(2*R*,1′*R*,3*R*,5*R*,6*R*)-5,6-Dimethoxy-2-(1′-methoxymethylhydroxy-but-3′-ene-1′-yl)-5,6-dimethyl-1,4-dioxane-3-carbaldehyde (19)

DMSO (335 μL, 4.72 mmol) as a solution in CH_2Cl_2 (6 mL) was added to a solution of oxalyl chloride (206 μL, 2.36 mmol) in CH_2Cl_2 (6 mL) at –78°C. The reaction was stirred for 30 min at –78°C before alcohol (581 mg, 1.81 mmol) as a solution in CH_2Cl_2 (6 + 3 mL) was added over 30 min. The reaction was then stirred at –78°C for 1 h before Et_3N (885 μL, 6.35 mmol) was added dropwise over 30 min. The reaction was then allowed to warm to room temperature over 1 h then diluted with CH_2Cl_2 (150 mL). The CH_2Cl_2 solution was washed with water (2 × 150 mL), the combined aqueous layers reextracted with CH_2Cl_2 (100 mL), organics dried ($MgSO_4$), and concentrated in vacuo. The aldehyde (R_f = 0.36 (petrol–ether, 1:1)) was used without further purification in the next reaction.

(*E*)-(2*S*,3*R*,5*R*,6*R*,1′*R*,5″*S*)-5,6-Dimethoxy-2-(1′-methoxymethylhydroxy-but-3′-ene)-5,6-dimethyl-3-(5″-methyltetradec-1″,13″-diene-1″-yl-3″one)-1,4-dioxane (21) and (*Z*)-(2*S*,3*R*,5*R*,6*R*,1′*R*,5″*S*)-5,6-dimethoxy-2-(1′-methoxymethylhydroxy-but-3′-ene)-5,6-dimethyl-3-(5″-methyltetradec-1″,13″-diene-1″-yl-3″one)-1,4-dioxane

Phosphonate **5** (758 mg, 2.18 mmol) as a solution in MeCN (9 mL) was added to a suspension of LiCl (92 mg, 2.18 mmol) in MeCN (3 mL) at room temperature. The aldehyde **19** (1.81 mmol, crude) and DIPEA (316 μL, 1.81 mmol) were then added as a solution in MeCN (6 + 3 mL). The reaction was stirred at room temperature for 16 h before being diluted with ether (100 mL) and washed with water (60 mL). The organic layer was washed again with water (60 mL), the aqueous layers reextracted with ether (100 mL), and the combined organic layers dried ($MgSO_4$) and concentrated in vacuo. Purification by flash column chromatography (petrol–ether (4:1) + 1% Et_3N) gave α,β-unsaturated ester as 2 double bond isomers in a combined yield of 66% from the alcohol.

*(*E*)-(2*S*,3*R*,5*R*,6*R*,1′*R*,5″*S*)-5,6-Dimethoxy-2-(1′-methoxymethylhydroxy-but-3′-ene)-5,6-dimethyl-3-(5″-methyl-tetradec-1″,13″-diene-1″-yl-3″one)-1,4-dioxane (21)*

Cyclization–cycloaddition cascades for the construction of azapolycyclic ring systems

Albert Padwa, William S. Kissell, and Cheryl K. Eidell

Abstract: Cyclic 2-amidofuranones were obtained from the Rh(II)-catalyzed reaction of α-diazoketo substituted pyrrolidine derivatives. These compounds are derived by a [1,4]-hydrogen transfer from an initially formed carbonyl ylide dipole. Acylation of the amido-substituted furanone with pivalyl chloride provided a fused amidofuran, which underwent bimolecular Diels-Alder cycloaddition with *N*-phenylmaleimide. The Rh(II)-catalyzed decomposition of ethyl 2-diazo-3-oxo-(2-oxo-1-pent-4-enoyl-pyrrolidine-3-yl)propionate was also examined. In this case, the alkenyl group tethered to the amido carbonyl underwent smooth intramolecular [4+2]-cycloaddition with the amidofuran obtained from the acylation reaction. An alternate route for the synthesis of cyclic amidofurans was developed using a Pummerer induced cyclization of the thiophenyl substituted acetal derived from the aldol reaction of methoxyphenylsulfanyl acetaldehyde with α-valerolactam. Treatment of the amido-substituted acetal with dimethyl(methylthio)sulfonium tetrafluoroborate (DMTSF) generated an oxonium ion, which readily cyclized onto the adjacent carbonyl group. The amidofuran that was formed underwent an intramolecular Diels-Alder reaction when heated at 110°C in toluene. Subsequent ring opening of the transient [4+2]-cycloadduct followed by elimination of methanol and tautomerization of the resulting cyclohexadienone gave rise to the observed phenolic lactam in good overall yield.

Key words: intramolecular, cyclization, Diels-Alder, diazo-ketoamide, rhodium(II).

Résumé : On a obtenu des 2-amidofuranones cycliques par la réaction catalysée par du Rh(II) de dérivés α-diazocétopyrrolidines substituées. Ces composés dérivent d'un transfert [1,4] d'hydrogène à partir d'un dipôle ylure de carbonyle formé initialement. L'acylation de l'amidofuranone substituée à l'aide de chlorure de pivaloyle conduit à un amidofurane ponté qui peut donner lieu à une réaction de cycloaddition de Diels-Alder bimoléculaire avec le *N*-phénylmaléimide. On a aussi étudié la réaction de décomposition du 2-diazo-3-oxo-(2-oxo1-pent-4-énoyl-pyrrolidine-3-yl)propionate d'éthyle catalysée par le Rh(II). Dans ce cas, le groupe alcényle attaché au carbonyle de l'amido donne lieu à une réaction facile de cycloaddition [4+2] intramoléculaire avec l'amidofurane obtenu par la réaction d'acylation. On a aussi développé une autre voie de synthèse des amidofuranes cycliques; elle fait appel à une réaction de cyclisation induite à la façon de Pummerer de l'acétal substitué par un thiophényle, dérivé de la réaction aldolique du méthoxyphénylsulfanylacétaldéhyde avec le α-valérolactame. Le traitement de l'acétal substitué par un amido à l'aide de tétrafluoroborate de diméthyl(méthylthio)sulfonium conduit à la formation d'un ion oxonium qui peut se cycliser facilement sur le groupe carbonyle adjacent. Lorsqu'on le chauffe à 110°C dans le toluène, l'amidofurane qui s'est formé subi une réaction de Diels-Alder intramoléculaire. L'ouverture de cycle subséquente du cycloadduit [4+2] transitoire, suivie d'une élimination de méthanol et d'une tautomérisation de la cyclohexadiénone résultante fournit le lactame phénolique observé, avec un bon rendement global.

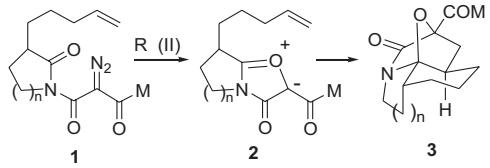
Mots clés : intramoléculaire, cyclisation, Diels-Alder, diazo-cétoamide, rhodium(II).

[Traduit par la Rédaction]

Introduction

Construction of azapolyheterocycles through metal intervention has been a particularly fruitful area of investigation, and the synthesis of various types of alkaloids by this approach has been carried out by several investigators (1–11). Recent papers from these laboratories have described a route to azapolycyclic ring systems that involved the tandem cyclization–cycloaddition of a transient rhodium carbenoid (Scheme 1) (12). Isomünchnone **2** was easily prepared by the rhodium(II) catalyzed cyclization of a suitable diazoimide precursor **1** (13). The mesoionic oxozolium ylide **2** is the cyclic equivalent of a carbonyl ylide and readily undergoes 1,3-dipolar cycloaddition with suitable dipolarophiles (14). This reaction is an integral part of our program aimed at developing new cascade reactions and achieving the total syntheses of various nitrogen-containing heterocycles (15). Our more recent achievements in this area involve the use of diazo ketoamides

Received April 6, 2001. Published on the NRC Research Press Web site at http://canjchem.nrc.ca on November 12, 2001.



This paper is dedicated to Victor A. Snieckus on the occasion of his 64th birthday and for his many significant contributions to the art of organic synthesis.

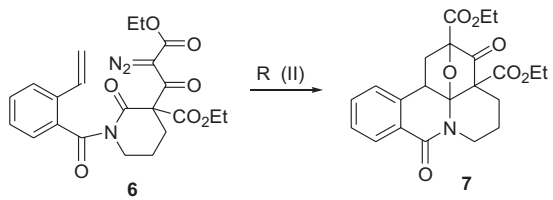
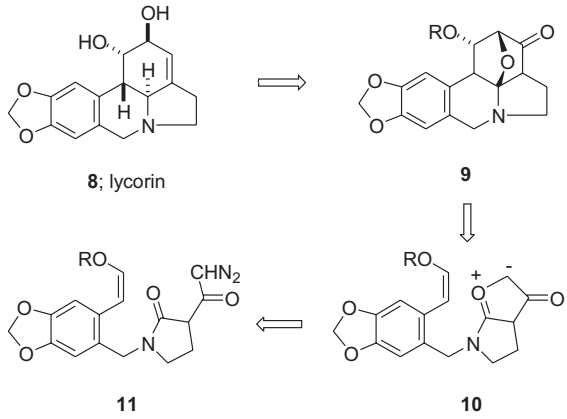
such as **4** (16). Intramolecular attack of the amido carbonyl oxygen at the rhodium carbenoid center produces a carbonyl ylide (i.e., **5**) (eq. [1]) that is isomeric with the isomünchnone class of dipoles. Several key questions emerged as a result of these investigations (17): (*i*) does the size of the lactam ring influence the efficiency of dipole formation, (*ii*) how would the nature of the substituent groups (R^1–R^3) impact on dipole reactivity, (*iii*) would intramolecular dipolar-cycloaddition of push–pull stabilized ylides such as **5** occur, and (*iv*) if so, what effect would the nature and length of the tether have on the course of the cycloaddition? We, therefore, initiated a study to not only probe these issues but also to use this sequence for the synthesis of various nitrogen heterocycles. In this paper we report results emanating from this investigation.



[1]

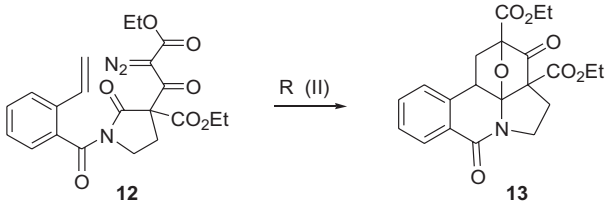
Results and discussion



To help address the above questions, the Rh(II)-catalyzed reaction of diazoamido ester **6** was examined. The prerequisite diazo amide necessary for dipole generation was obtained from the reaction of 3-carboethoxy-2-piperidone with ethyl 2-diazomalonyl chloride (18) and this was followed by acylation with *o*-vinyl benzoyl chloride. Formation of the push–pull carbonyl ylide dipole proceeded smoothly upon heating a sample of **6** in benzene in the presence of $Rh_2(OAc)_4$ (eq. [2]). The resultant dipole was trapped by the adjacent vinyl group to afford cycloadduct **7** in 92% yield. The structural assignment was made on the basis of its NMR spectral properties and by comparison with related cycloadducts prepared in other studies in our laboratory (17). Cycloadduct **7** is produced with complete diastereoselectivity and is the result of *endo* cycloaddition with respect to the dipole and *anti* with respect to the carboethoxy group at the ring juncture.

[2]

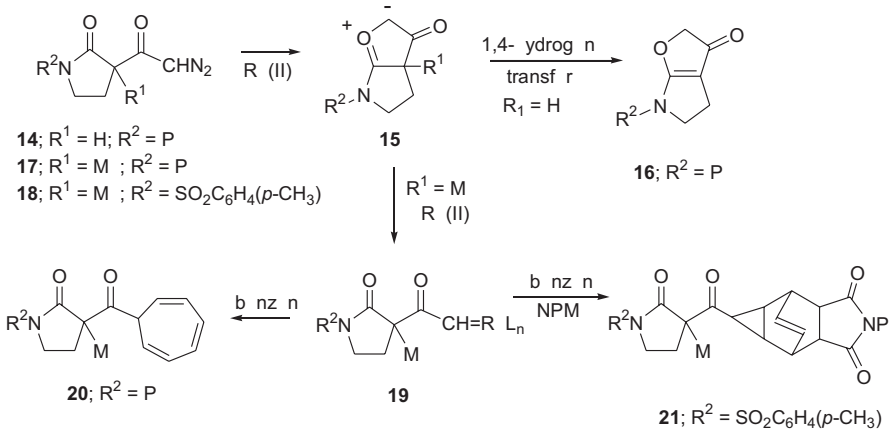
Prompted by the facility with which **6** underwent cycloaddition to give **7**, we became interested in determining



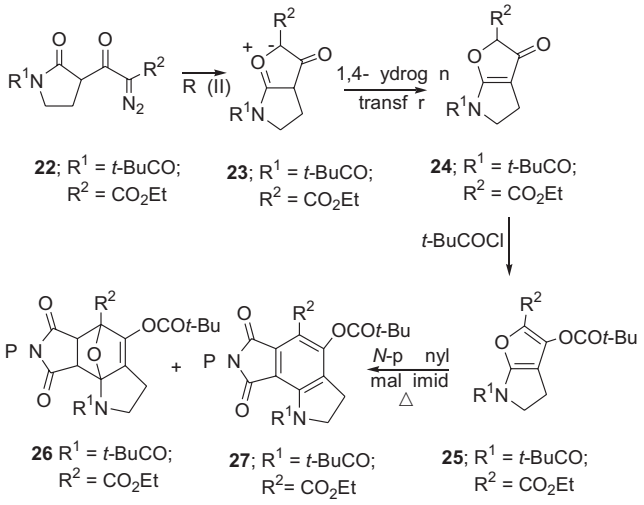
Scheme 2.

whether a related process could be used to assemble the carbon framework of lycorine (**8**). The lycorine alkaloids, a group of compounds isolated from *Amarylidaceae* plants, have attracted the attention of chemists and pharmacologists due to the interesting properties of some of its members (19, 20). Several of these alkaloids possess antineoplastic and antimitotic activities, while others are known to exhibit insect antifeedent activity (19). Lycorine (**8**) was first isolated in 1877 and was shown to be a powerful inhibitor of growth and cell division in higher plants and also to possess antiviral activity (21, 22). Consequently, considerable effort has been directed toward the synthesis of the oxygenated octahydroindole skeleton found in this class of alkaloids (23–29). We envisioned diazoamide **11** functioning as a possible precursor for the generation of dipole **10**. Intramolecular cycloaddition across the neighboring enol ether π-bond followed by reductive ring opening of the transient azabicyclic adduct **9** would provide the lycorine skeleton with the correct stereochemistry (Scheme 2).

As a model system for exploring the cyclization-cycloaddition sequence for an eventual synthesis of lycorine, diazoamide **12** was first examined. In this case, the cascade sequence would lead directly to the proper galanthan skeleton of lycorine. We carried out the Rh(II)-catalyzed reaction under the same conditions employed for the homologous diazoamide **6** and isolated the expected cycloadduct **13**, but only in 40% yield (eq. [3]).



[3]



Raising the temperature or extending the reaction time resulted in extensive decomposition, probably as a consequence of the reactivity of the styryl portion of the molecule. We initially thought that a change in the trajectory of attack on the π-bond from the smaller lactam ring may have been responsible for the reduced yield of the cycloaddition. However, reaction of diazoamide **12** with external dipolarophiles provided little or no cycloaddition product. Bimolecular stud-

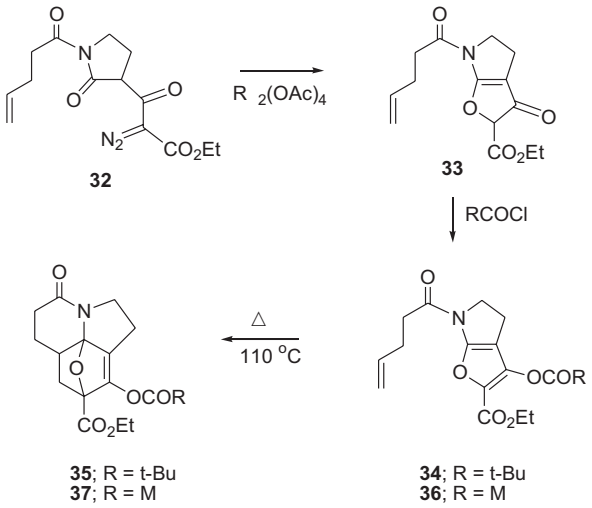
Scheme 5.



ies with a related diazoamide that did not contain the *o*-vinyl group were also unsatisfactory, clearly indicating that polymerization is not the sole cause of the reduced yields. An extensive study using different rhodium(II) ligands did not lead to an improvement in the yield of cycloadduct **13**. This would tend to imply that the decomposition of the diazoamide either does not lead to significant amounts of the dipole or that the dipole is not long lived enough to react with a dipolarophile in either an inter- or intramolecular fashion. Possibly, this may be due to the strain energy associated with formation of the carbonyl ylide. Presumably, the dipole fused to the five membered pyrrolidine ring would have a larger strain energy associated with it than would the dipole fused to the more flexible piperidine six-membered ring.

We next examined the possibility of using other five-membered push–pull dipoles (e.g., **10**) for further cycloaddition chemistry directed toward alkaloid synthesis. We reasoned that removal of the bulky carboethoxy group at the ring fusion might relieve some of the ring strain and allow the cyclization reaction to proceed with higher efficiency. In addition, the carboethoxy group is not necessary for the alkaloids we had in mind as we would eventually need to remove it in a subsequent step. This analysis led us to study the Rh(II) behavior of diazoamide **14**. Reaction of **14** with $Rh_2(OAc)_4$ led to the expected push–pull dipole **15**. However, even in the presence of an excess of a reactive trapping agent such as DMAD, a rapid [1,4]-hydrogen shift to furanone **16** occurred before bimolecular cycloaddition (Scheme 3). Although the formation of **16** from **14** is somewhat disappointing, it comes as no real surprise since one of the characteristic reactions of carbonyl ylides derived from the reaction of α-diazoalkanes with ketones consists of an intramolecular proton transfer (30). The earliest example of this process was reported by Kharasch and co-workers in 1953 and many related cases have been recorded since that time (30).

Despite our inability to isolate a dipolar cycloadduct from the Rh(II)-catalyzed reaction of diazoamide **14**, we were still interested in determining the efficiency with which cyclization of the pyrrolidinone ring system occurred. To this end, we prepared diazoamides **17** and **18**, which incorporate a methyl substituent in the α-position so as to block the deprotonation step. When submitted to the cyclization–cycloaddition conditions using *N*-phenylmaleimide as the trapping agent, no products resulting from dipolar-cycloaddition could be detected. Rather the product of solvent insertion **20** (or **21**) was isolated in 73 and 68% yield, respectively (Scheme 3). This

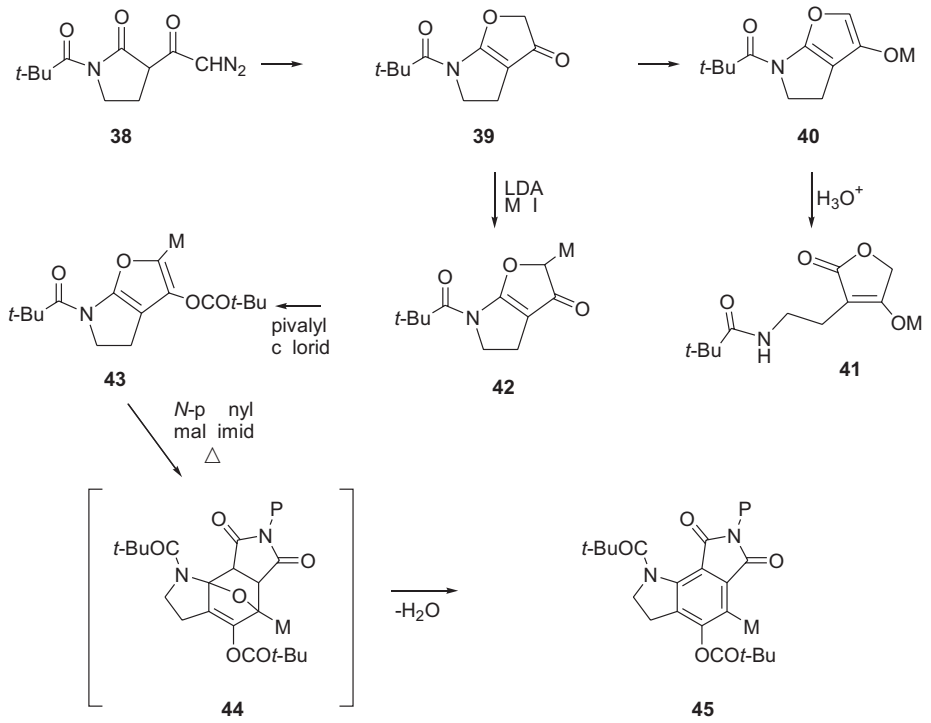
Scheme 6.

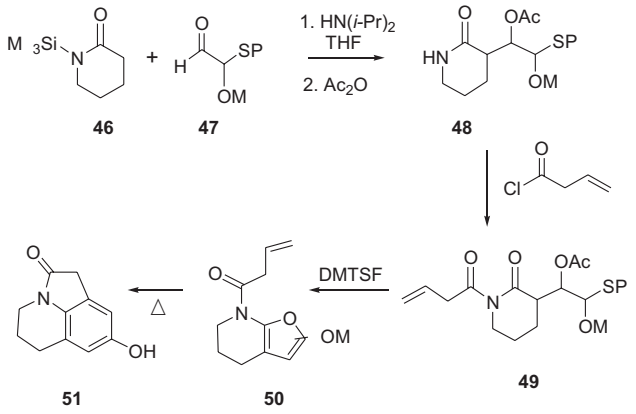
result suggests that in the presence of the Rh(II)-catalyst, formation of the carbonyl ylide intermediate **15** is reversible and that the bimolecular insertion of **19** into the solvent proceeds at a faster rate than dipolar-cycloaddition of **15** (R^1 = Me) with the added dipolarophile (31).

At this point in time, we decided to use the furanone ring to our advantage for an anticipated Diels-Alder cycloaddition. It was envisioned that acylation of the furanone would provide a fused amidofuran (i.e., **25**) that could be subsequently utilized in a bimolecular cycloaddition reaction (Scheme 4) (32). Exploring this approach required that three key steps be tested. First, the diazoimide must be able to efficiently cyclize to form the furanone ring. Secondly, the furanone would need to readily react with an acylating agent to furnish the fused amidofuran **25**. Finally, the tetrasubstituted furan would need to undergo a facile Diels-Alder reaction with an electron deficient π-bond (33). Diazoimide **22** was synthesized from *N*-pivalyl-pyrrolidinone by deprotonation with $NaN(TMS)_2$ followed by treatment with benzylchloroformate. Hydrogenolysis of the benzyl ester to the carboxylic acid was followed by conversion to the acid chloride and reaction with ethyl diazoacetate. Decomposition of **22** using $Rh_2(OAc)_4$ gave furanone **24** which was transformed into amidofuran **25** by treatment with pivalyl chloride and NEt_3. Heating a sample of **25** with *N*-phenyl maleimide afforded a 1:3-mixture of cycloadduct **26** together with indoline **27**, derived by oxabicyclic ring opening followed by elimination of water, in 95% overall yield (Scheme 4). Indeed, treatment of **26** in the presence of acid afforded **27** in high yield. Interestingly, the reaction of **25** with DMAD afforded a mixture of cycloadduct **28** (15%), indole **29** (22%) and the rearranged cyclohexa-dienone **31** (35%) (Scheme 5). The structure of **31** was unequivocally established by a crystal X-ray analysis, and its formation can be rationalized by a ring opening – rearrangement reaction analogous to that reported in the furo[3,4-*d*]oxazole series (34).



Having established the feasibility of the bimolecular cycloaddition sequence using activated π-bonds, we initiated a study of the intramolecular reaction related to that outlined in Scheme 2. Specifically, we were interested in examining a case where an alkenyl group would be tethered to the imido nitrogen atom. Diazoimide **32** was synthesized in a manner similar to that used to prepare pyrrolidinone **22**. As before, decomposition of the diazoimide using $Rh_2(OAc)_4$ provided the intermediate furanone **33**, which was reacted with pivalyl chloride to furnish amidofuran **34**. Heating a toluene solution of **34** at reflux provided cycloadduct **35** as the only detectable product in high overall yield for the three-step process (70%) (Scheme 6). A similar [4+2]-cycloaddition reaction occurred with the corresponding acetate **36**, but with lower overall yield (25%), perhaps as a consequence of a competitive thermal deacetylation reaction.

We quickly realized that application of this cyclization–cycloaddition sequence to amido furanone **39**, in turn derived from the Rh(II)-catalyzed cyclization of α-diazo keto pyrrolidinone **38**, would represent a new approach to various azapolycyclic ring systems. To further test the generality and scope of the sequence, furanone **39** was treated with trimethyloxonium tetrafluoroborate so as to effect O-methylation. The initially formed methoxyfuran **40** was extremely labile and instead of undergoing [4+2]-cycloaddition with added dienophiles, it readily underwent hydrolysis to give propionamide **41** (Scheme 7). On the other hand, when **39** was treated with LDA followed by reaction with methyl iodide, the *C*-alkylated furanone **42** was formed in 37% yield. Subsequent treatment of **42** with pivalyl chloride in the presence of NEt_3 gave **43** which was immediately allowed to react with *N*-phenylmaleimide. The initially formed Diels-Alder cycloadduct **44** underwent ready dehydration to produce maleimide **45** in 52% overall yield (Scheme 7).



As a consequence of some of the difficulties encountered with the diazo ketoamide cyclizations, we decided to explore an alternate tactic for the preparation of cyclic amidofurans. As detailed in an earlier paper from our laboratory (35), we had employed a Pummerer cyclization of an imido dithioacetal as a method for constructing 2-amido substituted furans. In the current investigation, we found that a similar reaction occurred using the aldol product (i.e., **48**) derived from the reaction of *N*-trimethylsilyl α-valerolactam (**46**) (36) with methoxyphenylsulfanyl acetaldehyde (**47**) (37). Quenching the reaction with acetic anhydride followed by aqueous workup provided the expected acetate **48** in 68% yield as a complex mixture of diastereomers. Cyclic lactam **48** was acylated with 3-butenoyl chloride using powdered 4 Å molecular sieves as a neutral acid scavenger (38) to provide the corresponding imide **49** in 94% yield. It was known from earlier work in the literature that treatment of thioketals with dimethyl(methyl-thio)sulfonium tetrafluoroborate (DMTSF) causes the carbon–sulfur bond to become labile upon methylthiolation (39). The initially formed alkylthiosulfonium ion easily dissociates to produce a thionium ion and methyl sulfide (40). In a similar fashion, treatment of **49** with DMTSF generates an oxonium ion, which cyclizes onto the imido carbonyl group to give amidofuran **50** in 65% yield. Thermolysis of **50** at 110°C for 30 min produced phenol **53** in 58% yield (Scheme 8). The thermal reaction is best rationalized by an initial Diels-Alder reaction of the furan across the tethered π-bond (41) to produce cycloadduct **51** as a transient intermediate. A subsequent ring opening followed by elimination of methanol produces cyclohexadienone **52**, which rapidly tautomerizes to give the observed phenol **53** (Scheme 9).

Scheme 8.

Scheme 9.

In conclusion, this paper describes several cyclization–cycloaddition cascade sequences that can be used for the construction of various azapolyheterocyclic ring systems. The synthetic procedures described here involve (*i*) the Rh(II)-catalyzed reaction of diazo amidoketones; (*ii*) acylation of an amido substituted furanone followed by a bimolecular Diels-Alder cycloaddition; and (*iii*) the DMTSF induced cyclization–cycloaddition reaction of an imido thiophenylmethoxy substituted acetal. Further studies of the IMDAF cycloaddition of cyclic 2-amidofurans are in progress and will be reported in due course.

Experimental

Melting points are uncorrected. Mass spectra were determined at an ionizing voltage of 70 eV. Unless otherwise noted, all reactions were performed in flame dried glassware under an atmosphere of dry argon. Solutions were evaporated under reduced pressure with a rotary evaporator and the residue was chromatographed on a silica gel column using an ethyl acetate – hexane mixture as the eluent unless specified otherwise. All solids were recrystallized from ethyl acetate – hexane for analytical data.

3-(Diazoethoxycarbonylacetyl)-2-oxo-piperidine-3-carboxylic acid ethyl ester

To a stirred solution of 3-carboethoxy-2-piperidone (0.5 g, 2.9 mmol) in THF (25 mL) at 0°C was added a 2.0 M isopropyl magnesium chloride solution (1.6 mL, 3.2 mmol) over a 20 min period. The reaction mixture was allowed to stir at 0°C for 1 h, and then ethyl 2-diazomalonyl chloride (18) (0.6 g, 3.5 mmol) was added dropwise. After stirring

© 2001 NRC Canada

for 1 h at 0°C, the reaction mixture was quenched with water (50 mL) and extracted with ethyl acetate. The combined extracts were washed with brine, dried over anhydrous $MgSO_4$, filtered, and concentrated under reduced pressure. The residue was subjected to flash chromatography on silica gel to give 0.23 g (25%) of the titled compound as a pale yellow oil. IR (neat) (cm^{-1}): 2139, 1737, 1717, 1677, 1643. ^1H NMR (300 MHz, $CDCl_3$) δ: 1.25–1.31 (m, 6H), 1.71–1.82 (m, 2H), 2.38–2.59 (m, 2H), 3.28–3.45 (m, 2H), 4.21–4.30 (m, 4H), 6.70 (s, 1H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 13.7, 14.1, 18.7, 27.1, 41.7, 61.5, 62.0, 66.9, 128.1, 160.6, 165.9, 167.3, 186.9. This material was used in the next step without further purification.

3-(Diazoethoxycarbonylacetyl)-2-oxo-1-(2-vinylbenzoyl)-piperidine-3-carboxylic acid ethyl ester (6)

To a sample of *o*-vinyl benzoic acid (42) (0.06 g, 0.39 mmol) in CH_2Cl_2 (10 mL) was added oxalyl chloride (0.12 mL, 1.4 mmol) followed by one drop of DMF. The solution was allowed to stir at rt for 1 h and was concentrated under reduced pressure to remove the excess oxalyl chloride. The residue was dissolved in benzene (8 mL) and this was slowly added to a solution of benzene (5 mL) and the above diazo amide (0.1 g, 0.3 mmol), which contained triethylamine (0.14 mL, 1.0 mmol) at 0°C. The reaction was maintained at 0°C for 30 min and was stirred at rt for 24 h. The solution was quenched with water (50 mL) and extracted with ethyl acetate. The combined extracts were washed with a saturated $NaHCO_3$ solution, brine, dried over anhydrous $MgSO_4$, filtered, and concentrated under reduced pressure. The residue was subjected to flash chromatography on silica gel to give 0.05 g (35%) of **6** as a yellow oil. IR (neat) (cm^{-1}): 2141, 1738, 1712, 1678, 1639. ^1H NMR (300 MHz, $CDCl_3$) δ: 1.21–1.36 (m, 6H), 1.86–2.09 (m, 2H), 2.41 (td, 1H, J = 11.0, 4.2 Hz), 2.64 (m, 1H), 3.90 (td, 1H, J = 11.0, 4.2 Hz), 4.01–4.35 (m, 5H), 5.24 (d, 1H, J = 11.1 Hz), 5.66 (d, 1H, J = 17.3 Hz), 6.79 (dd, 1H, J = 17.3, 11.0 Hz), 7.12–7.34 (m, 3H), 7.54 (d, 1H, J = 7.8 Hz). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 13.9, 14.2, 20.4, 28.4, 44.8, 61.7, 62.8, 69.3, 77.1, 116.1, 125.8, 125.9, 126.8, 129.5, 134.3, 135.3, 136.5, 160.8, 166.2, 167.1, 173.3, 186.4. This material was used in the next step without further purification.

Ethyl 9-aza-13-(ethoxycarbonyl)-16-oxa-8,14-dioxopentacyclo[13.2.1.$0^{2,7}$.$0^{9,17}$-.$0^{13,14}$]octadeca-2(3),4,6-triene-15-carboxylate (7)

To a mixture of diazo amido ester **6** (0.05 g, 0.11 mmol) in benzene (5 mL) was added rhodium(II) acetate (2 mg). The mixture was allowed to stir at 50°C for 6 h. The solvent was removed under reduced pressure, and the residue was subjected to flash chromatography on silica gel to afford 0.05 g (92%) of cycloadduct **7** as a pale yellow solid: mp 176–177°C. IR (neat) (cm^{-1}): 1782, 1736, 1664, 1599. ^1H NMR (300 MHz, $CDCl_3$) δ: 1.19–1.35 (m, 6H), 1.89–1.92 (m, 1H), 2.05–2.13 (m, 2H), 2.29–2.33 (m, 1H), 2.53 (dd, 1H, J = 13.3, 5.0 Hz), 2.94 (dd, 1H, J = 13.3, 9.4 Hz), 3.19–3.21 (m, 1H), 3.97 (dd, 1H, J = 9.4, 5.0 Hz), 4.21–4.32 (m, 4H), 4.66–4.71 (m, 1H), 7.11 (d, 1H, J = 7.7 Hz), 7.34–7.38 (m, 1H), 7.53 (t, 1H, J = 7.5 Hz), 8.17 (d, 1H, J = 7.7 Hz). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 13.9, 14.0, 19.4, 27.1, 36.9, 38.9, 39.4, 58.5, 62.3, 62.4, 85.4, 94.2, 125.3, 126.6, 127.3, 128.7, 133.3, 138.9, 163.7, 164.5, 167.8, 198.2. Anal. calcd. for $C_{22}H_{23}NO_7$: C 63.91, H 5.62, N 3.39; found: C 63.93, H 5.65, N 3.37.

3-(Diazo-ethoxycarbonyl-acetyl)-2-oxo-pyrrolidine-3-carboxylic acid ethyl ester

To a stirred solution of 3-carboethoxy-2-pyrrolidone (43) (1.0 g, 6.4 mmol) in THF (40 mL) at 0°C was added a 2.0 M isopropyl magnesium chloride solution (3.5 mL, 7.0 mmol) dropwise over a 30 min period. The mixture was allowed to stir at 0°C for 1 h and then ethyl 2-diazomalonyl chloride (1.3 g, 7.6 mmol) was added dropwise. After stirring for 1 h at 0°C, the reaction mixture was quenched with water (100 mL) and extracted with ethyl acetate. The combined organic extracts were washed with brine, dried over anhydrous $MgSO_4$, filtered, and concentrated under reduced pressure. The residue was subjected to flash chromatography on silica gel to give 1.1 g (58%) of the titled compound as a colorless oil. IR (neat) (cm^{-1}): 2139, 1743, 1709, 1641. ^1H NMR (300 MHz, $CDCl_3$) δ: 1.18–1.30 (m, 6H), 2.33–2.41 (m, 1H), 3.04–3.11 (m, 1H), 3.19–3.28 (m, 1H), 3.38–3.44 (m, 1H), 4.14–4.29 (m, 4H), 7.54 (br s, 1H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 13.8, 14.1, 30.2, 39.4, 61.7, 62.1, 66.9, 75.1, 160.8, 167.1, 170.8, 185.8. This material was used in the next step without further purification.

3-(Diazoethoxycarbonylacetyl)-2-oxo-1-(2-vinylbenzoyl)-pyrrolidine-3-carboxylic acid ethyl ester (12)

To a sample of *o*-vinyl benzoic acid (0.3 g, 2.0 mmol) in CH_2Cl_2 (25 mL) was added oxalyl chloride (0.6 mL, 7.3 mmol) and two drops of DMF. The solution was allowed to stir at rt for 1 h and was concentrated under reduced pressure to remove the excess oxalyl chloride. The residue was dissolved in benzene (5 mL) and this solution was added slowly to a solution of benzene (5 mL) and the above diazo amido ester (0.48 g, 1.6 mmol), which contained triethylamine (0.7 mL, 5.0 mmol) at 0°C. The mixture was maintained at 0°C for 30 min and was stirred at rt for 24 h. The solution was quenched with water (50 mL) and extracted with ethyl acetate. The combined organic extracts were washed with a saturated sodium bicarbonate solution, brine, dried over anhydrous $MgSO_4$, filtered, and concentrated under reduced pressure. The residue was subjected to flash chromatography on silica gel to give 0.48 g (72%) of **12** as a colorless oil. IR (neat) (cm^{-1}): 2143, 1766, 1637, 1595. ^1H NMR (300 MHz, $CDCl_3$) δ: 1.20–1.33 (m, 6H), 2.50–2.58 (m, 1H), 3.03–3.13 (m, 1H), 3.70–3.79 (m, 1H), 4.09–4.32 (m, 5H), 5.34 (d, 1H, J = 11.1 Hz), 5.71 (d, 1H, J = 17.4 Hz), 6.30 (dd, 1H, J = 17.4, 11.1 Hz), 7.28–7.45 (m, 3H), 7.58 (d, 1H, J = 7.8 Hz). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 13.6, 14.0, 26.3, 42.2, 60.1, 61.8, 62.3, 69.6, 116.8, 125.4, 126.9, 127.0, 129.9, 133.4, 133.6, 135.3, 160.5, 165.5, 166.6, 169.3, 185.2. This material was used in the next step without further purification.

Ethyl 9-aza-12-(ethoxycarbonyl)-15-oxa-8,13-dioxopentacyclo[12.2.1.$0^{2,7}$.$0^{9,16}$-.$0^{12,16}$]heptadeca-2(3),4,6-triene-14-carboxylate (13)

To a sample of diazo amide **12** (0.35 g, 0.8 mmol) in benzene (10 mL) was added rhodium(II) acetate (2 mg). The reaction mixture was allowed to stir at 50°C for 6 h. The solvent was removed under reduced pressure, and the resi-

3-Diazoacetyl-2-oxo-1-phenylpyrrolidine (14)

A mixture containing 2-oxo-1-phenylpyrrolidine carboxylic acid (44) (2.0 g, 9.6 mmol), triphosgene (1.0 g, 3.2 mmol), and 1 drop of DMF in *m*-dichlorobenzene (20 mL) was stirred at 60°C for 24 h. The reaction mixture was allowed to cool to rt and was poured into an ethereal solution containing diazomethane (50 mmol). The reaction mixture was stirred overnight and a yellow precipitate formed. The crude product was chromatographed on silica gel to give 1.6 g (75%) of diazo pyrrolidine **14** as a pale yellow solid: mp 127–128°C. MS *m*/*z*: 229 (M^+), 219, 201, 172, 160, 144, 130, 119, 106, 105, 104. IR (neat) (cm^{-1}): 2108, 1690, 1636, 1497, 1304, 1224, 752, 690. ^1H NMR (300 MHz, $CDCl_3$) δ: 2.20–2.31 (m, 1H), 2.68–2.80 (m, 1H), 3.53 (q, 1H, *J* = 3.0 Hz), 3.78–3.98 (m, 2H), 5.92 (s, 1H), 7.16 (t, 1H, *J* = 7.5 Hz), 7.36 (t, 2H, *J* = 7.5 Hz), 7.56 (d, 2H, *J* = 8.4 Hz). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 19.7, 47.2, 54.0, 55.2, 120.0, 125.0, 128.8, 138.7, 169.6, 188.8. Anal. calcd. for $C_{12}H_{11}N_3O_2$: C 62.86, H 4.84, N 18.34; found: C 62.74, H 4.77, N 18.19.

4,5-Dihydro-3-oxo-6-phenyl-2*H*-furo[2,3-*b*]pyrrole (16)

A solution containing diazo pyrrolidine **14** (0.28 g, 1.2 mmol) in CH_2Cl_2 (1 mL) was treated with rhodium(II) acetate (10 mg). The reaction was stirred for 24 h, filtered, and concentrated under reduced pressure to give a quantitative yield of dihydropyrrole **16** as a clear oil. IR ($CHCl_3$) (cm^{-1}): 3066, 2988, 1670, 1584, 1301, 933. ^1H NMR (300 MHz, $CDCl_3$) δ: 2.78 (t, 2H, *J* = 8.1 Hz), 4.32 (t, 2H, *J* = 8.1 Hz), 5.09 (s, 2H), 7.08 (t, 1H, *J* = 7.8 Hz), 7.24 (d, 2H, *J* = 7.8 Hz), 7.32 (t, 2H, *J* = 7.8 Hz). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 18.6, 55.2, 85.4, 95.4, 116.6, 123.6, 129.3, 137.8, 183.5, 184.0. Anal. calcd. for $C_{12}H_{11}NO_2$: C 71.61, H 5.51, N 6.96; found: C 71.53, H 5.44, N 6.85.

3-Diazoacetyl-3-methyl-2-oxo-1-phenylpyrrolidine (17)

To a solution containing diazo pyrrolidine **14** (0.5 g, 2.2 mmol) in dry DMF (5 mL) was added sodium hydride in mineral oil (0.1 g, 60%, 2.5 mmol). The reaction mixture was stirred for 15 min after which time methyl iodide (1.4 g, 10 mmol) was introduced and stirring was continued for an additional 18 h. The reaction was poured into water and extracted with dichloromethane. The solvent was removed under reduced pressure and the crude product was chromatographed on silica gel to give 0.3 g (57%) of **17** as a pale yellow oil. IR (neat) (cm^{-1}): 2110, 1740, 1695, 1600, 1460, 1350, 1050, 770, 700. ^1H NMR (300 MHz, $CDCl_3$) δ: 1.49 (s, 3H), 1.84–1.94 (m, 1H), 2.94–3.02 (m, 1H), 3.65–3.85 (m, 2H), 5.91 (s, 1H), 7.13–7.64 (m, 5H). This material was used in the next step without further purification.

3-(Cyclohepta-2′,4′,6′-trienyl)formyl-3-methyl-2-oxo-1-phenylpyrrolidine (20)

A solution containing rhodium(II) acetate (2 mg) and diazo pyrrolidine **17** (0.2 g, 0.8 mmol) in benzene (20 mL) was heated at 95°C for 1.5 h. The solvent was removed under reduced pressure and the crude mixture was chromatographed on silica gel to give 53% of 3-(cycloheptatrienyl)-pyrrolidinone **20** as a clear oil. HRMS calcd. for $C_{19}H_{19}NO_2$: 293.1416; found: 293.1416. IR (neat) (cm^{-1}): 3036, 1683, 1592, 1492, 1393, 1294, 750, 690. ^1H HMR (300 MHz, $CDCl_3$) δ: 1.53 (s, 3H), 1.93 (dd, 1H, *J* = 12.9, 8.2 Hz), 2.27 (t, 1H, *J* = 5.1 Hz), 2.75–2.85 (m, 1H), 3.70–2.82 (m, 2H), 3.98 (q, 2H, *J* = 2.4 Hz), 6.20–6.38 (m, 4H), 7.13 (t, 1H, *J* = 7.2 Hz), 7.34 (t, 2H, *J* = 8.1 Hz), 7.58 (d, 2H, *J* = 7.8 Hz). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 20.7, 28.9, 36.1, 45.6, 59.3, 119.8, 124.7, 125.9, 126.1, 127.0, 128.8, 139.1, 172.3, 208.0.

3-Methyl-2-oxo-1-(*p*-toluenesulfonyl)pyrrolidine-3-carboxylic acid benzyl ester

To a suspension containing *N*-tosyl-2-pyrrolidinone (45) (7.6 g, 32 mmol) in THF (150 mL) at –78°C was added a 1.0 M solution of $NaN(TMS)_2$ in THF (32 mL). After stirring for 30 min, methyl iodide (2.9 mL, 47 mmol) was added. The mixture was stirred for an additional 1 h while warming to room temperature. The solution was quenched by the addition of a saturated aqueous NH_4Cl solution, extracted with ether, washed with H_2O, and dried over $MgSO_4$. The solvent was removed under reduced pressure, and the residue was purified by flash silica gel chromatography to give 6.9 g (87%) of 3-methyl-1-(*p*-toluenesulfonyl)-pyrrolidinone. Recrystallization from EtOAc–hexane provided a pure sample as white needles: mp 83–85°C. IR (film) (cm^{-1}): 1730, 1353, 1168. ^1H NMR (400 MHz, $CDCl_3$) δ: 1.54 (d, 3H, *J* = 7.0 Hz), 1.70 (m, 1H), 2.56 (m, 1H), 2.43 (s, 3H), 2.47 (m, 1H), 3.68 (td, 1H, *J* = 9.6, 6.9 Hz), 3.59 (m, 1H), 7.33 (d, 2H, *J* = 8.4 Hz), 7.92 (d, 2H, *J* = 8.4 Hz). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 14.9, 21.7, 27.1, 38.2, 45.2, 128.0, 129.6, 135.1, 145.1, 175.8. Anal. calcd. $C_{12}H_{15}NO_3S$: C 56.90, H 5.97, N 5.53; found: C 56.75, H 5.95, N 5.50.

To a solution containing (1.9 g, 7.6 mmol) the above amide in THF (50 mL) was added a 1.0 M solution of $NaN(TMS)_2$ in THF (8 mL). After stirring the solution for 30 min, the mixture was added to a solution containing benzyl chloroformate (1.2 mL, 8.0 mmol) in THF (20 mL). The mixture was quenched by the addition of a saturated NH_4Cl solution, diluted with ether, washed with H_2O, dried over $MgSO_4$, and concentrated under reduced pressure. The residue was purified by flash silica gel chromatography to give 2.3 g (78%) of the titled compound as a colorless oil. HRMS calcd. for $C_{20}H_{21}NO_5S$: 387.1140; found: 387.1149. IR (neat) (cm^{-1}): 1747, 1735, 1166. ^1H NMR (400 MHz, $CDCl_3$) δ: 1.40 (s, 3H), 1.99 (dt, 1H, *J* = 13.1, 8.6 Hz), 2.40 (s, 3H), 2.45 (m, 1H), 3.78 (m, 1H), 3.93 (m, 1H), 4.86 (d, 1H, *J* = 12.4 Hz), 5.05 (d, 1H, *J* = 12.4 Hz), 7.13 (m, 2H), 7.26 (m, 2H), 7.32 (m, 3H), 7.88 (d, 2H, *J* = 8.0 Hz). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 19.6, 21.7, 31.0, 44.6, 52.8,

3-Methyl-2-oxo-1-(*p*-toluenesulfonyl)pyrrolidine-3-carboxylic acid

A sample of the above benzyl ester (6.7 g, 17 mmol) was dissolved in EtOH (50 mL) and Pd/C (5%, 0.67 g) was added. The reaction mixture was stirred under a hydrogen atmosphere for 24 h. The catalyst was filtered and the solvent was removed under reduced pressure. The residue was taken up in an aqueous solution containing 1 equiv. of Na_2CO_3 and extracted with ether. The solution was acidified to pH 1 by the dropwise addition of concentrated HCl and the aqueous layer was extracted with ether. The combined organic layers were dried over $MgSO_4$ and concentrated under reduced pressure to give 4.1 g (80 %) of the titled compound as a white solid: mp 134 –135°C. IR (film) (cm^{-1}): 3296 (br), 1744, 1737. ^1H NMR (400 MHz, $CDCl_3$) δ: 1.39 (s, 3H), 2.04 (dt, 1H, *J* = 13.4, 7.6 Hz), 2.44 (s, 3H), 2.52 (ddd, 1H, *J* = 13.4, 7.3, 4.7 Hz), 3.80 (br s, 1H), 3.90 (m, 2H), 7.33 (d, 2H, *J* = 8.1 Hz), 7. 90 (d, 2H, *J* = 8.1 Hz). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 19.5, 21.7, 30.6, 44.4, 52.5, 128.1, 129.7, 134.1, 145.6, 171.6, 175.5. Anal. calcd. $C_{13}H_{15}NO_5S$: C 52.51, H 5.08, N 4.71; found: C 52.65, H 4.96, N 4.68.

3-Diazoacetyl-3-methyl-1-(*p*-toluenesulfonyl)pyrrolidinone (18)

To a solution containing the above acid (1.0 g, 3.4 mmol) in ether (20 mL) was added of Et_3N (1.4 mL, 10 mmol) followed by pivalyl chloride (0.5 mL, 4.4 mmol). After stirring for 30 min, the mixed anhydride was filtered into a freshly prepared ether solution of diazomethane (13.4 mmol) at 0°C. The mixture was stirred for 1 h and was concentrated under reduced pressure. Flash chromatographic purification of the residue on silica gel provided 1.0 g (97%) of diazo ketoamide **18** as a yellow oil. IR (neat) (cm^{-1}): 3111, 2108, 1730, 1631. ^1H NMR (400 MHz, $CDCl_3$) δ: 1.36 (s, 3H), 1.82 (dt, 1H, *J* = 13.1, 8.5 Hz), 2.44 (s, 3H), 2.83 (ddd, 1H, *J* = 13.1, 7.3, 3.2 Hz), 3.73 (ddd, 1H, *J* = 9.9, 8.6, 7.2 Hz), 3.85 (ddd, 1H, *J* = 10.1, 8.6, 3.2 Hz), 5.52 (s, 1H), 7.35 (d, 2H, *J* = 8.2 Hz), 7.89 (d, 2H, *J* = 8.2 Hz). This material was used in the next step without further purification.

4-Aza-9-((3-methyl-1-*p*-toluenesulfonyl-2-oxopyrrolidin-3-yl)-carbonyl)-4-phenyl-tetracyclo[5.3.2.$0^{2,6}$.$0^{8,10}$]dodeca-11-ene-3,5-dione (21)

To a solution containing diazo ketoamide **18** (0.22 g, 0.68 mmol) and *N*-phenylmaleimide was added rhodium(II) perfluorobutyrate (4 mg). After stirring overnight, the reaction mixture was concentrated under reduced pressure. Flash chromatography provided adduct **21** as a white solid: mp 219–220°C. IR (film) (cm^{-1}): 1733, 1708, 1171. ^1H NMR (300 MHz, $CDCl_3$) δ: 1.37 (s, 3H), 1.47 (m, 1H), 1.80 (m, 2H), 1.99 (t, 1H, *J* = 2.9 Hz), 2.50 (s, 3H), 2.71 (ddd, 1H, *J* = 12.9, 6.8, 2.9 Hz), 3.03 (dd, 1H, *J* = 8.1, 3.4 Hz), 3.10 (dd, 1H, *J* = 8.1, 3.4 Hz), 3.17 (m, 1H), 3.57 (m, 1H), 3.64 (m, 1H), 3.86 (ddd, 1H, *J* = 10.0, 9.8, 2.9 Hz), 5.89 (m, 2H), 7.15 (d, 2H, *J* = 8.4 Hz), 7.39 (m, 5H), 7.89 (d, 2H, *J* = 8.4 Hz). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 20.1, 21.6, 23.4, 23.7, 24.0, 28.4, 33.0, 33.1, 44.2, 44.4, 59.2, 126.3, 128.0, 128.1, 128.3, 128.6, 129.0, 129.5, 131.5, 134.6, 145.5, 171.8, 176.4, 176.5, 202.5. Anal. calcd. $C_{30}H_{28}N_2O_6S$: C 66.16, H 5.18, N 5.14; found: C 65.90, H 5.09, N 5.03.

1-(2′,2′-Dimethylpropionyl)-2-oxopyrrolidine-3-carboxylic acid

A solution containing $NaN(TMS)_2$ (80 mL, 1.0 M) in THF was cooled to –78°C and 1-(2′,2′-dimethylpropionyl)-pyrrolidin-2-one (46) (6.4 g, 38 mmol) in THF (20 mL) was added. After stirring for 30 min at rt, benzyl chloroformate (5.4 mL, 38 mmol) in THF (20 mL) was added dropwise. After stirring for 30 min at –78°C, the mixture was quenched by the addition of a 10% solution of aqueous HCl. The solution was extracted with ether, and the organic layer was dried over $MgSO_4$. The crude product was used in the next step without further purification.

The crude benzyl ester (10.3 g) was taken up in EtOH (200 mL) and 5% Pd/C was added. The mixture was shaken in a Parr shaker for 30 min under a hydrogen atmosphere at 40 psi. The Pd/C catalyst was filtered, and the solution was concentrated under reduced pressure. The residue was taken up in water containing 2 equiv. of Na_2CO_3 and was washed with ether. The aqueous layer was acidified to pH 1 by the dropwise addition of concentrated HCl, and the precipitate was filtered to provide 5.1 g (62%) of the titled compound as a pale yellow solid: mp 153–154°C. IR (film) (cm^{-1}): 3068 (br), 1752, 1730, 1645. ^1H NMR (400 MHz, $CDCl_3$) δ: 1.34 (s, 9H), 2.41 (m, 2H), 3.67 (t, 1H, *J* = 9.5 Hz), 3.76 (ddd, 1H, *J* = 12.6, 8.8, 8.0 Hz), 3.96 (ddd, 1H, *J* = 12.6, 8.0, 4.4 Hz). Anal. calcd. for $C_{10}H_{15}NO_4$: C 56.33, H 7.09, N 6.57; found: C 56.48, H 7.16, N 6.62.

2-Diazo-3-[1′-(2′′,2′′-dimethylpropionyl)-2′-oxopyrolidin-3′-yl]-3-oxopropionic acid ethyl ester (22)

To a solution containing the above carboxylic acid (1.0 g, 4.7 mmol) and hexachloroacetone (0.6 g, 2.4 mmol) was added dropwise triphenyl phosphine (1.2 g, 4.7 mmol) in THF (20 mL). After stirring for 30 min at rt, the solution was added dropwise to a solution of ethyl diazoacetate (1.1 g, 9.4 mmol) in THF (5 mL). The mixture was heated at 50°C for 2 h. After cooling, the solution was concentrated under reduced pressure, and the residue was purified by flash chromatography to give 1.0 g (70%) of **22** as a yellow oil. IR (neat) (cm^{-1}): 2143, 1716, 1687, 1652. ^1H NMR (400 MHz, $CDCl_3$) δ: 1.31 (s, 9H), 1.34 (t, 3H, *J* = 7.2 Hz), 2.04 (m, 1H), 2.45 (dq, 1H, *J* = 12.8, 9.2 Hz), 3.75 (ddd, 1H, *J* = 11.5, 8.5, 7.6 Hz), 3.94 (ddd, 1H, *J* = 11.5, 8.9, 3.7 Hz), 4.32 (q, 2H, *J* = 7.2 Hz), 4.97 (t, 1H, *J* = 9.2). This material was used in the next step without further purification.

2,2-Dimethylpropionic acid 6-(2′,2′-dimethylpropionyl)-5,6-dihydro-4*H*-furo[2,3-*b*]-pyrrol-3-yl ester (25)

A solution containing diazoketone **22** (0.4 g, 1.3 mmol) and rhodium(II) acetate (3 mg) in benzene (7 mL) was heated at reflux for 30 min. After cooling to rt, Et_3N (0.4 mL, 2.7 mmol) was added followed by pivalyl chloride (0.25 mL, 2.0 mmol). After stirring for 1 h, the reaction mixture was filtered and concentrated under reduced pressure. Flash chromatography on silica gel provided 0.36 g (74%) of furan **25** as a colorless oil. IR (neat) (cm^{-1}): 1766, 1702, 1652, 1616, 1545. ^1H NMR (300 MHz, $CDCl_3$) δ: 1.33 (t, 3H, *J* =

7.3 Hz), 1.36 (s, 9H), 1.37 (s, 9H), 2.88 (m, 2H), 4.30 (q, 2H, *J* = 7.1 Hz), 4.41 (m, 2H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 14.5, 21.5, 26.5, 27.0, 39.3, 39.7, 55.1, 60.2, 104.7, 130.4, 142.7, 153.0, 157.4, 174.3, 174.4. Anal. calcd. for $C_{19}H_{27}NO_6$: C 62.45, H 7.45, N 3.83; found: C 62.56, H 7.55, N 3.88.

A sample of the highly reactive (2′,2′-dimethylpropionyl)-5,6-dihydro-4*H*-furo[2,3-*b*]pyrrol-3-one (**24**) intermediate was obtained from the column as a minor product and showed the following NMR properties: ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.34 (t, 3H, *J* = 7.2 Hz), 1.36 (s, 9H) 2.66 (m, 2H), 4.34 (m, 2H), 4.43 (m, 2H), 5.57 (s, 1H).

2,10-Diaza-2-(2,2-dimethyl-propanoyl)-7-(ethoxycarbonyl)-13-oxa-9,11-dioxo-10-phenyltetracyclo[5.5.0^{1,5}.0^{8,12}]-tridec-5(6)-en-6-yl-2,2-dimethyl propanoate (26)

A solution containing amidofuran **25** (0.35 g, 1.0 mmol) and *N*-phenylmaleimide (2.0 g, 1.1 mmol) in toluene (5 mL) was heated at reflux for 2 h. The solution was concentrated under reduced pressure and subjected to flash silica gel chromatography to give 0.5 g (95%) of a 1:3 mixture of compounds **26** and **27**. Chromatographic separation afforded a pure sample of **26** as a clear oil: IR (film) (cm^{-1}): 1769, 1727, 1658, 1623, 1147. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.21 (t, 3H, *J* = 7.1 Hz), 1.35 (s, 9H), 1.36 (s, 9H), 2.77 (ddd, 1H, *J* = 15.4, 7.2, 1.1 Hz), 2.97 (m, 1H), 4.08–4.32 (m, 5H), 5.74 (ddd, 1H, *J* = 9.8, 2.9, 0.7 Hz), 7.26 (m, 2H), 7.44 (m, 3H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 13.7, 26.7, 27.1, 27.4, 39.1, 40.5, 41.1, 46.4, 51.0, 63.5, 82.0, 117.3, 126.4, 128.7, 129.0, 131.6, 154.4, 167.0, 170.6, 173.0, 176.8, 179.8, 182.2. Anal. calcd. for $C_{29}H_{34}N_2O_8$: C 64.67, H 5.20, N 5.38; found: C 64.37, H 6.24, N 5.09.

1-(2,2-Dimethylpropionyl)-4-(2,2-dimethylpropionyloxy)-6,8-dioxo-7-phenyl-1,2,3,6,7,8-hexahydro-1,7-diaza-as-indacene-5-carboxylic acid ethyl ester (27)

The major fraction isolated from the silica gel chromatographic separation was a white solid whose structure was assigned as **27** on the basis of the following spectral data: mp 198–200°C. IR (film) (cm^{-1}): 1765, 1724, 1692, 1284. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.36 (s, 9H), 1.38 (t, 3H, *J* = 7.1 Hz), 1.41 (s, 9H), 3.07 (t, 2H, *J* = 7.9 Hz), 4.21 (t, 2H, *J* = 7.9 Hz), 4.41 (q, 2H, *J* = 7.1 Hz), 7.32–7.48 (m, 5H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 14.0, 27.0, 28.0, 28.0, 39.3, 40.4, 51.0, 62.4, 116.0, 120.7, 126.8, 128.0, 128.9, 130.2, 131.6, 133.9, 143.8, 147.9, 163.4, 163.5, 164.8, 174.7, 178.7. Anal. calcd. for $C_{29}H_{32}N_2O_7$: C 66.91, H 6.20, N 5.38; found: C 66.89, H 6.10, N 5.55.

2-(2,2-Dimethylpropionyl)-6-(2,2-dimethylpropionyloxy)-10-oxa-2-azatricyclo-[5.2.1.0^{1,5}]deca-5,8-diene-7,8,9-tricarboxylic acid 7-ethyl ester 8,9-dimethyl ester (28)

A solution containing amidofuran **25** (1.7 mmol) and dimethyl acetylenedicarboxylate (0.3 mL, 2.6 mmol) in toluene (8 mL) was heated at reflux for 24 h. The solution was concentrated under reduced pressure and subjected to flash silica chromatography to give three major fractions. The minor fraction contained 0.12 g (14%) of **28** as yellow oil. HRMS calcd. for $C_{25}H_{33}NO_{10}$: 507.2104; found: 507.2107. IR (neat) (cm^{-1}): 1759, 1695, 1659, 1211. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.23 (s, 9H), 1.26 (t, 3H, *J* = 7.1 Hz), 1.30 (s, 9H), 2.95 (m, 2H), 3.69 (s, 3H), 3.75 (s, 3H), 4.20 (m, 2H), 4.31 (m, 2H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 13.8, 26.7, 27.4, 38.6, 40.2, 50.4, 52.5, 52.7, 63.3, 81.6, 121.7, 128.2, 139.9, 153.2, 161.5, 163.3, 163.9, 176.2, 180.2, 183.9.

1-(2,2-Dimethylpropionyl)-4-hydroxy-1*H*-indole-5,6,7-tricarboxylic acid 5-ethyl ester 6,7-dimethyl ester (29)

The middle fraction from the silica gel column contained 0.36 g (22%) of indole **29** as a white solid: mp 149–150°C. IR (film) (cm^{-1}): 1745, 1735, 1706, 1660, 1607. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.49 (s, 9H), 1.51 (t, 3H, *J* = 7.1 Hz), 3.88 (s, 3H), 3.93 (s, 3H), 4.53 (q, 2H, *J* = 7.1 Hz), 7.10 (d, 1H, *J* = 3.8 Hz), 7.77 (d, 1H, *J* = 3.8 Hz), 11.77 (s, 1H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 14.2, 28.5, 41.4, 52.7, 52.8, 62.2, 105.1, 108.1, 119.1, 125.8, 126.6, 129.5, 131.7, 156.8, 165.6, 166.5, 170.4, 178.1. Anal. calcd. for $C_{20}H_{23}NO_8$: C 59.25, H 5.72, N 3.45; found: C 59.14, H 5.61, N 3.38.

1-(2,2-Dimethylpropionyl)-4-(2,2-dimethylpropionyloxy)-5-oxo-1,2,3,5-tetrahydro-indole-6,6,7-tricarboxylic acid ethyl ester dimethyl ester (31)

The third fraction contained 0.23 g (35%) of **31** as a pale yellow solid: mp 70–71°C. IR (film) (cm^{-1}): 1766, 1738, 1652, 1289. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.27 (t, 3H, *J* = 7.1 Hz), 1.32 (s, 9H), 1.34 (s, 9H), 2.85 (t, 2H, *J* = 6.9 Hz), 3.71 (s, 3H), 3.81 (s, 3H), 4.12 (m, 2H), 4.72 (m, 2H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 13.6, 25.9, 26.9, 27.6, 39.0, 40.5, 48.8, 51.6, 53.7, 63.1, 70.5, 112.7, 139.3, 139.4, 143.4, 163.9, 164.7, 164.9, 174.6, 177.6, 182.2. Anal. calcd. for $C_{25}H_{33}NO_{10}$: C 59.16, H 6.55, N 2.76; found: C 59.31, H 6.66, N 2.63.

2-Oxo-pyrrolidine-3-carboxylic acid *tert*-butyl ester

A solution containing *N*-trimethylsilylpyrrolidinone (47) (25.0 g, 260 mmol) in THF (150 mL) at –78°C was treated with a 1.0 M solution of $NaN(TMS)_2$ in THF (159 mL). The mixture was stirred for 30 min, and di-*tert*-butyldicarbonate (17.3 g, 80 mmol) in THF (50 mL) was added. The reaction mixture was stirred for 30 min and was quenched by the addition of a saturated NH_4Cl solution, diluted with ether, and dried over magnesium sulfate. The solvent was removed under reduced pressure, and the residue was purified by silica gel chromatography to give 9.1 g (62%) of the title compound as a white solid: mp 79–80°C. IR (film) (cm^{-1}): 3246, 3111, 1730, 1695. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.48 (s, 9H), 2.34 (m, 1H), 2.43 (m, 1H), 3.24 (dd, 1H, *J* = 9.3, 6.7 Hz), 3.34 (td, 1H, *J* = 8.8, 6.1 Hz), 3.48 (td, 1H, *J* = 8.9, 5.3 Hz), 6.53 (s, 1H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 25.1, 27.9, 40.8, 48.8, 81.7, 169.3, 174.4. Anal. calcd. for $C_9H_{15}NO_3$: C 58.36, H 8.16, N 7.56; found: C 58.10, H 8.18, N 7.48.

2-Oxo-1-pent-4-enylpyrrolidine-3-carboxylic acid *tert*-butyl ester

A suspension of the above pyrrolidone (8.9 g, 48 mmol) in THF (250 mL) at –78°C was treated with a 2.5 M solution of *n*-butyllithium in hexane (39 mL, 97 mmol). After stirring at 78°C for 30 min, pentenoyl chloride (5.7 g, 48 mmol) in THF (20 mL) was added dropwise. The reaction mixture was allowed to warm to rt and was quenched by the addition of a saturated NH_4Cl solution. The mixture was diluted with ether, washed with a NH_4Cl solution, and dried

© 2001 NRC Canada

over magnesium sulfate. Purification of the residue by silica gel chromatography afforded 9.8 g (76%) of the title compound as a white solid: mp 51–52°C. IR (film) (cm^{-1}): 1729, 1641, 1359, 1709, 1143. ^1H NMR (400 MHz, $CDCl_3$) δ: 1.50 (s, 9H), 2.26 (m, 1H), 2.33 (m, 1H), 2.40 (m, 2H), 3.01 (td, 2H, *J* = 7.3, 2.4 Hz), 3.51 (dd, 1H, *J* = 9.1, 7.9 Hz), 3.71 (dt, 1H, *J* = 11.4, 7.6 Hz), 3.92 (ddd, 1H, *J* = 11.5, 8.5, 5.1 Hz), 5.00 (dq, 1H, *J* = 10.2, 1.4 Hz), 5.07 (dq, 1H, *J* = 17.1, 1.7 Hz), 5.85 (ddt, 1H, *J* = 17.0, 10.3, 6.6 Hz). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 21.5, 27.9, 28.0, 36.2, 43.8, 51.9, 82.7, 115.4, 136.9, 167.7, 170.8, 173.5. Anal. calcd. for $C_{14}H_{21}NO_4$: C 62.90, H 7.92, N 5.24; found: C 63.02, H 7.84, N 5.19.

2-Oxo-1-pent-4-enyl-pyrrolidinone-3-carboxylic acid

A sample of the above *tert*-butyl ester (4.4 g, 17 mmol) was dissolved in a mixture of trifluoroacetic acid (10 mL) and CH_2Cl_2 (10 mL), and the solution was stirred vigorously at rt for 2 h. The solvent was removed under reduced pressure, and the residue was dissolved in water which contained 2 equiv. of Na_2CO_3. The solution was extracted with ether and acidified to pH 1 by the addition of concentrated HCl. The aqueous solution was extracted with ether, and the combined organic layers were dried over magnesium sulfate. The solvent was removed under reduced pressure to give 3.4 g (96%) of the title compound as a colorless oil. HRMS calcd. for $C_{10}H_{13}NO_4$: 211.0845; found: 211.0842. IR (neat) (cm^{-1}): 3190, 1744, 1701, 1370. ^1H NMR (400 MHz, $CDCl_3$) δ: 2.41 (m, 4H), 3.01 (t, 2H, *J* = 7.4 Hz), 3.68 (t, 1H, *J* = 9.0 Hz), 3.73 (dt, 1H, *J* = 11.8, 7.9 Hz), 3.98 (ddd, 1H, *J* = 11.8, 7.3, 5.7 Hz), 5.00 (dd, 1H, *J* = 10.0, 1.2 Hz), 5.08 (dq, 1H, *J* = 10.0, 1.5 Hz), 5.85 (m, 1H), 6.58 (br s, 1H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 21.1, 27.8, 36.2, 43.7, 50.4, 115.5, 136.6, 170.5, 172.6, 173.5.

Ethyl 2-diazo-3-oxo-3-(2-oxo-1-pent-4-enoylpyrrolidine-3-yl) propionate (32)

A sample of the above ketoamide (0.6 g, 2.9 mmol) was dissolved in a 2.0 M solution of $(COCl)_2$ in CH_2Cl_2 (2.9 mL, 5.8 mmol) and one drop of DMF was added. The solution was stirred at rt for 2 h, and the solvent was removed under reduced pressure. The residue was dissolved in benzene (5 mL) and this mixture was added to a solution of ethyl diazoacetate in benzene (10 mL). After stirring for 2 h, the solution was concentrated under reduced pressure, and the residue was purified by flash silica gel chromatography to give 0.5 g (55%) of diazo amido ester **32** as a yellow oil. HRMS calcd. for $C_{14}H_{17}N_3O_5$: 307.1168; found: 307.1158. IR (neat) (cm^{-1}): 2143, 1702, 1645, 1367. ^1H NMR (400 MHz, $CDCl_3$) δ: 1.34 (t, 3H, *J* = 7.2 Hz), 2.22 (m, 1H), 2.38 (m, 2H), 2.45 (m, 1H), 2.89 (t, 2H, *J* = 7.4 Hz), 3.70 (dt, 1H, *J* = 11.6, 8.1), 3.95 (ddd, 1H, *J* = 11.6, 9.0, 4.0 Hz), 4.32 (q, 2H, *J* = 5.3 Hz), 5.00 (m, 1H), 5.00 (dq, 1H, *J* = 10.2, 1.7 Hz), 5.06 (dq, 1H, *J* = 17.2, 1.7 Hz), 5.84 (ddt, 1H, *J* = 17.1, 10.4, 6.4 Hz). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 14.2, 20.5, 27.9, 36.1, 43.6, 52.8, 61.8, 115.3, 136.8, 160.7, 170.9, 173.2, 187.4.

6-Aza-1-(ethoxycarbonyl)-12-oxa-7-oxotetracyclo-[8.2.1.0^{3,11}.0^{6,11}]tridec-2-en-2-yl 2,2-dimethyl-propanoate (35)

A solution containing diazo amido ester **32** (0.1 g, 0.3 mmol) in benzene (2 mL) was added dropwise to benzene (2 mL) at reflux that contained rhodium(II) acetate (2 mg). After heating for 30 min, the solution was allowed to cool to room temperature and Et_3N (0.18 mL, 1.3 mmol) was added followed by pivalyl chloride (0.09 mL, 0.75 mmol). After stirring for 1 h, the solution was filtered and the solvent was removed under reduced pressure. The residue was dissolved in toluene (4 mL) and heated at reflux for 20 h. The solvent was removed under reduced pressure and the residue was purified by flash silica gel chromatography to give 0.09 g (70%) of cycloadduct **35** as a white solid: mp 107–109°C. IR (neat) (cm^{-1}): 2975, 1730, 1666, 1617. ^1H NMR (400 MHz, $CDCl_3$) δ: 1.26 (s, 9H), 1.27 (t, 3H, *J* = 7.1 Hz), 1.65 (dq, 1H, *J* = 13.1, 4.6 Hz), 2.10 (m, 1H), 2.22 (dd, 1H, *J* = 12.5, 11.5 Hz), 2.56 (ddd, 1H, *J* = 17.5, 13.2, 5.0 Hz), 2.67 (ddd, 1H, *J* = 17.5, 4.6, 2.1 Hz), 2.82 (m, 2H), 2.88 (dd, 1H, *J* = 12.5, 5.0 Hz), 3.21 (m, 1H), 3.92 (td, 1H, *J* = 11.8, 7.4 Hz), 4.03 (td, 1H, *J* = 11.8, 6.4 Hz), 4.23 (m, 2H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 13.8, 23.7, 26.0, 26.8, 29.7, 32.1, 37.4, 38.8, 45.8, 62.1. Anal. calcd. for $C_{19}H_{25}NO_6$: C 62.78, H 6.94, N 3.86; found: C 62.91, H 6.87, N 3.84.

6-Aza-1-(ethoxycarbonyl)-12-oxa-7-oxotetracyclo-[8.2.1.0^{3,11}.0^{6,11}]tridec-2-en-2-yl acetate (37)

A solution containing diazoketone **32** (0.1 g, 0.3 mmol) in benzene (2 mL) was added dropwise to benzene (2 mL) at reflux that contained rhodium(II) acetate (2 mg). After heating for 30 min, the solution was allowed to cool to room temperature and Et_3N (0.18 mL, 1.3 mmol) was added followed by acetyl chloride (0.06 mL, 0.65 mmol). After stirring for 1 h, the solution was filtered, and the solvent was removed under reduced pressure. The residue was dissolved in toluene (4 mL) and heated at reflux for 20 h. The solvent was removed under reduced pressure, and the residue was purified by flash silica gel chromatography to give 0.03 g (24%) of cycloadduct **37** as a white solid: mp 171–173°C. IR (neat) (cm^{-1}): 1739, 1725, 1690, 1665, 1606. ^1H NMR (400 MHz, $CDCl_3$) δ: 1.24 (t, 3H, *J* = 7.0 Hz), 1.63 (m, 1H), 2.08 (m, 1H), 2.14 (s, 3H), 2.22 (dd, 1H, *J* = 12.7, 11.5 Hz), 2.56 (ddd, 1H, *J* = 17.5, 13.3, 5.0 Hz), 2.68 (ddd, 1H, *J* = 17.5, 4.7, 2.3 Hz), 2.83 (m, 2H), 2.93 (dd, 1H, *J* = 12.7, 5.2 Hz), 3.23 (m, 1H), 3.91 (td, 1H, *J* = 11.5, 7.8 Hz), 4.03 (m, 1H), 4.23 (m, 2H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 13.9, 21.0, 23.8, 26.1, 29.8, 32.1, 37.4, 45.8, 62.4, 82.5, 116.0, 160.7, 167.5, 167.7, 169.6, 184.1. Anal. calcd. for $C_{16}H_{19}NO_6$: C 59.79, H 5.96, N 4.36; found: C 59.88, H 5.71, N 4.35.

3-(2-Diazoacetyl)-1-(2,2-dimethylpropionyl)pyrrolidin-2-one (38)

To a solution containing 1-(2′,2′-dimethylpropionyl)-2-oxopyrrolidine-3-carboxylic acid (1.0 g, 4.7 mmol) and hexachloroacetone (0.6 g, 2.4 mmol) was added dropwise triphenyl phosphine (1.2 g, 4.7 mmol) in THF (20 mL) After stirring for 30 min, the solution was allowed to warm to rt and was added dropwise to a solution containing freshly prepared diazomethane (19 mmol) in ether (40 mL). After stirring for 2 h, the solution was concentrated and the residue was purified by flash silica gel chromatography to give 0.5 g (45%) of **38** as a yellow oil. IR (neat) (cm^{-1}): 3103, 2968, 2108, 1738, 1681, 1631. ^1H NMR (400 MHz, $CDCl_3$) δ:

© 2001 NRC Canada

1.30 (s, 9H), 2.10–2.18 (m, 1H), 2.53–2.61 (m, 1H), 3.49–3.54 (m, 1H), 3.72–3.88 (m, 2H), 5.76 (s, 1H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 19.8, 26.2, 41.8, 46.8, 55.5, 55.9, 169.9, 180.1, 187.9. This material was used in the next step without further purification.

6-(2,2-Dimethylpropionyl)-5,6-dihydro-4*H*-furo[2,3-*b*]-pyrrol-3-one (39)

A solution containing diazoketone **38** (0.5 g, 2.1 mmol) and rhodium(II) acetate (3 mg) in CH_2Cl_2 (10.0 mL) was heated to reflux for 20 min. The solution was concentrated under reduced pressure and the residue was purified by flash silica gel chromato-graphy to give 0.3 g (68%) of **39** as a white solid: mp 110–111°C. IR (film) (cm^{-1}): 3482, 2986, 2939, 1751, 1680, 1582, 1490, 1291. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.32 (s, 9H), 2.63–2.67 (m, 2H), 4.38–4.42 (m, 2H), 5.08 (s, 2H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 17.6, 26.6, 40.4, 56.0, 84.6, 100.7, 175.5, 180.7, 186.7. Anal. calcd. for $C_{11}H_{15}NO_3$: C 63.14, H 7.23, N 6.69; found: C 62.97, H 7.28, N 6.60.

***N*-[2-(4-Methoxy-2-oxo-2,5-dihydrofuran-3-yl)-ethyl]-2,2-dimethyl-propionamide (41)**

To a solution containing furanone **39** (0.2 g, 1.1 mmol) in CH_2Cl_2 (15 mL) was added trimethyloxonium tetrafluoroborate (0.2 g, 1.1 mmol). After stirring at rt for 36 h, the reaction mixture was concentrated under reduced pressure to afford furan **40** as a very labile oil. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.34 (s, 9H), 3.19 (t, 2H, *J* = 10.2 Hz), 4.25 (s, 3H), 4.66 (t, 2H, *J* = 10.2 Hz), 5.83 (s, 1H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 19.0, 26.3, 26.5, 41.7, 58.8, 62.3, 86.4, 107.7, 175.4, 184.2. This material was rapidly converted into **41** when exposed to moisture and this material was obtained as a colorless oil. HRMS calcd. for $C_{12}H_{19}NO_4$: 241.1314; found: 241.1324. IR (neat) (cm^{-1}): 3370, 2963, 2868, 1758, 1663, 1534, 1385, 1047. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.14 (s, 9H), 2.47 (t, 2H, *J* = 8.8 Hz), 3.32 (q, 2H, *J* = 16.0, 8.8 Hz), 3.97 (s, 3H), 4.66 (s, 2H), 6.43 (br s, 1H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 22.0, 27.7, 38.8, 39.3, 58.2, 66.1, 100.9, 173.8, 175.7, 178.9.

6-(2,2-Dimethylpropionyl)-2-methyl-5,6-dihydro-4*H*-furo[2,3-*b*]pyrrol-3-one (42)

To a solution containing diisopropylamine (0.08 mL, 0.6 mmol) in THF (2 mL) was added a solution of *n*-butyllithium in hexane (1.5 M, 0.4 mL, 0.6 mmol) at –78°C. After stirring for 10 min, the reaction was warmed to rt and stirred for 15 min. The temperature was lowered to –78°C and furanone **39** (0.1 g, 0.5 mmol) in THF (7 mL) was added dropwise. The mixture was stirred at this temperature for 30 min and then methyl iodide (0.03 mL, 0.5 mmol) was added. After stirring for 2 h, the reaction was quenched by the addition of a saturated aqueous NH_4Cl solution, extracted with ethyl acetate, and dried over $MgSO_4$. The solvent was removed under reduced pressure, and the residue was purified by flash silica gel chromatography to give 0.04 g (37%) of **42** as a yellow oil. HRMS calcd. for $C_{12}H_{17}NO_3$: 223.1208; found: 223.1213. IR (neat) (cm^{-1}): 3487, 2965, 2863, 1680, 1577, 1490, 1285, 1198. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.32 (s, 9H), 1.63 (d, 3H, *J* = 7.2 Hz), 2.61–2.66 (m, 2H), 4.36–4.40 (m, 2H), 5.21 (q, 1H, *J* = 7.2 Hz). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 17.3, 17.9, 26.9, 40.7, 56.0, 94.6, 99.6, 175.8, 179.2, 190.1.

2,2-Dimethylpropionic acid 1-(2,2-dimethylpropionyl)-5-methyl-6,8-dioxo-7-phenyl-1,2,3,6,7,8-hexahydrobenzo-[2,1-*b*:3,4-*c*]dipyrrol-4-yl ester (44)

To a solution containing furanone **42** (0.04 g, 0.2 mmol) in benzene (1.5 mL) was added Et_3N (0.04 mL, 0.3 mmol) followed by pivalyl chloride (0.03 mL, 0.2 mmol). After stirring at rt for 1 h, the reaction mixture was filtered and concentrated under reduced pressure. The residue was dissolved in toluene (10 mL) and heated under reflux for 36 h with *N*-phenylmaleimide (0.03 g, 0.2 mmol). The solution was concentrated under reduced pressure and subjected to flash silica gel chromatography to give 0.04 g (52%) of **44** as a yellow solid: mp 219–221°C. IR (film) (cm^{-1}): 2970, 2929, 1757, 1716, 1685, 1495, 1367, 1101. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.40 (s, 9H), 1.42 (s, 9H), 2.51 (s, 3H), 3.01 (t, 2H, *J* = 7.6 Hz), 4.27 (t, 2H, *J* = 7.6 Hz), 7.32–7.48 (m, 5H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 10.9, 27.4, 28.2, 28.3, 39.7, 40.4, 51.2, 116.9, 127.2, 127.7, 128.0, 129.1, 129.6, 132.1, 133.4, 140.9, 150.7, 164.3, 167.6, 175.5, 178.7. Anal. calcd. for $C_{27}H_{30}N_2O_5$: C 70.11, H 6.54, N 6.06; found: C 70.25, H 6.70, N 5.90.

Acetic acid 2-methoxy-1-(2-oxopiperidin-3-yl)-2-phenylsulfanyl ethyl ester (48)

To a solution containing diisopropylamine (6.5 mL, 46 mmol in THF (150 mL) was added a (1.6 M) solution of *n*-butyllithium in hexanes (29 mL 45 mmol) at –40°C. After stirring for 1 h, the reaction mixture was cooled to –75°C and *N*-trimethylsilyl-2-piperidone (**48**) (36) (7.4 g, 43 mmol) in THF (25 mL) was added. The temperature was raised to –40°C, and the mixture was stirred for 30 min. The temperature was lowered to –75°C and methoxyphenylsulfanyl acetaldehyde (**47**) (37) (8.2 g, 45 mmol) in THF (40 mL) was added over 45 min. Following the addition, the mixture was stirred for an additional 30 min and then acetic anhydride (4.5 mL, 48 mmol) was added. The solution was slowly warmed to rt overnight and was then poured into a saturated aqueous $NaHCO_3$ solution and extracted with CH_2Cl_2. The solvent was removed under reduced pressure and the crude reaction mixture was subjected to flash silica gel chromatography to give 8.1 g (68%) of **48** as a yellow oil, which consisted of a complex mixture of diastereomers. For analytical purposes, the major two diastereomers were separated using HPLC. HRMS calcd. for $C_{16}H_{21}NO_4S$: 323.1191; found: 323.1190. IR (neat) (cm^{-1}): 3303, 3206, 3062, 2945, 1747, 1660, 1491, 1372, 1229. ^{1}H NMR (400 MHz, $CDCl_3$) δ: major diastereomer: 1.64–1.93 (m, 4H), 2.06 (s, 3H), 3.22–3.28 (m, 3H), 3.47 (s, 3H), 5.20 (dd, 1H, *J* = 10.8, 3.6 Hz), 5.54 (d, 1H, *J* = 10.8 Hz), 5.92 (br s, 1H), 7.27–7.33 (m, 3H), 7.46–7.56 (m, 2H); δ minor diastereomer: 1.64–1.93 (m, 4H), 2.08 (s, 3H), 2.93 (ddd, 1H, *J* = 14.7, 7.8, 2.8 Hz), 3.22–3.28 (m, 2H), 3.53 (s, 3H), 5.15–5.19 (m, 1H), 5.43 (d, 1H, *J* = 12.0 Hz), 5.82 (br s, 1H), 7.27–7.33 (m, 3H), 7.46–7.56 (m, 2H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 21.2, 21.4, 22.2, 22.3, 25.4, 42.0, 42.3, 45.1, 56.9, 74.6, 75.7, 91.1, 91.7, 127.7, 127.9, 128.9, 129.2, 132.9, 133.2, 133.4 133.7, 170.5, 170.8, 171.1, 171.2.

Acetic acid 1-(1-but-3-enoyl-2-oxopiperin-3-yl)-2-methoxy-2-phenylsulfanyl ethyl ester (49)

To a solution containing lactam **22** (0.6 g, 2 mmol) in CH_2Cl_2 (9 mL) was added 3-butenoyl chloride (0.3 g, 3 mmol) (**23**) (48) followed by powdered molecular sieves (1.9 g). After stirring at rt overnight, the suspension was filtered through a pad of silica and washed several times with ether. The filtrate was washed with a saturated aqueous $NaHCO_3$ solution, dried over $MgSO_4$, and concentrated under reduced pressure. The crude reaction mixture was subjected to flash silica gel chromatography to give 0.7 g (94%) of **49** as a yellow oil which consisted of a complex mixture of diastereomers. For analytical purposes, the major two diastereomers were separated using HPLC. FAB-HRMS calcd. for $C_{20}H_{25}NO_5S$: 391.1453; found: 391.1452. IR (neat) (cm^{-1}): 2945, 1747, 1690, 1475, 1291, 1224, 1163. ^1H NMR (400 MHz, $CDCl_3$) δ: major diastereomer: 1.56–1.61 (m, 1H), 1.73–1.80 (m, 1H), 1.84–1.90 (m, 2H), 2.05 (s, 3H), 3.32–3.37 (m, 1H), 3.51 (s, 3H), 3.62–3.65 (m, 2H), 3.67–3.73 (m, 2H), 5.11–5.17 (m, 2H), 5.26 (d, 1H, *J* = 7.2 Hz), 5.32 (dd, 1H, *J* = 7.2, 3.6 Hz), 5.95–6.04 (m, 1H), 7.29–7.34 (m, 3H), 7.50–7.52 (m, 2H); δ minor diastereomer: 1.68–1.79 (m, 2H), 1.87–1.93 (m, 1H), 2.01–2.08 (m, 1H), 2.07 (s, 3H), 3.02–3.07 (m, 1H), 3.47 (s, 3H), 3.62–3.68 (m, 2H), 3.74–3.79 (m, 2H), 4.88 (d, 1H, *J* = 6.8 Hz), 5.09–5.15 (m, 2H), 5.61 (dd, 1H, *J* = 6.8, 3.4 Hz), 5.95–6.04 (m, 1H), 7.28–7.34 (m, 3H), 7.48–7.53 (m, 2H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: major diastereomer: 21.1, 21.7, 24.3, 43.7, 44.2, 45.3, 56.9, 75.0, 91.3, 118.3, 128.2, 129.3, 131.5, 132.8, 133.5, 170.5, 173.1, 174.9; δ minor diastereomer: 21.2, 21.8, 22.1, 43.7, 44.2, 45.6, 56.9, 73.4, 92.3, 118.3, 128.1, 129.3, 131.5, 132.5, 133.3, 133.6, 169.9, 173.6, 175.0.

1-(2-Methoxy-5,6-dihydro-4*H*-furo[2,3-*b*]pyridin-7-yl)-but-3-en-1-one (50)

To a solution containing lactam **49** (0.5 g, 1 mmol) in CH_2Cl_2 (7 mL) was added DMTSF (0.3 g, 1 mmol) in one portion at –40°C. The temperature was allowed to warm slowly to 15°C over 2 h and then Et_3N (1 mL, 7 mmol) was added. The reaction mixture was diluted with ether, poured over a saturated aqueous $NaHCO_3$ solution, extracted with ether, and dried over K_2CO_3. The solvent was removed under reduced pressure and the crude residue was subjected to flash silica gel chromatography to give 0.2 g (65%) of **50** as a yellow oil. HRMS calcd. for $C_{12}H_{15}NO_3$: 221.1052; found: 221.1054. IR (neat) (cm^{-1}): 3073, 2935, 1752, 1670, 1639, 1603, 1434, 1378. ^1H NMR (400 MHz, $CDCl_3$) δ: 1.86–1.94 (m, 2H), 2.43 (t, 2H, *J* = 8.6 Hz), 3.46 (d, 2H, *J* = 8.6 Hz), 3.77–3.82 (m, 2H), 3.83 (s, 3H), 5.08 (s, 1H), 5.13–5.18 (m, 2H), 5.94–6.06 (m, 1H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 21.0, 23.7, 40.6, 43.2, 58.3, 81.6, 92.3, 118.1, 131.5, 133.6, 157.3, 174.9.

8-Hydroxy-5,6-dihydro-1*H*,4*H*-pyrrolo[3,2,1-*ij*]quinolin-2-one (53)

A solution of furan **50** (0.04 g, 0.2 mmol) in toluene (5 mL) was heated under reflux for 30 min. The solvent was removed under reduced pressure and the residue was subjected to flash silica gel chromatography to give 0.02 g (58%) of **53** as a white solid: mp 200–201°C. HRMS calcd. for $C_{11}H_{11}NO_2$: 189.0780; found: 189.0787. IR (film) (cm^{-1}): 3134, 2975, 2934, 1654, 1629, 1480, 1280. ^1H NMR (400 MHz, $CDCl_3$) δ: 1.92–1.98 (m, 2H), 2.67 (t, 2H, *J* = 6.0 Hz), 3.42 (s, 2H), 3.61–3.64 (m, 2H), 6.48 (br s, 1H), 6.59 (br s, 1H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 22.7, 25.4, 37.7, 40.2, 111.4, 114.0, 122.7, 125.9, 134.5, 154.8, 176.2.

Spectroscopic studies of the electrophilic activation of amides with triflic anhydride and pyridine

André B. Charette and Michel Grenon

Abstract: The reaction of amides with trifluoromethanesulfonic (triflic) anhydride in the presence of pyridine was thoroughly investigated by NMR spectroscopic techniques. Different pyridinium intermediates were generated from secondary amides, tertiary amides with enolizable protons, and tertiary amides lacking enolizable protons. It was found that the actual triflating reagent is *N*-(trifluoromethylsulfonyl)pyridinium triflate **11** which is formed by the initial reaction of triflic anhydride with pyridine. The alcoholysis of these intermediates yields *O*-alkyliminium ethers which can then be easily hydrolyzed under mild acidic conditions to the corresponding esters.

Key Words: amides, triflic anhydride, pyridinium intermediates, NMR study.

Résumé : La réaction entre un amide et l'anhydride trifluorométhanesulfonique (triflique) en présence de pyridine a été examinée minutieusement à l'aide de nombreuses techniques de spectroscopie RMN. Des intermédiaires pyridiniums différents ont été générés à partir d'amides secondaires, d'amides tertiaires avec des protons énolisables et d'amides tertiaires ne possédant pas de protons énolisables. Nous avons aussi démontré que le triflate de *N*-(trifluorométhylsulfonyl)pyridinium **11**, formé lors de la réaction initiale entre l'anhydride triflique et la pyridine, est le véritable agent de triflation. L'alcoolyse de ces intermédiaires donne des éthers *O*-alkyliminiums qui peuvent être facilement hydrolysés dans des conditions légèrement acides aux esters correspondants.

Mots clés : amides, anhydride triflique, intermédiaires pyridiniums, études RMN.

Introduction

In recent years, trifluoromethanesulfonic (triflic) anhydride has proven to be a very useful reagent for the activation of amides and their subsequent transformation into other functional groups (for a recent review on the use of triflic anhydride in synthetic organic chemistry see ref. 1). Our research group has recently extended the use of this reagent to the synthesis of amidines, thiazolines, thioamides, esters as well as cyclic orthoesters from simple amides (2–6) (Scheme 1).

A variety of intermediates have been either isolated or postulated from the reaction of secondary or tertiary amides with triflic anhydride under different conditions (Scheme 2). *O*-Triflyliminium triflates **1** and **2** have been postulated as potential intermediates when secondary and tertiary amides were treated with triflic anhydride either in the presence or absence of a non-nucleophilic base (7–10). In the case of tertiary amides bearing enolizable protons it was found that when the sulfonylation was performed in the presence of a tertiary base, the *O*-sulfonylated derivatives were converted into (*N*,*N*-dialkylamino)alkenyl triflates **3** (11). These can then spontaneously generate keteniminium triflates which are valuable intermediates in [2 + 2] cycloadditions (12–20). Yet another intermediate was observed when tertiary amides were left to react with only 0.5 equiv of triflic anhydride. Stable dicationic ether salts such as **4** were isolated, which presumably arise from the attack of the amide on the initially formed *O*-triflyliminium triflate **2** (21).

Since the nature of the intermediates formed upon exposure of amides to triflic anhydride is dependent upon several variables such as the amide structure, the amount of anhydride used, and the nature of the base (if present), we decided to carry out a careful spectroscopic study to identify the structure of the intermediates generated according to a new reaction protocol developed in our laboratory. This procedure differs from others in that in most cases, we need at least 2 equiv of pyridine to get optimal yields of the desired products. It is noteworthy that pyridine can not only act as a proton scavenger in these reactions but also as a nucleophilic partner. Herein, we disclose the detailed spectroscopic investigation of the reaction of secondary and tertiary amides with triflic anhydride in the presence of pyridine. The emphasis will be on the spectroscopic identification of the reac-

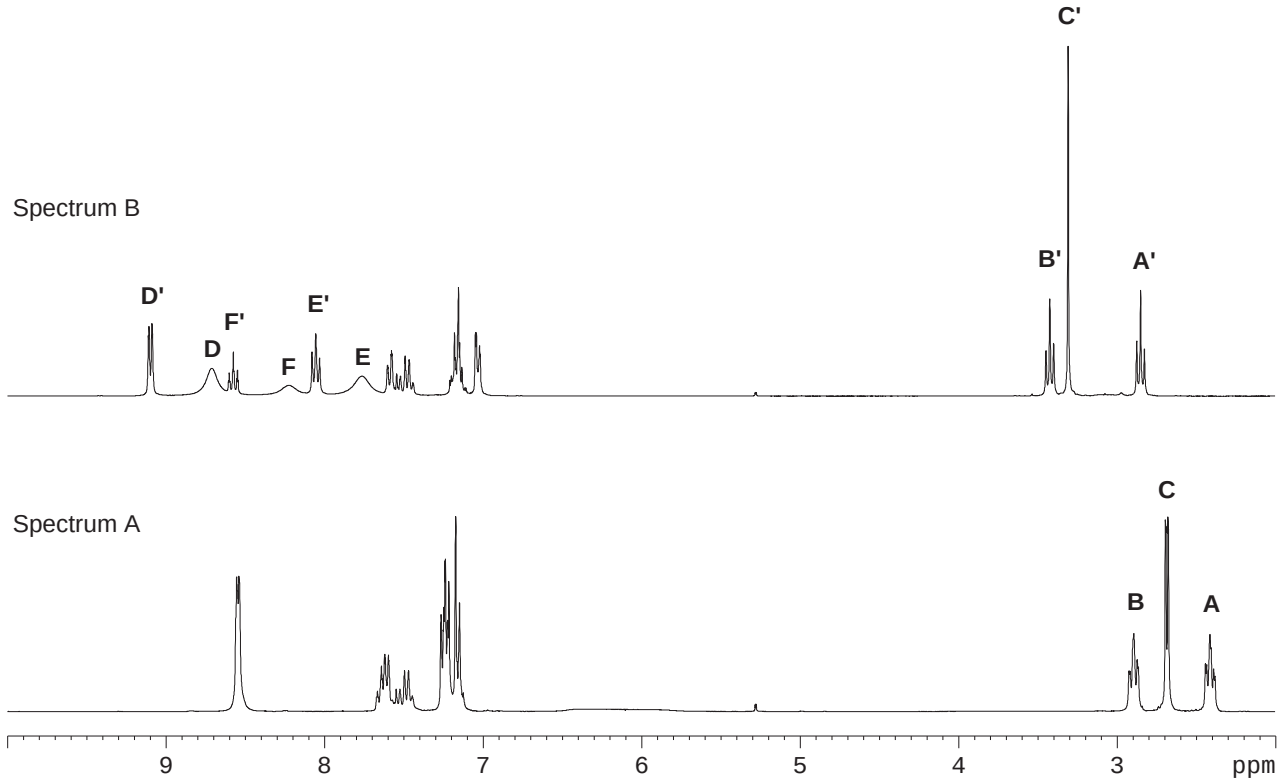
tive intermediates and of the triflating agent, and their subsequent conversion to ethyl esters.

Results and discussion

Reaction of secondary amides with triflic anhydride in the presence of pyridine

In an effort to identify the nature of the intermediates formed in the activation process, we decided to monitor the reactions by NMR spectroscopic techniques. ^{1}H and ^{19}F NMR spectroscopy are particularly suited in view of the inherent ease of analysis and the large amount of structural information it provides.

The first set of experiments involved the slow addition of triflic anhydride to a solution of 1.0 equiv of *N*-methyl-3-phenylpropionamide **5** and 3.0 equiv of pyridine in CD_2Cl_2. After the addition, the solution was warmed to room temperature and the NMR spectra were recorded. NMR analysis indicated that 1-pyridylimidoyl triflate **6** was formed quantitatively in less than 2 h (eq. [1]) (22).



5 **6**

Telltale signs of the existence of this intermediate are found in the ^{1}H NMR spectrum where two distinct sets of signals are found for the pyridine unit. The first set of signals is assigned to pyridinium **6** (see **D′**, **E′**, and **F′**, Spectrum B, Fig. 1). This assignment of the resonances of pyridinium **6** was also confirmed by NOESY. The other set of signals (**D**, **E**, **F**) corresponds to pyridinium hydrotriflate and free pyridine that are involved in a rapid proton exchange process. This was also confirmed by comparing the spectrum with an independent sample prepared by mixing 2 equiv of pyridine and 1 equiv of TfOH. In addition, the doublet (δ = 2.7 ppm) corresponding to the methyl group of the starting amide

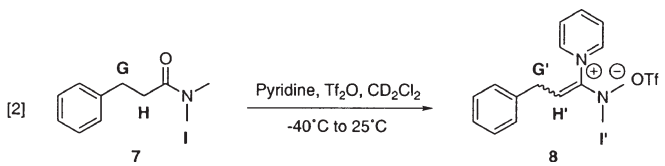
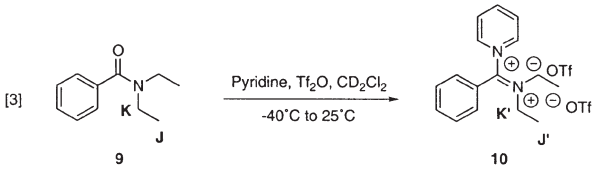
Fig. 1. ^{1}H NMR of the reaction of *N*-methyl-3-phenylpropionamide **5** with triflic anhydride in the presence of pyridine. Spectrum A: amide **5** (1.0 equiv) + pyridine (3.0 equiv) + α,α,α-trifluorotoluene (1.0 equiv, used as internal standard) in CD_2Cl_2. Spectrum B: 2 h after the addition of triflic anhydride (1.2 equiv).



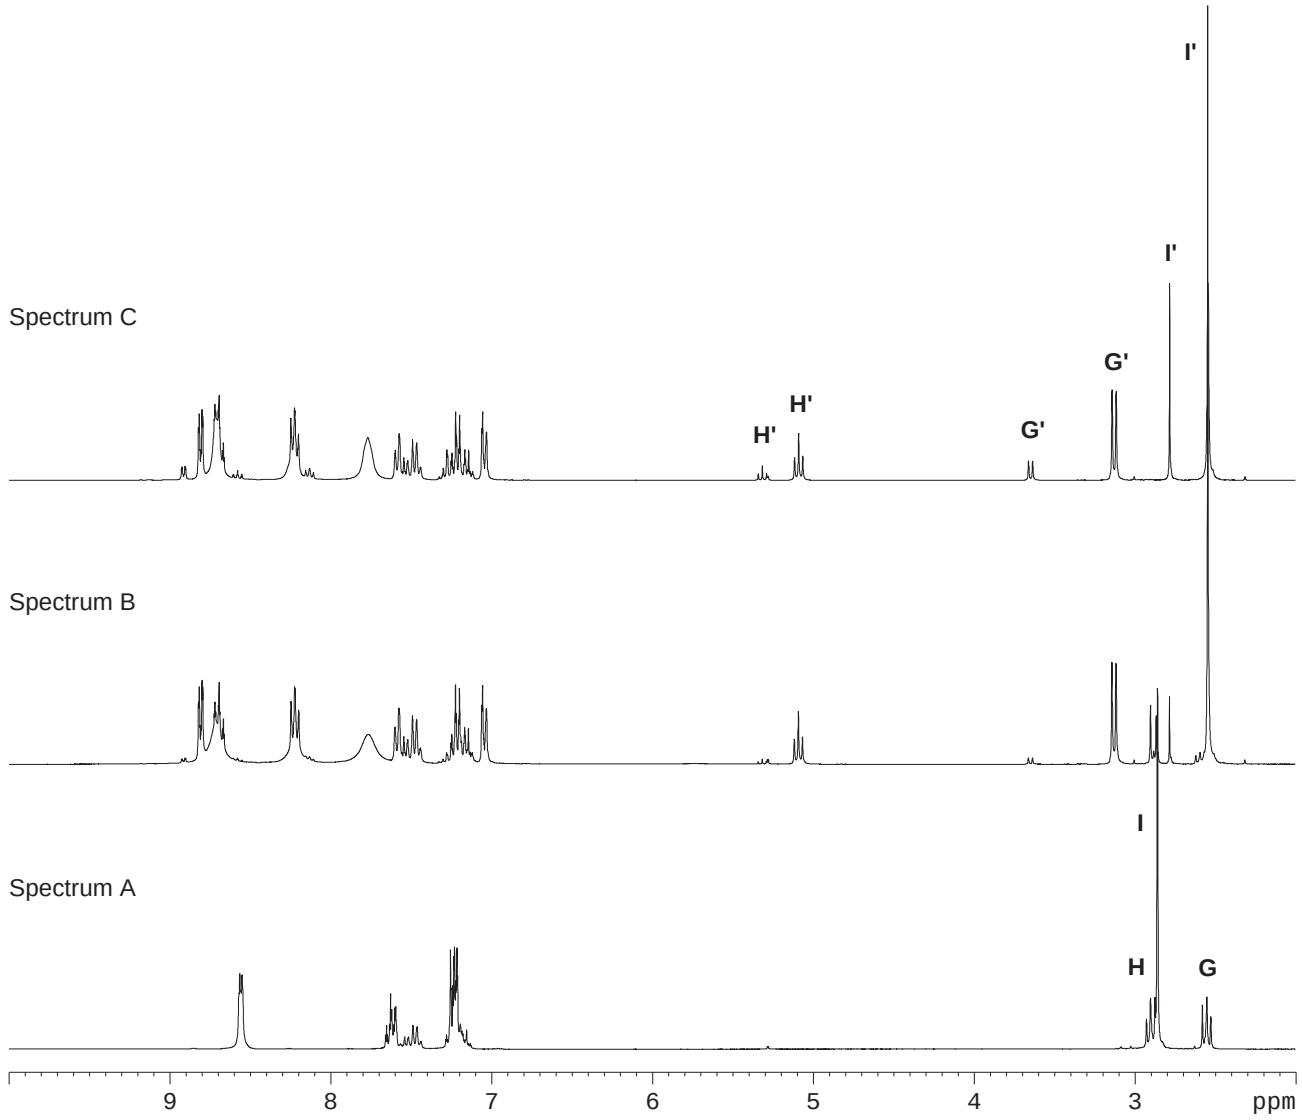
(Spectrum A) is converted into a singlet (δ = 3.3 ppm), which is also consistent with the formation of adduct **6**.

Further evidence is provided by ^{19}F NMR where signals corresponding to the triflate anion (–79.8 ppm) and *N*-(trifluoromethylsulfonyl)pyridinium **11** (–75.9 ppm) are exclusively observed, the latter compound arising from the reaction of the excess triflic anhydride with pyridine (23, 24). Pyridinium **6** proved to be very stable under the reaction conditions, showing no signs of decomposition after 6 days at –3°C under dry atmosphere. It is noteworthy that this behaviour is quite general and has been observed for a vast array of secondary amides. Another striking feature of the activation process is that at no time during the reaction are signals corresponding to the *O*-triflyliminium or *O*-triflylimidate observed, indicating that these intermediates, when formed, react rapidly with pyridine to generate **6**.



Reaction of tertiary amides with triflic anhydride in the presence of pyridine

Our next spectroscopic study of the activation process was done with tertiary amides with α-enolizable protons. The reaction of *N*,*N*-dimethyl-3-phenylpropionamide **7** with triflic anhydride and pyridine was carried out in a fashion similar to that described above to afford *N*,*N*-(dimethylamino)-alkenylpyridinium triflate **8** as a 5:1 mixture of *Z*:*E* isomers (eq. [2]).



Evidence for the formation of **8** is provided by the ^{1}H NMR spectrum shown in Fig. 2 (Spectrum C). Two triplets corresponding to protons **H′** (δ = 5.3 and 5.1 ppm, *J* = 7.6 Hz), two doublets corresponding to protons **G′** (δ = 3.6 and 3.1 ppm, *J* = 7.6 Hz), and two singlets for protons **I′** (δ = 2.8 and 2.5 ppm) are consistent with the formation of both isomers. Once again, three sets of signals are observed for the pyridine units. Two of them arise from both isomers of **8** and one additional signal arises from the pyridinium hydrotriflate – pyridine equilibrium. Once again, the ^{19}F NMR spectrum shows only signals associated with the triflate anion (–79.8 ppm) and *N*-(trifluoromethylsulfonyl)pyridinium **11** (–75.9 ppm).

Having established the nature of the intermediate formed in the reaction of a tertiary amide with enolizable protons with triflic anhydride in the presence of pyridine, we focused next on the activation of tertiary amides lacking enolizable protons since these substrates can also be activated under these reaction conditions and be converted into esters upon ethanol addition. The reaction of *N*,*N*-diethylbenzamide **9** with triflic anhydride in the presence of pyridine was monitored by NMR spectroscopy and it appears that this amide, quite surprisingly, was also converted into a pyridinium adduct which was assigned as 1-pyridyl-*N*,*N*-diethyliminium ditriflate **10** (eq. [3]).

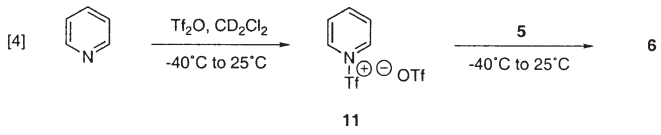

Fig. 2. [1]H NMR of the reaction of *N*,*N*-dimethyl-3-phenylpropionamide **7** with triflic anhydride in the presence of pyridine. Spectrum A: amide **7** (1.0 equiv) + pyridine (3.0 equiv) + α,α,α-trifluorotoluene (1.0 equiv, used as internal standard) in CD_2Cl_2. Spectrum B: 2 h after the addition of triflic anhydride (1.2 equiv). Spectrum C: 3 h after the addition of triflic anhydride.

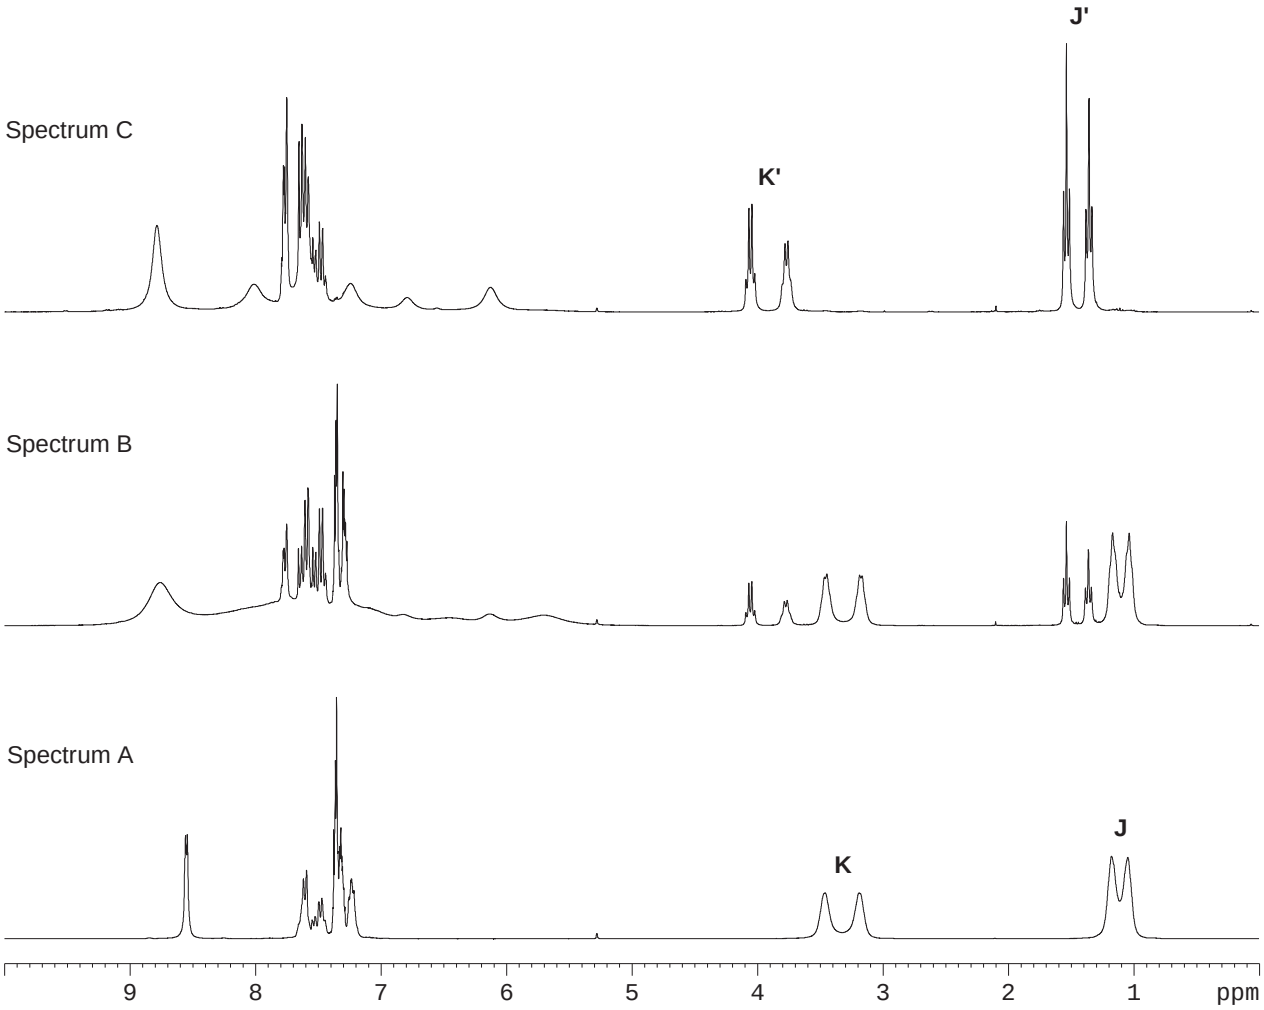
Longer reaction times were required to get complete consumption of the starting material (Fig. 3). The [1]H NMR spectrum of the reaction mixture shows only 28% conversion of the amide **9** to pyridinium intermediate **10** after 2 h (Spectrum B, Fig. 3). *N*-(trifluoromethylsulfonyl)pyridinium **11** was the major species in the reaction mixture as observed by [19]F NMR (–75.9 ppm). However, after 4 h the [1]H NMR spectrum of the dark blue solution shows complete conversion to pyridinium **10** (Spectrum C, Fig. 3). In contrast with intermediates **6** and **8**, the signals associated with the pyridine unit are much broader and they cover a wider portion of the spectrum. The protons corresponding to the *N*-Et groups (**K′** and **J′**) are well-defined (Spectrum C, Fig. 3). Once again, after 4 h of reaction time, the [19]F NMR spectrum shows only the signals corresponding to triflate anion (OTf^-) and *N*-(trifluoromethylsulfonyl)pyridinium **11**.



Nature of the triflating agent

An interesting aspect of this amide activation protocol is to further investigate the nature of the triflating reagent. When triflic anhydride is added to a mixture of the amide *and* pyridine in dichloromethane, it can either react with the amide to generate an *O*-triflyliminium intermediate or it can generate *N*-(trifluoromethylsulfonyl)-pyridinium triflate **11**. In principle, both pathways should be competing but what is less clear is whether **11** is sufficiently electrophilic to react with the amide. To clarify this issue, we monitored by NMR the reaction of *N*-methyl-3-phenylpropionamide **5** with *preformed N*-(trifluoromethylsulfonyl)-pyridinium triflate **11** to verify whether this reagent was electrophilic enough to convert amide **5** into the pyridinium intermediate **6** in the presence of pyridine (eq. [4]).

Fig. 3. ^{1}H NMR of the reaction of *N*,*N*-diethylbenzamide **9** with triflic anhydride in the presence of pyridine. Spectrum A: amide **9** (1.0 equiv) + pyridine (3.0 equiv) + α,α,α-trifluorotoluene (1.0 equiv, used as internal standard) in CD_2Cl_2. Spectrum B: 2 h after the addition of triflic anhydride (1.2 equiv). Spectrum C: 4 h after the addition of triflic anhydride.

As expected, the reaction of pyridine with triflic anhydride led to the instantaneous appearance of two signals of equal intensities in the ^{19}F NMR spectrum (Spectrum B, Fig. 4). The triflic anhydride was completely consumed and a precipitate was formed instantly upon its addition. At this point, amide **5** was added at low temperature to *N*-(trifluoromethylsulfonyl)pyridinium triflate **11** and the reaction was allowed to warm to room temperature and monitored by NMR (Fig. 4). After the usual activation period, ^{19}F NMR analysis indicated that the resonance corresponding to the *N*-triflyl group in **11** (–75.9 ppm) significantly decreased in favor of that of triflate anion (–79.8 ppm). In addition, the ^{1}H NMR spectrum obtained after the activation was identical to that observed when our standard activation protocol was used (Spectrum B, Fig. 1). This observation strongly supports the fact that *N*-(trifluoromethylsulfonyl)pyridinium triflate **11** is capable of activating amide **5** by converting it into the pyridinium intermediate **6**.

In a parallel experiment, triflic anhydride was added to amide **5** at –40°C to produce a precipitate that was assigned as the *O*-triflyliminium triflate **12** (eq. [5]). As anticipated, the ^{19}F NMR spectrum showed a signal corresponding to triflate anion (–79.8 ppm) and to the cationic component of adduct **12** (–72.8 ppm). The latter displays a chemical shift very close to that of triflic anhydride (Spectrum B, Fig. 5). Low-temperature addition of pyridine to the reaction mixture followed by the usual activation period resulted in the disappearance of the cationic component of adduct **12** and an increase in the concentration of triflate ion (Spectrum C, Fig. 5). A small amount of *N*-(trifluoromethylsulfonyl)-pyridinium **11** was also observed due to the reaction of the excess triflic anhydride with pyridine. The ^{1}H NMR spectrum of the activated specie is identical to that obtained when the conventional activation protocol was used (Spectrum B, Fig. 1).

Since triflic anhydride and *N*-(trifluoromethylsulfonyl)-pyridinium triflate **11** were both capable of reacting with amides to afford pyridinium intermediates upon exposure to

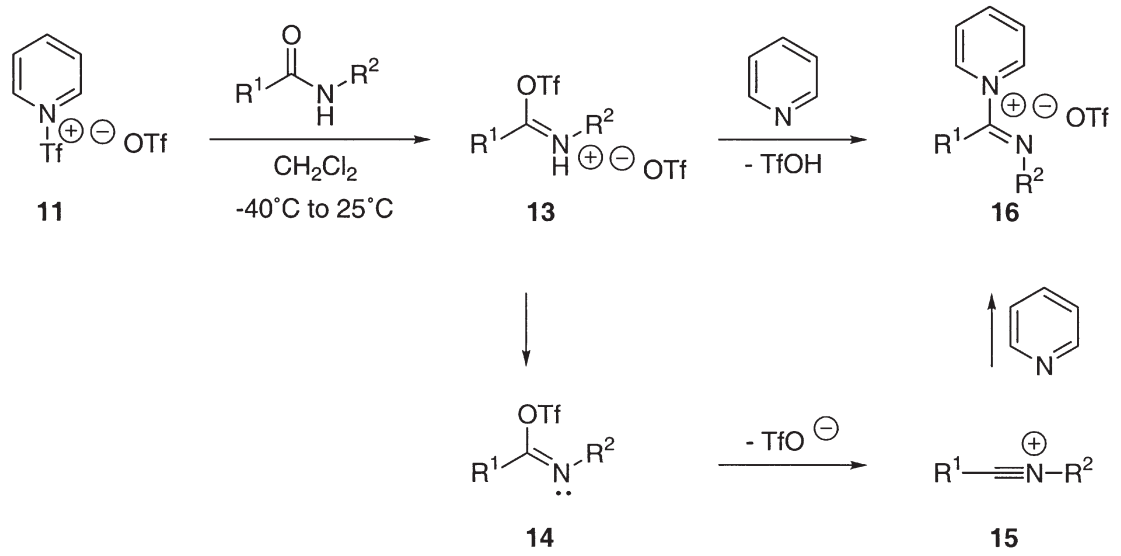
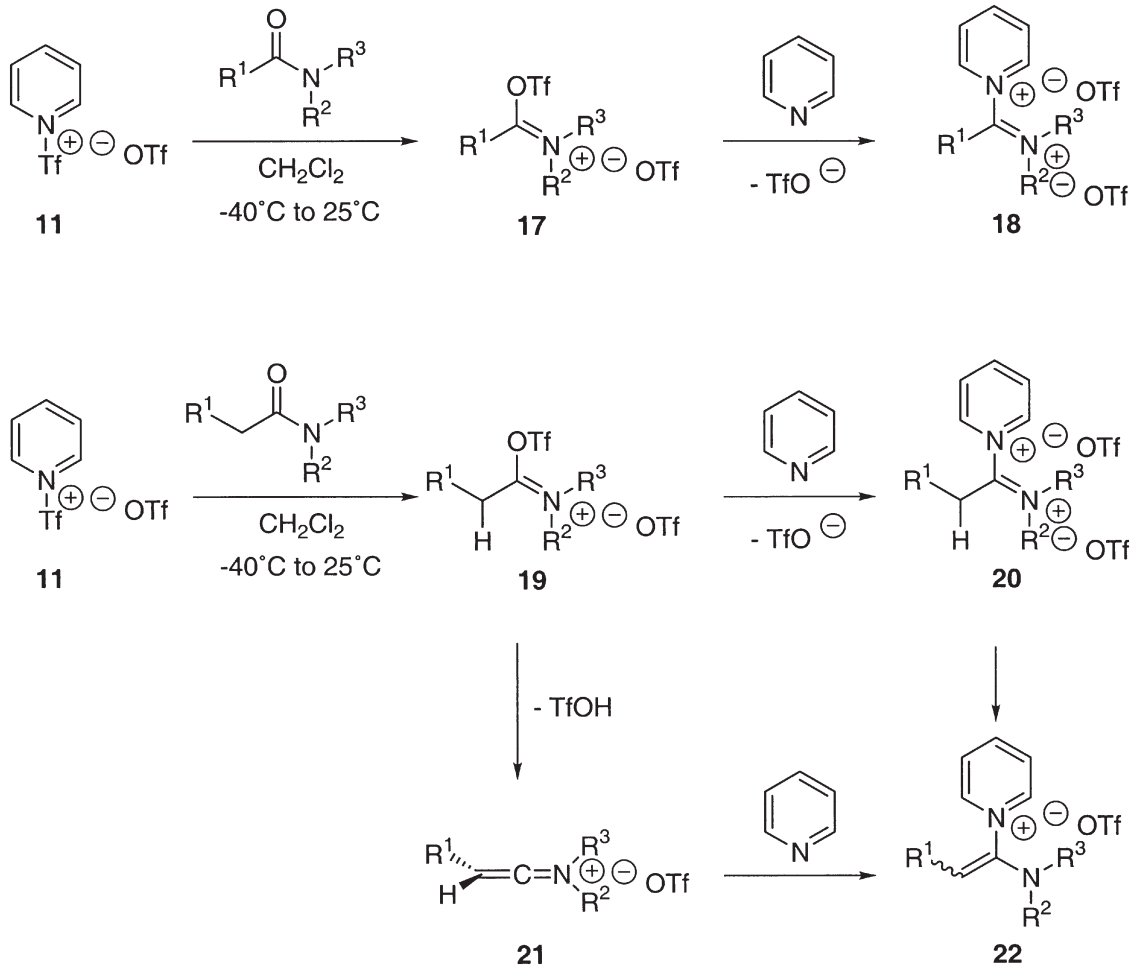
excess pyridine, we carried out low-temperature NMR experiments to establish with which species triflic anhydride reacted first when it was added to a mixture of the amide and pyridine. Accordingly, after adding triflic anhydride to a mixture of the amide **5** and pyridine in CD_2Cl_2 at –40°C, the NMR tube was rapidly transferred to the precooled spectrometer probe at the same temperature. The ^{19}F NMR spectrum of the reaction mixture taken after 16 min showed complete consumption of the triflic anhydride and the exclusive formation of *N*-(trifluoromethylsulfonyl)pyridinium triflate **11**. No detectable amount of adduct **12** was observed. The ^1H NMR spectrum also showed that the amide **5** was left unchanged in the first minutes after the addition. The pyridinium intermediate **6** started to appear only when the reaction mixture was allowed to warm up to higher temperatures. With this experiment in mind, we can conclude that the triflic anhydride reacts initially with pyridine to form *N*-(trifluoromethylsulfonyl)pyridinium triflate **11** which is the actual triflating reagent in these amide activation reactions.



General mechanisms for the amide activation process and conversion of the intermediates into ethyl esters

With these results in hand, we were able to suggest the following mechanistic pathways for the reaction of secondary and tertiary amides with triflic anhydride in the presence of pyridine. Initially, the anhydride reacts with pyridine to form *N*-(trifluoromethylsulfonyl)pyridinium triflate **11**. This is then followed by the reaction of secondary amides with **11** upon warming to yield *O*-triflyliminium triflates **13**, which have not been observed in solution since they reacted immediately with the excess pyridine to yield pyridinium intermediates **16** (Scheme 3). The latter step can proceed through a stepwise addition of pyridine to **13** followed by the expulsion of triflic acid. Alternatively, the elimination of triflate anion from imidoyl triflates **14** can generate nitriliums **15** which then further reacts with pyridine to produce pyridinium intermediates **16**.



Tertiary amides lacking enolizable protons can also react via a similar reaction pathway (Scheme 4). For these substrates, longer activation times are required to ensure com-

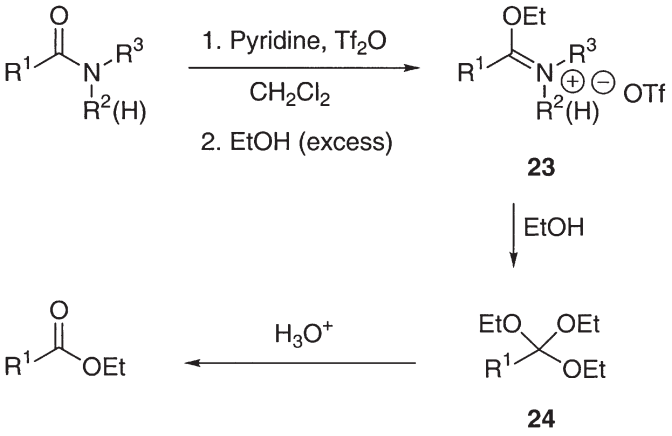
Scheme 3. Proposed mechanistic pathways for the conversion of secondary amides to pyridinium intermediates.



Scheme 4. Proposed mechanistic pathways for the conversion of tertiary amides to pyridinium intermediates.

plete conversion to the pyridinium intermediates **18**. Once again, *O*-triflyliminium triflates **17** are not observed in solution due to their rapid reaction with pyridine. In the case of tertiary amides bearing enolizable protons, two different routes could lead to pyridinium intermediates **22** after the initial formation of adducts **19** (Scheme 4). The first route involves the ejection of triflic acid by deprotonation to yield keteniminium triflates **21** which could then further react

© 2001 NRC Canada

Scheme 5. Alcoholysis of activated amides to form esters.

with excess pyridine. Alternatively, the sequential addition of pyridine and expulsion of triflate anion could afford intermediates **20**. Proton abstraction could then generate pyridiniums **22**.

It is important to point out that all these pyridinium intermediates (**16**, **18**, **22**) are converted into their corresponding ethyl esters upon ethanol addition and work-up. In our original communication on the alcoholysis of amides (5), we postulated that acidic hydrolysis of the acyclic orthoester **24** was the leading pathway to yield the observed esters (Scheme 5). Conversely, there are numerous reported examples of hydrolysis of *O*-alkyliminium ethers such as **23** under acidic (25–31) or basic conditions (32–39). In an effort to identify which of these two intermediates was formed, we decided to monitor the alcoholysis of 1-pyridylimidoyl triflate **6** with ethanol-d_6 by ^{1}H NMR (Fig. 6).

Following the addition of ethanol-d_6, the pyridinium **6** was rapidly converted to the *O*-ethyliminium triflate (Spectrum B, Fig. 6). The latter intermediate persisted in the reaction mixture over an extended period of time, showing only slight decomposition after 9 h at room temperature. No detectable amount of an acyclic orthoester intermediate was observed over the course of the reaction.[2] Interestingly, the alcoholysis of 1-pyridyl-*N*,*N*-diethyliminium ditriflate **10** also occurred rapidly at room temperature requiring less than 1 h, while *N*,*N*-(dimethylamino)alkenylpyridinium triflate **8** required about 6 h. Acidic hydrolysis of these *O*-ethyliminium triflates afforded the expected esters.

Experimental

General

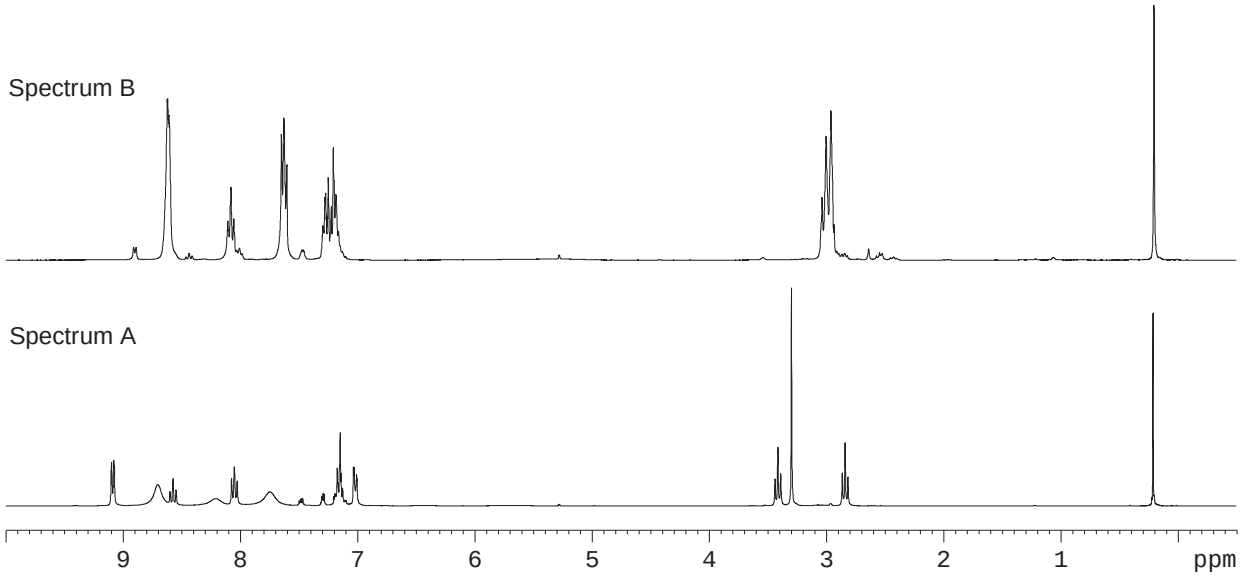
NMR spectra were recorded on a Brucker AV-300 spectrometer, while variable-temperature NMR experiments were performed on a Brucker ARX-400 spectrometer. Pyridine was distilled over CaH_2 prior to use. Triflic anhydride was distilled over a small amount of phosphorus pentoxide before use. Dichloromethane-d_2 was purchased from CDN Isotopes. Ethanol-d_6 was purchased from CIL. Pyridine-d_5, phenyltrimethylsilane. and α,α,α-trifluorotoluene were purchased from Aldrich.

Reaction of N-*methyl-3-phenylpropionamide* ***5*** *with triflic anhydride in the presence of pyridine (eq. [1] and Fig. 1)*

To a dry NMR tube was added *N*-methyl-3-phenylpropionamide **5** (32.6 mg, 0.2 mmol) which was then capped with a rubber septum and purged with nitrogen. Dichloromethane-d_2 (1.0 g) was then added and the NMR tube slightly shaken. Pyridine (48 μL, 0.6 mmol) and α,α,α-trifluorotoluene (24.5 μL, 0.2 mmol) were then added and the NMR tube was shaken again. At this point ^{1}H NMR and ^{19}F NMR reference spectra were taken. The tube was then cooled to −40°C under a nitrogen atmosphere and triflic anhydride (40 μL, 0.24 mmol) was slowly added. The mixture was allowed to slowly warm up to –5°C in the acetone bath over 2 h after which ^{1}H NMR and ^{19}F NMR spectra of the golden solution were taken showing complete consumption of the starting material and formation of 1-pyridylimidoyl triflate **6**.

Reaction of N,N-*dimethyl-3-phenylpropionamide* ***7*** *with triflic anhydride in the presence of pyridine (eq. [2] and Fig. 2)*

To a dry NMR tube was added *N*,*N*-dimethyl-3-phenylpropionamide **7** (35.5 mg, 0.2 mmol) which was then capped with a rubber septum and purged with nitrogen. Dichloromethane-d_2 (1.0 g) was then added and the NMR tube slightly shaken. Pyridine (48 μL, 0.6 mmol) and α,α,α-trifluorotoluene (24.5 μL, 0.2 mmol) were then added and the NMR tube was shaken again. At this point ^{1}H NMR and ^{19}F NMR reference spectra were taken. The tube was then cooled to −40°C under a nitrogen atmosphere and triflic anhydride (40 μL, 0.24 mmol) was slowly added. The mixture was allowed to slowly warm up to –5°C in the acetone bath over 2 h after which ^{1}H NMR and ^{19}F NMR spectra of the reaction mixture were taken. The NMR tube was then kept under nitrogen and left to react for an additional hour at room temperature. ^{1}H NMR and ^{19}F NMR spectra of the deep orange solution showed complete consumption of the starting material and formation of *N*,*N*-(dimethylamino)-alkenylpyridinium triflate intermediates **8** as a 5:1 mixture of isomers.



Reaction of N,N-*diethylbenzamide* **9** *with triflic anhydride in the presence of pyridine (eq. [3] and Fig. 3)*

To a dry NMR tube was added *N*,*N*-diethylbenzamide **9** (35.5 mg, 0.2 mmol) which was then capped with a rubber septum and purged with nitrogen. Dichloromethane-d_2 (1.0 g) was then added and the NMR tube slightly shaken. Pyridine (48 μL, 0.6 mmol) and α,α,α-trifluorotoluene (24.5 μL, 0.2 mmol) were then added and the NMR tube was shaken again. At this point ^{1}H NMR and ^{19}F NMR reference spectra were taken. The tube was then cooled to −40°C under a nitrogen atmosphere and triflic anhydride (40 μL, 0.24 mmol) was slowly added. The mixture was allowed to slowly warm up to –5°C in the acetone bath over 2 h after which ^{1}H NMR and ^{19}F NMR spectra of the reaction mixture were taken. The NMR tube was then kept under nitrogen and left to react for two more hours at room temperature. ^{1}H NMR and ^{19}F NMR spectra of the deep blue

[2] It is interesting to note that when 2,2-bis(hydroxymethyl)-1-propanol is used as the nucleophile, we observed the in situ formation of the orthoester. In this case, the formation of the orthoester is probably an entropy driven cyclization.

Fig. 6. ^{1}H NMR monitoring of the reaction of 1-pyridylimidoyl triflate **6** with ethanol-d_6. Spectrum A: reaction mixture containing 1-pyridylimidoyl triflate **6** and phenyltrimethylsilane (used as internal standard). Spectrum B: 1 h after the addition of ethanol-d_6 (33 equiv).

solution showed complete consumption of the starting material and formation of 1-pyridyl-*N*,*N*-diethyliminium ditriflate **10**.

Reaction of N-*methyl-3-phenylpropionamide* ***5*** *with* N-*(trifluoromethylsulfonyl)pyridinium triflate* ***11*** *in the presence of pyridine (eq. [4] and Fig. 4)*

To a dry NMR tube capped with a rubber septum and purged with nitrogen was added dichloromethane-d_2 (1.0 g) and α,α,α-trifluorotoluene (24.5 μL, 0.2 mmol). Triflic anhydride (40 μL, 0.24 mmol) was then added and the NMR tube was slightly shaken. At this point ^{1}H NMR and ^{19}F NMR reference spectra were taken. The NMR tube was then cooled to −40°C under a nitrogen atmosphere and pyridine (48 μL, 0.6 mmol) was slowly added. After 30 min, the NMR tube was warmed up to room temperature at which point ^{1}H NMR and ^{19}F NMR spectra were taken showing the complete consumption of triflic anhydride and formation of *N*-(trifluoromethylsulfonyl)pyridinium triflate **11**. The mixture was then cooled again to −40°C and *N*-methyl-3-phenylpropionamide (32.6 mg, 0.2 mmol) was quickly added. The NMR tube was allowed to slowly warm up to –5°C in the acetone bath over 2 h after which ^{1}H NMR and ^{19}F NMR spectra of the reaction mixture were taken showing complete consumption of the amide and formation of pyridinium intermediate **6**.

Reaction of N-*methyl-3-phenylpropionamide* ***5*** *with triflic anhydride (eq. [5] and Fig. 5)*

To a dry NMR tube was added *N*-methyl-3-phenylpropionamide **5** (32.6 mg, 0.2 mmol) which was then capped with a rubber septum and purged with nitrogen. Dichloromethane-d_2 (1.0 g) was then added and the NMR tube slightly shaken. α,α,α-Trifluorotoluene (24.5 μL, 0.2 mmol) was then added and the NMR tube was shaken again. At this point ^{1}H NMR and ^{19}F NMR reference spectra were taken. The NMR tube was then cooled to −40°C under a nitrogen atmosphere and triflic anhydride (40 μL, 0.24 mmol) was slowly added. After 30 min, the NMR tube was warmed up to room temperature at which point ^{1}H NMR and ^{19}F NMR spectra were taken showing the complete consumption of the amide and formation of *O*-triflyliminium triflate **12**. The mixture was then cooled again to −40°C and pyridine (48 μL, 0.6 mmol) was slowly added. The NMR tube was allowed to slowly warm up to –5°C in the acetone bath over 2 h after which ^{1}H NMR and ^{19}F NMR spectra of the reaction mixture were taken showing complete consumption of *O*-triflyliminium triflate **12** and formation of the pyridinium intermediate **6**.

Alcoholysis of 1-pyridylimidoyl triflate ***6*** *with ethanol-d_6 (Fig. 6)*

To a dry NMR tube was added *N*-methyl-3-phenylpropionamide **5** (32.6 mg, 0.2 mmol) which was then capped with a rubber septum and purged with nitrogen. Dichloromethane-d_2 (1.0 g) was then added and the tube slightly shaken. Pyridine (48 μL, 0.6 mmol) and phenyltrimethylsilane (7.0 μL, 0.04 mmol) were added and the tube was shaken again. The tube was then cooled to −40°C under a nitrogen atmosphere and triflic anhydride (40 μL, 0.24 mmol) was slowly added. The mixture was allowed to slowly warm up to –5°C in the acetone bath over 2 h after which a ^{1}H NMR spectrum was taken. The tube was then kept under nitrogen and ethanol-d_6 (390 μL, 6.6 mmol) was added at room temperature. The tube was shaken and left to react at room temperature. ^{1}H NMR spectra were then recorded at different time intervals.

Conclusion

The reaction of secondary and tertiary amides with triflic anhydride in the presence of pyridine has been investigated by various NMR spectroscopic techniques. Pyridinium intermediates were generated in all cases studied, demonstrating the crucial effect of the base used in the activation processes. We have also demonstrated that *N*-(trifluoromethylsulfonyl)-pyridinium triflate **11**, which is formed by the reaction of

© 2001 NRC Canada

triflic anhydride with the pyridine present during the initial stage of the reaction, was the activating reagent. Alcoholysis of the intermediates affords the expected *O*-alkyliminium triflates which are then converted into esters under the mild acidic work-up conditions.

Catalysis of transesterification reactions by lanthanides — Unprecedented acceleration of methanolysis of aryl and alkyl esters promoted by $La(OTf)_3$ at neutral $^{S}_{S}$pH and ambient temperatures

Alexei. A. Neverov, Todd McDonald, Graham Gibson, and R.S. Brown

Abstract: La^{3+} catalysis of the methanolysis of the esters *p*-nitrophenyl, 2,4-dinitrophenyl, and phenyl acetate (**1**–**3**), phenyl benzoate (**4**), and ethyl, *i*-propyl, cyclohexyl, and *tert*-butyl acetate (**5**, **6a**, **6b**, **7**) was studied at 25°C as a function of $^{S}_{S}$pH and $[La(OTf)_3]$. The active form of the catalyst is attributed to a dimethoxy-bridged dimer of stoichiometry $(La^{3+})_2(^{-}OCH_3)_2$, having maximum activity at $^{S}_{S}$pH 8 to 9. For preparative reactions, the active catalyst can be made in situ simply by adding 0.01 equiv of $La(OTf)_3$, and 0.01 equiv of $NaOCH_3$ to a methanol solution containing the ester (1 M). Strong catalysis of methanolysis of both aryl and alkyl esters was observed, although *tert*-butyl acetate was inert. At $^{S}_{S}$pH 8.5, where the catalyst is maximally active, the transesterification reactions are accelerated by 40 000-fold to 18 000 000-fold in the presence of as little as 5 mM catalyst relative to the background reaction depending on the ester structure. A mechanism for catalysis of transesterification is presented wherein the reactive species is generated by breaking a single La—OCH_3 bond of the dimethoxy-bridged dimer to reveal a nucleophilic metal-bound methoxide – Lewis acid La^{3+} electrophilic pair.

Key words: lanthanides, transesterification, methanolysis, catalysis, kinetics.

Résumé : Opérant à 25°C, on a étudié la catalyse de la méthanolyse d'esters (acétates de *p*-nitrophényle (**1**), de 2,4-dinitrophényle (**2**), de phényle (**3**), benzoate de phényle (**4**) et acétates d'éthyle (**5**), d'*i*-propyle (**6a**), de cyclohexyle (**6b**) et de *tert*-butyle (**7**)) par le La^{3+}, en fonction du $^{S}_{S}$pH et de la $[La(OTf)_3]$. La forme active du catalyseur est attribuée à un dimère avec un pont diméthoxy, de stoechiométrie $(La^{3+})_2(^{-}OCH_3)_2$, dont l'activité maximale se situe à un $^{S}_{S}$pH allant de 8 à 9. Pour des réactions préparatives, on peut préparer le catalyseur actif in situ en ajoutant simplement 0,01 équiv de $La(OTf)_3$ et 0,01 équiv de $NaOCH_3$ à une solution méthanolique d'ester (1 M). On observe une forte catalyse de la méthanolyse des esters des séries tant alkyles qu'aryles, même si l'acétate de *tert*-butyle est inerte. À un $^{S}_{S}$pH de 8,5, alors que le catalyseur est à son activité maximale, la présence de quantités de catalyseur aussi faibles que 5 mM permet d'accélérer les réactions de transestérification par des facteurs allant de 40 000 à 18 000 000 selon la structure de l'ester. On propose un mécanisme de catalyse de la transestérification dans lequel l'espèce réactive est générée par la scission d'une seule liaison La—OCH_3 du dimère avec un pont diméthoxy qui met en présence une paire formée d'un méthylate nucléophile lié à un métal et d'un La^{3+} électrophile qui agit comme acide de Lewis.

Mots clés : lanthanides, transestérification, méthanolyse, catalyse, cinétique.

[Traduit par la Rédaction]

Introduction

Acyl transfer reactions from esters to water or alcohols are important from biological, industrial and academic standpoints (1). Much is known about the mechanism and catalysis of hydrolysis of esters, (2) and considerable attention has been devoted to transesterification reactions, including the acid- (Fischer esterification) and base-promoted pathways (3). Substantial information is available concerning the mechanisms of action of catalysts developed to promote transesterification (4). Examples of metal-catalyzed transesterification have appeared (5), and a recent report has described the related use of lanthanides as recyclable catalysts for the direct acylation of alcohols with acetic acid (6) although, for the most part, the mechanisms of these processes were not reported.

Recently we reported the rapid methanolyses of two *N*-acetylimidazole derivatives (7) and some phosphate diesters (8) catalyzed by $La(OTf)_3$. In the case of *N*-acetylimidazole (7), detailed studies indicated the catalytically active form was $(La^{3+})_2(CH_3O^{-})_2$ and that the mechanism did not involve precoordination of the metal ion to the distal nitrogen of the

substrate, but rather a transient interaction of the La^{3+} dimer with the C=O. It seemed reasonable to expect similar catalysis of acyl transfer from other species including esters **1**–**9**, the preliminary studies of which form the subject of the present report.

Experimental

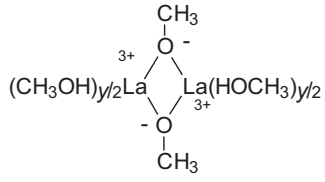
Materials

$La(OTf)_3$ (Aldrich) was used as received to prepare stock solutions in methanol. $NaOCD_3$ (0.62 M) was prepared in CD_3OD by adding sodium metal to CD_3OD NMR solvent, and was subsequently titrated with standard (0.02 M) HCl in aqueous solution using a combination (glass/calomel) electrode. Ester substrates (**1**–**7**) and dimethyl terephthalate (**8**) and glycerol triacetate (triacetin) (**9**), as well as glycerol and ethylene glycol were all commercial materials and were used as received.

Kinetics

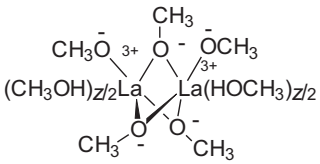
UV kinetics of methanolysis of the aromatic esters were monitored by observing the rate of loss of starting material **1** at 265 nm or **2** at 279 nm or by appearance of *p*-nitrophenol at 311 nm (for **1**), 2,4-dinitrophenol at 325 nm (for **2**), or phenol at 279 nm (for **3** and **4**) under pseudo-first- order conditions of excess metal ([ester] = 4–8 × 10^{-5} M) at 25°C using an OLIS® modified Cary 17 UV–vis spectrophotometer. For these runs, the kinetics were determined under buffered conditions. The methods for determining and controlling the $^{s}_{s}$pH in methanol with buffers are reported in our earlier publications (7, 8) and are based on procedures described by Bosch and co-workers (9). Pseudo-first-order rate constants (k_{obs}) were evaluated by fitting the Abs. vs. time traces (followed for at least three half-times) to a standard exponential model.

Kinetics of transesterification of the other substrates were determined by ^{1}H NMR at 25°C using Bruker AC 200 and Avance 400 NMR machines. The active lanthanum species was generated in situ using 1 × 10^{-2} M $La(OTf)_3$ and 1 equiv (1 × 10^{-2} M) $NaOCH_3$ or $NaOCD_3$ in CD_3OD, after which the substrates, all in 1 M concentrations, were added. For *i*-propyl acetate (**6a**), the kinetics were determined monitoring the change in intensity of each of the $(CH_3)_2$CH-O-C(O)-C*H*$_3$ peaks at δ 1.93, the (C*H*$_3$)$_2$CH-O-C(O)-CH$_3$ peak at δ 1.17, and the $(CH_3)_2$C*H*-O-C(O)-CH$_3$ peak at δ 4.91. For cyclohexyl acetate (**6b**), the ester >C*H*-OC(O)C*H*$_3$ peaks at δ 4.61 and 1.96 were used. For *tert*-butyl acetate (**7**), the (C*H*$_3$)$_3$C-O-C(O)-CH$_3$ peak at δ 1.40 was used. For dimethyl-1,4-terephthalate, a crystalline solid, dissolution in methanol was difficult, so a saturated solution in CD_3OD was prepared, later estimated to be about 0.047 M by an NMR experiment measuring the peak ratio of the aryl ring protons against ethyl acetate as an internal standard. For this substrate, the disappearance of the 1,4-(C*H*$_3$-O-C(O)-)$_2$C$_6$H$_4$ signals at δ 3.92 were used to follow the kinetics. In each case, the pseudo-first-order rate constant (k_{obs}) for transesterification of the substrate was determined by fitting the peak intensity vs. time data to a standard exponential model.



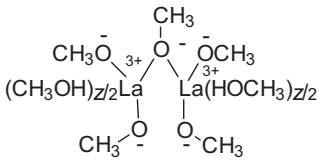
Pseudo-first-order rate constants for transesterification of the above esters in the absence of La^{3+} were determined under conditions of excess [CH_3O^-] (0.01–0.1 M) by UV–vis spectrophotometry or ^{1}H NMR as described above. The second-order rate constants for the methoxide reactions were calculated as k_{obs}/[CH_3O^-]. Given in Table 1 are the second-order rate constants for the methoxide reactions along with those for the La^{3+}-catalyzed reactions.

Electrospray MS



Mass spectra of 0.001 M solutions of $La(OTf)_3$ in methanol were determined using a VG Quattro mass spectrometer equipped with an electospray source operating at cone voltages between 20 and 50 V. Both monomeric and dimeric species' peaks related to $[La(CF_3SO_3)_2]^+$ and $[La_2(CF_3SO_3)_5]^+$can be observed, appearing as clusters having solvating methanol molecules, the number and intensity of which was found to be dependent on cone voltage (Fig. 1). Higher order aggregates are not observed up to mass 2500. The electrospray MS of complexes of La^{3+} with added methoxide anions was undertaken using methanol solutions containing 0.001 M of both $La(OTf)_3$ and Bu_4NOH.

Results and discussion



Potentiometric titration of La^{3+} in MeOH at 25°C, undertaken as described in our previous reports (7, 8), indicates sequential consumptions of first, a single CH_3O^-/La^{3+} (apparent $^{s}_{s}pK_a$ 7.55), and then 1.5 CH_3O^-/La^{3+} (apparent $^{s}_{s}pK_a$ 10.2). The methoxy-bridged dimeric structures **10** and **11** suggested previously (7, 8), are consistent with the stoichiometry and with the detailed kinetic data described below for La^{3+}-promoted methanolysis of ester **1**. However, to gain more information about the speciation of La^{3+} in methanol solution, we undertook electrospray MS studies.

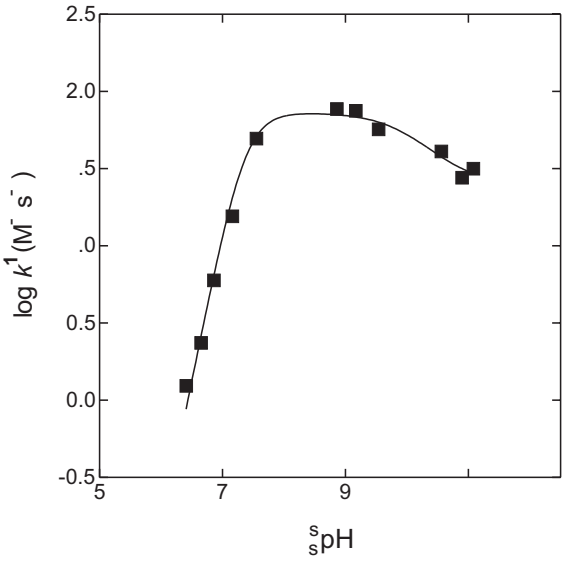
Fig. 1. ES–MS spectra of a 0.001 M solution of $La(OTf)_3$ in methanol, cone voltage 39, showing the presence of monomeric (a) and dimeric (b) La^{3+} forms with associated counter-ions and methanols of solvation.

Shown in Fig. 1 is the electrospray MS of $La^{3+}(OTf^-)_3$ in methanol taken at a cone voltage of 39 V which reveals the presence of a $[La(CF_3SO_3)_2]^+$ monomeric and $[La_2(CF_3SO_3)_5]^+$ dimeric forms with associated methanols of solvation. Stewart and Horlick (10) have reported an extensive study of the ES–MS of Ln^{x+} ions in methanol and acetone and while monomeric Ln^{3+} clusters were observed, their instrument had limited mass range such that the presence of dimers and higher order aggregates could not be ascertained. The number of methanol molecules associated with the cations is dependent on the spectrometer's cone voltage (the potential difference between the sampling plate and skimmer)), with lower voltages promoting higher solvation number. The max solvation number in our case was found to be 4 for $[La(CF_3SO_3)_2(CH_3OH)_4]^+$ (m/z = 565) and 6 for $[La_2(CF_3SO_3)_5(CH_3OH)_6]^+$ (m/z = 1214) (cone voltage 30 V). The increase in cone voltage causes "striping" of solvated methanol molecules due to increasing the energy of collisions between the curtain gas and the analyte ions which results in a decrease of max observed solvation number as well as median solvation number (10).



ES–MS analysis of complexes of La^{3+} with methoxide anions was undertaken using a methanol solution of 0.001 M in each of $La(OTf)_3$ and Bu_4NOH. Due to the much higher concentration of methanol compared to the water present in the Bu_4NOH, and their similar ${}^{s}_{s}pK_a$ values, we assumed that most of the hydroxide ions were converted to methoxide, a fact that seems verified by the lack of observation of substantial HO^- based peaks in the ES–MS. The spectrum taken at a cone voltage of 55 V (not shown) reveals the presence of a monomeric species containing one methoxide ($[La(CF_3SO_3^-)(CH_3O^-)]^+$ (m/z = 319)), as well as dimers containing two and three methoxides ($[La_2(CF_3SO_3^-)_3(CH_3O^-)_2]^+$ (m/z = 787) and $[La_2(CF_3SO_3^-)_2(CH_3O^-)_3]^+$ (m/z = 669)). That the above MS spectra clearly indicate the presence of a monomeric La^{3+} species, and not the presence of a dimeric form with charge = 2, can be ascertained from the presence of M^+ + 2 peaks, attributable to the presence of the ^{34}S isotope in the triflate.

(A) Aryl and alkyl ester methanolysis

Determination of the pseudo-first-order rate constants (k_{obs}) for methanolysis of **1** as a function of both $[La^{3+}]_t$ and ${}^{s}_{s}pH$ (9) at 25°C under buffered conditions (7, 8), immediately indicated that the catalytic mechanism involves a greater-than-first-order dependence on both $[La^{3+}]$ and $[CH_3O^-]$. Plots of

Fig. 2. Plot of second-order rate constant (k_2) vs. $^{S}_{S}$pH for $(La^{3+})_2$-dimer-promoted methanolysis of *p*-nitrophenyl acetate (**1**) (T = 25°C). Line through data from NLLSQ fits to eq. [1].

the k_{obs} for transesterification of **1** vs. $[La^{3+}]_t$ at a given $^{s}_{s}$pH (not shown) showed significant upward curvature at low $[La^{3+}]$ ($<10^{-4}$ M), suggesting that the catalytically active species contains two (or more) La^{3+} ions. These plots culminate in straight lines, indicating the complete formation of what we interpret as catalytically active La-dimers at concentrations greater than 3–4 × 10^{-4} M as was observed in our previous work with acetylimidazole (7). Plots of the log second-order rate constant (k_2) for dimeric La^{3+} catalysis (computed from the linear portions of the k_{obs} vs. $[La^{3+}]_t$ plots) vs. $^{s}_{s}$pH (as illustrated for **1** in Fig. 2) show an ascending domain at low $^{s}_{s}$pH having a slope of 2, requiring that two methoxides are present in the catalytically active species, followed by a plateau at $^{s}_{s}$pH 8–9. Further increases in $^{s}_{s}$pH beyond the plateau region gave a decrease in catalytic rate.

Given in Scheme 1 is a mechanism that accounts for the kinetic behavior, including the drop in activity at high $^{s}_{s}$pH which is attributed to the reduced activity of any dimeric La^{3+} species containing more than two CH_3O^-. The latter species are collectively illustrated in Scheme 1 as $(La^{3+})_2(CH_3O^-)_3(CH_3OH)_y$, but also comprise $(La^{3+})_2(CH_3O^-)_4$ and $(La^{3+})_2(CH_3O^-)_5$ with an unspecified number of solvating methanols produced at progressively higher $^{S}_{S}$pH, (subsequent discussion will ignore the presence of solvating methanols). The available data did not allow us to determine whether the reduced activity species $(La^{3+})_2(CH_3O^-)_3$, has residual activity, but this is not important for the subsequent discussion since we focus on the maximally active species (**10**) generated between $^{s}_{s}$pH 8–9. NLLSQ-fitting of the log k_2 vs. $^{s}_{s}$pH data to eq. [1], derived for the process given in Scheme 1,[2] gives the solid line through the data in Fig. 2 and values of 7.35 ± 0.1 for the kinetic $^{S}_{S}pK_a$ for formation of the $La^{3+}{}_2(CH_3O^-)_2$ dimer and 72 M^{-1} s^{-1} for k_2.[2]

$$[1] \qquad k_2 = k_2^{ester}\,{}^{S}_{S}K_a[H^+]/((2({}^{S}_{S}K_a + [H^+]^2)({}^{S}_{S}K'_a + [H^+])) + k'^{ester}_2\,{}^{S}_{S}K'_a/2({}^{S}_{S}K'_a + [H^+])$$

These constants indicate that at a concentration of 5 × 10^{-3} M of La^{3+}-dimer (produced at a $[La^{3+}]_t$ of 1 × 10^{-2} M), $^{s}_{s}$pH 8–9, the half-time for methanolysis of **1** is ~2 s, corresponding to an impressive 243 000-fold acceleration over the spontaneous methanolysis reaction at that $^{s}_{s}$pH.

Since the catalyzed methanolysis of **1** reaches maximal rate constants under conditions where the dimer is fully formed ($[La^{3+}]_t$ > 3–4 × 10^{-4} M) and when it is associated with two methoxides ($^{s}_{s}$pH 8–9), these conditions were utilized to determine the maximal catalytic k_2^{ester} constants exhibited for methanolysis of esters **2**–**4** by $(La^{3+})_2(CH_3O^-)_2$ at 25°C. The data given in Table 1 indicate that there is relatively little dependence of k_2^{ester} on the nature of the aryloxy leaving group, and that there is a 20-fold reduction in activity for phenyl benzoate relative to phenyl acetate, probably due to a steric effect at the acyl portion. Also given in Table 1, for comparison purposes, are the corresponding second-order rate constants for OCH_3^- attack on the esters, the k_{OMe-}^{ester} values for **1**–**3** being available from the literature, while those for **4**–**7** were determined in this work.

To determine both the rate constants of, and the synthetic utility for, methanolysis of alkyl esters, we established a protocol where esters **5**–**7** (1 M) and a catalytic amount of $La(OTf)_3$ (0.01 equiv relative to ester) was placed in d_4-methanol along with 0.01 equiv of $NaOCH_3$. These are conditions where the $(La^{3+})_2(CD_3O^-)_2$ active form of the catalyst is generated in situ. For **5**–**7**, this reaction is conveniently monitored in d_4-methanol at 25°C by ^{1}H NMR as a function of time by integrating the -OC*H*< signals for **5** and **6**, and the -OC(CH_3)$_3$ signals for **7**. Shown in Fig. 3 are kinetic plots from which the pseudo-first-order rate constants (k_{obs}) can be calculated by NLLSQ-fitting to a standard exponential model.[3] Given a concentration of the active dimer of 5 × 10^{-3} M, second-order rate constants of 1.43 × 10^{-1} M^{-1} s^{-1}, 8.3 × 10^{-3} M^{-1} s^{-1}, and 9.36 × 10^{-3} M^{-1} s^{-1} can be computed for k_2^5, k_2^{6a}, and k_2^{6b}, respectively; no reaction of **7** was observed after 28 days, so an upper limit of <5.7 × 10^{-6} M^{-1} s^{-1} is estimated for k_2^7, pointing to a large steric and possibly leaving-group effect for the catalyzed reaction of alkyl esters.

(B) Trigyceride methanolysis model

Triglycerides comprise an important class of biological molecules that store chemical energy as the glycerol esters of long-chain fatty acids to fuel subsequent metabolism by the organism (11). The methanolysis of triglycerides yields

[2] Derivation of the expression given in eq. [1] follows the exact procedure given in ref. 7*b* and considers the equations for the conservation of mass of the La^{3+} species and the various equilibrium and dissociation constants.

[3] Since the transesterification reaction is an equilibrium process, the position of which depends on the relative rate constants for the forward and reverse reactions and the relative concentrations of the reactants, the computed k_{obs} values are the sum of the forward and reverse rate constants. That the actual reaction attains an equilibrium position is readily apparent from the NMR data for **5** and **6**, since at completion, residual starting material is observed. This method could be used to conveniently determine the equilibrium position and the factors affecting this for a variety of esters.

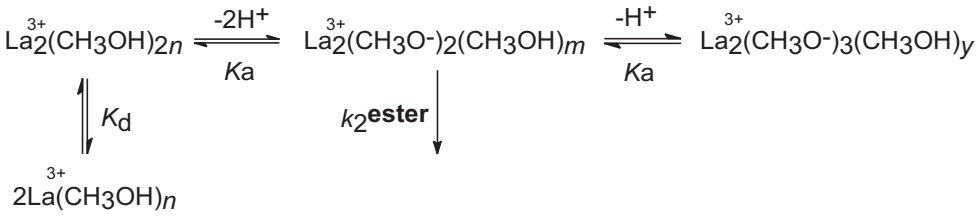

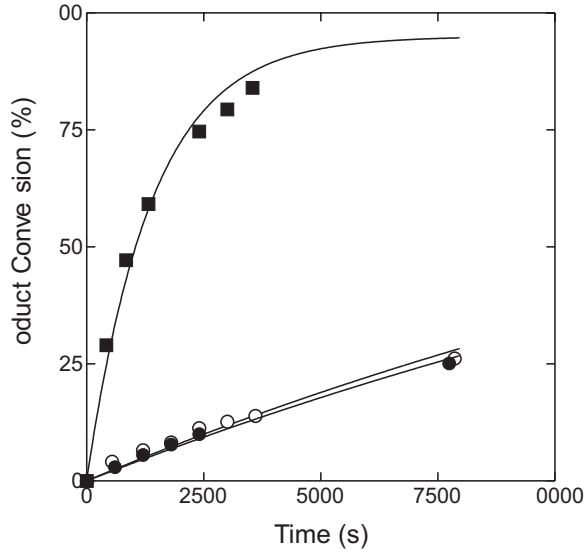

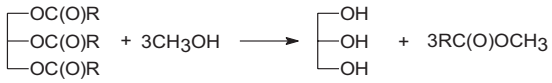

Fig. 3. Plots of % product formed as a function of time as determined by ^{1}H NMR for methanolysis of esters **5**, **6a**, **6b** at ambient temperature: [ester] = 1.0 M, [La(OTf)$_3$] = [$CH_3O^-Na^+$] = 0.01 M, d_4-methanol. ■ (**5**) (k_{obs} = 7.15 × 10^{-4} s^{-1}), ● (**6a**) (k_{obs} = 4.15 × 10^{-5} s^{-1}) ○ (**6b**) (k_{obs} = 4.68 × 10^{-5} s^{-1}).

three methyl esters of fatty acid chains of varying length and saturation, as well as glycerol as in eq. [2]. The combustion properties of long-chain fatty acid methyl esters make for a rich, renewable source of energy known as "biodiesel" (12), the production of which is of current interest as an alternative diesel fuel.

[2] 

Methanolysis of a 1 M solution of the model triglyceride, glycerol triacetate (triacetin, **9**), was studied by ^{1}H NMR in CD_3OD in the presence of 5 × 10^{-3} M dimeric catalyst formed by the addition of 1 × 10^{-2} M La(OTf)$_3$ and 1 × 10^{-2} M Na(OCD_3). Following the reaction by NMR proved difficult both because of the complexity of the multiplets that arise from the glyceryl protons and the complexity of the reaction itself, with the possibility of four distinct intermediates being formed before complete conversion to product. Despite these complications, the disappearance of starting material can be followed by monitoring the rate of change of the AcO-CH_2-C*H*(OAc)-CH_2-OAc signal at δ 5.23 referenced to the sum of all the CH_3 acetate peaks. Under the above conditions, the initial rate of loss of starting material was very fast and ~29% of starting material was converted to one of the intermediates after 9 min. There did not appear to be any great selectivity for methanolysis among the primary and secondary acetates of **9**, a somewhat peculiar observation considering the 17-fold difference noted above for methanolysis of ethyl and *i*-propyl acetates. After the initial rapid methanolysis, further conversion progressed much more slowly, and loss of starting material was observed to be only 36% after 60 min. The kinetic behavior suggests an inhibitory effect either of one of the diol intermediates or the small quantities of the final glycerol product of methanolysis through tight binding to the La^{3+} catalyst. In another experiment when the reaction mixture comprised equimolar amounts of triacetin, $NaOCD_3$ and [La^{3+}] (1 × 10^{-2} M), ~80% conversion was observed in less than 10 min. In this case, the greater conversion can be explained by the smaller product:catalyst ratio consistent with the idea that product inhibition would require more formation of product.

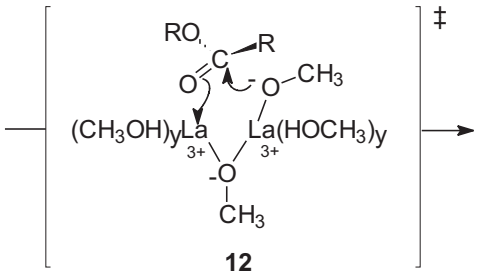
To investigate further the inhibitory effect of polyols on La^{3+} catalysis, the methanolysis of 1 M ethyl acetate was studied (CD_3OD in the presence of 1 × 10^{-2} M each of La(OTf)$_3$ and $NaOCD_3$, and 5 × 10^{-2} M of glycerol). Whereas La^{3+}-catalyzed methanolysis of ethyl acetate at these concentrations normally has a $t_{1/2}$ of about 8 min, (k_{obs}= (7.2 ± 0.4) × 10^{-4} s^{-1}), the added glycerol increases the $t_{1/2}$ to 160 h, (k_{obs} ≅1.2 × 10^{-6} s^{-1}), corresponding to a 600-fold reduction in rate. A similar experiment using 0.1 M ethyl acetate in methanol containing 1 × 10^{-2} M each of La(OTf)$_3$ and $NaOCD_3$ in the presence of 5 × 10^{-2} M ethylene glycol, gave a rate constant for methanolysis of (1.02 ± 0.02) × 10^{-4} s^{-1}, corresponding to a sevenfold rate reduction. These experiments indicate that at the same concentration of 5 × 10^{-2} M, glycerol is about a 100-fold better inhibitor of catalysis than is ethylene glycol.

(C) Complexation of La^{3+} by ethylene glycol and glycerol

The inhibition of catalysis described above suggests strong complexation of the metal ion by polyols to create a bound inactive form. An ^{1}H NMR experiment was performed where the CH_2 signals of an ethylene glycol (0.01 M in CD_3OD) was monitored as a function of varying aliquots of a 0.05 M $La^{3+}(OTf^-)_3$ solution (0, 0.5, 1, 1.5, 2, 3.5, and 5 equiv). The ethylene glycol signal at δ 3.60 asymptotically approaches a value of δ 3.85 for the completely bound form, from which a dissociation constant of 0.006 M can be estimated for the La^{3+}–$(CH_2OH)_2$ complex. This binding constant indicates that at a [La^{3+}] of 1 × 10^{-2} M and [ethylene glycol] of 5 × 10^{-2} M, roughly 85–90% of the metal is bound under these neutral conditions. Such binding can ex-

© 2001 NRC Canada

plain the drop in catalytic activity for methanolysis of ethyl acetate seen in part B above. The existence of complexed forms under neutral conditions could also be confirmed by an ES–MS experiment with a methanol solution of 5×10^{-3} M $La^{3+}(OTf^{-})_3$ containing 5×10^{-2} M $(CH_2OH)_2$ which gives a strong peak at *m*/*z* = 1146, corresponding to $La_2(OTf)_5((CH_2OH)_2)_2$ and *m*/*z* = 499 corresponding to $La(OTf)_2(CH_2OH)_2$. Interestingly, when the ES–MS experiment is done with 5×10^{-3} M $La^{3+}(OTf^{-})_3$ and 5×10^{-3} M $(n\text{-Bu})_4NOH$, conditions similar to the kinetic experiment described in part B above, one sees a very prominent peak at *m*/*z* = 846 corresponding to $La_2(OTf)_3(HOCH_2CH_2O^{-})_2$ with a smaller one at *m*/*z* = 349 corresponding to $La(OTf)(HOCH_2CH_2O^{-})$. The fact that there is no evidence of any methoxide-bound monomer or dimer indicates that the association of the ethylene glycol anion must be very much stronger, and indeed further promotes the formation of a dimeric form.



The binding of La^{3+} by glycerol is even stronger than that of ethylene glycol as revealed by ^1H NMR spectra of a 0.01 M solution of glycerol in CD_3OD, recorded in the presence of varying concentrations of $La(OTf)_3$ (0–0.02 M). The addition of 0.5 equiv of $La(OTf)_3$ causes a significant downfield shift of the >C*H*(OH)-signal at δ 3.64–4.04 ppm, while the addition of another 0.5 equiv of $La(OTf)_3$ gives a further downfield shift of the signal to δ 4.20 ppm. Subsequent increases in the $[La(OTf)_3]$ up to 0.02 M (2 equiv) produces almost no change in the signal indicating complete formation of a 1:1 complex at equimolar 0.01 M concentration, which explains the dramatic loss in catalytic activity seen above. ES–MS of a 1:1 0.01 M solution of each (neutral conditions) also reveals the presence of a $La_2(OTf)_5(C_3H_8O_3)_2$ complex (*m*/*z* = 1206) and a monomer peak at *m*/*z* = 529 corresponding to $La(OTf)_2(C_3H_8O_3)$. Under basic conditions, ES–MS of a 1:1:1, 0.01 M solution in each of $La(OTf)_3$, glycerol, and $(n\text{-Bu})_4NOH$, reveals a major peak at *m*/*z* = 906 corresponding to a dimer $((La_2(OTf)_3(C_3H_7O_3^{-})_2)$ and a smaller peak at 379 corresponding to $La(OTf)(C_3H_7O_3)$. As in the case of ethylene glycol under basic conditions, the ES–MS gave no indication of La^{3+} monomers or dimers having associated methoxides, once again pointing to the much stronger complexation by an anionic polyol relative to CH_3O^{-}, probably resulting from polydentate binding. The combined NMR and ES–MS experiments suggest that the origin of the inhibitory effect of polyols results from a decrease in concentration of the catalytically active $(La^{3+})_2(CH_3O^{-})_2$ form due to a displacement of methoxide by the polyols or at higher pH, the polyol anion.

(D) Methanolysis of dimethyl terephthalate

Current industrial protocols for polyester recycling employ methanolysis for digestion into the corresponding methyl esters and dialcohols arising from aliphatic spacer groups (13) or transesterification involving ester–ester interchange catalyzed by various metallic species including dimeric difunctional tetraorganodistannoxanes and titanium tetraalkoxides at elevated temperatures (14). The above studies indicate that La^{3+}-promoted methanolysis of esters is subject to strong inhibition by ethylene glycol, and as such is likely to be the situation with attempted methanolysis of the ethylene glycol – terephthalate polymers. Thus, we preliminarily investigated a simplified model, the methanolysis of dimethyl terephthalate in CD_3OD, by observing the rate of loss of both the CH_3 signals of **9** at δ 3.92. In the presence of 1×10^{-2} M each of $La^{3+}(OTf^{-})_3$ and $NaOCH_3$, the reaction of a 0.047 M solution of **9** (saturated at 25°C), proceeds with an observed pseudo-first-order rate constant of $(5.8 \pm 0.2) \times 10^{-4}$ s^{-1}, corresponding to a $k_2^{\mathbf{9}}$ second-order rate constant of 0.116 M^{-1} s^{-1} which is some 26 times slower than catalyzed methanolysis of phenyl benzoate **4**.

Conclusions

The work herein with esters shows that the La^{+}-catalyzed methanolysis of esters involves an activated complex having one molecule of ester, two La^{3+} ions, and two methoxides; the likely transition structure for transesterification is given in **12**. This is consistent with what we proposed for La^{3+}-catalyzed methanolysis of *N*-acetylimidazole (**7**), wherein one of the methoxy bridges opens to reveal a transient reactive complex with a nucleophilic La^{3+}-$^{-}OCH_3$ portion in close proximity to an electrophilic La^{3+} partner.

12

The La^{3+} catalysis of methanolysis is inhibited by the presence of polyols such as ethylene glycol or glycerol due to strong complex formation with the metal ion which becomes even stronger under conditions where the monodeprotonated polyol exists.

The finding that La^{3+} catalysis of ester methanolysis is optimal at a $[La^{3+}]/[CH_3O^{-}] = 1$ explains the attenuated catalytic propensities reported (5*a*) for $Ln(O\text{-}i\text{-}Pr)_3$ in promoting transesterifications of various esters to primary and secondary alcohols even at high temperatures and prolonged reaction times. This underscores the importance of mechanistic considerations in developing effective catalysts.

The catalyst can be made in situ simply by adding equimolar amounts of CH_3O^{-} and La^{3+} to create an exceptionally active methoxy-bridged dimeric form at neutral $^{s}_{s}$pH which, at concentrations of 5 mM, can accelerate the methanolysis of the esters studied by as much 4×10^4- to 1.8×10^7-fold relative to the background reaction. Interestingly, compared to the OCH_3^{-} reaction, the catalyst is more effective for esters containing poor leaving groups than those having the better NO_2-substituted aryloxy leaving groups. Importantly, the fact that the kinetics are strictly first-order indicates strong turnover of the catalyst with no loss in activity even under conditions where the [ester] > > $[La^{3+}]_t$. These findings suggest that many other active catalysts for involving other lanthanides and alcohols could be developed as will be reported in our subsequent publications.

Synthesis of highly functionalized naphthoate precursors to damavaricin D — Observation of kinetically stable benzocyclohexadienones in the bromination reactions of highly functionalized β-naphthol derivatives

William R. Roush, David J. Madar, and D. Scott Coffey

Abstract: Selective syntheses of the highly substituted bromonaphthoates **4a**, **4b**, **19**, and **22** are reported. These compounds were targeted as precursors to the naphthoquinone nucleus of damavaricin D; compound **22** ultimately was used in the successful total synthesis. The synthesis of **22** features the Diels–Alder reaction of the oxygenated diene **5** and 2,6-dibromo-3-methylbenzoquinone **6** to establish the core naphthalenic unit. The quinone was protected throughout this synthesis as a 1,4-bis-methoxymethyl-1,4-dihydroquinone (see **36**). The C-2-carboalkoxy group of **22** was added by carboxylation of the aryllithium intermediate generated from **36**, and protected as a β-trimethylsilylethyl ester. Finally, the C-8-Br substituent was introduced by NBS bromination of **38**. This reaction proceeds by way of bromobenzocyclohexadienone **39**. Related bromobenzo-cyclohexadienones **13** and **29** were observed in the NBS brominations of the highly functionalized β-naphthyl MOM ethers **11** and **28**. The bromobenzocyclohexadienones **29** and **39** undergo facile substitution reactions with chloride ion and reduction with bromide ion at rates competitive with base-promoted aromatization. The surprising kinetic stability of these intermediates is attributed to a combination of steric and stereoelectronic factors.

Key words: damavaricin D, naphthoate precursors, kinetically stable benzocyclohexadienones, aromatic bromination.

Résumé : On a réalisé des synthèses sélectives des bromonaphtoates hautement substitués **4a**, **4b**, **19** et **22**. Ces composés pourraient servir de précurseurs du noyau naphtoquinone de la damavaricine D; dans la synthèse totale, on a finalement utilisé avec succès le composé **22**. La synthèse du composé **22** implique une réaction de Diels–Alder du diène oxygéné **5** et de la 2,6-dibromo-3-méthylbenzoquinone (**6**) pour obtenir l'unité naphtalénique fondamentale. La quinone a été protégée durant toute la synthèse sous la forme d'une 1,4-bis-méthoxyméthyl-1,4-dihydroquinone (voir **36**). Le groupe C-2-carboalkoxy du composé **22** a été ajouté par carboxylation de l'intermédiaire aryllithium généré à partir du composé **36** et il a été protégé sous la forme d'un ester β-triméthylsilyléthyle. Enfin, le substituant C-8-Br a été introduit par une bromation du composé **38** à l'aide de la NBS. Cette réaction se produit par l'intermédiaire de la bromobenzocyclohexadiénone **39**. On a aussi observé la présence des bromobenzocyclohexadiénones **13** et **29** lors des bromations par le NBS des éthers β-naphtylés hautement fonctionnalisés **11** et **28**. Les bromobenzocyclohexadiénones **29** et **39** donnent des réactions faciles de substitutions avec l'ion chlorure et de réduction avec l'ion bromure, avec des vitesses qui sont en compétition avec l'aromatisation catalysée par les bases. On attribue la stabilité cinétique surprenante de ces intermédiaires à une combinaison de facteurs stériques et stéréoélectroniques.

Mots clés : damavaricine D, précurseurs naphtoates, benzocyclohexadiénones cinétiquement stables, bromation aromatique.

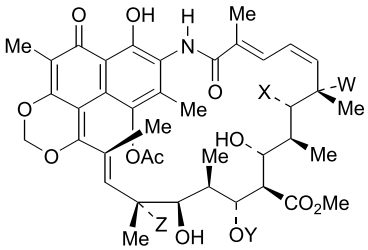
interest as potential antiviral agents owing to their ability to inhibit RNA-directed DNA polymerase (i.e., reverse transcriptase) (3–7).

The stereochemistry of streptovaricin C (SvC) was assigned based on the X-ray analysis of a *p*-bromobenzeneboronate derivative (8,[2] 9). The stereochemical assignments for the remaining streptovaricins are based on chemical and biosynthetic interconversions and spectroscopic correlations to SvC (2, 10, 11). Chemical degradations performed on the streptovaricins led to additional interesting products. For example, treatment of streptovaricin D (SvD) with ammonia in methanol provided damavaricin D (DmD) (11). Interestingly, DmD was later found to be a biosynthetic precursor of all of the more highly functionalized members of the streptovaricin family (2, 11). The damavaricins retain many of the important biological properties of the streptovaricin family (4–7).

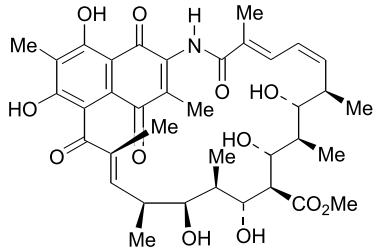
Several studies on the synthesis of streptovaricins A, D, and G (12–20) streptovaricin U (an early stage biosynthetic precursor) (21, 22), and damavaricin D (23) have been reported. We initiated studies on the synthesis of the streptovaricin D ansa chain in 1988 (24). However, in view of the structural complexity and chemical sensitivity (11) of the quinone methide unit of the streptovaricins, we decided to focus our efforts on the structurally simpler damavaricins in hopes that a late-stage, biomimetic conversion of the damavaricins to the streptovaricins could be developed. While the latter goal has not yet been realized, we have developed a total synthesis of damavaricin D (DmD) (25). Our DmD synthesis is the only synthesis of any member of the streptovaricin or damavaricin family completed to date.



We report herein the details of our synthesis of highly functionalized naphthoate precursors to DmD, including our observations of kinetically stable benzocyclohexadienone intermediates in the bromination of highly functionalized β-naphthol derivatives. Preliminary accounts of this work have been published (25–27). The full details of our synthesis of the fully elaborated ansa chain fragments as well as the successful fragment assembly and deprotection sequence culminating in the total synthesis of DmD will be reported elsewhere.[3]

Results and discussion

Initial synthetic strategy



In planning the synthesis of DmD, we hoped to achieve as much convergence as possible by postponing the coupling of the aromatic unit to the ansa chain until late in the synthesis and therefore initially targeted intermediates **1** and **2** (24) for these purposes (Scheme 3). The naphthalenic ring systems of many members of the rifamycin, streptovaricin, and damavaricin families have been assembled by routes involving Diels–Alder reactions (13, 22, 28–32). Indeed, Trost and

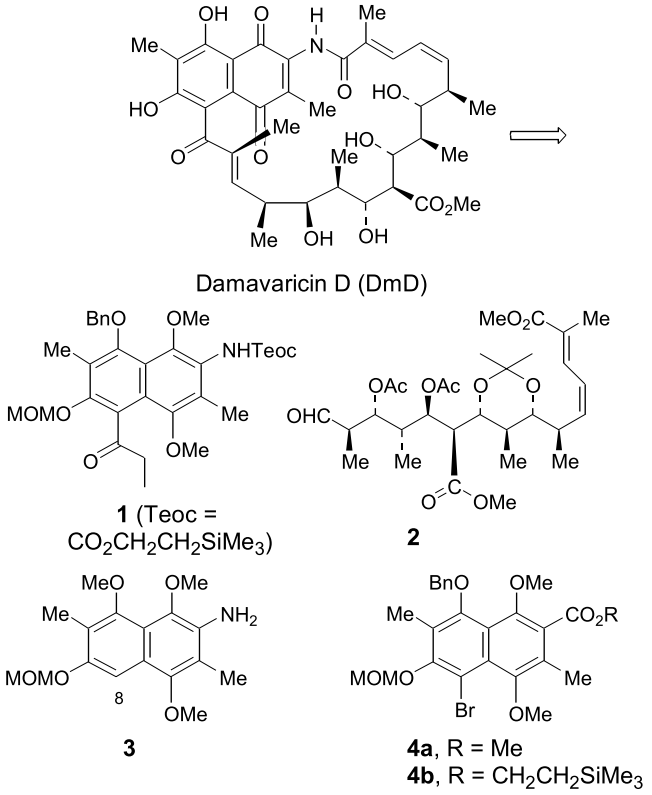
Damavaricin D (DmD)

Pearson (13) had reported an extremely brief Diels–Alder based synthesis of naphthyl amine **3** (33), and we hoped that we would be able to adopt their route for preparation of **1**. However, we experienced difficulties in attempts to introduce the aniline unit according to the Trost–Pearson protocol, and the Wisconsin group had also been unable to introduce an ethyl ketone substituent at C-8 on intermediates deriving from **3** (34).[4] Consequently, we decided to target the bromonaphthoate **4a** as a precursor to **1**. We anticipated that the C-8-Br substituent would provide the means to introduce C-8 ethyl ketone, and that the protected aniline unit of **1** would be elaborated by a Curtius degradation of the carbomethoxyl group.

*Synthesis of bromo naphthoate (**4a**)*

The synthesis of bromonaphthoate **4a** commenced with the known (13) Diels–Alder reaction of the oxygenated diene **5** (13) and 2,6-dibromo-3-methylbenzoquinone **6** (35). This provided the crystalline cycloadduct **7** in 70–75% yield (Scheme 4). Although the regiochemistry of the Diels–Alder reactions of highly oxygenated dienes and substituted quinones has been extensively documented by Roberge and Brassard (36), we felt it necessary to confirm the regio-



[2] The stereochemistry at C-6 and C-7 of SvC are drawn incorrectly in the two-dimensional structure presented in this paper; the stereoscopic views, however, are correct. The SvC derivative reported in this paper is also in the unnatural atropisomeric configuration (see K.L. Rinehart, Jr., W.M. J. Knöll, K. Kakinuma, F.J. Antosz, I.C. Paul, A.H.-J. Wang, F. Reusser, L.H. Li, and W.C. Krueger. J. Am. Chem. Soc. **97**, 196 (1975)).

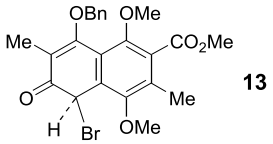
Scheme 4.

chemistry of the reaction leading to **7** before proceeding with the synthesis. Accordingly, we established that the Diels–Alder reaction of **5** and **6** does indeed provide **7** with the correct regioselectivity by performing long-range selective ^{1}H NMR decoupling experiments (37) on the derived MOM ether **8** (which was prepared according to Trost's procedure) (13). The gated decoupled ^{13}C NMR spectrum of **8** displays the C-4 carbonyl carbon as a singlet (δ 181.3) and the C-1 carbonyl carbon as a quintet (δ 181.0, J = 17 Hz). Irradiation of the C-2-Me causes the C-1 carbonyl to collapse to a doublet, while irradiation of the C-8-H caused the C-1 carbonyl to simplify to a quartet.

At this stage, we departed from Trost's sequence, in anticipation that the C-5 methyl ether (see **3**) would not be easy to deprotect deeper into the synthesis. Rather, we decided to protect the C-5-phenol as a benzyl ether, which was accomplished by treatment of **8** with excess benzyl bromide and Ag_2O in $CHCl_3$. Attempted use of other conventional methods for introducing the benzyl ether were unsuccessful. The resulting quinone **9** was reduced by using $NaBH_4$ and $CeCl_3$ (38) in dioxane and the resulting (air sensitive!) 1,4-dihydroquinone was methylated in situ by treatment with Me_2SO_4 and 50% aq NaOH, with careful exclusion of O_2 (13). This one-pot reduction–methylation procedure provided the 1,4-di-*O*-methyldihydroquinone **10** in 89% yield. Next, treatment of **10** with *n*-BuLi in THF at –78°C followed by addition of methyl chloroformate provided naphthoate **11** in 98% yield.



We were now ready to explore the introduction of the C-8 ethyl ketone fragment of **1**. However, attempts to accomplish this reaction by Friedel–Crafts acylation of **11** with propionyl chloride and BF_3 or $AlCl_3$, or by Fries rearrangement of the propionate ester prepared after hydrolysis of the MOM ether, were unproductive. Consequently, we turned to a bromination sequence to introduce a functional group handle at C-8 to facilitate introduction of the targeted ethyl ketone. Accordingly, intermediate **11** was brominated at C-8 by exposure to NBS in $CHCl_3$ at reflux. Chromatographic purification of the crude reaction product afforded the bromophenol **12**, and not the expected bromo MOM ether **4a**. Therefore, the MOM ether was reintroduced by treatment of **12** with MOM-Cl and Hunig's base.

Interestingly, ^{1}H NMR analysis of the crude NBS bromination product mixture (prior to chromatographic purification) revealed that **12** was not present! Rather, the spectrum of the crude product exhibited a sharp, one proton singlet at δ 5.55, and an AB pattern for the benzyl -CH_2 unit, indicating that the molecule possessed a center of asymmetry. These data, plus the observation that treatment of the crude, unchromatographed product with MOM-Cl and Hunig's base provided the phenolic MOM ether **4a** in 84% overall yield, led us to conclude that the initial intermediate observed in the crude reaction mixture was the benzocyclohexadienone **13** (Scheme 5). While it is known that bromocyclohexadienones are intermediates in the bromination of phenols, these compounds are usually transient intermediates and rapidly isomerize to the corresponding bromophenols (39–43). We were not aware of any previous reports of cyclohexadienone intermediates in the bromination reactions of phenolic ethers; additional encounters with intermediates of this type are described subsequently.

The synthesis of the initially targeted napthyl ethyl ketone **1** was completed as follows (see Scheme 6). A –100°C solution of **4a** in THF was treated with *n*-BuLi for 3 min, then

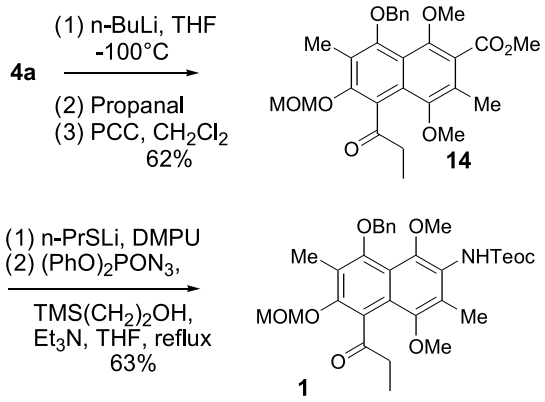
Scheme 5.



propionaldehyde was added (44). The resulting benzylic alcohol, obtained in 80% yield, was oxidized using PCC to give ethyl ketone **14** in 77% yield. Finally, deprotection of the methoxycarbonyl unit of **14** by treatment with *n*-PrSLi in DMPU (45),[5] followed by Curtius rearrangement of the resulting acid using the Shiori protocol ($(PhO)_2PON_3$, Et_3N, THF, reflux) (46) in the presence of 2-trimethylsilyl ethanol provided the targeted ethyl ketone **1** in 63% yield.

*Synthesis of bromo naphthoate (**4b**)*

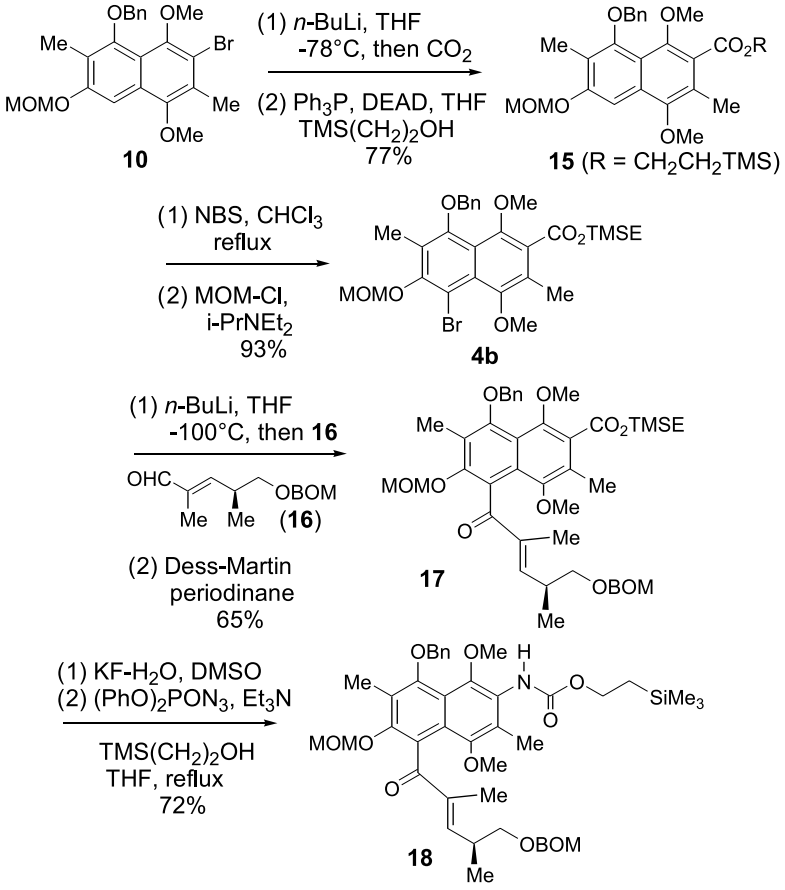
We originally planned to perform an aldol reaction between **1** and the damavaricin ansa chain, represented by aldehyde **2**, as part of the late stage fragment assembly sequence. However, preliminary attempts to perform aldol reactions between **1** or **14** and simpler model aldehydes were unpromising. This necessitated that we reconsider our options for coupling of the advanced ansa chain and aromatic segment precursors. Because we had successfully demonstrated that the aryllithium generated from **4a** could be added efficiently to propionaldehyde (en route to **14**), our strategy refocused on use of a fully elaborated α,β-unsaturated ansa chain aldehyde in a coupling reaction with **4a**. However, because deprotection of the methyl ester of **14** was challenging owing to the steric hindrance imposed by the two flanking aromatic substituents, we decided to synthesize bromonaphthoate **4b** that contained a trimethylsilylethyl (TMSE) ester, which we anticipated could be deprotected under much milder conditions than the methyl ester of **4a**.

The synthesis of bromonaphthoate **4b** (Scheme 7) began by carboxylation of the aryllithium intermediate generated from **10**, followed by conversion of the resulting carboxylic acid to the β-trimethylsilyl ethyl ester under Mitsunobu conditions (47). This two-step sequence provided **15** in 77% yield from **10**. Intermediate **15** was brominated by using the conditions described for the synthesis of **11**, and **4b** was obtained in 93% yield after reintroduction of the MOM ether that was lost during the NBS bromination step. To gain confidence that these intermediates might be suitable for eventual coupling with the ansa chain fragment, bromonaphthoate **4b** was metallated by treatment with *n*-BuLi in THF at –100°C, and the resulting aryllithium intermediate was added to the model α,β-unsaturated aldehyde **16**. Oxidation of the resulting mixture of diastereomers with the Dess–Martin periodinane reagent then provided enone **17** in 65% overall yield (48). Finally, deprotection of the β-trimethylsilyl ethyl ester of **17** by treatment with KF-dihydrate in DMSO (23°C, 70 h) and then Curtius degradation (46) of the intermediate carboxylic acid in the presence of β-trimethylsilyl ethanol, then provided **18** in 72% yield. Enones **17** and **18** were obtained as ca. 1:1 mixtures of atropisomers. Variable temperature ^1H NMR studies performed with **17** indicated that the coalescence temperature for the equilibration of the two atropisomers was approximately 125°C, suggesting the barrier to rotation about the aryl—acyl bond is on the order of 20 kcal mol^{-1} (for general reviews of atropisomerism see ref. 49).

Scheme 6.

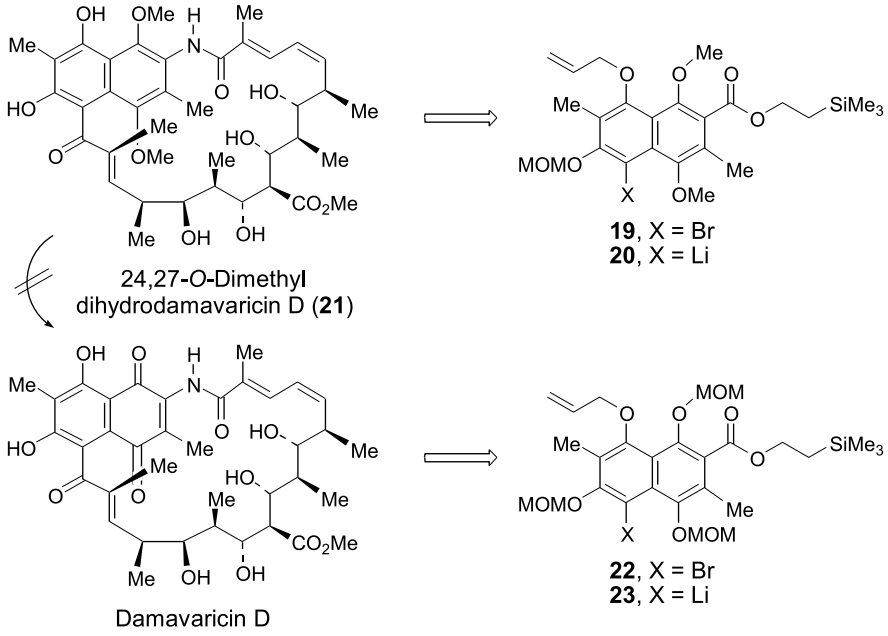
Revised protecting group scheme

As the synthesis of damavaricin D continued to progress, it became apparent that the benzyl ether used to protect the C-5-phenol could not be removed in the presence of the diene function present in late-stage intermediates. Therefore, an initial, conservative change involved replacing the C-5-benzyl ether with an allyl ether, which we anticipated could be deprotected by using Pd(0)-mediated methods (50). Bromonaphthoate **19** indeed proved useful for the synthesis of 24,27-di-*O*-methyl damavaricin D (**21**), by way of the derived aryllithium intermediate **20** (Scheme 8) (27). However, we were unable to complete a total synthesis of damavaricin D via **21** or its immediate precursors owing to an unexpected oxidative cyclization reaction that occurred during attempts to convert the di-*O*-methyl-1,4-dihydroquinone oxidatively to the quinone nucleus of the natural product. For example, attempted CAN-mediated oxidative deprotection (51) of **24**, an immediate precursor to **21**, provided the interesting but synthetically unproductive (i.e., unstable) heterocycle **25** (Scheme 9) (27). In view of these difficulties, it ultimately proved necessary to use naphthoate **22** with the dihydroquinone protected as the nonconventional bis-MOM ether for completion of the damavaricin D total synthesis (25). We present syntheses for both **19** and **22** here, as kinetically stable benzocyclohexadienone intermediates were observed in each case.



*Synthesis of bromo naphthoate (**19**)*

The synthesis of naphthoate **19** (Scheme 10) originated from the mono-protected bromo naphthoquinone **8** (13). Treatment of **8** with allyl bromide and Ag_2O in $CHCl_3$ provided allyl ether **26** in 86% yield. Reduction of the quinone under Luche conditions (13, 38) followed by in situ methylation of the air-sensitive hydroquinone with Me_2SO_4 and 50% aq NaOH then provided **27** in 84% yield. Metal halogen exchange by treatment of **27** with *n*-BuLi in THF at



[5] We substituted DMPU for the more hazardous HMPA.

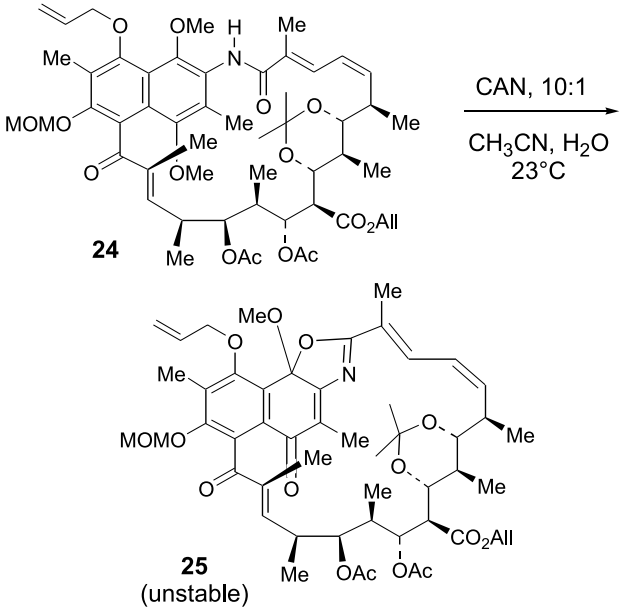
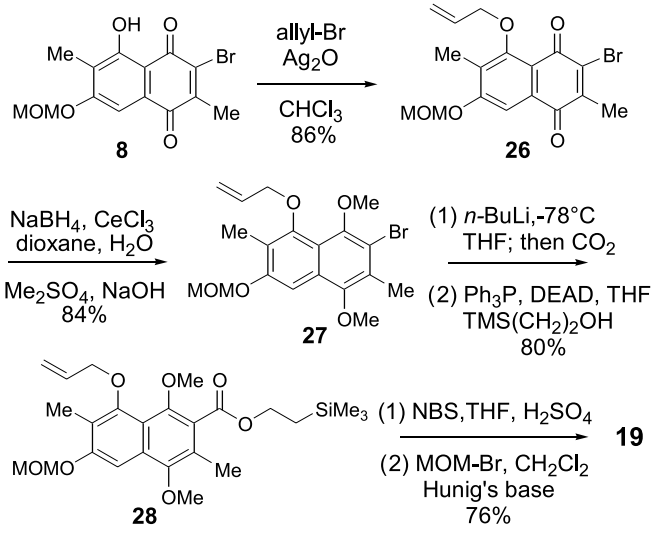
Scheme 7.



Scheme 8.



–78°C followed by carboxylation of the aryllithium intermediate with dry CO_2 gave the carboxylic acid. Esterification of this intermediate with β-trimethylsilylethanol by using the Mitsunobu protocol yielded naphthoate **28** in 80% yield (47). Finally, bromination of **28** with NBS in THF containing catalytic H_2SO_4 (52) and reintroduction of the MOM

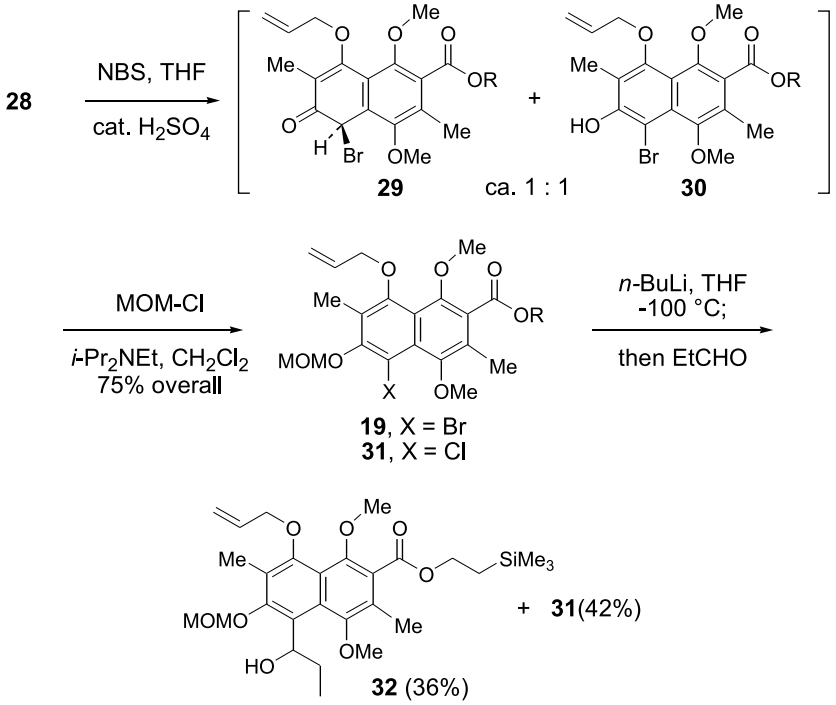
Scheme 9.

Scheme 10.

group that was lost during the bromination step provided the bromonaphthoate **19** in 76% yield. It proved necessary to use *MOM-Br* and Hunig's base to reintroduce the MOM group, as discussed in the following paragraph.

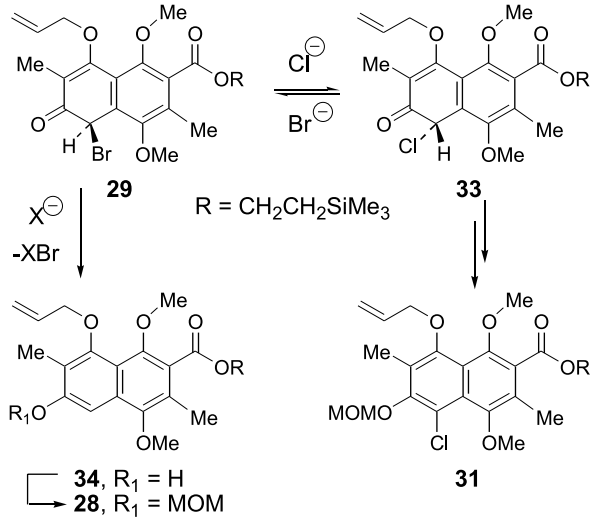
^{1}H NMR analysis of the crude product obtained from the NBS bromination of **28** (before reintroduction of the MOM ether!) indicated that this material consisted of a ca. 1:1 mixture of the bromobenzocyclohexadienone **29** and bromophenol **30** (Scheme 11). When this mixture was treated with MOM-Cl and Hunig's base, using the protocol followed in the preparation of **4a**, a chromatographically inseparable 1:1 mixture of naphthyl bromide **19** and *naphthyl chloride* **31** was obtained. That chloride **31** was the second product of the bromination–protection sequence became obvious after a 1:1 mixture of **19** and **31** was treated with 1 equiv of *n*-BuLi in THF at –100°C, followed by addition of propionaldehyde at –78°C. This reaction provided benzylic alcohol **32** in 36% yield, along with recovered chloride **31** in 42% yield. When the mixture of **29** and **30** was purified by silica gel chromatography, **29** was not completely converted to **30**; treatment of the chromatographed sample with MOM-Cl and Hunig's base provided **19** with about 90% purity, the remainder being chloride **31**. Consequently, the best method for synthesis of **19** involved treatment of the **29** and **30** mixture with MOM-Br and Hunig's base, so that there was no opportunity for **29** to react with chloride ion to give the corresponding α-chlorobenzocyclohexadienone **33** prior to the aromatization reaction (see Scheme 12). Interestingly, in several instances small amounts of **28** were also recovered from these experiments, even though ^{1}H NMR analysis indicated that **28** and the corresponding phenol **34** were completely absent from the crude bromination product mixture. This indicates that the C—Br bond of bromobenzocyclohexadienone **29** is subject to reduction (40) as well as displacement by halide ions.



Synthesis of bromo naphthoate (22)

The synthesis of bromonaphthoate **22** (Scheme 13) originated from bromoquinone **26**. It was necessary to replace the MOM ether by a *tert*-butyldiphenylsilyl (TBDPS) ether at the outset, since we found that the bromination reaction leading to **22** was successful only when the C-7-phenol was unprotected. However, attempts to prepare **35** directly from the Diels–Alder adduct **7** were unsuccessful. Therefore, cleavage of the MOM ether of **26** by using *p*-TsOH in MeOH gave the corresponding phenol which was reprotected as a TBDPS ether under standard conditions. Reduction of the quinone and protection of the very sensitive dihydroquinone as a bis-MOM ether proved to be quite challenging, much more so than the reductive protections of intermediates **9** and **26** previously described. Ultimately, we found that the reduction of **35** was best accomplished by using dithionite in an aqueous dichloromethane mixture containing Adogen 464 as a phase transfer agent (53). Addition of aq NaOH and MOM-Cl to the reduction mixture then provided the protected dihydroquinone **36** in 82% overall yield. Elaboration of **36** to the naphthoate **37** proceeded smoothly (77% yield) using the conditions described for the synthesis of **15**. At this stage, the TBDPS protecting group was removed by using $Et_3N{\cdot}HF$ in CH_3CN, giving phenol **38** in 98% yield.

Bromination of phenol **38** was best accomplished by treatment with NBS in $CHCl_3$ at ambient temperature. In this case, the bromobenzocyclohexadienone **39** was the exclusive product obtained following extractive work-up (42). The ^{1}H NMR spectrum of this intermediate contained a sharp, one proton singlet at δ 5.60, assigned to the α-bromo ketone methine, and the two MOM methylene resonances appeared as AB patterns. The ^{13}C NMR spectrum exhibited a resonance at δ 193.4 assigned to the ketone carbonyl (the ester carbonyl resonance appears at δ 166–170 in **38**, **39**, and immediate precursors), and the IR spectrum contained two carbonyl bands (1725 and 1672 cm^{-1}). When **39** was exposed to silica gel, partial aromatization to phenol **40** occurred, with the ratio of **39**:**40** depending on the time of exposure. Under optimal chromatographic conditions (10% EtOAc–hexane), a 1:1 mixture of **39**:**40** was obtained. However, treatment of this mixture with MOM-Br and Hunig's base under the condi-

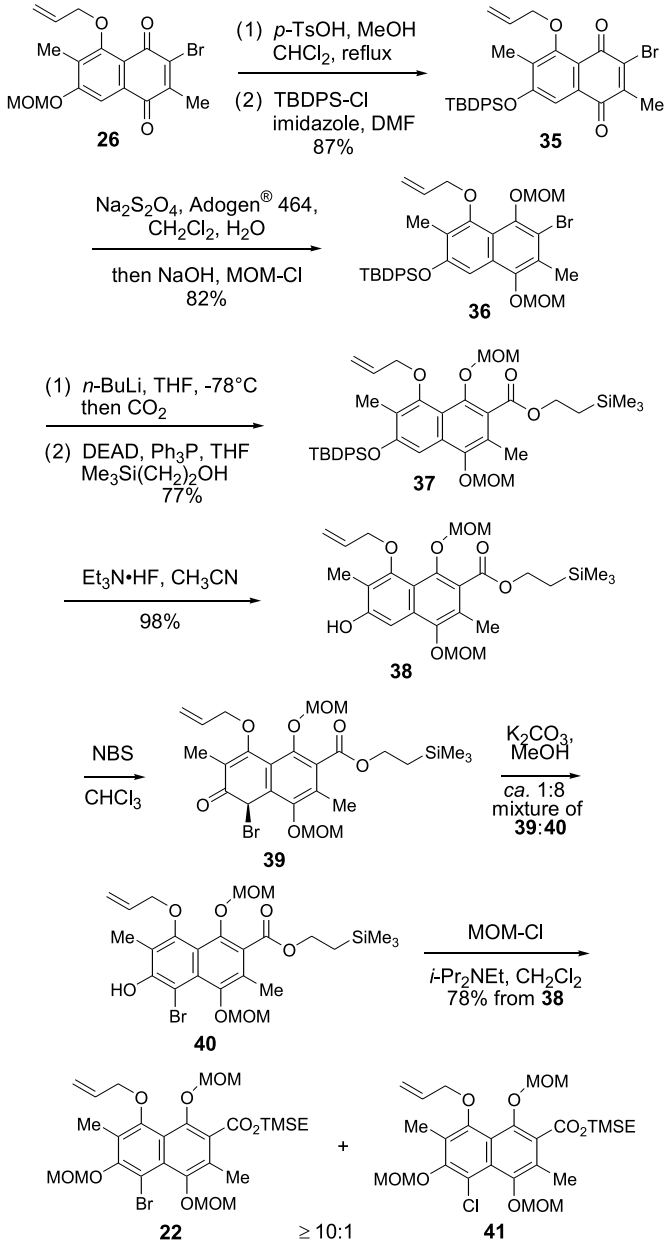


© 2001 NRC Canada

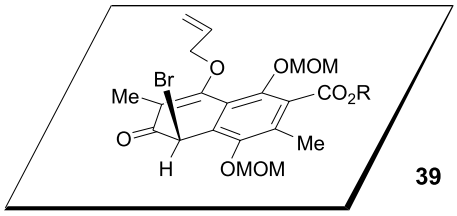
Scheme 11.

tions successfully employed in the preparation of **19** gave **22** in only 40–50% yield, with considerable quantities of the MOM ether of **38** (resulting from reduction of **39**) also being produced. Ultimately, the best method for conversion of **39** to **22** involved treatment of **39** with K_2CO_3 in MeOH, which provided a ca. 8:1 mixture of phenol **40** and the keto tautomer **39**. This mixture was then treated with MOM-Cl and *i*-Pr_2NEt in CH_2Cl_2, which provided a ≥10:1 mixture (inseparable) of the fully protected bromonaphthoate **22** and the corresponding chloronaphthoate **41** in 78% yield overall from **38**. Naphthyl bromide prepared in this way was used for completion of the damavaricin synthesis (25). While production of **41** could be avoided by using MOM-Br in the final protection step, the yield of **22** was considerably lower owing to the reduction of **39** that occurs under these conditions.

Scheme 12.



Concerning the kinetic stability of the bromo benzocyclohexadienone intermediates



The kinetic stability of the bromo benzocyclohexadienones **13**, **29**, and especially **39** is attributable both to steric effects which slow the rate of enolization to the phenols (39), as well as to stereoelectronic effects. Specifically, allylic strain considerations (54) dictate that the bromine substituent should preferentially adopt a pseudoaxial position on the benzocyclohexadienone ring to avoid 1,3-interactions with the peri-MOM ether unit (43). This imposes an additional kinetic barrier on the enolization process, since the carbonyl α-hydrogen is in the plane of the σ system; for this proton to be removed, it must be aligned with the π system of the carbonyl. This conformational picture also nicely explains the high reactivity of **29** and **39** with chloride ion, as well as the propensity of **29** and **39** to be reduced with bromide ion. While bromobenzocyclohexadienones **13**, **29**, and **39** might be expected to be considerably less stable than their phenolic isomers **12**, **30**, and **40**, the evidence reported here for the **29**/**30** and **39**/**40** pairs suggests that the energy difference between the two tautomers is not particularly great. Presumably, both torsional strain in the phenol tautomer **40**, due to the high density of substituents on the naphthalene nucleus, plus the fact that the β-alkoxy enone unit of the benzocyclohexadienone is resonance stabilized contribute to this situation. To the best of our knowledge, the substitution reactions of **29** and **39** with chloride ion are the first documented examples of reactions of enolizable bromobenzocyclohexadienone intermediates.

Scheme 14.

Experimental section

General

All reactions were conducted in oven-dried (125°C) or flame-dried glassware under dry argon or nitrogen. All solvents were purified before use. Ether and THF were distilled from sodium benzophenone ketyl. Dichloromethane (CH_2Cl_2), toluene, and acetonitrile were distilled from CaH_2. Methanol was distilled from magnesium turnings.

^{1}H NMR spectra were measured at 400 MHz on a Varian VNMR 400 instrument or at 500 MHz on a Varian Inova 500 instrument. Chemical shifts are reported in δ units with coupling constants reported in Hz. Residual chloroform (δ 7.26 ppm) was used as internal reference for spectra measured in $CDCl_3$. ^{1}H NMR spectra measured in C_6D_6 were referenced against residual C_6D_5H (δ 7.15). ^{13}C NMR spectra were recorded at 100 MHz. Chemical shifts are reported relative the δ 77.0 ppm resonance of $CDCl_3$ or the δ 128.0 ppm resonance of C_6D_6.

Infrared spectra were recorded using a Mattson Instruments 4020 Galaxy Series FT IR spectrophotometer. High-resolution mass spectra (HRMS) for intermediates with molecular weights ≤900 and low-resolution mass spectra (LRMS) were recorded using a Kratos GC–MS 80 RFA mass spectrometer under electrically or chemically induced ionization at the Indiana University Mass Spectrometry Laboratory. High-resolution mass spectra (HRMS) for intermediates with molecular weights ≥900 were recorded in the Mass Spectrometry Laboratory, School of Chemical Sciences, University of Illinois using a ZAB-SE mass spectrometer, which was purchased in part with grants from the Division of Research Resources, National Institutes of Health (RR 01575), the National Science Foundation (PCM 8121494), and the National Institute of General Medical Sciences (GM 27029). Optical rotations were measured on a Rudolph Autopol III polarimeter using a 1 mL capacity quartz cell with a 10 cm path length. Elemental analyses were performed by Robertson Microlit Laboratories, Inc., Madison, N.J.

Analytical and semipreparative HPLC separations were performed by using an HPLC system composed of two Rainin HXPL pumps (gradient), a Rheodyne 7125 injector, a Dynamax UV-C detector, and a Shimadzu CR601 integrator. Analytical thin layer chromatography (TLC) was performed by using plates coated with a 0.25-mm thickness of silica gel containing PF 254 indicator (Analtech). Compounds were visualized by staining (and charring) of the TLC plates with a solution of ceric sulfate and ammonium molybdate in aqueous sulfuric acid or with a solution of *o*-vanillin in ethanol with acetic and sulfuric acid. Flash chromatography was performed as described by Still et al. (55) using Kieselgel 60 (230–400 mesh) silica gel. Unless otherwise noted, all compounds purified by chromatography are sufficiently pure (>95% by ^{1}H NMR analysis) for use in subsequent reactions.

*5-Benzyloxy-3-bromo-7-methoxymethoxy-2,6-dimethyl-1,4-naphthoquinone (***9***)*

To a 0°C solution of benzyl bromide (3.10 mL, 25.9 mmol) in $CHCl_3$ (80 mL) and silver oxide (7.50 g, 32.3 mmol) was added a solution of phenol **8** (13, 33) (2.20 g, 6.5 mmol) in $CHCl_3$ (40 mL) dropwise via canula. The resulting slurry was stirred for 24 h at 23°C. The reaction mixture was then filtered through a pad of Celite®, which was washed with EtOAc (2 × 100 mL). The filtrate was concentrated in vacuo and the crude benzyl ether was purified by flash chromatography with 15% EtOAc–hexanes

*5-Benzyloxy-3-bromo-1,4-dimethoxy-7-methoxymethoxy-2,6-dimethoxy naphthalene (**10**)*

To a solution of quinone **9** (2.45 g, 5.7 mmol) in dioxane (50 mL) and H_2O (25 mL) was added $CeCl_3 \cdot 7H_2O$ (3.2 g, 8.5 mmol). The reaction mixture was cooled to 0°C and $NaBH_4$ (395 mg, 10.4 mmol) was added in portions over 15 min. During this time the bright yellow color of the quinone disappeared. After H_2 evolution had ceased, the reaction was warmed to 23°C, 15 mL of Me_2SO_4 was added, and the flask was evacuated and filled with Ar. NaOH (50% aqueous, 3 mL) was added dropwise over 15 min. The reaction mixture was stirred at 23°C for 1 h, cooled to 0°C, and concd NH_4OH (50 mL) and ether (250 mL) were added. The organic layer was washed with 1:1 concd NH_4OH–H_2O (2 × 300 mL), brine (1 × 300 mL), dried over $MgSO_4$, filtered, and concentrated in vacuo. Purification of the residual oil by flash chromatography with 10% ether–hexane afforded dimethyl ether **10** (2.34 g, 89% yield) as a light yellow oil. HRMS calcd. for $C_{23}H_{25}BrO_5$ (M^+): 462.0855; found: 462.0836. IR ($CHCl_3$) (cm^{-1}): 3005, 2920, 1615, 1580, 1560, 1480, 1450, 1410, 1380, 1350, 1320, 1250, 1150, 1120, 1070, 1030. ^1H NMR (300 MHz, $CDCl_3$) δ: 7.71–7.28 (m, 6H), 5.36 (s, 2H), 4.91 (s, 2H), 3.85 (s, 3H), 3.79 (s, 3H), 3.54 (s, 3H), 2.52 (s, 3H), 2.35 (s, 3H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 155.0, 152.4, 149.8, 148.6, 137.8, 128.7, 128.4, 128.3, 127.8, 127.2, 122.2, 118.4, 117.4, 100.0, 94.6, 76.4, 61.8, 61.0, 56.1, 16.8, 9.7. Anal. calcd. for $C_{23}H_{25}BrO_5$: C 60.13, H 5.43; found: C 59.87, H 5.30.

*5-Benzyloxy-3-carbomethoxy-1,4-dimethoxy-7-methoxymethoxy-2,6-dimethylnaphathalene (**11**)*

To a cold (–78°C) solution of bromide **10** (2.40 g, 5.2 mmol) in THF (50 mL), was added *n*-BuLi (2.5 M, 4.23 mL, 6.8 mmol). The mixture was stirred at –78°C for 15 min. The resulting dark red-yellow anion solution was then treated with methyl chloroformate (0.53 mL, 6.8 mmol) and the resulting mixture was gradually warmed to room temperature over a 4 h period. The reaction mixture was quenched with H_2O (25 mL) and diluted with ether (150 mL). The organic layer was separated, dried with $MgSO_4$, filtered, and concentrated in vacuo to a light yellow oil. Purification of the crude product by flash chromatography with 20% ether–hexane afforded ester **11** (2.28 g, 98% yield) as a clear oil. HRMS calcd. for $C_{25}H_{28}O_7$ (M^+): 440.1835; found: 440.1854. IR ($CHCl_3$) (cm^{-1}): 3020, 2955, 2945, 1725, 1610, 1440, 1340, 1240, 1130, 1070, 1010. ^1H NMR (400 MHz, $CDCl_3$) δ: 7.56–7.35 (m, 6H), 5.37 (s, 2H), 4.89 (s, 2H), 3.89 (s, 3H), 3.84 (s, 3H), 3.54 (s, 3H), 2.34 (s, 3H), 2.32 (s, 3H). Anal. calcd. for $C_{25}H_{28}O_7$: C 68.15, H 6.42; found: C 67.92, H 6.25.

*5-Benzyloxy-8-bromo-3-carbomethoxy-1,4-dimethoxy-7-methoxy-1,4-dimethylnaphthalene (**4a**)*

To a solution of the naphthoate **11** (7.48 g, 17.0 mmol) in $CHCl_3$ (110 mL) was added *N*-bromosuccinimide (3.93 g, 22.0 mmol) in portions over 15 min. The resulting solution was heated at reflux for 6 h at which point the mixture was cooled and diluted with CH_2Cl_2 (150 mL). The organic layer was washed with satd. $NaHSO_3$ (50 mL), dried over $MgSO_4$, filtered, and concentrated in vacuo. The crude oil, consisting primarily of the bromobenzocyclohexadienone **13** (^1H NMR (400 MHz, $CDCl_3$) δ: 7.44–7.34 (m, 5H), 5.55 (s, 1 H), 5.15 and 4.76 (AB, J = 12 Hz), 3.97 (s, 3H), 3.94 (s, 3 H), 3.73 (s, 3H), 2.26 (s, 3H) and 1.80 (s, 3H)) was dissolved in CH_2Cl_2 (150 mL). To the resulting solution was added diisopropylethylamine (4.44 mL, 25.0 mmol) and MOM-Cl (1.68 mL, 22.0 mmol). This mixture was stirred at 23°C for 4 h, then diluted with ether (400 mL). The organic layer was washed with 1 M $NaHSO_4$ (150 mL), satd. $NaHCO_3$ solution (150 mL), and brine (150 mL), then dried over $MgSO_4$, and concentrated in vacuo. The crude residue was purified by flash chromatography with 15% ether–hexane affording bromonaphthoate **4a** (7.40 g, 84% yield) as a thick yellow oil. HRMS calcd. for $C_{25}H_{27}O_7Br$ (M^+): 518.0941; found: 518.0919. IR ($CDCl_3$) (cm^{-1}): 2960, 2640, 1735, 1600, 1450, 1435, 1335, 1315, 1250, 1120, 1060, 1010. ^1H NMR (400 MHz, $CDCl_3$) δ: 7.51–7.35 (m, 5H), 5.19 (s, 2H), 4.85 (s, 2H), 3.99 (s, 3H), 3.76 (s, 3H), 3.71 (s, 3H), 3.69 (s, 3H), 2.42 (s, 3H), 2.37 (s, 3H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 168.2, 155.1, 152.9, 150.2, 148.1, 137.2, 128.4, 128.1, 127.9, 127.7, 126.0, 125.9, 121.1, 105.9, 100.1, 76.6, 64.1, 61.7, 57.9, 52.3, 13.2, 11.3. Anal. calcd. for $C_{25}H_{27}O_7Br$: C 57.78, H 5.25; found: C 58.09, H 4.96.

If the bromination reaction mixture was purified by silica gel chromatography prior to being treated with MOM-Cl and diisopropylethylamine, phenol **12** was obtained. ^1H NMR (400 MHz, $CDCl_3$) δ: 7.52–7.34 (m, 5H), 6.80 (s, 1 H), 4.84 (s, 2H), 3.99 (s, 3H), 3.76 (s, 3H), 3.70 (s, 3H), 2.36 (s, 6H).

*5-Benzyloxy-3-carbomethoxy-1,4-dimethoxy-7-methoxymethoxy-2,6-dimethyl-(8-propan-1′-one)naphthalene (**14**)*

To a solution of bromide **4a** (572 mg, 1.1 mmol) in THF (8 mL) at –100°C was added *n*-BuLi (2.5 M, 0.55 mL, 1.3 mmol). The resulting deep orange solution was stirred for 3 min at which point propanal (0.11 mL, 1.4 mmol) was added. The reaction mixture was warmed to 0°C, diluted with ether (40 mL) and brine (15 mL). The organic layer was separated, dried with $MgSO_4$, and concentrated in vacuo. The crude alcohol was purified by chromatography on silica gel with 20–50% ether–hexane giving the intermediate benzylic alcohol (428 mg, 80% yield) as light yellow oil. HRMS calcd. for $C_{28}H_{34}O_8$ (M^+): 498.2254; found: 498.2236. IR ($CDCl_3$) (cm^{-1}): 3500 (br), 3020, 3010, 2960, 2940, 1710, 1435, 1415, 1220, 1160, 1110, 1090, 1055, 1010, 910. ^1H NMR (500 MHz, $CDCl_3$) δ: 7.49–7.32 (m, 5H), 5.67–5.62 (m, 1H), 5.20 and 5.11 (AB, J = 5.6 Hz, 2H), 4.87 and 4.82 (AB, J = 10.4 Hz, 2H), 4.34 (d, J = 11.4 Hz, 1H), 3.98 (s, 3H), 3.75 (s, 3H), 3.71 (s, 3H), 3.65 (s, 3H), 2.35 (s, 3H), 2.30 (s, 3H), 2.13–2.01 (m, 1H), 1.89–1.79 (m, 1H), 0.93 (t, J = 7 Hz, 3H). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 168.6, 156.4, 152.7, 151.3, 148.8, 137.5, 128.6, 128.5, 128.4, 128.3, 128.0, 127.7, 127.1, 126.9, 124.5,

124.4, 120.1, 100.7, 76.5, 64.0, 61.6, 57.9, 52.3, 30.8, 13.4, 11.6, 11.3.

To a solution of the benzylic alcohol from the previous experiment (340 mg, 0.7 mmol) in CH_2Cl_2 (5 mL) was added sodium acetate (74 mg, 0.9 mmol) and pyridinium chlorochromate (186 mg, 0.9 mmol). The reaction mixture was stirred at 23°C for 26 h at which point the solution was filtered through a Celite® plug. The Celite® plug was washed with CH_2Cl_2 (3 × 20 mL). Purification of the crude product by flash chromatography with 50% ether–hexane afforded recovered benzyl alcohol (57 mg, 17%) and ethyl ketone **14** (262 mg, 77%, 94% yield based on recovered starting material) as light yellow oils. HRMS calcd. for $C_{28}H_{32}O_8$ (M^+): 496.2098; found: 496.2102. IR ($CDCl_3$) (cm^{-1}): 3005, 2940, 1725, 1695, 1605, 1580, 1560, 1480, 1450, 1440, 1410, 1390, 1350, 1330, 1210, 1160, 110, 1050, 955, 930, 910, 700. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.50–7.35 (m, 5H), 5.04 and 5.00 (AB, J = 5.6 Hz, 2H) 4.90 and 4.86 (AB, J = 10.4 Hz, 2H), 3.99 (s, 3H), 3.78 (s, 3H), 3.59 (s, 3H), 3.53 (s, 3H), 2.88 (dt, J = 18 Hz, 7.2 Hz, 1H), 2.56 (dt, J = 18 Hz, 7.2 Hz, 1H), 2.35 (s, 3H), 2.33 (s, 3H), 1.18 (t, J = 7.2 Hz, 3H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 205.1, 168.3, 153.5, 152.0, 149.4, 148.6, 137.3, 128.4, 128.0, 127.6, 127.0, 125.7, 123.5, 119.5, 101.5, 76.7, 64.2, 61.3, 57.6, 52.4, 38.3, 13.1, 10.6, 7.9.

*5-Benzyloxy-1,4-dimethoxy-7-methoxymethoxy-2,6-dimethyl-8-(propan-1′-one)-3-{*N*-[2″-(trimethylsilyl)ethoxycarbonyl] amino}naphthalene (**1**)*

To a solution of methyl ester **14** (70 mg, 0.01 mmol) in degassed DMPU (1 mL) was added a solution of lithium *n*-propylmercaptide in DMPU (ca. 0.3 M, 2.0 mL, 0.6 mmol). The resulting mixture was stirred at 23°C for 3 h at which point the solution was acidified with 1 M HCl and diluted with ethyl acetate (15 mL). The organic layer was washed with H_2O (3 × 5 mL), dried over $NaSO_4$, filtered, and concentrated in vacuo. Purification of the crude product by flash chromatography using 45% ether:50% hexane:5% acetic acid afforded the intermediate carboxylic acid (59 mg, 87% yield) as a yellow syrup. HRMS calcd. for $C_{27}H_{30}O_8$ (M^+): 482.1974; found: 482.1974. IR ($CDCl_3$) (cm^{-1}): 3500–2700 (br), 3005, 2960, 1700, 1600, 1580, 1560, 1450, 1335, 1160, 1110, 1050, 1010, 950, 910. ^{1}H NMR (500 MHz, $CDCl_3$) δ: 7.52–7.30 (m, 5H), 5.04 and 5.00 (AB, J = 5.6 Hz, 2H), 4.91 and 4.86 (AB, J = 10.4 Hz, 2H), 3.84 (s, 3H), 3.59 (s, 3H), 3.54 (s, 3H), 2.90 (dt, J = 18.2 Hz, 7.2 Hz, 1H), 2.58 (dt, J = 18.2 Hz, 7.2 Hz, 1H), 2.44 (s, 3H), 2.36 (s, 3H), 1.19 (t, J = 7.2 Hz, 3H).

To a solution of the above carboxylic acid (36 mg, 0.07 mmol) was added diphenylphosphoryl azide (20 μL, 0.08 mmol), β-trimethylsilylethanol (70 μL, 0.39 mmol), and triethylamine (15 μL, 0.1 mmol). The resulting solution was heated at reflux for 20 h. The reaction mixture was diluted with EtOAc (15 mL) and the resulting solution was extracted with 1 M HCl (1 × 5 mL) and H_2O (1 × 5 mL). The organic layer was dried with $NaSO_4$, filtered, and concentrated in vacuo. Purification of the crude product by flash chromatography with 5:1 hexane–EtOAc afforded carbamate **1** (32 mg, 73% yield) as a thick yellow oil. HRMS calcd. for $C_{32}H_{43}NO_8Si$ (M^+): 597.2759; found: 597.2746. IR ($CDCl_3$) (cm^{-1}): 3420 N-H, 3050, 2660, 2940, 1730, 1700, 1480, 1340, 1220, 1170, 1090, 1060, 1010, 950, 860, 840. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.55–7.35 (m, 5H, Bzl-*H*), 6.60 (br s, 1H, N*H*), 5.02 and 4.98 (AB, J = 5.2 Hz, 2H), 4.93 and 4.77 (AB, J = 10.4 Hz, 2H), 4.27 (t, J = 8.4 Hz, 2H, OCH_2CH_2TMS), 3.67 (s, 3H), 3.59 (s, 3H), 3.57 (s, 3H), 2.93 (dt, J = 18 Hz, 7.2 Hz, 1H), 2.60 (dt, J = 18 Hz, 7.2 Hz, 1H), 2.38 (s, 3H), 2.36 (s, 3H), 1.20 (t, J = 7.2 Hz, 3H), 1.05 (t, J = 8.4 Hz, 2H, CH_2TMS). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 205.4, 155.4, 152.8, 150.7, 149.9, 137.5, 128.4, 128.3, 127.9, 126.9, 126.2, 125.5, 119.1, 101.5, 76.3, 63.9, 62.5, 61.1, 57.7, 38.3, 17.8, 12.6, 10.6, 7.9, –1.4. Anal. calcd. for $C_{32}H_{43}NO_8Si$: C 64.29, H 7.26, N 2.34; found: C 64.07, H 7.02, N 2.16.

*5-Benzyloxy-1,4-dimethoxy-7-methoxymethoxy-2,6- dimethyl-3-[2-(trimethylsilyl)ethoxycarbonyl]naphthalene (**15**)*

To a solution of bromide **10** (840 mg, 1.8 mmol) in THF (8 mL) at –78°C, was added *n*-BuLi (2.5 M, 0.89 mL, 2.2 mmol) dropwise over 5 min. The resulting dark red-brown solution was stirred for 5 min, then CO_2 was bubbled through the reaction mixture for a period of 30 min. The reaction mixture was allowed to warm to 23°C over 3 h at which point 1 M $NaHS0_4$ (20 mL) and EtOAc (40 mL) were added. The organic layer was dried over $MgSO_4$ and concentrated in vacuo. Purification of the crude oil by flash chromatograpy with 2:1 hexane – ethyl acetate:5% acetic acid yields 63 mg of recovered naphthalene **10** and the product carboxylic acid as a white solid (708 mg, 90% yield), mp 140–142°C. HRMS calcd. for $C_{24}H_{26}O_7$ (M^+): 426.1678; found: 426.1680. IR ($CHCl_3$) (cm^{-1}): 3500 (br), 3020, 3000, 2940, 1700, 1640, 1530, 1450, 1430, 1380, 1330, 1250, 1150, 1130, 1090, 1070, 1010, 990, 960, 950. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.59–7.36 (m, 6H), 5.39 (s, 3H), 4.92 (s, 3H), 3.89 (s, 3H), 3.88 (s, 3H), 2.51 (s, 3H), 2.35 (s, 3H). ^{13}C NMR (100 MHz, $CDCL_3$) δ: 156.0, 153.2, 149.8, 149.4, 137.5, 130.7, 128.4, 128.4, 127.9, 124.0, 122.3, 117.2, 99.8, 94.4, 76.6, 64.6, 61.0, 56.3, 13.1, 9.6. Anal. calcd. for $C_{24}H_{26}O_7$: C 67.78, H 6.16; found: C 67.58, H 6.19.

To a solution of the carboxylic acid (1.30 g, 3.0 mmol) and triphenylphosphine in THF (15 mL) (1.89 g, 7.2 mmol) was added β-trimethylsilylethanol (0.65 mL, 4.5 mmol). The solution was cooled to 0°C and diethyl azodicarboxylate (1.0 mL, 6.6 mmol) was added dropwise. The reaction was warmed to 23°C and stirred for 4 h. Water (5 mL) and ether (50 mL) were added, the organic layer was washed with 1 M $NaHSO_4$ (1 × 15 mL), satd. $NaHCO_3$ (1 × 15 mL), brine (1 × 15 mL), dried over $MgSO_4$, filtered, and concentrated to a thick oil. Purification of the crude product by flash chromatography with 15% ether–hexanes produced ester **15** (1.35 g, 85% yield) as a clear oil. HRMS calcd. for $C_{29}H_{38}O_7Si$ (M^+): 526.2387; found: 526.2366. IR ($CHCl_3$) (cm^{-1}): 3020, 3010, 2960, 1720, 1620, 1570, 1450, 1400, 1380, 1335, 1250, 1150, 1130, 1070, 1010. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.57–7.34 (m, 6H), 5.37 (s, 2H), 4.90 (s, 2H), 4.50 (t, J = 9.0 Hz, 2H), 3.85 (s, 3H), 3.81 (s, 3H), 3.54 (s, 3H), 2.36 (s, 3H), 2.33 (s, 3H), 1.19 (t, J = 9.0 Hz, 2H, 0.09 (s, 9H). ^{13}C NMR (400 MHz, $CDCl_3$) δ: 168.9, 155.5, 153.1, 149.5, 148.5, 137.7, 130.1, 128.5, 128.3, 127.8, 126.3, 122.9, 121.9, 117.5, 99.7, 94.4, 76.5, 64.1, 63.6, 60.9, 56.3, 17.6, 12.8, 9.6, –1.5. Anal. calcd. for $C_{29}H_{38}O_7Si$: C 66.12, H 7.29; found: C 65.89, H 7.43.

*5-Benzyloxy-8-bromo-1,4-dimethoxy-7-methoxymethoxy-2,6-dimethyl-3-[2-(trimethylsilyl)ethoxycarbonyl]naphthalene (**4b**)*

A solution of naphthoate **15** (1.10g, 2.1 mmol) and *N*-bromosuccinimide (480 mg, 2.7 mmol) in chloroform (20 mL) was heated at reflux for 8 h. The reaction was cooled, ether (75 mL) was added, and the mixture was extracted with satd. $NaHCO_3$ (25 mL), brine (25 mL), dried over $MgSO_4$, filtered, and concentrated. The crude reddish-brown oil was dissolved in CH_2Cl_2 (20 mL) and sequentially treated with diisopropylethyl amine (0.8 mL, 4.5 mmol) and MOM-Cl (0.3 mL, 4.0 mmol). This mixture was stirred at 23°C for 1 h then diluted with ether (100 mL), extracted with 1 M $NaHSO_4$ (30 mL), satd. $NaHCO_3$ (30 mL), brine (30 mL), dried over $MgSO_4$, filtered, and concentrated in vacuo. Purification of the crude product by flash chromatography with 15% ether–hexane afforded bromonaphthoate **4b** (1.16 g, 93% yield) as a light yellow oil. HRMS calcd. for $C_{29}H_{38}O_7{}^{81}BrSi$ (M + 1): 607.1836; found: 607.1519. IR ($CHCl_3$) (cm^{-1}): 3010, 2960, 1720, 1600, 1580, 1450, 1330, 1250, 1160, 1120, 1060, 930, 860, 840, 700. ^1H NMR (400 MHz, $CDCl_3$) δ: 7.51–7.35 (m, 5H), 5.19 (s, 2H), 4.85 (s, 2H), 4.50 (t, *J* = 8.5 Hz, 2H), 3.77 (s, 3H), 3.71 (s, 3H), 3.69 (s, 3H), 2.42 (s, 3H), 2.39 (s, 3H), 0.09 (s, 9H). ^{13}C NMR (400 MHz, $CDCl_3$) δ: 167.9, 155.0, 153.0, 150.2, 148.0, 128.7, 128.4, 127.9, 125.9, 121.2, 105.9, 100.2, 76.6, 64.1, 63.8, 61.8, 61.7, 57.9, 17.5, 13.2, 11.4, –1.5. Anal. calcd. for $C_{29}H_{38}O_7BrSi$: C 57.51, H 6.17; found: C 57.77, H 6.20.

*5-Benzyloxy-8-[(4′*S*,2′*E*)-5′-benzyloxymethoxy-2′,4′-dimethyl-pent-2′-en-1′-one]-1,4-dimethoxy-7-methoxymethoxy-2,6-dimethyl- 3-[2″-(trimethylsilyl)ethoxy-carbonyl]naphthalene (**17**)*

To a solution of bromide **4b** (675 mg, 1.1 mmol) in THF (8 mL) at –100°C was added *n*-BuLi (2.5 M, 0.40 mL, 1.0 mmol) The resulting solution was stirred for 5 min at –100°C and enal **16** (189 mg, 0.80 mmol) was added via cannula. The reaction mixture was gradually warmed over 8 h to 0°C, then was quenched wtih brine solution (2 mL), diluted with ether (50 mL), washed with brine (2 × 15 mL). The combined extracts were dried over $MgSO_4$, filtered, and concentrated in vacuo. Purification of the crude product by flash chromatography with 30% ether–hexane to 50% ether–hexane provided recovered enal **16** (23 mg), recovered bromo ester **4b** (58 mg), ester **15** (140 mg (from protonation of the aryllithium intermediate)), and desired allylic alcohol as a 1:1 mixture of diastereomers (470 mg, 75% based on aldehyde). The diastereomers were separable by HPLC using a Whatman M9 column and a flow rate of 4 mL min^{-1} and 25% EtOAc–hexane as eluent. Data for diastereomer A: ^1H NMR (400 MHz, C_6D_6) δ: 7.42–7.07 (m, 10H), 6.72 (d, *J* = 11.6 Hz, 1H), 5.53 (d, *J* = 9.2 Hz, 1H), 5.00 and 4.89 (AB, *J* = 6 Hz, 2H), 4.79 and 4.69 (AB, *J* = 10.4 Hz, 2H), 4.60 (s, 2H), 4.52 (t, *J* = 7.2 Hz, 2H), 4.50 (s, 2H), 3.90 (s, 3H), 3.47–3.35 (m, 2H), 3.40 (s, 3H), 3.29 (s, 3H), 2.84–2.76 (m, 1H), 2.43 (s, 3H), 2.34 (s, 3H), 1.80 (s, 3H), 1.11 (t, *J* = 7.2 Hz, 2 H), 1.01 (d, *J* = 6.4 Hz, 3H), –0.08 (s, 9H). Data for diastereomer B: HRMS calcd. for $C_{44}H_{59}O_{10}Si$ (M + 1): 775.3877; found: 775.3923. IR (CCl_4) (cm^{-1}): 3500 (br), 3020, 2980, 2960, 2940, 2930, 1730, 1590, 1500, 1340, 1250, 1110, 1050. ^1H NMR (400 MHz, C_6D_6) δ: 7.41–7.08 (m, 10H), 6.73 (d, *J* = 10.8 Hz, 1H), 5.54 (d, *J* = 8.8 Hz, 1H), 4.99 and 4.90 (AB, *J* = 6 Hz, 2H), 4.79 and 4.69 (AB, *J* = 10.4 Hz, 2H), 4.57 (s, 2H), 4.53 (t, *J* = 7.2 Hz, 2H), 4.49 (s, 2H), 3.89 (s, 3H), 3.47–3.35 (m, 2H), 3.42 (s, 3H), 3.29 (s, 3H), 2.84–2.76 (m, 1H), 2.44 (s, 3H), 2.34 (m, 3H), 1.78 (s, 3H), 1.11 (t, *J* = 7.2 Hz, 3H), 1.03 (d, *J* = 6.8 Hz, 3H), –0.08 (s, 9H).

To a solution of Dess–Martin periodinane (197 mg, 0.47 mmol) and pyridine (0.1 mL, 0.47 mmol) in CH_2Cl_2 (1.0 mL) at 0°C was added the allylic alcohols from the preceding experiment (239 mg, 0.31 mmol) in CH_2Cl_2 (1 mL) via cannula. The reaction mixture was stirred at 23°C for 5 h, then was diluted with ether (20 mL) and H_2O (10 mL). The organic layer was washed with satd. $NaHCO_3$ (5 mL), 1 M $NaHSO_4$ (2 × 5 mL), dried over $MgSO_4$, filtered, and concentrated in vacuo. Purification of the crude product by flash chromotography with 30% ether–hexanes produced enone **17** (221 mg, 92% yield) as a 1:1 mixture of atropisomers. HRMS calcd. for $C_{42}H_{51}O_9Si$ (M–C_2H_5O): 727.3304; found: 727.3259. IR ($CHCl_3$) (cm^{-1}): 3060, 3000, 2960, 1720, 1650, 1605, 1570, 1560, 1495, 1480, 1450, 1415, 1395, 1375, 1350, 1320, 1265, 1250, 1215, 1160, 1120, 1100, 1050, 955, 930, 860, 840, 695. ^1H NMR (400 MHz, C_6D_6) δ: 7.42–7.07 (m, 20H), 6.06 (dd, *J* = 6.2 Hz, *J* = 1.2 Hz, 1H), 6.03 (dd, *J* = 6.2 Hz, *J* = 1.2 Hz, 1H), 5.24 and 5.14 (AB, *J* = 5.6 Hz, 2H), 5.25 and 5.13 (AB, *J* = 5.6 Hz, 2H), 4.79–4.71 (m, 4 H), 4.51–4.45 (m, 8H), 4.42 and 4.36 (AB, *J* = 6.4 Hz, 2H), 4.38 and 4.31 (AB, *J* = 12 Hz, 2H), 3.89 (s, 3H), 3.88 (s, 3H), 3.388 (s, 3H), 3.387 (s, 3H), 3.35 (s, 3H), 3.33 (s, 3H), 3.22–3.11 (m, 4H), 2.79–2.71 (m, 2H), 2.44 (s, 3H), 2.41 (s, 3H), 2.39 (s, 3H), 2.35 (s, 3H), 2.21 (d, *J* = 1.2 Hz, 3H), 2.19 (d, *J* = 1.2 Hz, 3H), 1.09–1.04 (m, 4H), 0.79 (d, *J* = 6.8 Hz, 3H), 0.69 (d, *J* = 6.8 Hz, 3H), 0.09 (s, 18 H). ^{13}C NMR (100 MHz, C_6D_6, atropisomers) δ: 196.5, 167.8, 154.1, 150.7, 149.0 (2 Cs), 145.1, 145.0, 139.5, 139.4, 138.7, 138.0, 129.6, 129.5 (2 Cs), 128.8. 128.5, 127.5, 127.4, 127.3, 127.0, 126.3 (2 Cs), 125.8 (2 Cs), 124.2, 120.3, 101.9 (2 Cs), 94.6, 94.3, 76.6, 72.1, 71.9, 69.0 (2 Cs), 64.5, 63.5, 61.4, 57.2, 34.4, 17.7, 16.5, 16.3, 13.4, 12.1, 11.0, –1.7. *5-Allyloxy-3-bromo-1,4-dimethoxy-7-methoxymethoxy-2,6-dimethylnaphthalene (**27**)*

To a degassed, 0°C solution of quinone **26** (9.0 g, 23.6 mmol) and $CeCl_3 \cdot 7H_2O$ (13.1 g, 35.2 mmol) in dioxane (225 mL) and H_2O (115 mL) was added $NaBH_4$ (1.8 g, 47.2 mmol) over a period of 20 min. The solution was allowed to warm to 23°C, then dimethyl sulfate (Me_2SO_4) (45 mL) was added. The flask was evacuated, filled with Ar then 50% aq NaOH (9 mL) was added. The resulting solution was stirred for 2 h then cooled to 0°C. Concentrated NH_4OH (100 mL) and Et_2O (500 mL) were then added. The phases were separated, and the aqueous phase was extracted with Et_2O (2 × 250 mL). The combined organic extracts were dried over $MgSO_4$, filtered, and concentrated. Purification of the crude product by flash chromatography (5% EtOAc–hexanes) afforded the protected dihydroquinone **27** (8.1 g, 84% yield) as a light yellow oil. HRMS (CI, CH_4) calcd. for $C_{19}H_{24}O_5Br$ (M^+ + 1) (*m*/*z*): 413.0812; found: 413.0788. IR ($CHCl_3$) (cm^{-1}): 3022, 2935, 2861, 1616, 1582, 1484, 1450, 1384, 1350, 1320, 1247. ^1H NMR (400 MHz, $CDCl_3$) δ: 7.41 (s, 1H), 6.26–6.16 (m, 1H), 5.49 (apparent dq, *J* = 17.2, 1.7 Hz, 1H), 5.35 (s, 2H), 5.28 (apparent dq, *J* = 10.4, 1.7 Hz 1H), 4.41 (broad d, *J* = 5.6 Hz, 2H), 3.85 (s, 3H), 3.83 (s, 3H), 3.53 (s, 3H), 2.50 (s, 3H), 2.35 (s, 3H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 154.9, 152.3, 149.7, 148.3, 134.3, 128.5, 127.2, 122.0, 118.3, 117.3, 117.1, 99.6, 94.4, 75.4, 61.9, 61.1, 56.2, 16.8, 9.6.

*8-Allyloxy-1,4-dimethoxy-6-methoxymethoxy-3,7-dimethylnaphthalene-2-carboxylic acid 2-β-(trimethylsilyl) ethyl ester (**28**)*

To a –78°C solution of bromide **27** (2.1 g, 5.1 mmol) in THF (26 mL) was added *n*-BuLi (2.4 mL, 6.1 mmol, 2.5 M). The solution was stirred for 5 min, then CO_2 was bubbled through the solution for 30 min. The solution was allowed to warm to 23°C then partitioned between 1.0 M $NaHSO_4$ (50 mL) and EtOAc (100 mL). The aqueous phase was extracted with EtOAc (2 × 50 mL). The combined organic extracts were dried $MgSO_4$, filtered, and concentrated to give a yellow oil. Purification of the crude product by flash chromatography (5% HOAc:30% EtOAc:65% hexanes) afforded the carboxylic acid (1.7 g, 89% yield) as a light yellow oil.

To a 0°C solution of the carboxylic acid (1.7 g, 4.5 mmol), PPh_3 (2.8 g, 10.7 mmol) and β-trimethylsilylethanol (0.97 mL, 6.8 mmol) in THF (23 mL) was added diethyl azodicarboxylate (DEAD) (1.6 mL, 9.9 mmol). The resulting solution was warmed to 23°C and stirred for 4 h. The solution was then partitioned between Et_2O (100 mL) and satd. aq $NaHCO_3$ (50 mL). The aqueous phase was extracted with Et_2O (2 × 50 mL). The combined organic extracts were dried over $MgSO_4$, filtered, and concentrated to afford a yellow oil. Purification of the crude product by flash chromatography (10% EtOAc–hexanes) afforded the desired ester **28** (1.9 g, 90% yield) as a clear oil. HRMS (CI, CH_4) calcd. for $C_{25}H_{37}O_7Si$ (M^+ + 1) (*m*/*z*): 477.2309; found: 477.2303. 17.5, 12.7, 9.6, –1.5. Anal. calcd. for $C_{25}H_{36}O_7Si$: C 63.00, H 7.61; found: C 63.04, H 7.60.

*8-Allyloxy-5-bromo-1,4-dimethoxy-6-methoxymethoxy-3,7-dimethyl-naphthalene-2-carboxylic acid 2-β-(trimethylsilyl)-ethyl ester (**19**)*

Method A: To a solution of naphthoate **28** (140 mg, 0.29 mmol) and H_2SO_4 (1 μL) in THF (1.5 mL) was added *N*-bromosuccinimide (NBS) (68 mg, 0.38 mmol). The resulting solution was stirred for 2.5 h then partitioned between satd. aq $NaHCO_3$ (25 mL) and Et_2O (50 mL). The aqueous phase was extracted with Et_2O (2 × 25 mL). The combined organic extracts were dried over $MgSO_4$, filtered, and concentrated. The crude product (which consisted of a ca. 1:1 mixture of bromobenzocyclohexadienone **29** and the phenol tautomer **30** according to ^1H NMR analysis) was filtered through a plug of silica gel using 10% EtOAc–hexanes to afford a yellow oil. This material was dissolved in CH_2Cl_2 (1.5 mL), then MOM-Cl (110 μL, 1.4 mmol) and Hunig's base (300 μL, 1.7 mmol) were added. The solution was stirred for 1 h then partitioned between satd. aq $NaHCO_3$ (25 mL) and Et_2O (50 mL). The aqueous phase was extracted with Et_2O (2 × 25 mL). The combined organic extracts were dried over $MgSO_4$, filtered, and concentrated. Purification of the crude product by flash chromatography (10% EtOAc–hexanes) afforded an inseparable 1:1 mixture of naphthyl bromide **19** and naphthyl chloride **31** (120 mg, 75% combined yield). Pure choride **31** was obtained by treating the **19**–**31** mixture with *n*-BuLi followed by the addition of propanal. Unreacted chloride **31** was isolated from the reaction mixture. Data for chloride **31**: HRMS (CI, CH_4) calcd. for $C_{25}H_{36}O_7ClSi$ ($M^+ + 1$) (*m*/*z*): 511.1920; found: 511.1928. ^1H NMR (400 MHz, $CDCl_3$) δ: 6.18–6.09 (m, 1H), 5.42 (apparent dq, *J* = 17.2, 1.6 Hz, 1H), 5.26 (broad d, *J* = 10.4 Hz, 1H), 5.19 (s, 2H), 4.48 (t, *J* = 8.8 Hz, 2H), 4.33 (broad d, *J* = 5.6 Hz, 2H), 3.81 (s, 3H), 3.72 (s, 3H), 3.69 (s, 3H), 2.42 (s, 3H), 2.36 (s, 3H), 1.16 (t, *J* = 8.8 Hz, 2H), 0.09 (s, 9H). Data for bromide **19**: HRMS (CI, CH_4) calcd. for $C_{25}H_{36}O_7BrSi$ ($M^+ + 1$) (*m*/*z*): 555.1414; found: 555.1421. IR ($CHCl_3$) (cm^{-1}): 3072, 2960, 2902, 2862, 1721, 1584, 1451, 1395, 1332, 1250, 1160, 1116, 1059. ^1H NMR (400 MHz, $CDCl_3$) δ: 6.18–6.09 (m, 1H), 5.42 (apparent dq, *J* = 17.2, 1.5 Hz, 1H), 5.26 (broad d, *J* = 10.3 Hz, 1H), 5.19 (s, 2H), 4.49 (t, *J* = 8.8 Hz, 2H), 4.34 (broad d, *J* = 5.2 Hz, 2H), 3.81 (s, 3H), 3.70 (s, 3H), 3.68 (s, 3H), 2.44 (s, 3H), 2.36 (s, 3H), 1.16 (t, *J* = 8.8 Hz, 2H), 0.09 (s, 9H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 168.0, 155.0, 153.0, 150.2, 147.9, 134.0, 128.6, 127.5, 125.8, 121.2, 117.4 (2C), 105.8, 100.2, 75.5, 64.2, 63.9, 61.7, 58.0, 17.5, 13.1, 11.0, –1.5.

Method B: To a solution of **28** (1.8 g, 3.8 mmol) and H_2SO_4 (3 μL) in THF (19 mL) was added *N*-bromosuccinimide (NBS) (2.0 g, 11.4 mmol). The resulting solution was stirred for 9 h, then more NBS (300 mg, 1.7 mmol) and H_2SO_4 (1 μL) were added. The resulting solution was stirred for 1.5 h then partitioned between satd. aq $NaHCO_3$ (30 mL) and Et_2O (50 mL). The aqueous phase was extracted with Et_2O (2 × 50 mL). The combined organic extracts were dried over $MgSO_4$, filtered, concentrated and filtered through a plug of silica gel using 10% EtOAc–hexanes affording a yellow oil. This material was dissolved in CH_2Cl_2 (19 mL) and Hunig's base (2.0 mL, 11.4 mmol) was added. The resulting solution was cooled to 0°C then MOM-Br (620 μL, 7.6 mmol) was added. The solution was stirred overnight then partitioned between satd. aq $NaHCO_3$ (30 mL) and Et_2O (50 mL). The aqueous phase was extracted with Et_2O (2 × 50 mL). The combined organic extracts were dried over $MgSO_4$, filtered, and concentrated. Purification of the crude product by flash chromatography (5% EtOAc–hexanes) afforded bromide **19** (1.6 g, 76% yield) as a yellow oil.

*5-Allyloxy-3-bromo-7-(*tert*-butyldiphenylsilyloxy)-2,6-dimethyl-[1,4]-naphthoquinone (**35**)*

A solution of quinone **26** (5.8 g, 15 mmol) and *p*-TsOH (11.4 g, 60 mmol) in MeOH (75 mL) and CH_2Cl_2 (30 mL) was heated at reflux for 6 h. The solution was partitioned between satd. aq $NaHCO_3$ (200 mL) and EtOAc (200 mL). The aqueous phase was extracted with EtOAc (3 × 200 mL). The combined organic extracts were dried over $MgSO_4$, filtered, and concentrated to give an orange solid. A solution of this solid in DMF (75 mL) was treated with imidazole (2.2 g, 33 mmol) and TBDPS-Cl (7.8 mL, 30 mmol). The resulting mixture was stirred for 14 h then partitioned between H_2O (200 mL) and EtOAc (200 mL). The aqueous phase was extracted with EtOAc (2 × 150 mL). The combined organic extracts were dried over $MgSO_4$, filtered, and concentrated to afford a dark yellow oil. Purification of the crude product by flash chromatography (5% Et_2O–hexanes) afforded the TBDPS-protected quinone **35** (7.4 g, 87% yield) as a yellow solid, mp 136–138°C. HRMS (CI, NH_3) calcd. for $C_{31}H_{31}O_4Br$ (M^+) (*m*/*z*): 574.1175; found: 574.1151. IR ($CHCl_3$) (cm^{-1}): 3073, 2957, 2932, 2859, 1670, 1608, 1577, 1464, 1427, 1360, 1325, 1259, 1134, 1114. ^1H NMR (400 MHz, $CDCl_3$) δ: 7.70–7.67 (m, 4H), 7.48–7.38 (m, 6H), 7.00 (s, 1H), 6.27–6.17 (m, 1H), 5.43 (apparent dq, *J* = 17.2, 1.5 Hz, 1H), 5.30 (broad d, *J* = 9.4 Hz, 1H), 4.45 (broad d, *J* = 5.9 Hz, 2H), 2.39 (s, 3H), 2.17 (s, 3H), 1.14 (s, 9H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 181.3, 175.4, 159.4, 159.3, 145.9, 141.0, 135.3, 133.6, 131.6, 131.4, 130.9, 130.4, 128.0, 118.2, 117.6, 113.8, 74.8, 26.6, 19.6, 17.4, 10.6.

*5-Allyloxy-3-bromo-7-(*tert*-butyldiphenylsilyloxy)-1,4-bis-methoxymethoxy-2,6-dimethylnaphthalene (**36**)*

To a deoxygenated solution of quinone **35** (6.5 g, 11 mmol) and Adogen 464® (1.6 g, 3.4 mmol) in CH_2Cl_2 (240 mL) and H_2O (240 mL) under Ar was added $Na_2S_2O_4$ (7.8 g, 45 mmol). The solution was stirred for 30 min, then NaOH (38 mL, 113 mmol, 3.0 M) was added. The solution was stirred for 10 min and then cooled to 0°C. MOM-Cl (6.0 mL, 79 mmol) was then added dropwise over a period of 30 min. The resulting solution was allowed to warm to 23°C, stirred for 1 h then partitioned between H_2O (250 mL) and CH_2Cl_2 (200 mL). The aqueous phase was extracted with CH_2Cl_2 (2 × 100 mL). The combined organic extracts were dried over $MgSO_4$, filtered, and concentrated to afford a yellow oil to afford a mixture of mono- and di-MOM-protected hydroquinones. The crude product mixture was dissolved in CH_2Cl_2 (55 mL). To this solution was added MOM-Cl (2.6 mL, 34 mmol) and Hunig's base (7.9 mL, 45 mmol). The resulting solution was stirred for 4 h then partitioned between satd. aq $NaHCO_3$ (150 mL) and Et_2O (150 mL). The aqueous phase was extracted with Et_2O (2 ×

© 2001 NRC Canada

100 mL). The combined organic extracts were dried over $MgSO_4$, filtered, and concentrated. The crude product was purified by flash chromatography (5% Et_2O–hexanes → 10% Et_2O–hexanes) giving the protected hydroquinone **36** (6.0 g, 82% yield) as a light yellow oil. HRMS (CI, NH_3) calcd. for $C_{35}H_{42}O_6BrSi$ ($M^+ + H$) (*m*/*z*): 665.1934; found: 665.1944. IR (thin film) (cm^{-1}): 3071, 3060, 2954, 2931, 2857, 1612, 1582, 1476, 1427, 1319, 1159, 1136. ^1H NMR (400 MHz, $CDCl_3$) δ: 7.74–7.72 (m, 4H), 7.45–7.34 (m, 6H), 6.74 (s, 1H), 6.26–6.12 (m, 1H), 5.44 (apparent dd, *J* = 17.0, 1.5 Hz, 1H), 5.28 (apparent dd, *J* = 10.4, 1.5 Hz, 1H), 5.10 (s, 2H), 4.37 (broad d, *J* = 5.7 Hz, 2H), 4.17 (s, 2H), 3.70 (s, 3H), 3.12 (s, 3H), 2.49 (s, 3H), 2.38 (s, 3H), 1.13 (s, 9H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 153.3, 152.2, 146.8, 145.3, 135.4, 134.3, 132.3, 130.0, 128.4, 127.9, 127.7, 123.7, 117.5, 117.3, 117.2, 105.6, 101.4, 99.3, 75.3, 58.6, 57.3, 26.5, 19.6, 17.9, 10.7. Anal. calcd. for $C_{35}H_{41}O_6BrSi$: C 63.15, H 6.21; found: C 63.25, H 6.22.

*8-Allyloxy-6-(*tert*-butyldiphenylsilyloxy)-1,4-bis-methoxymethoxy-3,7-dimethylnaphthalene-2-carboxylic acid 2-*β*-trimethylsilyl)ethyl ester (**37**)*

To a –78°C solution of bromide **36** (5.8 g, 8.7 mmol) in THF (43 mL) was added *n*-BuLi (4.2 mL, 2.5 M, 10.4 mmol). The solution was stirred for 10 min, then CO_2 was bubbled through the solution for 20 min. The solution was allowed to warm to 23°C then partitioned between 1.0 M $NaHSO_4$ (150 mL) and Et_2O (150 mL). The aqueous phase was extracted with Et_2O (2 × 100 mL). The combined organic extracts were dried $MgSO_4$, filtered, and concentrated to give a yellow oil. Purification of the crude product by flash chromatography (5% HOAc:30% EtOAc:65% hexanes) afforded the desired carboxylic acid (4.5 g, 82% yield) as a light yellow oil. HRMS (CI, NH_3) calcd. for $C_{36}H_{42}O_8Si$ (M^+) (*m*/z): 630.2649; found: 630.2653. IR ($CHCl_3$) (cm^{-1}): 3018 (br), 2962, 2934, 2860, 1734, 1615, 1427, 1331, 1256, 1158, 1139, 1114, 1073. ^1H NMR (400 MHz, $CDCl_3$) δ: 7.74–7.72 (m, 4H), 7.45–7.35 (m, 6H), 6.78 (s, 1H), 6.20–6.16 (m, 1H), 5.45 (apparent dq, *J* = 17.3, 1.6 Hz, 1H), 5.30 (apparent dq, *J* = 10.4, 1.6 Hz, 1H), 5.15 (s, 2H), 4.34 (broad d, *J* = 5.7 Hz, 2H), 4.19 (s, 2H), 3.42 (s, 3H), 3.13 (s, 3H), 2.49 (s, 3H), 2.32 (s, 3H), 1.14 (s, 9H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 169.7, 154.5, 153.1, 147.3, 145.5, 235.4, 134.0, 132.2, 130.5, 130.1, 128.0, 124.8, 124.2, 124.0, 117.6, 116.0, 105.8, 101.5, 99.2, 75.3, 57.5, 57.2, 26.5, 19.6, 14.0, 10.6.

To a 0°C solution of carboxylic acid (3.4 g, 5.4 mmol), PPh_3 (3.4 g, 13.4 mmol), and β-trimethylsilylethanol (1.2 mL, 8.1 mmol) in THF (27 mL) was added diethyl azodicarboxylate (1.9 mL, 12.0 mmol). The resulting solution was warmed to 23°C and stirred for 1 h. The solution was then partitioned between Et_2O (150 mL) and satd. aq $NaHCO_3$ (100 mL). The aqueous phase was extracted with Et_2O (2 × 100 mL). The combined organic extracts were dried over $MgSO_4$, filtered, and concentrated to afford a yellow oil. Purification of the crude product by flash chromatography (10% EtOAc–hexanes) afforded the desired ester **37** (3.5 g, 90% yield) as a clear oil. HRMS (CI, NH_3) calcd. for $C_{41}H_{54}O_8Si_2$ (M^+) (*m*/*z*): 730.3357; found: 730.3362. IR (thin film) (cm^{-1}): 3072, 3061, 2954, 2895, 2856, 2827, 1727, 1615, 1426, 1331, 1243, 1159, 1136, 1114. ^1H NMR (400 MHz, $CDCl_3$) δ: 7.74–7.71 (m, 4H), 7.45–7.34 (m, 6H), 6.76 (s, 1H), 6.24–6.14 (m, 1H), 5.43 (apparent dq, *J* = 17.1, 1.6 Hz, 1H), 5.27 (apparent dq, *J* = 10.4, 1.6 Hz, 1H), 5.06 (s, 2H), 4.43–4.39 (m, 4H), 4.17 (s, 2H), 3.49 (s, 3H), 3.11 (s, 3H), 2.48 (s, 3H), 2.21 (s, 3H), 1.14–1.09 (m, 2H), 1.13 (s, 9H), 0.06 (s, 9H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 168.2, 153.9, 153.2, 146.7, 145.1, 135.4, 134.3, 132.3, 130.0, 130.0, 127.9, 126.2, 123.5, 123.4, 117.2, 117.0, 105.6, 101.7, 99.1, 75.3, 63.4, 57.5, 57.1, 26.5, 19.6, 17.4, 13.7, 10.6, –1.5. Anal. calcd. for $C_{41}H_{54}O_8Si_2$: C 67.36, H 7.45; found: C 67.17, H 7.34.

*8-Allyloxy-6-hydroxy-1,4-bis-methoxymethoxy-3,7-dimethylnaphthalene-2-carboxylic acid 2-*β*-(trimethylsilyl)ethyl ester (**38**)*

To a solution of ester **37** (1.3 g, 1.8 mmol) in CH_3CN (15 mL) was added a solution of $Et_3N{\cdot}HF$ (0.44 g, 3.6 mmol) in CH_3CN (3 mL). The resulting solution was stirred for 10 min then partitioned between Et_2O (500 mL) and H_2O (200 mL). The organic phase was washed with H_2O (2 × 200 mL), dried over $MgSO_4$, filtered, and concentrated to give a yellow oil. The crude product was purified by flash chromatography (25% EtOAc–hexanes) affording the desired phenol **38** (0.87 g, 98% yield) as a clear oil. HRMS (CI, NH_3) calcd. for $C_{25}H_{36}O_8Si$ (M^+) (*m*/*z*): 492.2179; found: 492.2180. IR (thin film) (cm^{-1}): 3072, 3061, 2954, 2895, 2856, 2827, 1727, 1615, 1426, 1331, 1243, 1159, 1136, 1114. ^1H NMR (400 MHz, $CDCl_3$) δ: 7.22 (s, 1H), 6.20–6.11 (m, 1H), 5.42 (apparent dq, *J* = 17.3, 1.6 Hz, 1H), 5.33 (s, 1H), 5.25 (apparent dq, *J* = 10.4, 1.6 Hz, 1H), 5.06 (s, 2H), 5.02 (s, 2H), 4.46 (t, *J* = 8.8 Hz, 2H), 4.37 (broad d, *J* = 5.7 Hz, 2H), 3.65 (s, 3H), 3.50 (s, 3H), 2.36 (s, 3H), 2.31 (s, 3H), 1.16 (t, *J* = 8.8 Hz, 2H), 0.08 (s, 9H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 168.5, 154.6, 153.3, 146.4, 145.6, 134.2, 130.7, 125.8, 123.4, 120.2, 117.3, 116.7, 101.7, 100.7, 99.7, 75.3, 63.7, 57.9, 57.5, 17.4, 13.8, 9.4, –1.5. Anal. calcd. for $C_{25}H_{36}O_8Si$: C 60.95, H 7.37; found: C 60.89, H 7.23.

*8-Allyloxy-5-bromo-1,4,6-tris-methoxymethoxy-3,7-dimethylnaphthalene-2-carboxylic acid 2-*β*-trimethylsilyl)ethyl ester (**22**)*

To a solution of phenol **38** (0.67 g, 1.4 mmol) in $CHCl_3$ (14 mL) was added *N*-bromosuccinimide (0.27 mg, 1.5 mmol). The resulting solution was stirred for 20 min then partitioned between aq $NaHCO_3$ (40 mL) and Et_2O (100 mL). The organic phase was dried over $MgSO_4$, filtered, and concentrated to give a bright yellow oil. The crude product (consisting of bromobenzocyclohexadienone **39**) was dissolved in MeOH (14 mL), then K_2CO_3 (0.39 g, 2.8 mmol) was added. The resulting solution was stirred for 10 min then partitioned between 1.0 M $NaHSO_4$ (40 mL) and Et_2O (100 mL). The organic phase was dried over $MgSO_4$, filtered, and concentrated to afford a yellow oil. The crude product (a ca. 8:1 mixture of phenol **40** and cyclohexadienone **39**) was dissolved in CH_2Cl_2 (14 mL). To this solution was added MOM-Cl (320 μL, 4.2 mmol) followed by Hunig's base (0.98 mL, 5.6 mmol). The resulting solution was stirred for 1.5 h then partitioned between satd. aq $NaHCO_3$ (40 mL) and Et_2O (100 mL). The aqueous phase was extracted with Et_2O (50 mL). The combined organic ex-

© 2001 NRC Canada

tracts were dried over $MgSO_4$, filtered, and concentrated to afford a yellow oil. Purification of the crude product by flash chromatography (10% EtOAc–hexanes) afforded the desired bromide **22** (0.67 g, 78% yield) (containing ca. 7% of chloride **41**) as a light yellow oil. HRMS (CI, NH_3) calcd. for $C_{27}H_{39}BrO_9Si$ (M^+) (*m*/*z*): 614.1547; found: 614.1564. Conclusions

We have developed efficient, Diels–Alder based syntheses of several highly functionalized bromonaphthoate derivatives of interest as intermediates in the total synthesis of damavaricin D. Of these, bromonaphthoate **22** played a pivotal role in completion of the total synthesis (25); the full details of this synthesis will be reported elsewhere.[3] Of considerable interest in the work described here is the detection of kinetically stable benzocyclohexadienone intermediates (**13**, **29**, and **39**) from the bromination reactions of β-naphthol derivatives **11**, **28**, and **38**, respectively. It was established that these intermediates undergo displacement with chloride ion at rates competitive with mild base-induced aromatization, and that reduction of the bromobenzocyclohexadienone intermediates also occurs with bromide ion. The surprising stability of the benzocyclohexadienones **13**, **29**, and **39** is presumably due to a combination of steric and stereoelectonic effects that result in the preferential placement of the bromine substituent in an axial position on the benzocyclohexadienone ring system, with the α-C-H placed in the σ-plane of the carbonyl group.

Enantioselective syntheses of (+)- and (–)-nephrosteranic acid employing the Nicholas–Schreiber reaction

Peter A. Jacobi and Prudencio Herradura

Abstract: (+)- and (–)-Nephrosteranic acid (**16**) have been prepared in an enantioselective fashion from alkyne acid **19** (or *ent*-**19**) by a three step sequence involving debenzylation–lactonization, oxidative cleavage, and selective epimerization at C_4. Acids **19** and *ent*-**19** were obtained as single enantiomers employing a Nicholas–Schreiber reaction.

Key words: paraconic acids, nephrosteranic acid, butyrolactones, Nicholas–Schreiber reaction.

Résumé : On a préparé les acides (+)- et (–)-néphrostéraniques (**16**) de façon énantiosélective à partir des alcynes acides **19** (ou *ent*-**19**), par une séquence de trois réactions impliquant une débenzylation–lactonisation, un clivage oxydant et une épimérisation sélective en C_4. Les acides **19** et *ent*-**19** ont été obtenus sous la forme d'énantiomères uniques en faisant appel à la réaction de Nicholas–Schreiber.

Mots clés : acides paraconiques, acide néphrostéranique, butyrolactones, réaction de Nicholas–Schreiber.

[Traduit par la Rédaction]

Introduction

The Nicholas reaction was discovered in 1977 and provides an efficient means for effecting the nucleophilic displacement of propargyl alcohols and related materials (1). This transformation takes advantage of the fact that alkyne cobalt complexes of general structure **2** greatly facilitate the heterolytic cleavage of adjacent alcohols or ethers, which upon acid catalysis afford cobalt stabilized carbocations **3** (Fig. 1). Capture of **3** with nucleophiles such as electron rich aromatics (1*a*), ketone or ester enolates (1*d*, *e*), and enol ethers (1*c*), then affords the products of nucleophilic displacement **4**, which are readily cleaved to the parent alkynes **5** under mild oxidative conditions (1*c*). In 1987 Schreiber et al. (1*h*) reported the first example of a Nicholas reaction employing a homochiral nucleophile. In this work, alkylation of boron enolate **6** with the cobalt complex **7** gave a 12:1 mixture of *syn*-adduct **8** and the corresponding 2,3-*anti*-isomer (not shown). Oxidative decomplexation with CAN then afforded the parent alkyne **9**.

Recently we have extended the Nicholas–Schreiber methodology to prepare a variety of enantiomerically pure alkyne acids **12** (2), which are versatile precursors to natural products as diverse as phytochrome (**13**) (2*a*), thienamycin (**14**) (2*b*), and blastmycinone (**15**) (2*c*, *d*) (Fig. 2). In this paper we describe the application of this methodology to enantioselective syntheses of (+)- and (–)-nephrosteranic acid (**16**) (for isolation and structure of **16**, see refs. 3*a*, *b*; for biological activity of paraconic acids, see refs. 3*c*, *d*), which are members of the paraconic acid family of γ-butyrolactones (**17**). Compounds of this family have attracted considerable recent attention, in part because of their novel biological activity (3*c*, *d*). In addition, the stereochemical relationship between C_3, C_4, and C_5 presents a significant synthetic challenge (3*d*, 4). Nearly all possible combinations are known (e.g., *TT*, *TC*, *CT*, and *CC*), and variants of this type have a pronounced effect on biological properties. Finally it is noteworthy that certain paraconic acids occur naturally in both dextro- and levorotatory forms (3*c*, *d*).

Our strategy for the enantioselective synthesis of (+)-nephrosteranic acid (**16**) is outlined in Scheme 1. Based upon literature precedent (2*b*), we expected that the matched condensation of cobalt complex *R*-**18** with the boron enolate **6** would afford the *syn*-alkyne **19**. Adduct **19** incorporates the desired absolute stereochemistry at C_3 and C_5 in (+)-**16**, and we planned to employ this material as a masked dicarboxylic acid (the common structural feature of the paraconic acids). Next, alkyne **19** would be converted to the lactone **20** by debenzylation followed by cyclization (2*c*, *d*). Finally, oxidative cleavage of the triple bond in **20**, followed by selective epimerization at C_4, would give (+)-**16** in enantiomerically pure form. Beginning with *S*-**18** and *ent*-**6**, we also hoped to prepare (–)-**16** (vide infra).

Each of these transformations was first explored in model studies (Scheme 2). Thus, reaction of boron enolate **6** with cobalt complex **21a** provided a >90% yield of *syn*-adduct

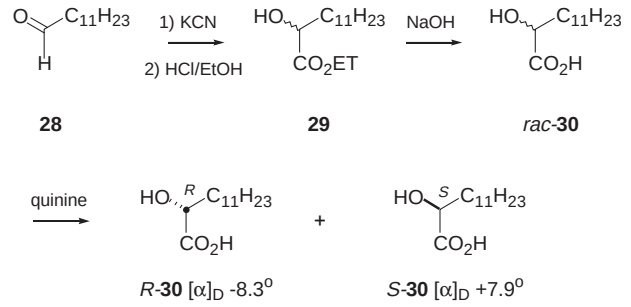
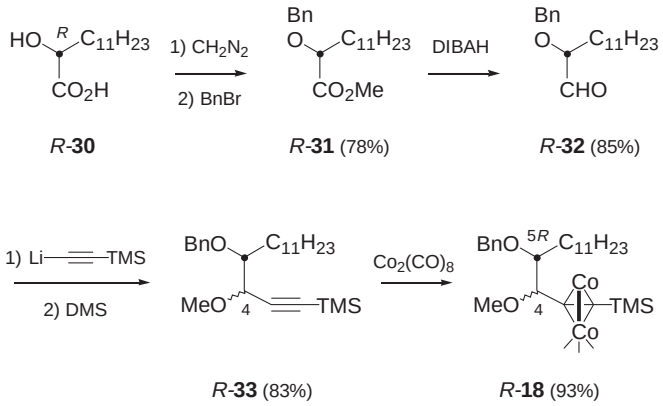
22a (R = Me), which upon hydrolysis and debenzylation gave an 80–90% overall yield of alkyne lactone **23a**. In analogous fashion, but employing cobalt complex **21b**, we obtained excellent overall yields of alkyne lactone **23b** (R = C_5H_{11}). As expected, C_3-epimerization of **23a** and **23b** was

Scheme 1.



Scheme 2.



facile (DBU) and afforded an equilibrium mixture of **24** and **23** (**24**:**23**, 85:15; 80–85% yield **24**). The more pertinent study of selective epimerization at C_4 was initially performed with the alkyne lactone **23a** (R = Me). Alkyne **23a** gave a >80% overall yield of methyl ester **25a** upon oxidation with $RuCl_3$–NaIO4 (5), followed by esterification (CH_2N_2). Disappointingly, however, **25a** (R = Me) underwent exclusive epimerization at C_3 to afford the *CT* isomer **26a** (90%; 7% return of **25a**). No trace of the desired all trans (*TT*) isomer **27a** could be detected. In the hope that steric factors would have a positive influence upon thermodynamic equilibration, we repeated the same experiments with the alkyne lactone **23b** (R = C_5H_{11}). In this case we were pleased to find that treatment of methyl ester **25b** with DBU gave predominantly epimerization at C_4, providing the *TT* isomer **27b** in 82% yield (~1–10% return of **25b**; ~1–10%

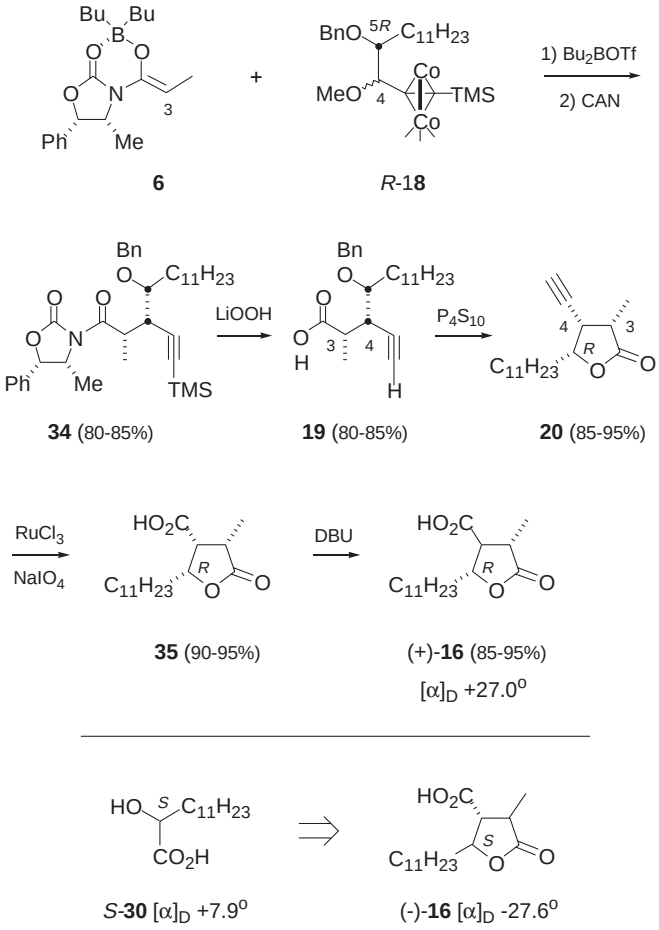
Scheme 4.



epimerization at C_3). Based upon these results it appears that preferential epimerization at C_4 is a general phenomenon when relatively large R groups occupy C_5. In any event, these model studies were readily extended to the synthesis of nephrosteranic acid (**16**).

Our initial targets for the synthesis of (+)- and (–)-**16** were the homochiral α-hydroxyacids *R*- and *S*-**30** (Scheme 3). Acids of this type are readily accessible by asymmetric reduction of the corresponding trichloromethylketones (6) or by asymmetric hydroxylation (7). In the present case, however, the resolution procedure of Hauser et al. (8) was the most convenient method for providing multigram quantities of starting material. Racemic **30** was easily prepared from dodecylaldehyde (**28**) by initial cyanohydrin formation and ethanolysis to afford **29** (90%), followed by base hydrolysis (99%). Resolution was then accomplished employing quinine for *R*-**30** ($[\alpha]_D$ –8.3) and dehydroabietylamine for *S*-**30** ($[\alpha]_D$ +7.9) (8).

The conversion of *R*-**30** to the requisite cobalt complex *R*-**18** proved to be straightforward (Scheme 4; see also Scheme 1) (2). Thus, *R*-**30** was efficiently transformed to the aldehyde *R*-**32** by a three step sequence involving esterification (CH_2N_2, 96%), alcohol benzylation (BnBr, Ag_2O, 81%), and DIBAH reduction (85%). Condensation of *R*-**32** with lithiotrimethylsilylacetylene, followed by in situ methylation (DMS), then afforded the methyl propargyl ether *R*-**33** in 83% yield (mixture of C_4-epimers). Finally, this last material gave a 93% yield of *R*-**18** upon treatment with $Co_2(CO)_8$.

Once in hand, the condensation of cobalt complex *R*-**18** and boron enolate **6** was carried out in exactly the same

Scheme 5.

manner as described in our model studies (Scheme 5; also see Scheme 2). This reaction gave a 80–85% overall yield of the *syn*-adduct **34** after CAN decomplexation. Upon LiOOH hydrolysis (9), **34** was cleanly converted to the target alkyne acid **19** (80–85%), which was obtained as a single enantiomer. Our plan now called for selective removal of the benzyl protecting group in **19** followed by lactonization. We were pleased to find that this transformation could be accomplished in a single step (85–95%), simply by stirring **19** at rt in CH_2Cl_2 with excess P_4S_{10} (2*c*, *d*). The structure of the alkyne-lactone **20** was readily apparent from its highly characteristic NMR and IR spectra, and also by its eventual conversion to (+)-**16** (vide infra). A possible mechanism for conversions of type **19** → **20** is discussed in ref. 2*c*.

As in our previous studies (Scheme 2), oxidative cleavage of the alkyne bond in **20** was cleanly effected with the reagent system $RuCl_3$–$NaIO_4$ (5), which gave a 90–95% yield of the all-*cis* lactone **35**. Lactone **35** is the C_4-epimer of (+)-nephrosteranic acid (**16**), and we expected to accomplish epimerization by initial conversion of **35** to the corresponding methyl ester (cf. Scheme 2). Surprisingly, however, prior esterification of acid **35** turned out to be unnecessary. Although relatively slow (72 h), **35** was directly epimerized to (+)-**16** upon heating with DBU in toluene (86%). In this case no other isomers of (+)-**16** could be detected (TLC). (+)-Nephrosteranic acid (**16**) thus prepared had closely matching spectral data as that reported in the literature, and was ob-

© 2001 NRC Canada

tained as a single enantiomer [mp 95–97°C (lit. mp 95°C (3*a*), 96–98°C (4*b*)); $[\alpha]_D^{26}$ +27.0 (*c* 1.2, $CHCl_3$) (lit. $[\alpha]_D^{26}$ +27.2 (*c* 1.45, $CHCl_3$))] (4*b*).

In identical fashion but beginning with hydroxyacid *S*-**30** and boron enolate *ent*-**6**, we also prepared (–)-nephrosteranic acid (**16**) (Scheme 5). The material thus obtained had identical spectral and physical properties, and essentially equal but opposite rotation to (+)-**16** [mp 96–98°C; $[\alpha]_D^{26}$ –27.6 (*c* 1.5, $CHCl_3$) (lit. $[\alpha]_D^{26}$ –28.14 (*c* 1.020, $CHCl_3$))] (4*a*). We believe that in some cases the methodology described in this paper will have advantages over more traditional syntheses of these lactones, especially when maximum flexibility is desired in controlling both relative and absolute stereochemistry

Experimental

Melting points were determined in open capillaries and are uncorrected. ^{1}H NMR spectra were recorded at 300, 400, or 500 MHz and are expressed as ppm downfield from tetramethylsilane. All reactions were carried out in oven-dried glassware under an inert atmosphere of nitrogen or argon.

2-Hydroxytridecanoic acid (*rac*-30)

Following the procedure of Hauser et al. (8), a mixture of dodecylaldehyde (**28**) (50 g, 271.3 mmol) in Et_2O (150 mL), potassium cyanide (19.4 g, 298.4 mmol), ice (50 g), and H_2O (100 mL) at 0°C was treated with sodium metabisulfite (31.9 g, 162.8 mmol). The mixture was stirred for 15 min each at 0°C and at rt. The reaction was extracted with Et_2O (3 × 150 mL), and the combined organic extracts were dried over anhydrous $MgSO_4$, filtered, and concentrated under reduced pressure to give a crude cyanohydrin derivative. IR (film) (cm^{-1}): 3350 (OH), 2142 (CN).

The crude cyanohydrin derivative from above in EtOH (350 mL) at 0°C was saturated with hydrogen chloride and was allowed to stand overnight. Excess ethanolic HCl was removed under reduced pressure, and the resulting solid material was treated with ice water (200 mL). The mixture was rapidly extracted with Et_2O (2 × 250 mL) and $CHCl_3$ (2 × 250 mL). The combined organic extracts were dried over anhydrous $MgSO_4$, filtered, and concentrated under reduced pressure to give a solid crude material. The residue was purified by flash chromatography (eluent: 10% EtOAc–hex) to afford 63 g (90%) of the ester derivative **29** as a white solid material. IR (CH_2Cl_2) (cm^{-1}): 3380 (OH), 1731 (CO_2Et).

A mixture of the ester derivative **29** (20 g, 77.4 mmol) in H_2O (100 mL) and dioxane (100 mL) was treated with NaOH (3.7 g, 92.9 mmol) and then the mixture was stirred overnight. The solution was acidified with conc HCl and was extracted with Et_2O (3 × 100 mL). The combined organic extracts were dried over anhydrous $MgSO_4$, filtered, and concentrated under reduced pressure. The residue was purified by flash chromatography (eluent: 20% EtOAc–hex) to afford *rac*-2-hydroxytridecanoic acid (*rac*-**125**) (17.5 g, 98.6%) as a white crystalline solid: mp 70–72°C. IR (CH_2Cl_2) (cm^{-1}): 3410 (OH), 1713 (CO_2H).

2-(*R*)-Hydroxytridecanoic acid (*R*-30)

A solution of anhydrous quinine (14.8 g, 45.6 mmol) and 2-hydroxydodecanoic acid (*rac*-**30**) (10.4 g, 45.2 mmol) in MeOH (200 mL) was heated to boiling. The reaction was treated with hot H_2O (500 mL) and then hot MeOH was added to clarify the solution. The resulting solution was cooled and the salt crystallized from it. The salt was collected and washed with 2:5 MeOH–H_2O followed by drying in vacuo. Recrystallization in 2:5 MeOH–H_2O afforded 10.7 g of crystalline salt.

A solution of crystalline salt (8.1 g, 14.7 mmol) in 2:5 MeOH–H_2O (50 mL) was treated with 20% NaOH solution to pH 8–10. The resulting solution was extracted with Et_2O (3 × 50 mL) to remove quinine. The aqueous portion was acidified to pH 3–4 with conc HCl and was extracted with Et_2O (3 × 150 mL). The combined organic extracts were dried over anhydrous $MgSO_4$, filtered, and concentrated under reduced pressure to afford a crystalline solid. Recrystallization from hexanes gave 3.2 g (42.9%) of optically active 2-(*R*)-hydroxytridecanoic acid (*R*-**30**): mp 71–73°C. $[\alpha]_D^{26}$ –8.3 (*c* 10.4, MeOH). R_f = 0.12 (40% EtOAc–hex + 0.2% AcOH). IR (CH_2Cl_2) (cm^{-1}): 3548, 2951, 2845, 1684, 1476, 1259, 1136, 1101, 1072. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 0.92 (t, *J* = 6.3 Hz, 3H), 1.30–1.50 (m, 16H), 1.73 (m, 2H), 1.88 (m, 2H), 4.23 (m, 1H). ^{13}C NMR (300 MHz, $CDCl_3$) δ: 14.4, 23.0, 25.0, 29.5, 29.6, 29.7, 29.8, 29.9 (2), 32.2, 34.5, 70.5, 180.2. Anal. calcd. for $C_{13}H_{26}O_3$: C 67.79, H 11.38; found: C 67.81, H 11.28.

2-(*S*)-Hydroxytridecanoic acid (*S*-30)

The filtrate from the first crystallization of the quinine salt was treated with conc HCl to pH 3–4, and was extracted with Et_2O (3 × 50 mL). The combined organic extracts were dried over anhydrous $MgSO_4$, filtered, and concentrated under reduced pressure to give a partially resolved 2-(*S*)-hydroxytridecanoic acid.

A solution of dehydroabeitylamine (6.0 g, 19.3 mmol) and the partially resolved acid (4.0 g, 17.5 mmol) in MeOH (100 mL) was heated to boiling. The reaction was treated with hot H_2O (30 mL), and then hot MeOH was added to clarify the solution. The resulting solution was cooled and the salt crystallized from it. The salt was collected and washed with 2:5 MeOH–H_2O followed by drying in vacuo. Recrystallization in 2:5 MeOH–H_2O afforded 8.0 g of the crystalline salt.

A solution of the crystalline salt (7.8 g, 15 mmol) in 2:5 MeOH–H_2O (100 mL) was treated with 20% NaOH solution to pH 8–10. The resulting solution was extracted with Et_2O (3 × 75 mL) to remove dehydroabeitylamine. The aqueous portion was acidified to pH 3–4 with conc HCl, and extracted with Et_2O (3 × 50 mL). The combined organic extracts were dried over anhydrous $MgSO_4$, filtered, and concentrated under reduced pressure to afford a crystalline solid material. Recrystallization from hexanes gave 3.0 g (89%) of optically active 2-(*S*)-hydroxytridecanoic acid (*S*-**30**): mp 73–74°C. $[\alpha]_D^{26}$ +7.9 (*c* 12.3, MeOH). R_f = 0.12 (40% EtOAc–hex + 0.2% AcOH). IR (CH_2Cl_2) (cm^{-1}): 3549, 2951, 2846, 1683, 1468, 1260, 1136, 1101, 1073. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 0.92 (t, *J* = 6.3 Hz, 3H), 1.30–1.51 (m, 16H), 1.71 (m, 2H), 1.87 (m, 2H), 4.33 (m, 1H). ^{13}C NMR (300 MHz, $CDCl_3$) δ: 14.4, 23.0, 25.0, 29.5, 29.6, 29.7, 29.8, 29.9 (2), 32.2, 34.5, 70.5, 180.2. Anal. calcd. for $C_{13}H_{26}O_3$: C 67.79, H 11.38; found: C 67.74, H 11.17.

Methyl 2-(*R*)-hydroxytridecanoate

A solution of 2-(*R*)-hydroxytridecanoic acid (*R*-**30**) (2.7 g, 11.5 mmol) in Et_2O (100 mL) at 0°C was treated with excess CH_2N_2 until the color of the solution turned yellowish. Nitrogen gas was bubbled into the solution to remove excess CH_2N_2 until it became colorless. Et_2O was removed under reduced pressure, and the residue was purified by flash chromatography (eluent: 10% EtOAc–hexanes) to give 2.7 g (96%) of methyl 2-(*R*)-hydroxytridecanoate: mp 33–34°C. $[\alpha]_D^{26}$ –16.9 (*c* 11.7, MeOH). R_f = 0.46 (20% EtOAc–hex). IR (CH_2Cl_2) (cm^{-1}): 3468, 2923, 2853, 1738, 1457, 1216, 1133, 1096. ^1H NMR (300 MHz, $CDCl_3$) δ: 0.91 (t, *J* = 6.9 Hz, 3H), 1.29–1.45 (m, 16H), 1.70 (m, 2H), 1.81 (m, 2H), 2.70 (br s, 1H), 3.82 (s, 3H), 4.23 (m, 1H). Anal. calcd. for $C_{14}H_{28}O_3$: C 68.81, H 11.55; found: C 69.01, H 11.69.

Methyl 2-(*S*)-hydroxytridecanoate

A solution of 2-(*S*)-hydroxytridecanoic acid (*S*-**30**) (2.9 g, 12.5 mmol) in Et_2O (100 mL) at 0°C was treated with excess CH_2N_2 until the color of the solution turned yellowish. Nitrogen gas was bubbled into the solution to remove excess CH_2N_2 until it became colorless. Et_2O was removed under reduced pressure, and the residue was purified by flash chromatography (eluent: 10% EtOAc–hexanes) to give 2.7 g (89%) of methyl 2-(*S*)-hydroxytridecanoate: mp 32–33°C. $[\alpha]_D^{26}$ +18.3 (*c* 8.7, MeOH). R_f = 0.46 (20% EtOAc–hex). IR (CH_2Cl_2) (cm^{-1}): 3473, 2921, 2853, 1733, 1456, 1215, 1133, 1097. ^1H NMR (300 MHz, $CDCl_3$) δ: 0.92 (t, *J* = 6.9 Hz, 3H), 1.29–1.50 (m, 16H), 1.68 (m, 2H), 1.79 (m, 2H), 3.82 (s, 3H), 4.23 (m, 1H). Anal. calcd. for $C_{14}H_{28}O_3$: C 68.81, H 11.55; found: C 69.06, H 11.68.

Methyl 2-(*R*)-benzyloxytridecanoate (*R*-31)

A solution of methyl 2-(*R*)-hydroxytridecanoate (1.4 g, 5.73 mmol) in Et_2O (20 mL) at 0°C under a nitrogen atmosphere was treated with Ag_2O (1.5 g, 6.3 mmol) and then with BnBr (0.75 mL, 6.3 mmol) in Et_2O (5 mL). The resulting suspension was allowed to warm to rt and stirred overnight. Excess Ag_2O was filtered and washed with Et_2O (3 × 10 mL). The combined organic extracts were concentrated under reduced pressure, and the residue was purified by flash chromatography (eluent: 5% EtOAc–hexanes) to give 1.6 g (81%) of methyl 2-(*R*)-benzyloxytridecanoate (*R*-**31**). $[\alpha]_D^{26}$ –30.3 (*c* 12.7, MeOH). R_f = 0.47 (10% EtOAc–hex). CI-HRMS calcd. for $C_{21}H_{34}O_3$ ($[M - H]^+$): 333.2422; found: 333.2422. IR (CH_2Cl_2) (cm^{-1}): 3063, 3030, 2924, 2853, 1752, 1455, 1266, 1201, 1133, 1112, 1027, 735, 697. ^1H NMR (300 MHz, $CDCl_3$) δ: 0.92 (t, *J* = 6.6 Hz, 3H), 1.28–1.44 (m, 18H), 1.80 (m, 2H), 3.80 (s, 3H), 3.98 (t, *J* = 6.3 Hz, 1H), 4.44 (d, *J* = 11.7 Hz, 1H), 4.74 (d, *J* = 11.7 Hz, 1H), 7.36 (m, 5H). ^{13}C NMR (300 MHz, $CDCl_3$) δ: 14.4, 23.0, 25.5, 29.5, 29.6, 29.7, 29.8, 29.9, 32.2, 33.3, 52.1, 72.6, 78.3, 128.1, 128.3, 128.6, 137.8, 173.8.

Methyl 2-(*S*)-benzyloxytridecanoate (*S*-31)

A solution of methyl 2-(*S*)-hydroxytridecanoate (2.1 g, 8.6 mmol) in Et_2O (25 mL) at 0°C under a nitrogen atmosphere was treated with Ag_2O (2.2 g, 9.4 mmol) and BnBr (1.1 mL, 9.4 mmol) in Et_2O (8 mL). The resulting suspension was allowed to warm to rt and stirred overnight. Excess Ag_2O was filtered and washed with Et_2O (3 × 20 mL). The combined organic extract were dried over anhydrous $MgSO_4$, filtered, and concentrated under reduced pressure. The residue was purified by flash chromatography (eluent: 5% EtOAc–hexanes) to afford 2.5 g (86%) of methyl 2-(*S*)-benzyloxytridecanoate (*S*-***31***). $[\alpha]_D^{26}$ +33.1 (*c* 10.1, MeOH). R_f = 0.47 (10% EtOAc–hex). CI-HRMS calcd. for $C_{21}H_{34}O_3$ ($[M - H]^+$): 333.2422; found: 333.2421. IR (CH_2Cl_2) (cm^{-1}): 3063, 3030, 2924, 2854, 1753, 1496, 1455, 1436, 1267, 1201, 1132, 1112, 1026, 734, 697. ^1H NMR (300 MHz, $CDCl_3$) δ: 0.92 (t, *J* = 6.6 Hz, 3H), 1.28–1.45 (m, 18H), 1.78 (m, 2H), 3.79 (s, 3H), 3.98 (t, *J* = 6.6 Hz, 1H), 4.44 (d, *J* = 11.7 Hz, 1H), 4.74 (d, *J* = 11.7 Hz, 1H), 7.35 (m, 5H). ^{13}C NMR (300 MHz, $CDCl_3$) δ: 14.4, 23.0, 25.1, 29.5, 29.6, 29.7, 29.8, 29.9, 32.2, 33.3, 52.1, 72.6, 78.4, 111.6, 128.1, 128.3, 128.7, 137.8, 173.8.

2-(*R*)-Benzyloxytridecanal (*R*-32)

A solution of methyl 2-(*R*)-benzyloxytridecanoate (*R*-**31**) (1.4 g, 4.0 mmol) in CH_2Cl_2 (50 mL) at –78°C under a nitrogen atmosphere was treated with DIBAL-H in toluene (1.0 M, 6 mL, 6.0 mmol. The mixture was stirred for 60 min followed by quenching with MeOH at –78°C. The reaction was allowed to warm to rt and stirred for an additional 5 min, at which time a sodium potassium tartrate solution (1.0 M, 100 mL) was added. The mixture was extracted with CH_2Cl_2 (3 × 200 mL). The combined organic extracts were dried over anhydrous $MgSO_4$, filtered, and concentrated under reduced pressure to afford 1.0 g (85%) of 2-(*R*)-benzyloxytridecanal (*R*-**32**). $[\alpha]_D^{26}$ –24.5 (*c* 16.3, MeOH). R_f = 0.57 (10% EtOAc–hex). CI-HRMS calcd. for $C_{20}H_{32}O_2$ ($[M - H]^+$): 303.2324; found: 303.2308. IR (CH_2Cl_2) (cm^{-1}): 3031, 2924, 2854, 1706, 1456, 1285, 1112, 1080, 969, 735, 697. ^1H NMR (300 MHz, $CDCl_3$) δ: 0.92 (t, *J* = 6.6 Hz, 3H), 1.29–1.43 (m, 18H), 1.73 (m, 2H), 3.79 (td, *J* = 6.3, 2.1 Hz, 1H), 4.57 (d, *J* = 12.0 Hz, 1H), 4.72 (d, *J* = 12.0 Hz, 1H), 7.38 (m, 5H), 9.69 (d, *J* = 2.1 Hz, 1H). ^{13}C NMR (300 MHz, $CDCl_3$) δ: 14.4, 23.0, 25.0, 29.6, 29.7, 29.8, 29.9, 30.3, 32.2, 72.8, 83.8, 128.2, 128.3, 128.8, 137.7, 204.2.

2-(*S*)-Benzyloxytridecanal (*S*-32)

A solution of methyl 2-(*S*)-benzyloxytridecanoate (*S*-**31**) (560 mg, 1.6 mmol) in CH_2Cl_2 (10 mL) at –78°C under a nitrogen atmosphere was treated with DIBAL-H in toluene (1.0 M, 2.4 mL, 2.4 mmol). The resulting mixture was stirred in 60 min followed by quenching with MeOH at –78°C. The reaction was allowed to warm to rt and stirred for an additional 5 min, at which time a sodium potassium tartrate solution (50 mL, 1.0 M) was added. The mixture was extracted with CH_2Cl_2 (3 × 100 mL) and the combined organic extracts were dried over anhydrous $MgSO_4$, filtered, and concentrated under reduced pressure to afford 485 mg (99%) of 2-(*S*)-benzyloxytridecanal (*S*-**32**): $[\alpha]_D^{26}$ +29.2 (*c* 11.5, MeOH). R_f = 0.56 (10% EtOAc–hex). CI-HRMS calcd. for $C_{20}H_{32}O_2$ ($[M - H]^+$): 303.2324; found: 303.2331. IR (CH_2Cl_2) (cm^{-1}): 3031, 2924, 2853, 1707, 1454, 1284, 1111, 1070, 1028, 970, 734, 697. ^1H NMR (300 MHz, $CDCl_3$) δ: 0.92 (t, *J* = 6.9 Hz, 3H), 1.29–1.49 (m, 18H), 1.73 (m, 2H), 3.79 (td, *J* = 6.3, 2.1 Hz, 1H), 4.57 (d, *J* = 12.0 Hz, 1H), 4.72 (d, *J* = 12.0 Hz, 1H), 7.35 (m, 5H), 9.69 (d, *J* = 2.1 Hz,

1H). ^{13}C NMR (300 MHz, $CDCl_3$) δ: 14.4, 23.0, 25.0, 29.6, 29.7, 29.8, 29.9, 30.3, 32.2, 72.8, 83.8, 128.2, 128.3, 128.8, 137.7, 204.2.

Methyl propargyl ether derivative *R*-33

A solution of trimethylsilylacetylene (350 mg, 3.6 mmol) in THF (25 mL) at –78°C under a nitrogen atmosphere was treated with *n*-BuLi in hexanes (1.6 M, 2.4 mL, 3.8 mmol) and was stirred for 20 min. A solution of 2-(*R*)-benzyloxytridecanal (*R*-**32**) (1.0 g, 3.3 mmol) in THF (25 mL) was added to the solution above. The reaction was stirred for an additional 20 min, at which time DMS (0.93 mL, 9.9 mmol) was added. The resulting solution was allowed to warm to rt and stirred for 48 h. The reaction was quenched with saturated NH_4Cl (50 mL) and the mixture was extracted with Et_2O (3 × 20 mL). The combined extracts were dried over anhydrous $MgSO_4$, filtered, and concentrated under reduced pressure. The residue was purified by flash chromatography (eluent: 5% EtOAc–hexanes) to afford 1.1 g (83%) of the corresponding methyl propargyl ether derivative *R*-**33** (diastereomeric mixture): $[\alpha]_D^{26}$ –10.7 (*c* 14.9, MeOH). R_f = 0.63 (5% EtOAc–hex). CI-HRMS calcd. for $C_{26}H_{44}O_2Si$ ($[M - H]^+$): 415.3033; found: 415.2845. IR (CH_2Cl_2) (cm^{-1}): 3030, 2955, 2924, 2853, 2822, 2170, 1724, 1496, 1465, 1454, 1250, 1111, 1028, 844, 760, 734, 697. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 0.18 (s, 9H), 0.92 (t, *J* = 6.3 Hz, 3H), 1.27–1.70 (m, 18H), 1.68 (m, 2H), 3.48 (d, *J* = 4.8 Hz, 3H), 3.54 (m, 2H), 4.07 (m, 1H), 4.60 (m, 1H), 4.62 (d, *J* = 11.7 Hz, 1H), 4.83 (d, *J* = 11.7 Hz, 1H), 7.33 (m, 5H). ^{13}C NMR (300 MHz, $CDCl_3$) δ: 0.2, 14.4, 23.0, 29.7, 29.9, 30.0, 32.2, 57.3 (2), 73.1, 73.7, 74.4, 75.6, 81.0, 81.1, 127.8, 128.0, 128.2, 128.4, 128.5, 128.7, 139.1.

Methyl propargyl ether derivative *S*-33

A solution of trimethylsilylacetylene (142 mg, 1.4 mmol) in THF (12.5 mL) at –78°C under a nitrogen atmosphere was treated with *n*-BuLi in hexanes (1.6 M, 0.9 mL, 1.4 mmol) and was stirred for 20 min. A solution of 2-(*S*)-benzyloxytridecanal (*S*-**32**) (400 mg, 1.3 mmol) in THF (10 mL) was added to the solution above. The reaction was stirred for an additional 20 min, at which time DMS (0.37 mL, 3.94 mmol) was added. The resulting solution was allowed to warm to rt and stirred for 48 h. The reaction was quenched with saturated NH_4Cl (25 mL) and the mixture was extracted with Et_2O (3 × 25 mL). The combined extracts were dried over anhydrous $MgSO_4$, filtered, and concentrated under reduced pressure. The residue was purified by flash chromatography (eluent: 5% EtOAc–hexanes) to afford 495 mg (90%) of the corresponding methyl propargyl ether derivative *S*-**33** (diastereomeric mixture): $[\alpha]_D^{26}$ +14.4 (*c* 9.2, MeOH). R_f = 0.63 (5% EtOAc–hex). CI-HRMS calcd. for $C_{26}H_{44}O_2Si$ ($[M - H]^+$): 415.3033; found: 415.2863. IR (CH_2Cl_2) (cm^{-1}): 3031, 2924, 2854, 2170, 1739, 1496, 1465, 1349, 1250, 1111, 1028, 844, 760, 733. 697. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 0.19 (s, 9H), 0.92 (t, *J* = 6.2 Hz, 3H), 1.29–1.69 (m, 18H), 1.68 (m, 2H), 3.48 (d, *J* = 4.6 Hz, 3H), 3.54 (m, 2H), 4.06 (m, 1H), 4.61 (m, 1H), 4.62 (d, *J* = 11.7 Hz, 1H), 4.83 (d, *J* = 11.7 Hz, 1H), 7.36 (m, 5H). ^{13}C NMR (300 MHz, $CDCl_3$) δ: 0.2, 14.4, 23.0, 29.7, 29.9, 30.1, 32.2, 57.4 (2), 73.1, 73.8, 74.4, 75.6, 81.0, 81.1 (2), 127.8, 128.1, 128.2, 128.4, 128.5, 128.7, 139.2.

Oxazolidinone adduct 34

A solution of *N*-acyloxazolidinone derivative **6** (730 mg, 3.1 mmol) in CH_2Cl_2 (20 mL) at 0°C under a nitrogen atmosphere was treated with *i*-Pr_2NEt (0.54 mL, 3.1 mmol) and then with a solution of Bu_2BOTf in CH_2Cl_2 (1.0 M, 3.1 mL, 3.1 mmol). The solution was stirred for 20 min, after which time additional solution of Bu_2BOTf in CH_2Cl_2 (1.0 M, 1.56 mL, 1.6 mmol) was added. A solution of cobalt complexed derivative *R*-**18** (1.1 g, 1.6 mmol) in CH_2Cl_2 (15 mL) was added to the solution above at –78°C. When addition was complete, the resulting mixture was allowed to warm to 0°C and rt for 20 min, respectively. A pH 7 buffered solution (50 mL) was subsequently added and layers separated. Aqueous layer was further extracted with CH_2Cl_2 (3 × 25 mL). The combined organic extracts were dried over anhydrous $MgSO_4$, filtered, and concentrated under reduced pressure. The residue was passed through a column of silica gel to remove excess *N*-acyloxazolidinone **6** (eluent 5% EtOAc–hexanes) to afford 1.25 g (89%) of the cobalt complex product.

A solution of the above cobalt complex product (1.2 g, 3.3 mmol) in acetone (25 mL) at rt was treated with CAN (1.8 g, 3.3 mmol). Additional CAN (0.9 g, 1.7 mmol) was used and the solvent was removed under reduced pressure. The resulting residue was treated with H_2O (50 mL) and Et_2O (50 mL), and layers were separated. Aqueous layer was further extracted with Et_2O (3 × 30 mL). The combined organic extracts were dried over anhydrous $MgSO_4$, filtered and concentrated under reduced pressure. The residue was purified by preparative chromatography (eluent: 10% EtOAc–hexanes) to afford 660 mg (80%) of **34** as single diastereomer: $[\alpha]_D^{26}$ +60.1 (*c* 7.5, MeOH). R_f = 0.42 (20% EtOAc–hex). CI-HRMS calcd. for $C_{38}H_{55}NO_4Si$ ($[M + H]^+$): 618.3978; found: 618.3985. IR (CH_2Cl_2) (cm^{-1}): 3031, 2924, 2854, 2170, 1786, 1701, 1455, 1367, 1342, 1249, 1195, 1120, 1068, 959, 842, 760, 699. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 0.12 (s, 9H), 0.95 (t, *J* = 7.2 Hz, 3H), 1.18 (d, *J* = 6.9 Hz, 3H), 1.30–1.40 (m, 23H), 3.02 (dd, *J* = 10.5, 3.0 Hz, 1H), 3.61 (td, *J* = 6.6, 2.7 Hz, 1H), 4.42 (m, 1H), 4.62 (d, *J* = 12.0 Hz, 1H), 4.70 (d, *J* = 12.0 Hz, 1H), 4.87 (quint, *J* = 6.6 Hz, 1H), 5.70 (d, *J* = 7.2 Hz, 1H), 7.40 (m, 10 H). ^{13}C NMR (300 MHz, $CDCl_3$) δ: 0.4, 14.4, 15.0, 16.1, 23.0, 26.2, 29.7, 29.8, 29.9 (2), 30.0, 31.4, 32.2, 39.0, 39.4, 55.0, 70.8, 76.9, 78.8, 88.1, 105.6, 125.9 (2), 127.7, 128.1, 128.6, 129.0, 133.8, 139.0, 152.8, 176.3.

Oxazolidinone adduct *ent*-34

A solution of *N*-acyloxazolidinone *ent*-**6** (260 mg, 0.92 mmol) in CH_2Cl_2 (10 mL) at 0°C under a nitrogen atmosphere was treated with *i*-Pr_2NEt (0.32 mL, 1.8 mmol) and then with a solution of Bu_2BOTf in CH_2Cl_2 (1.0 M, 1.85 mL, 1.8 mmol). The solution was stirred for 20 min, after which time additional a solution of Bu_2BOTf in CH_2Cl_2 (1.0 M, 0.92 mL, 0.92 mmol) was added. A solution of cobalt complexed derivative *S*-**18** (650 mg, 0.92 mmol) in CH_2Cl_2 (10 mL) was added to the solution above at –78°C. When addition was complete, the resulting mixture was allowed to warm to rt to 0°C and then at rt for 20 min. A pH 7 buffered solution (30 mL) was subsequently added and layers separated. Aqueous layer was further extracted with CH_2Cl_2 (3 × 40 mL) and the combined organic extracts were

© 2001 NRC Canada

dried over anhydrous $MgSO_4$, filtered, and concentrated under reduced pressure. The residue was passed through a column of silica gel to remove excess *N*-acyloxazolidinone (eluent: 5% EtOAc–hexanes) to afford 675 mg (90%) of the cobalt complex product.

A solution of the above cobalt complex product (670 mg, 0.82 mmol) in acetone (30 mL) at rt was treated with CAN (1.14 g, 2.1 mmol). Additional CAN (570 mg, 1.0 mmol) was used and the solvent was removed under reduced pressure. The resulting residue was treated with H_2O (50 mL) and Et_2O (50 mL), and layers were separated. Aqueous layer was further extracted with Et_2O (3 × 75 mL). The combined organic extracts were dried over anhydrous $MgSO_4$, filtered and concentrated under reduced pressure. The residue was purified by preparative chromatography (eluent: 5% EtOAc–hexanes) to afford 400 mg (93%) of *ent*-**34** as a single diastereomer: $[\alpha]_D^{26}$ –70.3 (*c* 8.6, MeOH). R_f = 0.24 (5% EtOAc–hex). IR (CH_2Cl_2) (cm^{-1}): 3030, 2933, 2860, 2170, 1783, 1703, 1480, 1456, 1385, 1250, 1218, 1107, 1043, 999, 948, 844, 759, 699. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 0.16 (s, 9H), 0.92 (t, *J* = 6.6 Hz, 3H), 1.18 (d, *J* = 6.6 Hz, 3H), 1.29–1.85 (m, 20H), 2.98 (dd, *J* = 3.3, 9.3 Hz, 1H), 3.61 (td, *J* = 3.3, 6.6 Hz, 1H), 4.01 (m, 1H), 4.24 (m, 1H), 4.37 (m, 2H), 4.56 (d, *J* = 11.7 Hz, 1H), 4.72 (d, *J* = 11.7 Hz, 1H), 7.37 (m, 5H).

Alkyne acid derivative 19

A solution of **34** (500 mg, 0.81 mmol) in THF:DMF:H_2O (1.5:1.5:2.0 mL) at 0°C was treated with 30% H_2O_2 (0.83 mL, 8.1 mmol) and then with $LiOH{\cdot}H_2O$ (170 mg, 4.0 mmol). The mixture was allowed to warm to rt and stirred overnight. The mixture was treated with a sodium sulfite solution (20 mL, 1.5 N) at 0°C. The reaction was allowed to warm to rt and stirred for an additional 1 h, and was quenched with 6 mL saturated $NaHCO_3$. THF was removed under reduced pressure. The aqueous residue was washed with CH_2Cl_2 (3 × 20 mL) and acidified to pH 3 with conc HCl followed by 5.0 N HCl solution. The resulting mixture was extracted with EtOAc (6 × 30 mL) and the combined organic extracts were dried over anhydrous $MgSO_4$, filtered, and concentrated under reduced pressure. The resulting residue was purified by flash chromatography (eluent: 20% EtOAc–hexanes + 0.2% AcOH) to give 260 mg (85%) of the corresponding acetylenic acid derivative **137**: $[\alpha]_D^{26}$ +7.3 (*c* 7.8, MeOH). R_f = 0.20 (20% EtOAc–hex + 0.2% AcOH). CI-HRMS calcd. for $C_{25}H_{38}O_3$ ($[M + H]^+$): 387.2899; found: 387.2893. IR (CH_2Cl_2) (cm^{-1}): 3310, 3030, 2924, 2853, 2200, 1711, 1456, 1260, 1072, 733, 697, 643. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 0.92 (t, *J* = 7.2 Hz, 3H), 1.18 (d, *J* = 6.6 Hz, 1H), 1.30–1.44 (m, 18H), 1.81 (m, 2H), 2.22 (d, *J* = 2.4 Hz, 1H), 2.81 (m, 2H), 3.56 (m, 1H), 4.56 (d, *J* = 12.0 Hz, 1H), 4.74 (d, *J* = 12.0 Hz, 1H), 7.35 (m, 5H). ^{13}C NMR (300 MHz, $CDCl_3$) δ: 14.4, 15.8, 23.0, 25.9, 29.6, 29.8, 29.9 (3), 30.0, 31.6, 32.2, 38.9, 41.9, 71.6, 72.5, 76.9, 82.1, 128.0, 128.3, 128.7, 138.4, 181.1.

Alkyne acid derivative *ent*-19

A solution of *ent*-**34** (380 mg, 0.72 mmol) in THF:DMF:H_2O (10:10:3.3 mL) at 0°C was treated with 30% H_2O_2 (0.7 mL, 7.2 mmol) and then with $LiOH{\cdot}H_2O$ (150 mg, 3.6 mmol). The mixture was allowed to warm to rt and stirred for 2 d. The mixture was treated with a sodium sulfite solution (15 mL, 1.5 N) at 0°C. The reaction was allowed to warm to rt and stirred for an additional 1 h, and was quenched with saturated $NaHCO_3$ (5 mL). THF was removed under reduced pressure. The aqueous residue was washed with CH_2Cl_2 (3 × 15 mL) and acidified to pH 3 with conc HCl followed by 5.0 N HCl solution. The resulting mixture was extracted with EtOAc (6 × 30 mL) and the combined organic extracts were dried over anhydrous $MgSO_4$, filtered, and concentrated under reduced pressure. The residue was purified by flash chromatography (eluent: 20% EtOAc–hexanes + 0.2% AcOH) to give 232 mg (82.7%) of the corresponding acetylenic acid derivative *ent*-**19**: $[\alpha]_D^{26}$ –6.2 (*c* 11.8, MeOH). R_f = 0.23 (20% EtOAc–hex + 0.2% AcOH). CI-HRMS calcd. for $C_{25}H_{38}O_3$ ($[M + H]^+$): 387.2899; found: 387.2893. IR (CH_2Cl_2) (cm^{-1}): 3308, 3030, 2922, 2852, 1700, 1652, 1456, 1284, 1069, 733, 696, 668, 641. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 0.92 (t, *J* = 6.6 Hz, 3H), 1.17 (d, *J* = 6.9 Hz, 1H), 1.31–1.45 (m, 18H), 1.82 (m, 2H), 2.21 (d, *J* = 2.4 Hz, 1H), 2.83 (m, 2H), 3.57 (m, 1H), 4.56 (d, *J* = 12.0 Hz, 1H), 4.72 (d, *J* = 12.0 Hz, 1H), 7.38 (m, 5H). ^{13}C NMR (300 MHz, $CDCl_3$) δ: 14.4, 15.8, 23.0, 25.9, 29.7, 29.8, 29.9 (2), 30.0 (2), 32.2, 38.9, 41.9, 71.6, 76.9, 82.1, 128.0, 128.2, 128.3, 128.6, 128.7, 138.4, 181.3.

4-(*S*)-Ethynyl-3-(*S*)-methyl-5-(*R*)-undecyloxolan-2-one (20)

A solution of alkyne acid **19** (210 mg, 0.54 mmol) in CH_2Cl_2 (20 mL) at rt under a nitrogen atmosphere was treated with P_4S_{10} (500 mg, 1.1 mmol) and stirred for 24 h. The mixture was filtered and washed with CH_2Cl_2 (20 mL), and the filtrate was concentrated under reduced pressure. The residue was purified by flash chromatography (eluent: 10% EtOAc–hexanes) to afford 135 mg (90%) of 4-(*S*)-ethynyl-3-(*S*)-methyl-5-(*R*)-undecyloxolan-2-one (**20**): $[\alpha]_D^{26}$ +133.4 (*c* 10.7, MeOH). R_f = 0.66 (30% EtOAc–hex). IR (CH_2Cl_2) (cm^{-1}): 2924, 2854, 2120, 1779, 1456, 1379, 1180, 1128, 998, 962, 854, 641. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 0.92 (t, *J* = 6.9 Hz, 3H), 1.28–1.51 (m, 16H), 1.40 (d, *J* = 6.5 Hz, 3H), 1.82 (m, 2H), 1.99 (m, 2H), 2.34 (d, *J* = 2.7 Hz, 1H), 2.85 (m, 1H), 3.37 (m, 1H), 4.30 (m, 1H). ^{13}C NMR (300 MHz, $CDCl_3$) δ: 11.5, 14.4, 23.0, 25.5, 29.6 (2), 29.7, 29.8, 29.9, 31.7, 32.2, 38.5, 40.1, 76.6, 76.9, 79.7, 111.6, 177.6. Anal. calcd. for $C_{18}H_{30}O_2$: C 77.65, H 10.86; found: C 77.76, H 10.93.

4-(*R*)-Ethynyl-3-(*R*)-methyl-5-(*S*)-undecyloxolan-2-one (*ent*-20)

A solution of acetylenic acid *ent*-**19** (190 mg, 0.49 mmol) in CH_2Cl_2 (25 mL) at rt under a nitrogen atmosphere was treated with P_4S_{10} (550 mg, 1.2 mmol) and stirred for 24 h. The mixture was filtered and washed with CH_2Cl_2 (100 mL), and the filtrate was concentrated under reduced pressure. The residue was purified by flash chromatography (eluent: 10% EtOAc–hexanes) to afford 118 mg (84%) of 4-(*R*)-ethynyl-3-(*R*)-methyl-5-(*S*)-undecyloxolan-2-one (*ent*-**20**): $[\alpha]_D^{26}$ –129.7 (*c* 13.9, MeOH). R_f = 0.66 (30% EtOAc–hex). IR (CH_2Cl_2) (cm^{-1}): 2917, 2848, 2112, 1758, 1463, 1395, 1360, 1327, 1189, 1000, 957, 770, 702, 623. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 0.91 (t, *J* = 6.6 Hz, 3H), 1.28–1.52 (m, 16H), 1.40 (d, *J* = 6.3 Hz, 3H), 1.83 (m, 2H), 1.99 (m, 2H), 2.34 (d, *J* = 2.4 Hz, 1H), 2.85 (m, 1H), 3.38 (m, 1H), 4.32 (m, 1H).

Anal. calcd. for $C_{18}H_{30}O_2$: C 77.65, H 10.86; found: C 77.81, H 10.87.

4-(*S*)-Methyl-5-oxo-2-(*R*)-undecyloxolane-3-(*R*)-carboxylic acid (35)

A solution of 4-(*S*)-ethynyl-3-(*S*)-methyl-5-(*R*)-undecyloxolan-2-one (**20**) (54 mg, 0.19 mmol) in a solvent system of CCl_4:CH_3CN:H_2O (4.3:4.3:6.4 mL) at 0°C was treated with $NaIO_4$ (580 mg, 2.72 mmol). The mixture was treated with $RuCl_3 \cdot H_2O$ (2.4 mg, 0.01 mmol) at 0°C and was allowed to warm to rt for 2 h. H_2O (10 mL) and Et_2O (10 mL) were added, respectively, and layers were separated. The aqueous layer was further extracted with Et_2O (3 × 15 mL). The combined organic extracts were dried over anhydrous $MgSO_4$, filtered, and concentrated under reduced pressure to afford a white solid material. Recrystallization (1:2 Et_2O–hexanes) of the white solid material afforded 53.3 mg (92%) 4-(*S*)-methyl-5-oxo-2-(*R*)-undecyloxolane-3-(*R*)-carboxylic acid (**35**): mp 103–105°C. $[\alpha]_D^{26}$ +80.7 (*c* 8.9, MeOH). R_f = 0.60 (40% EtOAc–hex + 0.4% AcOH). CI-HRMS calcd. for $C_{17}H_{30}O_4$ ($[M + H]^+$): 299.2222; found: 299.2221. IR (CH_2Cl_2) (cm^{-1}): 3375, 3031, 2919, 2869, 1766, 1695, 1456, 1241, 1185, 1002, 966. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 0.92 (t, *J* = 6.9 Hz, 3H), 1.35 (d, *J* = 6.9 Hz, 3H), 1.29–1.65 (m, 16H), 1.70 (m, 2H), 1.90 (m, 2H), 2.99 (quint, *J* = 7.2 Hz, 1H), 3.37 (m, 1H), 4.47 (m, 1H). ^{13}C NMR (300 MHz, $CDCl_3$) δ: 10.6, 14.4, 23.0, 26.2, 29.5, 29.6, 29.7, 29.8, 29.9 (2), 31.2, 32.2, 39.4, 50.5, 79.1, 174.8, 177.1.

4-(*R*)-Methyl-5-oxo-2-(*S*)-undecyloxolane-3-(*S*)-carboxylic acid (*ent*-35)

A solution of 4-(*R*)-ethynyl-3-(*R*)-methyl-5-(*S*)-undecyloxolan-2-one (*ent*-**20**) (60 mg, 0.21 mmol) in a solvent system of CCl_4:CH_3CN:H_2O (5.7:5.7:8.6 mL) at 0°C was treated with $NaIO_4$ (630 mg, 3.0 mmol). The mixture was treated with $RuCl_3 \cdot H_2O$ (2.7 mg, 0.01 mmol) at 0°C and was allowed to warm to rt and stirred for 2 h. H_2O (15 mL) and Et_2O (10 mL) were added, respectively, and layers were separated. The aqueous layer was further extracted with Et_2O (3 × 20 mL). The combined organic extracts were dried over anhydrous $MgSO_4$, filtered, and concentrated under reduced pressure to afford a white solid material. Recrystallization (Et_2O–hexanes, 1:2) of the white solid material afforded 55.3 mg (86%) 4-(*R*)-methyl-5-oxo-2-(*S*)-undecyloxolane-3-(*S*)-carboxylic acid (*ent*-**35**): mp 100–102°C. $[\alpha]_D^{26}$ –75.5 (*c* 7.1, MeOH). R_f = 0.58 (40% EtOAc–hex + 0.4% AcOH). CI-HRMS calcd. for $C_{17}H_{30}O_4$ ($[M + H]^+$): 299.2222; found: 299.2222. IR (CH_2Cl_2) (cm^{-1}): 3300, 3034, 2919, 2850, 1750, 1698, 1456, 1240, 1187, 1002, 966, 909, 872, 781, 733, 668, 596. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 0.92 (t, *J* = 7.2 Hz, 3H), 1.35 (d, *J* = 6.9 Hz, 3H), 1.29–1.64 (m, 16H), 1.69 (m, 2H), 1.87 (m, 2H), 2.97 (m, 1H), 3.30 (m, 1H), 4.38 (m, 1H). ^{13}C NMR (300 MHz, $CDCl_3$) δ: 10.6, 14.4, 23.0, 26.1, 29.5, 29.6, 29.7, 29.8, 29.9, 30.0 (2), 31.2, 32.2, 39.4, 50.5, 79.1, 174.5, 177.1.

(+)-Nephrosteranic acid (16)

A solution of 4-(*S*)-methyl-5-oxo-2-(*R*)-undecyloxolane-3-(*R*)-carboxylic acid (**35**) (30 mg, 0.10 mmol) in toluene (5 mL) under a nitrogen atmosphere at 0°C was treated with DBU (0.16 mL, 1.01 mmol). The solution was heated at reflux for 3 days. Toluene was removed under reduced pressure. The residue was purified by flash chromatography (eluent: 10% EtOAc–hexanes + 0.1% AcOH) to give 25.8 mg (86%) of (+)-nephrosteranic acid (**16**): mp 95–97°C. $[\alpha]_D^{26}$ +27.0 (*c* 1.2, $CHCl_3$). R_f = 0.72 (40% EtOAc–hex + 0.4% AcOH). CI-HRMS calcd. for $C_{17}H_{30}O_4$ ($[M + H]^+$): 299.2222; found: 299.2217. IR (CH_2Cl_2) (cm^{-1}): 3300, 2953, 2917, 2870, 1747, 1717, 1257, 1200, 1172, 697, 673. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 0.92 (t, *J* = 6.8 Hz, 3H), 1.40 (d, *J* = 7.1 Hz, 3H), 1.28–1.92 (m, 20H), 2.74 (m, 1H), 3.02 (m, 1H), 4.51 (m, 1H). ^{13}C NMR (300 MHz, $CDCl_3$) δ: 14.9, 23.4, 26.1, 30.0, 30.1 (2), 30.3, 30.4 (2), 30.5, 32.7, 35.7, 40.6, 54.5, 80.0, 176.2, 177.3.

(–)-Nephrosteranic acid (*ent*-16)

A solution of 4-(*R*)-methyl-5-oxo-2-(*S*)-undecyloxolane-3-(*R*)-carboxylic acid (*ent*-**35**) (28 mg, 0.09 mmol) in toluene (5 mL) under a nitrogen atmosphere at 0°C was added DBU (0.07 mL, 0.47 mmol). The solution was heated at reflux for 3 days. Toluene was removed under reduced pressure. The residue was purified by flash chromatography (eluent: 10% EtOAc–hexanes + 0.1% AcOH) to give 23.8 mg (85%) of (–)-nephrosteranic acid (*ent*-**16**): mp 96–98°C. $[\alpha]_D^{26}$ –27.6 (*c* 1.5, $CHCl_3$). R_f = 0.72 (40% EtOAc–hex + 0.4% AcOH). CI-HRMS calcd. for $C_{17}H_{30}O_4$ ($[M + H]^+$): 299.2222; found: 299.2227. IR (CH_2Cl_2) (cm^{-1}): 3300, 3031, 2953, 2917, 2850, 1747, 1470, 1316, 1257, 1200, 1172, 697. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 0.92 (t, *J* = 6.8 Hz, 3H), 1.41 (d, *J* = 7.2 Hz, 3H), 1.28–1.91 (m, 20H), 2.74 (m, 1H), 3.05 (m, 1H), 4.51 (m, 1H). ^{13}C NMR (300 MHz, $CDCl_3$) δ: 14.8, 23.0, 25.6, 29.5, 29.6, 29.7, 29.8, 29.9, 30.0, 32.2, 40.1, 54.0, 76.9, 79.6, 175.5, 176.8.

Synthesis of substituted phenols by directed *ortho*-lithiation of in situ *N*-silyl-protected *O*-aryl *N*-monoalkylcarbamates

Matthias Kauch and Dieter Hoppe

Abstract: A simple, high-yield procedure has been developed for the *ortho*-lithiation and subsequent *ortho*-substitution of phenols by a manifold of electrophiles. *N*,*C*-Dilithiation of *O*-aryl *N*-monoalkylcarbamates proved to be impossible due to a cleavage reaction of the monolithiated intermediates. However, in situ *N*-silylation of *O*-aryl *N*-isopropylcarbamates proceeds smoothly with trialkylsilyl triflates – *N*,*N*,*N*′,*N*′-tetramethylethylenediamine (TMEDA). Separation of the formed *O*-aryl *N*-isopropyl-*N*-trialkylsilylcarbamates from the byproduct TMEDA·HOTf, which is insoluble in diethyl ether or toluene, is not required. *ortho*-Lithiation with *n*-butyllithium–TMEDA at –78°C leads to the corresponding aryllithium, which does not undergo anionic *ortho*-Fries rearrangement under the reaction conditions, but is efficiently substituted by electrophilic reagents. During the aqueous work-up, the *N*-silyl group is removed and the corresponding *ortho*-substituted *O*-aryl *N*-isopropylcarbamate is isolated. Among the introduced electrophiles are: Me_3Si, Bu_3Sn, PhS, I, Br, Cl, alkyl, α-hydroxyalkyl. Liberation of the free phenols is performed under mild alkaline conditions.

Key words: directed *ortho*-metalation, *ortho*-lithiated *O*-aryl carbamates, *ortho*-substituted phenols, in situ protection of *N*-monoalkylcarbamates.

Résumé : On a mis au point une méthode simple qui permet d'effectuer avec des rendements élevés l'*ortho*-lithiation et l'*ortho*-substitution subséquente de phénols par un grand nombre d'électrophiles. Les *N*,*C*-dilithiations d'*O*-aryl *N*-monoalkylcarbamates s'avèrent impossibles en raison de la réaction de clivage des intermédiaires monolithiés. Toutefois, la *N*-silylation in situ des *O*-aryl *N*-isopropylcarbamates peut être réalisée facilement avec les couples triflates de trialkylsilyle – *N*,*N*,*N*′,*N*′-tétraméthyléthylènediamine (TMEDA). Il n'est pas nécessaire de séparer les *O*-aryl *N*-isopropyl-*N*-trialkylsilylcarbamates des sous-produits, TMEDA·HOTf qui sont insolubles dans l'éther éthylique ou le toluène. L'*ortho*-lithiation avec du *n*-butyllithium–TMEDA, à –78°C, conduit à la formation de l'aryllithien correspondant, qui ne donne pas lieu à un réarrangement d'*ortho*-Fries anionique dans les conditions de la réaction mais qui donne lieu à des réactions de substitution sous l'influence de réactifs électrophiles. Lors de la procédure d'extraction, le groupe *N*-silyle est éliminé et on peut isoler le *O*-aryl *N*-isopropylcarbamate *ortho*-substitué. Les électrophiles qui ont été introduits sont: Me_3Si, Bu_3Sn, PhS, I, Br, Cl, alkyle, α-hydroxyalkyle. La libération des phénols se fait dans des conditions alcalines douces.

Mots clés : *ortho*-métallation orientée, *O*-aryl carbamates *ortho*-lithiés, phénols *ortho*-substitués, protection in situ de *N*-monoalkylcarbamates.

[Traduit par la Rédaction]

Introduction

Within the last two decades, the directed *ortho*-metalation (DoM) reaction turned out as an important and powerful tool for the construction of polysubstituted aromatics (for reviews see ref. 1*a*–*c*; for a short summary of recent developments in the Snieckus group see ref. 1*d*; for a critical view on DoM and its mechanisms see ref. 2). This strategy supersedes the classical aromatic electrophilic substitution reactions with reference to milder reaction conditions, control of regioselectivity, and the range of functional groups which can be introduced. New applications of DoM chemistry also include the substitution of aromatic ligands of metal complexes leading to planar chiral ferrocenes (3) or arene tricarbonylchromium complexes (for recent work in this field see ref. 4) if chiral bases are employed.

The tertiary carbamoyloxy group has proven to be one of the most powerful directed metalation groups (DMGs). The

Scheme 1.

Scheme 2. *SiPG* = TMS, TBDMS, or TIPS. The following standard conditions and reagents are used unless otherwise specified: (*a*) 1.05 to 1.10 equiv of TMSOTf (solution in pentane), TMEDA, Et_2O, 0°C → rt, 0.5 h; (*b*) 2.0 equiv of *n*- or *s*-BuLi – TMEDA, –78°C, 1 h; (*c*) 2.5 to 3.5 equiv of EX, –78°C, 1 to 2 h; (*d*) MeOH, 2 M HCl, –78°C → rt.

N,*N*-diisopropylcarbamoyl and the *N*,*N*-diethylcarbamoyl group were employed for the directed α-lithiation of allylic and benzylic alcohols (for *O*-allyl carbamates see refs. 5*a* and 5*b*; for *O*-benzyl carbamates see ref. 5*c*). The *N*,*N*-diethylcarbamoyloxy group was extensively used by Snieckus for DoM reactions of aromatic compounds (6). A disadvantage of both DMGs is that for deprotection vigorous conditions have to be used. Only reductive methods with lithium aluminium hydride, diisobutylaluminium hydride, or strong basic conditions lead to carbamate ester cleavage, causing problems with sensitive groups. The strength of this group lies in its capability of undergoing anionic *ortho*-Fries rearrangements (1*a*, 6; for recent applications of further O → C carbamoyl transfer reactions in natural product synthesis see ref. 7).

Very recently, the *N*-cumyl-*N*-methylcarbamoyl group, offering hydrolytic lability for a two-step cleavage, was established by Snieckus and co-workers (8). Decumylation with trifluoroacetic acid and subsequent hydrolytic deprotection with bases proceed under mild conditions.

In our group, several carbamoyl residues had been developed for directed lithiation reactions of *O*-alkyl, *O*-allyl, and *O*-benzyl carbamates and their *S*-analogues which are easier to remove than the original *N*,*N*-diisopropylcarbamoyl group (9). *N*-Monoalkylcarbamoyl groups were first used for the generation of *N*,*C*-dilithiated intermediates from *O*-allyl (10) and recently *S*-allyl compounds (11). In our attempt, employing the *N*-isopropylcarbamoyl group for phenol activation, we found that the corresponding *O*-aryl carbamates **1** could not be converted to the dianionic species **3**. The intermediate *N*-lithiated carbamates **2** undergo a cleavage reaction to phenolates **4** and isocyanate, followed by an irreversible addition of the alkyllithium base to the intermediate isocyanate to give the *N*-lithiocarboxamide **5** (Scheme 1).

Herein we report on the simple solution of the problem. *O*-Aryl *N*-monoalkylcarbamates **1** can be in situ transformed into *N*-alkyl *N*-silyl derivatives **6** (12) which are stable substrates for the directed *ortho*-lithiation reaction. The lithiated carbamates **7** react with a broad range of electrophilic reagents to the *ortho*-substituted protected phenols **8** in which the *N*-silyl group is completely removed during aqueous work-up. Subsequently, the carbamoyl residue can easily be removed by mild basic hydrolysis to furnish the free phenols.

Results and discussion

The *O*-aryl *N*-isopropylcarbamates **10a**, **10b**, **10c**, and **15** were easily prepared by addition of the corresponding phenols onto isopropyl isocyanate (THF, DMAP, 60°C) and were isolated as crystalline solids in high yields.

The following standard protocol was employed for directed *ortho*-lithiation reactions (Scheme 2): The *O*-aryl carbamates **1** were *N*-silyl protected by means of trimethylsilyl triflate in the presence of TMEDA. The resulting *N*-silyl intermediates **6** (*SiPG* = TMS) were lithiated with *n*- or *s*-BuLi–TMEDA in diethyl ether at –78°C. The following

10a **11** **12**

reaction with electrophiles and acidic work-up furnished the *ortho*-substituted products **9**.

Voyer and co-workers (12) recently reported on the preparation and characterization, and, as well, deprotonation of *O*-methyl and *O*-*tert*-butyl *N*-silyl-*N*-benzylcarbamates adjacent to the nitrogen atom. In this two-step sequence, the *N*-silyl protected amines were isolated before subjection to metalation. X-ray crystallography of one compound proved the *N*-silyl group (12*c*). Therefore, we strongly suggest that silyl protection of secondary *O*-aryl carbamates occurs, as well, at the carbamoyl nitrogen atom.

To investigate suitable conditions for the protection and deprotonation step, several reagents were used for *ortho*-trimethylsilylation of the 2-biphenylyl carbamate **10a** with TMSCl as electrophile (Table 1). Consecutive lithiation with *n*- or *s*-BuLi in diethyl ether at –78°C, electrophilic quench, and hydrolysis afforded the substitution product **13aa** in excellent yields (entries 1 and 2) whereas deprotonation with LDA (entry 3) did not occur. Several silyl sources can be employed in the *N*-protection step. The use of TMS nonaflate (entry 4), TBDMS triflate, or even the bulkier TIPS triflate (entries 5 and 6) did not affect the yields significantly. Although diethyl ether is employed as standard solvent for the reaction sequence, toluene and THF were used without loss in the yield (entries 7 and 8).

Under our reaction conditions, TMEDA·HOTf separates from the reaction mixture and solidifies on cooling to below –70°C. Although the salt is neutralized only slowly by butyllithium, 2.0 equiv of the alkyllithium were applied for achieving maximum yields.[2]

It is noteable that lithiation and substitution of the *N*,*N*-diethylcarbamoyl-protected phenol require much lower reaction temperatures to avoid the anionic *ortho*-Fries rearrangement (13). No carbamoyl migration product could be detected in reactions under the usual conditions applying *N*-isopropyl-*N*-silylcarbamoyl phenols. Therefore, this DMG may be advantageously used when inter- or intramolecular attack of the carbonyl group must be avoided. Formation of the *ortho*-hydroxy carboxamide **12** was achieved with 63% yield besides 33% of the arylsilane **13aa**, when the solution of the lithiated carbamate **11** was allowed to warm to 0°C (Scheme 3). **12** was also obtained (79%) by stirring the *N*-silyl-protected urethane with 2.5 equiv of lithium diisopropylamide at 0°C to room temperature.

Carbamate **10a** reacted under the above described standard protocol with a variety of electrophilic reagents to give the substituted products **13a** in good to excellent yields (Table 2, Scheme 4). In particular, introduction of heteroatom-based functional groups occurred with high yields (entries 1–6). Only ethylation, allylation (entries 8 and 9) or, in some cases, the reaction with ketones bearing acidic α-hydrogen atoms (entries 14 and 16) gave somewhat lower yields, but these still remained above 60%.

Comparable high yields were achieved with the unsubstituted *O*-phenyl carbamate **10b** and the 2-chloro-functionalized substrate **10c** (Table 2, entries 17–21 and 22–29). In the second case, *n*-BuLi–TMEDA could be advantageously used to give a cleaner lithiation rather than *s*-BuLi–TMEDA (entries 22 and 23). The *O*-1-naphthyl carbamate **15** gave the same results concerning the yields of DoM-substitution sequences (entries 30–34, Scheme 5). In

[2]Using 1.1 equiv of *s*-BuLi after addition of 1.5 equiv TMSC1 (Table 1, entry 9) a yield of 96% of **13aa** was isolated. This result demonstrates that the *C*-deprotonation is much more rapid than deprotonation of the solid ammonium triflate.

15 **16**

accordance with observations of Snieckus with the *N*,*N*-diethylcarbamate, lithiation of **15** proceeded exclusively at the 2-position (1*a*, 6). No product resulting from lithiation in the *peri*-position could be detected.

Two procedures, using mild bases, have been established for the deprotection of the *ortho*-substituted products (Scheme 4, **13** → **14**). Treatment of several carbamates **13a** and **13c** with 2 M NaOH in ethanol at room temperature afforded phenols **14a** and **14c** in excellent to quantitative yields within 2 h (Table 3). Even substrates **13aa** and **13ca** bearing a base-sensitive TMS group could be deprotected without desilylation (entries 1 and 7). The *o*-iodoaryl carbamates **13ac** and **13cc** reacted smoothly to yield iodophenols **14ab** and **14cb** with complete retention of the iodine substituent as well (entries 3 and 8). The

carbamoyl group of the *N*-monoalkylcarbamates can also be removed by stirring with a slurry of potassium carbonate in ethanol at room temparature (entry 2).

Experimental section

General information

All reactions were carried out under Ar in flame-dried glassware. All solvents were purified and dried prior to use: Et_2O and toluene were distilled from sodium benzophenone ketyl. THF was distilled from potassium benzophenone ketyl. Pentane was distilled from CaH_2. *N*,*N*,*N*′,*N*′-Tetramethylethylenediamine (TMEDA) was purchased from Merck, refluxed and distilled from CaH_2 before use. *n*-BuLi (1.6 M in hexane) and *s*-BuLi (1.3 M in cyclohexane–hexane = 92:8) were purchased from Acros. The solution of *s*-BuLi was filtered using Celite® and titrated against phenylacetic acid prior to use. Trimethylsilyl trifluoromethanesulfonate was purchased from Acros.

^1H and ^{13}C NMR spectra were recorded on Bruker ARX 300 or AMX 400 spectrometers in $CDCl_3$ solutions using tetramethylsilane as internal standard. IR spectra were recorded on a Nicolet 5DXC spectrometer. Melting points were obtained on Gallenkamp melting point apparatus MFB-595 and are uncorrected. Microanalyses were performed at the Organisch-Chemisches Institut der WWU Münster with Heraeus CHN-O-Rapid or Elementar Analysensysteme VarioEL III analysers. HRMS were recorded on a Finnigan MAT 8200 mass spectrometer (EI, 70 eV).

Products were purified by flash column chromatography on Merck silica gel 60 (0.040–0.063 mm); PE = light petroleum ether, bp 36–46°C.

General procedure for the preparation of O-*aryl* N-*ispropylcarbamates* ***10*** *and* ***16***

To a cooled (0°C) solution of the phenol and DMAP (0.10 equiv) in dry THF (0.5 mL:1 mmol phenol), isopropyl isocyanate (1.10 equiv) was added. The reaction mixture was stirred at 60°C for 24 h, cooled to rt, and treated with 2 M HCl (1.0 mL:1 mmol phenol). After addition of Et_2O, the aqueous layer was separated, extracted with Et_2O, and the combined organic extracts were washed with saturated $NaHCO_3$ solution, dried over $MgSO_4$, filtered, and concentrated in vacuo. The crude product was purified by flash chromatography on silica gel (Et_2O–PE gradient).

O-*2-Biphenylyl* N-*isopropylcarbamate* ***(10a)****:* 2-Hydroxybiphenyl (5.11 g, 30.0 mmol) was stirred with isopropyl isocyanate (3.24 mL, 33.0 mmol) to afford **10a** (7.60 g, 29.8 mmol, 99%) as a white solid, mp 89°C (Et_2O–PE). IR (KBr) ν (cm^{-1}): 3322, 1710, 1539, 769, 742, 696. ^1H NMR (400 MHz) δ: 1.06 (d, ^3J = 6.0 Hz, 6H), 3.74 (m, 1H), 4.69 (s, 1H), 7.18–7.43 (m, 9H). ^{13}C NMR (100 MHz) δ: 22.7, 43.3, 123.2, 125.7, 127.2, 128.1, 128.3, 129.0, 130.7, 135.1, 137.9, 148.0, 153.6. Anal. calcd. for $C_{16}H_{17}NO_2$ (255.32): C 75.27, H 6.71, N 5.49; found: C 75.25, H 6.92, N 5.47.

General procedure for the ortho-lithiation of O-*aryl* N-*isopropylcarbamates **10** and **15***

A solution of the carbamate **10** or **15** (1.00 mmol) in dry Et_2O (10 mL) under Ar in a flask, sealed with a rubber septum, was cooled to 0°C. TMEDA (0.128 g, 1.10 mmol, 1.10 equiv) was introduced, and to the solution was added dropwise, via a syringe, TMSOTf (1.05 to 1.10 mmol, 1.05 to 1.10 equiv, 1.25 to 1.35 M solution in pentane). The resulting mixture was stirred for 5 min, allowed to warm to rt over a period of 30 min, and cooled to –78°C. TMEDA (0.232 g, 2.00 mmol, 2.00 equiv) and *n*-BuLi or *s*-BuLi (2.00 mmol, 2.00 equiv) were added consecutively. The reaction mixture was stirred for 1 h and treated with the electrophile (2.50 to 3.50 mmol, 2.50 to 3.50 equiv). After an additional stirring for 1 to 2 h, 0.1 mL of MeOH and 5 mL of 2 M HCl were added and the mixture was allowed to warm to rt. The phases were separated and the aqueous layer was extracted with Et_2O (3 × 20 mL). The combined organic phases were washed with saturated $NaHCO_3$ solution (10 mL), dried over $MgSO_4$, filtered, and concentrated in vacuo to afford the crude product. Flash chromatography on silica gel (Et_2O–PE gradient) gave the *ortho*-substituted carbamate.

O-*3-Trimethylsilyl-2-biphenylyl* N-*isopropylcarbamate (**13aa**):* Reaction of **10a** (0.255 g) with TMSOTf (1.10 mmol), *n*-BuLi, and TMSCl (0.32 mL, 2.5 mmol, 1 h) afforded **13aa** (0.318 g, 0.971 mmol, 97%) as a white solid, mp 161°C (Et_2O–PE). IR (KBr) ν (cm^{-1}): 3329, 1710, 1545, 834, 788, 755, 709. ^1H NMR (300 MHz) δ: 0.30 (s, 9H), 0.94 (d, ^3J = 6.3 Hz, 6H), 3.55 (m, 1H), 4.50 (s, 1H), 7.26–7.47 (m, 8H). ^{13}C NMR (75 MHz) δ: –0.7, 22.6, 43.0, 125.7, 127.0, 128.0, 129.1, 132.1, 133.4, 134.2, 135.6, 138.5, 152.7, 152.9. Anal. calcd. for $C_{19}H_{25}NO_2Si$ (327.50): C 69.68, H 7.69, N 4.28; found: C 69.59, H 7.74, N 4.12.

O-*3-Tributylstannyl-2-biphenylyl* N-*isopropylcarbamate (**13ab**):* Reaction of **10a** (0.255 g) with TMSOTf (1.10 mmol), *s*-BuLi, and Bu_3SnCl (0.68 mL, 2.5 mmol, 1 h) yielded **13ab** (0.467g, 0.858 mmol, 86%) as a white solid, mp 70°C (Et_2O–PE). IR (KBr) ν (cm^{-1}): 3317, 1708, 1528, 782, 754, 701. ^1H NMR (300 MHz) δ: 0.89 (t, ^3J = 7.4 Hz, 9H), 0.95 (d, ^3J = 6.4 Hz, 6H), 1.05–1.13 (m, 6H), 1.25–1.43 (m, 6H), 1.49–1.61 (m, 6H), 3.56 (m, 1H), 4.42 (d, 1H), 7.21–7.44 (m, 8H). ^{13}C NMR (75 MHz) δ: 10.0, 13.6, 22.7, 27.4, 29.1, 43.0, 125.8, 126.9, 128.0, 129.0, 131.1, 135.2, 136.0, 136.2, 139.0, 153.0, 153.2. Anal. calcd. for $C_{28}H_{43}NO_2Sn$ (544.36): C 61.78, H 7.96, N 2.57; found: C 62.18, H 8.06, N 2.66.

O-*3-Iodo-2-biphenylyl* N-*isopropylcarbamate (**13ac**):* Reaction of **10a** (0.255 g) with TMSOTf (1.05 mmol), *n*-BuLi, and I_2 (0.761 g in 3 mL of Et_2O, 3.0 mmol, 1 h) afforded **13ac** (0.366 g, 0.881 mmol, 88%) as a white solid, mp 127°C (Et_2O–PE). IR (KBr) ν (cm^{-1}): 3355, 1719, 1523, 780, 759, 710. ^1H NMR (400 MHz) δ: 1.07 (d, ^3J = 6.4 Hz, 6H), 3.72 (m, 1H), 4.71 (s, 1H), 7.00 (t, 1H), 7.28–7.42 (m, 6H), 7.79 (dd, 1H). ^{13}C NMR (100 MHz) δ: 22.7, 43.4, 92.8, 127.5, 127.6, 128.2, 128.8, 130.9, 137.3, 137.7, 138.4, 148.4, 152.1. Anal. calcd. for $C_{16}H_{16}INO_2$ (381.21): C 50.41, H 4.23, N 3.67; found: C 50.77, H 4.48, N 3.40.

O-*3-Bromo-2-biphenylyl* N-*isopropylcarbamate (**13ad**):* **10a** (0.255 g) reacted with TMSOTf (1.05 mmol), *n*-BuLi, and $BrCH_2CH_2Br$ (0.30 mL, 3.5 mmol, 1 h) to give **13ad** (0.304 g, 0.910 mmol, 91%) as a white solid, mp 123°C (Et_2O–PE). IR (KBr) ν (cm^{-1}): 3362, 1729, 1539, 776, 760, 709. ^1H NMR (300 MHz) δ: 1.08 (d, ^3J = 6.4 Hz, 6H), 3.75 (m, 1H), 4.74 (s, 1H), 7.14 (t, 1H), 7.26–7.43 (m, 6H), 7.57 (dd, 1H). ^{13}C NMR (75 MHz) δ: 22.6, 43.4, 118.4, 126.9, 127.6, 128.2, 128.9, 129.8, 132.3, 137.4, 138.0, 145.6, 152.2. Anal. calcd. for $C_{16}H_{16}BrNO_2$ (334.21): C 57.50, H 4.83, N 4.19; found: C 57.58, H 4.87, N 4.48.

O-*3-Chloro-2-biphenylyl* N-*isopropylcarbamate (**13ae**):* Reaction of **10a** (0.255 g) with TMSOTf (1.10 mmol), *n*-BuLi, and C_2Cl_6 (0.592 g in 3 mL of Et_2O, 2.5 mmol, 1 h) afforded **13ae** (0.270 g, 0.932 mmol, 93%) as a white solid, mp 110°C (Et_2O–PE). IR (KBr) ν (cm^{-1}): 3362, 1723, 1539, 779, 760, 706. ^1H NMR (300 MHz) δ: 1.09 (d, ^3J = 6.4 Hz, 6H), 3.76 (m, 1H), 4.76 (s, 1H), 7.16–7.43 (m, 8H). ^{13}C NMR (75 MHz) δ: 22.6, 43.5, 126.4, 127.6, 128.2, 128.9, 129.1, 129.1, 129.2, 137.2, 137.8, 144.5, 152.4. Anal. calcd. for $C_{16}H_{16}ClNO_2$ (289.76): C 66.32, H 5.57, N 4.83; found: C 66.43, H 5.79, N 4.99.

O-*3-Phenylsulfanyl-2-biphenylyl* N-*isopropylcarbamate (**13af**):* Reaction of **10a** (0.255 g) with TMSOTf (1.05 mmol), *n*-BuLi, and $(PhS)_2$ (0.546 g in 3 mL of Et_2O, 2.5 mmol, 1 h) furnished **13af** (0.341 g, 0.938 mmol, 94%) as a white solid, mp 115°C (Et_2O–PE). IR (KBr) ν (cm^{-1}): 3335, 1703, 1532, 778, 756, 703. ^1H NMR (300 MHz) δ: 1.04 (d, ^3J = 6.4 Hz, 6H), 3.70 (m, 1H), 4.63 (s, 1H), 7.13–7.18 (m, 2H), 7.20–7.46 (m, 11H). ^{13}C NMR (75 MHz) δ: 22.7, 43.3, 125.2, 126.3, 127.4, 128.2, 129.0, 129.2, 129.6, 131.2, 131.5, 131.9, 134.6, 136.8, 137.7, 146.6, 152.7. Anal. calcd. for $C_{22}H_{21}NO_2S$ (363.47): C 72.70, H 5.82, N 3.85; found: C 72.79, H 5.98, N 4.01.

O-*3-Methyl-2-biphenylyl* N-*isopropylcarbamate (**13ag**):* **10a** (0.255 g) reacted with TMSOTf (1.10 mmol), *s*-BuLi, and MeI (0.20 mL, 2.5 mmol, 1 h) to give **13ag** (0.223 g, 0.828 mmol, 83%) as a white solid, mp 109°C (Et_2O–PE). IR (KBr) ν (cm^{-1}): 3326, 1710, 1529, 783, 761, 699. ^1H NMR (300 MHz) δ: 1.05 (d, ^3J = 6.4 Hz, 6H), 2.26 (s, 3H), 3.73 (m, 1H), 4.60 (s, 1H), 7.14–7.22 (m, 3H), 7.27–7.43 (m, 5H). ^{13}C NMR (75 MHz) δ: 16.4, 22.7, 43.2, 125.7, 127.1, 128.1, 128.3, 129.1, 130.2, 131.9, 135.8, 138.4, 146.7, 153.3. Anal. calcd. for $C_{17}H_{19}NO_2$ (269.34): C 75.81, H 7.11, N 5.20; found: C 75.78, H 7.24, N 5.30.

O-*3-Ethyl-2-biphenylyl* N-*isopropylcarbamate (**13ah**):* **10a** (0.255 g) reacted with TMSOTf (1.05 mmol), *s*-BuLi, and EtI (0.20 mL, 2.5 mmol, 2 h) to give **13ah** (0.192 g, 0.678 mmol, 68%) as a white solid, mp 92°C (Et_2O–PE). IR (KBr) ν (cm^{-1}): 3347, 1709, 1528, 786, 759, 704. ^1H NMR (300 MHz) δ: 1.02 (d, ^3J = 6.5 Hz, 6H), 1.02 (t, ^3J = 7.6, 3H), 2.64 (q, 2H), 3.69 (m, 1H), 4.60 (s, 1H), 7.14–7.44 (m, 8H). ^{13}C NMR (100 MHz) δ: 14.1, 22.7, 23.3, 43.2, 125.9, 127.0, 128.0, 128.3, 128.4, 129.1, 135.9, 137.5, 138.5, 146.2, 153.4. Anal. calcd. for $C_{18}H_{21}NO_2$ (283.36): C 76.29, H 7.47, N 4.94; found: C 76.11, H 7.17, N 4.85.

O-*3-Allyl-2-biphenylyl* N-*isopropylcarbamate (**13ai**):* Reaction of **10a** (0.255 g) with TMSOTf (1.10 mmol), *s*-BuLi, and

O-*2-Methyl-1-naphthyl* N-*isopropylcarbamate (**16c**):* Reaction of **15** (0.229 g) with TMSOTf (1.10 mmol), *s*-BuLi, and MeI (0.20 mL, 2.5 mmol, 1 h) afforded **16c** (0.209 g, 0.860 mmol, 86%) as a white solid, mp 129°C (Et_2O–PE). IR (KBr) ν (cm^{-1}): 3286, 1705, 1538, 818, 770, 747. ^{1}H NMR (300 MHz) δ: 1.22 (d, ^3J = 6.4 Hz, 6H), 2.36 (s, 3H), 3.91 (m, 1H), 5.09 (s, 1H), 7.30 (d, 1H), 7.36–7.50 (m, 2H), 7.62 (d, 1H), 7.74–7.87 (m, 2H). ^{13}C NMR (75 MHz) δ: 16.2, 22.8, 43.5, 120.9, 125.3, 125.4, 126.3, 127.2, 127.7, 128.1, 128.7, 132.2, 144.3, 153.3. Anal. calcd. for $C_{15}H_{17}NO_2$ (243.13): C 74.05, H 7.04, N 5.76; found: C 73.82, H 7.07, N 5.51.

O-*2-(Hydroxyphenylmethyl)-1-naphthyl* N-*isopropylcarbamate (**16d**):* **15** (0.229 g) reacted with TMSOTf (1.10 mmol), *s*-BuLi, and PhCHO (0.26 mL, 2.5 mmol, 1 h) to give **16d** (0.277 g, 0.826 mmol, 83%) as a white solid, mp 174°C dec (Et_2O–PE). IR (KBr) ν (cm^{-1}): 3564, 3310, 1698, 1533, 757, 727, 700. ^{1}H NMR (300 MHz) δ: 1.29/1.28 (d, ^3J = 6.4 Hz, 6H), 3.16 (s, 1H), 3.93 (m, 1H), 5.18 (d, 1H), 6.20 (s, 1H), 7.20–7.38 (m, 4H), 7.39–7.56 (m, 4H), 7.67 (d, 1H), 7.77–7.84 (m, 1H), 7.87–7.94 (m, 1H). ^{13}C NMR (75 MHz) δ: 22.8, 43.9, 69.8, 121.5, 125.7, 126.3, 126.4, 126.5, 126.7, 127.1, 127.8, 127.9, 128.2, 133.2, 134.2, 142.5, 143.7, 154.4. Anal. calcd. for $C_{21}H_{21}NO_3$ (335.40): C 75.20, H 6.31, N 4.18; found: C 75.10, H 6.01, N 3.88.

O-*2-(Hydroxydiphenylmethyl)-1-naphthyl* N-*isopropylcarbamate (**16e**):* Reaction of **15** (0.229 g) with TMSOTf (1.05 mmol), *n*-BuLi, and Ph_2CO (0.456 g in 3 mL of Et_2O, 2.5 mmol, 1 h) afforded **16e** (0.357 g, 0.868 mmol, 87%) as a white solid, mp 117°C dec (Et_2O–PE). IR (KBr) ν (cm^{-1}): 3411, 3343, 1706, 1525, 765, 746, 711. ^{1}H NMR (300 MHz) δ: 1.05 (d, ^3J = 6.5 Hz, 6H), 3.61 (m, 1H), 4.51 (d, 1H), 4.58 (s, 1H), 6.97 (d, 1H), 7.18–7.33 (m, 6H), 7.40–7.52 (m, 6H), 7.57 (d, 1H), 7.73–7.84 (m, 2H). ^{13}C NMR (75 MHz) δ: 22.6, 43.5, 80.9, 121.9, 125.3, 126.6, 126.6, 126.8, 127.3, 127.7, 127.8, 128.8, 129.8, 134.3, 135.8, 144.5, 146.6, 153.5. Anal. calcd. for $C_{27}H_{25}NO_3$ (411.49): C 78.81, H 6.12, N 3.40; found: C 78.53, H 5.99, N 3.21.

General procedure for deprotection of N-*isopropylcarbamates **13a** and **13c***

To a solution of the *N*-isopropylcarbamate **13** (0.50 mmol) in EtOH (5 mL) under Ar in a flask was added at rt 2 M NaOH (1.0 mL, 2.0 mmol, 4.0 equiv). The resulting reaction mixture was stirred for 2 h. Then, 2 mL of 2 M HCl and 10 mL of Et_2O were added, the phases were separated, and the aqueous layer was extracted with Et_2O (3 × 10 mL). The combined organic phases were washed with saturated NaCl solution (5 mL), dried over $MgSO_4$, and filtered. Evaporation of the solvents provided the crude product. Flash chromatography on silica gel (Et_2O–PE mixtures) afforded the free phenol **14**.

*2-Hydroxy-3-trimethylsilylbiphenyl (**14aa**):* **13aa** (0.164 g) was deprotected to yield **14aa** (0.120 g, 0.495 mmol, 99%) as a colourless oil, which solidifies after a few days to give a white solid, mp 39°C (Et_2O–PE). IR (KBr) ν (cm^{-1}): 3531, 841, 763, 708. ^{1}H NMR (300 MHz) δ: 0.32 (s, 9H), 5.39 (s, 1H), 6.98 (t, 1H), 7.21–7.24 (m, 1H), 7.35–7.52 (m, 6H). ^{13}C NMR (75 MHz) δ: –0.9, 120.4, 125.8, 127.2, 127.9, 129.2, 129.5, 131.3, 134.8, 137.3, 157.0. Anal. calcd. for $C_{15}H_{18}OSi$ (242.39): C 74.33, H 7.48; found: C 74.39, H 7.72.

*2-Hydroxy-3-iodobiphenyl (**14ab**):* **13ac** (0.191 g) was deprotected to give **14ab** (0.145 g, 0.490 mmol, 98%) as a white solid, mp 42°C (Et_2O–PE). IR (KBr) ν (cm^{-1}): 3452, 756, 735, 700. ^{1}H NMR (300 MHz) δ: 5.54 (s, 1H), 6.74 (t, 1H), 7.21–7.25 (m, 1H), 7.34–7.50 (m, 5H), 7.67 (dd, 1H). ^{13}C NMR (75 MHz) δ: 85.8, 122.5, 128.0, 128.8, 129.1, 129.1, 131.0, 137.3, 138.1, 151.6. Anal. calcd. for $C_{12}H_9IO$ (296.10): C 48.68, H 3.06; found: C 48.75, H 3.18.

*3-Bromo-2-hydroxybiphenyl (**14ac**) (17):* **13ad** (0.167 g) was deprotected to yield **14ac** (0.123 g, 0.494 mmol, 99%) as a white solid, mp 59°C (Et_2O–PE) (lit. (17) mp 38 to 39°C). IR (KBr) ν (cm^{-1}): 3498, 759, 733, 701. ^{1}H NMR (300 MHz) δ: 5.65 (s, 1H), 6.87 (t, 1H), 7.22–7.26 (m, 1H), 7.33–7.54 (m, 6H). ^{13}C NMR (75 MHz) δ: 111.0, 121.7, 127.8, 128.5, 129.2, 129.7, 130.1, 131.5, 137.2, 149.3. Anal. calcd. for $C_{12}H_9BrO$ (249.10): C 57.86, H 3.64; found: C 58.08, H 3.46.

*2-Hydroxy-3-phenylsulfanylbiphenyl (**14ad**):* Deprotection of **13af** (0.182 g) gave **14ad** (0.138 g, 0.496 mmol, 99%) as a colourless oil, which solidifies after a few days to give a white solid, mp 71°C (Et_2O–PE). HRMS calcd. for $C_{18}H_{14}OS$ (278.37): 278.0765; found: 278.0759. IR (KBr) ν (cm^{-1}): 3394, 761, 741, 701, 690. ^{1}H NMR (300 MHz) δ: 6.67 (s, 1H), 6.92 (t, 1H), 7.03–7.54 (m, 12H). ^{13}C NMR (75 MHz) δ: 117.7, 121.1, 126.4, 127.4, 127.5, 127.6, 128.2, 128.9, 129.2, 133.0, 135.6, 135.7, 137.6, 154.0.

*2-Hydroxy-3-(hydroxydiphenylmethyl)biphenyl (**14ae**):* **13am** (0.219 g) was deprotected to yield **14ae** (0.169 g, 0.480 mmol, 96%) as a colourless oil, which solidifies after a few days to give a white solid, mp 129°C dec (Et_2O–PE). IR (KBr) ν (cm^{-1}): 3471, 803, 760, 701. ^1H NMR (300 MHz) δ: 4.17 (s, 1H), 6.52 (dd, 1H), 6.80 (t, 1H), 7.22–7.52 (m, 17H). ^{13}C NMR (75 MHz) δ: 83.9, 119.3, 127.4, 127.7, 127.8, 128.1, 128.5, 129.5, 129.7, 129.9, 130.5, 131.4, 137.6, 145.4, 152.1. Anal. calcd. for $C_{25}H_{20}O_2$ (352.43): C 85.20, H 5.72; found: C 84.85, H 5.50.

*2-Chloro-6-trimethylsilylphenol (**14ca**):* Deprotection of **13ca** (0.143 g, 0.500 mmol) furnished **14ca** (0.099 g, 0.493 mmol, 99%) as a colourless liquid. HRMS calcd. for $C_9H_{13}ClOSi$ (200.74): 200.0424; found: 200.0388. IR (film) ν (cm^{-1}): 3539, 842, 759. ^1H NMR (300 MHz) δ: 0.31 (s, 9H), 5.72 (s, 1H), 6.84 (dd, 1H), 7.25 (dd, 1H), 7.30 (dd, 1H). ^{13}C NMR (75 MHz) δ: –1.1, 119.5, 121.1, 127.1, 129.8, 133.7, 155.3. Anal. calcd.: C 53.85, H 6.53; found: C 54.14, H 6.71.

*2-Chloro-6-iodophenol (**14cb**) (18):* **13cc** (0.170 g) was deprotected to yield **14cb** (0.119 g, 0.468 mmol, 94%) as a white solid, mp 59°C (Et_2O–PE) (lit. (18) mp 38 to 39°C). IR (KBr) ν (cm^{-1}): 3433, 760. ^1H NMR (300 MHz) δ: 5.91 (s, 1H), 6.62 (t, 1H), 7.30 (dd, 1H), 7.61 (dd, 1H). ^{13}C NMR (75 MHz) δ: 83.5, 119.3, 122.8, 129.6, 137.8, 150.9. Anal. calcd. for C_6H_4ClI (254.45): C 28.32, H 1.58; found: C 28.31, H 1.82.

*2-Chloro-6-phenylsulfanylphenol (**14cc**):* **13cd** (0.161 g) was deprotected to afford **14cc** (0.108 g, 0.456 mmol, 91%) as a white solid, mp 67°C (Et_2O–PE). HRMS calcd. for $C_{12}H_9ClOS$ (263.72): 236.0063; found: 236.0051. IR (KBr) ν (cm^{-1}): 3408, 774, 739, 690. ^1H NMR (300 MHz) δ: 6.59 (s, 1H), 6.86 (t, 1H), 7.13–7.30 (m, 5H), 7.32–7.40 (m, 2H). ^{13}C NMR (75 MHz) δ: 119.8, 120.8, 121.3, 126.9, 128.5, 129.4, 131.5, 134.1, 134.7, 152.5.

LDA-mediated ortho*-Fries rearrangement of carbamate **10a***

N-*Isopropyl-2-hydroxybiphenyl-3-carboxamide (**12**) (19):* **10a** (0.255 g) was *N*-trimethylsilyl-protected according to the general procedure described above. The resulting mixture was cooled to 0°C and LDA solution (2.50 mmol, 2.50 equiv; prepared by stirring a 1:1 mixture of diisopropylamine (0.253 g) and *n*-BuLi in 2 mL of Et_2O at 0°C for 30 min) was added slowly. The resulting mixture was stirred at 0°C for 4 h and warmed to rt. After an additional stirring for 2 h, 5 mL of 2 M HCl was added, the phases were separated, and the aqueous layer was extracted with Et_2O (3 × 20 mL). The combined organic phases were washed with saturated NaCl solution (10 mL), dried over $MgSO_4$, filtered, and evaporated in vacuo. Purification of the crude product by flash chromatography on silica gel (Et_2O–PE gradient) gave **12** (0.201 g, 0.787 mmol, 79%) as a white solid, along with **13aa** (0.052 g, 0.159 mmol, 16%), mp 119°C (Et_2O–PE) (lit. (19) mp 118 to 119°C). IR (KBr) ν (cm^{-1}): 3399, 1642, 1585, 1540, 766, 752, 700. ^1H NMR (300 MHz) δ: 1.27 (d, ^3J = 6.6 Hz, 6H), 4.29 (m, 1H), 6.17 (s, 1H), 6.87 (t, 1H), 7.29–7.36 (m, 2H), 7.37–7.46 (m, 3H), 7.55–7.61 (m, 2H), 11.35 (s, 1H). ^{13}C NMR (75 MHz) δ: 22.6, 41.8, 114.7, 118.2, 124.5, 127.2, 128.1, 129.3, 131.3, 134.8, 137.5, 158.9, 169.5. Anal. calcd. for $C_{16}H_{17}NO_2$ (255.32): C 75.27, H 6.71, N 5.49; found: C 75.37, H 6.79, N 5.35.

Conclusions

In summary, we found a simple protocol for the electrophilic *ortho*-substitution of phenols. The in situ generated *N*-alkyl-*N*-silylcarbamoyl group serves as a powerful DMG for lithiation reactions. Several silyl sources could be used for in situ silyl protection and complete metalation could be achieved by means of *n*-BuLi–TMEDA at low temperatures. The deprotection of the *N*-monoalkylcarbamates to phenols proceeds quantitatively under mild basic conditions.

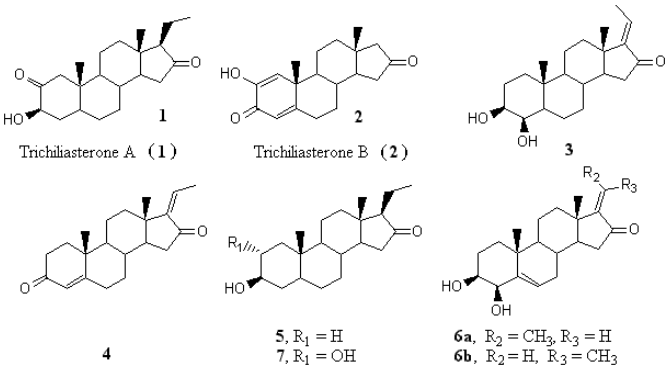
Synthesis of trichiliasterones A and B — 16-Ketosteroids isolated from *Trichilia hirta* and *Trichilia americana*

Susanne M. Hantos, Sasmita Tripathy, Najma Alibhai, and Tony Durst

Abstract: The syntheses of trichiliasterone A (3β-hydroxypregnan-2,16-dione) and trichiliasterone B (2-hydroxyandrost-1,4-diene-3,16-dione) have been carried out starting from isoandrosterone and testosterone acetate, respectively. In each synthesis the functionality in the D ring was installed prior to working on ring A. In the case of trichiliasterone A, the D ring chemistry involved a Wittig reaction to generate the 17-methylene group, followed by SeO_2 oxidation to give an α,β-unsaturated ketone. Reaction with lithium dimethyl cuprate gave the required 17-ethyl-16-keto functionality. A 2,3-epoxy enol acetate served as the key intermediate for the generation of the 2-keto-3-hydroxy functions in ring A. The transposition of the keto function from C-16 to C-17 in the synthesis of trichiliasterone B was accomplished via oxymercuration–demercuration of the $\Delta^{16—17}$ double bond followed by oxidation. The hydroxyl group at C-2 and the additional ring A unsaturation were introduced by lead tetra-acetate treatment of the 3-keto-4-enone function and subsequent air oxidation.

Key words: 16-ketosteroids, plant steroids, *Trichilia hirta*, trichiliasterones.

Résumé : On a réalisé les synthèses de la trichiliastérone A (3β-hydroxypregnane-2,16-dione) et de la trichiliastérone B (2-hydroxyandros-1,4-diène-3,16-dione) à partir de l'isoandrostérone et de l'acétate de testostérone respectivement. Dans chacune de ces synthèses, la fonctionnalité dans le cycle D a été installée avant de modifier le cycle A. Dans le cas de la trichiliastérone A, la chimie du cycle D implique une réaction de Wittig pour générer le groupe 17-méthylène, suivie d'une oxydation à l'aide de SeO_2 pour obtenir une cétone α,β-insaturée. La réaction du cuprate de diméthyle et de lithium fournit la fonctionnalité 17-éthyl-16-céto requise. Un acétate énolique 2,3-époxy a servi d'intermédiaire clé dans la génération des fonctions 2-céto-2-hydroxy du cycle A. Dans la synthèse de la trichiliastérone B, la transposition de la fonction céto de la position 16 en position 17 a été réalisée par le biais d'une oxymercuration–démercuration de la double liaison en 16—17, suivie d'une oxydation. Le groupe hydroxyle en C-2 et l'insaturation additionnelle du cycle A ont été introduits par un traitement de la fonction 3-céto-4-énone par du tétraacétate de plomb et une oxydation subséquente à l'air.



Mots clés : 16-cétostéroïdes, stéroïdes extraits de plantes, *Trichilia hirta*, trichiliastérones.

[Traduit par la Rédaction]

Introduction

Several years ago we reported that the ethanol extracts of the wood and bark of *Trichilia hirta*, a member of the Meliaceae family native to Costa Rica, exhibited significant growth inhibition of larvae of *Ostrinia nubilalis* (European corn borer) and *Peridroma sancia* (variegated cutworm) (1). Partitioning the crude extracts between water and CH_2Cl_2 concentrated the biological activity in the organic layer. Further purification via silica gel chromatography, followed by preparative HPLC afforded two steroids. These were identified as 3β-hydroxypregnan-2,16-dione (**1**) and 2-hydroxyandrost-1,4-diene-3,16-dione (**2**), and given the trivial names, trichiliasterones A and B, respectively. Both possess the relatively rare 16-keto functionality. Additionally, in **1** the ring A substitution pattern is 2-keto-3-hydroxy rather than the more commonly encountered 2-hydroxy-3-keto arrangement.

Relatively few other 16-keto plant steroids have been reported. These include lanisterone E (**3**) isolated from *Lansium anamallayanum* (2), z-guggulsterone (**4**) from *Comminphora mukul* (3), and **5** from *Solanum hainanense*, native to Vietnam (4). Recently, McLaughlin and co-workers (5) reported the isolation of a series of 16-ketosteroids from *Melia volkensii* including E and Z volkendousin (**6a** and **6b**) and meliavosin (**7**). Compounds such as **3** and **5** have been shown to have insecticidal (5), antitumor (5), antiinflammatory (3*a*) and hypocholesteremic (3*a*) activity.

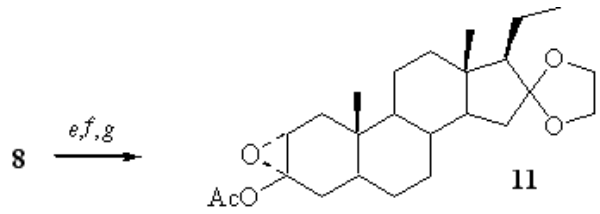
Scheme 1.

Isolation of **1** and **2** was lengthy and yielded only 0.001% of each component based on dry sawdust. To confirm the structural assignments, based mainly on nanoprobe INADEQUATE NMR technology (1), and to have material available for more complete bioassays, we decided to synthesize both compounds. We also report the synthesis of **5** and the 2-methoxy derivative of **2** which has been isolated from the wood of *Trichilia americana* (Costa Rica).[2]

Results and discussion

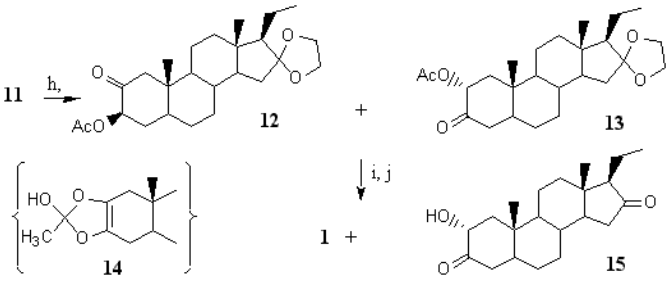
Trichiliasterone A



The retrosynthetic analysis for trichiliasterone A (**1**) starting from isoandrosterone (**10**) is shown in Scheme 1. Isoandrosterone was treated with 5 equiv of methylenetriphenylphosphorane affording the corresponding 17-methylene derivative in 88% yield (6). Allylic oxidation with SeO_2-*tert*-butyl hydroperoxide (7) followed by treatment of the crude product mixture, containing both the C-16 allylic alcohol and the enone **9**, with MnO_2 in acetone gave **9** in 48% overall yield. IR (cm^{-1}): 1725 (α,β-unsaturated ketone). ^1H NMR δ: 5.77 and 4.98 (=CH_2).

Reaction of **9** with 2.3 equiv of $(CH_3)_2CuLi$ in diethyl ether at 0°C (8) gave the natural product **5** (4), mp 152 to 153°C (lit. (4) mp 152 to 153°C) in 95% yield. The 16-keto group in **5** was then protected as the ethylene ketal prior to installing the substituents in ring A.

Work on ring A commenced with oxidation of the 3-hydroxy group in **8** with PDC in CH_2Cl_2. The 3-keto derivative (IR (cm^{-1}): 1701 (C=O)), obtained in 96% yield, was converted to the enol acetate **8a** in 84% isolated yield by reaction with excess lithium hexamethyldisilazide followed by acetic anhydride (IR (cm^{-1}): 1602, 1745. ^1H NMR δ: 2.07 (s, 3H), 5.23 (bs, 1H). Subsequent oxidation with MCPBA gave 72% of the epoxy acetate **11** as the major isomer. The structure of **11** (^1H NMR δ: 2.02 (s, 3H), 3.29 (d, J = 5.6 Hz, 1H)) is assumed to be that shown, based on the notion that attack by the oxidizing agent should occur from the less-hindered α-face.



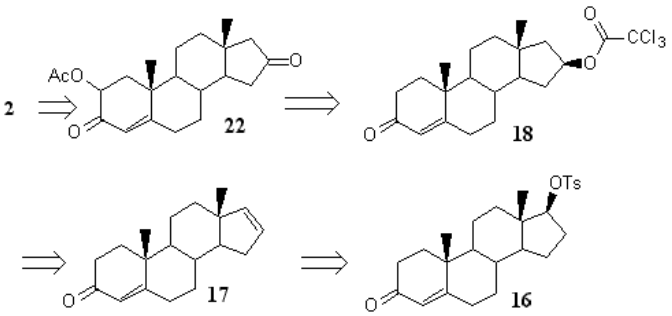
Reagents:
(*a*) $Ph_3{=}CH_2$–DMSO (88%);
(*b*) SeO_2–*t*BuOOH, then MnO_2 – $CHCl_3$ (48%);
(*c*) $(CH)_2CuLi$–ether (95%);
(*d*) $HOCH_2CH_2OH$–H^+ (73%).

Reagents:
(*e*) PDC (96%);
(*f*) $LiN[SiMe_3]_2$–Ac_2O (84%);
(*g*) MCPBA (72%).

The epoxy acetate **11** rearranged upon heating at 160°C and subsequent exposure to basic alumina to a mixture of the acetoxy ketones **12** and **13**. The presumed intermediate in this isomerization is the ortho acetal (partial structure **14** (9)). Since this mixture was difficult to separate, it was subjected to sequential hydrolysis of the ketal and acetate groups. Thus, treatment of the crude mixture of **12** and **13** with PPTS in refluxing aqueous acetone afforded the deprotected C-16 ketones in about 90% crude yield. Further reaction with LiOH in aq THF at 0°C gave 57% of a 1:4 mixture of **1** and **15** that was separated by careful silica gel chromatography. The properties of the sample identified as **1** were identical to those of the natural product trichiliasterone A (1). Trichiliasterone A and the isomeric **15** showed several diagnostic differences in their ^1H NMR spectra which were also noted for **12** and **13** and the sets of partially deprotected intermediates. Most noticeable was that the close spacing of the methyl groups in **1** (δ = 0.67 and 0.76 ppm) vs. a substantial difference for **15** (δ = 0.70 and 1.12 ppm).

Reagents:
(*h*) 160°C, the basic alumina, 24 h;
(*i*) PPTS, acetone, reflux;
(*j*) LiOH–THF, 0°C.

Trichiliasterone B



Trichiliasterone B (**2**) was prepared in nine steps starting with testosterone tosylate **16**; the retrosynthetic analysis is outlined in Scheme 2.

Testosterone tosylate was heated with tetrabutylammonium acetate in *N*-methylpyrrolidone at 160°C for 4 h (10). This generated a mixture of the desired alkene **17** (11) and 17-α-acetoxy testosterone, resulting from SN_2 attack by acetate on

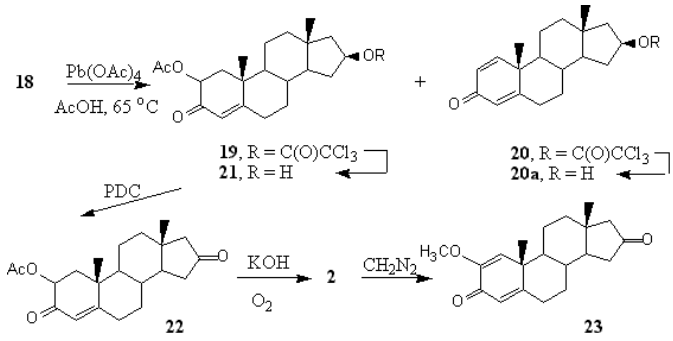
Scheme 2.



16. Surprisingly, these two reaction products showed almost identical TLC behavior. Therefore, the crude reaction mixture was stirred with KOH in ethanol to generate the more polar 17-α-alcohol that was easily separated from **17**; the yield of **17** was 61%. Other attempts at preparing **17** from **16** either by solvolysis or a DBU-catalyzed elimination reaction were not successful. The former approach resulted in extensive carbocation induced rearrangements while the latter returned only starting material even after 5 h of refluxing in toluene or 24 h refluxing in neat DBU.

Reagents:
(*a*) $Bu_4N^{(+)}AcO^{(-)}$, *N*-methylpyrrolidone, 160°C, 4 h;
(*b*) KOH–methanol;
(*c*) $Hg(OAc)_2$–THF–H_2O;
(*d*) $NaBH_4$–NaOH;
(*e*) $CCl_3C(O)Cl$–DMAP.

Oxymercuration–demercuration of **17** was carried out by stirring with mercuric acetate in a 1:1 mixture of THF–H_2O for 3 days, followed by reduction with sodium borohydride in the presence of NaOH. Surprisingly, no reduction of the A-ring enone system was observed under these conditions and the 16-β alcohol (IR (cm^{-1}): 3624 (OH), 1675, 1618 (enone). ^1H NMR δ: 5.70 (H-4) and 4.4 (H-16)) was obtained in 45% overall yield. Although not crucial, the stereochemistry of the C-16 hydroxyl group was assigned the expected β-stereochemistry based on the presumed attack by $Hg(OAc)_2$ on the less-hindered α-face of the C-16—C-17 double bond. The lack of an observable nOe between H-16 and the C-18 methyl group supports this assignment. In anticipation of the required manipulations in ring A, the C-16 hydroxyl group was protected as the acid-resistant but base-labile trichloroacetate, yielding **18.**

Reaction of **18** with 2 equiv of $Pb(OAc)_4$ in CH_3CO_2H containing a catalytic amount of TsOH for 4 h afforded a 4:1 mixture of the desired 2-acetoxy derivative **19**, as a 1:1 mixture of stereoisomers, and the dienone **20**, based on ^1H NMR analysis of the crude reaction product. Refluxing of this mixture with benzylamine in ethanol for 4 h caused selective removal of the trichloroacetate group yielding the C-16 alcohol **21**. Separation of **21** from the accompanying dienol **20a** was facile. Oxidation of **21** with PDC in CH_2Cl_2 gave 2-acetoxy-androsten-4-ene-3,16-dione **22** (IR (cm^{-1}): 1743 and 1680). Finally, deacetylation of **22** with KOH in methanol under aerobic conditions resulted in the formation of trichiliasterone B (**2**), mp 188 to 189°C, $[\alpha]_D$ = –220° (c = 0.84, CH_2Cl_2), in essentially quantitative yield. The spectroscopic properties of the synthetic product were identical with those of the compound isolated from *T. hirta* (1).

The 2-methyl ether of trichiliasterone B was identified as a component of the CH_2Cl_2 soluble, insecticidally active fraction obtained from the wood of *T. americana*.[2] Reaction of **2** with diazomethane afforded a product whose spectroscopic properties matched those of the natural product thereby confirming its structure assignment as **23**.

Experimental section

General methods

Melting points were determined using a Thomas Hoover capillary melting point apparatus. Mass spectra were determined on a VG 7070E or Kratos concept 2H instrument, using EI unless otherwise specified. ^1H and ^{13}C NMR spectra were obtained as $CDCl_3$ solutions either on a Varian Gemini or Brooker AMX-500 spectrometer. Optical rotations were determined using a PerkinElmer polarimeter (241) set at the sodium D line. Solvents used for reactions or chromatographic separations were distilled prior to use. Usual work-up refers to separating the reaction mixture into aqueous and organic solvent soluble components, drying the organic fraction with $MgSO_4$, and evaporating the solvent.

3-β-Hydroxy-17(20)ene-homoandrostane

n-Butyllithium (8.0 mmol) was added to a suspension of (2.95 g, 8.0 mmol) methyltripenylphosphonium bromide in 45 mL of dry THF at 0°C. The mixture was stirred for 1.5 h and 480 mg (1.65 mmol) of isoandrostane in 30 mL of THF was added. The mixture was stirred overnight at room temperature and then refluxed for 4 h. The cooled mixture was poured into water and extracted twice with 60 mL of ether. Further work-up followed by chromatography (80 g of basic alumina, 9:1 hexane–ethyl acetate) afforded 418 mg (88%) of the title compound, mp 144 to 145°C, (lit. (6) mp 144 to 145°C. IR (CH_2Cl_2) (cm^{-1}): 3313, 1655. ^1H NMR (500 MHz) δ: 4.59–4.57 (m, 2 H) 3.55 (sept. *J* = 4.9 Hz, 1H), 3.44 (bs, 1H), 2.47–2.41 (m, 1H), 2.20–2.17 (m, 1H), 1.78–1.51 (m, 8H), 1.42–1.14 (m, 8H), 1.11–0.87 (m, 2H), 0.79 (s, 3H), 0.73 (s, 3H), 0.74–0.60 (m, 2H). ^{13}C NMR (125 MHz): 161.9, 100.6, 71.2, 54.4, 54.4, 44.9, 38.1, 37.0, 35.7, 35.4, 31.9, 31.4, 29.3, 28.6, 21.1, 18.5, 12.3.

*3β-Hydroxy-16-one-17(20)-ene-homoandrostane (**9**)*

To a mixture of *tert*-butyl hydroperoxide (70%, 0.80 mL, 7.8 mmol) and selenium dioxide (151 mg, 1.34 mmol) in 10 mL of CH_2Cl_2 at room temperature was added 393 mg (1.36 mmol) of 3-β-hydroxy-17(20-ene-homoandrostane in 5 mL of CH_2Cl_2. The reaction mixture was stirred for 48 h. Benzene (10 mL) was added and the solvents were evaporated under reduced pressure. The residue was suspended in CH_2Cl_2 (100 mL) and washed with 10% KOH solution and brine. The organic soluble residue was dissolved in acetic acid (1.5 mL) and stirred with excess dimethyl sulfide (3 mL) for 4 h. Work-up afforded 338 mg of a mixture of **9** and the corresponding allylic alcohol. This mixture was dissolved in 80 mL of $CHCl_3$ and stirred with 1.6 g of activated MnO_2 for 24 h. The mixture was filtered through a Celite pad and the solvent evaporated. Chromatography (18 g silica, 5:1 hexane – ethyl acetate afforded 199 mg (48%) of **9** as a white solid, mp 148–150°C. HRMS calcd. for $C_{20}H_{30}O_2$: 302.2247; found: 302.2238. IR (cm^{-1}): 3393, 1725, 1645. ^{1}H NMR δ: 5.77 (s, 1H), 4.98 (s, 1H), 3.58 (m, 1H), 2.30–1.98 (m, 2H), 1.93–1.90 (m, 1H), 1.83–1.79 (m, 1H), 1.77–1.54 (m, 6H), 1.59–1.21 (m, 8H), 1.17–1.09 (m, 1H), 1.01–0.93 (m, 1H), 0.93 (s, 3H), 0.89–0.76 (m, 1H), 0.84 (s, 3H). ^{13}C NMR δ: 207.0, 156.9, 111.9, 71.2, 54.5, 49.4, 44.5, 42.9, 38.1, 38.0, 36.7, 35.8, 35.4, 34.5, 32.0, 31.4, 28.4, 20.8, 19.2, 12.3.

*3β-Hydroxypregnan-16-one (**5**)*

A 1.4 M solution of CH_3Li in ether (31.4 mL, 43.9 mmol) was added dropwise to a suspension of copper(I) iodide (4.18 g, 0.022 mol) in dry ether (235 mL) at 0°C. After 2 min, an orange solution of the cuprate had formed and a solution of 3β-hydroxy-16-one-17(20)-ene-homoandrostane (**9**) (2.85 g, 9.42 mmol) in dry ether (300 mL) was added dropwise over 30 min. The reaction mixture was warmed to room temperature and allowed to stir for 2 h before quenching with 0.2 M aqueous sulfuric acid (200 mL) and a saturated aqueous solution of ammonium chloride (100 mL). Further work-up and purification by flash chromatography (111 g of silica gel, 9:1 hexanes – ethyl acetate) yielded **5** (2.84 g, 95%) as a white solid, mp 152 to 153°C, (lit. (4) mp 152 to 153°C. IR (cm^{-1}): 3338, 1739. ^{1}H NMR δ: 3.57 (m, 1H), 2.18 (dd, *J* = 18.3, 7.5 Hz, 1H), 1.86 (dd, *J* = 8.6, 2.8 Hz, 1H), 1.84–1.46 (m, 10H), 1.43–1.18 (m, 8H), 1.14–1.08 (m, 1H), 1.00 (t, *J* = 7.5 Hz, 3H), 1.00–0.89 (m, 2H), 0.81 (s, 3H, H-19), 0.81–0.77 (m, 1H), 0.66 (s, 3H). ^{13}C NMR δ: 219.6, 71.1, 65.3, 54.3, 50.5, 44.8, 42.1, 38.5, 38.2, 38.0, 36.7, 35.6, 34.5, 32.2, 31.4, 28.4, 20.7, 17.6, 13.4, 13.4, 12.3.

*3β-Hydroxy-16-ethylenedioxypregnane (**8**)*

A solution of TsOH (5 mg), ethylene glycol (0.46 mL, 8.25 mmol), and **5** (110 mg, 0.344 mmol) was refluxed in dry benzene (12 mL) for 18 h. Water was removed with a Dean–Stark trap. The opaque solution was washed with a saturated aqueous solution of sodium bicarbonate (5 mL) and water (2 × 5 mL). Further work-up, followed by chromatography (11 g of neutral alumina, 9:1 hexanes – ethyl acetate followed by 2:1 hexanes – ethyl acetate) yielded **8** (91 mg, 73%) as a white solid, mp 155–161°C. IR (cm^{-1}): 3412, 1171, 1095, 1022. HRMS calcd. for $C_{23}H_{38}O_3$: 362.2822; found: 362.2830. ^{1}H NMR δ: 3.91–3.85 (m, 2H), 3.84–3.79 (m, 1H), 3.73–3.66 (m, 1H), 3.54 (sept. *J* = 5.0 Hz, 1H), 1.81–1.62 (m, 6H), 1.58–1.19 (m, 13H), 1.16–1.05 (m, 3H), 0.99–0.85 (m, 2H), 0.86 (t, *J* = 7.5 Hz, 3H), 0.77 (s, 3H), 0.68 (s, 3H). ^{13}C NMR δ: 117.5, 71.19, 64.8, 62.9, 60.8, 54.5, 52.1, 44.8, 42.2, 39.9, 38.6, 38.1, 36.8, 35.6, 34.6, 32.0, 31.4, 28.6, 20.8, 17.0, 13.5, 12.9, 12.9.

16-Ethylenedioxypregnan-3-one

Pyridinium dichromate (154 mg, 0.410 mmol) was added to a solution of **8** (59.5 mg, 0.164 mmol) in dry CH_2Cl_2 (1.0 mL) at room temperature. The reaction mixture was stirred for 48 h, diluted with ether (2.0 mL), filtered through anhydrous magnesium sulfate and Celite and rinsed with ether (100 mL). Chromatography of the crude product (7 g of neutral alumina, 4:1 hexanes–acetate) yielded (60 mg, 96%) of the title compound mp 149–151°C. IR (cm^{-1}): 1707, 1172, 1155, 1092 and 1024. HRMS calcd. for $C_{23}H_{36}O_3$: 360.2666; found: 360.2679. ^{1}H NMR δ: 3.92–3.86 (m, 2H), 3.85–3.81 (m, 1H), 3.72–3.67 (m, 1H), 2.38–2.20 (m, 3H), 2.05 (dt, *J* = 15.0, 3.7 Hz, 1H), 1.98 (ddd, *J* = 13.2, 6.4, 2.1 Hz, 1H), 1.81 (dd, *J* = 12.5, 7.0 Hz, 1H), 1.74 (dt, *J* = 12.5, 7.0 Hz, 2H), 1.63–1.22 (m, 11H), 1.18–1.08 (m, 2H), 0.98 (s, 3H), 0.96–0.86 (m, 1H), 0.88 (t, *J* = 7.0 Hz, 3H), 0.78 (dt, *J* = 12.3, 4.0 Hz, 1H), 0.72 (s, 3H). ^{13}C NMR δ: 211.9, 117.4, 64.9, 62.9, 60.8, 53.9, 51.9, 46.6, 44.6, 42.2, 40.0, 38.5, 38.4, 38.2, 35.8, 34.6, 31.7, 28.8, 21.0, 17.0, 13.5, 12.9, 11.5.

*3-Acetoxy-16-ethylenedioxy-2-pregnene (**8a**)*

$LiN(TMS)_2$ (2 equiv) was added to 25 mg (0.069 mmol) of 16-ethylenedioxypregnan-3-one in 5 mL of dry THF at –78°C. The reaction mixture was stirred for 1 h; 3 equiv of acetic anhydride was added and the reaction progress was monitored using TLC (12:1 toluene–acetone). The reaction mixture was quenched after 30 min with water and extracted with EtOAc (3 × 10 mL). Usual work-up provided the title compound in 84% yield as white crystals mp 100–104°C. IR (cm^{-1}): 1745, 1602. HRMS calcd. for $C_{25}H_{38}O_4$: 402.2777; found: 402.2782. ^{1}H NMR δ: 0.71–1.01 (m, 4H), 0.88 (t, 3H, *J* = 7.0 Hz), 0.80 (s, 3H), 0.70 (s, 3H), 1.10–1.61 (m, 11H), 1.81 (ddd, 2H, *J* = 12.8, 7.0 Hz), 1.74 (dt, 1H, *J* = 6.7, 3.7 Hz), 1.91–1.95 (m, 2H), 2.00 (dd, 1H, *J* = 17.0, 3.3 Hz), 2.07 (s, 3H), 3.67–3.72 (m, 1H), 3.81–3.86 (m, 1H), 3.87–3.92 (m, 2H), 5.23 (d, 1H). ^{13}C NMR δ: 169.5, 147.0, 117.5, 112.5, 64.9, 62.9, 60.8, 53.7, 52.0, 42.1, 41.8, 40.0, 38.6, 38.1, 34.7, 31.6, 31.4, 28.3, 21.0, 20.7, 17.0, 13.5, 12.9, 11.7.

*3β-Acetoxy-2α,3α-epoxy-16-ethylenedioxypregnane (**11**)*

To a cooled (0°C) solution of **7** (0.174 g, 0.43 mmol) in dry CH_2Cl_2 (25 mL) was added 2 equiv of MCPBA in one portion. The reaction mixture was warmed to room temperature, stirred for 24 h, and then washed successively with sodium sulfite solution (sat., 2 × 5 mL), sodium bicarbonate (sat., 2 × 5 mL), and water (2 × 10 mL). The resulting oily residue, obtained upon further work-up, was purified by flash column chromatography (9:1 hexane – ethyl acetate) affording 0.13 g, (72%) of **11** as white crystals, mp 95–100°C. IR (cm^{-1}): 1745, 1601. HRMS calcd. for $C_{25}H_{38}O_5$: 418.2720; found: 418.2745. ^{1}H NMR δ: 0.78–0.84 (m, 1H),

© 2001 NRC Canada

0.66–0.69 (m, 1H), 0.68 (s, 3H), 0.87 (t, 3H, *J* = 7.0 Hz), 0.93 (s, 3H), 0.95–1.54 (m, 14H), 1.72 (dt, 1H, *J* = 9.0, 3.0 Hz), 1.79 (dd, 1H, *J* = 12.9, 7.0 Hz), 1.88 (dd, 1H, *J* = 14.0, 11.0 Hz), 1.97–2.07 (m, 2H), 2.02 (s, 3H), 3.29 (d, 1H, *J* = 5.6 Hz), 3.67–3.70 (m, 1H), 3.81–3.86 (m, 1H), 3.87–3.90 (m, 2H). ^{13}C NMR δ: 169.3, 117.4, 83.0, 64.8, 62.9, 60.7, 58.3, 53.5, 51.9, 41.9, 39.9, 38.7, 38.6, 38.4, 34.6, 34.4, 31.5, 30.7, 27.9, 21.1, 20.5, 16.9, 13.4, 12.8, 12.7.

*3β-Hydroxypregnan-2,16-dione (**1**) and 2α-hydroxypregnan-3,16-dione (**15**)*

Compound **11** (220 mg, 0.53 mmol) was heated neat at 160°C for 15 min and then loaded on a basic Al_2O_3 column for 24 h. Elution with solvent ethyl acetate:hexane (3:7) provided a mixture of compound **12** and **13** (132 mg, 60%) as a solid (^{1}H NMR spectrum shows a multiplet at the δ 5.17–5.31 region of the spectrum accounting for the -CH attached to acetate groups). To a solution of the above acetal (**12** and **13**) (132 mg, 0.32 mmol) in aqueous acetone (5 mL) was added pyridinium tosylate (PPTS) (23.0 mg, 0.095 mmol). The resultant solution was refluxed for 3 h. Solvent was removed in vacuo and the residue was extracted into ethyl acetate and was washed with an aqueous solution of sodium bicarbonate and brine. The organic layer was separated and dried and the crude product was used without any further purification. (The ^{1}H NMR spectrum showed the absence of signal due to ethylenedioxy group (δ = 3.8 to 3.9).

To a solution of the above acetates (106 mg, 0.28 mmol) in a THF:H_2O mixture (5 mL, 3:1) at 0°C, was added LiOH (1 M solution, 0.6 mL, 0.56 mmol). The solution was stirred at 0°C for 2 h. The mixture was extracted into ethyl acetate (10 mL) and was washed with water (2 mL). The organic layer was separated, dried, and concentrated. Chromatography (3:7, ethyl acetate: hexane) afforded **1** (12.0 mg, 13%) and **15** (40 mg, 43%).

For compound **1**: mp 144 to 145°C, $[\alpha]_D$ = –78° (c 0.47, MeOH). HRMS calcd. for $C_{21}H_{32}O_3$: 332.2351; found: 332.2336. The spectroscopic properties were identical with the reported data (1). Compound **15**: mp 136 to 137°C. IR (cm^{-1}): 1714, 1734. HRMS calcd. for $C_{21}H_{32}O_3$: 332.2351; found: 332.2359. ^{1}H NMR δ: 4.20 (dd, *J* = 7.1, 12.0 Hz, 1H), 3.50 (bs, 1H, OH), 2.46 (dd, *J* = 7.0, 12.5 Hz, 1H), 2.39 (t, *J* = 13.9 Hz, 1H), 2.27 (dd, *J* = 3.7, 14.1 Hz, 1H), 2.19 (dd, *J* = 7.6, 18.2 Hz, 1H), 1.92 (dt, *J* = 2.9, 12.5 Hz, 1H), 1.78–0.90 (m, 16H), 1.08 (s, 3H), 0.97 (t, *J* = 7.5 Hz, 3H), 0.68 (s, 3H). ^{13}C NMR ($CDCl_3$) δ: 12.8, 13.3, 13.5, 17.5, 21.1, 28.2, 31.8, 33.6, 37.2, 38.0, 38.3, 42.1, 42.2, 48.1, 48.2, 50.1, 53.7, 65.2, 72.6, 210.7, 218.2.

*Androsta-4,16-dien-3-one (**17**)*

Tetrabutylammonium acetate (17.4 g, 57.8 mmol) was added to a clear yellow solution of testosterone tosylate (**16**) (4.15 g) in dry *N*-methylpyrrolidinone (90 mL) at room temperature and warmed to 160°C. The reaction mixture was stirred 4 h, dissolved in ether (200 mL), and washed with water (3 × 50 mL). The aqueous layer was extracted with ether (2 × 100 mL) and the combined extracts were dried (anhydrous magnesium sulfate), filtered through a sintered glass funnel, and concentrated in vacuo. The *N*-methylpyrrolidinone was removed by vacuum distillation (54°C, 5 mmHg (1 mmHg = 133.322 Pa)) and the resulting residue was dissolved in 95% ethanol (60 mL). A 0.54 M aqueous solution of potassium hydroxide (57 mL) was added and the mixture was stirred at room temperature for 48 h. The reaction mixture was diluted with ethyl acetate (120 mL) and neutralized to pH 7.0 with 5% aqueous hydrochloric acid. Further work-up afforded a yellow solid. Column chromatography (200 g of neutral alumina, 2:1 petroleum ether – ether) yielded **17** (1.54 g, 61%) as a pale yellow solid, mp 131–135°C (lit. (11) mp 131–133°C).

16β-Hydroxyandrost-4-en-3-one

Water (10 mL) and mercuric acetate (1.43 g, 4.5 mmol) were added to a solution of androsta-4–16-dien-3-one (**17**) (1.22 g, 4.5 mmol) in THF (10 mL) at room temperature. The reaction mixture was stirred 3 days, 3.0 M aqueous sodium hydroxide (10 mL) was added followed by 0.5 M sodium borohydride in 3.0 M aqueous sodium hydroxide (10 mL), added in 2 mL aliquots. The mixture was stirred for 2 min, stirring was stopped, and mercury was allowed to settle. Salt was added to saturate the aqueous layer followed by THF (6 mL). The mixture was stirred for 30 min, filtered through a cotton plug with suction and the layers were separated. Further usual work-up followed by chromatography (150 g of neutral alumina, 9:1 hexane–ether) afforded the title compound (0.584 g, 45%) as a white solid mp 153.5–155.5°C; 0.22 g, 18% of starting material **17** were reisolated. For 16β-hydroxyandrost-4-en-3-one: IR (5% in CCl_4, solution cell) (cm^{-1}): 3624, 1675, 1618. HRMS calcd. for $C_{19}H_{28}O_2$: 288.2090; found: 288.2087. ^{1}H NMR δ: 5.70 (s, 1H), 4.41–4.36 (m, 1H), 2.43–2.14 (m, 5H), 2.02–1.97 (m, 1H), 1.85–1.80 (m, 1H), 1.76–1.40 (m, 8H), 1.31 (dt, *J* = 13.1, 5.5 Hz, 1H), 1.17 (s, 3H, H-19), 1.17–0.88 (m, 4H), 0.98 (s, 3H). ^{13}C NMR δ: 199.5, 171.2, 123.8, 71.7, 53.8, 53.4, 51.1, 40.0, 38.6, 38.6, 37.0, 35.6, 35.3, 33.9, 32.8, 32.2, 20.6, 18.8, 17.3.

*16β-Trichloroacetoxyandrost-4-en-3-one (**18**)*

Triethylamine (0.69 mL, 0.50 mmol), trichloroacetyl chloride (0.44 mL, 0.40 mmol), and *N*,*N*-dimethylaminopyridine (4.1 mg, 0.040 mmol) were added to a solution of 16β-hydroxyandrost-4-en-3-one (96 mg, 0.33 mmol) in dry methylene chloride (7.5 mL) at 0°C. The reaction mixture was stirred for 30 min at 0°C and 2 h at room temperature, poured into water (10 mL), and worked up in the appropriate manner. Flash chromatography (6 g of silica gel, 9:1 hexanes – ethyl acetate) yielded **18** (120 mg, 83%) as a yellow solid; starting material (20 mg, 11%) was also recovered. For **17**: mp 147–149°C. HRMS calcd. for $C_{21}H_{27}{}^{35}Cl_3O_3$: 432.1028; found: 432.1049. IR (cm^{-1}): 1759, 1669, 1615. ^{1}H NMR δ: 5.69 (s, 1H), 5.29–5.27 (m, 1H), 2.43–2.26 (m, 5H), 2.01–1.98 (m, 1H), 1.99–1.74 (m, 3H), 1.67–1.44 (m, 6H), 1.16 (s, 3H), 1.15–0.99 (m, 4H), 0.95 (s, 3H). ^{13}C NMR δ: 199.2, 170.5, 161.4, 124.0, 80.2 (2 C), 53.7, 53.0, 47.3, 39.9, 38.6, 38.1, 35.6, 35.3, 33.9, 33.8, 32.6, 32.0, 20.6, 17.8, 17.3.

*2β-Acetoxy-16β-trichloroacetoxy-androst-4-en-3-one, 2α-acetoxy-16β-trichloroacetoxy-androst-4-en-3-one (**19**), and 16β-trichloroacetoxyandrosta-1,4-dien-3-one (**20**)*

Lead tetraacetate (719 mg, 1.61 mmol), recrystallized from hot glacial acetic acid, was dissolved in glacial acetic acid (9 mL) at 50°C. The mixture was stirred for 15 min. A

solution of 16β-trichloroacetoxyandrost-4-en-3-one (**18**) (631 mg, 1.50 mmol) and TsOH (approximately 10 mg) in glacial acetic acid (8 mL) was added and the mixture was warmed to 60–70°C for 19 h. The mixture was cooled to room temperature, diluted with ethyl acetate (125 mL), and washed with water (2 × 10 mL) and a saturated aqueous solution of sodium bicarbonate (4 × 10 mL). The crude product (620 mg) was judged to be a mixture of the three title compounds and was used as is.

*2β-Acetoxy-16β-hydroxyandrost-4-en-3-one, 2α-acetoxy-16β-hydroxyandrost-4-en-3-one (**21**) and 16β-hydroxyandrosta-1,4-dien-3-one (**20a**)*

A solution of 2α- and 2β-acetoxy-16β-trichloroacetoxyandrost-4-en-3-one (**19**) and 16β-trichloroacetoxyandrostan-1,4-dien-3-one (**20**) (250 mg) in absolute ethanol (20 mL) was warmed to 30°C and stirred for 1 h. Triethylamine (0.49 mL, 3.5 mmol) and benzylamine (0.41 mL, 3.8 mmol) were added and the mixture was heated at reflux for 4 h. The reaction mixture was diluted with ethyl acetate (100 mL) and washed with 5% aqueous hydrochloric acid (3 × 10 mL) and water (3 × 10 mL). Flash chromatography (32 g of silica gel, 4:1 hexanes – ethyl acetate) yielded a 1:2.4 mixture of **21** (176 mg, 47%) as a yellow solid and **20a** (39 mg, 27%) as a white solid.

For the mixture of 2α- and 2β-acetoxy compounds: IR (cm^{-1}): 3484, 1748, 1686, 1614. ^1H NMR δ (major isomer): 5.71 (d, J = 1.5 Hz, 1H, H-4), 5.41 (dd, J = 14.1, 5.4 Hz, 1H, H-2), 2.13 (s, 3H, H-21, 2-OAc), 1.30 (s, 3H, H-19); (minor isomer): 5.74 (d, J = 1.2 Hz, 1H, H-4), 5.28 (dd, J = 13.2, 4.5 Hz, 1H, H-2), 2.11 (s, 3H, H-21, 2-OAc), 1.17 (s, 3H, H-19); (major + minor): 4.37–4.25 (m, 2H, H-16), 2.51–2.14 (m, 8H), 2.11, 1.95–1.70 (m, 8H), 1.60–1.25 (m, 12H), 1.08–0.85 (m, 8H), 0.96 (s, 6H).

For 16β-hydroxyandrostan-1,4-dien-3-one (**20a**): mp 173–175°C. IR (cm^{-1}): 3407, 1695, 1617. HRMS calcd. for $C_{19}H_{26}O_2$: 286.1934; found: 286.1989. ^1H NMR δ: 7.03 (d, J = 10.2 Hz, 1H), 6.14 (dd, J = 10.2, 1.9 Hz), 6.04 (s, 1H), 4.42–4.32 (m, 1H), 2.49–2.40 (m, 1H), 2.39–2.29 (m, 1H), 2.25–2.11 (m, 2H), 1.98–0.79 (m, 12H), 1.22 (s, 3H), 1.00 (s, 3H). ^{13}C NMR δ: 186.3, 169.1, 153.8, 127.46, 123.8, 71.66, 53.3, 53.1, 51.1, 43.6, 40.3, 38.5, 37.2, 35.3, 33.8, 32.8, 22.6, 19.0, 18.7.

*2α- and 2β-Acetoxyandrost-4-en-3,16-dione (**22**)*

Pyridinium dichromate (89 mg, 0.24 mmol) was added to a solution of 2α- and 2β-acetoxy-16β-hydroxyandrost-4-en-3-one (55 mg, 0.16 mmol) in dry methylene chloride (1 mL) at room temperature. The reaction mixture was stirred for 20 h, diluted with ether (2 mL), filtered through anhydrous magnesium sulfate and Celite in a sintered glass funnel. The product was concentrated in vacuo affording **22** (46 mg, 83%) as a white solid, mp 201 to 202°C. IR (cm^{-1}): 1743, 1650, 1617. ^1H NMR δ (major isomer): 5.75 (d, J = 1.5 Hz, 1H), 5.44 (d, J = 14.1, 8.7 Hz, 1H, H-2), 2.43–2.11 (m, 3H), 2.15 (s, 3H, H-21), 1.98–1.04 (m, 14H), 1.34 (s, 3H, H-19), 0.92 (s, 3H, H-18); (minor isomer): 5.78 (d, J = 1.3 Hz, 1H, H-4), 5.30 (dd, J = 12.5, 5.0 Hz, 1H, H-2), 2.13 (s, 3H, H-21, 2-OAc); all other peaks buried under the major isomer. ^{13}C NMR δ (major isomer): 17.26, 193.4, 170.2, 169.7, 122.1, 71.1, 55.5, 54.0, 50.9, 41.2, 40.6, 39.0, 38.8, 37.6, 35.1, 32.1, 32.0, 22.0, 20.8, 18.1, 17.9.

*2-Hydroxyandrosta-1,4-diene-3,16-dione (**2**)*

A solution of 2α- and 2β-acetoxyandrost-4-ene-3,17-dione (**16**) (118 mg, 0.343 mmol) in 95% ethanol (14 mL) was stirred at room temperature for 30 min. A solution of potassium hydroxide (192 mg, 3.43 mmol) in water (7 mL) was added and the mixture was stirred vigorously for 1 h. Stirring was stopped and the flask was left open to the air for 4 days. The reaction mixture was diluted with ethyl acetate (28 mL), neutralized with 5% aqueous hydrochloric acid, and washed with water (1 × 10 mL) and brine (1 × 10 mL). The aqueous layer was extracted with ethyl acetate (1 × 20 mL) and the combined extracts were dried (anhydrous magnesium sulfate), filtered through a sintered glass funnel, and concentrated in vacuo affording a pale yellow solid. Flash chromatography (10 g of silica gel, 3:1 hexanes – ethyl acetate) yielded **2** (103 mg, 100%) as a white solid, mp 188 to 189 °C. The spectroscopic properties matched those reported (1). Anal. calcd. for $C_{19}H_{24}O_3$: C 75.97, H 8.05; found: C 75.84, H 8.36.

*2-Methoxyandrost-1,4-diene-3,16-dione (**23**)*

A solution of diazomethane in ether (1 mL, approximately 2.8% w/v prepared from nitrosomethylurea) was added to 2-hydroxyandrosta-1,4-diene-3,16-dione (**2**) (21 mg, 0.071 mmol) in methylene chloride (5 mL) at 5°C. The reaction mixture was stirred for 21 h at room temperature and was opened to air to facilitate the evaporation of excess diazomethane and solvent. The pale yellow solid was purified by flash chromatography (2 g of silica gel, 3:1 hexanes – ethyl acetate) yielding **23** (4.2 mg, 19%) as a white solid; (14 mg, 65%) of **2** was recovered. For **23**: HRMS calcd. for $C_{20}H_{26}O_3$: 314.1901; found: 314.1893. ^1H NMR δ: 6.11 (d, J = 1.2 Hz, 1H, H-4), 5.93 (s, 1H, H-1), 3.66 (s, 3H-H-20), 2.51–2.38 (m, 2H), 2.23–2.12 (m, 2H), 2.07–1.71 (m, 5H), 1.53–1.37 (m, 2H), 1.27 (s, 3H), 1.26–1.07 (m, 4H), 0.95 (s, 3H, H-18). These data matched those of the product isolated from *T. americana* (6).

Acknowledgements

We sincerely thank Professor J.B. Orr, Department of Biochemistry, Memorial University of Newfoundland, St. John's, Newfoundland, for a generous donation of testosterone and isoandrostane, the starting materials in our syntheses. The continued support of the Natural Sciences and Engineering Research Council of Canada (NSERC) in the form of an operating grant (TD) is also acknowledged.

Ortho-directed metallation of π-deficient heterocycles in connection with palladium-catalyzed biaryl cross-coupling — Synthesis of marine alkaloids of the pyridoacridine series

A. Godard, P. Rocca, F. Guillier, G. Duvey, F. Nivoliers, F. Marsais, and G. Quéguiner.

Abstract: Connection between *ortho*-directed metallation of π-deficient heterocycles and Suzuki cross-coupling reactions provides a very efficient and fruitful strategy to polycyclic molecules of biological interest. The methodology is used to synthesize alkaloids or precursors and analogues of natural compounds of the pyrido[2,3,4-*k*,*l*]acridine series.

Key words: marine alkaloids, pyrido[2,3,4-*k*,*l*]acridines, metallation, cross-coupling.

Résumé : L'association des réactions de métallation et de couplage croisé de type Suzuki est une méthode efficace et fructueuse de synthèse de molécules polycycliques possédant des propriétés biologiques intéressantes. Cette méthode a été utilisée pour synthétiser des composés précurseurs ou analogues de composés naturels de la famille des pyrido[2,3,4-*k*,*l*]acridines.

Mots clès : alcaloïdes marins, pyrido[2,3,4-*k*,*l*]acridines, metallation, couplage croisé.

Introduction

For many years metallation has been an essential tool for the functionalization of aromatics under mild conditions, regioselectively and in good yields. Application of this methodology to π-deficient heterocycles was difficult due to their high electrophilic reactivity, which was overcome in a few laboratories using specific conditions (1). This reaction is now widely used for the synthesis of functionalized pyridines, quinolines, and diazines of biological interest. Moreover, it has been successfully connected to other methodologies, leading to complex molecules via short routes and in good overall yields (2). One of these complementary reactions is the biaryl cross-coupling reaction catalyzed by transition metals. "The connection between the DoM and Suzuki cross-coupling reactions provides an entry into highly functionalized biaryls, *m*-teraryls, and tetraaryls whose generality, and regioselectivity allow anticipation of broad application for the synthesis of polyaryls with interesting properties" wrote Snieckus in 1990 (3). To emphasize this sentence we wish to review herein the main results obtained in the synthesis of a recently discovered series of marine alkaloids.

A wide range of polycyclic alkaloids which contain the common 7*H*-pyrido[2,3,4-*k*,*l*]acridine moiety **1** have been discovered since the isolation of amphimedine **2** in 1983 (4). Ascidiademine **3**, meridine **4**, and cystodytins **5** are a few examples of this family. Most of these natural products exhibit interesting biological properties (Ca-releasing, antiviral, antimicrobial activities, cytotoxicity against L_{1210} cells, topoisomerase inhibitors, etc.) and different syntheses have been published (4).

Our experience in the synthesis of complex polyaromatics prompted us to look for a general route to 4*H*-pyrido[2,3,4-*k*,*l*]acridin-4-ones **6**. As shown on the retrosynthetic pathway depicted on Scheme 1, the intermediate benzo[*c*]-2,7-naphthyridine **7** could be synthesized by a cross-coupling and (or) condensation sequence from 2,3,4-trisubstituted pyridines **8**. We wish to report in the paper the synthesis of polysubstituted pyridines **8** as precursors of pyrido-acridones **6** via the diazaphenanthrenes **7**.

Synthesis of pyridine cross-coupling partners

LDA deprotonation of commercial 4-chloropyridine **9** followed by carboxylation afforded the corresponding 4-chloronicotinic acid **10** which was easily esterified to **11** in 93% overall yield (Scheme 2). Application of LiTMP–TMEDA metallation conditions on the 2-methoxy-nicotinamide **12**, followed by reaction of iodine, furnished

the 4-iodo derivative **13** in modest yield (55%). The same methodology was used for the preparation of the 4-(9-borabicyclononanyl) nicotinamide **14** from **12** (62%) (5) (Scheme 2).

It was established in 1993 by our group (6), that metallation of iodopyridines **15** and **16** by LDA at low temperature was feasible when the pyridine nucleus bears a second halogen (chloro or fluoro). In most cases, lithiation of haloiodopyridines **15** and **16** was regioselectively directed by the iodo group, which subsequently migrates to give the more stabilized 2-substituted 3-lithio-4-iodo-

Synthesis of alkaloids of pyrido[2,3,4-*k*,*l*]-acridine series and analogues

Some 4-iodopyridines (**19**–**21**) were involved in cross-coupling reactions with 2-pivaloylamino phenyl boronic acid **22** under Suzuki conditions (8) to give 4-phenylpyridines, which were cyclized later on to 4,5-disubstituted benzo[*c*]-2,7-naphthyridines, precursors of polycyclic natural alkaloids or analogues (9).[2]

Synthesis of perlolidine 24

Although perlolidine **24** does not strictly belong to the pyrido-acridine series, its synthesis is representative of the reported methodology (6). Reaction between 2-fluoro- or 2-chloro-4-iodo-3-pyridine carboxaldehyde (**19f** or **20f**) with phenylboronic acid **22** using $Pd(PPh_3)_4$ as catalyst, resulted in hetero cross-coupling and subsequent cyclization to 3,6-diazaphenanthrene **23a**–**b**. Hot acid treatment of the fluoro compound **23a** induces hydrolysis to perlolidine **24**, an alkaloid of New Zealand perennial rye grass *Lolium perenne* L which is effective on plant growth (6) (Scheme 4).

Formal synthesis of amphimedine 2

Amphimedine **2** is the first alkaloid isolated in the pyrido[2,3,4-*k*,*l*]acridine series. This compound possesses interesting cytotoxic properties (10). Compounds **25** (X = OH, Cl) have been described by Prager and co-workers (11) as intermediates in the total synthesis of amphimedine **2**. They could be synthesized from trisubstituted pyridines **13** or **14** as shown on the retrosynthetic pathway depicted on Scheme 5.

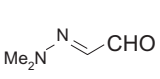
The cross-coupling reaction between *N*-pivaloylamino-phenylboronic acid **22** and 4-iodonicotinamide **13** gives the corresponding biaryl compound **27** which, unfortunately, could not be cyclized to the desired tricyclic compound under the conditions used (7) (Scheme 6).

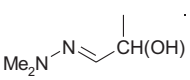
To use milder cyclization conditions, we decided to work on an unprotected amino derivative (5). The corresponding 4-(*ortho*-aminophenyl)pyridine structure was prepared by coupling pyridylborane **14** with *ortho*-iodoaniline under modified Suzuki conditions ($Pd(PPh_3)_4$ – aq NaOH) (12). Biaryl **28** was thus obtained in good yield (Scheme 7). It was subjected to cyclization by treatment with LDA in excess to give a resulting orange substance which was difficult to purify, but its ^{1}H NMR spectrum is consistent with the cyclized structure. Subsequently, it was identified as the benzonaphthyridine triflate **26**, after treatment by triflic anhydride, in an overall yield of 30% from the biaryl **28**.

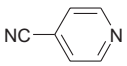
Compound **26** was then subjected to cross-coupling with 4-(tributylstannyl)pyridine under typical Stille conditions (13). Prager's intermediate **29** was obtained in excellent yield by demethylation of **29** with BBr_3 (Scheme 7). The synthesis of **29** proves the feasibility of the method but the overall yield is low (5% in five steps starting from **12**) (5).

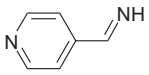
To improve the previous strategy, we decided to introduce the exocyclic pyridine ring before the cross-coupling and cyclization steps (14). Thus, imines **20m** and **21m** (previously obtained from 2-chloro- and *N*,*N*-diisopropyl-2-carboxamido-3-iodopyridines **16** and **17**; Scheme 3, Table 1) were submitted to the cross-coupling reaction with phenylboronic acid **22** following a Suzuki procedure. Spontaneous cyclization of the intermediate phenylpyridines, respectively, led to the expected 4-chloro- and 4-(*N*,*N*-disopropylcarboxamido)-5-(4-pyridyl)benzo[*c*]-2,7-naphthyridines (**30a**–**b**) in high yields (82% and 72%) (Scheme 8). The overall yield is also good (57% for **30a** from **16**, and 53% for **30b** from **17**) (14).

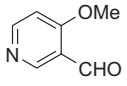
The synthesis of **30a** was carefully studied, and it was found that the overall yield could be improved using a "one-pot" procedure from pyridine **16** (14). Metallation, isomerization, cross-coupling, and cyclisation were performed without isolation of any intermediate (LiOH resulting from hydrolysis of the lithiation mixture acted as a base for the cross-coupling step) (Scheme 9). An excellent overall yield could be then observed: 82% from **16** (14).

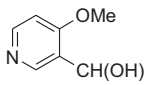












Synthesis of an "open-ring" amphimedine (31)

A rapid and efficient synthesis of an open-ring analogue **31** of amphimedine was achieved (15) by anionic acylation

[2] Gronowitz synthesized some benzo[*c*]-2,7-naphthyridines by cross-coupling between a 4-pyridyl stannane and *ortho*-bromoanilides.

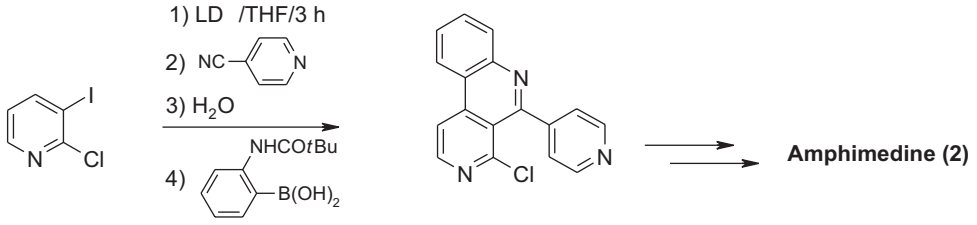
Synthesis of open-ring analogues of meridine 32 and 33

Meridine **4** is a marine alkaloid, isolated by Schmitz et al. (10*c*) in 1991. The natural compound **4** possesses very interesting cytotoxic (10*b*) and antifungal activities (18). Moreover, meridine **4** is a topoisomerase II inhibitor. It was first synthetized by Kubo and co-workers (19) in 1994.

Synthesis of an acyclic analogue (**32**) of meridine (7) was achieved from a 3,3-dipyridylmethanol prepared via a metallation-halogen dance strategy applied on 2-*N*,*N*-diisopropylcarboxamido-3-iodopyridine **17** (Scheme 3, Table 1). Thus, oxidation of alcohol **21n** with manganese dioxide in refluxing toluene led to ketone **34**. Reaction between this ketone and phenyl boronic acid using $Pd(PPh_3)_4$ as the catalyst resulted in hetero ring cross-coupling to the expected 4-phenylketopyridine **35**, which was almost quantitatively cyclized in refluxing formic acid to **32** (Scheme 11). Unfortunately, we were not able to cyclize **32** to meridine, whatever the reaction conditions.

The previously used Miyashita route to seco-amphimedine **31** (16) was successfully applied to the synthesis of a meridine analogue (Scheme 12). Anionic acylation of **23b** with 4-methoxypicolinaldehyde in the presence of imidazolium iodide (1.2 equiv) and sodium hydride afforded **33** in a fairly good yield (65%). Unfortunately, hydrolysis of the methoxy group to seco-meridine could not be cleanly achieved. However, treatment of **33** with hydroiodic acid and sodium iodide gave a mixture from which **36**, an isomer of meridine, could be identified (15).



Synthesis of 4*H*-pyrido[2,3,4-*k*,*l*]acridine-4-ones (precursors of cystodytin alkaloids)

Cystodytins belong to a class of more than 10 compounds containing the same 4*H*-pyrido[2,3,4-*k*,*l*]acridine-4-one skeleton (17*a*). Most of them have interesting cytotoxic activity and are topoisomerase inhibitors (17*b*).

When acetylpyridine **20i** was coupled with the ortho-aminophenylboronic acid **22** under modified Suzuki conditions, the corresponding benzonaphthyridine **37** was obtained in good yield (87%) (20). Cross-coupling of the chloro compound **37** with ethoxyvinylstannane almost quantitatively led to 4-(ethoxy-1-vinyl)-5-methylbenzo[*c*]-2,7-naphthyridine (**38**). Treatment of **38** with SeO_2 gave the 4*H*-pyrido[2,3,4-*k*,*l*]acridin-4-one (**39**) in a poor 11% yield, and also a selenylated product with a structure that could be defined

Scheme 9.

16 **30a**

Scheme 10.

23b **31**

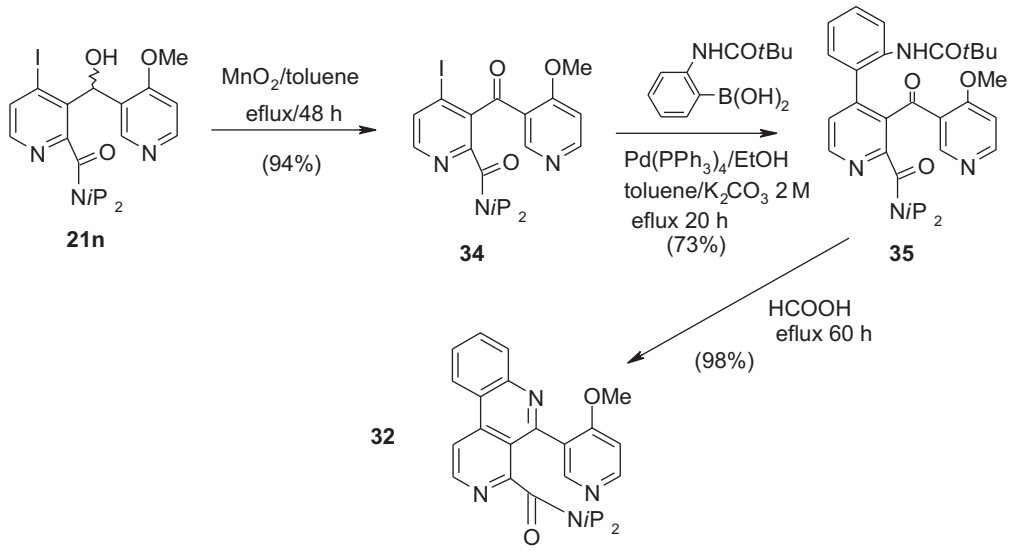
as **40** (20) (Scheme 13). Compound **39** is an unsubstituted cystodytin.

The low overall yield of **39** prompted us to look for another route to the pyrido[2,3,4-*k*,*l*]acridin-4-one skeleton; among different opportunities, we decided (21) to prepare benzo[*c*]-2,7-naphthyridines bearing two protected carbonyl groups (acetyl or formyl) at C-4 and C-5, allowing aldol-type construction of the quinone ring of cystodytin under mild conditions.

Synthesis of 5,6-dihydro-4,5-bis(ethoxyvinyl)benzo[*c*]-2,7-naphthyridine (**42**) was first achieved by a preliminary cross-coupling reaction between ethoxyvinylstannane and 4-chlorobenzo[*c*]-2,7-naphthyridine (**23b**) to give **41**. This latter compound was subjected to nucleophilic addition of 1-ethoxyvinyllithium on the 5,6-imine bond (Scheme 14). The resulting bis-protected 4,5-diacetylbenzonaphthyridine derivative **42** was then cyclized to 6-methyl-4*H*-pyrido[2,3,4-*k*,*l*]acridin-4-one (**43**) by treatment with ethanolic hydrogen chloride. Unfortunately, the yield of the last cyclisation step is still very low, and the deacetylated compound **44** was isolated as a side-product (Scheme 14) (21).

Based on the reactivity of diacetyl derivative **42**, the previous strategy could be modified by working on a bis-protected form of 5-formyl-4-acetylbenzo[*c*]-2,7-naphthyridine (22). Thus, oxidation of the activated methyl group of 5-methyl-2-chlorobenzo[c]-2,7-naphthyridine (**37**) by SeO_2, followed by acetalization of the intermediate aldehyde, afforded **45** in a good 71% overall yield (Scheme 15). The latter compound was then subjected to cross-coupling with ethoxyvinyl stannane to give **46**. One-pot cyclization under Mukaiyama conditions (23) and oxidation gave the expected pyridoacridone **47** in good yield (22).

Conclusion



Connection between *ortho*-directed metallation and biaryl cross-coupling provides a very efficient route to polyaromatics of the 7*H*-pyrido[2,3,4-*k*,*l*]acridine series. Analogues or precursors of marine alkaloids such amphimedine, meridine, or cycstodytins have been synthesized with short pathways and in good yields.

Synthesis, characterization, and application in asymmetric catalysis of dendrimers containing chiral ferrocenyl diphosphines

Christoph Köllner and Antonio Togni

Abstract: Starting from the functionalized Josiphos derivatives (*R*)-1-[(*S*)-2-(diphenylphosphino)-1′-(dimethyl-3″-aminopropylsilyl)-ferrocenyl]ethyldicyclohexylphosphine ((*R*)-(*S*)-**3**), (*R*)-1-[(*S*)-2-(diphenylphosphino)-1′-(hydroxymethyl)ferrocenyl]ethyldicyclohexylphosphine ((*R*)-(*S*)-**4**), and (*R*)-1-[(*S*)-2-(diphenylphosphino)-1′-(3″-hydroxypropyl)ferrocenyl]ethyldicyclohexylphosphine ((*R*)-(*S*)-**5**), a series of dendrimers containing up to sixteen ferrocenyl diphosphine units were prepared. Dendrimer cores are based on benzene 1,3,5-tricarboxylic acid and 1,3,5,7-adamantanetetracarboxylic acid, with 5-substituted isophthalic acid derivatives constituting the branching units. The dendrimers have been used in three different asymmetric catalytic reactions: Rh-catalyzed hydrogenation of dimethyl itaconate, Pd-catalyzed allylic substitution, and Rh-catalyzed hydroboration of styrene with catecholborane. In all three reactions the selectivity obtained with the dendrimers was very similar to the one obtained with the parent ligand Josiphos.

Key words: dendrimer, asymmetric catalysis, ferrocenyl ligands, hydrogenation.

Résumé : Utilisant les dérivés fonctionnalisés suivants du josiphos comme produits de départ, (*R*)-1-[(*S*)-2-(diphénylphosphino)-1′-(diméthyl-3″-aminopropylsilyl)ferrocényl]éthyldicyclohexylphosphine ((*R*)-(*S*)-**3**), (*R*)-1-[(*S*)-2-(diphénylphosphino)-1′-(hydroxyméthyl)ferrocényl]éthyldicyclohexylphosphine ((*R*)-(*S*)-**4**) et (*R*)-1-[(*S*)-2-(diphénylphosphino)-1′-(3″-hydroxypropyl)ferrocényl]éthyldicyclohexylphosphine ((*R*)-(*S*)-**5**), on a préparé une série de dendrimères comportant jusqu'à seize unités ferrocényldiphosphine. Les dendrimères fondamentaux ont comme base de l'acide benzène-1,3,5-tricarboxylique et de l'acide adamantane-1,3,5,7-tétracarboxylique alors que les unités de ramification sont formées de dérivés de l'acide isophtalique substitués en position 5. On a utilisé les dendrimères dans trois réactions catalytiques asymétriques différentes: l'hydrogénation catalysée par le Rh de l'itaconate de diméthyle; la substitution allylique catalysée par le Pd et l'hydroboration catalysée par le Rh du styrène par le catécholborane. Dans chacune de ces trois réactions, la sélectivité obtenue avec les dendrimères était très semblable à celle obtenue avec le ligand josiphos parent.

Mots clés : dendrimère, catalyse asymétrique, ligands ferrocényles, hydrogénation.

[Traduit par la Rédaction]

Introduction

The peripheral functionalization of dendrimers (for reviews, see ref. 1) with catalytically active modified transition metal complexes (2), pioneered by van Koten and co-workers (3), has been addressed from the point of view of combining the typical reactivity features of low-molecular-weight homogeneous catalysts with the distinctive physical properties of heterogeneous catalysts. In other words, a major goal being pursued is the incorporation of homogeneous catalysts preserving their selectivity and activity features into dendrimers, but amenable of easy recovery and reuse by virtue of their molecular size (4). Depending on the type of ligands and complexes being incorporated and on the reaction type being catalyzed, the size and structural nature of the dendrimer may have a positive, a neutral, but also a deleterious effect on the catalytic and selectivity properties of the homogeneous catalyst being modified (5). Thus, the first significant cooperative effect in asymmetric catalysis with dendrimers has been reported recently by Breinbauer and Jacobsen (6). In the asymmetric ring opening of epoxides catalyzed by Co(salen) complexes, known to involve bimetallic catalysis, a substantial increase in catalytic activity, attributed to proximity effects between single catalyst units, has been observed upon incorporation into small dendritic structures. Caminade, Majoral, and co-workers (7) also reported a higher activity of dendritic Ru complexes as catalysts for Knoeveagel and Michael-type reaction as compared to the corresponding monomeric species. On the other hand, van Koten and co-workers (8) have nicely demonstrated that

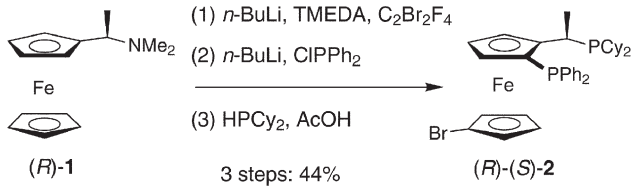
for Ni complexes, catalytically active in the Kharasch reaction, their fixation at the surface of carbosilane dendrimers may severely affect their catalytic properties. In this case the proximity effect does not lead to improved catalysts.

When the mononuclear nature of a catalyst is known, an initial task with its dendritic forms should be that of clarifying whether the peripheral catalyst units retain their properties, and thus are not altered by the nature of the dendrimer backbone. Functional groups present in the dendrimer and length and conformational rigidity of the branches and spacers, for example, are factors of potential importance when evaluating a dendritic catalyst. This is particularly true for asymmetric catalysts, for which already subtle conformational changes may significantly influence stereoselectivity.

We previously demonstrated that chiral ferrocenyl diphosphines of the Josiphos-type (9), modified with an ω-aminoalkyl side chain, may be incorporated into dendrimers having benzene, adamantane, or phosphazene cores, and aryl amide and (or) ester connecting groups (10). We report here full experimental details on synthesis, spectroscopic characterization, and use in three different asymmetric catalytic reactions of ferrocenyl dendrimers containing up to sixteen Josiphos units.

Results and discussion



Synthesis and characterization of Josiphos dendrimers

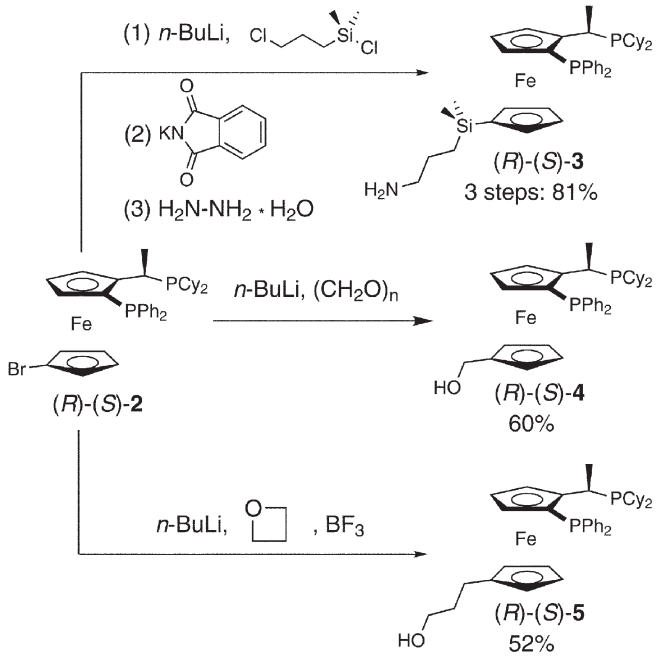
To incorporate ferrocenyl ligands of the Josiphos type into dendritic structures a functionalization and a spacer are required. The choice of the anchoring point and the nature of the spacer on the ferrocenyl ligand molecule is of great importance, and may ultimately influence the catalyst performance by virtue of intramolecular interactions. Intuitively, an anchoring point remote from the two phosphine units should be the best suited because it allows to minimize possible contacts between ligand fragment and dendrimer backbone. This general idea calls for a functionalization of the unsubstituted Cp ring. We previously communicated the synthesis of derivative (*S*)-(*R*)-**2**, a 1′-bromo-Josiphos, which is set up for the introduction of a variety of possible spacers via metallation and reaction with a suited electrophile (10*a*). As shown in Scheme 1, the key intermediate **2** is accessible from the commercially available **1** in three steps and a moderate overall yield of 44%. In the course of this study we prepared derivatives containing three different spacers of different chain length and containing either a primary amine or a primary alcohol as the linking functionalities, as illustrated in Scheme 2.

Thus, after lithiation, (*R*)-(*S*)-**2** reacts with (3-chloropropyl)dimethylchlorosilane almost quantitatively (98%). In a straight forward Gabriel-synthesis (11) with potassium phthalimide and subsequent liberation of the protected amine group with hydrazine hydrate (12), (*R*)-(*S*)-**3** may be easily obtained in gram quantities. Reaction of the lithiated (*R*)-(*S*)-**2** with either paraformaldehyde or trimethylene oxide leads after aqueous work up directly to (*R*)-(*S*)-**4** and (*R*)-(*S*)-**5**, respectively, in moderate yields, both compounds bearing a hydroxyalkyl spacer.

The three Josiphos derivatives **3**–**5** may now be utilized for the reaction with internal dendrimer units bearing acid

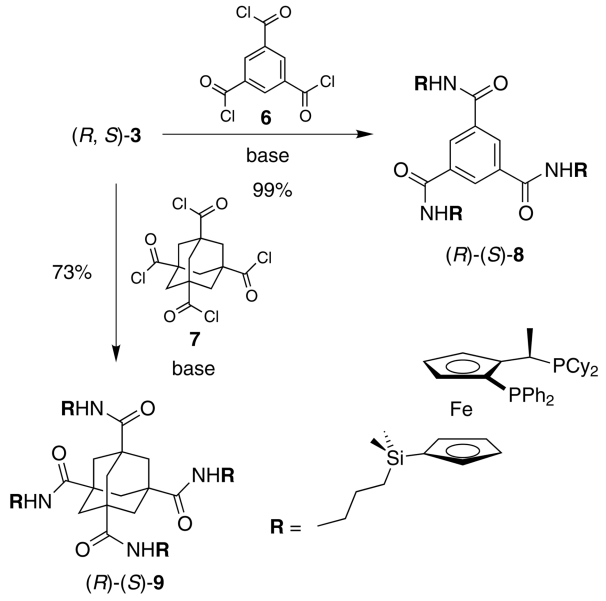
Scheme 1.

chloride groups, thus forming amide or ester connecting groups easily and mostly quantitatively.



The first simple dendrimer synthesis was realized with (*R*)-(*S*)-**3** and benzene-1,3,5-tricarboxylic acid trichloride (**6**) yielding, in the presence of NEt_3, the zeroth-generation dendrimer **8** (see Scheme 3). The trichloride **6** was used because of its availability and easy handling, which is probably the reason why it is often exploited as core in dendrimer chemistry (13). A slight excess (10%) of the ferrocenyl ligand was used to ensure complete reaction of all three acid chloride functionalities. Purification of (*R*)-(*S*)-**8**, therefore consisting mainly in the separation from the excess (*R*)-(*S*)-**3**, was achieved by simple chromatography on silica gel. Because of its less polar character, as compared to the amine (*R*)-(*S*)-**3**, the zeroth-generation dendrimer was eluted with less polar solvents, and excess (*R*)-(*S*)-**3** could be easily recovered and reused.

1,3,5,7-Adamantanetetracarboxylic acid tetrachloride is a useful core molecule, as the four connecting groups are arranged in a tetrahedral fashion and therefore force the branches to extend in all three dimensions, more so than a planar aromatic core. 1,3,5,7-Adamantanetetracarboxylic acid tetrachloride was prepared in situ from the corresponding tetraacid (14) using thionyl chloride. The dendrimer (*R*)-(*S*)-**9** (Scheme 3) was obtained in a yield of only 73% probably because of an incomplete in situ formation of the tetrachloride from the tetraacid. In fact, as opposed to **6**, which was purified before the reactions by distillation, intermediate **7** was used without isolation and purification. However, possible side products of the synthesis still containing free carboxylic groups can easily be separated chromatographycally from the desired product by virtue of their drastically different polarity. Both hydroxy alkyl ferrocene derivatives (*R*)-(*S*)-**4** and (*R*)-(*S*)-**5** reacted with **6** only in moderate yields to the corresponding dendrimer of the zeroth-generation (*R*)-(*S*)-**10** and (*R*)-(*S*)-**11** (Scheme 4). These two compounds are relevant in terms of a comparison of the possible influence of the spacer length on the catalytic properties (activity, selectivity). As we shall see later, the differences observed for three diverse catalytic reaction types are almost negligible. Therefore, in view of the lower yields obtained in the synthesis of the hydroxy derivatives and their dendrimers, as compared with intermediate **2**, we decided not to pursue the chemistry of these compounds any further.



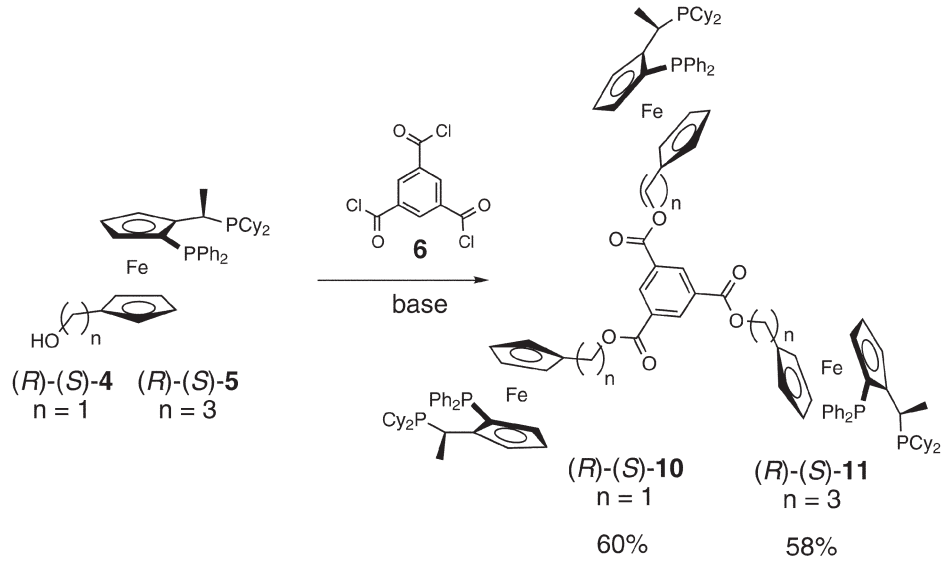
For the convergent synthesis of dendrimers of higher generations based on the modified ligand **3**, the preparation of corresponding dendrons was required. As branching units we adopted isophthalic acid derivatives containing either an amino or a hydroxyl group in position 5. The reasons for this choice were again the type of linkages that would result (amide or ester), the availability and proven utility of these

© 2001 NRC Canada

Scheme 2.

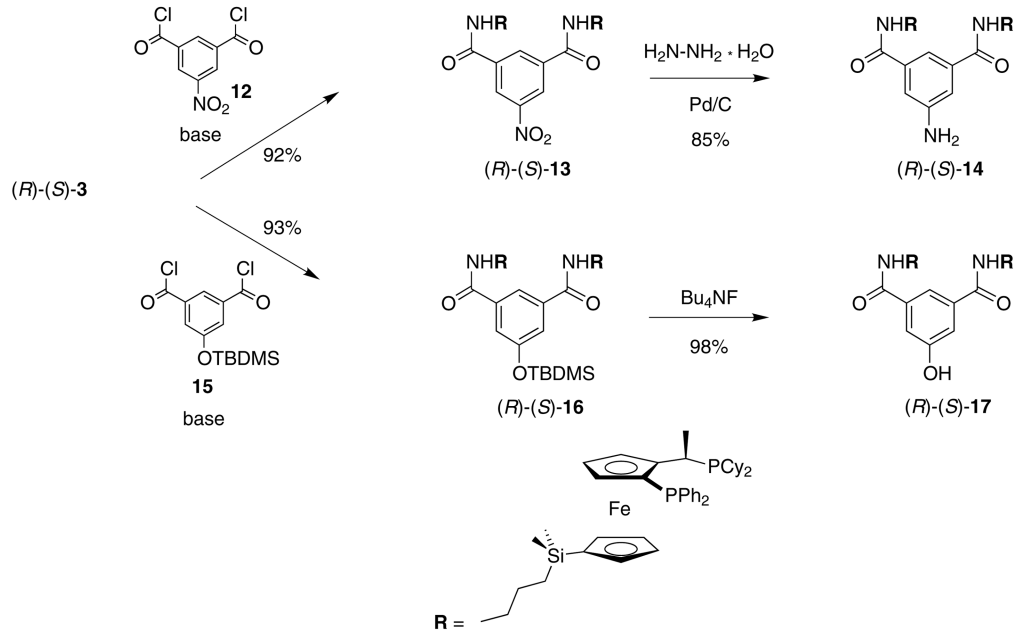
Scheme 3.

groups, as well as the relative conformational rigidity they would confer to the inner core of the small dendrimers. Thus, as illustrated in Scheme 5, reaction of the diacid dichlorides **12** (15) and **15** (16) with (*R*)-(*S*)-**3** in the presence of a base gave high yields of the intermediates **13** and **16**. Whereas the deprotection of the silyl ether **16** under standard conditions (17) afforded the desired dendron **17** almost quantitatively, the reduction of the nitro group of **13** proved unexpectedly problematic. The only method affording the aniline **14** in good yield was the Pd/C-catalyzed reaction with hydrazine hydrate, catalytic hydrogenation procedures under variable hydrogen pressures giving only modest yields (up to 33%).



The dendrons **14** and **17** could be coupled to the triacid trichloride **6** or the tetraacid tetrachloride **7** in good to excellent yields, affording the first generation dendrimers **18**–**21** containing six or eight Josiphos units (see Scheme 6). As observed before, the yields tend to be lower when utilizing the adamantane derived core. However, as for the dendrimers of zeroth generation discussed above, the four new compounds **18**–**21** were obtained in analytically pure form after simple chromatographic purification. This allowed the separation of the slight excess of dendron and of any compounds derived from uncomplete core functionalization from the desired products.

The small dendron **14** was then reacted with the diacid **15** and, after deprotection, the doubly branched unit **22** containing four ferrocenyl ligands was obtained in good yield (76%). With this compound in hand, and by following the known procedure, the second generation dendrimers **23** and **24** could be obtained in excellent yield, as shown in Scheme 7. These two macromolecules contain twelve and sixteen Josiphos units at their periphery, respectively. Despite the already relatively high molecular weight of ca. 10 000 and 13 000, respectively, these materials still behave as normal molecules, thus susceptible of standard chromatographic purification. However, in the case of derivative **24**, the isolated material was shown by ^{31}P NMR spectroscopy to contain small amounts of phosphine oxide derivatives, corresponding to an estimated maximum equivalent of one phosphine oxide unit per dendrimer, probably deriving from prolongued exposure to air during the workup and purification operations. The impurities could not be separated from the main product by column chromatography.



All Josiphos dendrimers prepared during this study are in general, orange solids with melting points above 100°C. They display good to excellent solubility in several common organic solvents including diethyl ether, THF, methylene chloride, chloroform, benzene, and toluene. The ^{31}P NMR spectra of all species show a single AB-spin system, virtually identical to the one of the parent compound Josiphos. We take this observation as an indication of the monodispersity of these compounds. Furthermore, one can assume that the single Josiphos units at the periphery of the dendrimers, because they are not affected in their spectroscopic properties by the linking to the dendrimer, they will also chemically behave as if they were monomeric species. This is reinforced also by the ^{1}H and ^{13}C NMR spectroscopic characteristics, showing one well-defined set of signals for the ligand fragments. However, the larger dendrimers gave relatively broad signals in the aromatic region of the spectra due to the inner part of the molecules, when dissolved in $CDCl_3$ at room temperature. To obviate to this problem and to detect crucial signals of the inner core of the dendrimers, NMR experiments were done with solutions in DMSO-d_6 or DMSO-d_6–$CDCl_3$ mixtures at temperatures up to 100°C, and assignments were done by standard 2D-NMR experiments. Figure 1 shows an example of the phenyl region in both ^{1}H (top) and ^{13}C (bottom) NMR spectra of dendron **22** and dendrimer **23**. Note for comparison that the signals *g* (^{1}H) and *k*, *l*, and *m* (^{13}C) identifying the dendrimer core of **23** are absent in the spectra of dendron **22**. Further diagnostic resonances are those of the inner branching unit. So protons *e* and *f* in **22** are shifted to lower field upon the

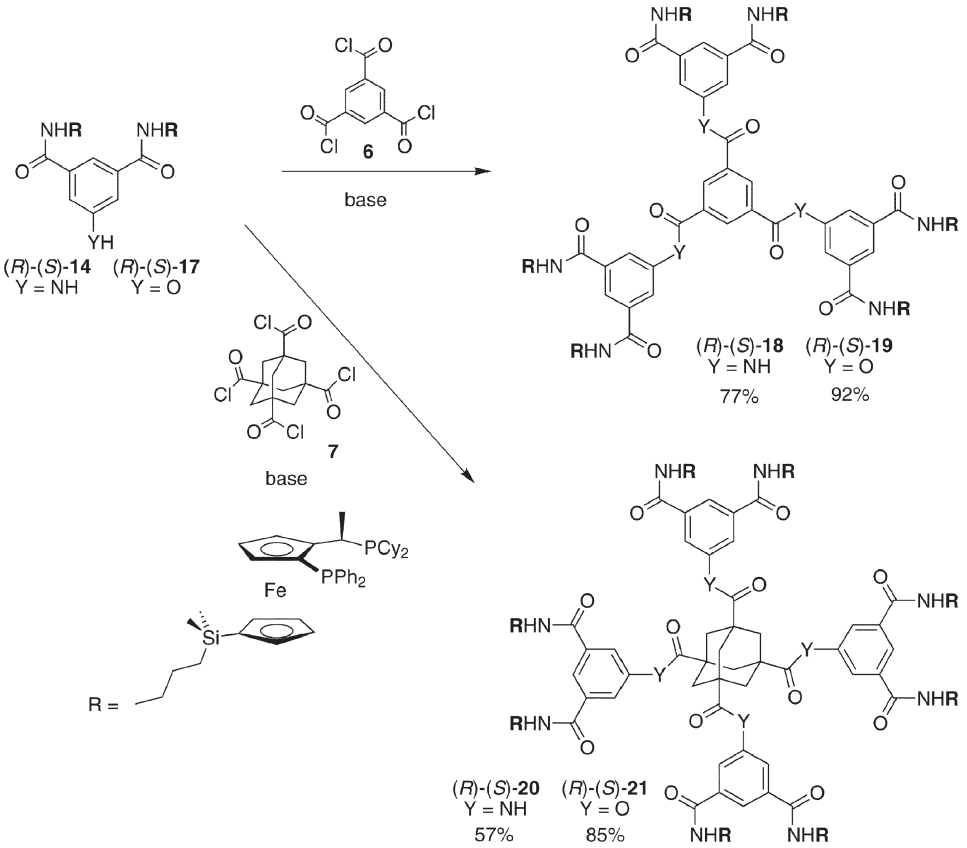
Scheme 5.



esterification reaction leading to the dendrimer. The dendrimer shows three different signals for the carbonyl groups in the ^{13}C NMR spectrum (*a*, *f*, and *k*), whereas signal *k* is absent in the dendron. Furthermore, carbon nuclei *h*, *i*, and *j* of the phenolic group of **22** are affected by the dendrimer formation, where they reside at the inner branching unit.

For the mass spectroscopic characterization of our dendrimers we used FAB and (or) MALDI-TOF techniques. With the exception of the two largest dendrimers **23** and **24**, signals corresponding to the calculated molecular ion peak could be found. Figure 2 shows an example of a MALDI spectrum of the first generation dendrimer **21**. The highest intensity peak at *m*/*z* 6504.6 is in very good agreement with the calculated molecular weight of 6502.95, and should be assigned to the protonated form of **21**. Interestingly, one observes in the MALDI spectra of these dendrimers in-source fragmentation patterns (18) corresponding to the loss of fragments, as shown by smaller Josiphos derivatives under EI or FAB ionization conditions. Thus, very typically, the loss of PCy_2 groups or of the upper Cp ring of the ligand with its substituents, is characteristic for these type of compounds. Furthermore, peaks revealing the loss of a whole branching unit can be seen in the MALDI spectra of the dendrimers. As mentioned above, for the second generation dendrimers **23** and **24** the molecular ion peak could not be observed. However, in the case of compound **23**, for example, a fairly broad peak at *m*/*z* 10 372 was observed instead. This appears to correspond to the fully oxidized form of the polyphosphine ligand, with a calculated molecular weight of 10 367. This appears to be corroborated by fragmentation patterns indicating the loss of Cp units containing the two

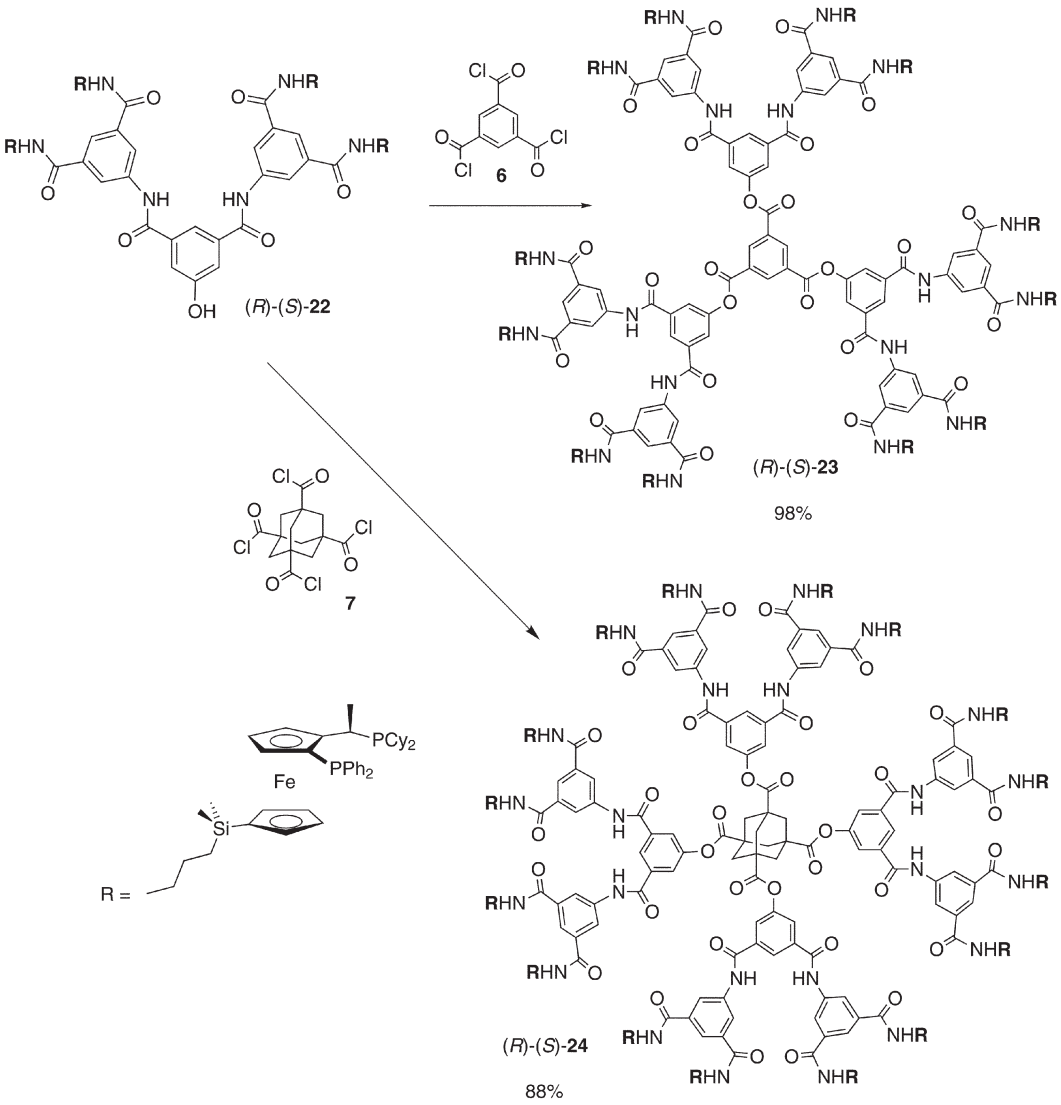
Scheme 6.

oxidized phosphine groups. Why the larger dendrimers suffer this oxidation problem under otherwise identical conditions as applied to their smaller counterparts is not clear at the present time. A more systematic study concerning the MALDI-TOF characterization of this kind of macromolecules would be required to clarify this point, and, at least with our compounds, this technique cannot be applied in a routine fashion yet.

Asymmetric catalytic reactions using Josiphos dendrimers

We have investigated the use of our chiral dendrimers in three different types of well-known catalytic asymmetric reactions, shown in Scheme 8, for which the performance of the parent ligand Josiphos has been reported previously by us (19). This study was carried out in particular with the aim of clarifying the influence of the dendritic backbone on the stereoselectivity and catalytic activity.



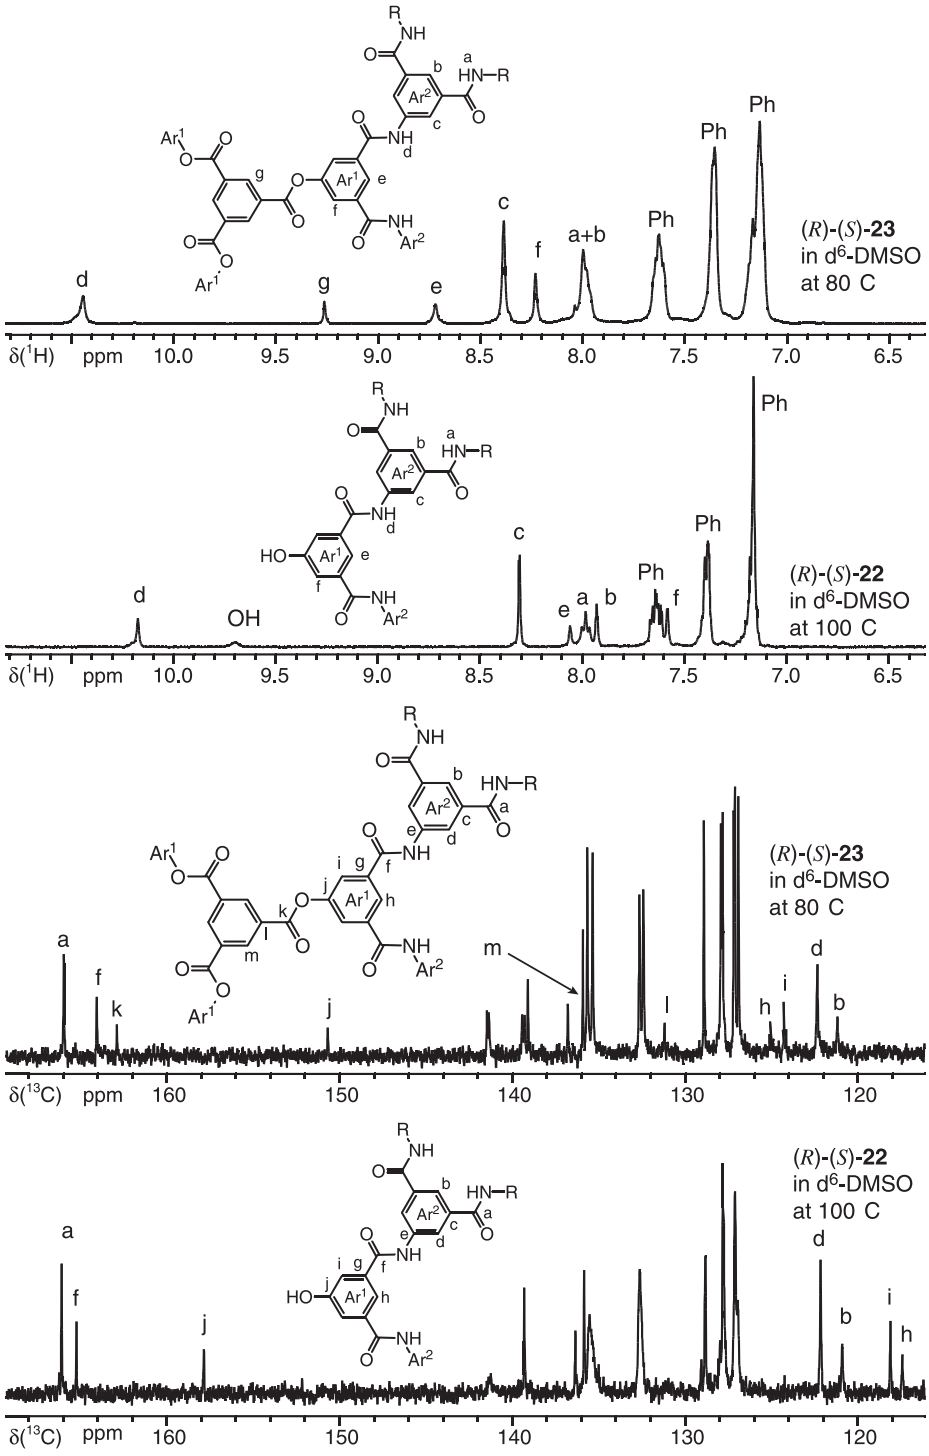
The first standard reaction was the Rh-catalyzed hydrogenation of dimethyl itaconate. The catalyst precursor was generated in situ from the poly(diphosphine) ligand and $[Rh(COD)_2]BF_4$, as it is often done for mononuclear Rh catalysts of this type. The formation of the cationic Rh(I) units [Rh(PP)(COD)] at the periphery of the dendrimers could easily be monitored by ^{31}P NMR spectroscopy in CD_2Cl_2 solution. On mixing one equivalent of a Josiphos dendrimer with as many equivalents of $[Rh(COD)_2]BF_4$ corresponding to the number of ferrocene units in the dendrimer, the clean conversion of all ligand sites into complex sites could be observed. Figure 3 illustrates this experiment for dendrimers **8** and **23**. In both cases the AB-spin system of the equivalent diphosphine sites is converted into an ABX system in which the AB part shows the expected P–Rh coupling (see Fig. 3). Chemical shifts and coupling constants for the new derivatives are virtually identical to those of the corresponding monomeric complex (20).

The hydrogenation reactions were carried out in MeOH. Because most of the dendrimers were only poorly soluble in MeOH, the dendritic catalyst precursors had to be generated in situ in CH_2Cl_2. After evaporation of this solvent, redissolution of the residue in MeOH gave clear solutions ready for the hydrogenation reactions. The results for the reduction of dimethyl itaconate are presented in Table 1. All dendritic catalysts afforded enantioselectivities (ee) only slightly lower than those obtained with the corresponding monomeric Josiphos catalyst (entry 11, 99.0% ee) (19). There was a small, but significant and reproducible difference in the enantioselectivities between the zeroth-generation dendrimers and their first- and second-generation counterparts. Whereas the zeroth-generation catalysts (entry 1–4) reached values close to 99% ee (er $\leq$ 200:1), all other dendrimers (entry 5–10) afforded a decreased enantioselectivity around 98% ee (er 100:1). That the lost of stereoselectivity is relatively minimal and that the dendrimers still give excellent catalysts for this reaction indicates that the modified molecular environment of the single catalyst units due to the incorporation into dendritic structures leads to practically negligible effects.

We also monitored the hydrogen uptake for reaction catalyzed by different dendritic species to compare the different catalysts in simple overall kinetic terms. In Fig. 4 the hydro-

© 2001 NRC Canada

Scheme 7.



gen uptake vs. time is illustrated for four dendritic ligands and for Josiphos for equal total Rh concentrations. All curves display the same shape and indicate full conversion times similar for all species considered. Full catalytic activity is not present from the beginning, since COD hydrogenation has to take place to generate the actual catalyst, leading to the characteristic increase of the H_2 uptake rate during at least 50% of the reaction time. The curves in Fig. 4 show that the different catalysts display similar but not identical reaction rates. However, no trend dependent on dendrimer size is apparent. Since these reactions have been carried out under 1 atm of hydrogen at room temperature and with magnetic stirring, some uncertainties could derive from the nonideally controlled hydrogen mass transport from the gas phase into solution. It is therefore reasonable and safe to claim that the different dendritic catalysts display very similar reaction rates in the hydrogenation of dimethylitaconate.

The dendritic ligands were also used in the palladium catalyzed substitution of allylic acetate **27** by a soft carbon nucleophile, with the catalyst generated in situ from $Pd(dba)_2$ and a corresponding amount of the dendrimer, such as to ensure a slight excess ligand with respect to Pd. The results are summarized in Table 1. The enantioselectivities afforded by the zeroth- and first-generation dendrimers, with up to eight catalyst units (entry 1–8) were rather constant, i.e., in the narrow range of 89–91% ee, with the exception of (*R*)-(*S*)-**11** which gave only 85% ee. As compared to the parent ligand Josiphos (entry 11, 93% ee) this means a slight loss in selectivity that is comparable, or even less significant, in energetic terms of $\Delta\Delta G^{\ddagger}$, than the one observed for the Rh-catalyzed hydrogenation of dimethyl itaconate described above. For the larger dendrimers (*R*)-(*S*)-**23** and (*R*)-(*S*)-**24** (entry 9, 10), slower catalytic reactions and lower selectivities were observed. However, these results appear to be less reliable than those with other dendrimers, mainly due to the low solubility of the respective catalysts generated in situ. In fact, it was not possible in this case to obtain clear homogeneous solutions of the neutral catalyst precursors.

Rhodium catalyst precursors for the hydroboration of styrene were generated in situ in the same way as for the hydrogenation reactions. Hydroboration reactions were carried out for comparison at room temperature, although the best enantioselectivities were obtained with Josiphos at –78°C (91.5% ee). At this temperature, however, the dendrimers do

© 2001 NRC Canada

Fig. 1. Sections of the ^{1}H and ^{13}C NMR spectra of dendron **22** and dendrimer **23** showing key resonances of the dendrimer backbone.

not display sufficient solubility. The products were analyzed as the resultant alcohols after oxidative workup of the organoboron intermediate. The results are collected in Table 1. There are two possible products, the branched (**30**) and linear (**31**) phenylethanol. The regioselectivity afforded by Josiphos (entry 11) is excellent, with virtually only the branched alcohol being formed. However, the enantioselectivity is with 60–65% ee (depending on the exact reaction condition) only moderate. The stereoselectivity afforded by the dendritic catalysts is in the range 61–68% ee, thus in $\Delta\Delta G^{\ddagger}$ terms virtually identical to that given by the parent catalyst. On the other hand, the regioselectivity dropped slightly. In fact, up to 11% of the undesired linear 2-phenylethanol was formed. The reasons for this drop in regioselectivity are not clear.

Conclusions

We have shown that the functionalization of Josiphos in 1′-position of the ferrocene fragment allows the introduction

of a tether by which Josiphos can be attached to the periphery of dendrimers. Corresponding macromolecules containing up to sixteen diphosphine units could be prepared in high yield. Their spectroscopic characterization has shown that these derivatives are monodisperse and that the single ligand units are independent from one another, this being an important prerequisite for the dendritic catalysts to preserve the properties of the parent compound. This was largely confirmed by the catalysis experiments carried out with our dendrimers for three different reaction types, and showing that the stereoselectivities obtained are very similar to, but not significantly better than those afforded by Josiphos. This very point appears to be, in general, the best possible scenario one can expect when working with peripherally functionalized dendrimers, in particular when cooperativity effects between single catalyst units do not play any relevant role. The small but significant loss of stereoselectivity observed, e.g., in the Rh-catalyzed hydrogenation of dimethyl itaconate, could be due to local concentration effects, becoming important in the case of cationic catalyst species, in particular. Similar considerations apply to the observation of lower regioselectivity in the hydroboration reaction. However, it is clear that such minor dendritic effects on selectivity cannot be fully explained based on the available data.

Experimental

Reagents and techniques

Et_2O and THF were purified by distillation from sodium–benzophenone, while CH_2Cl_2 was distilled from CaH_2, EtOH and toluene from sodium, and MeOH from $Mg(OMe)_2$. All solvents were distilled under Ar. All reactions with air sensitive materials were carried out under Ar. (*R*)-*N*,*N*-Dimethyl-1-ferrocenylethylamine ((*R*)-**1**) was a generous gift from

Novartis Ltd. Benzene-1,3,5-tricarboxylicacid trichloride (**6**) (21), 1,3,5,7-adamantanetetracarboxylic acid tetrachloride (**7**) (in situ from 1,3,5,7-adamantanetetracarboxylic acid (14), 5-nitro-isophthaloyl dichloride (14) (**12**), 5-(*tert*-butyldimethylsilyloxy)isophthaloyl dichloride (16) (**15**), $[Rh(COD)_2]BF_4$ (22), $Pd(dba)_2$ (23), as well as substrate **27** (24) were prepared according to literature procedures. The preparation of (*R*)-(*S*)-**2**, (*R*)-(*S*)-**3**, (*R*)-(*S*)-**8**, (*R*)-(*S*)-**9**, (*R*)-(*S*)-**16**, (*R*)-(*S*)-**17**, (*R*)-(*S*)-**19**, and (*R*)-(*S*)-**21** was carried out as previously reported from our laboratory (10*a*). Further chemicals, including substrates **25** and **29** were purchased from Fluka or Aldrich and used as received.

HPLC-analysis were performed with a Hewlett-Packard Series 1050 with UV-detector (wavelength is given); chiral columns: Daicel Chiralcel OD-H (4.6 × 250 mm), Daicel Chiralcel OB-H (4.6 × 250 mm).

General procedure for the reaction of acid chlorides with alcohols or amines

To a solution of the alcohol or amine and a base (NEt_3 and (or) 4-(pyrrolidino)pyridine) in toluene or CH_2Cl_2 was added a solution of the acid chloride in toluene or CH_2Cl_2. After stirring for the given time the solution was filtered through Celite in case of a precipitation and the solvent was removed in vacuo. The products were purified by silica gel flash chromatography.

No correct elemental analysis could be obtained.

Dimethyl methylsuccinate (26)

The literature procedure (19) was slightly modified. $[Rh(COD)_2]BF_4$ (19.1 μmol) and the chiral ligand (21.0 μmol divided by the number of ferrocene units in the molecule) were dissolved in 2 mL of CH_2Cl_2 and stirred 15 min at rt. After removing the solvent in vacuo, the residue was dissolved in MeOH. This solution was added to a solution of **25** (302 mg, 1.91 mmol) in 5 mL of MeOH. The inert gas was replaced by hydrogen and a hydrogen filled balloon was connected to the reaction flsk. The solution was stirred vigorously. After 30 min, the solvent was removed in vacuo and the product purified via Kugelrohr distillation (150°C, 10 mbar, 1 bar = 0.1 MPa). Isolated yield: 80–90%. ^{1}H NMR (250 MHz, $CDCl_3$) δ: 3.69 (s, 3H), 3.67 (s, 3H), 2.93 (m, 1H), 2.74 (dd, J = 16.5, 8.1, 1H), 2.40 (dd, J = 16.5, 6.0, 1H), 1.21 (d, J = 7.1, 3H). ee determination by HPLC: OD-H, at 23°C; hexane–*i*-PrOH = 97/3; flow 0.5 mL min^{-1}. Retention times: (*R*) = 13.1 min, (*S*) = 21.5 min (UV: 210 nm).

(1,3-Diphenyl allyl)malonic acid dimethyl ester (28)

The literature procedure (19) was slightly modified. $Pd(dba)_2$ (12.8 μmol) was dissolved in 5 mL of CH_2Cl_2 and the chiral ligand (14.1 μmol divided by the number of ferrocene units in the molecule) was added. This solution was stirred until the color changed from dark red to light orange (up to 16 h). Racemic (*E*)-1,3-diphenyl-2-propenyl-acetate (**27**, 323 mg, 1.28 mmol), dimethyl malonate (338 mg, 2.56 mmol), *N*,*O*-bis(trimethylsilyl)acetamide (BSA) (521 mg, 2.56 mmol), and KOAc (6 mg, 0.06 mmol) were added in this order. After 20 h, the solvent was removed in vacuo and the product was purified by silica gel flash chromatography (hexane – ethyl acetate, 5:1). Isolated yield: 90–99%. ^{1}H NMR (250 MHz, $CDCl_3$) δ: 7.40–7.15 (m, 10H), 6.50 (d, J = 15.8, 1H), 6.33 (dd, J = 15.8, 8.3, 1H), 4.28 (dd, J = 10.9, 8.3, 1H), 3.96 (d, J = 10.9, 1H), 3.71 (s, 3H), 3.52 (s, 3H). ee determination by HPLC: OD-H, at 23°C; hexane–*i*-PrOH = 98/2; flow 0.5 mL min^{-1}. Retention times: (*R*) = 17.7 min, (*S*) = 18.8 min (UV: 254 nm).

1-Phenylethanol (30) and 2-phenylethanol (31)

The literature procedure (19) was slightly modified. $[Rh(COD)_2]BF_4$ (19.1 μmol) and the chiral ligand (21.0 μmol divided by the number of ferrocene units in the molecule) were dissolved in 2 mL of CH_2Cl_2 and stirred for 15 min at rt. After removal of the solvent in vacuo, the residue was dissolved in THF. Styrene (**29**) (199 mg, 1.91 mmol) and 1,3,2-benzodioxaborole (catecholborane) (252 mg, 2.10 mmol) were added in this order. After 5 h, aq.

NaOH solution (4.8 mL, 3 M) and an H_2O_2 solution (0.41 mL, 35% in H_2O) were added and vigorous stirring was continued during 3 h. The mixture was then extracted with Et_2O and the organic extracts were washed twice with 1 M NaOH and once with sat. NH_4Cl solution. After drying over anhydrous magnesium sulfate, the solvent was removed in vacuo and the product purified by Kugelrohr distillation (150°C, 10 mbar). Isolated yield: 60–94%. (**30**): ^{1}H NMR (250 MHz, $CDCl_3$) δ: 6.6–7.4 (m, 5H), 4.89, (q, J = 6.4, 1H), 1.50 (d, J = 6.4, 3H). (**31**): ^{1}H NMR (250 MHz, $CDCl_3$) δ: 6.6–7.4 (m, 5H), 3.87 (t, J = 6.6, 2H), 2.88 (t, J = 6.6, 2H). ee determination by HPLC: OB-H, at 23°C; hexane–*i*-PrOH = 97/3; flow 0.5 mL min^{-1}. Retention times: (*S*)-**30** = 21.5 min, **31** = 24.0 min, (*R*)-**30** = 31.5 min (UV: 214 nm).

Attempted enantiotopic group selective cyanohydrin formation from α-alkoxy aldehydes by double stereodifferentiation

Dale E. Ward, Marcelo Sales, and Matthew J. Hrapchak

Abstract: Enantiotopic group selectivity can result from the competition between substrate and reagent double stereodifferentiation. We have examined this approach for enantioselective hydrocyanation of racemic α-alkoxy aldehydes (e.g., 2-(phenylmethoxy)heptanal (**1**)). Reaction of **1** with TMSCN mediated by chiral nonracemic alkoxy Ti(IV) reagents under conditions known to be reasonably enantioface selective in reactions with achiral aldehydes, proceeded with very low enantiotopic group selectivity (<2:1). It was established that TMSCN can react with Ti(IV) reagents to produce "TiCN" adducts that are capable of hydrocyanation but with low substrate-controlled diastereoselectivity in reactions with **1**. The poor enantiotopic group selectivity observed can be rationalized to result from this low diastereoselectivity despite the respectable levels of enantioface selectivity associated with these reagents in hydrocyanation of achiral aldehydes. Highly diastereoselective hydrocyanation of α-alkoxy aldehydes can be achieved with TMSCN in the presence of excess $MgBr_2 \cdot OEt_2$. High diastereoselectivity was also observed using achiral and chiral TiCN adducts in place of TMSCN. Although the putative TiCN adducts obtained from nonracemic alkoxy Ti(IV) reagents are implicated in enantioface selective hydrocyanation, these reagents were not enantiotopic group selective under these conditions and showed no evidence of double stereodifferentiation. The use of nonracemic bisoxazoline ligands for Mg(II) was also ineffective.

Key words: cyanohydrin, 2-alkoxyalkanal, double stereodifferentiation, enantiotopic group selective reaction, kinetic resolution.

Résumé : La sélectivité énantiotopique de groupe peut découler d'une compétition entre la stéréodifférenciation double entre le substrat et le réactif. On a examiné cette approche pour l'hydrocyanuration énantiosélective d'α-alkoxyaldéhydes racémiques (par exemple, le 2-(phénylméthoxy)heptanal (**1**)). Lors de la réaction avec le TMSCN, sous l'influence de réactifs chiraux non racémiques de type alkoxy Ti(IV), dans des conditions reconnues pour être énantiosélectives au cours de réactions avec les faces d'aldéhydes achiraux, la sélectivité énantiotopique de groupe était très faible (< 2:1). Il a été établi que le TMSCN peut réagit avec les réactifs du Ti(IV) pour conduire à la production d'adduits "TiCN" qui, lors de réactions avec le composé **1**, peuvent donner lieu à une hydrocyanuration pour laquelle la diastéréosélectivité contrôlée par le substrat est faible. On peut imaginer que la faible sélectivité énantiotopique de groupe observée résulte de cette faible diastéréosélectivité malgré les niveaux respectables de énantiosélectivité par rapport aux faces qui sont associées à ces réactifs dans l'hydrocyanuration d'aldéhydes achiraux. On peut réaliser des hydrocyanurations hautement diastéréosélectives d'α-alkoxyaldéhydes à l'aide de TMSCN, en présence d'un excès de $MgBr_2 \cdot OEt_2$. On a aussi observé une diastéréosélectivité lorsqu'on a utilisé des adduits TiCN achiraux et chiraux à la place du TMSCN. Les adduits TiCN présumés, obtenus à partir de réactifs non racémiques de type alkoxy Ti(IV), sont impliqués dans des hydrocyanurations énantiosélectives par rapport aux faces; toutefois, dans ces conditions, ces réactifs ne donnent pas lieu à de la sélectivité énantiotopique de groupe et ne présentent pas de signe de double stéréodifférenciation. L'utilisation de ligands bisaxozolines non racémiques pour des composés de type Mg(II) est aussi inefficace.

Mots clés : cyanohydrine, 2-alkoxyalcanal, double stéréodifférenciation, réaction avec sélectivité énantiotopique de groupe, dédoublement cinétique.

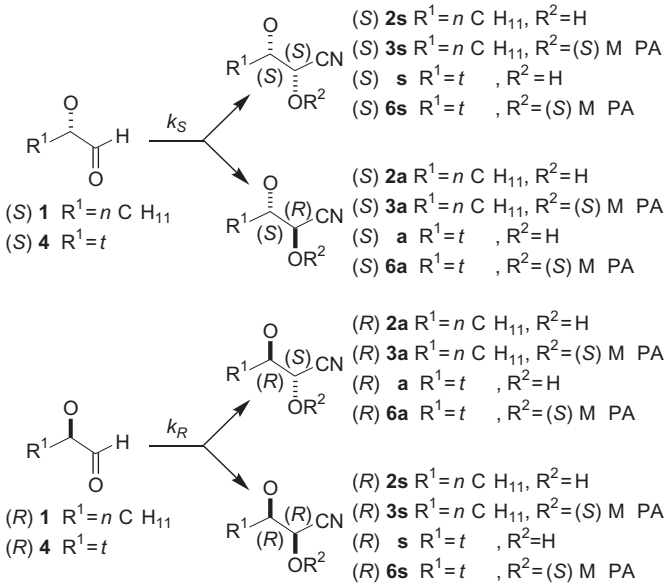
Introduction



The development of new methods for asymmetric synthesis continues to attract considerable attention (1). Although the majority of known methods involve enantioselective addition to a π-bond of an achiral substrate (i.e., an enantiotopic face selective reaction), the use of enantiotopic group selective reactions for desymmetrization of achiral C_s (or C_i) symmetric substrates has recently emerged as an alternative strategy (2). This approach is particularly effective when the enantiotopic groups can react sequentially thereby coupling an asymmetric synthesis with a kinetic resolution and producing products with high stereoisomeric purity (3). We have previously shown that such processes can yield products with very high stereoisomeric purity from reactions with modest enantioselectivity (4) and even from mixtures of substrate stereoisomers (5). Both the efficiency and efficacy of these processes are improved with recycling, especially if the enantioselectivity is modest (4, 5). Because recycling requires that the product(s) (or byproducts) be efficiently converted back into the starting material(s), enantiotopic group selective reactions that are easily "reversed" are desirable. We have previously targeted enantioselective reduction of chiral aldehydes (reversed by oxidation of the product alcohols) (4) and enantioselective enolization (reversed by protonation of the enolate derivative) (6) as reactions for development. The potential for stereoselective formation of cyanohydrins from aldehydes (vide infra) and the facile loss of HCN from such cyanohydrins prompted us to examine enantiotopic group selective cyanohydrin formation from α-alkoxy aldehydes.

Few design elements are available to guide the development of enantiotopic group selective reactions and many of the successful examples (2) involve application of previously established "reagent-controlled" enantioface selective reactions to chiral[2] or C_s symmetric substrates that impart significant "substrate-controlled" diastereoface selectivity (7).[3] In such cases, enantiotopic group selectivity can be rationalized to result from the matching and mismatching of substrate diastereotopic face selectivity with reagent enantiotopic face selectivity (4, 8, 9). The magnitude of the enantiotopic group selectivity (E) can be estimated from eq. [1] where **r** is the enantiotopic face selectivity associated with the chiral reagent acting on a "model" achiral substrate and **s** is the diastereotopic face selectivity of the chiral substrate with a model achiral reagent (4, 9).[4]

$$[1] \qquad E = \frac{(\mathbf{r})(\mathbf{s}) + 1}{\mathbf{r} + \mathbf{s}}$$

The stereoselective formation of cyanohydrins from aldehydes dates back to the late 19th century when Emil Fischer reported that addition of HCN to L-arabinose gave a 2:1 mixture of cyanohydrins in favor of the *manno* (i.e., 2,3-*anti*) diastereomer (10). Subsequently, this reaction has proven to be quite useful for the chain extension of monosaccharides (11). Cyanohydrins are generally recognized as versatile synthetic intermediates for the preparation of a variety of useful compounds (12, 13). As a consequence, the development of methods for enantioselective formation of cyanohydrins from achiral aldehydes has attracted considerable attention (13) and several highly enantioselective methods using chiral Lewis acid catalysts have been reported recently (14). By contrast, cyanohydrins are often formed with poor diastereoselectivity from chiral aldehydes (15), even in enzyme-mediated processes (16). For example, diastereoselectivities of only 1.5–5:1 in favor of the *syn* isomer have been reported for cyanohydrin formation from α-alkoxy aldehydes using trimethylsilylcyanide (TMSCN) in the presence of various Lewis acids (17). Because the predicted selectivity (*E*) is limited by the lower of **r** and **s** (eq. [1]), the low substrate diastereoselectivity noted above suggested that cyanohydrin formation from α-alkoxy aldehydes would result in poor enantiotopic group selectivity even using methods with excellent enantioface selectivity. We now report several experiments which support this hypothesis and on our efforts to improve on the substrate diastereoselectivity in an attempt to achieve enantiotopic group selective cyanohydrin formation by double stereodifferentiation.

Scheme 1

Results and discussion

We selected the racemic α-alkoxy aldehydes **1** and **4** as substrates to investigate enantiotopic group selective cyanohydrin formation. Under the influence of a chiral nonracemic reagent or catalyst, the individual enantiomers of the aldehyde

[2] Enantiotopic group selective reaction of chiral substrates is equivalent to kinetic resolution. In this case, groups on enantiomeric substrates are enantiotopic by external comparison.

[3] For a discussion and definition of reagent- and substrate-controlled stereoselectivity, see ref. 8.

[4] The face selectivity for one group will be (**r**)(**s**):1 (i.e., "matched"); total reactivity is (**r**)(**s**) + 1. The face selectivity for the enantiotopic group will be (**r**):(**s**) (i.e., "mismatched"); total reactivity is (**r**) + (**s**). The accuracy of this estimation depends on the suitability of the models used for the determination of **r** and **s**. For a detailed discussion of the derivation, assumptions, and sources of error in the above multiplicativity rule, see ref. 8.

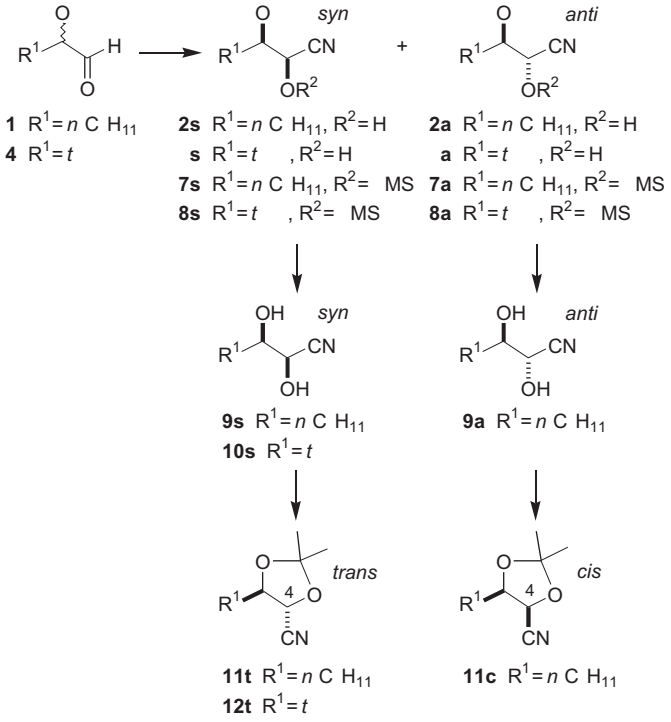
Table 1. Enantiotopic group selective hydrocyanation of **1** and **4** with TMSCN–(*i*-Pr-O)$_2$TiCl$_2$–TADDOL at –23°C.[a]

Entry	Aldehyde	Time (h)	(*C*)[b,c]	(*R*)-**2s**[c,d] (%)	(*R*)-**2a**[c,d] (%)	(*S*)-**2s**[c,d] (%)	(*S*)-**2a**[c,d] (%)	k_S/k_R[e]
1	**1**	1	0.31	27	10	42	21	2.0
2	**1**	3	0.68	33	11	39	16	1.5
3	**1**	8	0.87	35	12	37	17	1.6
4	**4**	3	0.71	20[f]	25[f]	43[f]	13[f]	1.5
5	**1**[g]	3	0.20	46	6	23	25	0.91



[a]Reagent preparation: TADDOL (1.5 equiv) was added to a toluene solution of (*i*-Pr-O)$_2$TiCl$_2$ (1.5 equiv) at room temperature. After 1 h, MS4A and TMSCN were added.
[b]Determined by ^{1}H NMR of the crude reaction mixture.
[c]Estimated relative error of ±10%.
[d]Determined by ^{1}H NMR of the corresponding Mosher's esters.
[e]Calculated according to footnote 5.
[f]Refers to cyanohydrins **6** (not **2**).
[g](+)-BINOL was used instead of TADDOL.

(e.g., **1**) should form cyanohydrins at different rates (i.e., a kinetic resolution) and with different diastereoselectivities to produce the four possible stereoisomeric products (e.g., (*R*)-**2a**, (*R*)-**2s**, (*S*)-**2a**, and (*S*)-**2s**) (18).

The relative amounts of the product stereoisomers from a reaction of low or known conversion can be used to calculate the relative rates of hydrocyanation of the individual substrate enantiomers (i.e., the enantiotopic group selectivity).[5] Alternatively, the enantiomeric purity of the recovered α-alkoxy aldehyde from a hydrocyanation reaction of known conversion can be used to determine the selectivity.[6] Thus, a method to analyze the composition of the four stereoisomeric cyanohydrins was required.

The relative stereochemical configurations of the cyanohydrins **2** and **5** were determined via NMR analysis of the derived acetonides (17*a*). Reaction of **1** with trimethylsilylcyanide (TMSCN) in the presence of Et_3N (19) gave **7** as a 2:1 mixture of racemic diastereomers in quantitative yield. Hydrolysis of **7** (a 2:1 mixture of diastereomers) with dilute acid gave a 2:1 mixture of cyanohydrins **2.** Alternatively, treatment of **7** with $TiCl_4$ gave the diols **9**, also as a 2:1 mixture of diastereomers, which produced a 2:1 mixture of acetonides **11**. The minor acetonide was assigned as *cis* (i.e., **11c**) on the basis of an 8% nOe observed for HC-5 upon irradiation of HC-4 (nOe was not observed between HC-4 and HC-5 in the major acetonide, **11t**); thus, the major cyanohydrin formed was assigned as the *syn* diastereomer **2s**. Similar processing of **4** gave a separable 3:1 mixture of cyanohydrins **5**; the major diastereomer was assigned as *syn* (i.e., **5s**) on the basis of an 18% nOe observed for HC-4 upon irradiation of the $(H_3C)_3C$ protons in the derived acetonide **12t**. A method for determining the absolute configurations of the four stereoisomers of **2** was established by conversion (20) of a 2.4:1 mixture of racemic **2s** and **2a**, respectively, to a 2.6:2.6:1:1 mixture of diastereoisomeric Mosher's esters (21) **3** in 88% yield from excess (2*S*)-3,3,3-trifluoro-2-methoxy-2-phenylpropanoic acid [(*S*)-MTPA-OH].[7] Assignment of individual signals in the ^{1}H NMR spectrum of the mixture of esters to individual diastereomers was possible on the basis of intensity (i.e., major signals from *syn* diastereomers and minor signals from *anti* diastereomers), homonuclear decoupling experiments (i.e., identifying the pairs of HC-2–HC-3 and H_2CO signals for individual diastereomers), and application of the advanced Mosher's method (22).[8] The same strategy was successfully applied for analysis of the four stereoisomers of **6**.

Scheme 2.

[5] At low conversion, k_S/k_R (= *E*) is closely approximated by ([(*S*)-**2a**] + [(*S*)-**2s**])/([(*R*)-**2a**] + [(*R*)-**2s**]). At higher conversions (*C*) with product stereoisomeric excess (se = ([(*S*)-**2a**] + [(*S*)-**2s**] – [(*R*)-**2a**] – [(*R*)-**2s**])/([(*S*)–**2a**] + [(*S*)-**2s**] + [(*R*)-**2a**] + [(*R*)-**2s**])), *E* = {ln (1 – *C*(1 + se)}/{ln (1 – *C*(1 – se)}. For a discussion, see ref. 18.
[6] If the ee of recovered **1** is ([(*R*)-**1**] – [(*S*)-**1**])/([(*R*)-**1**] + [(*S*)-**1**]) at conversion *C*, then k_S/k_R = *E* = {ln [(1 – *C*)(1 – ee)]}/{ln [(1 – *C*)(1 + ee)]}. For a discussion, see ref. 18.
[7] A control experiment established that acetylation of **2** under these conditions occurred without loss of stereochemical integrity.
[8] This method predicts that for the (*S*)-MTPA esters **3** (and **6**), the HC-2 and H_2CO (and *t*-Bu) signals for the (1*S*) diastereomers will appear downfield relative to the (1*R*) diastereomers.

With an analytical method in place, we chose to examine cyanohydrin formation using TMSCN mediated by the chiral alkoxytitanium generated in situ by mixing (*i*-Pr-O)$_2$TiCl$_2$ and (2*R*,3*R*)-2,3-*O*-(1-phenylethylidene)-1,1,4,4-tetraphenyl-1,2,3,4-butanetetrol (**13**, TADDOL) in the presence of 4 Å molecular sieves (MS4A) as described by Narasaka and co-workers (23). Using this system, 3-phenylpropanal was reported to give the (*R*)-cyanohydrin in high yield and in 74–91% ee depending on the procedure employed. In our hands, the same cyanohydrin was obtained in >80% yield under the reported conditions but in only 60 ± 5% ee despite numerous attempts including using alternative methods (24) for preparing the precatalyst **14a**. Despite this modest result (i.e., 4:1 selectivity for addition of cyanide to the *si* face of the aldehyde), we attempted enantiotopic group selective hydrocyanation of **1** using the Narasaka reagent; the results are presented in Table 1.[9] Although the selectivity (i.e., k_S/k_R) was predictably low,[10] it was surprising that hydrocyanation of **1** occurred without evidence of double stereodifferentiation (8). That is, the cyanohydrins from (*R*)-**1** and (*S*)-**1** were formed with comparable levels of *syn* diastereoselectivity (i.e., 2–3:1; compare (*R*)-**2s**:(*R*)-**2a** with (*S*)-**2s**:(*S*)-**2a** in Table 1, entries 1–3) with the *slower* reacting (*R*)-enantiomer giving slightly higher diastereoselectivity. A 1.5–2:1 enantiotopic group selectivity for hydrocyanation of **1** under these conditions was observed at three different conversions and was confirmed by measuring the ee of the recovered aldehyde.[11]

Formation of cyanohydrins from **4** using the Narasaka reagent also proceeded with low enantiotopic group selectivity (Table 1, entry 4). However in this case, the reaction occurred with the expected double stereodifferentiation (8). Thus, the faster reacting (*S*)-**4** gave cyanohydrins with 3.3:1 *syn* diastereoselectivity (i.e., (*S*)-**4s**/(*S*)-**4a**) whereas the slower reacting (*R*)-**4** was slightly *anti* selective (i.e., (*R*)-**4a**/(R*S*)-**4s** = 1.25); addition of cyanide occurred preferentially to the *si* face of both enantiomers of **4** as expected for this reagent (23) and indicating that the reagent *si* face selectivity was higher than the substrate *syn* diastereoselectivity. We also attempted cyanohydrin formation by replacing TADDOL with (*R*)-(+)-1,1′-bi-2-naphthol (BINOL) in the Narasaka protocol (25).[12] Hydrocyanation of **1** with this modified procedure also showed double stereodifferentiation but very low enantiotopic group selectivity (Table 1, entry 5).

Although the observation of double stereodifferentiation in the hydrocyanation of **1** was encouraging, the very low enantiotopic group selectivity obtained suggested that both the reagent enantioselectivity and the substrate diastereoselectivity required improvement. The low diastereoselectivity observed for cyanohydrin formation from α-alkoxy aldehydes on reaction with TMSCN in the presence of various Lewis acids (17) is in stark contrast to the excellent selectivity often associated with nucleophilic additions to these aldehydes under chelation-controlled conditions (26). For example, Reetz et al. (17*a*) reported that reaction of 2-(phenylmethoxy)propanal with TMSCN mediated by TiCl$_4$ (1 equiv) at –78°C gave a 4:1 mixture of *syn:anti* cyanohydrins in good yield. We obtained the same diastereoselectivity (i.e., a 4:1 mixture of **2s** and **2a**) on hydrocyanation of **1** under these conditions (27). This moderate diastereoselectivity prompted us to investigate this reaction more closely.

Varying amounts of TMSCN were added to a solution of TiCl$_4$ in CDCl$_3$ to determine if these two reagents undergo any reaction. The ^{1}H NMR spectra of the yellow solutions obtained after addition of 1, 2, or 4 equiv of TMSCN showed a single signal (δ 0.43) indistinguishable from chlorotrimethylsilane (TMSCl);[13] addition of 10 equiv of TMSCN gave a 3:2 ratio signals assigned[13] to TMSCN (δ 0.36) and TMSCl, respectively. The propensity of mixtures of TiCl$_4$ and TMSCN to produce cyanohydrins from benzaldehyde and from **1** was assessed (Table 2). Clearly, excess TMSCN was required for high conversions (Table 2, entries 1–3) although the diastereoselectivity was unchanged (Table 2, entries 4–5). Interestingly, the cyanohydrin **2** was produced in similar yield and diastereoselectivity by addition of TMSCN to a solution of **1** and TiCl$_4$ or by addition of **1** to a premixed solution of TiCl$_4$ and TMSCN (cf. entries 5 and 6). To obtain further information on the nature of this reagent, solutions of TMSCN (2, 4, and 6 equiv) and TiCl$_4$ in C$_6$D$_6$ were concentrated in vacuo (0.2 torr 1 torr = 133.322 Pa)) collecting the volatile components in a cold trap. Analysis of the resulting yellow residue by ^{1}H NMR (in C$_6$D$_6$) consistently showed the presence of a single signal at ca. 0.18 indistinguishable from TMSCl.[13] The ^{1}H NMR spectrum (in C$_6$D$_6$) of the volatile components obtained from the 2:1 mixture of TMSCN:TiCl$_4$ indicated the absence of both TMSCl and TMSCN, whereas that from the 4:1 mixture showed the presence of ca. 2 equiv of TMSCl[13] and that from the 6:1 mixture contained ca. 2 equiv each of TMSCl and TMSCN δ (–0.17).[13,14] These ex-

[9] The configurational stability of the cyanohydrins under the reaction conditions was confirmed by control experiments.

[10] Reaction of **1** with TMSCN (2 equiv) in the presence of (*i*-Pr-O)$_2$Cl$_2$Ti(IV) (1 equiv) at 0°C in CH$_2$Cl$_2$ gave a 2.5:1 mixture of *syn:anti* cyanohydrins **2s** and **2a** (cf. 4:1, *syn:anti* diastereoselectivity in TiCl$_4$ mediated reaction of α-alkoxy aldehydes with TMSCN (17*a*)). Assuming a reagent enantioselectivity of 4:1 and a substrate diastereoselectivity of 2.5:1, eq. [1] predicts an enantiotopic group selectivity of 1.5:1.

[11] Aldehyde **1** was recovered (50% yield) from a hydrocyanation reaction proceeding to 35% conversion (^{1}H NMR) and found to have 15% ee in favor of (*R*)-**1** by ^{1}H NMR of the Mosher's ester of the corresponding alcohol (NaBH$_4$, 0°C, MeOH; quantitative). Using the equation in footnote 6, the calculated enantiotopic group selectivity from this data (C = 0.35, ee = 0.15) is 2:1.

[12] Subsequent to our work, Nakai and co-workers (25) reported hydrocyanation of aldehydes with the reagent prepared by mixing (*R*)-BINOL and (*i*-Pr-O)$_4$Ti(IV) (0.2 equiv each, rt, 0.5 h) in CH$_2$Cl$_2$ followed by addition of TMSCN (2.5 equiv, 0°C, 0.5 h) (putative catalyst: (BINOL)(CN)$_2$Ti(IV)). With this reagent, addition of cyanide was *re* face selective giving (*S*) cyanohydrins (10–75% ee) from simple aliphatic aldehydes.

[13] Confirmed by addition of an authentic sample(s).

[14] Experiments were conducted at least in triplicate. Quantification was achieved by addition of internal standards (TMSCN and (or) TMSCl). Varying amounts of TMSOH (δ 0.12) were observed; this signal was counted as being derived from TMSCl which was confirmed (^{1}H NMR) by adding controlled amounts of water to a C$_6$D$_6$ solution of TMSCl and TMSCN. Variation of the calculated stoichiometry among "identical" experiments was ca. ±15%.

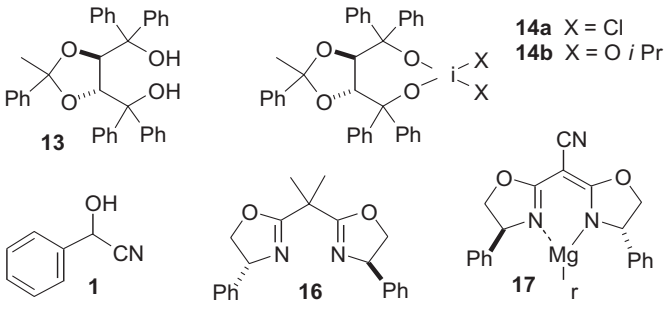
periments suggest that reaction of $TiCl_4$ with TMSCN produces an initial 1:2 adduct (e.g., $TiCl_4CN_2^{2-}(TMS^+)_2$) and that additional TMSCN results in the substitution of two Cl ligands with two CN ligands [e.g., $TiCl_2CN_4^{2-}(TMS^+)_2$] with concomitant formation of TMSCl. The capability of the residues obtained after concentration of mixtures of $TiCl_4$ and TMSCN to produce cyanohydrins was confirmed by reactions with benzaldehyde and with **1** (Table 2, entries 7–10). The reagents derived from 6:1 and from 4:1 mixtures of TMSCN:$TiCl_4$ (nominal stoichiometry $TiCl_2CN_4^{2-}(TMS^+)_2$) generated 3 equiv (based on Ti) of mandelonitrile (**15**) from benzaldehyde within 30 min at room temperature. Reaction of excess benzaldehyde with the reagent obtained from a 2:1 mixture of TMSCN:$TiCl_4$ (nominal stoichiometry $TiCl_4CN_2^{2-}(TMS^+)_2$) under similar conditions produced 1.3 equiv of mandelonitrile (**15**); reaction of the same reagent with **1** gave a 2:1 mixture of **2s** and **2a**. We also briefly examined cyanohydrin formation using a reagent prepared by addition of TMSCN (6 equiv) to a solution of (*i*-Pr-O)$_4$Ti in C_6D_6. After 15 min, the pale yellow solution was concentrated in vacuo to produce a residue with a nominal stoichiometry of "(*i*-Pr-O)$_3$TiCN" based on analysis of the volatile components by ^{1}H NMR.[15] Addition of **1** (1 equiv based on Ti) to a CH_2Cl_2 solution of the above residue gave a 1:1.2 mixture of **2s** and **2a** (75%) (Table 2, entry 11).

[15]The amounts of *i*-Pr-OR (*R* = H, TMS, 0.9 to 1.1 equiv), and TMSCN (4.5 to 5.1 equiv) in the "distillate" were quantified using an internal standard.



© 2001 NRC Canada

To summarize, TMSCN reacts with $TiCl_4$ and with (*i*-Pr-O)$_4$Ti to give adducts that can generate cyanohydrins from benzaldehyde and from **1**. The low diastereoselectivity observed in reactions with **1** can be rationalized by considering the decreased Lewis acidity of these adducts due to the strongly donating CN ligand(s) which disfavors a "chelation-controlled" pathway. Furthermore, the formation of such adducts suggests that the primary role of the Ti(IV) in these reactions may be to activate the TMSCN rather than the aldehyde. In any event, it seemed apparent that realization of enantiotopic group selective cyanohydrin formation from α-alkoxy aldehydes would require conditions to achieve cyanohydrin formation with much higher diastereoselectivity. We undertook a systematic investigation of cyanohydrin formation from **1** using a variety of cyanide sources (TMSCN, Et_4NCN, $Et_4NAg(CN)_2$), Lewis acids ($BF_3{\cdot}OEt_2$, $TiCl_4$, $SnCl_4$, $ZnBr_2$, $MgBr_2$), and reaction conditions (27). This study revealed Mg(II) as a unique promoter of hydrocyanation as it is capable of chelation of **1** and does not react appreciably with the cyanide source. Under optimized conditions (27), the cyanohydrin **2** was obtained in high yield as a 24:1 mixture of *syn:anti* diastereomers **2s** and **2a**, respectively.[16] Adapting this diastereoselective method to achieve enantiotopic group selectivity would require a chiral nonracemic version of $MgBr_2$ and (or) a chiral nonracemic cyanide source. The latter strategy appeared more promising because optimal diastereoselectivity requires the use of excess solid $MgBr_2{\cdot}OEt_2$ (27) and chiral nonracemic Ti(IV) cyanides are readily available and have been implicated in enantioselective hydrocyanation (14*d*, 23, 25).

Initial experiments evaluated the possibility for diastereoselective cyanohydrin formation from **1** using an achiral "TiCN" reagent in the presence of $MgBr_2{\cdot}OEt_2$ (Table 3). Although the reagent obtained by concentration of a 6:1 mixture of TMSCN and $TiCl_4$ (nominal stoichiometry $TiCl_2CN_4^{2-}(TMS^+)_2$) gave **2** with poor diastereoselectivity (Table 3, entry 3), the reagent prepared from a 6:1 mixture of TMSCN and (*i*-Pr-O)$_4$Ti (nominal stoichiometry (*i*-Pr-O)$_3$TiCN) generated **2** with a diastereoselectivity nearly as high as that obtained with TMSCN (Table 3, cf. entries 1 and 4). The reagent obtained analogously from a 6:1 mixture of TMSCN and **14b** was also very diastereoselective in the presence of $MgBr_2{\cdot}OEt_2$ but produced **2** with very low enantiotopic group selectivity and without evidence for double stereodifferentiation (Table 3, entry 7). We also examined reagents derived from Et_4NCN and Ti(IV) alkoxides in the presence of excess $MgBr_2{\cdot}OEt_2$ for hydrocyanation. The Mg(II) mediated hydrocyanation of **1** with Et_4NCN is a relatively poor method (Table 3, entry 2) (27). However, slow addition of Et_4NCN to a suspension of **1** and $MgBr_2{\cdot}OEt_2$ in the presence of (*i*-Pr-O)$_4$Ti was as effective as TMSCN–$MgBr_2{\cdot}OEt_2$ for stereoselective synthesis of **2s** (Table 3, cf. entries 1 and 5). The successful moderation of the reactivity of Et_4NCN towards $MgBr_2$ (27) by (*i*-Pr-O)$_4$Ti suggests the possible formation of a TiCN reagent under these conditions. Although the chiral titanium alkoxide **14b** was also effective for diastereoselective hydrocyanation of **1** under analogous conditions, the reaction proceeded with very low enantiotopic group selectivity and without double stereodifferentiation.[17]

We briefly examined enantiotopic group selective hydrocyanation using TMSCN in the presence of "chiral versions" of Mg(II). Hydrocyanations of **1** with TMSCN–$MgBr_2{\cdot}OEt_2$ in the presence or absence of the nonracemic bisoxazoline ligand **16** (28) were virtually indistinguishable (cf. Table 3, entries 1 and 8). Finally, the use of the nonracemic Mg(II) reagent **17** (29) in place of $MgBr_2{\cdot}OEt_2$ resulted in low diastereoselectivity (**2s**:**2a** = 2:1), very low enantiotopic group selectivity, and proceeded without double stereodifferentiation (Table 3, entry 9).

In conclusion, attempted hydrocyanations of α-alkoxy aldehydes with TMSCN using chiral nonracemic alkoxy Ti(IV) reagents proceeded with low enantiotopic group selectivity (<2:1). It was established that TMSCN can react with Ti(IV) reagents to produce TiCN adducts that are capable of hydrocyanation but with low substrate-controlled diastereoselectivity in reactions with α-alkoxy aldehydes. The poor enantiotopic group selectivity observed can be rationalized to result from this low diastereoselectivity despite the respectable levels of enantioface selectivity associated with these reagents in hydrocyanation of achiral aldehydes. Highly diastereoselective hydrocyanation of α-alkoxy aldehydes can be achieved with TMSCN in the presence of excess $MgBr_2{\cdot}OEt_2$ (27). High diastereoselectivity was also observed using achiral and chiral TiCN adducts in place of TMSCN. Although the putative TiCN adducts obtained from nonracemic alkoxy Ti(IV) reagents are implicated in enantioface selective hydrocyanation, these reagents were not enantiotopic group selective under these conditions and showed no evidence of double stereodifferentiation. The use of nonracemic bisoxazoline ligands for Mg(II) was also ineffective.

Experimental

General methods

All solvents were distilled prior to use. Et_3N was distilled from CaH_2 and stored over KOH pellets. Anhydrous solvents were distilled under argon as follows: ether and tetrahydrofuran (THF) from benzophenone potassium ketyl; benzene, toluene, and CH_2Cl_2 from P_2O_5 and stored over 3 Å molecular sieves; MeOH from $Mg(OMe)_2$. Unless otherwise

[16]Conditions: $MgBr_2{\cdot}OEt_2$ (5 equiv), $Et_4NAg(CN)_2$ (2 equiv) in CH_2Cl_2, –78 to –20°C, 2 h. This level of diastereoselectivity is five times greater than previously reported for α-alkoxy aldehydes.
[17]Reaction of benzaldehyde under these conditions gave **15** with <10% ee.

© 2001 NRC Canada

noted, reactions were carried out under an atmosphere of argon and reaction temperatures refer to the bath. Concentration refers to removal of volatiles at water aspirator pressure on a rotary evaporator.

Preparative TLC (PTLC) was carried out on glass plates (20 × 20 cm) precoated (0.25 mm) with silica gel 60 F_{254}. Materials were detected by visualization under an ultraviolet lamp (254 nm) and (or) by treating a 1 cm vertical strip removed from the plate with a solution of phosphomolybdic acid (5%) containing a trace of ceric sulfate in aqueous sulfuric acid (5% v/v), followed by charring on a hot plate. Flash column chromatography (FCC) was performed according to Still et al. (30) with Merck silica gel 60 (40–63 μm). Dry FCC was performed according to Harwood (31). All mixed solvent eluents are reported as v/v solutions.

Spectral data

High resolution mass spectra (HRMS) and low resolution mass spectra (LRMS) were obtained on a VG 70E double focussing high resolution spectrometer; only partial data are reported. EI ionization was accomplished at 70 eV and CI at 50 eV with ammonia as the reagent gas; only partial data are reported. IR spectra were recorded on a Fourier transform interferometer using a diffuse reflectance cell (DRIFT); only diagnostic and (or) intense peaks are reported. Unless otherwise noted, NMR spectra were measured in $CDCl_3$ solution at 300 MHz for ^{1}H and 75 MHz for ^{13}C. For ^{1}H NMR, residual $CHCl_3$ in $CDCl_3$ was employed as the internal standard (7.26 δ); for ^{13}C NMR, $CDCl_3$ was employed (77.2 δ). The ^{1}H NMR chemical shifts and coupling constants were determined assuming first-order behavior. Multiplicity is indicated by one or more of the following: s (singlet), d (doublet), t (triplet), q (quartet), m (multiplet), br (broad), ap (apparent); the list of couplings constants (*J*) corresponds to the order of the multiplicity assignment. ^{1}H NMR spectra were normally obtained with a digital resolution of 0.244 Hz/pt (sweep width = 4000 Hz, FID = 32 K data points) and coupling constants are reported to the nearest 0.5 Hz. The ^{1}H NMR assignments were made on the basis of chemical shift and multiplicity and were confirmed, where necessary, by homonuclear decoupling and (or) NOE experiments. The multiplicity of ^{13}C NMR signals refers to the number of attached Hs (i.e., s = C, d = CH, t = CH_2, q = CH_3) and was determined by *J*-modulation (32).

Materials

TMSCN (33), (*i*-Pr-O)$_2$TiCl$_2$ (34), TADDOL (23), (*i*-Pr-O)$_2$Ti(TADDOL) (24), and **18** (29) were prepared according to literature procedures. The aldehydes **1** and **4** were prepared from hexanal and pivaldehyde, respectively, by addition of vinlymagnesium bromide, benzylation, and ozonolyisis according to the procedure of Midland and Koops (35). $TiCl_4$ and (*i*-Pr-O)$_4$Ti were freshly distilled prior to use. All other reagents were commercially available and, unless otherwise noted, were used as received.

General procedure for preparation Mosher's esters

A solution of (*R*)-MTPA-Cl (prepared (20) from (*S*)-MTPA-OH; 1.2 to 1.5 equiv) in CH_2Cl_2 (ca. 0.05 M) was added via syringe to a stirred solution of the alcohol, Et_3N (2.5 equiv), and DMAP (ca. 1 mg) in CH_2C_l (ca. 0.1 M in alcohol) at room temperature. After stirring for 1–3 h, the reaction mixture was concentrated to give the crude Mosher's esters (quantitative conversion was verified by ^{1}H NMR).

General procedure for hydrocyanation with TMSCN–(i-Pr-O)$_2$TiCl$_2$–TADDOL (or BINOL)

A solution of (*i*-Pr-O)$_2$TiCl$_2$ (1.5 equiv) in toluene (ca. 0.5 M) was added via syringe to a stirred solution of TADDOL (1.5 equiv) in toluene (ca. 0.5 M) at room temperature. After 1 h, MS4A (ca. 150 mg/mmol of aldehyde) and then TMSCN (5 equiv) were added and the mixture was cooled to –23°C. A solution of aldehyde (ca. 0.2 mmol) in toluene (ca. 0.1 M) was added to the mixture. After the appropriate time, phosphate buffer (pH 7) was added and the mixture was allowed to warm to room temperature (ca. 25 min) and then was filtered (Celite®) and extracted with EtOAc (×3). The combined organic layers were washed with brine, dried over Na_2SO_4, and concentrated to give the crude cyanohydrin. The conversion was determined by ^{1}H NMR of the crude by integrating signals due to **1** (or **4**) and **2** (or **5**). Fractionation of the crude by PTLC (25% EtOAc in hexane) gave recovered **1** (or **4**) and the cyanohydrins **2** (or **5**) as a mixture of diastereomers; the stereoisomeric composition was determined by ^{1}H NMR of the corresponding Mosher's esters.

General procedure for hydrocyanation with TMSCN–TiCl$_4$ reagents

$TiCl_4$ (11 mg, 0.06 mmol) in $CDCl_3$ (40 μL) was added via syringe to a solution of TMSCN (1, 2, or 4 equiv) in $CDCl_3$ (0.5 mL). After standing at room temperature for 1 h, PhCHO (6 mg, 0.06 mmol) or **1** (13 mg, 0.06 mmol) was added. After standing at room temperature for 1 h, the mixture was poured over H_2O, diluted with CH_2Cl_2, filtered (Celite®), dried over Na_2SO_4, and concentrated giving **15** or **2** as a yellow oil. Analysis and fractionation were performed as described above.

General procedure for hydrocyanation with TiCN reagents

$TiCl_4$ (19 mg, 0.10 mmol) in C_6D_6 (0.2 mL) was added via syringe to a solution of TMSCN (2, 4, or 6 equiv) in C_6D_6 (0.3 mL) in an NMR tube (5 mm). After standing for 15 min, concentrated by freeze drying under high vacuum (0.2 torr (1 torr = 133.322 Pa)) with the volatile components being collected in a liquid nitrogen cooled trap and analyzed by ^{1}H NMR. The yellowish solid residue was dissolved in C_6D_6 (0.5 mL) and PhCHO (63 mg, 0.60 mmol) or **1** (44 mg, 0.20 mmol) was added via syringe. After 30 min, phosphate buffer (pH 7) was added and the mixture was extracted with CH_2Cl_2 (×3). The combined organic extracts were dried over Na_2SO_4 and concentrated to give a mixture of **15** (or **2**) as a yellow oil. Analysis and fractionation as described above. Analogous procedures using (*i*-Pr-O)$_4$Ti or **14b** in place of $TiCl_4$ were employed to prepare and use (*i*-Pr-O)$_3$TiCN or "(TADDOL)(*i*-Pr-O)TiCN", respectively.

General procedure for hydrocyanation with TiCN reagents in the presence of MgBr$_2$·OEt$_2$

A solution of **1** (20 mg, 0.091 mmol) in CH_2Cl_2 (0.5 mL) was added to a stirred suspension of $MgBr_2.OEt_2$ (115 mg,

© 2001 NRC Canada

0.45 mmol) in CH_2Cl_2 (1.5 mL) at room temperature. After stirring for 5 min, the reaction mixture was cooled to 0°C. A solution of the cyanating reagent (TMSCN or Et_4NCN or TiCN) (0.3–1 equiv) was added via syringe. After 1 h at 0°C, phosphate buffer (pH 7, 5 mL) was added and the reaction mixture processed as above to give the crude **2**. For entry 8 of Table 3, **1** was added to a suspension the $MgBr_2 \cdot OEt_2$ containing the ligand **16** (1 equiv). For entry 9 of Table 3, reagent **17** (1 equiv) was used instead of $MgBr_2 \cdot OEt_2$ (5 equiv). Analysis and fractionation were performed as described above.

*2-(Phenylmethoxy)heptanal (**1**):* LRMS (CI, NH_3) *m/z* (relative intensity): 238 ($[M + 18]^+$, 10), 221 ($[M + 1]^+$, 2), 191 (36), 108 (64), 91 (100). Elemental anal. calcd. for $C_{24}H_{26}F_3NO_4$: C 64.13, H 5.83, N 3.12; found: C 64.42, H 5.82, N 3.13.

*2,3-Dihydroxyoctanenitrile (**9**):* TMSCN (100 mg, 1.01 mmol) and Et_3N (41 μL, 30 mg, 0.30 mmol) was added to a stirred solution of aldehyde (150 mg, 0.68 mmol) in toluene (10 mL) containing powdered MS4A (100 mg). After stirring for 2 h the reaction was filtered and concentrated to give a 2:1 mixture of **7s** and **7a**, respectively, (197 mg, 90%). ^1H NMR δ for the *syn* isomer: 7.33–7.28 (5H, m, ArH), 4.68 (1H, d, *J* = 11.5 Hz, HC-Ar), 4.63 (1H, d, *J* = 11.5 Hz, HC-Ar), 4.38 (1H, d, *J* = 5.5 Hz, HC-2), 3.46 (1H, ddd, *J* = 3, 5.5, 8.5 Hz, HC-3), 1.80–1.20 (8H, m, H_2C-4, H_2C-5, H_2C-6, H_2C-7), 0.90 (3H, m, H_3C-8), 0.19 (9H, s, $(H_3C)_3Si$); δ for the *anti* isomer: 7.33–7.28 (5H, m, ArH), 4.80 (1H, d, *J* = 11.5 Hz, HC-Ar), 4.62 (1H, d, *J* = 11.5 Hz, HC-Ar), 4.33 (1H, d, *J* = 6 Hz, HC-2), 3.59 (1H, ddd, *J* = 5, 6, 7 Hz, HC-3), 1.80–1.20 (8H, m, H_2C-4, H_2C-5, H_2C-6, H_2C-7), 0.90 (3H, m, H_3C-8), 0.22 (9H, s, $(H_3C)_3Si$). Addition of one drop of DCl to the NMR sample resulted in hydrolysis of **7** to give a 2:1 mixture of **2s** and **2a**, respectively. To a stirred solution of **7** (2:1 mixture of **7s**:**7a**; 190 mg, 0.596 mmol) in CH_2Cl_2 (20 mL) was added $TiCl_4$ (71 μL, 123 mg, 0.65 mmol). After 1 h, the reaction was quenched by addition of NH_4Cl (1 M, 20 mL). The mixture was extracted with Et_2O (×3) and the combined organic layers were washed with brine, dried over Na_2SO_4, concentrated, and the residue fractionated by FCC (35% EtOAc in hexane) to give the diol **9** as a 2:1 mixture of **9s** and **9a**, respectively, (54 mg, 58%). LRMS (CI, NH_3) *m/z* (relative intensity): 175 ($[M + 18]^+$, 5), 148 (100), 99 (36), 83 (17). HRMS *m/z* calcd. for $C_8H_{15}NO_2$: 175.1447 (= $[M + NH_4]^+$); found: 175.1447 (CI, NH_3). IR ν_{max} (cm^{-1}): 3421, 2929, 1465, 1077. ^1H NMR δ for **9a**: 4.42 (1H, d, *J* = 3.0 Hz, HC-2), 3.92–3.80 (1H, m, HC-3), 1.72–1.43 (2H, m, H_2C-4), 1.42–1.24 (6H, m, H_2C-5, H_2C-6, H_2C-7), 0.94–0.85 (3H, t, *J* = 6.5 Hz, H_3C-8); for **9s**: 4.33 (1H, d, *J* = 4.5 Hz, HC-2), 3.92–3.80 (1H, m, HC-3), 1.72–1.43 (2H, m, H_2C-4), 1.42–1.24 (6H, m, H_2C-5, H_2C-6, H_2C-7), 0.94–0.85 (3H, t, *J* = 6.5 Hz, H_3C-8). ^{13}C NMR δ for **9a**: 117.9 (s, C-1), 72.6 (d, C-3), 66.0 (d, C-2), 32.6 (t, C-4), 31.5 (t, C-6), 25.0 (t, C-5), 22.4 (t, C-7), 13.9 (q, C-8); δ for **9s**: 118.8 (s, C-1), 72.6 (d, C-3), 64.9 (d, C-2), 32.1 (t, C-4), 31.5 (t, C-6), 25.0 (t, C-5), 22.4 (t, C-7), 13.9 (q, C-8).

(2R,3R*)-2,3-Dihydroxy-4,4-dimethylpentanenitrile (**10s**):* A solution of $TiCl_4$ (0.030 mL, 52 mg, 0.27 mmol) in CH_2Cl_2 (0.2 mL) was added via syringe to a stirred solution of **4s** (32 mg, 0.14 mmol) in CH_2Cl_2 (2.3 mL) at 25°C. After 0.5 h, H_2O was added and the mixture was extracted with CH_2Cl_2 (×3). The combined organic layers were filtered (Celite®), and the filtrate was dried over Na_2SO_4, concentrated, and the residue (29 mg) fractionated by dry FCC (0–50% Et_2O in hexane, gradient elution) to give **10s** as a white solid (10 mg, 51%). LRMS (CI, NH_3) *m/z* (relative intensity): 161 ($[M + 18]^+$, 62), 134 (100). HRMS *m/z* calcd. for $C_7H_{13}NO_2$: 161.1290 (= $[M + NH_4]^+$); found: 161.1284 (CI, NH_3). IR ν_{max} (cm^{-1}): 3416, 3291, 2959, 2873, 2238 (w), 1110, 1020. ^1H NMR δ: 4.61–4.56 (1H, br s, HC-2), 3.59–3.55 (1H, br s, HC-3), 1.00 (9H, br s, *J* = 1 Hz, $(H_3C)_3$). ^{13}C NMR: 120.1 (s, C-1), 78.9 (d, C-2), 61.8 (d, C-3), 35.2 (s, C-4), 26.4 (3q, $(CH_3)_3$). Elemental analysis calcd. for $C_7H_{13}NO_2$: C 58.72, H 9.15, N 9.78; found: C 58.86, H 8.95, N 9.51.

(4R,5R*)-2,2-Dimethyl-5-pentyl-1,3-dioxolane-4-carbonitrile (**11t**) and (4R*,5S*)-2,2-dimethyl-5-pentyl-1,3-dioxolane-4-carbonitrile (**11c**)*

TsOH (24 mg, 0.13 mmol) was added to a stirred solution of **9** (a 2:1 mixture of **9s** and **9a**; 50 mg, 0.32 mmol) in dimethoxypropane (10 mL) at room temperature. After 12 h, the reaction mixture was diluted with CH_2Cl_2 (15 mL), washed sequentially with sat. $NaHCO_3$ (×2) and H_2O, dried over Na_2SO_4, and concentrated giving a colorless oil the crude **11** as 2:1 ratio of *trans*:*cis* diastereomers by ^1H NMR (67 mg). The residue was fractionated by FCC (10% EtOAc in hexane) giving **11t** (25 mg), a 1:1 mixture of **11t** and **11c** (13 mg), and **11c** (12 mg, 80%).

*Spectral data for **11t**:* LRMS (CI, NH_3) *m/z* (relative intensity): 215 ($[M + 18]^+$, 8), 198 ($[M + 1]^+$, 26), 182 (78), 171 (19), 61 (100). HRMS *m/z* calcd. for $C_{11}H_{19}NO_2$: 215.1760 (= $[M + NH_4]^+$); found: 215.1758 (CI). IR ν_{max} (cm^{-1}): 2933, 1460, 1383, 1218, 1067. ^1H NMR δ: 4.36 (1H, ddd, *J* = 6, 6, 6 Hz, HC-5), 4.15 (1H, d, *J* = 6 Hz, HC-4), 1.72–1.63

(2H, m, H_2C-1′), 1.49 (3H, s, H_3CC-2), 1.45 (3H, s, H_3CC-2), 1.40–1.27 (6H, m, H_2C-2′, H_2C-3′, H_2C-4′), 0.93–0.87 (3H, m, H_3C-5′). ^{13}C NMR δ: 117.9 (s, CN), 112.3 (s, C-2), 80.3 (d, C-4), 67.7 (d, C-5), 32.8 (t, C-1′), 31.5 (t, C-3′), 26.8 (t, C-2′), 25.0 (2q, CH_3C-2), 22.4 (t, C-4′), 13.9 (q, C-5′). Elemental anal. calcd. for $C_{11}H_{19}NO_2$: C 66.97, H 9.70, N 7.10; found: C 67.21, H 9.86, N 6.89.

*Spectral data for **11c**:* LRMS (CI, NH_3) *m*/*z* (relative intensity): 215 ($[M + 18]^+$, 8), 198 ($[M + 1]^+$, 26), 182 (78), 171 (19), 61 (100). HRMS *m*/*z* calcd. for $C_{11}H_{19}NO_2$: 215.1760 (= $[M + NH_4]^+$); found: 215.1759 (CI, NH_3). IR ν_{max} (cm^{-1}): 2935, 1467, 1374, 1227, 1064. ^{1}H NMR δ: 4.73 (1H, d, *J* = 5 Hz, HC-4), 4.15 (1H, ddd, *J* = 5, 6, 7 Hz, HC-5), 1.97–1.86 (1H, m, HC-1′), 1.81–1.70 (1H, m, HC-1′), 1.56 (3H, s, H_3CC-2), 1.52–1.44 (1H, m, HC-2′), 1.37 (3H, s, H_3CC-2), 1.39–1.32 (5H, m, HC-2′, H_2C-3′, H_2C-4′), 0.90 (3H, br t, *J* = 7 Hz, H_3C-5′). ^{13}C NMR δ: 116.5 (s, CN), 111.8 (s, C-2), 77.5 (d, C-4), 68.2 (d, C-5), 31.6 (t, C-3′), 30.3 (t, C-1′), 27.2 (t, CH_3C-2), 25.8 (q, C-2′), 25.5 (q, CH_3C-2), 22.4 (t, C-4′), 13.9 (q, C-5′).

*(4*R**,5*R**)-2,2-Dimethyl-5-(1′,1′-dimethylethyl)-1,3-dioxolane-4-carbonitrile (**12t**):*

A solution of **10s** (16 mg, 0.11 mmol) and TsOH (ca. 2 mg) in dimethoxypropane (1.5 mL) was stirred a room temperature for 17 h. The reaction mixture was diluted with CH_2Cl_2, washed sequentially with sat. $NaHCO_3$ (×2) and H_2O, dried over Na_2SO_4, and concentrated to give a yellow oil (19 mg). Bulb-to-bulb distillation (Kugelrohr, 15 torr (1 torr = 133.322 Pa), 90°C) of the residue distillation gave **12t** as a colorless oil (12 mg, 60%). LRMS (CI, NH_3) *m*/*z* (relative intensity): 201 ($[M + 18]^+$, 79), 168 (100), 157 (92). HRMS *m*/*z* calcd. for $C_{10}H_{17}O_2N$: 201.1603 (= $[M + NH_4]^+$); found: 201.1606 (CI, NH_3). IR ν_{max} (cm^{-1}): 2961, 2874, 2250 (w), 1479, 1379, 1214, 1072. ^{1}H NMR δ: 4.56 (1H, d, *J* = 7 Hz, HC-4), 4.13 (1H, d, *J* = 7 Hz, HC-5), 1.50 (3H, s, H_3C-C-2), 1.45 (3H, s, H_3C-C-2), 0.96 (9H, s, $(H_3C)_3C$). ^{13}C NMR δ: 119.2 (s, CN), 112.6 (s, C-2), 88.1 (d, C-4), 64.2 (d, C-5), 33.1 (s, $C(CH_3)_3$), 26.4 (q, CH_3C-2), 25.4 (3q, $(CH_3)_3C$), 24.5 (q, CH_3C-2).

Absolute stereochemistry of the spiroxins

Tao Wang, Osamu Shirota, Koji Nakanishi, Nina Berova, Leonard A. McDonald, Laurel R. Barbieri, and Guy T. Carter

Abstract: The absolute configuration of spiroxin A has been determined by exciton-coupled circular dichroism (CD). Namely, the difference CD between spiroxin A – bis-methoxycinnamate, as well as that between spiroxin A – bis-retinoate, both exhibit negative exciton couplings between the acylated phenolic hydroxyl group chromophores. This establishes the absolute configuration as 2*S*,3*R*,4*S*,2′*S*,3′*R*,4′*S*.

Key words: circular dichroism, exciton coupling, spiroxins, antitumor, antifungal.

Résumé : Faisant appel au dichroïsme circulaire (DC) avec couplage d'exciton, on a déterminé la configuration absolue de la spiroxine A. Cette conclusion découle du fait que la différence dans le DC du couple spiroxine A – bis-méthoxycinnamate ainsi que celle du couple spiroxine A – bis-rétinoate présentent toutes les deux des couplages négatifs d'exciton entre les groupes chromophores des hydroxyles phénoliques acétylés. Ces travaux permettent d'établir que la configuration absolue est 2*S*,3*R*,4*S*,2′*S*,3′*R*,4′*S*.

Mots clés : dichroïsme circulaire, couplage d'exciton, spiroxines, antitumoral, antifongique.

[Traduit par la Rédaction]

Introduction

A variety of natural products that contain spiroketal moieties as elements of their molecular framework have been isolated and their structures have been determined. Among them are the preussomerins (1–3), palmarumycins (4–8), diepoxins (9, 10), cladospirone bisepoxides (11, 12), Sch series (13–16), and cladosporol (17). Compounds of this family exhibit significant antitumor and antifungal activities while some demonstrate inhibitory activity against phospholipase D (15).

Recently, a new series of bisnaphthospiroketal compounds, spiroxin A–E (**1**–**5**), have been isolated from a marine fungus (18). These compounds share a common bisnaphthospiroketal skeleton, differing from each other in their levels of oxygenation and halogenation. The absolute configuration of spiroxin A, the relative stereochemistry of which had been determined previously by NMR (18), is described in the following.

Circular dichroic (CD) exciton chirality has been widely used to determine the absolute configuration and (or) conformation of a variety of organic molecules (19). It is based on the through-space chiral interaction between the electric transition moments of two or more chromophores, which preexist in the molecule or, more often, are introduced by derivatization of functional groups (e.g., -OH, $-NH_2$). Herein we wish to report the absolute configuration of the spiroxins as determined by the CD exciton chirality method.

Results and discussions

The absolute configuration of spiroxin A, the major component produced by the fungal strain LL-37H248, has been determined by application of the exciton chirality method after suitable derivatization. The electrophilic activity of the two phenolic hydroxyl groups should distinguish themselves from other functional groups (oxirane, carbonyl, and ketal) in the molecule. Spiroxin A contains several UV–vis absorption bands (in CH_3CN), one at 264 nm (strong, ε = 12 300), and the other at a longer wavelength, 362 nm (weak, ε = 5600) (Fig. 2), which is associated with n-π^* and L_b(π-π^*) transitions of polysubstituted acetophenone chromophores. Therefore, we considered the derivatization of two free phenolic hydroxyl groups with red-shifted chromophores (19, 20). In particular, we selected the *p*-dimethylaminobenzoic group (λ_{max} = 307 nm, ε = 28 200, in CH_3CN), the *p*-methoxycinnamic group (λ_{max} = 306 nm, ε = 23 400, in CH_3CN), the all-*trans* retinoic group (λ_{max} = 356 nm, ε = 39 500, in CH_3CN), and the 5-(4′-carboxylphenyl)-10,15,20-triphenylporphyrin group (TPP) (λ_{max} = 419 nm, ε = 440 000, in CH_2Cl_2). We expected that due to their intense UV–vis absorption above 300 nm, such groups would not interact strongly with the preexisting chromophore(s). On the other hand, the resulting CD exciton coupling between the two new introduced chromophores should be readily distin-

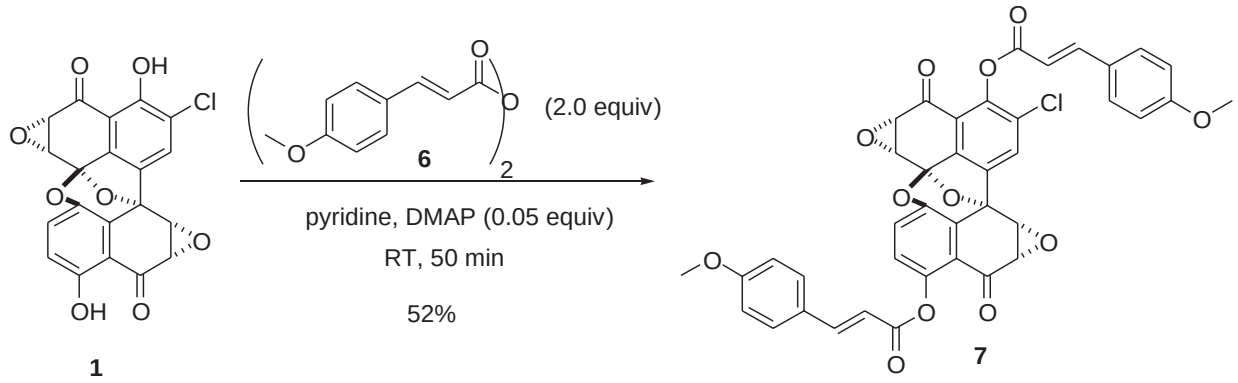
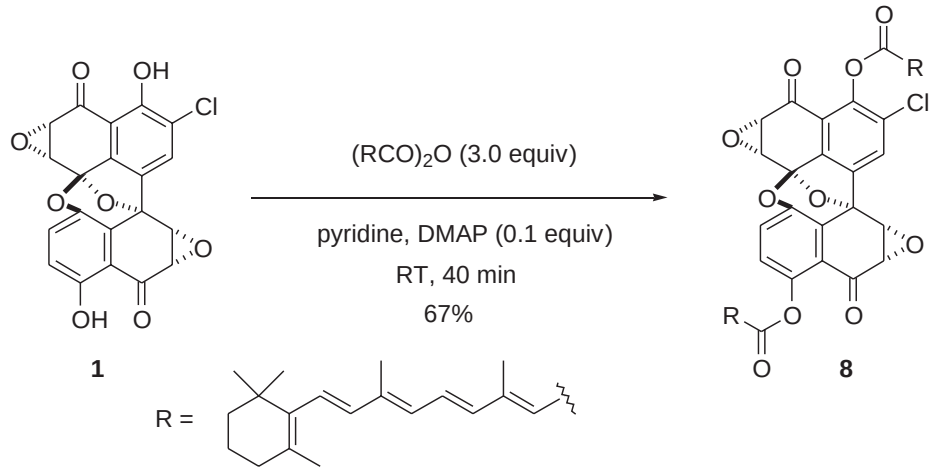
guished either directly or in the difference CD after subtracting the underivatized spiroxin spectrum.

Spiroxin A (1) is highly unstable to acidic treatment. The presence of the oxirane ring also makes it susceptible to nucleophilic reagents. Furthermore, spiroxin A decomposes over prolonged treatment with pyridine, the solvent of choice for esterification of hydroxyl groups, especially in case of chelated hydroxyl functions to break the H-bonding. In addition, since the total amount of compound available was ca. 3.0 mg, derivatization and exploratory experiments with this unstable compound had to be carried out at the microscale level. Incorporation of the tetraphenylporphyrin (TPP) and *p*-dimethylaminobenzoate groups were first attempted. Standard coupling reactions between **1** and 5-(4′-carboxylphenyl)-10,15,20-triphenylporphyrin with

Fig. 3. (*a*) CD (solid line) and UV (dashed line) spectra of spiroxin A – biscinnamate in CH_3CN (1.5×10^{-5} M). (*b*) Difference (biscinnamate–SpA) CD (solid line) and UV (dashed line) spectra of spiroxin–biscinnamate.



DCC–DMAP led to the decomposition of the starting material. Reactions involving the *p*-dimethylaminobenzoic group (either acid or its anhydride) also led to degradation of the starting material. Treatment of **1** with DBU and *p*-methoxycinnamic anhydride **6**, which had been prepared from the corresponding acid (21), also resulted in decomposition. Base-free acylation of **1** with **6** catalyzed by TMSOTf (22) or $Sc(OTf)_3$ (23) (either catalytic or stoichiometric) did not proceed, leaving the starting material intact. After several unsuccessful trials, it was discovered that the reaction of spiroxin A (1) with anhydride **6** proceeded in pyridine–DMAP at room temperature under argon in 50 min, to give the desired biscinnamate **7** in 52% isolated yield. This reaction had to be monitored very carefully by TLC to check for the decomposition of the product and (or) starting material.



The CD and UV–vis spectra of biscinnamate **7** are shown in Fig. 3*a*. The CD exhibited a negative peak at 336 nm ($\Delta\varepsilon = -28.9$). However, no positive Cotton effect (CE) around the cinnamate absorption could be detected. As Fig. 2 illustrates, the CD spectrum of spiroxin A in CH_3CN exhibits several Cotton effects related to the polysubstituted acetophenone chromophores. The difference CD and difference UV–vis spectra, resulting from subtraction of the respective observed spectra of **1** from those of biscinnamate **7**, are shown in Fig. 3*b*. While the difference

Scheme 2. Synthesis of spiroxin A bisretinoate.

CD in the shorter wavelength region (200–280 nm) mainly shows changes in the intensity of CEs exhibited by spiroxin A itself, at 280 and 338 nm a clear positive ($\Delta\varepsilon$ = +15) – negative ($\Delta\varepsilon$ = –13) couplet is seen. The position of the new bisignate CE centered at 309 nm is very slightly red-shifted when compared with typical data for bis-*p*-methoxycinnamate couplings (287 and 325 nm, centered at 306 nm) (24).

In general, the difference CD spectrum is especially useful when the chiral substrate contains preexisting chromophore(s) and exhibits, before derivatization, an intense and complex CD. Recent examples include strevertenes (25), vinblastine (26), and nemadectines (27). In all three cases, the parent compounds exhibited CD spectra with multiple Cotton effects and only after subtraction of such CD from the CD of the corresponding chromophoric derivative did the net exciton-coupled contribution become clear. In the case of **7**, however, the interaction between *p*-methoxycinnamate with the polysubstituted acetophenone group in the spiroxin A cannot be completely excluded and this is the most likely the reason for the slight deviation in the λ_{max} of the couplet from that of a typical *p*-methoxycinnamate. We, therefore, attempted to incorporate the more red-shifted all-*trans* retinoic group into spiroxin A since the interaction of its chromophore with the innate spiroxin A chromophore would be minimized. The all-*trans* retinoic methyl ester has a λ_{max} at 356 nm (ε = 39 500) with the corresponding electric transition dipole moment (μ) polarized almost parallel to the all-*trans* polyene side chain, as is the case with other known polyene ester systems (19, 20).

Fortunately, the incorporation of all-*trans* retinoic chromophore proceeded smoothly. Treatment of **1** with all-*trans* retinoic anhydride under conditions similar to those described above produced spiroxin A bis-retinoate **8** in 67% yield (Scheme 2). The CD and UV–vis spectra for **8** are shown in Fig. 4*a*. The CD spectrum shows a negative peak at 391 nm ($\Delta\varepsilon$ = –14.6). The difference CD spectrum exhibits a negative peak at 385 nm ($\Delta\varepsilon$ = –17.3) and a positive peak at 331 nm ($\Delta\varepsilon$ = +17.4), *A* = –34.7 (Fig. 4*b*), giving rise to a typical negative bisignate curve with crossover around 359 nm, close to the max of the isolated retinoate chromophore (356 nm).

The difference CD obtained here is in good agreement with the model compound, *trans*-(1*R*,2*R*)-cyclohexanediol derivative **9** prepared earlier (unpublished results). As seen in Fig. 5, the CD spectrum of **9** exhibits a negative peak at 381 nm and a positive peak at 331 nm, *A* = –40.1. Since the parent cyclohexanediol only contains hydroxyl groups absorbing ca. 200 nm, the observed CD represents a typical conservative couplet, i.e., true exciton coupling between two retinoate chromophores. The surprisingly good agreement in position and intensity between the CD spectrum of **9** and the difference CD spectrum shown in Fig. 4*b* exemplifies the ad-

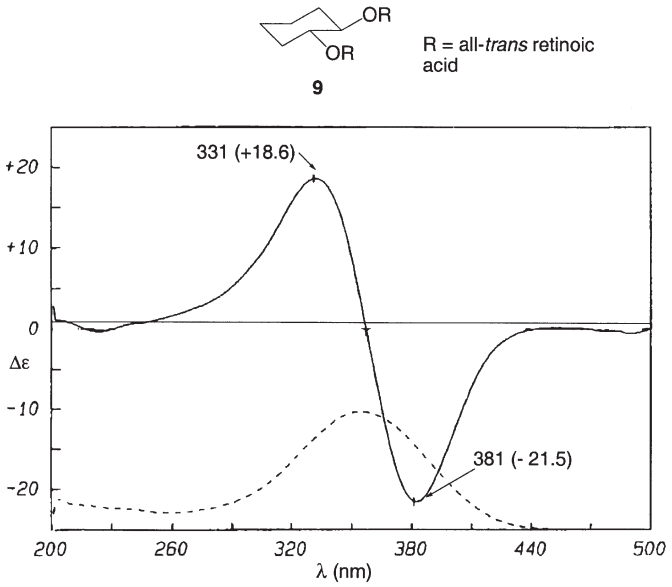

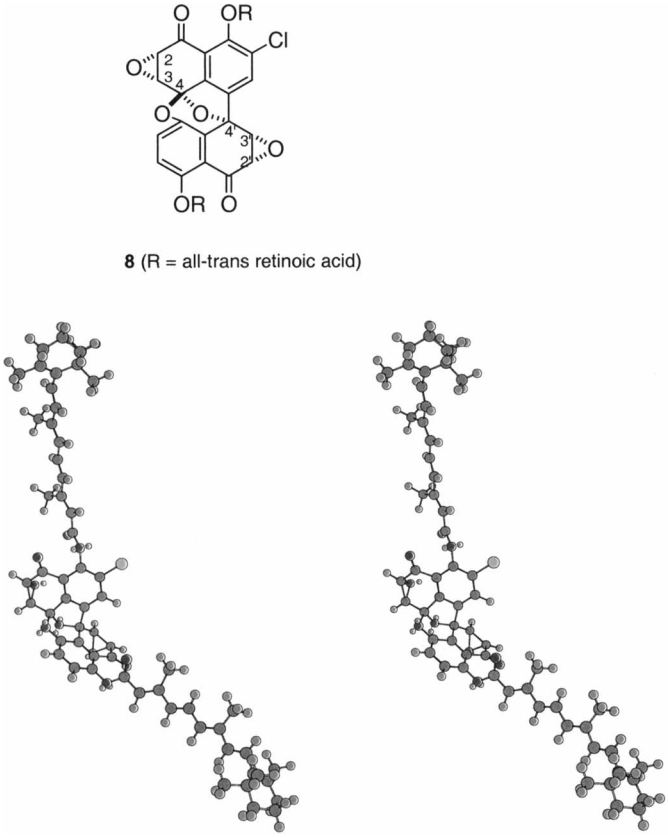

Fig. 6. Lowest energy conformer of **8** (stereo view) from Monte Carlo conformation search (MM2, 1000 structures), and absolute stereochemistry of the six stereogenic centers on compound **8** was determined as 2*S*,3*R*,4*S*,2′*S*,3′*R*,4′*S*.

vantage of using the red-shifted retinoate for the CD analysis of spiroxin A.

Thus, the obtained difference CD couplet at 385 and 331 nm with amplitude $A = -34.7$ represents straightforward evidence for the negative chirality between the two all-*trans* retinoic chromophores, and hence leads to the assignment of the absolute configuration of spiroxin A. For the relative and absolute configuration shown in **8**, the Monte Carlo conformation search (MM2 as force field, 1000 structures) gave the lowest energy conformer shown in Fig. 6, where the two all-*trans* retinoic chromophores form a negative chiral twist. Additionally, all 22 other distinct conformers whose energies fall within a 1 kcal mol^{-1} range of the global min gave negative chirality. Consequently, based on the observed negative couplet in the difference CD, the structure **8** represents the absolute configuration of spiroxin A as 2*S*,3*R*,4*S*,2′*S*,3′*R*,4′*S*.

Conclusion

In summary, based on an exciton-coupled CD study of spiroxin A biscinnamate **7** and spiroxin A bisretinoate **8**, the absolute configurations of the six stereogenic centers of spiroxin A have been determined as 2*S*,3*R*,4*S*,2′*S*,3′*R*,4′*S*. Since NMR studies have shown (18) that all five spiroxins (**A**–**E**) share the same skeletal structure, the absolute

© 2001 NRC Canada

configuration of spiroxin A can be extended to the four other members (**B**–**E**) of the spiroxins.

Experimental

General methods

TLC was performed on a Merck DC-alufolien with Kieselgel 60F-254 and column chromatography was carried out on silica gel 60 (Merck, 230–400 mesh ASTM). ^{1}H and ^{13}C NMR spectra were measured on a Bruker DMX-400 NMR spectrometer in $CDCl_3$ or benzene-d_6. Chemical shifts (δ) were reported in ppm downfield from internal TMS and coupling constants (*J*) in Hz. UV–vis spectra were measured on a PerkinElmer Lambda 6 UV–vis spectrophotometer. CD spectra were measured on a JASCO J-810 spectropolarimeter. The following parameters were employed: band width 1.0 nm, auto slit width, sensitivity 20 mdeg, response 2 s, start wavelength 400 nm or 500 nm, end wavelength 210 nm, scan speed 100 nm min^{-1}, step resolution 0.5 nm, accumulation 8. Mass spectra were measured on a JEOL JMS-DX303 HF mass spectrometer. All molecular mechanics were carried out with MacroModel V6.0 on Silicon Graphics 3D workstation at the Department of Chemistry, Columbia University. The Monte Carlo conformation search was carried out by using MM2 as the force field, and 1000 structures were generated.

Materials

All chemicals were purchased from Aldrich Co. (Milwaukee, Wisconsin) and purified before use by standard methods. Acetonitrile used for UV and CD analysis was of spectrophotometric grade. Dichloromethane was distilled immediately prior to use under nitrogen from calcium hydride.

*Preparation of spiroxin A bis-cinnamate (**7**)*

To a solution of spiroxin A (2.0 mg, 4.85 μmol) and *p*-methoxycinnamic anhydride **6** (3.28 mg, 9.7 μmol) in distilled pyridine (80 μL) under argon at room temperature was added a solution of 4-dimethyaminopyridine in pyridine (0.02 M, 18 μL, 0.36 μmol) and the reaction mixture was stirred for 50 min. The reaction mixture was diluted with ether (20 mL) and the solution was washed with saturated $CuSO_4$ solution and brine. The mixture was dried over anhyd Na_2SO_4 and the solvent was removed in vacuo. Column chromatography on silica gel (hexanes:ethyl acetate = 2:1 to 1:1) gave the desired product **7** (1.8 mg, 52%) as a white solid. APCI MS *m*/*z*: 750.3 $[M + NH_4]^+$. UV–vis λ_{max} (nm) (ε) (CH_3CN): 227.5 (52 000), 320 (67 000). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 3.83 (d, *J* = 3.7 Hz, 1 H), 3.87 (s, 6 H), 3.97 (d, *J* = 4.1 Hz, 1 H), 4.17 (d, *J* = 4.0 Hz, 1 H), 4.24 (d, *J* = 3.7 Hz, 1 H), 6.54 (t, *J* = 15.8 Hz, 2 H), 6.94 (dd, *J* = 8.7, 1.3 Hz, 4 H), 7.08 (d, *J* = 8.9 Hz, 1 H), 7.15 (d, *J* = 8.9 Hz, 1 H), 7.56 (dd, *J* = 8.7, 1.3 Hz, 4 H), 7.86 (t, *J* = 15.8 Hz, 2 H).

*Spiroxin A bisretinoate (**8**)*

FAB–HRMS *m*/*z* calcd. for $C_{60}H_{61}ClO_{10}$: 976.3953; found: 976.3936 (Δ = –1.8 ppm). UV–vis λ_{max} (nm) (ε) (CH_3CN): 374 (50 800). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.04 (s, 12 H), 1.25 (m, 4 H), 1.48 (m, 4 H), 1.54 (m, 4 H), 1.73 (s, 6 H), 2.03 (s, 6 H), 2.39 (s, 3 H), 3.80 (d, *J* = 3.7 Hz, 1 H), 3.95 (d, *J* = 4.1 Hz, 1 H), 4.14 (d, *J* = 4.1 Hz, 1 H), 4.23 (d, *J* = 3.7 Hz, 1 H), 6.01 (s, 1 H), 6.07 (s, 1 H), 6.15–6.20 (m, 4 H), 6.30 (d, *J* = 6.0 Hz, 1 H), 6.34 (d, *J* = 6.9 Hz, 1H), 6.37 (d, *J* = 3.9 Hz, 1 H), 6.41 (d, *J* = 3.7 Hz, 1 H), 6.98–7.16 (m, 4 H), 7.47 (s, 1 H).

*trans-(1*R*,2*R*)-Cyclohexanediol bisretinoate (**9**)*

To a solution of *trans*-(1*R*,2*R*)-cyclohexanediol (1.9 mg, 16.6 μmol) and all-*trans* retinoic triazole (18 mg, 57.3 μmol) in distilled CH_2Cl_2 (1 mL) was added five drops of DBU (0.1 M in CH_2Cl_2) and the reaction mixture was stirred for 20 h. The reaction mixture was diluted with ether (20 mL) and the solution was washed with brine. The mixture was dried over anhyd Na_2SO_4 and the solvent was removed in vacuo. Column chromatography on silica gel (hexanes:ethyl acetate = 5:1) gave the desired product **9** (0.9 mg, 8%) as a white solid. FAB–HRMS *m*/*z* calcd. for $C_{46}H_{64}O_4$: 680.9980; found: 680.9568 (Δ = 6.0 ppm). UV–vis λ_{max} (nm) (ε) (CH_3CN): 352 nm (58 000). ^{1}H NMR (300 MHz, $CDCl_3$) δ: 1.07 (s, 12 H), 1.22 (m, 4 H), 1.45 (m, 8 H), 1.55 (m, 6 H), 1.73 (s, 10 H), 2.07 (s, 6 H), 2.40 (m, 4 H), 4.88 (m, 2 H), 5.72 (m, 2 H), 6.10–6.30 (m, 4 H), 6.98–7.05 (m, 4 H), 7.52 (m, 2 H).

Studies on enolate chemistry of 8-thiabicyclo[3.2.1]-octan-3-one: enantioselective deprotonation and synthesis of sulfur analogs of tropane alkaloids

Marek Majewski, Marc DeCaire, Pawel Nowak, and Fan Wang

Abstract: Enantioselective deprotonation of 8-thiabicyclo[3.2.1]octan-3-one (**1**) with chiral lithium amides, followed by reactions with electrophiles affords sulfur analogs of tropane alkaloids of pyranotropane family. Thus, deprotonation of **1** with (*S*)-*N*-(diphenyl)methyl-1-phenylethylamine (**11d**), followed by the reaction of the resulting nonracemic enolate with benzaldehyde gives the corresponding aldol product as one diastereoisomer (*exo*, threo) and in high enanatiomeric purity (95% ee). Trimethylsilyl chloride, acetic anhydride, and acyl cyanides react readily with the lithium enolate to give the corresponding derivatives of **1**, however common alkylating agents fail to provide *C*-alkylated products. The reaction with acyl cyanides derived from α,β-unsaturated carboxylic acids (e.g., cinnamoyl cyanide) can be utilized in synthesis of thia-analogs of tropane alkaloids physoperuvine and isobellendine (**13**, **15**).

Key words: enantioselective deprotonation, tropane alkaloids.

Résumé : La déprotonation énantiosélective de la 8-thiabicyclo[3.2.1]octan-3-one à l'aide d'amides de lithium chiraux, suivie de réactions avec des électrophiles, conduit à la formation d'analogues sulfurés des alcaloïdes du tropane, de la famille du pyranotropane. Ainsi, la déprotonation du produit **1** avec de la (*S*)-*N*-(diphényl)méthyl-1-phényléthylamine (**11d**), suivie d'une réaction de l'énolate non racémique qui en résulte avec du benzaldéhyde, conduit à la formation du produit aldolique correspondant, sous la forme d'un diastéréoisomère (*exo*, thréo) et avec une pureté énantiotopique éleveée (95% ee). Le chlorure de triméthylsilyle, l'anhydride acétique et les cyanures d'acyles réagissent facilement avec l'énolate de lithium pour conduire à la formation des dérivés correspondants du produit **1**. Toutefois, les agents alkylants habituels ne conduisent pas à la formation de produits *C*-alkylés. On peut toutefois utiliser la réaction avec des cyanures d'acyles dérivés d'acides carboxyliques α,β-insaturés (par exemple, le cyanure de cinnamoyle) pour effectuer la synthèse de la physopéruvine et de l'isobellendine, des analogues sulfurés des alcaloïdes du tropane (**13**, **15**).

Mots clés : déprotonation énantiosélective, alcaloïdes du tropane.

[Traduit par la Rédaction]

Introduction

8-Thiabicyclo[3.2.1]octan-3-one (**1**) is a simple, readily available symmetrical ketone that can be viewed as a potential scaffold for construction of diverse compounds of medium complexity and, perhaps most notably, as a scaffold for construction of sulfur analogs of tropane alkaloids. These alkaloids comprise a group of over 200 natural products of general structure **2** (R groups are typically alkyls or acyls, brackets signify that the group can be at e.g., C-2 or C-4, R and R′ can be connected forming a heterocycle), built around a common 8-azabicyclo[3.2.1]octane skeleton (1). During the last few years we have developed a comprehensive strategy for stereoselective synthesis of tropane alkaloids based on enantioselective deprotonation of tropinone (**3**) with chiral lithium amides (e.g., **4**) as the key reaction. A number of tropane alkaloids were synthesized (2–5), and an elegant synthesis of cocaine utilizing our strategy, which allowed setting up the absolute and relative stereochemistry around all 4 stereogenic centers in 2 steps, has recently been reported by Cha and co-workers (6). Replacement of the nitrogen atom in a biologically active natural product by the sulfur atom is a well known strategy in medicinal chemistry often leading to substantial changes in biological activity of the compound (7, 8). TBON had been used as a replacement for alkaloid intermediates during studies on alkaloid metabolism and on biosynthesis of cocaine (9). We were interested in developing a general synthesis of sulfur analogs of tropane alkaloids and, towards this end, we initiated an investigation of lithiation of **1** with chiral lithium amides and of reactions of the corresponding enolate.

Enantioselective deprotonation of symmetrical ketones (note the enantiotopic protons in structures **1** and **3**) with chiral lithium amides is a relatively new methodology (2,

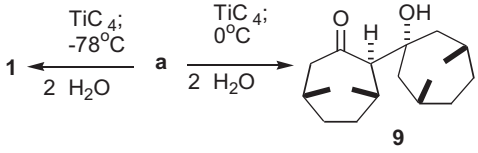
10). A number of diverse ketones have been investigated over the last decade and, even though the mechanism of the reaction is still not fully understood, several trends have emerged: (*i*) certain level of conformational rigidity is necessary for achieving high level of enantioselectivity. Thus, 4-*tert*-butylcyclohexanone could be deprotonated with higher enantioselectivity than the 4-methyl analog (11). (*ii*) Bicyclic, bridged ketones are especially good substrates in reaction with chiral lithium amides (high enantioselectivity) (2, 10). (*iii*) Addition of certain salts, especially LiCl, can be very beneficial from the standpoint of reaction selectivity (12). (*iv*) There is no straightforward correlation between the structure of the ketone, the lithium amide, and selectivity. There is no magic bullet; certain lithium amides can be very selective with some ketones but show poor selectivity in other systems. Thus, every new system must be researched experimentally. It should be noted that a few other heterocyclic compounds containing sulfur have been investigated in the context of enantioselective deprotonation (13, 14). One precedent involving TBON was reported previously by Simpkins and co-workers (15), who also noted a strong effect of the $ZnCl_2$ additive on the selectivity of deprotonation with the chiral base **4**.

On the basis of the foregoing TBON looked like a promising substrate for synthesis using deprotonation with chiral lithium amides as the key step, but it should be emphasized that, as with any new system, the conditions for successful selective deprotonation had to be elaborated from the beginning. Apart from being interesting in the purely theoretical sense TBON could provide a useful starting material for construction of α-substituted cycloheptanones (after desulfurization), and it should be noted that the presence of the sulfur atom in the bridge offers potential for much more diverse chemistry than the corresponding carbon-, oxygen-, or nitrogen-bridged systems due to the ability of dialkylsulfur compounds to exist in three oxidation states (as sulfides, sulfoxides, or sulfones).

Results and discussion

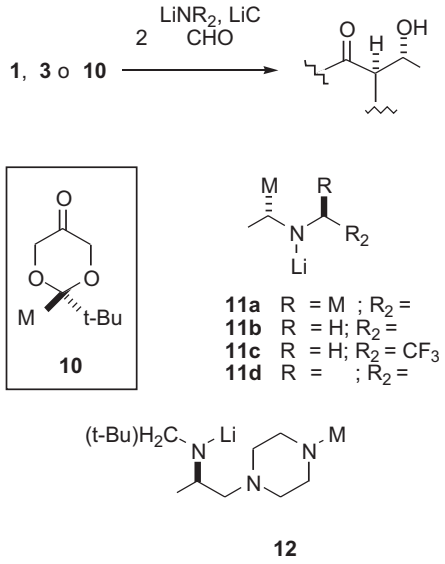
Since little was known about chemical properties of TBON we started by running a series of typical experiments. Lithiation of **1** with LDA proceeded in the usual fashion and the resulting enolate could be efficiently trapped with TMS-Cl, Ac_2O, benzaldehyde, or methyl cyanoformate to afford the corresponding silyl enol ether **5a** (96% isolated yield), enol acetate **5b** (97%), aldol product **7** (92%), or β-ketoester **6** (98%), respectively (Scheme 1). We were, however, unable to effect alkylation of TBON lithium enolate. Most of the attempts with reactive alkylating agents: methyl or ethyl iodide, benzyl bromide, or butyl tosylate gave numerous products that were difficult to purify; in some cases the starting material was recovered. It should be noted that similar failures of the well-known, and all too often taken for granted, alkylation reaction were observed before in cases involving other ketone enolates (16).

Scheme 1.



The aldol reaction leading to product **7** proceeded with very high diastereoselectivity and only one isomer out of possible four diastereoisomeric aldols was formed (to the limit of the NMR detection in the crude product). In analogy to tropinone (2) we have assigned the *exo–anti* relative configuration (as drawn) to this compound. The *exo* orientation of the CHOHPh group was also supported by NOE studies. The proton NMR spectrum of the crude aldol product indicated a presence of a minor by-product (ca. 6% by integration). We made no effort to isolate this product from the mixture, but we believe it to be the bis-aldol **8**. Compound **8** was produced in good yield (61%) in a separate experiment involving the titanium enolate of **1** (Scheme 1) and the NMR spectrum of **8** was consistent with the *exo*,*exo*,*anti*,*anti* relative configuration. In the mixture, the bis-aldol **8** could be easily confused with the expected minor product i.e., the *syn* isomer of the aldol **7**, because the benzylic protons of this compounds appear ca. 0.35 ppm downfield of the signal characteristic of the benzylic proton of compound **7**; an accidental juxtaposition of signals resembling a typical mixture of erythro (*syn*) and threo (*anti*) aldols (17). The formation of a bis-aldol as the major product of addition of the titanium enolate of TBON to benzaldehyde is unusual — the expected result would be the *syn* isomer of **7** as the major product (18).

Some oxygen-bridged ketones similar to **1** are known to undergo a ring opening to the corresponding cycloheptenone derivatives upon treatment of their silyl enol ethers with Lewis acids (19). In an attempt to recreate this reaction on TBON, we treated the TMS enolate **5a** with titanium tetrachloride (Scheme 2). There was no evidence of ring opening, however, depending on the reaction temperature, either the self-aldol product **9** was formed in good yield (70% of **9** was isolated when the experiment was done at 0°C) or, at low temperature, the enol ether was presumably cleanly transmetalated and, upon quenching, converted cleanly and quantitatively into the parent ketone **1**.



Having achieved reasonable predictability of behavior of the TBON enolate a brief experimental study of enantio-

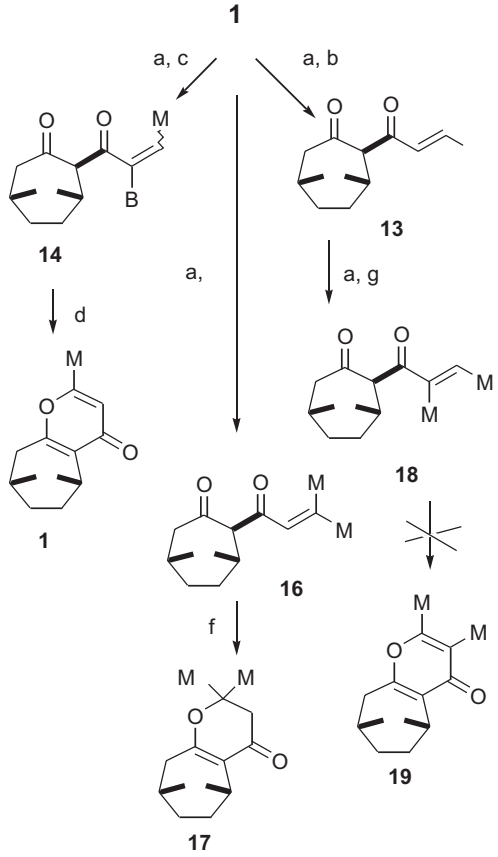

Scheme 3.

selective deprotonation was launched. The chiral lithium amides used in this study are shown in Scheme 3; the aldol addition to benzaldehyde was used as the model reaction because the enantiomeric excess (ee) could be easily measured on the aldol **7** using NMR with a chiral solvating agent [(*S*)-(+)-2,2,2-trifluoro-1-(9-anthryl)ethanol]. The absolute stereochemistry of deprotonation has not been established, but, by analogy to tropinone, we believe that the major, dextrorotatory enantiomer of **7**, which was produced in each case, should be as drawn in Scheme 1. The results are summarized in Table 1, which also includes, for comparison, enantioselectivities attained using the same reagents with other heterocyclic ketones: tropinone **3** and dioxanone **10**. All reactions were done in the presence of LiCl (one mol per one mol of the amide). The reaction with base **4** (i.e., with the enantiomer of **11a**) had been previously reported to proceed with 84% ee (15). Despite numerous attempts the highest ee in our experiments was 70% (as measured by NMR on the crude product; the optical purity of the sample could be easily increased by crystallization). The reaction seemed to be fairly capricious and substantial amounts of the bis-aldol were observed in all experiments involving base **11a** (15–25%). We also noticed that in experiments that yielded more bis-aldol product the optical purity of compound **7** was higher (e.g., 58% ee of **7** at **7**:**8** ratio of 85:15 and 70% ee of **7** at **7**:**8** ratio of 75:25), suggesting that the second aldol reaction had introduced an element of kinetic resolution. In an effort to optimize this reaction we tried a number of conditions and finally we observed that the best selectivity was consistently achieved when the amine hydrochloride was

Scheme 4. Reagents: (*a*) LiCl; (*b*) PhCH=CHCOCN; (*c*) MeCH=CBrCOCN; (*d*) Et_3N; (*e*) Me_2C=CHCOCN; (*f*) Na_2CO_3, EtOH; (*g*) MeCH=CMeCOCN.

used to generate the LiCl–$LiNR_2$ mixture in situ (19) and when the ketone was added slowly (over 90 min) to the solution of the amide (see *Experimental*). All experiments were subsequently run under these conditions. The most selective base turned out to be compound **11d** (Table 1, entry 4). It was interesting to note that bases **11a** and **12**, which provided high selectivity in tropinone deprotonation, were ineffective in both the TBON and the dioxanone systems, and conversely, base **11d** by far the best as far as TBON deprotonation was concerned, performed worse than other bases with substrate **3**, and gave only modest selectivity with compound **10**. Amide **11c**, developed by Aoki and Koga (20) and known to be selective in several systems (2, 21) was not very effective with TBON.

We had previously described stereoselective syntheses of a number of tropane alkaloids via the enantioselective deprotonation strategy (2). Extension of this approach to synthesis of sulfur analogs of tropane alkaloids e.g., chalcostrobamine and darlingine appeared straightforward. Enantioselective deprotonation of TBON with the chiral amide **11d** followed by treatment of the resulting enolate with an acyl cyanide (Scheme 4) proceeded readily to give the corresponding β-diketone (**13**, **14**, **16**, or **18**). The sulfur analog of chalcostrobamine **13** was produced in a modest yield of 61%, even though an analogous reaction with LDA (leading to the racemate of **13**) was very efficient (92% yield). Acylation with 2-bromo-2-butenoyl cyanide gave compound

14 that, without purification, was converted into a sulfur analog of isobellendine **15** by heating with triethylamine. This sequence of three reactions was quite efficient (48% overall yield, 87% ee). Compound **17**, which is not an analog of a known tropane alkaloid, was produced by a similar reaction sequence (78% yield, 92% ee). We have also attempted a synthesis of a sulfur analog of darlingine, but, even though the acylation proceeded well, we were unable to find an efficient method to introduce the double bond into the pyranone ring. Overall, enantioselective deprotonation of TBON coupled with acylation using acyl cyanides provided an easy entry into sulfur analogs of alkaloids of pyranotropane family.

Experimental

All air sensitive reactions were carried out under nitrogen. Tetrahydrofuran and diethyl ether were distilled under nitrogen from sodium and benzophenone. Dichloromethane and diisopropylamine were distilled from calcium hydride. Lithium chloride was dried at 130–150°C in vacuum overnight and it was used as a solid or as a solution in tetrahydrofuran. *n*-Butyllithium was periodically titrated using 2,5-dimethoxybenzyl alcohol. Flash column chromatography (FCC) and dry flash chromatography (DFC) were carried out using Merck silica gel 60 (230–400 mesh) and Sigma silica gel Type H (10–40 μm), respectively. Thin layer chromatography (TLC) was performed on precoated glass plates (Merck, silica gel 60, F254). The spots were detected using UV light (254 nm) or with a developing solution by charring on a hot plate. The developing solution was prepared by dissolving concentrated sulfuric acid (50 g), cerium(IV) sulfate (10 g), and phosphomolybdic acid hydrate (40 g) in water (1 L). Optical rotations were measured on a Elmer 241 Polarimeter (1 dm, 1 mL cell), all concentrations are given in g per 100 mL. Proton magnetic resonance (^{1}H NMR) and carbon magnetic resonance (^{13}C NMR) spectra were recorded on a Bruker AM-300 (300 MHz) spectrometer in chloroform-*d* solvent unless otherwise noted. Chemical shifts are reported in ppm of δ scale with TMS as the internal standard. Coupling constants (*J*) are reported to the nearest 0.5 Hz.

General procedure A

Diisopropylamine (0.17 mL, 1.20 mmol) was dissolved in THF (10 mL) and the solution was cooled to 0°C. *n*-BuLi (0.44 mL, 2.5 M solution in hexanes, 1.10 mmol) was added dropwise and the solution was stirred for 0.5 h at 0°C was cooled to –78°C, and then **1** (0.142 g, 1.00 mmol) in THF (0.5 mL) was added dropwise over 1 min. The resulting mixture was then stirred for 2 h. Next, the electrophile (1.20 mmol) was added. After 0.5 h, the reaction mixture was quenched with saturated aqueous $NaHCO_3$ solution (5 mL). The reaction mixture was then allowed to warm up to room temperature. Water was added (20 mL) and the mixture was extracted with diethyl ether (3 × 50 mL). The combined organic extracts were washed with saturated aqueous $NaHCO_3$ solution (1 × 20 mL), brine (1 × 20 mL), and dried ($MgSO_4$). The solvent was then removed (rotovap) and the product was purified by dry flash chromatography (hexane → hexane–ethyl acetate, 1:1).

General procedure B

Hydrochloride of the chiral amine **11** (1.10 mmol) was dissolved in THF (10 mL) and cooled to 0°C. *n*-BuLi (0.88 mL, 2.5 M solution in hexanes, 2.20 mmol) was added dropwise and the solution was stirred for 1.5 h. After cooling the amide solution to –78°C, compound **1** (0.142 g, 1.00 mmol) in THF (1.0 mL) was added dropwise over 0.5 h (syringe pump). The resulting mixture was then stirred for 2 h and the electrophile (1–1.2 mmol) in THF (1 mL) was added. After 0.5 h the reaction mixture was quenched with saturated aqueous $NaHCO_3$ solution (5 mL) and was then allowed to warm up to room temperature. Water was added (20 mL) and the mixture was extracted with diethyl ether or with chloroform (3 × 50 mL). The combined organic extracts were washed with saturated aqueous $NaHCO_3$ solution (1 × 20 mL), brine (1 × 20 mL), and dried ($MgSO_4$). The solvent was then removed. The amount of side product (e.g., **8**) and the ee of the main product (e.g., **7**) was next determined by ^{1}H NMR In experiments involving the aldol **7** samples were prepared by dissolving the product (2.5 mg) and the chiral solvating agent (*S*)-(+)-2,2,2-trifluoro-1-(9-anthryl)ethanol (TFAE, 10.0 mg) in C_6D_6 (0.5 mL). The signal at 5.07 ppm showed best splitting and was used to determine ee. The crude product was then purified by dry flash chromatography (hexane → hexane–ethyl acetate, 1:1).

8-Thiabicyclo[3.2.1]octan-3-one (1)

This compound was prepared according to the literature procedure (9*a*). Yield 50%. R_f = 0.3 (hexane–ethyl acetate,

4:1). ^{1}H NMR δ: 3.84–3.79 (m, 2H), 2.78 (dd, *J* = 20.0, 3.0 Hz, 2H), 2.65 (dd, *J* = 16.5, 3.0 Hz, 2H), 2.24–2.07 (m, 2H), 2.07–1.95 (m, 2H). ^{13}C NMR δ: 208.8, 52.8, 45.4, 34.2.

8-Thiabicyclo[3.2.1]oct-2-en-3-yl trimethylsilane (5a)

Diisopropylamine (1.19 mL, 8.40 mmol) was dissolved in THF (50 mL) and cooled to 0°C. *n*-BuLi (3.08 mL, 2.5 M solution in hexanes, 7.70 mmol) was added dropwise and the solution stirred for 0.5 h. After cooling the amide solution to –78°C, trimethylchlorosilane (2.14 mL, 16.80 mmol) was added followed by 8-thiabicyclo[3.2.1]octan-3-one (0.994 g, 7.00 mmol) in THF (5 mL). The resulting mixture was then stirred for 1 h at –78°C and then for 1 h at 0°C. The reaction mixture was then allowed to warm up to room temperature. The solvents and the excess of trimethylsilane were removed and the residue was dissolved in diethyl ether (100 mL). The solution was next washed with saturated aqueous $NaHCO_3$ solution (3 × 25 mL), brine (1 × 25 mL), and dried ($MgSO_4$). The solvent was then removed in vacuum and the product purified by dry flash chromatography (hexane → hexane–ethyl acetate, 4:1). The product was obtained as colorless semisolid (1.435 g, 96%). R_f = 0.59 (hexane–ethyl acetate, 4:1). ^{1}H NMR δ: 5.33 (d, *J* = 7.5 Hz, 1H), 3.89–3.80 (m, 1H), 3.69–3.60 (m, 1H), 2.68–2.56 (m, 1H), 2.38–2.12 (m, 2H), 2.10–1.82 (m, 3H), 0.13 (s, 9H). ^{13}C NMR δ: 150.0, 111.5, 45.6, 43.5, 43.3, 41.6, 34.4, 0.2.

8-Thiabicyclo[3.2.1]oct-2-en-3-ol acetate (5b)

Lithium enolate of 8-thiabicyclo[3.2.1]octan-3-one was generated according to the general procedure A. Acetic anhydride (0.13 mL, 1.25 mmol) was added to the enolate solution. The reaction mixture was stirred at –78°C for 1 h and then at 0°C for another 1 h. The reaction mixture was quenched with saturated aqueous $NaHCO_3$ solution (5 mL). The reaction mixture was then allowed to warm up to room temperature. Water was added (20 mL) and the mixture extracted with diethyl ether (3 × 50 mL). The combined organic extracts were washed with saturated aqueous $NaHCO_3$ solution (1 × 20 mL), brine (1 × 20 mL), and dried ($MgSO_4$). The solvent was then removed in vacuum and the product purified by dry flash chromatography (hexane → ethyl acetate). The product (0.177 g, 97%) was obtained as colorless semisolid. R_f = 0.37 (hexane–ethyl acetate, 4:1). EI-MS *m*/*z* (%): 184 (M^+, 40), 149 (28), 142 (100), 114 (25), 113 (53), 109 (27), 99 (18). HRMS calcd. for $C_9H_{12}O_2S$: 184.0558; found: 184.0559. IR (cm^{-1}): 1755, 1208, 1115. ^{1}H NMR δ: 5.90 (d, *J* = 7.5 Hz, 1H), 3.98–3.90 (m, 1H), 3.78–3.70 (m, 1H), 2.80–2.70 (m, 1H), 2.52–2.41 (m, 1H), 2.33–2.19 (m, 2H), 2.18–2.00 (m, 2H), 2.09 (s, 3H). ^{13}C NMR δ: 169.0, 147.8, 120.9, 45.2, 42.8, 40.9, 40.0, 34.2, 20.8.

2-Methoxycarbonyl-8-thiabicyclo[3.2.1]octan-3-one (6)

This compound was synthesized via lithium enolate of **1** as described in general procedure A. Methyl cyanoformate (0.10 mL, 1.25 mmol) was used as the electrophile. The product (0.180 g, 98%) was obtained as a clear oil, which was comprised of 3 isomers in a ratio of 52:15:33 (established by ^{1}H NMR integration of the OCH_3 signal). Since these compounds could not be separated due to easy equilibration, characterization was done on the acetate derivative. Compound **6** (0.180 g, 0.98 mmol) was dissolved in pyridine (5 mL) and acetic anhydride was added (1 mL). The reaction mixture was stirred at rt for 24 h. Next, water was added (20 mL) and the mixture was extracted with diethyl ether (3 × 50 mL). The combined organic extracts were washed with saturated aqueous $NaHCO_3$ solution (2 × 20 mL), brine (1 × 20 mL), and dried ($MgSO_4$). The solvent was then removed and the product was purified by dry flash chromatography (hexane → hexane–ethyl acetate, 1:1), which yielded a colorless oil (0.221 g, 98%). R_f = 0.23 (hexane–ethyl acetate, 1:1). EI-MS *m*/*z* (%): 242 (M^+, 9), 200 (64), 169 (18), 168 (100), 140 (22), 139 (10). HRMS calcd. for $C_{11}H_{14}O_4S$: 242.0613; found: 242.0607. IR (cm^{-1}): 1765, 1715, 1202, 1163. ^{1}H NMR δ: 4.38 (d, *J* = 5.0 Hz, 1H), 3.89–3.77 (m, 1H), 3.72 (s, 3H), 2.90–2.62 (m, 1H), 2.51–2.40 (m, 1H), 2.30 (dd, *J* = 18.5, 2.5 Hz, 1H), 2.24–2.10 (m, 2H), 2.17 (s, 3H), 2.08–1.97 (m, 1H). ^{13}C NMR δ: 168.4, 164.0, 155.9, 125.7, 51.8, 45.0, 44.0, 42.3, 40.8, 34.6, 20.8.

***exo*-2-(Hydroxybenzyl)-8-thiabicyclo[3.2.1]octan-3-one (7)**

Compound **7** was obtained as described in general procedure A and was further purified by using one of the following methods:

Method 1: The crude aldol product (containing some residual amine and bisaldol **8**) was taken in hexane (40 mL) and brought to reflux. The heating was removed and dichloromethane was added dropwise till the aldol product became soluble. The solution was left in an open flask for 3 h, after which time long needle crystals of **7** (76%) were collected.

Method 2: The crude aldol product was purified by dry flash chromatography (hexane → hexane–ethyl acetate, 1:1) which yielded pure **7** (90%) and **8** (6% when LDA was used as the base): mp 140–142°C. R_f = 0.38 (hexane–ethyl acetate, 1:1). EI-MS *m*/*z* (%): 248 (M^+, 24), 142 (100), 114 (21), 113 (44), 109 (18), 107 (34), 106 (21), 105 (34), 85 (20), 70 (43), 77 (60). HRMS calcd. for $C_{14}H_{16}O_2S$: 248.0871; found: 248.0868. IR (cm^{-1}): 3438, 1706, 1051. ^{1}H NMR ($CDCl_3$) δ: 7.47–7.28 (m, 5H), 5.13 (dd, *J* = 9.0, 2.5 Hz, 1H), 3.40 (s, 1H), 3.16–3.12 (m, 1H), 3.05–2.96 (m, 1H), 2.81 (d, *J* = 2.5 Hz, 1H), 2.75–2.71 (m, 1H), 2.71–2.66 (m, 1H), 2.10–1.82 (m, 4H). ^{1}H NMR (C_6D_6) δ: 7.39–7.30 (m, 2H), 7.28–7.03 (m, 3H), 5.07 (dd, *J* = 9.0, 3.0 Hz, 1H), 3.03–2.90 (m, 2H), 2.84 (d, *J* = 3.0 Hz, 1H), 2.58–2.47 (m, 2H), 2.23 (dd, *J* = 16.5, 3.0 Hz, 1H), 1.57–1.22 (m, 4H). ^{13}C NMR δ: 210.8, 141.0, 128.7, 128.3, 127.0, 75.3, 66.6, 51.6, 48.4, 45.8, 33.8 (2 signals). Note: optically active compound was synthesized using procedure B with chiral Li-amide **11d**. After one recrystallization the compound was enantiomerically pure: $[\alpha]_D^{25}$ +105.7 (*c* 2.04, CH_2Cl_2; c.f., ref. 15).

Compound 8

The lithium enolate of **1** (1.00 mmol) was generated as described in procedure A. Triisopropoxytitanium chloride (0.690 g, 3.00 mmol) was added and the mixture was kept at –78°C for 1 h, warmed up to 0°C and cooled again to –78°C. Benzaldehyde (3.00 mmol, 0.31 mL) was added and the mixture was stirred for another 4 h. The reaction was quenched with water (20 mL), extracted with diethyl ether (3 × 50 mL), dried with anhydrous $MgSO_4$, and

© 2001 NRC Canada

the solvent was evaporated. The ratio of **7**:**8** (18:82) was measured by ^{1}H NMR. The crude mixture was purified by dry flash chromatography (dichloromethane → dichloromethane–ethyl acetate, 1:1), which yielded pure **8** as a white solid (0.217 g, 61%) and pure **7** (0.038 g, 13%).

Properties of **8**: mp 162–164°C. R_f = 0.59 (hexane–ethyl acetate, 1:1). CI-MS (NH_3) *m*/*z* (%): 304 (27), 232 (17), 231 (87), 162 (63), 160 (19), 143 (16), 142 (80), 124 (20), 114 (50), 109 (15), 106 (24), 105 (100), 94 (29), 91 (14), 81 (15), 78 (23), 77 (24), 74 (19), 61 (65). IR (cm^{-1}): 3510, 1701, 1190, 1050. ^{1}H NMR δ: 7.50–7.28 (m, 10H), 5.45 (d, *J* = 9.5 Hz, 2H), 3.20–3.10 (m, 2H), 2.85 (d, *J* = 8.0 Hz, 2H), 2.07–1.80 (m, 6H). ^{13}C NMR δ: 210.5, 141.2, 128.8, 128.5, 127.0, 75.9, 68.0, 48.9, 33.4.

Compound 9

8-Thiabicyclo[3.2.1]oct-2-en-3-yl trimethylsilane (**5a)** (0.320 g, 1.50 mmol) was dissolved in dichloromethane (10 mL), the solution was cooled down to –78°C, and $TiCl_4$ (0.17 mL, 1.50 mmol) was added. The mixture was stirred for 1 h at –78°C and then for 2 h at 0°C. The reaction was then quenched with saturated solution of $NaHCO_3$ (10 mL). Diethyl ether (100 mL) was added, and the organic phase was separated and washed with saturated $NaHCO_3$ (2 × 25 mL), brine (25 mL), and dried with $MgSO_4$. The solvent was evaporated under vacuum and the product was subjected to dry flash chromatography (hexane → hexane–ethyl acetate, 4:1), which yielded two products: **1** (0.037 g, 17%) and **9** (0.150 g, 70%).

Properties of **9**: mp 135–137°C. R_f = 0.19 (hexane–ethyl acetate, 4:1). EI-MS *m*/*z* (%): 284 (M^+, 8), 266 (60), 233 (28), 142 (100), 114 (35), 99 (24), 85 (68), 69 (82). HRMS calcd. for $C_{14}H_{20}O_2S_2$: 284.0905; found: 284.0909. IR (cm^{-1}): 3435, 1696, 1052. ^{1}H NMR δ: 4.18–4.05 (br s, 1H), 3.96–3.87 (m, 1H), 3.83–3.75 (m, 1H), 3.71–3.63 (m, 1H), 3.61–3.52 (m, 1H), 2.88–2.77 (m, 1H), 2.66–1.77 (m, 14H). ^{13}C NMR δ: 208.7, 72.9, 68.7, 53.3, 46.8, 46.5, 46.3, 45.9, 45.8, 45.5, 33.8, 33.4, 33.0, 32.9.

(–)-2-Cinnamoyl-8-thiabicyclo[3.2.1]octan-3-one (13)

Lithium enolate of **1** (0.5 mmol) was prepared as described in procedure B (base **11d**). After stirring at –78°C for 3 h, cinnamoyl cyanide (100 mg, 0.60 mmol) in THF (1 mL) was added to the enolate, and the resulting mixture was stirred at –78°C for 30 min, followed by quenching with 40% K_2CO_3 (2 mL). After warming up to rt, the reaction mixture was extracted with $CHCl_3$ (3 × 10 mL). The combined extracts were dried over $MgSO_4$ and the solvent was removed under vacuum. Column chromatography (SiO_2, hexane–ethyl acetate, 4:1) afforded the pure product **13** as a yellow oil (83 mg, 61%). This product had 87% ee as determined by NMR with (*S*)-(+)-TFAE. $[\alpha]_D^{25}$ –330 (*c* 0.99, MeOH). R_f = 0.40 (hexane–ethyl acetate, 4:1). HRMS calcd. for $C_{16}H_{16}O_2S$: 272.0871; found: 272.0866. IR (cm^{-1}): 1626, 1576, 1558, 1540. ^{1}H NMR δ: 7.67 (d, *J* = 15.5 Hz, 1H), 7.60–7.54 (m, 2H), 7.43–7.33 (m, 3H), 7.01 (d, *J* = 15.5 Hz, 1H), 4.56–4.49 (m, 1H), 3.92–3.78 (m, 1H), 3.00 (dd, *J* = 19.0, 6.0 Hz, 1H), 2.58 (dd, *J* = 19.0, 2.0 Hz, 1H), 2.40–2.20 (m, 4H), 2.10–1.93 (m, 1H). ^{13}C NMR δ: 199.3, 169.8, 140.9, 135.3, 129.9, 128.8, 127.9, 117.6, 116.5, 48.8, 44.4, 44.0, 40.0, 34.5.

5,5-Dimethyl-6-oxa-12-thia-tricyclo[7.2.1.0^{2,7}]dodec-2(7)-en-3-one (17)

Lithium enolate of **1** (0.5 mmol) was prepared according to procedure B (base **11d**). Senecioyl cyanide (0.055 mL, 0.72 mmol) in THF (1 mL) was added, and the resulting mixture was stirred at –78°C for 30 min, followed by quenching with 40% K_2CO_3 (2 mL). After warming up to rt the reaction mixture was extracted with ether (3 × 10 mL). The combined extracts were dried over $MgSO_4$ and the solvent was removed under vacuum to give the crude product **16**. Compound **16** was subjected to cyclization without purification: the entire sample was dissolved in EtOH (7 mL), anhydrous Na_2CO_3 (0.14 g) was added, and the mixture was heat at reflux for 1 h. The solvent was then removed under vacuum, the residue was taken in ether and the carbonate was filtered off. Column chromatography (hexane–EtOAc, 4:1) afforded the product **17** as a white solid (91 mg, 81%). This sample had 92% ee as determined by HPLC using a ChiraDex 250–4 column (Merck), an UV detector (at 254 nm) in 50% MeOH – phosphate buffer (pH = 6.8, *c* = 0.025 M), flow: 0.4 mL min^{-1}. mp 90–92°C (note: racemate mp 75–77°C). $[\alpha]_D^{25}$ –94.1 (*c* 1.03, MeOH). R_f = 0.20 (hexane–EtOAc, 4:1). EI-MS *m*/*z* (%): 224 (100), 209 (76), 168 (26), 155 (13), 140 (44), 135 (11), 97 (12), 85 (10), 83 (10), 79 (17), 71 (23). IR (cm^{-1}): 1652, 1603. ^{1}H NMR δ: 1.35 (s, 3H), 1.37 (s, 3H), 1.80–1.88 (m, 1H), 2.10–2.31 (m, 4H), 2.42 (d, *J* = 16.6 Hz, 1H), 2.49 (d, *J* = 16.6 Hz, 1H), 2.79 (dq, *J* = 18.6, 2.1 Hz, 1H), 3.87(m, 1H), 4.55 (m,1H). ^{13}C NMR δ: 25.8, 27.2, 34.4, 40.1, 40.6, 42.3, 45.0, 47.3, 80.5, 119.5, 168.4, 188.3. Anal. calcd. for $C_{12}H_{16}O_2S$: C 64.26, H 7.19; found: C 64.47, H 7.17.

5-Methyl-6-oxa -12-thia-tricyclo[7.2.1.0^{2,7}]dodeca-2(7)-4-dien-3-one (15)

Lithium enolate of **1** (0.5 mmol) was generated according to procedure B (base **11d**). 2-Bromo-2-butenoyl cyanide (95 mg, 97%, 0.53 mmol) in THF (1 mL) was then added and the resulting mixture was stirred at –78°C for 30 min. followed by quenching with 40% K_2CO_3 (2 mL). After warming up to rt the reaction mixture was extracted with ether (3 × 10 mL). The combined extracts were dried over $MgSO_4$ and the solvent was removed under vacuum to give the crude product **14** that was refluxed over 3 h in triethylamine (5 mL). The solvent (Et_3N) was then removed under vacuum. The residues were basified with 40% K_2CO_3 (10 mL) and extracted with ether (3 × 10 mL). The extracts were dried over $MgSO_4$. After removal of the solvent, column chromatography afforded the product as oil (53 mg, 51%). This sample had 87% ee as determined by ^{1}H NMR with (*S*)-(+)-TFAE. R_f = 0.50 (CH_2Cl_2–MeOH, 9:1). EI-MS *m*/*z* (%): 208 (100), 180 (65), 179 (34), 175 (55), 161 (13), 91 (9),77 (5). HRMS calcd. for $C_{11}H_{12}O_2S$: 208.0557 (M^+); found: 208.0558. IR (cm^{-1}): 1659, 1611, 1596. ^{1}H NMR δ: 1.82–1.93 (m, 1H), 2.16 (s, 3H), 2.10–2.40 (m, 3H), 2.52 (dd, *J* = 18.1, 2.3 Hz, 1H), 3.08 (dq, *J* = 18.1, 2.1 Hz, 1H), 3.95 (m, 1H), 4.67 (d, *J* = 4.9 Hz, 1H), 6.03 (s, 1H). ^{13}C NMR δ: 20.0, 34.6, 39.8, 40.4, 40.5, 44.9, 113.5, 129.6, 162.3, 165.1, 176.1. The use of palladium chloride as a precatalyst for the amination of aryl bromides

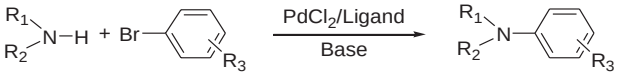
Xiao-Xiang Zhang, Michele C. Harris, Joseph P. Sadighi, and Stephen L. Buchwald

Abstract: The use of palladium chloride as a precatalyst for the amination of aryl bromides is reported. To overcome the poor solubility of palladium chloride in commonly used solvents, a procedure was developed in which $PdCl_2$ was preheated with neat amine in the presence of a phosphine ligand before the addition of the other reaction components. This protocol is effective for a broad range of substrate combinations using several types of phosphine ligands.

Key words: palladium chloride, amination, aryl bromide, phosphine ligand.

Résumé : On démontre l'utilité du chlorure de palladium comme précatalyseur pour l'amination de bromures d'aryle. Pour surmonter la piètre solubilité du chlorure de palladium dans les solvants normalement utilisés, on a mis au point une procédure dans laquelle le $PdCl_2$ est préchauffé avec de l'amine pure, en présence d'un ligand phosphine, avant l'addition des autres réactifs. Ce protocole est efficace pour un large spectre de combinaisons de substrats faisant appel à plusieurs types de ligands phosphines.



Mots clés : chlorure de palladium, amination, bromure d'aryle, ligand phosphine.

[Traduit par la Rédaction]

Introduction

The palladium-catalyzed amination of aryl halides and triflates has proven to be a useful method for the formation of carbon–nitrogen bonds and has found numerous applications (1), including the synthesis of natural products (2), biologically and pharmaceutically important compounds (3), and new ligands and materials (4). A variety of amines can be coupled with aryl halides and aryl triflates when a palladium precatalyst is combined with an appropriate phosphine ligand (5–9, and for the use of other electron-rich bulky phosphine ligands for amination reactions, see ref. 10).

We have commonly employed $Pd_2(dba)_3$ and $Pd(OAc)_2$ as precatalysts in our C–N bond-forming protocol. Although $PdCl_2$ is readily available and cheaper than $Pd(OAc)_2$ and $Pd_2(dba)_3$, it hasn't found wide application in Pd-catalyzed cross-coupling methodology, due to its insolubility in commonly used solvents. We have found that when $PdCl_2$ and a suitable ligand are preheated in the neat amine prior to the addition of other reaction components until a homogeneous solution was obtained, the coupling reactions proceed smoothly (for a recent report that described the use of $PdCl_2$ for amination, see ref. 11). Using this new protocol, we have demonstrated that $PdCl_2$ is an efficient palladium source for the arylation of primary anilines and other amines with aryl bromides (eq. [1]); the results are summarized in Tables 1 and 2.

[1] 

The chelating ligand bis[2-(diphenylphosphino)phenyl] ether (DPEphos) has been recently demonstrated to be an effective ligand for the palladium-catalyzed aryl amination reaction (6, 12). Most of the reactions with $PdCl_2$ were carried out using DPEphos as the supporting ligand. Typically, reactions were performed in toluene at 80 or 100°C using 0.5 mol% $PdCl_2$ (L/Pd = 1.5) in the presence of 1.4 equiv. of base, NaO-*t*-Bu. The $PdCl_2$ and DPEphos were first heated with the arylamine under an inert atmosphere to generate a clear solution, followed by sequential addition of aryl bromide and the base. Using this procedure, most reactions proceed to completion in ≤18 h. The results (Table 1) indicate that the combination of $PdCl_2$ and DPEphos is as active as $Pd(OAc)_2$–DPEphos (6) or $Pd(OAc)_2$–BINAP (5) for the amination of the examples listed.

Both *para*- and *otho*-substituted anilines can been efficiently coupled with electron-neutral or electron-rich bromides (Table 1, entries 1–4). As was the case for the $Pd(OAc)_2$–DPEphos system (6), the combination of $PdCl_2$ and a chelating phosphine can be used to effect couplings of highly steric substrates. For example, the sterically demanding 2,6-diisopropylaniline can be coupled with 2-methylbromobenzene in 96% yield (Table 1, entry 10). When 4-bromochlorobenzene was used (Table 1, entry 9), 2,6-diisopropylaniline was chemoselectively coupled with

[a]**1**: 2-(di-*tert*-butylphosphino)biphenyl; **2**: 2-(dicyclohexylphosphino)biphenyl.

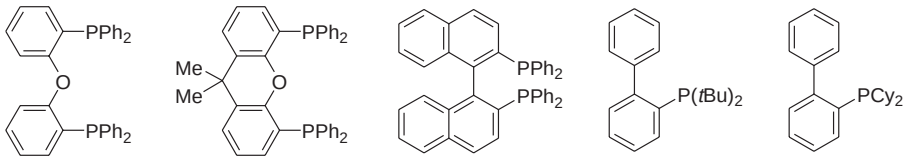
[b]Reaction times have not been optimized.

[c]Yields represent isolated yields (average of two runs) of compounds estimated to be >95% pure by ^{1}H NMR, GC, and for new compounds, combustion analysis.

[d]The reaction was conducted at 100°C using K_3PO_4 as the base and DME as the solvent.

catalyzing C–N bond forming reactions, as is shown for the bisphosphine ligands Xantphos (Table 1, entry 5) and BINAP (entry 6) as well as for biphenyl-based electron-rich bulky monophosphine ligands (Fig. 1) (9) 2-(di-*tert*-butylphosphino)biphenyl (**1**) and 2-(dicyclohexylphosphino)-biphenyl (**2**) (Table 2). By applying the combination of $PdCl_2$ and **1** or **2**, secondary cyclic amines such as pyrrolidine and morpholine can be effectively coupled with electron-rich (Table 2, entry 1), -neutral (entry 5), and -poor (entry 6) aryl bromides to afford the corresponding desired products in good to excellent yields. Acyclic primary (Table 2, entry 2) and secondary (entry 3) amines as well as *N*-ethylaniline (entry 4) are also suitable for coupling with aryl bromides. When the weak base K_3PO_4 was used instead of NaO-*t*-Bu, 4-bromobenzonitrile was successfully coupled with morpholine to give *N*-(4-cyanophenyl)-morpholine in good yield in DME at 100°C using a combination of $PdCl_2$ (3.0 mol%) and **2** (Table 2, entry 6).

In conclusion, we have demonstrated a procedure to use $PdCl_2$ in the amination of aryl bromides. This protocol was successfully applied with several different phosphine ligands and substrate combinations. In general, the effectiveness of the use of $PdCl_2$ as a precatalyst in the amination of aryl bromides is comparable with $Pd(OAc)_2$ and $Pd_2(dba)_3$ when the common bisphosphine ligands are applied. However, at present, it is less effective when the biphenyl-based electron-rich bulky monophosphine ligands are employed. This causes it to be ineffective for the amination of aryl chlorides, as indicated by our preliminary results. The reason for these limitations will be the subject of future research in our laboratory.



Experimental

General

All reactions were carried out under an argon atmosphere in oven-dried glassware. Elemental analyses were performed by Atlantic Microlabs Inc., Norcross, GA. Toluene was distilled under nitrogen from molten sodium. Aryl halides were purchased from commercial sources and were used without further purification. Amines were purchased from commercial sources and were passed through alumina before use. DPEphos and Xantphos were prepared as previously described (6, 7). Palladium chloride, *rac*-BINAP, **1**, and **2** were purchased from Strem Chemical company. Sodium *tert*-

butoxide was purchased from Aldrich; the bulk of this material was stored under nitrogen in a Vacuum Atmospheres glovebox, small portions (1–2 g) were removed from the glovebox in glass vials, stored in the air in desiccators filled with anhydrous calcium sulfate, and weighed in the air. Proton and carbon nuclear magnetic resonance spectra (^{1}H and ^{13}C NMR) were recorded on a Varian Mercury 300 spectrometer and referenced with respect to TMS internal standard. Infrared spectra were obtained using a PerkinElmer 1600 Series FT-IR spectrometer. Samples were prepared as films on NaCl plate by evaporating $CHCl_3$ solutions. High-resolution mass spectroscopy (HRMS) was performed by the MIT Department of Chemistry Instrumentation Facility on a Finnigan MAT system 8200 double-focusing sector mass spectrometer using electron impact (EI) ionization technique. Yields in Tables 1 refer to isolated yields (average of two runs) of compounds estimated to be >95% pure as determined by ^{1}H NMR and GC analysis or combustion analysis.

General procedure

Arylamine (2.40 mmol), $PdCl_2$ (1.8 mg, 0.010 mmol, 0.5 mol%), and bisphosphine (0.015 mmol, 0.75 mol%) were placed in a dried, resealable Schlenk tube, which was fitted with a Teflon screwcap, evacuated, and backfilled with argon. The tube was sealed, and its contents were heated at 80°C until a clear solution formed (ca. 30 min). The tube was then cooled to room temperature, and the Teflon screwcap was replaced with a rubber septum. Toluene (2 mL) was added via syringe, followed by aryl bromide (2.00 mmol). The resulting solution was stirred for a few seconds, then the septum was removed. Sodium *tert*-butoxide was added, then the septum was replaced. An additional portion of toluene (2 mL) was added to wash into the reaction any base adhering to the side of the tube. The tube was purged with argon for 3 min, then the septum was replaced with the Teflon screwcap. The tube was sealed, and its contents were heated at 80°C with stirring until the starting aryl bromide was completely consumed as judged by GC analysis. The reaction mixture was then cooled to room temperature, taken up in diethyl ether (50 mL), and washed with brine (30 mL). The resulting solution was dried over anhydrous potassium carbonate, filtered, and concentrated in vacuo. The crude product was purified by flash column chromatography on silica gel.

N-(*p*-Tolyl)-*o*-anisidine (Table 1, entry 1) (13)

The general procedure was used for coupling *p*-toluidine with 2-bromoanisole, using DPEphos as the supporting ligand and a reaction time of 3 h. The title compound was isolated as a colorless oil (413 mg, 97%). EI-HRMS calcd. for $C_{14}H_{15}NO$: 213.1154; found: 213.1158 (M^+). IR (film, cm^{-1}): 3411, 3022, 2937, 2862, 2834, 1600, 1519, 1243, 740. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.21–7.18 (m, 1H), 7.09–7.02 (m, 4H), 6.86–6.75 (m, 3H), 6.05 (s, 1H), 3.85 (s, 3H), 2.29 (s, 3H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 147.9, 139.9, 133.9, 131.1, 129.9, 120.9, 119.7, 119.3, 113.8, 110.4, 55.7, 21.0.

N-(*p*-Tolyl)-2,5-dimethylaniline (Table 1, entry 2) (13)

The general procedure was used for the coupling of *p*-toluidine with 2-bromo-*p*-xylene, using DPEphos as the supporting ligand and a reaction time of 17 h. The title compound was obtained as an orange solid (414 mg, 98%): mp 49–50°C. EI-HRMS calcd. for $C_{15}H_{17}N$: 211.1361; found: 211.1356 (M^+). IR (film, cm^{-1}): 3414, 3020, 2917, 2862, 1610, 1577, 1526, 1511, 814, 800. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.06 (d, J = 8.1 Hz, 2H), 7.02 (d, J = 7.5 Hz, 1H), 6.98 (s, 1H), 6.89 (d, J = 8.1 Hz, 2H), 6.68 (d, J = 7.5 Hz, 1H), 5.23 (s, 1H), 2.29 (s, 3H), 2.24 (s, 3H), 2.19 (s, 3H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 141.9, 141.2, 136.5, 130.7, 130.4, 129.9, 124.0, 121.9, 118.8, 118.0, 21.5, 21.0, 17.7.

N-(2-Methoxyphenyl)-3,5-dimethylaniline (Table 1, entry 3) (6)

The general procedure was used for the coupling of *o*-anisidine with 5-bromo-*m*-xylene, using DPEphos as the supporting ligand and a reaction time of 17 h. The title compound was obtained as a pale yellow oil (443 mg, 97%). EI-HRMS calcd. for $C_{15}H_{17}NO$: 227.1310; found: 227.1304 (M^+). IR (film, cm^{-1}): 3411, 3024, 3001, 2939, 2916, 2855, 2833, 1590, 1520, 1494, 1463, 829, 742. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.30–7.27 (m, 1H), 6.87–6.82 (m, 3H), 6.77 (s, 2H), 6.58 (s, 1H), 6.06 (s, 1H), 3.84 (s, 3H), 2.27 (s, 3H), 2.26 (s, 3H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 148.2, 142.7, 139.0, 133.2, 123.1, 120.9, 119.7, 116.4, 114.9, 110.5, 55.8, 21.7.

N-(2-Methoxyphenyl)-2,5-dimethylaniline (Table 1, entry 4) (6, 9*c*)

The general procedure was used for the coupling of *o*-anisidine with 2-bromo-*p*-xylene, using DPEphos as the supporting ligand and a reaction time of 4 h. The title compound was isolated as a white solid (424 mg, 93%): mp 88.5–90.5°C. EI-HRMS calcd. for $C_{15}H_{17}NO$: 227.1310; found: 227.1306 (M^+). IR (film, cm^{-1}): 3409, 3061, 3042, 3003, 2962, 2930, 2833, 1560, 1573, 740. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.12 (s, 1H), 7.07 (d, J = 7.6 Hz, 1H), 7.01 (dd, J = 6.9, 2.4 Hz, 1H), 6.88–6.77 (m, 3H), 6.75 (d, J = 7.6 Hz, 1H), 5.82 (s, 1H), 3.87 (s, 3H), 2.27 (s, 3H), 2.21 (s, 3H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 148.0, 140.6,

136.4, 134.0, 130.8, 126.3, 123.1, 120.9, 120.3, 119.2, 114.5, 110.4, 55.8, 21.5, 17.7.

2-[3-(*N*-Methylanilino)phenyl]-1,3-dioxolane (Table 1, entry 5)

The general procedure was used for the coupling of *N*-methylaniline with 2-(3-bromophenyl)-1,3-dioxolane, using Xantphos as the supporting ligand and a reaction time of 4 h. The title compound was isolated as a colorless oil (470 mg, 92%). EI-HRMS calcd. for $C_{16}H_{17}NO_2$: 255.1259; found: 255.1264 (M^+). IR (film, cm^{-1}): 3058, 3035, 2950, 2884, 2815, 1609, 1595, 1585, 1496, 696. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.29–7.21 (m, 3H), 7.12 (m, 1H), 7.06–6.92 (m, 5H), 5.73 (s, 1H), 4.12–3.96 (m, 4H), 3.31 (s, 3H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 149.1, 148.9, 139.0, 129.3, 129.2, 121.7, 121.0, 120.9, 119.1, 117.8, 103.9, 65.4, 40.5. Anal. calcd. for $C_{16}H_{17}NO_2$: C 75.27, H 6.71; found: C 75.36, H 6.75.

***N*-(3,5-Dimethylphenyl)-benzylamine (Table 1, entry 6) (14)**

The general procedure was used for the coupling of benzylamine with 5-bromo-*m*-xylene, using *rac*-BINAP as the supporting ligand and a reaction time of 3 h. The title compound was isolated as a colorless oil (368 mg, 87%). EI-HRMS calcd. for $C_{15}H_{17}N$: 211.1361; found: 211.1354 (M^+). IR (film, cm^{-1}): 3409, 3027, 2915, 2856, 1603, 1512, 1494, 1473, 1452, 1337, 1182, 821. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.35–7.21 (m, 5H), 6.36 (s, 1H), 6.25 (s, 2H), 4.26 (s, 2H), 3.84 (br s, 1H), 2.21 (s, 6H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 148.4, 139.7, 139.0, 128.7, 127.6, 127.2, 119.7, 110.8, 48.5, 21.8.

4-(Diphenylamino)biphenyl (Table 1, entry 7) (15)

The general procedure was used for the coupling of diphenylamine with 4-bromobiphenyl, using DPEphos as the supporting ligand and a reaction time of 18 h. The reaction was conducted at 100°C with 1.0 mol% $PdCl_2$ and 1.5 mol% DPEphos. The title compound was isolated as white crystals (553 mg, 86%): mp 111–112°C. EI-HRMS calcd. for $C_{24}H_{19}N$: 321.1518; found: 321.1509 (M^+). IR (film, cm^{-1}): 3058, 3030, 1589, 1519, 1485, 1280, 747, 693. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.58–7.52 (m, 2H), 7.48–7.36 (m, 4H), 7.31–7.20 (m, 5H), 7.12 (d, J = 7.5 Hz, 6H), 7.01 (t, J = 7.2 Hz, 2H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 147.7, 147.2, 140.7, 135.2, 129.4, 128.8, 127.9, 126.9, 126.8, 124.5, 124.0, 123.0.

2,4,6-Trimethyl-2′-ethyldiphenylamine (Table 1, entry 8) (6)

The general procedure was used for the coupling of 2,4,6-trimethylaniline with 2-ethylbromobenzene, using DPEphos as the supporting ligand and a reaction time of 18 h. The title compound was isolated as a tan solid (465 mg, 97%): mp 74–75°C. EI-HRMS calcd. for $C_{17}H_{21}N$: 239.1674; found: 239.1678 (M^+). IR (film, cm^{-1}): 3384, 2965, 2912, 1601, 1582, 1505, 1496, 1454, 1252, 744. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.12 (dd, J = 7.2, 1.5 Hz, 1H), 6.94 (td, J = 7.5, 1.2 Hz, 1H), 6.93 (s, 2H), 6.71 (td, J = 7.5, 1.2 Hz, 1H), 6.13 (dd, J = 7.2, 1.5 Hz, 1H), 4.96 (s, 1H), 2.67 (q, J = 7.8 Hz, 2H), 2.30 (s, 3H), 2.13 (s, 6H), 1.35 (t, J = 7.8 Hz, 3H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 143.9, 136.0, 135.7, 135.2, 129.3, 128.3, 127.9, 126.9, 118.0, 111.8, 24.5, 21.2, 18.5, 13.5.

2,6-Diisopropyl-4′-chlorodiphenylamine (Table 1, entry 9) (6)

The general procedure was used for the coupling of 2,6-diisopropylaniline with 4-bromochlorobenzene, using DPEphos as the supporting ligand and a reaction time of 18 h. The reaction was conducted at 100°C. The title compound was isolated as a red-orange oil (564 mg, 98%). EI-HRMS calcd. for $C_{18}H_{22}ClN$: 287.1441; found: 287.1447 (M^+). IR (film, cm^{-1}): 3412, 2962, 2928, 2867, 1600, 1587, 1493, 1466, 1304, 817. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.31–7.19 (m, 3H), 7.06 (d, J = 9.0 Hz, 2H), 6.38 (d, J = 9.0 Hz, 2H), 5.11 (s, 1H), 3.14 (sept, J = 6.8 Hz, 2H), 1.13 (d, J = 6.8 Hz, 12H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 147.6, 146.9, 134.8, 129.2, 127.7, 124.1, 122.3, 114.1, 28.5, 24.1.

2,6-Diisopropyl-2′-methyldiphenylamine (Table 1, entry 10) (6)

The general procedure was used for the coupling of 2,6-diisopropylaniline with 2-methylbromobenzene, using DPEphos as the supporting ligand and a reaction time of 18 h. The reaction was conducted at 100°C. The title compound was isolated as a light-orange oil (511 mg, 96%). EI-HRMS calcd. for $C_{19}H_{25}N$: 267.1987; found: 267.1982 (M^+). IR (film, cm^{-1}): 3425, 2961, 2926, 2867, 1606, 1585, 1500, 1464, 1442, 746. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.31–7.19 (m, 3H), 7.11 (dd, J = 7.5, 1.2 Hz, 1H), 6.93 (td, J = 7.5, 1.2 Hz, 1H), 6.65 (td, J = 7.5, 1.2 Hz, 1H), 6.11 (dd, J = 7.5, 1.2 Hz, 1H), 4.89 (s, 1H), 3.10 (sept, J = 6.9 Hz, 2H), 2.33 (s, 3H), 1.16 (d, J = 6.9 Hz, 6H), 1.11 (d, J = 6.9 Hz, 6H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 147.3, 146.1, 135.8, 130.2, 127.2, 127.1, 123.9, 121.4, 117.6, 111.5, 28.5, 25.0, 23.3, 17.9.

2,6-Diisopropyl-2′,6′-dimethyldiphenylamine (Table 1, entry 11) (6, 9*c*)

The general procedure was used for the coupling of 2,6-diisopropylaniline with 2-bromo-*m*-xylene, except that the reaction was carried out at 100°C, using 5 mol% $PdCl_2$ and 7.5 mol% DPEphos. The title compound was isolated as a red-brown oil (514 mg, 91%). EI-HRMS calcd. for $C_{20}H_{27}N$: 281.2144; found: 281.2150 (M^+). IR (film, cm^{-1}): 3433, 2961, 2927, 2867, 1596, 1472, 1446, 1333, 795. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.15–7.07 (m, 3H), 6.92 (d, J = 7.5 Hz, 2H), 6.70 (t, J = 7.5 Hz, 1H), 4.78 (s, 1H), 3.14 (sept, J = 6.9 Hz, 2H), 1.97 (s, 6H), 1.11 (d, J = 6.9 Hz, 12H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 144.2, 143.2, 138.9, 129.6, 125.7, 124.9, 123.4, 119.7, 28.3, 23.8, 19.7.

***N*-(2-Methoxyphenyl)pyrrolidine (Table 2, entry 1)**

The general procedure was used for the coupling of pyrrolidine with 2-bromoanisole, using **1** as the supporting ligand and a reaction time of 43 h. The title compound was isolated as a colorless liquid (0.216 g, 61%). IR (film, cm^{-1}): 3060, 2960, 2830, 1504, 1232, 730. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 6.90–6.85 (m, 3H), 6.82–6.78 (m, 1H), 3.84 (s, 3H), 3.30–3.26 (m, 4H), 1.95–1.91 (m, 4H). ^{13}C (75 MHz, $CDCl_3$) δ: 150.6, 140.0, 121.3, 119.8, 115.6, 111.7, 55.7,

50.6, 24.8. Anal. calcd. for $C_{11}H_{15}NO$: C 74.54, H 8.53; found: C 74.30, H 8.52.

***N*-(3-Methoxyphenyl)-benzylamine (Table 2, entry 2)**

The general procedure was used for the coupling of benzylamine with 3-bromoanisole, using **1** as the supporting ligand and a reaction time of 23 h. The title compound was isolated as a yellow liquid (0.397 g, 93%). IR (film, cm^{-1}): 2970, 2917, 1590, 1495, 692. ^1H NMR (300 MHz, $CDCl_3$) δ: 7.40–7.27 (m, 5H), 7.08 (t, J = 8.1 Hz, 1H), 6.31–6.25 (m, 2H), 6.21–6.19 (m, 1H), 4.32 (s, 2H), 4.10 (br s, 1H), 3.75 (s, 3H). ^{13}C (75 MHz, $CDCl_3$) δ: 160.9, 149.7, 139.4, 130.1, 128.7, 127.6, 127.4, 106.1, 102.7, 98.9, 55.2, 48.4. Anal. calcd. for $C_{14}H_{15}NO$: C 78.84, H 7.09; found: C 78.76, H 7.01.

***N*-(3-Methoxyphenyl)-di-*n*-butylamine (Table 2, entry 3)**

The general procedure was used for the coupling of di-*n*-butylamine with 3-bromoanisole, using **1** as the supporting ligand and a reaction time of 21 h. The title compound was isolated as a yellow liquid (0.415 g, 88%). IR (film, cm^{-1}): 2956, 2871, 1609, 1500, 1204, 746. ^1H NMR (300 MHz, $CDCl_3$) δ: 7.10 (t, J = 8.1 Hz, 1H), 6.29–6.25 (m, 1H), 6.21–6.18 (m, 2H), 3.78 (s, 3H), 3.24 (t, J = 7.8 Hz, 4H), 1.61–1.51 (m, 4H), 1.40–1.28 (m, 4H), 0.95 (t, J = 6.9 Hz, 6H). ^{13}C (75 MHz, $CDCl_3$) δ: 161.0, 149.7, 129.9, 105.1, 99.7, 98.4, 55.2, 51.0, 29.6, 20.5, 14.2. Anal. calcd. for $C_{15}H_{25}NO$: C 76.55, H 10.71; found: C 76.40, H 10.59.

***N*-(3,5-Dimethylphenyl)-*N*-ethylaniline (Table 2, entry 4)**

The general procedure was used for the coupling of *N*-ethylaniline with 5-bromo-*m*-xylene, using **1** as the supporting ligand and a reaction time of 28 h. The title compound was isolated as a yellow liquid (0.308 g, 68%). IR (film, cm^{-1}): 3415, 3027, 2834, 1614, 1162. ^1H NMR (300 MHz, $CDCl_3$) δ: 7.27–7.21 (m, 2H), 6.96–6.90 (m, 3H), 6.64–6.63 (m, 3H), 3.75 (q, J = 7.2 Hz, 2H), 2.26 (s, 6H), 1.21 (t, J = 7.2 Hz, 3H). ^{13}C (75 MHz, $CDCl_3$) δ: 148.0, 147.7, 139.0, 129.3, 123.6, 120.5, 120.3, 119.5, 46.6, 21.6, 12.9. Anal. calcd. for $C_{16}H_{19}N$: C 85.29, H 8.50; found: C 85.39, H 8.49.

***N*-(4-*tert*-Butylphenyl)morpholine (Table 2, entry 5)**

The general procedure was used for the coupling of morpholine with 1-bromo-4-*tert*-benzene, using **1** as the supporting ligand and a reaction time of 21 h. The title compound was isolated as a yellow solid (0.403 g, 92%): mp 53–55°C. IR (film, cm^{-1}): 2958, 2853, 1612, 1118. ^1H NMR (300 MHz, $CDCl_3$) δ: 7.31 (d, J = 8.7 Hz, 2H), 6.86 (d, J = 9.0 Hz, 2H), 3.87–3.84 (m, 4H), 3.15–3.12 (m, 4H), 1.30 (s, 9H). ^{13}C (75 MHz, $CDCl_3$) δ: 149.0, 142.9, 126.1, 115.5, 67.1, 49.7, 34.1, 31.6. Anal. calcd. for $C_{14}H_{21}NO$: C 76.67, H 9.65; found: C 76.56, H 9.57.

***N*-(4-Cyanophenyl)morpholine (Table 2, entry 6)**

The general procedure was used for the coupling of morpholine with 4-bromobenzonitrile, using **2** as the supporting ligand, K_3PO_4 as the base, DME as the solvent, and a reaction time of 28 h. The reaction was conducted at 100°C. The title compound was isolated as a yellow solid (0.287 g, 76%): mp 73–75°C. IR (film, cm^{-1}): 2980, 2831, 2217, 1606, 1116. ^1H NMR (300 MHz, $CDCl_3$) δ: 7.53 (d, J = 8.7 Hz, 2H), 6.87 (d, J = 9.0 Hz, 2H), 3.88–3.85 (m, 4H), 3.31–3.27 (m, 4H). ^{13}C (75 MHz, $CDCl_3$) δ: 153.6, 133.6, 120.0, 114.2, 101.1, 66.6, 47.4. Anal. calcd. for $C_{11}H_{12}N_2O$: C 70.19, H 6.43; found: C 69.93, H 6.27.

Diastereotopic group recognition in the solid state — A unique intramolecular β-cyclodextrin inclusion complex

Manfred T. Reetz, Joachim Rudolph, and Richard Goddard

Abstract: The phenomenon of diastereotopic group recognition has been structurally documented for the first time. A diphenylphosphine-modified β-cyclodextrin having two diastereotopic phenyl groups in close vicinity to the inner cavity of this host was prepared. The crystal structure analysis reveals selective intramolecular complexation of one of the two diastereotopic phenyl groups.

Key words: supramolecular chemistry, stereotopic group recognition, cyclodextrins, intramolecular complexation.

Résumé : Le phénomène de reconnaissance de groupement diastéréotopique a été structurellement demontré pour la première fois. Une β-cyclodextrine fonctionnalisée avec un groupement diphénylphosphine a été synthétisée. Les deux groupements phényle sont situés à proximité de la cavité de la cyclodextrine et la structure déterminée par rayons X fait apparaître une complexation sélective et intramoléculaire d'un des deux groupement phényle.

Mots clés : chimie supramoléculaire, reconnaissance de groupement stéréotopique, cyclodextrines, complexation intramoléculaire.

Introduction

Although enantio- or diastereo-differentiation of prochiral groups is the crucial step in desymmetrization reactions, little is known about what occurs during the actual molecular recognition process. The desymmetrization of a prochiral or a *meso*-compound is usually achieved by enzymes, chiral chemical reagents, or by synthetic catalysts (1–6).

The actual chemical conversion of prochiral compounds bearing enantiotopic groups is believed to be preceded by selective recognition of one of these groups. However, in spite of the large body of experimental results in the area of reagent controlled or catalytic desymmetrization, the actual recognition process itself has only recently become the subject of investigation. We reported the first direct evidence for enantiotopic group recognition in solution, the system being based on a chiral crown ether as the host and *meso*-diammonium compounds as guest molecules (7, 8). The chiral crown ether binds selectively to one of the two enantiotopic ammonium groups as demonstrated by NMR spectroscopy. Subsequently, we described a case in which enantiotopic group recognition can be observed both in solution and solid state (9, 10). In this example, selective group recognition was induced by reversible formation of a chiral borate complex. In addition, we were able to show that in a subsequent chemical reaction step, a chiral product is obtained with an enantiomeric purity corresponding to the diastereoselectivity occurring in the preceding enantiotopic group recognition event (9, 10).

Although the general phenomenon of enantiotopic group recognition (Scheme 1) in this case was successfully elucidated by means of NMR spectroscopy and X-ray crystallography (9, 10), until now we have not come across direct evidence of the second variant of stereotopic group recognition, i.e., the case of *dia*stereotopic group recognition. This occurs when selective recognition of heterotopic groups occurs within *the same* molecule (Scheme 2). Here we report what we believe to be the first example of such a case.

Results and discussion

Some time ago we described the preparation of a water-soluble, phosphine-modified β-cyclodextrin **3** (Scheme 3) and its corresponding rhodium complex (11–13). Our intention was to test the catalytic activity of such a potential supramolecular catalyst in a two-phase (org.–H_2O) system. The idea was to combine possible host–guest effects with transition-metal catalysis and phase-transfer catalysis. The choice of β-cyclodextrin as the host was based on extensive previous work concerning its supramolecular chemistry (14–17).

Scheme 2. Diastereotopic group recognition by a chiral host.

Furthermore, since β-cyclodextrin is chiral, it has also been used as an auxiliary for asymmetric transformations (14–17). However, the Rh-complex of **3** was not an effective catalyst, in contrast to diphosphine analogs (18, 19). As a result the chemistry of ligand **3** remained largely unexplored.

β-Cyclodextrin has a hydrophobic inner cavity capable of hosting organic molecules, especially aromatic compounds (14–17). Indeed, intramolecular complexation in the form of self-inclusion compounds are known (20–22). It is therefore conceivable that intramolecular complexation of the phenyl groups of the phosphine moiety in compound **3** can occur. If this were to be the case, then the phenomenon of diastereotopic group recognition could arise. Two different diastereomeric complexes are possible, depending upon which of the two diastereotopic phenyl groups enters the cavity of the chiral β-cyclodextrin host. To see whether this is the case, we prepared crystals of **3** and performed an X-ray structure analysis. The results of the investigation are summarized in Fig. 1, which shows the structure of the molecule. The atom numbering system is given in Scheme 4.

The compound crystallizes as the undecahydrate and the water molecules are omitted from the figure for clarity. The structure analysis reveals that the β-cyclodextrin annulus adopts an almost ideally symmetrical structure in which only one of the diastereotopic phenyl rings of the diphenyl phosphinyl groups is included into the hydrophobic β-cyclodextrin cavity. The centroid of the phenyl ring lies in the mean plane of the C-5 atoms of the glucose subunits of the β-cyclodextrin ring (±0.1 Å). P and S lie, respectively, 3.1(1) and 2.8(1) Å above this plane. The β-cyclodextrin ring has approximate seven-fold symmetry and is largely undistorted by the inclusion of the phenyl group. The P atom lies almost on the mean rotation axis of the β-cyclodextrin ring. Important is the fact that the same diastereotopic phenyl group is intramolecularly incorporated in all molecules of the crystal. To stipulate which phenyl group it is, the CIP nomenclature (23) needs to be extended. We propose that of the two relevant diastereotopic groups the supramolecularly complexed phenyl entity has the higher priority. Consequently, phosphorus adopts the *S*-configuration (Fig. 1). To determine whether the incorporation of the pro-S phenyl group into the β-cyclodextrin cavity was fortuitous, we recrystallized the sample, took another crystal and also determined its structure. In this crystal we also found that the pro-S phenyl group is intramolecularly encapsulated in the β-cyclodextrin annulus. Attempts to determine whether the crystalline sample was uniform by means of powder diffraction were unsuccessful since the mortared sample was amorphous, presumably as a result of loss of water from the crystals during preparation of the powder.

Why does the β-cyclodextrin appear to preferentially select the pro-S phenyl group? Two alternative explanations are examined. The first possibility is that of diastereotopic group selectivity, i.e., the pro-S configuration is energetically more stable than the corresponding pro-R arrangement (Scheme 2). It may, however, be that the chiral conformation of the diphenylphosphine moiety is limited to the crystalline state, and that the observed configuration is a result of preferential precipitation of one of the two diastereomeric complexes, either because its crystals are formed more quickly (kinetic control) or because the crystals are inherently more stable (thermodynamic control). In the following, we confine ourselves to a discussion of whether intramolecular interactions alone or a combination of intramolecular and intermolecular interactions may predominate.

To establish whether incorporation of the pro-S phenyl group into the β-cyclodextrin cavity is the energetically favoured conformation, we undertook force field calculations

on both diastereomers in the free state (24).[3] First, we simulated the *R*-configuration by rotating the diphenyl phosphine group of the X-ray structure around the P—C-40 bond until the pro-R phenyl group was situated in the cavity at the position previously occupied by pro-S phenyl group. As the

starting point for the structure containing the pro-S phenyl group, we used the geometry observed in the crystal. The energies of both diastereomers were then minimized under equivalent conditions and compared (same force-field parameters, absence of solvent) (24).[3] There was no appreciable energy difference between the two minimized structures (<2.1 kcal mol^{-1}). Apart from the location of the phenyl groups, the largest difference in the conformation of the two structures was found in the chain linking the phosphine to the β-cyclodextrin annulus. Table 1 gives the torsion angles along this chain. Although the differences are small, the torsion angles most affected involve the S atom. This appears to be a result of the fixed arrangement of the C-51—C-61 bond relative to the β-cyclodextrin group, which has a built-in handedness and is necessarily directed to one side of the ring.

Since force field calculations suggest that energy difference between both diastereomers is relatively small, we turn our attention to the results of the X-ray analysis for a possible explanation of the observed diastereomer. The crystal structure contains much information about the intramolecular and intermolecular interactions that may affect the stabilization of the *S*-configuration. Figure 2 shows the packing of the substituted β-cyclodextrin and water molecules in the unit cell. Inspection of the figure and examination of the shortest intermolecular distances (Table 2) reveal that the β-cyclodextrin rings stack in a head-to-tail fashion in columns, as has been observed previously for unsubstituted cyclodextrin molecules (25). The columns are essentially separated by solvate water molecules, which are located in channels between the β-cyclodextrin molecules and extend contiguously throughout the structure. Particularly worthy of note is the number of water molecules in the crystal. The compound crystallizes with no less than 11 solute water molecules for each substituted β-cyclodextrin annulus. Consequently, most of the intermolecular interactions are between the substituted β-cyclodextrin and water molecules and between the water molecules themselves. Indeed, there are only four short intermolecular interactions (<3.1 Å) between the substituted β-cyclodextrin molecules and three of them involve hydrogen bonds between primary hydroxyl groups on one ring and secondary hydroxyl groups on the β-cyclodextrin annulus above it (Table 2). This suggests that the water molecules make an important contribution to the packing of the molecules in the crystal. Interestingly, the region of space which we would expect to be occupied by pro-R phenyl group in the other diastereomer is completely occupied by solute water molecules and hence strongly hydrophilic. Moreover, one water molecule appears to be strongly bound to the P atom since its O atom lies 3.43(3) Å from P along the axis of the expected position of the P lone pair. Unfortunately, we have thus far not been able to obtain crystals of the

[a]Primary hydroxyl groups.
[b]Secondary hydroxyl groups.

diastereomer. It seems, however, that if crystal packing forces are the reason for the preferred configuration then the observed diastereomer must be a result of a subtle interplay between the requirement for close packing of the substituted β-cyclodextrin molecules and strong cooperative intermolecular interactions between the solvate water molecules (26).

To establish whether selective intramolecular complexation occurs in solution, NMR experiments were performed. ^1H and ^{13}C NMR measurements of a solution of the compound showed the presence of two, but not four, magnetically nonequivalent phenyl groups. This shows that either neither of the two phenyl rings is incorporated in the cavity or that the two phenyl groups of the two possible diastereomers equilibrate rapidly on the NMR timescale. The latter would mean that the process of entering and leaving the cavity by the phenyl groups is fast. Unfortunately, upon cooling the sample to –78°C the compound precipitated. Thus, it was not possible to detect the two diastereomeric complexes nor to determine their ratio, which would be a measure of diastereotopic group recognition in solution. We observed the same phenomenon upon treating β-cyclodextrin itself with such prochiral compounds as diphenylsufoxide or benzhydryl alcohol (13). In both cases 1:1 host–guest complexes were detected by NMR spectroscopy, two different phenyl groups being observed. This is in line with a single diastereomer and 100% enantiotopic group recognition, or two rapidly equilibrating diastereomers. It was impossible to resolve this because at lower temperatures the material precipitated.

Experimental

General

Melting points were obtained on a Gallenkamp melting point apparatus and are uncorrected. Elemental analyses were performed at the Microanalytisches Labor Kolbe, Mülheim/Ruhr. Optical rotations were measured on a JASCO digital polarimeter (model DIP 360). ^1H NMR spectra were recorded on a Bruker WH 400 spectrometer in DMF-d_7 or pyridine-d_5 using the solvent signals as internal references; in the case of pyridine, the β-H at δ = 7.38 and the β-C at δ = 123.6 were taken as references. The chemical shifts are reported in δ (ppm) relative to TMS and in the case of ^{31}P NMR spectra, relative to 85% aqueous phosphoric acid (0.0 ppm). The coupling constants (*J*) are given in Hertz (Hz). FAB mass spectrometry was performed on a Finnigan-MAT 95 mass spectrometer using diethanolamine as matrix.

*Mono[6-deoxy-6-(2′-diphenylphosphinoethyl)thio]-β-cyclodextrin (**3**)*

In an inert atmosphere, the known (27) 6-mono-6-*p*-toluenesulfonyl-β-cyclodextrin (**2**) (2.0 g, 1.55 mmol) was dissolved in a mixture of 100 mL water and 25 mL ethanol. Na_2CO_3 was added to give a pH of 12. Then 2-(diphenylphosphino)ethane thiol (2.0 g, 8.1 mmol) was added under argon and the mixture was vigorously stirred for 2 days at 50°C. After cooling, oxygen-free 1 N aq HCl solution was added until a pH of 6 to 7 was reached. The excess thiol was removed in a micro perforator using ether as extractant for 3 days. The product together with inorganic salts remained in the aqueous phase while the thiol accumulated in the ether phase. After recrystallization from water–ethanol (95:5) and drying in vacuo, product **3** (1.4 g, 1.03 mmol, 66%) was obtained as a white powder, mp 302–310°C (dec.). $[\alpha]^{22}_{D}$ = +12.0 (*c* 2.5, DMF). FAB-MS (pos.) $[M + H]^+$: 1363. ^1H NMR (400 MHz, pyridine-d_5) δ: 2.76 (m, 2H, CH_2-P), 3.19 (m, 2H, CH_2-S), 3.55 (dd, 1H, *J* = 14 Hz, 6 Hz, H-6a′), 3.80 (d, 1H, *J* = 13 Hz, H-6b′), 4.29–4.36 (m, 7H, H-2), 4.29–4.41 (m, 7H, H-4), 4.54–4.68 (m, 16H, H-5,6, H_2O), 4.80–4.91 (m, 7H, H-3), 5.72–5.94 (m, 7H, H-1), 7.44–7.52, 7.71–7.75 (m, 10H, arom. H). ^{13}C NMR (100.6 MHz, pyridine-d_5) δ: 28.9 (d, $J_{P,C}$ = 15.3 Hz, CH_2-P), 30.1 (d, $J_{P,C}$ = 20.9 Hz, CH_2-S), 34.0 (C-6′), 61.4–61.6 (C-6), 73.0 (C-5′), 73.7–74.6 (C-2, 3, 5), 83.1–83.4 (C-4), 85.9 (C-4′), 103.5–103.8 (C-1), 128.7, 133.0, 138.8 (m, dd, d, arom. C). ^{31}P NMR (161.3 MHz, DMF-d_7) δ: –17.2. Anal. calcd. for $C_{56}H_{83}O_{34}PS$: C 49.33, H 6.14, S 6.14, P 2.35; found: C 49.32, H 6.16, S 6.16, P 2.39.

Copies of the data can be obtained, free of charge, on application to the Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, U.K. (Fax: 44-1223-336033 or e-mail: deposit@ccdc.cam.ac.uk).

Conclusion

The crystal structure of the phosphine-modified β-cyclodextrin **3** shows selective intramolecular complexation of one of the diastereotopic phenyl groups. This unique process induces chirality at phosphorus. To specify which phenyl group participates, an extension of the CIP nomenclature to include supramolecular interactions is required. Neither molecular modeling calculations nor inspection of the crystal packing gives an unequivocal explanation for the observed *S*-configuration in the crystal, and until we have further examples of this interesting phenomenon for comparison we are not in a position to say what the determining factor is in this case.

Total synthesis of polyoximic acid

Stephen Hanessian and Jian-min Fu

Abstract: The structure and stereochemistry of polyoximic acid, a degradation product of polyoxins, was originally designated as *trans*-3-ethylidene-L-azetidine-2-carboxylic acid. However, total synthesis revealed that the correct structure was in fact *cis*-3-ethylidene-L-azetidine-2-carboxylic acid, which was confirmed by X-ray crystallography. The synthesis of the *trans*-isomer was also done and its identity was confirmed by X-ray analysis as well. The key step for constructing the four-membered ring was a rhodium catalyzed carbenoid insertion into the N—H bond of a β-amino acid derivative. The stereoselectivity of the *exo*-double bond was controlled by conducting a Horner-Emmons-Wadsworth or a Wittig reaction to generate the *trans*- and *cis*-isomers, respectively. Weinreb's amide was used as a latent methyl group for the separation of *trans* and *cis* mixtures. The double bond stereochemistry of polyoximic acid in the parent polyoxin was also confirmed to be *cis* by extensive 2D NMR studies.

Key words: diazoinsertion, azetidine, olefination.

Résumé : La structure et la stéréochimie originalement attribuées à l'acide polyoximique, un produit de dégradation des polyoxines, étaient celles de l'acide *trans*-3-éthylidène-L-azétidine-2-carboxylique. Une synthèse totale a toutefois permis de démontrer qu'il s'agit plutôt de son isomère, l'acide *cis*-3-éthylidène-L-azétidine-2-carboxylique, ce qui a été confirmé par diffraction des rayons X. On a aussi réalisé la synthèse de l'isomère *trans* et son identité a aussi été confirmée par diffraction des rayons X. L'étape clé dans la construction du cycle à quatre chaînons est une insertion de carbénoïde dans la liaison N—H d'un dérivé d'acide β-aminé, catalysée par le rhodium. La stéréosélectivité de la double liaison *exo* est contrôlée en procédant à une réaction d'Horner-Emmons-Wadsworth ou d'une réaction de Wittig qui conduisent respectivement aux isomères *trans* et *cis*. L'amide de Weinreb a été utilisé comme groupe méthyle latent pour la séparation des mélanges *trans* et *cis*. En se basant sur des études approfondies de RMN 2D, on a aussi confirmé que la stéréochimie de la double liaison de l'acide polyoximique de la polyoxine de base est aussi *cis*.

Mots clés : diazoinsertion, azétidine, oléfination.

[Traduit par la Rédaction]

Introduction

In the 1960's, Isono and co-workers (1*a*, *c*–*j*) first isolated and characterized a series of nucleoside antibiotics designated as the polyoxins from culture broths of *Streptomyces cacacoi var asoensis*. Since then, new members were added to this family that constitute the fifteen known polyoxins A–O (2). These compounds are potent inhibitors of chitin synthetase and could be used as fungicides for treating plant diseases (3) and other applications (for other biological uses of polyoxins, see ref. 4). Consequently a great deal of effort has been devoted to the structural elucidation (5), biosynthesis (6), structural–activity relationships (7), and total synthesis (8) of this small family of antibiotics. The structures and configurations of the polyoxins, represented by polyoxin A and its degradation product polyoximic acid (**1**), were proposed as depicted in Fig. 1.

The structural elucidation was based on the analysis of the degradation products (5). For example, treatment of polyoxin A (Scheme 1) with acid or base led to the generation of 5-hydroxymethyl uracil (**3**), polyoxin C (**4**), polyoxamic acid (**5**), and polyoximic acid (**1**). The latter is a unique amino acid that is a component of polyoxins A, F, H, and K. Total syntheses of polyoxin C (9), polyoxins B and D (10), polyoxins J and L (11), and polyoxamic acid (12) have been reported. Only two reports in the literature address the total synthesis of polyoximic acid (13, 14). Baumann and Duthaler (13) described an approach using a Claisen rearrangement or cycloaddtion reaction for the synthesis of key intermediates. Emmer (14) reported a total synthesis of racemic *trans*-polyoximic acid using a rhodium catalyzed intramolecular carbenoid insertion reaction.

Initially, racemic polyoximic acid (*rac*-**1**) was obtained from polyoxin A by either basic or acidic hydrolysis (Scheme 2) (5). Upon ozonolysis, the characterizable product **6** was produced, thus establishing the atomic composition of the molecule. The stereochemistry of the exocyclic double bond was established as *trans* based on an NOE study using a 60 MHz NMR instrument. Additionally, hydrogenolysis of the parent polyoxin A produced the saturated intermediate

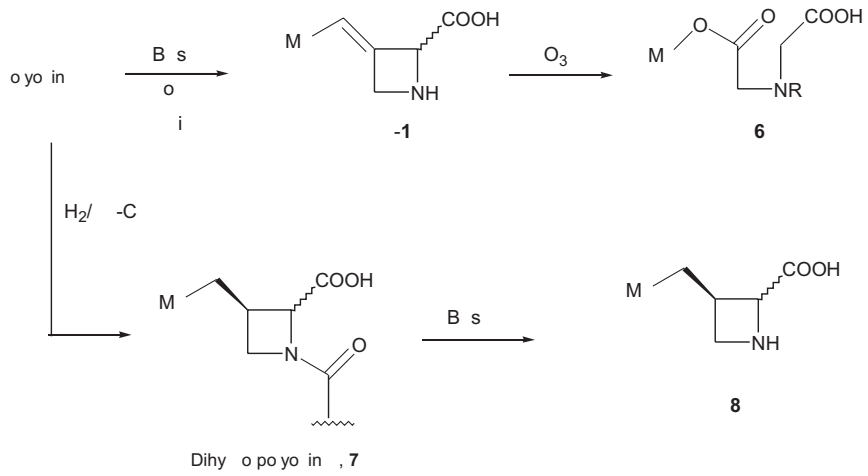
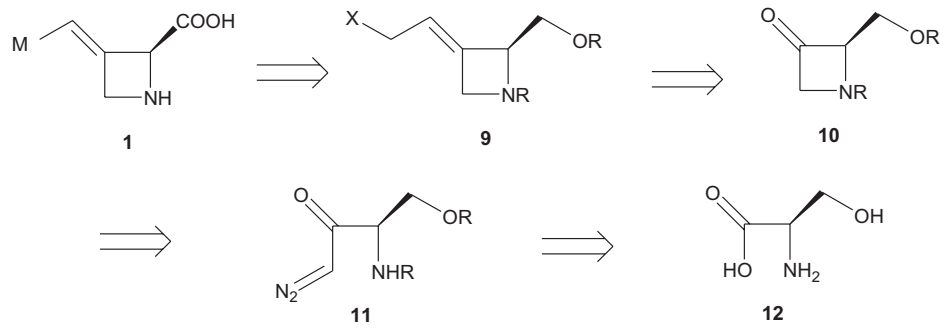
dihydropolyoxin A **7**, and subsequent basic hydrolysis generated the dihydro polyoximic acid **8**, which was converted to its *N*-dithiocarbethoxy derivative whose positive Cotton effect was compared to that of the known analogous derivative prepared from L-azetidine-2-carboxylic acid. Thus, the absolute configuration of the amino acid was established as (*S*) (5).



In the course of our studies (15*a*) directed at the total synthesis of polyoximic acid, we discovered that the structure was originally assigned incorrectly as the *trans*-isomer (15*b*). Here we wish to report in detail the total synthesis of this four-membered amino acid as the *cis*-isomer, as well as a synthesis of the *trans*-isomer.

Results and discussion



We envisioned that the total synthesis of polyoximic acid could be accomplished from D-serine, as illustrated by the disconnections shown in Scheme 3. The carboxylic acid could be derived from a latent functional group like an alcohol **9**, and the *exo*-double bond would originate from a Wittig reaction on the azetidinone **10**. The four-membered ring of **10**

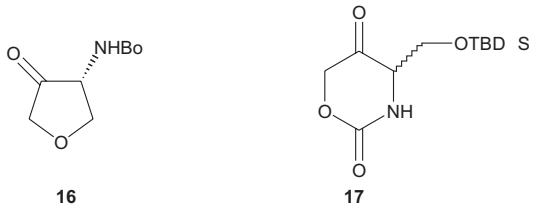
Scheme 3.

Scheme 4.

would be constructed by an intramolecular rhodium catalyzed carbene insertion into the N—H bond of the diazoketone, which in turn could be generated from the amino acid D-serine (**12**). This approach to the synthesis does not require us to build any new stereogenic centers on an sp^3 carbon, and relies on the general design principles embodied in the "Chiron" approach (16).

Thus, the formation of azetidinone **10**, from the rhodium catalyzed intramolecular carbenoid insertion reaction, would be the pivotal step of the total synthesis. Although rhodium catalyzed carbene insertions to C—H and O—H bonds have been extensively studied (17), to our knowledge, there was no precedence in the literature of using rhodium catalysis to promote an intramolecular carbene insertion into an N—H bond to form a four-membered ring from enantiopure α-amino acids (18). Hence, a methodological study was carried out first on simple amino acid templates such as phenylalanine and alanine (Scheme 4, Table 1) to explore the appropriate conditions. The diazoketones **14a–f** were prepared from different amino acids by reacting with diazomethane via either a mixed anhydride (method A) or an acyl chloride (method B). Subjection of the phenylalanine diazoketone **14a** to catalysis by rhodium(III) at different temperatures (rt, –20, –40, –78°C) revealed that –40°C was the optimal temperature giving a 70% yield of the expected 3-azetidinone. This temperature (–40°C) appeared to work well for the alanine system (Table 1, entries 6 and 7) with Cbz and Ts as the amino protecting groups. In contrast, when the amino protecting group was changed to Boc, the reaction led to the formation of unidentified materials (Table 1, entries 5 and 9) and no product could be isolated. Normally, carbene insertion reactions are carried out at rt or higher (17).



These low temperature conditions were then applied to the synthesis of polyoximic acid, starting with D-serine (**12**). In sharp contrast to the phenylalanine and alanine systems, the Boc group emerged as a better amino protecting group than Cbz (Scheme 4, Table 1, entries 10 and 11). In addition, the TBDPS (19) hydroxyl protecting group was found better than TBDMS (20). From the rhodium catalyzed reaction of diazoketone **14h**, two side products **16** and **17** were isolated in addition to the desired product **15h**. Compound **16** was formed by insertion of the carbene into the oxygen—silicon

Scheme 5.

bond, and **17** was derived from the ylide, which was formed by reaction of the carbene with the Boc carbonyl. Since the four-membered ring product **15h** was the kinetic product, lower temperature was presumed to be beneficial. When the reaction was carried out at –78°C, the yield increased to 57% (Table 1, entry 12). A further decrease of the reaction temperature to –95°C furnished **15h** in 67% yield. A temperature lower than –95°C was not pursued since the reaction mixture starts to freeze at –95°C in CH_2Cl_2. The highest yield (75%) was observed in the case of the N-Ts analog **15e**. However, the synthesis was continued with the N-Boc derivative **15h** for ease of deprotection.

Having secured a method to construct the four-membered ring skeleton, the next stage of the synthesis was to introduce the ethylidene group by conducting the Wittig reaction. Under normal Wittig conditions (Scheme 5 and Table 2, entry 1), a 1:2 mixture of *E*:*Z* olefins **18** was produced in favor of the *Z* isomer, which were not separable by normal chromatography methods. The stereoselectivity of the double bond formation was not improved by solvent variations (toluene, HMPA, Table 2, entries 2 and 3), or by using salt free conditions (entry 4). In addition, Schlosser's conditions (21) (entry 5) reversed the stereoselectivity in favor of the *E* isomer (*E*:*Z*, 2:1).

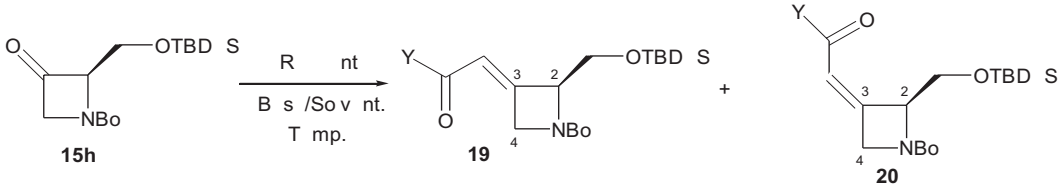
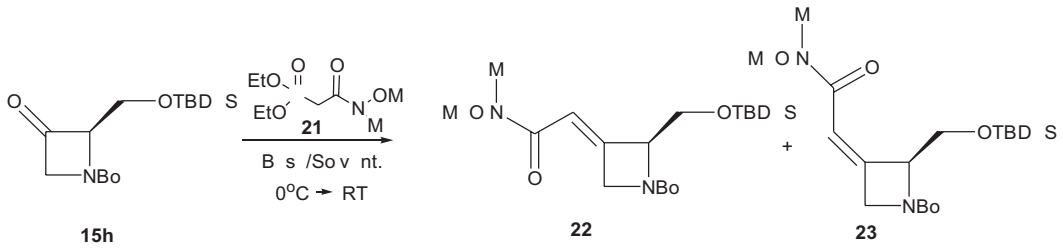
5	THF[b]	24	61:39



[a]Salt free conditions: NaHMDS, 0°C.
[b]Wittig–Schlosser conditions (ref. 21).

To better control the stereochemistry of the double bond, we changed the Wittig ylide from an unstabilized one to a stabilized one with either an aldehyde or ester (Scheme 6), since stabilized ylides normally favor *E*-isomer formation (22). Moreover, the aldehyde or ester could be considered as a latent methyl group as required in polyoximic acid. The results (Table 3, entries 1–6) showed that the stereoselectivity was not improved, and the *E*:*Z* mixture of olefins was still inseparable for both the aldehyde and the ester cases. Alternatively, an Horner-Emmons-Wadsworth reaction was considered. Indeed, *E*-isomer formation was favored, and the ratio was improved as expected (Table 3, entries 7–10). We then turned our attention to the cyano group (Table 3, entries 11–17), and found that the *E*:*Z* mixture of cyano olefins could be separated by iterative preparative TLC. It appeared that the phosphine oxide was the best choice with respect to obtaining a higher *E*:*Z* ratio (Table 3, entries 16 and 17). With both isomers in hand, we could determine the double bond geometry by an NOE study (Fig. 2). Although the enhancement was not significant, the *E*- and *Z*-isomers were differentiated by comparing the corresponding enhancements of the two isomers. Retrospectively, this evidence was used to confirm the stereochemical outcome of the Wittig and Horner-Emmons-Wadsworth reactions for the inseparable *E*- and *Z*-product mixtures (Schemes 5 and 6) by comparing their ^{1}H NMR spectra.



After separation of the cyano olefins **19** and **20**, the *E*-isomer was subjected to reduction to obtain the corresponding aldehyde. Unfortunately, using DIBAL-H (1–5 equiv.) in

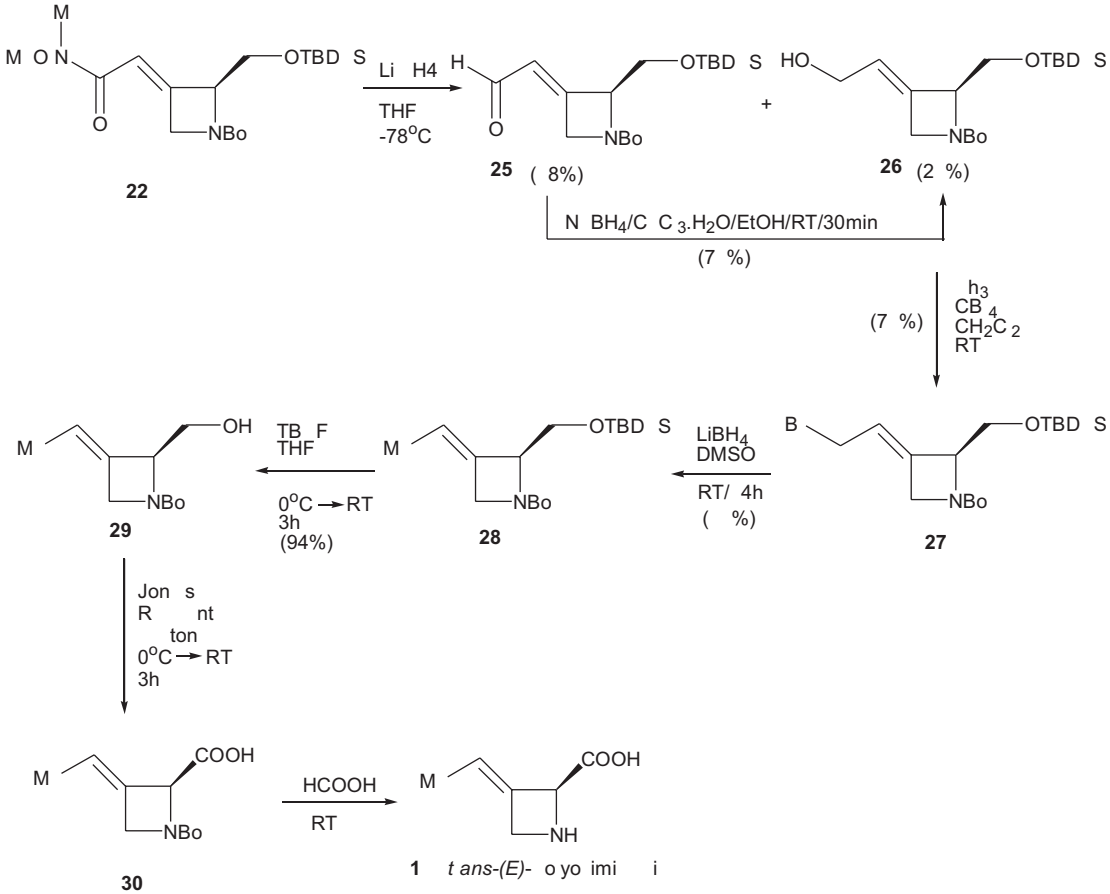

Scheme 6.

Scheme 7.

Scheme 8.

Et_2O or toluene at 0, –40, or –78°C gave at best 30% yield of the expected aldehyde. Either products of decomposition or starting material was recovered from the reduction. Therefore this route using the cyano group as the latent methyl group in the natural product was not pursued further.

Nevertheless, we discovered that the phosphonate amide by Nahm and Weinreb (23) provided a solution for this problem since it could be reduced more easily than the cyano group. Different conditions for the Horner-Emmons-Wadsworth reaction (Scheme 7) of compound **15h** with reagent **21** were explored. A mixture of *E*- (**22**) and *Z*- (**23**) isomers was obtained and separated by column chromatography. Sodium hydride in THF (Table 4, entry 5) was found to give the best result with a 94:6 ratio in favor of the *E*-iso-

Luche conditions (25) to the alcohol **26** in good yield. The latter was converted to the bromide **27**, which was further reduced to the methyl compound **28**. Removal of the TBDPS group of **28** and attempts to oxidize the alcohol group in **29** to the carboxylic acid **30** proved problematic. The corresponding aldehyde, obtained from Swern or Dess-Martin oxidations was unstable. Eventually, the classic Jones oxidation emerged as the best method to yield **30** in 40% yield. Finally, the *N*-Boc protecting group was removed by stirring compound **30** with formic acid to produce the *trans*-(*E*)-polyoximic acid **1**, as a crystalline solid, whose structure was definitively confirmed by X-ray analysis. After completing the synthesis of *trans*-(*E*) **1**, and being unaware of the incorrect stereochemistry of the natural product, we compared the ^{1}H NMR spectrum of the synthetic sample with an

© 2001 NRC Canada

Scheme 9.

authentic one kindly provided by Professor Isono. The spectra were in fact different, and we had synthesized the incorrect isomer.

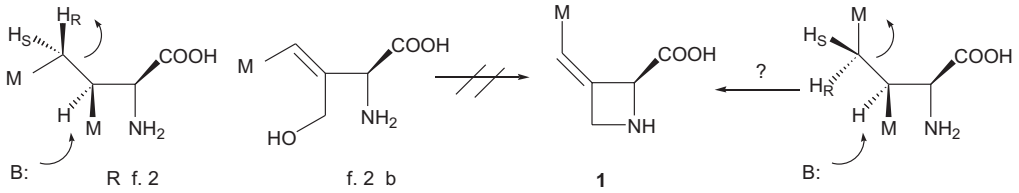
Faced with this dilemma, we were fortunate that the sample of racemic polyoximic acid received from Professor Isuno was in excellent physical state and amenable to X-ray analysis. The result shown in Fig. 3 confirms unambiguously that the geometry of the exocyclic double bond of the natural product is indeed *cis*-(*Z*), contrary to the original assignment (5).

With this important stereochemical revision, we turned our attention to the synthesis of the natural *cis*-(*Z*)-polyoximic acid **2**. The ready availability of the 3-azetidinone **15h** (Scheme 6), urged us to develop methodology directed at enriching the desired *Z*-isomer. Our studies on olefin formation had shown that the Wittig reaction favors the *Z*-product particularly in a protic solvent (Table 3, compare with Table 4). Therefore the Weinreb ester of the Wittig reagent became a logical choice as a (*Z*)-olefinating reagent in methanol (Scheme 9). Under these conditions, the *E*:*Z*-mixture of olefins was obtained in 73% yield and in a ratio of 10:90. In acetonitrile or THF, the ratios were 64:36 and 61:39, respectively, as determined by ^{1}H NMR spectroscopy. With a satisfactory method to obtain the (*Z*)-isomer **23**, the synthesis was carried out in a manner similar to that of the (*E*)-isomer, affording crystalline *cis*-(*Z*)-polyoximic acid **2** (Scheme 9).

Comparison of the spectroscopic and physical data of the synthetic material **2** with that of the natural product, confirmed the proposed structure, and the geometry of the double bond. The spectra in CD_3OD for the *cis*-(*Z*)- and *trans*-(*E*)-synthetic products, as well as that of the racemic natural product are shown in Fig. 4. It is interesting that the vinylic proton and the methyl protons in the *trans*-isomer **1** are shifted downfield and upfield, respectively, compared to the signals of the *cis*-isomer **2**. This pattern was also found in

© 2001 NRC Canada

Scheme 10.



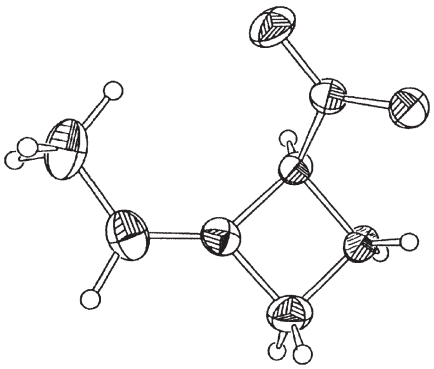


Fig. 3. Ortep drawing and structure of racemic *cis*-polyoximic acid.

D_2O and DMSO-d_6. The amino acid **2** was partially racemized in methanol containing a drop of Et_3N (~50% within 20 h at rt).

The geometry of the exocyclic double in the 3-azetidinone **15h**, could be controlled by conducting either the Horner-Emmons-Wadworth reaction or the Wittig reaction to generate a (*E*)- or (*Z*)-olefin preponderantly. Apparently, the Horner-Emmons-Wadsworth reaction gives the thermodynamic product as a major isomer at 0°C, and the Wittig reaction gives the kinetic product. To what extent, the nature of the Weinreb amide influences the respective transition states compared to normal esters is a matter of speculation (Tables 3 and 4). Dipolar and stereoelectronic effects could be playing important roles in both reactions. In addition, the nature of the solvent and cation is important in the phosphonate case, while the protic medium may promote a faster collapse of the more congested (*Z*)-betaine via the corresponding oxaphosphetane.

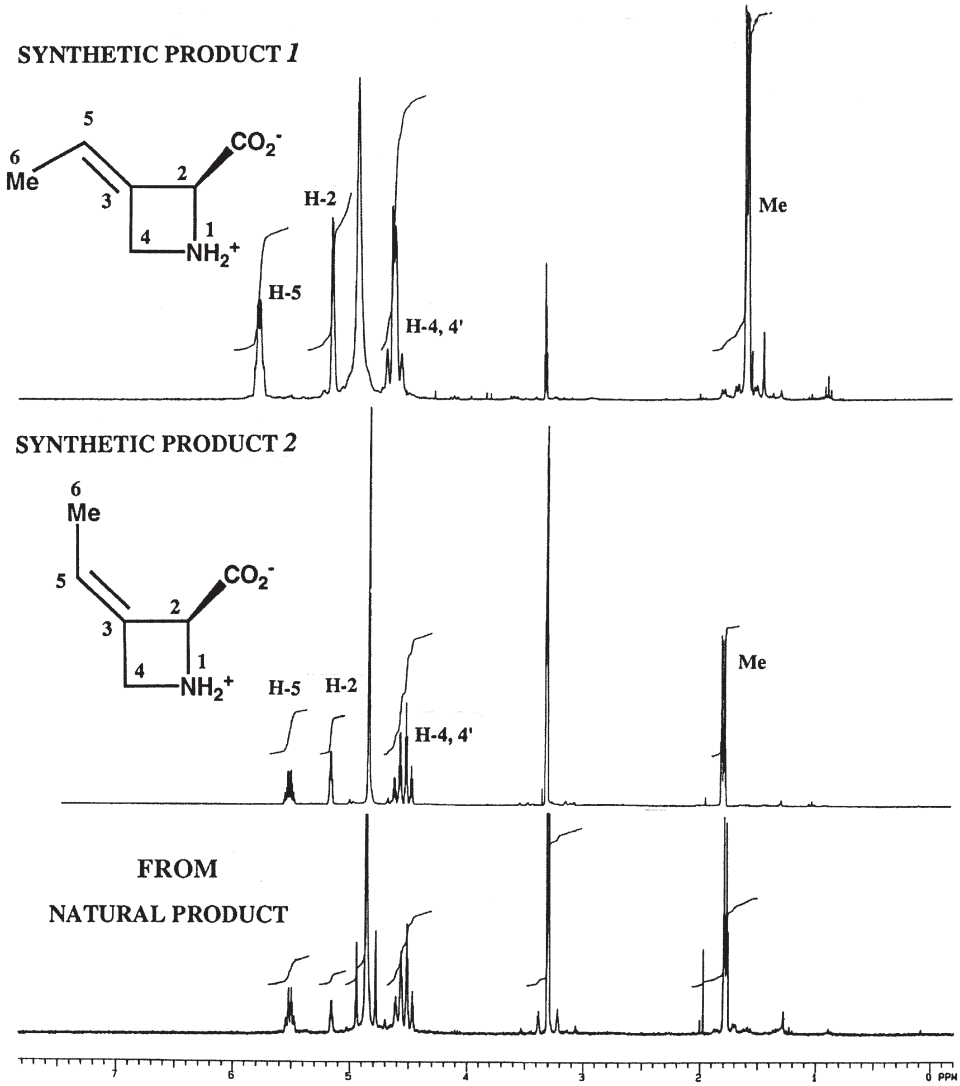
Since polyoximic acid was the degradation product of polyoxin, we had to be assured that no isomerization of the double bond had occurrred during the hydrolysis process or subsequent isolation. The 1D ^1H NMR spectrum of polyoxin A provided by Professor Isono is shown in Fig. 5, where the 6″-methyl, 5″-vinylic, and 2″-α-carboxyamide protons are clearly distinguishable. These correspond in pattern and in chemical shift differences to the *cis*- rather than the *trans*-polyoximic acid moiety.

Proton connectivities by the J-correlated spectroscopy (COSY) technique located the "intact" polyoximic acid moiety. Next, we carried out a 2D NOE correlated spectroscopy experiment (NOESY) to secure the *cis* orientation of the ethylenic group vis-à-vis the carboxamide group. Positive enhancements were observed between the ethylene methyl group and the α-carboxamide hydrogen, which is consistent with a *cis*-type geometry. These were independently corroborated by NOE studies on the *cis*- and *trans*-polyoximic acids in D_2O and DMSO-d_6.

With the establishment of the *cis* stereochemistry for polyoximic acid, the proposal of an elimination of the pro-*R* hydrogen at C-4 of L-isoleucine (26*a*), and the possible intermediacy of a hypothetical precursor, L-2-amino-3-hydroxymethyl-3-pentenoic acid (26*b*), must be reassessed (Scheme 10). If the double bond is indeed introduced by an enzymatic process, it most likely involves a synperiplanar elimination.

Finally, it is of interest to point out that the structures of polyoximic acids **1** and **2**, and related structures resulting from the methodology developed in this work represent constrained analogs of amino acids (27) such as L-isoleucine, L-vinyl glycine (28), and their congeners. As such, they are interesting structures for exploitation as β-turn mimetics (for selected reviews, see ref. 29) in a variety of peptide-like motifs.

In summary, after more than 30 years since the isolation and structure determination of polyoxin (5), the diminutive yet intriguing amino acid polyoximic acid was synthesized in enantiopure form, and the geometry of the double bond was reassigned as *cis* rather than *trans* through NMR spectroscopy and X-ray crystallography.



Experimental

General procedure

Flash chromatography was carried out using 230–400 mesh silica gel. Mixtures of ethyl acetate–hexanes were used as the eluents unless otherwise specified. Analytical thin layer chromatography (TLC) was performed on glass plates coated with 0.02 mm layer of silica gel 60 F-254. Melting points were uncorrected. IR spectra were recorded as films. ^1H NMR and ^{13}C NMR spectra were recorded at 300 and 75 MHz, respectively, and the chemical shifts are reported in parts per million on the δ scale with $CDCl_3$ as reference unless otherwise specified. MS and HRMS spectra were recorded using electron ionization (EI) or by the FAB technique. Elemental analyses were performed by Guelph Laboratories, Guelph, Ontario. Optical rotations were measured in $CHCl_3$ at 23°C. All reactions were carried out under nitrogen or argon atmosphere unless otherwise specified. The –78°C temperature is approximate as achieved by a dry ice – acetone bath. The –95°C temperature is approximate as achieved by a liquid nitrogen – methanol bath. The term "normal workup" means the addition of saturated aqueous NH_4Cl solution to the reaction mixture, followed extraction with ethyl acetate, drying over Na_2SO_4, filtration, and evaporation of the filtrate in vacuo to afford the crude product.

Fig. 4. 300 MHz ^{1}H NMR (CD_3OD) spectra of synthetic *trans* **1**, synthetic *cis*-**2** obtained by acid hydrolysis (ref. 5).

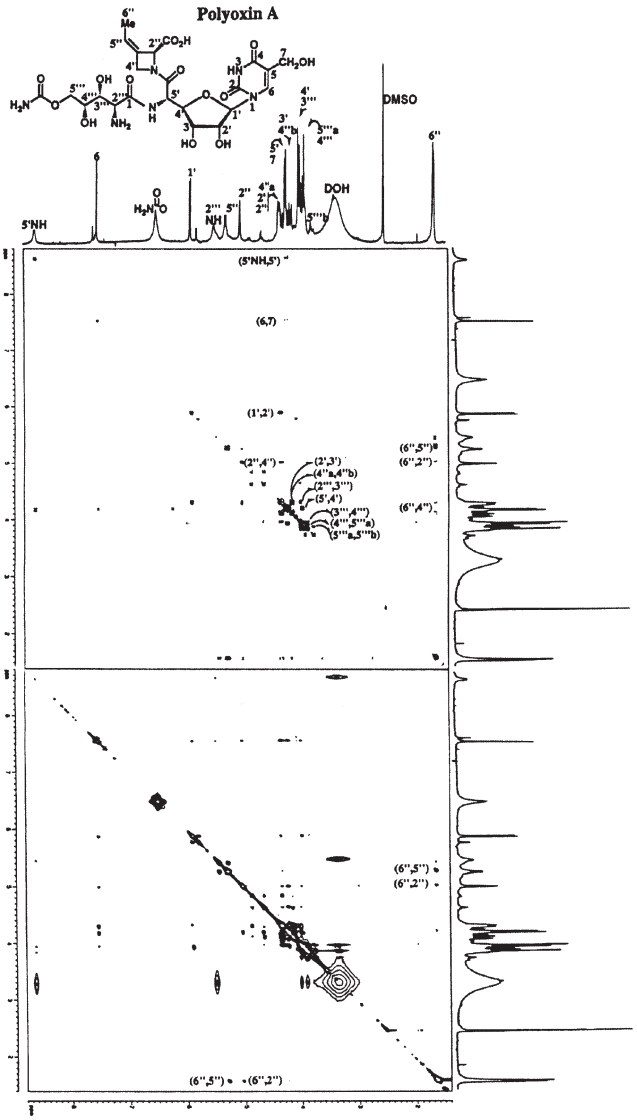
General procedure for the preparation of diazoketones (method A)

To a solution of the protected amino acid (1.00 mmol) in dichloromethane at –10°C was added simultaneously isobutyl chloroformate (1.07 mmol) and 4-methylmorpholine (1.07 mmol). After stirring for 45 min at –10°C, a solution of freshly prepared diazomethane in ether (18.75 mL, 6.68 mmol) was added, and stirring continued for 7 h at rt, followed by concentration in vacuo to dryness. The residue was subjected to column chromatography to afford the desired product.

*(3*R*)-1-Diazo-3-(*N*-benzyloxycarbonylamino)-4-phenyl-2-butanone (**14a**)*

According to method A, the title compound was prepared in 74% yield: mp 82–83°C (hexanes–CH_2Cl_2); $[\alpha]_D$ –13 (*c* 1.2, $CHCl_3$). FAB-MS (NBA) *m/z* (rel intensity): 324 ($[M + 1]^+$, 3), 307 (13), 289 (16), 154 (100), 136 (91), 106 (58). HRMS calcd. for $C_{18}H_{18}N_3O_3$ + H: 324.1349; found: 324.1329. IR (KBr) υ_{max} (cm^{-1}): 3335, 3082, 2118, 1700, 1626. ^{1}H NMR δ: 3.04 (d, *J* = 6.6 Hz, 2H), 4.46–4.55 (m, 1H), 5.08 (s, 2H), 5.20 (s, 1H), 5.38–5.40 (m, 1H), 7.15–7.38 (m, 10H). ^{13}C NMR δ: 54.6, 58.7, 67.0, 127.0, 128.0, 128.1, 128.4, 128.5, 128.6, 129.1, 129.2, 135.8, 136.0, 155.6, 192.6.

*(3*R*)-1-Diazo-3-(*N*-tert-Butyloxycarbonylamino)-4-phenyl-2-butanone (**14b**)*



According to method A, the title compound was prepared in 71% yield: mp 87–89°C (hexanes–CH_2Cl_2); $[\alpha]_D$ –8.1 (*c* 1.02, $CHCl_3$). FAB-MS (NBA) *m/z* (rel intensity): 290 ($[M + 1]^+$, 18), 206 (100), 164 (31), 154 (70), 136 (52), 120 (84). HRMS calcd. for $C_{15}H_{20}N_3O_3$: 290.1506; found: 290.1472. IR (KBr) υ_{max} (cm^{-1}): 3340, 2102, 1690, 1640. ^{1}H NMR δ: 1.39 (s, 9H), 2.98–3.09 (m, 2H), 4.35–4.48 (br s, 1H), 5.14 (d, *J* = 7.7 Hz, 1H), 5.23 (s, 1H). ^{13}C NMR ($CDCl_3$) δ: 28.1, 38.4, 54.2, 58.3, 79.9, 126.8, 128.5, 129.2, 136.2, 155.0, 193.2.

*(3*R*)-1-Diazo-3-(*N*-benzyloxycarbonylamino)-2-butanone (**14c**)*

According to method A, the title compound was prepared in 69% yield: mp 92–94°C (hexanes–CH_2Cl_2); $[\alpha]_D$ +4.1 (*c* 1.0, $CHCl_3$). FAB-MS (NBA) *m/z* (rel intensity): 268 ($[M + 1]^+$, 16), 240 (38), 197 (62), 154 (100), 139 (20). HRMS calcd. for $C_{12}H_{14}N_3O_3$ + H: 248.1036; found: 248.1037. IR ($CHCl_3$) υ_{max} (cm^{-1}): 3326, 2124, 1730, 1650. ^{1}H NMR δ:

Fig. 5. 2D COSY NMR spectrum of natural polyoxin A in DMSO-d_6 at 400 MHz (top); 2D NOESY NMR spectrum in DMSO-d_6 at 400 MHz (bottom).

1.35 (d, *J* = 7.1 Hz, 3H), 4.20–4.37 (m, 1H), 5.11 (s, 2H), 5.40 (s, 1H), 5.47 (br, 1H), 7.31–7.37 (m, 5H). ^{13}C NMR ($CDCl_3$) δ: 18.5, 53.4, 53.5, 66.9, 128.0, 128.1, 128.4, 136.0, 155.5, 193.6.

rac-*1-Diazo-3-(*N-tert-*butyloxycarbonylamino)-2-butanone (**14f**)*

According to method A, the title compound was prepared in 95% yield: mp 87–89°C (hexanes–CH_2Cl_2). FAB-MS (NBA) *m*/*z* (rel intensity): 214 ([M + 1]$^+$, 35), 158 (50), 154 (80), 144 (26), 136 (71), 130 (100). ^{1}H NMR δ: 1.31 (d, *J* = 7.1, 3H), 1.43 (s, 9H), 4.14–4.29 (br s, 1H), 5.09–5.21 (br s, 1H), 5.44 (s, 1H). ^{13}C NMR ($CDCl_3$) δ: 18.3, 28.2, 53.0, 53.2, 79.9, 155.0, 194.3.

*(3*R*)-1-Diazo-3-(*N-tert-*butyloxycarbonyl)amino-4-*tert-*butyl-diphenyl-silyloxy-2-butanone (**14h**)*

According to method A, the title compound was prepared in 97% yield: mp 89–90°C (hexanes). [α]$_D$ –0.67 (*c* 1.05, $CHCl_3$). FAB-MS (NEA) *m*/*z* (rel intensity): 468 ([M + H]$^+$, 49), 410 (16), 199 (64), 135 (100). HRMS calcd. for $C_{25}H_{34}N_3O_4Si$ (M + H): 468.2320; found: 468.2266. IR ($CHCl_3$) υ$_{max}$ (cm^{-1}): 2103, 1711, 1641. ^{1}H NMR δ: 1.06 (s, 9H), 1.46 (s, 9H), 3.79–3.84 (dd, *J* = 10.2, 4.8 Hz, 1H), 3.96–4.01 (dd, *J* = 10.2, 3.9 Hz, 1H), 4.20–4.38 (br s, 1H), 5.35–5.38 (d, *J* = 7.8 Hz, 1H), 5.49 (s, 1H), 7.40–7.45 (m, 6H), 7.61–7.64 (m, 4H). ^{13}C NMR δ: 19.1, 26.4, 28.2, 54.1, 59.0, 64.0, 80.0, 127.7, 129.8, 132.6, 135.4, 155.2, 192.8.

(3*R*)-(+)-1-Diazo-3-(*N*-4-toluenesulphonylamino)-2-butanone (14e) (method B)

To a solution of *N*-4-toluenesulphonyl-D-alanine (5.73 g, 23.6 mmol) in ether (55.0 mL) was added pentachlorophosphorus (10.1 g, 48.3 mmol). After vigorous stirring at rt for 1 h, the reaction mixture was filtered. To the filtrate was added hexane (200 mL). The generated solid was filtered and collected to give 5.00 g (82%) of the chloride compound. The chloride was dissolved in ether (50.0 mL). To this solution was added diazomethane-etherate solution (140 mL) at 0°C. After 1 h, the reaction mixture was filtered through a pad of silica gel. The filtrate was concentrated in vacuo to dryness. The residue was subjected to column chromatography (EtOAc–hexane, 1:2) to afford 3.94 g (77%) of the desired product: oil. [α]$_D$ +116.2 (*c* 2.36, $CHCl_3$). FAB-MS *m*/*z* (rel intensity): 268 ([M + 1]$^+$, 16), 240 (35), 197 (61), 154 (100). HRMS calcd. for $C_{11}H_{14}N_3O_3S$: 268.0757; found: 268.0788. IR (neat) υ$_{max}$ (cm^{-1}): 3260, 2105, 1735, 1641, 1366. ^{1}H NMR δ: 1.24 (d, *J* = 7.1 Hz, 3H), 2.40 (s, 3H), 3.76–3.89 (m, 1H), 5.45 (s, 1H), 5.51 (d, *J* = 7.5 Hz, 1H), 7.28 (d, *J* = 8.0 Hz, 2H), 7.69–7.73 (m, 2H). ^{13}C NMR ($CDCl_3$) δ: 19.4, 21.4, 53.9, 55.2, 127.0, 129.7, 136.6, 143.7, 192.7.

General procedure for the preparation of azetidinone 15 (method C)

To a solution of the diazo compound **14** (1.00 mmol) in dichloromethane (10.0 mL) at the reaction temperature indicated was added rhodium acetate dimer (0.009 g, 0.020 mmol). The resulting reaction mixture was stirred that reaction temperature for 1 h and allowed to warm to rt for 14 h. The solvent was removed and the residue was subjected to column chromatography.

*(2*R*)-1-Benzyloxycarbonyl-2-benzyl-3-azetidinone (**15a**)*

The reaction was carried out at –40°C to give 70% of product **15a**: mp 85–87°C (hexanes–CH_2Cl_2). [α]$_D$ –124.6 (*c* 1.0, $CHCl_3$). EI-MS *m*/*z* (rel intensity): 295 (M$^+$, 3), 267 (18), 204 (38), 132 (30), 88 (100). HRMS calcd. for $C_{18}H_{17}NO_3$: 295.1209; found: 295.1238. IR (neat) υ$_{max}$ (cm^{-1}): 1819, 1691. ^{1}H NMR δ: 3.14 (dd, *J* = 14.3, 4.0 Hz, 1H), 3.24 (dd, *J* = 14.3, 6.3 Hz, 1H), 4.08 (dd, *J* = 16.5, 4.4 Hz, 1H), 4.59 (d, *J* = 16.5 Hz, 1H), 5.20 (s, 2H), 5.21–5.25 (m, 1H), 7.12–7.15 (m, 2H), 7.23–7.29 (m, 2H), 7.35–7.41 (m, 6H). ^{13}C NMR ($CDCl_3$) δ: 35.4, 67.3, 69.2, 83.5, 126.9, 128.1, 128.2, 128.4, 128.5, 129.7, 134.9, 136.0, 155.8, 198.7.

*(2*R*)-1-Benzyloxycarbonyl-2-methyl-3-azetidinone (**15c**)*

The reaction was carried out at –40°C to give 71% of product **15c**: mp 80–81°C (hexane–CH_2Cl_2). [α]$_D$ –39.7

© 2001 NRC Canada

(*c* 0.99, $CHCl_3$). EI-MS *m*/*z* (rel intensity): 219 (M^+, 1), 191 (4), 91 (100). HRMS calcd. for $C_{12}H_{13}NO_3$: 219.0896; found: 219.0935. Anal. calcd for $C_{29}H_{40}N_2O_5Si$: C 66.38, H 7.68, N 5.34; found: C 66.38, H 7.62, N 5.25.

(2*S*,*E*)-1-*tert*-Butyloxycarbonyl-2-*tert*-butyldiphenylsilyloxymethyl-3-(formyl)methylidene-azetidine (25)

To a solution of **22** (8.70 g, 16.6 mmol) in THF (170 mL) at –78°C was added lithium aluminum hydride (3.15 g, 82.9 mmol). The resulting reaction mixture was stirred at –78°C for 1 h and quenched with H_2O (3.15 mL) at –78°C. After warming to rt, a 15% NaOH solution (3.15 mL) was added and the slurry was stirred for 15 min at rt followed by addition of H_2O (6.30 mL). The reaction mixture was filtered and the filtrate was concentrated in vacuo to dryness. Column chromatography (EtOAc–hexanes, 1:3) afforded 5.23 g (68%) of product **25** as a colorless oil and 1.65 g (21%) of product **26** as a colorless oil. For **25**: $[\alpha]_D$ –16.0 (*c* 2.01, $CHCl_3$). FAB-MS (NEA) *m*/*z* (rel intensity): 466 ($[M + H]^+$, 5), 427 (9), 352 (12), 197 (74), 154 (64), 135 (100). HRMS calcd. for $C_{27}H_{36}N_3O_4Si$ (M + H): 466.2415; found: 466.2390. IR ($CHCl_3$) υ_{max} (cm^{-1}): 2739, 1703, 1696. ^1H NMR δ: 1.05 (s, 9H), 1.43 (s, 9H), 3.87–3.91 (dd, *J* = 10.6, 2.7 Hz, 1H), 4.00–4.17 (br s, 1H), 4.86–4.88 (m, 2H), 4.93 (br s, 1H), 6.07–6.10 (m, 1H), 7.35–7.47 (m, 6H), 7.61–7.67 (m, 4H), 9.62–9.65 (d, *J* = 6.8 Hz, 1H). ^{13}C NMR δ: 19.4, 26.9, 28.4, 60.0, 62.2, 63.4, 71.6, 79.6, 122.4, 128.6, 130.1, 133.9, 135.9, 155.4, 159.2, 187.8.

(2*S*,*E*)-1-*tert*-Butyloxycarbonyl-2-*tert*-butyldiphenyisilyloxymethyl-3-(hydroxymethyl)methylidene-azetidine (26)

To a solution of **25** (5.11 g, 11.0 mmol) in ethanol (300 mL) at rt was added sodium borohydride (0.415 g, 11.0 mmol) and cerium trichloride heptahydrate (4.10 g, 11.0 mmol) simultaneously. The resulting reaction mixture was stirred at rt for 30 min and quenched with H_2O (300 mL). The aqueous solution was extracted with ethyl acetate (3 × 500 mL) and the combined ethyl acetate solution was dried (Na_2SO_4) and filtered. The filtrate was concentrated in vacuo to dryness. Column chromatography (CH_2Cl_2–hexanes–EtOAc, 2:1:1) afforded 4.54 g (89%) of product **26** as a colorless oil: $[\alpha]_D$ –13.3 (*c* 1.56, $CHCl_3$). FAB-MS (NBA) *m*/*z* (rel intensity): 468 ($[M + H]^+$, 20), 429 (18), 354 (44), 334 (43), 307 (40), 198 (63), 154 (90), 136 (100). HRMS calcd. for $C_{27}H_{38}NO_4Si$ (M + H): 468.2571; found: 468.2618. IR ($CHCl_3$) υ_{max} (cm^{-1}): 3420, 1700, 1676. ^1H NMR δ: 1.06 (s, 9H), 1.41 (s, 9H), 3.83–3.87 (dd, *J* = 10.4, 3.0 Hz, 1H), 3.95–4.09 (br s, 1H), 4.10–4.12 (d, *J* = 5.7 Hz, 2H), 4.51 (br s, 2H), 4.73 (br s, 1H), 5.61 (m, 1H), 7.35–7.43 (m, 6H), 7.65–7.70 (m, 4H). ^{13}C NMR δ: 19.2, 26.7, 28.3, 55.8, 60.0, 63.5, 70.1, 79.5, 120.8, 127.6, 129.6, 133.3, 133.4, 135.5, 155.8.

(2*S*,*E*)-1-*tert*-Butyloxycarbonyl-2-*tert*-butyldiphenylsilyloxymethyl-3-(bromomethyl)methylidene-azetidine (27)

To a solution of **26** (1.98 g, 4.23 mmol) in dichloromethane (85.0 mL) at rt was added triphenylphosphine (1.67 g, 6.35 mmol) and carbon tetrabromide (2.11 g, 6.35 mmol). The resulting reaction mixture was stirred at rt for 14 h and concentrated in vacuo to dryness. Column chromatography (EtOAc–hexanes, 1:6) afforded 1.67 g (75%) of product **27** as a colorless oil: $[\alpha]_D$ –10.9 (*c* 2.27, $CHCl_3$). FAB-MS (NBA) *m*/*z* (rel intensity): 532 ($[M + H]^+$, 3), 530 ($[M + H]^+$, 1), 418 (14), 416 (12), 199 (55), 197 (52), 135 (100). HRMS calcd. for $C_{27}H_{37}BrNO_3Si$ (M + H): 530.1727; found: 530.1783. IR ($CHCl_3$) υ_{max} (cm^{-1}): 1702. ^1H NMR δ: 1.06 (s, 9H), 1.41 (s, 9H), 3.84–3.88 (m, 3H), 3.90–4.10 (br s, 1H), 4.51 (br s, 2H), 4.76 (br s, 1H), 5.77 (m, 1H), 7.36–7.46 (m, 6H), 7.66–7.73 (m, 4H). ^{13}C NMR δ: 19.1, 26.6, 27.3, 28.2, 54.3, 63.1, 69.9, 79.7, 118.4, 127.6, 129.6, 133.1, 135.5, 138.3, 155.6.

(2*S*,*E*)-1-*tert*-Butyloxycarbonyl-2-*tert*-butyldiphenylsilyloxymethyl-3-ethylidene-azetidine (28)

To a solution of **27** (2.85 g, 5.36 mmol) in dimethyl sulphoxide (110 mL) at rt was added lithium borohydride (5.36 mL, 2.0 M solution in THF, 10.7 mmol). The resulting reaction mixture was stirred at rt for 14 h. Water (110 mL) was added followed by extraction with ethyl acetate (3 ×

© 2001 NRC Canada

200 mL). The combined ethyl acetate solution was dried (Na_2SO_4) and filtered. The filtrate was concentrated in vacuo to dryness. Column chromatography (EtOAc–hexanes, 1:8) afforded 1.60 g (66%) of product **28** as a colorless oil: $[\alpha]_D$ –10.7 (*c* 1.34, $CHCl_3$). FAB-MS (NBA) *m*/*z* (rel intensity): 452 ($[M + H]^+$, 9), 396 (7), 338 (100), 318 (84), 199 (83), 154 (42), 135 (100). HRMS calcd. for $C_{27}H_{37}NO_3Si$ (M + H): 452.2685; found: 452.2667. IR ($CHCl_3$) υ_{max} (cm^{-1}): 1701. ^1H NMR δ: 1.05 (s, 9H), 1.40 (s, 9H), 1.58–1.60 (m, 3H), 3.79–3.83 (dd, *J* = 10.3, 2.9 Hz, 1H), 3.90–4.10 (br s, 1H), 4.41 (br s, 2H), 4.67 (br s, 1H), 5.39–5.50 (m, 1H), 7.34–7.46 (m, 6H), 7.65–7.72 (m, 4H). ^{13}C NMR δ: 13.5, 19.5, 26.6, 28.3, 55.1, 63.6, 69.9, 79.2, 116.8, 127.5, 129.5, 131.5, 133.4, 135.5, 155.9.

(2*S*,*E*)-1-*tert*-Butyloxycarbonyl-2-hydroxymethyl-3-ethylidene-azetidine (29)

To a solution of compound **28** (0.589 g, 1.30 mmol) in THF (40.0 mL) at 0°C was added tetrabutylammonium fluoride (1.96 mL, 1.0 M solution in THF, 1.96 mmol). The resulted reaction mixture was stirred towards rt for 3 h. The reaction mixture was concentrated in vacuo to dryness. Column chromatography (EtOAc–hexanes, 1:3) afforded 0.261 g (94%) of product **29** as a colorless oil: $[\alpha]_D$ –8.9 (*c* 1.56, $CHCl_3$). FAB-MS (NBA) *m*/*z* (rel intensity): 214 ($[M + H]^+$, 78), 182 (54), 158 (100), 136 (98), 126 (81), 107 (96), 97 (74). HRMS calcd. for $C_{11}H_{20}NO_3$ (M + H): 214.1444; found: 214.1422. IR ($CHCl_3$) υ_{max} (cm^{-1}): 3425, 1701, 1658. ^1H NMR δ: 1.43 (s, 9H), 1.50–1.53 (m, 3H), 3.66–3.78 (m, 2H), 4.31–4.42 (m, 2H), 4.81 (br s, 1H), 5.30–5.40 (m, 1H). ^{13}C NMR δ: 13.3, 28.1, 55.1, 65.6, 71.3, 80.3, 117.7, 128.7, 156.9.

(2*S*,*E*)-1-*tert*-Butyloxycarbonyl-carboxylic acid 3-ethylidene-2-azetidine (30)

To a solution of **29** (64.6 mg, 0.30 mmol) in acetone (3.00 mL) at 0°C was added chromic acid (1.16 mL, 2.6 M solution, 3.03 mmol). The resulting reaction mixture was stirred towards rt for 3 h. Isopropanol was added to destroy the residual chromic acid followed by the addition of water (5.00 mL). The mixture was extracted with ether (3 × 10.0 mL) and the combined ether solution was dried (Na_2SO_4), filtered, and the filtrate was concentrated in vacuo to dryness. Column chromatography (EtOAc–hexanes, 1:2, with 1% of AcOH) afforded 26.5 mg (39%) of product **30**: mp 138–140°C (CH_2Cl_2–hexane). $[\alpha]_D$ –63.5 (*c* 1.28, $CHCl_3$). FAB-MS (NBA) *m*/*z* (rel intensity): 228 ($[M + H]^+$, 8), 220 (45), 172 (25), 154 (100), 136 (98), 107 (89). HRMS calcd. for $C_{11}H_{18}NO_4$ (M + H): 228.1236; found: 228.1244. IR ($CHCl_3$) υ_{max} (cm^{-1}): 3700–2500, 1729, 1707, 1687. ^1H NMR δ: 1.45 (s, 9H), 1.57–1.61 (m, 3H), 4.39–4.57 (m, 2H), 5.19 (br s, 1H), 5.78 (br s, 1H). ^{13}C NMR δ: 13.5, 28.2, 55.5, 67.9, 81.7, 120.7, 124.9, 156.6, 171.7. Anal. calcd for $C_{11}H_{17}NO_4$: C 58.14, H 7.54, N 6.16; found: C 57.99, H 7.57, N 6.12.

(2*S*,*E*)-3-Ethylidene-azetidine-2-carboxylic acid (1)

A solution of compound **30** (0.104 g, 0.459 mmol) in formic acid (5.00 mL) was stirred at rt for 5 h. After filtration through a fine sintered glass funnel, the filtrate was concentrated in vacuo on an oil pump to dryness to give 0.058 g (100%) of product **1**: mp 147–149°C (triturated with methanol and isopropanol). $[\alpha]_D$ +17.3 (*c* 2.10, MeOH). CI-MS *m*/*z* (rel intensity): 129 ($[M + H]^+$, 98), 84 (100). HRMS calcd. for $C_6H_{10}NO_2$ (M + H): 128.0794; found: 128.0722. IR (neat) υ_{max} (cm^{-1}): 3700–2000, 1614, 1379, 1291, 759, 690. ^1H NMR (CD_3OD) δ: 1.56–1.58 (m, 3H), 4.50–4.70 (m, 2H), 5.09 (br s, 1H), 5.70–5.83 (m, 1 H). ^1H NMR (D_2O) δ: 1.53–1.56 (m, 3H), 4.60–4.73 (m, 2H), 5.24 (br s, 1H), 5.66–5.77 (m, 1H). ^{13}C NMR (CD_3OD) δ: 13.1, 53.3, 70.7, 121.3, 128.4, 170.6.

(2*S*,*Z*)-1-*tert*-Butyloxycarbonyl-2-*tert*-butyldiphenylsilyl-oxymethyl-3-(formyl)methylidene-azetidine (31)

Compound **23** (0.505 g, 0.962 mmol) was reduced with lithium aluminum hydride (0.192 g, 95%, 4.81 mmol) at –78°C for 2 h to afford 0.274 g (61%) of **31** and 0.109 g (24%) of **32** both as colorless oils. For **31** : $[\alpha]_D$ +35.9 (*c* 1.79, $CHCl_3$). FAB-MS (NBA) *m*/*z* (rel intensity): 466 ($[M + H]^+$, 31), 427 (17), 352 (12), 198 (72), 154 (76), 135 (100). lithium borohydride (0.54 mL, 2.0 M solution in THF, 1.08 mmol) to afford 0.181 g (79%) of **34** as a colorless oil: $[\alpha]_D$ +4.4 (*c* 1.38, $CHCl_3$). FAB-MS (NBA) *m/z* (rel intensity): 452 ($[M + H]^+$, 20), 396 (19), 352 (18), 338 (54), 318 (51), 225 (52), 199 (61), 154 (82), 136 (100). HRMS calcd. for $C_{27}H_{38}NO_3Si$ (M + H): 452.2685; found: 452.2598. IR (neat) υ_{max} (cm^{-1}): 1700. ^1H NMR δ: 1.08 (s, 9H), 1.43 (s, 9H), 1.59–1.61 (m, 3H), 3.85–3.89 (dd, *J* = 10.7, 2.1 Hz, 1H), 4.00–4.25 (br s, 1H), 4.30–4.52 (m, 2H), 4.82 (br s, 1H), 5.39–5.50 (m, 1H), 7.35–7.47 (m, 6H), 7.67–7.75 (m, 4H). ^{13}C NMR δ: 13.6, 19.2, 26.8, 28.3, 56.1, 62.5, 70.2, 79.1, 117.3, 127.5, 129.5, 130.8, 133.3, 135.5, 155.6.

(2*S*,*Z*)-1-*tert*-Butyloxycarbonyl-2-hydroxymethyl-3-ethylidene-azetidine (35)

Compound **34** (0.912 g, 2.02 mmol) was reacted with tetrabutylammonium fluoride (3.03 mL, 1.0 M solution in THF, 3.03 mmol) to afford 0.418 g (97%) of **35** as a colorless oil: $[\alpha]_D$ –12.3 (*c* 1.98, $CHCl_3$). FAB-MS (NBA) *m/z* (rel intensity): 214 ($[M + H]^+$, 20), 158 (55), 136 (100), 107 (92). HRMS calcd. for $C_{11}H_{20}NO_3$ (M + H): 214.1444; found: 214.1460. IR (neat) υ_{max} (cm^{-1}): 3423, 1701, 1658. ^1H NMR δ: 1.45 (s, 9H), 1.57–1.61 (m, 3H), 3.78–3.85 (dd, *J* = 11.6, 7.6 Hz, 1H), 3.90–3.95 (dd, *J* = 11.6, 7.6 Hz, 1H) 4.32–4.34 (m, 2H), 4.96 (br s, 1H), 5.31–5.42 (m, 1H). ^{13}C NMR δ: 13.6, 28.2, 55.9, 64.5, 71.3, 80.4, 119.0, 128.1, 154.6.

(2*S*,*Z*)-1-*tert*-Butyloxycarbonyl-3-ethylidene-azetidine-2-carboxylic acid (36)

Compound **35** (0.178 g, 0.840 mmol) was oxidized with chromic acid (3.22 mL, 2.6 M solution, 8.36 mmol) to afford 76.0 mg (40%) of **36**: mp 83–84°C (CH_2Cl_2–hexane). $[\alpha]_D$ –15.3 (*c* 2.10, $CHCl_3$). EI-MS *m/z* (rel intensity): ($[M + H]^+$, 21), 182 (52), 172 (58), 154 (33), 142 (58), 126 (74), 76 (100). HRMS calcd. for $C_{11}H_{18}NO_4$ (M + H): 228.1236; found: 228.1214. IR (neat) υ_{max} (cm^{-1}): 3700–2500, 1731, 1702, 1690. ^1H NMR δ: 1.45 (s, 9H), 1.69–1.72 (m, 3H), 4.36–4.42 (m, 1H), 4.50–4.58 (m, 1H), 5.21 (m, 1H), 5.48–5.59 (m, 1H). ^{13}C NMR δ: 13.5, 28.2, 56.8, 68.0, 81.0, 121.3, 125.1, 155.8, 172.4. Anal. calcd for $C_{11}H_{17}NO_4$: C 58.14, H 7.54, N 6.16; found: C 57.81, H 7.42, N 6.06.

(2*S*,*Z*)-3-Ethylidene-azetidine-2-carboxylic acid (2)

A solution of **36** (0.107 g, 0.472 mmol) in formic acid (5.00 mL) was stirred at rt for 5 h. After filtration through a fine sintered glass funnel, the filtrate was concentrated in vacuo on an oil pump to dryness to afford 0.060 g (100%) of **2**: mp 153–155°C (triturated with methanol and EtOAc). $[\alpha]_D$ +41.3 (*c* 0.55, MeOH). CI-MS *m/z* (rel intensity): 128 ($[M + H]^+$, 20), 84 (43), 82 (100), 68 (48). HRMS calcd. for $C_6H_{10}NO_2$ (M + H): 128.0794; found: 128.0722. IR (neat) υ_{max} (cm^{-1}): 3700–2000, 1640, 1383, 1290, 851, 690. ^1H NMR (CD_3OD) δ: 1.76–1.80 (m, 3H), 4.45–4.63 (m, 2H), 5.14–5.16 (br s, 1H), 5.46–5.56 (m, 1H). ^1H NMR (D_2O) δ: 1.63–1.68 (m, 3H), 4.49–4.68 (m, 2H), 5.29 (m, 1H), 5.50–5.60 (m, 1H). ^{13}C NMR (CD_3OD) δ: 13.6, 54.7, 71.2, 122.8, 127.7, 170.1.

Acknowledgments

We are grateful to NSERC for financial support of this work. We thank Drs. J.-L. Chiara and R. DiFabio for initial studies in carbenoid insertions, and Dr. Y. Tu for NMR experiments. We are grateful to Professor K. Isono for an authentic samples of polyoximic acid and polyoxin A and to Dr. Michel Simard for X-ray analyses.

Studies of palladium-catalyzed coupling reactions for preparation of hindered 3-arylpyrroles relevant to (–)-rhazinilam and its analogues

Léon Ghosez, Cécile Franc, Frédéric Denonne, Claire Cuisinier, and Roland Touillaux

Abstract: Suzuki cross-coupling reactions of 3-pyrroleboronic acid derivatives with haloaromatics and the reverse process i.e., the coupling of 3-iodo(bromo)pyrroles with arylboronic acids have been investigated as a potential key step in the synthesis of (–)-rhazinilam and analogues. It was found that 3-iodo-2-formyl-1-tosylpyrroles efficiently coupled with a variety of arylboronic acids in the presence of $PdCl_2$(dppf) as catalyst. This catalytic system is compatible with a broad spectrum of arylboronic acids — electron-rich, electron-poor, hindered, heterocyclic — which easily coupled with the pyrrole substrate.

Key words: 2-substituted-3-arylpyrroles, biaryls, coupling reactions, arylboronic acids, palladium coupling, catalysis.

Résumé : Nous avons étudié les réactions de couplage de Suzuki entre les acides 3-pyrroleboroniques et divers aromatiques halogénés ainsi que les réactions inverses de couplage entre les 3-iodo(bromo)- pyrroles avec des acides boroniques aromatiques. Cette réaction de couplage pourrait être une étape clé dans la synthèse du (–)-rhazinilame. Nous avons découvert que les 3-bromo- et 3-iodo-2-formyl-1-tosylpyrroles pouvaient être couplés efficacement avec un grand nombre d'acides boroniques en utilisant $PdCl_2$(dppf) comme catalyseur. Ce catalyseur permet d'introduire facilement une grande diversité d'acides arylboroniques (riches ou pauvres en électrons, encombrés ou hétérocycliques) en position 3 du pyrrole.

Mots clés : pyrroles 2-substitués-3-halogénés, biaryles, réactions de couplage, acides arylboroniques, couplage au palladium, catalyse.

Introduction

The pyrrole ring is common to many compounds which have found applications in the pharmaceutical field (1) and also in material sciences (see for example ref. 2). Not surprisingly, they have represented a continuous challenge for synthetic chemists (1, 3). In the context of a total synthesis of the alkaloid (–)-rhazinilam **1**, an inhibitor of microtubules disassembly (4) (Scheme 1), we became interested in the development of a convenient synthetic route towards 1,2-disubstituted-3-aryl pyrroles. Our goal was to develop a method applicable to the synthesis of the natural product and a large variety of simpler analogues **2**.

A literature survey indicated that efficient methods of synthesis of 1,2,3-trisubstituted pyrroles are not numerous (5). Most of them give rather low yields or lack generality. On the other hand, coupling reactions of aromatic compounds in the presence of Pd^0 or Ni^0 catalysts are nowadays part of the armamentarium of synthetic chemists (for a recent review see ref. 6). The palladium-catalyzed cross-coupling of arylboronic acids with aryl bromides or iodides was first described by Suzuki and co-workers (for recent reviews, see ref. 7). It has been shown to be applicable to the coupling of pyrrole derivatives with other aromatic compounds (8, 9). We selected a Suzuki coupling reaction of **3** with **4** as an attractive approach towards **2** since: (*i*) it is highly convergent; (*ii*) aryl- and heteroaryl halides as well as boron derivatives are easily available and readily undergo the cross-coupling reaction (see for example refs. 10, 11); (*iii*) the presence of a carbonyl or a carboxyl group at C-2 of the pyrrole should allow numerous transformations; (*iv*) a tosyl group on nitrogen should be a good model for a polymer-bound arylsulfonic group. An account of our first results was published in 1999 (12). Two more recent papers also report the

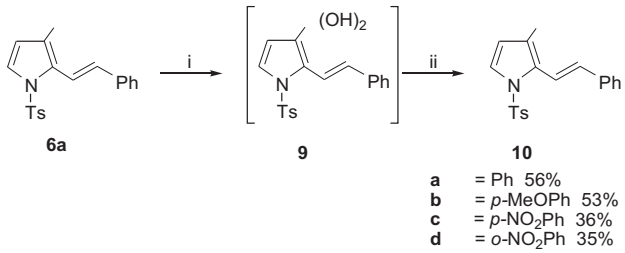
use of a cross-coupling reaction involving substituted 3-iodopyrroles for the synthesis of analogues of (–)-rhazinilam (13). We now report the full details of our studies.



Synthesis of 1,2-disubstituted 3-halopyrroles

Our strategy required an easy access to 3-halopyrroles **3** (Y = Br, I) and the corresponding boronic acid (Y = $B(OH)_2$). We selected the efficient method described by Masquelin and Obrecht (3) using aldimines and acetylenic acetals or ketones as starting materials. Compound **5** was obtained in excellent yields as described (Scheme 2).

However, very low yields (<3%) of **6a** were obtained from the treatment of **5** with 2.4 M aq HBr as described by the authors. The use of a more concentrated HBr solution at 80°C for 15 min gave **6a** in 78% yield. Similarly, treatment of **5** with 57% aq HI gave a 71% yield of **6b** if the temperature was kept at –10°C to avoid degradation of the product under these strongly acidic conditions. This practical sequence has been applied to the preparation of up to 23 g of **6a** and 43 g of **6b**.

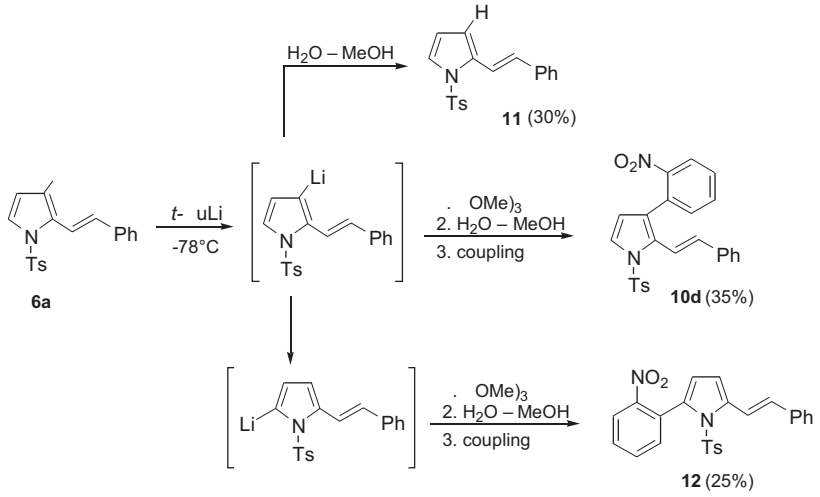
Pyrroles are extremely sensitive to oxidizing agents (1). However, the selective oxidation of the olefinic double bond of a 3-vinylpyrrole bearing an electron-withdrawing benzenesulfonyl group on nitrogen has been successfully performed with $NaIO_4$–OsO_4 cat (14). However, under these conditions, the oxidation of the styryl double bond of **6a**, **6b** took approximately 5 days. The oxidative cleavage with aq $KMnO_4$ was much faster. At room temperature, the products were the expected aldehydes **7a**, **7b**. At 90°C, hydrolytic cleavage of the tosyl group simultaneously occurred to yield **8a**, **8b**.

Scheme 3. Reagents and conditions: (*i*) *t*-BuLi in hexane, THF, –78°C then $B(OMe)_3$, –78°C then H_2O–MeOH, work-up; (*ii*) compound **9** (1.5 equiv), ArX (1 equiv), benzene–water–methanol (5:1.5:1), $Ba(OH)_2$ (1.5 equiv), $Pd(PPh_3)_4$ (5%), reflux.

Coupling reactions with 1-tosyl-2-styrylpyrrole boronic acid (9)

We first studied the synthesis of pyrroleboronic acid **9** and its coupling reaction with aryl iodides. Compound **9** was obtained from **6a** by a metal-bromide exchange with *t*-BuLi followed by treatment with trimethylborate and hydrolysis (Scheme 3).

Compound **9** was used without purification. The coupling reactions were performed under the conditions described by Muchowski (8*a*) for related cases. Yields were moderate with phenyl iodide and *o*-iodoanisole. However the presence of an electron-withdrawing nitro group in *para* or *ortho* position of the iodide considerably lowered the yields. The coupling of **9** with *o*-iodonitrobenzene was of special interest in the context of the rhazinilam problem. Next to the expected coupling product **10d**, we found a reduction product **11** (30%) and, more surprisingly, a compound **12** (25%) resulting from a coupling at position 5 of pyrrole **9** (Scheme 4).



We were able to show that the reduction product was formed as a result of the incomplete conversion of the organolithium intermediate into the corresponding boronic acid. Product **12** could be the result of an isomerization of the 3-lithio compound to the thermodynamically more stable 5-lithio isomer. There was little hope to improve the yields of **10d** by bringing the temperature further down; this would probably slow down the isomerization of the organolithium compound but also increase the amount of reduction product. We thus decided to study the Suzuki coupling reactions between 3-bromo- or 3-iodo-pyrrole derivatives **6a**, **6b** and **7a**, **7b** with various arylboronic acids.

Study of the coupling conditions of 1,2-disubstituted-3-halopyrroles with arylboronic acids

We first examined the reaction of **6b** with the commercially available phenylboronic acid **13a**. We used $Ba(OH)_2$ (15) as base (Scheme 5, Table 1). In the presence of $Pd(PPh_3)_4$ as catalyst, no coupling product **10a** was obtained in solvent mixtures (entries 1 and 2) which had been successfully used in similar coupling reactions (6, 7).

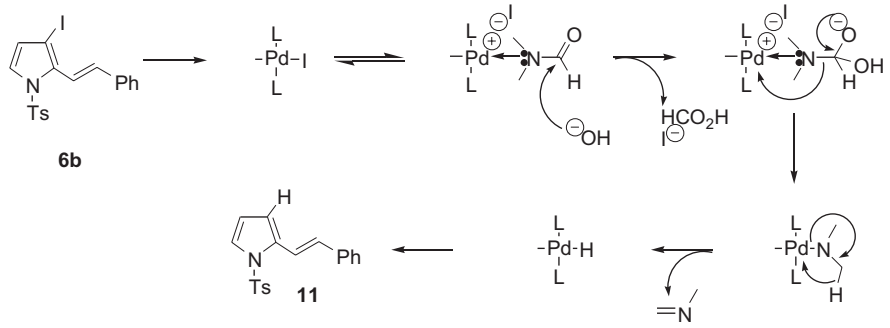
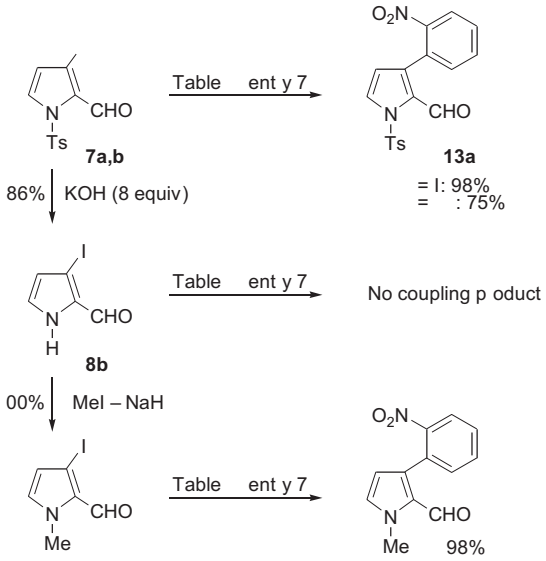
5	$Ba(OH)_2$	$DCON(CD_3)_2$–H_2O (1:1)	**d-1**



Scheme 6.



Running the coupling reaction in a more polar solvent (entry 3) led to a high yield of **10a**. The accelerating effect of a polar solvent such as DMF had been used before to effect Suzuki coupling reactions (15*b*, 15*e*) of bromo- and iodo-pyrroles (9*a*). However, when we applied these conditions to the coupling of **6b** with the electron-deficient and hindered *o*-nitrophenylboronic acid, we observed a dramatic decrease of the yield of coupling product **10b**, even at higher temperatures (entry 4). The presence of chloride ion (16) or the use of a bidentate phosphine (17) such as dppe (18) (entries 5 and 6) did not much improve the yield of coupling product **10b**. The major product **11** of the reaction resulted

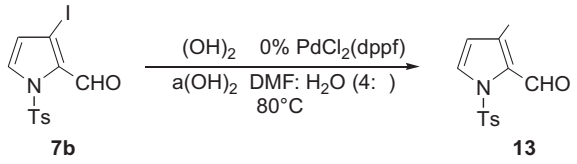


Scheme 7.

Scheme 8.

Scheme 9.

from the reductive cleavage of the carbon—iodine bond. We also observed variable amounts of nitrobenzene resulting from a base-catalyzed hydrolysis of *o*-nitrophenylboronic acid (19).

The use of 1,1′-bis(diphenylphosphino)ferrocene (dppf) bidentate ligand (20*a*, 20*b*; for a more recent example see ref. 20*c*) on palladium led to a significant increase of rate and yield (entries 7 and 8); the reaction was over in a few minutes even at 80°C and yields of coupling product **10b** were up to 80%. After completion of our work, Buchwald, Hermann, Fu and co-workers (21) reported new efficient catalysts for Suzuki cross-coupling reactions. However, no cross-coupling reactions involving a pyrrole derivative was described and we have not examined these new catalysts.

The palladium-catalyzed dehalogenation of aromatic compounds has been abundantly documented (review see ref. 22). Hydrodehalogenation products have sometimes been observed as by-products of Pd-catalyzed cross-coupling reactions (23). In these cases, water or tertiary amines have been assigned the role of hydride donors. In Table 2, we describe a study of the hydrodeiodination reaction of **6b** (Scheme 6).

It shows that: (*i*) no hydrodeiodination was observed in the absence of base or when DMF was replaced by *N*,*N*-dimethylacetamide (entries 1 and 2); (*ii*) no incorporation of deuterium was observed in the presence of D_2O or $Me_2NC(O)D$ (entries 3 and 4); (*iii*) incorporation of deuterium at C-3 of **11** occurred when the reaction was run in $(D_3C)_2NC(O)D$ (entry 5). These observations were rationalized by the mechanism outlined in Scheme 7.

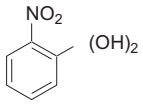
We have successfully applied the conditions of Table 1, entry 7 to the coupling of 2-formyl-3-halo-1-tosylpyrroles **7a**, **7b** with *o*-nitrophenylboronic acid (Scheme 8). Under these conditions, $Ba(OH)_2$ did not add to the aldehyde function of **7a**, **7b** (NMR control) and was thus available for the coupling reaction.

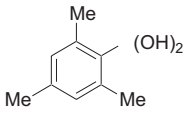
As expected, the reaction of iodopyrrole was much faster than that of the corresponding bromide and gave a higher yield of **13a**. The coupling reaction could also be effected in very high yield on the *N*-methylated pyrrole but did not occur when nitrogen was unsubstituted.

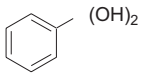
Generalization of the coupling reaction

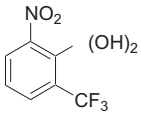
With these optimized conditions in hand, we carried out the cross-coupling reaction of **7b** with a wide variety of aryl and heteroarylboronic acids (Scheme 9, Table 3).

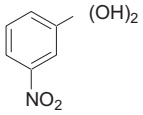
High yields of cross-coupled 1,2-disubstituted-3-arylpyrroles have been obtained. The reaction tolerates both electron-rich and electron-poor arylboronic acids. It could also be applied successfully to the coupling of **7b** with the sterically hindered mesitylboronic acid.

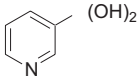


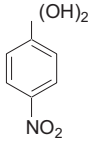


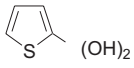


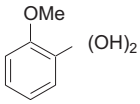


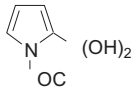












The electron-poor 2-nitro-6-(trifluoromethyl)phenylboronic acid **14** was prepared by nitration of 2-(trifluoromethyl)-phenylboronic acid (Scheme 10). The conditions described for the nitration of boric acid (28), gave no reaction and sulfuric acid had to be used to obtain **14** in a 42% yield, together with its isomer **15** (12%). However, 2-nitro-6-(trifluoromethyl)phenylboronic acid **14** gave no coupling product. Interestingly, the corresponding aniline **16** gave 3-tosyl-9-(trifluoromethyl)-3*H*-pyrrolo[2,3-*c*]-quinoline **17** in 26% yield (Scheme 10).

This illustrates a further application of this coupling reaction for the synthesis of pyrroles fused to other heterocycles. However, at this stage, we did not try to optimize the reaction.

In conclusion, we have fulfilled our goal and developed a practical synthetic route towards 1,2-disubstituted-3-aryl-(heteroaryl)pyrroles. The method should offer the possibility of

were performed on GEMINI-200, GEMINI-300, and Brucker AM-500 spectrometers. Internal standards were TMS (^{1}H NMR) and $CDCl_3$ (77.23 ppm, ^{13}C NMR). IR spectra were recorded on PerkinElmer 681 and Bio-Rad FTS 135 spectrometers (polystyrene ref. 1601 cm^{-1}). Mass spectra were recorded on Varian MAT-44 or FINNIGAN-MAT TSQ-70 spectrometers (electronic impact 70 eV or chemical ionization 100 eV with 2 μbar isobutane as the ionizing gas).

Tetrakis(triphenylphosphine)palladium (29) and dichloro-(diphenylphosphinoferrocene)palladium (30), *o*-nitrophenylboronic and *p*-nitrophenylboronic acids were prepared as described in the literature (28). Unless otherwise noted, the other boronic acids used were purchased from commercial sources. THF and toluene were distilled from sodium-benzophenone. Organic phases were dried over magnesium sulphate. Solvents were degassed by bubbling argon for at least 15 min. Chromatographic separations were performed with silica gel purchased from Merck (thickness 40–63 μm)

*3-Bromo-2-styryl-1-tosylpyrrole (**6a**) (RN: 168030-84-0)*

To a solution of *(E)-N*-(4,4′-diethoxy-1-styrylbut-2-ynyl)-4-toluenesulfonamide (3) (18 g, 45 mmol) in toluene (100 mL) was added bromohydric acid (48% aqueous, 48 mL, 425 mmol). The reaction mixture was stirred for 10 min at 80°C and then allowed to cool to room temperature. It was poured into ice and ether, sodium hydroxide (14.4 g, 360 mmol) was then added, and the pH adjusted to 7 with 1 N aqueous sodium hydroxide. The aqueous phase was extracted with ether, the organic layers were washed with brine, dried and concentrated in vacuo. Purification by flash chromatography on silica gel (10% diethyl ether in petroleum ether) Yield of **4**: 14.1 g, 78%, pale yellow solid (mp 97°C). R_f = 0.38 (30% diethyl ether in petroleum ether). MS (EI) *m*/*z* (IE, 70 eV): 403 (100, $[M + 2]^{\bullet+}$), 401 (80, $M^{\bullet+}$), 249 (18, $[M + 2\text{-Tos} + H]^{\bullet+}$), 247 (20, $[M\text{-Tos} + H]^{\bullet+}$), 168 (48), 167 (97, (249 and 247 -Br)$^{\bullet+}$), 166 (14), 139 (14). IR: 3149–3025, 1596, 1469, 1371, 1145–1089, 1028, 965. ^{1}H NMR ($CDCl_3$, 500 MHz) δ: 7.67 (d, ^3J = 8.5 Hz, 2H, $NSO_2C(CHCH)_2CCH_3$), 7.49 (d, ^3J = 8.3 Hz, 2H, $CHC(CHCH)_2CH$), 7.38 (t, ^3J = 8.3 Hz, 2H, $CHC(CHCH)_2CH$), 7.36 (d, ^3J = 16.5 Hz, 1H, $CHCHC(CHCH)_2CH$), 7.33 (d, ^3J = 3.4 Hz, 1H, $NCHCH$), 7.35–7.22 (m, 1H, $CHC(CHCH)_2CH$), 7.23 (d, ^3J = 8.5 Hz, 2H, $NSO_2C(CHCH)_2CCH_3$), 7.20 (d, ^3J = 16.5 Hz, 1H, $CHCHC(CHCH)_2CH$), 6.35 (d, ^3J = 3.4 Hz, 1H, $NCHCH$), 2.36 (s, 3H, CH_3). ^{13}C NMR ($CDCl_3$, 125 MHz) δ: 145.33 ($NSO_2C(CHCH)_2CCH_3$), 136.81 ($CHC(CHCH)_2CH$), 135.27 ($NSO_2C(CHCH)_2CCH_3$), 133.81 ($CHC(CHCH)_2CH$), 129.19 (NCC), 129.85 ($NSO_2C(CHCH)_2CCH_3$), 128.65 ($CHCHC(CHCH)_2CH$), 128.05 ($CHCHC(CHCH)_2CH$), 127.13 ($NSO_2C(CHCH)_2CCH_3$), 126.47 ($CHCHC(CHCH)_2CH$), 122.32 ($NCHCH$), 116.15 ($NCHCH$), 115.18 ($CHCHC(CHCH)_2CH$), 102.13 (NCC), 21.48 (CH_3).

*3-Iodo-2-styryl-1-tosylpyrrole (**6b**) (RN: 233770-17-7)*

To a solution of *(E)-N*-(4,4′-diethoxy-1-styrylbut-2-ynyl)-4-toluenesulfonamide **5** (3) (25 g, 61 mmol) in toluene (200 mL) at –10°C was added iodohydric acid (57% aqueous, 57 mL, 424 mmol). The mixture was stirred for 1 h at room temperature then poured into ice and ether. Sodium hydroxide (13.3 g, 333 mmol) was then added and the pH adjusted to 7 with 1 N aqueous sodium hydroxide. The aqueous phase was extracted with ether, the combined organic layers washed with brine, dried and concentrated in vacuo. Purification by flash chromatography on silica gel (10% diethyl ether in petroleum ether) Yield of **4**: 19 g, 71%, pale solid (mp 119°C). R_f = 0.7 (30% diethyl ether in petroleum ether). Yield of **8b**: 20 mg, 40%, white solid (decomposed at 128°C). R_f = 0.57 (50% diethyl ether in petroleum ether). MS (EI) *m/z* (70 eV): 221 (100, $M^{\bullet+}$), 220 (100, $[M - H]^+$), 192 (16, $[M - COH]^+$). IR: 3255, 1635, 1340, 758, 737. ^{1}H NMR ($CDCl_3$, 200 MHz) δ: 9.90 (br s, 1H, N*H*), 9.45 (s, 1H, C*H*O), 7.12–7.05 (m, 1H, NC*H*CH), 6.53 (t, ^3J = ^4J = 2.55 Hz, 1H, NCHC*H*). ^{13}C NMR ($CDCl_3$, 50 MHz) δ: 180.00 (*C*HO), 130.78 (*C*CHO), 126.98 (N*C*H), 119.21 (NCH*C*H), 77.23 (*C*I).

*2-Styryl-1-tosylpyrrole boronic acid (**9**)*

To a solution of 3-bromo-2-styryl-1-tosylpyrrole **6a** in dry THF (12 mL) at –78°C was added *t*-BuLi (1.7 M in pentane, 3.3 mL, 5.3 mmol). The mixture was stirred for 25 min and turned brown. A solution of trimethyl borate (2.8 mL, 25 mmol) in THF (50 mL) at –78°C was then added via cannula. The reaction mixture turned orange. After 45 min, the reaction was quenched by adding 0.5 mL of methanol and 0.5 mL of water. The solution was poured into water (20 mL), the aqueous phase extracted with diethyl ether. The combined organic phases were washed with brine, dried and concentrated in vacuo. The crude product was used in the coupling reaction without further purification.

Coupling reactions

Method A refers to the coupling reaction of 2-styryl-1-tosylpyrrole boronic acid **9** with iodoaryls: A mixture of aryliodide (1 equiv), crude boronic acid **9** (1.5 equiv, 0.16 M), barium hydroxide octahydrate (1.5 equiv), and tetrakis(triphenylphosphine)palladium (0.05 equiv) in a degassed mixture of water, methanol, and benzene (3:2:10) was refluxed for 16 h. It was then concentrated and the crude material was dissolved in ethyl acetate and filtered on a Celite® pad to remove metallic palladium. The filtrate was then dried and concentrated in vacuo. The crude product was purified by flash chromatography on silica gel.

Method B refers to the coupling reaction of 3-iodo-2-styryl-1-tosylpyrrole **6b** with an arylboronic acid: A mixture of 3-iodo-2-styryl-1-tosylpyrrole **6b** (1 equiv, 0.044 M), boronic acid (1.5 equiv), barium hydroxide octahydrate (1.5 equiv), and catalyst (0.05 or 0.1 equiv) in a degassed mixture of DMF and water (4:1) was placed in a bath which had been preheated to 120°C. After 20 min, it was cooled to room temperature and diluted with ethyl acetate and water. After filtration on a Celite® pad, the solution was washed with water, brine, dried and concentrated in vacuo. The crude product was purified by flash chromatography on silica gel.

Method C refers to the coupling reaction of 2-formyl-3-iodo-1-tosylpyrrole **7b** with an arylboronic acid: A mixture of 2-formyl-3-iodopyrrole (1 equiv, 0.044 M), aryl boronic acid (1.5 equiv), barium hydroxide octahydrate (1.5 equiv) and dichloro(diphenylphosphinoferrocene)palladium(II) (0.1 equiv) in a degassed mixture of DMF and water (4:1) was placed in a bath which had been preheated to 80°C. After 5 min, it was cooled to room temperature and diluted with ethyl acetate and water. After filtration on a Celite® pad, the solution was washed with water, brine, dried and concentrated in vacuo. The crude product was purified by flash chromatography on silica gel.

*3-Phenyl-2-styryl-1-tosylpyrrole (**10a**)*

Method A: 1.36 g (3.71 mmol) of the crude boronic acid **9**, 0.5 g (2.47 mmol) of iodobenzene, 1.17 g (3.71 mmol) of barium hydroxide octahydrate, 57 mg (0.05 mmol) of tetrakis(triphenylphosphine)palladium. Eluent: 10% of diethyl ether in petroleum ether. Yield of **10a**: (560 mg, 56%).

Method B: 0.3 mg (0.7 mmol) of the 3-iodo-2-styryl-1-tosylpyrrole **6b**, 0.5 mg (1 mmol) of phenylboronic acid, 0.17 mg (1 mmol) of barium hydroxide octahydrate, and 38 mg (0.03 mmol) of tetrakis(triphenylphosphine)palladium. Eluent: 10% diethyl ether in petroleum ether. Yield of **10a**: 240 mg, 90%, white solid (mp 140°C). R_f = 0.74 (30% diethyl ether in petroleum ether). MS (CI) *m/z*: 400 (100, $[M + 1]^+$), 247 (46, $[400 - SO_2C_6H_4CH_3]^{\bullet+}$), 157 (16, $[SO_2C_6H_5CH_3 + 2H]^+$). HRMS calcd. for $C_{25}H_{22}NO_2S$: 400.1371; found: 400.1351. *2-Nitro-6-trifluoromethylboronic acid (**14**) and 4-nitro-6-trifluoromethylboronic acid (**15**)*

To a solution of nitric acid (90% aqueous, 2.25 mL, 48 mmol) and sulfuric acid (6.8 mL, 128 mmol) and a few urea crystals at 0°C, a solution of 2-(trifluoromethyl)phenylboronic acid (3.2 g, 16 mmol) in acetic anhydride (42 mL) was slowly added through an addition funnel. During the addition, the temperature was kept under 5°C. After the addition, the mixture was stirred for 4 h at 0°C and overnight at room temperature. It was then poured onto ice (500 mL) and sodium hydroxide was added until the pH reached a value between 3 and 5. The aqueous phase was then extracted with diethyl ether. The organic layer was washed with brine, dried and concentrated in vacuo. The purification by reverse-phase MPLC yielded 2-nitro-6-trifluoromethylboronic acid (**14**) (1.6 g, 42%) as a white solid (mp 154°C) and 4-nitro-2-trifluoromethylboronic acid (**15**) (0.46 g, 12%) as a white solid (mp 141°C).

***(14)**:* r.t. = 11.9 min (col. MATREX 4 RP 18 15 μ; eluent: CH_3CN–H_2O, 35:65; flow 0.5 mL min^{-1}; UV detector 254 nm, 25°C). MS (EI) *m/z*: 235 (3, $M^{\bullet+}$), 191 (100, $[M - B(OH)_2 + H]^{\bullet+}$), 171 (88, $[M - NO_2\text{-}F]^+$). HRMS calcd. for $C_7H_5BF_3NO_4$: 235.0263; found: 235.0266. IR: 3591 and 3385, 1543, 1387–1292 (B—OH), 1134. ^{1}H NMR (DMSO-d_6, 500 MHz) δ: 8.46 (d, ^3J = 7.6 Hz, 1H, C*H*CNO_2), 8.28 (s, 2H, $B(OH)_2$), 8.14 (d, ^3J = 7.6 Hz, 1H, C*H*CF_3), 7.81 (t, ^3J = 7.6 Hz, 1H, CHC*H*CH). ^{13}C NMR (DMSO-d_6, 75 MHz) δ: 150.47 (*C*NO_2), 133.5–132 (m, C-B), 131.77 (CH*C*HCH), 130.02 (*C*HCCF_3), 125.32 (*C*CF_3), 126.56 (*C*HCNO_2), 120.92 (*C*F_3).

***(15)**:* r.t. = 19.2 min (col. MATREX 4 RP 18 15 μ; eluent: CH_3CN–H_2O 35:65; flow 0.5 mL min^{-1}; UV detector 254 nm, 25°C). *2-Amino-6-trifluoromethylboronic acid (**16**)*

Palladium (10% on activated carbon, 38 mg) was added to a solution of *o*-nitro-*o*′-trifluoromethylboronic acid (**14**) in ethanol (10 mL). The resulting suspension was then stirred under hydrogen (2 bar) overnight, filtered on a Celite® pad and concentrated in vacuo. Owing to its unstability, the product was used in the coupling reaction without further purification.

*3-Tosyl-9-(trifluoromethyl)-3*H*-pyrrolo[2,3-*c*]-quinoline (**17**)*

Method C: 150 mg (0.4 mmol) of the 3-iodo-2-formyl-1-tosylpyrrole **7b**, 120 mg (0.6 mmol) of the crude *o*-amino-*o*′-trifluoromethylboronic acid (**16**), 189 mg (0.6 mmol) of barium hydroxide octahydrate, 30 mg (0.04 mmol) of dichloro(diphenylphosphinoferrocene)palladium(II). Eluent: 30% ethyl acetate in petroleum ether. Yield of **17**: 40 mg, 26%, pale yellow solid (mp 163°C). R_f = 0.5 (70% diethyl ether in petroleum ether). MS (EI) *m*/*z*: 390 (100, $M^{\bullet+}$), 235 (15, $[M - C_7H_7SO_2]^+$), 155 (29, $[C_7H_7SO_2]^+$), 91 (21, $[C_7H_7]^+$) HRMS calcd. for $C_{19}H_{13}F_3N_2O_2S$: 390.0649; found: 390.0654. IR: no carbonyl signal. ^{1}H NMR ($CDCl_3$, 500 MHz) δ: 9.70 (s, 1H, C*H*N), 8.40 (d, ^3J = 8.0 Hz, 1H, C*H*CCCF$_3$), 8.02 (d, ^3J = 8.0 Hz, 1H, C*H*CCF$_3$), 7.86 (d, ^3J = 3.7 Hz, 1H, NC*H*CH), 7.85 (d, ^3J = 8.5 Hz, 1H, $NSO_2C(CHCH)_2CCH_3$), 7.69 (t, ^3J = 8.0 Hz, 1H, CHCHCCF$_3$), 7.45–7.43 (m, 1H, NCHC*H*), 7.26 (d, ^3J = 8.6 Hz, 2H, $NSO_2C(CHCH)_2CCH_3$), 2.34 (s, 3H, CH_3). ^{13}C NMR ($CDCl_3$, 125 MHz) δ: 145.94 ($NSO_2C(CHCH)_2CCH_3$), 144.74 (*C*NCH), 138.73 (CN*C*H), 135.26 (*C*HCNCCCF$_3$), 134.72 ($NSO_2C(CHCH)_2CCH_3$), 130.22 ($NSO_2C(CHCH)_2CCH_3$), 128.90 (N*C*C), 128.03 (N*C*H), 126.96 ($NSO_2C(CHCH)_2CCH_3$), 126.03 (*C*HCCF$_3$), 125.83 (NCCH*C*HCHCCF$_3$), 21.51 (*C*H$_3$).

Acknowledgements

This work was supported by fellowships from the European Community (C.F.), the Fonds National de la Recherche Scientifique, and the European Institute for Chemistry and Biology (F.D.). We thank the Ministère de l'Education et de la Recherche Scientifique de la Communauté Française de Belgique (Action concertée 96/01–197) for a generous grant. We also thank L. Delhaye and V. Gevears for technical help.

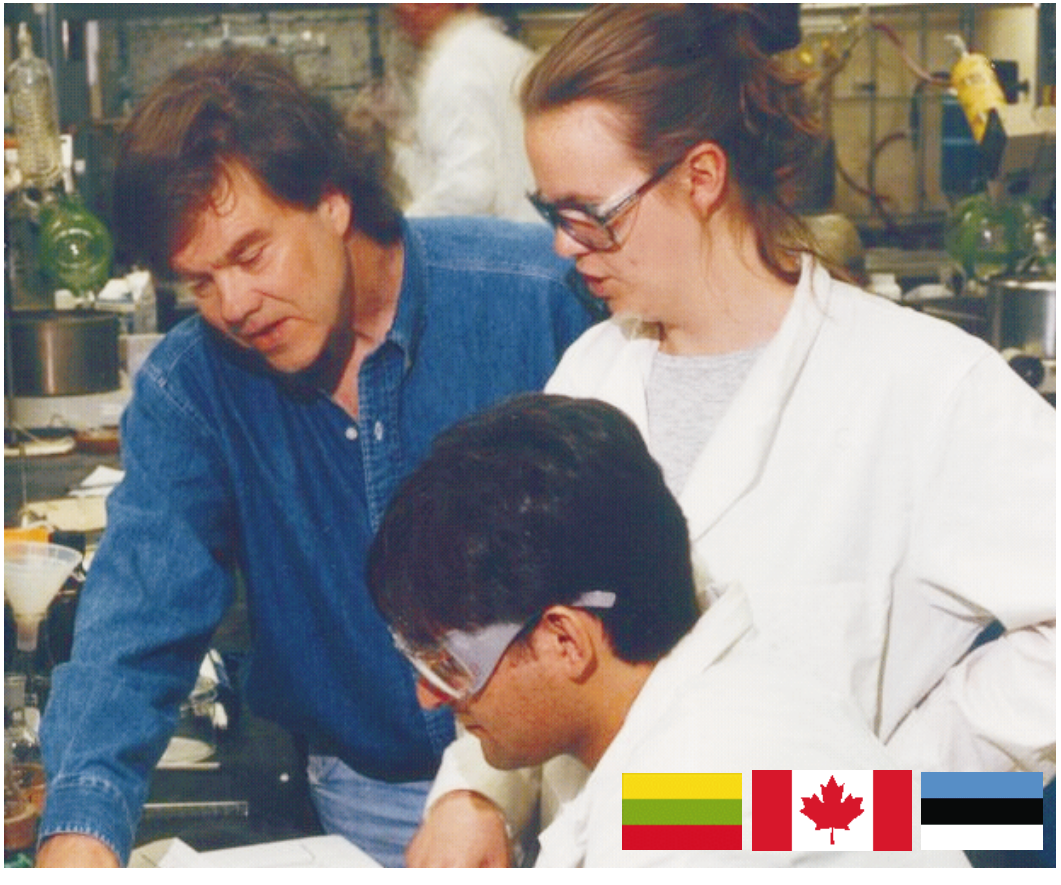
This issue is dedicated to

Professor Victor Snieckus

for his outstanding contributions to the field of synthetic organic chemistry



Associate Editors: R. Green and R. Kazlauskas

Le présent numéro est dédié au

Professeur Victor Snieckus

pour ses precieuses contributions au domaine de la chimie organique de synthèse

Directeurs scientifiques associés : R. Green et R. Kazlauskas

Professor Victor Snieckus

This Special Issue of The Canadian Journal of Chemistry honours the scientific accomplishments of Victor Snieckus. The contributions to this issue are indicative of the many researchers influenced by his chemistry and the number of areas on which he has had impact.

Victor was born in Kaunas, Lithuania, on Aug. 1, 1937 to an Estonian mother and a Lithuanian father. His early years were influenced by the onset of World War II; his family spent the war years in Germany, and immigrated to Canada in 1948, arriving in Foremost, AB, and ultimately settling in Calgary. Victor completed his B.Sc. (Honours) at the University of Alberta (1959), acquired an M.Sc. degree with D.S. Noyce at the University California, Berkeley (1961), and completed his Ph.D. degree with Virgil Boekelheide at the University of Oregon (1965). Following postdoctoral work with Ted Edwards at the NRC (1965–66), Victor then joined the University of Waterloo as an Assistant Professor, becoming an Associate Professor in 1971, and a Full Professor in 1979. From 1992–98, Victor held an NSERC–Monsanto Industrial Research Chair in Chemical Synthesis and Biomolecular Design. In 1998, he moved to Queen's University, where he was appointed to the inaugural Bader Chair in Organic Chemistry.

His early research career at Waterloo was focused on heterocyclic chemistry, particularly on the chemistry of the new 1,2-diazepine system. The realization of the practical synthetic potential of directed *ortho* lithiation of tertiary benzamides altered his direction permanently, beginning in 1978–79. Since this time, Victor has advanced the directed metalation (DoM) process to a point where it is commonly employed tactic in organic synthesis in both academic and industrial settings. He and his group have developed a number of directed metalation groups, particularly the *O*-aryl carbamate. En route, his group has discovered the anionic *ortho* Fries rearrangement, directed benzylic and remote metalation (DreM) and advanced new carbanionic chemistry of aliphatic amides and carbamates. As the DoM reaction matured, he linked the tactic to other processes such as cross-coupling reactions of several different types, radical cyclizations, and ring-closing metathesis. Throughout, his work has been characterized by a thoroughness of investigation and by the application of new methodological results to practical synthetic questions. In industrial labs, "let's do it by Snieckus chemistry" is an immediately understood phrase.

Victor has trained 61 graduate students, including 30 Ph.D.s, and has supervised over 70 postdoctoral fellows.[1] Group members will remember his endlessly positive style of motivation, his attention to detail and the literature, and a genuine interest in their progress after they leave the VS group. He is also known for his availability, patience, and willingness to talk to absolutely anyone on any subject, but especially to share and understand chemical ideas. As someone who interacts regularly and willingly with his students, Victor is renowned for group Christmas parties that invariably turn into road-hockey games, and for a suspiciously consistent inability to remember his wallet on trips to the Graduate Club.

Professeur Victor Snieckus

Ce numéro spécial du Journal canadien de chimie est publié pour rendre hommage aux réalisations scientifiques de Victor Snieckus. Les contributions contenues dans ce numéro mettent en relief l'importance du nombre des chercheurs qui ont été influencés par sa chimie et de la diversité des domaines sur lesquels il a eu un impact.

Victor est né à in Kaunas, en Lituanie, le premier août 1937, d'une mère estonienne et d'un père lithuanien. Ses jeunes années ont été marquées par la deuxième guerre mondiale pendant laquelle ses parents ont vécu en Allemagne avant d'immigrer au Canada en 1948, alors qu'ils sont arrivés à Foremost, AB, avant de s'établir à Calgary. Victor a obtenu un B.Sc. (Honours) à l'Université d'Alberta (1959), un M.Sc. à l'Université de la Californie, Berkeley (1961) pour des travaux effectués sous la direction de D. S. Noyce , et un Ph.D. de l'Université de l'Orégon (1965), pour des travaux réalisés sous la direction de Virgil Boekelheide. Après avoir effectué des travaux postdoctoraux au Conseil National de Recherches sous la direction de Ted Edwards (1965–66), Victor a été engagé comme Assistant professeur à l'Université de Waterloo où il est devenu professeur agrégé en 1971 et professeur titulaire en 1979. De 1992–98, Victor a été le titulaire d'une chaire de recherches industrielles CRSNG/Monsanto en synthèse chimique et en modélisation biomoléculaire. In 1998, il s'est déplacé vers l'Université Queens où il a été le premier titulaire de la nouvelle chaire Bader en chimie organique.

Ses travaux de recherches à l'Université de Waterloo étaient orientés vers la chimie hétérocyclique, principalement vers la chimie du nouveau système des 1,2-diazépines. À partir de 1978–79, la réalisation du potentiel pratique en synthèse des réactions de lithiation de benzamides tertiaires orientées en *ortho* l'a amené à modifier ces orientations d'une façon permanente. Depuis lors, Victor a tellement bien développé les réactions de métalations orientées («DoM») qu'elles sont maintenant utilisées d'une façon tactique, en synthèses organiques, tant dans les milieux académiques qu'industriels. Avec son groupe, il a mis au point un certain nombre de groupes permettant de réaliser des métalations orientés, en particulier le carbamate de *O*-aryle. En route, son groupe a découvert le réarrangement d'*ortho* Fries anionique, la métallation à distance et orienté par un groupe benzylique («DreM») et une nouvelle chimie carbanionique avancée des amides et des carbamates aliphatiques. Une fois la réaction «DoM» bien établie, il a lié cette tactique à d'autres processus, tels que les réactions de couplage croisé de plusieurs types différents, aux réactions de cyclisations radicalaires, et aux réactions de fermeture de cycle de métathèse. Tous ses travaux ont été caractérisés par des investigations minutieuses et par l'application de nouveaux résultats méthodologiques à des questions synthétiques pratiques. Dans les laboratoires industriels, la phrase "Faisons cela par la chimie de Snieckus" est immédiatement comprise.

Victor a dirigé les travaux de 61 étudiants gradués, y compris 30 au Ph.D. et il a supervisé les travaux de plus de 70 postdoctorants. Les membres de son groupe de recherche se souviennent de son style de motivation qui était toujours positif, de son attention aux détails et à la littérature ainsi qu'à son intérêt manifeste pour l'évolution de leur carrière une fois après avoir quitté le groupe VS. Il est aussi connu pour sa dis-

© 2001 NRC Canada

With the increased acceptance of the DoM strategy and its synthetic connections has come recognition in the form of awards which include the Alfred Bader Award (1993), Fellow, Royal Society of Canada (1993), Humbolddt-Forschungspreis (1996), R.U. Lemieux Award (1997), Fellow, Lithuanian Academy of Sciences (1999), Killam Fellowship (2000–01), ISHC Award in Heterocyclic Chemistry (2001), and the Cope Scholar Award (2001). He is the Organic Editor for the Canadian Journal of Chemistry, Editor for the American Continents for Synlett, and Topical Editor for Polycyclic Aromatic Compounds. In addition, he has contributed to the organic chemistry community as a member of the Editorial Board for Organic Process Research & Development, the Editorial Advisory Board of Advanced Synthesis and Catalysis, and as a past member of Editorial Advisory Board for the Journal of Organic Chemistry and Progress in Heterocyclic Chemistry. He was Chair of the International Conference in Heterocyclic Chemistry (1985) and Balticum Organicum Syntheticum (BOS 2000). Victor served as President of the International Society of Heterocyclic Chemistry (1985) and Chairman of the ACS Organic Division (1989–90). For over a decade, he has actively promoted closer interaction between the Canadian Society for Chemistry and the American Chemical Society. Most recently, he has been tireless in his efforts to assist in the exposure of the organic chemistry community of the Baltic States to Western chemists.

A long time before metalating (1966), Victor married Anne and they have two children, Darius and Naomi. He readily acknowledges his family's encouragement and support of his dedication to chemistry and particularly Anne, whose sustenance of VS groups over the years are cherished by all.

The article authors and the editors are pleased to offer this Special Issue. We anticipate continuing contributions of importance from his research group. Victor has every intention of exploring new directions of research, and mentoring many more young scientists (7 students are graduating as of this writing).

James R. Green

ponibilité et sa patience alors qu'il est toujours prêt à parler à quiconque de n'importe quel sujet, mais particulièrement pour échanger et comprendre des idées chimiques. Comme il s'agit d'une personne qui interagit d'une façon régulière et empressée, Victor est réputé pour les parties de Noël de son groupe qui se terminent toujours par des parties de hockey dans la rue ainsi que par son inhabilité proverbiale à oublier son portefeuille chaque fois qu'il se rend au Graduate Club.

Avec l'augmentation de l'acceptation de la stratégie «DoM» et de ses implications synthétiques, la valeur de ses travaux a été reconnue par des prix et des distinctions honorifiques: Alfred Bader Award (1993), Fellow, Royal Society of Canada (1993), Humbolddt-Forschungspreis (1996), R. U. Lemieux Award (1997), Fellow, Lithuanian Academy of Sciences (1999), Killam Fellowship (2000–01), ISHC Award in Heterocyclic Chemistry (2001) et la Cope Scholar Award (2001). Il est aussi éditeur pour le Journal Canadien de Chimie (organique), éditeur pour les continents américains pour Synlett, et Topical Editor pour Polycyclic Aromatic Compounds. De plus, il a contribué à la communauté de la chimie organique en agissant comme membre de l'Editorial Board de Organic Process Research & Development, d'Advanced Synthesis and Catalysis, and comme ancien membre de l'Editorial Advisory Board du Journal of Organic Chemistry et de Progress in Heterocyclic Chemistry. Il a été le président de la Conférence international de chimie hétérocyclique (1985) et du Balticum Organicum Syntheticum (BOS 2000). Victor a aussi agit comme Président de l'International Society of Heterocyclic Chemistry (1985) et comme président de la division organique de l'ACS (1989–90). Pendant plus de dix ans, il a travaillé activement à la promotion de meilleures interactions entre la Société canadienne de chimie et l'American Chemical Society. Plus récemment, il n'a pas ménagé ses efforts pour faire la promotion de la communauté de chimie organique des pays de la Baltique auprès des chimistes de l'Ouest.

Longtemps avant de procéder à des métalations (1966), Victor s'est marié à Anne et ils ont deux enfants, Darius et Naomi. Il est toujours fier de reconnaître tout le support et l'encouragement qui lui a été apporté par sa famille dans son attachement à la chimie, particulièrement celui d'Anne qui a si bien soutenu les groupes VS au cours des années, un support qui a été apprécié de tous.

Les auteurs des articles et les éditeurs sont heureux de lui offrir ce numéro spécial. Nous espérons que son groupe continuera à produire des contributions importantes. Victor compte bien explorer de nouvelles voies de recherche et de superviser plusieurs autres jeunes scientifiques (Au moment d'écrire cette introduction, il est encore entouré de sept étudiants gradués).

2001 E.W.R. Steacie Award Lecture The imido ligand in main group element chemistry[1]

Tristram Chivers

Abstract: The imido group (NR) is a versatile ligand in main group chemistry. The high reactivity of multiply bonded (terminal) imido derivatives of *p*-block elements is used, for example, in the aza-Wittig reaction, allylic aminations, and in peptide synthesis. As a bridging ligand, the imido group provides a cornerstone for a wide variety of binary cluster structures. This review is primarily concerned with the synthesis, structures, reactions, and ligand behaviour of imido derivatives of the heavy chalcogens (selenium and tellurium) as exemplified by the tellurium diimide dimer *t*-BuNTe(μ-N-*t*-Bu)$_2$TeN-*t*-Bu and the homoleptic trisimido-tellurite dianion $[Te(N\text{-}t\text{-}Bu)_3]^{2-}$. The synthesis and cluster structures of alkali metal and alkaline earth metal derivatives of heteroleptic imido-oxo anions of sulfur, e.g., $[O_xS(NR)_{3-x}]^{2-}$ (x = 1, 2) and $[O_2S(\mu\text{-}NPh)SO_2]^{2-}$, are also discussed.

Key words: main group chemistry, imido ligand, chalcogens.

Résumé : Le groupe imido est un ligand versatile dans la chimie du groupe principale. On utilise, par exemple, la grande réactivité des dérivés imido à liaisons multiples (terminaux) des éléments du bloc-p dans la réaction aza-Wittig, les aminations allyliques et en synthèse peptidique. Comme ligand formant un pont, le groupe imido est la pierre angulaire d'une grande variété de structures binaires d'agrégats. Cette revue est orientée principalement vers la synthèse, les structures, les réactions et le comportement comme ligand de dérivés imido de chalcogènes lourds (sélénium et tellure) tels que représentés par le dimère du diimide de tellure, *t*-BuNTe(μ-N-*t*-Bu)$_2$TeN-*t*-Bu, et le dianion trisimido-tellurite homoleptique, $[Te(N\text{-}t\text{-}Bu)_3]^{2-}$. On discute aussi de la synthèse et des structures des agrégats des dérivés des métaux alcalins et alcalino-terreux des anions imido-oxo hétéroleptiques du soufre, par exemple $[O_xS(NR)_{3-x}]^{2-}$ (x = 1, 2) et $[O_2S(\mu\text{-}NPh)SO_2]^{2-}$.

Mots clés : chimie du groupe principal, ligand imido, chalcogènes.

[Traduit par la Rédaction]

Introduction

The work described in this account began with the discovery of the first tellurium diimides about 7 years ago (1–3). Investigations of the reactivity of these multiply bonded species led to the generation of some of the first examples of homoleptic polyimido anions of the *p*-block elements in the form of chalcogen-centered anions that are isoelectronic with common oxo anions such as tellurite, selenite, or sulfite (4–6). As a natural extension, we have also studied the related imido-oxo systems (7–8).

The emphasis in this work initially was on the structures of the multiply bonded systems and the clusters that are formed by alkali metal derivatives of the homoleptic and heteroleptic anions with the long-term goal of being able to control the formation of extended structures with specific cavity sizes (9). In addition to their structural interest, these cluster systems are noteworthy as precursors of intensely coloured, long-lived radicals and the anions themselves, especially in the case of tellurium, have an extensive coordination chemistry involving metal complexes that are potential single-source precursors to semiconducting metal chalcogenides.

By way of introduction, let us begin by considering the properties and applications of multiply bonded imido derivatives of *p*-block elements. Monomeric iminoboranes RB=NR′ are metastable at room temperature and convert to cyclic oligomers in a few days even when the organic groups attached to boron and nitrogen are bulky (10). Very recently, monomeric imides of the heavier group 13 elements aluminum and gallium have been stabilized by the use of extremely bulky groups on nitrogen and the metal (11). Certain carbodiimides, e.g., CyN=C=NCy, are commercially available reagents that are widely used as coupling reagents in peptide synthesis. Such reagents are familiar to organometallic chemists as a source of amidinate ligands by reaction with organolithium reagents (12, 13). Iminophosphoranes (R_3P=NR′) are useful

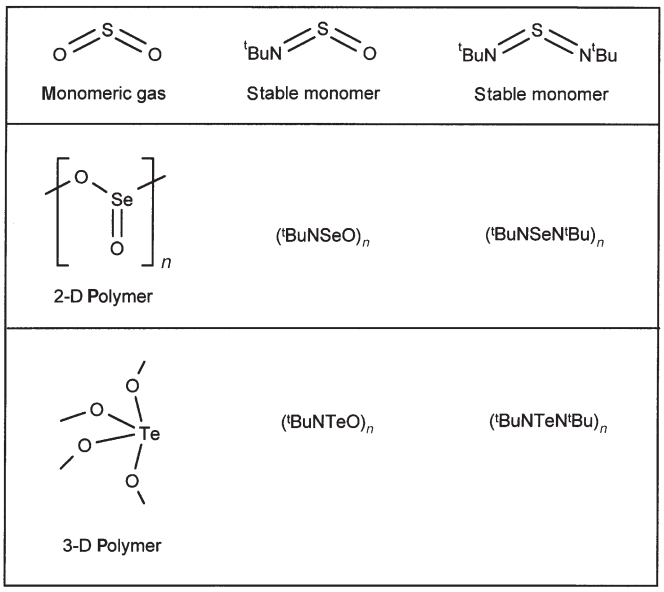
Fig. 1. The imido ligand (NR) as a cornerstone in cluster structures.

for the conversion of carbonyl to imido functionalities in the so-called aza-Wittig reaction (14). Sulfur diimides (RN=S=NR) are versatile ligands that adopt several different bonding modes towards transition metals (15) and the selenium analogues have been utilized for allylic aminations (16).



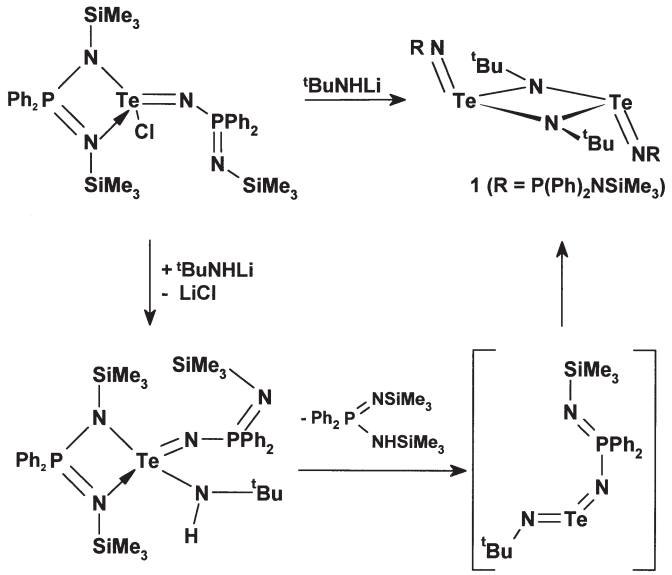
The imido ligand may also participate in a variety of cluster structures as illustrated by the selected examples of binary systems shown in Fig. 1. A cubic arrangement is characteristic of the group 14 imides as exemplified by the *tert*-butylimidotin tetramer (17). Magnesium anilide adopts a hexameric structure in the form of a hexagonal prism (or cyclic ladder) (18). The imidoalanes form an especially rich series of clusters compounds depending on the size of the substituent attached to aluminum or nitrogen (19), e.g., an octamer that can be viewed as a face-to-face dimer of a cube and an 18-atom cage, which is related to a hexagonal prism via insertion of three monomer units between the hexagonal faces.

Selenium and tellurium diimides

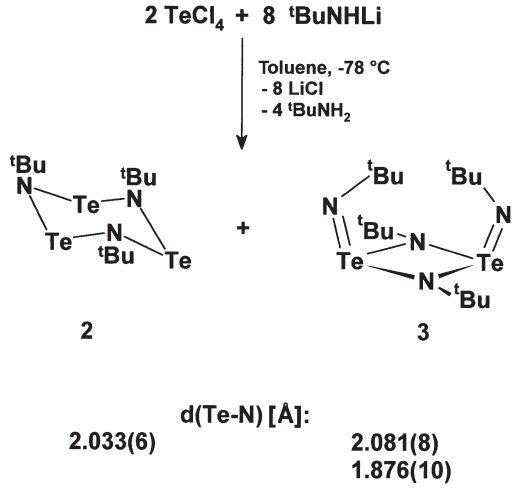
Chalcogen diimides are isoelectronic with the well-known chalcogen dioxides, which exhibit structural trends that reflect the preference of the heavier chalcogens for the formation of single bonds (Scheme 1). Sulfur dioxide is a monomer whereas the heavier chalcogen congeners adopt either two- or three-dimensional polymeric structures. Sulfur diimides invariably form monomers with formal S=N double bonds. At the beginning of our work, selenium diimides RN=Se=NR (*R* = *t*-Bu, *t*-Oct) (20) and the hybrid imido-oxo system *t*-BuNSeO (21) had been obtained as thermally unstable yellow oils, but they had not been structurally characterized in the solid state. Tellurium diimides of the type $(RN{=}Te{=}NR)_n$ (R = alkyl, aryl) were unknown.

The first tellurium diimide **1** was discovered accidentally when Dr. Gao was investigating the reactions of a hybrid PN–TeN ring system. As illustrated in Scheme 2, an attempt to replace the Cl substituent on tellurium with a *tert*-butylimido group resulted in the formation of a tellurium diimide dimer as the *trans*-isomer (1). It is reasonable to assume that the first step in this transformation involves nucleophilic displacement

Scheme 1.



of chloride by the *t*-BuNH group. Subsequent elimination of the imido–amido phosphorane $Ph_2P(NSiMe_3)(NHSiMe_3)$, which was identified by ^{31}P NMR, yields the putative tellurium diimide monomer, which spontaneously associates to give the observed dimer **1**. Interestingly, the *trans* isomer isomerizes to the *cis*-isomer in solution over a period of 1 day (3).



Following this discovery, Dr. Gao was able to show that a symmetrical tellurium diimide, with *tert*-butyl groups attached to both nitrogen atoms, could be obtained by the reaction of tellurium tetrachloride with *tert*-butylamidolithium in the appropriate stochiometry (Scheme 3). When this reaction is carried out in toluene some reduction of tellurium(IV) to tellurium(II) occurs to give the cyclic tellurium imide $(TeN\text{-}t\text{-}Bu)_3$ **2** (2). This minor product is a six-membered ring in the chair conformation with Te—N bond lengths in the range expected for single bonds. Interestingly, the tellurium diimide dimer **3** is obtained as the *cis*-isomer with terminal

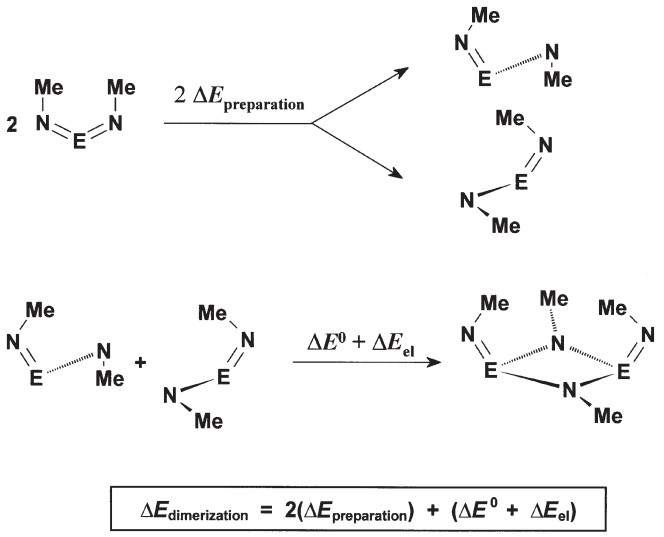
Scheme 2.

Scheme 3.

tert-butyl groups in the *endo,endo* conformation. The TeN bond lengths are consistent with double bonds for the terminal imido groups and single bonds for the bridging imido groups. This orange compound exhibits remarkable thermal stability for a tellurium–nitrogen compound. It can be sublimed without decomposition at 95°C. When THF is used as the solvent for this reaction, the yield of **3** is ca. 80% and the cyclic tellurium(II) imide **2** is not formed (22).

To gain some insight into the different structures of chalcogen diimides, Nicole Sandblom carried out Density Functional Theory calculations on the dimerization of model systems with methyl groups attached to the nitrogen atoms, i.e., MeN=E=NMe (E = S, Se, Te) (23). The dimerization process can be viewed in two steps (Scheme 4). The first involves distortion of two monomeric systems and the stretching of one of the Te=N double bonds in each monomer. The second step includes both a steric and an electronic component. The calculations show that formation of a tellurium diimide dimer is strongly exothermic (ΔE = –82.9 kJ mol^{-1}) whereas

Scheme 4.



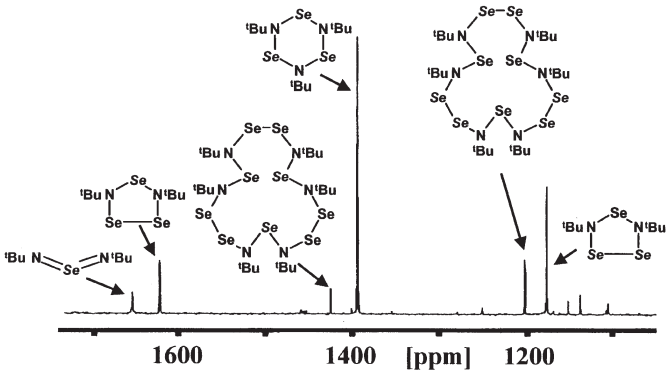


Fig. 2. ^{77}Se NMR spectrum of *t*-BuNSeN-*t*-Bu in toluene at 20°C after 2 days. Peak assignments are designated by *Se* atoms in italics.

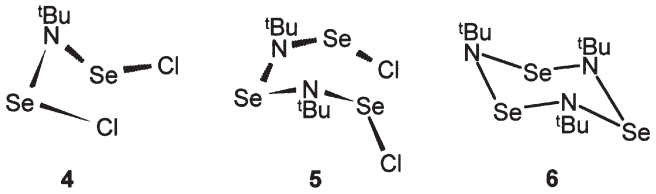
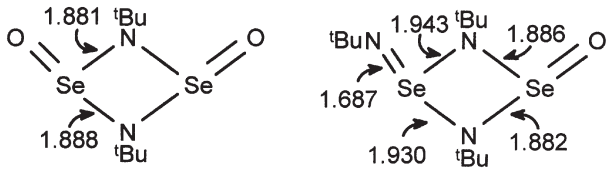


the dimerization energy for the sulfur analogue is endothermic (ΔE = +34.9 kJ mol^{-1}), consistent with experimental observations. Interestingly, the calculated dimerization energy for the corresponding selenium diimide is approximately thermoneutral (ΔE = –2.8 kJ mol^{-1}), so it was not clear from the calculations whether a monomeric or a dimeric structure will be preferred.

In the light of this uncertainty, it is appropriate to turn now to a consideration of selenium imides. In addition to $SeCl_4$, we have the advantage in selenium chemistry of the availability of pure $SeCl_2$, which Arto Maaninen has shown to be stable in THF solution (24). Tellurium dichloride is not available as a stable reagent in the absence of donor ligands such as thioureas. The reaction of selenium dichloride with *tert*-butylamine is noteworthy for two reasons. Firstly, it gives rise to the imidoselenium dihalides **4** and **5**, which represent the first two members of a new class of compounds in chalcogen–nitrogen chemistry (25). Secondly, an increase in the amount of *tert*-butylamine leads to the formation of the six-membered ring (SeN-*t*-Bu)$_3$ (**6**), which has a chair structure like the tellurium analogue **2** and exhibits a characteristic ^{77}Se NMR resonance at ca. 1400 ppm. The characterization

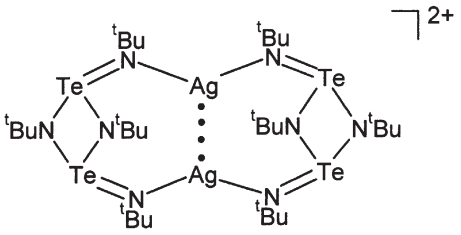
© 2001 NRC Canada



of **2** enabled us to identify the products of decomposition of the corresponding selenium(IV) diimide.

4 **5** **6**

Tiina Maaninen monitored the decomposition of the selenium diimide *t*-BuN=Se=N-*t*-Bu by ^{77}Se NMR and the spectrum of the mixture of products that is obtained after 2 days at 20°C is shown in Fig. 2 (26). The resonance for the selenium diimide had almost disappeared after this time. The major product is the six-membered ring **6**, which is readily evident from the central resonance at ca. 1400 ppm. It can be isolated from the reaction mixture by fractional crystallization. The other two major products are ring systems containing both diselenido and monoselenido bridges between imido groups. The 15-membered ring is a known compound, previously reported by Roesky et al. (27). The second, more abundant, oligomer is a new compound that we have tentatively identified as a five-membered (or, less likely, a 10-membered) ring (26).

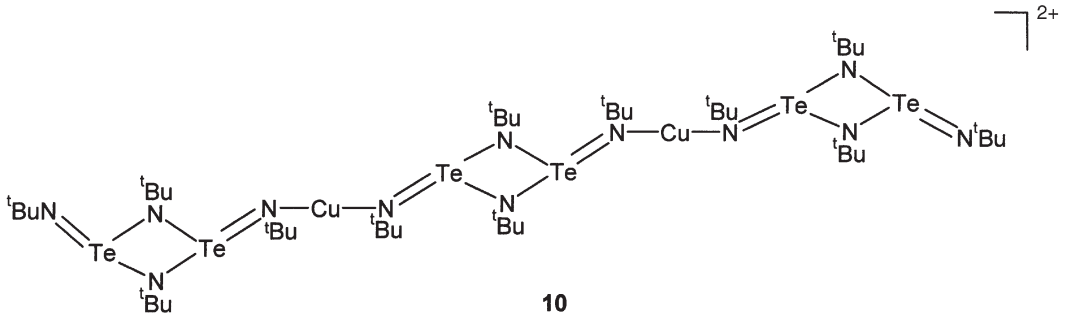


Although we know what happens when *t*-BuNSeN-*t*-Bu decomposes, the solid-state structure of this low-melting chalcogen diimide has not yet been determined. Our Finnish collaborators have, however, been able to show that the symmetrical and asymmetrical imido-oxo systems **7**[3] (1) and **8** (26), respectively, both exhibit dimeric structures with long, presumably weak, bridging selenium–nitrogen bonds. Although the values of 1.88 to 1.89 Å in the symmetrical system **7** are only slightly longer than the expected single bond value of 1.85 Å (28), the bridging SeN bonds adjacent to the terminal *tert*-butylimido group in the unsymmetrical system **8** are elongated to 1.93 to 1.94 Å. These recent findings lead to the suggestion that the corresponding selenium diimide (*t*-BuNSeN-*t*-Bu) may be a weakly associated dimer in the solid state.

7 **8**

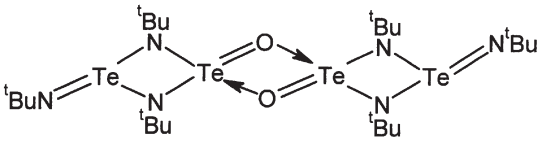
Let us return now to the tellurium diimide dimers. We have seen that these potentially interesting ligands can form *trans*- or *cis*-isomers in the solid state. In the two examples that have been structurally characterized (**1** and **3**), the terminal R groups adopt an *endo,endo* arrangement (1–3). Other isomers in which one or both of the terminal imido groups adopt an *exo* orientation can be envisaged (Fig. 3). This versatility leads to the prediction that these imido systems could behave as either bridging or chelating ligands towards metal centres. The complexes of the tellurium diimide dimer **3** with coinage metals provide a nice illustration of this versatility (29).

Dr. Schatte has shown that the reaction of the *cis*-dimer **3** with silver triflate produces complex **9** in which the ligand retains the *cis* geometry, but the terminal *tert*-butyl groups flip to the *exo* positions. The two Ag^+ ions bridge the terminal N-*t*-Bu groups of two ligands. Alternatively, this complex can be viewed as involving chelation of both ligands to an Ag^{2+} unit. Indeed, the structural parameters indicate some sort of attractive force between the two Ag^+ ions in this complex; in particular, the bond angle ∠ N-Ag-N is distinctly nonlinear (163°) (for a discussion of d^{10}–d^{10} metallophilic interactions see ref. 30). A different type of behaviour is observed for the reaction of **3** with copper triflate. In this case, the product **10** contains two Cu^+ ions bridging three dimeric tellurium diimide ligands. Most significantly, the central ligand adopts the *trans (exo,exo)* conformation, while the two terminal ligands retain the *cis* geometry, but with *exo,endo* terminal substituents. Thus, it appears that Cu^+ ions promote the *cis* → *trans* isomerization of **3**. Complex **10** can be viewed as a small section of a polymeric chain in which Cu^+ ions bridge alternating *cis* and *trans*-isomers of **3**. Interestingly, hydrolysis of this copper complex results in the replacement of one terminal *tert*-butylimido group in the tellurium diimide dimer by an oxo ligand to give [*t*-BuNTe(μ-N-*t*-Bu)$_2$Te(μ-O)]$_2$ (**11**) complexed via terminal N-*t*-Bu groups to two Cu^+ ions. Unlike the selenium analogue **7**, **11** forms a dimer with a central, unsymmetrical Te_2O_2 ring (31).



9

Another interesting feature of the chemistry of tellurium diimide dimer **3** involves the reactions with heteroallenes as illustrated by the example of *tert*-butyl isocyanate (Scheme 5). With equimolar amounts of **3** and *t*-BuNCO, Dr. Schatte showed that a ureato ligand is generated in a manner reminiscent of the behaviour of certain transition-metal imides (32). The product (**12**) of this reaction can be viewed as the result of a [2 + 2] cycloaddition of a tellurium diimide monomer and the isocyanate. In the presence of an excess of *tert*-butyl isocyanate, the ureato telluroxide **13** is formed, formally by the replacement of a terminal imido group in **12** by an oxo ligand. This transformation brings to mind the behaviour of iminophosphoranes in the aza-Wittig reaction (14). The telluroxide **13** has a dimeric structure in which the ureato ligands adopt a *cis* arrangement with respect to the central Te_2O_2 ring. In the solid state **13** forms an extended helical network via weak ›C=O···Te interactions (Te···O = 3.020(2) Å) (33).



The tellurium diimide dimer **3** also readily undergoes redistribution with tellurium tetrahalides in THF to give *tert*-butylimidotellurium dihalides (22). Nicole Sandblom

has shown that the dichloride **14** is obtained in essentially quantitative yield as mica-like golden crystals by this reaction (Scheme 5). In the solid state, **14** exists as a hexamer in which three dimeric units are connected by chloride bridges (22). More importantly, this new class of compound is a potentially useful reagent for extending tellurium–nitrogen chemistry via nucleophilic replacement of the chloride ligands. For example, the reaction of the dichloride with 2 equiv of potassium *tert*-butoxide produces the corresponding bis(*tert*-butoxy) derivative **15**, which is a weakly associated dimer in the solid state (22). The geometry at tellurium in **15** is that of a distorted trigonal bipyramid with the lone pair in one of the equatorial positions. Most significantly, there is a large difference, ca. 0.27 Å, between the axial and equatorial Te—N bond lengths. In particular, the value of 1.94 Å for the equatorial TeN bonds suggests that the monomeric units retain substantial double bond character in the dimer as depicted by the schematic drawing of **15** in Scheme 5. Accordingly, the generation of a monomeric tellurium imide by the attachment of even more bulky alkoxy or aryloxy groups to tellurium seems feasible.

Trisimidochalcogenite anions

The tellurium diimide dimer **3** is, as expected, readily susceptible to nucleophilic attack at the tellurium centre. Thus, the reaction of **3** with potassium *tert*-butoxide generates the pyramidal *tert*-butoxybis(*tert*-butylimido)tellurite anion $[Te(N\text{-}t\text{-}Bu)_2(O\text{-}t\text{-}Bu)]^-$ (34). In the solid state, as its potassium salt, this anion adopts the dimeric arm-chair structure **16** with five-coordinate K^+ ions (Scheme 6). A similar type of behaviour is observed in the reaction of **3** with lithium *tert*-butylamide. In this case, however, the final product is the tris(*tert*-butylimido)tellurite dianion, isoelectronic with

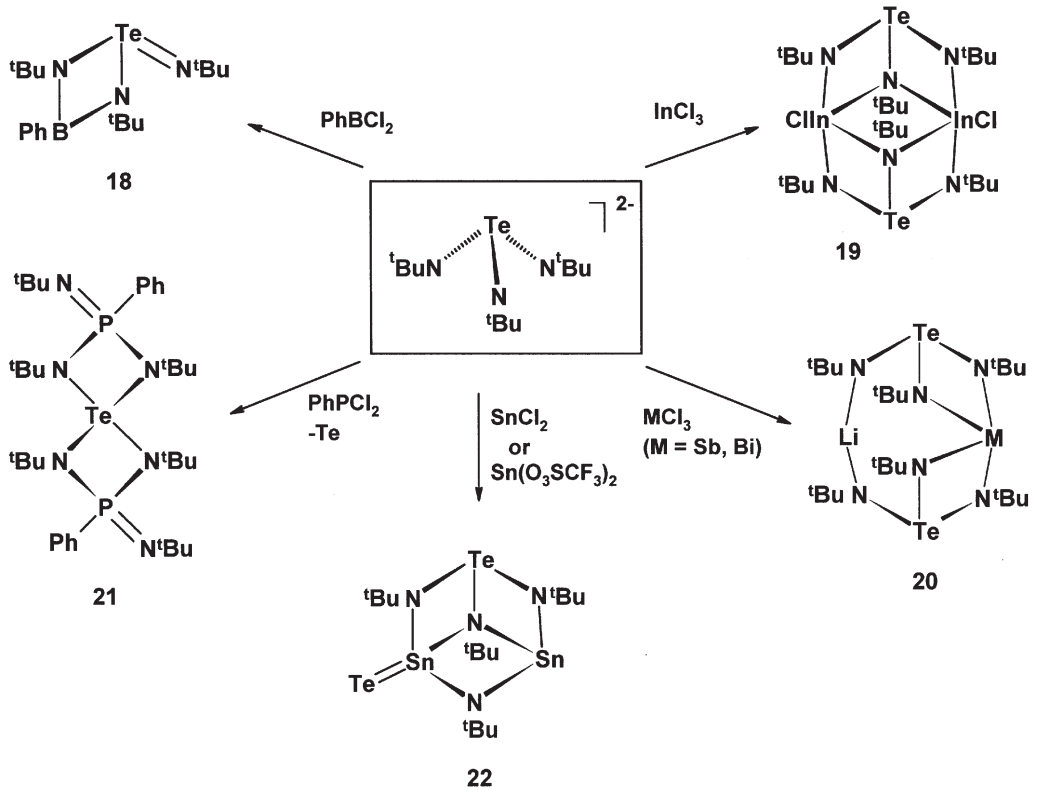
Scheme 6.

the tellurite ion TeO_3^{2-} (4). As its dilithium derivative, this dianion forms the dimer **17** with a hexagonal prismatic (or cyclic ladder) structure (Scheme 6). By analogy with the reaction with potassium *tert*-butoxide, the formation of this cluster likely involves the initial formation of the monoanion $[Te(N\text{-}t\text{-}Bu)_2(NH\text{-}t\text{-}Bu)]^-$, which is subsequently deprotonated by lithium *tert*-butylamide to give the pyramidal tris(*tert*-butylimido) tellurite dianion.



A similar approach can be used to prepare the sulfur and selenium analogues of the tris(*tert*-butylimido)tellurite dianion (5, 6). The dilithium derivatives of these dianions are made by the reaction of the chalcogen diimide with the appropriate amount of lithium *tert*-butylamide in a hydrocarbon solvent (eq. [1]). These ternary cluster systems also adopt hexagonal prismatic structures, which are more distorted than that of the tellurium analogue as a result of the shorter chalcogen—nitrogen distances. Stalke and co-workers (6) reported the characterization of the sulfur analogue while we described the selenium system (5).

$$[1] \qquad 2t\text{-BuN=E=N-}t\text{-Bu} + 4\text{LiNH-}t\text{-Bu} \xrightarrow[-78°C]{\text{toluene}} [Li_2E(N\text{-}t\text{-}Bu_3)_3]_2 + 2t\text{-BuNH}_2 \quad (E = S, Se)$$

A fascinating feature of these cluster systems is the formation of intensely coloured solutions upon exposure of hydrocarbon solutions to oxygen. For example, a deep blue colour is immediately apparent if a solution of $[Li_2S(N\text{-}t\text{-}Bu)_3]_2$ is allowed to come in contact with a trace of air (6, 8, 35). The EPR spectra of these coloured solutions show essentially the same pattern for both the sulfur and selenium systems (8, 35) (Fig. 4). The spectra consist of a septet of decets and the simulated spectra show a good fit for coupling of the unpaired

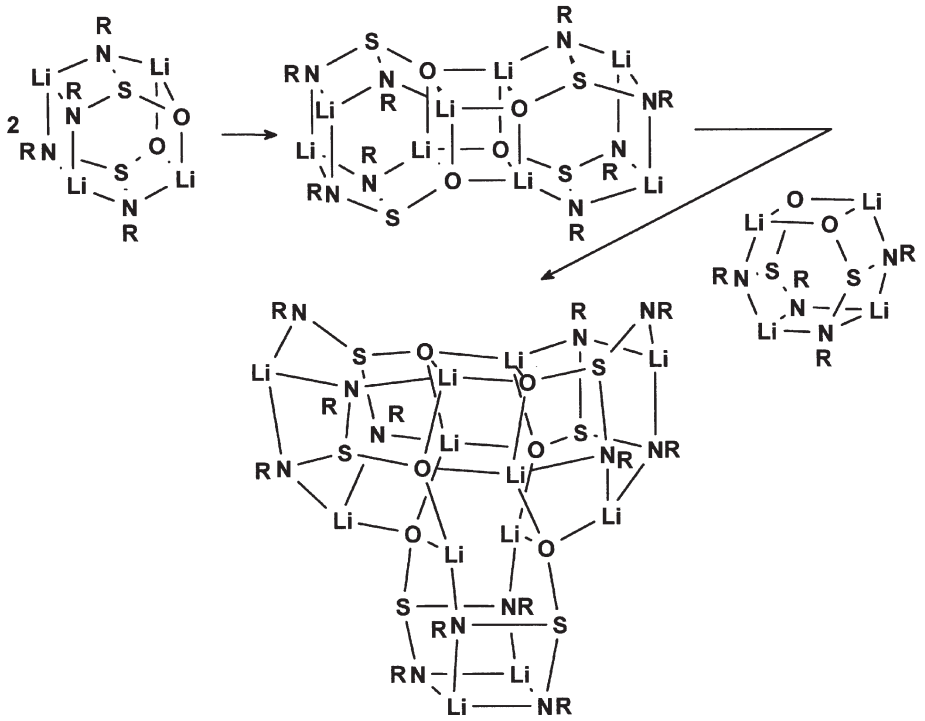
electron with three equivalent ^{14}N nuclei (I = 1), which gives rise to a 1:2:3:4:3:2:1 septet, and three equivalent ^{7}Li nuclei (I = 3/2), which generates the decet. On the basis of these EPR data, it has been suggested that the one-electron oxidation of these clusters is accompanied by the removal of one Li^+ ion from the hexagonal prism to give a neutral radical that consists of a radical anion and a dianion bridged by the remaining three Li^+ ions (8, 35) (Fig. 4).



In view of the facile oxidation of the tris(*tert*-butylimido) sulfite dianion it is not surprising that Fleischer and Stalke (36) have found that attempts to coordinate this tripodal ligand to metal centres frequently result in redox behaviour. On the other hand, our results show that the tris(*tert*-butylimido)tellurite dianion has a rich coordination chemistry as illustrated in Scheme 7, although redox processes are sometimes observed. For example, this pyramidal dianion reacts with $PhBCl_2$ to give the *N*,*N*′-chelated complex **18** (4), which is an unique example of a monomeric tellurium imide apparently stabilized by the dianionic boramidinato ligand $[PhB(N\text{-}t\text{-}Bu)_2]^{2-}$ (37). The dimeric cluster **19**, obtained from the reaction with $InCl_3$, involves a second chelation of the tris(*tert*-butylimido)tellurite ligand to the other monomeric unit to give five-coordinate indium centres in an arm-chair structure.[4] The tris(*tert*-butylimido)tellurite ligand also chelates to heavier group 15 centres in the complexes **20** (M = Sb, Bi) in which the terminal N-*t*-Bu groups are bridged by the Li^+ counter-ion (38). By contrast, redox behaviour is observed in the reaction of $[Te(N\text{-}t\text{-}Bu)_3]^{2-}$ with phenyldichlorophosphine (4). In this reaction, half of the tellurium is reduced to tellurium metal while the two phosphorus atoms are oxidized from the +3 to the +5 oxidation state to give **21**, a spirocyclic complex of tellurium(IV) chelated by two tris(*tert*-butylimido)phenylphosphonate ligands ($[PhP(N\text{-}t\text{-}Bu)_3]^{2-}$). To our knowledge, this is the first example of a complex of this dianion, which is isoelectronic with the well-known phenylphosphonate ligand $[PhPO_3]^{2-}$.

An especially intriguing outcome of a redox process results from the reaction of the tris(*tert*-butylimido)tellurite dianion with tin(II) chloride or triflate (39). The pyramidal ligand can be readily discerned in the complex **22** (Scheme 7) bridging two tin atoms in different oxidation states, one of which is attached to a terminal telluride. This is the first stannatellurone that involves four-coordinate tin; the only previous example of this particular type of "heavy ketone" has a five-coordinate tin centre (40). The overall redox process for the formation of **22** involves the six-electron reduction of one tellurium(IV) centre to tellurium (-II) (telluride), accompanied by oxidation of one tin atom from +2 to +4 and the formation of *tert*-butyldiazene from the oxidation of two *tert*-butylimido ligands (Scheme 8). The SnTe bond length of 2.59 Å is, as expected, a little shorter than the value of 2.62 Å reported by Leung et al. (40) for the related

complex with five-coordinate tin. It is also predictably somewhat longer than the value of 2.54 Å calculated for the prototypical three-coordinate stannatellurone ($H_2Sn{=}Te$), derivatives of which are not known (41).

Heteroleptic imido-oxo anions of chalcogens

A logical sequel to investigations of homoleptic polyimido anions of chalcogens is the study of heteroleptic systems in which both imido groups and oxo ligands are attached to the central *p*-block element, e.g., sulfur. The synthetic methodology used to prepare bisimidosulfites is similar to that used for trisimidochalcogenites. Justin Brask has shown that the dithium derivatives are obtained in excellent yields by the reaction of a sulfinylamine with two equivalents of the lithium derivative of a primary amine (eq. [2]) (7). This is a versatile route that can be applied to a variety of R and R′ groups. Our initial interest was in the structures of the clusters formed by dilithium derivatives of bisimidosulfites. In particular, what is the effect of replacing one of the bulky N-*t*-Bu groups in $[Li_2E(N\text{-}t\text{-}Bu)_3]_2$ (E = S, Se, Te) by an oxo ligand? Does changing the R group have an additional structural effect? Preliminary answers to those questions have been obtained from the structural characterization of two derivatives (7).

[2] $$RNSO + 2LiNHR' \xrightarrow[-78°C]{\text{toluene}} \{Li_2[OS(NR)(NR')]\}_n + R'NH_2$$

The heteroleptic system containing two N-*t*-Bu groups and one oxygen atom attached to sulfur forms a hexameric 36-atom cluster $\{Li_2[OS(N\text{-}t\text{-}Bu)_2]\}_6$ (**23**, R = *t*-Bu) (Fig. 5). Perusal of the structure of **23** reveals that aggregation has occurred through the lithium—oxygen bonds, all of which are in the centre of the molecule while the lipophilic N-*t*-Bu groups occupy the peripheral positions. A closer look suggests that this self-assembly process involves the trimerization of hexagonal prisms as depicted in Fig. 5. The observed structure can be derived from three hexagonal prisms in which the lithium—oxygen bonds, i.e., the most polar bonds, are juxtaposed to give a four-membered Li_2O_2 face in each unit. Aggregation of two of these fundamental building blocks by their Li_2O_2 faces formally generates a dimer. The interposition of the Li_2O_2 face of a third hexagonal prism gives rise to the 36-atom cluster **23** with a central Li_6O_6 scaffold.

Interestingly, the subtle change of replacing one of the *t*-Bu groups in the bis(*tert*-butylimido)sulfite dianion by a trimethylsilyl group has a remarkable effect on the cluster structure. Like **23**, the cluster $\{Li_2[OS(N\text{-}t\text{-}Bu)(NSiMe_3)\}_6$ (**24**) is hexameric and involves 36 atoms. In this case, however, the fundamental building block is an 18-atom cluster reminiscent of the nonameric alumoxane system shown in Fig. 1 (42). The cluster **24** can be viewed to result from the face-to-face dimerization of two of these building blocks via their Li_3O_3 faces. Thus, the common feature of the cluster structures **23** and **24** is self-assembly via highly polar, sterically unencumbered lithium–oxygen faces of smaller building blocks.

Unsymmetrical bisimidosulfites containing an arylimido group can be generated by using magnesium anilide as the source of the arylimido group. For example, the reaction of $[Mg(NPh)]_6$ with *t*-BuNSO generates the dimer **25** (43). More interesting, however, is the reaction of the hexameric magnesium anilide with an excess of sulfur dioxide which produces the 48-atom cluster **26** (Scheme 9) (43). The insertion of a single SO_2 molecule into a metal-amide bond is a known process, e.g., for Me_3SnNMe_2 (44). The cluster **26** is formally derived from six double insertions of SO_2 molecules into the magnesium-nitrogen bonds of the hexamer $[Mg(NPh)]_6$, which generates the novel imidodisulfite dianion $[O_2S(\mu\text{-}NPh)SO_2]^-$ (**27**). Each of these dianions bridges two Mg^{2+} cations in the observed hexameric cluster **26**.

The next phase of this work is to determine whether extended structures can be generated from building blocks which contain two Li_2O_2 or Li_3O_3 faces as depicted in Scheme 10. These structural units can be anticipated for lithium derivatives of monoalkylimidosulfites, which are readily prepared by reaction of SO_2 with 2 equiv of the lithium derivative of a primary amine (8). The products of these reactions have not yet been structurally characterized primarily because of their tendency to form gels in organic solvents, an observation that may indicate the formation of extended structures with the incorporation of solvent molecules. This intriguing prospect and the synthesis of alkylimido analogues of aluminophosphates, for which it may be able to control cavity size by suitable variations in the R group attached to nitrogen, is currently being pursued.

Acknowledgements

I wish to thank all members of my research group for their dedicated work, especially Dr. X. Gao, Dr. G. Schatte, Justin Brask, Arto Maaninen, Tiina Maaninen, and Nicole Sandblom for their contributions to the experimental studies described in this account. Collaboration with Professor Risto Laitinen (selenium chemistry) has been especially fruitful. The expertise of Professors R.T. Boeré and B. McGarvey (EPR spectroscopy), Professor T. Ziegler (DFT calculations), and the invaluable assistance of X-ray crystallographers Drs. M. Parvez and G. Schatte (University of Calgary), Dr. R. MacDonald (University of Alberta), Dr. G.P.A. Yap (University of Ottawa), and Dr. G. Enright (NRC, Ottawa) have been pivotal in our work on chalcogen imide chemistry. The continued financial support of the Natural Sciences and Engineering Research Council of Canada (NSERC) is gratefully acknowledged.

Geometric and solvent effects on intramolecular phenolic hydrogen abstraction by carbonyl *n*,π* and π,π* triplets

Edward C. Lathioor and William J. Leigh

Abstract: The photochemistry of a series of alkoxyacetophenone, -benzophenone, and -indanone derivatives, which contain a remote phenolic group linked to the ketone by a *para*,*para*′- or *meta*,*meta*′-oxyethyl spacer, has been studied in acetonitrile and dichloromethane solutions using laser flash photolysis techniques. The corresponding methoxy-substituted compounds and, in the case of the alkoxyindanones, derivatives bearing just a remote phenyl substituent, have also been examined. The triplet lifetimes of the phenolic compounds are determined by the rates of intramolecular abstraction of the remote phenolic hydrogen, and depend on the solvent, the geometry of attachment and the configuration of the lowest triplet state. In contrast to the large (>500-fold) difference in lifetime of the *para*,*para*′- and *meta*,*meta*′-alkoxyacetophenone derivatives, both of which have lowest π,π* triplet states, smaller differences are observed for the alkoxyindanone (lowest charge transfer triplet, ~twofold difference) and alkoxybenzophenone (lowest *n*,π* triplet, ~18-fold difference) derivatives in acetonitrile solution. The triplet lifetimes of the acetophenone and benzophenone are significantly shorter in dichloromethane than in acetonitrile, consistent with the intermediacy of a hydrogen-bonded triplet exciplex in the reaction. This is not the case with the *para*,*para*′-indanone derivative, sugesting that hydrogen abstraction in this compound is dominated by a mechanism involving initial charge transfer rather than hydrogen bonding. This is most likely due to orientational constraints that prevent the remote phenolic -O-H group from adopting a coplanar arrangement with the *n*-orbitals of the carbonyl group.

Key words: photochemistry, aromatic ketone, phenol, triplet, intramolecular, quenching, hydrogen abstraction, phenoxyl radical, kinetics, kinetic isotope effect, laser flash photolysis.

Résumé : Faisant appel à des techniques de photolyse éclair au laser et opérant dans des solutions d'acétonitrile et de dichlorométhane, on a étudié la photochimie d'une série de dérivés alkoxyacétophénones, -benzophénones et -indanones comportant un groupe phénolique dans une position éloignée, mais liée à la cétone par un espaceur oxyéthyle en *para*,*para*′- ou *méta*,*méta*′-. On a aussi étudié les composés correspondants portant des substituants méthoxy ainsi que, dans le cas des alkoxyindanones, des dérivés ne portant qu'un substituant phényle en position éloignée. On a déterminé les temps de vie du triplet des composés phénoliques à partir des vitesses d'enlèvement intramoléculaire de l'hydrogène phénolique éloigné; ils dépendent du solvant, de la géométrie de fixation et de la configuration de l'état triplet le plus bas. Par opposition à la grande différence (>500 fois) dans les temps de vie des dérivés *para*,*para*′- et *méta*,*méta*′-alkoxyacétophénones qui ont tous les deux des états triplets π,π* plus faibles, on observe des différences plus faibles pour les dérivés alkoxyindanones (triplet de transfert de charge le plus faible; différence du simple au double) et alkoxybenzophénones (triplet *n*,π* le plus faible; différence correspondant à une réaction environ 18 fois plus rapide) dans une solution d'acétonitrile. Les temps de vie des dérivés de l'acétophénone et de la benzophénone sont beaucoup plus courts en solution dans le dichlorométhane que dans l'acétonitrile; ce résultat ets en accord avec une réaction se produisant par l'intermédiaire d'un exciplex triplet avec liaison hydrogène. Ce n'est pas le cas pour le dérivé *para*,*para*′-indanone et ce résultat suggère l'enlèvement de l'hydrogène dans ce composé est dominé par un mécanisme impliquant dans un premier temps un transfert de charge plutôt que la formation d'une liaison hydrogène. Cette différence résulte vraisemblablement de contraintes qui font que le groupe -O-H phénolique éloigné ne peut s'orienter dans un arrangement coplanaire avec les orbitales *n* du groupe carbonyle.

Mots clés : photochimie, cétone aromatique, phénol, triplet, intramoléculaire, piégeage, enlèvement d'hydrogène, radical phénoxyle, cinétique, effet isotopique cinétique, photolyse éclair au laser.

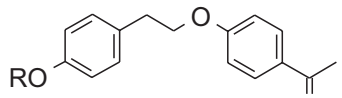
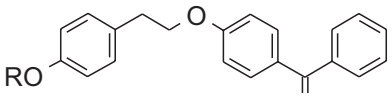
Introduction



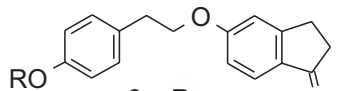
Hydrogen abstraction from phenols by the excited triplet states of most aromatic ketones occurs at rates in excess of 1×10^9 M^{-1} s^{-1} in solution, resulting in the formation of the corresponding phenoxyl and hemipinacol radicals in close to unit quantum yields (1–6). Unlike hydrogen abstraction from alkanes, alcohols, or substituted toluenes (7), however, the

 DOI: 10.1139/cjc-79-12-1851 © 2001 NRC Canada



normal dependence of the rate constant for reaction on the configuration of the lowest triplet state is not observed, and ketones with lowest π,π* triplet states tend to exhibit greater reactivity than those with lowest *n*,π* triplets. This characteristic is suggestive of an electron-transfer mechanism, where the hydrogen atom is transferred as a proton after initial electron transfer to yield the corresponding $PhOH^{\cdot+}/Ar_2CO^{\cdot-}$ radical ion pair. While recent work suggests that this is indeed the mechanism followed by benzophenone and other aromatic ketones in pure water (8, 9), electron transfer is more endergonic in nonaqueous solvents, where the reduction potentials of ketones are higher than in hydroxylic media (10). To be sure, previous kinetic studies indicate that the situation in nonaqueous solvents is generally more complicated than a simple electron transfer mechanism can accommodate (3, 11).

We have recently proposed that in acetonitrile solution, quenching of π,π* aromatic ketone triplets proceeds via electron and (or) proton transfer within a hydrogen-bonded triplet exciplex, in which the hydrogen bond serves mainly to facilitate electron transfer from the phenol to the ketone by lowering the oxidation and reduction potentials of the redox pair (11). Phenolic quenching of ketones with lowest *n*,π* triplet states was suggested to proceed by two mechanisms, depending on the triplet state reduction potential and the proximity of the higher lying π,π* triplet state, on the basis of the observation of a V-shaped Hammett plot for the quenching of a series of substituted benzophenone triplets by *para*-cresol. Electron-acceptor-substituted benzophenone derivatives were proposed to be quenched by the charge-transfer exciplex mechanism common to abstraction from substituted toluenes (12–15), which presumably transforms into the "simple" electron transfer mechanism when the reduction potential of the ketone is low enough. Quenching of electron-donor-substituted derivatives, on the other hand, was proposed to proceed via the hydrogen-bonded exciplex mechanism and involve the higher lying, relatively basic π,π* triplet state.



Phenolic quenching of aromatic ketone triplets also occurs *intra*molecularly, as has been demonstrated in a study of the photochemistry of the oxyethyl-linked phenolic ketones **1a**–**3a** (11, 16, 17). The triplet lifetimes of these compounds in acetonitrile solution at room temperature are in the 10–30 ns range, orders of magnitude shorter than the corresponding methoxy-substituted analogues (**1b**–**3b**), and they vary throughout the series in a similar way as do the rate constants for bimolecular quenching of the corresponding (methoxy-substituted) model compounds by *para*-cresol under the same conditions (11). Surprisingly, this correlation fails for the *meta,meta′*-analogue of the phenolic acetophenone derivative **1a**, 3-[2-(3′-hydroxyphenyl)ethoxy]acetophenone (**4a**) (18). The triplet lifetime of this compound exceeds 10 μs in acetonitrile solution at 23°C and is similar to that of the methoxy analogue **4b**, indicating that intramolecular abstraction of the remote phenolic hydrogen is over 500 times slower in this compound than in **1a**. The rate constant for the analogous bimolecular reaction is quite fast, so the very low reactivity of the triplet state of **4a** must be due to specific geometrical factors that are not present in the *para,para′*-derivative **1a**. Molecular mechanics calculations indicate that **4a** can adopt several conformations in which the phenolic hydrogen is within abstracting distance (less than ca. 2.65 Å) of the carbonyl oxygen, but in which there is little or no overlap between the aryl rings. We have proposed that the much longer lifetime of **4a** is due to the preferred formation of one or more of these exciplex conformers, in which quenching is presumably relatively slow, as well as orbital symmetry restrictions to electron and (or) proton transfer in the (higher energy) sandwich-like conformer similar to the one that must be involved in intramolecular hydrogen abstraction in **1a**.

In the present paper, we report the results of further studies of the role of geometrical factors in intramolecular phenolic hydrogen abstraction by aromatic ketone triplets, and the effects of solvent polarity on the rate constants. We have thus prepared two new phenolic ketones (**5a** and **6a**), which feature the same *meta,meta′*-linkage as is present in **4a**, and have examined their photochemistry under similar conditions as the *para,para′*-analogues **2a** and **3a**. As with **1a**–**3a**, the main difference between the three *meta,meta′*-substituted compounds (**4a**–**6a**) is the configuration of the lowest triplet state (π,π* in **4a** and **6a**; *n*,π* in **5a**). Further, **4a** and **6a** differ in the degree of charge-transfer character associated with their lowest π,π* triplet states, an effect which is due to the differing abilities of the carbonyl group to twist out of the plane of its attached aromatic ring in the two molecules. As before, the role of intramolecular hydrogen abstraction in controlling the triplet lifetimes of the two compounds is assessed through a comparison to the triplet state behavior of the corresponding methoxy-analogues (**5b** and **6b**, respectively), and in the case of the indanone derivatives, to the phenyl-substituted analogues **6c** and **7** as well. Finally, the triplet state behavior of the entire series of compounds (**1**–**7**), as well as rate constants for bimolecular phenolic hydro-

gen abstraction in appropriate model compounds, have been determined in dichloromethane solution. Comparison of these data to those in acetonitrile solution allows an assessment of the effects of (aprotic) solvent polarity on the rates of both inter- and intramolecular versions of the reaction.

Results

Compounds **5a** and **6a** were prepared by reaction of the ditosylate ester of 3-hydroxy-β-phenethyl alcohol (**8a**) with 3-hydroxybenzophenone (**9**) and 6-hydroxy-1-indanone (**10**), respectively, in acetone solution, followed by alkaline hydrolysis in methanol (eqs. [1] and [2]). The others (**5b**, **6b**, **6c**, and **7**) were prepared in similar fashion, by reaction of the tosylate esters of 3-methoxy-β-phenethyl alcohol (**8b**) or β-phenethyl alcohol (**8c**) with **9**, **10**, or 5-hydroxy-1-indanone (**11**). The structures of **5**–**7** were assigned on the basis of their ^{1}H and ^{13}C NMR, IR and mass spectra, and combustion analyses.

As was found previously for **1**–**4** (11, 18), ultraviolet absorption spectra of **5** and **6** in acetonitrile were in each case indistinguishable from those of the corresponding model compounds **12** and **13**, indicating that no ground-state interactions exist between the carbonyl group and the remote aryl group in these molecules. The same conclusion was derived from comparison of the UV absorption spectra of **1**–**7** with those of the corresponding model compounds (**12**–**17**) in dichloromethane solution.

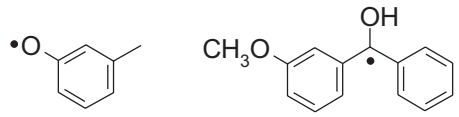
17

Phosphorescence emission spectra of **5a** and **6a** were recorded in 4:1 ethanol:methanol glasses at 77 K, with similar measurements made on the model compounds for comparison. The spectra of **5a**, **5b**, and **12** were similar, as were those of **6a**, **6b**, and **13**. Triplet energies were estimated from the short wavelength onset of the 0–0 emission bands in the spectra; these are 68.3 ± 0.3 kcal mol^{-1} for **5a**, **b** and 71.4 ± 0.1 kcal mol^{-1} for **6a**, **b**. The appearance of the spectra are consistent with an n,π^* assignment for the lowest triplet states of **5a**, **b**, and a π,π^* assignment for **6a**, **b**.

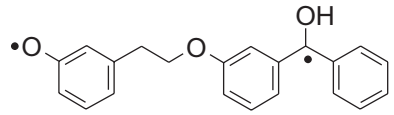
Steady state photolyses (300 nm) were carried out on deoxygenated 0.0025 M acetonitrile solutions of **5a** and **6a**, with periodic monitoring of the solutions by gas chromatography. As observed previously for **1a**–**3a** (11, 18), no photoproducts of similar or lower molecular weight to the starting ketones could be detected in any case. Exhaustive irradiation of the solutions produced small amounts of high molecular weight materials. Quantum yields for substrate photolysis were estimated to be in the 0.001–0.01 range using the disappearance of **1a** (Φ = 0.006) (16) as actinometer. Compounds **5b** and **6b** were found to be similarly unreactive.

Nanosecond laser flash photolysis (NLFP) experiments employed a pulsed excimer laser filled with N_2–He (337 nm, 4 mJ, 6 ns), Xe–HCl–He (308 nm, 55 mJ, 15 ns), or Kr–F_2–N (248 nm, 100 mJ, 25 ns) for excitation, and a microcomputer-controlled detection system (19). Sample concentrations were such that the absorbance at the excitation wavelength (3- or 7-mm path length) was 0.2–0.9 and each sample was deoxygenated with argon or dry nitrogen until constant transient lifetimes were obtained.



© 2001 NRC Canada

Absolute rate constants for bimolecular quenching of the triplet states of **12**–**17** by *para*- or *meta*-cresol were determined in acetonitrile and (or) dichloromethane solution at 23–25°C using the 337 nm laser for excitation. In each case, the pseudo-first-order triplet decay rate constant (k_{decay}) was determined at or near the triplet–triplet absorption maximum (380 nm for the acetophenone and indanone derivatives; 525 or 600 nm for the benzophenone derivatives) as a function of concentration of added phenol. Addition of the phenols resulted in an increase in triplet decay rate and the formation of new, long-lived absorptions assignable to *para*- or *meta*-cresyloxyl radicals and the corresponding hemipinacol radicals. While these absorptions overlap with those due to the ketone triplets at 380 nm, they were sufficiently long-lived that triplet decay rate constants could generally be determined with reasonable accuracy by simply taking the absorption due to the radical products as the infinity level in the least-squares analyses of the ΔOD vs. time data. At low phenol concentrations where the triplet lifetime was only ≤5 times shorter than those of the radicals, the triplet decay rates were determined by two-exponential least-squares fitting of the data. Bimolecular quenching rate constants (k_q) were determined from plots of the ketone triplet decay rate (k_{decay}) vs. cresol concentration ([Q]) according to eq. [3], where k_o is the pseudo-first-order rate constant for triplet decay in the absence of quencher. The results of these experiments are collected in Table 1.



$$[3] \qquad k_{decay} = k_o + k_q[Q]$$

Laser flash photolysis of solutions of the non-phenolic ketones **5b**, **6b**, **c**, and **7** in deoxygenated, dry acetonitrile solution led to the formation of strongly absorbing transients which decayed with clean pseudo-first-order kinetics (at low laser intensities) and exhibited lifetimes in the 1–10 μs range. These were assigned to the corresponding triplet states on the basis of their absorption spectra, which were indistinguishable from those of the corresponding model compounds (**12** in the case of **5b**, **13** in the case of **6b** and **6c**, and **15** in the case of **7**), and the fact that they are quenched rapidly by 1,3-cyclohexadiene (CHD, k_q = 6–9 × 10^9 M^{-1} s^{-1}) and oxygen ($k_q > 1 \times 10^9$ M^{-1} s^{-1}). The triplet–triplet absorption spectra of **5b** and **6b** in acetonitrile are shown in Fig. 1, while the inserts show typical decay profiles recorded at 600 and 385 nm, respectively. The spectra shown were recorded over ca. 200 ns time windows, starting just after the peak in the transient decay profiles.

The transient absorption spectra from flash photolysis of the phenolic ketones **5a** and **6a** are significantly different from those of the corresponding methoxy analogues. For example, Fig. 2*a* shows the spectra obtained from a 2.2×10^{-4} M solution of **5a** in acetonitrile (λ_{exc} = 248 nm), at the point corresponding to the peak in the transient decay profile and over the 0.5–1.0 μs time window after the peak. For comparison, spectra recorded of an acetonitrile solution containing **12** (0.0076 M) and *meta*-cresol (0.0058 M) over similar time windows, using the 337 nm laser for excitation, are shown in Fig. 2*b*. The early spectrum of Fig. 2*b* is a superposition of spectra due to the triplet state of **12** (λ_{max} = 330 nm, plus a broad absorption centered at λ ~ 530 nm) and the monoradicals **18** (λ_{max} = 405 nm) and **19** (λ_{max} = 330, 545 nm), while that recorded at later times is due to **18** and **19** alone. The spectra of Fig. 2*a* can thus be assigned to mixtures of the triplet state of **5a** and biradical **20**, with the later spectrum consisting of a correspondingly greater proportion of biradical relative to triplet. The decays followed clean pseudo-first-order kinetics at all wavelengths between 300 and 700 nm, but exhibited different lifetimes and quenching behavior depending on the monitoring wavelength. Decays recorded above 600 nm exhibited a lifetime of ~280 ns and were quenched cleanly by CHD ($k_q = 7.5 \times 10^9$ M^{-1} s^{-1}), indicating them to be due to the triplet state of the ketone exclusively. Those recorded at 520 or 300 nm exhibited lifetimes of ~850 ns; the lifetime did not change upon addition of the diene, although the intensities of the absorptions appeared to decrease as the diene concentration was increased. This behavior suggests that the transient absorptions in the 300–550 nm region of the spectrum are mainly due to the biradical (**20**), which is formed by intramolecular hydrogen abstraction in the triplet state of the ketone. Oxygen quenched the lifetime of the transient absorptions throughout the complete range of the spectrum, with a rate constant $k_{O2} \sim 1 \times 10^9$ M^{-1} s^{-1}.

18 **19**

20

As expected, the triplet lifetime of **5a** (measured at 600 nm) varies with the concentration of the ketone. Figure 3 shows a plot of the triplet decay rate constant (τ_T^{-1}) vs. [**5a**] in deoxygenated acetonitrile solution at 25.0°C. The intercept of the plot affords the infinite dilution triplet lifetime (τ_T = 362 ± 16 ns) while the slope is the bimolecular rate constant for self-quenching of the triplet state of **5a** by the ground state ketone (k_{sq} = (2.2 ± 0.4) × 10^9 M^{-1} s^{-1}). The latter agrees quite well with the bimolecular rate constant for quenching of the triplet state of 3-methoxybenzophenone (**12**) by *meta*-cresol under similar conditions (Table 1).

The transient absorption spectrum obtained from 248 nm laser flash photolysis of **6a** under similar conditions is shown in Fig. 4. In this case, however, the spectrum changes imperceptibly (other than in intensity) with time, and there is no variation in lifetime (τ ~ 630 ns) throughout the wavelength range monitored. The lifetime of the absorption is shortened upon addition of oxygen ($k_{O2} \sim 1 \times 10^9$ M^{-1} s^{-1}), but addition of CHD resulted only in reductions in the initial transient absorbance (ΔOD_{max}) at each wavelength, to an extent that depends on the concentration of CHD added. This behavior indicates that the species is a product of the triplet state of the ketone, and we hence assign it to biradical **21**. As expected, the spectrum is similar to that of a mixture of the analogous monoradicals **18** and **22**, generated by 308 nm flash photolysis of **13** (0.001 M) and *meta*-cresol (0.0011 M) in acetonitrile (not shown).

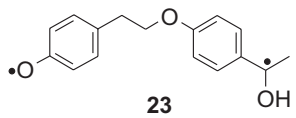
Figure 5 shows a Stern–Volmer plot of the maximum signal intensities at 385 nm (ΔOD_{max}) obtained by flash photolysis of **6a** in the presence of CHD at various concentrations. The data were analyzed according to eq. [4], where $(\Delta OD_{max})_0$ is the value in the absence of diene, $(\Delta OD_{max})_{[Q]}$ is the value in the presence of diene at concentration [Q], k_q is the rate constant for quenching of the triplet state of the ketone by the diene, and τ_T is the ketone triplet lifetime. A triplet lifetime of $\tau_T = 53 \pm 5$ ns was obtained from the slope of the plot ($k_q\tau_T = 564 \pm 42$ M^{-1}), using a value of $k_q = 1.05 \times 10^{10}$ M^{-1} s^{-1}, the rate constant for bimolecular quenching of the triplet state of **13** by CHD in acetonitrile at 23°C.

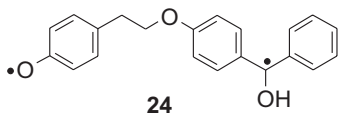
[4] $$(\Delta OD_{max})_0/(OD_{max})_{[Q]} = 1 + k_q\tau_T[Q]$$

21



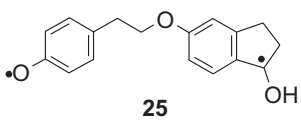
22

Addition of 0.028 M H_2O or D_2O to the acetonitrile solutions of **5a** and **6a** resulted in small changes in triplet lifetime (determined in the same fashion as described above) compared to those obtained in the dry solvent, but the lifetimes were slightly greater in D_2O–MeCN than in H_2O–MeCN. Table 2 lists the triplet lifetimes determined for **5**–**7** under the three sets of conditions, k_H/k_D values calculated from the lifetimes in wet acetonitrile, and the analogous data for **1**–**4** (11) for purposes of comparison.



Laser flash photolysis of **1**–**7** in deoxygenated dichloromethane solution afforded similar results to those obtained in acetonitrile (see above and ref. 11), and triplet lifetimes were measured in analogous fashion in each case. Those of the non-phenolic ketones (**1b**–**6b**, **6c**, and **7**) and the phenolic compounds **4a** and **5a** were long enough that they could be measured directly, and so they were determined using the 248 nm laser and solutions containing ~2×10^{-4} M ketone. Doubling the concentration of ketone had no discernible effect on the lifetime of **5a** but did in the case of **4a**, so the infinite dilution lifetime was estimated from a plot of τ_T^{-1} vs. [**4a**], constructed from solutions of various concentrations up to ~0.002 M and using the 308 or 337 nm lasers for solutions of higher concentrations. The data afforded a value of $k_{sq} = (4.6 \pm 0.8) \times 10^9$ M^{-1} s^{-1} for the self-quenching rate constant and an infinite dilution triplet lifetime of $\tau_T = 1.6 \pm 0.3$ μs at 23°C.

Only biradical absorptions could be detected in the cases of **1a**–**3a** and **6a** in dichloromethane, as shown by the response of the signals to added oxygen and CHD. Thus, triplet lifetimes were determined either by Stern–Volmer quenching with CHD (**3a** and **6a**) or the 1-methylnaphthalene (MN) probe technique (20) (**1a** and **2a**) (21), with solutions containing ~0.01 M ketone and using the 337 nm laser for excitation. For example, Fig. 6 shows plots of ΔOD_{max} at 425 nm (the maximum in the triplet–triplet absorption spectrum of MN) vs. [MN] for **1a** and **3a**. The solid lines in the plots represent the best fit of the data to the expression of eq. [5], where *C* is a constant proportional to the pathlength, the extinction coefficient of the MN triplet–triplet absorption at 425 nm, the light intensity, and the intersystem crossing yield of the ketone triplet. Triplet lifetimes were calculated from the Stern–Volmer constants ($k_q\tau_T$) using a value of $k_q = (7.5 \pm 0.4) \times 10^9$ M^{-1} s^{-1} for the rate constant for ketone triplet quenching by MN, determined for ketones **16** and **17** under similar conditions. The dichloromethane data for **1**–**7** are listed in Table 2 along with those for acetonitrile solution. Table 3 lists the lifetimes of the phenoxyl-hemipinacol biradicals **20**, **21**, and **23**–**25** in the two solvents.



[5] $$\Delta OD_{max} = Ck_q\tau_T[MN]/(1 + k_q\tau_T[MN])$$

Discussion

From the transient spectra, isotope effects on the triplet lifetimes, and a comparison of the triplet lifetimes of the phenolic compounds **5a** and **6a** with those of their methoxy analogues **5b** and **6b**, it is clear that triplet state deactivation

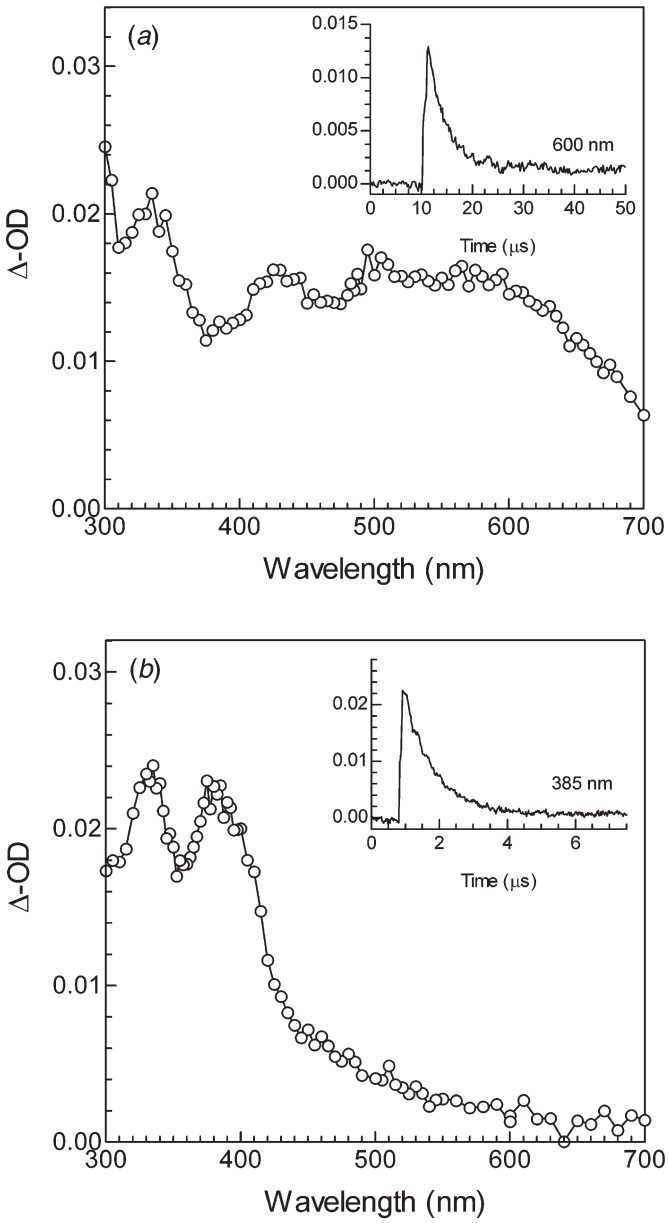
Fig. 1. Transient absorption spectra from laser flash photolysis of deoxygenated ~1 × 10^{-4} M acetonitrile solutions of **5b** (*a*) and **6b** (*b*) at 25.0 ± 0.2°C. The inserts show decay traces monitored at 600 nm (**5b**) and 385 nm (**6b**).



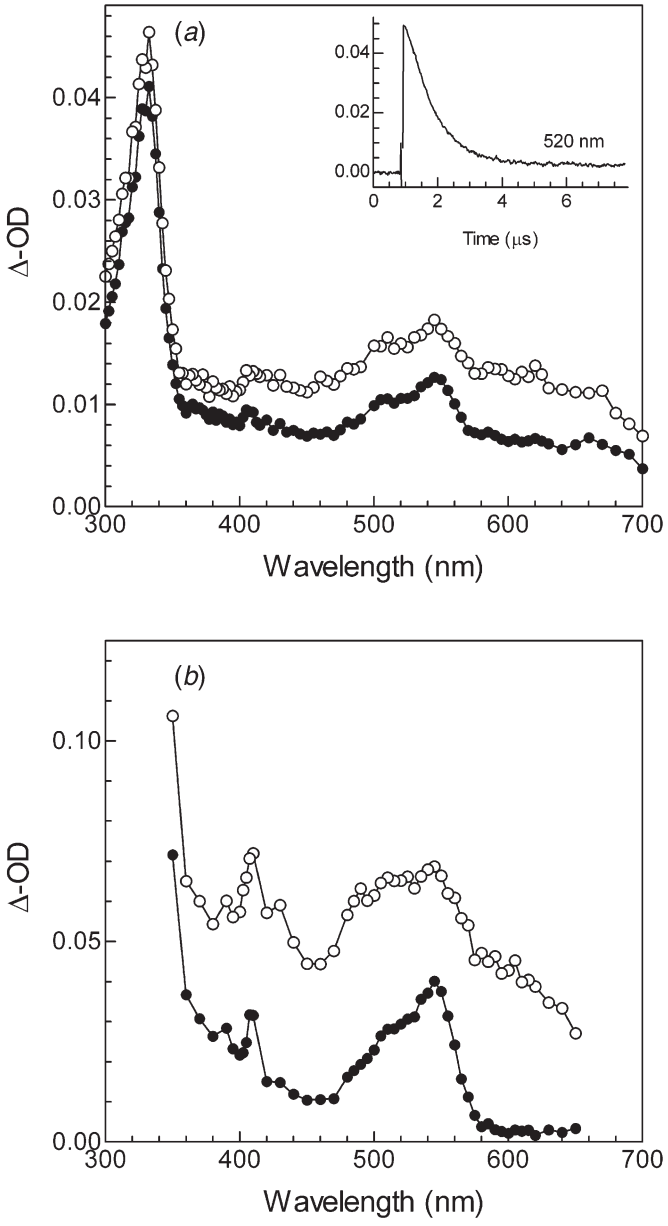


Fig. 2. (*a*) Transient absorption spectra from 248 nm laser flash photolysis of a deoxygenated 2 × 10^{-4} M solution of the phenolic ketone **5a** in dry acetonitrile solution at 25.0 ± 0.2°C, at the peak of the decay profile (○) and 0.5 to 1.0 μs later (●). The insert shows a typical decay trace, recorded at a monitoring wavelength of 520 nm. (*b*) Transient absorption spectra from 337 nm laser flash photolysis of an acetonitrile solution containing *meta*-methoxybenzophenone (**12**, 0.0076 M) and *meta*-cresol (0.0058 M) at 23.0 ± 0.2°C, 75–85 ns (○) and 4.0 to 4.3 μs (●) after the pulse.

in the two phenolic ketones is dominated by remote phenolic hydrogen atom abstraction, as we found previously for **1a**–**3a** (11). Both ketones exhibit significantly longer triplet lifetimes than their *para*,*para*′-positional isomers (**2a** and **3a**, respectively) in dry acetonitrile, but in contrast to the situation with the acetophenone derivatives **1a** and **4a** ($\tau_T^{4a}/\tau_T^{1a} \geq 500$) (18), the geometric dependence of the rates is much smaller in the benzophenone ($\tau_T^{5a}/\tau_T^{2a} \sim 18$) and indanone ($\tau_T^{6a}/\tau_T^{3a} \sim 2.5$) derivatives. As the data in Table 1 show, these differences are well beyond what might be expected on the basis of the (small) differences in the rate constants for the corresponding bimolecular hydrogen abstraction processes. The individual triplet lifetimes of the acetophenone and benzophenone derivatives are consistently shorter in dichloromethane than in acetonitrile solution, but the differences between *para*,*para*′- and *meta*,*meta*′-positional isomers follow the same trends in the two solvents; in dichloromethane at 23°C, the lifetime ratios are a $\tau_T^{4a}/\tau_T^{1a} \sim 800$, $\tau_T^{5a}/\tau_T^{2a} \sim 25$ for the acetophenone and benzophenone derivatives, respectively. In contrast, the corresponding lifetime ratio for for the indanone derivatives is inverted in dichloromethane relative to acetonitrile.

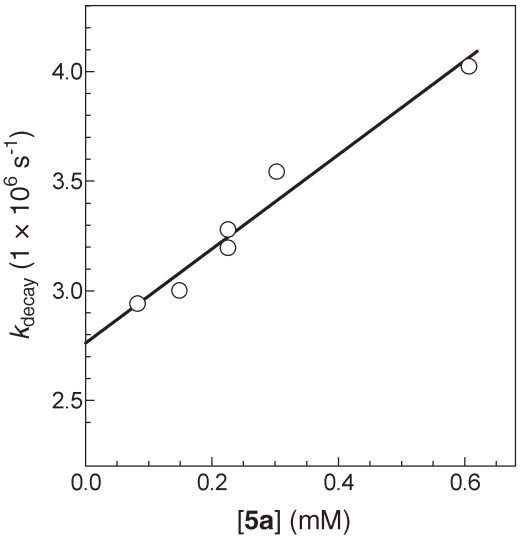

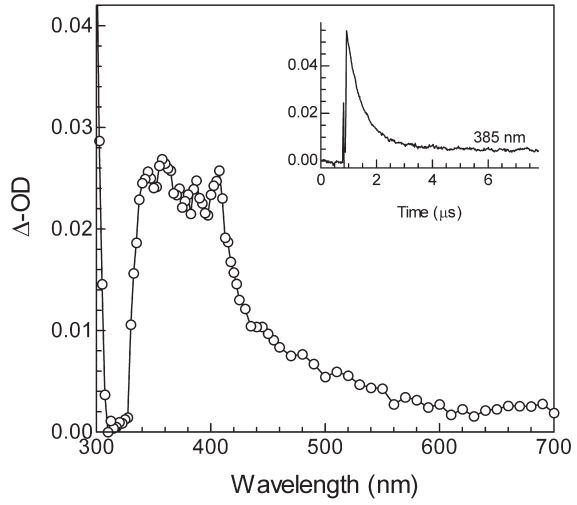

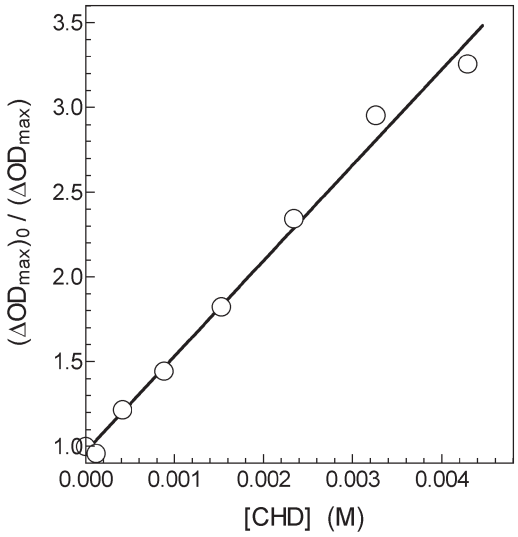

Fig. 4. Transient absorption spectrum from 248 nm laser flash photolysis of a deoxygenated 2 × 10^{-4} M solution of the phenolic ketone **6a** in dry acetonitrile solution at 23.0 ± 0.2°C, corresponding to the peak of the decay profile (ΔOD_{max}). The insert shows a typical decay trace recorded at a monitoring wavelength of 385 nm.

In principle, hydrogen abstraction from phenols might be expected to proceed by at least three distinct mechanisms depending on the configuration and electronic structure of the lowest triplet state of the ketone, and the redox potentials of the ketone and the phenol in the particular solvent of interest. Two of these are analogous to those proposed for the photoreduction of benzophenone and acetophenone derivatives by substituted toluenes (13): (*i*) sequential electron and (or) proton-transfer ("ET–PT") when electron transfer is sufficiently exergonic; (*ii*) when it is not, charge transfer assisted hydrogen abstraction (without prior hydrogen bonding), via an "*n*-type" exciplex for lowest *n*,π* triplet ketones ("*n*X–HT") or a "π-type" exciplex for lowest π,π* triplets. In the latter cases, charge transfer from the phenol to the triplet ketone should increase the acidity of the phenolic

Fig. 5. Stern–Volmer quenching of the initial yield (ΔOD_{max}) of the transient from 337 nm laser flash photolysis of ketone **6a** (0.0015 M) in dry acetonitrile in the presence of various concentrations of 1,3-cyclohexadiene (CHD), monitored at 385 nm (see eq. [4]).

hydrogen and the basicity of the carbonyl oxygen, effectively enhancing the rate of hydrogen transfer above what might be expected on the basis of a "pure" hydrogen abstraction model. The third possibility (*iii*) involves the intermediacy of a hydrogen-bonded, "π-type" triplet exciplex that collapses to radicals by coupled electron- and proton-transfer ("HBX–EPT"). Reaction by this mechanism should be favored in ketones with particularly basic lowest triplet states, and hence should be fastest in ketones with lowest charge-transfer π,π* triplet states. Reaction of *n*,π* ketone triplets by this mechanism presumably requires the involvement of the higher lying π,π* state, so will be fastest in those cases where the *n*,π*–π,π* triplet energy gap is small and the upper state is relatively basic. The three mechanistic possibilities are shown in Scheme 1.

The rate of reaction by any of these three mechanisms is expected to be sensitive to solvent polarity. It is well-known that reaction by the ET–PT (22, 23) and charge-transfer assisted (12, 13) mechanisms proceeds with enhanced rates as solvent polarity increases. In contrast, reaction by the HBX–EPT mechanism can be expected to be faster in solvents of low polarity, because hydrogen bonding is favored in nonpolar solvents. This leads to the conclusion that for the acetophenone and benzophenone chromophores, the triplet states of both isomers react via the HBX–EPT mechanism. This may also be true of the *meta*,*meta′*-phenolic indanone (**6a**), but the results for the *para*,*para′*-derivative (**3a**) are more consistent with a mechanism in which the phenolic hydrogen is activated toward abstraction by π-type charge transfer interactions between the aryl rings rather than by hydrogen-bonding.

The very slow rate of intramolecular hydrogen abstraction in **4a** compared to that in its *para*,*para′*-positional isomer **1a** has been proposed to result from a combination of conformational and orbital symmetry effects on the rate of electron/proton transfer within the hydrogen-bonded triplet

Fig. 6. Plot of transient ΔOD_{max} vs. 1-methylnaphthalene concentration for **1a** (□) and **3a** (○) in deoxygenated dichloromethane at 25.0 ± 0.2°C. The solid lines represent the least-squares fits to eq. [5].

exciplex (18). Intramolecular hydrogen bonding in the lowest triplet state of **1a** can only take place in a conformer in which the two aryl rings are arranged in a sandwich-like structure; this obviously represents a "good" quenching geometry because the triplet lifetime of the molecule is so short. On the other hand, there are a number of conformers accessible to the *meta*,*meta′*-isomer (**4a**) which would allow hydrogen bonding between the phenolic hydrogen and the carbonyl oxygen, but in which there is little or no overlap between the π-systems of the two aryl rings. These are calculated to be of considerably lower energy than the sandwich-like conformer analogous to that of **1a**, and hence should dominate the conformational equilibrium. This will lead to a much longer triplet lifetime if electron/proton transfer within these conformers is slow. Secondly, orbital overlap between the two phenyl rings in the (relatively high energy) sandwich-like exciplex conformer akin to **1a** is unfavorable, as a result of the nodal properties of the HOMO-1 and HOMO of the acceptor and donor, respectively. This can be expected to lead to a modest retardation of the rate of intramolecular electron transfer within the sandwich-like exciplex, relative to that in **1a** (24–30). At any rate, we consider the almost three-orders-of-magnitude difference between the triplet lifetimes of **4a** and **1a** to be a characteristic of intramolecular phenolic hydrogen abstraction by ketones tethered via *meta*,*meta′*- vs. *para*,*para′*-oxyethyl linkages, when the lowest triplet states are of the π,π* configuration and possess moderate charge transfer character.

Table 3. Lifetimes (in ns) of the phenoxyl-hemipinacol biradicals **20**, **21**, and **23**–**25** in dry acetonitrile ([H_2O] ~ 1×10^{-4} M) and in dichloromethane at 23–25°C.[a]

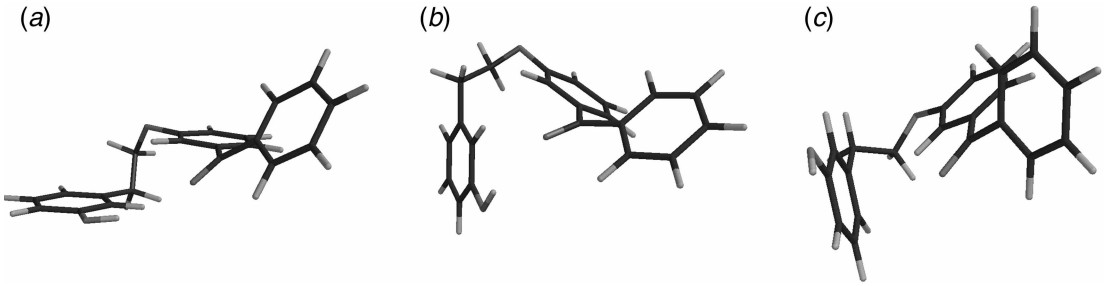
The triplet decay rates of the *para*,*para′*-phenolic benzophenone derivative (**2a**) and its acetophenone counterpart

© 2001 NRC Canada

Scheme 1.

(**1a**) correlate with the relative rates of bimolecular hydrogen abstraction from *para*-cresol by the corresponding model compounds, *para*-methoxybenzophenone (**16**) and *para*-methoxyacetophenone (**17**), respectively. The slower rates of inter- and intramolecular reaction of the 4-alkoxybenzophenone derivatives compared to the 4-alkoxyacetophenones are suggested to be due to the fact that the former have lowest n,π^* triplet states, and are intrinsically less reactive than lowest π,π^* triplets of comparable reduction potential. As mentioned above, it is thought that they react as fast as they do because the lowest triplet state has some π,π^* character, the amount of which increases as the energy separation between the zero-order n,π^* and π,π^* states decreases. If this is true, then on the basis of the relative reactivities of **1a** and **4a**, one would expect the rate of intramolecular hydrogen abstraction in the *meta*,*meta′*-phenolic benzophenone **5a** to be significantly slower than in the *para*,*para′*-isomer **2a**, in agreement with the observed results.



The rate deceleration caused by the *meta*,*meta′*-linkage in **5a** is at least an order of magnitude less pronounced than in the acetophenone series (**1a** and **4a**), however. The reason for this may be related to the fact that unlike the case with the acetophenone and indanone compounds, the bimolecular reactivity of the *meta*,*meta′*-pair (as defined by the rate of quenching of **12** by *meta*-cresol, see Table 1) is significantly *higher* than that of the *para*,*para′*-pair (i.e., **16** + *para*-cresol). This may be the result of the net electron-withdrawing character of the *meta*-alkoxy substituent, which places **12** (and **5a**) within the group of n,π^* benzophenone triplets in which the *n*X–HT mechanism is thought to be the predominant quenching pathway (11). In fact, molecular models indicate that the *meta*,*meta′*-linkage allows the facile formation of conformers in which the *n*-orbital of the carbonyl oxygen is directed into the π-system of the remote phenolic group. This is illustrated in Fig. 7, which shows three of the possible quenching conformers available to **5a**: a displaced face-to-face conformer (*a*); a face-to-face conformer (*b*); and an *n*-type exciplex conformer (*c*). While the solvent effect on τ_T (Table 2) suggests that the *main* quenching mechanism in **5a** is the same as in the *para*,*para′*-analogue **2a** (i.e., the HBX–EPT pathway), it is possible that quenching via the *n*X–HT mechanism competes to a small extent, resulting in somewhat higher reactivity than would be expected on the basis of the behavior of the *meta*,*meta′*-acetophenone derivative **4a**. Quenching via the *n*X–HT mechanism is geometrically impossible in the *para*,*para′*-analogue.

Even smaller differences in reactivity are observed for the *para*,*para′*- and *meta*,*meta′*-indanone derivatives (**3a** and **6a**), in spite of the fact that like **1a** and **4a**, both possess lowest π,π^* triplet states. The reason for this most likely originates in the coplanar arrangement of the carbonyl group and its associated aryl ring that is enforced by the benzannelated C-5 ring in these compounds. This results in a greater degree of charge-transfer in the π,π^* triplet state, which should have the effect of increasing its basicity. Thus, in the absence of geometric constraints, the rate of phenolic hydrogen abstraction should be higher than in the corresponding acetophenone derivatives if the quenching proceeds via the hydrogen-bonded exciplex mechanism. Indeed, the rate constants for bimolecular phenolic hydrogen abstraction by the model compounds **13** and **15** are significantly higher than those for the analogous acetophenone derivatives **14** and **17**, respectively, (see Table 1). In spite of this, intramolecular abstraction in the *para*,*para′*-derivative **3a** is significantly slower than in the acetophenone **1a**, a result which has been attributed to the less than optimal geometry for intramolecular hydrogen bonding that is enforced at the carbonyl group by the benzannelated C-5 ring. The fact that the triplet lifetime of **3a** is increased in dichloromethane relative to acetonitrile suggests that this explanation is correct, and hydrogen bonding is indeed not involved in the dominant quenching mechanism for this compound. This problem should be much less severe in **6a**, because the *meta*,*meta′*-linkage allows hydrogen bonding between the carbonyl and the remote phenolic group to occur with much greater facility than in the *para*,*para′*-derivatives.

Also relevant to this discussion are the unusually short triplet lifetimes of the anisyl derivatives of these two ketones, which indicates that they possess a route for nonproductive intramolecular triplet deactivation that is not present to the same extent in the corresponding acetophenone and benzophenone derivatives. For example, the triplet lifetimes of **3b** (τ_T = 280 ns) and **6b** (τ_T = 970 ns) in deoxygenated acetonitrile are more than an order of magnitude shorter than those of **15** and **13** under the same conditions (τ_T > 10 μs), while those of the phenyl-derivatives **7** (τ_T = 1.4 μs) and **6c** (τ_T = 3.2 μs) are intermediate between these extremes. These effects appear to be strictly confined to the intramolecular systems, since the bimolecular rate constants for 1,4-dimethoxybenzene quenching of the triplet states of **15** ($k_q = (4.8 \pm 0.8) \times 10^7$ M^{-1} s^{-1}) and **13** ($k_q = (1.8 \pm 0.4) \times 10^7$ M^{-1} s^{-1}) in acetonitrile are nearly identical to the corresponding values for the acetophenone homologues **17** ($k_q = (4.4 \pm 0.4) \times 10^7$ M^{-1} s^{-1}) and

Fig. 7. Potential quenching geometries for **5a**: (*a*) lowest energy H-bonded conformer; (*b*) sandwich-like H-bonded conformer; (*c*) *n*-type exciplex conformer.

14 (k_q = (2.2 ± 0.2) × 10^7 M^{-1} s^{-1}), respectively, under the same conditions.[2] A charge transfer quenching mechanism, presumably via the π-type triplet exciplex pathway first suggested by Singer and co-workers (31), is suggested by the fact that the triplet lifetimes of the four compounds are longer in the less polar solvent dichloromethane. Certainly, (endothermic) triplet energy transfer can most likely be ruled out as a possibility. We suspect that the reason for the enhanced intramolecular charge transfer quenching in the indanone series compared to the acetophenones may be related to exciplex structure; the results suggest that the optimum exciplex geometry for charge transfer between the aroyl and the donor aryl rings is somewhat different in the indanones than in the acetophenones, with that in the former being more compatible with the orientational constraints placed on the molecules by the oxyethyl tether in the intramolecular systems. In any event, the solvent effects on the triplet lifetimes of **3a** and **6a** suggest that this mechanism dominates over the hydrogen-bonded exciplex mechanism in **3a** (in which geometric factors prevent in-plane bonding between the carbonyl oxygen and the phenolic hydrogen); but only competes with it in **6a**, where these constraints are relaxed.

Summary and conclusions

The intriguing geometry dependence on the rate constants for remote phenolic hydrogen abstraction in the π,π* triplet states of the *para*,*para′*- and *meta*,*meta′*-oxyethyl linked phenolic ketones **1a** and **4a** has been investigated in the corresponding benzophenone (*n*,π* lowest triplet) and indanone (CT–π,π* lowest triplet) homologues. Solvent effects on the triplet lifetimes suggest that all ketones in the series but one react mainly via a hydrogen-bonded triplet exciplex, which collapses to the corresponding biradical by coupled electron and (or) proton transfer.

The new compounds exhibit similar structural dependences on intramolecular reactivity as observed for the acetophenone derivatives **1a** and **4a**, but the differences between *meta*,*meta′*- and *para*,*para′*-positional isomers are an order of magnitude smaller for the benzophenone derivatives (**2a** and **5a**), and two orders of magnitude smaller for the indanones (**3a** and **6a**). In the benzophenone case, the higher than expected reactivity of the *meta*,*meta′*-isomer may be due to competing reaction via the *n*-type exciplex (*n*X–HT) mechanism analogous to that involved in the quenching of benzophenone *n*,π* triplets by substituted toluenes. The even higher relative reactivity of the *meta*,*meta′*-indanone derivative is proposed to be due to more facile charge transfer between the two aryl rings in the hydrogen-bonded exciplex associated with this compound. In the *para*,*para′*-isomer, on the other hand, a relatively poor geometry for intramolecular hydrogen bonding is enforced by the benzannelated C-5 ring, which prevents the remote O—H bond from adopting a coplanar arrangement with the carbonyl group. As a result, hydrogen abstraction is initiated by a simple charge transfer interaction between the electron-rich phenolic ring and the indanone moiety, which increases the acidity of the phenolic hydrogen and activates its transfer. Supporting evidence for this conclusion is derived from the behavior of analogues bearing remote anisyl groups, which exhibit significantly shorter triplet lifetimes than do the corresponding anisyl-substituted acetophenone derivatives.

Future work in this area will further address the factors responsible for the substantial structural dependence on the rates of intramolecular phenolic hydrogen abstraction in acetophenone derivatives, and explore the mechanisms of the bimolecular process in aromatic ketones of various structure.

Experimental

^{1}H and ^{13}C NMR spectra were recorded on Bruker AC200 (200 MHz) or AC300 (300 MHz) spectrometers in deuterated solvents, and are reported in ppm downfield from tetramethylsilane. Ultraviolet absorption spectra were recorded on Cary 50 or Cary 300 UV–vis spectrophotometers. Mass spectra and exact masses were recorded on a VG Analytical ZABE mass spectrometer employing a mass of 12.000000 for carbon. Infrared spectra were recorded on a Biorad FTS-40 FT IR spectrometer. Melting points were determined on a polarizing microscope fitted with a Mettler hot stage and Mettler FP80 processor, and are not corrected. Gas chromatographic analyses employed a Hewlett-Packard 5890 Series 2 gas chromatograph equipped with a flame ionization detector, a Hewlett-Packard 3396A recording integrator, and a 15 m × 0.53 mm DB-17A or 5 m × 0.53 mm HP-1 column (Chromatographic Specialties, Inc.). Radial chromatography was carried out using a Chromatotron® (Harrison Research) with 4 mm silica gel 60 (EM Science) thick-layer plates. Elemental analyses were carried out by Guelph Chemical Laboratories, Inc.

Acetone (Caledon Reagent) was dried over anhydrous potassium carbonate and freshly distilled before use, hexanes

[2] E.C. Lathioor, and W.J. Leigh. Unpublished results.

(Caledon Reagent) were distilled, acetonitrile (Caledon reagent) was distilled from calcium hydride and passed repeatedly through activated Brockmann alumina (Aldrich), and pyridine (Fisher Reagent) was distilled from barium oxide. All other solvents were reagent grade and were used as received from the suppliers (Caledon or Fisher).

meta-Cresol (Caledon) and 3-hydroxybenzophenone (Aldrich) were used as received, while 1,3-cyclohexadiene (Aldrich) was bulb-to-bulb distilled and stored at –20°C under argon. 6-Hydroxy-1-indanone was prepared by demethylating 6-methoxy-1-indanone (Aldrich) with $AlCl_3$ as described by Miyake et al. (32), followed by recrystallization from water. 3-Methoxybenzophenone was prepared by Friedel–Crafts acylation of benzene with *meta*-anisoyl chloride, and purified by silica gel chromatography. 1-Bromo-2-(3-methoxyphenyl)ethane and 1-tosyloxy-2-(3-tosyloxyphenyl)ethane were prepared as previously described (18).

3-[2-(3-Hydroxyphenyl)ethoxy]benzophenone (5a)

To a 100 mL round-bottom flask attached to a reflux condenser and equipped with a magnetic stir bar was added anhydrous acetone (50 mL), 3-hydroxybenzophenone (1 g, 0.005 mol), 1-tosyloxy-2-(3-tosyloxyphenyl)ethane (4.50 g, 0.011 mol), and anhydrous potassium carbonate (0.87 g, 0.006 mol). The mixture was refluxed for 72 h, after which it was stripped of solvent on the rotary evaporator, acidified with dilute HCl until gas evolution ceased, and then taken up in ethyl acetate (50 mL). The orange-colored organic phase was then washed with water (2 × 50 mL) and saturated brine (50 mL), dried with anhydrous magnesium sulfate, filtered, and concentrated under reduced pressure. The crude tosylate ester was hydrolyzed by dissolving in methanol (100 mL) containing potassium carbonate (10 g, 0.07 mol) and refluxing for 80 h. Work-up as before yielded 2.54 g of a light brown oil consisting of a mixture of the desired product with minor amounts of 3-hydroxystyrene. Purification by radial chromatography (30% ethyl acetate in hexanes as eluant), followed by column chromatography (3% ether in dichloromethane with 10 drops acetic acid/100 mL as eluant) yielded a colorless oil (1.2 g, 0.0040 mol, 80%) which was identified as **5a** on the basis of the following data. MS (*m*/*e*) (I): 318 (10), 199 (3), 121 (100), 105 (23), 91 (16), 77 (45), 65 (8), 51(8). HRMS calcd. for $C_{21}H_{18}O_3$: 318.12564; found: 318.125592. 6-[2-(3-Hydroxyphenyl)ethoxy]-1-indanone (6a)

To a 100 mL round-bottom flask attached to a reflux condenser and equipped with a magnetic stir bar was added anhydrous acetone (50 mL), 6-hydroxy-1-indanone (0.68 g, 0.00459 mol), anhydrous potassium carbonate (1.42 g, 0.0103 mol), and 1-tosyloxy-2-(3-tosyloxyphenyl)ethane (2.24 g, 0.00510 mol). The mixture was refluxed with stirring for 10 h, additional quantities of potassium carbonate (0.71 g, 0.005 mol) and the ditosylate (1.02 g, 0.0023 mol) were added, and the reflux continued for a further 60 h. The reaction mixture was stripped of solvent on the rotary evaporator and then acidified with dilute HCl until gas evolution ceased. The aqueous mixture was extracted with ethyl acetate (50 mL), which caused the formation of an emulsion that was clarified with the addition of brine (25 mL). The orange-colored organic phase was washed with water (2 × 80 mL) and saturated brine (100 mL), dried with anhydrous magnesium sulfate, filtered, and concentrated under reduced pressure. The mixture was then taken up in methanol (25 mL), potassium carbonate (5.0 g, 0.04 mol) was added, and the resulting solution was refluxed for 48 h. Work-up as above yielded a deep brown oil (1.76 g). Column chromatography on silica gel with chloroform as eluant yielded compound **6a** (0.34 g, 0.0013 mol, 30%) as light yellow crystals, which were recrystallized from chloroform–cyclohexane with 1% methanol (mp 135.5 to 136.0°C) and identified on the basis of the following data. MS (*m*/*e*) (I): 268 (25), 121 (100), 103 (31), 91 (39), 77 (44), 65 (12). HRMS calcd. for $C_{17}H_{16}O_3$: 268.1072; found: 268.1099. UV λ_{max} (MeCN) (nm): 219 (ε 32 650 M^{-1} cm^{-1}) 244 (sh), 275, 280, 317. 3-[2-(3-Methoxyphenyl)ethoxy]benzophenone (5b)

A mixture of 3-hydroxybenzophenone (2.50 g, 0.0126 mol), 1-bromo-2-(3-methoxyphenyl)ethane (4.79 g, 0.0223 mol), and anhydrous potassium carbonate (1.74 g, 0.013 mol) were combined in acetone (20 mL), and stirred under reflux for 16 h. A second portion of potassium carbonate (0.50 g, 0.0036 mol) was added, and the mixture was refluxed for a further 4 days. The reaction was still not complete, so additional potassium carbonate (0.025 g, 0.0018 mol) and bromide (2.02 g, 0.009 mol) were added and reflux was continued for another 5 days. The ^{1}H NMR spectrum of a portion of the reaction mixture (after work-up as described below) indicated only 80% consumption of the 3-hydroxybenzophenone starting material, so an additional portion of bromide (1.09 g, 0.005 mol) was added and the mixture was refluxed for a further 3 days. The reaction mixture was cooled, and then taken up in a mixture of 1:1 ether:ethyl acetate (50 mL) and water (50 mL). The layers were separated, the aqueous portion was acidified with 3 M HCl, and extracted with ether (50 mL) and ethyl acetate (2 × 25 mL). The combined organic layers were washed with water (200 mL), 5% aq sodium bicarbonate (100 mL) and brine (100 mL), dried over anhydrous magnesium sulfate, and fil-

tered. Removal of the organic solvents on the rotary evaporator yielded an orange-brown oil, which was purified by silica gel column chromatography using 1:1 hexane:dichloromethane as eluant to yield a yellow oil (2.73 g, 0.008 mol, 65%). The compound was identified as **5b** on the basis of the following data. MS (*m*/*e*) (I): 332(10), 135(100), 120(7), 105(56), 91(28), 77(68), 65(12), 51(16). HRMS calcd. for $C_{22}H_{20}O_3$: 332.1413; found: 332.1413. UV λ_{max} (MeCN) (nm): 220 nm) (ε 28 300 M^{-1} cm^{-1}), sh. 252, 305. IR (KBr, cm^{-1}): 3060 (w), 2939 (w), 2835 (w), 1658 (m), 1596 (m), 1488 (m), 1438 (m), 1281 (s), 1164 (m), 1043 (s), 971 (w), 872 (w), 781 (s), 724 (s). ^{1}H NMR ($CDCl_3$) δ: 3.07 (t, 2H, *J* = 7 Hz), 3.77 (s, 3H), 4.20 (t, 2H, *J* = 7 Hz), 6.75–6.86 (m, 3H), 7.08–7.12 (m, 1H), 7.20 (d, 1H, *J* = 8 Hz), 7.31–7.35 (m, 3H), 7.42–7.47 (m, 2H), 7.53–7.58 (m, 1H), 7.76–7.79 (m, 2H). ^{13}C NMR ($CDCl_3$) δ: 35.6, 55.0, 68.6, 111.7, 114.7, 115.0, 119.2, 121.2, 122.7, 128.1, 129.1, 129.4, 129.9, 132.3, 137.7, 138.7, 139.5, 158.6, 159.6, 196.3. 6-[2-(3-Methoxyphenyl)ethoxy]-1-indanone (6b)

To a 25 mL round-bottom flask fitted with a condenser, nitrogen inlet, and magnetic stirrer was added anhydrous potassium carbonate (0.47 g, 0.0034 mol), acetone (10 mL), 6-hydroxy-1-indanone (0.46 g, 0.0034 mol), and 1-bromo-2-(3-methoxyphenyl)ethane (1.51 g, 0.007 mol). The mixture was refluxed under a nitrogen atmosphere for 10 days, with periodic monitoring by TLC. Additional quantities of acetone (10 mL) and potassium carbonate (0.50 g) were added, and the mixture was then refluxed for a further 5 days. The mixture was filtered and the solvent was removed on the rotary evaporator to yield a red oil, which was taken up in ether (50 mL) and 2% aq HCl (50 mL). The layers were separated, and the aqueous fraction was extracted with ether (2 × 50 mL). The organic fractions were combined, washed with water (100 mL) and brine (100 mL), dried with anhydrous magnesium sulfate, and filtered. Removal of the ether under reduced pressure yielded an orange oil (1.4 g), which was purified by column chromatography using 10% ethyl acetate in hexanes as eluant, followed immediately by column chromatography using chloroform as an eluant. The product was obtained as a yellow oil (0.47 g, 0.0016 mol, 53%), which was identified as **6b** on the basis of the following data. ^{1}H NMR ($CDCl_3$) δ 2.61 (m, 2H), 3.00 (m, 4H), 3.71 (s, 3H), 4.12 (t, *J* = 7 Hz, 2H), 6.65–6.72 (m, 1H), 6.8 (m, 2H), 7.08–7.2 (m, 3H), 7.22 (d, *J* = 8 Hz, 1H), 7.74 (d, *J* = 3 Hz, 1H). ^{13}C NMR ($CDCl_3$) δ: 25.1, 35.6, 37.0, 68.9, 105.9, 111.9, 114.8, 121.3, 124.3, 127.4, 128.3, 129.5, 138.2, 139.6, 148.0, 158.6, 159.8, 206.9. UV λ_{max} (MeCN) (nm): 218 (ε 29 250 M^{-1} cm^{-1}), sh. 243, 272, 279, 315. 6-[2-(Phenyl)ethoxy]-1-indanone (6c)

To an oven-dried 100-mL round-bottom flask equipped with magnetic stirrer, reflux condenser, and nitrogen inlet was added freshly distilled acetone (50 mL), 1-tosyloxy-2-phenylethane (0.50 g, 0.0018 mol), anhydrous potassium carbonate (0.28 g, 0.002 mol), and 6-hydroxy-1-indanone (0.24 g, 0.0016 mol). The mixture was then refluxed under nitrogen for 48 h. The dark brown mixture was stripped of solvent to leave a grey-brown residue, which was acidified by the addition of 0.4 M H_2SO_4 (20 mL) and concd HCl (1 mL), and then extracted with a mixture of ether (50 mL) and benzene (5 mL). The resulting bright yellow organic phase was washed with 10% aq NaOH (30 mL), water (30 mL), and brine (30 mL), and then dried with anhydrous magnesium sulfate. The solvent was removed under reduced pressure to yield an orange semisolid (0.44 g), which was recrystallized from methanol to yield yellow needles (mp 69.0–71°C; 0.26 g, 0.001 mol, 64%). The compound was identified as **6c** on the basis of the following data. MS (*m*/*e*) (I): 252 (10), 105 (100), 91 (13), 79 (20), 77 (23), 65 (7), 51 (10). 5-[2-(Phenyl)ethoxy]-1-indanone (7)

This compound was prepared in analogous fashion to **6c**, from 1-tosyloxy-2-phenylethane (1.16 g, 0.0042 mol), 5-hydroxy-1-indanone (0.61 g, 0.0041 mol), and anhydrous potassium carbonate (0.70 g, 0.005 mol) in dry acetone (50 mL). After refluxing under nitrogen for 5 days, the reaction mixture was worked up as above to yield an orange solid (1.09 g), which was recrystallized from methanol to yield a pale yellow powder (mp 79 to 79.5°C; 0.48 g, 0.0019 mol, 46%). The compound was identified as **7** on the basis of the following data. ^{1}H NMR ($CDCl_3$) δ: 2.59 (t, 2H, *J* = 6 Hz), 2.99 (t, 2H, *J* = 6 Hz), 3.06 (t, 2H, *J* = 7 Hz), 4.18 (t, 2H, *J* = 7 Hz), 6.83 (d, 2H, *J* = 6 Hz), 7.18–7.27 (m, 5H), 7.61 (d, 1H, *J* = 9 Hz). ^{13}C NMR ($CDCl_3$) δ: 26.0, 35.7, 36.5, 69.2, 110.6, 115.7, 125.5, 126.8, 128.7, 129.1, 130.6, 137.9, 158.1, 164.6, 205.2. UV λ_{max} (MeCN): 200 (ε 24 500 M^{-1} cm^{-1}), 220 (ε 17 000 M^{-1} cm^{-1}), 264 (ε 17 800 M^{-1} cm^{-1}), 287 (ε 10 000 M^{-1} cm^{-1}), 295 (ε 10 000 M^{-1} cm^{-1}). with Xe–HCl–H_2He (308 nm, 15 ns, ca. 40 mJ) or N_2–He (337 nm, 6 ns, ca. 4 mJ), a Lumonics 510 excimer laser filled with Kr–F_2–He (248 nm, 20 ns, ca. 60 mJ), or a Lambda Physik Compex 120 filled with Kr–F_2–Ne (248 nm, 25 ns, 100–140 mJ), and a computer-controlled detection system which has been described elsewhere (17, 19). All samples were contained in 3 × 7 mm or 7 × 7 mm Suprasil quartz cells which were sealed with rubber septa. Substrate concentrations were adjusted to yield an absorbance between 0.2 and 0.9 at the excitation wavelength. Each solution was deoxygenated with dry nitrogen or argon until constant lifetimes were achieved. Quenchers were added as aliquots of standard solutions.

Phosphorescence emission spectra were determined with either a PerkinElmer LS-5 or Photon Technologies LS-100 spectrofluorimeter. Sample concentrations were ~1 mg mL^{-1} and were contained in 2-mm i.d. Suprasil quartz tubes that were sealed with rubber septa and deoxygenated with dry nitrogen.

Steady-state irradiations were performed in a Rayonet Reactor (New England Ultraviolet Co.) using RPR-300 lamps and a merry-go-round apparatus. Samples were contained in 3-mm i.d. quartz tubes sealed with rubber septa, and were deoxygenated with nitrogen. Progress of the photolyses was monitored periodically by GC using the disappearance of **1a** as an actinometer. Hexadecane was employed as an internal standard.

Semiempirical (AM1) calculations were carried out using Spartan™ 5.0.3 (Wavefunction, Inc.) on a dual-processor Silicon Graphics Octane workstation. The (ground state) hydrogen-bonded conformers of Figs. 7*a*, 7*b* (ΔH_f = –39.61 and –40.19 kcal mol^{-1}, respectively) were minimized with the OH—OC distance constrained at 2.60 Å, while the *n*-type exciplex conformer of Fig. 7*c* (ΔH_f = – 36.50 kcal mol^{-1}) was minimized with a constrained distance of 3.60 Å between the carbonyl oxygen and the *ortho*- (with respect to the linker group) carbons of the remote phenolic ring.

Volumes of activation for electrode processes of various charge-types in nonaqueous solvents

Mitsuru Matsumoto, Delanie Lamprecht, Michael R. North, and Thomas W. Swaddle

Abstract: Volumes of activation ($\Delta V^{\ddagger}_{el}$) are reported for electron transfer at a Pt electrode of Mn(CN-*cyclo*-C_6H_{11})$_6^{2+/+}$ in acetonitrile, acetone, methanol, and propylene carbonate, and of Fe(phen)$_3^{3+/2+}$ in acetonitrile. In all cases, $\Delta V^{\ddagger}_{el}$ is markedly positive, whereas for the homogeneous self-exchange reactions of these couples in the same solvents the corresponding parameter is known to be strongly negative. The rate constants for the electrode reactions correlate loosely with the mean reactant diffusion coefficients (i.e., with solvent fluidity) and the $\Delta V^{\ddagger}_{el}$ values with the volumes of activation for diffusion (i.e., for viscous flow), consistent with solvent dynamical control of the electrode reaction rate in organic solvents. A detailed analysis of $\Delta V^{\ddagger}_{el}$ values of the kind presented for a couple with an uncharged member (Zhou and Swaddle, Can. J. Chem. **79**, 841 (2001)) fails, however, either because of ion-pairing effects with these more highly charged couples or because of breakdown of transition-state theory in predicting the contribution of the activational barrier. Attempts to measure $\Delta V^{\ddagger}_{el}$ for the oxidation of the uncharged molecule ferrocene at various electrodes in acetonitrile were unsuccessful, although $\Delta V^{\ddagger}_{el}$ was again seen to be clearly positive.

Key words: electrode kinetics, volumes of activation, nonaqueous electron transfer, solvent dynamics.

Résumé : On a mesuré les volumes d'activation, $\Delta V^{\ddagger}_{él}$, pour le transfert d'électron d'une électrode de platine de Mn(CN-*cyclo*-C_6H_{11})$_6^{2+/+}$, dans l'acétonitrile, l'acétone, le méthanol et le carbonate de propylène ainsi que de Fe(phen)$_3^{3+/2+}$ dans l'acétonitrile. Dans tous les cas, le $\Delta V^{\ddagger}_{él}$ est très positif alors que, pour les réactions d'auto-échange homogènes de ces couples, dans les mêmes solvants, on sait que le paramètre correspondant est fortement négatif. Il existe une légère corrélation entre les constantes de vitesse pour les réactions à l'électrode et les coefficients de diffusion moyens des réactifs (c'est-à-dire avec la fluidité du solvant) ainsi que pour les valeurs de $\Delta V^{\ddagger}_{él}$ avec les volumes d'activation de la diffusion (c'est-à-dire avec l'écoulement visqueux); ces corrélations sont en accord avec le contrôle dynamique par le solvant de la vitesse de réaction à l'électrode dans les solvants organiques. Toutefois, on ne peut faire d'analyse détaillée des valeurs de $\Delta V^{\ddagger}_{él}$, du type présenté pour un couple avec un membre ne portant pas de charge (Zhou et Swaddle, Can. J. Chem. **79**, 841 (2001)); cet échec résulte de la formation de paires d'ions avec les couples portant des charges plus grandes ou du fait que la théorie de l'état de transition ne permet pas de prédire la contribution de la barrière d'activation. Il a été impossible de mesurer la valeur du $\Delta V^{\ddagger}_{él}$ pour l'oxydation de la molécule de ferrocène non chargée, à diverses électrodes, dans l'acétonitrile; il apparaissait toutefois que le $\Delta V^{\ddagger}_{él}$, est clairement positif.

Mots clés : cinétique à l'électrode, volumes d'activation, transfert d'électron en milieu non aqueux, dynamique de solvant.

[Traduit par la Rédaction]

Introduction

For outer-sphere electron transfer in cationic transition-metal couples $ML_x^{z+/(z-1)+}$ in *aqueous* solution at 25°C, the volumes of activation $\Delta V^{\ddagger}_{ex}$ and $\Delta V^{\ddagger}_{el}$ ($\Delta V^{\ddagger} = -RT(\partial \ln k/\partial P)_T$, where k is the corresponding rate constant) for the homogeneous self-exchange reaction and the equivalent electrode process respectively have invariably been found to be negative (1–5). Furthermore, for aqueous systems, $\Delta V^{\ddagger}_{el}$ is found (1–5) to be one-half of $\Delta V^{\ddagger}_{ex}$:

[1] $$\Delta V^{\ddagger}_{el} = (0.50 \pm 0.02)\Delta V^{\ddagger}_{ex}$$

which is consistent with the corresponding relationship proposed theoretically by Marcus (6) for the free energies of activation

[2] $$\Delta G^{\ddagger}_{el} = \Delta G^{\ddagger}_{ex}/2$$

As an "exception that proves the rule," $\Delta V^{\ddagger}_{ex}$ and $\Delta V^{\ddagger}_{el}$ for electron transfer in water can be positive where the reaction is *not* of the simple, bimolecular, outer-sphere type — for example, the self-exchange pathway for anionic cyanometalate couples that is mediated by alkali-metal cations (7, 8) — but even in such cases eq. [1] still holds with remarkable accuracy. We, therefore, refer to eq. [1] for convenience as the "50% rule." Since $\Delta V^{\ddagger}_{ex}$ for the uncatalyzed outer-sphere reactions can be accounted for in terms of an extension (9) of the Marcus and Sutin model (10) based on transi-

tion-state theory, $\Delta V^{\ddagger}_{el}$ for aqueous electrode reactions can be said to be understood on this same basis.

For *nonaqueous* electron transfer reactions, however, the high-pressure experimental information obtained to date has revealed a sharp dichotomy between homogeneous self-exchange reactions, for which $\Delta V^{\ddagger}_{ex}$ is negative (and, for polar solvents such as acetonitrile, quantitatively consistent with theory (9, 11, 12)), and the corresponding electrode processes, for which $\Delta V^{\ddagger}_{el}$ turns out to be quite strongly *positive*. In other words, eq. [1] as such seems not to apply to nonaqueous systems. On the other hand, $\Delta V^{\ddagger}_{el}$ for the nonaqueous systems does correlate loosely with the volume of activation $\Delta V^{\ddagger}_{diff}$ for diffusion of the reactants in the particular solvent, and $\Delta V^{\ddagger}_{diff}$ can be identified, through the Stokes–Einstein relation

$$[3] \qquad D = k_B T/6\pi r_{eff}\eta$$

(in which D is the diffusion coefficient of a solute molecule of effective radius r_{eff} in a solvent of viscosity η), with the volume of activation $\Delta V^{\ddagger}_{visc}$ for viscous flow of the solvent. The implication is that the electrode reactions in nonaqueous media are either diffusion-controlled (which is highly unlikely, as the rates are generally too low and dependent on the particular system) or controlled by solvent dynamics (solvent "friction"). The latter possibility has been put forward in the context of electrode reactions of transition-metal complexes by several research groups (13–21), and depends on the notion (19, 22–25) that η is at least approximately proportional to the longitudinal solvent relaxation time τ_L. In the event that solvent dynamical effects control the reaction rate, the preexponential factor of the Eyring equation is expected to be proportional to τ_L^{-1} (26–34) and, therefore, the rate constant to η^{-1}. As far as pressure effects on rate coefficients are concerned, this means that the observed volume of activation $\Delta V^{\ddagger}_{obsd}$ for a reaction subject to solvent dynamics comprises a (normally negative) term $\Delta V^{\ddagger}_{TST}$ representing the pressure dependence of the free-energy activation barrier $\Delta G^{\ddagger}_{SD}$ and a solvent-dynamical term $\Delta V^{\ddagger}_{SD}$ representing that of the frequency factor. The term $\Delta V^{\ddagger}_{SD}$ ($\approx RT(\partial \ln \tau_L/\partial P)_T$) can be replaced by the volume of activation for viscous flow of the solvent $\Delta V^{\ddagger}_{visc}$ ($= RT(\partial \ln \eta/\partial P)_T$) which, in high-pressure electrochemical experiments, is conveniently obtained from the pressure dependence of the mean diffusion coefficient D of the reactants:

$$[4] \qquad \Delta V^{\ddagger}_{obsd} = \Delta V^{\ddagger}_{TST} + \Delta V^{\ddagger}_{SD}$$

$$[5] \qquad \Delta V^{\ddagger}_{SD} \approx \Delta V^{\ddagger}_{visc} = \Delta V^{\ddagger}_{diff} = RT(\partial \ln D/\partial P)_T$$

Equations [4] and [5] have a counterpart in Zusman's proposal (22) that the apparent activation energy for an electrode reaction subject to solvent friction will be higher than that predicted by Marcus by an amount representing the activation energy for viscous flow of the solvent. Because $\Delta V^{\ddagger}_{diff}$ is strongly positive for solvents *other than water* (for which it is fortuitously negligible at near-ambient temperatures and the usual experimental pressure range of 0–200 MPa (5, 20)), we have a first-order explanation in terms of solvent dynamics for the fact that $\Delta V^{\ddagger}_{obsd}$ for electrode reactions (i.e., $\Delta V^{\ddagger}_{el}$) is typically negative for aqueous systems, representing $\Delta V^{\ddagger}_{TST}$ regardless of any solvent-dynamical control, but markedly positive for nonaqueous solvents, in which $\Delta V^{\ddagger}_{SD}$ overwhelms $\Delta V^{\ddagger}_{TST}$. For the corresponding bimolecular self-exchange reactions for nonaqueous as well as aqueous couples, however, $\Delta V^{\ddagger}_{obsd}$ (i.e., $\Delta V^{\ddagger}_{ex}$) is generally negative and consistent with expectations based on TST (9, 12), implying independence of solvent dynamics. Consequently, for a given couple for which the electrode reaction is subject to solvent friction in a nonaqueous solvent, one can, *in the absence of complicating effects such as ion-pairing*, equate $\Delta V^{\ddagger}_{TST}$ for the electrode process with $\Delta V^{\ddagger}_{ex}/2$ and relate $\Delta V^{\ddagger}_{el}$ to $\Delta V^{\ddagger}_{diff}$ through eqs. [4] and [5].

A refined form of eqs. [4] and [5] is given elsewhere (5, 20, 21), but the refinements tend to cancel, and eqs. [4] and [5] have proved adequate in accounting for the positive values of $\Delta V^{\ddagger}_{obsd}$ found for the electrode reaction in four polar nonaqueous solvents of the couple $Ru(hfac)_3^{3+/2+}$,[2] for which interpretation is simplified because, for such a one-electron transfer involving a neutral species, the coulombic work terms, medium effects of the Debye–Hückel type, and the effects of ion-pairing should all be negligible (21). Such is not the case, however, for couples in which both reactants are charged. For example, for the $Co(bpy)_3^{3+/2+}$ system, reported by Murray and co-workers (13–15) to display viscosity effects indicative of solvent dynamics, $\Delta V^{\ddagger}_{el}$ in acetonitrile, acetone and PC[2] is strongly positive and runs close to $\Delta V^{\ddagger}_{diff}$, suggesting that $\Delta V^{\ddagger}_{TST}$ is close to zero, yet $\Delta V^{\ddagger}_{el}$ for the same couple in water is strongly negative, indicating just the opposite (20). Thus, eqs. [4] and [5] are not quantitatively applicable to the $Co(bpy)_3^{3+/2+}$ couple, and the most likely explanation is that these highly charged ions are sufficiently ion-paired with the counter-ion in organic solvents to invalidate these relationships while leaving $\Delta V^{\ddagger}_{SD}$ as the dominating component of $\Delta V^{\ddagger}_{el}$.

The object of the present study was to extend the very limited database on $\Delta V^{\ddagger}_{el}$ in nonaqueous solvents and to examine the validity of eqs. [4] and [5] for a range of couples of various charge-types. Because, for an electrode reaction, $\Delta V^{\ddagger}_{TST}$ in eq. [4] can be expected to equal 50% of $\Delta V^{\ddagger}_{ex}$ for the corresponding self-exchange reaction (5, 20, 21), attention was focused upon couples for which $\Delta V^{\ddagger}_{ex}$ data are available. The selected couples were, therefore, ferricenium/ferrocene ($FeCp_2^{+/0}$) (35), $Mn(CNchx)_6^{2+/+}$ (36, 37), and $Fe(phen)_3^{3+/2+}$ (38). The last couple is advantageous in that $\Delta V^{\ddagger}_{ex}$ is available for both water and a nonaqueous solvent (38), and that electron transfer is of the low-spin – low-spin type (in contrast to the previously studied $Co(bpy)_3^{3+/2+}$ (13, 14, 20), in which electron transfer entails a spin-state change with attendant interpretational challenges (9)).

Experimental

Materials

$[Mn(CNchx)_6](BF_4)$ and $FeCp_2$ were made and purified by published methods (39, 40). $[Fe(phen)_3](ClO_4)_2$ was made by precipitation from an aqueous solution of the sul-

[2] Abbreviations: ($hfac^-$) 1,1,1,5,5,5-hexafluoroacetylacetonate, (bpy) 2,2′-bipyridine, (PC) propylene carbonate, (chx) cyclohexyl, (phen) 1,10-phenanthroline, (Cp) cyclopentadienyl, (TBAP) tetrabutylammonium perchlorate, (TBAHFP) tetrabutylammonium hexafluorophosphate, (CV) cyclic voltammogram and (or) voltammetry, (ACV) alternating current voltammogram and (or) voltammetry.

fate salt (38) with aq $NaClO_4$. TBAP and TBAHFP[2] (Fluka, puriss.) were used as received. Acetone (BDH, ACS Assured) was refluxed with $KMnO_4$ until the purple color persisted, then shaken with Na_2CO_3 to remove acidic impurities and distilled twice, the second time from anhyd $CaSO_4$. Acetonitrile (BDH, ACS Assured) was distilled from P_2O_5 under N_2 and stored over activated 4 A molecular sieves. Methanol was dried by refluxing it over iodine-activated Mg turnings and distilling it twice. PC[2] (Aldrich, anhydrous, 99.7%) was used as received.

Electrochemical measurements

CVs and ACVs[2] were obtained as functions of pressure (0.1–200 MPa) as described previously (1–4, 20, 21), except that a PARC Model 273 potentiostat was generally used in place of the Model 173/175 combination and the O-rings in the electrochemical cell were of silicone rubber rather than viton or neoprene which were attacked by acetonitrile and some other solvents. The working and counter electrodes were of Pt wire. Before each experiment, the working electrode was gently polished with 0.05 μm Al_2O_3 powder and then sonicated, first in aq HNO_3 (6 mol L^{-1}) and then water, for 10 s each. The potential cycling procedure used in earlier work (1–4) to clean electrodes in situ during high pressure runs on aqueous solutions proved to be impracticable with the present nonaqueous systems. The reference electrode was a silver rod in contact with $AgNO_3$ solution (0.01 mol L^{-1}) in acetonitrile. Solutions contained 1.0–2.5 mmol L^{-1} of the complex salt, and 0.1 to 0.5 mol L^{-1} of the supporting electrolyte. As $Mn(CNchx)_6^{2+}$ was only generated transiently, the need to work at low temperatures to avoid its decomposition, as advocated by Wherland and co-workers (36), was obviated.

Results

For each sample at every pressure, electrode reaction rate constants k_{el} were derived from corrected phase angles f obtained from ACVs for three frequencies f (25–45 Hz for $Mn(CNchx)_6^{2++}$, 25–85 or 45–150 Hz for $Fe(phen)_3^{3+/2+}$, and 25–85 Hz for $FeCp_2$) in conjunction with determinations of the uncompensated resistance R_u at 10 kHz at a potential 250 mV away from the ACV peak potential E_{max}, in the manner previously described (2, 20, 21). Only those pressure cycles for which the initial and final (lowest-pressure) measurements agreed within the experimental uncertainty were accepted.

$$[6] \qquad \cot \phi = 1 + (2D\omega)^{1/2}/\alpha^{-\alpha}(1-\alpha)^{-(1-\alpha)}k_{el}$$

In eq. [6], ω is the AC angular frequency (= $2\pi f$) and D is the mean diffusion coefficient of the redox-active species (concentration c), determined from the peak currents I_p of CVs taken over a range of scan rates v:

$$[7] \qquad I_p = 2.686 \times 10^5 AD^{1/2}v^{1/2}c$$

where the effective electrode area A was determined from an I_p vs. $v^{1/2}$ plot for a solution of $FeCp_2$ in acetonitrile (c = 2.4 mmol L^{-1}, $D = 2.4 \times 10^{-5}$ cm^2 s^{-1} (41)) at 0.1 MPa and 25°C. It was acceptable to use a mean value of D for both the oxidized and reduced species, since the oxidation and reduction peak currents of the CVs were essentially the same. The transfer coefficients α were obtained from the relation

$$[8] \qquad E_{dc} = \Delta E_{cell} + (RT/F) \ln [\alpha/(1-\alpha)]$$

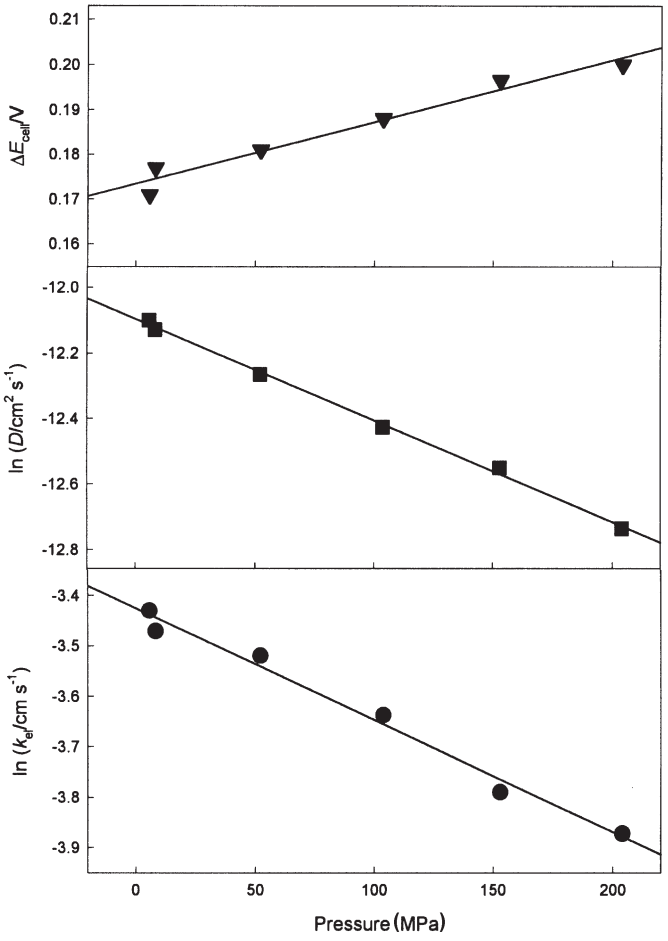
where E_{dc} is the potential corresponding to the max current in ACV and ΔE_{cell} is the half-wave potential found in CV. In all cases, $0.50 \le \alpha \le 0.60$. In this frequency range, k_{el} was independent of f. Because R_u was fairly large (100–200 Ω in acetone, acetonitrile, and methanol and 450 Ω in PC, at 0.1 MPa) and increased with increasing pressure, it is important to note that R_u was carefully measured and corrected for in calculating k_{el}. Thus, the k_{el} data reported here are not artifacts arising from R_u. The authenticity of k_{el} was confirmed by its reproducibility and its independence of f and the metal-complex concentration.

From ΔE_{cell} and the mean diffusion coefficients D, obtained from CVs at variable pressure relative to the reported atmospheric pressure value for $FeCp_2^+$ (41), the volume of reaction ΔV_{cell} for the cell (i.e., for the particular couple relative to the $Ag/AgNO_3$–CH_3CN electrode) and the volume of activation for diffusion $\Delta V_{diff}^{\ddagger}$ were calculated:

$$[9] \qquad \Delta V_{cell} = -F(\partial \Delta E_{cell}/\partial P)_T$$

$$[10] \qquad \Delta V_{diff}^{\ddagger} = -RT(\partial \ln D/\partial P)_T$$

Substitution of E_{max} (from ACVs) for ΔE_{cell} in eq. [9] gave the same ΔV_{cell} values, within the experimental uncertainty, regardless of the value of α. A set of typical pressure dependences of $E_{1/2}$, ln D, and k_{el} is shown in Fig. 1, and similar representative diagrams for the other four systems for which reproducible data were obtained are available as material on deposit (Figs. S1–S4). The numerical results are summarized in Table 1. The value of $E_{1/2}$ for $Mn(CNchx)_6^{2+/+}$ relative to that for $FeCp_2^{+/0}$ agreed well with the reported value (0.057 V (42)). Values of ΔV_{cell} for $FeCp_2^{+/0}$ and $Fe(phen)_3^{3+/2+}$ in acetonitrile are in acceptable agreement with those of Tregloan and co-workers (43), given the differences in the nature and concentrations of the supporting electrolytes.



Discussion

For the $Mn(CNchx)_6^{2+/+}$ system, the ΔV_{cell} values of Table 1 are remarkably consistent between the various media except for methanol, which is the only solvent listed for which hydrogen bonding is operative. For the Fe and Mn complexes taken together, the lack of any obvious correlation of ΔV_{cell} with charge type of the sort found by Tregloan and co-workers (44) for a series of related Fe(III/II) couples in water is not surprising, as the couples of Table 1 differ from each other chemically.

The mean diffusion coefficients D given in Table 1 for the $Mn(CNchx)_6^{2+/+}$ couple with TBAP (0.5 mol L^{-1}) suggest an effective radius r_{eff} of 710 ± 15 pm for these complex ions in acetonitrile, methanol, and PC, according to the Stokes–Einstein relation (eq. [3]) in which η is taken to be the viscosity of the pure solvent. A larger value of r_{eff} (910 pm) obtained for the same couple in acetone presumably reflects the expected influence of ion pairing due to the lower dielectric constant of this solvent.

Fig. 1. Pressure dependence of electrode reaction properties of the $Mn(CNchx)_6^{2+/+}$ couple ($[Mn(CNchx)_6(BF_4)]$ = 1.06 mmol L^{-1}) at 25.0°C in methanol containing TBAP (0.5 mol L^{-1}). Duplicate low-pressure data are initial and final measurements in the pressure cycle. Top frame: reaction volume relative to Ag/0.01 mol L^{-1} $AgNO_3$–CH_3CN (from CV). Middle frame: Logarithm of mean reactant diffusion coefficient (from CV). Bottom frame: Logarithm of standard electrode reaction rate constant (from current maxima in ACV).

The k_{el} values for $Mn(CNchx)_6^{2+/+}$ in Table 1 correlate roughly with D, with $k_{el} \sim 4.7 \times 10^3 D$ for acetonitrile and acetone (0.5 mol L^{-1} TBAP) and some 30% faster than this for the non-Debye solvents methanol and PC (Fig. S5, material on deposit). As noted previously (21), proportionality between the preexponential factor of the Eyring equation and η^{-1} (and hence the validity of eqs. [4] and [5]) is expected only for Debye solvents, i.e., those which can be represented in terms of quasispherical molecules rotating freely in a continuous dielectric, whereas methanol is subject to hydrogen-bonding complications and PC has an irregular shape and a high dipole moment. Nevertheless, the rough proportionality between k_{el} and D strongly suggests solvent dynamical control of the electrode reaction rate.

The salient feature of the $\Delta V_{el}^{\ddagger}$ data of Table 1 is that they are all quite strongly positive, whereas the corresponding parameters $\Delta V_{ex}^{\ddagger}$ for the homogeneous self-exchange reactions are all markedly negative. An approximate dependence of $\Delta V_{el}^{\ddagger}$ on $\Delta V_{diff}^{\ddagger}$ is also evident (Table 1) — for the Mn couple (Fig. S6, material on deposit), the slope is about 1.5, but this is strongly influenced by the one point for PC as solvent. In the event that the activational barrier contribution $\Delta V_{TST}^{\ddagger}$ (eq. [4]) were negligible, the slope of this correlation would be 1.0. If, however, $\Delta V_{TST}^{\ddagger}$ can be identified even roughly with 0.5 $\Delta V_{ex}^{\ddagger}$, then it is clear that eqs. [4] and [5] fail for the 2+/+ and 3+/2+ couples considered here, despite their applicability to the reduction of the uncharged $Ru^{III}(hfac)_3$ complex (21). Furthermore, the discrepancy is most evident for the most highly charged couple, $Fe(phen)_3^{3+/2+}$, for which $\Delta V_{el}^{\ddagger}$ is actually much larger than $\Delta V_{diff}^{\ddagger}$ in CH_3CN despite an anticipated $\Delta V_{TST}^{\ddagger}$ contribution of about –3 cm^3 mol^{-1} based on $\Delta V_{ex}^{\ddagger}$. It was also noted previously (20) that the $\Delta V_{TST}^{\ddagger}$ contribution is not clearly evident for the $Co(bpy)_3^{3+/2+}$ electrode reaction in nonaqueous solvents.

In gross terms, then, the very sharp contrast between $\Delta V_{el}^{\ddagger}$ and $\Delta V_{ex}^{\ddagger}$ (and the general parallelism between k_{el} and D) in organic solvents for all couples studied to date implies solvent dynamical control of the electrode, but not the homogeneous, electron transfer reactions. On the other hand, the present work makes it clear that a more detailed analysis of $\Delta V_{el}^{\ddagger}$ along the lines of eqs. [4] and [5] is not possible for couples in which both reactants are charged (particularly highly charged). This is not surprising, as extensive ion pairing is expected for complexes of charge 2+ or more in organic solvents, but it is not clear at this time what influence (if any) ion pairing should have on k_{el} or $\Delta V_{el}^{\ddagger}$. For self-exchange electron transfer reactions in aqueous systems, counter-ion effects are strong only for anion–anion electron transfer reactions (7). It is not clear how counter-ion effects would affect electrode reaction kinetics in nonaqueous solvents. Table 1 shows that changing the anion of the supporting electrolyte from perchlorate to hexafluorophosphate reduces k_{el} significantly but has only a small effect on $\Delta V_{el}^{\ddagger}$. Fawcett and co-workers (19) found that ion pairing did not affect the rate of the $Ru(phen)_3^{3+/2+}$ electrode reaction appreciably in aprotic solvents, and Pyati and Murray (13) considered the possibility of ion-pairing effects on the kinetics of the $Co(bpy)_3^{3+/2+}$ electrode reaction in nonaqueous media but decided that they were not a major factor (both groups, however, concluded that the reaction rates were controlled by solvent dynamics). An alternative qualitative interpretation is that transition-state theory breaks down completely for charged couples in nonaqueous electrode reactions, leaving $\Delta V_{SD}^{\ddagger}$ (represented at least approximately by $\Delta V_{diff}^{\ddagger}$) to determine $\Delta V_{el}^{\ddagger}$.

It is unfortunate that we were unable to measure $\Delta V_{el}^{\ddagger}$ for the much-studied $FeCp_2^{+/0}$ couple accurately at Pt, Au, or glassy carbon electrodes, as this could have confirmed or denied the applicability of eqs. [4] and [5] to couples with an uncharged member. Qualitatively, we found that the apparent k_{el} decreased substantially with increasing pressure even after an approximate correction for its drift to smaller values in the time frame of a high pressure experiment had been applied. Thus, $\Delta V_{el}^{\ddagger}$ was again unequivocally positive, in contrast with the negative $\Delta V_{ex}^{\ddagger}$ value reported for $FeCp_2^{+/0}$ in CH_3CN (35) and consistent with the picture of solvent dynamical control of the rates of electrode reactions, but not of the corresponding homogeneous reactions, in organic solvents.

The $Fe(phen)_3^{3+/2+}$ couple is of particular interest in that it is the only couple for which we now have $\Delta V^{\ddagger}_{el}$ and $\Delta V^{\ddagger}_{ex}$ data for both aqueous and nonaqueous systems (2, 38). For the aqueous electron transfer reaction, both $\Delta V^{\ddagger}_{el}$ and $\Delta V^{\ddagger}_{ex}$ are small negative numbers (–1.6 and –2.2 $cm^3\ mol^{-1}$, respectively) and, given their numerical smallness, are consistent with the 50% rule as well as with theoretical predictions (9). In acetonitrile, $\Delta V^{\ddagger}_{ex}$ is again negative (Table 1) and in close accord with theoretical predictions, but $\Delta V^{\ddagger}_{el}$ is strongly positive and substantially exceeds $\Delta V^{\ddagger}_{diff}$. Thus, the special character of the nonaqueous electrode reaction is highlighted, as is the inadequacy of eqs. [4] and [5] in the case of this highly charged couple. Either there are strong electrostatic effects (presumably ion-pairing) that invalidate eqs. [4] and [5], or else the assumption that $\Delta V^{\ddagger}_{ex}$ can serve as even an approximate measure of $\Delta V^{\ddagger}_{TST}$ in nonaqueous solvents is unjustified.

In closing, we reiterate that the pressure criterion of the incursion of solvent dynamics is inapplicable in aqueous systems at near-ambient temperatures because the pressure dependence of the viscosity of water is fortuitously negligible over the usual experimental pressure range (0–200 MPa). Accordingly, it could be that solvent dynamics control the rates of aqueous as well as nonaqueous electrode reactions. However, the $\Delta V^{\ddagger}_{el}$ data for the aqueous and nonaqueous electrode reactions of both $Co(bpy)_3^{3+/2+}$ and $Fe(phen)_3^{3+/2+}$ stand in such sharp contrast as to imply that electrode dynamics in water need to be treated differently from those in organic solvents.

Effect of the molecular weight on the lower critical solution temperature of poly(*N*,*N*-diethylacrylamide) in aqueous solutions[1]

D.G. Lessard, M. Ousalem, and X.X. Zhu

Abstract: The molecular weight dependence of the lower critical solution temperature of poly(*N*,*N*-diethylacrylamide) was studied with 11 samples of the polymer with a number-average molecular weight (M_n) ranging from 9.6×10^3 to 1.3×10^6 g mol^{-1} and relatively narrow polydispersity indices from 1.19 and 2.60. These samples were obtained by fractional precipitation of the polymer. LCST values of polymers were measured by turbidimetry and microcalorimetry. An inverse dependence of LCST on the molar mass was found and the LCST of the samples remained more or less a constant above a critical molecular weight of ca. 2×10^5 g mol^{-1}. The enthalpy and the entropy changes as well as the LCST of the polymer depend strongly on the molar mass of the polymer, especially in low molecular weight range.

Key words: poly(*N*,*N*-diethylacrylamide), LCST, thermosensitive, phase diagram, effect of molecular weight.

Résumé : L'effet de la masse molaire sur la température critique de dissolution inférieure (LCST) du poly(*N*,*N*-diéthylacrylamide) a été étudié sur 11 fractions de masses molaires moyennes en nombre (M_n) variant entre 9.6×10^3 à 1.3×10^6 g mol^{-1} et ayant un indice de polydispersité situé entre 1.19 et 2.60. Ces échantillons ont été obtenus par précipitation fractionée. La LCST des solutions aqueuses du polymère a été mesurée par turbidimétrie et par microcalorimétrie. Il a été constaté que la LCST diminue avec la masse molaire de l'échantillon. Les valeurs de la LCST demeurent cependant relativement constantes pour des masses molaires supérieures à 2×10^5 g mol^{-1}. L'enthalpie et l'entropie associées aux changements de phases diminuent de la même façon avec l'augmentation de la masse molaire.

Mots clés : poly(*N*,*N*-diéthylacrylamide), température critique de dissolution inférieure, thermosensible, diagramme de phase, effet de la masse molaire.

Introduction

Thermosensitive polymers are known to undergo changes in their physical properties when the temperature is varied. Many *N*-substituted polyacrylamides in water exhibit reversible-phase separation upon heating. The temperature at which precipitation of the polymer occurs is called the lower critical solution temperature (LCST). Materials which show this behavior in water are of a great interest for medical (1) and industrial (2) applications. The most extensively studied polymer in this family is probably poly(*N*-isopropylacrylamide) (PNIPAM). Our research focuses on the effect of the molar mass on the LCST of aqueous solutions of poly(*N*,*N*-diethylacrylmide) (PDEA), which behaves similarly as PNIPAM.

Different researchers have explained the LCST phenomenon of polymers in water. It was ascribed to the greater entropy in the two-phase system than in a homogeneous solution (3, 4), the formation of hydrogen bonds between the polymer and water (3, 5), the hydrophobic interactions between the polymer side chain groups (3, 6), and the disruption of specific hydrogen-bonded cyclic structure in alkyl amide units and hydroxyl functions of water (7).

Only a few studies were conducted on PDEA even though this polymer behaves similarly as PNIPAM without the ability to form hydrogen bridges with a proton on the amide group and the solvent. This polymer may be synthesized by anionic polymerization (8, 9), group transfer polymerization (8, 10), or free radical polymerization (7, 8, 10–14). It was observed that for PDEA of low molar masses ($M_n < 5000$ g mol^{-1}) the transition temperature is 10°C higher for isotactic polymers than for their syndiotactic homologues. Different initiators were used for these tactic samples and the difference in the end-group was attributed as the origin of the discrepancy in their LCST values (8).

The aqueous solutions of PDEA can undergo precipitation between 25 and 36°C as determined by means of turbidimetry (8, 11, 15–17), differential scanning calorimetry (7, 8, 11, 17, 18), small angle neutron scattering (20), dynamic and static light scattering (10), IR spectroscopy (7), and rheology (10, 14). Early research focused on the parameters such as the addition of salts (11, 15, 17) and surfactant (11), co-monomer content (13, 14, 17, 19), and concentration of the polymer (8, 11, 16). The self-diffusion coefficients of small molecules in PDEA aqueous solutions and gels were also determined by the use of pulsed-gradient spin-echo

NMR techniques (12). Most of these studies dealt with polydisperse PDEA samples, and none of them addressed clearly the question of the molecular weight effect on the LCST of the polymers.

In the present work, using fractional precipitation, we prepared 11 PDEA fractions with molar masses ranging from 9.6×10^3 to 1.3×10^6 g mol^{-1}. Turbidimetry, also called cloud point technique, and microcalorimetry were used to study the effect of molecular weight on the LCST of these fractions in aqueous solutions.

A number of parameters have been reported to influence the LCST of thermosensitive polymers. It was shown that the presence of salts in the solution generally decrease the LCST of the solution (5, 20) and added surfactants improve the solubility of the polymer, thereby raising the LCST (20–22). Also, phase separations were studied as functions of the amount of cosolvent (23), polymer concentration (24), and pressure (25). Investigations of molecular weight influence on the LCST, however, showed a large discrepancy in the results obtained. Some authors reported an inverse dependence of the LCST on the molar mass (5, 24), while others claimed the opposite (26). Several studies also reported that the molecular weight had no influence on the LCST (6, 27). It is worthwhile to mention that the fractionation of this kind of polymers is quite difficult due to the amphiphilicity of the macromolecule.

Experimental section

All chemicals were purchased from Sigma (St. Louis, Missouri, U.S.A.) and Aldrich (Milwaukee, Wisconsin, U.S.A.) and were used as received. Ammonium persulfate was recrystallized before use.

Polymer synthesis

N,*N*-Diethylacrylamide (DEA) was prepared, as reported previously (11), by reacting acryloyl chloride (97%) with an excess of diethylamine (98%) in methylene chloride at 0°C. The salt was filtered off and the solvent was evaporated. Distillation of the liquid under 0.5 mmHg (1 mmHg = 133.322 Pa) vacuum at 40–50°C in the presence of hydroquinone yielded a clear liquid, which was kept in a freezer until use.

PDEA was obtained by radical solution polymerization of DEA using ammonium persulfate as the initiator and *N*,*N*,*N*′,*N*′-tetramethylethylenediamine as the accelerator. Purified water was degassed with nitrogen and was used as the solvent. The reaction was carried out at room temperature for 4 h. The solvent was then evaporated and PDEA, after dissolution into a small amount of acetone, was purified twice by precipitation in petroleum ether, resulting in a white solid.

Fractionation and characterization

PDEA fractions were obtained by fractional precipitation using acetone as the solvent and hexane as the nonsolvent. To ensure good results, the concentration of the PDEA solution was kept low (less than 0.1 wt%) and the temperature was maintained constant at 25°C. Hexane was added until the solution turned cloudy. Then the temperature was raised by 1 or 2°C to dissolve the precipitated polymer and then allowed to cool down to the precipitation temperature. The system was kept without stirring for at least 1 day before the precipitated fraction was recovered. The remaining solution underwent further precipitation in the same way as described above. This process was repeated to obtain further fractions. In total, 11 fractions were obtained.

The molecular weight and its distribution of the polymer samples were determined by size exclusion chromatography (SEC) on a Waters system equipped with an online Waters 410 differential refractometer and a set of three Ultrastyragel columns. Tetrahydrofuran was used as the mobile phase, and polystyrene samples as the standards in the calibration of the molar masses.

Determination of LCST

The cloud point of PDEA in water was set as the temperature at the inflexion point of the curve obtained by turbidimetry. A CARY 1 BIO UV–vis spectrophotometer coupled to a temperature controller was used in the absorbance mode at a wavelength of 500 nm. A 1-cm sample cell containing ca. 80 μL of solution was used for the measurement against deionized Milli-Q water as the reference. The cloud point of sample with higher concentration was impossible to determine with enough precision due to the saturation of the signal on the spectrophotometer.

Microcalorimetry was also used to determine the LCST of PDEA aqueous solutions. The endothermic signal at its maximum (corresponding to the LCST) was recorded for each sample on a DSC VP-microcalorimeter from Microcal Inc. A cell filled with deionized Milli-Q water was used as the reference. Heating rates of 0.1 and 1.0°C min^{-1} were used, with both methods, to see their effect on the LCST.

The LCST values of aqueous PDEA solutions with different molecular weight were determined by means of turbidimetry and microcalorimetry at a concentration of 1 wt% to ensure an exact value of the cloud point and the LCST.

Results and discussion

The fractionated samples of PDEA have a wide range of molar masses, from 9.6×10^3 to 1.3×10^6 g mol^{-1}. The polydispersity of the fractions were lower than that of the bulk sample ($M_w/M_n = 3.59$) as shown in Table 1.

The LCST of a solute dissolved in a solvent can be obtained from the phase diagram of the system. The phase diagrams of two polymer samples F2 and F9 are shown in Fig. 1, where the cloud point is plotted as a function of concentrations ranging from 0.0001 to 10 wt%. The LCST is given by the lower temperature at which the phase transition occurs. It appears that the most accurate value of the LCST can be obtained for concentrations ranging from 1 to 5 wt% for low and high molecular weight samples, and no significant differences on the LCST are observed within this interval of polymer concentrations.

As shown in Fig. 2*a*, the transmittance of the 1 wt% PDEA solution decreases sharply at a certain temperature owing to the turbidity of the solutions when precipitation occurred. The exact values of the cloud point (LCST), ΔH, and ΔS are listed in Table 1. The general trend observed for this series of samples is that the LCST is lower for the higher molecular weight polymers.

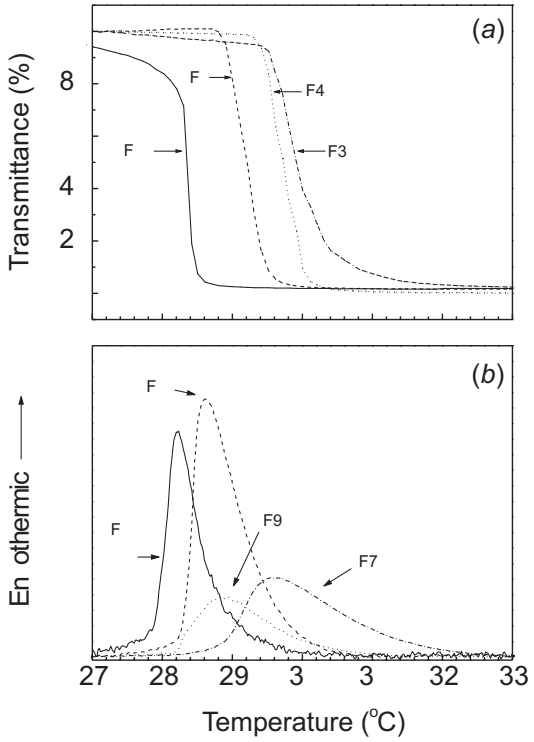
[a]Heating rate at 0.1°C min^{-1}.

Fig 1. Phase diagram of the aqueous solution of PDEA of a low molar mass fraction F2 (open circles) and high molar mass fraction F9 (closed circles).

Microcalorimetric studies confirmed the general tendency of the behavior of the PDEA fractions. The endothermic phase transition occurs at lower temperatures for higher molecular weight samples as illustrated in Fig. 2*b*.



The inverse dependence on molar mass of the LCST was recently observed on PNIPAM (24). This phenomenon is attributed to the difference in the free volumes caused by the polymer chains and the solvent molecules. This difference is much more significant for the longer polymer chains, since they should precipitate at lower temperatures (28, 29). It was demonstrated by Patterson (28) that the LCST is proportional to the critical value of the Flory–Huggins interaction parameter (χ_c) and that the LCST decreases with the ratio of the molar volume of the polymer to that of the solvent (r):

$$[1] \qquad \chi_c = 1/2(1 + r^{-1/2})^2$$

In eq. [1], if the molar volume of the polymer increases with the length of the chain, it is clear that the LCST of the polymer must decrease with the molecular weight of the polymer.

The shape of the curves presented in Fig. 3 suggests a more pronounced effect for lower molecular weight fractions. The slope is steep for values of M_n lower than 2×10^5 g mol^{-1} and becomes more gradual for higher values of M_n. This may explain the broadening of the transmittance curves (Fig. 2*a*) and of the endothermic peaks as M_n decreases (Fig. 2*b*). This implies a minor role of the polydispersity on the width of transition for heavier fractions. A critical value of M_n seems to lie at ca. 2×10^5 g mol^{-1}, after which the LCST values of the samples in water remained nearly constant.

Fig. 2. LCST of 1 wt% aqueous solutions of selected PDEA fractions (see Table 1) obtained at a heating rate of 0.1°C min^{-1} by: (*a*) turbidimetry; and (*b*) microcalorimetry.

The effect of the heating rate (1.0 and 0.1°C min^{-1}) was also investigated. At higher heating rates, the transition temperature is expected to be overestimated because of the poor heat transfer. When working with the 1.0 wt% PDEA fractions, the cloud point technique was found to be more sensitive to the heating rate as shown in Fig. 3*a*, where the LCST

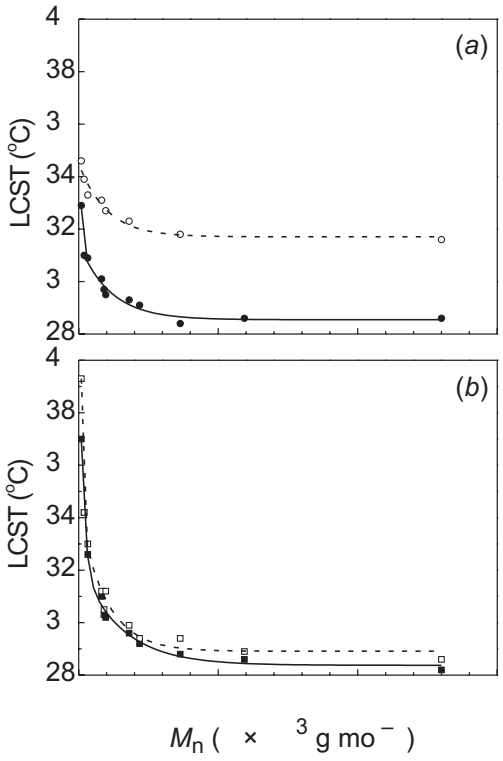
Fig. 3. Effect of the molecular weight on the LCST of the PDEA fractions measured by: (*a*) spectrophotmetry (circles); and (*b*) microcalorimetry (squares) for different heating rates. Open symbols, heating at 1.0°C min^{-1}; closed symbols, 0.1°C min^{-1}.



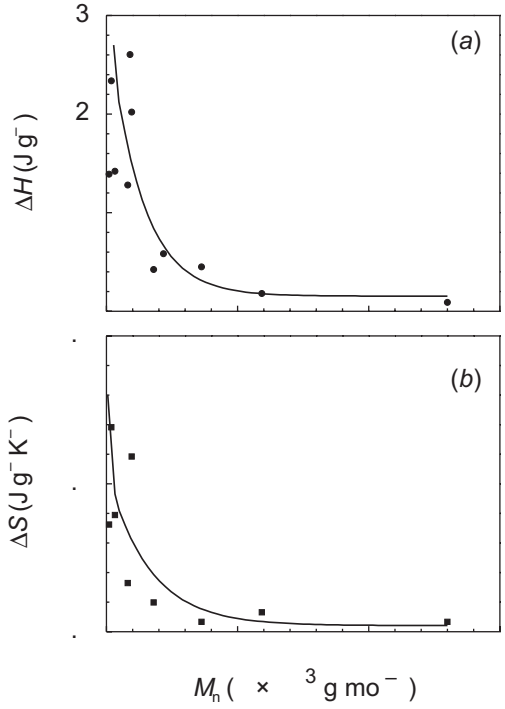


Fig. 4. Effect of the molecular weight on: (*a*) ΔH; and (*b*) ΔS for the PDEA fractions obtained by microcalorimetry at a heating rate of 0.1°C min^{-1}.

obtained at 0.1°C min^{-1} were 3°C lower than those measured at 1.0°C min^{-1}. Such a dependence of the LCST on the heating rate was already reported for a polydisperse sample (11). This was attributed to the poor heat transfer inherent to the method where the recorded temperature is higher than the effective temperature of the sample. Microcalorimetry has a much better heat transfer and, therefore, this effect is less pronounced as shown in Fig. 3*b*.

As seen in Fig. 4, microcalorimetry can be used also to determine the enthalpy (ΔH) and the entropy (ΔS) at the transition. These quantities seem to be strongly dependent on the molecular weight. ΔH and ΔS follow the same trend as the LCST for the samples, i.e., a hyperbolic decrease from 21.0 J g^{-1} and 0.070 J g^{-1} K^{-1} for ΔH and ΔS to limit values of 0.6 J g^{-1} and 0.003 J g^{-1} K^{-1}, respectively. In each case, the final plateau corresponds to a sample with a molar mass of 2×10^5 g mol^{-1}. The value obtained here for ΔH is consistent with that reported by Idziak et al. (11) for a PDEA sample (ΔH = 22.9 J g^{-1} for $M_n = 2.0 \times 10^4$ g mol^{-1}).

It is understandable that the entropy change is smaller for the longer polymer chains. The ΔS values decrease as a function of the average molar mass of the polymer and remain constant after a critical point at $M_n = 2 \times 10^5$ g mol^{-1}. When a hydrophobic solute such as PDEA is dissolved in water, the surrounding molecules tend to organize themselves in an ice-like structure (3). The order created decreases the entropy of the solution. The LCST phenomenon for polymer in aqueous media is possible only if the dissolution is exothermic and the entropy of the mixture is negative (28). A low molar mass polymer at a given weight concentration needs to interact with more water molecules to be solvated, creating more order in the system. This increased order decreases the overall entropy of the solution. The ΔS of the transition is therefore greater.

It can also be demonstrated mathematically that lower molecular weight polymers correspond to higher the ΔH values. It is known that χ_c decrease with the molecular weight of the polymer (28) because the lower molar volume of the polymer gives a lower value of the ratio (r) in eq. [1]. Since χ_c is proportional to the energy required to break the contact between the polymer and the solvent (28), the energy needed to induce the phase separation (ΔH) will be greater for shorter polymer chains.

Conclusion

PDEA fractions were prepared by fractional precipitation despite the amphiphilicity of the polymer. The phase diagrams showed that the changes of the LCSTs of the PDEA aqueous solutions are not significant in the concentration range from 1 to 5 wt%. Low heating rates provide more reliable results with turbidimetry, but this effect is negligible for microcalorimetric measurements. Turbidimetric and microcalorimetric measurements have shown a sharp decrease in their LCST, ΔH, and ΔS values as a function of the molar mass of PDEA. The values become constant after a critical molar mass at ca. $M_n = 2 \times 10^5$ g mol^{-1}. Polydispersity of the polymer seems to plays a minor role for the heavier PDEA fractions.

Kinetic stabilizing effect of the 4-*N*-methylacetamido substituent on the phenylnitrenium ion

Patrick H. Ruane and Robert A. McClelland

Abstract: Photolysis of 4-(*N*-methylacetamido)phenyl azide in aqueous solution results in quantitative formation of the 4-(*N*-methylacetamido)phenylnitrenium ion, this cation arising from solvent protonation of an initially formed singlet arylnitrene. The cation is observed by flash photolysis, and is identified through characteristic quenching by azide ion and by 2′-deoxyguanosine, both excellent nucleophiles for arylnitrenium ions in water. The nitrenium ion is protonated in acidic solutions to form the 4-(*N*-methylacetamido)aniline dication, whose pK_a is determined to be 1.5 based on the rate–pH profile. This means that the nitrenium ion is relatively basic, which suggests that there is significant positive charge on the *N*-methylacetamido group. Further evidence for this is seen in the remarkably long lifetime (5 ms) of the nitrenium ion in water. In fact, the 4-(*N*-methylacetamido)phenylnitrenium ion is 5000-fold longer-lived than the 4-methoxy-substituted analog. A 4-methoxy substituent on a phenyl ring is more electron donating according to σ^+ values (–0.78 for MeO vs. –0.60 for NMeAc). The dramatic reversal in the arylnitrenium ions is another example of the failure of these to follow the carbocation scale.

Key words: nitrenium ion, flash photolysis, amide substituent.

Résumé : La photolyse de l'azoture de 4-(*N*-méthylacétamido)phényle, en solution aqueuse, conduit à la formation quantitative de l'ion 4-(*N*-méthylacétamido)phénylnitrénium qui découle de la protonation par le solvant de l'arylnitrène singulet qui se forme originalement. On observe ce cation par photolyse éclair et on l'a identifié par un piégeage caractéristique à l'aide de l'ion azoture ou de la 2′-désoxyguanosine qui sont deux excellents nucléophiles pour les ions arylnitrénium dans l'eau. L'ion nitrénium se protone en solutions acides pour former le dication 4-(*N*-méthylacétamido)aniline qui, sur la base d'un profil vitesse–pH, aurait un pK_a de 1,5. Ce résultat indique que l'ion nitrénium est relativement basique et ceci suggère que le groupe *N*-méthylacétamido porte une charge positive importante. Cette suggestion est confirmée par le temps de vie relativement long (5 ms) de l'ion nitrénium dans l'eau. En fait, le temps de vie de l'ion 4-(*N*-méthylacétamido)phénylnitrénium est 5000 fois plus long que celui de son analogue portant un substituant 4-méthoxy. Un substituant 4-méthoxy sur un noyau phényle est plus électrorépulsif selon les valeurs de σ^+ (–0,78 pour MeO vs. –0,60 pour NMeAc). Cette inversion dramatique dans les ions arylnitrénium est un autre exemple du fait que ces entités ne suivent pas l'échelle des carbocations.

Mots clés : ion nitrénium, photolyse éclair, substituant amide.

[Traduit par la Rédaction]

The carcinogenicity observed with many aromatic amines is now recognized to be the result of metabolic activation (1–3). This bioactivation involves oxidation to a hydroxylamine derivative **2** followed by *O*-esterification, with either an acetyl or a sulfate transferase. Heterolysis of the N—O bond of the acetate or sulfate ester **3** yields a nitrenium ion **4**, which reacts with DNA, principally at the C-8 position of guanine. Adducts such as the C-8 adduct **5** have been characterized in both biological and model systems (Scheme 1) (4–6).

Arylnitrenium ions have not been spectroscopically characterized in super acids (7–9), although there have been reports of their observation in electrochemical experiments (10–12). Our group (13–23), as well as others (24–27), have recently reported their observation using laser flash photolysis (LFP) with aryl azides serving as the photochemical precursors. Nitrenium ions have also been observed with LFP by the Falvey group (28–31) using other photochemical methods. As shown in Scheme 1, the nitrenium ion from the aryl azide arises through protonation of a singlet nitrene **7**. The latter is the initial product of photolysis, being formed by loss of nitrogen from the azide. Singlet nitrenes are highly reactive species (32), but they are also remarkably basic (14). The singlet 4-biphenylylnitrene **7** (R = Ph), for example, is protonated by a solvent water molecule on the ps time scale in 20% acetonitrile:80% water (14).

Included amongst the intermediates that we have studied were a series of 4-alkoxyphenylnitrenium ions (15, 19). The

Scheme 1.

4-ethoxyphenylnitrenium ion would be derived from the carcinogen phenacetin, an analgesic long removed from the market. These cations were obtained essentially quantitatively upon irradiation of the appropriate azide in aqueous solutions; they had lifetimes in water of the order of 1 ms.

In this paper, we report a study of the *N*-(methylacetamido) phenylnitrenium ion, generated from the appropriate azide. This represents the first spectroscopic detection of an arylnitrenium ion bearing a 4-acetamido substituent. A para amido substituent, on the σ^+ scale, is substantially electron donating ($\sigma^+ = -0.60$) but it is not as good as *p*-methoxy ($\sigma^+ = -0.78$). One of the objectives of our work was to see if the σ^+ order was also observed when these substituents were present on nitrenium ions.

Experimental section

4-Acetamidophenyl azide (6, R = $NHCOCH_3$)

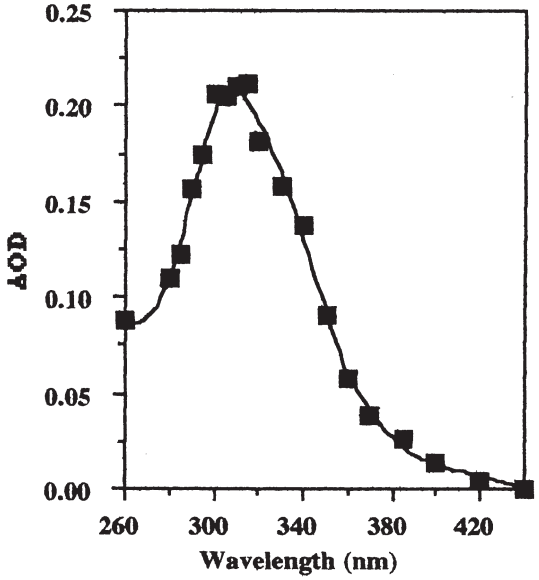
4′-Aminoacetanilide (0.1 mol) was dissolved in 95% ethanol (100 mL) and, with cooling in an ice bath, 5.0 mL of concentrated sulfuric acid was added. After 10 min, amyl nitrite (6.0 mL) was added in small portions. The reaction temperature was raised to 35–40°C for 20 min, and after cooling, the aryldiazonium salt was precipitated by the addition of ether (200 mL). The resultant precipitate was washed repeatedly with ether until the ethereal washings gave no coloration. The semiwet precipitate with ether was treated at 0°C with a solution of sodium azide (5.0 g) and sodium acetate (10 g) in 50 mL of water. After stirring for 1 h, the product was extracted into ether, which was washed with dilute sulfuric acid, water, 10% sodium carbonate, and water. The ethereal extract was dried over magnesium sulfate and the solvent was evaporated under reduced pressure. 4-Acetamidophenyl azide was obtained as a solid with mp 114–118°C which was judged sufficiently pure to proceed to the next reaction stage. ^{1}H NMR (200 MHz, DMSO-d_6) δ: 10.02 (s, 1H, disappeared in D_2O), 7.63 (d, J = 8.8 Hz, 2H), 7.04 (d, J = 8.5 Hz, 2H), 2.04 (s, 3H).

4-(*N*-Methylacetamido)phenyl azide (6, R = $N(CH_3)COCH_3$)

The 4-acetamidophenyl azide (2.5 mmol) and methyl iodide (3.0 mmol) were dissolved in anhydrous dimethyl sulfoxide (50 mL) and sodium hydride hydride (95%, 3.0 mmol) was added under argon. After stirring for 1 h at room temperature, the reaction mixture was diluted with ether (150 mL) and the organic layer was washed with water, dried over magnesium sulfate, and the solvent evaporated under reduced pressure to give an oily residue which solidified on standing. The crude product was purified by column chromatography on silica gel eluting with 50:50 ethyl acetate:hexanes. 4-(*N*-Methylacetamido)phenyl azide decomposed on heating above 100°C. HRMS *m*/*z* 190.0859; $C_9H_{10}N_4O$ requires 190.0855. IR (cm^{-1}): 2219. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.62 (d, J = 8.5 Hz, 2H), 7.10 (d, J = 8.5 Hz, 2H), 3.26 (s, 3H), 1.94 (s, 3H). HPLC (see below) showed only a single peak.

Laser flash photolysis experiments involved ca. 20 ns pulses at 248 nm (60–120 mJ per pulse) from a Lumonics excimer laser. A pulsed Xenon lamp providing monitoring light. The sample was placed in a 4 × 1 × 1 cm cuvette, irradiated with the laser on the 4 × 1 face, and monitored perpendicular so that the path length was 4 cm. The cuvette was replaced with a fresh solution after each irradiation. After passing through a monochromator, the signal from the photomultiplier tube was digitized and sent to a computer for analysis.

Conventional flash photolysis experiments were performed using an apparatus previously described (33) with the sample being irradiated with a broad band flash lamp of ca. 100 μs duration.



Product analyses were performed with a Waters HPLC system using a C^{18} column with 2 mL per minute flow rate and the UV–vis detector set at 260 nm. Elution was carried out with isocratic 60:40 acetonitrile:water. The 4-(*N*-methylacetamido)phenyl azide was dissolved in water and dilute aqueous buffers to give solutions of concentration 5×10^{-4} M. Injection of these solutions before irradiation gave only one peak in the chromatogram. As discussed in the *Results section*, irradiation of this aqueous solution at 254 nm in a Rayonet reactor resulted in clean conversion to a peak for an unstable species, which thermally converted over time to a third peak with a retention time identical to that of *p*-benzoquinone. That this peak did correspond to benzoquinone was verified from a scaled-up reaction where the product was isolated and its ^{1}H NMR spectrum recorded. The conversions of the azide to the benzoquinone were quantitatively analyzed by determining the response factors for the two, and using these to correct peak areas of the irradiated solutions.

Results and discussion

As shown in Fig. 1, 248 nm laser irradiation of an aqueous solution of 4-(*N*-methylacetamido)phenyl azide resulted in a strong absorbance with a λ_{max} at 310 nm. This absorbance was quite stable, showing only a small decay at the longest times available with our laser apparatus (1 ms). Addition of small concentrations of sodium azide accelerated the decay, resulting in excellent first-order plots proceeding to the baseline above 290 nm. A plot of the decay

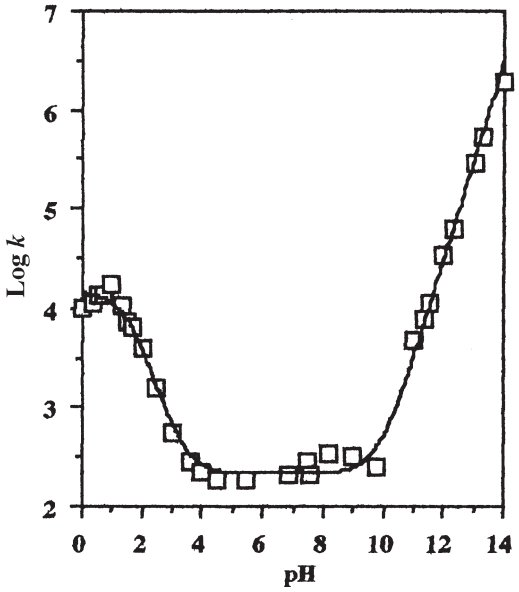
Fig. 1. Transient spectrum obtained on 248 nm laser irradiation of a solution of 4-(*N*-methylacetamido)phenyl azide (2×10^{-4} M) in water. (Note that this is a difference spectrum, i.e., the optical density after the laser pulse – the optical density before the pulse).

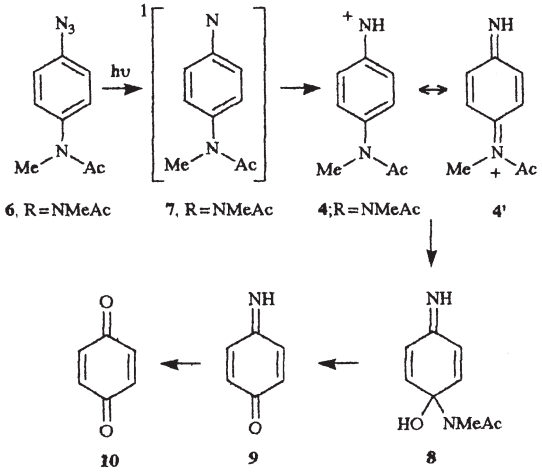


rate constants *k* (obs) vs. the concentration of azide was linear, with a slope of 3.9×10^9 M^{-1} s^{-1}.

Highly efficient quenching by azide ion is a characteristic of carbocations and arylnitrenium ions (34). More compelling evidence for the 4-(*N*-methylacetamido)phenylnitrenium ion comes in the analysis of the products of irradiation in aqueous solutions. Protonation of a singlet arylnitrene is obvious in the products (14), since the nucleophilic adducts derived from the further reactions of a nitrenium ion are very different in nature from the products associated with other reactions of singlet arylnitrenes, such as intersystem crossing to a triplet or ring expansion to a didehydroazepine. In the case of the nitrenium ion in question in this study, we anticipated that the reaction with water would follow the course outlined in Scheme 2. The solvent should react at the position para to the formal nitrenium center, the normal fate of simple arylnitrenium ions in water (14, 35–37). This would give an intermediate **8** which would eliminate *N*-methylacetamide to give the monoimine of benzoquinone **9**. This species is unstable in aqueous solutions, undergoing hydrolysis of the imine to give *p*-benzoquinone **10** (38).

Indeed irradiation of 4-(*N*-methylacetamido)phenyl azide at 254 nm in aqueous solutions for times up to 75% conversion resulted in the formation of benzoquinone as the only stable product that could be observed by HPLC. The yield of this product, based upon quantitative HPLC analysis, was 100% (95 ± 5%). A second peak could be seen at early times. This peak disappeared and was replaced by the peak for the benzoquinone. The material responsible for this early peak can be identified as the quinoneimine **9**. This assignment is based upon an identical UV spectrum and, in particular, kinetic behavior for this material with that previously published for an authentic sample of the quinoneimine (38). This same imine was also observed in our earlier studies with the *p*-alkoxyphenyl azides (19). The nitrenium ions derived from these azides react in an analogous manner, with

Fig. 2. Log rate vs. pH for the 4-(*N*-methylacetamido)phenylnitrenium ion. Points are experimental and have been extrapolated to zero buffer concentration where measurements were performed in buffers. The line through the experimental points has been drawn according to the equation $k_{OH}[OH^-] + (k_w^+{}^2[H^+] + k_w^+K_a)$: $([H^+] + K_a)$ using the values for the parameters given in the text. It can be noted that the plateau in acid decreases slightly. This may be related to a specific salt effect, as was observed in a previous study (14).



water reacting at the para position to give an adduct that eliminates an alcohol to give the same imine **9**.

It can be noted that there is an alternative mechanism for the formation of **9** from the *N*-methylacetamidophenyl nitrenium ion. This involves hydrolytic deacylation of the nitrenium ion, rather than water addition at the para position. This route can be ruled out on two grounds. The first is that this reaction results in an intermediate bis-imine, 1-imino–4-methyliminobenzoquinone. According to data for the analog without the methyl group (38) this should be long-lived, particularly at higher pH. The second is that the bis-imine is likely to hydrolyze both imino groups at comparable rates, so that there would be two different monoimine intermediates, **9** and the *N*-methyl analog of **9**. Thus, this route predicts that there could be three intermediates observable by HPLC. In fact, there is only one such intermediate.

While the decay of the nitrenium ion in water alone was too slow for the apparatus, it could be observed by irradiating an aqueous solution of 4-(*N*-methylacetamido)phenyl azide with a lamp flash photolysis apparatus. This showed an excellent first-order decay occurring on the ms time scale with a rate constant of 2×10^2 s^{-1}. The rate constant for quenching by azide ion is interesting in this regard, since the value, 3.9×10^9 M^{-1} s^{-1}, is still quite close to the maximum value of 9 to 10×10^9 $M^{-1}s^{-1}$ found for more reactive nitrenium ions (16). This maximum is associated with the azide–nitrenium combination becoming diffusion controlled, i.e., the rate-limiting step is encounter (16, 34). Combinations of azide and short-lived benzylic-type carbocations are also diffusion-controlled (34, 39). What is interesting is that

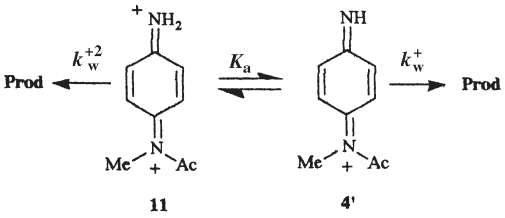
Scheme 2.

6, R=NMeAc 7, R=NMeAc 4;R=NMeAc 4' 10 9 8

the break to rate-limiting bond formation as the carbocation becomes less reactive occurs at a much earlier point then it does with a nitrenium ion. For example, a triphenylmethyl cation that reacted with water with a rate constant of 2×10^2 s^{-1} would react with azide ion with a rate constant around 1×10^8 M^{-1} s^{-1}, well below the diffusion limit (39).

Figure 2 provides further kinetic information about the behavior of the nitrenium ion in the form of the dependence of its rate constant for decay as a function of pH. This figure was constructed through a combination of experiments with laser and lamp flash photolysis, the latter being used for the solutions with pH 2–10, and the former for the faster reactions in the acidic and basic solutions. It can be seen that there is a pH-independent region from pH 4–10. This represents the reaction of the cation with water. In more basic solutions, this breaks to a linear dependence on hydroxide ion, with the slope $k_{OH} = 3 \times 10^6$ M^{-1} s^{-1}. This is clearly explained by reaction with hydroxide ion. The acceleration in acid is a feature of nitrenium ions that we have observed previously (14, 19). It is explained by the mechanism of Scheme 3, whereby under acidic conditions, reaction occurs via the dication **11**, the conjugate acid of the nitrenium ion.



The levelling below pH 2 indicates that the protonation equilibrium actually shifts to the dication. The experimental data can be fit to eq. [1],

$$[1] \qquad k_{obs} = \frac{F(k_w^{+2}[H^+] + k_w^+ K_a}{[H^+] + K_a}$$

where k_w^{+2} and k_w^+ are the rate constants for the reaction of water with the dication and monocation, respectively, and K_a is the acidity constant of the dication. Parameters obtained from this fit are provided in Table 1, where they are also compared with values obtained from other systems.

The basicity of the NH group of an arylnitrenium ion is one indicator that the structure Ar-N^+H is only a very minor resonance contributor. There must, in fact, be little positive charge at this nitrogen, i.e., that the cation is better written as a cyclohexadienyl cation with an imine substituent, as in the resonance structure **4′** in Scheme 3. Recent time-resolved IR (30, 31) and resonance Raman (27) spectra have provided excellent evidence for this. The data in Table 1 show that the

Scheme 3.

11 4'

nitrenium ion of this study is one of the more basic examples, although it is not nearly as basic as the nitrenium ion derived from benzidine (23). This suggests that the *N*-methylacetamido group in the cation bears a considerable fraction of the positive charge. This is clearly also evident in the kinetic stability of this cation.

The 4-(*N*-methylacetamido)phenylnitrenium ion was also generated from the azide in the presence of 2′-deoxyguanosine. The nucleoside did quench the cation, with a rate constant k_{dG} of 9.0×10^6 M^{-1} s^{-1}. Efficient quenching by guanine derivatives is also a characteristic of arylnitrenium ions. We have previously determined k_{dG} values for a series of biphenylylnitrenium ions (17). The reactive derivatives in this series combined at the diffusion limit with a constant k_{dG} of 2×10^9 M^{-1} s^{-1}. The less reactive derivatives react more slowly, and showed a constant k_{dG}:k_w selectivity of 2 to 3×10^4 M^{-1}. The value of k_{dG}:k_w for the cation of this study is 4.5×10^4 M^{-1}. Thus, this cation is behaving in a similar manner as the biphenylyl derivatives.

One of the remarkable features of the 4-(*N*-methylacetamido)phenylnitrenium ion is its long lifetime in water. This is dramatically illustrated in Fig. 3 in terms of a Hammett plot of the rate constants for water addition vs. σ^+. As originally noted by Novak et al. (35) this correlation is scattered. What is particularly notable is that the lifetime of the 4-NMeAc derivative is 5000-fold longer than that of the 4-methoxy-substituted cation, despite the fact that 4-MeO is more electron donating according to its σ^+ value (–0.78 for MeO vs. –0.60 for NMeAc (40)). As noted above, there is now excellent evidence that arylnitrenium ions have substantial cyclohexadienyl cation character. With heteroatom substituents such as oxygen and nitrogen, the positive charge will be further significantly delocalized onto the heteroatom. Thus, the 4-methoxyphenylnitrenium ion is probably best described as an oxocarbocation (C=O$^+$Me), and the cation of this study as a acyliminium ion (C=N$^+$MeAc). Since σ^+ calibrates the effect of a substituent on the transition state for a developing positive charge on a benzylic carbon, it is therefore not surprising that the arylnitrenium correlation is poor. There is in fact some evidence that intrinsic barriers for addition to oxocarbocations are low, i.e., that the cations are inherently reactive (41). No such data exists for acetylated iminium ions. The present study suggests that this class of cation is inherently less reactive.

In conclusion, this paper further describes the remarkable basicity of singlet nitrenes, especially those bearing an electron-donating group in the 4- position. The results provide further confirmation that arylnitrenium ions are better described as imino cyclohexadienyl cations. The 4-*N*-methylacetamidophenylnitrenium ion is in fact remarkably long lived in aqueous solution especially when compared to

Reaction of arylnitrenium ions with guanine derivatives: N^1-methylguanosine and N^2,N^2-dimethylguanosine

Bernice Cheng and Robert A. McClelland

Abstract: A prior flash photolysis study of the direct reaction of arylnitrenium ions with 2′-deoxyguanosine identified a second intermediate that grew in as the transient nitrenium ion reacted with the nucleoside. This intermediate was identified as the the product of the addition of the nitrenium ion to the C-8 position of guanine prior to loss of the C-8 proton — the C-8 intermediate. A feature of the C-8 intermediate is that it exists in acid–base forms. This behavior was evident in both a spectroscopic analysis as well as in the rate–pH profile, which showed a break around pH 4 from a pH-independent reaction to a reaction that was first-order in H^+. The present study was designed to identify the structure of the conjugate base form. This involved a kinetic study of the decay of the C-8 intermediate derived from the reaction of the 2-fluorenylnitrenium ion with N^1-methylguanosine and N^2,N^2-dimethylguanosine. The rationale was that the former is unable to lose the N-1 proton, while the latter cannot deprotonate at the NH_2 group. The rate–pH profiles clearly show that it is the N-1 proton that is acidic. The rate constants for the C-8 intermediate of N^2,N^2-dimethylguanosine show the same downward break observed with 2′-deoxyguanosine and guanosine associated with conversion to the conjugate base form. In contrast, the rate constants for the N^1-methylguanosine intermediate are independent of pH. Rate constants for the reaction forming the C-8 intermediate are also reported. These show that the reaction of nitrenium ions with the N^2,N^2-dimethylguanine derivative is significantly faster (except where the reactions are diffusion controlled). This is consistent with the initial step of the reaction of an arylnitrenium ion and guanine occurring by direct addition at C-8. The developing positive charge in such a reaction can be delocalized to the C-2 position where π donors such as NH_2 and NMe_2 can exert a stabilizing effect.

Key words: nitrenium, arylnitrenium, guanosine, DNA adduct.

Résumé : Une étude antérieure par photolyse éclair de la réaction directe des ions arylnitrénium avec la 2′-désoxyguanosine a identifié une deuxième intermédiaire dont la concentration croissait alors que l'ion nitrénium réagissait avec le nucléoside. L'intermédiaire avait été identifié comme le produit d'addition de l'ion nitrénium sur la position C-8 de la guanine, avant la perte du proton C-8 — l'intermédiaire C-8. Une caractéristique de l'intermédiaire C-8 est sa possibilité d'exister sous les formes acide et base. Ce comportement était évident tant dans une analyse spectroscopique que dans le profil vitesse–pH qui mettait bien en évidence un bris autour du pH 4 d'une réaction indépendante du pH à une réaction du premier ordre en ions H^+. L'étude présente a été réalisée afin d'identifier la structure de la forme de la base conjuguée. Elle implique une étude cinétique de la décroissance de l'intermédiaire C-8 obtenu par réaction de l'ion 2-fluorénylnitrénium avec les N^1-méthyl- et N^2,N^2-diméthylguanosines. La base de ce choix réside dans le fait que le premier intermédiaire ne peut perdre de proton en N-1 alors que le deuxième ne peut pas se déprotoner au niveau du groupe NH_2. Les profils de vitesse–pH montrent clairement que le proton acide est en N-1. Les constantes de vitesse de l'intermédiaire de la N^2,N^2-diméthylguanosine présentent la même diminution que celles observées avec la 2′-désoxyguanosine et la guanosine associées avec la conversion en forme conjuguée basique. Par ailleurs, les constantes de vitesse pour l'intermédiaire de la N^1-méthylguanosine sont indépendantes du pH. On a aussi déterminé les constantes de vitesse pour la formation de l'intermédiaire C-8. Celles-ci démontrent que la réaction des ions nitrénium avec le dérivé N^2,N^2-diméthylguanidine est beaucoup plus rapide (à l'exception des cas où les réactions sont sous le contrôle de la diffusion). Ce résultat est en accord avec une étape initiale de la réaction d'un ion arylnitrénium avec la guanidine qui se produirait par une addition directe en C-8. La charge positive qui se développerait dans une telle réaction peut être délocalisée vers la position C-2 dans laquelle des donneurs π tels que NH_2 et NMe_2 peuvent exercer un effet stabilisant.

Mots clés : nitrénium, arylnitrénium, adduit avec l'ADN, guanosine.

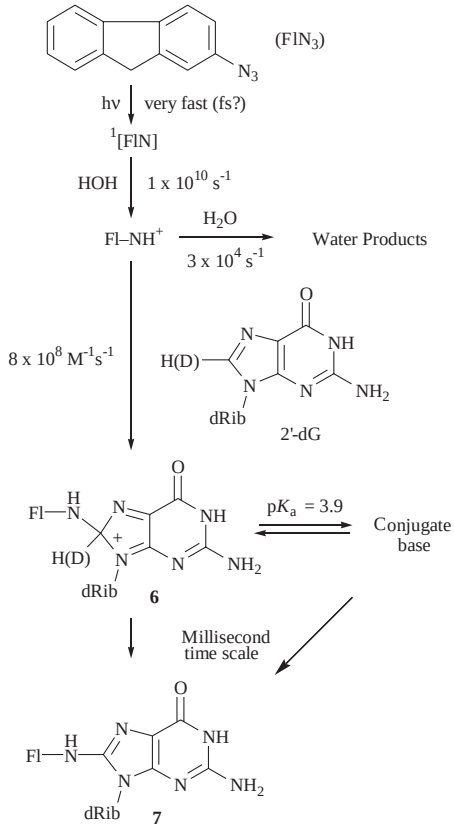
Scheme 1.



A common product formed in vivo with arylamine carcinogens **1** is a covalent DNA adduct **5** derived from arylamination at the C-8 position of guanine residues (1). The reactive intermediate responsible for this product is an arylnitrenium ion **4** (2–5). This electrophile is obtained after metabolic activation of the arylamine (6–8) – P450-mediated oxidation to a hydroxylamine **2**, followed by acetylation or sulphation to a reactive ester **3** whose S_N1-type ionization produces the nitrenium ion (Scheme 1).

While there can be no doubt these days that the C-8 adduct is obtained from the reaction of the nitrenium ion and guanine (2–5), there has been debate over the reaction mechanism. Based upon experiments with C-8-methylated guanine derivatives, both Humphreys et al. (9) and Kennedy et al. (3) have suggested that the nitrenium ion reacts initially at the N-7 position, followed by migration to C-8. This same suggestion has been advanced in a recent paper, also from the Guengerich group (10). Our group, however, has suggested that the mechanism is essentially a straightforward electrophilic aromatic substitution, with initial reaction directly at the C-8 carbon, followed by loss of the C-8 proton (5).

Our evidence was based on experiments employing flash photolysis where arylnitrenium ions were observed as transient intermediates, and their reactions with guanine derivatives directly monitored (5). The important aspects of this work are summarized in Scheme 2 with the 2-fluorenylnitrenium ion ($Fl–NH^+$).

The cation is obtained in the flash photolysis experiments by irradiation of 2-azidofluorene (FlN_3). Photolysis of this azide results in extremely rapid (probably fs time scale (11)) loss of nitrogen to give a singlet nitrene ^{1}[FlN]. In aqueous solutions, this is protonated by the solvent on the ps time scale (12) to give the conjugate acid, the nitrenium ion. This cation is observed on the ns time scale in laser flash photolysis experiments as an intensely absorbing transient intermediate with λ_{max} at 450–460 nm. Assignment of this transient as the ground state 2-fluorenylnitrenium ion was based on a number of arguments (12); this assignment has recently been confirmed by time-resolved resonance Raman spectroscopy (13). The nitrenium ion decays with a lifetime of 30 μs in water alone, and at the completion of the decay there is little absorbance above 310 nm. Guanine derivatives are excellent nucleophiles for arylnitrenium ions, and compete very effectively even with the aqueous solvent (2–4). Thus, with 2′-deoxyguanosine (dG) present, the decay is significantly accelerated. Moreover, as the cation decays, there is a significant growth in absorbance in the region 310–400 nm. This new absorbance turns out to be associated with a second intermediate, whose reaction to give the stable C-8 adduct **7** can be observed with lamp flash photolysis on the ms time scale. Several pieces of evidence identify this intermediate as being derived from addition of the nitrenium ion to the C-8 carbon prior to loss of the C-8 proton and the formation of the final C-8 adduct. We will term this species the "C-8 intermediate" to distinguish it from the stable final product derived from loss of the C-8 proton — "the C-8 adduct". As expected, there is a large primary kinetic isotope effect for the decay of the C-8 intermediate when dG is substituted with deuterium at the 8-position. A small inverse kinetic isotope effect observed for the initial reaction forming the C-8 intermediate indicates that the nitrenium ion adds directly to the C-8 position, i.e., that the mechanism is an addition–elimination at the C-8 carbon as shown in Scheme 2. The latter isotope effect eliminates mechanisms where the C-8 intermediate is formed after initial addition at N-7; the latter possibility can also be ruled out on the basis of kinetic arguments (5).

Scheme 2.

One of the features of the second intermediate is that it exists in conjugate acid–base forms. This was seen both in the rate–pH profile for its subsequent reaction to the stable C-8 adduct and in the change in its spectra as a function of pH. Acidity constants were obtained with both methods, and were in agreement, at $pK_a = 3.9$. While the conjugate acid of this intermediate must be the cation **6**, there was uncertainty in the structure of the base form. In this paper this question has been addressed by generating this second intermediate from N^1-methylguanosine, where loss of the N^1-H proton cannot occur, and from N^2,N^2-dimethylguanosine, where loss of an NH_2 proton has been eliminated. Derivatives of

guanosine, rather than 2′-deoxyguanosine, were employed for economical reasons. A further aspect of the present study involves the measurement of the kinetics of the initial reaction of the two methylated guanine derivatives with nitrenium ions. These show some interesting effects that are also consistent with the initial reaction occurring at the C-8 position.

Experimental section

2-Fluorenyl azide (12), 4-biphenylyl azide (12), 4′-methyl-4-biphenylyl azide (14), and 4′-methoxy-4-biphenylyl azide (14) were from previous studies. N^1-Methylguanosine was prepared by the reaction of guanosine and *N*,*N*-dimethylacetamide dimethyl acetal in methanol (15). N^2,N^2-Dimethylguanosine was prepared in a multistep procedure: (*i*) guanosine was converted to 2′,3′,5′-tri-*O*-acetylguanosine by the reaction with acetic acid anhydride in the presence of 4-dimethylpyridine and triethylamine (16); (*ii*) 2′,3′,5′-tri-*O*-acetylguanosine was reacted with phosphorus oxychloride in acetonitrile containing tetraethylammonium chloride and *N*,*N*-dimethylaniline to give 2-amino-6-chloro-9-(2, 3, 5-tri-*O*-acetyl-β-D-ribofuranosyl)purine (17); (*iii*) this was converted to 2-amino-6-chloro-9-β-D-ribofuranosylpurine by treatment with saturated methanolic ammonia (18); (*iv*) the 2-amino-6-chloro-9-β-D-ribofuranosylpurine was reacted with sodium benzyloxide in benzyl alcohol to give 2-amino-6-benzyloxy-9-β-D-ribofuranosylpurine (91); (*v*) diazotization with sodium nitrite in 48% aqueous fluoroboric acid afforded 2-fluoro-6-benzyloxy-9-β-D-ribofuranosylpurine (19); (*vi*) the fluoride was substituted in 20% methanolic dimethylamine to give 2-dimethylamino-6-benzyloxy-9-β-D-ribofuranosylpurine (19); (*vii*) hydrogenolysis with palladium on carbon gave the desired product N^2,N^2-dimethylguanosine (19). Full experimental details of our preparations of N^1-methylguanosine and N^2,N^2-dimethylguanosine are available as supplementary material.[2]

Laser flash photolysis experiments involved ca. 20 ns pulses at 308 nm (60–120 mJ per pulse) from a Lumonics excimer laser. A pulsed Xenon lamp provided the monitoring light. After passing through a monochromator, the signal from the photomultiplier tube was digitized and sent to a computer for analysis. Stock solutions of the nucleosides — guanosine (0.001 M), N^1-methylguanosine (0.001 M), and N^2,N^2-dimethylguanosine (0.0004 M) — were prepared in 20% acetonitrile containing 0.002 M NaH_2PO_4:0.002 M Na_2HPO_4. For each nucleoside, a series of solutions of 100 mL volume were prepared by adding volumes of the stock solutions — 100, 80, 60, 40, 20, 0 mL — to a 100 mL volumetric flask, and filling to the mark with the 20% acetonitrile solution containing the phosphate buffer. These 100 mL solutions were divided into four 25 mL volumetric flasks. A concentrated acetonitrile solution of the four azides — 2-fluorenyl, 4-biphenylyl, 4′-methyl-4-biphenylyl, and 4′-methoxy-4-biphenylyl azide — was added to each of these flasks immediately before irradiation to give a solution of final concentration ~10 μM. This solution was transferred to a 4 × 1 × 1 cm cuvette, and irradiated at 308 nm, with the decay of the transient nitrenium ion being monitored at its λ_{max} (14) — 2-fluorenyl (450 nm), 4-biphenylyl (455 nm), 4′-methyl-4-biphenylyl (475 nm), and 4′-methoxy-4-biphenylyl (500 nm). First-order rate constants were obtained by fitting the decay traces to the equation for a single exponential process. Solutions were flashed once and replaced with 4 to 5 kinetic runs being performed with each solution.

Lamp flash photolysis experiments were performed using an apparatus previously described (20). Aqueous solutions were prepared containing 2×10^{-4} M of the nucleoside. The pH was maintained by HCl, acetate buffer, or cacodylate buffer. In the case of the buffers, serial buffer dilutions were employed so that rate constants could be extrapolated to zero buffer concentrations. Shortly before irradiation, a concentrated acetonitrile solution of 2-fluorenyl azide was added to give a final azide concentration of 8 μM. The solution was irradiated with a broad band flash lamp of ca. 100 μs duration. The absorbance decay at 365 nm was monitored and fit to the exponential equation. For a given solution, 4 to 5 kinetic traces were obtained and the rate constants for these averaged. After irradiation, the pH of the solution was measured.

Results

Laser flash photolysis — Reaction of arylnitrenium ions and nucleosides

In these experiments, four nitrenium ions were generated and their decay studied in the presence of the three nucleosides guanosine, N^1-methylguanosine, and N^2,N^2-dimethylguanosine. The nucleosides significantly accelerated the decay of the nitrenium ion. Plots of the observed first-order rate constant for the decay were linear in the concentration of the nucleosides. The slopes of these plots are the second-order rate constants for the reaction of the nitrenium ion and the nucleoside. These rate constants are provided in Table 1, along with pertinent values that had been previously obtained.

Lamp flash photolysis — Decay of intermediate

These experiments were conducted with the intermediate formed by the reaction of the 2-fluorenylnitrenium ion and the three nucleosides guanosine, N^1-methylguanosine, and N^2,N^2-dimethylguanosine. Concentrations of the nucleosides were kept constant at 200 μM, a concentration where greater than 90% of the nitrenium ion reacts with the added nucleoside. As observed in the previous experiments with 2′-deoxyguanosine, a second intermediate is observed following the initial reaction of the nitrenium ion and the nucleoside. We monitored the decay of this intermediate at 365 nm, a wavelength where there is a significant difference between the absorbance of the intermediate and the absorbance of the final product. Rate constants were obtained in a series of HCl solutions and in acetate and cacodylate buffers. In the case of the buffers, serial buffer dilutions were performed. The buffer does accelerate the rate of decay (5). This aspect of the kinetics was not investigated in detail in this study, since our interest was in the rate constant extrapolated to zero buffer concentration. These rate

Effect of pH on the rate constants at 20°C for the decay of the intermediate formed by the reaction of the 2-fluorenylnitrenium ion and nucleosides: guanosine (closed squares), N^1-methylguanosine (open squares), N^2,N^2-dimethylguanosine (closed circles), and 2′-deoxyguanosine (open circles) (data from ref. 5). Rate constants have been measured in HCl solutions (pH < 3.5) and in acetate and phosphate buffers; for the latter the values plotted are based on extrapolation to zero buffer concentration. The points are experimental; the lines have been based on eq. [1].

constants, alongside data previously obtained with 2′-deoxyguanosine (5), are depicted in the form of a rate–pH profile in Fig. 1.

Discussion

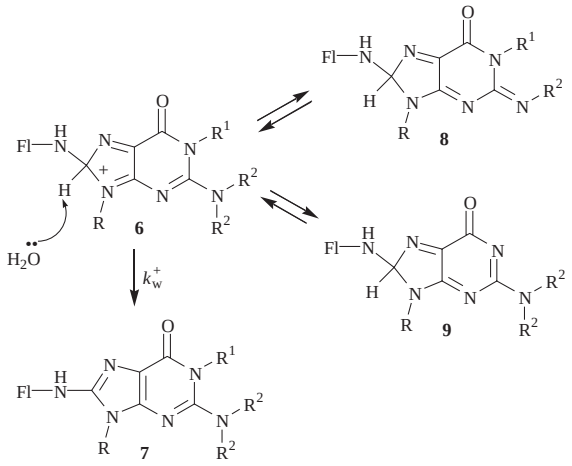
Structure of the conjugate base of C-8 intermediate

Using flash photolysis, two short-lived intermediates can be observed for the reaction that produces the C-8 adduct found as a product of the interaction of arylamine carcinogens and guanine — the arylnitrenium ion and the subsequent intermediate that we have identified as the C-8 intermediate. This second intermediate is relatively long-lived. Its deprotonation to give the final product, the stable C-8 adduct, occurs on the ms time scale.

The open circles in Fig. 1 show the acidic portion of the rate–pH profile previously obtained for the decay of the C-8 intermediate derived from the reaction of 2′-deoxyguanosine with the 2-fluorenylnitrenium ion (5). The present study shows that a C-8 intermediate is also observed in the reaction of this nitrenium ion with guanosine as well as with N^1-methylguanosine and with N^2,N^2-dimethylguanosine. The rate constants for the breakdown of the guanosine C-8 intermediate, shown in Fig. 1 as closed squares, are not surprisingly very similar to those of the deoxy derivative. These two profiles show a region in acidic solutions where the rate constant is essentially unchanged with changing pH, with a break around pH 4 to a reaction which is first-order in H^+. It was this downward break that indicated the presence of acid–base forms of the C-8 intermediate; this was verified by obtaining spectra as a function of pH (5).

While other mechanisms operate at higher pH (5), the rate–pH profile in acid is explained by the mechanism of Scheme 3. This involves a rapid and reversible equilibration of the cationic form of the C-8 intermediate **6** with a conjugate base. The cation is the reactive species, with the C-8 proton being transferred to a water molecule.

The rate equation for this mechanism is given in eq. [1],



$$[1] \qquad k = \frac{k_w^+[H^+]}{[H^+] + K_a}$$

where k_w^+ is the first-order rate constant for the removal of the C-8 proton in the cation by the solvent and K_a is the acidity constant for conversion to the conjugate base form. There are two candidates for the conjugate base form, structure **8** that is derived from loss of one of the NH_2 protons and structure **9** that is derived from loss of the N-1 proton. These are tautomers of one another, and also tautomers of the stable C-8 adduct. The tautomer **8** or **9** is derived from loss of proton from a heteroatom, a process that is very fast. Thus, this conjugate base will form as a kinetic product in solutions that have a pH higher than the pK_a. The slower loss of the C-8 proton results in the thermodynamic product.

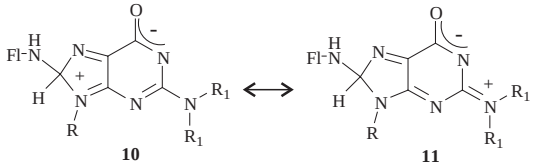
To determine the structure of the conjugate base form, rate–pH profiles were obtained for the C-8 intermediates derived from N^1-methylguanosine and N^2,N^2-dimethylguanosine. The former is obviously unable to lose the N-1 proton, while the

© 2001 NRC Canada

Scheme 3.

latter cannot deprotonate at the NH_2 group. The results in Fig. 1 show that it is the intermediate from N^1-methylguanosine that lacks the break associated with the deprotonation. Rate constants for this species are the same within experimental error from pH 2 to pH 6. The N^2,N^2-dimethyl derivative, on the other hand, shows qualitatively the same behavior as the non-methylated analogs. Thus, it is the N-1 proton that is being lost when the C-8 intermediate undergoes ionization, and the conjugate base is **9**.

Table 2 provides values of the rate constants k_w^+ and the acidity constants (as pK_a values) obtained by fitting the experimental data to eq. [1] (with only k_w^+ obviously available for N^1-methylguanosine). The values of k_w^+ are within a factor of two of one another. The one significant difference is the pK_a of the C-8 intermediate from the dimethylguanosine that shows that this species is one log unit more acidic than the intermediates from guanosine and 2′-deoxyguanosine. There is no obvious reason for this difference. The N-1 proton in guanosine is acidic (pK_a = 9.2). This acidity can be explained by delocalization of the negative charge onto the adjacent oxygen. Thus, one possibility to explain the behavior in the C-8 intermediates is that these have significant contributions from zwitterionic resonance contributors such as structures **10** and **11** of Scheme 4. According to their σ^+ values (21), the *N*,*N*-dimethylamino group is better than NH_2 at providing resonance stabilization to positive charge. Thus, the contribution from the zwitterionic resonance contributor **11** would be more important with the dimethylamino group as opposed to the simple amino group. This resonance contributor has the closer proximity of the positive and negative charge, so that this effect would be overall stabilizing to the compound.



Effect of substituents on reactions of nitrenium ions with guanosine derivatives

The greater stabilizing effect of NMe_2 over NH_2 can also be seen in the rate constants for the reaction where the C-8 intermediate forms from the arylnitrenium ion and the guanosine derivative. As shown in Table 1, we investigated four nitrenium ions with lifetimes in water varying by three orders of magnitude. The rate constants for the most reactive, the 4-biphenylyl derivative, are, within experimental error, the same, with values around 2×10^9 M^{-1} s^{-1}. We have argued that this rate constant corresponds to a cation–nucleoside combination that is diffusion controlled (or very close to diffusion controlled). Thus, there is no discrimination between the four guanine derivatives. This is also the case for the next most reactive member of the series, the 4′-methylbiphenylyl derivative, although the rate constants are somewhat smaller than the value associated with diffusion control. Selectivity starts appearing with the 2-fluorenylnitrenium ion. With this cation, guanosine, the 2′-deoxy derivative and the N^1-methyl derivative, have very similar reactivities, with rate constants below the diffusion limit. The dimethyl analog in contrast is over twofold more reactive, and its rate constant is at the diffusion limit. This difference with the dimethylamino derivative also applies to the least reactive member of the series, the 4′-methoxy-4-biphenylyl cation. Here, however, the effect is quite substantial, with an order of magnitude difference between the dimethylguanosine and the other three.

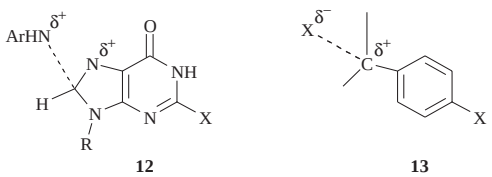


Table 2. Rate constants k_w^+ and acidity constants pK_a for the C-8 intermediates derived from the reaction of the 2-fluorenylnitrenium ion with guanine derivatives.

Nucleoside	k_w^+ (s^{-1})	pK_a
2′-Deoxyguanosine (5)	1.6×10^3	3.9
Guanosine	1.3×10^3	4.1
N^2,N^2-Dimethylguanosine	7.8×10^2	2.9
N^1-Methylguanosine	1.0×10^3	—

Scheme 4.

When an electrophile such as a nitrenium ions adds at the C-8 carbon of a purine ring, there is a formal build-up of positive charge at N-7, as shown in the transition-state structure **12**. Conjugative electron donating substituents at C-2 of the purine, such as the NH_2 group of a guanine derivative, are located in a position para to this developing positive charge. The interaction with this charge should therefore occur in exactly the same fashion as that of a para substituent in an S_N1 solvolysis of a benzyl derivative, i.e., as in the transition-state structure **13**. The effects of such substituents in the latter solvolysis are measured on the σ^+ scale. Relevant values (21) are σ^+ = 0.00 (H), –1.3 (NH_2). and –1.7 (NMe_2).

© 2001 NRC Canada

With this analogy to S_N1 solvolysis, it is not surprising that a 6-oxopurine derivative with a hydrogen at C-2 (2′-deoxyinosine) does not react efficiently with nitrenium ions in comparison to a guanine derivative, where there is an NH_2 group. Replacing the NH_2 group with NMe_2 adds further stabilization, with a further increase in reactivity. The order of reactivity — H << NH_2 < NMe_2 — is a further indication that the reactions of arylnitrenium ions and guanine derivatives are occurring via direct addition at the C-8 carbon, as shown in Scheme 2 in the introduction. Substituents at the 2-position of a purine are unlikely to show the same large effects for a reaction where the rate-limiting step involves bonding to the N-7 nitrogen. Although there is positive charge developing at N-7 in the transition state for such a reaction, this charge cannot be delocalized to a π-donor at C-2.

The nature of the transition state in diarylmethyl cation – nucleophile combination reactions as probed by secondary α-deuterium isotope effects

Thuy Van Pham and Robert A. McClelland

Abstract: Transition-state structures for the carbocation–nucleophile combination reactions of (4-substituted-4′-methoxydiphenyl)methyl cations with water, chloride, and bromide ions in acetonitrile–water mixtures have been investigated by measuring the secondary α-deuterium kinetic and equilibrium isotope effects. Rate constants in the combination direction were measured with laser flash photolysis. Equilibrium constants were measured for the water reaction by a comparison method in moderately concentrated sulfuric acid solutions, for the bromide reaction via the observation of reversible combination, and for the chloride reaction from the ratio of the combination rate constant and the rate constant for the ionization of the diarylmethyl chloride product. The fraction of bond making in the transition state has been calculated as the ratio log (kinetic isotope effect):log (equilibrium isotope effect). For the water reaction, there is 50–65% bond making in the transition state; this is also true for cations that are many orders of magnitude less reactive. The same conclusions, 50–65% bond formation in the transition state independent of reactivity, have previously been made in correlations of log k_w vs. log K_R. Thus, two quite different measures of transition structure provide the same result. The k^H:k^D values for the halide combinations in 100% acetonitrile are within experimental error of unity. This is consistent with suggestions that these reactions are occurring with diffusional encounter as the rate-limiting step. Addition of water has a dramatic retarding effect on the halide reactions, with rate constants decreasing steadily with increased water content. Small inverse kinetic isotope effects are observed (in 20% acetonitrile:80% water) indicating that carbon—halogen bond formation is rate-limiting. Comparison of the kinetic and equilibrium isotope effects shows ~25 and ~40% bond formation in the transition states for the reactions with bromide and chloride, respectively.

Key words: carbocation, isotope effect, transition state, halide.

Résumé : On a étudié les structures des états de transition pour les réactions carbocation–nucléophile de cations (4-X-4′-méthoxydiphényl)méthyles avec l'eau et les ions chlorure et bromure, en solution dans des mélanges acétonitrile–eau, en se basant sur des mesures d'effets isotopiques d'équilibre et cinétiques secondaires de deutérium en α. Les constantes de réaction dans la direction de la combinaison ont été déterminées en faisant appel à la photolyse éclair au laser. Les constantes d'équilibre ont été mesurées: pour la réaction de l'eau, par une méthode de comparaison dans des solutions relativement concentrées d'acide sulfurique; pour la réaction de l'ion bromure, par le biais de l'observation de la combinaison réversible; et pour la réaction de l'ion chlorure, à partir du rapport de la constante de constante de vitesse de la combinaison et la constante de vitesse pour l'ionisation du produit, le chlorure de diarylméthyle. On considère que la fraction de formation de liaison dans l'état de transition est égale au rapport log (effet isotopique cinétique) : log (effet isotopique d'équilibre). Dans le cas de l'eau, le pourcentage de formation de liaison dans l'état de transition est de 50 à 65 %; ceci est aussi vrai pour des cations qui sont plusieurs ordres de grandeur moins réactifs. Dans des corrélations faites antérieurement entre le log k_w en fonction de log K_R, des conclusions similaires ont été obtenues: valeurs de 50 à 65 % pour le pourcentage de formation dans l'état de transition. Deux méthodes fort différentes de mesure de l'état de transition conduisent donc au même résultat. Les valeurs de k^H : k^D pour les combinaisons des halogénures dans l'acétonitrile à 100 % sont égales à l'unité, dans les limites des erreurs expérimentales. Ce résultat en accord les suggestions à l'effet que ces réactions se produisent par une étape dont la vitesse est limitée par la diffusion. L'addition d'eau diminue de façon dramatique les vitesses de réaction des ions halogénures; cet effet augmente avec une augmentation de la quantité d'eau ajoutée. On observe de faibles effets isotopiques cinétiques inverses (dans un mélange 20 % acétonitrile : 80 % eau); ceci indique que l'état cinétiquement limitante est la formation de la liaison carbone—halogène. Une comparaison des effets isotopiques cinétiques et d'équilibre montre que, pour les réactions des ions bromure et chlorure, les pourcentages de formation de liaison dans les états de transition sont respectivement d'environ 25 et 40 %.

Mots clés : carbocation, effet isotopique, état de transition, halogénure.

Introduction

Several methods have now been described for the direct study of diarylmethyl cations using the technique of laser flash photolysis (LFP) (1). One of the principle ones is photosolvolysis, in which a diarylmethyl-leaving group bond is formally cleaved upon excitation. This reaction occurs with a variety of leaving groups. These include acetate (2, 3), 4-cyanophenoxide (2, 3), chloride (4), bromide (4), and triphenylphosphine (5). The initial photochemical event is very fast, and results in ion pairs (6, 7), possibly via electron transfer in initially formed radical pairs (8, 9). On the timescale of a ns LFP experiment where observation occurs after a 10–20 ns laser pulse, the intermediate is a free ground state cation (1, 6, 7). The time-resolved measurements that can be performed with LFP then provide direct kinetic data for the capture of the cation. Included here are the reactions with alcohol and aqueous solvents, as well as the combinations with added nucleophiles present in these solvents. The parent diphenylmethyl cation (Ph_2CH^+) turns out to be very short-lived in water, ethanol, and methanol, with a lifetime of less than 1 ns (10). This means that this particular cation is too reactive to be observed by ns LFP in these solvents, although it can be observed with this technique in solvents of lower nucleophilicity such as 2,2,2-trifluoroethanol (2). Diarylmethyl cations with at least one of the phenyl rings bearing a 4-methoxy substituent are longer-lived. Such cations have lifetimes of 100 ns to 10 ms in water (2, 3), and thus, can be studied in this solvent with ns LFP.

In this paper, we describe the measurement of secondary α-hydrogen and (or) deuterium kinetic isotope effects and equilibrium isotope effects for reactions of diarylmethyl cations with water, bromide ion, and chloride ion. The experiments were carried out in acetonitrile:water mixtures and in 100% acetonitrile. Because of the constraints imposed by lifetimes referred to in the last paragraph, at least one of the phenyl rings bore a 4-methoxy substituent. The objective of this study was to obtain information about the nature of the transition state for these cation–nucleophile combination reactions, and in particular to see how this is affected by changing the substituents on the cation, the nucleophile and the solvent.

Secondary α-kinetic isotope effects have been extensively employed to probe the mechanism and transition state of solvolysis reactions (11). For an S_N1 reaction, a normal k_H/k_D is observed. This is mainly caused by a change of the frequency of the C_a–H out-of-plane bending vibration in proceeding from reactant to transition state. Based upon a change in the out-of-plane bending vibration from 1350 cm^{-1} to 800 cm^{-1}, Streitweiser et al. (12) initially concluded that the maximum k^H/k^D would be 1.41. Bartell (13), however, pointed out that steric crowding at the α-carbon can alter these frequencies. Experimental studies, performed mainly by the Shiner group (14–18) found k^H/k^D values ranging from 1.10–1.25. The general conclusions for S_N1 solvolytic displacements is that the α-kinetic isotope effects are not very dependent upon the solvent or upon the substituent for a particular structure type. There is, however, a predictable (16, 18, 19) variation with the nature of the leaving group.

In contrast to the situation with S_N1 solvolysis, there is very limited data concerning α-kinetic isotope effects for cation–nucleophile combinations. Mayr et al. (20) have examined the reaction of a diarylmethyl cation with three alkenes. Values of k^H/k^D of 0.79 to 0.80 were obtained. Inverse isotope effects are, of course, expected since in such reactions, the carbon bearing the isotope is being converted from sp^2 to sp^3 hybridization. The relatively large inverse values were interpreted in terms of a tight, product-like, transition state. In an earlier study, Bunton et al. (21) examined reactions of two ferrocenyl-substituted cations. With water as the nucleophile, both the kinetic and equilibrium isotope effects were obtained. These results will be discussed later in a comparison with data obtained in the present study.

Experimental section

Compounds — diarylmethyl chlorides

Deuterated and undeuterated chlorides were prepared by modification of the method of Schneider and Mayr (22). A typical preparation is as follows:

Previously prepared (4-methoxydiphenyl)methanol, 0.45 g (2.1 mmol) was dissolved in 30 mL of dry CH_2Cl_2 and stirred with 2 g of finely ground anhyd $CaCl_2$. After cooling to –78°C, a stream of HCl gas was bubbled through the mixture for 3 min. After warming to room temperature, the mixture was gravity filtered and the solvent removed with a rotary evaporator. Distillation at 10 torr (1 torr = 13.322 Pa) and 170–175°C gave (4-methoxydiphenyl)methyl chloride (0.31 g), mp 61 to 62°C (lit. (23) mp 61 to 62°C, lit. (24) mp 62 to 63°C). ^{1}H NMR (200 MHz, $CDCl_3$) δ: 3.82 (s, 3H), 6.18 (s, 1H), 6.91 (d, 2H), 7.37 (m, 5H), 7.48 (d, 2H). ^{13}C NMR (200 MHz, $CDCl_3$) δ: 55.25, 64.19, 113.83, 127.59, 127.84, 128.37, 129.02, 133.30, 141.15, 159.24.

Similarly prepared from the corresponding alcohols were:

*(4-Methoxydiphenyl)methyl-α-*d *chloride*

^{1}H NMR (200 MHz, $CDCl_3$) δ: 3.82 (s, 3H), 6.91 (d, 2H), 7.37 (m, 5H), 7.48 (d, 2H). At high magnification, a peak at 6.18 ppm due to C*H*Cl was observed. Based upon the integration of the peaks at 6.18 ppm and 3.78 ppm, the compound was 98% deuterated at the α-carbon.

(4-Methyl-4′-methoxydiphenyl)methyl chloride

^{1}H NMR (200 MHz, $CDCl_3$) δ: 2.45 (s, 3H), 3.86 (s, 3H), 6.23 (s, 1H),6.98 (d, 2H), 7.26 (d, 2H), 7.46 (two overlapping doublets, 4H). ^{13}C NMR (200 MHz, $CDCl_3$) δ: 21.00, 55.12, 64.15, 113.68, 127.45, 128.88, 128.97, 133.35, 137.53, 138.24, 159.08.

*(4-Methyl-4′-methoxydiphenyl)methyl-α-*d *chloride*

^{1}H NMR was identical to that of undeuterated compound, except that deuterated compound had only a very small peak at 6.23 ppm seen at higher magnification. Integrating at 6.23 ppm vs. 2.45 ppm shows 98% deuteration.

(4-Trifluoromethyl-4′-methoxydiphenyl)methyl chloride

^{1}H NMR (200 MHz, $CDCl_3$) δ: 3.82 (s, 3H), 6.18 (s, 1H), 6.92 (s, 2H), 7.32 (d, 2H), 7.5–7.6 (overlapping doublets, 4H). ^{13}C NMR (200 MHz, $CDCl_3$) δ: 55.29, 63.19, 114.07, 125.36, 127.98, 129.00, 130.0 (quartet, CF_3), 132.43, 138.74, 145.04, 159.55.

© 2001 NRC Canada

(4-Trifluoromethyl-4′-methoxydiphenyl)methyl-α-d chloride

^{1}H NMR was identical to that of undeuterated compound except for the peak at 6.18 ppm; the α-position was 98% deuterated based upon integration at 6.18 and 6.92 ppm.

Diarylmethanols

(4,4′-Dimethoxydiphenyl)methanol was prepared by adding 2.0 g (8.0 mmol) of 4,4′-dimethoxybenzophenone dissolved in 50 mL of dry tetrahydrofuran (THF) to a stirred suspension of 0.75 g (19.8 mmol) of lithium aluminum hydride in 50 mL of anhydrous diethyl ether. After refluxing for 1 h, the mixture was cooled to –78°C and quenched with ethyl acetate followed by 5% aq H_2SO_4. Standard work-up of the organic portion, drying over $MgSO_4$, filtration and removal of the solvents with a rotary evaporator gave a white solid that was recrystallized from diethyl ether:hexanes. Yield: 1.50 g, mp 66.5 to 67.5°C (lit. (23) 67.5 to 68.5°C). ^{1}H NMR (200 MHz, $CDCl_3$) δ: 3.40 (s, 1H, OH), 3.89 (s, 6H), 5.80 (s, 1H), 6.86 (d, 4H), 7.38 (d, 4H). ^{13}C NMR (200 MHz, $CDCl_3$) δ: 55.0, 74.9, 113.5, 127.6, 136.3, 158.5.

(4,4′-Dimethoxydiphenyl)methanol-α-*d* was prepared in a similar manner using $LiAlD_4$ (Aldrich, 98% D). This sample had an identical NMR to the undeuterated sample except for the α-CH peak at 5.80 ppm. Integration of the small peak at 5.80 ppm and the peak at 3.89 ppm indicated 98% deuteration.

(4-Methoxydiphenyl)methanol and (4-methoxydiphenyl) methanol α-D were prepared in a similar manner through the reduction of 4-methoxybenzophenone with $LiAlH_4$ and $LiAlD_4$ respectively. The undeuterated compound had mp 64.5 to 66°C (lit. (24) 65 to 66°C). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 2.65 (d, 1H, OH), 3.77 (s, 3H), 5.74 (d, 1H), 6.84 (d, 2H), 7.30–7.35 (m, 5H), 7.37 (d, 2H). ^{13}C NMR (400 MHz, $CDCl_3$) δ: 55.15, 75.58, 113.68, 126.26, 127.20, 127.76, 128.24, 136.06, 145.89, 158.75. The deuterated compound had a mp of 64.5 to 65.5°C, with the same NMR except for the doublet at 5.74 ppm. Integration of the small peak at 5.74 ppm vs. the peak at 3.75 ppm indicated 98% deuteration.

(4-Methyl-4′-methoxydiphenyl)methanol and (4-trifluoromethyl-4′-methoxy-diphenyl)methanol were prepared by adding 4-tolualdehyde and α,α,α-trifluoro-4-tolualdehyde (dissolved in dry ether) to a slight excess of 4-methoxyphenyl magnesium bromide in dry ether. After quenching and work-up procedures standard for Grignard–aldehyde reactions, the alcohols were purified by silica gel column chromatography using 15% by volume ethyl acetate in hexane. The alcohols were recrystallized from diethyl ether:hexanes. The 4-methyl derivative had a mp of 60.5 to 62°C (lit. (25) 60 to 61°C). ^{1}H NMR (200 MHz, $CDCl_3$) δ: 2.28 (d, 1H, OH), 2.33 (s, 3H), 3.78 (s, 3H), 5.75 (d, 1H), 6.84 (d, 2H), 7.14 (d, 2H), 7.27 (overlapping doublets, 4H). ^{13}C NMR (400 MHz, $CDCl_3$) δ: 21.11, 55.24, 75.57, 113.73, 126.28, 127.70, 129.01, 136.24, 136.97, 141.07, 158.80. The trifluoromethyl derivative had a mp of 75 to 76°C (lit. (26) 76 to77°C). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 2.25 (d, 1H, OH), 3.78 (s, 3H), 5.82 (d, 1H), 6.86 (d, 2H), 7.30 (d, 2H), 7.40 (d, 2H), 7.54 (d, 2H). ^{13}C NMR (400 MHz, $CDCl_3$) δ: 55.31, 75.29, 114.07, 124.05 (q, $^1J_{C–F}$ = 272.4 Hz), 125.27 (q, $^3J_{C–F}$ = 3.7 Hz), 126.46, 127.97, 129.10 (q, $^2J_{C–F}$ = 32.2 Hz), 135.40, 147.67, 159.30.

4-Methyl-4′-methoxybenzophenone and 4-trifluoromethyl-4′-methoxybenzophenone were prepared by chromic acid oxidation of the above diarylmethanols following literature procedures (27–29). The 4-methyl derivative had a mp of 89 to 90.5°C (lit. (30) 90–92°C). ^{1}H NMR (200 MHz, $CDCl_3$) δ: 2.44 (s, 3H), 3.89 (s, 3H), 6.96 (d, 2H), 7.28 (d, 2H), 7.68 (d, 2H), 7.82 (d, 2H). ^{13}C NMR (200 MHz, $CDCl_3$) δ: 21.51, 55.37, 113.40, 128.78, 129.89, 130.39, 132.31, 135.44, 142.49, 162.95, 195.18. The trifluoromethyl derivative had a mp of 120 to 120.5°C (lit. (31) 119–121°C). ^{1}H NMR (200 MHz, $CDCl_3$) δ: 3.90 (s, 3H), 6.96 (d, 2H), 7.7–7.8 (three overlapping doublets, 6H). ^{13}C NMR (200 MHz, $CDCl_3$) δ (ppm): 55.51, 113.79, 123.72 (q, $^1J_{C–F}$ = 272.6 Hz), 125.22 (q, $^3J_{C–F}$ = 3.8 Hz), 129.34, 129.75, 132.58, 133.21, (q, $^2J_{C–F}$ = 32.7 Hz), 141.51, 163.71, 194.18.

(4-Methyl-4′-methoxydiphenyl)methanol-α-D and (4-trifluoromethyl-4′-methoxydiphenyl)methanol-α-D were prepared by reducing the appropriate benzophenones with $LiAlD_4$ as described previously. The 4-methyl derivative had a mp of 60–62°C, and the 4-trifluoromethyl derivative had a mp of 75 to 75.5°C. The ^{1}H NMR (400 MHz, $CDCl_3$) of both alcohols indicated 98% deuteration.

Diarylmethyl 4-cyanophenyl ethers were prepared by treating freshly prepared diarylmethyl chloride (typically 15 mmol) with excess sodium 4-cyanophenoxide (25 mmol) in dry THF (200 mL). The cyanophenoxide was prepared by treating 4-cyanophenol (11.8 g) in anhydrous methanol (100 mL) with slightly less than 1 equiv of 1 M sodium methoxide in ethanol. After removal of the methanol with a rotary evaporator, the salt was washed several times with dry ether. The mixtures of the sodium cyanophenoxide and the diarylmethyl chloride were refluxed in dry THF, typically for 3 days. The reaction mixture was poured into 200 mL of water, the organic phase separated and washed with dilute aqueous sodium hydroxide to remove residual 4-cyanophenol. After drying (Na_2SO_4) and filtration, the solvent was removed and the product purified by silica gel column chromatography using ethyl acetate:hexanes (5.95 to 20:80).

(4-Methyl-4′-methoxydiphenyl)methyl 4-cyanophenyl ether had a mp of 78.5–81°C. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 2.37 (s, 3H), 3.82 (s, 3H), 6.25 (s, 1H), 6.9–7.5 (m, 12H). ^{13}C NMR (400 MHz, $CDCl_3$) δ: 21.10, 55.21, 81.59, 103.88, 114.06, 116.62, 119.14, 126.56, 128.12, 129.39, 132.23, 133.78, 137.17, 137.80, 159.30, 161.32.

(4-Methoxydiphenyl)methyl 4-cyanophenyl ether had a mp of 74.5–77°C. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 3.77 (s, 3H), 6.23 (s, 1H), 6.9–7.5 (m, 12H). ^{13}C NMR (400 MHz, $CDCl_3$) δ: 55.19, 81.65, 103.99, 114.08, 116.59, 119.08, 126.54, 127.97, 128.17, 128.69, 132.01, 133.78, 140.12, 159.34, 161.21.

(4-Trifluoromethyl-4′-methoxydiphenyl)methyl 4-cyanophenyl ether had a mp of 93.5–95.5°C. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 3.78 (s, 3H), 6.29 (s, 1H), 6.9–7.7 (m, 12H). ^{13}C NMR (400 MHz, $CDCl_3$) δ: 55.18, 80.95, 104.44, 114.29, 116.57, 118.92, 123.85 (q, $^1J_{C–F}$ = 272.4 Hz), 125.65 (q, $^3J_{C–F}$ = 3.6 Hz), 126.75, 128.14, 130.08 (q, $^2J_{C–F}$ = 21.7 Hz), 131.16, 133.85, 144.27, 159.62, 160.77.

The α-deuterated versions of these three ethers were also prepared: (4-methyl-4′-methoxydiphenyl)methyl-α-D 4-cyanophenyl ether, mp 77–79°C; (4-methoxydiphenyl) methyl-α-D 4-cyanophenyl ether, mp 78.85–81°C; (4-trifluoromethyl-4′-

© 2001 NRC Canada

methoxydiphenyl)methyl-α-D 4-cyanophenyl ether, mp 83–90°C. In each case, a small peak corresponding to an α-CH proton could be observed in the ^{1}H NMR at high magnification. Integration relative to the OCH_3 peak indicated 98% deuteration.

Diarylmethylmethyl acetates were prepared by refluxing for 14 h a mixture of the diarylmethanol (typically 1 g), pyridine (2 mL), and acetic anhydride (10 mL). After quenching with 100 mL of water, the product was extracted with three portions of 50 mL of diethyl ether. The combined ether reactions were washed with aq 0.1 N NaOH, 5% aq H_2SO_4, and then twice with water. After drying ($MgSO_4$) and filtration, the solvent was removed on a rotary evaporator.

(4-Methoxydiphenyl)methyl acetate was a viscous oil that was distilled at 170–175°C and 10 torr (1 torr = 133.322 Pa). ^{1}H NMR (200 MHz, $CDCl_3$) δ: 2.12 (s, 3H), 3.75 (s, 3H), 6.87 (d, 2H), 6.90 (s, 1H), 7.31 (m, 5H), 7.37 (d, 2H). ^{13}C NMR (200 MHz, $CDCl_3$) δ: 21.20, 55.10, 76.43, 113.76, 126.73, 127.64, 128.35, 128.59, 132.31, 140.32, 159.21, 169.95.

(4-Methyl-4′-methoxydiphenyl)methyl acetate recrystallized slowly in hexane to white needles, mp 80–82°C. ^{1}H NMR (200 MHz, $CDCl_3$) δ: 2.18 (s, 3H), 2.37 (s, 3H), 3.80 (s, 3H), 6.88 (d, 2H), 6.90 (s, 1H), 7.15 (d, 2H), 7.36–7.40 (overlapping doublets, 2H). ^{13}C NMR (200 MHz, $CDCl_3$) δ: 20.95, 21.13, 25.05, 76.36, 113.71, 126.76, 128.42, 128.99, 132.49, 137.31, 137.43, 159.11, 169.87.

(4-Trifluoromethyl-4′-methoxydiphenyl)methyl acetate was a viscous oil after purification by silica gel column chromatography. ^{1}H NMR (200 MHz, $CDCl_3$) δ: 2.17, (s, 3H), 3.80 (s, 3H), 6.84 (d, 2H), 6.87 (s, 3H), 7.26 (d, 2H), 7.47 (d, 2H), 7.60 (d, 2H). ^{13}C NMR (200 MHz, $CDCl_3$) δ: 20.99, 55.10, 75.88, 114.01, 123.92 (q, $^1J_{C-F}$ = 272 Hz), 125.35 (q, $^3J_{C-F}$ = 3.87 Hz), 126.97, 128.72, 129.13 (q, $^2J_{C-F}$ = 32.62 Hz), 131.53, 144.45, 159.56, 169.74. The three α-deuterated acetates were also prepared in the same manner, the 4-methyl compound as a solid with mp 76–79°C, and the other two as viscous oils.

Measurements of kinetic isotope effects for reaction with water

(1) Three 25 mL volumetric flasks each containing exactly 25 mL of a particular water:acetonitrile mixture were prepared. Into one flask, the blank, was injected 20 μL of pure acetonitrile, into one flask was injected 20 μL of an 0.05 M solution of an undeuterated diarylmethyl acetate or 4-cyanophenyl ether, and into the third flask was injected 20 μL of an 0.05 M solution of the corresponding α-deuterated substrate. These three solutions were thermostated at 25 ± 0.1°C in a water bath.

(2) After temperature equilibration, kinetic measurements were performed by transferring 4 mL of the blank solution to a 1 × 1 × 4 cm UV cuvette.

(3*a*) This cell was placed in a sample holder which was thermostated at 25°C, and the remaining solution returned to the water bath. After temperature equilibration, a 20 ns 248 nm laser pulse was applied perpendicular to the cuvette onto one of the 1 × 4 faces. The absorbance changes in the cuvette were followed by passing a UV–vis beam through the long axis into a detection system set at the λ_{max} of the cation: 482 nm for 4-Me, 4′-MeO, 464 nm for 4-H, 4′-MeO, and 436 nm for 4-CF_3, 4′-MeO. The voltage output from the detector was digitized with a Tektronix SCD-1000 transient digitizer, and then passed to a DX-386 computer where the signal was converted to optical density based upon the base line output from the photomultiplier tube just before the laser pulse.

(3*b*) The solution was removed from the UV cuvette, the cuvette cleaned and dried, and 4 mL of the 25 mL stock solution of the undeuterated substrate was added. This cuvette was placed in the sample holder, and after temperature equilibrium, the solution was irradiated under identical conditions to those employed in step 3*a*. Procedures 3*a* and 3*b* were then repeated two to four times, alternating blank and undeuterated substrate.

(4) The procedures described in steps (3*a*) and (3*b*) were then repeated with the deuterated substrate.

(5) Each digitized signal was converted into a Microsoft Excel file of 512 data points. A solvent corrected trace was then obtained for each transient decay by subtracting the blank data from the data obtained immediately afterwards with substrate present. The computer program Grafit was then used with the corrected data to obtain first-order rate constants (k_{obs}), by fitting to the exponential equation, $A_{time} = (A_0 - A)\exp(-k_{obs}t) + A$, where A_0 is the initial absorbance and A the final absorbance (normally near zero). Average values of k_w^H and k_w^D were then obtained from the three to five k_{obs} obtained with the undeuterated and deuterated substrate, respectively; k_w^H:k_w^D was then calculated from these values. For each substrate, this whole procedure was repeated five times on five different days. The five k_w^H:k_w^D values so obtained were then averaged.

Measurements of kinetic isotope effects for reactions with bromide and chloride

A similar procedure was employed for the combinations with the halide ions, except that now seven solutions of varying concentrations of the halide (supplied as the tetra-*n*-butylammonium salt) were employed. These concentrations were incremental and were chosen after preliminary experiments such that each incremental increase in concentration caused an approximately 50% increase in k_{obs} over the value obtained with no halide present. Second-order rate constants were then obtained from the least-squares slopes of plots of k_{obs} vs. halide concentration. Excellent linear correlations were observed, with correlation coefficients of at least 0.997. On a given day, the set of experiments were performed with both the undeuterated and deuterated substrate; this generated two lines, and one value of k_X^H:k_X^D calculated from the two slopes. As above, the entire set of experiments was repeated three to five times with a given cation in a given solvent, and an average value of k_X^H:k_X^D obtained.

Measurement of equilibrium isotope effects for reactions of diarylmethyl cations with water

Before measuring the equilibrium isotope effect, a "titration curve" was constructed applying method C of Deno et al. (32). This curve plots the optical density vs. sulfuric acid concentration at the λ_{max} of the cation for a series of solutions containing the same concentration of added diarylmethanol. This optical density ranges from zero in dilute

© 2001 NRC Canada

acids where there is no cation present in the diarylmethanol–diarylmethyl cation equilibrium to some constant value in concentrated acids where the equilibrium has completely shifted to the cation side.

From the titration curve for each diarylmethanol, one H_2SO_4 concentration corresponding to max cation formation was chosen, along with three to four concentrations near the midpoint, i.e., where there are significant amounts of both cation and alcohol in equilibrium. Three 25 mL volumetric flasks were then prepared each containing sulfuric acid solution near the midpoint, one for a blank, one for the undeuterated alcohol, and one for the deuterated alcohol. Seven 25 mL flasks were prepared for the concentration corresponding to 100% cation solution; one for a blank, three for undeuterated, and three for deuterated alcohols. The volumetric flasks were equilibrated at 25°C, and measurements started by rapidly injecting 50 μL of an acetic acid solution containing 5.0×10^{-3} M of undeuterated or deuterated diarylmethanol (or just 50 μL of acetic acid for the blank). A digital clock was started as the solution was prepared. The reaction flask was shaken for 10 s, placed back in the thermostating bath until bubbles had cleared, transferred to a UV cuvette, and the absorbance recorded at the λ_{max} of the cation for 3–5 min. The absorbance reading was then extrapolated to zero time using the computer programs Microsoft Excel and Grafit. This extrapolation was necessary since the diarylmethyl cations were unstable at the intermediate acidities (32), with approximately a 10% decrease in absorbance over 10 min. The equilibrium isotope effects were calculated from the extrapolated absorbances, as will be discussed in the *Results* section.

Measurement of kinetic isotope effects for solvolysis reactions of diarylmethyl chlorides in 2:98 water:acetonitrile

A solution containing 50 mL of an 0.001 M hydroxide solution was prepared by slowly mixing 1 mL of 0.05 M aqueous tetramethylammonium hydroxide with acetonitrile in a 50 mL volumetric flask and filling to the mark. This solution was thermostated at 25.0 ± 0.1°C, and 3 mL aliquots transferred to a UV cuvette which was further thermostated at 25.0 ± 0.1°C in a Cary 2200 spectrophotometer. Kinetic runs were initiated by injecting 3 μL of a stock solution of the diarylmethyl chloride (0.05 M) into the cuvette. An absorbance decrease at 249 nm was monitored, with the absorbance–time data being directly digitized. Observed first-rate constants were obtained by converting to Grafit files and fitting to the exponential equation as above. Four kinetic runs were performed for the deuterated and undeuterated substrates; the data for each were averaged to provide individual k^H or k^D values, and k^H:k^D ratio calculated. This procedure was repeated on several different days, and the k^H:k^D values averaged.

Results

As has been previously described (3), the diarylmethyl cations were generated in LFP experiments from acetate and 4-cyanophenoxide precursor. In most cases, the latter was employed because of its strong absorbance at the exciting wavelength of 248 nm. Following the laser pulse, the decay in absorbance at the λ_{max} of the cation was monitored. Because of a small absorbance drift (especially at times longer than 5 ms), the signal was corrected by subtracting a base line signal obtained without the substrate. With the exception of some of the experiments with bromide ion as nucleophile, the experimental data fit well to a single exponential equation.

Reactions with water

A typical set of experimental data is shown in Table 1. To ensure good precision, rate constants were measured on different days. The individual rate constants did vary slightly from day to day, probably due to small fluctuations in temperature. The values however did not vary as much. When calculated as the average over several days, the errors were less than 2%.

Table 2 summarizes the k_w^H:k_w^D values for three diarylmethyl cations, each in two solvents, 80:20 and 10:90 water:acetonitrile. Within the experimental uncertainty, all these kinetic isotope effects are identical, with k_w^H:$k_w^D \sim 0.89$. This is true even upon inclusion of the literature data (21) for the considerably more stabilized ferrocenyl-substituted cations.

Reactions with bromide and chloride ions

Second-order rate constants for reactions with the two halide ions were obtained as the slopes of the plots of k_{obs} vs. halide concentration. Six to seven different concentrations of tetra-*n*-butylammonium bromide or chloride were employed, with the undeuterated and deuterated compounds been studied in parallel in the same set of solutions. The correlation coefficients of the least-squares fits were at least 0.999. A given set of data generated one k_X^H:k_X^D value. As with the water reaction, a given experiment was repeated three to five times to generate an average. Table 3 summarizes the results. The kinetic isotope effects in 100% acetonitrile are all, within experimental error, equal to unity, while there is a small but statistically significant inverse kinetic isotope effect in 80:20 water:acetonitrile.

As shown by the data in Table 4, and as depicted graphically in Fig. 1, solvent composition has a dramatic effect on the actual rate constants for the reactions of the diarylmethyl cations with bromide and chloride ions. Both halides react in 100% acetonitrile with similar rate constants in the range 2 to 3×10^{10} M^{-1} s^{-1} and there is little or no effect of aromatic substituent. The rate constants decrease in a continuous fashion as water is added, reminiscent of behavior previously seen with diarylmethyl cations and primary amines (34). As soon as there is water present in the solvent, bromide ion is always more reactive than chloride ion for a given cation in a given solvent. In addition, for a particular nucleophile in a given solvent, there is a normal substituent effect, the trifluoromethyl substituted cation being the most reactive and the methyl derivative the least.

Equilibrium with water

The pseudo acid:base reaction of eq. [1] is the equilibrium of interest. Equilibrium constants are defined as K_R and have been measured in the past using the acidity function method (32).

Fig. 1. Variation in rate constants (plotted as log *k*) for the combination of bromide ion (closed symbols) and chloride ion (open symbols) with diarylmethyl cations in acetonitrile:water mixtures. (4-Trifluoromethyl-4′-methoxydiphenyl)methyl cation (squares), (4-methoxydiphenyl)methyl cation (triangles), (4-trifluoromethyl-4′-methoxy-diphenyl)methyl cation (circles).

Thus, for a given sulfuric acid solution, eq. [2] applies,

$$[2] \qquad K_R = ([ROH]/[R^+]) \times (f_{ROH}/f_R^+) \times (a_{H_2O}/a_H^+)$$

where f_{ROH} and f_R^+ are activity coefficients for the alcohol and cation and a_{H_2O} and a_H^+ are the activities of water and the proton. When the equilibria involving the undeuterated and α-deuterated systems are compared in the same acid solution, eq. [3] can be derived from eq. [2]. The common terms in a_{H_2O} and a_H^+ cancel, as do the terms in the activity coefficients, since these should not be affected significantly by isotopic variation.

$$[3] \qquad K_R^H/K_R^D = ([ROH]/[R^+])_H/([ROH]/[R^+])_D$$

Thus measurement of the ratios $[ROH]:[R^+]$ for the undeuterated and deuterated systems in the same acid solution furnishes the required equilibrium isotope effect (without even measuring K_R).

For experiments in which the same amount of alcohol is added to solutions of varying acid concentrations, the desired ratio is calculated by eq. [4],

$$[4] \qquad [ROH]/[R^+] = (A_{Acid} - A/A - A_{dil})$$

where the *A*s are optical densities measured at the λ_{max} of the cation; *A* being the value in the solution of interest, A_{acid} being the value at high acid concentration where there is only cation present, and A_{dil} being the value in dilute acid

© 2001 NRC Canada

where there is only alcohol present. The last value is in fact zero, since the alcohol does not absorb at the cation λ_{max}. To obtain the equilibrium isotope effect, absorbances were measured at several acid concentrations along with one in concentrated acid. This was done in the same solutions for both the undeuterated and deuterated systems, and eq. [5] was then employed to calculate the isotope effect.

$$[5] \qquad K_R^H/K_R^D = (A_{Acid} - A/A)_H/(A_{Acid} - A/A)_D$$

Data were obtained with three to four different acid concentrations on a given day, providing K_R^H:K_R^D values with a standard deviation of 2 to 3%. This error was reduced by repeating the procedure several times. The average values so obtained are given in Table 2. The trifluoromethyl cation could not be studied since the decomposition of this system in moderately dilute acids was too rapid to permit accurate extrapolation to zero time. To provide a third equilibrium isotope effect, we examined the bis-4-methoxyphenyl compound. As can be seen in Table 2, the three diarylmethyl cations examined in this work have the same equilibrium isotope effects within experimental error. Mocek and Stewart (35) previously obtained an equilibrium isotope effect of 0.847 for the bis-*p*-methoxyphenyl cation, in good agreement with the value obtained in the present work for the same system.

Equilibration with bromide ion

The equilibrium isotope effect for the (4-methyl-4′-methoxydiphenyl)methyl cation reacting with bromide ion in 20:80 acetonitrile could be measured directly in the LFP experiments. The approach took advantage of the fact that this reaction proved to be reversible in this solvent. Such reversibility had previously been observed for the combination of the triphenyl methyl cation and bromide in 1:2 acetonitrile:water (36). The kinetic system that applies in the present case is shown in eqs. [6] and [7].

$$[6] \qquad Ar_2C^+H(D) + Br^- \rightleftharpoons ArCH(D)\text{-}Br$$

$$[7] \qquad Ar_2C^+H(D) + H_2O \rightarrow ArCH(D)\text{-}OH$$

Bromide ion combines with the cation with a pseudo first-order rate constant equal to $k_{Br}[Br^-]$ (since bromide is in excess). On the same time scale, the diarylmethyl bromide that is the product of this combination is undergoing ionization back to the cation with a first-order rate constant of k_{ion}. The cation is reacting with water with a first-order rate constant k_w; the alcohol is ultimately the predominant product because of the reversibility of the bromide addition.

Evidence for this behavior was the appearance of decay traces that no longer fit to a single exponential equation, but which were satisfied by a double exponential (Absorbance = $A_1\exp(-k_1t) + A_2\exp(-k_2t)$. Solution of the differential equations applicable to this kinetic system (37) provides the two exponential coefficients, k_1 and k_2, as shown in eq. [8].

$$[8] \qquad k_1,\ k_2 = 1/2\{(k_{ion} + k_{Br}[Br^-] + k_w) \pm \sqrt{(k_{ion} + k_{Br}[Br^-] + k_w)^2 - 4k_{ion}k_w)}\}$$

The sum of the two is a simple expression: $k_1 + k_2 = (k_{ion} + k_w) + k_{Br}[Br^-]$. Thus, for a series of experiments at different concentrations of bromide, a plot of the sum of the two exponential coefficients ($k_1 + k_2$) vs. [Br^-] is predicted to be linear with a slope equal to k_{Br} and an intercept equal to the sum ($k_{ion} + k_w$).

Experiments were therefore performed in which the undeuterated and deuterated cations were generated by LFP and reacted in the presence of five to six different concentrations of bromide. Three to five traces were obtained at each bromide concentration. Each trace was fit to a double exponential, and plots of ($k_1 + k_2$) vs. bromide constructed, one for the undeuterated and one for the deuterated cation. Excellent linear correlations were obtained with least-squares correlation coefficients of at least 0.995. The rate constant k_{Br} comes directly from the slope. The intercept provides ($k_{ion} + k_w$). To obtain k_{ion}, k_w was measured at the same time from the single exponential decay in a solution with no bromide present. The ratio k_{Br}:k_{ion} then provides the equilibrium constant written in the direction $Ar_2CH^+ + Br^- \rightleftharpoons Ar_2CHBr$.

This set of experiments was performed five times on five different days; the average values of the rate constants, equilibrium constants, and kinetic and equilibrium isotope effects are provided as the entry for reaction A in Table 5. It can be seen that while k_{Br}^H:k_{Br}^D is obtained with good precision, there are larger errors in k_{ion}^H:k_{ion}^D and the equilibrium isotope effect. This arises since k_{ion} is obtained as an intercept of a linear plot, after subtraction of a the rate constant k_w which has a similar magnitude. It can be noted that the value of the equilibrium isotope effect when written in the ionization direction $Ar_2CHBr\ A \rightleftharpoons Ar_2CH^+ + Br^-$ is 1.18 ± 0.03. This is within the range of the max value of 1.15 for k^H:k^D suggested by other workers (18) for an S_N1 solvolysis of a secondary alkyl bromide.

Equilibration with chloride ion

The equilibrium isotope effect for a chloride combination, was obtained by measuring the rate constants and kinetic isotope effects for the reactions in both the forward and reverse directions. The appropriate ratios then provides the equilibrium constants and equilibrium isotope effects. The isotope effect in the cation:anion combination direction (k_{Cl}^H:k_{Cl}^D) was obtained using LFP in the normal manner (see the last entry in Table 3). The isotope effect in the ionization direction (k_{ion}^H:k_{ion}^D) was obtained through a kinetic study of the solvolysis of undeuterated and deuterated (4-methoxydiphenyl)methyl chlorides in 2:98 water:acetonitrile containing 0.001 M tetramethylammonium hydroxide. This particular solvent combination was chosen so that the solvolysis occurred with a reasonable rate when studied in a conventional spectrometer. The hydroxide ion was added so as to quench the cation as it formed, i.e., so that the ionization was rate-limiting. Experiments with the undeuterated substrate verified that the rate constant for the solvolysis was not affected by either varying the concentration of hydroxide ion or by changing to 0.001 M azide ion as the trapping nucleophile. Although the chloride–cation combination in this solvent combination occurs with a rate constant of ~2×10^{10} M^{-1} s^{-1} (Table 3), this is also true for hydroxide ion[2]

Table 5. Rate constants, equilibrium constants, kinetic and equilibrium isotope effects for reaction A ((4-methyl-4′-methoxydiphenyl)methyl cation plus bromide ion in 80:20 W:AN) and reaction B ((4-methoxydiphenyl)methyl cation and chloride ion in 2:98 W:AN).

Constant	Reaction A	Reaction B
k_{ion}^{H} (s^{-1})	(3.8 ± 0.4) × 10^{5}	(3.50 ± 0.01) × 10^{-2}
k_{X}^{H} (M^{-1} s^{-1})	(1.53 ± 0.07) × 10^{8}	(1.68 ± 0.016) × 10^{10}
$K_{eq}^{H} = k_{X}^{H}:k_{ion}^{H}$ (M^{-1})	(4.0 ± 0.5) × 10^{3}	(4.80 ± 0.05) × 10^{11}
$k_{ion}^{H}:k_{ion}^{D}$	1.13 ± 0.03	(1.154 ± 0.009)
$k_{X}^{H}:k_{X}^{D}$	0.950 ± 0.005	(0.999 ± 0.021)
$K_{eq}^{H}:K_{eq}^{D}$	0.840 ± 0.023	0.860 ± 0.019

and for azide ion (38). Since the concentration of chloride ion is always much lower than that of either hydroxide or azide, the cation, when formed in an ionization, is trapped by the added nucleophile so that cation formation is rate-limiting.

To minimize experimental error, the kinetic isotope effect for the solvolysis was measured by performing four kinetic runs with each substrate on a given day; this procedure was repeated for a total of 7 days The data are provided as the entry under reaction B in Table 5. Because of the high acetonitrile content of the solvent employed in this study (see *Discussion*), the kinetic isotope effect for the cation–anion combination reaction is unity, so that the equilibrium isotope effect is determined by the kinetic isotope effect for the ionization. This value is 1.155, when written in the ionization reaction $Ar_2CH(D)\text{-}Cl \rightarrow Ar_2C^{+}H(D) + Cl^{-}$. This is in good agreement with the max $k^{H}:k^{D}$ predicted for S_N1 solvolysis with chloride as the leaving group (18).

Discussion

Bond formation in the transition state for the water reaction

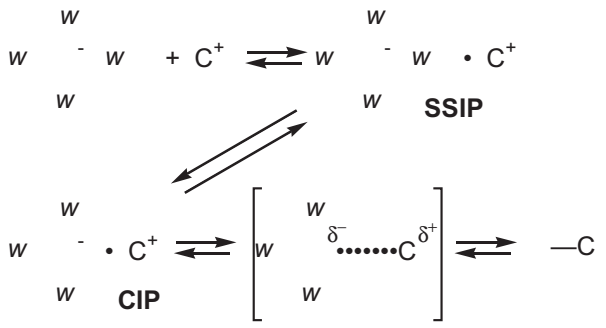
Kinetic isotope effects can change because of a different size of the nucleophile or because of different extents of bond formation in the transition state. To eliminate the former so that the latter can be evaluated, it is necessary to compare the kinetic isotope effect with the equilibrium isotope effect for the same reaction. As discussed by Schowen (39), the fraction of bond formation in the transition state can be calculated by dividing the logarithm of the kinetic isotope effect by the logarithm of the equilibrium isotope effect for the reaction in the same direction. The final column of Table 2 shows the results of such a calculation for the reactions of diarylmethyl cations with water. Included in this table are the literature data (21) for the considerably more stabilized ferrocenyl derivatives. The values range from 0.49 to 0.64. Since the uncertainties are of the order of 0.05 to 0.1, these are not distinguishable. In other words, within experimental error, there is 50–65% C_α—OH_2 bond formation in the transition state for the reaction of these diarylmethyl cations with water. What is particularly interesting is that this is true in spite of a 1 × 10^{8}-fold change in the rate constant k_w and a 1 × 10^{15}-fold change in the equilibrium constant. Thus, the position of the transition state does not change even though there is a large variation in the reactivity of the cations.

These same conclusions, 50–65% bond formation in the transition state independent of reactivity, are also made with rate-equilibrium correlations (40, 41) where log k_w is plotted against log K_R for cations with changing substituents in the aryl rings attached to the C^+ center. A series of such plots is shown in Fig. 3 of ref. 1. While the data separate into families dependent on the type of cation, there is a good linear correlation within each family. Slopes range from 0.54 to 0.68; the diarylmethyl cation family has a slope of 0.54, the triarylmethyl cation family, a slope of 0.60. The data extend over very wide ranges of reactivity, with changes in k_w and K_R of 1 × 10^{15} and 1 × 10^{25}, respectively. Within experimental error, there is little sign of curvature. Thus, despite the change in reactivity, the position of the transition state is relatively unchanged.

The slope of the plot of log k_w – log K_R can be taken as a measure of the change in charge at the C^+ center in the transition state (41). Thus, there has been approximately 60% charge neutralization at the transition state. The log $(k_w^H:k_w^D)$:log $(K_R^H:K_R^D)$ values can be taken as a measure of the extent of geometry change and bond formation. Thus, there is approximately 60% bond formation at the transition state. The two approaches provide different measures of the nature of the transition state, with different assumptions inherent in each. That each leads to the same conclusion, a transition state that is about 60% developed, provides confidence that this is a true picture.

Transition states for halide reactions

In 100% acetonitrile, there is no kinetic isotope effect in the reaction of the diarylmethyl cations with either bromide or chloride ion (Table 3). Moreover the rate constants lie within the range 2 to 3 × 10^{10} M^{-1} s^{-1}, regardless of both the substituents present in the diarylmethyl cation and the anionic nucleophile. The latter two observations have previously been made and include other anionic nucleophiles (3, 38). This has led to the conclusion that diarylmethylcation–anion combinations in 100% acetonitrile are diffusion controlled; i.e., the rate-limiting step is the encounter of the cation and the anion. The kinetic isotope effects are clearly consistent with this interpretation. Rate-limiting encounter means that there is no bond formation in the transition state. Thus, no isotope effect is expected.



In 20% acetonitrile, 80% water on the other hand, small inverse kinetic isotope effects are observed. This shows that bond formation has become rate-limiting, with some C_α—halide bond making in the transition state. This, in fact, must be true for the reactions in virtually all of the acetonitrile:

© 2001 NRC Canada

water mixtures. This conclusion can be made on the basis of the observation that once water is present, the rate constants become dependent on the nature of the substituent in the diarylmethyl cation, with the expected order $CH_3 < H < CF_3$. In 100% acetonitrile, the halide ion is poorly solvated. Once there is some water present to solvate the anion, the reaction switches from rate-limiting encounter to rate-limiting bond formation. One also sees the effect of rate constants decreasing with increased water content, presumably associated with the halide ions becoming more strongly hydrated and consequently less reactive. The greater reactivity of bromide over chloride is likely associated with the greater hydration of the latter.

The extent of bond formation in the transition states in 20% acetonitrile can be determined as discussed above, by calculating the ratios log (k_X^H:k_X^D):log (K_{eq}^H:K_{eq}^D). Such a calculation shows that the reactions have ~25% bond formation

Scheme 1.

with bromide as the nucleophile and ~40% with chloride. Thus, the transition states become more reactant-like as one moves from water to chloride to bromide, i.e., as the reactivity of the nucleophile increases.

Scheme 1 provides the mechanism of a cation–halide combination in an aqueous solutions, based on the classic ion pair mechanism for solvolysis written in reverse. The hydrated halide ion ("*w*" = waters of hydration) diffuses to the cation to form a solvent-separated ion pair **SSIP**, which then eliminates a water (or waters) of hydration to form the contact ion pair **CIP**. The rate-limiting step in the present case is the halide—carbon bond formation within this ion pair. As noted in the previous paragraph the transition state (in 20% acetonitrile) is reached at about 25 and 40% bond formation with bromide and chloride, respectively. As seen in Fig. 1, increasing the amount of water in an acetonitrile:water mixture has a dramatic retarding effect on the rate for this reaction. There are two factors that could contribute to this. In the cation–anion combination direction, the contact ion pair is in equilibrium with the solvent-separated ion pair as well as the free ions. Adding water will shift the equilibrium away for the contact ion pair, thus lowering its concentration in the solution, and slowing the rate. In addition, the contact ion pair will still be associated with waters of hydration which will modify its reactivity. Increasing the water content in the solution could well increase the binding of these additional waters, thus decreasing the reactivity of the ion pair.

Rhodium-catalyzed hydroborations of allylamine and allylimines[1]

Christopher M. Vogels, Paul E. O'Connor, Trevor E. Phillips, Keith J. Watson, Michael P. Shaver, Paul G. Hayes, and Stephen A. Westcott

Abstract: The in situ rhodium-catalyzed addition of catecholborane (HBcat, cat = 1,2-$O_2C_6H_4$) and pinacolborane (HBpin, pin = 1,2-$O_2C_2Me_4$) to allylamine, allylimine, 2- and 4-vinylpyridines, and a thienyl imine has been examined using multinuclear NMR spectroscopy. Although reactions of allylamine ($H_2NCH_2CH{=}CH_2$) and HBcat gave complex product distributions arising from competing dehydrogenative borylation pathways, addition of HBpin to allylamine using a rhodium catalyst afforded only products arising from hydroboration (RN(Bpin)$CH_2CH_2CH_2$Bpin, where R = H, Bpin) and hydrogenation (RN(Bpin)$CH_2CH_2CH_3$). Hydroboration of allylimines (RHC=N$CH_2CH{=}CH_2$, R = Ar) with HBcat occurs initially at the more reactive imine functionality to give unsaturated borylamines (RCH_2N(Bcat)$CH_2CH{=}CH_2$). Further reaction with HBcat gives varying amounts of hydroboration products RCH_2N(Bcat)$CH_2CH_2CH_2$Bcat and RCH_2N(Bcat)CH_2CH(Bcat)CH_3 as well as the diboration product RCH_2N(Bcat)CH_2CH_2CH(Bcat)$_2$, depending on the choice of catalyst. Reactions with related unsaturated pyridine derivatives are complicated by extensive degradation, which can be avoided by coordination of the pyridine nitrogen to a Lewis acid. The first examples of metal-catalyzed hydroboration of imines using HBpin are also reported.

Key words: catalysis, hydroboration, boronate esters, dehydrogenative borylation, allylimines.

Résumé : Faisant appel à la spectroscopie RMN multinucléaire, on a étudié la réaction in situ, catalysée par le rhodium, du catécholborane (HBcat, cat= 1,2-$O_2C_6H_4$) et du pinacolborane (HBpin, pin = 1,2-$O_2C_2Me_4$) avec l'allylamine, l'allylimine, les 2- et 4-vinylpyridines et une thiénylimine. Même si les réactions de l'allylamine ($H_2NCH_2CH{=}CH_2$) avec le HBcat conduisent à des distributions complexes de produits provenant de voies de borylation déshydrogénante en compétition, l'addition du HBpin à l'allylamine en présence d'un catalyseur de rhodium ne conduit qu'aux produits provenant d'une hydroboration (RN(Bpin)$CH_2CH_2CH_2$Bpin dans lequel R = H ou Bpin) ou d'une hydrogénation (RN(Bpin)$CH_2CH_2CH_3$). L'hydroboration des allylimines (RHC=N$CH_2CH{=}CH_2$, R = Ar) à l'aide de HBcat se produit initialement au niveau de la fonctionnalité imine qui est la plus réactive pour conduire à la formation de borylamines (RCH_2N(Bcat)$CH_2CH{=}CH_2$). Une réaction subséquente avec du HBcat conduit à des quantités variables de produits d'hydroboration, RCH_2N(Bcat)$CH_2CH_2CH_2$Bcat et RCH_2N(Bcat)CH_2CH(Bcat)CH_3 ainsi qu'au produit de diboration, RCH_2N(Bcat)CH_2CH_2CH(Bcat)$_2$, suivant le catalyseur choisi. Les réactions avec les dérivés insaturés de la pyridine apparentés sont compliquées par d'importantes réactions de dégradation que l'on peut éviter en procédant à une coordination de l'azote de la pyridine à l'aide d'un acide de Lewis. On rapporte aussi les premiers exemples de réactions d'hydroboration, catalysées par des métaux, d'imines à l'aide de HBpin.

Mots clés : catalyse, hydroboration, esters de l'acide boronique, borylation déshydrogénante, allylimines.

[Traduit par la Rédaction]

Introduction

The hydroboration of alkenes and alkynes, which constitutes the formal addition of a B—H bond across a carbon—carbon multiple bond, is an extremely important reaction in organic synthesis (1). Although simple boron hydride reagents such as borane ($H_3B{\cdot}X$, where X is a Lewis base) and 9-borabicyclo[3.3.1]nonane react readily with alkenes at room temperature, hydroborations with catecholborane (HBcat, cat = 1,2-$O_2C_6H_4$) generally require elevated temperatures. The discovery that transition metals can be used to catalyze the addition of HBcat to organic substrates has become an important and well-established technique in organic synthesis (for an excellent review on hydroborations catalyzed by transition-metal complexes, see ref. 2) (3, 4). These reactions can have regio-, chemo-, or stereoselectivities, complementary, or more remarkably, opposite to those from products obtained via the uncatalyzed variant. Indeed, hydroborations of 5-hexene-2-one with HBcat proceed readily at room temperature to give exclusive formation of a borate product where the borane has added to the more reactive carbonyl double bond (4). However, when the reaction is carried out at 0°C in the pres-

Scheme 1.

ence of a catalytic amount of Wilkinson's catalyst ($RhCl(PPh_3)_3$), addition of the B—H bond occurs primarily at the less reactive alkene moiety to give an organoboronate ester product (Scheme 1).

Organoboronate esters ($RB(OR')_2$) and boronic acids ($RB(OH)_2$) belong to a remarkable class of compounds that have been used extensively in organic (5–9), organometallic (10, 11), and solid-phase synthesis (12, 13), as well as in macrocyclic chemistry (14), molecular recognition (15), transporting molecules across biological membranes (16), redox switching (17), and as glucose sensors (18, 19). Interest in these compounds also arises from their unique biological activities (20). For instance, peptide boronic acids are among the most potent, known inhibitors of serine proteases (21). As a result, the synthesis of boron-containing amino acid derivatives has become an area of considerable interest (22, 23).

Hydroborations of tertiary allylic amines ($R_2NCH_2CH{=}CH_2$, R = alkyl, aryl) with borane ($H_3B{\cdot}X$, X = SMe_2, THF) are known to give initial formation of the expected *anti*-Markovnikov products, $R_2NCH_2CH_2CH_2BH_2$ (6, 24–26). Analogous reactions with primary and secondary amines, however, are complicated by direct interaction with the N—H bond to give a number of *N*-boryl products (27, 28). Protection of the N—H bond is usually required in these reactions to ensure chemoselective addition of the borane at the allyl group (29, 30). Unfortunately, deprotection methodologies frequently compromise the integrity of the B—C bond (31). We, therefore, decided to investigate the in situ reactions of allylamine ($H_2NCH_2CH{=}CH_2$, **1**) and related allylimine derivatives with catecholborane (HBcat, cat = 1,2-$O_2C_6H_4$) and pinacolborane (HBpin, pin = 1,2-$O_2C_2Me_4$) to see if we could generate novel aminoboron compounds without using a protecting group.

Experimental

All reagents and solvents used were obtained from Aldrich Chemicals. Complexes $RhCl(PPh_3)_3$ (32), $[RhCl(coe)_2]_2$ (coe = *cis*-cyclooctene, (33)), and $[RhCl(cod)]_2$ (cod = *cis*-cyclooctadiene, (34)) were prepared as described elsewhere. Imines were prepared by well-established procedures (35–38). NMR spectra were recorded on a JEOL JNM-GSX270 FT NMR spectrometer. ^{1}H NMR chemical shifts are reported in ppm and referenced to residual protons in deuterated solvent at 270.1 MHz. ^{11}B NMR chemical shifts are referenced to external $F_3B{\cdot}OEt_2$ at 86.6 MHz. ^{13}C NMR chemical shifts are referenced to solvent carbon resonances as internal standards at 67.8 MHz. Multiplicities are reported as (s) singlet, (d) doublet, (t) triplet, (q) quartet, (m) multiplet, (br) broad, and (ov) overlapping. Infrared spectra were obtained using a Mattson Genesis II FT IR spectrometer and are reported in cm^{-1}. Microanalyses for C, H, and N were carried out at Desert Analytics (Tucson, Arizona).

Preparation of $Rh(acac)(coe)_2$

$Rh(acac)(coe)_2$ was prepared by modification of an established procedure (39). Tl(acac) (0.42 g, 1.40 mmol) was dissolved in 10 mL of THF and added dropwise to a solution of $[RhCl(coe)_2]_2$ (0.50 g, 0.70 mmol) in 10 mL of THF. The reaction was allowed to stir for 18 h then stored for 48 h at –25°C. A greenish precipitate was filtered whereupon subsequent removal of the THF under vacuum afforded an orange solid. IR (Nujol): 2904, 1581, 1520, 1464, 1377, 1317, 1269, 1020, 897, 766, 735, 604, 550, 519. ^{1}H NMR (in C_6D_6) δ: 5.03 (s, 1H), 2.51 (br, 4H), 2.41 (br, 8H), 1.68 (br s, 12H), 1.55 (br, 4H), 1.40 (br, 6H). ^{13}C NMR δ: 185.0, 98.8 (CH), 78.0 (d, $J_{C\text{-}Rh}$ = 12 Hz, -CH=CH-), 30.3 (CH_2), 27.9 (CH_2), 27.0 (CH_2), 26.8 (CH_3).

Addition of catecholborane (HBcat) to allylamine (1)

In a typical reaction, 2 equiv of HBcat in 0.5 mL of C_6D_6 were added dropwise to a 0.5 mL C_6D_6 solution of allylamine. The mixture was allowed to stir for 1 h and then analyzed by multinuclear NMR spectroscopy. Attempts to control the selectivity of these reactions always gave minor amounts of **2**, which precipitated out of solution after ca. 1 h. **2**: IR (Nujol): 3200, 2940, 2868, 2443, 1600, 1464, 1377, 1350, 1232, 1099, 1057, 1083, 912, 808, 739, 700. ^{1}H NMR (in d_6-acetone) δ: 8.00 (br, cat), 7.09 (br ov m, cat), 6.48 (br, cat), 6.05 (br ov m, 1H, $CH{=}CH_2$), 5.40 (br ov m, 2H, $CH{=}CH_2$), 3.88 (br, 2H, -CH_2CH=CH_2). ^{11}B NMR δ: 23 (br, NBcat), 13 (s, N → HBcat). **3**: ^{1}H NMR (in C_6D_6) δ: 7.01 (d of d, *J* = 6, 3 Hz, 4H, cat), 6.73 (d of d, *J* = 6, 3 Hz, 4H, cat), 5.82 (ov d of d of t, *J* = 17, 10, 7 Hz, 1H, -C*H*=CH_2), 5.16 (d of d, *J* = 17, 2 Hz, 1H, -CH=C*H*H), 4.94 (d of d, *J* = 10, 2 Hz, 1H, -CH=CH*H*), 3.92 (d, *J* = 7 Hz, 2H, -CH_2CH=CH_2). ^{11}B NMR δ: 26 (br, NBcat). ^{13}C NMR δ: 148.6, 136.3, 122.3, 115.1, 112.1, 46.3.

Catalyzed hydroborations of allylamine (1) with HBcat

In a typical reaction, 5 equiv of HBcat in 0.5 mL of C_6D_6 were added to a 0.5 mL C_6D_6 solution of allylamine and 1 mol% $RhCl(PPh_3)_3$. The mixture was allowed to stir for 1 h and then analyzed by multinuclear NMR spectroscopy. **4**: IR

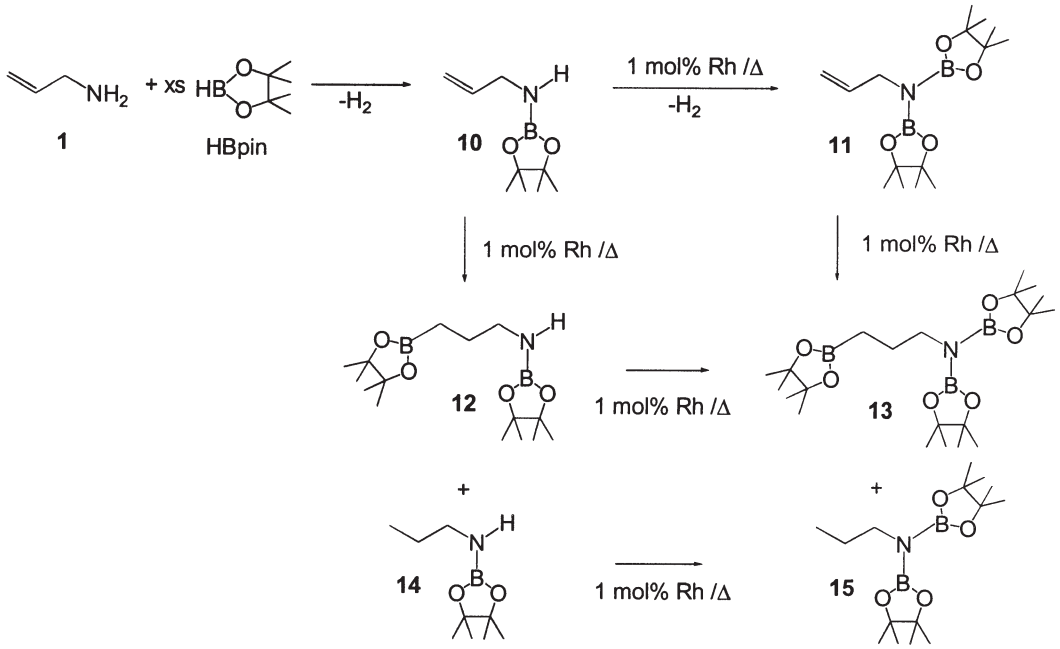
Results and discussion

As with reactions using borane, we have found that the in situ addition of HBcat to allylamine (**1**) resulted in the initial formation of a mixture of products. Although minor amounts of Lewis acid–base adducts HBcat·HNRCH$_2$CH=CH$_2$ (**2**, R = H, Bcat) are formed (40), a competing reaction gave N(Bcat)$_2$CH$_2$CH=CH$_2$ (**3**) as the major boron-containing product in solution. No adduct formation is observed with **3**, however, as coordination of two electron-withdrawing boryl groups has either significantly reduced the nucleophilic nature of the amine or increased the steric hindrance around the nitrogen atom. Although HBcat eventually adds to the activated allyl group in these aminoboryl species, reactions take several days. However, we have found that certain rhodium complexes can be used to catalyze this addition. Rhodium-catalyzed hydroborations are believed to arise via oxidative addition of the B—H bond of the boronate ester at the metal centre, followed by coordination and subsequent insertion of the alkene into the Rh—H or Rh—B bond (41). Reductive elimination affords the desired organoboronate ester product.

Addition of excess HBcat is required in all of these catalyzed reactions to ensure 100% conversion of the starting alkene. While hydroboration of intermediate **2** gave minor amounts of HBcat·HNRCH$_2$CH$_2$CH$_2$Bcat (**4**, R = H, Bcat), reactions with **3** gave surprisingly complex product distributions, regardless of the catalyst system used to affect this transformation (Scheme 2). Although significant amounts of the hydroboration products **5** and **6** were formed in these reactions, products (such as **8**) derived from a competing dehydrogenative borylation pathway were also observed (by NMR spectroscopy). We propose that these unique products originate from the transient alkenylboronate ester **7**, which presumably results from insertion of the activated alkene into the Rh—B bond (3, 41). Subsequent β-hydride elimination would afford the alkenylboronate ester with concomitant formation of dihydrogen (2, 41). It is possible that "hydroboration product" **5** also arises from hydrogenation of alkenylboronate ester **7**. Hydride elimination appears to be specific as products arising from abstraction of a methylene hydrogen α to the activated amine group are not observed. Alkenylboronate ester **7** can also add another equiv of HBcat to give **8**. Interestingly, we have found that compound **8** can also be generated as the major product in analogous hydroborations of H$_2$NCH$_2$C≡CH. As with most catalyzed hydroboration reactions, a small amount of hydrogenation product (**9**) is almost always observed.



The formation of these products is somewhat unusual as catalyzed hydroborations of simple alkenes, such as 1-octene, proceed smoothly to give predominant formation of the expected organoboronate ester product (2, 4). In this study, replacement of the two N—H bonds with N-Bcat groups in **3** appears to be ineffective in deactivating the amine group and catalyzed reactions proceed to give complex product distributions. The formation of multiple boronated compounds has recently been an area of considerable interest (42–44).

Metal-catalyzed hydroborations of unsaturated C—C bonds using HBpin have been reported previously (45–47).[3] In a further attempt to control selectivity we decided to examine hydroborations using HBpin (Scheme 3). Unlike reactions with HBcat, which is a stronger Lewis acid, no adduct formation was observed. Addition of excess HBpin gave the monoboryl amine HN(Bpin)CH$_2$CH$_2$=CH$_2$ (**10**), where a second equiv of the boronate ester failed to add to the amine N—H bond even at elevated temperatures. Remarkably, we have found

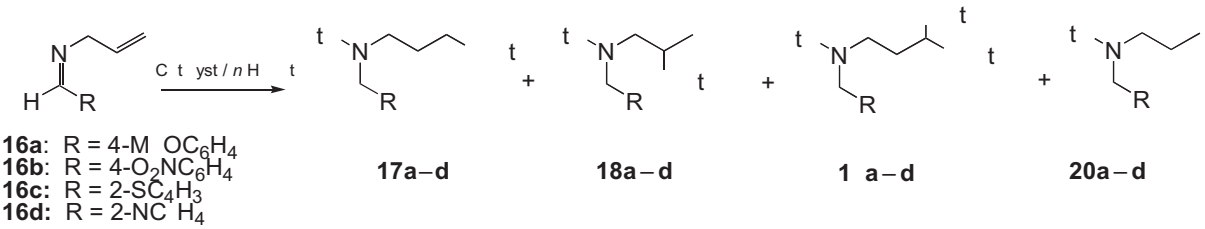
Scheme 3.

that a rhodium catalyst could be used to facilitate the addition of another equiv of HBpin to give $N(Bpin)_2CH_2CH_2{=}CH_2$ (**11**). This observation provides the first example of a metal-catalyzed hydroboration of N—H bonds.

Compound **11** was observed in only minor amounts (<5% by ^{1}H NMR spectroscopy) as a competing hydroboration reaction occurred at the alkene moiety to afford a mixture of $HN(Bpin)CH_2CH_2CH_2Bpin$ (**12**) and $N(Bpin)_2CH_2CH_2CH_2Bpin$ (**13**). Not surprisingly, significant amounts of hydrogenation products $RN(Bpin)CH_2CH_2CH_3$ (where R = H or Bpin, **14** and **15**, respectively) were also observed in these reactions. The ^{1}H NMR data for the propyl group in **13** is similar to that observed for **12**, except that chemical shifts are moved to a lower field due to addition of another electron-withdrawing Bpin group. For instance, the middle CH_2 resonance in **12** is observed as an overlapping triplet of triplets at 1.60 ppm, yet for **13** this peak is found at 2.04 ppm. The ^{11}B NMR of $RN(Bpin)CH_2CH_2CH_2Bpin$ (where R = H or Bpin) shows a peak at 25 ppm corresponding to the B—N bond and a resonance at 33 ppm for the new B—C bond. No appreciable intramolecular interactions are observed in these molecules as the boron atoms appear to be three-coordinate (40, 48). This result is consistent with previous NMR data on related $NH_2CH_2CH_2CH_2B(OH)_2{\cdot}HCl$ which shows a peak in the ^{11}B NMR at 32.6 ppm (49). Interestingly, the analogous neutral compound ($NH_2CH_2CH_2CH_2B(OH)_2$) displays a resonance at 8 ppm suggesting intramolecular adduct formation between the nitrogen and the boron atom (50).



To avoid complications arising from addition of the boronate esters at the amine N—H bond, we decided to investigate hydroborations of allylimine derivatives **16a**–**d**. Addition of 1 equiv of catecholborane to allylimines **16a**–**c** proceeds cleanly to give the corresponding borylamines, where the electron-deficient boron group has added to the nitrogen atom of the imine double bond (51). A rhodium catalyst can once again be used to facilitate the addition of a second equiv of HBcat to the alkene moiety. While selectivity to 3-aminopropylboronate esters has been increased in these reactions, products arising from competing Markovnikov hydroboration, dehydrogenative borylation, and hydrogenation are all still observed to some extent (Table 1).

Reactions with **16c** were carried out with 3 equiv of HBcat to ensure complete conversion of the allyl group. Although $RhCl(PPh_3)_3$ (entry 1) gave 71% of the *anti*-Markovnikov product **17c**, use of $[RhCl(coe)_2]_2/4PPh_3$ (coe = *cis*-cyclooctene, entry 7) as a catalyst precursor gave 88% of this desired product (using ^{1}H NMR spectroscopy). Significant amounts (23%) of the hydroboration product **18c** were observed in reactions using $[RhCl(coe)_2]_2$ as a catalyst precursor (entry 6). This product arises from a Markovnikov addition of the borane to the allyl moiety. Remarkably, the diboronated ester **19c** was a major product (38%) in reactions using $Rh(acac)(coe)_2$/dppm (dppm = 1,1-bis(diphenylphosphino)methane) (entry 10). Catalyst precursors of this type are known to generate the active zwitterionic catalyst Rh(dppm)(η^6-catBcat) (52, 53). It is interesting to note that no significant change in product distributions is observed when reactions were conducted using an excess of HBcat (entry 12) or when hydroborations were carried out in $CDCl_3$ (entry 11). Although only minor differences in product distributions were observed when **16a** was used as the substrate (cf. entries 1 and 13), reactions with **16b** gave significant amounts of hydrogenation product **20b** (entry 14). Hydrogenation products are also observed in other reactions where extensive borane and (or) catalyst decomposition occurs (entries 6 and 8; (29)).

Hydroborations of the pyridine derivative **16d** gave rise to a number of different boron-containing products, also arising from the degradation of HBcat (2). Since no degradation was observed with the thiophene imine **16c** using HBcat, it is plausible that the harder nitrogen atom in the pyridine ring is responsible for this unwanted degradation pathway. To test this hypothesis, we decided to investigate the analogous hydroborations with 2- and 4-vinylpyridine (**21** and **23**, respectively). Catalyzed hydroborations of styrene proceed

smoothly to give selective formation of either the Markovnikov or *anti*-Markovnikov product, depending upon the metal catalyst employed (2). Not surprisingly, we have found that catalyzed reactions of the vinylpyridines with HBcat gave a mixture of hydroboration products, along with a significant amount of ethylpyridine. Although a number of metal complexes were examined as catalysts for this reaction, all gave mixtures of products. Oxidation of the resulting hydroborated mixtures with NaOH–H_2O_2 gave 4-ethylpyridine as the only isolable organic product (54). Similar results are also seen in reactions with HBpin. Coordination of a strong Lewis acid, such as BF_3 (55–57), to the vinylpyridines effectively eliminated these degradation pathways and the Marknovnikov hydroboration products (**22** and **24**, respectively) could be obtained in high yields (>95% by NMR spectroscopy) using $Rh(acac)(coe)_2$/dppb (dppb = 1,4-bis(diphenylphosphino)butane) as a catalyst precursor (Scheme 4) and HBcat. Reactions with HBpin gave a mixture of hydroboration products along with a significant amount of hydrogenation. Unfortunately, attempts to protect the nitrogen group with BF_3 in the hydroboration of allylamines **1** and **16d** led to polymerization of the activated alkene moiety.

We then decided to examine the rhodium-catalyzed hydroboration of allylimine **16c** using HBpin. Although no reaction was observed at room temperature, complex product distributions arising from addition at the allyl group and the imine functionality were observed when reactions were carried out at elevated temperatures (60°C). Reduction of the imine was observed by disappearance of the aldimine hydrogen at 7.89 ppm with concomitant appearance of a benzylic hydrogen at 4.36 ppm. A peak at 24 ppm in the ^{11}B NMR spectrum arises from the newly formed N—Bpin bond. This result is somewhat surprising as previous attempts to hydroborate imines using HBpin proved unsuccessful (58). To confirm that the imine was being reduced in these reactions, we decided to investigate hydroborations with saturated aldimine **25** (Scheme 5). Indeed, these reactions proceeded

© 2001 NRC Canada

to give selective formation of the desired *N*-boryl product **26** and represent the first examples of a metal-catalyzed hydroboration of an imine using HBpin (45–47).[3] Although the synthesis of chiral amines is of utmost importance in organic and medicinal chemistry, the enantioselective reduction of simple ketimine derivatives is often a synthetically challenging problem (59). As a result, future work in this area will focus on the asymmetric reduction of related ketimines using HBpin.

Conclusion

We have found that the in situ addition of HBcat to allylamine using a number of rhodium catalysts gave products derived from competing hydroboration and dehydrogenative borylation pathways.[4] The use of HBpin effectively eliminated the dehydrogenative borylation reaction and a novel rhodium-catalyzed hydroboration of N—H bonds was observed to give $N(Bpin)_2CH_2CH_2CH_2Bpin$ along with various amounts of hydrogenation product. Hydroboration of allylimines with HBcat occurs initially at the more reactive imine functionality to give unsaturated borylamines. Further reaction gives the corresponding *anti*-Markovnikov and Markovnikov hydroboration products. Reactions with related unsaturated pyridine derivatives are complicated by extensive degradation, which can be avoided by coordination of the pyridine nitrogen to a Lewis acid. We have also shown that catalyzed hydroborations of aldimines can be accomplished using HBpin. Further work will examine other catalyst systems to fine-tune product selectivities in these reactions.

Microwave-assisted Diels-Alder synthesis

Christopher K. Jankowski, Gaëtan LeClair, Jacqueline M.R. Bélanger, Jocelyn R.J. Paré, and Marie-Rose VanCalsteren

Abstract: The synthesis of isoquinolinone carboxylates was performed using arecoline or its isomer *N*-methyl tetrahydro pyridine carboxylate with Danishefsky's diene via thermal or microwave assisted Diels-Alder reaction. The comparison of both condensation modes showed that the microwave method not only afforded higher yields of the adducts, but also lead to the formation of a new α,β-unsaturated pyridyl ketone. All structures were identified with the help of high resolution 2D NMR.

Key words: Diels-Alder microwave assisted reaction, microwave synthesis, Michael, diene, isoquinoline carboxylate synthesis, Danishefsky diene synthesis, MAP Diels-Alder[2].

Résumé : On a réalisé des synthèses d'isoquinoléinone carboxylates à partir de l'arécoline ou de son isomère (des *N*-méthyl tétrahydropyridine carboxylates) et du diène de Danishefsky, par le biais d'une réaction de Diels-Alder thermique ou assistée par microondes. Une comparaison des deux modes de condensation a montré que la méthode aux microondes conduit à des rendements supérieurs d'adduits avec la formation d'une nouvelle pyridylcétone α,β-insaturée. Toutes les structures ont été identifiées à l'aide de la RMN bidimensionnelle à haute résolution.

Mots clés : réaction de Diels-Alder assistée par microondes, Michael, diène, synthèse d'isoquinoléine carboxylate, synthèse à l'aide du diène de Danishefsky, « MAP » Diels-Alder.

[Traduit par la Rédaction]

Introduction

The Diels-Alder reaction remains one of the most fascinating and useful condensation reactions leading to functionalized heterocyclic or carboxylic unsaturated compounds. The diene and dienophile react without particular restriction, producing adducts under several thermal, photochemical, or catalytical (e.g., acid or Lewis acid) conditions displaying important stereo- and regioselectivities. Two variations, thermal and photochemical, are also well studied because of strict rules governing the stereochemistry of adduct formation (Woodward-Hoffmann). Despite this, the yield of some adducts coming from less activated substrates, e.g., because of the poor electronic compatibility of the diene–dienophile couple, is low. Also, some of the reactions are still taking a considerable amount of time, and the diene, in particular, can undergo the polymerization.

Here, we report on the Diels-Alder cycloaddition between some heterocyclic vinylic α,β-unsaturated esters and active (hot) diene, such as Danishefsky's diene family, leading to the *N*-methyloctahydro isoquinoline adducts, important by-products, e.g., for the design and synthesis of pharmaceuticals.

The thermal condensation of the arecoline (**1**) (methyl *N*-methyl-1,2,5,6-tetrahydropyridine-3-carboxylate) or its isomer **2** (ethyl *N*-methyl-1,2,3,6-tetrahydropyridine-4-carboxylate) with Danishefsky's diene (1-methoxy-3-trimethylsilyloxy-1,3-butadiene) under thermal conditions (160°C in toluene for 5 days) gave 30% of the methyl *cis*-*N*-methyl isoquinolidin-8-en-7-one-10-carboxlyate (**3**) adduct for arecoline and 50% for the isomeric dienophile — ethyl *cis*-*N*-methylisoquinolidin-6-en-7-one-5-carboxylate (**4**) (Fig. 1, Scheme 1). Both adducts were fully characterized by spectroscopic methods (see *Experimental*).

Under thermal reaction conditions, however, a significant level of diene decomposition and polymerization as well as the presence of dienophile dimers was observed. For the Lewis acid ($AlCl_3$, BF_3) catalysis of these reactions, the adduct yield remains low.

The spontaneous formation of the α,β-unsaturated ketone in the newly formed ring is observed accordingly to the usual behaviour of these dienes (1–6). The vinylic esters, which are not considered particularly active dienophiles, do not react more readily at this time; however, the carboalkoxy group of the adducts is suitably situated in the *cis* fused bicyclic compound for further transformations, such as the synthesis of HIV protease inhibitor isoquinoline carboxylate pharmaceuticals (7).

When the same two reactions were carried out using the microwave-assisted processes (MAP™) (8–11) in sealed

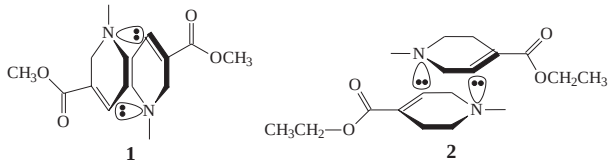
Scheme 1.

tubes as a toluene solution for 5 min the same adducts, of the identical stereochemistry, were obtained in both series. It is to be noted that this process involves the irradiation of the reaction vessel with a focalized beam of microwaves and not the scattered microwaves from a conventional oven. This focalized beam gives the user control over the amount of energy given to the vessel, and hence, thermal loss is kept to a minimum. The yield of these two adducts improved significantly, for both **3** (73%) as well as **4** (63%) (Table 1), and the dimerization of the dienophiles, as identified from GC–MS experiments, was lower. In addition, the remaining diene could be recovered.

The dimerization of vinylic dienophiles in Diels-Alder reactions are not surprising. Studied under electron impact mass spectrometry conditions using direct inlet introduction of both dienophiles arecoline (**1**) and its isomer **2** displayed, after 48 h, an important dimerization level: up to 40% for **2** and 18% for **1**, which were liberated from its hydrobromide. However, using freshly purified arecoline (distilled on a cold finger) reduced the dimer concentration. Also, once treated with microwave both dienophiles displayed an important reduction of the dimers (at *m*/*z* 310 and 338 for **1** and **2**, respectively) within 2–3% range only. One of the possible explanations for better yield of the Diels-Alder condensation under microwave conditions, could then be that this treatment maintains the dienophile in its monomeric form.



Searching for an explanation of dienophile dimer formation, molecular modelling was performed. The absence of spectral evidences on the presence of the cyclobutane structures for these dimers led to a hypothesis of strongly bound electrostatic dimers between the N-CH_3 lone pair of the first molecule and the positive pole of the α,β-unsaturated ester of the other molecule. Molecular mechanics modelling of two resulting structures showed that the arecoline **1** dimer is more stable by 1.5 kcal mol^{-1} than the similar dimer of **2** (Fig. 2).

The reaction of dienophile **2** with Danishefsky's diene under microwaves also produced an unexpected product (~50%),

Table 1. Yield (%) of Diels-Alder adducts.

Adduct	Thermal reaction	Microwave reaction
3	30	73
4	50	63

Fig. 2. Dimer structures from tetrahydropyridine carboxylates **1** and **2**.

identified as ethyl *N*-methyl-3-(oxo-3′-buten-1′-yl)-1,4,5,6-tetrahydropyridine carboxylate (**5**). The formation of this product can be explained by the isomerization of the double bond of dienophile **2** from the conjugated position 3 to position 2, which then subsequently reacts with the diene to afford compound **5**.

The absence of a similar compound for the arecoline (**1**) can be rationalized by the fact that under microwave conditions the β-aminovinyl ester is analogously isomerized to the fairly stable enamine-vinyle **1a** (difference of 1 kcal mol^{-1}) ester, which does not react with Danishefsky's diene.

Although the microwave assisted Diels-Alder condensations (as well as the retro Diels-Alder reactions) have been tried for several compounds (12–22), to our knowledge the MAP Diels-Alder condensation reported here is the first condensation of less reactive enol ester and cyclic amines. This method is an important practical improvement of the condensation conditions. The mechanism of these reaction under microwave treatment remains unknown. The analogy to thermal reaction is confirmed from our study and the adduct stereochemistry for both dienophiles is the same as in thermal condensation. The reaction time, however, was reduced and the reaction was carried out in much simpler and cleaner ways. The additional product formation observed for the dienophile **2**, the enamine formation and suggestions prior to condensation, is an interesting feature of the microwave Diels-Alder reaction.

Experimental

The diene and dienophiles were purchased from Aldrich and Coger-Acros Chemicals. The arecoline hydrobromide was freed from its hydrobromide by potassium bicarbonate 10% solution treatment under ethyl ether extraction with the quantitative yield, prior to the condensation. Thermal condensation of Danishefsky's diene with dienophile **1** or **2** was performed in toluene in sealed tube, the post-reaction work-up was done according to our previous methodology (1, 5, 21, 22). The mixture was treated as follows: the solvent was evaporated in vacuo and resulting oil was purified using flash chromatography (12–15 cm column) over silica gel using acetone–benzene elution system. After the separation of dienophiles in the first fraction (10% acetone) the adducts were isolated (25% acetone). Under these conditions both the desilylation of adducts and their demethanolysis took

© 2001 NRC Canada

place. The diene was used in slight excess (1.1 mol). MAP Diels-Alder reactions were carried out on a Soxwave-10 (Prolabo prototype) atmospheric pressure focused microwave-assisted extraction system (Prolabo, Fontenay-Sous-Bois, France). The Soxwave-10 is made up of one command box and one microwave cavity able to accommodate 20 mL type headspace vials. The system used operated with an emission frequency of 2450 MHz and a continuously variable power output of 10–200 watts. A sealed tube containing the reaction mixture (1 mmol of dienophile, 1.1 mmol of diene, 10 mL of toluene) was introduced into the microwave cavity. The sample tube bulb was warm when taken out of microwave cavity. The power was set at 20% (40 watts) and the sample mixture was irradiated for 5 min. The sample was then taken out of the cavity and allowed to cool before proceeding with the next steps.

The NMR spectra were recorded on Bruker 200 MHz (UdeM), 300 MHz (St. Hyacinthe), or 500 MHz (Instituto de Quimica) apparatus. The samples were dissolved in $CDCl_3$ and TMS was used as an internal standard. The typical NMR high-resolution experiments were run according to the procedure described in our previous paper (23).

The chemical shifts (^{13}C or ^{1}H) are expressed in δ (ppm) and the coupling constants (*J*) in Hz. The complete set of 1D high resolution and different 2D experiments for compounds **1**–**5** are available on request from CKJ.

The positive ion (PI) mass spectra were determined on Nermag Riber R-1010 (CEA) apparatus in either EI or DCI (NH_3) mode using EI–CI source. The ion chromatograms were used to follow-up the progress of purification of adducts **3**–**5** from their characteristic protonated pseudo-molecular ion sweeping and retention time values.

The molecular mechanics calculations were done with the help of HyperChem Mm^+ program for PC at the Université de Moncton.

Molar excess volumes of ternary mixtures containing ether

V.K. Sharma and Romi

Abstract: Molar excess volumes (V^E_{ijk}) of 1,3-dioxolane (*i*) + benzene (*j*) + cyclohexane (*k*); 1,3-dioxolane (*i*) + benzene (*j*) + *n*-hexane (*k*); and 1,3-dioxolane (*i*) + benzene (*j*) + *n*-heptane (*k*) ternary mixtures have been measured dilatometrically as a function of composition at 298.15 K. The observed data have been analysed in terms of (*i*) Graph theoretical approach; (*ii*) Flory's theory; and (*iii*) Lacombe and Sanchez's theory of liquid mixtures. It has been observed that V^E_{ijk} values predicted by graph theoretical approach compare better with the corresponding experimental values than with the V^E_{ijk} data predicted by other approaches.

Key words: molar excess volumes, molar volume interaction parameters, connectivity parameter of third degree $^3\xi$.

Résumé : Faisant appel à la dilatométrie et opérant à 298,15 K, on a mesuré les volumes molaires en excès (V^E_{ijk}), de mélanges ternaires 1,3-dioxolane (*i*) + benzène (*j*) + cyclohexane (*k*); 1,3-dioxolane (*i*) + benzène (*j*) + hexane (*k*); et 1,3-dioxolane (*i*) + benzène (*j*) + heptane (*k*). On a analysé les données obtenues en termes de (*i*) l'approche théorique graphique; (*ii*) la théorie de Flory; et (*iii*) la théorie des mélanges liquides de Lacombe et Sanchez. On a observé que les valeurs de V^E_{ijk} prédites par l'approche théorique graphique se rapprochent plus des valeurs expérimentales que celles prédites par les autres méthodes.

Mots clés: volumes molaires en excès, paramètres molaires d'interaction volumique, paramètres de connectivité du troisième degré $^3\xi$.

[Traduit par la Rédaction]

Introduction

Recent studies (1–4) have shown that thermodynamic properties of ternary mixtures can be determined from the thermodynamic properties of the respective binary mixtures. In continuation of our earlier work (5, 6) on molar excess volumes and molar excess enthalpies of 1,3-dioxolane (*i*) + benzene, toluene, or -xylenes (*j*) or + cyclohexane, *n*-hexane, or *n*-heptane (*j*) binary mixtures, we report here molar excess volumes data (V^E_{ijk}) for 1,3-dioxolane (*i*) + benzene (*j*) + cyclohexane (*k*); 1,3-dioxolane (*i*) + benzene (*j*) + *n*-hexane (*k*); and 1,3-dioxolane (*i*) + benzene (*j*) + *n*-heptane (*k*) ternary mixtures as a function of composition at 298.15 K. It would be of interest to see how various theories of liquid mixtures explain the V^E_{ijk} data of the studied mixtures.

Experimental

1,3-Dioxolane (D) (Fluka), benzene, cyclohexane, *n*-hexane, and *n*-heptane (AR Grade) were purified by standard methods (7). The purities of the purified liquids were checked by measuring their densities at 298 ± 0.01 K and 293 ± 0.01 K (for 1,3-dioxolane) and these agreed to within $\pm 5 \times 10^{-5}$ gm cm^{-3} with the values reported in literature (7).

Received April 12, 2001. Published on the NRC Research Press Web site at http://canjchem.nrc.ca on December 14, 2001.

V.K. Sharma[1] and Romi. Department of Chemistry, Maharshi Dayanand University, Rohtak-124001, India.

[1]Corresponding author (e-mail: vksharma17@redifmail.com).

Molar excess volumes (V^E_{ijk}) for the various ($i + j + k$) ternary mixtures were measured in a three limbed dilatometer in the manner as described elsewhere (8). The change in liquid level of the dilatometer capillary was measured with a cathetometer that could read to ±0.001 cm and the uncertainties in our measured values are of the order of 0.5%.

Results

The measured V^E_{ijk} for *D* (*i*) + benzene (*j*) + cyclohexane, *n*-hexane, or *n*-heptane (*k*) ternary mixtures as a function of composition at 298.15 K (recorded in Table 1 and plotted in Figs. (1–3)) were fitted to eq. [1].

$$[1]\quad V^E_{ijk} = x_i x_j \left[\sum_{n=0}^{2} V^{(n)}_{ij}\,(x_i - x_j)^n\right] + x_j x_k \left[\sum_{n=0}^{2} V^{(n)}_{jk}(x_j - x_k)^n\right] + x_k x_i \left[\sum_{n=0}^{2} V^{(n)}_{ik}\,(x_k - x_i)^n x_i^{\,n}\right] + x_i x_j x_k \left[\sum_{n=0}^{2} V^{(n)}_{ijk}\,(x_j - x_k)^n x_i^{\,n}\right]$$

$V^{(n)}_{ij}$ (n = 0–2) are parameters characteristics of ($i + j$), ($j + k$), and ($k + i$) binary mixtures and have been taken from literature (5–11), whereas $V^{(n)}_{ijk}$ (n = 0–2) are parameters charac-

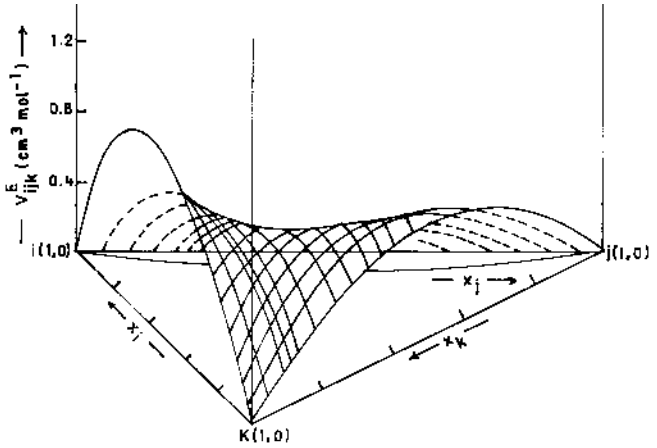

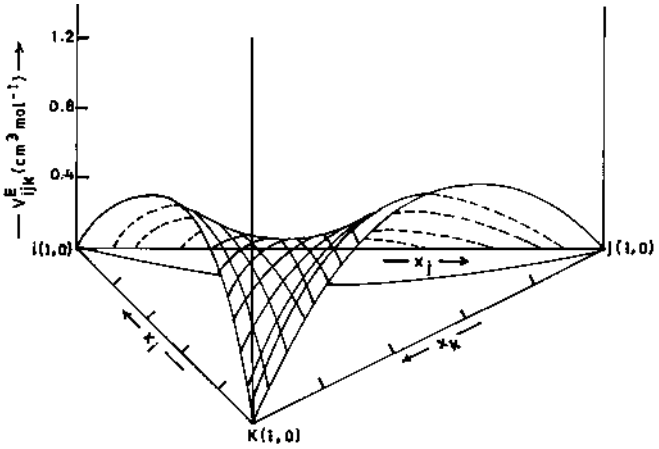

Fig 2. Molar excess volume (V^E_{ijk}) of 1,3-dioxolane (i) + benzene (j) + n-hexane (k) at 298.15 K.

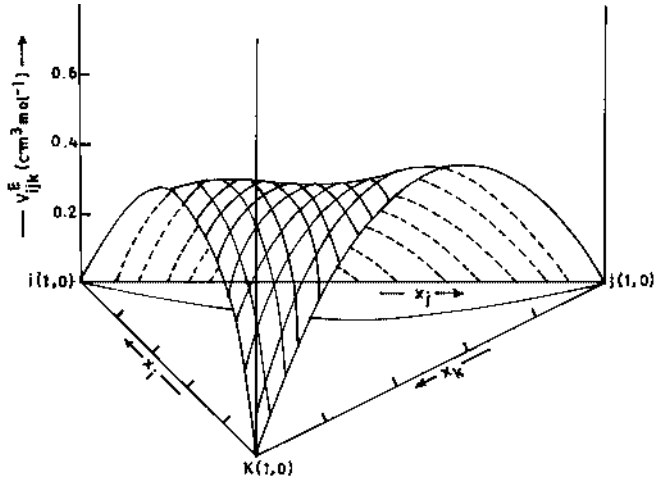

teristic of ($i + j + k$) ternary mixtures and were calculated by fitting experimental V^E_{ijk} to the following expression:

$$[2]\quad \left(\begin{array}{l} V^E_{ijk} \quad - x_i x_j\left[\sum_{n=0}^{2} V^{(n)}_{ij}(x_i - x_j)^n\right] \\ \qquad - x_j x_k\left[\sum_{n=0}^{2} V^{(n)}_{jk}(x_j - x_k)^n\right] \\ \qquad - x_k x_i\left[\sum_{n=0}^{2} V^{(n)}_{ik}(x_k - x_i)^n\right] \end{array}\right) \times [x_i x_j x_k]^{-1} = V^{(0)}_{ijk} + V^{(1)}_{ijk}(x_j - x_k)x_i + V^{(2)}_{ijk}(x_j - x_k)^2 x_i^2$$

by the least square method. Such parameters along with the standard deviation, $\sigma(V^E_{ijk})$ expressed by the following relation:

$$[3]\quad \sigma(V^E_{ijk}) = \left[\sum \{V^E_{ijk\,(\text{exptl})} - V^E_{ijk\,(\text{cald})}\}\right]^2/[(m-n)]^{0.5}$$

Fig. 3. Molar excess volume (V^E_{ijk}) of 1,3-dioxolane (i) + benzene (j) + n-heptane (k) at 298.15 K.

where m is the number of data points and n is the number of adjustable parameters of eq. [1] are recorded in Table 1.

Discussion

We are unaware of any V^E_{ijk} data of the present mixtures with which to compare our results.

Conceptual aspect of the Graph approach and results

Recent studies (5) have revealed that D (i) + benzene, toluene, or -xylene (j) binary mixtures are characterized by (i) specific interactions between delocalized π-electrons of benzene of aromatic hydrocarbons and π-electrons of the oxygen atoms in D (i). Consequently, change in molar property X^E($X = V$ or H) due to these interactions were expressed (5) by eq. [4]

$$[4]\quad X^E_{(X = V \text{ or } H)} = [x_i x_j V_j/\Sigma\, x_i V_i]\,[\chi_{ij} + x_j \chi_{12}]$$

where χ_{ij} and χ_{12} are molar volumes interaction parameters due to unlikely contact i–j formation and specific interaction between the i and j components, respectively. Furthermore, in D (i) + cyclohexane, n-hexane, or n-heptane (j) binary mixtures, if D (i) and cyclohexane, n-hexane, or n-heptane undergo weak specific interactions, then $X^E_{(X = V \text{or } H)}$ data of these mixtures would be expressible (6) by the following relation:

$$[5]\quad X^E = [x_i x_k (V_i)/\Sigma\, x_i V_i]\,\chi_{ik}$$

The basic arguments in deriving eqs. [4] and [5] were justified (5, 6) as X^E data of these binary mixtures were reproduced by employing χ_{ij}, χ_{12}, and χ_{ik} parameters (evaluated from X^E data at $x_i = 0.4$ and 0.5).

If a hydrocarbon such as cyclohexane, n-hexane, or h-heptane (k) is added to D (i) + benzene (j) mixture, then ternary ($i + j + k$) mixture formation would involve the establishment of i–j (a), j–k (b), and i–k (c) contacts (process 1) between i, j, and k components of ($i + j + k$) mixture, with specific interaction between i and j component to yield i–j molecular entity (process 2). Consequently if χ'_{ij}, χ'_{jk}, χ'_{ik} are the molar volume interaction parameter of unlike contacts,

© 2001 NRC Canada

then change in molar properties (12–14), due to process 1 (*a*, *b*, and *c*) are given by the following expression:

$$[6] \quad \Delta X_1 = x_i \chi'_{ij} S_j + x_j \chi'_{jk} S_k + x_k \chi'_{ij} S_i$$

where S_i etc. are defined by $S_i = x_i V_i / \Sigma x_i V_i$.

$$\Delta X_1 = [x_i x_j V_j / \Sigma x_i V_i]\chi'_{ij} + [x_j x_k V_k / \Sigma x_k V_i]\chi'_{jk} + [x_k x_i V_i / \Sigma x_k V_k]\chi'_{ik}$$

Furthermore, if χ_{12} is the molar interaction parameter due to specific interactions (leading to formation of *i*–*j* molecular entity), then change in molar property (14) due to process 2, can be expressed by eq. [7].

$$[7] \quad \Delta X_2 = x_i x_j^2 \chi_{12} / \sum x_i V_i$$

The overall change in thermodynamic property due to processes 1 (*a*, *b*, *c*) and 2 is given by

$$[8] \quad V^E_{ijk} = [x_i x_j V_j / xIV_i + xjV_j]\,[\chi'_{ij} + x_j \chi_{12}] + [x_j x_k V_k / x_j V_j + x_k V_k]\chi'_{jk} + [x_i x_k V_i / x_i V_k + x_k V_k]\chi'_{ik}$$

Since $V_i/V_j = {}^3\xi_j/{}^3\xi_i$, where ${}^3\xi_i$ etc., are the connectivity parameters of third degree of *i*th etc. component of the mixture, are defined by (15)

$$[9] \quad {}^3\xi_i = \sum_{m<n<o<p} \delta^v_m \delta^v_n \delta^v_o \delta^v_p$$

where δ^v_m reflects explicitly the valence of *m*th vertex in molecular graph, and is related to maximum valency (Z_m) and number of hydrogen atoms attached to mth vertex by $\delta^v_m = Z_m - h_m$. Equation [8] then reduces to:

$$[10] \quad V^E_{ijk} = [x_i x_j({}^3\xi_i/{}^3\xi_j)/x_i + x_j({}^3\xi_i/{}^3\xi_j)][\chi'_{ij} + x_j\chi_{12}] + [x_j x_k({}^3\xi_j/{}^3\xi_k)/x_j + x_i({}^3\xi_j/{}^3\xi_k)]\chi'_{ij} + [x_i + x_k({}^3\xi_i/{}^3\xi_k)/x_i + x_k({}^3\xi_i/{}^3\xi_k)]\chi'_{ik}$$

Furthermore, if it be assumed that $\chi_{ij} \simeq \chi_{12} = \chi''_{ij}$, then eq. [10] reduces to eq. [11] expressed by

$$[11] \quad V^E_{ijk} = [x_i x_j({}^3\xi_i/{}^3\xi_j)]/[x_i + x_j({}^3\xi_i/{}^3\xi_j)][(1 + x_j)\chi''_{ij}] + [x_j x_k({}^3\xi_j/{}^3\xi_k)]/[x_j + x_k({}^3\xi_j/{}^3\xi_k)]\chi'_{jk} + [x_k x_i({}^3\xi_k/{}^3\xi_{i2})]/[x_i + x_{i2}({}^3\xi_i/{}^3\xi_i)]\chi'_{ik}$$

Equation [11] contains three unknown parameters χ''_{ij}, χ'_{ij}, and χ'_{ik}. These parameters were calculated employing experimental V^E_{ijk} data of these ternary mixtures at three compositions and were subsequently utilized to predict V^E_{ijk} values at other values of x_i. Such predicted V^E_{ijk} values along with various parameters are recorded in Table 1.

Examination of Table 1 reveals that V^E_{ijk} values evaluated from the Graph approach compare well with the corresponding experimental values (for $x_i \leq 0.2$, the calculated V^E_{ijk} values are of the correct magnitude, but quantitative agreement is not good) and thus lends support to the assumptions made in deriving eq. [11].

V^E_{ijk} values were next analyzed in terms of Lacombe and Sanchez theory (16, 17). According to this theory, V^E_{ijk}, for a ternary mixture is given by

$$[12] \quad V^E_{ijk} = r_{\text{mix}} v^*_{\text{mix}} \left[\bar{v}_{\text{mix}} - \sum \phi_i \bar{v}_i\right]$$

where

$$[13] \quad \phi_i = m_i(\rho^*_i)^{-1}\left[\sum (m_i \rho^*_i)^{-1}\right]$$

$$[14] \quad m_i = x_i M_i \left[\sum (x_i M_i)^{-1}\right]$$

$$[15] \quad r_{\text{mix}} = \sum_{l=i}^{k} x_i r_i$$

$$[16] \quad r_i = r_i^0 [v^*_i (v^*_{\text{mix}})^{-1}]$$

$$[17] \quad v^*_{\text{mix}} = \sum \phi^*_i v^*_i$$

$$[18] \quad \bar{v}_{\text{mix}} = 1 / \bar{\rho}_{\text{mix}}$$

$$[19] \quad \phi^0_i = m_i(\rho^*_i v^*_i)^{-1}\left[\sum (m_i/\rho_i v^*_i)^{-1}\right]$$

and all the terms have the same significance as described elsewhere (16, 17).

Evaluation of V^E_{ijk} according to this theory requires a knowledge of reduced density of ternary mixture ($\bar{\rho}_{ijk}$) and can be determined from the equation of state of the mixture

$$[20] \quad (\bar{\rho}_{ijk})^2 + \bar{P} + [RT/\epsilon^*_{\text{mix}}][\ln[1 - \bar{\rho}_{ijk}] + [1 - [r_{\text{mix}}]^{-1}]\bar{\rho}_{ijk}] = 0$$

where

$$\epsilon^*_{\text{mix}} = \left[\phi_i^2 \epsilon_{ii} + \phi_j^2 \epsilon_{jj} + \phi_k^2 \epsilon_{kk}\right] - \left[\sum \phi_i \phi_j \chi^*_{ij}\right]$$

χ^*_{ij} etc. are the parameters characteristics for the ($i + j$), ($j + k$), and ($i + k$) binary mixture and have been evaluated from the experimental H^E data (18–20) ($x_i = 0.5$) by means of eq. [21].

$$[21] \quad H^E_{ij} = 2\phi_i \phi_j \chi_{ij} \bar{\rho}_{ij}(\epsilon^*_{ii} + \epsilon^*_{jj} - 2\epsilon^*_{ij}) + RT\, r_{\text{mix}}\left[\sum (\phi^0_i \bar{\rho}_i - \bar{\rho}_{ij}\phi_i)(\bar{T}_i)^{-1}\right]$$

As ($i + j$) and ($j + k$) are ($i + k$) binary mixtures of the studied ($i + j + k$) mixtures that satisfy eq. [22].

$$[22] \quad (\bar{\rho}_{ij})^2 + \bar{P} + RT/\epsilon^*_{ij}\,[\ln[1 - \bar{\rho}_{ij}) + [1 - r_{\text{mix}}{}^{-1}]\rho_{ij}] = 0.008 - 0.029$$

It suggests that ($i + j + k$) mixture would not satisfy eq. [20]. In view of the fact, that present mixtures satisfy equation of state like (20), it is considered that the extent to which ternary mixture deviates from eq. [20] would be nearly one third of the sum to which sub-binary mixtures deviated from eq. [22]. Consequently, eq. [20] reduces to

$$[23] \quad (\bar{\rho}_{ijk})^2 + \bar{P} + [RT/\epsilon^*_{\text{mix}}][\ln(1 - \bar{\rho}_{ijk}) + (1 - r_{\text{mix}}{}^{-1})\bar{\rho}_{ijk}] = (1/3)\left[\sum \text{R.H.S of eq. [11] for } (i + j), (j + k), \text{ and } (i + k) \text{ mixtures}\right]$$

and the V^E_{ijk} values were then predicted using established equation of state (23). Such V^E_{ijk} values along with χ^*_{ij}, χ^*_{jk}

© 2001 NRC Canada

and χ_{ik}^{*} parameters are recorded in Table 1 and are also compared with their experimental values.

According to Flory's theory (18, 19), V_{ijk}^{E} for a ternary mixture is given by

$$[24] \quad V_{ijk}^{E} = \overline{V}_{\text{cal}}^{E}[\bar{x}_i v_i^{*} + x_j v_j^{*} + x_k v_k^{*}]$$

where

$$[25] \quad \bar{v}_i^{-1} = [\{\alpha_i T/(3\alpha_i T + 3) + 1\}]^3$$

$$[26] \quad v_i^{*} = v_i[\bar{v}_i]^{-1}$$

$$[27] \quad T_i^{*} = T_i \bar{v}_i^{4/3}[\bar{v}_i^{1/3} - 1]^{-1}$$

$$[28] \quad P^{*} = \sum \phi_i^{*} P_i^{*} - \sum \phi_i^{*} \theta_j \chi_{ij}^{**}$$

$$[29] \quad \overline{T}_0 = [\bar{v}_0^{1/3} - 1] / \bar{v}_0^{4/3}$$

$$[30] \quad \overline{V}_{\text{cal}}^{E} = \bar{v}_0^{7/3}[\overline{T} - \overline{T}_0] / (4/3) - \bar{v}_0]$$

all the terms have the same significance as described by Flory (18, 19).

Evaluation of V_{ijk}^{E} by Flory's theory requires a knowledge of adjustable parameter $\theta_j \chi_{ij}^{**}$ etc. characteristic of $(i + j)$, $(j + k)$, and $(i + k)$ binary mixture of $(i + j + k)$ ternary mixture. These parameters were determined by fitting H^E experimental data (18–20) at $x_i = 0.5$ to eq. [31].

$$[31] \quad H_{ij}^{E} = \sum x_i \rho_i^{*} V_i^{*} (\overline{V}_i^{-1} - \overline{V}_{\text{cal}}^{-1}) + x_i V_i^{*} \theta_j \chi_{ij}^{**} \overline{V}_{\text{cal}}^{-1}$$

The parameters of pure component were determined using isothermal compressibility values (k_T) reported in the literature (20). k_T values of 1,3-dioxolane was calculated using ΔH_V values (7) in manner as suggested by Hildebrand (21). Such V_{ijk}^{E} values alongwith $\theta_j \chi_{ij}^{**}$ etc. parameters are recorded in Table 1 and are also compared with their corresponding experimental values.

Examination of data in Table 1 reveals that V_{ijk}^{E} values evaluated by Lacombe and Sanchez approach are of the right of order of magnitude, but the quantitative argument is not impressive. This may be attributed to the failure of the assumption that χ_{ij} etc. values are constant over the entire values of x_i, x_j, or x_k. However, V_{ijk}^{E} values predicted by Flory's theory make only qualitative agreement.

MONOREG – an expert system for structural elucidation of monoterpenes

Marcelo J.P. Ferreira, Gilberto V. Rodrigues, and Vicente P. Emerenciano

Abstract: This paper describes a new expert system denominated MONOREG for structural determination of monoterpenes. This system is composed of five programs capable of performing ^{13}C NMR spectra data analyses and analyses of systematic data from living organisms. At the end of this procedure, it shows the likely skeletons of the compound in question as well as the substructures compatible with the ^{13}C NMR data. The system was tested on the skeleton elucidation of 40 monoterpenes from a wide variety of structure types and exhibited excellent results in the skeleton prediction process.

Key words: monoterpenes, ^{13}C NMR, structure elucidation, computer-aided analyses, expert system.

Résumé : Cet article décrit un nouveau système expert, dénommé MONOREG, utilisé pour la détermination structurale des monoterpènes. Ce système se compose de cinq programmes qui réalisent l'analyse RMN du ^{13}C d'un composé et utilize aussi des données de systématiques d'organismes vivants. Les squelettes probables sont déterminés ainsi que les sous-structures compatibles avec les données spectrales. Le système a été testé pour l'élucidation de 40 monoterpènes qui appartiennent à divers types de squelettes, et montre d'excellents résultats.

Mots clés : monoterpènes, RMN du ^{13}C, élucidation structurale, analyse assisteé par ordinateur, système expert.

Introduction

The quick development of computers in the last decades has allowed researchers of a wide variety of knowledge fields to develop computational methods capable of aiding them in solutions of complex problems in their work (1).

The programs that use computational techniques that try to simulate human reasoning to solve complex problems are called expert systems (2). They act in the problem solutions of restricted domains, using an individual method based on a computational model of the specialist's logic.

Several types of problems are solved through expert systems, especially in scientific and technologic areas. Various examples of expert system for chemistry in the structural determination area may be cited,such as DENDRAL (3), ACCESS (4), DARC/EPIOS (5–9), SpecInfo (10), and more recently, the Assemble 2.0 systems (11, 12).

In the last couple of years, our research group has developed the SISTEMAT expert system (13, 14), whose objective is to aid natural product researchers in the structural determination process of organic substances. For that, the SISTEMAT system utilizes, principally, ^{13}C NMR, mass spectrometry (MS), and systematic information (family, genus, and species) data. Thus, some natural product classes have been studied by us, for example, sesquiterpenes, sesquiterpene lactones, diterpenes, and triterpenes (15–19), by using the programs of the SISTEMAT, to construct, at the end of the work, a system for elucidation of any terpenoid structure.

The aim of this paper is to present an expert system, denoted MONOREG, capable of structural determination of monoterpenes,.

Methodology

For the database, elaborations were collected from the literature (1960–95) of monoterpenes showing ^{13}C NMR or systematic data. The obtained monoterpenes were automatically encoded by our DATASIS program (20, 21). The database we built for this work contains 2328 monoterpenes distributed in 158 different skeletons, 1369 ^{13}C NMR spectra data, and 13 067 occurrences in 124 families of plants, marine organisms, and fungi.

The MONOREG system

MONOREG is a system that performs data analyses of monoterpenes. The idea for this name comes from the Portuguese words monoterpenos (Engl., monoterpenes) and regras (Engl. rules). Basically, this system is composed of five programs: MACRONO, SISCONST, C13MACH, SISOCBOT,

and REGRAS, which propose, at the end of analysis, a probable skeleton compatible with the entered data. This system is also capable of carrying out analyses of data from MS, however, these data were not inserted in the system. Therefore, they were not evaluated. The programs mentioned above are described below.

The MACRONO program

The MACRONO program (22, 23) identifies the common substituent groups present in the natural products, such as acetate, angelate, tiglate. From the ^{13}C NMR chemical shifts and respective multiplicities of the substance in question, the program searches the database for the most probable substituent groups present in this substance and shows to the user the selected substituent groups together with their average error range of chemical shifts. The average error range is the average deviation calculated from the chemical shifts of the sample in question and then matched with the chemical shifts values stored in the database. Therefore, the smaller the range, the more reliable the result be will.

The database especially elaborated for this program contains 161 substituent groups that are frequently encountered in terpenoid compounds. It is essential that the MACRONO program is the first program to be used in the MONOREG

© 2001 NRC Canada

Table 5. Summary of the skeleton probability displayed by the MONOREG system.

Skeleton	SISCONST	C13MACH	SISOCBOT	REGRAS	GLOBAL
Menthane	98.5	60.5	91.5	100.0	89.3
Pinane	—	9.9	6.4	—	3.3
Myrcane	—	10.0	2.1	—	2.5
7-Norpinane	—	10.0	—	—	2.3
Thujane	—	9.6	—	—	2.2
7-Normenthane	1.5	—	—	—	0.4

system. This procedure is done because the MACRONO program removes all the ^{13}C NMR signals corresponding to the substituent groups. Thus, the other programs of the MONOREG system, which carry out analysis and prediction of skeletons from ^{13}C NMR data, can in fact work with a better performance, showing a greater hit probability, once the chemical shift signals pertaining to the substituent groups are removed from and thereby do not interfere with the skeleton analysis.

To exemplify the use of the MACRONO program, a monoterpene pertaining to menthane skeleton, which was isolated from *Sphaeranthus suaveolens* — Compositae (24) (Fig. 1), was selected. After the ^{13}C NMR experimental data are inserted in the system, the MACRONO program accomplishes the analysis by matching these data with the ^{13}C NMR data of the database. This analysis is performed with an error range previously chosen by the user. In this specific case, we have chosen δ 1.0 as the error range. From this process, the program selects the most probable substituent groups for a data set. The proposed substituent groups for the monoterpene in Fig. 1 are displayed in Table 1. We can verify, from the MACRONO program analysis, that the substituent groups proposed by the program (tigloyl and acetyl) are present in the monoterpene structure. It is necessary to point out here that, after removing the ^{13}C NMR signals of these substituent groups, the remaining chemical shifts, which belong to the rest of the structure, will be utilized by other programs of the MONOREG system.

The SISCONST program

The name of this program originates from the words SISTEMAT, which is our system's name, and the English word for constraint, and it is used as a constraint generator. The SISCONST program (25) performs ^{13}C NMR data analysis. From the chemical shifts and multiplicities of a given sample, the program predicts its' probable skeleton. After that, the program identifies the substructures (parts of a structure) with their suitable attributed signals compatible with the experimental ^{13}C NMR data and then shows them to the user.

The SISCONST program only selects substructures that have a minimum number of carbon atoms and their respective interlinked chemical shifts. This minimum number is chosen by the user, to whom it is suggested to select about half the total number of carbons of the chemical class in question. Hence, the minimum number for monoterpenes is always five carbon atoms.

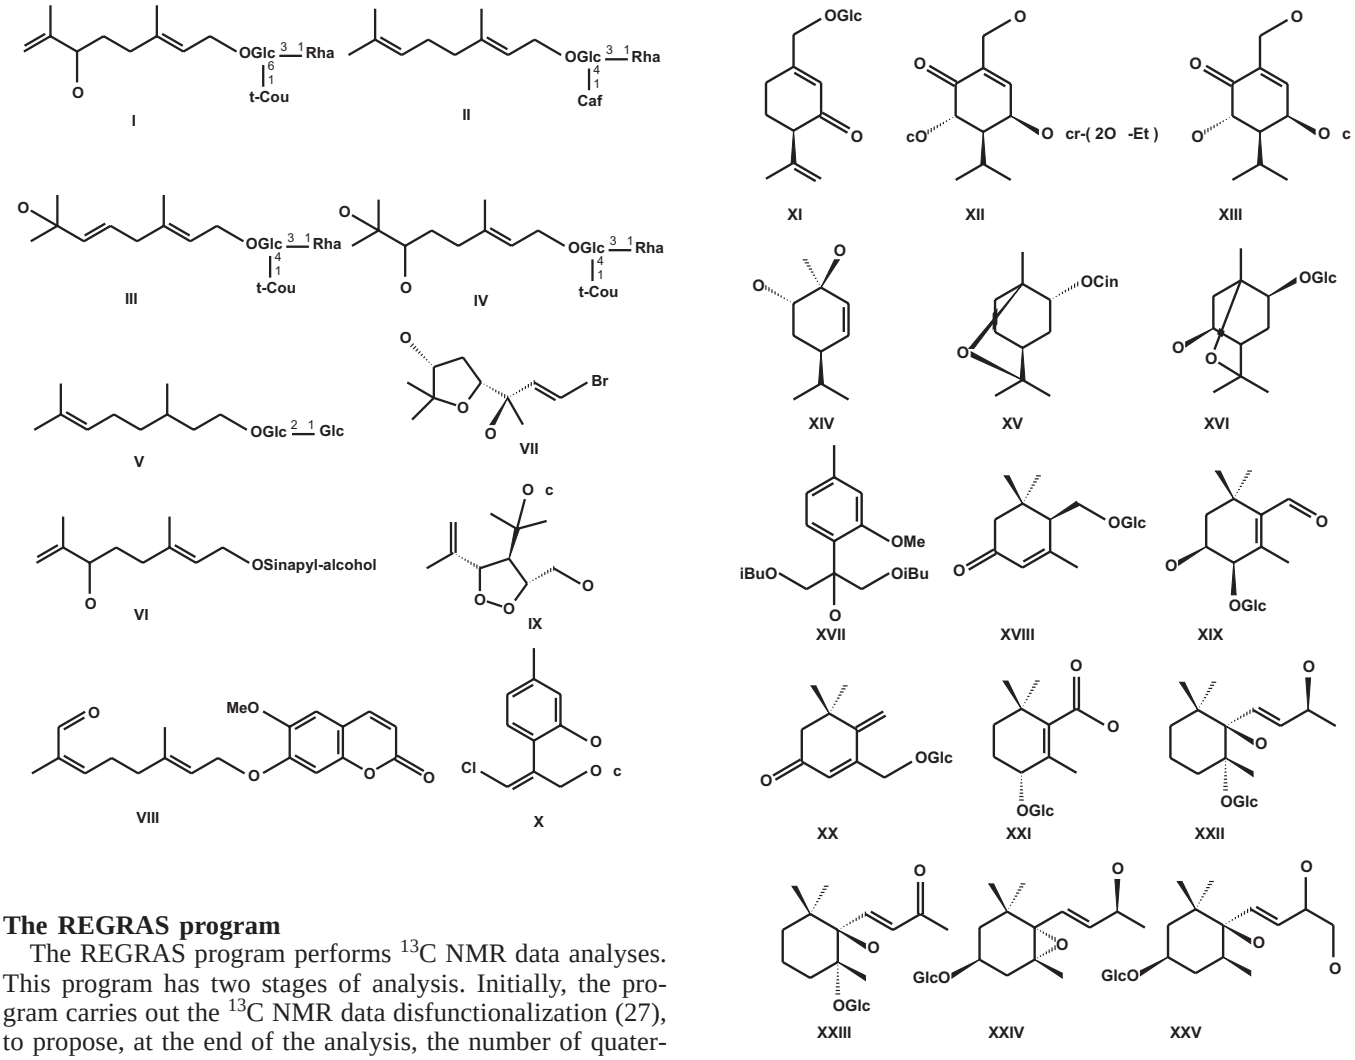
The SISCONST program works by matching the signals of the experimental spectrum with those of all spectra stored in the database. If a spectrum signal and its respective multiplicity are present in a determined carbon atom, the signals of the interlinked carbons are matched with those from the experimental data. This searching process is repeated to obtain the largest substructures. All selected substructures will show a minimum number of the carbon atoms as requested by the user as well as the chemical shifts compatible with the experimental ^{13}C NMR data. The skeleton probability of the substance is computed from the compounds that have a substructure containing at least half of the total carbon number. So, from each chosen compound and for its skeleton, the program calculates the skeleton probability as previously described (25).

The ^{13}C NMR data that remained after the MACRONO program analysis were submitted to SISCONST program. The program exhibited the skeleton probability (Table 2) and the two substructures with signal attributions (Fig. 2). The substructures, when overlapped as in the DARC system (5–9), give a larger substructure compatible with the correct structure.

The C13MACH program

The C13MACH program executes ^{13}C NMR data analysis too. From the chemical shifts and multiplicities this program selects *x*-compounds (*x* may change from 1 to 50) that display higher similarity index (SI) with the experimental data according to the system of Bremser and co-workers (26). From the listed compounds, the program computes the skeleton probability. In this program, the chemical shifts do not need to be necessarily interlinked like those in the SISCONST program.

For the monoterpene shown in Fig. 1, the C13MACH program calculates the skeleton probability (Table 3), and Fig. 3 shows the three compounds with a high similarity index in relation to the monoterpene tested.



The SISOCBOT program

The SISOCBOT program (23) was developed mostly to analyze botanical data. By this reason, it was given this name originating from the Portuguese words SISTEMAT, ocorrência (Engl. occurrence), and botânica (Engl. botanical). The program carries out the analysis of the information originated from the systematic classification of any organism. From the family and genus names of plants, marine organisms, fungi, etc., the program searches in the database for the number of skeleton occurrences present in the family and genus of the species in question. And then it estimates and supplies to the user the probability of finding any carbonic skeleton in the determined organism.

For the monoterpene displayed in Fig. 1, the skeleton probability calculated by the SISOCBOT program is shown in Table 4.

Fig. 5. Monoterpenes used to test the MONOREG system.

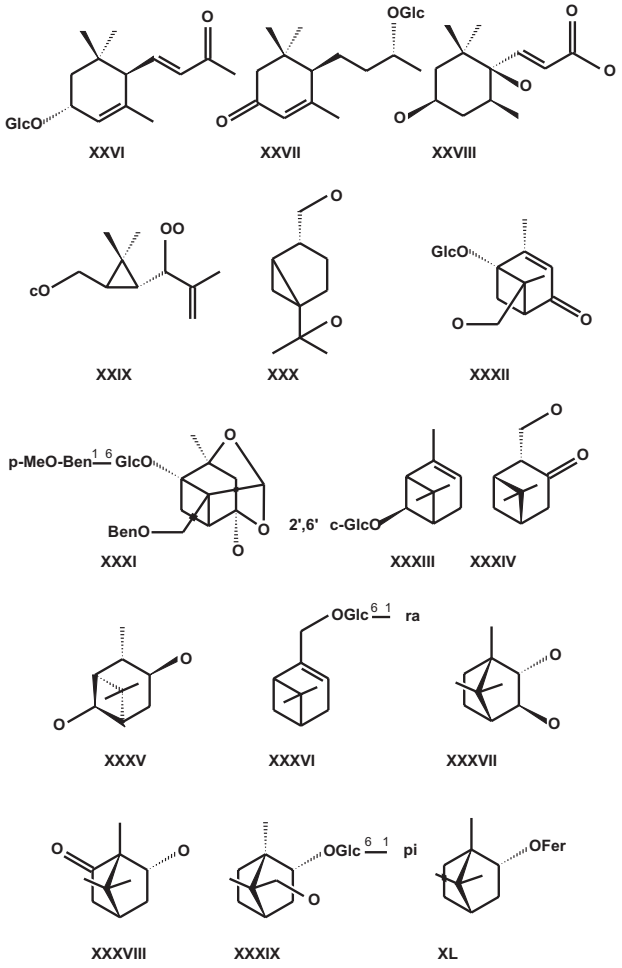
The REGRAS program

The REGRAS program performs ^{13}C NMR data analyses. This program has two stages of analysis. Initially, the program carries out the ^{13}C NMR data disfunctionalization (27), to propose, at the end of the analysis, the number of quaternary, methine, methylene, and methyl carbons on the skeleton of the substance in question. After obtaining these data, the program matches the types of carbon atoms found with a database containing this information for all the skeletons of a determined chemical class, thus getting all the likely skeletons of the substance. Secondly, from the proposed skeletons at the first step, the program accomplishes a search for possible skeletons through the characteristic chemical shift ranges. For each monoterpene skeleton, a set of chemical shift ranges was selected that characterize it toward other skeleton types (28).

Summarizing, the REGRAS program exhibits two analysis steps: the first is a rough search, which is fundamental, by means of ^{13}C NMR data disfunctionalization. Skeletons that show a determined set of carbon atoms are selected. At the second analysis step, the program, from these previously selected skeletons, performs a fine search through the characteristic chemical shift ranges of each skeleton or subskeleton.

To test the REGRAS program, the ^{13}C NMR data of the monoterpene (Fig. 1) were analyzed. After the data disfunctionalization and search through the characteristic chemical shift ranges, the REGRAS program showed the following skeleton probability: menthane skeleton, 100.0%.

The global probability



At the end of all analyses, the results obtained from each program are combined, thereby generating a global probability. The global probability is computed from the weighed mean of the results of each program. Thus, the following weights 0.9, 0.7, 0.5, and 1.0 were assigned to programs SISCONST, C13MACH, SISOCBOT, and REGRAS, respectively. The weights assigned to each program varied from 0 to 1 and the vaules were obtained by testing 20 substances to assess the hit percental of each program. The global probability calculated for the monoterpene (Fig. 1) is shown in Table 5 together with the skeleton probabilities displayed by each program. Figure 4 shows the work flow chart of the PASCAL language written MONOREG system.

Results and discussion

To test the performance and efficiency of the MONOREG system, our option was to randomly collect the data of 40 new monoterpenes (Fig. 5) from recently published literature (29–55). These data, which are not yet inserted in our database, were then submitted to analyses in the programs. Ini-

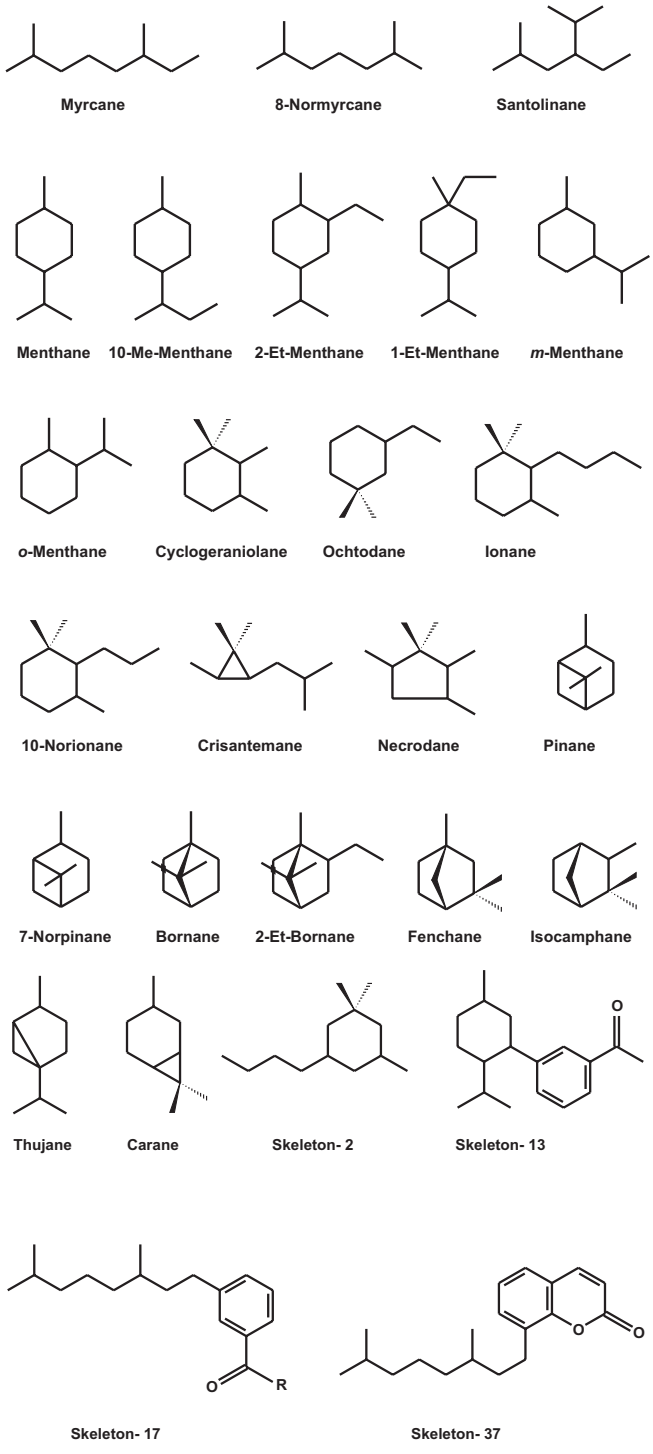
Fig. 5 (*concluded*).



tially, the MACRONO program removed all the ^{13}C NMR chemical shifts signals attributed to the substituent groups. The remaining signals pertaining to the rest of the molecular skeletons were then tested in the other programs of the MONOREG system. The results obtained with the SISCONST, C13MACH, SISOCBOT, and REGRAS programs are shown in Table 6. This table also exhibits the first three monoterpene skeletons suggested by the system (see Fig. 6), the global skeleton probability, their ^{13}C NMR data, and respective references.

From the results obtained and exhibited in Table 6 one can verify that the MONOREG system showed the correct skeleton for the compounds in 97.5% of the cases. Only in test XXVIII did the system not supply the correct skeleton of the substance because the 10-norionane skeleton is a new skeleton whose data were not present in our database. The most probable skeleton proposed by the system is, however, the biogenetic precursor. If we consider the tests of the substances whose skeletons are present in the database, the skeleton prediction percental hit of the MONOREG system was 100.0%.

Analyzing each program separately, the SISCONST program showed the correct skeleton in 85.0% of the studied cases, with the remaining cases distributed among incorrect skeletons (tests XVIII, XXVIII, and XXX) and tests where

Fig. 6. Skeletons proposed by the MONOREG system.

the program did not display skeleton prediction (tests III, XX, and XXIX).

In general it has been observed that the SISCONST program, even with having an 85.0% hit in skeleton prediction, can show wrong results in the following cases: (*i*) the number of the substances referring to such a skeleton is very small or nonexistent (tests XXVIII, XXIX, and XXX); (*ii*) the compound shows a rare functionalization for such a skeleton (tests III and XX); or (*iii*) the ^{13}C NMR spectra

[b]The skeletons in italics represent the correct skeleton of the substance.

[c]The correct skeleton is 10-norionane

© 2001 NRC Canada

data of the substance in question are very similar to those of other substance belonging to another skeleton (test XVIII).

If one analyzes the SISCONST's results through the skeleton series, itcan be seen that the cyclogeraniolane series (XVIII–XXI) is the most atypical, as the results are not uniform. Regarding test XVIII, the incorrect skeleton proposed by the SISCONST program was that of ionane. However, this mistake can occur and be easily explained, since there are in the database data of several substances bearing the ionane skeleton, which present the structural nucleus of the substance XVIII. Concerning the tests XIX and XXI, the program furnished the correct skeleton of the substance, but, on the other hand, there was variation in percental hits observed. This occurred because the program considers the carbon numbers of the substructure selected in the analysis as well as the skeleton type which these substructures belong to. In test XX, the program did not provide skeleton prediction, because the substance shows an unusual functionalization for its corresponding skeleton as previously commented.

By comparing the results obtained by the C13MACH program, which showed the correct skeleton in 67.5% of the studied cases, with those of the SISCONST program, the SISCONST program is shown to be more efficient because it selects only monoterpenes that contain a minimum number of carbon atoms interlinked for skeleton prediction, whereas the C13MACH program does not have this restriction.

The REGRAS program predicted the correct skeleton of the compounds in 95.0% of the cases. Two errors were detected: (*i*) in test XXVIII, the program recongnized the correct disfunctionalization of the ^{13}C NMR data, however, during the search only the 1-ethylmenthane skeleton was found, as the 10-norionane skeleton is a new compound whose data was not registered in our database; and (*ii*) in test XXXI, the REGRAS program rendered incorrect disfunctionalization of the ^{13}C NMR data. This fact occurred with the chemical shift at 71.3 (s) ppm, which is related to C_8. This chemical shift should not be disfunctionalized because it refers to a quaternary carbon. However, as this chemical shift is found in the C-OR range, established in the program (27), it was disfunctionalized to a methine carbon.

In relation to the 40 tests here shown, the MACRONO program was used for 32 of them. In all 32 tests, the program correctly identified the substituent groups present in the respective substances.

The SISOCBOT program showed the correct skeleton of the substance in 68.75% of the cases. When the analyzed substance belongs to a genus that is absent in the database, the search may be accomplished at family level, however, as the result is less reliable, the search was only conducted at genera level present in the database. When we compared the results of the SISOCBOT program with those of the C13MACH program, we found that the former displayed a slightly higher percentual hit, thereby demonstrating the validity and importance of the systematic data for skeleton prediction of substances from natural sources.

Conclusions

The results of the analyses of monoterpenes in this work show an excellent performance of the programs comprised of the MONOREG system for the identification and skeleton prediction with 97.5% hits. From the obtained results, we can conclude that this system may be introduced as a valuable tool for the process of monoterpene skeleton determination, thereby increasing the spectral interpretation capacity of the researchers, once the characterization of the skeleton type of new natural products is at the crucial point in structural elucidation of these compounds.

The information obtained from the programs of the MONOREG system, such as skeleton types, substructures, probable substituent groups bonded to structures, might be utilized as a restriction module for the structure generator that is being developed for the expert SISTEMAT system, i.e., instead of the generator working with all the skeletons of a class of substance to start the process of generation of likely structures, it will only have to initiate the process utilizing just three or four first skeletons proposed by the MONOREG system. The immediate consequence of the utilization of this system on the structure generator will be the reduction of computational time and of the number of displayed structural proposals, hence avoiding the combinatorial explosion problem observed in other expert systems developed up to now (9, 11, 12, 56, 57).

Acknowledgments

Kinetics and mechanistic study of the ruthenium(III) catalyzed oxidative deamination and decarboxylation of L-valine by alkaline permanganate

Dinesh C. Bilehal, Raviraj M. Kulkarni, and Sharanappa T. Nandibewoor

Abstract: The kinetics of ruthenium(III) catalyzed oxidation of L-valine by permanganate in alkaline medium at a constant ionic strength has been studied spectrophotometrically. The reaction between permanganate and L-valine in alkaline medium exhibits 2:1 stoichiometry ($KMnO_4$:L-valine). The reaction shows first-order dependence on the concentration of permanganate and ruthenium(III) and less than unit-order dependence on the concentrations of L-valine and alkali. The reaction rate increases both with an increase in ionic strength and a decrease in solvent polarity of the medium. Initial addition of reaction products did not significantly affect the rate. A mechanism involving the formation of a complex between catalyst and substrate has been proposed. The activation parameters were computed with respect to the slowest step of the mechanism.

Key words: oxidation, L-valine, catalysis, ruthenium(III), kinetics.

Résumé : Faisant appel à des méthodes spectrophotométriques, on a étudié la cinétique de l'oxydation de la L-valine par le permanganate, catalysée par le ruthénium(III), en milieu alcalin et à force ionique constante. En milieu alcalin, la réaction entre le permanganate et la L-valine présente une stoechiométrie de 2:1 ($KMnO_4$:L-valine). La réaction présente une dépendance du premier ordre avec les concentrations de permanganate et de ruthénium(III) et cette dépendance est inférieure à l'unité pour les concentrations de L-valine et de base. La vitesse de réaction augmente avec une augmentation de la force ionique et avec une diminution dans la polarité du solvant. L'addition initiale de produits réactionnels n'affecte pas la vitesse de façon significative. On propose un mécanisme impliquant la formation initiale d'un complexe entre le catalyseur et le substrat. On a calculé les paramètres d'activation par rapport à l'étape la plus lente du mécanisme.

Mots clés : oxydation, L-valine, catalyse, ruthénium(III), cinétique.

[Traduit par la Rédaction]

Introduction

Potassium permanganate is widely used as an oxidizing agent in synthetic as well as in analytical chemistry and also as a disinfectant. The reactions with permanganate are governed by pH of the medium. Among the six oxidation states of manganese from 2+ to 7+, permanganate Mn(VII) is the most potent oxidation state in both acid and alkaline medium.

The manganese chemistry involved in these multistep redox reactions is an important source of information as the manganese intermediates are relatively easy to identify when they have sufficiently long life times and the oxidation states of the intermediates permit useful conclusions as to the possible reaction mechanism including the nature of intermediates.

The oxidation by permanganate ion finds extensive applications in organic syntheses (1–7), especially since the advent of phase transfer catalysis (3, 4, 6), which permits the use of solvents such as methylene chloride and benzene. Kinetic studies are important sources of mechanistic information on the reactions, as demonstrated by the results referring to unsaturated acids in both aqueous (1, 3, 7) and nonaqueous media (8).

During the oxidation by permanganate, it is evident that permanganate is reduced to various oxidation states in acidic, alkaline, and neutral media. Furthermore, the mechanism by which the multivalent oxidant oxidizes a substrate depends not only on the substrate but also on the medium (9) used for the study. In strongly alkaline medium, the stable reduction product (10, 11) of permanganate ion is manganate ion, MnO_4^{2-}. No mechanistic information is available to distinguish between a direct one-electron reduction to Mn(VI) (Scheme 1) and a mechanism in which a hypomanganate is formed in a two-electron reduction followed by a rapid oxidation of the hypomanganate ion (12) (Scheme 2).

L-valine is one of the essential basic amino acids, which is essential in the nutrition of mammals. Its role is crucial in

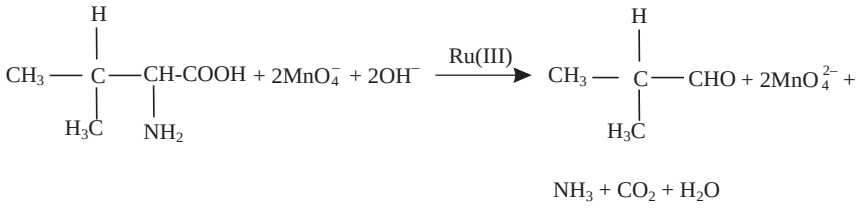
the development of organs, especially in children. It also finds applications in medicine and pharmaceuticals. Amino acids have been oxidized by a variety of oxidizing agents (13). Although several types of organic (14) and inorganic (10, 11) substrates are oxidized by permanganate in aqueous alkaline medium, there are only a few reports on the oxidation of amino acids by aqueous alkaline permanganate. The kinetic investigation of the oxidation of amino acids has been carried out under different experimental conditions (15). In many cases it was reported that amino acids undergo oxidative decarboxylation. Jayaprakash Rao et al. (16) suggested that the oxidation of amino acids by two-electron oxidants such as diperiodatoargentate(III) in alkaline medium involves a two-electron transfer, which produces an imino acid intermediate in the rate determining step. This intermediate subsequently undergoes hydrolysis to yield the keto acids. One electron oxidants such as ceric sulphate (17), peroxomonosulphate (18), and hexacyanoferrate(III) (19) also oxidize amino acids to keto acids. But other studies with amino acids report the oxidation products as the corresponding aldehydes (20). Thus, the study of amino acids becomes important because of their biological significance and their selectivity towards the oxidants.

Ruthenium(III) is known to be an efficient catalyst in several redox reactions particularly in alkaline medium (21). The mechanism of catalysis can be quite complicated due to the formation of different intermediate complexes, free radicals, and different oxidation states of ruthenium. The kinetics of fast reactions between ruthenate(VII), RuO_4^-, and manganate(VI), i.e., MnO_4^{2-}, have been studied (22) and the reaction is presumed to proceed via an outer-sphere mechanism. The rapid exchange between MnO_4^{2-} and MnO_4^- has been studied in detail by a variety of techniques (23). The uncatalyzed reaction between L-valine and permanganate in alkaline medium has been studied previously (24). A micro amount of ruthenium(III) is sufficient to catalyze the reaction in alkaline medium and a variety of mechanisms are possible. Thus, to explore the mechanism of oxidation by permanganate ion in strongly aqueous alkaline medium and to check the selectivity of L-valine towards permanganate in catalyzed system, we have selected ruthenium(III) as a catalyst. The present study deals with the title reaction to investigate the redox chemistry of permanganate and L-valine in presence of a catalysis.

Fig. 1. Spectral changes during the ruthenium (III) catalyzed oxidation of L-valine by alkaline permanganate (scanning time interval = 1 min). $[MnO_4^-] = 2.0 \times 10^{-4}$, [L-valine] = 2.0×10^{-3}, [Ru(III)] = 7.5×10^{-8}, $[OH^-] = 0.30$, $I = 0.50$ mol dm^{-3}.



Experimental

Materials and methods

Stock solution of L-valine (Sisco Research Labs, India) was prepared by dissolving the appropriate amount of sample in doubly distilled water. The solution of potassium permanganate (BDH) was prepared and standardized against oxalic acid (25). Potassium manganate solution was prepared as described by Carrington and Symons (26).The solution was standardized by measuring the absorbance on a Hitachi 150-20 spectrophotometer with a 1 cm quartz cell at 608 nm (ε = 1530 ± 20 dm^3 mol^{-1} cm^{-1}). The ruthenium(III) solution was prepared by dissolving a known weight of $RuCl_3$ (S.D. Fine Chemicals) in 0.20 mol dm^{-3} HCl. Mercury was added to the ruthenium(III) solution to reduce any Ru(IV) formed during the preparation of ruthenium(III) stock solution and kept for a

© 2001 NRC Canada

[1] 

day. The ruthenium(III) concentration was assayed (27) by EDTA titration.

All other reagents were of analytical grade and their solutions were prepared by dissolving the requisite amounts of the samples in doubly distilled water. NaOH and $NaClO_4$ were used to provide the required alkalinity and to maintain the ionic strength, respectively.

Kinetic procedure

All kinetic measurements were performed under pseudo-first-order conditions with [L-valine]:[MnO_4^-] ≥ 10:1 at a constant ionic strength of 0.50 mol dm^{-3}. The reaction was initiated by mixing previously thermostated solutions of MnO_4^-, and L-valine, which also contained the necessary quantities of Ru(III), NaOH, and $NaClO_4$ to maintain the required alkalinity and ionic strength, respectively. The temperature was uniformly maintained at 26 ± 0.1°C. The course of reaction was followed by monitoring the decrease in the absorbance of MnO_4^- in a 1 cm quartz cell of a Hitachi model 150-20 spectrophotometer at its absorption maximum of 526 nm as a function of time. The application of Beer's law to permanganate at 526 nm had been verified, giving ε = 2083 ± 50 dm^3 mol^{-1} cm^{-1} (lit. (10) ε = 2200 dm^3 mol^{-1} cm^{-1}). The first-order rate constants (k_{obs}) were evaluated by plots of log [MnO_4^-] vs. time. The first-order plots in almost all cases were linear to 80% completion of the reaction and k_{obs} were reproducible within ±5%.

During the course of measurements, the solution changed from violet to blue and then to green. The spectrum of the green solution was identical to that of MnO_4^{2-}. It is probable that the blue colour originated from the violet of permanganate and the green from the manganate, excluding the accumulation of hypomanganate. It is also evident from the Fig. 1 that the absorbance of permanganate decreases at 526 nm, whereas the absorbance of manganate increases at 608 nm.

The effect of dissolved oxygen on the rate of reaction was checked by preparing the reaction mixture and following the reaction in an atmosphere of nitrogen. No significant difference between the results obtained under the nitrogen and in the presence of air was observed. In view of the ubiquitous contamination of basic solutions by carbonate, the effect of carbonate on the reaction was also studied. Added carbonate had no effect on the reaction rate. However, fresh solutions were used when conducting the experiments.

Results

Stoichiometry and product analysis

The reaction mixtures containing an excess permanganate concentration over L-valine and constant concentration of Ru(III) (0.30 mol dm^{-3}), NaOH, and an adjusted ionic strength of 0.50 mol dm^{-3} was allowed to react for 2 h at 26 ± 0.1°C. After completion of the reaction, solid KI was added followed by acidification by 10% H_2SO_4. The remaining MnO_4^- was then titrated against standard sodium thiosulphate (28). The results indicated that two mol of MnO_4^- are consumed by one mol of L-valine as given by eq. [1]. The main reaction products were identified as aldehyde by spot test (29), ammonia by Nessler's reagent (30), and manganate by its visible spectrum. CO_2 was qualitatively detected by bubbling N_2 gas through the acidified reaction mixture and passing the liberated gas through a tube containing lime water (31). The quantitative estimation of aldehyde by 2,4-DNP derivative (32), yielded nearly 74%. The nature of the aldehyde, was confirmed by its IR spectrum (33), which showed a carbonyl stretching at 1729 cm^{-1} and a band at 2928 cm^{-1} due to aldehydic C—H stretching, thus confirming the presence of isobutylaldehyde. It was further observed that the aldehyde does not undergo further oxidation under the present kinetic conditions. The test for corresponding acid was negative.

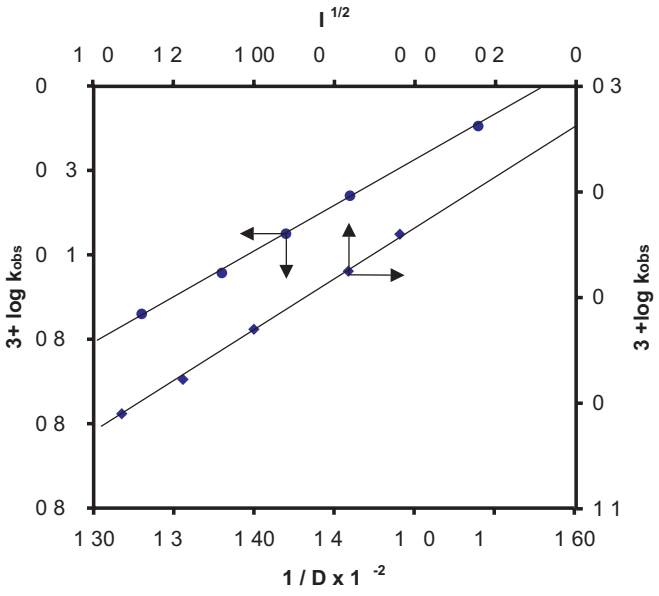
Reaction orders

The reaction orders were determined from the slopes of log k_{obs} vs. log (concentration) plots by varying the concentration of reductant, catalyst, and alkali in each, while keeping others constant. The oxidant, potassium permanagate, concentration was varied in the range of 5.0×10^{-5} to 5.0×10^{-4} mol dm^{-3}, and the fairly constant k_{obs} values indicate that the order with respect to [MnO_4^-] was one. This was also confirmed by varying the concentration of MnO_4^-, which did not show any change in pseudo-first-order constants (k_{obs}) values as shown in Table 1. The substrate L-valine was varied in the range of 5.0×10^{-4} to 5.0×10^{-3} mol dm^{-3} at 26°C; the order with respect to [L-valine] was found to be less than unity. The catalyst Ru(III) was varied in the range of 1.0×10^{-8} to 1.0×10^{-7} mol dm^{-3} at 26°C; the order with respect to [Ru(III)] was found to be unity. The effect of alkali on the reaction was studied at constant concentrations of L-valine, Ru(III), and potassium permanganate and at a constant ionic strength of 0.50 mol dm^{-3} at 26°C. The rate constant increased with the increase in the concentration of alkali, indicating an apparent less than unit order dependence on [alkali] as given in Table 1.

Effect of initially added products

The externally added products such as manganate, ammonium hydroxide, and aldehyde did not show any significant effect on the rate of the reaction.

Effect of ionic strength and dielectric constant



The effect of ionic strength was studied by varying the sodium perchlorate concentration from 0.3 to 2.0 mol dm^{-3} at constant concentrations of permanganate, L-valine, and

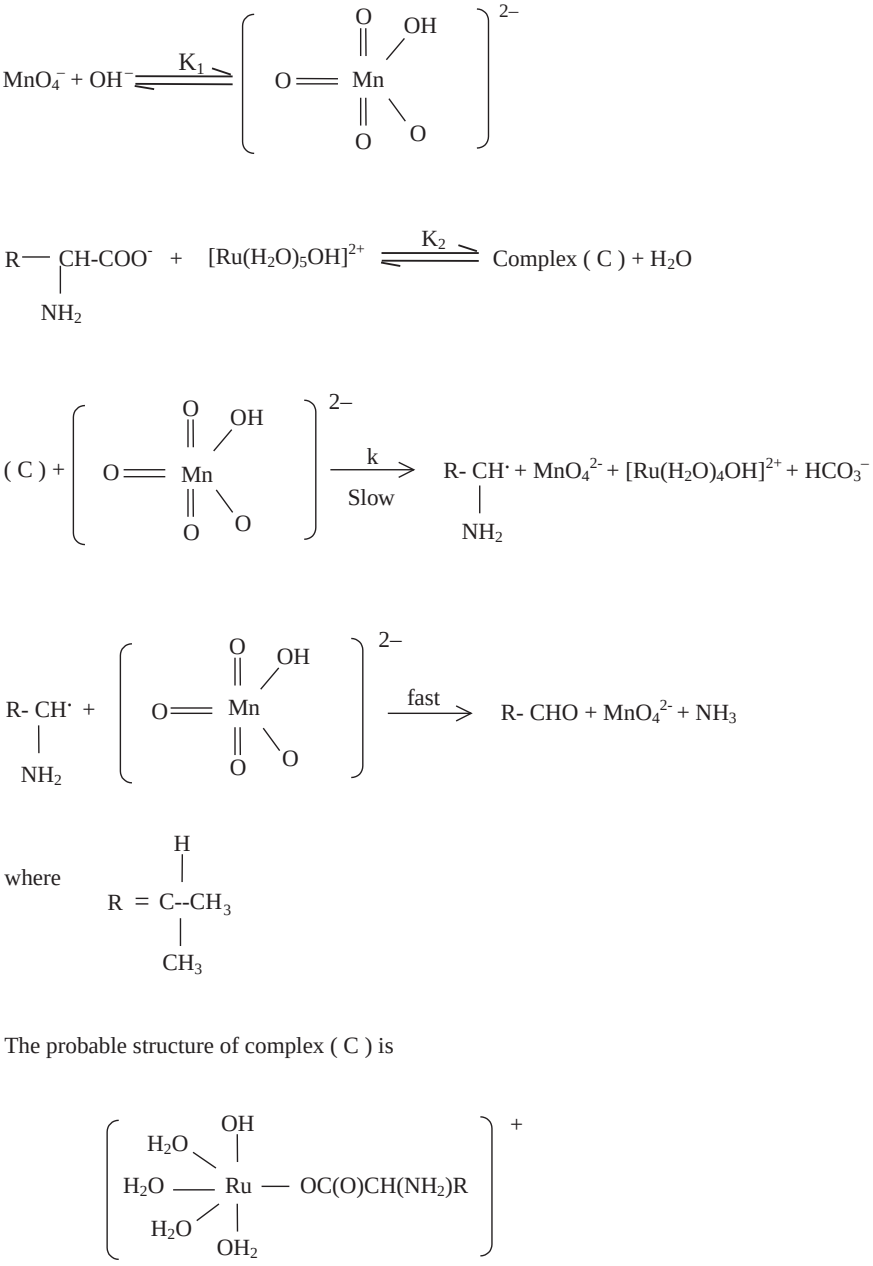
alkali. It was found that the rate constant increased with increase in concentration of $NaClO_4$ and the plot of log k_{obs} vs. $I^{1/2}$ was linear (Fig. 2).

The effect of dielectric constant (D) was studied by varying the *tert*-butanol–water content in the reaction mixture with all other conditions being constant. Attempts to measure the relative permittivities were not successful. However, they were computed from the values of pure liquids (34). The solvent did not react with the oxidant under the experimental conditions. The rate constants (k_{obs}) increased with a decrease in the dielectric constant of the medium. The plot of log k_{obs} vs. 1/D was linear with positive slope as shown in Fig. 2.

Table 2. Thermodynamic activation parameters for the ruthenium(III) catalyzed oxidation of L-valine by aqueous alkaline permanganate with respect to slow step of Scheme 3.

Activation parameters	Values
Ea (kJ mol^{-1})	72 (±4)
$\Delta H^{\ddagger}$ (kJ mol^{-1})	69 (±4)
$\Delta S^{\ddagger}$ (J K^{-1} mol^{-1})	75 (±4)
$\Delta G^{\ddagger}$ (kJ mol^{-1})	46 (±3)

Test for free radicals



The reaction mixture was mixed with acrylonitrile monomer and kept for 2 h in an inert atmosphere. On diluting with methanol a white precipitate was formed, indicating the intervention of free radicals in the reaction.

Effect of temperature

The rate of the reaction was measured at four different temperatures with varying the concentration of OH^-, keeping other conditions constant. The rate was found to increase with increase in temperature. The rate constant (k) of the slow step of Scheme 3 were obtained from the intercept of the plots of [Ru(III)]/k_{obs} vs. 1/[OH^-] for different temperatures. The energy of activation corresponding to these constants were evaluated from the plot of log k vs. 1/T and other activation parameters for reaction were calculated and are given in Table 2.

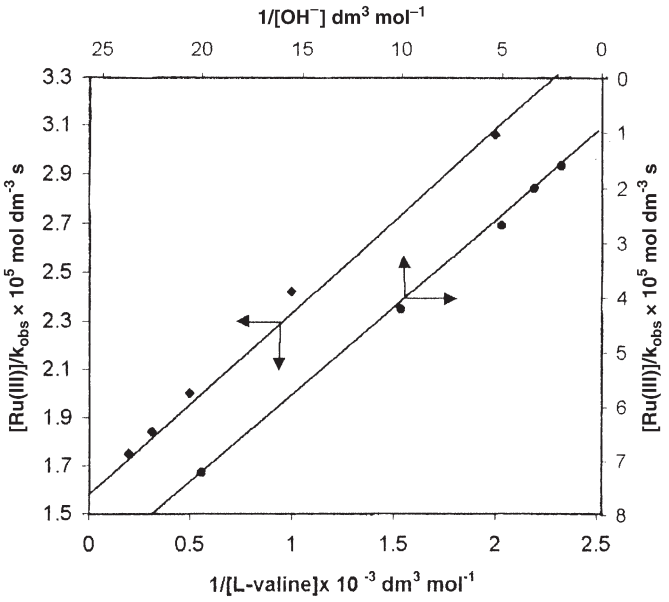
Scheme 3.

Discussion



Permanganate ion (MnO_4^-) is a powerful oxidant in an aqueous alkaline medium, and because it exhibits many oxidation states, the stoichiometric results and pH of the reaction media play an important role. Under the prevailing experimental conditions at pH > 12, the reduction product of Mn(VII) is stable and further reduction of Mn(VI) might be stopped (10, 11). Diode Array Rapid Scan Spectrophotometric (DARSS) studies have shown that at pH > 12, the product of Mn(VII) is Mn(VI) and no further reduction was observed as reported by Simandi et al. (10). However, on prolonged standing, the green Mn(VI) is reduced to Mn(IV) under our experimental conditions.

The permanganate in alkaline medium exhibits various oxidation states, such as Mn(VII), Mn(V), and Mn(VI). The colour of the solution changed from violet to blue and further to green excluding the accumulation of hypomanganate. The violet colour originates from pink of permanganate and blue from hypomanganate is observed during the course of the reaction. The colour change of $KMnO_4$ solution from the violet Mn(VII) ion to the dark green Mn(VI) ion through the blue Mn(IV) ion has been observed.

It is interesting to identify the probable species of ruthenium(III) chloride in alkaline medium. Electronic spectral studies (21) have confirmed that ruthenium(III) chloride exists in hydrated form as $[Ru(H_2O)_6]^{3+}$. In the present study it is quite probable that the species $[Ru(H_2O)_5OH]^{2+}$ might assume the general form $[Ru(III)(OH)_x]^{3-x}$. The value of x would always be less than six because there are no definite reports of any hexahydroxy species of ruthenium. The remainder of the coordination sphere will be filled by water mol-

Fig. 3. Plot of [Ru(III)]/ k_{obs} vs. 1/[L-valine] and [Ru(III)]/k_{obs} vs. 1/[OH^-] (conditions as in Table 1).

ecules. Hence under the experimental conditions [OH^-] >> [Ru^{III}], Ru^{III} is mostly present as the hydroxylated species $[Ru(H_2O)_5OH]^{2+}$.

The reaction between permanganate and L-valine in alkaline medium has a stoichiometry of 1:2 with a first-order dependence on the concentration of MnO_4^- and Ru(III) and less than unit order dependence on both theconcentration of alkali and L-valine. No effect of added products such as aldehyde and ammonia was observed. It is known that L-valine exists as deprotonated form in basic medium (24). The results suggest that first alkali combines with permanganate to form an alkali–permanganate species $[MnO_4 \cdot OH]^{2-}$ in a pre-equilibrium step (35). L-valine in the deprotonated form reacts with ruthenium(III) species to form a complex (*C*). Complex *C* reacts with the alkali–permanganate species in a slow step to form a free radical derived from L-valine, which further reacts with another permanganate species in a fast step to yield the products. The experimental results can be accommodated as seen in Scheme 3.

Spectroscopic evidence for complex formation was not successful, since there is no change in the λ_{max} (except some hyperchromicity is observed) for the mixture of L-valine and ruthenium(III) compared with that of L-valine or ruthenium(III) itself. This might be due to the involvement of weak interactions. However, the evidence for complex formation is obtained by kinetic studies (i.e., from the Michaelis–Menten plot). The plot of [Ru(III)]/k_{obs} vs. 1/[L-valine] is linear with an intercept supporting the Ru(III)–L-valine complex. Such type of substrate–catalyst complex formation has been reported previously (36). The observed modest enthalpy of activation, relatively low value of the entropy of activation and higher rate constant for the slow step of the mechanism, indicates that oxidation presumably occurs by an inner-sphere mechanism. This conclusion is supported by earlier work (37). Since Scheme 3 is in accordance with generally well-accepted principle of non-complementary oxidations taking place in a sequence of one-electron steps, the reaction would involve a radical intermediate. Since permanganate is a one-electron oxidant in alkaline medium, the reaction between substrate and oxidant would give rise to a radical intermediate. A free radical scavenging experiment revealed such a possibility. This type of radical intervention in the oxidation of amino acids has also been observed earlier (20).

The thermodynamic quantities for the first equilibrium step in Scheme 3 and activation parameters for the limiting step in Scheme 3 can be evaluated as follows: the hydroxyl ion concentration as in Table 1 was varied at four different temperatures and the K_1 value was determined at each temperature. The values of K_1 (dm^3 mol^{-1}) were obtained as 3.2, 5.0, 6.8, and 8.1 at 26, 30, 35, and 40°C, respectively. A Vant Hoff's plot was made for the variation of K_1 with temperature (i.e., log K_1 vs. 1/*T*) and the values of the enthalpy of the reaction (ΔH), entropy of the reaction (ΔS), and free energy of reaction (ΔG), were calculated as 47.9 kJ mol^{-1}, –74.3 J K^{-1} mol^{-1}, and 70.6 kJ mol^{-1}, respectively. Similarly the L-valine concentration as in Table 1 was varied at four different temperatures and the K_2 value was determined at each temperature. The values of K_2 (dm^3 mol^{-1}) were obtained as 2.2×10^3, 3.5×10^3, 4.7×10^3, and 6.4×10^3 at 26, 30, 35, and 40°C, respectively. A plot was made for the variation of K_2 with temperature (i.e., log K_2 vs. 1/*T*) and the values of ΔH, ΔS, and ΔG, were calculated as 51.9 kJ mol^{-1}, –6.1 J K^{-1} mol^{-1}, and 53.8 kJ mol^{-1}, respectively. A comparison of the latter values with those obtained for the slow step of the reaction shows that these values mainly refer to the rate limiting step, supporting the fact that the reaction before the rate determining step are fairly rapid and involves only little activation energy.

Scheme 3 leads to the following rate law, and can be derived as follows:

$$[2] \qquad \frac{\text{Rate}}{[MnO_4^-]} = k_{obs} = \frac{kK_1K_2[\text{L-val}][\text{Ru(III)}][OH^-]}{1 + K_1[OH^-] + K_2[\text{L-val}] + K_1K_2[OH^-][\text{L-val}]}$$

The terms $(1 + K_1K_2[OH^-][Ru(III)][MnO_4^-])$, $(1 + K_1[MnO_4^-])$, and $(1 + K_2[Ru(III)])$ also should be in the denominator of eq. [2], but in view of low concentration of MnO_4^- and ruthenium(III) used, they approximate to unity. Thus the above eq. [2] can be rearranged to the following form, which is used for the verification of the rate law.

$$[3] \qquad \frac{[\text{Ru(III)}]}{k_{obs}} = \frac{1}{kK_1K_2[\text{L-val}][OH^-]} + \frac{1}{kK_2[\text{L-val}]} + \frac{1}{kK_1[OH^-]} + \frac{1}{k}$$

According to eq. [3], the plots of [Ru(III)]/k_{obs} vs. 1/[L-val] and [Ru(III)]/k_{obs} vs. 1/[OH^-] should be linear, which is verified in Fig. 3. The slopes and intercepts of such plots lead to the values of *k*, K_1, and K_2 at 26°C of 12.2 (±0.6) × 10^4 dm^3 mol^{-1} s^{-1}, 3.2 (±0.1) dm^3 mol^{-1}, and 2.2 (±0.1) × 10^3 dm^3 mol^{-1}, respectively. Using these values, the rate constants under different experimental conditions were calculated by eq. [2] and compared with experimental data. There is a good agreement between them, which supports the

Scheme 3. The value of K_1 is in good agreement with earlier work (38).

The effect of ionic strength on the rate can be understood essentially on the basis of ionic species as in Scheme 3. The effect of solvent on the reaction kinetics has been described detail in the literature (39). In the present study the rate determining step involves the reaction between two ions and so eq. [4] is applicable:

$$[4] \qquad \ln k = \ln k_\infty - Z_A Z_B e^2/k_B T r_{AB} D$$

where k_∞ is the rate constant in a medium of infinite dielectric constant, r_{AB} is the sum of the ionic radii, Z_A and Z_B are the charges on the two ions, and D is the dielectric constant of the medium. The observed linear plot of log k_{obs} vs. $1/D$ with positive slope (Fig. 2) is in accordance with eq. [4] as Z_A and Z_B have opposite charges (Scheme 3). The values of $\Delta H^\ddagger$ and $\Delta S^\ddagger$ were both favourable for electron transfer process. The value of $\Delta S^\ddagger$, within the range for radical reaction, has been ascribed to the nature of electron pairing and unpairing processes and to the loss of degree of freedom formerly available to the reactants upon the formation of a rigid transition state (40).

Conclusions

It is interesting that the oxidant species [MnO_4^-] requires a pH > 12, below which the system becomes disturbed and the reaction will proceed further to give a reduced product of the oxidant as Mn(IV), which slowly develops yellow turbidity. Hence, it becomes apparent that in carrying out this reaction the role of pH in a reaction medium is crucial. It is also noteworthy that under the conditions studied the reaction occurs in two successive one-electron reductions (Scheme 3) rather than two-electron in a single step (Scheme 2). A micro amount of Ru(III) is sufficient to catalyze the title reaction. It is interesting to note that uncatalyzed reaction follows a two path mechanism, while catalyzed reaction follows a single path. The description of the mechanism is consistent with all the experimental evidence including both kinetic and product studies.

Stereoselective syntheses of α-amino acid and peptide derivatives by the U-4CR of 5-desoxy-5-thio-D-xylopyranosylamine

Günther Ross and Ivar Ugi

Abstract: Since 1961, the synthesis of α-amino acids derivatives by the four-component reaction of isocyanides (U-4CR) as a one-pot reaction has been developed. Only recently it was found that a variety of these α-amino acids compounds can be formed stereoselectively by the U-4CR using 1-amino-5-deoxy-5-thio-2,3,4-tri-*O*-isobutanoyl-β-D-xylopyranose as the amine component. The stereoselectivity inducing auxiliary 5-desoxy-5-thio-D-xylopyranosyl group of the so-formed products can be replaced selectively by hydrogen.

Key words: stereoselective U-4CR, chiral amine component, amino carbohydrate, α-amino acid derivatives.

Résumé : La synthèse de dérivés d'acides α-aminés par le biais de la réaction monotope d'isocyanures à quatre composants (U-4CR) a été développée depuis 1961. Ce n'est que récemment qu'il a été observé qu'une variété de ces dérivés d'acides α-aminés peuvent se former de façon stéréosélective par la réaction U-4CR en utilisant le 1-amino-5-désoxy-5-thio-2,3,4-tri-*O*-isobutanoyl-β-D-xylopyranose comme composant aminé. Le groupe auxiliaire 5-désoxy-D-xylopyranosyle qui induit la stéréosélectivité peut être remplacé sélectivement par de l'hydrogène à partir des produits qui se forment ainsi.

Mots clés : U-4CR stéréosélective, composant aminé chiral, hydrate de carbone aminé, dérivés d'acides α-aminés.

[Traduit par la Rédaction]

The four decades of developing the U-4CR

In 1959, the four-component one-pot reaction of the isocyanides (1–5) was introduced, and shortly later the term Ugi reaction (U-4CR) (4*a*, 5) was increasingly often used by colleagues. Due to the variability of the educts and products of the U-4CR, more chemical compounds have thus been prepared than by other reactions (5).

In 1961, it was also realized that derivatives of chiral α-amino acids and peptides **6** can be prepared by the stereoselective U-4CR of suitable chiral primary amines **1**, aldehydes **2**, carboxylic acids **3**, and isocyanides **4** (2, 3, 6). The products **6** must be cleavable into **7** and **8**, and it would be advantageous to resynthesize the initial chiral educt **1** from **8** by converting the group X, like an OH-group, into an amino group.

In 1966, Bodanszky and Ondetti (7) mentioned the potentially great preparative advantages of peptide syntheses by the one-pot U-4CR, compared to the usual multistep procedures, particularly if the α-amino acids and their derivatives are not readily available as natural compounds.

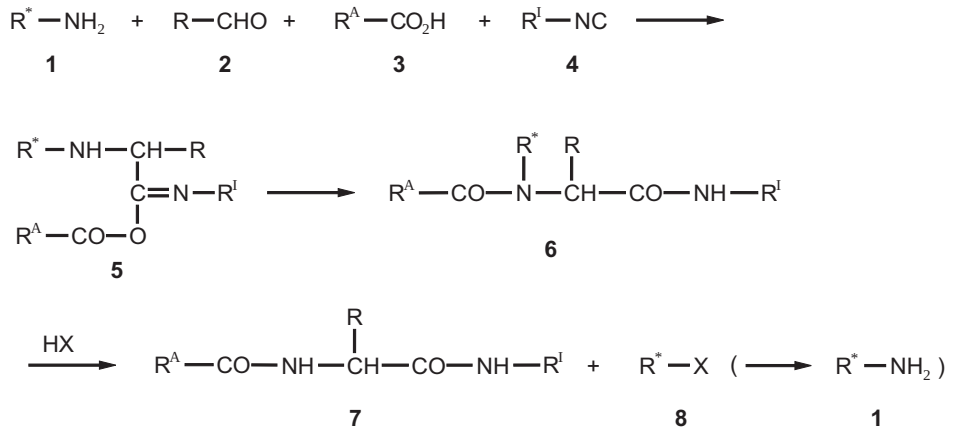
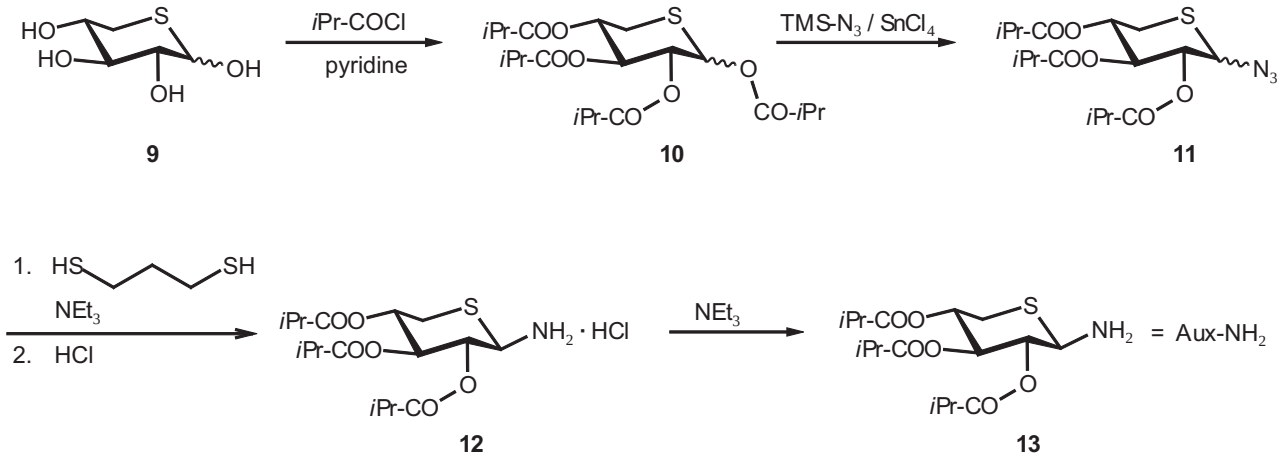
It took almost four decades until the peptide derivatives **7** could be sufficiently well prepared by stereoselective U-4CRs and the subsequent selective cleavage of the chiral auxiliary group.



The first achiral peptide derivatives were prepared by U-4CR in 1961 (8), and shortly thereafter, stereoselective syntheses of diastereoisomeric products could be formed by the U-4CR of chiral primary amines (2, 9) with a stereoselectivity of up to 80:20. The reaction mechanism of an U-4CR in methanol at 0°C was investigated from 1964–1967 (3, 10). During that time, the equilibrium between isobutyraldehyde-(*S*)-α-phenylethylimine and benzoic acid with their cations and anions was determined. In a second series of experiments, the stereoselectivities of the U-4CR with *tert*-butylisocyanide was investigated. It was then found that four different reaction mechanisms compete. Depending on the reaction conditions, one or the other chiral product can be formed preferentially.

It was also realized early on that the preparation of peptides from chiral primary amines requires the removability of the corresponding *N*-alkyl group of the amine component. The prestudies of the cleavage of the corresponding group began in 1964 when alkyl- and alkenyl-groups were used as models (11).



In 1969, the first peptide syntheses were accomplished by stereoselective U-4CRs with suitable chiral α-ferrocenylalkylamines (3, 6, 12). The necessary ferrocene derivatives were not readily available at that time, and therefore, the necessary chemistry was developed (6, 13, 14). The U-4CR products of suitable chiral ferrocene derivatives can be cleaved in a way that chiral ferrocenyl alkyl cations result,

Scheme 1.

Scheme 2.

which subsequently react with ammonia and allow, in that way, the regeneration of the initial chiral α-ferrocenyl-alkylamine (6). This chemistry was intensely investigated for more than two decades (6, 14), but it was ultimately realized that peptide syntheses by the U-4CR with α-ferrocenylalkylamine had too many preparative disadvantages, and therefore, this methodology was given up.

Likhosherstov et al. (15, 16) realized that 1-amino-carbohydrates can be directly prepared from carbohydrates and ammonia. The chiral 1-amino-carbohydrates of xylose, glucose and 2-acetylamino-glucose were thus prepared, however, the stereoisomeric desirable U-4CR products of these amines were hardly separable from the by-products.[2]

In 1988, Kunz et al. (17–20) introduced the highly stereoselective formation of α-amino acid derivatives by U-4CRs with *O*-pivaloyl amino-carbohydrates in the presence of zinc chloride etherates. Thus, products could be achieved in often excellent yields (85–95%) and with a stereoselectivity of up to 92:8. However, the disadvantage is that no peptide derivatives can be formed since only formic acid can be used as the acid component in these reactions. Furthermore, these U-4CR products could only be converted into α-amino acids or their amides by hydrolyzing them in hot one-to-one mixtures of concentrated hydrochloric acid and methanol. Kunz and co-workers (21) have recently also prepared α-amino acid derivatives by stereoselective solid-phase U-4CRs with *O*-acetylated galactosylamine.

In 1990, Goebel and Ugi (22) formed peptide derivatives by the U-4CR with tetra-*O*-alkyl-1-glucopyranosylamines. These reactions had the advantage that any carboxylic acid could participate in such U-4CRs. However, the auxiliary groups of those products could not be easily removed under sufficiently mild conditions either.

Lehnhoff et al. (23) used 1-amino-2-deoxy-2-*N*-acetyl-3,4,6-tri-*O*-acetyl-β-D-glucopyranose as the amine component of the U-4CR. A large collection of the corresponding peptide derivatives could be prepared stereoselectively in excellent yields (24), but also their auxiliary group could not easily be removed under sufficiently mild conditions.

Zychlinski (25) prepared by a synthesis of 11 steps the 1-amino-2-deoxy-2-acetamido-3,4,6-tri-*O*-acetyl-β-D-glucopyranose. This amine component forms peptide derivatives very well by the U-4CRs. However, the products are quite unstable since they are already in neutral media partly cleaved. Therefore, this amine component does not yet have all the desirable properties. It is conceivable that more stable U-4CR products can be formed from 1-amino-2-acylamino-carbohydrates with other *N*-acyl groups.

1-Amino-5-deoxy-5-thio-2,3,4-tri-*O*-isobutyryl-β-D-xylopyranose as a particularly suitable chiral amine component of stereoselective U-4CRs

1-Amino-5-deoxy-5-thio-2,3,4-tri-*O*-isobutanoyl-β-D-xylopyranose hydrochloride **12** can be prepared from xylose via the 5-desoxy-5-thio-D-xylopyranose **9** (26–28).

5-Desoxy-5-thio-D-xylopyranose **9** is acylated by isobutanoic acid chloride in the presence of pyridine (29), and the product **10** is reacted with trimethylsilylazide and tin tetrachloride to yield **11** (30, 31). The azide **11** is reduced by 1,3-propanedithiol (32) to give the preferentially storable 1-amino-5-deoxy-5-thio-2,3,4-tri-*O*-isobutanoic-β-D-xylopyranose hydrochloride **12**. The hydrochloride **12** can easily be converted into the free amine **13** (33).

The U-4CR of the amine component **13** with isovaleraldehyde, benzoic acid, and *tert*-butylisocyanide in the presence of zinc(II) chloride forms stereoselectively the *R*-leucine derivative **16A**, whose absolute configuration was confirmed by an X-ray structure analysis of its deacylated product **17** (34).[3] Therefore, we assume the U-4CR runs via a mechanism involving a chelate complex **15** of the precondensed imine **14** with the zinc(II) chloride (Scheme 3). This could explain the high degree of stereoselectivity (92% de at −40°C) and the high yield (91.8%) of this U-4CR. The complexation causes a strong activation of the imine and enhances the rigidity of the system. Thus, for the α-addition of the isocyanide and the carboxylic acid the *si*-attack is strongly preferred.

After the U-4CR, the chiral template can be easily removed in a two-step process. First, the thiosugar rest is deacylated by aminolysis with methylamine, then the thioxylopyranosyl group of **17** is cleaved by treatment with dilute trifluoroacetic acid and mercury(II) acetate for 3 h at room temperature.

The variability of 1-amino-5-deoxy-5-thio-2,3,4-tri-*O*-isobutanoyl-β-D-xylopyranose **13** as a chiral amino component in the U-4CR is illustrated by its use in the synthesis of a phenylglycine derivative **16B** (57% de at 20°C, yield 91.2%) and a dipeptide **16C** (61% de at 20°C, yield 69.6%). Of course, in these cases higher diastereomeric excesses would have been reached at lower reaction temperatures. According to the proofed configuration of **16A**/**17**, we assume that the *R*-configuration of the newly synthesized amino acid unit is preferred.

The relatively bulky *O*-isobutanoyl groups of **13** allow the U-4CRs to proceed in a stereoselective way. Even at room temperature, de values of about 60% are obtained; if the reaction temperature is reduced to −40°C, U-4CR products in a purity of more than 90% de are formed. On the other hand, the *O*-isobutanoyl groups of **13** cause less hindrance than the *O*-pivaloyl group and allow reaction rates of more than 90% within days (17–20).[2]

A particular advantage of the amine component **13** from xylose is, that, besides the D-isomer, the other diastereomeric amine can be prepared, using the well available L-xylose.

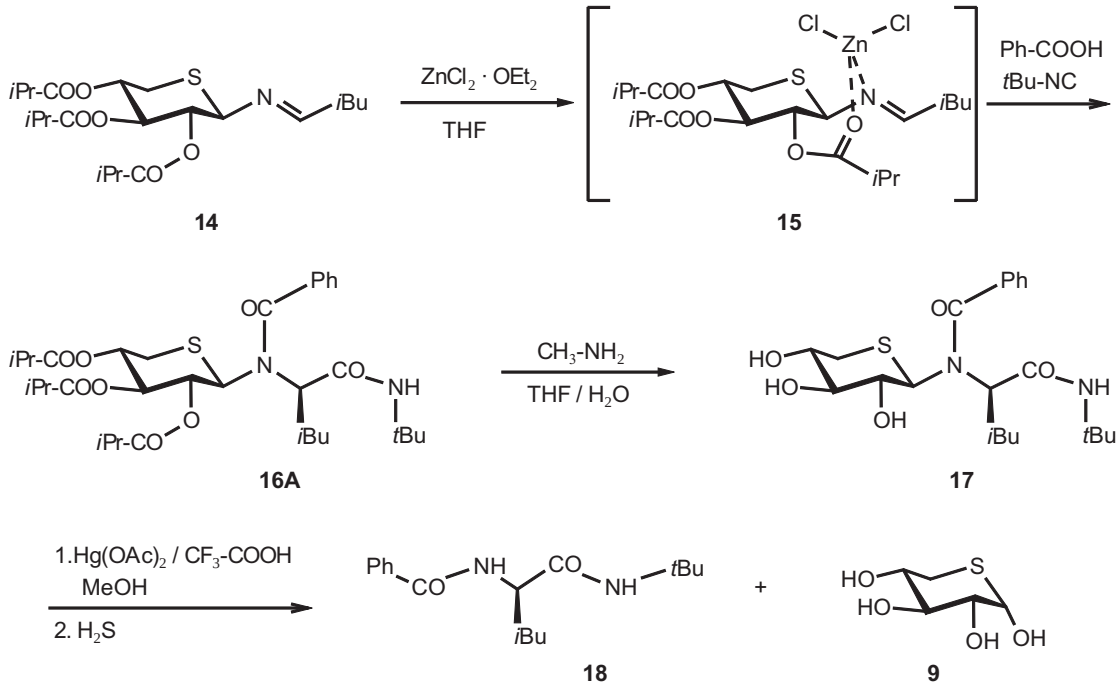
Experimental

1,2,3,4-Tetra-*O*-isobutanoyl-5-desoxy-5-thio-D-xylopyranose (10)

At 0°C, 6.30 g (38 mmol) of 5-desoxy-5-thio-D-xylopyranose in 20 mL pyridine **9** was reacted with 20.24 g (190 mmol) of isobutanoic acid chloride until the precipitate dissolved. This mixture was allowed to further react at 20°C for 1 h. Then 100 mL of 1 N hydrochloric acid and 100 mL methylene chloride were added. The organic solution of the product was washed by an aqueous sodium bicarbonate solution, dried with magnesium sulphate, and evaporated. 16.12 g (95%) of **10** was obtained as an anomeric mixture. ^{1}H NMR ($CDCl_3$): α-anomer: 6.11 (d, 1H, ^3J = 2.75), 5.52 (dd, 1H, ^3J = 10.08), 5.24 (dd, 1H), 5.14 (m, 1H), 2.99 (dd, 1H, ^3J = 10.97, ^2J = 12.2), 2.78 (dd, 1H, $^3J_{4,5eq}$= 3.65), 2.6 (m, 4H), 1.15 (m, 24H). β-anomer (only characteristic signals): 5.9 (d, 1H, ^3J = 9.15), 5.39 (dd, 1H, ^3J = 9.15). ^{13}C NMR ($CDCl_3$): α-anomer: 175.14, 174.96, 174.8, 172.76, 73.7, 72.44, 70.84, 69.83, 34.02, 33.87, 33.86, 33.84, 26.50, 19.33, 19.15, 19.13, 19.10, 19.06, 19.04, 18.99, 18.94. β-anomer (only characteristic signals): 72.94, 72.02, 71.85, 71.63, 27.93.

2,3,4-Tri-*O*-isobutanoic-5-desoxy-5-thio-D-xylopyranosyl-azide (11)

In 50 mL methylene chloride, 4.30 g (9.60 mmol) of 1,2,3,4-tetra-*O*-isobutanoic-5-desoxy-5-thio-D-xylopyranose **10** and 1.30 g (11.04 mmol, 1.11 equiv) trimethylsilylazide were dissolved. At 0°C, 2.10 g (8.16 mmol, 0.85 equiv) tin tetrachloride was added, and this mixture was kept for 2 h at 20°C. After adding 50 mL of ice water, the organic layer was separated and filtred through Celite®, washed twice with sodium bicarbonate solution, dried with magnesium sulphate, and the solvent evaporated. The product was obtained in a yield of 90% as the anomeric mixture of α/β = 0.43:1. ^{1}H NMR ($CDCl_3$): β-anomer: 5.39 (t, 1H, ^3J = 9.78), 5.05 (m, 2H), 4.46 (d, 1H, ^3J = 9.15), 2.97 (dd, 1H, ^2J = 13.1), 2.7 (dd, 1H, ^3J = 3.67), 2.45 (m, 3H), 1.1 (m, 18H). α-anomer (only characteristic signals): 4.46 (d, 1H, ^3J = 2.63). ^{13}C NMR ($CDCl_3$): β-anomer: 175.49, 175.28, 175.13, 73.64, 73.33, 72.08, 63.24, 33,75, 33.73, 28.46, 18.74, 18.71, 18.64, 18.60, 18.56. α-anomer (only characteristic signals): 62.57, 25.73.



2,3,4-Tri-*O*-isobutanoic-5-desoxy-5-thio-D-xylopyranosyl-amine hydrochloride (12)

2,3,4-Tri-*O*-isobutanoic-5-desoxy-5-thio-D-xylopyranosyl-azide (**11**) (5.82 g, 14.5 mmol) was dissolved in 50 mL of methylene chloride. Subsequently, 50 mL methanol, 3.30 g (29 mmol, 2.0 equiv) 1,3-propanedithiol, and 3.0 g (29 mmol, 2.0 equiv) triethylamine were added. This mixture was stirred at 20°C for 2 to 3 h until no further nitrogen was formed. All volatile compounds were evaporated in vacuo and the residue was dissolved in 50 mL diethyl ether. Insoluble compounds were removed by filtration. Concentrated hydrochloric acid (2 mL) was stirred with this solution and the β-anomer **12** crystallized. The remaining volatile res-

idues were removed in vacuo. Thus, **12** was obtained as an anomeric mixture in a yield of 35%. ^{1}H NMR (DMSO-d_6, D_2O): 5.26 (t, 1H, ^3J = 9.15), 5.17 (dd, 1H, ^3J = 9.46), 4.96 (ddd, 1H, ^3J = 10.68, ^3J = 4.76), 4.75 (d, 1H, ^3J = 9.46), 3.09 (dd, 1H, ^2J = 13.43), 2.95 (dd, 1H), 2.7–2.4 (m, 3H), 1.05 (m, 18H). ^{13}C NMR (DMSO-d_6, D_2O): 175.36, 175.28, 174.98, 72.41, 71.95, 71.46, 50.54, 33.17, 33.02, 27.24, 18.67, 18.51, 18.34, 18.31, 18.12, 17.73.

2,3,4-Tri-*O*-isobutanoyl-5-desoxy-5-thio-D-xylopyranosylamine (13)

The amine hydrochloride **12** can be converted into the corresponding free amine **13** by treatment with triethylamine in ether. ^{1}H NMR ($CDCl_3$): 5.15–5.03 (m, 3H), 4.04 (d, 1H, ^3J = 9.25), 2.77 (dd, 1H, ^3J = 4.86, ^2J = 13.72), 2.68 (dd, 1H, ^3J = 10.19), 2.58–2.43 (m, 3H), 1.17–1.09 (m, 18H). ^{13}C NMR ($CDCl_3$): 176.54, 175.84, 175.57, 75.53, 72.67, 72.63, 57.76, 34.02, 33.95, 33.93, 29.29, 19.01, 18.87, 18.83, 18.8.

2,3,4-Tri-*O*-isobutanoyl-5-desoxy-5-thio-D-xylopyranosylimines (14)

General procedure

In 20 mL diethyl ether, 0.752 g (2 mmol) of **12**, 2.4 mmol (1.25 equiv) of an aldehyde, and 2.4 mmol (1.25 equiv) triethylamine were combined. Magnesium sulphate (2.0 g) was added. After 12 h, the solid materials were removed and the solvent was evaporated.

The formation of U-4CR products 16 from 14, carboxylic acids, and isocyanides

General procedure

In 10 mL THF at 20 to –40°C, 2.00 mmol of 2,3,4-tri-*O*-isobutanoic-5-desoxy-5-thio-D-xylopyranosylimine (**14**) and 2.2 mmol (1.1 equiv) of $ZnCl_2 \cdot OEt_2$ were mixed and 15 min later, 2.2 mmol (1.1 equiv) of the isocyanide and 2.2 mmol (1.1 equiv) of the carboxylic acid were added. When the reaction was finished, according to the DC-control (ethylacetate–hexane, 1:2), the solvent was evaporated. The

© 2001 NRC Canada

residue was dissolved in 50 mL of diethyl ether, washed with 0.5 N hydrochloric acid and with aqueous sodium bicarbonate. This solution was dried over magnesium sulphate and then evaporated in vacuo. Solid products in 70–95% yields were isolated.

_N_-Benzoyl-_N_-(2,3,4-tri-_O_-isobutanoyl-5-desoxy-5-thio-β-D-xylopyranosyl)-leucin-_tert_-butylamide (16A)

Imine **14** was formed from **12**, triethylamine, and 0.207 g (2.4 mmol) isovaleraldehyde.

To the precondensed imine **14** in THF were added (at −40°C): $ZnCl_2 \cdot OEt_2$, 0.182 g (2.2 mmol) *tert*-butylisocyanide, and 0.269 g (2.2mmol) benzoic acid. After stirring for 72 h at −40°C, 1.19 g (91.8%) of product **16A** with 92% de (according to HPLC–MS) was obtained. ^{1}H NMR ($CDCl_3$): 7.95 (s, 1H), 7.60–7.45 (m, 5H), 5.31 (d, 1H, ^3J = 10.2), 5.18 (t, 1H, ^3J = 9.29), 5.08 (t, 1H), 4.97 (dt, 1H, ^3J = 4.18, ^3J= 10.31), 4.01 (dd, 1H, ^3J = 4.86, ^3J = 9.72), 2.83 (dd, 1H, ^2J= 13.28), 2.53–2.32 (m, 6H), 1.72 (m, 1H), 1.34 (s, 9H), 1.19–0.99 (m, 24H). ^{13}C NMR ($CDCl_3$): 175.71, 175.61, 175.60, 173.93, 169.49, 135.28, 131.12, 128.73, 126.65, 74.01, 72.94, 72.02, 64.00, 63.10, 50.87, 40.51, 33.96, 33.90, 33.79, 28.68, 28.31, 25.67, 23.55, 22.22, 18.93–18.53.

_N_-Benzoyl-_N_-(2,3,4-tri-_O_-isobutanoyl-5-desoxy-5-thio-β-D-xylopyranosyl)-_p_-methoxy-phenylglycin-_tert_-butylamide (16B)

Imine **14** was formed from **12**, triethylamine, and 0.300 g (2.4 mmol) *p*-methoxybenzaldehyde.

To the precondensed imine **14** in THF were added (at 20°C): $ZnCl_2 \cdot OEt_2$, 0.182 g (2.2 mmol) *tert*-butylisocyanide, and 0.269 g (2.2mmol) benzoic acid. After stirring for 48 h at 20°C, 1.27 g (91.2%) of product **16B** with 57% de (according to HPLC–S) was obtained. ^{1}H NMR ($CDCl_3$): 7.64–7.43 (m, 7H), 6.91 (m, 2H), 5.18–4.70 (m, 5H), 3.89 (s, 1H), 2.91–2.07 (m, 3H), 1.22 (s, 9H), 1.08–0.82 (m, 6H). ^{13}C NMR ($CDCl_3$): 175.75, 175.55, 175.40, 172.97, 167.85, 159.75, 135.57, 131.99, 130.95, 128.73, 128.59, 126.83, 114.30, 74.06, 72.62, 71.76, 70.27, 63.90, 63.00, 55.28, 51.17, 34.15, 33.86, 33.46, 29.57, 28.49, 19.08–18.12.

Bz-_N_-Gly-_N_-(2,3,4-tri-_O_-isobutanoyl-5-desoxy-5-thio-β-D-xylopyranosyl)-leucine-_tert_-butyl-amide (16C)

Imine **14** was formed from **12**, triethylamine, and 0.207 g (2.4 mmol) isovaleraldehyde.

To the precondensed imine **14** in THF were added (at 20°C): $ZnCl_2 \cdot OEt_2$, 0.182 g (2.2 mmol) *tert*-butylisocyanide, and 0.394 g (2.2 mmol) *N*-benzoylglycine. After stirring for 48 h at 20°C, 0.98 g (69.6%) of product **16C** with 61% de (according to HPLC–MS) was isolated. ^{1}H NMR ($CDCl_3$): 7.98 (d, 2H, ^3J = 8.34), 7.86 (bs, 2H), 7.57 (t, 1H, ^3J = 7.06), 7.49 (t, 2H), 5.5–5.0 (m, 6H), 3.89 (dd, 1H, ^3J = 9.72, ^3J = 3.53), 3.03 (t, 1H, $^3J_{4,5\ ax} = {}^2J_{5ax,5eq}$ = 12.38), 2.9–2.4 (m, 6H), 1.83 (m, 1H), 1.36 (s, 9H), 1.16–1.09 (m, 18H), 0.96–0.89 (m, 6H). ^{13}C NMR ($CDCl_3$): 176.01, 176.92, 175.73, 173.63, 168.01, 163.40, 132.80, 128.83, 128.58, 127.81, 74.30, 73.14, 72.89, 61.64, 59.17, 51.45, 43.30, 42.88, 33.97, 33.88, 33.84, 28.63, 24.16, 23.75, 22.01, 21.80, 18.89–18.56.

The _O_-deacylation of 16A to yield 17

In 100 mL THF, 3.00 g (4.60 mmol) *N*-benzoyl-*N*-(2,3,4-tri-*O*-isobutanoyl-5-desoxy-5-thio-β-xylopyranosyl)-leucine-*tert*-butylamide **16A** and 60 mL of 40% aqueous methylamine were reacted at 20°C for 24 h. The volatile compounds was removed in vacuo, and the *N*-methylisobutyramide was removed by its solubility in diethyl ether. Thus, 1.94 g (96%) *N*-benzoyl-*N*-(5-deoxy-5-thio-β-xylopyranosyl)-leucine-*tert*-butylamide (**17**) was obtained. The X-ray structure of product **17** was recently confirmed (31). ^{1}H NMR ($CDCl_3$): 7.79 (d, 2H, ^3J = 7.3), 7.51 (t, 1H, ^3J = 7.2), 7.43 (t, 2H), 6.77 (bd, 1H, ^3J= 8.2), 6.00 (bs, 1H), 4.54 (dt, 1H, ^3J = 8.2, ^3J = 5.8), 1.76–1.60 (m, 3H), 1.35 (s, 9H), 0.97 (2 × d, 6H). ^{13}C NMR ($CDCl_3$): 171.75, 167.06, 133.86, 131.21, 128.15, 127.12, 52.67, 51.02, 41.22, 28.48, 24.76, 22.84, 22.10.

Cleavage of chiral auxiliaries of 17 to form 9 and 18

At 20°C, 0.50 g (1.14 mmol) of the U-4CR product **17** and 0.36 g (1.14 mmol) of mercury(II) acetate in 20 mL methanol and 10 mL of trifluoroacetic acid were reacted for 3 h. Subsequently, 150 mL of saturated aqueous sodium bicarbonate and 50 mL of diethyl ether were added, and then solid sodium bicarbonate was added until a neutral solution resulted. The divalent mercury was precipitated by hydrogen sulfide. The product solution filtered through Celite®, and the solvent was evaporated in vacuo. NMR (MeOH-d_4) and HPLC–MS spectroscopic data indicated that there was a mixture of equal amounts of **9** and **18**. This mixture was extracted with chloroform. The solvent was evaporated in vacuo, and 200 mg (60%) of the solid product **18** resulted. ^{1}H NMR ($CDCl_3$): 7.79 (d, 2H, ^3J = 7.3), 7.51 (t, 1H, ^3J = 7.2), 7.43 (t, 2H), 6.77 (bd, 1H, ^3J= 8.2), 6.00 (bs, 1H), 4.54 (dt, 1H, ^3J = 8.2, ^3J = 5.8), 1.76–1.60 (m, 3H), 1.35 (s, 9H), 0.97 (2 × d, 6H). ^{13}C NMR ($CDCl_3$): 171.75, 167.06, 133.86, 131.21, 128.15, 127.12, 52.67, 51.02, 41.22, 28.48, 24.76, 22.84, 22.10.

Quasiclassical trajectory studies on the gas-phase BrO self-reaction

Demetrios K. Papayannis and Agnie M. Kosmas

Abstract: The effect of initial vibrational energy and the mode of disposal of available energy into products for the disproportionation reaction between BrO radicals are studied using the quasiclassical trajectory (QCT) technique. The calculations are performed on an analytical potential enegy surface based on ab initio results reported for the three isomeric forms of $(BrO)_2$ system. The results indicate a mild dependence on reactant vibrational energy, which is discussed in terms of the mechanistic aspects of the reaction. The study of the distribution of total accessible energy among products indicates a different mode of energy disposal in each path and hence important differences on the mechanism by which each channel takes place.

Key words: quasiclassical trajectories, internal energy, disposal of total energy.

Résumé : La méthode des trajectoires quasi-classiques est employée a l'étude de l'éfet de l'énergie vibrationale à la réactivité de la réaction entre des radicals de BrO et la distribution de l'énergie totale entre des produits. Les calculations sont executées sur une surface potentielle analytique, fondée aux résultats quantomechaniques pour les isomers du système de $(BrO)_2$. Les résultas indiquent une dépendence faible de l'énergie vibrationale à la réactivité de la réaction. Enfin la distribution de l'énergie totale entre des produits manifeste des différences importantes au méchanisme pour chaque canal de la réaction.

Mots clés : trajectoires quasi-classiques, énergie intérieure, la distribution de l'énergie totale.

Introduction

The disproportionation reactions between halogen monoxide radicals have received considerable attention over the last years, due to their important role in the stratospheric ozone depletion cycles (1–8). Numerous experimental studies have been devoted to this subject (9–24), and in addition, several quantum mechanical electronic structure calculations (25–32) have investigated the geometry and the stability of the various intermediate complexes and their role in the mechanism of these reactions.

The reaction between BrO radicals is an interesting such system that has been found to proceed through two main channels:

$$(a)\ BrO(^2\Pi) + BrO(^2\Pi) \rightarrow BrOO + Br \rightarrow 2Br + O_2(^3\Sigma_g^-) \qquad \Delta H^\circ_{298} = -6.6 \text{ kcal mol}^{-1}$$

$$(b)\quad BrO(^2\Pi) + BrO(^2\Pi) \rightarrow Br_2(^1\Sigma_g^+) + O_2(^3\Sigma_g^-) \qquad \Delta H^\circ_{298} = -52.6 \text{ kcal mol}^{-1}$$

Channel (*a*) is the major pathway at 298 K and produces atomic bromine and BrOO, which instantly decomposes into Br and O_2 as a result of the very low Br—O bond energy of about 1 kcal mol^{-1} (17). The molecular elimination channel (*b*), although the most exothermic, is the secondary channel. However, it gains in significance at lower temperatures as the branching ratio for channel (*a*) drops from 0.84 at 298 K to 0.68 at 220 K (20), where this decrease benefits the second pathway. Several measurements of the total rate coefficient (*k*) have been reported in the literature(14–24) and the most recent values range from (2.98 ± 0.42) to (2.59 ± 0.28) × 10^{-12} cm^3 $molecule^{-1}$ s^{-1} (22–24).

In a recent theoretical study (31), we examined the effect of initial translational energy (E_T) on the rate coefficient to investigate the increasing importance of the second channel as the temperature lowers. Employing a simple, six-dimensional analytical potential energy surface we carried out quasiclassical trajectory calculations for a series of values of the initial kinetic energy (E_T) between 0.5 and 5.0 kcal mol^{-1}. These calculations produced reactive cross sections, rate coefficients, and branching ratios in fair consistency with the experimental values, indicating a reasonable description of the reaction by the constructed surface.

The reactant vibration is another significant factor that has been shown to affect the dynamics of several gas-phase elementary reactions (33). Also, the mode of disposal of available energy in large exothermicity pathways is of interest. In the present work we extend the previous studies and employ the constructed surface to examine the effect of initial vibrational excitation on the reactivity of BrO self-reaction. Reactive cross sections are calculated for a series of vibrational quantum numbers and the results are discussed. The mode of

disposal of total available energy into products is also investigated and the results are analyzed in terms of the mechanism of the reaction.

PES and trajectory calculations

A short outline of the potential energy surface (PES) will be presented here since the detailed description has been given elsewhere (31). The lowest singlet PES was constructed based on the LEPS-type functional form including a three-body polynomial Sorbie–Murrell-type term to describe the BrOO triatomic in channel (*a*). Despite their simplicity, LEPS surfaces have been widely used for the kinetic and dynamic investigation of many triatomic systems with good success and have served with suitable modifications as the starting point for the description of more complex polyatomic systems. In a recent study, Espinosa-Garcia (34) reviewed the applicability of LEPS-type functional forms for collinear reactions and examined their possibilities to adequately describe the kinetics and dynamics of systems with non-collinear reaction paths.

The six-dimensional analytical PES employed to describe the BrO + BrO reaction has been given the following form:

$$[1]\qquad V(r_{ij}) = V_{\mathrm{LEPS}}(r_{ij}) + V_{\mathrm{M}}(r_{\mathrm{OO'}}, r_{\mathrm{OBr}}, r_{\mathrm{O'Br}}) + V_{\mathrm{M}}(r_{\mathrm{OO'}}, r_{\mathrm{OBr'}}, r_{\mathrm{O'Br'}})$$

where $V_{\mathrm{LEPS}}(r_{ij})$ represents an extended four-atom LEPS-type function (35, 36)

$$[2]\qquad V_{\mathrm{LEPS}}(r_{ij}) = W_{\mathrm{BrO}} + W_{\mathrm{OO'}} + W_{\mathrm{OBr'}} + W_{\mathrm{BrO}} + W_{\mathrm{BrBr'}} + W_{\mathrm{O'Br'}} - (1/4)[(J_{\mathrm{BrO}} - J_{\mathrm{OO'}})^2 + (J_{\mathrm{OO'}} - J_{\mathrm{O'Br'}})^2 + (J_{\mathrm{O'Br'}} - J_{\mathrm{Br'Br}})^2 + (J_{\mathrm{Br'Br}} - J_{\mathrm{Br'O}})^2 + (J_{\mathrm{Br'O}} - J_{\mathrm{O'Br}})^2 + (J_{\mathrm{O'Br}} - J_{\mathrm{BrO}})^2]^{1/2}$$

with

$$[3]\qquad W_{ij} = [D^e_{ij}/4(1 + S_{ij})]\{(3 + S_{ij})\exp[-2\beta_{ij}(r_{ij} - r^e_{ij})] - 2(1 + 3S_{ij})\exp[-\beta_{ij}(r_{ij} - r^e_{ij})]\}$$

$$[4]\qquad J_{ij} = [D^e_{ij}/4(1 + S_{ij})]\{(1 + 3S_{ij})\exp[-2\beta_{ij}(r_{ij} - r^e_{ij})] - 2(3 + S_{ij})\exp[-\beta_{ij}(r_{ij} - r^e_{ij})]\}$$

and $V_{\mathrm{M}}(s_i)$ is the three-atom Sorbie–Murrell-type term (37).

$$[5]\qquad V_{\mathrm{M}}(s_i) = D^{\mathrm{o}}_{\mathrm{BrOO}}\,P(s_1, s_2, s_3)Q(s_1, s_2, s_3) = [1 + c_1s_1 + c_2(s_2 + s_3) + c_{11}s^2 + c_{22}(s_2^2 + s_3^2) + c_{12}s_1(s_2 + s_3) + c_{23}s_2s_3][1 - \tanh(0.5\gamma_1s_1)] \times [1 - \tanh(0.5\gamma_2s_2)][1 - \tanh(0.5\gamma_2s_3)]$$

The extended four-atom LEPS function has been employed to describe the four-body interaction and the two corrective Sorbie–Murrell-type, three-body polynomial terms, V_{M} were added to help reproduce as close as possible the BrOO′Br′ well and the BrOO′ + Br or Br′OO′ + Br exit channels.

Great care has been taken in the calibration of the PES to reproduce the three energy minima corresponding to the three isomeric structures of Br_2O_2 system, i.e., BrOOBr, $BrBrO_2$, and BrOBrO, possibly formed in the course of the reaction. These structures have been identified in extended ab initio calculations at the B3LYP/6–311++G(3*df*, 3*dp*) (27), MP2/AREP-TZ(2*df*) (29), and MP2(full)/6–311++G(2*d*) (31) levels of theory. Also, the *cis*- and *trans*-conformations of the skewed BrOOBr isomer were incorporated, which have been fully characterized by frequency analysis and have been shown to be saddle points in the internal rotational motion of BrOOBr (38). Based on these results and reported ab initio values for the related triatomic and diatomic fragments of Br_2O_2 system, the systematic optimization of the adjustable parameters of the PES have been carried out. The adjustable parameters include the Sato parameters and the Sorbie–Murrell polynomial coefficients. Due to the symmetry of the system there are only three Sato parameters (S_{ij}) for the diatomic pairs O–O, Br–Br, and O–Br that have to be varied for surface optimization. The most critical one is the O–Br parameter, which appears in four out of the six diatomic interactions and severely affects the magnitude of the energy minima. The displacement coordinates (s_i) in eq. [5] are given by $r_i - r_i^{\mathrm{o}}$, where the r_i^{o} distances represent the equilibrium reference frame distances for BrOO′ or Br′OO′ triatomics and have been approximated by the equilibrium values reported in the ab initio studies of these triatomics by Pacios and Gomez (39). A final point that has been taken into account in the calibration of the PES is the experimental evidence (40) for a low energy barrier (E_b) of about 1 kcal mol^{-1} at the entrance valley of the reaction. Thus, the constructed surface was optimized to present such an energy barrier as the two BrO radicals approach in a near-linear geometry. In summary, the three Sato parameters (S_{OO}, S_{BrBr}, S_{OBr}) and the Sorbie–Murrell parameters D^{o}, c_i, c_{ij}, and γ_i were optimized to yield a PES function that reproduces the three ab initio determined bound intermediates in the correct energy order BrOOBr < $BrBrO_2$ < BrOBrO, the *cis*- and *trans*-BrOOBr conformers, the two exit channels Br + BrOO and Br_2 + O_2, and the low energy barrier of about 1 kcal mol^{-1} at the entrance of the reaction.

The resulting reaction path involves the formation of the non-planar BrOOBr isomer as a reaction intermediate, which either decomposes into BrOO + Br or leads to the bimolecular elimination channel Br_2 + O_2. Figure 1 presents a schematic energy diagram of the various species possibly involved in the BrO + BrO reaction, and Fig. 2 depicts the potential energy profile for the approach of the oxygen ends of two colliding BrO radicals with and without the additional Sorbie–Murrell terms and for both BrO bond dstances fixed at the equilibrium value. The ambiguous point that arises here and in general, in the PES describing the XO + YO (X, Y = H, halogen atom) systems in which the XOOY intermediate formation is considered, is the concern about the spin conservation rules. The second pathway, channel (*b*), produces ground state oxygen molecules, yet if a singlet state intermediate formation intervenes, spin conservation requires that singlet state oxygen ($^1\Delta$)O_2 is the product. The problem then is the probability of a singlet–triplet crossing mechanism. The subject has been discussed several times and various workers adopt different views. In recent theoretical studies of OH + ClO reaction (41, 42) the spin conservation rule was followed and the calculations adopted HCl +

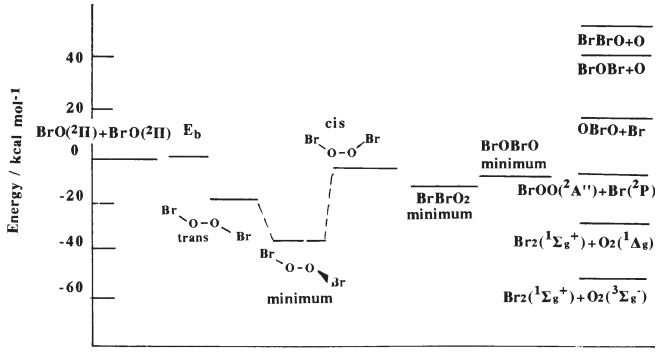

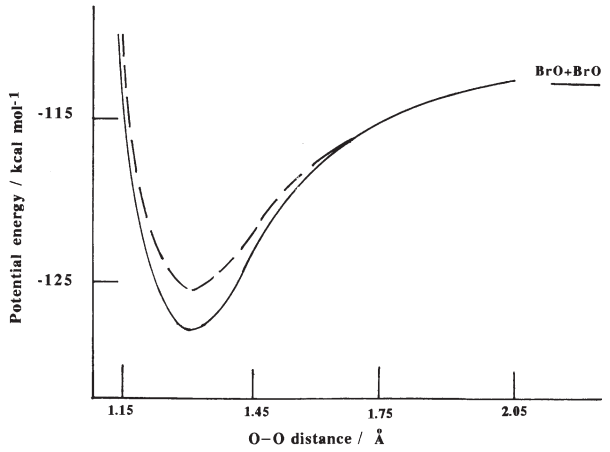

Fig. 2. Potential energy profile for the approach of the O ends of two colliding BrO radicals with both BrO bond distances held constant at the equilibrium values. The dashed line represents the LEPS function solely and the solid line incorporates the Sorbie–Murrell term.

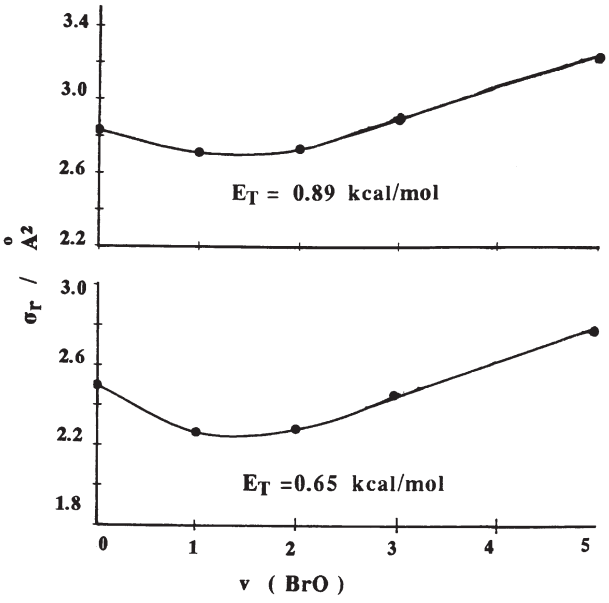
$(^1\Delta_g)O_2$ as the products of the molecular elimination channel. However, in other occasions as in the experimental study of OH + BrO reaction (43) the singlet–triplet crossing has been assumed as the mechanism leading to ground-state molecular oxygen produced in the second channel. We adopt such a mechanism in our heavy system here too, i.e., we assume that spin-orbit induced quenching to ground state triplet O_2 may operate somewhere in the exit channel or alternatively a removal of spin conservation restriction between singlet and triplet states may occur by the heavy Br atom (44).

The kinetics and dynamics of the reaction on the constructed energy surface were followed by three-dimensional quasiclassical trajectory calculations performed using an appropriate version of Hase's Mercury program (45) modified to incorporate the optimized surface. The accuracy of the numerical integration was checked by the total energy and angular momentum conservation criteria; the time interval was set to 2.5×10^{-16} s and the initial reactant separation to 5.0 Å. Values of b_{max} in the range 3.9–4.0 Å were used. Two values of the initial collision energy E_T (0.65 and 0.89 kcal mol^{-1}) were studied, which, assuming Boltzmann thermal energy distribution, correspond to 220 and 298 K, respectively, temperatures at which the reaction has been studied experimentally.

Fig. 3. Effect of reagent vibrational excitation on the reactive cross section for channel (*a*). Solid line represents the best line drawn through the calculated points.



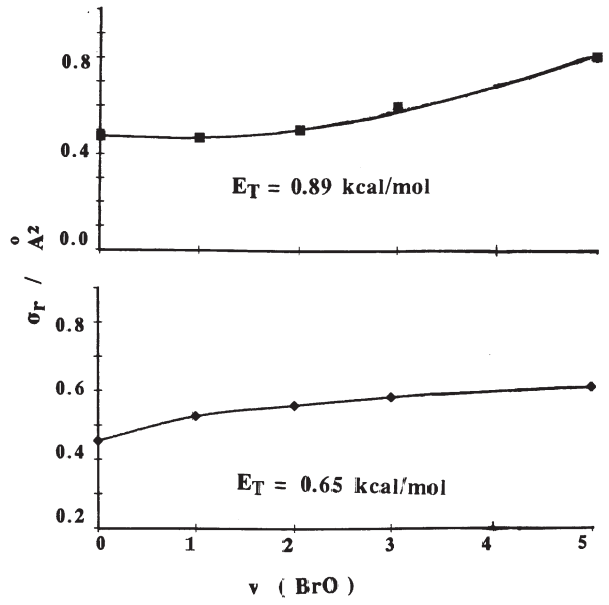


Fig. 4. Effect of reagent vibrational excitation on the reactive cross section for channel (*b*). Solid line represents the best line drawn through the calculated points.

The effect of the initial vibration was examined using a series of vibrational quantum numbers in the initial conditions for both BrO partners while keeping fixed the initial rotational energy at the most probable *J* values at 220 and 298 K of 13 and 15, respectively. Although the range of vibrational energies is higher and not directly related to the range of temperatures in stratospheric conditions, it is worthwhile to study the effect of reactant vibration since the present system is also an interesting diatom–diatom reaction.

At each collision energy and for each initial vibrational number 20 000 trajectories were run. The large number of

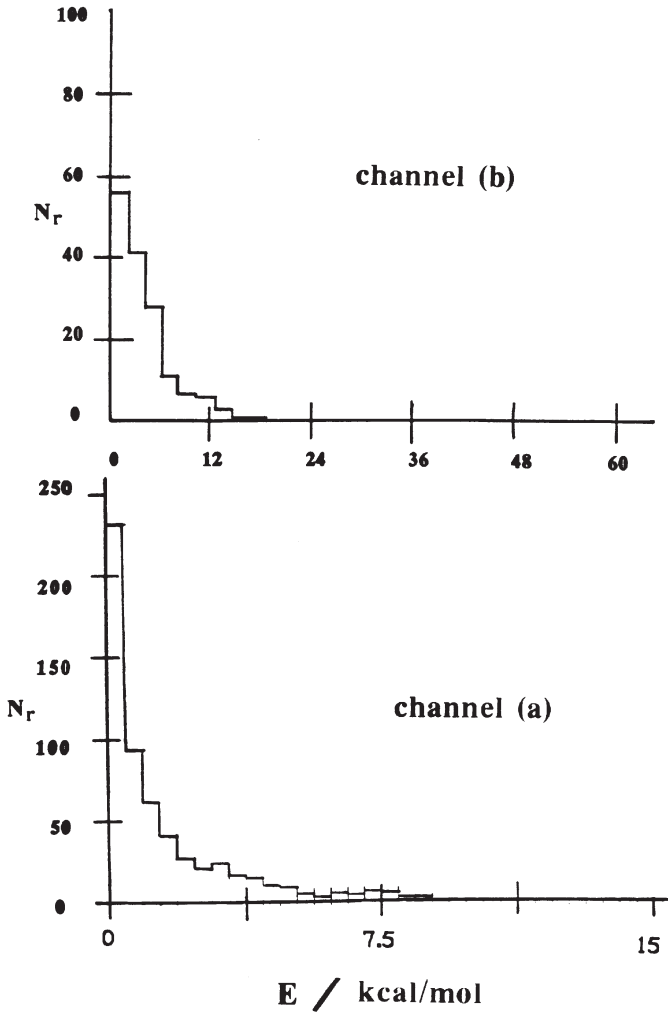

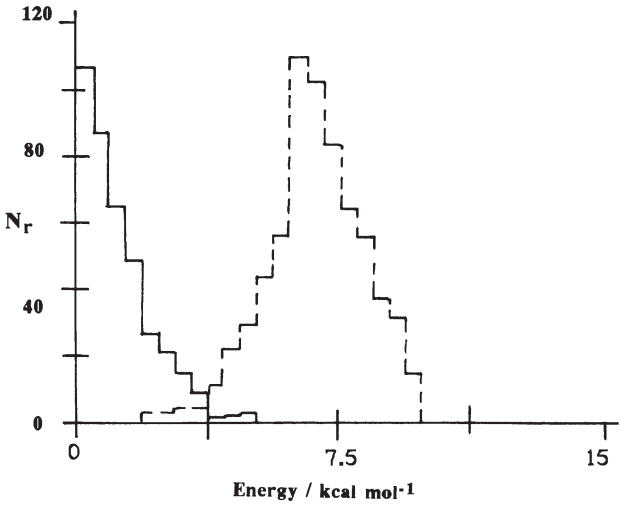

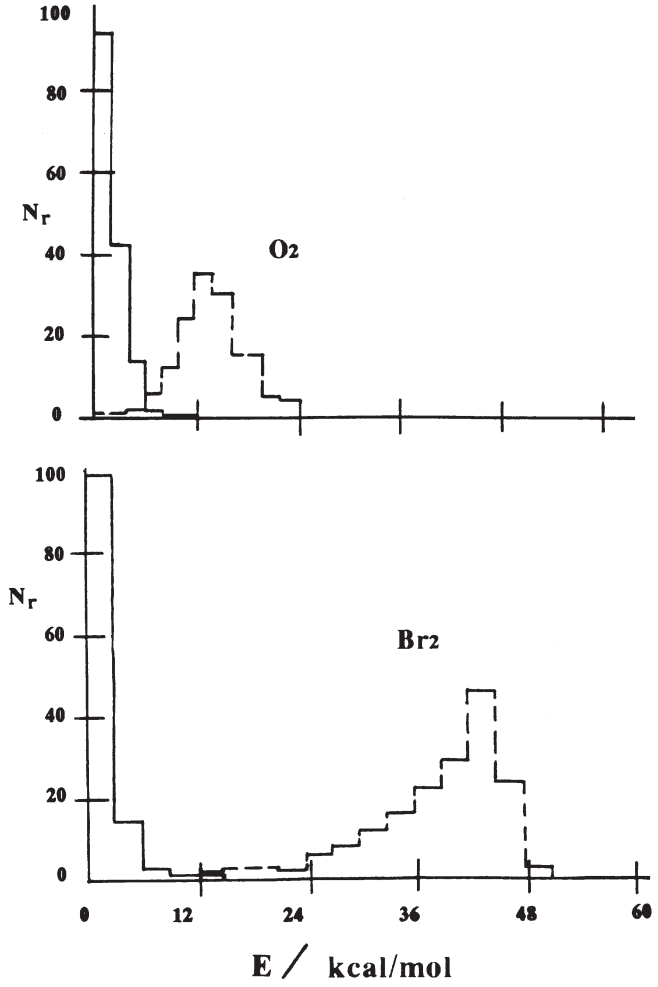

Fig. 6. Product rotational (solid line) and vibrational (dashed line) distribution, channel (*a*).

trajectories was necessary to obtain a satisfactory statistics for each run especially for the low yield second channel. The outcome of the trajectories into the various reactive

events has been classified according to the following reactive paths:

path 1 BrO + BrO

path 2 BrOO + Br

path 3 BrBr + OO

The distribution of total available energy into products was examined for both E_T = 0.65 and 0.89 kcal mol^{-1} and for the corresponding most probable rotational levels, J = 13 and 15 with zero-point reactant vibrational energy. However, since the distributions obtained for each initial collision energy are quite similar, results are presented only for E_T = 0.89 kcal mol^{-1}. The total energy (E_{tot}) accessible in a collision between BrO radicals results from three contributions: the difference in binding energies between reactants and products (ΔD_e), the thermal collision kinetic energy (E_T), and the internal energy of reactants (rotational and zero-point energies of BrO radicals)

$$[6] \qquad E_{tot} = \Delta D_e + E_T + E_{int} = E'_T + E'_{int}$$

where the prime quantities refer to products. This energy is distributed among translational and internal energies of the products and the mode of disposal can reveal interesting fea-

© 2001 NRC Canada

tures of the mechanism of the reaction. In particular, the second channel is very exothermic and there is a considerable amount of total available energy of about 53 kcal mol^{-1} to be disposed between oxygen and bromine molecules. Hence the mode of disposal is significant. A smaller amount of energy of about 7 kcal mol^{-1} is to be disposed in the first channel.

Results and discussion

Figures 3 and 4 present the effect of initial reactant vibration for channels (*a*) and (*b*), respectively, displaying the corresponding reactive cross sections from

$$[7] \qquad \sigma_r(v, J, E_T) = \pi b_{max}(E_T)[N_r(v, J, E_T)/N_{tot}]$$

for the various initial conditions studied. It is seen that the initial vibrational excitation leads to a modest overall effect on the reactive cross sections and shows a rather weak influence on the reactivity of the system. The BrO ($v = 1$) results are about the same as the BrO ($v = 0$) for both channels within the statistical uncertainty. Furthermore, vibrational excitation in the first channel causes a slight decrease in the cross section as a result of the effect of the small energy barrier present at the entrance valley of the PES. When the number of vibrational quanta increases further a gradual increase in the reactivity is observed resulting from the increased total available initial energy. In the second channel a definite increase in reactivity is obtained as the initial vibrational excitation increases, manifested stronger at the lower kinetic energy studied, $E_T = 0.65$ kcal mol^{-1}, where the importance of the second pathway is increased. Such an increase in reactivity with reactant vibration is consistent with the assumption of the existence of another energy barrier located late in the exit valey of the PES (33). Consequently, we suggest that the reaction path for channel (*b*) involves the passage of the non-planar BrOOBr intermediate through a four-center, planar saddle point configuration that subsequently leads to the elimination products $Br_2 + O_2$. Such a saddle point geometry is the cis-planar conformer of bromine peroxide where the two Br atoms approach and eventually produce Br_2.

At first glance the above results are in contrast with other diatom–diatom systems where reagent vibrational excitation, especially that of the breaking bond is known to produce a severe enhancement in reactivity. Examples include the H_2 ($v = 1$) + OH, CN, BO cross sections, which have been found considerably larger than in H_2 ($v = 0$) + OH, CN, BO cross sections (46–49) and the same effect has been observed in the study of NH + NO and OH + Cl_2 reactions (50–52). However, a much milder influence of reagent vibrational excitation is expected in cases where a bound intermediate is formed like the OH + CO reaction at the low energy region. In the quasiclassical trajectory study of OH + CO → H + CO_2 reaction by Schatz and co-workers (53), reagent vibrational excitation was found to lead to only modest increases in the reactive cross sections. They found that the mild influence of reagent vibration is consistent with the assumption of a bound complex formation mechanism, which is dominant at low energies for the OH + CO system. With the same arguments the present results support and enhance the assumption that the disproportionation reaction of BrO radicals proceeds through the intervening formation of the bound indermediate. This is the skewed BrOOBr isomer, which contains the reactant initial energy and thus, it is formed in an energy rich state, BrOOBr*. This intermediate either dissociates directly producing mainly BrOO + Br in channel (*a*) or a significant percentage of it proceeds to the molecular elimination channel (*b*) through the *cis*-conformational barrier of this complex.

The distribution of total energy into products at $E_T = 0.89$ kcal mol^{-1} of the initial collision energy for both reaction pathways is presented in Figs. 5–7, where $< f_v' >$, $< f_R' >$, and $< f_T' >$ represent the average fractions of total available energy directed into products. We see that the larger part of the available energy, i.e., of the exothermicity of each channel is released into product vibration ($< f_v' > = 85$–90%) with negligible parts going into translation and rotation ($< f_R' > + < f_T' > = 15$–10%), as expected of a reaction proceeding through a bound complex formation. However, an interesting selectivity is observed in the partitioning of product vibrational energy among oxygen and bromine molecules produced in the second pathway. Although the large energy release in the second channel covers several quanta of possible O_2 vibrational excitation, the major part of it is directed preferably into bromine vibration. This is probably the result of the high tension associated with the close approach of the two Br atoms in the cyclic *cis*-conformation of BrOOBr isomer to form the Br_2 molecule.

We conclude that the internal energy effect and the mode of disposal of total energy are consistent with the hypothesis of an intermediate energy-rich complex formation, BrOOBr*. In channel (*a*) the two colliding radicals after passing through this energized form of BrOOBr peroxide dissociate directly into products. In the second pathway however, the intermediate formed, better stabilized as the temperature drops, proceeds through a *cis*-saddle point configuration, which facilitates the production of highly excited vibrationally molecular bromine.

Summary

The reagent vibrational excitation effect and the mode of disposal of the total available energy into products for the self-reaction of BrO radicals are studied, using the quasiclassical trajectory technique. The results indicate a only weak influence of initial vibration on reactivity, which is consistent with the assumption of a bound intermediate formation. In both channels the major part of the total available energy is converted into product vibration. In particular, the strong tension that accompanies the four-center intermediate geometry involved in the second channel to bring the two Br atoms close and produce molecular bromine, leads the greater part of the large exothermicity of the second channel into Br_2 vibration.

Dominique Vichard, Taoufik Boubaker, François Terrier, Marie-José Pouet, Julian M. Dust, and Erwin Buncel The versatile reactivity of 2-aryl-4,6-dinitrobenzotriazole 1-oxides in Diels–Alder type condensations and in σ-complexation — A relationship between superelectrophilicity and pericyclic reactivity **1617**

Ken-ichiro Imamura, Eiji Yoshikawa, Vladimir Gevorgyan, Tomoko Sudo, Naoki Asao, and Yoshinori Yamamoto Lewis acid-mediated intramolecular addition of silyl enol ethers to internal unactivated alkynes **1624**

Richard R. Hark, Diane B. Hauze, Olga Petrovskaia, and Madeleine M. Joullié Synthetic studies of novel ninhydrin analogs **1632**

Alan R. Katritzky, Novruz G. Akhmedov, Sergey N. Denisenko, and Subbu Perumal An ^{1}H and ^{13}C NMR conformational study of 2-(benzotriazol-1-yl)-substituted tetrahydropyrans **1655**

Stefan Schilling, Uwe Rinner, Collin Chan, Ion Ghiviriga, and Tomas Hudlicky Structure assignment of aminoconduritols by ^{15}N NMR correlation spectroscopy; synthesis of a positional isomer of 7-deoxypancratistatin **1659**

Darren J. Dixon, Alison C. Foster, and Steven V. Ley The total synthesis of (+)-aspicilin using 2,3-butane diacetal protected butane tetrols via a chiral memory protocol **1668**

Albert Padwa, William S. Kissell, and Cheryl K. Eidell Cyclization–cycloaddition cascades for the construction of azapolycyclic ring systems **1681**

André B. Charette and Michel Grenon Spectroscopic studies of the electrophilic activation of amides with triflic anhydride and pyridine **1694**

Alexei. A. Neverov, Todd McDonald, Graham Gibson, and R.S. Brown Catalysis of transesterification reactions by lanthanides — Unprecedented acceleration of methanolysis of aryl and alkyl esters promoted by $La(OTf)_3$ at neutral $\overset{S}{S}$pH and ambient temperatures **1704**

William R. Roush, David J. Madar, and D. Scott Coffey Synthesis of highly functionalized naphthoate precursors to damavaricin D — Observation of kinetically stable benzocyclohexadienones in the bromination reactions of highly functionalized β-naphthol derivatives **1711**

Peter A. Jacobi and Prudencio Herradura Enantioselective syntheses of (+)- and (–)-nephro-steranic acid employing the Nicholas–Schreiber reaction **1727**

Matthias Kauch and Dieter Hoppe Synthesis of substituted phenols by directed *ortho*-lithiation of in situ *N*-silyl-protected *O*-aryl *N*-monoalkylcarbamates **1736**

Susanne M. Hantos, Sasmita Tripathy, Najma Alibhai, and Tony Durst Synthesis of trichiliasterones A and B — 16-Ketosteroids isolated from *Trichilia hirta* and *Trichilia americana* **1747**

A. Godard, P. Rocca, F. Guillier, G. Duvey, F. Nivoliers, F. Marsais, and G. Quéguiner *Ortho*-directed metallation of π-deficient heterocycles in connection with palladium-catalyzed biaryl cross-coupling — Synthesis of marine alkaloids of the pyridoacridine series **1754**

Christoph Köllner and Antonio Togni Synthesis, characterization, and application in asymmetric catalysis of dendrimers containing chiral ferrocenyl diphosphines **1762**

Dale E. Ward, Marcelo Sales, and Matthew J. Hrapchak Attempted enantiotopic group selective cyanohydrin formation from α-alkoxy aldehydes by double stereodifferentiation **1775**

Tao Wang, Osamu Shirota, Koji Nakanishi, Nina Berova, Leonard A. McDonald, Laurel R. Barbieri, and Guy T. Carter Absolute stereochemistry of the spiroxins **1786**

© 2001 NRC Canada

Marek Majewski, Marc DeCaire, Pawel Nowak, and Fan Wang Studies on enolate chemistry of 8-thiabicyclo-[3.2.1]-octan-3-one: enantioselective deprotonation and synthesis of sulfur analogs of tropane alkaloids **1792**

Xiao-Xiang Zhang, Michele C. Harris, Joseph P. Sadighi, and Stephen L. Buchwald The use of palladium chloride as a precatalyst for the amination of aryl bromides **1799**

Manfred T. Reetz, Joachim Rudolph, and Richard Goddard Diastereotopic group recognition in the solid state — A unique intramolecular β-cyclodextrin inclusion complex **1806**

Stephen Hanessian and Jian-min Fu Total synthesis of polyoximic acid **1812**

Léon Ghosez, Cécile Franc, Frédéric Denonne, Claire Cuisinier, and Roland Touillaux Studies of palladium-catalyzed coupling reactions for preparation of hindered 3-arylpyrroles relevant to (–)-rhazinilam and its analogues **1827**

PREVIEW / APERÇU

Forthcoming special issues / Numéros spécials à paraître

June 2002	In honour of Professor J. Bryan Jones
August 2002	In honour of Professor Ray Lemieux
November 2002	In honour of Professor Tris Chivers
June 2003	In honour of Professor Don Arnold

Forthcoming articles / Articles à paraître

Electron-spin conservation and methyl-substitution effects on bonds in closed- and open-shell systems — A G3 ab initio study of small boron-containing molecules and radicals	C. Poon and P.M. Mayer
Inhibition de la corrosion de l'alliage d'aluminium 6063 au moyen de composes inorganiques dans une solution de chlorure de sodium à 3%	L. Bazzi, R. Salghi, E. Zine, S. El Issami, S. Kertit, and P. Hammouti
Cationic thiolate and selenolate complexes of platinum(IV)	M.C. Janzen, M.C. Jennings, and R.J. Puddephatt
Synthesis and reactivity of novel Schiff bases containing boronate esters	D.W. Norman, J.P. Edwards, C.M. Vogels, A. Decken, and S.A. Westcott
Iron complexes of the dibenzophospholyl ligand — A synthetic and crystallographic study	A. Decken, M.A. Neil, C.A. Dyker, and F. Bottomley
Environmental photodegradation of pyrimidine fungicides — Kinetics of the visible-light-promoted interactions between riboflavin and 2-amino-4-hydroxy-6-methylpyrimidine	E. Haggi, S. Bertolotti, S. Miskoski, F. Amat-Guerri, and N.A. García
Synthesis of a hexasaccharide fragment of the capsular polysaccharide of *Streptococcus pneumoniae* type 3	D.J. Lefeber, E.A. Arévalo, J.P. Kamerling, and J.F.G. Vliegenthart
Kinetics and mechanism of hydrolysis of 3-diazobenzofuran-2-one and its hydrolysis product (3-hydroxybenzofuran-2-one)	Y. Chiang, A.J. Kresge, and Q. Meng
Monte-Carlo calculation of the primary yields of the primary yields of H_2O_2 in the $^{1}H^{+}$, $^{2}H^{+}$, $^{4}He^{2+}$, $^{7}Li^{3+}$, and $^{12}C^{6+}$ radiolysis of liquid water at 25 and 300°C	J. Meesungnoen, J.-P. Jay-Gerin, A. Filali-Mouhim, and S. Mankhetkorn
On the generation of oxirene and dimethyloxirene by retro Diels–Alder reactions, and reactions of dimethyloxirene — A computational study	C. Delamere, C. Jakins, and E. Lewars
Mechanistic studies of photohydration of *m*-hydroxy-1,1-diaryl alkenes	J.G. Cole and P. Wan
The endothermic nature of the binding of anionic bile salts to a cationic adsorbent	C.K. Williams, W.C. Galley, and G.R. Brown
1-Propanol hydrate by IR spectroscopy	J.-J. Max, S. Daneault, and C. Chapados
Mother Nature and the molecular Big Bang	R.J.D. Miller
