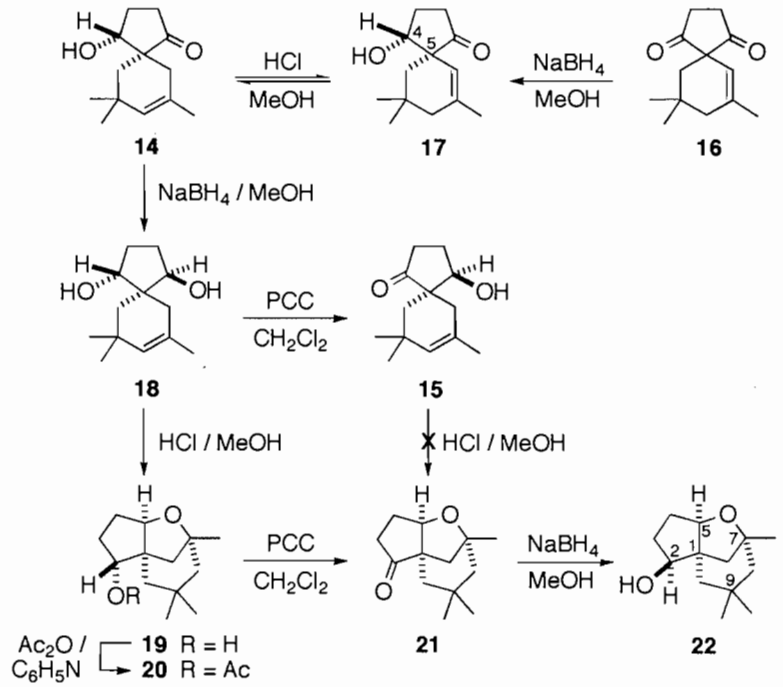
Ozonolysis of **9** gave an unstable tetracarbonyl compound **10**, but this was recyclized immediately under acidic conditions to the spiro[4.4]nonene derivative **11** in 52% yield (Scheme 2). It was not surprising that a second aldol to close ring B was not obtained, because the annular double bond would have imparted considerable strain. However, it was disappointing that the hydrogenated compound **12** was destroyed much more rapidly than it would cyclize to the tricyclic enone **13** under either acidic or basic conditions.

This failure could be attributed to the sensitivity of the 1,3-cyclopentanedione moiety of **12**. In the pentalenene synthesis (10) this problem was avoided by the conversion of one of the ketones to a C=C double bond. Therefore, for the present application, one of the ketones in **9** was reduced to the secondary alcohol and protected (see below). The reduction of **9** with sodium borohydride, followed by work-up with 10% aqueous HCl, gave a 1:1 mixture of isomeric mono-alcohols. Although production of the diastereomeric compounds **14** and **15** might have been expected, significant differences in the mass spectra of the two products suggested that the difference between them was not one of relative stereochemistry. Sodium borohydride reduction of **9** with neutral work-up gave only one of the mono-alcohol products, which later proved to be **14**. However, attempts to establish the relative stereochemistry of this mono-alcohol from nuclear Overhauser effect (NOE) measurements were inconclusive. Reduction of the diketone **16**, which is a double-bond isomer of **9** and which was the result of geminal acylation directly on isophorone (7), with neutral work-up provided exclusively the second mono-alcohol. NOE measurements unequivocally established its relative stereochemistry at C-4 and C-5 as that of **17** (Scheme 3). The relative stereochemistry of **14** must have been the same because treatment of mono-alcohol **14** with HCl in methanol once again gave the same 1:1 mixture of **14** and **17**. The genuine epimeric mono-alcohol **15** could be produced by reduction of **14** to the *trans*-diol **18**, followed by partial reoxidation with PCC to a mixutre of **14** and **15**. It was interesting that **18** very cleanly gave the tricyclic ether **19** in acidic solutions. Only one of the alcohols can cyclize to give *cis*-fused five-membered rings so the relative stereochemistry for **19** must be as shown. (The NOE data for **19** were not helpful in conclusively corroborating this relative stereochemistry, nor were the NOE data for the corresponding acetate **20**.) On the other hand, the mono-alcohol **15** would not cyclize at all to **21** in acid. Ketone **21** was available for comparison by PCC oxidation of **19**, and reduction of **21** with sodium borohydride yielded **22**, the carbinol epimer of **19**.

There was a very high degree of facial selectivity in the reduction of **9** to **14**. We have synthesized a number of diketones related to **9**, and the results of reactions with sodium borohydride and with methyllithium point to a stereoelectronic phenomenon as the factor governing the facial selectivity in these reactions (9).

Protection of the alcohol function **14** as the *tert*-butyldimethylsilyl ether **23** was straightforward. As before, ozonolysis gave a somewhat unstable product **24** that was cyclized without delay (Scheme 4). In this instance an acidic medium gave a very poor yield of enone, but, in contrast with **10**, methoxide did effect the cyclization to **25**. Also, a small amount of the deprotected, but cyclized, product **26** was isolated. Catalytic hydrogenation of the double bond of **25** afforded **27** as a homogeneous compound, but the relative stereochemistry at C-6 was not determined. Nevertheless, it was very gratifying that base-induced cyclization of ring B proceeded to give the triquinane **28** in 83% yield.

In the synthesis of pentalenene there was only modest control of the relative stereochemistry of the methyl group at C-9 (10), but the short route to **28** described above exploited the extremely high selectivity in the $NaBH_4$ reduction step (**9** → **14**) to ultimately provide only one epimer at C-9.



Synthesis of the tricyclo[6.2.1.$0^{1,5}$]undecane system

Treatment of the mono-acetal of 1,4-cyclohexanedione **26** with methyllithium gave a tertiary alcohol, and spiroannulation with **5** catalyzed by $BF_3 \cdot Et_2O$ proceeded with concomitant dehydration of the alcohol to give the desired diketone **30** in 71% yield from **29** (Scheme 5). Addition of excess methyl-

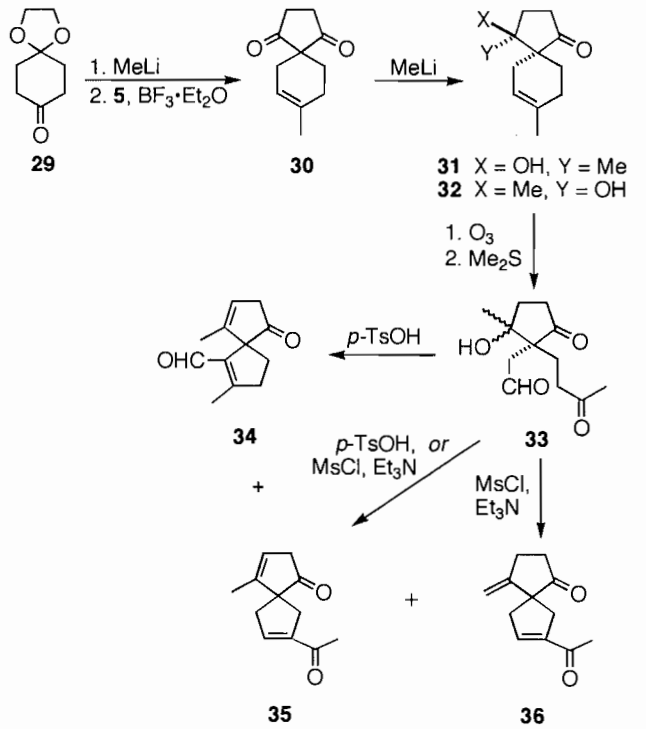
Scheme 3.

Scheme 4.



lithium to **30** gave only two mono-alcohols in a 4:1 ratio. Some of the major one was obtained by painstaking chromatography, and NOE measurements established its relative stereochemistry as that of **31**. However, separation of **31** and **32** was unnecessary. Ozonolysis of the mixture gave unstable **33**, which was introduced immediately into a solution of *p*-toluenesulfonic acid in benzene. The major product was the keto-aldehyde **34** rather than the desired diketone **35**, which was a minor component of the product mixture. Addition of methoxide to **33** led to rapid decomposition, but treatment with mesyl chloride in triethylamine resulted in aldol cyclization only in the desired direction and elimination of the tertiary alcohol. Nevertheless, this still gave a 1:1 mixture of the endocyclic and exocyclic double-bond isomers **35** and **36**. Catalytic hydrogenation of this mixture gave the saturated diketone **37** as a mixture of four isomers. Chromatography yielded two pairs of (inseparable) compounds in a 7:3 ratio. Each pair could be cyclized independently and in good yield with *tert*-butoxide, but each pair yielded **38** and **39** in the same ratio of 1:1.2, respectively. Hence, the chromatographic process could effectively separate C-7 epimers, but not C-4 epimers. This was unfortunate as C-7 was epimerizable whereas C-4 was not. In the pentalenene synthesis (10), the ratio of cyclized products analogous to **38** and **39** could be reversed (from 1:3.5 to 2:1 with a methyl substituent, and from 1:5 to 4:1 with an ethyl substituent) by ensuring that the conjugated double bond be reduced first. In this instance the change in ratio was very modest. Dissolving metal reduction of the mixture of **35** and **36** followed by catalytic hydrogenation and then cyclization gave **38** and **39** in a ratio of 1.2:1, albeit in a reasonable yield of 63% over the three steps (Scheme 6). Separation of the epimers **38** and **39** was carried out over $AgNO_3$-impregnated silica gel, but NOE measurements did not give unequivocal evidence for their relative

stereochemistry at C-2. This was determined by conversion to known tricyclic ketones. Reduction of the double bond of **38** under dissolving metal conditions or by catalytic hydrogenation gave the same product **40**, which had ^{1}H NMR data similar to those given by Weisner and co-workers (11). This was corroborated by double methylation of **40** to provide **41**, for which NMR spectra were reported by Mori and co-workers (12).

Experimental

General

Melting points (mp) were determined on a Fisher–Johns apparatus and are uncorrected. Infrared (IR) spectra were recorded on a Mattson FT instrument as thin films. Nuclear magnetic resonance (NMR) spectra were obtained on a General Electric GE 300-NB instrument as $CDCl_3$ solutions; ^{1}H shifts were calibrated relative to internal tetramethylsilane; ^{13}C shifts were calibrated relative to the solvent resonance (δ 77.0). Each ^{13}C chemical shift is followed in parentheses by the number of attached protons, as determined by APT and heteronuclear correlation spectra. Nuclear Overhauser effect (NOE) measurements were made by the difference method, as described previously (13). Mass spectral (MS) data were obtained with a V.G. Micromass 7070HS instrument, except in some instances in which data were from a Hewlett–Packard 5970 mass selective detector (GC–MS). MS data have this form: *m/z* (% of base peak). 1,2-Bis((trimethylsilyl)oxy)cyclobutene (**5**) was prepared by the method of Bloomfield and Nelke (2), and the diketone **9** was obtained from **8** following our own procedure (4, 10). Reactions were run under N_2. Solvents and boron trifluoride etherate were distilled. Flash chromatography ("chromatography") used 230–400 mesh silica gel; eluents were either "actone" = acetone in petroleum ether (30–60°C boiling fraction) or "EtOAc" = ethyl acetate in hexanes.

6-Acetyl-8,8-dimethylspiro[4.4]non-6-ene-1,4-dione 11

Ozone was passed through a solution of **9** (200 mg, 0.97 mmol) in CH_2Cl_2 at −78°C until the blue color persisted. Excess O_3 was removed by bubbling O_2 through the solution for 5 min, then N_2 for 10 min. After addition of Me_2S (3.0 mL), the solution was stirred overnight while it was allowed to rise to room temperature. Concentration under vacuum provided crude **10**. MS (from GC–MS): no M^+, 210 (2), 195 (2), 178 (4), 167 (13), 154 (23), 139 (13), 125 (15), 112 (30), 111 (17), 107 (14), 97 (10), 55 (19), 43 (100), 41 (19). A solution of the crude **10** and *p*-TsOH (200 mg) in C_6H_6 was heated at reflux with azeotropic removal of H_2O for 2 h. After cooling, the solution was washed with saturated $NaHCO_3$, and the aqueous layer was re-extracted with ether (×3). The combined organic solutions were washed with saturated $NaHCO_3$ and brine (×2), then dried over $MgSO_4$, and concentrated under vacuum. Chromatography (3% acetone) of the residue provided **11** (113 mg, 52% from **9**) as a colorless oil: IR: 1725, 1665, 1625 cm^{-1}; ^{1}H NMR δ: 6.76 (1H, s), 3.08 (2H, m), 2.73 (2H, m), 2.25 (3H, s), 1.89 (2H, s), 1.32 (6H, s); MS: 220 (13, M^+), 205 (5), 201 (6), 192 (44), 177 (33), 163 (24), 135 (28), 55 (25), 43 (100). Exact Mass calcd. for $C_{13}H_{16}O_3$: 220.1098; found: 220.1087.

6-Acetyl-8,8-dimethylspiro[4.4]nonane-1,4-dione 12

A solution of **11** (55 mg, 0.25 mmol) in dry MeOH (30 mL) was shaken with 5% Pd on carbon (30 mg) under 300 kPa of H_2 for 1 h. After filtration and concentration, **12** (55 mg, 100%) was obtained as a colorless oil: IR: 1715 (br) cm^{-1}; ^{1}H NMR δ: 3.64 (1H, dd, J = 7.0, 13.8 Hz), 3.00–2.60 (4H, m), 2.35 (1H, dd, J = 11.7, 13.8 Hz), 2.09 (3H, s), 2.00 (1H, dd, J = 7.0, 11.7 Hz), 1.72 (1H, d, J = 13.4 Hz), 1.56 (1H, d, J = 13.4 Hz), 1.19 (3H, s), 1.17 (3H, s); ^{13}C NMR δ: 217.9 (0), 216.3 (0), 208.2 (0), 65.4 (1), 62.3 (0), 48.9 (2), 43.5 (2), 40.2 (0), 35.6 (2C, 2), 30.0 (3), 29.6 (3), 27.8 (3); MS: 222 (2, M^+), 179 (100), 165 (5), 161 (4), 137 (38), 43 (52). Exact Mass calcd. for $C_{13}H_{18}O_3$: 222.1256; found: 222.1273.

(4*R**,5*R**)-4-Hydroxy-7,9,9-trimethylspiro[4.5]dec-7-en-1-one 14

To a solution of **9** (300 mg, 1.46 mmol) in MeOH (10 mL) at 0°C was added $NaBH_4$ (14 mg, 0.37 mmol) in small portions.

For personal use only.

The mixture was stirred for a further 30 min before H_2O was added. Much of the MeOH was removed under vacuum before extraction with ether (×3). The combined organic solutions were washed with brine (×2), dried over $MgSO_4$, and concentrated under vacuum. Chromatography of the residue (2% acetone) provided **14** (243 mg, 80%) as a colorless oil, and 28 mg (9%) of **9** was recovered. For **14**: IR: 3460 (br), 1730 cm^{-1}; ^1H NMR δ: 5.23 (1H, br s), 4.23 (1H, m), 2.64–1.51 (9H, m), 1.64 (3H, s), 1.04 (3H, s), 1.02 (3H, s); ^{13}C NMR δ: 222.0 (0), 131.8 (1), 127.3 (0), 74.5 (1), 54.4 (0), 35.0 (2), 34.8 (2), 33.2 (2), 32.0 (3), 31.2 (0), 30.3 (3), 28.0 (2), 27.3 (3); MS: 208 (52, M^+), 193 (13), 175 (87), 149 (78), 133 (86), 131 (32), 121 (42), 119 (55), 107 (50), 105 (38), 91 (62), 81 (32), 79 (34), 77 (37), 55 (47), 53 (33), 43 (74), 41 (100). Exact Mass calcd. for $C_{13}H_{20}O_2$: 208.1462; found: 208.1462. Treatment of **14** with PCC gave only **9**.

(4*R**,5*S**)-4-Hydroxy-7,9,9-trimethylspiro[4.5]dec-6-en-1-one 17

*By equilibration of **14***

To a MeOH solution of **14** (42 mg, 0.20 mmol) was added 10% HCl, and the mixture was stirred at room temperature for 10 min. After addition of H_2O, much of the MeOH was removed under vacuum, and the mixture was extracted with ether (×3). The combined organic solutions were washed with H_2O (×2), saturated $NaHCO_3$ (×2), and brine (×2). The solution was dried over $MgSO_4$, then concentrated under vacuum to give a 1:1 mixture of **14** and **17** (42 mg, 100%).

*By reduction of **16***

To a solution of **16** (15.1 mg, 0.073 mmol) in MeOH at 0°C was added $NaBH_4$ (1.0 mg, 0.026 mmol). The mixture was stirred for a further 30 min before H_2O was added. Much of the MeOH was removed under vacuum before extraction with ether (×3). The combined organic extracts were washed with brine (×2), dried over $MgSO_4$, and concentrated under vacuum. Chromatography of the residue (2% acetone) provided **17** (10.4 mg, 69%) as a colorless oil: IR: 3464 (br), 1731 cm^{-1}; ^1H NMR δ: 4.96 (1H, br s, irradiation gave a 1.4% NOE at 4.22), 4.22 (1H, narrow m, irradiation gave a 4.4% NOE at 4.96), 2.55–2.17 (4H, m), 2.02 (1H, m), 1.88 (1H, br d, J = 17.3 Hz), 1.68 (2H, s), 1.63 (3H, s), 1.02 (3H, s), 0.97 (3H, s), and the signal to which δ 1.88 is coupled must be buried δ 1.68–1.62; ^{13}C NMR δ: 219.1.(0), 137.7 (0), 116.4 (1), 76.5 (1), 58.3 (0), 43.8 (2), 33.7 (2), 32.8 (2), 30.8 (3), 29.4 (0), 27.5 (3), 27.4 (2), 24.5 (3); MS: 208 (28, M^+), 175 (72), 149 (100), 137 (26), 133 (30), 123 (28), 121 (69), 119 (33), 109 (21), 107 (74), 105 (30), 93 (44), 91 (51), 81 (28), 79 (43), 77 (38), 69 (28), 57 (29), 55 (47), 41 (70). Exact Mass calcd. for $C_{13}H_{20}O_2$: 208.1462; found: 208.1462. Treatment of **17** with PCC gave only **16**.

trans-7,9,9-Trimethylspiro[4.5]dec-7-ene-1,4-diol 18

$NaBH_4$ (23 mg, 0.62 mmol) was added in portions to a solution of **14** (64 mg, 0.31 mmol) in MeOH (20 mL) at 0°C. The mixture was stirred for another 30 min at 0°C, then H_2O was added and much of the MeOH was removed under vacuum. The product was extracted into ether (×3), and the combined organic solutions were washed with brine (×2), then dried over $MgSO_4$ and concentrated under vacuum. Chromatography (5% acetone) of the residue provided **18** (65 mg, 100%) as a colorless oil: IR: 3340 (very br) cm^{-1}; ^1H NMR δ: 5.19 (1H, s), 4.10 (1H, t, J = 7.9 Hz), 3.97 (1H, dd, J = 0.9, 5.2 Hz), 2.23–2.10 (3H, m), 1.66 (3H, s), 1.66–1.20 (7H, m), 1.06 (3H, s), 1.03 (3H, s); ^{13}C NMR δ: 131.3 (1), 129.4 (0), 77.4 (1), 76.7 (1), 48.5 (0), 38.6 (2), 32.0 (2C, 0 and 3), 31.1 (2C, 2 and 3), 29.6 (2), 29.0 (2), 24.1 (3); MS: 210 (6, M^+), 195 (26), 192 (21), 177 (36), 159 (70), 149 (21), 148 (20), 136 (29), 135 (32), 133 (100), 123 (35), 121 (25), 119 (33), 109 (20), 107 (38), 105 (39), 93 (27), 91 (38), 81 (29), 55 (32), 43 (64), 41 (70). Exact Mass calcd. for $C_{12}H_{19}O_2$ ($M^+ - CH_3$): 195.1384; found: 195.1379.

(4*R**,5*S**)-4-Hydroxy-7,9,9-trimethylspiro[4.5]dec-7-en-1-one 15

PCC (11 mg, 0.05 mmol) was added to a solution of **18** (11 mg, 0.05 mmol) in CH_2Cl_2 at room temperature, and the solution was stirred for a further 3 h. Filtration through a Florisil pad removed a black precipitate, and ether was passed through the pad. The combined organic solutions were concentrated under vacuum, and chromatography (3% acetone) of the residue provided a 1:1 mixture of **14** and **15** (7.2 mg, 67%). For **15** (from the mixture): ^1H NMR δ: 5.24 (1H, br s), 4.32 (1H, t, J = 5.8 Hz), 2.57–1.45 (8H, m), 1.06 (3H, s), 0.98 (3H, s); MS (from GC–MS): 208 (18, M^+), 175 (78), 149 (87), 133 (100), 131 (40), 121 (62), 119 (63), 107 (60), 105 (51), 93 (31), 91 (71), 85 (23), 81 (37), 79 (42), 77 (46), 69 (37), 67 (26), 65 (32), 57 (31), 55 (61), 53 (33), 44 (36), 43 (82), 41 (97). Further oxidation of this mixture gave **9** cleanly.

(1*R**,2*S**,5*S**,7*S**)-7,9,9-Trimethyl-6-oxatricyclo[5.3.1.0^{1,5}]undecan-2-ol 19

A solution of **18** (56 mg, 0.27 mmol) in MeOH was adjusted to pH 2 by addition of 10% HCl, and the mixture was stirred at room temperature for 30 min. Much of the MeOH was removed under vacuum, and the product was extracted with ether (×3). The combined organic solutions were washed with H_2O (×2), saturated $NaHCO_3$ (×2), and brine (×2), then dried over $MgSO_4$ and concentrated under vacuum. Chromatography (20% acetone) of the residue provided **19** (53 mg, 100%) as a colorless solid: mp 82–83°C; IR: 3405 (br), 1463 cm^{-1}; ^1H NMR δ: 4.52 (1H, dd, J = 4.4, 8.6 Hz), 4.03 (1H, dd, J = 1.4, 5.0 Hz), 2.34 (1H, br m), 2.16 (1H, br m), 1.89 (1H, br dd, J = 1.8, 13.4 Hz), 1.76–1.24 (8H, m), 1.28 (3H, s), 1.21 (3H, s), 1.00 (3H, s); ^{13}C NMR δ: 84.4 (1), 83.1 (0), 77.0 (1), 57.6 (0), 51.0 (2), 46.3 (2), 42.5 (2), 36.6 (3), 32.5 (2C, 2 and 3), 31.5 (2), 30.4 (0), 26.8 (3); MS: 210 (40, M^+), 195 (10), 165 (11), 154 (16), 153 (24), 109 (100), 95 (32), 57 (29), 43 (84), 41 (43). Exact Mass calcd. for $C_{13}H_{22}O_2$: 210.1619; found: 210.1602.

(1*R**,2*S**,5*S**,7*S**)-2-Acetyloxy-7,9,9-trimethyl-6-oxatricyclo[5.3.1.0^{1,5}]undecane 20

Acetic anhydride (0.5 mL) was added to a solution of **19** (7.8 mg, 0.037 mmol) in pyridine (0.5 mL), and the solution was stirred at room temperature for 30 min. After addition of H_2O, the product was extracted with ether (×3). The combined organic solutions were washed with water (×2), 5% HCl (×3), and brine (×2), then dried over $MgSO_4$ and concentrated under vacuum. Chromatography (5% acetone) of the residue provided **20** (8.3 mg, 89%) as a colorless oil: IR: 1746 cm^{-1}; ^1H

NMR δ: 5.08 (1H, dd, J = 2.1, 5.5 Hz), 4.50 (1H, dd, J = 4.9, 8.4 Hz), 2.35 (1H, br m), 2.10 (1H, br m), 2.06 (3H, s), 1.75–1.53 (4H, m), 1.45 (1H, d, J = 11.5 Hz), 1.41 (1H, d, J = 8.6 Hz), 1.35 (1H, d, J = 8.6 Hz), 1.29 (3H, s), 1.27 (1H, d, J = 11.5 Hz), 1.20 (3H, s), 0.96 (3H, s); MS: 252 (10, M^+), 237 (3), 192 (34), 165 (19), 136 (27), 135 (54), 109 (24), 57 (49), 56 (27), 43 (100), 42 (21), 41 (64).

(1*R,5*S**,7*S**)-7,9,9-Trimethyl-6-oxatricyclo[5.3.1.0^{1,5}]undecan-2-one 21**

PCC (39 mg, 0.18 mmol) was added to a solution of **19** (25 mg, 0.12 mmol) in CH_2Cl_2, and the solution was stirred at room temperature for 14 h. Filtration through a Florisil pad removed a black precipitate, and ether was passed through the pad. The combined organic solutions were concentrated under vacuum to provide **21** (25 mg, 100%) as a colorless solid: mp 25°C; IR: 1740 cm^{-1}; ^{1}H NMR δ: 4.60 (1H, t, J = 7.6 Hz), 2.64 (1H, br m), 2.37–2.17 (2H, m), 1.96 (1H, dt, J = 2.4, 11.2 Hz), 1.87 (1H, d, J = 14.0 Hz), 1.76 (1H, br m), 1.64 (1H, br d, J = 13.9 Hz), 1.49 (1H, br d, J = 14.0 Hz), 1.37 (1H, d, J = 11.2 Hz), 1.36 (3H, s), 1.32 (1H, d, J = 13.9 Hz), 1.20 (3H, s), 1.01 (3H, s); ^{13}C NMR δ: 216.3 (0), 85.5 (0), 83.8 (1), 58.5 (0), 50.7 (2), 44.0 (2), 41.9 (2), 37.3 (2), 35.9 (3), 32.2 (3), 30.2 (0), 28.5 (2), 26.3 (3); MS: 208 (13, M^+), 180 (14), 165 (13), 152 (38), 96 (100), 95 (17), 57 (17), 43 (39), 41 (23). Exact Mass calcd. for $C_{13}H_{20}O_2$: 208.1462; found: 208.1463.

(1*R,2*R**,5*S**,7*S**)-7,9,9-Trimethyl-6-oxatricyclo-[5.3.1.0^{1,5}]undecan-2-ol 22**

$NaBH_4$ (15 mg, 0.40 mmol) was added in small portions to a solution of **21** (81 mg, 0.39 mmol) in MeOH at 0°C. The mixture was stirred for 30 min before water was added and much of the MeOH was removed under vacuum. The product was extracted with ether (×3), and the combined organic solutions were washed with water, then brine (×2), dried over $MgSO_4$, and concentrated under vacuum. Chromatography (5% acetone) of the residue provided **22** (78 mg, 96%) as a colorless oil: IR: 3420 cm^{-1}; ^{1}H NMR δ: 4.27 (1H, dd, J = 4.8, 7.9 Hz), 3.85 (1H, t, J = 7.9 Hz), 2.13 (1H, br, O*H*), 2.00–1.78 (4H, m), 1.60 (1H, partially overlapped d, J = 14.4 Hz), 1.44 (1H, br dd, J = 1.9, 13.4 Hz), 1.323 (3H, s), 1.320 (1H, d, J = 14.4 Hz), 1.27 (1H, d, J = 11.1 Hz), 1.19 (3H, s), 0.98 (3H, s); ^{13}C NMR δ: 84.4 (0), 83.8 (1), 77.0 (1), 56.7 (0), 51.1 (2), 46.7 (2), 41.7 (2), 36.3 (3), 32.6 (3), 30.8 (2), 30.5 (0), 29.2 (2), 26.9 (3); MS: 210 (33, M^+), 195 (8), 165 (10), 154 (15), 153 (24), 109 (100), 95 (28), 57 (26), 43 (53), 41 (27). Exact Mass calcd. for $C_{13}H_{22}O_2$: 210.1619; found: 210.1619.

(4*R,5*R**)-4-((*tert*-Butyldimethylsilyl)oxy)-7,9,9-trimethylspiro[4.5]dec-7-en-1-one 23**

A solution of **14** (161 mg, 0.77 mmol), *tert*-butylchlorodimethylsilane (232 mg, 1.54 mmol), imidazole (157 mg, 2.31 mmol), and 4-dimethylaminopyridine (10 mg) in dry DMF (7.0 mL) was heated at 80°C for 15 h. Ether and water were added to the cooled solution. The aqueous layer was re-extracted with ether (×3), and the combined organic solutions were washed with water (×2) and brine (×2), then dried over $MgSO_4$, and concentrated under vacuum. Chromatography (5% acetone) of the residue provided **23** (113 mg, 46%) as a colorless oil, and 76 mg (47%) of **14** was recovered. For **23**: IR: 1740 cm^{-1}; ^{1}H NMR δ: 5.18 (1H, br s, $W_{1/2}$ = 5.4 Hz), 3.99 (1H, br t, J = 5.6 Hz), 2.42 (1H, br m), 2.22–1.93 (3H, m), 1.82–1.70 (3H, m), 1.67 (3H, br s), 1.56 (1H, d, J = 14.3 Hz), 0.96 (3H, s), 0.91 (3H, s), 0.88 (9H, s), 0.09 (3H, s), 0.05 (3H, s); ^{13}C NMR δ: 220.1 (0), 131.7 (1), 128.2 (0), 76.6 (1), 54.2 (0), 35.1 (2), 33.7 (2), 33.5 (2), 32.2 (3), 31.7 (0), 30.0 (3), 27.7 (2), 25.9 (3C, 3), 23.7 (3), 18.1 (0), −3.8 (3), −4.6 (3); MS: 322 (43, M^+), 265 (33), 179 (17), 175 (18), 173 (45), 164 (28), 149 (31), 147 (45), 133 (27), 131 (26), 129 (45), 119 (22), 105 (22), 101 (23), 91 (22), 75 (100), 73 (90), 59 (31), 57 (26), 41 (45). Exact Mass calcd. for $C_{19}H_{34}O_2Si$: 322.2326; found: 322.2293.

(4*R,5*S**)-6-Acetyl-4-((*tert*-butyldimethylsilyl)oxy)-8,8-dimethylspiro[4.4]non-6-en-1-one 25 and (4*R**,5*S**)-6-acetyl-4-hydroxy-8,8-dimethylspiro[4.4]non-6-en-1-one 26**

Ozone was passed through a solution of **23** (113 mg, 0.35 mmol) in MeOH (15 mL) at −78°C until the blue color persisted. Excess O_3 was removed by bubbling O_2 through the solution for 5 min, then N_2 for 10 min. After addition of Me_2S (2.0 mL), the solution was stirred overnight while it was allowed to rise to room temperature. Concentration under vacuum provided crude **24**: MS (from GC–MS): no M^+, 297 (15), 279 (14), 239 (12), 225 (13), 213 (13), 211 (15), 205 (18), 197 (16), 195 (18), 169 (34), 163 (27), 151 (18), 145 (12), 139 (17), 75 (100), 73 (78), 43 (92), 41 (32). To dry MeOH (10 mL) at 0°C was added sodium metal (24.2 mg, 1.05 mmol), followed a few min later by a solution of the crude **24** in MeOH. This solution was stirred at 0°C for 8 min. Water was added and much of the MeOH was removed under vacuum before extraction with ether (×3). The combined organic extracts were washed with brine (×2), dried over $MgSO_4$, and concentrated under vacuum. Chromatography (2% acetone) provided **25** (25 mg, 21%) as a colorless oil and 2.0 mg (3%) of **26**.

For 25: IR: 1745, 1670, 1625 cm^{-1}; ^{1}H NMR δ: 6.69 (1H, s), 4.69 (1H, dd, J = 6.4, 10.6 Hz), 2.52–2.32 (3H, m), 2.28 (3H, s), 2.16 (1H, m), 1.58 (1H, m), 1.44 (1H, d, J = 13.2 Hz), 1.21 (6H, s), 0.88 (9H, s), 0.02 (3H, s), −0.05 (3H, s); ^{13}C NMR δ: 217.2 (0), 196.0 (0), 158.4 (1), 141.8 (0), 72.9 (1), 67.6 (0), 45.8 (0), 39.9 (2), 35.6 (2), 30.0 (2), 29.7 (3), 28.9 (3), 26.7 (3), 25.9 (3C, 3), 18.0 (0), −4.5 (3), −4.7 (3); MS: 336 (4, M^+), 321 (2), 303 (5), 280 (23), 279 (100), 261 (23), 237 (40), 235 (15), 193 (17), 189 (11), 161 (14), 159 (14), 145 (16), 75 (34), 73 (37), 43 (42).

For 26: ^{1}H NMR δ: 6.72 (1H, s), 4.69 (1H, dd, J = 4.0, 6.5 Hz), 2.65–2.26 (3H, m), 2.298 (3H, s), 2.296 (1H, d, J = 13.3 Hz), 1.80 (1H, br), 1.62 (1H, m), 1.53 (1H, d, J = 13.3 Hz), 1.24 (6H, s); MS: 222 (4, M^+), 207 (4), 204 (10), 189 (7), 179 (10), 176 (17), 163 (17), 162 (32), 161 (42), 147 (37), 133 (15), 121 (14), 119 (25), 43 (100). Treatment of **26** with PCC provided **11**.

(4*R,5*S**,6ξ)-6-Acetyl-4-((*tert*-butyldimethylsilyl)oxy)-8,8-dimethylspiro[4.4]nonan-1-one 27**

A solution of **25** (40 mg, 0.12 mmol) in dry MeOH (25 mL) was shaken with 5% Pd on carbon (30 mg) under 300 kPa of H_2 for 1 h. After filtration and concentration, **27** (41 mg, 100%) was obtained as a colorless solid: mp 77–77.5°C; IR:

1740, 1690 cm^{-1}; ^1H NMR δ: 4.39 (1H, dd, J = 6.2, 10.0 Hz), 2.95 (1H, dd, J = 6.9, 13.5 Hz), 2.33 (2H, m), 2.25 (1H, dd, J = 11.6, 13.5 Hz), 2.13 (3H, s), 2.11 (1H, m), 2.04 (1H, br d, J = 13.5 Hz), 1.86 (1H, dd, J = 6.9, 11.6 Hz), 1.53 (1H, m), 1.28 (1H, d, J = 13.5 Hz), 1.11 (3H, s), 1.06 (3H, s), 0.90 (9H, s), 0.08 (3H, s), 0.05 (3H, s); ^{13}C NMR δ: 219.4 (0), 209.9 (0), 75.0 (1), 62.4 (0), 57.7 (1), 44.4 (2), 41.2 (2), 37.9 (0), 36.0 (2), 30.2 (3), 30.0 (2C, 2 and 3), 29.4 (3), 25.8 (3C, 3), 18.0 (0), −4.3 (3), −4.7 (3); MS: no M^+, 323 (0.3), 295 (5), 281 (61), 263 (16), 239 (10), 189 (22), 161 (17), 147 (34), 75 (100), 73 (88), 62 (25), 45 (71), 43 (79). Exact Mass calcd. for $C_{15}H_{25}O_3Si$ ($M^+ - (CH_3)_3C$): 281.1573; found: 281.1573.

(4*R,8*R**,9*R**)-9-((*tert*-Butyldimethylsilyl)oxy)-6,6-dimethyltricyclo[6.3.0.0^{4,8}]undec-1-en-3-one 28**

To dry MeOH (10 mL) at 0°C was added sodium metal (6.1 mg, 0.27 mmol), followed a few minutes later by a solution of **27** (30 mg, 0.089 mmol) in MeOH. This solution was stirred at 0°C for 10 min. Water was added and much of the MeOH was removed under vacuum before extraction with ether (×3). The combined organic solutions were washed with brine (×2), dried over $MgSO_4$, and concentrated under vacuum. Chromatography (4% acetone) of the residue provided **28** (24 mg, 83%) as a colorless oil: IR: 1741, 1711, 1630 cm^{-1}; ^1H NMR δ: 5.81 (1H, br s), 3.82 (1H, dd, J = 7.9, 9.6 Hz), 2.83–1.03 (9H, m), 1.04 (3H, s), 0.90 (9H, s), 0.87 (3H, s), 0.05 (6H, s); MS: no M^+, 305 (3), 281 (14), 263 (100), 235 (6), 207 (6), 189 (7), 161 (12), 147 (10), 145 (12), 105 (15), 91 (19), 77 (15), 75 (94), 73 (71), 59 (21), 43 (26), 41 (30). Exact Mass calcd. for $C_{15}H_{23}O_2Si$ ($M^+ - (CH_3)_3C$): 263.1466; found: 263.1464.

8-Methylspiro[4.5]dec-7-ene-1,4-dione 30

To a solution of **29** (2.40 g, 15.6 mmol) in ether (80 mL) at −78°C was added 13.4 mL (18.7 mmol) of 1.4 M CH_3Li in ether. The mixture was stirred for 2 h before it was allowed to warm above 0°C and water was added. The product was extracted with ether (×3), and the combined organic solutions were washed with water and brine (×2), then dried over $MgSO_4$ and concentrated under vacuum. Chromatography (8% EtOAc) of the residue provided 0.19 g (7%) of recovered **29** and *8-methyl-1,4-dioxaspiro[4.5]decan-8-ol* (2.43 g, 91%) as colorless crystals: mp 68–69°C; IR: 3300 (br), 3263 cm^{-1}; ^1H NMR δ: 3.94 (4H, m), 1.94–1.84 (2H, m), 1.80 (1H, s, O*H*), 1.72–1.54 (6H, m), 1.25 (3H, s); ^{13}C NMR δ: 108.6 (0), 68.6 (0), 64.0 (2C, 2), 36.5 (2C, 2), 30.6 (2C, 2), 29.6 (3); MS: 172 (0.5, M^+), 100 (85), 99 (100), 86 (56), 71 (13), 55 (24), 42 (15). A solution of this alcohol (1.53 g, 9.94 mmol) in CH_2Cl_2 (100 mL) was cooled to −78°C before freshly distilled $BF_3 \cdot Et_2O$ (18.3 mL, 149 mmol) was added, followed over 20 min by a solution of **5** (7.9 mL, 30 mmol) in CH_2Cl_2 (25 mL). The mixture was stirred overnight while it attained room temperature. After pouring into ice-cold saturated $NaHCO_3$ solution, the aqueous layer was extracted with CH_2Cl_2. The combined organic solutions were washed with saturated $NaHCO_3$ and brine (×2), then dried over $MgSO_4$ and concentrated under vacuum. Chromatography (5% EtOAc) of the residue afforded **30** (1.23 g, 78% from the hydroxy-acetal, 71% from **29**) as colorless crystals: mp 76–77°C (lit.(14) mp 81.5–83°C); IR: 1716, 1410 cm^{-1}; ^1H NMR δ: 5.40 (1H, m), 3.00–2.61 (4H, m), 2.13 (2H, sextet, J = 2.1 Hz), 2.02 (2H, apparent t, J = 5.7 Hz), 1.75 (2H, t, J = 6.3 Hz), 1.70 (3H, br s); ^{13}C NMR δ: 214.7 (2C, 0), 132.8 (0), 116.7 (1), 55.1 (0), 34.2 (2C, 2), 27.6 (2), 26.7 (2), 25.7 (2), 23.3 (3); MS: 178 (62, M^+), 149 (25), 136 (22), 135 (100), 121 (34), 107 (31), 94 (21), 93 (35), 91 (45), 57 (21), 55 (43), 51 (29), 43 (24), 41 (39). Exact Mass calcd. for $C_{11}H_{14}O_2$: 178.0993; found: 178.0991. Anal. calcd. for $C_{11}H_{14}O_2$: C 74.13, H 7.92; found: C 74.23, H 7.99.

(4*R,5*S**)-31 and (4*R**,5*R**)-4-Hydroxy-4,8-dimethylspiro[4.5]dec-7-en-1-one 32**

To a solution of diketone **30** (603 mg, 3.39 mmol) in ether (40 mL) at −78°C was added 4.8 mL (6.8 mmol) of 1.4 M CH_3Li in ether. The mixture was stirred for 2 h before it was allowed to warm above 0°C and water was added. The aqueous layer was extracted with ether (×3), and the combined organic solutions were washed with water and brine (×2), then dried over $MgSO_4$ and concentrated under vacuum. Chromatography (6% EtOAc) of the residue gave 454 mg (69%) of **31**, 131 mg (20%) of **32**, and 42 mg (6%) of recovered **30**.

For 31: mp 67–68°C; IR: 3480 (br), 1728 cm^{-1}; ^1H NMR δ: 5.31 (1H, narrow d, J = 1.5 Hz, irradiation gave a 2% NOE at 1.92, 1% NOE at 1.67), 2.46 (1H, br m), 2.24–2.00 (3H, m), 2.04–1.68 (7H, m including O*H*), 1.67 (3H, br s, irradiation gave a 9% NOE at 5.31), 1.27 (3H, s, irradiation gave a 3% NOE at 1.92); ^{13}C NMR δ: 220.6 (0), 134.0 (0), 117.7 (1), 79.6 (0), 53.7 (0), 34.3 (2), 34.0 (2), 28.5 (2), 27.0 (2), 24.5 (3), 23.3 (3), 23.0 (2); MS: 194 (10, M^+), 136 (57), 121 (26), 119 (18), 118 (37), 93 (25), 91 (24), 79 (23), 77 (25), 55 (23), 43 (100), 41 (25). Exact Mass calcd. for $C_{12}H_{18}O_2$: 194.1306; found: 194.1310.

For 32: mp 98–99°C; IR: 3499 (br), 1723 cm^{-1}; ^1H NMR δ: 5.46 (1H, m), 2.40–2.34 (2H, m), 2.18–1.86 (7H, m including O*H*), 1.68 (3H, br s), 1.65–1.48 (2H, m), 1.28 (3H, s); ^{13}C NMR δ: 219.9 (0), 133.2 (0), 118.8 (1), 85.5 (1), 54.3 (0), 33.6 (2), 33.3 (2), 33.3 (2), 26.8 (2), 25.2 (2), 23.3 (3), 22.6 (3); MS essentially the same as for **31**. Exact Mass calcd. for $C_{12}H_{18}O_2$: 194.1306; found: 194.1307.

6-Formyl-4,7-dimethylspiro[4.5]nona-3,6-dien-1-one 34 and 7-acetyl-4-methylspiro[4.4]nona-3,7-dien-1-one 35

Ozone was passed through a solution of the keto-alcohols **31** and **32** (254 mg, 1.31 mmol) in CH_2Cl_2 (40 mL) at −78°C until the blue color persisted. The excess ozone was removed by bubbling O_2, then N_2, through the solution. Me_2S (3.0 mL) was introduced, and the mixture was stirred overnight during which time the mixture attained room temperature. The solvent was evaporated under vacuum to give crude *3-hydroxy-3-methyl-2-(3-oxobutyl)-2-(2-oxoethyl)cyclopentanone* **33** as a yellow oil (91% by GC–MS), which was used without further purification: MS: 226 (1, M^+), 165 (12), 147 (10), 141 (11), 110 (10), 109 (18), 99 (39), 71 (11), 55 (14), 43 (100). A solution of this crude **33** and 50 mg of *p*-TsOH in C_6H_6 (40 mL) was heated at reflux for 2 h with azeotropic removal of water. After cooling, saturated $NaHCO_3$ was added to the reaction mixture. The aqueous layer was extracted with ether (×3). The combined organic solutions were washed with $NaHCO_3$, water, and brine, then dried over $MgSO_4$ and concentrated under vacuum. Chromatography (4% EtOAc) of the residue provided **34** (77 mg, 31%) as an oil and 113 mg (45%) of a 1:1.2 mixture of **34** and **35**, respectively. For **34**: IR: 1739,

1654, 1620 cm^{-1}; ^1H NMR δ: 9.08 (1H, s), 5.74 (1H, q, J = 1.8 Hz), 3.24 (1H, dt, J = 2.4, 22.9 Hz), 2.86 (1H, dt, J = 3.3, 22.9 Hz), 2.69 (2H, m), 2.23 (3H, s), 2.17–1.80 (2H, m), 1.63 (3H, dd, J = 1.7, 2.4 Hz); ^{13}C NMR δ: 221.4 (0), 187.3 (1), 167.6 (0), 143.4 (0), 139.9 (0), 122.3 (1), 69.2 (2), 43.5 (2), 40.7 (2), 33.0 (2), 16.0 (3), 15.3 (3); MS: 190 (55, M^+), 147 (73), 133 (21), 119 (100), 105 (40), 91 (73), 79 (31), 77 (54), 65 (28), 53 (33), 51 (42), 50 (14), 41 (46). Exact Mass calcd. for $C_{12}H_{14}O_2$: 190.0993; found: 190.0984. Anal. calcd. for $C_{12}H_{14}O_2$: C 75.76, H 7.42; found: C 75.59, H 7.33. (For **35** see below.)

7-Acetyl-4-methylspiro[4.4]nona-3,7-dien-1-one 35 and 7-acetyl-4-methylenespiro[4.4]non-7-en-1-one 36

To a solution of crude **33**, derived as above from 206 mg (1.06 mmol) of a mixture of **31** and **32**, in CH_2Cl_2 (20 mL) at 0°C was added Et_3N (3.0 mL), followed dropwise by an excess (0.5 mL) of MsCl. The mixture was warmed to room temperature and stirred for 1 h. The mixture was poured into water, and this was extracted with CH_2Cl_2(×2). The combined organic solutions were washed with 1 M HCl, water, and brine, then dried over $MgSO_4$ and concentrated under vacuum. Chromatography on silica gel failed to separate **35** and **36**, but 138 mg (68% from **31** and **32**) of the 1:1 mixture was obtained as a colorless oil: IR: 1742, 1664, 1630 cm^{-1}. Exact Mass calcd. for $C_{12}H_{14}O_2$: 190.0993; found 190.0993.

*For **35*** (from the mixture): ^1H NMR δ: 6.65 (1H, m), 5.67 (1H, t, J = 1.8 Hz), 3.42–2.40 (6H, m), 2.35 (3H, s), 1.71 (3H, q, J = 2.4 Hz); ^{13}C NMR δ: 218.7 (0), 195.4 (0), 153.4 (0), 143.1 (0), 140.7 (1), 119.5 (1), 57.5 (0), 41.4 (2), 38.2 (2), 27.3 (2), 26.3 (3), 13.5 (3); MS (from GC–MS): 190 (0.2, M^+), 162 (15), 119 (23), 91 (24), 43 (100), 41 (15).

*For **36*** (from the mixture): ^1H NMR δ: 6.66 (1H, m), 5.01 (1H, t, J = 1.8 Hz), 4.90 (1H, t, J = 1.8 Hz), 3.42–2.40 (8H, m), 2.34 (3H, s); ^{13}C NMR δ: 220.5 (0), 195.4 (0), 144.1 (0), 142.1 (0), 140.9 (1), 106.2 (2), 58.6 (0), 43.2 (2), 42.2 (2), 41.0 (2), 39.0 (2), 27.7 (3); MS: essentially the same as for **35**.

7-Acetyl-4-methylspiro[4.4]nonan-1-one 37

Excess lithium (40 mg) was added to ammonia (30 mL) at −78°C followed by a solution of **35** and **36** (142 mg, 0.749 mmol) in dry THF (5.0 mL). The temperature of the reaction was raised to −35°C, and this was stirred for 30 min. Solid NH_4Cl was added until the blue color disappeared, and the ammonia was allowed to evaporate at room temperature. Water was added, and this was extracted with ether (×3). The combined organic solutions were washed with water and brine (×2), then dried over $MgSO_4$ and concentrated under vacuum. The resulting crude product showed NMR signals for alcohols, so the product was stirred with PCC (0.65 g, 3.0 mmol) in CH_2Cl_2 (30 mL) overnight. The solution was filtered through a Florisil pad to remove a black precipitate, and the pad was washed with ether. Concentration of the filtrate and the organic extracts provided 126 mg of an oily product, *(5*R*, 7*S*)- and (5*R*, 7*R*)-7-acetyl-4-methylspiro[4.4]non-3-en-1-one*: MS: 192 (22, M^+), 164 (35), 149 (30), 121 (51), 119 (23), 105 (26), 93 (41), 91 (36), 79 (44), 77 (31), 55 (25), 43 (100), 41 (24). A MeOH (30 mL) solution of this crude product was maintained under 300 kPa of H_2 for 1 h in the presence of 10% palladium on charcoal (50 mg). Filtration removed the catalyst, and the filtrate was concentrated under vacuum. Chromatography (6% EtOAc) of the residue provided 31 mg (24%) of **37a/b** and 80 mg (63%) of **37c/d**.

*For **37a/b***: IR: 1733, 1709 cm^{-1}; ^1H NMR (selected signals) δ: 3.22–3.08 (2H, m), 2.18 (3H, s), 2.17 (3H, s), 1.01 (6H, d, J = 2.6 Hz); MS: 194 (6, M^+), 137 (17), 133 (16), 123 (15), 111 (57), 95 (21), 79 (16), 67 (22), 55 (25), 43 (100), 41 (30). Exact Mass calcd. for $C_{12}H_{18}O_2$: 194.1306; found: 194.1306.

*For **37c/d***: IR: 1732, 1709 cm^{-1}; ^1H NMR (selected signals) δ: 2.90–2.78 (2H, m), 2.19 (3H, s), 2.17 (3H, s), 1.03 (3H, d, J = 2.4 Hz), 1.01 (3H, d, J = 2.7 Hz); MS essentially the same as for **37a/b**. Exact Mass calcd. for $C_{12}H_{18}O_2$: 194.1306; found: 194.1299.

(1*R**,2*R**,8*R**)- 38 and (1*R**,2*S**,8*R**)-2-Methyltricyclo[6.2.1.0^{1,5}]undec-5-en-7-one 39

Potassium *tert*-butoxide (114 mg, 1.01 mmol) was added to a solution of **37a–d** (98 mg, 0.51 mmol) in C_6H_6 (30 mL) at room temperature. After stirring for 20 min, TLC revealed essentially complete conversion so water was added. The aqueous layer was extracted with ether (×3). The combined organic solutions were washed with water and brine (×2), then dried over $MgSO_4$ and concentrated under vacuum. Chromatography (5% EtOAc) of the residue gave a mixture of the tricyclic enones **38** and **39** (64 mg, 72% combined) in a 1.2:1 ratio, respectively. For spectra of **38** and **39**, see below.

Separation of 38 and 39

Chromatography of a 1.2:1 mixture of enones **38** and **39** (148 mg) on 25% silver nitrate-impregnated silica gel with 2% ethyl acetate in hexane as the eluent provided homogeneous samples of **38** (48 mg, 32%) and **39** (29 mg, 20%) with the remainder of the fractions being a mixture of **38** and **39**.

*For **38***: IR: 1677 cm^{-1}; ^1H NMR δ: 5.74 (1H, q, J = 1.8 Hz), 2.90 (1H, m), 2.62–2.56 (2H, m), 2.20–1.99 (3H, m), 1.82–1.71 (3H, m), 1.62–1.47 (3H, m), 0.94 (3H, d, J = 6.9 Hz); ^{13}C NMR δ: 204.3 (0), 180.7 (0), 119.6 (0), 57.0 (0), 50.2 (1), 40.3 (2), 39.5 (1), 36.0 (2), 32.6 (2), 30.4 (2), 25.5 (2), 16.7 (3); MS: 176 (42, M^+), 135 (100), 134 (17), 133 (22), 107 (15), 105 (17), 91 (35), 79 (22), 77 (16), 41 (15). Exact Mass calcd. for $C_{12}H_{16}O$: 176.1200; found: 176.1204. Anal. calcd. for $C_{12}H_{16}O$: C 81.77, H 9.15; found: C 81.65, H 9.17.

*For **39***: IR: 1678 cm^{-1}; ^1H NMR δ: 5.72 (1H, q, J = 1.8 Hz), 2.85 (1H, m), 2.66–2.42 (2H, m), 2.17–1.98 (3H, m), 1.84–1.71 (3H, m), 1.63–1.37 (3H, m), 1.04 (3H, d, J = 6.6 Hz); ^{13}C NMR δ: 204.1 (0), 180.9 (0), 119.4 (0), 56.2 (0), 49.5 (1), 42.0 (2), 38.8 (1), 32.4 (2), 32.3 (2), 26.0 (2), 25.3 (2), 16.6 (3); MS: essentially the same as for **38**. Regio- and stereoselective ring openings of unsymmetrical oxatricyclo adducts

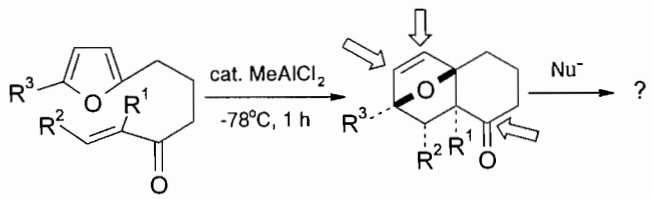
Simon Woo, Masood Parvez, and Brian A. Keay

Abstract: S_N2' ring-opening reactions of a number of substituted 11-oxatricyclo[6.2.1.$0^{1,6}$]undec-9-en-5-ones prepared via the intramolecular Diels–Alder reaction employing a furan diene (IMDAF) are reported. Primary, secondary, and tertiary organolithium reagents were capable of effecting the ring-opening reaction, while methyllithium required activation before any ring opening was observed. Hydride reagents, organocuprates, and Grignard reagents were generally ineffective. The ring-opening reaction was highly regio- and stereoselective for attack at C_9 *syn* to the bridging oxygen atom provided that C_8 was not substituted. A highly stereoselective nucleophilic addition to the carbonyl group *anti* to the bridging oxygen was also observed. The high selectivity appears to be due to a combination of steric and electronic effects.

Key words: S_N2' reactions, oxatricyclo adducts, Diels–Alder reaction, ring opening.

Résumé : On a effectué des réactions d'ouverture de cycles S_N2' sur un certain nombre de 11-oxatricyclo[6.2.1.$0^{1,6}$]undéc-9-én-5-ones substituées préparées par une réaction de Diels–Alder intramoléculaire à l'aide d'une furane diène («IMDAF»). Les réactifs organolithiens primaires, secondaires et tertiaires permettent d'effectuer la réaction d'ouverture de cycle; toutefois, avec le méthyllithium, il est nécessaire de procéder à une activation avant de pouvoir observer une ouverture. Les hydrures, les organocuprates et les réactifs de Grignard sont généralement inefficaces. Lorsque le carbone en C-8 n'est pas substitué, la réaction d'ouverture de cycle est extrêmement régio- et stéréosélective par rapport aux attaques en C-9 *syn* relatives à l'atome d'oxygène format le pont. On a aussi observé une réaction d'addition extrêmement stéréosélective sur le groupe carbonyle en *anti* par rapport à l'atome d'oxygène formant le pont. La sélectivité élevée semble être due à une combinaison d'effets stériques et électroniques.



Mots clés : réactions S_N2', adduits oxatricyclo, réaction de Diels–Alder, ouverture de cycle.

[Traduit par la rédaction]

Introduction

The intramolecular Diels–Alder reaction with a furan diene (IMDAF) is capable of forming oxatricyclo adducts (Scheme 1) with a great deal of stereocontrol, producing only *exo* products with the sidearm oriented *syn* relative to the bridging oxygen atom (1). Preliminary experiments with DIBAL-H in 1986 had suggested that these cycloadducts may be amenable to ring openings; however, at that time, the methodology for preparing the cycloadducts had not been fully developed. By 1990, the oxatricyclo adducts were readily accessible using methodology developed in our laboratory (1), and the S_N2' ring-opening studies were initiated. At that time, ring openings on oxatricyclo adducts had not been attempted (2). In addition, when these studies were first started in 1990, little was known about the factors affecting the regioselectivity of the S_N2' ring openings of unsymmetrical oxabicyclo systems, as only the group of Arjona and Plumet (3) had observed a large degree of regioselectivity at that time. Lautens et al. had also reported a regioselective opening of some oxabicyclo adducts but the regioselectivity was reported to be marginal (60:40) (4). More recently, however, many groups have reported on several advances in the S_N2' ring-opening reactions of oxa-*n*-cyclic compounds and a review on this topic has recently been published (2).

Scheme 1.

A number of questions about the reactivity of the IMDAF cycloadducts with regard to the S_N2' ring-opening reactions therefore remained unanswered in 1990. These questions included:

1. What conditions were required to effect an S_N2' ring opening of the IMDAF cycloadducts?
2. What was the chemoselectivity with respect to nucleophilic addition to the ketone carbonyl group versus the S_N2' ring opening (arrows in Scheme 1)?
3. What degree of regioselectivity would be observed in the ring opening-reactions of the unsymmetrical IMDAF cycloadducts?

Received October 21, 1996.

This paper is dedicated to Professor William A. Ayer on the occasion of his 65th birthday.

[a]Other unidentified side-products produced as well.

4. What degree of stereoselectivity would be observed with both the nucleophilic addition to the carbonyl group and the ring opening, and from which face would nucleophilic attack predominantly occur?
5. What effect would the presence of other substituents on the IMDAF cycloadducts have on these variables, if any?

With these questions answered, an assessment of the applicability of an IMDAF ring-opening reaction sequence for the synthesis of natural products would be possible. As a result, a study of the scope and limitations of the S_N2' ring-opening reactions of the IMDAF cycloadducts was undertaken and our initial results communicated (5, 1*c*). Recently, an application illustrating the usefulness of the IMDAF ring-opening sequence towards the C_{15}–C_{23} fragment of venturicidin A was described (6). In this paper, a full account of the S_N2' ring openings of the IMDAF oxatricyclo adducts is reported.

Results

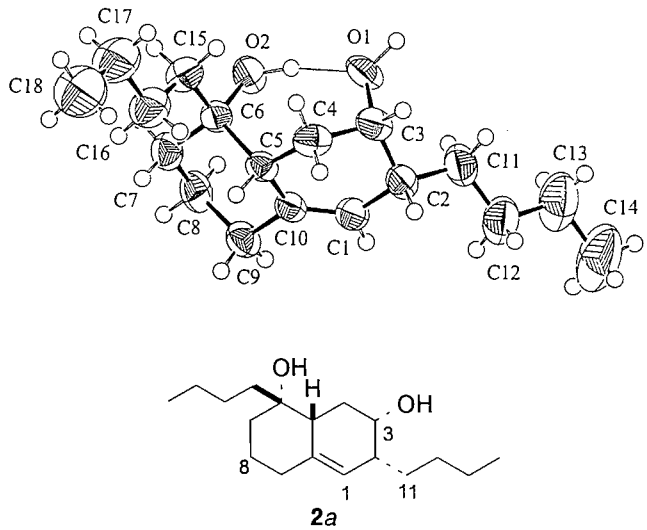
Oxatricyclo adducts **1**, **14**, **29**, and **35** with methyl substituents at various positions were prepared as previously described (1*d*, 1*e*) and subjected to a number of reaction conditions to investigate the scope and limitations of the ring-opening reaction.

The simplest of these systems, **1**, was chosen for initial study to determine the conditions required for the S_N2' ring openings. Compound **1** was treated with a variety of organometallic reagents, and the results are summarized in Table 1. Primary (*n*-butyllithium), secondary (isopropyllithium (7)), and tertiary (*tert*-butyllithium) organolithium reagents were capable of effecting a highly regio- and stereoselective ring opening of **1** and a highly stereoselective nucleophilic addition to the ketone carbonyl group, so that only one diastereomer **2** was produced in good to excellent yields (Table 1, entries 1–3). *sec*-Butyllithium reacted similarly, but a mixture of diastereomers was formed due to the presence of an additional stereogenic centre in the nucleophile.

The direction of regioselectivity was evident from the integration of the ^{1}H NMR spectrum, since the broadened signal at 5.3–5.5 ppm, assigned to the alkene proton of **2**, integrated to one proton instead of the two alkene protons required for the regioisomer. The stereochemistry of the resulting products was not easily determined by ^{1}H NMR, so a suitable crystal of **2***a*, produced by recrystallization from hexane, was subjected to X-ray crystallographic analysis.[2] The ORTEP plot (Fig. 1) clearly shows that *n*-butyllithium attacked the ketone carbonyl from the α-face, and had effected a ring-opening reaction by attacking C_9 from the β-face.[3]

The crystal structure of **2***a* also aided in the explanation of the appearance of the alkene proton as a broadened signal in the ^{1}H NMR spectrum rather than a doublet with additional coupling. The solution structure should also show the intramolecular hydrogen bonding in an aprotic solvent such as deuteriochloroform, and should therefore resemble the crystal structure. Examination of molecular models shows that, in this conformation, the dihedral angle between H_7 and H_8 is close to

[2] Details of the X-ray crystal analysis, including tables of atomic coordinates, bond lengths and angles, anisotropic displacement parameters, torsion angles, and nonbonded contacts, have been deposited as supplementary material and can be purchased from: The Depository of Unpublished Data, Document Delivery, CISTI, National Research Council Canada, Ottawa, Canada K1A 0S2. Except for the tables of anisotropic displacement parameters, torsion angles, and nonbonded contacts, this material has also been deposited with the Cambridge Crystallographic Data Centre, and can be obtained on request from The Director, Cambridge Crystallographic Data Centre, University Chemical Laboratory, 12 Union Road, Cambridge, CB2 1EZ, U.K.



[3] The numbering of atoms in the compounds will reflect the numbering required to name the compound by IUPAC rules. As a result, the number of a particular atom may be different in the reactants versus the products.

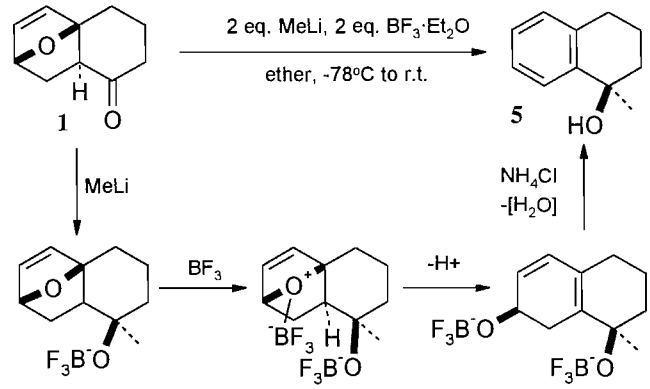
Fig. 1. X-ray crystal structure of compound **2***a*.

2*a*



Scheme 2.

90° so that the vicinal coupling between these protons should be small. When this small coupling is combined with the several small allylic couplings between H_8 and the protons on C_1 and C_5, the net result is expected to be a broadened signal. Since the ^{1}H NMR signals for the alkene protons of **2***b* and **2***c* were similar to that of **2***a* in appearance, the same analysis holds and the stereochemistry of all three products should be the same.

Other less reactive organometallic reagents did not cause any ring opening, but did react stereoselectivity with the ketone carbonyl group to generate **3**, indicating that nucleophilic addition to the ketone carbonyl was more facile than the ring opening. Reagents in this category included Grignard reagents, organocuprate reagents ($Me_2CuLi{\cdot}LiCN$ (8) and $Me_2CuLi{\cdot}LiI$ (9)), and the less reactive organolithium reagents phenyllithium and methyllithium (Table 1, entries 4–8). Although some ring opening was observed with methyllithium when the reaction was carried out in refluxing diethyl ether (Table 1, entry 9), the reaction was slow. Increasing the reaction temperature further was not an option, since the reaction of **1** with methylmagnesium chloride in refluxing THF had produced some of the fragmentation product **4** (Scheme 2). This product likely resulted from a Grob-type fragmentation (10) of the intermediate alkoxide. Addition of a second equivalent of methylmagnesium chloride to the resulting alkoxyketone, followed by aromatization by dehydration on work-up, would generate **4**. The inability to easily cause an S_N2' ring opening with methyllithium was disappointing so methods for assisting the ring opening or enhancing the reactivity of the methyllithium were therefore investigated.

Scheme 3.

The use of lithium salts for increasing the rate of nucleophilic addition of methyllithium to ketones has been reported (11). This effect has been attributed to the complexation of the lithium salt with the ketone carbonyl group, allowing the lithium salt to act as a Lewis acid catalyst. A similar assistance in the S_N2' ring openings could result from the complexation of a lithium salt to the bridging oxygen atom. The addition of excess lithium iodide or lithium perchlorate to a mixture of **1** and methyllithium, however, produced less than 10% of the ring-opened product based on integration of the ^{1}H NMR spectrum of the crude reaction mixture. Boron trifluoride etherate has also been employed in the reaction of organolithium reagents with epoxides and oxetanes (12). Only **3***e* was produced when **1** was treated with methyllithium and boron trifluoride etherate at −78°C. Slowly increasing the reaction temperature to 25°C produced **5** (Scheme 3). This product presumably arose from cleavage of the oxygen bridge via a Lewis acid assisted β-elimination followed by aromatization on work-up. The addition of the methyl moiety to the carbonyl group could either precede, as drawn, or succeed the elimination step.

Since the attempts to facilitate the ring opening were unsuccessful, altering the reactivity of the methyllithium was tried next. Electron-donating solvents or additives such as HMPA and TMEDA have been reported to increase the nucleophilicity of organolithium reagents (13). This higher reactivity has traditionally been attributed to the formation of more reactive lower aggregates of the organolithium in the presence of electron donors, but this explanation was questioned recently by Collum (14). He argued that the lability of the organolithium–ligand complex may be more important, or that the stabilization of transition states by the additive may be the source of increased reactivity. Regardless of the reason for the effect, the increase in reactivity could allow for the S_N2' ring opening of **1** to be accomplished at room temperature. Although the addition of HMPA to the reaction mixture still resulted in the production of only **3***e*, a substantial amount of **2***e* was observed in addition to **3***e* (Table 1, entry 10) when TMEDA was employed as a cosolvent with diethyl ether. The ^{1}H NMR

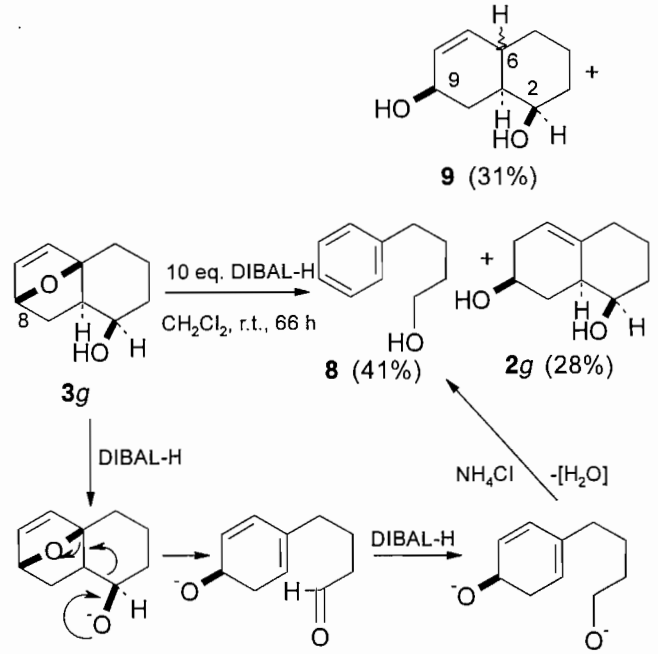
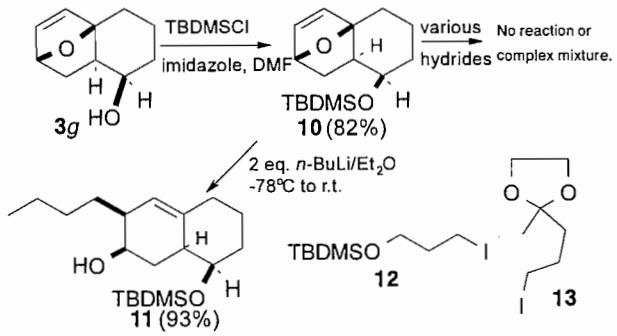
spectrum of the crude reaction mixture, however, showed the presence of a significant amount of unidentified side products as well.

DME has been reported to be a slightly weaker activator than TMEDA (see ref. 13, p. 7). The use of DME as the electron-donating reaction solvent provided the best results since **2***e* was formed in good yield and fewer side products were observed (Table 1, entry 11). Unfortunately, since organolithium reagents react with DME (15) at the higher reaction temperatures required for the ring-opening reaction, a large excess of methyllithium was required to ensure enough reagent was present to drive the reaction to completion. The use of less methyllithium resulted in the production of a mixture of **2***e* and **3***e*. DME that was freshly distilled from benzophenone ketyl was essential for the success of the reaction, since the use of Aldrich Sure-Seal® DME gave only **3***e*. The only observed side product was tentatively identified as **6**. This structural assignment was based on the ^{13}C NMR spectrum, which was very similar to the ^{13}C NMR spectrum **2***e* but contained an additional signal at 24.3 ppm resulting from a methylene carbon based on DEPT experiments. A similar product resulting from the reaction of methyllithium with another oxatricyclo adduct in DME has also been characterized by X-ray crystallography. This X-ray crystal structure and a possible mechanism for the formation of these side products will be discussed later.



The treatment of **1** with DIBAL-H (16), in an attempt to effect a reductive ring opening, produced a complex mixture of products. The isolation of both **3***g* and the epimeric alcohol **7** from the reaction mixture indicated that the complexity of the mixture was due, in part, to the fact that the reduction of the ketone carbonyl group was not stereoselective.

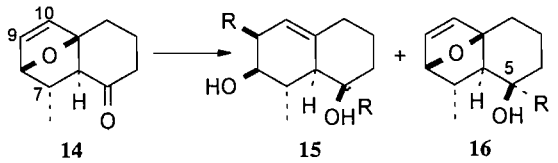


This problem of a non-stereoselective ketone reduction was circumvented by reducing the ketone in a separate step with a bulkier hydride reagent, lithium *tert*-butyldiisobutylaluminohydride (17), to form the axial alcohol **3***g* exclusively (Table 1, entry 12). When **3***g* was treated with DIBAL-H, a mixture of three products was formed (Scheme 4). The ring-opened product **2***g* was accompanied by a considerable amount of 4-phenyl-1-butanol (**8**). This product was possibly formed via a Grob-type fragmentation (10) of the initially formed alkoxide, and reduction of the resulting alkoxyaldehyde to produce a dialkoxide, followed by aromatization upon work-up with saturated ammonium chloride as illustrated in Scheme 4. The third product, which could not be completely separated from **2***g*, was tentatively identified as **9** with unknown stereochemistry at C_6. This product may have been formed from a direct reduction of the oxygen bridge. If the reduction had occurred via an S_N2-like process, attack should have occurred at the less hindered carbon atom, C_8, of **3***g*. Due to the Lewis acidic nature of DIBAL-H, however, the reduction may be more S_N1-like so that **9** was produced.

In an attempt to suppress the fragmentation reaction, compound **3***g* was converted to its *tert*-butyldimethylsilyl ether **10**

Scheme 4.

Scheme 5.



under standard conditions (18) (Scheme 5). When the protected compound was treated with DIBAL-H, however, no reaction was observed. A number of other reducing agents, including 9-BBN (19), sodium amalgam (16), lithium di-*tert*-butylbiphenyl (LiDBB) radical anion (20), and Super-Hydride® (21), also returned only unreacted starting material. Both lithium aluminum hydride (22) and DIBAL-H in hexanes produced a complex mixture of products in which the unprotected alcohol **3***g* was the major component. Although the reducing agents were unable to effect an S_N2' ring opening of compound **10**, *n*-butyllithium reacted in a highly regio- and stereoselective manner to produce **11** in high yield. This reaction illustrated that a free alkoxide was not required for the regiochemical control and that two different groups could be introduced due to the difference in the rates of the ring-opening reaction and nucleophilic attack at the ketone carbonyl. Unfortunately, attempts to extend this reaction to the functionalized nucleophiles derived from lithium–halogen exchange of the iodides **12** and **13** were unsuccessful, and only unreacted starting material was isolated.

The initial studies with **1** provided some idea of the condi-

tions required to induce the S_N2' ring openings of the IMDAF cycloadducts. The effect of methyl substituents was examined next. Compound **14**, with a methyl group at C_7, was subjected to some of the reaction conditions that were successful with **1**. The results of these experiments are presented in Table 2.

n-Butyllithium smoothly reacted with **14** to generate **15***a* exclusively, showing that a C_7 methyl group had no effect on the regioselectivity of the ring-opening reaction. Surprisingly, however, the methyllithium–TMEDA system did not successfully cleave the bridging ether linkage. While the methyllithium–DME reagent was not tried with **14**, it was successful with the related compounds **17**, **20**, and **24**, giving **18**, **21**, and **25**, respectively (Scheme 6). Compounds **17**, **20**, and **24** were prepared as previously described (1). In each of these reactions, varying amounts of the ethyl derivatives **19**, **23**, and **26** were formed as side products. All three compounds were detected by GC–MS, and the *p*-nitrobenzoate ester **27**, prepared from the hydrogenation product of **26**, was characterized by X-ray crystallography. While the X-ray diffraction data were not good enough to allow for complete refinement of the crystal structure (R = 0.108), the identity and relative stereochemistry of the compound was still clearly established. Compound **20** also reacted cleanly with *n*-butyllithium, providing **22** in good yield. The reactions of **20** and **24** provided additional proof that the regioselectivity was not dependent on the presence of a free alkoxide.

Since the formation of the ethyl derivatives was both unexpected and intriguing, possible mechanisms for their formation were investigated further. The fact that the reaction was observed with **20** and **24** in addition to **17** suggested that a free alkoxide at C_5 was not involved in the reaction mechanism. Several possible mechanisms are illustrated in Scheme 7. The first possibility, mechanism A, requires the presence of ethyllithium as an impurity in the methyllithium or the formation, in some way, of ethyllithium under the reaction conditions. The homologation of secondary and tertiary organolithium reagents, usually by two carbon atoms, due to reaction with diethyl ether at room temperature is known (23). An S_N2' ring-opening reaction by the ethyllithium would then produce the

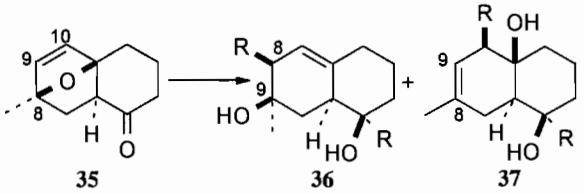
observed products. A second potential mechanism, mechanism B, involves an α-elimination from the DME-derived primary anion to produce a carbene or carbenoid. The decomposition of α-haloorganolithium (see ref. 13, pp. 169–172) and α-phenoxyorganolithium (24) reagents to carbenes or carbenoids has been reported and, while an alkoxide is a poorer leaving group than either a halide or a phenoxide, the proposed α-elimination is still reasonable. The carbene or carbenoid could then react with the strained double bond of the IMDAF cycloadducts to introduce a cyclopropane ring. Attack of methyllithium to cleave the cyclopropane ring and effect the ring opening would then furnish the observed product. The chemical reactivity of cyclopropanes is similar to that of alkenes (25), and this type of reaction leading to the cleavage of the cyclopropane ring in 1-cyclopropyl-1-bromoalkanes by organocuprates (26) or piperidine (27) is known. Several experiments were performed on both the cycloadducts and on model compounds in an attempt to find support for these mechanisms.

One of the first experiments involved treatment of acetophenone with methyllithium, but no product of ethyl addition to acetophenone was detected. In addition, only 2-phenyl-2-propanol was formed when acetophenone was treated with an aliquot of a mixture of methyllithium and DME that had been stirred at room temperature for 1.5, 8.5, or 25 h. There was a possibility that any other organolithium reagents formed were simply behaving as bases with acetophenone and causing enolate formation rather than reacting with the carbonyl group. This possibility was addressed by carrying out the same experiment with benzaldehyde since benzaldehyde cannot enolize. Once again, however, only 1-phenylethanol, resulting from the addition of methyllithium to benzaldehyde, was observed. These experiments appeared to refute mechanism A since products resulting from the addition of the ethyl anion required for this mechanism should have occurred.

The treatment of **1** with trideuteriomethyllithium in DME provided **28** (Scheme 6). The mass spectrum of the reaction mixture showed that three deuterium atoms had been incorporated into **28** (M^- = 223). This result provided support for mechanism B (Scheme 7) since, in this mechanism, the methylene and methyl groups of the ethyl moiety originate from the DME and MeLi, respectively. An attempt to provide additional support for mechanism B involved performing a Simmons–Smith cyclopropanation (28) on compound **1** to introduce a cyclopropane ring on the strained double bond. Treatment of this compound with methyllithium in DME, however, returned only the cyclopropanated product, suggesting that mechanism B was not operating.

A potential explanation using a combination of mechanisms A and B is shown in mechanism C (Scheme 7). This involves the formation of ethyllithium from methyllithium and a carbene or carbenoid species generated from DME. The ethyllithium formed could then react with the oxatricyclo compound (mechanism A). In the absence of the oxatricyclo compound to immediately trap the ethyllithium formed, however, the ethyllithium could decompose the DME by the more conventional route of deprotonation of one of the methylene groups followed by β-elimination. As a result, none of the products resulting from the addition of ethyllithium to acetophenone or benzaldehyde was observed in the quenching experiments. This last explanation is purely speculative, and the possibility of a different mechanism has not been refuted.



Compound **14** reacted with lithium *tert*-butyldiisobutylaluminohydride to produce the axial alcohol **16***c* exclusively in excellent yield (Table 2). The proton on C_5 appeared as a broadened multiplet at 3.99 ppm, establishing the stereochemistry of the hydroxyl group. This result also confirmed that the ketone carbonyl group of **14** was still biased towards attack from the α-face. When **16***c* was treated with DIBAL-H, a complex mixture of compounds was produced. As the production of the complex mixture meant that the reaction would not be synthetically useful, no attempt was made to characterize any of the compounds in the mixture.

The effect of a methyl group adjacent to the carbonyl group in the IMDAF cycloadducts was probed with **29** and the results are shown in Table 3. *n*-Butyllithium once again caused a regioselective S_N2' ring opening; however, the major product isolated was **30***a*, in which nucleophilic addition to the carbonyl group had *not* occurred. A small amount of the "normal" product **31***a* was also isolated. The methyl group adjacent to the carbonyl group was apparently hindering nucleophilic attack at the carbonyl group from the α-face so that the ring-opening reaction became comparatively more facile. However, slightly less bulky alkyl groups, such as methyllithium, could still attack the carbonyl group. In fact, the methyllithium–TMEDA mixture attacked the carbonyl group, producing only **32***b*, and did not produce any ring-opened products. The production of the axial alcohol **32***c* exclusively upon treatment of **29** with lithium *tert*-butyldiisobutylaluminohydride illustrated that reaction at the carbo-

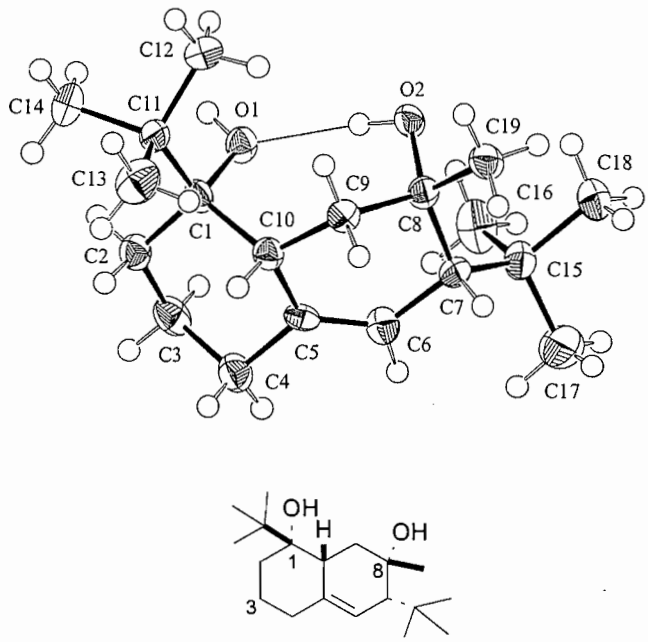
nyl group was still biased towards attack from the α-face. Treatment of **32***c* with DIBAL-H produced predominantly the fragmentation product **33**. The formation of **33** could occur via the same mechanism for the formation of **8** from **3***g* (Scheme 4) under the same conditions.

Finally, compound **35** was used to investigate the effect of a methyl group on the bridgehead position of the IMDAF cycloadducts. The results of these experiments are summarized in Table 4. Although the ring-opening reaction could be effected with organolithium reagents, the presence of the bridgehead methyl group caused a dramatic decrease in the regioselectivity so that both **36** and **37** were formed in ratios varying from 1.5:1 to 2.2:1. In the case of the reaction with *tert*-butyllithium, a small amount (12%) of **34** was isolated as



well. Because the two regioisomers were not easily separated by column chromatography and only the regioisomer that eluted first could be cleanly isolated, the ratios of products were determined by integration of the alkene protons. The major isomer from the reaction with *t*-BuLi was confirmed by an X-ray crystal structure (Fig. 2) and assigned structure **36***c*.[2] The X-ray crystal structure also established the facial selectivity of both the ring-opening reaction and the nucleophilic addition to the carbonyl group.

None of the normal S_N2' ring-opened products was observed when **35** was treated with the methyllithium–TMEDA reagent. Instead, a mixture of the non-ring-opened product **38** and the diene **39** was isolated (Scheme 8). Compound **39** was presumably formed via a β-elimination reaction as shown in Scheme 8. A similar reaction has been reported by Arjona et al. (29). This compound was somewhat unstable, and decomposed overnight upon storage in deuteriochloroform.

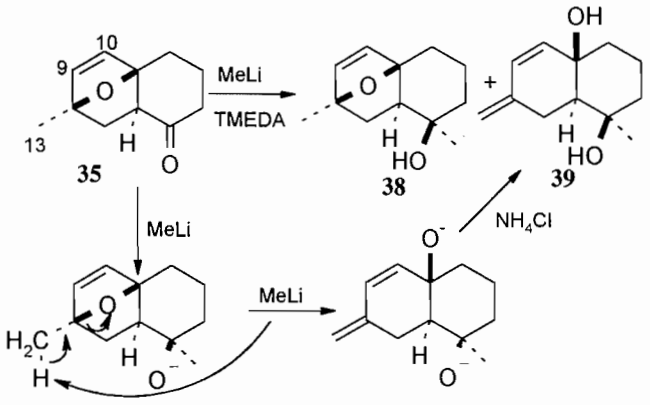
Discussion

Three items regarding the selectivity of the reaction of the organolithium reagents with the IMDAF cycloadducts need to be addressed. These items are the regioselectivity of the ring-opening reactions, the stereoselectivity of the ring-opening reactions, and the stereoselectivity of the nucleophilic addition to the ketone carbonyl group.

Fig. 2. X-ray crystal structure of compound **36***c*.

36*c*

Since the nucleophile would be donating electrons into the lowest unoccupied molecular orbital (LUMO) of the IMDAF cycloadducts, a difference in the lobe sizes at C_9 and C_{10} of the LUMO could be used to explain the regioselectivity. The LUMOs of several IMDAF cycloadducts, calculated at the AM1 semiemperical level using the SPARTAN molecular modelling program,[4] did not show a noticeable variation in the C_9 and C_{10} lobe sizes. Other explanations were therefore investigated.



The regioselectivity could be rationalized by electronic effects. Because the organolithium reagents also behave as Lewis acids, coordination of the lithium to the bridging oxygen atom likely occurs first. The developing positive charge

Table 5. Carbon–oxygen bond lengths of 3-21G(*) optimized structures of intermediates **40** and **43**.

Bond lengths for **40** (Å)		Bond lengths for **43** (Å)	
C_1–oxygen	1.5430	C_1–oxygen	1.5366
C_8–oxygen	1.5144	C_8–oxygen	1.5230
Difference	0.0286	Difference	0.0136

on the oxygen atom could be stabilized by resonance structures **41** or **42** for the intermediate **40** or structures **44** or **45** for the intermediate **43** (Scheme 9). For **40**, the resonance structure **41** should make a greater contribution to the resonance hybrid since the positive charge resides on a tertiary allylic carbon atom as opposed to a secondary allylic carbon atom in **42**. As a consequence, the C_1—O bond should be longer and weaker than the C_8—O bond, so that attack of a nucleophile at C_9 of **40** in an S_N2' fashion should be more facile than attack at C_{10}. On the other hand, the positive charge resides on a tertiary allylic carbon atom in both resonance structures **44** and **45**, so that these two structures should contribute equally to the resonance hybrid. As a result, the carbon–oxygen bond lengths should be more similar, and attack at C_9 or C_{10} of **43** should have more similar energy barriers. This argument was supported by the calculated structures of the intermediates **40** and **43** at the 3-21G(*) level using the SPARTAN molecular modelling program[3] (Table 5). The C_1—O bond length is longer than the C_8—O bond length in **40** and **43**; however, the difference is smaller in **43**. The slightly longer C_1_O bond length in **43** could also account for the slight preference for attack at C_9 in **35**. A similar argument has been used to rationalize the regioselectivity of acid-catalyzed ring openings of epoxides (30).

Steric arguments could also be used to rationalized the observed regioselectivity. The space-filling model of the 3-12G(*) optimized structure of **1** indicated that one of the hydrogen atoms on C_2 hinders attack at C_{10}, while attack at C_9 is less encumbered. The space-filling model of **35** indicated the same hindrance at C_{10}, but attack at C_9 is also obstructed by the hydrogen atoms (H_{13}) of the methyl group on C_8. As a result, the steric environments are more similar, leading to a corresponding decrease in the regioselectivity. A combination of steric and electronic effects is likely responsible for the observed regioselectivity.

The stereoselectivity of the S_N2' ring opening may be the result of the approach of the nucleophile from the less sterically hindered *exo* face of the oxatricyclic system (31). Coordination of the organolithium to the bridging oxygen atom or stereoelectronic effects favouring a *syn* S_N2' attack (32) are other possible contributing factors.

Steric effects are likely responsible for the stereoselective nucleophilic addition to the ketone carbonyl group. A steric argument is the classical explanation for the preference for equatorial attack at the carbonyl group of cyclohexanone when larger nucleophiles are employed (33). A different view of the space-filling model of **1** (optimized at the 3-21G(*) level) illustrated that the face of the carbonyl group opposite the bridging oxygen atom is more accessible to an attacking nucleophile.

Conclusions

The IMDAF cycloadducts are amenable to S_N2' ring openings by organolithium reagents. The minimum reactivity of the organolithium reagent required to effect the ring-opening reaction appeared to lie somewhere between that of *n*-butyllithium and methyllithium, since the former reagent and more reactive secondary and tertiary organolithium reagents were able to cause the ring opening, while methyllithium required activation by DME before any ring opening was observed. Less reactive organometallic reagents provided no ring-opened products. The reaction showed high facial selectivity for attack *syn* to the bridging oxygen atom, and was highly regioselective for attack at C_9 providing that the bridgehead position (C_8) of the IMDAF cycloadducted was not substituted. A combination of steric and electronic effects may be responsible for the high degree of selectivity. Substituents at other positions (C_3, C_6, and C_7) of the IMDAF cycloadducts were tolerated, and had no effect on the regioselectivity or stereoselectivity of the reaction.

Nucleophilic addition to the ketone carbonyl group of the IMDAF cycloadducts was generally more facile than the S_N2' ring-opening reaction unless the carbon atom adjacent to the carbonyl group bore a substituent. This addition was also highly stereoselective, providing products resulting from nucleophilic attack at the carbonyl group from the face opposite to the bridging oxygen atom. The IMDAF–S_N2' ring-opening reaction sequence provided products with up to five contiguous asymmetric centres of known relative stereochemistry in good to excellent yields.

All of the questions posed at the beginning of this article were answered by this study. With the viability of the S_N2' ring-openings established, we are continuing to apply this methodology to the enantioselective synthesis of natural products (6).

Experimental section

General experimental

Melting points were determined on solids purified by column chromatography using an Electrothermal® melting point apparatus and are uncorrected. Boiling points are uncorrected and refer to air-bath temperatures using a Kugelrohr short-path distillation apparatus. Optical rotations were measured with a Rudolph Research Autopol® III polarimeter using a 1 cm path length cell. Infrared spectra were recorded using a Mattson Galaxy Series 4030 FT-IR spectrophotometer. Solid samples were handled as pressed KBr discs, while liquid samples were placed neat between NaCl plates. Nuclear magnetic resonance spectra were obtained on either a Bruker ACE-200 (^{1}H 200 MHz, ^{13}C 50 MHz) or Bruker AM-400 (^{1}H 400 MHz, ^{13}C 100 MHz) spectrometer using deuteriochloroform as solvent. ^{13}C NMR spectra were referenced to the ^{13}C resonance of deuteriochloroform (δ 77.0), while ^{1}H NMR spectra were referenced to the ^{1}H resonance of residual chloroform (δ 7.27). Low-resolution mass spectra were either obtained using a Hewlett Packard 5890 Series II gas chromatograph interfaced to a Hewlett Packard 5971A mass selective detector or acquired by Mrs. Q. Wu (University of Calgary) using a VG-7070 spectrometer. High-resolution mass spectra were obtained by Mrs. D. Fox (University of Calgary) on a Kratos MS-80 spectrometer. Elemental analyses were also performed by Mrs. D. Fox using a Control Equipment Corporation 440 elemental analyzer. Chiral phase gas–liquid chromatography was performed on a Shimadzu GC-9A gas chromatograph equipped with a flame ionization detector using a 25 m × 0.33 mm (i.d.) × 0.25 μm (film thickness) Cydex-B (Scientific Glass Engineering) fused silica column. Analytical gas–liquid chromatography was performed on the same instrument using a 25 m × 0.53 mm (i.d.) × 3 μm (film thickness) 007 Series Methyl Silicone (Quadrex Corporation) fused silica column. Helium was used as the carrier gas in both cases. Flash column chromatography was accomplished with silica gel 60 (E. Merck, 0.04–0.063 mm, 230–400 mesh). Radial plate chromatography was performed with a Chromatotron (Harrison Research, model 7924T) with plates bearing 1, 2, or 4 mm thicknesses of silica gel (EM Science silica gel 60 PF_{254} with gypsum binder). Solvent systems refer to mixtures, by volume, of hexanes and ethyl acetate unless otherwise specified.

General procedure 1 for the S_N2' ring openings

A N_2-purged three-neck round-bottom flask equipped with an addition funnel containing a solution of the oxatricyclo compound (0.32 mmol) in anhydrous Et_2O (6 mL) was cooled with a −78°C bath. The flask was charged with anhydrous Et_2O (4 mL) and the organometallic reagent (1.0 mmol), and the solution of the oxatricyclo compound was added dropwise from the addition funnel. The mixture was warmed to 0°C and, if the reaction was not complete within 2 h, was then warmed to room temperature and stirred overnight. Wet Et_2O (10 mL) and saturated aqueous NH_4Cl (10 mL) were added sequentially, and the aqueous layer was extracted with Et_2O (4 × 10 mL). After the combined organic layers had been dried over anhydrous Na_2SO_4 and filtered, the solvent was removed in vacuo to provide the crude product. Purification was effected by flash column chromatography.

General procedure 2 for the S_N2' ring openings with methyllithium

A solution of the oxatricyclo compound (1.1 mmol) in anhydrous DME (29 mL) in a N_2-purged three-neck round-bottom flask was cooled with a −23°C bath. Methyllithium (33 mmol, 1.4 M in Et_2O) was added to the cooled reaction mixture, which was then warmed to 0°C and allowed to slowly reach room temperature overnight. The reaction was cooled back down to −23°C, and wet Et_2O (30 mL) and saturated aqueous NH_4Cl (30 mL) were cautiously added sequentially. The aqueous layer was extracted with Et_2O (4 × 30 mL), and the combined organic layers were dried over anhydrous Na_2SO_4. The dried solution was filtered, and the solvent was removed in vacuo to provide the crude product. Purification was effected by flash column chromatography.

(1*RS*,2*SR*,8*RS*,9*SR*)-2,8-Dibutylbicyclo[4.4.0]dec-6-en-2,9-diol (2*a*)

General procedure 1 was used to prepare compound **2***a*. Cycloadduct **1** (52.7 mg, 0.321 mmol) was treated with *n*-butyllithium (0.40 mL of 2.5 M in hexanes, 1.00 mmol) for 16 h to give diol **2***a* (59.4 mg, 0.212 mmol) as a white solid in 66% yield following purification by flash column chromatography (5:1); mp 104–105°C; IR (KBr): 3192 cm^{-1}; ^{1}H NMR (400 MHz): 0.92 and 0.93 (overlapping t, 6H, J = 7.0 Hz), 1.23–1.42 (m, 10H), 1.48–1.70 (m, 7H), 1.79 (ddd, 1H, J = 3.1 Hz, J = 8.8 Hz, J = 14.4 Hz), 1.96–2.05 (m, 2H), 2.13 (ddd, 1H, J = 3.4 Hz, J = 6.0 Hz, J = 14.4 Hz), 2.20–2.25 (m, 2H), 2.86 (br s, 1H), 3.88 (m, 1H), 5.36 (br s, 1H); ^{13}C NMR (50 MHz): 2 × 14.1, 22.5, 23.0, 23.3, 26.3, 28.1, 29.4, 31.0, 35.4, 36.6, 40.1, 40.3, 42.6, 66.4, 74.2, 124.5, 136.3; MS: 280 (8, M^+), 113 (100). Anal. calcd. for $C_{18}H_{32}O_2$: C 77.09, H 11.50; found: C 77.43, H 11.12.

X-ray crystal data for compound 2*a*

A sample of **2***a* was recrystallized from hexane to give colorless needles that were submitted for X-ray crystallographic analysis. See Fig. 1 for the X-ray crystal structure. Crystal data: empirical formula $C_{18}H_{32}O_2$; space group $P2_1/n$; a = 12.566(2) Å; b = 8.617(3) Å; c = 16.227(2) Å; β = 90.50(1)°; V = 1757.0 Å^3; Z = 4; d = 1.06 g/cm^3; Mo-Kα radiation (22°C); total of 3564 reflections in the range $2° < \theta < 25°$, of which 2247 were used ($I > 3\sigma(I)$) in the structure solution; R = 0.0516 and Rw = 0.0575.

(1*RS*,2*RS*,8*RS*,9*SR*)-2,8-Di(1-methylethyl)bicyclo[4.4.0]dec-6-en-2,9-diol (2*b*)

A solution of isopropyllithium was prepared using the method of Gilman et al. (7). An argon-purged three-neck round-bottom flask equipped with a glass-coated stirring bar and a dropping funnel containing a solution of freshly distilled 2-chloropropane (1.60 g, 2.04 mmol) in dry pentane (7 mL) was charged with dry penatane (13 mL). Freshly cut pieces of high-sodium (1%) lithium wire (0.2 g, 28.8 mmol) were added to the three-neck flask and the 2-chloropropane solution was

added dropwise to the reaction mixture. The addition funnel was replaced with a condenser and the solution was heated at reflux overnight. The resulting purple suspension was allowed to settle, and the supernatant was withdrawn and used. Standardization against 2,5-dimethoxybenzyl alcohol (34) indicated that the supernatant was 0.33 M in isopropyllithium.

General procedure 1 was used to prepare compound **2***b*. Cycloadduct **1** (48.2 mg, 0.294 mmol) was treated with the prepared solution of isopropyllithium (3.1 mL of 0.33 M in pentane, 1.02 mmol) for 16 h to give diol **2***b* (50.3 mg, 0.199 mmol) as a white solid in 68% yield following purification by flash column chromatography (5:1); mp 140–141.5°C; IR (KBr): 3250, 3117, 1385, 1363 cm^{-1}; ^1H NMR (200 MHz): 0.89 (d, 3H, J = 7.0 Hz), 0.95 (d, 3H, J = 6.8 Hz), 1.02 (d, 6H, J = 6.0 Hz), 1.35–1.83 (m, 7H), 1.98–2.37 (m, 5H), 2.97 (br s, 2H), 4.01 (m, 1H), 5.48 (br t, 1H, J = 1.6 Hz); ^{13}C NMR (50 MHz): 16.6, 17.6, 20.8, 20.8, 22.4, 28.3, 28.6, 29.5, 34.1, 34.1, 40.8, 47.1, 64.3, 76.3, 121.7, 137.1; MS: 252 (11, $M^{+\cdot}$), 131 (100). Exact Mass calcd. for $C_{16}H_{28}O_2$: 252.2089; found: 252.2084.

(1*RS*,2*SR*,8*SR*,9*SR*)-2,8-Di(1,1-dimethylethyl)bicyclo[4.4.0]dec-6-en-2,9-diol (2*c*)

General procedure 1 was used to prepare compound **2***c*. Cycloadduct **1** (49.8 mg, 0.303 mmol) was treated with *tert*-butyllithium (0.40 mL of 1.7 M in hexanes, 0.68 mmol) for 2 h at 0°C to give diol **2***c* (76.8 mg, 0.274 mmol) as a white solid in 90% yield following purification by flash column chromatography (9:1; mp 144–145.5°C; IR (KBr): 3231, 1395, 1365 cm^{-1}; ^1H NMR (400 MHz): 1.04 and 1.09 (two s, 9H each), 1.59–1.87 (m, 6H), 1.95–2.06 (m, 1H), 2.22–2.27 (m, 1H), 2.44 (br d, 1H, J = 7.1 Hz), 2.69 (dd, 1H, J = 4.2 Hz, J = 15.1 Hz), 2.82 (br s, 1H), 3.96 (br s, 1H), 4.16 (m, 1H), 5.49 (br t, 1H, J = 1.7 Hz); ^{13}C NMR (50 MHz): 23.8, 27.8, 28.2, 32.3, 32.7, 34.3, 36.9, 38.6, 42.5, 49.7, 65.4, 78.4, 121.7, 137.9; MS: 280 (4, $M^{+\cdot}$), 57 (100). Exact Mass calcd. for $C_{18}H_{32}O_2$: 280.2402; found: 280.2412.

(1*RS*,5*SR*,6*RS*,8*RS*)-5-Ethenyl-11-oxatricyclo[6.2.1.0^{1,6}]undec-9-en-5-ol (3*d*)

General procedure 1 was used to prepare compound **3***d*. Cycloadduct **1** (45.6 mg, 0.278 mmol) was treated with vinylmagnesium bromide (0.83 mL of 1.0 M in THF, 0.83 mmol) for 20 h to give alcohol **3***d* (39.2 mg, 0.204 mmol) as a slightly yellow oil in 73% yield following purification by flash column chromatography (3:1); bp 40–45°C/0.06 Torr (1 Torr = 133.3 Pa); IR (neat): 3478, 1630 cm^{-1}; ^1H NMR (200 MHz): 1.26 (dd, 1H, J = 8.0 Hz, J = 11.8 Hz), 1.42–1.67 (m, 3H), 1.72–2.32 (m, 5H), 3.52 (br s, 1H), 4.88 (dd, 1H, J = 1.7 Hz, J = 4.9 Hz), 5.00 (dd, 1H, J = 1.9 Hz, J = 10.6 Hz), 5.26 (dd, 1H, J = 1.9 Hz, J = 17.2 Hz), 5.75 (dd, 1H, J = 10.6 Hz, J = 17.2 Hz), 5.93 (d, 1H, J = 5.7 Hz), 6.47 (dd, 1H, J = 1.7 Hz, J = 5.7 Hz); ^{13}C NMR (50 MHz): 16.4, 27.6, 28.4, 36.9, 41.1, 71.9, 78.4, 87.7, 112.0, 137.2, 139.1, 144.0; MS: 192 (1, $M^{+\cdot}$), 94 (100). Exact Mass calcd. for $C_{12}H_{16}O_2$: 192.1150; found: 192.1138.

(1*RS*,5*RS*,6*RS*,8*RS*)-5-Methyl-11-oxatricyclo[6.2.1.0^{1,6}]undec-9-en-5-ol (3*e*)

General procedure 1 was used to prepare compound **3***e*. Cycloadduct **1** (48.6 mg, 0.296 mmol) was treated with methyllithium (0.46 mL of 1.4 M in Et_2O, 0.64 mmol) for 22 h to give alcohol **3***e* (34.1 mg, 0.189 mmol) as a colorless oil in 64% yield following purification by flash column chromatography (20:1 benzene:acetone); bp 50–60°C/0.07 Torr; IR (neat): 3497 cm^{-1}; ^1H NMR (200 MHz): 1.12 (s, 3H), 1.25–1.63 (m, 4H), 1.67–2.01 (m, 3H), 2.17–2.30 (m, 2H), 3.36 (br s, 1H), 4.89 (dd, 1H, J = 1.7 Hz, J = 4.9 Hz), 5.93 (d, 1H, J = 5.7 Hz), 6.47 (dd, 1H, J = 1.7 Hz, J = 5.7 Hz); ^{13}C NMR (50 MHz): 16.7, 27.8, 28.5, 28.9, 38.6, 42.7, 69.5, 78.5, 88.0, 137.5, 138.8; MS: 180 (weak, $M^{+\cdot}$), 94 (100). Exact Mass calcd. for $C_{11}H_{16}O_2$: 180.1150; found: 180.1154.

(1*RS*,5*RS*,6*SR*,8*RS*)-5-Phenyl-11-oxatricyclo[6.2.1.0^{1,6}]undec-9-en-5-ol (3*f*)

General procedure 1 was used to prepare compound **3***f*. Cycloadduct **1** (47.3 mg, 0.288 mmol) was treated with phenyllithium (0.45 mL of 2.0 M in cyclohexane–Et_2O, 0.90 mmol) for 18 h to give alcohol **3***f* (60.6 mg, 0.250 mmol) as a yellow solid in 87% yield following purification by flash column chromatography (5:1); mp 114–115°C; IR (KBr): 3459, 1491, 1451 cm^{-1}; ^1H NMR (200 MHz): 1.11 (dd, 1H, J = 7.8 Hz, J = 11.7 Hz), 1.67–1.76 (m, 1H), 1.87–2.13 (m, 6H), 2.36–2.42 (m, 1H), 4.13 (s, 1H), 4.91 (dd, 1H, J = 1.7 Hz, J = 4.7 Hz), 6.00 (d, 1H, J = 5.7 Hz), 6.48 (dd, 1H, J = 1.7 Hz, J = 5.7 Hz), 7.19–7.52 (m, 5H); ^{13}C NMR (50 MHz): 17.2, 27.6, 28.5, 39.1, 43.4, 73.3, 78.5, 88.2, 124.8, 126.2, 127.9, 137.2, 139.1, 147.7; MS: 242 (1, $M^{+\cdot}$), 94 (100). Exact Mass calcd. for $C_{16}H_{18}O_2$: 242.1307; found: 242.1305.

(1*RS*,2*SR*,8*RS*,9*SR*)-2,8-Dimethylbicyclo[4.4.0]dec-6-en-2,9-diol (2*e*) and (1*RS*,2*SR*,8*RS*,9*SR*)-8-ethyl-2-methylbicyclo[4.4.0]dec-6-en-2,9-diol (6)

(a) Using methyllithium–TMEDA

Anhydrous Et_2O (2 mL) was placed in a N_2-purged three-neck round-bottom flask equipped with an addition funnel containing a solution of cycloadduct **1** (48.0 mg, 0.292 mmol) in anhydrous Et_2O (5 mL). The flask was cooled with an ice bath, and methyllithium (0.80 mL of 1.4 M in Et_2O, 1.12 mmol) and dry TMEDA (7.8 mL) was added. The solution of **1** was added dropwise from the addition funnel, and the reaction was warmed to room temperature and stirred for 48 h. Wet Et_2O (10 mL) and saturated aqueous NH_4Cl (10 mL) were then added sequentially, and the aqueous layer was extracted with Et_2O (4 × 10 mL). The combined organic layers were washed with 10% aqueous $CuSO_4$ (2 × 30 mL), dried over anhydrous Na_2SO_4, and filtered. The solvent was removed from the filtrate in vacuo. The crude product contained a mixture of **2***e*:**3***e* in a ratio of approximately 1:1. Flash column chromatography (3:1) provided **3***e* (17.5 mg, 0.0971 mmol) and **2***e* (16.9 mg, 0.0861 mmol) in yields of 33 and 30%, respectively.

(b) Using methyllithium–DME

Cycloadduct **1** (36.0 mg, 0.219 mmol) was treated with methyllithium (6.30 mL of 1.4 M in Et_2O, 8.82 mmol) for 22 h according to general procedure 2. Flash column chromatography (3:1) provided diol **2***e* (31.6 mg, 0.161 mmol) and a compound tentatively identified as **6** (12.0 mg, 0.0570 mmol) in yields of 74 and 26%, respectively. Compound **2***e* was characterized as a white solid, mp 124–125°C; IR (KBr): 3244 cm^{-1}; ^1H NMR (200 MHz): 1.05 (d, 3H, J = 7.2 Hz), 1.26 (s, 3H), 1.44–2.35 (m, 10H), 2.89 (br s, 2H), 3.84 (m, 1H), 5.33 (br s,

For personal use only.

1H); ^{13}C NMR (50 MHz): 16.0, 22.6, 27.7, 28.1, 35.0, 35.1, 40.3, 45.2, 67.9, 72.0, 126.1, 136.0; MS: 196 (6, $M^{+\cdot}$), 120 (100). Anal. calcd. for $C_{12}H_{20}O_2$: C 73.41, H 10.29; found: C 73.27, H 10.10.

The second compound (**6**) was also a white solid, but was contaminated. ^{1}H NMR (200 MHz): 1.00 (t, 3H, J = 7.3 Hz), 1.27 (s, 3H), 1.32–2.33 (m, 18H, high due to contaminant), 3.00 (br s, 2H), 3.91 (br m, 1H), 5.34 (br s, 1H); ^{13}C NMR (50 MHz): 12.0, 22.7, 24.3, 28.0, 28.7, 35.4, 40.4, 42.1, 44.9, 66.0, 72.2, 124.0, 136.2; MS: No $M^{+\cdot}$, 192 (27, $M^{+\cdot} - H_2O$).

(1*RS*,5*RS*,6*RS*,8*RS*)-11-Oxatricyclo[6.2.1.0^{1,6}[undec-9-en-5-ol (3*g*) and (1*RS*,5*SR*,6*RS*,8*RS*)-11-oxatricyclo[6.2.1.0^{1,6}]undec-9-en-5-ol (7)

(a) Using DIBAL-H

Cycloadduct **1** (77.3 mg, 0.471 mmol) was placed in a N_2-purged three-neck round-bottom flask and dissolved in CH_2Cl_2 (10 mL). The solution was cooled using a −78°C cold bath, and DIBAL-H (1.10 mL of 1.0 M in THF, 1.10 mmol) was added by syringe. The reaction was warmed to 0°C, and then slowly warmed to room temperature and stirred for 22 h. Wet Et_2O (10 mL) and saturated aqueous NH_4Cl (10 mL) were then added to quench the reaction, and the mixture was filtered through Celite.® The Celite® was washed well with several portions of Et_2O. The aqueous layer was extracted with Et_2O (4 × 10 mL) and the combined organic layers were dried with anhydrous Na_2SO_4. The drying agent was removed by filtration, and the solvent was removed in vacuo to provide a crude reaction product. Flash column chromatography (3:1, then 1:1) provided **3***g* (13.2 mg, 0.0794 mmol) and **7** (29.0 mg, 0.174 mmol) in yields of 17 and 37%, respectively. A mixture of uncharacterized compounds (29.9 mg) was also isolated.

(b) Using lithium tert-butyldiisobutylaluminohydride

Cycloadduct **1** (71.0 mg, 0.432 mmol) was placed in a N_2-purged three-neck round-bottom flask and dissolved in THF (6 mL). The solution was cooled using a −78°C cold bath, and lithium *tert*-butyldiisobutylaluminohydride (0.65 mL of 1.0 M in THF, 0.65 mmol) was added by syringe. The mixture was stirred at −78°C until analysis by TLC indicated that the starting material had been consumed (15 min). Solid $Na_2SO_4 \cdot 10H_2O$ (274 mg, 0.850 mmol) was added, and the reaction was poured into a mixture of 0.5 M aqueous $KHSO_4$ (8 mL) and $CHCl_3$ (6 mL) and stirred for 15 min. The aqueous layer was extracted with $CHCl_3$ (4 × 10 mL). After the combined organic layers had been dried with anhydrous Na_2SO_4 and filtered, the solvent was removed in vacuo to give **3***g* (59.9 mg, 0.360 mmol) exclusively in 83% yield after purification by flash column chromatography (3:1). Compound **3***g* was characterized as a colorless oil, bp 44–50°C/0.08 Torr; IR (neat): 3493 cm^{-1}; ^{1}H NMR (200 MHz): 1.38 (dd, 1H, J = 8.1 Hz, J = 11.5 Hz), 1.43–2.08 (m, 6H), 2.17–2.33 (m, 2H), 3.08 (d, 1H, J = 8.2 Hz), 3.82–3.99 (br m, 1H), 4.90 (dd, 1H, J = 1.7 Hz, J = 4.9 Hz), 5.91 (d, 1H, J = 5.7 Hz), 6.47 (dd, 1H, J = 1.7 Hz, J = 5.7 Hz); ^{13}C NMR (50 MHz): 14.7, 27.9, 29.5, 32.0, 37.5, 67.2, 78.1, 87.6, 137.2, 138.8; MS: 166 (1, $M^{+\cdot}$), 94 (100). Exact Mass calcd. for $C_{10}H_{14}O_2$: 166.0994; found: 166.0980.

Compound **7** was characterized as a colorless oil, bp 40–50°C/0.08 Torr; IR (neat): 3392 cm^{-1}; ^{1}H NMR (200 MHz): 1.29–1.98 (m, 9H), 2.16–2.26 (m, 1H), 3.39 (ddd, 1H, J = 3.8 Hz, J = 9.2 Hz, J = 11.2 Hz), 4.95 (dd, 1H, J = 1.7 Hz, J = 4.5 Hz), 5.99 (d, 1H, J = 5.7 Hz), 6.38 (dd, 1H, J = 1.7 Hz, J = 5.7 Hz); ^{13}C NMR (50 MHz): 20.5, 28.2, 33.8, 34.8, 44.0, 76.0, 78.9, 88.3, 137.5, 137.8; MS: 166 (1, $M^{+\cdot}$), 94 (100). Exact Mass calcd. for $C_{10}H_{14}O_2$: 166.0994; found: 166.0996.

(1*RS*,2*SR*,9*RS*)-Bicyclo[4.4.0]dec-6-en-2,9-diol (2*g*) and (1*RS*,2*SR*,6*SR*,9*SR*)- or (1*RS*,2*SR*,6*RS*,9*SR*)-bicyclo[4.4.0]dec-7-en-2,9-diol (9)

Compound **3***g* (51.8 mg, 0.312 mmol) was placed in a N_2-purged three-neck round-bottom flask and dissolved in CH_2Cl_2 (10 mL). The solution was cooled using a −78°C cold bath, and DIBAL-H (3.20 mL of 1.0 M in THF, 3.20 mmol) was added by syringe. The reaction was warmed to 0°C, and then slowly warmed to room temperature and stirred for 66.5 h. Wet Et_2O (10 mL) and saturated aqueous NH_4Cl (10 mL) were then added to quench the reaction, and the mixture was filtered through Celite.® The Celite® was washed well with several portions of Et_2O. The aqueous layer was extracted with Et_2O (4 × 10 mL) and the combined organic layers were dried with anhydrous Na_2SO_4. The drying agent was removed by filtration, and the solvent was removed in vacuo to provide a crude reaction product. Flash column chromatography (1:5) provided 4-phenyl-1-butanol **8** (19.1 mg, 0.127 mmol), **2***g* (14.8 mg, 0.0880 mmol), and a third compound tentatively identified as **9** (16.2 mg, 0.0963 mmol, contaminated by **2***g*) in yields of 41, 28, and 31%, respectively. Compound **2***g* was characterized as a white solid. IR (KBr): 3395 cm^{-1}; ^{1}H NMR (200 MHz): 1.53–2.40 (m, 11H), 2.74 (br s, 2H), 3.89 (br s, 1H), 4.03 (m, 1H), 5.45 (br s, 1H); ^{13}C NMR (50 MHz): 20.9, 33.2, 2 × 33.8, 34.9, 40.8, 64.5, 71.3, 118.5, 136.0; MS: 168 (23, $M^{+\cdot}$), 55 (100). Exact Mass calcd. for $C_{10}H_{16}O_2$: 168.1150; found: 168.1148.

The impure sample of **9** was partially characterized. ^{13}C NMR (50 MHz) following elimination of signals due to **2***g*: 20.6, 32.2, 33.4, 34.5, 36.9, 44.1, 69.1, 70.3, 130.0, 134.7. 4-Phenyl-1-butanol **8** exhibited ^{1}H NMR (200 MHz): 1.30 (br s, 1H) 1.40–1.85 (m, 4H), 2.63 (t, 2H, J = 7 Hz), 3.69 (t, 2H, J = 7 Hz), 7.11–7.36 (m, 5H).

(1*RS*,5*RS*,6*RS*,8*RS*)-5-(*tert*-Butyldimethylsiloxy)-11-oxatricyclo[6.2.1.0^{1,6}]undec-9-ene (10)

Compound **3***g* (0.112 g, 0.676 mmol) was dissolved in dry DMF (2 mL) in a N_2-purged three-neck round-bottom flask. Freshly distilled TBDMSCl (0.369 g, 2.45 mmol) and imidazole (0.349 g, 5.13 mmol) were added, and the reaction was stirred at room temperature for 16 h. When analysis by TLC indicated that the reaction was complete, Et_2O (10 mL) and saturated aqueous NaCl (3 mL) was added. The organic layer was separated and washed with additional saturated aqueous NaCl (3 × 3 mL). After the organic phase had been dried with anhydrous Na_2SO_4 and filtered, the solvent was removed in vacuo. Purification by flash column chromatography (20:1) provided **10** (0.156 g, 0.554 mmol) as a colorless liquid in 82% yield; bp 50–60°C/0.06 Torr; IR (neat): 2900 cm^{-1}; ^{1}H NMR (200 MHz): 0.04 (s, 6H), 0.91 (s, 9H), 1.23 (dd, 1H, J = 8.3 Hz, J = 10.7 Hz), 1.35–1.57 (m, 3H), 1.80–2.12 (m, 4H), 2.22–2.28 (m, 1H), 4.03 (br m, 1H), 4.83 (dd, 1H, J = 1.6 Hz, J = 4.7 Hz), 5.96 (d, 1H, J = 5.6 Hz), 6.33 (dd, 1H, J = 1.6 Hz, J = 5.6 Hz); ^{13}C NMR (50 MHz): −5.2, −4.3, 15.1, 18.1, 25.8,

(1*RS*,2*SR*,8*RS*,9*RS*,10*RS*)-2,8-Dibutyl-10-methylbicyclo[4.4.0]dec-6-en-2,9-diol (15*a*)

General procedure 1 was used to prepare compound **15***a*. Cycloadduct **14** (30.3 mg, 0.170 mmol) was treated with *n*-butyllithium (0.20 mL of 2.5 M in hexanes, 0.50 mmol) for 16 h to give diol **15***a* (36.1 mg, 0.123 mmol) as a white solid in 72% yield following purification by flash column chromatography (5:1); mp 122–123°C; IR (KBr): 3198 cm^{-1}; ^1H NMR (200 MHz): 0.93–0.97 (d and two overlapping t, 9H, J = 7.3 Hz (for d)), 1.22–2.18 (m, 19H), 2.21–2.28 (m, 1H), 2.37 (dq, 1H, J = 2.7 Hz, J = 7.3 Hz), 3.55 (2 overlapping br s, 3H), 5.23 (br s, 1H); ^{13}C NMR (50 MHz): 14.1, 14.1, 20.5, 22.9, 23.0, 23.4, 26.5, 29.3, 31.1, 32.7, 35.6, 36.3, 37.2, 40.8, 50.1, 70.7, 74.7, 122.3, 135.0; MS: 294 (1, $M^{+\cdot}$), 174 (100). Exact Mass calcd. for $C_{19}H_{34}O_2$: 294.2559; found: 294.2566.

(1*RS*,5*RS*,6*RS*,7*SR*,8*SR*)-5,7-Dimethyl-11-oxatricyclo[6.2.1.0^{1,6}]undec-9-en-5-ol (16*b*)

Anhydrous Et_2O (2 mL) was placed in a N_2-purged three-neck round-bottom flask equipped with an addition funnel containing a solution of cycloadduct **14** (56.7 mg, 0.318 mmol) in anhydrous Et_2O (5 mL). The flask was cooled with an ice bath, and methyllithium (0.70 mL of 1.4 M in Et_2O, 0.98 mmol) and dry TMEDA (7.7 mL) were added. The solution of **14** was added dropwise from the addition funnel, and the reaction was warmed to room temperature and stirred for 312 h. Wet Et_2O (10 mL) and saturated aqueous NH_4Cl (10 mL) were added sequentially, and the aqueous layer was extracted with Et_2O (4 × 10 mL). The combined organic layers were washed with 10% aqueous $CuSO_4$ (2 × 30 mL), dried over anhydrous Na_2SO_4, and filtered. The solvent was removed from the filtrate in vacuo. Flash column chromatography (20:1 benzene:acetone) provided **16***b* (58.5 mg, 0.301 mmol) as a white solid in 95% yield; mp 41–42°C; IR (KBr): 3492 cm^{-1}; ^1H NMR (200 MHz): 0.92 (d, 3H, J = 7.1 Hz), 1.03 (d, 1H, J = 3.0 Hz), 1.18 (s, 3H), 1.30–1.97 (m, 5H), 2.10–2.24 (m, 1H), 2.71 (m, 1H), 3.33 (s, 1H), 4.72 (dd, 1H, J = 1.7 Hz, J = 4.9 Hz), 6.05 (d, 1H, J = 5.8 Hz), 6.43 (dd, 1H, J = 1.7 Hz, J = 5.8 Hz); ^{13}C NMR (50 MHz): 16.6, 18.1, 28.1, 29.0, 35.3, 38.5, 51.6, 69.7, 81.9, 88.9, 136.4, 138.7; MS: 194 (weak, $M^{+\cdot}$), 94 (100). Exact Mass calcd. for $C_{12}H_{18}O_2$: 194.1307; found: 194.1312.

(1*RS*,5*RS*,6*RS*,7*SR*,8*SR*)-7-Methyl-11-oxatricyclo[6.2.1.0^{1,6}]undec-9-en-5-ol (16*c*)

Cycloadduct **14** (51.0 mg, 0.286 mmol) was placed in a N_2-purged three-neck round-bottom flask and dissolved in THF (4 mL). The solution was cooled using a −78°C cold bath, and lithium *tert*-butyldiisobutylaluminohydride (0.43 mL of 1.0 M in THF, 0.43 mmol) was added by syringe. The mixture was stirred at −78°C until analysis by TLC indicated that the starting material had been consumed (50 min). Solid $Na_2SO_4 \cdot 10H_2O$ (150 mg, 0.466 mmol) was added, and the reaction was poured into a mixture of 0.5 M aqueous $KHSO_4$ (10 mL) and $CHCl_3$ (5 mL) and stirred for 30 min. The aqueous layer was extracted with $CHCl_3$ (4 × 10 mL). After the combined organic layers had been dried with anhydrous Na_2SO_4 and filtered, the solvent was removed in vacuo to give **16***c* (51.5 mg, 0.286 mmol) exclusively in 100% yield after purification by flash column chromatography (5:1). Compound **16***c* was characterized as a colorless oil, bp 45–50°C/0.05 Torr; IR (neat): 3501 cm^{-1}; ^1H NMR (200 MHz): 0.86 (d, 3H, J = 7.0 Hz), 1.14 (t, 1H, J = 3.6 Hz), 1.20–1.52 (m, 2H), 1.69–2.01 (m, 3H), 2.17–2.24 (m, 1H), 2.64–2.90 (overlapping m and br s, 2H), 3.99 (br t, 1H), 4.71 (dd, 1H, J = 0.9 Hz, J = 4.6 Hz), 6.01 (d, 1H, J = 5.8 Hz), 6.41 (dd, 1H, J = 0.9 Hz, J = 5.8 Hz); ^{13}C NMR (50 MHz): 14.5, 16.6, 28.2, 31.8, 35.7, 46.7, 66.1, 81.7, 88.3, 136.2, 138.5; MS: 180 (1, $M^{+\cdot}$), 94 (100). Exact Mass calcd. for $C_{11}H_{16}O_2$: 180.1150; found: 180.1151.

(1*S*,2*R*,4*S*,8*S*,9*S*,10*S*)-2,4,8,10-Tetramethylbicyclo[4.4.0]dec-6-en-2,9-diol ((+)-18)

Cycloadduct (−)-**17** (prepared according to ref. 1*c*) (123.8 mg, 0.644 mmol) was treated with methyllithium (14.0 mL of 1.4 M in Et_2O, 20 mmol) for 16 h according to general procedure 2. Integration of the alkene signals of the ^1H NMR spectrum of the crude reaction mixture showed the presence of (+)-**18** and a compound tentatively identified as the ethyl derivative **19** in a 3.5:1 ratio. Flash column chromatography (3:1) provided diol (+)-**18** (106.6 mg, 0.4751 mmol) as a white solid in 74% yield; mp 139.5–141°C; $[\alpha]_D^{23}$ +40.7 (*c* 3.08, $CHCl_3$); IR (KBr): 3253 cm^{-1}; ^1H NMR (200 MHz): 0.89, 0.98, and 1.07 (d, 3H each, J = 6.4 Hz, J = 7.3 Hz, J = 7.3 Hz), 1.22 (dd, 1H, J = 12.1 Hz, J = 13.5 Hz), 1.28 (s, 3H), 1.55–1.78 (m, 3H), 1.80–1.97 (m, 1H), 2.17–2.30 (m, 2H), 2.39 (dq, 1H, J = 3.2 Hz, J = 7.3 Hz), 3.47 (br m, 1H), 3.72 (br s, 2H), 5.14 (br s, 1H); ^{13}C NMR (50 MHz): 16.8, 20.7, 21.9, 28.3, 29.2, 30.3, 33.2, 44.7, 49.7, 51.7, 72.3, 72.5, 123.3, 134.8; MS: 224 (5, $M^{+\cdot}$), 107 (100). Exact Mass calcd. for $C_{14}H_{24}O_2$: 224.1776; found: 224.1774.

Compound **19** was detected by GC–MS. MS: 238 (3, $M^{+\cdot}$), 220 (15, $M^{+\cdot}$ − H_2O), 180 (31, retro Diels–Alder), 133 (100).

(1*RS*,2*RS*,3*RS*,4*RS*,8*RS*,10*SR*)-10-Methoxy-2,4,8,10-tetramethylbicyclo[4.4.0]-dec-5-en-3-ol (21)

Cycloadduct **20** (174.7 mg, 0.786 mmol) was treated with methyllithium (17.0 mL of 1.4 M in Et_2O, 24 mmol) for 16 h according to general procedure 2. Integration of the alkene signals of the ^1H NMR spectrum of the crude reaction mixture showed the presence of **21** and a compound tentatively identified as the ethyl derivative **23** in a 6.25:1 ratio. Flash column chromatography (3:1) provided **21** (114.5 mg, 0.480 mmol) as a viscous colorless oil in 61% yield. Since this compound was

prone to decomposition, it was not fully characterized; bp 70–80°C/0.05 Torr; ^{1}H NMR (200 MHz): 0.89, 0.98, and 1.08 (three d, 3H each, J = 6.1 Hz, J = 7.4 Hz, J = 7.3 Hz), 1.03 (overlapping with doublets, 1H), 1.24 (s, 3H), 1.58–1.74 (m, 3H), 1.95–2.04 (m, 1H), 2.16–2.27 (m, 2H), 2.39 (dq, 1H, J = 3.2 Hz, J = 7.4 Hz), 3.15 (s, 3H), 3.35 (br s, 1H), 4.83 (br s, 1H), 5.11 (br m, 1H); ^{13}C NMR (50 MHz): 17.2, 21.4, 21.8, 22.1, 28.4, 30.5, 33.6, 42.9, 44.6, 48.6, 52.5, 71.9, 77.2, 124.1, 133.8; MS: 238 (3, $M^{+\cdot}$), 99 (100).

Compound **23** was detected by GC–MS. MS: 252 (1, $M^{+\cdot}$), 237 (weak, $M^{+\cdot} - CH_3$), 220 (4, $M^{+\cdot}$ − MeOH), 202 (2, $M^{+\cdot}$ − MeOH − H_2O), 191 (6, $M^{+\cdot} - CH_3OH - CH_2CH_3$), 163 (7, $M^{+\cdot} - CH_3O$ retro Diels–Alder), 99 (100).

(1*RS*,2*RS*,3*RS*,4*RS*,8*RS*,10*SR*)-4-Butyl-10-methoxy-2,8,10-trimethylbicyclo[4.4.0]dec-5-en-3-ol (22)

Cycloadduct **20** (39.3 mg, 0.177 mmol) was treated with *n*-butyllithium (0.15 mL of 2.5 M in Et_2O, 0.38 mmol) for 6 h according to general procedure 1. Flash column chromatography (3:1) provided **22** (35.2 mg, 0.125 mmol) as a viscous colorless oil in 71% yield; bp 85–95°C/0.08 Torr; IR (neat): 3368 cm^{-1}; ^{1}H NMR (200 MHz): 0.89, 0.92, and 0.97 (overlapping d, t, and d, 9H, coupling for doublets J = 6.0 Hz, J = 7.4 Hz), 1.03 (dd, 1H, J = 11.6 Hz, J = 14.2 Hz), 1.24 (s, 3H), 1.29–1.74 (m, 9H), 1.96–2.05 (m, 2H), 2.21–2.27 (m, 1H), 2.36 (dq, 1H, J = 2.9 Hz, J = 7.4 Hz), 3.15 (s, 3H), 3.45 (dm, 1H, J = 9.2 Hz), 4.91 (d, 1H, J = 9.2 Hz), 5.18 (br s, 1H); ^{13}C NMR (50 MHz): 14.1, 21.4, 21.8, 22.1, 23.0, 28.4, 29.4, 31.4, 33.5, 35.8, 42.8, 44.7, 48.6, 52.8, 70.2, 77.2, 122.9, 133.8; MS: 280 (1, $M^{+\cdot}$), 99 (100). Exact Mass calcd. for $C_{18}H_{32}O_2$: 280.2402; found: 280.2410.

(1*RS*,2*SR*,3*SR*,4*SR*,8*SR*)-2,4,8-Trimethyl-10-methylidenebicyclo[4.4.0]dec-5-en-3-ol (25) and (1*RS*,2*SR*,3*SR*,4*SR*,8*SR*)-4-ethyl-2,8-dimethyl-10-methylidenebicyclo-[4.4.0]dec-5-en-3-ol (26)

Compound **24** (6) (1.027 g, 5.40 mmol) was treated with methyllithium (116 mL of 1.4 M in Et_2O, 162 mmol) for 24 h according to general procedure 2. Flash column chromatography (9:1) provided **25** (0.755 g, 3.66 mmol) and **26** (0.136 g, 0.615 mmol) in yields of 68 and 11%, respectively. Both compounds were relatively unstable and were therefore not fully characterized. Compound **25** was a viscous colorless oil that sometimes crystallized upon storage in the refrigerator; mp 61–62.5°C; ^{1}H NMR (200 MHz): 0.94, 0.98, and 1.08 (d, 3H each, J = 6.2 Hz, J = 7.0 Hz, J = 6.3 Hz), 1.36–1.61 (m, 2H), 1.75 (apparent br t composed of 2 overlapping br d at 1.72 and 1.78, 2H, J = 12.6 Hz, J = 12.2 Hz), 2.12–2.42 (m, 5H), 3.60 (dd, 1H, J = 4.8 Hz, J = 8.8 Hz), 4.76–4.79 (m, 2H), 5.28 (m, 1H); ^{13}C NMR (50 MHz): 14.9, 17.7, 22.1, 31.3, 33.8, 35.7, 44.1, 45.9, 50.1, 74.8, 106.1, 123.2, 137.6, 149.4; MS: 206 (2, $M^{+\cdot}$), 188 (27, $M^{+\cdot} - H_2O$), 173 (35, $M^{+\cdot} - H_2O - CH_3$), 148 (100, retro Diels–Alder).

Compound **26** was a viscous colorless oil. ^{1}H NMR (200 MHz): 0.98 and 1.05 (overlapping d and t, d, 9H, J = 6.2 Hz, J = 6.2 Hz, J = 6.3 Hz), 1.12–1.32 (m, 1H), 1.33–1.89 (m, 5H), 1.97–2.15 (br s, 1H), 2.20–2.48 (m, 4H), 3.65 (br s, 1H), 4.80 (br s, 2H), 5.33 (m, 1H); ^{13}C NMR (50 MHz): 11.9, 18.1, 22.1, 23.3, 31.9, 35.8, 40.1, 44.4, 46.0, 49.6, 73.9, 106.2, 121.2, 137.7, 149.7; MS: 220 (2, $M^{+\cdot}$), 202 (27, $M^{+\cdot} - H_2O$), 162 (100, retro Diels–Alder).

(1*RS*,2*RS*,3*RS*,4*RS*,8*SR*,10*SR*)-4-Ethyl-2,8,10-trimethylbicyclo[4.4.0]dec-5-en-3-ol from hydrogenation of 26

Compound **26** (51.8 mg, 0.235 mmol) was dissolved in a mixture of EtOH (10 mL) and benzene (1 mL) in a round-bottom flask. Platinum oxide hydrate (10 mg) was added, and the reaction vessel was evacuated with a water aspirator and back-purged with hydrogen three times. After the reaction had been stirred under a balloon atmosphere of hydrogen for 50 min at room temperature, the catalyst was removed by filtration and the reaction flask and catalyst were washed well with additional ethanol. The solvent was removed from the combined organic phases in vacuo to give the hydrogenated compound (52.2 mg, 0.235 mmol) as a white solid in 100% yield following purification by flash column chromatography (5:1). Sublimation point 64–70°C/0.05 Torr; IR (KBr): 3393 cm^{-1}; ^{1}H NMR (200 MHz): 0.80, 0.86, and 1.01 (d, 3H each, J = 7.0 Hz, J = 6.0 Hz, J = 6.2 Hz), 0.98 (t, 3H, J = 6.9 Hz), 1.05–1.27 (m, 2H), 1.42–1.82 (m, 7H), 2.03–2.22 (m, 3H), 3.50 (dd, 1H, J = 5.3 Hz, J = 10.7 Hz), 5.57 (dt, 1H, J = 1.7 Hz, J = 6.2 Hz); ^{13}C NMR (50 MHz): 12.2, 14.4, 15.9, 22.5, 22.8, 26.9, 30.3, 32.5, 42.4, 42.8, 44.0, 49.2, 75.5, 123.7, 136.9; MS: 222 (23, $M^{+\cdot}$), 204 (9, $M^{+\cdot} - H_2O$) 135 (100, $M^{+\cdot} - CH_2CH_3$ retro Diels–Alder). Exact Mass calcd. for $C_{15}H_{26}O$: 222.1984; found: 222.1975.

(1*RS*,2*RS*,3*RS*,4*RS*,8*SR*,10*SR*)-4-Ethyl-2,8,10-trimethylbicyclo-[4.4.0]dec-5-en-3-yl *p*-nitrobenzoate (27)

The hydrogenated compound produced above (33.3 mg, 0.150 mmol) was sublimed under reduced pressure (0.05 Torr) and dissolved in dry CH_2Cl_2 (5 mL) in a N_2-purged round-bottom flask. DMAP (27.9 mg, 0.228 mmol) and *para*-nitrobenzoyl chloride (41.7 mg, 0.225 mmol) were added to the flask and the reaction mixture was stirred at room temperature for 19 h. Et_2O (20 mL) and H_2O (5 mL) were added to the reaction, and the organic layer was washed with 1% aqueous HCl (3 mL) and 5% aqueous $NaHCO_3$ (5 mL). After the organic layer had been dried with anhydrous Na_2SO_4 and filtered, the solvent was removed in vacuo to provide ester **27** (55.5 mg, 0.149 mmol) as a slightly yellow solid in 99% yield after purification by flash column chromatography (9:1); mp 141–142°C; ^{1}H NMR (200 MHz): 0.85 and 0.87 (overlapping d and t, 6H, J = 6.8 Hz, J = 7.0 Hz), 0.97 (d, 6H, J = 6.6 Hz), 1.18–1.37 (m, 2H), 1.57–1.74 (m, 4H), 1.89–2.30 (m, 2H), 2.30–2.49 (m, 1H), 5.03 (dd, 1H, J = 5.4 Hz, J = 11.3 Hz), 5.59 (br d, 1H, J = 6.3 Hz), 8.21–8.34 (AA′BB′ m, 4H); ^{13}C NMR (50 MHz): 12.0, 14.4, 15.8, 22.5, 23.7, 26.8, 30.1, 30.4, 39.4, 42.6, 43.7, 48.9, 79.9, 122.8, 123.6, 130.6, 136.2, 137.1, 150.5, 164.2.

X-ray crystal structure data for compound 27

A sample of **27** was recrystallized from pentane to give slightly yellow plates, which were submitted for X-ray crystallographic analysis. Crystal data: empirical formula $C_{22}H_{29}NO_4$; space group $C2/c$ (no. 15); a = 10.678(7) Å, b = 9.076(8) Å; c = 42.37(2) Å; β = 93.24(5)°; V = 4099(4) Å^3; Z = 8; d = 1.204 g/cm^3; Mo-Kα radiation (−73°C); total of 3046 reflections in the range $0 < 2\theta < 50.1°$, of which 517 were used ($I > 3\sigma(I)$) in the structure solution; R = 0.108 and Rw = 0.119.

(1*RS*,8*RS*,9*SR*)-8-Butyl-9-hydroxy-1-methylbicyclo[4.4.0]dec-6-en-2-one (30*a*) and (1*RS*,2*SR*,8*RS*,9*SR*)-2,8-dibutyl-1-methylbicyclo[4.4.0]dec-6-en-2,9-diol (31*a*)

General procedure 1 was used to prepare compounds **30*a*** and **31*a***. Cycloadduct **29** (55.3 mg, 0.310 mmol) was treated with *n*-butyllithium (0.37 mL of 2.5 M in hexanes, 0.93 mmol) for 89 h to give ketone **30*a*** (45.1 mg, 0.191 mmol) and diol **31*a*** (7.6 mg, 0.026 mmol) in yields of 6 and 8%, respectively, following purification by flash column chromatography (3:1). Compound **30*a*** was a white solid, mp 55–57°C; IR (KBr): 3445, 1707, 1659 cm^{-1}; ^1H NMR (200 MHz): 0.88 (br m, 3H), 1.10–1.40 (m, 5H), 1.33 (s, 3H), 1.46 (dd, 1H, J = 2.6 Hz, J = 14.1 Hz), 1.50–1.80 (m, 2H), 1.78 (br s, 1H), 1.98–2.15 (m, 2H), 2.16–2.41 (m, 2H), 2.44–2.74 (overlapping m, 3H), 3.95–4.02 (m, 1H), 5.36 (poorly resolved dd, 1H, J = 1.4 Hz, J = 3.0 Hz); ^{13}C NMR (50 MHz): 14.0, 22.9, 26.0, 26.5, 29.4, 30.0, 30.5, 36.4, 37.7, 40.3, 51.0, 66.7, 125.6, 139.0, 214.5; MS: 236 (17, $M^{+\cdot}$), 192 (28, retro Diels–Alder), 137 (100). Exact Mass calcd. for $C_{15}H_{24}O_2$: 236.1776; found: 236.1768.

Compound **31*a*** was characterized as a white solid, mp 104–106°C; IR (KBr): 3348 cm^{-1}; ^1H NMR (200 MHz): 0.91 and 0.92 (two overlapping br t, 6H), 1.15 (s, 3H), 1.22–1.74 (m, 18H), 1.90–2.38 (m, 4H), 2.33 (dd, 1H, J = 8.0 Hz, J = 13.9), 3.89 (m, 1H), 5.41 (poorly resolved dd, 1H, J = 1.7 Hz, J = 3.8 Hz); ^{13}C NMR (50 MHz): 14.1, 14.2, 22.3, 23.0, 23.6, 25.4, 25.5, 29.6, 30.4, 31.3, 31.4, 34.6, 36.7, 40.4, 44.6, 67.3, 76.2, 125.5, 141.9; MS: 294 (1, $M^{+\cdot}$), 276 (8, $M^{+\cdot} - H_2O$), 41 (100). Exact Mass calcd. for $C_{19}H_{34}O_2$: 294.2559; found: 294.2534.

(1*RS*,5*RS*,6*RS*,8*RS*)-5,6-Dimethyl-11-oxatricyclo[6.2.1.0^{1,6}]undec-9-en-5-ol (32*b*)

Anhydrous Et_2O (2 mL) was placed in a N_2-purged three-neck round-bottom flask equipped with an addition funnel containing a solution of cycloadduct **29** (67.7 mg, 0.380 mmol) in anhydrous Et_2O (5 mL). The flask was cooled with an ice bath, and methyllithium (0.80 mL of 1.4 M in Et_2O, 1.1 mmol) and dry TMEDA (7.8 mL) were added. The solution of **29** was added dropwise from the addition funnel, and the reaction was warmed to room temperature and stirred for 312 h. Wet Et_2O (10 mL) and saturated aqueous NH_4Cl (10 mL), were then added sequentially, and the aqueous layer was extracted with Et_2O (4 × 10 mL). The combined organic layers were washed with 10% aqueous $CuSO_4$ (2 × 30 mL), dried over anhydrous Na_2SO_4, and filtered. The solvent was removed from the filtrate in vacuo. Flash column chromatography (20:1 benzene:acetone) provided **32*b*** (44.9 mg, 0.231 mmol) as a colorless oil in 61% yield; bp 40–50°C /0.07 Torr; IR (neat): 3457 cm^{-1}; ^1H NMR (200 MHz): 0.91 (d, 1H, J = 11.5 Hz), 0.96 (s, 3H), 1.10 (d, 3H, J = 1.1 Hz), 1.51–2.25 (m, 6H), 2.66 (dd, 1H, J = 5.2 Hz, J = 11.5 Hz), 4.42 (d, 1H, J = 1.1 Hz), 4.84 (dd, 1H, J = 1.7 Hz, J = 5.2 Hz), 6.04 (d, 1H, J = 5.8 Hz), 6.48 (dd, 1H, J = 1.7 Hz, J = 5.8 Hz); ^{13}C NMR (50 MHz): 16.7, 21.3, 25.5, 26.7, 34.7, 35.7, 44.3, 73.1, 78.6, 91.6, 137.6, 138.0; MS: 194 (weak, $M^{+\cdot}$), 176 (4, $M^{+\cdot} - H_2O$), 94 (100). Exact Mass calcd. for $C_{12}H_{18}O_2$: 194.1307; found: 194.1294.

(1*RS*,5*RS*,6*RS*,8*RS*)-6-Methyl-11-oxatricyclo[6.2.1.0^{1,6}]undec-9-en-5-ol (32*c*)

Cycloadduct **29** (56.4 mg, 0.316 mmol) was placed in a N_2-purged three-neck round-bottom flask and dissolved in THF (4 mL). The solution was cooled using a −78°C cold bath, and lithium *tert*-butyldiisobutylaluminohydride (0.48 mL of 1.0 M in THF, 0.48 mmol) was added by syringe. The mixture was stirred at −78°C until analysis by TLC indicated that the starting material had been consumed (30 min). Solid $Na_2SO_4 \cdot 10H_2O$ (150 mg, 0.466 mmol) was added, and the reaction was poured into a mixture of 0.5 M aqueous $KHSO_4$ (10 mL) and $CHCl_3$ (5 mL) and stirred for 30 min. The aqueous layer was extracted with $CHCl_3$ (4 × 10 mL). After the combined organic layers had been dried with anhydrous Na_2SO_4 and filtered, the solvent was removed in vacuo to give **32*c*** (57.0 mg, 0.316 mmol) exclusively in 100% yield after purification by flash column chromatography (5:1). Compound **32*c*** was characterized as a colorless oil, bp 45–50°C/0.05 Torr; IR (neat): 3488 cm^{-1}; ^1H NMR (200 MHz): 0.95 (overlapping s and d, 4 H, J = 11.4 Hz for d), 1.46–1.52 (m, 1H), 1.72–2.19 (m, 5H), 2.66 (dd, 1H, J = 5.2 Hz, J = 11.4 Hz), 3.27 (br s, 1H), 3.58 (br s, 1H), 4.82 (dd, 1H, J = 1.6 Hz, J = 5.2 Hz), 5.98 (d, 1H, J = 5.8 Hz), 6.50 (dd, 1H, J = 1.6 Hz, J = 5.8 Hz); ^{13}C NMR (50 MHz): 15.0, 22.4, 25.5, 28.5, 37.5, 40.5, 73.4, 78.2, 90.5, 136.6, 138.7; MS: 180 (1, $M^{+\cdot}$), 162 (3, $M^{+\cdot} - H_2O$), 94 (100). Exact Mass calcd. for $C_{11}H_{16}O_2$: 180.1150; found: 180.1154.

(1*RS*,2*SR*,8*RS*,9*SR*)-2,8-Dibutyl-9-methylbicyclo[4.4.0]dec-6-en-2,9-diol (36*a*) and (1*RS*,5*RS*,6*RS*,10*RS*)-5,10-dibutyl-8-methylbicyclo[4.4.0]dec-8-en-1,5-diol (37*a*)

General procedure 1 was used to prepare a mixture of compounds **36*a*** and **37*a***. Cycloadduct **35** (69.5 mg, 0.390 mmol) was treated with *n*-butyllithium (0.47 mL of 2.5 M in hexanes, 1.2 mmol) for 16 h to give compounds **36*a*** and **37*a*** in a 1.7:1 ratio based on the integration of the alkene signals at 5.50 and 5.23 ppm, respectively, in the crude ^1H NMR spectrum. These two compounds could not be separated by column chromatography. Fortunately, compound **36*a*** was slightly less soluble in a mixture of 1:1 petroleum ether:Et_2O so that washing the mixture of compounds with this solvent system provided a pure sample of **36*a*** (25.6 mg, 0.0869 mmol) along with a mixture of both compounds (66.0 mg, 0.224 mmol) in a combined yield of 80%. Attempts to secure a pure sample of **37*a*** through recrystallization were not successful.

Compound **36*a*** was characterized as a white solid, mp 132–133°C; IR (KBr): 3230 cm^{-1}; ^1H NMR (200 MHz): 0.92 and 0.93 (overlapping t, 6H, J = 7.0 Hz), 1.22 (s, 3H), 1.11–1.78 (m, 18H), 1.79–2.04 (overlapping m and dd, 3H, J = 4.7 Hz, J = 13.9 Hz for dd), 2.11–2.28 (m, 2H), 2.63 (br s, 1H), 5.50 (br s, 1H); ^{13}C NMR (50 MHz): 14.1, 14.1, 22.5, 23.0, 23.3, 26.2, 28.3, 29.9, 30.1, 30.1, 34.4, 35.0, 36.5, 43.5, 45.2, 69.7, 74.3, 125.2, 135.3; MS: 294 (3, $M^{+\cdot}$), 276 (49, $M^{+\cdot} - H_2O$), 174 (100). Exact Mass calcd. for $C_{19}H_{34}O_2$: 294.2559; found: 294.2559.

Since compound **37*a*** could not be purified, it was not characterized. The ^1H NMR spectrum showed signals at 1.75 (br s, 3H) and 5.23 (br s, 1H). The compound was detected by GC–MS. MS: 294 (100, $M^{+\cdot}$), 276 (78, $M^{+\cdot} - H_2O$), 258 (13, $M^{+\cdot} - 2H_2O$), 237 (17, $M^{+\cdot} - n$-Bu), 219 (41, $M^{+\cdot} - H_2O - n$-Bu), 201 (39, $M^{+\cdot} - 2H_2O - n$-Bu).

(1*RS*,2*RS*,8*RS*,9*SR*)-9-Methyl-2,8-di-(1-methylethyl)bicyclo[4.4.0]dec-6-en-2,9-diol (36*b*) and

For personal use only.

(1*RS*,5*SR*,6*RS*,10*RS*)-8-methyl-5,10-di-(1-methylethyl)bicyclo[4.4.0]dec-8-en-1,5-diol (37*b*)

A solution of isopropyllithium was prepared using the method of Gilman et al. (7) as described for compound **2***b*. Standardization against 2,5-dimethoxybenzyl alcohol (34) indicated that the supernatant was 0.22 M in isopropyllithium.

General procedure 1 was used to prepare a mixture of compounds **36***b* and **37***b*. Cycloadduct **35** (51.2 mg, 0.287 mmol) was treated with the prepared solution of isopropyllithium (5.6 mL of 0.22 M in pentane, 1.2 mmol) for 16 h to give compounds **36***b* and **37***b* in a 1.5:1 ratio based on the integration of the alkene signals at 5.43 and 5.23 ppm, respectively, in the crude ^{1}H NMR spectrum. Flash column chromatography (5:1) provided a pure sample of **37***b* (18.6 mg, 0.0698 mmol) and a mixture of **36***b* and **37***b* (54.2 mg, 0.203 mmol) in a combined yield of 95%.

An impure mixture of **36***b* containing approximately 15% of **37***b* was partially characterized. ^{1}H NMR (200 MHz, not including signals due to **37***b*): 0.88 (d, 3H, J = 7.1 Hz), 0.93 (d, 6H, J = 6.7 Hz), 1.01 (d, 3H, J = 7.0 Hz), 1.22 (s, 3H), 1.24–2.50 (m, 13H), 2.82 (br s, 1H), 5.43 (br s, 1H); ^{13}C NMR (50 MHz, not including signals due to **37***b*): 16.4, 17.4, 19.3, 22.4, 23.9, 26.8, 29.2, 29.5, 33.6, 34.9, 35.3, 42.4, 50.2, 70.1, 76.4, 121.9, 136.6; MS: 266 (1, $M^{+\cdot}$), 248 (7, $M^{+\cdot} - H_2O$), 230 (0.3, $M^{+\cdot} - 2H_2O$), 223 (1, $M^{+\cdot} - (CH_3)_2CH$), 43 (100).

Compound **37***b* was characterized as a white solid, mp 109–111°C; IR (KBr): 3430, 3373 cm^{-1}; ^{1}H NMR (200 MHz): 0.80, (d, 3H, J = 7.0 Hz), 0.88 (d, 3H, J = 6.6 Hz), 0.91 (d, 3H, J = 6.6 Hz), 0.96 (d, 3H, J = 7.0 Hz), 1.05–1.30 (m, 3H), 1.51–2.02 (m, 7H), 1.77 (br s, 3H), 2.02–2.41 (m, 3H), 3.95 (br s, 1H), 5.23 (br s, 1H); ^{13}C NMR (50 MHz): 15.7, 16.4, 17.4, 18.0, 23.4, 23.7, 25.3, 26.2, 29.0, 33.3, 35.0, 42.7, 51.8, 74.2, 75.8, 118.1, 135.1; MS: 266 (8, $M^{+\cdot}$), 248 (1, $M^{+\cdot} - H_2O$), 230 (0.3, $M^{+\cdot} - 2H_2O$), 223 (1, $M^{+\cdot} - (CH_3)_2CH$), 113 (100). Exact Mass calcd. for $C_{17}H_{30}O_2$: 266.2246; found: 266.2243.

(1*RS*,2*SR*,8*SR*,9*SR*)-2,8-Di(1,1-dimethylethyl)-9-methylbicyclo[4.4.0]dec-6-en-2,9-diol (36*c*), (1*RS*,5*RS*,6*SR*,10*SR*)-5,10-di-(1,1-dimethylethyl)-8-methylbicyclo[4.4.0]dec-8-en-1,5-diol (37*c*), and (1*RS*,6*SR*,7*RS*)-7-(1,1-dimethylethyl)-6-hydroxy-9-methylbicyclo[4.4.0]dec-8-en-2-one (34)

General procedure 1 was used to prepare a mixture of compounds **36***c*, **37***c*, and **34**. Cycloadduct **35** (56.4 mg, 0.316 mmol) was treated with *tert*-butyllithium (0.56 mL of 1.7 M in hexanes, 0.95 mmol) for 3 h at 0°C to give compounds **36***c*, **37***c*, and **34**. The ratio of **36***c*:(**37***c* and **34**) was 2.2:1 based on the integration of the alkene signals at 5.54 and 5.35 ppm, respectively, in the crude ^{1}H NMR spectrum. Flash column chromatography (9:1) provided a pure sample of **36***c* (31.7 mg, 0.108 mmol) and a mixture of **36***c* and **37***c* (19.1 mg, 0.0648 mmol) in a combined yield of 55%. Compound **34** (8.8 mg, 0.037 mmol) was also isolated in 12% yield.

Compound **36***c* was characterized as a white solid, mp 128–129°C; IR (KBr): 3439, 3362 cm^{-1}; ^{1}H NMR (200 MHz): 1.07 and 1.11 (two s, 9H each), 1.30 (s, 3H), 1.26–1.73 (m, 6H), 1.80–2.05 (m, 3H), 2.13–2.41 (m, 3H), 5.54 (m, 1H); ^{13}C NMR (50 MHz): 23.4, 27.7, 30.3, 32.6, 33.7, 35.2, 36.1, 38.6, 39.6, 44.2, 53.7, 72.8, 78.1, 125.5, 136.8; MS: no $M^{+\cdot}$, 276 (8, $M^{+\cdot} - H_2O$), 261 (0.5, $M^{+\cdot} - H_2O - CH_3$), 237 (0.5, $M^{+\cdot} - t$-Bu), 57 (100). Anal. calcd. for $C_{19}H_{34}O_2$: C 77.48, H 11.66; found: C 77.39, H 11.21.

X-ray crystal structure data for compound 36*c*

A sample of **36***c* was recrystallized from pentane to give colorless prisms that were submitted for X-ray crystallographic analysis. See Fig. 2 for the X-ray crystal structure. Crystal data: empirical formula $C_{19}H_{34}O_2$; space group $P2_1/c$ (no. 14); a = 8.715(3) Å; b = 20.215(4) Å; c = 9.866(3) Å; β = 94.01(2)°; V = 1733.9(8) Å^3; Z = 4; d = 1.128 g/cm^3; Mo-Kα radiation (−123°C); total of 3396 reflections in the range $0 < 2\theta < 50.1°$, of which 1941 were used ($I > 3\sigma(I)$) in the structure solution; R = 0.066 and Rw = 0.091.

Since compound **37***c* could not be purified, it was not characterized. The ^{1}H NMR spectrum showed signals at 1.02 and 1.08 (two s, 9H each), 1.78 (br s, 3H), and 5.35(br s, 1H).

Compound **34** was characterized as a white solid, mp 80–82.5°C; IR (KBr): 3501, 1703 cm^{-1}; ^{1}H NMR (200 MHz): 1.10 (s, 9H), 1.51–1.80 (m, 2H), 1.77 (br s, 3H), 1.88–2.56 (m, 8H), 2.67–2.81 (dm, 1H, J = 13.7 Hz), 5.35 (br s, 1H); ^{13}C NMR (50 MHz): 21.8, 23.8, 25.3, 30.6, 35.4, 37.7, 41.4, 54.8, 55.9, 78.6, 122.2, 133.0, 211.0; MS: 236 (2, $M^{+\cdot}$), 221 (1, $M^{+\cdot} - CH_3$), 218 (1, $M^{+\cdot} - H_2O$), 180 (15, $M^{+\cdot} - C_4H_8$), 109 (100). Exact Mass calcd. for $C_{15}H_{24}O_2$: 236.1776; found: 236.1774.

(1*RS*,5*RS*,6*RS*,8*RS*)-5,8-Dimethyl-11-oxatricyclo[6.2.1.0^{1,6}]undec-9-en-5-ol(38) and (1*RS*,5*RS*,6*RS*)-5-methyl-8-methylidenebicyclo[4.4.0]dec-9-en-1,5-diol (39)

Anhydrous Et_2O (2 mL) was placed in a N_2-purged three-neck round-bottom flask equipped with an addition funnel containing a solution of cycloadduct **35** (59.9 mg, 0.366 mmol) in anhydrous Et_2O (5 mL). The flask was cooled with an ice bath, and methyllithium (0.70 mL of 1.4 M in Et_2O, 0.98 mmol) and dry TMEDA (7.8 mL) were added. The solution of **35** was added dropwise from the addition funnel, and the reaction was warmed to room temperature and stirred for 53 h. Wet Et_2O (10 mL) and saturated aqueous NH_4Cl (10 mL) were then added sequentially, and the aqueous layer was extracted with Et_2O (4 × 10 mL). The combined organic layers were washed with 10% aqueous $CuSO_4$ (2 × 30 mL), dried over anhydrous Na_2SO_4, and filtered. The solvent was removed from the filtrate in vacuo. Flash column chromatography (5:1) provided **38** (22.1 mg, 0.114 mmol) and **39** (25.8 mg, 0.133 mmol) in yields of 31 and 36%, respectively.

Compound **38** was characterized as a colorless oil, bp 40–50°C/0.07 Torr; IR (neat): 3485 cm^{-1}; ^{1}H NMR (200 mHz): 1.12 (s, 3H), 1.15–1.62 (m, 4H), 1.63–1.98 (m, 3H), 1.61 (s, 3H), 2.21–2.34 (m, 2H), 3.46 (br s, 1H), 5.95 (d, 1H, J = 5.6 Hz), 6.30 (d, 1H, J = 5.6 Hz); ^{13}C NMR (50 MHz): 16.7, 28.2, 35.1, 38.6, 18.7, 28.9, 46.2, 69.4, 86.5, 88.2, 138.2, 141.8; MS: 194 (1, $M^{+\cdot}$), 176 (1, $M^{+\cdot} - H_2O$), 161 (1, $M^{+\cdot} - H_2O - CH_3$), 108 (100). Exact Mass calcd. for $C_{12}H_{18}O_2$: 194.1307; found: 194.1293.

Compound **39** was characterized as a light tan solid, mp 129–135°C (dec.); IR (KBr): 3456, 1634, 1597 cm^{-1}; ^{1}H NMR (200 MHz): 1.20 (s, 3H), 1.31–1.59 (m, 4H), 1.71–2.11 (m, 3H), 2.20–3.10 (overlapping m and br s, 4H), 4.96–4.99 (m, 2H), 5.64 and 6.16 (d, 1H each, J = 9.5 Hz); ^{13}C NMR (50 MHz): 17.1, 25.3, 38.2, 40.6, 27.6, 47.2, 69.8, 71.9, 114.2, 131.4, 134.2, 142.9; MS: 194 (4, $M^{+\cdot}$), 176 (17, $M^{+\cdot} - H_2O$),

Synthesis of 10-methyl-Δ^4-octalins by Diels–Alder reactions of 2*H*-thiopyran surrogates for 1-ethenyl-2-methylcyclohexene

Dale E. Ward and Yuanzhu Gai

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 88.146.161.215 on 09/08/12
For personal use only.

Abstract: Diels–Alder reactions of 1-ethenyl-2-methylcyclohexene derivatives could be a versatile route to a variety of natural product skeletons that possess a 10-methyldecalin substructure with additional substitution at C-8 and C-9. These dienes are unreactive due (in part) to the presence of the vinyl methyl group, which destabilizes the necessary s-*cis* conformation. The use of 2*H*-thiopyran diene surrogates for 1-ethenyl-2-methylcyclohexene is investigated. The desired Diels–Alder adducts were not obtained by reaction of 6,7,8,8a-tetrahydro-5,5-dimethyl-3-tris(1-methylethyl)silyloxy-1*H*-2-benzothiopyran (**7***c*) or 1,5,7,8-tetrahydrospiro[6*H*-2-benzothiopyran-6,2′-[1,3]dioxolane] (**17**) with *N*-phenylmaleimide. Reactions of 3-[2-(2-methyl-1,3-dioxolan-2-yl)ethyl]-4-[(tris(1-methylethyl)silyl)oxy]-2*H*-thiopyran (**19**) with maleimide, *N*-methylmaleimide, and *N*-phenylmaleimide under thermal conditions and with *N*-methylmaleimide, *N*-phenylmaleimide, 3-(propenoyl)-2-oxazolidinone, and methyl acrylate under Lewis acid mediated conditions ($EtAlCl_2$, $TiCl_4$) gave Diels–Alder adducts in moderate to good yields. In each case, those adducts were readily converted into products that are synthetically equivalent to Diels–Alder adducts of **17** with the same dienophiles. Desulfurization of those products gives 10-methyl-Δ^4-octalins (2,3,4,4a,5,6,7,8-octahydro-4a-methylnapthalenes) that are synthetically equivalent to hypothetical Diels–Alder adducts of 1-ethenyl-2-methylcyclohexene-5-one.

Key words: Diels–Alder, 2*H*-thiopyran, *cis*-substituted 1,3-diene surrogate, 1-ethenyl-2-methylcyclohexene, octahydro-4a-methylnapthalene derivatives.

Résumé : Les réactions de Diels–Alder des dérivés du 1-éthényl-2-méthylcyclohexène pourraient être des voies versatiles pour atteindre les squelettes de produits naturels comportant une sous-structure 10-méthyldécaline et des substituants additionnels en C-8 et en C-9. Ces diènes ne sont pas réactifs à cause (en partie) de la présence du groupe vinyle qui déstabilise la conformation s-*cis* nécessaire. On a étudié la possibilité d'utiliser un diène du 2*H*-thiopyrane comme substitut du 1-éthényl-2-méthylcyclohexène. On n'a pas obtenu les adduits de Diels–Alder désirés lors de la réaction de la *N*-phénylmaléimide avec le 6,7,8,8a-tétrahydro-5,5-diméthyl-3-tris(1-méthylethyl)silyloxy-1*H*-2-benzothiopyrane (**7***c*) ou avec le 1,5,7,8-tétrahydrospiro[6*H*-2-benzothiopyrane-6,2′-[1,3]dioxolane] (**17**). Les réactions du 3-[2-(2-méthyl-1,3-dioxolan-2-yl)éthyl]-4-[(tris(1-méthyléthyl)silyl)oxy]-2*H*-thiopyrane (**19**) avec les maléimide, *N*-méthylmaléimide et *N*-phénylmaléimide dans des conditions thermiques et avec les *N*-méthylmaléimide et *N*-phénylmaléimide, la 3-(propénoyl)-2-oxazolidinone et l'acrylate de méthyle dans des conditions catalysées par un acide de Lewis ($EtAlCl_2$, $TiCl_4$) ont permis d'obtenir des adduits de Diels–Alder avec de bons rendements. Dans chacun des cas, il a été possible de transformer facilement ces adduits en produits synthétiquement équivalents aux adduits de Diels–Alder du produit **17** avec les mêmes diénophiles. La désulfurisation de ces produits fournit les 10-methyl-Δ^4-octalines (2,3,4,4a,5,6,7,8-octahydro-4a-méthylnapthalenes) qui sont synthétiquement équivalentes aux adduits hypothétiques de Diels–Alder de la 1-éthényl-2-méthylcyclohexèn-5-one.

Mots clés : Diels–Alder, 2*H*-thiopyrane, substitut d'un 1,3-diène *cis*-substitué, 1-éthényl-2-méthylcyclohexène, dérivés octahydro-4a-méthylnapthalènes.

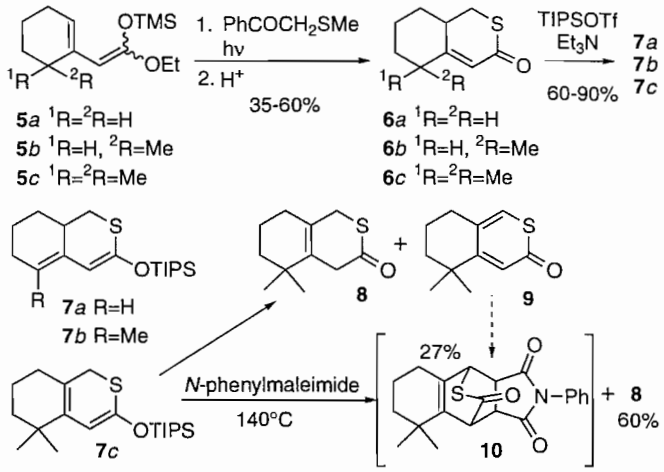
Scheme 1.

Scheme 2.



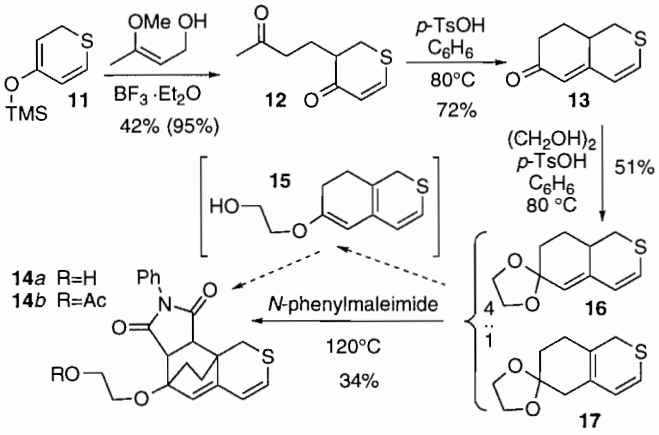
Introduction

The Diels–Alder reaction is perhaps the most powerful and versatile reaction in the synthetic chemist's arsenal (1). The increase in molecular complexity resulting from the simultaneous formation of two σ-bonds and up to four stereogenic centers coupled with the attributes of wide generality, atom economy, and predictable regio- and stereoselectivity contribute to the unrivaled synthetic utility of this reaction. The scope of this process is often limited by the poor reactivity associated with *cis*-substituted dienes (2) (Scheme 1). Recently, we have investigated the potential of 2*H*-thiopyrans to act as surrogates for *cis*-dienes in a strategy to overcome this limitation and thereby expand the scope of the Diels–Alder reaction (3). We have developed methods for the preparation of various substituted 2*H*-thiopyrans and have systematically investigated their Diels–Alder reactivity under a variety of conditions in both inter- (3*b*, 3*d*) and intra-molecular cases (3*g*). Adducts resulting from reactions of 2*H*-thiopyrans with dienophiles are, after desulfurization, synthetically equivalent to adducts from unreactive *cis*-dienes (3*a*, 3*g*).

Several structurally and biologically interesting natural products have substructures that incorporate a fused decalin ring system with a C-10 angular methyl group and alkyl substitution at C-8 and C-9 (**1**; e.g., drimanes, labdanes, triterpenes, steroids, etc.) (4). The most commonly employed synthetic approaches to this type of structure include Robinson annulation, polyene cyclization, or Diels–Alder reaction (5). These methods are not always compatible with the required substitution pattern of many of the target structures, often necessitating a linear multistep adjustment (5). For example, a Diels–Alder reaction of the generalized diene and dienophiles **2** and **3** could provide a versatile approach to these structures (Scheme 2). However, despite several attempts (6), this approach is successful only when $^1R = {}^2R$ =Me and only with certain dienophiles (e.g., dimethyl acetylenedicarboxylate, quinone). By contrast, to the best of our knowledge, there are no reports of successful Diels–Alder reaction of the diene **2** with $^1R = {}^2R$ = H. Dienes such as **2** can be regarded as *cis*-substituted and, as such, their low Diels–Alder reactivity can be attributed (in part) to the steric destabilization of the s-*cis* conformation. The modest success observed with **2** ($^1R = {}^2R$ = Me) is presumably due to the destabilization of the s-*trans* conformation by the geminal dimethyl group. We considered that the low reactivity of dienes such as **2** could be overcome by exploiting the chemistry of 2*H*-thiopyrans (e.g., **4**). Herein we report our preliminary results on the synthesis of 10-methyloctalins by Diels–Alder reactions of 2*H*-thiopyran surrogates of **2**.

Scheme 3.

Results and discussion



Our initial attempts at the synthesis of a 5,6,7,8-tetrahydro-1*H*-2-benzothiopyran (**4**) derivative involved the Diels–Alder reaction of the trimethylsilyl dienolate of cyclohexylideneacetate (**5***a*) with thioformaldehyde generated in situ according to the method of Vedejs et al. (7) to give the benzothiopyranone **6***a* after work-up (Scheme 3). Enolsilylation of **6***a* according to the usual protocol (3*b*) gave only the exocyclic diene **7***a*. The 5-methylbenzothiopyranone **6***b* was similarly prepared as a 1:1 mixture of diastereomers but also gave the exocyclic diene **7***b* upon enolsilylation. Reactions of the dienes **7***a* and **7***b* with *N*-phenylmaleimide in the presence of dichloromaleimide (8)[2] failed to give Diels–Alder adducts. Finally, treatment of the 5,5-dimethylbenzothiopyranone derivative **6***c* with triisopropylsilyl trifluoromethansulfonate (TIPSOTf) and Et_3N gave the unstable endocyclic diene **7***c*. Attempted Diels–Alder reaction of **7***c* with *N*-phenylmaleimide did not produce the expected product but gave an adduct tentatively identified as **10** in low yield. Subsequently, we found that **7***c* is rapidly converted into a mixture of **8** and **9** on standing and therefore presume that **10** resulted from the reaction of **9** (formed from **7***c* in situ) with the dienophile.

[2] Dichloromaleimide promotes diene isomerization (8) (cf. ref. 3*b*).

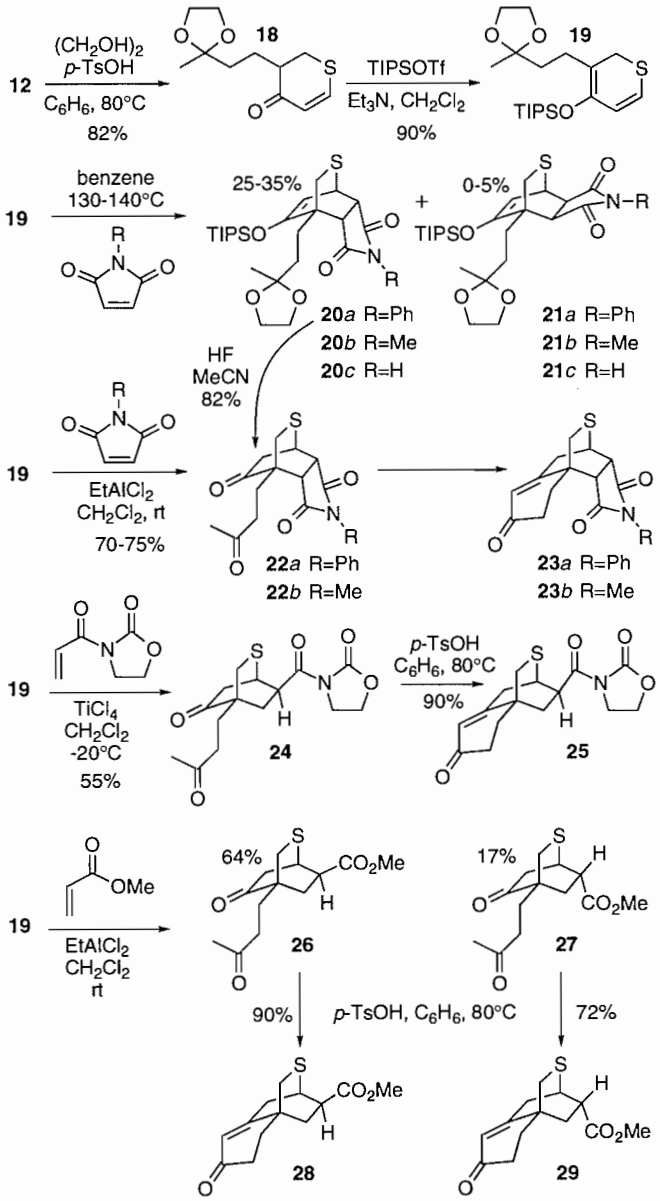
Scheme 4.

In an effort to form a more stable benzothiopyran derivative, the diene **11** (3b) was treated with 3-methoxy-2-butenol (9) and $BF_3{\cdot}Et_2O$ to give **12** (10) (Scheme 4). Cyclization of **12** under acidic conditions gave the dienone **13**, which, after reaction with ethylene glycol and 4-methylbenzenesulfonic acid (*p*-TsOH), gave a 4:1 mixture of the exocyclic and endocyclic dienes **16** and **17**, respectively. Reaction of the **16/17** mixture with *N*-phenylmaleimide again did not produce the expected adduct but gave **14***a* in 34% yield.[3] Although the mechanism is uncertain, the structure of **14***a* is consistent with a Diels–Alder reaction of the dienophile and the putative diene (i.e., **15**) resulting from elimination of the ethylene ketal in **16** and (or) **17**.

The failure of our 5,6,7,8-tetrahydro-1*H*-2-benzothiopyran derivatives **7***c* and **17** to undergo the expected Diels–Alder reactions led us to consider an alternative scenario where the desired adduct would result from an initial Diels–Alder reaction of a suitably substituted thiopyran diene followed by closure of the second carbocyclic ring (Scheme 5). Towards this end, the dione **12** was converted into the monoketal **18**, which, upon treatment with TIPSOTf and Et_3N, gave the diene **19**. Reaction of **19** with maleimide or *N*-substituted derivatives in benzene solution at 130–140°C gave ca. 7–10:1 mixtures (^{1}H NMR) of *endo* and *exo* Diels–Alder adducts **20** and **21**, respectively, in 30–35% yield.[4] The stereochemistry of the adducts was readily assigned, as previously (3*b*,*d*,*g*), based on the characteristic magnitudes of the H–H coupling constants observed for 2-thiabicyclo[2.2.2]octanes (see Fig. 1). Treatment of **20***a* with aqueous HF in acetonitrile provided the dione **22***a*, which, gratifyingly, underwent acid-catalyzed cyclization to **23***a* on heating with *p*-TsOH. The enone **23***b* was prepared analogously. Diels–Alder reactions of **19** with *N*-phenyl- and *N*-methylmaleimide in the presence of $EtAlCl_2$ gave the diones **22***a* and **22***b*, respectively, in good yields after acidic work-up (3*d*). Lewis acid mediated reactions of **19** with 3-propenoyl-2-oxazolidinone and with

Scheme 5.



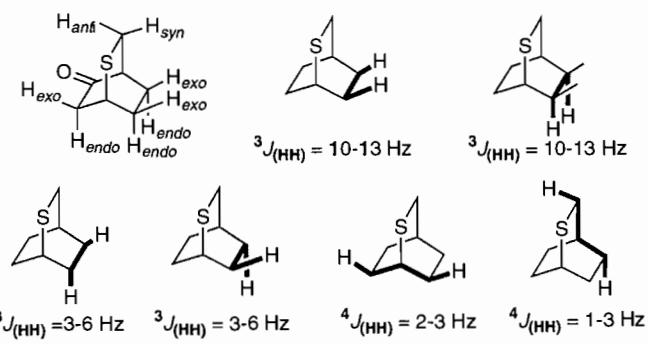


Fig. 1. Typical $^3J_{(HH)}$ and $^4J_{(HH)}$ coupling constants for 2-thiabicyclo[2.2.2]octan-5-ones.

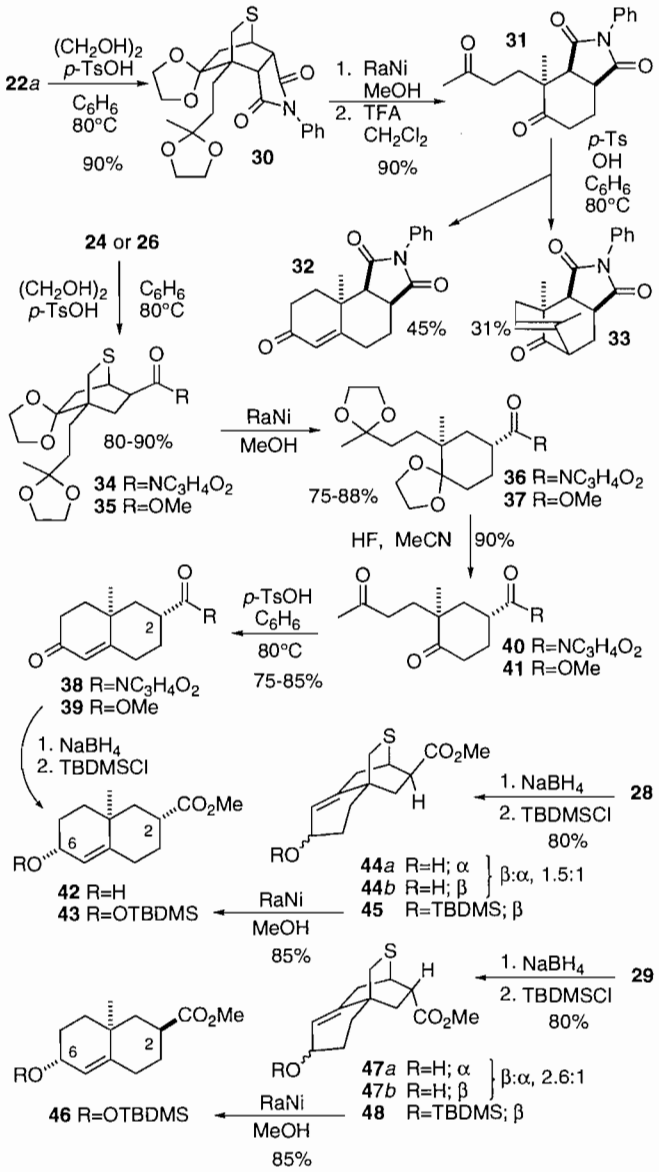

[3] The corresponding acetate **14***b* was also characterized.

[4] The *endo* adducts **20***a*,*b*,*c* were isolated and characterized. In each case, the corresponding *exo* adducts could be detected in the ^{1}H NMR spectra of the reaction mixtures (*endo*:*exo* ca. 7–10:1) but only **21***a* was isolated and characterized.

Scheme 6.

methyl acrylate were highly *exo*-selective in analogy with similar reactions with a less substituted thiopyran diene (cf. **11**) (3*d*). The product diones **24**, **26**, and **27** readily cyclized to the corresponding enones **25**, **28**, and **29**. The enones **23**, **25**, **28**, and **29** can be regarded as synthetically equivalent to Diels–Alder adducts of the 5,6,7,8-tetrahydro-1*H*-2-benzothiopyran derivative **17**.

Despite considerable experimentation, we were unable to cleanly obtain 10-methyl-Δ^4-octalin-3-one derivatives by direct desulfurization of the enones **23**, **25**, **28**, and **29** with Raney nickel or with nickel boride (11). In each case, a mixture of products was obtained in which reduction or migration of the double bond and (or) reduction or deoxygenation of the ketone had occurred in addition to desulfurization. This problem could be avoided by effecting desulfurization prior to the aldol cyclization (Scheme 6). Thus, acid-catalyzed reaction of **22***a* (or **20***a*) with ethylene glycol gave the bisketal **30**, which was smoothly desulfurized on treatment with Raney Ni to give the diketone **31** after an acidic work-up. Aldol condensation of **31** gave the desired **32** along with a substantial amount of the regioisomeric product **33**. Similarly, the diones **24** and **26** were subjected to the same series of reactions to obtain the desired 10-methyl-Δ^4-octalin-3-one derivatives **38** and **39**.[5] The expected *cis* stereochemistry for **38** and **39** was confirmed by the small vicinal coupling constants for HC-2 (numbering according to formal nomenclature)[5] in the respective ^{1}H NMR spectra, which clearly indicated an equatorial proton.[5]

Alternatively, the enones **28** and **29** were reduced with $NaBH_4$ in methanol to give, in each case, a diastereoisomeric mixture of alcohols **44***a*,*b* and **47***a*,*b*, respectively. The major alcohol isomers **44***b* and **47***b* were each converted into the corresponding *tert*-butyldimethylsilyl (TBDMS) ethers (**45** and **48**) and then desulfurized by treatment with Raney nickel to give the desired 10-methyl-Δ^4-octalin-3-one derivatives **43** and **46**,[5] respectively (Scheme 6).[6] The expected relative stereochemistry between the methyl and methoxycarbonyl groups was confirmed as *cis* for **43** and *trans* for **46** by the vicinal coupling constants observed for HC-2 in the ^{1}H NMR spectra; this proton was clearly equatorial in **43** and axial in **46**. The relative stereochemistry at C-6 in **43** (and thus in **45** and **44***a*,*b*) was determined by $NaBH_4$ reduction of **39** followed by formation of the TBDMS ether which gave a product (**43**) identical to that obtained from desulfurization of **45**. Ample literature precedent suggests that hydride reduction of Δ^4-octalin-3-one derivatives like **39** should selectively produce the alcohol with the hydroxyl group *cis* to the substituent at the ring junction (i.e., Me) (12). The stereochemistry at C-6 in **46** was assigned based on the close similarity of the HC-6 protons in the NMR spectra of **43** and **46** and on the assumption that the reductions of **28** and **29** occur with the same diastereofacial selectivity.

In summary, the 5,6,7,8-tetrahydro-1*H*-2-benzothiopyran derivatives **7***c* and **17**, prepared as surrogates for the unreactive 1-ethenyl-2-methylcyclohexene, failed to produce the desired Diels–Alder adducts. By contrast, the protected 2-oxobutyl-2*H*-thiopyran diene **19** reacted with maleimide and acrylate dienophiles to give adducts (**20**, **22**, **24**, **26**) in modest to good yields. The observed stereoselectivities, *endo* with maleimides and *exo* with acrylate dienophiles, are in accord with previous results obtained with less substituted 2*H*-thiopyran dienes like **11**. The Diels–Alder adducts are easily and efficiently converted into products that are synthetically equivalent to Diels–Alder adducts of **17**. Desulfurization of those products gives 10-methyl-Δ^4-octalin derivatives that are synthetically equivalent to hypothetical Diels–Alder adducts of 3-ethenyl-4-methyl-3-cyclohexenone. Depending on the scope and stereoselectivity of the Diels–Alder reactions of **19** and analogues, this approach should be applicable to the synthesis of a variety of natural product skeletons. We are actively investigating this strategy.

[5] Formally these are 1,2,3,4,6,7,8,8a-octahydro-8a-methyl-6-oxonaphthalene-2-carboxylic acid derivatives.

[6] Similar reaction of the minor alcohol isomers proceeded analogously; however, the products were not fully characterized in these cases.

Experimental

General methods

All solvents were distilled prior to use. Pyridine and Et_3N were distilled from CaH_2 and stored over KOH pellets. i-Pr_2NH was freshly distilled from CaH_2. Anhydrous solvents were distilled under argon as follows: ether and tetrahydrofuran (THF) from benzophenone potassium ketyl; benzene, toluene, and CH_2Cl_2 from P_2O_5 and stored over 3Å molecular sieves; MeOH from $Mg(OMe)_2$. Benzene solutions for Diels–Alder reactions were degassed by bubbling argon through the solvent (solution) followed by three freeze–thaw cycles under high vacuum (0.01 Torr; 1 Torr = 133.3 Pa). Unless otherwise noted, reactions were carried out under an atmosphere of argon and reaction temperatures refer to the bath. Concentration refers to removal of volatiles at water aspirator pressure on a rotary evaporator.

Preparative TLC was carried out on glass plates (20 × 20 cm) precoated (0.25 mm) with silica gel 60 F_{254}. Materials were detected by visualization under an ultraviolet lamp (254 nm) and (or) by treating a 1 cm vertical strip removed from the plate with a solution of phosphomolybdic acid (5%) containing a trace of ceric sulfate in aqueous sulfuric acid (5% v/v), followed by charring on a hot plate. Flash column chromatography (FCC) was performed according to the method of Still et al. (13) with Merck Silica Gel 60 (40–63 μm). Medium-pressure chromatography (MPC) was performed with minor modifications of the procedure reported by Taber (14). All mixed solvent eluents are reported as v/v solutions.

Spectral data

Low-resolution mass spectra (LRMS) were recorded on a magnetic scanning MS-12 instrument. EI ionization was accomplished at 70 eV and CI at 50 eV with ammonia as the reagent gas; only partial data are reported. IR spectra were recorded on a Fourier transform interferometer using a diffuse reflectance cell; only diagnostic peaks are reported. Unless otherwise noted, NMR spectra were measured in $CDCl_3$ solution at 300 MHz for ^1H and 75 MHz for ^{13}C. For ^1H NMR, residual $CHCl_3$ in $CDCl_3$ was employed as the internal standard (7.26 δ); for ^{13}C NMR, $CDCl_3$ was employed (77.0 δ). The ^1H NMR chemical shifts and coupling constants were determined assuming first-order behavior. Multiplicity is indicated by one or more of the following: s (singlet), d (doublet), t (triplet), q (quartet), m (multiplet), br (broad), ap (apparent); the list of coupling constants (J) corresponds to the order of the multiplicity assignment. ^1H NMR spectra were normally obtained with a digital resolution of 0.244 Hz/pt (sweep width = 4000 Hz, FID = 32 K data points) and coupling constants are reported to the nearest 0.5 Hz. The ^1H NMR assignments were made on the basis of chemical shift and multiplicity and were confirmed, where necessary, by homonuclear decoupling and (or) NOE experiments. The multiplicity of ^{13}C NMR signals refers to the number of attached H's (i.e., s = C, d = CH, t = CH_2, q = CH_3) and was determined by J-modulation (15). The ^{13}C assignments were made on the basis of chemical shift, multiplicity, and consistency within a series of similar structures. Assignments for ^{13}C signals of the same multiplicity and similar chemical shift (i.e., $\Delta\delta < 1$ ppm) are tentative. Elemental analyses were performed using a Perkin–Elmer 2400 CHN elemental analyzer.

Materials

2,2-Dimethylcyclohexanone (16), methyl phenacyl sulfide (17), 3-methoxy-2-butenol (9), **11** (3b), 3-propenoyl-2-oxazolidinone (18) were prepared as reported. Methyl acrylate was freshly distilled. All other reagents were commercially available and, unless otherwise noted, were used as received.

General procedure for preparation of ***5***

Ethyl cyclohexylidenethanoate and the 2′-methyl and 2′,2′-dimethyl derivatives were prepared in 60–70% yields by reactions of triethyl phosphonoacetate with the corresponding cyclohexanones according to the procedure of Wood and coworkers (19). Vinyl ketene acetals were prepared according to the procedure of Savard and Brassard (20): The esters (1–1.5 g) were added dropwise to a stirred solution of LDA (prepared from i-Pr_2NH (1.1 equiv.) and n-BuLi (1 equiv.)) in dry THF (1 mL/mmol of ester) at −78°C. After 1 h, TMSCl (1.5 equiv.) was added to the mixture at −78°C. The reaction mixture was allowed to slowly warm to room temperature (rt) and then was concentrated and the residue distilled to give the products.

*1-[2-Ethoxy-2-(trimethylsilyloxy)ethenyl]cyclohexene (****5****a)* (1 g, 80% yield): bp 95–100°C (3 Torr). ^1H NMR δ: 5.56 (1H, dd, J = 3, 3 Hz, HC-2), 4.08 (1H, s, HC-1′), 3.75 (2H, q, J = 7 Hz, H_2CO), 2.28–220 (2H, m), 2.12–2.00 (2H, m), 1.70–1.48 (4H, m), 1.28 (3H, t, J = 7 Hz, H_3CC), 0.22 (9H, s, H_3CSi).

*1-[2-Ethoxy-2-(trimethylsilyloxy)ethenyl]-6-methylcyclohexene, (****5****b)* (1.4 g, 75% yield): bp 95–100°C (2 Torr). ^1H NMR δ: 5.12 (1H, dd, J = 4, 4 Hz, HC-2), 3.98 (1H, s, HC-1′), 3.77 (2H, q, J = 7 Hz, H_2CO), 2.50–2.40 (1H, m), 2.07–1.98 (2H, m), 1.80–1.40 (4H, m), 1.26 (3H, t, J = 7 Hz, H_3CCH_2), 1.15 (3H, d, J = 7 Hz, H_3CC-6), 0.23 (9H, s, H_3CSi).

*1-[2-Ethoxy-2-(trimethylsilyloxy)ethenyl]-6,6-dimethylcyclohexene (****5****c)* (0.72 g, 62% yield): bp 92–95°C (3 Torr). ^1H NMR δ: 5.87 (1H, t, J = 4 Hz, HC-2), 4.00 (1H, s, HC-2′), 3.77 (2H, q, J = 7 Hz, H_2CO), 2.10–2.00 (2H, m, H_2C-3), 1.70–1.40 (6H, m), 1.29 (3H, t, H_3CCH_2), 1.02 (6H, s, H_3CC-6), 0.22 (9H, s, H_3CSi).

General procedure for the preparation of ***6***

A degassed solution of methyl phenacyl sulphide (19) (1 equiv.) and the ketene acetal **5** (2 equiv.) in dry benzene (5 mL/mmol of **5**) was irradiated at rt for 2 h through a 6% aqueous $CuSO_4$ filter using a 100 W sun lamp. Trifluoroacetic acid (TFA; several drops) was added to the mixture and, after stirring for 1.5 h at rt, the reaction mixture was concentrated and fractionated by FCC (15–30% ether in hexane) to give the products.

*1,5,6,7,8,8a-Hexahydro-3*H*-2-benzothiopyran-3-one, (****6****a)* (100 mg, 60% yield): IR ν_{max}: 2931, 1639, 1207, 1156 cm^{-1}; ^1H NMR δ: 5.93 (1H, dd, J = 2, 2 Hz, HC-4), 3.08–3.02 (2H, m, HC-1), 2.60–2.40 (2H, m, HC-5), 2.32–2.18 (1H, m, HC-8a), 2.08–1.83 (3H, m), 1.61–1.25 (3H, m); ^{13}C NMR δ: 189.9 (s, C-3), 163.9 (s, C-4a), 123.7 (d, C-4), 36.7 (d, C-8a), 36.1 (t, C-5), 33.1 (t), 33.0 (t), 26.4 (t), 25.2 (t); LRMS (EI), m/z (relative intensity): 168 ([M]$^+$, 15), 140 (100), 111 (28), 97 (24), 79 (26). General procedure for enolsilylation of thiopyranones
A solution of thiopyranone (1 equiv.), Et_3N (2.5 equiv.), and TIPSOTf (1.25 equiv.) in CH_2Cl_2 (ca. 10 mL/mmol of thiopyranone) was stirred under argon at rt for 0.5–3 h. The mixture was poured onto 5% Na_2CO_3 and extracted with ether (×3). The combined organic layers were dried over Na_2SO_4, concentrated, and fractionated by FCC (hexane; SiO_2 pretreated with Et_3N in hexane) to give the product. The dienol silyl ethers were freshly prepared and used immediately and the proposed structures were characterized only by ^1H NMR.

*6,7,8,8a-Tetrahydro-3-tris(1-methylethyl)silyloxy-1*H*-2-benzothiopyran (7*a*)* (3 h; 64 mg, 98%): ^1H NMR δ: 5.61 (1H, s, HC-4), 5.28 (1H, br s, HC-5), 2.73 (1H, dd, J = 11, 12 Hz, HC-1), 2.66 (1H, dd, J = 3.5, 12 Hz, HC-1), 2.48–2.33 (1H, m, HC-8a), 2.12–2.05 (2H, m, HC-6), 1.95–1.78 (2H, m), 1.68–1.51 (1H, m), 1.25–1.05 (21H, m).

*6,7,8,8a-Tetrahydro-5-methyl-3-tris(1-methylethyl)silyloxy-1*H*-2-benzothiopyran (7*b*)* (2 h; 15 mg, 72%): ^1H NMR δ: 5.90 (1H, s, HC-4), 2.72 (1H, dd, J = 12, 12 Hz, HC-1), 2.62 (1H, dd, J = 3.5, 12 Hz, HC-1), 2.42–2.38 (1H, m, HC-8a), 2.15–1.50 (6H, m), 1.66 (3H, br s, H_3CC-5).

*6,7,8,8a-Tetrahydro-5,5-dimethyl-3-tris(1-methylethyl)silyloxy-1H-2-benzothiopyran (7*c*)*
This diene was particularly unstable. Work-up of a reaction of **6***c* (5 mg, 0.025 mmol), Et_3N (0.02 mL, 0.15 mmol), and TIPSOTf (0.015 mL, 0.05 mmol) after 20 min gave a crude product that was a 1.8:1 mixture of **7***c* and **6***c*, respectively; ^1H NMR δ for **7***c*: 5.58 (1H, s, HC-4), 3.24 (1H, s, HC-1), 2.07 (2H, br t, J = 6 Hz, HC-8), 1.75–1.55 (2H, m), 1.48–1.40 (2H, m), 1.30–1.00 (21H, m, H_3CCHSi), 0.96 (6H, s, H_3CC-5). Fractionation by PTLC (66% ether in hexane) of the residue after concentration gave 5,6,7,8-tetrahydro-5,5-dimethyl-1*H*-2-benzothiopyran-3(4*H*)-one (**8**; 1.2 mg, 24%): ^1H NMR δ: 3.45 (2H, s, HC-1), 3.12 (2H, s, HC-4), 2.15 (2H, br t, J = 6 Hz, HC-8), 1.71–1.60 (2H, m), 1.52–1.45 (2H, m), 1.00 (6H, s, H_3C); and 5,6,7,8-tetrahydro-5,5-dimethyl-3*H*-2-benzothiopyran-3-one (**9**; 1.4 mg, 29%): ^1H NMR δ: 7.00 (1H, s, HC-1), 6.65 (1H, s, HC-4), 2.68 (2H, br t, J = 6 Hz, HC-8), 1.80–1.70 (2H, m), 1.67–1.57 (2H, m), 1.26 (6H, s, H_3C).

*Attempted Diels–Alder reaction of 7*c
Enolsilylation of **6***b* (8.8 mg, 0.045 mmol) for 30 min at rt gave an oil (14 mg) after work-up and fractionation. A solution of the oil and *N*-phenylmaleimide (8 mg, 0.045 mmol) in $C_6D_5CD_3$ (0.4 mL) was sealed in a NMR tube and heated at 140°C for 72 h. The mixture was concentrated and fractionated by PTLC (66% ether in hexane) to give **8** (4.7 mg, 60%) and a product tentatively indentified as 3a,4,5,6,7,8,9,9a-octahydro-5,5-dimethyl-2-phenyl-9,4-epithiomethano-1*H*-benz[*e*]isoindole-1,3(2*H*),11-trione (**10**; 4 mg, 27%): ^1H NMR δ: 7.16–7.50 (5H, m, Ar-H), 4.36 (1H, d, J = 4 Hz, HC-9), 4.20 (1H, d, J = 3 Hz, HC-4), 3.75 (1H, dd, J = 4, 9 Hz, HC-9a), 3.50 (1H, dd, J = 3, 9 Hz, HC-3a), 2.35–2.12 (2H, m, H_2C-8), 1.80–1.55 (2H, m), 1.50–1.40 (2H, m), 1.02 (3H, s, H_3C), 0.86 (3H, s, H_3C).

*3,4-Dihydro-3-(3-oxobutyl)-4*H*-thiopyran-4-one (**12**)*
A solution of $BF_3{\cdot}Et_2O$ (0.35 mL, 2.7 mmol) in dry ether (0.4 mL) was added dropwise to a stirred solution of **11** (2.8 g, 15 mmol) and 3-methoxy-2-butenol (9) (1.02 g, 10 mmol) in CH_3NO_2 (28 mL) at −20°C under argon. After 1 h, the reaction mixture was quenched by addition of saturated $NaHCO_3$ and was extracted with CH_2Cl_2 (×3). The combined organic layers were dried over Na_2SO_4, concentrated, and fractionated by FCC (75% ether in hexane) to give recovered starting material as 2,3-dihydro-4*H*-thiopyran-4-one (1 g, 58%) and **12** (10) (0.78 g, 42%): IR ν_{max}: 3033, 1712, 1657, 1583, 1551 cm^{-1}; ^1H NMR δ: 7.37 (1H, dd, J = 10 Hz, HC-6), 6.10 (1H, d, J = 10 Hz, HC-5), 3.33 (1H, dd, J = 4, 13.5 Hz, HC-2), 3.07 (1H, dd, J = 9, 13.5 Hz, HC-2), 2.58 (2H, t, J = 7.5 Hz, H_2C-2′), 2.59–2.50 (1H, m, HC-3), 2.16 (3H, s, H_3C-4′), 2.16–2.07 (1H, m, HC-1′), 1.88–1.79 (1H, m, HC-1′); ^{13}C NMR δ: 208.1 (s, C-3′), 195.5 (s, C-4), 145.4 (d, C-6), 122.9 (d, C-5), 44.3 (d, C-3), 40.8 (t, C-2′), 32.4 (t, C-2), 30.0 (q, C-4′), 22.8 (t, C-1′); LRMS (CI, NH_3), *m/z* (relative intensity): 185 ($[M+1]^+$, 100), 167 (34), 113 (18).

*1,7,8,8a-Tetrahydro-6*H*-2-benzothiopyran-6-one (**13**)*
A solution of **12** (0.184 g, 1 mmol) and *p*-TsOH (10 mg, 0.05 mmol) in benzene (10 mL) was heated under reflux for 4.5 h. The cooled (rt) reaction mixture was washed with 5% Na_2CO_3 and water, dried over Na_2SO_4, concentrated, and fractionated by FCC (75% ether in hexane) to give recovered **12** (26 mg, 14%) and **13** (0.12 g, 72%): IR ν_{max}: 3038, 1641, 1583, 1548 cm^{-1}; ^1H NMR δ: 6.73 (1H, d, J = 10 Hz, HC-3), 6.34 (1H, d, J = 10 Hz, HC-4), 5.78 (1H, s, HC-5), 2.85–2.75 (3H, m, H_2C-1, HC-8a), 2.56 (1H, ddd, J = 2.5, 4.5, 17 Hz, HC-7), 2.43 (1H, ddd, J = 5, 14, 17 Hz, HC-7), 2.22–2.12 (1H, m, HC-8), 1.82–1.68 (1H, m, HC-8); ^{13}C NMR δ: 198.7 (s, C-6), 153.6 (s, C-4a), 132.9 (d, C-3), 124.6 (d, C-4), 123.2 (d, C-5), 37.9 (t, C-7), 35.9 (d, C-8a), 31.3 (t, C-1 or C-8), 30.6 (t, C-8 or C-1); LRMS (EI), *m/z* (relative intensity): 166 ($[M]^+$, 100), 138 (36), 110 (98).

*3a,9b-Dihydro-4-[(2-hydroxyethyl)oxy]-9*H*-4,9a-ethanothiopyrano[3,4-e]isoindole-1,3(2*H*,4*H*)-trione (**14***a*)*
A solution of the 4:1 mixture of **16** and **17** (18 mg, 0.085 mmol) and *N*-phenylmaleimide (15 mg, 0.085 mmol) in C_6D_6 (0.5 mL) was sealed in a NMR tube and heated at 120°C. After 87 h, ^1H NMR revealed the absence of **16** and **17**. The solution was concentrated and fractionated by FCC (ethyl acetate) to

For personal use only.

give **13** (4 mg, 28%) and **14***a* (11 mg, 34%): IR ν_{max}: 3411, 1703, 1497 cm^{-1}; ^1H NMR δ: 7.38–7.29 (3H, m, Ar-H), 7.05–7.00 (2H, m, Ar-H), 6.30 (1H, d, *J* = 9.5 Hz, HC-7), 6.23 (1H, d, *J* = 9.5 Hz, HC-6), 5.87 (1H, s, HC-5), 4.16 (1H, d, *J* = 13 Hz, HC-3b), 3.90–3.68 (4H, m, H_2CO), 3.34 (1H, d, *J* = 8.5 Hz, HC-9), 2.99 (1H, d, *J* = 8.5 Hz, HC-9), 2.49 (1H, d, *J* = 13 Hz, HC-9b), 2.33–2.20 (1H, m, HC-10 or HC-11), 2.10–1.95 (1H, m, HC-10 or HC-11), 1.65–1.48 (2H, m, HC-10, HC-11); ^{13}C NMR δ: 175.4 (s, C=O), 174.0 (s, C=O), 135.4 (s, C-5a), 131.9 (s, C_6H_5), 128.5 (d ×2, C_6H_5), 128.0 (d, C_6H_5), 126.6 (d ×2, C_6H_5), 126.6 (d, C-7), 123.5 (d, C-5 or C-6), 123.4 (d, C-5 or C-6), 78.3 (s, C-4), 64.1 (t, CH_2O), 60.5 (t, CH_2O), 48.2 (d, C-3a), 44.6 (d, C-9b), 40.6 (s, C-9a), 30.4 (t, C-9), 27.9 (d, C-10 or C-11), 27.5 (t, C-10 or C-11); LRMS (CI, NH_3), *m/z* (relative intensity): 384 ($[M+1]^+$, 100), 210 (38).

*2-[(1,2,3,3a,4,9b-Hexahydro-1,3-dioxo-9*H*-4,9a-ethanothiopyrano[3,4-*e*]isoindol-4-yl)oxy]ethyl ethanoate (**14***b*)*

A solution of **14***a* (9 mg, 0.023 mmol), pyridine (1 drop), and acetic anhydride (2 drops) in CH_2Cl_2 (ca. 1 mL) was stirred at rt for 38 h. The mixture was diluted with CH_2Cl_2, washed with 1 N HCl and water, dried over Na_2SO_4, and concentrated from toluene (×2) to give **14***b* (9 mg, 92%); IR ν_{max}: 3062, 1773, 1735, 1701, 1596, 1497 cm^{-1}; ^1H NMR δ: 7.46–7.30 (3H, m, Ar-H), 7.18–7.11 (2H, m, Ar-H), 6.38 (1H, d, *J* = 10 Hz, HC-7), 6.30 (1H, d, *J* = 10 Hz, HC-6), 5.97 (1H, s, HC-5), 4.36 (1H, d, *J* = 13 Hz, HC-3a), 4.34–4.28 (2H, m, H_2COCO), 4.07–4.00 (1H, m, HCO), 3.85–3.77 (1H, m, HCO), 3.35 (1H, d, *J* = 8.5 Hz, HC-9), 3.02 (1H, d, *J* = 8.5 Hz, HC-9), 2.54 (1H, d, *J* = 13 Hz, HC-9b), 2.33–2.24 (1H, m, HC-10 or HC-11), 2.08 (3H, s, H_3CCO), 2.06–1.95 (1H, m, HC-10 or HC-11), 1.62–1.45 (2H, m, HC-10, HC-11); ^{13}C NMR δ: 175.3 (s, C=O), 173.3 (s, C=O), 171.3 (s, O=CCH_3), 136.2 (s, C-4a), 131.7 (s, C_6H_5), 129.1 (d ×2, C_6H_5), 128.6 (d, C_6H_5), 126.5 (d ×2, C_6H_5), 126.3 (d, C-7), 124.9 (d, C-5 or C-6), 123.5 (d, C-5 or C-6), 79.1 (t, CH_2O), 63.7 (t, CH_2O), 61.3 (s, C-4), 49.0 (d, C-3a), 45.4 (d, C-9b), 41.5 (s, C-9a), 32.0 (t, C-9), 28.9 (t, C-10 or C-11), 28.4 (t, C-10 or C-11), 21.0 (q, CH_3CO); LRMS (CI, NH_3), *m/z* (relative intensity): 426 ($[M+1]^+$, 24), 87 (100).

*1,7,8,8a-Tetrahydrospiro[6*H*-2-benzothiopyran-6,2′-[1,3]dioxolane] (**16**) and 1,5,7,8-tetrahydrospiro[6*H*-2-benzothiopyran-6,2′-[1,3]dioxolane] (**17**)*

A solution of **13** (50 mg, 0.3 mmol), ethylene glycol (ca. 0.1 mL), and pyridinium *p*-toluenesulfonate (PPTS, 3 mg) in benzene (1 mL) was heated under reflux for 2 h. The cooled (rt) reaction mixture was diluted with benzene, washed with 5% Na_2CO_3 and water, dried over Na_2SO_4, concentrated, and fractionated by FCC (75% ether in hexane) to give recovered **13** (12 mg, 24%) and product as a 4:1 mixture of **16** and **17** (32 mg, 51%): IR ν_{max}: 3019, 1629, 1373, 1124 cm^{-1}; ^1H NMR δ for **16**: 6.24 (1H, dd, *J* = 1.5, 10 Hz, HC-3), 6.14 (1H, d, *J* = 10 Hz, HC-4), 5.36 (1H, br s, HC-5), 4.05–3.85 (4H, m, H_2CO), 2.77 (1H, d, *J* = 12.5 Hz, HC-1), 2.66 (1H, ddd, *J* = 1.5, 3.5, 12.5 Hz, HC-1), 2.58–2.46 (1H, m, HC-8a), 2.03–1.78 (3H, m, H_2C-7, HC-8), 1.57 (1H, m, HC-8); δ for **17**: 6.15 (1H, d, *J* = 10 Hz, HC-3), 5.89 (1H, d, *J* = 10 Hz, HC-4), 3.18 (2H, br s, H_2C-1), 2.71 (2H, s, H_2C-5); ^{13}C NMR δ for **16**: 138.4 (s, C-4a), 124.0 (d, C-3), 123.8 (d, C4 or C-5), 123.6 (d, C5 or C-4), 106.3 (s, C-6), 64.9 (t, CH_2O), 64.4 (t, CH_2O), 36.3 (d, C-8a), 34.0 (t, C-1), 31.6 (t, C-7), 28.8 (t, C-8); LRMS (CI, NH_3), *m/z* (relative intensity): 211 ($[M+1]^+$, 100), 182 (20), 163 (8), 138 (22), 110 (15).

*3,4-Dihydro-3-[2-(2-methyl-1,3-dioxolan-2-yl)ethyl]-4*H*-thiopyran-4-one (**18**)*

A solution of **12** (230 mg, 1.25 mmol), ethylene glycol (0.5 mL, excess), and PPTS (20 mg) in benzene (15 mL) was heated under reflux for 2 h. The cooled (rt) reaction mixture was washed with 5% Na_2CO_3 and water, dried over Na_2SO_4, and concentrated to give an oil (this was a mixture of mono- and bis-ketals). The oil was dissolved in acetone that contained several drops of water and stirred with PPTS (20 mg) for 2 h. The mixture was concentrated, diluted with ether, washed with 5% Na_2CO_3 and water, dried over Na_2SO_4, concentrated, and fractionated by FCC (75% ether in hexane) to give **18** (234 mg, 82%): IR ν_{max}: 1658, 1551, 1060 cm^{-1}; ^1H NMR δ: 7.45 (1H, d, *J* = 10 Hz, HC-6), 6.12 (1H, d, *J* = 10 Hz, HC-5), 3.99–3.87 (4H, m, H_2CO), 3.31 (1H, dd, *J* = 3.5, 13.5 Hz, HC-2), 3.05 (1H, dd, *J* = 9, 13.5 Hz, HC-2), 2.58–2.48 (1H, m, HC-3), 2.02–1.92 (1H, m, HC-1′), 1.80–1.55 (3H, m, HC-1′,H_2C-2′), 1.24 (3H, s, H_3C); ^{13}C NMR δ: 195.9 (s, C-4), 145.1 (d, C-6), 123.0 (d, C-5), 109.6 (s, C-2″), 64.7 (t, CH_2O), 64.6 (t, CH_2O), 45.1 (d, C-3), 36.2 (t, C-2), 31.8 (t, C-2′), 23.9 (q, CH_3), 22.7 (t, C-1′); LRMS (CI, NH_3), *m/z* (relative intensity): 229 ($[M+1]^+$, 100), 87 (66). Elemental anal. calcd. for $C_{11}H_{16}O_3S$: C 57.87, H 7.06, found: C 58.06, H 7.05.

*3-[2-(2-Methyl-1,3-dioxolan-2-yl)ethyl]-4-[(tris(1-methylethyl)silyl)oxy]-2*H*-thiopyran (**19**)*

TIPSOTf (0.24 mL, 0.90 mmol) was added to a stirred solution of **18** (171 mg, 0.75 mmol) and Et_3N (0.32 mL, 2.2 mmol) in CH_2Cl_2 (8 mL) at rt. After 20 min, the reaction mixture was concentrated and fractionated by FCC (pentane; silica gel pretreated with 10% v/v Et_3N in pentane) to give **19** (260 mg, 90%): IR ν_{max}: 1657, 1611, 1463, 1223 cm^{-1}; ^1H NMR δ: 6.18 (1H, d, *J* = 9.75 Hz, HC-6), 5.94 (1H, d, *J* = 9.75 Hz, HC-5), 3.99–3.90 (4H, m, H_2CO), 3.30 (2H, s, H_2C-2), 2.39–2.30 (2H, m, H_2C-1′), 1.80–1.70 (2H, m, H_2C-2′), 1.16 (3H, s, H_3CC-2″), 1.20–1.00 (21H, m, $(H_3C)_2CHSi$); ^{13}C NMR δ: 144.0 (s, C-4), 122.9 (d, C-6), 122.3 (d, C-5), 109.8 (s, C-3′), 107.0 (s, C-3), 64.7 (t ×2, CH_2O), 37.0 (t, C-2), 29.4 (t, C-1′), 24.6 (t, C-2′), 23.9 (q, CH_3C-2″), 18.0 (q, CH_3CHSi), 13.2 (d, CHSi); LRMS (CI, NH_3), *m/z* (relative intensity): 385 ($[M+1]^+$, 100), 227 (76).

*General procedure for thermal Diels–Alder reactions of **19** with maleimides*

A solution of **19** (0.07–0.15 g), BHT (0.1 equiv.), and the maleimide derivative (1.2 equiv.) in C_6D_6 or C_6H_6 (0.5–1 mL) was sealed in an NMR tube and heated at 130–140°C for 48–72 h. ^1H NMR of the reaction mixture indicated the presence of a 7–10:1 mixture of *endo*:*exo* adducts. The cooled (rt) solution was concentrated and fractionated by FCC (50% ethyl acetate in hexane) to give the adduct(s).

*General procedure for $EtAlCl_2$ mediated Diels–Alder reactions of **19** with maleimides*

$EtAlCl_2$ (1 M solution in hexane; 1 equiv.) was added to a stirred solution of the dienophile (1.2 equiv.) in dry CH_2Cl_2 (20 mL/mmol of **19**) at rt. A solution of **19** (20–50 mg; 1 equiv.) in CH_2Cl_2 (10 mL/mmol of **19**) was added via a

For personal use only.

syringe to the mixture and, after 1 h, the reaction was quenched by addition of saturated aqueous $NaHCO_3$. The mixture was extracted with CH_2Cl_2 and the combined organic layers were dried over Na_2SO_4 and concentrated. The enol ethers **20** could be obtained by fractionation of the residue by FCC (75% ether in hexane); however, because some hydrolysis could usually be detected at this point, it was convenient to complete the hydrolysis by dissolving the residue in CH_2Cl_2 (2 mL) containing TFA (2 drops). After stirring overnight, the mixture was concentrated and fractionated by FCC (ether) to provide **22**.

General procedure for aldol cyclodehydration of 1,5-diones

A solution of dione and *p*-TsOH (0.05–0.15 equiv.) in C_6H_6 (ca. 20 mL/mmol of dione) was heated under reflux. When the reaction was complete (TLC), the cooled (rt) mixture was diluted with C_6H_6, washed with 5% Na_2CO_3 and water, dried over Na_2SO_4, concentrated, and fractionated by FCC (25–50% ethyl acetate in hexane or ether) to provide the product.

To a stirred solution of 3-propenoyl-2-oxazolidinone (40 mg, 0.03 mmol) in CH_2Cl_2 (2 mL) at −20°C was added $TiCl_4$ (0.2 M solution in CH_2Cl_2; 1 mL, 0.2 mmol). A solution of **19** (92 mg, 0.24 mmol) in CH_2Cl_2 (2 mL) was added to the mixture. After 1 h, the reaction was quenched by addition of 1 N HCl. The mixture was diluted with CH_2Cl_2, washed with saturated $NaHCO_3$, dried over Na_2SO_4, concentrated, and fractionated by FCC (50% ethyl acetate in hexane) to give **12** (9 mg, 20%), the Michael adduct 3-[3,4-dihydro-3-(3-oxobutyl)-4-oxo-2*H*-thiopyran-3-yl]propanoyl-2-oxazolidinone (5 mg, 6%):[7] IR ν_{max}: 1775, 1707, 1698, 1652, 1560, 1388 cm^{-1}; ^{1}H NMR δ: 7.30 (1H, dd, J = 1, 10 Hz, HC-6″), 6.03 (1H, d, J = 10 Hz, HC-5″), 4.41 (2H, ap t, J = 8 Hz, H_2C-5), 4.00 (2H, ap t, J = 8 Hz, H_2C-4), 3.27 (1H, d, J = 13.5 Hz, HC-2″), 3.03 (1H, dd, J = 1, 13.5 Hz, HC-2″), 2.98–2.75 (2H, m, H_2C-2′), 2.56–2.28 (2H, m, H_2C-2‴), 2.17–2.05 (2H, m, H_2C-1‴), 2.13 (3H, s, H_3C-4‴), 1.99–1.82 (2H, m, H_2C-1′); ^{13}C NMR δ: 207.7 (s, C-3‴), 196.4 (s, C-4″), 172.7 (s, C-1′), 153.5 (s, C-2), 144.9 (d, C-6″), 122.8 (d, C-5″), 62.1 (t, C-5), 44.9 (s, C-3″), 42.6 (t, C-4), 38.0 (t, C-2‴), 36.1 (t, C-2′), 30.0 (t, C-2″), 27.7 (t, C-1‴ or C-3′), 26.3 (t, C-1‴ or C-3′); LRMS (CI, NH_3), *m/z* (relative intensity): 343 ([M+18]$^+$, 25), 326 ([M+1]$^+$, 100), 254 (29), 239 (28), 183 (71); and the *exo* Diels–Alder adduct **24** (43 mg, 55%): IR ν_{max}: 2919, 1775, 1768, 1721, 1692, 1650 cm^{-1}; ^{1}H NMR δ: 4.47 (2H, ap t, J = 8.5 Hz, H_2C-5), 4.22–4.00 (3H, m, H_2C-4, HC-6′), 3.52 (1H, ddd, J = 3, 3, 6.5 Hz, HC-1′), 2.93 (1H, d, J = 11 Hz, HC-3′$_{syn}$), 2.85 (2H, d, J = 3 Hz, HC-7′), 2.71 (1H, dd, J = 3, 11 Hz, HC-3′$_{anti}$), 2.61 (1H, dd, J = 5, 14 Hz, HC-5′$_{exo}$), 2.51 (2H, ap t, J = 8 Hz, HC-2″), 2.16 (3H, s, H_3C-4″), 1.93–1.80 (2H, m, HC-1″), 1.73 (1H, ddd, J = 3, 10.5, 14 Hz, HC-5′$_{endo}$); ^{13}C NMR δ: 211.8 (s, C-8′), 207.8 (s, C-3″), 172.0 (s, O=CC-6′), 153.4 (s, C-2), 62.4 (t, C-5), 48.5 (t, C-4), 44.2 (s, C-4′), 43.8 (d, C-6′), 43.1 (t, C-7′), 38.4 (t, C-2″), 36.7 (d, C-1′), 31.6 (t, C-3′), 29.9 (q, CH_3), 28.3 (t, C-1′), 28.1 (t, C-5); LRMS (EI), *m/z* (relative intensity): 325 ([M]$^+$, 44), 307 ([M−H_2O]$^+$, 11), 267 (46), 191 (28), 88 (39), 43 (100).

*General procedure for preparation of bisketals **30**, **34**, and **35***
A solution of the dione, ethylene glycol (10–25 equiv.), and *p*-TsOH (0.05–0.15 equiv.) in benzene (ca. 25 mL/mmol of dione) was heated under reflux for 1.5–2 h. When the reaction was complete (TLC), the cooled (rt) mixture was diluted with C_6H_6, washed with 5% Na_2CO_3 and water, dried over Na_2SO_4, concentrated, and fractionated by FCC (10–20% ethyl acetate in hexane) to give product.

*(3a*S**, 4*R**, 7*R**, 7a*S**)-1,2,3,3a,4,6,7,7a-Octahydro-7-[2-(2-methyl-1,3-dioxolan-2-yl)ethyl]-1,3-dioxo-2-phenylspiro-[4,7-ethanothiopyrano[3,4-c]pyrrole-8,2′-*[1,3]dioxolane] (**30**) (70 mg, 93% from **22***a*): IR ν_{max}: 2980, 1775, 1710, 1597, 1498, 1382, 1183 cm^{-1}; ^1H NMR δ: 7.48–7.20 (5H, m, C_6H_5), 3.95–3.83 (8H, m, H_2CO), 3.53 (1H, ddd, J = 1.5, 3, 10 Hz, HC-3a), 3.38 (1H, ddd, J = 3, 3, 3 Hz, HC-4), 3.08 (1H, d, J = 10 Hz, HC-7a), 2.99 (1H, d, J = 11.5 Hz, HC-6_{syn}), 2.84 (1H, d, J = 11.5 Hz, HC-6_{anti}), 2.45–2.10 (4H, m, H_2C-2′, H_2C-9), 1.65–1.55 (2H, m, H_2C-1′), 1.38 (3H, s, H_3C); ^{13}C NMR δ: 175.8 (s ×2, C═O), 132.3 (s, C_6H_5), 129.2 (d ×2, C_6H_5), 128.6 (d, C_6H_5), 126.6 (d ×2, C_6H_5), 110.2 (s, C-8 or C-2′), 108.5 (s, C-8 or C-2′), 65.5 (t, CH_2O), 65.0 (t, CH_2O), 64.6 (t ×2, CH_2O), 47.1 (d, C-3a), 43.6 (t, C-9), 42.7 (s, C-7), 41.9 (d, C-7a), 32.8 (t), 31.9 (d, C-4), 28.1 (t), 24.1 (t), 23.7 (q, CH_3); LRMS (EI), *m/z* (relative intensity): 445 ($[M]^+$, 63), 430 (23), 400 (65), 383 (100), 358 (20).

General procedure for Raney Ni desulfurization
A suspension of sulfide and W2 Raney Ni (21) (ca. 1–3 mL/mmol of sulfide) in methanol (ca. 20 mL/mmol of sulfide) was heated under reflux for 2–4 h. When the reaction was complete (TLC), the mixture was filtered through Celite and the combined filtrate and washings were concentrated and, if necessary, fractionated FCC (ethyl acetate in hexane or ether) to give the product.

*(3a*S**,4*S**,7a*S**)-3a,6, 7,7a-Tetrahydro-4-methyl-4-(3-oxobutyl)-2-phenylisoindole-1,3,5(2*H*,4*H*)-trione (**31**)* The crude product from desulfurization of **30** (55 mg, 0.12 mmol) was dissolved in CH_2Cl_2 (3 mL) containing TFA (several drops) and stirred at rt overnight. The mixture was concentrated and fractionated by FCC (10% ethyl acetate in ether) to give **31** (36 mg, 92%): IR ν_{max}: 2972, 1774, 1708, 1497, 1380, 1193 cm^{-1}; ^1H NMR δ: 7.53–7.26 (5H, m, Ar-H), 3.38–3.28 (1H, m, HC-7a), 3.12 (1H, d, J = 10 Hz, HC-3a), 2.70–2.40 (5H, m), 2.40–2.20 (1H, m), 2.20–2.05 (1H, m), 2.09 (3H, s, H_3C-4′), 1.70–1.60 (1H, m), 1.39 (3H, s, H_3CC-4); ^{13}C NMR δ: 211.5 (s, C-5), 209.0 (s, C-3′), 177.5 (s, C═O), 175.7 (s, C═O), 131.7 (s, C_6H_5), 129.3 (d ×2, C_6H_5), 128.9 (d, C_6H_5), 126.5 (d ×2, C_6H_5), 48.4 (s, C-4), 48.0 (d, C-3a), 38.6 (d, C-7a), 37.7 (t), 36.7 (t), 30.1 (q, C-4′), 27.4 (t), 21.5 (q, CH_3C-4), 19.7 (t); LRMS (EI), *m/z* (relative intensity): 327 ($[M]^+$, 21), 299 (17), 271 (20), 270 (21), 257 (33), 187 (44), 110 (46), 95 (29), 43 (100).

CH_3CN (2 mL) was stirred at rt for 30 min. The mixture was diluted with CH_2Cl_2, washed with 5% Na_2CO_3 and water, dried over Na_2SO_4, concentrated, and fractionated by PTLC (10% ethyl acetate in ether) to give **41** (14 mg, 94%): IR ν_{max}: 2954, 1732, 1709, 1435, 1200 cm^{-1}; ^1H NMR δ: 3.68 (3H, s, J = 3.5, 12.5 Hz, H_3CO), 3.00 (1H, dddd, J = 3.5, 3.5, 12.5, 12.5 Hz, HC-1), 2.60–2.00 (7H, m), 2.11 (3H, s, H_3C-4′), 1.90–1.70 (2H, m), 1.66–1.54 (1H, m), 1.00 (3H, s, H_3CC-3); ^{13}C NMR δ: 213.5 (s, C-4), 207.6 (s, C-3′), 174.9 (s, OC═O), 52.0 (q, CH_3O), 47.1 (s, C-3), 42.0 (t), 37.9 (t), 37.8 (d, C-1), 37.2 (t), 30.7 (t), 30.1 (q, C-4′), 29.2 (t), 21.9 (q, CH_3C-3′); LRMS (CI, NH_3), *m/z* (relative intensity): 258 ([M+18]$^+$, 33), 241 ([M+1]$^+$, 100).

*Methyl (2*R**, 6*R**, 8a*S**)-1,2,3,4,6,7,8,8a-octahydro-8a-methyl-6-[(dimethyl(1,1-dimethylethyl)silyl)oxy]naphthalene-2-carboxylate (**43**)*

Method A: $NaBH_4$ (2 mg, 0.05 mmol) was added to a solution of **39** (2 mg, 0.009 mmol) in 50% CH_3OH – CH_2Cl_2 (0.8 mL) and the mixture was stirred at rt for 30 min. The mixture was diluted with CH_2Cl_2, washed with water, dried over Na_2SO_4, and concentrated to give the crude alcohol (2 mg). A solution of the alcohol, TBDMSCl (3.4 mg, 0.022 mmol), and imidazole (1.2 mg, 0.018 mmol) in CH_2Cl_2 (0.6 mL) was stirred at rt for 16 h. The mixture was diluted with CH_2Cl_2, washed with water, dried over Na_2SO_4, and concentrated to give the crude TBDMS ether (3 mg), which was identical by TLC and by ^1H NMR with the product obtained from **45** as described below.

Method B: (16 mg, 85% from desulfurization of **45**): IR ν_{max}: 2932, 1735, 1471, 1204, 1158, 1130 cm^{-1}; ^1H NMR δ: 5.26 (1H, br s, HC-5), 4.25–4.18 (1H, m, HC-6), 3.69 (3H, s, H_3CO), 2.65–2.58 (1H, m, HC-2), 2.52–2.38 (1H, m, HC-4), 2.26 (1H, dddd, J = 2.5, 2.5, 2.5, 13 Hz, HC-3), 2.14 (1H, ddd, J = 2.5, 2.5, 13.5 Hz, HC-1), 1.95–1.85 (1H, m, HC-4), 1.81–1.70 (1H, m, HC-7), 1.60–1.25 (5H, m), 0.98 (3H, s, H_3CC), 0.90 (9H, s, $(H_3C)_3$), 0.08 (3H, s, H_3CSi), 0.07 (3H, s, H_3CSi); ^{13}C NMR δ: 176.1 (s, C═O), 144.2 (s, C-4a), 125.3 (d, C-5), 69.0 (d, C-6), 51.5 (q, CH_3O), 42.9 (t, C-1), 37.8 (d, C-2), 37.4 (t), 35.0 (s, C-8a), 29.0 (t), 28.8 (t), 28.0 (t), 26.0 (q, $(CH_3)_3$), 23.9 (q, CH_3C), 18.4 (s, CSi), −4.4 (q, CH_3Si), −4.5 (q, CH_3Si); LRMS (EI), *m/z* (relative intensity): 338 ([M]$^+$, 14), 281 (54), 207 (20), 147 (100), 105 (36), 91 (35), 75 (54).

*Methyl (3*R**, 6*S**, 8a*R**, 10*R**)-3,4,7,8-tetrahydro-6-hydroxy-6H-3,8a-ethano-1H-2-benzothiopyran-10-carboxylate (**44**a)*

$NaBH_4$ (ca. 10 mg, 0.26 mmol) was added in one portion to a stirred solution of **26** (32 mg, 0.13 mmol) in 50% CH_3OH in CH_2Cl_2 (3 mL) at rt. The mixture was stirred for 30 min and then was diluted with CH_2Cl_2, washed with water, dried over Na_2SO_4, concentrated, and fractionated by MPC (40% ethyl acetate in hexane) to give **44***b* (17.5 mg, 54%) and **44***a* (12 mg, 37%): IR ν_{max}: 3388, 2930, 1736, 1666, 1434, 1203, 1180 cm^{-1}; ^1H NMR δ: 5.63 (1H, ddd, J = 2, 2, 3.5 Hz, HC-5), 4.21–4.15 (1H, m, HC-6), 3.74 (3H, s, CH_3O), 3.21 (1H, ddd, J = 3, 3, 3 Hz, HC-3), 2.96 (1H, ddd, J = 3, 6, 11 Hz, HC-10), 2.85–2.75 (2H, m, H_2C-4), 2.70 (1H, dd, J = 2.5, 10.5 Hz, HC-1_{anti}), 2.56 (1H, d, J = 10.5 Hz, HC-1_{syn}), 2.23 (1H, dd, J = 6, 13.5 Hz, HC-9_{exo}), 1.90 (1H, m, HC-7), 1.79 (1H, ddd, J = 3, 11, 13.5 Hz, HC-9_{endo}), 1.68–1.54 (2H, m, HC-7, HC-8), 1.47–1.34 (1H, m, HC-8); ^{13}C NMR δ: 173.8 (s, OC═O), 141.1 (s, C-4a), 125.3 (d, C-5), 65.2 (d, C-6), 52.1 (q, CH_3O), 44.9 (d, C-10), 38.5 (t, C-4), 34.9 (d, C-3), 34.4 (t, C-1), 33.3 (t), 32.3 (s, C-8a), 31.2 (t), 28.8 (t); LRMS (EI), *m/z* (relative intensity): 254 ([M]$^+$, 52), 223 (11), 192 (12), 175 (21), 147 (100), 134 (76), 131 (38), 91 (74).

*Methyl (3*R**, 6*R**, 8a*R**, 10*R**)-3,4,7,8-tetrahydro-6-hydroxy-6H-3,8a-ethano-1H-2-benzothiopyran-10-carboxylate (**44**b)*: IR ν_{max}: 3383, 2931, 1731, 1666, 1433, 1201, 1012 cm^{-1}; ^1H NMR δ: 5.62 (1H, br s, HC-5), 4.22–4.13 (1H, m, HC-6), 3.74 (3H, s, H_3CO), 3.20 (1H, ddd, J = 3, 3, 3 Hz, HC-3), 2.97 (1H, ddd, J = 3, 5, 11 Hz, HC-10), 2.85 (1H, br d, J = 17.5 Hz, HC-4), 2.70–2.65 (2H, m, HC-1_{anti}, HC-4), 2.61 (1H, d, J = 10 Hz, HC-1_{syn}), 2.21 (1H, dd, J = 5.5,13.5 Hz, HC-5_{exo}), 1.95–1.84 (1H, m, HC-7), 1.58 (4H, m, HC-5_{endo}, HC-7, H_2C-8); ^{13}C NMR δ: 173.8 (s, OC═O), 140.9 (s, C-4a), 125.7 (d, C-5), 65.9 (d, C-6), 52.0 (q, CH_3O), 45.0 (d, C-10), 38.5 (t), 34.7 (d, C-3), 34.6 (t), 33.2 (t), 32.2 (s, C-8a), 32.0 (t), 29.0 (t); LRMS (EI), *m/z* (relative intensity): 254 ([M]$^+$, 70), 236 (78), 223 (19), 147 (87), 129 (93), 91 (100).

*Methyl (3*R**, 6*R**, 8a*R**, 10*R**)-3,4,7,8-tetrahydro-6-[(dimethyl(1,1-dimethylethyl)silyl)oxy]-6H-3,8a-ethano-1H-2-benzothiopyran-10-carboxylate (**45**)*

A solution of **44***b* (17 mg, 0.067 mmol), TBDMSCl (25 mg, 0.17 mmol), and imidazole (9 mg, 0.13 mmol) in CH_2Cl_2 (3 mL) was stirred at rt for 20 h. The mixture was diluted with CH_2Cl_2, washed with water, dried over Na_2SO_4, concentrated, and fractionated by FCC (10% ether in hexane) to give **45** (21.5 mg, 87%). IR ν_{max}: 2949, 1741, 1666, 1434, 1213, 1109, 1071 cm^{-1}; ^1H NMR δ: 5.49 (1H, br s, HC-5), 4.22–4.13 (1H, m, HC-6), 3.74 (3H, s, H_3CO), 3.17 (1H, ddd, J = 3, 3, 3 Hz, HC-3), 2.99 (1H, ddd, J = 3, 5, 11 Hz, HC-10), 2.90–2.80 (2H, m, HC-1_{anti}, HC-4), 2.69 (1H, ddd, J = 3, 5, 17 Hz, HC-4), 2.58 (1H, d, J = 10 Hz, HC-1_{syn}), 2.23 (1H, dd, J = 5, 13.5 Hz, HC-9_{exo}), 1.85–1.74 (1H, m, HC-7), 1.65–1.38 (4H, m, HC-7, H_2C-8, HC-9_{endo}), 0.89 (9H, s, $(H_3C)_3C$), 0.07 (3H, s, H_3CSi), 0.07 (3H, s, H_3CSi); ^{13}C NMR δ: 173.9 (s, OC═O), 138.8 (s, C-4a), 127.1 (d, C-5), 67.1 (d, C-6), 52.1 (q, CH_3O), 45.3 (d, C-10), 38.4 (t), 34.8 (d, C-4), 34.7 (t), 33.6 (t), 32.8 (t), 32.0 (t, C-8a), 29.4 (t), 26.0 (q, $(CH_3)_3$), 18.3 (s, $C(CH_3)_3$), −4.5 (q, CH_3Si); LRMS (EI), *m/z* (relative intensity): 368 ([M]$^+$, 17), 353 (32), 337 (100).

*Methyl (2*S**, 6*R**, 8a*S**)-1,2,3,4,6,7,8,8a-octahydro-8a-methyl-6-[(dimethyl(1,1-dimethylethyl)silyl)oxy]naphthalene-2-carboxylate (**46**)* (5 mg, 87% from desulfurization of **48**): IR ν_{max}: 2933, 1738, 1471, 1435, 1251, 1160, 1078 cm^{-1}; ^1H NMR δ: 5.26 (1H, br s, HC-5), 4.26–4.18 (1H, m, HC-6), 3.66 (3H, s, H_3CO), 2.67 (1H, dddd, J = 3.5, 3.5, 12.5, 12.5 Hz, HC-2), 2.28–2.12 (1H, m, HC-4), 2.10–1.95 (2H, m, HC-1, HC-4), 1.85–170 (2H, m, HC-1, HC-3), 1.65–1.30 (5H, m), 1.12 (3H, s, H_3CC), 0.90 (9H, s, $(H_3C)_3$), 0.09 (3H, s, CH_3Si), 0.08 (3H, s, CH_3Si); ^{13}C NMR δ: 176.2 (s, C═O), 142.8 (s, C-4a), 125.8 (d, C-5), 68.9 (d, C-6), 51.6 (q, CH_3O), 44.4 (t, C-1), 39.4 (d, C-2), 37.4 (t), 34.7 (s, C-8a), 31.1 (t), 30.6 (t), 29.2 (t), 26.0 (q, $(CH_3)_3$), 23.8 (q, CH_3C), 18.4 (s, CSi), −4.4 (q, CH_3Si), −4.6 (q, CH_3Si); LRMS (CI, NH_3), *m/z* (relative intensity): 339 ([M+1]$^+$, 2), 282 (5), 208 (100).

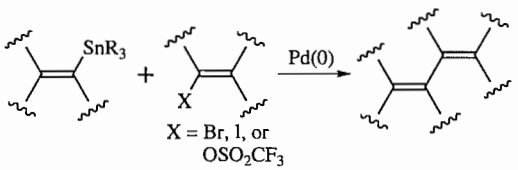
Copper(I) chloride-mediated oxidative coupling of alkenyltrialkylstannyl functions: efficient stereocontrolled syntheses of uniquely functionalized conjugated diene systems

Edward Piers, Ernest J. McEachern, Miguel A. Romero, and Patricia L. Gladstone

Abstract: Treatment of the β-trialkylstannyl α,β-unsaturated esters **1–9** with 2.5 equivalents of copper(I) chloride in *N,N*-dimethylformamide at room temperature results in the efficient, stereocontrolled production of the highly functionalized conjugated dienes **10–18**, respectively. In each of these oxidative couplings, production of 1 equivalent of product is accompanied by the formation of 2 equivalents of both the trialkylstannyl chloride and copper metal.

Key words: alkenyltrialkylstannanes, copper(I) chloride, transmetalation, conjugated dienes, oxidative coupling, β-trialkylstannyl α,β-unsaturated esters, substituted dialkyl muconates, organostannane, organocopper.



Résumé : La réaction des esters β-trialkylstannyl-α,β-insaturés **1–9** avec 2,5 équivalents de chlorure cuivreux, dans le *N,N*-diméthylformamide, à la température ambiante, conduit à la formation efficace et stéréocontrôlée des dienes conjugués hautement fonctionnalisés **10–18** respectivement. Dans chacun de ces couplages oxydants, la production d'un équivalent de produit s'accompagne de la formation de deux équivalents respectivement de chlorure de trialkylstannyle et de cuivre métallique.

Mots clés : alcénytrialkylstannanes, chlorure cuivreux, transmétalation, dienes conjugués, couplage oxydant, esters β-trialkylstannyl-α,β-insaturés, muconates de dialkyle substitués, organostannane, organocuivre.

[Traduit par la rédaction]

Introduction

The palladium(0)-catalyzed intermolecular cross-couplings represented in general terms by eq. [1], collectively known as the Stille coupling, are now well known protocols for the stereospecific syntheses of conjugated diene systems (1–5). Indeed, both the inter- and intramolecular versions of this process have been employed effectively in the synthesis of a wide variety of structurally complex organic compounds (1–5). In 1990, an important paper by Liebeskind and Fengl (6) disclosed that Pd(0)-catalyzed cross-couplings of alkenyltrialkylstannanes with alkenyl bromides and iodides are cocatalyzed by Cu(I) salts. This modified protocol, which generally leads to increased reaction rates and higher product yields, has been employed to advantage in a number of different contexts (see references 7–10 and citations therein) and has proven to be particularly good for successfully carrying out Stille-type couplings that are sluggish or inefficient under the "conventional" experimental conditions. A recent detailed study of this process led to very reasonable proposals regarding the cocatalytic role of Cu(I) in the overall coupling reaction (11).

[1] 

In 1993, a report (12) from this laboratory disclosed that *intra*molecular couplings of alkenyltrimethylstannane and alkenyl halide (I, Br) functions can be accomplished smoothly and efficiently by treatment of the requisite substrates with copper(I) chloride (~2–3 equivalents) in *N,N*-dimethylformamide (DMF). Examples are shown in eqs. [2] and [3]. The presence of a palladium(0) catalyst is not required and, in fact, we have subsequently found[2] that the CuCl-mediated processes are, in some instances, cleaner and more efficient than the corresponding Pd(0)-catalyzed transformations.

Very recently, a synthetically valuable extension to this

[2] 

[3] 

methodology was described by Allred and Liebeskind (13), who found that *inter*molecular cross-couplings of alkenyl- and aryltributylstannanes with alkenyl and aryl iodides can be successfully mediated by copper(I) thiophene-2-carboxylate (CuTC) in *N*-methylpyrrolidone (NMP). An example is provided in eq. [4].

[4] 

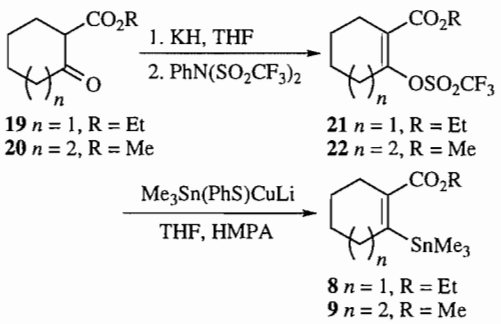
Further research in our laboratory related to the use of Cu(I)-mediated processes in organic synthesis has led to the discovery that CuCl also effects the inter- (14) and intramolecular (15) coupling of two alkenyltrimethylstannane functions. We report herein the details of a study (14) that revealed that treatment of alkyl 3-trialkylstannyl-2-alkenoates and alkyl 2-trimethylstannyl-1-cycloalkenecarboxylates with 2.5 equivalents of CuCl in DMF at room temperature results in the assembly of structurally novel, highly functionalized conjugated diene systems via the stereospecific coupling of the vinylic carbons bearing the R_3Sn function.

In connection with the results described in this paper, recent reports (16–21) emanating from other laboratories should be mentioned. Four of these reports (16–19) describe the *copper(II) nitrate*-mediated intermolecular coupling of alkenyltributylstannane functions, although the papers by Kyler and co-workers (16), Zhang et al. (17), and Crisp and Glink (18) collectively give a total of only seven examples. On the other hand, in the work by Quayle and co-workers (19), the carbon atom bearing the Bu_3Sn group was, in each of the substrates, also attached to a heteroatom (oxygen or sulfur) and, therefore, all the products possess either vinyl ether or vinyl sulfide linkages. The recent publications by Falck et al. (20) and Takeda et al. (21) describe the copper(I) salt-mediated cross-coupling of α-heteroatom-substituted *alkyl*tributylstannane functions with a variety of organic halides and the CuI-promoted *allylation* of alkenyltributylstannanes, respectively.

Results and discussion

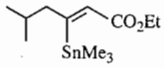
The coupling reactions

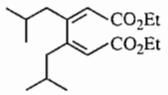
The structural formulas of the substrates (**1–9**) employed in this study are shown in Table 1. In connection with our continuing investigations into the preparation and synthetic uses of alkenyltrialkylstannanes, compounds **1** (22), **2** (23), **3** (23), **4** (24), **5** (25), **6** (23), and **7** (26) have been reported previously. The cyclic unsaturated esters **8** and **9** were prepared via a method modified from that described by Piers and Tse (26). Thus, sequential treatment of each of the keto esters **19** and **20** with potassium hydride and *N*-phenyltrifluoromethanesulfonimide in dry tetrahydrofuran (THF) provided excellent yields of the corresponding alkenyl trifluoromethanesulfonates **21** and **22** (eq. [5]). When the latter two compounds were allowed to react with lithium (phenylthio)(trimethylstannyl)cuprate (27) in THF containing hexamethylphosphoramide (HMPA), the substrates **8** and **9** were obtained in yields of 90 and 82%, respectively.

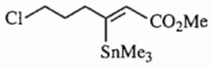


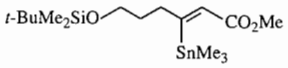
[5] 

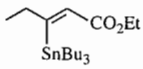
Table 1 contains a summary of the coupling processes that were carried out during the course of this investigation. Addition of solid copper(I) chloride (2.5 equivalents) to a solution of ethyl (*Z*)-5-methyl-3-trimethylstannyl-2-hexenoate (**1**) in DMF, followed by stirring of the reaction mixture at room temperature for 1 h, provided diethyl (*Z*,*Z*)-3,4-bis(2-methylpropyl)muconate (**10**) in 96% yield (entry 1). In a very similar fashion, the β-trimethylstannyl α,β-unsaturated esters **2**, **3**, and **5–9** were transformed cleanly and efficiently into the corresponding functionalized dienes **11**, **12**, and **14–18** (entries 2, 3, and 5–9). Although we have not studied extensively the use of tributylstannanes in this research, the conversion of **4** into **13** (entry 4) indicates that this type of substrate can also be successfully employed in this coupling protocol.

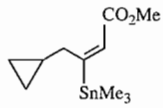


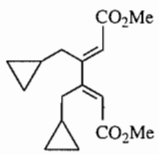


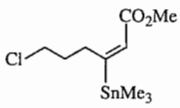


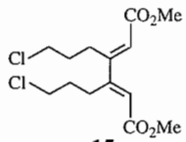


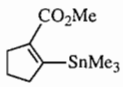


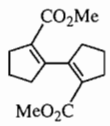


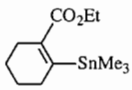


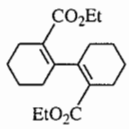


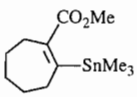


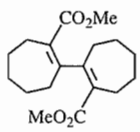












The results summarized in Table 1 show that the new coupling method is efficient and tolerates a variety of functional groups. From the viewpoint of synthesis, it is particularly noteworthy that the process occurs without loss of configurational integrity. Indeed, the data given in Table 1 show that the coupling process is stereospecific and that each of the reactions proceeds with retention of configuration at the alkenyl centers that are being coupled.

Of the products listed in Table 1, ethyl 2-(2-ethoxycarbonyl-1-cyclohexen-1-yl)-1-cyclohexenecarboxylate (**17**) (28) has been reported previously. The geometric configurations of the products **10–15** were established by use of nuclear magnetic resonance (NMR) spectroscopy. An examination of the ^1H and ^{13}C NMR spectra of the substances **10–15** shows clearly that each of the products possesses an element of symmetry. For example, the ^1H NMR spectrum of the diester **11** displays a 6-proton singlet for the two methoxy groups, a 2-proton triplet (J = 1 Hz) for the two olefinic hydrogens, and three 4-proton multiplets derived from the three magnetically different methylene units of the two 3-chloropropyl groups. In a similar vein, the ^{13}C NMR spectrum of **11** contains reso-

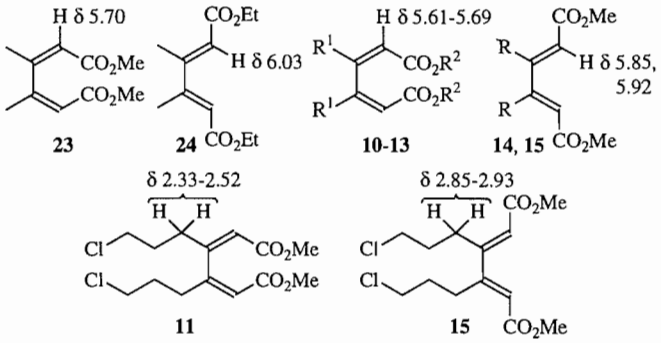
Table 1. Intermolecular coupling of alkenyltrialkylstannane functions.[a]

Entry	Starting material	Product (yield, %)	
1	 **1**	 **10**	(96)
2	 **2**	 **11**	(90)
3	 **3**	 **12**	(86)
4	 **4**	 **13**	(97)
5	 **5**	 **14**	(92)
6	 **6**	 **15**	(82)
7	 **7**	 **16**	(99)
8	 **8**	 **17**	(80)
9	 **9**	 **18**	(86)

[a]All the coupling reactions were carried out with 2.5 equivalents of CuCl in *N,N*-dimethylformamide at room temperature. The reaction time was 1 h in each case, except for the experiment summarized in entry 5; in this case, the reaction time was 2 h.



nances for only seven magnetically different carbon atoms. The ^{1}H and ^{13}C NMR spectra of the other acyclic products listed in Table 1 exhibit analogous characteristics.

In the ^{1}H NMR spectra ($CDCl_3$) of the known diesters **23** (29) and **24** (30), the olefinic protons resonate at δ 5.70 and 6.03, respectively. In the same solvent, the signals due to the olefinic hydrogens of compounds **10**–**13** appear at δ 5.63, 5.69, 5.68, and 5.61, respectively. On the other hand, the corresponding resonances in the spectra of **14** and **15** are found at δ 5.85 and 5.92, respectively. These data provide strong evi-

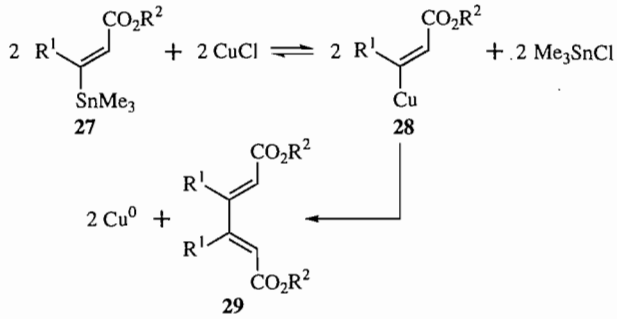
For personal use only.

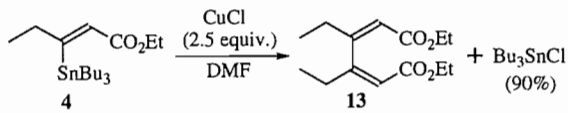
dence for the configurational assignments. It should also be noted that the protons of the allylic CH_2 groups in the (*Z,Z*)-diene **11** resonate at δ 2.33–2.52 (multiplet), while the corresponding protons of the (*E,E*)-diene **15** give rise to a multiplet at δ 2.85–2.93.[3] Since, in compounds **11** and **15**, the CH_2 groups in question are *trans* and *cis*, respectively, to the methoxycarbonyl group, the relative chemical shifts are as expected. Similar chemical shift patterns can be observed in the ^{1}H NMR spectra of substances **10** and **12–14**.

Further evidence for the structure of the diester **15** was obtained as follows. Treatment of this material with 2 equivalents of diisobutylaluminum hydride in diethyl ether at −78°C afforded a mixture consisting of the starting material **15**, the ester alcohol **25**, and the diol **26** (eq. [6]). Flash chromatography of this mixture on silica gel (31) provided, in addition to recovered **15** (24%), the two products **25** and **26** in yields of 41 and 27%, respectively. Key ^{1}H NMR nuclear Overhauser enhancement difference experiments were carried out on compound **25**. Thus, irradiation at δ 4.32 (doublet due to H_A protons)[3] caused enhancement of the signals derived from the olefinic proton H_B (triplet at δ 5.94) and the allylic protons H_C (triplet at δ 2.42). On the other hand, irradiation at δ 2.42 caused an increase in the intensity of each of the resonances at δ 1.74–1.83 (multiplet, H_D protons), 4.32, and 5.86 (singlet, H_E). These experiments clearly establish the configuration of **25** and confirm the earlier conclusions regarding the stereochemistry of the diester **15**.



[6]

Mechanistic considerations



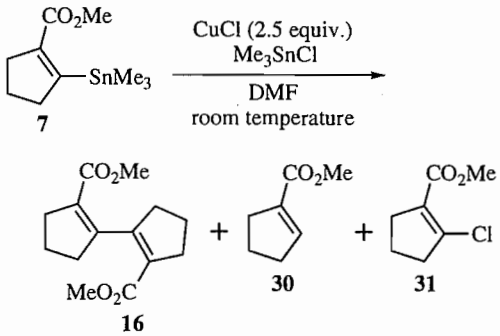
Detailed mechanistic studies related to the new coupling method have not been carried out. However, on the basis of observations derived from previous investigations (11, 13, 32), along with the results of experiments described below, it seems reasonable to propose, in a rather sketchy fashion, that the oxidative couplings take place via the pathway outlined in Scheme 1.

Scheme 1.

Liebeskind and co-workers (11) have shown that, in polar solvents, alkenyltrialkylstannanes undergo transmetalation with copper(I) halides to produce trialkylstannyl halides and, presumably, the corresponding alkenylcopper(I) derivatives. It has also been proposed that these reactions are reversible (13). The postulate that the overall coupling process is initiated by such a transmetalation process (initial equilibrium step shown in Scheme 1) was supported by an experiment involving the conversion of **4** into **13** (eq. [7]). Thus, flash chromatography (31) of the crude product derived from treatment of **4** with 2.5 equivalents of CuCl gave, in addition to the coupled product **13**, a 90% yield of tributylstannyl chloride.

[7]

Support for the reversible nature of the transmetalation step was obtained from a number of experiments. Scheme 1 suggests that the conversion of starting material to product should proceed to completion by treatment of the former with 1 equivalent of CuCl. However, experiments show that when this quantity of the reagent is employed, the reaction is initially quite facile but becomes very sluggish with time. For example, a solution of **1** in DMF was treated with 1 equivalent of CuCl and the progress of the reaction was monitored by periodic removal of aliquots, which were subjected to an appropriate work-up procedure and analysis by gas–liquid chromatography (GLC). After a period of 30 min, approximately 50% of the starting material **1** had been converted to the product **10**. However, a reaction time of ~14 h was required for complete consumption of the starting material.[4] On the other hand, use of 2.5 equivalents of CuCl alleviates this problem and the reaction proceeds to completion within a relatively short reaction time (Table 1, entry 1). The same is true of the other coupling reactions summarized in Table 1. Presumably, the function of the excess reagent (CuCl) is to push the equilibrium between **27** and **28** (Scheme 1) to the right.



In connection with the conversion of substrate **7** into the diene diester **16**, it was demonstrated that addition of trimethylstannyl chloride to the reaction mixture prior to addi-

[3] The resonance assignments were readily confirmed by ^{1}H NMR COSY experiments.

[4] The isolated yield of the product **10** at this stage was ~90%.

© 1997 NRC Canada

tion of the CuCl reagent is also deleterious to the reaction efficiency (eq. [8]). In the absence of added Me_3SnCl, the reaction

[8] 

affords the product cleanly and efficiently (Table 1, entry 7). However, addition of the stannyl chloride decreased significantly the rate of consumption of the starting material **7**. Furthermore, under these conditions, the formation of the coupled product **16** was accompanied by the production of the protio- and chlorodestannylated products **30** and **31**, respectively.[5] For example, treatment of a solution of **7** in DMF with 1 equivalent of Me_3SnCl prior to the addition of 2.5 equivalents of CuCl increased the time necessary for consumption of the starting material from 1 h (Table 1, entry 7) to ~9 h. The product **16**, which was isolated in a yield of 75%, was accompanied by ~20% of a mixture of **30** and **31** in a ratio (GLC) of ~1:2, respectively. In a separate experiment, it was found that disappearance of the starting material **7** after addition of 2.5 equivalents of Me_3SnCl required ~20 h. In this case, the crude product consisted of **16** (isolated yield 57%) and a mixture (~35%) of **30** and **31** (ratio ~1:1.5). Although the overall role(s) that the added Me_3SnCl plays in these reactions is probably complex, it is reasonable to conclude that its function in decreasing the rate of starting material consumption is related primarily to shifting the equilibrium reaction shown in Scheme 1 to the left.

Observation of the reaction mixtures derived from the coupling processes summarized in Table 1 indicated that, in each case, copper metal was produced. The amount of Cu^0 formed per mmol of substrate employed was quantified by an experiment involving conversion of **1** into **10** (Table 1, entry 1). Suitable work-up of the reaction mixture derived from treatment of 1 equivalent of **1** with 2.5 equivalents of CuCl in DMF, followed by an appropriate analytical procedure (33), showed that 0.92 equivalents of Cu^0 had been produced. Thus, the coupling of two molecules of the alkenyltrimethylstannane **27** to produce one molecule of the diene **29** is accompanied by the production of two copper atoms (Scheme 1). Although, as discussed above, it seems likely that this process proceeds via the intermediacy of the alkenylcopper(I) species **28**, the mechanistic details of the transformation of **28** into **29** remain obscure.

[5] The presence of **30** and **31**, indicated by the ^1H NMR spectrum of the crude product, was confirmed by analysis of the mixture by GLC – high-resolution mass spectrometry, which showed the presence of three components with molecular masses 126.0684 (**30**, calcd. for $C_7H_{10}O_2$: 126.0681), 160.0291 (**31**, calcd. for $C_7H_9{}^{35}ClO_2$: 160.0291), and 250.1208 (**16**, calcd. for $C_{14}H_{18}O_4$: 250.1205).

Conclusion

The investigations described above show that copper(I) chloride effectively mediates the oxidative dimerization of β-trialkylstannyl α,β-unsaturated esters. This new coupling method should be of considerable value for the concise synthesis of usefully functionalized conjugated diene systems. Alkenyltrialkylstannanes possessing a wide variety of functionalized carbon skeletons are readily prepared (12, 22–27, 32, 34) and, therefore, several extensions to this work can be envisaged. A number of possibilities are currently being pursued.

Experimental

General information

Melting points and distillation temperatures (short-path Kugelrohr distillations) are uncorrected. Infrared (IR) spectra were recorded using potassium bromide pellets or liquid films on sodium chloride discs. Proton (^1H) and carbon (^{13}C) nuclear magnetic resonance (NMR) spectra were recorded using $CDCl_3$ solutions. Signal positions in ^1H NMR spectra were measured relative to signals for Me_4Si (δ 0) (internal standard) or $CHCl_3$ (δ 7.24), while resonances in ^{13}C NMR spectra were recorded relative to the signal for $CDCl_3$ (δ 77.0). Tin–hydrogen coupling constants (J_{Sn-H}) are given as the average of the ^{117}Sn and ^{119}Sn values. Molecular mass determinations (high-resolution mass spectrometry) for substances containing Me_3Sn are based on ^{120}Sn. Flash chromatography (31) was carried out with 230–400 mesh silica gel (E. Merck). Thin-layer chromatography (TLC) was accomplished with commercial aluminum-backed plates (E. Merck, Type 5554). Gas–liquid chromatography (GLC) was performed on instruments equipped with flame ionization detectors and 25 m × 0.20 mm fused silica columns coated with HP-5 (cross-linked 5% phenyl methyl silicone).

Petroleum ether refers to a mixture of alkanes with bp 35–60°C. Commercial copper(I) chloride (99.995%) and *N*-phenyltrifluoromethanesulfonimide were used without further purification.

Aqueous NH_4Cl–NH_4OH (pH 8) was prepared by the addition of ~50 mL of aqueous ammonia (58%) to ~950 mL of saturated aqueous NH_4Cl.

Note: Unless otherwise stated, all reactions were carried out under an atmosphere of dry argon in oven- (110°C) or flame-dried glassware.

General procedure 1. Preparation of the alkenyl trifluoromethanesulfonates 21 and 22

A suspension of KH (1.1 equiv.) in dry THF (~5 mL per mmol of substrate) was cooled to 0°C and the neat β-keto ester (**19** or **20**) (1 equiv.) was added dropwise. After the mixture had been stirred for 30 min, *N*-phenyltrifluoromethanesulfonimide (1.2 equiv.) was added as a solid in one portion and stirring was continued for 30 min at 0°C and for 1 h at room temperature. Petroleum ether (~1.5 mL per mmol of substrate) was added and the mixture was filtered through a plug of silica gel (~1.5 g per mmol substrate) presoaked with 1:1 petroleum ether – Et_2O. The silica gel was eluted with the same solvent mixture. The filtrate was concentrated and the crude oil was purified by flash chromatography on silica gel.

The following compounds were prepared via this general procedure.

*Ethyl 2-(trifluoromethanesulfonyloxy)-1-cyclohexene-carboxylate (**21**)*

Purification (flash chromatography, 230 g of silica gel, 95:5 to 3:1 petroleum ether – Et_2O) of the crude product obtained from 2-ethoxycarbonylcyclohexanone (5.32 g, 31.3 mmol) and *N*-phenyltrifluoromethanesulfonimide (12.8 g, 1.2 equiv.) gave 8.90 g (94%) of the alkenyl trifluoromethanesulfonate **21**, a colourless oil that displayed IR (neat): 1719, 1672, 1287, 1142, 1094, 1044, 916 cm^{-1}; ^1H NMR (400 MHz, $CDCl_3$) δ: 1.30 (t, 3H, J = 7 Hz), 1.60–1.70 (m, 2H), 1.71–1.85 (m, 2H), 2.35–2.42 (m, 2H), 2.43–2.50 (m, 2H), 4.25 (q, 2H, J = 7 Hz); ^{13}C NMR (75 MHz, $CDCl_3$) δ: 14.0. 21.0, 22.2, 26.1, 28.5, 61.6, 120.4, 123.2, 151.3, 164.8. Exact Mass calcd. for $C_{10}H_{13}F_3O_5S$: 302.0436; found: 302.0435.

*Methyl 2-(trifluoromethanesulfonyloxy)-1-cycloheptene-carboxylate (**22**)*

This compound was prepared from 2-methoxycarbonylcycloheptanone (2.94 g, 17.3 mmol) and *N*-phenyltrifluoromethanesulfonimide (7.62 g, 1.2 equiv.). Flash chromatography of the crude product on silica gel (150 g, petroleum ether to 95:5 petroleum ether – Et_2O) gave 4.94 g (95%) of **22** as a colourless oil that exhibited IR (neat): 1728, 1659, 1423, 1249, 1212, 1141, 1003, 867 cm^{-1}; ^1H NMR (400 MHz, $CDCl_3$) δ: 1.60–1.79 (m, 6H), 2.49–2.59 (m, 4H), 3.78 (s, 3H); ^{13}C NMR (75 MHz, $CDCl_3$) δ: 23.7, 25.2, 28.0, 30.7, 34.0, 52.3, 118.3, 127.8, 155.0, 166.1. Exact Mass calcd. for $C_{10}H_{13}F_3O_5S$: 302.0436; found: 302.0431. Anal. calcd. for $C_{10}H_{13}F_3O_5S$: C 39.74, H 4.33, S 10.61; found: C 39.97, H 4.41, S 10.57.

General procedure 2. Preparation of the alkenyltrimethylstannanes 8 and 9

To a cold (−20°C), stirred solution of lithium (phenylthio)(trimethylstannyl)cuprate (27) (1.5 equiv.) in dry THF (~15 mL per mmol of substrate) was added a solution of the alkenyl trifluoromethanesulfonate (**21** or **22**) (1 equiv.) in dry THF (~0.7 mL per mmol of substrate). After the mixture had been stirred at −20°C for 1 h, dry HMPA (2 equiv.) was added, the mixture was allowed to warm to 0°C, and was stirred for an additional 1 h. Saturated aqueous ammonium chloride (~14 mL per mmol of substrate) and 4:1 petroleum ether – Et_2O (~14 mL per mmol substrate) were added and the mixture was stirred until the organic layer was colourless. The mixture was filtered to remove the solid material. The filtrate was washed (saturated aqueous copper(II) sulfate, water, brine), dried ($MgSO_4$), and concentrated. The crude product was purified by flash chromatography on silica gel followed, for compound **8**, by distillation.

The following compounds were prepared via this general procedure.

*Ethyl 2-(trimethylstannyl)-1-cyclohexenecarboxylate (**8**)*

Flash chromatography (220 g of silica gel, 4:1 petroleum ether – benzene) of the crude product derived from the alkenyl trifluoromethanesulfonate **21** (8.90 g, 29.5 mmol), followed by distillation (85–95°C/0.1 Torr) of the derived oil, provided 8.41 g (90%) of **8** as a colourless oil that showed IR (neat): 1694, 1593, 1448, 1367, 1250, 1056, 768 cm^{-1}; ^1H NMR (400 MHz, $CDCl_3$) δ: 0.08 (s, 9H, $^2J_{Sn-H}$ = 54 Hz), 1.26 (t, 3H, J = 7 Hz), 1.50–1.69 (m, 4H), 2.26–2.43 (m, 4H), 4.16 (q, 2H, J = 7 Hz); ^{13}C NMR (75 MHz, $CDCl_3$) δ: −7.4, 14.3, 22.2, 22.8, 26.4, 33.9, 60.6, 136.0, 163.1, 169.0. Exact Mass calcd. for $C_{11}H_{19}O_2Sn$ (M^+ − Me): 303.0407; found: 303.0401. Anal. calcd. for $C_{12}H_{22}O_2Sn$: C 45.27, H 7.00; found: C 45.39, H 7.16.

*Methyl 2-(trimethylstannyl)-1-cycloheptenecarboxylate (**9**)*

This substance was prepared from the alkenyl trifluoromethanesulfonate **22** (2.52 g, 8.34 mmol). Flash chromatography of the crude product on silica gel (53 g, petroleum ether to 30:1 petroleum ether – Et_2O) afforded 2.17 g (82%) of **9** as a colourless oil that exhibited IR (neat): 1694, 1583, 1435, 1281, 1259, 1205, 1156, 1071, 769 cm^{-1}; ^1H NMR (400 MHz, $CDCl_3$) δ: 0.09 (s, 9H, $^2J_{Sn-H}$ = 53 Hz), 1.38–1.45 (m, 4H), 1.75–1.81 (m, 2H), 2.53–2.63 (m, 4H), 3.70 (s, 3H); ^{13}C NMR (75 MHz, $CDCl_3$) δ: −6.8, 24.8, 26.0, 28.3, 32.6, 34.8, 51.9, 143.5, 169.7, 170.0. Exact Mass calcd. for $C_{11}H_{19}O_2Sn$ (M^+ − Me): 303.0407; found: 303.0407. Anal. calcd. for $C_{12}H_{22}O_2Sn$: C 45.27, H 7.00; found: C 45.35, H 6.97.

General procedure 3. Copper(I) chloride–mediated coupling reactions

To a stirred solution of the alkenyltrialkylstannane in DMF (~0.5 mL per mmol of substrate) at room temperature was added solid copper(I) chloride (2.5 equiv.) and the resulting brown solution was stirred for 1 h. Aqueous NH_4Cl–NH_4OH (pH 8, the same volume as DMF) was added and the mixture was stirred, open to the atmosphere, until the aqueous phase turned deep blue. The phases were separated and the aqueous layer was extracted three times with Et_2O. The combined organic extracts were washed (water, brine), dried ($MgSO_4$), and concentrated. The crude product was purified by flash chromatography on silica gel.

The following compounds were prepared via this general procedure.

*Diethyl (Z,Z)-3,4-bis(2-methylpropyl)muconate (**10**)*

This material was synthesized from ethyl (*Z*)-5-methyl-3-trimethylstannyl-2-hexenoate (**1**) (250 mg, 0.78 mmol). Flash chromatography of the crude oil on silica gel (10 g, 4:1 pentane–Et_2O) afforded 117 mg (96%) of **10**, a colourless oil that displayed IR (neat): 1724, 1653, 1619, 1467, 1176, 1063 cm^{-1}; ^1H NMR (400 MHz, $CDCl_3$) δ: 0.94 (br signal, 12H), 1.20 (t, 6H, J = 7 Hz), 1.87 (m, 2H, J = 7 Hz), 1.95–2.08 (br m, 2H), 2.22–2.35 (br m, 2H), 4.06 (q, 4H, J = 7 Hz), 5.63 (t, 2H, J = 1 Hz); ^{13}C NMR (50.3 MHz, $CDCl_3$) δ: 14.2, 22.7, 25.5, 46.4, 59.7, 115.1, 159.9, 165.4. Exact Mass calcd. for $C_{18}H_{30}O_4$: 310.2144; found: 310.2148. Anal. calcd. for $C_{18}H_{30}O_4$: C 69.64, H 9.74; found: C 69.86, H 9.74.

*Dimethyl (Z,Z)-3,4-bis(3-chloropropyl)muconate (**11**)*

This compound was prepared from methyl (*Z*)-6-chloro-3-trimethylstannyl-2-hexenoate (**2**) (140 mg, 0.43 mmol). Flash chromatography of the crude product on silica gel (10 g, 4:1 pentane–Et_2O) afforded 63 mg (90%) of **11**, a colourless oil that showed IR (neat): 1724, 1621, 1435, 1176, 1040, 871, 654 cm^{-1}; ^1H NMR (400 MHz, $CDCl_3$) δ: 1.91–2.05 (br m, 4H), 2.33–2.52 (br m, 4H), 3.50–3.59 (br m, 4H), 3.60 (s, 6H), 5.69 (t, 2H, J = 1 Hz); ^{13}C NMR (50.3 MHz, $CDCl_3$) δ: 29.7, 34.2,

44.2, 51.2, 114.9, 159.4, 165.6. Exact Mass calcd. for $C_{14}H_{20}{}^{35}Cl_2O_4$: 322.0739; found: 322.0731. Anal. calcd. for $C_{14}H_{20}Cl_2O_4$: C 52.03, H 6.24; found: C 52.20, H 6.24.

*Dimethyl (Z,Z)-3,4-bis(3-(*tert*-butyldimethylsiloxy)propyl)-muconate (**12**)*

Flash chromatography (2 g of silica gel, 9:1 to 3:2 pentane–Et_2O) of the crude oil obtained from methyl (*Z*)-6-(*tert*-butyldimethylsiloxy)-3-trimethylstannyl-2-hexenoate (**3**) (104 mg, 0.25 mmol) provided 55 mg (86%) of **12**, a colourless oil that exhibited IR (neat): 1732, 1655, 1621, 1473, 1436, 1256, 1105, 836 cm^{-1}; ^1H NMR (400 MHz, $CDCl_3$) δ: 0.01 (s, 12H), 0.85 (s, 18H), 1.65–1.80 (m, 4H), 2.21–2.46 (m, 4H), 3.51–3.70 (m, 4H), 3.60 (s, 6H), 5.68 (s, 2H); ^{13}C NMR (50.3 MHz, $CDCl_3$) δ: −5.3, 18.2, 25.9, 30.1, 33.8, 51.0, 62.3, 113.8, 161.9, 165.8. Exact Mass calcd. for $C_{26}H_{50}O_6Si_2$: 514.3146; found: 514.3146. Anal. calcd. for $C_{26}H_{50}O_6Si_2$: C 60.66, H 9.80; found: C 60.76, H 9.76.

*Diethyl (Z,Z)-3,4-diethylmuconate (**13**)*

Purification (flash chromatography, 10 g of silica gel, 4:1 pentane–Et_2O) of the crude product obtained from ethyl (*Z*)-3-tributylstannyl-2-pentenoate (**4**) (207 mg, 0.50 mmol) gave 74 mg (97%) of **13**, a colourless oil that displayed IR (neat): 1719, 1655, 1620, 1300, 1176, 811 cm^{-1}; ^1H NMR (400 MHz, $CDCl_3$) δ: 1.08 (t, 6H, *J* = 7 Hz), 1.18 (t, 6H, *J* = 7 Hz), 2.08–2.46 (br m, 4H), 4.04 (q, 4H, *J* = 7 Hz), 5.61 (t, 2H, *J* = 1 Hz); ^{13}C NMR (50.3 MHz, $CDCl_3$) δ: 11.2, 14.1, 30.2, 59.7, 113.2, 163.5, 165.6. Exact Mass calcd. for $C_{14}H_{22}O_4$: 254.1518; found: 254.1512. Anal. calcd. for $C_{14}H_{22}O_4$: C 66.12, H 8.72; found: C 66.33, H 8.84.

*Dimethyl (E,E)-3,4-bis(cyclopropylmethyl)muconate (**14**)*

Note: The reaction time in this case was 2 h. Flash chromatography (10 g of silica gel, 4:1 pentane–Et_2O) of the crude product derived from methyl (*E*)-4-cyclopropyl-3-trimethylstannyl-2-butenoate (**5**) (250 mg, 0.83 mmol) afforded 106 mg (92%) of **14**, a colourless oil that showed IR (neat): 1719, 1629, 1340, 1173, 1020, 872 cm^{-1}; ^1H NMR (400 MHz, $CDCl_3$) δ: 0.10–0.20 (m, 4H), 0.33–0.41 (m, 4H), 0.69–0.81 (m, 2H), 2.75 (d, 4H, *J* = 7 Hz), 3.66 (s, 6H), 5.85 (s, 2H); ^{13}C NMR (50.3 MHz, $CDCl_3$) δ: 4.8, 10.0, 33.3, 51.2, 117.5, 161.2, 166.5. Exact Mass calcd. for $C_{16}H_{22}O_4$: 278.1518; found: 278.1519. Anal. calcd. for $C_{16}H_{22}O_4$: C 69.04, H 7.97; found: C 69.15, H 8.02.

*Dimethyl (E,E)-3,4-bis(3-chloropropyl)muconate (**15**)*

This compound was derived from methyl (*E*)-6-chloro-3-trimethylstannyl-2-hexenoate (**6**) (250 mg, 0.77 mmol). Flash chromatography (10 g of silica gel, 4:1 pentane–Et_2O) of the crude oil afforded 102 mg (82%) of **15**, a colourless, crystalline solid (mp 52–53° C) that exhibited IR (KBr): 1709, 1601, 1438, 1340, 1178, 869, 539 cm^{-1}; ^1H NMR (400 MHz, $CDCl_3$) δ: 1.79–1.89 (m, 4H), 2.85–2.93 (m, 4H), 3.52 (t, 4H, *J* = 6 Hz), 3.69 (s, 6H), 5.92 (s, 2H); ^{13}C NMR (50.3 MHz, $CDCl_3$) δ: 26.5, 31.5, 44.5, 51.4, 119.3, 158.5, 166.1. Exact Mass calcd. for $C_{14}H_{20}{}^{35}Cl_2O_4$: 322.0739; found: 322.0739. Anal. calcd. for $C_{14}H_{20}Cl_2O_4$: C 52.03, H 6.24; found: C 52.02, H 6.40.

*Methyl 2-(2-methoxycarbonyl-1-cyclopenten-1-yl)-1-cyclopentenecarboxylate (**16**)*

This substance was prepared from methyl 2-(trimethylstannyl)-1-cyclopentenecarboxylate (**7**) (57 mg, 0.20 mmol). Flash chromatography of the crude product on silica gel (1 g, 9:1 to 3:2 pentane–Et_2O) afforded 25 mg (99%) of **16**, a colourless solid (mp 78–79°C) that displayed IR (KBr): 1718, 1667, 1604, 1439, 1257, 1050, 773 cm^{-1}; ^1H NMR (400 MHz, $CDCl_3$) δ: 1.94 (quintet, 4H, *J* = 8 Hz), 2.58–2.72 (m, 8H), 3.54 (s, 6H); ^{13}C NMR (50.3 MHz, $CDCl_3$) δ: 22.5, 33.4, 38.1, 51.2, 128.4, 154.4, 165.4. Exact Mass calcd. for $C_{14}H_{18}O_4$: 250.1205; found: 250.1200. Anal. calcd. for $C_{14}H_{18}O_4$: C 67.17, H 7.25; found: C 67.46, H 7.45.

*Ethyl 2-(2-ethoxycarbonyl-1-cyclohexen-1-yl)-1-cyclohexenecarboxylate (**17**)*

Flash chromatography (2 g of silica gel, 9:1 to 3:2 pentane–Et_2O) of the crude product derived from ethyl 2-(trimethylstannyl)-1-cyclohexenecarboxylate (**8**) (100 mg, 0.315 mmol) gave 38 mg (80%) of **17**, a colourless oil that exhibited IR (neat): 1715, 1650, 1615, 1449, 1230, 1050, 967 cm^{-1}; ^1H NMR (400 MHz, $CDCl_3$) δ: 1.18 (t, 6H, *J* = 7 Hz), 1.64 (br signal, 8H), 2.16 (br signal, 4H), 2.29 (br signal, 4H), 4.05 (q, 4H, *J* = 7 Hz); ^{13}C NMR (75 MHz, $CDCl_3$) δ: 14.3, 22.0, 22.2, 25.6, 31.0, 59.8, 122.0, 152.6, 167.7. Exact Mass calcd. for $C_{18}H_{26}O_4$: 306.1831; found: 306.1828. Anal. calcd. for $C_{18}H_{26}O_4$: C 70.55, H 8.56; found: C 70.32, H 8.47.

*Methyl 2-(2-methoxycarbonyl-1-cycloheptenyl-1-yl)-1-cycloheptenecarboxylate (**18**)*

This compound was derived from methyl 2-(trimethylstannyl)-1-cycloheptenecarboxylate (**9**) (68 mg, 0.21 mmol). Flash chromatography of the crude product on silica gel (5 g, 4:1 petroleum ether – Et_2O) provided 28 mg (86%) of **18** as a colourless oil that exhibited IR (neat): 1713, 1640, 1621, 1435, 1260, 1208, 1117, 1015 cm^{-1}; ^1H NMR (400 MHz, $CDCl_3$) δ: 1.38–1.85 (m, 12H), 2.22–2.54 (m, 8H), 3.59 (s, 6H); ^{13}C NMR (50.3 MHz, $CDCl_3$) δ: 25.7, 26.2, 29.8, 32.3, 35.2, 51.3, 128.4, 155.7, 169.8. Exact Mass calcd. for $C_{18}H_{26}O_4$: 306.1831; found: 306.1830. Anal. calcd. for $C_{18}H_{26}O_4$: C 70.55, H 8.56; found: C 70.62, H 8.67.

Methyl (*E,E*)-3,4-bis(3-chloropropyl)-6-hydroxy-2,4-hexadienoate (25) and (*E,E*)-3,4-bis(3-chloropropyl)-2,4-hexadiene-1,6-diol (26)

To a cold (−78°C), stirred solution of dimethyl (*E,E*)-3,4-bis(3-chloropropyl)muconate (**15**) (75 mg, 0.23 mmol) in dry Et_2O (2 mL) was added a 1.0 M solution of diisobutylaluminum hydride in hexanes (0.46 mL, 0.46 mmol). After 1 h, the solution was warmed to room temperature, saturated aqueous sodium potassium tartrate (2 mL) was added, and the resultant gelatinous emulsion was stirred for 2 h. The aqueous phase was extracted with Et_2O (3 × 10 mL). The combined organic layers were washed (brine, 10 mL), dried ($MgSO_4$), and concentrated. Flash chromatography (5 g of silica gel, 1:1 pentane–Et_2O) of the crude oil afforded 18 mg (24%) of the starting material **15**, 17 mg (27%) of the diol **26**, and 28 mg (41%) of the partial reduction product **25**, a colourless crystalline solid (mp 87–88°C) that displayed IR (KBr): 3437, 1714, 1607, 1437, 1175, 1025, 875 cm^{-1}; ^1H NMR (400 MHz, $CDCl_3$) δ: 1.54 (br s, 1H), 1.74–1.83 (m, 2H), 1.83–1.92 (m, 2H), 2.42 (t, 2H, *J* = 8 Hz), 2.88–2.95 (m, 2H), 3.49 (t, 2H, *J* = 6 Hz), 3.56 (t, 2H, *J* = 7 Hz), 3.69 (s, 3H), 4.32 (d, 2H, *J* = 6 Hz), 5.86 (s, 1H), 5.94 (t, 1H, *J* = 6 Hz); ^{13}C NMR (50.3 MHz,

$CDCl_3$) δ: 25.1, 26.4, 31.1, 32.0, 44.3, 44.8, 51.2, 59.5, 116.9, 131.7, 140.7, 159.1, 166.8. Exact Mass calcd. for $C_{13}H_{20}{}^{35}Cl_2O_3$: 294.0790; found: 294.0781. Anal. calcd. for $C_{13}H_{20}Cl_2O_3$: C 52.89, H 6.83; found: C 53.14, H 7.00.

The diol **26**, a colourless crystalline solid (mp 92–93°C), showed IR (KBr): 3369, 1616, 1419, 1032, 844, 780, 648 cm^{-1}; ^1H NMR (400 MHz, $CDCl_3$) δ: 1.37 (br s, 2H), 1.75–1.84 (m, 4H), 2.39 (t, 4H, J = 8 Hz), 3.49 (t, 4H, J = 6 Hz), 4.28 (d, 4H, J = 7 Hz), 5.73 (t, 2H, J = 7 Hz); ^{13}C NMR (50.3 MHz, $CDCl_3$) δ: 25.0, 31.3, 44.5, 59.4, 127.8, 141.2. Exact Mass calcd. for $C_{12}H_{20}{}^{35}Cl_2O_2$: 266.0841; found: 266.0839. Anal. calcd. for $C_{12}H_{20}Cl_2O_2$: C 53.94, H 7.54; found: C 53.63, H 7.43.

Oxidative coupling of 4: determination of the amount of Bu_3SnCl produced

Following general procedure 3, ethyl (*Z*)-3-tributylstannyl-2-pentenoate (**4**) (30 mg, 0.072 mmol) was treated with CuCl (18 mg, 2.5 equiv.) in DMF (0.5 mL). Flash chromatography (3 g of silica gel, Et_2O) of the resulting crude oil afforded 21 mg (0.90 equiv., 90%) of Bu_3SnCl. This material exhibited a ^1H NMR spectrum identical with that of an authentic sample and displayed in a low resolution mass spectrum a peak for the molecular ion at *m/e* = 326.

Oxidative coupling of 1: determination of the amount of copper metal produced

To a stirred solution of ethyl (*Z*)-5-methyl-3-trimethylstannyl-2-hexenoate (**1**) (244 mg, 0.76 mmol) in DMF (5 mL) at room temperature was added solid copper(I) chloride (189 mg, 2.5 equiv.) and the resulting brown solution was stirred for 1 h. Diethyl ether (3 mL) and saturated aqueous NH_4Cl (3 mL) were added and the resulting mixture was stirred, open to the atmosphere, for 10 min. The mixture was filtered through a medium-frit sintered glass funnel and the reaction flask and the collected material were washed successively with DMF (2 mL), hot distilled deionized water (20 mL), and diethyl ether (30 mL). The filtrate flask was replaced by a clean flask and the copper residue on the walls of the reaction flask was dissolved in 50% v/v aqueous HNO_3 (2 mL). This acidic solution was also used to dissolve the copper deposited on the funnel. The reaction flask and funnel were washed successively with 10% v/v aqueous HNO_3 (8 mL) and distilled, deionized water (15 mL). The collected acidic filtrate was neutralized with concentrated aqueous NH_4OH until a dark blue colour persisted, then the filtrate was reacidified to pH ~5 with a few drops of 50% v/v aqueous acetic acid. To the resulting solution was added solid urea (125 mg, 2.1 mmol), followed by a 50% w/w aqueous solution of KI (6 mL). The dark brown solution was immediately titrated with a 0.1073 M solution of $Na_2S_2O_3$ until the brown iodine colour had almost dissipated, then a freshly prepared 0.5% w/w aqueous solution of starch (1 mL) was added, and the titration was continued until the blue starch–iodine colour was discharged. The total volume of the $Na_2S_2O_3$ solution used in the titration was 6.52 mL. Thus, the amount of copper metal produced was determined to be 44.5 mg (0.92 equiv., 92% yield).

Synthesis and characterization of organometallic hydro-tris-pyrazolylborate derivatives of scandium via alkane elimination

James Blackwell, Corinne Lehr, Yimin Sun, Warren E. Piers, Susan D. Pearce-Batchilder, Michael J. Zaworotko, and Victor G. Young, Jr.

Abstract: Reaction between the potassium salts of the hydro-tris-pyrazolylborate ligands $Tp^{Me,Me}$ and $Tp^{tBu,Me}$ and the tris THF adduct of scandium trichloride lead to isolation of the scandium complexes $(Tp^{Me,Me})ScCl_2(THF)$, **1***a*, and $(Tp^{tBu,Me})ScCl_2$, **1***b*, in 65 and 49% yield, respectively. Subsequent reactions between **1***a* and **1***b* and alkyl lithium reagents RLi (R = Me, CH_2SiMe_3, and $CH(SiMe_3)_2$) gave the lithium salts of the Tp ligands as the major isolated products in all cases but one. The complex $(Tp^{Me,Me})Sc(CH_2SiMe_3)_2(THF)$, **2***a*, could be obtained contaminated with at least 10% $Tp^{Me,Me}Li$ via this methodology. A salt-free alkane elimination route to bis-trimethylsilylmethyl complexes **2***a* and the THF-free $(Tp^{tBu,Me})Sc(CH_2SiMe_3)_2$, **2***b*, involving reaction between in situ generated $Sc(CH_2SiMe_3)_3(THF)_2$ and the protonated ligands, $Tp^{R,Me}H$, gave samples of the desired bis-alkyl derivatives in 67 and 87% yield, respectively. In solution, complexes **2***a* and **2***b* are both fluxional at room temperature. These dynamic processes were frozen out on the NMR time scale at lower temperatures and interpreted on the basis of the ^1H NMR spectra obtained as well as information obtained from the solid state structures of both compounds. **2***a*: monoclinic, space group $P2_1/c$, a = 11.765(4) Å, b = 14.8311(20) Å, c = 20.891(5) Å, β = 105.69(3)°, V = 3509.4(15) Å^3, Z = 4, R = 0.088, R_w = 0.082. **2***b*: triclinic, space group $P\bar{1}$, a = 11.9427(2) Å, b = 20.3641(3) Å, c = 26.5602(2) Å, α = 112.192(1)°, β = 100.569(1)°, γ = 92.928(1)°, V = 5830.38(14) Å^3, Z = 6, R = 0.0500, R_w = 0.1137.

Key words: organoscandium complexes, hydro-tris-pyrazolylborate ligands, alkane elimination.

Résumé : La réaction des sels de potassium des coordinats hydro-tris-pyrazolylborate $Tp^{Me,Me}$ et $Tp^{tBu,Me}$ et l'adduit tris THF du trichlorure de scandium permet d'isoler les complexes du scandium $(Tp^{Me,Me})ScCl_2(THF)$, **1***a*, et $(Tp^{tBu,Me})ScCl_2$, **1***b*, avec des rendements respectivement de 65 et 49%. Dans tous les cas, à l'exception d'un, des réactions subséquentes des produits **1***a* et **1***b* avec des réactifs alkyllithium, RLi (R = Me, CH_2SiMe_3 et $CH(SiMe_3)_2$), conduisent aux sels de lithium des coordinats Tp comme produits principaux. Par le biais de cette méthodologie, il a été possible d'obtenir le complexe $(Tp^{Me,Me})Sc(CH_2SiMe_3)_2(THF)$, **2***a*, contaminé par au moins 10% du $Tp^{Me,Me}Li$. Une voie d'élimination d'alcane sans sel conduisant aux complexes bis-triméthylsilylméthyles **2***a* et $(Tp^{tBu,Me})Sc(CH_2SiMe_3)_2$, sans THF, **2***b*, et impliquant une réaction entre du $Sc(CH_2SiMe_3)_3(THF)_2$ généré in situ et les coordinats protonés, $Tp^{R,Me}H$, ont permis d'obtenir des échantillons des dérivés bis-alkylés désirés avec des rendements respectifs de 67 et 87%. En solution, à la température ambiante, les complexes **2***a* et **2***b* sont tous les deux en fluxion. En opérant à des températures plus faibles, ces processus dynamiques ont pu être figés à l'échelle de temps de la RMN et on a pu les interpréter sur la base des spectres RMN du ^1H obtenus ainsi que des informations obtenues à partir des structures des deux composés à l'état solide. Le composé **2***a* est monoclinique, groupe d'espace $P2_1/c$, a = 11,765(4), b = 14,8311(20) et c = 20,891(5) Å, β = 105,69(3)°, V = 3509,4(15) Å^3, Z = 4, R = 0,088 et R_w = 0,082. Le composé **2***b* est triclinique, groupe d'espace $P\bar{1}$, a = 11,9427(2), b = 20,3641(3) et c = 26,5602(2) Å, α = 112,192(1)°, β = 100,569(1)° et γ = 92,928(1)°, V = 5830,38(14) Å^3, Z = 6, R = 0,0500 et R_w = 0,1137.

Mots clés : complexes organoscandium, coordinats hydro-tris-pyrazolylborate, élimination d'alcane.

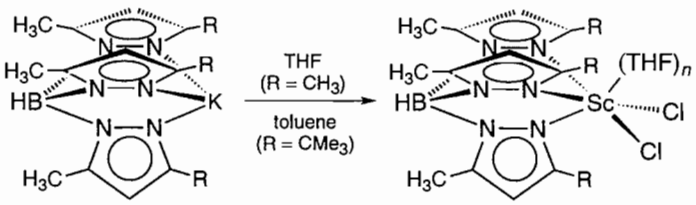
Hydro-tris-pyrazolylborate ("$Tp^{R,R'}$")[2] ligands are among the most versatile and ubiquitous supporting ligands in inorganic chemistry (1). This versatility is in part due to the tunability of these ligands, particularly from a steric point of view, via modification of substitution patterns on the pyrazolyl rings. Atoms or ions of varying size can be bound in a range of coordination environments depending on the steric properties of the groups in the 3 and 5 positions of the pyrazolyl ring. Thus, complexes of almost every transition metal exist and several examples each of Tp complexes with *s* and *p*-block elements (2), the lanthanides (3), and actinides (1*b*) are known.

Despite the maturity of Tp coordination chemistry, scandium complexes of these ligands are, to our knowledge, unreported in the chemical literature.[3] Examples of related yttrium (4), lanthanum (5), aluminum (6), gallium (7), and indium (7, 8) Tp complexes have been reported but scandium appears to have been neglected. This was a surprise to us when we settled on the hydro-tris-pyrazolylborate ancillary to begin studying the chemistry of bis-alkyl derivatives of scandium, which until recently (9) have also been overlooked. As reported herein, $Tp^{R,Me}$ (R = Me, *t*Bu) complexes of scandium are readily prepared using an alkane elimination protocol that we recently developed (10).



Results and discussion

Reactions between one equivalent of the potassium salts of the hydro-tris-pyrazolylborate ligands $Tp^{Me,Me}$ and $Tp^{tBu,Me}$ and $ScCl_3{\cdot}THF_3$ in THF or toluene yields the dichloride complexes $(Tp^{Me,Me})ScCl_2(THF)$, **1***a*, and $(Tp^{tBu,Me})ScCl_2$, **1***b* (eq. [1]). Longer reaction time is required for the bulkier $Tp^{tBu,Me}$ ligand but both complexes were prepared in good yield. The less bulky $Tp^{Me,Me}$ ligand allows one THF ligand to remain in the scandium coordination sphere, as indicated by the solution NMR spectra (see Table 1); resonances for the pyrazolyl ring substituents in **1***a* are split into two sets in a 2:1 ratio as would be predicted for a six-coordinate, octahedral complex. Although the five-coordinate complex **1***b* would be expected to also have inequivalent pyrazolyl rings in a static structure, by ^1H and $^{13}C\{^1H\}$ NMR spectroscopy, all three rings are equivalent. The ^1H NMR spectra of **1***b* at lower temperatures exhibits broadening and changes in the observed chemical shifts but the process responsible for exchanging the substituents on the pyrazolyl rings could not be frozen out at accessible temperatures.

As starting materials for bis-alkyl derivatives of scandium, **1***a* and **1***b* have limited utility. As shown in eq. [2], when treated with two equivalents of trimethylsilylmethyl lithium, a bis-alkyl derivative of **1***a* could be generated but the isolated product was contaminated with variable amounts of an impurity identified as the lithium salt of the $Tp^{Me,Me}$ ligand. Under certain reaction conditions (see Experimental section) followed by careful fractional crystallization, 90% pure samples of **2***a* could be obtained but the procedure was unsatisfying and tedious. The situation was worse for derivatization of **1***b*; only small amounts of the desired alkyl derivative **2***b* were observed and the major product in all reactions performed was $Tp^{tBu,Me}Li$. Use of other alkylating agents, including MeLi, $LiCH(SiMe_3)_2$, and $KCH_2C_6H_5$, for both **1***a* and **1***b* gave even less satisfactory results.

Clearly, other routes to **2***a* and **2***b* were necessary. Recently we have reported on alkane elimination protocols for attaching cyclopentadienyl-amido type ligands to both scandium (10) and zirconium (11). These procedures involve treatment of in situ generated metal alkyl complexes with proteo ligands; the elimination of alkanes provides the driving force for the reaction and yields organometallic compounds directly. Since proton salts of hydro-tris-pyrazolylborate ligands are available (12), adaptation of our alkane elimination procedure seemed promising for the synthesis of **2***a* and **2***b* in a "salt-free" manner.

Accordingly, in situ generated $Sc(CH_2SiMe_3)_3{\cdot}THF_2$ (13), when treated with $Tp^{Me,Me}H$ or $Tp^{tBu,Me}H$, led directly to bis-alkyl compound **2***a* and **2***b* in good to excellent yields (eq. [3]). The products were completely free of the lithium salts of the

[1] $ScCl_3{\cdot}THF_3$ + 

ligand, provided the solutions of $Sc(CH_2SiMe_3)_3{\cdot}THF_2$ were filtered prior to treatment with the $Tp^{R,Me}H$ reagents.

Access to pure samples of bis-alkyls **2** allowed us to fully characterize these compounds both in solution and in the solid state (vide infra). In solution, both compounds exhibit dynamic behavior that serves to exchange related pyrazolyl substituent groups rapidly at room temperature. In the case of **2***a*, this behavior appears to be driven by a more labile THF ligand in comparison to the dichloride **1***a*, perhaps because of the moderately bulky trimethylsilylmethyl ligands. Although the THF cannot be removed from **2***a* even upon exposure to high vacuum for several hours, variable temperature ^1H NMR spectra suggest that **2***a* is in equilibrium with a fluxional five-coordinate species. Upon cooling, the singlets for each of the C-3, -4, and -5 substituents on the pyrazolyl ring coalesced and reappeared in patterns similar to those found for the static

[2] The abbreviation convention introduced in ref. 1*b* is employed in this paper.

[3] The synthesis of $(Tp^{Me,Me})ScCl_2(THF)$ (**1***a* in this paper) was, however, disclosed publically at an ACS meeting several years ago: R. Ball, J.G. Matisons, and J. Takats. Abstract 291, 190th Meeting of the American Chemical Society, Chicago (1985).

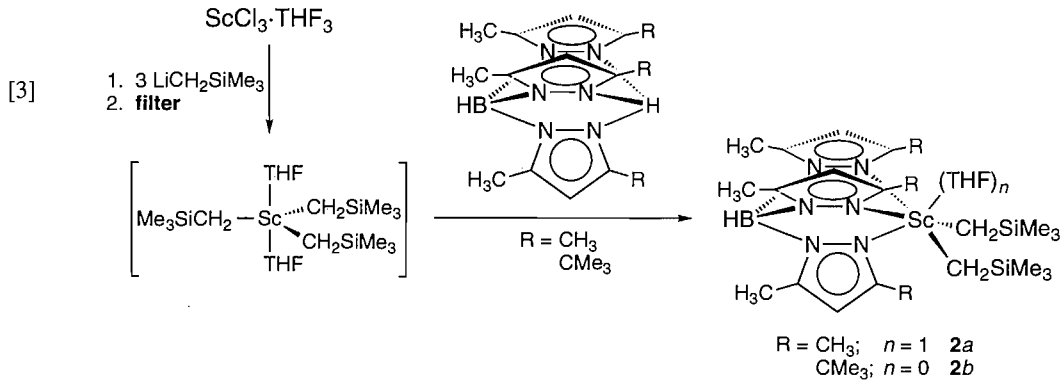

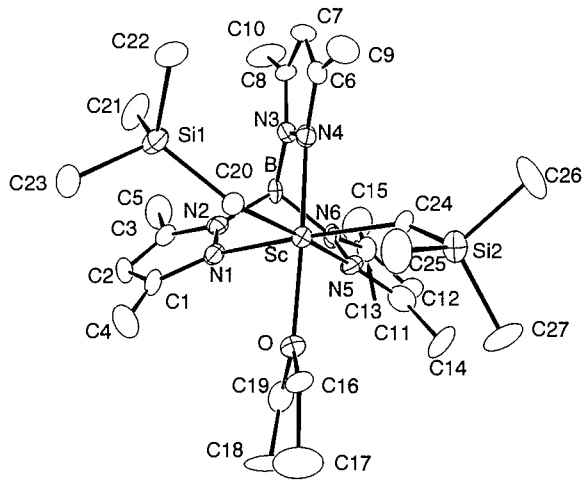

Fig. 1. ORTEP drawing of $(Tp^{Me,Me})Sc(CH_2SiMe_3)_2(THF)$, **2***a*.

six-coordinate dichloride, consistent with the observed solid state structure (vide infra). Curiously, the signals for the THF protons also coalesce, which perhaps implies a separate exchange process involving free and bound THF[4] or restricted rotation of the THF ligand at lower temperatures, resulting in different environments for the two halves of the ligand.

X-ray quality crystals of **2***a* were obtained from benzene; an ORTEP representation of the compound is given in Fig. 1 and molecular coordinates and selected metrical parameters can be found in Tables 2 and 3, respectively. The formally 12-electron scandium center is octahedrally coordinated with distortions from the ideal attributable to the contraints of the chelating $Tp^{Me,Me}$ ligand. The Sc—C20 and Sc—C24 distances are virtually identical and closely compare with the Sc—C distance in $Cp^*_2ScCH_3$ of 2.243(11) Å (14). The THF ligand contains an sp^2 hybridized, trigonal planar oxygen atom, the plane of which bisects the C20-Sc-C24 angle. Thus, the filled unhybridized *p* orbital on oxygen is potentially available to π donate to an empty *d* orbital not involved in σ bonding to the alkyl and pyrazolylborate ligands. The Sc—O distance of 2.206(10) Å is comparable to analogous bond lengths in $ScCl_3(THF)_3$ (2.236(8), 2.147(7), and 2.164(7) Å) and $Cp_2Sc(THF)Si(SiMe_3)_3$ (2.216(3) Å) (15).

The steric properties of the $Tp^{tBu,Me}$ ligand are sufficient to preclude coordination of THF to the scandium center; by NMR spectroscopy, **2***b* is completely THF free (Table 1). A static five-coordinate structure would be expected to exhibit inequivalent pyrazolyl rings in a 2:1 ratio but at room temperature all rings are equivalent; however, as the sample was cooled, coalescence behavior was observed. A series of ^1H NMR spectra at various temperatures is shown in Fig. 2. As can be seen, the C-3 methyl and C-4 H resonances, which are singlets at room temperature, coalesce at about 242 K and reappear as two singlets in a 2:1 ratio. The resonances associated with the trimethylsilylmethyl ligands also collapse at about 242 K and in the low-temperature limit give distinct resonances for each group.

This spectrum is consistent with the solid state structural results in which one of the pyrazolyl rings is only weakly bound to the scandium center in this extremely sterically crowded molecule. Crystals of **2***b* were obtained from toluene–hexanes and, upon analysis, three independent molecules were discovered in the unit cell. Since the metrical parameters for these independent molecules were very similar, data for molecule A only are presented herein (Tables 4 and 5); full details on the other molecules are included in the deposited material.

Figure 3 shows an ORTEP diagram of molecule A of **2***b*. The scandium center is trigonal bipyramidal in geometry with N2, N6, and C25 occupying the equatorial positions and N4 and C29 the apical sites. Although **2***b* is formally only a 10-electron complex, clearly the scandium center is sterically saturated. Indeed, the $Tp^{tBu,Me}$ ligand has been termed a "tetrahedral enforcer" (16) because of its steric bulk and five-coordinate structures of complexes incorporating this ligand are rare outside of the lanthanides. Examination of the Sc—N bond distances reveals that the apical Sc—N4 distance of 2.493(2) Å is more than 0.2 Å longer than the other two Sc—N bond lengths. This lengthening is probably a result of the steric interaction between this ring's C-3 *tert*-butyl group and the equatorial alkyl group. Alternation of this more weakly bound ring between the three pyrazolyl groups is a plausible fluxional process (Scheme 1) that accounts for the observed temperature dependence of the ^1H NMR spectra. Similar behaviour has been observed in the related compound $(Tp^{Me,Me})GaMe_2$ (17). In this compound, the tris-pyrazolylborate ligands are η^2 bound to a tetrahedral gallium center in the solid state but the

[4] Although the observed solid state structure of **2***a* shows the presence of only one THF molecule in the crystal, integration of the THF resonances in the ^1H NMR spectra were always slightly higher than expected.

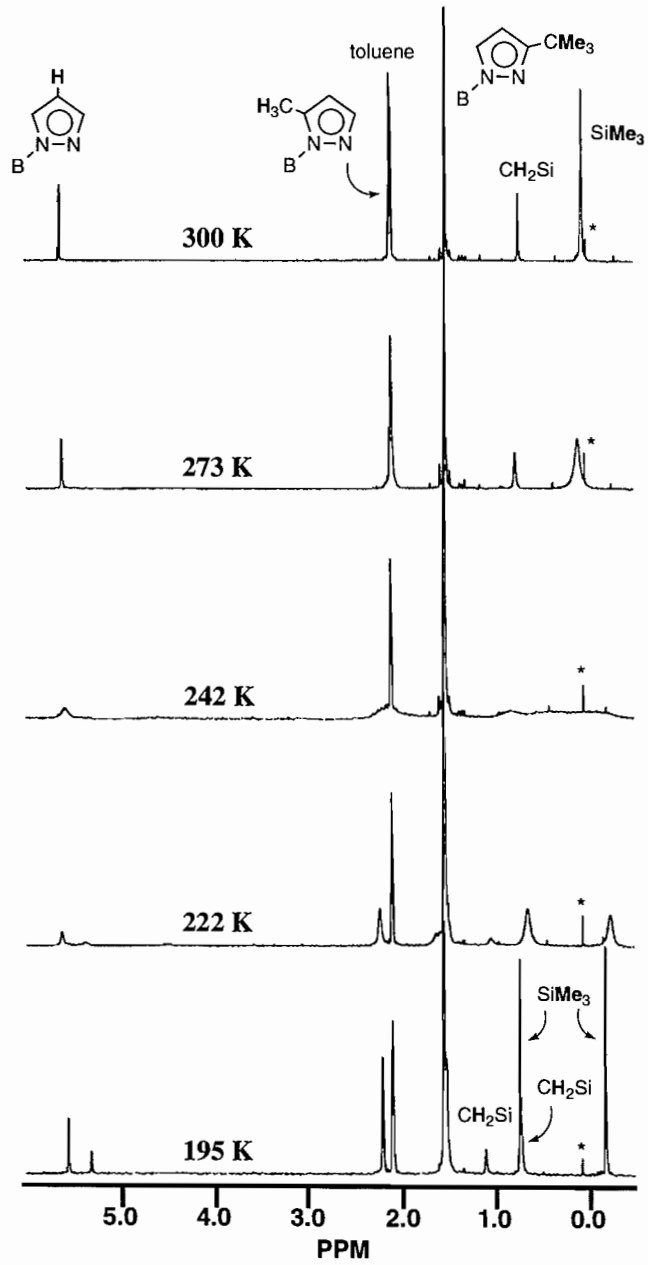
rings and the two alkyl groups exchange rapidly on the NMR time scale in solution at room temperature.



These structural features help to explain some of the observations we have made in preliminary reactivity studies of **2***b* in which the $Tp^{tBu,Me}$ ligand is readily removed from the metal. For example, the compound is extremely sensitive to water but protonolysis of the $Tp^{tBu,Me}$ ligand is competitive with loss of Me_4Si as evidenced by the presence of $Tp^{tBu,Me}H$ in samples intentionally treated with fractional equivalents of water. Furthermore, stirring a THF solution of **2***b* with an excess of dry LiCl led to slow formation of $Tp^{tBu,Me}Li$ and an unidentified scandium product, emphasizing the need to filter away the LiCl by-product from $Sc(CH_2SiMe_3)_3 \cdot THF_2$ before treating with $Tp^{tBu,Me}H$ (see eq. [3] above). These observations suggest that the more weakly bound (or dissociated) pyrazolyl nitrogen is the kinetically favoured site for reactivity with incoming electrophiles. We are currently probing the reactivity of these hydro-tris-pyrazolylborate scandium bis-trimethylsilylmethyl complexes in more detail and will report on this chemistry in due course.

Experimental section

General

All operations were performed under a purified argon atmosphere using glove box or high vacuum lines using standard techniques (18). Solvents were purified as follows: toluene

Fig. 2. ^1H NMR spectra of $(Tp^{tBu,Me})Sc(CH_2SiMe_3)_2$, **2***b*, in C_7D_8 at various temperatures. The peak marked by an asterisk (*) is due to an impurity.

was distilled from sodium benzophenone ketyl and stored over "titanocene" (19); tetrahydrofuran (THF) was predried with activated (10^{-4} Torr (1 Torr = 133.3 Pa), 200°C, 3 h) 3Å molecular sieves, distilled from, and stored over, sodium benzophenone ketyl; hexanes were distilled from lithium aluminum hydride (Aldrich) and stored over "titanocene"; dichloromethane was distilled from CaH_2; d_6-benzene was dried sequentially over activated 3Å sieves and "titanocene" and stored in the glove box; other NMR solvents were dried analogously to the perprotio solvents. ^1H and $^{13}C\{^1H\}$ NMR spectra were recorded on Bruker AC-200 and WH-400 MHz spectrometers. Elemental analyses were performed by Oneida Research Services, Inc., One Halsey Road, Whitesboro, NY

[a] U_{eq} is one third of the trace of the orthogonalized U_{ij} tensor.

13492, or in house using a Control Equipment Corporation model 440 elemental analyzer. Materials were purchased from Aldrich Chemical Company and used as received or purified using standard procedures (20). The compounds $ScCl_3 \cdot THF_3$ (21), $Tp^{R,Me}K$ (12, 22), and $Tp^{R,Me}Tl$ (22) were synthesized according to published procedures. Protonated ligands $Tp^{R,Me}H$ were prepared by treating the thallium salts with excess hydrogen sulfide (Matheson).[5]

[5] G. Parkin, personal communication.

Fig. 3. ORTEP drawing of $(Tp^{tBu,Me})Sc(CH_2SiMe_3)_2$, **2***b*.

Synthesis of $(Tp^{Me,Me})ScCl_2(THF)$, 1*a*

$ScCl_3 \cdot THF_3$ (5.0 g, 13.6 mmol) and $Tp^{Me,Me}K$ (4.41 g, 13.1 mmol) were combined in a flask and attached to a swivel frit apparatus. The assemblage was evacuated and THF (150 mL) was vacuum transferred into the vessel at −78°C. The reaction was stirred for 4 h at room temperature at which time the THF was removed in vacuo and replaced by toluene (150 mL). After sufficient extraction, the white suspension was filtered, the solution was concentrated, and hexanes were added. The resulting precipitate was isolated by filtration and washed with cold hexanes. Yield: 4.3 g, 65%. Anal. calcd. for $C_{19}H_{30}N_6Cl_2BOSc$: C 47.04, H 6.23, N 17.32; found: C 47.91, H 6.03, N 16.86.

Synthesis of $(Tp^{tBu,Me})ScCl_2$, 1*b*

$ScCl_3 \cdot THF$ (4.3 g, 11.8 mmol) and $Tp^{Me,tBu}K$ (5.02 g, 11.8 mmol) were combined in a flask and attached to a swivel frit apparatus. The assemblage was evacuated and toluene (50 mL) was vacuum transferred into the vessel at −78°C. The reaction was stirred for 24 h at room temperature at which time the toluene was removed in vacuo and replaced by methylene chloride (50 mL). After sufficient extraction, the white suspension was filtered and the methylene chloride was completely removed. The resulting white solid was triturated with hexanes and isolated by filtration. Yield: 3.1 g, 49%. Anal. calcd. for $C_{24}H_{40}N_6Cl_2BSc$: C 53.72, H 7.53, N 15.65; found: C 53.02, H 7.25, N 15.38.

Synthesis of $(Tp^{Me,Me})Sc(CH_2SiMe_3)_2(THF)$, 2*a* by metathesis

$(Tp^{Me,Me})ScCl_2(THF)$ (0.98 g, mmol) and solid $LiCH_2SiMe_3$ (1.95 equiv.) were combined in a flask and attached to a swivel frit apparatus. The assemblage was evacuated and toluene (≈25 mL) was vacuum transferred into the vessel at −78°C. The reaction was stirred at −78°C for 30 min and warmed gradually to room temperature. The suspension was filtered and concentrated; hexanes were added (toluene:hexanes, 1:4). The white precipitate was isolated by filtration. Yield: 0.85 g

(71%) of a ≈90% pure material. Further recrystallizations failed to improve the purity.

Synthesis of $(Tp^{Me,Me})Sc(CH_2SiMe_3)_2(THF)$, 2*a*, by alkane elimination

$ScCl_3(THF)_3$ (0.62 g, 1.7 mmol) and $LiCH_2SiMe_3$ (0.47 g, 5.0 mmol) were combined in a flask and attached to a swivel frit apparatus. The assemblage was evacuated and hexanes (≈25 mL) were vacuum transferred into the vessel at −78°C. The mixture was stirred at 0°C for 2 h, then filtered to remove LiCl. To the filtrate was added a solution of $Tp^{Me,Me}H$ (0.5 g, 1.7 mmol) in 10 mL of toluene at 0°C. The reaction solution was stirred at room temperature for 30 min, then reduced in volume to 5 mL and diluted with hexanes. The solid product (0.64 g, 67%) was collected on a frit, washed with cold hexanes, and dried under vacuum. Satisfactory microanalytical data could not be obtained on this compound, despite several attempts.

Synthesis of $(Tp^{tBu,Me})Sc(CH_2SiMe_3)_2$, 2*b*

$ScCl_3(THF)_3$ (0.50 g, 1.4 mmol) and $LiCH_2SiMe_3$ (0.38 g, 4.1 mmol) were combined in a flask and attached to a swivel frit apparatus. The assemblage was evacuated and hexanes (≈25 mL) were vacuum transferred into the vessel at −78°C. The mixture was stirred at 0°C for 2 h, then filtered to remove LiCl. To the filtrate was added a slurry of $Tp^{tBu,Me}H$ (0.57 g, 1.4 mmol) in 10 mL of hexanes at 0°C. The reaction solution was stirred at room temperature for 18 h, then reduced in volume to 5 mL and cooled to −35°C. Two crops of microcrystalline product (0.76 g, 87%) were collected by decanting away the mother liquor, then were washed with cold hexanes and dried under vacuum. Anal. calcd. for $C_{32}H_{62}N_6Si_2BSc$: C 59.79, H 9.72, N 13.04; found: C 55.61, H 9.44, N 12.84. This was the best of several microanalyses. The low carbon value is due either to incomplete combustion or the presence of a minor (<3%) unidentified impurity that could not be completely removed (see Fig. 2).

Identification of $Tp^{R,Me}Li$

$Tp^{R,Me}H$ (≈20 mg) was dissolved in 0.3 mL of C_6D_6. To this was added a solution of one equivalent of $LiCH_2SiMe_3$ in 0.4 mL of C_6D_6 in a dropwise fashion. The resulting cloudy solution was loaded into an NMR tube and the ^1H NMR spectrum was recorded. ^1H NMR spectrum for $Tp^{Me,Me}Li$ (200 MHz, C_6D_6, ppm): 5.78 (s, C*H*); 2.35 (s, C5-CH_3); 1.76 (C3-CH_3). ^1H NMR spectrum for $Tp^{tBu,Me}Li$ (200 MHz, C_6D_6, ppm): 5.71 (s, C*H*); 2.32 (s, C5-CH_3); 1.30 (s, C3-C(CH_3)$_3$.

X-ray crystallographic analysis of $(Tp^{Me,Me})Sc(CH_2SiMe_3)_2(THF)$, 2*a*

Single crystals suitable for X-ray crystallography were mounted in thin-walled glass capillaries and optically centered in the X-ray beam of an Enraf Nonius CAD-4 diffractometer. Unit cell dimensions were determined via least-squares refinement of the setting angles of 24 high-angle reflections and intensity data were collected using the ω–2θ scan mode. Data were corrected for Lorentz, polarization, and absorption effects but not for extinction. Pertinent data collection and structure refinement parameters are presented in Table 6. The

structure was solved using direct methods. All non-hydrogen atoms were refined with anisotropic thermal parameters. Aryl and methylene hydrogens were placed in calculated positions (D_{C-H} = 1.00 and 1.08 Å, respectively) whereas methyl hydrogen atoms were located via inspection of difference Fourier maps. Hydrogen atoms were given isotropic temperature factors based upon the atom to which they are bonded and fixed during least-squares refinement. A weighting scheme based upon counting statistics was used with the weight modifier *k* in kF_o^2 being determined via evaluation of variation in the standard reflections that were collected during the course of data collection. Neutral atom scattering factors were taken from *International tables for X-ray crystallography* (23). Values of *R* and R_w are given by $R = (F_o - F_c)/EF_o$ and $R_w = [E(w(F_o - F_c))^2/E(wF_o^2)]^{1/2}$. All crystallographic calculations were conducted with the PC version of the NRCVAX program package (24) locally implemented on an IBM-compatible 80486 computer. Anisotropic thermal parameters and hydrogen atom parameters are available as supplementary material.[6]

[6] Copies of material on deposit may be purchased from: The Depository of Unpublished Data, Document Delivery, CISTI, National Research Council Canada, Ottawa, Canada K1A 0S2. Tables of atomic coordinates and of bond lengths and angles have also been deposited with the Cambridge Crystallographic Data Centre, and can be obtained on request from The Director, Cambridge Crystallographic Data Centre, University Chemical Laboratory, 12 Union Road, Cambridge, CB2 1EZ, U.K.

X-ray crystallographic analysis of $(Tp^{tBu,Me})Sc(CH_2SiMe_3)_2$, 2*b*

A crystal of **2***b* was attached to a glass fiber and mounted on the Siemens SMART system for a data collection at 173(2) K. An initial set of cell constants was calculated from reflections harvested from three sets of 30 frames. Final cell constants were calculated from a set of 8082 strong reflections from the actual data collection. See Table 6 for additional crystal and refinement information.

In the hemisphere collection technique employed here, a randomly oriented region of reciprocal space is surveyed to the extent of 1.3 hemispheres to a resolution of 0.84 Å. Three major swaths of frames are collected with 0.30° steps in ω. This collection strategy provides a high degree of redundancy in the data, providing good ψ input in the event that an empirical absorption correction is applied (see Table 6). Frames were 45 s in duration.

The space group $P\bar{1}$ was determined based on systematic absences and intensity statistics. A successful direct-methods solution was calculated that provided most non-hydrogen atoms from the *E*-map. Several full-matrix least-squares difference/Fourier cycles were performed that located the remainder of the non-hydrogen atoms. All non-hydrogen atoms were refined with anisotropic displacement parameters. All hydrogen atoms were placed in ideal positions and refined as riding atoms with individual (or group, if appropriate) isotropic displacement parameters. In the space group $P\bar{1}$, $Z = 6$, so three independent molecules were found in the asymmetric unit. All calculations were performed using SGI INDY

Synthesis of 1-*N*-hydroxyhydantoin 5-phosphates as potential fungicides

Stephen Hanessian, Rui-Yang Yang, and Jean-Yves Sancéau

Abstract: Two hydantoin analogs were synthesized utilizing an organometallic allylation reaction in aqueous solution as a key step. One of the derivatives showed weak fungicidal activity.

Key words: hydantoin, fungicide, phosphate.

Résumé : Deux dérivés hydantoïniques ont été synthétisés utilisant une allylation organométallique en milieux aqueux comme réaction clé. L'un des dérivés a démontré une activité fongicidale faible.

Mots clés : hydantoïne, fongicide, phosphate.

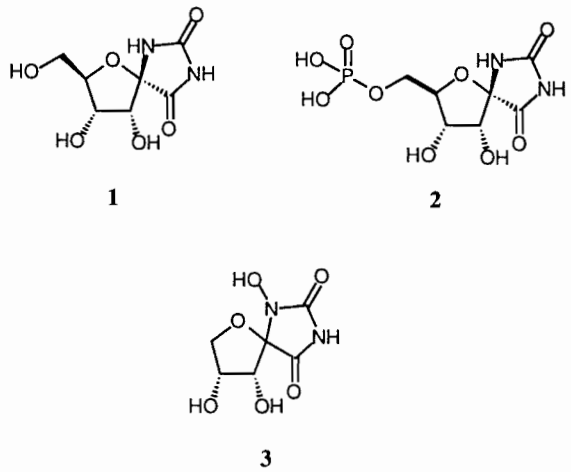
For personal use only.

Since the discovery of hydantocidin **1** (1), a potent nontoxic herbicide, a number of syntheses of this unusual compound (2) together with modifications of both the hydantoin ring (3) and the sugar unit (4) have been reported (5). Detailed investigations on its mode of action have recently shown that a phosphorylation occurs at the 5′-position to form the active principle **2** (6). In a previous paper, we described the synthesis of a prototype structure that incorporates an 1-*N*-hydroxyhydantoin motif as shown in express ion **3** (7). Continuing our interest in the design and synthesis of structurally novel 1-*N*-hydroxy hydantoins, we describe herein new target molecules of type **4**, in which the carbohydrate moiety of the parent hydantocidin **1** has been replaced by an acyclic chain terminating with a phosphate ester (Fig. 1).



The retrosynthetic route of **4** is shown in Fig. 2, and relies on a recently published method from our laboratory for the asymmetric synthesis of L-allylglycine (8). Variations in the length of the acyclic chain at C-5 of the heterocycle can be easily obtained from the allyl group via simple chemical transformations.

The target molecules were prepared as shown in Schemes 1 and 2. Thus, reaction of allyl bromide, the *O*-benzyl oxime of 2-propyl glyoxylate **5**, and commercial zinc powder in aqueous NH_4Cl–THF solution gave the allylglycine derivative **6** in 98% yield. The crude product **6** was pure enough for the next reaction, where it was reacted with chlorosulfonyl isocyanate in CH_2Cl_2 at −78°C to afford the *N*-benzyloxy urea derivative **7**. The latter was treated with TBAF in refluxing THF to give the key intermediate 1-*N*-benzyloxy-5-allylhydantoin **8**. Hydroboration with 2 equivalents of 9-BBN, followed by oxidation with 30% H_2O_2 in 3 M NaOAc aqueous solution at 50°C provided the hydroxy compound **9** in 63% yield. These oxidation conditions were crucial for the success of this reaction, since other conditions (for example, 30% H_2O_2 in NaOH, MCPBA, etc.) resulted in unacceptably low yields. Treatment of **9** under Mitsunobu conditions gave the corresponding dibenzyl phosphate ester, which upon hydrogenolysis led to the target compound **4a**.

The two-carbon chain analog **4b** was obtained from the common intermediate **8** (Scheme 2). Thus, ozonolysis followed by reduction with $NaBH_4$ afforded **11**. A Mitsunobu reaction with dibenzylphosphoric acid and hydrogenolysis of the product **12** gave *N*-hydroxy hydantoin 5-phosphate **4b**.

Compounds **4a** and **4b** were tested for fungicidal activity. Interestingly, weak but reproducible inhibitory activity was found against *Erysiphe graminis* (mildew) by foliar application for compound **4a**, but not for the two-carbon chain analog **4b**. Thus, structural and functional features present in hydantoin motifs such as **4a** are of interest, and further exploration of this venerable heterocycle in connection to fungicidal and related activities are worthy of further study.

Experimental

Tetrahydrofuran was distilled over benzophenone and potassium prior to use. Analytical thin-layer chromatography (TLC) was carried out on Merck Kieselgel silica gel 60 F_{254} glass plates. ^{1}H nuclear magnetic resonance spectra were obtained on a Bruker WH-400 spectrometer. ^{1}H multiplicities are recorded by use of the following abbreviations: s, singlet; d, doublet; m, multiplet; br, broad; *J*, coupling constant (Hz). High-resolution mass spectra were recorded by means of Kratos MS5OTCTA and AEI-MS 902 spectrometers at l'Université de Montréal. Melting points were measured on a Buchi apparatus and are uncorrected. Column chromatography was done using the flash technique (9).

N-Benzyloxy-allylglycine 2-propyl ester (6)

Commercial zinc powder (114 mg, 1.8 mmol) was added portionwise to a biphasic solution containing oxime **5** (221 mg, 1.0 mmol), allyl bromide (1.4 mmol) in THF (1 mL), and aqueous NH_4Cl (2 mL) at room temperature (rt). The mixture was stirred for 5 min, the reaction mixture was extracted with ethyl acetate (10 mL × 3), and dried over $MgSO_4$. After concentration, the crude product was purified by column chromatography on silica gel with 10% ethyl acetate in hexanes as eluent to give pure product **6** as an oil (258 mg, 98%). ^1H NMR ($CDCl_3$) δ: 1.26 (d, J = 6.3 Hz, 3H), 1.29 (d, J = 6.3 Hz, 3H), 2.32–2.37 (m, 2H), 3.66 (t, J = 6.8 Hz, 1H), 4.74 (s, 2H), 5.06–5.16 (m, 2H), 5.68–5.82 (m, 1H), 7.27–7.36 (m, 5H). ^{13}C NMR ($CDCl_3$) δ: 21.78, 21.81, 33.85, 63.20, 68.44, 76.08, 117.98, 127.70, 128.22, 128.29, 133.08, 137.70, 172.55 ppm. MS (FAB) *m/z*: 264(M+H, 100), 222(10), 176(7). HRMS calcd. for $C_{15}H_{22}NO_3$ (M+H): 264.1600; found: 264.1585.

N-Benzyloxy-N-ureido allylglycine 2-propyl ester (7)

To a solution of **6** (263 mg, 1.0 mmol) in CH_2Cl_2 at −78°C was added chlorosulfonylisocyanate (212 mg, 1.5 mmol) under argon, and the resulting solution was stirred for 2 h at that temperature. Water (10 mL) was added and the reaction mixture was allowed to slowly warm to rt. After stirring overnight, the reaction mixture was extracted with CH_2Cl_2 (3 × 10 mL), the combined organic phase was dried over Na_2SO_4 and concentrated. The residue was purified by column chromatography on silica gel (30% EtOAc – hexanes) to give 243 mg of a white solid **7** (79%), mp 64–66°C. ^1H NMR ($CDCl_3$) δ: 1.24 (d, J = 5.2 Hz, 3H), 1.26 (d, J = 5.2 Hz, 3H), 2.67–2.87 (m, 2H), 4.86 (dd, J = 5.6 Hz, J' = 9.6 Hz, 1H), 4.90–4.98 (m, 2H), 5.05 (sept, 1H), 5.10–5.19 (m, 2H), 5.45 (br, 2H), 5.83–5.97 (m, 1H), 7.37 (s, 5H). ^{13}C NMR ($CDCl_3$) δ: 21.70, 32.08, 62.04, 69.01, 78.27, 117.73, 128.67, 128.77, 128.86, 134.29, 134.96, 169.59 ppm. MS (FAB) *m/z*: 307(M+H, 100), 264(92), 222(27), 176(20). HRMS calcd. for $C_{16}H_{23}N_2O_4$ (M+H): 307.1658; found: 307.1668.

1-N-Benzyloxy-5-allylhydantoin (8)

To a solution of **7** (0.955 g, 3.11 mmol) in THF (5 mL) was added tetra-*n*-butylammonium fluoride (TBAF) in THF (1 M, 4.5 mL), and the resulting mixture was brought to reflux until all the starting material was consumed. After cooling to rt, water (10 mL) was added, the resulting mixture was then extracted with ethyl acetate (10 mL × 3), and the combined organic phase was washed throughly with water to remove TBAF. The organic phase was dried with Na_2SO_4 and concentrated, and the residue was purified by column chromatography on silica gel (20% EtOAc – hexanes) to give **8** in 87–90% yield. ^1H NMR ($CDCl_3$) δ: 2.46–2.64 (m, 2H), 3.97 (t, J = 4.8Hz, 1H), 5.05 (AB, J = 10.7 Hz, J = 16.4 Hz, 2H), 5.16–5.20 (m, 2H), 5.61–5.74 (m, 1H), 7.27–7.46 (m, 5H). ^{13}C NMR ($CDCl_3$) δ: 32.52, 64.22, 79.16, 120.36, 128.61, 129.05, 129.43, 130.47, 134.89, 157.47, 169.55 ppm. MS (FAB) *m/z*: 247.1(M+H, 100). HRMS calcd. for $C_{13}H_{15}N_2O_3$: 247.1083; found: 247.1094.

1-N-Benzyloxy-5-(3-hydroxypropyl)-hydantoin (9)

To a solution of **8** (437 mg, 1.78 mmol) in THF (8 mL) was added 7.8 mL of a THF solution of 9-BBN (0.5 M, 3.9 mmol), at 10°C to 0°C and the resulting solution was stirred for 2.5 h below −5°C. A solution of 30% H_2O_2 (3 mL) was added, followed by 5 mL of 3 M aqueous sodium acetate, and the resulting mixture was heated at 50°C for 4 h. After cooling to rt, the reaction mixture was extracted with EtOAc (15 mL × 4), and the combined organic phase was dried over Na_2SO_4 and concentrated. The residue was purified by column chromatography on silica gel (70% EtOAc – hexanes) to give a white solid **9** (297 mg, 63%), mp 87–89°C. ^1H NMR ($CDCl_3$) δ: 1.38–1.59 (m, 2H), 1.68–1.93 (m, 2H), 2.40 (br, 1H), 3.54 (t, J = 6.3 Hz, 2H), 3.96 (dd, J = 4.1 Hz, J' = 5.6 Hz, 1H), 5.03 (AB, quart. J = 11.0 Hz, J' = 18.5 Hz, 2H), 7.27–7.45 (m, 5H), 8.97 (s, 1H). ^{13}C NMR ($CDCl_3$) δ: 24.56, 26.52, 61.64, 63.86, 79.01, 128.59, 129.01, 129.55, 135.03, 158.37, 171.31 ppm. MS *m/z*: 266(M+2, 20), 265(M+H, 100), 181(12). HRMS calcd. for $C_{13}H_{17}N_2O_4$ (M+H): 265.1188; found: 265.1179.

1-N-Benzyloxy-5-(3-dibenzylphosphorylpropyl)-hydantoin (10)

To a solution of **9** (132 mg, 0.5 mmol), dibenzylphosphoric acid (140 mg, 0.5 mmol), and PPh_3 (131 mg, 0.5 mmol) in THF (6 mL) was added dropwise DEAD (0.17 mL, 1.0 mmol) under argon at rt. After 2 h, another portion of dibenzylphosphoric acid (140 mg, 0.5 mmol) and PPh_3 (131 mg, 0.5 mmol) was added, followed by 0.16 mL DEAD (1.0 mmol), dropwise, and the resulting mixture was stirred overnight. The reaction mixture was quenched with water, extracted with EtOAc (15 mL × 3), and the combined organic phase was dried over Na_2SO_4 and concentrated. The residue was purified by column chromatogarphy on silica gel (60% EtOAc – hexanes) to give **10** as a white solid (200 mg, 76%), mp 78–80°C. ^1H NMR ($CDCl_3$) δ: 1.51–1.70 (m, 3H), 1.76–1.85 (m, 1H), 3.84–3.93 (m, 3H), 4.94–5.10 (m, 6H), 7.35–7.42 (m, 15H), 8.98 (s, 1H). ^{13}C NMR ($CDCl_3$) δ: 24.47, 24.57, 63.65, 66.87, 69.27, 69.34, 79.05, 127.91, 128.50, 128.53, 128.58, 129.02, 129.51, 135.00, 135.66, 135.75, 158.00, 169.94 ppm. MS *m/z*: 525(M+H, 26), 417(5), 247(43), 181(51), 91(100). HRMS calcd. for $C_{27}H_{29}N_2O_7P$ (M+H): 525.1791; found: 525.1808.

1-N-Hydroxy-5-(3-dihydrophosphorylpropyl)-hydantoin (4a)

A solution of **10** (131 mg, 0.25 mmol) in MeOH (5 mL) was subjected to hydrogenolysis under H_2 (1 atm (= 101.3 kPa)) in the presence of 5% Pd–C (10 mg) at rt overnight. After filtration, the filtrate was concentrated to give **4a** in quantitative yield. ^1H NMR (CD_3OD) δ: 1.67–2.05 (m, 4H), 3.99–4.03 (m, 2H), 4.18 (t, J = 3.0 Hz, 1H). ^{13}C NMR (CD_3OD) δ: 25.97, 26.28 (d), 65.66, 67.10 (d), 160.37, 173.14 ppm. HRMS calcd. for $C_6H_{12}N_2O_7P$ (M+H): 254.0279; found: 254.0280.

1-N-Benzyloxy-5-(2-hydroxyethyl)-hyantoin (11)

A stream of ozone was passed through a solution of **8** (121 mg, 0.5 mmol) in a mixture of CH_2Cl_2–MeOH (10 mL, 1/1) at −78°C until a blue color persisted (10 min). A solution of $CeCl_3 \cdot 7H_2O$ (465 mg, 1.2 mmol) was added, followed by $NaBH_4$ (50 mg, 1.2 mmol). The cooling bath was removed and the mixture was allowed to warm to 0°C. After 1 h of stirring, it was neutralized with 5% aqueous acetic acid, then concentrated. The aqueous solution was extracted several times with EtOAc, and the organic phase was washed with brine, dried (Na_2SO_4), and concentrated. The residue was purified by column chromatography on silica gel (EtOAc – hexanes, 1/1) to

give the alcohol **11** as a white solid (81 mg, 66%), mp 62°C. ^{1}H NMR ($CDCl_3$) δ: 1.84–2.06 (m, 2H), 3.66–3.71 (m, 2H), 4.01 (t, J = 6.6 Hz, 1H), 5.05 (dd, 2H), 7.40–7.46 (m, 5H), 7.70 (s, 1H). ^{13}C NMR ($CDCl_3$) δ: 30.73, 57.79, 61.84, 78.99, 128.58, 128.99, 129.35, 134.98, 158.33, 172.10 ppm. HRMS calcd. for $C_{12}H_{14}N_2O_4$ (M+H): 251.1032; found: 251.1045.

1-*N*-Benzyloxy-5-(2-dibenzylphosphorylethyl)-hydantoin (12)

Triphenylphosphine (162 mg, 0.62 mmol), and dibenzylphosphate (166.3 mg, 0.62 mmol) were added to a solution of alcohol **11** (75 mg, 0.31 mmol) in dry THF (2 mL). DEAD (0.195 μL, 1.24 mmol) was slowly added to the solution and, after 5 h of stirring, the solvent was evaporated. The crude product was chromatographed (EtOAc – hexanes, 4/1) to yield **12** (85 mg, 55%). ^{1}H NMR ($CDCl_3$) δ: 1.75–2.05 (m, 2H), 3.85–3.97 (m, 4H), 4.85–4.98 (m, 6H), 7.18–7.29 (m, 15H). ^{13}C NMR ($CDCl_3$) δ: 29.00(d), 60.60, 62.97(d), 69.29(d), 77.32, 78.82, 127.85, 128.41, 128.45, 128.89, 129.43, 134.80, 135.41, 135.50, 158.14, 170.00 ppm. HRMS calcd. for $C_{26}H_{28}N_2O_7P$ (M+H): 510.1678; found: 510.1584.

1-*N*-Hydroxy-5-(2-dihydrophosphorylethyl)-hydantoin (4b)

The dibenzylphosphate hydantoin **12** (80 mg, 0.156 mmol) in MeOH (10 mL) was hydrogenolyzed in the presence of 10% Pd–C (10 mg) under atmospheric pressure for 5 h. The catalyst was filtered off and the solvent was evaporated to give **4b** in 95% yield (35 mg). ^{1}H NMR (CD_3OD) δ: 1.95 (m, 2H), 3.90 (m, 2H), 3.97 (t, J = 5.8 Hz, 1H). ^{13}C NMR (CD_3OD) δ: 31.3(d), 63.1, 63.56(d), 160.59, 173.12 ppm. HRMS calcd. for $C_5H_{10}N_2O_7P$ (M+H): 240.0123; found 240.0156.

Bioactive compounds from an endophytic fungus from eastern larch (*Larix laricina*) needles

John A. Findlay, Guoqiang Li, and John A. Johnson

Abstract: The structures of two novel metabolites isolated from cultures of an unidentified endophytic fungus obtained from an eastern larch (*Larix laricina* (Du Roi) K. Koch) needle were shown to be 8,1′,5′-trihydroxy-3′,4′dihydro-1′*H*-[2,4′]binaphthalenyl-1,4,2′-trione, **1**, and 2-methyloctanoic acid 6-oxo-2-propenyl-3,6-dihydro-2*H*-pyran-3-yl ester, **2**. Structures were determined by spectroscopic means. Compound **1** was toxic to spruce budworm (*Choristoneura fumiferana Clem.*) larvae while **2** was active against *Vibrio salmonicida*, *Pseudomonas aeruginosa*, and *Staphylococcus aureus*.

Key words: insect toxin, *Larix laricina* endophyte, antimicrobial, endophyte metabolite.

Résumé : On a établi les structures de deux nouveaux métabolites isolés de cultures d'un champignon endophytique non identifié des aiguilles d'un mélèze de l'Est (*Larix laricina* (Du Roi) K. Koch); il s'agit de la 8,1′,5′-trihydroxy-3′,4′dihydro-1′*H*-[2,4′]binaphthalényl-1,4,2′-trione, **1**, et de l'ester 2-méthyloctanoic de 6-oxoprop-2-ényl-3,6-dihydro-2*H*-pyran-3-yle ester, **2**. On a déterminé les structures par des méthodes spectroscopiques. Le composé **1** est toxique pour les larves de la tordeuse des bourgeons d'épinette (*Choristoneura fumiferana Clem.*) alors que le composé **2** est actif contre les *Vibrio salmonicida*, *Pseudomonas aeruginosa* et *Staphylococcus aureus*.

Mots clés : insecticide, endophyte *Larix laricina*, antimicrobien, métabolite d'endophyte.

[Traduit par la rédaction]

In the past we reported on the isolation of several insect toxins from cultures of endophytic fungi originating from conifer needles. Thus, by bioassay-guided fractionation, rugulosin was isolated as the toxic agent produced by a strain of *Hormonema dermatioides*, and heptelidic acid and two novel derivatives were isolated from cultures of a *Phyllosticta* sp. strain (1). More recently we characterized two novel isopimarane diterpenoids responsible for the insect toxicity of an unidentified endophyte from balsam fir (*Abies. balsamea* (L.) Mill.)(2) and two toxic isocoumarins from a culture of *Conoplea elegantula* originating from black spruce (*Picea mariana* BSP) needles (3).

Continuing our search for bioactive agents from conifer needle endophytes, we have examined the constituents of cultures of an unidentified endophyte L1930 obtained from an eastern larch (*Larix laricina* (Du Roi) K. Koch) needle. This endophyte displayed significant inhibition of the salmon pathogen *Vibrio salmonicida*, as well as *Pseudomonas aeruginora* and *Staphylococcus aureus* in agar diffusion assays (4). We now report the isolation and structure elucidation of two novel bioactive agents from cultures of L1930.

Compound **1** was isolated as an optically active ($[\alpha]_D$ +178), yellow crystalline (mp 214–216°C), UV-active (λ max 212, 256, 334, 418 nm) substance of composition $C_{20}H_{14}O_6$ as revealed by HREIMS. Strong absorptions in the IR spectrum (3500, 1635, 1610 cm^{-1}) were indicative of hydroxyl, conjugated carbonyl, and aromatic features. Due to low solubility in $CDCl_3$ and overlap of some aromatic signals in methanol-d_4 and acetone-d_6, the NMR data (Table 1) were recorded in pyridine-d_5 despite slow decomposition of **1** in this medium. In the ^1H NMR spectrum in acetone-d_6, three signals exchange in D_2O, two of which are attributed to phenolic (δ12.43, 12.00) features and the other (δ4.88) to a secondary hydroxyl, in view of its coupling (J = 4.8 Hz) to a methine proton at δ5.03 as revealed by the COSY spectrum in acetone-d_6.

The ^1H NMR and COSY spectra (pyridine-d_5) showed the presence of an AMX system comprising methylene protons at δ3.77 and δ2.82 coupled with a methine at δ4.11. In addition, two AMX systems, typical of 1,2,3-trisubstituted benzene rings, gave rise to mutually coupled signals at δ7.63 (dd, J = 7.4, 1.0 Hz), 7.54 (dd, J = 8.6, 7.4 Hz), 7.30 (dd, J = 8.6, 1.0 Hz) and δ7.06 (dd, J = 8.6, 1.0 Hz), 7.48 (dd, J = 8.6, 7.6 Hz), 7.09 (bd, J = 7.6 Hz). A small (allylic) coupling (J = 1.2 Hz) also exists between the methine signals at δ4.11 and δ5.35 and between δ4.11 and δ7.39 noted in the COSY spectrum and confirmed by decoupling experiments. Thus the ^1H NMR spectral data support the structural feature -CH═C-CH(CH_2)C═C-CHOH in addition to two 1,2,3-trisubstituted benzene rings.

The presence of these moieties together with three ketonic

[a]Assignments facilitated by COSY, HMQC, and HMBC data.

carbonyls and two phenolic OHs was confirmed by the ^{13}C NMR (Table 1), HMBC, HMQC, and DEPT spectra. The ^{13}C chemical shifts of the 8-hydroxy-1,4-naphthoquinone moiety closely resemble those of juglone (5). Analysis of HMBC correlations (Table 2) allowed us to extend the structure to **1**. The attachment of the hydroxy naphthoquinone moiety from C2 to C4′ of the 2-tetralone moiety is supported by the observation that the signals for protons H-1′, H-3′α, H-3′β, and H-4′ undergo deuterium exchange when a sample of **1** is equilibrated in pyridine-d_5–D_2O.

The relative stereochemistry was established by NOE difference spectroscopy, the results of which are summarized in Table 2. In particular, the strong NOEs between H-1′ and H-4′ indicate a *cis* relationship while the 20.3% enhancement of the signal for H-3 when H-3′β is irradiated indicates their close proximity.

Thus we conclude that **1** is 8,1′,5′-trihydroxy-3′,4′-dihydro-1′*H*-[2,4′]binaphthalenyl-1,4,2′-trione, and its preferred conformation is as depicted.

While decaketides featuring substituted 5-hydroxy-1,4-naphthoquinone moieties have been reported (6) as fungal metabolites, they are generally derivatives of extended 9,10-anthraquinone systems, for example, 6-deoxyversicolorin C from *Dothistoma pini* (7) or bipolarin from *Bipolarus sp* (8). On the other hand 1,1′ binaphthyl-type dimeric pentaketides of fungal origin are known (9) as well as naphthoquinone derivatives such as 2,7-dimethoxy-5-hydroxy-4-naphthoquinone from an Actinomycete (10). We are not aware of any dimeric 1,2′ binaphthyl-type pentaketides and thus compound **1** represents a new skeletal type of probable pentaketide dimerization biogenesis.

This compound displayed significant insect toxicity (96% mortality) when fed to spruce budworm larvae at 0.0004 g/g diet in a feeding assay (1).

[a]Assignments facilitated by COSY, HMQC, and HMBC data.

Compound **2** was isolated as an optically active ($[\alpha]_D$ +264) oil and displayed strong IR absorptions at 1730 and 1739 cm^{-1} attributed to α,β-unsaturated and saturated ester moieties, respectively. The ^{13}C NMR spectrum shows a total of 17 carbons comprising 3 methyls, 5 methylenes, 7 methines, and 2 quaternary carbonyl carbons as revealed by DEPT analysis. Four of the methine carbons are sp^2 hybridized while two others are oxygen bearing in view of their chemical shifts (Table 3).

The ^{1}H NMR, ^{1}H–^{1}H COSY, and HMBC spectra revealed the coupling sequence H_3-8 to H-7 to H-6 to H-5 to H-4 to H-3 to H-2 as contained in structure **2**. Another coupling sequence supports the unsaturated alkyl side chain and ring proton connectivity (H-5′ → H_3-9′).

The ^{1}H–^{13}C long-range correlations revealed by the HMBC experiment are contained in Table 4 and allowed us to derive

Scheme 1.

the complete structure **2**. Compound **2** does not provide a molecular ion in HREIMS due to its propensity to undergo both (*a*) cleavage at the ester ethereal bond to give a base peak corresponding to the side chain $C_9H_{17}O$ and (*b*) reverse Diels–Alder to afford the major fragment $C_{13}H_{20}O_3^+$ and the complementary fragment C_4H_7O in Scheme 1. The *cis* relationship of H-2′ and H-3′ is inferred by the small coupling ($J = 3.2$ Hz) and confirmed by strong NOEs between these signals (Table 4). Thus we conclude that compound **2** is 2-methyloctanoic acid 6-oxo-2-propenyl-3,6-dihydro-2*H*-pyran-3-yl ester.

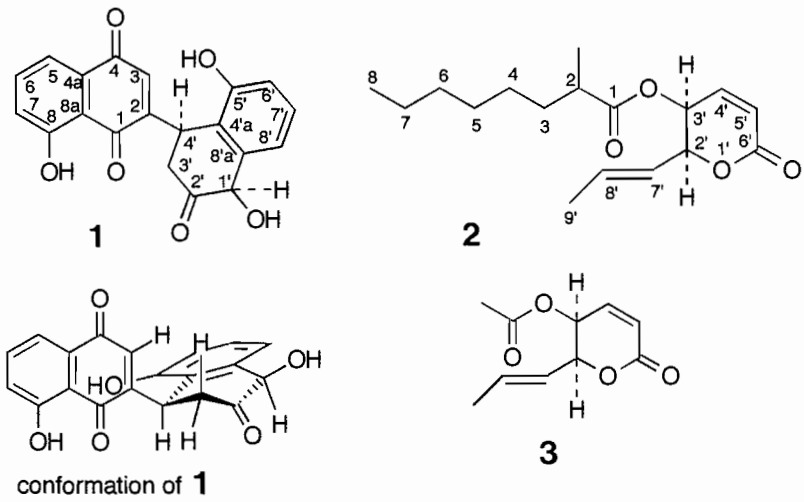
Compound **2** is closely related to several antimicrobial metabolites previously isolated from *Aspergillus crespitosus*, such as 5, 6-dihydro-5(*S*)-acetoxy-6(*S*)-(1,2-*trans* propenyl)-2*H*-pyran-2-one, **3**, whose published (11) ^{1}H NMR data for the pyranone and propenyl side-chain moieties are virtually coincident with those for **2** except for H-4′, which is at δ6.69 instead of δ6.92 in **2**. The strong +'ve optical rotations of **3** ($[\alpha]_D$ +311.8) and **2** imply that they possess the same absolute configuration.

Compound **2** displayed significant inhibitory activity in disk assays at 100 μg against the bacteria *Vibrio salmonicida*, and *Staphylococcus aureus* and at 500 μg against *Pseudomonas aeruginosa*.

Experimental

General

High-resolution mass spectra were recorded on a Kratos MS-50 instrument. Optical rotations were measured on a Perkin–Elmer 241 polarimeter. Melting points were taken with a Kofler hot-stage apparatus and are uncorrected. The IR spectra were recorded as films on a Bruker IF-S25 spectrometer. PTLC was performed with precoated Si gel F_{254} (0.5 or 0.25 mm) plates. NMR data were recorded on a Varian Unity 400 spectrometer, using the solvent as reference. All 2D NMR spectra were recorded non-spinning at 25°C. The UV spectra were measured on a Hewlett Packard 8452A diode array spectrophotometer.



Fungal strain

The endophyte strain L1930 was isolated from eastern larch (*Larix laricina* (Du Roi) K. Koch) needles from trees in Rockwood Park, Saint John, N.B., Canada (12). This isolate failed to produce spores, other structures, or cultural features to permit identification. L1930 was grown on 2% malt extract agar (MEA), potato dextrose agar (PDA), cornmeal agar (CA), Czapex-*d*ox, and tap water agar. It is deposited in the Herbarium Collection, Forestry Canada, Quebec Region (1055 du P.E.P.S., P. O. Box 3800, Saint Foy, QC G1V 4C7).

This endophyte was cultured as previously described (1, 4). After filtration the hyphae and medium were freeze-dried and kept in cold storage until used.

Disk assays

Vibrio salmonicida cultures were grown on brain heart infu-

sion agar (BHIA) (37 g of Lab M (Amersham) brain heart infusion medium/L, 15 g of Difco bactoagar/L) at 17°C. *Pseudomonas aeruginosa* and *Staphylococcus aureus* were grown on tryptic soy agar (TSA) (40 g of Difco tryptic soy agar/L) at 37°C. Controls consisted of 10 μL of methanol, 100 units of Penicillin G, and 100 units of Streptomycin in water. The assays were carried out with test material at 50, 100, and 500 μg/disk delivered in 10 μL of solvent.

Isolation

The freeze-dried medium (68.9 g) from cultures (8 L) of endophyte L1930 was extracted with acetone (3 × 350 mL) yielding a crude extract (0.10 g) after solvent evaporation. This extract was chromatographed on a silica gel column (Kieselgel 60G, 3.0 × 3.3 cm) and eluted with a discontinuous gradient of $CHCl_3$–CH_3OH (1:0 → 4:1) to give 14 fractions (40 mL each). Evaporation of fractions 4 and 5 gave crude **1**, which was further purified by PTLC using $CHCl_3$ (R_f = 0.16) followed by PTLC using nC_6H_{14}:C_6H_6: EtOAc (3:5:2), to give pure **1** (7.1 mg, R_f = 0.38).

The freeze-dried hyphae (2.2 g) from cultures (5 L) of endophyte L1930 was extracted with acetone (3 × 30 mL) yielding a crude extract (0.09 g) after solvent evaporation. This extract was subjected to chromatography on a short silica gel column (Kieselgel 60G, 2.2 × 2.5 cm) eluting with $CHCl_3$, giving eight fractions (35 mL each). Fractions 2–5 were combined (15 mg) and purified by PTLC using C_6H_6: $CHCl_3$ (2:3) to yield pure **2** (1.7 mg, R_f = 0.35).

Compound 1

Yellow powdery solid, mp 214–216°C (sublimes 190°C), $[\alpha]_D$ +178 (acetone, c = 0.0075). UV, $\lambda_{max}(\varepsilon)$: 212 (84 800), 256 (36 700), 334 (9 590), 418 (7 250) nm. Further examples of photocycloadditions of 1,3-diketonatoboron difluorides to olefins: a description of the reaction pattern and mechanism

Yuan L. Chow, Xianen Cheng, Shi S. Wang, and Susan P. Wu

Abstract: The photocycloaddition of dibenzoylmethanatoboron difluoride ($DBMBF_2$) with conjugated nitriles, ketones, and esters occurs more slowly than that with simple olefins and with fair regioselectivity. For these electron-deficient olefins, the cyclic analogues react more slowly than the acyclic ones and the cyano analogues react more slowly than all others; also a β-methyl substituent reverses the regioselectivity in adduct formation. Benzoylacetonatoboron difluoride ($BABF_2$) photocycloadds to simple cyclic olefins from the excited state isomer in which the double bond is conjugated with the phenyl group, and occurs more slowly than that of the corresponding reaction of $DBMBF_2$. The efficiency and regiochemistry of these cycloadditions have been explained with respect to the exciplex as the immediate intermediate.

Key words: photocycloaddition, dibenzoylmethanatoboron difluoride, benzoylacetonatoboron difluoride, exciplex.

Résumé : Les photocycloadditions du difluorure de dibenzoylméthanabore ($DBMBF_2$) sur les nitriles, cétones et esters conjugués s'effectuent plus lentement que celles sur les oléfines simples et leurs régiosélectivités sont correctes. Dans le cas de ces oléfines électrodéficientes, les analogues cycliques réagissent plus lentement que les acycliques et les analogues cyanés réagissent plus lentement que tous les autres; de plus, une substitution par un groupe β-méthyle inverse la régiosélectivité lors de la formation de l'adduit. Le difluorure de benzoylacétonatobore ($BABF_2$) conduit à une réaction de photocycloaddition sur les oléfines cycliques simples par le biais de l'isomère de l'état excité dans lequel la double liaison est conjuguée au groupe phényle; cette réaction est plus lente que la réaction correspondante du $DBMBF_2$. On a expliqué l'efficacité et la régiochimie de ces cycloadditions par le biais de l'exciplexe comme intermédiaire immédiat.

Mots clés : photocycloaddition, difluorure de dibenzoylméthanabore, difluorure de benzoylacétonabore, exciplexe.

[Traduit par la rédaction]

Introduction

Photochemistry of 1,3-diketonatoboron difluorides has been investigated (1–7) in order to remedy the low quantum yields of the de Mayo reaction (i.e., the photoaddition of 1,3-diketones with olefins)(8), and been shown not only to give good quantum yields in the photocycloaddition (1–4) but also to possess electron transfer reactivities (4, 7) and to show interesting photophysical phenomena (5, 6). The singlet excited state of these boron difluorides interacts with various types of electron-rich as well as electron-poor π-bond substrates. Both dibenzoylmethanatoboron difluoride ($DBMBF_2$, **1***a*) (1) and acetylacetonatoboron difluoride ($AABF_2$, **1***c*) (2) have been used as models to show that their singlet excited state either undergoes electron transfer with a substrate at the collision complex distance (ca. 7 Å) to form solvent-separated radical ion pairs, or approaches further to collapse to exciplexes (6, 7). The former radical ion pairs are preferentially formed in the interaction with electron-rich olefins or arenes, such as conjugated dienes, anethole, quadricyclane, etc., and constitute the initiation of observed radical cation reactions from such substrates (4). The formation of exciplexes can be observed with arenes through their fluorescence spectra, particularly in nonpolar solvent (6); exciplexes with olefins are assumed to be formed and act as the discrete intermediates in the photocycloaddition, although the corresponding exciplex fluorescence bands have not been detected.

Photocycloaddition of $DBMBF_2$ can occur with olefins ranging from electron-rich conjugated dienes and enol ethers (4) to electron-deficient conjugated ketones and esters (3), although the reaction with substituted benzenes has not been observed and is replaced instead by exciplex fluorescence in many cases (6, 7). It is noteworthy that, in the reaction with electron-rich olefins, solvent polarity can be adjusted to manipulate the reaction in favor of either the cation radical reaction or cycloaddition in a continuous pattern (4). In con-

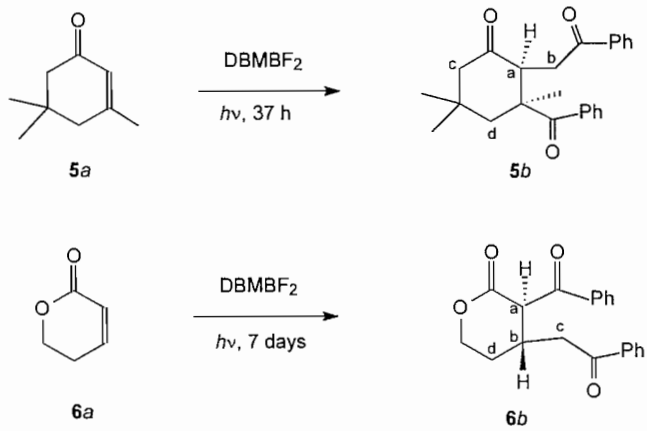
Scheme 1.

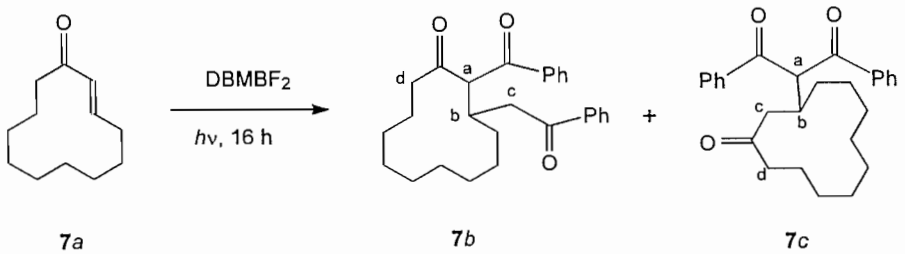


trast, $AABF_2$ does undergo photocycloaddition with substituted benzenes and simple olefins (2), but shows no photoreactivity toward enol ethers or conjugated dienes even in nonpolar solvent. Mechanistic studies using $DBMBF_2$ as the model compound have yielded sufficient information to allow us to describe the basic pattern of photoreactions of the boron compounds and substrates (6). This paper attempts to clarify some pockets left unexplored previously, and to reconfirm certain unusual conclusions made before. It will be discussed in the light of the overall mechanism recently proposed (6).

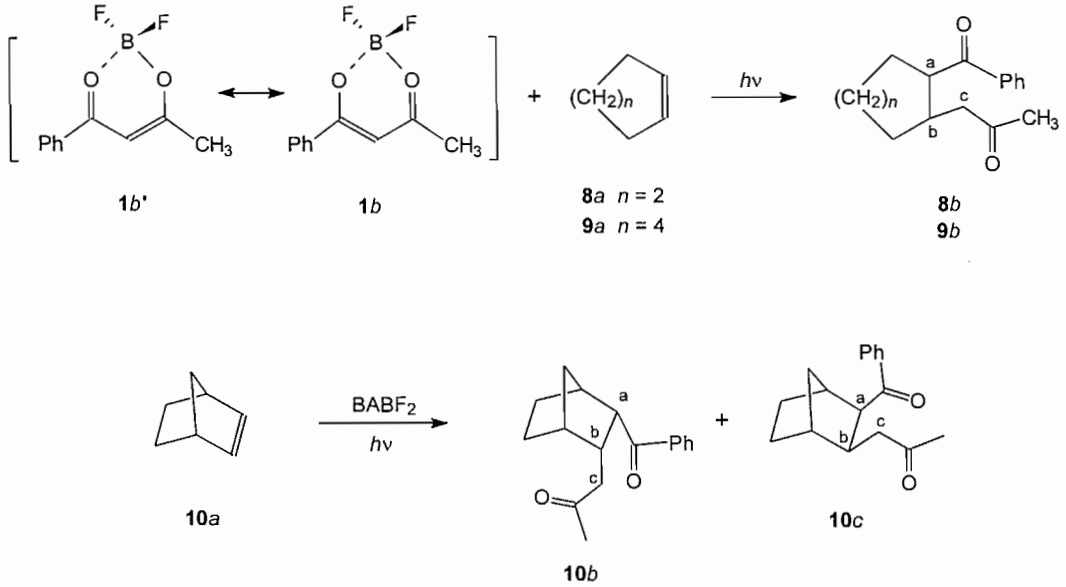
Results

We wish to report, first of all, the photocycloaddition of $DBMBF_2$ to olefins whose C=C bond is conjugated with a nitrile, ester, or ketone group, followed by the addition of benzoylacetonatoboron difluoride ($BABF_2$, **1***b*) to simple olefins. Some examples of the former addition to the conjugated esters and ketones were reported in 1993 (3) to occur more slowly than comparable simple olefins; similar photoreaction with the conjugated cyano derivatives, crotononitrile (**2***a*) and acrylonitrile (**3***a*), was found to be even less efficient. The photoreaction was carried out by the method and conditions similar to those reported before (1–3); a solution of $DBMBF_2$ (0.05 M) and a substrate (0.5 M) in acetonitrile was distributed in Pyrex tubes and irradiated with Rayonet 350 nm lamps. The progress of the reaction was monitored with GC analysis. The products were isolated by silica gel chromatography. The photoaddition to acrylonitrile **3***a* gave polymeric precipitate and was stopped when $DBMBF_2$ was only 25% consumed; single product **3***b* was isolated in 59% yield based on consumed $DBMBF_2$ (% yields for others were calculated the same way unless specified otherwise). Similar reaction with crotononitrile **2***a* did not give precipitates, and gave 41% of *threo*-**2***b* on nearly 50% conversion (Scheme 1). Both reactions followed the regiospecific orientation of substrates shown in **4** (arbitrarily defined as head-to-head) to give single products; as there were unisolated minor products, the regioselectivity was good but not complete. The sample of **2***b* contained the major compound (90%) showing a NMR spectrum with the H_a signal at 4.81 ppm (J_{ab} 3.6 Hz), and a weak signal at 4.64 ppm (J_{ab} 4.8 Hz); the latter

Scheme 2.



must arise from the minor component of the isomer at the "a"-position. Although, on the basis of the well-established concerted *cis*-photocycloaddition, this reaction should result in *erythro*-**2***b*, the stereochemistry of the isolated compound could not be defined for certain due to the facile isomerization. Such an isomerization at the "a"-position is facile because of double activations by two electron-withdrawing groups and has also been reported in a previous paper (3). Both products **2***b* and **3***b* exhibited pertinent IR, MS, and NMR (^1H and ^{13}C) parameters as shown in the experimental. The presence of cyano group was indicated by the ^{13}C NMR signal at 117.21 and 115.93 ppm and IR absorptions at 2251 and 2248 cm^{-1}, respectively.



The photoaddition of $DBMBF_2$ to isophorone was carried out to completion to give amorphous product **5***b* (44%) (Scheme 2), which was derived from the alternative orientation (head-to-tail) (3) in the first cycloaddition step; similar reversal of the orientation caused by a β-methyl group was observed before in allied photocycloadditions to mesityl oxide and crotonates (3). The structure was proven by the well-defined ABX system of H_a and H_b in **5***b*; the stereochemistry should be as shown since an isomerization at the "a"-position is not rapid. A similar photocycloaddition to the cyclic lactonic

© 1997 NRC Canada

Scheme 3.

Scheme 4.

olefin **6***a* (9) was very slow, consuming 70% of $DBMBF_2$ in 7 days to give the adduct *trans*-**6***b* (37%) from the regular head-to-head cycloaddition; the adduct must be the more stable *trans* configuration as shown by the coupling constant J_{ab} 8.2 Hz (1, 3) for H_a at 4.59 ppm. The initial product was no doubt *cis*-**6***b*, which must be isomerized in the slow photoreaction and decreased during isolation to about 10% as shown by the weak ^1H NMR signal at 5.07 ppm with J_{ab} 4.6 Hz.

E-2-Cyclododecenone **7***a* was prepared by the known method (10) and underwent the photocycloaddition readily to give adducts **7***b* (42%) and **7***c* (14%), which were formed from the regular head-to-head addition (Scheme 3). In addition to this, a mixture fraction (about 20%) of more than 10 dimers of enone **7***a* was also formed as shown by GC–MS (with M^+ 360). The sample of **7***b* was contaminated with 8% of its isomer at the "a"-position as shown by a weak NMR signal at 5.21 ppm (J_{ab} 3.5 Hz); the stereochemistry could not be defined easily owing to the facile isomerization. The *cis* cycloaddition of $DBMBF_2$ to the *trans* olefinic bond must lead to the *erythro* configuration, which should converge to the more stable isomer by such an isomerization. The NMR spectrum of **7***b* showed J_{ab} 11.1 Hz for the H_a at 4.92 ppm; these data unfortunately could not be interpreted unambiguously to define the *erytho–threo* configuration. Compound **7***c* was derived from the alternate electronic shifts in the intermediate stage (e.g., **4**) involving the other carbonyl as the sink (3). The sample was not obtained in a pure state, but the structure was supported by the low-field doublet H_a at 6.14 ppm, in analogy to the similar photoreaction with other enones.

Using the same apparatus and conditions described before, the quantum yields of 2-cyclopentenone, 2-cyclohexenone, **5***a*, 2-cyclooctenone, and **7***a* were determined to be 0.003, 0.007, 0.006, 0.052, and 0.057, respectively. It was noteworthy that, in contrast to low quantum yields of five- and six-membered cyclic enones, the larger ring enones gave reasonably good yields. The quantum yields of photocycloadditions to **2***a*, **3***a*, and **6***a* were too low for determination.

The photocycloaddition of $BABF_2$ to cyclohexene (**8***a*) and cyclooctene (**9***a*) (Scheme 4) was not as fast as that of $DBMBF_2$, and was terminated in 15 h to give about 50% of the $BABF_2$ consumption; the products **8***b* and **9***b* were isomerized during the reaction and isolation, which led to difficulty in purification and low isolated yields of 19 and 59%, respectively. The isomerization was faster with **8***b*, the isolated sample of which obviously possessed the *trans* configuration as shown by J_{ab} 8 Hz (1) obtained by decoupling experiments of H_a at 3.64 ppm. The corresponding J_{ab} in **9***b* was also ascertained to be 4.0 Hz by decoupling, which indicated the *cis* configuration for **9***b* in analogy to the allied eight-membered ring adducts reported before (1, 3).

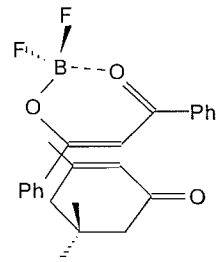
A similar photoreaction with norbornene consumed all $BABF_2$ in 10 h to give *cis,endo*-adduct **10***b* (68%) and an impure sample of *cis-exo*-**10***c* (8%); the formation of the former *cis-endo*-**10***b* as the major product was analogous to the case of $DBMBF_2$ photoreaction (1), and its structure was suggested by the lack of long-range coupling of H_a with the vicinal bridge and *anti* bridgehead protons. Both compounds had a strong *m/e* 199 derived from the elimination of the CH_3COCH_2 fragment. The H_a signal of **10***b* at 3.35 ppm with J_{ab} 9.1 Hz was easily located by decoupling with H_b (2.78 ppm). Irradiation of H_a caused a strong NOE effect on the H_b and *syn* bridgehead proton that unambiguously determined the *endo-cis* configuration. It is interesting to mention that irradiation of H_b did not cause NOE effects on the *syn* bridgehead proton, probably owing to twisting of the ring. The structure of **10***c* was suggested from MS showing a stronger *m/e* 189 peak than did **10***b*; this fragment must be derived from a McLafferty rearrangement and elimination. The same fragmentation pattern was also observed with the allied adduct of $DBMBF_2$, and used as evidence for the structural assignment (1).



Discussion

First of all, the $DBMBF_2$ photocycloaddition will be discussed. The examples of addition to conjugated nitriles, cyclic ketones, and esters described above extend the observations in our previous publication and reinforce those conclusions (3). They are as follows: (*i*) the effect of the β-methyl group is to reverse the orientation; (*ii*) cyclic enones and esters (lactones) tend to undergo photoreaction much more slowly than their acyclic analogues; (*iii*) conjugated nitriles react most slowly but still give the expected products, and finally; (*iv*) the adducts isomerize under the reaction conditions. As an exciplex is assumed to be the immediate precursor of the cycloaddition, the results summarized above, except the last, must originate from and be controlled by the properties of exciplexes, that is, the nature and configuration of exciplexes govern the orientation and efficiency of the cycloaddition. Owing to the short lifetimes of exciplexes, their nature is not known in detail and probably will not be readily available for some time. At present the properties and nature of exciplexes are elucidated from their spectroscopic data (6) and may be augmented by reverse reasoning from the product data. The studies from our laboratory have established that the BF_2 exciplexes possess charge transfer (CT) and locally excited (LE) contributions (6). Further, we have come to the conclusion that, while the LE component provides the driving force for exciplex formation (and therefore, cycloaddition), the CT component determines the regiospecificity of the cycloaddition by generating the dipoles (6). These conclusions will be used for discussion here.

Whereas five- or six-membered cyclic conjugated esters and ketones have mandatory *cis* configuration, acyclic analogues are more likely to have the *trans* configuration under the photolysis conditions. The slower photocycloaddition of the former (particularly cyclohexenone, cyclopentenone, and **6***a*) as compared with that of the latter suggests that such an exciplex formation is crowded to the extent that the cyclobutane bond formation is counteracted. Taking the head-to-head orientation as a requirement, complex **11** shows the approach of cyclohexenone (X = CH_2) and a probable hindrance from the *cis* double bond. For the approach of lactone **6***a* (X = O), the crowding may arise from the lone pair electrons of the heteroatoms. In the presence of the β-methyl group (**5***a* or mesityl

11

12

oxide), the steric factor should force a drastic reorientation of the exciplex partners to avoid excessive hindrance as suggested by the product regiochemistry. In particular, as enone **5***a* must avoid the crowding of the 5,5′-dimethyl group, **12** is proposed as a possible exciplex conformation. As a cyano group is a powerful electron withdrawer, in conjugation with an olefin it may accumulate a high electron density terminal to create a repulsive force against the BF_2 group. These represent only speculations to rationalize the results and, unavoidably, must remain imprecise until more knowledge on exciplexes becomes available.

The X-ray analysis of $BABF_2$ (11) has proven that the chelate ring shows extensive delocalization of the electrons so that both C—C and B—O bonds are equidistant. The product pattern suggests that singlet excited $BABF_2$ reacts from the structure **1***b* in Scheme 4, so that the adducts have the benzoyl and acetonyl groups attached to the original double bond. Addition products from the alternative structure **1***b*′, if formed at all, are probably in small yields as shown by small GC peaks. Using the concept of exciplexes as the cycloaddition intermediate, $*BABF_2$ may form a less tight intermediate with substrates, in general, than $*DBMBF_2$, and therefore shows a lesser tendency to undergo cycloaddition. This is caused by weaker LE interactions (i.e., weaker electronic coupling matrix element) generated by $*BABF_2$ than by $*DBMBF_2$ in forming exciplexes. The dipoles of $*BABF_2$–olefin exciplexes (generated by the CT interactions) can be dependent on the C=C position in the borate ring, which in turn directs the location of the cycloaddition. In contrast to the generally observed *exo* approach of addenda to a norbornene ring, it is unusual that $*BABF_2$ reacts with norbornene preferentially from the *endo* face to give the *cis-endo* configuration in analogy to that observed in the $DBMBF_2$ case (1); such a reaction pattern with norbornene is rare and, so far as we are aware, has not been previously found. This again must arise from the preferred geometry in the exciplexes, which have different electronic and steric factors than the corresponding ground state complexes.

Experimental section

Materials, apparatus, and conditions were the same as those published in the previous reports (1, 3).

General conditions of the photocycloaddition of $DBMBF_2$

The method of the photocycloaddition of $DBMBF_2$ to conjugated nitriles, ketones, and esters was the same as that

described by Chow et al. (3). A 30 mL acetonitrile solution of $DBMBF_2$ (0.05 M) and freshly distilled α,β-unsaturated ketone or ester (0.5 M) was distributed into six Pyrex test tubes (100 x 13 mm). The solution was purged with dry nitrogen and then placed in the Rayonet photoreactor for irradiation with a 350 nm light source. The photoreaction was monitored by GC or TLC to follow the disappearance of $DBMBF_2$. The yellowish or brownish solution was evaporated in vacuo and the residue was chromatographed on silica gel. Some typical runs were described below. The spectral data are collected in Tables 1–4.

Photoaddition to acrylonitrile (3*a*) and crotononitrile (2*a*)

$DBMBF_2$ (340 mg, 1.25 mmol) and **3***a* (663 mg, 12.5 mmol) were dissolved in 25 mL of *p*-dioxane. After irradiation for 26 h, some polymer had precipitated in the test tubes. This was collected (0.1 g, insoluble in acetone and water). The filtrate contained one major product by GC and TLC analysis. Evaporation and addition of ether:hexane (1:2) gave $DBMBF_2$ as a yellow precipitate, 0.29 g (25% conversion). The filtrate was chromatographed on silica gel using hexane:dichloromethane:ether (5:0.8:0.2–3.5:0.8:0.2). The pale-yellow oil **3***b* was isolated (66 mg, 59% based on the consumed $DBMBF_2$): R_f 0.074 (SiO_2, hexane:dichloromethane:ether = 3.5:0.8:0.2.

Similar photolysis of a 25 mL *p*-dioxane solution of $DBMBF_2$ (340 mg, 1.25 mmol) and **2***a* (839 mg, 12.5 mmol) for 26 h yielded no polymer. The $DBMBF_2$ was recovered as a yellow powder, 0.16 g (47% conversion). Chromatography (hexane:ethyl acetate = 8:1) produced 100 mg of **2***b* (41%), mp 98–99°C, R_f 0.21 (SiO_2, hexane:dichloromethane:ether = 5:0.8:0.2). Anal. calcd. for $C_{19}H_{17}O_2N$: C 78.35, H 5.84, N 4.81; found: C 78.30, H 5.89, N 4.69.

Photoaddition to isophorone (5*a*)

$DBMBF_2$ (204 mg, 0.75 mmol) and **5***a* (1.04 g, 7.5 mmol) were dissolved in 15 mL of acetonitrile. After 37 h of irradiation, GC analysis showed that $DBMBF_2$ had almost disappeared. One product spot was observed by TLC at R_f 0.18 (SiO_2, hexane:ethyl acetate = 6:1). The photolysate was

Photoaddition to 5,6-dihydro-2*H*-pyran-2-one (6*a*)

5,6-Dihydro-2*H*-pyran-2-one was prepared by refluxing of vinylacetic acid (31.6 g, 1 mol) with paraformaldehyde (43 g, 0.5 mol) in 125 mL of acetic acid containing 3 mL concentrated sulfuric acid (9). The distillation of the crude product at ~115°C/18 Torr (1 Torr = 133.3 Pa) gave 5.6 g of **6***a* (11%). The GC purity was 98% with RT 3.32 min at 80°C (on a 15 m OV–1 capillary column); ^{1}H NMR (100 MHz, $CDCl_3$) δ: 2.33–2.54 (2H, m), 4.40 (2H, t), 5.98 (H, dt), 6.93 (H, m) ppm; MS (EI) *m/z*: 98 (M^+, 23), 68 (M-18, 100).

$DBMBF_2$ (272 mg, 1 mmol) and **6***a* (981 mg, 10 mmol) were dissolved in 20 mL of acetonitrile. After a 9 day irradiation, GC analysis showed that $DBMBF_2$ conversion had reached 70%, and on TLC one product spot was found at R_f 0.11 (SiO_2, hexane:ethyl acetate = 4:1). The clear brown photolysate was mixed with 60 mL ether and washed with saturated aqueous sodium bicarbonate. The solution was adsorbed onto 3 g of silica gel and chromatographed on a 20 × 3 cm column with hexane:ethyl acetate (6:1–4:1) to give 0.11 g of a yellow oil. Further purification was performed by preparative TLC with hexane:dichloromethane:acetone (2:0.9:0.1) to yield 84 mg of a oil (37%) identified as *trans*-**6***b* (R_f 0.09).

© 1997 NRC Canada

cis-**6***b* was also observed in the ^{1}H NMR spectrum as a ~5% impurity in the isolated product.

Photoaddition to *E*-2-cyclododecenone (7*a*)

E-2-Cyclododecenone was prepared from cyclododecanone according to the published procedure, and showed the reported spectral properties (10). $DBMBF_2$ (204 mg, 0.75 mmol) and **7***a* (540 mg, 3 mmol) were dissolved in 15 mL of acetonitrile. After a 16 h irradiation, GC analysis showed nearly complete disappearance of $DBMBF_2$. TLC showed products at R_f 0.18 and at 0.13 (hexane:acetone = 15:1).

The dark-red solution was mixed with ether, washed with saturated aqueous sodium bicarbonate, and chromatographed on a 30 x 3 cm silica gel column. Elution with hexanes gave 0.1 g of an oil containing more than 10 components. Most of these showed similar dimer fragmentation on GC–MS (EI): *m/z*: 360 (M^+, 18), 342 (4), 275 (3), 233 (5), 222 (8), 207 (10), 193 (9), 181 (23), 180 (14), 162 (29), 152 (10), 135 (15), 121 (24), 109 (29), 95 (47), 81 (80), 79 (46), 69 (50), 67 (81), 55 (100).

Further elution with hexane:acetone (20:1) produced 0.17 g of a yellow solid (56%), as two components at R_f 0.18 and 0.13 in the ratio ~74:26. Recrystallization from hexanes yielded 109 mg of the major adduct **7***b* (R_f 0.18), mp 155–157°C. Anal. calcd. for $C_{27}H_{32}O_3$: C 80.20, H 7.92, found: C 79.94, H 8.01. The mother liquor was chromatographed on a 20 × 20 cm TLC plate with hexanes:acetone (15:1) to yield 14 mg of the minor adduct **7***c* (R_f 0.13).

Photocycloaddition of $BABF_2$ with simple olefins

The photocycloaddition of $BABF_2$ to simple olefins was carried out according to the procedure described in ref. 1. A solution of $BABF_2$ (0.05 M, 210 mg) and an olefin (0.5 M) in acetonitrile was kept under nitrogen in Pyrex tubes that were irradiated with the same apparatus as above. The photoreaction with **8***a* and **9***a* consumed 50% $BABF_2$ in 15 h. The crude adduct from **8***a* decreased and became more complex during the chromatography, from which **8***b* was obtained in 19% yield. Under similar conditions and operation **9***b* was isolated in 59% yield.

A similar reaction with norbornene consumed >90% of $BABF_2$ in 18 h and afforded **10***b* in 68% isolated yield and an impure fraction containing **10***b* and **10***c*. The yield of **10***c* was estimated from GC analysis to be 8%.

Four new hydrolyzable tannins and an acylated flavonol glycoside from *Euphorbia maculata*

Yoshiaki Amakura, Keita Kawada, Tsutomu Hatano, Isao Agata, Takeshi Sugaya, Sansei Nishibe, Takuo Okuda, and Takashi Yoshida

Abstract: The structure of a new acylated flavonol glycoside from the leaf extract of *Euphorbia maculata* was characterized as quercetin 3-*O*-(2″,3″-di-*O*-galloyl)-β-D-glucopyranoside. Four new hydrolyzable tannins together with twelve known tannins were also isolated and their structures were established by spectral and chemical means as 1,2,6-tri-*O*-galloyl-α-D-glucose, 1-*O*-galloyl-2,4;3,6-di-*O*-chebuloyl-β-D-glucose (eumaculin E), and dimers (eumaculins B and D) having a tergalloyl and a macaranoyl group as the linking unit of monomers, respectively.

Key words: *Euphorbia maculata*, Euphorbiaceae, tannin, eumaculin B, eumaculin E.

Résumé : On a déterminé la structure d'un nouveau glycoside acylé du flavonol extrait de la feuille d'*Euphorbia maculata*; il s'agit du 3-*O*-(2″,3″-di-*O*-galloyl)-β-D-glucopyranoside de quercétine. On a aussi isolé quatre nouveaux tannins hydrolysables ainsi que douze tannins connus et on a déterminé leurs structures à l'aide de méthodes tant spectrales que chimiques; il s'agit du 1,2,6-tri-*O*-galloyl-α-D-glucose, du 1-*O*-galloyl-2,4;3,6-di-*O*-chébuloyl-β-D-glucose (eumaculine E) et de dimères (eumaculines B et D) comportant respectivement un groupe tergalloyle et un groupe macaranoyle pour relier les unités de monomère.

Mots clés : *Euphorbia maculata*, Euphorbiaceae, tannin, eumaculine B, eumaculine E.

[Traduit par la rédaction]

Introduction

Many plants of the family Euphorbiaceae that grow in warm and temperate climates have been widely used as folk medicines in various areas of the world including East Africa, Southeast Asia, China, and Japan. The plants in this family, particularly *Euphorbia*, *Phyllanthus*, and *Macaranga* species, have been recognized to produce the ellagitannins with a vast structural diversity as represented by the geraniin metabolites (1–5). Amongst them, euphorbin A (**1**) and its analogous dimers possessing the geraniin unit as a constructing component were characterized as the abundant constituent of chemotaxonomical significance in many euphorbiaceous plants (5).

We previously examined the tannins of *Euphorbia maculata* L. (Euphorbiaceae), which has been used as a folk medicine for wound treatment in Mexico and China (6), and as an antidiarrheal in China (7), and isolated a new dimeric hydrolyzable tannin, eumaculin A (**11**), which contains the $^1C_4$ and $^4C_1$ glucopyranose cores linked through a valoneoyl group (8). Further investigation on the polyphenolic constituents in the leaf extract of the plant has revealed the presence of euphorbin A (**1**) and its analogs, euphorbins B (1) and D (9). In addition to these dimers together with eight known tannins, a new digalloylated flavonol glycoside (**2**) and four new hydrolyzable tannins (**3**, **4**, **9**, **10**) have also been isolated. This paper describes the structural elucidation of the new compounds.

Results and discussion

The aqueous acetone homogenate of dried leaves of *E. maculata* was extracted successively with ether, EtOAc, and *n*-BuOH. The EtOAc extract was chromatographed over Toyopearl HW-40 and MCI-gel CHP-20P to yield 17 polyphenolics including new compounds **2**–**4**, **9**, and **10**. Among them, 12 were identified as 1,3,6-tri-*O*-galloyl-β-D-glucose, 3,4,6-tri-*O*-galloyl-D-glucose, 1,2,3,4,6-penta-*O*-galloyl-β-D-glucose (10), euphormisin M_3 (2), chebulanin (11), chebulagic acid (**8**) (12), tercatain (13), granatin B (14), excoecarianin (15), and euphorbins A (**1**) (16, 17), B (1, 16, 17), and D (9), by direct comparisons with authentic specimens or by comparisons of their physical data with those reported in the literature.

Compound **2** showed UV absorption bands characteristic of a flavonol derivative. The ^{1}H NMR spectrum of **2** indicated the presence of a quercetin moiety as revealed by 1,3,4-trisubstituted benzene proton signals at δ 7.78 (d, J = 2.5 Hz), 7.59 (d, J = 2.5, 8.5 Hz), and 6.94 (d, J = 8.5 Hz) and *meta*-coupled signals at δ 6.45 (d, J = 2 Hz) and 6.22 (d, J = 2 Hz). Besides these signals, two singlets attributable to two galloyl

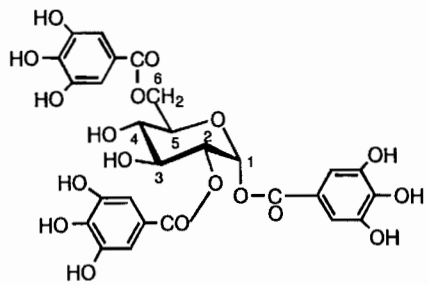
groups (δ 7.04, 7.10, each 2H) were observed in the aromatic region. The coupling patterns of the aliphatic proton signals, which were assigned with the aid of ^{1}H–^{1}H shift correlation spectroscopy (COSY), were consistent with those of $^4C_1$ glucopyranose. The ^{13}C NMR resonances of the aglycone moiety were also in agreement with those of isoquercitrin (18). These data coupled with the FABMS data (*m/z* 791 $(M+Na)^+$) indicated that **2** is a digallate of isoquercitrin. The galloyl groups in **2** were located at O-2 and O-3 of the glucose residue based on the remarkable downfield shifts of the H-2″ (δ 5.39) and H-3″ (δ 5.51) signals. Enzymatic hydrolysis of **2** with tannase yielded gallic acid, isoquercitrin, and quercetin 3-*O*-(2″-*O*-galloyl)-β-D-glucopyranoside (19). The compound **2** was thus characterized as quercetin 3-*O*-(2″,3″-di-*O*-galloyl)-β-D-glucopyranoside (**2**). Although various acylated flavonol glycosides are found widely in the plant kingdom (20), digallates such as **2** are quite rare, and to our knowledge compound **2** is the first example of a natural flavonol glycoside galloylated at O-3 of the glucose residue.

Compound **3** gave an $(M+Na)^+$ ion peak at *m/z* 659 corresponding to the molecular formula $C_{27}H_{24}O_{18}$ in the FABMS. Its ^{1}H NMR spectrum showed signals attributable to three galloyl groups (δ 7.16, 7.12, 7.06, each 2H singlet) and seven aliphatic protons characteristic of a $^4C_1$ glucopyranose residue. The glucose H-3 and H-4 signals were observed at higher field (δ 4.26, 3.83) than the other proton signals, indicating that the hydroxyl groups at C-3 and C-4 are not acylated, while the others are all acylated. The α-configuration of the galloyloxy group at the anomeric center was apparent from the small coupling constant (J = 3.5 Hz) of the H-1 signal. Compound **3** was thus characterized as 1,2,6-tri-*O*-galloyl-α-D-glucose[2] (**3**).



A new compound (**4**), which was designated as eumaculin E, showed an ion peak $(M+H)^+$ at *m/z* 973 in the FABMS. The ^{1}H NMR spectrum of **4** displayed a two-proton singlet at δ 7.22 due to a galloyl group, and signals assignable to two chebuloyl groups (12) (δ 2.18 (2H, m), 2.26 (dd, J = 3.5, 17 Hz), 2.18 (dd, J = 12, 17 Hz) (H-5); 3.87 (ddd, J = 1.5, 5, 11 Hz), 3.80 (ddd, J = 2, 3.5, 12 Hz) (H-4); 5.10 (dd, J = 1.5, 7 Hz), 4.94 (dd, J = 2,7 Hz), (H-3); 4.87 (d, J = 7 Hz), 4.82 (d, J = 7 Hz) (H-2); 7.52 (s) and 7.48 (s) (H-3′)). The presence of the chebuloyl groups in **4** was also substantiated by the ^{13}C NMR spectrum (δ 66.4 (2C, C-2), 39.9, 41.1 (C-3), 39.3, 39.6 (C-4), 30.5, 30.7 (C-5) and eight carbonyl carbon resonances), and by the formation of trimethyl tri-*O*-methylchebulate (**6**) (23) and methyl tri-*O*-methylgallate (**5**) on methanolysis of the methylated derivative of **4**. The coupling patterns of the sugar proton signals were characteristic of glucopyranose adopting a skew-boat conformation (24). The positions of the acyl groups in **4** were determined by HMBC measurement ($^{2,3}J_{C-H}$ = 8 Hz). The presence of the galloyl group at O-1 was indicated by correlation of the galloyl proton signal through three-bond coupling with an ester carbonyl carbon signal at δ 165.1 that also showed a cross peak with the anomeric proton. The signals at δ 7.52 and δ 7.48 (chebuloyl H-3′) showed correlations with the H-6 and H-2 signals through common ester carbonyl carbon signals at δ 167.5 and 165.6, respectively (Fig. 1), establishing the orientation of the chebuloyl groups at O-2/O-4 and O-3/O-6 of the glucose core. Although the stereochemistry of the chebuloyl moieties is apparent from the CD spectrum of **6**, which is identical with that of authentic specimens (23),

[2] Although the structure **3** was once assigned to a constituent of *Nuphar japonicum* (21), it was later revised to 1,2,4-tri-*O*-galloyl-α-D-glucose (22), and thus **3** is a new compound.

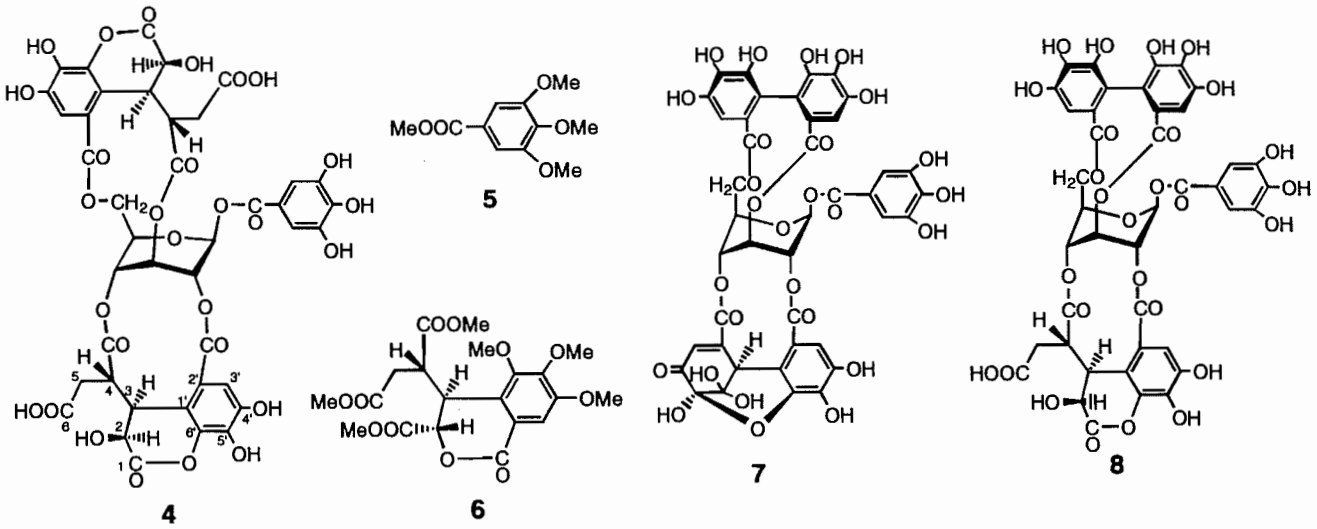
further evidence for the absolute configuration at C-3 of each chebuloyl group in **4** was provided by ROE's between the chebuloyl H-3 signals (δ 5.10, 4.94) and the glucose proton signals (H-1, H-3 and H-2, H-4, respectively), in rotating-frame nuclear Overhauser enhancement spectroscopy (ROESY). On the basis of these results, the structure of eumaculin E was established as 1-*O*-galloyl-2,4;3,6-di-*O*-chebuloyl-β-D-glucopyranose (**4**). Tannin **4** might be regarded as a metabolite which can be produced via chebulagic acid (**8**) by structural modifications of geraniin (**7**) .



Compounds **9** and **10** were shown to be new dimers analogous to eumaculin A (**11**) as described below, and thus named eumaculins B and D, respectively. The molecular formula of eumaculin B (**9**), $C_{68}H_{52}O_{44}$, was deduced from an $(M+Na)^+$ ion peak at *m/z* 1595 in the FABMS. The ^1H NMR spectrum of **9** disclosed signals due to five galloyl groups (δ 7.17, 7.13, 7.11, 7.05, 7.02 (each 2H, s)), three aromatic protons (δ 6.98, 6.84, 6.48 (each 1H, s)), and two glucose cores (see Table 1). The coupling patterns of the glucose protons are typical for those of $^4C_1$ and $^1C_4$ glucopyranoses. The hydroxyl groups on the $^4C_1$ glucopyranose core are fully acylated as revealed by the chemical shifts of the H-1–H-4 and H-6 signals, whereas the hydroxyl groups at C-2′ and C-4′ in the $^1C_4$ glucose core were shown to be unacylated by the appearance of H-2′ (δ 4.12) and H-4′ (δ 4.60) in the high-field region. These NMR features of **9** were similar to those of eumaculin A (8), indicating that **9** is a dimer composed of corilagin and pentagalloylglucose units like **11**. A spectral difference between **9** and **11** includes a remarkable downfield shift of one of the aromatic 1H-singlets (δ 6.19 in **11** → δ 6.48 in **9**), which suggested that the linking unit of the monomers in eumaculin B (**9**) differs from that (valoneoyl group) of eumaculin A (**11**). Methylation of **9** with dimethyl sulphate and potassium carbonate in acetone and subsequent methanolysis yielded methyl tri-*O*-

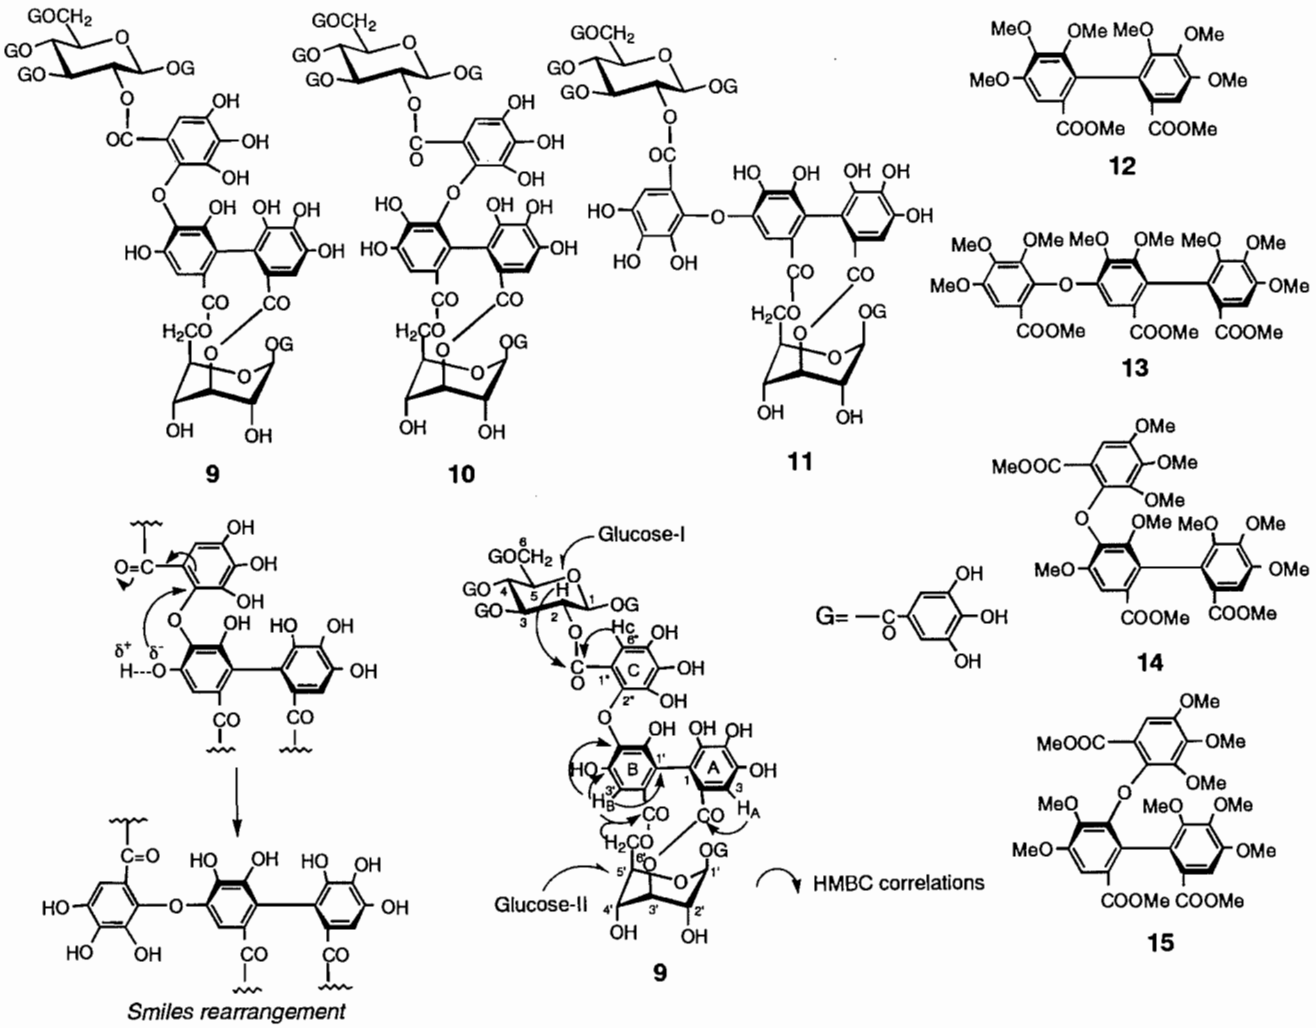
methylgallate (**5**) and trimethyl octa-*O*-methyltergallate (**14**) (1, 25), as major products. The linking unit of the monomers in eumaculin B (**9**) was thus confirmed to be a tergalloyl group. Dimethyl hexamethoxydiphenate (**12**) and trimethyl octa-*O*-methylvaloneate (**13**) were also obtained as minor products in the above reaction. These two products were regarded as secondary products derived from the tergalloyl moiety in **9** by cleavage of the biphenyl ether bond and Smiles-type rearrangement, respectively (1). The HMBC ($^{2,3}J_{C-H}$ = 8 Hz) of **9** showed a cross peak by three-bond coupling between the glucose H-6′ signal (δ 4.92 (t, J = 11 Hz)) and the ester carbonyl carbon resonance at δ 168.3, which, in turn, correlated with the aromatic proton signal at δ 6.48. This aromatic proton signal was assigned to H_B of the tergalloyl group based on its correlation through two-bond coupling with the signal attributed to C-4′ (δ 149.1) of the tergalloyl B-ring (4), and also through three-bond coupling with C-1′ (δ 115.3). The connectivity between the tergalloyl B-ring and C-6′ of the glucose core-II was thus established. The structure **9** thus proposed for eumaculin B was substantiated by chemical transformation of eumaculin B (**9**) into eumaculin A (**11**) through Smiles-type rearrangement (1, 25). Namely, an aqueous solution of **9** containing a small amount of phosphate buffer (pH 7.4) was left at room temperature for 5 h to give an isomerized product identical with **11**. Based on these findings, the structure of eumaculin B including the orientation and absolute configuration of the tergalloyl group at O-3/O-6 of glucose was represented by the formula **9**.



Eumaculin D (**10**) showed an ion peak at *m/z* 1595 ascribable to $(M+Na)^+$ in the FABMS, and gave a large retention volume on normal-phase HPLC, like **11** and **9**, suggesting it to be a dimeric hydrolyzable tannin (5). The ^{1}H NMR spectrum of **10** measured in acetone-d_6 and D_2O at ambient temperature showed duplicate signals for each proton, probably due to the presence of rotamers resulting from restricted rotation about the ether linkage of a macaranoyl group. The spectrum of **10** measured in MeOH-d_4, which was simplified by enhanced ratio of one rotamer, was similar to those of **11** and **9**, particularly in the chemical shifts and coupling patterns of the sugar moieties. A significant difference in the ^{1}H NMR spectra among **10**, **9**, and **11** was a downfield shift of one of the aromatic 1H singlets in **10** (δ 6.19 in **11**; δ 6.48 in **9** → δ 6.67 in **10**), which suggested that the linking unit of two monomers in **10** is different from that in both **11** and **9**. Methylation of eumaculin D (**10**) with dimethyl sulphate and potassium carbonate in acetone, followed by methanolysis with sodium methoxide, yielded methyl tri-*O*-methylgallate (**5**) and trimethyl octa-*O*-methylmacaranate (**15**) (1), as major products, accompanied by the minor products **12**, **13**, and **14**. The latter three were regarded as secondary products formed from the macaranoyl group in a similar manner to that from the tergalloyl group in **9**. The position and orientation of the macaranoyl group were based on the HMBC measurement ($^{2,3}J_{C-H}$ = 8 Hz) of **10**, which revealed the connectivity between glucose H-6 and the macaranoyl H_B signal through three-bond couplings with an ester carbonyl carbon signal at δ 170.1. The assignment of the macaranoyl H_B signal was based on two- and three-bond couplings with the macaranoyl C-4′ and C-1′ signals. Eumaculin D (**10**) was thus concluded to be an isomer of **11** and **9** differing only in the structure of the linking unit of the monomeric constituents. The structure **10** for eumaculin D was finally substantiated by chemical correlation between **10** and **11**. The isomerized product obtained by the Smiles-type rearrangement upon treatment of **10** with phosphate buffer (pH 7.4) was identical in all respects with eumaculin A (**11**).

Experimental

^{1}H and ^{13}C NMR spectra were recorded on a Varian VXR-500 instrument at 500 MHz and 126 MHz, respectively, and chemical shifts are given in δ values (ppm), based on the ^{1}H and ^{13}C signals of solvents (acetone-d_6 (δ_H 2.04; δ_C 29.8) or CD_3OD (δ_H 3.30; δ_C 49.0)) on a TMS scale. EI and FAB mass spectra were measured on a JEOL GMS HX-100 or a VG 70-SE mass spectrometer. ESI mass spectra were carried out with a Micromass AutoSpec OA-Tof mass spectrometer (solvent: MeOH-H_2O (1:1) + 0.1% $AcONH_4$, flow rate: 20 μL/min). Optical rotations were obtained on a JASCO DIP-1000 digital polarimeter, CD spectra on a JASCO J-720W spectropolarimeter, and UV spectra on a Shimadzu UV-180 spectrophotometer. Normal-phase HPLC was carried out with a Shimadzu LC-6A using a YMC-Pack SILA-003 column (4.6 × 250 mm) devel-

oped with *n*-hexane–MeOH–THF – formic acid (60:45:15:1, v/v) containing oxalic acid (500 mg/1.2 L) (flow rate, 1.5 mL/min; detection 280 nm) at room temperature. Reversed-phase HPLC was performed on a YMC-Pack A312 (ODS) column (4.6 × 150 mm) developed with 0.01 M H_3PO_4 – 0.01 M KH_2PO_4 – CH_3CN (41:41:18, v/v) (flow rate, 1.0 mL/min; detection 280 nm) at 40°C. TLC was conducted on Kieselgel 60 PF_{254} (Merck) plates with *n*-hexane–$CHCl_3$–acetone (4:6:1). Column chromatography was performed on Toyopearl HW-40 (coarse and fine grades, Tosoh), Sephadex LH-20 (Pharmacia Fine Chemicals), Dia-ion HP-20, and MCI-gel CHP-20P (Mitsubishi Kasei Industry).

Plant material

The leaves of *E. maculata* L. were collected at the campus of Okayama University in summer 1992 and a voucher specimen has been deposited at the Herbal Garden of the Faculty of Pharmaceutical Sciences, Okayama University.

Extraction and isolation

The dried leaves (2.0 kg) were homogenized (× 3) in acetone–H_2O (7: 3) (12 L × 3) and the homogenate was filtered. The filtrate was concentrated and further extracted with Et_2O (3 L × 3), EtOAc (3 L × 6), and *n*-BuOH saturated with H_2O (3 L × 6). A part (6.0 g) of the EtOAc extract (124.5 g) was chromatographed over Toyopearl HW-40 (fine) (2.2 cm i.d. × 35 cm) with MeOH–H_2O (5:5 → 6:4 → 7:3) → MeOH–H_2O–acetone (7:2:1 → 6:2:2) → acetone–H_2O (7:3) in a stepwise gradient mode. The fractions showing similar HPLC patterns were combined and further purified by rechromatography over Sephadex LH-20 with EtOH and (or) MCI-gel CHP-20P with aqueous MeOH to afford 3,4,6-tri-*O*-galloyl-D-glucose (1.7 mg), 1,3,6-tri-*O*-galloyl-β-D-glucose, euphormisin M_3 (1.3 mg), 1,2,3,4,6-penta-*O*-galloyl-β-D-glucose (8 mg), chebulanin (16 mg), chebulagic acid (**8**) (3 mg), tercatain (5 mg), granatin B (4 mg), excoecarianin (14 mg), euphorbin A (**1**) (53 mg), euphorbin B (5 mg), euphorbin D (99 mg), quercetin 3-*O*-(2″,3″-di-*O*-galloyl)-β-D-glucopyranoside (**2**) (7.6 mg), 1,2,6-tri-*O*-gallyl-α-D-glucose (**3**) (2 mg), eumaculin E (**4**) (4.8 mg), eumaculin B (**9**) (30 mg), and eumaculin D (**10**) (45 mg). To obtain additional crops of the new tannins, the other part (10 g) of the EtOAc extract was similarly fractionated by repeated column chromatographies over Toyopearl HW-40 (fine), Sephadex LH-20, and MCI-gel CHP-20P to give eumaculin E (**4**) (25 mg), eumaculin B (**9**) (50 mg), and eumaculin D (**10**) (55 mg).

Enzymatic hydrolysis of ***2***

An aqueous solution of **2** (5 mg/ 3 mL) was incubated at 37°C with tannase that was prepared from *Aspergillus niger* (26), and the progress of the reaction was monitored by HPLC. The formation of isoquercitrin and quercetin 3-*O*-(2″-*O*-galloyl)-β-D-glucopyranoside, together with gallic acid, was observed by the accompanying disappearance of the starting material, and these products were identified by co-chromatography on HPLC with authentic samples.

1,2,6-Tri-O-*galloyl*-α-D-glucose (**3**): off-white amorphous powder; $[\alpha]_D$ +31 (*c* 0.5, MeOH); UV λ_{max} MeOH nm (log ε): 218 (4.79), 277 (4.42); ^{1}H NMR (500 MHz, acetone-d_6 + D_2O) δ: 7.16, 7.12, 7.06 (each 2H, s, galloyl), 6.50 (1H, d, *J* = 3.5 Hz, Glc H-1), 5.02 (1H, dd, *J* = 3.5, 10 Hz, Glc H-2), 4.26 (1H, t, *J* = 10 Hz, Glc H-3), 3.83 (1H, t, *J* = 10 Hz, Glc H-4), 4.16 (1H, m, Glc H-5), 4.52 (1H, dd, *J* = 2, 12 Hz, Glc H-6), 4.12 (1H, dd, *J* = 4, 12 Hz, Glc H-6). Anal. calcd. for $C_{68}H_{52}O_{44}\cdot 6H_2O$: C 48.58, H 3.83; found: C 48.60, H, 4.16. FABMS: m/z 1595 $(M+Na)^+$; HRESIMS: m/z 1590.2370 (calcd. for $C_{68}H_{56}NO_{44}$: 1590.2175 $(M+NH_4)^+$).

*Methylation of **10** followed by methanolysis*

A solution of **10** (10 mg), K_2CO_3 (200 mg), and $(CH_3)_2SO_4$ (0.02 mL) in acetone (3 mL) was stirred overnight at room temperature, and then heated at reflux for 4 h. After removal of the inorganic material by centrifugation, the supernatant was evaporated to dryness. The residue was directly methanolyzed with 1% NaOMe in MeOH (1 mL) at room temperature overnight. After acidification with AcOH and evaporation, the residue was subjected to preparative TLC (Kieselgel PF_{254}, *n*-hexane–$CHCl_3$–acetone, 3:7:1) to give **5** (2.2 mg), trimethyl octa-*O*-methylmacaranate (**15**) (1.0 mg, EIMS m/z 660 $(M)^+$), **12** (0.2 mg), **13** (0.5 mg), and **14** (0.3 mg), which were identical in all respects by direct comparison with authentic samples.

*Isomerization of **9** and **10** to **11***

A solution of **10** (3 mg) (or **9** (3 mg)) in 0.02 M phosphate buffer (KH_2PO_4–Na_2PO_4, pH 7.4) (2 mL) was left standing at room temperature and the progress of reaction was monitored by HPLC. After disappearance of the starting material (3 h) (or 5 h for eumaculin B), the reaction mixture was acidified with dilute HCl, and applied to a Sep-Pak cartridge (Waters). After washing with H_2O, the products were eluted with MeOH to yield **11** (2.8 mg from **10**; 2.5 mg from **9**), which was identical with an authentic sample by ^{1}H NMR spectral comparison.

Identification of iridals as piscicidal components of Iridaceous plants and their conformations associated with CD spectra

Yoko Miyake, Hideyuki Ito, and Takashi Yoshida

Abstract: Upon toxicity-guided fractionation of the extractives of the *Iris germanica* rhizomes and *I. japonica* roots using killie-fish (*Oryzias latipes*), 12 iridal-type triterpenoids including three new iridals were isolated as piscicidal constituents. Of these, iriflorental, iripallidal, and γ-irigermanal exhibited a potent activity at a concentration of less than 1 μg/mL. The structures of new iridals, irisgermanicals A (**7**), B (**10**), and C (**11**), from *I. germanica* were elucidated based on the spectral analysis. The absolute configuration at C-13 of the known spiroiridal (**15**) from *I. japonica*, which remained to be solved, was defined as *R* on the basis of NOE measurement. The hitherto unreported correlation between the Cotton effects in the CD spectra of some iridals and their conformations was also discussed on the basis of molecular modeling.

Key words: *Iris germanica*, *Iris japonica*, iridal-type triterpenoid, piscicidal activity, CD spectra.

Résumé : Faisant appel à des poissons (*Oryzias latipes*), on a fractionné des extraits de rhizomes de l'*Iris germanica* et de racines de l'*I. japonica*, guidé par la toxicité, et on a isolé 12 triterpénoïdes du type iridal, y compris trois nouveaux iridals, à partir des constituants présentant une activité piscicide. Parmi ceux-ci, l'iriflorental, l'iripallidal et le γ-irigermanal présentent une grande activité à des concentrations inférieures à 1 μg/mL. On a élucidé les structures des nouveaux iridals, les irisgermanicals A (**7**), B (**10**) et C (**11**) isolés de l'*I. germanica*, en se basant sur des analyses spectrales. La configuration absolue en C-13 du spiroiridal connu (**15**) isolé de l'*I. japonica*, qui n'avait pas encore été déterminée, a été définie comme *R* en se basant sur des mesures d'EON. En se basant sur du modelage moléculaire, on discute aussi de la corrélation, qui n'avait pas été rapportée antérieurement, entre les effets Cotton des spectres de DC de quelques iridals et leurs conformations.

Mots clés : *Iris germanica*, *Iris japonica*, triterpénoïde de type iridal, activité comme piscicide, spectres de DC.

[Traduit par la rédaction]

Introduction

Among numerous biologically active natural products, the piscicidal substances have often been found to show such various other biological activities as exemplified by the insecticidal, aphrodisiac, and antitumor promoting activities (1) of piscicidal rotenone, potent tumor-promoting activity (2) of phorbol-type diterpenoids (3), antifungal activity of 5-*O*-methylembelin (4), and antitumor and inflammatory activities (unpublished data) of buddledin A (5), etc. In a continuing study on biologically active natural products using piscicidal bioassay as a primary screening, MeOH extracts of *Iris germanica* and *I. japonica* (Iridaceae) were found to exhibit potent toxicity to *Oryzias latipes* (killie-fish; Japanese name, medaka). Many isoflavonoids (6), quinones (7) and iridals (8–11) are reportedly contained in the rhizomes of Iridaceous plants. Amongst them, iridals, which are biogenetically interesting mono- and bicyclic triterpenoids discovered first by Marner et al. (8, 9), have been recognized during the last decade as the metabolites characteristic of Iridaceae (8–11). Some possible roles in living plant cells, such as antioxidant function (12) and drought-resistant activity (13), are suggested for the iridals. The biological activities of these components have, however, been little known except for antiulcer activity in experimental stress ulcers (14), and differentiation-inducing activity in HL-60 promyelocytic leukemia cells (15) for some iridals. Toxicity-guided fractionation has resulted in the isolation of eight piscicidal substances including three new compounds named irisgermanicals A (**7**), B (**10**), and C (**11**), from *I. germanica*, and four from *I. japonica*. This paper describes the isolation and characterization of the piscicidal components of both *Iris* species.

Received October 31, 1996.

This paper is dedicated to Professor William A. Ayer on the occasion of his 65th birthday.

Results and discussion

The rhizomes of *I. germanica* were percolated with MeOH. The concentrated solution was extracted with *n*-hexane, EtOAc, and *n*-BuOH to give the respective extracts and the residue obtained after concentration of the water-soluble portion. Of these, the *n*-hexane and EtOAc extracts exhibited a potent toxicity to killie-fish with a lethal concentration of 20 μg/mL, giving no survivors after 1.5–2.5 h among five fishes tested. Toxicity-guided fractionation of the active extract by

column chromatography over silicic acid and subsequent purification by preparative HPLC afforded 11 compounds including irisgermanicals A (**7**), B (**10**), and C (**11**). Eight of these were identified as the known iridal-type triterpenoids, isoiridogermanal (**1**) (8), 16-*O*-acetylisoiridogermanal (**2**) (11), α-irigermanal (**3**) (8), γ-irigermanal (**4**) (8), α-dehydroirigermanal (**5**) (9), iridal (**6**) (9), iriflorental (**8**) (9), and iripallidal (**9**) (9), by comparison of their spectral data with the literature values. The active Et_2O extract of *I. japonica* roots was similarly fractionated by a combination of normal and reversed-phase column chromatographies to yield six iridals, which were identical with belamcandal (**12**) (11), 28-deacetylbelamcandal (**13**) (11), isoiridogermanal (**1**), iridal (**6**), (+)-(6*R*,10*S*,11*S*,14*S*,26*R*)-26-hydroxy-15-methylidenespiroirid-16-enal (**14**) (16), and (6*R*,10*S*,11*R*)-26-ζ-hydroxy-13ζ-oxaspiroirid-16-enal (**15**) (17), by comparison of their physical data with those already reported. This is the first report of the isolation of **2** and **6** from *I. germanica*, and also of **6** and **15** from *I. japonica*.

Structures of irisgermanicals A, B, and C

A new compound, irisgermanical A (**7**), showed the presence of an α,β-unsaturated aldehyde group in the ^1H and ^{13}C NMR spectra (δ_H 10.19 (1H, s), δ_C 190.0, 133.3, and 162.7). The ^1H NMR spectrum also showed signals for a secondary methyl and six tertiary methyl groups, an exomethylene (δ 4.49 and 4.72), a primary alcohol function (δ 3.61 (2H, t, J = 6 Hz)), and three olefinic protons at δ 5.20, 5.64, and 5.94. These spectral features, together with 9 sp^2 and 22 sp^3 carbon resonances in the ^{13}C NMR, suggested that **7** is an analog of γ-type bicyclic iridal. The ^1H and ^{13}C NMR spectra of **7** were closely similar to those of iriflorental (**8**), except for the presence of a tertiary methyl signal at δ_H 1.10, δ_C 18.0 and absence of the primary alcohol group (δ_C 68.3) (see Experimental), indicating **7** to be 26-deoxyiriflorental. The appearance of an $(M+H)^+$ ion peak at *m/z* 471 in the FABMS supported this structure. The CD spectrum of **7** showed a positive Cotton effect at 230 nm (Δε +8.5) and a negative one at 260 nm (Δε −8.5), which were almost superimposable on those of **8**, indicating that the absolute stereochemistry of **7** should be the same as that of **8**.

Irisgermanical B (**10**) was determined to have the molecular formula $C_{31}H_{50}O_4$ (HRFABMS). The ^1H NMR (Table 1) and ^{13}C NMR spectra of **10** displayed close resemblance with those of iriflorental (**8**), particularly in the chemical shifts and coupling patterns of the signals due to the C-11 side chain in the ^1H NMR spectrum. Hence, **10** also has a bicyclic iridal skeleton. However, the H-6 methine and one of the H-8 methylene proton signals in the ^1H NMR spectrum were shifted to higher (Δδ 0.57 ppm) and lower field (Δδ 0.69 ppm), respectively, than the corresponding signals of **8**. Furthermore, a remarkable difference was observed in the chemical shift of the C-6 resonance between the ^{13}C NMR spectra

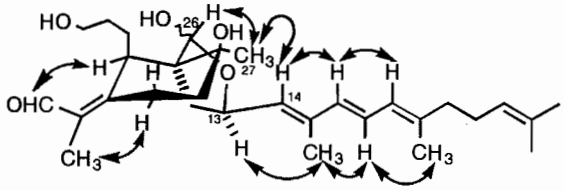
[a]The *J* values (Hz) are in parentheses.

of **8** and **10**. All the above data clearly indicated that compound **10** is the geometrical isomer of **8** at the conjugated aldehyde system. The relevant evidence for the structure of **10** was obtained from the NOESY measurement. Compound **8** exhibited NOEs between the aldehyde proton (δ 10.22) and H-6 proton (δ 3.61) and between the vinyl methyl (δ 1.84) and H-8 proton (δ 2.54) in the NOESY spectrum, while the aldehyde proton (δ 10.22) and vinyl methyl (δ 1.82) signals of **10** showed NOE correlations with one of the C-8 methylene protons (δ 3.23) and H-6, respectively.

Irisgermanical C (**11**), $C_{31}H_{50}O_4$, showed ^{1}H NMR (Table 1) and ^{13}C NMR spectra closely similar to those of iripallidal (**9**). However, the ^{1}H NMR signals for the H-6 proton and one of the C-8 methylene protons in **11** were shifted to higher and lower field, respectively, in comparison with those of **9**, as in the case of **10**. It became evident from the observed differences between the NOESY spectra of **11** and **9** that compound **11** is a geometrical isomer of **9** at the α,β-unsaturated aldehyde moiety. The CD spectra of **10** and **11** showed Cotton effects similar to those of **8** and **9**, although their amplitudes were somewhat different from each other. The dihydro derivatives (**10***a* and **11***a*) prepared by $NaBH_4$ reduction of **10** and **11** also showed CD spectra similar to those of the corresponding derivatives (**8***a* and **9***a*) of **8** and **9**, clearly indicating that these compounds have the same stereostructures.



Irisgermanicals B (**10**) and C (**11**) seem to be generated from the keto–enol tautomerization of **8** and **9**, respectively. Therefore, the isomerization of the iridals under a variety of conditions was examined. Treatment of the mono- and bicyclic iridals with *p*-toluenesulfonic acid (TsOH) or MeOH–HCl revealed a formation of the corresponding geometrical isomers at the α,β-unsaturated aldehyde moiety. For example, α-irigermanal (**3**) partly transformed into its geometrical isomer (**3***a*) upon treatment with TsOH at room temperature for several hours. The structure of **3***a* was proved by analyzing its ^{1}H NMR and NOESY data. The corresponding isomers from iridal (**6**) and γ-irigermanal (**4**) were also detected on HPLC of the reaction mixture. Similarly, tautomerization of **8** and **9** was shown by HPLC, which showed identical peaks with those of **10** and **11**. Although α-irigermanal (**3**) and iridal (**6**) are abundant constituents of *I. germanica* and their yields were much higher than that of iripallidal (**9**), the corresponding geometrical isomers of the former two have never been detected even in a trace amount from the extracts and any fractions on HPLC. The isolation of irisgermanicals B and C was reproducible, as also confirmed by extraction from both the fresh and dried rhizomes of *I. germanica*. These two iridals are thus most likely to be genuine natural products. However, the possibility that they are artifacts arising from tautomerization of **8** and **9** during the isolation procedure might not be completely ruled out.

Absolute configuration at C-13 of spiroiridal (15)

Spiroiridal (**15**), which exists as an equilibrium mixture of epimers at the hemiacetal carbon (C-26), had first been isolated from *Iris pseudacorus* and the structure was proposed as **15** without assigning the configuration at C-13 (17). The absolute configuration at C-13 has now been proposed to be *R* by the NOESY spectrum of **15**. The C-27 methyl signals showed

cross peaks with H-26 and H-14, while H-13 disclosed an NOE with one of the vinyl methyl signals at δ 1.80. The other NOE correlations are shown by arrows in Fig. 1, and are consistent with the proposed structure **15**, including an (all-*E*)-triene chain.

CD spectra of iridals and their correlation with conformations

Iridal-type triterpenoids characterized so far are classified largely into three groups according to their structures: monocyclic- (e.g., **1**, **2**, and **6**), bicyclic- (e.g., **3**–**5** and **7**–**11**), and spiroiridals (e.g., **12**–**15**). Although the CD spectral data of a series of iridals have been reported in the individual structural determinations, little has been hitherto discussed on the nature of each Cotton effect. This fact prompted us to examine the correlation between their Cotton effects and stereostructures. The CD spectra of mono- and bicyclic iridals (e.g., **3** and **4**) having only an α,β-unsaturated chromophore as the conjugated system show an intense positive Cotton effect at about 254 nm and a weakly negative multiple one at nearly 340 nm, which are typically associated with π–π* (conjugated carbonyl group) and *n*–π* (carbonyl group) transitions in an asymmetric surrounding, respectively (18) (Fig. 2). On the other hand, the bicyclic iridals (e.g., **7**–**11**) with a conjugated diene chromophore in the side chain at C-11 exhibited intense Cotton effects of opposite sign centered at around 245 nm (Fig. 2). These CD bands have been indicated to result from exciton-coupling interaction between the conjugated aldehyde and apparently remote side-chain chromophores by the following observations. Dihydro derivatives **8***a*–**11***a* showed negative CD bands at 238 nm associated with their UV absorption maxima due to the conjugated diene chromophore. The CD curves calculated by simple summation of the curves of **8***a* and **4** were definitely different from the observed curve of **8** as shown in Fig. 2, indicating that the two chromophores in **8** electrically interact with each other. To ascertain the conformation of

these iridals, their structures were calculated using the Insight II molecular modeling program with the Consistent Valence force field. The side chain with the diene chromophore in the lowest energy conformation (**8***c*) of iriflorental as shown in Fig. 2 is in a favorable position to allow a π–π* stacking interaction with the conjugated aldehyde chromophore at a distance of 5.8 Å.

The right-handed chirality is consistent with the observed negative first Cotton effect of **8** according to the exciton chirality rule (19). Similar analysis and interpretation were possible for spiroiridal (**15**) (Fig. 2). Interestingly, the energy minimization revealed that the iridals having no conjugated diene function at the side chain at C-11 adopt a different conformation with the long side chain expanded far from the cyclohexane ring, which is similar to that in the solid state as revealed by X-ray crystallographic analysis of **4** (8).

Piscicidal activity

Piscicidal activity of the compounds isolated in the present study was evaluated using medaka according to the method previously reported (3). As shown in Table 2, iriflorental (**8**) exhibited the most potent activity with 0.1 μg/mL of median tolerance limit (TLm) value after 24 h. The other bicyclic iridals, except for **10** and **11**, showed the activity of TLm 0.5–0.9 μg/mL. Spiro-type iridals exhibited moderate activity (TLm 1–2.5 μg/mL), while the TLm values of **10**, **11**, and **15** were 3–3.5 μg/mL. The monocyclic iridals were all inactive, indicating that the strength of the piscicidal activity seems to depend largely on the structure of the substituent (side chain) at C-11 and also on the geometry of the α,β-unsaturated aldehyde moiety.

It is noteworthy that iridal (**6**), iriflorental (**8**), iripallidal (**9**), and irigermanals (**3**, **4**), which were reported to exhibit an in vivo antiulcer activity in several experimental mouse ulcers (14), have also been isolated as potent active principles upon piscicide-directed fractionation. This finding provides additional evidence to the supposition that piscicidal assay may play the part of useful primary screening in making a survey of bioactive natural products. In fact, regarding investigation of the other biological activities of iridals, some piscicidal compounds were found to exhibit significant inhibitory effects on activation of TPA-induced Epstein-Barr virus early antigen and on protein kinase C, which might be associated with antitumor promoting activity.[2]

Experimental

UV spectra and optical rotations were taken on a Hitachi 100-10 spectrophotometer and on a Jasco DIP-1000 polarimeter. ^1H and ^{13}C NMR spectra were measured in $CDCl_3$ on a Varian VXR-500 instrument (500 MHz for ^1H NMR and 126 MHz for ^{13}C NMR) and chemical shifts are given in δ values (ppm) relative to that of solvent (residual $CHCl_3$ (δH 7.26; δC 77.0)) on a TMS scale. FABMS were recorded on VG 70-SE and Micromass AutoSpec OA-Tof mass spectrometers using 3-nitrobenzyl alcohol as the matrix agent, and CD spectra were measured on a Jasco J-720W spectrometer. Reversed-phase HPLC was performed on a LiChrospher RP-18 (4 × 250 mm) or a Superspher RP-18 (4 × 250 mm) column developed with MeOH-H_2O (9:1 (A) or 85:15 (B)) (flow rate, 1 mL/min; detection 254 nm) at 40°C using a Shimadzu SPD-6A or Union Giken MCPD-350 detector. Analytical and preparative TLC were carried out on Kieselgel PF_{254} with toluene–MeCN–AcOEt (1:1:9). Solvent was evaporated under reduced pressure below 40°C.

Extraction and isolation

The fresh rhizomes of *I. germanica* (2.6 kg), collected in July 1995, were cut off, soaked in MeOH (9 L × 3), and filtered. The concentrated solution (ca. 150 mL) was diluted with H_2O (100 mL) and extracted successively with *n*-hexane (250 mL × 4), EtOAc (250 mL × 4), and *n*-BuOH saturated with H_2O (250 mL × 4). The *n*-hexane extract (21.5 g), which showed potent piscicidal activity to killie-fish, was chromatographed over silica gel with *n*-hexane→*n*-hexane–EtOAc(9:1→8:2→7:3→6:4→1:1→4:6) →EtOAc → EtOAc–acetone (4:1→1:1)→ acetone → acetone – MeOH (4 : 1). The toxic fractions were purified by repeated column chromatography over silica gel, Chromatorex ODS, and (or) YMC-GEL ODS-AQ 120-S50 using MeOH–H_2O (8 : 2 → 95 : 5) as eluant to yield iriflorental (**8**, 56.3 mg), iripallidal (**9**, 9.1mg), α-irigermanal (**3**, 164.3 mg), γ-irigermanal (**4**, 20.7 mg), isoiridogermanal (**1**, 1.2 mg), 16-*O*-acetylisoiridogermanal (**2**, 4.8 mg), iridal (**6**, 39.1 mg), irisgermanical A (**7**, 6.7 mg), irisgermanical B (**10**, 3.3 mg), and irisgermanical C (**11**, 2.9 mg).

The bark of dried rhizomes of *I. germanica* (765 g), collected in March 1994, was treated as mentioned above. The EtOAc extract (1.4 g) was subjected to column chromatography over silica gel with $CHCl_3$ → $CHCl_3$–acetone (20:1→5:4)→ acetone. The toxic fractions to killie-fish were purified by preparative HPLC (reversed-phase) with MeOH–H_2O (85:15) to give iriflorental (**8**, 6.3 mg), iripallidal (**9**, 9.5 mg), α-irigermanal (**3**, 14.8 mg), γ-irigermanal (**4**, 8.4 mg), α-

dehydroirigermanal (**5**, 3.1 mg), isoiridogermanal (**1**, 26.3 mg), 16-*O*-acetylisoiridogermanal (**2**, 11.3 mg), irisgermanical A (**7**, 8.1 mg), irisgermanical B (**10**, 3.6 mg), and irisgermanical C (**11**, 5.3 mg).

The chipped fresh roots of *I. japonica* (1.34 kg), collected in November 1995, were soaked in *n*-hexane (3 L × 2) and filtered. The solvent was removed to give the *n*-hexane extract (2.23 g). The residue was then extracted with MeOH (3 L × 3) and filtered. After removal of an oil (17 g) deposited upon concentration of the filtrate, the concentrated solution was extracted successively with Et_2O and *n*-BuOH saturated with H_2O. A part (10 g) of the oil was subjected to column chromatography over silica gel with $CHCl_3$ → $CHCl_3$–acetone (20:1→1:9)→ acetone. The toxic fractions were further chromatographed over Chromatorex ODS and YMC-GEL ODS-AQ 120-S50 with MeOH–H_2O (8:2→ 95:5) to yield six known iridals, which were identical with belamcandal (**12**, 30 mg), 28-deacetylbelamcandal (**13**, 210 mg), isoiridogermanal (**1**, 330 mg), iridal (**6**, 80 mg), (+)-(6*R*,10*S*,11*S*,14*S*,26*R*)-26-hydroxy-15-methylidene-spiroirid-16-enal (**14**, 20 mg), and (6*R*,10*S*,11*R*)-26-ζ-hydroxy-13*R*-oxaspiroirid-16-enal (**15**, 25 mg), respectively, by comparison of their physical data with the reported values.

*Reduction of iriflorental (**8**), iripallidal (**9**), irisgermanical B (**10**), and irisgermanical C (**11**)*

A mixture of the compound (1–4 mg) and $NaBH_4$ (7–15 mg) in EtOH (1–4 mL) was left standing for 30 min at room temperature. After excess of $NaBH_4$ was quenched with acetone, solvents were dispersed with N_2. The residue was partitioned with dilute HCl and $CHCl_3$, and the $CHCl_3$ layer was evaporated to give the corresponding dihydro derivatives, **8***a* (3.5 mg) from **8** (3.6 mg); **9***a* (1.0 mg) from **9** (1.1 mg); **10***a* (1.0 mg) from **10** (1.1 mg); and **11***a* (0.8 mg) from **11** (0.9 mg).

Tautomerization of iridals

A solution of α-irigermanal (**3**) (9.8 mg) and *p*-toluenesulfonic acid (2.0 mg) in $CHCl_3$ (5 mL) was kept at room temperature for 2 h. The reaction mixture was diluted with $CHCl_3$ (5 mL), and washed with saturated aqueous $NaHCO_3$ (5 mL × 2) and then with H_2O (5 mL). The $CHCl_3$ layer was evaporated to dryness to give crude products (9.0 mg), HPLC of which showed two peaks of close retention times (t_R 17.08 and 17.63 min, solvent A). The mixture was chromatographed over YMC-GEL ODS-AQ 120-S50 with MeOH–H_2O (85:15) as eluent to give α-irigermanal (**3**) (2.5 mg) and its isomer (**3***a*) (3.0 mg). **3***a*: glassy solid, $[\alpha]_D$ +31.8 (*c* 0.5, CH_2Cl_2); UV λ_{max} (MeOH) nm (log ε): 257 (4.10); 1H NMR ($CDCl_3$) δ: 10.24 (s, H-25), 5.31 (1H, brs, H-20), 4.97 (1H, t, *J* = 6 Hz, H-14), 3.61 (1H, t, *J* = 6 Hz, H-3), 3.2 (1H, brd, *J* = 13.5 Hz, H-8), 2.80 (1H, brd, *J* = 12 Hz, H-6), 2.60 (^{1}H, brt, *J* = 14, H-8), 1.81 (3H, d, *J* = 1.5 Hz, H-1), 1.69 (3H, brs, H-28), 1.59 (3H, s, H-29), 1.17 (3H, s, H-27), 1.01 (3H, s, H-26), 0.87 (3H, s, H-30), 0.83 (3H, d, *J* = 6.5 Hz, H-31), 0.62 (3H, s, H-24).

Similar tautomerization was observed for **4**, **8**, and **6**. HPLC peaks (solvent A) of each reaction mixture were as follows: t_R 15.35 (**4**) and 15.78 min (isomer) for **4**; t_R 8.69 (**8**) and 8.22 (isomer (**10**)) for **8**; t_R 11.92 (**6**) and 12.20 (isomer) for **6**.

Piscicidal activity

The assay was conducted essentially in the same way as reported previously (3), using the medaka (killie-fish; *Oryzias latipes*) (170–350 mg in weight and 2.5–3.5 cm in length) as the test fish. A test solution was prepared by adding an acetone or a MeOH solution (0.5 mL) of the compounds of known concentration into aerated H_2O (100 mL). The median tolerance limit (TLm) after 24 h was evaluated for five fish/group by straight-line graphical interpolation. A control experiment was carried out under the same conditions, adding only acetone or MeOH (0.5 mL).

On a new synthesis of sterpurene and the bioactivity of some related *Chondrostereum purpureum* sesquiterpene metabolites

George M. Strunz, Richard Bethell, Michael T. Dumas, and Nick Boyonoski

Abstract: Sterpurene, a sesquiterpene hydrocarbon metabolite of *Chondrostereum purpureum*, a plant pathogen and potential mycoherbicide, was synthesized by a six-step sequence, in 33% overall yield. The key steps were a thermal [4 + 2] (Diels–Alder) cycloaddition of a ketene acetal diene with a conjugated ester dienophile, and a remarkably stereoselective [2 + 2] photocycloaddition of ethylene with the resulting conjugated ketone. Several related, more highly oxygenated, metabolites isolated from culture filtrates of *C. purpureum* (cf. Ayer) were tested for toxicity to cells of a hybrid aspen, *Populus deltoides* X *nigra*. Their phytotoxicity, at concentrations as low as 10 ppm, suggests that, like the *endo*-polygalacturonase produced by the fungus, these sesquiterpenes may be partially responsible for the foliar lesions associated with infection of deciduous species by the pathogen.

Key words : *Chondrostereum purpureum*, mycoherbicide, metabolites, sterpurenes, synthesis, Diels–Alder, photocycloaddition, pyramidalization, phytotoxicity.

Résumé : Nous avons synthétisé, en six étapes et avec un rendement global de 33%, la sterpurène, un métabolite sesquiterpénique hydrocarbonique de la *Chondrostereum purpureum*, qui est un pathogène des plantes et qui a du potentiel en tant que mycoherbicide. Les étapes clés étaient une cycloaddition [4 + 2] thermale (Diels–Alder) entre un acétal céténique diénique avec un ester conjugué diénophilique, et une photocycloaddition [2 + 2] entre la cétone conjuguée résultante avec l'éthylène, qui se produit avec une stéréosélectivité remarquable. Nous avons fait plusieurs épreuves sur des métabolites apparentés plus oxygénés, isolés (d'après Ayer) de cultures de *C. purpureum*, pour évaluer leur toxicité contre les cellules de *Populus deltoides* X *nigra*. Leur phytotoxicité, à des concentrations aussi basses que 10 ppm, suggère que, tout comme l'*endo*-polygalacturonase produite par le champignon, ces sesquiterpènes seraient en partie responsables des lésions des feuilles associées à l'infection par la pathogène des espèces décidues.

Mots clés : *Chondrostereum purpureum*, mycoherbicide, métabolites, sterpurènes, synthèse, Diels–Alder, photocycloaddition, pyramidalisation, phytotoxicité.

Introduction

The fungus *Chondrostereum purpureum* (Pers. ex Fr.) Pouz. (= *Stereum purpureum* (Pers. ex Fr.) Fr.) is widespread in North American forests and fruit orchards. The organism is a pathogen of a variety of deciduous species, causing, in fruit trees, a destructive condition designated silver leaf disease (1, 2). The foliar "silvering" symptoms result from reflection of light from leaf surfaces in which the epidermal cells have separated from the palisade cells (2), and the disease can lead to death of the host tree. *Chondrostereum purpureum* can colonize coniferous wood as a saprophyte but, in contrast to its pathogenicity to hardwoods, it is not known to cause any disease of conifers (1).

Concerns about non-target effects of synthetic herbicides have led to major constraints on the use of these compounds in forestry operations, and biological control is emerging as an attractive alternative for suppressing the development of competing vegetation in the early growth stages of crop trees. During 1995 and 1996, extensive field trials were conducted by Canadian Forest Service scientists and cooperators to test the efficacy of *C. purpureum* as a mycoherbicide in preventing regrowth of hardwood stump sprouts. The promising results of these trials have kindled our interest in examining chemical aspects of the bioactivity of this pathogen.

Pioneering studies by Ayer in the early 1980s on metabolites of *C. purpureum* led to the discovery of a novel class of sesquiterpenes that embody the carbon skeleton of sterpurene, **1**, at various states of oxidation (3). The hydrocarbon **1** was found in the mycelium of *C. purpureum* (3), while sterpuric acid **2** and sterpurene-3,12,14 triol **4** were the major components of the broth extract, which also contained **3** (3, 4). In addition, the biogenetically related isolactaranes, sterepolide **5**

and dihydro sterepolide **6**, were produced by *C. purpureum* (5, 6). Other related metabolites of *C. purpureum* were later identified (7), and sterpurene-type sesquiterpenes were also found to be elaborated by other microorganisms (8).

Miyaire et al. (2, 9) identified an *endo*-polygalacturonase from filtrates of *C. purpureum* that induced silver leaf symptoms when injected at low doses into apple trees (~25 μg per tree). On the other hand, crude material from ethyl acetate extracts of *C. purpureum* culture broths also caused the symptoms (4), although the purified sesquiterpenes were never tested individually for phytotoxicity.[2] In an attempt to clarify chemical aspects of the interaction between pathogen and host, we reisolated a number of the sesquiterpene metabolites described by Ayer, and tested them for phytotoxicity, using cells of a hybrid aspen, *Populus deltoides* X *nigra*, for the bioassay. Another component of our research program on *C. purpureum* metabolites was the exploration and development of an efficient strategy for synthesis of sterpurene, with the potential for modification to give access to the more highly oxygenated congeners of the sesquiterpene.

The first synthesis of sterpurene, a biomimetic route from humulene, was reported in 1981 (10, cf. refs. 6, 11). This was followed by several elegant routes, each designed to exploit novel synthetic methodology (12–15).

The simplest retrosynthetic analysis, Scheme 1, suggests two formal routes, each having, as the key step, construction of a cyclobutane ring, in principle feasible by a photocycloaddition process. Inspection of models and mechanistic considerations indicated that the success of the intramolecular cyclization process (path (b) in Scheme 1), leading to simultaneous formation of six- and four-membered rings with appropriate stereochemistry, was by no means assured. Indeed, in considering products (e.g., **8**, **9**, or **9′**) that might result from photoirradiation of **7** (Scheme 2), **8** (derived by "head-to-tail" cycloaddition (16)) seemed the more probable outcome. The latter product was not, however, devoid of interest, as its reaction with methyl Grignard reagent should afford carbinol **10**,

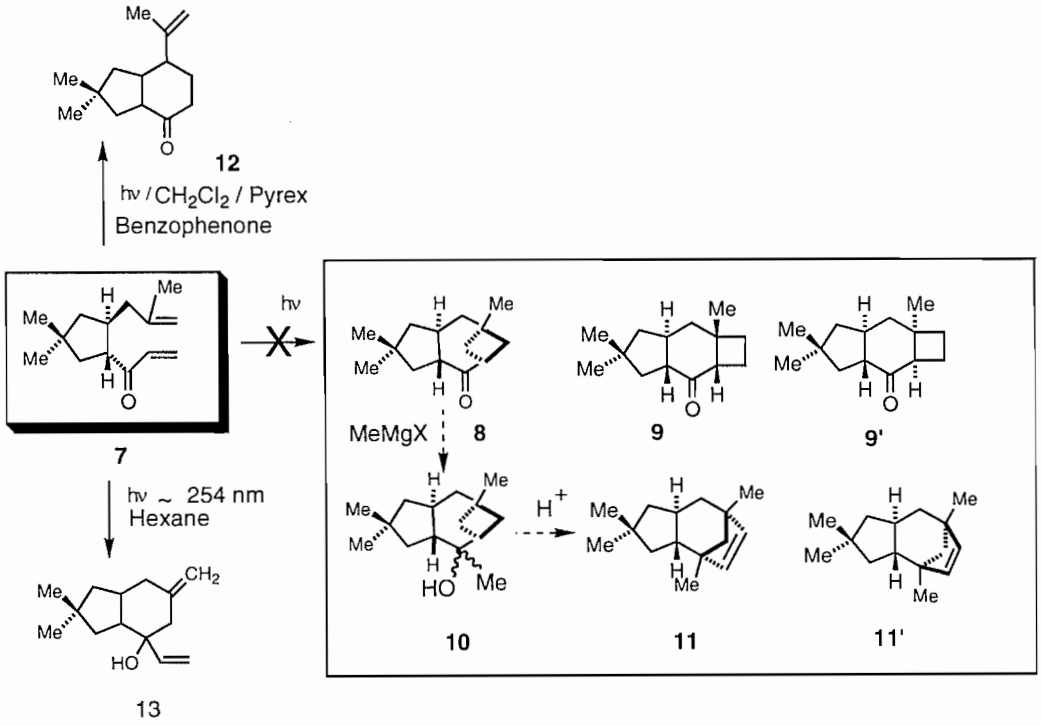
Scheme 1.

which, on protonation, could be expected to rearrange to **11** (**11′**). An intermediate embodying the same carbon skeleton has been postulated in the biosynthesis of sterpurene (6, 11) (Scheme 2), giving us some incentive for exploring briefly the photochemistry of **7**.

The more promising intermolecular photocycloaddition strategy, path (a) (Scheme 1) was employed by Little and co-workers (12) and Paquette et al. (17) in the synthesis of sterpurene, **1**, and sterpuric acid, **2**, respectively. In the course of both these syntheses, interesting stereochemical effects were observed that seemed to warrant further investigation.

This paper reports our contributions to date in the arena of bioactivity and synthesis of *C. purpureum* metabolites.

Results and discussion



The starting material for both inter- and intramolecular photocycloaddition routes, methyl 4,4-dimethylcyclopent-1-ene carboxylate **14** (Scheme 3), was readily prepared from commercially available 4,4-dimethyl-2-cyclohexen-1-one by hydrogenation to 4,4-dimethylcyclohexanone, α-carboxymethylation (18), and chlorination. Dehydrochlorination–decarbonylation of the α-chloro-β-ketoester product, by treatment with sodium carbonate in boiling xylene according to Buchi et al. (19), gave the desired conjugated ester **14**. The overall yield of **14** from 4,4-dimethyl-2-cyclohexen-1-one (Scheme 3) was 52%, making this route a useful alternative to an earlier synthesis, via photoirradiation of diazodimedone (20).

Ester **15** was prepared in 40% (not optimized) yield by conjugate addition of isobutenyltrimethyl silane to **14**, catalyzed by tetrabutylammonium fluoride according to Majetich et al.

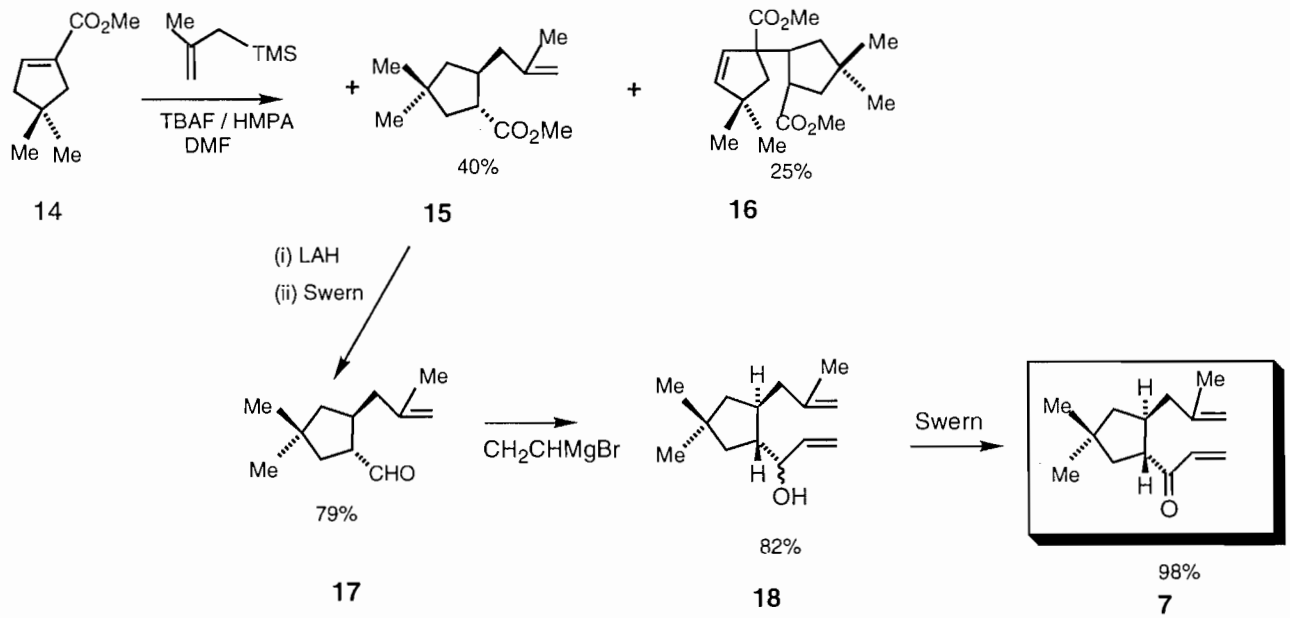
Scheme 3.



(21) (Scheme 4). (A by-product (25%) of this process was the dimeric ester product **16**, which was accessible in preparatively useful yield (~75%) when the silane was omitted. Synthetic applications of this fluoride-catalyzed dimerization and related processes are being investigated independently.) Conversion of ester **15** to the aldehyde **17** was effected in two steps, via reduction to the alcohol and reoxidation using the Swern procedure (22). Addition of vinyl magnesium bromide to the aldehyde afforded **18**, in 82% yield, and the synthesis of the desired conjugated ketone **7** (98%) was completed by Swern oxidation of the carbinol. (A minor by-product (<10%), not readily separable from **7**, was tentatively identified as the corresponding *cis* isomer.) Enone **7**, prepared thus, exhibited an ultraviolet absorption maximum (in cyclohexane solution) at 221 nm (ε 2145). The low extinction coefficient of this absorption band suggests deviation from coplanarity in the conjugated system (23).

In preliminary experiments, external irradiation (Hanovia 200 W mercury arc lamp) of a dichloromethane solution of **7** at room temperature for several hours through Pyrex (λ > 280 nm) or Corex (λ > 260 nm) filters led to recovery of unchanged starting material, (along with a small amount of presumably polymeric material, which was immobile on silica gel chromatography). Irradiation of a solution of **7** in the same solvent for 1 h at 0°C through a Vycor filter (5% transmission at 220 nm, 45% at 240 nm) led to extensive decomposition, but allowed recovery of ~4% of an isomeric product. The latter was obtained in a somewhat more satisfactory yield (39%) by photoirradiation of a dichloromethane solution of **7** at 0°C through Pyrex for 30 min, using benzophenone as sensitizer. The photoproduct was identified as **12** (Schemes 2 and 5) on the basis of its spectroscopic characteristics, especially aspects of the ^{1}H NMR spectrum. The three signals between δ 6.38 and 5.74, characteristic of the vinyl ketone, were no longer present, whereas signals at δ 4.63 and 1.65, corresponding, respectively, to the *geminal* vinyl methylene and allylic methyl hydrogens of the isopropenyl group, were retained. A multiplet at δ 2.75–2.60 could be assigned to the three protons α to the carbonyl group. Peaks attributable to a minor diastereomer were also observed (see Experimental). Infrared

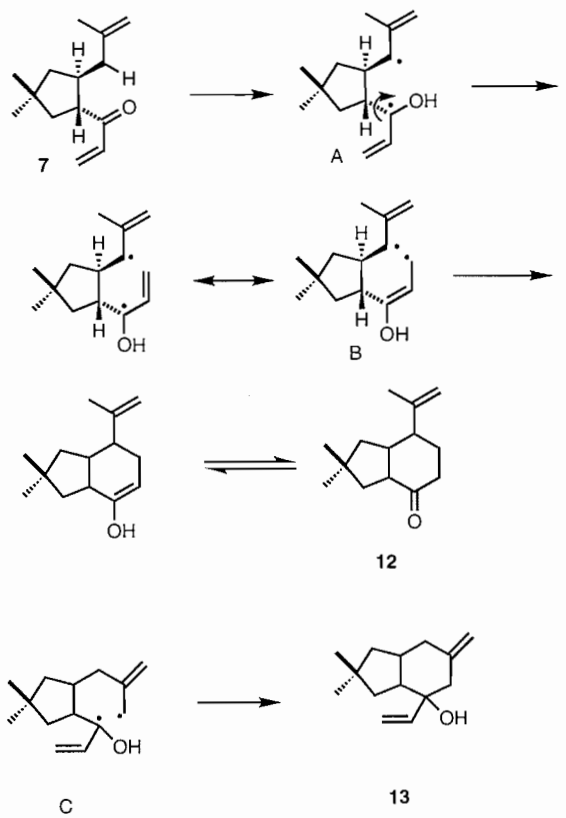
Scheme 4.

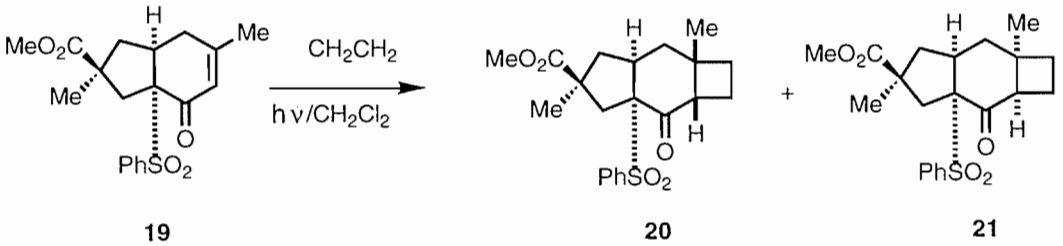


absorption at 1705 cm^{-1}, associated with the (nonconjugated) ketone group, was consistent with structure **12**.

In another experiment, a dilute hexane solution of **7** at room temperature in a quartz cell was irradiated (externally) at 254 nm for 48 h with a 4 W Spectroline E-Series UV lamp. Starting material was consumed, with concomitant formation of a complex product mixture. Separation attempts afforded material (ca. 20%) that was apparently homogeneous by TLC, but resolved by GC on a capillary column into two major products in the approximate ratio 2:3. These were shown by GC–MS to be isomers (and isomeric with the starting material), *m/z* 206. Whereas the available data were insufficient for rigorous identification of these products, they suggested the vinyl alcohol **13** and a tricyclic ketone (lacking olefinic protons) (cf. Scheme 2). Thus, the NMR spectrum of the mixture was free of signals below δ 3.0, other than a clean pattern for five vinylic protons that was fully consistent with the vinyl carbinol structure **13**. Major ions in the mass spectrum of the smaller GC peak with lower retention time supported this tentative assignment. All hydrogens of the second isomer must be assigned among the abundant NMR signals in the region above δ 3.0, not inconsistent with a tricyclic product. Significant absorptions in the infrared spectrum of the mixture are comparable to peaks in the spectrum of **29**. Ions at *m/z* 178 and 82, which are abundant in the mass spectrum of the major GC peak (and insignificant in the smaller peak), corresponding in the HREIMS of the mixture to $(M - C_2H_4)^+$ and $(C_5H_6O)^+$, can be rationalized in terms of structure **9** or **9′** (or corresponding diastereomeric structures[3] arising from photocyclization of the minor *cis* isomer (<10%) accompanying **7**) (cf. spectrum of **29**, experimental section).

A reasonable mechanism for formation of **12** from the photoirradiation of **7** might involve γ-hydrogen transfer (24, 25) producing the diradical **A**, which, after bond rotation, could cyclize to the enol form of **12**, as depicted in Scheme 5. Under different conditions, appropriate hydrogen transfer in either **7** or the diradical **A** could afford diradical **C**, suitably disposed for cyclization to **13**.

Scheme 5.



[3] A referee has pointed out that a photoproduct obtained in a yield of this magnitude could well arise not from **7**, but from the small amount of *cis* isomer accompanying it.

Scheme 6.

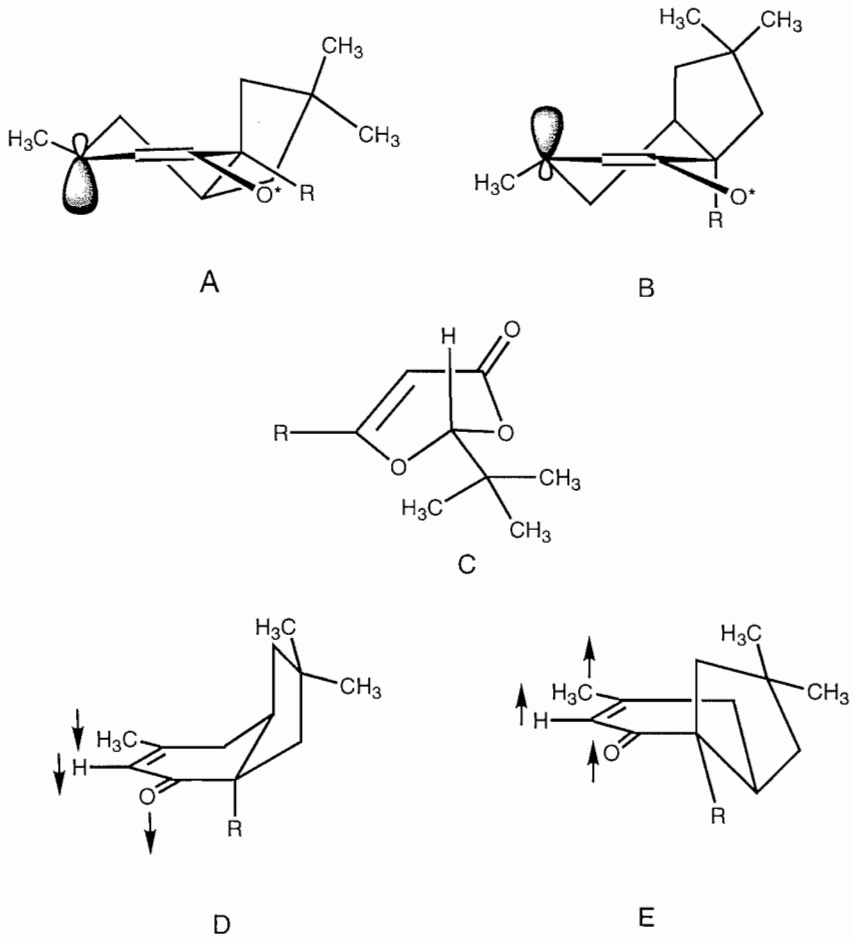
Scheme 7.

This cursory preliminary examination of the photochemical behavior of **7**, in which tricyclic product(s) were produced, if at all, in very low yield, did little to allay our reservations about path (b) (Scheme 1), and we refocussed our attention on the intermolecular photocycloaddition strategy, path (a).

In the synthesis of sterpuric acid, **2**, Paquette et al. (17) observed that photocycloaddition of ethylene to the sulfone **19** occurred with only modest stereoselectivity, affording a mixture of the desired product **20** and the diastereomeric **21,** in a ratio of 3:1 (Scheme 6). As it appeared highly probable that the sulfone and methyl ester functionalities in the *cis*-fused ring system **19** were playing a significant role in determining the stereochemical outcome of the ethylene photocycloaddition (cf. ref. 12), it was of some interest to examine the stereochemistry of photocycloaddition to the *cis*-indane-ester-enone **22** (Scheme 7), which is a logical intermediate for the synthesis of sterpurene.

Bicyclic enone **22** was readily synthesized, in 67% yield, by thermal Diels–Alder reaction of methyl 4,4-dimethylcyclopent-1-ene carboxylate **14** (prepared above) with ketene acetal **23** (26), and deprotection of the acetal product **24** (Scheme 7). Irradiation of **22** in methylene chloride solution in the presence of a large excess of ethylene at −78°C was conducted to approximately 50% conversion of enone (cf. ref. 17) using a Hanovia 200 W mercury arc lamp. The total yield of cycloaddition product, based on consumed starting material, was 97%, and it was gratifying to observe that the ratio of desired product **25** to its diastereomer **26** (Scheme 7) was 12:1 !

An empirical model for predicting stereoselectivity in photocycloaddition of olefins to cyclic α,β-unsaturated ketones was advanced by Wiesner some 20 years ago (27). This was based on the concept that "the preferred configuration of the excited state determined the configuration of the major photoadduct." It was proposed that, in the excited state, the α-carbon could be considered trigonal and that the most stable configuration of a *pyramidalized* β-carbon would determine the facial selectivity of the photoaddition (27). Notwithstanding the manifestly empirical nature of these ideas, which Wiesner was at pains to emphasize, and although the model has encountered some skepticism (28), its ability to predict stereoselectivity in photocycloadditions of olefins to enones has been impressive. Insofar as it can be applied in the present case, the stereoselectivity predicted seems to be in accord with our observed results. Thus, according to the model, the excited state of **22** may be regarded as resembling one of the conformers **A** or **B** (R = CO_2CH_3), with the methyl group in the more stable pseudoequatorial configuration (Fig. 1). Inspection of molecular models and simple MM2 calculations (29) on conformers of a formally similar (ground state) structure[4] suggest that both conformers, **A** and **B** (R = CO_2CH_3), could be present under the reaction conditions, with the former predominating. For steric reasons, reaction at the α-face of **A** (R = CO_2CH_3), giving the observed major product **25**, would then appear to be more favorable than attack at the β-face of **B** (R = CO_2CH_3) (cf. ref. 12).



More recently, attempts have been made to understand the stereoselectivity of ground state and excited state additions to enones in the context of pyramidalization of the three trigonal carbon atoms of the conjugated system, predicted on the basis of X-ray crystallographic structures and theoretical calcula-

[4] The enol of the saturated ketone corresponding to **22** was used for modeling, approximately, the Wiesner empirical representation of the excited state.

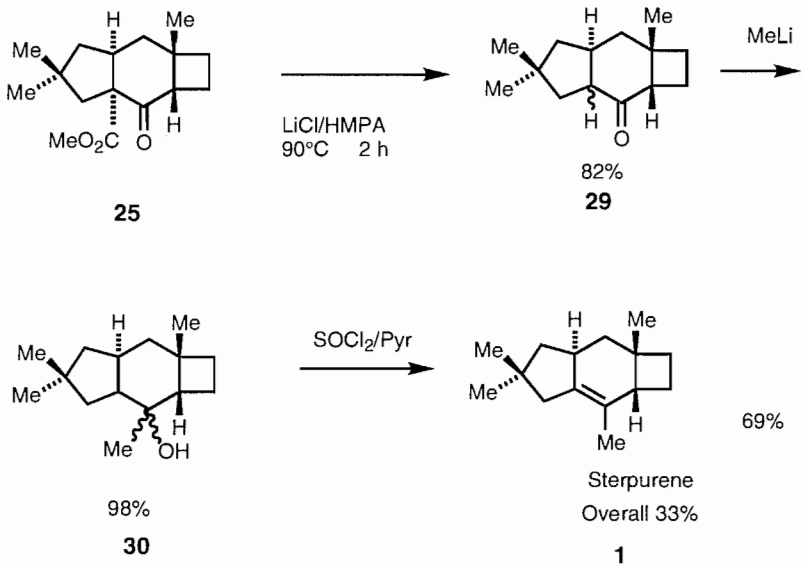
Fig. 1.

tions. Thus, Seebach et al. (30) analyzed factors controlling or associated with facial selectivity in addition of organocuprates to (and catalytic hydrogenation of) dioxinones containing a stereogenic acetal center, e.g., **C** (Fig. 1). He noted that "the stereoselectivities of thermal and photochemical additions to dioxinones and other systems are correlated with pyramidalizations of the reacting centers," suggesting that "the steric course of attack on a trigonal center can be predicted from the direction of its pyramidalization." (30). There is strong pyramidalization in the excited state, with two of the three computed triplet states pyramidalized in the direction opposite to that in the ground state (30), which could account for the observation that ground state conjugate additions and photocycloadditions have opposite facial selectivity (31, 32).[5]

Lange and co-workers (33) reported further studies on the facial selectivity of ground state and excited state reactions of related systems, in the context of enone pyramidalization. In the course of this work, he observed that some simple cyclohexenones also displayed pyramidalization of trigonal carbons in the ground state, though to a lesser extent. It was noted that "in those systems where there is significant pyramidalization, the groups at C-4 to C-6 are always bent below the plane, i.e., away from the pucker at C-2" (33), (numbering as for 1,3-dioxin-4-one).



Simple molecular mechanics calculations (MM2* force field using MacroModel 4.5) (29) suggest that of the sofa conformations of our bicyclic enone **22**, represented approximately as **D** (R = CO_2CH_3) and **E** (R = CO_2CH_3) (Fig. 1), the former are all more stable than the latter, with an average energy difference of ~2 kcal/mol (signifying a significant preponderance of the former conformers at −78°C). In the absence of high-level calculations, an attempt to extend Lange's findings on ground state pyramidalization in simple cyclohexenones to the excited state of a system such as **D** (R = CO_2CH_3) is clearly fraught with pitfalls! It may, nevertheless, be more than coincidence that an analysis, based roughly on the observations of Lange and Seebach, appears to point to the observed facial selectivity for photocycloaddition of ethylene to **22**. Thus, the three trigonal carbon atoms of the preferred conformers **D** (R = CO_2CH_3) might be slightly pyramidalized

[5] The calculated opposite pyramidalization for enone ground and excited states (30) does not, however, appear to account adequately for the fact that facial selectivity was the *same for Diels–Alder reactions and photocycloadditions* (32). In Sato's view, cycloaddition reactions occur at the less hindered face of dioxinone enones in the sofa conformation "irrespective of the electronic states of the substrates," whereas the facial selectivity of "rather exceptional" thermal reactions occurring under kinetic control at the opposite face may be associated with pyramidalization (32).

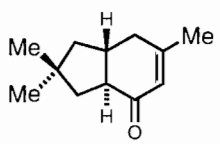
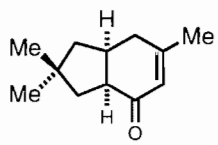
Scheme 8.



25 **29** **30** **1**



in the ground state, with displacement of the attached groups below the approximate plane formed by five of the ring carbons (away from the "pucker") as shown by the arrows (33) (Fig. 1). If, then, pyramidalization is reversed in the excited state, in accordance with Seebach's proposal (30), reaction at the bottom face of **D** (R = CO_2CH_3) would indeed be preferred.

The fact that the stereoselectivity observed by Paquette et al. (17) was somewhat lower in photocycloaddition of ethylene with **19** could be due to differences in conformation associated with the large sulfone group and the ester on the five-membered ring, and other steric effects.

Little and co-workers reported (12) that, whereas photocycloaddition of ethylene to the *trans*-fused enone **27** (lacking substitution at the ring junction) proceeded smoothly, the *cis*-fused isomer **28** *was unreactive under the same conditions*. This result is surprising. Molecular mechanics calculations indicate that the two sofa conformations of **28**, **D** (R = H) and **E** (R = H) (Fig. 1), do not differ significantly in energy. The former, which should be reactive in photocycloaddition, is more stable by ~0.3 kcal/mol. In the light of the above discussion, it does not seem obvious why **22** and **28** should differ so dramatically in their reactivity with respect to photocycloaddition.

27

28

Whatever the basis for the satisfactory stereoselectivity of the photocycloaddition of **22** with ethylene, the stage was now set for completion of the synthesis of racemic sterpurene (Scheme 8). Demethoxycarbonylation of **25**, by Krapcho's procedure, using LiCl–HMPA (34), afforded a mixture of two epimeric ketones **29** (82%) that, without separation, was treated with methyllithium to give a diastereoisomeric mixture of methyl carbinols **30** in a total yield of 98%. Finally, treatment of **30** with thionyl chloride and pyridine (12) effected dehydration, affording a 69% yield (33% overall from **14**) of racemic sterpurene **1**, whose spectra were in accord with those in the literature (3) and with data kindly supplied by Professor Ayer. (The structure of synthetic **1** and NMR assignments were confirmed by 2-D NMR experiments.)

Biological activity of some *C. purpureum* sesquiterpene metabolites

Several metabolites, previously described by Ayer et al. (3–6), were reisolated from culture filtrates of *C. purpureum*, and sterpuric acid **2**, sterepolide **5**, and dihydrosterepolide **6**, as well as synthetic sterpurene **1**, were assayed for phytotoxicity to cells of hybrid aspen, *Populus deltoides X nigra*. The results in Table 1 show that, of the compounds tested, sterpuric acid **2** is the most toxic to the aspen cells, but that the dose response curve for **2** is steeper in the concentration range studied (50–10 ppm) than for sterepolide **5** and dihydrosterepolide **6**. Sterpurene **1** was devoid of phytotoxicity to *P. deltoides X nigra* cells at the levels tested. The crude methylene chloride extract at 500 ppm exhibited approximately the same degree of phytotoxicity as sterpuric acid at 50 ppm.

Conclusions

We have synthesized the *C. purpureum* sesquiterpene metabolite, sterpurene **1** by a six-step pathway including a relatively stereoselective [2 + 2] photocycloaddition process, in an overall yield of 33% (the highest yield for any synthesis of the hydrocarbon reported to date).

Some metabolites of *C. purpureum,* previously described by Ayer, were reisolated, and bioassays of sterpuric acid **2**, sterepolide **5**, and dihydrosterepolide **6** showed them to be toxic to cells of hybrid aspen, *P. deltoides X nigra* at concentrations as low as 10 ppm. This suggests that sesquiterpene metabolites may play a role, along with the *endo*-polygalacturonase described by Miyaire et al. (2, 9), in the pathogenicity of *C. purpureum* to hardwood trees.

Experimental

General

Melting points were determined on a hot-stage apparatus and are uncorrected. Infrared spectra were recorded on a Philips Pye Unicam PU9516 infrared spectrophotometer and the ultraviolet spectra on a Philips PU 8800 UV–VIS spectrophotometer. Accurate mass measurements were made on a Kratos MS-50 instrument, which was also used for obtaining the FAB spectra. The GC–MS analysis was conducted using a HP 5989A (Engine). (The sample, in methanol solution, was injected onto a 30 m DB-1ht column (injection temperature 250°C, temperature program 60–300°C at 20°C/min). Source and transfer line temperatures were 275°C and 280°C, respectively, and data were acquired in full scan, EI mode, over the range 40–359 amu, 1.65 scans/s). NMR spectra were recorded in $CDCl_3$ on a Varian XL-200 spectrometer operating at a frequency of 200.068 MHz for ^1H, and on a Varian Unity 400 operating at a frequency of 399.946 MHz for ^1H and 100.564 MHz for ^{13}C.

2-Carbomethoxy-4,4-dimethyl-1-cyclohexanone

2-Carbomethoxy-4,4-dimethyl-1-cyclohexanone was prepared, in two steps from commercially available 4,4-dimethyl-2-cyclohexene-1-one, essentially according to Liu's procedure (35). Hydrogenation of the starting material at atmospheric pressure (101.3 kPa) (rather than at 15 psi (1 psi = 6.9 kPa) (35)), and the addition of a catalytic amount of potassium hydride with the sodium hydride in the carboxymethylation step (18), did not affect the yields (overall 82%).

2-Chloro-2-carbomethoxy-4,4-dimethyl-1-cyclohexanone

Chlorine gas was passed into a vigorously stirred solution of 2-carbomethoxy-4,4-dimethyl-1-cyclohexanone (23.5 g, 128 mmol) in freshly distilled CH_2Cl_2 maintained at 0°C. During a period of 10–20 min, color changes from pale yellow to dark green to pale orange occurred, at which time chlorine addition was discontinued. (Thin-layer chromatography indicated that all starting material had been consumed at this stage.) The mixture was purged with argon, and solvent was removed in vacuo. The crude oily residue was purified by flash chromatography on a column of silica gel, eluting with hexane–EtOAc (10:1) to furnish the oily chloro ketoester (27.0 g, 97%); IR ($CHCl_3$): 3100–2800, 1730, and 1435 cm^{-1}; ^1H NMR ($CDCl_3$, 200 MHz) δ: 3.81 (3H, s), 2.82–2.65 (3H, m), 2.07–2.00 (1H, m), 1.77–1.69 (2H, m), 1.09 (3H, s), 1.04 (3H, s); EIMS, *m/z* (relative intensity) (ion): 220 (8) $(M + 2)^+$, 219 (6) $(M + 1)^+$, 218 (18) (M^+).

Methyl 4,4-dimethyl-1-cyclopentenecarboxylate, 14 (cf. refs. 19, 20)

A solution of the chloro ketoester (315 mg, 1.44 mmol) in distilled xylenes (10 mL) was heated under reflux in an atmosphere of argon with anhydrous sodium carbonate (160 mg, 1.51 mmol) for 24 h. The mixture was cooled, filtered, and concentrated under reduced pressure. Flash chromatography of the crude residue on a silica gel column (hexane–EtOAc, 10:1) afforded 147 mg (66%) of the oily conjugated ester, **14**; IR ($CHCl_3$): 3100–2800, 1705, 1630, 1500–1400 cm^{-1}; ^1H NMR ($CDCl_3$, 200 MHz) δ: 6.64 (1H, m), 3.70 (3H, s), 2.37–2.28 (4H, m), 1.08 (6H, s); EIMS, *m/z* (relative intensity) (ion): 154 (15) (M^+), 139 (10) $(M - CH_3)^+$, 126 (34) $(M - CO)^+$, 111 (15), 95 (30) $(M - CO_2CH_3)^+$, 79 (25) , 71 (100) $(C_5H_{11})^+$, 70 (31) $C_5H_{10})^+$.

Methyl 2-(2′-methyl-2′-propenyl)-4,4-dimethylcyclopentanecarboxylate, 15

Tetrabutylammonium fluoride (trihydrate) (460 mg, 1.46 mmol: previously dried under high vacuum for 1 h) in anhydrous DMF (3.0 mL) was treated in a flame-dried flask with activated 4 Å molecular sieves at ambient temperature for 30 min. The solution was transferred to another flame-dried flask containing activated 4 Å molecular sieves, and conjugated ester **14** (1.0 g, 6.49 mmol) in anhydrous DMF (5.0 mL) was added, followed by dropwise addition of a solution of isobutenyltrimethylsilane (2.50 g, 19.5 mmol) and distilled HMPA (3.4 mL, 19.5 mmol) in anhydrous DMF (5 mL) (cf. ref. 21). The reaction mixture was stirred at ambient temperature for 1 h, when additional isobutenyltrimethylsilane (831 mg, 6.49 mmol) was added and stirring continued for 4 h. Work-up consisted of addition of methanol, then water, followed by thorough ether extraction. The combined extracts were washed with water and brine, dried over $MgSO_4$, and concentrated in vacuo. Flash chromatography of the crude product on a silica gel column (hexane–EtOAc, 10:1) afforded the desired ester **15** (550 mg, 40%) as an oil; IR ($CHCl_3$): 3100–2800, 1725, 1650, 1440, and 1370 cm^{-1}; ^1H NMR ($CDCl_3$, 200 MHz) δ: 4.63 (2H, br), 3.63 (3H, s), 2.50 (2H, m), 2.12 (1H, m), 2.0–1.88 (1H, m), 1.78–1.63 (3H, m), 1.67 (3H, s), 1.15–1.07 (1H, m), 1.02 (3H, s), 1.00 (3H,s); HREIMS, *m/z* (relative intensity) (ion): 210.1634 (10) (M^+) (calcd. for $C_{13}H_{22}O_2$: 210.1620), 195 (100) $(C_{12}H_{19}O_2)$ $(M - CH_3)^+$, 155 (24) $(C_9H_{15}O_2)$ $(M - C_4H_7)^+$, 150 (25) $(C_{11}H_{18})$ $(M - H/CO_2CH_3)^+$, 139 (36) $(C_8H_{11}O_2)$ $(M - C_5H_{11})$, 135 (39) $(C_{10}H_{15})$, 123 (11) $(C_8H_{11}O)$, 109 (19) (C_8H_{13}), 107 (10) (C_7H_7O), 95 (74) (C_7H_{11}), 93 (16) (C_7H_9).

A by-product of the reaction was the dimer **16** (350 mg), IR ($CHCl_3$) 2960, 2875, 1725, and 1480–1410 cm^{-1}; ^1H NMR ($CDCl_3$, 200 MHz) δ: 5.51 (1H, m), 5.42 (1H, m), 3.62 (6H, s),

3.08–3.00 (1H, m), 2.68–2.63 (1H, m), 2.33–2.27 (1H, dd), 1,75–1.62 (2H, m), 1.54–1.46 (2H, m), 1.22–1.13 (1H, m), 1.11–0.99 (12 H, m); ^{13}C NMR (100 MHz, $CDCl_3$) (two stereoisomers) δ: 176.8/176.7 (s), 176.7/176.4 (s), 143.0/142.8 (d), 128.9/128.8 (d), 62.9/62.5 (s), 51.9/51.8 (q), 51.6/51.6 (q), 48.1/48.1 (d), 45.8/45.8 (t), 45.5/45.4 (d), 44.9/44.8 (s), 44.0/43.6 (t), 43.5/43.4 (t), 38.2/38.0 (s), 29.9/29.8 (q), 29.5/29.3 (q), 29.3/29.2 (q), 29.0/28.9 (q) . HREIMS, *m/z* (relative intensity) (ion): 249.1855 (100) $(M - CO_2CH_3)^+$ (calcd. for $C_{16}H_{25}O_2$: 249.1854), 233 (8) ($C_{15}H_{21}O_2$), 217 (15) ($C_{15}H_{21}O$), 189 (94) ($C_{14}H_{21}$), 173 (9) ($C_{13}H_{17}$), 154 (33) ($C_9H_{14}O_2$), 139 (20) ($C_8H_{11}O_2$).

1-Formyl-2-(2′-methyl-2′-propenyl)-4,4-dimethylcyclopentane, 17

Ester **16** (500 mg, 2.62 mmol) was added to 95% LAH (105 mg, 2.62 mmol) in anhydrous THF (15 mL) under an argon atmosphere at 0°C. The mixture was allowed to attain ambient temperature and was set aside with stirring for 3 h. Work-up consisted of addition of water (1 equiv.) followed by aqueous NaOH (1 equiv. 15% solution), and then water (3 equiv.). The mixture was filtered and the filtrates evaporated under reduced pressure. Flash chromatography of the residue on silica gel with hexane–EtOAc (10:1) as eluent afforded the corresponding amorphous alcohol (389 mg, 90%); IR ($CHCl_3$): 3625 (sharp), 3100–2800, 1650, 1480–1410, 1405–1345, and 900 cm^{-1}; ^{1}H NMR ($CDCl_3$, 200 MHz) δ: 4.67 (2H, br s), 3.66 (1H, dd, J = 10.4 and 4.7 Hz), 3.48 (1H, dd, J = 10.5 and 6.5 Hz), 2.25–2.21 (1H, m), 1.93–1.80 (3H, m), 1.72–1.57 (2H, m), 1.68 (3H, s), 1.40 (1H, s), 1.29–1.04 (2H, m), 1.00 (3H, s), and 0.98 (3H, s); EIMS, *m/z* (relative intensity) (ion): 182 (9) (M^+), 167 (52) $(M - CH_3)^+$, 164 (23) $(M - H_2O)^+$, 125 (100) $(M - C_4H_9)^+$.

Anhydrous DMSO (0.77 mL, 10.9 mmol) in freshly distilled dichloromethane (5.0 mL) was added to a solution of oxalyl chloride (0.47 mL, 5.40 mmol) in dichloromethane (20 mL) at −78°C under an argon atmosphere. After 2 min, the alcohol prepared as above (660 mg, 3.63 mmol) in dichloromethane (5 mL) was added dropwise at −78°C during a 5 min period. Stirring was continued at this temperature for 30 min and, after addition of dry triethylamine (2.52 mL, 18.1 mmol), for a further 5 min, when the mixture was allowed to warm to ambient temperature. After addition of water and dichloromethane extraction, the extracts were washed with water and brine, dried over $MgSO_4$, and concentrated in vacuo. Flash chromatography of the residue, eluting with hexane–EtOAc (10:1), afforded aldehyde **17** (625 mg, 96%) as an oil: IR ($CHCl_3$): 2950, 2870, 1715, 1650, and 1480–1400 cm^{-1}; ^{1}H NMR ($CDCl_3$, 200 MHz) δ: 9.58 (1H, d, J = 2.3 Hz), 4.67 (2H, br s), 2.53–1.71 (4H, m), 1.68 (3H,s), 1.65–1.09 (4H, m), 1.02 (3H, t), and 0.96 (3H, s); EIMS, *m/z* (relative intensity) (ion): 181 (54) ($M^+ + 1$), 180 (16) (M^+), 165 (31) $(M - CH_3)^+$, 151 (11) $(M - CHO)^+$, 136 (15) $(M - CHO - CH_3)^+$, 125 (37) $(M - C_4H_7)^+$, 124 (27) $(M - C_4H_8)^+$, 123 (77) $(M - C_4H_9)^+$ or $(M - C_3H_5O)^+$, 122 (36), 121 (18), 111 (10), 109 (27), 107 (30), and 96 (100) $(C_7H_{12})^+$.

1-(1′-Hydroxy-2′-propenyl)-2-(2″-methyl-2″-propenyl)-4,4-dimethylcyclopentane, 18

Vinyl magnesium bromide (2.0 mL 1.0 M solution in THF, 2.00 mmol) was added at 0°C under anhydrous conditions and an argon atmosphere to the aldehyde **17** (325 mg, 1.80 mmol) in freshly distilled THF (30 mL). The mixture was allowed to attain ambient temperature and was set aside with stirring for 1.5 h. After addition of saturated NH_4Cl solution, the mixture was extracted with ether, and the extracts were dried over $MgSO_4$ and concentrated in vacuo. Flash chromatography of the residue, eluting with hexane–EtOAc (10:1), afforded vinyl carbinol **18** (310 mg, 82%) as an oil; IR ($CHCl_3$) 3600 (sharp), 2950, 2940, 2865, 1650, 1600 and 1480–1400 cm^{-1}; ^{1}H NMR ($CDCl_3$, 200 MHz) δ: 5.94–5.76 (1H, m), 5.25–5.05 (2H, m), 4.65 (2H, br s), 4.14–4.00 (1H, m), 2.39–2.25 (1H, m), 2.13–1.72 (2H, m), 1.68 (3H,s), 1.65–1.03 (5H, m), and 0.98 (6H, overlapping singlets); EIMS, *m/z* (relative intensity) (ion): 208 (8) (M^+), 193 (13) $(M - CH_3)^+$, 190 (15) $(M - H_2O)^+$, 175 (24) $(M - CH_3 - H_2O)^+$, 165 (20), 152 (29) $(M - C_4H_8)^+$, or $(M - C_3H_4O)^+$, 151 (100) $(M - C_4H_9)^+$ or $(M - C_3H_5O)^+$, 147 (29) , 136 (27), and 135 (19).

1-(1′-Oxo-2′-propenyl)-2-(2″-methyl-2″-propenyl)-4,4-dimethylcyclopentane, 7

The Swern oxidation (22) of vinyl carbinol **18** was conducted as described above using oxalyl chloride (0.19 mL, 2.18 mmol), anhydrous DMSO (0.31 mL, 4.37 mmol), and triethylamine (1.0 mL, 7.2 mmol) for oxidation of the alcohol (300 mg, 1.44 mmol). The yield of product **7**, after work-up and chromatography, was 290 mg, 98%; IR ($CHCl_3$): 2950, 2865, 1690, 1670, 1610, 1450, 1405, and 1370 cm^{-1}; UV λ_{max} (cyclohexane): 221 nm (ε 2145); ^{1}H NMR ($CDCl_3$, 200 MHz) δ: 6.38 (1H, dd, J = 10.2 and 18.1 Hz), 6.13 (1H, dd, J = 1.7 and 17.6 Hz), 5.74 (1H, dd, J = 1.7 and 10.1 Hz), 4.61 (2H, br), 2.98–2.85 (1H, m), 2.78–2.63 (1H, m), 2.12–1.44 (5H, m), 1.65 (3H, s), 1.21–1.10 (1H, m), 1.03 (3H, s), and 1.00 (3H,s); HREIMS, *m/z* (relative intensity) (ion): 191.1426 (29) $(M - CH_3)^+$, (calcd. for $C_{13}H_{19}O$: 191.1436), 173 (14) ($C_{13}H_{17}$), 138 (23) ($C_9H_{14}O$), and 95 (100) (C_7H_{11}) (in the GC–MS (total ion current), a small shoulder (<10%) on the longer retention side of the main peak, whose MS was very similar to that of **7**, is presumed to represent the corresponding *cis* isomer).

Photoirradiation of 7

(*i*) In a cylindrical Pyrex vessel, a solution of ene-enone **7** (31 mg, 0.15 mmol) in freshly distilled dichloromethane (11.0 mL) containing benzophenone (7 mg, 0.038 mmol) was purged with argon for 30 min. The solution at ~0°C was irradiated (externally) for 30 min using a Hanovia 200 W mercury arc lamp in a quartz well, the latter apparatus and the contiguous reaction vessel being cooled in an ice bath. At this stage, TLC analysis indicated that no unchanged starting material remained. The solution was allowed to attain ambient temperature, and the solvent was removed under reduced pressure. Chromatography of the product on a preparative TLC plate, eluting with hexane–EtOAc (10:1), afforded 12 mg (39%) of photoproduct **12**; IR ($CHCl_3$): 3050–2800, 1705, 1600, 1480–1400, 1390–1360, and 900 cm^{-1}; ^{1}H NMR ($CDCl_3$, 200 MHz) δ: 4.63 (2H, narrow m), 2.75–2.60 (3H, m), 2.10–1.65 (6H m), 1.65 (~0.75 Me, s), 1.54 (~0.25 Me), 1.55–1.05 (2H, m), 1.04 (s), 1.02 (s), and 0.99 (s) (6H) (peaks at δ: 1.54 and 1.04 attributed to methyl groups of minor diastereomer); LREIMS, *m/z* (relative intensity) (ion): 206 (20) (M^+), 191 (29) $(M - CH_3)^+$, 163 (43) $(M - CH_3 - C_2H_4)^+$, or $(M - CH_3 - CO)^+$, 151 (84)

$(M - C_4H_7)^+$ or $(M - C_3H_3O)^+$, 136 (29) $(M - C_5H_{10})^+$, 123 (80) $(M - C_6H_{11})^+$, 109 (45) $(C_7H_9O)^+$, 95 (100) $(C_7H_{11})^+$, 81 (84) $(C_6H_9)^+$, 67 (25) $C_5H_7)^+$, 55 (59) $(C_3H_3O)^+$ or $(C_4H_7)^+$; HREIMS, *m/z* (relative intensity) (ion): 206.1676 (38) (M^+) (calcd. for $C_{14}H_{22}O$: 206.1671).

(*ii*) A solution of ene-enone **7** (38 mg, 0.184 mmol) in distilled hexane (3.0 mL) (0.0615 M) at ambient temperature in a quartz cell was irradiated at 254 nm for 71 h using a 4 W Spectroline E-Series UV lamp. The solution was concentrated and the residue subjected to preparative TLC on a silica gel plate (hexane–EtOAc, 10:1). Material (8 mg, ca 20%) from an apparently homogeneous band on the plate was found by GC–MS to consist of two isomeric products in the approximate ratio 2:3. The spectra of the mixture contained features in accord with structure **13**; IR ($CHCl_3$): 3600, 2940, 2870, 1690, and 1455 cm^{-1}; ^1H NMR ($CDCl_3$, 200 MHz) δ: 5.86 (1H, dd, J = 17.4 and 10.7 Hz), 5.26 (1H, dd, J = 17.2 and 1.5 Hz), 5.05 (1H, dd, J = 10.7 and 1.4 Hz), 4.86 (1H, br), 4.77 (1H,br), and 2.80–0.85 (~60 H, m); GC–MS (minor peak: (**13**) (4.41 min)) *m/z* (proposed ion): 206 $(M)^+$ $(C_{14}H_{22}O)^+$, 151 $(M - C_4H_7)^+$, 109 $(C_7H_9O)^+$, 95 $(C_7H_{11})^+$, 81 $(C_6H_9)^+$, 55 $(C_4H_7)^+$ or $(C_3H_3O)^+$; (major peak: (**9** or **9′**?) (5.12 min)) *m/z*: 206 $(M)^+$ $(C_{14}H_{22}O)^+$, 191 $(M - CH_3)^+$, 178 $(C_{12}H_{18}O)^+$, $(M - C_2H_4)^+$, 163 $(M - CH_3 - C_2H_4)^+$, 122 $(C_8H_{10}O)^+$, 95 $(C_7H_{11})^+$, 82 $(C_5H_6O)^+$, and 55 $(C_4H_7)^+$.

Diels–Alder addition of conjugated ester, 14, and ketene acetal, 23

A mixture of ester **14** (130 mg, 0.84 mmol) and ketene acetal **23** (650 mg, crude, ca. 5.15 mmol, prepared according to Boehler and Konopelski (26)) with K_2CO_3 (10 mg) was heated under argon in a sealed tube at 150°C for 10 days. Flash chromatography of the product, eluting with hexane–EtOAc (10:1), afforded the Diels–Alder adduct **24** (160 mg, 68 %); IR ($CHCl_3$): 3100–2800, 1720, and 1500–1400 cm^{-1}; ^1H NMR ($CDCl_3$, 200 MHz) δ: 5.40 (1H, s), 3.98–3.79 (4H, m), 3.67 (3H, s), 3.00 (1H, m), 2.40–2.15 (2H, m), 1.83–1.69 (5H, m), 1.63–1.52 (1H, m), 1.31–1.20 (1H, m), 1.01 (3H, s), and 0.86 (3H, s); HREIMS, *m/z* (relative intensity) (ion): 280.1668 (13) $(M)^+$ (calcd. for $C_{16}H_{24}O_4$, 280.1674), 249 (15) $(C_{15}H_{21}O_3)$ $(M - OCH_3)^+$, 221 (48) $(C_{14}H_{21}O_2)$ $(M - CO_2CH_3)^+$, 191 (14) $(C_{13}H_{19}O)$, 177 (15) $(C_{12}H_{17}O)$, 176 (14) $(C_{12}H_{16}O)$, 161 (17) $(C_{11}H_{13}O)$, 142 (13) $(C_7H_{10}O_3)$, 127 (100) $(C_7H_{11}O_2)$, 123 (16) $(C_8H_{11}O)$, 121 (12) (C_8H_9O), 111 (15) (C_6H_7O), 105 (12) (C_8H_9), 99 (22) $(C_5H_7O_2)$, 93 (11) (C_7H_9), 91 (20) (C_7H_7).

Deprotection of Diels–Alder adduct

Acetal **24** (320 mg, 1.14 mmol), from the Diels–Alder reaction, was stirred in THF (6.0 mL) containing 5% aqueous HCl (2.4 mL) at ambient temperature for 36 h. Work-up afforded the chromatographically homogeneous bicyclic enone ester **22** in a yield of 265 mg (98%); IR ($CHCl_3$): 3150–2800, 1720, 1660, and 1440 cm^{-1}; ^1H NMR ($CDCl_3$, 400 MHz) δ: 5.95 (1H, s), 3.65 (3H, s), 3.00–2.94 (1H, m), 2.72 (1H, dd, J = 19.3 and 6.2 Hz), 2.50 (1H, d, J = 13.7 Hz), 2.14 (1H, d, J = 19.3 Hz), 1.96 (1H, d, J = 13.8 Hz), 1.93 (3H, s), 1.58 (1H, dd, J = 12.6 and 6.8 Hz), 1.41 (1H, t, J = 13.0 Hz), 1.06 (3H, s), 0.95 (3H, s); HREIMS, *m/z* (relative intensity) (ion): 236.1399 (8) $(M)^+$, (calcd. for $C_{14}H_{20}O_3$, 236.1412), 221 (1) $(C_{13}H_{17}O_3)$ $(M - CH_3)^+$, 205 (2) $(C_{13}H_{17}O_2)$ $(M - OCH_3)^+$, 204 (2) $(C_{13}H_{16}O_2)$, 177 (14) $(C_{12}H_{17}O)$, 176 (4) $(C_{12}H_{16}O)$, 161 (6) $(C_{11}H_{13}O)$, 123 (2) $(C_8H_{11}O)$, 121 (3) (C_8H_9O), 82 (100) (C_5H_6O).

Photocycloaddition of ethylene to 22

A solution of enone ester **22** (117 mg, 0.496 mmol) in freshly distilled dichloromethane (20 mL) contained in a cylindrical Pyrex vessel was purged with argon for 30 min. As ethylene (excess) was bubbled in, the solution was irradiated (externally) for 2 h using a Hanovia 200 W mercury arc lamp in a quartz well, the latter apparatus and the contiguous reaction vessel being cooled in a Dry Ice – acetone bath. After the photocycloaddition, the solution was allowed to attain ambient temperature, and the solvent was removed under reduced pressure. Preparative thin-layer chromatography of the crude product (132 mg) on a silica gel plate, eluting with hexane–EtOAc (10:1), afforded unreacted enone ester **22** (50 mg) and 73 mg (97% based on consumed starting material) of a mixture of isomeric photoadducts **25** and **26** in the ratio (by NMR) 12:1. The isomers were separated chromatographically with the major (desired) product, **25**, eluting more slowly than its stereoisomer. Photoadduct **25**, mp 49°C, displayed the following spectroscopic properties: IR ($CHCl_3$) 3000–2800, 1730, 1690, and 1480–1400 cm^{-1}; ^1H NMR ($CDCl_3$, 400 MHz) δ: 3.73 (3H, s), 3.53–3.43 (1H, m), 2.75–2.71 (1H, dd, J = 10.2 and 6.6 Hz), 2.22–2.00 (5H, m), 1.90–1.85 (1H, dd, J = 13.0 and 7.7 Hz), 1.82–1.75 (2H, m), 1.41–1.36 (1H, dd, J = 13.0 and 6.7 Hz), 1.33–1.25 (1H, m), 1.22 (3H, s), 1.05 (3H, s), and 0.98 (3H, s); ^{13}C NMR (100 MHz, $CDCl_3$) δ: 210.4 (s), 173.4 (s), 65.8 (s), 52.7 (q), 51.2 (d), 48.0 (t), 47.7 (t), 42.3 (d), 41.0 (s), 39.2 (t), 37.5 (s), 31.5 (q), 30.9 (t), 30.5 (q), 29.9 (q), and 17.9 (t); HREIMS, *m/z* (relative intensity) (ion): 264.1712 (8) $(M)^+$ (calcd. for $C_{16}H_{24}O_3$, 264.1725), 249 (3) $(C_{15}H_{21}O_3)$ $(M - CH_3)^+$, 233 (5) $(C_{15}H_{21}O_2)$ $(M - OCH_3)^+$, 232 (9) $(C_{15}H_{20}O_2)$, 217 (5) $(C_{14}H_{17}O_2)$, 193 (9) $(C_{12}H_{17}O_2)$, 177 (27) $(C_{12}H_{17}O)$, 155 (15) $(C_9H_{15}O_2)$, 82 (100) (C_5H_6O).

Minor photoadduct **26** displayed the following spectroscopic properties: IR ($CHCl_3$): 2960, 2875, 1705, and 1480–1405 cm^{-1}; ^1H NMR ($CDCl_3$, 400 MHz) δ: 3.68 (3H, s), 3.64–3.54 (1H, m), 2.75–2.71 (1H, m), 2.46 (1H, d, J = 13.8 Hz), 2.31–2.22 (1H, m), 2.16–2.07 (1H, m), 1.84–1.61 (5H, m), 1.33 (3H, m), 1.31–1.21 (1H, m), 1.15–1.09 (1H, m), 1.04 (3H, s), and 0.95 (3H, s); ^{13}C NMR (100 MHz, $CDCl_3$) δ: 211.0 (s), 174.0 (s), 64.5 (s), 52.6 (q), 49.4 (t), 48.9 (d), 45.4 (t), 44.2 (d), 43.7 (s), 40.9 (t), 38.4 (s), 32.9 (t), 29.3 (q), 27.5 (q), 26.4 (q), and 17.4 (t); HREIMS, *m/z* (relative intensity) (ion): 264.1725 (18) $(M)^+$ (calcd. for $C_{16}H_{24}O_3$, 264.1725), 249 (12) $(C_{15}H_{21}O_3)$ $(M - CH_3)^+$, 233 (9) $(C_{15}H_{21}O_2)$ $(M - OCH_3)^+$, 232 (11) $(C_{15}H_{20}O_2)$, 217 (7) $(C_{14}H_{17}O_2)$, 177 (29) $(C_{12}H_{17}O)$, 176 (19) $(C_{12}H_{16}O)$, 155 (15) $(C_9H_{15}O_2)$, 123 (20) $(C_8H_{11}O)$, 110 (27) $(C_7H_{10}O)$, and 82 (100) (C_5H_6O).

Demethoxycarbonylation of 25: tricyclic ketone, 29

The major photoadduct **25** (295 mg, 1.12 mmol) dissolved in distilled HMPA (10 mL) was heated at 100°C with LiCl (95 mg, 2.24 mmol) in an argon atmosphere under anhydrous conditions for 20 h (cf. ref. 34). Work-up and flash chromatography in the normal manner afforded the desired tricyclic ketone, **29** (188 mg, 82%), IR ($CHCl_3$): 2940, 2870, 1680, 1455, and 1370 cm^{-1}; ^1H NMR ($CDCl_3$, 400 MHz) δ: 3.29–3.21 (1H, m), 3.13–3.06 (1H, m), 2.66–2.62 (1H, m), 2.27–

2.14 (2H, m), 2.04–1.95 (1H, m), 1.90–1.81 (2H, m), 1.64–1.59 (3H, m), 1.16 (3H, s), 1.11–1.06 (1H, m), 1.07 (3H, s), 0.99 (3H, s), and 0.93–0.87 (1H, m); HREIMS, *m/z* (relative intensity) (ion): 206.1682 (21) $(M)^+$ (calcd. for $C_{14}H_{22}O$, 206.1671), 191 (38) $(C_{13}H_{19}O)$ $(M - CH_3)^+$, 178 (64) $(C_{12}H_{18}O)$ $(M - C_2H_4)^+$,123 (23) $(C_8H_{11}O)$, 82 (100) (C_5H_6O).

Tricyclic carbinol 30

A solution of methyllithium in ether (0.65 mL, containing 0.909 mmol) was added to tricyclic ketone **29** (170 mg, 0.825 mmol) in freshly distilled ether (10 mL) at 0°C in an atmosphere of argon under anhydrous conditions. The reaction mixture was set aside at 0°C with stirring for 10 min, after which saturated NH_4Cl solution was added. Ether extraction and standard work-up afforded, without chromatography, 179 mg (98%) of a mixture of stereoisomeric alcohols **30**; IR ($CHCl_3$): 3600 (sharp), 2940, 2870, 1690, 1455, and 1375 cm^{-1}; ^1H NMR ($CDCl_3$, 200 MHz) δ: 2.52–1.05 (13 H, m), 1.12 (3H, s), 1.07 (3H, s), 0.98 (3H, s), and 0.97 (3H, m); HREIMS, *m/z* (relative intensity) (ion): 204.1892 (15) $(M - H_2O)^+$ (calcd. for $C_{15}H_{24}$, 204.1878), 189 (9) $(C_{14}H_{21})$ $(M - H_2O - CH_3)^+$, 176 (100) $(C_{13}H_{20})$, 175 (51) $(C_{13}H_{19})$, 161 (78) $(C_{12}H_{17})$, 149 (6) $(C_{11}H_{17})$, 121 (22) (C_9H_{13}), 120 (31) (C_9H_{12}), 119 (28) (C_9H_{11}), 107 (21) (C_8H_{11}), 105 (45) (C_8H_9), 95 (5) (C_7H_{11}), and 91 (17) (C_7H_7).

Sterpurene, 1

Carbinol (mixture) **30** (39 mg, 0.176 mmol) was stirred with thionyl chloride (0.03 mL, 0.411 mmol) and dry pyridine (0.2 mL) at 0°C in an atmosphere of argon under anhydrous conditions for 1.5 h. After addition of water, the mixture was extracted with ether and worked up in the conventional manner. Flash chromatography of the crude product on a silica gel column eluting with *n*-pentane afforded pure racemic sterpurene (23.4 mg, 69%); IR ($CHCl_3$): 3025–2800, 1480–1400, and 1400–1345 cm^{-1}; ^1H NMR ($CDCl_3$, 400 MHz) δ: 2.63 (1H, m), 2.41–2.31 (1H, m), 2.12–2.06 (3H, m), 1.96–1.88 (1H, m), 1.68–1.64 (1H, m), 1.55–1.51 (4H, m), 1.47–1.38 (2H, m), 1.20 (3H, s), 1.11–1.05 (1H, m), 1.07 (3H, s), 1.05 (3H, s), and 0.70–0.64 (1H, m); ^{13}C NMR (100 MHz, $CDCl_3$) δ: 136.5 (s), 127.7 (s), 48.6 (t), 44.6 (d), 44.4 (t), 39.3 (t), 38.0 (s), 37.6 (d), 36.5 (s), 30.2 (q), 29.4 (q), 29.3 (q), 27.9 (t), 24.7 (t), and 17.8 (q); HREIMS, *m/z* (relative intensity) (ion): 204.1892 (15) $(M)^+$ (calcd. for $C_{15}H_{24}$, 204.1878), 189 (9) $(C_{14}H_{21})$ $(M - CH_3)^+$, 176 (100) $(C_{13}H_{20})$, 175 (51) $(C_{13}H_{19})$, 161 (78) $(C_{12}H_{17})$, 149 (6) $(C_{11}H_{17})$, 121 (22) (C_9H_{13}), 120 (31) (C_9H_{12}), 119 (28) (C_9H_{11}), 107 (21) (C_8H_{11}), 105 (45) (C_8H_9), 95 (5) (C_7H_{11}), and 91 (17) (C_7H_7).

Natural products

Isolation of sterpuric acid **2**, sterepolide **5**, and dihydrosterepolide **6** from culture filtrates of *C. purpureum* was previously described by Ayer et al. (3–6). Physical properties and spectroscopic characteristics of these metabolites, isolated in the present study from 30-day-old cultures, were in agreement with the literature data.

Bioassays

A callus line was initiated from a bud of *P. deltoides X nigra* (DN17) and maintained on half-strength Gamborg medium at 25°C in the dark. Ten-day-old cells were removed using a sterile bacteriological loop and approximately 5 mg (fresh weight) was added to 2 mL of the above medium (minus agar) containing the test compound dissolved in 25 μL 50% aqueous acetone. The cells were incubated in this mixture at 25°C in the dark with shaking (100 rpm) for 2 h. Viable cells could be distinguished from dead cells by their fluorescence under UV after adding fluorescein diacetate (2 μL of solution containing 5 mg/mL). For each treatment, 100 cells were examined and the ratio of living to dead cells gave the % viability.

Acknowledgements

Financial support from the Canadian Forest Service Green Plan BICOVER Network, the Ontario Ministry of Natural Resources (ARIO), and the Natural Sciences and Engineering Research Council of Canada is gratefully acknowledged. We thank Dr. J.A. McLaughlin for providing us with the *C. purpureum* culture. We are grateful to a referee for a constructive criticism of our original disussion on the facial selectivity of the photocycloaddition. His comments engendered the discussion as presented herewith in the revised version. We wish also to thank Professors Z. Valenta and G. Deslongchamps for an exchange of ideas on this subject, and we are particularly indebted to the latter colleague for conducting the MM2 calculations. We thank Professor G. Lange for reading the manuscript and for his comments. We are grateful to Mr. Dan Drummond and Dr. Larry Calhoun, University of New Brunswick, for recording the mass spectra and some of the NMR spectra, respectively, and to Ms. Linda MacDonald, Canadian Forest Service, Sault Ste. Marie, for the GC–MS analysis.

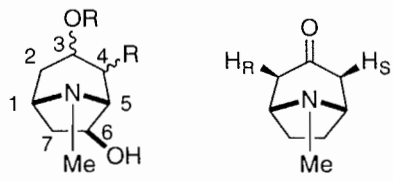
Enantioselective ring opening of tropinone. A new entry into tropane alkaloids

Marek Majewski, Ryszard Lazny, and Agnieszka Ulaczyk

Abstract: The lithium enolate of tropinone reacts with alkyl chloroformates to give 6-*N*-carboalkoxy-*N*-methyl-2-cycloheptenones (**4**). These compounds can be produced enantioselectively, in up to 95% ee, if chiral lithium amides (derived from optically pure amines **5**–**7**) are used for deprotonation of tropinone in the presence of additives. The effect of additives such as LiCl, LiBr, LiF, $LiClO_4$, $CeCl_3$, $ZnCl_2$, LiOH, TMEDA, HMPA, and DMPU on enantioselectivity of this deprotonation – ring opening sequence varies from slight to very large depending on the chiral amide – additive combination. Especially large increases in enantioselectivity are observed when the chiral, C2 symmetrical, lithium bis-α,α′-methylbenzylamide (Li-**5***a*) is used with one equivalent of LiCl. This reagent is best generated in situ from the corresponding amine hydrochloride and *n*-BuLi (2 equiv.). The ring-opening reaction combined with transposition of the carbonyl group (via Wharton reaction or allylic oxidation) provides a new method of stereoselective synthesis of tropane alkaloids having a protected hydroxyl at C-6 or C-7 (6β- and 7β-acetoxytropanes **14***a*, *b*) and physoperuvine (**19**).

Key words: enantioselective deprotonation, tropane alkaloids.

Résumé : L'énolate de lithium de la tropinone réagit avec les chloroformiates d'alkyles pour conduire à 6-*N*-carboalkoxy-*N*-méthylcyclopent-2-énones (**4**). Il est possible de produire ces composés avec une énantiosélectivité allant jusqu'à 95% ee si l'on utilise des amides de lithium chiraux (obtenus à partir des amines optiquement pures, **5**–**7**) pour effectuer la déprotonation de la tropinone, en présence d'additifs. L'effet de ces additifs, tels que LiCl, LiBr, LiF, $LiClO_4$, $CeCl_3$, $ZnCl_2$, LiOH, TMEDA, HMPA et DMPU, sur l'énantiosélectivité de cette séquence de déprotonation et d'ouverture de cycle peut être léger ou important suivant la nature de la combinaison de l'amide chiral et de l'additif. On observe des augmentations d'énantiosélectivité particulièrement importantes lorsqu'on utilise du bis-α,α′-méthylbenzylamide de lithium chiral, symétrique en C2 (Li-**5***a*), avec un équivalent de LiCl. Les meilleurs résultats sont obtenus en générant ce réactif in situ à partir du chlorhydrate de l'amine correspondant et du *n*-BuLi (2 équiv.). La réaction d'ouverture de cycle combinée avec la transposition du groupe carbonyle (via une réaction de Wharton ou une oxydation allylique) fournit une nouvelle méthode de synthèse stéréosélective des alcaloïdes du tropane comportant un groupe hydroxyle protégé en position C-6 ou C-7 (6β- ou 7β-acétoxytropanes, **14***a*, *b*) et de la physopéruvine (**19**).



Mots clés : déprotonation énantiosélective, alcaloïdes du tropane.

[Traduit par la rédaction]

Introduction

Tropane alkaloids are a group of natural products isolated from plants (mainly of the *Solanaceae* family) and comprise over 200 compounds of which some 30% are chiral (1). This family of alkaloids includes some species famous (or infamous) for their biological activity, e.g., cocaine, atropine, scopolamine. Structurally, all tropane alkaloids contain the tropane (8-methyl-8-azabicyclo[3.2.1]octane) skeleton and a number of functional groups that, most often, are: a functionalized hydroxyl at C-3 (α or β), a side chain at C-2 or C-4 (α or β; the side chain is usually carbonyl based or is either an alkyl or a hydroxyalkyl group), and a β-hydroxyl at C-6 or C-7 (Fig. 1).

Fig. 1. Tropane alkaloids (**1**, generalized structure) and tropinone (**2**).

1 **2**

Tropinone (**2**) could be envisaged as a convenient starting material for synthesis of diverse tropane alkaloids provided that several stereoselectivity problems can be solved. A few years ago we began studying the enolate chemistry of tropinone with the aim of using this readily available symmetrical ketone as the starting material for synthesis of tropane alkaloids (2). During the early studies we established that tropinone lithium enolate (**3**), resulting from deprotonation of tropinone with LDA, undergoes a novel ring-opening reaction

Received December 11, 1996.

upon treatment with a chloroformate (2*e*,*f*) to yield the substituted cycloheptenone **4** (Scheme 1). This compound can be produced enantioselectively when chiral lithium amides are used for deprotonation (3). Below, we describe the effects of additives on the enantioselectivity in this system and applications of the ring opening to the synthesis of physoperuvine and dihydroxytropanes.

Results and discussion

Our initial experiments with the deprotonation of tropinone using chiral lithium amides gave products in low enantioselectivity. We decided to evaluate several different bases and, since deprotonation reactions are often strongly affected by organic or inorganic additives (4) like lithium halides, amines (e.g., TMEDA), or by small amounts of polar cosolvents (e.g., HMPA, DMPU), we also used the chiral lithium amides in the presence of such additives.

Structures of chiral amines used as precursors for the chiral lithium amide bases in this study are shown in Fig. 2 and the experiments that involved deprotonation of **2** with these bases, followed by treatment of the resulting enolate with trichloroethyl chloroformate to give **4***c*, are summarized in Table 1. The dextrarotoatory isomer of **4***c* was the major product in all cases; the absolute stereochemistry of this isomer was established by correlation with anhydroecgonine (2*a*) and is as shown in Scheme 1. Most of the lithium amides tested gave low enantioselectivity in the absence of additives. The two exceptions were the lithiated bidentate amines **7***a*, *b* developed by Koga (5) that gave **4***c* in over 80% ee when the reaction was

Table 1. Formation of compound **4***c* (cf Scheme 1) using chiral lithium amides derived from chiral amines **5**, **6**, or **7**.

Entry	Lithium amide	Additive	ee[a] (%)	Yield[b] of **4***c* (%)
1	Li-**5***a*	—	44	80
2	Li-**5***a*	LiCl[c]	96	92

[d]Amine hydrochloride was used to generate the 1:1 Li-amide–LiCl complex.

run in THF (Table 1, entries 11 and 13). Addition of one equivalent of lithium chloride prior to enolization resulted in great enhancement of enantioselectivity when lithiated monodentate amines, and especially the C2 symmetrical amide Li-**a***a*, were used (Table 1, entries 1 and 2). Lithium chloride had a much smaller effect on the already efficient reactions involving the bidentate amides **7***a* and **7***b* (Table 1, entries 11 and 12, 13 and 14), but still caused the reaction selectivity, i.e., the k_{HS}/k_{HR} ratio, to increase by a factor of 2 (or greater).

Lithium amide derived from the C2 symmetrical amine **5***a* appeared to be the base of choice; the reagent used in the presence of LiCl was as efficient as Li-**7***a* or Li-**7***a*. The parent amines of the two latter compounds are much more difficult, and expensive, to make. We decided to investigate the effect of additives on the behavior of Li-**5***a* in greater detail: variable amounts of LiCl were tried as well as different lithium salts, salts of other metals, and also organic additives: TMEDA and cosolvents such as HMPA and DMPU. The results are summarized in Table 2.

Addition of even small amounts of LiCl or LiBr resulted in an increase of enantioselectivity. The salt effects leveled off after one (LiCl) or two (LiBr) equivalents of the halide were added. The dependence of enantioselectivity on the number of equivalents of LiCl and LiBr is shown in Fig. 3. Lithium iodide, fluoride, or perchlorate had no effect on the selectivity of deprotonation. Cerium trichloride and zinc chloride showed salt effects similar to LiCl or LiBr but it should be noted that all our experiments with $ZnCl_2$ resulted in low yields. Organic additives, i.e., TMEDA, HMPA, and DMPU, had little effect. Interestingly, deliberate addition of water followed by the addition of the corresponding excess of BuLi (Table 2, entries 20 and 21; water and BuLi should translate into addition of 0.05 or 0.20 molar equivalent of LiOH, respectively) essen-

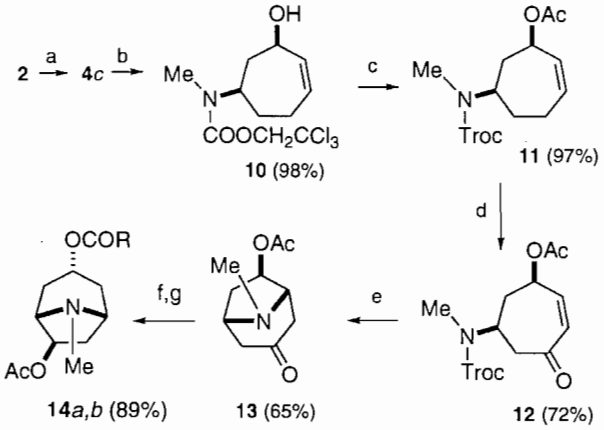
[c]Excess BuLi (5% or 20%) was used in these experiments.

Fig. 3. Effect of LiCl and LiBr on enantioselectivity of formation of **4***c* (curves were fitted arbitrarily).

Scheme 2.

tially destroyed reaction selectivity and resulted in low yields. In all cases the yields were much lower than would be indicated by a simple assumption that a certain percentage of the base or the enolate was quenched. This underscores the need for thorough drying of the reagents and also the fact that it is not enough to titrate *n*-BuLi prior to use; if the reagent is contaminated with appreciable quantities of LiOH it will not work despite the reasonably high concentration of BuLi present. The great change in the reaction selectivity when a small amount of LiCl or LiBr was added precipitated the question of how halide-free was the commercial *n*-BuLi solution used in these experiments. This question was addressed by cyclic voltammetry: the amount of halide ions in a sample of *n*-BuLi hydrolyzed with MeOH was found to be smaller than 0.003 mole per mole of *n*-BuLi and thus could be assumed to have no effect on deprotonation.

It appeared that some salts, and especially LiCl and LiBr, had a strong influence on enantioselectivity of deprotonation of tropinone with the amide Li-**5***a*. A similar (but shorter) study with the lithium amide Li-**7***a* revealed that addition of LiCl resulted in some increase in selectivity that was independent of the amount of LiCl in the 0.1–2.0 equivalent range (using 0.1 or 2.0 equiv. LiCl gave **4***c* in 94% ee in both cases); addition of HMPA had no effect (variable amounts of HMPA from 0.1 to 3.0 molar equivalents were tried) and addition of 0.20 molar equivalents of H_2O resulted in loss of selectivity and very low yields (6% ee and 8% yield of **4***c*).



It can be concluded that addition of one equivalent of LiCl greatly increases enantioselectivity of deprotonation of tropinone with some lithium amides. The amide Li-**5***a* used in the presence of one molar equivalent of LiCl is a very efficient reagent in this system. Lithium chloride can be easily generated in situ, and its is usually better to use the hydrochloride of the amine (e.g., **5***a*-HCl) with 2 molar equivalents of *n*-BuLi to obtain the required 1:1 amide–LiCl complex. In many cases the crystalline hydrochloride salts are easier to purify and to dry than the viscous liquid amines. The hydrochlorides are also much more stable than the parent amines (longer shelf life, especially in the presence of moisture, oxygen, and CO_2) and can be easily manipulated.

After elaborating the optimal conditions for the enantioselective ring-opening reaction the stage was set for applications of this method to synthesis of tropane alkaloids. A number of these natural products have a hydroxy group at C-6 (or C-7; alkaloid numbering) of the tropane skeleton (cf Scheme 1) and we thought that the ring opening could provide a good enantioselective entry into these systems. It should be noted that the amine **5***a* is available in both enantiomeric forms and thus the enantioselective ring-opening reaction, described above, provides a way to render either C-6 or C-7 allylic. However, we quickly found out that we were unable to either hydroxylate or brominate the γ position in the enone functional group of compound **4**, even after protecting the C=O groups as an acetal. In the end we developed a strategy for synthesis of 7β-acetoxy tropanes based on the 1,4-transposition of the carbonyl group in compound **4** (Scheme 2).

Enantioselective syntheses of two natural products, 7β-acetoxy-3α-tigloyloxytropane and 3α,7β-diacetoxytropane, are shown in Scheme 3. Reduction of the substituted cyclo-

heptenone **4***c* proceeded selectively under conditions developed by Luche (6), i.e., with $CeCl_3$–$NaBH_4$. The allylic alcohol product **10** had to be protected before the oxidation was attempted. Several groups (e.g., 1-methoxy-1-methylethyl, TBDMS) were tried but failed to provide sufficient protection under typical allylic oxidation conditions (*t*-BuOOH–PDC, SeO_2). Finally the acetate **11**, which could lead directly to 7-acetoxy alkaloids, proved stable under these conditions. Another serious problem, however, was that none of the oxidants mentioned above was sufficiently effective. Best results were obtained with H_2SeO_3 in wet dioxane, but the reaction did not proceed beyond 15% conversion and produced a complex mixture of three oxidation products (two diasteroisomeric allylic alcohols and the enone **12**) and several unidentified byproducts. Increasing the reaction time, using an excess of the oxidant or adding the selenium reagent in small portions over a long time, did not improve the effectiveness of this process. However, after observing that substantial amounts of selenium were produced as a colloidal suspension, scavenging the selenium with Celite increased in the reaction yield significantly. To avoid dealing with the mixtures of allylic alcohols and the ketone **12** we decided on an oxidative work-up. Transformation of the acetate **11** to the enone **12** was finally accomplished in 72% yield by oxidation with H_2SeO_3–Celite followed by PDC (Scheme 3). Removal of the 2,2,2-trichloroethylcarbamate group from **12** with zinc in ethanol was followed by an immediate cyclization to give 7β-acetoxytropinone **13** in 95% ee. Scalemic **13** served as the key intermediate in the synthesis of two optically active tropane alkaloids: (+)-3α,7β-diacetoxytropane (**14***a*) and (−)-7β-acetoxy-3α-tigloyloxytropane (**14***b*). Stereoselective reduction of the carbonyl group in **13** was accomplished by hydrogenation over Adams' catalyst (Scheme 3).

A different transposition of the C=O group in **4** was used in the synthesis of physoperuvine **19** (Scheme 4). The cyclic hemiaminal functional group in this alkaloid can readily open (in fact physoperuvine exists in equilibrium with the ring-open form **18**) and, thus protected, 6-aminocycloheptenone **4** could be a precursor to **19** via a 1,3-transposition of the carbonyl group in the enone system. The Wharton reaction (7) provided a successful solution to this problem. Thus, after enantioselective deprotonation of tropinone with Li-**5***a*–LiCl (the lithium amide was generated in situ from the hydrochloride of **5***a*) and ring opening using benzyl chloroformate (CbzCl), the double bond in compound **4***b* was epoxidized using alkaline hydrogen peroxide. Although methanol is typically used as the solvent for epoxidation of enones, aqueous THF had to be used in this case to avoid the competing conjugate addition of methanol to **4***b*. The Wharton rearrangement was done by treatment of the mixture of two isomeric epoxides **15** with hydrazine and a catalytic amount of acetic acid. The rearranged allylic alcohol **16** was easily oxidized to the corresponding enone **17** using PDC. The ^{1}H NMR spectrum of this product is very similar to the spectrum of the enone **4***b*; however, a close examination of the spectra showed small differences in chemical shifts of the vinylic hydrogens, indicating that the two enones, **4***b* and **17**, are regioisomers. The transformation of this enone to physoperuvine (**19**) was precedented in the literature (8) but no experimental details were given. Hydrogenation of **17** provided the natural alkaloid, which exists predominantly in its hemiaminal form **19** (9).

Conclusions

Opening the five-membered ring of tropinone by deprotonation with a lithium amide base followed by treatment with a chloroformate was the source of protected 6-aminocycloheptenone **4**. The ketone can be produced enantioselectively by using chiral, nonracemic lithium amide bases for enantioselective deprotonation. The selectivity of this reaction depends on the structure of the base and on the reaction conditions (additives, cosolvents). The C2 symmetrical lithium amide Li-**a***a* generated in situ from the hydrochloride salt of the corresponding amine **5***a* and *n*-BuLi (2 equivalents) is the best reagent for this transformation. The ring-opening reaction was used for synthesis of physoperuvine **19** and two natural products from the 7β-acetoxytropane group (**14**).

Experimental part

All air-sensitive reactions were carried out under argon (10). Tetrahydrofuran was distilled under nitrogen from sodium and benzophenone. Diisopropylamine and other amines used as a

precursors for lithium amides were distilled from calcium hydride and stored over 4 Å molecular sieves. Chiral amines were prepared as described previously (11). Lithium chloride, bromide, and iodide were dried at 130–150°C under vacuum for 12 h and lithium perchlorate was dried (melted) at 200°C in an over for 12 h. The salts were then dissolved in THF and stored under argon. Butyllithium (*n*-BuLi solution in hexanes, Aldrich) was periodically titrated using 2,5-dimethoxybenzyl alcohol as the indicator. Tetramethylethylenediamine (TMEDA), hexamethylphosphoric triamide (HMPA), and 1,3-dimethyl-3,4,5,6-tetrahydro-2(1*H*)-pyrimidinone (DMPU) were distilled from calcium hydride.

Flash column chromatography (FCC) (12) and dry-column flash chromatography (DFC) (13) were carried out using Merck silica gel 60 (230–400 mesh) and Sigma silica gel type H (10–40 μm), respectively, and thin-layer chromatography (TLC) was performed on precoated glass plates (Merck, silica gel 60, F254). The spots were detected using UV light (254 nm), the Dragendorff reagent (14), or with a developing solution of phosphomolybdic acid and ceric sulfate followed by charring on a hot plate.

Optical rotation was measured on a Perkin Elmer 241 polarimeter (1 dm cell); all concentrations are given in g/100 mL. Mass spectra are reported as *m/z* ratio (relative intensity); electron impact (EI) ionization was accomplished at 70 eV and chemical ionization (CI) at 50 eV. Infrared (IR) spectra were recorded on a Biorad FTS-40 Fourier Transform interferometer by a diffuse reflectance cell method; only diagnostic peaks are reported. Gas chromatography was performed using a Hewlett Packard 5890A instrument fitted with a methyl silicone gum column (HP-1, 5 m × 0.53 mm) unless otherwise stated.

Chromatographic analyses of enantiomeric purity of compound **4***c* were done on a chiralpack AD column. The solvent used was 15:1 hexane:isopropanol at 0.8 mL/min flow rate, and the sample concentration was 1 mg/mL. Statistically estimated error was ±1% ee. It should be noted, however, that differences between any two different experiments could be larger; the critical parameter for good reproducibility (and higher ee) seems to be slow rate of addition of the ketone to the lithium amide.

To obtain a high signal-to-noise ratio, ^{1}H NMR spectra for analysis of the ee were recorded on 20–25 mg samples in 0.4 mL $CDCl_3$ in the presence of 20 mg of *S*-(+)-2,2,2-trifluoro-1-(9-anthryl)ethanol (*S*-(+)-TFAE). Statistically estimated error of the measurement was ±2% ee.

Generation of nonracemic tropinone lithium enolate using chiral amine hydrochloride

A solution of *n*-BuLi in hexanes (2.49 M, 7.12 mL, 17.7 mmol) was added to a suspension of (*S,S*)-(−)-*N,N*-bis(1-phenylethyl)amine hydrochloride (2.307 g, 8.80 mmol) in THF (80 mL) at 0°C and the mixture was stirred for 45 min. After cooling to −78°C for 20 min, tropinone (1.112 g, 8 mmol) in THF (8 mL) was added via a syringe pump (over 105 min) and the resulting solution was stirred for 120 min.

6-[*N*-(2,2,2-Trichloroethoxy)carbonyl-*N*-methyl]amino-2-cyclohepten-1-one (4*c*)

2,2,2-Trichloroethyl chloroformate (0.16 mL, 0.246 g, 1.16 mmol) was added to a solution of tropinone lithium enolate (1 mmol) at −78°C and the mixture was stirred for 30 min. After quenching with 40% K_2CO_3 (4 mL) and warming to room temperature (rt), the reaction mixture was extracted with ether (3 × 10 mL). The extracts were washed with 5% H_2SO_4 (to remove the chiral amine, 98% recovery) and brine, and were then dried ($MgSO_4$). The solvent was removed under vacuum to give the crude scalemic product, which was purified by crystallization from 5 mL of hexane (white solid, 0.289 g, 92%). The chiral amine was left in the mother liquor; mp (racemic): 59–61°C; mp (scalemic): 89–90°C; $[\alpha]_D^{26}$ +55.4 (*c* 1.05, MeOH), second crystallization +56.5 (*c* 1.04, MeOH); IR: 1713 (C=O), 1666 (C=O) cm^{-1}; ^{1}H NMR: 6.64 (ddd, *J* = 12 Hz, *J* = 6 Hz, *J* = 5 Hz, 1H), 6.05 (d, *J* = 12 Hz, 1H), 4.75 (s, 2H), 4.55 (br, 1H), 2.90 (s, 3H), 2.92–2.82 (m, 2H), 2.68–2.45 (m, 2H), 2.20–1.90 (m, 2H); ^{13}C NMR: 200.0, 154.0, 146.4, 132.4, 95.5, 75.0, 51.8, 47.9, 30.6, 29.3, 27.7 (some signals appeared as two peaks of unequal height due to amide isomerism); MS (EI): 315 (4), 313 (4), 124 (29), 108 (100), 109 (38), 82 (59), 81 (31), 80 (20). Anal. calcd. for $C_{11}H_{14}NO_3Cl_3$: C 41.99, H 4.48, N 4.45; found: C 42.-0, H 4.37, N 4.26.

(1*R*,6*R*)-6-[*N*-(2,2,2-Trichloroethoxy)carbonyl-*N*-methyl]amino-2-cyclohepten-1-ol (10)

A solution of $CeCl_3 \cdot 7H_2O$ (2.73 g, 7.32 mmol) in MeOH (15 mL) was added to an ice-cooled solution of the enone **4***c* (2.302 g, 7.33 mmol) in MeOH (25 mL). Solid $NaBH_4$ (0.280 g, 7.37 mmol) was added in small portions to the solution over 45 min. The reaction mixture was warmed up to rt (TLC showed absence of the starting material) and most of the solvent was removed under vacuum. The residue was treated with aqueous K_2CO_3 (2 g in 200 mL) and was extracted with CH_2Cl_2 (3 × 30 mL). The extracts were washed with water and brine, and were dried ($MgSO_4$). The solvent was removed under vacuum and the crude product (2.293 g, 99%) was used in the next step. An analytical sample was obtained by DFC (4:1 hexane–AcOEt). Properties: colorless oil, R_f = 0.56 (1:1 hexane–AcOEt); $[\alpha]_D^{26}$ +17.4 (*c* 1.32, MeOH); IR: 3453 (OH), 1711 (CO) cm^{-1}; ^{1}H NMR: 5.82–5.68 (m, 2H), 4.80–4.70 (m, 2H), 4.45–4.38 (m, 1H), 4.30–4.12 (m, 1H), 2.88 (s, 3H), 2.35–2.18 (m, 1H), 2.10–1.68 (m, 4H), 1.62–1.45 (m, 1H); ^{13}C NMR: 153/7, 138.6, 127.7, 95.4, 74.7, 68.1, 55.8, 40.5, 30.2, 28.4, 24.7; MS (EI): 300 (3), 397 (11), 234 (11), 232 (12), 149 (14), 110 (28), 92 (37), 84 (100). Anal. calcd.: C 41.72, H 5.09, N 4.42; found: C 41.97, H 5.13, N 4.31.

(1*R*,6*R*)-1-Acetoxy-6-[*N*-(2,2,2-trichloroethoxy)carbonyl-*N*-methyl]amino-2-cycloheptene (11)

A solution of the allylic alcohol **10** (2.200 g, 6.96 mmol) in CH_2Cl_2 (6 mL) and Et_3N (4 mL) containing DMAP (0.02 g) was cooled to 0°C. Acetic anhydride (1.0 mL, 10.6 mmol) was added and the reaction mixture was left at rt for 24 h. The reaction mixture was then shaken with aqueous K_2CO_3 (1.5 g in 20 mL) for 20 min, diluted with water (30 mL), and extracted with CH_2Cl_2 (3 × 30 mL). The combined extracts were washed with water (90 mL), dried ($MgSO_4$), and concentrated under vacuum. The residue was subjected to DFC (5–10% AcOEt–hexane), which gave the pure product as a colorless oil (2.410 g, 97%); R_f = 0.79 (1:1 hexane–AcOEt); $[\alpha]_D^{26}$ +16.7 (*c* 1.05, MeOH); IR: 1714, 1739 cm^{-1}; ^{1}H NMR: 5.88–5.25 (m, 1H), 5.65 (d, *J* = 12 Hz, 1H), 5.48–5.37 (m, 1H), 4.90–4.68 (m, 2H), 4.45–4.15 (m, 1H), 2.88 (s, 3H), 2.39–2.20 (m, 1H), 2.07

(s, 3H), 2.18–1.72 (m, 4H), 1.68–1.48 (m, 1H); ^{13}C NMR: 169.9, 153.8, 134.7, 129.4, 95.8, 75.0, 71.1, 56.2, 37.1, 30.5, 28.9, 24.9, 21.2; MS (EI): 359 (5), 357 (5), 324 (65), 322 (100), 318 (31), 317 (28), 316 (86), 315 (34), 314 (88). Anal. calcd.: C 43.53, H 5.06, N 3.90; found: C 43.56, H 5.13, N 3.92.

(4*R*,6*S*)-4-Acetoxy-6-[*N*-(2,2,2-trichloroethoxy)carbonyl-*N*-methyl]amino-2-cyclohepten-1-one (12)

A solution of H_2SeO_3 (0.942 g, 7.32 mmol) in wet dioxane (35 mL dioxane + 0.4 mL water) was added to a stirred mixture of allylic acetic **11** (2.399 g, 6.70 mmol), Celite (9 g), and dioxane (30 mL). The resulting mixture was refluxed with stirring for 18 h, diluted with EtOH (30 mL), and refluxed for a further 10 min. The black mixture was then filtered through Celite and the solvents were removed under vacuum. The residue was dissolved in 10% MeOH – CH_2Cl_2 and filtered through TLC-grade silica. Solvents were thoroughly removed from the filtrate and the residue was treated with CH_2Cl_2 (45 mL) and PDC (5.64 g, 15 mmol) for 12 h. The reaction mixture was then diluted with Et_2O (100 mL) and filtered through Celite/Florisil. The solvents were removed under vacuum and the residue was subjected to DFC (15–20% AcOEt – hexane), which provided the recovered starting material (0.963 g, 40%) and the product (1.086 g, 44%, 73% yield based on recovered starting material). Properties: colorless oil, R_f = 0.62 (1:1 hexane–AcOEt); $[\alpha]_D^{26}$ +22.5 (*c* 1.52, MeOH); IR: 1739, 1715, 1670 cm^{-1}; ^{1}H NMR: 6.48 (dd, *J* = 12.5 Hz *J* = 4 Hz, 1H), 6.03 (dd, *J* = 12 Hz, *J* = 4 Hz, 1H), 5.55 (br d, *J* = 12 Hz, 1H), 4.65 (s, 2H), 4.65–4.50 (m, 1H), 2.87 (s, 3H), 2.98–2.75 (m, 2H), 2.35–2.08 (m, 2H), 2.05 (s, 3H); ^{13}C NMR: 198.3, 169.5, 153.8, 144.9, 131.2, 95.3, 75.0, 69.2, 48.7, 47.5, 36.7, 29.6, 20.8; MS (CI-NH_3): 374 (10), 372 (10), 282 (34), 280 (54), 279 (30), 198 (44), 140 (100), 107 (50), 61)50). Anal. calcd.: C 41.90, H 4.38, N 3.76; found: C 41.77, H 4.28, N 3.63.

(−)-7β-Acetoxytropinone (13) (ref. 15)

A mixture of the enone **12** (1.030 g, 2.77 mmol) and zinc powder (3.9 g) in 95% EtOH (60 mL) was refluxed for 2 h (TLC showed the absence of the starting material). Most of the solvent was removed under vacuum and the residue was treated with 25% aqueous NH_3 (2 mL), CH_2Cl_2 (80 mL), Celite, and $MgSO_4$. The resulting suspension was filtered, the solvent was evaporated under vacuum, and the residue was subjected to DFC (2% MeOH – CH_2Cl_2). A yellowish oil was obtained (0.382 g, 70%). Kugelrohr distillation (at 120°C/0.5 Torr (lit. (16) bp 110°C/0.03 Torr); 1 Torr = 133.3 Pa) gave the pure product (0.354 g, 65%); R_f = 0.35 (3% MeOH in CH_2Cl_2), R_f = 0.60 (10% MeOH in CH_2Cl_2); $[\alpha]_D^{26}$ −20.2 (*c* 1.10, MeOH), 95% ee *S*-(+)-TFAE; IR: 1713, 1732 cm^{-1}; ^{1}H NMR: 4.88 (dd, *J* = 4, 6.5 Hz, 1H), 3.60 (br s, 1H), 3.46 (br d, 1H), 2.70 (d, *J* = 5 Hz, 1H), 2.64 (d, *J* = 5 Hz, 1H), 2.60 (s, 3H), 2.30 (d, *J* = 16.5 Hz, 1H), 2.18–2.08 (m, 3H), 2.01 (s, 3H); ^{13}C NMR: 206.9, 170.3, 77.6, 65.6, 59.3, 44.2, 42.0, 37.3, 35.8, 20.8.

(+)-7β-Acetoxy-3α-hydroxytropane (13*a*) (ref. 15)

A solution of the ketone **14** (0.298 g, 1.51 mmol) in 95% EtOH (18 mL) with PtO_2 (0.03 g) was hydrogenated in a Paar apparatus at 50 psi (1 psi = 6.9 kPa) and at rt for 12 h. The mixture was filtered through Celite and the solvent was removed under vacuum. A yellowish oil was obtained (0.290 g, 97%). An analytical sample was purified through DFC; R_f = 0.13 (10% MeOH in CH_2Cl_2); $[\alpha]_D^{26}$ +21.3 (*c* 1.05, MeOH); IR: 3162, 1733 cm^{-1}; ^{1}H NMR: 5.63 (dd, *J* = 3, 7.5 Hz, 1H), 4.09 (t, *J* = 5 Hz, 1H), 3.39–3.30 (m, 1H), 3.18 (br s, 1H), 2.90 (br, 1H), 2.74 (dd, *J* = 7.5, *J* = 14 Hz, 1H), 2.53 (s, 3H), 2.26–2.03 (m, 3H), 2.06 (s, 3H), 1.79 (d, *J* = 15 Hz, 1H), 1.58 (d, *J* = 15 Hz, 1H); ^{13}C NMR: 171.0, 79.3, 65.4, 63.5, 59.3, 38.3, 36.0, 35.0, 34.1, 21.2.

(+)-3α,7β-Diacetoxytropane (14*a*) (refs. 16, 17)

A solution of the alcohol **13*a*** (0.127 g, 0.638 mmol) in CH_2Cl_2 (0.5 mL) and Et_3N (0.5 mL) containing DMAP (0.005 g) was treated with Ac_2O (0.097 g, 0.95 mmol) and the reaction mixture was left at rt for 24 h. The reaction mixture was then shaken with aqueous K_2CO_3 for 10 min, diluted with water (10 mL), and extracted with CH_2Cl_2 (3 × 15 mL). The extracts were dried ($MgSO_4$) and evaporated under vacuum. The residue was subjected to DFC (3–6% MeOH – CH_2Cl_2), which gave the pure product as a colorless oil (0.143 g, 93%); R_f = 0.42 (10% MeOH – CH_2Cl_2); $[\alpha]_D^{26}$ +15.5 (*c* 1.04 EtOH) (lit. (16) $[\alpha]_D^{26}$ (enantiomer) −16.6; 96% optical purity); IR: 1734 cm^{-1}; ^{1}H NMR: 5.45 (dd, *J* = 3, 7.5 Hz, 1H), 5.04 (t, *J* = 5 Hz, 1H), 3.43–3.34 (m, 1H), 3.22 (s br, 1H), 2.57 (dd, *J* = 7.5, 14 Hz, 1H), 2.55 (s, 3H), 2.32–2.05 (m, 3H), 2.09 (s, 3H), 2.08 (s, 3H), 1.83 (d, *J* = 15.5 Hz, 1H), 1.61 (d, *J* = 15.5 Hz, 1H); ^{13}C NMR: 170.4, 169.5, 78.5, 66.4, 64.6, 58.7, 38.0, 35.7, 32.2, 30.6, 21.0, 20.8.

(−)-7β-Acetoxy-3α-tigloyloxytropane (14*b*) (refs. 18, 19)

The alcohol **13*a*** (0.100 g, 0.502 mmol) was dissolved in dry pyridine (1.2 mL) and dry benzene (0.6 mL), and treated with DMAP (0.026 g) and tigloic anhydride (Tg_2O; 0.2 g, 1.1 mmol) for 3.5 days. The mixture was then diluted with $CHCl_3$ shaken with aqueous K_2CO_3 solution, and extracted with $CHCl_3$ (3 × 20 mL). The extracts were washed with water, dried ($MgSO_4$), and the solvent was removed under vacuum. The residue was subjected to DFC (1% MeOH – CH_2Cl_2 eluted unreacted anhydride, 3% eluted with product), which gave the pure product as a colorless oil (0.130 g, 92%); R_f = 0.47 (10% MeOH – CH_2Cl_2); $[\alpha]_D^{25}$ −14.6 (*c* 2.03, EtOH) (lit. (18) $[\alpha]^{20}$D −11.5 (*c* 12.4, EtOH); −9.0 (*c* 1.55, $CHCl_3$) (lit. (19) $[\alpha]_D^{19}$ −13 ($CHCl_3$); IR: 1734, 1707, 1650 cm^{-1}; ^{1}H NMR: 6.91 (tt, *J* = 1, 7 Hz, 1H), 5.50 (dd, *J* = 3, 7.5 Hz, 1H), 5.23 (t, *J* = 5 Hz, 1H), 3.45–3.36 (m, 1H), 3.26 (s br, 1H), 2.63 (dd, *J* = 14, *J* = 7.5 Hz, 1H), 2.57 (s, 3H), 2.36–2.22 (m, 2H), 2.20–2.10 (m, 1H), 2.08 (s, 3H), 1.89 (s, 3H), 1.84 (dd, *J* = 7 Hz, *J* = 1 Hz, 3H), 1.65 (br d, *J* = 15 Hz, 1H); ^{13}C NMR: 170.4, 166.5, 137.2, 128.3, 78.5, 66.2, 64.5, 58.8, 38.1, 36.1, 32.4, 30.9, 20.8, 14.1, 11.6.

5-(*N*-Benzyloxycarbonyl-*N*-methyl)amino-2-cyclohepten-1-one (4*b*)

Benzyl chloroformate (0.17 mL, 0.204 g, 1.20 mmol) was added to a solution of tropinone lithium enolate (1 mmol) at −78°C and the mixture was stirred for 30 min. After quenching with 40% K_2CO_3 (4 mL) and warming to rt, the reaction mixture was extracted with ether (3 × 10 mL). The extracts were washed with 5% H_2SO_4 (to remove the chiral amine, 98% recovery) and brine, and were dried ($MgSO_4$). The solvent was removed under vacuum to give the crude product, which was subjected to chromatographic purification by DFC

(5–50% hexane – AcOEt, R_f = 0.43 in 1:1 hexane–AcOEt). The product was obtained as a colorless oil (0.232 g, 85%); $[\alpha]_D^{24}$ +70.0 (*c* 1.04, MeOH); IR: 1697, 1666 cm^{-1}; ^1H NMR: 7.35–7.20 (m, 5H), 6.64 (ddd, *J* = 12 Hz, *J* = 6 Hz, *J* = 5 Hz, 1H), 6.05 (d, *J* = 12 Hz, 1H), 5.13 (s, 2H), 4.50 (br, 1H), 2.90–2.80 (m, 2H), 2.85 (s, 3H), 2.65–2.40 (m, 2H), 2.12–1.88 (m, 2H); ^{13}C NMR: 200.2, 155.5, 146.2, 136.5, 132.3, 128.3, 127.8, 127.6, 67.0, 51.2, 48.0, 30.8, 29.2, 27.6; MS (EI): 273 (1), 167 (11), 138 (23), 110 (20), 107 (11), 92 (21), 91 (100), 65 (17). Anal. calcd. for $C_{16}H_{19}NO_3$: C 70.31, H 7.01, N 5.12; found: C 70.16, H 7.83, N 5.07.

(−)-6-(*N*-Benzoyloxycarbonyl-*N*-methyl)amino-2,3-epoxycycloheptan-1-one (15)

Compound **4***b* (1.215 g, 4.45 mmol) was dissolved in a mixture of THF (20 mL) and water (5 mL), and the solution was cooled to ca. −10°C (ice–acetone bath). A hydrogen peroxide solution (30%, 3 mL, 26 mmol), followed by a solution of KOH (0.05 g, 0.9 mmol) in water (2 mL), was added to the stirred mixture. After min the reaction mixture was warmed to rt and was further stirred for 15 min. TLC showed absence of the starting material. The reaction mixture was diluted with water (80 mL) and was extracted with $CHCl_3$ (4 × 40 mL). The extracts were dried ($MgSO_4$), the solvent removed under vacuum, and the residue was subjected to DFC. a mixture of two isomeric epoxides (3:1) was obtained (1.20 g, 93%) as a colorless oil (major isomer R_f = 0.53, minor isomer R_f = 0.44 in 1:1 hexane–AcOEt); $[\alpha]_D^{24}$ −48 (*c* 1.1, MeOH), major isomer; IR: 1703 cm^{-1}; ^1H NMR: 7.43–7.30 (m, 5H), 5.16 (s, 2H), 4.05–3.75 (m, br, 1H), 3.46–3.42 (m, 2H), 3.20 (t, *J* = 12 Hz, 1H), 2.85 (s, 3H), 2.44–2.40 (m, 1H), 2.34 (d, *J* = 10 Hz, 1H), 2.28–2.22 (m, 1H), 2.10–1.90 (m, 1H), 1.70–1.60 (m, 1H); ^{13}C NMR: 206.7, 155.0, 136.2, 128.0, 127.6, 127.4, 66.8, 58.8, 55.3, 51.8, 44.2, 28.0, 27.0, 24.3; MS (EI): 289 (4), 146 (30), 111 (9), 92 (100), 83 (12), 65 (11), 57 (11), 55 (7); HRMS: 289.132 (M^+); calcd. for $C_{16}H_{19}NO_4$: 289.131.

(−)-5-(*N*-Benzyloxycarbonyl-*N*-methyl)amino-2-cyclohepten-1-ol (16)

The epoxide **15** (1.00 g, 3.46 mmol) was dissolved in dry MeOH and a solution of hydrazine (0.34 g, 19.6 mmol in 5 mL of MeOH dried with 3Å molecular sieves) was added at rt with stirring. After addition of glacial AcOH (2 drops), stirring was continued for another 2 h (N_2 evolved and the reaction mixture warmed up slightly). The resulting solution was then diluted with $CHCl_3$ (25 mL) and was washed with 5% H_2SO_4. The acid washings were extracted with $CHCl_3$ (3 × 20 mL). The combined extracts were dried ($MgSO_4$), filtered through a small pad of TLC-grade silica, and the solvent was removed under vacuum. The resulting residue was subjected to DFC (35–50% AcOEt in hexane). A mixture of two isomers was obtained (0.476 g, 50%). Major isomer R_f = 0.32, minor isomer R_f = 0.27 (1:1 hexane–AcOEt); $[\alpha]_D^{24}$ −66 (*c* 1.1, MeOH), major isomer; IR: 3415, 1695, 1677 cm^{-1}; ^1H NMR: 7.40–7.25 (m, 5H), 5.85–5.10 (m, 2H), 5.13 (s, 2H), 4.50–4.10 (m, 1H), 2.80 (s, 3H), 2.52–2.45 (m, 2H), 2.35 (d, *J* = 10 Hz, 1H), 2.20–2.08 (m, 1H), 2.07–1.70 (m, 4H); ^{13}C NMR: 155.7, 135.0, 128.3, 127.8, 127.7, 127.6, 124.9, 71.5, 68.5, 66.9, 54.2, 53.7, 35.4, 32.3; MS ($CI0NH_3$): 276 (20), 274 (11), 259 (18), 258 (100), 168 (17), 166 (27), 108 (28), 91 (65); HRMS: 275.152 (M^+); calcd. for $C_{16}H_{21}NO_3$: 275.152.

(5*R*)-5-(*N*-Benzyloxycarbonyl-*N*-methyl)amino-2-cyclohepten-1-one (17) (ref. 8)

A solution of the alcohol **16** (0.448 g, 1.63 mmol) in CH_2Cl_2 (25 mL) was treated with PDC (0.94 g, 2.50 mmol) for 12 h at rt. The reaction mixture was diluted with Et_2O (75 mL) and filtered through a pad of Celite and TLC-grade silica (washed with 1:1 hexane–AcOEt). After removing the solvents the crude product was obtained as a colorless oil (0.400 g, 90%); R_f = 0.35 (1:1 hexane–AcOEt); $[\alpha]_D^{25}$ +93 (*c* 1.0, MeOH); IR: 1693, 1679 cm^{-1}; ^1H NMR: 7.42–7.25 (m, 5H), 6.57 (ddd, *J* = 12 Hz, *J* = 6.5 Hz, *J* = 5 Hz, 1H), 6.07 (d, *J* = 12 Hz, 1H), 5.13 (s, 2H), 4.50 (br, 1H), 2.89 (s, 3H), 2.80–2.53 (m, 4H), 2.09–1.85 (m, 2H); ^{13}C NMR: 201.7, 155.1, 142.2, 136.2, 132.1, 128.0, 127.5, 127.3, 66.6, 54.2, 39.8, 33.3, 29.0, 25.0.

(+)-Physoperuvine (19) (refs. 4*c*, 4*d*, 20)

A solution of the enone **17** (0.340 g, 1.24 mmol) in MeOH (12 mL) was hydrogenated in the presence of 30% Pd/C (0.026 g) over 2 h at 30 psi in a Paar apparatus. The mixture was filtered through Celite and the solvent was removed under vacuum to provide an off-white solid (0.163 g, 92%). Analytically pure material was obtained through Kugelrohr sublimation (at 100–120°C/0.5 Torr). Properties: white solid, R_f = 0.66 (5:4:1 $CHCl_3$–MeOH – 25% aqueous NH_3); mp (racemic) 72–73°C (acetone) (lit. (21) mp 75°C); $[\alpha]_D^{25}$ +17.9 (*c* 1.30, H_2O), 95% ee with (*S*)-(+)-TFAE (lit. (21) $[\alpha]_D$ +1.2 (*c* 1.3, H_2O); mp (opt. active) 48–50°C (sublimed) (lit. (20) mp 47°48°C); IR: 3099 (OH) cm^{-1}; ^1H NMR: 3.13 (br s, 1H), 2.38 (s, 3H), 2.15–1.87 (m, 4H), 1.82–1.52 (m, 5H), 1.34–1.20 (m, 1H).

Synthesis of sugar-modified 2,6-diaminopurine and guanine nucleosides from guanosine via transformations of 2-aminoadenosine and enzymatic deamination with adenosine deaminase[1]

Morris J. Robins, Ruiming Zou, Fritz Hansske, and Stanislaw F. Wnuk

Abstract: Treatment of 2,6-diaminopurine riboside (2-aminoadenosine) with α-acetoxyisobutyryl bromide in acetonitrile gave mixtures of the *trans* 2′,3′-bromohydrin acetates **2**. Treatment of **2** with zinc–copper couple effected reductive elimination, and deprotection gave 2,6-diamino-9-(2,3-dideoxy-β-D-*erythro*-pent-2-enofuranosyl)purine (**3***a*). Treatment of **2** with Dowex 1 × 2 (OH^-) resin in methanol gave the 2′,3′-anhydro derivative **4**. Stannyl radical-mediated hydrogenolysis of **2** and deprotection gave the 2′-deoxy **6***a* and 3′-deoxy **7***a* nucleosides. Treatment of the 3′,5′-*O*-(tetraisopropyldisiloxanyl) derivative (**5***a*) with trifluoromethanesulfonyl chloride – 4-(dimethylamino)pyridine gave 2′-triflate **5***c*. Displacement with lithium azide – dimethylformamide and deprotection gave the arabino 2′-azido derivative **8***a*, which was reduced to give 2,6-diamino-9-(2-amino-2-deoxy-β-D-arabinofuranosyl)purine (**8***b*). Sugar-modified 2,6-diaminopurine nucleosides were treated with adenosine deaminase to give the corresponding guanine analogues.

Key words: adenosine deaminase, 2,6-diaminopurine nucleosides, deoxygenation, guanine nucleosides, nucleosides.

Résumé : Le traitement du riboside de 2,6-diaminopurine (2-aminoadénosine) par du bromure d'α-acétoxyisobutyryle, dans l'acétonitrile, conduit à un mélange des acétates de la *trans*-2′,3′-bromohydrine (**2**). Le traitement de **2** par le couple zinc–cuivre provoque une élimination réductrice et une déprotection subséquente conduit à la 2,6-diamino-9-(2,3-didésoxy-β-D-*érythro*-pent-2-énofuranosyl)purine (**3***a*). Le traitement de **2** par de la résine Dowex 1 × 2 (OH^-) dans le méthanol conduit au dérivé 2′,3′-anhydro (**4**). Une hydrogénolyse du composé **2** catalysée par le radical stannyle, suivie d'une déprotection, fournit les nucléosides 2′-désoxy (**6***a*) et 3′-désoxy (**7***a*). Le traitement du dérivé 3′,5′-*O*-(tétraisopropyldisiloxanyl) (**5***a*) par du chlorure de trifluorométhanesulfonyle dans la 4-(diméthylamino)pyridine conduit au 2′-triflate (**5***c*). Un déplacement par de l'azoture de lithium dans le diméthylformamide, suivi d'une déprotection, conduit au dérivé 2′-azido-arabino (**8***a*) qui, par réduction, conduit à la 2,6-diamino-9-(2-amino-2-désoxy-β-D-arabinofuranosyl)purine (**8***b*). Les nucléosides de la 2,6-diaminopurine comportant des sucres modifiés ont été traités par de la désaminase d'adénosine pour conduire aux analogues guanines correspondantes.

Mots clés : désaminase d'adénosine, nucléosides de la 2,6-diaminopurine, désoxygénation, nucléosides de la guanine, nucléosides.

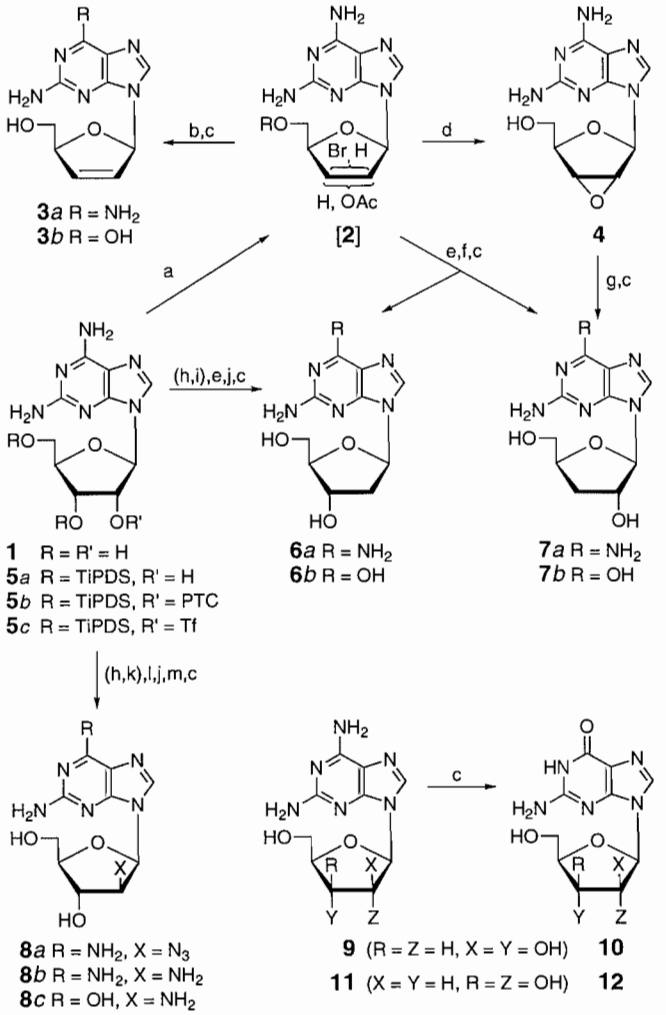
Introduction

Transformations of adenosine to give sugar-modified adenine nucleosides are well known (2, 3). However, analogous transformations of guanosine are plagued by experimental problems including poor solubility, instability, and formation of gels (4, 5). Vorbrüggen and Krolikiewicz reported an efficient transformation of the lactam functionality of guanosine into the cyclic amidine of 2,6-diamino-9-(β-D-ribofuranosyl)purine (**1**, 2,6-diaminopurine riboside, DAPR) (6), and DAPR (2-aminoadenosine) is a substrate (7) of calf intestinal adenosine deaminase (ADA; adenosine aminohydrolase, EC 3.5.4.4). Thus, conversion of the troublesome guanosine system into a chemical analogue of adenosine and subsequent enzymatic conversion of modified 2,6-diaminopurine nucleosides to their guanine counterparts allows convenient use of DAPR as a "masked guanosine" precursor for modifications of the sugar moiety (8). ADA also effects hydrolytic replacement of chloro and methoxy groups from 2-amino-6-chloropurine (9*a*) and 2-amino-6-methoxypurine (9*b*) nucleosides to give the corresponding guanine derivatives. The scope of such chemical/enzymatic syntheses is not limited to the specificity of mammalian ADA (10*a*) since this enzyme activity from *Aspergillus oryzae* has less stringent substrate requirements at C5′ (10*b*) and adenylic acid deaminase has broad tolerance for conversions to 6-oxopurine nucleosides (10*c*).



ADA is an ubiquitous human enzyme and sugar-modified 2,6-diaminopurine nucleosides are prodrugs of sugar-modified guanine nucleosides (11–13). Thus, 2,6-diamino-9-(2,3-dideoxy-β-D-*glycero*-pentofuranosyl)purine (2,6-diaminopurine 2′,3′-dideoxyriboside, ddDAPR) is an effective inhibitor of hepatitis B virus (11) and also has anti-HIV activity (12). We now report sugar modifications with DAPR and deaminations with ADA to give their guanine counterparts.

Results and discussion

DAPR (**1**, Scheme 1) was prepared from guanosine by modification (14) of the known method (6). Treatment of **1** with α-acetoxyisobutyryl bromide gave a mixture of *trans* bromo acetates **2** (R = H or 2,5,5-trimethyldioxolan-4-on-2-yl) (3, 15). Treatment of **2** with Dowex 1 × 2 (OH^-) resin in MeOH gave the 2′,3′-anhydro nucleoside **4** (81% from **1**). Lithium triethylborohydride effected selective cleavage (3, 16) of the epoxide O—C3′ bond of **4** to give 3′-deoxyDAPR (**7***a*, 85%). Treatment of **2** with tributyltin hydride and deprotection (NH_3–MeOH) gave 2′-deoxyDAPR (**6***a*, 16%) and 3′-deoxyDAPR (**7***a*, 59%), which were separated by ion-exchange chromatography with Dowex 1 × 2 (OH^-).

Treatment of **2** with zinc–copper couple in *N,N*-dimethylformamide (DMF) effected reductive elimination of bromide and acetate to give 2′,3′-didehydro-2′,3′-dideoxyDAPR (**3***a*), which was hydrogenated to give ddDAPR (3, 15*b*). A sample of DAPR containing 2′*R*[^{2}H] (~20% 2′[^{2}H]-**1**, obtained as the minor product from oxidation of **5***a* and reduction ($NaBD_4$) of the 2′-ketone (17)) was subjected to the sequence **1** → **2** → **3***a*. The product (containing 2′[^{2}H]-**3***a*) was analyzed by ^{1}H (3) and ^{13}C (Table 1) NMR. The higher field ^{1}H NMR signal at δ 6.10 (H2′) was diminished by ~20% relative to the signal at δ 6.42 (H3′) in agreement with the inverted signal positions observed with 3′[^{2}H]-adenosine as starting material (3, 15*a*). Also, the higher field vinyl ^{13}C signal was assigned to C2′ (δ 125.9) on the basis of selective ^{13}C–^{1}H decoupling and its reduced intensity relative to the signal at δ 134.5 (C3′).

Scheme 1.

(a) $(CH_3)_2C(OAc)COBr/CH_3CN/H_2O$; (b) Zn-Cu/DMF; (c) ADA/buffer; (d) Dowex 1 × 2 (OH^-)/MeOH; (e) Bu_3SnH/AIBN/toluene/Δ; (f) NH_3/MeOH; (g) $LiEt_3BH$/THF/DMSO; (h) $TiPDSCl_2$/pyridine; (i) PTCCl/DMAP/CH_3CN; (j) TBAF/THF; (k) TfCl/DMAP/CH_2Cl_2; (l) LiN_3/DMF; (m) N_2H_4/Raney Ni/EtOH.

Treatment of **1** with 1,3-dichloro-1,1,3,3-tetraisopropyldisiloxane ($TiPDSCl_2$) gave **5***a*, which was acylated with phenoxythiocarbonyl (PTC) chloride (18). Thionocarbonate **5***b* was reduced (tributyltin hydride) and deprotected (tetrabutylammonium fluoride, TBAF) to give 2′-deoxyDAPR (**6***a*, 41% from **1**). Triflation of **5***a* gave **5***c*, which was treated with lithium azide and deprotected (TBAF) to give the arabino 2′-azido analogue **8***a* (59%). Hydrogenolysis (Raney nickel) of **8***a* gave 2,6-diamino-9-(2-amino-2-deoxy-β-D-arabinofuranosyl)purine (**8***b*, 85%). Triflation of an analogously protected guanosine derivative had given a 2′,6-bis-*O*-(trifluoromethanesulfonyl) by-product (19) and other 6-*O*-triflyl derivatives of 2-deoxyguanosine have been reported (13*b*).

Enzymatic conversion of **3***a*, **6***a*, **7***a*, and **8***b* to their guanine counterparts **3***b*, **6***b*, **7***b*, and **8***c*, respectively, was effected with ADA in aqueous sodium phosphate buffer. Isolated

yields of the guanine nucleosides were >80%, except for the 2′,3′-unsaturated nucleoside **3***b*. Complete deamination of **3***a* (a potent inhibitor of ADA (12)) required 10 days and the somewhat unstable **3***b* partially decomposed during the extended reaction period, which makes this route to **3***b* less appealing than direct deoxygenation of guanosine (3, 20). The arabino **9** and xylo **11** epimers of DAPR were subjected to deamination to give AraG (**10**) and XyloG (**12**), respectively, in high yields. An oxidation–reduction sequence at C2′ of protected guanosine (17) had given 9-(β-D-arabinofuranosyl)guanine (**10**). Coupling of 2-amino-6-chloropurine (followed by 7/9 isomer separation and base conversion to guanine (21*a*)) or 2-*N*-acetylguanine (followed by 7/9 isomer separation (21*b*)) (8) with xylofuranose derivatives had been employed to prepare 9-(β-D-xylofuranosyl)guanine (**12**).

In summary, this indirect approach (conversion of guanosine to DAPR, modification of the sugar, and enzymatic deamination to give the guanine nucleoside) is more experimentally convenient in many instances than direct sugar transformations with guanosine. Separation of isomers and purification of intermediates can be achieved readily since 2,6-diaminopurine nucleosides are amenable to ion-exchange chromatography with Dowex 1 × 2 (OH^-) resin and usually crystallize without difficulty.

Experimental

Uncorrected melting points were obtained with a hotstage apparatus. UV spectra were determined with solutions in MeOH unless otherwise noted. ^1H (200 or 400 MHz) and ^{13}C (50 or 100 MHz, Table 1) NMR spectra (Me_4Si–Me_2SO-*d6*) were recorded with Bruker spectrometers. Mass spectra (EI MS, CI, FAB) were determined at 20 or 70 eV. Solvents were purified, dried (CaH_2 or $LiAlH_4$), and distilled before use. Pyridine was dried by refluxing with and distillation from CaH_2. Reagent grade chemicals were used without further purification. TLC was performed with silica gel 60 F_{254} sheets, and silica gel (200–425 mesh) was used for column chromatography. Elemental analyses were determined by the Microanalytical Laboratory at the University of Alberta. Calf intestinal adenosine deaminase (ADA, 2.7 units/mg protein) was obtained from Sigma.

2,6-Diamino-9-(2,3-anhydro-β-D-ribofuranosyl)purine 4

Amorphous solid **2** (prepared (3, 15*b*) from **1** (2 mmol)) was dissolved in a minimal volume of MeOH and the solution was applied to a column of Dowex 1 × 2 (OH^-) resin previously soaked in and washed with MeOH. The column was allowed to stand for 1 h at ambient temperature and the product was eluted with MeOH (crystallization occurred in early fraction-collecting tubes). Evaporation of appropriate fractions and recrystallization (MeOH) gave **4** (427 mg, 81% from **1**); mp ~180°C (dec.); UV max: 255, 280 nm (ε 9900, 10 300); ^1H NMR δ: 3.55 (m, *J* = 11.5, 5.5, 5.0 Hz, 2H), 4.15 (t, *J* = 5.0 Hz, 1H), 4.17 (d, *J* = 2.5 Hz, 1H), 4.37 (d, *J* = 2.5 Hz, 1H), 5.09 (t, *J* = 5.0 Hz, 1H), 5.85 (s, 2H), 6.01 (s, 1H), 6.77 (s, 2H), 7.92 (s, 1H); MS *m/z*: 264.0968 (23, M^+ = 264.0971). Anal. calcd. for $C_{10}H_{12}N_6O_3$: C 45.45, H 4.58, N 31.80; found: C 45.35, H 4.75, N 31.48.

2,6-Diamino-9-(2-deoxy-β-D-*erythro*-pentofuranosyl)-purine 6*a* and 2,6-diamino-9-(3-deoxy-β-D-*erythro*-pentofuranosyl)purine 7*a*

Amorphous solid **2** (prepared (3, 15*b*) from **1** (2 mmol)) was dissolved in deoxygenated toluene (80 mL), AIBN (64 mg, 0.4 mmol) and Bu_3SnH (2.2 mL, 2.38 g, 8.2 mmol) were added, and the solution was refluxed for 1 h. Volatiles were evaporated, the residue was dissolved in CH_3CN–H_2O (100 mL, 1:1), and this solution was washed with pentane (100 mL) and then evaporated. The residue was stirred with NH_3–MeOH (50 mL, saturated at −10°C) at ambient temperature for 4 h and volatiles were evaporated. The residue was chromatographed (Dowex 1 × 2 (OH^-), H_2O) and recrystallized (MeOH) to give **6***a* (85 mg, 16% from **1**); mp 154–155°C (lit. (22) mp 147–149°C); UV max: 256, 280 nm (ε 10 100, 10 600); ^1H NMR δ: 2.20 (m, *J* = 13.0, 6.0, 3.0 Hz, 1H); 2.62 (m, *J* = 13.0, 8.0, 5.5

Hz, 1H), 3.54 (m, J = 12.0, 6.0, 4.0 Hz, 1H), 3.60 (m, J = 12.0, 5.0 Hz, 1H), 3.86 (m, J = 2.0 Hz, 1H), 4.37 (m, J = 4.0 Hz, 1H), 5.26 (d, J = 4.0 Hz, 1H), 5.29 (dd, J = 6.0, 5.0 Hz, 1H), 5.76 (s, 2H), 6.19 (dd, J = 8.0, 6.0 Hz, 1H), 6.76 (s, 2H), 7.92 (s, 1H); MS *m/z*: 266.1128 (12, M^+ = 266.1127). Anal. calcd. for $C_{10}H_{14}N_6O_3$: C 45.11, H 5.30, N 31.56; found: C 45.01, H 5.41, N 31.31.

Further elution of the ion-exchange column (30% MeOH–H_2O) and recrystallization of the residue (MeOH) gave **7***a* (316 mg, 59% from **1**); mp 198–199°C; MS *m/z*: 266.1129 (11, M^+ = 266.1127); other data identical to those with **7***a* prepared by the following reduction of **4**.

2,6-Diamino-9-(3-deoxy-β-D-*erythro*-pentofuranosyl)-purine 7*a*

$LiEt_3BH$–THF (1 M; 25 mL, 25 mmol) was added dropwise to a stirred solution of **4** (528 mg, 2 mmol) in DMSO (40 mL) at 10°C under N_2. The cooling bath was removed after 1 h and the reaction mixture was stirred at ambient temperature for 3 days. H_2O (60 mL) was added carefully and the solution was purged vigorously with N_2 to remove *pyrophoric* triethylborane. Volatiles were evaporated in vacuo (~0.5 Torr; 1 Torr = 133.3 Pa) at <60°C and the residue was chromatographed (Dowex 1 × 2 (OH^-), H_2O followed by 30% MeOH–H_2O) and recrystallized (MeOH) to give **7***a* (453 mg, 85%), mp 198–199°C, mp 122–123°C (from H_2O) (lit. (23) mp 120–121°C (from H_2O)); UV max: 255, 280 nm (ε 10 200, 10 700); ^{1}H NMR δ: 1.92 (m, J = 13.0, 6.5, 3.5 Hz, 1H), 2.24 (m, J = 13.0, 8.0, 6.0 Hz, 1H), 3.50 (m, J = 11.5, 5.5, 4.0 Hz, 1H), 3.65 (m, J = 11.5, 5.5, 3.5 Hz, 1H), 4.30 (m, 1H), 4.51 (m, J = 4.5, 2.5 Hz, 1H), 5.18 (t, J = 5.5 Hz, 1H), 5.56 (d, J = 4.5 Hz, 1H), 5.70 (d, J = 2.5 Hz, 1H), 5.78 (s, 2H), 6.75 (s, 2H), 7.92 (s, 1H); MS *m/z*: 266.1124 (16, M^+ = 266.1127). Anal. calcd. for $C_{10}H_{14}N_6O_3$: C 45.11, H 5.30, N 31.56; found: C 44.90, H5.31, N 31.52.

2,6-Diamino-9-(3,5-*O*-(1,1,3,3-tetraisopropyldisilox-1,3-diyl)-β-D-ribofuranosyl)purine 5*a*

$TiPDSCl_2$ (4 mL, 3.88 g, 12.3 mmol) was added to a stirred suspension of **1** (2.82 g, 10 mmol) in dried pyridine (50 mL) at ambient temperature. EtOH (5 mL) was added after 6 h and volatiles were evaporated. Toluene was added and evaporated several times and the residue was partitioned ($CHCl_3$–H_2O, 1:1; 600 mL). The organic layer was concentrated and chromatographed (silica gel, 10% MeOH–$CHCl_3$) to give **5***a* (5.12 g, 97%) as an amorphous solid with data as reported (24); ^{1}H NMR δ: 1.94–2.14 (m, 28H), 3.90–4.14 (m, 3H), 4.31 (m, J = 5.0, 1.5 Hz, 1H), 4.45 (dd, J = 8.0, 5.0 Hz, 1H), 5.61 (d, J = 5.0 Hz, 1H), 5.72 (d, J = 1.5 Hz, 1H), 5.79 (s, 2H), 6.79 (s, 2H), 7.78 (s, 1H); MS *m/z*: 524.2602 (8, M^+ ($C_{22}H_{40}N_6O_5Si_2$) = 524.2599).

2,6-Diamino-9-(2-deoxy-β-D-*erythro*-pentofuranosyl)-purine 6*a*

PTCCl (0.40 mL, 380 mg, 2.2 mmol) was added to a suspension of **5**a (obtained from **1** (2 mmol)) in dried CH_3CN (20 mL) containing DMAP (489 mg, 4 mmol) at ambient temperature. Stirring was continued for 1 h and the resulting solution was diluted (EtOAc, 100 mL), washed (AcOH–H_2O, $NaHCO_3$–H_2O), dried (Na_2SO_4), evaporated, and coevaporated successively with toluene, $CHCl_3$, and Et_2O. The resulting amorphous **5***b* was dried in vacuo at ambient temperature for 2 h and dissolved in toluene (20 mL). AIBN (66 mg, 0.4 mmol) and Bu_3SnH (0.85 mL, 920 mg, 3.2 mmol) were added and the solution was deoxygenated (N_2, 30 min) and heated at 80°C overnight. TBAF–THF (1 M; 4 mL, 4 mmol) was added and heating was continued for 3 h. Volatiles were evaporated and the residue was partitioned (H_2O–Et_2O, 1:1; 200 mL). The aqueous phase was concentrated and applied to a column of Dowex 1 × 2 (OH^-). Elution (H_2O) and recrystallization (MeOH) of the residue gave **6***a* (216 mg, 41% from **1**); mp 154–155°C; MS *m/z*: 266.1124 (15, M^+ = 266.1127) with data identical to those with **6***a* from debromination of **2**.

2,6-Diamino-9-(2-azido-2-deoxy-β-D-arabinofuranosyl)-purine 8*a*

CF_3SO_2Cl (0.15 mL, 237 mg, 1.4 mmol) was added to a cold (~0°C) stirred suspension of **5***a* (525 mg, 1 mmol) and DMAP (367 mg, 3 mmol) in dried CH_2Cl_2 (10 mL). $CHCl_3$ (50 mL) was added after 30 min and the solution was washed (2% HOAc–H_2O, brine), dried (Na_2SO_4), and evaporated. The residue was successively coevaporated with toluene, $CHCl_3$, and Et_2O to give amorphous **5***c*, which was dried in vacuo at ambient temperature for 4 h. A solution of this **5***c* and dried LiN_3 (196 mg, 4 mmol) in dried DMF (10 mL) was stirred at ambient temperature overnight and volatiles were evaporated. The residue was dissolved (EtOAc, 50 mL) and the solution was washed (brine) and evaporated. The residue was dissolved (THF, 10 mL) and stirred with TBAF–THF (1 M; 3 mL, 3 mmol) at ambient temperature overnight. Evaporation of volatiles and chromatography of the residue (Dowex 1 × 2 (OH^-), H_2O and then 20% MeOH–H_2O) gave crystalline **8***a* (181 mg, 59%); mp ~262°C (dec.); UV max: 255, 280 nm (ε 10 300, 10 800); ^{1}H NMR δ: 3.64 (m, J = 12.0, 5.5, 4.5 Hz, 1H), 3.72 (m, J = 12.0, 5.5, 3.0 Hz, 1H), 3.76 (m, J = 7.5 Hz, 1H), 4.35 (m, J = 7.5, 5.5 Hz, 1H), 4.49 (dd, J = 7.5, 6.5 Hz, 1H), 5.20 (t, J = 5.5 Hz, 1H), 5.83 (s, 2H), 5.99 (d, J = 5.5 Hz, 1H), 6.19 (d, J = 6.5 Hz, 1H), 6.78 (s, 2H), 7.90 (s, 1H); MS *m/z*: 307.1141 (13, M^+ = 307.1141). Anal. calcd. for $C_{10}H_{13}N_9O_3$: C 39.09, H 4.25, N 41.03; found: C 38.85, H 4.35, N 40.63.

2,6-Diamino-9-(2-amino-2-deoxy-β-D-arabinofuranosyl)-purine 8*b*

Hydrazine (95%, 1 mL) was added to a stirred suspension of **8***a* (307 mg, 1 mmol) in EtOH–H_2O (3:1, 20 mL) containing Raney Ni (100 mg) at ambient temperature. The reaction mixture was filtered after 6 h and the solid was washed (EtOH–H_2O, 8:2). The filtrate and washings were combined, concentrated, and chromatographed (Dowex 1 × 2 (OH^-), H_2O) to give crystalline **8***b* (238 mg, 85%); mp 289–292°C; UV (H_2O) max: 255, 280 nm (ε 9 800, 10 300); ^{1}H NMR δ: 1.20–1.80 (br s, 2H), 3.40 (t, J = 6.5 Hz, 1H), 3.58 (dd, J = 12.5, 4.5 Hz, 1H), 3.68 (dd, J = 12.5, 2.5 Hz, 1H), 3.70 (m, 1H), 4.01 (m, 1H), 4.60–5.60 (br s, 1H), 5.39 (d, J = 4.5 Hz, 1H), 5.76 (s, 2H), 6.02 (d, J = 6.5 Hz, 1H), 6.68 (s, 2H), 7.88 (s, 1H); MS *m/z*: 281.1232 (10, M^+ = 281.1236). Anal. calcd. for $C_{10}H_{15}N_7O_3$: C 42.70, H 5.38, N 34.86; found: C 42.56, H 5.38, N 34.87.

2′-Deoxyguanosine 6*b* (deamination procedure)

ADA (10 mg; Sigma, 2.7 units/mg protein) was added to a solution of **6***a* (266 mg, 1 mmol) in DMSO (5 mL) and aque-

ous sodium phosphate buffer (0.1 M, 25 mL; pH 7.4) and stirring was continued at ambient temperature overnight (reaction progress was monitored by thin-layer electrophoresis). Volatiles were evaporated in vacuo and the residue was applied to a column of Dowex 1 × 2 (OH^-), which was washed successively with H_2O, 80% MeOH–H_2O, and H_2O. The product was then eluted (30 mM aqueous $Et_3NH{\cdot}HCO_3$) and fractions were evaporated, coevaporated several times with H_2O, and recrystallized (H_2O) to give **6***b* (250 mg, 91%); mp ~250°C (dec.) (lit. (18) mp 251–252°C); UV (H_2O) max: 252 nm (ε 13 400); ^1H NMR δ: 2.20 (m, J = 13.0, 6.0, 3.0 Hz, 1H), 2.50 (m, J = 13.0, 7.5, 5.5 Hz, 1H), 3.52 (m, J = 12.0, 5.5, 4.5, Hz, 2H), 3.80 (m, 1H), 4.34 (m, 1H), 4.95 (t, J = 5.5 Hz, 1H), 5.26 (d, J = 4.0 Hz, 1H), 6.12 (dd, J = 7.5, 6.0 Hz, 1H), 6.46 (s, 2H), 7.92 (s, 1H), 10.64 (s, 1H); MS (FAB) *m/z*: 268 (6, MH^+). Anal. calcd. for $C_{10}H_{13}N_5O_4{\cdot}0.5H_2O$: C 43.48, H 5.11, N 25.35; found: C 43.42, H 4.90, N 25.62.

3′-Deoxyguanosine 7*b*

Treatment of **7***a* (266 mg, 1 mmol) with ADA (as described for **6***b*) and recrystallization (H_2O) gave **7***b* (239 mg, 87%) as a hemihydrate; mp ~250°C (dec.) (lit. (25) mp >300°C (dec.)); UV (H_2O) max: 252 nm (ε 13 600); ^1H NMR δ: 1.89 (m, J = 13.5, 6.5, 3.0 Hz, 1H), 2.20 (m, J = 13.5, 9.0, 5.5 Hz, 1H), 3.51 (dd, J = 12.0, 4.5 Hz, 1H), 3.64 (dd, J = 12.0, 3.5 Hz, 1H), 4.31 (m, 1H), 4.46 (m, 1H), 4.60–5.90 (br s, 2H), 5.70 (d, J = 2.0 Hz, 1H), 6.49 (s, 2H), 7.94 (s, 1H), 10.65 (s, 1H); MS (FAB) *m/z*: 268 (6, MH^+). Anal. calcd. for $C_{10}H_{13}N_5O_4{\cdot}0.5H_2O$: C 43.48, H 5.11, N 25.35; found: C 43.38, H 4.89, N 25.39.

9-(2,3-Dideoxy-β-D-*glycero*-pent-2-enofuranosyl)guanine 3*b*

Treatment of **3***a* (248 mg, 1 mmol; prepared as described (3, 15b)) with ADA (reaction mixture stirred at ambient temperature for 10 days with additions of ADA (20 mg) every second day) gave a residue that was chromatographed (Dowex 1 × 2 (OH^-), $Et_3NH{\cdot}HCO_3$–H_2O) and recrystallized (H_2O (gentle heating)) to give **3***b* (130 mg, 50%) with data as reported (3, 20); mp ~200°C (dec.); UV (H_2O) max: 252 nm (ε 13 800); MS (FAB) *m/z*: 250 (16, MH^+). Anal. calcd. for $C_{10}H_{11}N_5O_3{\cdot}0.5H_2O$: C 46.51, H 4.68, N 27.12; found: C 46.20, H 4.58, N 27.07.

9-(2-Amino-2-deoxy-β-D-arabinofuranosyl)guanine 8*c*

Treatment of **8***b* (141 mg, 0.5 mmol) with ADA (pH 6.5, stirred at ambient temperature for 15 days with addition of ADA (8 mg) every second day) gave a residue that was chromatographed (Dowex 1 × 2 (OH^-), $Et_3NH{\cdot}HCO_3$–H_2O) to give **8***c* as a mixed salt and free 2′-amine. Further ion-exchange chromatography and recrystallization (H_2O) gave **8***c* (131 mg, 90%) with data as reported (26); mp ~230°C (dec.) (lit. (26) mp 193–196°C (dec.)); UV (H_2O) max: 252 nm (ε 13 000); MS (FAB) *m/z*: 283 (57, MH^+). Anal. calcd. for $C_{10}H_{14}N_6O_4{\cdot}0.5H_2O$: C 41.24, H 5.19, N 28.85; found: C 41.38, H 4.93, N 28.68.

9-(β-D-Xylofuranosyl)guanine 12

Treatment of **11** (282, 1 mmol) (prepared by coupling ($SnCl_4$–CH_3CN (27)) 2,6-diacetamidopurine (28*a*) with 1,2,3,5-tetra-*O*-acetyl-D-xylofuranose and deprotection (NH_3–MeOH), with data as reported (28*b*, 29); mp 159-161°C (lit. (28*b*) mp 160–163°C); MS *m/z*: 282.1080 (8, M^+ ($C_{10}H_{14}N_6O_4$) = 282.1076)) with ADA (stirred at ambient temperature for 3 days with addition of ADA (20 mg) each day) gave a residue that was chromatographed (Dowex 1 × 2 (OH^-), $Et_3NH{\cdot}HCO_3$–H_2O) and recrystallized (H_2O) to give **12** (242 mg, 83%); mp ~250°C (dec.) (lit. (21*a*) mp 236–240°C); UV (H_2O) max: 252 nm (ε 13 300); MS (FAB) *m/z*: 284 (28, MH^+); and other data as reported (21*a*). Anal. calcd. for $C_{10}H_{13}N_5O_5{\cdot}0.5H_2O$: C 41.10, H 4.83, N 23.96; found: C 41.01, H 4.63, N 23.63.

9-(β-D-Arabinofuranosyl)guanine 10

Deamination of **9** (17) proceeded analogously to give **10** with data identical to those of a sample prepared previously (17).

New antifungal metabolites from the coprophilous fungus *Cercophora sordarioides*

Authrine C. Whyte, Katherine B. Gloer, James B. Gloer, Brenda Koster, and David Malloch

Abstract: A chemical investigation of the coprophilous fungus *Cercophora sordarioides* has led to the isolation of arthrinone (**1**), a known fungal metabolite, and three new related compounds: 1-dehydroxyarthrinone (**2**), 3a,9a-deoxy-3a-hydroxy-1-dehydroxyarthrinone (**3**), and cerdarin (**4**). These metabolites were obtained from antifungal ethyl acetate extracts of liquid cultures of *C. sordarioides* through bioassay-guided fractionation, and their structures were assigned on the basis of 1D-NMR, HMQC, and HMBC results. Compounds **2** and **4** exhibited anti-*Candida* activity.

Key words: antifungal, fungal metabolite, natural product, *Cercophora sordarioides.*

Résumé : Une investigation chimique du champignon coprophileux *Cercophora sordarioides* a permis d'isoler l'arthrinone (**1**), une métabolite connu de champignons, et trois nouveaux composés qui lui sont apparentés : la 1-déshydroxyarthrinone (**2**) la 3a,9a-déoxy-3a-hydroxy-1-déshydroxyarthrinone (**3**) et la cerdarine (**4**). On a isolé ces métabolites à partir des extraits à l'acétate d'éthyle des antifongicides des cultures liquides du *C. sordarioides*, par un fractionnement guidé par des bioessais, et on en a attribué les structures sur la base de résultats de RMN en 1D, de « HMCQ » et de « HMBC ». Les composés **2** et **4** présentent une activité anti-*Candida.*

Mots clés : antifongicide, métabolite de champignons, produit naturel, *Cercophora sordarioides.*

[Traduit par la rédaction]

Antagonistic interactions among coprophilous (dung-colonizing) fungi often involve the production of a chemical agent by one species that inhibits the growth of another (1, 2). Our studies of these fungi have led to the discovery of a variety of new antifungal agents (3, 4). Recently, we reported the isolation of several new cytotoxic and antifungal metabolites from *Cercophora areolata* (5). As part of a continuing study of coprophilous fungi of this genus, we investigated the chemistry of an isolate of *C. sordarioides* that displayed antifungal activity. This investigation led to the isolation of the known fungal metabolite arthrinone (**1**) (6) and three new related compounds: 1-dehydroxyarthrinone (**2**), 3a,9a-deoxy-3a-hydroxy-1-dehydroxyarthrinone (**3**), and cerdarin (**4**). Compounds **2** and **4** exhibited anti-*Candida* activity. This report describes the isolation, structure elucidation, and biological activities of these metabolites.

Results and discussion

An isolate of *C. sordarioides* (JS 271 = UAMH 7495) obtained from cow dung was grown in liquid shake culture for 30 days. The EtOAc extract of the resulting broth was fractionated directly by reversed-phase HPLC to afford arthrinone (**1**) and three related metabolites (**2–4**).

Arthrinone (**1**) was originally reported as a metabolite of an *Arthrinium* sp., and its structure and relative stereochemistry were confirmed by X-ray crystallographic analysis (6). The sample obtained from *C. sordarioides* was identified through analysis of HREIMS and NMR data, and by comparison of these and other data with literature values (6). This assignment was confirmed by ^{1}H NMR analysis of a 1:1 mixture of the sample with an authentic standard of **1**, which revealed that all signals were coincident.

The HREIMS and NMR data for compound **2** indicated that it is closely related to **1**, but contains one less oxygen atom. ^{1}H NMR (Table 1), ^{13}C NMR (Table 2), and DEPT data revealed the presence of a pair of *meta*-coupled aromatic protons, two oxygenated methylene groups, an oxygenated sp^3 methine carbon, two oxygenated quaternary carbons, a conjugated ketone, a methoxy group, and two hydroxy signals, one of which (11.6 ppm) was consistent with the presence of an intramolecularly hydrogen-bonded phenol moiety. The absence of an oxygenated methine signal near 95 ppm and the appearance of a new oxygenated methylene resonance at 66.6 ppm in the ^{13}C NMR spectrum suggested that the hemiacetal group present in **1** was replaced by an oxygenated methylene unit in **2**.

HMBC correlations (Table 3) observed for the aryl protons (H-5 and H-7), the oxymethine proton (H-4), the methoxy group (H_3-10), and the hydrogen-bonded phenolic proton (OH-8) in **2** were consistent with correlations noted for arthrinone (**1**) (6). Reciprocal HMBC correlations observed for the oxymethylene groups (H_2-1 and H_2-3), and correlations linking these groups with C-3a and C-9a, provided evidence

Received November 1, 1996.

for the epoxy-tetrahydrofuran system. An additional HMBC correlation of OH-4 (5.24 ppm) with C-3a (71.0 ppm) and a selective INEPT correlation of H-4 with C-9a (65.5 ppm) established the NMR assignments for the oxygenated quaternary carbons in **2**. Compound **2** was therefore determined to be 1-dehydroxyarthrinone.

The absolute stereochemistry at C-4 of **2** was assigned by application of Helmchen's rules (7). Treatment of a sample of **2** with (*R*)-2-phenylbutyric acid (PBA) and dicyclohexylcarbodiimide (DCC) resulted in monoacylation at the 4-OH group. The (*S*)-PBA monoester was obtained by similar treatment of **2** with racemic PBA–DCC, followed by HPLC separation of the resulting diastereomeric mixture. Independent confirmation of the chemical shift assignments for the *R*-PBA

[a]Recorded at 600 MHz (^{1}H dimension).
[b]These correlations were also observed in selective INEPT experiments optimized for J = 4 Hz.
[c]These correlations were observed in a D-HMBC experiment optimized for J = 4 Hz.
[d]Represents a four-bond correlation.

ester was achieved through analysis of COSY, HMQC, and HMBC data for this derivative. The absolute configuration at C-4 was deduced to be (*R*), based on downfield shifts of the H-5, H-7, OH-8, and H_3-10 signals and upfield shifts of the H_2-1 and H_2-3 signals in the spectrum of the (*R*)-PBA ester relative to those in the spectrum of the (*S*) derivative. Assuming a similar biosynthetic pathway for **1** and **2**, and considering the close NMR similarities, the relative stereochemistry for **2** is proposed to be the same as that reported for arthrinone (**1**). Therefore, the absolute configurations at C-3a and C-9a are each proposed to be (*S*) in **2**.

The molecular formula of a third related metabolite (compound **3**) was established as $C_{13}H_{14}O_6$ (seven unsaturations) by analysis of HREIMS and ^{13}C NMR data. The presence of a ketone carbonyl and six olefinic or aromatic carbons in the ^{13}C NMR spectrum indicated a tricyclic structure for **3**, and changes in several NMR signals (Tables 1 and 2) clearly indicated the absence of an epoxy group in this case. HMBC results (Table 3) confirmed that the 1,2,3,5-tetrasubstituted benzene subunit found in **1** and **2** was also present in **3**.

COSY data revealed that the C-1 oxymethylene protons are vicinally coupled with H-9a. In contrast to the data for **1** and **2**, the H_2-1 signals showed HMBC correlations with the aryl ketone carbonyl carbon (C-9), thereby unambiguously placing C-9a between C-9 and C-1. HMBC correlations of the benzylic H-4 signal with the second oxygenated methylene carbon (C-3) and the oxygenated quaternary carbon C-3a, together with the lack of COSY correlations between H-4 and H_2-3, indicated that C-3a (82.5 ppm) is located between C-4 and C-3. Correlations of H-9a with C-3, and of H_2-3 with C-1 and C-3a, provided evidence for the presence of a tetrahydrofuran ring. On the basis of these and other correlations (Table 3), as well as the molecular formula, C-3a must be attached to C-9a, and must bear a hydroxy group. The structure of **3** was therefore assigned as 3a,9a-deoxy-3a-hydroxy-1-dehydroxyarthrinone.

The relative stereochemistry at positions C-4 and C-9a of **3** was proposed on the basis of a NOESY correlation observed between the signals for H-4 and H-9a. To accommodate this correlation, Dreiding molecular models suggest that the C-3a to C-9a ring fusion is most likely *trans*; however, the lack of other useful NOESY correlations renders this assignment inconclusive, so the relative configuration at position C-3a remains undefined.

The HREIMS, ^{13}C NMR (Table 2), and DEPT data for cerdarin (**4**) suggested a molecular formula of $C_{14}H_{12}O_6$ (nine unsaturations) for this metabolite. Signals for two methoxy groups, an oxygenated methylene group, two *meta*-coupled aromatic protons, an intramolecularly hydrogen-bonded phenolic proton, and a downfield-shifted signal (6.18 ppm) consistent with an olefinic proton or an acetal moiety were observed in the ^{1}H NMR spectrum of **4** (Table 1). The ^{13}C NMR spectrum contained two conjugated ketone carbonyl signals (185.6 and 181.5 ppm), and nine additional signals consistent with the presence of a benzenoid ring, a tetrasubstituted olefinic unit, and an acetal carbon. These data satisfied seven of the unsaturations required by the molecular formula, leaving two more rings to be established.

HMBC correlations for H-5, H-7, OH-8, and H_3-10 were analogous to those observed for the aromatic subunit of **1–3**, except that H-5 showed a correlation to the carbonyl signal at 181.5 ppm (C-4) rather than to an oxymethine signal, requiring that this carbonyl be attached to C-4a. As in **1–3**, the remaining ketone carbonyl signal at 185.6 ppm (C-9) in **4** must be attached to C-8a to account for the downfield chemical shift of OH-8.

The chemical shifts of 6.18/108.1 ppm for the C-3 methine unit, together with reciprocal HMBC correlations observed between this unit and OCH_3-11, indicated that C-3 is part of an acetal functionality. Further reciprocal correlations between this unit and the oxygenated methylene group (CH_2-1) required that C-1 and C-3 share the only remaining oxygen atom through an ether linkage. Additional HMBC correlations between H_2-1 and the sp^2 carbon signals at 143.5 and 150.9 ppm (C-3a and C-9a), and between H-3 and the signal at 150.9 ppm, permitted construction of a dihydrofuran ring. Interestingly, an unusually large homoallylic coupling (4.0 Hz) was observed between H_a-1 and one of the protons on C-3.

The final ring in cerdarin (**4**) must result from connection of

the dihydrofuran ring with carbonyl carbons C-4 and C-9 to form a quinone subunit. The ^{13}C NMR chemical shifts of these carbons are consistent with the presence of a naphthoquinone moiety (8). However, a question remained regarding the regiochemistry of the dihydrofuran ring (i.e., the positioning of the CH_3O substituent at C-1 vs. C-3) because the HMBC experiment showed no correlations of either H-1 or H-3 with C-4 or C-9. Compounds **1–4** appear to be closely related hexaketide-type metabolites, and the regiochemistry of the furan ring in **4** was intially presumed to be analogous to that of **1** based on simple biogenetic analogy. However, one could also envision formation of the alternative regioisomer via a process involving additional reduction and (or) allylic oxidation steps. Therefore, in an effort to make an unambiguous assignment, a D-HMBC (9) experiment optimized for J = 4 Hz was conducted. This experiment revealed correlations of both C-1 protons with the carbonyl resonance at 185.6 ppm (C-9), strongly suggesting placement of the oxymethylene group adjacent to C-9 on the quinone ring. Four-bond heteronuclear correlations are possible, and although molecular models indicate that neither proton can adopt a coplanar W-relationship with C-4, one could envision observation of heteronuclear allylic coupling in such a system. Ultimately, however, the presence of correlations of C-9 with *both* methylene protons, together with the lack of possible conformations that would place both protons at ca. 90° vicinal angles with respect to C-9, argues for their assignment as three-bond correlations. Thus, the structure of cerdarin is proposed as shown in **4**, with the furanoid ring regiochemistry opposite to that of **1**. The absolute stereochemistry at C-3 was not determined.

Signals consistent with those observed for compounds **1–4** were present in the ^1H NMR spectrum of the unprocessed extract, indicating that these compounds are not artifacts of the isolation process. Compounds **1**, **2**, and **4** caused complete growth inhibition of the early successional coprophilous fungus *Ascobolus furfuraceus* in centerpoint disk inoculation assays at 200 μg/disk. Cerdarin (**4**) also completely inhibited the growth of *Sordaria fimicola* at the same level, but arthrinone (**1**) and dehydroxyarthrinone (**2**) showed only modest activity against this coprophilous fungal competitor. Compounds **1** and **2** also exhibited antibacterial activity against *B. subtilis* (21 and 25 mm zones of inhibition, respectively) and *S. aureus* (17 mm zones of inhibition), and **2** displayed activity against *Candida albicans* (11 mm zone of inhibition) at 200 μg/disk. Cerdarin displayed more significant anti-*Candida* and antibacterial activity in disk assays at the same level (20, 35, and 23 mm zones of inhibition against *C. albicans*, *B. subtilis*, and *S. aureus*, respectively). Compounds **1** and **2** exhibited limited cytotoxicity in the NCI 60-tumor cell line bioassay panel, displaying average GI_{50} values of 1.0 and 9.4 μg/mL, respectively.

Experimental section

General experimental procedures

Semipreparative HPLC purifications employed a Beckman Ultrasphere C_8 column (5-μm particles, 25 × 1.0 cm) at a flow rate of 2.0 mL/min with UV detection at 215 nm, with a gradient solvent system of 50–100% MeOH – H_2O, unless otherwise indicated. HPLC retention times are reported for an isocratic solvent system of 50% MeOH – H_2O. NMR spectra were recorded in Me_2CO-d_6 solutions, and chemical shifts were referenced relative to the corresponding solvent signals (2.04 ppm/29.8 ppm). Carbon multiplicities were established by DEPT experiments, and are consistent with the assignments. Specific rotations were measured on a Jasco model DIP-1000 digital polarimeter. Descriptions of NMR parameters, as well as NMR, MS, UV, IR, and mp instrumentation (10), and details of the antifungal bioassays (11), have been provided elsewhere. Chemical reagents were used as purchased without further purification. The THF employed in the esterification of **2** was freshly distilled from Na–benzophenone.

Cultivation of *C. sordarioides*

The isolate of *C. sordarioides* (JS 271) was obtained from a sample of cow dung collected by B. Koster in Issy l'Eveque, France, in August, 1994. A subculture has been deposited at the University of Alberta Mycological Herbarium Collection and was assigned the accession number UAMH 7495. Four 2-L Erlenmeyer flasks, each containing 400 mL of potato dextrose broth (Difco), were each inoculated with two 1-cm^2 agar plugs taken from stock cultures of *C. sordarioides*. Flask cultures were incubated at 25–28°C and aerated by agitation on an orbital shaker at 160 rpm for 30 days.

Isolation and characterization of arthrinone (1), 1-dehydroxyarthrinone (2), 3a,9a-deoxy-3a-hydroxy-1-dehydroxyarthrinone (3), and cerdarin (4)

The mycelia and culture broth from the fermentation of *C. sordarioides* (1600 mL) were together extracted with EtOAc (3 × 1000 mL), and the organic phase was dried ($MgSO_4$) and concentrated to yield 434 mg of a dark red solid. A portion of the extract (237 mg) was directly subjected to semipreparative reversed-phase HPLC to afford arthrinone (**1**; 58 mg), 1-dehydroxyarthrinone (**2**; 14 mg), and cerdarin (**4**; 3.7 mg).

To obtain an additional sample of **2** for stereochemical studies, a second liquid fermentation culture of *C. sordarioides* was generated using the conditions described. The broth (400 mL) and mycelia from this fermentation were together extracted using EtOAc (2 × 400 mL), and the organic phase was dried ($MgSO_4$) and concentrated to yield 37 mg of a brown solid. This extract was subjected to semipreparative reversed-phase HPLC to yield 1-dehydroxyarthrinone (**2**; 18 mg) and 3a,9a-deoxy-3a-hydroxy-1-dehydroxyarthrinone (**3**; 1.4 mg).

Arthrinone (1): $[\alpha]_D$ −5.3 (*c* 0.0019 g/mL). Spectral data and other physical properties for **1** have been previously reported (6).

1-Dehydroxyarthrinone (2): amber solid; mp 193–195°C; $[\alpha]_D$ +2.3 (*c* 0.001 g/mL, MeOH); HPLC t_R: 15.3 min; UV (MeOH) λ_{max}: 331 (ε 3400), 303 (3500), 257 (4700), 241 (3500) nm; IR (NaCl) ν_{max}: 3590, 2927, 1627, 1382, 1295, 1206, 1155 cm^{-1}; EIMS (70 ev) *m/z*: 264 (M^+, rel. int. 100), 246 (9), 206 (19), 177 (15), 151 (47); ^1H NMR, ^{13}C NMR, and HMBC data, see Tables 1, 2, and 3; HREIMS *m/z* calcd. for $C_{13}H_{12}O_6$: 264.0634; found: 264.0626 (M^+).

Esterification of 1-deoxyarthrinone (2)

A solution of (*R/S*)-2-phenylbutyric acid (PBA; 4.8 mg; 0.03 mmol) in 1 mL THF was added to a stirred solution of 1,3-dicyclohexylcarbodiimide (DCC; 6.2 mg; 0.03 mmol in 1 mL THF). A solution of compound **2** (4.0 mg; 0.015 mmol) in 1 mL THF was then added, followed by dimethylaminopyridine (40 μg), and the resulting mixture was allowed to stir at room temperature for 24 h. A white precipitate (DCC-urea) was formed. The THF was evaporated under N_2 flow, and the residue was redissolved in 3 mL of Et_2O. The organic solution was washed successively with 4 mL of 2% HOAc solution, 5 mL H_2O, and 5 mL of 3% $NaHCO_3$, and was then dried with $MgSO_4$. After removal of the solvent in vacuo, the organic residue was subjected to reversed-phase semipreparative HPLC using a gradient system of 80–100% MeOH – H_2O for 15 min to afford the acylated products (2.7 mg (*R*)-ester and 2.1 mg (*S*)-ester; 78% yield). Similar treatment of **2** with (*R*)-PBA/DCC yielded a sample of the (*R*) diastereomer.

New terpenoid metabolites from the skin extracts, an egg mass, and dietary sponges of the Northeastern Pacific dorid nudibranch *Cadlina luteomarginata*

Eric J. Dumdei, Julia Kubanek, John E. Coleman, Jana Pika, Raymond J. Andersen, Jorge Rios Steiner, and Jon Clardy

Abstract: Chemical investigations of *Cadlina luteomarginata* skin extracts, egg masses, and dietary sponges have led to the identification of the novel terpenoids cadlinaldehyde (**30**), spongian **32**, seco-spongian **35**, 20-acetoxy-12-marginatone (**38**), and lutenolide (**39**) from the nudibranch skin extracts, the new drimane sesquiterpenoid 1α,2α-diacetoxyalbicanyl acetate (**40**) from the nudibranch's egg mass, and the new sesquiterpenoids *O*-methyl-9-oxofurodysininlactone (**47**), 2-oxomicrocionin-2-lactone (**48**), and *O*-methyl-2-oxomicrocionin-2-lactone (**49**), from the dietary sponge *Pleraplysilla* sp. The known terpenoids furodysinin (**1**), furodysin (**16**), marginatafuran (**21**), and 9,11-dihydrogracillin A (**37**), which have been frequently isolated from *C. luteomarginata* skin extracts, were found for the first time in extracts of the dietary sponges *Pleraplysilla* sp. and *Aplysilla* sp. One of the new terpenoids, cadlinaldehyde (**30**), has an unprecedented degraded sesterterpenoid skeleton.

Key words: nudibranch, sponge, terpenoids, structure elucidation.

Résumé : Des investigations chimiques d'extraits de peau, de masses des oeufs et d'éponges alimentaires du *Cadlina luteomarginata* ont permis d'identifier la présence des terpénoïdes cadlinaldéhyde (**30**), spongiane **32**, séco-spongiane **35**, 20-acétoxy-12-marginatone (**38**) et luténolide (**39**) dans les extraits de peau du nudibranche, du nouveau sesquiterpénoïde du drimane, l'acétate de 1α,2α-diacétoxyalbicanyle (**40**), à partir de la masse des oeufs du nudibranche ainsi que les nouveaux sesquiterpénoïdes *O*-méthyl-9-oxofurodysininlactone (**47**), 2-oxomicrocionine-2-lactone (**48**) et *O*-méthyl-2-oxomicrocionine-2-lactone (**49**) à partir des éponges alimentaires de l'espèce *Pleraplysilla*. Les terpénoïdes connus furodysinine (**1**), furodysine (**16**), marginatafurane (**21**) et 9,11-dihydrogracilline A (**37**), fréquemment isolés des extraits de peau du *C. luteomarginata*, ont été retrouvés pour la première fois dans les extraits d'éponges alimentaires des espèces *Pleraplysilla* et *Aplysilla*. L'un des nouveaux terpénoïdes, le cadlinaldéhyde (**30**), présente un squelette de sesterterpénoïde dégradé jamais rencontré antérieurement.

Mots clés : nudibranch, sponge, terpenoids, structure elucidation.

[Traduit par la rédaction]

Introduction

Cadlina luteomarginata is a relatively common dorid nudibranch that is found in rocky intertidal and shallow subtidal habitats all along the west coast of North America from Auke Bay, Alaska, to Point Eugenia, Mexico. Skin extracts of *C. luteomarginata* have proven to be an extremely rich source of terpenoid metabolites that in some instances apparently play a role in defending these shell-less molluscs from predation (1–7). Many of the terpenoids obtained from *C. luteomarginata* have been shown to be sequestered unchanged by the molluscs from the marine sponges that make up their diets (2, 5–7). It has also been found that the terpenoid content of skin extracts of specimens of *C. luteomarginata* can vary dramatically from collecting site to collecting site, reflecting the different terpenoid constituents present in the dietary sponges available at each site. The initial discovery of geographic variability in *C. luteomarginta* terpenoid constituents prompted investigations of geographic variance in metabolite content of other species and led ultimately to the general proposal that geographic invariance of metabolite content in nudibranch skin extracts was a good predictor of de novo biosynthesis of the metabolites (8). Recently, a number of biosynthetic investigations of nudibranch terpenoids and polyketides have provided support for this proposal (9–11).

The terpenoid constituents present in skin extracts of *C. luteomarginata* have been identified for specimens collected

Received December 2, 1996.

This manuscript is dedicated to Professor William Ayer, an inspirational teacher, mentor, and role model, on the occasion of his 65th birthday.

at both the southern and northern extremes of their geographic range (Fig. 1). Shown in Fig. 2 are the metabolites **1–15** that have been isolated from specimens collected in Southern California along with the dietary sponge source where it is known (2). As illustrated, the Southern California specimens yielded sesquiterpenoid and sesterterpenoid furans along with a number of sesquiterpenoid isonitriles, isothiocyanates, and formamides. Shown in Fig. 3 are the terpenoids **1**, **7**, **9**, and **16–29**, which have been reported to date from *C. luteomarginata* specimens collected at various sites along the coast of British Columbia all the way from Vancouver to the Alaskan border (1, 3–7). There are some similarities and some clear differences between the terpenoids reported from the B.C. and California populations of *C. luteomarginata*. Both groups of nudibranchs yielded sesquiterpenoid furans, isonitriles, isothiocyanates, and formamides; however, only three specific compounds, furodysinin (**1**), isonitrile **7**, and formamide **9**, have been reported from both populations. The B.C. specimens are unique in that they contain the drimane sesquiterpenoid albicanyl acetate (**19**) as the major constituent and the degraded sesterterpenoid luteone (**20**) as a minor constituent in their extracts at nearly all locations from Vancouver to Alaska. A group of degraded and rearranged spongian diterpenoids (i.e., **22–24**) and a marginatane diterpenoid (**21**), whose occurrence is very site dependent, have also been found in the B.C. specimens but have not been reported from the California specimens.

The terpenoid chemistry of *C. luteomarginata* has continued to attract our attention for a number of reasons. First, *C. luteomarginata*'s capacity for feeding on and efficiently sequestering terpenoid metabolites from a wide variety of sponge species makes it a useful surrogate for investigations of the terpenoid constituents of many sponges in B.C. waters that are rare and, therefore, not readily collectable in sufficient quantities for direct chemical studies. Thus, we have continued to collect specimens from as many different B.C. sites as possible in an attempt to identify novel terpenoids. Second, the true origin of *C. luteomarginata* terpenoids is of considerable interest. There is indirect evidence that *C. luteomarginata* might have the capability of making some terpenoids via de novo biosynthesis or perhaps even modifying some sequestered metabolites. Thus, we have attempted to link as many *C. luteomarginata* skin metabolites as possible directly to a sponge source. Finally, there has been an ongoing interest in understanding what ecological role if any the terpenoids might play. An opportunity to examine the terpenoid constituents in a *C. luteomarginata* egg mass has helped to identify one possible ecological role as well as shedding some light on the question of de novo biosynthesis. Presented below are the results of our recent chemical investigations of *C. luteomarginata* skin extracts, egg masses, and dietary sponges. These studies have led to the identification of the novel terpenoids **30**, **32**, **35**, **38**, and **39** from the nudibranch skin extracts, the new drimane sesquiterpenoid **40** from the nudibranch's egg mass, the new sesquiterpenoids **47** – **49** from the dietary sponge *Pleraplysilla* sp., and the known terpenoids **21** and **37** from the dietary sponge *Aplysilla* sp. One of the new terpenoids, cadlinaldehyde (**30**), has a unprecedented degraded sesterterpenoid skeleton.

Results

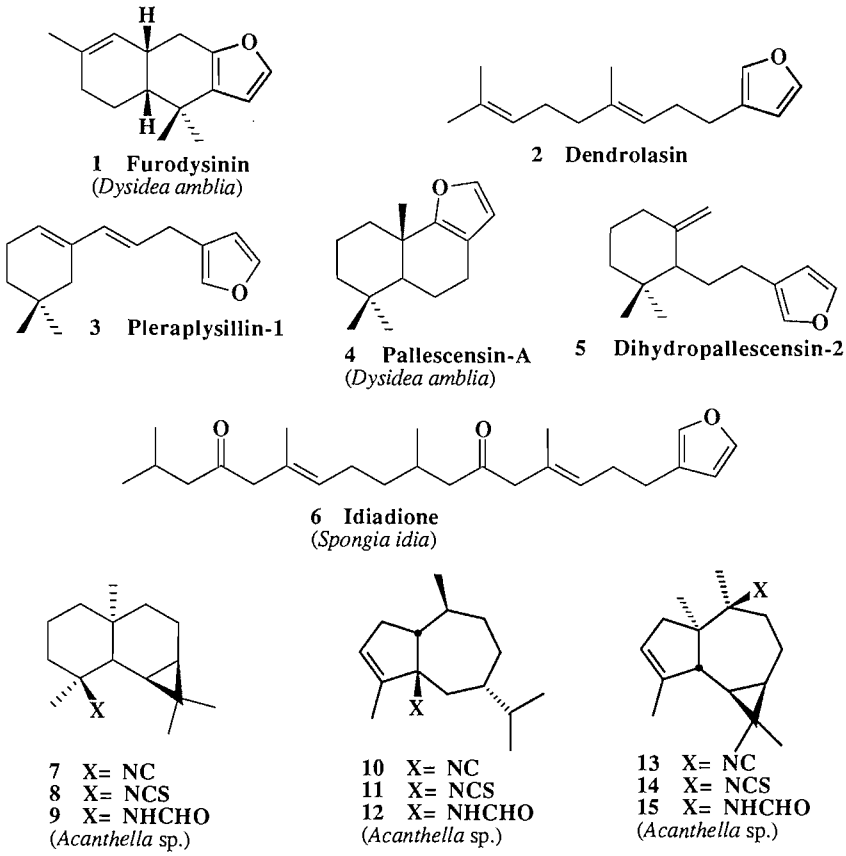

Figure 1 shows the sites along the B.C. coast from which specimens of *C. luteomarginata* have been collected. Animals collected at the Agamemnon Channel, Jervis Inlet site, yielded the known terpenoids albicanyl acetate (**19**) (3), luteone (**20**) (1), and the spongian **31** (12) as well as the new terpenoids cadlinaldehyde (**30**) and the spongian derivative **32**. The known compounds **19** and **31** were identified by comparing their spectroscopic data with literature values. Luteone (**20**), an extremely volatile compound that is largely responsible for the pleasant odor of B.C. specimens of *C. luteomarginata*, was originally isolated in trace amounts only as its nonvolatile dinitrophenylhydrazone derivative (1). The Agamemnon Channel collection of *C. luteomarginata* provided sufficient quantities of the underivatized luteone (**20**) to permit for the first time a complete assignment of its ^{1}H and ^{13}C NMR spectra as presented in Table 1.

Cadlinaldehyde (**30**) was obtained as optically active colorless needles (mp 65°C) that gave a parent ion in the HREIMS at *m/z* 318.2489 corresponding to a molecular formula of $C_{21}H_{34}O_2$. The ^{13}C/APT and HMQC spectra (Table 1) of **30** identified resonances for all 21 carbons (4 × C, 4 × CH, 9 × CH_2, 4 × CH_3) and they further showed that all of the protons

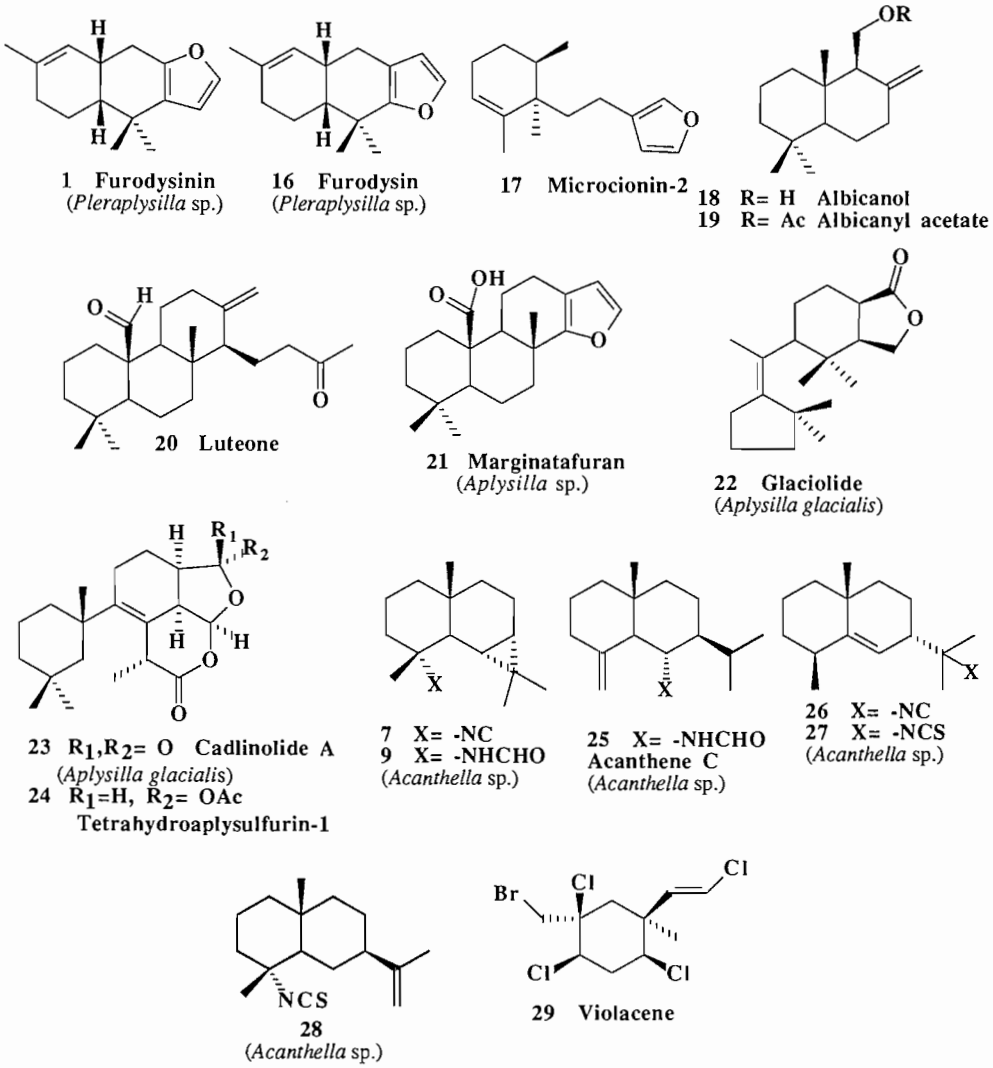
Fig. 2. Terpenoids isolated from Southern California specimens of *Cadlina luteomarginata* (2).

in the molecule were attached to carbon atoms. Only one site of unsaturation, represented by an aldehyde functionality (^{13}C δ 206.4: ^{1}H δ 10.7), could be directly identified from the NMR data, indicating that cadlinaldehyde had to be tetracyclic in order to satisfy the unsaturation number of five required by the molecular formula. A quaternary carbon at δ 79.5 (C13) and a methylene carbon at δ 64.9 (C16) could be assigned to the attachment points of the remaining oxygen atom in **30**, which had to be present as an ether. One of the methylene protons (H16: δ 3.80) attached to the carbon at δ 64.9 (C16) showed a strong HMBC correlation to the carbon at δ 79.5 (C13) confirming the ether linkage. COSY correlations observed between both of the geminal methylene proton resonances at δ 3.80 (H16) and 3.88 (H16′) and a pair of geminal methylene proton resonances at δ 1.70 (H15) and 1.80 (H15′), and between the methylene resonance at δ 1.70 (H15) and a methine proton resonance at δ 1.39 (H14), identified an -O-CH_2-CH_2-CH- fragment. A singlet methyl proton resonance at δ 0.98 (Me21) showed HMBC correlations to a methylene carbon resonance at δ 39.2 (C12), to the quaternary ether carbon resonance at δ 79.5 (C13), and to a methine carbon resonance at δ 59.5 (C14), which in turn showed a HMQC correlation to the proton resonance at δ 1.39 (H14). The latter pair of HMBC correlations indicated that the ether was part of a tetrahydrofuran fragment that was joined to the rest of the molecule through the vicinal quaternary ether (C13: δ 79.5) and methine (C14: δ 59.5) carbons.



Comparison of the remaining NMR data for cadlinaldehyde (**30**) (Table 1) with the NMR data for luteone (**20**) suggested that the two molecules contained identically substituted *trans* decalin A/B ring systems. Three methyl singlets at δ 0.70, 0.77 and 0.92, assigned to Me19, Me18, and Me17, respectively, along with the aldehyde resonance at δ 10.07 in the ^{1}H NMR spectrum of cadlinaldehyde (**30**) served as useful HMBC antennae to confirm the nature of the A/B ring system. The Me18 ^{1}H resonance at δ 0.77 showed HMBC correlations to ^{13}C resonances assigned to Me17 (δ 31.9), C3 (41.7), C4 (33.6), and C5 (55.6), while the aldehyde ^{1}H resonance at δ 10.07 showed HMBC correlations to ^{13}C resonances assigned to C10 (δ 53.4) and C1 (34.4). A proton resonance at δ 2.49 ($H1_{eq}$), which showed a HMQC correlation to the methylene carbon at δ 34.4 (C1), gave HMBC correlations to ^{13}C resonances assigned to C5 (δ 55.6) and C3 (41.7). The $H1_{eq}$ resonance at δ 2.49 also showed COSY correlations to its geminal partner at δ 0.70 ($H1_{ax}$) and to the H2/H2′ geminal methylene proton resonances at δ 1.26 and 1.42, which in turn showed HMBC correlations to the C3 resonance at δ 41.7. A HMQC correlation between the H2/H2′ resonances at δ 1.26 and 1.42 and a methylene carbon resonance at δ 19.3 completed the assignments for the A ring of cadlinaldehyde (**30**) and, along with the HMBC and COSY correlations described above, confirmed the proposed connectivity.

The Me19 ^{1}H resonance at δ 0.70 showed HMBC correlations to ^{13}C resonances assigned to C7 (δ 40.4), C8 (36.5), C9 (61.4), and the methine carbon (C14: 59.5) of the tetrahydrofuran ring. An HMQC correlation showed that the methine carbon resonance at δ 61.4, assigned to C9, was attached to a proton with a chemical shift of δ 1.22 (H9). The H9 proton

Fig. 3. Terpenoids isolated from British Columbia specimens of *Cadlina luteomarginata* and already reported in the literature (1, 3–7) along with the dietary sponge source where it is known.

resonance (δ 1.22) in turn showed HMBC correlations to the ^{13}C resonances assigned to Me19 (δ 16.6) and C20 (206.4), thereby establishing the C8/C9/C10 connectivity. COSY correlations between H5 (δ 1.24) and $H6_{ax}$ (δ 1.10) confirmed the C5/C6 connectivity and HMBC correlations between the $H7_{eq}$ (δ 1.70) and C5 (δ 55.6), and the $H6_{eq}$ (δ 1.84) and C7 (δ 40.4) and C8 (δ 36.5) resonances, confirmed the presence of the -CH_2-CH_2- bridge between C5 and C8. The Me19 to C14 HMBC correlation described above required that the Me19 bearing quaternary carbon C8 be bonded directly to the tetrahydrofuran methine carbon C14. HMQC correlations were observed between the ^{13}C resonance for the methylene carbon (C12: δ 39.2) attached to the quaternary carbon (C13) of the tetrahydrofuran ring and a pair of proton resonances at δ 1.30 ($H12_{ax}$) and 1.88 ($H12_{eq}$). One of these methylene proton resonances ($H12_{eq}$: δ 1.88) showed a COSY correlation to a vicinal methylene proton resonance at δ 1.77 ($H11_{ax}$), which in turn showed a COSY correlation to a resonance at δ 1.90 ($H11_{eq}$), assigned to its geminal partner, and an HMQC correlation to a methylene carbon resonance at δ 17.4 (C11). An HMBC correlation between the $H12_{eq}$ resonance at δ 1.88 and the C9 resonance at δ 61.4, in conjunction with the COSY, HMQC, and HMBC correlations described above, confirmed the connectivity between C9 and C11.

A series of nOe difference experiments established the relative stereochemistries of the A/B and B/C ring junctions in **30**. Irradiation of H20 (δ 10.07) induced nOes in the Me18 (δ 0.77), Me19 (δ 0.70), and $H6_{ax}$ (δ 1.10) resonances demonstrating that the A and B rings were in chair conformations, that the A/B ring junction was *trans*, and that Me18, Me19, and C20 were all axial. Irradiation of the Me21 resonance at δ 0.98 induced an nOe in the Me19 resonance at δ 0.70 indicating that the B/C ring junction was also *trans*, that ring C was in a chair conformation, and that Me21 was axial. The relative configuration at C14 could not be determined by nOe experiments. To determine the relative configuration at C14 and to confirm the connectivity determined by NMR analysis, cadlinaldehyde (**30**) was subjected to single crystal X-ray diffraction analysis. Figure 5 shows a computer-generated perspective drawing of cadlinaldehyde (**30**) that confirms the

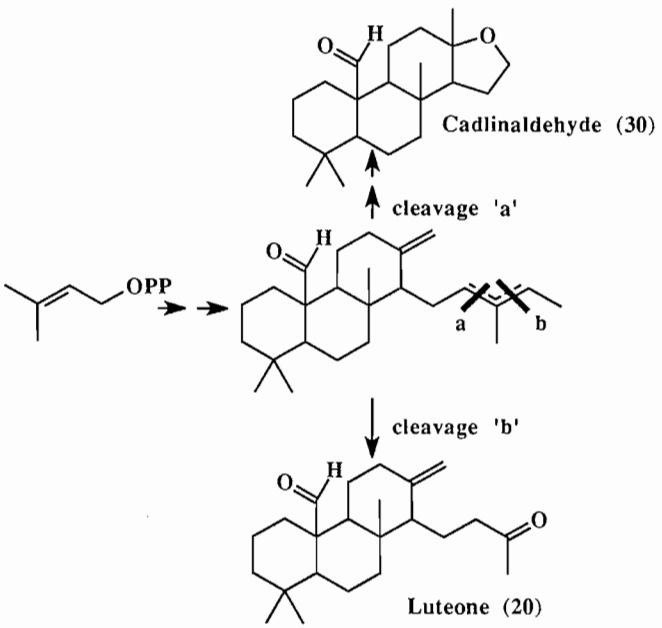
proposed constitution and establishes the relative stereochemistry at C14. Cadlinaldehyde (**30**) has an unprecedented 21 carbon terpenoid skeleton that we have named the cadlinalane skeleton. It seems most likely that cadlinaldehyde (**30**) and luteone (**20**) are degraded sesterterpenoids (Scheme 1).

Spongian **32** was isolated as a colorless oil that gave a parent ion in the HREIMS at *m/z* 376.2249 appropriate for a molecular formula of $C_{22}H_{32}O_5$. Comparison of the ^{1}H and ^{13}C NMR data (Table 2) obtained for **32** with that for the co-occurring known metabolite **31** (12) showed that the two molecules were closely related. Further detailed analysis of the NMR data for **32** showed that it was simply the acetate of the known compound **33**, which was previously isolated from the Australian nudibranch *Ceratosoma brevicaudatum* and the sponge *Dendrilla rosea* (13). The main differences in the ^{1}H NMR data of **32** and **33** are the presence of the acetate resonance (δ 2.04, s, 3H) in **32** and the downfield shift of H17 (**32** δ 6.29: **33** δ 5.50). The α-acetoxy stereochemistry at C17 of **32** was assigned on the basis of the similarity in chemical shift of H17 in **32** (δ 6.29 s) and the known analog **34** (δ 6.20) (13).



Specimens of *C. luteomarginata* collected at Sanford Island in Barkley Sound yielded the known compounds albicanyl acetate (**19**), luteone (**20**), glaciolide (**22**), and cadlinaldehyde (**30**) along with a new seco-spongian derivative **35**. Seco-spongian **35** was isolated as a colorless oil that gave a parent ion in the HRCIMS at *m/z* 422.26805 appropriate for a molecular formula of $C_{24}H_{38}O_6$. The ^{13}C NMR spectrum of **35** contained resolved resonances for all 24 carbon atoms (Table 2) and the HMQC data indicated that all of the hydrogen atoms were bonded to carbon. Only two sites of unsaturation, represented by ester carbonyls (δ 170.3 and 175.7), could be identified from the ^{13}C NMR data, indicating that **35** was tetracyclic. Comparison of the ^{1}H and ^{13}C NMR data (Table 2) obtained for the seco-spongian **35** with the literature data for the spongian derivative **36** (12) suggested that the two molecules were closely related, even though **36** was pentacyclic and **35** was tetracyclic. The HMBC, HMQC, and COSY data for **35** confirmed that the A, B, and C rings in **35** were identical to those present in **36** and they identified the regions of difference in the two molecules.

Fig. 4. Terpenoids isolated from skin extracts and an egg mass of British Columbia specimens of *Cadlina luteomarginata* during the current study.

Scheme 1. Proposed biogenesis of the luteane and cadlinalane carbon skeletons.

HMBC correlations between a methyl resonance at δ 2.06 (Me22) and a carbonyl resonance at δ 170.3 (C21), and between a deshielded methyl resonance at δ 3.62 (Me23) and a carbonyl resonance at δ 175.7 (C16), identified acetate and methyl ester functionalities in **35**. Additional HMBC correlations between a second deshielded methyl resonance at δ 3.30 (Me24) and a methine carbon resonance at δ 105.2 (C17), and between the H9 (δ1.67) resonance and the same methine carbon resonance (δ 105.2: C18) identified a methyl acetal functionality and tentatively located it at C17. The acetal methine proton resonance (δ 5.16: H17) showed an HMBC correlation to an oxygen-bearing methylene carbon resonance at δ 66.1 assigned to C15, which identified the second alkoxy component of the acetal functionality. HMQC data showed that C15 (δ 66.1) was attached to a pair of protons that gave resonances at δ 3.64 (H15β) and 3.80 (H15α). In the COSY spectrum, the H15 resonances gave correlations to a methine resonance at δ 2.46, assigned to H14 (HMQC to δ 44.4), which was in turn correlated to a methine resonance at δ 2.71, assigned to H13 (HMQC to δ 39.0), thereby identifying an -O-CH_2-CH-CH- fragment. The methine resonance assigned to H13 (δ 2.71) and the carbon it was attached to (C13: δ 39.0) had chemical shifts nearly identical to those assigned to H13 (δ 2.74) and C13 (δ 37.6) in **36**, suggesting that the methyl ester functionality in **35** was attached to C13.

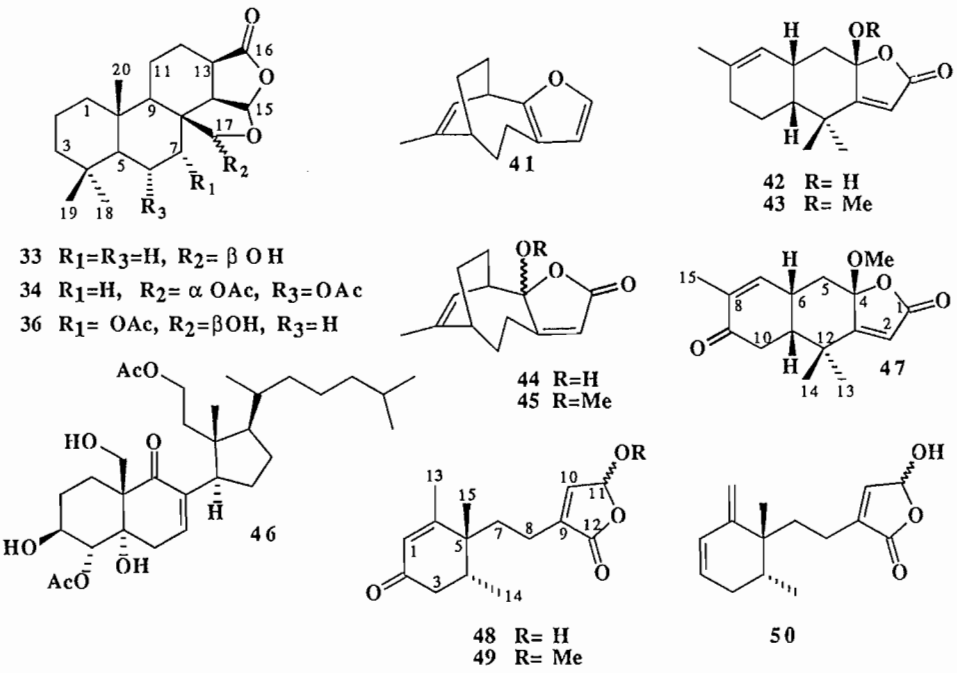

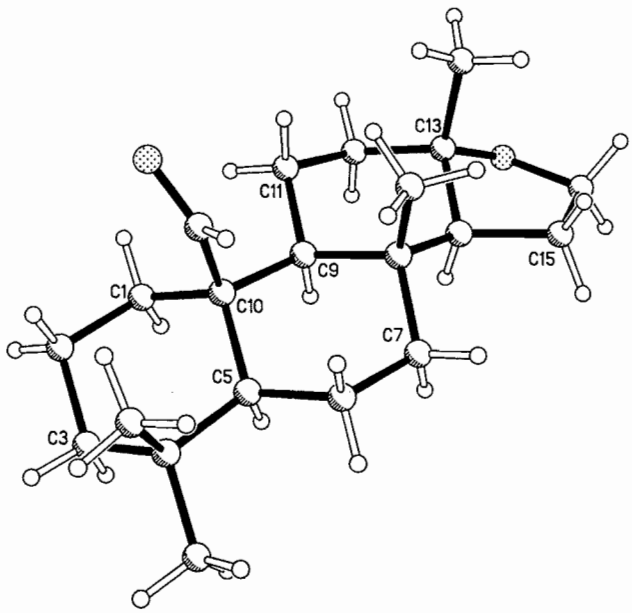

Fig. 5. Computer-generated perspective drawing of cadlinaldehyde (**30**).

A series of difference nOe experiments established the relative stereochemistry in the seco-spongian **35**. Irradiation of H7 (δ 5.28) induced an nOe in H14 (δ 2.46) indicating that H14 was α and H7 was β; irradiation of H17 (δ 5.16) induced an nOe in Me20 (δ 0.87) demonstrating that C17 was axial and that H17 was β; and irradiation of H13 (δ 2.71) induced an nOe in H9 (δ 1.67) that showed that ring C was in a boat conformation with H13 α. The downfield shift of H7 (δ 5.28) in **35** relative to H7 in **36** (δ 4.73) was consistent with the expected deshielding influence of the α-oriented C17 methoxy substituent in **35** relative to the influence on H7 of the β-oriented C17 hydroxyl substituent in **36**.

Specimens of *C. luteomarginata* collected on the eastern side of Anthony Island yielded the known diterpenoids marginatafuran (**21**) and 9,11-dihydrogracillin A (**37**) along with the two new diterpenoids 20-acetoxy-12-marginatone (**38**) and lutenolide (**39**). 9,11-Dihydrogracillin A (**37**) had been previously isolated from the Antarctic sponge *Dendrilla membranosa* (14) and marginatafuran (**21**) had been previously isolated from *C. luteomarginata* (4). Both compounds were identified by comparing their spectroscopic data with the literature values. 20-Acetoxy-12-marginatone (**38**) was isolated as a colorless oil that gave a molecular ion at *m/z* 358.2144 in the HREIMS corresponding to a molecular formula of $C_{22}H_{30}O_4$. The ^{13}C NMR spectrum of **38** showed resolved resonances for all 22 carbon atoms and an APT spectrum indicated that all the protons were attached to carbon (4 × CH_3, 7 × CH_2, 4 × CH, 7 × C) (Table 3). Resonances at δ 193.6 and 174.4 in the ^{13}C NMR spectrum were assigned to ketone and ester carbonyls, respectively, while four deshielded resonances at δ 106.7 (CH), 118.9 (C), 142.3 (CH), and 170.0 (C) were assigned to sp^2 hybridized carbons, accounting for a total of four sites of unsaturation. The remaining four sites of unsaturation required by the molecular formula of **38** had to be present as rings.

A number of features of the NMR data obtained for **38** suggested that it was closely related to the co-occurring diterpenoid marginatafuran (**21**) (Table 3). Thus, the four sp^2 carbons (δ 106.7 (C15), 118.9 (C13), 142.3 (C16), and 170.0 (C14)) and the two attached protons (δ 6.65 (H15) and 6.84 (H16)) could be assigned to an α,β-disubstituted furan ring system identical to the one present in **21**. In addition, the ^1H NMR spectrum of **38** contained three methyl singlet resonances (δ 0.67 (Me18), 0.71 (Me17), and 1.10 (Me19)) as well as a pair of deshielded geminal methylene proton resonances at δ 4.05 (dd, J = 12, 2 Hz: H20) and 4.67 (d, J = 12 Hz: H20′), that made up an isolated spin system assigned to an acetoxymethyl

[a]Signal not seen due to small sample size.

residue, thereby accounting for the four quaternary methyl appendages required by the marginatane diterpenoid skeleton. The acetoxy, ketone, and furan functionalities accounted for all four oxygen atoms present in the molecular formula of **38**. What remained was to identify the location of the ketone and acetoxy functionalities on the marginatane skeleton. The relatively shielded chemical shift of the ketone carbonyl (δ 193.6) indicated that it was conjugated and, therefore, it had to be situated at C12 in **38**. COSY and HMQC data identified an isolated spin system consisting of a methine proton resonance at δ 1.5 (H9) and a pair of methylene protons resonances at δ 2.75 (H11, H11′). The only position on the 12-ketomarginatane skeleton to situate an isolated -CH-CH_2- spin system was at C9/C11. In support of this assignment was the observed chemical shift of the methylene protons (δ 2.75: H11, H11′), which was consistent with a placement adjacent to the C12 ketone functionality.

A series of difference nOe experiments and long-range COSY correlations identified the location of the acetoxymethyl group and established the relative stereochemistry of **38**. Irradiation of the H11/H11′ resonance at δ 2.75 induced nOe's in resonances assigned to $H1_{eq}$ (δ 1.79), H9 (1.5), Me19 (1.10), and the acetate methyl (1.58); irradiation of the H20′ resonance at δ 4.67 induced nOe's in resonances assigned to H20 (δ 4.05), Me18 (0.67), and $H2_{ax}$ (1.5); irradiation of the H20 resonance at δ 4.05 induced nOe's in resonances assigned to H20′ (δ 4.67), Me19 (1.10), and $H6_{ax}$ (1.16). This set of nOe's was only consistent with the *trans/anti/trans* stereochemistry of the A/B/C rings and the placement of the acetoxymethyl group at C20 as shown in **38**. COSY correlations, assigned to W coupling, observed between H20′ (δ 4.67) and H9 (1.5) and between H20 (δ 4.05) and $H1_{ax}$ (δ 0.41) were consistent with this assignment.

Lutenolide (**39**) was isolated as a colorless oil that failed to give a parent ion in the HREIMS. The highest mass peak observed in the HREIMS was at *m/z* 300.2091 corresponding to a molecular formula of $C_{20}H_{28}O_2$. Analysis of the NMR data for **39** (Table 3) indicated that this peak corresponded to loss of acetic acid from the molecular ion of an acetoxy diterpenoid, leading to the molecular formula $C_{22}H_{32}O_4$ for the intact natural product. A (M + NH_4) peak observed at *m/z* 378 in the LRCIMS of **39** confirmed this interpretation. The limited

For personal use only.

quantity of lutenolide that was available gave a very weak ^{13}C NMR spectrum that showed resonances for all of the carbons except the two ester carbonyls (C16 and C21) and the two aliphatic quaternary carbons (C4 and C10). Resonances were present in the ^1H NMR spectrum of **39** that could be assigned to a pair of olefinic methylene protons (δ 5.00, bs, H17 and 5.12, bs H17': HMQC correlation to δ 110.4), to an acetoxy methine (δ 5.59, H11 and 1.99, s, 3H, Me22), to three quaternary methyls (δ 0.79, s, 3H, Me19; 0.81, s, 3H, Me20; 0.83, s, 3H, Me18), to a proton on a trisubsituted olefin (δ 7.19, H14), and to a pair of oxymethylene protons (δ 4.74, m, 2H, H15/H15'). The IR spectrum contained two carbonyl stretching bands at 1735 and 1752 cm^{-1} that were both assigned to ester functionalities, accounting for the four oxygen atoms in the molecular formula. An HMBC correlation between the acetate methyl proton resonance at δ 1.99 and a carbon resonance at δ 171 confirmed the presence of the acetoxy group. The strongly deshielded chemical shift of the olefinic methine proton resonance (δ 7.19: H14) and of the corresponding carbon resonance (δ 145.8: C14) indicated that the proton was on the β carbon of an α,β-unsaturated ester substructure. A strong COSY correlation between the olefinic methine proton resonance (δ 7.19: H14) and the two proton oxymethylene resonances at δ 4.74 (H15/H15') indicated that olefin and methylene protons were vicinal to each other. Linking the carbonyl of the α,β-unsaturated ester to the oxygen atom of the oxymethylene group attached to the β carbon of the unsaturated ester system identified a butenolide substructure in **39** as shown.

The butenolide, acetoxy, and olefinic methylene functionalities accounted for five of the seven sites of unsaturation required by the molecular formula of lutenolide, indicating that the remainder of the structure had to be bicyclic. COSY data helped elucidate the remaining portion of the molecule and link it to the already identified fragments. The acetoxy methine proton resonance at δ 5.59 (H11) showed COSY correlations to a pair of geminal methylene proton resonances at δ 2.61 (H12) and 2.83 (H12') that were in turn correlated to each other. Correlations in the long-range COSY spectrum between both the methylene proton resonances (δ 2.61 (H12) and 2.83 (H12')) and the butenolide olefinic methine proton resonance at δ 7.19 (H14) could be assigned to homoallylic coupling, thereby linking the methylene carbon of the -CH_2-CHOAc- fragment to the α carbon (C13) of the butenolide. Additional correlations in the long-range COSY spectrum between the acetoxy methine resonance (δ 5.59, H11) and a methine proton resonance at δ 1.82 (H9), and between this methine resonance (H9) and the olefinic methylene proton resonance at δ 5.12 (H17'), linked the methine carbon (C11) of the -CH_2-CHOAc- fragment to the quaternary carbon of the olefin (C8) via an intermediate methine carbon (C9).

Comparison of the remaining NMR data for lutenolide (Table 3) with the NMR data for albicanyl acetate (**19**) (1) (Table 4) revealed a close correspondence, suggesting that the two molecules had identical A/B ring systems and leading to the proposed overall structure **39** for lutenolide. COSY, HMBC, and difference nOe data supported this assignment. The long-range COSY spectrum showed correlations between the olefinic methylene proton resonance at δ 5.00 (H17) and a methylene proton resonance at δ 1.96 that was assigned to $H7_{ax}$. In the normal COSY spectrum, the $H7_{ax}$ resonance (δ 1.96) showed correlations to resonances at δ 2.35, assigned to $H7_{eq}$, and to δ 1.34 and 1.69, assigned to $H6_{ax}$ and $H6_{eq}$, respectively. The $H6_{ax}$ (δ 1.34) and $H6_{eq}$ (1.69) resonances showed further COSY correlations to a methine resonance at δ 0.99 that was assigned to H5. HMBC correlations consistent with the proposed structure **39** were observed between the Me20 proton resonance at δ 0.81 and carbon resonances assigned to C1 (δ 39.0) and C9 (δ 59.6); between the Me19 proton resonance at δ 0.79 and carbon resonances assigned to C3 (δ 41.9) and Me18 (δ 33.7); between the Me18 proton resonance at δ 0.83 and carbon resonances assigned to C3 (δ 41.9), C5 (δ 56.2), and Me19 (δ 21.7); between the H17 and H17' proton resonances at δ 5.00 and 5.12 and carbon resonances assigned to C9 (δ 59.6) and C7 (δ 39.2); and between both the H12 and H15/H15' proton resonances at δ 2.83 and 4.74, respectively, and a carbon resonance at δ 130, assigned to C13. The similarity in the ^{13}C NMR chemical shifts assigned to the A/B rings of lutenolide and those of the corresponding carbons in albicanyl acetate (**19**) indicated that the A/B rings and substituents in lutenolide had the relative stereochemistry shown in the proposed structure **39**. Irradiation of the H5 resonance at δ 0.99 induced a difference nOe in the H9 resonance at δ 1.82 in agreement with this stereochemical assignment. The relative stereochemistry at C11 in **39** remains undetermined.

A chance encounter with a specimen of *C. luteomarginata* that was laying eggs at a dive site in Rennell Sound provided us with an opportunity to examine the egg mass for the presence of terpenoids. Extracts of the single egg mass yielded small samples of two drimane terpenoids whose ^1H NMR data indicated that they were mono- and diacetoxy derivatives of albicanyl acetate (**19**). Only one of the albicanyl acetate derivatives, 1α,2α-diacetoxyalbicanylacetate (**40**), was obtained in sufficient quantity to permit complete structural characterization. Compound **40** was isolated as a colorless oil that failed to show a molecular ion in the HREIMS. The highest mass observed in the HREIMS of **40** was at *m/z* 320.1985 corresponding to an elemental composition of $C_{19}H_{28}O_4$. Complete analysis of the NMR data for **40** revealed that it was a diacetoxy derivative of albicanyl acetate (**19**) and, therefore, the MS peak at *m/z* 320.1985 could be assigned to a fragment ion formed by loss of acetic acid from the natural product.

The ^1H NMR spectrum of **40** (Table 4) contained three deshielded resonances at δ 1.94 (s, 3H), 1.96 (s, 3H), and 2.16 (s, 3H) that were assigned to acetate methyls; two deshielded methine proton resonances at δ 5.18 (ddd, J = 12, 5, 3 Hz: H2) and 5.25 (bs: H1), assigned to acetoxy methine protons; a pair of deshielded geminal methylene protons resonances at δ 4.08 (dd, J = 11, 10 Hz : H12) and 4.18 (dd, J = 11, 3 Hz: H12'), assigned to an acetoxy methyl residue; a pair of deshielded resonances at δ 4.65 (bs: H11) and 4.95 (bs: H11'), assigned to a pair of olefinic methylene protons; and three shielded methyl resonances at δ 0.92 (s, 3H: Me15), 0.93 (s, 3H: Me14), and 1.02 (s, 3H: Me13), assigned to three quaternary methyl groups. COSY correlations were observed between both of the acetoxy methyl resonances at δ 4.08 (H12) and 4.18 (H12') and an aliphatic methine resonance at δ 2.48, assigned to H9, and between the aliphatic methine resonance (δ 2.48: H9) and the olefinic methylene proton resonances at δ 4.65 (H11) and 4.95 (H11'). The fragment defined by the above COSY correlations in **40** corresponded to the C11/C8/C9/C12 substructure

present in albicanyl acetate (**19**). Long-range COSY correlations were observed between the olefinic methylene proton resonances at δ 4.65 (H11) and 4.95 (H11′) and an aliphatic resonance at δ 2.00, assigned to H7. The H7 resonance showed additional COSY correlations to a resonance at δ 2.40, assigned to its geminal partner H7′, and to a pair of resonances at δ 1.33 and 1.75, assigned to $H6_{ax}$ and $H6_{eq}$, respectively. Both the $H6_{ax}$ (δ 1.33) and $H6_{eq}$ (δ 1.75) resonances showed COSY correlations to a resonance at δ 1.59, assigned to H5. This latter set of COSY correlations confirmed that the C5/C6/C7 portion of the B ring of **40** was identical to that in **19**.

What remained was to locate the positions of the two acetoxy substituents on the available sites at C1, C2, and C3 of ring A in **40**. COSY correlations were observed between the acetoxy methine proton resonance at δ 5.18 (H2) and a pair of geminal methylene proton resonances at δ 1.42 ($H3_{ax}$) and 1.80 ($H3_{eq}$). The second acetoxy methine proton resonance at δ 5.25 (H1) failed to show COSY correlations to either the other acetoxy methine resonance (δ 5.18: H2) or the geminal methylene proton resonances (δ 1.42, $H3_{ax}$: 1.80, $H3_{eq}$). Fortunately, a pair of double resonance experiments involving independent selective irradiation of the two acetoxy methine proton resonances at δ 5.18 (H2) and 5.25 (H1) showed that they were indeed coupled to each other with a very small coupling constant. Therefore, **40** had to contain the substructure -CH_2-CHOAc-CHOAc-. A series of difference nOe experiments, conducted in C_6D_6 for increased dispersion, provided evidence for the placement of the two acetoxy substituents at C1/C2 as well as establishing the relative stereochemistry of **40**. Thus, irradiation of the H1 resonance at δ 5.52 induced nOe's in the H2 (δ 5.34), H12′ (δ 4.45), and Me15 (δ 0.78) resonances; irradiation of the H2 resonance at δ 5.34 induced nOe's in the H1 (δ 5.52), Me14 (δ 0.71), and Me15 (δ 0.78) resonances; irradiation of the Me15 resonance at δ 0.78 induced nOe's in the H1 (δ 5.52), H2 (δ 5.34), H12 (δ 3.94), and Me14 (δ 0.71) resonances; and irradiation of the Me14 resonanace at δ 0.71 induced nOe's in the H2 (δ 5.34), $H3_{eq}$ (δ 1.4), $H6_{ax}$ (δ 1.1), Me13 (δ 0.83), and Me15 (δ 0.78) resonances. The above set of nOe's were consistent only with the regio- and stereochemistry shown for **40**.

Part of our ongoing investigation of *C. luteomarginata* terpenoid chemistry has involved an attempt to determine the

true origin of the metabolites. Consequently, chemical investigations of sponges collected at the same sites as specimens of *C. luteomarginata* previously resulted in the identification of dietary sponge origins for a number of terpenoids found in skin extracts of B.C. specimens of *C. luteomarginata* (i.e., **22** and **24** from *Aplysilla glacialis* and **25–29** from *Acanthella* sp.). Continuing chemical investigations of sponges found in the same habitats as *C. luteomarginata* have identified two additional undescribed species, a *Pleraplysilla* sp. and an *Aplysilla* sp., which contain terpenoids that have also been found in the nudibranch skin extracts.

Samples of *Pleraplysilla* sp. were collected at Checleset Bay and Botanical Beach, B.C. Extracts of *Pleraplysilla* sp. yielded a number of known terpenoids, including furodysinin (**1**) (15), furodysin (**16**) (15), nakafuran-8 (**41**) (16), furodysinin lactone (**42**) (17), its methoxybutenolide derivative **43** (17), nakafuran-8 lactone (**44**) (16), its methoxy butenolide derivative **45** (16), and blancasterol (**46**) (18), that were identified by comparison of their spectroscopic data to the literature values. The *Pleraplysilla* sp. metabolites furodysinin (**1**) and furodysin (**16**) are two of the more commonly encountered terpenoids in skin extracts of B.C. specimens of *C. luteomarginata*. Three new terpenoids, *O*-methyl-9-oxofurodysininlactone (**47**), 2-oxomicrocionin-2-lactone (**48**), and *O*-methyl-2-oxomicrocionin-2-lactone (**49**), were also isolated from the *Pleraplysilla* sp. extracts.

O-Methyl-9-oxofurodysinin lactone (**47**) was isolated as a colorless glass that gave a parent ion in the HREIMS at *m/z* 276.1371 corresponding to a molecular formula of $C_{16}H_{20}O_4$. Comparison of the ^{1}H NMR data obtained for **47** with those obtained for the co-occurring known metabolites furodysinin lactone (**42**) and *O*-methylfurodysinin lactone (**43**) (17) (Table 5) revealed that the three metabolites were closely related. The major difference in the spectroscopic data for the molecules was ^{13}C NMR (δ 198.1) and IR (1665 cm^{-1}) evidence for the presence of an α,β-unsaturated ketone functionality in **47**. COSY correlations between an olefinic methine proton resonance at δ 6.74, assigned to H7, and olefinic methyl (δ 1.77) and allylic methine (δ 3.09) proton resonances assigned to Me15 and H6, respectively, confirmed the presence of a $\Delta^{7,8}$ olefin in **47**. HMBC correlations between the H7 (δ 6.74) and Me15 (δ 1.77) proton resonances and the ketone carbonyl resonance at δ 198.1 supported the placement of the ketone functionality at C9. All of the remaining COSY, HMBC, HMQC, and difference nOe data obtained for **47** were consistent with the structure shown.

2-Oxomicrocionin-2-lactone (**48**) was obtained as a colorless oil that gave a molecular ion in the HREIMS at *m/z* 264.1317 appropriate for a molecular formula of $C_{15}H_{20}O_4$ requiring six sites of unsaturation. The IR spectrum of **48** contained absorption bands at 1650, 1758, and 3317 cm^{-1} that were assigned to α,β-unsaturated ketone, α,β-unsaturated γ-lactone, and hydroxyl functionalities, respectively, by comparison with the IR data for **47**. ^{13}C NMR resonances at δ 198.8 and 170.9 were assigned to the α,β-unsaturated ketone and α,β-unsaturated γ-lactone carbonyls, respectively, and four deshielded resonances at δ 128.8 (CH), 167.3 (C), 138.2 (C), and 143.1 (CH) accounted for the two olefinic functionalities

For personal use only.

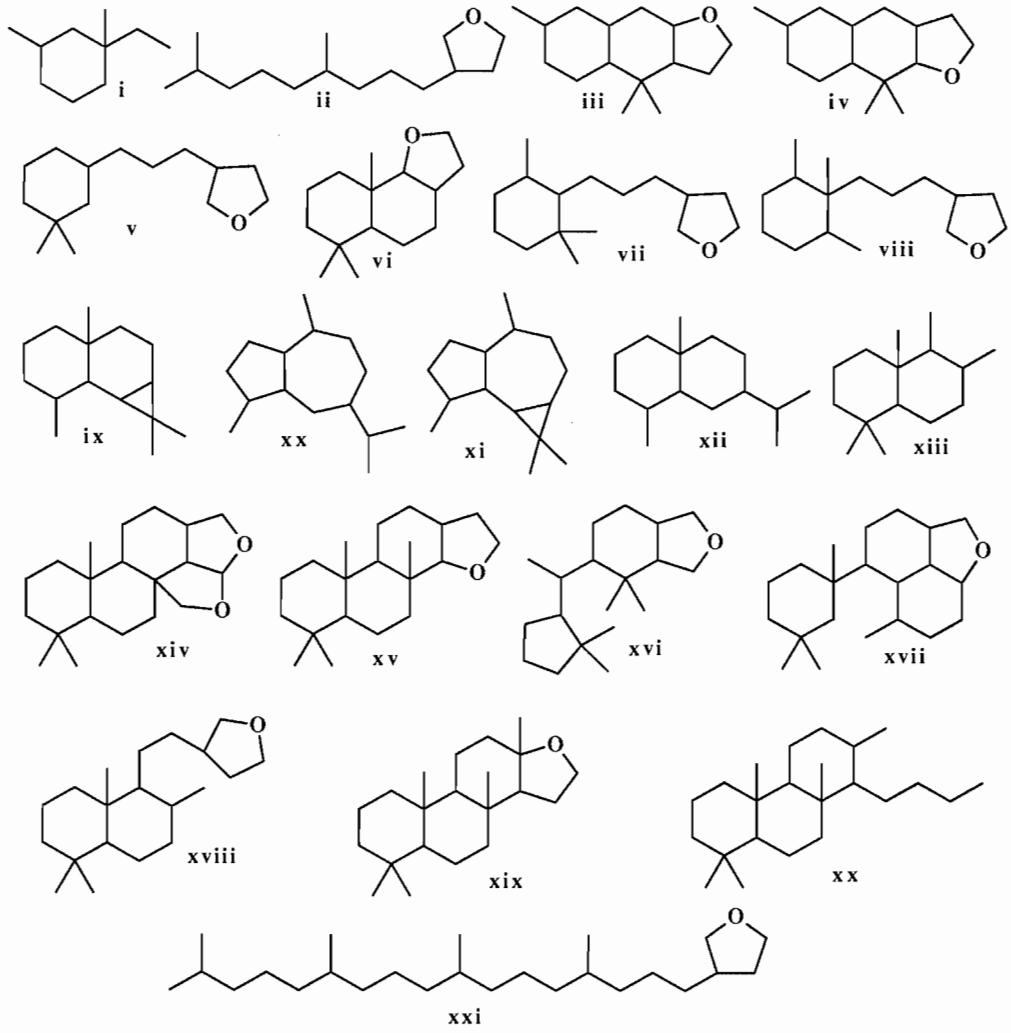
conjugated to the carbonyls (Table 5). The remaining two sites of unsaturation required by the molecular formula of **48** had to be present as rings. A series of NMR experiments further elaborated the γ-lactone fragment. HMBC correlations were observed between an olefinic methine proton resonance at δ 6.87 (H10) and the lactone carbonyl resonance at δ 170.9 (C12) and an acetal carbon resonance at δ 96.4 (C11). The acetal resonance at δ 96.4 (C11) showed a HMQC correlation to a proton resonance at δ 6.11 (bs: H11) that in turn showed COSY correlations to the olefinic methine proton resonance at δ 6.87 (H10) and to an exchangable proton resonance at δ 3.50 (OH). Additional COSY correlations were observed between the olefinic methine proton resonance at δ 6.11 (H10) and a pair of geminal allylic methylene proton resonances at δ 2.03 (H8) and 2.33 (H8′). The above data suggested the presence of an α-methylene-substituted γ-hydroxy-α,β-butenolide fragment in **48**. Comparison of the data listed above for this fragment in **48** with the data reported for the identical fragment in the known compound **50** (^{1}H NMR δ: 6.1 (C*H*OH), 6.8 (O=C-C=C*H*); ^{13}C NMR δ: 172.5, s, 143.5, d, 138.5, s, 97.3, d; IR: 3380 and 1755 cm^{-1}) confirmed the assignment.

COSY correlations between the allylic methylene proton resonances at δ 2.03 (H8) and 2.33 (H8′) and a two-proton multiplet at δ 1.81, assigned via HMQC data to a pair of geminal methylene protons (H7, H7′: C7 δ 33.9) that showed no additional COSY correlations, expanded the α substituent on the hydroxybutenolide fragment to a -CH_2-CH_2- residue. HMBC, HMQC, and COSY data provided evidence for the remaining cyclohexenone fragment of **48** and linked it to the already identified hydroxybutenolide fragment. Thus, HMBC correlations were observed between a methyl proton resonance at δ 1.06 (s, Me15) and carbon resonances assigned to C4 (δ 33.8), C5 (δ 42.1), C6 (δ 167.3), and C7 (δ 33.9); between a methyl proton resonance at δ 1.00 (d, J = 6 Hz, Me14) and carbon resonances assigned to C3 (δ 41.8), C4 (δ 33.8), and C5 (δ 42.1); between a methyl proton resonance at δ 1.98 (s, Me13) and carbon resonances assigned to C1 (δ 128.8), C5 (δ 42.1), and C6 (δ 167.3); between an olefinic methine proton resonance at δ 5.91 (H1) and carbon resonances assigned to C3 (δ 41.8) and Me13 (δ 20.2); and between a methylene proton resonance at δ 2.29 (H3) and a carbon resonance at δ 198.8 assigned to C2. COSY correlations observed between the H1 resonance (δ 5.91) and the Me13 resonance (δ 1.98), and between the H4 resonance (δ 2.33) and both the H3 (δ 2.29) and H3′ (δ 2.37) resonances, were consistent with the proposed structure **48**. Difference nOe's were observed between H4 (δ 2.33) and Me15 (δ 1.06) and between Me14 (δ 1.00) and H7/H7′ (δ 1.81), indicating that the relative stereochemistry at C4 and C5 was as shown in **48**. 2-Oxomicrocionin-2-lactone (**48**) is closely related to microcionin-2 (**17**) (19), which is frequently encountered in skin extracts of B.C. specimens of *C. luteomarginata*.

O-Methyl-2-oxomicrocionin-2-lactone (**49**) was isolated as a clear glass that gave a molecular ion in the HREIMS at *m/z* 278.1508, corresponding to a molecular formula of $C_{16}H_{22}O_4$. Examination of the NMR data obtained for **49** (Table 5) readily showed that it was simply the C12 methoxy analog of **48**. Since methanol was used in the extraction of terpenoids from *Pleraplysilla* sp. it is likely that **49** is an artifact formed from **48** during the extraction process. Similarly, the -OMe residues in compounds **35**, **45**, **43**, and **47** are also probably artifacts introduced during extraction of *C. luteomarginata* and *Pleraplysilla* sp. specimens with methanol.

Samples of an undescribed species of *Aplysilla* were collected in the high intertidal zone at Botanical Beach on Vancouver Island, B.C. Examination of the terpenoids present in the methanol extracts of the *Aplysilla* sp. revealed the presence of the two known compounds marginatafuran (**21**) and 9,11-dihydrogracillin A (**37**) that have both been found repeatedly in *C. luteomarginata* skin extracts. Compounds **21** and **37** were identified by comparison of their spectroscopic data with the literature values (4, 14). A number of additional unknown terpenoids were also encountered in the extracts of *Aplysilla* sp., and their structures, which are currently under investigation, will be reported elsewhere.

Discussion



Chemical investigations of *C. luteomarginata* have resulted in the identification of a truly remarkable collection of terpenoid metabolites. To date, a total of 37 terpenoids representing twenty-one different carbon skeletons (Fig. 6) have been isolated from *C. luteomarginata* skin and egg mass extracts. The 21 carbon skeletons include monoterpenoid, sesquiterpenoid, diterpenoid, sesterterpenoid, degraded diterpenoid, and degraded sesterterpenoid representatives. Four of these skeletons, the marginatane (**xv**) (4), glaciane (**xvi**) (5), cadlinalane (**xx**), and luteane (**xxi**) (1) skeletons, were first encountered in *C. luteomarginata* metabolites. The *C. luteomarginata* terpenoids represent a rarely encountered range of biosynthetic diversity in the secondary metabolites obtained from a single living organism. This great metabolite diversity results primarily from *C. luteromarginata*'s highly developed capabilities for sequestering terpenoids from sponges in its diet. Thus, *C. luteomarginata* has not had to develop the biosynthetic capabilities required to make this wide range of compounds de novo.

A number of interesting observations emerge from a more detailed analysis of the relationship between terpenoids isolated from *C. luteomarginata* and terpenoids isolated from putative dietary sponges. The monoterpenoid violacene (**29**) was found in the sponge *Acanthella* sp. collected in the Queen Charlotte Islands. Violacene (**29**) is a known metabolite of red algae in the genus *Plocamium* (20) and its presence in the sponge *Acanthella* sp. can be best explained by the sponge concentrating the compound from exudates of specimens of *Plocamium* species living near to the sponge. A related observation has been reported by Giordano et al. who isolated halogenated metabolites typical of *Laurencia* species of red algae from the Mediterranean sponge *Mycale rotilis* (21). If this scenario is correct, it represents an interesting example of metabolite transfer from a red alga to a sponge and then to a nudibranch. *Acanthella* sp. collected in both the Queen Charlotte Islands and in Southern California contained the isonitrile (i.e., **7**, **10**, **13**, **26**), isothiocyanate (i.e., **8**, **11**, **14**, **27**), and formamide (i.e., **9**, **12**, **15**, **25**) sesquiterpenoids found in skin extracts of specimens of *C. luteomarginata* collected in both locations.

A major group of *C. luteomarginata* metabolites are sesquiterpenoids, diterpenoids, degraded diterpenoids, and sesterterpenoids that appear to have a common biogenetic origin from linear furanoterpenoid precursors. In California

waters, two of the furanosesquiterpenoids, furodysinin (**1**) and pallescensin-A (**4**), have been found in the dietary sponge *Dysidea amblia*. Idiadione (**6**), the lone furanoseterterpenoid isolated to date from *C. luteromarginata*, has been also found in the California sponge *Spongia idia*. In B.C. waters, the furanosesquiterpenoids furodysinin (**1**) and furodysin (**16**) have now been found in the sponge *Pleraplysilla* sp. The same *Pleraplysilla* sp. contains 2-oxomicrocionin-2-lactone (**48**), an oxidized analog of microcionin-2 (**17**) that has been isolated from B.C. specimens of *C. luteomarginata*. A number of the diterpenoids and degraded diterpenoids isolated from B.C. specimens of *C. luteomarginata* have also been found in two *Aplysilla* sp. collected at the same locales. Thus, *Aplysilla glacialis* has yielded glaciolide (**22**) and cadlinolide A (**23**), while an undescribed species of *Aplysilla* has yielded marginatafuran (**21**) and 9,11-dihydrogracillin A (**37**). Another group of diterpenoids, including tetrahydroaplysulfurin-1 (**24**), the spongians **31**, **32**, **35**, and 20-acetoxy-12-marginatone (**38**), are closely related to known *Aplysilla* metabolites but they have not yet been found in B.C. sponges.

Five terpenoids isolated from B.C. specimens of *C. luteomarginata* do not fit the profile of sequestered metabolites. These are the drimane sesquiterpenoids albicanol (**18**) and albicanyl acetate (**19**) obtained from skin extracts, 1α, 2α-diacetoxyalbicanyl acetate (**40**) obtained from the egg mass, and luteone (**20**) and cadlinaldehyde (**30**) also obtained from skin extracts. Albicanyl acetate (**19**) is the major metabolite found in *C. luteomarginata* extracts at all locations in B.C. and its occurrence over the range of B.C. sites does not show the geographic variation typical of the terpenoids such as furodysinin (**1**) or cadlinolide A (**23**) that are known to be sequestered from sponges. Furthermore, the derivative 1α,2α-diacetoxyalbicanyl acetate (**40**), which was found in the egg mass, has never been found in skin extracts or whole body extracts and, therefore, it seems likely that it is being made in whole or in part by *C. luteomarginata*. Albicanyl acetate (**19**) is a reasonably potent fish antifeedant (2). Therefore, the presence of acetoxy derivatives of **19** in the nudibranch's egg mass suggests a protective role for these compounds and, from an evolutionary perspective, it perhaps makes sense for the nudibranch to produce these compounds de novo in order to have complete control over the critical issue of protection of their egg masses. The possibility of de novo biosynthesis of **18**, **19**, and **40** by *C.*

luteomarginata has precedent in the literature reports that several other species of dorid nudibranchs, including *Dendrodoris limbata* (22) and *Archidoris montereyensis* (10), are capable of de novo biosynthesis of drimane sesquiterpenoids. It has also been reported that *Dendrodoris grandiflora* sequesters sponge metabolites (23) as well as making drimane sesquiterpenoids via de novo biosynthesis (24) and depositing them in its egg masses.

Luteone (**20**) and cadlinaldehyde (**30**) have unprecedented degraded skeletons comprising 23 and 21 carbon atoms, respectively. The luteane and cadlinalane skeletons can be envisaged to arise from degradation of a common tricyclic sesterterpenoid skeleton as shown in Scheme 1. To date, terpenoids related to **20** and **30** have not been detected in extracts of sponges collected in B.C. Since discovering these two compounds and developing competent analytical methodology for detecting them, it has been found that they are present in skin extracts of all B.C. specimens of *C. luteomarginata*, regardless of collection site. Therefore, luteone (**20**) and cadlinaldehyde (**30**) also fail to show the geographic variation within B.C. collecting sites typical of sequestered metabolites, suggesting that they may be biosynthesized de novo by *C. luteomarginata*. Prompted by the above arguments concerning the true origin of compounds **19**, **20**, and **30**, biosynthetic studies have been initiated with *C. luteomarginata* using the stable isotope methodology recently applied to other dorids found in B.C. waters (9–11). Initial results are consistent with de novo biosynthesis of all three compounds. Full details of these experiments will be published elsewhere.

Experimental

General methods

High-performance liquid chromatography was performed on a Waters 501 system using a Perkin–Elmer LC25 refractive index detector. Optical rotations were determined on a Perkin–Elmer 241MC polarimeter. Ultraviolet spectra were recorded using a Hewlett–Packard 8452A diode array spectrophotometer and IR spectra with a Perkin–Elmer 1710 FTIR instrument. ^{1}H, COSY, and nOe NMR experiments were run on a Bruker WH-400 spectrometer and are recorded in ppm referenced to $CDCl_3$ (δ 7.24) or C_6D_6 (δ 7.15). ^{13}C, HMQC, and HMBC NMR experiments were run on a Bruker AMX-500 spectrometer.

Isolation of luteone (20), cadlinaldehyde (30), spongian 32, and secospongian 35

Specimens of *Cadlina luteomarginata* were collected by SCUBA at depths of 10–50 feet in Agamemnon Channel, Jervis Inlet, and in Barkley Sound, B.C. Each collection of animals was processed separately following the same protocol outlined below. The animals were immersed in methanol immediately upon collection and extracted exhaustively with methanol (two times) and methanol/methylene chloride (1:1) (three times). The extracts were combined, reduced in vacuo, and partitioned between water and ethyl acetate. The ethyl acetate extracts were dried over anhydrous magnesium sulfate, combined, and reduced in vacuo to yield a fragrant yellow oil (≈ 500 mg per 20 animals). This oil was fractionated on a silica gel flash column using a gradient eluent system (9:1 hexanes/ethyl acetate to ethyl acetate). Fractions were further purified by C_{18} reversed-phase high-performance liquid chromatography (9:1 methanol/water) to yield pure albicanyl acetate (**19**), luteone (**20**), cadlinaldehyde (**30**), spongian **31**, and spongian **32** from the Agamemnon Channel specimens and albicanyl acetate (**19**), luteone (**20**), cadlinaldehyde (**30**), and seco-spongian **35** from the Barkley Sound specimens.

Luteone (20): white crystalline solid; $[\alpha]^{25}_D$ ($CHCl_3$) +12; UV ($CHCl_3$) λ_{max}: 244 (log ε = 2.42) nm; IR (film) ν_{max}: 3078, 2931, 2849, 2750, 1708, 1646, 1457, 1363, 1161 cm^{-1}; ^{1}H NMR (see Table 1); ^{13}C NMR (see Table 1); HREIMS *m/z*: 344.2717 ($C_{23}H_{36}O_2$ requires 344.2715).

Cadlinaldehyde (30): white amorphous solid subsequently recrystallized from methanol to yield white needles; $[\alpha]^{25}_D$ ($CHCl_3$) +25; UV ($CHCl_3$) λ_{max}: 246 (log ε = 2.66), 250sh (log ε = 2.59) nm; IR (film) ν_{max}: 2926, 2750, 1705, 1457, 1377 cm^{-1}; ^{1}H NMR (see Table 1); ^{13}C NMR (see Table 1); HREIMS *m/z*: 318.2489 ($C_{21}H_{38}O_2$ requires 318.2589).

Spongian 32: colorless oil; IR (film) ν_{max}: 1784, 1755 cm^{-1}; ^{1}H NMR (see Table 2); ^{13}C NMR (see Table 2); HREIMS *m/z*: 376.2249 ($C_{22}H_{32}O_5$ requires 376.2249).

Seco-spongian 35: clear colorless oil; $[\alpha]^{25}_D$ ($CHCl_3$) −5.5; UV ($CHCl_3$) λ_{max}: 248sh (log ε = 2.64), 252 (log ε = 2.68) nm; IR (film) ν_{max}: 2926, 1737, 1464, 1374, 1241 cm^{-1}; ^{1}H NMR (see Table 2); ^{13}C NMR (see Table 2); HRCIMS *m/z*: 422.26805 ($C_{24}H_{38}O_2$ requires 422.26685); HREIMS *m/z*: 391.24876 (M − MeO $C_{23}H_{35}O_5$ requires 391.24844).

Isolation of 20-acetoxymarginatone (38) and lutenenolide (39)

Specimens of *C. luteomarginata* collected at Anthony Island (Queen Charlotte Islands, B.C.) were immersed in methanol immediately upon collection. After one further extraction, the combined methanol extracts were concentrated in vacuo to give an aqueous suspension that was partitioned between water and methanol/methylene chloride (1:1). The water layer was further extracted with methylene chloride and the organic layers combined, dried over magnesium sulfate, and reduced to dryness in vacuo. The resulting oil was fractionated by sequential application of silica gel flash column chromatography, silica gel radial thin-layer chromatography, and normal phase high-performance liquid chromatography, resulting in pure samples of 20-acetoxymarginatone (**38**) (1.8 mg per animal) and lutenenolide (**39**) (0.05 mg per animal).

20-Acetoxymarginatone (38): clear colorless oil; IR (film) ν_{max}: 2937, 2870, 1738, 1681, 1455, 1441, 1234, 1047 cm^{-1}; ^{1}H NMR (see Table 3); ^{13}C NMR (see Table 3); HREIMS *m/z*: 358.2144 ($C_{22}H_{30}O_4$ requires 358.2144).

Lutenolide (39): clear colorless oil; IR (film) ν_{max}: 2928, 1752, 1735, 1654, 1235, 1061 cm^{-1}; ^{1}H NMR (see Table 3); ^{13}C NMR (see Table 3); LRDCIMS (NH_3) *m/z* 378; HREIMS *m/z*: 300.2091 (M − HOAc $C_{20}H_{28}O_2$ requires 300.2089).

Isolation of monoacetoxyalbicanyl diacetate and 1α,2α-diacetoxyalbicanylacetate (40)

During a SCUBA dive in Rennell Sound, Queen Charlotte

Islands, B.C., a specimen of *C. luteomarginata* was found to be laying eggs. The egg mass was collected and worked up as described above for the isolation of 20-acetoxymarginatone (**38**) and lutenenolide (**39**). The egg mass extract yielded the pure compounds monoacetoxyalbicanylacetate (0.3 mg) and 1α,2α-diacetoxyalbicanylacetate (**40**) (1.5 mg). The quantity of monoacetoxyalbicanylacetate that was obtained was not sufficient to permit complete characterization.

Monoacetoxyalbicanylacetate: clear colorless oil; ^{1}H NMR (C_6D_6) δ: 0.64 (s, 3H), 0.75 (s, 3H), 0.88 (s, 3H), 1.75 (s, 3H), 2.06 (s, 3H), 2.30 (m, 1H), 2.68 (m, 1H), 4.15 (t, J = 11.6 Hz, 1H), 4.49 (dd, J = 4,0, 11.6 Hz, 1H), 4.81 (bs, 1H), 4.95 (bs, 2H); HREIMS *m/z*: 322.2140 ($C_{19}H_{30}O_4$ requires 320.1988).

*1*α,2α-Diacetoxyalbicanylacetate (**40**): clear colorless oil; IR (film) ν_{max}: 2937, 1736, 1702, 1458, 1364, 1248, 1039 cm^{-1}; ^{1}H NMR (see Table 4); ^{13}C NMR (see Table 4); HREIMS *m/z*: 320.1985 (M − HOAc $C_{19}H_{28}O_4$ requires 320.1988).

Isolation of terpenoids from *Pleraplysilla* sp.

Samples of *Pleraplysilla* sp. were collected from exposed pools during low tide at Botanical Beach on Vancouver Island, B.C. A voucher sample of *Pleraplysilla* sp. was submitted to Professor Rob van Soest at the University of Amsterdam for identification and archival purposes. The sponge specimens were identified as an undescribed species belonging to the genus *Pleraplysilla*. Freshly collected specimens of *Pleraplysilla* sp. (20 g) were soaked in methanol (30 mL) and stored at 7°C for 5 weeks. The extract was filtered and the methanol filtrate was concentrated in vacuo. The resultant dark oil was partitioned between brine (50 mL) and ethyl acetate (4 × 25 mL). The ethyl acetate extracts were pooled, dried over anhydrous sodium sulfate, and evaporated in vacuo to yield a brown oil (68 mg). This oil was fractionated using Sephadex LH-20 size-exclusion chromatography with ethyl acetate/methanol/water (20:5:2) as the eluent. Terpenoid-rich fractions were pooled and further partitioned using silica gel gradient flash chromatography (diethyl ether/dichloromethane (1:19) to ethyl acetate) followed by normal phase high-performance liquid chromatography (hexane/dichloromethane (3:7)) to yield pure furodysinin lactone (**42**) (2 mg), *O*-methyl furodysinin lactone (**43**) (1 mg), nakafuran-8 lactone (**44**) (1 mg), *O*-methyl nakafuran-8 lactone (**45**) (0.2 mg), blancasterol (**46**) (1 mg), *O*-methyl 9-oxofurodysinin lactone (**47**) (0.5 mg), 2-oxomicrocionin-2 lactone (**48**) (0.8 mg), and *O*-methyl 2-oxomicrocionin-2 lactone (**49**).

O-*Methyl 9-oxofurodysinin lactone (**47**)*: colorless glass; UV λ_{max} (hexane): 220 nm (log ε = 3.43); IR (film) ν_{max}: 1767, 1665 cm^{-1}; CD (hexane) $(\Theta)_{223}$ −31 000; ^{1}H NMR (see Table 5); ^{13}C NMR (see Table 5); HREIMS *m/z*: 276.1371 ($C_{16}H_{20}O_4$ requires 276.1362).

*2-Oxomicrocionin-2 lactone (**48**)*: colorless oil; IR (film) ν_{max}: 3317, 1758, 1650 cm^{-1}; ^{1}H NMR (see Table 5); ^{13}C NMR (see Table 5); HREIMS *m/z*: 264.1317 ($C_{15}H_{20}O_4$ requires 264.1322)

O-*Methyl 2-oxomicrocionin-2 lactone (**49**)*: translucent white glass; IR (film) ν_{max}: 1764, 1663 cm^{-1}; ^{1}H NMR (see Table 5); ^{13}C NMR (see Table 5); HREIMS *m/z*: 278.1508 ($C_{16}H_{22}O_4$ requires 278.1509).

Isolation of terpenoids from *Aplysilla* sp.

Samples of a second sponge, distinct from *Pleraplysilla* sp., were also collected during low tides at Botanical Beach on Vancouver Island, B.C. A voucher sample was submitted to Professor Patricia Berquist, University of Auckland, for taxonomic and archival purposes. The sponge was identified as an undescribed species belonging to the genus *Aplysilla*. A repetition of the extraction procedure described above for *Pleraplysilla* sp. yielded a crude oil from the *Aplysilla* sp. that after fractionation by reversed-phase HPLC gave pure samples of marginatafuran (**21**) (8 mg) and 9,11-dihydrogracillin A (**37**) (2 mg) along with several other unknown diterpenoids.

X-ray diffraction analaysis of cadlinaldehyde (30)

All pertinent crystallographic data are summarized in Table 1 of the Supplementary Material.[2] Data were collected at room temperature on a Siemans R3m/V diffractometer (Cu K_α, λ = 1.54178 Å, graphite monochromator) using ω/2Θ scan mode. Unit-cell parameters were obtained from 25 reflections in the range of 25°–45°. Data were corrected for Lorentz and polarization effects. The structure was solved by direct methods (25) that revealed the presence of two molecules in an asymmetric unit. Hydrogen atoms were introduced geometrically and were given displacement parameters based on the carbon atom to which they were bonded. The structure was refined anisotropically with riding H atoms (26). The two symmetrically independent molecules have essentially the same geometry: weighted r.m.s. deviation is equal 0.021 Å. All calculations were effected on a Pentium IBM compatible computer. Fractional atomic coordinates and isotropic thermal parameters are given in Table 2 of the Supplementary Material. A full table of bond lengths and angles and a table of anisotropic displacement parameters have also been deposited.

Acknowledgements

Funding was provided by grants to R.J.A. from the Natural Sciences and Engineering Research Council of Canada and to J.C. from the National Institues of Health (CA 24487). The authors wish to thank Mike LeBlanc, the staff of the Bamfield Marine Station, and the crew of the J.P. Tulley for assisting the collections of *C. luteomarginata*, and Professor Rob Van Soest, Professor Patricia Bergquist, and Dr. Bill Austin for sponge taxonomy.

Synthesis and evaluation of thio-trisaccharides as acceptors for *N*-acetylglucosaminyltransferase-V

Pu-Ping Lu, Ole Hindsgaul, Hong Li, and Monica M. Palcic

Abstract: *N*-Acetylglucosaminyltransferase-V (GlcNAcT-V) transfers a β-linked GlcNAc residue from UDP-GlcNAc to the 6-OH group of the αMan residue in oligosaccharides terminating in the sequence β-D-Glc*p*NAc-(1→2)-α-D-Man*p*-(1→6)-β-D-Glc*p*-OR (**5**, R = $(CH_2)_7CH_3$). The terminal GlcNAc moiety may be replaced by a Glc residue to produce trisaccharide **6**. Two thio analogs (**7**, **8**) of trisaccharide **6**, where the oxygen atoms in the glycosidic linkages between sugar residues were replaced by sulfur, were prepared by multistep chemical synthesis that made use of the key intermediates 1,2-anhydro-3,4,6-tri-*O*-benzyl-α-D-glucose (**10**) and 1,2-anhydro-3,4,6-tri-*O*-benzyl-β-D-mannose (**13**) as donors for the glycosylations. The thio analogs (**7**, **8**) were kinetically evaluated as substrates for GlcNAcT-V and found to be acceptors with two- to three-fold increase in V_{max} but higher K_m values (**7**, K_m = 376 μM; **8**, K_m = 300 μM) than their parent compound **6** (K_m = 111 μM), which has the natural oxygen linkage. The thio analogs **7** and **8** could be quantitatively converted into the expected product tetrasaccharides (**27**, **28**) by incubation with GlcNAcT-V and UDP-GlcNAc. The enzymatic results indicate that GlcNAcT-V tolerates the substitution of the natural oxygen linkage of the acceptor by a sulfur linkage.

Key words: *N*-acetylglucosaminyltransferase-V, enzyme acceptors, trisaccharide analogs, thioglycosides.

Résumé : La *N*-acétylglucosaminyltransférase-V (GlcNAcT-V) permet de transférer un résidu GlcNAc lié en β d'un UDP-GlcNAc à un groupe 6-OH d'un résidu α-Man d'oligosaccharides se terminant par une séquence β-D-Glc*p*NAc-(1→2)-α-D-Man*p*-(1→6)-β-D-Glc*p*-OR (**5**, R = $(CH_2)_7CH_3$). On peut remplacer la portion GlcNAc terminale par un résidu Glc pour produire le trisaccharide **6**. En procédant à une synthèse en plusieurs étapes faisant appel aux intermédiaires clés 1,2-anhydro-3,4,6-tri-*O*-benzyl-α-D-glucose (**10**) et 1,2-anhydro-3,4,6-tri-*O*-benzyl-β-D-mannose (**13**) comme donneurs lors des glycosylations, on a préparé deux analogues thio (**7**, **8**) du trisaccharide **6**, dans lesquels les atomes d'oxygène des liaisons glycosidiques entre les unités de sucre ont été remplacés par des atomes de soufre. On a évalué le comportement cinétique des dérivés thio (**7**, **8**) comme substrats de la GlcNAcT-V et on a trouvé qu'ils sont de meilleurs accepteurs avec des augmentations par des facteurs de 2 à 3 dans les valeurs de V_{max}; les valeurs de K_m sont toutefois plus élevées (**7**, K_m = 376 μM; **8**, K_m = 300 μM) que celle de leur composé parent (**6**, K_m = 111 μM) comportant la liaison oxygénée normale. Par incubation avec de la GlcNAcT-V et du UDP-GlcNAc, on peut transformer quantitativement les analogues thio en tétrasaccharides attendus (**27**, **28**). Les résultats enzymatiques indiquent que la GlcNAcT-V tolère la substitution de la liaison oxygène naturelle de l'accepteur par une liaison sulfurée.

Mots clés : *N*-acétylglucosaminyltransférase-V, accepteurs d'enzyme, analogues trisaccharides, thioglycosides.

[Traduit par la rédaction]

Introduction

UDP-GlcNAc: α-mannoside β (1→6)-*N*-acetylglucosaminyltransferase-V (GlcNAcT-V, EC 2.4.1.155) transfers an *N*-acetyl-D-glucosamine (GlcNAc) residue from uridine 5′-diphospho-GlcNAc (UDP-GlcNAc) to natural glycopeptide acceptors bearing the minimum heptasaccharide sequence **1** (Scheme 1), converting it to the octasaccharide **2** (1, 2). This enzyme plays a key role in the biosynthesis of highly branched asparagine-linked oligosaccharides (1, 2). A strong correlation between an increase in the activity of this enzyme and the increased metastatic potential of several cancer cell lines has been demonstrated (3–5). This enzyme has, therefore, become a target for the development of glycosyltransferase inhibitors.

Knowledge of the detailed substrate specificity of GlcNAcT-V is essential for a rational approach to inhibitor design. We previously found that the much simpler synthetic trisaccharide **3**, a partial structure of **1**, is also an effective substrate for the enzyme, yielding the expected tetrasaccharide **4** (6). The enzyme tolerates the substitution of the βMan residue in **3** by a βGlc residue since trisaccharide **5** was found to be an excellent acceptor (7). The enzyme further tolerates the substitution of the terminal GlcNAc moiety by a βGlc

residue, since the trisaccharide **6** was also found to be a good acceptor (8). The aliphatic aglycons in **3** and **5** were incorporated into these structures in order to facilitate the enzyme assay procedures (9). We report here a continuation of these enzyme-specificity studies where the requirement of the natural intra-residue oxygen linkage of **6** in substrate recognition by GlcNAcT-V is probed through the synthesis and enzymatic analysis of the two thio analogs **7** and **8**, which have an intersaccharidic sulfur atom. The use of the 1,2-anhydro sugars (glycal epoxides) as building blocks provided short synthetic routes to these thio-linked trisaccharides.

Results and discussion

Since only small (mg) quantities of **7** and **8** were required, the synthetic plan was to devise short reaction sequences even if yields were found to be low by normal synthetic criteria. The retrosynthetic analysis for the preparation of **7** and **8** is shown in Scheme 2. In designing the synthesis of **7**, we chose 1,2-anhydro-3,4,6-tri-*O*-benzyl-α-D-glucopyranose (**10**) as the central building block. The opening of epoxide **10** by **9** was expected to produce an α/β mixture of disaccharides with OH-2′ free. After conversion of OH-2′ into a leaving group, S_N2 displacement using a protected 1-thio-D-glucose (**11**) was then envisioned to produce the desired trisaccharide. In designing the synthesis of **8**, we chose 1,2-anhydro-3,4,6-tri-*O*-benzyl-β-D-mannopyranose (**13**) as the central building block. The opening of the epoxide **13** by highly nucleophilic **12** would provide a disaccharide with OH-2′ free for further coupling to give the desired trisaccharide.

The three building blocks required for the synthesis of **7** were prepared according to published procedures (**9** (7), **10** (10), **11** (11)). The coupling of **10** with alcohol **9** was carried out in THF at −78°C using trifluoromethanesulfonic acid as catalyst, to afford the desired α-linked disaccharide **15** along with the β-linked disaccharide **16** in 24% and 47% yield, respectively (based on consumed alcohol). Treatment of **15** with excess trifluoromethanesulfonic anhydride in anhydrous pyridine gave the 2′-triflate (**17**) in quantitative yield. The S_N2 displacement of **17** was carried out by using the sodium salt of the 1-thio-D-glucose derivative (**11**) in DMF. The sodium salt was made by treating **11** with sodium hydride in THF. The trisaccharide **18** was obtained in 25% yield. Zemplén deacetylation of **18** yielded **19**. Final debenzylation of **19** by treatment with Na/liquid NH_3 afforded target trisaccharide **7** in 79% yield (Scheme 3).

For the synthesis of **8**, compound **13** was prepared by treatment of 3,4,6-tri-*O*-benzyl-D-mannopyranose (12) with hydrogen chloride in ether, followed by work-up with NH_3 (13). Mesylation of **9**, followed by reaction with potassium thioacetate and deacetylation, provided **12** with the required free 6-thiol group (Scheme 4). Imidate (**14**) was prepared from hemiacetal **23** by reaction with trichloroacetonitrile and sodium hydride in dichloromethane according to standard procedures (14). Compound **23** was prepared by treating **22** (15) with silver carbonate in wet acetone (Scheme 4). The opening of the epoxide **13** by the sodium salt of **12** gave the α-linked disaccharide **24** (63%) with OH-2′ for subsequent coupling. Using *O*-(2-*O*-acetyl-3,4,6-tri-*O*-benzyl-α-D-glucopyranosyl)-trichloroacetimidate (**14**) as donor, glycosylation of **24** afforded the desired β-linked trisaccharide in 88% yield. After Zemplén deacetylation (92%), debenzylation with Na/liquid NH_3 furnished the target trisaccharide in 82% yield (Scheme 5).

Compounds **7** and **8** were characterized by ^1H NMR, ^1H–^1H 2D COSY, ^{13}C NMR (APT), HMQC, and high-resolution FAB mass spectrometry. The anomeric configurations of the mannopyranosyl and glucopyranosyl linkages were further verified by measurement of the ^1J heteronuclear coupling constants (16) of the anomeric carbon atoms for compounds **7** and **8**.

Evaluation of thioglycoside analogs as acceptors for GlcNAcT-V

Compounds **7** and **8** and the unmodified structure **6** were kinetically evaluated as acceptors for GlcNAcT-V using the cloned rat kidney enzyme (17). The enzyme experiments were performed according to a well-established radioactive "Sep-Pak assay" method (9, 18–20). The results of the kinetic evaluations are reported in Table I. Both compounds (**7**, **8**) are relatively good substrates for GlcNAcT-V. The V_{max} values are two- to three-fold higher than those of their parent compound (**6**); however, their binding is likely weaker as reflected in the higher K_m values for the analogs. Trisaccharide **8** was also evaluated with GlcNAcT-V isolated from hamster kidney (18–20). As was previous found (21), both sources of GlcNAcT-V have essentially identical substrate specificity.

To confirm that the thio analogs **7** and **8** were indeed acceptors of GlcNAcT-V, preparative enzymatic syntheses were performed. When the acceptors were incubated with UDP-GlcNAc and GlcNAcT-V, the enzyme transferred a β-D-GlcNAc residue to the 6-OH of the core D-Man*p* unit of the acceptors, converting **7** and **8** into the expected tetrasaccharides **27** and **28**, respectively (Scheme 6). The structures of tetrasaccharides **27** and **28** were confirmed by ^1H NMR and FAB mass spectrometry.

This work indicates that neither of the intersaccharidic oxygen atoms in the trisaccharide acceptor are involved in specific recognition by GlcNAcT-V. The enzyme tolerates the substitution of the natural intersaccharidic oxygen linkages by sulfur. Since thioglycosides are resistant to cleavage by glycosidases, these structures should prove useful as metabolically stable acceptors for assaying GlcNAcT-V.

Experimental

General methods

TLC was performed on Silica Gel 60-F254 (E. Merck) with detection by quenching of fluorescence, and (or) by charring

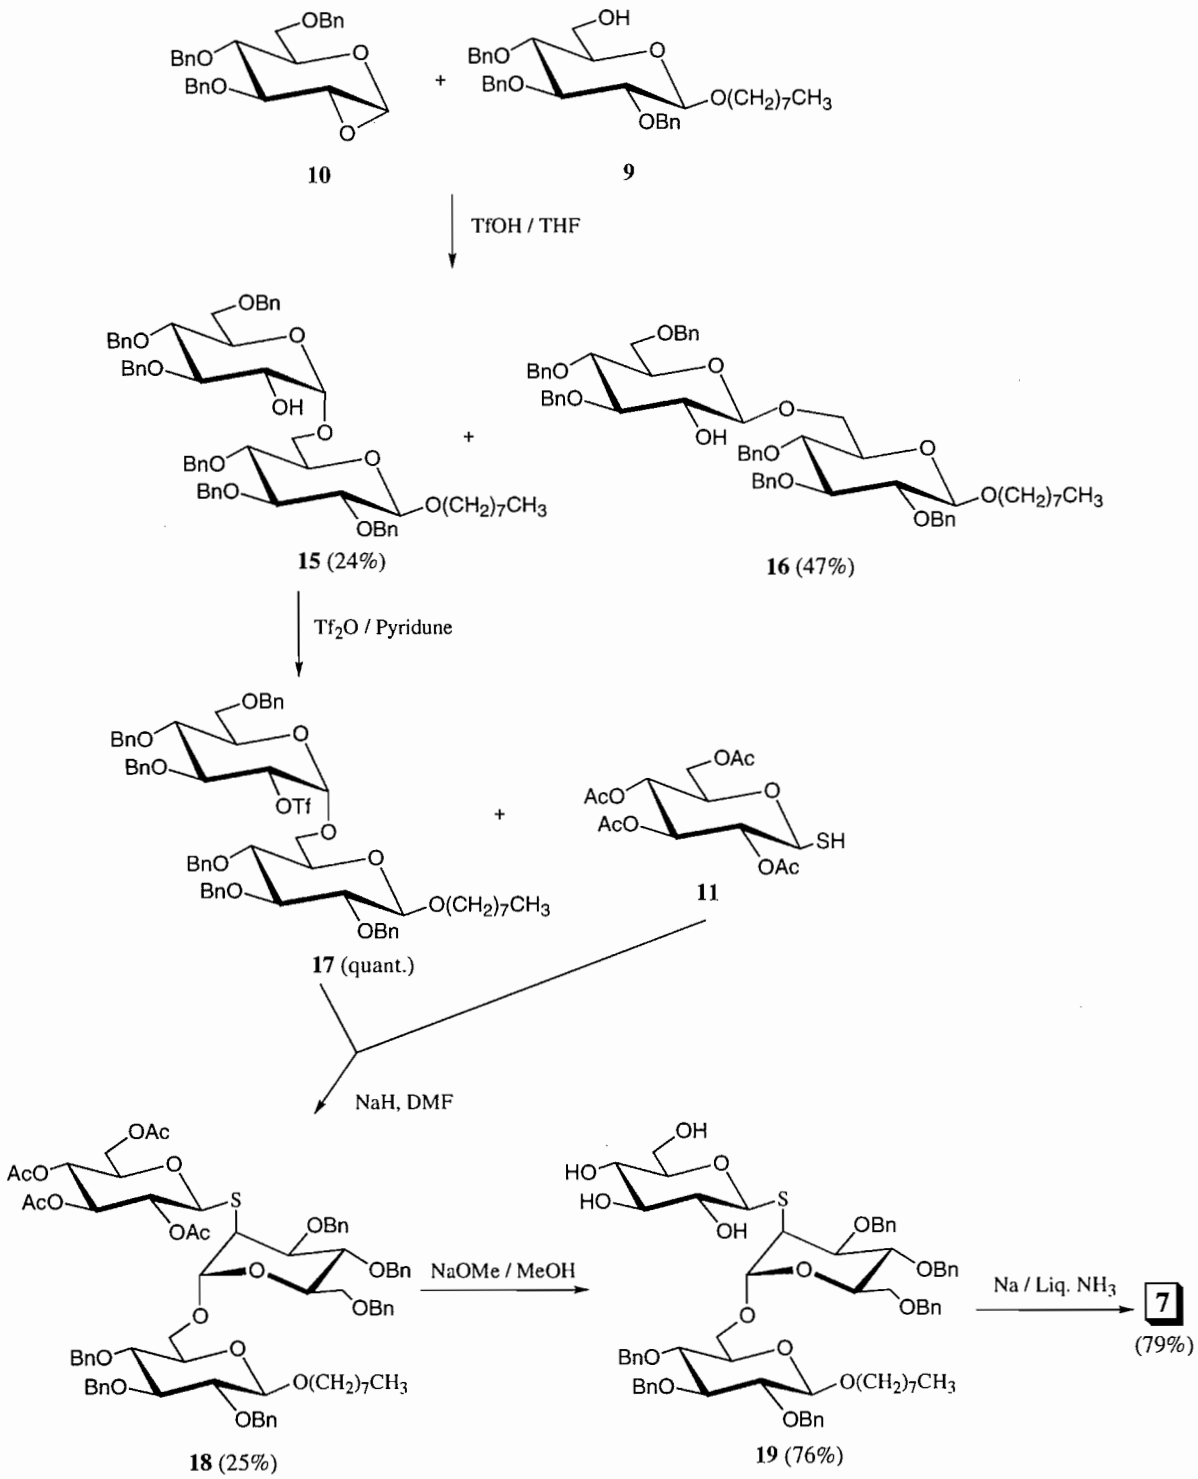
with H_2SO_4. Unless otherwise noted, column chromatography was performed on Silica Gel 60 (E. Merck, 40–63 mm). Iatrobeads were from Iatron Laboratories, Inc. (Japan). C-18 Sep-Pak sample preparation cartridges were from Waters Associates. Millex-GV (0.22 μm) filter units were from Millipore. Optical rotations were measured with a Perkin–Elmer 241 polarimeter at 22°C. IR spectra were recorded with a Nicolet SX-20 FTIR by the spectral services laboratory of the Chemistry Department. ^{1}H NMR spectra were recorded at 360 MHz (Bruker AMR 360), at 400 MHz (Bruker AM 400), or at 500 MHz (Varian UNITY 500) on solutions in $CDCl_3$ (internal Me_4Si, δ 0) or D_2O. ^{13}C NMR spectra were recorded at 75.5 MHz, 100.6 MHz, or 125 MHz, respectively, on the same instruments in $CDCl_3$ (internal Me_4Si δ 0) or D_2O (internal 1,4-dioxane, δ 67.4). The assignments of ^{13}C NMR are tentative. FAB mass spectra (FAB MS) were obtained on a Kratos AEIMS9 instrument using glycerol as matrix. Electrospray ionization mass spectra (ESI MS) were obtained from a Micromass ZabSpec Hybrid Sector-TOF instrument using methanol–toluene as liquid carrier. Elemental analyses were carried out on a Carlo Erba EA1108. For the enzyme experiments, cloned rat kidney GlcNAcT-V was a generous gift from Dr. M. Pierce (17); partially purified GlcNAcT-V was isolated from hamster kidney by a modification (20) of published procedures (18, 19). UDP-^{3}H-GlcNAc was from American Radiolabeled Chemicals, Inc. (specific activity 40–60 Ci/mmol). UDP-GlcNAc (disodium salt) was from Sigma.

Octyl 3,4,6-tri-*O*-benzyl-α-D-glucopyranosyl-(1→6)-2,3,4-tri-*O*-benzyl-β-D-glucopyranoside (15)



A mixture of **9** (7) (600 mg, 1.07 mmol) and trifluoromethanesulfonic acid (17.6 μL, 0.2 mmol) in dry THF (20 mL) was cooled to −78°C. To the resulting mixture was added dropwise a solution of 1,2-anhydro-3,4,6-tri-*O*-benzyl-α-D-glucopyranose **10** (432 mg, 1.0 mmol) in dry THF (10 mL). The reaction mixture was stirred at −78°C for 2 h, then warmed to room temperature (r.t.) and stirred for 10 h. The reaction mixture was then concentrated and the residue was dissolved in

9.5 Hz, H-2), 0.87 (t, 3H, J_{vic} 7.0 Hz, octyl CH_3); ^{13}C NMR (100.6 MHz) δ: 138.5, 138.4, 138.0 (benzyl C1), 128.4, 128.4, 128.3, 128.1, 128.0, 127.9, 127.8, 127.7, 127.64, 127.59, 127.5 (Ar), 103.5 (C-1), 99.2 (C-1′), 75.7, 75.2, 74.94, 74.86, 74.83, 73.4 (Ph*C*H_2), 70.2 (octyl C1), 68.4 (C-6″), 67.0 (C-6), 31.8, 29.8, 29.4, 29.2, 26.2, 22.6 (octyl C2–C7), 14.1 (octyl CH_3). Anal. calcd. for $C_{62}H_{74}O_{11}$ (995.27): C 74.82, H 7.49; found: C 74.90, H 7.61.

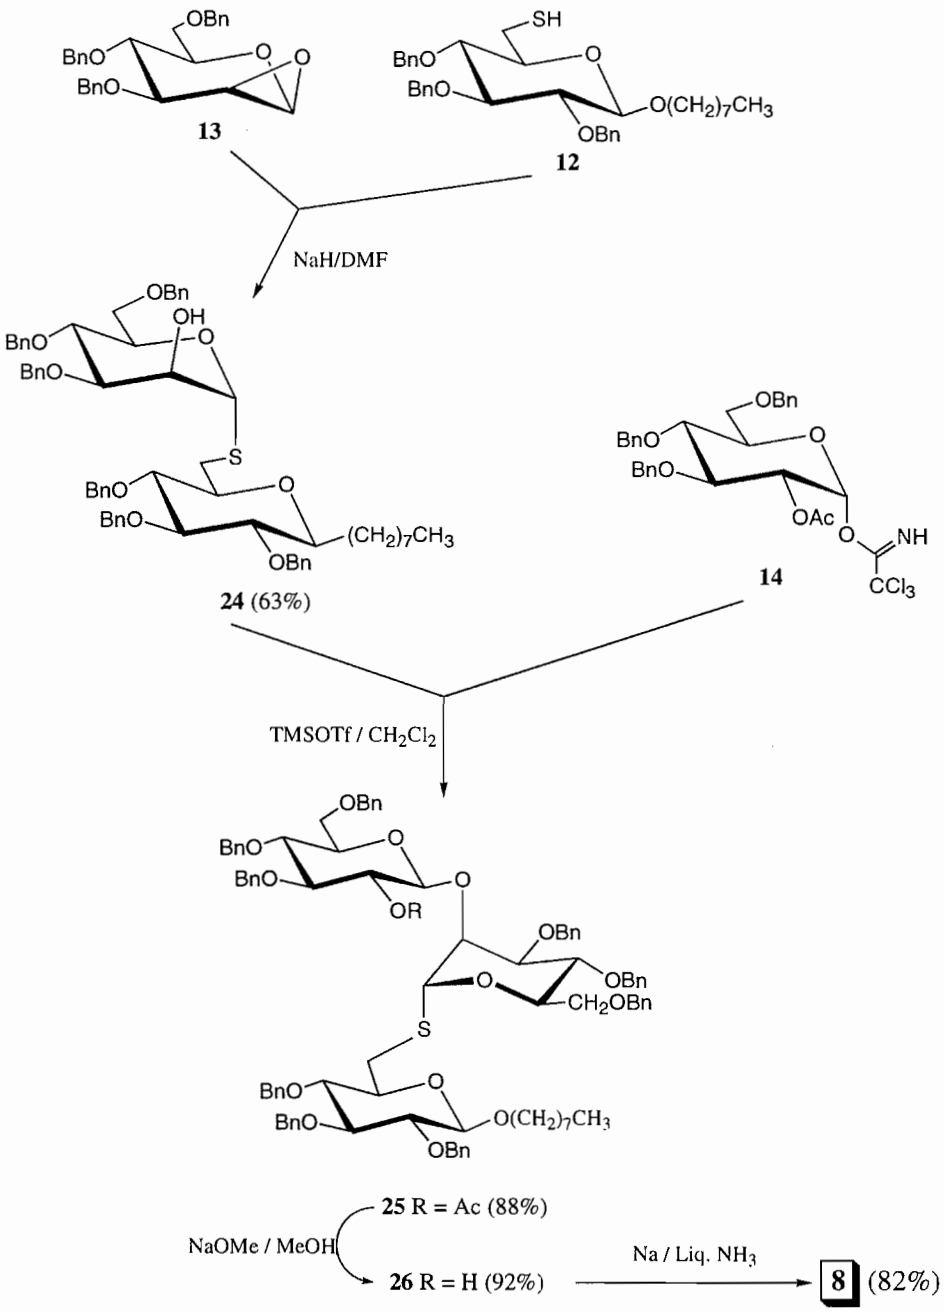
Octyl 3,4,6-tri-*O*-benzyl-2-*O*-trifluoromethanesulfonyl-α-D-glucopyranosyl-(1→6)-2,3,4-tri-*O*-benzyl-β-D-glucopyranoside (17)

To a mixture of compound **15** (115 mg, 0.116 mmol) in dry pyridine (2 mL) at −22°C was added trifluoromethanesulfonic anhydride (85 μL, 0.505 mmol). The reaction mixture was allowed to warm to r.t. and then stirred for 1 h. After addition of ice-cold 1 M HCl (10 mL), the reaction mixture was stirred for 30 min and extracted with CH_2Cl_2. The CH_2Cl_2 solution was washed with saturated $NaHCO_3$ and water, and dried over anhydrous $MgSO_4$. Filtration followed by evaporation of the CH_2Cl_2 gave the title product (130 mg, 100%) as a syrup. ^1H NMR (360 MHz, $CDCl_3$) δ: 7.40–7.05 (m, 30H, Ar-H), 5.175 (d, 1H, $J_{1',2'}$ 3.5 Hz, H-1′), 4.96, 4.95, 4.94, 4.89, 4.85, 4.78, 4.78, 4.76 (8d, each 1H, J_{gem} 11.0 Hz, $PhCH_2$), 4.74 (dd, 1H, $J_{2',3'}$ 9.5 Hz, H-2′), 4.71 (d, 1H, J_{gem} 11.0 Hz, $PhCH_2$), 4.60 (d, 1H, J_{gem} 12.0 Hz, $PhCH_2$), 4.58 (d, 1H, J_{gem} 11.0 Hz, $PhCH_2$), 4.45 (d, 1H, J_{gem} 12.0 Hz, $PhCH_2$), 4.39 (d, 1H, $J_{1,2}$ 7.8 Hz, H-1), 4.05 (dd, 1H, $J_{3',4'}$ 9.5 Hz, H-3′), 0.87 (t, 3H, J_{vic} 7.0 Hz, octyl CH_3).

Octyl 2,3,4,6-tetra-*O*-acetyl-β-D-glucopyranosyl-(1→2)-3,4,6-tri-*O*-benzyl-2-deoxy-2-thio-α-D-mannopyranosyl-(1→6)-2,3,4-tri-*O*-benzyl-β-D-glucopyranoside (18)

To a solution of 2,3,4,6-tetra-*O*-acetyl-1-thio-β-D-glucopyranose **11** (11) (105 mg, 0.288 mmol) in dry THF (2 mL) was added sodium hydride (60% suspension in oil, 13 mg, 0.318 mmol). The mixture was stirred, resulting in the evolution of bubbles. After the sodium salt (white solid in THF) was produced, the THF was evaporated using a stream of argon. To the resulting residue was added a solution of **17** (130 mg, 0.115 mmol) in dry DMF (2 mL). The reaction mixture was stirred at r.t. for 12 h, and methanol (2 mL) was added to quench the reaction. The reaction mixture was concentrated to dryness and the residue was dissolved in CH_2Cl_2 (10 mL). The CH_2Cl_2 solution was washed with water, dried over $MgSO_4$, filtered, and concentrated. Purification of the residue by column chromatography using hexane–EtOAc (2:1) as eluant gave the title compound (38 mg, 25%); ^1H NMR (360 MHz, $CDCl_3$) δ: 5.24 (dd, 1H, $J_{2'',3''}$, $J_{3'',4''}$ 9.2 Hz, H-3″), 5.14 (dd, 1H, $J_{1',2'}$ 2.0 Hz, H-1′), 5.10 (dd, 1H, $J_{4'',5''}$ 9.5 Hz, H-4″), 5.06 (dd, 1H, $J_{1'',2''}$ 9.6 Hz, H-2″), 4.98, 4.95, 4.86, 4.82, 4.81, 4.80. 4.78, 4.71 (8d, each 1H, J_{gem} 11.0 Hz, $PhCH_2$), 4.48 (d, 1H, H-1″), 4.40 (d, 1H, $J_{1,2}$ 8.0 Hz, H-1), 4.37 (d, 1H, J_{gem} 10.5 Hz, $PhCH_2$), 4.22 (dd, 1H, J_{gem} 12.5 Hz, $J_{5'',6''a}$ 5.5 Hz, H-6″a), 4.14 (dd, 1H, $J_{5'',6''b}$ 2.0 Hz, H-6″b), 3.38 (dd, 1H, $J_{2,3}$ 9.0 Hz, H-2), 2.01, 1.98, 1.97, 1.96 (4s, each 3H, 4 Ac), 0.87 (t, 3H, J_{vic} 7.0 Hz, octyl CH_3); ^{13}C NMR (75.5 MHz) δ: 174.2, 170.6, 170.1, 169.4 (C═O), 138.5, 138.4, 138.2, 138.1, 137.9 (benzyl C1), 128.5, 128.4, 128.3, 128.2, 128.1, 128.0, 127.9, 127.9, 127.8, 127.6, 127.5 (Ar), 103.7 (C-1), 101.3 (C-1″), 87.6 (C-1′), 70.5 (octyl C1), 68.8 (C-6″), 66.1 (C-6), 62.3 (C-6′), 47.0 (C-2′), 31.7, 29.7, 29.5, 29.3, 26.2, 22.7 (octyl C2–C7), 20.7 (*C*H_3CO), 14.10 (octyl CH_3). ESI MS *m/z*: 1363.7 $(M+Na)^+$.

Octyl β-D-glucopyranosyl-(1→2)-3,4,6-tri-*O*-benzyl-2-deoxy-2-thio-α-D-mannopyranosyl-(1→6)-2,3,4-tri-*O*-benzyl-β-D-glucopyranoside (19)



Compound **18** (30 mg, 22.4 μmol) was treated with methan-

Octyl β-D-glucopyranosyl-(1→2)-2-deoxy-2-thio-α-D-mannopyranosyl-(1→6)-β-D-glucopyranoside (7)

A solution of **19** (13 mg, 11.1 μmol) in THF (0.5 mL) was added to a mixture of liquid NH_3 (10 mL, distilled over Na) and *tert*-butanol (50 μL) at −78°C. Small pieces of sodium were added until the reaction mixture remained blue, and the mixture was stirred at −78°C for 4 h. Ammonium chloride (solid) was then added until the blue color disappeared. The liquid NH_3 was allowed to evaporate slowly and the remaining solution was concentrated to dryness. The residue was dissolved with Milli-Q water. The aqueous solution was loaded onto a C-18 Sep-Pak cartridge. The cartridge was washed with water (2 × 10 mL) followed by methanol (10 mL). The methanolic eluate was concentrated to dryness. The residue was dissolved with Milli-Q water, passed through a Millex filter, and the filtrate was lyophilized to give **7** (5.5 mg, 79%); $[\alpha]_D$ +1.1 (*c* 0.7, CH_3OH); ^1H NMR (500 MHz, D_2O) δ: 5.15 (d, 1H, $J_{1',2'}$ 1.0 Hz, H-1′), 4.55 (d, 1H, $J_{1'',2''}$ 10.0 Hz, H-1″), 4.45 (d, 1H, $J_{1,2}$ 8.0 Hz, H-1), 4.18 (dd, 1H, $J_{2',3'}$ 4.5 Hz, $J_{3',4'}$ 9.5 Hz, H-3′), 3.91 (dd, 1H, J_{gem} 11.2 Hz, $J_{5,6a}$ 5.4 Hz, H-6a), 3.88 (dd, 1H, J_{gem} 12.5 Hz, $J_{5',6'a}$ 2.2 Hz, H-6′a), 3.84 (dd, 1H, J_{gem} 11.9 Hz, $J_{5'',6''a}$ 2.5 Hz, H-6″a), 3.78 (dd, 1H, $J_{5,6b}$ 2.0 Hz, H-6b), 3.72 (dd, 1H, $J_{5',6'b}$ 6.9 Hz, H-6′b), 3.67 (dt, 1H, J_{gem} 10.5 Hz, J_{vic} 7.0 Hz, octyl C1-H_b), 3.63 (dd, 1H, H-2′), 3.58 (m, 1H, H-5), 3.51 (dd, 1H, $J_{4',5'}$ 9.6 Hz, H-4′), 3.48 (dd, 1H, $J_{2'',3''}$, $J_{3'',4''}$ 9.6 Hz, H-3″), 3.45 (dd, 1H, $J_{2,3}$, $J_{3,4}$ 9.5 Hz, H-3), 3.42 (dd, 1H, $J_{4'',5''}$ 9.5 Hz, H-4″), 3.36 (dd, 1H, H-2″), 3.25 (dd, 1H, H-2), 1.62 (p, 2H, J_{vic} 7.0 Hz, octyl C2-H), 1.38–1.24 (m, 10H, octyl CH_2), 0.86 (t, 3H, J_{vic} 7.0 Hz, octyl CH_3); ^{13}C NMR (125.7 MHz, D_2O) δ: 103.2 (C-1, $J_{C\text{-}1,H\text{-}1}$ 160.4 Hz), 101.3 (C-1′, $J_{C\text{-}1',H\text{-}1'}$ 174.3 Hz), 86.0 (C-1″, $J_{C\text{-}1'',H\text{-}1''}$ 156.4 Hz), 80.8 (C-3), 77.84 (C-5″), 76.9 (C-3″), 74.9 (C-5), 74.0 (C-5′), 73.8 (C-2), 73.1 (C-2″), 71.6 (octyl C1), 70.4 (C-4), 70.2 (C-4″), 69.7 (C-3′), 68.6 (C-4′), 66.7 (C-6), 61.6 (C-6′), 61.4 (C-6″), 51.1 (C-2′), 31.9, 29.6, 29.3, 29.2, 25.9, 22.9 (octyl C2–C7), 14.3 (octyl CH_3): FAB MS *m/z*: 671.0 $(M+K)^+$, 655.0 $(M+Na)^+$, 633.0 $(M+H)^+$.

Octyl 2,3,4-tri-*O*-benzyl-6-*O*-methanesulfonyl-β-D-glucopyranoside (20)

To a solution of **9** (213 mg, 0.370 mmol) in pyridine at −25°C was added dropwise methanesulfonyl chloride (292 μL, 3.79 mmol). The reaction mixture was warmed to r.t. over 30 min and stirred at r.t. for 4 h. The mixture was then poured into ice-cold 0.5 N aqueous HCl and extracted with CH_2Cl_2. The CH_2Cl_2 solution was washed by saturated $NaHCO_3$ and water. Concentration gave **20** (234 mg, 97%). ^1H NMR (360 MHz, $CDCl_3$) δ: 7.35–7.10 (m, 15H, Ar-H), 4.96, 4.94, 4.89, 4.80, 4.71, 4.62 (6d, each 1H, J_{gem} 11.0 Hz, $PhCH_2$), 4.46 (dd, 1H, J_{gem} 11.5 Hz, $J_{5,6a}$ 1.0 Hz, H-6a), 4.41 (d, 1H, $J_{1,2}$ 7.8 Hz, H-1), 4.33 (dd, 1H, $J_{5,6b}$ 4.0 Hz, H-6b), 3.90 (dt, 1H, J_{gem} 10.0 Hz, J_{vic} 6.5 Hz, octyl C1-H_a), 3.67 (ddd, 1H, $J_{4,5}$ 9.5 Hz, H-5), 3.59 (dt, 1H, octyl C1-H_b), 3.42 (dd, 1H, $J_{2,3}$ 9.2 Hz, H-2), 3.03 (s, 3H, mesyl CH_3), 1.63 (p, 2H, J_{vic} 7.0 Hz, octyl C2-H), 1.41–1.19 (m, 10 H, octyl CH_2), 0.88 (t, 3H, J_{vic} 7.0 Hz, octyl CH_3).

Octyl 6-*S*-acetyl-2,3,4-tri-*O*-benzyl-6-deoxy-6-thio-β-D-glucopyranoside (21)

A mixture of **20** (230 mg, 0.359 mmol) and potassium thioacetate (433 mg, 3.79 mmol) in dry DMF (15 mL) was stirred at r.t. for 16 h. TLC showed incomplete reaction. The reaction mixture was then stirred at 40°C for an additional 2 h and concentrated to dryness. The residue was dissolved in CH_2Cl_2,

washed with water, and concentrated. The residue was purified by silica gel chromatography using hexane–EtOAc (6:1) as eluant to afford **21** (195 mg, 88%). ^{1}H NMR (360 MHz, $CDCl_3$) δ: 7.35–7.10 (m, 15H, Ar-H), 4.95, 4.93, 4.88, 4.78, 4.70, 4.64 (6d, each 1H, J_{gem} 11.0 Hz, $PhCH_2$), 4.36 (d, 1H, $J_{1,2}$ 8.0 Hz, H-1), 3.91 (dt, 1H, J_{gem} 9.8 Hz, J_{vic} 7.0 Hz, octyl C1-H_a), 3.63 (dd, 1H, $J_{2,3}$, $J_{3,4}$ 9.5 Hz, H-3), 3.60 (dd, 1H, J_{gem} 14.0 Hz, $J_{5,6a}$ 2.7 Hz, H-6a), 3.57 (dt, 1H, octyl C1-H_b), 3.46–3.31 (m, 3H, H-2, H-4, H-5), 2.97 (dd, 1H, $J_{5,6b}$ 7.5 Hz, H-6b), 2.36 (s, 3H, CH_3CO), 1.65 (p, 2H, J_{vic} 7.0 Hz, octyl C2-H), 0.89 (t, 3H, J_{vic} 7.0 Hz, octyl CH_3); ^{13}C NMR (75.5 MHz, $CDCl_3$) δ: 194.9 (C=O), 138.5, 138.4, 137.8 (benzyl C1), 128.5, 128.4, 128.34, 128.26, 128.1, 127.9, 127.6 (Ar), 103.5 (C-1), 75.7, 75.1, 74.8 (Ph*C*H_2), 31.8 (C-6), 31.1 (octyl C2), 30.5 (*C*H_3CO), 29.8, 29.4, 29.2, 26.2, 22.7 (octyl C3–C7), 14.1 (octyl CH_3). Anal. calcd. for $C_{37}H_{48}O_6S$ (620.84): C 71.58, H 7.79, S 5.16; found: C 71.27, H 8.15, S 5.52.

Octyl 2,3,4-tri-*O*-benzyl-6-deoxy-6-thio-β-D-glucopyranoside (12)

Compound **21** (133 mg, 0.214 mmol) was treated with methanolic NaOMe (0.05 N, 45 mL) at r.t. for 30 min. Neutralization with Amberlite IR-120 (H^+) resin, removal of the resin by filtration, and concentration gave **12** (124 mg, 96%); ^{1}H NMR (360 MHz, $CDCl_3$) δ: 7.40–7.10 (m, 15H, Ar-H), 4.96, 4.95, 4.89, 4.79, 4.72, 4.62 (6d, each 1H, J_{gem} 11.0 Hz, $PhCH_2$), 4.42 (d, 1H, $J_{1,2}$ 8.0 Hz, H-1), 3.95 (dt, 1H, J_{gem} 9.6 Hz, J_{vic} 6.5 Hz, octyl C1-H_a), 3.66 (dd, 1H, $J_{2,3}$, $J_{3,4}$ 9.5 Hz, H-3), 3.56 (dt, 1H, octyl C1-H_b), 3.47 (dd, 1H, $J_{4,5}$ 9.5 Hz, H-4), 3.43 (dd, 1H, $J_{2,3}$ 9.5 Hz, H-2), 3.37 (ddd, 1H, $J_{5,6a}$ 2.8 Hz, $J_{5,6b}$ 7.5 Hz, H-5), 2.89 (ddd, 1H, J_{gem} 14.0 Hz, $J_{6a,SH}$ 9.5 Hz, H-6a), 2.63 (ddd, 1H, $J_{6b,SH}$ 7.6 Hz, H-6b), 1.70 (dd, 1H, SH, D_2O exchangeable), 1.66 (p, 2H, J_{vic} 7.0 Hz, octyl C2-H), 0.88 (t, 3H, J_{vic} 7.0 Hz, CH_3).

2-*O*-Acetyl-3,4,6-tri-*O*-benzyl-α-D-glucose (23)

To a solution of 2-*O*-acetyl-3,4,6-tri-*O*-benzyl-α-D-glucopyranosyl bromide (**22**) (15) (313 mg, 0.563 mmol) in acetone (4 mL) at 0°C was added water (1 drop) and silver carbonate (192 mg, 0.698 mmol). The reaction mixture was vigorously stirred, warmed to r.t., and stirred overnight. The reaction mixture was filtered through a Celite bed that was washed with acetone. The acetone filtrate was concentrated, and the residue was purified by chromatography using hexane–EtOAc (2:1) as eluant to afford **23**. Compound **23** was not characterized but was used directly for the preparation of imidate **14**.

***O*-(2-*O*-Acetyl-3,4,6-tri-*O*-benzyl-α-D-glucopyranosyl)-trichloroacetimidate (14)**

To a solution of **23** (64 mg, 0.130 mmol) in dry CH_2Cl_2 was added NaH (60% suspension in oil, 5.2 mg, 0.130 mmol) and trichloroacetonitrile (60 μL). The reaction mixture was stirred at r.t. for 2 h and was concentrated. The residue was purified by chromatography using hexane–ether–Et_3N (50:50:1) as eluant to afford imidate **14** (50 mg, 60%); ^{1}H NMR (360 MHz, $CDCl_3$) δ: 8.58 (s, 1H, NH), 7.30–7.10 (m, 15H, Ar-H), 6.53 (d, 1H, $J_{1,2}$ 3.5 Hz, H-1), 5.07 (dd, 1H, $J_{2,3}$ 9.6 Hz, H-2), 4.86 (d, 1H, J_{gem} 11.5 Hz, $PhCH_2$), 4.84 (d, 1H, J_{gem} 10.8 Hz, $PhCH_2$), 4.77 (d, 1H, J_{gem} 11.5 Hz, $PhCH_2$), 4.64 (d, 1H, J_{gem} 11.8 Hz, $PhCH_2$), 4.58 (d, 1H, J_{gem} 10.8 Hz, $PhCH_2$), 4.50 (d, 1H, J_{gem} 11.8 Hz, $PhCH_2$), 4.10 (dd, 1H, $J_{3,4}$ 9.5 Hz, H-3), 4.02 (ddd, 1H, $J_{4,5}$ 9.5 Hz, H-5), 3.88 (dd, 1H, H-4), 3.82 (dd, 1H, J_{gem} 11.2 Hz, $J_{5,6a}$ 3.5 Hz, H-6a), 3.70 (dd, 1H, $J_{5,6b}$ 2.0 Hz, H-6b), 1.92 (s, 3H, Ac).

Octyl 3,4,6-tri-*O*-benzyl-α-D-mannopyranosyl-(1→6)-2,3,4-tri-*O*-benzyl-6-deoxy-6-thio-β-D-glucopyranoside (24)

To a solution of **12** (124 mg, 0.214 mmol) in dry THF (5 mL) was added sodium hydride (60% suspension in oil, 13 mg, 0.321 mmol). The resulting mixture was stirred at r.t. for 30 min. After the sodium salt (white precipitate) was produced, THF was removed using a stream of argon. The residuum sodium salt was dissolved with DMF (2 mL) and was added dropwise to a solution of 1,2-anhydro-3,4,6-tri-*O*-benzyl-β-D-mannose **13** (13) (85 mg, 0.195 mmol) in DMF (1 mL). The reaction mixture was stirred at r.t. for 1 h. Methanol (1 mL) was added to the reaction mixture; the reaction mixture was then concentrated and the residue was purified by column chromatography using hexane–EtOAc (3:1) as eluant to give **24** (94 mg, 63%); $[\alpha]_D$ +83.4 (*c* 0.5, CH_2Cl_2); ^{1}H NMR (360 MHz, $CDCl_3$) δ: 5.44 (d, 1H, $J_{1',2'}$ 1.5 Hz, H-1′), 4.96, 4.94, 4.85, 4.82, 4.76, 4.71 (6d, each 1H, J_{gem} 11.0 Hz, $PhCH_2$), 4.62 (d, 1H, J_{gem} 12.2 Hz, $PhCH_2$), 4.57, 4.51 (2d, each 1H, J_{gem} 11.0 Hz, $PhCH_2$), 4.44 (d, 1H, J_{gem} 12.2 Hz, $PhCH_2$), 4.38 (d, 1H, $J_{1,2}$ 8.0 Hz, H-1), 4.14 (ddd, 1H, $J_{2',3'}$ 3.2 Hz, $J_{2',OH}$ 2.7 Hz, H-2′), 4.12 (ddd, 1H, H-5′), 3.93 (dt, J_{gem} 10.0 Hz, J_{vic} 6.5 Hz, octyl C1-H_a), 3.91 (dd, 1H, $J_{4',5'}$, $J_{3',4'}$ 9.5 Hz, H-4′), 3.85 (dd, 1H, H-3′), 3.75 (dd, 1H, J_{gem} 11.8 Hz, $J_{5',6'a}$ 4.5 Hz, H-6′a), 3.63 (dd, 1H, $J_{2,3}$, $J_{3,4}$ 9.5 Hz, H-3), 3.61 (dd, 1H, $J_{5',6'b}$ 2.0 Hz, H-6′b), 3.50 (dt, 1H, octyl C1-H_b), 3.48 (dd, 1H, $J_{4,5}$ 9.5 Hz, H-4), 3.48 (m, 1H, H-5), 3.41 (dd, 1H, H-2), 3.07 (dd, J_{gem} 14.0 Hz, $J_{5,6a}$ 2.5 Hz, H-6a), 2.78 (dd, 1H, $J_{5,6b}$ 6.0 Hz, H-6b), 2.57 (d, 1H, C2′-OH), 0.87 (t, 3H, J_{vic} 7.0 Hz, octyl CH_3); ^{13}C NMR (100.6 MHz, $CDCl_3$) δ: 138.6, 138.5, 138.4, 138.2, 137.7 (benzyl C1), 128.6, 128.4, 128.3, 128.1, 128.0, 127.91, 127.86, 127.6, 127.5 (Ar), 103.5 (C-1), 84.5 (C-1′), 75.6, 75.2, 75.1, 74.8, 73.4, 72.0 (Ph*C*H_2), 70.2 (octyl C1), 68.9 (C-6′), 31.9 (C-6), 31.8, 29.8, 29.4, 29.3, 26.2, 22.7 (octyl C2–C7), 14.1 (octyl CH_3). Anal. calcd. for $C_{62}H_{74}O_{10}S$ (1011.33): C 73.63, H 7.38, S 3.17; found: C 73.18, H 7.44, S 3.30.

Octyl 2-*O*-acetyl-3,4,6-tri-*O*-benzyl-β-D-glucopyranosyl-(1→2)-3,4,6-tri-*O*-benzyl-α-D-mannopyranosyl-(1→6)-2,3,4-tri-*O*-benzyl-6-deoxy-6-thio-β-D-glucopyranoside (25)

A mixture of **14** (48 mg, 75.4 μmol), **24** (66 mg, 65.2 μmol), powdered molecular sieve 4Å (60 mg), and CH_2Cl_2 (3 mL) was stirred at r.t. for 30 min. To the mixture was added a solution of TMSOTf (1.45 μL, 7.5 μmol) in CH_2Cl_2 (150 μL) under argon. After stirring for 1 h, Et_3N (0.1 mL) was added and the mixture was filtered through Celite and concentrated. The residue was purified by chromatography using hexane–EtOAc (3:1) as eluant to afford **25** (44 mg, 88% based on consumed alcohol) and recovered alcohol **24** (32 mg, 49%); $[\alpha]_D$ +37.7 (*c* 1.2, CH_2Cl_2): ^{1}H NMR (360 MHz, $CDCl_3$) δ: 5.40 (d, 1H, $J_{1',2'}$ 1.2 Hz, H-1′), 5.15 (dd, 1H, $J_{1'',2''}$ 8.5 Hz, $J_{2'',3''}$ 9.0 Hz, H-2″), 4.47 (d, 1H, H-1″), 4.39 (d, 1H, $J_{1,2}$ 8.0 Hz, H-1), 4.27 (dd, 1H, $J_{2',3'}$ 3.2 Hz, H-2′), 4.08 (ddd, 1H, $J_{4',5'}$ 9.6 Hz, $J_{5',6'a}$ 6.4 Hz, $J_{5',6'b}$ 2.0 Hz, H-5′), 3.97 (dt, 1H, J_{gem} 10.0 Hz, J_{vic} 6.5 Hz, octyl C1-H_a), 3.82 (dd, 1H, $J_{3',4'}$ 9.5 Hz, H-3′), 3.62 (dd, 1H, $J_{3,4}$ 9.5 Hz, H-3), 3.53 (dt, 1H, octyl C1-H_b), 3.44 (dd, $J_{2,3}$

Evaluation of trisaccharide analogs as acceptors for GlcNAcT-V

Materials

The cloned rat kidney GlcNAcT-V was from Dr. M. Pierce. Partially purified GlcNAcT-V was prepared by a modification (20) of published procedures (18, 19). The activity of cloned GlcNAcT-V was 10 mU/mL with **5** as acceptor (protein content = 0.286 mg/mL, specific activity = 35 mU/mg). The activity of isolated GlcNAcT-V was 1.0 mU/mL with **5** as acceptor. Enzyme was stored at 4°C in 50 mM MES buffer, pH 6.5, containing 300 mM NaCl, and 5 mM EDTA.

Methods

A standard assay contained final concentrations of 40 μM **5** as acceptor, 550 μM UDP GlcNAc including UDP-^{3}H-GlcNAc (~200 000 dpm) as donor substrates, 5–9 μU cloned GlcNAcT-V (0.5–0.9 μL), in 25 mM sodium cacodylate buffer, pH 6.5, 0.05% Triton X-100, 10% glycerol, 5 mM EDTA, and 0.5 mg/mL BSA, in a total volume of 20 μL. Assay tubes were incubated for 30–60 min at 37°C, then quenched with 0.5 mL water. Radiolabeled product was separated from unreacted donor on Sep-Pak C-18 reversed-phase cartridge and quantitated by liquid scintillation counting in 10 mL of Ecolite cocktail (ICN) (9, 18–20).

Kinetics

Kinetic parameters for acceptors were determined with the radiochemical assay described above. Assays contained buffer, donor, ^{3}H donor, and enzyme concentrations as for the standard assay. Assays were performed in duplicate with six different acceptor concentrations. Tubes were incubated at 37°C for 60 or 30 min and processed on C-18 Sep-Pak cartridges as for the standard assay. Kinetic data (K_m and V_{max}) listed in Table 1 were obtained by fitting the initial rate data to the Michaelis-Menten equation using nonlinear regression analysis (Sigma Plot 4.10) (9).

Preparative enzymatic synthesis of octyl β-D-glucopyranosyl-(1→2)-[2-acetamido-2-deoxy-β-D-glucopyranosyl-(1→6)]-2-deoxy-2-thio-α-D-mannopyranosyl-(1→6)-β-D-glucopyranoside (27)

A mixture of **7** (0.49 mg, 0.774 μmol), UDP-GlcNAc (2 mg, 3 μmol), cloned rat kidney GlcNAcT-V (17) (0.5 mL, 1.48 mU/mL), and buffer (170 mM sodium cacodylate buffer, pH 6.5, 70% glycerol, 35 mM EDTA, and 3.5 mg/mL BSA, in a total volume of 200 μL) was incubated at r.t. for 48 h. The mixture was diluted with Milli-Q water and loaded onto a C-18 Sep-Pak cartridge. The cartridge was eluted with water (3 × 10 mL) followed by methanol (10 mL). The methanolic eluate was concentrated to dryness, and the residue was dissolved in Milli-Q water and passed through a Millex filter. Compound

27 was obtained as a white powder in 100% yield after lyophilization of the filtrate. ^{1}H NMR (500 MHz, D_2O) δ: 5.13 (d, 1H, $J_{1',2'}$ 0.5 Hz, H-1′), 4.53 (d, 1H, $J_{1'',2''}$ 10.5 Hz, H-1″), 4.45 (d, 1H, $J_{1,2}$ 8.0 Hz, H-1), 4.52 (d, 1H, $J_{1''',2'''}$ 8.0 Hz, H-1‴), 4.17 (dd, 1H, $J_{2',3'}$ 4.5 Hz, $J_{3',4'}$ 9.8 Hz, H-3′), 3.61 (dd, 1H, H-2′), 3.38 (dd, 1H, $J_{2'',3''}$ 9.5 Hz, H-2″), 3.26 (dd, 1H, $J_{2,3}$ 9.5 Hz, H-2), 2.09 (s, 3H, Ac), 1.63 (p, 2H, J_{vic} 7.0 Hz, octyl C2-H), 1.40–1.24 (m, 10H, octyl CH_2), 0.86 (t, 3H, J_{vic} 7.0 Hz, octyl CH_3); FAB MS *m/z*: 858.1 $(M+Na)^+$.

Preparative enzymatic synthesis of octyl β-D-glucopyranosyl-(1→2)-[2-acetamido-2-deoxy-β-D-glucopyranosyl-(1→6)]-α-D-mannopyranosyl-(1→6)-6-deoxy-6-thio-β-D-glucopyranoside (28)

A mixture of **8** (0.50 mg, 0.789 μmol), UDP-GlcNAc (1.5 mg, 2.3 μmol), partially purified GlcNAcT-V (1.5 mL, 1 mU/mL) from hamster kidneys (18–20), and buffer (150 mM sodium cacodylate buffer, pH 6.5, 60% glycerol, 30 mM EDTA, and 3 mg/mL BSA, in a total volume of 500 μL) was incubated at r.t. for 72 h. The mixture was diluted with Milli-Q water and loaded onto a C-18 Sep-Pak cartridge. The cartridge was eluted with water (3 × 10 mL) followed by methanol (10 mL). The methanolic eluate was concentrated to dryness, and the residue was purified by chromatography on Iatrobeads using $CHCl_3$–MeOH–H_2O (65:35:8) as eluant to give the crude product. The crude product was dissolved in Milli-Q water and was loaded onto a C-18 Sep-Pak cartridge. The cartridge was washed with water (10 mL) followed by methanol (10 mL). The methanolic eluate was concentrated to dryness, the residue was dissolved in Milli-Q water and passed through a Millex filter. Compound **28** was obtained as a white powder in 100% yield after lyophilization of the filtrate. ^{1}H NMR (500 MHz, D_2O) δ: 5.48 (d, 1H, $J_{1',2'}$ 1.0 Hz, H-1′), 4.52 (d, 1H, $J_{1'',2''}$ 8.4 Hz, H-1″), 4.48 (d, 1H, $J_{1''',2'''}$ 7.6 Hz, H-1‴), 4.45 (d, 1H, $J_{1,2}$ 8.1 Hz, H-1), 4.22 (dd, 1H, $J_{2',3'}$ 3.5 Hz, H-2′), 4.15 (dd, 1H, J_{gem} 11.0 Hz, $J_{5',6'a}$ 2.4 Hz, H-6′a), 4.11 (ddd, 1H, $J_{4',5'}$ 9.5 Hz, $J_{5',6'b}$ 4.8 Hz, H-5′), 3.94 (d, 1H, J_{gem} 12.0 Hz, $J_{5'',6''a}$ 2.0 Hz, H-6″a), 3.83 (dd, 1H, $J_{3',4'}$ 9.5 Hz, H-3′), 3.61 (ddd, 1H, $J_{4,5}$ 9.6 Hz, $J_{5,6a}$ 3.0 Hz, $J_{5,6b}$ 8.0 Hz, H-5), 3.26 (dd, 1H, $J_{2,3}$ 9.5 Hz, H-2), 3.17 (dd, 1H, J_{gem} 14.3 Hz, $J_{5,6a}$ 3.0 Hz, H-6a), 2.80 (dd, 1H, $J_{5,6b}$ 8.0 Hz, H-6b), 2.07 (s, 3H, Ac), 1.64 (p, 2H, J_{vic} 7.0 Hz, octyl C2-H), 0.87 (t, 3H, J_{vic} 7.0 Hz, octyl CH_3); FAB MS *m/z*: 874.2 $(M+K)^+$, 858.2 $(M+Na)^+$, 836.3 $(M+H)^+$.

Acknowledgments

We thank Ms. C.A. Compston for performing some of the enzyme experiments and Dr. Albin Otter for recording the 500 MHz NMR spectra of **7**, **8**, **27**, and **28**. The cloned GlcNAcT-V was a generous gift from Dr. M. Pierce, University of Georgia. This work was supported by grants from the Medical Research Council of Canada (M.M.P.) and the Natural Sciences and Engineering Research Council of Canada (O.H.). Pu-Ping Lu is the recipient of a scholarship from Alberta Heritage Foundation for Medical Research.

A new *ent*-kaurane from the root extract of *Chiococca alba*

Rocío Borges-Argáez, Leticia Medina-Baizabál, Filogonio May-Pat, and Luis M. Peña-Rodríguez

Abstract: A bioassay-guided purification of the methanolic crude extract obtained from the roots of *Chiococca alba* (L.) Hitchc. resulted in the isolation of a new, bioactive, metabolite identified as *ent*-17-hydroxy-16α-kauran-3-one (**1**). Elucidation of the new structure was based on analyses of the results obtained from various spectroscopic methods (IR, MS, ^{1}H NMR, and ^{13}C NMR) and chemical transformations. The stereochemistry at C16 was assigned by comparing both the proton and carbon chemical shifts of C17 with those reported in the literature. The new kaurane showed weak antimicrobial activity when tested against *Staphylococcus aureus*.

Key words: medicinal plants, *Chiococca alba*, Rubiaceae, kaurane, diterpene, antimicrobial.

Résumé : Une purification orientée par des bioessais d'extraits méthanoliques bruts obtenus des racines du *Chiococca alba* (L.) Hitchc. a permis d'isoler un nouveau métabolite bioactif identifié comme l'*ent*-17-hydroxy-16α-kauran-3-one (**1**). L'élucidation de la nouvelle structure est basée sur l'analyse des résultats obtenus par diverses méthodes spectroscopiques (IR, SM, RMN du ^{1}H et du ^{13}C) et transformations chimiques. La stéréochimie en C-16 a été attribuée par comparaison des déplacements chimiques tant du proton que du carbone du C-17 avec ceux rapportés dans la littérature. Le nouveau kaurane présente une faible activité antimicrobienne contre le *Staphylococcus aureus*.

Mots clés : plantes médicinales, *Chiococca alba*, Rubiaceae, kaurane, diterpène, antimicrobien.

[Traduit par la rédaction]

Introduction

As part of our continuing search for bioactive metabolites from Yucatecan medicinal plants, we have investigated the components present in the roots of *Chiococca alba* (L.) Hitchc. (Rubiaceae). This plant is one of the 10 most popular species used by the people of the Yucatan peninsula where it is commonly known as "t'unche'" or "kanchakche'" (1–4). The root decoction of *C. alba* is used in Yucatecan traditional medicine to cure dysentery, as a diuretic and cathartic, and against snake bites (5). The leaf infusion is used to alleviate a number of ailments such as asthma, headaches, and diarrhea, and a decoction of the whole plant is reported to be effective as a laxative and against gonorrhea, skin infections, and rheumatism (1, 3).

Although there are a number of phytochemical studies on the constituents of rubiaceus plants (6–11), there is limited knowledge about the chemical constituents of *C. alba*. Recent studies report the isolation and identification of two biologically active quinoline alkaloids (12) and a new oleanane-type triterpene (13) from the root extract of the plant, while two new ketoalcohols have been reported from the leaf extract (14). We wish to report here the isolation and identification of a new, biologically active, *ent*-kaurane derivative (**1**) from the root extract of *C. alba*.

Received December 10, 1996.

This paper is dedicated to Professor William A. Ayer on the occasion of his 65th birthday.

Results and discussion

During our investigation we found that the methanolic extract of the roots of *C. alba* showed antimicrobial activity when tested against *Staphylococcus aureus* (15). A bioassay-directed fractionation of the crude extract, using both an initial solvent partition procedure and successive chromatographic purifications, yielded a biologically active fraction showing a single component by TLC and GC. The bioactive metabolite **1** was obtained as an amorphous, wax-like, solid that could not be induced to crystallize. The parent ion peak at *m/z* 304 in the HREIMS of **1** corresponded to the molecular formula $C_{20}H_{32}O_2$, suggesting a diterpene structure. Two intense absorptions at 3430 and 1690 cm^{-1} in the IR spectrum indicated the presence of both an alcohol and keto groups in the structure of **1** and allowed for the assignment of the two oxygen atoms in the molecular formula. The primary nature of the alcohol group was evident from a fragment ion peak at *m/z* 273 (M^+-31) in the HREIMS of **1** and the presence of an AB quartet having two one-proton doublets of doublets at 3.42 (J = 12.0 and 3.2 Hz) and 3.37 ppm (J = 11.2 and 2.4 Hz) in its ^{1}H NMR spectrum. Treatment of **1** with acetic anhydride and pyridine yielded the expected monoacetate **2** showing a parent

ion peak at *m/z* 346 in its HREIMS, a lack of absorption bands in the hydroxyl region of the IR spectrum, and the expected downfield shift for the hydroxymethylene protons, to a two-proton doublet at 3.83 ppm (J_{AB} = 7.6 Hz), in its ^{1}H NMR spectrum. In the same manner, treatment of **1** with pyridinium chlorochromate (16) resulted in the obtention of aldehyde **3**, which showed, in its ^{1}H NMR spectrum, a characteristic one-proton doublet at 9.65 ppm (J = 1.2 Hz).

A careful analysis of the ^{13}C NMR spectrum and of the results from DEPT and HETCOR experiments permitted the assignment of all carbons in the structure of **1** as three methyl groups, nine methylenes, four methines, and four quaternary carbons. The three methyl singlets at 1.05, 1.04, and 1.01 ppm in the ^{1}H NMR of **1** further indicated their all being bonded to quaternary carbons. Since the only sp^2 carbon observed in the ^{13}C NMR of **1** corresponded to that of the ketone carbonyl group, the four remaining unsaturation sites implied by the molecular formula of **1** were assigned to four carbocyclic rings. A diterpene structure having four rings, four methines, and three methyl groups in quaternary carbons could only be accommodated in a kaurane skeleton having a primary alcohol and a keto group.

A closer analysis of both the ^{1}H NMR and the ^{1}H–^{1}H COSY spectra of **1** permitted the correct assignment of the location of the keto group in the structure. A two-proton doublet of doublets at 2.45 ppm (J = 6.4 and 8.4 Hz) showed cross peaks with two signals at 1.40 and 2.00 ppm, indicating a partial structure of two methylene groups in positions α and β to a carbonyl group. This type of partial structure could only be fitted in the kaurane skeleton if the ketone group was located in either position 1 or 3 of the structure. It could be argued that location of the carbonyl group at C3 is favored on biogenetic grounds, via the catalyzed cyclization of an epoxy-geranyl geranyl pyrophosphate unit, following a similar biosynthetic pathway to that of squalene leading to triterpenes (17, 18). Final confirmation of a C3 carbonyl group in the structure of **1** came from comparison of its virtually identical carbon chemical shift values with those reported for *ent*-17-norkaurane-3,16-dione (**4**) (Table 1) (19).

The additional coupling to a methine proton at 1.90 ppm shown by the hydroxymethyl group in the ^{1}H–^{1}H COSY spectrum of **1** allowed for the correct placement of the primary alcohol group at C17. Assignment of the stereochemistry at C16 was made by comparing both the proton and carbon chemical shift values of C17 in the corresponding spectra of **1** with those reported in the literature for C16α and β *ent*-kauranes. While the hydroxymethyl group protons and carbon chemical shift values in methyl 17-hydroxy-16β-(−)-kauran-19-oate (**5**) (20) appear at 3.70 ppm (d, J = 7 Hz) and 64.1 ppm, respectively, in the 16α epimer (**6**), as is the case for **1**, the C17 methylene protons and carbon appear at higher (3.40 ppm) and lower (67.4 ppm) fields, respectively (20). This effect is also observed in the corresponding acetylated derivatives **7** and **8**, as well as in other structurally similar *ent*-kauranes (**9**–**12**) (20–22). On this basis **1** was identified as the new bioactive metabolite *ent*-17-hydroxy-16α-kauran-3-one.

Although there are reports of kaurane diterpenes having been isolated from plants of the Rubiaceae family (11), little is known about their biological activity. Recent investigations have resulted in the isolation of several *ent*-kauranoids showing cytotoxic (23, 24) and anti-HIV (21, 25) activities. This is the first report of an *ent*-kaurane showing antimicrobial activity.

Experimental

General methods

IR spectra were recorded in $CHCl_3$ using a Perkin–Elmer 683 spectrophotometer. GC–MS analyses were performed on a Hewlett–Packard 5890 gas chromatograph (1.0 μL of 3% sample in $CHCl_3$, HP Ultra 2 column (crosslinked 5% Ph Me Silicone, 25 m × 0.32 mm × 0.52 μm film thickness), temperature program: T_1 = 150°C, T_2 = 300°C, gradient = 10°C/min, injector temperature = 300°C, detector temperature = 290°C) coupled to a Hewlett–Packard 5971A mass selective detector. HREIMS and CIMS spectra were recorded on Kratos AEI MS-50 and AEI MS-12 mass spectrometers, respectively. ^{1}H NMR (400 MHz) and ^{13}C NMR (100 MHz) spectra were obtained in $CDCl_3$ on a Varian Unity 400 spectrometer using the $CHCl_3$ signal (7.29 and 77.48 ppm, respectively) as reference. The strains used in the antimicrobial assay: *Bacillus subtilis* (ATCC 6633), *Candida albicans* (ATCC 10231), *Escherichia coli* (ATCC 10538), *Pseudomonas aeruginosa* (ATCC 15442), *Saccharomyces cerevisiae* (ATCC 9763), and *Staphylococcus aureus* (ATCC 6538) were obtained from the American Type Culture Collection. Analytical TLC analyses and preparative TLC purifications were carried out using precoated silica gel aluminum and glass plates, respectively (E.M. Merck DC Alufolien, Kieselgel 60 F254, 0.20 mm thickness and E.M. Merck DC Fertigplatten, Kieselgel 60 F254, 0.25 mm thickness). Chromatograms were examined under UV light in a UV-viewing cabinet (Spectroline model CX-20) and visualized by dipping in 4% phosphomolybdic acid solution containing a trace of ceric sulfate in 5% sulfuric acid, followed by drying and gentle heating. Medium-pressure

column chromatography (flash cc) purifications were run according to Still et al. (26) using silica gel 60 (230–400 mesh) from Aldrich Chemical Co.

Plant material

The roots of *C. alba* were collected in July 1992 from plants growing on a field located at km 24 of the Merida-Progreso highway. A voucher specimen has been deposited in the herbarium of the Natural Resources Department of Centro de Investigación Científica de Yucatán (CICY) under the collection number 696. The plant material was washed with tap water and dried, first for a week at room temperature and then for 72 h in an oven at 55°C. The dry roots were ground using a Brabender Dusiburg (880804 type) mill and collected using a No. 2 sieve.

Extraction and isolation

Soxhlet extraction of the ground plant material (195.12 g) using methanol (2 L) resulted in the obtention of 16.01 g of crude methanolic extract. Testing of a 5% solution of the crude extract in the antimicrobial assay showed a 1 mm inhibition zone against *Staphylococcus aureus*. The biologically active extract was suspended in a 3:2 mixture of water/methanol (ca. 100 mL of solution/300 mg of crude extract) and the resulting suspension was partitioned successively between hexane, dichloromethane, and ethyl acetate to yield the low-polarity (0.31 g), medium-low polarity (2.45 g), and medium polarity fractions (1.19 g), respectively. Successive flash cc (dichloromethane/acetone, 98:2) and preparative TLC (multiple elution, four times, hexane/acetone, 80:20) purifications of the bioactive low-polarity fraction yielded 15.0 mg (0.008%) of **1** in pure form. The isolated metabolite showed a 2 mm inhibition zone when tested at 1% against *Staphylococcus aureus*, but no activity was observed when **1** was evaluated against *B. subtilis*, *C. albicans*, *E. coli*, *P. aeruginosa*, and *S. cerevisiae*.

ent-*17-Hydroxy-16α-kauran-3-one (1)*

Obtained as an amorphous solid (mp 104–107°C) that could not be induced to crystallize. TLC: R_f 0.32 (hexane/acetone, 80:20); IR ν_{max} (KBr): 3430 (OH stretch), 2940 (CH_3 and CH_2, asymmetric stretch), 2860 (CH_3 and CH_2, symmetric stretch), 1690 (C=O stretch), 1370 and 1365 (*gem*-dimethyl, C-H bending) cm^{-1}; ^1H NMR ($CDCl_3$): 3.42 (1H, dd, J = 3.2, 12.0 Hz, H17a), 3.37 (1H, dd, J = 2.4, 11.2 Hz, H17b), 2.45 (2H, dd, J = 6.4, 8.4 Hz, H2), 2.00 (1H, m, H1a), 1.90 (1H, m, H13), 1.40 (1H, m, H1b), 1.05 (3H, s, H19), 1.04 (3H, s, H18), 1.01 (3H, s, H20) ppm; ^{13}C NMR ($CDCl_3$): see Table 1; HREIMS, *m/z* (relative intensity) calcd. for $C_{20}H_{32}O_2$: 304.2402; found: 304.2411 (M^+, 87.3), 286 (M^+-18, 10.4), 273 (M^+-31, 4.7); CIMS (NH_3), *m/z* (relative intensity): 322 (M^++18, 96.3), 305 (M^++1, 100.0).

ent-*17-Acetoxy-16α-kauran-3-one (2)*

A mixture of **1** (3.0 mg), acetic anhydride (1 mL), and pyridine (0.5 mL) was allowed to stir overnight at room temperature. The reaction mixture was poured over water (30 mL) and the resulting suspension extracted with ethyl acetate (3 times, 1:1, v/v). The organic layer was washed (1:1, v/v) successively with water, 5% HCl, 2.5% KOH, and a NaCl saturated solution; treatment of the solvent with anhydrous Na_2SO_4 followed by filtration and evaporation yielded 3.12 mg (91.5%) of **2**.

Diels–Alder adducts of *ortho*-benzoquinones: rearrangements and further transformations

Rina Carlini, Kerianne Higgs, Nicholas Taylor, and Russell Rodrigo

Abstract: *ortho*-Benzoquinones substituted with an electron-withdrawing group (EWG = CO_2Me, COSMe, $COCH_3$, CHO) at C-3 or C-4 react as dienophiles at the C3—C4 double bond in Diels–Alder reactions with several dienes, with predictable regiochemistry. The adducts undergo migration of the "angular" EWG substituent with concomitant aromatization to produce substituted catechols. The bicyclic products can be oxidized in situ and annelated by a further Diels–Alder reaction to yield 9,10-phenanthraquinone systems. When (2*E*)-2,4-pentadienol is employed as the diene in the second cycloaddition, reaction of the alcoholic hydroxyl group with one of the quinone carbonyl groups results in the production of tetracyclic lactols **22a**, **22b**, and **23**.

Key words: benzoquinone, Diels–Alder, rearrangement, phenanthraquinone, phenanthrofuran.

Résumé : Lors de réactions de Diels–Alder avec divers dienes, les *ortho*-benzoquinones substituées en positions C-3 ou C-4 par un groupe électroattracteur (GEA = CO_2Me, COSMe, $COCH_3$, CHO) réagissent comme diénophiles au niveau de la double liaison C3—C4 et la régiochimie de ces réactions peut être prédite. Les adduits subissent une migration du GEA «angulaire» avec une aromatisation concomitante conduisant à des catéchols substitués. Les produits bicycliques peuvent être oxydés in situ et subir une nouvelle annelation, par réaction de Diels–Alder, pour conduire aux systèmes de la 9,10-phénanthraquinone. Lorsqu'on utilise du (2*E*)-penta-2,4-diénol comme diène dans la deuxième cycloaddition, la réaction du groupe hydroxyle de l'alcool avec l'un des groupes carbonyles de la quinone conduit à la formation des lactols tétracycliques **22a**, **22b** et **23**.

Mots clés : benzoquinone, Diels–Alder, phénanthraquinone, phénanthrofurane.

[Traduit par la rédaction]

With some elegant exceptions (1), the notorious instability of *ortho*-benzoquinones has limited their employment as intermediates in the synthesis of complex natural products. In a recent paper (2) we reported the initial results of our attempts to generate substituted *o*-benzoquinones in situ and to investigate the regiochemistry of the intermolecular Diels–Alder reaction of these dienophilic intermediates with nonsymmetrical dienes. Effective regiocontrol at both components of the cycloaddition reaction was achieved by the placement of an electron-withdrawing group (EWG = CO_2H, CO_2Me, COSMe, CHO) at C-3 or C-4 of the *o*-benzoquinone. In the course of those investigations, we uncovered several interesting rearrangements of the initial adducts. Some of them, we believe, were responsible for the formation of mixtures of products, but others proceeded with greater efficiency and possessed much synthetic potential. Such rearrangements of *o*-benzoquinonoid adducts have not been reported before although a successful oxy-Cope rearrangement of a bridged intramolecular Diels–Alder adduct of an *o*-benzoquinonoid species has been reported (3) very recently.

Our initial investigations were conducted with the Diels–Alder adducts **1a**–**1d** and **3** (Table 1). The preparation of these compounds, with the exception of **1c** (26% yield) and **1d** (23% yield), from *o*-benzoquinones substituted at C-4 with carbomethoxy (CO_2Me) and carbothiomethyl (COSMe) has previously been described (2). Rearrangements were effected by stirring in neat trifluoroacetic acid (TFA) at ambient temperature for ca. 2 h. The first two adducts (**1a** and **1b**) underwent a smooth [1,2]-shift (a dienone–phenol rearrangement) of the C-4a ester groups to C-4 to yield 1,2-dihydroxynaphthalenes **2a** and **2b** almost quantitatively. No trace of any materials arising from shifts of ring carbon atoms C-5 or C-8 could be detected. Migrations of angular ester substituents in similar reactions have not been common but rearrangement of the dienone **4** by acid treatment to phenol **5** has been reported (4) to proceed in moderate yield. The presence of a methyl substituent at C-4 blocked the rearrangement process completely and the starting materials were recovered unchanged after extended treatment of **1c**, **1d**, and **3** with TFA.

Compounds **6a** and **6b**, derived from diketoadduct **7** (2) by enolization (**6a**) and subsequent O-methylation (**6b**), were examined next for susceptibility to rearrangement. Stirring these precursors in TFA at room temperature resulted in the

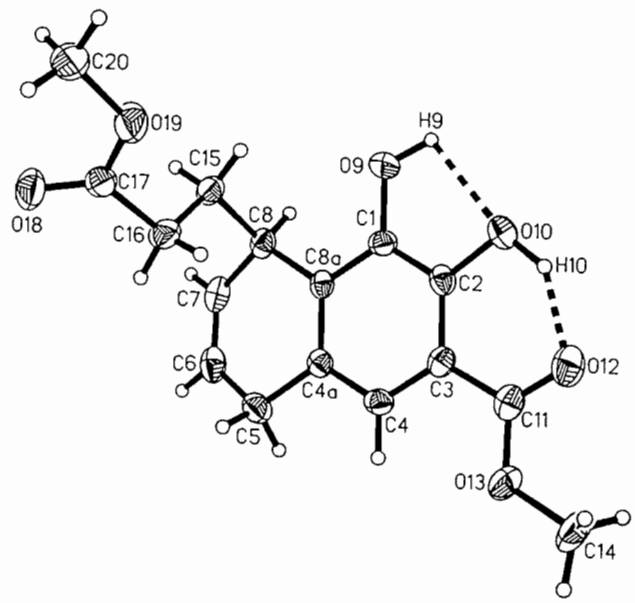
Table 1. Acid-catalyzed rearrangements of Diels–Alder adducts **1a–1d** and **3**.

1 2

	Diels–Alder adduct	Product (% yield)
1a	(R^1 = OMe, R^2 = R^4 = H, R^3 = CH_2CO_2Me,)	**2a** (90)
1b	(R^1 = SMe, R^2 = H R^3 = CO_2Et, R^4 = Me)	**2b** (98)
1c	(R^1 = SMe, R^2 = Me R^3 = CO_2Et, R^4 = H)	No reaction
1d	(R^1 = OMe, R^2 = Me R^3 = CO_2Me, R^4 = H)	No reaction
3		No reaction

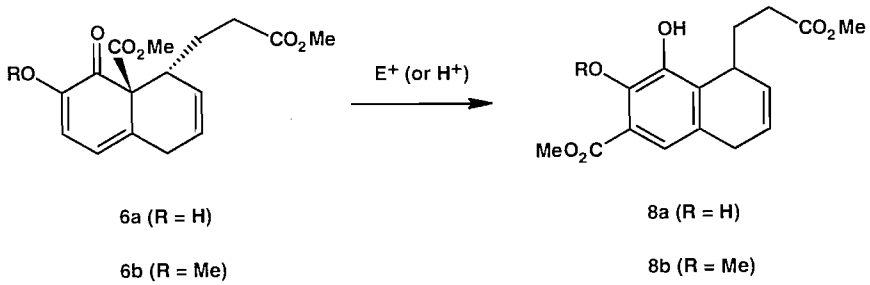


4 5

slow but complete conversion to aromatic esters (Table 2). The ^{1}H NMR spectrum of the product obtained from **6a** contained one aromatic proton at 7.16, one hydrogen-bonded hydroxyl proton at 10.6, and a second hydroxyl proton at 5.8 ppm. The regioisomeric structures **8a**, **9a**, and **10a** are consistent with these data. Structures **9a** and **10a** (Scheme 1) might have arisen from migration of C-8 to form a spiro intermediate (5) followed by a [1,2]-shift of C-5 or C-8, and this mechanism would have resulted in a product mixture. Since only one product was isolated from rearrangement of **6a**, structures **9a** and **10a** appear to be unlikely. Support for structure **8a** was obtained by NMR correlation methods (NOEDS, TOCSY, HMBC) but unequivocal proof of its identity was sought and obtained by a single-crystal X-ray analysis (Fig. 1). Rearrangement of **6b** gave an aromatic ester **8b** with the methoxyl group intact and no hydrogen-bonded hydroxyl proton in the ^{1}H NMR spectrum, a result that was consistent with structure **8b** but not with **9b** or **10b**.

The formation of **8a-b** from **6a-b** by migration of the C-8a ester to C-3 is unprecedented for *o*-benzoquinone adducts. Two mechanistic pathways can be postulated (Scheme 2) and a method for deciding between them became available when it was discovered that identical rearrangement products were obtained in comparable yields with trimethyloxonium tetrafluoroborate in methylene chloride. If pathway **B** operated, then treatment of **6a** or **6b** with triethyloxonium tetrafluoroborate should have produced at least some ethyl ester. However, no ethyl ester products were observed; only **8a** and **8b**

Fig. 1. Molecular plot of **8a**.



were obtained as in the TFA-catalyzed rearrangements. Rearrangements of *p*-benzoquinone adducts involving the migration of angular acetyl and carbomethoxy groups were studied earlier and a mechanism involving a [1,5]-shift of the acetyl group in the enol tautomer followed by a [1,2]-shift and

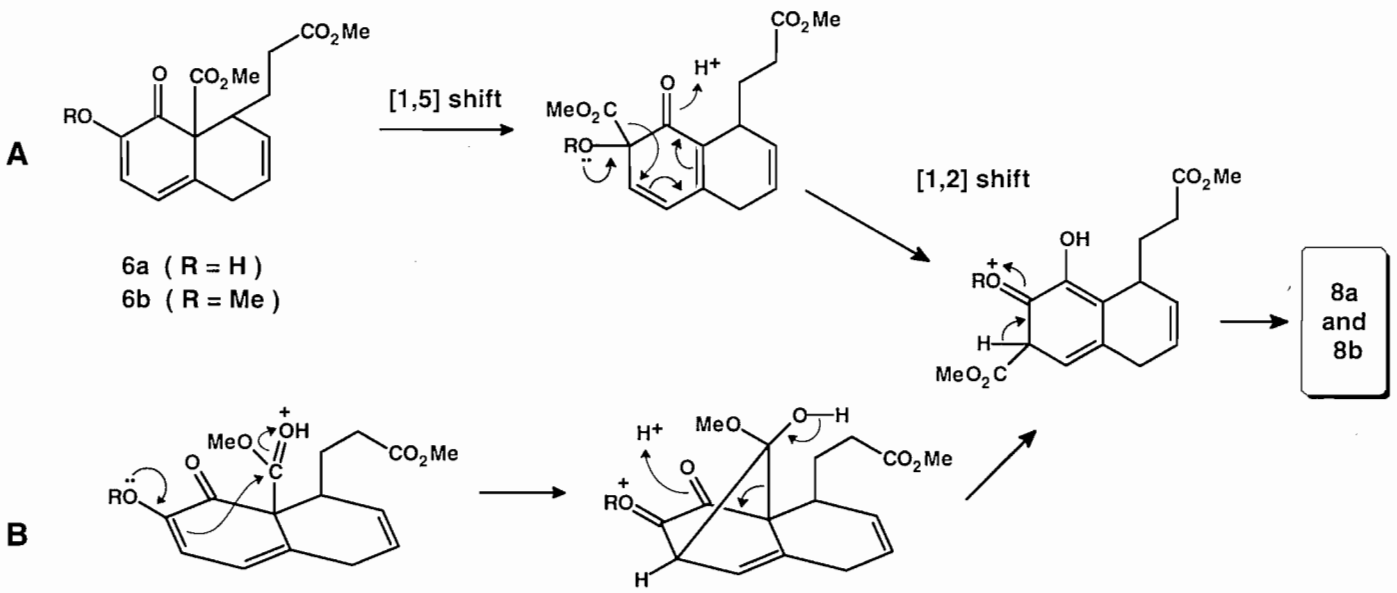
Scheme 1.



subsequent aromatization was proposed (6) (Scheme 3). The analogous methoxycarbonyl adduct did not rearrange under similar conditions, but heating with acetic anhydride and sodium acetate (140°C, 4 h) provoked a different migration of the ester, resulting in the isolation of the diacetate **11** (Scheme 3) in moderate yield. The pathway **A** in Scheme 2 also involves a [1,5]-shift of the ester followed by a [1,2]-shift in the second step. The latter is promoted by the C-2 oxygen sub-

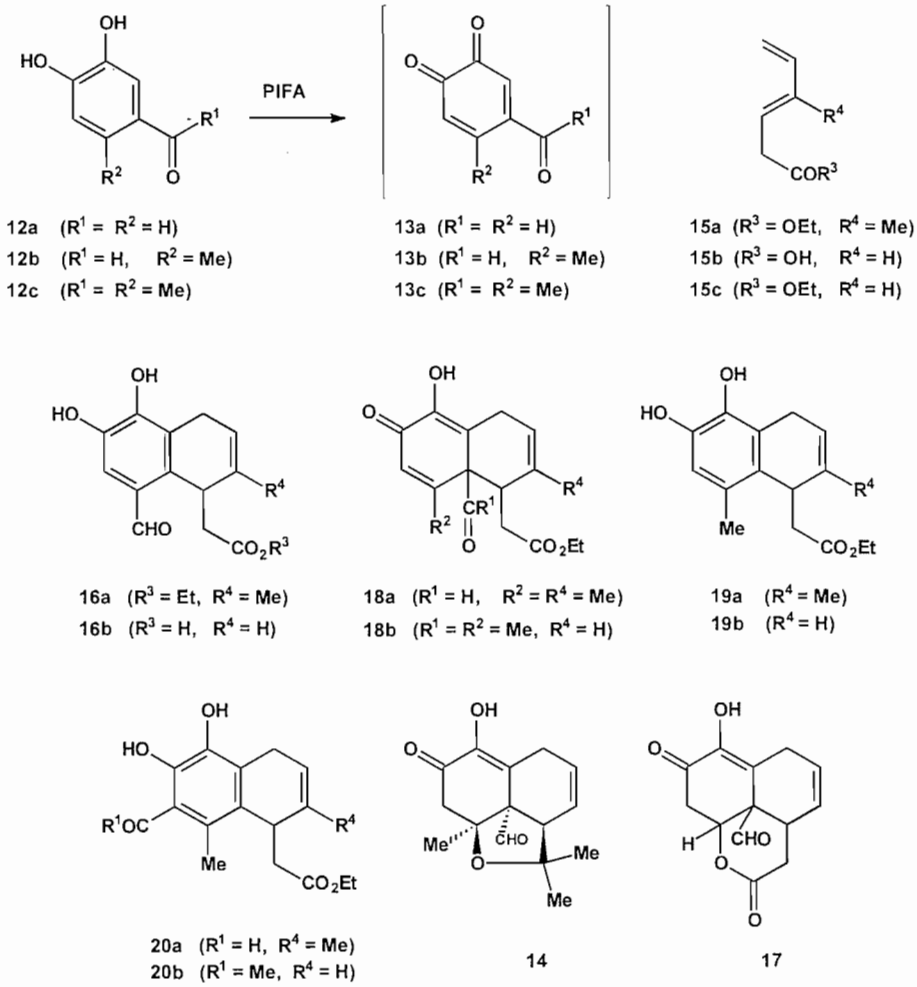
Scheme 3.

stituent, and this step bears resemblance to both the α-ketol and dienone–phenol rearrangements. Migration of the hydroxyl or methoxyl group instead of the ester group is obviously disfavoured by the fact that a positive charge would have to be generated between the two carbonyl groups.



Migratory aptitudes of substituents in these types of reactions had been previously estimated (7) to be in the order CHO > COMe > CO_2Me. We therefore turned our attention to the catechol aldehydes **12a** and **12b**, which were oxidized to *ortho*-benzoquinones **13a** and **13b** with phenyliodosyl bis(trifluoroacetate) (PIFA) in the presence of various dienes (8).[2] As reported earlier (2), naphthofuran **14**, a prospective intermediate for the synthesis of the tricyclic diterpene nardonoxide (9), was produced in one step from **12b** and (2*E*)-1,1-

[2] For the preparation of dienes, see: CH_2=CHC(CH_3)=$CHCH_2$-CO_2Et : ref. 8*a*; CH_2=CHCH=$CHCH_2CO_2Et$: ref. 8*b*; CH_2=CHCH=$CHCH_2OH$: ref. 8*c*; CH_2=CHCH=$CHCH_2CO_2R$, R = Me, H: ref. 8*d*.

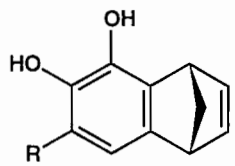
dimethyl-2,4-pentadienol, albeit in low yield. Reaction of **13a** with dienes **15a** and **15b**, where naphthofuran formation was not possible, gave adducts **16a** and **16b**, resulting from apparent addition to the less activated C5—C6 double bond of the *o*-quinone **13a**. To confirm this result an X-ray structure of **16a** was obtained (Fig. 2). In our opinion, products **16a** and **16b**, isolated in yields of 23% and 39%, respectively, were formed by Diels–Alder addition to the more dienophilic C3–C4 double bond of **13a** followed by rapid [1,2]-migration of the formyl group in the acidic medium of the reaction. The dienoic acid **15b** was investigated in the hope that the cycloaddition would be followed by cyclization to produce the δ-lactone **17**, thus saturating C-4 of the adduct and forestalling the migration of the aldehyde group. Unfortunately, this expectation was not realized and a probable explanation is that the 1,4-addition step was reversible and that the migration was followed by aromatization to give **16b** from which there could be no return. Another way of blocking the migration of the angular carbonyl group and subsequent aromatization was demonstrated with esters **1c** and **1d** where methyl groups are situated at C-4, the prospective terminus of the migration. Catechol aldehyde **12b** was expected to give an analogous adduct **18a** with a C-4 methyl substituent present to block the migration of the formyl group. However, oxidation in situ to *o*-quinone **13b** and subsequent reaction with diene **15a** did not

Fig. 2. Molecular plot of **16a**.



give the expected adduct **18a**, but rather compounds derived from that adduct in low yields, namely, the deformylated dihydroxynaphthalene **19a** and the product **20a** of an apparent [1,3]-migration of the formyl group. The aldehyde **20a** must have arisen from the initial adduct **18a** by two successive

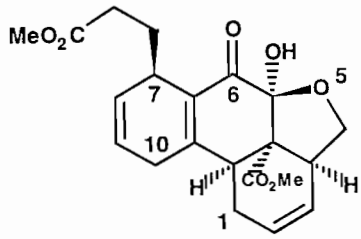
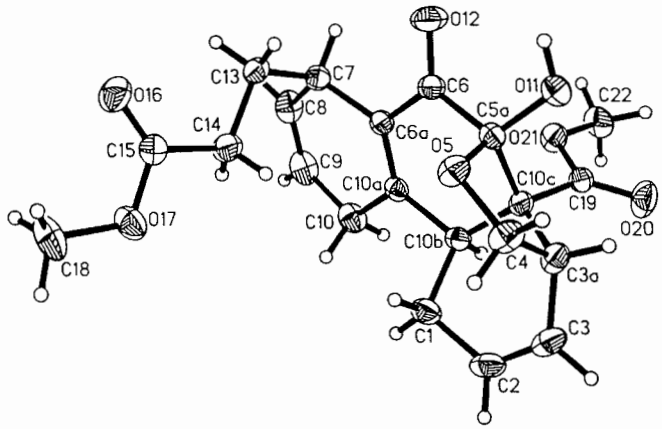
For personal use only.



[1,2]-migrations of the formyl group. The second [1,2]-migration could proceed by a mechanism similar to that suggested by Bruce and co-workers (6) (Scheme 3). In view of these facile aromatizations of the aldehyde adducts, we decided to investigate the cycloaddition of the *o*-quinone **13c** (from oxidation of catechol **12c** (10)) with diene **15c**, expecting that the adduct **18b** would be isolable because of the lower migratory aptitude of the acetyl group. Adduct **18b** was isolated in low yield along with the major product, which was the deacetylated dihydroxynaphthalene **19b**. The adduct **18b** rearranged upon standing to the product **20b**, again by an apparent [1,3]-shift of the acetyl group analogous to that proposed for the formation of aldehyde **20a** from **18a**. It therefore appears that in these vinylogous β-diketo systems the push to aromatization can be just as easily satisfied by decarbonylation processes as by [1,2]-migrations.

In view of the ease of the various rearrangements that end in aromatization and formation of substituted catechols, it is most likely that the Diels–Alder adducts represented by **21** do not arise by the "abnormal" addition of cyclopentadiene to the less dienophilic C5–C6 double bond of the C3-EWG substituted *o*-benzoquinone as claimed (11). Instead, the formation of the expected adduct at C3—C4 followed by rearrangements akin to the conversion of **6a** to **8a** must be responsible for the apparent anomaly.



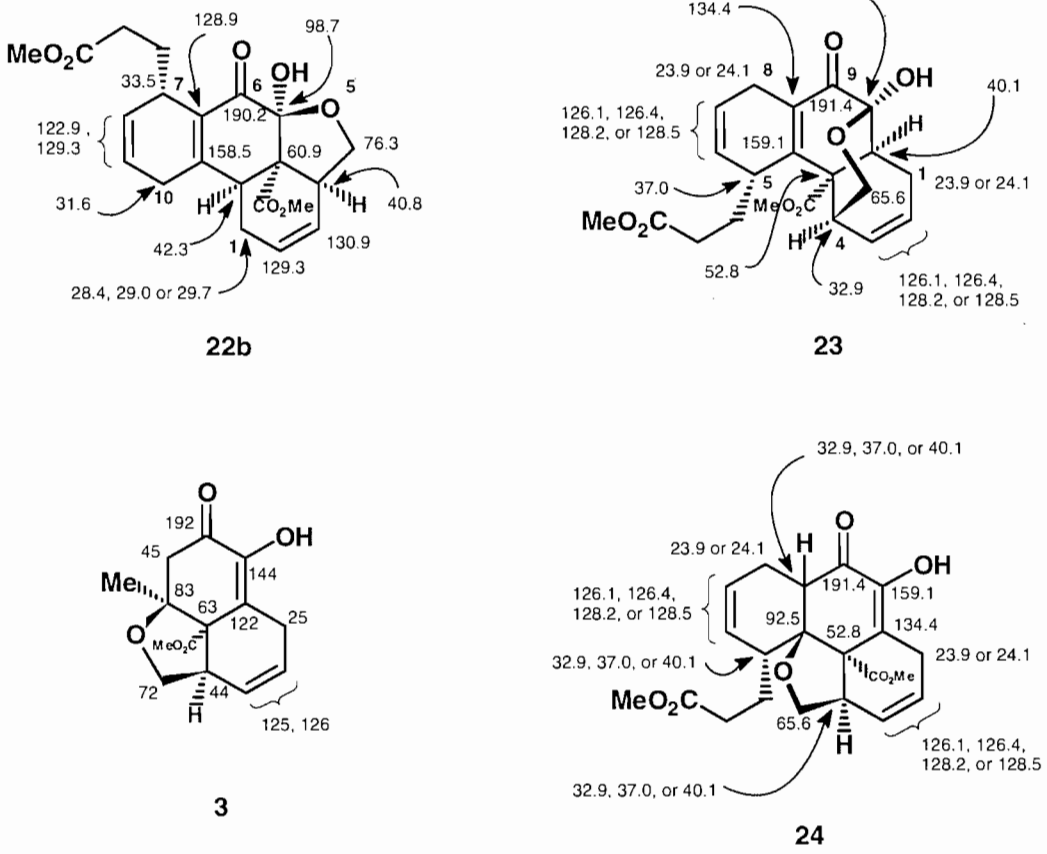
21 (R = CHO, COMe, CO_2Me, CN)

Migrations of the ester group (e.g., **1a**→**2a** and **6a**→**8a**) discussed herein result in the formation of catechols bearing such substituents at C-3 or C-4. Thus, just as the dienophilic double bonds of *p*-quinones permit successive Diels–Alder additions to produce linear tricyclic compounds, the rearrangement products **2a** and **8a** offer the possibility of generating angular tricyclic systems by oxidation and cycloaddition with a second diene. Treatment of **8a** with PIFA and (2*E*)-2,4-pentadienol[3] using conditions described earlier (2) resulted in a moderate yield (56%) of two diastereomeric adducts **22a** and **22b** in equal amounts. The diastereomers were separable by chromatography, but assignment of relative stereochemistry to each product, by analysis of NMR spectra alone, could not be accomplished with certainty. An X-ray crystallographic structure determination was therefore undertaken and the structure and relative configuration of one diastereomer was firmly established as **22a** (Fig. 3). Compounds **22a** and **22b** (Fig. 4) are phenanthrofurans, diastereomeric at C-7; the regiochemistry of the cycloaddition is controlled by the ester substitutent at C-3 of the *o*-quinonoid species and both are

22a

Fig. 3. Molecular plot of **22a**.

endo[4] adducts. *endo*-Cycloadducts are usually found (2) in intermolecular Diels–Alder reactions of *o*-benzoquinones, and this generalization appears to hold for these *o*-quinones as well.



The reaction was next attempted with **2a**, a case where the ester substituent is at C-4 rather than C-3. Only a single adduct could be isolated in low yield (ca. 11%). Its mass spectrum (at low and high resolution), as well as its ^1H and ^{13}C NMR spectra, was consistent with the structure and relative stereochemistry represented by the 4,10-methyleneoxy bridged phenanthrene **23** (Fig. 4). High-field ^1H and ^{13}C assignments were confirmed by HMQC as well as by homonuclear (^1H) decoupling experiments. However, an alternative structure **24**, analogous to the known naphthofuran **3** (2), also had to be considered. In Fig. 4, some important ^{13}C chemical shifts of the adduct (illustrated in possible structures **23** and **24**) were compared to spectral data for the known compounds **22b** and **3**. The data indicated that the assignments made for structure **23** bear a greater similarity to those of **22b** than the assignments for **24** do to naphthofuran **3**. In addition, the geminal coupling constant of the methylene group adjacent to oxygen, measured at 11.9 Hz, is more in keeping (12) with its presence in tetrahydropyran as in structure **23** rather than in a tetrahydrofuran ($J_{gem} \approx 8.0$–9.5 Hz) as required by structure **24**. The relative stereochemistry at C-4, C-4a, C-10, and C-10a in compound **23** was established by the cycloaddition (*endo*) and subsequent methyleneoxy bridging, while that of C-5 became evident from the detection of a small NOE in the difference spectrum between H-4 and H-5β.

[3] The preparation of (2*E*)-2,4-pentadienol from commercially available 1,4-pentadien-3-ol was accomplished in one step in 60.5% yield. This procedure is a more efficient method than that previously cited in the literature (8*c*). See experimental section.

[4] *endo*-Stereochemistry refers to the *o*-quininoid ring.

© 1997 NRC Canada

Fig. 4. Comparison of ^{13}C NMR assignments for ring carbon atoms of known compounds, **22b** and **3** (2), with hypothetical structures for adducts **23** and **24**.

The Diels–Alder→aromatization–rearrangement→Diels–Alder sequence outlined here with substituted *o*-benzoquinones generated in situ thus permits the rational construction of angular tricyclic and tetracyclic systems with complete control of regiochemistry at each step. This synthetic sequence has the potential for the elaboration of functionalized phenanthrene and phenanthrofuran ring systems found in complex natural products.

Experimental

Melting points were measured using a Gallenkamp melting point apparatus and are uncorrected. Infrared spectra were obtained with a Bomem FTIR spectrometer. Nuclear magnetic resonance spectra were performed on Bruker AM-250 and AMX-500 or Varian XL-200 spectrometers at 298 K, and coupling constants were measured directly from the spectra by first-order analysis and are approximate by ±0.3 Hz. NMR spectral assignments were confirmed by common 2D techniques (TOCSY, HMQC, NOESY). All spectra were run in $CDCl_3$ with tetramethylsilane as an internal standard unless otherwise indicated. Low- and high-resolution mass spectra were determined at the Southwestern Ontario Regional Mass Spectrometry Center at McMaster University, Hamilton, Ontario. Elemental analyses were determined by MHW Laboratories in Phoenix, Arizona. The dienes **15a**, **15b**, **15c**, and (*E*)-methyl-3,5-hexadienoate (for preparation of **1d**) were prepared as described in the literature (8) and were freshly distilled prior to use in a reaction. PIFA refers to the commercially available oxidant phenyliodosyl bis(trifluoroacetate), or bis(trifluoroacetoxy)iodobenzene (Aldrich®). Column chromatography was performed using Merck 230–400 mesh silica gel 60 with ethyl acetate – hexane (typically 1:4) used as eluant unless otherwise stated. Anhydrous sodium sulfate was used as the drying agent.

X-ray crystal structure determinations

A summary of crystallographic data is reported in Table 3. Crystal structure analyses were performed on an LT2 equipped Siemens P4 diffractometer using MoKα radiation (λ = 0.71073 Å). In each case, unit cell dimensions were obtained from 25 reflections well dispersed in reciprocal space. Data were collected by the ω-scan method with a scan width of 1.2° using variable scan speeds, the scan rate being determined by a fast prescan. Background measurements were made at the beginning and end of each scan for a total of half the scan time. Data were corrected for Lorentz and polarization effects and by face-indexed analytical absorption methods. The structures were solved by direct methods and refined by full-matrix least-squares methods using Siemens SHELXTL IRIS software. The function minimized in the least-squares process was $w(F_o - F_c)^2$. Hydrogen atoms were easily found by difference Fourier syntheses and were included in the refinements with refined isotropic thermal parameters. In the final

cycles of refinement, weighting schemes of the form $w^{-1} = \sigma^2(F)$ as well as extinction coefficients were employed. Final difference maps revealed no anomalous electron density peaks or holes. Supplementary data include a complete listing of atomic coordinates, bond lengths and angles, and anisotropic thermal parameters.[5]

General method A: rearrangements with trifluoroacetic acid (TFA)

Compounds were mixed with an excess amount of TFA (10–20 equivalents) and stirred at room temperature under an argon atmosphere for time periods ranging from 0.5 to 18 h, as monitored by thin-layer chromatography. The solution was concentrated in vacuo and the crude residue extracted into ether, and washed with either brine or dilute aqueous $NaHCO_3$ solution. The ether layer was dried and concentrated in vacuo. The resulting product was further purified either by recrystallization in ether and/or ether-hexane, or by column chromatography.

General method B: rearrangements with trialkyloxonium tetrafluoroborates

Compounds **6a** and **6b** were dissolved in dry CH_2Cl_2 and cooled to 0°C for 10 min. Approximately 1.2 equivalents of R_3OBF_4, either as a solution in dry CH_2Cl_2 (for Et_3OBF_4) or as a neat crystalline solid (for Me_3OBF_4), was added to the cooled solution of **6a** or **6b** under an argon atmosphere. The resulting brown mixture was stirred at 0°C for 30 min and then at room temperature for 10–48 h. The reaction was quenched with a saturated solution of NH_4Cl, and the CH_2Cl_2 layer was separated, washed with brine, dried, filtered, and concentrated in vacuo to a black oil. The product was purified by column chromatography.

General Procedure C: Diels–Alder reactions of 12a, 12b, and 12c, and preparation of 1c and 1d

To a cooled solution (0°C) of the catechol and the diene (7–10 equivalents) in dry THF was added PIFA (1.2 equivalents) in small portions under an argon atmosphere. Solid $NaHCO_3$ (2.4 equivalents) was added to neutralize the TFA produced upon catechol oxidation. The solution was stirred at room temperature for 1–12 h; then THF was removed in vacuo. The crude residue was dissolved in ethyl acetate, washed with brine, dried (Na_2SO_4), and concentrated in vacuo. The excess diene was removed by reduced pressure distillation and the product purified by column chromatography.

δ: 12.4, (SCH_3), 14.4 (OCH_2CH_3), 22.5 (6-CH_3), 25.6 (CH_2CO_2Et), 38.7 (C-5), 41.2 (C-8), 60.4 (OCH_2CH_3), 115.1 (C-3), 121.4 (C-7), 125.6, 127.8, 131.9 (C-4, C4a, and C-8a), 136.8 (C-6), 142.1 (C-2), 146.6 (C-1), 171.8 (CO_2Et), 193.3 (COSMe); MS(EI) *m/z* (relative %): 336 (M, <1), 248 (13), 201 (100); HRMS calcd. for $C_{17}H_{20}O_5S$: 336.1031; found: 336.1034.

*(8α,8aβ)-8-Carbomethoxyethyl-8a-carbomethoxy-2-hydroxy-1,5,8,8a-tetrahydronaphthalene-1-one (**6a**)*

A solution of diketoadduct **7** (2) (0.408 g, 1.33 mmol) in dry DME (30 mL) was heated at reflux for 8 h in the presence of solid $NaHCO_3$ (0.195 g, 2.33 mmol). The reaction was quenched at 0°C with 3 N HCl until the aqueous phase was mildly acidic (pH 4). The crude product was extracted into ether (100 mL), washed twice with brine solution, dried, filtered, and concentrated in vacuo to a brown oil. The product **6a** was purified by column chromatography, which gave a bright yellow solid (0.352 g) in 86% yield. Yields were variable due to the instability of **6a**, which was typically methylated to **6b** upon isolation. IR (neat): 3418 (OH, broad), 1736 (CO, ester), 1645 (CO, enone), 1216 cm^{-1}; ^{1}H NMR (500 MHz) δ: 1.33 (m, 1H, $CH_2CH_2CO_2CH_3$, J = 13.2, 6.0 Hz), 1.58 (m, 1H, $CH_2CH_2CO_2CH_3$, J = 12.7, 6.5, 5.8 Hz), 2.27 (m, 2H, $CH_2CH_2CO_2CH_3$, J = 14.6, 9.7 Hz), 3.00 (m, 2H, H-5, J = 20.9 Hz), 3.45 (m, 1H, H-8, J = 10.7, 5.3, 4.8 Hz), 3.63, 3.66 (s, 6H, 2 × CO_2CH_3), 5.68 (dt, 1H, H-6, J = 9.9, 3.4 Hz), 5.85 (m, 1H, H-7, J = 9.8, 5.3 Hz), 6.13 (s, OH), 6.25 (dd, 1H, H-4, J = 6.9, 2.0 Hz), 6.48 (d, 1H, H-3, J = 6.9 Hz); ^{13}C NMR (50 MHz) δ: 26.2 (C-8), 31.4, 32.8 ($CH_2CH_2CO_2CH_3$), 45.6 (C-5), 51.7, 53.4 (2 × CO_2CH_3), 65.9 (C-8a), 116.3, 119.0, 126.2, 128.4 (C-3, C-4, C-6, and C-7), 138.4 (C-4a), 145.9 (C-2), 167.8 (CO_2CH_3 at C-8a), 173.4 ($CH_2CH_2CO_2CH_3$), 193.7 (C-1); MS(EI) *m/z* (relative %): 306 (M$^+$, 1.5), 275 (M$^+$ − OCH_3, 4), 247 (M$^+$ − CO_2CH_3, 16), 215 (46), 187 (26), 173 (100), 143 (23), 115 (31).

*(8α,8aβ)-8-Carbomethoxyethyl-8a-carbomethoxy-2-methoxy-1,5,8,8a-tetrahydronaphthalene-1-one (**6b**)*

The pure product **6a** (0.43 g, 1.4 mmol) was dissolved in ether (20 mL) and stirred in ice while a freshly prepared ethereal solution of CH_2N_2 (ca. 4.2 mmol in 30 mL ether) was added dropwise over 30 min. The excess CH_2N_2 was neutralized with glacial acetic acid, and the product crystallized from ether as white needles (0.39 g) in 87% yield (an X-ray crystal structure has been reported (2)); mp 116–117°C; IR (KBr): 2961 (CH), 1744 (CO, esters), 1671 (CO, enone), 1642 (C=C) cm^{-1}; ^{1}H NMR (500 MHz) δ: 1.33 (m, 1H, $CH_2CH_2CO_2CH_3$, J = 13.2, 10.7, 5.7 Hz), 1.63 (m, 1H, $CH_2CH_2CO_2CH_3$, J = 13.1, 6.0, 4.3 Hz), 2.24 (m, 2H, $CH_2CH_2CO_2CH_3$, J = 16.3, 6.1 Hz), 2.95 (dm, 2H, H-5, J = 21.0 Hz), 3.39 (m, 1H, H-8, J = 10.8, 5.3, 4.8 Hz), 3.58 (s, 3H, $CH_2CH_2CO_2CH_3$), 3.62 (s, 3H, CO_2CH_3 at C-8a), 3.69 (s, 3H, OCH_3), 5.63 (dt, 1H, H-6, J = 9.8, 6.7 Hz), 5.83 (m, 1H, H-7,

Synthesis of (2E)-2,4-pentadienol

Commercially available 1,4-pentadien-3-ol (25 g, 0.297 mol) was distilled (bp 36°C/20 Torr; 1 Torr = 133.3 Pa) and dissolved in dry THF (20 mL). To this solution was added 10 mL of 1:1 conc. H_2SO_4–H_2O, and the mixture was stirred for 24–48 h at room temperature. The resulting yellow solution was neutralized with solid $NaHCO_3$, and extracted into ether (300 mL). The ether layer was washed with dilute aqueous $NaHCO_3$, and then brine, until the pH of the washings was 6–7. The ether layer was dried and the ether removed in vacuo, leaving the crude dienol product, which was distilled under reduced pressure (using a small amount of hydroquinone as stabilizer) to afford 15.12 g (60.5% yield) of pure (2*E*)-2,4-pentadienol (bp 62°C/20 Torr). The ^{1}H NMR spectral data were in accordance with values cited in the literature (8*c*).

*Diels–Alder reaction of **8a** and (2E)-2,4-pentadienol (adducts **22a** and **22b**)*

A solution of **8a** (0.2 g, 0.683 mmol) in dry THF (10 mL) was cooled to 0°C for 10 min, after which was added excess (2*E*)-2,4-pentadienol (0.4 g, 4.78 mmol) followed by PIFA (0.35 g, 0.82 mmol) in small portions. The reaction was stirred under an atmosphere of argon for 8 h, while warming to room temperature, to give a yellow-orange solution. The solution was concentrated in vacuo and the resulting orange oil purified by flash column chromatography to furnish a white solid (0.148 g, 56% yield) consisting of a 1:1 diastereomeric mixture of products **22a** and **22b**. The diastereomers were further resolved by column chromatography using 1:9 ether–CH_2Cl_2 as eluant.

*7β-Carbomethoxyethyl-10cα-carbomethoxy-5aα-hydroxy-1,3aα,4,5a,7,10,10bα,10c-octahydrophenanthro[10,1-bc]furan-6-one (**22a**)*: colorless prisms from ether; mp 122–123°C; IR (KBr): 3462 (OH, sharp), 1739 (CO, ester), 1677 (CO, enone) cm^{-1}; ^{1}H NMR (500 MHz) δ: 1.87 (m, 2H, $CH_2CH_2CO_2CH_3$, J = 15.4, 8.9 Hz), 2.06 (ddd, 1H, H-1, J = 18.2, 11.7, 3.1 Hz), 2.21 (m, 2H, $CH_2CH_2CO_2CH_3$), 2.35 (dd, 1H, H-10b, J = 11.6, 4.2 Hz), 2.47 (ddd, 1H, H-1, J = 15.1, 7.5, 4.9 Hz), 2.74 (dt, 1H, H-10, J = 23.1, 4.1 Hz), 3.12 (dd, 1H, H-10, J = 23.1, 5.4 Hz), 3.59 (dd, 1H, H-4, J = 8.0, 7.1 Hz), 3.60, 3.62 (s, 6H, 2 × CO_2CH_3), 3.62 (m, 1H, H-7), 4.00 (m, 1H, H-3a, J = 9.8, 7.0 Hz), 4.48 (dd, 1H, H-4, J = 9.8, 8.0 Hz), 4.71 (s, 1H, OH), 5.81 (narrow m, 2H, H-8 and H-9, J = 9.3, 6.1 Hz), 6.10 (ddd, 1H, H-2, J = 9.1, 7.5, 3.3 Hz), 6.24 (ddd, 1H, H-3, J = 9.1, 7.0, 3.0 Hz); MS(EI) *m/z* (relative %): 388 (M$^+$, 2), 371 (M$^+$ − OH, 100), 338 (33), 237 (13), 195 (24), 165 (30); HRMS calcd. for $C_{21}H_{24}O_7$: 388.1522; found: 388.1530 .

Synthesis of regiospecifically substituted 2-hydroxybenzocyclobutenones

Yvonne Lear and Tony Durst

Abstract: Regiospecifically substituted 2-hydroxybenzocyclobutenones were synthesized from the corresponding TBS protected 2-bromo-mandelate esters via halogen–metal exchange, cyclization, and subsequent deprotection.

Key words: 2-hydroxybenzocyclobutenones, halogen–metal exchange, benzocyclobutenediones, 2-bromomandelate esters.

Résumé : Opérant à partir des esters correspondants de l'acide 2-bromomandélique protégés par du «TBS» et procédant par le biais d'un échange halogène–métal, d'une cyclisation et d'une déprotection subséquente, on a réalisé la synthèse de 2-hydroxybenzocyclobuténones régiospécifiquement substituées.

Mots clés : 2-hydroxybenzocyclobuténones, échange halogène–métal, benzocyclobutènediones, esters de l'acide 2-bromomandélique.

Introduction

Benzocyclobutenediones have been shown to be useful intermediates in the synthesis of polycyclic natural products, in particular naphtha- and anthraquinones (1, 2) (Scheme 1). In general, the benzocyclobutenedione **1** is treated with a Grignard reagent to generate a 2-hydroxybenzocyclobutenone **2**. The thermal opening of the 2-hydroxybenzocyclobutenone **2** occurs at about 110°C and is governed by the torquoselectivity rules described by Houk and co-workers (3). This results exclusively in the formation of the intermediate **3** in which the aryl or vinyl substituent is suitably placed for an intramolecular acylation process. Thus anthraquinones or naphthaquinones are obtained, depending on whether an aryl or a vinyl Grignard reagent is used in the addition reaction. The regioselectivity of the addition of Grignard reagents to **1** is difficult to control except when R in **1** is a large *ortho* substituent (4). To have a general synthesis of specifically substituted anthraquinones **4**, based on such a reaction sequence, access to unsymmetrically substituted benzocyclobutenediones with one of the carbonyl moieties masked is needed. Ideally, such compounds would allow for the addition of an organometallic reagent at one of the carbonyl groups, followed by unmasking of the second carbonyl group, and the thermolysis reactions described above.

Previous efforts in this group involved the synthesis of 2-benzylidene-benzocyclobutenone **5** as an unsymmetrical benzocyclobuten-1,2-dione equivalent (5) (Scheme 2). Addition of organolithiums or Grignard reagents occurred exclusively by a 1,2 pathway to give **6** (R′ = aryl). The usefulness of **6** as a synthetic intermediate to anthraquinones suffered greatly since it was oxidized to **7** in only poor yields. Furthermore, thermolysis of **6**, prior to oxidation of the benzylidene group to a carbonyl function, led to a variety of ring enlargement products. The possibility of first protecting the ketone in **5** as a ketal to give **8**, then ozonolyzing the benzylidene group to reveal the other carbonyl group to give **9**, was also considered; again the oxidation step proceeded in only poor yield (6).

Since it had already been shown that benzocyclobutenols could be made by halogen–metal exchange in *o*-bromophenylacetone followed by cyclization (7), it was envisioned that this method could also be applied to the synthesis of benzocyclobutenones. It was necessary to generate a substrate that had a halogen *ortho* to a "functionalized arm" containing two oxygen functionalities: one as an ester to serve as an electrophile in the cyclization process and generate the benzocyclobutenone and the other a potential carbonyl group, for example, a protected hydroxy group (Scheme 3). The realization of such a process is described below.

Results and discussion

The known 6-bromopiperonal **12a** (8) (Scheme 4) was converted to the cyanohydrin **13a** using trimethylsilyl cyanide in dichloromethane with catalytic zinc iodide (9). Further treatment with hydrochloric acid in refluxing ethanol for 1 h afforded the hydroxy ester **14a**. The changes described were easily followed by NMR spectroscopy.

Gallagher and Beak have shown that, under halogen–metal exchange conditions, acidic protons are removed before the exchange reaction takes place (10). To avoid this complication, the hydroxy ester **14a** was protected using *tert*-butyldimethylsilyl chloride in DMF using imidazole as base. When the protected ester **15a** was treated with 2 equivalents of *tert*-

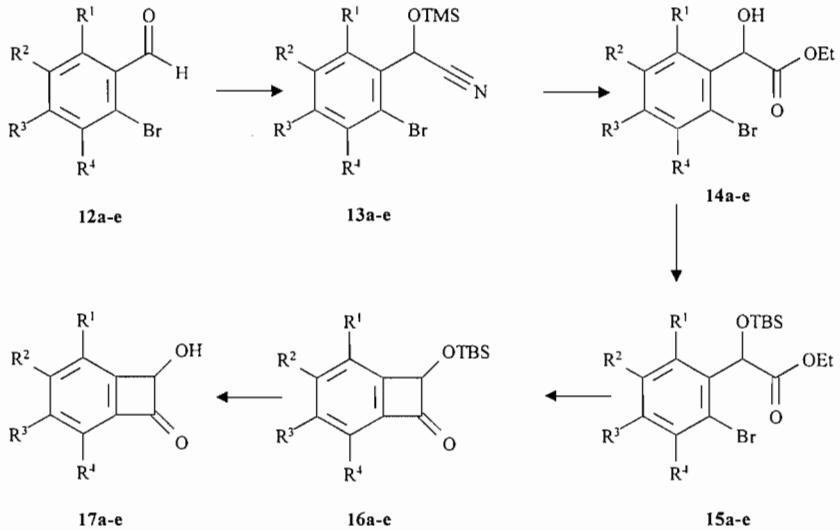
Scheme 2.

butyllitium at −78°C,[2] the desired cyclobutenone **16a** was formed but was accompanied by the tertiary alcohol **18a** (Scheme 5). Use of 1.1 equivalents of *tert*-butyllithium afforded a crude reaction mixture whose ^{1}H NMR spectrum indicated that approximately 60% of the starting material had been converted to the desired benzocyclobutenone. Reaction of **15a** with 1.5 equivalents of *tert*-butyllithium at −78°C for 15 min, followed by quenching of the reaction mixture with saturated ammonium chloride at that temperature, led to a 95% yield of the desired benzocyclobutenone. The compound could be purified by silica gel chromatography, or by simple recrystallization from hexanes – ethyl acetate. The ^{1}H NMR spectrum showed the disappearance of the ethyl group of the ester and the shift of the benzylic proton from 5.48 to 5.56 ppm

Scheme 3.

P=protecting group, L=leaving group, X=halogen



in going from **15a** to **16a**. The ^{13}C NMR peak at 187.5 ppm and the IR absorbtion at 1757 cm^{-1} are values associated with the carbonyl group in other benzocyclobutenones (5). Deprotection using tetra-*n*-butylammonium fluoride in THF afforded the hydroxybenzocyclobutenone **17a** in 80% yield.

The starting materials for the remaining cyclization precursors were the commercially available 2-bromobenzaldehyde, *m*-anisaldehyde, *p*-anisaldehyde, and 3-bromophenol. *m*-Anisaldehyde was brominated at the 2 position using the same method as for piperonal to give **12d**. *p*-Anisaldehyde was

[2] Halogen–metal exchange reactions are generally carried out using two equivalents of butyllithium, one to do the exchange reaction and the other consumed as base, causing an elimination from the butyl bromide formed from the reaction (11).

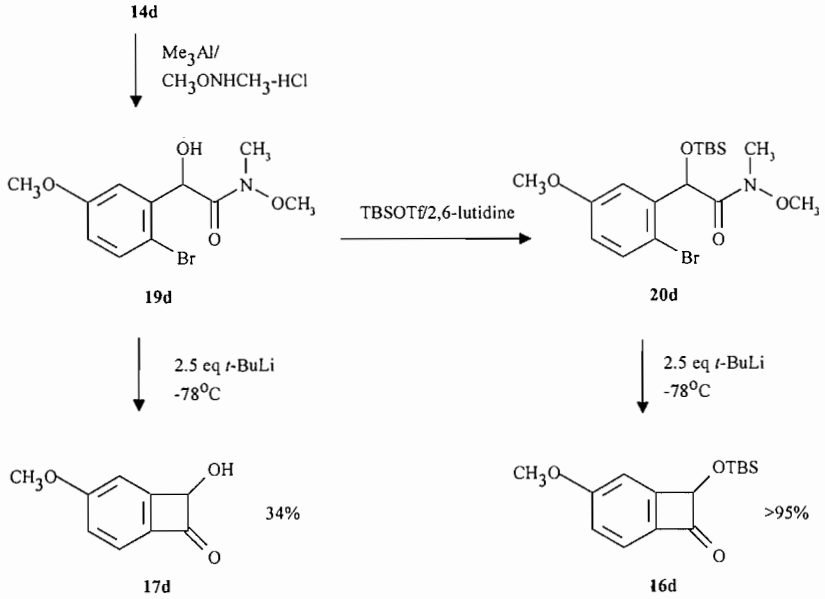
halogenated using Comins' procedure to afford **12e** (12, 13). *m*-Bromophenol was formylated under Reimer–Tiemann conditions (14) and methylated using potassium carbonate and methyl iodide in acetone to give **12c**.

The above *ortho*-bromobenzaldehydes were converted in >95% yield to the corresponding trimethylsilyl protected cyanohydrins **13a–e** using trimethylsilyl cyanide as previously described and were then converted to the ethyl esters. The reactivities of these cyanohydrins toward ethanolysis were variable. When the cyanohydrin **13e** was reacted under the conditions previously described for the piperonal system, a 1:1 mixture of the hydroxy ester **14e** and the corresponding α-ethoxy ester was obtained. This difference in reactivity is likely due to the methoxy group *para* to the benzylic alcohol that makes the benzylic hydroxyl group susceptible to exchange with the solvent ethanol. This reaction was suppressed by using hydrogen chloride gas bubbled through anhydrous ethanol instead of concentrated aqueous hydrochloric acid. This led to the exclusive formation of the desired hydroxy ester in 87% yield. The formation of the other hydroxy esters was carried out using aqueous acid in ethanol with yields ranging from 60 to 90%. (See Experimental section)

The α-hydroxy esters were protected as *tert*-butyldimethylsilyl (TBS) ethers using either TBSCl with imidazole as base, or *tert*-butyldimethylsilyl trifluoromethane sulfonate with 2,6-lutidine as base. For the hydroxy ester **14c**, protection using TBSCl with imidazole was incomplete after 3 days, necessitating the use of the triflate, which gave **15c** in >95% yield in 30 min.



As in the case of **15a** it was necessary to determine the appropriate amount of *tert*-butyllithium for optimum yields in the cyclization of **15b–e**. When the *ortho*-bromo ester **13d** was treated with two equivalents of *tert*-butyllithium at −78°C, the cyclized product **16b** was obtained in 90% isolated yield. Compounds such as **14e–16e** bearing an aryl methoxy group required only 1.2–1.5 equivalents of *tert*-butyllithium, as did the piperonal derivative **16a**.

When cyclization reactions were carried out on mandelic esters **15d** and **15e,** the ^{1}H NMR spectrum of the crude reaction mixtures generally showed mixtures of the starting material, the desired benzocyclobutenone, and a third compound in

Scheme 6.

Scheme 7.

which *tert*-butyllithium had added to the benzocyclobutenone. This indicated that the addition of *tert*-butyllithium to the benzocyclobutenone product begins before halogen–metal exchange is complete. Slower addition of *tert*-butyllithium and (or) lowering the reaction temperature did not improve the selectivity. The reactions were optimized with yields in the 60–70% range. This problem was overcome by converting the mandelic ester **14d** to the corresponding Weinreb amide **19d** (15, 16), which was protected using TBSOTf to give **20d**. When the protected hydroxy amide **20d** was reacted with 2.5 equivalents of *tert*-butyllithium at −78°C, the desired benzocyclobutenone **16d** was produced in essentially quantitative yield (Scheme 6). Attempts to shorten the sequence by direct cyclization of the unprotected hydroxy ester **19d** using 2.5 equivalents of *tert*-butyllithium at −78°C led to the cyclized product **17d** in only 34% yield, along with four other side products that were not identified.

Deprotection of the TBS derivatives **16** using tetra-*n*-butylammonium fluoride afforded the 2-hydroxybenzocyclobutenones **17** in 65–90% isolated yields. For the preparation of benzocyclobutenone **17e**, it was necessary to add acetic acid in the deprotection step in order to avoid base-catalyzed ring opening (17).

To try to shorten the reaction sequence, cyclization was attempted directly on the protected cyanohydrin **21** rather than the hydrolyzed cyanohydrin (Scheme 7). It was anticipated that halogen–metal exchange followed by cyclization would yield the iminium ion **22** as an intermediate and the benzocyclobutenone **11** upon aqueous work-up.

The cyanohydrin **21**, when treated with 1 equivalent of *t*-BuLi at −78°C for 5 min, afforded the rearranged nitrile **23** as the major product. The expected cyclization to **22** did occur but this intermediate underwent [2+2] ring opening even at −78°C; subsequent protonation afforded **23**. Biehl and co-workers had earlier noted the instability of the iminium ion of 2–phenylbenzocyclobutenone (18). We anticipated that cycloreversion of **22** would be considerably less favourable than **24** but unfortunately were unable to intercept it prior to ring opening.

Experimental section

General

Tetrahydrofuran (THF) was freshly distilled from sodium and benzophenone before use. Hexanes and ethyl acetate used for chromatography and distillation were routinely distilled before use. Melting points were determined using a Thomas Scientific melting point apparatus and are uncorrected. ^{1}H NMR and ^{13}C NMR spectra were recorded on either a Varian Gemini 200, Varian XL-300, or Bruker AMX 500 spectrometer in deuterated chloroform unless otherwise stated. IR spectra were recorded on a Bomem Michelson FTIR as solutions in CH_2Cl_2; then the solvent spectrum was subtracted.

Preparation of 6-bromopiperonal 12a

Piperonal (15 g, 0.10 mol) was stirred with 100 mL glacial acetic acid and bromine (6 mL, 0.12 mol) for 18 h. Water (300 mL) was added to precipitate the product. The solid was collected on a Buchner funnel and recrystallized from ethanol as colorless needles of **12a** (14.3 g, 63 mmol, 63% yield), mp 126–128°C (lit. (8) mp 127–129°C). ^{1}H NMR δ: 6.10 (s, 2H), 7.13 (s, 1H), 7.35 (s, 1H), 10.15 (s, 1H).

Preparation of 6-bromo-2-methoxybenzaldehyde 12c

A mixture of *m*-bromophenol (5 g, 29 mmol), calcium hydroxide (14 g, 0.19 mol), sodium carbonate (16 g, 0.13 mol), and 100 mL water was stirred and heated to 70°C. Chloroform (7 mL, 10.4 g, 87 mmol) was added at a rate such that a gentle reflux was maintained, about 90 min. Stirring was continued for 2 h. The mixture was acidified with concentrated sulfuric acid, extracted with CH_2Cl_2, dried with $MgSO_4$, and the solvent evaporated. Chromatography on silica gel (9:1 hexane/ethyl acetate) gave 6-bromo-2-hydroxybenzaldehyde (660 mg, 3.3 mmol, 12% yield), 600 mg of the other isomer, 2-hydroxy-4-bromobenzaldehyde, and about 1.2 g of starting material; mp 50–51°C (lit. (19) mp 52.5°C) ^{1}H NMR δ: 6.92 (dt, J = 8.9, 0.8 Hz, 1H), 7.14 (dd, J = 6.7, 0.8 Hz, 1H), 7.30 (dd, 6.7, 8.9 Hz, 1H), 10.31 (s, 1H), 11.96 (s, 1H). A mixture of 6-bromo-2-hydroxybenzaldehyde (380 mg, 2 mmol), potassium carbonate (1 g, 7.2 mmol), methyl iodide (2 mL, 4.56 g, 32 mmol), and 10 mL acetone was stirred for 20 h, diluted with 20 mL water, and extracted with ether. The organic extracts were dried with anhydrous $MgSO_4$ and evaporated to afford 400 mg crystalline **12c** (2 mmol, >95% yield), which was pure by ^{1}H NMR. mp 52–53°C. IR: 1585, 1697 cm^{-1}. ^{1}H NMR δ: 3.87 (s, 3H), 6.89 (dd, J = 1.1, 8.1 Hz, 1H), 7.16–7.32 (m, 2H), 10.36 (s, 1H). ^{13}C NMR δ: 55.86, 110.71, 124.29, 126.08, 131.07, 134.58, 161.61, 190.29. HRMS, calcd. for $C_8H_7O_2Br$: 213.9629; found: 213.9631.

Preparation of 2-bromo-5-methoxybenzaldehyde 12d

The procedure was the same as that used to prepare **12a** except the starting material was *m*-anisaldehyde. Isolated yield of **12d**: 16.5 g (70% yield), mp 71–73°C (lit. (20) mp 74°C). ^{1}H NMR δ: 3.83 (s, 3H), 7.01 (dd, J = 8.8, 3.0 Hz, 1H), 7.40 (d, J = 3.0 Hz, 1H), 7.45 (d, J = 3.0 Hz, 1H), 10.29 (s, 1H).

Preparation of 2-bromo-4-methoxybenzaldehyde 12e

To a stirred solution of trimethylethylenediamine (4.6 mL, 3.7 g, 36 mmol) in 80 mL THF at −20°C was added dropwise *n*-BuLi (13 mL 2.5 M, 32 mmol). The solution was stirred for 15 min, then *p*-anisaldehyde (3.7 mL, 4.4 g, 33 mmol) was added and stirred for 15 min. *n*-BuLi (39 mL, 2.5 M, 97.5 mmol) was added and the solution stirred, then let stand in a freezer (0°C) for 22 h. The solution was cooled to −78°C, carbon tetrabromide (30 g, 90 mmol) was added, and the solution allowed to warm to 25°C. A 10% HCl solution (300 mL) was added and extraction carried out with CH_2Cl_2. The combined organic extracts were washed with sodium thiosulfate until no cloudiness was imparted to the aqueous layer, then washed with water and brine. The organic solution was dried with anhydrous $MgSO_4$ and the solvent evaporated. The product was isolated by silica gel column chromatography (9:1 hexanes/ethyl acetate) and recrystallized from ethanol to afford 350 mg **12e** (54% yield), mp 70–71°C. IR: 1595, 1686 cm^{-1}. ^{1}H NMR δ: 3.79 (s, 3H), 6.82 (dd, 1H), 7.12 (d, 1H), 7.80 (d, 1H), 10.11 (s, 1H). ^{13}C NMR δ: 55.52, 113.74, 118.13, 126.59, 128.32, 130.93, 164.13, 190.12. HRMS, calcd. for $C_8H_7O_2Br$: 213.9629; found: 213.9622.

Preparation of cyanohydrins 13a–e

The cyanohydrins were prepared according to Gassman's procedure (9). The cyanohydrin was stirred for 1 h with 1.2 equivalents of trimethylsilyl cyanide in CH_2Cl_2. The product was isolated either by evaporating the solvent and using the crude product directly or by passing the reaction mixture through a short silica gel plug to remove the catalyst and then evaporating the solvent. The yield for all cyanohydrins was >95%, on scales from 100 mg to 15 g. **13a**: ^{1}H NMR δ: 0.23 (s, 9H), 5.67 (s, 1H), 6.01 (s, 2H), 6.98 (s, 1H), 7.16 (s, 1H). **13b**: ^{1}H NMR δ: 0.18 (s, 9H), 5.68 (s, 1H), 7.16 (dd, 1H), 7.32 (dd, 1H), 7.48 (d, 1H), 7.65 (d, 1H). **13c**: ^{1}H NMR δ: 0.18 (s, 9H), 3.91 (s, 3H), 6.16 (s, 1H), 6.87–6.91 (m, 1H), 7.18–7.21 (m, 2H). **13d**: ^{1}H NMR δ: 0.16 (s, 9H), 3.72 (s, 3H), 5.61 (s, 1H), 6.71 (dd, 1H), 7.15 (d, 1H), 7.34 (d, 1H). **13e**: ^{1}H NMR δ: 0.22 (s, 9H), 3.80 (s, 3H), 5.72 (s, 1H), 6.94 (dd, J = 2.6, 8.7 Hz, 1H), 7.10 (d, J = 2.6, 8.7 Hz, 1H).

Preparation of 2-bromohydroxy esters 14a–e

Procedure A

The cyanohydrin **13** in a solution of 3:2 ethanol/concentrated hydrochloric acid (1 g **13** in 15 mL acid solution) was refluxed for 1 h, the solution neutralized with sodium bicarbonate or sodium hydroxide, the ethanol evaporated, and extraction carried out with ether. The organic extracts were combined, dried with anhydrous $MgSO_4$, and the solvent was evaporated.

Procedure B

As for procedure A except reflux was continued for 20 h.

Procedure C

Anhydrous hydrogen chloride was bubbled through a solution of **13** in absolute ethanol for 30 min. Work-up was as for procedure A.

The crude product was generally clean by ^{1}H NMR, but could be purified by silica gel column chromatography (9:1 hexanes/ethyl acetate). The reactions were carried out on scales from 100 mg to 15 g with no decrease in yield.

14a: The compound was prepared by procedure A starting with 7.2 g **13a** (22 mmol); the yield of **14a** was 4.9 g

(16 mmol, 73% yield), mp 56–58°C. IR: 1731, 3528 cm^{-1}. ^1H NMR δ: 1.22 (t, J = 7.1 Hz, 2H), 3.49 (d, J = 4.7 Hz, 1H), 4.21 (m, 2H), 5.47 (d, J = 4.7 Hz, 1H), 5.96 (s, 2H), 6.82 (s, 1H), 6.99 (s, 1H). ^{13}C NMR δ: 14.0, 62.5, 72.1, 102.0, 108.0, 112.9, 114.4, 131.0, 147.7, 148.5, 173.3. HRMS, calcd. for $C_{11}H_{11}O_5Br$: 301.9789; found: 301.9779.

14b: This compound was prepared by procedure A starting with 1.42 g **13b** (5 mmol); the yield of **14b** was 1.13 g (4.3 mmol, 87% yield), oil. IR: 3693, 1703 cm^{-1}. ^1H NMR δ: 1.11 (t, J = 7.1 Hz, 3H), 3.40–3.60 (br, 1H), 3.95–4.25 (m, 2H), 5.45 (s, 1H), 7.06–7.11 (m, 1H), 7.15–7.35 (m, 2H), 7.46 (dd, J = 8.7 Hz, 1H). ^{13}C NMR δ: 13.6, 62.0, 72.0, 123.2, 127.4, 128.4, 129.5, 132.8, 137.5, 172.8. HRMS, calcd. for $C_{10}H_{11}O_3Br$: 257.9891; found: 257.9890.

14c: The compound was prepared by procedure B from 540 mg **13c** (1.7 mmol); the yield of **14c** was 280 mg (0.97 mmol, 57% yield), mp 102–103°C. IR: 1737 cm^{-1}. ^1H NMR δ: 1.19 (t, J = 7.6 Hz, 3H), 3.62 (d, J = 1.7, 6.8 Hz, 1H), 3.79 (s, 3H), 4.21 (q, J = 7.6 Hz, 2H), 5.66 (d, J = 6.8 Hz, 1H), 6.81 (dd, J = 1.7, 7.7 Hz, 1H), 7.10–7.24 (m, 2H). ^{13}C NMR δ: 14.1, 55.9, 61.8, 70.7, 110.4, 125.5, 127.2, 130.4, 158.3, 173.2 (two of the aromatic carbon signals apparently overlap). LRMS (CI,M+1), calcd. for $C_{11}H_{13}O_4Br$: 289.0; found: 288.9

14d: The compound was prepared by procedure A from 13.9 g **13d** (44 mmol); the yield of **14d** was 10.9 g (38 mmol, 86% yield), mp 60–62°C. IR: 3517, 1732 cm^{-1}. ^1H NMR δ: 1.19 (t, J = 7.1 Hz, 3H), 3.70 (br, 1H), 3.73 (s, 3H), 4.09–4.31 (m, 2H), 5.60 (s, 1H), 6.70 (dd, J = 3.0, 8.8 Hz, 1H), 6.88 (d, J = 3.0 Hz, 1H), 7.40 (d, J = 8.8 Hz, 1H). ^{13}C NMR δ: 13.6, 55.1, 62.1, 72.0, 113.4, 113.5, 115.7, 133.4, 138.3, 158.8, 172.7. HRMS, calcd. for $C_{11}H_{13}O_2Br$: 287.9997; found: 287.9998.

14e: The compound was prepared by procedure C from 100 mg **13e** (0.32 mmol); the yield of **14e** was 81 mg (0.28 mmol, 88% yield), mp 58–59°C. IR: 3519, 1732 cm^{-1}. ^1H NMR δ: 1.23 (t, J = 7.1 Hz, 3H), 3.48 (d, J = 5.0 Hz, 1H), 3.78 (s, 3H), 4.21 (m, 2H), 5.46, (d, J = 5.0 Hz, 1H), 6.84 (dd, J = 2.7, 8.7 Hz, 1H), 7.10 (d, J = 2.7 Hz, 1H), 7.24 (d, J = 8.7 Hz, 1H). ^{13}C NMR δ: 13.6, 55.2, 61.9, 71.6, 113.4, 117.9, 129.0, 129.6, 159.6, 173.1, 190.3. HRMS, calcd. for $C_{11}H_{13}O_2Br$: 287.9997; found: 287.9985.

Preparation of TBS protected esters 15a–e

Procedure A

The hydroxy ester was treated with 1.2 equivalents of *tert*-butyldimethylsilyl chloride and 2.2 equivalents of imidazole in DMF and stirred at 25°C for 24 h. The reaction mixture was diluted with water, extracted with CH_2Cl_2, and the organic extracts were washed with water until no concentration gradients were visible when water was added. The organic extracts were dried with anhydrous $MgSO_4$ and the solvent was evaporated. The compounds were isolated and purified by either silica gel column chromatography or reduced pressure distillation as indicated. This reaction was carried out on scales from 100 mg to 15 g with no effect on the yield.

Procedure B

The hydroxy ester was stirred with 1.5 equivalents of *tert*-butyldimethylsilyl trifluoromethanesulfonate and 2 equivalents of 2,6–lutidine in CH_2Cl_2 at 25°C for 30 min. Water was added and extraction carried out with CH_2Cl_2. The organic extracts were dried with anhydrous $MgSO_4$ and the solvent was evaporated. The crude material was purified by flash chromatography on silica gel (9:1 hexane/ethyl acetate).

15a: The compound was prepared by procedure A from 2.65 g **14a** (8.7 mmol); the yield of **15a** was 3.19 g (7.5 mmol, 87% yield), oil. IR: 1743 cm^{-1}. ^1H NMR δ: 0.03 (s, 3H), 0.11 (s, 3H), 0.89 (s, 9H), 1.21 (t, J = 7.1 Hz, 3H), 4.13 (q, J = 7.1 Hz, 2H), 5.48 (s, 1H), 5.96 (s, 1H), 6.94 (s, 1H), 7.07 (s, 1H). ^{13}C NMR δ: −5.1, −5.0, 14.1, 18.2, 25.7, 25.8, 61.2, 73.4, 101.8, 108.4, 112.2, 113.0, 132.4, 148.2, 171.2. LRMS (M^+ − t-Bu), calcd. for $C_{13}H_{16}O_5BrSi$: 359.0; found: 358.8.

15b: The compound was prepared by procedure A from 2.90 g **14b** (11 mmol); the yield of **15b** was 3.74 g (9.9 mmol, 90% yield), oil. IR: 3661, 1738 cm^{-1}. ^1H NMR δ: 0.03 (s, 3H), 0.12 (s, 3H), 0.89 (s, 9H), 1.20 (t, J = 7.1 Hz, 3H), 4.13 (q, J = 7.1 Hz, 2H), 5.57 (s, 1H), 7.15 (dd, J = 1.8, 9.4 Hz, 1H), 7.31 (m, 1H), 7.49 (d, J = 1.3, 9.4 Hz, 1H), 7.59 (dd, J = 1.8, 7.8 Hz, 1H). ^{13}C NMR δ: −4.7, −4.6, 13.6, 17.9, 25.2, 25.3, 60.8, 73.1, 122.1, 127.2, 128.5, 129.1, 132.1, 138.7, 170.8. LRMS (M^+ − t-Bu), calcd. for $C_{12}H_{16}O_3BrSi$: 315.0; found: 315.0.

15c: This compound was prepared by procedure B from 60 mg **14c** (0.2 mmol); 60 mg of **15c** (0.15 mmol, 75% yield) was isolated after flash chromatography on silica gel (9:1 hexanes/ethyl acetate as eluent), oil. IR: 1753 cm^{-1}. ^1H NMR δ: -0.05 (s, 3H), 0.14 (s, 3H), 0.85 (s, 9H), 1.18 (t, J = 7.1 Hz, 3H), 3.77 (s, 3H), 4.16 (dq, J = 3.2, 7.1 Hz, 2H), 5.74 (s, 1H), 6.80 (dd, J = 2.0, 7.6 Hz, 1H), 7.08–7.20 (m, 2H). ^{13}C NMR δ: −4.9, −4.6,14.3, 18.3, 25.8, 56.4, 61.0, 70.1, 110.9, 125.0, 125.6, 129.2, 130.1, 158.6, 172.6. MS (CI,M^++1), calcd. for $C_{17}H_{27}O_4BrSi$: 403.1; found: 402.9.

15d: This compound was prepared by procedure A from 1.25 g **14d** (4.3 mmol), the yield of **15d** was 1.59 g (3.9 mmol, 89% yield) after silica gel column chromatography, oil. IR: 1742 cm^{-1}. ^1H NMR δ: 0.04 (s, 3H), 0.12 (s, 3H), 0.90 (s, 9H), 1.21 (t, J = 7.1 Hz, 3H), 3.77 (s, 3H), 4.08–4.18 (dq, J = 7.1, 0.8 Hz, 2H), 5.50 (s, 1H), 6.71 (dd, J = 3.3, 8.8 Hz, 1H), 7.15 (d, J = 3.3 Hz, 1H), 7.38 (d, J = 8.8 Hz, 1H). ^{13}C NMR δ: −5.0, −5.1, 13.6, 17.9, 24.8, 25.3, 55.0, 60.8, 73.1, 112.4, 113.1, 115.7, 132.6, 139.5, 158.7, 170.6. HRMS (M^+ − t-Bu), calcd. for $C_{13}H_{18}O_4BrSi$: 345.0157; found: 345.0163.

15e: The compound was prepared by procedure B from 130 mg **14e** (0.45 mmol); the yield of **15e** was 180 mg (0.45 mmol, >95% yield) after flash chromatography on silica gel, oil. IR: 1722 cm^{-1}. ^1H NMR δ: 0.01 (s, 1H), 0.10 (s, 3H), 0.88 (s, 9H), 1.20 (t, J = 7.1 Hz, 3H), 3.77 (s, 3H), 4.12 (q, J = 7.1 Hz, 2H), 5.50 (s, 1H), 6.86 (dd, J = 2.6, 8.8 Hz, 1H), 7.04 (d, J = 2.6 Hz, 1H), 7.48 (d, J = 8.8 Hz, 1H). ^{13}C NMR δ: −4.9, −4.7, 14.0, 18.2, 25.5, 25.6, 55.4, 61.0, 73.0, 113.8, 117.4, 122.7, 129.4, 131.1, 159.7, 171.4. MS calcd. for $C_{17}H_{27}O_4SiBr$: 402.1(M^+), 345.0 for M^+−t-Bu; found CI (M^++1): 403.0; EI (M^+−t-Bu): 345.0.

Preparation of 2-tert-Butyldimethylsilyloxybenzocyclobutenones 16a–e

General method

tert-Butyllithium (equivalents as indicated for each compound) was added to a solution of ester **15** in THF under nitrogen atmosphere at −78°C and stirred for 15 min. The solution was quenched with saturated NH_4Cl solution and allowed to warm to room temperature. Extraction was carried out with diethyl ether, the organic extracts were dried with anhydrous $MgSO_4$, and the solvent was evaporated. Purification was carried out using flash chromatography on silica gel (9:1 hexanes/ethyl acetate as eluent). Recrystallization was carried out as noted for each compound.

16a: The compound was prepared by the general method using 1.5 equivalents of *tert*-butyllithium and 1.9 g of **15a** (4.5 mmol) as starting material; the yield of **16a** was 1.35 g (4.5 mmol, >95% yield), isolated as colorless prisms after recrystallization from hexanes – ethyl acetate, mp 104–105°C. IR: 1757 cm^{-1}. ^1H NMR δ: 0.15 (s, 3H), 0.17 (s, 3H), 0.92 (s, 9H), 5.56 (s, 1H), 6.07 (s, 2H), 6.80 (s, 1H), 6.99 (s, 1H). ^{13}C NMR δ: −4.7, −4.5, 18.3, 25.8, 83.9, 100.7, 102.2, 103.4, 140.5, 151.5, 154.4, 155.5, 187.5. HRMS, calcd. for $C_{15}H_{20}O_4Si$: 292.1131; found: 292.1108. Anal. calcd. for $C_{15}H_{20}O_4Si$: C 61.61, H 6.90%; found: C 61.48, H 6.86%.

16b: This compound was prepared by the general method using 2 equivalents of *tert*-butyllithium and 1.0 g **15b** (2.6 mmol); the yield of **16b** was 0.62 g (2.5 mmol, 96% yield) after purification by radial chromatography (9:1 hexanes/ethyl acetate), oil. IR: 1765 cm^{-1}. ^1H NMR δ: 0.20 (s, 3H), 0.22 (s, 3H), 0.96 (s, 9H), 5.78 (s, 1H), 7.44–7.68 (m, 4H). ^{13}C NMR δ: −4.8, −4.5, 18.3, 25.8, 86.2, 121.6, 123.6, 131.0, 135.4, 146.9, 158.0, 190.7. HRMS, calcd. for $C_{14}H_{20}O_2Si$: 248.1233; found: 248.1204.

16c: The compound was prepared by the general method using 1.2 equivalents *tert*-butyllithium and 750 mg **15c** (1.6 mmol), 386 mg **16c** (1.4 mmol, 88% yield) was isolated after purification by silica gel chromatography (9:1 hexanes/ethyl acetate), oil. IR: 1769 cm^{-1}. ^1H NMR δ: 0.18 (s, 3H), 0.19 (s, 3H), 0.91 (s, 9H), 4.00 (s, 3H), 5.83 (s, 1H), 7.01 (m, 2H), 7.41 (m, 1H). ^{13}C NMR δ: −4.5, −3.8, 18.8, 26.3, 57.8, 86.6, 112.9, 113.9, 121.8, 133.6, 142.6, 149.3, 157.1, 191.4. HRMS, calcd. for $C_{15}H_{22}O_3Si$: 278.1329; found: 278.1350.

16d: This compound was prepared by the general method using 1.5 equivalents of *tert*-butyllithium and 1 g **15d** (2.5 mmol); the yield of **16d** was 470 mg (1.7 mmol, 68% yield). Purification was carried out by flash chromatography on silica gel (9:1 hexanes/ethyl acetate), mp 43–44°C. IR: 1754 cm^{-1}. ^1H NMR δ: 0.18 (s, 3H), 0.21 (s, 3H), 0.95 (s, 9H), 3.91 (s, 3H), 5.68 (s, 1H), 7.00–7.08 (m, 1H), 7.05 (s, 1H), 7.36 (dd, J = 1.7, 7.5 Hz, 1H). ^{13}C NMR: δ: −4.8, −4.5, 18.3, 25.7, 55.8, 85.1, 105.9, 120.7, 123.6, 138.9, 160.4, 165.6, 188.1. HRMS, calcd. for $C_{15}H_{22}O_3Si$: 278.1329; found: 278.1315.

16e: The compound was prepared by the general method using 1.5 equivalents of *tert*-butyllithium and 120 mg **15e** (3.0 mmol); the yield of **16e** was 50 mg (1.8 mmol, 60% yield) after flash chromatography on silica gel, oil. IR: 1762 cm^{-1}. ^1H NMR δ: 0.15 (s, 3H), 0.17 (s, 3H), 0.92 (s, 9H), 3.80 (s, 3H), 5.67 (s, 1H), 6.87 (d, J = 2.0 Hz, 1H), 7.13 (dd, J = 2.0, 8.2 Hz, 1H), 7.53 (d, J = 8.2 Hz, 1H). ^{13}C NMR δ: −4.7, −4.5, 18.3, 25.8, 55.7, 85.0, 102.6, 124.6, 125.4, 148.3, 151.3, 162.3, 190.2. HRMS, calcd. for $C_{15}H_{22}O_3Si$: 278.1329; found: 278.1352.

Preparation of 2-hydroxybenzocyclobutenones 17a–e

General method

Tetra-*n*-butylammonium fluoride solution in THF (1 equivalent) was added to a stirred solution of the benzocyclobutenone in THF and immediately quenched with saturated aqueous NH_4Cl. The mixture was extracted with diethyl ether, the organic extracts were dried with anhydrous magnesium sulfate, and the solvent was evaporated. The compounds were purified by flash chromatography on silica gel (1:1 hexanes/ethyl acetate as eluent).

17a: This compound was prepared by the general method using 420 mg **16a** (1.4 mmol); the yield of **17a** was 190 mg (1.1 mmol, 79% yield) after silica gel column chromatography, mp 155–157°C. IR: 1756, 3581 cm^{-1}. ^1H NMR (d_6 acetone) δ: 5.35 (br, 1H), 5.50 (s, 1H), 6.19 (s, 2H), 6.86 (s, 1H), 7.16 (s, 1H). ^{13}C NMR (d_6 acetone) δ: 84.6, 100.6, 103.5, 104.2, 141.4, 152.5, 155.3, 157.1, 188.8. HRMS, calcd. for $C_9H_6O_4$: 178.0266; found: 178.0279. Anal. calcd. for $C_9H_6O_4$: C 60.68, H 3.39%; found: C 60.49, H 3.25%.

17b: This compound was prepared by the general method using 380 mg **16b** (1.5 mmol); the yield of **17b** was 132 mg (0.99 mmol, 66% yield) after silica gel column chromatography, mp 52.5–53.5°C. IR: 1766, 3582 cm^{-1}. ^1H NMR δ: 3.05 (br, 1H), 5.79 (s, 1H), 7.49–7.62 (m, 3H), 7.75 (m, 1H). ^{13}C NMR (d_6 acetone) δ: 87.1, 121.7, 124.6, 131.8, 136.2, 148.0, 159.6, 192.2. HRMS, calcd. for $C_8H_6O_2$: 134.0368; found: 134.0379. Anal. calcd. for $C_8H_6O_2$: C 71.64, H 4.51%; found: C 71.93, H 4.29%.

17c: The reaction was performed on 50 mg **16c** (0.18 mmol); isolated after column chromatography was 20 mg **17c** (0.12 mmol, 67% yield), which crystallized on standing, mp 70–72°C. IR: 1767, 3575 cm^{-1}. ^1H NMR δ: 3.50 (br, 1H), 4.03 (s, 3H), 5.85 (br, 1H), 7.01–7.07 (m, 2H), 7.45 (m, 1H). ^{13}C NMR δ: 57.3, 85.7, 113.5, 121.7, 133.4, 141.3, 148.9, 156.6, 191.3. HRMS, calcd. for $C_9H_8O_3$: 164.0473; found: 164.0487.

17d: This compound was prepared using the general method on 470 mg **16d** (1.7 mmol); the yield of **17d** was 240 mg (1.5 mmol, 88% yield) after silica gel column chromatography, mp 95.0–95.5°C. IR: 1758, 3587 cm^{-1}. ^1H NMR (d_6 acetone) δ: 3.95 (s, 3H), 5.63 (s, 1H), 7.12 (dd, J = 2.0, 8.5 Hz, 1H), 7.27 (d, J = 2.0 Hz, 1H), 7.38 (dd, J = 0.7, 8.5 Hz, 1H). ^{13}C NMR (d_6 acetone) δ: 56.4, 86.0, 107.1, 121.3, 123.7, 139.9, 162.2, 166.5, 189.5. HRMS, calcd. for $C_9H_8O_3$: 164.0473; found: 164.0453.

17e: TBAF (1 M, 0.16 mL, 0.16 mmol) was added to a solution of 11 mg **16e** (0.040 mmol) and 100 μL acetic acid in 5 mL THF. The solution was stirred for 1 h, washed with

© 1997 NRC Canada

saturated NH_4Cl, saturated $NaHCO_3$, and brine, then dried with anhydrous $MgSO_4$, and the solvent evaporated. Column chromatography on silica gel (ethyl acetate needed to remove **17e**) afforded approximately 2 mg of the desired hydroxy ketone **17e** (0.012 mmol, ~30% yield). ^{1}H NMR δ: 3.82 (s, 3H), 5.69 (br s, 1H), 6.88 (dd, J = 2.2, 0.4 Hz, 1H), 7.19 (dd, J = 8.3, 2.2 Hz, 1H), 7.62 (dd, J = 8.3, 0.4 Hz, 1H). ^{13}C NMR δ: 55.8, 85.1, 102.7, 124.9, 125.8, 148.8, 150.5, 162.7, 189.2. HRMS, calcd. for $C_9H_8O_3$: 164.0473; found: 164.0453.

Preparation of Weinreb amide 19d

Trimethylaluminum (4.3 mL, 2.0 M, 8.6 mmol) was added to a solution of *N,O*-dimethylhydroxylamine hydrochloride (370 mg, 3.8 mmol) in 10 mL dry CH_2Cl_2 under nitrogen atmosphere and the solution stirred for 15 min at 25°C. A solution of **14d** (1 g, 3.5 mmol) in dry CH_2Cl_2 was added and the solution refluxed for 24 h. Dilute HCl(aq) was **slowly and carefully** added dropwise through the condenser until gas evolution ceased and all remaining white precipitate had dissolved. The layers were separated and the aqueous layer extracted with CH_2Cl_2. The organic extracts were combined, washed with water and brine, dried with anhydrous $MgSO_4$, and the solvent was evaporated. Yield: ^{1}H NMR spectrum showed 60% conversion, 450 mg isolated, 73% based on conversion of starting material; mp 71.0–71.5°C. IR: 1662, 3447 cm^{-1}. ^{1}H NMR δ: 3.20 (s, 3H), 3.29 (s, 3H), 3.73 (s, 3H), 4.28 (br, 1H), 5.71 (br, 1H), 6.68–6.76 (m, 2H), 7.44 (d, J = 8.6 Hz, 1H). ^{13}C NMR δ: 55.1, 60.5, 70.4, 89.2, 113.2, 114.3, 115.6, 133.3, 139.3, 159.0, 172.7. HRMS, calcd. for $C_{11}H_{14}NO_4$ (M^+ − Br) 224.0923; found: 224.0914.

Preparation of 20d

A solution of **19d** (135 mg, 0.44 mmol), *tert*-butyldimethylsilyl triflate (154 μL, 0.66 mmol), and 2,6–lutidine (105 μL, 0.88 mmol) in 10 mL dry CH_2Cl_2 was stirred for 30 min at 25°C. The solution was diluted with water (10 mL) and extracted with CH_2Cl_2. The combined organic extracts were dried with anhydrous $MgSO_4$ and the solvent was evaporated leaving 179 mg **20d** (0.43 mmol, >95% yield), a pale yellow crystalline solid that was pure by ^{1}H NMR, mp 81.0–81.5°C. IR: 1677 cm^{-1}. ^{1}H NMR δ: −0.01 (s, 3H), 0.12 (s, 3H), 0.86 (s, 9H), 3.13 (s, 3H), 3.48 (s, 3H), 3.75 (s, 3H), 5.83 (s, 1H), 6.68–6.71 (m, 1H), 7.09–7.11 (m, 1H), 7.35–7.38 (m, 1H). ^{13}C NMR δ: −4.8, −4.6, 18.2, 25.8, 32.7, 55.5, 61.0, 71.8, 113.3, 114.5, 116.3, 132.9, 140.0, 159.1, 171.9. HRMS, calcd. for $C_{13}H_{19}BrNO_4Si$ (M^+ − *t*-Bu): 360.0267; found: 360.0279.

Preparation of 23

Compound **21** (300 mg, 0.88 mmol) in 10 mL THF was cooled to −78°C and *tert*-butyllithium (550 μL, 1.7 M, 0.94 mmol) was added and stirred for 15 min. The reaction was quenched with saturated NH_4Cl solution and allowed to warm to 25°C. Extraction was carried out with CH_2Cl_2, the solvent dried with anhydrous $MgSO_4$, and the solvent evaporated. The major compound isolated after chromatography on silica gel was **23**, oil. ^{1}H NMR δ: 1.4–1.9 (m, 6H), 3.45–3.63 (m, 1H), 3.82–3.97 (m, 1H), 4.58 (d, J = 18 Hz, 1H), 4.72–4.78 (m, 1H), 4.82 (d, J = 18 Hz, 1H), 5.98 (s, 1H), 6.04 (s, 2H), 6.98 (s, 1H), 7.02 (s, 1H). HRMS, calcd. for $C_{14}H_{15}O_4N$: 261.1002; found: 261.1008.

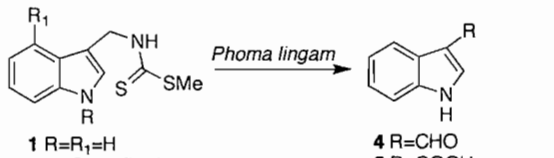
Preparation, biotransformation, and antifungal activity of methyl benzyldithiocarbamates

M. Soledade C. Pedras, Abdul Q. Khan, Kevin C. Smith, and Shawndra L. Stettner

Abstract: The biotransformation of three methyl benzyldithiocarbamates by the blackleg fungus (*Leptosphaeria maculans* (Desm.) Ces. et de Not., asexual stage *Phoma lingam* (Tode ex Fr.) Desm) was investigated. The main biotransformation products were isolated and their chemical structures were determined by spectroscopic methods. Similarly to our previous studies with the phytoalexin brassinin, these results suggest that virulent blackleg isolates are significantly more effective in metabolizing benzyldithiocarbamates than the related avirulent isolates.

Key words: benzyldithiocarbamates, brassinin, *Leptosphaeria maculans*, *Phoma lingam*, phytoalexins.

Résumé : On a étudié la biotransformation de trois benzyldithiocarbamates de méthyle par le champignon à jambe noire (*Leptosphaeria maculans* (Desm.) Ces. et de Not., stage asexué du *Phoma lingam* (Tode ex Fr.) Desm). On a isolé les principaux produits de biotransformation et on a déterminé leurs structures chimiques par des méthodes spectroscopiques. Comme ce fût le cas dans nos études antérieures sur la phytoalexine brassinine, ces résultats suggèrent que les souches virulents du champignon à jambe noire sont beaucoup plus efficaces à métaboliser les benzyldithiocarbamates que les souches avirulentes.



Mots clés : benzyldithiocarbamates, brassinine, *Lestosphaeria maculans*, *Phoma lingam*, phytoalexines.

[Traduit par la rédaction]

Although dithiocarbamates have long been known as a very important class of bioactive products (1), only recently were they reported to occur in plants. A group of phytoalexins containing a dithiocarbamate group attached to a 3-methylindolyl moiety, as, for example, the brassinins **1–3**, is produced by plants from diverse *Brassica* species (e.g., canola, rapeseed, broccoli, cabbage, turnip, etc.) in response to stress (2). In general, the production of phytoalexins is an important defense mechanism in plants (3). On the other hand, phytoalexin metabolism can be used by phytopathogens as a detoxification mechanism to overcome the plants' chemical defenses (4). Our studies to elucidate the metabolism of brassica phytoalexins by their pathogenic fungi suggest that detoxification mechanisms are related to fungal virulence (5, 6). In fact, detoxification of brassinin (**1**) appears to be one of the mechanisms by which the blackleg fungus (*Phoma lingam* (Tode ex Fr.) Desm., perfect stage *Leptosphaeria maculans* (Desm.) Ces. et de Not.) overcomes rapeseed/canola (*Brassica napus, B. rapa*) defenses (5). We established that the metabolism of brassinin (**1**) by diverse virulent isolates of *P. lingam* yields the aldehyde **4** and the significantly less toxic carboxylic acid **5**. Importantly, we determined that avirulent isolates of *P. lingam*[2] (7) follow a different metabolic pathway from that of virulent isolates, yielding mostly acetylamine **6** (5). It is noteworthy that other phytopathogens of brassicas, as, for example, *Alternaria brassicae* (blackspot disease), follow a pathway similar to that of avirulent isolates of *P. lingam*.[3] Because brassinin (**1**) is a biogenetic precursor of several other phytoalexins (8), its metabolism by fungi could deprive the plant of other important phytoalexins. The overall result would be a plant more susceptible to further fungal colonization.

We are currently investigating phytoalexin detoxification by fungal and bacterial pathogens of brassicas with the goal of devising new strategies for controlling plant fungal diseases (2*a*, 6). One important aspect of our investigation requires the isolation of the fungal enzymes and (or) genes involved in the detoxification of these phytolexins. An approach to isolate the fungal genes responsible for the detoxification of brassinin

Table 1. Metabolism of dithiocarbamates **7–9** by *Phoma lingam* isolates BJ-125 (virulent to canola) and Unity (avirulent to canola).

Fungal isolate (virulence)	Compound (concentration in fungal culture)	Products of metabolism, incubation time
BJ-125 (virulent)	Me 4-chlorobenzyldithiocarbamate (**7**) (10^{-4} M)	4-Chlorobenzoic acid, complete transformation in 6 h
	Me 2,4-dichlorobenzyldithiocarbamate (**8**) (10^{-4} M)	*N*-(2,4-Dichlorobenzyl)acetamide, complete transformation in 24 h
	Me 4-hydroxybenzyldithiocarbamate (**9**) (4×10^{-4} M)	Polar product(s), complete transformation in 10 h
	N-(2,4-Dichlorobenzyl)acetamide (**13**) (10^{-4} M)	No detectable transformation in 48 h
	4-Hydroxybenzoic acid (**14**) (4×10^{-4} M)	Polar product(s), 80% transformation in 8 h
Unity (avirulent)	Me 4-chlorobenzyldithiocarbamate (**7**) (6×10^{-5} M)	4-Chlorobenzoic acid, <10% in 48 h
	Me 2,4-dichlorobenzyldithiocarbamate (**8**) (6×10^{-5} M)	*N*-(2,4-Dichlorobenzyl)acetamide, <10% in 48 h
	Me 4-hydroxybenzyldithiocarbamate (**9**) (4×10^{-4} M)	Polar product(s), 70% transformation in 10 h

involves genetic transformation followed by selection of these transformants with brassinin. However, because of the low solubility of brassinin in the selection medium, it would be useful to have at hand brassinin analogs having stronger antifungal activity and (or) higher solubility in the selection medium. Towards this end we evaluated several dithiocarbamates and now wish to report the biotransformation of benzyldithiocarbamates **7**, **8**, and **9** by blackleg fungi.

Results and discussion

Benzyldithiocarbamates **7–9** were prepared from the corresponding benzylamines to investigate their antifungal activity and metabolism by isolates of *P. lingam*. Isolates BJ-125 (virulent to canola) and Unity (avirulent to canola) were grown in shake cultures. After 42–44 h, solutions of methyl 4-chlorobenzyldithiocarbamate (**7**) (various concentrations, 6×10^{-5} M to 4×10^{-4} M) in DMSO were added to fungal cultures and to uninoculated media. Control cultures of the fungus were grown separately. Cultures were incubated and samples were withdrawn at 2–24 h intervals (up to 6 days), extracted first with Et_2O, and then acidified and reextracted. Comparison of the HPLC chromatograms of extracts of control cultures and extracts of fungal cultures incubated with **7** indicated that the later extracts contained possible biotransformation products. The optimum incubation time for isolation of the putative products was determined by TLC and (or) HPLC analysis of each extract. Subsequently, the components of the neutral Et_2O extracts obtained from larger scale cultures (200 mL or more) were separated by preparative TLC and each constituent analyzed by ^1H and ^{13}C NMR, FTIR, and MS. Similar experiments were carried out for methyl 2,4-dichlorobenzyldithiocarbamate (**8**) and methyl 4-hydroxybenzyldithiocarbamate (**9**).

The rate and products of biotransformation of the two chlorobenzyldithiocarbamates differed significantly (Table 1); while the monochloro derivative **7** was metabolized by virulent isolate BJ-125 in less than 6 h to the corresponding 4-chlorobenzoic acid, the dichloro derivative **8** was metabolized to the corresponding 2,4-dichlorobenzylacetamide (**13**, R_1 = R_2 = Cl) in ca. 24 h. The corresponding carboxylic acid **11** (R_1 = R_2 = Cl), although a minor component, was also detected in the cultures incubated with dichloro derivative **8**; however no 2-chlorobenzylacetamide was detected in cultures incubated with the monochloro derivative **7**. The structure of 2,4-dichlorobenzylacetamide was deduced from spectroscopic data and corroborated by acetylation (Ac_2O) of 2,4-dichlorobenzylamine. 2,4-Dichlorobenzylacetamide was stable in fungal cultures and in uninoculated medium for at least 6 days. The structures of 2,4-dichloro and 4-chlorobenzoic acids were readily determined by comparison of their spectroscopic data with those of authentic samples and confirmed by methylation of each acid with diazomethane.[4] Furthermore, the dichlorobenzyldithiocarbamate **8** was significantly more toxic to isolate BJ-125 than the monochlorobenzyldithiocarbamate **7**. The latter compound **7**, even at a concentration of 4×10^{-4} M, was metabolized to the corresponding benzoic acid by this virulent isolate, whereas **8** at a similar concentration did not give biotransformation products (up to 6 days) and appeared to inhibit completely the growth of the fungal mycelium. On the other hand, the 4-hydroxybenzyldithiocarbamate (**9**) did not appear to have a detectable toxic effect even at a concentration of 4×10^{-4} M, as it was metabolized by the virulent isolate BJ-125 to unidentified polar product(s) in less than 10 h. The corresponding 4-hydroxybenzoic acid (**14**) was not detected either in neutral or acidic extracts of cultures incubated with **9**. However, the biotransformation of **9** is also likely to occur via the corresponding acid since the fungus metabolized 4-hydroxybenzoic acid (**14**) very rapidly to unidentified polar product(s).

The avirulent isolate Unity was also incubated with dithiocarbamates **7** and **8**; in contrast with the results obtained for the virulent isolate, the biotransformation appeared to be significantly slower. As shown in Table 1, less than 10% of each

[4] The methyl esters of both acids give well-resolved peaks by HPLC analysis.

Table 2. HPLC retention times (for conditions see experimental section) of dithiocarbamates **7–9**, their biotransformation products, and derivatives.

Compound	Retention time (min)
Me 4-chlorobenzyldithiocarbamate (**7**)	23.6
Me 2,4-dichlorobenzyldithiocarbamate (**8**)	27.3
Me 4-hydroxybenzyldithiocarbamate (**9**)	11.6
4-Chlorobenzoic acid (**10**)	ca. 5 (broad)
2,4-Dichlorobenzoic acid (**11**)	ca. 4 (broad)
N-(4-Chlorobenzyl)acetamide (**12**)	8.2
N-(2,4-Dichlorobenzyl)acetamide (**13**)	11.6
4-Hydroxybenzoic acid (**14**)	ca. 2 (broad)
Me 4-chlorobenzoate	20.4
Me 2,4-dichlorobenzoate	23.2

dithiocarbamate was metabolized in 48 h to either the corresponding 4-chlorobenzoic acid (**10**) or to the 2,4-dichloroacetamide (**13**), similar to the virulent isolate BJ-125. The 4-hydroxybenzyldithiocarbamate (**9**) did not appear to have a significant toxic effect on isolate Unity, even at a concentration of 4×10^{-4} M, as it was metabolized rapidly to unidentified polar product(s), although at a lower rate than the virulent isolate BJ-125 (Table 1).

As in our previous studies with brassinin (5) and brassicanal A (6), these results suggest that virulent blackleg isolates are significantly more effective in detoxifying benzyldithiocarbamates than the related avirulent isolates. However, we found an unexpected difference between the biotransformation of dithiocarbamates **7** and **8**. In contrast with our previous work on metabolism of brassinin (**1**) (5) and methyl 4-methylbenzyldithiocarbamate (9), this virulent isolate of *P. lingam* metabolized the dichlorinated dithiocarbamate **8** to the acetamide **13**. As expected, the metabolism of the monochlorinated dithiocarbamate **7** proceeded to give the corresponding carboxylic acid. On the other hand, the hydroxy dithiocarbamate **9** appeared to be rapidly transformed by both virulent and avirulent isolates to polar metabolite(s) via the corresponding 4-hydroxybenzoic acid (**14**). It is worth noting that the same virulent isolate BJ-125 metabolized brassinin to the corresponding nontoxic carboxylic acid.

Although our data are insufficient for a definite conclusion, it is not surprising to find that the chlorinated benzyldithiocarbamates **7** and **8** are more toxic than the hydroxybenzyldithiocarbamate **9**, as chlorinated compounds are known to have diverse toxic effects (10). The puzzling difference between the metabolism of the two chlorinated compounds may reflect in fact the higher toxicity of the dichlorobenzyldithiocarbamate. Nonetheless, both biotransformations yield products that are much less toxic to the fungal cells than any of the chlorinated dithiocarbamates **7** or **8**. A better understanding of these detoxification processes might be obtained with cell-free systems of virulent and avirulent fungal isolates.

Experimental

General

All chemicals were purchased from Aldrich Chemical Company, Inc., Madison, Wis., or Sigma Chemical Company, St. Louis, Mo. All solvents were HPLC grade and used as such. Preparative TLC: Merck, Kieselgel 60 F_{254}, 20 × 20 cm × 0.25 mm; analytical TLC: Merck, Kieselgel 60 F_{254}, aluminum sheets, 5 × 2 cm × 0.2 mm; compounds were visualized by exposure to UV and by dipping the plates in a 5% aqueous (w/v) phosphomolybdic acid solution containing a trace of ceric sulfate and 4% (v/v) H_2SO_4, followed by heating at 200°C. Flash column chromatography (FCC): silica gel Merck, grade 60, mesh size 230–400, 60 Å. HPLC analysis was carried out with a high-performance Hewlett Packard liquid chromatograph equipped with quaternary pump, automatic injector, and diode array detector (wavelength range 190–600 nm), degasser, and a Hypersil ODS column (5 μm particle size silica, 4.6 i.d. × 200 mm). HPLC mobile phase: 75% H_2O – 25% CH_3CN to 100% CH_3CN, for 35 min, linear gradient, and a flow rate 1.0 mL/min. Samples for HPLC analysis were dissolved in acetonitrile (ca. 0.5 mg/mL) and filtered through a cotton plug. NMR spectra were recorded on a Bruker AMX 500 or AM 300 spectrometer; for ^1H (300 or 500 MHz), δ values were referenced to $CHCl_3$ (7.24 ppm) and for ^{13}C (75.5 or 125.8 MHz), referenced to $CDCl_3$ (77.0 ppm). Fourier transform infrared (FTIR) spectra were obtained on a Bio-Rad FTS-40 spectrometer using a diffuse reflectance cell. Mass spectra (MS) were obtained on a VG 70 SE mass spectrometer (high resolution (HR), electron impact (EI)], employing a solids probe.

Fungal cultures

Phoma lingam virulent isolate BJ-125 and avirulent isolate Unity were obtained from Séguin-Swartz (Agriculture Canada Research Station, Saskatoon, Saskatchewan). The fungal isolates were grown on V8 agar (20% (v/v) V8 juice, 0.75 g/L $CaCO_3$, 100 mg/L streptomycin sulfate, 40 mg/L Rose Bengal, 15 g/L agar) plates at 21°C, 12 h photoperiod for 10 days. Spore suspensions of each isolate were prepared by overlaying the V8 agar plates with 10 mL sterile distill water and the plate surfaces were rubbed with a flamed glass rod to dislodge the spores. The suspension was transferred to centrifuge tubes and the spores were pelleted by centrifugation at 3000 g for 10 min. After washing once, the spores were stored in sterile distilled water at −20°C. Liquid cultures were initiated by inoculating fungal spores in sterile minimal medium (15 g/L glucose, 3.12 g/L KNO_3, 750 mg/L K_2HPO_4, 750 mg/L KH_2PO_4, 100 mg/L NaCl, 280 mg/L asparagine, 0.4 mg/L $ZnSO_4 \cdot 7\ H_2O$, 79 μg/L $CuSO_4 \cdot 5\ H_2O$, 41 μg/L $MnSO_4 \cdot 4\ H_2O$, 18 μg/L MoO_3, 0.5 mg/L ferric citrate, 38 μg/L $Na_2B_4O_7 \cdot 10\ H_2O$, 100 mg/L $CaCl_2 \cdot 2\ H_2O$, 0.5 g/L $MgSO_4 \cdot 7\ H_2O$, 0.1 mg/L thiamin, in distilled water).

Biotransformation of dithiocarbamates by blackleg isolates

Liquid shake cultures (100 mL media in 250 mL Erlenmeyer flasks) inoculated with fungal spores (2×10^7 spores per mL) of the two isolates listed above were used throughout the biotransformation studies. Control cultures of each isolate were grown separately. Solutions of Me 4-chlorobenzyldithiocarbamate (final concentrations $4 \times 10^{-4} - 6 \times 10^{-5}$ M) or Me 2,4-dichlorobenzyldithiocarbamate (10^{-4} and 6×10^{-5} M), Me 4-hydroxybenzyldithiocarbamate (final concentrations $4 \times 10^{-4} - 6 \times 10^{-5}$ M) in DMSO were administered to 42- to 44-hour-old fungal cultures and to uninoculated media and incu-

bated at 25 ± 2°C Samples (15 mL) were withdrawn at 2–24 h intervals up to 6 days, and were either frozen at −20°C, or immediately filtered and extracted with diethyl ether (20 mL); the aqueous phase was then acidified to pH of 1–2 (conc. HCl) and extracted with diethyl ether (2 × 20 mL). The extracts were dried (Na_2SO_4), concentrated, and analyzed by TLC and HPLC. The purification of metabolites resulting from the fungal transformation of dithiocarbamates **7** and **8** was carried out by PTLC (CH_2Cl_2–MeOH, 97:3). Compounds **7**–**14** were stable in uninoculated control cultures.

Preparation of 4-hydroxybenzylamine

4-Hydroxybenzylamine was obtained from 4-(benzyloxy)benzonitrile by reduction with $LiAlH_4$–$AlCl_3$ (11) followed by debenzylation of the resulting amine, as follows. Benzyl chloride (1.52 g, 12 mmol), K_2CO_3 (1.66 g, 12 mmol), and KI (33 mg, 0.2 mmol) were added to a solution of 4-hydroxybenzonitrile (1.19 g, 10 mmol) in DMF (10 mL) at 25°C. After 2 h the reaction mixture was diluted with H_2O (25 mL), extracted with Et_2O (2 × 30 mL), and the combined organic layers concentrated at reduced pressure. The crude product was crystallized from hexane–Et_2O to give 4-benzyloxybenzonitrile (2.03 g, 97%). The crystalline product (1.05 g, 5 mmol) was dissolved in Et_2O (10 mL) and added dropwise to a solution of $LiAlH_4$–$AlCl_3$ (228 mg, 6 mmol/800 mg, 6 mmol) in Et_2O (20 mL) and kept at 25°C for 2 h. Water (25 mL) was added dropwise to the reaction mixture and the aqueous layer was extracted with Et_2O (2 × 30 mL). The combined organic layers were dried over sodium sulfate and concentrated under reduced pressure to yield crude amine (1.04, 97%). A suspension of the crude amine (200 mg) and 10% Pd/C (50 mg) in EtOH–NH_4OH (10 mL:3 mL) was stirred under H_2 (1 atm (= 101.3 kPa)) for 1 h at 0°C. The reaction mixture was filtered, concentrated under reduced pressure, and the crude product purified by FCC (CH_2Cl_2–MeOH–NH_4OH, 90:10:1) to give 4-hydroxybenzylamine (96 mg, 83%).

Preparation of methyl benzyldithiocarbamates 7–9

Dithiocarbamates **7**–**9** were synthesized from the corresponding primary amines, similarly to brassinin (5). Typically, CS_2 (2.3 mmol) was added to a solution of the amine (2.3 mmol) in pyridine (1.2 mL) and triethylamine (2.3 mmol) at 0°C. After 60 min at 0°C, MeI (2.3 mmol) was added to the reaction mixture, and after further 12 h at 0°C the reaction mixture was poured onto 1.5 M sulfuric acid (35 mL) and extracted with Et_2O (2 × 140 mL); the combined organic layers were dried over sodium sulfate and concentrated under reduced pressure. After purification by FCC (CH_2Cl_2–hexane, 1:1) and crystallization (CH_2Cl_2–hexane) the products were obtained as colorless solids.

4-Hydroxybenzylamine: white powder, 83% yield; ^{1}H NMR (CD_3OH) δ: 7.14 (m, 2H), 6.73 (m, 2H), 3.68 (s, CH_2); ^{13}C NMR (CD_3OH) δ: 46.2 (t), 116.5 (d), 129.9 (d), 134.1 (s), 158.0 (s).

Methyl 2,4-dichlorobenzyldithiocarbamate: white powder, 75% yield; R_f 0.54, CH_2Cl_2–hexane (60:40); FTIR ν_{max}: 3212, 1498, 1368, 1327, 1102, 1048, 926 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ: 7.5 (br s, 1H, D_2O exchangeable), 7.42–7.40 (m, 2H), 7.23 (m, 1H), 5.00 (d, J = 4.8 Hz, CH_2), 2.65 (s, SCH_3); ^{13}C NMR ($CDCl_3$) δ: 18.6 (q), 48.0 (t), 127.6 (d), 129.7 (d), 131.9 (d), 132.7 (s), 134.7 (s), 134.9 (s), 199.9 (s); HREIMS *m/z* (% relative abundance) measured: 264.9556 (264.9553 calcd. for $C_9H_9{}^{35}Cl_2NS_2$); EIMS *m/z* (% relative abundance): 265 $[M]^+$ (2), 232 (30), 230 (72), 161 (64), 159 (100).

Methyl 4-chlorobenzyldithiocarbamate: white powder, 82% yield; R_f 0.52, CH_2Cl_2–hexane, (60:40); FTIR ν_{max}: 3258, 1491, 1376, 1328, 1236, 1090, 1014, 922, 800 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ: 7.9 (br s, 1H, D_2O exchangeable), 7.34–7.21 (m, 4H), 4.87 (d, J = 5.1 Hz, CH_2), 2.63 (s, SCH_3); ^{13}C NMR ($CDCl_3$) δ: 18.2 (q), 49.6 (t), 129.0 (d), 129.4 (d), 133.7 (s), 134.6 (s), 199.5 (s); HREIMS *m/z* (% relative abundance) measured: 230.9945 (230.9943 calcd. for $C_9H_{10}{}^{35}ClNS_2$); EIMS *m/z* (% relative abundance): 233 $[M]^{2+}$ (9), 231 $[M]^+$ (23), 127 (42), 125 (100).

Methyl 4-hydroxybenzyldithiocarbamate: yellowish powder, 98% yield; R_f 0.35, CH_2Cl_2–MeOH, (95:5); FTIR ν_{max}: 3330, 1515, 1380, 1328, 1214, 916 cm^{-1}; ^{1}H NMR (CD_3CN) δ: 7.15 (m, 2H), 6.91 (s, 1H, D_2O exchangeable), 6.75 (m, 2H), 4.75 (d, J = 5.6 Hz, CH_2), 2.53 (s, SCH_3); ^{13}C NMR (CD_3CN) δ: 18.3 (q), 50.5 (t), 118.4 (d), 129.4 (s), 130.6 (d), 157.3 (s), 199.6 (s); HREIMS *m/z* (% relative abundance) measured: 213.0282 (213.0282 calcd. for $C_9H_{11}NOS_2$); EIMS *m/z* (% relative abundance): 213·$[M]^+$ (35), 107 (100).

The design, production, purification, and testing of a chimeric antigen protein to be used as an immunosterilant in domestic animals

J.G. Manns, C. Barker, and S.K. Attah-Poku

Abstract: A method is described for the design of a protein that incorporates a carrier molecule fused to a novel tandem repeat configuration of a 10 amino acid peptide, Gonadotrophin Releasing Hormone (GnRH), which normally would not be immunogenic because it is a self-antigen. This molecule can be produced with adequate yield in *E. coli* bacteria and purified to homogeneity using standard chromatographic procedures. When low doses of the molecule are injected with an appropriate adjuvant, rats and pigs respond by producing high antibody titres to GnRH. The immunization results in a dramatic reduction of pituitary gonadotrophin secretion and, as a consequence, reduces steroid secretion and causes gonadal atrophy.

Key words: GnRH, fusion protein, immunosterilant, vaccine

Résumé : On décrit une méthode permettant de mettre au point une protéine incorporant une molécule porteuse attachée à une nouvelle configuration répétitive en tandem d'un peptide à 10 acides aminés, la gonadolibérine (GN-RH), qui ne serait normalement pas immunogène puisqu'elle est auto-antigène. Il est possible de produire cette molécule avec un rendement raisonnable à l'aide de la bactérie *E. coli*; les méthodes chromatographiques standards permettent de la purifier jusqu'à ce qu'elle soit homogène. Lorsqu'on injecte de faibles doses de la molécule en présence d'un adjuvant approprié, les rats et les cochons réagissent en produisant des titres élevés d'anticorps au GN-RH. L'immunisation provoque une réduction dramatique de sécrétion de la gonadotraphine pituitaire et, par voie de conséquence, une réduction de la sécrétion de stéroïde conduisant à une atrophie gonadale.

Mots clés : GN-RH, fusion de protéine, immunostérilisant, vaccine.

Introduction

Except in countries such as England, Australia, and Spain, male pigs are castrated surgically shortly after birth. This is done despite the fact that intact males utilize feed more efficiently and have a superior carcass (1, 2). Boars are not raised for meat production because at typical market weights some boars may reach sexual maturity, and androstenone (5α-androst-16-ene-3-one), a volatile, unpleasant smelling steroid, may be produced by the maturing testes and be present in edible tissues. This condition is called boar taint.

Steroid secretion by the testes is regulated principally by luteinizing hormone (LH), a pituitary glycoprotein that is controlled by the hypothalamic peptide, gonadotrophin releasing hormone (GnRH) (3–5). Therefore, it should be possible to block testicular steroid production by eliminating the secretion or neutralizing the effect of GnRH. One possible strategy would be to immunize animals against GnRH (1, 2, 6) with the goal of producing antibodies that could bind to GnRH and thereby block its effects.

Developing an efficacious, yet practical, GnRH antigen has proven to be problematic for a variety of reasons. GnRH is a 10 amino acid peptide that is structurally identical among mammals, and therefore immunization with the peptide alone is not effective because it is not recognized as a foreign molecule. Secondly, in animal health and human medical applications, antigens must be well characterized and produced with high purity at minimum cost. However, most antigens are large protein molecules that are not practical to synthesize by defined chemical processes. Furthermore, except for short peptides, chemical synthesis is expensive.

One strategy for preparing antigens against small self-peptides is to synthesize the peptide chemically and then conjugate it to a larger carrier protein using a coupling reagent such as carbodiimide (7). However, such methods generally create a number of reaction products that require extensive purification to provide a homogenous protein. Furthermore, the cost of peptide synthesis and other reagents adds considerably to

the cost of utilizing this method in the commercial production of vaccines.

An alternative strategy is to select a gene that codes for a carrier protein that contains a diverse population of T helper cell epitopes and therefore can generate a strong antibody response (8). Then, an oligonucleotide is synthesized that codes for the peptide against which an immune response is desired, and that piece of DNA is ligated to the gene for the carrier protein by placing it at the amino or carboxyl ends, or at internal positions as dictated by specific restriction sites in the DNA sequence coding for the carrier protein. Such a DNA sequence coding for a chimeric protein could then be transferred to a highly regulated bacterial expression system and identical copies of the antigen could be produced in high yield. A carrier protein molecule that meets such criteria is the bacterial protein called leukotoxin (LKT) from *Pasteurella haemolytica.* The present study describes a practical method for designing such a chimeric molecule, a simple but effective purification process, and experimental results that document the efficacy of a vaccine using this approach.

Materials and methods

Antigen design and production

Plasmid constructs

The plasmid pAA352, which carries a 96 kDa version of LKT under the Tac promoter, was used as the base plasmid for all GnRH fusion constructs (9). A complementary set of 154bp oligonucleotides coding for four copies of GnRH were synthesized and inserted into the BamHI site at the carboxyl end of the LKT gene. An additional four copies were added to provide eight copies, thereby creating the plasmid referred to as pCB112. To increase the amount of GnRH epitope per mole of protein, the LKT carrier was shortened to preserve the putative T-cell epitopes in the first 350 amino acids predicted by the method of Margalit et al. (8). pCB112 was digested with NaeI and BstBI; the ends were blunted with mungbean nuclease and allowed to self-ligate to create the plasmid pCB114. This plasmid codes for a 52 kDa LKT protein with eight copies of GnRH. This shortened version of LKT was used to produce a plasmid derived from pCB114 but containing eight additional copies of GnRH in the BglII site at the amino terminal region of the 52 kDa LKT. This gene, which codes for a 73 800 MW protein designated LKT.16GnRH, is present in the plasmid pCB122.

Protein production

Protein inclusion bodies of LKT:16GnRH were produced in *E. coli* strain W1485 transformed with the plasmid pCB122. A single colony was used to inoculate 10 mL of Terrific Broth (TB) (12 g tryptone, 24 g yeast extract, 4 mL glycerol, 2.31 g KH_2PO_4, and 12.54 g K_2HPO_4 in 1 L of H_2O) containing ampicillin at a final concentration of 100 μg/mL. The culture was incubated overnight on a rotary shaker at 37°C and was used to inoculate 1 L of TB containing ampicillin. This culture was incubated on a rotary shaker at 37°C until it reached an optical density of 0.6 at 660 nanometers. When it reached that cell density, the culture was induced to produce the recombinant protein by addition of 10 mL of 0.1 M isopropylthio-β-D-galactoside. The culture was incubated for 2 h longer and the cells were then harvested by centrifugation. The cell pellet was suspended in 20 mL of a 25% sucrose 0.05 M Tris pH 8.0 solution and frozen at −70°C until required for further processing.

The cells obtained from a 1 L culture were thawed, mixed with 100 mg of lysozyme, and incubated at room temperature for 30 min. Triton X-100 and ethylene diamine tetraacetic acid (EDTA) were then added to give a final concentration of 2% and 0.05 M, respectively, and the cells were vortexed and sonicated at full power for 3 × 30 s bursts. The disruptate was then centrifuged to collect the protein inclusion bodies, which were washed twice with water and stored at 4°C.

For further processing, the inclusion bodies were dissolved in 4 M guanidine HCl and centrifuged to remove any undissolved material. The clarified protein solution was dialyzed against water for 48 h at 4°C and the protein, which precipitates out as the guanidine concentration decreases, was collected and lyophilized.

Purification of recombinant LKT-GnRH fusion protein

The first trials were conducted with a LKT-GnRH-8 produced from plasmid pCB114 and the following purification scheme, which was developed for that molecule, was also used to purify LKT-16 GnRH.

The crude protein sample containing LKT-16 GnRH was dissolved in 8 M guanidine and then diluted to 6 M guanidine with the elution buffer (4 M guanidine, 50 mM sodium phosphate, 50 mM sodium chloride, 1 mM disodium EDTA, 1 mM dithiothreitol pH 7.5) to give a protein concentration of 25 mg/mL. The solution was centrifuged at 10 000*g* for 10 min and the supernatant was filtered through a 0.45 μm filter. The filtrate was loaded on a Sephacryl S400HR size exclusion column (XK26/100, 100 cm long × 2.6 cm i.d., Pharmacia Biotechnology, Uppsala, Sweden) equilibrated with the elution buffer. The proteins were eluted with the elution buffer at a flow rate of 2 mL/min; protein concentration in the column effluent was monitored at 280 nm.

Purity of the various fractions was evaluated by sodium dodecyl sulfate polyacrylamide gel electrophoresis; an example is shown in Fig. 1. A Western blot analysis using polyclonal antibodies against the GnRH portion of the molecule was used (Fig. 2) to confirm that the protein band with the appropriate molecular weight contained GnRH.

Additional confirmation was obtained by determining the molecular weight of the purified antigen using MALDI-TOF mass spectrometry. The analysis was conducted using standard methods in the Department of Biochemistry, Mass Spectrometry Facility, University of Washington, Seattle.

Vaccine formulation and immunization trials

The LKT-GnRH vaccines were prepared by dissolving the antigen in 4 M guanidine HCl at a concentration of approximately 20 mg/mL and adding an appropriate volume of that solution, with agitation, to a commercially available oil-in-water based emulsion (MVP Laboratories, Ralston, Nebraska) along with 0.9% NaCl to give the desired antigen concentration. Although numerous antigens were evaluated, data from only the 8 and 16 copy molecules are presented.

The assay for GnRH antibody utilized monoiodinated GnRH-I^{125} in a competitive binding assay (2). This in vitro assay was conducted by adding 0.1 mL (10 000 – 15 000 cpm)

Lane 1, molecular weight standards; lane 2, purified LKT-16 GnRH; lane 3, crude LKT-16 GnRH; lane 4, purified LKT-16 GnRH. The mass of antigen in lane 4 was not sufficient to be visible in the photograph of the gel.

of iodinated GnRH to a series of tubes. An appropriate dilution of sera to be tested was added and the volume brought to 0.7 mL. After incubating for 48 h at 5°C the free GnRH-I^{125} was separated from antibody-bound material by adding 0.75 mL of a 0.5% charcoal suspension. After vortexing, the mixture was centrifuged, the supernatant was decanted, and the precipitate containing free GnRH-I^{125} was counted. These data along with the knowledge of the amount of GnRH-I^{125} added were used to calculate the per cent binding at a specific serum dilution.

Trial 1: At day 0 of the experiment 10 male Sprague Dawley rats were immunized with a single injection of 50 μg LKT-8 GnRH in 1.0 mL adjuvant and 10 male rats were injected with adjuvant only. Blood was collected at approximately 21 day intervals and assayed for GnRH antibodies and serum testosterone. Serum testosterone was measured using a standard radioummunoassay method in kits provided by Diagnostic Products Corp., Los Angeles. Assay sensitivity was approximately 0.1 ng/mL and coefficient of variation was less than 6%.

Trial 2: Twenty weanling pigs (10 male and 10 female) 21 days of age and weighing 3–5 kg were assigned to each treatment. They were injected with 1.0 mL of vaccine containing 0–160 μg of highly purified LKT-16 GnRH antigen at day 0 of the experiment. At day 35, a booster immunization with a similar dose was given and blood was collected 14, 33, and 49 days thereafter and assayed for serum antibody titres and serum LH. The LH assay used iodinated bovine LH and porcine LH as reference standard and has been validated for use in sera from pigs (10).

Results and discussion

The SDS-PAGE gel in Fig. 1 shows that the relatively impure protein prepared by dissolving inclusion bodies in 4 M guanidine HCl (lane 3) had several minor components. A large mass of protein purified using the chromagraphic procedure was run in lane 2 to highlight any minor impurities that might be present. A much smaller sample was applied in lane 4; it appears as a single band and we believe the protein is at least 90% pure. MALDI-TOF mass spectrometry gave a single peak with molecular weight of 73 600, which is nearly identical to the 73 800 MW estimated by the amino acid composition predicted by the known DNA base sequence. Figure 2 shows that the purified protein reacts with polyclonal antibodies directed against the GnRH portion of the molecule, thus confirming the identity of the molecule.

pCB114 derived protein (50 μg) injected into rats (Fig. 3) gave a remarkable response. The normal response to a single injection of an antigen in an oil-in-water adjuvant in most mammals would be to cause a short-lived, modest increase in antibody titres that would not result in observable biological effects (i.e., no neutralization of GnRH). However, in this species we observed a dramatic and sustained increase in antibody titres that resulted in serum testosterone concentrations similar to values expected in castrate males. When these animals were killed 224 days after the single injection, the immunized animals had testes which weighed 1.48 ± 0.24 g (mean ± s.d.) compared to 7.30 ± 0.10 g for control animals.

Doses as low as 1 μg of LKT-16 GnRH stimulated strong antibody production in pigs (Fig. 4). When a dose of 10 μg or greater was given 35 days after the primary immunization, all animals responded with antibody titres of at least 20% binding of GnRH-I^{125} when measured in a 1:5000 dilution of serum. Serum LH in 10 control castrate males had higher LH than 10 intact females (Fig. 5). This is expected since the negative arm of the feedback loop is absent in castrate animals. Serum LH

Fig. 3. Serum GnRH antibody titres (top panel) in immunized rats (1:5000 dilution) and placebo injected controls (1:100 dilution). Serum testosterone values (mean ± SE) are shown in the bottom panel.

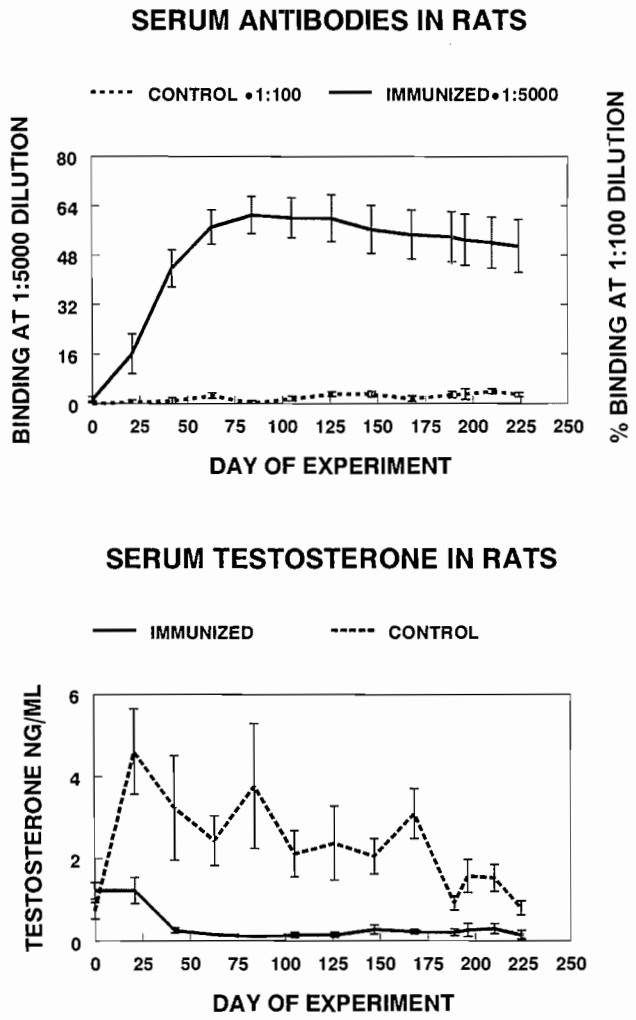

Fig. 4. Serum GnRH antibody titres (means ± SE) 14 days after the booster injection of 0–160 µg of pCB122 protein. There were 20 animals per group. The ratio at the top of each column indicates the proportion of animals responding with titres greater than 20% binding at 1:5000 serum dilution.

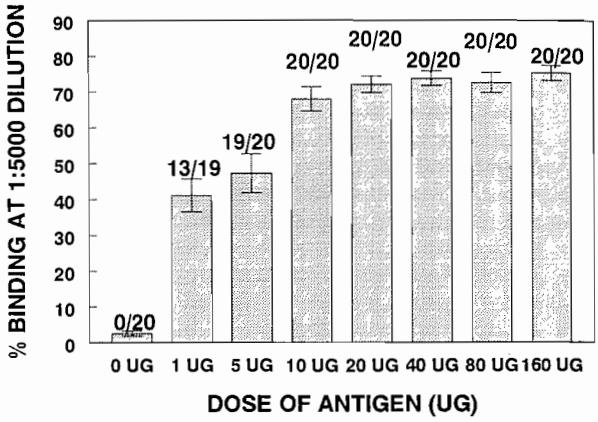

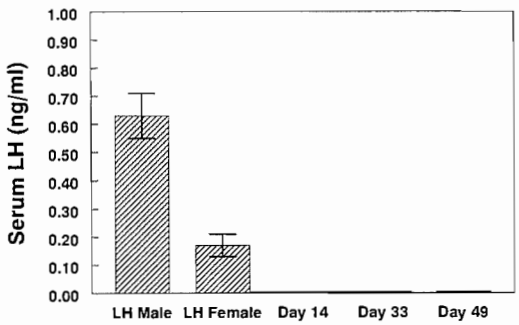

Fig. 5. Serum LH (ng/mL) in barrows (LH male) and gilts (LH female) injected with adjuvant only (control) compared to the pooled results for animals receiving 20, 40, or 80 µg of LKT-16 GnRH antigen. There were 10 animals in each of the LH male and LH female columns and 60 animals (30 male and 30 female) in each of the day 14, 33, and 49 columns.

was assayed in individual samples from all animals given 20, 40, and 80 µg of antigen; the results for each bleeding date were pooled and the mean is shown at 14, 33, and 49 days after the booster injection. Serum LH was not detectable in any of the samples, indicating that the antibodies had a powerful neutralizing effect on secreted GnRH.

Designing a protein with a desired molecular weight and a diverse population of strong T helper cell epitopes while incorporating tandem repeats of unique peptide sequences at various locations in the molecule is a useful strategy for constructing well-defined antigens. Such proteins can be produced from a single gene in a carefully controlled bacterial system, which ensures adequate yields of a homogeneous protein. The insolubility of the bacterial aggregate (inclusion bodies) can facilitate early stage purification using simple washing procedures. A single pass through a molecular sieving column of appropriate size provides a protein of high purity.

These studies indicate that production of proteins from DNA molecules that are engineered to contain two functional components is practical for commercial applications. Such an approach is useful where it is essential to have well-defined molecules that can be produced cheaply, reproducibly, and with high purity.

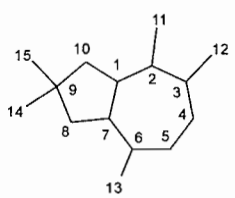
The biosynthesis of the new tremulane sesquiterpenes isolated from *Phellinus tremulae*

Elizabete R. Cruz

Abstract: The tremulane sesquiterpenes isolated from the wood-rotting fungus *Phellinus tremulae* are irregular isoprenoids derived from the cyclization and rearrangement of farnesyl pyrophosphate (FPP). The most interesting feature in the formation of the tremulane skeleton seems to involve the migration of a methyl group from one of the isoprene units. To investigate the biosynthetic origin of this unique sesquiterpene skeleton, labelling experiments were carried out by adding ^{13}C-labelled sodium acetate to liquid cultures of *Phellinus tremulae*. The labelling pattern was determined by ^{13}C NMR spectral analysis of labelled tremulenediol A, which was purified as its di-*p*-bromobenzoate. A possible route to the tremulane skeleton, which accounts for the observed labelling pattern, proceeds from FPP, via humulene. The stereochemical course of the tremulane biosynthesis is discussed.

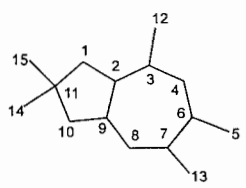
Key words: fungal metabolites, aspen, perhydroazulene sesquiterpenes, labelling experiments.

Résumé : Les sesquiterpènes dérivés du trémulane extraits du champignon *Phellinus tremulae*, qui provoquent le pourrissement du bois, sont des isoprénoïdes irréguliers produits par une cyclisation, accompagnée d'une transposition, du pyrophosphate de farnésyle (PPF). La caractéristique la plus intéressante de la formation du squelette du trémulane semble impliquer la migration d'un groupe méthyle de l'une des unités isopréniques. Dans le but d'étudier l'origine biosynthétique de ce squelette unique de sesquiterpène, on a réalisé des expériences de marquage en ajoutant de l'acétate de sodium marqué au ^{13}C aux liquides de culture du *Phellinus tremulae*. On a déterminé la distribution des marqueurs par une analyse des spectres RMN du ^{13}C du trémulènediol A marqué, purifié sous la forme de di-*p*-bromobenzoate. L'une des voies possibles de formation du squelette du trémulane, qui permet d'expliquer la distribution des marqueurs, procède du PPF par le biais de l'humulène. On discute des aspects stéréochimiques de la biosynthèse du trémulane.



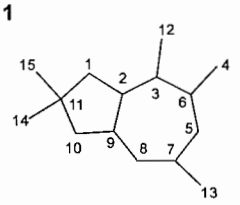
Mots clés : métabolites de champignons, peuplier, sesquiterpènes du perhydroazulène, expériences de marquage.

[Traduit par la rédaction]



Introduction

We recently reported the isolation of a new family of sesquiterpenes possessing a previously unreported carbon skeleton, which we call tremulane (**1**), produced by the wood-rotting fungus *Phellinus tremulae* (1, 2).[2] This fungus is the most serious fungal pathogen of aspen (*Populus tremuloides* Michx.) and greatly reduces the economic value of this resource in Canada (3).



Tremulane is a positional isomer of two other perhydroazulene-type carbon skeletons called lactarane (**2**) and merulane (**3**) (4, 5). The lactarane skeleton **2** and, presumably, the merulane skeleton **3** are formed from farnesyl pyrophosphate (FPP) via the humulene pathway (4). Since the tremulane (**1**) family could also be formed via this pathway through different rearrangement reactions, it was of interest to study the biosynthesis of this unique sesquiterpene skeleton. Labelling experiments were carried out using singly and doubly labelled sodium acetate, added periodically to liquid cultures of

P. tremulae; the acetate incorporation was investigated by ^{13}C NMR spectroscopy. The labelling results are presented for tremulenediol A (**4**), which can be isolated in reasonable amounts and is readily purified as its di-*p*-bromobenzoate.

Results and discussion

Phellinus tremulae was cultivated in shake culture on 2% malt extract broth for 16 days, in the presence of DIAION HP 20® resin,[3] and was periodically supplemented with injections of a sterile solution of labelled sodium acetate: [1-^{13}C], [2-^{13}C], and [1,2-$^{13}C_2$]. The culture broth was filtered and the resin and wet mycelium were extracted with dichloromethane. The tremulanes were isolated as reported previously (2). Since tremulenediol A (**4**) can be isolated in reasonable amounts (> 8 mg/400 mg of crude extract) and in pure form as its di-*p*-bromobenzoate **4a**, it was chosen as the substrate to study the incorporation pattern. The procedure for the separation and purification of **4a** also leads to the isolation of the di-*p*-bromobenzoate of tremulenediol B (**5a**), which was analyzed to confirm the results found for **4a**. The labelled compounds are identified as **4b**, **4c**, and **4d**, corresponding to the tremulenediol A incorporated with [1,2-$^{13}C_2$]acetate, [1-^{13}C]acetate, and [2-^{13}C]acetate, respectively. An equivalent identification is used for the di-*p*-bromobenzoate of tremulenediol B (**5a**).

4 R = H
4a R = OCO*p*BrPh
4b [1,2-$^{13}C_2$]acetate labelled
4c [1-^{13}C]acetate labelled
4d [2-^{13}C]acetate labelled

5 R = H
5a R = OCO*p*BrPh
5b [1,2-$^{13}C_2$]acetate labelled
5c [1-^{13}C]acetate labelled
5d [2-^{13}C]acetate labelled

The ^{13}C NMR spectrum of **4b** exhibits six pairs of spin-coupled doublets appearing as satellites about the enhanced natural abundance singlets, as well as three enhanced singlets. The results are presented in Table 1, along with the data for compound **5b**. Enrichment data are presented in the experimental section. The doublets result from coupling between two adjacent ^{13}C atoms coming from intact acetate units. The enhanced singlets are derived from fragmented acetate units. The fragmentation takes place during the conversion of mevalonate, a product of acetate metabolism, into isopentenyl pyrophosphate (IPP). In this process C-1 of mevalonate is lost and the result is the appearance of enhanced singlets in the ^{13}C NMR spectrum for the carbons derived from C-2 of mevalonate (7, 8). In the case of tremulane these singlet carbons are C-5, C-12, and C-14. An INADEQUATE (9) experiment (Fig. 1) confirms the spin-coupled carbons as the following pairs: C-1,C-10; C-2,C-11; C-3,C-4; C-6,C-13; C-7,C-8; and C-9,C-15. Carbons C-5, C-12, and C-14 do not give rise to cross peaks

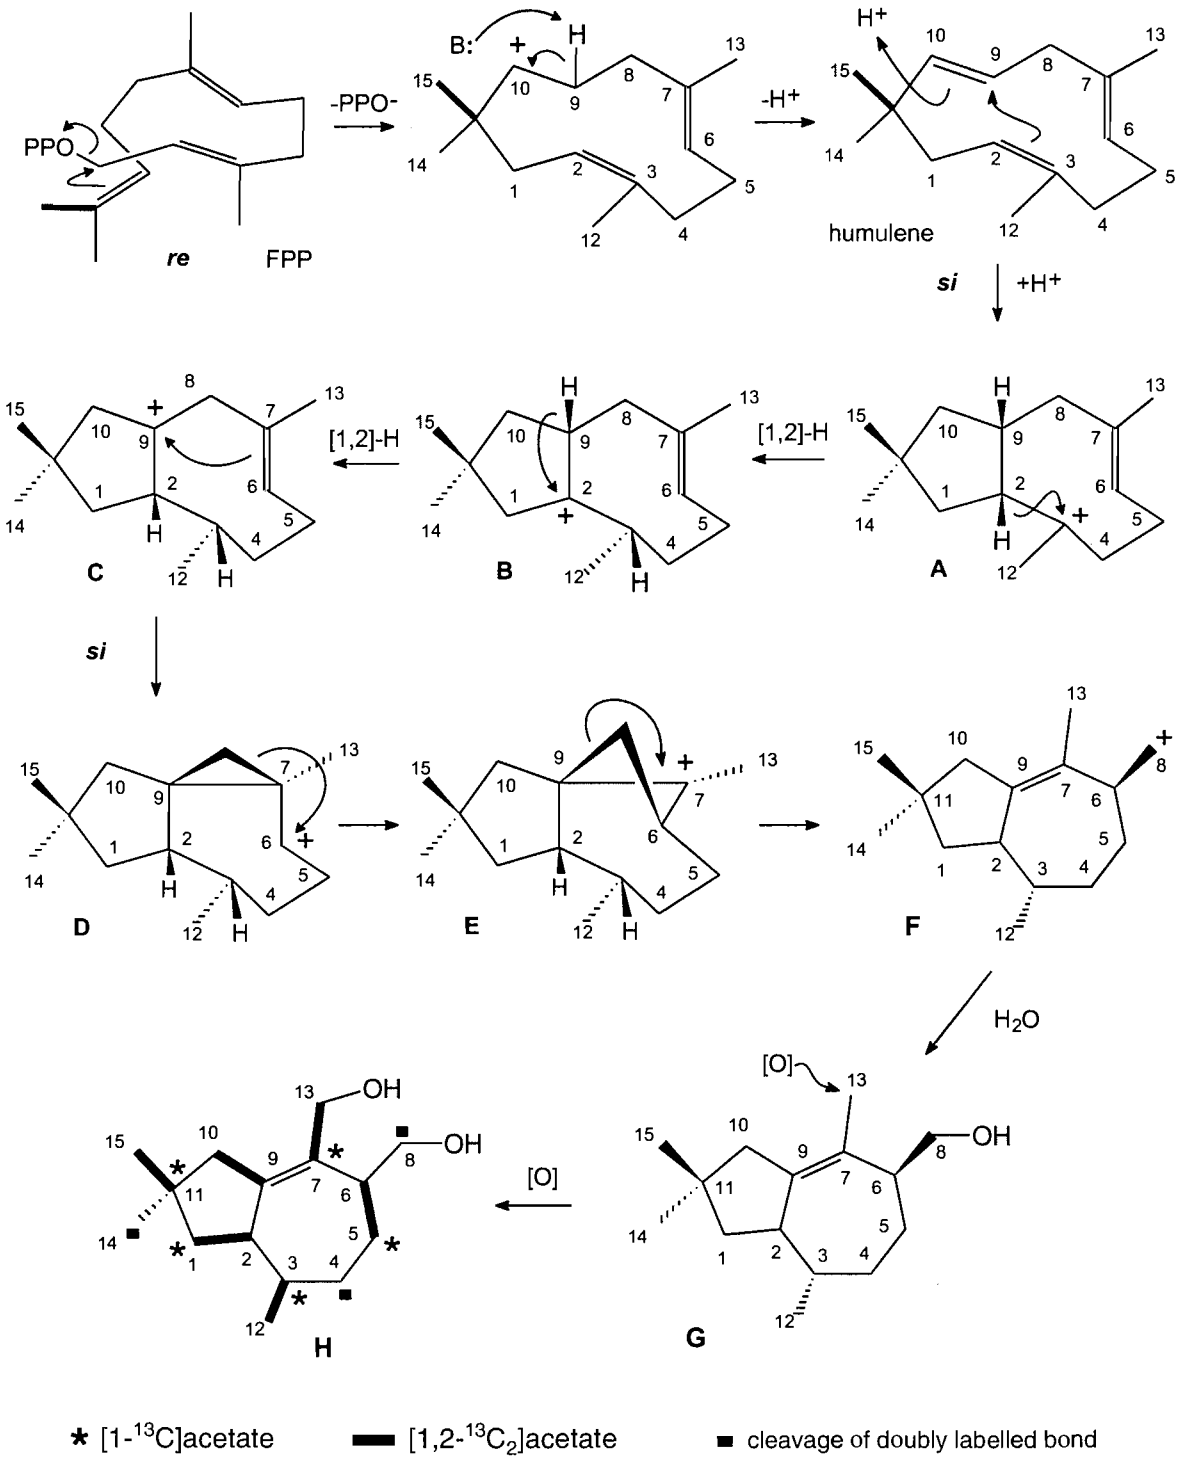
with other carbon resonances, showing that they are actually singlets. The same coupling pattern is observed for **4b** and **5b**, as indicated in the tremulane skeleton shown in Fig. 2. This result with doubly labelled acetate confirms that tremulane is formed by rearrangement of a methyl group in one of the isoprene units. To elucidate the nature of this rearrangement, singly labelled acetate (1-^{13}C and 2-^{13}C) was added to cultures of *P. tremulae* in the same manner as described above. Singly labelled tremulenediols A and B were isolated as their di-*p*-bromobenzoates **4a** and **5a** and analyzed by ^{13}C NMR spectroscopy. The broad-band ^{13}C spectrum was obtained using the same conditions for unlabelled (**4a**, **5a**), [1-^{13}C]acetate (**4c**, **5c**), and [2-^{13}C]acetate (**4d**, **5d**) labelled compounds. The enriched signals were identified by subtracting the natural abundance spectrum (unlabelled) from the labelled spectra (see experimental section for enrichment data). A summary of the results is presented in Fig. 2.

These results strongly support the previous observation of migration of one of the *geminal* methyl groups in one of the isoprene units. The most plausible mechanism to account for this rearrangement invokes the common pathway of sesquiterpene biosynthesis from *trans,trans*-farnesyl pyrophosphate (10) via humulene[4] (Scheme 1). The stereochemical course of the biosynthesis is based on the work of Cane and Nachbar (7), in which the condensation and cyclizations are related to the absolute stereochemistry at each chiral centre. All the chiral centres in the tremulane sesquiterpenes possess *S*-configuration (2). Cane and Nachbar have demonstrated that the intramolecular cyclization of *trans,trans*-FPP is a result of the electrophilic attack by the C-1 carbinyl carbon at C-11, which may occur on the *re* or *si* face of the terminal double bond. If attack occurs on the *re* face, the methyl group derived from an intact acetate unit becomes the *pro-R* methyl (C-15) of humulene. If the attack is on the *si* face the same methyl becomes *pro-S* (C-14). In the case of tremulane the distinction between the *geminal* methyl groups C-14 and C-15 was based on correlations observed in the NOESY spectrum of compound 4 and by comparison with the NMR data obtained for other tremulanes. It has been established by NMR and X-ray that the hydrogen at C-7 of the tremulane series is β-oriented (2). In the NOESY spectrum of **4**, we observe a cross peak between H-7 (δ 3.10) and the methyl group at δ 0.87, which is consistent with its assignment as H-15 (2). According to HMQC experiments, this hydrogen resonance at δ 0.87 correlates to the carbon at δ 26.9, therefore establishing the assignment of C-15. Since the labelling experiments indicate that C-15 in tremulane comes from an intact acetate unit, we can assume that FPP cyclization occurs on the *re* face of the terminal double bond. The mechanism continues with an intramolecular cyclization to form a *cis*-fused five-membered ring. To account for this stereochemistry the protonation of the 9,10-double bond at C-10 has to be followed by a *si* attack by the 2,3-double bond on C-9, which leads to the carbocation **A**. Then a double [1,2]-H shift takes place. The hydrogen at C-2 migrates to the upper face of the carbocation C-3 (**A**) and the hydrogen at C-9 shifts to the upper face of the newly formed carbocation C-2 (**B**) generating the intermediate **C**. This sets the *S* absolute stereochemistry at C-2 and C-3, which corresponds to the observed *S* stereochemistry at C-7 and C-6 of tremulane, respectively. A few cationic rearrangements are necessary to promote the migration of a methyl group to C-6. A *si* attack by the 6,7-double bond on C-9 leads to the formation of the cyclopropyl carbinyl cation **D**, which rearranges to form the tertiary cyclobutyl cation **E**. The migration of the β-oriented cyclopropyl at C-7 to the top face of the carbocation C-6 is imposed by the required *S* stereochemistry at C-6 of humulene (C-3 of tremulane) and by the fact that C-7,C-13 comes from an intact acetate unit according to experimental results with the doubly labelled acetate incorporation. Therefore, migration of C-13 has been ruled out. Further rearrangement within the cyclopropyl carbinyl-cyclobutyl reaction manifold results in cyclobutyl ring opening to the homoallylic cation **F**, which is quenched by nucleophilic water, affording **G**. Allylic oxidation at C-13 of **G** gives tremulenediol A, whose labelling pattern from humulene is shown in structure **H** (Scheme 1), with the numbering of humulene. This labelling pattern is consistent with that obtained for tremulane (Fig. 2).

The present study shows that the tremulane sesquiterpenes are irregular terpenoids derived from FPP via humulene. The stereochemical course of tremulane biosynthesis leads to the formation of the tremulane skeleton with the appropriate absolute stereochemistry. The migration of one of the methyl groups from one of the isoprene units occurs through a series of carbocationic rearrangements giving rise to the tremulane family.

Experimental



^{13}C nuclear magnetic resonance (NMR) spectra and Incredible Natural Abundance Double Quantum Transfer Experiment (INADEQUATE) for the doubly labelled acetate incorporation were obtained on a Varian Unity-500 spectrometer. The singly labelled acetate incorporation spectra were recorded on a Bruker 400 MHz spectrometer. All NMR spectra were recorded in $CDCl_3$ solution. The $CDCl_3$ chemical shift was used as reference for ^{13}C chemical shifts having tetramethylsilane as an internal standard. Universal Scientific Incorporated silica gel 60 (40 μm) was used for flash chromatography. Preparative thin-layer chromatography (PTLC) was performed on E. Merck precoated 20 × 20 glass plates of silica gel 60 F-254 or on prepared 20 × 20 glass plates using Aldrich silica gel for TLC with a fluorescent indicator. Analytical thin-layer chromatography (TLC) was carried out on cut sections of E. Merck precoated aluminium sheets of silica gel 60 F-254. Ultraviolet-active materials were detected by visualization under a UV lamp (254 nm). Liquid media were prepared

flasks charged with 2 L of sterile malt extract medium (40 g of malt extract broth DIFCO, 40 g of DIAION HP 20® resin (6), and 2 L of redistilled water). A 0.2 M sterile solution of labelled sodium acetate (0.75 g) in redistilled water (45 mL) was periodically added to a *P. tremulae* culture (2 L) by injecting 15 mL after day 1 and 10 mL each after days 3, 5, and 7 of growth. The work-up and separation were performed as described previously (2).

Growth of *Phellinus tremulae*: unlabelled metabolites

Unlabelled metabolites were obtained under the same growth conditions as described above for labelled metabolites but using unlabelled sodium acetate.

NMR spectra of unlabelled and singly labelled acetate metabolites

The NMR spectra were recorded using 40 and 15 mM solution in $CDCl_3$ for tremulenediol A and B, respectively. The spectra were obtained using the same parameters for unlabelled and labelled compounds: 4000 transients with acquisition time of 0.6 s. The transients were doubled for the 15 mM solutions.

[1,2-$^{13}C_2$]acetate-labelled metabolites

Tremulenediol A di-p-*bromobenzoate (**4b**)*: 14 mg. ^{13}C NMR ($CDCl_3$, 125 MHz) spin-coupled carbons, δ: 150.3 (C-1, $J_{1,10}$ = 40 Hz), 126.5 (C-2, $J_{2,11}$ = 48 Hz), 69.0 (C-11, $J_{2,11}$ = 48 Hz), 48.3 (C-10, $J_{1,10}$ = 40 Hz), 46.6 (C-7, $J_{7,8}$ = 35 Hz), 45.3 (C-8, $J_{7,8}$ = 35 Hz), 41.3 (C-3, $J_{3,4}$ = 34 Hz), 37.2 (C-9, $J_{9,15}$ = 36 Hz), 31.4 (C-6, $J_{6,13}$ = 36 Hz), 26.8 (C-15, $J_{9,15}$ = 36 Hz), 21.2 (C-4, $J_{3,4}$ = 34 Hz), 11.7 (C-13, $J_{6,13}$ = 36 Hz); enriched singlets, δ: 63.2 (C-12), 31.7 (C-5), 28.4 (C-14); INADEQUATE ($CDCl_3$, 125 MHz) cross peaks (two double quantum); δ: 150.3 (C-1) ↔ 48.3 (C-10); 126.5 (C-2) ↔ 69.0 (C-11); 41.3 (C-3) ↔ 21.2 (C-4); 31.4 (C-6) ↔ 11.7 (C-13); 46.6 (C-7) ↔ 45.3 (C-8); 37.2 (C-9) ↔ 26.8 (C-15); singlet carbons, δ: 63.2 (C-12), 31.7 (C-5), 28.4 (C-14). Oxygen insertion in *Sesamum indicum* furanofuran lignans. Diastereoselective syntheses of enzyme substrate analogues

Patrice A. Marchand, Jaroslav Zajicek, and Norman G. Lewis

Abstract: The furofuran lignans in sesame seed have an unusual oxygen insertion between their furan and aryl rings. In our continuing investigations on the isolation and characterization of the enzyme(s) involved, the diastereoselective syntheses of various substrate analogues for the oxygen insertion step were developed for future substrate specificity and inhibitor studies. This synthetic strategy also provided entry to so-called furofuranone epoxy-lignans, such as salicifoliol from *Bupleurum* sp., and acuminatolide from *Helichrysum* sp.

Key words: furofuran lignans, sesame, epimers, salicifoliol, acuminatolide.

Resumé : On observe dans les lignanes furanofuraniques des graines de sésame, une insertion d'oxygène typique entre le cycle tétrahydrofuranique et le cycle aromatique. Comme avant propos à l'étude et l'isolation des enzymes responsables de la biosynthèse de la sésamoline à partir du pinorésinol, nous décrivons ici la synthèse diastéréosélective des épimères de ces intermédiaires oxygénés. Une extension de cette voie synthétique nous a fournit la possibilité d'accéder aux furolactones, le salicifoliol et l'acuminatolide.

Mots clés : lignanes furofuraniques, sésame, épimères, salicifoliol, acuminatolide.

Introduction

The furofuran lignans present in sesame (*Sesamum indicum*) seed have many important roles. They can function as potent antioxidants (1–5), either directly or through conversion to sesaminol **1** (4), thereby enhancing the quality and shelf life of sesame seed oil. Sesame lignans can also act as synergists with pyrethrum insecticides (6, 7), or as cyclic AMP phosphodiesterase (8) and Δ-5 desaturase inhibitors in mammalian species (9). Moreover, addition of sesamin **2** to the diet reduces serum and liver cholesterol levels in rats (10) and has a hypocholesterolemic effect in humans (11). Dietary sesame lignans can protect against EtOH or CCl_4 induced liver damage (12), and enhance vitamin E activities (13) and the bioavailability of γ-tocopherol (14) in vivo.

Chemotaxonomic analyses of *Sesame* seed has established its major lignans as (+)-sesamin **2** and (+)-sesamolin **4** (Scheme 1) with the latter differing only by an oxygen insertion between the furofuran and piperonyl (3,4 methylenedioxyphenyl) groups. Biochemical entry to these furofuran lignans occurs via stereoselective coupling of two molecules of *E*-coniferyl alcohol **5** to give (+)-pinoresinol **3**, an enzymatic conversion of particular interest being the first example of regio- and stereospecific control of bimolecular phenoxy radical coupling (15–17). Although its enzymology of formation was first delineated in *Forsythia* sp. (15–17), (+)-pinoresinol **3** biosynthesis from *E*-coniferyl alcohol **5** in *Sesame* sp. is apparently engendered in a comparable manner (unpublished data).

Depending upon the species involved, (+)-pinoresinol **3** (a central intermediate in lignan biosynthesis) can be metabolized into a wide variety of different furofuran, furano, dibenzyl butane, dibenzyl butyrolactone, and aryl (tetrahydro)-naphthalene lignans (18, 19). For example, in *Forsythia intermedia*, enantiospecific reduction of (+)-pinoresinol **3** gives rise to (+)-lariciresinol **6** and (−)-secoisolariciresinol **7** (20–22), the dehydrogenation of which then affords (−)-matairesinol **8** (23). The NADPH-dependent enzyme catalyzing the sequential reductive steps leading to (−)-secoisolariciresinol **7** has been purified to apparent homogeneity, and the gene encoding the protein cloned (24).

In contrast, the lignan pathway in *Sesame* sp. converts (+)-pinoresinol **3** into (+)-sesamolin **4** via introduction of methylenedioxy bridges and an oxygen insertion between its aryl and furan rings. However, the sequence of oxidative/cyclization steps, and its associated enzymology, are as yet unknown. Scheme 2 shows plausible biosynthetic intermediates in the direct conversion of (+)-pinoresinol **3** to (+)-sesamolin **4**. At this juncture, it is emphasized that the nomenclature system adopted is that of the 8,8′-linked lignans; the other recommended systems (IUPAC and CAS) were not used since they lacked any internal numbering consistency between the

different classes of lignans (and lignan-derived substances) described in this paper.

As can be seen, oxygen insertion could initially occur with (+)-pinoresinol **3** (route **a**) to give (+)-pinoresinolin **9**, with sequential methylenedioxy bridge formation to afford (+)-piperitolin **10** and (+)-sesamolin **4**, respectively. Oxygen insertion could also either follow or precede methylenedioxy bridge formation, i.e., from (+)-piperitol **11** to give (+)-sesamolinol **12** (route **b**) or from (+)-piperitol **11** to (+)-piperitolin **10** (route **c**), respectively. Perhaps, more unlikely, (+)-sesamin **2** may be directly converted into (+)-sesamolin **4** (route **d**). Synthetic methodology to pinoresinol **3** (22, 25), piperitol **11** (26), sesamin **2** (27), sesamolin **4** (27), pinoresinolin **9**, piperitolin **10**, and sesamolinol **12** (manuscript in preparation) has already been established, thus setting the stage for systematic study of the biosynthetic sequence involved.

The purpose of this investigation was to synthesize "epimers" **13–15** of the plausible aryl-*O*-furofuran biosynthetic intermediates **9, 10**, and **12**, which differ only in their stereochemistry at C-7′ (Scheme 3). These are required to examine both the substrate specificity of the oxygen insertion reaction using epi-pinoresinol **16**, epi-piperitol **17**, and related compounds as enzyme substrate analogues, as well as determining whether they could function as inhibitors of the enzymatic transformation itself. Moreover, given our ongoing interest in the enantiospecificity of lignan biosynthetic conversions, and identification of the *precise* enzymology involved, it was important to obtain these putative substrate analogues in

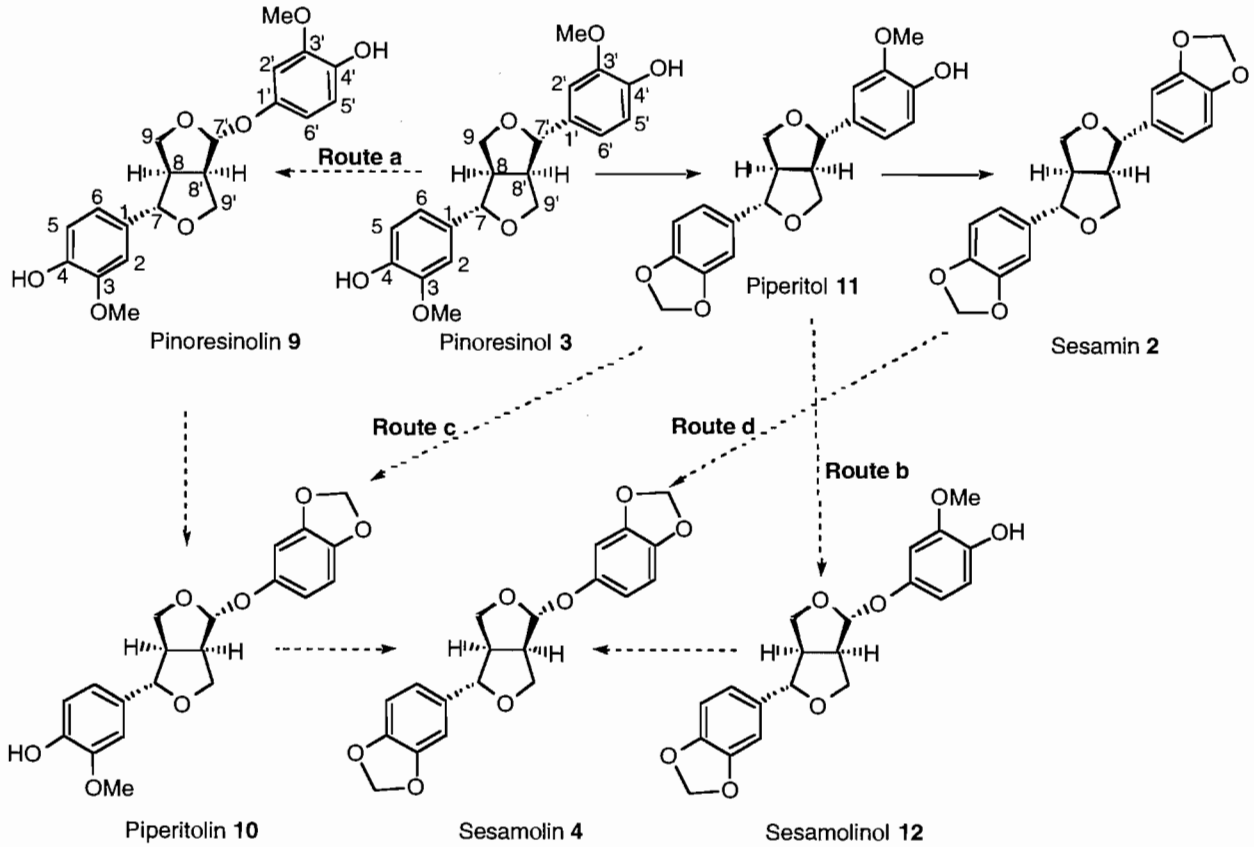
Fig. 1. General strategy to "oxygenated" lignans.

racemic form. This is because the various enantiomers can readily be separated by chiral column HPLC and, hence, provide the means to probe in detail both the enantiospecificity and diastereoselectivity of the oxygen insertion step. This approach has already been successfully applied to the study of (+)-pinoresinol **3** (15–17), (+)-lariciresinol **6**, (−)-secoisolariciresinol **7**, (−)-matairesinol **8** (20–24), and (−)-arctigenin **18** (28) biosynthesis.

Results and discussion

The main goal of this study was to develop a facile synthesis of the "oxygenated" lignans, epi-pinoresinolin **13**, epi-piperitolin **14**, and epi-sesamolinol **15**. To achieve this goal, we envisaged the best overall strategy to be that of synthesis of lactols of the type shown above, followed by aryl alkyl ether formation with inversion of configuration at C-7′ (see Fig. 1).

We sought first to establish the validity and usefulness of the proposed approach using, as synthon, the lactol samin **19**, which can readily be obtained in either racemic (±), (+), or (−) form (27, 29, 30). For this study, (+)-samin **19** (230 mg) was first conveniently prepared by acid hydrolysis (30, 31) of (+)-sesamolin **4** (527 mg), which in turn had previously been isolated from *S. indicum* seeds (Scheme 4).



In the ^{1}H NMR spectrum of the starting material, (+)-sesamolin **4**, the H_{ax} proton at C-7′ appears as a singlet resonance at δ 5.47 (32); its absence of coupling with the adjacent bridgehead proton at H-8′ is in agreement with the projected dihedral angle of ~90°. Importantly, the corresponding H_{ax} proton at C-7′ of (+)-samin **19** also gave a singlet at δ 5.45 (data not shown), indicating that the relative stereochemistry in both molecules was the same at this position. Although the (+)-samin **19** thus generated had essentially an identical melting point, as well as IR, UV, and ^{1}H/^{13}C NMR spectra, to that reported previously (29), additional verification of the configuration of the furofuranol skeleton of **19** was determined by its conversion via oxidation with pyridinium dichromate to give the lactone, (+)-acuminatolide **20**. Its (−) antipode had previously been isolated from *Helichrysum acuminatum* (33), as well as obtained by total synthesis (27). Other than its optical rotation, (+)-acuminatolide **20** was identical in every respect to that of the natural product, thus verifying the overall configuration of (+)-samin **19** to be as shown. Moreover, to our knowledge, this is the first (hemi)synthesis of (+)-acuminatolide **20**.

With the configuration of (+)-samin **19** so defined, attention was next directed to the synthesis of (+)-epi-sesamolinol **15**. First, 4-benzyloxy-3-methoxyphenol **22** was obtained by Bayer–Villiger oxidation (34, 35) of *O*-benzyl vanillin **21** (23) via the action of *m*-chloroperoxybenzoic acid (*m*-CPBA) and subsequent NaOH hydrolysis. Phenol **22** was then condensed with (+)-samin **19**, in the presence of PPh_3 and DEAD (36), to give **23**, subsequent deprotection of which with H_2/Pd/C

afforded (+)-epi-sesamolinol **15** in 60% overall yield. That the synthetic product so obtained had undergone an inversion of configuration at C-7′ could readily be determined by inspection of the ^{1}H NMR spectrum. The most striking change was the appearance of a doublet (J = 5.6 Hz) at 5.59 ppm, corresponding to the H_{eq} proton at C-7′ coupled to the C-8′ bridgehead proton. (This contrasts with the comparable H-7′$_{ax}$ resonance in (+)-sesamolin **4**, which has a singlet at δ 5.47 ppm.) This downfield shift of 0.15 ppm is consistent with related spectroscopic assignments for the naturally occurring lignan insecticidal agent, haedoxan A (H-7′$_{ax}$), to that of its epimeric synthetic product, isohaedoxan A (H-7′$_{eq}$), which showed a comparable downfield shift of 0.17 ppm (37). All other spectroscopic data supported epi-sesamolinol **15** to have the structure as shown. Consequently, not only does this represent the first (hemi)synthesis of (+)-epi-sesamolinol **15**, but adaptation of this approach using (±)-samin **19** gives a convenient route to racemic (±)-epi-sesamolinol **15**.

With the overall synthetic approach thus validated, attention was next directed to formation of the two other putative substrate analogues/inhibitors, epi-pinoresinolin **13** and epi-piperitolin **14**. In an analogous manner, this required synthesis of the pivotal lactol intermediate **24** (Scheme 5), which differs only from samin **19** by having a 4-benzyloxy-3-methoxyphenyl rather than a piperonyl group. Condensation of lactol **24** with either phenol **22** or its corresponding piperonyl analog would therefore afford (following deprotection) epi-pinoresinolin **13** and epi-piperitolin **14**, respectively (Schemes 5 and 6).

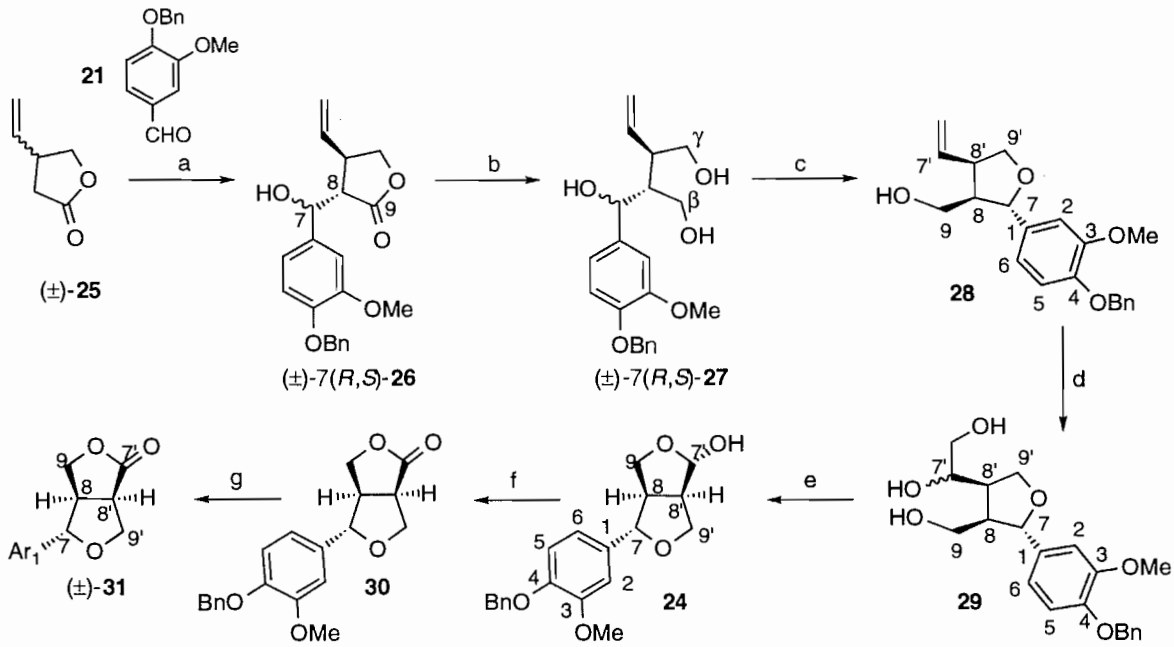
Scheme 4. Hemisynthesis of (+)-epi-sesamolinol **12** and (+)-acuminatolide **20**.

Legend: Ar_1 = 3-OMe-4-OH-Ph; Ar_2 = 3,4-OCH_2O-Ph; Bn = CH_2-Ph; a: H_3O^+, 65%; b: PPh_3, DEAD, THF, 80%; c: H_2/Pd/EtOAc, 75%; d: *m*-CPBA, CH_2Cl_2, then NaOH, MeOH, 64%; e: PDC, AcOH, 4 Å, CH_2Cl_2, 78%.

Lactol **24** was obtained from 4-vinylbutyrolactone **25** (38) as follows. Treatment of lactone **25** with LDA generated the corresponding lithiated form, which readily underwent diastereoselective addition with *O*-benzylvanillin **21**. This afforded exclusively the *trans* lactonic alcohol **26**, as a mixture of diastereoisomers in 92% yield (Scheme 5), which was used without further purification/resolution. (That the geometry of the pendant groups on the butyrolactone was indeed *trans* was based on a previous report of the configuration of the piperonyl analogue of **26**, prepared in a similar manner, which in turn was employed in the synthesis of the lignan insecticidal agents, haedoxan A, D, E, and their stereoisomers (37).)

Subsequent reduction of lactone **26** with $LiAlH_4$ and reaction of corresponding triol **27** with bromotrimethylsilane gave tetrahydrofuran **28**, presumed to possess both vinyl and hydroxymethyl substituents in a *syn* conformation, in 81% overall yield for both steps (37). Treatment of the vinyl group of alcohol **28** with OsO_4 in catalytic amount then afforded triol **29** as a mixture of diastereoisomers in 79% yield. Subsequent cleavage of its 1,2-diol by $NaIO_4$ gave the corresponding aldehyde, which underwent spontaneous cyclization, to afford lactol **24** in 84% yield. That this possessed a C-7′ H_{ax} was again established by inspection of the ^1H NMR spectrum, which displayed a 1H singlet at δ 5.35 ppm. Additionally, verification that only one stereoisomer resulted from this synthetic scheme was established via two pieces of interlocking evidence. The first involved oxidative conversion to the known lignan-derived furofuranone natural product, salicifoliol **31**, and the second by determination of the configuration of epi-pinoresinolin **13** via a combination of NOESY and HETCOR analyses (see later).



It had previously been established that the aerial portions of *Bupleurum salicifolium* Soland (39) contain salicifoliol **31**, in addition to the lignans (+)-pinoresinol **3**, (+)-eudesmin, and (+)-medioresinol. Thus, to verify the configuration of racemic lactol **24**, it was converted into salicifoliol **31** by oxidation with pyridinium dichromate (PDC) in the presence of AcOH and 4Å molecular sieves as before (40), with subsequent debenzylation (Scheme 5). That the synthetic product was indeed (±)-salicifoliol **31** was determined by its identical melting point to that of the natural product (101–102°C vs. 102–103°C (39)), as well as by comparison of its MS fragmentation patterns, $^1H/^{13}C$ NMR, UV, and IR spectra to those reported for (+)-salicifoliol **31**. Previous COSY experiments had shown that the pendant aryl group of salicifoliol **31** was *exo*, and that the bridgehead hydrogens were *cis* to each other. Thus, with all spectroscopic data identical to the naturally occurring product, with the exception of optical rotation, this represents the first synthesis of (±)-salicifoliol **31**. More importantly, it provided strong evidence that the configuration of lactol **24** was as shown.

With good evidence supporting the structure and configuration of lactol **24** as shown, attention was directed to the formation of (±)-epi-pinoresinolin **13** (Scheme 6). Again, *O*-benzylvanillin **21** was converted into the corresponding phenol **22**, via Bayer–Villiger oxidation with *m*-CPBA and subsequent NaOH hydrolysis. This was then reacted with lactol **24**, in the presence of PPh_3 and DEAD, to give **32**, subsequent

[a]Assigments are interchangeable for nonprotonated carbons.

nals derived from quaternary carbons were based on comparison with reported chemical shift data for (+)-sesamolin **4** (32).

To summarize, the NOESY spectra (mixing times 300 and 600 ms) showed a strong cross-peak between the H-8 and H-8′ proton signals suggesting that both were *cis* to each other. Moreover, the H-8 signal exhibited a correlation with the H-2 and H-6 proton resonances of the pendant aryl (Ar) group at δ 6.93 and 6.83, respectively, indicating that the 3-OMe-4-OH-phenyl group was attached to C-7 in a *cis* relationship to the H-8 and H-8′ protons. Significantly, although the NOESY spectra also displayed cross peaks between the H-7′ proton resonance and the H-2′ and H-6′ signals, none of the proton signals of the aryl group attached to the C-7′ showed any correlation to the H-8′ signal. In contrast, the H-7′ signal exhibited a correlation to the H-8′ signal, suggesting that the pendant aryl group attached to C-7′ was *trans* to the H-8 and H-8′ protons. The axial "β" configuration of the aryl group at C-7′ was again further supported by the fact that the signal of the H-$7'_{eq}$ proton was a downfield doublet ($J_{7',8'}$ = 5.6 Hz) at δ 5.6 ppm. Thus, via a combination of derivatization and spectroscopic analyses, the configuration of epi-pinoresinolin **13** was as shown.

Lastly, with the configuration of epi-pinoresinolin **13** unambiguously determined, sesamol **33** (3,4-methylenedioxy phenol) was condensed with lactol **24** to afford, after deprotection of **34**, (±)-epi-piperitol **14** in 75% overall yield.

Concluding remarks

This study provides a convenient synthetic strategy to the "oxygenated" lignans epi-pinoresinolin **13**, epi-piperitolin **14**, and epi-sesamolinol **15** in good overall yield. The configuration of each molecule was determined via a number of spectroscopic means as well as by chemical derivatization, the latter proceeding in a manner that also permitted the synthesis of furofuranone lignan-derived substances, such as acuminatolide **20** and salicifoliol **31**. Future studies will be directed to defining the enzymology of the "oxygen" insertion step, with the compounds so obtained used as substrate analogues or inhibitors.

Experimental

Unroasted and unbleached seeds of *Sesamum indicum* were purchased in a local grocery store. IR and UV spectra were recorded on Perkin–Elmer 1720-X FTIR and Lambda 6 UV/VIS spectrophotometers, respectively. NMR studies of epi-pinoresinolin **13** were performed on a Varian UNITY*plus* (599.89 MHz, ^1H) spectrometer, whereas all other $^1H/^{13}C$ spectra were obtained on a Brüker AMX-300 (300.14 MHz, ^1H) instrument. NMR spectra were recorded in $CDCl_3$ solution with TMS as an internal reference, with chemical shifts (δ) expressed in ppm and coupling constants (*J*) in Hz.

NOESY spectra were recorded using the standard pulse sequence (41), with mixing times, t_m, of 300 and 600 ms. HETCOR spectra were measured using the pulse sequence previously described (42). The ^1H chemical shifts and coupling constants were obtained by first-order analysis of 1D spectra. EIMS were carried out using a Waters Integrity HPLC/MS, whereas HRMS employed a VG 7070 EHF mass spectrometer with a temperature source of 250°C at 70 eV with Ar_1 = 3-methoxy-4-hydroxyphenyl and Ar_2 = 3,4-methylenedioxyphenyl for fragment interpretation. Solvents were either HPLC grade (CH_3CN, MeOH, AcOH, CH_2Cl_2, THF) or ACS grade (EtOAc, hexanes) and were obtained from Baker. Tetrahydrofuran (THF) and methylene chloride (CH_2Cl_2) were distilled over $LiAlH_4$–triphenylmethane and CaH_2, and column and analytical thin-layer chromatographic separations were performed using silica gel 60 (230–400 mesh) and AL SI G/UV 254 (Whatman), respectively.

(+)-Samin 19

This was synthesized as outlined (30, 31) but modified as follows. A suspension of (+)-sesamolin **4** (527 mg, 1.42 mmol), DOWEX 50 X2-200 (545 mg), NaOAc (150 mg, 1.83 mmol), and HCl 10% (1 mL) in CH_3CN (10 mL) was stirred under reflux for 2 h. The suspension was then cooled to room temperature, the resin removed by filtration, and the filtrate evaporated in vacuo, to give a dry solid. The resulting residue was dissolved in a minimum amount of $CHCl_3$ and subjected to silica gel column chromatography, eluted with hexanes:EtOAc 3:1 to 1:1, to give (+)-samin **19** (230.8 mg, 65%); mp 108–109°C (EtOAc:cyclohexane) (lit. (31) mp 106°C; (29) mp 108–109°C); $[\alpha]_D$ +104.65 (*c* 0.516, $CHCl_3$) (lit. $[\alpha]_D$ (30) +103); IR ($CHCl_3$) ν_{max}: 3400 (br, OH), 1610, 1505, 1490, 1446, 1245 cm^{-1}; MS *m/e* (relative %): 250 (M^+, 86), 232 ($M - H_2O^+$, 6), 194 ($M - C_2O_2^+$, 38), 176 (54), 149 (Ar_2CO^+, 100), 135 ($Ar_2CH_2^+$, 58), 122 (Ar_2H^+, 22); HRMS; calcd. for $C_{13}H_{14}O_5$: 250.0841 (M^+), found: 250.0805; for ^1H and ^{13}C NMR spectral analyses: see ref. 29.

(+)-Acuminatolide 20

To a solution of (+)-samin **19** (80 mg, 0.32 mmol) in dry CH_2Cl_2 (50 mL) was added pyridinium dichromate (PDC) (4 equiv., 481 mg), AcOH (1 equiv., 20 μL), and 4Å molecular sieves (500 mg). The resulting suspension was stirred for 6 h at room temperature (r.t.), then filtered through a plug of silica gel and the filtrate removed in vacuo to give a yellow solid. The residue was dissolved in a minimum amount of $CHCl_3$ and subjected to silica gel column chromatography, eluted with hexanes:EtOAc (2:1), to give **20** (61.84 mg, 78%); mp 118°C (EtOAc:hexanes) (lit. (27, 33) mp 118–119°C); $[\alpha]_D$ +100.2 (*c* 0.11, $CHCl_3$) (lit. $[\alpha]_D$ (27) −103.82 (*c* 0.31, $CHCl_3$); $[\alpha]_D$ (33) −37 (*c* 0.11, $CHCl_3$)); IR ($CHCl_3$) ν_{max}: 1775 (C=O), 1610, 1510, 1500 (C=CAr), 1245 (C-O) cm^{-1}; ^1H NMR δ: 6.80 (br s, 1H, H-2), 6.70 (br s, 2H, H-5 and H-6), 5.95 (s, 2H, OCH_2O), 4.57 (d, 1H, $J_{7,8}$ = 6.8, H-7), 4.46 (dd, 1H, $J_{9eq,9ax}$ = 6.8, $J_{8,9eq}$ = 9.7, H-9eq), 4.35–4.25 (m, 2H, H-9′ax and H-9ax), 4.14 (dd, 1H, $J_{9'eq,9'ax}$ = 3.6, $J_{8',9'eq}$ = 9.3, H-9′eq), 3.40 (ddd, 1H, $J_{7,8'}$ = 3.6, $J_{8',9'eq}$ = 9.3, $J_{8',8}$ = 9.0, H-8′), 3.05 (m, 1H, H-8); ^{13}C NMR δ: 178.16 (C-7′), 148.11 (C-3), 147.60 (C-4), 132.73 (C-1), 119.57 (C-6), 108.22 (C-5), 106.27 (C-2), 101.19 (OCH_2O), 85.92 (C-7), 69.93 and 69.77 (C-9/C-9′), 48.86 (C-8), 46.58 (C-8′) ppm; MS *m/e* (relative %): 248 (M^+, 100), 218 ($M - CH_2O^+$, 22), 163 (83), 150 (Ar_2CHO^+, 80), 149 (Ar_2CO^+, 100), 135 ($Ar_2CH_2^+$, 82), 121 (Ar_2^+, 38); HRMS, calcd. for $C_{13}H_{12}O_5$: 248.0685 (M^+); found: 248.0683.

4-Benzyloxy-3-methoxy phenol 22

Phenol **22** (139.5 mg, 0.64 mmol) was prepared from *O*-benzylvanillin **21** (242 mg, 1 mmol) (23) in 64% overall yield exactly as described (34, 35).

O-Benzyl-epi-sesamolinol 23

To a solution of (+)-samin **19** (29.8 mg, 0.12 mmol) in dry THF (10 mL), PPh_3 (31.6 mg, 0.12 mmol), and protected phenol **22** (26.2 mg, 0.12 mmol) was added diethylazodicarboxylate (DEAD) (19 μL, 1 equiv.). The mixture was stirred at r.t. for 24 h and the solvent removed in vacuo. The residue was next subjected to silica gel column chromatography, eluted with hexanes:EtOAc 3:1 (v/v), to give *O*-benzyl epi-sesamolinol **23** (44.8 mg, 80%). IR ($CHCl_3$) ν_{max}: 1600, 1510, 1450 (C=CAr), 1250, 1220 (C-O) cm^{-1}; ^1H NMR δ: 7.50–7.20 (m, 5H, Bn), 6.90–6.55 (m, 6H, C*H*Ar), 5.94 (s, 2H, OCH_2O), 5.62 (d, 1H, $J_{7',8'}$ = 5.6, H-7′), 5.10 (s, 2H, CH_2Ph), 4.80 (d, 1H, $J_{7,8}$ = 6.8, H-7), 4.45–4.38 (m, 1H, H-9′ax), 4.20–4.10 (m, 1H, H-9′eq), 4.15–4.10 (m, 1H, H-9ax), 4.05–3.95 (m, 1H, H-9eq), 3.87 (s, 3H, OCH_3), 3.35–3.25 (m, 1H, H-8′), 3.05–2.90 (m, 1H, H-8); ^{13}C NMR δ: 151.95, 151.14, 150.56, 147.92, 147.13 (C-3, C-4, C-1′, C-3′, C-4′), 134.79 (*C*q/Bn), 143.31 (C-1), 128.42, 128.38, 127.37 (*C*H/Bn), 119.42 (C-6), 115.27 (C-5′), 108.13 (C-5), 107.03 (C-6′), 106.39 (C-2), 102.65 (C-7′), 102.41 (C-2′), 101.02 (OCH_2O), 85.31 (C-7), 71.83 (CH_2Ph), 69.40 (C-9′), 67.08 (C-9), 55.93 (OCH_3), 52.85 (C-8), 51.09 (C-8′); MS *m/e* (relative %): 462 (M^+, 5), 243 (20), 230 (70), 203 (30), 165 (15), 149 (Ar_2CO^+, 15), 135 ($Ar_2CH_2^+$, 100), 121 (Ar_2^+, 70), 105 (15); HRMS, calcd. for $C_{27}H_{26}O_7$: 462.1679; found: 462.1671.

(+)-Epi-sesamolinol 15

(+)-*O*-Benzyl epi-sesamolinol **23** (59.2 mg, 0.13 mmol) in EtOAc (5 mL) was treated with Pd/C 10% (15 mg). The solution was then stirred for 3 h under H_2 atmosphere, following which it was filtered over a short path silica gel column eluted with EtOAc. The filtrate was removed in vacuo, and the resulting residue purified by silica gel column chromatography, eluted with EtOAc:hexanes 2:1 (v/v), to give (+)-epi-sesamolinol **15** (29 mg, 75%). $[\alpha]_D$ +182 (*c* 0.996 g/100 mL in $CHCl_3$); IR ($CHCl_3$) ν_{max}: 3425 (br, OH), 1613, 1510, 1490, 1448 (C=CAr), 1234, 1196 cm^{-1}; UV λ_{max}: 230, 285 nm; ^1H NMR δ: 6.90–6.70 (m, 6H), 5.95 (s, 2H, OCH_2O), 5.59 (d, 1H, $J_{7',8'}$ = 5.6, H-7′), 5.38 (br s, 1H, OH), 4.78 (d, 1H, $J_{7,8}$ = 7, H-7), 4.50–4.35 (m, 1H, H-9′ax), 4.20–4.10 (m, 1H, H-9′eq), 4.10–4.08 (m, 1H, H-9ax), 4.05–3.95 (m, 1H, H-9eq), 3.87 (s, 3H, OCH_3), 3.35–3.20 (m, 1H, H-8′), 3.05-2.95 (m, 1H, H-8); ^{13}C NMR δ: 150.69 (C-1′), 147.88 (C-3), 147.07 (C-4), 146.80 (C-3′), 140.82 (C-4′), 134.90 (C-1), 119.36 (C-6), 114.13 (C-5′), 108.56 (C-5), 108.26 (C-6′), 106.54 (C-2), 101.92 (C-7′), 101.15 (OCH_2O), 100.98 (C-2′), 85.44 (C-7), 69.47 (C-9), 67.23 (C-9′), 56.08 (OCH_3), 53.08 (C-8′), 51.26 (C-8); MS *m/e* (relative %): 372 (M^+, 5), 273 (5), 233 (28), 203 ($Ar_2C_5H_6O^+$, 45), 149 (Ar_2CHO^+, 30), 140 (70), 135 ($Ar_2CH_2^+$, 100), 121 (Ar_2^+, 25), 105 (18); HRMS, calcd. for $C_{20}H_{20}O_7$: 372.1209; found: 372.1194.

Lactone 26

To a solution of LDA (3.18 mmol, 1.1 equiv.), freshly prepared from diisopropyl amine (0.42 mL) and 1.6 M *n*-BuLi in hexanes (1.99 mL) at −15°C, in dry THF (10 mL) under argon at −78°C (acetone – Dry Ice bath), was added dropwise 4-vinyl butyrolactone **25** (323.5 mg, 2.88 mmol, 1 equiv.) in dry THF (6 mL) over 30 min. The resulting mixture was stirred at −78°C for 30 min, following which *O*-benzylvanillin **21** (578.5 mg, 2.39 mmol) in dry THF (5 mL) was added dropwise over 30 min with the mixture allowed to stir at −78°C for an additional 3.5 h. A saturated solution of $NH_4Cl_{(aq)}$ (0.5 mL) was added, and the resulting mixture was then allowed to warm to r.t. The mixture was sequentially extracted with diethyl ether (2 × 15 mL) and EtOAc (2 × 15 mL), with the combined organic layers dried (Na_2SO_4), evaporated in vacuo, and the resulting residue chromatographed on a silica gel column, eluted with hexanes:EtOAc 2:1 (v/v), to give the diastereoisomeric lactone **26** (779.7 mg, 92%) mixture, which was not resolved further. IR ($CHCl_3$) ν_{max}: 3492 (br, OH), 1762 (C=O), 1593, 1515, 1455 (C=CAr) cm^{-1}; ^1H NMR δ: 7.40–7.18 (m, 5H, Bn), 6.88–6.85 (m, 3H, C*H*Ar), 5.30–5.15 (m, 1H, =C*H*), 4.85–4.55 (m, 1H, C*H*OH), 4.35–4.15 (m, 2H, =CH_2), 4.15–3.90 (m, 2H, CH_2OCO), 3.74 (s, 3H, OCH_3), 3.25–3.10 and 2.85–2.70 (m, 1H, =CH-C*H*), 2.70–2.55 (m, 1H, CO-C*H*); ^{13}C NMR δ: 177.72, 177.46 (*C*O), 149.17, 149.07, 147.42, 146.76 (*C*q-O/Ar), 136.69, 136.65 (*C*q/Bn), 135.78, 134.46 (CH$_2$=*C*H), 134.26, 131.92 (*C*q/Ar), 128.04, 127.38, 126.92 (*C*H/Bn), 118.84, 117.46 (*C*H/Ar), 113.36, 113.16 (*C*H/Ar), 116.96, 116.38 (*C*H$_2$=), 110.05, 109.27 (*C*H/Ar), 72.90, 69.93 (*C*HOH), 70.44, 70.35 (*C*H$_2$O), 70.42 (*C*H$_2$Ph), 55.97 (O*C*H$_3$), 55.47, 51.58 (*C*H$_2$CO), 41.96, 38.58 (*C*H-CH=); MS *m/e* (relative %): 354 (M^+, 90), 337 (65), 336 (27), 315 (30), 243 (100), 151 (Ar_1CO^+, 80), 123 (Ar_1^+, 50); HRMS, calcd. for $C_{21}H_{22}O_5$: 354.1467; found: 354.1486.

Triol 27
